Results: LX2 were stimulated with GCDC (100–500 µM), CDC, taurocholate (TC) and deoxycholate (DC) at 10–100 µM, respectively. Among those, only GCDCA (minimal concentration 100 µM) and CDCA (minimal concentration 10 µM) specifically led to an increase in αSMA expression by 1.9 ± 0.4- and 1.4 ± 0.1-fold respectively, compared to control ($n = 4$, $p < 0.05$). In vivo, CCl_4 led to development of liver fibrosis, as expected. Supplementation with GCDC aggravated this phenotype, as evidenced by liver hydroxyproline (CCl_4+GCDC vs. CCl_4+Control: 383.6 ± 35.4 vs. 284.6 ± 68.5, $n = 5$, $p < 0.05$), sirius red staining (9.5% ± 3.3% vs. 5.9% ± 0.7%, $n = 5$, $p < 0.05$) and αSMA expression (0.9 ± 0.3 vs. 0.5 ± 0.1, $n = 4$, $p < 0.05$). ALT serum levels were unaltered by GCDC feeding in both control and CCl4-treated animals, excluding a direct co-toxic effect of GCDC. Identical results in regard to liver fibrosis were seen when unconjugated CDCA was used. In control animals without CCl4-treatment, bile salt feeding was without pro-fibrotic effects.

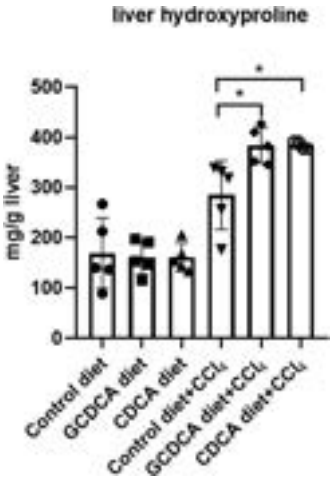

Figure:

Conclusion: Our data add to the growing body of evidence, that human, hydrophobic bile salts can directly activate hepatic stellate cells to promote liver fibrosis. Composition of the bile salt pool in mice may impact on the fibrotic phenotype not only in cholestasis, but on development of liver fibrosis in general. This way of 'humanization' of murine models should thus be further explored when studying liver pathophysiology or exploring novel pharmacological therapies in chronic liver disease.

Reactive oxygen species-mediated hepatic stellate cell activation via PI3K in liver cancer

Qi Ruan[1,2], Lu Cao[2], Haotian Yang[2], Leslie Burke[2], Kim Bridle[2], Darrell Crawford[2], Xiaowen Liang[1,2]. [1]*University of Queensland Diamantina Institute, Australia;* [2]*Gallipoli Medical Research Foundation, Australia*
Email: x.liang@uq.edu.au

Background and aims: One of the standard treatments of unresectable hepatocellular carcinoma (HCC) is transarterial chemoembolization (TACE), using cisplatin or doxorubicin. However, chemotherapy is considered as a "double-edged sword" through activating hepatic stellate cells (HSCs) which can promote tumour growth and chemoresistance. With a better understanding of the molecular mechanism mediated HSC activation in response to chemotherapy, novel potential targets could be revealed for improving the treatment efficacy of liver cancer.
Method: Cancer associated fibroblasts (CAFs) in HCC patients with or without TACE treatment were analysed using a single cell RNA sequencing dataset. The effect of chemotherapeutic drugs on HSC activation was examined in two *in vitro* models, mixed-cell spheroids and treatment of conditioned medium (CM) of cisplatin- or doxorubicin-pretreated Huh7 cells in LX2 cells. LX2 cells were transfected by a pFRET HSP33 plasmid for monitoring reactive oxygen species (ROS) levels of LX2 cells cultured in Huh7-CM. RNA sequencing was conducted to profile gene expression of primary HSCs cultured in Huh7 CM. Three *in vivo* models of HCC were used to validate these results, including orthotopic HCC mouse model, HCC mouse model with fibrosis background induced by thioacetamide acid, and spontaneous HCC model using 11 month-Mdr2 knockout mice. Chemotherapeutic drugs, cisplatin or doxorubicin, were given a total of four doses. Tumour tissues were collected for immunofluorescence staining and western blot. Finally, tumour samples from TACE-treated or untreated patients were collected and stained for the expressions of alpha-smooth muscle actin (SMA) and PI3K p110 alpha.
Results: The proportion of activated CAFs showed a huge increase from 28.3% to 72% of alpha-SMA positive subpopulation and 7% to 27.8% of COL1A1 positive subpopulation in liver cancer patients after TACE treatment. Using two *in vitro* models, LX2 cells were activated by cisplatin-pretreated Huh7 cells but not doxorubicin, with a significant increase in the expression of activation markers. Cisplatin CM obviously increased ROS in LX2 cells, indicating ROS might mediate HSC activation in response to platinum-based drug. Furthermore, RNA sequencing revealed that PI3K pathway contributes to HSC activation among a total of 55 upregulated and 47 downregulated genes. The key genes such as PIK3R3 and PIK3C2B were significantly increased in HSCs cultured in cisplatin CM. Consistent with in vitro results, PI3K pathway related-molecules were significantly increased and its downstream molecules, AKT and ERK, were activated in the tumour tissues of HCC-bearing mice treated by cisplatin. Finally, the expressions of alpha-SMA and PI3K were increased in patient liver tumour samples after TACE treatment.

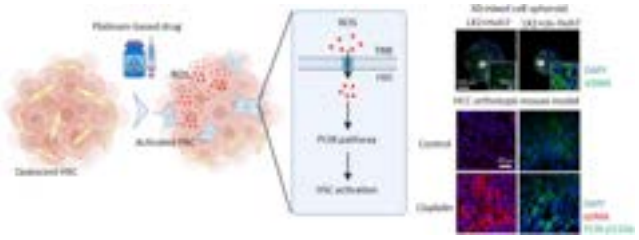

Figure:

Conclusion: Liver cancer patients with TACE or chemotherapy had a higher level of HSC activation. We have confirmed HSCs can be activated through paracrine factors from cisplatin- but not doxorubicin-treated liver cancer cells through a ROS-mediated pathway. Finally, we concluded that the activation of PI3K pathway contributes to ROS mediated-HSC activation in response to platinum-drug treatment. Understanding the HSC activation mechanism induced by chemotherapy could provide potential therapeutic targets as a complement to chemotherapy against liver cancer.

WED-230

Hepatic stellate cells from zone 1 do not transform into myofibroblasts but engage in capillarization in preclinical models of liver fibrosis

Muhammad Ashfaq-Khan[1], Julian Fischer[1], Fabian Schwiering[1], Dieter Groneberg[1,2], Andreas Friebe[1]. [1]*Universität Würzburg, Germany;* [2]*Fraunhofer Institut für Silicatforschung ISC, Germany*
Email: andreas.friebe@uni-wuerzburg.de

Background and aims: Hepatic stellate cells (HSC) reside in the sinusoids of the liver lobule. Recently, two different types of HSC have been described in mice which are located either close to the central vein or near the portal field. We here identify a novel subgroup of HSC. These PDGFRβ-positive cells are found in zone 1 (thus named zone 1-HSC) of the lobule and form a subpopulation of the portal field-associated HSC. In this project, we identified the origin and function of zone 1-HSC in mice.
Method: Mice expressing Cre recombinase under the control of the smooth muscle myosin heavy chain (Myh11) promotor (SMMHC-CreER^{T2}) in combination with the tdTomato reporter were used to identify and trace zone 1-HSC under physiological and pathophysiological conditions. Two different models of hepatic fibrosis, CCl_4 and a Western diet in combination with cholesterol and fructose, were used. Immunofluorescence analysis was performed using confocal microscopy.
Results: Using SMMHC-Cre-induced tdTomato expression in combination with zone-specific antibodies (anti-GS and anti-NGFR), we identify a subtype of HSC in zone 1 of the liver lobule. Under physiological conditions, tdTomato-labeled cells remain in zone 1 even 1 year after reporter induction. Short time induction shows progenitor cells near the canal of Hering in close association with OPN/SOX9- and CK19-positive cells.

After induction of hepatic fibrosis (CCl_4 and Western diet), zonation is lost as zone 1-HSC migrate into zones 2 and 3. Surprisingly, zone 1-HSC do not become myofibroblasts (as shown by lack of αSMA and col1α1 expression) but rather appear to engage in the capillarization of sinusoids. As expected, regular HSC (not tdTomato-labeled by SMMHC-Cre) can be shown to engage in the fibrotic reaction as αSMA-expressing myofibroblasts.

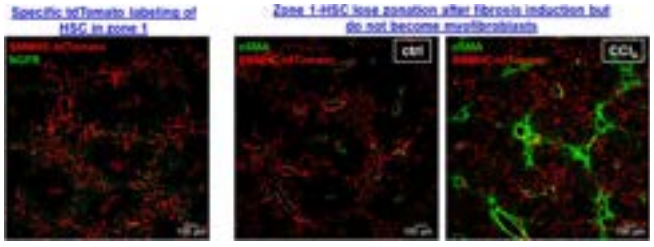

Figure:

Conclusion: Our data allow to differentiate HSC into the regular central HSC that become myofibroblasts under fibrotic conditions, and zone 1-HSC which do not transform into myofibroblasts in two different fibrosis models. Thus, HSC are not a group of cells that are uniformly involved in fibrosis but rather subdivide into mediators of capillarization and myofibroblast precursors.

WED-231

Role of the hepatocyte Epidermal Growth Factor Receptor (EGFR) pathway on the cellular interactome within the liver fibrotic niche

Ester Gonzalez-Sanchez[1,2], Javier Vaquero[1,2], Daniel Caballero-Díaz[1,2], Jan Grzelak[2], Esther Bertran[1,2], Josep Amengual[2], Juan García-Sáez[3,4], Pilar Valdecantos[5,6], Angela Martinez Valverde[5,6], Aranzazu Sanchez[3,4], Blanca Herrera[3,4], Isabel Fabregat[1,2]. *[1]CIBER de Enfermedades Hepáticas y Digestivas-CIBEREHD, Spain; [2]Bellvitge Biomedical Research Institute-IDIBELL, L'Hospitalet, Barcelona, Spain; [3]Faculty of Pharmacy, Complutense University of Madrid (UCM), Madrid, Spain; [4]Health Research Institute of the 'Hospital Clínico San Carlos' (IdISSC), Madrid, Spain; [5]"Alberto Sols" Biomedical Research Institute, Spanish National Research Council and Autonomous University of Madrid (IIBM, CSIC-UAM), Madrid, Spain; [6]Biomedical Research Networking Center in Diabetes and Associated Metabolic Disorders of the Carlos III Health Institute (CIBERDEM-ISCIII), Madrid, Spain*
Email: ifabregat@idibell.cat

Background and aims: Liver fibrosis is the consequence of chronic liver injury in the presence of an inflammatory component. Although the main executors of this activation are known, the mechanisms that lead to the inflammatory process that mediates the production of profibrotic factors are not well characterized. The Epidermal Growth Factor Receptor (EGFR) signaling in hepatocytes is essential for the regenerative process of the liver; however, its potential role in regulating the fibrotic niche is not yet clear.

Method: Our group generated and validated a mouse model that expresses an inactive truncated form of the EGFR in hepatocytes (ΔEGFR mice). Here, we have analyzed the role of the hepatocyte EGFR pathway in the fibrotic niche cell interactome in WT and ΔEGFR mice subjected to CCl4-induced liver fibrosis.

Results: The analysis of the in vivo model indicated that the hepatocyte-specific EGFR activity may be contributing to the proinflammatory response, activated due to the liver damage. Indeed, the absence of EGFR activity in hepatocytes induces changes in the pattern of immune cells in the liver, with a notable change in the population of macrophages that display a bias toward an M2 phenotype more related to fibrosis resolution, as well as an increase in the population of lymphocytes related to eradication of the damage. The hallmarks of liver fibrosis are attenuated in CCl4-treated ΔEGFR mice when compared to WT mice, coinciding with a faster resolution of the fibrotic process and an ameliorated damage. *In vitro* studies have revealed that hepatocytes may directly regulate the macrophage phenotype by inducing the secretion of specific factors,

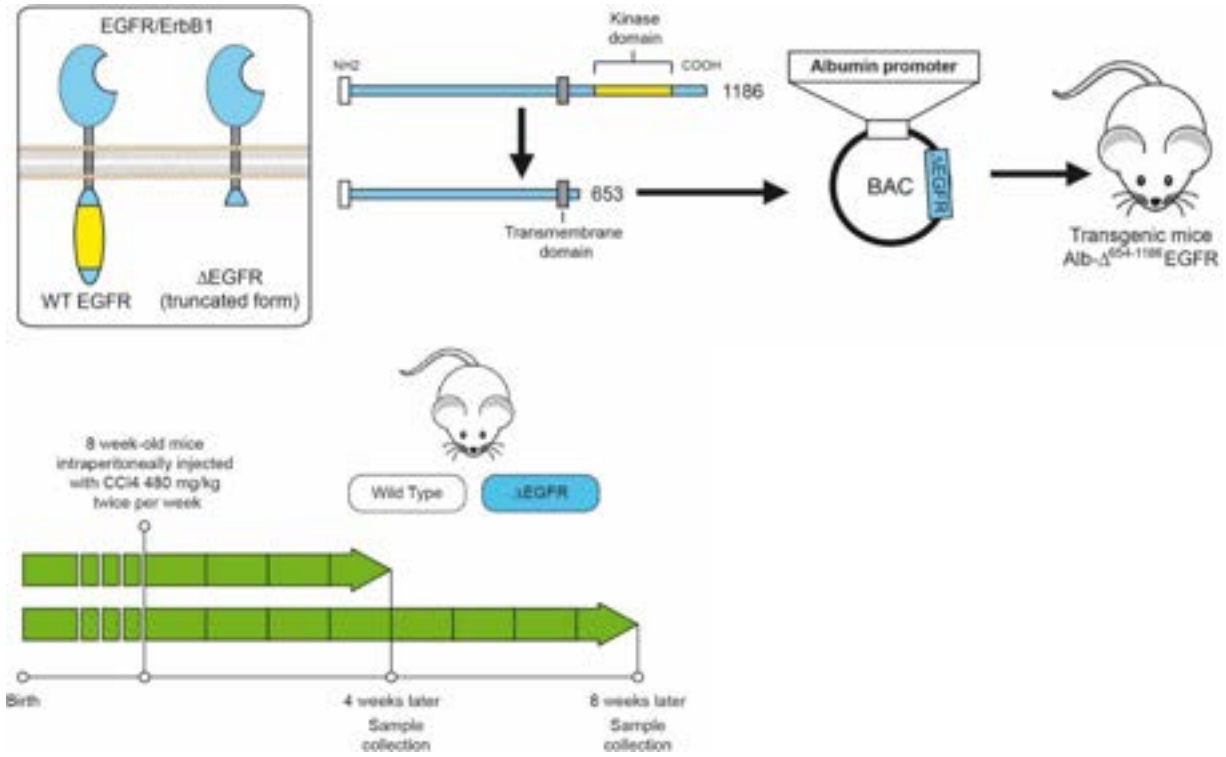

Figure: (abstract: WED-231): Transgenic model Alb-$\Delta^{654-1186}$EGFR (ΔEGFR) mice (up) and experimental model of CCl4-induced liver fibrosis (bottom).

whose expression depends on the activation of the EGFR pathway. Transcriptomic and proteomic studies, currently being performed, will allow to elucidate the specific molecular mechanisms regulated by EGFR that are responsible for the observed changes in the hepatocyte secretory phenotype.
Conclusion: EGFR inactivation specifically in hepatocytes leads to a profound alteration in the liver inflammatory response in experimental fibrosis, with a clear immune cell switch into a pro-restorative phenotype. Besides supporting a pro-fibrogenic role for EGFR activity, our study provides new mechanistic insights on EGFR kinase-dependent actions during chronic liver damage.
This work has been supported by the Ramon Areces Foundation: 20th National Competition for Scientific and Technical Research in Life and Matter Science (2020), grant CIVP20A6593. We help the initial contribution of Drs. Lluis Montoliu and Jose Carlos Segovia in the generation of the transgenic mice.

Discovery of novel small molecule inhibitors of HDAC6 that suppress liver fibrosis
Maria Teresa Borrello[1], Dusan Ruzic[2], Fiona Oakley[1], Katarina Nikolic[2], Jelena Mann[1], Derek Mann[1]. [1]*Biosciences Institute, 4th Floor, William Leech Building, Newcastle University, Medical School, Newcastle Fibrosis Research Group, Newcastle upon Tyne, United Kingdom;* [2]*University of Belgrade, Faculty of Pharmacy, Department of Pharmaceutical Chemistry, Belgrade, Serbia*
Email: jelena.mann@newcastle.ac.uk

Background and aims: Liver fibrosis is a dynamic process characterized by deposition of scar tissue within hepatic parenchyma. At a molecular level, fibrosis is associated with perturbations in expression of histone deacetylases, therefore specific HDAC inhibitors (HDACis) could have a role as therapeutic agents for liver fibrosis. HDAC6, a microtubule-associated deacetylase, is increased in expression in fibrotic liver. Recent studies have shown that HDAC6 enzyme could be selectively targeted, mostly because of its cytoplasmic localisation. Selective HDAC6i have shown promise in diverse number of fibrotic diseases, which led us to investigate novel HDAC6i as potential therapeutic agents for liver fibrosis.
Method: Structure-based molecular modelling studies were conducted in order to rationalise selective HDAC6 inhibitory profiles. The biological activities of the hydroxamic acid derivatives DR-3 and FDR-2 were profiled in an enzymatic assay and their anti-fibrotic potential evaluated in *in vitro* and *in vivo* human and murine models.
Results: The novel compounds FDR-2 and DR-3 were found to be nM inhibitors of HDAC6 enzymatic activity with high selectivity towards HDAC6 over HDAC1/8. Biological and biochemical evaluation demonstrated that DR-3 and FDR-2 were capable of suppressing the activation of primary rat hepatic stellate cells, significantly decreasing the expression of profibrogenic markers. Both compounds markedly reduced TGF-β1-induced SMAD3 activation. Finally, the compounds demonstrated anti-fibrotic pharmacological activities at 5 uM in human precision cut liver slices (hPCLS). hPCLS retain structure and cellular composition of the native human liver and represent a state-of-art preclinical model to study liver fibrosis. The antifibrotic activity of DR-3 and FDR-2 in hPCLS was assessed by Picrosirius Red, α-smooth muscle actin staining and soluble ELISAs. Both FDR2 and DR-3 blunted the progression of fibrosis in hPCLS with no obvious signs of toxicity.
Conclusion: Combining structural analyses and molecular modelling efforts, we generated a series of novel, highly selective HDAC6 inhibitors named DR-3 and FDR-2. Both compounds demonstrate synthetic accessibility, high potency and interesting preliminary pharmacological profile, including low toxicity in hPCLS. These results emphasised the important role that HDAC6 inhibition plays in liver fibrosis. This evidence was further confirmed by the attenuation of TGF-β1-dependent fibrogenesis in hepatic stellate cells as well as reduction in histological and protein markers of fibrosis in human PCLS after culturing with compounds DR-3 and FDR-2. Overall, this work provides robust evidence for HDAC6 inhibitors as potential therapeutic tools for the treatment of liver fibrosis and paves the way for the development of novel lead compounds.

WED-233
MCPIP1 inhibits hepatic stellate cell activation in autocrine and paracrine manner
Natalia Pydyn[1], Anna Ferenc[1], Katarzyna Trzos[1], Piotr Major[1], Mateusz Wilamowski[1], Tomasz Hutsch[2], Andrzej Budzyński[1], Jolanta Jura[1], Jerzy Kotlinowski[1]. [1]*Jagiellonian University, Poland;* [2]*Veterinary Diagnostic Laboratory ALAB Bioscience, Poland*
Email: j.kotlinowski@uj.edu.pl

Background and aims: Hepatic fibrosis is characterized by enhanced deposition of extracellular matrix (ECM) which results from the wound-healing response to the chronic, repeatable injury of any etiology. Upon injury hepatic stellate cells (HSCs) activate and secrete ECM proteins, forming a scar tissue, which results in liver dysfunction. Monocyte-chemoattractant protein-induced protein 1 (MCPIP1) encoded by *ZC3H12A* gene is a protein which possesses anti-inflammatory activity. It is an RNase that degrades a wide plethora of transcripts for example coding for proinflammatory cytokines like IL-1β or IL-6. MCPIP1 overexpression reduces liver injury in septic mice. Also, mice with deletion of Mcpip1 in liver epithelial cells, develop features of primary biliary cholangitis. In this study, we analyzed MCPIP1 level in human fibrotic livers and hepatic cells isolated from murine fibrotic livers. We also investigated MCPIP1 impact (coculture of murine primary cells and Mcpip1 in vivo overexpression) on HSCs activation.
Method: We analyzed MCPIP1 level in patients' fibrotic livers and hepatic cells isolated from fibrotic murine livers. We used both CCl4 treated mice and livers from Mcpip1 knock-out animals (Mcpip1fl/flAlbCre). Paracrine effect of Mcpip1 on HSCs activation was studied by coculture of Mcpip1 KO or WT primary hepatocytes with HSCs. Silencing and overexpression of *ZC3H12A* in LX-2 cell line was used for analysis of autocrine effects of MCPIP1. *In vitro* experiments were conducted on primary HSCs, cholangiocytes and hepatocytes. To overexpress Mcpip1 *in vivo*, we used AAV8 vectors encoding GFP (control) or Mcpip1 injected to tail vain at the dose of 1 × 10^11 cfu.
Results: MCPIP1 level is induced in patients' fibrotic livers in comparison to non-fibrotic counterparts. Similarly, both mRNA and protein Mcpipi1 levels were induced in primary HSCs isolated from murine fibrotic livers in comparison to control cells. Mcpip KO hepatocytes were characterized by increased expression of Ctgf protein in comparison to control cells. High level of Ctgf produced by Mcpip1 KO hepatocytes resulted in enhanced activation of HSCs cocultured with these cells. Overexpression of MCPIP1 in LX-2 cells led to decreased mRNA expression of HSCs activation markers e.g. Acta2, Tgfb, Col1a1 and α-SMA protein level. Contrary, MCPIP1 silencing in LX-2 cells resulted in their increased activation status. *In vivo* overexpression of Mcpip1 in corn-oil treated mice reduced hepatic expression of *Tgfb1*, *Acta2*, *Mmp3*, *Col3a1* and amount of Il-6 and Tgfb proteins, although did not impact degree of fibrosis after CCl4 administration.
Conclusion: MCPIP1 is induced in human fibrotic livers and regulates activation of HSCs cells in both autocrine and paracrine manner. Our results indicate that MCPIP1 could have a potential role in development or resolution of liver fibrosis.
Acknowledgments: This study was supported by National Science Centre, grant number K/PBM/000672 and 2021/42/E/NZ5/00169.

WED-234

The proto-oncogene Bmi1 is a novel regulator of the activated hepatic stellate phenotype

Kim Su[1,2], Elliot Jokl[1], Karen Piper Hanley[1,3]. [1]*University of Manchester, Diabetes, Endocrinology and Gastroenterology, Manchester, United Kingdom;* [2]*Blackpool Victoria Hospital, Gastroenterology, Blackpool, United Kingdom;* [3]*University of Manchester, Wellcome Trust Centre for Cell-Matrix Research, Manchester, United Kingdom*
Email: kim.su@nhs.net

Background and aims: Epigenetic regulation of gene expression has been implicated in liver fibrosis and is an important mechanism underlying hepatic stellate cell (HSC) activation. Polycomb repressor complexes (PRC) are a key class of epigenetic regulators. Whilst PRC2 components have been implicated in HSC activation, the role of PRC1 in liver fibrosis has not been explored. The proto oncogene B-cell specific Moloney murine leukemia virus integration site 1 (Bmi1) is a key component of the PRC1 complex. Bmi1 is implicated in hepatocellular carcinomas (HCC) and cholangiocarcinomas (CCA) but its role in liver fibrosis and HSC biology is unknown. We have utilized *in vivo* and *ex vivo* murine models to examine the role of Bmi1 in liver fibrosis.
Method: The murine *Schistosomiasis mansoni* (*S. mansoni*) model of liver fibrosis was used for *in vivo* detection of BMI1 by immunoblotting. HSCs were extracted by enzyme mediated perfusion of isolated mouse livers and activated on tissue culture. The small molecule inhibitor PTC-209 was used to inhibit BMI1 in *ex vivo* culture activated HSCs. BMI1, mono-ubiquitinated Histone 2A (H2AK119ub), fibrosis markers and HSC activation markers were assessed with immunocytochemistry (ICC), immunoblotting and qPCR. HSC proliferation and cell cycle analysis were conducted using immunoblotting for proliferating cell nuclear antigen (PCNA) and propidium iodide flow cytometry. Statistical analyses were carried out using Student's t-test (Graphpad Prism 8).
Results: *In vivo* expression of BMI1 is significantly increased in *S. mansoni* infected livers versus uninfected controls ($p < 0.05$). *Ex vivo* HSC culture reveals BMI1 is upregulated in activated HSCs (aHSCs) at day 7 compared to quiescent HSCs (qHSCs) at day 0 ($p < 0.01$). This is associated with increased expression of alpha-smooth muscle actin, (Asma), collagen I (Col1a1), Yes associated protein 1 (Yap1) and SRY-Box Transcription Factor 9 (Sox9), all established markers of the aHSC phenotype. ICC staining confirms nuclear localisation of BMI1 in the aHSC. PTC-209 mediated BMI1 inhibition in aHSCs was associated with reduced levels of BMI1 protein in HSCs and reduced levels of H2AK119ub, reflecting diminished PRC1 ubiquitin ligase activity. BMI1 inhibition diminished the profibrotic phenotype of aHSCs. Significant reduction in protein and mRNA levels of collagen I ($p < 0.01$), a fibrillar collagen that is a hallmark of liver fibrosis was detected. Markers of HSC activation were also diminished, with reduced levels of platelet derived growth factor receptor-beta (PDGFRB) protein ($p < 0.01$) and reduced transcript levels of Pdgfrb ($p < 0.001$) and Asma ($p < 0.01$). These observations are unlikely due to diminished cell survival, as no significant changes in PCNA or cell cycle kinetics were detected at PTC-209 doses utilized in this study.
Conclusion: In this study, we provide proof-of-concept data demonstrating *ex vivo* inhibition of BMI1 abrogates the profibrotic phenotype of activated HSCs. Moreover, we have identified a potentially new target linked to epigenetic mechanisms in the ongoing search for anti-fibrotic therapies in chronic liver disease.

3D engineered perihepatic endothelial cell implants reduce fibrosis and inflammation, boosting liver regeneration in fibrotic hepatectomized mice

Mireia Medrano-Bosch[1], Alazne Moreno-Lanceta[1,2], Blanca Simón-Codina[1], Laura Macias-Muñoz[2], Elazer Edelman[3,4], Wladimiro Jiménez[1,2,5], Pedro Melgar-Lesmes[1,2,3]. [1]*School of Medicine, University of Barcelona, Department of Biomedicine, Barcelona, Spain;* [2]*Institut d'Investigacions Biomèdiques August Pi-Sunyer (IDIBAPS), Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd); Spain,* [3]*Institute for Medical Engineering and Science, Massachusetts Institute of Technology, United States;* [4]*Cardiovascular Division, Brigham and Women's Hospital, Harvard Medical School, United States;* [5]*Biochemistry and Molecular Genetics Service, Hospital Clinic Universitari, Spain*
Email: pmelgar@ub.edu

Background and aims: Endothelial cells (ECs) display a myriad of protective effects that contribute to the minimization of liver injury and the restoration of hepatic function. Embedding healthy ECs in a 3D collagen-based scaffold shields their immunogenicity and maximizes their protective roles. Indeed, a previous study has shown that matrix-embedded endothelial cells (MEEC) can protect the liver against ischemic injury. Here, we evaluate whether perihepatic implantation of MEECs might be of therapeutic interest in the context of fibrosis with liver resection.
Method: Fibrosis was induced in BALB/c mice ($n = 12$) by i.p. injection of CCl4 twice weekly for 8 weeks. Acellular matrices or MEECs were implanted between the median and right lobe in fibrotic mice with partial hepatectomy (40% resection, HP40). After 7 days, serum and hepatic samples were collected for fibrosis (Sirius Red staining) and liver function analysis. The expression of genes associated with extracellular matrix turnover, hepatic stellate cell (HSC) activation, or inflammation were quantified by Real-time PCR. Liver restoration rate, proliferating cell nuclear antigen (PCNA) immunostaining and the expression of different growth factors were also studied.
Results: Perihepatic implantation of MEECs in HP40 fibrotic mice promoted a 27% reduction in hepatic fibrosis area and significant improvement in liver function (2-fold reduction in transaminases-ALT, 139 ± 19.5 vs 60 ± 10.4 U/L, $p < 0.01$; AST, 608 ± 105 vs 253 ± 37 U/L, $p < 0.01$). HSC activation was similarly mitigated with concomitant 2-fold reduction in expression of extracellular matrix turnover genes (Collagen I, 1.0 ± 0.1 vs 0.65 ± 0.1, fold change (fc), $p < 0.01$; alpha-SMA, 1.1 ± 0.1 vs 0.5 ± 0.1 fc, $p < 0.01$; TIMP1, 1.0 ± 0.1 vs 0.6 ± 0.1 fc, $p < 0.05$). MEECs also promoted a significant down-regulation of macrophage-derived HSC activators and pro-inflammatory genes, and a parallel increased expression of anti-inflammatory genes. Beneficial anti-fibrotic and anti-inflammatory effects of MEECs implantation in HP40 fibrotic mice were associated with restoration of liver mass (7.0 ± 0.1 g/body weight, BW vs. 7.9 ± 0.1 g/BW, $p < 0.05$). Indeed, tissue preservation correlated with induced cell growth as the number of proliferating cells in livers from mice implanted with MEECs was three times higher than in mice receiving acellular implants (PCNA positive cells, 5.3 ± 0.3% vs. 15.4 ± 1.5%, $p < 0.001$). This hepatic proliferation correlated with an upregulation of hepatocyte growth factor expression (1.0 ± 0.1 vs 1.7 ± 0.2 fc, $p < 0.001$) but not with insulin growth factor 1 induction (1.0 ± 0.1 vs 1.1 ± 0.1 fc).
Conclusion: 3D engineered perihepatic ECs implants reduce fibrosis and inflammation and induce hepatic regeneration in fibrotic mice with hepatectomy. This study emphasizes the therapeutic potential of MEECs to improve the recovery of patients with fibrosis and liver resection.

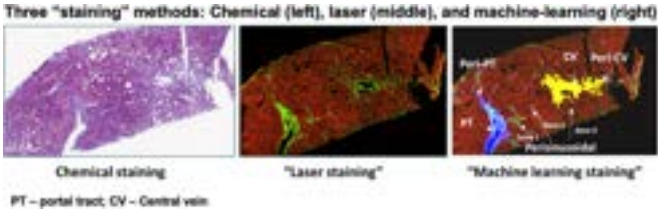
WED-236

Artificial Intelligence analysis of liver biopsies in pre-cirrhotic NASH: qFibrosis explained

Dean Tai[1], Elaine Chng[1], Kutbuddin Akbary[1], Yayun Ren[1], Pol Boudes[2]. [1]*HistoIndex Pte Ltd, Singapore;* [2]*Galectin Therapeutics, United States*
Email: akbary.kutbuddin@histoindex.com

Background and aims: Liver histopathology is a primary outcome for non-alcoholic steatohepatitis (NASH) candidate drugs registration. Besides biopsy size, tissue homogeneity, and staining quality, intra and inter observer variability confound the interpretation of available semi-quantitative scales for fibrosis. We designed an innovative

processing and analysis of digitized liver tissue and submit it to artificial intelligence analysis to provide a more sensitive and fully quantitative analysis of fibrosis.
Method: Unstained tissue obtained from liver biopsy are digitized using a proprietary system and submitted to two detection methods (Genesis®200): a second harmonic generation (SHG) microscopy to identify collagen and a laser two-photon excited fluorescence (TEPF) microscopy to identify hepatocytes. A fully automated machine-learning (ML) image analysis processes information. Algorithms identify portal, septal and fibrillar collagen and exclude portal tracts and central veins pixels, as well as sinusoidal spaces, and extract multiple features of tissue fibrosis. Finally, for each biopsy tissue, a fully quantitative value, qFibrosis, is obtained. Quantitative and semi-quantitative results are compared.
Results: A total of 17 collagen features were selected by ML for the qFibrosis equation, among which, the most important features (with largest coefficients) are number of intersections and number of short and aggregated fiber in the overall tissue region. qFibrosis has open-ended ranges, but typical values are between 0 and 3.7 in pre-cirrhotic NASH (F0-F3) patients, with higher values representing increasing severity of fibrosis. The correlation of qFibrosis values correlate with semi-quantitative fibrosis scores and are 0.761, 0.882, and 1.491 for F1, F2, and F3, respectively.



Conclusion: The combination of digitization, laser imaging and machine learning allows for a quantitative analysis of fibrosis on unstained liver biopsy tissue. This methodology can improve the evaluation of NASH candidate treatments and offers advantages to address liabilities of current methods. By capturing and quantifying important morphological features, it is more precise and more amenable to detecting changes. With further validation data, qFibrosis could provide liver biopsy information that are more clinically relevant to support diagnosis and treatment decisions.

WED-237
Advancement of artificial intelligence in digital pathology: from exploratory end point to primary end point in non-alcoholic steatohepatitis clinical trials

Dean Tai[1], Kutbuddin Akbary[1], Yayun Ren[1], Elaine Chng[1]. [1]*HistoIndex Pte Ltd, Clinical Research, Singapore*
Email: Dean.Tai@histoindex.com

Background and aims: Improvements in liver histology is the current accepted surrogate end point for accelerated approval for access to treatment before the impact on clinical outcomes are known in patients with non-alcoholic steatohepatitis (NASH). Recent clinical data has demonstrated the regression of NASH as a dynamic and heterogeneous process. Depending on the effects of different disease-modifying drugs, fibrosis may regress differently, with variations in morphological and architectural features across zonal regions. Hence, a histological system developed based on changes in untreated individuals does not account well for changes after an intervention. To address this, sponsors and regulatory agencies are working to explore the use of artificial intelligence (AI) in digital pathology to facilitate accurate fibrosis assessment. qFibrosis has been used in the past in phase 2 trials to help stratify patient inclusion criteria for successful phase 3 trials. The most recent development is the US Food and Drug Administration (FDA) approving the use of qFibrosis as a primary end point in a NASH phase 2 study.
Method: Using a stain-free second harmonic generation and two-photon excitation fluorescence (SHG/TPE) imaging technology, qFibrosis is an AI-based tool which offers a reproducible and quantitative way to assess liver fibrosis on a continuous scale. It is a knowledge-based machine learning tool capable of automatically identifying and differentiating portal tracts and central veins, as well as to quantify collagen characteristics such as length, width, and area to provide an objective assessment on fibrosis patterns including peri-portal fibrosis, bridging fibrosis, of which these are key morphological features defined in NASH fibrosis system.
Results: qFibrosis models have demonstrated correlation with histologically determined NASH scores, with significant correlation observed for qFibrosis (r = 0.776) whereas the correlation between central pathologists' ranges from between 0.57 to 0.81 in retrospective studies. Furthermore, qFibrosis provides additional insights such as identification of the most potent fibrosis response in baseline F3 patients in some trials. Increasingly, qFibrosis is included in prospective studies, first as exploratory end point to supplement analysis done by pathologists (NCT03900429), then as a secondary end point in a NASH phase 2b study (NCT04906421), and most recently as a primary end point in another phase 2 NASH study (NCT05519475).
Conclusion: qFibrosis has the potential to provide a quantitative understanding of subtle morphological changes due to treatment-induced fibrosis regression, allowing it to be more sensitive to change within the timeframes of typical phase 2 and 3 NASH trials. This can be used for better stratification of patient inclusion criteria, which is crucial for efficacy evaluation during drug development, as well as for diagnosis once the drug is approved. This clearly demonstrates the utility of AI in digital pathology in a real-world clinical setting.

WED-238
Repeatability and reproducibility assessment and its acceptable standard error of means for qFibrosis system in multi-site NASH clinical trials

Jason Pik Eu Chang[1], Claudia Filozof[2], Dean Tai[3], Kutbuddin Akbary[3], Yayun Ren[3], Elaine Chng[3], Feng Liu[4], Lai Wei[5], David E Kleiner[6], Arun Sanyal[7]. Email: akbary.kutbuddin@histoindex.com

Background and aims: Accurate quantification of fibrosis is critical in clinical trials in NASH. In recent years, the application of digital pathology with artificial intelligence (AI), including qFibrosis has gained increased attention due to the potential to quantify fibrosis features from liver biopsies with better inter-/intra observer agreements as compared to conventional reads. Our group has recently reported the inter-system (repeatability) and intra-system (reproducibility) of qFibrosis. In this study, we aim to describe an acceptable standard error of means for the qFibrosis system in NASH clinical trials.
Method: The study included 41 core biopsies with confirmed NASH, of which 9, 9, 13 and 10 samples were staged F1, F2, F3 and F4, respectively. Scanning was conducted with 3 Genesis200® machines, using second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy on unstained slides. 3 repeated scans were conducted for each sample by each machine (reproducibility) and by three different machines (repeatability) at different time points, and a qFibrosis continuous value (qFC) is generated based on an AI algorithm for each sample per scan. The standard error of means

(SEM) was determined by 2 methods: 1) cohort based: taking the qFC for each patient (the median of 9 scans); 2) sample based: taking the 9 scans for each patient; with the same fibrosis stages.
Results: The SEM for F1, F2, F3, F4 are 0.1924, 0.1917, 0.3595, 1.1038 respectively using cohort-based method. And the SEM for F1, F2, F3, F4 are 0.1334, 0.1081, 0.1417 0.3464 respectively using sample-based method. Note that the SEM values are progressively larger for higher stage of fibrosis using the cohort-based method, this is due to the fact the qFC is generally larger for higher stage of fibrosis. This is not the case for sample-based method, as the SEM is dependent on system repeatability and reproducibility instead of the value of qFC.
Conclusion: In our recent efforts in establishing repeatability and reproducibility in the advent of AI digital pathology, there is still a gap in determining the acceptable SEM for these quantitative measurements. This study aims to summarize different approaches to determine SEMs and their results. The group intends to further investigate impact of SEM on the result of assessment in NASH clinical trials with additional approaches such as Obuchowski index and report these findings to the clinical trials community.

WED-239

The anti-HIV drug Rilpivirine downregulates migration and proliferation of activated hepatic stellate cells: relevance for the purpose of drug repurposing in liver fibrosis

Ana Benedicto[1,2], Isabel Fuster-Martínez[1,2], Aleksandra Gruevska[1,2], Eduardo Carbonell[1], Alessandra Caligiuri[3], Fabio Marra[3], Elena Muñoz[4], Dimitri Dorcaratto[4], Juan V. Esplugues[1,2,5], Ana Blas-García[2,5,6], Nadezda Apostolova[1,2,5]. *[1]Department of Pharmacology, University of Valencia, Valencia, Spain, Spain; [2]FISABIO, University Hospital Dr. Peset, Valencia, Spain, Spain; [3]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, Italy; [4]Department of Surgery, Liver, Biliary, and Pancreatic Unit, Biomedical Research Institute INCLIVA, Hospital Clínico University of Valencia, Valencia, Spain, Spain; [5]Biomedical Research Networking Center in Hepatic and Digestive Diseases (CIBERehd), Valencia, Spain, Spain; [6]Departament of Physiology, University of Valencia, Valencia, Spain, Spain*
Email: nadezda.apostolova@uv.es

Background and aims: Liver fibrosis, a common denominator in most liver diseases, lacks specific pharmacological treatment. Rilpivirine (RPV), a widely used anti-HIV drug, has shown anti-fibrotic properties in several murine models of hepatic injury. Specifically, it reduces the activation of hepatic stellate cells (HSCs) and induces cell death in activated HSCs. Nevertheless, the exact mechanisms behind these actions are still unknown.
Method: Primary human HSCs were activated with the profibrogenic cytokine TGF-beta or with PDGF-beta and co-treated with clinically relevant concentrations of RPV for 48h. For RNA sequencing transcriptomic analysis, mRNAs libraries were obtained using total RNA, their size was assessed and sequencing was performed through a single read of 75 cycles (1 × 75 bp). After differential gene expression analysis, over-representation analysis was performed using the databases Gene Ontology (GO), KEGG pathways and Reactome. Then, we validated the implication of RPV on PDGF-beta-induced chemotaxis and cell proliferation (transwell chemoattraction assay in Boyden chamber and counting the cells with trypan blue). The involvement of several protein kinases downstream of PDGF was analysed by Western Blot.
Results: In the transcriptomic analysis, 2309 genes were differentially expressed by RPV's treatment. When analyzing the pathways and processes changed, RPV showed several effects in accordance with the previous published studies, including downregulation on collagen biosynthesis and upregulation of apoptosis. Nonetheless, in the comparison of RPV at highest concentration + TGFbeta vs TGFbeta novel pathways were revealed, being the top 5 downregulated reactome pathways with highest strength of the enrichment: "unwinding of DNA," Smooth Muscle contration," "XBP1 (S) activates chaperone genes," "Signaling by PDGF" and "Collagen biosynthesis and modifying enzymes"; and the top upregulated: "OAS antiviral response," "keratan sulfate degradation," "STING mediated induction of host immune responses," "interferon α/β signaling" and "stabilization of p53." Similar results were obtained when analysing GO terms. Downregulation of the activated cell migration capacity and the PDGF signaling pathway stood out in the different analysis. These findings were validated in PDGF– treated HSCs in which RPV inhibited both PDGF-beta-induced chemotaxis and cell proliferation. Moreover, RPV downregulated PDGF downstream signaling pathways of AKT and JNK, but not of p38 and ERK1/2.
Conclusion: RPV reduces the PDGF-beta-induced chemotaxis and proliferation of HSCs, which may be relevant for in the antifibrotic properties of this drug already shown in mouse models of hepatic fibrosis. These finding might shed more light on the HSCs pathophysiology and give hints for novel pharmacological targets of chronic liver diseases.

WED-240

Is the fibrosis phenotype in pre- and post-menopausal F2/F3 women the same?

Isabel Fernández-Lizaranzu[1], Emilio Gomez-Gonzalez[1], Helena Pastor[2], Rocío Gallego-Durán[2], Rocío Montero-Vallejo[2], Louis Petitjean[3], Mathieu Petitjean[3], Manuel Romero Gomez[2].

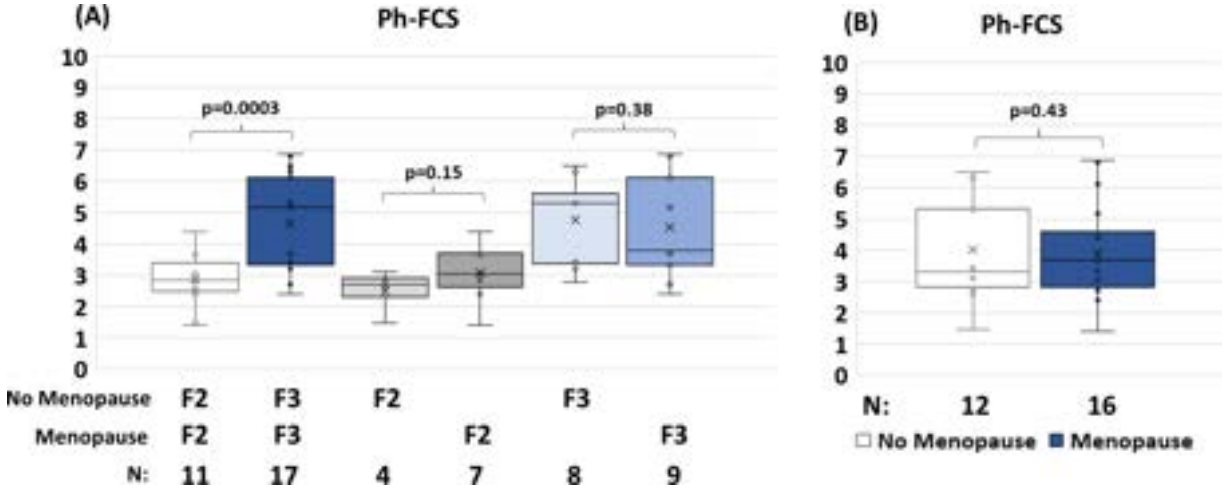

Figure: (abstract: WED-240): Phenotypic Fibrosis Severity Score (Ph-FCS) and qFTs of different groups under analysis

[1]*Interdisciplinary Physics Department. Virgen del Rocío University Hospital; SeLiver Group, Biomedicine Institute of Seville (HUVR/CSIC/US), Medicine Department, University of Sevilla; CIBEREHD, Seville, Spain;* [2]*Liver and Digestive Diseases Unit. Virgen del Rocío University Hospital; SeLiver Group, Biomedicine Institute of Seville (HUVR/CSIC/US), Medicine Department, University of Sevilla; CIBEREHD, Seville, Spain;* [3]*PharmaNest, Princeton, NJ, United States*
Email: ifernandez14@us.es

Background and aims: While several teams have hypothesized that the hepatic phenotype of pre- and post- menopausal women should be different, current histological methods (semi-quantitative categorical stages) do not have the analytical sensitivity to address the question. Here we use high-resolution, single-fiber digital pathology quantitative pathology and AI (FibroNestTM) to distinguish different phenotypes of fibrosis between pre- and post-menopausal patients with moderate (F2/F3 stages) fibrosis.
Method: This study was performed on a retrospective cohort of 28 biopsy-proven patients recruited between 2010 and 2018 at seven different Spanish hospitals. The overall cohort consisted of female patients with two different stages of fibrosis, 11 (39%) were F2 and 17 (61%) were F3, 16 (57%) had menopause and 12 (43%) didn't have it, a median age of 56 (±11) years. FFPE liver biopsies were stained with Masson Trichrome, scanned using 20X light microscopy and quantified using FibroNest™ for the Phenotypic Quantification of Fibrosis and its associated features. This method provides a continuous phenotypic Fibrosis Composite Severity (Ph-FCS) scores that ranges from 1 to 10 fibrosis severity observed in the liver. The Ph-FCS were evaluated at different groups: F2, F3, Menopause, No Menopause, F3-No menopause (N = 8), F3-Menopause (N = 9), F2-No menopause (N = 4), F2-Menopause (N = 7).
Results: F2 cases had lower Ph-FCS than F3 cases with a significant difference between them independently of the menopause state (Student's t-Test p = 0.0003) (Figure, A). When F2/F3 cases were compared considering the menopause stage, there was no significant difference between pre-/post-menopause (p = 0.15 for F2 and p = 0.38 for F3) (Figure, B). Yet, we found 55 phenotypes that changed significantly in both cases (pre-/post-menopause), among them perimeter and filled to area ratio of assembled collagen phenotypes. We found 16 phenotypes changed significantly for only post-menopause cases and 75 phenotypes changed significantly only for pre-menopause cases.
Conclusion: Quantitative Digital Pathology analysis, using FibroNestTM, was able to distinguish severity groups in concordance with NASH CRN stages in this limited cohort, as reported elsewhere. In each severity group and in aggregate we do not find statistically significant differences in fibrosis severity between pre- and post-menopausal women. It was also able to identify specific differences in the progression of fibrosis between pre- and post- menopausal women.

WED-241
Amelioration of CCl4 induced hepatic fibrosis in-vitro and in-vivo by bone marrow derived mesenchymal stromal cells lysate loaded nanostructured lipid carriers

Sabeen Malik[1], Sana Awan[2], Tehreem Malik[3]. [1]*The University of Lahore, Institute of Molecular Biology and Biotechnology, Lahore, Pakistan;* [2]*Kinnaird College for Women, Department of Zoology, Lahore, Pakistan;* [3]*Rehbar Medical and Dental College, Lahore, Pakistan*
Email: sabeen004@gmail.com

Background and aims: Bone marrow mesenchymal stromal cells (BMSCs) are considered a novel strategy to treat hepatic fibrosis. BMSCs lysate was encapsulated in nanostructured lipid carriers (NLC) to deliver cellular contents and regulatory elements of BMSCs at the injury site. This study was designed to evaluate the therapeutic potential of BMSCs lysate loaded NLC (BMSCs-L-NLC) in carbon tetrachloride (CCl_4) induced liver fibrosis *in-vitro* and *in-vivo*.
Method: NLC was prepared by using the nano-template engineering method. CCl_4 induced hepatotoxicity in hepatocytes (in-vitro) and rats (in-vivo) was used to evaluate the therapeutic potential of BMSCs-L-NLC.
Results: NLC preparation and loading with BMSCs lysate was confirmed via size and morphology analysis, and ELISA of lysate proteins. *In-vitro*, BMSCs-L-NLC treatment increased the viability of injured hepatocytes, elevated antioxidants (superoxide dismutase (SOD), glutathione reductase (GR), ascorbate peroxidase (APX) and catalase (CAT)) and alleviated liver markers (alanine aminotransferase (ALAT), alkaline phosphatase (ALP), and lactate dehydrogenase (LDH)) in hepatocytes secretome. *In-vivo*, rats exposed to CCl_4 developed liver injury characterized by a significant increase in liver enzymes, apoptosis, and decreased liver markers expression and proliferation. Treatment with BMSCs-L-NLC enhanced liver state effectively. It significantly decreased the elevated liver enzymes (bilirubin, ALT, ALP, and LDH), apoptosis (measured via p53, Bax, Caspase-3 expression), and immunosuppression of annexin V and increased liver markers (measured via ALB, AFP, and IGF-1), proliferation (measured via Ki-67, PCNA and TOP2A expression), antioxidants and immunoexpression of liver marker ALB. Histopathological studies confirmed the therapeutic effects of BMSCs-L-NLC.

Figure:
Conclusion: BMSCs-L-NLC could restore liver structure and function in CCl_4-induced liver fibrosis *in-vitro and* in-vivo by ameliorating the toxicity of CCl_4 and improving liver functioning as indicated by biochemical, histological, immunohistochemical, and gene expression results.

WED-242
Characterizing the long-term stability of human pluripotent stem cell-derived non-parenchymal liver cells

Ingrid Wilhelmsen[1,2], Mikel Martinez[1], Justyna Stokowiec[1], Aleksandra Aizenshtadt[1], Stefan Krauss[1,2]. [1]*University of Oslo, Institute of Basic Medical Sciences, Hybrid Technology Hub, Oslo, Norway,* [2]*Oslo University Hospital, Institute of Clinical Medicine, Department of Immunology, Oslo, Norway*
Email: ingrid.wilhelmsen@medisin.uio.no

Background and aims: There is a significant need for predictive and stable *in vitro* human liver models for disease modelling and drug testing. Hepatic stellate cells (HSCs) and liver sinusoidal endothelial cells (LSECs) are important non-parenchymal cell (NPC) components of a variety of such models, particularly models involving hepatic fibrosis. However, the use of primary human HSCs and LSECs is significantly limited by the availability of donor material and rapid loss of cell-specific phenotype and functionality during isolation and *in vitro* culture. Recently published approaches to obtaining pluripotent stem cell- (PSC-) derived HSCs and LSECs offer an attractive alternative to primary human material; yet, the suitability of PSC-derived HSCs and LSECs for extended *in vitro* modelling has not been characterized. In this study, we aimed to describe changes in cell-specific phenotype and functionality of PSC-derived HSCs and LSECs during long-term *in vitro* culture.

Method: PSC-derived HSCs and LSECs (differentiated from hESC line H1 and iPSC lines WTC-11, WTSli28-A and WTSli013-A) were cultured *in vitro* for 14 days post-differentiation. Cell-specific phenotypes were evaluated by cell morphology, immune fluorescence, gene- and protein expression. Functionality was assessed in HSCs by their capacity for intracellular storage of vitamin A and response to pro-fibrotic stimuli induced by TGF-beta 1 and in LSECs by nitric oxide- and factor VIII secretion as well as endocytic uptake of bioparticles and acetylated low density lipoprotein. Notch pathway inhibition by treatment with DAPT and co-culturing HSCs and LSECs were separately tested as options for enhancing long-term stability and maturation of the PSC-derived NPCs.
Results: Both cell types exhibited significant changes in their phenotype and functionality during the long-term culture, acquiring signs of activation and decline in functionality. Notch pathway inhibition modestly improved the stability of both PSC-derived HSCs and LSECs in a cell line-dependent manner. Long-term co-culturing of PSC-derived HSCs and LSECs showed signs of improved HSC function as judged by vitamin A storage and responsiveness to pro-fibrotic stimuli.
Conclusion: PSC-derived HSCs and LSECs show a deteriorating phenotype and functionality during extended post-differentiation culture. Choice of PSC line and a limited experimental timeframe is crucial when designing *in vitro* platforms involving PSC-derived HSCs and LSECs. While Notch inhibition offers a promising approach to extend post-differentiation monoculture, co-culturing PSC-derived HSCs and LSECs could be used for both prolonged phenotypic and functional stability as well as HSC maturation.

WED-243
3D Extracellular matrix human liver hydrogels for the investigation of genetic variants in hepatic stellate cells

Elisabetta Caon[1], Philipp Schwabl[1], Luca Frenguelli[1], Hannah Evans[1], Margarita Papatheodoridi[1], Zalike Keskin-Erdogan[2], Nicola Mordan[2], Jonathan Knowles[2], Giuseppe Mazza[1], Massimo Pinzani[1], Krista Rombouts[1]. [1]*University College of London, Royal Free Campus, Regenerative Medicine and Fibrosis Group, Institute for Liver and Digestive Health, United Kingdom;* [2]*University College of London, Royal Free Campus, Biomaterials and Tissue Engineering Division, Eastman Dental Institute, United Kingdom*
Email: elisabetta.caon.17@ucl.ac.uk

Background and aims: Liver fibrosis is a crucial pathophysiological step in chronic liver diseases (CLD). Activated hepatic stellate cells (HSCs) are the key mediators of fibrogenesis and, therefore, research has been focusing on identifying and addressing pro-fibrogenic mechanisms in HSCs for the development of new drug candidates to treat fibrogenic liver diseases. This process has been hampered by the lack of appropriate in vitro models. In addition, only recently attention has been given to the importance of genetic polymorphisms for the onset of CLD, with numerous new variants being discovered, although their molecular role is still largely unclear. In this project, the synergic impact of the PNPLA3 I148M and TM6SF2 E156K SNP variants on the pro-fibrogenic behaviour of HSCs has been investigated, utilizing a newly developed platform of 3D hydrogels obtained from the decellularized extracellular matrix (ECM) of healthy and diseased human livers.
Method: Healthy or cirrhotic decellularized human liver ECM 3D scaffolds were lyophilized and solubilized to yield liver ECM solution. The ECM solution was mixed with a nanocellulose-based gelling agent to form hydrogels for culturing primary human HSCs WT or mutant for the PNPLA3 I148M and TM6SF2 E156K genetic variants in a 3D setting. Following evaluation of the ECM hydrogels mechanical properties by Dynamic Mechanical Analysis (DMA) and SEM, cell behaviour of HSCs cultured in ECM hydrogels and treated with/without TGFB1/Endothelin-1 was investigated using various molecular biology techniques.
Results: Hydrogels made with human liver ECM proved to be mechanically stable and with a stiffness comparable to that of healthy human livers. Both healthy and cirrhotic ECM liver hydrogels supported HSC viability and responsiveness to pro-fibrogenic agents such as TGFB1, with an increase in COL1A1, TIMP1 and TGFB1 gene expression. Furthermore, HSCs showed similar behaviour when cultured in an established model of 3D ECM scaffolds or ECM hydrogels and featured a less activated phenotype (lower expression of ACTA2, COL1A1, TIMP1 and higher CYGB) compared to 2D plastic culture. HSCs carrying the PNPLA3 I148M and TM6SF2 E156K variants showed an increased basal contraction and activation (increased COL1A1 and TIMP1) compared to WT HSCs. This effect was strongly increased by the presence of cirrhotic ECM.
Conclusion: This study introduces and provides a technical characterization of liver ECM hydrogels as high throughput 3D cell culture models recapitulating the cellular microenvironment of normal or fibrotic human liver, to be employed in unravelling the pro-fibrogenic behaviour of HSCs in presence of different genetic variants and their role in the progression of CLD.

WED-244
Analysis of alpha adrenoblocker as antifibrotic and hepatoprotective agent in a Wistar rat model of cirrhosis

Mariana Yazmin Medina Pizaño[1], María de Jesús Loera Arias[1], Roberto Montes de Oca Luna[1], Odila Saucedo Cárdenas[1], Javier Ventura Juarez[2], Martin Muñoz Ortega[3]. [1]*Autonomous University of Nuevo Leon, Histology, Monterrey, Mexico;* [2]*Autonomous University of Aguascalientes, Morphology, Aguascalientes, Mexico;* [3]*Autonomous University of Aguascalientes, Chemistry, Aguascalientes, Ags., Mexico*
Email: mariana93medina@gmail.com

Background and aims: Liver cirrhosis is a major public health problem and a significant source of morbidity and mortality. Cirrhosis is the histological development of regenerative nodules surrounded by fibrous bands in response to chronic liver injury. In the liver, damage-activated stellate cells or hepatic myofibroblasts play a key role in the initiation and progression of the disease. The liver has a cellular compartment with neuroendocrine characteristics composed of progenitor cells and hepatic stellate cells. There is increasing evidence that the sympathetic and parasympathetic nervous systems influence this cellular compartment. Evaluation of the effects of alpha and beta adrenoblockers on a murine cirrhosis model concludes that the reduction of type I collagen after the treatment is achieved by reducing the profibrotic activities of TGF-β, a decrease in fibrotic tissue and increase of liver function. In this study, we aimed to analyze tamsulosin's antifibrogenic and hepatoprotective capacity in a Wistar rat model of cirrhosis.
Method: Wistar rats were injected twice per week with thioacetamide to induce liver cirrhosis. Rats were treated with tamsulosin, an alpha adrenoblocker, five times per week, and samples were taken after 4 weeks. The serum was collected and tested for the activity levels of aminotransferases (AST or GOT and ALT or GPT) and alkaline phosphatase (ALP). Collagen deposition was analyzed on HandE, Masson's trichrome, and Sirius red staining. The expression of molecular markers of collagen deposit and hepatoprotective effect were evaluated by RT-qPCR (collagen I, PPARγ, α-SMA, Nrf2 and HO-1). To study the interaction between stellate cells and tamsulosin, a stellate cell line (LX2) was co-cultured using viability assays (calcein-AM and SYTOX Green), and oxidative stress was analyzed at 24 h using dihydroethidium (DHE). The activation of HSCs was observed by Oil Red O Staining and the migratory response of HSCs by scrape wound healing assay.
Results: Masson's trichrome and Sirius red staining showed a significant decrease in collagen deposition with tamsulosin treatment compared to controls. Liver sections of the control group exhibited normal lobular architecture, whereas liver sections of the thioacetamide-intoxicated group exhibited typical architectural

distortions with regenerative nodules surrounded by proliferative connective tissue; co-treatment with tamsulosin improved the architecture of liver parenchyma. Study results indicated that the activity of the aminotransferases (AST and ALT) and ALP increased significantly in thioacetamide-treated rats compared to control animals. However, tamsulosin showed a decrease in activity. Treatment with tamsulosin regulates the oxidative stress through mRNA expression of hepatoprotector markers (Nrf2, PPARγ and HO-1) and decrease the expression of collagen I and α-SMA. Tamsulosin treatment significantly inhibits the LX2 cell proliferation activation and migration (without affecting its viability).

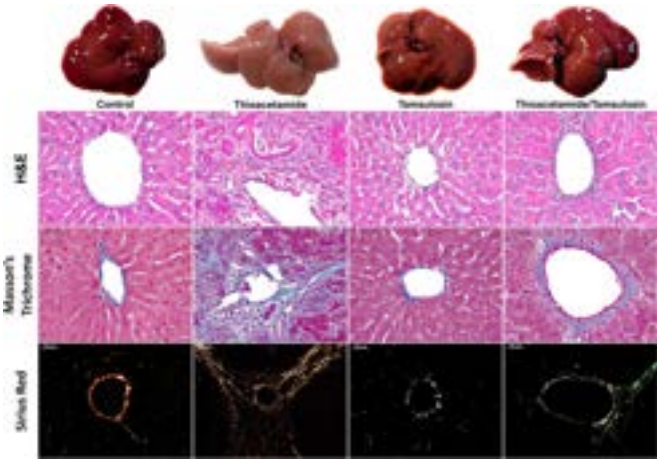

Figure:

Conclusion: The present study demonstrated that tamsulosin may enhance hepatic efficiency in Wistar rats by a decrease of collagen synthesis and an increase of liver function. Therefore, tamsulosin retards the proliferation, activation, and migration of LX2 cells without inducing cytotoxicity and oxidative stress.

WED-245

MicroRNA-29b involves in the progression of NAFLD to liver fibrosis

Qihua Duan[1], Qiaozhu Su[2]. [1]*Institute for Global Food Security, School of Biological Sciences, Queens University Belfast, Belfast, United Kingdom;* [2]*Institute for Global Food Security, School of Biological Sciences, Queens University Belfast, United Kingdom*
Email: q.su@qub.ac.uk

Background and aims: Liver fibrosis, a pathological consequence of multiple injurious insults in liver, is the late stage of Non-alcoholic fatty liver disease (NAFLD) that can lead to liver failure. MicroRNAs (miRNAs) are small non-coding RNAs that can regulate their target mRNAs and impact diverse cellular processes by complementary base-pairing the 3'-UTR of the target mRNAs. MiR-29 family has been implicated in the pathogenesis of pulmonary fibrosis and cardiac fibrosis, however, its role in liver fibrosis is unclear. In this study, we investigated the mechanism of miR-29b in the progression of NAFLD to liver fibrosis.
Method: In vivo, a mouse model was established by feeding high-fat diet (HFD) and treating the mice with miR-29 mimics. In vitro, the Murine hepatocytes cell line AML12, and Hepatic stellate cells (HSC) are used treated with inflammatory cytokine TNFα and free fatty acid Palmitic acid (PA), Hedgehog Inhibitors MDB5 and/or miR-29b mimics.
Results: Q-RT-PCR analysis revealed that HFD induced liver injury from NAFLD to liver fibrosis, which was associated with the significant decrease of miR-29b in the liver tissues of the HFD feeding mice. Treated the mice with nanoparticles encapsulated with miR-29b mimics significantly improved liver fibrosis and enhanced insulin sensitivity. In vitro, TNFα or PA treatment inhibited miR-29b in the moue hepatocytes, AML-12, whereas, incubation with a hedgehog inhibiter MDB5 upregulated miR-29b expression, suggesting the crucial role of miR-29b in Hedgehog pathway and liver fibrosis. Moreover, upregulated cellular miR-29b by transient transfection improved expression of genes involved in mitochondrial energy homeostasis and fatty acid β-oxidation. mRNA levels of PPARα and CPT1α were increased in AML12 cells treated with miR29 mimics ($p < 0.001$).
Conclusion: Novel findings from demonstrate the essential role of miR-29b in preventing the progression of NAFLD to liver fibrosis.

WED-246

Novel Pathways implicated in the seladelpar-mediated reductions of established liver fibrosis are identified from RNA-SEQ data using plex search and two independent mouse pharmacology datasets

Edward Cable[1], Doug Selinger[2], Yun-Jung Choi[1], Charles McWherter[1]. [1]*CymaBay Therapeutics Inc., Newark, United States,* [2]*Plex Research, Inc, Cambridge, United States*
Email: ecable@cymabay.com

Background and aims: Seladelpar is a selective peroxisome proliferator delta (PPARD) agonist that reduced established liver fibrosis in the Amylin-diet NASH and CCl_4 chemical injury models. In each model, an induction period for fibrosis is followed by a treatment period during which the fibrotic stimuli is maintained. End points include evaluation of fibrosis and RNA-seq analysis. The aim of our analysis is to uncover novel aspects of seladelpar's anti-fibrotic mechanism using liver RNA-seq datasets from these models together with the Plex AI-analytical platform to search relevant large public data bases. Unlike bioinformatics methods that insinuate biological importance with the magnitude of change, Plex allows the use of an omics data set as a search query in a search engine interface against aggregated data from publicly available databases. The search results can suggest novel associations as hypotheses not evident in bioinformatic evaluation of the original omics data set.
Method: RNA-seq from the livers of mice treated in the Amylin-diet model (43w induction, 12w Tx; [n = 12 (V), n = 11 (Tx]) and CCl_4 (5w induction, 3w Tx; [n = 20]) were analyzed and the top 100 differentially expressed genes were used as query gene lists in Plex's search platform (www.plexresearch.com). Liver tissue samples were obtained after sacrifice at 2 (Amylin diet) and 24 hours (CCl_4) post last dose. Plex queries with the RNA-seq data sets identified enrichment of the differentially expressed genes in multiple data domains. Gene family results were obtained by this analysis.
Results: The lipocalin family members (transporters of small hydrophobic molecules) were reduced in both models with amongst the highest observed scores. Lipocalins have not been associated with PPARD but levels are correlated with fibrosis. Decreases in lipocalin-2 have been accompanied by decreased inflammation in disease models. In addition, the clade A serpin protease inhibitors were reduced in both models whereas serpins from clades B-D were minimally changed. The reduction of serpin

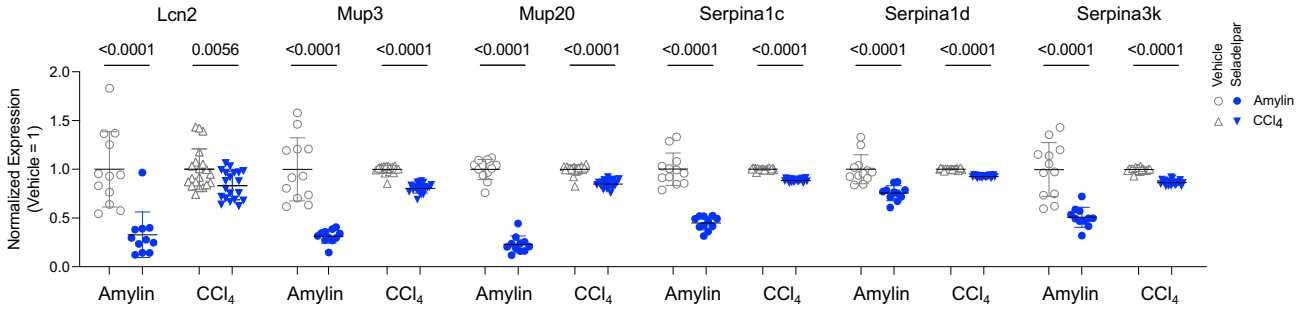

Figure: (abstract: WED-246).

protease inhibitors could implicate proteolytic fibrolysis contributing to the decrease in fibrosis. Seladelpar treatment also led to decreases in protein families related to hedgehog signaling, intracellular chloride channels, glutathione reductase transferases, and rhodopsin-like GPCRs, gene families that have been previously associated with fibrosis. Shown in the graph below are the three highest expressing genes in the lipocalin and serpin families.

Conclusion: The use of a novel search platform along with transcriptomics data sets produced consistent findings for two different fibrosis models. The results identified several pathways to investigate for their role in the reduction of fibrosis by seladelpar observed in mice. Understanding the roles of these pathways will assist in our understanding of the relevance of mechanisms for human disease.

WED-247

Cathepsin D expressed in hepatocytes does not participate in the development of liver fibrosis after chronic CCl4 administration

Paloma Ruiz-Blazquez[1,2], Maria Fernandez-Fernandez[1,2], Valeria Pistorio[3,4], Susana Núñez[2], M. Carmen Garcia-Ruiz[1,2,5,6], José Fernandez-Checa[1,2,5,6], Anna Moles[1,2,5]. *[1]Instituto de Investigaciones Biomédicas de Barcelona (IIBB-CSIC), Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Spain; [3]Sorbonne Université, Inserm, Centre de Recherche Saint-Antoine (CRSA), France; [4]University of Naples Federico II, Italy; [5]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Spain; [6]USC Research Center for ALPD, United States*
Email: anna.moles.fernandez@gmail.com

Background and aims: During liver fibrosis, proteolytic activity is timely regulated in infiltrating and resident cells depending on the cellular demands. Proteolytic modification of certain substrates such as growth factors, chemokines and extracellular matrix proteins among others, results in important changes in inflammation, apoptosis, extracellular matrix remodeling and autophagy paving the way for fibrosis development, progression and reversion. Despite our growing understanding of the roles played by lysosomal proteases in liver fibrosis, our knowledge of their specific targets and signaling networks remains still limited. Thus, the aim of this study was to analyze cathepsin D (CtsD) cell-specific role in hepatocytes during liver fibrosis.

Method: We generated a novel knock-out mouse strain by breeding Albumin-Cre (hepatocytes) mice with CtsD floxed mice. $CtsD^{\Delta Hep}$ mice was validated by CtsD WB in primary mouse hepatocytes and dual IF (F4/80-CtsD) in liver sections. Fibrosis was established by chronic administration of CCl_4 twice a week for 8 weeks or bile duct ligation for 14 days in $CtsD^{F/F}$ and $CtsD^{\Delta Hep}$ mice. Liver damage was determined by serum ALT. CtsD deletion was assessed by enzymatic activity assay, WB, IF and RTPCR. Fibrosis was analysed by Sirius Red staining, liver hydroxyproline, α-SMA IHP and α-SMA, Col1A1 and TGF-β RTPCR. Liver inflammation was determined by NIMP and F4/80 IHP and TNF-α, CCL3 and CCL4 RTPCR.

Results: CtsD cell-specific deletion in hepatocytes was validated by CtsD WB in primary mouse hepatocytes and dual IF (F4/80-CtsD) in liver section from CtsDF/F and $CtsD^{\Delta Hep}$ mice. Of note, CtsD expression remained unaffected in liver non-parenchymal cells. Next, fibrosis was established for 8 weeks by CCl_4 administration. CtsD deletion in $CtsD^{\Delta Hep}$ livers was confirmed by CtsD IHP and gene expression. CtsD deletion in hepatocytes did not affect liver damaged (ALT) and liver fibrosis as determined by Sirius red staining, α-SMA IHP and hepatic α-SMA, Col1A1 and TGF- β gene expression. Furthermore, liver inflammation was also not significantly affected in $CtsD^{\Delta Hep}$ mice after CCl_4 as assessed by NIMP and F4/80 IHP and TNF-α, CCL2 and CCL3 gene expression. In agreement, no significant changes in liver damage, fibrosis and inflammation were observed after 14 days BDL between $CtsD^{F/F}$ and $CtsD^{\Delta Hep}$ mice supporting our results in the CCl_4 model.

Conclusion: CtsD expressed in hepatocytes does not play an essential role in liver fibrosis development.

WED-248

Myeloperoxidase from neutrophile granulocytes accomplish destruction of Schistosoma mansoni eggs

Ricarda Sölter[1], Verena von Buelow[1], Dorothee Dreizler[1], Grit Stampa[1], Thomas Quack[2], Christoph G. Grevelding[2], Max Moescheid[2], Annette Tschuschner[1], Heike Mueller[1], Martin Roderfeld[1], Elke Roeb[1]. *[1]Justus-Liebig-University and University Hospital UKGM, Gastroenterology, Giessen, Germany; [2]Institute for Parasitology, Justus-Liebig-University and University Hospital UKGM, Giessen, Germany*
Email: Ricarda.N.Soelter@med.uni-giessen.de

Background and aims: Schistosomiasis is a highly relevant parasitic diseases with worldwide over 200 million affected people. Schistosome parasite pairs occur in the mesenteric veins and produce eggs. These eggs can be flooded into different organs like the liver and lead to a chronic inflammation, causing liver portal hypertension and fibrosis. These hepatic eggs can be removed by immune cells after the treatment with Praziquantel, but neither a precise cellular mechanisms nor molecular processes of this elimination have been described so far.

Method: Male C57BL/6 mice were infected with 100 cercariae of the species *Schistosoma mansoni*. Histologic grading, myeloperoxidase (MPO)- and CD11b-immunohistochemistry were conducted to determine the inflammation and involved immune cells. Furthermore, *S. mansoni* eggs were cultivated in vitro with active and inactivated MPO for 48 hours, and stained stained with Calcein, Hoechst, and SytoxOrange afterwards to determine their vitality.

Results: *S. mansoni* is able to induce a typical hepatic granulomatous inflammation in infected mice. About 20% of the analyzed eggs, however, appeared destroyed and partly entered by immune cells. These immune cells were CD11b-positive. The nuclear shape of the CD11b+ cells match that of neutrophile granulocytes. MPO-immunohistochemistry showed several MPO-expressing cells within the granulomas and also next to destroyed *S. mansoni* eggs. Moreover, the

in vitro cultivation of *S. mansoni* eggs with MPO significantly reduced their viability compared to the control eggs cultivated with heat-inactivated MPO.

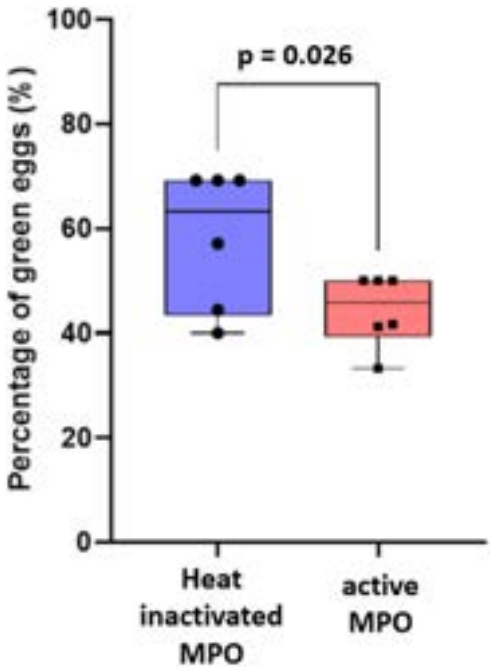

Figure:

Conclusion: Our results suggest that neutrophil granulocyte derived MPO is able to devitalize and to remove *S. mansoni* eggs from mouse liver *in vivo* and *in vitro*.

WED-249

Identification of pseudo-immune tolerance for chronic hepatitis B patients : development and validation of a non-invasive prediction model

Shuo Li[1,2], Zhiguo Li[3], Xiaoke Li[1,2], Xiaobin Zao[1,2], Yufeng Xing[4], Yong'an Ye[1,2]. [1]*Dongzhimen Hospital, Beijing University of Chinese Medicine, China;* [2]*Institute of Liver Diseases, Beijing University of Chinese Medicine, China;* [3]*Beijing Fengtai Hospital of Integrated Traditional and Western Medicine, China;* [4]*Shenzhen Traditional Chinese Medicine Hospital, China*
Email: yeyongan@vip.163.com

Background and aims: Patients with chronic hepatitis B (CHB) in the immune tolerant (IT) phase were thought to have no or slight inflammation or fibrosis in the liver. Indeed, some patients with normal ALT levels still experience liver fibrosis. This study aimed to develop and validate a non-invasive model for identifying pseudo-immune tolerance of CHB by predicting significant liver fibrosis.
Method: This multi-center study enrolled a total of 445 IT-phase patients who had undergone liver biopsy for the training cohort (n = 289) and validation cohort (n = 156) during different time periods. A risk model (IT-3) for predicting significant liver fibrosis (Ishak fibrosis score ≥3) was developed using high-risk indicators that were identified using multivariate stepwise logistic regression. Next, an online dynamic nomogram was created for the clinical usage. The receiver operating characteristic (ROC) curve and the area under the ROC curve (AUC) were used to assess the discrimination of the model. Calibration curves were used to evaluate the models' calibration. The clinical practicability of the model was evaluated using decision curve analysis and clinical impact curves.
Results: Aspartate aminotransferase (AST), hepatitis B e-antigen (HBeAg) and platelet (PLT) were included in the IT-3 model. The IT-3 model showed good calibration and discrimination both in the training and validation cohorts (AUC = 0.888 and 0.833, respectively). At a cut-off value of 106 points, the sensitivity and specificity were 91.7% and 70.2%, respectively. The decision curve analysis and clinical impact curves indicated that the IT-3 model had good clinical application.
Conclusion: The IT-3 model proved an accurate non-invasive method in predicting significant liver fibrosis for CHB patients with pseudo-immune tolerance, which can help to formulate more appropriate treatment strategies.

WED-250

The anti-fibrotic efficacy of Adelmidrol depends in the level of hepatic PPAR gama

Huanyu Xiang[1], Jing Xiao[1], Zilin Sun[1], Zongyi Liu[1], Junhao Zhang[1], Hongyan Xiang[1], Hong Ren[1], Peng Hu[1], Ming-Li Peng[1]. [1]*The Second Affiliated Hospital, Chongqing Medical University, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, Department of Infectious Diseases, Chongqing, China*
Email: peng_mingli@hospital.cqmu.edu.cn

Background and aims: Effective anti-inflammatory therapy is beneficial to delay the progression of liver fibrosis. Adelmidrol, a potent anti-inflammatory small-molecule compound, has been reported to treat inflammatory diseases like arthritis and colitis. The study is aimed to investigate the effect of adelmidrol on hepatic fibrosis.
Method: Experimental liver fibrosis was induced by chronic CCl_4 exposure or choline-deficient, L-amino acid-defined, high-fat diet (CDAA-HFD). Histopathological signs and serum markers were used to evaluate the pharmacological activity of adelmidrol.
Results: Firstly, adelmidrol had different anti-fibrotic effects in these two liver fibrotic models. In the CCl_4 model, serology and liver pathology showed adelmidrol significantly improved liver injury and fibrosis by significantly reducing ALT, AST, and the deposition of extracellular matrix. While adelmidrol exhibited limited anti-fibrotic effect in CDAA-HFD-induced fibrosis, instead, aggravated the hepatic steatosis and TG content. Secondly, the inconsistencies of expression trend in liver PPARgama were observed in both models. The CCl_4 injury led to the continuous decrease of hepatic PPARgama levels, and the CDAA-HFD diet induced the increased PPARgama level. Long-time adelmidrol administration significantly increased hepatic PPARgama levels of both models. Interestingly, GW9662 (a specific PPARgama antagonist) pretreatment prevented the up-regulation of PPARgama induced by adelmidrol in both models, which counteracted the anti-fibrotic effect of adelmidrol in the CCl_4 model, and reversed the aggravating steatosis effect of adelmidrol in the CDAA-HFD model. Thirdly, liver RNA-Seq analysis and immunohistochemistry demonstrated adelmidrol markedly inhibited the activation of hepatic macrophages and stellate cells (HSCs) in the CCl_4 model, and vitro and vivo experiments confirmed adelmidrol aggravated steatosis in hepatocytes by activating the PPARγ/CD36 pathway in the CDAA-HFD model.
Conclusion: Adelmidrol significantly up-regulates the level of PPARgama in liver tissue, which is mainly expressed in hepatocytes, macrophages, and HSCs. The anti-fibrotic effect of adelmidrol finally depends on the synergistic interactions among hepatocytes,

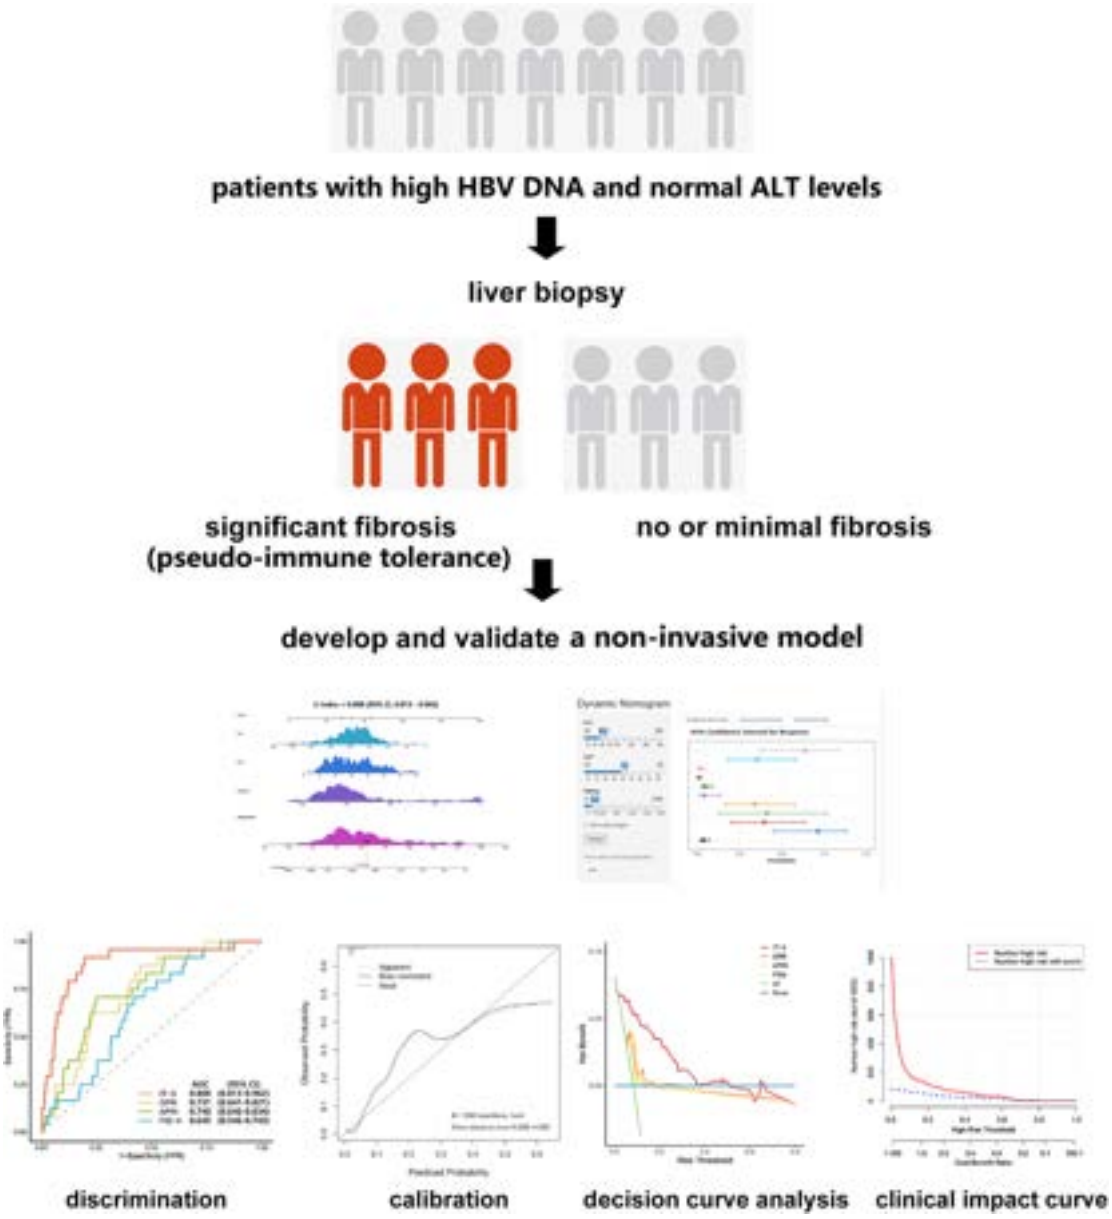

Figure: (abstract: WED-249).

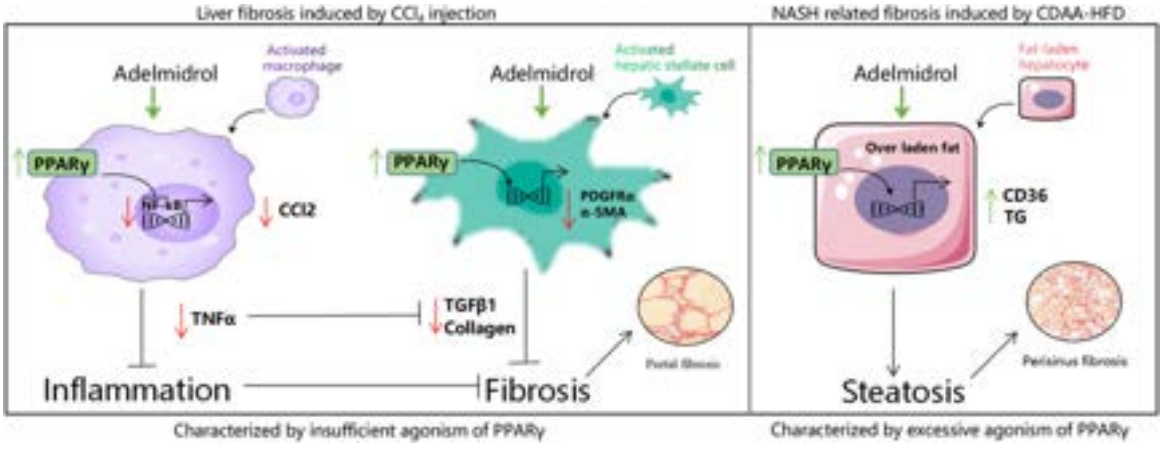

Figure: (abstract: WED-250).

macrophages, and HSCs in different pathological states. For liver injury characterized by insufficient agonism of PPARgama, adelmidrol tends to inhibit macrophage and HSCs activation to improve fibrosis. Conversely, it may aggravate steatosis.

Gut microbiota and liver disease Liver-organ crosstalk

Gut viral and bacterial alterations modulate the presence and dynamics of minimal hepatic encephalopathy at baseline and longitudinally

Thananya Jinato[1], Andrew Fagan[2], Masoumeh Sikaroodi[1], Patrick Gillevet[1], Jasmohan S. Bajaj[2]. [1]*George Mason University, United States;* [2]*Virginia Commonwealth University, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Minimal hepatic encephalopathy (MHE) is associated with an altered gut-brain axis. However, most recent data are focused on bacteria but viruses, especially phages could affect brain dysfunction in cirrhosis. Aim: Determine linkage of cognitive function with MHE and bacteria and viruses cross-sectionally and longitudinally.
Method: Outpts with cirrhosis underwent cognitive testing using psychometric hepatic encephalopathy score (PHES) to diagnose MHE using local norms cross-sectionally. A subset was followed over time and MHE dynamics were determined over time. Stool was collected for metagenomics at all time points. Bacteria and viruses were evaluated and linked with MHE/no at baseline and over time using DESeq2. Correlation networks between cognitive testing, viruses and bacteria were created and compared using R.
Results: Clinical: *Cross-sectional*: 138 cirrhosis pts; 46% MHE, 52% prior HE, (50 HCV, 49 alcohol, 23 both and rest NAFLD). MHE pts were older (62 vs 58, p = 0.04) but had similar prior HE (51% vs 53%) and MELD (10.7 vs 10.9) as no-MHE pts. PPI (40 vs 40), lactulose (40 vs 31) and rifaximin use (27 vs 24) were similar between groups. *Longitudinal*: 36 pts were followed for 9 ± 4 mths, when testing was repeated. 23 had MHE at baseline. Over time, MHE status changed in 9 pts;5 pts developed new MHE and 4 resolved their MHE. Rest were stable from an MHE perspective. α-diversity: *Cross-sectional*: Shannon index for bacteria (2.6 ± 0.5vs 2.5 ± 0.8, p = 0.8) and viruses (1.2 ± 0.6 vs 1.3 ± 0.6, p = 0.8) was similar in MHE vs no-MHE.Chao1 for bacteria was similar (79.4 ± 20.0 vs 82.8 ± 20.1, p = 0.4) but higher in MHE vs no-MHE for viruses (19.6 ± 8.9 vs 14.5 ± 9.6, p = 0.03). *Longitudinal*: Shannon for resolved (2.6 ± 0.6 vs 2.8 ± 0.3 developed MHE, p = 0.9) for bacteria and viruses (1.4 ± 0.8 vs 1.1 ± 0.7 developed, p = 0.5). Chao1 for resolved (86.6 ± 21.8 vs 88.2 ± 17.9 developed MHE, p = 0.9) for bacteria and viruses (20.6 ± 12.8 vs 14.6 ± 12.2 developed, p = 0.3). Individual taxa: *Cross-sectional*: No-MHE had higher commensals (*Lachnospiraceae*, *Ruminococcus*, *Anaerostipes* and *Eubacterium* spp) while potential pathobionts (*Escherichia, Klebsiella*) and lactate producers (*Streptococcus* and *Lactobacillus* spp) were higher in MHE pts (FigA). *CrAssphage* and Siphoviridae were lower and *Streptococcus Javan* and Azobacteroides phage were higher in MHE pts. *Longitudinal*: Commensals were ↑ in resolved MHE (Ruminococcaceae and Lachospiraceae spp) while pathobionts were ↑ in MHE developers (*Enterococcus*, Enterobacteraceae spp). *Bacteroides* phage were lower and *Lactobacillus* phage LfeSau and Phage-DP 2017a was higher in those whose MHE resolved vs those who developed it (FigB). Correlation network characteristics: MHE pts had ↑network heterogeneity (1.08 vs 0.94) and centralization (0.20 vs 0.13) than no-MHE pts. Resolved MHE pts had ↑network heterogeneity (0.65 vs 0.53) and centralization (0.29 vs 0.18) than those who developed MHE.
Conclusion: In addition to bacteria, changes in viruses such as phages linked with *Streptococcus* and *Lactobacillus* are associated with MHE at baseline and in those followed over time for MHE resolution and those who developed new-onset MHE. Viral-bacterial correlation characteristics with cognitive function are also different between MHE and no-MHE and change over time. Viral and bacterial interactions are important to study in the modulation of brain function in cirrhosis.

TOP-039

Tissue resident NK NTCP-transplanted to immunosuppressed mice exhibiting liver fibrosis and fed with high fat diet (HFD) alleviate intestinal fibrosis

Johnny Amer, Ahmad Salhab, Rifaat Safadi. *Hadassah Hebrew University Hospital, Liver Institute, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: NOD-*scid IL2rγ*^{null} (NSG) mouse is one of the most widely used immunosuppressed mouse strains. We adapted this model as it exhibits absent T, B, and NK cells and allowed us to study the effects of transplanted NK cells expressing or not expressing the sodium taurocholate co-transporting polypeptide (NTCP); a transmembrane protein highly expressed in human hepatocytes that mediates the transport of bile acids.

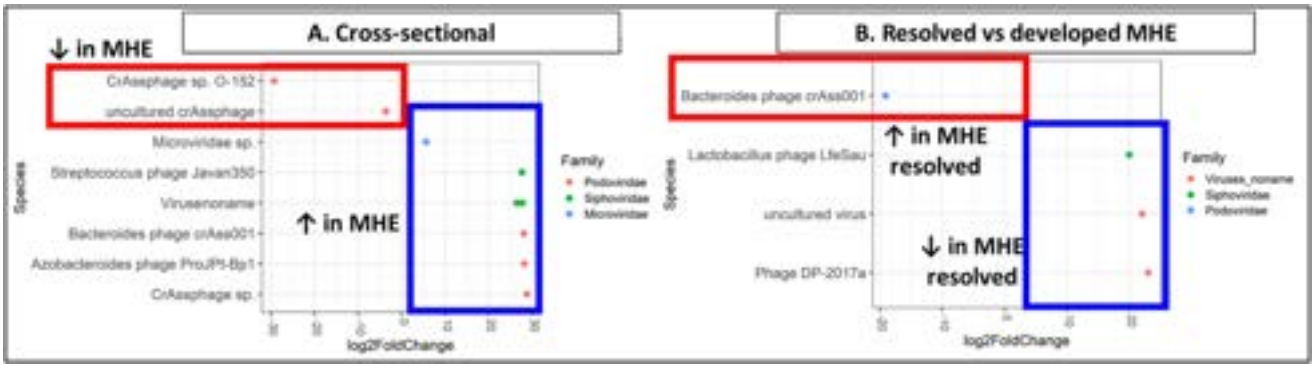

Figure: (abstract: TOP-038).

Method: Tissue resident (tr) NK cells obtained from livers of naïve C. B-17 scid (having NK cells while lacking T and B cells) were sorted according to NTCP expressions and transplanted to the CCl_4-induced liver fibrosis immunosuppressed mice fed with HFD. Inflammatory (HandE staining, and pro-inflammatory panel of cytokines), fibrosis (Sirius red staining, a-smooth muscle actin, collagen, and fibronectin) and metabolic (BAs, cholesterol, triglyceride, glucose tolerance test (GTT) and fasting blood sugar (FBS)) profiles were assessed.
Results: Our data showing $trNK^{NTCP+}$ displaying higher expressions of exhaustion markers of PD-1, TIGIT and LAG-3 as compared to their $trNK^{NTCP-}$ counterparts. Moreover, these populations showed a reduction in their activation markers profile of NKp46, NKp30 and CD107a expressions. HandE staining from non-treated mice (NT) intestines showed swelled cells with and large necrotic areas of high infiltrating inflammatory cells with steatosis while mice transplanted with $trNK^{NTCP+}$ showed a delayed in these histological findings with a significant reduction in micro- and macrovascular steatosis. Sirius Red staining in NT demonstrated increased collagen deposition in perisinusoidal areas; transplantation with $trNK^{NTCP+}$ resulted in a remarkable reduction in the fibrous dense tissue of the stained area and significant inhibitions in aSMA and Col III in the $trNK^{NTCP-}$ transplanted mice (1.8-fold and 3.1-fold, respectively; $p < 0.0002$) as compared to NT mice. These results were associated with reductions in pro-inflammatory (TNF-a, IL-1b, IL-6 and IL-10) and pro-fibrotic (IL-4 and MCP-1) cytokines and amelioration lipid profile in the mice group receiving the $trNK^{NTCP+}$ while further significant reductions were obtained following the $trNK^{NTCP-}$ transplantations ($p < 0.05$). Moreover, IL-2 and INF-g showed substantial increase in the mice receiving the $trNK^{NTCP-}$ cells.
Conclusion: Our data clearly indicate effects of transplanted $trNK^{NTCP-}$ in intestinal fibrosis amelioration and improving intestine histology of inflammation and fibrosis sections.

THU-225

Impact of human gut microbiota from PSC patients on a mouse model of biliary disease

Petra Hradicka[1,2,3], Henrik Rasmussen[3,4], Georg Schneditz[1,2,3], Kristian Holm[1,2,3], Jørgen Bjørnholt[3,5], Espen Melum[1,2,3,6,7], Johannes R. Hov[1,2,3,6]. [1]*Oslo University Hospital, Rikshospitalet, Norwegian PSC Research Centre, Oslo, Norway;* [2]*Oslo University Hospital, Rikshospitalet, Research Institute of Internal Medicine, Oslo, Norway;* [3]*University of Oslo, Institute of Clinical Medicine, Faculty of Medicine, Oslo, Norway;* [4]*Oslo University hospital, Rikshospitalet, Department of comparative medicine, Oslo, Norway;* [5]*Oslo University Hospital, Rikshospitalet, Department of microbiology, Oslo, Norway;* [6]*Oslo University Hospital, Rikshospitalet, Department of transplantation medicine, Oslo, Norway;* [7]*University of Oslo, Hybrid Technology Hub-Centre of excellence, Faculty of medicine, Oslo, Norway*
Email: petra.hradicka@medisin.uio.no

Background and aims: The gut microbiota composition differs between primary sclerosing cholangitis (PSC) and healthy controls (HC). Transfer of PSC microbiota to mice with biliary disease has previously been reported to cause more severe disease with Th_{17} activation, associated with bacterial translocation of *Klebsiella pneumoniae*, *Enterococcus gallinarum* and *Proteus mirabilis*. In the present study, we further investigated the direct role of PSC microbiota in a gnotobiotic mouse model.
Method: Stool samples from HC (n = 4) and PSC patients (n = 3) were collected into a sterile pot containing an anaerobic generator. Fecal microbiota transplant (FMT) was prepared anaerobically and stored in 10% glycerol solution at −80°C. Germ-free 8-week old gender matched C57BL/6J mice were kept in individually ventilated cages and divided into 2 groups: HC-microbiota group colonized by FMT from HC (n = 10) and PSC-microbiota group colonized by FMT from PSC patients (n = 11). Mice were colonized for 3 weeks, after which cholestatic disease was induced in all animals by feeding 0.1% 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC)-enriched diet for 2 weeks. Animals were then sacrificed and samples for plasma biochemistry, cytokine tissue analysis and microbiota profiling by 16S rRNA sequencing were collected. Mesenteric lymph nodes were cultured.
Results: PSC-microbiota mice had an increased inflammatory response, e.g., increased levels of TNF-alpha and IL-17 in liver tissue ($p < 0.05$) accompanied by increased relative liver weight ($p < 0.01$), suggesting disease worsening. There were no significant differences in plasma liver enzymes between the experimental groups. Mesenteric lymph node cultures were mainly positive for *Escherichia coli* and *E. faecalis,* which were found in both groups. Microbiota profiling of mucosa and fecal/cecal material showed distinct clustering of the experimental groups, using both unweighted UniFrac and Jaccard distance analysis ($p < 0.01$ and $p < 0.001$, respectively). Differential abundance testing identified several altered genera, including significant decreases in *Akkermansia* and *Anaerostipes* in the PSC-microbiota group, which are observed to be depleted in PSC and ulcerative colitis (Figure).

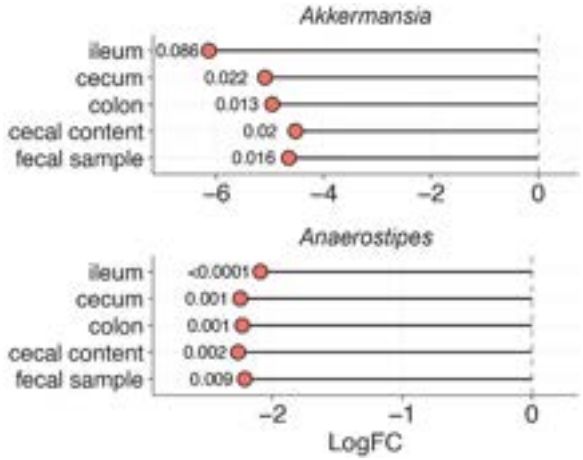

Figure: Differential abundance test showing log fold change (LogFC) in bacterial genera significantly decreased in PSC-microbiota group in various sample types. p values are displayed for each sample type.

Conclusion: We demonstrated an association between PSC microbiota and increased liver inflammation in the gnotobiotic DDC model. In addition, differences in microbiota composition in PSC and HC colonized mice were observed, while microbial translocation was common irrespective of microbiota source. Further experiments are necessary to verify the effect on disease severity and whether these can be linked to bacterial translocation or other mechanisms.

Pasteurized Akkermansia muciniphila inhibits fibrosis progression in mouse cirrhosis model and induces changes in the gut microbiome

Sung-Min Won[1], Jin-Ju Jeong[1], Satya Priya Sharma[1], Raja Ganesan[1], Haripriya Gupta[1], Mi Ran Choi[1], Ki Kwang Oh[1], Young Lim Ham[2], Ki Tae Suk[1]. [1]*Institute for Liver and Digestive Diseases, Rep. of South Korea;* [2]*Daewon Univ Coll, Dept Nursing, Rep. of South Korea*
Email: ktsuk@hallym.ac.kr

Background and aims: Cirrhosis is the final stage of chronic liver disease, and the gut microbiome acts as one of the key factors in the development and progression of disease. There is evidence that some probiotic microorganisms contribute to the recovery of gut dysbiosis in patient with cirrhosis and help treatment of complications due to cirrhosis. We identified the specific relative abundance of *Akkermansia muciniphila* in the gut microbiome of patients with cirrhosis and evaluated the molecular mechanisms and effects of live or pasteurized *Akkermansia muciniphila* on the gut microbiome in a mouse model of liver cirrhosis.
Method: 57 healthy controls and 93 cirrhotic patients were enrolled for microbiome analysis. Six-week-old male C57BL/6J mice were divided into 4 groups (n = 5/group; control, 3,5-Diethoxycarbonyl-1,4-Dihydrocollidine diet-fed [DDC, 0.05%], and 2 DDC diet-fed + *Akkermansia muciniphila* [10^9 CFU/200 μl for 8 weeks; live *Akkermansia muciniphila*, pasteurized *A. muciniphila*]). The gut microbiome of mice was initialized by administering antibiotics cocktail (ampicillin [100 mg/kg], vancomycin [50 mg/kg], metronidazole [100 mg/kg], neomycin [100 mg/kg], amphotericin B [1 mg/kg]) before strain treatment. The weight, pathology, molecular analysis, and microbiome analysis were examined.
Results: The significant relative abundance differences of *akkermansia muciniphila* in the gut microbiome of healthy and cirrhosis patients was identified. In a cirrhosis model in which liver damage with fibrosis was induced over 8 weeks by feeding mice DDC diet, supplementation with *akkermansia muciniphila* inhibited disease progression. In particular, supplementation with pasteurized *A. muciniphila* effectively ameliorated the decrease in tumor necrosis factor-alpha and liver fibrosis markers more effectively than supplementation with live strains. In gut microbiome analysis, shifts in alpha and beta diversity and microbial composition were observed in pasteurized *A. muciniphla* group compared to live *A. muciniphlia* group.
Conclusion: The significant relative abundance differences of *akkermansia muciniphila* in the gut microbiome of healthy and cirrhosis patients was identified. In a cirrhosis model in which liver damage with fibrosis was induced over 8 weeks by feeding mice DDC diet, supplementation with *akkermansia muciniphila* inhibited disease progression. In particular, supplementation with pasteurized *A. muciniphila* effectively ameliorated the decrease in tumor necrosis factor-alpha and liver fibrosis markers more effectively than supplementation with live strains. In gut microbiome analysis, shifts in alpha and beta diversity and microbial composition were observed in pasteurized *A. muciniphla* group compared to live *A. muciniphlia* group.

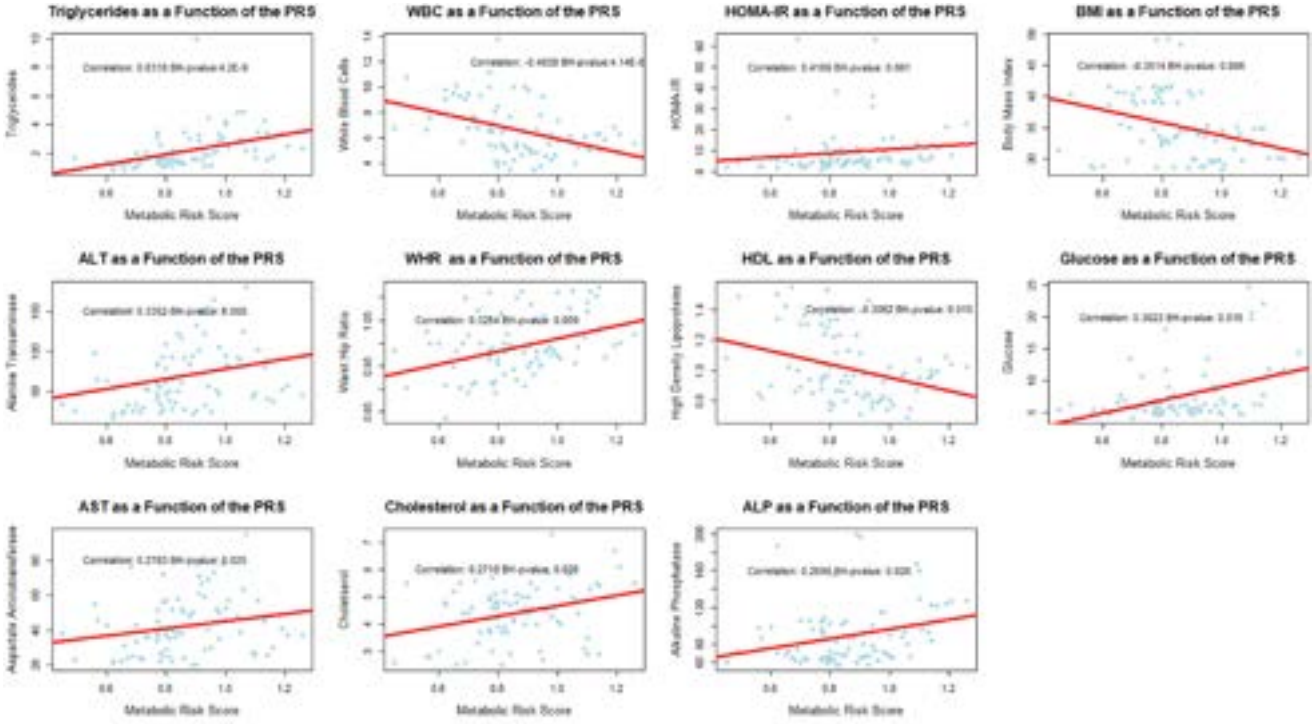

Figure 1. Significant correlations between the poly-metabolic risk score and key clinical parameters in NAFLD.

Figure: (abstract: THU-228).

London, Metabolism, Digestion and Reproduction, United Kingdom; [2]*AstraZeneca, Biopharmaceuticals Research and Early Development, Translational Science and Experimental Medicine, United Kingdom;* [3]*Imperial College London, Heart and Lung Institute, United Kingdom*
Email: nh819@ic.ac.uk

Background and aims: Gut microbiota changes contribute to the pathogenesis and progression of non-alcoholic fatty liver disease (NAFLD) by increasing intestinal permeability and facilitating the translocation of gut microbiome-modulated metabolites and bacterial products to the liver. Faecal microbiota transplant (FMT) may restore pre-morbid microbiome-metabolome interactions and mitigate NAFLD. We aimed to develop a plasma metabolite scoring model that distinguished NAFLD from healthy patients, and which allowed longitudinal tracking of the impact of FMT upon NAFLD patients' metabolism in a clinical study. Furthermore, we aimed to examine whether this 'polymetabolic risk score (PRS)' correlates with clinical parameters of the NAFLD/NASH FMT recipients throughout the clinical trial.
Method: Untargeted ^{1}H-NMR spectroscopy was used to obtain metabolic profiles of plasma samples from biopsy-proven NASH patients (n = 54) and NAFLD patients (n = 213) recruited from the specialist NAFLD clinic, St Mary's Hospital (London, UK) and healthy controls (n = 534), selected from the AIRWAVE population study, to build a polymetabolic scoring model by OPLS-DA multivariate analysis (0 = Healthy, 1 = NAFLD/NASH). Plasma samples from NAFLD patients (n = 13) were collected serially (approximately fortnightly, week 0–24) throughout an ongoing longitudinal trial in which they received up to three healthy donor capsulised FMT. Fasted plasma samples from the trial's FMT recipients collected thus far (n = 82) were examined by ^{1}H-NMR spectroscopy and scored based on their full metabolic profiles. The NAFLD FMT recipients calculated polymetabolic risk scores were compared to their clinical features at each timepoint of the trial using Spearman correlation; p values were adjusted using the Benjamini-Hochberg method.
Results: Triglycerides (p = 4.2E-9), HOMA-IR (p = 0.001), ALT (p = 0.008), waist-hip ratio (p = 0.009), glucose (p = 0.015), AST (p = 0.025), cholesterol (p = 0.026) and ALP (p = 0.026) showed significant positive correlations to the PRS towards the NAFLD phenotype, while WBC (p = 4.14E-5), HDL (p = 0.015), and unexpectedly, BMI (p = 0.006) showed significant negative correlations to the PRS. In contrast, weight (p = 0.306), insulin (p = 0.103), creatinine (p = 0.115), albumin (p = 0.366), bilirubin (p = 0.366), LDL (p = 0.366), GGT (p = 0.398), C-reactive Protein (p = 0.572) and HbA1c (p = 0.672) did not exhibit correlation with the PRS thus far throughout the trial.
Conclusion: We have demonstrated that the pre-calculated ^{1}H-NMR plasma PRS developed for predicting the NAFLD phenotype strongly correlates to routinely-measured hepatic enzymes and common clinical markers of dysmetabolism measured longitudinally throughout the trial. This gives further insight into the potential contribution of the gut microbiome to metabolic perturbations in NAFLD. This also shows potential for a multi-profile risk assessment based on clinical parameters and the plasma ^{1}H-NMR PRS.

THU-229
Identifying the role of gut-vascular barrier associated macrophages in liver cirrhosis

Lena Smets[1], Maria Viola[1], Hannelie Korf[1], Frederik Nevens[2], Guy Boeckxstaens[1], Schalk van der Merwe[1,2]. [1]*KULeuven, CHROMETA, Belgium;* [2]*UZ Leuven, Belgium*
Email: lena.smets@kuleuven.be

Background and aims: During cirrhosis where progressive liver dysfunction prevails, there is a simultaneous breach in intestinal barrier integrity. Failure of either the intestinal epithelial- and/or gut-vascular barrier (GVB) allows pathological bacterial translocation to the circulation and liver, driving a gut-liver crosstalk that perpetuates systemic inflammation and hepatic injury. The mechanisms for intestinal barrier failure during cirrhosis remain incompletely understood. In this project, we investigated the importance of

specialized macrophages in maintaining vascular barrier integrity and consequently in protecting the host against pathological bacterial translocation during the development of experimental cirrhosis.
Method: Liver cirrhosis was induced in genetically modified mice by subcutaneous injection of CCl_4 for 20 weeks. Bacterial translocation was evaluated in ileal loop experiments by injecting fluorescent E.coli bioparticles into closed-off ileal loops of animals with progressive cirrhosis, followed by the microscopic fluorescein quantification in the liver. We performed single-cell transcriptomics of the lamina propria macrophage population from cirrhotic and control animals.
Results: Exposing Cx3cr1CreERT2.Rosa26-LSL-YFP mice (a state-of-the-art tool to identify intestinal long-lived GVB-associated macrophages) to CCL_4, resulted in a decrease and/or possible dysfunction of YFP^+ cells lining the vasculature. The loss or dysfunction of YFP^+ macrophages coincided with the breach in intestinal barrier integrity and bacterial translocation to the cirrhotic liver. In addition, we established a causal link between the absence of GVB-associated macrophages and the breach of GVB integrity. Hereto, we used tamoxifen injected Cx3cr1CreERT2.Rosa26-iDTR mice to allow the specific depletion of long-lived macrophages by the injection of diphtheria toxin. Following depletion of these macrophages, bacterial translocation to the circulation was evaluated using ileal loop experiments. The data revealed that even at early disease time points (with intact barrier integrity), elevated fluorescein signal in the liver sections of long-lived macrophage-depleted mice could be detected, pointing towards an accelerated vascular barrier breach. Currently, we are mapping the single cell transcriptomes of these long-lived GVB-associated macrophages along with all other lamina propria myeloid cells in experimentally induced cirrhosis versus control animals, to pinpoint the reason for their defective functionality in supporting vascular barrier integrity.
Conclusion: We provide novel insights into the role of long-lived GVB-associated macrophages in supporting intestinal barrier integrity and in bacterial translocation in an experimental model of liver cirrhosis.

THU-230
Altered gut microbiome and stool bile acids in sarcopenia in cirrhosis

Benard Aliwa[1,2], Angela Horvath[3,4], Nicole Feldbacher[3,4], Julia Traub[5], Günter Fauler[6], Vanessa Stadlbauer[3,4]. *[1]Medical university of Graz, Gastroenterology and Hepatology, Graz, Austria; [2]University of Nairobi, Food Science, Nutrition and Technology, Kenya; [3]Medical University of Graz, Gastroenterology and Hepatology, Austria; [4]Centre of Biomarker Research in Medicine (CBmed), Austria; [5]University Hospital Graz, Clinical Medical Nutrition, Austria; [6]Medical University of Graz, Austria*
Email: benard.aliwa@medunigraz.at

Background and aims: Sarcopenia in cirrhosis is associated with low quality of life and high mortality risk. The pathogenesis is not fully understood yet. We previously showed that secondary bile acids (sec-BAs) such as deoxycholic acid (DCA) and lithocholic acid (LCA) were significantly elevated in serum samples of cirrhotic patients with sarcopenia compared to cirrhotic patients without sarcopenia. Since sec-BAs are produced by the gut microbiome, we hypothesize that stool BAs composition differs between cirrhotic patients with and without sarcopenia and is related to stool microbiome composition and abundance of genes involved in BAs transformation.
Method: Sarcopenia was diagnosed according to the European working group on sarcopenia in older people. Fecal BAs composition by ultra-high-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS in cirrhotic patients with ($n = 78$) and without ($n = 38$) sarcopenia. Microbiome composition was analyzed by 16s rDNA sequencing and stool BAs gene abundances were analyzed by qPCR.
Results: We observed that cholic acid (CA) and cholic acid to chenodeoxycholic acid (CA: CDCA) were significantly reduced in the stool of cirrhotic patients with sarcopenia compared to cirrhotic patients without sarcopenia ($p = 0.02$ and $p = 0.03$, respectively). Compared to cirrhotic patients without sarcopenia, the ratios of deoxycholic acid to cholic acid (DCA: CA) and lithocholic acid to chenodeoxycholic acid (LCA: CDCA) were significantly elevated in the stool of cirrhotic patients with sarcopenia ($p = 0.014$ and $p = 0.042$, respectively) indicating an enhanced transformation of primary to secondary bile acids by the gut microbiome. Furthermore, bacterial species linked to sarcopenia in cirrhosis (*Bacteroides fragilis*, *Blautia marseille*, and *Sutterella* spp) clustered together and correlated positively with DCA: CA and LCA: CDCA indicating that *Bacteroides fragilis*, *Blautia marseille*, and *Sutterella* spp may individually or collectively enhance the transformation of primary to secondary BAs. Despite alterations in BAs composition in stool, the gene abundances of bile salt hydrolase (BSH) and 7 alpha-dehydroxylase (7 alpha-HSDH) were comparable between cirrhotic patients with and without sarcopenia.
Conclusion: Changes in BAs composition occur in sarcopenic cirrhotic and are linked to compositional changes in the gut microbiome; however, we observed no difference in BAs transforming genes between sarcopenic and non-sarcopenic microbiomes in cirrhosis. Thus, the study demonstrated a potential functional gut microbiome-host interaction linking sarcopenia with the changes in the gut microbiome and stool BAs profiles pointing towards a potential mechanistic interplay in understanding sarcopenia pathogenesis.

THU-231
The gut (and its microbiota)-liver axis in liver disease associated with alpha-1-antitrypsin deficiency

Francesco Annunziata, Nunzia Pastore. *Telethon Institute of Genetics and Medicine, Pozzuoli, Italy*
Email: f.annunziata@tigem.it

Background and aims: Alpha-1-Antitrypsin Deficiency (AATD) is an inherited genetic disorder caused by mutations in the *SERPINA1* gene. The most common variant is the Z allele (ATZ), which leads to improper protein folding causing retention of the polymeric ATZ protein in the hepatocytes inducing a cascade of hepatotoxic events resulting in chronic liver inflammation, fibrosis, cirrhosis and increased risk of hepatocellular carcinoma (HCC). Despite the common genetic mutation, patients suffer from different onset and severity of the liver disease; of note, most of the patients with the homozygous ATZ mutation will never develop any liver disease. The reason for this phenotypic variability is unknown. Several studies have been carried out to investigate the involvement of genetic and environmental modifiers and their influence on the expression and severity of the liver disease among patients. The aim of our study is to investigate the gut-liver axis in AATD, focusing in particular on the gut functionality and the possible connection between AATD-associated liver disease and the gut microbiota as modifier of the liver phenotype.
Method: Methods for the characterization of the gut and its functionality:Bulk- and single cell-(sc)RNA sequencing. Immunoblots and Immunostainings.Organoid forming assays. Methods for the analysis of the intestinal microbiota composition: Metagenomic sequencing.
Results: PiZ mice (an AATD mouse model) show a reduction in body weight compared to age-matched controls. We hypothesized defects in gut functionality and nutrient absorption. Interestingly, we found high ATZ mRNA and protein levels in the intestine of PiZ mice, particularly in the ileum, the region where the majority of microbes resides. Single cells RNA (scRNA)-sequencing analysis revealed that ATZ mRNA is expressed in all the intestinal cell types. We confirmed this data by co-immunostaing for human ATZ and cell-specific markers. Of note, we found ATZ polymers in Goblet, Enteroendocrine and Paneth cells, responsible for the secretion of the gut protective mucus layer, of hormones reflecting dietary intake, of factors necessary for stem cell function, and molecules with antimicrobial

properties. In addition, we observed differences between WT and PiZ intestinal crypts-derived organoids, with the latter showing impaired differentiation, likely due to accumulation of the toxic polymeric ATZ. Lastly, from metagenomic analyses we observed that WT and PiZ mice have a well distinguished intestinal microbiota composition with many bacterial strains up-regulated in PiZ mice demonstrated to be increased in many liver diseases.

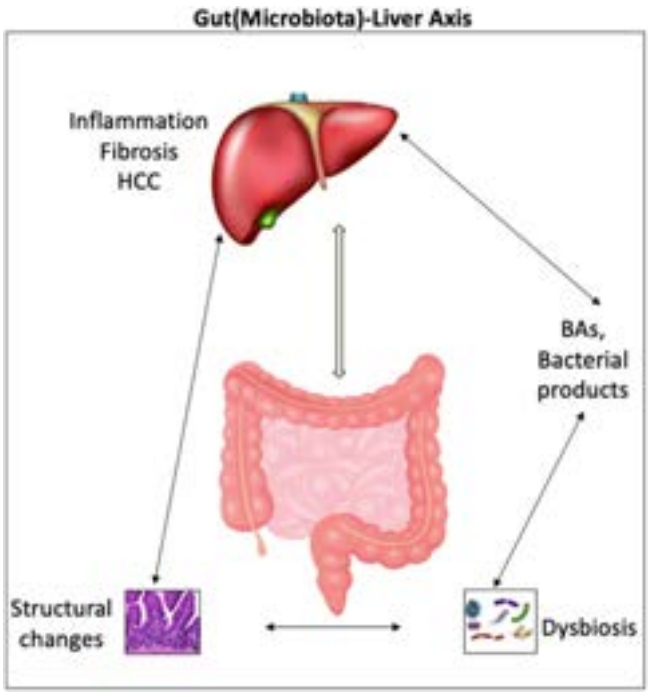

Figure:

Conclusion: Our preliminary data suggest that ATZ expression and accumulation in intestinal cells may affect the gut and its microbiota, thus affecting the continuous bidirectional crosstalk between gut and liver and being a candidate for the different onset and severity of liver disease in AATD.

THU-232

Intestinal dysbiosis exacerbates gut barrier dysfunction via inhibiting FXR-FGF15 in intra-abdominal sepsis

Shuwen Qian[1], Xiaomei Wang[2], Qiaohao Hou[2], Zehua Su[3], Haobing Shi[3], Lijun Liao[3], Xiangrui Wang[3]. [1]*Yangpu Central Hospital affiliated to Tongji University, Shanghai, China;* [2]*Shanghai East Hospital, School of Medicine, Tong ji University, Shanghai, China;* [3]*Shanghai East Hospital, School of Medicine, Tong ji University, China*
Email: Shuwen_Qian@tongji.edu.cn

Background and aims: Intestinal barrier dysfunction due to intestinal dysbiosis is considered a major cause of initiation and development of intra-abdominal sepsis and multiple organ dysfunction. Farnesoid X receptor (FXR) plays an important role in enteroprotection, but the exact mechanism is still unclear. This study was to determine whether intestinal dysbiosis aggravate intestinal barrier impairment by inhibiting FXR-FGF15 in intra-abdomimal and its probable mechanism.
Method: Caecal ligation and puncture (CLP) and fecal microbiota transplanted (FMT) from septic mice constructed a model of intestinal flora dysbiosis, intestinal FXR and FGF15 expressions and the gut barrier function were examined and compared. INT-747, an agonist of FXR, was assessed whether improve the phenotype of CLP mice or gut barrier. The relevance of intestinal epithelial cell-sepecific deletion of MyD88 (MyD88$^{\triangle IEC}$) on FXR-FGF15 axis as well as microbiota and barrier were studied. The role of probiotics on FXR was also discussed. Intestinal flora was analyzed by 16S rRNA metagenomic sequence.
Results: In intra-abdominal sepsis mice model, FXR and FGF15 in ileum displayed significantly decreased, along with cholestasis, impairment barrier function and flora dysbiosis. Upregulation of FXR by INT-747 and significantly improved survival, barrier function and other phenotypes in septic mice. In FMT, septic intestinal flora activated intestinal myd88 expression and reduced intestinal FXR and FGF15 expression. After myd88 knockdown in intestinal epithelial villi, the index of FXR was elevated, ZO-1 was improved, IL-6 and IL-1β were reduced, and the abundance and diversity of flora were increased. Strikingly, Probiotics boost FXR-FGF axis to improve intestinal function.

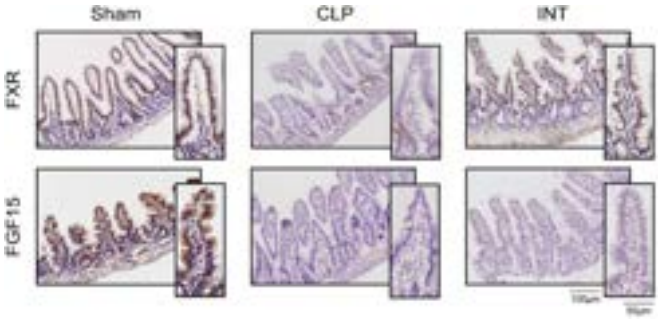

Figure:

Conclusion: Intestinal dysbiosis triggers over activation of MyD88 in intestinal epithelial cells in intra-abdominal septic mice, and subsequent inhibited the FXR-FGF15 signalling associated with gut barrier function deteriorated.

THU-233

Viral like particle analysis shows changes with PPIs and may be more sensitive than metagenomics to study PPI modulation of virome in cirrhosis

Marcela Peña Rodríguez[1,2], Masoumeh Sikaroodi[3], Patrick Gillevet[3], Jasmohan S. Bajaj[4]. [1]*University of Guadalajara, Mexico;* [2]*Laboratory for the Diagnosis of Emerging and Reemerging Diseases (LaDEER), Microbiología y Patología, Guadalajara, Mexico;* [3]*George Mason University, United States;* [4]*Virginia Commonwealth University, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: In addition to bacteria, gut microbiota has viruses, which could impact outcomes in cirrhosis. Current cirrhosis studies have analyzed metagenomics but not direct viral like particle (VLP) analysis. These could reflect changes with proton pump inhibitor (PPI) therapy. Aim: Determine the changes in VLPs in cirrhosis vs controls, changes with addition/removal of PPI and compare VLP to metagenomics.
Method: Healthy controls (not on PPI) and cirrhotic outpatients underwent stool collection. A group of cirrhotics on PPI underwent PPI withdrawal for 14 days while in another group not on PPI Omeprazole 40 mg was added for 14 days. Stools were collected at baseline and day 14 for PPI addition and removal. Demographics, medications, cirrhosis details and PPI use were recorded. Virome analysis: Stool analysis was performed using VLP enrichment. Only abundant contigs were analyzed, those with at least 100 (transcripts per million) tpm in the dataset and with a threshold of at least 5 tpm mapped to the contig by Kallisto and at least 5 tpm present in 3% of samples. Mean log10 scaled abundances were analyzed for control vs cirrhosis and between controls and pts with cirrhosis ± PPI use. A subset was sent for metagenomics in addition to VLP and viruses detected by both techniques were compared. α diversity and DESeq2, using raw read counts. A p value <0.05 and a log2 fold change >2 was

Figure: (abstract: THU-233).

considered statistically significant. Metagenomics to VLP: compared with LeFSe.

Results: Clinical data: 110 subjects (20 controls and 90 cirrhosis) were enrolled. Controls (60.8 ± 6.9 years, 13 men) and cirrhotic outputs (62.1 ± 7.0 yrs, 72 men with 15 HCV, 29 alcohol, 12 both, 17 NAFLD and 3 other etiologies) had similar demographics. 38 had HE, 41 ascites and 38 were on omeprazole 31 ± 17 mg/day. PPI users had similar MELD (11.7 ± 5.4 vs 11.0 ± 6.3, p = 0.52), HE pts (37% vs 46%, p = 0.38) and lower ascites (29% vs 52%, p = 0.006) than non-users. 27 cirrhotics (14 on and 13 not on PPI had) both VLP and metagenomics done. PPI trials: 8 compensated pts (age 58 yrs) underwent addition and 8 other compensated pts (age 59 yrs)underwent PPI withdrawal and addition respectively over 14 days. No clinical changes were found. VLP changes (Fig): Cirrhotics had lower viral α-diversity. No change in PPI cross-sectionally or before/after addition or withdrawal was seen on viral α-diversity. DESeq2 showed higher Bacteroides phages in controls and higher Siphoviridae, Gokushovirinae and Drulisviruses (Enterobacterial phages) in cirrhotics. PPI linked with higher Siphoviridae, mastadenonovirus and lower CrAss-like viruses and Microviridae. PPI addition reduced Bacteroides phage and some crasslike viruses while removal reduced other CrAss-like viruses. VLP vs metagenomics: Metagenomics did not differentiate between PPI use but VLP showed that crAss_likeviruses cat8522, Przondovirus spp, unclassified Siphoviridae andand Podoviridae sp_ctfa10 were higher in the PPI group while Microviridae, Gokushovirinae, Bacteroidesphages were higher in no-PPI group.

Conclusion: Viral-like particle analysis shows important phage and eukaryotic viral changes in patients with cirrhosis vs controls and especially those with PPI use. A direct comparison of these analysis with metagenomics shows that VLP may be more sensitive to the role of PPIs in cirrhosis.

THU-234

Edible exosomes oral administration restores gut homeostasis and reduces systemic ammonia level in rodent model

P. Debishree Subudhi[1], Jitendra Kumar[1], Anupama Parasar[1], Shivani Gautam[1], Ashmit Mittal[1], Varun Suroliya[2], Shruti Sureshan[2], Dinesh Mani Tripathi[1], Chhagan Bihari[3], Shiv Kumar Sarin[4], Sukriti Sukriti[1]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Genome Sequencing Laboratory, India; [3]Institute of Liver and Biliary Sciences, Department of Pathology, India; [4]Institute of Liver and Biliary Sciences, Department of Hepatology, India*
Email: sukritibiochem@gmail.com

Background and aims: Elevated plasma ammonia is attributed to hepatic dysfunction and gut dysbiosis along with systemic inflammation. There is an urgent need of agents which can reinstate the gut commensals and reduce ammonia levels. We investigated the effects of Carrot Edible Exosomes (CEE) on gut microbiome and hepatic injury.

Method: CEE were fractioned from black carrots [*Dacus carota*] by differential ultracentrifugation and characterized by transmission electron microscopy and nanoparticle tracking assay. Proteomics was performed to evaluate cargoes. Stability, viability were assessed using *in-vitro* stomach/intestine like digestion and also by co-culture with hepatocytes. Prophylactic oral administration of CEE was done in Thioacetamide (TAA) induced acute hyperammonemia model, compared with vehicle and lactulose. Behavioral, biochemical markers of hepatic injury, ammonia, intestinal permeability and liver histology were investigated. Gut microbiota were assessed by 16s metagenomics.

Results: The size of CEE ranges (52 nm–331 nm) with concentration of $2.65 \times 10^9 \pm 0.65$/ml with zeta potential −17.7 ± 2.4 mV. Total 647 proteins were identified as CEE cargoes, highly enriched with superoxide dismutase, ferritin and aspartate aminotransferase. After stomach like *in-vitro* digestion, no changes in concentration were found withparticle size reduced ($p = 0.02$) with intact zeta potential. Upon CEE co-culture with hepatocytes after LPS injury, ornithine transcarbamylase (otc; $p = 0.0004$) and Arginosuccinate synthetase (ass; $p = 0.0331$) were upregulated and IL-1b and Caspase3 ($p < 0.001$) mRNA levels reduced within 30 mins than controls. CEE administration in TAA compared to vehicle and lactulose reduced the plasma ammonia levels [Vehicle-145.3 ± 43.6; CEE-92.2 ± 23.2; lactulose-124.8 ± 12.5 μmol/L ($p = 0.03$)], ALT and bilirubin ($p = 0.006$; $p = 0.007$). CEE improved sensory motor activity ($p < 0.001$), hepatic necrosis and inflammation. ZO-1 expression was

Figure

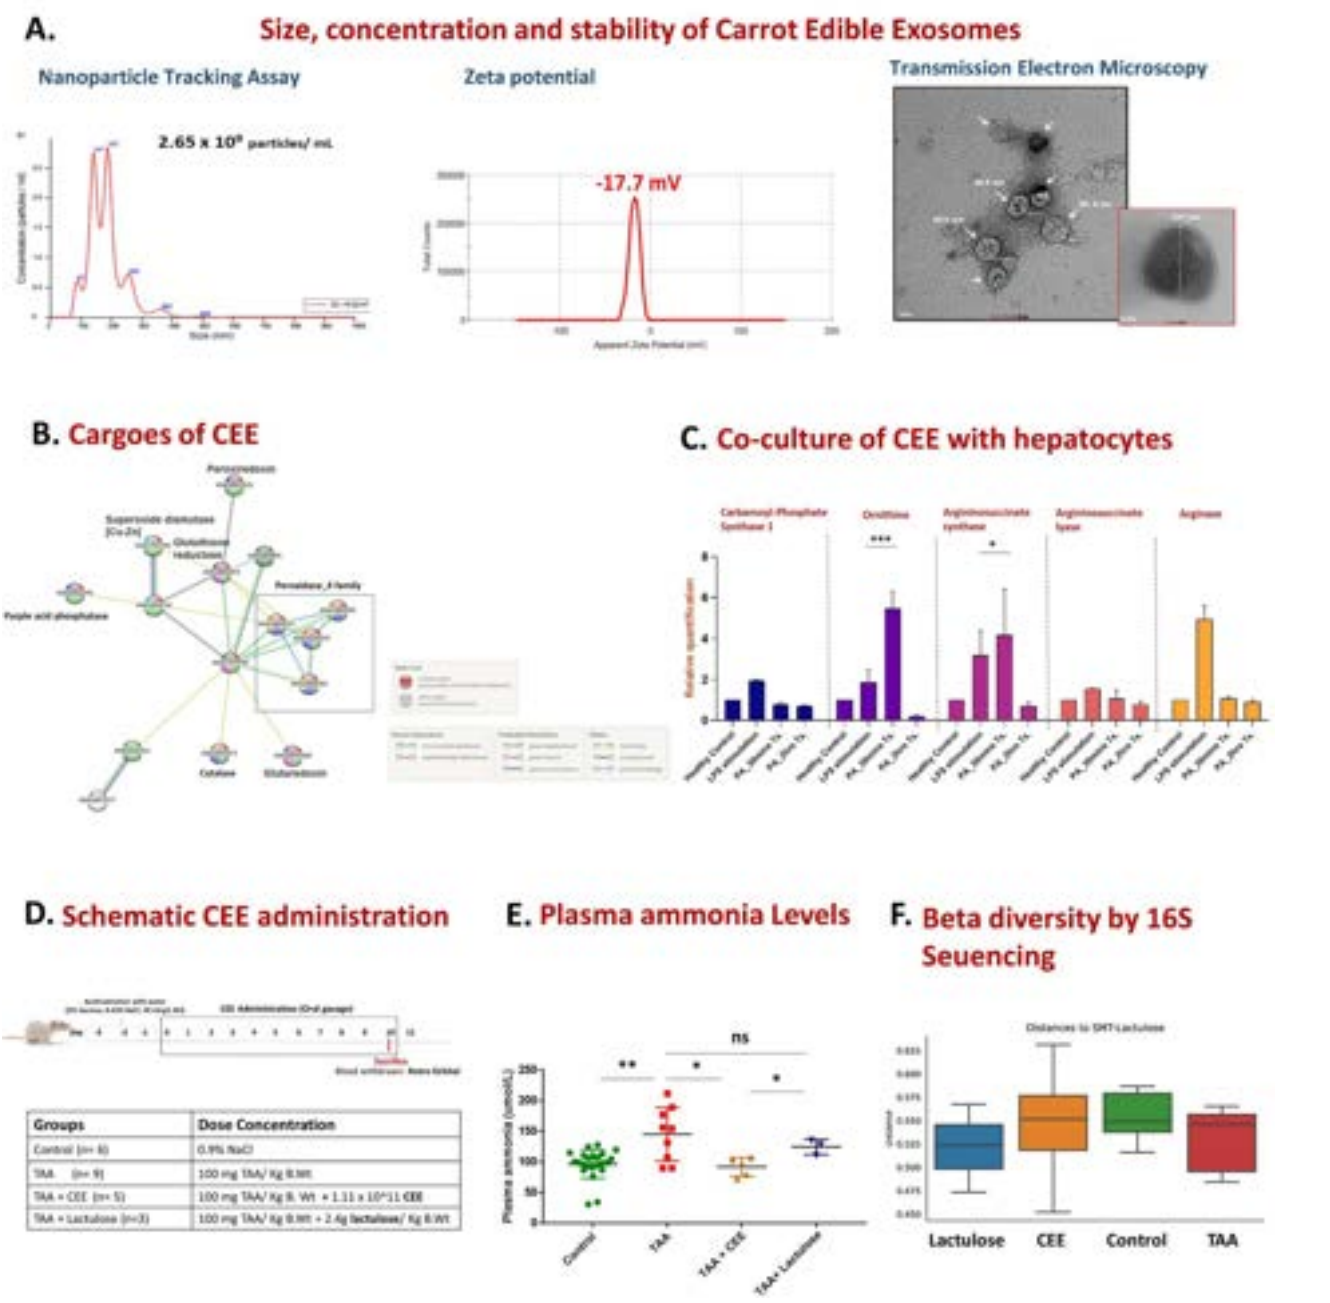

Figure: (abstract: THU-234).

higher in CEE than lactulose or vehicle ($p < 0.001$). CEE enhanced abundance of Firmicutes [Peptococcaceae, Lachnospiraceae, Ruminococcaceae ($p < 0.001$)] provides energy to maintain gut epithelia, aid in SCFA production. CEE increased growth of *Desulfovibrio* responsible for acetic acid levels and reduced inflammation by producing α-synuclein protein.

Conclusion: CEE potentiate the hepatic urea cycle and lower plasma ammonia levels in acute hyperammonemic rodent model. The CEE carry strong hepatoprotective cargoes which help restore the gut homeostatis and restore gut permeability and can be considered as therapeutic nutritional tools.

THU-235

Microbiota-targeted interventions in the gut-liver axis for chronic liver disease of DUAL etiology

Email: yulianev@ucm.es

Background and aims: Emerging evidence highlights the role of gut microbiome in chronic liver disease (CLD). In the present work, we used our recently published DUAL preclinical model of steatohepatitis and fibrosis and aimed to analyse the relevance of the liver-gut-microbiome crosstalk in order to define potential therapeutic circuits in DUAL model.
Method: C57BL/6 male mice received 10% alcohol in drinking water together with a Western diet (WD) for 10 and 23 weeks (DUAL model). Liver and gut tissue histology, hepatic inflammation, intestinal permeability and 16S rRNA microbiome profiling were analysed. Feeding of 10 weeks was used to evaluate the effects of microbiota modulation after: (i)Short-term (10 days) oral administration of antibiotics and (ii) Fecal matter transplantation (FMT) from healthy donor.
Results: 23 weeks DUAL feeding resulted in reduction of colon length accompanied by a significant decrease in the height of colonic crypts. The rate of apoptosis in intestinal epithelial cells (IEC) exceeded the rate of compensatory proliferation in colon. Pathological IEC shedding resulted in gap formation in the epithelium and decreased expression of tight junctions (occluding, ZO1). These changes were accompanied by degradation of mucus layer and by the accumulation of giant inflammatory foci in the colon submucosal layer formed by CD3+ T and B220+ B lymphocytes. Consistently, gut permeability, translocation of microbial products (LPS) to the circulation significantly increased and overexpression TLR2/4/9 was detected in the DUAL livers. Microbiome profiling of DUAL animals revealed decreased alpha diversity, elevated proportions of Gram-negative Bacteroidaceae and lower presence of other commensal taxa. Similarly, 16S rRNA sequencing of stool samples from obese patients with mild alcohol consumption revealed reduced overall microbiota diversity and increase in gram-negative LPS producing Bacteroides.
Short-term oral application of antibiotics to 10 weeks DUAL-fed mice markedly improved hepatic steatosis, attenuated liver damage, lowered serum transaminases, decreased CD45 and F4/80 positive infiltrates, decreased the expression of TLR2/4/9 and reduced collagen accumulation in the liver. The implementation of FMT resulted in decreased accumulation of triglycerides in the liver, reduction in hepatic inflammation and fibrosis.

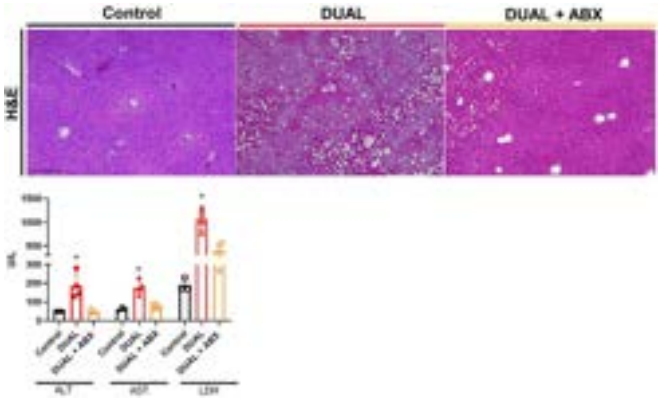

Figure:

Conclusion: Dysbiosis is a critical factor in the regulation of steatohepatitis/fibrosis of DUAL etiology. Gut-based early therapeutic interventions could be beneficial to halt CLD development.

THU-236
The novel class of microbially conjugated bile salts activate the main host bile salt receptors FXR and TGR5

Ümran Ay[1], Martin Lenicek[2], Raphael Haider[3], Arno Classen[4], Hans van Eijk[5], Carsten Hoffmann[3], Carsten Bolm[4], Steven Olde Damink[1,5], Frank Schaap[1,5]. *[1]University Hospital RWTH Aachen, Surgery, Germany; [2]Institute of Medical Biochemistry and Laboratory Diagnostics, Czech Republic; [3]University Hospital Jena, Molecular Cell Biology, Germany; [4]RWTH Aachen University, Organic Chemistry, Germany; [5]Maastricht University Medical Centre, Surgery, Netherlands*
Email: uay@ukaachen.de

Background and aims: A new class of bile salt metabolites comprising bile salts that are *N*-amidated with non-canonical amino acids by gut microbes, was recently reported. The function of these microbial bile salt conjugates (MBSCs) and their relevance for human (patho)physiology is unresolved. Initial disease associations were made for Crohn's disease and dysbiotic states. Here, we sought to determine if MBSCs can activate the main host bile salt receptors FXR and TGR5, and assessed their entrance into the circulation.
Method: *N*-amidates of cholic acid (CA) and chenodeoxycholic acid (CDCA) and leucine, tyrosine and phenylalanine were synthesized, and assayed for binding to FXR and TGR5 using coactivator and $G_{s\alpha}$ recruitment assays, respectively. Activation of FXR by MBSCs, and requirement for an uptake transporter, was further studied by reporter assays in 293 embryonic kidney cells, and in HuH7 hepatoma cells using a transcriptional read-out. For initial explorations, levels of aforementioned MBSCs were determined using LC-MS in relevant patient cohorts in chyme and blood samples, including mesenteric venous blood.
Results: CDCA-based MBSCs elicited dose-dependent recruitment of SRC1 coactivator peptide to the ligand-binding domain of FXR, with Tyrosine-CDCA having the highest affinity (EC_{50} = 2.8 µM). Treatment of HuH7 cells with CA- or CDCA-based MBSCs resulted in elevated mRNA levels of FXR target genes (e.g. *SHP, OSTβ*), in a manner dependent on the bile salt uptake transporter NTCP. Both intestine- and liver-predominant FXR isoforms (α4 and α2, resp.) were activated by MBSCs in luciferase reporter assays, provided that a bile salt uptake

transporter (ASBT or NTCP) was present. MBSCs were also ligands of TGR5 as evidenced by dose-dependent recruitment of the stimulatory $G_{s\alpha}$ subunit in a nanoBRET assay. CDCA-based MBSCs displayed higher affinity than their CA-based counterparts. Moreover, MBSCs induced downstream activation of a cAMP-driven reporter in an TGR5-dependent manner. Using a LC-MS assay with nanomolar range sensitivity, MBSCs were readily detected in chyme of patients with intestinal failure (n = 12), where MBSCs comprised a minor fraction (up to 40 ppm) of total bile salts. MBSCs could not be detected in matched systemic blood of these patients, or in systemic blood of patients with morbid obesity (n = 8) or PSC (n = 6), or mesenteric and portal blood of patients with a pancreatic malignancy with/without cholestasis (n = 6).
Conclusion: MBSCs are agonists of FXR and TGR5, and substrates for the intestinal and hepatic bile salt uptake transporters. Initial pilot data indicates that absorption and entry into the host circulation of MBSCs, is unsubstantial. Degradation of MBSCs by host carboxypeptidases and bacterial bile salt hydrolases may contribute to this. Follow-up studies are required to unravel the function of MBSCs and their relevance for human disease.

THU-237
The bile acid chenodeoxycholic acid increases muscle insulin sensitization via FOXO1

Aileen Shiqi Zhong[1], Maria Corlianò[1], Raphael Chevré[2], David Castano Mayan[1], Blake Cochran[3], Bert Groen[4], Kerry Ann Rye[3], Hong Chang Tan[5], Roshni Rebecca Singaraja[1]. *[1]National University of Singapore, Singapore; [2]Agency for Science technology and Research, Singapore; [3]University of New South Wales, Australia; [4]University of Amsterdam, Netherlands; [5]Singapore General Hospital, Singapore*
Email: mdcrrs@nus.edu.sg

Background and aims: CYP8B1 acts in the bile acid (BA) synthesis pathway to generate 12α-hydroxylated BAs which were associated with insulin resistance in humans. We identified the first carriers of mutations in *CYP8B1*, a bile acid (BA) synthesis gene. These carriers showed increased circulatory primary BA cholic acid (CA):chenodeoxycholic acid (CDCA) ratio and peripheral insulin sensitivity. In vitro, CDCA increased glucose uptake in myotubes. However, it's unclear whether CDCA alone increases insulin sensitization and if skeletal muscle-mediated mechanisms contribute in vivo.
Method: We generated *Cyp8b1*$^{-/-}$ and *Cyp2c70*$^{-/-}$ mice with increased circulatory CDCA.
Results: *Cyp8b1*$^{-/-}$ mice showed increased insulin sensitivity and muscle insulin signaling, while β-cell insulin secretion was decreased and hepatic glucose metabolism remained unchanged. Muricholic acids (MCAs) were also increased in *Cyp8b1*$^{-/-}$ mice. In mice, *Cyp2c70* generates MCAs from CDCA. To exclude contributions by MCAs to insulin sensitivity, we generated *Cyp2c70*$^{-/-}$ mice with almost absent MCAs. These mice showed increased circulatory CDCA, increased insulin sensitivity and increased muscle-specific glucose uptake, despite the near absent MCAs. *Wild-type* mice administered CDCA reproduced these phenotypes, confirming that CDCA increases muscle insulin sensitization. In *Cyp8b1*$^{-/-}$, *Cyp2c70*$^{-/-}$, and CDCA-administered *wild-type* mice, muscle Insulin receptor expression increased, as did activity of it's transcription factor Forkhead Box O1 (FOXO1). The CDCA-mediated increase in muscle insulin signaling was attenuated by inhibition of FOXO1.

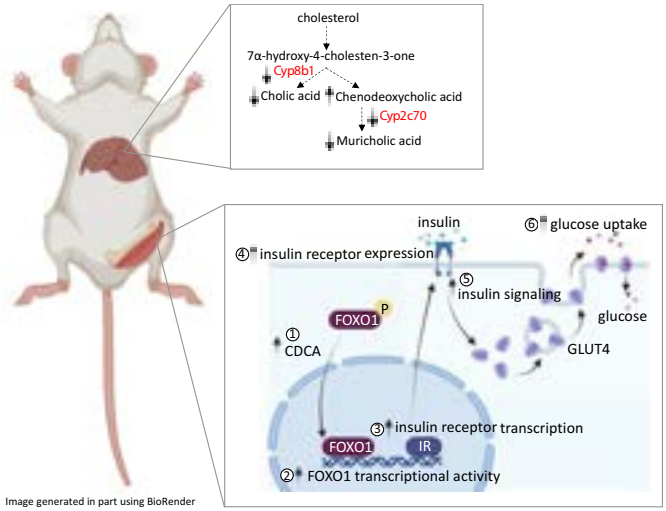

Figure:

Conclusion: Our study demonstrates that CDCA signals in skeletal muscle through the FOXO1 pathway to increase whole organism insulin sensitization.

THU-238
Characterization of pattern recognition receptor expression for regulating myeloid cell responses in the gut-liver axis in non-alcoholic fatty liver disease and cholangiopathies

Alix Bruneau, Simon Wdowinski, Linda Hammerich, Burcin Özdirik, Michael Sigal, Münevver Demir, Frank Tacke. *Charité Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany*
Email: alix.bruneau@hotmail.fr

Background and aims: The gut-liver axis is a key pathogenic circuit in the progression of liver diseases. Changes in the composition of the gut microbiota in patients with Primary Sclerosing Cholangitis (PSC) and Non-Alcoholic Fatty Liver Disease (NAFLD) have been reported, suggesting a role of microbiota in their pathogenesis. Microbial signals can be recognized by immune cells in the circulation and in the liver via Pattern Recognition Receptors (PRRs), mainly Toll-like receptors (TLRs). Here, we characterized PRR/TLR expression patterns on immune cells of these patients in order to understand relevant (dys)regulations and determine their potential as therapeutic targets.
Method: We performed multiplex immunofluorescence staining on liver and colon samples of patients as well as mouse models of PSC and NAFLD. A panel with 16 different antibodies was used to characterise TLR expression on immune cells of PSC/NAFLD patients as well as in the *mdr2 -/-* PSC-like model (in the presence or absence of dysbiosis) as well as in mice subjected to western diet (NAFLD model). In parallel, we developed a 26-colour panel for full spectrum flow cytometry on peripheral immune cells isolated from patients. This study included 140 samples divided in 4 cohorts: healthy donors, PSC, NAFLD and inflammatory bowel disease.
Results: We observe unique variations in TLR9 expression in myeloid populations for NAFLD and PSC patients compared to controls in both liver and peripheral blood. Moreover, in PSC a decrease in lymphoid cell populations can be observed, which is associated with an overexpression of several PRRs, as well as bile acid and chemokine receptors. PRR/TLR expression data correlate with parameters indicating disease severity and/or progression, supporting their potential as novel biomarkers.

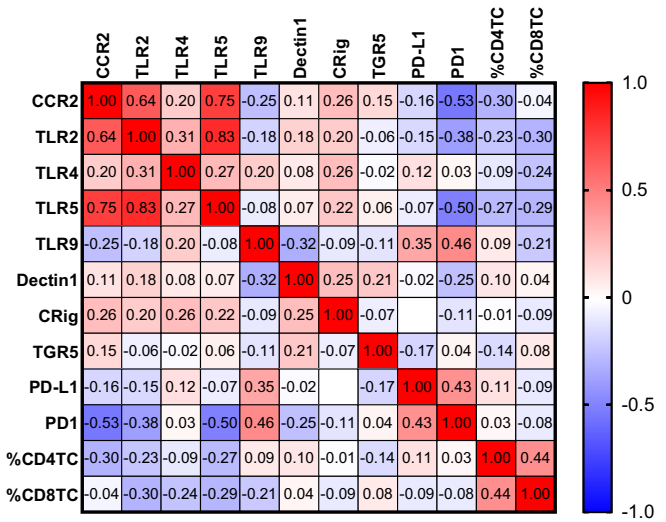

Figure: Heat map for markers expression in classical monocytes (CD14+; CD16low) across 40 PSC patients (Spearman r correlation)

Conclusion: Our results indicate that specific modulation of PRRs in immune cells occurs for PSC and NAFLD patients. These data provide the basis to establish early non-invasive markers for those pathologies and might become potential therapeutic targets for the treatment of chronic liver diseases.

THU-239

Gut microbial proteomic changes from commensal bacteria are associated with development of first decompensation in cirrhosis

Katarzyna Tyc, Xixian Jiang, Jinze Liu, Jasmohan S. Bajaj. *Virginia Commonwealth University, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Prediction of who will develop their first decompensating event in cirrhosis is difficult using clinical biomarkers. Microbiota composition is related to cirrhosis change but proteomics could offer a deeper understanding. Aim: Determine impact of inferred microbial proteomics in differentiating between compensated cirrhotic patients who remain stable versus those that develop their first decompensation.
Method: Compensated outpatients with cirrhosis underwent stool collection and were followed over time for development of their first decompensation. Demographics, cirrhosis severity and medications were collected at baseline and over time. Stool was analyzed for deep metagenomics and inferred proteomics linked with specific taxa were evaluated at baseline between groups who remained stable over time vs decompensated as well as pre/post were analyzed using MetaWIBELE. Microbially-associated proteins with absolute log fold change greater than 1 between groups, MetaWIBELE priority score >0.9 and p value <0.05 were selected and characterized proteins were closely investigated.
Results: We enrolled 68 patients with compensated cirrhosis, of whom 19 decompensated on follow-up for 429 (391) days. The 19 who decompensated developed ascites (n = 10), hepatic encephalopathy (HE, n = 6) or both (n = 3). At baseline, there was no difference in age (59 vs 59 yrs), MELD (8.9 vs 9.2, p = 0.87), albumin level (3.8 vs 3.5, p = 0.62), or medication use (PPI, statins and opioids). Both groups were followed for a similar time period 435 (429) vs 426 (321) days. Inferred Protein analysis: *Baseline comparison*: We found 3,120 proteins significantly different between groups (158 down/2962 up in unstable vs stable). Fig. 1A shows the top 10 proteins and linked bacterial species. Several proteins related to cell-wall integrity (blue color), and virulence/anti-bacterial resistance (red color) were seen in those who ultimately decompensated. Proteins related to bioenergetics (yellow highlights) in commensals belonging to Firmicutes were over-represented in those who remained stable. *Pre and post-1st decompensation*: We found 3,086 proteins changed over time (8 up/3,078 down in post compared to pre). Fig. 1B shows the *E.coli* and *S.pyogenes* expressing sulfur-reducing enzymes and resistance-associated proteins were higher post-decompensation. Commensal Firmicutes-associated proteins involved in energy metabolism were higher at baseline.
Conclusion: Inferred microbial proteomics in patients with compensated cirrhosis show significant difference that span several important processes such as bioenergetics, cell wall, and antibiotic resistance between those who ultimately developing their first decompensation as well as after the development of decompensation compared to their baseline. Microbial function through proteomics could be promising to predict first decompensation in stable outpatients with compensated cirrhosis.

Altered levels of secondary bile acids in enterohepatic circulation impairs liver regeneration in a rat model of partial hepatectomy

Impreet Kaur[1], Rajnish Tiwari[1], Pinky Juneja[1], Ashwini Vasudevan[1], Akash Kumar Mourya[1], Michael Trauner[2], Shiv Kumar Sarin[3], Dinesh Mani Tripathi[1], Savneet Kaur[1]. [1]*Institute of Liver and Biliary*

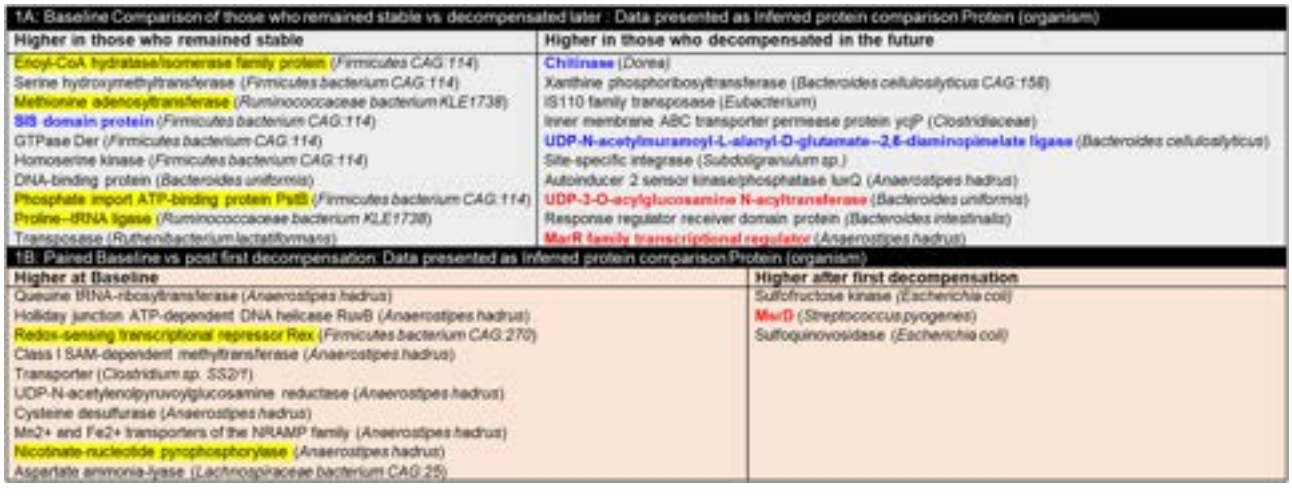

Figure: (abstract: THU-239).

Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Medical University of Vienna, Wien, Austria; [3]Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India
Email: savykaur@gmail.com

Background and aims: Liver is exposed to gut-derived components via portal vein that regulates host metabolism and tissue homeostasis. Here, we aim to explore gut microbiota-associated metabolites during liver regeneration in response to 70% partial hepatectomy (PHx).
Method: Liver regeneration was studied in PHx and compared to gut microbiota-modulated PHx, achieved by 3-week antibiotic (Abx) treatment prior to PHx (Abx+PHx). Sham without Abx served as controls and were compared to Abx+controls. Relative abundance of dominant gut phyla was evaluated in faeces by RT-PCRs. Primary hepatocytes and liver sinusoidal endothelial cells (LSECs) were isolated by collagenase perfusion. Liver regeneration was assessed by proliferating cell nuclear antigen (PCNA) in liver tissues by immunohistochemistry and cell cycle gene expression in primary hepatocytes by RT-PCRs. Untargeted metabolomics of portal and peripheral serum was performed and differentially abundant metabolites (DAMs) were identified between different study groups. In vitro effects of few DAMs were studied on viability and proliferation of hepatocytes and secretory factors of LSECs.
Results: We observed reduction in bacterial phyla, *Firmicutes* (2-fold), *Actinobacteria* (2.4-fold) and *Bacteriodetes* (2.3-fold) ($p < 0.0001$ each) post Abx treatment in controls and PHx. Compared to controls (13.4 ± 3.2%) PHx showed an increase (44.6 ± 6.9%); ($p < 0.001$) in PCNA positivity in livers that correlated with cell cycle genes involved in hepatocyte proliferation at day 2 post-PHx. In Abx-treated PHx, there was reduced PCNA (9 ± 3%); ($p < 0.001$) and cyclins' gene expression in hepatocytes as compared to PHx (cyclin B1 = 8-fold, cyclin D1 = 4-fold, cyclin E = 20-fold; $p < 0.0001$ each). In both portal and peripheral serum, we obtained about 800 total metabolites each, where we identified 224 DAMs between PHx and controls while 189 DAMs between Abx+PHx vs PHx in portal serum at day 2 post-PHx. 70 common metabolites showed exactly opposite levels between PHx vs controls and Abx+PHx vs PHx in portal serum. 3-hydroxysebacic acid and secondary bile acids such as deoxycholic (DCA) and lithocholic acid (LCA) were enhanced in PHx vs controls while decreased in Abx +PHx vs PHx. In vitro treatment with DCA (10 µM) significantly enhanced PCNA-positivity in hepatocytes (52.6 ± 7.3% vs 32.4 ± 7.9%, $p < 0.05$) and secretion of angiocrine factors, HGF (122.06 ± 9.7 pg/ml vs 77.8 ± 7.2 pg/ml) and Wnt 2 (74.5 ± 6.8 pg/ml vs 57 ± 5.3 pg/ml); ($p < 0.001$ each) in LSECs as compared to DMSO treatment.
Conclusion: We report that altered levels of secondary bile acids such as DCA in portal serum or enterohepatic circulation in Abx-treated rats lead to impaired hepatocyte proliferation, angiocrine factor secretion by LSECs and hence liver regeneration post 70% PHx. The study underscores a crucial role of secondary bile acids in liver regeneration through varied cellular mechanisms.

THU-241

Gut-liver crosstalk in hepatocellular carcinoma and non-selective beta-blockers: is there a link?

Tasnim Mahmoud[1], Olfat Hammam[2], Mahmoud Khattab[3], Aiman El-Khatib[3], Yasmeen Attia[4]. *[1]The British University in Egypt, Pharmacology and Biochemistry, Egypt; [2]Theodor Bilharz Research Institute, Pathology, Egypt; [3]Faculty of Pharmacy, Cairo University, Pharmacology and Toxicology, Egypt; [4]The British University in Egypt, Pharmacology, Egypt*
Email: yasmeen.attia@bue.edu.eg

Background and aims: The bidirectional relationship between the gut and liver orchestrated by the portal vein and dubbed the "gut-liver axis" is becoming increasingly recognized. The interest in its impact on disease onset and severity has also surged recently. Microbial dysbiosis, intestinal permeability, and compromised tight junctional proteins are manifestations in the gut that hugely provoke immune remodeling in the liver. Likewise, hepatocellular carcinoma (HCC) and its ensuing alterations on the liver microenvironment were found to govern the inflammatory milieu in the gut. An intriguing bridge linking both edges of the gut-liver axis seems to be presented in the toll-like receptor 4 (TLR4) signaling. Non-selective beta blockers (NSBBs) are known for their protective effect against intestinal permeability and dysbiosis, especially in cirrhotic patients.

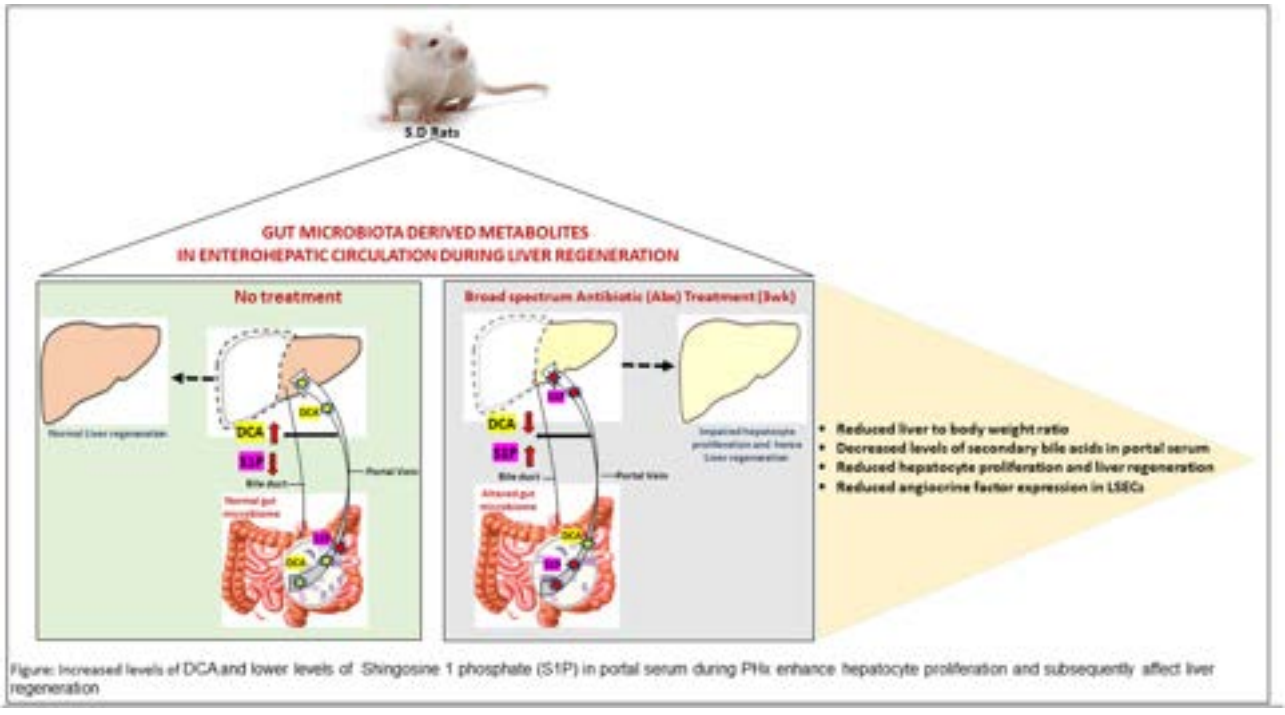

Figure: (abstract: THU-240).

Moreover, an established role for NSBBs in cancer was alluded to by the overexpression of beta receptors in solid tumors. Thus, the present study sought to unleash the likely gut barrier dysfunction in an experimental model of HCC and whether a protective role exists for carvedilol (CAR), a NSBB, on both gut- and liver-related disruptions via modulating the TLR4 signaling.

Method: Male Sprague Dawley rats received weekly intraperitoneal injections of 50 mg/kg of diethyl nitrosamine (DEN) for 16 weeks. Daily treatment with CAR started at week 18 for a period of 4 weeks, at a dose of 10 mg/kg/day, p.o. After sacrifice, livers, ileums, and colons were collected for further analysis. Histopathological examination was performed on harvested tissues. TLR4, occludin, and claudin-1 intestinal immunoreactivities were investigated using immunohistochemistry. Liver and intestinal phosphorylated nuclear factor kappa B (p-NF-kB) along with hepatic TLR4 were also estimated using ELISA.

Results: Our findings showed epithelial hyperplasia apparent as elongated crypts along with increased inflammatory infiltrates in the intestinal sections of the DEN-treated group. These results were coupled with increased pleomorphic hepatocytes with a high nuclear-to-cytoplasmic ratio in the livers of the control untreated group. These effects were, however, abrogated by CAR treatment. The DEN-treated group also demonstrated increased TLR4 hepatic levels along with surged p-NF-kB, as compared to normal animals. These effects paralleled an increase in TLR4 intestinal immunoreactivity and NF-kB levels along with altered occludin and claudin-1 levels. CAR treatment was capable of reversing both the hepatic and intestinal changes observed in the untreated DEN-treated group with significant reductions in TLR4 levels (Fig. 1) and restoration of tight junctional protein expression.

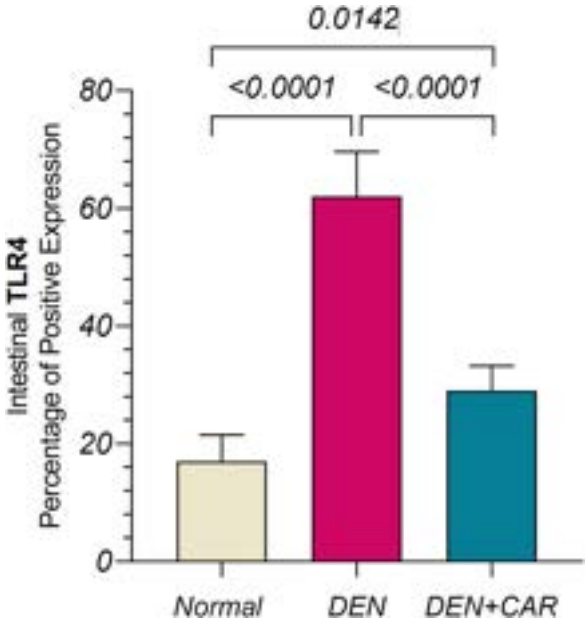

Figure: Effect of CAR treatment on intestinal immunohistochemical expression of TLR4 in normal, DEN-treated, and DEN+CAR-treated groups. Data are analyzed using one-way ANOVA followed by Tukey's for multiple comparisons. Data are presented as mean + S.D. P values less than 0.05 are considered statistically significant.

Conclusion: These findings, therefore, suggest a likely protective role of CAR in the gut-liver crosstalk in an HCC setting.

THU-242
Phascolarctobacterium as a predictor for survival in cirrhotic patients

Rosa Haller[1], Stefan Fürst[1], Johannes Woltsche[1], Lukas Gulden[1], Jakob Schwarzl[1], Julia Traub[1], Nicole Feldbacher[1,2], Benard Aliwa[1,3], Tobias Madl[4], Günter Fauler[5], Angela Horvath[1,2], Vanessa Stadlbauer[1,2]. *[1]Medical University of Graz, Institute of Gastroenterology and Hepatology, Graz, Austria; [2]CBmed GMBH, Graz, Austria; [3]University of Nairobi, Department of Food Science, Nutrition and Technology, Kenya; [4]Medical Universtiy of Graz, Gottfried Schatz Research Center, Graz, Austria; [5]Medical Universtiy of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria*
Email: rosa.haller@medunigraz.at

Background and aims: Previously we linked zonulin, a marker for intestinal permeability, to an increased risk of mortality in cirrhosis and subsequent microbiome analysis identified *Phascolarctobacterium* to be associated with improved zonulin levels and better survival over 36 months. We aim to verify the role of *Phascolarctobacterium* in liver cirrhosis.

Method: Stool, serum and urine samples from 92 cirrhotic patients (62 ± 11 years, 24 female) were obtained. *Phascolarctobacterium* abundance was extracted from 16s rRNA sequencing data. Kaplan-Meier survival analysis, group comparisons and correlation analysis were performed.

Results: A higher abundance (>50 counts per 8000 sequences) of *Phascolarctobacterium* was associated with a higher chance of survival over 36 months (log rank mantel cox, $p = 0.027$). In accordance with the previous analysis, higher abundance of *Phascolarctobacterium* was associated with better liver function (higher total protein ($p = 0.025$), higher fibrinogen levels ($p = 0.0011$) lower international normalized ratio ($p = 0.016$), lower bilirubin levels ($p = 0.009$)) and better intestinal permeability (lower zonulin levels ($p = 0.047$)), but not with etiology ($p = 0.29$). In addition to the previous study we found higher *Phascolarctobacterium* abundance in men ($p = 0.011$), higher age ($p = 0.0055$), patients with higher neutrophil ($p = 0.031$), monocyte ($p = 0.044$) and thrombocyte counts ($p = 0.0096$) and lower lymphocyte counts ($p = 0.028$).

Higher *Phascolarctobacterium* abundance was associated with changes in the metabolome (lower stool succinate and glucose, higher serum glucose, urine acetoacete and phenylalanine; all $p < 0.05$) and bile acids (lower total primary bile acids, total glucoursodeoxycholic acid and a lower ratio of 12α hydroxylated bile acids to non 12α hydroxylated bile acids, all $p < 0.05$) in stool.

Conclusion: Higher *Phascolarctobacterium* abundance in the gut microbiome of cirrhotic patients is again linked to better survival, better hepatic function and decreased intestinal permeability in this validation cohort. *Phascolarctobacterium* is associated with stool, serum and urine metabolomic changes, as well as changes in stool bile acid composition, indicating a potential role of *Phascolarctobacterium* in short chain fatty acid, glucose, amino-acid and bile acid metabolism in cirrhosis. Increasing *Phascolarctobacterium* could therefore be a therapeutic target to modulate the gut-liver axis.

THU-243
Long-term benefit of direct-acting antivirals on gut dysbiosis and microbial translocation in HCV-infected patients with and without HIV coinfection

Natthaya Chuaypen, Thananya Jinato, Pisit Tangkijvanich. *Faculty of Medicine, Chulalongkorn University, Biochemistry, Bangkok, Thailand*
Email: pisittkvn@yahoo.com

Background and aims: Emerging evidence indicate that direct-acting antivirals (DAAs) could alleviate gut dysbiosis in patients with hepatitis C virus (HCV) infection who achieve sustained virological response (SVR). However, limited data are available regarding the long-term effect of DAAs on gut microbial composition, short-chain fatty acids (SCFAs) and microbial translocation in patients with chronic HCV infection.

Method: A prospective longitudinal study of 50 patients with HCV monoinfection and 19 patients with HCV/HIV coinfection received DAAs were conducted. Fecal specimens collected at baseline and at

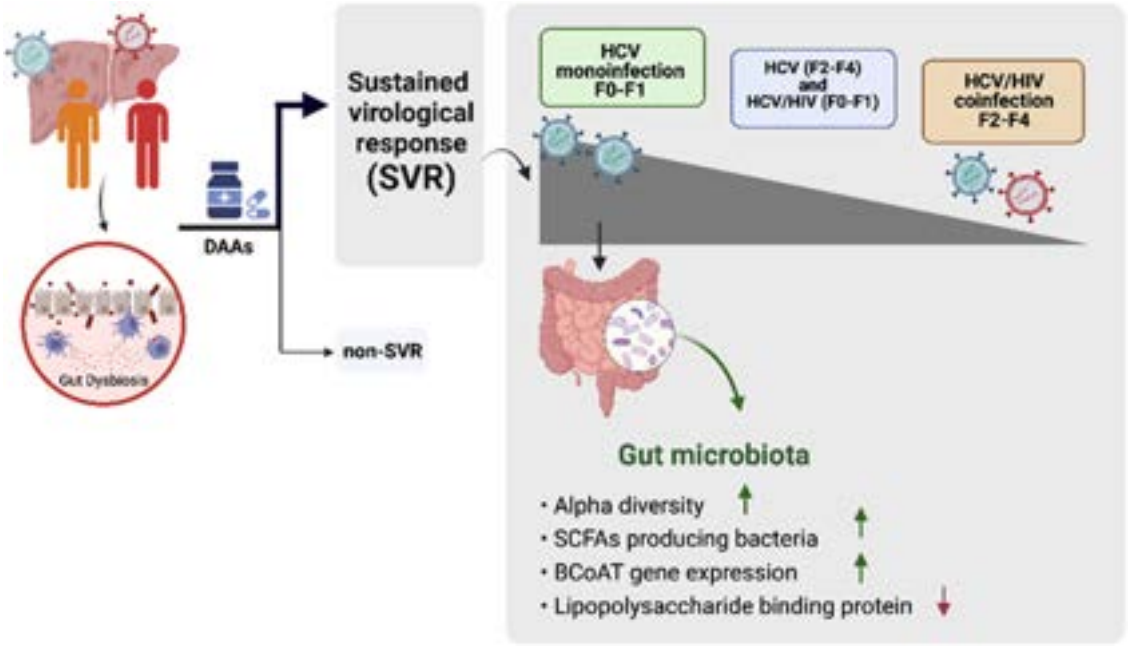

Figure: (abstract: THU-243).

week 72 after treatment completion (FUw72) were analyzed for gut microbiota by 16S rRNA sequencing and estimation expression of butyryl-CoA:acetateCoA transferase (BCoAT) in microbiota using real-time PCR. Plasma lipopolysaccharide binding protein (LBP) and intestinal fatty acid binding protein (I-FABP) were quantified by ELISA assays.

Results: In this study, SVR rates in mono- and coinfected patients were comparable (94% vs.100%). The improvement of gut dysbiosis and microbial translocation was found in responders but was not in non-responders. Among responders, significant restoration of alpha-diversity, BCoAT and LBP were consistently observed in HCV-monoinfected patients with low-grade fibrosis (F0-F1), while HCV/HIV-coinfected patients exhibited partial improvement at FUw72. Plasma I-FABP was not declined significantly in responders. Treatment-induced microbiota changes were associated with increasing abundance of SCFAs-producing bacteria, including *Blautia, Fusicatenibacter, Subdoligranulum and Bifidobacterium*.

Conclusion: Our results provided a perspective regarding long-term effect of successful DAAs in restoration of gut dysbiosis and microbial translocation. However, early initiation of DAAs possibly required an alteration in gut microbiota, especially enhanced SCFAs-producing bacteria, toward the reduction of HCV-related complications.

THU-244

The intestinal immune barrier is associated with bile acid pool modifications in mice suffering from non-alcoholic steatohepatitis

Simon Peschard[1], Margaux Nawrot[1], Olivier Molendi-Coste[1], Emmanuelle Vallez[1], Amandine Descat[2], Véronique Touche[1], Joel Haas[1], Anne Tailleux[1], David Dombrowicz[1], Bart Staels[1], Sophie Lestavel[1]. [1]*Univ. Lille, Inserm, CHU Lille, Institut Pasteur de Lille, U1011, EGID, Lille, France;* [2]*Univ. Lille, PSM-ULR7365 GRITA, Lille, France*
Email: simon.peschard@univ-lille.fr

Background and aims: Obesity and insulin resistance are usually associated with metabolic liver injuries such as non-alcoholic steatohepatitis (NASH). To go deeper into the alterations of the gut-liver crosstalk in this pathology, we used a well characterized diet-induced NASH mouse model to study the intestinal immune barrier and the intra-caecal bile acid (BA) composition.

Method: Eight-week-old C57Bl6/J male mice were fed for 24 weeks with a high fat/high sucrose diet supplemented with cholesterol to induce histological NASH and impaired glucose sensitivity, and were compared to their littermate controls under chow diet. Liver and gut samples were collected for histological analysis. Immunophenotyping was performed on alive cells purified from the lamina propria of the small intestine. A panel of 18 antibodies was used to identify immune cell subtypes by flow cytometry (Fortessa X20). Results were analyzed using FlowJo software. Caecal content of NASH and control mice were collected, freeze-dried prior to bile acid extraction and dosage by tandem mass spectrometry.

Results: As expected, liver of mice under NASH diet were consistent with histological features of the human disease, with hepatic steatosis, inflammation and fibrosis in a context of obesity. Serum alanine aminotransferase levels and oral glucose intolerance were also induced by the diet. Despite no histological remodeling of the small intestine, the intestinal immunological barrier was found altered in NASH animals. In particular, a decrease of CD8+ T lymphocyte proportions was found and regardless of TCR and CD8 subtypes. Proportions of B lymphocytes and myeloid-derived cells seem not to be affected by the diet. NASH mice display an overall increase of BA with an increase of primary to secondary BA ratio. More interestingly, BA described as functional regulators of immune cells such as isodeoxycholic acid, leucine-, phenylalanine- or tyrosine-conjugated cholic acid were also found increased in the intestine of NASH mice.

Conclusion: We have shown that in parallel to diet-induced histological features of NASH, intestinal immunity and bile acid homeostasis are altered. Whether specific BA could modulate the intestinal immune barrier in NASH remains to be elucidated, as well as the importance of these data and the molecular mechanisms involved in the intestine that may participate to the hepatic histological development of NASH.

THU-245

Identification of gut microbiota signature for differentiating between viral- and non-viral related hepatocellular carcinoma

Natthaya Chuaypen, Thananya Jinato, Pisit Tangkijvanich. *Faculty of Medicine, Chulalongkorn University, Biochemistry, Bangkok, Thailand*
Email: pisittkvn@yahoo.com

Background and aims: Altered gut microbiota have been associated with the development of hepatocellular carcinoma (HCC). In this report, our aim was to identify gut microbiota signature in differentiating between viral-related HCC (Viral-HCC) and non-hepatitis B-, non-hepatitis C-related HCC (NBNC-HCC).
Method: Fecal samples obtained from 16 healthy controls, 33 patients with Viral-HCC (17 and 16 patients with HBV and HCV infection, respectively) and 18 patients with NBNC-HCC were analyzed using 16S rRNA sequencing. Bioinformatic analysis was performed with the dada2 pipeline in R program. The 16 of significantly different genera from top 50 relative abundance were used to classify between Viral- and NBNC-HCC by using Random Forest machine learning algorithm.
Results: The mean age of patients with NBNC-HCC was significantly older than the Viral-HCC group. However, there was no significant difference between groups regarding sex, biochemical parameters, alpha-fetoprotein level, presence of cirrhosis and tumor stage. The HCC group showed reduced alpha-diversity and altered gut microbial composition compared with healthy controls. Within the top 50 relative abundance, there were 11 genera such as *Faecalibacterium*, *Agathobacter* and *Coprococcus* significantly enriched in the Viral-HCC subgroup, while 5 genera such as *Bacteroides, Streptococcus* and *Erysipelatoclostridium* were significantly increased in the NBNC-HCC subgroup (Table). Based on their distinct signatures, a high diagnostic accuracy to classify the HCC subgroups was achieved with an area under the curve (AUC) of 0.90 by Random Forest classifier. Compared to the Viral-HCC subgroup, we also demonstrated significant reduction of fecal butyrate levels but increased plasma surrogate markers of microbial translocation in patients with NBNC-HCC.

Figure: Top 50 relative abundance at the genus level

	Viral-HCC		NBNC-HCC		*p*
	Median	IQR	Median	IQR	*values*
Bacteroides	0.085	0.099	0.123	0.076	0.029
Faecalibacterium	0.081	0.063	0.031	0.061	0.004
Streptococcus	0.005	0.027	0.026	0.086	0.035
Agathobacter	0.028	0.034	0.000	0.023	0.014
Prevotella	0.000	0.057	0.000	0.000	0.049
Ruminococcus gnavus group	0.002	0.023	0.028	0.038	0.001
Coprococcus	0.012	0.030	0.000	0.009	0.022
Subdoligranulum	0.017	0.029	0.000	0.000	<0.001
Parabacteroides	0.003	0.006	0.010	0.021	0.034
Ruminococcus gauvreauii group	0.004	0.011	0.000	0.002	0.041
Lachnospiraceae ND3007 group	0.005	0.010	0.000	0.003	0.006
Erysipelotrichaceae UCG-003	0.001	0.014	0.000	0.000	0.016
CAG56	0.002	0.010	0.000	0.000	0.001
Holdemanella	0.000	0.013	0.000	0.000	0.048
Erysipelatoclostridium	0.000	0.001	0.005	0.013	0.001
Lachnospiraceae UCG-004	0.004	0.006	0.000	0.004	0.010

Conclusion: Our result demonstrated that gut dysbiosis was distinct regarding different etiological factors of HCC. Additionally, the NBNC-HCC subgroup appeared to have reduced fecal butyrate but increased microbial translocation compared with viral-related HCC. The gut microbiota signature might serve as a potential biomarker for the diagnosis and therapeutic options for HCC.

THU-246

Pemafibrate modulates microbiota profile in a dietary model of fatty liver in rat

Roger Bentanachs[1,2], Lluïsa Miró[3,4], Cristina Rosell-Cardona[3,4], Concepció Amat[3,4], Marta Alegret[1,2,5], Núria Roglans[1,2,5], Anna Pérez-Bosque[3,4], Juan Carlos Laguna[1,2,5]. [1]*University of Barcelona, School of Pharmacy and Food Sciences, Pharmacology, Toxicology and Therapeutic Chemistry, Spain;* [2]*Institute of Biomedicine of the University of Barcelona, Spain;* [3]*University of Barcelona, School of Pharmacy and Food Sciences, Biochemistry and Physiology, Spain;* [4]*Institute of Nutrition and Food Safety of the University of Barcelona, Spain;* [5]*CIBER de Fisiopatología de la Obesidad y Nutrición, Instituto de Salud Carlos III, Spain*
Email: alegret@ub.edu

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a prevalent and progressive disease with no drug available for its prevention or treatment. Therefore, the aim of this study was to analyze the effect of pemafibrate on the microbiota profile in a dietary model of NAFLD, namely feeding a high-fat, high-fructose rat diet, described previously (Velázquez et al., Mol. Nutr. Food Res 2022, 2101115).
Method: The study has been conducted in female Sprague-Dawley rats, that were randomly distributed into 3 groups (n = 8): (1) control (CT; standard rodent chow); (2) high-fat diet with 10% w/v fructose in drinking water (HFHFr); (3) HFHFr plus pemafibrate at 1 mg/Kg/day (PEMA). The experimental design consisted in feeding the rats with the HFHFr diet or standard rodent chow for three months. Rats from the PEMA group were fed with the high fat diet supplemented with the drug pemafibrate for the last month. Hepatic triglycerides (TG) were determined at the end of experimental period. Fecal microbiota profile was analyzed by using 16S rRNA sequencing.
Results: NAFLD induced by HFHFr produced profound changes in the microbiota profile (Figure 1A), which were partially attenuated by PEMA treatment. Specifically, HFHFr rats showed an increase in Phylum Firmicutes and a reduction in Phylum Bacteroidetes, increasing the ratio between them (F/R ratio). PEMA treatment attenuated the effects on Firmicutes and F/R ratio (both $p < 0.05$). Furthermore, changes in Firmicutes abundance as well as F/R ratio correlated positively with liver TG concentration (Figure 1B). Within the phylum Firmicutes we find families such as Clostridiaceae, which contain genera associated with inflammatory processes. This bacterial family was increased in HFHFr animals and decreased in PEMA-treated rats (both, $p < 0.05$).
Conclusion: In our dietary model of NAFLD in rat, pemafibrate treatment was able to modulate the microbiota profile. Some of these changes correlate with the reduction of liver TG. This work was supported by grants PID2020-112870RB-I00, funded by CIN/AEI/10.13039/501100011033 and 2021SGR-00345.

THU-247

Culturomics study of gut microbiota in NASH patients and healthy controls

Babacar Mbaye[1], Patrick Borentain[2], Matthieu Million[1], René Gerolami[1,2]. [1]*IHU Méditerrénée Infection, Aix-Marseille Université, Marseille, France;* [2]*CHU Timone. Assistance Publique Hopitaux de Marseille, Hepatologie, Marseille, France*
Email: rene.gerolami@ap-hm.fr

Background and aims: The gut microbiota has been extensively studied in patients with NASH. Metagenomic studies have suggested a dysbiotic signature characterised by an increase in *Proteobacteria* at the phylum level, *Enterobacteriaceae* and *Lactobacillaceae* at the family level and *Clostridium*, *Escherichia* and *Lactobacillus* at the genus level. No large-scale bacterial culturomic studies have been published to date. In this study, we report the results of metagenomic and culturomic analysis of the gut microbiota in 41 NASH patients and 24 controls.

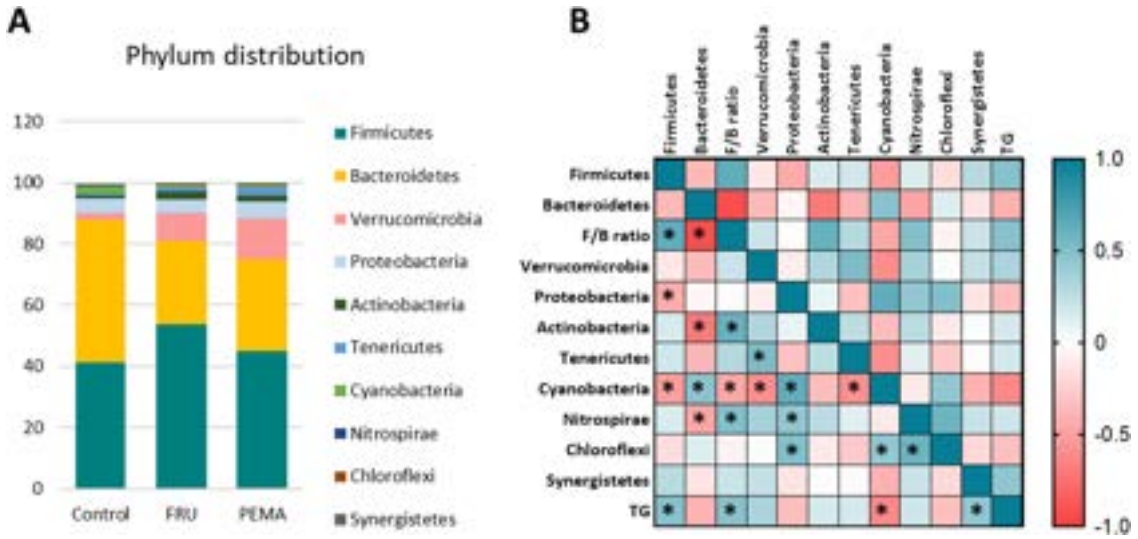

Figure: (abstract: THU-246): Phylum distribution (A) and correlation between the top ten Phylum taxa and hepatic TG (B). * Indicates significant correlation ($p < 0.05$).

Method: Sequencing of 16S rRNA amplicons was performed on fecal samples from all patients using the Illumina MiSeq instrument. Bacterial culturing was performed on fecal samples from 14 NASH patients and 11 controls using COS and YCFA (Yeast Casitone Fatty Acids Broth with Carbohydrates) agar plates, under anaerobic and aerobic conditions. In a second approach, we used a liquid enrichment step with sterile rumen juice and defibrinated sheep blood. Each sample was inoculated for 30 days. On day 1, day 3, day 7, day 10, day 15, day 21 and day 30, the contents of the flask were sampled, followed by ten 10-fold serial dilutions and inoculation onto COS and YCFA agar. All colonies in each sample were identified by MALDI-TOF mass spectrometry. Unidentified colonies were subjected to genome sequencing to decipher new putative species.
Results: Analysis of the cultures identified 1446 bacterial strains, representing 371 different species including 5 new species. Seven bacterial species were significantly enriched in NASH and five in controls (Figure). Three strains were found only in NASH: *Enterocloster bolteae*, *Facklamia hominis* and *Streptococcus constellatus*. In contrast, *Lentilactobacillus parabuchneri*, *Lacticaseibacillus casei* and *Phascolarctobacterium faecium*, which are known to be associated with health, were only found in controls. *Lactobacillus gasseri* and *Limosilactobacillus fermentum*, a species capable of producing ethanol, were found to be enriched in NASH. Only *L. fermentum* and *L. gasseri* (enriched in NASH), *P. faecium* and *Alistipes communis* (enriched in controls) were significantly different between NASH and controls in both culturomic and metagenomic analyses.
Conclusion: Here, we have confirmed a microbial signature associated with NASH, in particular bacteria known to produce ethanol. Culturomics has the unique advantage of providing bacterial strains which can be stored and subsequently analyzed. Further studies will evaluate their metabolic properties, including ethanol and triglyceride production *in vitro*, to confirm their role in the pathophysiology of NASH.

THU-248

Oral microbiome signature associated with liver graft dysfunction

Shruti Sureshan, Rosmy Babu, Varun Suroliya, Prince Garg, Pooja Rao, Viniyendra Pamecha, Chhagan Bihari, Shiv Kumar Sarin. *Institute of Liver and Biliary Sciences, India*
Email: drcbsharma@gmail.com

Background and aims: Stool and saliva dysbiosis in patients with cirrhosis incites changes in bacterial defences and higher risk for bacterial infections. As most of the studies have been conducted on gut microbiome from stool samples, here we profiled the salivary microbiome in pre-and post- LT patients along with their living donors to identify oral microbiome signature associated with early graft dysfunction.
Method: Saliva samples of cirrhosis patients between the age group 18–65 years admitted for living donor liver transplant and their

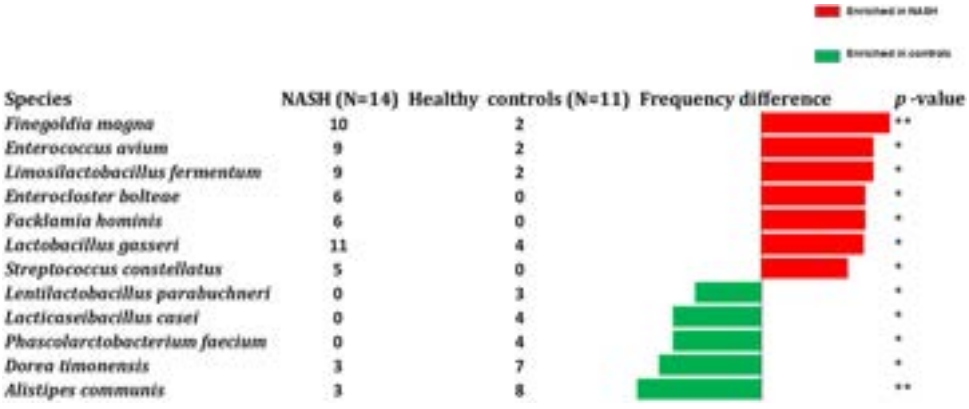

Figure: (abstract: THU-247): Bacterial species with a significant frequency difference between 14 NASH and 11 controls by culturomics

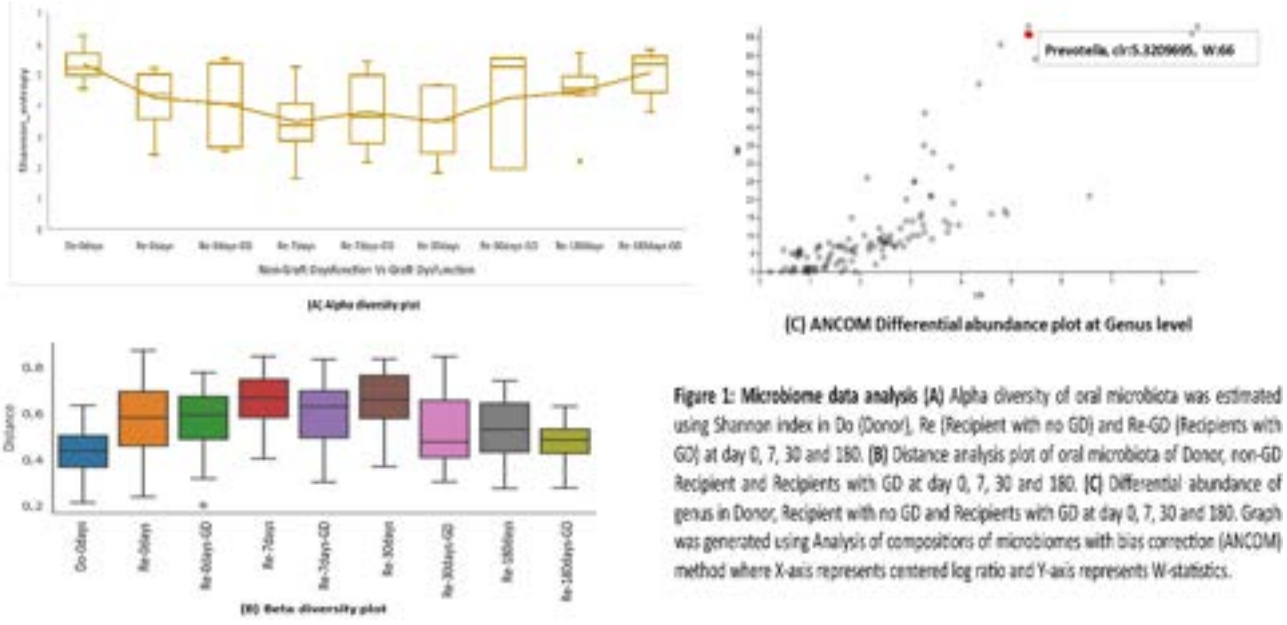

Figure 1: Microbiome data analysis (A) Alpha diversity of oral microbiota was estimated using Shannon index in Do (Donor), Re (Recipient with no GD) and Re-GD (Recipients with GD) at day 0, 7, 30 and 180. (B) Distance analysis plot of oral microbiota of Donor, non-GD Recipient and Recipients with GD at day 0, 7, 30 and 180. (C) Differential abundance of genus in Donor, Recipient with no GD and Recipients with GD at day 0, 7, 30 and 180. Graph was generated using Analysis of compositions of microbiomes with bias correction (ANCOM) method where X-axis represents centered log ratio and Y-axis represents W-statistics.

Figure: (abstract: THU-248).

donors were collected at different time-point with the informed consent. V3-V4 Amplicon sequencing was performed on Illumina MiSeq instrument and microbiome analysis was performed using QIIME pipeline. Patient with Acute Liver Failure/Acute-on-chronic liver failure, pregnant, cancer, surgical liver complications post LT, on pro/symbiotic were excluded from the study.

Results: A total of 47 participants, 21 donors (Do) (32.4 ± 9 years) and 27 recipients (Re) (46.6 ± 10 years) were selected for this study. Recipient saliva samples were collected at 4 time-points: before transplant (n = 27), post-transplant 7 days, 30 days, and 180 days. On follow-up nine recipients had graft dysfunction (GD) based on transaminitis and biopsy proven rejections and the remaining 18 patients were noted as non-GD. Any of the donor did not have any complications after LT.

Alpha diversity was higher ($p < 0.00003$, Fig. 1A) and beta diversity was lower at 180 days compared to baseline in GD recipient ($p < 0.05$, Fig. 1B). Differential abundance of family Prevotellaceae was high in patients with GD at baseline with a decreasing trend till 30 days and eventually increasing by 180 days. At genus level, the abundance of *Prevotella* was consistently higher across all time points, and *Lacticaseibacillus*, a probiotic was higher at baseline but was reduced after 7 days in GD recipients ($p < 0.05$, Fig. 1.C).

Conclusion: Oral bacteria was significantly altered at both genus and family level within 180 days in GD recipients in comparison to non-GD recipients. Abundance of *Prevotella* were noted to be elevated and could be a potential bacterial signature to identify liver GD.

Background and aims: Loss of hepatic HNF4α expression is frequently observed in end-stage liver disease (ESLD) and associated with loss of vital liver functions and thus increases mortality. Details of how HNF4α is suppressed are largely unknown to date. It has been proposed that TGF-β inhibits HNF4α via SMAD2/3 complex and thus initiates hepatocyte epithelial-to-mesenchymal transition (EMT) *in vitro*. However, many patients express hepatic HNF4α despite the presence of high levels of TGF-β. To address this conundrum, we scrutinized how TGF-β regulates *HNF4A* transcription in different disease conditions.
Method: Expression of hepatic transcription factors was examined in 98 HBV-infected patients. The effects of TGF-β on *HNF4A* transcription and EMT were investigated *in vitro*.
Results: *HNF4A* transcription requires both SMAD2/3 and C/EBPα binding to the *HNF4A* promoter. Although SMAD2/3 binding does not directly influence *HNF4A* transcriptional activity, SMAD2/3-recruited acetyltransferase CBP/p300 is essential for C/EBPα binding. *In vivo*, 67 patients positive for hepatic HNF4α express both p-SMAD2 and C/EBPα, whereas 22 patients negative for HNF4α expression lack either p-SMAD2 or C/EBPα. Interestingly, TGF-β-activated SMAD2/3 represses *CEBPA* transcription. Thus, long-term TGF-β stimulation results in C/EBPα depletion, which eventually inhibits HNF4α expression. Insulin inhibits SMAD2/3 binding to the *CEBPA*, but not the *HNF4A* promoter. Maintaining insulin concentrations in culture medium not only sustains HNF4α expression, but also inhibits TGF-β-induced hepatocyte EMT, because insulin inhibits SMAD2/3 binding to the promoters of core EMT transcription factor SNAI1. ESLD patients lacking HNF4α usually demonstrate insulin resistance.
Conclusion: Insulin signalling is crucial to maintain HNF4α expression in hepatocytes.

FRI-382
3D digital histopathology: a new methodology for morphological characterization of the human liver

Mathieu de Langlard[1,2], Olivier Trassard[2,3], Messina Antonietta[2,4], Nassima Benzoubir[2,4], Anne Dubart-Kupperschmitt[2,4], Jean-Charles Duclos-Vallée[2,4], Catherine Guettier[2,4,5], Irene Vignon-Clementel[1,2], Dirk Drasdo[1,2]. *[1]Inria Saclay, Palaiseau, France; [2]Fédération Hospitalo-Universitaire Hépatinov, Hôpital Paul Brousse, Villejuif, France; [3]UMS44 Inserm-Paris-Saclay University, Le Kremlin-Bicêtre, France; [4]UMR_S1193 Inserm-Paris-Saclay University, Villejuif, France; [5]Pathology Unit, Bicêtre Universitary Hospital, Assistance Publique-Hôpitaux de Paris, Le Kremlin-Bicêtre, France*
Email: mathieu.de-langlard@inria.fr

Background and aims: 2D histopathology is a common technic for the diagnosis and study of diseases of the liver tissue as many of these diseases are directly linked to structural disorders at the micro- and mesoscale. However, the complexity of the liver organization calls for richer and more consistent data representation, hence for spatially resolved 3D visualization and analysis of histological images. This analysis, called here 3D *histopathology*, would enable better understanding and earlier diagnosis of liver disorders.
Method: A tissue of approximately 14 mm × 9 mm × 9 mm is taken from a patient liver from a surgical specimen removed for liver cell adenoma at the Centre Hépato-Biliaire/Paul-Brousse Hospital. After fixation and paraffin inclusion, 300 serial sections of 3 μm thick are individually labelled with the antibodies anti-EpCAM for the bile ducts, and anti-CD31 for the vessels, and stained with haematoxylin for the nuclei. Due to the physical sectioning, misalignment and deformation of the tissue occur, hence the first step of the image analysis pipeline is the registration of the 300 images. The reconstructed tissue volume is further segmented for the sinusoids, hepatocyte nuclei, biliary ducts, portal venules, hepatic arteries and central venules, and post-processed. Besides, the liver primary units, called lobules, are automatically reconstructed using the morphological watershed algorithm.
Results: The vascular system and the bile ducts at the micro- and mesoscale were reconstructed and visualized in 3D. The topology of the vascular and biliary trees was described using the so-called

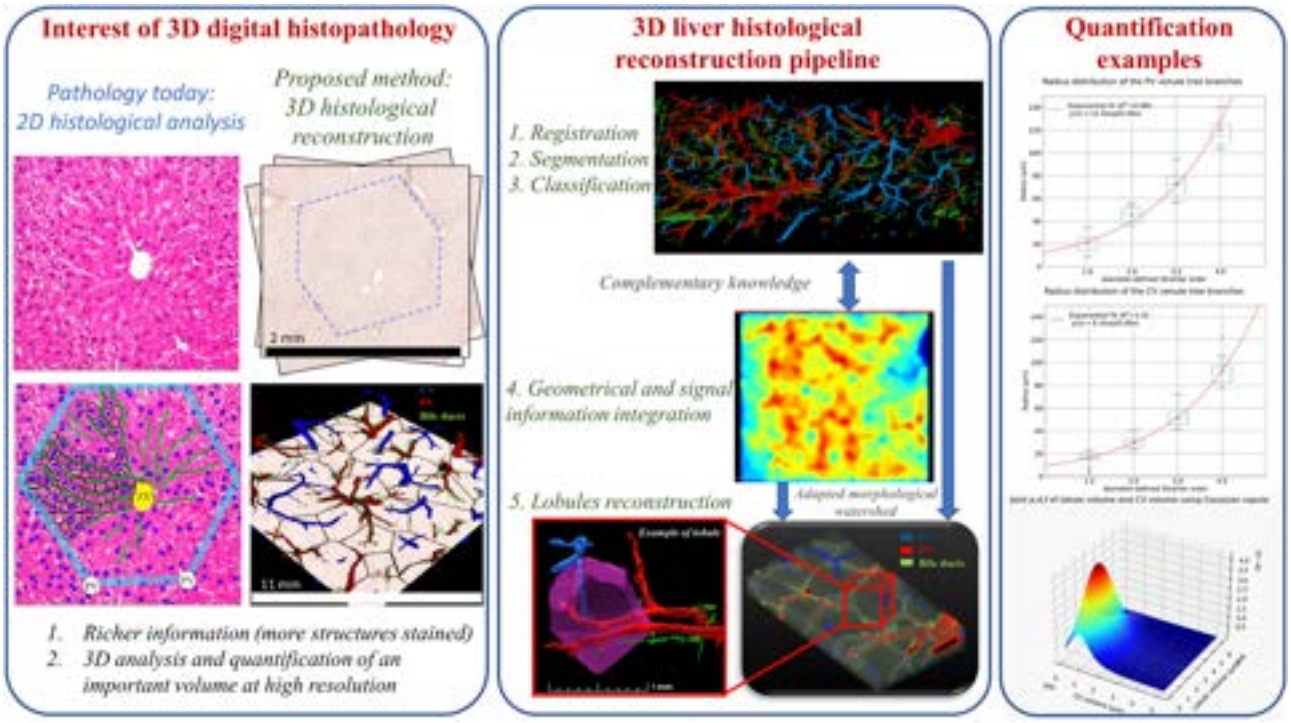

Figure: (abstract: FRI-382): Pipeline of the proposed 3D digital histopathology approach.

diameter-defined Strahler system. The morphology of the vascular and biliary trees was then computed, i.e. the mean diameter and length of the segments with respect to their order. The mean radius of the segments with respect to the Strahler order follows an exponential law (for the central and portal venules), which is coherent with the literature for larger liver vessels and other organs (e.g. heart and lungs). Moreover, a statistically representative number of entire lobules were automatically reconstructed. The sinusoids cross-section orientation significantly correlates with the reconstructed lobule borders: the sinusoids are rather radially directed in the pericentral region and orthoradially oriented at the periportal regions, where the center is chosen to be the closest central venules.
Conclusion: For the first time, a large human liver tissue volume is reconstructed in 3D and morphologically quantified from a stack 2D histological images i.e. from the micro- to the mesoscale. Such visualization at the micro- and mesoscale have not yet been obtained in the field of 3D imaging at the microscale, hence highlighting the innovation of this work. We proposed several quantification criteria which were evaluated on a healthy tissue which can serve as *benchmark*. This new digital histology approach can be readily applied to pathological cases where spatial and morphological abnormalities could be analyzed more consistently in three dimensions and bring new information on detailed morphological alterations of liver structures according the different liver disease stages.

FRI-383

Magnesium content decreases and transient receptor potential melastatin-subfamily member 7 expression increases in hepatocytes as liver inflammation and cirrhosis worsen in liver transplant candidates

Simona Parisse[1], Michela Fratini[2], Francesco Luigi Gambaro[3], Alessandra Gianoncelli[4], Emil Malucelli[5], Giulia Andreani[6], Giuliana Aquilanti[4], Flaminia Ferri[1], Ilaria Carlomagno[4], Monica Mischitelli[1], Quirino Lai[7], Gianluca Mennini[7], Massimo Rossi[7], Irene Pecorella[3], Cira Di Gioia[3], Gloria Isani[6], Stefano Iotti[5], Stefano Ginanni Corradini[1]. Email: simona.parisse@gmail.com

Background and aims: It has been proposed that low magnesium (Mg) intake or depletion could be implicated in the pathogenesis and progression of chronic liver disease. A major Mg cellular transport mechanism is Transient Receptor Potential Melastatin-subfamily member 7 (TRPM7) chanzyme, also involved, in experimental studies, in hepatic necrosis, inflammation and fibrosis. The aim of this study is to measure, for the first time in human liver cirrhosis, the Mg content of the liver and in hepatocytes and the expression of TRMP7 in these cells, correlating these variables with indices of liver inflammation and disease prognosis.
Method: We analyzed 58 biopsies of cirrhotic livers and 16 of healthy donor livers before ischemia obtained at liver transplantation (LT). Atomic absorption spectrometry (AAS) and synchrotron-based X-ray microscopy (SXRM) were used to estimate the Mg content in the liver and within hepatocytes, respectively. Hepatocyte intracellular expression of TRPM7 was evaluated by immunohistochemistry and expressed as the percentage of stained hepatocytes per 500 cells. Delta-MELDNa was calculated as: ((MELDNa at the time of trans-plant-MELDNa at the time of listing)/time elapsed between listing and transplant expressed in days).
Results: At AAS Mg median content was significantly ($p < 0.001$) lower in cirrhosis [117.2 (IQR 110.5–132.9) μg/g] compared to healthy livers [162.8 (IQR 155.9–169.8) μg/g]. All cirrhosis samples were clearly positive for cytosolic expression of TRPM7 in hepatocytes, whereas this was barely detectable in normal liver tissue. In cirrhotic patients the following correlations were present after adjustment for confounding factors in different multiple linear regression models: (a) inverse correlations between liver Mg content measured with AAS

and both MELDNa (B = –0.102 95% CI –0.207 to 0.005; p < 0.05) and serum AST activity (B = –0.824 95% CI-1.560 to –0.288 p < 0.01) at LT; (b) direct correlations between the percentage of hepatocytes intensely stained for TRPM7 and both MELDNa (B = 0.297 95% CI 0.175–0.578; p < 0.01) and serum AST activity (B = 3.256 95% CI 0.758–6.208 p < 0.05) at LT; (c) direct correlation between the percentage of hepatocytes intensively stained for TRPM7 and Delta-MELDNa (B = 0.436; 95% CI 0.179–0.670; p < 0.01). To test whether the severity of cirrhosis prognosis correlated with the Mg content within hepatocytes, the latter was measured in 15 cirrhotic liver samples using SXRM and confirmed the inverse correlation between Mg in hepatocytes and MELDNa a LT (r = –0.531; p < 0.05).

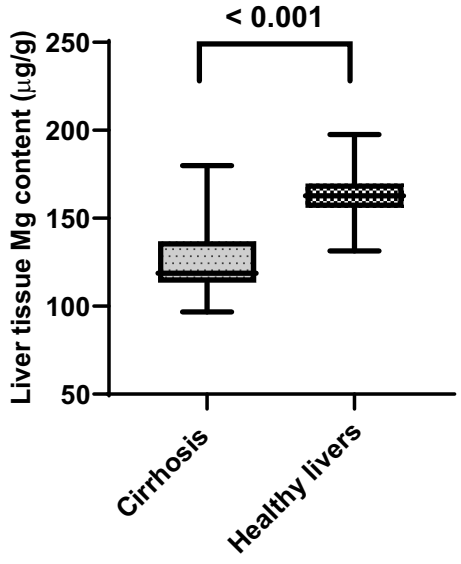

Figure:

Conclusion: The more severe the liver inflammation and the prognosis of liver cirrhosis, the more severe the magnesium depletion and the higher the expression of TRPM7 in hepatocytes. The latter could represent an attempt to restore intracellular Mg, but be one of the causes of disease progression.

FRI-384

Three-dimensional single-cell digital atlas of liver tissue architecture

Dilan Martinez[1], Valentina Maldonado[1], Cristian Perez[1], Valeria Candia[1], Hernan Morales-Navarrete[2], Fabián Segovia-Miranda[1]. [1]*Universidad de Concepción, Department of Cell Biology, Chile;* [2]*University of Konstanz, Department of Systems Biology of Development, Germany*
Email: fabiansegovia@udec.cl

Background and aims: The liver is an organ that performs a wide variety of functions that are highly dependent on its complex 3D structure. Geometrical models (digital representations of tissues) represent a versatile technique for characterizing 3D tissues as well as obtaining quantitative insights into structure-function relationships. Till date, these models are incomplete due to experimental limitations in acquiring multiple (>4) fluorescent channels at once. Indeed, geometrical models have been restricted to few tissue (sinusoids and bile canaliculi) and cellular components (nuclei and hepatocytes), excluding important cellular populations such as stellate and Kupffer cells. Here, we aimed to generate a "3D single-cell atlas of liver tissue architecture," i.e., a full 3D geometrical model that includes all the main tissue and cellular components simultaneously.
Method: We overcame the technical constraints by using deep tissue immunostaining, multiphoton microscopy, deep learning techniques, and 3D image processing. As a proof of concept, we used the 3D atlas to describe the morphological changes that occur in the mouse liver during post-natal early development and adulthood.
Results: We described how liver tissue architecture progressed from postnatal day one to adulthood by a novel set of morphometric cellular and tissue parameters. Our analysis revealed unknown details about the spatial organization of different liver cell types. Unexpected spatiotemporal patterns of non-parenchymal cells and hepatocytes with differing in size, number of nuclei, and DNA content were uncovered. We also provided information regarding the remodeling of the bile canaliculi and sinusoidal networks.

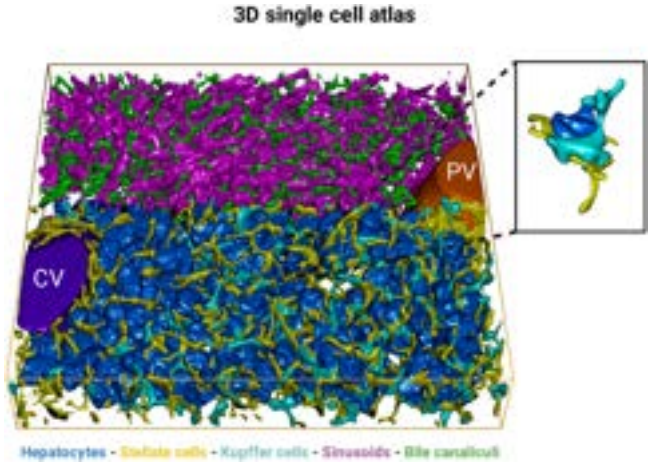

Figure: 3D single-cell atlas of liver tissue architecture: Central vein (dark blue), portal vein (orange). Upper part: sinusoids (magenta), bile canaliculus (green). Lower part: nuclei (not visible), hepatocytes (blue), stellate cells (yellow) and Kupffer cells (light blue).

Conclusion: These findings revealed novel characteristics of liver heterogeneity and have important implications for both the structural organization of liver tissue and its functional features. 3D single-cell atlas will provide a powerful tool for understanding liver tissue architecture, under both physiological and pathological conditions.

Multiomic profiling associated with lipid remodeling in senescent primary human hepatocytes

Sin-Tian Wang[1], Wei-Chia Chen[1], Li-Chi Chi[1], Yi-Hsuan Tsai[1], Kung-Chia Young[1,2]. [1]*National Cheng Kung University, Department of Medical Laboratory Science and Biotechnology, Taiwan;* [2]*National Cheng Kung University, Institute of Basic Medicine, Taiwan*
Email: t7908077@mail.ncku.edu.tw

Background and aims: Metabolic associated fatty liver disease (MAFLD), also as non-alcoholic fatty liver disease, is characterized by the excessive lipid accumulation in liver with pathological progress, from simple steatosis, steatohepatitis, cirrhosis, to hepatocellular carcinoma. The development of MAFLD is long-term affected by multiple factors, including aging. However, the pathogenic changes in normal human hepatocyte during aging remained uncovered. In this study, we investigated the lipid remodelling from young to senescent primary hepatocytes by multiomic analysis.
Method: First, we characterized the lipid metabolism of primary human hepatocytes (PHH) with the expression of senescent biomarkers. Next, we analysed the changes of metabolic gene expression and lipid contents by transcriptomic and lipidomic analysis. Finally, we investigated the pathogenic mechanism of lipid remodeling in aging by PHHs and animal model treated with senolytic or senomorphics agents.
Results: The PHHs were monitored for the expression of senescent biomarkers of p16, p21 and p53, then classified into three stages by different passages, including young (passage (P)3 to P5), early

senescence (P7 to P9) and late senescence (P11 to P13). With transcriptomic analysis by mRNA-sequencing, the differentially upregulated/downregulated genes in senescent PHH were determined, revealing the genes (P4 *vs.* P8 and P8 *vs.* P12) in six categories, namely development processes, multicellular organismal process, cellular anatomical entity, structural molecule activity, binding and molecular function regulator activity; the genes (P4 *vs.* P8) in four categories, namely reproduction, cellular process, protein-containing complex and catalytic activity; and the genes (P8 *vs.* P12) in two categories, namely metabolic process and transporter activity. With lipidomic analysis, the results showed the differentially contents of lipids from young to senescent PHH, including lipid class of cholesteryl ester (CE), phosphatidylcholine (PC), PC O-ether-linked PC, phosphatidylethanolamine, phosphatidylinositol, and sphingomyelin. In senescent PHH, the lipid contents were increased as compared to young hepatocytes, including triglyceride (TG; by 10 folds), free cholesterol (FC; by 3 folds) and cholesteryl ester (CE; by 2 folds). Additionally, it was confirmed in the liver of 50~62 weeks-old female mice by accumulation of excessive lipids with lipid quantification and oil red staining.
Conclusion: In conclusion, the transcriptional and lipidomic profiling associated with lipid accumulation in aging PHH were deciphered.

FRI-386
Tick-tock-Uncovering new aspects of circadian-regulated liver metabolism by kinetic modeling
Christiane Körner[1,2], Madlen Matz-Soja[1,2], Fritzi Ott[1,2], Eugenia Marbach-Breitrück[2], Rolf Gebhardt[2], Thomas Berg[3], Nikolaus Berndt[4]. *[1]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Laboratory for Clinical and Experimental Hepatology, Leipzig, Germany; [2]Rudolf-Schönheimer-Institute of Biochemistry, Faculty of Medicine, Leipzig University, Leipzig, Germany; [3]Clinic of Gastroenterology, Hepatology, Infectious Diseases and Pneumology, Germany; [4]Institute of Computer-Assisted Cardiovascular Medicine, Charité-Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany*
Email: christiane.rennert2@medizin.uni-leipzig.de

Background and aims: The circadian rhythm is a decisive regulator for metabolic homeostasis especially in the liver. The importance of diurnal control is highlighted by the increased risk of liver diseases, obesity and metabolic syndrome due to disturbance of circadian rhythms. However, time resolved *in vivo* studies of liver metabolism are rare and molecularly resolved, kinetic models can be used for metabolic phenotyping based on proteomic data, enabling linking circadian rhythmicity of protein abundances to metabolic regulation. We aim to investigate whether hepatic metabolism is regulated by central circadian mechanisms or nutrition availability in plasma.
Method: We investigated the rhythmicity of liver metabolism in male C57BL/6N mice in transcriptomic and proteomic data using liver samples isolated throughout a day. We incorporated the proteomic data of each time point in kinetic models to identify circadian rhythms of metabolic pathways. Additionally, we correlated plasma metabolite profiles with metabolic liver functions and validated the model predictions with biochemical assays.
Results: Our analysis revealed clusters of typical regulated expressions of various metabolic genes. The kinetic models showed circadian rhythms for lipid metabolism, ethanol detoxification and partly carbohydrate metabolism in the liver. However, gluconeogenetic capacity, fructose and urea synthesis capacity were obviously not underlying circadian regulation. We could show a correlation between plasma fatty acid concentrations and fatty acid liver metabolism. Concerning detoxification capacities, ethanol utilization capacity was highly associated with plasma glucose concentrations, but no significant correlations with plasma metabolites could be found for urea synthesis and ammonia uptake capacities.
Conclusion: The model helps to better understand whether circadian rhythms are intrinsic and independent of nutrient availability or follow diurnal dietary patterns. By accounting for the circadian regulatory properties of all enzymes, our model integrates the accumulated knowledge from decades of biochemical research and allows quantitative predictions of system behavior as a function of circadian rhythmicity.

Dickkopf-1 inhibitor enhances the anti-tumor effects of sorafenib through inhibition of PI3K/Akt/Wnt signaling in hepatocellular carcinoma
Sang Hyun Seo[1,2], Kyung Joo Cho[3], Hye Jung Park[3], Hye Mi Kim[4], Jae Seung Lee[3,5], Hye Won Lee[3,5], Beom Kyung Kim[3,5], Jun Yong Park[3,5], Do Young Kim[3,5], Sang Hoon Ahn[3,5], Seung Up Kim[3,5]. *[1]Department of Internal Medicine, Graduate School of Medical Science, Brain Korea 21 Project, Yonsei University College of Medicine, Rep. of South Korea; [2]Yonsei Liver Center, Severance Hospital, Rep. of South Korea; [3]Yonsei Liver Center, Severance Hosipital, Rep. of South Korea; [4]Department of Microbiology and Immunology, Yonsei University College of Medicine, Rep. of South Korea; [5]Department of Internal Medicine, Institute of Gastroenterology, Yonsei University College of Medicine, Rep. of South Korea*
Email: ksukorea@yuhs.ac

Background and aims: Sorafenib prolongs overall survival in patients with advanced hepatocellular carcinoma (HCC). Dickkopf-1 (DKK1) is frequently overexpressed in HCC. This study investigated whether the inhibition of DKK1 enhances anti-tumor efficacy of sorafenib in patients with advanced HCC.
Method: The high expression of DKK1 level in HCC was confirmed by TCGA datasets, IF stain and ELISA in human tissues. HCC cells were treated with sorafenib and/or WAY-262611, which is an inhibitor of DKK1, to identify the additional efficacy of DKK1 inhibition on proliferation, migration, invasion, apoptosis. Transgenic mouse models using hydrodynamic injection were also used. The mice were orally injected with sorafenib (32 mg/kg), WAY-262611 (16 mg/kg), or sorafenib/WAY-262611 for 10 days.
Results: DKK1 was significantly overexpressed in patients with HCC, compared with healthy subjects and those with chronic liver diseases, but without HCC (all $P < 0.05$). DKK1 expression was also high in transgenic mouse models (all $P < 0.01$). Sorafenib combined with WAY-262611 significantly inhibited the cell viability, migration, and invasion by altering apoptosis in HCC cells, compared with sorafenib alone (all $P < 0.05$). In addition, we found that sorafenib combined with WAY-262611 inhibited p110α, phospho-Akt (all $P < 0.05$), active β-catenin (all $P < 0.05$), phospho-Ser9-GSK-3β, whereas phospho-Tyr216-GSK-3β increased *in vitro* and *in vivo*, compared with sorafenib alone. Moreover, sorafenib combined with WAY-262611 increased cleaved Caspase-3 ($p < 0.01$), but decreased the Ki67 ($p < 0.05$) and EMT markers, compared with sorafenib alone.

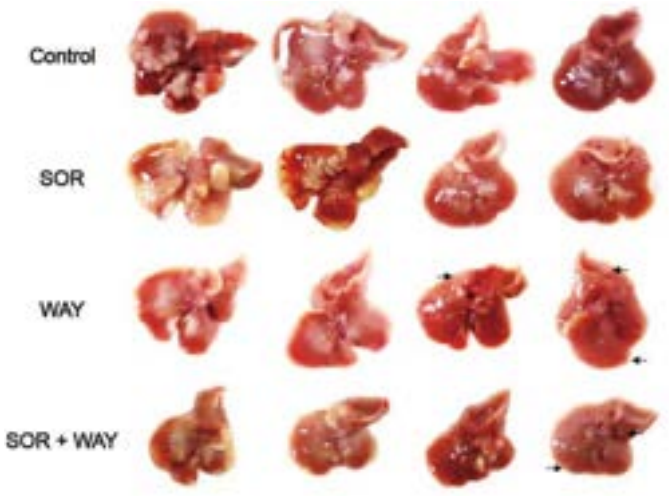

Figure:

Conclusion: Inhibition of DKK1 significantly enhanced anti-tumor efficacy of sorafenib through inhibition of PI3K/Akt/Wnt signaling, which might be a novel therapeutic strategy in HCC.

FRI-388

Liver spheroids engrafted in the anterior chamber of the eye-a novel platform to study hepatic physiology and pathology

Francesca Lazzeri-Barcelo[1], Nuria Vilarnau[2], Barbara Leibiger[1], Volker Lauschke[2], Ingo Leibiger[1], Per-Olof Berggren[1], Noah Moruzzi[1]. *[1]Karolinska Institute, Molecular Medicine and Surgery, Stockholm, Sweden; [2]Karolinska Institutet, Physiology and Pharmacology, Stockholm, Sweden*
Email: francesca.lazzeri.barcelo@ki.se

Background and aims: The tools for liver research have hugely advanced in the last decades, but the field still contends with two important limitations; the de-differentiation of primary hepatocytes outside the liver, and longitudinal *in vivo* imaging at cellular resolution. Liver spheroids are the current gold standard for *in vitro* liver studies, but lack the complexities of the natural microenvironment. The anterior chamber of the eye (ACE) of mice can be used as a transplantation site, where the cornea acts as a natural window, through which microtissues engrafted on the iris can be imaged by confocal microscopy. In this work, we aim to establish and characterise a platform for non-invasive *in vivo* longitudinal imaging of mouse liver spheroids engrafted in the ACE and explore its suitability for different areas of liver research.
Method: Mouse liver spheroids were generated *in vitro* and transplanted into the ACE of recipient mice, where they engrafted and were imaged by confocal microscopy. Fluorescent probes were administered intravenously during *in vivo* imaging to identify cells and structures. *Ex vivo* techniques such as immunofluorescence, transmission electron microscopy, RNA *in situ* hybridization and RNA sequencing were used to characterise the engrafted liver spheroids. To investigate the functions of the engrafted spheroids, hepatic fat accumulation was induced by feeding transplanted recipient mice a high-fat-high-fructose diet (HFHFrD) or control diet for 12 weeks.
Results: Transplanted liver spheroids engraft on the iris and become vascularised and innervated. *In vivo* imaging of liver spheroids in the eye shows functional vascular and bile canaliculi networks and active hepatic LDL uptake. *Ex vivo* characterisation demonstrates that the liver spheroids recapitulate hepatic markers and architectural features of the liver. Lipid droplet staining confirmed fat accumulation in the ACE-liver spheroids of mice fed a HFHFrD in comparison to control animals, suggesting that engrafted liver spheroids can mirror and report on endogenous liver function.

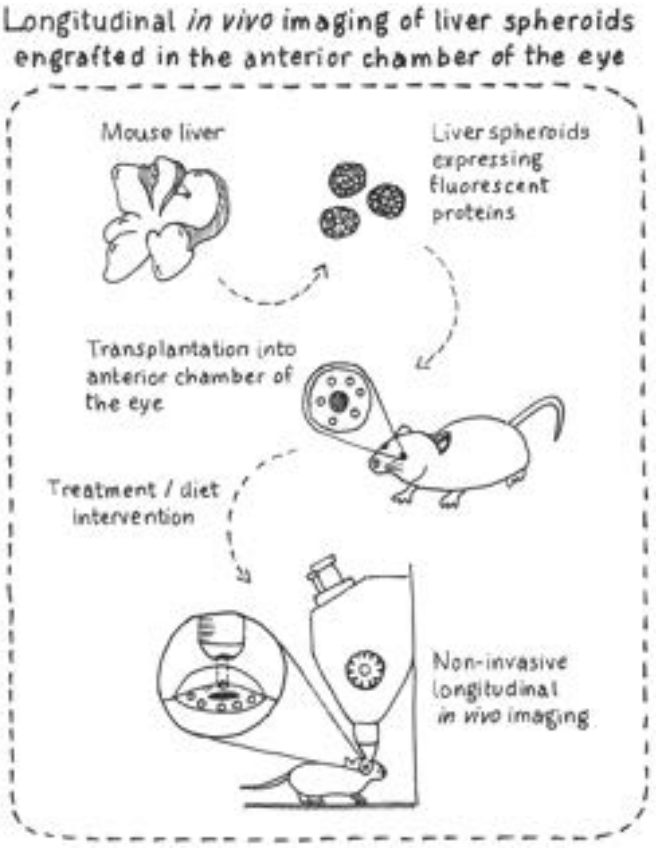

Figure:

Conclusion: We have established and characterised a platform for intraocular non-invasive imaging of liver-like tissue, opening the way for longitudinal study of liver functions. Our data show ACE-engrafted liver spheroids retain overall differentiation and functionality status post-transplantation. This liver spheroid ACE imaging platform therefore has potential to facilitate the longitudinal study of liver pathophysiology in both pre-clinical and basic research.

FRI-389

With-in patient comparison of single-cell versus single-nucleus sequencing on human transjugular liver biopsies

Lukas Van Melkebeke[1,2], Jef Verbeek[1,2], Dóra Bihary[3,4], Markus Boesch[1], Hannelie Korf[1], Diether Lambrechts[3,4], Schalk van der Merwe[1,2]. *[1]KU Leuven, Laboratory of Hepatology, Belgium; [2]University hospitals Leuven, Gastro-enterology and Hepatology, Belgium; [3]KU Leuven, Laboratory for Translational Genetics, Belgium; [4]VIB, Center for Cancer Biology, Belgium*
Email: lukas.vanmelkebeke@kuleuven.be

Background and aims: RNA sequencing at single cell level has advanced discoveries in translational research. In patients with advanced liver disease, with ascites or coagulation defects, transjugular liver biopsy (TJB) is the only safe way to obtain liver tissue. The ability to successfully apply single-cell (scRNA-seq) or single-nucleus RNA-sequencing (snRNA-seq) using TJB has the potential to uncover unique pathways and targets for therapy in advanced liver diseases.
Method: A protocol was developed for scRNA-seq and snRNA-seq on TJB. A within-patient comparison was made between both techniques in 3 patients with alcohol-related cirrhosis. The analysis was performed using R (v4.1.2). All samples were anchor integrated using Seurat (v4.1.1). Doublets were identified using DoubletFinder (v2.0.3).
Results: In total 31,055 single nuclei and 6,160 single cells were isolated from TJBs, with a significantly higher number of nuclei than cells per sample. All major cell types including hepatocytes, cholangiocytes, mesenchymal, endothelial, NK/T-, myeloid, and B-

cells could be identified (Figure 1). Furthermore, these cell types could be subtyped into 17 different known subclusters. Cell composition differed significantly between both techniques with significantly higher percentages of hepatocytes ($p < 0.05$) and sinusoidal endothelial cells ($p < 0.05$), and significantly lower percentages of NK/T-cells ($p < 0.05$), endothelial cells ($p < 0.01$), vascular smooth muscle cells ($p < 0.05$), hepatic artery endothelial cells ($p < 0.05$) and monocytes ($p < 0.05$) in snRNA-seq compared to scRNA-seq. In absolute numbers, there was a significantly higher number of hepatocytes ($p < 0.05$) in snRNA-seq. In a direct comparison of snRNA-seq and scRNA-seq, long non-coding RNA was upregulated in snRNA-seq, and mitochondrial and ribosomal RNA were upregulated in sc-RNAseq. Importantly, stress-related genes (e.g. heat shock proteins) were also upregulated in scRNA-seq. Based on the gene signature of scRNA-seq, we could correctly identify the cell type of 96.9% of the nuclei and vice versa for 96.7% of the cells. gProfiler was used to compare functional pathways (gene ontology) between cell types. The top upregulated functional pathways calculated for one cell type using one technique were highly significantly upregulated in the corresponding cell type with the other technique.

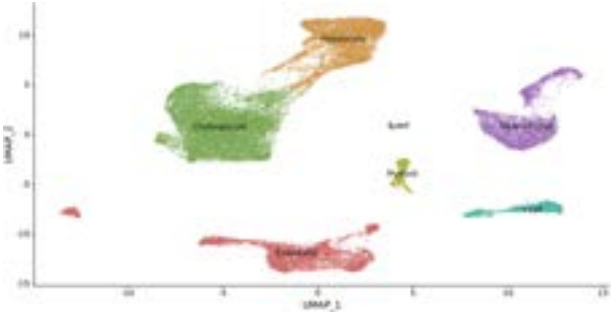

Figure 1: UMAP of the integrated dataset

Conclusion: We describe a working protocol enabling the use of scRNA-seq and snRNA-seq on TJBs, allowing the application of these techniques in advanced liver disease. Furthermore, using a within-patient comparison of both techniques, we found that both techniques recover hepatic cell types at a different composition. Importantly, the gene signature and top upregulated functional pathways of the cell types were highly comparable between the two techniques.

Email: zerial@mpi-cbg.de

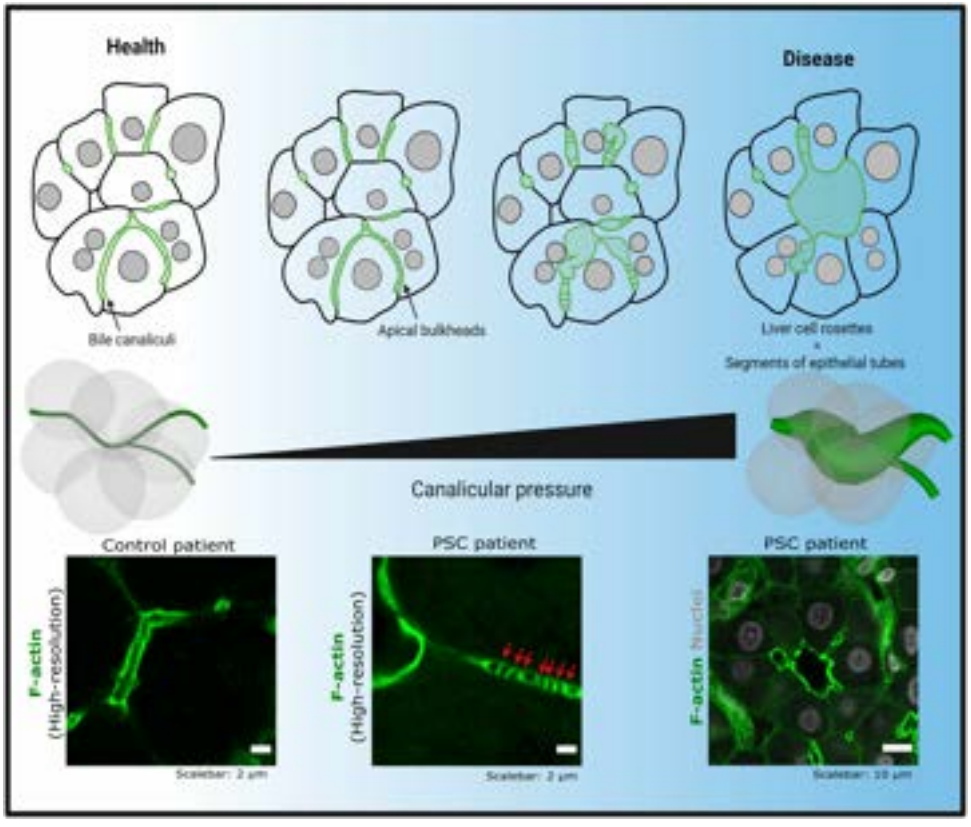

Figure: (abstract: FRI-390).

Background and aims: Hepatocytes form a network of bile canaliculi that dynamically respond to the signaling activity of bile acids and to changes in bile flow. During embryonic development hepatocytes assemble specialized structures, termed apical bulkheads, that enforce the elongation of bile canaliculi.
Method: We hypothesized that apical bulkheads protect bile canaliculi against impaired bile flow and increased canalicular pressure in the adult liver.
Results: We found that hepatocytes accumulate apical bulkheads in liver tissue from patients with primary sclerosing cholangitis (PSC) and different mouse models, suggesting that apical bulkheads are an adaptive response of adult hepatocytes towards changes in bile flow. We assessed the underlying molecular mechanism in primary hepatocytes and 3D organoids in-vitro and determined that high-pressure conditions can induce abnormally dilated and rearranged bile canaliculi that are characterized by the absence of apical bulkheads. We found morphologically similar structures in patients with PSC, that resemble so-called liver cell rosettes described in other liver diseases. Using 3D reconstruction of the bile canalicular network in PSC patients and mathematical modeling to infer canalicular pressure, we found that the formation of liver cell rosettes positively correlates with canalicular pressure and occurs already early in PSC progression.
Conclusion: Our results reveal a novel protective mechanism against impaired bile flow and highlight the role of canalicular pressure in the pathogenesis of liver diseases with potential implications for diagnosis and treatment.

FRI-391

Long-term effects in primary human hepatocytes (PHH) after exogenous exposure to human intestinal microbiome secretome peptides

Natalia Sanchez-Romero[1,2], Pilar Sainz de la Maza Arnal[1,2], Maria Jesus Lozano Limones[1,2], Mario Fernández Sanz[1], Alvaro Blanes Rodriguez[1], Sandra Melitón Barbancho[1], Sara Borrego Bernal[1], Pedro Baptista[1,3,4,5]. *[1]Health Research Institute of Aragón (IIS Aragón), Zaragoza, Spain; [2]Cytes Biotechnologies SL, Spain, Spain; [3]Department of Biomedical and Aerospace Engineering, Carlos III University of Madrid, Spain, Spain; [4]ARAID Foundation, Zaragoza, Spain; [5]CIBERehd, Spain*
Email: nsanchez@cytesbiotech.com

Background and aims: The human intestinal microbiome's effects on the liver are finally starting to be unveiled in health and disease. If its action in the origin of several diseases is already well-known, its outcomes on liver maturation and function are still recognized to a lesser extent. Notably, the potential effects in the liver of the peptides generated by the gut enzymes' activity on the microbiome's secreted proteins are entirely unknown. Hence, we sought to determine their role in hepatic function and metabolism maintenance and induction in cultured PHH *in vitro* for up to 3 weeks.
Method: Several synthetic peptides were produced after an *in-silico* digestion of the whole secretome of the human intestinal microbiome when exposed to all the known gut enzymes. Preliminary work with selected synthetic peptides identified four peptides capable of inducing hPSC-derived hepatocyte differentiation and functionalization. Then, cryopreserved PHH (Cytes Biotechnologies) were thawed and plated in 24-well collagen I coated plates and cultured in Human Hepatocyte Maintenance Medium (Cytes Biotechnologies) with each one of these four peptides shown to be active in the preliminary screening. After three weeks, PHH (from 6 distinct donors) were tested for cell viability (Presto Blue), morphology, albumin secretion, drug metabolization (bupropion, midazolam, phenacetin, 7-OH coumarin), and gene expression (ALB, HNF4a, CYP3A4, CYP2C9, CYP2B6, GAPDH). In addition, cell morphology was observed by phase-contrast microscopy, albumin secretion was quantified by ELISA, and metabolites were quantified by LC-MS/MS and normalized to cell viability and gene expression determined by RT-qPCR and RNA seq.
Results: After three weeks in culture, PHH exposed to each peptide showed a slight increase in survival compared to control. Cell morphology was kept constant in all conditions, but PHH exposed to the microbiome's peptides showed higher expression of CYP3A4, CYP2C9, CYP2B6, and upregulation of ALB and HNF4a. We also showed that these peptides stimulation caused a significant increase in albumin secretion, when compared with control. Likewise, we determined that these peptides could significantly increase phase 1 and 2 drug metabolization *in vitro,* even after three weeks of *in vitro* culture of PHH. Finally, RNAseq analysis showed an increase in hepatic, survival and drug metabolism genes, when compared with unstimulated controls.

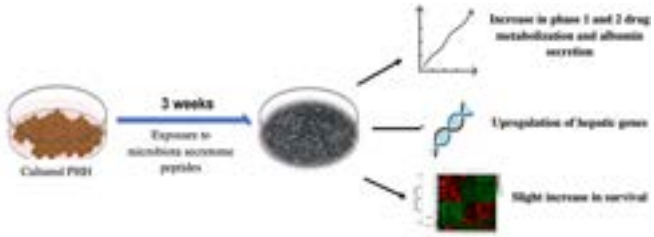

Figure:

Conclusion: Considering that PHH lose their metabolic function quite rapidly (within days) *in vitro*, the long-term maintenance of PHH survival and function by these microbiome's secretome peptides is, in our view, quite significant. Additional efforts are needed to unravel these mechanisms. However, it already hints at the potential that the unexplored protein fraction of the human intestinal microbiome secretome might have in hepatocyte homeostasis, function and regulation and its potential role in biotechnological and possible therapeutic applications.

FRI-392

Integrated metabolomic and transcriptomic analyses implicate specific metabolic pathways in crocin-induced apoptosis of HCC cells

Amr Amin. *UAE University, United Arab Emirates*
Email: a.amin@uaeu.ac.ae

Background and aims: Saffron, the golden spice, is known for its wide spectrum of health-promoting characteristics including but not limited to it potent anticancer effects. Saffron is really the stigmas of the beautiful flower of *Crocus sativus*. Among more than a hundred others, crocin is a major constituent of saffron that is responsible for its yellow color. Crocin's therapeutic effects are well documented. However, the molecular mechanisms underlying crocin's anti-cancer effect remains unclear.
Method: This study investigated the impact of crocin, a water-soluble carotenoid and saffron's secondary metabolite, on the HCC cell line HepG2 using integrated metabolomic (HPLC-MS) and transcriptomic analyses (RNAseq).
Results: Up-regulated genes were enriched with double-strand break repair via homologous recombination which included RAD51, RAD51C, BRCA2, XRCC2 and XRCC3. The down-regulated genes were involved in positive regulation of I-kapppB kinase/NF-kappaB signaling, angiogenesis and wound healing. TNF-α, TNF receptor 1 (TNFR1) and NF-κB-p65 were also reduced after treatment with crocin. Most dysregulation of metabolites we reported was centered on several biomarkers for liver stress, including lipidomic profile and indicators of antioxidant status. The highest up- and down-regulated

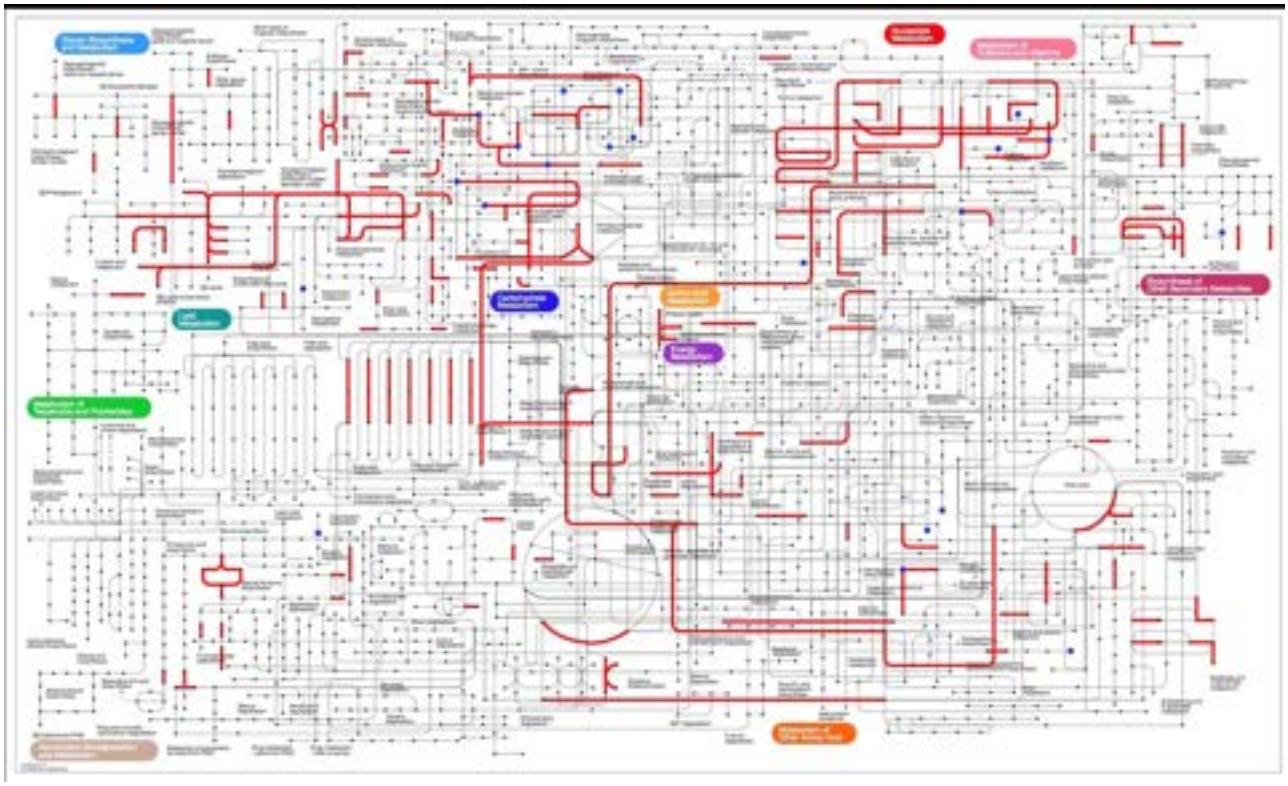

Figure: (abstract: FRI-392).

metabolites were dopamine glucuronide and L-carnitine intermediate molecules, respectively.
Conclusion: The dual omics datasets describe routes to widespread protein destabilization and DNA damage from crocin-induced oxidative stress in HepG2 cells.

Email: conrado.fernandez@salud.madrid.org

Background and aims: About one third of patients with primary biliary cholangitis (PBC) have a suboptimal response to ursodeoxycholic acid (UDCA) and have a worse prognosis. Although clinical trials have shown varying degrees of response to second line therapies, there are few data on their long-term effectiveness and safety. Our aim was to determine the long-term effect of second-line therapies on liver function, POISE response and GLOBE-PBC and 5-yr-UK-PBC scores in a multicentre cohort of patients with PBC who did not respond to UDCA according to Paris II criteria.
Method: Prospective, multicenter, real practice study cohort of Paris II UDCA non-responders from 17 hospitals who received obeticholic acid (OCA) or OCA plus fibrates. End points were effect on

biochemical, liver function, GLOBE-PBC and 5yr-UK-PBC scores and response to POISE criteria at 12, 24 and 36 months and liver-related survival and safety.

Results: One hundred and ninety-one patients were included; median follow-up 26.6 months (IQR 16.1–36.9). There was a reduction in alkaline phosphatase (ALP), GGT, aminotransferases and GLOBE-PBC score ($p < 0.01$) and an increase in serum albumin levels ($p = 0.012$) (Fig. 1). By intention-to-treat (ITT), 40.1% (95% CI 32.9–47.8) achieved POISE response at 12 months. Triple therapy was associated with POISE response (Adjusted aRR = 0.63, 95% CI 0.43–0.93, $p = 0.02$). Compared to POISE responders at 12 months, late-responders had a longer time from diagnosis ($p = 0.007$) and lower albumin levels ($p = 0.009$) (Fig. 1). Liver-related events occurred more frequently in patients with cirrhosis ($p < 0.001$). Within this group, events were limited to those patients with abnormal platelets value and serum albumin below 1.3 times the normal value.

POISE response rate over time, factors associated to early and late POISE response and effect on serum albumin

Figure:

Conclusion: This study shows long-term improvement in biochemistry, liver function and Globe-PBC in patients on second line treatment. POISE response was associated with earlier stages of disease and triple therapy. Treatment was safe in patients with early-stage cirrhosis.

TOP-062

Change in serum bile acids correlates with improvement in itch in patients with primary biliary cholangitis receiving linerixibat

Eleni Karatza[1], Fernando Carreño[2], Sumanta Mukherjee[2], Linda Casillas[2], James Fettiplace[3], Megan McLaughlin[2], Brandon Swift[4]. *[1]The University of North Carolina at Chapel Hill, NC, United States; [2]GSK, Collegeville, PA, United States; [3]GSK, London, United Kingdom; [4]GSK, Durham, NC, United States*
Email: brandon.x.swift@gsk.com

Background and aims: Pruritus (itch) affects up to 3/4 of patients with primary biliary cholangitis (PBC) over the course of their illness. Bile acids (BA) are an important pathophysiological mediator of cholestatic pruritus. Linerixibat, a selective small-molecule inhibitor of the ileal bile acid transporter, reduced circulating BA levels and improved itch in patients with PBC.[1] Here, we analyse the relationship between linerixibat dose and change in total serum BA (TSBA) over time and explore correlation between change in TSBA and change in itch.

Method: Data from Phase 1/2 studies of healthy volunteers or patients with PBC were used to develop a population dose-pharmacodynamic (k-PD) model to characterise the linerixibat dose-TSBA relationship. Simulations were performed to explore the effect of linerixibat dose and regimen on daily TSBA profiles. Individual Bayesian parameter estimates for subjects in GLIMMER, a Phase 2b study of linerixibat in patients with PBC and moderate to severe pruritus (NCT02966834),[1] were used to derive the area under the TSBA concentration-curve (AUC_{0-24}). These post hoc estimates of AUC_{0-24} were correlated with itch reported on a 0–10 numerical rating scale (NRS). In GLIMMER, 4 weeks single-blind placebo (baseline = Week 4) was followed by a randomised, double-blind 12-week treatment period with linerixibat or placebo (to Week 16), and a further 4 weeks single-blind placebo (to Week 20).[1] Mean worst daily itch (MWDI) and monthly itch score (MIS) were calculated as described previously[1]. Itch responders were defined as having a ≥2 point improvement in itch score from baseline.

Results: The final population k-PD model successfully described the effect of linerixibat on TSBA in PBC. Linerixibat treatment resulted in a rapid dose-dependent decrease in TSBA AUC_{0-24}; the reduction in TSBA AUC_{0-24} reached steady-state after approximately 10 days. Baseline TSBA concentrations did not correlate with change from baseline in MIS at Week 16 ($r = -0.13$, $p = 0.14$). At Week 16, there was a moderate correlation between change in TSBA AUC_{0-24} and change in MIS from baseline ($r = 0.27$, $p = 0.002$), which dissipated during the placebo washout period (Week 20; $r = 0.011$, $p = 0.91$). Change in TSBA AUC_{0-24} strongly correlated with improvement in MWDI score from baseline over the 12-week treatment period ($r = 0.52$, $p < 0.0001$; Figure). A ≥30% decrease in TSBA AUC_{0-24} was approximately 64% associated with an itch response.

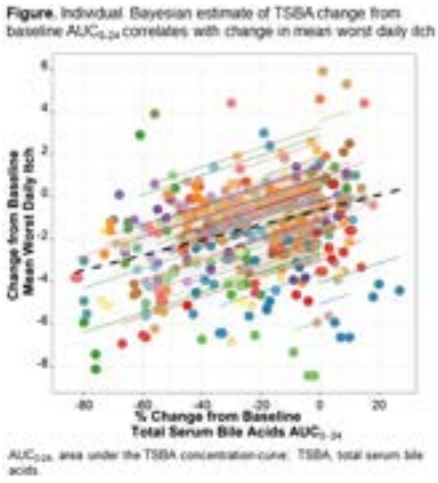

Figure. Individual Bayesian estimate of TSBA change from baseline AUC_{0-24} correlates with change in mean worst daily itch

AUC_{0-24}, area under the TSBA concentration-curve; TSBA, total serum bile acids

Figure:

Conclusion: Linerixibat treatment leads to rapid and dose-dependent reductions in TSBA. Baseline TSBA levels do not correlate with on-treatment change in NRS itch score, suggesting they do not predict linerixibat response. Change in TSBA over the double-blind treatment period correlates significantly with, and can be predictive of, improvement in itch in patients with PBC.

Seladelpar treatment resulted in correlated decreases in serum IL-31 and pruritus in patients with primary biliary cholangitis (PBC): post-hoc results from the phase 3 randomized, placebo-controlled ENHANCE study

Andreas E. Kremer[1], Marlyn J. Mayo[2], Gideon Hirschfield[3], Cynthia Levy[4], Christopher Bowlus[5], David Jones[6], Charles McWherter[7], Yun-Jung Choi[7]. *[1]University Hospital Zürich, Department of Gastroenterology and Hepatology, Zürich, Switzerland; [2]University of Texas SW Medical Center, Division of Digestive and Liver Diseases, United States; [3]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [4]University of Miami Miller School of Medicine, Division of Digestive Health and Liver Diseases, Miami, United States; [5]University of California Davis, Department of Internal Medicine, Sacramento, United States; [6]Newcastle University, Clinical and Translation Research Institute, Newcastle upon Tyne, United Kingdom; [7]CymaBay Therapeutics, Inc., Newark, United States*
Email: andreas.kremer@usz.ch

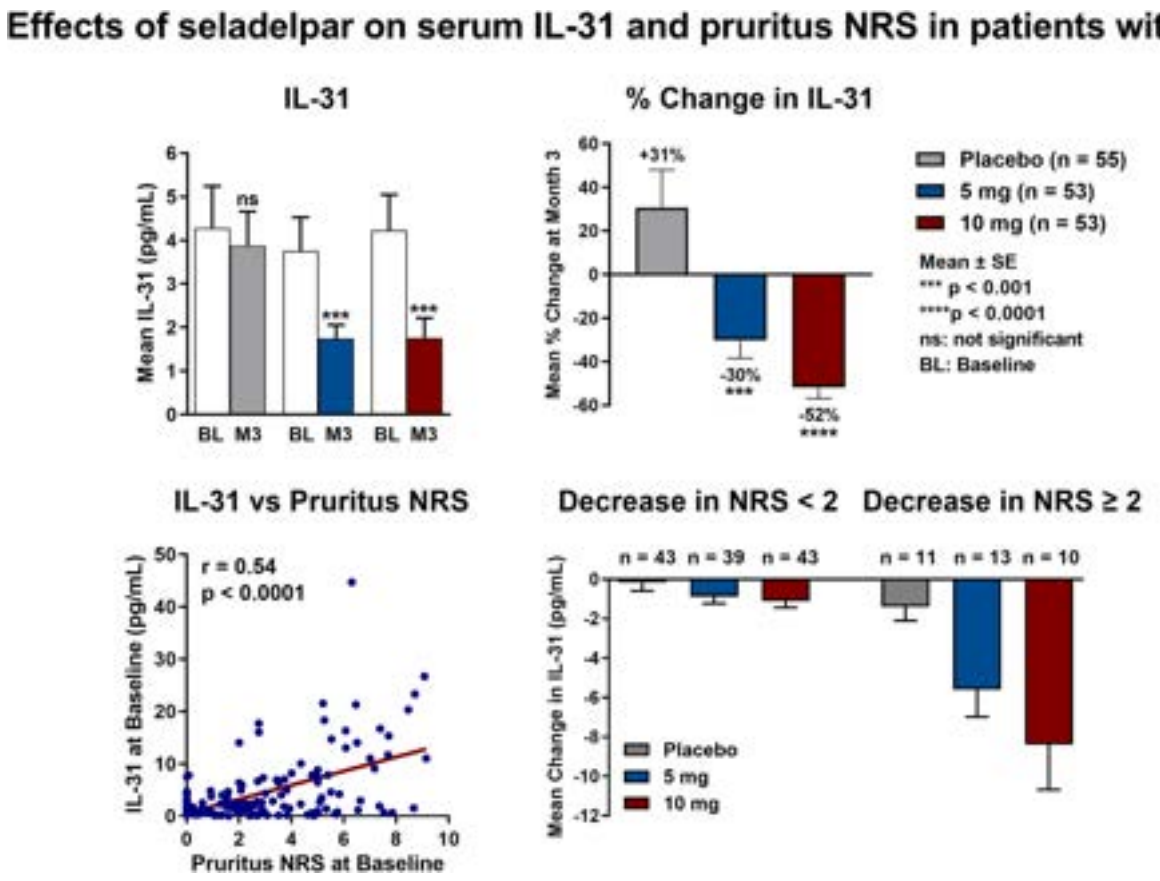

Figure:

Background and aims: Pruritus is a debilitating symptom impacting the quality of life for many people living with PBC. Interleukin-31 (IL-31) is a cytokine reported to be mechanistically relevant to pruritus and its treatment, including those with cholestasis. Treatment with seladelpar, a selective PPAR-delta agonist, is associated with significant improvement in pruritus in PBC. Here we report the effect of seladelpar on serum IL-31 levels and its association with pruritus in patients with PBC.

Method: IL-31 levels were quantified in serum samples from the ENHANCE study of seladelpar (EudraCT 2018-001171-20) in patients with PBC who received daily oral doses of placebo (n = 55), seladelpar 5 mg (n = 53) or 10 mg (n = 53) for 3 months. Serum IL-31, bile acids and their correlation with patient-reported pruritus numerical rating scale (NRS, 0–10) were assessed.

Results: Baseline IL-31 levels positively correlated with pruritus NRS ($r = 0.54$, $p < 0.0001$). Patients with NRS ≥ 4 had significantly higher baseline median [IQR] IL-31 compared to patients with pruritus NRS < 4 (7.6 pg/ml [1.2, 14.5] vs 1.2 pg/ml [0.3, 2.8], $p < 0.0001$). At baseline, IL-31 was also correlated with serum total bile acids ($r = 0.54$, $p < 0.0001$) and ALP ($r = 0.44$, $p < 0.0001$). Seladelpar treatment strongly decreased mean IL-31 levels from baseline to Month 3: seladelpar 5 mg (3.8 to 1.7 pg/ml, $p < 0.001$), 10 mg (4.2 to 1.7 pg/ml, $p < 0.001$) compared to placebo (4.3 to 3.9 pg/ml, not significant). A substantial dose-dependent % decrease in IL-31 was observed with seladelpar treatments: seladelpar 5 mg (−30%, $p < 0.001$) and 10 mg (−52%, $p < 0.0001$) compared to placebo (+31%). Patients with a clinically meaningful improvement in pruritus NRS (≥2 decrease) demonstrated greater dose-dependent reductions in IL-31 from baseline compared to those without pruritus improvement. We also observed significant correlations between changes in IL-31 vs pruritus NRS ($r = 0.54$, $p < 0.0001$) and ALP ($r = 0.40$, $p < 0.01$), but neither with ALT nor AST, in the seladelpar 10 mg group. Changes in IL-31 and total bile acids correlated in the seladelpar 10 mg group ($r = 0.63$, $p < 0.0001$).

Conclusion: Seladelpar dose-dependently decreased IL-31 in patients with PBC. Reduction in serum IL-31 correlated with pruritus improvement. These results suggest that IL-31 may have a role in pruritus in patients with PBC. It may also be a biomarker related to the anti-pruritic effects of seladelpar.

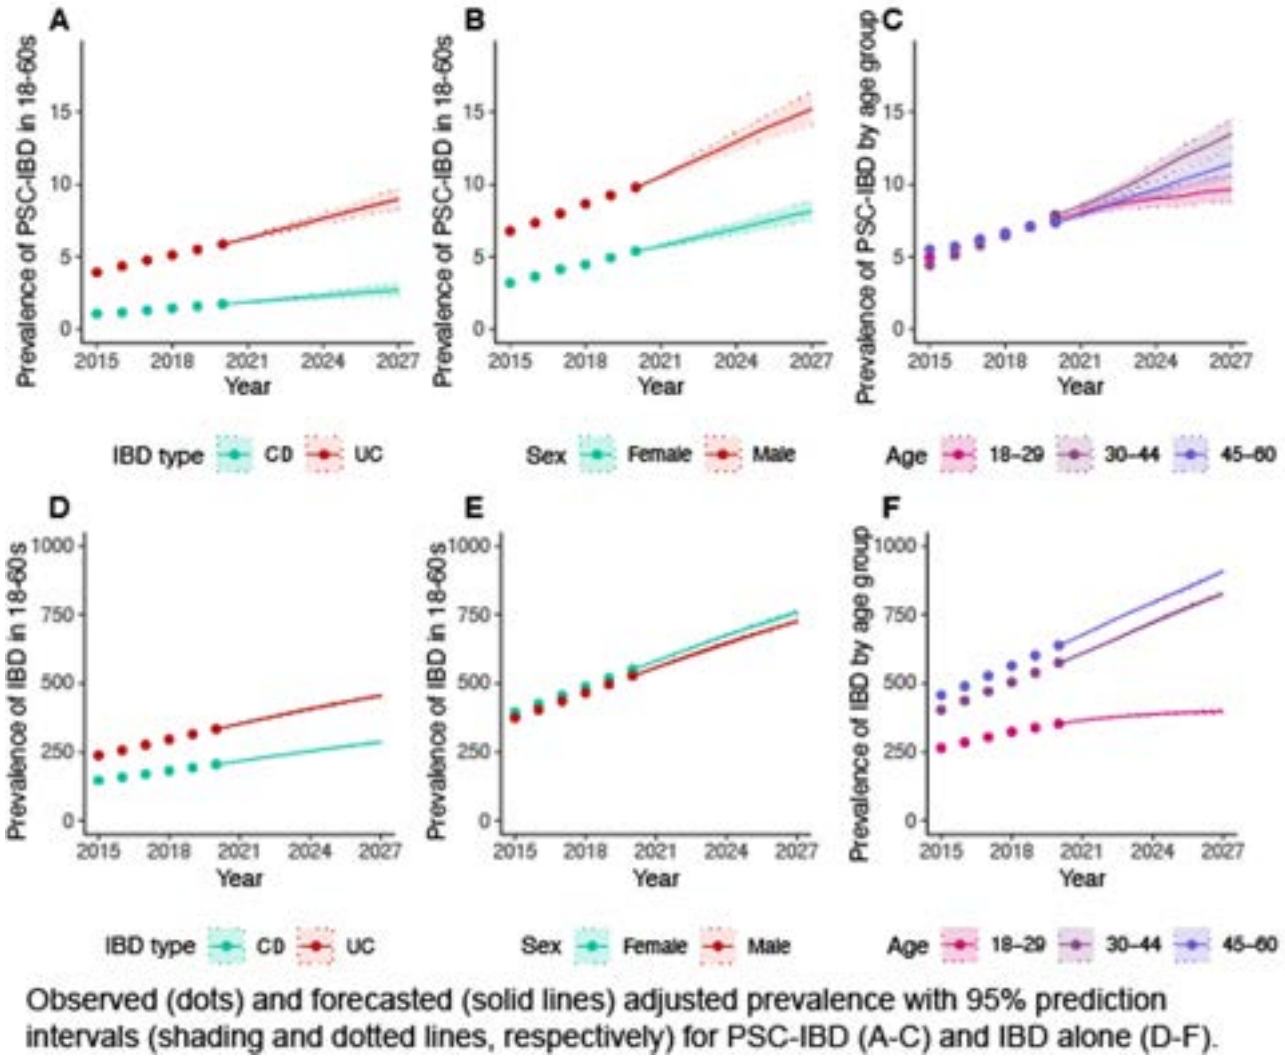
Predicting the current and future prevalence of primary sclerosing cholangitis with inflammatory bowel disease (PSC-IBD): a nationwide population-based study

Hannah Crothers[1], James Ferguson[1], Tariq Iqbal[2], Nabil Quraishi[1], Rachel Cooney[1], Katherine Reeves[1], Palak Trivedi[2]. *[1]University Hospitals Birmingham, United Kingdom; [2]University of Birmingham, National Institute for Health Research (NIHR) Birmingham Biomedical Research Centre (BRC), Birmingham, United Kingdom*
Email: p.j.trivedi@bham.ac.uk

Background and aims: Primary sclerosing cholangitis (PSC) is a leading indication for transplantation and a major risk factor for colorectal cancer in patients (pts) with inflammatory bowel disease (IBD). However, the scale of unmet need is not well defined, and it is not known how the epidemiology of PSC is changing as that of IBD evolves.

Method: We quantified the prevalence of PSC-IBD in 18 to 60-year-olds using nationwide population-based health administrative data across the whole of England (start: 1st Jan 2015). Incidence and

Figure 1: Current and Future Prevalence of PSC-IBD and IBD Alone Across England



Observed (dots) and forecasted (solid lines) adjusted prevalence with 95% prediction intervals (shading and dotted lines, respectively) for PSC-IBD (A-C) and IBD alone (D-F).

Figure:

mortality models were fitted and combined with population projections from the Office for National Statistics to forecast prevalence with 95% prediction intervals (PIs) from 2020 to 2027. Prevalence estimates were censored at the point of death or transplantation.

Results: We identified 1550 individuals with PSC and prior diagnosis of IBD on 1st Jan 2015, yielding a point prevalence of 5.0 per 100,000 population. An additional 12% were diagnosed with IBD in the 5 years following PSC presentation, yielding an estimated adjusted point prevalence of 5.6. Comparatively, point prevalence of IBD alone was 384.3. The prevalence of PSC-IBD increased to 7.6 in Jan 2020, and for IBD alone to 538.7. The average annual percentage change (AAPC) was 8.8% for PSC-IBD and 7.0% for IBD alone. The region with peak PSC-IBD prevalence was the East of England (9.4) and lowest in the Southwest (6.4). Reciprocally for IBD alone, peak prevalence was observed in the Northeast (585.2) and the lowest in the West Midlands (482.6).

The group of PSC-IBD pts estimated to have the largest growth during this time were men compared to women (AAPC 11.1% and 7.6%, respectively), PSC with Crohn's disease (CD) over PSC with ulcerative colitis (UC) (10.3% and 8.4%), and pts aged 30–44y (18–29y: 8.8%, 30–44y: 12.3%, 45–60y: 5.9%). By contrast for IBD alone, the AAPC for men and women, CD and UC, and across age groups were all similar, falling between 5.9% and 7.3%.

The prevalence of PSC-IBD in year 2027 is forecasted to increase to 11.7 per 100,000 (95% PI: 10.8–12.7) yielding an estimated 3683 people living with the condition (Fig. 1A–C). This increases to 4125 when including pts diagnosed with IBD after PSC. The largest group of people living with PSC-IBD in 2027 are estimated to be men (15.2 per 100,000; 14.1–16.4), with PSC-UC (9.0; 8.3–9.7), and aged 30–44y (13.5; 12.5–14.6). In turn, the number of people aged 18–60 years living with IBD alone is estimated to increase to 233,603 in 2027 (Fig. 1D–F). The largest group of individuals with IBD alone are estimated to be women (758.7 per 100,000; 95% PI: 750.3–767.4), with UC (455.7; 451.0–460.4), and those aged 30–44y (908.7; 900.3–916.5).

Conclusion: The rate of growth in PSC-IBD is not explained by that of IBD alone and unique with regards areas of heightened prevalence. Additionally, our data provides nationwide estimates reflecting the current and future landscape of PSC-IBD, which may be used to inform health technology assessments, service evaluation, and allow policy makers to develop strategies for high-quality and cost-effective care in rare liver disease.

WED-252

Maralixibat leads to significant reductions in pruritus and improvements in sleep for children with progressive familial intrahepatic cholestasis: data from MARCH-PFIC

Richard Thompson[1], Douglas Mogul[2], Tiago Nunes[2], Will Garner[2], Pamela Vig[2], Alexander Miethke[3]. [1]*King's College London, Institute of Liver Studies, London, United Kingdom;* [2]*Mirum Pharmaceuticals, Inc., Foster City, California, United States;* [3]*Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio, United States*
Email: richard.j.thompson@kcl.ac.uk

Background and aims: Progressive Familial Intrahepatic Cholestasis (PFIC) is a collection of disorders in bile formation leading to intrahepatic cholestasis, chronic liver disease, and severe pruritus with markedly reduced quality of life from several domains including sleep. MARCH-PFIC was a phase 3, 26-week randomized trial of maralixibat (MRX), an ileal bile acid transporter (IBAT) inhibitor, that achieved its primary and key secondary end points of improvements in pruritus and serum bile acids for patients with PFIC. Here, we further characterize the pruritus response and changes in sleep in the MARCH-PFIC trial.

Method: Key inclusion criteria for MARCH-PFIC were genetically-confirmed PFIC and ItchRO (Obs) >1.5 (moderate-to-severe pruritus). Participants were randomized to receive MRX 570 µg/kg BID or placebo (PBO). The primary analysis evaluated pruritus as assessed by the caregiver using ItchRO (Obs) 0–4 scale; as well as by physician using the Clinician Scratch Scale (CSS). Sleep was assessed using the Exploratory Diary Questionnaire (EDQ[Obs]). Responses for pruritus and sleep were determined as the average in weekly score using a mixed-effects model with recurrent measurements for Change from Baseline (CFB) through Week 26.

Results: 64 patients [nt-BSEP (n = 31), FIC1 (n = 13), MDR3 (n = 9), TJP2 (n = 7), and MYO5B (n = 4)] were randomized to MRX (n = 33) or PBO (n = 31). Baseline characteristics were well-balanced as previously reported. Baseline pruritus score was 2.9 vs 2.7 for MRX and PBO. From Baseline to Week 26, the proportion (SE) of pruritus assessments ≤1 was greater in MRX [0.62 (0.06)] vs PBO [0.28 (0.06)] groups and the difference was significant [delta (95% CI): 0.34 (0.19, 0.50)]. From Weeks 15–26, the median proportion of reported days with 0–1 pruritus was 95% for MRX and 9% for PBO ($p = 0.0005$). Pruritus response from Weeks 15–26 using ItchRO (Obs) was greater in the MRX group when measured in the morning [delta (95% CI): −1.17 (−1.71, −0.64)], evening [delta: −1.13 (−1.67, −0.60)], or max daily [delta: −1.17 (−1.71, −0.63)]. Pruritus response measured with the CSS was greater in MRX [delta: −1.8 (−2.2, −1.53)] vs PBO [delta: −0.7 (−1.1, −0.3)] groups and the difference was significant [delta: −1.1 (−1.7, −0.6); $p < 0.0001$]. The CFB in sleep was greater in MRX [delta: −1.74 (−2.15, −1.33)] vs PBO [delta: −0.55 (−0.99, −0.11)] groups and the difference was significant [delta: −1.19 (−1.78, −0.60); $p = 0.0002$]. Throughout the study, there was a strong correlation between pruritus and sleep (spearman $r = 0.93$; $p < 0.0001$) and for CFB for pruritus and sleep ($r = 0.93$; $p < 0.0001$).

Conclusion: MRX was associated with complete or near-complete resolution of pruritus in the majority of patients with PFIC and the effect was independent of how it was measured, or who made the assessments. Changes with pruritus were strongly correlated with changes in sleep, suggesting that use of MRX may yield meaningful improvements in this domain of quality of life.

WED-253

Dominant strictures in patients with primary sclerosing cholangitis: comparison between old and new definition

Andrea Tenca[1], Hannu Kautiainen[2], Mathias Thylin[3], Lauri Puustinen[1], Nina Barner-Rasmussen[1], Kalle Jokelainen[1], Martti Färkkilä[1]. [1]*Helsinki University Central Hospital, Finland;* [2]*Medcare, Finland;* [3]*Porvoon Hospital, Finland*
Email: ante14@hotmail.it

Background and aims: Patients with primary sclerosing cholangitis (PSC) may develop a dominant stricture (DS) in up to 50% of the cases. DS is associated with an impaired prognosis and its presence in the hilum should always be regarded as a warning sign for cholangiocarcinoma (CC). The traditional definition of DS (TDS, i.e., a narrowing ≤1 mm in the common hepatic duct, CHD, 2 cm within the bifurcation and ≤1.5 mm in the common bile duct, CBD) has been recently replaced by a new definition (NDS) which combines patient's symptoms and signs of cholestasis, elevation of alkaline phosphatase (P-ALP) and P-bilirubin and response to the endotherapy (i.e., dilatation and/or stenting). However, the impact of the NDS definition in disease course of PSC has not been evaluated.

Method: In this longitudinal prospective cohort study, all PSC patients referred for endoscopic retrograde cholangio-pancreatography (ERCP) to confirm diagnosis or to screening biliary dysplasia have been recruited between October 2021–2022. Symptoms of cholestasis and laboratory tests before and after ERCP were collected. Cholangiographic images were scored by using Helsinki score and the presence of TDS and NDS was reported. In addition, need for dilation or stenting and data of brush cytology findings were also collected. Variables were presented as median and interquartile range (IQR) or mean and standard deviation (SD) when ordinal and as number and percentage (%) when nominal. Fishe's exact test, Chi-squared test and Mann-Whitney tests were used when appropriate.

Results: Overall, 248 patients underwent ERC for confirmation of diagnosis in 28 (11%) or screening for biliary dysplasia in 216 (89%). TDS was detected in 62 (25%) and NDS in 43 (17%) patients, respectively; in the remaining 143 patients no DS was observed. Patients with NDS had more symptoms (NDS 17, 40% vs TDS 1, 2%, $p < 0.001$). P-ALP, NDS 288 IU/l (IQR 233–419) vs TDS 94 IU/l (IQR 74–129), and P-bilirubin, NDS = 17, µmol/l (IQR 11–28) vs TDS 13; (IQR 9–17), were elevated in patients with NDS compared with those with TDS. Helsinki-score showed more advanced bile duct disease in patients with NDS, 10 (SD 2.1); vs TDS 8 (SD 2.4), $p < 0.001$. As expected, patients with NDS needed more dilatation, NDS 35; (81%) vs TDS 37; (60%), $p < 0.001$) and stenting, NDS 9 (21%) vs TDS 3 (5%), $p < 0.001$. After endotherapy P-ALP decreased more in patients with NDS, 258 IU/l (IQR 211–354) vs TDS 114 IU/l (IQR 77–192), $p = 0.001$. Biliary dysplasia was detected more frequently in patients with NDS (9%) vs TDS (5%), $p = 0.004$.

Conclusion: According to the new definition, DS is frequent in patients with PSC and associated with increased signs of cholestasis, more advanced bile duct disease and more frequent prevalence of biliary dysplasia.

WED-254

Mitochondrial dysfunction and lipid alterations in primary sclerosing cholangitis

Guri Fossdal[1,2,3], Peder Rustøen Braadland[1,4], Johannes R. Hov[1,4], Eystein Husebye[3], Trine Folseraas[1,4], Tom Hemming Karlsen[1,4], Rolf Berge[3], Mette Vesterhus[1,2,3]. [1]*Oslo Universitetssykehus HF, Rikshospitalet, Norwegian PSC Research Center, Norway;* [2]*Haraldsplass Diakonale Sykehus, Department of Medicine, Bergen, Norway;* [3]*University of Bergen, Department of Clinical Science, Bergen, Norway;* [4]*University of Oslo, Institute of Clinical Medicine, Oslo, Norway*
Email: mette.vesterhus@uib.no

Background and aims: Liver diseases commonly present with indices of mitochondrial dysfunction, yet little is known about this in primary sclerosing cholangitis (PSC). By analysing circulating and liver-resident molecules that indirectly reflect mitochondrial dysfunction, we aimed to comprehensively characterize the degree of this deficit in PSC, and whether this was PSC specific or corresponded to the degree of cholestasis.

Method: In this cross-sectional study, we included 190 non-transplant PSC patients (NoPSC biobank, Norway) and 100 healthy controls (mean age ± SD: 41 ± 14.1 and 42.4 ± 6.6, respectively) who had donated blood, and explanted liver tissue extracts from 24 PSC patients and 18 non-cholestatic liver disease controls (AIH and ARLD). Using mass spectroscopy, we profiled fatty acids, carnitine and

acylcarnitines, and metabolites in the tryptophan-kynurenine-nicotinamide (Trp-Kyn-NAD) pathway.
Results: Compared to healthy controls, we found that PSC patients had increased palmitate (C16:0) but reduced levels of long-chain saturated fatty acids (SFAs) and higher levels of all measured monounsaturated fatty acids (MUFAs) in the circulation. Notably, these characteristics were more pronounced in PSC patients with cholestasis (bilirubin levels ≥ULN [25 μmol/L]). Several n-3 polyunsaturated fatty acids were elevated in PSC but were similar among cholestatic and non-cholestatic patients. We found reduced acylcarnitine ratios C2/C5 and C2/C3 in PSC, indicating deficits in mitochondrial fatty acid oxidation, and larger deficits in cholestatic patients. Levels of intermediates in the tryptophan-kynurenine pathway indicated reduced NAD biosynthesis, which is compatible with impaired energy supply to mitochondria in PSC. While not as apparent as in plasma, explanted liver tissue from PSC patients with high bilirubin at time of surgery also showed evidence of decreased long-chain SFAs and elevated MUFAs. However, fatty acid profiles were overall similar between livers from PSC and non-cholestatic liver disease patients, suggesting that the observed indications of mitochondrial biosynthesis in PSC may not be conditional on cholestasis.

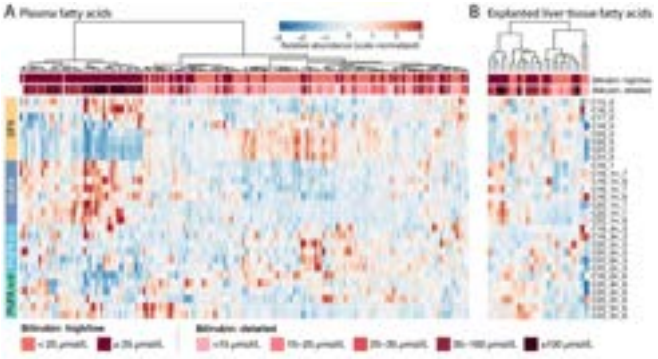


Figure: Fatty acid profiles in PSC patients with various levels of cholestasis

Conclusion: Using indirect measures of mitochondrial dysfunction in blood, we find that mitochondrial dysfunction is prominent in PSC and worsens with disease progression and increasing cholestasis. The important but unresolved question is whether impaired mitochondrial function is mainly a marker of liver disease and severity, or an underlying disease driver that could be targeted therapeutically.

WED-255

The socioeconomic status, epidemiology, and outcomes of people living with primary sclerosing cholangitis-inflammatory bowel disease in Ontario, Canada: a two-decade analysis

Kristel Leung[1,2], Wenbin Li[1], Bettina Hansen[1,2,3], Abdel Aziz Shaheen[4], Aliya Gulamhusein[2], Jennifer Flemming[5,6], Gideon Hirschfield[2].
[1]Institute of Health Policy, Management and Evaluation, Toronto, Canada; [2]Toronto Centre for Liver Disease, University Health Network, University of Toronto, University Health Network, Canada; [3]Erasmus MC, Rotterdam, Netherlands; [4]University of Calgary, Division of Gastroenterology and Hepatology, Department of Medicine and Community Health Sciences, Canada; [5]Institute for Clinical Evaluative Sciences (ICES), Canada; [6]Queen's University, Division of Gastroenterology, Department of Medicine, Kingston, Canada
Email: k.leung333@gmail.com

Background and aims: Understanding the total disease burden of primary sclerosing cholangitis (PSC) with inflammatory bowel disease (IBD) in the diverse province of Ontario (population ~15 million) is important to anticipate healthcare needs and improve outcomes.
Method: A population-based cohort of individuals with PSC-IBD was derived using health administrative data at the Institute for Clinical Evaluative Sciences in Ontario from 2002 to 2018. Patients were excluded if transplant occurred prior to PSC diagnostic code use or had competing liver disease diagnoses for other autoimmune liver diseases, hemochromatosis, alpha-1-antitrypsin deficiency, and/or Wilson disease. We described individual (age, sex) and census dissemination area-level demographics (household income, ethnic diversity, material deprivation, residential instability, and financial dependency). We also described incidence/prevalence (standardized to the 2011 Canadian population) and transplant-free survival (censored December 31, 2021). Changes in incidence and prevalence over time were evaluated using joinpoint regression.
Results: There were 888 incident cases of PSC-IBD identified: 62% were male, with median age at PSC diagnosis of 47 yrs. (IQR 32–62 yrs.). The majority were long-term residents/citizens (92%) and resided in non-rural areas (87%) at diagnosis, with an equal distribution diagnosed in areas of varying ethnic diversity. Patients identified tended to be more from areas of higher income (49.7% in two highest quintiles) and lower material deprivation (49.6% in two lowest quintiles). This disparity was also reflected in residential instability and financial dependency indices. The overall age and sex-adjusted incidence and prevalence rate of PSC-IBD in Ontario was 0.46 (95% CI 0.43–0.49) and 5.5 (95% CI 5.4–5.6) per 100,000 person-years respectively. Incidence increased at a 1.60 average annual percent change (APC). Prevalence increased at a 4.84 average APC 2002–2015; from 2015 to 2018, prevalence increased slightly less at a 2.44 average APC. Patients who are diagnosed with IBD prior to PSC have worse clinical outcomes, with twice the rate of death/transplant compared to vice versa (Figure), with 5-year transplant-free survival from PSC diagnosis of 68% vs. 90% (log-rank p value <0.001). Increasing age at diagnosis and long-term residence in Ontario were also significantly associated with increased rates of death/transplant in PSC-IBD.

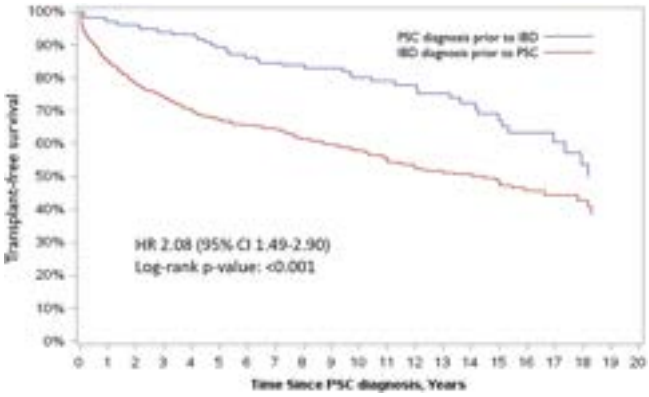

Figure:

Conclusion: There is a clear gradient favouring PSC-IBD diagnosis in those with higher socioeconomic status on a background of steadily increasing incidence and prevalence in Ontario. Transplant-free survival is significantly worse in those diagnosed with IBD prior to PSC compared to those diagnosed with PSC first.

WED-256

Baseline characteristics and risk profiles of 1111 patients with primary biliary cholangitis (PBC) in need of second-line therapy

Gideon Hirschfield[1], Kris Kowdley[2], Andreas E. Kremer[3], John M. Vierling[4], Christopher Bowlus[5], Cynthia Levy[6], Marlyn J. Mayo[7], Daria B. Crittenden[8], Mary Standen[8], Ke Yang[8], Yun-Jung Choi[8], Charles McWherter[8]. *[1]Toronto Centre for Liver Disease, University Health Network and Division of Gastroenterology and Hepatology, Toronto, Canada; [2]Liver Institute Northwest, Seattle, United States; [3]University Hospital Zürich, Zurich, Switzerland; [4]Baylor College of Medicine, Houston, United States; [5]University of California Davis School of Medicine, Sacramento, United States; [6]Schiff Center for Liver*

Diseases, University of Miami Miller School of Medicine, Miami, United States; [7]University of Texas Southwestern, Dallas, United States; [8]CymaBay Therapeutics, Newark, United States
Email: gideonhirschfield@gmail.com

Background and aims: Ursodexoxycholic acid (UDCA) is the first-line treatment for primary biliary cholangitis (PBC). Up to 40% of patients receiving UDCA have an alkaline phosphatase (ALP) ≥ 1.67 × ULN and are usually considered for second-line therapy to prevent progression. Cohort studies confirm that targeting normal ALP and bilirubin are better treatment goals. We examined patients who screen failed due to elevated ALp < 1.67 × ULN to further characterize this population, including presence of additional risk factors for progression.
Method: In four clinical trials with seladelpar from 2015 to 2022, 1111 patients with PBC were screened at 197 clinical sites in 27 countries after treatment with UDCA for ≥12 months, or intolerance to UDCA. ALP levels of ≥1.67 × ULN were required for enrollment. We compared the baseline characteristics and risk profiles of patients enrolled (ALP ≥ 1.67 × ULN) to those who screen failed due to ALP ≥ ULN, but <1.67 × ULN. We stratified using proportions with Enhanced Liver Fibrosis (ELF) values ≥10.0 or bilirubin levels >0.6 × ULN. The relationship of ELF and liver stiffness assessed with FibroScan® was confirmed when available.
Results: The 1111 screened patients were predominantly female (94%) with a mean (SD) age of 57 ± 9.5 years. Studies enrolled 54% of screened patients (n = 603) (EN cohort) with a duration of PBC of 8 ± 6.5 years and on a UDCA dose of 15 ± 3.9 mg/kg/day (92% were on UDCA). Overall, 26% of patients (n = 284) screen failed due to ALp > ULN, but <1.67 × ULN (SF Cohort). The most common reasons for screen failure in the remaining 20% of patients were ALT and AST > 3 × ULN, ALP < 1 × ULN, and EGFR < 60. Meaningful differences in baseline values in the EN and SF cohorts were in ALP, GGT and ALT. Higher-risk bilirubin levels were present in 51.1% and 42.0% of EN and SF cohorts, respectively. Elevated risk based on ELF was identified in 43.2% of the EN and 27.2% of the SF cohorts. Liver stiffness was assessed in 66% of EN patients, and a mean liver stiffness of 9.7 kPa correlated with ELF (r = 0.50, p < 0.001).

Baseline Characteristics

Parameter Mean (SD)	EN (N=603)	SF (N=284)	Total (N=1111)
ALP (U/L)	303.6 (123.58)	160.9 (19.02)	275.8 (162.24)
Total Bilirubin (mg/dL)	0.7 (0.32)	0.7 (0.36)	0.8 (0.56)
>0.6xULN, n (%)	308 (51.1)	119 (42.0)	575 (51.8)
GGT (U/L)	246.0 (213.83)	117.2 (85.46)	226.5 (255.24)
ALT (U/L)	46.7 (22.33)	30.8 (15.79)	47.2 (35.45)
ELF	9.9 (1.03)	9.5 (0.90)	9.9 (1.06)
≥10.0, n (%)	223 (43.2)	65 (27.2)	377 (40.8)
Liver Stiffness (kPa)	9.7 (6.38)	NA	NA

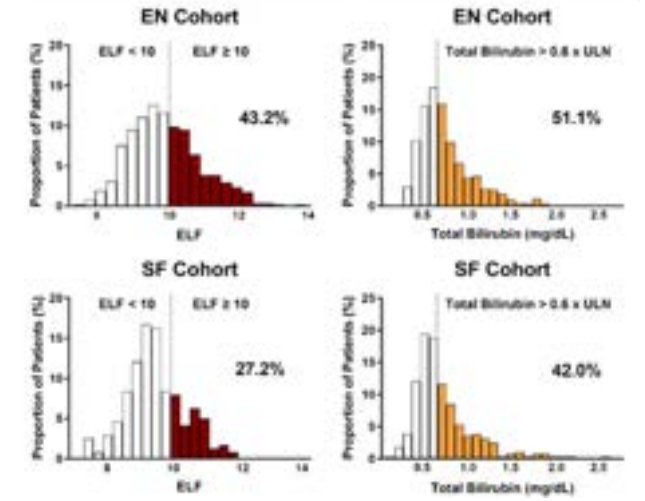

Figure:

Conclusion: We found that in this large international cohort of UDCA treated PBC patients, clinical risk factors for disease progression were common in patients achieving ALP levels >ULN, but <1.67 × ULN. Consideration should be given to including this population in clinical research of second-line therapies with a goal of normalization of ALP.

WED-257

Impact of maralixibat on cholestatic pruritus in adults aged 16 years and older with Alagille syndrome

Gideon Hirschfield[1], Douglas Mogul[2], Marshall Baek[2], Pamela Vig[2], Binita M. Kamath[3]. *[1]University of Toronto, Toronto Centre for Liver Disease, University Health Network, Toronto, Ontario, Canada; [2]Mirum Pharmaceuticals, Inc., Foster City, California, United States; [3]The Hospital for Sick Children and the University of Toronto, Division of Gastroenterology, Hepatology and Nutrition, Toronto, Ontario, Canada*
Email: gideon.hirschfield@uhn.ca

Background and aims: Alagille syndrome (ALGS) is an inherited multisystem disorder that is predominantly characterized by bile duct paucity with cholestasis, as well as variable abnormalities in the heart, eyes, face, skeleton, kidneys, and vasculature. Maralixibat (MRX), an inhibitor of the ileal bile acid transporter, was recently approved by the FDA and EMA for the treatment of cholestatic pruritus in patients with ALGS ≥ 1 year of age and ≥2 months of age, respectively. Data in ALGS has primarily been focused on paediatric patients, however adults with ALGS who survive with their native liver may require treatment for cholestasis and pruritus. We report here for the first time on the efficacy and safety of MRX in adults aged 16 years and older with ALGS transitioning to adult care, and adults that initiate treatment.
Method: Individuals with ALGS were included if they received at least one dose of MRX ≥ 16 years of age within the MRX clinical development program. Pruritus [assessed with ItchRO (Obs), a 0–4 scale with ≥1-point reduction considered clinically meaningful] and serum bile acids (sBA) were assessed at Baseline, average of two values both before and after 16 years, and at end of study. Changes in sBA and pruritus were measured using t-tests.
Results: 14 individuals met inclusion criteria. 11 began treatment at 16 years of age with a median (min, max) age of 13 (11, 15) years at start of therapy and duration of therapy of 3.7 (1.5, 5.9) years with the oldest patient taking MRX at 21 years; 3 patients began MRX ≥ 16 years and were followed for a mean of 3.1 years. All patients received the daily dose appropriate for their weight, with an adult maximum dose of 28.5 mg/day. For individuals that started MRX < 16 years of age, Baseline mean (SE) ItchRO (Obs) was 2.5 (0.21), and significantly decreased to 0.8 (delta = –1.7; p = 0.002), meaning minimal to no itch, prior to age 16 years; pruritus response was durable with no significant change before and after age 16 years (delta = –0.2; p = 0.2), or to end of therapy (delta = 0.2; p = 3). Baseline mean sBA was 130 µmol/L, and significantly decreased to 52 µmol/L (delta = –79; p = 0.03) prior to age 16 years; the reduction was durable with no significant change before and after age 16 years (delta = –7; p = 0.3), or to end of therapy (delta = 3; p = 0.4). The three individuals that started MRX ≥ 16 years had improvements in pruritus from baseline (delta in ItchRO[Obs] of –2.8, –0.6, and –1.0). One patient had a large decrease in sBA (delta = –112 µmol/L) and two had small increases in sBA (delta = 8 and 11 µmol/L). MRX was generally well tolerated with the same safety and tolerability profile observed across the program previously reported.
Conclusion: MRX was effective, durable and well tolerated in ALGS patients aged 16 years and older, providing critical data for patients who transition to adulthood while on therapy. These data support an ongoing role for treatment in adults with ALGS that survive with their native livers into adulthood.

WED-258

Non-adherence to standard pharmacotherapy in autoimmune hepatitis is associated with over-the-counter medication and steroid treatment. Results from the ERN online survey

Ewa Wunsch[1], Linda Krause[2], Ansgar W. Lohse[3,4], Christoph Schramm[4,5], Bernd Löwe[5], Natalie Uhlenbusch[5], Romée Snijders[4,6], José Willemse[7], Piotr Milkiewicz[1,4,8], Tom Gevers[4,6]. [1]*Pomeranian Medical University in Szczecin, Department of Translational Medicine, Poland;* [2]*University Medical Centre Hamburg-Eppendorf, Institute of Medical Biometry and Epidemiology, Germany;* [3]*University Medical Centre Hamburg-Eppendorf, Department of Medicine, Germany;* [4]*RARE-LIVER European Reference Network, Germany;* [5]*University Medical Centre Hamburg-Eppendorf, Department of Psychosomatic Medicine and Psychotherapy, Germany;* [6]*Maastricht University Medical Center, Department of Internal Medicine, Netherlands;* [7]*Dutch Liver Patients Association, Netherlands;* [8]*Warsaw Medical University, Liver and Internal Medicine Unit, Poland*
Email: ewa.wunsch@gmail.com

Background and aims: Adherence to treatment is of particular importance to achieving therapy goals in autoimmune hepatitis (AIH), however, several factors can affect medication intake by patients. The aim of this study was to assess adherence to treatment and related factors in AIH among a large, transnational group of patients with autoimmune liver disease (AILD).
Method: A European cross-sectional online survey was conducted in patients with AIH and in a comparison group of patients with primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC). Standard prescribed medication was defined as the use of steroids, azathioprine, and other immunosuppressants in AIH; ursodeoxycholic acid in PBC and PSC; and over-the-counter (OTC) medication as non-prescribed drugs and diet supplements, based on patients' statements. Adherence to prescribed treatment was inferred from the patients' anonymous answers to questions about the regularity of prescribed treatment intake and defined as skipping their medication less than three times a month and never reducing or stopping their medication by themselves. Multivariable logistic regression analyses were used to identify potentially modifiable factors associated with adherence to treatment while adjusting for known confounders.
Results: A total of 1102 patients with AILD (80% female, mean age 48 ± 14 years) who took prescribed pharmacotherapy for their liver disease were included in the analysis: 444 patients with AIH (85% female, mean age 47 ± 15 years) and 653 patients from the comparison group (77% female, mean age 48 ± 13 years). Based on the applied definition, patients with AIH were the most non-adherent group (47%), in comparison to those suffering from PBC (29%), and PSC (38%). In the multivariable logistic regression models (Figure), OTC medication use was identified as one common important factor negatively associated with treatment adherence in all patients, most relevant for the AIH group. Among standard treatments, steroids but not azathioprine were negatively associated with adherence in the AIH group.

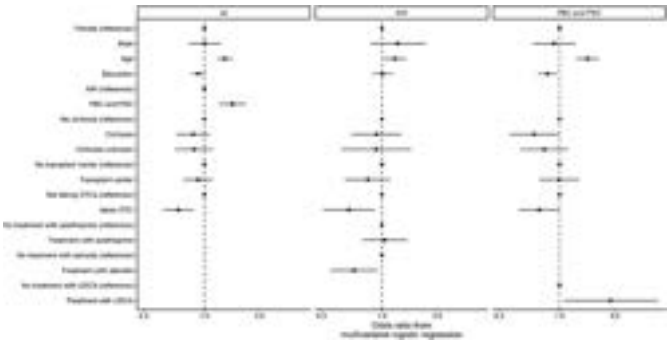

Figure: Variables influencing adherence to treatment in all patients, the study group (AIH) and in the control group (PBC and PSC).

Conclusion: This anonymous survey revealed high non-adherence in patients with AIH, particularly in those treated with steroids. OTC medication intake may reflect low treatment confidence in standard treatment and should be carefully assessed in patients with AILD in a clinical setting.

Email: montanol@ualberta.ca

Background and aims: Autoimmune hepatitis (AIH) is a heterogenous liver disease that varies widely in clinical response and prognosis. The assessment of liver fibrosis in a non-invasive manner during follow-up seems fundamental to predicting disease prognosis and evaluating the effectiveness of therapies. In this study, we aimed to investigate the usefulness of vibration-controlled transient elastography (VCTE) in prognosis in a large cohort multicentric study of patients with AIH across Canada.
Method: We evaluated 761 patients with AIH who had a simplified international score ≥6 from the Canadian Network for Autoimmune Liver Diseases (CaNAL). All patients had at least one reliable liver stiffness measurement taken by VCTE. The primary end point was the time to adverse outcomes defined as death or liver transplantation. Hazard ratios (HR) for adverse outcomes were determined using a Cox regression univariate and multivariate analysis.
Results: 566 were female (74%) and the median age at diagnosis was 45 years (IQR 28–58). 564 patients (76%) were Caucasians. The first VCTE was performed with a median of 35.7 months (IQR 2.9–111.6) after AIH diagnosis. The median value of the VCTE was 8.80 kPa (IQR 5.8–17.3). The liver stiffness measurement value was significantly associated with clinical adverse outcomes (HR 1.05, 95%CI 1.04–1.07; p < 0.001). Considering the first VCTE as time zero, liver stiffness was independently associated with clinical outcomes (HR 1.03, 95% CI 1.02–1.04, P < 0.001), after adjustment for age (HR 1.04, 95% CI 1.02–1.06, P < 0.001), female sex (HR 0.83, 95% CI 0.57–2.00, P = 0.8), cirrhosis at diagnosis (HR 0.87, 95% CI 0.56–1.98, P = 0.8), and time from AIH diagnosis to first VCTE (HR 0.99, 95% CI 0.98–0.99, P < 0.001, Figure 1a). Patients were classified into low, moderate, and high-risk groups for adverse outcomes based on VCTE cut-off values: <8 kPa (reference group, n = 331), ≥8 and <14 kPa (n = 184, HR 2.98, 95% CI 1.25–7.15, P = 0.01) and ≥14 kPa (n = 246, HR 7.36, 95% CI 3.38–16.00, P < 0.001). The adverse event-free survival curves according to the low, medium and high-risk groups are presented in Figure 1b (Log Rank 0.001).

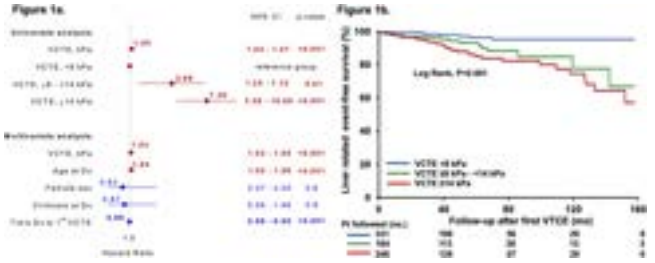

Figure: Parameters associated with adverse outcomes in AIH.

Conclusion: Without reference to the type of treatment or biochemical response, liver stiffness measurement by VCTE is an important tool to predict adverse outcomes in AIH. VCTE should be considered as a tool for stratification and potential surrogate end points in clinical practice and controlled trials.

WED-260

RESIST criteria accurately rule-out high-risk esophageal varices in patients with primary biliary cholangitis and compensated advanced chronic liver disease

Vincenza Calvaruso[1], Ciro Celsa[1], Laura Cristoferi[2], Miki Scaravaglio[2], Luigi Capodicasa[1], Luca Cadamuro[1], Gabriele Di Maria[1], Vito Di Marco[1], Alessio Gerussi[2], Federica Malinverno[2], Pietro Lampertico[3,4], Nora Cazzagon[5], Marco Marzioni[6], Umberto Vespasiani Gentilucci[7], Pietro Andreone[8], Ana Lleo[9], Cristina Rigamonti[10,11], Edoardo Giovanni Giannini[12], Maurizio Russello[13], Ester Vanni[14], Federica Cerini[15], Gabriele Missale[16], Maurizia Brunetto[17], Grazia Niro[18], Giovanni Vettori[19], Antonino Castellaneta[20], Domenico Alvaro[21], Valeria Pace Palitti[22], Francesco Bellanti[23], Pietro Invernizzi[2], Calogero Camma[1], Marco Carbone[2]. *[1]University of Palermo, UOC di Gastroenterologia, Dipartimento di Promozione della Salute, Materno Infantile, Medicina Interna e Specialistica (PROMISE), Palermo, Italy; [2]Fondazione IRCCS San Gerardo dei Tintori, Division of Gastroenterology, Center for Autoimmune Liver Diseases, Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [3]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; [4]CRC "A. Email: vincenza.calvaruso@unipa.it

Background and aims: Non-invasive criteria to identify patients with Primary Biliary Cholangitis (PBC) and compensated Advanced Chronic Liver Disease (cACLD) who can avoid esophagogastroduodenoscopy (EGD) are lacking. Aim of this study was to evaluate the diagnostic performance of RESIST criteria to rule out high-risk esophageal varices (HRV) in patients with PBC related cACLD.

Method: Data of patients with PBC and cACLD from 24 centres belonging to "Italian PBC registry," were captured. All patients who performed an EGD for evaluation of signs of portal hypertension were analyzed. Patients were classified as RESIST low risk if platelets were $>120 \times 10^9$/L and serum albumin >3.6 g/dL or RESIST high risk if platelets were $<120 \times 10^9$/L or serum albumin <3.6 g/dL. Outcomes were the presence of HRV at EGD. The decision curve analysis (DCA) of non-invasive criteria were calculated. RESIST criteria were compared with elastography-based criteria (Baveno VI, Expanded Baveno VI, and Baveno VII criteria).

Results: The cohort consisted of 204 Child-Pugh class A patients. At EGD 101 patients (49.5%) had no varices, 67 (32.8%) had low-risk varices and 36 (17.6%) had HRV. Liver stiffness by Fibroscan was available in 159 patients (78%). The correctly spared endoscopies (true negative) for HRV were: 95% (96/101), 84% (42/50), 86.1% (68/79) and 81.8% (18/22) respectively by RESIST, Baveno VI, Expanded Baveno VI, and Baveno VII criteria. DCA demonstrates the highest net benefit of RESIST criteria compared to elastography-based criteria in ruling out HRV (Figure).

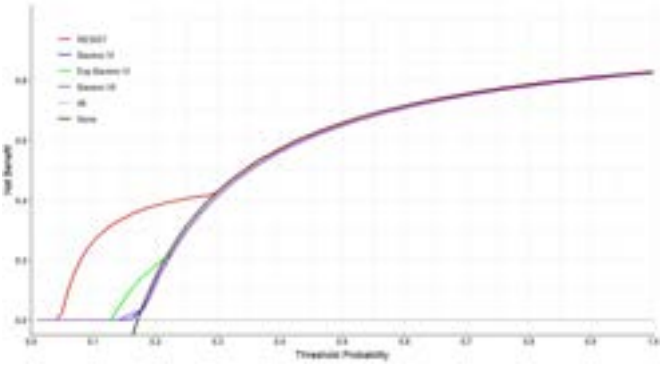

Figure:

Conclusion: Biochemical-based RESIST criteria are useful to easily rule out HRV in patients with PBC and compensated Advanced Chronic Liver Disease.

Clinical significance of F-actin IgA and gliadin IgA antibodies in primary sclerosing cholangitis

Ewa Wunsch[1], Małgorzata Milkiewicz[2], Gary Norman[3], Piotr Milkiewicz[1]. *[1]Pomeranian Medical University in Szczecin, Department of Translational Medicine, Poland; [2]Pomeranian Medical University in Szczecin, Department of Medical Biology, Poland; [3]Werfen, Research and Development, San Diego, United States*
Email: ewa.wunsch@gmail.com

Background and aims: Both gliadin IgA and F-actin IgA antibodies, primary detected in sera of patients with gluten sensitive enteropathy, have been postulated to corelate with disease severity in PSC. We aimed to assess the frequency of examined autoantibodies in PSC and define their potential value as predictors of progressive disease course and poor outcome in a large, well-defined cohort of PSC patients.
Method: Enzyme-linked immunosorbent assay (Werfen, San Diego, USA) was applied for detection of gliadin IgA and F-actin IgA antibodies in sera of 623 patients with PSC (age range 16–73, 65% male, 22% cirrhotic) and 305 gender- and age-matched healthy controls. Poor PSC outcome was defined as liver transplantation and/or liver-related death during a median follow-up of 19 months.
Results: Both gliadin and F-actin antibodies were more frequent in PSC than in healthy controls (28.9% vs 12.8% and 12.0% vs 2.9%, respectively; $p < 0.0001$ for both). Examined autoantibodies were associated with poor liver function and risk scores (Table). F-actin antibody was associated with cirrhosis (RR = 2.48, 95%CI = 1.9–3.3, $p < 0.001$). Significant associations between gliadin and F-actin antibodies and poor outcome were found (Chi2 = 6.4, HR = 1.6, 95% CI = 1.1–2.4, $p = 0.01$ and Chi2 = 32.1, HR = 5.5, 95%CI = 3.1–10.0, $p < 0.001$, respectively).
Conclusion: Gliadin IgA and F-actin IgA antibodies identify a subgroup of PSC patients at risk of more aggressive course, poor outcome and may be of prognostic value in PSC.

WED-262

Clinicopathological features and prognosis of early primary biliary cholangitis with clinically significant portal hypertension

Qi Zheng[1], Bin Wang[2], Ruimin Lai[1], Huaying Lai[1], Xiaoyu Lin[1]. *[1]The First Affiliated Hospital, Fujian Medical University, Hepatology Research Institute, Fuzhou, China; [2]Fujian Medical University, China*
Email: zhengqi0825@sina.com

Background and aims: Early primary biliary cholangitis (PBC) may progress to clinically significant portal hypertension (CSPH) before the development of cirrhosis. This study assessed different pathological features and explored the correlation between liver histopathologic features and long-term prognosis in early PBC patients with CSPH.
Method: Patients with PBC were prospectively enrolled in the study. All the patients were performed to clarify the prevalence, characteristics, pathologic features and prognosis. The independent risk factors for CSPH were identified and selected using logistic regression analysis, and the correlation between baseline pathological features and prognosis was evaluated by COX regression analysis in PBC patients.
Results: A total of 180 PBC patients were included in this study, and 108 had liver biopsy (71 patients with pathological stage I to II, 2 patients between pathological stage II and stage III). Features of CSPH were showed in 45% (81/180) of PBC patients at assessment, and 21.1% (15/71) of patients with early PBC. During median follow-up 4 (IQR 1.1–6.3) years, 19.2% (15/78) developed CSPH, 18.0% (16/89) hepatic decompensation events, 1.7% (3/180) liver transplantation events, and 17.8% (32/180) deaths. Prolonged prothrombin time (PT) and low platelet counts were associated with the presence of CSPH in early PBC ($p = 0.034$, $p = 0.017$, respectively). The 1-, 3- and 5-year cumulative survival rates of PBC patients with baseline CSPH features were 81.4%, 72.5%, and 65.2%, respectively, and CSPH was an important risk factor for adverse outcomes (HR 7.942, $p < 0.001$). Perisinusoidal fibrosis and nodular regenerative hyperplasia (NRH) were the common histopathological features of early PBC with CSPH.

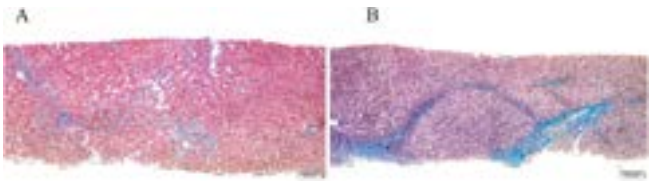

Figure: Pathological features of perisinusoidal fibrosis and NRH in patients with early PBC. A: Perisinusoidal fibrosis with Masson staining (×50), B: NRH with Masson staining (×50)

Conclusion: In early PBC, the event rates for features of CSPH were substantial. Comorbid CSPH at baseline evaluation indicated an increased risk for subsequent adverse outcomes. Hence, early identification of CSPH was crucial, and perisinusoidal fibrosis and NRH served as the valuable histological features of CSPH in early PBC.

WED-263

A two-step algorithm avoids corticosteroids in two-thirds of cancer patients with severe immune-mediated hepatitis due to immune checkpoint inhibitors

Background and aims: Preliminary data suggest some patients with immune-mediated hepatitis (IMH) may recover after immune checkpoint inhibitors (ICI) discontinuation. Our primary aim was to assess the performance of a 2-step algorithm for management of severe IMH, based on ICI temporary discontinuation (first step) and in case of lack of improvement, indication of corticosteroids based on the degree of necroinflammation at biopsy (second step).
Method: Prospective study that included all subjects with grade-3/4 IMH, after excluding alternative diagnosis. Study protocol: ICIs were discontinued in all patients (Step 1). After 48–72 hours, a new blood test including extended peripheral immunophenotyping was performed. Those who showed a 20% drop in AST/ALT levels were maintained without ICI until grade-1 hepatitis or normalization, when ICI were restarted. In the case of absence of improvement in transaminases, a liver biopsy was performed within 24–48 hours (Step 2); Indication for corticosteroids was severe necroinflammation at biopsy, or mild or moderate necroinflammation but progressive worsening at analytical values in the following days.
Results: From January/2020 to November/2022, 94 patients were assessed, and 59 (62.7%) were excluded, with cancer progression as the most common alternative diagnosis. Thirty-five individuals with grade-3/4 IMH were included: 54% women, median age 61 years,

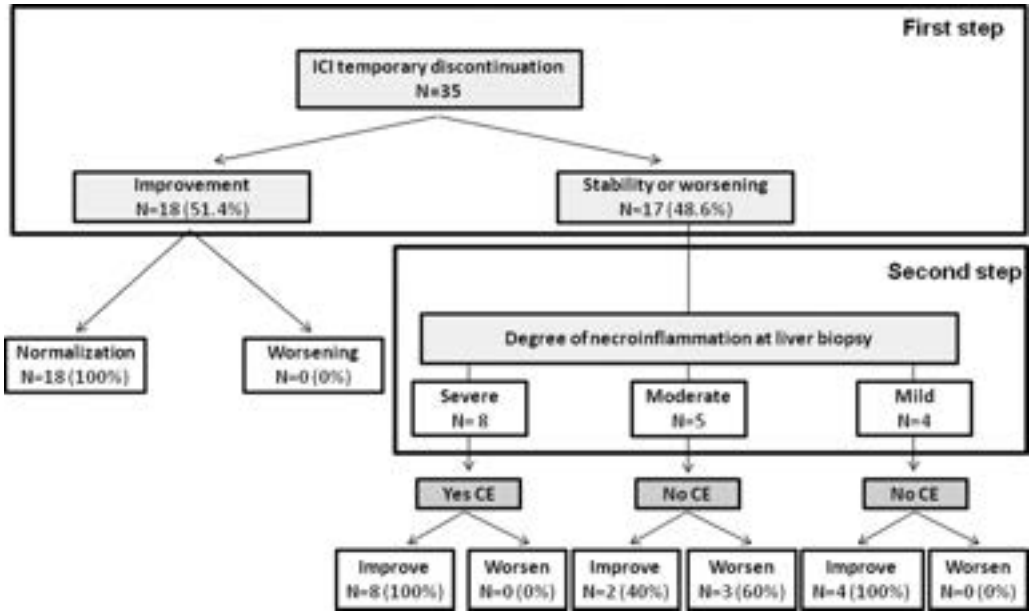

Figure: (abstract: WED-263)

31.4% lung cancer and 25.7% melanoma. ICI: 68.5% anti-PD1/anti-PD-L1, 22.8% combined, 8.6% anti-CTLA-4; CTCAE severity: 27 grade-3, 8 grade-4; DILI severity score: 28 mild, 6 moderate, 1 severe. Overall, 24/35 (68.6%) patients benefited from avoidance of corticosteroids: 18 (51.4%) according to the first step (ICI discontinuation), and 6 (17.1%) to the second step (necroinflammation degree). No patient with mild necroinflammation required corticosteroids, since all presented progressive transaminases normalization. However 3/5 subjects with moderate necroinflammation required corticosteroids during follow-up due to lack of analytical improvement in the following days. Results of the algorithm are shown in the Figure. Liver biopsy mainly impacted on patients with grade-3 IMH, sparing corticosteroids in 6/11 non-improved patients with just ICI discontinuation. Patients requiring corticosteroids had a significant increase in HLA-DR expression on CD8+ lymphocytes (p = 0.002), in central memory CD4+ (p = 0.065), and a lower effector-memory CD4+ (p = 0.014).

Conclusion: A two-step algorithm including discontinuation of immunotherapy and liver biopsy allows avoidance of corticosteroids in almost 70% of patients with severe immune-mediated hepatitis.

Email: diazg.alvaro@gmail.com

Background and aims: A high prevalence of metabolic pathology has been described in patients with primary biliary cholangitis (PBC). However, its impact on the evolution of these patients is controversial. To describe the prevalence and the impact of the metabolic profile on the response and evolution in patients with PBC.

Method: Retrospective study from the Spanish ColHai registry in which patients who met the following criteria were included: (a) Diagnosis of PBC; (b) Treated with ursodeoxycholic acid (UDCA); (c) Minimum follow-up of 1 year; (d) Registered metabolic profile. Patients with variant syndromes were excluded. Response to UDCA was assessed using the Paris II criteria, prognosis using the GLOBE scale (≤0.3 vs >0.3) and liver fibrosis using FIB-4.

Results: A total of 802 patients were included, 90.6% women with a median age of 54.4 years. Considering the metabolic profile, 69.2% had hypercholesterolemia, 62% overweight/obesity, 27.9% arterial hypertension (AHT), 14% type 2 diabetes mellitus (DM2), 8.3% HBP and DM2 (AHT + DM2). and 14% hypertriglyceridemia (hyperTAG). At baseline, GGT values were higher in patients with AHT (228 UI/L vs 168 UI/L, p = 0.001) and in those with dyslipidemia (204 UI/L vs 155 UI/L, p = 0.002).

One year after starting UDCA, 437 patients (60.3%) had a response according to Paris II, 461 (63%) GLOBE ≤ 0.3 and 469 (63.8%) FIB4 ≤ 1.45. GGT values persisted higher in patients with dyslipidemia (64 vs 48 UI/L, p = 0.004) and DM2 (79 UI/L vs 56 UI/L, (p = 0.06)).
Presence of DM2 (OR 2.25; IC95 1.42–3.58), AHT (OR 2.62; IC95 1.84–3.74) and AHT + DM2 (OR 2.81; IC95 1.57–5.01) were associated with greater risk of fibrosis in the univariate analysis. In the multivariate analysis, the presence of AHT (OR 2.66; IC95 1.46–4.88) and AHT +DM2 (OR 3.12; IC95 1.23–7.91) were independently associated with an increased risk.
On the other hand, presence of DM2 (OR 1.98; IC95 1.13–3.48), AHT (OR 2.54; IC95 1.65–3.91) and AHT + DM2 (OR 2.24; IC95 1.12–4.50) were associated with a worse prognosis (GLOBE > 0.3). In the multivariate analysis, the presence of AHT (OR 2.37; IC95 1.41–3.99) and AHT + DM2 (OR 2.56; IC95 1.19–5.45) independently predicted a dismal prognosis. However, the presence of hypercholesterolemia, hyperTAG, or overweight/obesity was not associated with a worse prognosis by means of GLOBE score or FIB-4.
Conclusion: The metabolic profile impacts the evolution of patients with PBC. The concomitant presence of AHT + DM2 represents the scenario with the highest risk of unfavorable evolution. However, the isolated presence of AHT is also independently associated with a worse prognosis. Finally, the presence of hypercholesterolemia did not negatively impact the risk of these patients.

Email: miriam.duell@uk-erlangen.de

Background and aims: Chronic pruritus as a symptom of cholestatic liver diseases represents a major unmet clinical need. The underlying pathophysiological mechanisms are only partially elucidated. Sensory C-nerve fiber endings in the skin act as pruritoceptors and can be activated by previously identified mediators of hepatic pruritus such as lysophosphatidic acid. We therefore assessed C-fiber function in patients with cholestatic liver disorders with and without chronic pruritus.
Method: We included 56 clinically well-characterized patients with cholestatic liver diseases consisting of PBC (n = 22), PSC (n = 17) and other causes of cholestasis (n = 17). Pruritus was evaluated using validated questionnaires including a numeric rating scale (NRS). Patients underwent testing of skin nerve fiber function including an electrical stimulation protocol using sine-wave stimuli on the forearm and dorsum of the foot to selectively activate C-fibers in the skin. We additionally obtained skin punch biopsies at the forearm to analyze histology and intraepidermal nerve fiber density (IENFD).
Results: Patients were divided into those with significant chronic pruritus as defined of a mean itch rating of NRS ≥ 3 (pruritus high; n = 26) and those without clinically significant pruritus (pruritus low, NRS < 3; n = 30). Both patient groups were comparable regarding age, liver and kidney function tests, disease entity and stage of liver disease including proportion of patients with liver cirrhosis. Singular sine-wave stimulation (0.025–0.4 mA) of the skin caused a dose-dependent pain sensation in both, the pruritus low and high group (Figure 1), in a comparable range of healthy subjects. Intriguingly, in addition to pain, solely the high pruritus group experienced a dose-dependent itch sensation (Figure 1B). This difference occurred both at the level of the forearm and the forefoot. Similarly, a prolonged electrical sine-wave stimulation of 60 s resulted in a significant itch sensation only in the high pruritus group. Adaptation was observed to pain but not itch intensity. In skin biopsies, the mean IENFD was strongly reduced (p < 0.001) in patients with cholestatic liver diseases (5.1 IENF/mm) compared to age- and sexed-matched healthy controls (12.3 IEFN/mm), with a trend towards lower IENFD in patients in the high pruritus group (4.7 IEFN/mm) compared to patients with low-intensity pruritus (6.1 IEFN/mm).

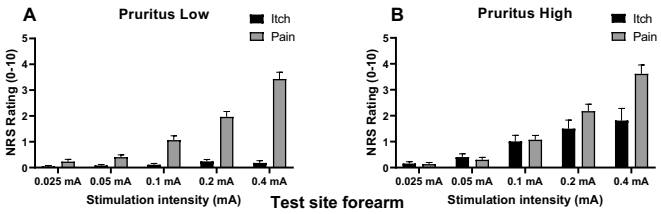

Figure 1:

Conclusion: Patients with chronic cholestatic pruritus exhibit functional changes in sensory C-fiber function to which altered intraepidermal nerve fiber anatomy could contribute.

WED-266

Vitamin D associates with clinical outcomes in patients with primary sclerosing cholangitis

Maryam Ebadi, Elora Rider, Catherine Tsai, Sarah Wang, Ellina Lytvyak, Andrew L. Mason, Aldo J. Montano-Loza. *University of Alberta, Medicine, Edmonton, Canada*
Email: montanol@ualberta.ca

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by progressive biliary inflammation and fibrosis. Given the importance of vitamin D in the modulation of inflammatory and immune-mediated pathways, vitamin D status may impact the PSC course. The objectives of this study were to identify the prevalence of severe vitamin D deficiency in patients with PSC and to investigate its association with cirrhosis progression, hepatobiliary malignancies and liver-related events (liver transplantation or mortality).
Method: Patients with a diagnosis of PSC (n = 354), followed by our autoimmune liver disease clinic were included. Patients with vitamin D levels <25 nmol/L were defined as severely deficient. In addition, patients were divided into three groups regarding longitudinal vitamin D deficiencies as always deficient, less than 50% of the time-points deficient, and never deficient. The types of hepatobiliary malignancies included were cholangiocarcinoma, hepatocellular carcinoma, and gallbladder cancer. Univariate and multivariate analyses were conducted using the Cox proportional hazards regression models.
Results: The mean vitamin D level was 59 ± 2 nmol/L, and 63 patients (18%) had a severe vitamin D deficiency. Patients with a severe vitamin D deficiency were 2.5 times more likely to experience hepatobiliary malignancies (HR 2.55, 95% CI, 1.02–6.40, p = 0.046). However, this association was no longer significant when adjusting for the bilirubin level (HR 1.86, 95% CI, 0.65–5.31, p = 0.25). Of 316 patients without cirrhosis at diagnosis, 151 (44%) developed cirrhosis during follow-up. Serum vitamin D level as a continuous variable was only associated with cirrhosis development in univariate analysis (HR 0.99, 95% CI, 0.99–0.999, p = 0.02). There was no association between severe vitamin D deficiency at presentation and the risk of developing

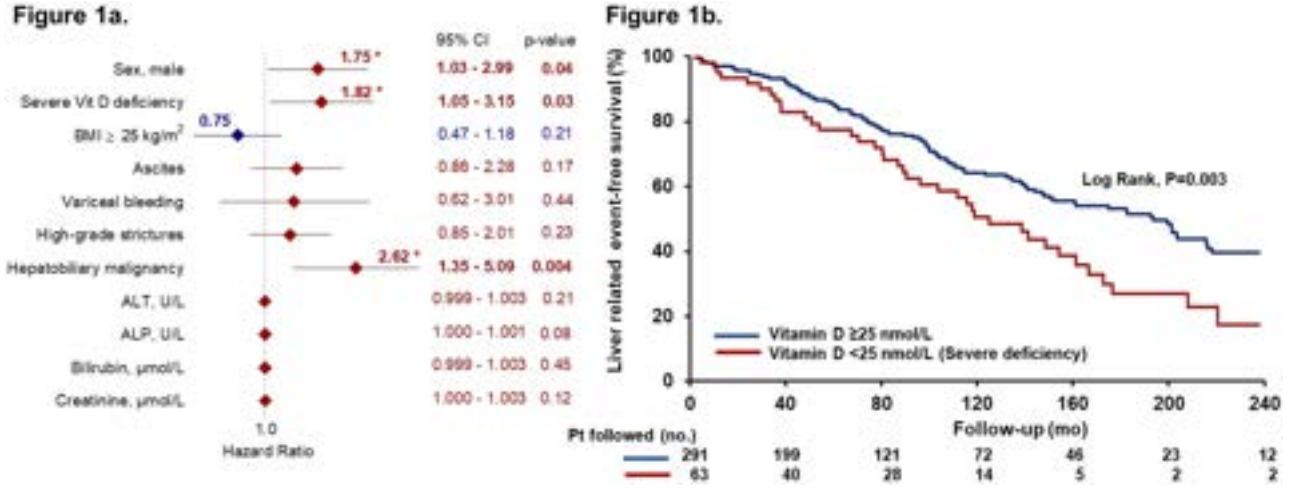

Figure: (abstract: WED-266): Parameters Associated with Liver-Related Events in PSC.

cirrhosis. Over a median follow-up period of 153 months (95% CI, 130–177), 24 deaths were attributed to liver-related disease and 137 patients underwent liver transplantation. Severe vitamin D deficiency at diagnosis (HR 1.82, 95% CI, 1.05–3.15, p = 0.03) was independently associated with a higher risk of liver-related events (Figure 1a). Liver-related event-free survival was shorter in patients with severe deficiency (119 months; 95% CI, 81–156 vs. 185 months; 95% CI, 146–224, p = 0.003; Figure 1b). Patients with persistent severe vitamin D deficiencies at all time points (10% of the population) had more than two-fold higher risk of liver-related events after adjusting for confounding predictors (HR 2.26, 95% CI, 1.17–4.37, p = 0.02).
Conclusion: Severe vitamin D deficiency presented in 18% of patients with PSC at diagnosis and was associated with a higher frequency of liver-related events and hepatobiliary malignancies. Persistent severe vitamin D deficiency was common among 10% of the patients and was associated with a two-times-higher risk of adverse events.

WED-267

Modulation of alkaline phosphatase levels by obeticholic acid in clinical trials and cultured human hepatocytes

Alan Bonder[1], Nicholas Procaccini[2], Mary Erickson[2], Erik Ness[2], Antonio Civitarese[2], Kris Kowdley[3]. [1]*Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States;* [2]*Intercept Pharmaceuticals, Inc., San Diego, United States;* [3]*Liver Institute Northwest and Elson S. Floyd College of Medicine, Washington State University, United States*
Email: erik.ness@interceptpharma.com

Background and aims: Obeticholic acid (OCA), a potent farnesoid X receptor (FXR) agonist, was approved in 2016 as a second-line treatment for primary biliary cholangitis (PBC) in combination with ursodeoxycholic acid (UDCA) based on reduction of serum alkaline phosphatase (ALP) and total bilirubin levels. However, data from trials of OCA monotherapy in patients with non-alcoholic steatohepatitis (NASH) have shown 15–20% stable mean increases in ALP without mean elevation of other liver biochemical markers including gamma-glutamyl transferase (GGT), aspartate aminotransferase (AST), and alanine transaminase (ALT), indicating that ALP fluctuations may be independent of cholestasis or inflammation, and may occur by an unknown mechanism. Importantly, ALP is anchored to the cell membrane by glycosylphosphatidylinositol, which may be cleaved by phospholipase D (PLD), thus releasing ALP into the plasma. We investigated whether OCA affected ALP or PLD gene expression in human hepatocytes in vitro.
Method: Human sandwich-cultured hepatocytes were treated up to 48 hours with 0.1% dimethyl sulfoxide (DMSO; vehicle) or 0.1–100 µM of OCA. Using quantitative PCR, mRNA concentrations were determined for each treatment group relative to the expression of a control gene (GAPDH).
Results: Cultured human hepatocytes exposed to OCA for 48 hours showed no significant changes in relative levels of ALP mRNA compared to the vehicle control; however, hepatocytes displayed dose-dependent increases in PLD mRNA levels. The highest dose of OCA (100 µM) showed a statistically significantly increase in PLD expression compared with the vehicle (Figure).

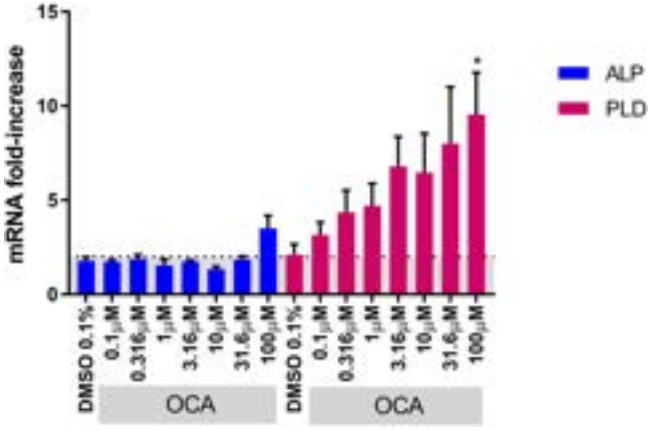

Figure: Assessment of ALP and PLD gene expression levels in human hepatocytes. After 48 hours of OCA exposure, hepatocytes exhibited no significant increases in ALP mRNA levels compared with vehicle, but dose-dependent increases in PLD mRNA levels were observed. ALP indicates alkaline phosphatase; DMSO, dimethyl sulfoxide; OCA, obeticholic acid; PLD, phospholipase D. Data are mean ± SD. Statistics were performed using a 2-way unpaired Student's t test. n = 3 per treatment group. Shaded area represents a 2-fold increase vs internal control. *p < 0.05 compared with DMSO 0.1% (vehicle).

Conclusion: These results support that the approximate 15–20% stable mean increase in plasma ALP levels observed after administration of OCA in NASH clinical trials, in the absence of mean increases in other liver biochemical markers, is not suggestive of liver injury. The likely mechanism of action elevating plasma ALP is via increased expression of PLD, which may in turn release ALP from the cell surface into the bloodstream. This potential mechanism of action may attenuate the observed mean reduction of ALP believed to reflect improved hepatic function in people living with PBC.

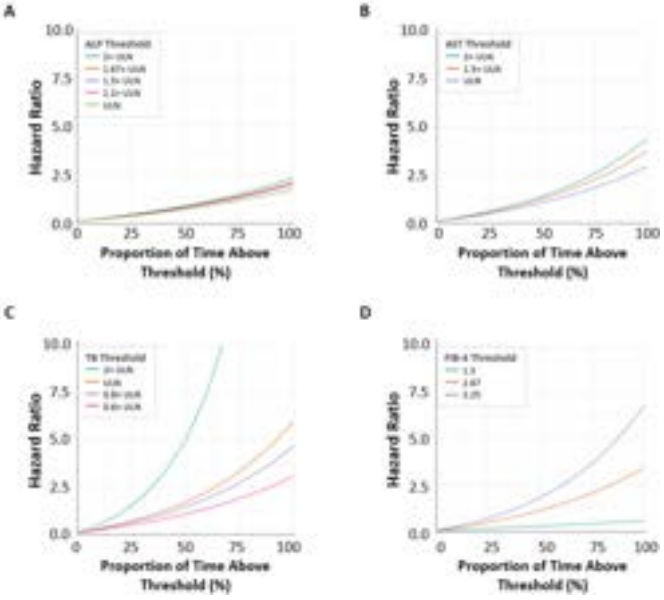
WED-268

Risk of death, liver transplant or hepatic decompensation in primary biliary cholangitis increases with increased duration and degree beyond established clinical thresholds for hepatic biomarkers and fibrosis scores

Kris Kowdley[1], Tracy Mayne[2], Erik Ness[2], Darren Wheeler[2], Radhika Nair[2], Nicholas Procaccini[2], Leona Bessonova[2], Joanna MacEwan[3], Alina Levine[3], Gideon Hirschfield[4]. [1]*Liver Institute Northwest and Elson S. Floyd College of Medicine, Washington State University, United States;* [2]*Intercept Pharmaceuticals Inc, Morristown, United States;* [3]*Genesis Research, Hoboken, United States;* [4]*Toronto Centre for Liver Disease, University of Toronto, Division of Gastroenterology and Hepatology, Toronto, Canada*
Email: erik.ness@interceptpharma.com

Background and aims: Current primary biliary cholangitis (PBC) risk scores use biomarkers from a single point in time to predict clinical outcomes. Recent data showed higher rates of liver transplant or death associated with serum alkaline phosphatase (ALP) and total bilirubin (TB) maintained below current PBC treatment guideline thresholds (ALp < 1.67× upper limit of normal [ULN] and TB < ULN). We aimed to confirm these results and assess additional serum biochemistries and liver fibrosis scores (fibrosis-4 [FIB-4], aspartate aminotransferase [AST] to platelet ratio index [APRI]) and duration of elevations as predictors of the risk of clinical outcomes.
Method: A cohort of patients ≥18 years old with ≥1 inpatient or ≥2 outpatient PBC diagnosis claims separated by ≥30 days (baseline) between January 1, 2014 and April 1, 2022 was created using the Komodo Health database merged with national lab data. Those with ≥2 measures of ALP, TB, AST, alanine aminotransferase (ALT), albumin (ALB), or platelets separated by >1 day were included in the analysis. Patients with a history of hepatic decompensation, liver transplant, major comorbidities, or prescribed obeticholic acid or fibrates (second-line [2L] therapies) were excluded. Survival analysis examined the proportion of follow-up time that liver biochemistries exceeded limits of normal/specific thresholds as a time-dependent covariate on time to first occurrence of hospitalization for hepatic decompensation, liver transplant, or death. Patients were censored at initiation of 2L treatment, end of insurance enrollment, or end of follow-up.

Figure 1. Incremental risk of negative outcomes in real-world sample patients with primary biliary cholangitis by the proportion of time that liver biochemistries ([A] alanine phosphatase, [B] aspartate aminotransferase, [C] total bilirubin) and (D) fibrosis-4 score were above thresholds.



Results: A total of 3929 patients (87.8% female; mean [SD] age 59 [12.7] years) met eligibility criteria; 77.7% had a history of UDCA use, 8.4% had baseline cirrhosis, and the mean (SD) duration of follow-up was 3.0 (2.1) years. For ALP and AST, all results above ULN were associated with increased risk of negative outcomes and risk increased as time above ULN increased (Figure 1A, B). This was also observed for TB > 0.6 × ULN (Figure 1C) and FIB-4 > 2.67 (Figure 1D). Similar associations were observed for ALT, albumin, platelets, and APRI.
Conclusion: Liver biochemistries and fibrosis scores at thresholds lower than those in current PBC treatment guidelines were associated with an increased risk of hospitalization for hepatic decompensation, liver transplant, or death. Risk of negative outcomes increased as time above each threshold increased. These data suggest that risk of hepatic events should be evaluated using measures over time. Guidelines should consider revising treatment recommendations to incorporate chronic elevations at levels meaningfully below current static thresholds to improve clinical outcomes in people living with PBC.

WED-269

Accuracy of controlled attenuation parameter (CAP) measurement for the detection of steatosis in autoimmune liver diseases

Silja Steinmann[1,2], Johannes Hartl[1,2], Sören Alexander Weidemann[3], Füssel Katja[1], Claudia Kroll[1], Ansgar W. Lohse[1,4,5], Christoph Schramm[1,4,5,6]. [1]*University Medical Centre Hamburg-Eppendorf (UKE), 1st Department of Medicine, Hamburg, Germany;* [2]*European Reference Network for Hepatological Diseases (ERN-RARE LIVER), Hamburg, Germany;* [3]*University Medical Centre Hamburg-Eppendorf (UKE), Institute of Pathology with the Sections Molecular Pathology and Cytopathology, Hamburg, Germany;* [4]*European Reference Network for Hepatological Diseases (ERN-RARE LIVER), Hamburg, Germany;* [5]*University Medical Centre Hamburg-Eppendorf (UKE), Hamburg Centre for Translational Immunology (HCTI), Hamburg, Germany;* [6]*University Medical Centre Hamburg-Eppendorf (UKE), Martin Zeitz Center for Rare Diseases, Hamburg, Germany*
Email: sfk.steinmann@outlook.com

Background and aims: Concurrent fatty liver disease represents an emerging challenge in the care of people with autoimmune liver diseases (AILD). Therefore, we here aimed to validate controlled-attenuation parameter (CAP) as a non-invasive tool to detect hepatic steatosis in people with AILD. Method: People with AILD (AIH, PBC, PSC, or variant syndromes) who underwent liver biopsy at the University Medical Center Hamburg-Eppendorf between 2015 and 2020 were included. The diagnostic performance of CAP to determine biopsy-proven hepatic steatosis (>5%) was assessed by calculating area under the receiver operating characteristic (AUROC) curves. Optimal cut-offs to detect hepatic steatosis were determined by Youdeńs index. In AIH, the impact of disease activity was explored by assessing changes of CAP upon resolution of hepatic inflammation during follow-up.
Results: 433 people with AILD (AIH: 218, PBC: 51, PSC: 85, AIH/PBC: 63, AIH/PSC: 16) were included. Histologically proven steatosis was present in 90 individuals (20.7%). Steatosis was less frequently observed in PSC (14%) than in other AILD. CAP strongly correlated with grade of steatosis ($\rho = 0.39$) and BMI ($\rho = 0.53$). In PBC and PSC, ROC curves defined an AUROC of 0.81 and 0.93 for detecting steatosis at an optimal cut-off of 276 (sensitivity: 0, 71; specificity: 0, 82) and 254 (sensitivity: 0.91, specificity: 0.85) dB/m, respectively. In AIH, the diagnostic performance of CAP was significantly lower (AUROC: 0.72). However, resolution of hepatic inflammation under treatment was associated with a significant increase of CAP levels (median +38.0 dB/m) and considerably improved diagnostic accuracy (AUROC: 0.85; cut-off: 288 dB/m; sensitivity: 0.67, specificity: 0.90).

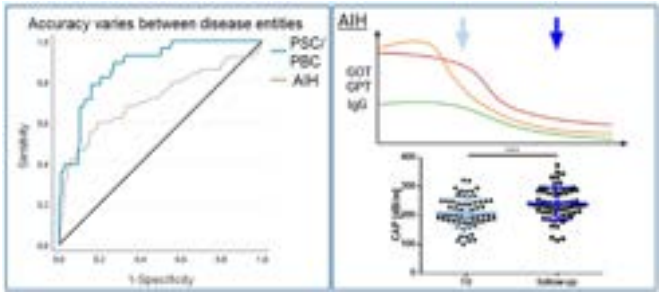


Figure:

Conclusion: In PBC and PSC, hepatic steatosis can be reliably detected by applying disease-specific thresholds of CAP. In AIH, the diagnostic accuracy of CAP is moderate at diagnosis, but improves after acute hepatitis has resolved.

WED-270

Risk of decompensated cirrhosis in patients with primary biliary cholangitis under first, second and third-line therapies

Morillas[8], Luisa Garcia-Buey[9], Miguel Angel Simon[10], Maria Carlota Londoño[11], Jose manuel Sousa-Martin[1], Conrado Fernández-Rodríguez[12], Javier Martinez[13], Judith Gómez-Camarero[14], Antonio Olveira Martin[15], Nerea Quintans[16], Diana Horta[17], Álvaro Díaz-González[18], Indhira Perez Medrano[19], Carmen Álvarez-Navascués[20], Montserrat García-Retortillo[21], Javier Ampuero[1,22]. *[1]Hospital Universitario Virgen del Rocio, Sevilla, Spain; [2]Hospital Universitario Clínico, Santiago de Compostela, Spain; [3]Hospital Universitario de Canarias, Tenerife, Spain; [4]Hospital Universitario La Fe, Valencia, Spain; [5]Hospital Universitario 12 de Octubre, Madrid, Spain; [6]Hospital Universitario Torrecárdenas, Almería, Spain; [7]Complejo Asistencial de León, León, Spain; [8]Hospital Germans Trias i Pujol, Badalona, Spain; [9]Hospital Universitario La Princesa, Madrid, Spain; [10]Hospital Clínico, Zaragoza, Spain; [11]Hospital Clinic, Barcelona, Spain; [12]Hospital Universitario Alcorcón, Alcorcón, Spain; [13]Hospital Universitario Ramón y Cajal, Madrid, Spain; [14]Hospital Universitario de Burgos, Burgos, Spain; [15]Hospital Universitario La Paz, Madrid, Spain; [16]Hospital Universitario Álvaro Cunqueiro, Vigo, Spain; [17]Hospital Mutua, Terrasa, Spain; [18]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [19]Complejo Hospitalario de Pontevedra, Pontevedra, Spain; [20]Hospital Universitario Central de Asturias, Oviedo, Spain; [21]Hospital del Mar, Barcelona, Spain; [22]Instituto de Biomedicina de Sevilla, Sevilla, Spain*
Email: javi.ampuero@gmail.com

Background and aims: About 25% of patients with primary biliary cholangitis (PBC) inadequately respond to ursodeoxycholic acid (UDCA) and, thus, require a second-line therapy. In this setting, patients with cirrhosis receiving obeticholic acid (OCA) and fibrates have been poorly represented to date. Therefore, we aimed to: (a) assess the risk of decompensation in PBC cirrhotic patients receiving first, second and third-line treatments; (b) determine risk factors associated with the occurrence of a decompensation event in patients taking OCA.

Method: Multicenter and retrospective study from the COLHAI registry (belonging to the Spanish Association for the Study of the Liver), including 272 PBC patients showing liver cirrhosis, which was defined by liver biopsy, ultrasound, or transient elastography (>16.9 kPa). Patients were classified according to receiving first (UDCA), second (UDCA and OCA or fibrates), and third-line therapies (UDCA and OCA and fibrates). Outcomes were decompensation events and mortality during the follow-up from the beginning of each treatment.

Results: We included patients with UDCA (n = 173), UDCA+OCA (n = 37), UDCA + fibrates (n = 39), and UDCA + OCA + fibrates (n = 23). Baseline features of the patients are shown in Table. Decompensation by 100-person-years was: (a) UDCA, 2.73 (events = 47; follow-up: 10.1 years); (b) UDCA+OCA, 11.1 (events = 10; follow-up: 2.5 years); (c) UDCA+OCA additionally including those with triple therapy, 12.1 (events = 17; follow-up: 2.42 years); (d) UDCA+fibrates 5.8 (events = 8; follow-up: 3.54 years); (e) UDCA + fibrates additionally including those with triple therapy, 6.83 (events = 15; follow-up: 3.59 years). Serum levels of bilirubin (OR 2.43 (IC95% 1.09–5.46; p = 0.031), albumin (OR 0.09 (IC95% 0.01–0.66; p = 0.018), and presence of type 2 diabetes mellitus (OR 11.35 (IC95% 1.94–66.36; p = 0.007) were independently associated with the occurrence of a decompensation event in PBC patients with OCA (ROC 0.89 (IC95% 0.80–0.98; p = 0.0001)). Fifteen patients taking OCA discontinued the drug (7 due to disease progression and 8 to adverse events).

Characteristic	UDCA (n=173)	UDCA + OCA (n=60) (including double and triple therapy)	UDCA + Fibrates (n=62) (including double and triple therapy)
Female sex	86.7% (150/173)	93.3% (56/60)	95.2% (59/62)
Age: years ± SD	68.3 ± 11.1	61 ± 11.3	60.5 ± 11.9
Obesity (BMI ≥ 30 kg/m2)	23.1% (40/173)	25% (15/60)	22.6% (14/62)
Arterial Hypertension	37.6% (65/173)	15% (9/60)	21% (13/62)
Type 2 Diabetes Mellitus	20.2% (35/173)	18.3% (11/60)	16.1% (10/62)
Dyslipidemia	30.1% (52/173)	48.3% (29/60)	45.2% (28/62)
AST ± SD (IU/L)	70 ± 121	58 ± 81	55 ± 43
ALT ± SD (IU/L)	64 ± 91	51 ± 48	48 ± 36
GGT ± SD (IU/L)	200 ± 212	136 ± 118	178 ± 156
Alkaline phosphatase ± SD (IU/L)	287 ± 382	251 ± 185	241 ± 143
Bilirubin ± SD (mg/dL)	1.05 ± 1.45	1.20 ± 0.97	1.54 ± 1.33
Albumin ± SD (g/dL)	3.98 ± 0.53	4.04 ± 0.44	4.06 ± 0.45
Creatinine ± SD (mg/dL)	0.80 ± 0.28	0.75 ± 0.26	0.80 ± 0.17
Platelet count ± SD (x 10^3/L)	170 ± 79	172 ± 90	190 ± 80
INR ± SD	1.08 ± 0.32	1.09 ± 0.3	1.05 ± 0.22
Decompensated cirrhosis	0% (0/173)	13.3% (8/60)	6.5% (4/62)
Transient elastography (kPa)	19.5 ± 14.3	24.5 ± 17.5	26.4 ± 18.4
Overlap syndrome	16.2% (28/173)	23.3% (14/60)	29% (18/62)

Figure:

Conclusion: Patients with cirrhosis secondary to PBC under double and triple therapy were at a relatively high risk of decompensation, particularly those receiving OCA, probably because they were sicker at the beginning of the treatment. Serum bilirubin and albumin levels, as well as the presence of diabetes mellitus, predicted the risk of decompensation in patients with OCA.

WED-271

Improved survival with regular surveillance imaging in patients with primary sclerosing cholangitis

Natassia Tan[1,2], Natalie Ngu[2,3], Thomas Worland[4], Tanya Lee[5], Tobie Abrahams[5], Keval Pandya[6], Elliot Freeman[1], Nicholas Hannah[7,8], Kathryn Gazelakis[9], Richie Madden[10], Kate Lynch[10], Zina Valaydon[9], Siddarth Sood[7,8], Anouk Dev[2,3], Sally Bell[2,3], Alexander Thompson[5,8], John Nik Ding[5,8], Amanda Nicoll[2,11], Ken Liu[6], Paul Gow[4,8], John Lubel[1,2], William Kemp[1,2], Stuart Roberts[1,2], Ammar Majeed[1,2]. *[1]The Alfred, Melbourne, Australia; [2]Monash University Clayton Campus, Clayton, Australia; [3]Monash Medical Centre, Clayton, Australia; [4]Austin Hospital, Heidelberg, Australia; [5]St. Vincent's Hospital Melbourne, Fitzroy, Australia; [6]Royal Prince Alfred Hospital, Camperdown, Australia; [7]The Royal Melbourne Hospital, Parkville, Australia; [8]University of Melbourne, Parkville, Australia; [9]Western Health, St Albans, Australia; [10]Royal Adelaide Hospital, Adelaide, Australia; [11]Eastern Health, Box Hill, Australia*
Email: natassiapinpintan@gmail.com

Background and aims: The benefits of regular surveillance imaging for cholangiocarcinoma (CCA) in patients with primary sclerosing cholangitis (PSC) are unclear. Hence, we aimed to evaluate the impact of regular magnetic resonance imaging with cholangiopancreatography (MRCP) on outcomes of patients with PSC in Australia, where the practice of MRCP surveillance is variable.
Method: We evaluated MRCP surveillance and outcome data from a multicentre, retrospective cohort of PSC patients from 9 tertiary liver centres in Australia. An inverse probability of treatment weighting (IPTW) approach was used to balance groups across potentially confounding covariates to achieve a standardized difference of less than 0.10. IPTW-weighted Cox proportional hazard models was conducted to assess the risk of death in those undergoing regular surveillance compared to those who were not. A competing risk analysis was conducted whereby liver transplant (LT) was considered a competing risk for death. IPTW-weighted Kaplan-Meier method was used to estimate survival time from diagnosis of PSC and CCA diagnosis.
Results: A total of 298 PSC patients with 2,117 person-years (median 6, interquartile range 3–11 years) of follow-up were included. Two hundred and twenty patients (73.8%) had undergone MRCP surveillance. Forty-six patients (15.4%) had a liver transplant and 35 (11.7%) died during the follow-up period. Patients who had regular surveillance were younger at diagnosis, more likely to have dominant strictures and higher alkaline phosphatase at last follow-up. Eleven patients (5%) in the surveillance group and 2 (2.6%) in the non-surveillance group developed CCA (p = 0.560). IPTW was performed with age of diagnosis, sex, Model for End-Stage Liver Disease score, presence of cirrhosis or dominant stricture, liver transplant, and serum alkaline phosphatase level at follow-up as covariates. Regular surveillance was significantly associated with 62% reduced risk of death on multivariate weighted Cox analysis (p = 0.005). Improved survival was also demonstrated on weighted Kaplan-Meier curves (p = 0.009) as shown below. The cumulative incidence of death was significantly lower in the surveillance group with LT as a competing event (p = 0.017). However, survival post CCA diagnosis was not significantly different between both groups (p = 0.74). Patients who had surveillance of less than one scan a year (N = 41) had comparable survival (p = 0.231) compared to patients who had surveillance at least yearly (N = 172).

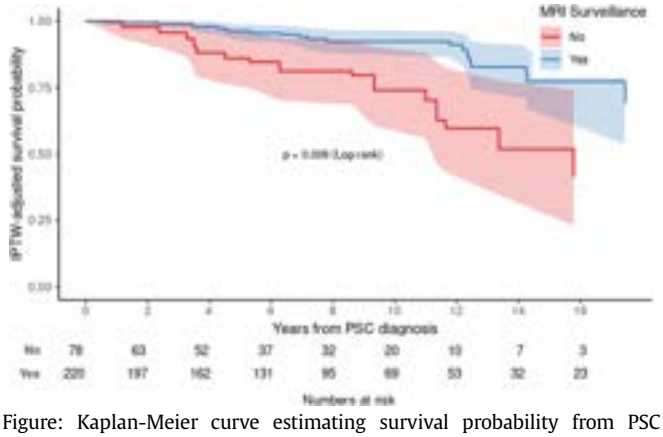

Figure: Kaplan-Meier curve estimating survival probability from PSC diagnosis

Conclusion: In this large multicentre retrospective cohort study that employed IPTW to minimize selection bias, regular MRCP surveillance is associated with improved overall survival in PSC patients, however there was no difference in survival after CCA. Further prospective studies are needed to determine the optimal interval of surveillance imaging and follow-up in patients with PSC.

WED-272

Relative enhancement and spleen volume predict clinical outcomes in primary sclerosing cholangitis

Laura Cristoferi[1,2], Cesare Maino[3], Paolo Marra[4,5], Alberto Savino[1,2], Ilaria Ripamonti[1,2], Marta La Milia[4,5], Davide Bernasconi[6], Miki Scaravaglio[1,2], Alessio Gerussi[1,2], Alberto Rossi[1,2], Eugenia Vittoria Pesatori[1,2], Luisa Pasulo[4], Stefano Fagiuoli[4,5], Pietro Invernizzi[1,2], Davide Ippolito[3,5], Sandro Sironi[4,5], Marco Carbone[1,2]. *[1]Fondazione IRCCS San Gerardo dei Tintori, Department of Medicine and Surgery-University of Milano Bicocca, Monza, Italy; [2]European Reference Network on Hepatologial Diseases (ERN RARE-LIVER), Italy; [3]Fondazione IRCCS San Gerardo dei Tintori, Department of Radiodiagnostics, Italy; [4]ASST Papa Giovanni XXIII Hospital, Bergamo, Italy; [5]University of Milano Bicocca, School of Medicine and Surgery, Italy; [6]University of Milano Bicocca, Bicocca Bioinformatics Biostatistics and Bioimaging Centre-B4, Italy*
Email: l.cristoferi@campus.unimib.it

Background and aims: Magnetic resonance cholangiopancreatography (MRI-MRCP) assessment in primary sclerosing cholangitis (PSC) is currently based on qualitative or semi-quantitative parameters and has high inter-observer variability. In this study, we aimed to explore the predictive performance of quantitative and reproducible MRI-MRCP features, reflecting hepato-biliary function and portal hypertension, to enhance risk stratification in PSC.
Method: This is a retrospective cohort study of PSC patients with at least one complete gadoxetate disodium-enhanced MRI available from 2015 to 2021. Patients with overlapped chronic liver disease and a follow-up shorter than 6 months were excluded. The composite clinical end point was liver-related death, liver transplantation (LT), or hepatic decompensation. Signal intensities were measured in each liver segment. Mean relative enhancement and spleen volume were calculated for each exam. Liver stiffness measurement (LSM), Mayo risk score (MRS), Amsterdam Oxford model (AOM) and blood test within one month from MRI-MRCP were collected. Cox proportional hazards regression was used for the time-to-event analysis. Multivariable model has been internally validated using k-fold cross-validation.
Results: The study cohort included 71 patients. 43 (60.6%) were male, median age at diagnosis of 29 years [IQR 21–45.5], 44 (62.0%) had concomitant IBD, and median follow-up of 614 days (IQR 402–1090). 13 (14.3%) patients reached the outcome (7 LT, 1 liver-related death, 5 hepatic decompensation). At the univariate analysis, spleen volume, spleen cranio-caudal diameter, platelets count, LSM, MRS, AOM, and RE were predictive of outcomes and were taken forward. At the multivariable analysis, the RE and the spleen volume were the only independently associated with the occurrence of adverse event with an HR of 0.29 (per unit, CI 95% 0.09–0.98, p = 0.047) and 1.13 (per 50 cm^3, CI 95% 1.07–1.21, p < 0.0001), respectively and a C-statistic of 0.89. The model was internally validated and outperformed the MRS and AOM in our cohort (C-statistic of 0.82 vs 0.74 and 0.76, respectively). The discriminative power of the score on survival is shown in figure 1 (mean value of the score as cut-off).

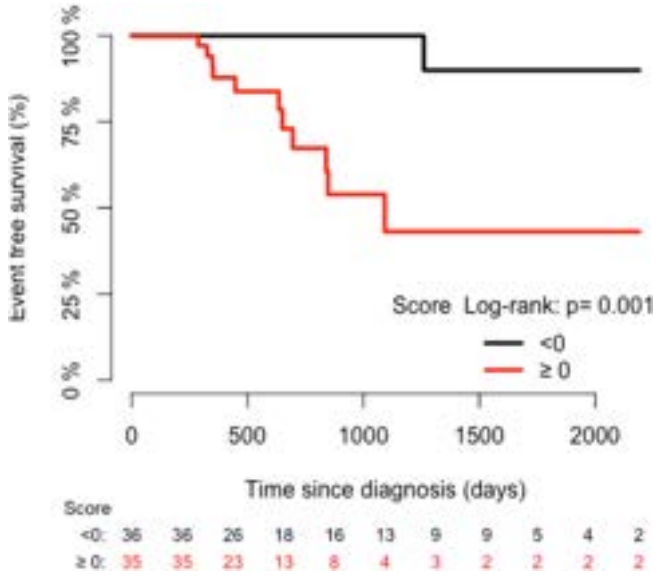

Figure:

Conclusion: Relative enhancement and spleen volume are quantitative, reproducible, simple MRI-metrics, which provide complementary information in predicting event-free survival in PSC.

WED-273

Hepatic steatosis in patients with autoimmune hepatitis: relationship with corticosteroid treatment and long-term outcome

Sarah Flatley[1], Asha Dube[1], Victoria Gordon[2], Barbara Hoeroldt[1], Laura Harrison[1], Elaine Wadland[1], Dermot Gleeson[1]. [1]*Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom;* [2]*University Hospitals Coventry and Warwickshire NHS Trust, United Kingdom*
Email: s.flatley@nhs.net

Background and aims: We have previously reported (Gut 2010:52; 431) an association between worsening steatosis and corticosteroid treatment in autoimmune hepatitis (AIH). Here, we aimed to assess further, associations of steatosis with corticosteroids, fibrosis progression and long-term outcome.
Method: Retrospective/prospective single centre audit of patients with AIH (1999 IAIHG criteria) and followed to death, transplant, loss to follow-up or 31/12/21. Necroinflammatory (NI) score, fibrosis stage (both Ishak) and steatosis grade were assessed by one histopathologist (AKD). Steatosis was graded by percent of hepatocytes containing fat (0: <5%, 1: 5–33%, 2: 34–66%, 3: >67%). Steatohepatitis was defined as hepatocyte ballooning ± neutrophils in zone 3 and graded using Brunt criteria.
Results: 354 patients (81% women, age (median (range)) 55 (2–82) yr, 96% receiving steroids) had an evaluable diagnostic liver biopsy (biopsy 1) and were followed up for 10 (0–47) years. 242 (68%) had a follow-up biopsy (biopsy 2) after 26 (3–174) months. On biopsy 1, 89 (25%) had steatosis (Grade 1, 2 and 3: 70, 18 and 1 respectively) and 6 (2%) had steatohepatitis. Patients with steatosis (vs those without) were older (58 vs 49 years, $p < 0.001$), had higher BMI (29.1 vs 27.3, $p = 0.04$), and more were diabetic (15% vs 7%, $p = 0.02$), They had a lower NI score (9.4 vs 11.5, $p < 0.001$) and AIH histology grade (3.1 vs 3.9, $p < 0.001$) but similar IAIHG diagnostic score and fibrosis stage. On biopsy 2,117 (48%) had steatosis and 9 (4%) steatohepatitis. Steatosis had appeared/worsened in 83 patients (34%), overall grade increasing from (0.3 (0–3) to 0.6 (0–3), $p < 0.001$). Worsening steatosis was positively associated with age ($p = 0.002$), initial prednisolone dose ($p < 0.001$), BMI ($p = 0.005$), and weight gain ($p = 0.05$) but was unrelated to diabetes or biopsy interval. Steatosis (biopsy 1, 2 or change between biopsies) was unrelated to: (a) NI score or % in histological remission (NI score <4) on biopsy 2, (b) fibrosis score on biopsy 2, or (c) fibrosis progression between biopsies 1 and 2. 89 patients died (15 liver-related, 72 non-liver, 2 cause unknown) and 7 underwent liver transplantation. All-cause 10- and 20-yr death/transplantation rates were 16 ± 2% and 45 ± 4% respectively. We confirmed independent associations of death/transplantation rate with older age, cirrhosis at diagnosis, failure of ALT normalisation by 12 months, and with diabetes (onset anytime), which we recently reported (Flatley Gut 2022; 71: A74). All-cause death/transplantation rate was associated with steatosis at diagnosis on univariate ($p = 0.03$), but not on multivariate analysis; there was no association with worsening steatosis.
Conclusion: Steatosis is present at diagnosis in 25% of AIH patients and worsens during steroid treatment. However, steatosis is not associated with histological remission or fibrosis progression and shows no independent association with long-term outcome.

WED-274

Antibodies against multiple post-translationally modified proteins aid in diagnostic work-up of autoimmune hepatitis and associate with complete biochemical response to treatment

Anna Stoelinga[1], Michelle van den Beukel[2], Adriaan Van der Meer[3], Stef van der Meulen[2], Lu Zhang[2], Maarten Tushuizen[1], Leendert Trouw[2], Bart Van Hoek[1]. [1]*Leiden University Medical Center (LUMC), Department of Gastroenterology and Hepatology, Leiden, Netherlands;* [2]*Leiden University Medical Center (LUMC), Department of Immunology, Leiden, Netherlands;* [3]*Erasmus MC, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: a.e.c.stoelinga@lumc.nl

Background and aims: 'Autoimmune liver disease' (AILD) includes autoimmune hepatitis (AIH), primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC). Inflammation occurs in both AIH and cholestatic liver disease. During sustained inflammation and oxidative stress post-translational modifications (PTMs) can be generated. In rheumatoid arthritis, autoantibodies against PTMs are used as diagnostic and prognostic markers, respectively. We studied the presence of six anti-PTM antibodies in patients with AILD and non-AILD.
Method: Patients with AILD were eligible for inclusion. Serum samples were taken simultaneously with routine laboratory assessments. Antibodies against six PTMs (nitration (NT), Cit, acetylation (AL), advanced glycation end-products (AGE), CarP and malondialdehyde-acetaldehyde adducts (MAA)) were tested in collected sera of patients with AILD, and compared to patients with non-AILD and healthy controls (HC). Levels and positivity were correlated with clinical and biochemical features in a well-defined cohort of untreated AIH patients. Differences in levels of anti-PTM antibodies between HCs, AILD and non-AILD were assessed. Analyses of correlation between anti-PTM antibody levels and clinical variables were done.
Results: Anti-PTM IgG antibody levels were measured in 106 patients with AILD, 101 patients with non-AILD and 100 HCs in two academic hospitals in the Netherlands. Anti-PTM antibodies were more often detectable in sera from AILD patients compared with HCs (anti-AL: 18.9% vs 5.0%, anti-AGE: 36.8% vs 4.0%, anti-CarP: 47.2% vs 5.0% and

anti-MAA: 67.9% vs 2.0%). Patients with AILD more frequently harboured at least one type of anti-PTM antibody compared to non-AILD and HCs (AILD: 81.2%, non-AILD: 58.4% and HCs: 20%). The AILD group was dissected into AIH, PBC and PSC. Patients with AIH harboured significantly more anti-MAA, anti-CarP and anti-AGE antibodies compared to non-AILD patients (anti-MAA: 77.3% vs 26.7%, anti-CarP: 63.6% vs 27.7% and anti-AGE: 48.5% vs 17.5%, all p < 0.001, respectively). Patients with AIH harboured anti-PTM antibodies more often compared to other subgroups of AILD. In untreated AIH (N = 58), time to complete biochemical response (CBR) was associated with anti-MAA, anti-CarP, anti-AGE and anti-AL antibodies. Significantly more patients with at least three anti-PTM antibodies attained CBR at 12 months of treatment (13 vs 3 p = 0.01).

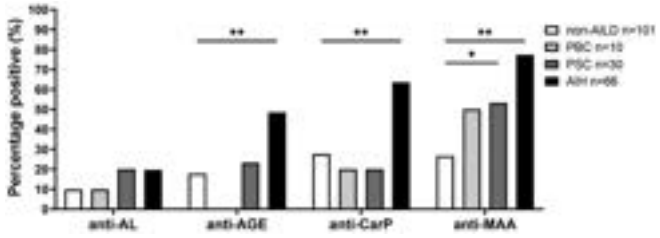

Figure: The association between the presence of anti-PTM antibodies and the three major autoimmune liver diseases

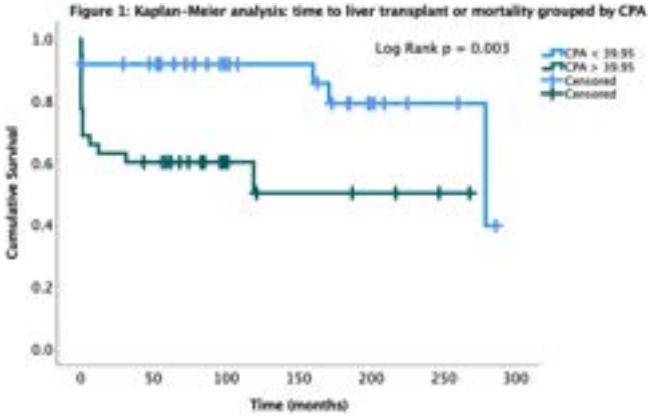
Conclusion: Anti-PTM antibodies are frequently present in AILD. The presence of anti-AGE, anti-CarP and anti-MAA antibodies correlates with the presence of AIH within this cohort. In AIH, harbouring at least three positive anti-PTM antibody responses is positively associated with CBR. Determination of anti-PTM antibodies in liver disease may have diagnostic and prognostic value.

WED-276

Collagen proportionate area is associated with adverse clinical outcomes and allows risk stratification of patients with autoimmune hepatitis

Neil Halliday[1,2], Andrew Hall[2,3], Alessio Gerussi[4], Najeeha Siddiqi[1], Jennifer Watkins[1,3], Aileen Marshall[1,2], Alberto Quaglia[1,3], Douglas Thorburn[1,2]. *[1]University College London, UCL Institute for Liver and Digestive Health, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, Sheila Sherlock Liver Centre, United Kingdom; [3]Royal Free London NHS Foundation Trust, Department of Cellular Pathology, London, United Kingdom; [4]University of Milano- Bicocca, Division of Gastroenterology and Center for Autoimmune Liver Diseases, Milan, Italy*
Email: neilhalliday@doctors.org.uk

Background and aims: The diagnosis of autoimmune hepatitis (AIH) remains reliant on histological assessment of the liver. However, AIH-specific scoring systems for histological stage have not been determined and are complicated by the coexistence of fibrosis and parenchymal collapse. Novel, reproducible predictors of clinical outcomes are required for risk stratification and prognostication in patients with AIH. Collagen proportionate area (CPA) represents a reproducible, quantitative measure of collagen deposition and also captures the presence of collapse due to the increased density of extracellular matrix proteins. CPA is predictive of clinical outcomes in other liver diseases, hence we sought to determine whether CPA was reflective of fibrosis stage and clinical outcomes in AIH.
Method: Patients from a single centre, with definite or probable AIH were identified; demographics, clinical features and outcomes were recorded and liver biopsies re-reviewed by 2 independent pathologists. CPA was measured on all biopsies and correlated with clinical outcomes by Kaplan-Meier analysis and Cox proportional hazard modelling.
Results: 71 patients with a median follow-up of 78 months (IQR 29–163) were included. CPA correlated with Ishak stage (Spearman Rank p < 0.001). Lower CPA was associated with improved liver transplant-free survival in Kaplan-Meier analysis (figure 1) (Log rank p = 0.003), however Ishak stage was not (p = 0.25). Receiver operator curve analysis identified an optimum CPA cut off of 34.0% which provided a sensitivity of 71% and specificity of 60% for the prediction of transplantation or all-cause mortality. CPA was associated with an elevated hazard of transplant or all cause mortality in univariate Cox-proportional hazard models (HR 1.04, 95% CI 1.01–1.06, p = 0.003), but not in multivariate analysis (HR 1.14, 95% CI 0.99–1.33, p = 0.08). However, in multivariate analysis CPA was associated with an increased hazard of all-cause mortality, transplant or decompensation (HR 1.13, 1.04–1.23, p = 0.005).



Conclusion: Increasing CPA was associated with adverse patient outcomes in AIH. Although true CPA may be overestimated due parenchymal collapse in AIH, it still provided a quantitative measure that correlated with important clinical outcomes and was more strongly associated with transplant free survival than Ishak fibrosis stage. CPA represents a potentially useful, reproducible tool for prognostication and risk stratification in AIH.

WED-277

Patient reported gaps between current practice and new practice guidelines for primary sclerosing cholangitis

Annika Bergquist[1], Martine Walmsley[2], David Tornai[3], Nora Cazzagon[4], Angela Leburgue[5], Anna Mrzljak[6], Henrike Lenzen[7], Marco Carbone[8], Joao Madaleno[9], Ana Lleo[10], Norman Junge[7], Christoph Schramm[11]. *[1]Karolinska University Hospital and Karolinska Institutet, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Sweden; [2]PSC Support UK, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), United Kingdom; [3]University of Debrecen, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Hungary; [4]University of Padua, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Italy; [5]Association Albi European Reference Network on Hepatological Diseases (ERN RARE-LIVER), France; [6]University Hospital Center Zagreb, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Croatia; [7]Hannover Medical School, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Germany; [8]University of Milano-Bicocca, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Italy; [9]CH Univ Coimbra, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Portugal; [10]Humanitas University, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Italy; [11]Martin Zeitz Center for Rare Diseases, University Medical Center Hamburg Eppendorf, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Germany*
Email: annika.bergquist@ki.se

Background and aims: Management and follow-up strategies for primary sclerosing cholangitis (PSC) vary. A new European practice guideline for management of PSC was recently published. The aim of the present study was to assess patient reported quality of care and

identify gaps in current practice in Europe in relation to the new guidelines.
Method: Data was collected via an online survey hosted on the EU Survey platform in 11 languages between October 2021 and January 2022. Questions were asked about the disease, symptoms, treatment, investigations, and quality of care. Responses were received from participants in 36 countries around the world and included transplanted and non-transplanted respondents. Only responses from non-transplanted individuals were analysed in detail (n = 798). They were reviewed against the recommendations in the EASL guidelines for management of PSC. Respondent ages were grouped as follows: Children: aged 7–15 years, young adults: 16–25 years, adults: 26–60 years, seniors: 61+ years. Selection of response to open ended answers (quotes) was used to support and give examples of the findings.
Results: In total, 798 non-transplanted people with PSC from 33 countries responded. Eighty-six % of respondents reported having had at least one symptom. Twenty-four percent had never undergone an elastography, 8% had not had a colonoscopy. Of responders with IBD, 15% had a colonoscopy less frequently than every 2 years. Nearly half (49%) had never undergone a bone density scan. Ursodeoxycholic acid (UDCA) was used in 90–93% in France, Netherlands, and Germany, and 49–50% in the United Kingdom and Sweden. Itch was common (60%), and 50% of those had received any medication. Antihistamines were taken by 27%, cholestyramine 21%, rifampicin 13%, and bezafibrate 6.5%. Forty-one % had been offered participation in a clinical trial or research. The majority (91%) reported that they were confident with their care although half of the individuals reported need for more information on disease prognosis and diet. *Quote: "I would like to know the vital prognosis and life expectancy for these diseases because on the internet the data is old and frightening." Responder ERN431, France*

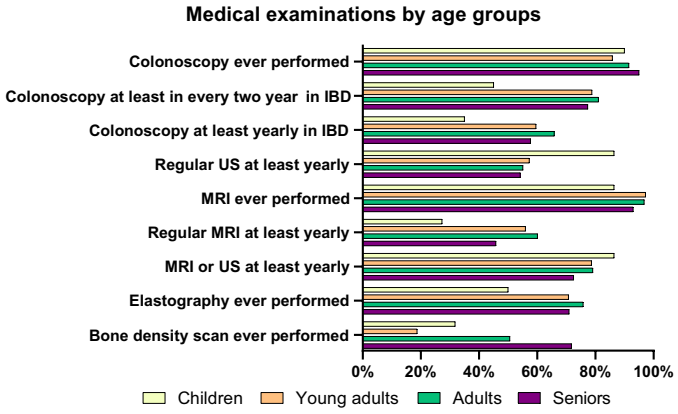


Figure: Examinations performed per age group

Conclusion: Our findings suggest that current practice needs to change if the new EASL clinical practice recommendations are to be universally followed. Identified areas of improvement are prognostication and disease monitoring with more widespread use of elastography, bone density scan, and appropriate treatment for itch.

WED-278

The changing clinical phenotype of autoimmune hepatitis across the millennium. A 40 year cohort study in Bologna, Italy

Marco Ferronato[1], Chiara De Molo[2], Marco Lenzi[1], Luigi Muratori[1].
[1]*IRCCS Azienda Ospedaliero Universitaria di Bologna, Center for the Study and Treatment of Autoimmune Diseases of the Liver and Biliary System, Bologna, Italy;* [2]*IRCCS Azienda Ospedaliero Universitaria di Bologna, Interventional, Diagnostic and Therapeutic Ultrasound Unit, Department of Organ Insufficiency and Transplantation, Bologna, Italy*
Email: marco.ferronato@studio.unibo.it

Background and aims: Autoimmune hepatitis (AIH) is a liver disease with heterogeneous clinical expression, diagnosed at any age and at any latitude. We aim to evaluate modifications of the clinical-epidemiological phenotype of AIH patients from 1980 to our days in Italy.
Method: Single-center observational retrospective study, among 507 AIH patients. Patients were divided into 4 subgroups according to the decade of diagnosis: 1981–1990, 1991–2000, 2001–2010 and 2011–2020. We collected clinical, laboratory and immunological features at diagnosis and assessed the response to treatment 6–12 months thereafter. We defined AIH presentation as "acute" when an increase in transaminases of at least 10-fold the UNL and/or a bilirubin greater than 5 mg/dl is observed, with or without jaundice. Clinical progression is defined as cirrhosis development in non-cirrhotic AIH patients and clinical decompensation and/or HCC development in compensated autoimmune cirrhosis.
Results: Mean age at diagnosis increased among each decade (31.44, 32.96, 39.99, 49.63 years, $p < 0.001$). Acute disease onset progressively increased (39.0% [N = 16/41], 47.3% [N = 44/93], 42.0% [N = 73/174], 52.4% [N = 88/168], $p = 0.014$) and the ratio of cirrhosis at diagnosis decreased (36.5% [N = 19/52], 16.1% [N = 15/93], 10.8% [N = 17/158], 8.7% [N = 14/161], $p < 0.001$). Complete response rates rose between 1981 and 2000 and 2001–2020 (39.3% [N = 46/117], 74.7% [N = 233/312], $p < 0.001$) and clinical progression during follow-up decreased (54.3% [N = 19/35], 29.9% [N = 26/87], 16.9% [N = 27/160], 10.6% [N = 15/142], $p < 0.001$). Anti-nuclear antibodies positivity at diagnosis increased (40.7% [N = 22/54], 52.0% [N = 53/102], 73.7% [N = 123/167], 79.3% [N = 134/169], $p < 0.001$), while positivity for anti-LKM and for anti-LC1 became less frequent (20.8%, 19.4%, 16.0%, 4.3% [$p < 0.001$] and 20.8%, 14.1%, 6.9%, 5.3% [$p = 0.005$] respectively). IgG level at diagnosis progressively decreased (17.40, 17.50, 13.80 and 13.00 g/l, $p < 0.001$).
Conclusion: In the new millennium in Italy at the time of diagnosis the typical AIH patient is older, more often presents with acute hepatitis, cirrhosis is less frequent and complete response to treatment is more commonly achieved. These epidemiological changes can be due to a better understanding of the spectrum of manifestations of AIH, especially the acute onset, together with a larger availability of standardized assays for autoantibody detection. In addition, they may also reflect the constant population ageing. In addition to the classical onset in young women with manifestations of advanced liver disease and high immunoglobulins, AIH can manifest in the context of acute hepatitis, among elderly patients or in more elusive contexts.

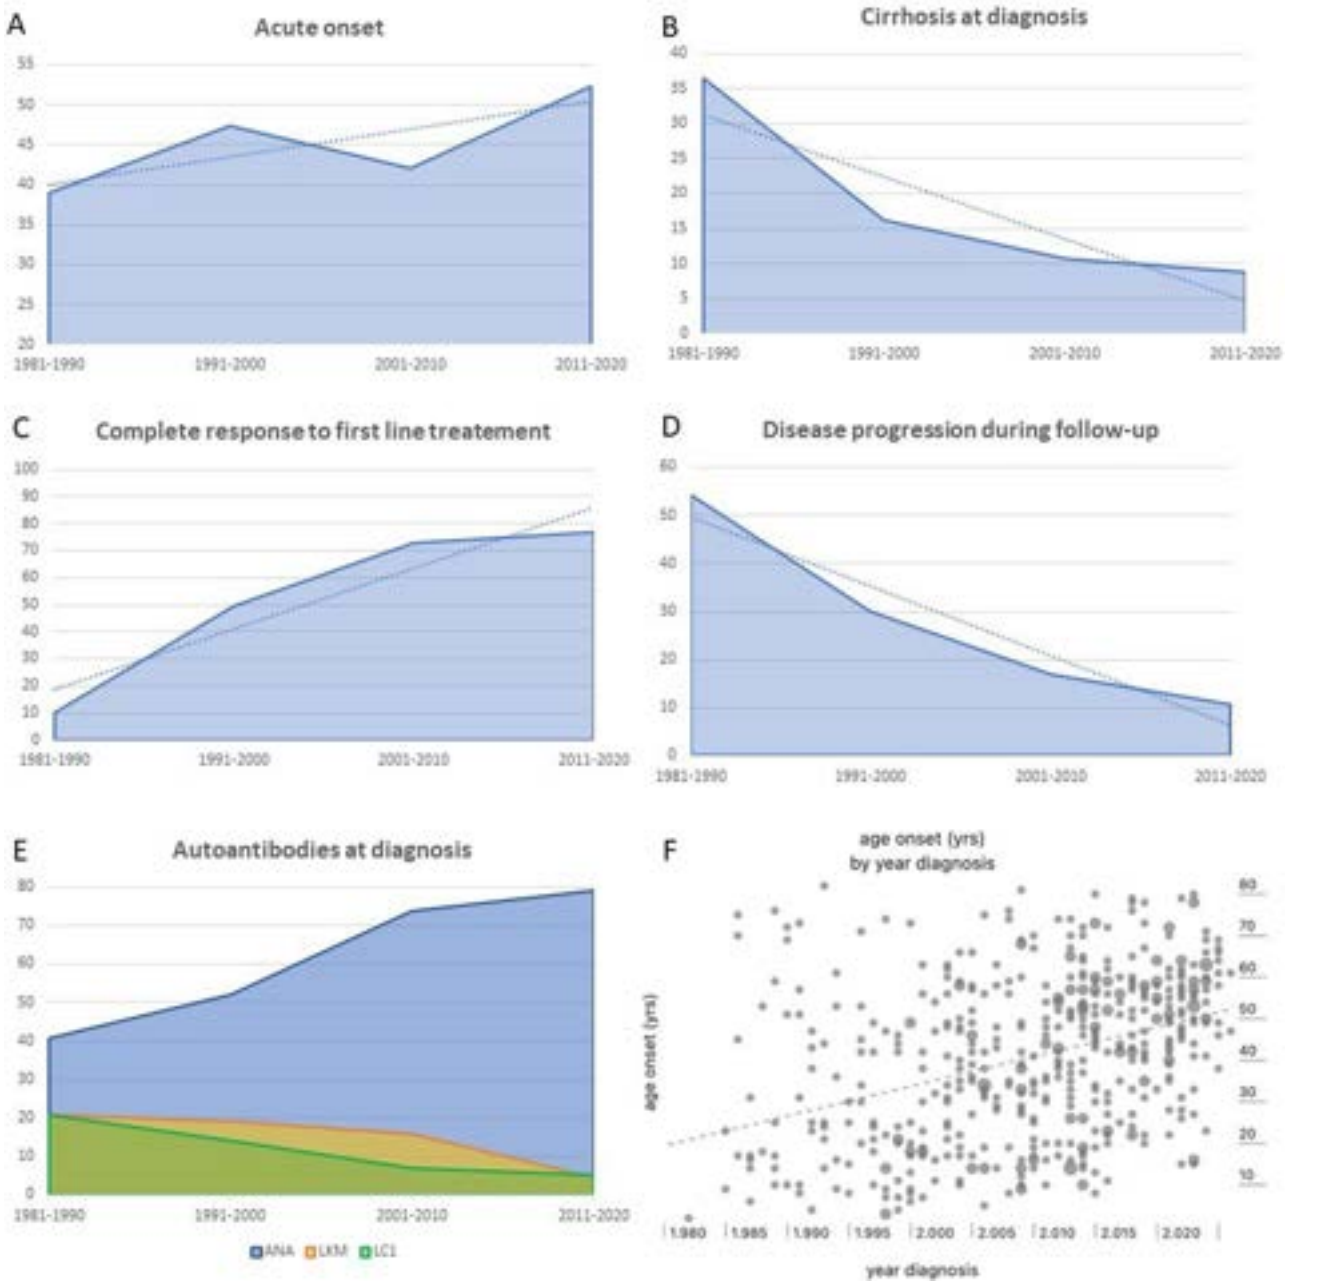

Figure: (abstract: WED-278): (A) Acute disease onset among each decade, showing an increasing trend ($p = 0.014$). (B) Cirrhosis at diagnosis among each decade, showing a clear decreasing trend ($p < 0.001$). (C) Patients with complete response rates after one year with first line treatment, showing a clear increasing trend ($p < 0.001$). (D) Patients with disease progression among each decade, showing a decreasing trend ($p < 0.001$). (E) Autoantibodies at diagnosis showing an increase of ANA positivity ($p < 0.001$) and a decrease of anti-LC1 and anti-LKM ($p < 0.001$ and $p = 0.005$ respectively). (F) Progressive increase of age at diagnosis among each decade ($R = 0.381$, $p < 0.001$).

WED-279

Clinical characteristics, hospitalization, and mortality outcomes of Coronavirus Disease 2019 in primary sclerosing cholangitis liver transplant patients

Stela Celaj[1], Vibhu Chittajallu[2], Scott Martin[3], Jaime Perez[3], Emad Mansoor[2]. *[1]Division of Gastroenterology, Hepatology and Nutrition, University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania, United States; [2]Division of Gastroenterology and Liver Disease, University Hospitals Cleveland Medical Center, Case Western Reserve University, Cleveland, Ohio, United States; [3]Clinical Research Center, University Hospitals Cleveland Medical Center, Cleveland, Ohio, United States*
Email: celajs@upmc.edu

Background and aims: It remains unclear whether the outcomes of liver transplant (LT) patients with COVID-19 differ based on the etiology of liver disease. Primary sclerosing cholangitis (PSC) patients are particularly of interest given the autoimmune nature of disease, and the associated cholangiopathy, which has been independently described during COVID-19 infection. Therefore, we sought to study the outcomes of PSC LT patients with COVID-19.

Method: We used a large healthcare research network (TriNetX) to compile the electronic medical records of LT patients (age ≥ 18 years)

with PSC and confirmed COVID-19 (PSC cohort) from 75 healthcare organizations in the USA, between 1 January-31 December 2020. LT patients of other etiologies (non-PSC cohort) with COVID-19 were also identified during the same time. We studied the risk of hospitalization (composite outcome of inpatient or critical care services), mortality, thrombosis (composite outcome of deep vein thrombosis, acute pulmonary embolism, stroke or myocardial infarction) and intensive care unit (ICU) (requiring mechanical ventilation or extracorporeal membrane oxygenation) within 90 days of COVID-19 diagnosis. We performed 1 : 1 propensity score matching (PSM) using a greedy nearest-neighbor matching algorithm to account for potential confounding variables.

Results: We identified 78 PSC LT patients and 1370 non-PSC LT patients with COVID-19. PSC LT patients were younger than the non-PSC cohort (50.5 ± 14.7 vs 57.4 ± 13.7, p < 0.001). Though most of the comorbidities (hypertension, chronic kidney disease, nicotine dependence, heart failure, alcohol related disorders, chronic lower respiratory diseases and ischemic heart disease) were equally distributed among the two groups, the percentage of diabetes and cerebrovascular diseases statistically differed between the cohorts. Therefore, PSM was performed for demographics, comorbidities (including body mass index) as well as immunosuppression regimen. Following PSM, the PSC and non-PSC cohorts were relatively balanced (n = 74 each cohort). PSC LT patients were more likely to experience symptomatic COVID-19 infection with hypoxemia, fever, nausea, emesis, diarrhea and abdominal pain when compared to non-PSC LT patients. Mean values of alkaline phosphatase were also higher in the PSC cohort compared to non-PSC (223 vs 140 U/L, p = 0.03), whereas the rest of liver enzymes were similar among the groups. However, when looking at COVID-19 outcomes, we found no significant difference in mortality, hospitalization, thrombosis or ICU care between PSC and non-PSC LT patients (as seen in the Figure).

	Before Matching				After Matching			
Outcome	PSC (n=78)	non-PSC (n=1370)	OR (95% CI)	P value	PSC (n=74)	non-PSC (n=74)	OR (95% CI)	P value
	n (%)	n (%)			n (%)	n (%)		
Mortality	10 (12.8)	114 (8.3)	0.617 (0.309 to 1.232)	0.167	10 (13.5)	10 (13.5)	1 (0.390 to 2.564)	1
Thrombosis	10 (12.8)	152 (11)	0.849 (0.428 to 1.685)	0.638	10 (13.5)	10 (13.5)	1 (0.390 to 2.564)	1
Hospitalization	26 (33)	550 (40.1)	1.422 (0.873 to 2.316)	0.155	25 (33)	30 (40.5)	1.312 (0.749 to 2.916)	0.33
ICU Care	10 (12.8)	123 (8.9)	0.671 (0.337 to 1.334)	0.253	10 (13.5)	10 (13.5)	1 (0.390 to 2.564)	1

Figure:

Conclusion: To our knowledge, this is the largest study to date looking at PSC LT patients outcomes with COVID-19 in the USA. We found that though PSC LT patients were more likely to experience symptomatic COVID-19, reassuringly they did not carry a higher risk of mortality, hospitalization, thrombosis or ICU care requirement compared to LT patients of other liver disease etiologies.

WED-280

INTEGRIS-PSC phase 2a study: evaluating the safety, tolerability, and pharmacokinetics of bexotegrast (PLN-74809) in participants with primary sclerosing cholangitis

Gideon Hirschfield[1], Palak Trivedi[2,3], Cynthia Levy[4,5], Christoph Schramm[6], Kris Kowdley[7], Michael Trauner[8], Richard Pencek[9], Hardean Achneck[9], Eric Lefebvre[9]. *[1]University of Toronto, Toronto Centre for Liver Disease, Toronto, ON, Canada; [2]University of Birmingham, 1. National Institute for Health and Care Research Birmingham Biomedical Research Centre, Centre for Liver and Gastroenterology Research, United Kingdom; [3]University Hospitals Birmingham Queen Elizabeth, Liver Unit, Birmingham, United Kingdom; [4]University of Miami, Division of Digestive Health and Liver Diseases, Miami, FL, United States; [5]University of Miami, Schiff Center for Liver Diseases, Miami, FL, United States; [6]University Medical Center Hamburg-Eppendorf, Department of Medicine, Martin Zeitz Center for Rare Diseases, Hamburg Center for Translational Immunology, Hamburgh, Germany; [7]Liver Institute Northwest, Seattle, WA, United States; [8]Medical University of Vienna, Wien, Austria; [9]Pliant Therapeutics, South San Francisco, United States*
Email: rpencek@pliantrx.com

Background and aims: Transforming growth factor beta (TGF-beta) signaling is a key driver of liver fibrosis. In primary sclerosing cholangitis (PSC), integrins over-expressed on injured cholangiocytes (alpha-v/beta-6) and myofibroblasts (alpha-v/beta-1) regulate TGF-beta activity. Bexotegrast (PLN-74809) is an oral, once-daily, dual-selective inhibitor of integrins alpha-v/beta-6 and alpha-v/beta-1 in development for the treatment of PSC and idiopathic pulmonary fibrosis (IPF). The primary objective of the present study is to assess the safety and tolerability of bexotegrast in participants with PSC. Additional end points include pharmacokinetics and exploratory biomarkers of fibrosis.

Method: INTEGRIS-PSC is an ongoing, randomized, placebo-controlled 12-week Phase 2a study evaluating the safety and tolerability of multiple doses of bexotegrast in participants with PSC (EudraCT: 2020-001428-33, NCT04480840). The study uses an ascending dose model (Figure): dosing cohorts (~28 participants/cohort) are enrolled and evaluated in a sequential manner with an independent data safety monitoring board review before proceeding to higher dosing cohorts. Entry criteria include established diagnosis of large duct PSC with evidence of hepatic fibrosis based on biopsy, ELF ≥ 7.7, transient elastography >8 kPa or magnetic resonance elastography >2.4 kPa and stable disease in participants with IBD. Randomization to bexotegrast or placebo (3 : 1) is stratified by UDCA use. At the time of abstract submission, enrollment of the 40 mg cohort was completed and was ongoing for the 80 and 160 mg cohorts. An additional cohort of 320 mg is planned.

Results: INTEGRIS-PSC is ongoing and blinded. As of the last safety review, 64 participants were randomized. Participants were mean 45 years old with a duration of PSC of 9 years, 78% male, and 61% with IBD. Mean (SD) baseline liver chemistries were: ALP: 273 (146) U/L, ALT: 84 (61) U/L, bilirubin: 0.8 (0.4) mg/dL. 13% (each) had history of fatigue and pruritus. 49 participants completed the study, 13 were ongoing and 2 discontinued due to adverse events (COVID, Insomnia). Most reported adverse events on blinded study drug were Grade 1 or 2 severity (93%). The most common were: pruritus (14%), fatigue (13%), headache (11%), abdominal pain (6%), cholangitis (6%), COVID (6%), nausea (6%) and upper abdominal pain (6%). 2 participants experienced serious adverse events: one had a grade 3 event of ascending cholangitis, and another had grade 3 events of concurrent abdominal pain with cholecystitis; all serious events resolved, were not considered related to study medication and both participants continued in the study.

Figure:

Conclusion: The INTEGRIS-PSC phase 2a study evaluating the safety, tolerability, and pharmacokinetics of bexotegrast in participants with primary sclerosing cholangitis continues without modification by the Data Safety Monitoring board. Results from this study are expected in 3Q2023.

WED-281

Peri-procedural complications in people with primary sclerosing cholangitis undergoing endoscopic retrograde cholangiopancreatography-evaluating a high-volume programme

Kristel Leung[1,2,3], Yasi Xiao[3], Jeff Mosko[3,4], Aliya Gulamhusein[1,3], Bettina Hansen[2,5], Gary May[3,4], Gideon Hirschfield[1,3]. Email: k.leung333@gmail.com

Background and aims: Endoscopic retrograde cholangiopancreatography (ERCP) is an important component of the care for people living with primary sclerosing cholangitis (PSC). Frequently it is performed to address complex biliary concerns, including obstruction, source control for infection, or evaluation for biliary malignancy. We sought to characterize the peri-procedural course for people living with PSC undergoing ERCP in a high-volume therapeutic endoscopy centre at a single-centre hospital receiving quaternary care referrals from the province of Ontario, Canada.
Method: Using hospital procedural codes to find ERCPs from April 2011 to July 2021, patients who underwent ERCP with PSC were identified. Procedure-related complications (up to 90 days post-procedure) and clinical characteristics information was retrospectively collected. Mixed model logistic regression was performed to evaluate factors associated with post-ERCP complications.
Results: In 78 patients who underwent 271 ERCPs, two-thirds were male and median age at ERCP was 45 years (IQR 31–59 years). In 39% (89) of ERCPs, patients had been diagnosed with liver cirrhosis. Jaundice (152, 59%), abdominal pain (133, 52%), and subjective fevers (88, 34%) were the most common patient-reported indications. Procedural indication was biliary obstruction in 86%, cholangitis in 38%, and malignancy concerns in 20%. Biliary cannulation was successful in 251 ERCPs (97%). Pancreatic duct cannulation occurred in 6.6% (17), while preferential contrast injection into the cystic duct occurred in 32 ERCPs (12%). Balloon dilatation was completed in 61% of cases, while stent insertion, removal, and biliary brushings was performed in 31%, 25%, and 39% respectively. Technical success with satisfactory biliary drainage and flow post-ERCP was reported in 92%. Post-ERCP, biliary blockage, post-ERCP cholangitis, and post-ERCP pancreatitis was reported in 66 (29%), 45 (20%), 11 (4.9%) cases respectively. No perforations occurred. In 1% of cases, post-ERCP bleed, cholecystitis, or respiratory complications occurred. There were 5 deaths in the post-ERCP follow-up period. Post-ERCP hospitalization occurred in 86 cases (37%), with 28 (14%) for an ERCP-related complication, and 8 (9.3%) for liver failure. Repeat ERCP at the same centre within 90 days occurred in 88 (32%) of cases. Male sex (OR 2.79, 95%CI 1.38–6.07), cirrhosis (OR 1.92, 95% CI 1.06–3.50) and stent insertion were associated with post-ERCP complications on univariable analysis (OR 2.37, 95% CI 1.34–4.22); only stent insertion (OR 2.82, 95% CI 1.31–6.05) was significantly associated on multivariate analysis.
Conclusion: For people living with PSC, ERCP remains an important component of their complex care; procedural morbidity and mortality occur but at relatively infrequent rates.

WED-282

Analysis of safety in maralixibat-treated participants with progressive familial intrahepatic cholestasis: data from MARCH-PFIC

Background and aims: Maralixibat (MRX) is a novel, minimally absorbed, orally administered inhibitor of the ileal bile acid transporter (IBAT) that interrupts the enterohepatic circulation of bile acids to improve cholestatic pruritus. MARCH-PFIC, a 26-week randomized Phase 3 study, is the largest and most genetically inclusive clinical trial of Progressive Familial Intrahepatic Cholestasis (PFIC) to date, and achieved primary and key end points of reduction in cholestatic pruritus, serum bile acids (sBA), improved bilirubin, and growth. Here, we provide a detailed analysis of safety data observed in the study.
Method: Treatment-emergent adverse events (AEs) and laboratory data from MARCH-PFIC were analysed.
Results: 93 PFIC patients were randomized to MRX 570 µg/kg twice daily (n = 47) or placebo (PBO; n = 46). Median (min, max) treatment exposure was 183 (10, 203) days. AEs included diarrhea (57.4% vs 19.6%), and abdominal pain (25.5% vs 13%) for MRX vs PBO, respectively. Diarrhea was mostly grade 1, transient, with a median duration of 5.5 days; there were no severe or serious events. One

patient with mild diarrhea discontinued therapy. Abdominal pain was also mostly mild and transient and, in nearly all instances, was concurrent with diarrhea. There were no clinically meaningful changes observed in either groups from baseline in transaminase levels. Transaminase AEs were observed in 17% and 6.5% of MRX and PBO patients, respectively. Among the 8 MRX patients with transaminase elevations, 6 had resolution of the elevation without drug interruption; 2 patients had ongoing stable elevation even after drug interruption (n = 1) or dose reduction (n = 1) and both ultimately resumed prior maximum dose. No patients discontinued MRX due to transaminase elevation. Bilirubin increase was less common in MRX vs PBO (14.9% vs 19.6%). FSV deficiency, which was reported as an adverse event, was also less common in MRX vs PBO (27.7% vs 34.8%). Fractures were seen in 6.4% of MRX and in 0% of PBO; none were considered related as all had clear alternative causes for fracture, including pre-existing vitamin D deficiency which were stable or improved on MRX. Serious AEs were reported in 10.6% of MRX and 6.5% of PBO patients; none were deemed related (except 1 event of mild bilirubin increased in MRX); all resolved without any dose modifications.

Conclusion: The MARCH-PFIC study is the largest PFIC study conducted across PFIC types. MRX was well-tolerated, with GI effects being the most frequent event but generally mild and self-limiting. FSV deficiency and bilirubin increase were more frequently seen in the PBO group.

WED-283

Investigating the cholestatic pruritus of primary sclerosing cholangitis (ItCh-PSC): a study of patients participating in the consortium for autoimmune liver disease (CALiD)

Richard Dean[1], Maryam Yazdanfar[1], Joseph Zepeda[1], Cynthia Levy[2], Stuart C. Gordon[3], Lisa Forman[4], Craig Lammert[5], David N. Assis[6], Daniel Pratt[7], Usha Gungabissoon[8], Ashleigh McGirr[9], Sumanta Mukherjee[10], Megan McLaughlin[10], Christopher Bowlus[1].

Email: clbowlus@ucdavis.edu

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease that causes significant impairments to quality of life. Compared with other cholestatic liver diseases, pruritus has not been well studied in patients with PSC. The aim of this study was to determine the prevalence, severity and treatment patterns for pruritus among patients with PSC.

Method: Patients with PSC were identified from a multicentre, retrospective cohort study of the Consortium for Autoimmune Liver Disease (CALiD). Electronic medical records were searched for keyword terms “itch” and “pruritus” to identify “pruritus” encounters. The severity of pruritus was graded for each pruritus encounter as absent, mild, moderate or severe based on descriptors in the medical record. Medications and endoscopic retrograde cholangiopancreatography (ERCP) planned to treat pruritus was recorded. Patients with more than one pruritus encounter were categorised according to the encounter with the maximum severity of pruritus.

Results: A total of 724 patients were included in the study. Pruritus terms were recorded in 1178 encounters from the medical records of 372 (51.4%) patients. Patients with a pruritus encounter (N = 372, 51.4%) compared with those without (N = 352, 48.6%) had a lower frequency of small duct PSC (4% vs 8%, p = 0.02) but were comparable in terms of inflammatory bowel disease (IBD), cirrhosis, hepatic decompensation, and baseline laboratories, except for international normalised ratio (INR) 1.2 + 0.4 vs 1.2 + 0.4, p = 0.02). Among those with a pruritus encounter, the maximum pruritus severity was graded as mild in 142 (38.2%), moderate in 140 (37.6%), severe in 77 (20.7%), and pruritus was recorded as absent in 13 (3.5%) patients. IBD diagnosis, PSC type, cirrhosis and hepatic decompensation did not differ by the maximum severity of pruritus (Table). However, baseline alkaline phosphatase (ALP), aspartate transaminase (AST) and total bilirubin were greater in those with more severe itch. Anti-pruritic medication usage among patients with any degree of itch included bile acid-binding resins (36.5%), hydroxyzine (22.6%), rifampin (11.4%) and sertraline (9.7%). Two or more medications were used by 46.7% of patients with severe itch. ERCP was planned in 13 (2.5%), 34 (8.4%), 27 (17.3%) encounters with mild, moderate and severe pruritus, respectively.

Table. Baseline clinical and laboratory values by maximum itch severity[1]

	Absent[2] N=13	Mild N=142	Moderate N=140	Severe N=77	p-value
IBD Diagnosis					0.69
Total IBD UC/CD/IC	7 (54%) 7/0/0	76 (54%) 60/15/1	76 (54%) 56/18/2	42 (55%) 34/6/2	-
None	6 (46%)	41 (29%)	37 (26%)	20 (26%)	-
Unknown	0%	25 (18%)	27 (19%)	15 (19%)	-
PSC Type					0.51
Large duct	11 (85%)	91 (64%)	87 (62%)	51 (66%)	-
PSC/AIH	0%	6 (4%)	14 (10%)	5 (6%)	-
Small duct	1 (8%)	6 (4%)	5 (4%)	2 (3%)	-
Unknown	1 (8%)	39 (27%)	34 (24%)	19 (25%)	-
Cirrhosis	2 (15%)	33 (23%)	36 (26%)	16 (21%)	0.54
ALP	186 (119–392)	171 (94–299)	236 (139–481)	246 (158–435)	0.02
AST	52 (34–65)	40 (27–56)	57 (35–108)	53 (32–88)	0.003
ALT	58 (38–84)	45 (28–76)	60 (32–136)	63 (38–87)	0.06
Total bilirubin, mg/dL	0.9 (0.5–1.4)	0.8 (0.6–1.4)	1.1 (0.7–2.4)	1.0 (0.6–2.2)	0.03
INR	1.1 (1.0–1.2)	1.0 (1.0–1.2)	1.0 (1.0–1.2)	1.0 (1.0–1.1)	0.87
Haemoglobin	13.3 (12.2–13.8)	13.6 (12.2–14.5)	13.2 (11.3–14.2)	13.1 (11.6–14.6)	0.49
Platelets	296 (268–366)	229 (149–300)	212 (147–281)	219 (146–302)	0.12

[1]Only patients with an itch encounter included. [2]Itch recorded as being absent. Continuous variables represented by median (IQR). Comparisons by Chi-square and Kruskal-Wallis.

AIH, autoimmune hepatitis; ALP, alkaline phosphatase; ALT, alanine transaminase; AST, aspartate transaminase; CD, Crohn's disease; IBD, inflammatory bowel disease; IC, indeterminate colitis; INR, international normalised ratio; IQR, interquartile range; PSC, primary sclerosing cholangitis; UC, ulcerative colitis.

Conclusion: Pruritus in patients with PSC is not well documented but is frequent and often severe. Patients who experience severe pruritus have more severe liver disease and frequently require multiple anti-pruritic medications and ERCP. These results establish the clinical significance of pruritus in PSC and support the need for prospective studies to accurately ascertain itch prevalence and the unmet need for therapies to treat pruritus among patients with PSC.

WED-284

Spleen stiffness measurement predicts decompensation risk in primary biliary cholangitis

Giulia Francesca Manfredi[1,2], Carla De Benedittis[2], Francesca Baorda[1,2], Davide Di Benedetto[1,2], Michela Burlone[2], Rosalba Minisini[1], Mario Pirisi[1,2], Cristina Rigamonti[1,2]. *[1]Università degli Studi del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]AOU Maggiore della Carità, Division of Internal Medicine, Novara, Italy*
Email: cristina.rigamonti@uniupo.it

Background and aims: Primary biliary cholangitis (PBC) is a slowly progressive cholestatic disease, which may lead to portal hypertension (PH) and its complications even in a pre-cirrhotic stage. Spleen stiffness measurement (SSM) by vibration-controlled transient elastography (VCTE) is predictive of PH. We aimed to investigate in PBC patients the prognostic value of SSM in stratifying the risk of decompensation and SSM ability to identify those at low probability of high-risk varices.
Method: Monocentric study of 88 PBC patients, who underwent VCTE for liver stiffness measurement (LSM) and SSM with a spleen dedicated module. Demographic and clinical features at baseline and at the time of VCTE examination were recorded. Screening for varices with esophagogastroduodenoscopy (EGDS) was performed according to Baveno VI guidelines and proposed to all patients with SSM >40 kPa, independently of LSM.
Results: Among the 88 patients (95% women, median age 62 years, median disease duration 40 months, 14% cirrhotic, 94% on monotherapy with ursodeoxycholic acid, 6% on combination therapy with obeticholic acid): median LSM was 6.3 kPa (IQR 4.7–8.9), being≥10 kPa in 15/88 (17%). Median SSM was 22.4 kPa (IQR 19–29.5), resulting >40 kPa in 15/88 (17%). None of the subjects with SSM ≤ 40 kPa who underwent EGDS had esophageal varices, regardless of LSM value and platelet count. Varices were found in 11/13 (85%) patients with SSM > 40 kPa who underwent EGDS (2 patients refused endoscopy); high-risk varices were found in 2/11 patients. LSM was <10 kPa in 2/11 (18%) patients with varices and SSM > 40 kPa. During a median follow-up of 10 months (IQR 9–26) after VCTE examination, 4 (4%) patients developed liver decompensation. Stratifying the 88 patients based on the LSM value (LSM < 10 kPa vs. LSM ≥ 10 kPa), the probability of liver decompensation was significantly higher among patients with LSM ≥ 10 kPa (21% vs. 0% at 12 months, 41% vs 0% at 24 months, p < 0.0001). Similarly, stratification upon SSM value (SSM ≤ 40 kPa vs. SSM > 40 kPa), showed a probability of decompensation of 21% at 12 months for patients with SSM > 40 kPa vs. 0% for those with SSM ≤ 40 kPa (p < 0.0001) and a probability of decompensation of 48% vs 0% at 24 months (p < 0.0001). LSM ≥ 10 kPa and SSM > 40 kPa demonstrated 100% sensitivity in predicting the risk of liver decompensation.
Conclusion: Both LSM and SSM predict risk of decompensation in PBC patients. SSM > 40 kPa is predictive of presence of varices and might be used in combination with LSM and platelet count to improve prediction of complications related to portal hypertension.

WED-285

Rechallenge with anti-PD1 monotherapy after checkpoint inhibitor hepatitis is associated with low rates of recurrence: a single centre study

Nicola Jones[1], Dominique Parslow[2], Stewart Macdonald[3], Lucy Walker[3]. *[1]University Hospitals Plymouth, Oncology, Plymouth, United Kingdom; [2]University Hospitals Plymouth, Oncology, United Kingdom; [3]South West Liver Unit, Plymouth, United Kingdom*
Email: lucy.walker34@nhs.net

Background and aims: Immune checkpoint inhibitors are now widely used in numerous Oncology indications and the management of checkpoint inhibitor-induced liver injury (ChILI) is becoming routine in the practice of Oncologists and Hepatologists alike. Management of these patients is guided by the Oncology society guidelines at national and regional levels and include guidance regarding rechallenge of patients with ChILI. There is growing consensus that the use on anti-PD1 monotherapy is a safe approach, however, overall there is very little data within the public domain to support these guidelines and decisions.
Method: We performed a retrospective analysis of all patients who had developed ChILI between November 2016 and December 2022, including grade of index hepatitis by indication and regimen, rechallenge practice and outcome of rechallenge.
Results: 21 cases of ChILI were identified to have been treated in our center since November 2016. Of these 19% were treated for primary lung cancer and 81% melanoma. The majority of index hepatitis was grade 3 (71% overall; lung ca 50%; melanoma 70.6%), grade 4 14%, grade 2 10% and grade 1 5%. Ipilimumab/Nivolumab combination therapy caused the majority of ChILI events (66.7%) and 100% of the grade 4 events. Rechallenge was initiated in 38% of patients and 100% of these received anti-PD-1 monotherapy. Of these 50% had successful rechallenge and remain alive and on treatment, 25% had treatment withdrawn due to disease progression and 25% had recurrent ChILI. Of those with a successful rechallenge, 25% had a grade 2 index hepatitis and 50% had a grade 3 index hepatitis, compared to those with recurrent ChILI, where 100% had grade 3 index hepatitis.
Conclusion: Based on our data, rechallenge with single agent anti-PD1 inhibitors should be considered in patients up to grade 3 of index hepatitis. However the higher the grade of the index hepatitis, the greater the likelihood of developing recurrent ChILI.

WED-286

Transient elastography measurements of spleen stiffness are associated with treatment response to ursodeoxycholic acid in primary biliary cholangitis

Ilkay Ergenc[1], Hasan Yapici[2], Caglayan Keklikkiran[3], Yusuf Yilmaz[1,3,4]. *[1]Marmara University School of Medicine, Gastroenterology and Hepatology, Istanbul, Turkey; [2]Marmara University School of Medicine, Turkey; [3]Rize Recep Tayyip Erdoğan University Faculty of Medicine, Gastroenterology and Hepatology, Turkey; [4]Marmara University Institute of Gastroenterology, Turkey*
Email: ergencilkay@gmail.com

Background and aims: The biochemical response criteria fail to predict disease progression in up to 20% of patients with Primary Biliary Cholangitis (PBC).[1] Recent evidence has suggested a prognostic role of portal pressure in PBC.[2] Alterations in the biomechanical properties of the spleen can be quantified by transient elastography (TE) and represent a reliable surrogate marker of portal pressure. This cross-sectional study investigated the association between Spleen Stiffness Measurements (SSMs) by TE and biochemical response to UDCA.
Method: Patients with PBC who had undergone at least two outpatient visits over the last 12 months were deemed eligible. Diagnosis and clinical management were per the European Association for the Study of Liver PBC guidelines. Biochemical response to UDCA was determined according to the Paris II criteria. A single experienced gastroenterologist performed all SSMs by TE (FibroScan® Expert 630; Echosens). The diagnosis of cirrhosis was established histologically or based on clinical and laboratory findings combined with characteristic radiological features.
Results: A total of 107 patients with PBC (101 women and 6 men; mean age at diagnosis: 45.9 ± 11 years) were included in the study. The median duration of follow-up after UDCA treatment was 4.6 years (range, 1–7.75 years). All patients had at least one positive diagnostic serological marker of PBC, and 60 (56.1%) had undergone liver biopsy at the time of diagnosis. On histopathological examination, 19 patients (33.3%) had no fibrosis, 25 (43.9%) F1 fibrosis, 8 (14.0%) F2 fibrosis, 2 (3.5%) F3 fibrosis, and 3 (5.3%) F4 fibrosis according to Metavir scoring system. Fifteen patients met the diagnostic criteria for cirrhosis. We identified 28 (26.2%) patients who were

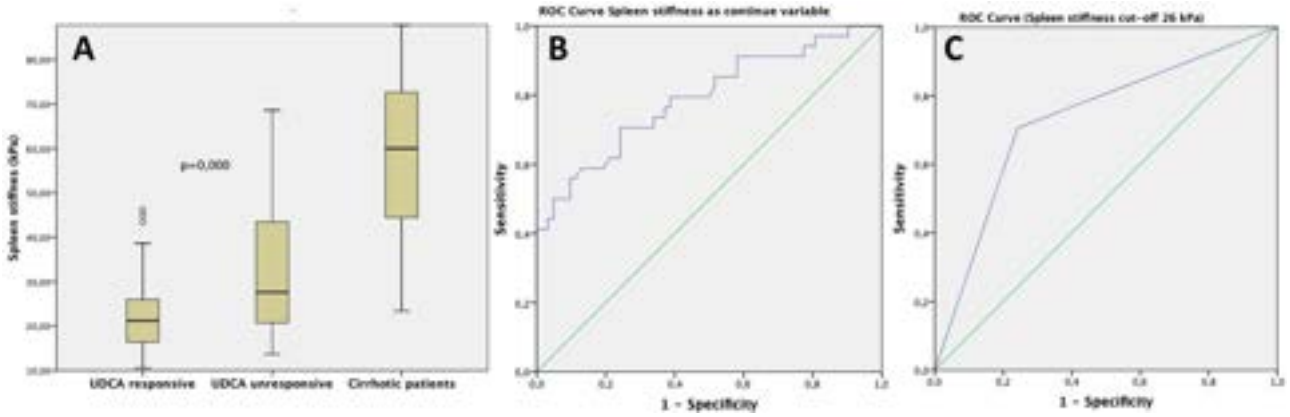

Figure: (abstract: WED-286): SSMs according to the presence of cirrhosis and response to UDCA treatment (panel a) and ROC curve analysis of SSMs in predicting response to UDCA (continuous variable, panel b; dichotomized according to the optimal cut-off, panel c).

unresponsive to UDCA treatment according to the Paris II criteria. Mean SSMs in patients with cirrhosis, unresponsive to UDCA without cirrhosis, and responsive to UDCA without cirrhosis were 60.6 ± 21.8 kPa, 32.8 ± 15.3 kPa, and 22.6 ± 8.5 kPa, respectively. After the exclusion of cirrhotic patients, SSMs were significantly higher in patients who did not respond to UDCA (32.9 ± 15 kPa) than in those who did (22.6 ± 9 kPa; $p < 0.001$). In receiver operating characteristic (ROC) curve analysis, the optimal cut-off value for SSMs in identifying patients who did not respond to UDCA was 26 kPa (sensitivity, 70.6%; specificity, 75.8%; area under the curve, 0.732).
Conclusion: Cross-sectional SSMs by TE are significantly higher in patients with PBC who did not respond to UDCA treatment than in those who did. Longitudinal studies are required to establish the prognostic role of elevated SSMs in PBC.

WED-287
Associations between patient-reported outcomes, liver inflammation and fibrosis in patients with primary sclerosing cholangitis
Emilie Eifer Møller[1], Henning Grønbæk[1], Søren Peter Jørgensen[1], Rasmus Hvidbjerg Gantzel[1], Anders Mellemkjær[1], Lars Bossen[1].
[1]*Aarhus University hospital, Hepatology and Gastroenterology, Aarhus, Denmark*
Email: emimol@rm.dk

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic liver disease characterized by hepatic inflammation and biliary fibrosis leading to cholangitis and cirrhosis. Patients with PSC have impaired quality of life (QoL); however, the relationship between QoL, liver fibrosis stage, and liver inflammation remains unclear. We aimed to investigate the associations between QoL, liver fibrosis, and inflammation.
Method: We prospectively included patients with PSC followed at the Department of Hepatology and Gastroenterology, Aarhus University Hospital, Denmark. The QoL was quantified using the general EQ-5D-5L questionnaire and the newly developed PSC-specific PSC PRO instrument. Liver fibrosis was estimated using FibroScan and liver inflammation by the macrophage-specific biomarker sCD163.
Results: Seventy-one patients were included with a median age of 44 years (IQR: 31–56). Forty-five (63.4%) were male and 60 (84.5%) had concomitant inflammatory bowel disease. The overall QoL expressed with the EQ-5D-5L utility score was similarly high in patients with PSC and the general population ((mean ± SD) 0.86 ± 0.13 vs. 0.90 ± 0.16). The PSC PRO total score was similar across fibrosis stages ($p = 0.164$). However, patients with F4-fibrosis tended to report lower QoL on the EQ-5D-5L visual analog scale (VAS) than patients with F0-F3-fibrosis ($p = 0.08$). Notably, patients with previous hospitalization due to episodes of cholangitis reported significantly higher median PSC PRO total score (20.8 (11.8–64.5) vs. 13.9 (8.9–26.3), $p = 0.047$)) and lower median EQ-5D-5L ((71 (IQR: 56–81.5) vs. 85 (75–91), $p = 0.017$)) than patients with no previous episodes of cholangitis. Finally, we observed a significant correlation between sCD163 and PSC PRO total score ($R = 0.36$, $p = 0.003$), and a weak trend towards a negative correlation between sCD163 and EQ-5D-5L VAS score ($R = -0.20$, $p = 0.099$).
Conclusion: In this cohort, patients with PSC generally reported a high QoL. There was no association between QoL and the stage of liver fibrosis. However, patients with previous episodes of cholangitis reported a lower QoL. Further, liver inflammation determined by sCD163 levels was associated with low QoL. This may suggest that inflammation is more important than fibrosis, when looking at the effect on QoL in PSC patients.

WED-288
Non-invasive evaluation of progression to primary biliary cholangitis in patients with positive antimitochondrial antibodies
Alvaro Diaz Gonzalez[1,2], Marta Alonso-Peña[2], Maria Monte[3,4], Christie Perelló[5], Paula Iruzubieta[1,2], Marina Cobreros[1,2], Juan Irure[6], Marcos López-Hoyos[6], José Luis Calleja Panero[5], Jose Marin[3,4], Javier Crespo[1,2]. [1]*Marqués de Valdecilla University Hospital, Gastroenterology and Hepatology Department, Clinical and Translational Research in Digestive Diseases Group, Santander, Spain;* [2]*Research Institute Marques de Valdecilla (IDIVAL), Clinical and Traslational Research in Digestive Pathology Group, Santander, Spain;* [3]*University of Salamanca, Experimental Hepatology and Drug Targeting (HEVEPHARM), SALAMANCA, Spain, Salamanca, Spain;* [4]*Carlos III National Institute of Health, Center for the Study of Liver and Gastrointestinal Diseases (CIBERehd), Madrid, Spain;* [5]*Department of Gastroenterology and Hepatology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain;* [6]*Marques de Valdecilla University Hospital, Immunology Department, Santander, Spain*
Email: diazg.alvaro@gmail.com

Background and aims: Only a small percentage of people with positive antimitochondrial antibodies (AMA+) develop primary

biliary cholangitis (PBC). However, there is no tool to predict who will do so and what their management should be. Here, we aim to evaluate the usefulness of serum bile acid (BA) profile as a non-invasive follow-up and predictive tool in AMA+ patients.
Method: Bicenter ambispective study in AMA+ individuals identified in the ETHON cohort (Spanish population-based cross-sectional study) between 2015 and 2017 in Cantabria and Madrid (Spain). Twenty BA species and 7alpha-hydroxy-4-cholesten-3-one (C4) were analyzed in serum samples by mass spectrometry (HPLC-MS/MS), both at inclusion and follow-up. Patients with a diagnosis of PBC at inclusion were excluded
Results: Fifty-four AMA+ individuals were identified, of whom 38 (73%) were women with a median age of 49.5 years. None had alterations in liver biology. Baseline liver stiffness was normal (4.5 kPa). Of the initial cohort, 47 (87%) continued follow-up and 6 (12.7%) developed PBC over a median of 5.3 years. The BA profile of non-progressors (NOPROG) vs those who progressed to PBC (PROG) during follow-up was assessed at both baseline and progression. At baseline, PROG individuals had a higher concentration of non-12-alpha-hydroxylated BAs (non-12aOH) (PROG 2.49 vs NOPROG 1.45 uM; p = 0.04) and glycoconjugated BAs (PROG 1.75 vs NOPROG 1.03 uM; p = 0.06 at the limit of significance), as well as lower percentage distribution of cholic acid (CA) family with respect to NOPROG (9.9 vs 17.1% p = 0.02). At follow-up, PROG patients presented higher values in 12aOH (PROG 1.75 vs NOPROG 0.69 uM; p = 0.01), non-12aOH (PROG 2.00 vs NOPROG 0.84 uM; p = 0.04), glycoconjugated (PROG 1.86 vs NOPROG 0.69; p = 0.05) and free (PROG 1.05 vs NOPROG 0.49 uM; p = 0.07 at the limit of significance) BAs concentrations. In paired analysis, PROG patients had increased concentration and percentage of CA family (p = 0.02 and p = 0.04, respectively) and deoxycholic acid family (p = 0.07 at the limit of significance), an increase that was also reflected in the concentration of 12aOH BAs. Moreover, the concentration of non-12aOH BAs in PROG patients remained elevated and stable (p = 0.91). On the other hand, in NOPROG subjects, the profile of all BAs remained stable during follow-up, showing no alterations in serum BA concentrations or in their percentage distribution
Conclusion: AMA+ individuals without progression to PBC show a stable and non-pathological serum BA profile, whereas those who progress show significant changes in the BA profile. Patients who progress show significantly higher non-12aOH BAs values at baseline than those who do not progress, which may be a useful early biomarker for the development of PBC.

WED-289
Does fibrosis regression in autoimmune hepatitis require histological as well as biochemical remission?

Sarah Flatley[1], Asha Dube[1], Barbara Hoeroldt[1], Laura Harrison[1], Elaine Wadland[1], Dermot Gleeson[1]. [1]*Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom*
Email: s.flatley@nhs.net

Background and aims: Prevention of fibrosis progression, an important aim of autoimmune hepatitis (AIH) treatment, is associated with histological remission. Complete biochemical remission (CBR) has been proposed as the best surrogate marker for histological remission (Hartl, J Hepatol 2018), although it may be less reliable in patients with cirrhosis (Laschtowitz, JHep Rep 2021). We aimed to assess the association of biochemical and histological remission with fibrosis regression, in cirrhotic and non-cirrhotic AIH patients.
Method: Retrospective/prospective single centre audit of patients with AIH (1999 IAIHG Criteria) presenting 1998–2020. All patients had a liver biopsy at diagnosis and a follow-up biopsy once in CBR (defined as normal ALT, AST, and IgG), after (median (range)) 27 (12–123) months of immunosuppressive treatment. Biopsies were assessed by one histopathologist (AKD) using a predesigned proforma. Histological remission was defined as Ishak histological activity index (HAI) ≤ 3 and fibrosis regression as Ishak decrease of ≥1.
Results: Of 90 patients who had an evaluable biopsy in CBR (79% women, age 56 (7–75), follow-up 7 (2–23) years), only 36 (40%) were also in histological remission. Fibrosis regressed in 27 (30%), progressed in 33 (37%) and was unchanged in 30 patients (33%). Patients achieving histological remission were more likely to have fibrosis regression (50% vs 18%, p < 0.001) than those with persisting histological activity. Fibrosis stage increased in patients with persisting histological activity (2 (0–6) to 3 (0–6), Z = –2.277, p = 0.023) but did not change in patients achieving histological remission (3 (0–6) to 2 (0–6), Z = –1.170, p = 0.242). On regression analysis, only achieving histological remission was independently associated with fibrosis regression (OR 4.22, 95% CI 1.6–11.4). Cirrhosis (Ishak stage 5–6) was present in 12 patients at diagnosis, developing in a further 6 on follow-up biopsy. Rates of histological remission did not differ between patients with and without cirrhosis at diagnosis (50% vs 42.3%, p = 0.617) or on follow-up biopsy (35.7% vs 44.7%, p = 0.531). Patients with cirrhosis showed a similar association between histological remission and fibrosis regression as the overall group (Table, not significant due to small sample size).
Conclusion: Only 40% of patients with AIH in CBR achieved histological remission, with similar rates in those with and without cirrhosis. Fibrosis regressed in 30% overall and more (50%) if histological remission was achieved. CBR is not an adequate surrogate marker for histological remission in cirrhotic or non-cirrhotic AIH patients. These data support a role for follow-up biopsy to assess response and guide further treatment of AIH.

Table: (abstract: WED-289)

		No cirrhosis (n = 72)			Cirrhosis either biopsy (n = 18)		
		Regressed	Same	Progressed	Regressed	Same	Progressed
Histological remission	Yes	13 (42%)	9 (29%)	9 (29%)	5 (63%)	0 (0%)	3 (37%)
	No	7 (17%)	19 (46%)	15 (37%)	2 (20%)	2 (20%)	6 (60%)

Email: peni.arvaniti@gmail.com

Background and aims: One third of patients with autoimmune hepatitis (AIH) have already advanced fibrosis or cirrhosis at diagnosis. Although treatment administration is strongly recommended in this group, there are no established guidelines about the management of patients with AIH and decompensated cirrhosis at diagnosis. The aim of this study was to assess the efficacy and safety of immunosuppressive treatment in AIH-related decompensated cirrhosis and to establish predictive models of favorable outcome and treatment response.

Method: This is a multicenter retrospective study of 134 patients with AIH and decompensated cirrhosis at diagnosis confirmed by liver biopsy. Competing risk analysis was used to determine cumulative incidence of survival (liver transplantation, LT was considered a competing event). Predictive models of transplant-free survival, and recompensation were calculated with Cox regression analysis. A decision tree analysis was used to determine the patients who will benefit from treatment.

Results: Eighty five patients (63%) were female, with median age of 58 years old (IQR: 48–68) and median follow-up of 28 months (IQR: 5–65). One hundred twenty five (93%) had ascites and 54 (40%) had hepatic encephalopathy (HE) at diagnosis. Thirteen (10%) patients did not receive treatment; all of them died or required LT. Treated patients (n = 121, 90%) had higher levels of ALT (333 vs. 42, p < 0.001), modified hepatic activity index (mHAI) (9 vs. 3, p < 0.001) and of bilirubin (7 vs. 2.7, p = 0.001). Cumulative incidence of mortality was significantly higher in untreated patients (36% vs. 54%, p = 0.002). The most efficient predictive model of transplant-free survival (AUC: 0.75; 95% CI: 0.66–0.83) included the absence of HE and MELD-Na score at diagnosis. Using decision tree analysis, patients with HE ≥ grade 2 and MELD-Na > 23.5 (Figure) had higher probability of dying or requiring a LT after treatment initiation. In the remaining patients, a decrease in MELD-Na ≥ 5.5 points after 4 weeks of treatment had a negative predictive value for death of 100%. Sixty two (51%) patients recompensated. Factors associated with recompensation were the absence of HE (OR: 0.193 p < 0.001, 95%CI: 0.0, 084–0, 441) and serum sodium levels (OR: 1,111, p = 0, 03, 95%CI: 1,013–1,234) at diagnosis. During follow-up, 26 patients stopped treatment, 20 during the first 4 weeks, and 18 due to non-response. HE ≥ grade 2 was associated with treatment withdrawal.

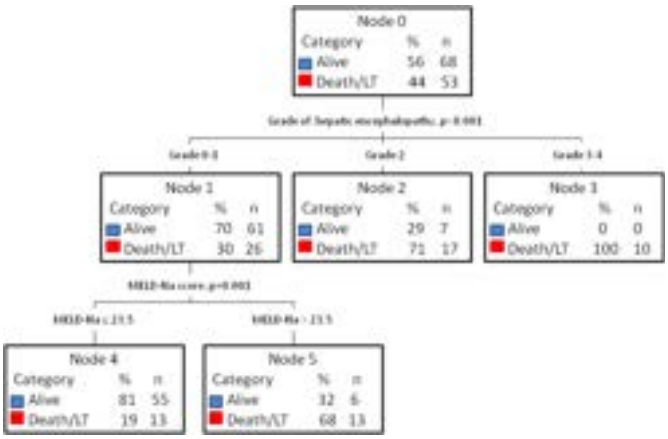

Figure:

Conclusion: Patients with AIH-related decompensated cirrhosis and active disease can benefit from treatment initiation. The grade of HE at diagnosis is strongly associated with outcome, cirrhosis recompensation and treatment withdrawal. The grade of HE, the value of MELD-Na score at diagnosis and the reduction of MELD-Na during the first 4 weeks of treatment can guide treatment decisions and predict transplant-free survival.

Anti-Saccharomyces cerevisiae antibodies predict severe liver disease and advanced fibrosis in patients with primary sclerosing cholangitis and inflammatory bowel disease

Lian Bannon[1], Niv Zmora[1], Roie Tzadok[1], Haim Leibovitzh[1], Ehud Zigmond[1]. [1]*Tel Aviv Sourasky Medical Center-Ichilov, Department of Gastroenterology and Hepatology, Tel-Aviv Sourasky Medical Center, Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Tel Aviv-Yafo, Israel*
Email: liandhn@gmail.com

Background and aims: Primary Sclerosing Cholangitis (PSC) Risk Estimate Tool (PREsTo) is a novel prognostic tool, which is used to predict hepatic decompensation in patients with PSC. Anti-Saccharomyces cerevisiae antibody (ASCA) is one of the main serological markers used in Inflammatory Bowel Diseases (IBD) which is more prevalent in Crohn's disease (CD) and is associated with a more aggressive IBD phenotype. Nevertheless, data on the association between ASCA and adverse liver outcomes in PSC-IBD is limited. We aimed to explore whether ASCA is associated with liver disease severity, predicted by the PREsTo score, and with the degree of liver fibrosis measured by Transient Elastography (TE) in PSC-IBD patients.
Method: We conducted a retrospective study on adult patients with PSC-IBD, at a single tertiary center in Tel Aviv, Israel, between 2010 and 2023. Medical records were reviewed for baseline demographics, clinical data, including IBD subtype, PSC and IBD disease duration, blood tests assessed at the last documented visit and serum ASCA. Severity of liver disease was assessed at the last documented visit using (1) the PREsTo score (risk of decompensation at 5 years [%]), which is composed of serum levels of bilirubin, albumin, alkaline phosphatase, aspartate aminotransferase, sodium, hemoglobin, platelets concentrations, patient's age and PSC duration, and (2) Degree of liver fibrosis measured by TE (FibroScan, measured in Kpa). Univariate (Student's t-test) and multivariable linear regression model adjusted for gender, IBD subtype, IBD duration and PSC duration was used to assess associations between ASCA and outcomes of PREsTo score and degree of liver fibrosis.
Results: The cohort comprised of 102 subjects with PSC-IBD. Fifty-six (54.9%) were males, mean age was 50.2 years (SD 17.05), 57 patients were diagnosed with ulcerative colitis (UC) and 45 with CD. The mean age of IBD and PSC diagnosis was 31.2 years (SD 15.6) and 39.5 years (SD 17.07), respectively. ASCA data was available for 59 (57.8%) subjects. Six of 30 (20%) patients with UC and 14 of 28 patients (50%) with CD had positive ASCA. PREsTo score was available for 51 (50%) subjects and TE measurements were available for 43 (42.1%) patients. In the univariate analysis both the PREsTo score ($p = 0.017$) and TE measurements ($p = 0.018$) were significantly higher in those with positive ASCA (Figure 1). In the multivariable model, ASCA positivity was still significantly associated with higher PREsTo scores (Estimate = 22.27, 95% CI 2.88–41.67, $p = 0.026$) and a higher TE measurements (Estimate 2.80, 95 CI 0.19–5.41, $p = 0.036$), even after adjustment for IBD subtype, IBD and PSC duration.

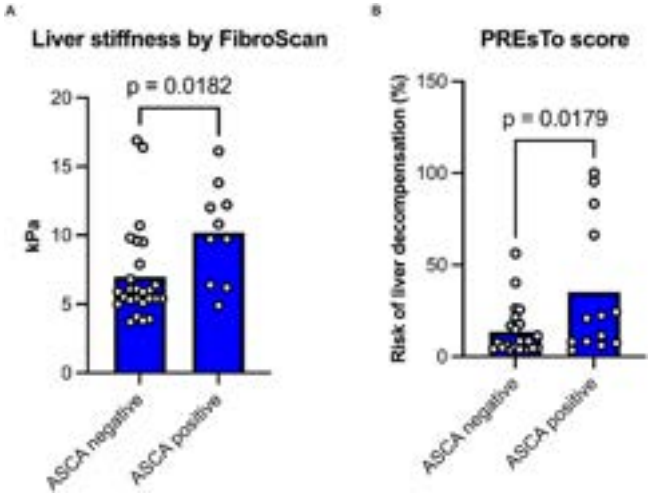

Figure:

Conclusion: In subjects with IBD with concomitant PSC, the presence of serum ASCA may be used to predict 5-years liver decompensation and degree of liver fibrosis. Further studies are warranted to explore the biological mechanism underlying this association

WED-292

Increased risk of osteoporotic fracture in patients with autoimmune hepatitis

Jihye Lim[1], Ye-Jee Kim[2], Seon-Ok Kim[2], Jonggi Choi[3]. [1]*Yeouido St. Mary's Hospital, Internal Medicine, Seoul, Rep. of South Korea;* [2]*Asan Medical Center, Rep. of South Korea;* [3]*Asan Medical Center, Gastroenterology, Liver Center, Rep. of South Korea*
Email: jkchoi0803@gmail.com

Background and aims: Chronic liver disease is a recognized risk factor for osteoporosis and fragility fractures. Especially, patients with autoimmune hepatitis (AIH) are thought to be more vulnerable to loss of bone mass in several aspects. From an epidemiologic perspective, AIH is a female-dominant disease, particularly in postmenopausal women who have an increased risk of developing osteoporosis. In addition, glucocorticoids, the most common cause of secondary osteoporosis, are frequently used. Few large-scale studies are published regarding the association between AIH and risk of osteoporotic fracture. This study aimed to determine the risk of developing an osteoporotic fracture in patients with AIH.
Method: We used claims data from the Korean National Health Insurance Service (NHIS) between 2007 and 2020. Patients with AIH ($n = 7062$) were matched with controls ($n = 28,122$) using a ratio of 1 : 4, based on age, sex, and duration of follow-up. Osteoporotic fractures, included fractures of the vertebral, hip, distal radius, and proximal humerus. Prescription of glucocorticoid or other immunosuppressive agent for 30 consecutive days after the diagnosis of AIH was used to assess medication utilization. The incidence rate (IR) and incidence rate ratio (IRR) of osteoporotic fracture were compared between the two groups and their associated factors were also evaluated. We performed subgroup analysis for the patients with AIH whose follow-up was at least ≥2 years to determine the association between the cumulative use of glucocorticoid or immunosuppressive agents during the initial 2 years and the risk of osteoporotic fractures.
Results: During a median follow-up period of 5.4 years, 712 osteoporotic fractures occurred in patients with AIH with an IR of 17.5 per 1,000 person-years (PYs) while 1,922 osteoporotic fractures with an IR of 11.6 per 1,000 PYs in the controls. Patients with AIH showed a significantly higher risk of osteoporotic fractures than matched controls, with an IRR of 1.24 (95% confidence interval, 1.10–1.39, $p < 0.01$) in the multivariable analysis. Vertebral fractures were significantly higher among the patients with AIH when compared to the controls in unadjusted (IRR: 1.66) and adjusted analyses (IRR:

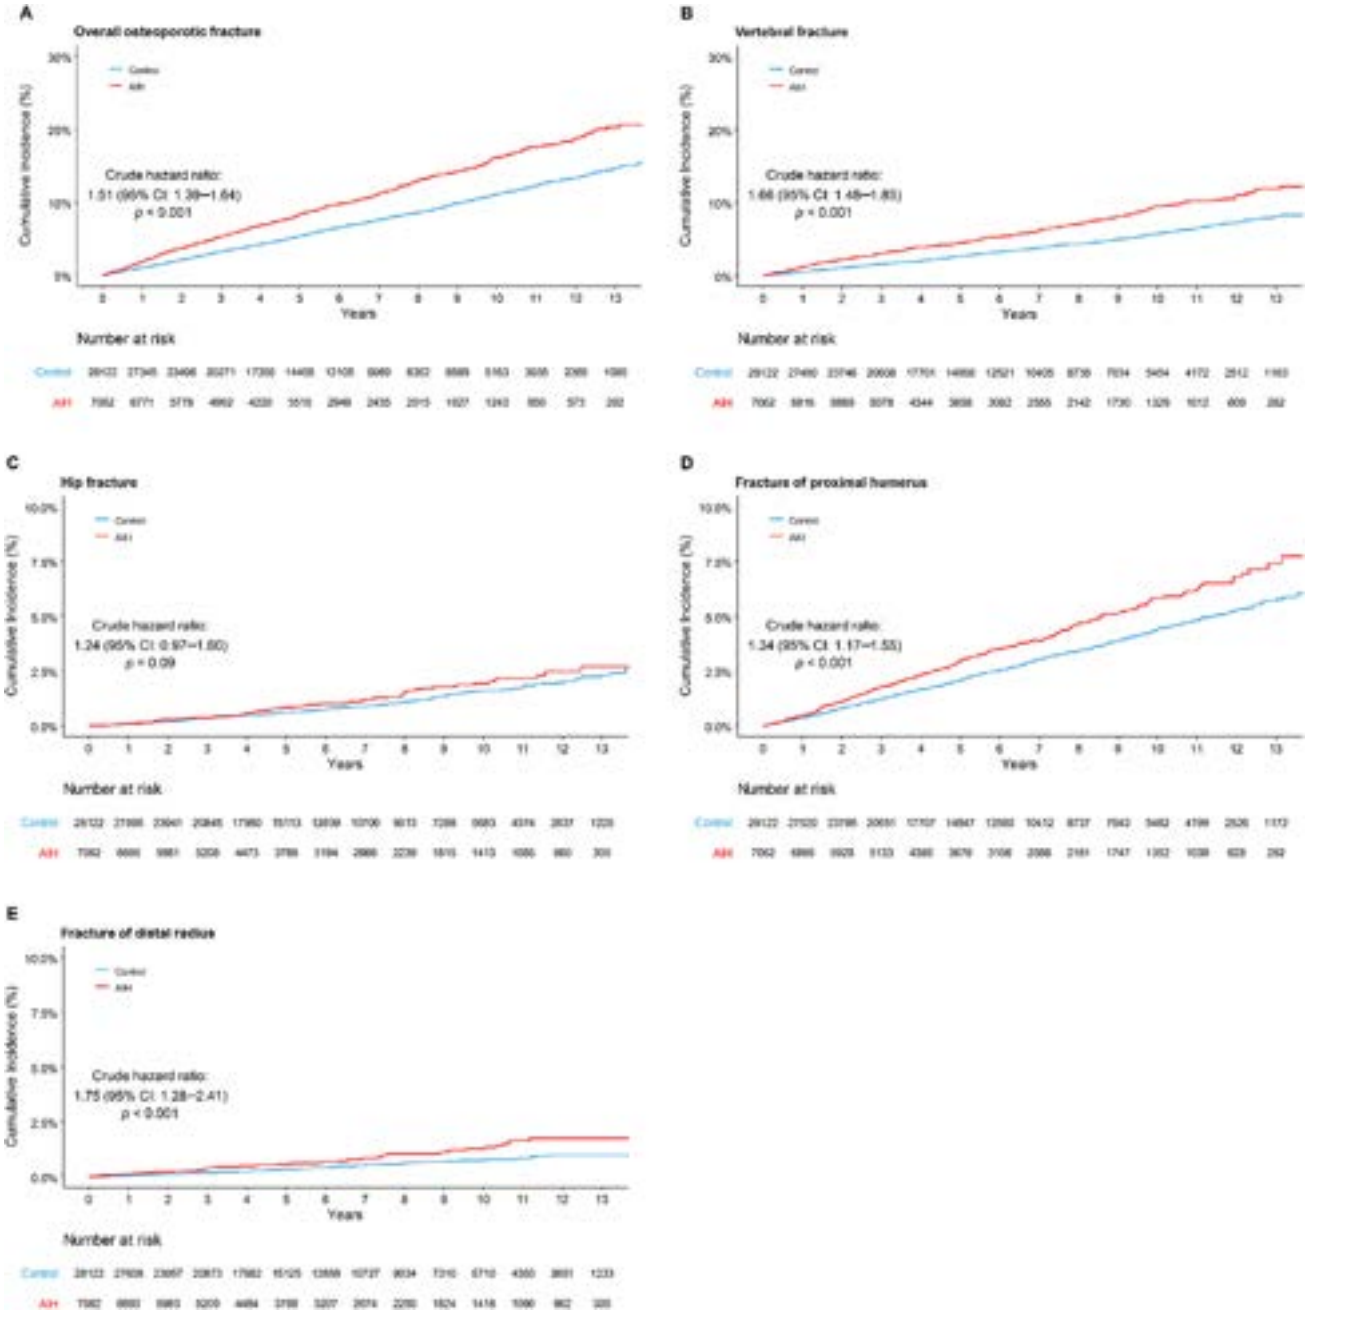

Figure: (abstract: WED-292): Cumulative risks of osteoporotic fractures in patients with autoimmune hepatitis and the control group. Overall osteoporotic fracture, (B) Vertebral fracture, (C) Hip fracture, (D) Fracture of proximal humerus, and (E) Fracture of distal radius.

1.31). Patients with AIH appeared to have a higher risk of hip (IRR: 1.24), proximal humerus (IRR: 1.34), and distal radius (IRR: 1.75) fracture than the controls in the unadjusted analysis, whereas this risk did not significantly differ after adjustment. Female sex, older age, history of stroke, presence of cirrhosis, and use of glucocorticoids were associated with an increased risk of osteoporotic fractures. In the two-year landmark analysis, long-term use of glucocorticoid had an increased risk of osteoporotic fracture in a dose-dependent manner (4% as per 10% increase in the duration of glucocorticoid use). **Conclusion:** In conclusion, the risk of osteoporotic fracture was significantly increased in the AIH patients. Female sex, old age, presence of cirrhosis, longer use of glucocorticoids increased the risk of fracture. Considering the morbidities from osteoporotic fracture, recognition of these risk factors and early diagnosis and intervention may be crucial in the care of patients with AIH.

WED-293

Prognostic value of serum ALP levels during additional treatment in Japanese patients with primary biliary cholangitis treated with ursodeoxycholic acid and bezafibrate

Background and aims: Treatment response in primary biliary cholangitis (PBC) is important in predicting long-term prognosis. The standard of care for PBC is ursodeoxycholic acid (UDCA), and various indices have been reported to evaluate the response to UDCA monotherapy. On the other hand, obeticholic acid (OCA) or bezafibrate (BZF) are used in the real world for patients who exhibited incomplete response to UDCA, but no clinical indices have been demonstrated for predicting the long-term outcome in patients with combination treatment. In this study, we investigated the association of ALP levels during additional BZF treatment with long-term outcomes in Japanese patients with PBC treated with UDCA and BZF.

Method: We took advantage of a retrospective cohort, consisting of 799 PBC patients (male/female = 120/679, age at initiation of treatment 58.9 ± 11.1 years) attending 19 centers in Japan. Date of birth and gender, date, presence of symptoms and biochemical test findings (ALP, total bilirubin, albumin) at baseline, treatment protocol (UDCA and/or BZF), serum ALP at 6 and 12 months of UDCA or additional BZF treatment, and the final follow-up date and outcomes (liver transplantation (LT) and all-cause death) were recorded in all patients. Using this cohort, the association of ALP levels at 6 and 12 months of treatment with outcomes was examined by Kaplan-Meier method and Cox proportional hazards model, along with other covariates.

Results: Among 799 patients, 619 and 180 patients were treated with UDCA monotherapy and UDCA/BZF combination therapy, respectively. All patients with combination therapy received UDCA first, followed by BZF. In the analysis of all 799 patients (observation period 7.4 ± 5.1 years, death/LT = 24/3), ALP levels at 12 months of treatment (UDCA or additional BZF; 1.5×, 1.67×, and 2 × ULN) and at 6 months (2 × ULN) were significantly associated with outcome, along with gender, presence of symptoms and albumin at baseline. In the analysis of 180 patients with a combination treatment of UDCA and BZF (observation period 6.8 ± 4.6 years, death/LT = 7/0), ALP levels at 12 months (2 × ULN) and at 6 months (1.5×, 1.67×, and 2 × ULN) of additional BZF treatment along with age and albumin at baseline were significantly associated with outcome. C-statistics were 0.968 (2 × ULN at 12 months), 0.968 (1.5 × ULN at 6 months), 0.968 (1.67 × ULN at 6 months) and 0.975 (2 × ULN at 6 months). In the figure, we demonstrate LT-free survival adjusted by clinical covariates according to serum ALP level 2 × ULN at 6 and 12 months of additional BZF in patients treated with combination treatment.

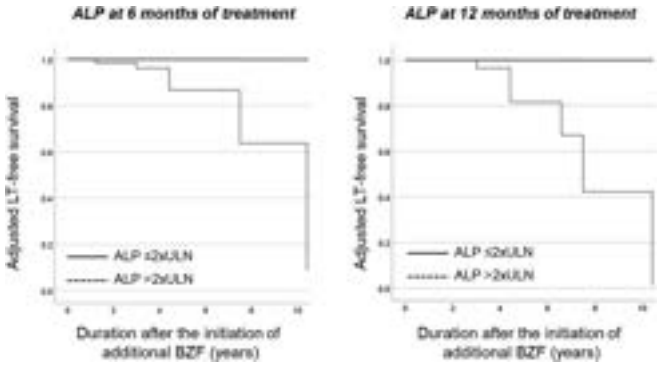

Figure:

Conclusion: In patients treated with a combination of UDCA and BZF, serum ALP values at 6 or 12 months of additional BZF treatment are significantly associated with long-term outcome, and are of value as prognostic tools.

WED-294

A novel web-based online nomogram to predict advanced liver fibrosis in patients with autoimmune hepatitis-primary biliary cholangitis overlap syndrome

Zhiyi Zhang[1], Jian Wang[2,3], Yun Chen[4], Yiguang Li[5], Li Zhu[6], Huali Wang[7], Yilin Liu[1], Chuanwu Zhu[6], Jie Li[1,2,3,4], Rui Huang[1,2,3,4], Chao Wu[1,2,3,4], Yuanwang Qiu[5]. Email: qywang839@126.com

Background and aims: Patients with autoimmune hepatitis-primary biliary cholangitis (AIH-PBC) overlap syndrome have a worse prognosis compared to AIH or PBC alone and accurately predicting the severity and dynamically monitoring the progression of disease are therefore essential. We aimed to develop a nomogram-based model to predict advanced liver fibrosis in patients with AIH-PBC overlap syndrome.

Method: A total of 121 patients with AIH-PBC overlap syndrome were retrospectively included and randomly assigned to a development set and a validation set. Backward stepwise multivariate regression's best model with the lowest AIC was employed to create a nomogram. Diagnose accuracy was evaluated using the area under the receiver operator characteristic curve (AUROC), calibration analysis, and decision curve analysis (DCA) and was compared with aspartate aminotransferase-to-platelet ratio (APRI) and fibrosis index based on four factors-4 (FIB-4) score.

Results: The median age of patients was 53.0 years (IQR: 46.0–63.0), and female patients accounted for 95.0%. Platelets, globulin, total bilirubin, and prothrombin time were associated with advanced fibrosis (≥S3) and used to construct an AIH-PBC overlap syndrome fibrosis (APOSF)-nomogram (available online at https://ndth-zzy.shinyapps.io/APOSF-nomogram/). The AUROCs of APOSF-nomogram were 0.845 (95% CI: 0.754–0.936) and 0.843 (95% CI: 0.705–0.982) in the development set and validation set respectively, which was significantly better than APRI and FIB-4. Calibration revealed that the estimated risk fits well with biopsy-proven observation. DCA

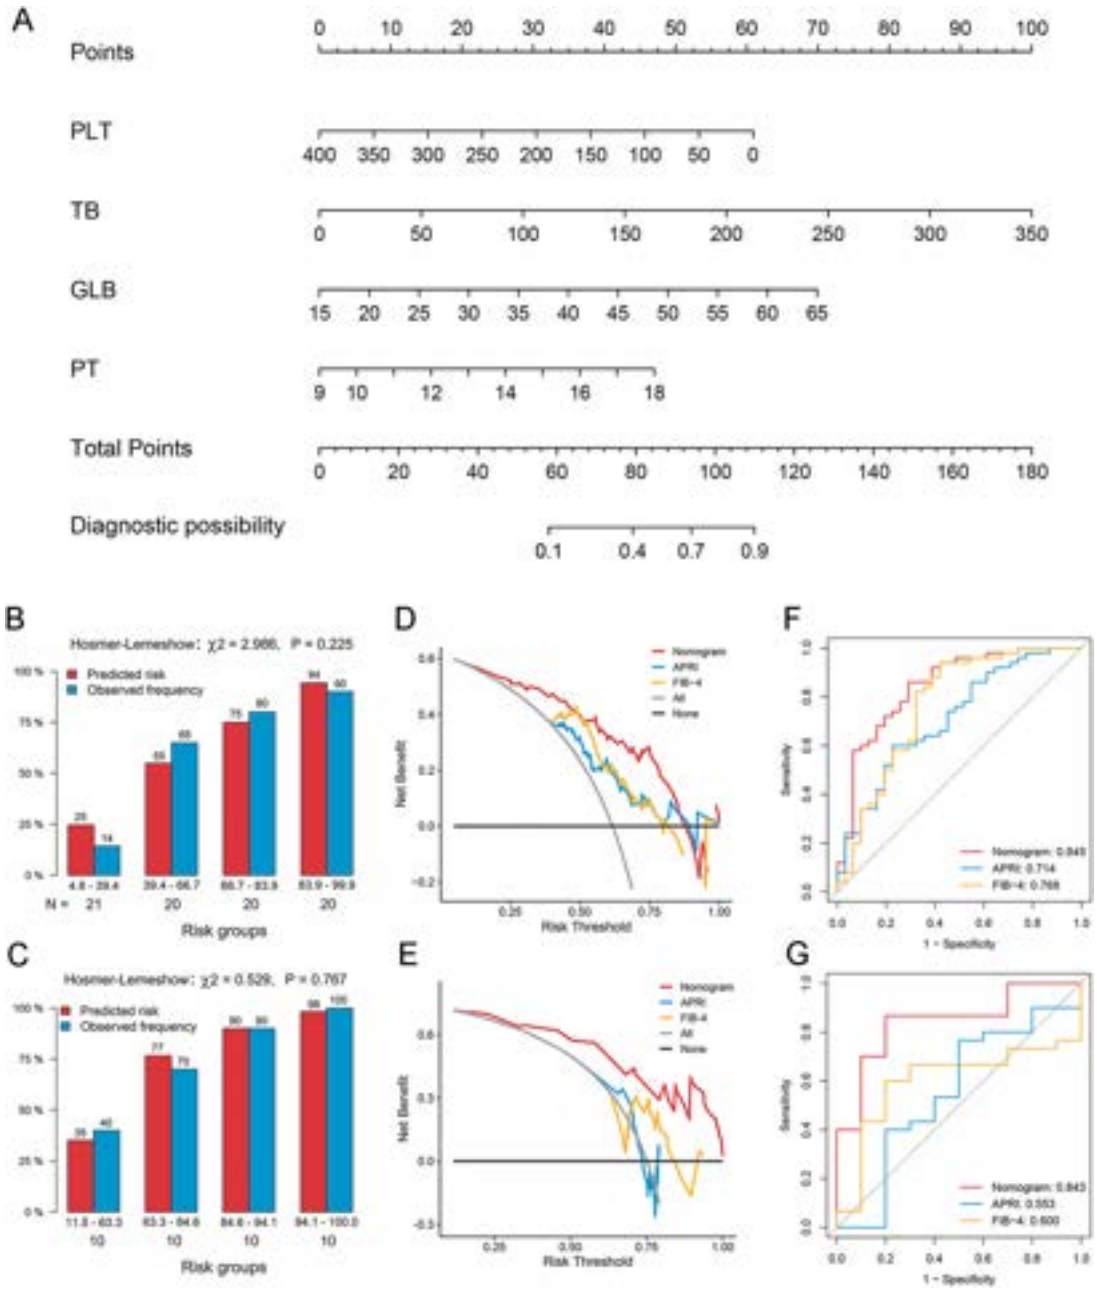

Figure: (abstract: WED-294): Nomogram-based model to predict advanced liver fibrosis in patients with AIH-PBC overlap syndrome

outperformed APRI and FIB4 in terms of net benefit, demonstrating clinical utility.

Conclusion: This novel non-invasive web-based online APOSF-nomogram provided a convenient tool for identifying advanced fibrosis in patients with AIH-PBC overlap syndrome.

WED-295

Presence of metabolic associated liver disease in autoimmune hepatitis is associated with advanced liver fibrosis

Alvaro Urzúa[1], Daniela Simian[1], Giselle Arevalo[1], Consuelo Palomo[1], Jaime Poniachik[1]. [1]*University of Chile Clinical Hospital, Gastroenterology Section, Santiago, Chile*
Email: dralvarourzua@gmail.com

Background and aims: Metabolic associated liver disease (MAFLD) is one of the most frequent causes of chronic liver disease worldwide. Steatohepatitis is a major risk factor for the development of fibrosis and its progression. MAFLD is very common and is present in other causes of chronic liver damage, such as autoimmune hepatitis (AIH). There is scarce information of the role of MAFLD in fibrosis in patients with AIH. We describe the frequency of steatosis, steatohepatitis, and fibrosis in AIH liver biopsies and the impact of steatosis and steatohepatitis on fibrosis severity.

Method: Observational and retrospective study of liver biopsies performed, prior to initiation of immunosuppressive therapy, between 2015 and 2018. Presence of steatosis, steatohepatitis and fibrosis was recorded. Alcohol and other etiologies of liver disease were excluded. Clinical data was obtained from electronic charts. Descriptive analysis was performed using media and median, comparative analysis was performed with chi 2 and exact Fisher test, $p < 0.05$ was considered statistically significant.

Results: 131 biopsies were analyzed for the presence of steatosis, steatohepatitis, and fibrosis with its staging, 76% were female, mean age 56 (15–83) years. Steatosis was present in 27%, steatohepatitis in

14% and advanced fibrosis (>F3) in 60%. Presence of steatosis and steatohepatitis were risk factors for advanced fibrosis (OR 2.97, CI 95% 1.22–7.21 p = 0.016). We performed a sub analysis to compare patients with and without steatosis, steatohepatitis, and advanced fibrosis, including 66 patients with complete clinical data (diabetes mellitus, hypertension, body mass index, bilirubin, platelet count, INR and mortality). Steatosis and steatohepatitis were more frequent in obese patients (p 0.0003 and 0.019). Mortality was higher in patients with steatosis (47% vs 14% p 0.011). All patients with steatohepatitis had advanced fibrosis (>F3).

Figure:

N = 66	With steatosis n = 15	Without steatosis n = 51	P value
Female vender	12 (80)	41 (80)	0.973
Age (median; min-max)	53 (29–72)	58 (20–83)	0.357
IMC (mediana; min-max)	31.2 (23.5–43.15)	25.4 (19–44.4)	0.0001
Co-Morbidities			
Diabetes	4 (27)	9 (18)	0.440
Hipertensión	6 (40)	11 (22)	0.151
Lab Tests (median; min-max)			
Bilirubin	1.3 (0.2–3.1)	1.4 (0.3–33)	0.481
INR	1.2 (1–2.08)	1.2 (0.9–2.28)	0.759
Platelets	133000 (60000–260000)	175000 (58000–491000)	0.085
Mortality	7 (47)	7 (14)	0.011

Conclusion: In this cohort of AIH liver biopsies, steatosis and steatohepatitis were risk factors for advanced fibrosis. All patients with steatohepatitis had advanced liver fibrosis and mortality was higher in patients with steatosis. In patients with AIH, MAFLD should be treated to avoid progression to fibrosis.

WED-296
Improving the diagnosis of primary biliary cholangitis through inmunology protocols

Mario de Bonis Encinoso[1], Javier Rodriguez Jiménez[1], Carmen Iglesias Sobrino[1], Hildo Rodriguez Santos[1], Cristina Suárez Montesdeoca[1], Paula Moreno Martin[1], Elisaul Suarez Zambrano[1], Esther Rodríguez Candelaria[1], Itahisa Marcelino-Rodriguez[2], Delia Almeida González[3], Francisco Andrés Pérez Hernández[1], Ana Arencibia Almeida[1].
[1]University Hospital of Nuestra Señora de la Candelaria, Gastroenterology and Hepatology Service, Santa Cruz de Tenerife, Spain; [2]University of La Laguna, Preventive Medicine and Public Health Area, San Cristóbal de La Laguna, Spain; [3]University Hospital of Nuestra Señora de la Candelaria, Inmunology Laboratory, Santa Cruz de Tenerife, Spain
Email: mario.dbencinoso@gmail.com

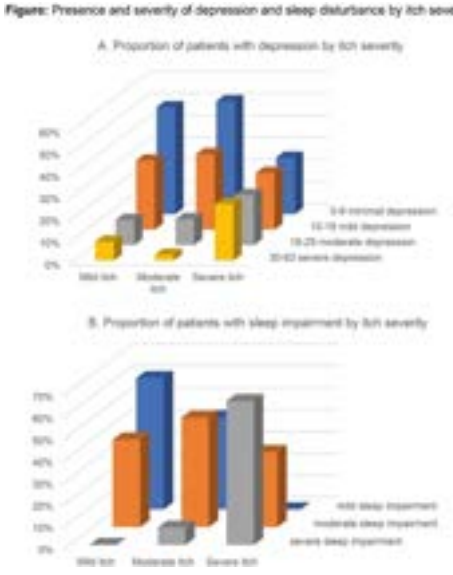
Background and aims: The diagnosis of primary biliary cholangitis (PBC) relies largely on the detection of antinuclear antibodies (ANA) and antimitochondrial antibodies (AMA) by indirect immunofluorescence (IIF). The primary aim of this study was to analyse the role of autoimmunity in the diagnosis of PBC. The secondary aim was to analyse differences in diagnosis rates between AMA-positive and AMA-negative patients, and to propose an immunological diagnostic algorithm designed to recruit the largest number of patients who meet PBC laboratory criteria.
Method: A descriptive observational study was conducted between 2015 and 2020. Patients with alkaline phosphatase (ALP) levels exceeding the upper limit of normal (ULN) and any PBC-specific antibody were followed up.
Results: 635 positive antibody determinations were recorded in 274 patients. From these, 89% were AMA-positive and 96% ANA-positive. Furthermore, 234 (85%) patients were AMA-ANA positive, whilst 30 (12%) were AMA-negative, but ANA-positive. The staining pattern obtained (by IIF on HEp-2 cells) was reticular mottled cytoplasmic pattern (AC21) in 219 patients, multiple nuclear dots (AC6) in 40 patients and punctate nuclear envelope (AC12) in 21 patients. Immunoblot was performed on 182 patients resulting in 179 subjects testing positive: 145 for AMA-M2, 117 for BPO, 55 for Gp210, 47 for Sp100, and 17 for PML; additionally, of these 145 AMA-M2 patients, 18 were AMA-negative, and all ANA-positive. 55.8% of the sample had a clinical diagnosis of PBC: 96% AMA-positive (147) and 4% AMA-negative (6); p < 0.001. 99.3% ANA-positive (152) and 1% ANA-negative (1); p < 0.001. 121 patients had no diagnosis; 80% AMA-positive (97) and 20% AMA-negative (24); p < 0.001; 92% ANA-positive (112) and 7% (9) ANA-negative. The sensitivity of AMA was 96% and that of ANA was 99%. 147 AMA-positive patients (60.2%) were diagnosed with PBC whilst 97 (39.8%) were undiagnosed; (p < 0.001). The Gastroenterology Department diagnoses a higher number of patients with PBC in relation to AMA request (p < 0.001) followed by Primary Care and Rheumatology. Statistically significant differences were observed between undiagnosed and diagnosed patients for AMA (p < 0.001), ANA (p = 0.007), immunoblot (p = 0.004), Gp210 (p = 0.001), AMA-M2 (p = 0.027), Sp100 (p = 0.005) and chronicity of ALP, altered GGT and AST (p < 0.001).
Conclusion: Although AMA are present in 90–95% of patients with PBC, IIF based on HEp-2 is more sensitive to detect autoantibodies associated with the disease than IIF in rodent tissue (99.3% vs. 96%). In cases where PBC is suspected, the most efficient action to take is to combine IIF on HEp-2 with specific autoantibody detection using immunoblotting. The immunology laboratory can approach the diagnosis of PBC through the standardization of algorithms, especially in patients whose autoimmunity was requested by other medical departments besides Gastroenterology.

WED-297
The devastating impact of severe pruritus in primary biliary cholangitis

Helen Smith[1], Megan McLaughlin[2], Sugato Das[3], Andrea Ribeiro[4], Philip Troke[1], Andreas E. Kremer[5], David Jones[6]. *[1]GSK, United Kingdom; [2]GSK, United States; [3]GSK, India; [4]GSK, Spain; [5]University of Zürich, Switzerland; [6]Newcastle University, United Kingdom*
Email: helen.t.smith@gsk.com

Background and aims: Pruritus associated with primary biliary cholangitis (PBC) affects sleep and, social and emotional wellbeing. The impact of itch severity on quality of life (QoL) using the EuroQol-5-Dimension 5-Level (EQ-5D-5L) health utility score was explored and quantified in a post hoc analysis of the Phase 2b GLIMMER study of linerixibat for the treatment of pruritus in PBC (NCT02966834). Pruritus (particularly severe pruritus) was previously found to have a significant negative impact on QoL and health utility: mean (standard deviation [SD]) baseline (BL) utility was 0.69 (0.23); patients with mild or moderate pruritus at BL had similar utilities (0.75 [0.17] and 0.76 [0.17], respectively) whereas patients with severe pruritus at BL had notably worse utility (0.49 [0.28]). Here we look in detail at factors impacting QoL in patients with PBC and pruritus.
Method: Patients in GLIMMER completed the EQ-5D-5L and Beck Depression Inventory (BDI-II) at BL, which followed a 4-week single-blind placebo run-in period. EQ-5D-5L is a generic, standardised and simple health-related QoL instrument. Scores range from 1 “perfect health” to 0 “death.” BDI is a 21-item, self-rated scale that evaluates key symptoms of depression. Patients were classified as having mild (<4, BL all mild were ≥ 3 to <4), moderate (≥4 to <7) or severe pruritus (≥ 7to 10) using the mean worst daily itch score. Sleep disturbance severity was based on the same numerical rating scale thresholds as those used for pruritus.
Results: There were striking associations between itch severity, sleep disturbance and health utility, and between itch severity, depression and health utility. Overall mean (SD) health utility was highest in

those with mild sleep impairment 0.83 (0.126). Those with severe sleep impairment had a much lower score and those with severe itch and severe sleep disturbance even lower (0.52 [0.30] and 0.47 [0.31], respectively). Interestingly, no patients with mild itch had severe sleep impairment and no patients with severe itch had mild sleep impairment. As might be expected, health utility was lower with worse depression; from 0.81 (0.18) with minimal depression to 0.39 (0.31) for those with severe depression; amongst those with moderate or severe depression the incremental impact of severe pruritus on health utility was striking, with utilities of 0.32 and 0.26, respectively. In mild and moderate itch, the distribution of depression severity was similar, with over 80% having minimal or mild depression. However, in the group with severe itch, 49% had moderate or severe depression.



Conclusion: Pruritus in PBC significantly impacts QoL. Severe sleep disturbance and moderate and severe depression were far more common in patients with severe pruritus. In patients suffering with both severe pruritus and moderate to severe depression, health utility was severely impaired.

WED-298

Variation in maintenance therapy practices in a large U.S. cohort of patients with autoimmune hepatitis

Therese Bittermann[1], Ranganath Kathawate[2], James Lewis[1], Cynthia Levy[3], David Goldberg[3]. [1]*University of Pennsylvania, United States;* [2]*Wayne State University, United States;* [3]*University of Miami, United States*
Email: therese.bittermann@pennmedicine.upenn.edu

Background and aims: The overarching goals of treating autoimmune hepatitis (AIH) are to induce remission and prevent disease progression while minimizing corticosteroids (CS) due to side effects. Data on maintenance therapy for AIH are largely derived from clinical trials or studies from tertiary care centers. "Real-world" data in a representative population are limited. We sought to determine patient factors associated with the use of CS-sparing and CS monotherapy regimens among patients receiving maintenance therapy for AIH.
Method: Retrospective cohort study of adults (≥18 years) with incident or prevalent AIH identified using a validated algorithm in the Optum® Clinformatics© Deidentified Data Mart, a U.S. health insurance database. All patients were followed 2 years: the first year served as a washout period to exclude instances of the induction phase of treatment and the second year served as the observation period during which the dominant maintenance AIH regimen was assessed. Dominant regimen was defined as that received >6 months during observation year. All patients in the cohort were required to have filled ≥1 prescription of any drug (AIH-related or not) during the observation period. Separate multivariable logistic regression models investigated patient factors independently associated with a dominant maintenance regimen of (i) azathioprine (AZA) or mycophenolate mofetil (MMF) monotherapy (vs AZA/MMF with prednisone [Pred]) and (ii) Pred monotherapy (vs AZA/MMF ± Pred).
Results: Among 3,591 AIH patients, 2,330 (64.9%) had ≥1 prescription for an AIH drug during the observation year. Patients who did not receive AIH treatment were largely similar to those receiving treatment. Dominant regimens during the observation period included: 41.5% AZA monotherapy, 13.4% AZA with Pred, 10.9% Pred monotherapy, 3.7% MMF monotherapy, 1.8% MMF with Pred, 1.6% Bud monotherapy, 0.3% tacrolimus (Tac) mono, 0.2% Tac with Pred, and 8.5% other regimens. Factors independently associated with decreased AZA/MMF monotherapy (vs AZA/MMF with Pred) as a dominant regimen included: male sex (OR 0.7; p = 0.007), age 18–39 years (OR 0.6 vs age 40–59 years; p = 0.025), Hispanic ethnicity (OR 0.6 vs White; p = 0.021), osteoporosis (OR 0.5; p < 0.001), and other autoimmune disease (OR 0.7; p < 0.001). Factors associated with increased use of Pred monotherapy as a dominant regimen included: age ≥ 70 (OR 2.7 vs age 40–59 years; p < 0.001) and history of other autoimmune disease (OR 2.0; p < 0.001).
Conclusion: Less than half of patients receiving AIH therapy in a large, diverse insurance-based cohort were treated with AZA or MMF monotherapy as their dominant regimen. Older patients ≥70 years were more likely to receive Pred monotherapy, which may be suboptimal in this group.

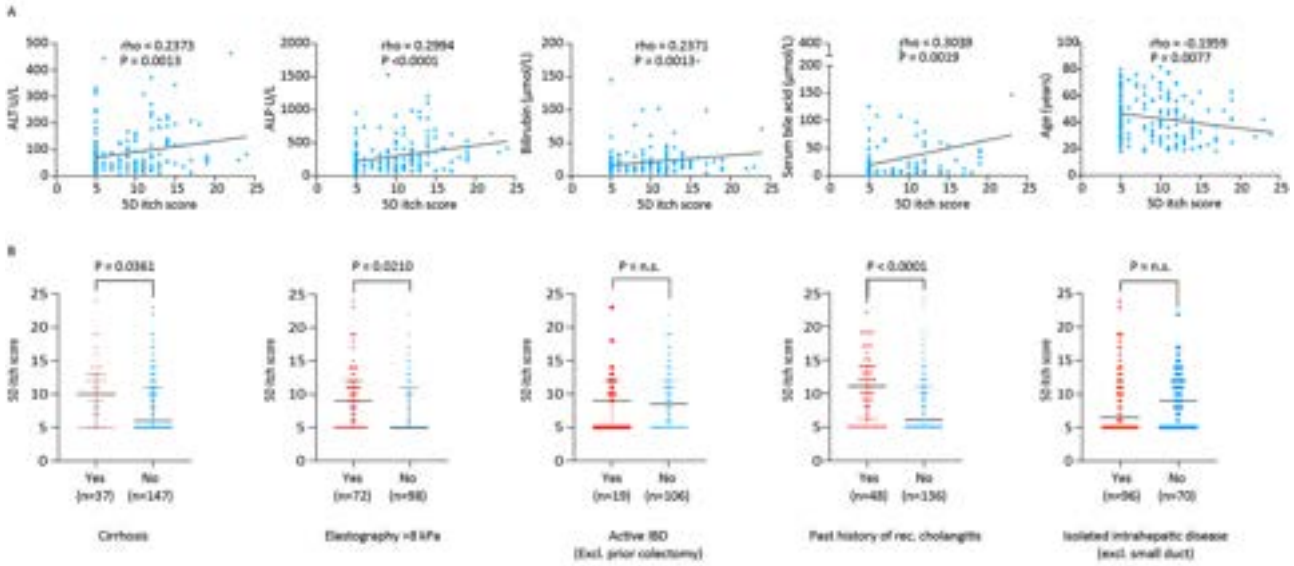
WED-299

Burden, impact and variability of pruritus in primary sclerosing cholangitis (PSC) over time: a prospective observational study

Nasir Hussain[1,2], Benjamin Hirschfield[2], James Ferguson[1,2], Nadir Abbas[1,2], Usha Gungabissoon[3], Khushpreet Bhandal[2], Emma Burke[2], Diana Hull[2], Penelope Rogers[2], Sumanta Mukherjee[3], Andrea Ribeiro[3], Martine Walmsley[4], Paula Hanford[4], Megan McLaughlin[4], Linda Casillas[3], Palak Trivedi[1,2]. [1]*University of Birmingham, National Institute for Health Research (NIHR) Birmingham Biomedical Research Centre (BRC), Birmingham, United Kingdom;* [2]*University Hospitals Birmingham, Liver Unit, Birmingham, United Kingdom;* [3]*GlaxoSmithKline, United States;* [4]*PSC Support, United Kingdom*
Email: nxh100@student.bham.ac.uk

Background and aims: Pruritus is a recognised symptom of PSC, although the prevalence, persistence and impact on quality of life (QoL) are unknown. The aims of this study are to (A) quantify the proportion of patients (pts) with PSC who experience pruritus, (B) identify factors associated with symptom intensity, and (C) determine the association between pruritus and overall health related QoL.
Method: Pts with a diagnosis of PSC (age >16 years; non-transplant) were invited to complete specific QoL tools: 5D itch, itch numerical rating scale (NRS), chronic liver disease questionnaire (CLDQ) and the EQ-5D-5L. Measures were obtained at 0, 3, 6, 9 and 12 months, alongside clinical and laboratory data. This multicentre, prospective observational study began recruitment in Aug '21. Follow-up is ongoing, and interim results are presented herein.
Results: Between Aug '21 and Nov '22, we accrued data from 184 pts. The majority had large duct disease (n = 166), were men (n = 105), with a median age of 41yrs (IQR 29–57), a history of inflammatory bowel disease (IBD, n = 156; 134 with quiescent activity) and a median MELD score of 7 (IQR 6–8). (A) Observing the cohort in its entirety, median baseline 5D itch score was 8 (IQR 5–12), with 92 pts. reporting any degree of itch according to the NRS. The latter included 23 pts. who reported itch despite taking anti-pruritic therapy. (B) 5D itch scores negatively correlated with age, positively correlated with

Figure 1: Baseline factors associated with pruritus intensity



ALP, alkaline phosphatase; ALT, alanine transaminase; IBD, inflammatory bowel disease.

Figure: (abstract: WED-299)

serum bilirubin, ALT, ALP and bile acid values, and was greater in pts with previous episodes of acute cholangitis, those with advanced fibrosis, and people with cirrhosis (Fig). No significant differences in 5D itch score were seen according to the presence/activity of IBD or extent of ductal disease (Fig). (C) The median baseline NRS score was 1 (IQR 0–3), with 37 pts (20%) scoring >4. According to the NRS, symptom severity associated with significantly poorer health utility: mean (SD) CLDQ scores in patients with no, mild, moderate, and severe itch were 5.6 (1.0), 5.1 (1.2), 4.4 (1.2) and 3.6 (1.3), respectively. Mean EQ-5D scores for no, mild, moderate, and severe itch were 77.0 (17.1), 72.9 (19.0), 64.1 (22.1) and 47.3 (16.4), respectively. At time of writing, 72/184 pts undertook repeat assessment over 12 months. In 42/72 pts (58%) with baseline pruritus, 28 reported unchanged or worsening itch over time (including 9/28 pts who were taking symptom-specific therapy).

Conclusion: Pruritus is commonly reported yet under-treated in PSC, has a propensity to persist over time, and with negative connotations on QoL. Those with a history of recurrent cholangitis, advanced fibrosis and cirrhosis have the greatest need for anti-pruritic therapy and must be prioritised for symptom-directed interventional trials.

WED-300

Variation in the presentation pattern of primary biliary cholangitis (PBC) in Spain according to the diagnostic period: data from the Spanish registry of cholestatic and autoimmune liver diseases (COLHAI)

Email: mlondono@clinic.cat

Background and aims: The incidence and prevalence of PBC has increased within the last years. This is most likely a result of earlier diagnosis and greater disease awareness. It is currently uncertain if this results in modifications to the pattern of presentation and treatment response. Therefore, the aim of the study was to assess the impact of the diagnostic period (P) in the characteristics of PBC at diagnosis and treatment response.

Method: Retrospective analysis of 795 patients with PBC included in COLHA registry. The inclusion criteria were: (1) diagnosis of PBC made after 1997 (when ursodeoxycholic acid, UDCA, was approved), (2) UDCA treatment for at least 1 year. Patients with variants forms (overlap syndromes) of PBC and other concomitant liver diseases were excluded. The cohort was divided in 3 periods according to the date of PBC diagnosis: P1 before April 2008, P2 between May 2008 and November 2013, and P3 after December 2013.

Results: Most of the patients were female (n = 713, 91%), with a median age of 55 years, 223 (28%) with autoimmune comorbidities. At diagnosis, patients from P3 had lower levels of alkaline phosphatase (ALP), transaminases, bilirubin, and total cholesterol than patients from P1 and P2 (Table). The proportion of patients with liver biopsy and ALT $\geq 2 \times$ ULN was lower in patients from P3 (44% vs. 31% vs. 24%, $p < 0.001$ y 49% vs. 43% vs 36%, $p = 0.012$, respectively). The mean time from diagnosis to UDCA initiation was lower in patients from P3 (9.8 vs. 4.3 vs. 2.9 months; $p = 0.006$). After 1 year of UDCA treatment, patients from P3 had lower transaminases, GGT, and bilirubin (Table). There was a trend towards a higher response rate (according to Paris-II criteria) in patients from P3, but the difference was not statistically significant (58% vs. 60% vs. 62%, p = 0, 754).

Variable	Period 1	Period 2	Period 3	*p* value
Age (years)	54 (23-87)	55 (20-86)	56 (30-88)	0.309
At diagnosis				
ALP (x ULN)	1.97 (1-20.7)	1.77 (1-18.7)	1.68 (1-15.7)	0.036
AST (U/L)	52 (17-957)	47 (14-362)	41 (12-727)	<0.001
ALT (U/L)	66 (8-683)	58 (12-427)	46 (7-489)	<0.001
GGT (U/L)	213 (21-1660)	215 (13-1363)	200 (12-1957)	0.336
Bilirubin (mg/dL)	0.6 (0.2-14.6)	0.5 (0.1-13.1)	0.5 (0.2-13)	0.011
Cholesterol (mg/dL)	224 (92-1847)	217 (76-651)	212 (103-1128)	0.011
Creatinine (mg/dL)	0.86 (0.4-2.5)	0.70 (0.4-2.1)	0.70 (0.2-2.5)	<0.001
1 year after UDCA				
ALP (x ULN)	1.17 (0.29-12.6)	1.25 (0.25-13)	1.22 (0.22-9.53)	0.180
AST (U/L)	31 (12-230)	30 (12-448)	27 (10-121)	<0.001
GGT (U/L)	65 (13-1402)	80 (6-1366)	59 (8-849)	0.016
Bilirubin (mg/dL)	0.6 (0.15-8.4)	0.5 (0.17-15.3)	0.5 (0.02-14)	0.021

Data are median (range)

Figure:

Conclusion: PBC is currently diagnosed with lower levels of ALP, transaminases, and bilirubin. The time from diagnosis until treatment initiation is shorter. However, these differences do not appear to influence treatment response

WED-301

Health-related quality of life and medication adherence in adult patients after liver transplantation due to autoimmune hepatitis: a pilot, single centre study

Maciej K. Janik[1], Joanna Łącz[1], Joanna Raszeja-Wyszomirska[1], Piotr Milkiewicz[1,2]. [1]*Medical University of Warsaw, Department of Hepatology, Transplantology and Internal Medicine, Poland;* [2]*Pomeranian Medical University, Translational Medicine Group, Poland*
Email: mjanik24@gmail.com

Background and aims: It has been shown that patients with autoimmune hepatitis (AIH) are prone to impaired HRQoL including increased incidence of depression, anxiety and fatigue. Here, we analyse HRQoL in patients with AIH who underwent liver transplantation (LT-AIH).
Method: We have enrolled 53 liver transplant recipients (74% women, mean age 45 ± 15 years) with AIH. Patients less than six months after LT and those with cholestatic variants of AIH were excluded. HRQoL assessment included following questionnaires: (i) Short Form-12 (SF-12) on physical (PCS) and mental (MCS), (ii) PHQ-9 for depression; (iii) GAD-7, STAI-1 (state) and STAI-2 (trait) for anxiety; (iv) MFIS for fatigue and (v) VAS (visual analogue scale) for self-assessed adherence. Data before and after LT was available in 24 patients. Healthy subjects, non-transplanted cirrhotic and non-cirrhotic patients with AIH, all matched in terms of age and gender served as controls.
Results: The mean time after LT was 4.9 ± 2.6 years. In paired observation before and after LT, all aspects of HRQoL, namely physical and mental component of SF-12, fatigue, anxiety (all $p < 0.01$) as well depression ($p = 0.016$) showed a significant improvement. Compared to healthy controls, only physical scale of HRQoL was impaired in liver recipients ($p = 0.002$), whereas all others were comparable. LT-AIH group when compared to non-cirrhotic AIH showed a significantly better scores in anxiety assessment (both as a state (STAI-1) and a trait (STAI-2) with $p < 0.01$). Finally, when analysing liver recipients and patients with AIH-related cirrhosis, LT-AIH patients had better physical HRQoL, lower fatigue (physical, psychical and total) (all $p < 0.05$) and lower anxiety ($p < 0.001$, for both STAI domains). VAS for self-assessed adherence to medication in LT-AIH group showed correlation with depression i.e. the better adherence the lower depression scores in PHQ-9 (rho – 0.43, $p = 0.002$) and lower anxiety estimated by GAD-7 (rho – 0.31, $p = 0.02$).
Conclusion: Patients after LT-AIH have a comparable HRQoL to healthy controls, except for the impaired physical domains. Liver recipients had better HRQoL than matched subjects with AIH, both cirrhotic and non-cirrhotic. Lower adherence to medication was associated with depression and anxiety, this issue needs a special clinical attention. A multicentre prospective study is required to confirm these findings.

WED-302

Autoimmune hepatitis (AIH) in Greece: first results from the Hellenic autoimmune liver diseases study group of the Hellenic association for the study of the liver (HASL)

Email: gatselis@me.com

Background and aims: AIH is an acute or chronic inflammatory disease of the liver, affecting people from all ethnic groups irrespective of age and sex. The Hellenic Autoimmune Liver Diseases Study Group of HASL was established in 2016, aiming to evaluate patients' characteristics, treatment practices and outcome, determine the unmet needs of patients, and develop and implement improved treatment approaches.
Method: We included data from 691 patients (518 females, 75%; mean age: 47.5 years) who were recorded in our database till 11/2022.

Results: There was a mean delay till diagnosis of 26.8 ± 60 months. One fifth of patients (20.4%) were initially evaluated by physicians other than Internists/General practitioners, Gastroenterologists or Pediatricians. At first evaluation, 441/691 (63.3%) patients were asymptomatic, 149/691 (21.6%) had general symptoms, while only 102/691 (14.8%) had icteric hepatitis. Extrahepatic autoimmune diseases were diagnosed in 34%. Cirrhosis was present in 153/691 (22.1%), with decompensation in 41/153 (26.8%). During follow-up, 541/691 (78.3%) received corticosteroids, 278/691 (40.2%) azathioprine and 282/691 (40.8%) mycophenolate mofetil (MMF). In 72/691 (10.4%) patients, immunomodulatory treatment changed between azathioprine and MMF. At last evaluation (n = 587 patients), 81.6% had complete biochemical response (CBR) on treatment, 13.5% insufficient response, 2.4% relapse and 2.4% no-response.
Conclusion: AIH is frequently misdiagnosed because of its heterogeneity, resulting in diagnosis delay and increased cirrhosis incidence. Approximately 1/5 of patients did not achieve CBR on treatment suggesting the need for strict follow-up and potential new therapies. Large databases will aid better understanding and management of AIH in Greece. [on behalf of the Hellenic Autoimmune Liver Diseases Study Group of HASL]

WED-303

May symptom combinations at initial diagnosis of primary biliary cholangitis implicate distinct natural history?

Atsumasa Komori[1], Yuki Kugiyama[2], Junko Hirohara[3], Toshiaki Nakano[3], Atsushi Tanaka[4]. *[1]National Hospital Organization Nagasaki Medical Center, Clinical Research Center, Omura, Japan; [2]National Hospital Organization Nagasaki Medical Center, Hepatology, Japan; [3]Kansai Medical University, The Third Department of Internal Medicine, Japan; [4]Teikyo University School of Medicine, Department of Medicine, Japan*
Email: atsuriko1027@yahoo.co.jp

Background and aims: It is generally appreciated that pruritus and jaundice, a hallmark cholestatic symptoms of primary biliary cholangitis (PBC), precede clinically significant portal hypertension (CSPH) in disease progression. Meanwhile, CSPH, esophagogastric varix in particular, may emerge as a sole initial symptom of PBC, in the absence of either pruritus or jaundice. The pattern of combination of liver-related symptoms, in conjunction with age, at initial diagnosis of PBC is a clue for a greater understanding of natural history and trajectories of disease progression in PBC. We analysed the association between symptom combinations of PBC and age at initial diagnosis in large nationwide Japanese PBC cohort.
Method: We performed a cross-sectional study using the nationwide registry in Japan, a cohort study of patients with PBC that has been conducted almost every 3 years by the Intractable Hepato-Biliary Diseases Study Group for Research on Measures for Intractable Disease, which is supported by Health Labour Science Research Grants in Japan. Patients who met at least 2 of the following criteria were diagnosed as having PBC: biochemical evidence of chronic cholestasis; positive AMA in sera; histologic features compatible with PBC. Prevalence and age distribution of patients with liver-related symptoms at diagnosis, comprising of pruritus (P), jaundice (≧2 mg/dl of total serum bilirubin: TSB) (J), esophagogastric varix (V), and ascites (A), were analysed.
Results: A total of 2985 patients (mean age 60.4 years) from 14th, 15th and 16th registry (n = 632, 2005–9; n = 1096, 2008–12; n = 1244, 2011–16) were enrolled for study. The mean age of patients with P at diagnosis (58.8; n = 521, 17.5%) was significantly younger than those with V (64.7; n = 201, 6.7%) (p < 0.0001) or A (67.1; n = 95, 3.2%) (p < 0.0001), but not than those with J (61.0; n = 160, 5.4%) (p = 0.6247). In 16th registry, patients presenting P and/or J with CSPH (either P/V, P/V/A, P/J/V, P/J/V/A, J/V or J/V/A: stringently cholestatic PBC with CSPH, n = 44) were significantly younger than those with V or V/A, but without P/J (CSPH-only PBC, n = 49) (59.9 vs 68.5, p = 0.00134). The median TSB and platelet count (PLT, ×10^{4}/microL) of CSPH-only PBC were 1.0 and 12.0, respectively; 13 (26.5%) were larger than 15.0 in PLT, suggesting possible inclusion of non-advanced chronic liver disease.
Conclusion: The age distribution of CSPH among PBC patients might be bimodal, reflecting two distinct trajectories toward CSPH in the natural history of PBC, that is, with or without overt cholestasis.

WED-304

Prevalence of celiac disease in adult patients with cryptogenic liver disease

Aditya Vikram Pachisia[1], Ankit Agarwal[1], Shubham Mehta[1], Alka Kumari[1], Anam Ahmed[1], Shubham Prasad[1], Vignesh Dwarkanathan[2], Sonu Sharma[1], Sambuddha Kumar[1], Prasenjit Das[3], Rimlee Dutta[3], Shalimar Shalimar[1], Vineet Ahuja[1], Govind Makharia[1]. *[1]All India Institute Of Medical Sciences, Gastroenterology, New Delhi, India; [2]All India Institute Of Medical Sciences, Community Medicine, New Delhi, India; [3]All India Institute of Medical Sciences, Pathology, India*
Email: avpafmc@gmail.com

Background and aims: In addition to the small intestine, liver also gets affected in them. The spectrum of liver disease in CeD may vary from hypertransaminasaemia, cirrhosis and autoimmune liver diseases. A recent systematic review, including studies with a small number of patients, has shown that 4.6% of patients with cryptogenic cirrhosis have CeD.
Method: Consecutive patients with cryptogenic liver disease with a spectrum ranging from cryptogenic hypertransaminasaemia to cryptogenic cirrhosis were recruited prospectively. All of them were screened for CeD using IgA anti-tissue transglutaminase antibody (anti-tTG ab) and if anti-tTG Ab was found positive, they were subjected to anti-endomysial antibody (AEA) testing and duodenal mucosal biopsy examination. Liver biopsies and corresponding duodenal biopsies of patients with cryptogenic cirrhosis and CeD were subjected to IgA/anti-tTG colocalization studies. For assessment of the prevalence of CeD in cryptogenic cirrhosis, 235 patients were required.
Results: Of 264 patients recruited, 232 had cryptogenic cirrhosis and 32 had cryptogenic hypertransaminasaemia. Of 232 with cryptogenic cirrhosis, 16 had high anti-tTG Ab mean (SD) fold rise of 16.9 (10.5) folds and 11 of them had biopsy-proven CeD, suggesting a prevalence of 4.7%. Of 11 patients with cryptogenic cirrhosis with CeD, AEA was positive in 9. IgA/anti-tTG Ab colocalization was demonstrated in 7/8 liver biopsies from cryptogenic cirrhosis with CeD, All patients with cryptogenic cirrhosis with CeD were started on a gluten-free diet (GFD). Till the writing of this abstract, 6 patients completed a follow-up of 6 months, and all of them had a trend towards improvement in liver functions (CTP score and Meld Na). Two out of 32 patients with cryptogenic hypertransaminasaemia had high anti-tTG Ab and 1 had biopsy-proven CeD

Figure: Individual patient characteristics with Cryptogenic liver cirrhosis with CeD (N=16/232)

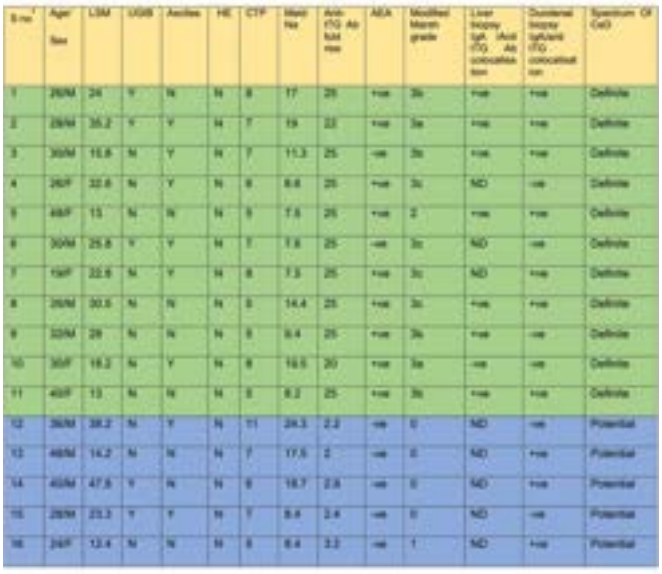

Figure:

Conclusion: Approximately 4.7% of patients with cryptogenic cirrhosis have biopsy-proven CeD which is substantially higher than the prevalence of CeD in the general population. Hence all patients with cryptogenic cirrhosis should be screened for CeD.

WED-305

Budesonide is associated with less weight gain than Prednisolone amongst patients with autoimmune hepatitis: results from long term follow-up in routine clinical care

Josh Orpen-Palmer[1], Thea Rodig[1], Alexander Grayston[1], Shannon Devlin[1], Michael Johnston[2], Jude Morris[3], Shouren Datta[4], Helen Cairns[5], Ewan Forrest[1], Stephen Barclay[1]. *[1]Glasgow Royal Infirmary, Glasgow, United Kingdom; [2]Royal Alexandra Hospital, United Kingdom; [3]Queen Elizabeth University Hospital, United Kingdom; [4]The New Victoria Hospital, United Kingdom; [5]Gartnavel General Hospital, United Kingdom*
Email: josh.orpen-palmer@ggc.scot.nhs.uk

Background and aims: The survival benefit of corticosteroid therapy in the management of autoimmune hepatitis is well recognised. Budesonide (Bude), an option in patients without cirrhosis, undergoes 90% first pass hepatic clearance with potentially fewer systemic effects than Prednisolone (Pred). A registration trial demonstrated fewer side effects, including lower rates of weight gain, with Bude vs Pred. However, data on the amount of weight gained was not reported and the comparative effects on weight in routine clinical practice over longer durations are unknown.
Method: A retrospective chart review of patients attending 5 Scottish hospitals with a diagnosis of autoimmune hepatitis was performed using a list prospectively kept to facilitate audit. Data was obtained from electronic health records supplemented by historic case notes. Patients diagnosed in paediatric care, with cirrhosis at diagnosis, not treated with steroids or treated with both regimens were excluded. Data on BMI, Diabetes, Diabetic medication and routine biochemistry were collected at diagnosis, end of steroid therapy and last known encounter. Comparison of changes in BMI from baseline to end of steroid therapy and end of follow-up were compared using a two-sample t-test.
Results: 291 patients were identified of whom 56 were excluded (35 cirrhosis, 13 paediatric and 8 receiving both regimens). Of 110 patients reviewed to date, 39/110 (39.4%) receiving Bude and 71/110 (64.5%) Pred. Mean age at diagnosis (57.5 and 52.8 p = 0.11), BMI at diagnosis (27.1 vs 28.7 p = 0.22), and diabetes at diagnosis (1//39 (2.56%) and 5/71 (7.04%), p = 0.42) were similar between both groups. Mean ALT at diagnosis was significantly higher in those receiving Pred (318 vs 744 p < 0.01). Median follow-up time was 49 months. Pred was associated with significantly increases in BMI at the end of steroid treatment (mean 1.49 (±2.63) vs (0.35 ± 2.66), p = 0.03), and a trend towards increased BMI at end of follow-up (1.20 (±4.02), budesonide – 0.24 (±3.60), p = 0.06). 2/71 Pred treated patients developed diabetes and 2/5 with existing diabetes required escalation of treatment whilst on steroids. Neither complication was seen in Bude treated patients.

Figure:

Conclusion: In a multi-centre retrospective cohort study, Bude demonstrated reduced rates of BMI gain, de-novo diabetes and deterioration in diabetic control compared with Pred. Weight gained tended to persist overtime, though changes in BMI at end of follow-up did not reach statistical significance in this interim data set. Further data will be presented.

WED-306

Unexpected high incidence of AMA positive primary biliary cholangitis in a northern Italian region

Davide Bitetto[1], Ezio Fornasiere[1], Elisa Fumolo[1], Annarosa Cussigh[2], Sara Cmet[2], Pierluigi Toniutto[1]. *[1]Hepatology and Liver Transplantation Unit, University of Udine, Udine, Italy; [2]Clinical Pathology, Azienda Ospedaliero Universitaria Friuli Centrale, Udine, Italy*
Email: davide_bitetto@yahoo.it

Background and aims: Primary Biliary Cholangitis (PBC) is probably underdiagnosed. This is due to the absence of clinical symptoms in the early phase of the disease and the low attention attributed to the mild alteration of cholestatic live function tests. Anti-mitochondrial antibodies (AMA) are a specific diagnostic marker of PBC and its widespread use of auto-antibody test panels in non-hepatological settings allows incidental findings of AMA patients.
Method: This is a case finding study. The study population consists of all subjects with AMA positive reports in a whole northern Italian region. The study period ranges from August 2018 to January 2023. All the AMA essays of this region are performed in the same laboratory. Clinical and biochemical information of all subjects were retrospectively collected since first appearance of AMA positivity by consulting medical reports.
Results: In a region of 521117 inhabitants, 261 tested positive for AMA for the first time, 83% of them were female with a median age 62 years (range 25–92). The overall yearly incidence was 11.13 cases per 100 000 persons. Out of these, 76 matched criteria for AMA positive PBC, 69 of which were female (91%), with an overall yearly incidence

of 3.24 cases per 100 000 persons, 0.6 cases per 100 000 males and 5.7 cases per 100 000 females. Only 73% of patients were referred to a Liver Unit and started UDCA treatment, out of these 70% underwent stadiation with transient elastography or liver biopsy. Stage III-IV liver fibrosis were present in 5% of them.
Conclusion: The present study found an unexpected high incidence of AMA positive PBC. This could be explained by the availability of all AMA reports of a whole region.

WED-307
Norucholic acid for the treatment of primary sclerosing cholangitis: baseline data from a phase III trial

Manns[15]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Graz, Department of Medicine, Graz, Austria; [3]University of Birmingham, NIHR Birmingham Biomedical Research Centre, Birmingham, United Kingdom; [4]University Hospital LMU, Department of Medicine II, Munich, Germany; [5]University of Helsinki and Helsinki University Hospital, Departement of Gastroenterology, Helsinki, Finland; [6]University Hospital Heidelberg, Division of Gastroenterology, Heidelberg, Germany; [7]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark; [8]University Hospital Tübingen, Department of Gastroenterology, Hepatology and Infectiology, Tübingen, Germany; [9]Akershus University Hospital, Dept. of Gastroenterology, Lørenskog, Norway; [10]Friedrich-Alexander-University Erlangen-Nürnberg, Department of Medicine 1, Erlangen, Germany; [11]Charité Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany; [12]University Hospital Zürich, Swiss-Hepato-Pancreato-Biliary Center and Department of Gastroenterology and Hepatology, Zürich, Switzerland; [13]University Medical Centre Hamburg-Eppendorf, Department of Medicine and Martin Zeitz Centre for Rare Diseases, Hamburg, Germany; [14]University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany; [15]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [16]University Hospital Freiburg, Department of Medicine II, Freiburg, Germany; [17]Amsterdam UMC, Locatie AMC, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands; [18]CHRU de Lille, Services des maladies de l'appareil digestif, Lille, France; [19]Dr. Falk Pharma GmbH, RandD, Freiburg, Germany*
Email: michael.trauner@meduniwien.ac.at

Background and aims: Primary sclerosing cholangitis (PSC) is a devastating inflammatory/fibro-obliterative bile duct disease lacking effective medical therapy. The role of ursodeoxycholic acid (UDCA) in the therapy of PSC remains unclear. Norucholic acid (NCA) is a side chain-shortened C23 homologue of UDCA which undergoes chole-hepatic shunting and has potent anti-cholestatic, anti-inflammatory and anti-fibrotic properties in preclinical mouse models of cholestatic liver injury with features of PSC. NCA was effective in reducing serum Alkaline Phosphatase (ALP) levels in a phase II trial. In the ongoing Phase III trial the efficacy and safety of 1500 mg/d of oral NCA and Placebo will be compared in the treatment of PSC.
Method: Patients with PSC, ALp >1.5 × ULN and bilirubin ≤4 mg/dL of either sex at the age of 16–75 years, were randomized to a 192-weeks treatment period followed by an open-label extension treatment. Randomized patients received either NCA or Placebo. Stable concomitant UDCA therapy was allowed. The primary efficacy end point was prespecified as partial normalization of ALP levels to <1.5 × ULN and no worsening of overall Nakanuma disease stage at week 96 compared to baseline in the Intention to treat population. For this purpose, the trial has been designed as a double-blind, randomized, multi-centre trial conducted in the form of a parallel group comparison.
Results: 77 sites from 17 European countries participated in the trial. 417 patients were screened, 303 were randomized and 302 received at least one treatment dose. Median age was 39 years, 71.5% were male, median BMI was 24.1, 78.8% were on UDCA, and 64.2% had inflammatory bowel disease, of which 89.2% had ulcerative colitis. Location of PSC-typical alterations were reported for both intra- and extra-hepatic bile ducts in 48.3% and median duration of PSC was 5.0 years. Median (IQR) laboratory parameters were: bilirubin 0.78 mg/dl (0.54, 1.19), albumin 4.4 mg/dl (4.2, 4.6), INR 1.0 (1.0, 1.1), platelets 235×10^3/cmm (182×10^3, 298×10^3), ALP 310 U/L (230, 437), GGT 274 U/L (159, 514). ELF and liver stiffness by transient elastography were 9.9 (9.2, 10.9) and 9.85 kPa (7.05, 14.40), respectively. Stage F4 liver stiffness was present in 25.4% of the patients. In 16.5% of all patients, clinical signs of liver cirrhosis were reported with a median (IQR) Child-Pugh score of 5.4 (5.0, 6.0). Median (IQR) values for Quality of Life at baseline were 168 (149, 182) for the Chronic Liver Disease Questionnaire (CLDQ) and 20 (15, 28) score points in the PBC-40 questionnaire (PSC adapted) for the domain fatigue.
Conclusion: Baseline characteristics of patients included in this Phase-3 trial NUC-5/PSC represent the typical distribution for a PSC population with active and advanced disease. The investigation of this trial population over a long-term period of 4 years appears adequate to study long-term clinical efficacy of NCA in PSC.

WED-308
Clinical, demographic, laboratory characteristics and disease progression of autoimmune hepatitis patients, asymptomatic at diagnosis, in a tertiary medical center in Israel
Fadi Kinaani[1], Lian Bannon[2], Majd Khader[2], Inbal Houri[2], Moshe Leshno[3], Oren Shibolet[2,3], Ehud Zigmond[1,3]. *[1]Tel Aviv Sourasky Medical Center-Ichilov, Gastroenterology, Tel Aviv, Israel; [2]Tel Aviv Sourasky Medical Center-Ichilov, Gastroenterology, Tel Aviv, Israel; [3]Tel Aviv University, Israel*
Email: zigmondu@gmail.com

Background and aims: Autoimmune hepatitis (AIH) is a rare chronic, inflammatory disease with variable presentation, ranging from a mild subclinical course to severe acute icteric disease rarely associated with fulminant hepatic failure. Asymptomatic patients are usually identified following an incidental finding of elevated liver enzymes in blood tests done for various reasons. We investigated the demographics, laboratory tests, liver histology features and disease progression in patients with asymptomatic versus symptomatic presentation of AIH.
Method: Clinical, demographic, laboratory and liver histology data were collected from electronic medical records of patients diagnosed with AIH followed in the hepatology outpatient clinic of a tertiary referral medical center in Israel between 2010 and 2021. Patients with features of overlap variants were excluded.
Results: One hundred and twenty-eight patients with AIH with a median follow-up time of 4.6 years since AIH diagnosis were included. Fifty one percent of the patients were asymptomatic at presentation. Asymptomatic patients were older at diagnosis (50.7 vs. 41.2 years, OR 1.031, $p < 0.01$), had higher female predominance (86% vs. 67%, $p < 0.05$) and among the Jewish population were more frequently from Ashkenazi ethnicity (73% vs. 41%, $p < 0.01$). The body mass index (BMI) tended to be higher among asymptomatic patients (27.1 vs, 24.4, $p = 0.058$). Liver enzymes and total bilirubin at diagnosis were lower among asymptomatic patients (ALT-271 vs. 826 U/l, $p < 0.0005$; AST-261 vs. 743 U/l, $p < 0.001$; total bilirubin 1.7 vs. 8, $p < 0.005$). Analysis of pathological reports of liver biopsies performed at diagnosis revealed that only 27% of the asymptomatic patients had no fibrosis (F0 stage) as compared to 45% among the symptomatic patients (OR 0.37, $p < 0.05$).

Interestingly, a higher proportion of asymptomatic patients progressed to liver cirrhosis as compared with the symptomatic group (37% vs. 21%, p < 0.03).
Conclusion: Our data demonstrates differences in demographic and laboratory parameters between patients with symptomatic and asymptomatic presentation of AIH and an increased progression rate to cirrhosis in patients who were asymptomatic at diagnosis. These findings may support screening for liver enzyme elevation in people at high risk to develop AIH.

WED-309
Prevalence and risk factors of osteoporosis in patients with primary biliary cholangitis in Chinese population
Jialiang Chen[1], Yao Liu[1], Yufei Bi[1], Guiqin Zhou[1], Xiaojing Wang[1], Xianbo Wang[1]. [1]*Beijing Ditan Hospital affiliated to Capital Medical University, Center of Integrative Medicine, China*
Email: wangxb@ccmu.edu.cn

Background and aims: Osteoporosis has been considered the metabolic bone disease associated with primary biliary cholangitis (PBC), which increases the risk of fractures and mortality in patients with PBC. However, there is a lack of epidemiological data on the prevalence of osteoporosis in patients with PBC from China and even the Asia-Pacific region. This study aimed to assess the prevalence and risk factors for osteoporosis in Chinese population with PBC
Method: The clinical data including bone mineral density information of patients with PBC from January 2013 to December 2021 from a tertiary hospital in China were retrospectively collected and analyzed. We defined individuals with T scores of –2.5 or less in any sites (L1 to L4, femoral neck, or total hip) as having osteoporosis based on dual-energy X-ray absorptiometry.
Results: A total of 1272 patients were diagnosed as PBC; 268 (21.1%; 236 women [88.1%]; mean [SD] age, 56.7 [10.6] years; 163 liver biopsies [60.8%]) had a qualified x-ray absorptiometry image at baseline. The prevalence of osteoporosis was 45.5% (95% CI, 39.5%–51.7%) among total population, 34.4% (95% CI, 18.6%-53.2%) among men and 47.0% (95% CI, 40.5%–53.6%) among women, respectively. Osteoporosis was associated with age, fatigue, previous glucocorticoid therapy, menopausal status, body mass index, splenomegaly, gastroesophageal varices, ascites, Mayo risk score, histological stage, alanine aminotransferase, albumin, bilirubin, platelets and international normalized ratio (INR). Multivariate regression analysis identified older age, higher Mayo risk score, lower body mass index, gastroesophageal varices and previous glucocorticoid therapy as the independent risk factors for osteoporosis.
Conclusion: Osteoporosis is very prevalent in Chinese population with PBC. Age, body mass index, severity of the disease and previous glucocorticoid therapy are the main risk factors for osteoporosis in PBC.

WED-310
Symptom burden in people living with primary biliary cholangitis does not associate with transient elastography measures
Inbal Houri[1], Madeline Cameron[1], Jonelle Pallotta[1], Aliya Gulamhusein[1], Kristel Leung[1], Gail Wright[2], Bettina Hansen[1,3,4], Gideon Hirschfield[1]. [1]*Toronto General Hospital, University Health Network, Toronto Centre for Liver Disease, Toronto, Canada;* [2]*Canada PBC Society, Canada;* [3]*Erasmus MC University Medical Center, Department of Epidemiology and Biostatistics, Rotterdam, Netherlands;* [4]*University of Toronto, IHPME, Canada*
Email: inbalhourio@gmail.com

Background and aims: The symptom burden for people living with primary biliary cholangitis (PBC) significantly impacts quality-of-life. Risk-assessment tools for disease prognosis include importantly transient elastography, a now well-demonstrated surrogate for patient outcome. We sought to evaluate whether a validated symptom burden score (PBC-40) correlated with elastography measures in a large cohort from a dedicated PBC clinic programme.
Method: The PBC-40 scores from people living with PBC cared for at the Toronto Centre for Liver Disease between 2018 and 2022 were correlated with clinical, demographic and laboratory data collected as standard of care.
Results: 243 patients (55% of the clinic cohort; n = 440) completed a total of 558 questionnaires. Mean age at questionnaire was 59.5 years (SD 10.74), 94% were female, and mean time from diagnosis was 10

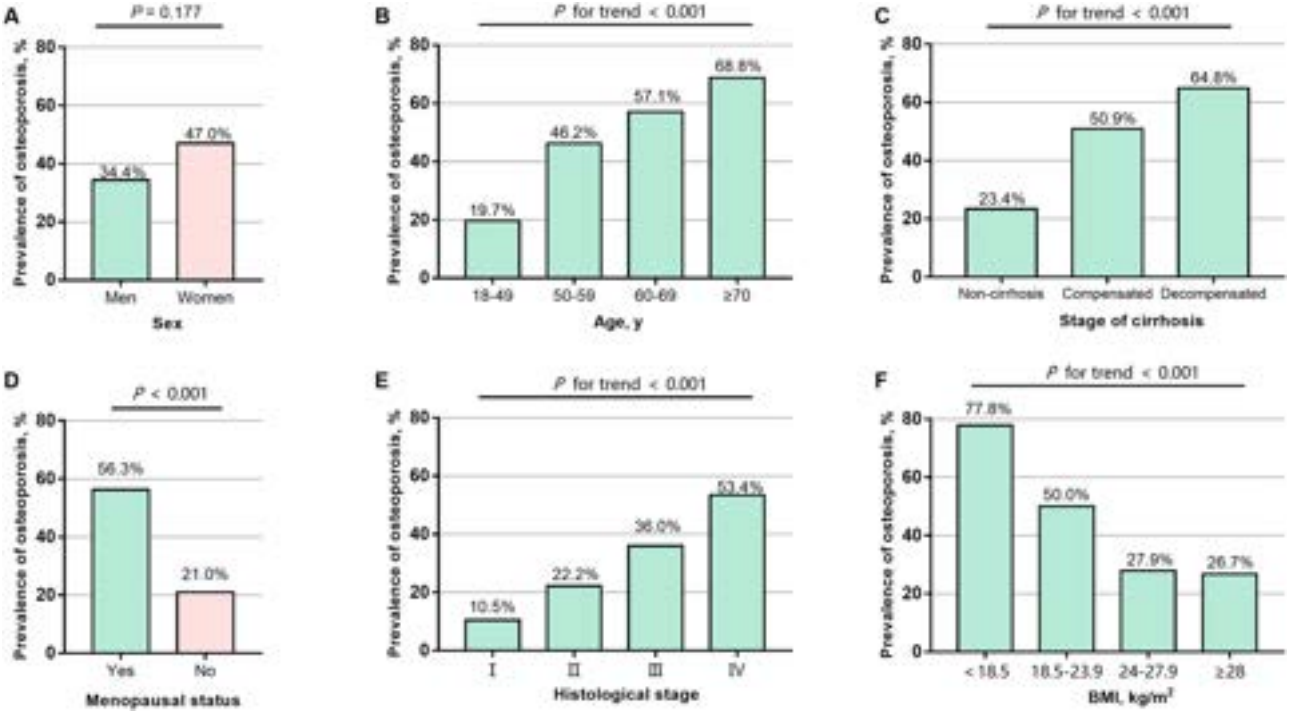

Figure: (abstract: WED-309): Prevalence of osteoporosis in Chinese population with primary biliary cholangitis.

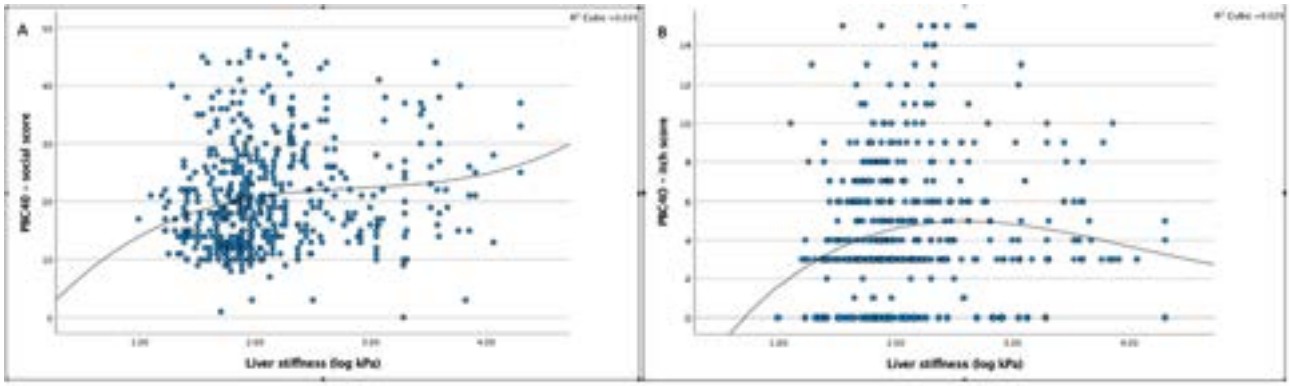

Figure: (abstract: WED-310)

years (SD 7.4). Mean ALP was 177 U/L (SD 125) and AMA was positive in 87.3%. The mean time on ursodeoxycholic acid (UDCA) treatment was 120 months (SD 85.5).
Elastography results were available for 93% of participants, with 61.1% < 8 kPa, 24.6% between 8 and 15 kPa and 14.2% > 15 kPa. In the PBC-40 questionnaire, mean symptom score was 14.11/35 (SD 4.99), fatigue score was 26.12/55 (SD 11.31), itch score was 4.34/15 (SD 3.35), cognitive function score was 11.17/30 (SD 5.9), social score was 20.54/50 (SD 9.01), and emotional score was 6.76/15 (SD 3.28).
Logistic regression did not show association between liver stiffness and total PBC-40 score. There was association between the itch and social sub-scores and liver stiffness of higher than 8 kPa, OR of 1.09 (1.03–1.15, p = 0.001) (Fig. A); 1.05 (1.03–1.07, p < 0.001) (Fig. B).
Conclusion: Symptom burden is significant for people living with PBC but is not a facet of disease severity as evaluated by elastography. Independent approaches to reducing symptoms for people living with PBC are needed alongside disease modifying therapy.

WED-311
Drug-induced autoimmune hepatitis or drug-induced liver injury with autoimmune features: two faces of the same coin?
Pinelopi Arvaniti[1,2], Olivas Ignasi[1], Sergio Rodriguez-Tajes[1], Anna Pocurull[1], Helena Hernandéz Evole[1], Xavier Forns[1], Maria Carlota Londoño[1]. [1]*Liver Unit, Hospital Clinic of Barcelona, Institute of Biomedical Investigations August Pi and Sunyer (IDIBAPS), CIBERehd, University of Barcelona, Barcelona, Spain;* [2]*Department of Medicine and Research Laboratory of Internal Medicine, Expertise Center of Greece in Autoimmune Liver Diseases, ERN RARE LIVER, University Hospital of Larissa, Greece*
Email: peni.arvaniti@gmail.com

Background and aims: The exposure to certain drugs and/or toxics can trigger liver immune response and unmask a previously unknown or induce de novo autoimmune hepatitis (DI-AIH). However, acute or chronic exposure to the same drugs can also cause drug-induced liver injury with autoimmune features (DILI-AI). Up to now, there are no standardized criteria to differentiate these two entities and the existence of distinct characteristics from idiopathic AIH (i-AIH) is a matter of debate. Therefore, the aims of the current study were to: (1) determine the prevalence of drug exposure among patients diagnosed with AIH, (2) describe the characteristics of DI-AIH and DILI-AI and (3) compare these two entities with i-AIH.
Method: This was a single center retrospective study of 295 patients diagnosed with AIH confirmed by a liver biopsy. Patients were categorized in 3 groups: (1) DILI-AI: patients consuming drugs/toxics known to be associated with DILI-AI and sustained complete biochemical response (CBR) after immunosuppressive treatment withdrawal, (2) DI-AIH: same characteristics, but without an attempt to stop treatment or presenting a relapse after treatment discontinuation and (3) i-AIH: cases without a clear trigger.
Results: Sixty-nine percent of patients (n = 203) were female with a median age of 53 years (interquartile range [IQR]: 39–63). Twenty-three percent (n = 69) were consuming drugs/toxics at diagnosis, 29 (42%) statins. Eleven patients (4%) were categorized as DILI-AI, 58 (20%) as DI-AIH (in 50 of them treatment was never stopped, while 8 relapsed after treatment withdrawal) and 226 (76%) as i-AIH. Patients with drug exposure (DIILI-AI/DI-AIH) were older (58 vs. 52, p = 0, 05), had higher ALT (867 vs. 555, p = 0, 034) and faster CBR (3 vs. 5 meses; p = 0, 01) than patients with i-AIH. In contrast, patients with i-AIH had higher rates of portal/peritportal fibrosis (62% vs. 47%; p = 0, 03) and established cirrhosis (17% vs. 4%; p = 0, 008) at diagnosis. No difference in the type of presentation (acute vs. insidious) or in the rate of CBR was noticed, but patients with DILI-AI/DI-AIH had lower levels of ALT and IgG at 12 months of follow-up than patients with i-AIH. Among patients with drug exposure, those with DILI-AI had higher ALT (1334 vs. 734, p = 0, 03), lower IgG (12 vs. 17; p = 0, 003) and lower simplified score (5 vs. 6; p = 0, 012) than patients with DI-AIH. No differences were detected in the time of drug exposure or in the rate of CBR.
Conclusion: Drugs/toxics can trigger AIH in a significant number of patients. The differences between these entities were subtle, but treatment withdrawal was attempted in a minority of cases. Consequently, patients with DILI-AI can be mis-diagnosed being exposed to side effects of unnecessary long lasting treatment regimens.

WED-312
To assess response to steroids and validate SURFASA score in Indian autoimmune hepatitis patients
Harsh Gandhi[1], Shubham Jain[1], Pravin Rathi[1], Sanjay Chandnani[1], Anuraag Jena[1]. [1]*B.Y.L. Nair Charitable Hospital, Gastroenterology, Mumbai, India*
Email: harshgandhi345@gmail.com

Background and aims: In Autoimmune hepatitis (AIH) patients response to steroids and optimal timing of liver transplantation is still a clinical dilemma. In clinical practice to assess response to steroids we monitor bilirubin, SGOT, SGPT, INR and look for signs of worsening in form of ascites or encephalopathy. Recently, a SURFASA score was introduced to identify patients who are not responding to steroids at day 3. The aims of study are: (1) To assess the response to steroids at day 3 from start of treatment. (2) To validate SURFASA score in Indian AIH patients.
Method: It is an interim analysis of an observational prospective study of 45 patients of AIH divided into: (1) Acute AIH (2) Acute severe (AS-AIH) and (3) Acute on chronic liver failure (ACLF) AIH (according to APASL guideline). Response to steroids was assessed at day 3.
Results: 51.1% (23) patients presented as Acute AIH, 28.8% (13) as ACLF and 20% (9) as AS-AIH. Patients (9) who succumbed belonged to ACLF group. Traditional scores such as CTP and MELD were accurate in

predicting response to steroids ($p < 0.001$). The cutoff of SURFASA score is <−2.8 in our patients.

Parameters	Improved(n=36)	Death(n=9)	P value
D0-CTP	9 (8-10)	12(12-13)	<0.001
D3-CTP	8.5 (8-9)	12.5(12-14)	<0.001
D0-MELD,mean(SD)	19.6 (2.8)	29.5(7.2)	0.001
D3-MELD,mean(SD)	17.7 (2.5)	31.3 (7)	<0.001
Δ%3-bilirubin	-0.1[-0.2-(-0.01)]	0.05(-0.1-0.1)	0.003
Δ%3-INR	-0.1(-0.4-0.3)	0.1(-0.04-0.7)	<0.001
SURFASA score	-4.7[-5.1-(-4.1)]	-2.8[-3.14-(-1.2)]	<0.001

Figure:

Conclusion: Patients with Acute and AS-AIH responded to steroids. However, only 30% ACLF AIH patients responded to steroids. SURFASA score and traditional scores (CTP and MELD) are accurate in predicting response to steroids and transplant free survival. Threshold of SURFASA score is different in our population group and so the score needs further validation.

WED-313

The natural history and prognosis of primary sclerosing cholangitis: a multi-center, retrospective cohort study in China

Mingxia Shi[1], Li Yang[2], Qiuxiang Lin[3], Xiaowei Liu[4], Lu Zhou[5], Yanhang Gao[6], Yonghong He[7], Huihong Yu[8], Yong-Jian Zhou[9], Yingmei Tang[10], Yiling Yi[11], Ying Sun[12], Min Lian[13], Xiong Ma[14]. *[1]Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China, Shanghai Institute of Digestive Disease, China; [2]Department of Gastroenterology, West China Hospital, Sichuan University, Chengdu, China; [3]Mengchao Hepatobiliary Hospital of Fujian Medical University, Fuzhou, China, Department of Hepatology, China; [4]Xiangya Hospital of Central South University, Changsha 410008, Hunan, China, Department of Gastroenterology, China; [5]General Hospital, Tianjin Medical University, Tianjin, China, Department of Gastroenterology and Hepatology, China; [6]First Hospital of Jilin University, Department of Hepatology, China; [7]Southwest Hospital, Third Military Medical University, Chongqing 400038, People's Republic of China, Department of Gastroenterology, China; [8]The Second Affiliated Hospital of Chongqing Medical University, Department of Gastroenterology, China; [9]Guangzhou First People's Hospital, Department of Gastroenterology, China; [10]the Second Affiliated Hospital of Kunming Medical University, Gastroenterology Department, China; [11]First Affiliated Hospital of China Medical University, ShenYang, China, Department of Gastroenterology, China; [12]the Fifth Medical Center of PLA General Hospital, Department of Liver Disease, Senior Department of Hepatology, China; [13]Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai Institute of Digestive Disease, Shanghai, China, Division of Gastroenterology and Hepatology, Key Laboratory of Gastroenterology and Hepatology, Ministry of Health, State Key Laboratory for Oncogenes and Related Genes, China; [14]Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai Institute of Digestive Disease, 145 Middle Shandong Road, Shanghai 200001, China, Division of Gastroenterology and Hepatology, Key Laboratory of Gastroenterology and Hepatology, Ministry of Health, State Key Laboratory for Oncogenes and Related Genes, China*
Email: maxiongmd@hotmail.com

Background and aims: Contemporary population-based cohorts describing the natural history and prognosis of primary sclerosing cholangitis (PSC) in Asia are scarce. This study aimed to clarify the disease characteristics and long-term outcomes in patients with PSC, and to compare the prognostic value of the Mayo risk score (MRS), UK-PSC score, and the Amsterdam-Oxford model (AOM) in a real-world clinical setting.
Method: We performed a retrospective outcome analysis of patients with PSC referred to 12 centers in China from January 2010 to December 2022. Clinical and laboratory data were collected until the last visit or time of liver transplantation or death. The discriminatory performance of the prognostic scores was assessed with concordance statistics at diagnosis.
Results: Of the 536 patients in the cohort, 371 met the primary end point, with a mean age of 43.2 ± 13.9 years, of whom 201 (54.2%) were male, 42.4% with inflammatory bowel disease (IBD). The diagnosis was large duct PSC in 251 (67.7%), PSC with features of autoimmune hepatitis in 61 (16.4%) and small-duct PSC in 59 (15.9%). Cholangiocarcinoma occurred in 1.6%. During a median follow-up of 42.3 (interquartile range 22.7–67.5) months, 16 patients underwent liver transplantation, and 18 patients died. Overall transplant-free survival was 90% at 5 years and 84% at 10 years. At diagnosis, the concordance statistic for the MRS was 0.689 (95% confidence interval [CI] 0.601–0.777), 0.686 (95% CI 0.612–0.760) for the UK-PSC score, 0.693 (95% CI 0.613–0.774) for the AOM.
Conclusion: In this large multicenter cohort of patients with PSC in China, patients with PSC are increasingly being diagnosed with a milder phenotype. All prognostic scores developed for PSC (MRS, UK-PSC, and AOM) demonstrated comparable discriminating performance for liver transplantation or death.

WED-314

Elevated GGT levels as predictor of non-response to ursodeoxycholic acid in patients with primary biliary cholangitis

Flor M. Fernandez-Gordón Sánchez[1], Elena Gómez Domínguez[1], Ana Martin Algibez[1], Inmaculada Fernández Vázquez[1]. *[1]Hospital Universitario 12 de Octubre, Spain*
Email: florfgs@hotmail.com

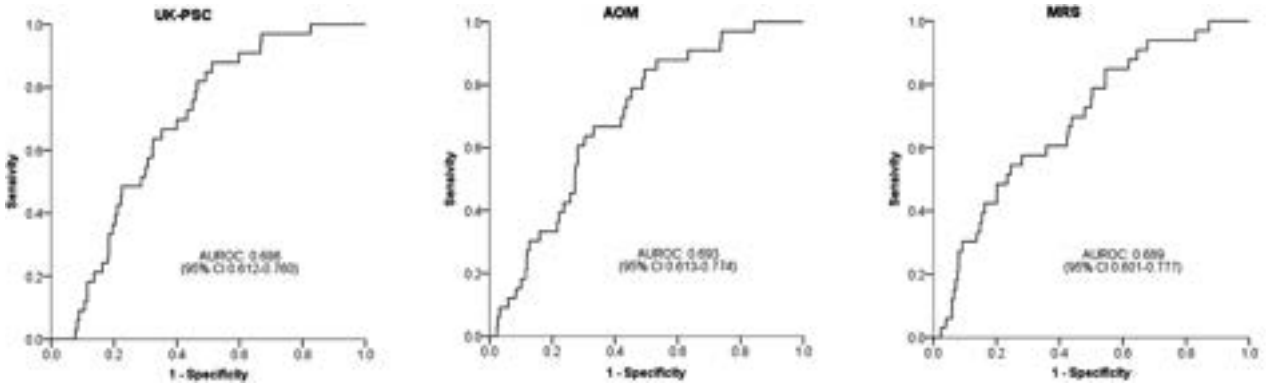

Figure: (abstract: WED-313)

Background and aims: Isolated gamma glutamyl transferase (GGT) values as predictor of response to ursodeoxycholic acid (UDCA) in patients with primary biliary cholangitis (PBC) are not yet well defined. We aimed to analyze the predictive value of GGT elevation at diagnosis and after one year of treatment with UDCA in patients with PBC; we aimed to establish a cut-off point to identify patients who are candidates to second-line therapies.
Method: This single center retrospective cohort study included two cohorts of patients diagnosed with PBC treated with UDCA, according to response to UDCA. Non-response was defined according to the Paris II Criteria. The study was developed between 2014 and 2022. Clinical and analytical variables at baseline and at one year of treatment were compared. ANOVA test and Youden Index were used to define optimal cut-off points in the ROC curve.
Results: 179 patients were included, mean age 60 years (51–71.5), 89.38% women, 152 UDCA responders and 27 non-responders. Liver biopsy was required in a higher percentage in non-responders (74.07 vs 34.67, $p < 0.001$). Non-responders were younger, mean age 51 years ($p < 0.001$), and had higher GGT values at diagnosis [195.00 vs 93.00, $p < 0.008$] and at one year of follow-up [127.00 vs 41.00, $p < 0.001$]. In addition, the alkaline phosphatase (AF) values in the UDCA non-responder group were significantly higher at diagnosis [210.00 vs 122.00, $p < 0.001$] and at one year of follow-up [197.00 vs 102.00, $p < 0.001$]. GGT levels ≥219 U/l (S 66.7%, E 88.9%, AUC-ROC 0.7778) and AF ≥ 164 U/l (S 61.9%, E 80%, AUC-ROC 0.7095) were established as cut-off points indicative of non-response after one year of treatment with UDCA. Fig. 1.

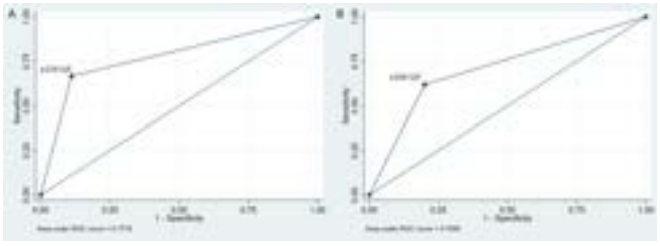

Figure: GGT (A) and AF (B) cut-off points for non-response at one year of treatment with UDCA.

Conclusion: Elevated baseline GGT levels and after one year of UDCA treatment were associated with a worse response. This study may help to identify patients with PBC who are potential candidates to second-line treatment.

WED-315
Celiac disease in patients with autoimmune hepatitis is associated with a milder liver disease course and a better chance of immunosuppressive treatment withdrawal

Francesco Pezzato[1,2], Erica D'Ovidio[1,2], Lisa Perini[1,2,3], Emanuela Bonaiuto[1,2], Paolo Rollo[1,1], Francesco Paolo Russo[1,2], Anna D'Odorico[1,2], Fabiana Zingone[1,2], Annarosa Floreani[4,5], Nora Cazzagon[1,2]. *[1]University of Padova, Department of Surgery, Oncology and Gastroenterology, Italy; [2]Padova University Hospital, Gastroenterology Unit, Padova, Italy; [3]Company Health Authority n. Serenissima 3, Mira, Italy; [4]University of Padova, Padova, Italy; [5]Ospedale Sacro Cuore Don Calabria, Negrar di Valpolicella, Italy*
Email: pezzatofrancesco94@gmail.com

Background and aims: Celiac Disease (CD) is 3-times more frequent in people with Autoimmune Hepatitis (AIH) than in the general population. In paediatric patients with AIH, CD is associated with a milder course of AIH and higher chances of immunosuppressive therapy withdrawal. Our aim is To assess the frequency of CD in AIH, and to analyse the features and the long-term response to immunosuppressive treatment in patients with AIH associated with CD (AIH-CD) compared to patients without CD (AIH-non-CD).
Method: A retrospective cohort study including all consecutive people with an established diagnosis of AIH in adulthood was performed. Exclusion criteria were the presence of overlap syndromes or concomitant liver diseases. Decompensation-free survival was calculated according to Kaplan-Meier estimates; data were censored at the date of the last visit or the occurrence of cirrhosis decompensation.
Results: 166 consecutive people (80% female, median age 52) diagnosed with AIH between 1990 and 2021 and followed-up for a median of 63 (24–125) months at the Gastroenterology Unit of the University Hospital of Padova were included. At diagnosis, 18% of patients were cirrhotic; 9 patients (5.4%) had a histologically confirmed diagnosis of CD. People with AIH-CD were treated with significantly lower doses of prednisone at 2 years from diagnosis (2.5 *vs* 5 mg/day $p = 0.007$) and at 3 years from diagnosis were more likely to have interrupted steroids (83% *vs* 31%, $p = 0.007$) compared to AIH-non-CD. During the follow-up, immunosuppressive therapy withdrawal was more frequent in AIH-CD compared to AIH-non-CD (44% *vs.* 13%, $p = 0.01$) while the need for immunosuppressive therapy reintroduction was similar (p = n.s.). We did not find any difference regarding cirrhosis development, cirrhosis decompensation, liver-related deaths or the number of relapses between people with AIH-CD and AIH-non-CD.

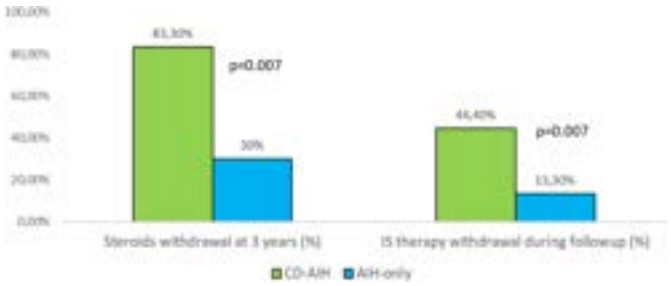

Figure:

Conclusion: In our cohort, CD is present in 5.4% of people with AIH. In people with AIH-CD, we observed a milder course and a higher possibility of immunosuppressive therapy withdrawal compared to AIH-non-CD.

WED-316
Outcome and prognostic factors of primary biliary cholangitis in South Korea

Kyung Ahkim[1], Hwa Young Choi[2], Moran Ki[2], Eun Sun Jang[3], Sook-Hyang Jeong[3]. *[1]INJE University Ilsan Paik Hospital, Internal Medicine, Goyang-si, Korea, Rep. of South; [2]National Cancer Center, Korea, Rep. of South; [3]Seoul National University Bundang Hospital, Korea, Rep. of South*
Email: kakim@paik.ac.kr

Background and aims: This study aimed to analyze changes in liver biochemistry after UDCA treatment and their prognostic impacts in patients with primary biliary cholangitis (PBC) using the Korean National Health Insurance System database.
Method: PBC patients who were diagnosed between 2010 and 2014 and had taken national health screening before and after PBC diagnosis were included. The Korean National health screening biennially includes aspartate aminotransferase (AST), alanine aminotransferase (ALT), and gamma-glutamyl transferase (GGT), but not alkaline phosphatase. Liver biochemistry measured 1–2 years before and 1–3 years after PBC diagnosis was regarded at baseline and after UDCA treatment. Adherence to UDCA treatment was assessed by calculating the medication possession ratio. Transplant-free survival was analyzed according to age, sex, UDCA treatment, and liver biochemistry using Kaplan-Meier and Cox regression analyses.
Results: A total of 1,449 patients (female 1,237, mean age 57.8) was included. The proportions of abnormal AST, ALT and GGT significantly

decreased from 64.3%, 66.7, and 90.8% at baseline to 25.2%, 25.0%, and 64.0% after UDCA treatment, respectively. The 5-year transplant-free survival rate was 92.2%. Old age, male, low adherence to UDCA, abnormal AST, and AST/ALT > 1 were associated with poor prognosis among baseline characteristics. Abnormal AST, AST/ALT > 1, and abnormal GGT were also associated with poor prognosis among features after UDCA treatment.

Table 1: Cox regression analysis of risk factors for death or liver transplantation

	All-cause death or liver transplantation	
	Hazard ratio (95% confidence interval)	
	Univariable	Multivariable
Sex (*vs.* female)		
male	2.17 (1.49–3.17)	2.14 (1.45–3.17)
Age (by 10-year increase)	2.11 (1.81–2.48)	1.90 (1.63–2.23)
MPR of UDCA (≥80% *vs.*<80%)	1.78 (1.36–2.33)	1.89 (1.45–2.47)
Baseline liver biochemistry		
AST>ULN (*vs.* ≤ULN)	2.14 (1.41–3.24)	2.16 (1.47–3.16)
AST/ALT>1 (*vs.* ≤1)	2.59 (1.79–3.73)	2.16 (1.47–3.16)
GGT>ULN (*vs.* ≤ULN)	1.11 (0.60–2.05)	0.88 (0.46–1.71)
Posttreatment liver biochemistry		
AST>ULN (*vs.* ≤ULN)	4.30 (2.73–6.76)	4.35 (2.67–7.07)
AST/ALT>1 (*vs.* ≤1)	1.75 (1.00–3.07)	1.84 (1.02–3.29)
GGT>ULN (*vs.* ≤ULN)	2.01 (1.16–3.47)	1.50 (0.83–2.74)

MPR, medication possession ratio; UDCA, ursodeoxycholic acid; AST, aspartate aminotransferase; ULN, upper limit of normal; ALT, alanine aminotransferase; GGT, gamma-glutamyl transferase

Conclusions: The poor prognostic factors in PBC patients were old age, male, low adherence to UDCA, baseline AST/ALT > 1 indicating advanced fibrosis, abnormal AST and GGT after UDCA treatment indicating insufficient UDCA response.

WED-317

The association between cholestatic biochemical markers and clinical symptoms in patients with non-end-stage primary sclerosing cholangitis

Tim Middelburg[1], Nahid Mostafavi[2], Seval Akbulut[1], Annika Bergquist[3], Olivier Chazouilleres[4], Astrid Kemgang[4], Hanns-Ulrich Marschall[5], Stephen Pereira[6], Lars Aabakken[7], Cyriel Ponsioen[1]. *[1]Amsterdam UMC, Locatie AMC, Gastroenterology and Hepatology, Amsterdam, Netherlands; [2]Amsterdam University Medical Center, Biostatistics Unit, Gastroenterology and Hepatology, Amsterdam, Netherlands; [3]Karolinska University Hospital, Gastroenterology and Hepatology, Sweden; [4]Hospital Saint-Antoine Ap-Hp, Hepatology, Paris, France; [5]Sahlgrenska University Hospital, Department of Medicine, Gastroenterology and Hepatology, Gothenburg, Sweden; [6]Institute of Liver and Digestive Health, University College London and Sheila Sherlock Liver Centre, Royal Free Hospital, London, United Kingdom; [7]Rikshospitalet, Gastroenterology and Hepatology, Norway*
Email: t.e.middelburg@amsterdamumc.nl

Background and aims: In primary sclerosing cholangitis (PSC) the absence of validated surrogate end points impedes treatment development. We aimed at assessing the correlation between biochemical markers of cholestasis and clinical symptoms in order to evaluate their construct validity as surrogate end points.
Method: Cholestatic biochemical markers and clinical symptoms measured by the simple cholestatic complaint score were collected from non-end-stage PSC patients who participated in the DILSTENT trial. The association between each biochemical marker and clinical symptom from baseline to 12 months post-intervention was explored using univariate and multivariate mixed-effect ordinal logistic regression analysis. Measures of associations were expressed as Odds Ratio (OR). Correlation was determined by using Spearman's rank correlation and was expressed as r.
Results: Data from 65 patients was included. The median level of alkaline phosphatase (ALP), bilirubin, gamma-glutamyltransferase (GGT), aspartate aminotransferase (AST) and the proportion of patients with a high levels of complaints decreased during follow-up. The levels of ALP, bilirubin and AST were significantly associated with pruritus levels (OR 1.01 (p < 0.001), OR 1.02 (p = 0.009), OR 1.01 (p = 0.004) respectively) in univariate analysis. Only ALP remained significant in multivariate analysis (OR 1.01, p < 0.001). ALP, bilirubin, GGT and AST were not significantly associated with fatigue, right upper quadrant pain or fever. A significant correlation was found between relative change in ALP and change in pruritus from baseline to month 3 post-intervention (r = 0.34; p = 0.02)
Conclusion: ALP is significantly associated with the most exigent symptom of cholestasis, i.e. pruritus. Our results corroborate the hypothesis that ALP has construct validity as a marker of cholestatic itch, thereby supporting its role as potential surrogate end point for clinical trials.

WED-318

Exploring the impact of ursodeoxycholic acid therapy on COVID-19 in a real-world setting

Christophe Corpechot[1], Marie Verdoux[2], Marie Frank-Soltysiak[3], Lamiae Grimaldi[2], Jean-Charles Duclos-Vallée[4]. *[1]Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Sorbonne University, Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, Paris, France; [2]Bicêtre Hospital, Assistance Publique-Hôpitaux de Paris, Paris-Saclay University, Department of clinical research, France; [3]Bicêtre Hospital, Assistance Publique-Hôpitaux de Paris, Paris-Saclay University, Department of medical information, France; [4]Paul-Brousse Hospital, Assistance Publique-Hôpitaux de Paris, Inserm UMR-S 1193, Paris-Saclay University, University Hospital Federation Hepatinov, Villejuif, France*
Email: christophe.corpechot@aphp.fr

Background and aims: Very recently, Brevini et al. demonstrated that ursodeoxycholic acid (UDCA)-mediated ACE2 downregulation reduces susceptibility to SARS-CoV-2 infection in vitro, in vivo and in human biliary and pulmonary organoids ex situ perfused (1). They also observed an association between UDCA therapy and positive clinical outcomes following COVID-19. Given the potentially important implications of this finding, the therapeutic value of UDCA in this infectious setting must to be confirmed. Our aim was to investigate the association between UDCA exposure and the occurrence of hospitalization for COVID-19.
Method: We designed a case-control study in the source population of adult patients followed up at the Assistance Publique-Hôpitaux de Paris (APHP), Paris Hospitals Group, France, through their medical records (APHP health data registry) and pre-diagnosed with primary biliary cholangitis (PBC) or primary sclerosing cholangitis (PSC). Liver transplant patients were excluded. Cases were patients hospitalized >24 h for COVID-19 as the primary diagnosis between 2020/03/01 and 2020/12/31 (1st stay of the first hospitalization if multiple stays). Controls were patients from the same source population, not hospitalized for COVID-19 as the primary diagnosis over the same period, secondarily matched on PBC/PSC, age, sex and index date (date of case admission). Exposure was defined by UDCA use prior to index date. The confounding factors, including age, severity of liver disease, autoimmune hepatitis, diabetes, cardiovascular disorders, obesity, alcoholism, chronic obstructive pulmonary disease, renal failure, chronic inflammation of gastrointestinal tract, and hospitalization prior to pandemics, were controlled for by a risk score.
Results: Among 1401 patients with PBC or PSC, 1330 (94.9%) were given UDCA therapy. Out of the 7 cases and 1394 unmatched controls identified during the study period, 6 (85.7%) and 1324 (95.0%) were exposed to UDCA. The matching yielded to 6 cases and 52 matched controls. Comparison of exposure between cases (n = 5, 83.3%) and matched controls (n = 48, 92.3%), using a conditional logistic regression model estimated a crude and adjusted odds ratio (95%

confidence interval, CI) of 0.84 (0.07–9.86) and 2.67 (0.11–63.93) respectively. Non-significant results were also obtained from the full unmatched population adjusted for age, sex, PBC/PSC and above-mentioned confounding factors (Table below).

Table Odds Ratios (95% CI) of UDCA exposure for hospitalization due to Covid-19.

Population	Exposed cases	Exposed controls	Unadjusted OR	Adjusted OR
Complete	6 (85.7%)	1324 (95.0%)	0.32 (0.04–2.67)	0.25 (0.03–2.25)
Matched	5 (83.3%)	48 (92.3%)	0.84 (0.07–9.86)	2.67 (0.11–63.93)

Conclusion: In this real-world data study, we could not establish evidence of an association between UDCA use and the occurrence of hospitalized COVID-19, a result that does not support a protective effect of UDCA against SARS-CoV2 infection. However, the high exposure to UDCA in this population as well as the limited number of cases resulted in a lack of statistical power that precludes any definitive conclusion. Larger studies are therefore warranted.

Bacteriophage therapy against pathological Klebsiella pneumoniae that determine the clinical course of primary sclerosing cholangitis

Masataka Ichikawa[1], Nobuhiro Nakamoto[1], Sharon Kredo-Russo[2], Eyal Weinstock[2], Iddo Nadav Weiner[2], Efrat Khabra[2], Noa Ben-Ishai[2], Dana Inbar[2], Noga Kowalsman[2], Ron Mordoch[2], Julian Nicenboim[2], Myriam Golembo[2], Naomi Zak[2], Takahiro Suzuki[1], Kentaro Miyamoto[1], Toshiaki Teratani[1], Sota Fujimori[1], Yoshimasa Aoto[3], Mikiko Konda[3], Naoki Hayashi[3], Po-Sung Chu[1], Nobuhito Taniki[1], Rei Morikawa[1], Ryosuke Kasuga[1], Takaya Tabuchi[1], Shinya Sugimoto[1], Yohei Mikami[1], Atsushi Shiota[4,5], Merav Bassan[2], Takanori Kanai[1]. *[1]Keio University School of Medicine, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Sinjuku-ku, Tokyo, Japan; [2]BiomX Ltd, Ness Ziona, Israel; [3]JSR-Keio University Medical and Chemical Innovation Center (JKiC), JSR Corp., Shinjuku-ku, Tokyo, Japan; [4]Department of Microbiology and Immunology, Keio University, Shinjuku-ku, Tokyo, Japan; [5]Microbiopharm Japan, Co. Ltd., Japan*
Email: ichikawa_mstk_19@yahoo.co.jp

Background and aims: Primary sclerosing cholangitis (PSC) is a cholestatic liver disease characterized by progressive biliary inflammation and fibrosis with a frequent complication of inflammatory bowel disease (IBD). We recently reported that specific gut microbiota, *Klebsiella pneumoniae* (Kp), *Proteus mirabilis* (Pm), and *Enterococcus gallinarum* (Eg), were frequently present in faecal samples from patients with PSC+IBD and the combination of these three gut bacteria contributed to the pathogenesis of the hepatobiliary phenotype. As a mechanism of pathogenesis, these bacteria translocated to mesenteric lymph nodes (MLN) and contributed to subsequent T helper 17 (TH17) cell induction in the liver. However, it remains unclear whether the abundance or combination of these microbiota is associated with the clinical outcome of PSC, and whether certain bacteria might serve as therapeutic targets. As a therapeutic tool for targeting specific gut microbiota, we developed a lytic bacteriophage cocktail specifically targeting PSC-derived Kp strains, which demonstrated a sustained suppressive effect in vitro.
Method: We collected faecal samples from 45 PSC patients, either complicated with IBD (n = 34) or without IBD (n = 11) and investigated whether carriage of each bacterium or its combination could affect the clinical course. Germ-free (GF) mice and specific pathogen free (SPF) mice were inoculated with PSC-derived Kp and administered with the phage cocktail, and Kp levels in faecal samples were measured. 16 s rRNA metagenome analysis was used to examine the effect of phage cocktail on the overall gut microbiota composition of faecal samples. Furthermore, to examine the effect of phage cocktail on experimental hepatobiliary injuries, Kp-colonized mice were given phage cocktail or vehicle orally or intravenously three times a week during 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) feeding for three weeks.
Results: We detected abundant Kp and Eg in faecal samples from 45 patients with PSC regardless of intestinal complications (Kp: PSC, 82% vs. PSC+IBD, 82%; Pm: PSC, 21% vs. PSC+IBD, 9%; and Eg: PSC, 73% vs. PSC+IBD, 76%). Carriers of both Kp and Eg (n = 28) exhibited higher serum ALP levels and poorer transplant-free survival compared to non-carriers (n = 17). Colonization of PSC-derived Kp in hepatobiliary injury-prone mice enhanced liver Th17 cell responses and exacerbated hepatobiliary injury through bacterial translocation to MLN. Oral administration of the phage cocktail reduced intestinal Kp levels in Kp-colonized mice by 2 log without inducing off-target dysbiosis. Furthermore, oral and intravenous administration of phage cocktail reduced Kp levels in hepatobiliary injury-prone SPF mice, and attenuated liver Th17 numbers, hepatobiliary inflammation, and fibrosis progression. Of note, the amount of Kp in the MLN significantly correlated with the degree of fibrosis in the phage-treated mice, suggesting that a direct targeting of the translocated Kp may be a more appropriate therapeutic approach.
Conclusion: Our results identified a clear association between specific gut microbiota Kp and the clinical course of PSC, and revealed that targeting a single Kp pathogen with a strain-specific phage cocktail is promising for the treatment of PSC.

Development of an in vitro bile-duct-on-a-chip-platform using patient-derived cholangiocytes

Anna Katharina Frank[1,2,3,4,5], Henry Hoyle[1,2,4,5], Kayoko Hirayama-Shoji[4,6], Mathias Busek[4,6], Aleksandra Aizenshtadt[4], Fotios Sampaziotis[7,8,9,10], Tom Hemming Karlsen[1,2,5,11], Stefan Krauss[4,6], Espen Melum[1,2,4,5,11]. *[1]Norwegian PSC Research Center, Department of Transplantation Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital Rikshospitalet, Oslo, Norway; [2]Research Institute of Internal Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital Rikshospitalet, Oslo, Norway; [3]Scientia Fellowship, European Union`s Horizon 2020 research and innovation program under the Marie Sklodowska-Curie grant agreement No 801133, Norway; [4]Hybrid Technology Hub, Institute of Basic Medical Science, University of Oslo, Oslo, Norway; [5]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway, [6]Department of Immunology and Transfusion Medicine, University of Oslo, Oslo, Norway; [7]Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute, Jeffrey Cheah Biomedical Centre, University of Cambridge, Cambridge, United Kingdom; [8]Department of Surgery, University of Cambridge, Cambridge, United Kingdom; [9]Department of Medicine, University of Cambridge, Cambridge, United Kingdom, [10]Cambridge Liver Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, [11]Section of Gastroenterology, Department of Transplantation Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital Rikshospitalet, Oslo, Norway*
Email: anna.frank@medisin.uio.no

Background and aims: Primary sclerosing cholangitis (PSC) is a progressive bile duct-based liver disease without medical treatment options. Cholangiocytes are the main target of destruction in PSC, yet the exact mechanisms that lead to cholangiocyte damage are not fully understood. A lack of representative disease models available is currently hindering advances in our understanding of PSC development and progression. Current *in vitro* bile-duct models are limited to the use of murine cholangiocytes and do not offer the inclusion of bile or other disease relevant cell types, such as immune cells. We aimed to develop a representative, robust and simplified *in vitro* model of a human bile duct that allows us to interrogate the cross-function between cholangiocytes and other disease-relevant components on a cellular level.

Method: Cholangiocytes were isolated from the bile ducts of PSC and healthy control patients undergoing routinely performed endoscopic retrograde cholangiopancreatography (ERCP) and propagated as organoids using previously established culture conditions. Cholangiocytes were then seeded into a perfused channel surrounded by a collagen/laminin mixture that resembles the in vivo environment within the bile ducts. Cells were grown for approximately 7 days before channel confluency was reached and then analyzed by fluorescent microscopy.

Results: We developed a robust and scalable in vitro platform that resembles the in vivo architecture of a bile duct (Fig. 1A and B). We optimized the chip design and materials for high-throughput analysis, advanced microscopy and drug screening compatibility and adjusted the channel size and coating mixture to maximize physiological resemblance. We further designed a fluidic system that allows incorporation of internal fluidics (bile/blood) to the system without the use of tubing. The chip design supports the stable growth of patient-derived cholangiocytes in form of a 3-dimensional gravity perfused bile-duct-like channel. Cholangiocytes grown in the chip form a confluent monolayer channel, express key markers of cellular identity and exhibit strong cell-cell contacts (Fig. 1C).

Conclusion: In this proof-of-concept study we provide a robust fluidic platform for culturing patient-derived cholangiocytes in a tubular structure resembling the in vivo architecture of a bile duct. The flexible chip design supports the inclusion of other disease-relevant components, such as bile or relevant immune cells, and can be used in future studies to model various aspects of cholangiopathies in vitro. The use of patient-derived cells further offers possibilities for personalized drug testing approaches.

FRIDAY 23 JUNE

FRI-330

Phenotypic diversity and regeneration in a model of Alagille syndrome recapitulate patient heterogeneity

Linde Sevenants[1], Stefaan Verhulst[2], Franziska Hildebrandt[3], Johan Ankarklev[3], Leo van Grunsven[2], Noémi K. M. Van Hul[1], Emma Andersson[1]. [1]*Karolinska Institute, Cell and Molecular Biology, Stockholm, Sweden;* [2]*Vrije Universiteit Brussel, Liver Cell biology research group, Brussels, Belgium;* [3]*Stockholm University, Department of Molecular Biosciences, Stockholm, Sweden*
Email: noemi.van.hul@ki.se

Background and aims: Alagille syndrome (ALGS) is caused by a mutation in *JAG1 or NOTCH2* and is characterized by bile duct paucity. There is a high phenotypic variability in disease presentation and a genotype-phenotype correlation is lacking. An estimated 60–75% of children with cholestatic ALGS will need a liver transplantation (LT), while others will spontaneously recover their biliary system. We use our *Jag1*$^{Ndr/Ndr}$ model recapitulating hallmark features of ALGS to (1) characterise disease presentation, (2) to identify biomarkers predicting the disease course, and (3) to study mechanisms driving bile duct recovery.

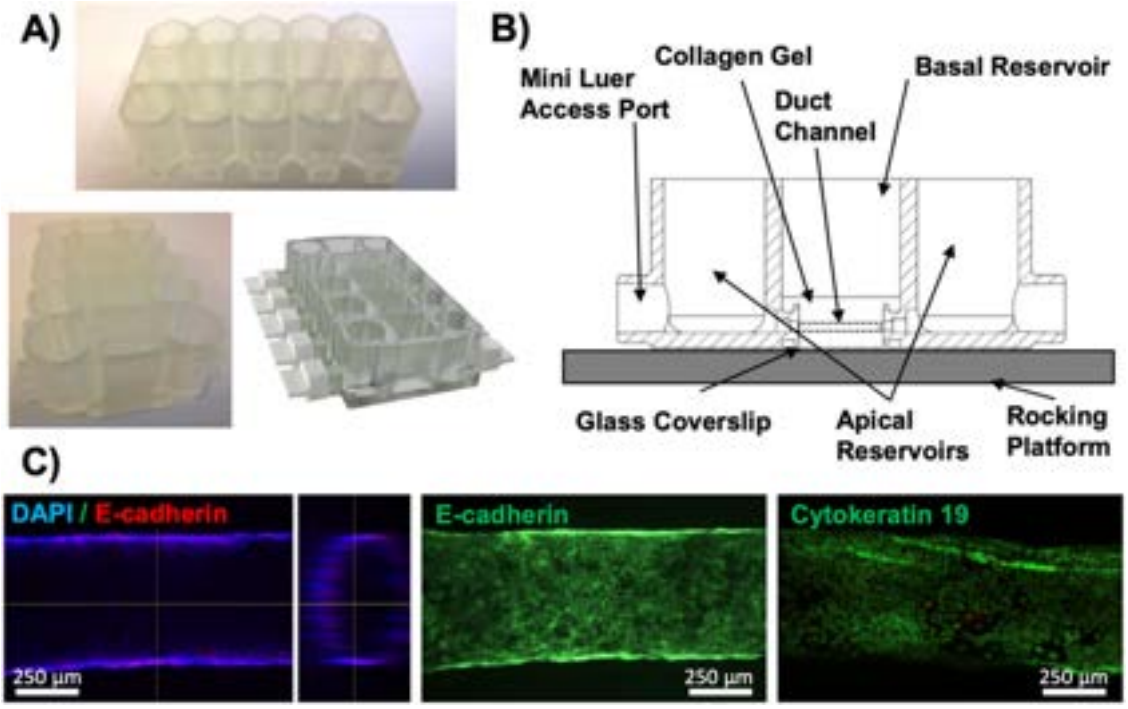

Figure: (abstract: TOP-064): The bile-duct-on-a-chip platform. A) Photos and a schematic of the chip. B) A cross section showing the compartments in the chip design. C) Fluorescent staining of cholangiocytes within the bile-duct-chip showing formation of a tubular structure through nuclear staining (DAPI) with expression of key proteins such as E-cadherin and Cytokeratin 19.

Method: Outbred *Jag1*$^{+/+}$ and *Jag1*$^{Ndr/Ndr}$ mice were sacrificed at P30. Plasma was analyzed for liver function (BR, BA, ALP, ALT). IHC was done on liver sections for early biliary marker SOX9, myofibroblast marker aSMA and proliferation marker Ki67. Spatial transcriptomics (ST) was performed on 4 liver sections from regenerating mice and 4 sections from mice with severe condition.
Results: All *Jag1*$^{Ndr/Ndr}$ pups display strong cholestasis at birth. At P30, three phenotypic groups can be distinguished: mice with (1) a mild phenotype with bile ducts and clear plasma (15 out of 47 mice, representing patients with recovered bile ducts), (2) intermediate severity phenotype with ongoing regeneration and bile infarcts (BIs) (21/47 mice), and (3) regeneration-incompetent mice with severe jaundice and large BIs (11/47 mice, representing patients in need of LT). The BIs in regenerating livers (3–10% of liver surface, preliminary data), were infiltrated by aSMA$^+$ cells and lined by SOX9$^+$hepatocytes implying ongoing biliary reprogramming in these areas. aSMA$^-$ BI (up to 16% of surface) were predominant in severe *Jag1*$^{Ndr/Ndr}$ mice, and SOX9$^+$ hepatocytes around the BIs were sparser and scattered. Finally, there was a strong proliferative response in intermediate mice (increase in Ki67$^+$ cells), but not in severe mice. ST sequencing data of regenerating and severe livers with an estimated 200 spatial spots covering BIs (each spotted array is 100 mm in diameter, and contains mRNA captured from 10 to 60 cells) is currently being analyzed.

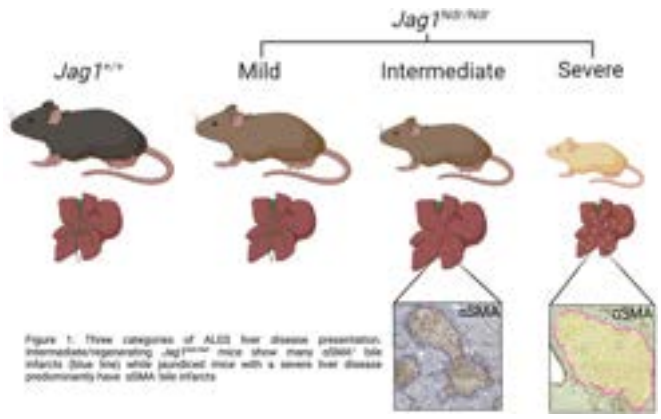

Figure:

Conclusion: *Jag1*$^{Ndr/Ndr}$ mice recapitulate a broad spectrum of liver disease in ALGS at P30. The data indicate a lack of reparative response in severe mice. We hypothesize that aSMA$^+$ BIs act as signaling centers for hepatocyte conversion and biliary regrowth. Using ST, we are investigating the molecular landscape of the BI microenvironment.

FRI-331
Identification of potential targets amenable to novel therapeutics to treat symptoms in primary biliary cholangitis

Email: aaron.wetten@nhs.net

Background and aims: Primary Biliary Cholangitis (PBC) is a progressive autoimmune cholestatic liver disease. Symptoms of pruritus, fatigue and cognitive impairment are common and have a significant negative impact on patients' quality of life. The PBC-40 is a validated, disease-specific, patient-reported outcome measure with well described and validated cut-offs for 'clinically significant' symptoms. The biological mechanisms underpinning these symptoms are poorly understood. The UK-PBC consortium recently published data on an inflammatory proteome associated with disease response. This study further explored the link between the proteome and symptoms in PBC.
Method: An exploratory cohort used O-link serum proteomics of 20 inflammatory markers previously associated with the pathogenesis of PBC were performed on 289 fully-characterised PBC patients from the UK-PBC nested cohort. They were compared to clinically significant symptoms, as assessed using the PBC-40. A validation cohort, using 6 of the markers showing positive associations and a further 5 biologically linked markers, was undertaken using a custom-made multiplex on a symptom heavy cohort of 160 PBC patients (identified from the BANC, RITPBC and UK-PBC cohorts) and 40 healthy controls.
Results: In both the exploratory and validation cohorts, younger age was associated with more severe fatigue (exploratory p = 0.016; validation p = 0.003), and cognitive symptoms (exploratory p < 0.001;

Figure 1: A) Serum IL-6 and clinically significant fatigue in exploratory cohort B) Serum IL-6 and clinically significant fatigue in validation cohort C) Serum IL-4RA and clinically significant pruritus in exploratory cohort D) Serum IL-4RA and clinically significant pruritus in validation cohort

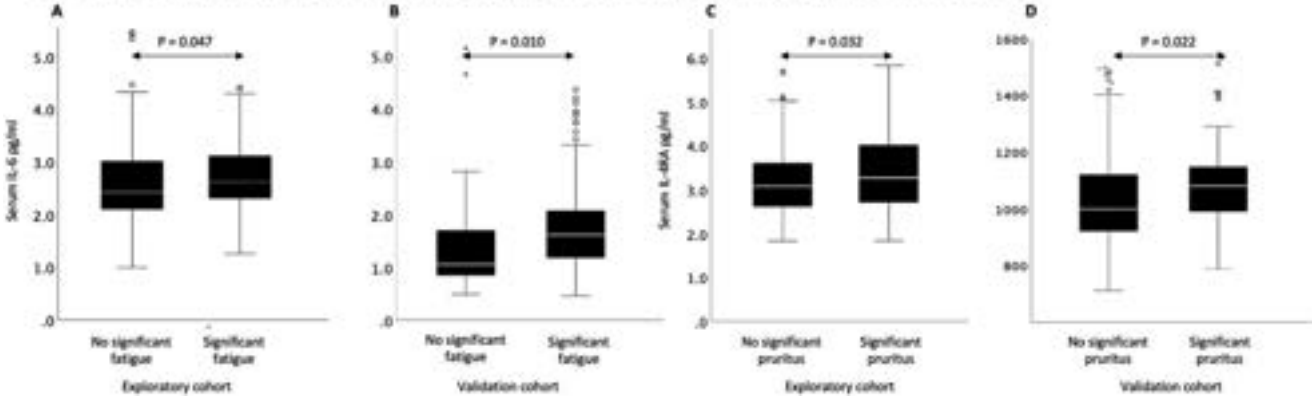

Figure: (abstract: FRI-331).

validation p < 0.001), but not pruritus. Interleukin-6 (IL-6) was positively associated with clinically significant fatigue, as compared with not clinically significant fatigue, in both studies (exploratory: median 2.63 (IQR 0.80) pg/ml vs 2.42 (0.89), p = 0.047; validation: 1.62 (0.89) vs 1.06 (0.86); p = 0.01) [Figure 1A and 1B]. Interluekin-4 Receptor Alpha (IL-4RA) was associated with clinically significant pruritus, as compared with not clinically significant pruritus in both cohorts (exploratory: 3.27 (1.30) pg/ml vs 3.09 (1.01), p = 0.032; validation: 1081 (173) vs 1000 (200); p = 0.022) [Figure 1C and 1D].
Conclusion: Pruritus treatments are effective in some, but not all, patients whilst there are no effective treatments for fatigue or cognitive symptoms. The development of novel therapeutics targeting symptoms remains a significant unmet need in PBC. IL-6 was consistently elevated in two distinct PBC groups with clinically significant fatigue. Elevated IL-6 has previously been implicated in chronic fatigue, skeletal muscle fatigability and mitochondrial dysfunction. With established IL-6 blockade therapies available, this may present a new therapeutic strategy for fatigue. IL-4RA demonstrated a positive association for clinically significant pruritus across both groups. A trial of Dupilumab, an IL-4RA receptor antagonist, is ongoing and may prove to be an effective treatment for cholestatic pruritus.

FRI-332
Anti-nucleosome antibodies as an important marker to distinguish between autoimmune hepatitis and drug-induced liver injury

Mirjam Kolev[1], Guido Stirnimann[1], Henning Nilius[2], Juliette Schlatter[2], Michèle Freiburghaus[1], Michael Nagler[2], Michael Horn[2], Nasser Semmo[1]. [1]*Inselspital, Bern University Hospital, University of Bern, Department of Visceral Surgery and Medicine, Bern, Switzerland;* [2]*Inselspital, Bern University Hospital, University of Bern, Department of Clinical Chemistry, Bern, Switzerland*
Email: nasser.semmo@insel.ch

Background and aims: Antinuclear antibodies (ANA) are positive in 70–100% of patients with autoimmune hepatitis (AIH) and in 22–33% of patients with drug-induced liver injury (DILI), yet little is known about their antigen-specificity. Differentiation between AIH and DILI is often difficult, especially in DILI cases with ANA positivity but no need for immunosuppression. Since treatment strategies differ, correct classification is important. Our aim was to investigate the antigen-specificity of ANA in AIH and DILI patients and to model their value in the classification of the two diseases.
Method: Samples were obtained from the Hepatology Biobank of the University Hospital Bern, Switzerland, from patients with AIH (n = 54) or DILI (n = 29) who were ANA positive at diagnosis or during follow-up. ANA testing was performed with indirect immunofluorescence (IIF), followed by pattern specific antibody testing with enzyme-linked immunosorbent assays (ELISA) according to the International Consensus on Antinuclear Antibody Pattern; e.g. anti-DNA, -histone and -chromatin/nucleosome, when a homogenous pattern was detected. Based on the descriptive results, we built a random forest model with the variables of significance.
Results: The median (IQR) age at diagnosis was 57 years (43.50, 67.75) in the AIH versus 58 years (40, 65) in the DILI group. In the AIH group, 74% were women, in the DILI group 65.5%. The median level of immunoglobulin G was higher in the AIH group (22.20 g/l (14, 31.2)) than in the DILI group (10.5 g/l (9.5, 14.7)) (p < 0.001). The most frequent ANA patterns in AIH were homogeneous in 76% and fine-speckled in 69%. In DILI patients, the most frequent ANA patterns were fine-speckled in 90% and homogenous in 48%. In AIH patients, anti-nucleosome antibodies were detected in 37% of patients compared to 7% in DILI patients (p < 0.01), anti-histone antibodies in 30% in AIH compared to 3% in DILI (p < 0.01). 26% of AIH and 34% of DILI patients remained non-specific after ELISA testing. The Figure shows the mean depth in the random forest model for anti-nucleosome and established AIH-related antibodies. The smaller the mean value, the higher the significance of the variable in the classification of the two diseases.

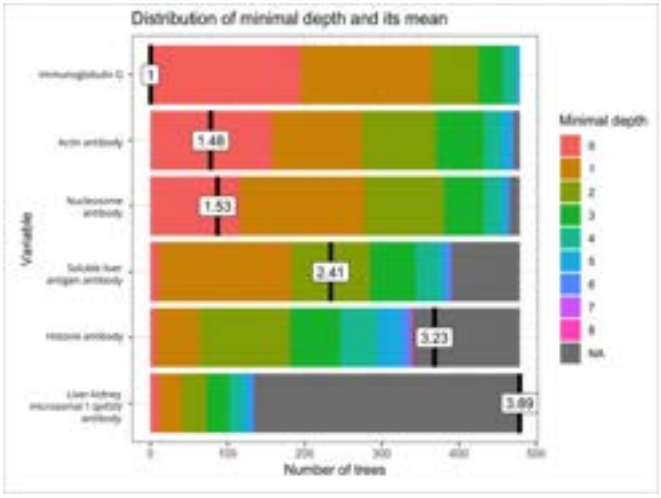

Figure:

Conclusion: Our data shows a significantly higher positivity of anti-nucleosome and anti-histone antibodies in patients with AIH compared to DILI patients. The random forest model shows that anti-nucleosome antibodies are almost as important as the established anti-actin antibody in the classification of AIH and DILI. Therefore, anti-nucleosome antibodies may be able to help distinguish between the two diseases. External validation is the next step to confirm this relationship.

FRI-333
Combination of intestinal bile salt uptake inhibition with pharmacological repression of bile salt synthesis improves liver health in cholestatic mice

Roni Kunst[1], Esther Vogels[1], Isabelle Bolt[1], Ronald Oude-Elferink[1], Stan van de Graaf[1]. [1]*Amsterdam UMC, Tytgat Institute for Liver and Intestinal Research, Netherlands*
Email: k.f.vandegraaf@amsterdamumc.nl

Background and aims: Intestine-restricted inhibitors of the apical sodium-dependent bile acid transporter (ASBT or IBAT) are approved as treatment against cholestasis but also associated with symptoms such as diarrhea and abdominal pain. Furthermore, blocking ASBT alone might be less effective in severe cases of cholestasis. We hypothesize that therapeutic interventions that lower bile salt synthesis provide an effective complementary treatment strategy. Here, we test combination therapies of intestinal ASBT inhibition in combination with obeticholic acid (OCA), cilofexor and NGM282 in a mouse model for cholestasis induced liver injury.
Method: Wild type male C57Bl6J/OlaHsd mice were fed a 0.05% 3,5-diethoxycarbonyl-1,4-dihydro-collidine (DDC)-diet and received daily oral gavage with either 10 mg/kg OCA, 30 mg/kg Cilofexor, 10 mg/kg GSK2330672 (ASBT inhibitor; ASBTi) or a combination. Alternatively, wild type male C57Bl6J/OlaHsd mice were injected with control AAV8 or AAV8-NGM282, a non-tumorigenic analogue of FGF19 to repress bile salt synthesis. While being fed a DDC diet, mice received daily oral gavage with ASBTi or placebo control.
Results: Combination therapy of OCA, Cilofexor and NGM282 with ASBTi effectively reduced fecal bile salt excretion. NGM282+ASBTi further lowered plasma bile salt levels compared to ASBTi monotherapy. Cilofexor+ASBTi and NGM282+ASBTi treatment reduced plasma alanine transaminase and aspartate transaminase levels. Gene expression analysis indicated dampening of inflammatory and fibrotic processes in Cilofexor+ASBTi and NGM282+ASBTi treated mice, and this was confirmed by histology.

Conclusion: Combination therapy of repressed bile salt synthesis and intestinal bile salt uptake is an effective treatment strategy to reduce liver injury while dampening the ASBTi-induced colonic bile salt load in a pre-clinical cholestasis model.

FRI-334

Cholestatic liver disease is alleviated by colitis-induced inhibition of bile acid synthesis

Wenfang Gui[1], Mikal Jacob Hole[2], Antonio Molinaro[3], Karolina Edlund[4], Kristin K. Jørgensen[5,6], Huan Su[1], Brigitte Begher-Tibbe[4], Nikolaus Gaßler[7], Carolin V. Schneider[1], Uthayakumar Muthukumarasamy[8], Antje Mohs[1], Lijun Liao[1,9], Julius Jäger[1], Christian Mertens[1], Ina Bergheim[10], Till Strowig[8], Jan G. Hengstler[4], Johannes R. Hov[2], Hanns-Ulrich Marschall[3], Christian Trautwein[1], Kai Markus Schneider[1]. *[1]University Hospital RWTH Aachen, Medicine III, Aachen, Germany; [2]Norwegian PSC Research Center, Section of Gastroenterology and Research Institute of Internal Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital and University of Oslo, Norway; [3]Department of Molecular and Clinical Medicine/Wallenberg Laboratory, Sahlgrenska Academy, University of Gothenburg, Sweden; [4]Leibniz Research Centre for Working Environment and Human Factors, Technical University Dortmund, Dortmund, Germany; [5]Norwegian PSC Research Centre, Department of Transplantation Medicine, Oslo University Hospital, Rikshospitalet, Norway; [6]Department of Gastroenterology, Akershus University Hospital, Lørenskog, Norway; [7]Institute for Legal Medicine, Section Pathology, University Hospital Jena, Jena, Germany; [8]Helmholtz Centre for Infection Research, Braunschweig, Germany and Hannover Medical School, Hannover, Germany; [9]Department of Anesthesiology and Pain Management, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China; [10]Department of Nutritional Sciences, Molecular Nutritional Science, University of Vienna, Vienna, Austria*
Email: kmschneider@ukaachen.de

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by inflammation and progressive fibrosis of the biliary tracts. The intriguing and strong epidemiological link between PSC and inflammatory bowel disease (IBD) is known for decades, but the mechanisms by which colitis affects cholestatic liver disease remain incompletely understood.
Method: To study the effects of colitis on liver injury, inflammation, fibrosis, and bile acid metabolism in cholestatic liver disease, we established acute and chronic mouse models of PSC-IBD by administering dextran sodium sulfate (DSS) to *Mdr2*$^{-/-}$ mice. The pathophysiological consequences of colitis treatment on WT and *Mdr2*$^{-/-}$ mice were studied based on transcriptomic analyses, histology, flow cytometry, Matrix Assisted Laser Desorption imaging of spatial BA distribution as well as comprehensive BA profiling using UPLC-MS/MS, including the BA synthesis marker C4 (7α-hydroxy-4-cholesten-3-one). By treating *Mdr2*$^{-/-}$ mice with lipopolysaccharide (LPS) and studying the impact of LPS on co-cultured human primary hepatocytes and Kupffer cells, we also investigated whether LPS could phenocopy the effects of bacterial translocation that occurs during colitis induction. Finally, we generated *Mdr2*$^{-/-}$*Nemo*$^{\Delta hepa}$ mice to explore whether hepatocytic NF-kappaB signaling plays a role in inflammation-mediated changes in bile acid metabolism.
Results: DSS treatment induced intestinal inflammation, barrier impairment, and bacterial translocation in WT and *Mdr2*$^{-/-}$ mice. Impaired barrier function was linked to bacterial translocation inducing an increased hepatic inflammatory response but was surprisingly associated with ameliorated liver injury and hepatocellular apoptosis in both acute and chronic DSS treated *Mdr2*$^{-/-}$ mice. Most interestingly, biliary septal fibrosis was improved in *Mdr2*$^{-/-}$ mice with chronic colitis induction. Inflammatory pathways and specifically hepatic NF-kappaB activation inversely correlated with bile acid synthesis reducing hepatic bile acid accumulation, thereby alleviating cholestatic liver injury and fibrosis. Importantly, LPS was sufficient to activate this protective circuit in-vitro and in-vivo, while the absence of NF-kappaB signaling in *Mdr2*$^{-/-}$*Nemo*$^{\Delta hepa}$ mice strongly exacerbated cholestasis.
Conclusion: Here, we identify an unexpected colitis-driven and hepatocytic NF-kappaB-dependent protective circuit in cholestatic liver disease. Our findings may have important implications for the treatment of individuals with PSC suffering from concomitant colitis.

FRI-335

Non-invasive imaging method demonstrates anti-fibrotic efficacy of a dual integrin alpha-v/beta-6 and alpha-v/beta-1 inhibitor in a rat model of biliary fibrosis

Johanna Schaub[1], Yingying Ning[2], Iris Y. Zhou[2], Nicholas Rotile[2], Avery Boice[2], Jessie Lau[1], Peter Caravan[2], Scott Turner[1]. *[1]Pliant Therapeutics, United States; [2]Massachusetts General Hospital and Harvard Medical School, United States*
Email: jschaub@pliantrx.com

Background and aims: There is an unmet need for antifibrotic treatments which can prevent, halt or reverse hepatic fibrosis in

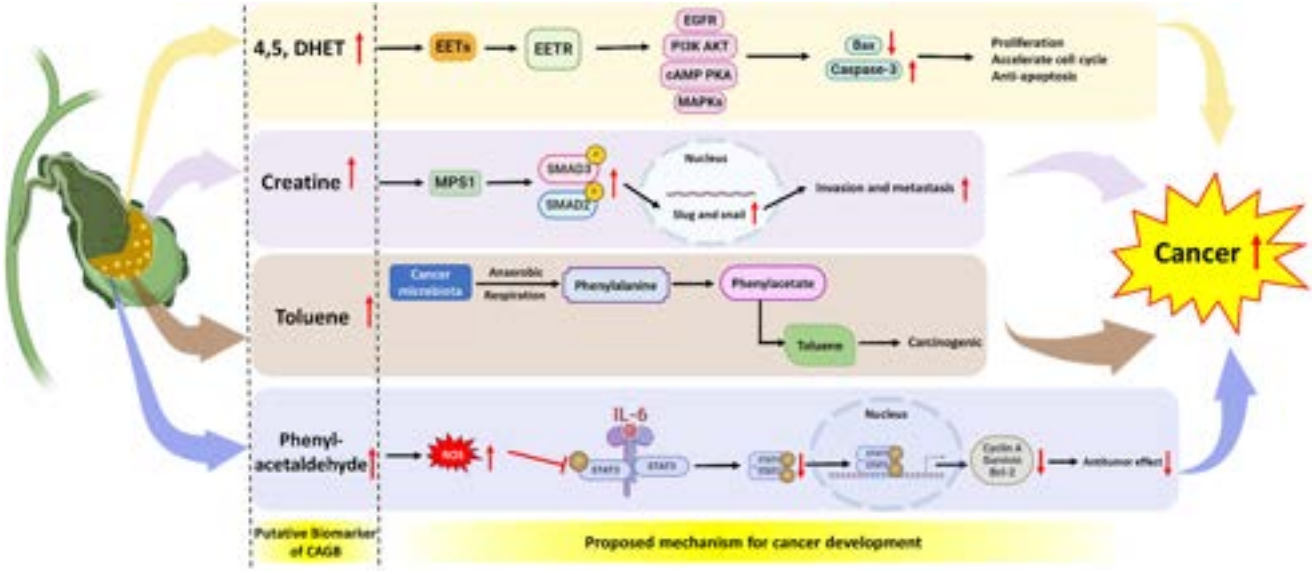

Figure: (abstract: FRI-344): Putative biomarkers and their proposed mechanism for CAGB

chronic liver diseases; however, drug development efforts have been hampered by a lack of non-invasive methods to measure fibrosis. In primary sclerosing cholangitis, integrins overexpressed on injured cholangiocytes (alpha-v/beta-6) and myofibroblasts (alpha-v/beta-1) are attractive therapeutic targets because they bind and activate latent TGF-beta, a key driver of liver fibrosis. Here, we used molecular MRI with CM-101, a type I collagen probe that directly measures fibrosis, and PET with an alpha-v/beta-6 probe to provide a non-invasive readout of anti-alpha-v/beta-6 and alpha-v/beta-1 antagonism in a rat model of biliary fibrosis.

Method: Liver fibrosis was induced in rats by ligation of the common bile duct (BDL). The selective integrin alpha-v/beta-6 and alpha-v/beta-1 antagonist PLN-169 was dosed orally 4–17 days post-BDL. MRI with CM-101 and PET with a ^{68}Ga-DOTA-alpha-v/beta-6 cysteine knot probe were performed on days 6 and 18 post-BDL. On day 18, livers were collected for histological and molecular analysis. Sirius Red was used to stain collagen and fibrosis assessment was performed measuring collagen proportional area (CPA) in ImageJ and with Fibronest (PharmaNest). Gene expression changes were measured using the NanoString platform.

Results: Bile duct ligation significantly increased the levels of integrin alpha-v/beta-6 in the liver 18 days post-surgery as assessed by ex vivo gene expression (>10×, $p < 0.05$) and by in vivo alpha-v/beta-6 PET imaging (2.6×, $p < 0.05$). BDL resulted in severe fibrosis with 22× increase in CPA and a significant increase in Phenotypic Fibrosis Composite Score (Ph-FCS) (both $p < 0.0001$). Treatment with PLN-169 significantly reduced hepatic accumulation of the alpha-v/beta-6 PET probe (34%, $p < 0.05$) and markedly attenuated histological measures of fibrosis with >50% decrease in CPA ($p < 0.0001$) and decreases in multiple phenotypic measures of fibrosis. MRI with CM-101 showed a significant increase in liver-to-muscle contrast to noise ratio (delta-CNR) in BDL animals compared to sham animals on day 18 (4.5×, $p < 0.0001$) as well as a significant decrease in BDL animals with PLN-169 treatment (45%, $p < 0.05$). Delta-CNR significantly increased in vehicle-treated animals from day 6 to day 18 (>2.0×, $p < 0.05$) but not in PLN-169-treated animals. Importantly, delta-CNR correlated with the direct measurement of collagen from digital pathology (CPA, $r = 0.65$, $p < 0.001$).

Conclusion: PET imaging for alpha-v/beta-6 and molecular MRI of collagen can non-invasively assess target expression, target engagement, and treatment response of an integrin alpha-v/beta-6 and alpha-v/beta-1 antagonist in a rat model of biliary fibrosis. This study raises the possibility that non-invasive methods may be valuable for evaluating treatment responses in liver fibrosis and supporting drug development in this field.

FRI-336

Blockade of IL-18 via long-acting IL-18 binding protein attenuates experimental diet-induced cholestatic disease

Dong-Hyun Kim[1], Jin Joo Park[2], Mi-Hyun Park[2], Kyungsun Lee[2], Jaekyu Han[2], Susan Chi[2], Moo Young Song[2], Seung Goo Kang[2,3], Sang-Hoon Cha[2], Yong-Hyun Han[1]. *[1]Laboratory of Pathology and Physiology, College of Pharmacy, Kangwon National University, Korea, Rep. of South; [2]AprilBio Co., Ltd., Korea, Rep. of South; [3]Division of Biomedical Convergence, College of Biomedical Science, Kangwon National University, Korea, Rep. of South*
Email: yhhan1015@kangwon.ac.kr

Background and aims: Primary sclerosing cholangitis (PSC) is defined as a cholestatic liver disease characterized by multiple segmental strictures in the hepatic bile ducts. Eventually, chronic biliary inflammation drives liver fibrosis and cirrhosis, and there are no clinically effective therapeutic drugs to cure PSC disease. IL-18 binding protein (IL-18BP) is a secretory protein and acts as a high affinity neutralizer for IL-18. Here, we developed SAFA-IL-18BP (APB-R3), a long-acting version of IL-18BP that covalently attached to an anti-serum albumin Fab (SAFA), and evaluated whether blockade of IL-18 via APB-R3 reduce PSC-induced injury markers such as bile ductal reactions, fibrosis, and senescence.

Method: To establish diet-induced PSC model, we provided 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) diet to mice. Mice were intraperitoneally injected with APB-R3 at a dose of 10 mg/kg in a volume of 5 ml/kg thrice a week from day 0 to day 20 of feeding period.

Results: We first found that expression of hepatic IL-18 and IL-18BP was enhanced in DDC diet-induced PSC conditions. We observed that administration of APB-R3 effectively decreased key indicators related with hepatobiliary disease such as plasma ALP and GGT activities as well as bile acid levels. Bile ductular reactions were also inhibited by APB-R3 injection. Furthermore, APB-R3 significantly suppressed periductal fibrosis and transcriptional activations of hepatic pro-fibrotic genes. Finally, we revealed that APB-R3 decreased senescence-associated secretory phenotype (SASP) markers such as TGFβ, IL-1β, MMP3 and p27.

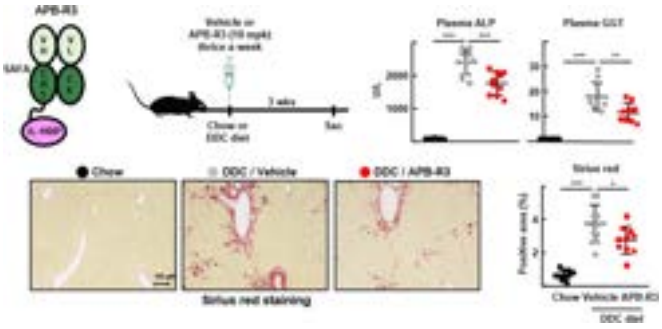

Figure:

Conclusion: The long-acting IL-18BP, APB-R3, effectively ameliorates DDC diet-induced biliary injuries in rodent PSC model. These pre-clinical results suggest that APB-R3 can be potential leading therapeutic drug to relieve PSC disease, and our results warrant further clinical trial studies.

FRI-344

Proteomics and metabolomics of bile reveal molecular insights and classify signatures predictive of carcinoma of gallbladder

Jaswinder Maras[1], Nupur Sharma[1], Sadam H. Bhat[1], Babu Mathew[1], Manisha Yadav[1], Gaurav Tripathi[1], Vasundhra Bindal[1], Neha Sharma[1], Sushmita Pandey[1], Hami Hemati[2,3], Deepika Bohra[4], Rashmi Rana[4], Sanyam Falari[5], Viniyendra Pamecha[5]. *[1]Institute of liver and biliary sciences, Molecular and cellular medicine, New Delhi, India; [2]University of Kentucky, Department of toxicology and cancer biology, Lexington, United States; [3]University of Kentucky, Department of Toxicology and Cancer Biology, Lexington, United States; [4]Sir ganga ram hospital, Department of research, New Delhi, India; [5]Institute of liver and biliary sciences, Department of liver transplant and hepato pancreato biliary surgery, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Carcinoma of the gall bladder (CAGB) has poor prognosis. Bile concentrated in the gallbladder (GB) is expected to recapitulate molecular (proteome/metabolome) alteration which may provide critical pathophysiological insight linked with the development of CAGB. Reliable biomarker-based assays with high sensitivity and specificity for detection of this cancer are a clinical need.

Method: In this cross-sectional study, 127 patients admitted at ILBS (CAGB, n = 37; Gallstone (GS), n = 60; Healthy liver donor (HC), n = 30) were classified into training and test cohort. In training cohort, bile samples (n = 87) were collected from patients undergoing cholecystectomy for GS disease and grouped as GS (n = 40) and patients undergoing surgery for CAGB were grouped as CAGB (n = 17); we also collected healthy liver donor samples (n = 30). Whereas in the test

cohort, both bile (T1, n = 20) and plasma (T2, n = 20) samples were analysed and validated using machine learning (ML) approach.
Results: Bile samples were screened for proteomics/metabolomics signatures capable of early detection of cancer in GB anomalies. Bile of CAGB showed distinct proteomic (217up- and 258 downregulated; FC>1.5) and metabolomic (111 up- and 505 downregulated; FC>1.5) profiles compared to GS or HC ($p < 0.05$, FDR<0.01). Partial least square discriminant analysis (PLS-DA) and unsupervised hierarchical clustering showed clear segregation of CAGB from other groups. CAGB bile was significantly enriched for proteins/metabolites linked to inflammation (complement and coagulation cascade, arachidonic acid metabolism, bile acid, tryptophan, and sphingolipid signaling, ferroptosis and others), alternate energy pathways (pentose phosphate pathway, amino acid metabolism, lipid metabolism, and others). Proteins/metabolites decreased were associated to glycolysis, cholesterol metabolism, PPAR, RAS and RAP1 signaling glutathione, pyruvate, histidine, purine metabolism, oxidative phosphorylation and others. Integration analysis revealed strong correlation ($r2 > 0.5$, $p < 0.05$) between significant proteins/metabolites and clinical parameters and showed alteration of pathways linked to lipid metabolism, platelet activation, amino acid metabolism and others ($p < 0.05$). Metabolite/protein signature based probability of detection for CAGB was >90% ($p < 0.05$) with AUC>0.94. Validation of top four metabolite panel: Toluene, 5, 6-DHET, Creatine and Phenyl acetaldehyde using five machine-learning algorithms in n = 40 samples from T1 and T2 showed highest accuracy (99%) and sensitivity/specificity (>98%) for CAGB detection.
Conclusion: Bile proteome/metabolome alteration provides key molecular insight in development of CAGB. We put forward a core set of bile signatures which may offer universal utility for early detection of CAGB.

FRI-345

Serum proteomics reveals association of CCL24 with key aspects of primary sclerosing cholangitis

Raanan Greenman[1], Tom Snir[1], Avi Katav[1], Omer Levi[1], Revital Aricha[1], John Lawler[2], Douglas Thorburn[3], Massimo Pinzani[4], Ilan Vaknin[1].
[1]Chemomab Ltd., Israel; [2]Chemomab Inc., Clinical Operations, United States; [3]Royal Free Hospital School Of Medicine, London, United Kingdom; [4]UCL Institute of Immunity and Transplantation, London, United Kingdom
Email: raanan@chemomab.com

Background and aims: CCL24, also known as Eotaxin-2, is a pro-inflammatory, pro-fibrotic chemokine overexpressed in livers of patients with primary sclerosis cholangitis (PSC), predominantly in areas of evident biliary injury. CCL24 blockade, using a monoclonal antibody, was shown to interfere with core pathways that induce PSC pathophysiology in pre-clinical models. Here, we further demonstrate the role of CCL24 in PSC and its association with disease related pathways through the analysis of proteomic data from the serum of patients with PSC and from an in-vitro model.
Method: Sera from healthy controls (n = 30) and patients with PSC (n = 45) were analyzed using the Olink proximity extension assay (PEA) of 3072 proteins. Individuals' demographics, enhanced liver fibrosis (ELF) scores and alkaline phosphatase (ALP) levels were documented. To evaluate the direct effect of CCL24 on hepatic cells, an LX2 hepatic stellate cell (HSC) line was stimulated with CCL24 and subsequently blocked by a neutralizing monoclonal antibody (CM-101). Conditioned media underwent proteomic profiling using a proteomic chip (L-507; RayBiotech). Data was analyzed using bioinformatic and computational tools.
Results: The serum proteomics data was stratified according to 3 comparisons: (1) healthy controls vs. patients with PSC, (2) fibrosis severity as defined by ELF score (9.8 cutoff) in patients, and (3) serum levels of CCL24 in patients. These stratifications identified differentially expressed proteins (DEP; by Welch two sample t-test). that were used for pathway enrichment analysis. This analysis found enriched pivotal pathways such as HSC activation/hepatic fibrosis, Th1/Th2 activation and granulocyte adhesion, that were activated in patients with PSC, patients with severe fibrosis and patients with elevated CCL24. Moreover, CCL24 levels were significantly correlated with serum proteins frequently associated with inflammation, fibrosis and vascularization (e.g., CXCL10, collagens, and VEGFA) in patients with ALp >1.5 ULN.
In-vitro, CCL24 stimulated HSC manifest a set of upregulated proteins that are commonly elevated in serum of patients with severe PSC. This CCL24 dependent altered protein expression was blocked following treatment with CM-101.

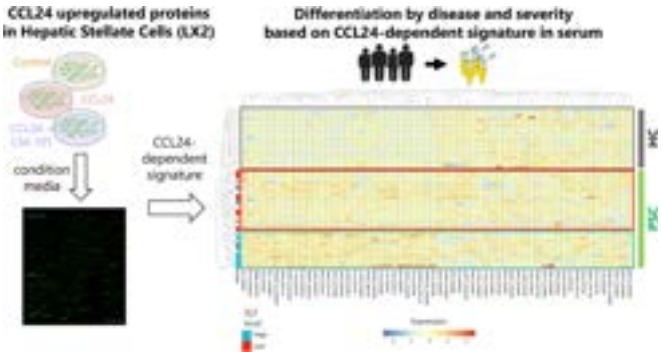

Figure:

Conclusion: This study provides novel insights into the role of CCL24 in PSC and its association with disease-related pathways and severity. We identified a potential CCL24 related signature in PSC that supports the ongoing phase 2 study of CM101 in patients with PSC.

FRI-346

Combination of Ileal bile acid transporter inhibitor and a non-steroidal Farnesoid X receptor agonist for reversal of cholestatic liver injury in Cyp2c70 KO mice with a humanized bile acid composition

Caroline Klindt-Morgan[1], Jennifer Truong[1], Ashley Bennett[1], Kimberly Pachura[1], Diran Herebian[2], Ertan Mayatepek[2], Saul J. Karpen[1], Paul Dawson[1]. *[1]Emory University School of Medicine and Children's Healthcare of Atlanta, Department of Pediatrics, Atlanta, United States; [2]Heinrich-Heine University, Department of General Pediatrics, Neonatology, and Pediatric Cardiology, Medical Faculty, Heinrich-Heine-University, Düsseldorf, Germany, Dusseldorf, Germany*
Email: cklindt@emory.edu

Background and aims: Cyp2c70 has been identified as the key enzyme in mice for synthesis of hepatoprotective 6-hydroxylated muricholates. *Cyp2c70 knockout (2c70 KO)* mice have a more hydrophobic human-like bile acid (BA)-composition and develop signs of cholestatic liver injury. Preventive monotherapy with an ileal BA transporter (IBAT) inhibitor reduces hepatic BA burden and alleviates liver injury in these mice. However, it is unclear if there is an intrahepatic BA threshold for onset of liver injury and if short-term complementary therapies designed to reduce the hepatic BA pool can reverse the hepatotoxicity in this model. The non-steroidal Farnesoid-X-Receptor (FXR) agonist Cilofexor inhibits BA-synthesis and has been shown to reduce fibrosis in a model for NASH in rats.
Method: 12-week-old male and female *2c70 KO* and wild type (WT) mice (C57Bl/6J) were fed chow or a diet containing an IBAT inhibitor (0.006% SC-435) and/or an FXR agonist (0.015% Cilofexor) for 14 days. Upon sacrifice, livers were collected for histology, immunohistochemistry, RT-PCR and gas-liquid chromatography. Blood samples were analyzed for serum biochemistry.
Results: By the age of 12 weeks, female *2c70 KO* mice exhibited cholestatic liver injury as indicated by elevated serum liver injury markers (AST and ALT) and histological evidence of liver inflammation and fibrosis. Therapy with SC-435 as well as Cilofexor

significantly reduced ALT and AST levels (e.g. AST decreased by >86% and 79% respectively compared to chow) after 14 days of treatment without significant additional effect in combination. Liver BAs were significantly reduced in all treatment groups as compared to chow. RT-PCR analysis showed a reduction of inflammatory markers in the Cilofexor and Cilofexor + SC-435 groups in comparison to chow (e.g. Tgf-beta reduced by >73% and 76% and Interleukin-1 beta reduced by >81% and 76% respectively). Fibrosis as indicated by Sirius Red staining showed a tendency for decrease especially after combination therapy without reaching significance (reduction of 62% in Cilofexor + SC-435 as compared to chow).

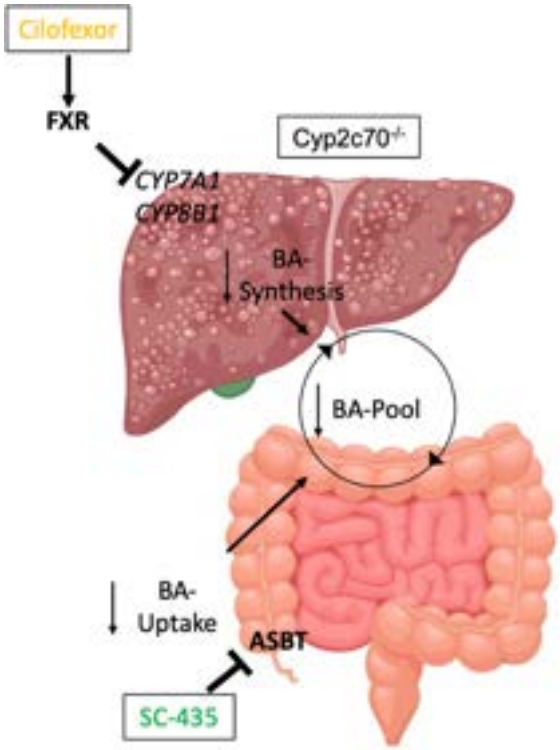

Figure:

Conclusion: Short term therapy with an IBAT inhibitor after onset of liver injury in *2c70 KO* mice can reduce liver injury but is insufficient for a complete rescue. The therapeutic benefit associated with short term combined administration of Cilofexor and SC-435 shows a tendency for a synergistic effect in reducing inflammation but has no significant effect on fibrosis.

FRI-347

Production of reactive oxidant species and fatty acid uptake is increased in regulatory T-cells in autoimmune hepatitis, and associated with down-regulation of markers linked to suppressor function

Scott Davies[1], Naomi Richardson[1], Grace Wootton[1], Ye Htun Oo[1,2], Palak Trivedi[1,2]. [1]*University of Birmingham, National Institute for Health Research (NIHR) Birmingham Biomedical Research Centre (BRC), Birmingham, United Kingdom;* [2]*University Hospitals Birmingham, Liver Unit, United Kingdom*
Email: p.j.trivedi@bham.ac.uk

Background and aims: Autoimmune hepatitis (AIH) is characterised by a breach in liver immune tolerance. Inflammatory triggers are largely unknown, but dysregulated activity and function of regulatory T cells (Tregs) are proposed to contribute. In this study, we evaluated metabolic functions of Tregs in patients with AIH with evidence of well-controlled disease, alongside expression of functional markers in liver-infiltrating cell populations.

Method: Peripheral blood mononuclear cells (PBMCs) were isolated from patients (pts) with AIH. Tregs were characterized according to the following profile: CD4+ $CD25^{hi}$, $CD127_{LO}$. Cells were then labelled with fluorescent dyes reporting the production of reactive oxidant species (ROS), fatty acid uptake and mitochondrial activity. All cells were analysed by flow cytometry whilst acquiring median fluorescence intensity values. Control blood samples were obtained from patients with haemochromatosis (HFE) undergoing venesection without evidence of liver disease. Disease control PBMCs were also obtained from individuals with primary biliary cholangitis (PBC) and alcohol-induced liver disease (ALD).

Results: Firstly, peripheral blood was obtained from 5 patients with AIH (median age 50, 60% men, median ALT and bilirubin values 36 U/L and 19 micromol/L, respectively). Circulating Tregs displayed higher production of ROS compared to that of patients with haemochromatosis. This observation was coupled with increased fatty acid uptake and reduction in mitochondrial mass (Fig 1A–C). Next, protein expression of functional markers was evaluated in Tregs derived from a separate cohort of AIH patients (median age 37.5, 43% men, median ALT and bilirubin values 46 U/L and 12.5 mg/dL, respectively). These included reductions in CD39 expression and lower values for CTLA-4 and FOXP3, as compared to HFE (Fig 1D–F). Such changes were not observed in peripheral blood Tregs obtained from patients with PBC and ALD.

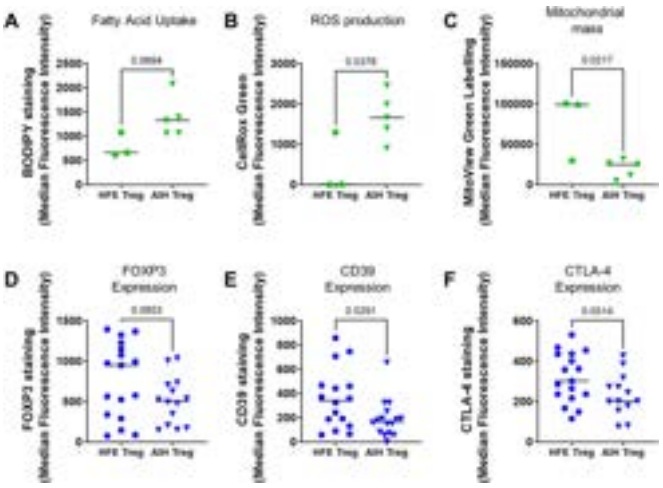

Figure:

Conclusion: In AIH, mitochondrial dysfunction and heightened fatty acid oxidation may lead to generation of ROS, reducing the suppressive activity of Tregs. Mitigating ROS production may rescue the immunosuppressive activity of Tregs and requires exploration as part of cell therapy trials to promote long-term immune tolerance.

FRI-348

The cell cycle protein Cyclin E1 mediates pro-inflammatory signals in a mouse model of acute hepatitis and in primary macrophages

Christian Penners[1], Anna Verwaayen[1], Antje Mohs[1], Alexander Jans[1], Julia Hennings[1], Matthias Bartneck[1], Christian Trautwein[1], Roland Sonntag[1], Christian Liedtke[1]. [1]*University Hospital RWHT Aachen, Department of Medicine III, Germany*
Email: cliedtke@ukaachen.de

Background and aims: Cyclin E1 is a regulatory subunit of cyclin-dependent kinase 2 (CDK2) and mediates the transition from quiescence into the S-Phase of the cell cycle. We previously identified unexpected essential functions of Cyclin E1 for liver fibrogenesis as well as for initiation and progression of hepatocellular carcinoma. However, the effector cells of Cyclin E1 in the liver have not yet been fully identified. In particular, the potential role of Cyclin E1 in liver

resident and circulating immune cells is poorly investigated. Therefore, in the present study we aimed to investigate the role of Cyclin E1 in immune cells during acute liver inflammation.

Method: For our study we used constitutive Cyclin E1 knockout (*Ccne1*$^{-/-}$) mice and Wildtype (WT) controls in a C57BL/6 background. Acute liver injury was induced using the established Concanavalin A (ConA) model of immune-mediated hepatitis; mice were sacrificed after 24 hours. Explanted livers were investigated by histological analysis, FACS, qPCR and ELISA. Bone marrow-derived macrophages (BMDM) were isolated from *Ccne1*$^{-/-}$ and WT mice and analyzed for differentiation, cell cycle activity and pro-inflammatory polarization. *In vitro* knockdown of *Ccne1* was performed using the macrophage cell line J774A.1 and anti-*Ccne1* siRNA encapsulated in lipid nanoparticles (LNP).

Results: Surprisingly, *Ccne1*$^{-/-}$ mice showed improved survival after ConA-treatment, which was associated with significantly reduced liver necrosis compared to WT controls. In addition, loss of *Ccne1* was related to down-regulation of pro-inflammatory mediators such as interleukin-6 (IL6), tumor necrosis factor alpha (TNF), and CC-chemokine ligand 2 (CCL2), which are typically expressed in macrophages. We thus tested the impact of *Ccne1* deletion in pro-inflammatory polarized BMDMs. Importantly, Ccne1$^{-/-}$ BMDMs also revealed reduced IL6 expression in comparison to WT controls. Of note, *Ccne1*$^{-/-}$ BMDMs did not show any changes in cell cycle progression or in myeloid progenitor cell to macrophage differentiation. These findings were validated in an interventional approach. To this end pro-inflammatory polarized J774A.1 cells were treated with anti-*Ccne1* siRNA-LNPs, which was sufficient to significantly reduce IL6 expression.

Conclusion: In this study we provide evidence for a novel, pro-inflammatory function of Cyclin E1, which is fully independent from its canonical role as a cell cycle mediator. This involves the transcriptional up-regulation of interleukin-6 via Cyclin E1 in macrophages. Our data suggest that interventional inhibition of Cyclin E1 could be a promising approach for treatment of acute immune-mediated hepatitis.

FRI-349

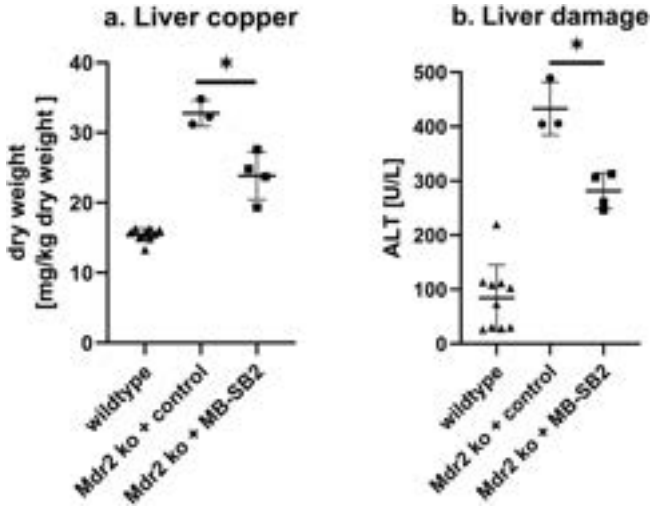
Depletion of excess liver copper ameliorates liver damage in a mouse model of chronic cholestatic liver disease

Dennis Koob[1], Judith Nagel[2], Jingguo Li[1,3], Sebastian Zimny[1], Ralf Wimmer[1], Gerald Denk[1], Martin Roderfeld[4], Elke Roeb[4], Svetlana Lutsenko[5], Hans Zischka[2,6], Simon Hohenester[1]. [1]*University Hospital LMU, Department of Medicine II, Munich, Germany;* [2]*Technical University of Munich, Deparment of Toxicology and Environmental Hygiene, Munich, Germany;* [3]*Affiliated Hospital of Zunyi Medical University, Deparment of Gastroenterology, Zunyi, China;* [4]*Justus Liebig University, Gastroenterology/Center for Internal Medicine, Gießen, Germany;* [5]*John Hopkins Medical Institute, Deparment of Physiology, Boston, United States;* [6]*Helmholtz Center Munich, Institute of Molecular Toxicology and Pharmacology, Munich, Germany*
Email: dennis.koob@med.uni-muenchen.de

Background and aims: Disturbed copper (Cu) homeostasis in the liver, as seen in Wilson's disease, can cause liver damage. Cu accumulation also occurs in cholestatic liver disease, though to a lesser extent. In primary sclerosing cholangitis, Cu accumulation, i.e. orcein staining as a component of the Nakanuma score, even seems to predict poor transplant-free survival. We hypothesize that Cu accumulation might not only be a consequence of cholestasis, but also modulate the course of disease. We aimed to investigate the role of Cu accumulation in animal models of cholestasis and identify potential treatment targets.

Method: Hepatic Cu content was determined in wild type and Mdr2ko animals on FVB, BL6 or BALBc background as well as in Atp7b/Mdr2 (BL6) double knockout mice (DKO). Mice were fed a control or Cu-enriched diet or treated with the potent Cu chelator methanobactin (MB)-SB2. The hepatocyte cell line HepG2 was stably transfected with Ntcp to allow for bile salt uptake and was stimulated with glycochenodeoxycholate (GCDC) and/or Cu (5–10μM, each). Cell survival and apoptosis were assessed, as well as the recently described cell death mode cuproptosis.

Results: While liver Cu was not different between Mdr2ko and wt mice on FVB background, we found a 1.5 ± 0.2-fold increase in Cu levels in Mdr2/BALBc (15.4 ± 0.9 vs. 24.5 ± 2.8 mg/kg in wt/BALBc vs. Mdr2/BALBc, n = 5, p < 0.05). This was associated with more advanced liver fibrosis (liver hydroxyproline 167.5 ± 31.7 vs. 252.8 ± 56.6 μg/g, Mdr2/BL6 vs. Mdr2/BALBc, n = 7, p < 0.05). In DKO, liver Cu was increased 1.5 ± 0.3 -fold (vs. Mdr2/BL6), again associated with a trend towards increased liver hydroxyproline. Feeding a Cu-enriched diet led to an increase in liver Cu in Mdr2/FVB, but not in wt FVB, again associated with a 2.2 ± 0.3-fold increase in liver hydroxyproline. Treatment of Mdr2/BALBc mice with MB-SB2 over 4 weeks was able to decrease excess liver Cu content (Figure 1a). This was associated with a marked amelioration of liver damage (ALT, Figure 1b). In HepG2, both GCDC and Cu were non-toxic in the concentrations applied in metabolic assays. Combination of both stimuli, however, led to a marked impairment of cell survival. While caspase-3/-7 assays excluded apoptosis, detection of DLAT-oligomers via Western blotting indicated presence of cuproptosis upon co-stimulation with Cu+GCDC. This was supported by the finding that preload of HepG2 with lipioic acid, intended to prevent cuproptosis, indeed improved cell survival (66.8 ± 13.9 vs. 83.8 ± 11.3% for Cu/GCDCA vs. Cu/GCDCA/lipioic acid, n = 6, p < 0.05).



Conclusion: Hepatic copper deposition in Mdr2 ko mice is associated with more advanced liver fibrosis, mimicking the human phenotype in PSC. Effective copper chelation by use of MB-SB2 ameliorated liver damage in Mdr2 ko animals. On a cellular level, bile salts and Cu act synergistically to cause cell death, potentially via the route of cuproptosis.

Genetic predisposition for liver inflammation and response to anti-cholestatic therapy in experimental sclerosing cholangitis

Ramesh Kudira[1], Srikar Pasula[1], Annika Yang vom Hofe[1], Liva Pfuhler[1], Manavi Singh[1], Jennifer Kasten[2], Anas Bernieh[2], Cory Kostrub[3], Pamela Vig[3], Ty Troutman[4], Alexander Miethke[1]. [1]*Cincinnati Children's Hospital Medical Center, Pediatric Gastroenterology, United States;* [2]*Cincinnati Children's Hospital Medical Center, Pediatric Pathology and Laboratory Medicine, United States;* [3]*Mirum Pharmaceuticals, United States;* [4]*Cincinnati Children's Hospital Medical Center, Allergy and Immunology, United States*
Email: alexander.miethke@cchmc.org

Background and aims: Genetic deletion of the phospholipid floppase MDR2 causes sclerosing cholangitis from biliary

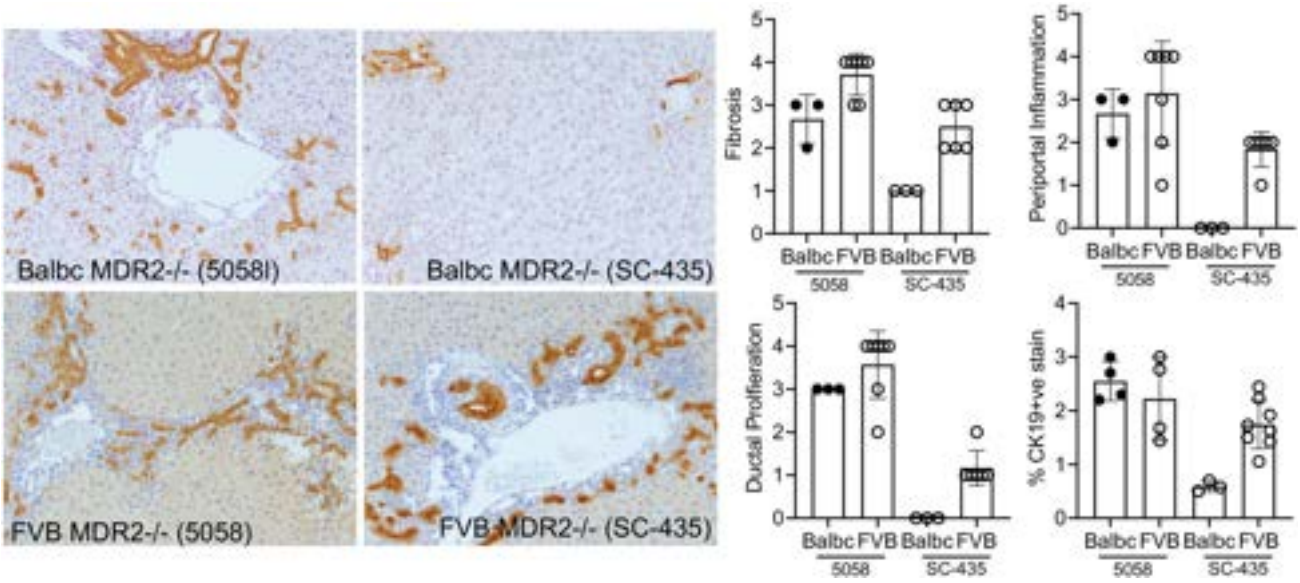

Figure: (abstract: FRI-350).

precipitation of unopposed bile acid microcrystals. FVB background mice with such deletion are prone to HCC, whereas BALB/c background mice with the same deletion display accelerated fibrosis. Here we examine treatment response differences between MDR2 $^{-/-}$ mice in FVB or BALB/c backgrounds receiving SC-435, a minimally absorbed inhibitor of IBAT-mediated intestinal bile acid reuptake. This may have clinical relevance for identifying novel injury pathways to be targeted in combination with current anti-cholestatic therapies.
Method: In 30-day-old female MDR2-/- mice, sclerosing cholangitis phenotype and treatment response to SC-435 admixed to chow were compared between FVB and BALB/c backgrounds using serum biochemistries, liver histomorphology, and flow cytometry.
Results: At 30 days of life, serum ALT and ALP levels were higher in MDR2$^{-/-}$ mice in FVB background compared with BALB/c, accompanied by more severe periportal inflammation and ductal proliferation. When mice were treated with SC-435 from days 30–45, greater ALT level reduction compared with median levels of age- and strain-matched MDR2$^{-/-}$ mice receiving 5058 chow occurred in BALB/c background (Δ ALT: – 93% vs – 37% in BALB/c vs FVB mice; $p < 0.0001$). ALP only improved in BALB/c mice (Δ ALP: – 63% vs + 62%, $p < 0.0001$). The differences were corroborated by liver histomorphology scoring on a 0 to 4+ scale and CK19 immunohistochemistry with image analysis to determine the biliary mass (Figure). 30-day-old MDR2$^{-/-}$ mice in FVB background had higher frequencies of CD3^{+} cells and lower frequencies of CD11b^{+}F4/80^{low} monocytes compared to BALB/c. Following treatment with SC-435, BALB/c background mice had significantly higher frequencies of anti-inflammatory Ly6C^{neg} monocytes (4.5 vs 0.43% of CD45+ cells, $p = 0.002$) and regulatory T cells (4.0 vs 1.4% of CD45+ cells, $p = 0.009$) relative to FVB mice.
Conclusion: Genetic traits underlying distinct injury responses in mice of different backgrounds control liver inflammation and response of bile duct epithelial injury to IBAT inhibitor treatment in experimental sclerosing cholangitis. Single-cell ATACseq studies on purified liver infiltrating myeloid and lymphocyte populations are underway to interrogate chromatin accessibility and underlying genetic variants contributing to the strain-dependent immune response differences.

FRI-351
In vitro modulation of fibrogenesis and inflammation in patient-derived cholangiocyte organoids

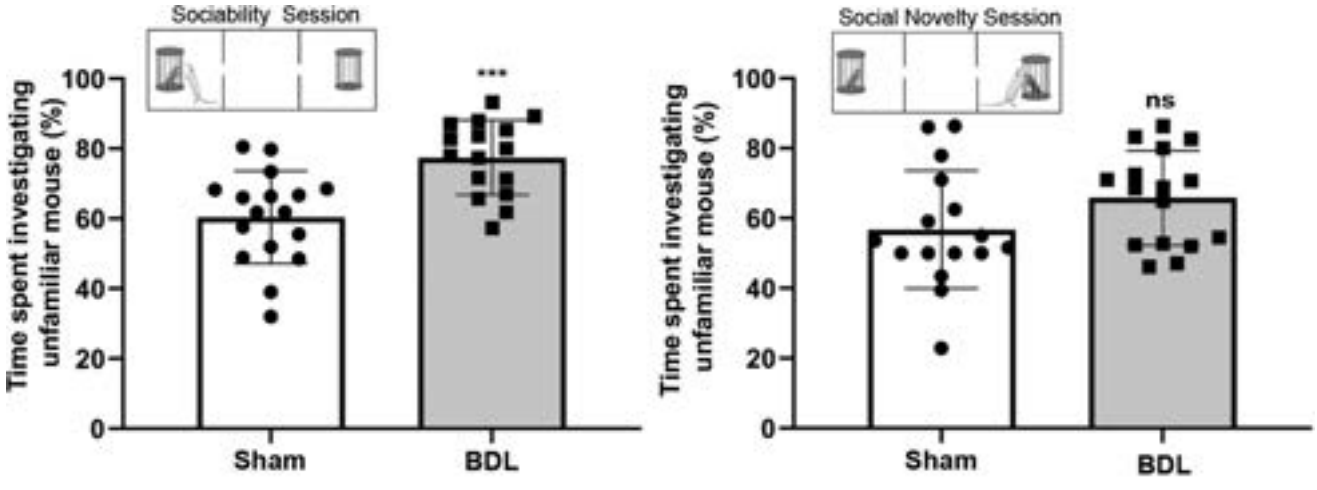
Email: anna.frank@medisin.uio.no

Background and aims: Cholangiocytes represent the main target in the disease process in primary sclerosing cholangitis (PSC), yet there is scarce knowledge on their role in the progression and resolution. Cholangiocyte senescence and senescence-associated secretion of inflammatory and fibrogenic mediators into the surrounding liver tissue are suggested as potential drivers of PSC. By obtaining a highly secretive phenotype, cholangiocytes could participate in modulating disease progression through recruitment and activation of immune

cell populations. We aimed to interrogate the inflammatory and fibrogenic capacity of patient-derived cholangiocytes after prolonged 3D cell culture.
Method: Human cholangiocytes were isolated from extrahepatic bile duct brushings of PSC patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) and propagated as organoids using previously established culture conditions. Organoids were treated for 5 days with a defined cocktail of inflammatory and fibrogenic cytokines (TNFα, IL-17, IL-6 and TGF-β). Treatment was performed with single cytokines at different concentrations and the complete cocktail mix. After treatment, senescence and secretion of inflammatory and fibrogenic mediators were assessed by microscopy and multiplex ELISA measuring a large panel of in total 26 inflammatory and fibrogenic analytes.
Results: Cholangiocyte organoids derived from the diseased bile ducts of PSC patients showed no evidence of cellular senescence and low levels of secretion of inflammatory or tissue-remodelling mediators under normal culture conditions. Treatment with a well-defined cocktail of inflammatory and fibrogenic cytokines, all of which have previously been shown to be present at high levels in diseased livers, lead to a change in cholangiocyte morphology towards a fibroblast-resembling phenotype, loss of organoid formation and upregulation of senescence-associated markers such as SA-β-Gal and PAI1. Cholangiocytes further obtained an activated and highly secretive phenotype, demonstrated by increased secretion of pro-inflammatory and tissue-remodelling mediators (IL-8, CXCL1, CXCL10, CCL2, MIF, S100A8/12, MMP9 and MMP2 among others) into the cell culture medium compared to untreated cells.
Conclusion: We here demonstrate that patient-derived cholangiocytes cultured as organoids, when brought into a disease-resembling in vitro environment, increase their secretion of mediators that are associated with immune-modulation and tissue remodelling. This highlights that cholangiocytes are not only a target during biliary disease, but likely also actively participate in modulating and driving disease progression. Our data show the potential of patient-derived cholangiocyte organoids as a powerful tool for unravelling disease-associated cellular mechanisms in PSC.

FRI-352
Cholestatic liver disease enhances sociability and leads to significant adaptative changes in amygdala neural circuits regulating social behavior in mice
Wagdi Almishri[1], Mark G. Swain[1,2]. [1]*Snyder Institute for Chronic Diseases, Medicine, Calgary, Canada;* [2]*University of Calgary Liver Unit, Department of Medicine, Canada*
Email: waalmish@ucalgary.ca

Background and aims: Social dysfunction is common in patients with cholestatic liver diseases (CLD). However, it is unclear whether this results from direct brain effects, or from the psychological impact, of CLD. The psychological aspects of disease are absent in an animal model; therefore, a strong behavioral phenotype suggests an organic basis for behavioral changes. Therefore, we examined the impact of CLD on social behavior in an animal model.
Method: Bile duct ligated (BDL) and sham control mice were studied 10 days post-surgery (model of CLD; male C57BL/6 mice; Jackson, 8–10 wks) to determine CLD impact on sociability and social memory (measured using automated 3 chamber sociability test). Mice from 5 separate cohorts of BDL/sham mice (n = 5–7/cohort) were studied. Additional cohorts of BDL/sham mice (n = 6/grp) were sacrificed at day 10 and the amygdala removed (key brain region regulating social behavior) and analyzed by RNAseq. Differentially expressed genes (DEG) between sham and BDL mice were then subjected to Ingenuity Pathway Analysis® (IPA; Qiagen) to determine CLD-related changes in social behavior-regulating amygdala neural pathways (neurotransmitters: glutamate, GABA; neuromodulators: dopamine, oxytocin). IPA z scores indicate predicted directionality of gene expression changes (–ve vs +ve).
Results: BDL mice showed enhanced sociability, reflected by a significant increase in social interactions during the sociability test phase (time investigating an unfamiliar juvenile mouse vs an inanimate object (Figure; left panel), compared to sham mice. Both sham/BDL mice had intact social memory in the novelty test phase (Figure; right panel). RNAseq showed increased numbers of DEGs in the amygdala of BDL vs sham mice (>3000 DEGs). IPA® analysis



3 Chamber Social Test: Sociability (propensity to investigate an unfamiliar mouse; left panel) and Social Novelty (propensity to investigate an unfamiliar vs familiar mouse; right panel) were both measured in BDL/sham mice during 10 min observation sessions. BDL mice exhibited enhanced sociability (***p=0.0003) and intact social novelty compared to sham mice (n=16 and 17 mice/grp). Data expressed as (%): (i) Sociability = % time spent investigating unfamiliar mouse ÷ entire time spent engaged in investigation of either cage, and (ii) Social Novelty = % time spent investigating unfamiliar mouse ÷ entire time spent engaged in investigation unfamiliar and familiar mouse.

Figure: (abstract: FRI-352).

revealed significant changes in genes in amygdala neural signaling pathways regulating social behavior in BDL vs sham mice. Specifically, significant alterations were observed in genes encoding the Canonical Pathway for Brain Oxytocin Signaling ($z = -1.64$; $p < 1.79 \times 10^{-3}$) and CREB Signaling in Neurons (positively regulated by glutamate signaling; $z = -1.943$; $p < 2.02 \times 10^{-3}$) pathways. Additionally, IPA® Upstream Regulator analysis predicted significant changes in numerous upstream transcriptional regulators for DEGs in BDL vs sham mice, including activity of upstream regulators for genes regulating dopaminergic ($z = 3.309$; $p < 1.02 \times 10^{-35}$), GABAergic ($z = -1.509$; $p < 1.69 \times 10^{-26}$), and glutaminergic ($z = -2.87$; $p < 2.87 \times 10^{-7}$) neural pathways.

Conclusion: Cholestatic mice demonstrate enhanced sociability with significant changes in amygdala gene expression profiles within neural pathways critically regulating social behavior. These findings suggest adaptive changes occur in brain neural pathways in CLD to preserve sociability and are consistent with clinical observations that social isolation leads to poor clinical outcomes.

FRI-353

Oxazolone-mediated bile duct inflammation reveals specific natural killer T cell-dependent inflammatory pathways

Markus Jördens[1,2,3,4], Kathrine Sivertsen Nordhus[1,2,4], Jonas Øgaard[1,2], Tom Lüdde[3], Tom Hemming Karlsen[1,2,4,5], Brian K. Chung[1,2,4], Espen Melum[1,2,4,5,6]. *[1]Oslo University Hospital and Institute of Clinical Medicine, University of Oslo, Norwegian PSC Research Center, Norway; [2]Oslo University Hospital, Rikshospitalet, Research Institute of Internal Medicine, Norway; [3]University Hospital Düsseldorf, Medical Faculty, Heinrich Heine University Düsseldorf, Department of Gastroenterology, Hepatology and Infectious Diseases, Germany; [4]University of Oslo, Institute of Clinical Medicine, Norway; [5]Oslo University Hospital, Rikshospitalet, Section for Gastroenterology, Department of Transplantation Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Norway; [6]University of Oslo, Hybrid Technology Hub-Centre of Excellence, Institute of Basic Medical Sciences, Faculty of Medicine, Norway*
Email: markus.joerdens@med.uni-duesseldorf.de

Background and aims: Primary sclerosing cholangitis (PSC) is an inflammatory bile duct disease characterized by cholangiocyte destruction. We modelled the inflammatory process by performing intrabiliary injection oxazolone which induces cholangitis driven by natural killer T (NKT) cells-a subset of innate-like lymphocytes enriched in liver that rapidly secrete inflammatory mediators upon recognition of CD1d-restricted lipid antigens. To examine the molecular granularity driving NKT-dependent biliary inflammation, we assessed livers from oxazolone-treated mice at multiple time-points by spatial transcriptomics and compared differential gene expression in biliary regions.

Method: Livers from male 10–12-week old C57Bl/6 wild-type (WT), were harvested at 1, 3, and 7 days after intrabiliary oxazolone or DMSO (vehicle) injection and processed for spatial transcriptomics (10X Genomics, USA). Similarly, livers from matched $Cd1d^{-/-}$ animals (lack both CD1d and NKT cells) and $Ja18^{-/-}$ mice (lack only Type I NKT cells) were harvested 3 days post-treatment. Spatial transcripts of all mice were aligned by Space Ranger and cluster analysis and differential gene expression was analyzed using Loupe Browser

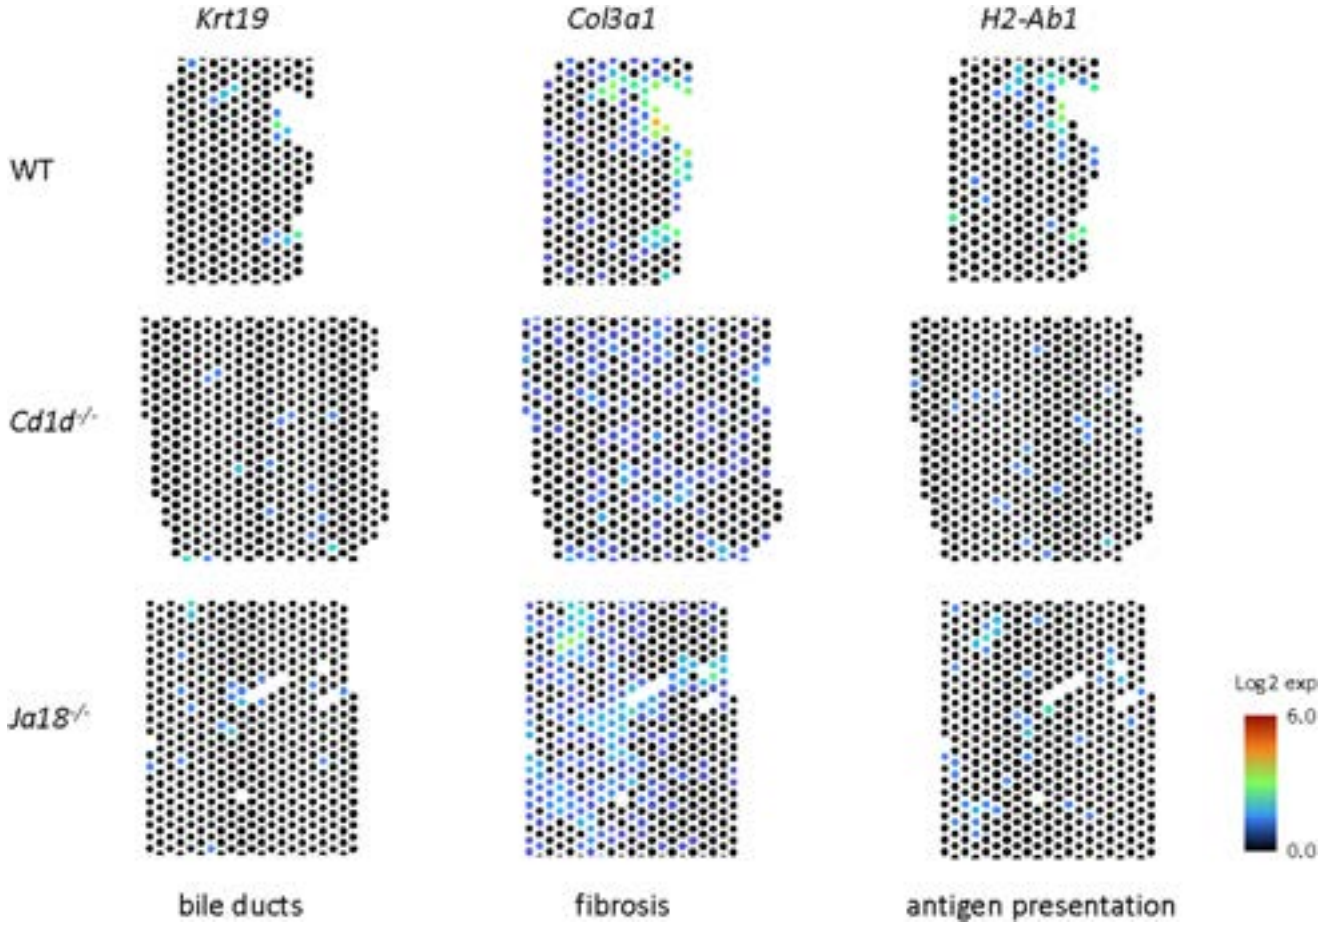


Figure 1: (abstract: FRI-353): Localization of markers for bile ducts (*Krt19*), fibrosis (*Col3a1*) and antigen presentation (*H2-Ab1*) in liver tissue of WT, $Cd1d^{-/-}$ and $Ja18^{-/-}$ mice 3 days after oxazolone injection. Log2 expression values are shown

(10X Genomics). Gene pathway enrichment was determined using STRING analysis.
Results: Differential gene analysis of biliary regions defined by spatial transcriptomics as cytokeratin 19 (Krt19) positive and confirmed by histological assessment showed no significant gene upregulation 1 day post-oxazolone versus DMSO ($p < 0.05$, Benjamini-Hochberg corrected), 124 genes 3 days post-oxazolone and zero genes after 7 days post-oxazolone. Genes upregulated on day 3 predominantly related to drug metabolism (*Cyp1a2, Cyp2b10, Cyp2c29, Aox3*), complement activation (*C8 g, C9, Mbl1, Mbl2, Hc*) and acute phase response (*Saa1, Saa2, Saa3, Orm2, Serpina3n, Crp*) pathways indicating oxazolone-induced inflammation peaks at day 3 and resolves by day 7. NKT cells had a marked effect on biliary gene expression as transcripts relating to MHC class II antigen processing (*Cd74, H2-Ab1*) and collagen organization (*Col1a2, Col1a1, Col3a1, Serpinh1*) were significantly upregulated in WT animals 3 days post-oxazolone compared to both $Cd1d^{-/-}$ ($n = 3$) and $Ja18^{-/-}$ ($n = 3$).
Conclusion: Spatial transcriptome analysis of oxazolone-induced bile duct inflammation revealed a distinct pattern relating to antigen presentation and fibrosis that was both temporal and NKT cell-dependent. The identified pathways could be of relevance as future treatment targets for inflammatory bile duct disorders such as PSC.

FRI-354
The significance of patatin-like phospholipase domain-containing protein-3 I148M genetic variant in autoimmune hepatitis

Kalliopi Azariadi[1,2], Angeliki Lyberopoulou[1,2], Pinelopi Arvaniti[1,2], Kalliopi Zachou[1,2], Nikolaos Gatselis[1,2], George Dalekos[1,2]. *[1]General University Hospital of Larissa, Department of Medicine and Research Laboratory of Internal Medicine, National Expertise Center of Greece in Autoimmune Liver Diseases, Larissa, Greece; [2]General University Hospital of Larissa, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Larissa, Greece*
Email: gatselis@me.com

Background and aims: Autoimmune hepatitis (AIH) is a relatively rare autoimmune disease with a strong genetic background. The concurrence of non-alcoholic fatty liver disease (NAFLD) in AIH possibly signifies a more severe disease. The patatin-like phospholipase domain-containing protein 3 (PNPLA3) I148M (rs738409 C/G) variant is well established genetic modifier of NAFLD. Our aim was to investigate the significance of the PNPLA3 I148M variant in AIH.
Method: Two-hundred patients with AIH followed in our Centre were evaluated while a hundred healthy subjects served as controls. Genotyping was performed with in-house allelic discrimination end point polymerase chain reaction (PCR).
Results: The I148M variant was present in 95/200 (47.5%) AIH patients compared to 47/100 (47%) healthy controls ($p = 1.000$). Patients with GG/CG genotypes were more likely to suffer from at least one metabolic risk factor (GG/CG 74.4% vs CC 61%, $p = 0.038$) and to present with decompensated cirrhosis at diagnosis (GG/CG 6.3% vs CC 1%, $p = 0.039$). Simple steatosis was present in 35/186 (18.8%) and steatohepatitis in 14/186 (7.5%) patients with available liver biopsy without correlation with the PNPLA3 genotype. The stage of fibrosis and grade of inflammation didn't correlate with any genotype. Response to treatment was also independent of the presence of the I148M variant. On Kaplan-Meier analysis homozygosity for the G allele corelated with reduced survival free of decompensation ($p = 0.006$), cirrhotic events (decompensation, liver transplantation, hepatocellular carcinoma) ($p = 0.001$) and liver related death or liver transplantation ($p = 0.011$) in treated patients.
Conclusion: The PNPLA3 I148M variant in AIH patients is associated with increased risk of advanced disease at diagnosis and reduced survival free of cirrhotic events and liver related death or liver transplantation, regardless of the presence of NAFLD. This signifies a potential role for the PNPLA3 IM48 variant as a new AIH biomarker allowing to identify patients with increased risk to disease progression.

FRI-355
Temporal characteristics of cell compartments in immune-mediated cholestatic disease

Markus Jördens[1,2,3,4], Kathrine Sivertsen Nordhus[1,2,3], Kristian Holm[1,2,3], Jonas Øgaard[1,2], Tom Lüdde[4], Tom Hemming Karlsen[1,2,3,5], Brian K. Chung[1,2,3], Espen Melum[1,2,3,5,6]. *[1]Oslo University Hospital and Institute of Clinical Medicine, University of Oslo, Norwegian PSC Research Center, Norway; [2]Oslo University Hospital, Rikshospitalet, Oslo, Research Institute of Internal Medicine, Norway; [3]University of Oslo, Institute of Clinical Medicine, Norway; [4]University Hospital Düsseldorf, Medical Faculty, Heinrich Heine University Düsseldorf, Department of Gastroenterology, Hepatology and Infectious Diseases, Germany; [5]Oslo University Hospital, Rikshospitalet, Section for Gastroenterology, Department of Transplantation Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Norway; [6]Faculty of Medicine, University of Oslo, Hybrid Technology Hub-Centre of Excellence, Institute of Basic Medical Sciences, Norway*
Email: markus.joerdens@med.uni-duesseldorf.de

Background and aims: Primary sclerosing cholangitis (PSC) and primary biliary cholangitis (PBC) are progressive liver disorders featuring peribiliary immune infiltration and cholangiocyte destruction with limited treatment options. The pathogenic interactions between immune cells and cholangiocytes remain unclear but can represent novel treatment targets. Using NOD.c3c4 mice that exhibit spontaneous bile duct inflammation as a model of PSC and PBC, we characterized the immunobiliary pathogenesis by defining the gene expression localized to the biliary microenvironment and examined whether progression from early to late disease correlated with alterations in the biliary immune compartment.
Method: Liver tissue from 10-, 20- and 40-week NOD.c3c4 mice ($n = 2–4$ per age group) were harvested and analyzed by spatial transcriptomics and single-cell RNA sequencing (scRNA-seq; 10X Genomics, USA). Transcriptomes were processed using Space Ranger (spatial) or Cell Ranger (scRNA-seq). Unsupervised k-means clustering and differential gene expression analysis was performed in Loupe Browser (10X Genomics). Relative cell abundances were estimated from spatial transcriptomes using scRNAseq profiles and CIBERSORTx and CARD deconvolution analyses.
Results: Spatial transcriptomes from 10-, 20- and 40-week NOD.c3c4 mice clearly demonstrated high expression of hepatocyte markers in histologically-defined parenchymal regions (*Muc9, Muc12, Muc17, Cyp2C67, Cyp2E1*) and cholangiocyte markers in biliary regions (*Tspan8, Krt19, Epcam*). The non-cholangiocyte markers demonstrating the highest differential expression in biliary regions were related to inflammation (*S100a6, Crip1, Cd24, Cd63*). Differential gene expression analysis of 10- and 20-week biliary regions (age-matched combined) showed four significant genes whereas comparisons between 10- and 40-week biliary regions showed 420 genes ($p < 0.05$, Benjamini-Hochberg corrected) with strongest upregulated expression in 40-week animals associated with cell proliferation (*Cd24a, Prom1, Dmbt1, Ccnd1*) and chronic inflammatory response (*Gja1, Camp, Mdk*). Deconvolution of spatial transcriptomes into immune cell types revealed biliary infiltration of granulocytes (*S100a9, S100a8, Il1b*), plasmacytoid dendritic cells (*Siglech*), monocytic phagocytes (*Lyz2, Clec4a3, Clec4a1*), dendritic cells (*Xcr1*), B cells (*Cd79a, Cd79b, Cd19*) and T cells (*Cd3 g, Cd3e, Nkg7*) in all age groups.

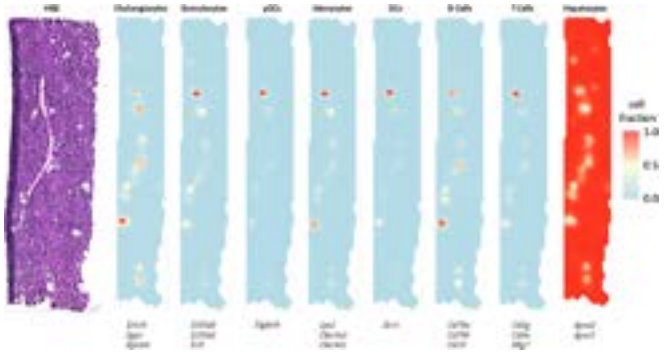

Figure 1: Hematoxylin and eosin (HandE) staining of 10-week NOD.c3c4 liver (left) and localization of indicated immune cell types in biliary regions (cholangiocytes) of the same tissue section using CARD deconvolution of spatial transcriptomes (right). Exemplar lineage markers and relative cell fractions are shown.

Conclusion: Spatial transcriptomics combined with scRNA-seq demonstrates that disease progression is driven by a defined and time-dependent molecular signature in biliary regions of NOD.c3c4 mice. These findings may point to immune pathways amenable to novel treatment approaches in PSC and PBC patients.

FRI-356

HSD17B13 inhibitors are hepatoprotective and anti-inflammatory in a mouse model of autoimmune hepatitis

Manuel Roqueta-Rivera[1], Yaohui Nie[1], Jordan Butts[1], Mary Chau[1], Kelsey Garlick[1], Archie C. Reyes[1], Jonathan Lloyd[1], Joshua Klaene[1], Yat-Sun Or[1], Bryan Goodwin[1]. [1]*Enanta Pharmaceuticals, Inc., Biology, Watertown, United States*
Email: mroqueta@enanta.com

Background and aims: Genome wide association studies identified a loss of function gene variant (rs72613567:TA) for 17-beta hydroxysteroid dehydrogenase 13 (HSD17B13), a lipid droplet-associated protein linked to decreased risk for chronic liver diseases. Delayed onset of autoimmune hepatitis (AIH) has also been observed in TA variant carriers. HSD17B13 inhibitors (HSDi), previously shown to be anti-inflammatory *in vivo* with modulation of sphingolipids, were evaluated in a mouse model of AIH for anti-inflammatory and hepatoprotective effects.
Method: Distinct chemical series of HSDi of sub-micromolar potency were tested in a concanavalin A (ConA) model of acute hepatitis. Mice were pretreated with HSDi by oral gavage, followed by intravenous delivery of ConA. Liver, spleen, and plasma were collected at 6 hours post-ConA injection. Hepatoprotection was assessed using plasma ALT. Inflammatory gene markers were evaluated in liver and spleen by qPCR. Cytokines and chemokines were measured in plasma by mesoscale immunoassay. The HSDi effect on sphingolipids was measured in mouse liver and primary human hepatocytes by mass spectrometry.
Results: HSDi from distinct chemical series were hepatoprotective and anti-inflammatory. Splenomegaly due to ConA was observed across all groups. However, elevation of plasma ALT and cytokines (TNF, IL1b, CXCL9) by ConA was attenuated by HSDi. In addition, HSDi decreased inflammatory gene markers (*Nlrp3, Il1, Il6, Ccl2*) in liver. The influx of T-cells (*Cd8*) to liver was not altered by HSDi, however, markers of immune cell activation (*Cd69, S1pr4*) and mediators of cell death (*Fasl*) were decreased. In line with a favorable anti-inflammatory and anti-apoptotic profile, liver ceramides (d18:0/16:0 and d18:1/24:1) were decreased in HSDi-treated livers. The modulation of these ceramides was confirmed in HSDi-treated primary human hepatocytes.
Conclusion: We have identified potent and selective HSDi that decrease ceramide levels in vitro and in vivo. The hepatoprotective effects by HSDi in an acute T-cell driven liver injury model of AIH may be partially mediated by the modulation of bioactive lipids responsible for cytotoxic immune cell activation.

FRI-357

Differential activation of regulatory CD4+ T cells via the JAK-STAT-pathway in Primary sclerosing cholangitis

Leona Dold[1], Sandra Kalthoff[1], Leonie Frank[1], Taotao Zhou[1], Pia Esser[1], Philipp Lutz[1], Christian Strassburg[1], Ulrich Spengler[1], Bettina Langhans[1]. [1]*University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany*
Email: Leona.Dold@ukbonn.de

Background and aims: Primary sclerosing cholangitis (PSC) is an autoimmune cholestatic liver disease of unknown aetiology. Regulatory $CD4^+$ T cells (Tregs) are important for induction/maintenance of self-tolerance and inhibition of autoimmunity. In PSC a low number of Tregs has been reported. However, their functionality is still unclear. Activation of the JAK-STAT (Janus kinase-signal transducer and activator of transcription) pathway plays a pivotal role in modulating T cell functions. Here, we analyzed cytokine-induced activation of different STAT proteins in Tregs from patients with PSC.
Method: 51 PSC-patients (37 with inflammatory bowel disease (IBD), 14 without IBD; all without acute cholangitis or colitis) and 36 healthy controls were enrolled in our study. We measured cytokines in serum via bead-based immunoassays. Using multiparameter phospho-flow cytometry we analyzed ex vivo frequencies of $Foxp3^+CD25^+CD127^{low}CD4^+$ Tregs and phosphorylation of STAT1/3/5/6 in Tregs after in vitro stimulation with recombinant IFN-gamma, IL-6, IL-2, and IL-4, respectively, and correlated the results to clinical data.
Results: Frequencies of peripheral Tregs were significantly reduced in PSC patients compared to healthy controls (p = 0.0028). In line, serum

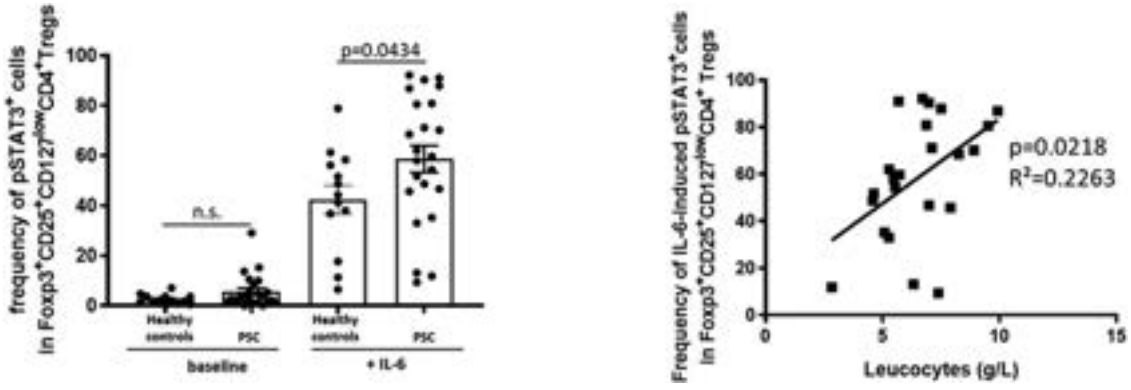

Figure: (abstract: FRI-357).

levels of IFN-gamma, IL-6, IL-2 and IL-4 were markedly higher in PSC patients than in healthy controls ($p < 0.05$ each). While none of these cytokines affected activation of STATs 1/5/6, IL-6 stimulation induced enhanced phosphorylation of STAT3 in Tregs of PSC patients (Figure 1A). Unlike to commonly proposed markers for PSC progression (bilirubin, alkaline phosphatase, MELD-score), the frequency of IL-6-induced phospho-STAT3$^+$ Tregs correlated to the leucocyte counts in PSC (Figure 1B).
Conclusion: Our data indicate differential JAK-STAT activation of CD4$^+$ Tregs in PSC. The correlation between IL-6-induced phospho-STAT3$^+$ Tregs and leukocyte counts may reflect triggering of this pathway in response to an infection.

FRI-358
scRNA transcriptomics reveal the role of cholangiocytes and neutrophils cross talk in PKHD1-KO mice
Zehra Syeda[1], Romina Fiorotto[1], Shakila Taleb[1], Tory Bauer-Pisani[1], Dejian Zhao[1], Mario Strazzabosco[1]. *[1]Yale School of Medicine, United States*
Email: mario.strazzabosco@yale.edu

Background and aims: Congenital hepatic fibrosis (CHF) and Caroli disease (CD) are caused by mutation in Polycystic kidney hepatic disease 1 gene (PKHD1) and lead to biliary malformations, cholangiocyte dysfunction and portal fibrosis. PKHD1 encodes for fibropolycystin (FPC), a protein expressed in cilia, plasma membrane and centromeres of cholangiocytes. FPC is involved in multiple cellular functions from polarity and cell matrix interactions to differentiation. This study was designed to investigate the relationships among the cell types present in the pericystic infiltrate in Pkhd1-KO mice at single cell level, to better understand the pathophysiology of CHF/CD.
Method: We isolated single cells from liver portal tract of 3 months old Pkhd1-KO and WT mice. Transcriptomics profiling of 16,383 single cells, yielded molecular definitions for cell types present in samples. Datasets were analyzed by Seurat and CellPhoneDB package in R.
Results: ScRNA seq analysis revealed 9 distinct populations in the portal tract of WT and Pkhd1-KO. Interestingly, a second population of cholangiocytes, having higher expression of chemokines (Cxcl5, Cxl2) along with other features of "reactive cholangiocytes," was exclusively present in Pkhd1-KO together with classical cholangiocytes. Gene ontology analysis in reactive cholangiocytes showed an enrichment of genes involved in the recruitment of neutrophils and activation of innate immune responses and suggested the potential involvement of microbial components Among 4 different subpopulations of T cells identified (i.e. CD4+, CD8+, CD4/CD8 double negative and NKT), CD8+ and Double Negative T Cells (DNT) are preset only in KO sample. DNT cells have previously shown a critical role in perpetuating inflammation. CellPhoneDB analysis showed that Cxcl5 and Cxcl1 play a major role in cross talk and recruitment of neutrophils by cholangiocytes. Cxcl16 attracts T cells and is expressed by cholangiocytes and macrophages in Pkhd1-KO. Neutrophils secrete Csf1 that promotes macrophage polarization. Neutrophils and macrophages express Ccl6, a chemoattractant for macrophages and T cells. Cd86 is expressed by Macrophages and provide signals for naive T cell activation and survival by binding to Cd28 on CD4 + and CD8+ T cells. IL17a is expressed by DNT cells in Pkhd1-KO. The IL17a receptor is expressed by neutrophils. IL-1β is highly expressed by neutrophils and macrophages in Pkhd1-KO. The receptor Il1r1 is expressed by DNT cells.
Conclusion: This study shows a complex signaling network originating from cholangiocytes and amplified by the recruited neutrophils and then T cells and macrophages in Pkhd1-KO. Many of the identified signals are druggable and therefore their blockade may bear therapeutic advantages to improve inflammation and progression to fibrosis in Pkhd1-KO model. The role of microbial population is of particular interest.

FRI-359
Golexanolone, a GABA receptor-modulating steroid antagonist, improves peripheral inflammation, fatigue, locomotor gait, motor incoordination and short-term memory in rats with cholestasis and hepatic encephalopathy due to bile duct ligation
Paula Izquierdo-Altarejos[1], Yaiza Arenas[1], Mar Martinez-Garcia[1], Carla Gimenez-Garzo[1], Gergana Mincheva[1], Magnus Doverskog[2], Marta Llansola[1], Vicente Felipo[1]. *[1]Centro de Investigacion Principe Felipe, Valencia, Spain; [2]Umecrine Cognition AB, Sweden*
Email: vfelipo@cipf.es

Background and aims: Cholestasis may appear in patients with primary sclerosing cholangitis, primary biliary cholangitis, or drug-induced liver injury. Patients with cholestasis may show fatigue and other symptomatic alterations that severely reduce their quality of life. Patients with liver disease may also eventually show hepatic encephalopathy, with cognitive and motor impairment. Rats with bile-duct ligation (BDL) are a common animal model both of cholestatic liver disease as well as of hepatic encephalopathy. Current management and treatment of cholestatic liver disease include secondary bile acids like ursodeoxycholic acid, UDCA. The licensed therapies are exclusively used to slow or prevent disease progression but have no impact on symptomatic alterations such as fatigue. There are presently no licensed or effective medications for the management of symptomatic alterations such as fatigue in PBC or any other liver disease but immunomodulatory treatments have been proposed. Golexanolone (GR3027), reduces GABAergic tone by reducing the potentiation of $GABA_A$ receptors activation by neurosteroids such as allopregnanolone. We have recently shown that golexanolone reduces peripheral inflammation and neuroinflammation and improves cognitive and motor function in rats with chronic hyperammonemia. The aims of this study were to assess if golexanolone treatment reduces peripheral inflammation and improves fatigue and cognitive and motor function in BDL rats.
Method: Rats were subjected to bile duct ligation. One week after surgery golexanolone was administered daily using intra-gastric probes to BDL and sham-operated controls. To assess the effects on peripheral inflammation several interleukins were analyzed in plasma. Fatigue was analyzed in the treadmill, motor coordination in the motorater, locomotor gait in the Catwalk, and short-term memory in the Y maze. These analyses were performed after 2–4 weeks of treatment with golexanolone.
Results: BDL increases the plasma levels of the pro-inflammatory interleukins TNFa, IL-6, IL-17 and IL-18. Golexanolone reverses the increases in these interleukins. BDL induces fatigue in the rats, motor incoordination in the motorater test and alters locomotor gait analyzed in the Catwalk. Golexanolone reverses these changes. BDL impairs short-term memory in the Y maze. Golexanolone improves this impairment.
Conclusion: Golexanolone reduces peripheral inflammation in BDL rats. This is associated with improvement in fatigue, locomotor gait and coordination, and short-term memory. Golexanolone may have beneficial effects to treat symptomatic alterations such as fatigue, and motor-, and cognitive impairment in patients with cholestatic liver disease, or hepatic encephalopathy.

FRI-360
Elevated JAG1-NOTCH Signaling is Associated with Fibrosis Stages in Patients with PSC
Michael Trauner[1], Kaiyi Zhu[2], Jun Xu[2], William Barchuk[2], Lisa Boyette[2], Timothy R. Watkins[2], Andrew Billin[2], Sharlene Lim[2], Vlad Malkov[2], Christopher Bowlus[3]. *[1]Medical University of Vienna, Austria; [2]Gilead Sciences. Inc., United States; [3]University of California Davis, United States*
Email: jun.xu@gilead.com

Background and aims: The canonical NOTCH signaling pathway is a fate-determinant factor for intrahepatic bile duct epithelium during liver organogenesis. Null mutations in the NOTCH ligand JAG1 or the

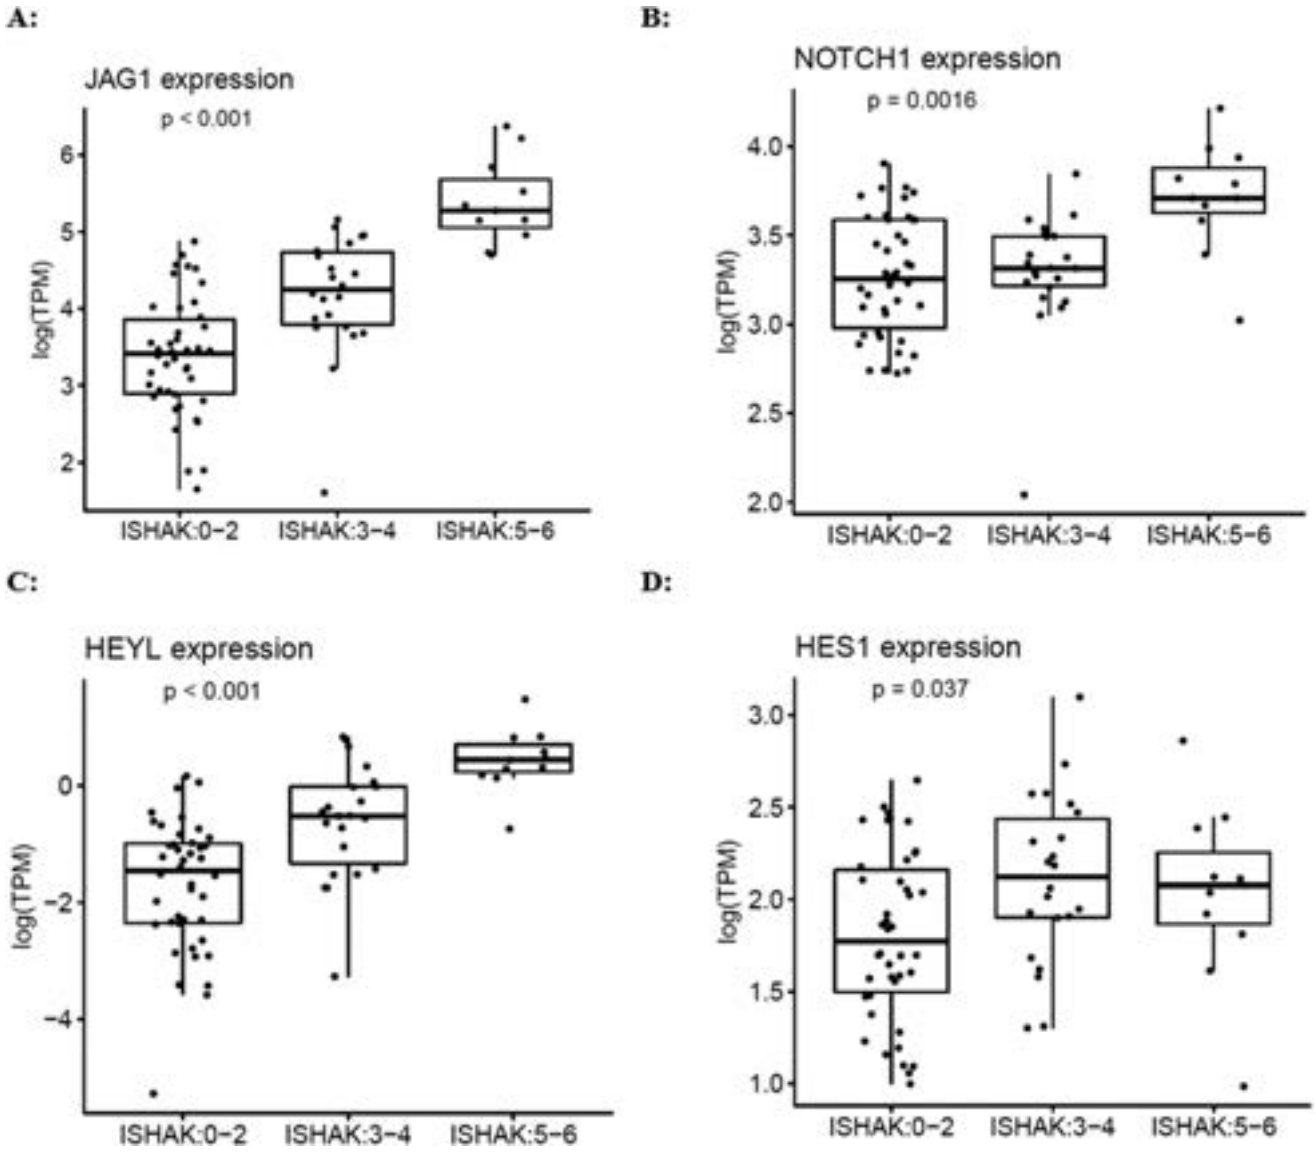

Figure: (abstract: FRI-360): Associations between JAG1-NOTCH Signaling and Ishak Fibrosis Stages in PSC

NOTCH2 receptor are associated with Alagille syndrome characterized by bile duct paucity. The ductular reaction is commonly observed in liver histology from patients with primary sclerosing cholangitis (PSC) or other cholestatic diseases, but the contribution of NOTCH signaling to abnormal bile duct proliferation driving biliary fibrosis is unknown. The aim of the study is to evaluate hepatic NOTCH signaling in patients with PSC.

Method: The study population comprised participants in a phase 2b, placebo-controlled trial of simtuzumab in PSC (NCT01672853). A transcriptomic analysis was performed on baseline liver biopsy samples. Fibrosis was staged according to the Ishak classification by a central pathologist. Mild fibrosis was defined by Ishak 0–2, moderate fibrosis by Ishak 3–4 and cirrhosis by Ishak 5–6. RNA-sequencing data was quantified in log2 transcripts per million (TPM). P values were derived by Kruskal-Wallis (KW) test, Wilcoxon test or Spearman correlation.

Results: A total of 75 PSC patients with mild (n = 42) and moderate (n = 22) fibrosis and cirrhosis (n = 11) were included with a median (IQR) expression of *JAG1*, the canonical ligand for NOTCH signaling, of 3.41 (2.89, 3.86), 4.25 (3.79, 4.74) and 5.28 (5.50, 5.68), respectively. *JAG1* expression levels were significantly associated with fibrosis stages with the highest levels in the cirrhosis cohort (KW p <0.001) (Figure 1A). The hepatic expression of *NOTCH1* was greater in the cirrhosis cohort [3.71 (3.63, 3.88)] compared to mild [3.25 (2.89, 3.86)] and moderate [3.32 (3.22, 3.50)] fibrosis cohorts (KW P = 0.0016) (Figure 1B). *NOTCH2* expression levels did not differ by different fibrosis stages (KW p = 0.068). In concordance with the elevated ligand expression of *JAG1-NOTCH*-responsive genes *HEYL* and *HES1* were increased in PSC with cirrhosis cohort compared to the mild and moderate cohorts (KW p <0.05) (Figure 1 C and D). In addition, *JAG1* (Wilcoxon p <0.001), *HES1* (Wilcoxon p = 0.015) and *HEYL* (Wilcoxon p <0.001) were elevated in patients with Enhanced Liver Fibrosis (ELF) score ≥9.8. In the liver of PSC patients, *JAG1* expression was positively correlated with *SOX9* ($\rho = 0.73$, $p < 0.001$), which determines cholangiocyte fate during liver development and negatively correlated with newly generated hepatocyte markers (PMID: 34792289), ALDOB ($\rho = -0.42$, $p < 0.001$), ASGR1 ($\rho = -0.38$, $p < 0.001$) and SERPINA1 ($\rho = -0.28$, $p = 0.014$)

Conclusion: JAG1-NOTCH signaling in PSC increases with fibrosis stages. The spatial expression pattern of JAG1 in the liver, cellular

interactions, and non-invasive tests to monitor elevated NOTCH signaling in PSC patients warrant further investigation.

FRI-361

Pyroptosis plays a key role in primary biliary cholangitis of humans and mice

Linxiang Huang[1], Wang Zilong[1], Zheng Jiarui[1], Zhicheng Liu[1], Bo Feng[1].
[1]*Peking University People's Hospital, China*
Email: fengbo@pkuph.edu.cn

Background and aims: Primary biliary cholangitis (PBC) is a progressive, non-suppurative, destructive intrahepatic cholestatic disease, which is considered to be an immunological disorder with both environmental and genetical participation. Around 40% PBC patients were reported to have an incomplete response to the first-line treatment, ursodeoxycholic acid (UDCA), leading to a poor prognosis and lack efficient treatment. Pyroptosis, a newly discovered cell death pathway, characterized by gasdermin-mediated programmed necrosis, were proved to be involved in many liver diseases. However, if pyroptosis is involved in the pathogenesis of PBC remains unclear. In this study, we aim to investigate the involvement of pyroptosis in PBC patients and mice and explore the potential of pyroptotic pathway as a possible treatment target.
Method: Liver tissue samples were collected from liver biopsy of six PBC patients with no history of other liver diseases from Hepatology Department of Peking University People's Hospital. Samples from control individuals with normal liver histology were collected from patients with no evidence of other liver diseases. Twenty female C57BL/6 mice of 4–6 months old were evenly divided into PBC group and control group. PBC mice were induced with two doses of 2-nonynoic acid (2OA-BSA) and polycytidylic acid (poly I: C) for total 12 weeks. Immunocyte type correlation analysis was performed on the GSE119600 dataset of Gene Expression Omnibus (GEO) database with whole blood samples from PBC patients (n = 90) and non-liver disease controls (n = 47). Immunohistochemistry (IHC) staining of gasdermin D (GSDMD) in liver samples of PBC patients and mice, and the expression levels of GSDMD and its classical pathway were determined in the PBC mice model.
Results: The immunocyte type correlation analysis reported that the expression of key transcription factors of M1 macrophages-NOS2, IRF5, PTGS2 were significantly higher in PBC patients than that of control group ($p < 0.05$, Fig. A). The expression levels of GSDMD in liver samples of PBC patients were significantly improved. Noteworthily, the IHC staining of GSDMD in the PBC liver sections showed a distribution pattern of macrophage (Fig. B). For the 2OA-induced PBC mice model, pyroptosis pathway was upregulated than control mice. Both the mRNA ($p < 0.05$, Fig. C) and protein levels ($p < 0.05$, Fig. D) of GSDMD significantly increased compared to normal controls, determined by qrt-PCR and western blotting, respectively. Besides, the qrt-PCR showed that the expression levels of all key elements of classical pyroptosis pathway (i.e., NLRP3-Caspase-1-GSDMD, Fig. C) was significantly higher than control ($p < 0.05$). IHC staining also revealed improved GSDMD and Caspase-1 expression in PBC mice, especially around the portal area (Fig. E).
Conclusion: Pyroptosis plays a key role in PBC patients and 2OA-BSA induced PBC mice, possibly macrophages being the most important executors. Inhibition of the pyroptosis pathway might be a potential target for the future treatment of PBC.

Background and aims: Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease that needs long-term immunosuppression. Biochemical remission (BR), defined by normalisation of IgG and transaminases, is the treatment goal and is associated with a favourable clinical outcome. Recently, it was proposed by the international AIH group to report outcomes at six and twelve months. Our exploratory analysis aims to investigate different molecular signatures between patients with BR at twelve months (BR12) and incomplete response at twelve months (IR) to immunosuppressive therapy using baseline biopsies.
Method: Forty AIH patients from Hannover Medical School (Hannover, Germany) were enrolled in this study; 20 with BR12 and 20 with IR. RNA was extracted from formalin-fixed, paraffin-embedded liver tissue and was sequenced using Illumina HighSeq 6000. Bulk RNA sequencing data were processed using nf-core/rnaseq pipeline. Further downstream analyses were performed using DESeq2 in R. Two samples from the IR group were excluded due to insufficient number of reads (n = 1) and sex mismatch (n = 1).
Results: Patients with BR12 had lower IgG (median 1.1 vs. 1.7 times upper limit of normal (xULN), p = 0.006) and higher AST (median 24.0 vs. 11.6 xULN, p = 0.045) but not ALT values (20.7 vs. 11.1 xULN, p = 0.133) than patients with IR. Other clinical variables did not differ, including histological inflammation (median mHAI 7 vs. 9 points, p = 1.000) and fibrosis stage (median Ishak F 1 vs. 2, p = 0.326). Top 20 principal components calculated from the gene expression were significantly correlated with group, sex, and age. Hence, we adjusted the molecular expression data for sex and age.
Compared to patients with IR, patients with BR12 showed higher expression of innate immunity related genes, such as Toll like receptor 4 (TLR4), interferon gamma receptor 2 (IFNGR2), colony-stimulating factor 3 receptor (CSF3R), sialic acid binding Ig like lectin 1 (SIGLEC1), and protein tyrosine phosphatase receptor type J (PTPRJ), suggesting that pro-inflammatory pathways are more prominent in BR12. In addition, the expression of CR1 (complement receptor 1) and LIL2RB (leukocyte immunoglobulin-like receptor B2) was higher in patients with BR12. These genes are involved in regulatory T cell (Treg) formation and Treg-mediated down-regulation of the immune response. The down-regulated genes were not linked to immunological processes but enriched in the muscle function pathway.

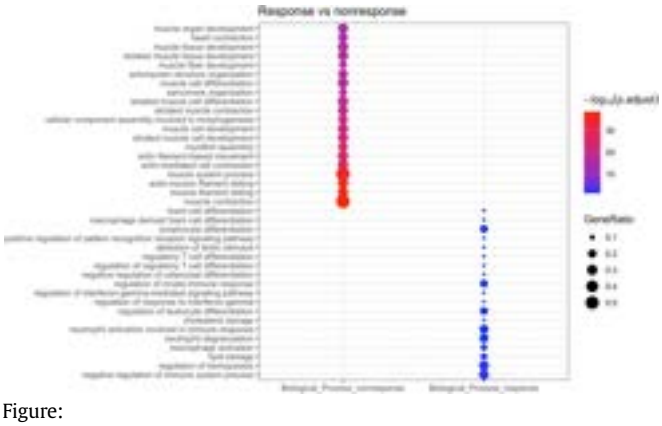

Figure:

Conclusion: BR12 was associated with pro-inflammatory pathways of innate immunity and with genes related to Treg differentiation. SIGLEC1-positive macrophages are involved in the regulation of immune homeostasis in multiple autoimmune diseases, and low CR1 is associated with poorer prognosis in systemic lupus erythematosus. Overall, our study confirms the notion that patients with more severe disease respond better or faster to treatment.

Email: am16@ualberta.ca

Background and aims: Patients with primary biliary cholangitis (PBC) have an increased risk of infectious diseases and cancers, and higher prevalence of alleles encoding genes in the interleukin (IL)-12 pathway. The prognostic role of immunodeficiency has been assessed by the Canadian Network of Autoimmune Liver Disease using the neutrophil to lymphocyte ratio (NLR) as a surrogate for lymphopenia in ~2,000 PBC patients. A high NLR following 12 months of ursodeoxycholic acid was found to be an independent risk factor for decreased liver transplant free survival. Herein we assess the immune subsets linked with adverse prognosis and whole blood transcriptional differences in PBC patients with and without lymphopenia.
Method: 140 PBC peripheral blood samples from CaNAL patients were used for flow cytometry to quantify subsets of B cells (CD19, IgD, CD27), T cells (CD3, CD4, CD8, CD27, CD45RA), NK (natural killer) and NK-like T cells (CD16, CD56). PBC Globe scores were assessed as categorical variables for adverse prognosis. An RNAseq database of whole blood RNA from 86 PBC patients in the POISE study was sorted by 50% highest versus lowest NLR calculated by transcripts per million of FCRGR3B (CD16b) divided by CD3e. Differential gene expression and gene set enrichment analyses by NLR were conducted using DESeq2 and gProfiler packages.
Results: PBC patients with reduced transplant free survival scores had decreased CD4, CD8, NK and NK-like T cells (Figure). Study of individual subsets revealed that all CD8 subsets (Naïve, central and effector memory, terminally differentiated) and terminally differentiated CD4 T cells were associated with reduced prognosis. Transcriptional profiling showed that the high NLR patients with lymphopenia had activation of several proinflammatory pathways including NFkappaB signalling, IL-1, IL-6 and IL-8 and type I interferon production pathways, whereas IL-12 production pathway was found to be deregulated with upregulation of both activation and inhibitory transcripts.

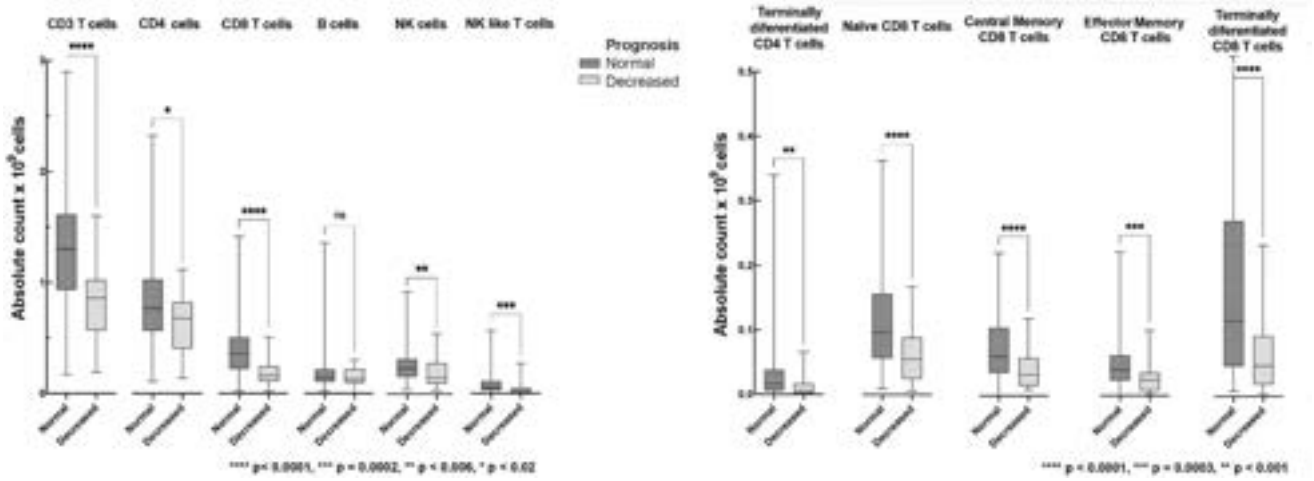

Figure: (abstract: FRI-363).

Conclusion: PBC patients with reduced transplant free survival scores had diminished innate and adaptive effector lymphocyte subsets and activated proinflammatory cytokine pathways. The decreased effector NK, CD4 and CD8 T-cells may reflect a degree of immune deficiency but the cause of loss is unknown. Further study of regulatory T cell function regarding IL-12 modulation of down-stream interferon-gamma pathways will be required to link lymphopenia and proinflammatory cytokine production with progressive liver disease.

FRI-364

The role of bile salts in cholestasis associated pruritus

Frank Wolters[1], Dagmar Tolenaars[1], Rudi de Waart[1], Arthur Verhoeven[1], Michel van Weeghel[2], Stan van de Graaf[1], Ulrich Beuers[1,3], Ronald Oude-Elferink[1]. *[1]Amsterdam University Medical Centers, University of Amsterdam, Tytgat Institute for Liver and Intestinal Research, Amsterdam, Netherlands; [2]Amsterdam UMC, University of Amsterdam, Core Facility Metabolomics, Amsterdam, Netherlands, [3]Amsterdam University Medical Centers, University of Amsterdam, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands*
Email: f.wolters@amsterdamumc.nl

Background and aims: Although it has repeatedly been reported that there is no good correlation between circulating bile salt levels and itch scores, the present dogma in the field remains that bile salts may act as pruritogens in cholestasis. The present treatment modalities of cholestatic pruritus, a major and poorly understood symptom, lack efficacy and would benefit greatly from a molecular rationale. At this moment, the effect of inhibiting MRGPRX4 in cholestatic patients with itch is studied in a clinical trial after the group of Meixiong et al. reported that bile salts and their conjugates activate this receptor, where deoxycholate was the most potent agonist. Our study aimed to evaluate bile salts as agonists of known pruriceptors (TRPA1, TRPV1, TRPV3, TRPV4, MRGPRX4) at (patho) physiological concentrations.

Method: Unconjugated and conjugated bile salts were tested for pruriceptor activation (intracellular free Ca^{2+} assays) on transduced HEK293T-rTTA3 cells (with and without the various receptor cDNAs). These assays were all done in the absence of albumin. Plasma concentrations were determined in 45 cholestatic patient samples and in 15 healthy controls by means of HPLC-MS.

Results: Most conjugated bile salts correlated with pruritus. Unconjugated bile salts did not, were not significantly elevated compared to controls, but were much more potent agonists to itch

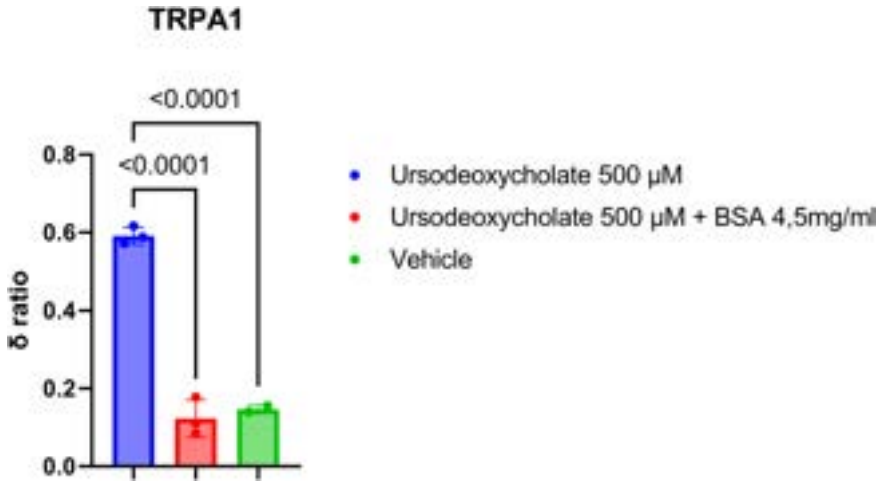

Figure:

receptors than their conjugated forms. The order of sensitivity to bile salts was TRPA1>MRGPRX4>TRPV3>TRPV4>TRPV1. Activation of all receptors only occurred in supra-pathophysiological levels. When incubations were done in the presence of 4.5% albumin (physiological plasma concentration) activation was virtually completely abrogated. **Conclusion:** Although most conjugated bile salts correlate with cholestatic pruritus, they do not activate itch receptors at patho-physiological concentrations. Given the extensive binding to albumin, it is highly unlikely that bile salts produce significant activation of this set of pruriceptors. In vitro evidence for bile salts as a pruritogens is therefore still lacking.

FRI-365

Spatial transcriptomics reveals shared gene and cellular composition in recurrent and primary sclerosing cholangitis

Mikal Jacob Hole[1,2,2,3], Kristian Holm[1,2,3], Jonas Øgaard[1,3], Peder Rustøen Braadland[1,2,3], Espen Melum[1,2,3,4,5], Johannes R. Hov[1,2,3,4], Brian K. Chung[1,3]. *[1]Research Institute of Internal Medicine, Oslo University Hospital, Rikshospitalet, Oslo, Norway, Norway; [2]Institute of Clinical Medicine, University of Oslo, Oslo, Norway, Norway; [3]Oslo University Hospital and University of Oslo, Norwegian PSC Research Center, Department of Transplantation Medicine, Norway; [4]Section of Gastroenterology, Department of Transplantation Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital, Rikshospitalet, Norway, Norway; [5]Hybrid Technology Hub-Centre of Excellence, Institute of Basic Medical Sciences, Faculty of Medicine, University of Oslo, Norway, Norway*
Email: m.j.hole@studmed.uio.no

Background and aims: Primary sclerosing cholangitis (PSC) is an autoimmune biliary disease with up to 30% recurrence (rPSC) following liver transplantation. Whether rPSC represents the same disease process as PSC is unclear, therefore we investigated if genes and cell types differ in rPSC liver explants compared to PSC and alcoholic liver disease (ALD).

Method: Spatial transcriptomics (Visium, 10X Genomics) was performed on snap-frozen liver explant tissue from rPSC (n = 7), PSC (n = 5) and ALD (n = 3). Sequenced transcripts were aligned and grouped using Space Ranger; k-means clustering and significant differential expression ($p < 0.05$, Benjamini-Hochberg corrected) of highly expressed genes (greater than one read per RNA capture spot) was analyzed in Loupe Browser (10X Genomics). Relative cell abundances were estimated using spatial transcriptomes and conditional autoregressive-based deconvolution (CARD) analysis (Figure 1). Differential cell abundances accounting for dependency of spots from the same liver sample was tested using linear mixed modeling (glmer package in R).

Results: Data-driven analysis of spatial transcriptomes from all fifteen liver samples identified two clusters that closely corresponded to histopathologically defined parenchymal and fibrotic tissue regions. Expectedly, the parenchymal cluster was enriched for known hepatocyte markers (*CYP2E1, C9, CYP2A6*), while genes relating to collagen deposition (*COL1A2, COL4A2, COL6A1*) and immune inflammation (*IGKC, CD74, C7*) were enriched in fibrotic regions. Gene analysis of rPSC and PSC parenchyma revealed only 51 differentially regulated genes whereas 226/277 (82%) genes were detected at similar levels. By contrast, rPSC *vs*. ALD parenchyma showed 93 differentially expressed genes and 258/351 (74%) detected at similar levels, suggesting that the rPSC parenchyma was transcriptionally more similar to PSC than ALD. Differential analysis of fibrotic regions between rPSC and PSC showed 539/719 (75%) expressed at similar levels whereas rPSC *vs*. ALD displayed similar expression of 876/993 (88%) genes. Estimated cellular composition using deconvolution of spatial transcriptomes showed similar proportions of different cell types in rPSC and PSC parenchyma. In contrast, increased mast cells (6-fold), plasma B cells (10-fold) and dendritic cells (3-fold) were seen in rPSC parenchyma *vs*. ALD. In fibrosis, rPSC and PSC *vs*. ALD showed similar proportions of immune infiltrate except a modest increase of plasma B cells (1.1-fold) in ALD, suggesting fibrotic pathways overlap irrespective of disease etiology.

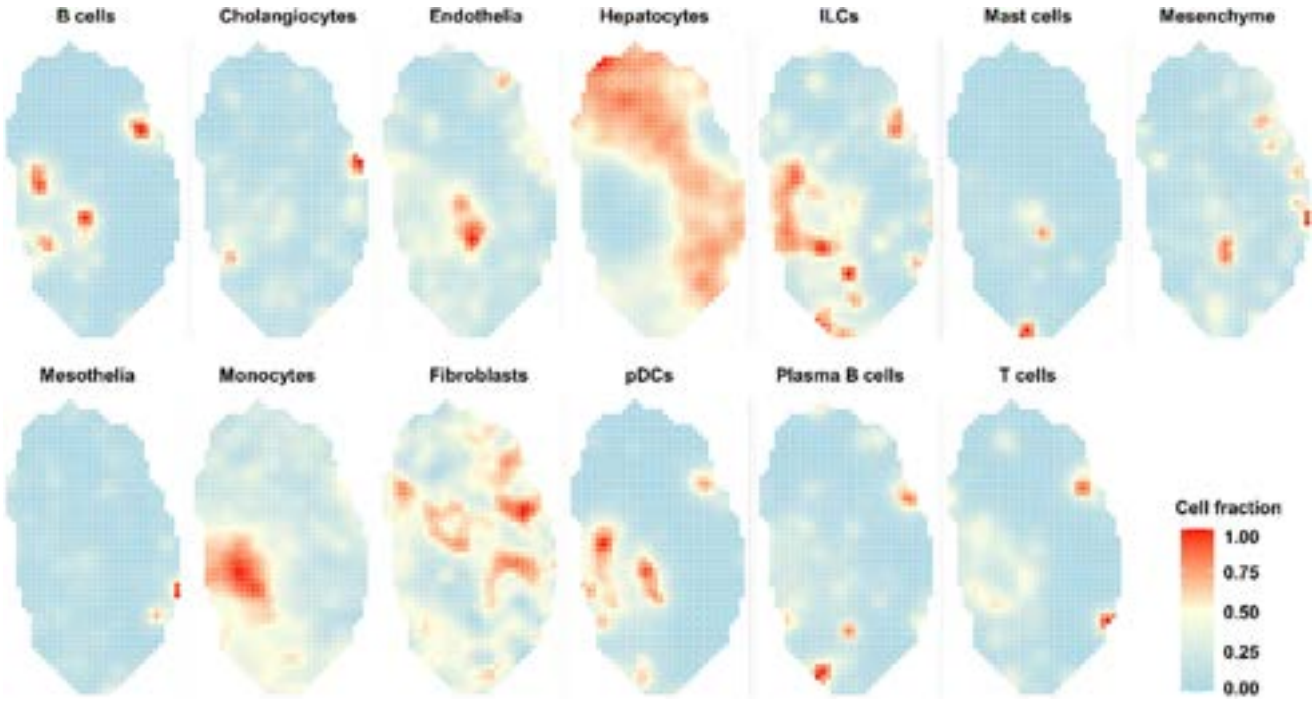

Figure: (abstract: FRI-365): Representative gene deconvolution (CARD) showing major immune cell types localize to regions of fibrosis; ILCs: innate lymphoid cells, pDCs: plasmacytoid dendritic cells.

Table 1A

$CD107a^+CD56^{high}$ NK	Baseline	+K562	+LPS	+K562+LPS	$+Pam_3Cys$	$+K562+Pam_3Cys$
Healthy controls	12.9%	62.1%	25.9%	72.6%	32.2%	74.5%
AIH	9.0%	56.5%	24.5%	68.4%	20.3%	64.8%
PSC	**4.5%***	**42.5%***	**5.3%***	**45.7%***	**5.7%***	**43.8%***

Table 1B

$CD107a^+CD56^{dim}$ NK	Baseline	+K562	+LPS	+K562+LPS	$+Pam_3Cys$	$+K562+Pam_3Cys$
Healthy controls	5.8%	36.3%	7.6%	40.9%	9.7%	42.8%
AIH	5.0%	37.0%	8.7%	41.9%	7.1%	39.4%
PSC	**2.9%***	**22.4%***	**3.3%***	**22.4%***	**3.7%***	**22.8%***

* $p<0.05$: PSC vs. healthy control and PSC vs. AIH

Table

Conclusion: We find that the liver parenchymal transcriptome and cellular composition in rPSC appears to more closely resemble PSC than ALD. Although this aligns with the presumed shared etiology between rPSC and PSC, the findings from fibrotic areas were more ambiguous. Nevertheless, our study underscores the potential utility of spatial analyses in delineating molecular features and potential targets in liver diseases and prompts replication in larger cohorts.

FRI-366

Cytotoxic activity of peripheral NK cells is decreased in primary sclerosing cholangitis

Jessica Wolf[1], Leona Dold[1], Sandra Kalthoff[1], Taotao Zhou[1], Pia Esser[1], Philipp Lutz[1], Christian Strassburg[1], Ulrich Spengler[1], Bettina Langhans[1]. [1]*University Hospital Bonn, Department of Internal Medicine I, Germany*
Email: Leona.Dold@ukbonn.de

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic inflammatory liver disease associated with progressive obliterative fibrosis of intra- and extrahepatic bile ducts which can lead to biliary cirrhosis and bile duct cancer. Although the cause of this disease is still unclear, it has been proposed that microbial triggers may lead to altered immune cell activation. Since natural killer (NK) cells regulate immune response and can kill altered cells, they are potential key features in autoimmune disorders. Here, we analysed frequency and cytotoxicity of peripheral NK cell subsets in PSC.

Method: We enrolled 12 patients with PSC (8 with inflammatory bowel disease (IBD), 4 without IBD), 15 patients with autoimmune hepatitis (AIH; all budesonide-treated) as disease control, and 12 age- and sex-matched healthy controls. Using multi-colour flow cytometry, we analysed frequencies of $CD56^{high}$ and $CD56^{dim}$ NK cell subsets ex vivo and studied their cytotoxic activity (CD107a assay) at baseline and after in vitro stimulation with K562 target cells and Toll-like receptor ligands (LPS, Pam_3Cys).

Results: Frequencies of NK cells subsets did not differ between PSC (7.1% $CD56^{high}$, 88.8% $CD56^{dim}$) and healthy controls (6.5% $CD56^{high}$, 90.5% $CD56^{dim}$) whereas a shift towards $CD56^{high}$ was found in AIH (22.7% $CD56^{high}$, 74.6% $CD56^{dim}$). Unlike AIH, fractions of $CD107a^+$ NK cells with cytotoxic activity in PSC were substantially reduced both in $CD56^{high}$ (Table 1A) and $CD56^{dim}$ (Table 1B) NK cell subsets at baseline and after *in vitro* stimulation (K562 cells). Importantly, added TLR ligands LPS and Pam_3Cys as well as their combination with K562 cells did not increase $CD107a^+$ NK cells (Table 1A, 1B).

Conclusion: The frequency of NK cells was not altered in PSC. However, a substantially reduced cytotoxic activity was found in $CD56^{high}$ and $CD56^{dim}$ NK cell subsets which was not overcome by stimulation with tumour cells or TLR ligands. This deficit in NK cell cytotoxic activity may play a role in PSC-related inflammation.

FRI-367

The effect of the combination of metformin with propionic acid on the indicators of oxidative stress in liver tissue of rats with type 2 diabetes mellitus

Olena Khokhliuk[1], Nataliia Shulha[2], Yuliia Klys[3], Yulia Osadchuk[3], Larysa Natrus[3]. [1]*Bogomolets National Medical University, Medical Faculty №2, Kyiv, Ukraine;* [2]*Bogomolets National Medical University, Medical Faculty №4, Kyiv, Ukraine;* [3]*Bogomolets National Medical University, Department of Modern Technologies of Medical Diagnostics and Treatment, Kyiv, Ukraine*
Email: natalishulha.ua@gmail.com

Background and aims: The main mechanism of type 2 diabetes mellitus (T2DM) contributing to liver damage is the activation of oxidative stress (OS), accompanied by excessive formation of reactive oxygen species in the mitochondria and depletion of the antioxidant defense system. Therefore, the aim was to investigate the effect of combined administration of metformin with propionic acid (PA) on the degree of oxidative damage in liver of rats with an experimental model of T2DM.

Method: Male Wistar rats were divided: (1) control, (2) T2DM, the group with experimentally induced T2DM by high-fat diet (HFD) for 3 months followed by a single injection of streptozotocin (STZ, 25 mg/kg); and T2DM groups that received the following (14 days, orally): (3) metformin (60 mg/kg), (4) PA (60 mg/kg), and (5) PA + metformin. The rate of generation of superoxide radicals (SR) by mitochondria in liver tissue samples was studied by electron paramagnetic resonance, by spectrophotometer were analyzed 8-oxoguanine, gas-liquid chromatography studies the composition of fatty acids (FAs). We have identified the nine most informative fatty acids (denoted as 100%), and calculated relative combination of saturated fatty acids (SFA), unsaturated fatty acids (USFA); and polyunsaturated fatty acids

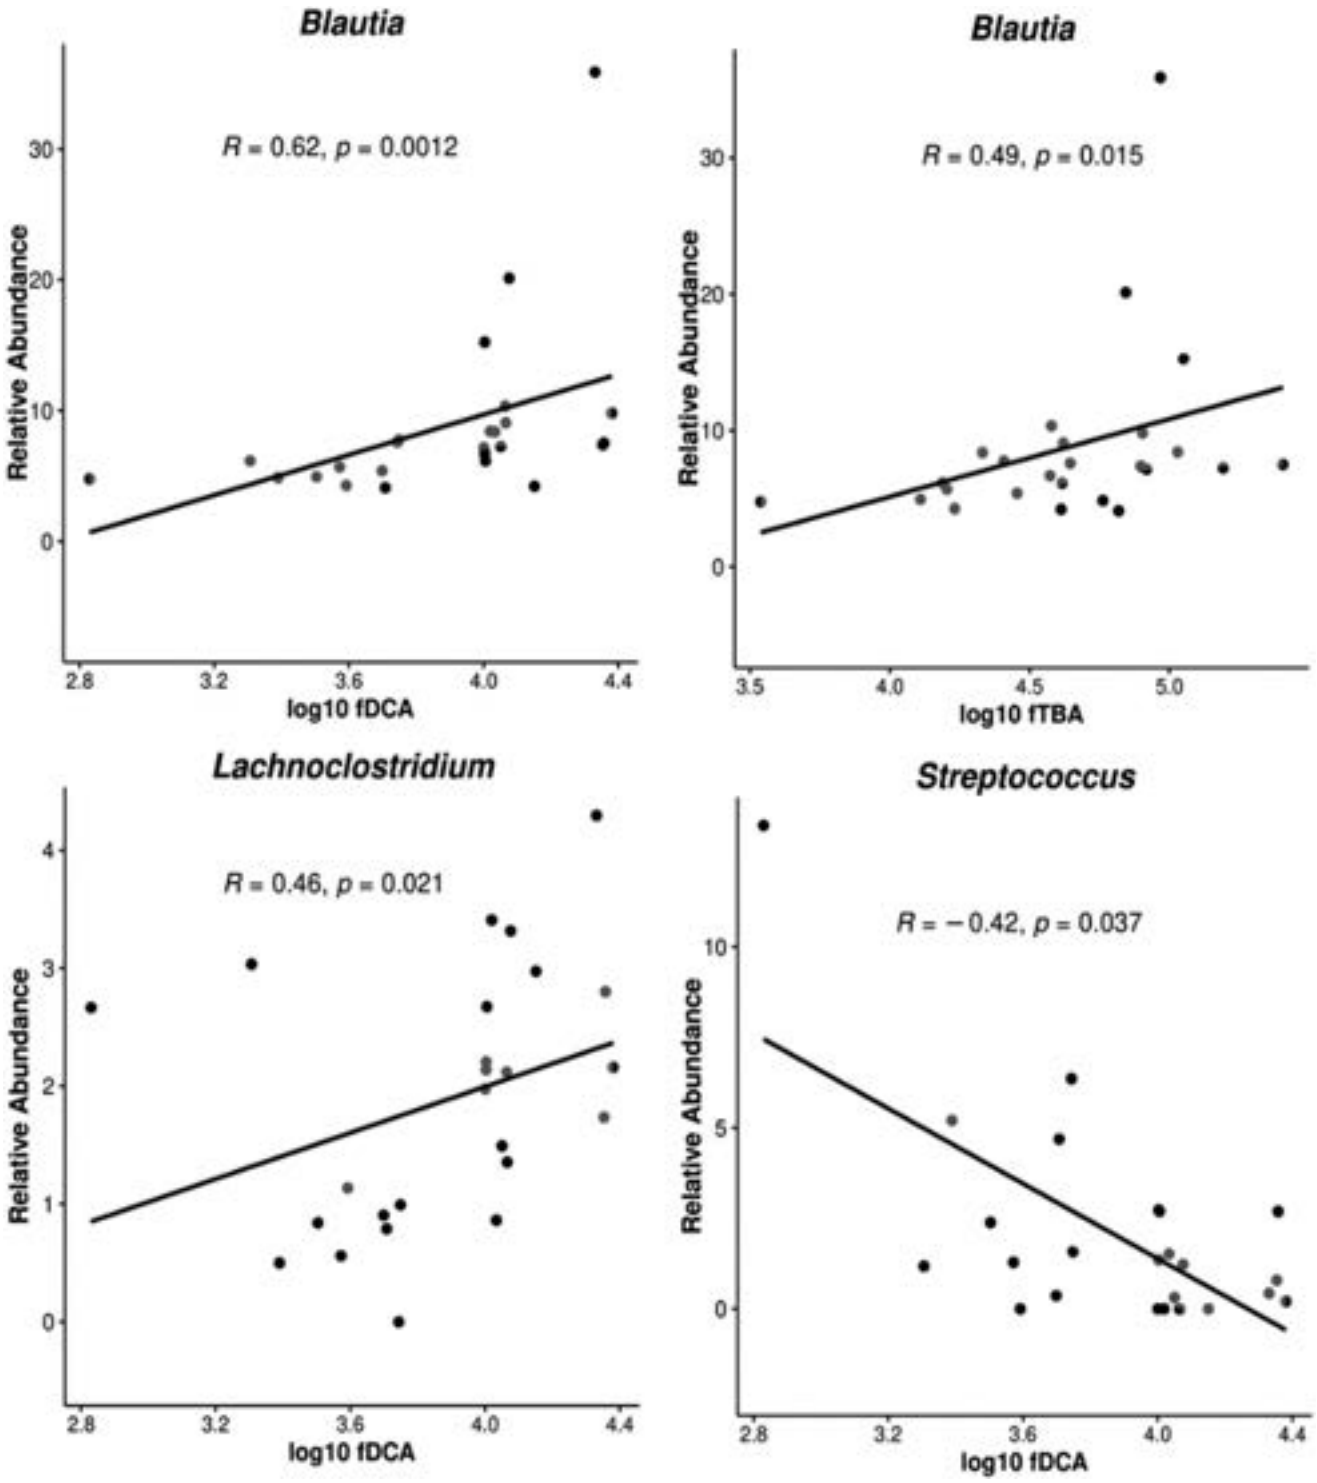

Figure: (abstract: FRI-368).

(PUFA). Statistical differences between groups were evaluated by ANOVA followed by Tukey post-hoc test.

Results: The effect of the combined administration of metformin with propionate on the indicators of OS was evaluated by the study of liver tissue.

SR in the liver tissue on the background of diabetes was increased by 3 times compared to the control group ($p < 0.01$). The introduction of metformin and PA led to a decrease of SR by 25% ($p < 0.01$), the use of combined treatment contributed to a decrease in the generation of SR by 36.5% in liver tissue ($p < 0.01$). The level of 8-oxoguanine in T2DM exceeded its content in the control group by 2.3 times ($p < 0.01$). The use of metformin, PA and simultaneous use of these drugs led to a decrease in this indicator by 27.1%, 16.9% and 31.7%, respectively ($p < 0.01$). The modeling of T2DM led to significant changes in the content

of fatty acids in the tissues of experimental animals compared to intact animals: a 1.3-fold increase in SFA ($p < 0.05$), due to a 1.3-fold decrease in USFA ($p < 0.05$), and a 1.8-fold decrease in PUFA ($p < 0.05$) Combined administration of metformin and propionate to rats with T2DM leads to changes in the redistribution of fatty acids. It increases the content of USFA and PUFA to 43.78 ± 2.4% and 32.02 ± 3.8% and decreases the content of SFA to 56.22 ± 2.9%.
Conclusion: Our study demonstrated that PA and its combination with metformin have beneficial effects on the indicators of OS in liver tissue of rats with T2DM. In our opinion, PA may be considered one of the promising substances for correcting damages of hepatocytes diabetic.

FRI-368
Associations of fecal bile acids, diet, and intestinal microbes with markers of disease progression in primary sclerosing cholangitis disease
Connie Chan[1], Mateus Lemos[2], Peter Finnegan[2], William Gagnon[3], Richard Dean[1], Joseph Zepeda[1], Maryam Yazdanfar[1], Marie-Claude Vohl[4], Joshua Korsenik[5], Olivier Barbier[3], Maria Marco[2], Christopher Bowlus[1]. *[1]University of California Davis, Gastroenterology and Hepatology, United States; [2]UC Davis, Food Science and Technology, United States; [3]Université Laval, CHU de Québec Research Center, Canada; [4]Université Laval, NUTRISS, Canada; [5]Brigham and Women's Hospital, Gastroenterology, United States*
Email: clbowlus@ucdavis.edu

Background and aims: Primary Sclerosing Cholangitis (PSC) disease progression is variable and associated with changes in bile acids (BA) and intestinal dysbiosis. The objective of this study was to elucidate relationships between diet, intestinal microbes, and fecal bile acids with markers of PSC progression.
Method: Stool and blood was collected from patients with early-stage, large duct PSC for measurements of bile acids (BA; LC-MS/MS) and fecal 16S rRNA DNA sequencing. Dietary intake of alcohol, fats, protein, and fiber was estimated from food frequency questionnaires. Healthy controls (HC) included individuals who had participated in a diet supplement clinical trial and had received placebo.
Results: A total of 25 patients with PSC (58.3% male, 70.8% with IBD) with a median [IQR] age 53.8 [43.2–65.4] years, alkaline phosphatase 174.5 [109.5–359.5] IU, and total bilirubin (TB) 17.1 [12.0–20.5] micromol/L, and 10 HC were enrolled. Unconjugated fecal BA (fDCA) was lower in PSC than HC ($p < 0.05$). No differences in other fecal BA were found. Among patients with PSC, fDCA, but no other BA, was negatively associated with TB after adjusting for IBD status and UDCA use ($B = -0.45$, $p = 0.006$). No fecal BA were associated with serum alkaline phosphatase. Surprisingly, fDCA was associated with greater serum C4 ($B = 4.5$, $p = 0.02$). Serum FGF19 was not associated with fDCA or C4. Alcohol intake, but not intake of fats, protein, or fiber, was associated with higher fDCA levels ($B = 423.6$, $p = 0.04$) and lower serum bilirubin ($B = -0.07$, $p < 0.001$). Microbiota analysis revealed correlations between fDCA and increasing abundance of *Blautia and Lachnoclostridium* ($r = 0.62$, $p = 0.001$ and $r = 0.46$, $p = 0.02$, respectively) and decreasing *Streptococcus* ($r = -0.42$, $p = 0.04$) (Figure 1). *Blautia* also correlated with total fecal BA ($r = 0.49$, $p = 0.01$).
Conclusion: In early-stage PSC, decreasing fDCA was associated with increasing TB but did not appear to be mediated through FXR. fDCA was associated with alcohol use and microbes involved in bile acid transformation which may lead to new avenues for treatment.

FRI-369
CD44 reduces fibrosis development in chronic cholestatic liver injury in Mdr2 knock-out mice
Franziska Ihli[1], Fabian Delugré[1], Sophia Bernatik[1], Kohnke-Ertel Birgit[1], Carolin Mogler[2], Simone Jörs[1], Fabian Geisler[1], Roland M. Schmid[1], Ursula Ehmer[1]. *[1]Klinikum rechts der Isar, Technische Universität München, Internal Medicine II, Munich, Germany; [2]Technische Universität München, Institute of Pathology and Unit of Comparative Experimental Pathology, Germany*
Email: ursula.ehmer@tum.de

Background and aims: In cholestatic liver injury, chronic inflammation is associated with the emergence of ductular reactions around the portal triad. In different animal models of liver injury, the expression of the cellular adhesion molecule CD44 in biliary epithelial cells/ductular reactions has been linked to fibrosis. However, the functional relevance of CD44 in the development of fibrosis remains unclear. To determine whether CD44 could present a potential target to reduce fibrosis in chronic cholestatic liver injury, we investigated the functional role of CD44 in *Mdr2*$^{-/-}$ mice.
Method: Livers of *Mdr2*$^{-/-}$;*Cd44*$^{-/-}$ double knock-out (DKO) mice and age-matched *Mdr2*$^{-/-}$ control mice were analyzed at different time points by histopathology. Protein expression of Ki67, CK19 and YAP was quantified by immunohistochemistry.
Results: At 6 months of age, ductular reactions in *Cd44*-deficient *Mdr2*$^{-/-}$ mice were more prominent in than in control mice but comprised a significantly lower number of CK19-positive biliary cells per area. Importantly, DKO livers showed higher levels of fibrosis in comparison to *Cd44*-proficient controls. By immunohistochemistry, cells in the periportal areas of DKO mice expressed lower levels of YAP-a CD44 downstream target-in comparison KO mice (56% vs. 68%, $p = 0.023$).
Conclusion: In the *Mdr2*$^{-/-}$ model of chronic cholestatic liver injury, CD44 protects against fibrosis development. While previous reports suggested that CD44 could contribute to liver fibrosis, our data indicate that CD44 instead has a protective role in chronic cholestatic liver injury. Here, we were able to show that loss of CD44 leads to a lower expression of YAP in ductular reactions as a potential mediator of this phenotype. YAP is a pro-proliferative transcriptional co-factor that is expressed biliary epithelial cells and contributes to their differentiation. In the *Mdr2*$^{-/-}$ model, loss of *Cd44* and reduced levels of YAP translate into lower levels of CK19-expressing cells-indicating that these cells might be essential in mitigating liver damage and consecutive liver fibrosis upon chronic cholestatic liver injury.

FRI-370
Results of pharmacological treatment of Mcpip1 knock-out mice which develop symptoms of primary biliary cholangitis
Katarzyna Trzos[1,2], Natalia Pydyn[1], Joanna Koziel[3], Magdalena Pilarczyk-Żurek[3], Jolanta Jura[1], Jerzy Kotlinowski[1]. *[1]Jagiellonian University, Faculty of Biochemistry, Biophysics and Biotechnology, Department of General Biochemistry, Kraków, Poland; [2]Jagiellonian University, Doctoral School of Exact and Natural Sciences, Faculty of Biochemistry, Biophysics and Biotechnology, Department of General Biochemistry, Kraków, Poland; [3]Jagiellonian University, Faculty of Biochemistry, Biophysics and Biotechnology, Department of Microbiology, Kraków, Poland*
Email: kat.trzos@doctoral.uj.edu.pl

Background and aims: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease that results from slow, progressive destruction of the intrahepatic bile ducts. PBC progression leads to the development of fibrosis, cholestasis, liver cirrhosis. Mcpip1fl/flAlbCre mice which are characterized by deletion of the Zc3h12a gene (encoding Mcpip1 protein) in liver epithelial cells and develop a number of typical PBC symptoms, such as presence of antimitochondrial (AMA) and antinuclear antibodies, total bile acids elevated, increased activity and alkaline phosphatase. Mcpip1fl/flAlbCre mice are also characterised by bile duct pathology which includes

hyperplasia of the intrahepatic bile ducts, bile duct epithelium disruption and fibrosis, resulting in lumen obstruction and bile duct destruction. The main goal of this project is to define the dynamics of PBC-like disease development in those mice after administration of first- and second-line therapy commonly used in patients suffering with PBC. The study was enriched with the use of a probiotic (Lactobacillus rhamnosus), since there is a growing number of evidence of a huge role that gut microbiota plays in PBC development and progression.

Method: Mcpip1fl/flAlbCre knock-out male mice and Mcpip1fl/fl control male mice at 6 weeks of age were randomly divided into five groups for drug treatment. Control group received corn oil, other groups received consecutively Lakcid (L. rhamnosus, 10^9 CFU per day) suspended in water, ursodeoxycholic acid (UDCA, 15 mg/kg body mass per day) diluted in corn oil, UDCA diluted in corn oil and Lakcid suspended in water, UDCA and obeticholic acid (OCA, 10 mg/kg body mass per day) both diluted in corn oil. After 6 weeks of treatment, the mice were sacrificed, and the collected material analysed by, amongst other, detailed serum liver tests, ELISA tests for the presence of anti-PDC-E2 autoantibodies, histological stainings (hematoxylin and eosin, picro Sirius red) and qPCRs.

Results: After 6-weeks of treatment we detected significant proliferation of cholangiocytes and fibrosis in livers from Mcpip1 knock-out mice, together with high serum level of total IgM, total bile acids and anti-PDC-E2 autoantibodies. Livers isolated from Mcpip1 knok-out mice were also characterized by high expression of Tgfb1, Il1b, Ngp and Ngf. There were no changes in serum levels of ALT, AST, bilirubin, cholesterol and LDH between Mcpip1fl/fl and Mcpip1fl/flAlbCre mice. Mcpip1fl/flAlbCre treated with Lakcid had reduced amount of total bile acids in the serum and decreased proliferation of cholangiocytes. Additionally, they had reduced amount of PDC-E2 autoantibodies to the level observed in Mcpip1fl/fl counterparts. Although Lakcid administration did not ameliorate liver fibrosis, mice from this group were chosen for further multiomic analysis of liver (nex generation sequencing, mass spectrometry) that are currently ongoing. Treatment with UDCA or with UDCA+OCA also reduced serum levels of TBA in Mcpip1fl/flAlbCre mice but had no effect on cholangiocytes' proliferation nor gene expression in the livers.

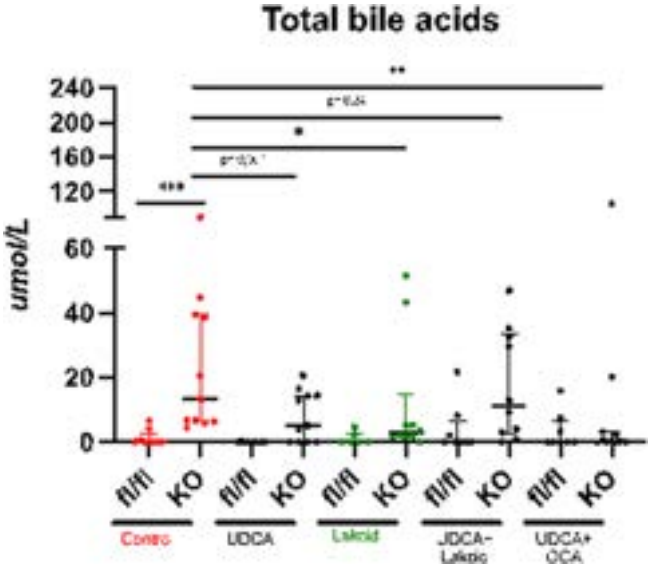

Figure:

Conclusion: Treatment of Mcpip1fl/flAlbCre mice with Lakcid had beneficial effects on PBC symptoms that are normally observed in these animals. We hope that analysis of Mcpip1fl/flAlbCre may shed a new light on the pathology of PBC development.

Acknowledgments: This study was supported by scientific grant awarded by Polpharma Scientific Foundation to dr Jerzy Kotlinowski.

The role of Type II and III Interferons in primary biliary cholangitis

Yooyun Chung[1,2,3], Phoebe Tsou[2,3,4], Michael Heneghan[1,2], Antonio Riva[2,4,5], Shilpa Chokshi[2,4,5]. *[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom; [3]Joint First Authors, United Kingdom; [4]The Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [5]Joint Senior Authors, United Kingdom*

Email: a.riva@researchinliver.org.uk

Background and aims: Primary biliary cholangitis (PBC) has a variable disease course with limited treatment options. There is a need for targeted therapeutic agents and prognostic biomarkers which would allow personalised risk stratification and management. Type I interferons (IFNs) have shown to play a role in murine PBC; however, little is known regarding their involvement and the role of type II/III IFNs in PBC patients. The aim of this investigation was to explore the involvement of IFNs in PBC.

Method: Plasma samples from 64 PBC patients between 2012 and 2022 were compared to 10 healthy controls (HC). PBC subgroups were 24 ursodeoxycholic acid (UDC) responders (UDCR) according to the Paris criteria, 18 UDC non-responders (UDCNR), 22 end stage PBC prior to liver transplantation (ESPBC). Luminex multiplex ELISA was used to quantify concentrations of 28 pro/anti-inflammatory cytokines including Type II and III IFNs and D-lactate was also measured.

Results: The majority of PBC patients were female (n = 62, 97%) with a mean age of 55 years. UDCR and UDCNR were mostly non-cirrhotic patients with 4 early cirrhotic patients in UDCR and 5 in UDCNR. ESPBC represented a distinct group with significantly higher liver prognostic scores compared to UDCR and UDCNR. All PBC subgroups had upregulation of CCL2, IL-7 and IL-8 compared to HC. IFN-gamma levels became progressively detectable as disease progressed to UDCNR and ESPBC (Chi-sq p = 0.007). IFN-gamma levels were not significantly different between UDCR and HC. However, the IFN-gamma levels became increasingly upregulated in UDCNR (p = 0.0262) and ESPBC (p = 0.0012) when compared to UDCR. The difference in IFN-gamma levels between UDCR and UDCNR was also maintained on excluding cirrhotic patients (p = 0.0056). In ESPBC, elevated IFN-gamma was accompanied by increased CXCL10. ESPBC expressed several predominantly pro-inflammatory cytokines including IL-6 and TNF-alpha compared to HC. Interestingly, IFN-lambda3, but not IFN-lambda2, was elevated in ESPBC when compared to all other subgroups, hinting at differential gut mucosal involvement. Using D-lactate, as an established marker of bacterial translocation, we found levels were equally elevated in all PBC subgroups compared to HC.

Conclusion: Type II and Type III Interferons are associated with PBC. IFN-gamma increased as disease progressed suggesting contributions from NK and/or T cells in the immunopathogenesis and may serve as a potential biomarker. IFN-lambda3 may have a role in advanced disease that is distinct to IFN-lambda2 and warrants further exploration. The increased gut permeability and bacterial translocation in PBC may indicate the gut microbiome as a potential therapeutic target.

Liver development and regeneration

SAT-353

Liver innervation is dysregulated in a mouse model of Alagille syndrome

Elisabeth Verboven[1], Noémi K. M. Van Hul[1], Simona Hankeova[1], Csaba Adori[1], Ewa Ellis[1], Björn Fischler[1], Emma Andersson[1].
[1]*Karolinska Institute, Stockholm, Sweden*
Email: elisabeth.verboven@ki.se

Background and aims: The liver is richly innervated, which is often overlooked despite the key roles of nerves in liver function. Liver innervation is enriched in the periportal area, where both mesenchyme and bile ducts are extensively innervated. In Alagille syndrome (ALGS), caused by mutations in Notch components, bile ducts do not develop properly, with severe consequences for liver function. Although Notch is well known for its role in development of the nervous system, it is not yet known whether liver innervation is affected in ALGS, and whether disturbed innervation might further aggravate liver function. The aim of this study is to determine how liver innervation interacts with and regulates bile duct development and homeostasis.
Method: I performed whole mount immuno-stainings for cholangiocytes and nerves in livers from wild-type and *Jag1*$^{Ndr/Ndr}$ mice (a model of ALGS). To test the function of liver innervation, wild-type mice were treated with the dopaminergic and noradrenergic neurotoxin 6-hydroxydopamine for nerve depletion. Lightsheet microscopy allowed visualization of the three-dimensional neural and biliary expansion throughout the liver, with analysis using Imaris software. Patient liver biopsies were analyzed with immunofluorescence to validate observations in humans.
Results: Preliminary timecourse data of the developing liver confirmed that innervation is first established in the hilar region of the liver, followed by outgrowth of the nerves into the periphery from postnatal day 6 (P6) on. In *Jag1*$^{Ndr/Ndr}$ livers, innervation was strongly reduced and mislocalized during development. The absence of liver nerves is physiologically relevant for patients with Alagille syndrome, and is not an indirect consequence of cholestasis, as we confirmed loss of innervation in biopsies from patients with ALGS, but not in progressive familial intrahepatic cholestasis (PFIC). Ablation of peripheral nerves in wild-type mice at P1 by injection of a neurotoxin did not compromise bile duct development.
Conclusion: We show that in addition to bile duct development, liver innervation is also impaired in ALGS. We developed and validated a method for postnatal denervation, showing that liver nerves are not required for bile duct development at this postnatal stage. The physiological consequences of dysregulated innervation in ALGS will be further investigated to identify how denervation impacts this cholangiopathy. Further research is ongoing to also investigate how bile ducts and nerves interact during development and to define the regulatory mechanisms that each exerts on the other.

SAT-354

A novel organoid model of human liver bud development

Charlotte Grey-Wilson[1], Sabitri Ghimire[1], Ludovic Vallier[1,2,3], Anna Osnato[1], Carola Maria Morell[1]. [1]*University of Cambridge, United Kingdom;* [2]*3Berlin Institute of Health (BIH), BIH Centre for Regenerative Therapies (BCRT), Charité- Universitätsmedizin, Berlin, Germany;* [3]*Max-Planck-Institut für molekulare Genetik, Berlin, Germany*
Email: cg697@cam.ac.uk

Background and aims: Understanding the mechanisms controlling the development of human liver is challenging due to technical and ethical limitations. Of particular interest, the process by which the human liver bud first arises from the foregut and the subsequent specification of the hepatoblasts, remains to be fully uncovered. To address these major questions, we decided to develop a novel 3D culture system allowing the differentiation on human induced Pluripotent Stem Cells (hiPSCs) into self-organising human liver buds.
Method: To generate a new model of liver bud development, we first tested popular foregut induction conditions across different hiPSC systems to develop and optimise a new protocol for the generation of hepatoblast and hepatocytes *in vitro*. This novel system uses a foregut induction step which has not been previously described in the context of liver development *in vitro*. Following 2–3 weeks of hepatic induction, cells are then dissociated into clumps and seeded in Matrigel to form liver bud organoids in conditions previously used to maintain primary hepatoblast organoids (pHBOs). When passaged sequentially, organoids persist as hiPSC-derived HBOs (iHBOs) which can be passaged similar to pHBOs. iHBOs were then tested for their ability to differentiate into hepatocytes and cholangiocytes.
Results: We first developed and optimised a protocol to drive differentiation of hiPSCs into a population of foregut cells containing progenitor (s) for pancreas, liver and extra-hepatic biliary cells. The resulting cells were then grown in 3D culture conditions known to support organoid formation. These cells rapidly self-organise into complex budding structures which appear to recapitulate the initial organogenesis of the liver bud *in vitro*. This includes the formation of a "bud" consisting of cell expressing HNF4A/ALB/AFP, extra-hepatic biliary cells expressing CK19 and also potential pancreato-biliary progenitors marked by PDX1. Thus, these organoids are composed of multiple cell types produced during the early hepato-biliary specification from the foregut. Finally, we decided to demonstrate the functional relevance of this 3D structure by deriving HBOs from *in vitro* generated liver bud. For that, liver bud organoids underwent serial passaging. We rapidly observed the formation of self-renewing organoids containing homogeneous population of cells expressing hepatoblast markers. These human iHBO were able to self-renew for an additional 8 passages while maintaining their morphological characteristics and initial results also suggest iHBO have a capacity to differentiate into cholangiocytes and hepatocytes.

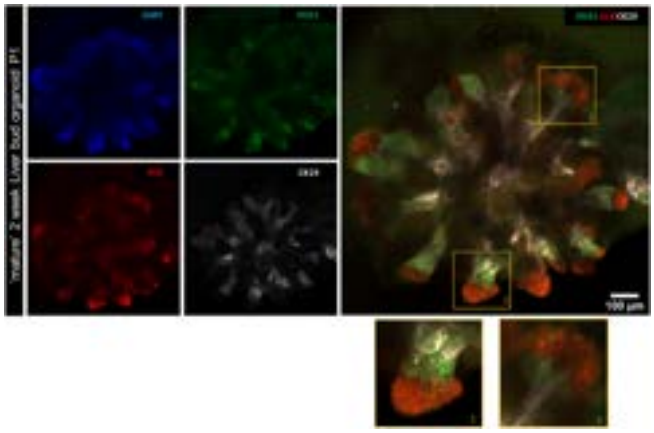

Figure: Two-week old liver bud organoids generated from hiPSCs.

Conclusion: Taken together, these results show that our model of liver bud development provides a new platform not only to study hepatobiliary lineage specification *in vitro* but also to produce cell types with a clinical interest.

SAT-355

Tunable host senescence determines the success of hepatocyte transplantation in a mouse model of liver injury

Victoria Gadd[1], Sofia Ferreira-Gonzalez[1], Wei-Yu Lu[2], Tak Yung Man[1], Alastair Kilpatrick[1], Ian Smith[1], Rhona E. Aird[1], Daniel Rodrigo-Torres[1], Stuart J. Forbes[1]. [1]*University of Edinburgh, Centre for Regenerative Medicine, United Kingdom;* [2]*University of Edinburgh, Centre for Inflammation Research, United Kingdom*
Email: victoria.gadd@ed.ac.uk

Background and aims: Hepatocyte transplantation has shown promise for genetic diseases but has mixed efficacy for acute and severe liver injury. One reason for this is poor function of donor hepatocytes in recipient liver. Hepatocyte senescence is a key feature of many liver diseases. We have sought to model this using $Ah^{cre}Mdm2^{fl/fl}$ mice, where genetic induction results in excision of hepatocyte Mdm2 (negative regulator of p53), leading to hepatocellular senescence and liver injury. We have used this model to determine the effects of host liver senescence upon human and mouse hepatocyte engraftment and function.
Method: Freshly isolated mouse, or human cryopreserved hepatocytes, were injected into the spleen of $Ah^{cre}Mdm2^{fl/fl}$ (immune competent and deficient strains) mice. Engraftment kinetics, donor cell and host liver function were assessed.
Results: Senescence-driven liver injury could be induced in $Ah^{cre+}Mdm2^{fl/fl}$ mice in controlled and predictable levels through excision of hepatocyte Mdm2. Host senescence and injury was a requirement for donor hepatocyte engraftment and repopulation, but too much was inhibitory to this. Mice with moderate senescence (30–50%) demonstrated up to 95% engraftment of transplanted mouse hepatocytes after 8 weeks. Human hepatocyte engraftment was also dependent upon host senescence in $Ah^{cre+}Mdm2^{fl/fl}Rag2^{-/-}Il2rg^{-/-}$ mice where 1 mg/ml of human albumin was detected in the serum of chimeric mice after 16 weeks. Histological features of injury (senescence, ductular reaction and fibrosis) were negatively associated with the level of hepatocyte engraftment. Importantly, in some $Ah^{cre}Mdm2^{fl/fl}$ mice (2/13), despite initial engraftment, transplanted hepatocytes failed to provide long-term functional support. Previously healthy donor hepatocytes acquired p21 expression and failed to expand, suggesting that host senescence had been transferred to donor cells in a paracrine manner. Further modelling using high levels of induced host senescence (>90%) resulted in rapid host-mediated paracrine senescence in donor cells. Paired proteomic and transcriptomic analysis of healthy vs senescent hepatocytes reveal a unique senescent signature associated with paracrine senescence. Inhibition studies are underway to assess the effects on host-mediated paracrine senescence and donor hepatocyte function. To test this hypothesis, pre-treatment of senotherapeutic drug ABT737 in host mice with high levels of senescence (>65%) improved proliferation in donor cells after 1 week.
Conclusion: Host liver senescence provides a required non-competitive niche for donor hepatocytes to repopulate the recipient liver. However, host-mediated paracrine senescence can impair donor hepatocyte function. Targeting paracrine senescence may be a way to improve donor hepatocyte function, optimise therapy and guide translation into the clinics.

SAT-356

Liver regeneration is regulated by intestinal sirtuin-1

Sian Seaman[1], Mar Moreno-Gonzalez[1], Mark Philo[2], Naiara Beraza[1]. [1]*Quadram Institute, Gut Microbes and Health Institute Strategic Programme, Norwich, United Kingdom;* [2]*Quadram Institute, Analytical Science Unit, Norwich, United Kingdom*
Email: naiara.beraza@quadram.ac.uk

Background and aims: Sirtuin1 (SIRT1) is recognised as a master regulator of bile acid (BA) metabolism in both the liver and the intestine. In the liver, SIRT1 has previously been hailed as crucial for successful liver regeneration by regulating BA metabolism through FXR. However, despite these findings and the recent interest in the gut-liver axis, the role of intestinal SIRT1 in liver regeneration remains undefined.
Method: We performed partial hepatectomy (PHx) on intestinal-specific SIRT1 knockout mice ($SIRT1^{int\text{-}KO}$) to stimulate liver regeneration. Samples were collected at intervals post-PHx and analysed via quantitative polymerase chain reaction (qPCR) to determine gene expression, immunoblotting and immunohistochemistry (IHC) to determine protein expression and liquid chromatography- mass spectrometry (LC-MS) to characterize the bile acid pool in both the liver and intestine.
Results: Liver weight: body weight ratio in $SIRT1^{int\text{-}KO}$ mice was comparable to that found in wildtype (WT) mice at 10 days post-PHx. However, $SIRT1^{int\text{-}KO}$ mice exhibited profuse liver injury at 24 hrs post-PHx associated with BA accumulation, suggesting increased hepatocellular death due to BA toxicity. Additionally, $SIRT1^{int\text{-}KO}$ mice presented signs of impaired hepatocyte proliferation through decreased expression of cell cycle proteins, cyclin D1 and delayed expression of cyclin E and A compared to WT mice. Further IHC analysis of pHistone-H3 showed significantly decreased presence of mitotic hepatocytes in $SIRT1^{int\text{-}KO}$ livers compared to WT mice at 48 hrs post-PHx. This reduced hepatocyte proliferation correlated with increased abundance of senescent hepatocytes shown by IHC analysis of P21 and qPCR analysis of P16 and P21. Remarkably, IHC analysis of cytokeratin-19 (CK-19), a liver progenitor cell (LPC) marker, revealed $SIRT1^{int\text{-}KO}$ livers had increased presence of LPCs in the parenchyma at 48 hrs post-PHx, denoting activation and expansion of the stem cell compartment to repopulate the liver as an alternative form of liver regeneration. Further study of intestinal BA metabolism regulation revealed that $SIRT1^{int\text{-}KO}$ mice exhibited a dysregulation of intestinal SIRT1 downstream targets, farnesoid x receptor (FXR) and fibroblast growth factor-15 (FGF15), during the regenerative process compared to WT mice.
Conclusion: We define intestinal SIRT1 as a key regulator of the regenerative response in the liver. Our results point towards intestinal BA metabolism factors, FXR and FGF15, as mechanistic mediators of the effects of intestinal SIRT1 in regulating hepatocyte proliferation during liver regeneration. Overall, our results shed light into the mechanisms regulating the liver regenerative response and highlights the importance of intestinal-derived signals to control liver regeneration.

SAT-357

IGF1 specifically rescues peripheral intrahepatic biliary organoids from a mouse model of Alagille syndrome

Afshan Iqbal[1], Noémi K. M. Van Hul[1], Lenka Belicova[1], Agustin Corbat[1], Simona Hankeova[1,2], Emma Andersson[1]. [1]*Karolinska Institute, Cell and Molecular Biology, Solna, Sweden;* [2]*Genentech, South San Francisco, United States*
Email: afshan.iqbal@ki.se

Background and aims: Patients with Alagille syndrome (ALGS) display peripheral intrahepatic bile duct paucity. Intriguingly, some patients and the *Jag1*$^{Ndr/Ndr}$ mouse model for ALGS can de novo generate their biliary system. We have shown that this occurs via distinct architectural mechanisms in the hilum and periphery. IGF1, a trophic factor for biliary cells, is downregulated in patients and *Jag1*$^{Ndr/Ndr}$ mice, making it an interesting possible therapeutic target for ALGS. Here, we investigated hilar and peripheral bile ducts from *Jag1*$^{Ndr/Ndr}$ mice, after recovery, to address biliary heterogeneity and mechanisms of recovery, and investigate potential therapeutic approaches.
Method: To investigate molecular differences in hilar and peripheral bile ducts, intrahepatic cholangiocyte organoids (ICOs) were derived from hilar and peripheral regions of adult *Jag1*$^{+/+}$ and *Jag1*$^{Ndr/Ndr}$ mouse livers (hICOs, and pICOs respectively, 3 cell lines from each region and genotype, 12 total). Region-specific ICOs were analyzed using RNA sequencing, live imaging, proliferation analysis (EdU assay), live/dead staining (CalceinAM/PI) and immunofluorescence. Organoids were treated with IGF1 to test whether this positively modulates organoid growth or survival.
Results: *Jag1*$^{Ndr/Ndr}$ hICOs and pICOs were functionally and molecularly distinct from one another and from corresponding *Jag1*$^{+/+}$ ICOs. *Jag1*$^{Ndr/Ndr}$ hICOs were significantly ($p < 0,0036$) smaller than *Jag1*$^{+/+}$ hICOs and *Jag1*$^{Ndr/Ndr}$ pICOs ($p < 0.0020$). Both *Jag1*$^{Ndr/Ndr}$ hICOs and pICOs were far less ($p < 0.0001$) proliferative than corresponding *Jag1*$^{+/+}$ ICOs. Bulk RNA sequencing analysis of regional ICOs revealed downregulated cell cycle-associated genes in *Jag1*$^{Ndr/Ndr}$ ICOs corroborating decreased proliferation. IGF1 treatment of regional ICOs specifically rescued survival and growth of *Jag1*$^{Ndr/Ndr}$ pICOs ($p < 0.0464$), while hICOs were not significantly affected. RNA sequencing analysis revealed that *Jag1*$^{Ndr/Ndr}$ hICOs were the most divergent ICOs and enrichment analysis demonstrated expression of a hepatocyte signature with activated IGF1 signaling pathway components. Finally, Notch components *Jag2* and *Nrarp we*re specifically downregulated in *Jag1*$^{Ndr/Ndr}$ hICOs.
Conclusion: *Jag1*$^{Ndr/Ndr}$ hilar and peripheral ICOs are molecularly distinct from one another and from corresponding *Jag1*$^{+/+}$ ICOs. *Jag1*$^{Ndr/Ndr}$ ICOs are growth-impaired, but cell cycle can be rescued in pICOs by IGF1. IGF1 furthermore improves survival of *Jag1*$^{Ndr/Ndr}$ pICOs and is thus a potential therapeutic target for ALGS. Hilar *Jag1*$^{Ndr/Ndr}$ ICOs are Notch-off and express a hepatocyte-like signature, associated with active Igf1 production/signaling, and are less benefitted by IGF1 treatment.

SAT-358

Endothelial autophagy is not required for liver regeneration after partial hepatectomy in mice with fatty liver

Adel Hammoutene[1,2], Marion Tanguy[1,2], Mélanie Calmels[1], Riccardo Pravisani[3], Chantal Boulanger[1], Valérie Paradis[2,4], Hélène Gilgenkrantz[2], Pierre-Emmanuel Rautou[1,2,5]. [1]*Université Paris Cité, PARCC, INSERM, F-75015 Paris, Paris, France;* [2]*Université Paris-Cité, Inserm, Centre de recherche sur l'inflammation, UMR 1149, Paris, France, France;* [3]*Service de chirurgie hépatobiliaire et pancréatique, Hôpital Beaujon, AP-HP, Clichy, France, France;* [4]*Service d'Anatomie Pathologique, Hôpital Beaujon, Assistance Publique-Hôpitaux de Paris, Clichy, France, France;* [5]*Service d'Hépatologie, AP-HP, Hôpital Beaujon, DMU DIGEST, Centre de Référence des Maladies Vasculaires du Foie, FILFOIE, ERN RARE-LIVER, Clichy, France, France*
Email: amsadel@hotmail.com

Background and aims: Patients with metabolic associated fatty liver disease (MAFLD) have impaired liver regeneration following liver resection. Liver endothelial cells play a key role in liver regeneration. Autophagy is a cellular conserved process involved in the degradation of dysfunctional material. In non-alcoholic steatohepatitis (NASH), liver endothelial cells display a defect in autophagy, thus contributing to NASH progression. We aimed in this study to determine the role of endothelial autophagy in liver regeneration following liver resection in MAFLD.
Method: We analyzed the effect of the defect in endothelial autophagy on liver regeneration by using mice deficient in endothelial autophagy (*Atg5*$^{lox/lox}$*-VECadherinCre*$^{+}$; n = 13) and littermate controls (*Atg5*$^{lox/lox}$, n = 15) mice, fed a high fat diet (HFD) for 16 weeks. Mice were subjected to 2/3 partial hepatectomy (removal of 70% of liver parenchyma) and liver regeneration was assessed by histology and western blot at two time points (40 and 48 hours after liver resection). We confirmed our finding using two other models of MAFLD.
Results: At the two time points of the liver regeneration process (40 and 48 hours), deficiency in endothelial autophagy had no impact on liver/body weight ratio, plasma AST, ALT and albumin concentration. Compared to control mice, *Atg5*$^{lox/lox}$*-VECadherinCre*$^{+}$ mice had similar liver protein expression of proliferation markers (proliferating cell nuclear antigen, PCNA) and cell-cycle markers (Cyclin D1 for G1/S phases and BrdU incorporation for S phase; phospho-Histone H3 for G2/M phases). Deficiency in endothelial autophagy did not affect either liver apoptosis as assessed by cleaved-Caspase-3 liver protein expression. Same results were observed in two other models of MAFLD, namely a model of simple steatosis (5 mice deficient in *ApoE*/*Atg5*$^{lox/lox}$*-VECadherinCre*$^{+}$ vs. 5 *ApoE*/*Atg5*$^{lox/lox}$), and model of NASH (5 *Atg5*$^{lox/lox}$*-VECadherinCre*$^{+}$ mice fed a methionine and choline deficient diet vs. 5 *Atg5*$^{lox/lox}$ mice fed the same diet) (data not shown).

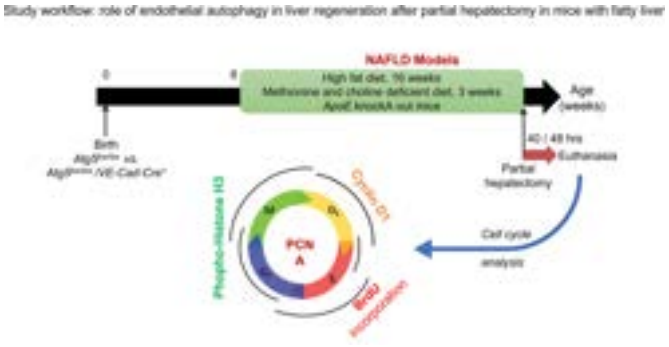

Figure:

Conclusion: Our results demonstrate that endothelial autophagy is not required for liver regeneration after partial hepatectomy in mice in the MAFLD setting. The defect in endothelial autophagy occurring

in NASH does not account for the impaired liver regeneration associated with MAFLD.

SAT-359

Transcriptomics confirm the establishment of a liver-immune dual-humanized mouse model after transplantation of a single type of human bone marrow mesenchymal stem cell

Suwan Sun[1,2], Hui Yang[1], Jiaojiao Xin[1], Heng Yao[1], Jing Jiang[1], Dongyan Shi[1], Jun Li[1]. [1]*The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Hangzhou, China;* [2]*The First Affiliated Hospital, Zhejiang University School of Medicine, Department of Endocrinology and Metabolic Disease, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Human bone marrow mesenchymal stem cells (hBMSCs) are important for developing a dual-humanized mouse model to clarify disease pathogenesis. We aimed to elucidate the characteristics of hBMSC transdifferentiation into liver and immune cells.

Method: A single type of hBMSCs was transplanted into immunodeficient *Fah*$^{-/-}$ *Rag2*$^{-/-}$ *IL-2Rγc*$^{-/-}$ SCID (FRGS) mice with fulminant hepatic failure (FHF). Liver transcriptional data from the hBMSC-transplanted mice were analysed to identify transdifferentiation with traces of liver and immune chimerism.

Results: Mice with FHF were rescued by implanted hBMSCs. Human albumin/leukocyte antigen (HLA) and CD45/HLA double-positive hepatocytes and immune cells were observed in the rescued mice during the initial 3 days. The transcriptomics analysis of liver tissues from dual-humanized mice identified two transdifferentiation phases (cellular proliferation at 1–5 days and cellular differentiation/maturation at 5–14 days) and ten cell lineages transdifferentiated from hBMSCs: human hepatocytes, cholangiocytes, stellate cells, myofibroblasts, endothelial cells and immune cells (T/B/NK/NKT/Kupffer cells). Two biological processes, hepatic metabolism and liver regeneration, were characterized in the first phase, and two additional biological processes, immune cell growth and extracellular matrix regulation, were observed in the second phase. Immunohistochemistry verified that the ten hBMSC-derived liver and immune cells were present in the livers of dual-humanized mice.

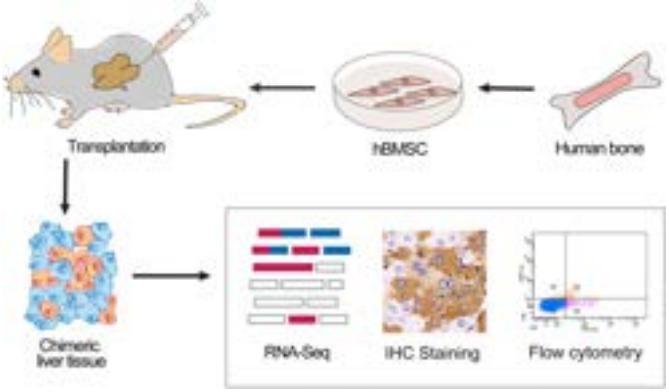

Figure:

Conclusion: A syngeneic liver-immune dual-humanized mouse model was developed by transplanting a single type of hBMSC. Four biological processes linked to the transdifferentiation and biological functions of ten human liver and immune cell lineages were identified, which may help to elucidate the molecular basis of this dual-humanized mouse model for further clarifying disease pathogenesis.

SAT-360

Skin-decellularized matrix-derived microgels accelerate 3D cultures of functional primary hepatocyte spheroids in vitro

Ashwini Vasudevan[1], Shreemoyee De[2], Neetu Singh[2], Shiv Kumar Sarin[3], Dinesh Mani Tripathi[3], Savneet Kaur[3]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India;* [2]*Indian Institute of Technology Delhi, India;* [3]*Institute of Liver and Biliary Sciences, India*
Email: savykaur@gmail.com

Background and aims: Tissue extracellular matrix (ECM) plays a major role in providing a suitable niche for cell growth and differentiation. Skin tissue ECM is extremely dynamic with inherent properties such as enhanced wound healing and regeneration in response to tissue damage. In the current study, we explored the skin matrix vis-a-vis liver matrix for *in vitro* cultures of primary hepatocytes.

Method: Skin decellularized matrix (SDCM) was prepared by carefully excising dorsal skin tissues from adult rats, and tissues were decellularized with TritonX-100 and SDS. Liver decellularized matrix (LDCM) was prepared by perfusing rat livers with detergents. Tissue acellularity post-decellularization was confirmed with HandE staining and DNA quantification and intact matrix components were studied by proteomic analysis using LC-MS. Rodent primary hepatocytes were isolated by collagenase perfusion method. Viable hepatocytes were mixed with digested matrices and 1% alginate, and encapsulation was performed with $CaCl_2$ solution to form microgels containing cells. Stiffness of the cell microgels was assessed by Young's modulus. Encapsulated hepatocytes were cultured in microgels for up to 21 days, studied by scanning electron microscopy (SEM) and their viability, gene expression and functions were assessed.

Results: Proteomic analysis of the decellularized matrices revealed 16 types of collagens predominantly Collagen I, III, IV and VI, and upregulated expression of elastin and laminin in SDCM as compared to LDCM. Microgels with the LDCM showed increased compressive stress (Σ2.4 Pa) when compared to SDCM (Σ0.98 Pa). SEM analysis confirmed the encapsulation of hepatocytes as 3D spheroids in the microgels. There was significant increase in viability of hepatocytes cultured on both SDCM and LDCM microgels at days 7, 15 and 21 in comparison with those on collagen. On day 21, >2-fold increase ($p < 0.05$) in viability was observed in hepatocytes on SDCM microgels in comparison to those on LDCM. Hepatocytes grown on SDCM microgels also showed a significant increase in the expression of hepatocyte-specific genes including Alb, ASGR1, HNF4-alpha in comparison to those cultured on LDCM microgels and collagen on both day 15 and day 21. Albumin and urea secretion in culture supernatants from hepatocytes on SDCM microgels showed a significant increase on all days (On day 21: Σ1250 mg/dl albumin and Σ50 g/dl urea) in comparison to those on LDCM (Σ750 mg/dl albumin and Σ30 g/dl urea on day 21) and collagen (Σ150 mg/dl albumin and Σ10 g/dl urea on day 21) ($p < 0.05$).

Conclusion: Hepatocytes cultured with the SDCM microgels grow as 3D spheroids and show significantly improved viability and functionality for 3 weeks in comparison to LDCM. SDCM thus forms a better and lucrative alternative to decellularized liver matrix for maintaining long-term cultures of hepatocytes.

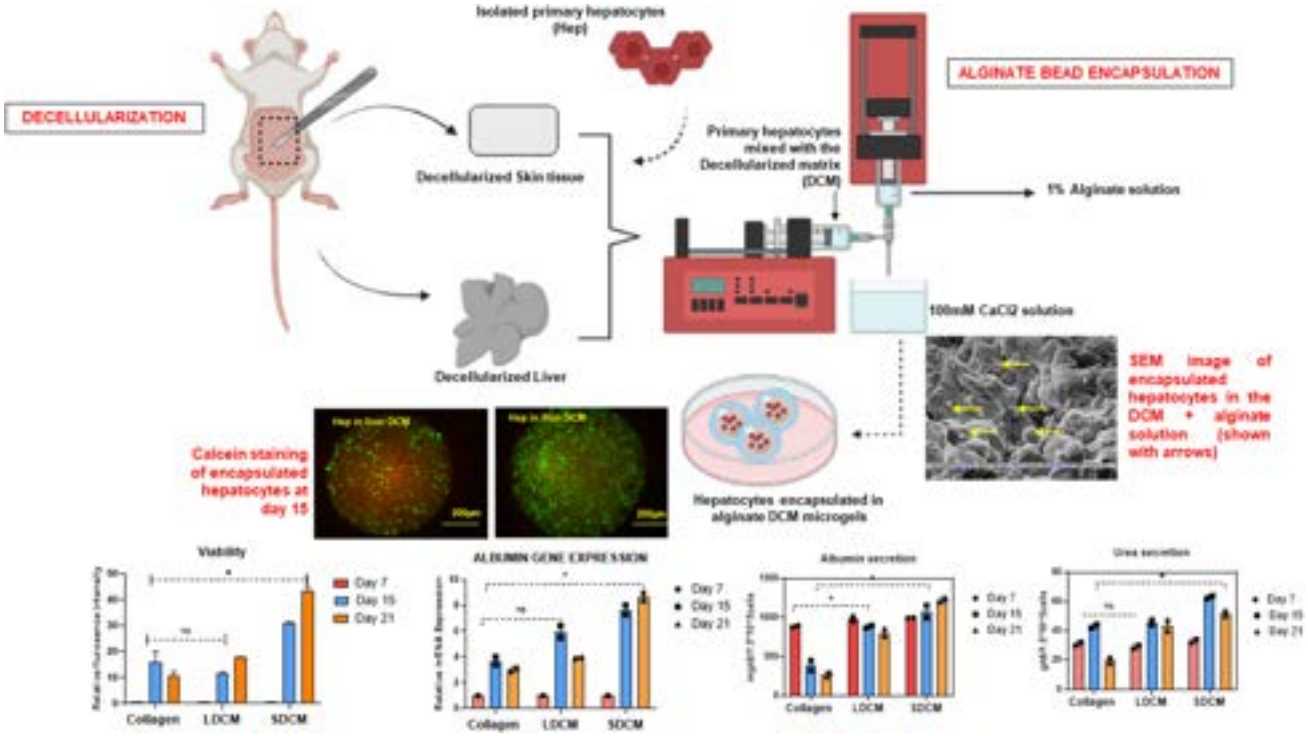

Figure: (abstract: SAT-360).

SAT-361

Autophagy regulates the generation and differentiation of chemically derived hepatic progenitors (CdHs)

Hayoon Kim[1,2], Myounghoi Kim[1], Elsy Soraya Salas Silva[1], Tae Hun Kim[1], Jiyoon Byeon[1], Michael Adisasmita[1], Min Kim[1], Ji Hyun Shin[1], Dongho Choi[1]. [1]*Research Institute of Regenerative Medicine and Stem Cells, Seoul, Korea, Rep. of South;* [2]*Hanyang University College of Medicine, Korea, Rep. of South*
Email: crane87@hanyang.ac.kr

Background and aims: Stem cell therapies have been proposed as a novel therapeutic strategy as an alternative to tissue transplantation for patients with liver diseases. To improve this, we have developed human chemically derived hepatocytes (hCdHs) that can be proliferated into hepatocytes (hCdH-Heps) and cholangiocytes in previous research. Moreover, we corroborated the successful engraftment of hCdHs in the mouse liver. However, despite its efficacy, the overall reprogramming mechanisms of CdHs during the generation and differentiation remain unclear. Autophagy, a self-degradation process, is a well-known pathway in cell reprogramming. Thus, we aimed to reveal autophagic activity throughout the whole reconstruction process of CdHs from generation to differentiation.
Method: Human and mouse primary hepatocytes (hPHs, mPHs) were cultured in reprogramming media containing HGF, A83-01, and CHIR99021 (HAC) for 7 days to generate human and mouse chemically derived hepatic progenitors (hCdHs, mCdHs). mPHs and hPHs maintained in basal media without HAC were used as a control. mCdHs were treated with bafilomycin A1 (Sigma-Aldrich, B1793) to inhibit autophagy flux. To induce differentiation of mCdHs and hCdHs into hepatocyte-like cells, mCdHs and hCdHs were cultured in hepatic differentiation medium, which contains oncostatin M, dexamethasone, and HGF. Then, expressions of major autophagy markers during CdHs generation and differentiation, such as p62 and LC3BII, were analyzed by western blotting and qPCR.
Results: mCdHs were generated from mPHs in the reprogramming medium, which contains HAC. It was primarily confirmed by observing cells expressing epithelial morphology. Also, mRNA expression of hepatic progenitor markers, such as Sox9, EpCAM, Ck19, CD90, CD44, and AFP, increased in mCdHs compared to mPHs. Furthermore, protein expression of two autophagy markers, p62 and LC3BII, was elevated while mCdHs were generated from mPHs, indicating that autophagy was suppressed. mCdHs on day 12, after the generation, expressed lower protein levels of p62 and LC3BII, which means the recovery of autophagy to the basal level. Moreover, bafilomycin A1, an autophagy inhibitor, accelerated the growth of mCdHs during the generation. However, there was no increase in the mRNA expression levels of hepatic progenitor markers except Sox9 in the presence or absence of bafilomycin A1. Also, during the differentiation of mCdHs into mCdH-Heps, cells expressed a continuously decreasing protein level of p62 and LC3BII from the early phase, which suggests that autophagy activity decreased. Lastly, hCdHs were also generated from hPHs by the HAC reprogramming medium. hCdHs showed epithelial morphology and increased gene levels of hepatic progenitor markers. Interestingly, autophagy was inhibited during generation and downregulated to the basal level during differentiation into hepatocyte-like cells in hCdHs as well as in mCdHs.

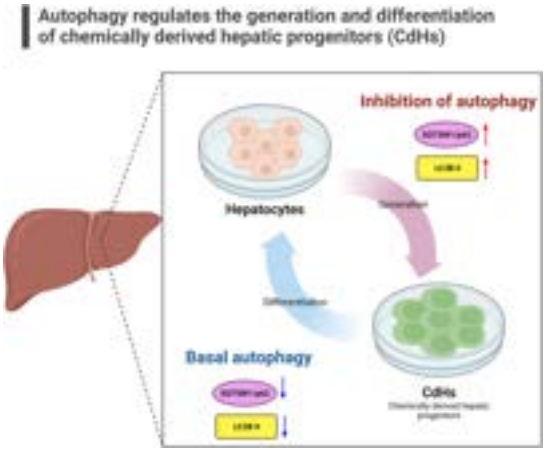

Figure:

Conclusion: In conclusion, all these findings indicate that autophagy regulates the generation of CdHs and the differentiation of CdHs into CdH-Heps.

SAT-362

Development of intrahepatic bile ducts during liver progenitor cell-driven liver regeneration is associated with epithelial cell adhesion molecule function

Eun Young Cho[1], Tae-Young Choi[2,3], Azra Memon[2], Donghun Shin[4], Hoon Gil Jo[1]. *[1]Wonkwang University, Department of Internal Medicine, School of Medicine, Iksan, Korea, Rep. of South; [2]Digestive Disease Research Institute of Wonkwang University, Department of Pathology, Iksan, Korea, Rep. of South; [3]Graduate School of Wonkwang University, Department of Biomedical Science, Iksan, Korea, Rep. of South; [4]McGowan Institute for Regenerative Medicine, University of Pittsburgh, Department of Developmental Biology, Pittsburgh, United States*
Email: choity76@wku.ac.kr

Background and aims: Epithelial cell adhesion molecule (EpCam) is a membrane glycoprotein involved in multiple functions, including cell-cell adhesion, proliferation, maintenance of undifferentiated states. During liver injury, EpCam-positive cells are associated with a population of cells within ductular reactions, thought to contain liver progenitor cells (LPCs). In this study, we aimed to analyze EpCam function, which might be involved with developing intrahepatic bile duct during LPC-driven liver regeneration.

Method: Using transgenic and mutant zebrafish (figure A), we examined the roles of Epcam on LPC-driven liver regeneration. These zebrafish assessed liver size; liver marker expression was analyzed by immunostaining, in situ hybridization, and quantitative PCR. Moreover, we used in vivo dye to visualize the development of intrahepatic bile ducts.

Results: After severe hepatocyte injury in the epcam mutants, we showed that the developing intrahepatic bile ducts were impaired, but not the regenerating liver size, indicating that LPC-driven liver regeneration proceeded; however, the maturation of intrahepatic bile ducts are impaired. Intriguingly, after BODIPY staining to visualize intrahepatic bile ducts, most of the biliary structure disconnected in the liver throughout (figure B-G), supporting the findings that epcam is associated with the developing intrahepatic bile duct during LPC-driven liver regeneration.

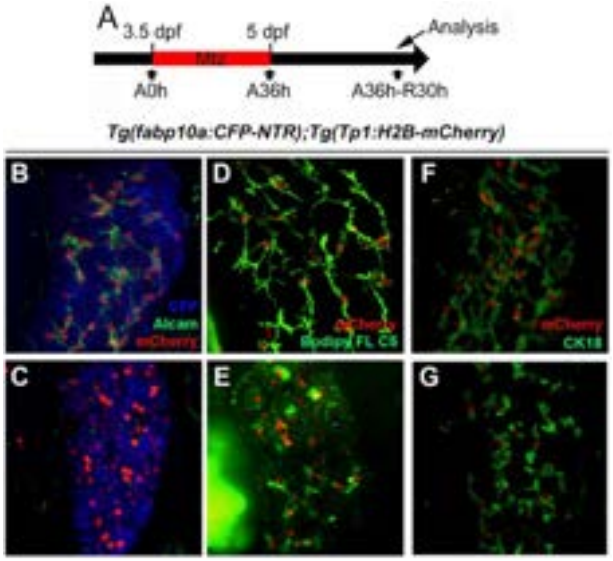

Figure:

Conclusion: These findings suggest that epcam positively regulates liver development, in particular, structure of intrahepatic bile duct, and play a potential role for bile duct epithelial cells to commit itself to a particular cell type during a regenerative response.

SAT-363

Excessive proliferation after extended hepatectomy compromises liver function in mice

Maxime De Rudder[1], Isabelle Leclercq[1], Alexandra Dili[1,2]. *[1]Institute of Experimental and Clinical Research, Laboratory of Hepato-Gastro-Enterology, Woluwé-saint-Lambert, Belgium; [2]CHU UCLouvain-Namur, Department of Surgery, Yvoir, Belgium*
Email: maxime.p.derudder@uclouvain.be

Background and aims: Small-for-size syndrome (SFSS) is a post-extended hepatectomy liver failure. After an extended hepatectomy, high portal pressure leads to vascular damage and induces hyper-proliferation of hepatocytes and disruption of the lobule arrangement in the liver remnant. Both factors are thought to be major culprits leading to the SFSS. Previously, we showed that mice exposed to an hypoxic environment after extended hepatectomy had higher survival rates compared to mice in normoxia (~70% vs ~35% respectively). With survival, hypoxia triggered early endothelial cell proliferation and subsequently a denser sinusoidal network with larger sinusoids, rescue of the disturbed perfusion found after a SFSS-setting hepatectomy, and recruitment of endothelial progenitor cells. Our first aim was to assess whether rescue of the sinusoidal network alone increases survival after a SFSS-setting hepatectomy. Surprisingly, hypoxia decreased hepatocyte proliferation but improved liver function. Thus, we investigated epithelial-to-mesenchymal transition (EMT) process in hepatocytes following a SFSS-setting hepatectomy.

Method: We removed 80% of the total liver to induce SFSS. Granulatory-colony stimulation factor (G-CSF) was administered 3 times intraperitoneally to replicate hypoxia's effects on the vascular network. Vascular diameter and density were assessed on CD31 staining. Recruitment of endothelial progenitors was assessed using Cdh5-Cre^{ERT2} × mTmG mice. Liver function was evaluated by ELISA for circulating factor V, circulating albumin by colorimetric test and hepatocyte glycogen content by PAS staining. EMT was evaluated by expression of E-Cadherin, Hes1 and Notch1 by immunofluorescence, and gene expression of HNF4A and Snai1 by qPCR.

Results: Administration of G-CSF increased vascular diameter and density and induced the recruitment of endothelial progenitors in regenerating livers compared to non-treated animals but did not positively impacted survival. We thus shifted our focus on the hepatocyte population. After a SFSS-setting hepatectomy, a large portion of the hepatocytes enters the cell cycle at the same time (around 50% at POD3). High proliferation was associated with significantly decreased circulating albumin and factor V, two proteins heavily produced by the liver. PAS staining revealed that only 30% of hepatocytes were PAS+, compared to 60% in mice kept in hypoxia. HNF4A, a master regulator of hepatocyte phenotype, was down-regulated in normoxia and its expression was inversely correlated with Snai1, a regulator of EMT. Concordantly, the epithelial marker E-Cadherin was faintly stained (Figure). We explored through which pathway EMT is induced in hepatocytes. Notch1 intracellular domain exhibited a nuclear staining in hepatocytes of mice kept in normoxia while none was found in hypoxia. Similarly, Hes1, a target of the Notch pathway, was more expressed in normoxia compared to hypoxia.

Conclusion: In this study, we found that rescue of vascular damage after a SFSS-setting is not sufficient to increase survival. Extravagant engagement in the cell cycle in hepatocytes was associated with decreased function of the liver remnant. We found that a large portion of the proliferative hepatocytes engaged in an EMT process through the Notch1/Hes1 pathway. Thus, we think that EMT engagement after a SFSS-setting hepatectomy disrupts the balance

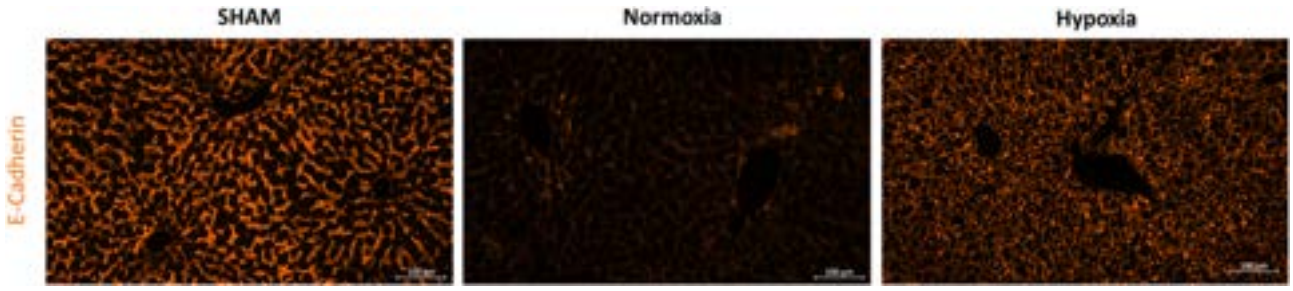

Figure: (abstract: SAT-363).

between function and proliferation in the remnant, leading to organ failure.

Conditioned medium from human allogeneic liver-derived progenitor cells protects against LPS-induced endothelial hyperpermeability via shingosine-1 phosphate

Audrey Ginion[1], Marine Angé[1], Pauline De Berdt[2], Mustapha Najimi[2,3], Etienne Sokal[2,3], Sandrine Horman[1]. [1]*Pole of Cardiovascular Research, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium;* [2]*Cellaïon, Mont-Saint-Guibert, Belgium;* [3]*Laboratory of Pediatric Hepatology and Cell Therapy, Institute of Experimental and Clinical Research (IREC), Université catholique de Louvain, Brussels, Belgium*
Email: mustapha.najimi@cellaion.com

Background and aims: Stem cells are recognized as an important tool for the treatment of several disease processes and injured tissues. Intravenous administration of mesenchymal stem cells, the stromal progenitor cells found within the bone marrow, has been shown to benefit a variety of disease models, including sepsis. The underlying mechanism results from direct interaction with the vascular endothelium and/or secretion of soluble factors. Human allogeneic liver-derived progenitor cells (HALPCs), currently under clinical development for the treatment of ACLF, display unique paracrine anti-inflammatory, immunomodulatory and regenerative features. This study tested the impact of conditioned medium derived from HALPCs (CM-HALPC) on microvascular permeability, a determinant factor in the pathophysiology of sepsis. Underlying mechanisms were also investigated.
Method: Conditioned media from HAPLCs were generated and kept frozen until analysis. Human dermal microvascular endothelial cells (HDMECs) were incubated with non-conditioned medium or CM-HALPC mixed with EGM-2 MV (1:1) for 24 hours prior to treatment with E. coli lipopolysaccharide (LPS 055:B5, 50 μg/ml). Functional endothelial permeability was measured by in vitro transwell assay, and quantification of cellular junctions (IEJs) in the plasma membrane was assessed by VE-Cadherin (VE-Cad) immunofluorescence.
Results: Preincubation of HDMECs with CM-HALPC preserved VE-Cad organization and protected endothelial barrier function against LPS injury. Since ELISA analysis revealed the presence in CM-HALPC of sphingosine-1-phosphate (S1P) and hepatocyte-growth factor (HGF), two factors known to be involved in the regulation of vascular permeability, we tested their contribution to the protective effect. Addition of a pharmacological antagonist of S1P to CM-HALPC was associated with the loss of the barrier-protective function. However, when HDMECs were treated with CM-HALPC supplemented with an anti-HGF antibody, the protective effect of the conditioned medium was not affected.
Conclusion: These results demonstrate that CM-HAPLC protects against LPS-induced hyperpermeability and preserves IEJs integrity, in part via S1P. These data have implications for the potential therapeutic use of those cells also in disease conditions characterized by compromised vascular integrity.

Lineage tracing of hepatic stellate cells with ultrasound-guided in utero nano-injection

Jingyan He[1], Lenka Belicova[1], Sandra De Haan[1], Noémi K. M. Van Hul[1], Stefaan Verhulst[1,2], Michael Ratz[1], Emma Andersson[1]. [1]*Karolinska Institutet, Department of Cell and Molecular Biology (CMB), Solna, Sweden;* [2]*Vrije Universiteit Brussel, Liver Cell Biology Research Group, Belgium*
Email: emma.andersson@ki.se

Background and aims: Hepatic stellate cells (HSCs) are essential mesenchymal cells in the liver and contribute to fibrosis upon liver injury. HSCs express both mesenchymal and neural markers, and current lineage tracing studies have demonstrated contribution of Mesp1- and Wt1-expressing mesodermal/mesenchymal cells to liver, as well as Wnt1- and Gfap-expressing cells. However, some of these studies have been contradicted by others. Thus, a definitive origin of HSCs and their relationship with other hepatic mesenchymal cells is still unclear. Traditional lineage tracing with Cre mouse models is powerful but has inevitable limitations for hybrid cell types.
To circumvent this limitation, we developed a novel Cre-independent method to trace HSC lineages and their clonal relationships with other mesenchymal cells.
Method: A diverse lentivirus barcode library was injected into the amniotic cavity (AC) or exoceolomic cavity (ExC) of mice at embryonic day (E)7.5 to target the neural crest or mesoderm, respectively. By using clonal TRacing and gene EXpression via scRNA-seq (TREX) and IF staining, E9.5–12.5 embryos were analyzed to trace the HSC trajectory, ≥E16.5 livers were analyzed to resolve clonal relations.
Results: In utero nano-injection with lentivirus results in successful transduction of septum transversum mesenchyme (STM) and intrahepatic mesenchymal cells, including HSCs.
Conclusion: Ultrasound-guided in utero nano-injection is a powerful Cre-independent method to lineage trace HSCs in the liver. It requires fewer mice, is faster and cheaper compared to using genetically engineered mice. By using this technique and TREX, we are now investigating the developmental trajectory of HSC lineages.

Email: ktoya@gesurg.med.osaka-u.ac.jp

Background and aims: There have been no established effective therapies for liver failure. Here, we focused on autologous skeletal myoblast cell-sheet transplantation, which is proved to improve

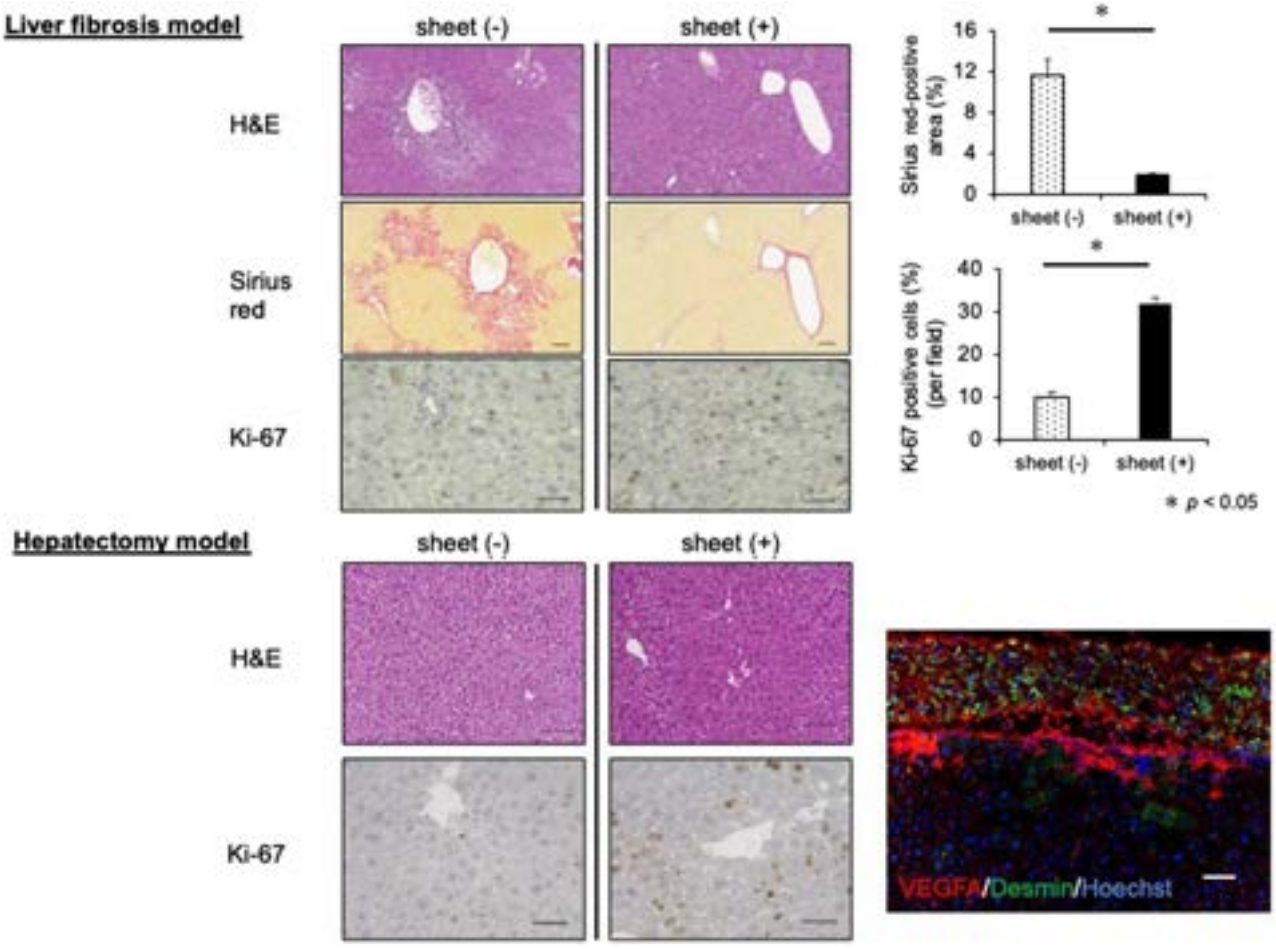

Figure: (abstract: SAT-366).

cardiac function in patients with heart failure, for the treatment of liver failure. Thus, in this study, we preclinically assessed the effect of the sheet transplantation on liver failure model mice.

Method: We assessed two liver failure model C57BL/6 mice; one was liver fibrosis mouse induced by intraperitoneal administration of thioacetamide (TAA), the other was 70% partial hepatectomy model mouse. The mice received the autologous skeletal myoblast cell-sheet transplantation. In fibrosis model, the effect of the sheet transplantation was examined in terms of the extent of the fibrosis judged by Sirius red and Masson trichrome staining and the expression of a hepatocyte proliferation marker, Ki-67, and liver fibrosis markers, Acta2 and Col1α-1, in the liver tissues after the transplantation with comparison to the control receiving sham surgery. In hepatectomy model, the effect was examined the remnant liver to body weight ratio and the expression of Ki-67 and a marker for angiogenesis, CD31. Furthermore, immunohistochemical analysis for VEGFA, which myoblast cells secreted, was assessed to investigate the mechanism for liver regeneration of myoblast cell sheet.

Results: In the TAA model, the liver tissue was analyzed 3-week and 5-week after the myoblast cell-sheet transplantation. The percentage of Ki-67-positive cells was significantly higher in the sheet transplantation group than in the control group. Sirius red and Masson trichrome staining showed that liver fibrosis is less severe in the transplantation group than the control group. Furthermore, mRNA expression levels of Acta2 and Col1α-1 were significantly lower in the transplantation group than the control group. In the hepatectomy model, the remnant liver to body weight ratio 2 days after hepatectomy and sheet transplantation was significantly higher in the sheet group than that in the control group. The percentage of Ki-67-positive cells was significantly higher in the sheet group than in the control group at the same time. Moreover, the expression of CD31 in the remnant liver was significantly increased in the sheet group. Additionally, VEGFA was overexpressed at the sheet and the remnant liver near the sheet.

Conclusion: These results suggested that the autologous skeletal myoblast cell-sheet transplantation significantly improved the liver fibrosis and accelerated liver regeneration in the mice models. The sheet transplantation has the potential to be a clinically therapeutic option for liver regeneration.

Background and aims: Primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) are biliary diseases characterized by the damage of mature cholangiocytes, diffuse inflammation and fibrosis of the bile ducts. PSC patients have a higher risk to develop cholangiocarcinoma (CCA) while patients PBC more likely develop hepatocellular carcinoma (HCC). In PBC and PSC, the epithelial-mesenchymal transition (EMT) inductors are essential for disease progression and fibrosis development. Another feature of both diseases is the presence of ductular reaction (DR) due to the activation of hepatic progenitor cells (HPCs), known as oval cells (OCs) in rodents. Interestingly, HPC proliferation has been involved in progression of the duct lesions in PSC towards CCA. The zinc finger transcription factor GATA4 is a master driver of liver organogenesis and cancer development. Until now, it was known that *Gata4* expression in the liver was restricted to endothelial and hepatic stellate cells (HSCs). However, we detected the expression of *Gata4* in OCs in culture, as well as in OCs located in the oval niche in mice. On that basis, our aim was to unravel the role of *Gata4* as modulator of OCs fate in the context of PBC and PSC progression.
Method: OCs in culture were exposed to TGF-b or hypoxia (1% O_2 saturation) and the correlation between EMT and *Gata4* and *Hif2a* expression levels were determined by qPCR and Western blot. A step further, we silenced *Gata4* in OCs in culture by infection with *shGata4* lentiviral particles to study a possible essential role like occur during liver development. Moreover, we analyzed the expression levels of GATA4 in liver samples from PSC and PBC patients by qPCR.
Results: Our results showed that OCs express the transcription factor *Gata4 in vitro* and *in vivo*. Surprisingly, OCs are sensitive to hypoxia that promotes EMT in these cells in parallel with GATA4 down-regulation. This was accompanied by the loss of cell identity monitored by reduction in the OC specific marker A6. Similar relationship between EMT, loss of cell identity and *Gata4* down-regulation was found upon treatment of OCs with TGFb. Silencing *Gata4* in OCs led to a loss of OCs viability since we did not obtain viable clones with *Gata4* downregulation, suggesting that *Gata4* might be essential for preserving OCs viability and survival. Moreover, the expression levels of *GATA4* in liver samples from PSC and PBC patients revealed a significant decrease in PSC patients and a decrease trend in PBC patients.

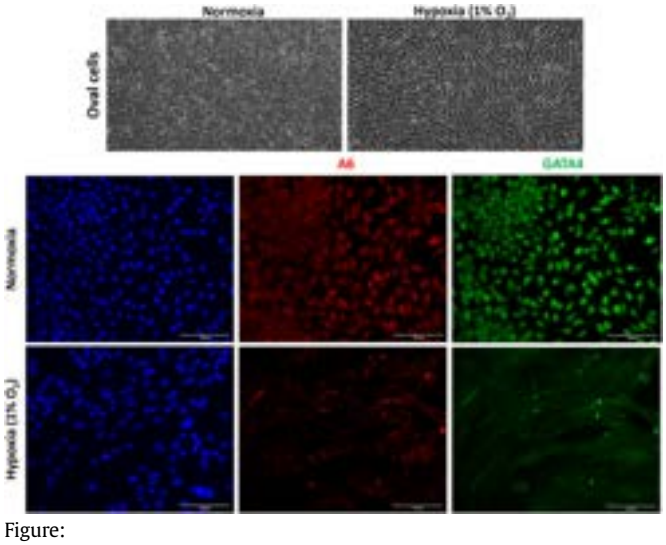

Figure:

Conclusion: Given the progenitor nature of OCs, the role of GATA4 in liver development and tumor suppression, and our data showing a correlation between *Gata4* expression and EMT in OCs, our results suggest that GATA4 could be a *bona fide* modulator of OC fate.

SAT-368

Rescue mechanism of hHIL-6 after partial hepatectomy

Julia Ettich[1], Hendrik Weitz[1], Melissa Nowak[2], Friedrich Reusswig[3], Tobias Buschmann[2], Kristina Vogel[1], Juergen Scheller[1]. *[1]Institut für Biochemie und Molekularbiologie II, Germany; [2]Institut für Molekulare Medizin III, Germany; [3]Research Group Experimental Vascular Medicine, Germany*
Email: jscheller@hhu.de

Background and aims: Previous reports show interleukin-6 (IL-6) is critically involved in liver regeneration after partial hepatectomy (PHx) comprising both IL-6 classic- and trans-signaling. However, the exclusive impact of IL-6 classic-signaling for liver regeneration after PHx is unknown due to the necessity of the IL-6R, which generates PHx-induced soluble IL-6R (sIL-6R) by disintegrin and metallo proteases enabling also IL-6 trans-signaling.
Method: Acute liver injury in mice investigates liver regeneration following surgical removal of 70% of the liver. RNA-sequencing analyzed the gene expression profile of liver tissue pre PHx, 6 h, and 24 h post PHx and were verified by RT-PCR. Serum protein levels (AST, ALT, Bilirubin, alkaline phosphatase) were analyzed. H/E-staining of liver sections and cytokine ELISAs were performed.
Results: IL-6R deficient mice after PHx resulted in significantly impaired survival. Elevated liver transaminases, accompanied by an elevation in cholestasis, and delayed bile acid synthesis affected liver regeneration following PHx. While the capacity for regeneration itself showed no effect, a delay in cell cycle gene expression and reduced proliferation supported with reduced SAA1 was given. Histopathology revealed a delayed lymphocyte infiltration in correlation with more necrotic areas of in IL6R-deficient mice following PHx. Application of human Hyper-IL-6 (hHIL-6), a fusion protein of sIL-6R and IL-6, rescued the impaired survival following PHx via IL-6 trans-signaling. To further investigate the role of hHIL-6 during regeneration, IL-6R deficient mice were analyzed in transcriptomic analysis. Besides the gene expression profiling, hHIL-6 treated animals displayed a significant increase in SAA1 activity already pre-PHx, indicating a sufficient and restored STAT3 activation. Within 24 h post PHx liver transaminases were significantly reduced, cholestasis marker stayed at moderate level and hHIL6-treated mice revealed reduced necrotic areas accompanied by an increase in proliferation.

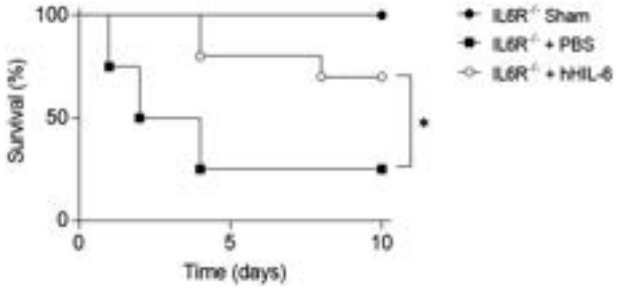

Figure:

Conclusion: IL-6R deficient mice can be rescued via synthetic hHIL-6 due to the protection of intrahepatic cholestasis-induced hepatocyte death during liver regeneration.

SAT-369

Hepatic progenitor cell activation through the interaction of mesenchymal stem cells and liver sinusoidal endothelial cells

Su Jung Park[1], Jin Suk Lee[1], Mi Ra Lee[1], Han Seul Ki[1,2], Soon Koo Baik[1,2], Moon Young Kim[1,2]. [1]*Yonsei University Wonju College of Medicine, Regenerative Medicine Research Center, Wonju-si, Korea, Rep. of South;* [2]*Yonsei University Wonju College of Medicine, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Wonju-si, Korea, Rep. of South*
Email: drkimmy@yonsei.ac.kr

Background and aims: The hepatic progenitor cell (HPC) is an innate stem cell in the liver and the main cell in liver regeneration. Induce that the proliferation and regenerative activity of HPC is the main issue in the liver regeneration field. Liver sinusoidal cells (LSECs) inactivation and stabilization are essential in accelerating the regression of fibrosis and inhibiting the progression of cirrhosis. LSEC also has been known to activate HPC through the Wnt-β-catenin signaling. However, the method to stabilize LSECs is not yet established. Therefore, we investigated the functional recovery of LSECs through mesenchymal stem cells (MSCs) and whether it can induce HPCs activation.
Method: To evaluate the stabilization of LSEC by MSC, the recovery of fenestrae of LSECs was confirmed by Scanning Electron Microscope (SEM) after co-culture. Changes in various factors affecting the stabilization of LSEC were also confirmed by real-time polymerase chain reaction and Western blot. The specific cell markers of the isolated mouse LSECs and MSCs were confirmed by FACS. In addition, HPCs were cultured using the culture soup obtained by co-culture of LSECs and MSCs, and the activities of HPCs were analyzed.
Results: In human-derived MSC and LSCE co-culture, LSEC showed recovery of fenestrae with increased expression of VEGF, eNOS, HGF, Wnt2, and Wnt9b in LSEC compared with control. Also, when LSECs and MSCs isolated from mice were co-cultured, the expression of VEGF and HGF, which play an important role in maintaining the morphology of LSEC, increased. The expression of Wnt9b, which acts as an angiocrine factor in liver regeneration, was also increased.
In the culture of HPC, when the soup obtained from LSEC during LSEC and MSC co-culture was added, an increase in HPC activity was observed compared to the control group. The proliferation of stem progenitor cells was doubled in both 24 and 48 hours compared to the control group. Also, the expression of VEGF and Wnt2 increased in HPC at 24 hours, and the expressions of HGF, VEGF, and Wnt9b increased at 48 hours.
Conclusion: MSC showed the property that can induce stabilization (undifferentiated) LSEC. Stabilized and functionally recovered LSEC by MSC also induced the proliferation and increased the activity of HPCs and which suggests a possibility that MSC-based recovery of LSEC in hepatic fibrosis can be helpful in the promotion of liver regeneration through HPC activation.

"Swarm hunting" of virus-specific CD8 T cells together with auto-aggressive CD8 T cells to achieve efficient killing of virus-infected hepatocytes

Ariane Eceiza Tenreiro[1], Michael Dudek[1], Dirk Wohlleber[1], Percy A. Knolle[1]. [1]*Institute of Molecular Immunology, Germany*
Email: percy.knolle@tum.de

Background and aims: Viral infections of the liver with hepatropic viruses, such as the hepatitis B virus, are most often successfully cleared by the adaptive immune response, in particular virus-specific CD8 T cells. Persistent infection occurs when antigen-specific immunity fails to eliminate virus-infected hepatocytes, the reasons of which are still unclear. In this project, we investigate the contribution of a novel form of metabolic T cell activation termed auto-aggressive T cells and its relevance to control of virus infection in hepatocytes.
Method: We used time-lapse cytotoxicity assays measuring cell impedance to determine the ability of antigen-specific CD8 T cells to engage in combination with auto-aggressive CD8 T cells in a synergistic fashion to achieve killing of virus-infected hepatocytes. We established cocultures of primary murine hepatocytes with conventional effector CD8 T cells and auto-aggressive CD8 T cells, and measured antigen-specific killing compared to auto-aggressive killing of hepatocytes.
Results: As expected, antigen-specific CD8 T-cells efficiently killed virus-infected hepatocytes within 12 hours. Conversely, high effector to target ratio (>10) of auto-aggressive T-cells exerted antigen independent *in vitro* hepatocyte killing. Strikingly, co-incubation of cytotoxic effector CD8 T cells and auto-aggressive CD8 T cells at effector to target ratios that would not elicit any hepatocyte killing by a single T cell population, led to efficient killing of hepatocytes. This demonstrated different pathways leading to hepatocyte killing that rely on synergistic effector functions exerted by conventional antigen-specific CD8 T cells and auto-aggressive CD8 T cells. Remarkably, we identified soluble factors secreted by conventional T cells that initiated auto-aggression by CD8 T cells.
Conclusion: Our results demonstrate that cytotoxic CD8 T cells and auto-aggressive CD8 T cells have a synergistic activity in eliciting killing of virus-infected hepatocytes. This unravels novel means of cooperation among T cells with effector functions. Future experiments will characterize how conventional effector CD8 T cells engage auto-aggressive CD8 T cells in a synergistic killing of virus-infected hepatocytes in a "swarm hunting" fashion.

Rheostat function of liver sinusoidal endothelial cells and macrophages limiting antiviral CD8 T cell immunity in the liver

Anna Fürst[1], Sutirtha Chattopadhyay[1], Hannah Wintersteller[1], Dirk Wohlleber[1], Miriam Bosch[1], Percy A. Knolle[1]. [1]*Institute of Molecular Immunology, Germany*
Email: anna.fuerst@tum.de

Background and aims: Hepatitis B virus (HBV) infection can be controlled by strong antiviral CD8 T cell immunity. However, in persisting HBV infection virus-specific CD8 T cells are scarce and lack effector functions. We aimed at investigating the local influence of liver sinusoidal endothelial cells (LSECs) and liver macrophages on antiviral CD8 T cell immunity against virus-infected hepatocytes.
Method: We used hepatotropic recombinant adenoviruses to transfer ovalbumin or HBV 1.3 overlength genomes into hepatocytes leading to either acute-resolving or persistent hepatocyte infection. We transferred virus-specific CD45.1$^+$ CD8 T cells before infection to study T cell immunity against infection with hepatotropic viruses. Liver tissue sections were analyzed for localization of T cells by volumetric confocal microscopy. Virus-specific T cells were co-cultured with LSECs and liver macrophages *in vitro,* and their phenotype and function were analyzed by flow cytometry and mass spectrometry imaging.
Results: During persistent viral infection, dysfunctional virus-specific CD8 T cells had a significantly shorter distance to and larger cumulative surface contact area with LSECs and liver macrophages compared to fully functional CD8 T cells after resolved infection. Remarkably, CD8 T cells engaging in close contact with LSECs or liver macrophages *ex vivo* upregulated CXCR6 expression, a marker previously described for tissue-resident T cells. Consequently,

dysfunctional CD8 T cells during persistent infection expressed higher CXCR6 levels compared to fully functional CD8 T cells after resolved infection. Moreover, co-culture with LSECs led to augmented protein kinase A phosphorylation and caused inhibition of T cell receptor signaling in CXCR6^{+}CD8 T cells pointing towards increased cAMP signaling as cause of T cell dysfunction during persistent hepatotropic infection. Mass spectrometry imaging of LSECs and CD8 T cells further identified changes in lipid and metabolite profiles associated with the distinct functional properties of virus-specific CD8 T cells.

Conclusion: Our results identify close physical interaction between virus-specific CD8 T cells and LSECs and liver macrophages as initial event in regulating loss of T cell function. Future work will aim at elucidating the exact molecular mechanism determining the metabolite-induced regulation of T cell function and their consequences for anti-viral immunity in the liver.

Email: rzhu7@its.jnj.com

Background and aims: Chronic hepatitis B viral infection (CHB) can lead to a state of immune exhaustion or dysfunction preventing the resolution of infection. AAV-HBV transduction leads to persistent HBV replication in immune-competent mice; comprehensive characterization of the liver immune microenvironment is however lacking. This study investigated the intrahepatic immune profile of AAV-HBV-transduced mice at the single cell level and compared these data to data of a human CHB dataset[1] across clinical stages of CHB.

Method: Liver immune cells were isolated from 4 to 5-week-old male C57/BL6 mice with AAV-HBV (n = 5), AAV control vector (n = 5) 24-weeks post-transduction or naïve (n = 5) mice. Cells were loaded on to a 10× Genomics platform (5′ capture protocol) for single-cell RNA sequencing analysis. Downstream analysis was performed using custom R scripts that utilized the Seurat, CellChat, and CellPhoneDB packages. The mouse model data was compared with a human CHB dataset[1], using the bioinformatics packages described above.

Results: A total of 107,925 high quality mouse immune cells were captured from the 15 samples, covering all major immune cell populations (Ts, Bs, NKs, DCs, monocytes and neutrophils) and hepatocytes. Pre-exhausted CD8+ T cells with self-renewing capacity (Tpex, TCF1+), and terminally exhausted CD8+ T cells (Tex, TCF1-) were identified in the AAV-transduced mice. The terminally exhausted CD8+ T cells (expressing PD-1, LAG-3, TIGIT) were significantly enriched in the AAV-HBV mouse group. Deconvolution of cell-to-cell signaling pathways identified CD4+ Th1 cells (Pdcd1lg2-Pdcd1 pathway) and mature B- cells (H2k1-Cd8a/b1 pathway) as major signal senders to CD8+ Tex cells, while resident regulatory T cells contributed to the Pvr-Tigit interaction with CD8+ Tex. We performed analogous single cell analyses across the Immuno-Tolerant (IT), Immuno-Active (IA), and HBV resolver (CR) patients as well as healthy donors of the human CHB dataset[1]. The immune cell population composition as well as ligand/receptor expression patterns observed in AAV-HBV mice were consistent with observations from IT and IA CHB patients (Figure 1).

Conclusion: Enrichment for exhausted CD8+ T cells was observed in the livers of AAV-HBV mice by expression of immune checkpoint marker genes (PD-1, LAG-3, TIGIT). We also observed immune cell crosstalk which may be driving or maintaining T cell exhaustion. The exhausted CD8 gene and pathway profiles were comparable between mouse AAV-HBV and the human CHB samples from Zhang et al[1]. These data support the use of the AAV-HBV mouse model in the study of liver immune tolerance mechanisms induced by HBV.

SAT-372

Developing highly pure, functional GMP grade Treg for the treatment of autoimmune liver disease

Naomi Richardson[1,2], Grace Wootton[1,2], Amber Bozward[1,2], Ye Htun Oo[1,3]. [1]*University of Birmingham, Centre for Liver and Gastrointestinal Research, Institute of Immunology and Immunotherapy, United Kingdom;* [2]*University of Birmingham, Advanced Therapies Facility, United Kingdom;* [3]*Queen Elizabeth Hospital Birmingham, Liver Medicine, United Kingdom*
Email: y.h.oo@bham.ac.uk

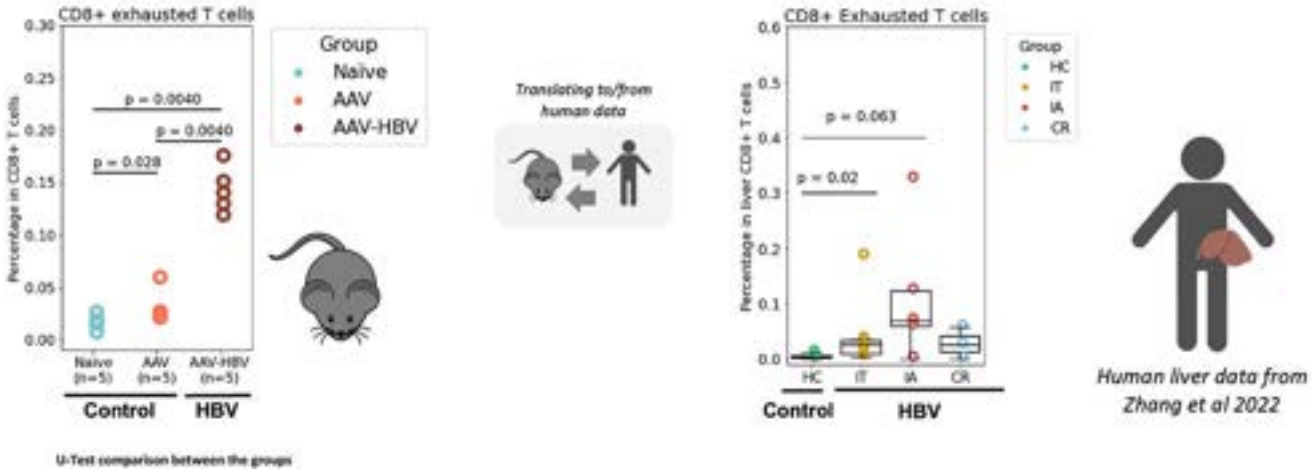

Figure 1: (abstract: SAT-371): AAV-HBV mouse model mimics the immune exhaustion pattern observed in chronic HBV patients.

Background and aims: Autoimmune liver diseases (AILD) are immune mediated liver diseases causing chronic damage to hepatocytes and biliary tissue. Regulatory T cells (Treg) are crucial to maintain peripheral immune tolerance, reduce inflammation and promote tissue repair. Our previous trial (AUTUMN) showed that >25% of natural Treg cells from autoimmune hepatitis (AIH) patients' blood effectively home to the liver and readily respond to IL-2 via STAT-5 signaling. We have now developed a platform to generate Good Manufacturing Practice (GMP) grade autologous Treg cells with potential to treat AILD and reduce reliance on immunosuppressive drugs.
Method: The isolation of highly pure, functional Treg cells from peripheral blood is achieved using Miltenyi Prodigy to enrich $CD25^+$ T cells, before careful cell sorting using the MACSQuant Tyto to remove $CD8^+$ T cells and gain $CD4^+CD25^+CD127^{low}$ bona fide Treg cells at >95% purity. Isolated Treg can be expanded *in vitro*, according to our optimized protocol, to achieve therapeutic doses of cells within 4 weeks ($>1 \times 10^9$ Treg cells). Treg expansion optimisation involved testing different medias, IL-2 concentrations, stimulation types and duration, seeding densities, culture vessels and mTOR inhibition. Measuring lactate enables effective monitoring of cell number throughout expansion without need for intervention.
Results: Treg cells manufactured at GMP grade retain their immunosuppressive phenotype, including expression of CTLA-4, CD39, FoxP3 as well as liver homing chemokine receptor CXCR3 and ratio of naïve:memory. Th1 and Th17 markers including Tbet, CCR6, CD161 are not increased after expansion. Treg final product is functional, suppresses CD4 conventional cells, and exhibits TSDR demethylation-albeit with slightly reduced potency compared to Treg cells prior to expansion.
Conclusion: We have developed a robust, reproducible protocol to manufacture high quality therapeutic GMP grade Treg cells, which will be applied in our upcoming ReSolving Primary biliary cholangitis with Regulatory T cell and INterleukin-2 GMP immunotherapy (SPRING) trial. SPRING trial will deliver 1) autologous GMP-Treg cells, 2) low-dose IL-2 or 3) GMP-Treg + low dose IL-2 to PBC patients, to directly compare the efficacy and immunological changes in blood and liver tissue of these novel treatments. This platform is readily transferable to any autoimmune or autoinflammatory disease in which GMP-Treg therapy is a viable treatment option.

SAT-373

ILT2 as a biomarker of impaired natural killer cells expressing excess lipid peroxidation in patients with hepatocellular carcinoma

Toshihiro Sakata[1,2], Sachiyo Yoshio[1], Masaaki Mino[1], Shiori Yoshikawa[1], Taiji Yamazoe[1], Taizo Mori[1], Eiji Kakazu[1], Taketomi Akinobu[2], Tatsuya Kanto[1]. [1]*National Center for Global Health and Medicine, Japan;* [2]*Hokkaido University, Japan*
Email: toshihiro0514sakata@gmail.com

Background and aims: Overall response rates of systemic therapies against advanced hepatocellular carcinoma (HCC) remain unsatisfactory despite the introduction of immune checkpoint inhibitor (ICI) to the clinic. Thus, exploring for new immunotherapy targets is indispensable. Natural killer (NK) cells play a pivotal role in immune surveillance against hepatocellular carcinoma (HCC). We previously identified some of signature NK cell receptors in HCC patients, ILT2 as an inhibitory and NKp46 as a stimulatory receptor, respectively. We aimed to explore potential targets for immune intervention by revealing NK cell function-related phenotypes in HCC patients.
Method: We enrolled 17 HCC patients who underwent liver tumor resection. We examined peripheral NK cells (pNK) and intrahepatic NK cells from cancerous (Ca-NK) and noncancerous liver tissues (NCa-NK). To evaluate the impact of aging on NK phenotypes, we also examined pNK from 42 healthy volunteers (HVs) whose age were at a range from 21 to 82 years old. We analyzed 39 surface markers on NK cells by mass cytometry. We separated ILT2+NKp46-, ILT2-NKp46- and NKp46+CD56dimNK cells and cultured them in the presence of K562 cells or Daudi cells as targets for cytotoxicity and ADCC assay. Cytotoxicity/ADCC assay was performed with ILT2+NKp46-CD56dimNK cells with or without anti-ILT2 neutralizing antibody or antioxidant compounds. We evaluated whether HLA-G, which is a ligand of ILT2, were expressed or not in cancerous and noncancerous liver tissues.
Results: The expression levels of activating NK cell markers, Siglec7, CD160 and NKp46, were decreased with aging. In contrast, an increasing trend with aging was observed for inhibitory receptors, ILT2, PD-1, LAG-3, Siglec10, TIGIT and KIR2DL2L3, and maturation marker CD57, respectively. In comparison of phenotypes of CD56dimpNK cells between age-matched HCC patients and HVs, ILT2, CD69, CX3CR1, CD49a and CD200R in patients were significantly higher, while DNAM-1and 2B4 were lower in HCC patients. ILT2 +CD56dimNK cells, which were enriched in cancer tissue, were NKp46-negative and highly positive for C11-BODIPY581/591 as a marker of lipid peroxidation. ILT2+NKp46-CD56dimNK cells exhibited lesser capacity of cytotoxicity and ADCC compared with ILT2-NKp46- and NKp46+CD56dimNK cells, the capacity of which was partially restored by ILT2 blockade or antioxidant compounds. The level of HLA-G expression was more in cancerous liver than those in noncancerous lesions.
Conclusion: ILT2+CD56dimNK cells in the HCC liver were functionally impaired with upregulation of lipid peroxidation. ILT2 could be a biomarker of NK cells as a target for immune or antioxidant intervention in HCC patients.

SAT-374

Interplay between hepatitis B virus replication and intrahepatic expression of VISTA and TIM-3 immune checkpoint markers in chronic hepatitis B patients

Kim Thys[1], Marianne Tuefferd[1], Thomas Derenne[1], Marjolein Crabbe[2], Clement Laloux[3], Alfonso Blazquez[1], Jeroen Aerssens[1], Cheng-Yuan Peng[4]. [1]*Janssen Pharmaceutica, Translational Biomarkers Infectious Diseases, Beerse, Belgium;* [2]*Janssen Pharmaceutica, Statistics and Decision Sciences, Beerse, Belgium;* [3]*PharmaLex, Friedrichsdorf, Hessen, Germany;* [4]*China Medical University Hospital, Taichung, China*
Email: mtueffe1@its.jnj.com

Background and aims: Host immune characterization of chronic hepatitis B (CHB) patients is usually limited to an assessment of the peripheral compartment as a consequence of the challenges to access samples from the site of the viral infection, the liver. However, the routine measurement of viral and immune markers in blood (serum hepatitis B virus [HBV] DNA, hepatitis B surface antigen [HBsAg], hepatitis B e-antigen [HBeAg], and alanine aminotransferase [ALT]) to monitor disease progression may not fully capture the dynamics and relationship between the host and virus in the liver.
Method: Core liver biopsies collected from 28 treatment naïve CHB patients, 5 HBeAg positive and 23 HBeAg negative, were characterized using Nanostring GeoMx® Digital Spatial Profiler technology. CD45-positive cells, HBsAg-positive hepatocytes, and HBsAg-negative hepatocytes were assessed for the expression of 72 proteins, including 16 immune checkpoint markers: 10 immune checkpoint receptors (PD-1, CTLA4, LAG-3, TIM-3, VISTA, GITR, ICOS, CD27, 4-1BB, and CD40) and 6 ligands (PD-L1, PD-L2, VISTA, B7-H3, OX40L, and CD80). For each liver biopsy, pools of 100 selected cells per cell type population were analyzed as areas of interest (AOIs). Up to 24 AOIs were collected per biopsy, resulting in a total of 732 AOIs analyzed. Linear models were applied comparing markers expression between HBsAg-positive and HBsAg-negative hepatocytes on one hand, and liver protein expression association with serum viral marker on a second hand. Significant associations after multiple testing correction are reported.
Results: Of the 72 proteins, CD45RO, GZMB, and CD44 showed significantly higher expression in HBsAg-positive hepatocytes than

HBsAg-negative hepatocytes, highlighting clearly different hepatocyte activation states. Four (CD80, GITR, PD-L1, and PD-L2) of the 16 immune checkpoint markers in the panel were not detected in any of the AOIs analyzed. PD-1 was detected in CD45-positive cells, but not significantly associated with any viral marker. VISTA and TIM-3 were significantly upregulated in CD45-positive cells collected in biopsies from HBeAg-positive CHB patients, but also in HBeAg-negative patients with high HBV DNA (>20,000 IU/ml) and/or high HBsAg (>1000 IU/ml) levels (false discovery rates: VISTA <5%; TIM-3 <10%). Upregulation of CTLA-4 was observed in intrahepatic CD45-positive cells from CHB patients with high HBV DNA and/or high HBsAg. Interestingly, TIM-3 overexpression was also observed in hepatocytes from patients with high peripheral HBsAg levels and high HBV DNA. Expression of OX40L, B7-H3, and IDO-1 in hepatocytes was negatively correlated with peripheral ALT levels, while no markers in CD45 cells were significantly associated with ALT levels.

Conclusion: Multiparametric profiling of immune checkpoint and activation markers in the livers of CHB patients highlights the interrelation between the HBV replication state and the host response.

SAT-375

Kupffer cell activation enhances systemic anti-bacterial immunity

Christian Zwicker[1,2], Anneleen Remmerie[1,2], Tinne Thoné[1,2], Liesbet Martens[1,2], Bavo Vanneste[1,2], Fleur Parmentier[1,2], Christopher Anderson[2,3], Charlotte Scott[1,2]. Email: christian.zwicker@irc.vib-ugent.be

Background and aims: Tissue resident macrophages are regarded as highly plastic cells able to rapidly respond to changes in their local microenvironment. However, we have recently shown that in a mouse model of non-alcoholic fatty liver disease Kupffer Cells (KCs), the resident macrophages of the liver, were gradually lost and did not exhibit an activated phenotyping questioning the plasticity of KCs in the liver. Given, that KCs have been proposed to have a crucial function in systemic immune surveillance, we sought to investigate whether these cells are able to respond to an acute bacterial infection.

Method: To investigate KC activation during systemic infection, we challenged mice with a sublethal dose of soluble LPS or the gram-negative pathogen *Salmonella enterica* serovar Typhimurium (S. Tm) and assessed KC fate and gene expression profiles. To manipulate the KC response to whole bacteria or purified bacterial components, we made use of the Clec4f-Cre mouse allowing KCs to be specifically targeted.

Results: Single cell RNA-sequencing and quantitative PCR revealed that KCs can mount an acute but temporally restricted pro-inflammatory response (*Il1b*, *Il6, Tnf* and *A20*) to free LPS peaking as early as 30 min post challenge and returning to baseline about 10 h later. Importantly, this tight regulation was crucial as mice lacking A20 specifically in KCs (Clec4f-Cre $A20^{fl/fl}$) which are unable to regulate this response, were highly susceptible to LPS and showed severe inflammation and mortality only 6–8 h after LPS challenge. This exaggerated response enhanced KC death in Clec4f-Cre $A20^{fl/fl}$ mice and just inhibiting KC death by removing RIPK3 (Clec4f-Cre × $A20^{fl/fl}$ × $RIPK3^{fl/fl}$) could rescue KCs and significantly reduce mortality. However, while KC-specific loss of A20 in Clec4f-Cre $A20^{fl/fl}$ mice was detrimental for host survival after challenge with soluble LPS, these mice exhibited strongly reduced bacterial load in liver and spleen after infection with pathogenic S. Tm compared with WT controls suggesting that hyperactivated KCs may promote systemic pathogen clearance. This protective effect was associated with increased monocyte and neutrophil infiltration in livers of Clec4f-Cre $A20^{fl/fl}$ mice.

Conclusion: We show that KCs are able to respond to an acute microbial insult, however, the exact nature of this response (protective vs pathogenic) strongly depends on the stimulus. While the response to free LPS needs to be tightly controlled to prevent excessive inflammation and to ensure host survival, recognition of whole bacteria by activated KCs enhances microbicidal cell recruitment and promotes pathogen clearance. Understanding the mechanisms underlying macrophages responses to microbes and microbial components may allow us to develop novel therapeutic strategies to activate these cells specifically and thereby improve patient outcomes in infectious diseases.

SAT-376

Osteopontin serves as a potential regulator of T cell immunity in patients with hepatocellular carcinoma

Tengfei Si[1], Zhenlin Huang[1], Shirin Elizabeth Khorsandi[2], Wayel Jassem[3], Abid Suddle[3], Ragai Mitry[1], Mark J W McPhail[1], Xiaohong Huang[1], Francesca Trovato[1], Salma Mujib[3], Salvatore Napoli[3], Ellen Jerome[3], Yun Ma[1], Nigel Heaton[1]. [1]*Institute of Liver Studies, King's College London, United Kingdom;* [2]*the Roger Williams Institute of Hepatology, United Kingdom;* [3]*King's College Hospital, United Kingdom*
Email: yun.ma@kcl.ac.uk

Background and aims: Osteopontin (OPN) is a secreted acidic protein which highly expressed in patients with hepatocellular carcinoma (HCC). Its involvement in the tumour invasion and metastasis has been defined recently. In our previous study we have found that it has a close association with PD-L1 in HCC setting, but little is known about its role in regulating the host cellular immunity. Through multiple assays and *in vitro* investigation, we aimed to define the interactions between OPN and the T cell mediated anti-tumour immunity.

Method: Blood samples were collected from patients with HCC (n = 40) for peripheral blood mononuclear cells (PBMCs) and plasma collection. Hepatic mononuclear cells (HMCs) were harvested from liver perfusate (n = 5) of pre-transplant donor graft, among which T cells were further isolated for 72-hour in vitro culture with different concentrations of OPN (0, 1 μg/ml, 5 μg/ml, 10 μg/ml). OPN and Th1 type cytokine (IFN-γ/TNF-α) levels were measured through enzyme-linked immunosorbent assay (ELISA). Cell phenotyping was conducted using flow cytometry. In addition, patients' RNA-secq data was used to analyse the association between the expression of OPN in tumour tissues and patients' prognosis after sorafenib treatment.

Results: Higher percentages of circulating $CD4^{pos}CD25^{pos}CD127^{low/neg}$ ($p = 0.0026$) and $CD4^{pos}CD25^{pos}CD39^{pos}$ ($p = 0.0004$) two Tregs subsets were observed in patients with elevated plasma OPN level, whereas the number of peripheral $CXCR3^{pos}$ CD8 T cells significantly decreased ($p = 0.0002$). After 72-hour *in vitro* culture, hepatic T cells from OPN-5 μg/ml group (8.724% vs 3.224%, $p = 0.043$) and OPN-10 μg/ml group (10.85% vs 3.224%, $p = 0.0007$) had higher portion of $CD4^{pos}CD25^{pos}$ Tregs compared to OPN-0 μg/ml group. The percentage of $Ki67^{pos}$ CD8 T cells decreased ($p < 0.05$) along with the increasing OPN concentrations in cell culture medium and the production of Th1 type cytokines IFN-γ ($p = 0.027$)/TNF-α ($p = 0.0005$) from T cells was also reduced with the upregulation of OPN. RNA-seq data revealed that patients with no response to sorafenib were companied with higher OPN expression in tumour compared to those who responded to treatment (TPM 974.7 vs 473.2, $p = 0.012$).

Conclusion: Overexpression of OPN could negatively regulate T cell immunity, featured by promoting the proliferation of Tregs, down-regulating the percentages of inflammatory T cells and inhibiting their ability of producing Th1 type cytokines. Targeting OPN in HCC may reverse the immunosuppression by restoring the T cell mediated anti-tumour immunity thus improving patients' prognosis.

SAT-377

Comprehensive phenotypical and molecular characterization of B lymphocytes in patients affected by intrahepatic cholangiocarcinoma

Giulia Milardi[1], Barbara Franceschini[1], Guido Costa[1], Cristiana Soldani[1], Paolo Uva[2], Davide Cangelosi[2], Barbara Cassani[1], Guido Torzilli[1], Matteo Donadon[3], Ana Lleo[4]. [1]*IRCCS Humanitas Research Hospital, Italy;* [2]*IRCCS Istituto Giannina Gaslini, Italy;* [3]*Università del Piemonte Orientale, Italy;* [4]*Humanitas University, Italy*
Email: giulia.milardi@st.hunimed.eu

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is a heterogeneous biliary tract cancer whose incidence is increasing worldwide. Due to the aggressive evolution of the disease, there is an urgent need for diagnostic and therapeutic alternatives. The immune infiltrate is a key component of the tumour microenvironment (TME), but remains poorly characterized, limiting development of successful immunotherapies. While there are many aspects related to T lymphocytes that are undergoing extensive studies, the effect exerted by B cells in iCCA development and progression is still controversial and no characterization has been performed. Herein, we aimed to define phenotypic and functional properties of B lymphocytes in the TME of iCCA, with the goal of finding new mechanisms important for cancer initiation and/or progression.
Methods: We used high-dimensional single-cell technologies to characterize the B-cell compartments of iCCA tissues, comparing these with their tumor-free tissues and circulating counterparts. We further performed gene expression analysis and cellular assays to define the B cell-specific role in iCCA tissues and investigate whether and how liver TME impact on B cell biology.
Results: Single-cell RNA-sequencing analysis of $CD20^+$ cells in iCCA patients ($n = 6$) identified four main subclusters of B and revealed an up-regulation of genes involved in neutrophil degranulation, cellular response to stress, GPCR binding and a downregulation of B cell activation/inflammatory genes in intratumoral compared to adjacent non-malignant tissue; suggesting an immunosuppressive role of B cells in iCCA TME. Multicolour flow cytometry analysis of B cells isolated from iCCA patients ($n = 13$) highlighted a higher frequency of naïve B cells respect to the memory phenotype. A reduction in B-cell effector functions was also detected. Immunohistochemical analyses showed that B cells, when infiltrate the tumour, create cellular aggregates similar to tertiary lymphoid structures.

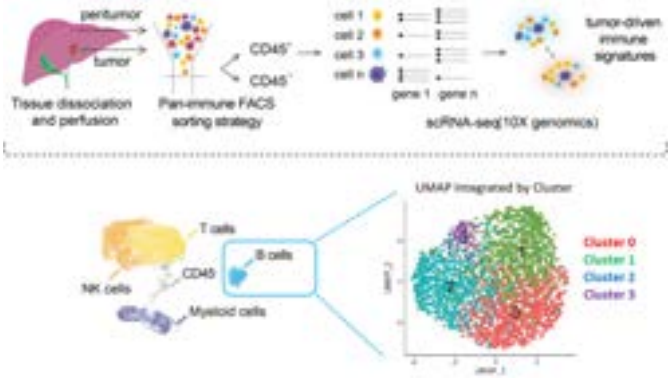

Figure: The present work was partially funded by the Associazione Italiana per la Ricerca sul Cancro (IG AIRC 2019-ID 23408 to A. Lleo).

Conclusion: Overall, these data suggest that iCCA tissue contain various B cells subtypes probably with an immunosuppresive role. However, a comprehensive characterization of B cell property, organization and crosstalk with other cells of iCCA milieu will elucidate mechanisms of tumour progression/control, exploitable for the development of novel immunotherapeutic approaches.

SAT-378

The Ninj1/Dusp1 axis contributes to liver ischemia reperfusion injury by regulating macrophage activation and neutrophil infiltration

Shun Zhou[1], Yuanchang Hu[1]. [1]*First Affiliated Hospital of Nanjing Medical University, Hepatobiliary Center and Research Unit of Liver Transplantation and Transplant Immunology, Nanjing, China*
Email: hand2399@njmu.edu.cn

Background and aims: Liver ischemia and reperfusion (IR) injury represents a major risk factor in both partial hepatectomy and liver transplantation. Nerve injury-induced protein 1 (Ninj1) is widely recognized as an adhesion molecule in leukocyte trafficking under inflammatory conditions, but its role in regulating innate immune during liver IR injury remains unclear.
Method: Myeloid Ninj1 deficient mice were generated by bone marrow chimeric models using Ninj1 knockout (KO) mice and wild type (WT) mice. In vivo, liver partial warm ischemia model was applied. Liver injury and hepatic inflammation were investigated. In vitro, primary Kupffer cells (KCs) isolated from Ninj1 KO and WT mice were used to explore the function and mechanism of Ninj1 in modulating KCs inflammation upon LPS stimulation.

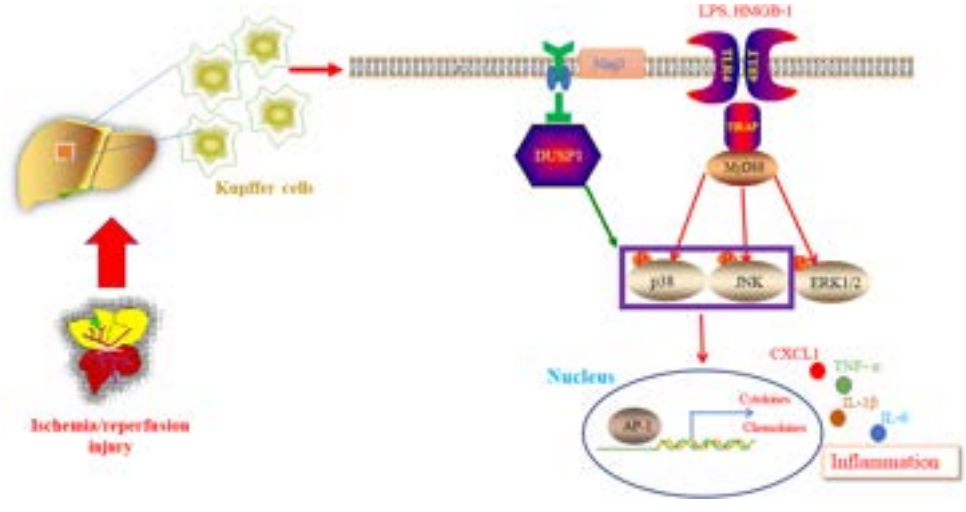

Figure: (abstract: SAT-378).

Results: Ninj1 deficiency in KCs protected mice against liver IR injury during the later phase of reperfusion, especially in neutrophil infiltration, intrahepatic inflammation, and hepatocyte apoptosis. This prompted ischemia-primed KCs to decrease proinflammatory cytokine production. In vitro and in vivo, using small interfering RNA against Dual specificity Phosphatase 1 (DUSP1), we found that Ninj1 deficiency diminished the inflammatory response in KCs and neutrophil infiltration through DUSP1-dependent deactivation of the JNK and p38 pathways. Sivelestat, a neutrophil elastase inhibitor, functioned similarly to Ninj1 deficiency, resulting in both mitigated hepatic IR injury in mice and a more rapid recovery of liver function in patients undergoing liver resection.
Conclusion: Ninj1/Dusp1 axis contributes to liver IR injury by regulating the proinflammatory response of KCs, and influences neutrophil infiltration, partly by subsequent regulation of CXCL1 production post-IR.

SAT-379

The decrease of HCV-specific neutralizing antibody responses after DAA therapy is associated with weak envelope-specific CD4 T cell immunity

Jana Gawron[1], Jill Werner[1], Lara Kelsch[1], Dorothea Bankwitz[2], Maike Hofmann[1], Robert Thimme[1], Thomas Pietschmann[2], Tobias Böttler[1]. [1]*University Hospital Freiburg, Department of Medicine 2, Freiburg, Germany;* [2]*Institute for Experimental Virology, TWINCORE, Hannover, Germany*
Email: jill.werner@uniklinik-freiburg.de

Background and aims: Despite the development of direct-acting antiviral agents (DAA) against hepatitis C virus (HCV) infections, the need for an effective vaccine remains. Many vaccines rely on the emergence of neutralizing antibodies (nAbs). Here, we aimed to get a more detailed understanding of the longevity and persistence of HCV-specific nAbs after DAA-mediated viral clearance and its relation to the CD4 T cell response, particularly follicular T helper cells (Tfh), targeting the HCV-envelope proteins in a longitudinal patient-based study.
Method: Neutralizing antibodies, B cells and Tfh cells were analyzed in human blood in a longitudinal cohort of 27 patients infected with HCV genotype 1a, 1b or 3a. Samples were collected before DAA therapy, at the end of therapy (EOT) and up to one year after end of therapy. HCV-specific secretion of IL-2, INFy and IL-21 by CD4 T cells were analyzed by flow cytometry after stimulation with *in silico* predicted, genotype-matched envelope proteins. nAbs were analyzed by co-incubation of Huh 7.5 cells with patient IgGs and HCV luciferase reporter viruses. Infectivity was assessed by luminescence measurements.
Results: nAb levels remained stable with some inter-patient variability between baseline and 5-to-7-months post EOT and uniformly decreased thereafter. Longitudinal analyses of bulk B or Tfh cells revealed no changes in frequencies of these populations. Envelope-specific CD4 T cells were detectable in 87.5% of patients, with low frequencies of cytokine expressing CD4 T cells. While the frequency of IL-21 producing HCV-envelope-specific CD4 T cells correlated with the nAb response at baseline, no changes were observed in the longitudinal analysis of HCV-envelope-specific CD4 T cells after viral clearance.

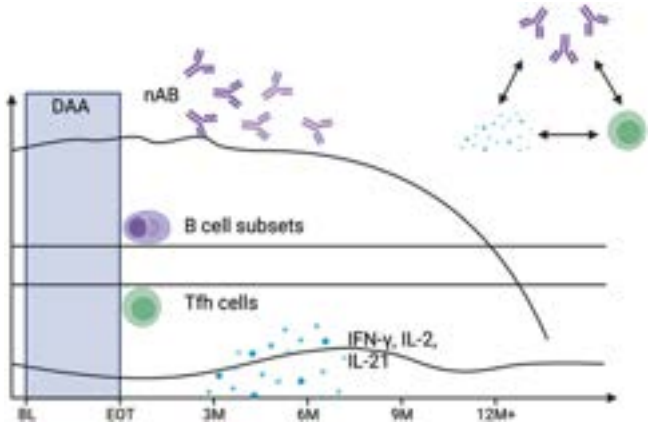

Figure:

Conclusion: A weak envelope-specific CD4 T cell response during chronic HCV infection might contribute to the failure to maintain nAb levels after DAA mediated viral clearance.

SAT-380

Epigenetic conversion of CD4+ T cells to stable and functioning induced regulatory T cells via cyclin-dependent kinase inhibition and CD28 signal deprivation in patients with primary biliary cholangitis

Vincenzo Ronca[1,2,3,4,5], Scott Davies[1,2], Kayani Kayani[1,2,4], Norihisa Mikami[4], Masaya Arai[4], Yamami Nakamura[4], Natsumi Okamoto[4], Jason White[4], Naomi Richardson[1,2], Naganari Ohkura[4], Pietro Invernizzi[3,5], Shimon Sagakuchi[4], Ye Htun Oo[1,2,5]. [1]*Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, UK, United Kingdom;* [2]*NIHR Birmingham Biomedical Research Centre, University of Birmingham and University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK, United Kingdom;* [3]*Division of Gastroenterology, Center for Autoimmune Liver Diseases, Department of Medicine and Surgery, University of Milano Bicocca, 20900 Monza, Italy., United Kingdom;* [4]*Laboratory of Experimental Immunology, WPI Immunology Frontier Research Center, Osaka University, Suita, Japan., Japan;* [5]*European Reference Network on Hepatological Diseases (ERN RARE-LIVER), United Kingdom*
Email: v.ronca@bham.ac.uk

Background and aims: Primary biliary cholangitis (PBC), is a chronic, autoimmune liver disease. Regulatory T cells (Treg) are a subset of CD4+ T lymphocytes whose activity is driven by the expression of a key transcription factor, Forkhead box P3 (FOXP3). A reduction in Treg frequency and functionality has been proposed as an underlying pathogenic mechanism of PBC. We aimed to characterise the natural Treg (nTreg) epigenetic profile in PBC patients. Additionally, we set out to induce functional and stable Treg cells (SF-iTregs) from PBC-derived effector CD4 cells in vitro, via cyclin-dependent kinase (CDK8/19) inhibition.
Method: CD4+ T cells were magnetically enriched from peripheral blood mononuclear cells (PBMCs) of PBC patients. CD4+T cells were activated by CD3+ activator beads and TCR stimulation without CD28 co-stimulatory signal, and cultured in presence of IL-2 and AS2863619 (CDK8/19 inhibitor). FoxP3, CTLA4 and Helios expression of SF-iTregs was assessed via flow cytometry and by bisulphite sequencing pre- and post-activation in presence of Th1 polarising cytokines. nTregs and SF-iTregs suppressive function was investigated by measuring CellTrace Violet dye-labelled effector T-cells proliferation co-culturing them with SF-iTregs at different diluition. nTregs and SF-iTregs Foxp3 gene locus for STAT5 binding, H3K27ac, and chromatin status was characterized by Chromatin immunoprecipitation followed by sequencing (ChIP-seq) and assay for transposase-accessible Chromatin sequencing (ATAC-seq).

Results: Deprivation of CD28 signal and chemical inhibition of cyclin-dependent kinase 8/19 of CD4 T cells is instrumental to induce DNA hypomethylation in Treg signature genes. Our protocol allowed us to obtain above 90% of FOXP3 expressing cells with a 100-fold increase in the cell number over 2 weeks. ATAC-seq and ChIP-seq confirmed that Treg specific epigenetic changes in the SF-iTregs were comparable to nTreg at the baseline. To resemble the liver inflammatory environment of PBC, we cultured nTreg and SF-iTregs in Th1-conditioned media containing IL-12 and IFN-γ for 6 days, demonstrating a better lineage stability in SF-iTregs compared with nTregs. In addition, SFiTreg maintain suppressive function in inflamed environment.
Conclusion: We apply a novel technique to generate abundant, functional induced regulatory T cells from peripheral conventional CD4+T cells in patients with primary biliary cholangitis. This approach would facilitate the production on a large scale of phenotypically stable, functional induced Tregs from antigen-experienced disease-mediating T cells to apply as GMP cellular therapy in PBC.

SAT-381
Intermediate monocytes and associated chemokines allow differentiation of idiosyncratic drug-induced liver injury (DILI) and autoimmune hepatitis (AIH)

Stuart Astbury[1], Edmond Atallah[1], Amber Bozward[2], Natalia Krajewska[2,3], Grace Wootton[2], Jane I. Grove[1], Ye Htun Oo[2], Guruprasad Aithal[1]. *[1]University of Nottingham, Nottingham Digestive Diseases Centre, Nottingham, United Kingdom; [2]University of Birmingham, United Kingdom; [3]University of Würzburg, Germany*
Email: stuart.astbury@nottingham.ac.uk

Background and aims: About 30% of AIH cases can present acutely and up to 9% of DILI cases share clinical, serological, and histological features with AIH. Distinguishing patients with DILI from AIH is of critical importance as the management of these two conditions differs substantially. Characterising different immune cell types may reveal different mechanisms underlying these conditions. These may have a clinical application as biomarkers to differentiate both types of liver injury.
Method: Patients with acute liver injury were enrolled prospectively. Following adjudication by an independent panel, patients were assigned to DILI (n = 13) or AIH (n = 6) groups according to criteria set by the DILI International Expert Working Group or International AIH Group respectively. These were compared with age-matched controls (n = 20).
Patients were sampled at time of liver injury, all AIH cases were steroid naive. Whole blood was stained using the Maxpar Direct Immune Profiling assay and analysed using a Helios mass cytometer. FlowSOM was used to identify cell populations from the 30 antibody panel, with monocyte clusters defined according to existing criteria of classical (CD14++CD16-), intermediate (CD14++CD16+) and non-classical (CD14+CD16++). The diffcyt R package was used to make pairwise comparisons between groups, with all p values adjusted for multiple comparisons.
Inflammatory cytokines were measured in plasma using the Human ProcartaPlex 20-plex Inflammation panel. Cytokines were compared between groups and correlated with immune cell subsets.
Results: We observed a significant decrease in classical monocyte frequency in AIH compared to both DILI and healthy controls (adjusted $p < 0.001$). Intermediate monocytes were significantly increased in AIH compared to DILI. Plasma CCL2 was negatively correlated with classical monocytes (Rho = –0.46, p = 0.04) and positively correlated with intermediate monocytes (Rho = 0.5, p = 0.028). Plasma CCL2, CCL3, CCL8, CXCL10, TNF-α and IL-17A were significantly increased in AIH compared to DILI.

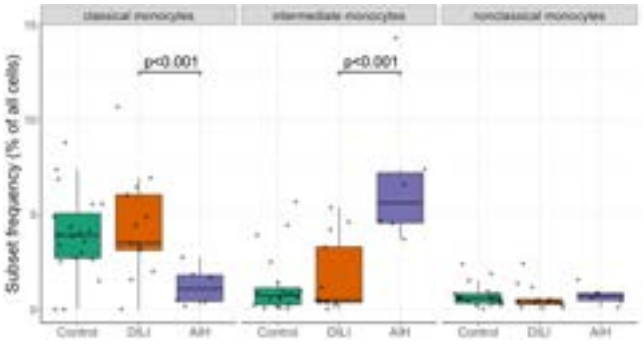

Figure:

Conclusion: Our results indicate the potential use of monocyte subtypes as a marker to distinguish between DILI and AIH. The significant increase in intermediate monocytes and monocyte chemoattractant protein 1 (MCP1/CCL2), MCP2/CCL8, monocyte inflammatory protein α (MIP-1α/CCL3), and hepatic homing chemokine CXCL10 highlight the role of intermediate monocytes as mediators of liver injury in acute AIH compared to DILI. The significant increases in proinflammatory cytokines: TNF-α and IL-17 indicate that both Th1/Th17 adaptive immune pathways are involved. Hepatic inflammation in idiosyncratic DILI is characterised by a Th1 dominant mechanism compared to AIH. Further work with liver infiltrating monocytes is required to dissect the innate and adaptive immune crosstalk in the pathogenesis of both diseases.

SAT-382
TIGIT inhibits the cytotoxic effects of NK cells towards biliary epithelial cells in autoimmune hepatitis

Amber Bozward[1,2,3,4], Rémi Fiancette[1,2], Scott Davies[1,2], Grace Wootton[1,2,3,4], Ye Htun Oo[1,2,3,4]. *[1]University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom; [2]NIHR Birmingham Biomedical Research Centre, University of Birmingham, Birmingham, United Kingdom; [3]Centre for Rare Diseases, European Reference Network on Hepatological Diseases (ERN RARE-LIVER) Centre, Birmingham, United Kingdom; [4]Birmingham Advanced Cellular Therapy Facility, University of Birmingham, Birmingham, United Kingdom*
Email: a.g.bozward@bham.ac.uk

Background and aims: Natural killer (NK) cells play an important role in autoimmune hepatitis (AIH) and are enriched in the liver, accounting for 25–40% of total intrahepatic lymphocytes. The interaction of checkpoint inhibitor, TIGIT, with its ligands, CD155 and CD112, has been shown to inhibit NK cytotoxicity in an oncological environment. However, little is known regarding the role of $TIGIT^+$NK cells in autoimmune hepatitis.
Method: $TIGIT^+$NK cell phenotype was investigated using 16 colour flow cytometry analysis of peripheral blood mononuclear cells (AIH = 12, PBC = 5, PSC = 2, NASH = 2, ALD = 1, healthy volunteers = 10) and liver infiltrating lymphocytes (PBC = 2, AIH/PSC/PVT = 1, AIH = 1, NASH = 1, ALD = 2, non-cirrhotic donor = 4). Immunohistochemistry was applied to investigate localisation of NK cells in explanted liver tissue. Coculture experiments were performed with peripheral blood $TIGIT^+$NK cells from AIH patients with either biliary epithelial cells (BEC) isolated from explant livers or sorted dendritic cells (DCs) and monocytes.
Results: NK cells were significantly upregulated in diseased livers compared to AIH blood (p = <0.0001). Immunohistochemistry staining demonstrated that $CD56^+$NK cells localise around the bile ducts and hepatocytes in AIH. TIGIT expression in AIH liver also localised around bile ducts and hepatocytes. TIGIT ligand CD112 is expressed on both hepatocytes and BEC and the other TIGIT ligand, CD155 is expressed predominantly on hepatocytes. Flow cytometry staining demonstrated that $TIGIT^+$NK cells in AIH patients express liver homing chemokine receptor, CXCR3 (7.53% ± 22.18), biliary homing

chemokine receptor, CCR6 (10.95% ± 65.45) and integrin, VLA-4 (56.15% ± 59.52). These cells also expressed tissue residency marker CD69 (13.48% ± 52.92). Coculturing co-inhibitory TIGIT$^+$NK cells with BEC did not lead to apoptosis/necrosis of BEC, despite their expression of cytotoxic molecules (granzymes A, B, K, perforin). Intrahepatic DC's and monocytes in AIH also express TIGIT ligands, CD112 and CD155; within DC's this expression was predominantly on myeloid DCs ($p < 0.0001$ and $p = 0.0096$ respectively compared to pDCs). Coculturing TIGIT$^+$NK cells with DCs and monocytes could mount a bi-directional T cell and antigen presenting cell immune response in both subsets.

Conclusion: We have shown that TIGIT$^+$NK cells are present in AIH liver. We also demonstrated the localisation of TIGIT ligands CD112 and CD155 in AIH livers. TIGIT$^+$NK cells express liver homing, biliary homing, and tissue resident phenotype. Our results indicate that TIGIT$^+$NK cells lack cytotoxicity towards biliary epithelial cells and could mount a tolerogenic immune response in AIH. TIGIT$^+$NK cells therefore may contribute to resolving inflammation in AIH.

SAT-383

Liver sinusoidal scavenger cells eliminate betaherpesvirus from the blood stream

Anett Kristin Larsen[1], Javier Sánchez Romano[1], Jaione Simón-Santamaria[1], Kim Erlend Mortensen[2], Ingelin Kyrrestad[1], Eirik Lænsman[1], Anne-Lotte Vada Hatlegjerde[1], Bård Smedsrød[1], Hans Hirsch[3], Christine Hanssen Rinaldo[4], Peter McCourt[1], Karen Kristine Sørensen[1]. *[1]UiT The Arctic University of Norway, Department of Medical Biology, Norway; [2]University Hospital of North Norway, Department of Gastrointestinal Surgery, Norway; [3]University of Basel, Department Biomedicine Transplantation and Clinical Virology, Switzerland; [4]University Hospital of North Norway, Department of Microbiology and Infection Control, Norway*
Email: anett.k.larsen@uit.no

Background and aims: The liver sinusoidal endothelial cells (LSECs) are pivotal as scavengers of circulating large molecules and nanoparticles. Hence, we hypothesize that LSECs, in collaboration with Kupffer cells, are key contributors to the cellular arm of the anti-viral innate immune system as virus scavengers. Most viruses taken up by LSECs will likely be eliminated through the effective degradative endolysosomal apparatus, but some viruses may escape. Murine LSECs have been shown to serve as a latent reservoir for murid betaherpesvirus (MuHV-1), but the permissivity of these specialized endothelial cells is less clear with regards to human betaherpesvirus 5 (HHV-5). The aim of this study was to reveal the role of the liver in blood clearance of betaherpesviruses, determine the capability of LSECs to scavenge larger enveloped viral particles, and investigate cellular effects following viral internalization. In addition, we compared if LSECs handle host-pathogenic viruses and similar non-pathogenic viruses differently.

Method: Murine models (C57Bl/6) were used to investigate blood clearance and organ distribution of HHV-5 and MuHV-1. Furthermore, liver tissue was obtained from patients undergoing hepatic resections. LSECs were isolated from the non-parenchymal liver cell fraction using MACS Microbeads, challenged with viruses, immunolabelled and imaged using different microscopy techniques. Primary LSECs of human and murine origin were used to investigate cellular uptake mechanisms, intracellular transport of endocytosed virus, susceptibility to infection as well as immune responses following viral challenge.

Results: HHV-5 and MuHV-1 were efficiently cleared from blood within 30 min in the mouse model and high uptake of viral particles in liver and spleen was confirmed. Association of HHV-5 with fenestrated human LSECs was verified using super-resolution light microscopy (see figure), whereas internalization of viral particles was confirmed using transmission electron microscopy. Internalized viruses colocalized with LAMP-1 positive structures already at 2 h post challenge. Early and late viral proteins were detected 24 and 72 h post challenge, respectively. Secretion of the cytokines TNFalpha and IL-6 following challenge with MuHV-1 was superior to levels detected following HHV-5-challenge in the murine model system. The latter confirmed that LSECs are capable of internalizing and degrading non-pathogenic viruses without eliciting an immune reaction.

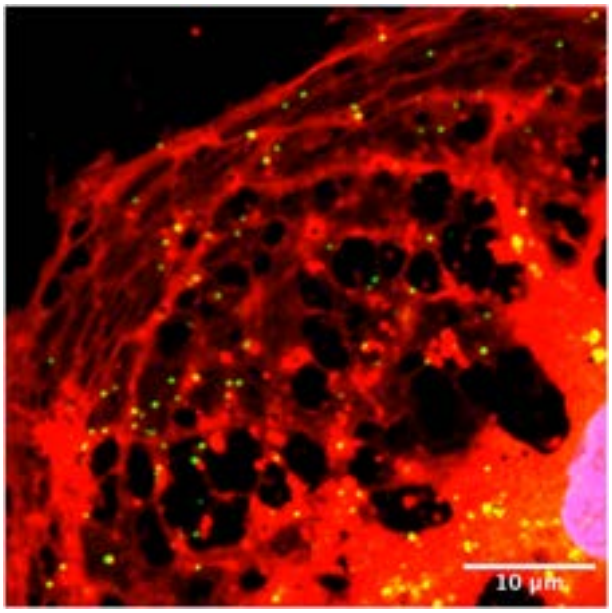

Figure:

Conclusion: The presented work confirms the essential role of the liver in elimination of betaherpesviruses from the circulation, with shared viral scavenging between LSECs and Kupffer cells. Human LSEC are permissive for HHV-5 infection, introducing the possibility of these cells contributing to latency.

SAT-384

Immune characterization of the melanocortin-4-receptor mouse model for non-alcoholic steatohepatitis using mass cytometry and imaging mass cytometry

Fabienne Birrer[1], Tess Brodie[1], Tural Yarahmadov[1], Deborah Stroka[1]. *[1]University of Bern, Inselspital, Bern University Hospital, Department of Visceral Surgery and Medicine, Bern, Switzerland*
Email: fabienne.birrer@unibe.ch

Background and aims: Dysregulated liver immune responses are critical in liver diseases, including non-alcoholic fatty liver disease (NAFLD), non-alcoholic steatohepatitis (NASH) and cirrhosis. Histological features of NASH are liver steatosis, inflammation, hepatocyte ballooning and fibrosis. There are many animal models used to study NAFLD and NASH, which are either genetically modified, chemically- or diet induced. The melanocortin-4-receptor knock out (MC4R-KO) mouse fed a western type diet (WD) is one of the models with the highest similarities to human NASH. However, the model was established only in 2019 and characterization, especially immune cell characterization, is not completed yet. Mass cytometry (MC) is a well-established method to phenotype cells in suspension by labelling them with metal tagged antibodies. Imaging mass cytometry (IMC) is a new high multiplexing imaging technology that provides complex cellular phenotyping on single cell level and interrelationships in spatial context at the same time. In this project, we aim to better characterize the MC4R NASH mouse model and describe a specific immune profile found during disease progression by using MC for phenotyping cells in suspension and IMC for cell localization and community building.

Method: We used the MC4R-KO mouse model to study NAFLD and NASH. MC4R-KO and wild-type mice were fed either a WD or normal

diet for 25 weeks. By immunohistochemistry stainings (IHC), we characterized liver tissue using the following parameters: micro- and macro vesicular steatosis (oil red and haematoxylin/eosin (HE)); fibrosis (sirius red; score 0–4); hepatocyte ballooning and mallory-denk bodies (HE; yes/no); inflammation (HE; degree 0–2); hepatic crown-like structures ((hCLS) HE; counts per 20x visual field). Parameters were scored by a pathologist. The immune cell composition was assessed in the liver and spleen, using a 32 target MC panel. To characterize the immune cell distribution in the liver, we used a 20 target IMC antibody panel in mouse formalin fixed paraffin embedded tissues.

Results: To define the liver condition of our experimental groups, we assessed the main parameters used for clinical diagnosis in patients. The livers of MC4R-KO mice on a WD had massive steatosis, fibrosis, inflammation and hepatocyte ballooning. There were hCLS in all MC4R-KO WD livers. The MC4R-KO on normal diet only exhibited massive steatosis but no other signs of NASH. The identified immune populations were B-cells, T-cell subsets, NK cells, infiltrated and liver resident myeloid cells, neutrophils and liver sinusoidal endothelial cells. There were several differences between controls, NAFLD and NASH in immune cell numbers in liver and spleen samples. The spatial distribution of immune cells in the livers of NAFLD and NASH mice by IMC showed structural and cell population differences between conditions.

Conclusion: Previously, the MC4R-KO mouse model has been described as a model that closely resembles human NASH. With our data, we can confirm that this model leads to the following conditions: healthy control group (WT on normal diet), NAFLD (MC4R-KO on normal diet) and NASH (MC4R-KO on WD). With this data we can study the immune cell changes during disease progression. Additionally, IMC data provides information about immune cell localization during disease progression. This helps to understand tissue architecture and cell communications in the liver, as well as important cell contributions in diseased states.

SAT-385

The effect of testosterone on human T cells in health and autoimmune liver disease

Lara Henze[1], Stephanie Stein[1], Jasper Meyer[1], Tobias Poch[1], Jenny Krause[1], Christian Casar[1,2], Dakyung Lee[1], Johannes Fuß[3,4], Thomas Renne[5], Dorothee Schwinge[1], Christoph Schramm[1,6,7].

Email: la.henze@uke.de

Background and aims: Females are more prone to develop autoimmune diseases, including primary biliary cholangitis (PBC). The underlying mechanisms are still unknown. We here aimed to unravel the effects of testosterone on T cell phenotype and function, and how this may contribute to the pathogenesis of PBC.

Method: Two unique clinical cohorts were analyzed: I) Female and male individuals with PBC compared to age and sex matched healthy controls and II) transgender men receiving gender-affirming testosterone treatment. *Ex vivo* multi-color flow cytometry, *in vitro* conversion assays and CITE-single cell sequencing were used to characterize T cells and to identify changes upon *in vivo* testosterone treatment.

Results: Immunophenotyping revealed increased TH1 cell numbers and reduced Tregs to TH17 cell ratio in female individuals with PBC compared to healthy controls. The shift towards pro-inflammatory immune responses was supported by significant increase of *in vitro* TH1 conversion rates in female individuals with PBC. Importantly, female people with PBC presented with lower serum testosterone levels compared to healthy female age matched controls. Reduced TNFα and IFNγ release by testosterone treated T cells confirmed a direct effect of testosterone on immune cell regulation. Moreover, we analyzed single cell T cell transcriptomes in the transgender cohort after high dose *in vivo* testosterone treatment and identified significant changes in CD4 as well as CD8 T cell subset composition.

Conclusion: Together these data suggest that testosterone has a regulatory effect on T cells in health and autoimmunity and that this may contribute to the pathogenesis of PBC.

SAT-386

CXCL9 does not ameliorate murine macrophage activation syndrome hepatitis

Tamir Diamond[1,2], Michelle Lau[2], Jeremy Morrissette[3], Niansheng Chu[2], Edward Behrens[1,2]. *[1]University of Pennsylvania, Pediatrics, Philadelphia, United States; [2]Children's Hospital of Philadelphia, Pediatrics, Philadelphia, United States; [3]University of Pennsylvania, Immunology, United States*
Email: diamondt@chop.edu

Background and aims: Macrophage activation syndrome (MAS) is a cytokine storm syndrome characterized by systemic inflammation, multiorgan dysfunction and hepatitis. It is a known cause for liver failure in pediatric population. Interferon gamma (IFNg) is a main mediator of disease in MAS. It's down stream Chemokine (C-X-C motif) ligand 9 (CXCL9) is a clinically established biomarker to measure disease activity. In previous published studies of murine MAS-like disease model through TLR9 stimulation by CpG DNA as well as human clinical data showed correlation of CXCL9 levels to hepatitis. However, it's biological role in pathogenesis of MAS-hepatitis through its leukocyte receptor C-X-C motif chemokine receptor 3 (CXCR3) has not been studied to date. This study aimed to determine this relationship using a *cxcl9*$^{-/-}$ (cxcl9 KO) murine mode of MAS.

Method: MAS was induced in cxcl9 KO and WT C57BL/6 mice using established method of repeated TLR9 stimulation by CpG (50mcg) on days 0, 2, 4, 7 and 9 with sacrifice at day 10. Immunopathology was assessed in various methods: (1) Peripheral blood samples to assess for cytopenia were collected on day 0 and sacrifice. (2) Serum was collected at sacrifice to measure alanine aminotransferase and serum cytokines (INFg, Ferritin and sIL2r). (3) Spleen and liver leukocytes were extracted using established methods to assess the hepatic inflammatory milieu. (4) Livers were fixed in 4% formalin for 24 hours and stained with haematoxylin and eosin for histological review.

Results: MAS features developed in both cxcl9-ko and WT groups with anemia, leukopenia, lymphopenia, hepatosplenomegaly, elevated sIL2r and ferritin. Features of MAS such as weight loss, splenomegaly, serum ferritin, sIL2r did not differ between groups. Mice from cxcl9-ko group had significantly larger livers (Fig 1A) but comparable serum ALT (Fig 1B). There was no significant difference in degree of hepatitis histologically or in hepatic leukocyte count by flow cytometry. Cxcl9-ko resulted in larger percentage of hepatic T-cells with reduction in NK cells and trend towards reduction in inflammatory monocytes (figure 1C). However, expression of CXCR3+

on these populations did not differ in these groups (figure 1D) suggesting alternative mechanism of hepatic immune recruitment in MAS-hepatitis.

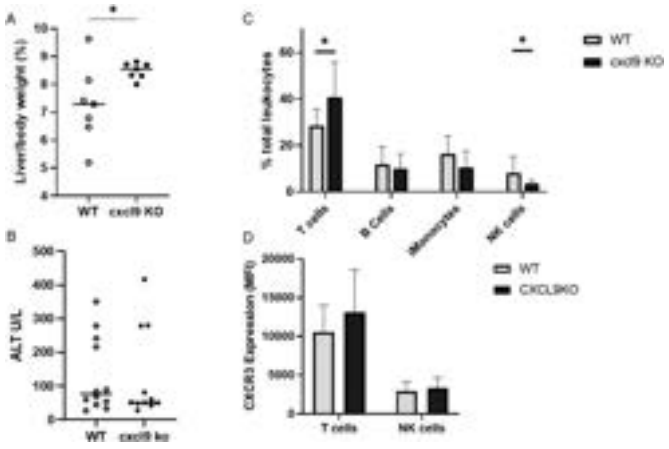

Figure:

Conclusion: Cxcl9 deficiency does not alter phenotype of hepatitis in murine model of MAS. Evaluation of alternative pathways of immune recruitment in MAS-hepatitis should be investigated. Cxcl9 is a useful biomarker to monitor IFNg activity but is unlikely to be a therapeutic target for MAS-hepatitis.

SAT-387

Characterisation of invariant natural killer T cells in human hepatic biopsies

Elena Jiménez-Martí[1,2], Maria Aguilar Ballester[2], Gema Hurtado-Genovés[2], Luis Sabater Ortí[2,3], Marina Garcés Albir[4], Dimitri Dorcaratto[4], Sergio Martínez-Hervás[5,6,7], Herminia González-Navarro[1,2,7]. *[1]University of Valencia, Biochemistry and Molecular Biology, València, Spain; [2]INCLIVA Institut d'Investigació Sanitària, Valencia, Spain; [3]Hospital Clínic Universitari, Department of Surgery, València, Spain; [4]Hepatobiliary and Pancreatic Unit, General and Digestive Surgery Department, València, Spain; [5]Hospital Clínic Universitari, Servicio de Endocrinología y Nutrición, València, Spain; [6]University of Valencia, Departamento de Medicina, València, Spain; [7]CIBER de Diabetes y Enfermedades Metabólicas asociadas (CIBERDEM), Spain*

Email: herminia.gonzalez@uv.es

Background and aims: Previous studies in human and mouse models have shown discrepant effects of hepatic NKT sublineages in complications associated with metabolic dysfunction-associated liver disease (MALD). In the present investigation the characterization of iNKT sublineages were done in human hepatic samples from patients undergoing surgical procedures for hepatic tumor or cyst resection.

Method: Human hepatic biopsies from patients were obtained from the Hospital Clínico Universitario de Valencia. Other relevant clinical data was also collected. Patients were grouped in low and high hepatic triglyceride (TG)-content groups for comparisons. Hepatic analysis consisted of collagen percentage area with Masson trichrome stained cross-sections, and TG content by a biochemical in vitro assay and determination of NAS score determined in Hematoxylin-Eosin stained cross-sections. Resident hepatic NKT subtypes in fresh samples were analyzed by flow cytometry using different markers for detection of NKT subsets including niNKT and iNKT and additional markers to define and analyse iNKT1, iNKT2, iNKT17 and iNKTreg. Gene expression analysis of different fibrosis and cancer markers was performed by RT-qPCR and data was relativised to low TG-content patient group.

Results: Consistently, increased classic NAS score, glucose levels and BMI were observed in the high TG-content patient group compared with low TG-content patients consistent with an augmented MAFLD. By contrary collagen are was reduced in patients with high hepatic TG content. Interestingly, TG content was inversely correlated with the intrahepatic CD3+ CD56+ NKT cells percentage. No significant differences were observed in NK and NKT cells between patients with low and high TG content. Likewise, similar levels were observed in the percentages of iNKTreg (CD3+ Va18J24+ Foxp3+ Tbet-), iNKT1 (CD3+ Va18J24+ Tbet+ PLZFlow ROR-), iNKT2 (CD3+ Va18J24+ Tbet- PLZFhi ROR+) and iNKT17 (CD3+ Va18J24+ Tbet- PLZFint ROR+) between patients' groups but iNKT17 and iNKT2 were discretely decreased. Gene expression analysis of genes related with fibrosis including MMP9, COL1A1, TIMP1 and ACTA2 were similar between patients' groups but SOX9, was significantly enhanced in patients with high TG content.

Conclusion: The present data indicate that patients with exhibiting augmented MALD, display increased SOX9 expression and a mild no significant decrease in iNKT17 and iNKT2. In addition, the inverse correlation between intrahepatic CD3+ CD56+ NKT and intrahepatic TG accumulation suggest a protective role of NKT in advanced hepatic diseased patients.

SAT-388

Mast cell activation index as a novel prognostic marker in a pan-analysis of gastrointestinal cancers

Nataliya Rohr-Udilova[1], Matthias Pinter[1], Erika Jensen-Jarolim[2,3], Michael Trauner[1], Rodolfo Bianchini[2,3]. *[1]Medical University of Vienna, Internal Medicine III, Gastroenterology and Hepatology, Wien, Austria; [2]Institute of Pathophysiology and Allergy Research, Center of Pathophysiology, Infectiology and Immunology, Wien, Austria; [3]The Interuniversity Messerli Research Institute, University of Veterinary Medicine Vienna, Medical University of Vienna, University of Vienna, Comparative Medicine, Vienna, Austria*

Email: nataliya.rohr-udilova@meduniwien.ac.at

Background and aims: Mast cells are key components of the allergic response, as they release mediators and cytokines when activated due to allergen binding. There is growing evidence supporting the role of mast cell activation in cancer, thus contributing to the novel field of Allergooncology. Machine learning algorithms can be used to quantify bulk gene expression data from tumours, including activated and resting mast cells (1, 2). Drawing from the preceding data on liver cancer, we hypothesized that mast cells could play a special role in the development of gastrointestinal cancers in general. To this end, we propose a novel marker, the mast cell activation index (MCAI), to evaluate the role of mast cells in GI cancers.

Method: Gene expression data from 1675 patients with GI cancers, including hepatocellular carcinoma, cholangiocarcinoma, esophageal carcinoma and adenocarcinomas of the pancreas, rectum, stomach and colon (TCGA), were evaluated using a machine learning algorithm (1) and compared to 7673 patients with non-GI cancers (2). The mast cell activation index (MCAI) was calculated as a ratio of activated mast cells to total mast cells. Based on the MCAI value, patients were stratified into three groups: i) MCAI = 0 (low, n = 712, zero mast cell activation), ii) 0 < MCAI < 1 (medium, n = 168, partial activation) and iii) MCAI = 1 (high, n = 795, full activation). The results were correlated with clinical characteristics such as overall survival (OS) and progression-free survival (PFS) using the Log-Rank Mantel-Cox test.

Results: Mast cell activation was found to be a favorable prognostic marker for GI cancers. The median PFS was 3 times longer in the high

MCAI group compared to the low MCAI group, with the medium MCAI group being in between (Low: 644 d, 95%CI 504–783 d; Medium: 1003 d, 95% CI 545–1460 d; High: 1929 d, 95% CI 1317–2540 d, p < 0.0001, Fig. 1A). The differences in OS were much less pronounced (Low: 1372 d, 95%CI 1162–1581 d; Medium: 2532 d, 95% CI 653–4411 d; High: 1849 d, 95% CI 1478–2220 d, p = 0.03, Fig. 1B). In contrast, a high MCAI was associated with worse OS and PFS outcomes in non-GI cancers (p < 0.0001, Fig. 1C, D).

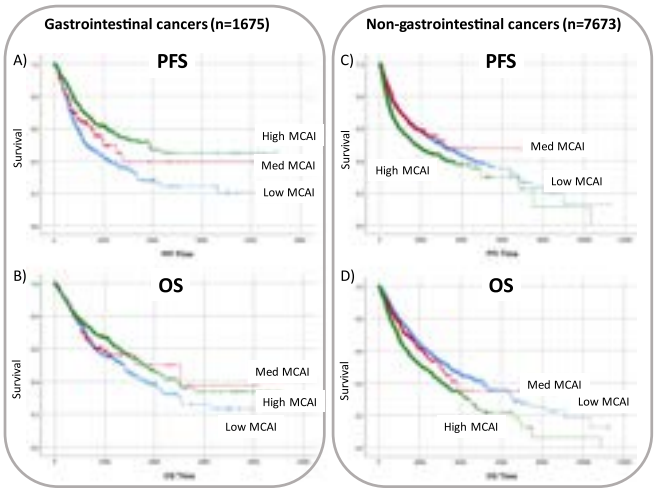

Figure 1: Kaplan-Mayer survival curves of cancer patients stratified according to the intratumoral mast cell activation index (MCAI).

Conclusion: Our pan-analysis of seven gastrointestinal cancers using a novel marker-mast cell activation index (MCAI)-showed that gastrointestinal tumour patients with fully active mast cells had a longer progression-free survival. This suggests that mast cell activation has a protective effect in GI cancers and merits further exploration. It is possible that mast cells may offer new therapeutic opportunities for treating gastrointestinal tumours.

The ascitic environment in cirrhosis upregulates the expression of the immune checkpoint CD155 on peritoneal macrophages

Joseph Delo[1,2], Daniel Forton[1,2], Evangelos Triantafyllou[3], Arjuna Singanayagam[1,2]. *[1]St George's University of London, United Kingdom; [2]St George's Hospital, United Kingdom; [3]Imperial College London, United Kingdom*
Email: joseph.delo@gmail.com

Background and aims: Peritoneal macrophages from the ascites of patients with decompensated cirrhosis (DC) are known to have impaired phagocytic and anti-microbial function. This is most profound in those with accompanying organ-failure (acute-on-chronic liver failure; ACLF). CD155 (poliovirus receptor) binds the inhibitory receptors TIGIT and CD96 on T cells and NK cells. CD155 on macrophages can mediate a transition to an M2-like, immunosuppressive, phenotype in tumour-associated macrophages. It has also been shown, in the context of other chronic diseases, to impair macrophage ability to activate T cells during antigen-presentation. A soluble form of CD155 is also produced by cells, which can inhibit NK cells. We hypothesised that peritoneal macrophages from patients with DC would express more CD155, and that this might be a result of chronic exposure to bacterial products translocating from the gut into the ascites.
Method: Peripheral blood mononuclear cells (PBMC) and peritoneal mononuclear cells from patients with DC (n = 11) were assessed for surface expression of CD155 on monocytes or macrophages by flow cytometry analysis. Peritoneal cells from patients with end-stage renal disease undergoing Continuous Ambulatory Peritoneal Dialysis (CAPD) were used as a control (n = 5). The concentration of soluble CD155 in ascitic fluid from DC patients, with or without ACLF, was determined by ELISA. Healthy control PBMCs were cultured in ascites, or in media with various Toll-Like Receptor (TLR) agonists, for 48 hours, and the surface expression of CD155 assessed.
Results: More peritoneal CD14+CD16- macrophages from the ascites of patients with DC expressed CD155 than those from CAPD controls (58.64 versus 26.09%, p = 0.0365, figure A). The concentration of soluble CD155 in ascites was higher in patients with ACLF compared to those without ACLF. Patients with DC had higher levels of CD155 on their peritoneal macrophages compared to their peripheral monocytes, indicating that the ascitic environment may influence CD155 expression. Indeed, culturing healthy PBMCs with ACLF ascites upregulated monocyte CD155 expression more than culture media alone or non-ACLF ascites (p = 0.0245, figure B). Similar upregulation of CD155 on monocytes was seen after culturing healthy PBMCs with lipopolysaccharide (LPS; a TLR-4 agonist).

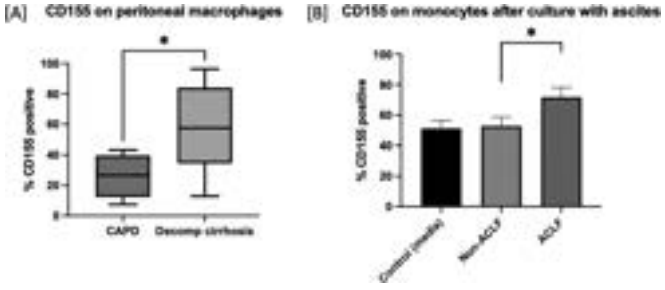

Figure:

Conclusion: The high expression of CD155 on peritoneal macrophages from patients with decompensated cirrhosis might in part explain their immunosuppressive phenotype and why patients are so susceptible to spontaneous bacterial peritonitis. This increase in CD155 expression is particular to the peritoneum, and not seen in the periphery, and can be induced by exposure to ascites and LPS, suggesting that bacterial translocation may be responsible.

SAT-390

Distinct immunometabolic signatures in circulating immune cells define disease outcomes in acute-on-chronic liver failure

Email: rita.azevedo@kuleuven.be

Background and aims: Acute-on-chronic liver failure (ACLF) is a devastating syndrome characterized by multiple organ failure and

high short-term mortality. The pathophysiology of ACLF is on the one side linked to elevated systemic inflammation that precipitate organ dysfunction and on the other side, immune dysfunction and increased susceptibility to bacterial infections. However, this immunological paradox is poorly understood and it is unclear how these aspects are associated with disease outcome. Here we map the single cell transcriptome of circulating cells from ACLF patients and we interrogated how specific immunometabolic signatures are linked to disease outcome.

Method: We performed single-cell transcriptomics of PBMC's from healthy (n = 3), acute decompensated (n = 3) and ACLF patients (n = 9). We further validated these findings in an independent cohort using bulk-sequencing, metabolomics and functional assay approaches.

Results: The data revealed two distinct classical monocyte (cMon) states that were uniquely linked to either ACLF-recovery (ACLF-R) or -non-recovery (ACLF-NR). Characteristic markers include VIM, LGALS2 and TREM1 for ACLF-NR cMon and RETN, S100A8/P and LGALS1 for ACLF-R cMon. Additionally, ACLF-NR cMon featured inflammation- and stress response transcriptional traits, while ACLF-R cMon were hallmarked by transcripts involved in stress tolerance, IFN signaling, superoxide scavenging, oxidative phosphorylation and refractory functionality. Interestingly, we observed a common stress-induced tolerant state, oxidative phosphorylation program, blunted activation and functionality also among lymphoid populations in ACLF-R compared to ACLF-NR patients.

Conclusion: This study uncovers unique cellular states and their underlying metabolite fingerprints that underlie disease outcome in ACLF patients. The data further provide important insights in disease pathogenesis and can act as foundation for larger studies to identify and validate targets for therapies.

SAT-391

RIPK3-mediated XBP1-Foxo1 axis controls NOD1 function and Calcineurin/TRPM7-induced cell death in liver inflammatory injury

Xiaoye Qu[1,2], Tao Yang[3], Xiao Wang[3], Dongwei Xu[2,3], Michael Ke[1], Jun Li[4], Longfeng Jiang[4], Qiang Xia[2], Douglas Farmer[1], Bibo Ke[3]. *[1]The Dumont-UCLA Transplant Center, Division of Liver and Pancreas Transplantation, Surgery, Los Angeles, United States; [2]Renji Hospital, Shanghai Jiaotong University School of Medicine, Liver Surgery, China; [3]The Dumont-UCLA Transplant Center, Division of Liver and Pancreas Transplantation, Surgery, Los Angeles, United States; [4]The First Affiliated Hospital, Nanjing Medical University, Infectious Diseases, China*
Email: bke@mednet.ucla.edu

Background and aims: RIPK3 is a central player in triggering necroptotic cell death. However, whether macrophage RIPK3 may regulate NOD1-dependent inflammation and Calcineurin/TRPM7-induced hepatocyte death in oxidative stress-induced liver inflammatory injury remains elusive.

Method: A mouse model of hepatic ischemia/reperfusion injury (IRI), the primary hepatocytes, and bone marrow-derived macrophages were used in the myeloid-specific RIPK3 knockout ($RIPK3^{M\text{-}KO}$) and RIPK3-proficient ($RIPK3^{FL/FL}$) mice.

Results: $RIPK3^{M\text{-}KO}$ diminished IR stress-induced liver damage with reduced serum ALT/AST levels, macrophage/neutrophil infiltration, and proinflammatory mediators compared to the $RIPK3^{FL/FL}$ controls. IR Stress activated RIPK3, IRE1α, XBP1, NOD1, NF-κB, Foxo1, Calcineurin A, and TRPM7 in ischemic livers. Conversely, $RIPK3^{M\text{-}KO}$ depressed IRE1α, XBP1, NOD1, Calcineurin A, and TRPM7 activation with reduced serum TNF-α levels. Moreover, $Foxo1^{M\text{-}KO}$ alleviated IR-induced liver injury with reduced NOD1 and TRPM7 expression. Interestingly, chromatin immunoprecipitation (ChIP) coupled with massively parallel sequencing (ChIP-Seq) revealed that macrophage Foxo1 colocalized with XBP1 and activated its target gene *Zc3h15*. Activating macrophage XBP1 enhanced *Zc3h15*, NOD1, and NF-κB activity. However, disruption of macrophage *Zc3h15* inhibited NOD1 and hepatocyte Calcineurin/TRPM7 activation, with reduced ROS production and LDH release after macrophage/hepatocyte co-culture. Furthermore, adoptive transfer of *Zc3h15*-expressing macrophages in $RIPK3^{M\text{-}KO}$ mice augmented IR-triggered liver inflammation and cell death.

Conclusion: Macrophage RIPK3 activates the IRE1α-XBP1 pathway and Foxo1 signaling in IR-stress livers. The XBP1-Foxo1 interaction is essential for modulating target gene *Zc3h15* function, which is crucial for the control of NOD1 and Calcineurin-mediated TRPM7 activation. XBP1 functions as a transcriptional coactivator of Foxo1 in regulating NOD1-driven liver inflammation and Calcineurin/TRPM7-induced cell death. Our findings underscore a novel role of macrophage RIPK3 in stress-induced liver inflammation and cell death, implying the potential therapeutic targets in liver inflammatory diseases.

Phenotypical and functional sub-classification of Kupffer cells and liver monocyte-derived macrophages in mice

Hiroyuki Nakashima[1], Azusa Kato[1], Bradley Kearney[1], Masahiro Nakashima[1], Hiromi Miyazaki[2], Seigo Ito[3], Manabu Kinoshita[1]. *[1]National Defense Medical College, Immunology and Microbiology, Tokorozawa, Japan; [2]National Defense Medical College Research Institute, Division of Biomedical Engineering, Tokorozawa, Japan; [3]Self-Defense Force Iruma Hospital, Department of Internal Medicine, Iruma, Japan*
Email: hiro1618@ndmc.ac.jp

Background and aims: The macrophages in the liver are critical components of systemic defense mechanisms. $F4/80^{high}$ Kupffer cells (KCs) are the most recognized liver macrophages, which efficiently contribute to the innate immune system. $F4/80^{low}$ monocyte-derived macrophages (MoMφs) are other essential macrophages that modulate liver immune functions. In this study, we aimed to achieve a detailed subclassification of each population and its possible implications in the pathogenesis of an experimental non-alcoholic steatohepatitis model.

Method: Male C57BL/6 mice were subjected to the experiments, and liver non-parenchymal cells were isolated with collagenase digestion and analyzed by flow cytometry. $F4/80^{high}$ and $F4/80^{low}$ macrophage populations were identified, and their subclassifications were analyzed using uniform manifold approximation and projection (UMAP).

Results: KCs were classified into CD163 (+) or (−) population, and liver capsular macrophages co-existed in the same $F4/80^{high}$ cells. CD163 (+)KCs had higher phagocytic and bactericidal activities and more complex cellular structures than CD163 (−) KCs. These three populations were eliminated by clodronate liposome treatment. $F4/80^{low}$ MoMφs were divided into four populations according to Ly6C and MHC class II expression. The number of these monocyte-derived cells decreased in the chemokine receptor CCR2 knock-out mice. In high-fat- and cholesterol-diet-fed mice, the number of MHC class II positive pro-inflammatory MoMφs was specifically increased and considered to be the critical cell cluster for the progression of the non-alcoholic steatohepatitis model.

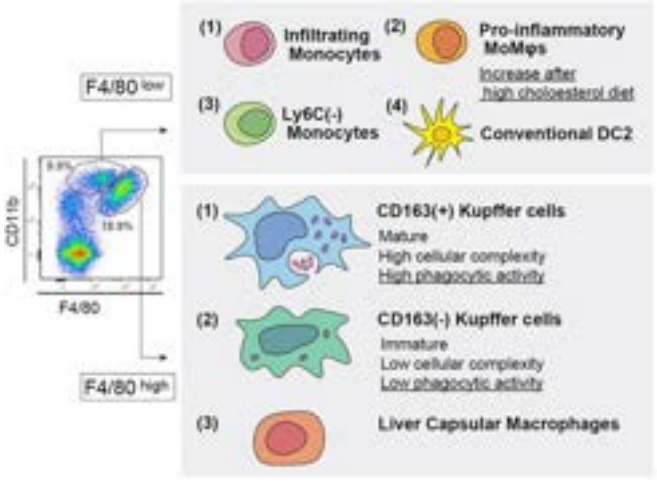

Figure:

Conclusion: CD163 expression effectively differentiated functional subclassification of Kupffer cells. F4/80^{low} pro-inflammatory MoMφs were the crucial effectors in accelerating inflammatory reactions in the liver. Our detailed subclassification and gating strategy can contribute to a better understanding of the complex immunological mechanisms in the liver.

Neoadjuvant PD-1 blockade with Pembrolizumab combined with Lenvatinib therapy in patients with hepatocellular carcinoma beyond Milan criteria before liver transplantation (PLENTY): a single-site pilot randomized controlled trial

Zicheng LV[1,2], Qiang Xia[3,4], Hao Feng[1,3]. [1]*Shanghai Engineering Research Center of Transplantation and Immunology, China;* [2]*Shanghai Engineering Research Center of Transplantation and Immunology, China;* [3]*Shanghai Renji Hospital, Dept. of Liver Surgery, China;* [4]*Shanghai Renji Hospital, Dept. Liver Surgery, China*
Email: surgeonfeng@live.com

Background and aims: Liver transplantation (LT) has become the most effective treatment for hepatocellular carcinoma (HCC); however, the high recurrent rate after LT remains a clinical challenge, especially for those exceeding the Milan criteria. Recently, there have been no approved standardized neoadjuvant or adjuvant therapies for hepatocellular carcinoma before LT. Therefore, we aim to investigate whether programmed death receptor 1 (PD-1) blockade plus lenvatinib as a neoadjuvant therapy before LT allows safely administered and effectively reduces post-LT recurrence for those patients with hepatocellular carcinoma beyond Milan criteria.
Method: In this prospective, randomized, open-label, pilot study, patients with hepatocellular carcinoma exceeding the Milan criteria were randomly assigned (1:1) to receive 200 mg of pembrolizumab every 3 weeks until approximately 6 weeks before LT and combined with lenvatinib 8 mg orally once daily until 1 week before LT (PLENTY group) or to receive routine treatments (control group) before LT. Patients were randomly assigned to the two groups by computer-generated random number codes concealed in opaque envelopes. The primary end point of the study was the recurrence-free survival after LT. Secondary end points were objective response rate, overall survival, and adverse events. This trial is registered with ClinicalTrial.gov (NCT04425226).
Results: Between February 3, 2020, and September 5, 2021, 22 patients were enrolled and randomly assigned: 11 to the PLENYT group and 11 to the control group. The 12-month tumor-specific recurrence-free survival after LT was significantly improved in the PLENTY group (62.5%, 95%CI 24.49–91.48) compared to the control group (37.5%, 95%CI 8.52–75.51) (log-rank p = 0·0028). The objective response rate in the PLENTY group was 30% (95%CI 6.67–65.2) and 60% (95%CI 26.2–87.8) when determined by RECIST 1.1 and mRECIST, respectively. In the PLENTY group, the disease control rate was 100% (95%CI 69.15–100) according to both RECIST 1.1 and mRECIST; Six patients had significant tumor necrosis (60%, 95%CI 26.2–87.8), including three who had complete tumor necrosis (30%, 95%CI 6.67–65.2) at histopathology. No acute allograft rejection after LT occurred in either group. No grade 4 or 5 adverse events were observed. Grade 3 adverse effects were observed in 30% (3/10) of patients in the PLENTY group.
Conclusion: Neoadjuvant pembrolizumab plus lenvatinib before LT appears to be safe and feasible in hepatocellular carcinoma patients; it would be a potential therapeutic option for patients exceeding the Milan criteria, associated with significantly better recurrence-free survival. Our findings support further studies of neoadjuvant immunotherapy in combination with TKIs in the bridging treatment for hepatocellular carcinoma.

Graft steatosis and donor diabetes mellitus additively increase the risk of retransplantation and death in adult liver transplantation -data from the Eurotransplant registry

Milan Sonneveld[1], Fatemeh Parouei[1], Caroline den Hoed[1], Jeroen de Jonge[1], Morteza Salarzaei[1], Robert Porte[1], Harry LA Janssen[1], Marieke van Rosmalen[2], Serge Vogelaar[2], Adriaan Van der Meer[1], Raoel Maan[1], Sarwa Darwish Murad[1], Wojciech Polak[1], Willem Pieter Brouwer[1]. [1]*Erasmus MC, Netherlands;* [2]*Eurotransplant, Netherlands*
Email: m.j.sonneveld@erasmusmc.nl

Background and aims: Presence of severe steatosis in the donor graft has been associated with an increased risk of adverse outcomes after liver transplantation. Recent studies indicate that presence of other metabolic risk factors increases the risk of advanced liver disease among patients with hepatic steatosis. Presence of metabolic risk factors in the donor may therefore confer additive risk for graft failure after transplantation. We studied the association between graft steatosis and metabolic risk factors in the donor with recipient outcomes after liver transplantation.
Method: We analysed data from all consecutive first adult full-graft DBD liver transplantations performed in the Eurotransplant region between 2010 and 2020. Presence of graft steatosis was assessed through review of individual donor imaging reports. Presence of diabetes mellitus (DM), hypertension (HT) and dyslipidaemia was assessed through review of individual donor medical history reports. The association between graft steatosis and metabolic risk factors in the donor with retransplantation-free survival of the recipient was assessed through the Kaplan-Meier method and multivariable Cox regression models, adjusted for Eurotransplant donor risk index (ET-DRI), donor and recipient sex, recipient age, and recipient labMELD.
Results: We studied 12174 transplantations. Median donor age was 56 (IQR 45–67), median donor BMI was 26 (24–28), median cold ischemia time (CIT) was 506 (403–610) minutes, median ET-DRI was 1.49 (1.24–1.76) and median recipient labMELD was 16 (10–26). Graft steatosis was detected in 2689 (22.1%), and diabetes mellitus, hypertension and dyslipidaemia was present in 1245 (10.2%), 5056 (41.5%) and 524 (4.3%) of donors. In univariable analysis, presence of graft steatosis (Hazard Ratio [HR] 1.247, p < 0.001), and presence of DM (HR 1.274, p < 0.001), HT (HR 1.144, p < 0.001), and higher BMI (HR 1.014, p < 0.001) in the donor were associated with impaired

retransplantation-free survival, whereas donor dyslipidaemia was not (HR 1.019, P = 0.810). In multivariable Cox regression analysis, graft steatosis (adjusted HR [aHR] 1.197, p < 0.001) and donor DM (aHR 1.157, p = 0.004) were independently associated with an increased risk of retransplantation or death in the recipient, whereas hypertension, dyslipidemia and donor BMI were not. When compared to donors without graft steatosis and DM, the risk of recipient retransplantation or death was increased for grafts from donors with DM alone (aHR 1.155, p = 0.019), or steatosis alone (aHR 1.199, p < 0.001) and highest for grafts obtained from donors with both steatosis and DM (aHR 1.362, p < 0.001). Observed retransplantation-free survival at 1, 5 and 10 years was 79%, 65% and 48% among recipients of a non-steatotic graft from a non-diabetic donor, compared to 69%, 53% and 29% for recipients of a steatotic graft from a diabetic donor (p < 0.001).

Conclusion: Graft steatosis and donor DM additively increase the risk of retransplantation or death in adult DBD liver transplantation. Future studies should focus on methods to assess and improve the quality of these high risk grafts. Until such time, caution should be exercised when considering these grafts for transplantation.

Two-year follow-up of liver grafts from COVID-19 donors

Margherita Saracco[1], Donatella Cocchis[2], Francesco Tandoi[2], Federica Rigo[2], Renato Romagnoli[2], Silvia Martini[1]. [1]*AOU Città della Salute e della Scienza di Torino, Gastrohepatology Unit, Italy;* [2]*AOU Città della Salute e della Scienza di Torino, General Surgery 2U, Liver Transplantation Center, Italy*
Email: margherita.saracco@gmail.com

Background and aims: SARS-CoV-2 infections complicated by thrombosis and secondary sclerosing cholangitis were reported; however, solid non-lungs transplantation from COVID-19 donors showed excellent early results, but medium/long-term data are lacking. We aimed to describe the outcome of our LT patients (pts) who received a graft from COVID-19 donors.

Method: We consecutively enrolled all pts transplanted in our Center from 11/2020 to 03/2022 who received a liver graft from COVID-19 donors. Pts underwent protocolar liver biopsy and magnetic resonance cholangiopancreatography (MRCP) after at least 1 year from LT. Follow-up was closed in January 2023.

Results: In the study period, among 213 adult LTs, 12 (5.6%) received a COVID-19 donor (11 active and 1 resolved COVID-19)[1]. Recipients' and donors' characteristics are reported in table 1. None of the pts developed COVID-19 after LT. Two recipients tested SARS-CoV-2 RNA positive in nasopharyngeal swab immediately before LT and one was treated with sotrovimab on day-1 after LT. Eleven pts underwent end-to-end biliary anastomosis and 1 biliodigestive anastomosis. One pt underwent successful hepatic artery thrombectomy at day-1. Eleven pts underwent protocolar MRCP (median time from LT 573 days, IQR 290–648), which showed: no visible abnormalities in 8, 1 donor-recipient's bile duct size discrepancy, and 2 caliber changes <50% at anastomotic level (without cholestasis and which were not treated). Ten pts underwent liver biopsy (median time from LT 557 days, 391–682) which showed 1 acute rejection (RAI 4/9) successfully treated with steroids and no signs of rejection, biliopathy or fibrosis in the other 9. After a median time from LT of 669 days (344–737) 11 pts are alive and 1 died after 320 days for hepatocellular carcinoma recurrence.

Table 1: Pts' and donors' characteristics at liver transplant

	Recipients n = 12	Donors n = 12
Age, years	61 [56–65]	59 [52–63]
Sex, male	9 (75%)	8 (67%)
Body mass index, kg/m^2	27 [24–28]	25 [24–27]
Hepatocellular carcinoma	9 (75%)	NA
Model for end stage liver disease at LT	10 (8–14)	NA
SARS-CoV-2 vaccination before LT	4 (33%)	1 (8%)
SARS-CoV-2 IgG positive before LT	12 (100%)	1 (8%)
SARS-CoV-2 RNA swab positive at LT	2 (17%)	2/3 (67%)
SARS-CoV-2 RNA BAL positive at LT	NA	9/9 (100%)
Donor risk index	2 (1.6–2.2)	
SARS-CoV-2 RNA PCR negative on liver biopsy	11/11, 100%^	
Hypothermic machine perfusion	3 (25%)	
Normothermic machine perfusion	1 (8%)	

^The COVID-19 resolved donor was not tested.

Conclusion: After a median time from LT of 1.8 years, 11/12 pts who received a liver graft from COVID-19 donors are alive, without evidence of SARS-CoV-2 RNA transmission. Protocolar MRCP and liver biopsy did not show signs of biliopathy or fibrosis supporting the safe utilization of COVID-19 donors to expand the donor pool and reduce the waiting list mortality.

Defective efferocytosis by aged macrophages promotes STING signaling mediated inflammatory liver injury

Haoran Hu[1], Zhuqing Rao[1], Xuyu Cheng[1], Jian Xu[1], Dongming Wu[1], Ping Wang[1], Haoming Zhou[1], Feng Cheng[1]. [1]*The First Affiliated Hospital of Nanjing Medical University, China*
Email: docchengfeng@njmu.edu.cn

Background and aims: Timely efferocytosis of apoptotic cells is a key mechanism for avoiding excessive inflammation and tissue injury. MerTK (c-mer proto-oncogene tyrosine kinase), a member of the TAM (Tyro3, Axl, and MerTK) family, plays an essential role in the regulation of efferocytosis. We previously found that aging promoted macrophage STING (stimulator of interferon genes) activation to aggravate inflammatory liver injury. Here, we investigated the alteration of efferocytosis by aged macrophages and its role in regulating macrophage STING signaling and ischemic liver injury.

Method: Young (8 weeks) and aged (100 weeks) STING myeloid-specific Cre mice and wild-type mice were subjected to a model of liver ischemia and reperfusion. Efferocytosis by macrophages was analyzed in vivo and in vitro macrophages co-cultured with apoptotic Jurkat cells. The MerTK CRISPR activation plasmid, ADAM17 (a disintegrin and metalloproteinase 17) siRNA and N-acetylcysteine were used to conduct rescue experiments.

Results: Aged macrophages exhibited impaired efferocytosis with decreased MerTK activation, which was reversed by treatment with the MerTK CRISPR activation plasmid. Increased MerTK cleavage by ADAM17 due to enhanced ROS levels contributed to defective MerTK-mediated efferocytosis by aged macrophages. MerTK activation by suppressing ADAM17 or ROS improves aged macrophage efferocytosis, leading to reduced liver inflammation and IR injury. Moreover, increased apoptotic hepatocytes, DNA accumulation, and

macrophage STING activation were observed in aged livers post-IR. Improvement in efferocytosis by aged macrophages via MerTK activation suppressed STING activation and inflammatory liver injury.

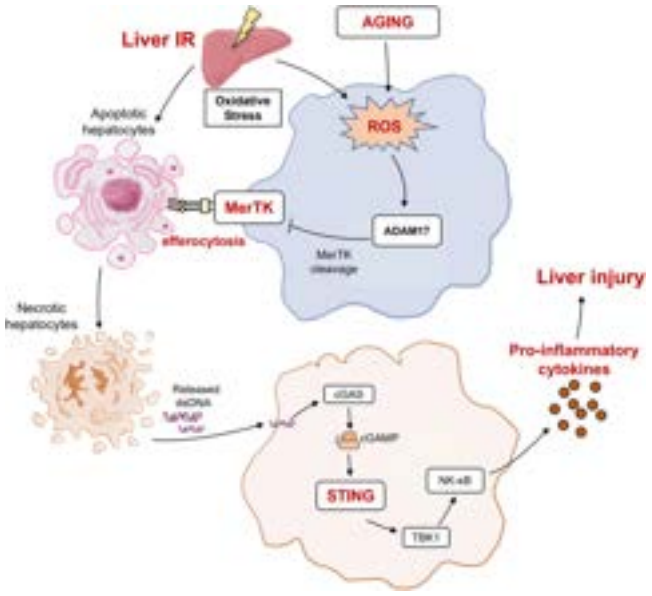

Figure:

Conclusion: Our study demonstrates that aging suppresses MerTK-mediated macrophage efferocytosis to promote macrophage STING activation and inflammatory liver IR injury, suggesting a new mechanism and potential therapy to promote inflammation resolution and efferocytosis in aging.

THU-478

C105SR, a novel non-peptidic small-molecule cyclophilin inhibitor with potent mitoprotective and hepatoprotective properties in the context of hepatic ischemia/reperfusion injury

Amel Kheyar[1,2], Nazim Ahnou[1,2], Hakim Ahmed-Belkacem[1,2], Bijan Ghaleh[2,3], Jean-François Guichou[4,5], Didier Morin[2,3], Jean-Michel Pawlotsky[1,6], Fatima Teixeira-Clerc[1,2]. *[1]INSERM U955, Équipe « Virus, Hépatologie, Cancer », Créteil, France; [2]Université Paris-Est, Créteil, France; [3]INSERM U955, Équipe « Pharmacologie et Technologies pour les Maladies Cardiovasculaires », Créteil, France; [4]CNRS UMR5048, INSERM U1054, Centre de Biochimie Structurale (CBS), Montpellier, France; [5]Université de Montpellier, Montpellier, France; [6]DMU de Biologie et Pathologie, Département Prévention, Diagnostic et Traitement des Infections, Créteil, France*
Email: fatima.clerc@inserm.fr

Background and aims: Mitochondrial permeability transition pore (mPTP) opening is critical in mediating cell death during hepatic ischemia/reperfusion injury. Blocking mPTP opening by inhibiting cyclophilin D (CypD) is a promising pharmacological approach for the treatment of ischemia/reperfusion injury. Here, we show that diastereoisomers of a new class of small-molecule cyclophilin inhibitors (SMCypIs) bear properties making them credible candidates for hepatic ischemia/reperfusion injury therapeutic development.
Method: Derivatives of the original SMCypI were synthetized and evaluated for their ability to inhibit CypD peptidyl-prolyl cis-trans isomerase (PPIase) activity and for their mitoprotective properties, assessed by measuring mitochondrial swelling and calcium retention capacity in mouse liver mitochondria. The ability of the selected compounds to inhibit mPTP opening was evaluated in cells subjected to hypoxia/reoxygenation using a calcein/cobalt assay. Their ability to inhibit cell death was evaluated in cells subjected to hypoxia/reoxygenation by measuring LDH release, propidium iodide staining and cell viability with a MTT assay. The best performing compound *in vitro* was selected for *in vivo* efficacy evaluation in a mouse model of hepatic ischemia/reperfusion injury.
Results: The two best compounds at inhibiting CypD PPIase activity and mPTP opening, C105 and C110, were selected. Their SR diastereoisomers carried the activity of the racemic mixture and exhibited mitoprotective properties superior to those of the known macrocyclic cyclophilin inhibitors cyclosporin A and alisporivir. C105SR was more potent than C110SR to inhibit mPTP opening and prevent cell death in a model of hypoxia/reoxygenation. Finally, C105SR substantially protected against hepatic ischemia/reperfusion injury *in vivo* by reducing hepatocyte necrosis and apoptosis.
Conclusion: We identified a novel cyclophilin inhibitor with strong mitoprotective and hepatoprotective properties both *in vitro* and *in vivo* that represents a promising candidate for cellular protection in hepatic ischemia/reperfusion injury.

THU-479

Application of human chemically-derived hepatic progenitors organoids (hCdHO) in regenerative medicine, hepatotoxic and disease modeling

Elsy Soraya Salas Silva[1], Yohan Kim[2], Tae Hun Kim[1], Myounghoi Kim[1], Daekwan Seo[3], Valentina M. Factor[4], Ji Hyun Shin[1], Dongho Choi[1]. *[1]Hanyang University, General Surgery, Seoul, Korea, Rep. of South; [2]Max Planck, Institute of Molecular Cell Biology and Genetics, Germany; [3]Psomagen Inc, United States; [4]National Institutes of Health, United States*
Email: crane87@hanyang.ac.kr

Background and aims: Chemically derived hepatic progenitors (hCdHs), reprogrammed from human primary hepatocytes (hPHs) were recently reported by our research group, which presented differentiation characteristics of both hepatocytes and cholangiocytes. The high percentage of EpCAM expression and other stemness markers allow to our hCdHs be a great source for organoid generation and longer culture maintenance. Our aim is to demonstrate the hCdH organoids (hCdHO) potency as a regenerative medicine, hepatotoxic test, and modeling disease tool.
Method: hCdHs and hPHs were embebbed on Matrigel with organoid medium to generate hCdHOs and liver organoids (hLOs) respectively.
Results: Our hCdHO showed a high expression in stemness markers compared with hLOs and higher organoid rate generation. We performed hepatic differentiation of organoids, termed hCdHO_DM and hLO_DM, and as we expected hCdHO_DM presented elevated expression of hepatic markers as well as functional markers, similar to those of hLOs. To address their regenerative capacity, the hCdHO were transplanted into FRG mice. The group that received the hCdHO transplant survived longer (for more than 100 days) than hLOs and control groups. In addition, the markers of liver damage decreased, and albumin and A1AT levels increased. We demonstrated the hCdHO_DM exhibit elevated drug sensitivity versus hPH and hCdHs. Finally, we developed a model of alcohol damage in organoids, where we observed that hCdHO_DM increased the activation of transcription factors and lipogenic-associated enzymes and inflammatory cytokines levels. Gene set enrichment analysis (GSEA) indicated that ethanol-treated hCdHO_DM showed strong induction of alcoholic metabolic process and fatty acid metabolism, reflected in lipid accumulation and loss of mitochondrial membrane potential

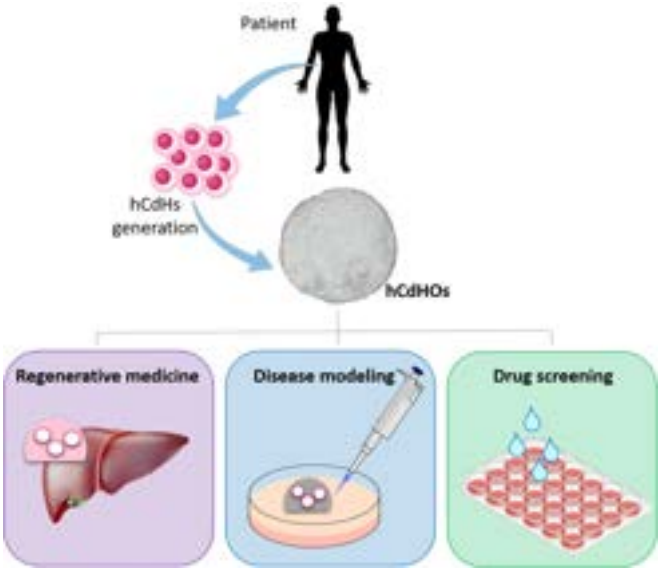

Figure:

Conclusion: These results show the potency of hCdHs in organoid generation, culture maintenance, and hepatic differentiation. hCdHO display an efficient repopulation in liver disease mice model, are more sensitive for hepatotoxic tests, and recapitulate alcohol-related liver disease features. This work was supported by Korean Fund for Regenerative Medicine funded by Ministry of Science and ICT, and Ministry of Health and Welfare (21A0401L1) and National Research Foundation of Korea (2022R1F1A1073058).

THU-480

In vitro model of liver ischemia/reperfusion injury identifies iRhom2 as new target of disease

Giovanni Zito[1], Matteo Calligaris[2], Vitale Miceli[1], Claudia Carcione[2], Chiara Gatto[1], Simone Scilabra[2], Duilio Pagano[1], Pier Giulio Conaldi[1]. *[1]IRCSS ISMETT, Regenerative Medicine, Palermo, Italy; [2]Fondazione Ri. MED, Italy*
Email: gzito@ismett.edu

Background and aims: Ischemia/reperfusion injury (IRI) represents one of the leading causes of primary-non function acute liver transplantation failure. IRI activates an inflammatory cascade from the resident Kupffer cells leading to neutrophils recruitment and apoptosis of the parenchyma. In the last decade, the pro-inflammatory protein iRhom2 has emerged as a central regulator of TNF release, one of the most prominent cytokines activated during IRI. However, no data described iRhome2 in liver IRI yet. Thus, our study focused on the evaluation of the primary role of iRhom2 in an in vitro model of liver IRI.
Method: IRI was tested on primary macrophages and hepatic cells. In vitro cold ischemia was performed with 2% O2 exposition in preservation medium. Warm reperfusion was performed at 1, 4 and 24 hrs. Cold ischemia and reperfusion effects on wt and iRhom2 KD cells were evaluated by ELISA, qPCR and ATP analysis. Shotgun proteomics was performed to compare wt and iRhom2 KD cells undergoing IRI.
Results: We found a positive association between iRhom2 expression and IRI in patients undergoing liver transplantation. Furthermore, iRhom2 transcripts are present in pre-reperfusion donor allografts, but its expression did not change in non-damaged livers, indicating iRhom2 as a mediator of the ischemic injury, rather than being a predictive risk factor of the injury. Next, we investigated the role of iRhom2 in IRI by using an in vitro model of IRI applied to M1 pro-inflammatory macrophages. In line with the in silico analysis, iRhom2 expression was enhanced by IRI during the early timepoints of macrophages reperfusion. These results showed that iRhom2 is involved in the progression of re-perfusion damage also the in vitro IRI model we established in the lab. These findings prompted us to further dissect iRhom2 function in vitro IRI context. For this purpose, we silenced iRhom2 in primary macrophages prior to IRI protocol. iRhom2 silencing was effective at all the timepoints analyzed. Furthermore, we found that iRhom2 KD reduced release of TNF and other IRI-related pro-inflammatory proteins, such as IL-18 and HMGB1. Interestingly, iRhom2 silencing accelerated macrophage recovery during re-perfusion, as shown by increased cell viability and reduced cytotoxicity in comparison with the control primary macrophages. Altogether, these data indicated that iRhom2 contributed to the progression of damage following IRI in vitro, not only by regulating pro-inflammatory cytokine secretion, but also by modulating cell survival. Interestingly, iRhom2 KD macrophages promoted a faster and better recovery of human hepatocyte-like cells compared to controls, when cells were co-cultured using a Transwell permeable supports and applied to the in vitro model of IRI. This suggested that iRhom2 silencing in macrophages could impair release of paracrine factors that contributed to IRI induction. Interestingly, proteomic approach revealed, among others, 7 proteins which are up-regulated during cold ischemia, such as ORM1, ORM2, AZGP1, LRG1, A1BG, CP, HPX. Interestingly, we found that the same proteins are strongly down-regulated in the secretome of macrophages undergoing IRI when iRhom2 was silenced. To note, their levels in the cell lysate were not affected by iRhom2 silencing.
Conclusion: Taken together, these data suggest that iRhom2, in response to IRI, could regulate secretion of these proteins post-transcriptionally, by a mechanism that might be independent from TNF pathway.

THU-481

HBV re-infection or de-novo infection in the course of liver transplantation in patients chronically infected with HBV, HBV/HDV, or HCV

Daniele Lombardo[1], Giuseppina Raffa[1], Irene Cacciola[1], Lucio Caccamo[2], Maria Francesca Donato[2], Giovanni Raimondo[1], Teresa Pollicino[1]. *[1]University of Messina, Clinical and Experimental Medicine, Messina, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Surgery, Italy*
Email: tpollicino@unime.it

Background and aims: Long-term anti-HBV prophylaxis has been highly effective in reducing the rate of HBV recurrence in HBsAg-positive patients or de novo infection in HBsAg-negative liver transplant recipients of anti-HBc positive hepatic grafts. However, HBV reinfection still occurs in several patients. Aim. To verify HBV reinfection in HBsAg-positive/HDV-negative and HBV/HDV coinfected patients as well as de novo infection in HBsAg-negative liver transplant (LT) recipients during the LT procedures.
Method: Virological analyses were performed on sera and hepatic tissues (native liver, pre- and post-perfusion allograft biopsies) from 21 LT patients (10 HCV-positive/HBsAg-negative, 5 HBsAg positive and 6 HBV/HDV positive). Moreover, liver biopsies from 6/21 cases (2 HCV-positive, 2 HBsAg positive and 2 HBV/HDV positive) obtained at 3 years post-LT were also analysed. Six of the 21 LT patients received anti-HBc positive liver graft.
Results: At the end of surgery, 2/5 HBsAg-positive patients, 2/6 HBV/HDV co-infected patients, and 2/10 HCV-infected patients showed HBV DNA (range: 6×10^{-4}–1×10^{-3} copies/cells) and HBV cccDNA (range: 2×10^{-5}–2×10^{-3} copies/cell) in the liver. All these patients received anti-HBc positive liver graft. Moreover, liver biopsies from all these patients at 3 years post-LT were HBV DNA positive despite the persistent HBsAg negativity, showing the presence of occult HBV infections (OBI). Furthermore, tissues from HBV/HDV positive patients were also positive for HDV RNA, which was not detected at the end of LT. Sequencing analysis of HBV DNA isolated from native livers and allografts revealed that the viruses present in liver biopsies 3 years after LT were viral strains of the donors. Of note, an HBV

positive LT patient showed HBV genotype D sequences in the native liver, whereas HBV genotype A was identified in the allograft both at the end of LT and 3 years after LT.
Conclusions: (1) OBI in anti-HBc positive liver graft persists over time both in HBsAg positive and negative recipients after LT. (2) HDV infects the transplanted liver subsequently to LT (3) HBV sequences persisting in transplanted liver are of donor origin.

THU-482

The impact of statin utilization on mortality in liver transplant recipients independent of underlying cardiovascular risk

Megan Ghai[1], Pooja Rangan[1], Rohit Nathan[2], Karn Wijarnpreecha[2], Mark Wong[2], Moises Nevah Rubin[2], Michael Fallon[2], Ma Ai Thanda Han[2]. [1]*University of Arizona College of Medicine Phoenix, Internal Medicine, Phoenix, United States;* [2]*University of Arizona College of Medicine Phoenix, Gastroenterology and Hepatology, Phoenix, United States*
Email: megan.b.ghai@gmail.com

Background and aims: Liver transplant recipients (LTRs) have a 55.3% risk of developing coronary artery disease within five years of transplant. However, statins are under-prescribed in LTRs despite this known risk. Studies reviewed showed only 23–41% of LTRs with obstructive coronary artery disease were initiated on a statin. It has been hypothesized that the concern for developing drug-induced liver injury in LTRs results in physician hesitancy to prescribe statins, though the estimated rate of statin-induced liver injury is only 1 in 100,000. This study aims to characterize the use of statins and its impact on mortality in LTRs.
Method: A retrospective analysis of adult LTRs from January 2012 through March 2022 at a single-center was performed. The population was split into two cohorts, those who had not been prescribed a statin versus those who had been prescribed a statin. Descriptive statistics, including patient demographics and comorbidities were produced. Lifetime major adverse cardiovascular events (MACE), as defined by myocardial infarction, cerebrovascular accident, congestive heart failure, and coronary revascularization, were calculated. Chi-squared and Fisher's exact tests and Wilcoxon Rank Sum tests were used to assess categorical and continuous variables, respectively. Multivariate logistic regression was used to assess the impact of statin use on mortality while controlling for lifetime MACE and known comorbidities of cardiovascular disease.
Results: Included were 776 LTRs ages 18–76 years, of whom 566 (72.9%) were not prescribed a statin and 210 (27.1%) were prescribed a statin (table 1). Demographic data and comorbidities are presented in Table 1. Prevalence of lifetime composite MACE was higher LTRs prescribed a statin (no statin = 26.68% vs statin = 46.19%, $p < 0.001$). However, mortality was lower in those with statin use (no statin = 27.24% vs statin = 13.33, $p < 0.001$]. The adjusted odds of death in LTR taking a statin were significantly less than those not taking a statin (aOR = 0.33, 95% CI [0.18, 0.54], $p < 0.001$).

Table 1: Descriptive Statistics & Severity

		Liver Transplant Recipient without a prescribed statin	Liver Transplant Recipients with a prescribed statin	P- value
Liver Transplant Recipients		566	210	
Patient Characteristics				
Sex, n(%)				p = 0.232
	Female	215 (37.99)	70 (33.33)	
	Male	351 (62.01)	140 (66.67)	
Mean Age, years(standard deviation)		54.44 (10.9)	59.36 (7.51)	p < 0.001
Race, n(%)				p = 0.489
	White	309 (54.59)	118 (56.19)	
	Black	21 (3.71)	5 (2.38)	
	Hispanic	165 (29.15)	68 (32.38)	
	Asian	20 (3.53)	3 (1.43)	
	Native American	41 (7.24)	14 (6.67)	
	Multiracial	10 (1.77)	2 (0.95)	
Comorbidities				
Diabetes Mellitus, n(%)		123 (21.77)	100 (47.62)	p < 0.001
Hypertension, n(%)		457 (80.74)	201 (95.71)	p < 0.001
Hyperlipidemia, n(%)		155 (27.39)	181 (86.19)	p < 0.001
Chronic Kidney Disease, n(%)		356 (62.90)	158 (75.24)	p = 0.001
Severity				
Myocardial Infarction, n(%)		28 (4.95)	24 (11.43)	p = 0.001
Cerebrovascular accident, n(%)		26 (4.59)	18 (8.57)	p = 0.033
Congestive Heart Failure, n(%)		113 (19.96)	68 (32.38)	p < 0.001
Coronary Revascularization, n(%)		13 (2.30)	43 (20.48)	p < 0.001
Composite MACE, n(%)		151 (26.68)	97 (46.19)	p < 0.001
Mortality, n(%)		152 (27.24)	28 (13.33)	p < 0.001

Conclusion: We have demonstrated that mortality is reduced in LTRs taking a statin in comparison those not taking a statin. The prevalence of lifetime composite MACE was higher in LTRs taking statins, suggesting that LTRs who have had a MACE are more likely to be prescribed a statin. These results indicate that statin use is an independent predictor of mortality in LTRs, irrespective of underlying cardiovascular risk. Future studies that stratify patients based on their known cardiovascular risk will allow us to clarify these results further.

THU-483

Quantification of remnant liver ischaemia after hepatectomy for hepatocellular carcinoma (HCC) using advanced 3D software analysis and its impact on disease recurrence

Acidi Belkacem[1], Mohammed Ghallab[1], Omar Ali[2], Nassiba Beghdadi[1], Nicolas Golse[1], Marc Antoine Allard[1], Antonio Sa Cunha[1], Daniel Azoulay[1], René Adam[1], Daniel Cherqui[1], Eric Vibert[1]. [1]*Chb-Centre Hépato-Biliaire, Villejuif, France;* [2]*Inserm 1193, Villejuif, France*
Email: gacem05@hotmail.com

Background and aims: Many patients with HCC are not candidates for resection. Those amenable to curative surgical resection, still have a poor prognosis with recurrence reported up to 70% at 5 years either by dissemination or de novo tumours with 15% of patients presenting with distant recurrence. Risk factors related to disease biology have been well studied. When it comes to surgical technique impacting oncologic outcomes this is still not the case. Some authors have shown superiority of anatomic resection (AR), other data have suggested that nonanatomic resection (NAR) had comparable outcomes. Few recent reports have examined the clinical relevance of remnant liver ischemia (RLI) after partial hepatectomy and its impact on patients' oncologic outcomes. Our aim was to objectively measure RLI volume after resection of HCC by processing medical imaging by advanced 3D software package (Synapse 3D). The primary outcome was the impact of the RLI volume on HCC recurrence (HR. Secondary outcomes were the impact of NAR vs AR on the presence or absence of RLI and oncologic outcomes
Method: We retrospectively analysed 239 medical records of patients who had surgery for HCC at our Hospital between 2012 and 2020. RLI was investigated on early postoperative computed tomographic scans. The detection of RLI was assisted by pre-existing tools within the medical imaging software to automatically detect hypodense

areas within the liver and quantified the total volume of RLI areas in millilitres.
Results: Among 239 patients *(median follow-up 60 months, 30-day mortality 1.3% Laparoscopic surgery in 36%*, AR was performed in 69% of patients. RLI was detected in 71% of patients, median volume of 11.5 ml (6–34.5). Univariate analysis showed that at 6 months, HR was 6% in the RLI group vs 0% in the group without RLI (p = 0.036). At 1 year this was 16% and 5% of HR respectively (p = 0.041). There was significantly less RLI in the AR group 23% compared to the NAR group 77% (p < 0, 01). Multivariate analysis showed the presence of RLI (2.18 (1.56; 3.06); p < 0.001) and the NAR (RR 2.55 (1.84–5.55); p < 0.01) were independent risk factors for HR. To identify the cut-off, point for RLI volume, a ROC curve analysis was done showing it to be 82mls with an AUC of 0.86.
Conclusion: Based on the results of this study, RLI has a significant impact on disease recurrence after surgery for HCC.Surgical technical refinements, surgical planning with 3D software and adjuncts like fluorescence-guided liver surgery to avoid significant RLI.

THU-484

Inequity in access to liver transplantation for critically ill patients with cirrhosis across U.S. transplant centers

Thierry Artzner[1], David Goldberg[2], Constantine Karvellas[3], Sumeet Asrani[4]. [1]*Hôpitaux Universitaires de Strabourg, France;* [2]*University of Miami, United States;* [3]*University of Alberta, Canada;* [4]*Baylor Medical Center Dallas, United States*
Email: thierry.artzner@gmail.com

Background and aims: Liver transplantation (LT) is the most effective treatment for critically ill patients with decompensated cirrhosis. Some European studies have suggested that access to LT for this category of patients varies across transplant centers. We used UNOS data to examine whether this was also the case across U.S. LT centers at the national and regional levels.
Method: We included adult patients who received a primary, single LT between 2011 and 2020 using data from the Scientific Registry of Transplant Recipients (SRTR). We distinguished five (non exclusive) categories of patients who received LT: (i) non-critically ill patients with cirrhosis, (ii) critically ill patients with cirrhosis, (iii) patients with MELD scores >35 at LT who were not critically ill, (iv) patients with hepatocellular carcinoma (HCC), and (v) patients transplanted with Status 1A at listing. Critically ill patients with cirrhosis were defined as being in the ICU at the time of LT with one or more of the following characteristics: (i) grade III/IV hepatic encephalopathy, (ii) mechanical ventilation, (iii) dialysis, (iv) vasopressors. We assessed the correlation between the total number of LTs in each center and the number of LTs for each category of patients.
Results: A total of 56,572 patients received a first, single LT over the study period in 109 LT centers, of which 45,512 (median: 82.7%, IQR: 77.8%-86.2%) had cirrhosis and were not critically ill, 4,459 (median: 5.5%, IQR: 3.1%-7.7%) had cirrhosis and were critically ill, 4,898 had a MELD score at LT >35 without being critically ill (median: 8.5%, IQR: 5.8%-11.4%), 20,461 (median: 36.7%, IQR: 32.1%-42.1%) had HCC, and 1,512 (median: 2.4%, IQR: 1.6%-4%) were transplanted with Status 1A. The total number of patients transplanted in each center correlated most strongly with the number of non-critically ill patients with cirrhosis (correlation coefficient = 0.98, panel A). By contrast, the number of critically ill patients with cirrhosis was most poorly correlated with the total number of patients transplanted in each center (correlation coefficient = 0.45, panel C). The correlation coefficient between the total number of patients transplanted and the number of patients transplanted for others indications was higher: 0.72 for patients transplanted with MELD scores >35 (panel B), 0.55 for patients with Status 1A, and 0.92 for patients transplanted with HCC.
Panel D illustrates the variability in LT activity across centers and among each UNOS region for critically ill patients with cirrhosis.
Conclusion: This study shows that the size of transplant centers correlates poorly with the number of critically ill patients with cirrhosis receiving LT and that there is more variability in LT for this indication than for other indications for which there is greater consensus (patients transplanted with HCC, MELD >35 or Status1A). It shows that there is both national and regional variability in this LT activity.
This study corroborates European observations and illustrates the lack of practical consensus concerning the role of LT in this indication.

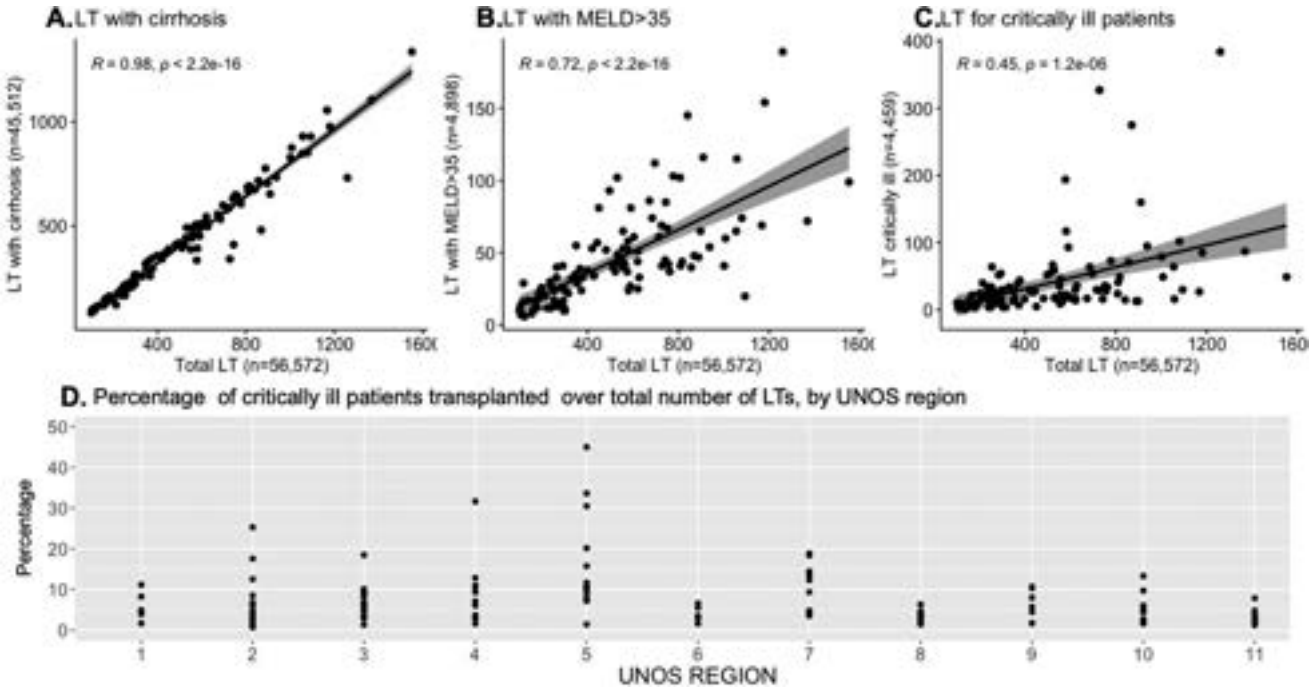

Figure: (abstract: THU-484).

In practice, it highlights inequities in access to this life-saving treatment for this subgroup of patients.

THU-485

Polycystic disease: a cumbersome benign indication for transplantation

Alberto Calleri[1], Bruna Lavezzo[2], Luigi Biancone[3], Renato Romagnoli[4], Silvia Martini[1]. [1]*Gastrohepatology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy, Italy;* [2]*Anesthesia and Intensive Care Unit 2, AOU Città della Salute e della Scienza di Torino, Turin, Italy, Italy;* [3]*Division of Nephrology Dialysis and Transplantation, Department of Medical Sciences, AOU Città della Salute e della Scienza di Torino, Turin, Italy, Italy;* [4]*General Surgery 2U, Liver Transplantation Center, AOU Città della Salute e della Scienza di Torino, Turin, Italy, Italy*
Email: alberto.calleri.md@gmail.com

Background and aims: polycystic liver disease (PCLD), usually associated with polycystic kidney disease (PCLKD), is a benign condition that potentially leads to abdominal fullness and portal hypertension (PH), burdened by increased risk of cyst-related infection and bleeding. Liver transplantation (LT) or simultaneous liver-kidney transplantation (SLKT) remains the only curative treatment for severe polycystic disease. We aimed at describing pre- and post-LT characteristics of patients (pts) who underwent LT/ SLKT for PCLD/PCLKD.

Method: Pts who underwent LT or SLKT for PCLD or PCLKD in our Center from January 1st, 2010 to September 30th, 2022 were enrolled. Follow-up was closed on December 31st, 2022.

Results: In the study period 1754 LTs were performed. Sixty-three LTs for PCLD (3.6%) have been carried out, of which 45 (71%) were SLKT. 48 (76%) pts were female, median age 52 years [IQR 48–56], median BMI 24 kg/m^2 [23–26]. Median serum creatinine (sCr) was 5.7 mg/dL [4.1–7.8] and median estimated-glomerular filtration rate (eGFR) was 11 ml/min [7–17] in pts affected by kidney failure who received SLKT (29/45 on pre-LT dialysis); median eGFR of pts listed for LT alone of 78 ml/min [68–94]. 58/63 (92%) pts underwent LT for abdominal fullness with sarcopenia (median liver weight 3950 g [2450–6750]; median largest cyst size 7 cm [5–9]); while 19/63 (30%) showed refractory ascites. Nine pts (2%) had pre-transplant cyst interventions. Of note, 10/63 (16%) were known to be pre-LT colonized by multidrug-resistant (MDR) bacteria. Median surgery duration was 357 min [307–456] for LT and 405 min [355–462] for SLKT with a median number of 7 [3–16] red blood units needed. The Piggy-back technique was possible in 18/63 (29%) and 9 pts (14%) underwent temporary porto-cava shunt while only 6 pts (10%) received venous-venous bypass. Among 48 pts listed for SLKT, 7 (15%) underwent a delayed kidney transplantation within 24 h and 3 (6%) were then listed for sequential kidney transplant due to the complexity of LT-surgery. Forty-one pts (65%) were extubated within the first 48-hours and the median ICU stay was 5 days [3–9]. Two pts had primary non-function and underwent re-LT after 3 days while only 1 pt had hepatic artery-thrombosis solved surgically. Moreover, 28 pts (44%) underwent early post-transplant surgical revisions. After a median 4.3 years [1.8–7.8] of follow-up: 59/63 (94%) were alive while 3 pts died for sepsis 3 weeks after transplant (l LT and 2 SLKT) and 1 pt died for HHV8-induced hemophagocytic syndrome 3 years after SLKT.

Conclusion: PCLD/PCLKD is an insidious benign disease for which high-complex surgical procedure such as transplantation is the ultimate solution. In our cohort 16% of pts were pre-transplant colonized by MDR bacteria and post-LT early surgical revisions were needed in 44% of cases. Nevertheless, the expertise of a high-volume transplant Centre allowed to achieve a 3-year survival rate of 94%.

THU-486

De novo cancers after liver transplantation: a French nationwide cohort

Ilias Kounis[1], Christophe Desterke[1], Paul Landais[1], Eric Vibert[1], Didier Samuel[1], Cyrille Feray[1]. [1]*INSERM 1193, France*
Email: cyrille.feray@gmail.com

Background and aims: *De novo* cancer (DNC) following liver transplantation (LT) have been reported as one of the major causes of post-transplant mortality. Everolimus is frequently prescribed to patients presenting *de novo* cancer after LT and those who are at risk of cancer recurrence. With this study we aimed to estimate the cancer burden after LT at a nationwide level and to evaluate the potential role of everolimus in *de novo* cancer occurrence.

Method: The French national health data system (SNDS), linked with the national hospital database (PMSI), contains information on at least 99% of the French population, concerning ICD-10 codes, medical procedures (MP), prescribed drugs and vital status. 8658 patients having received LT for hepatocellular carcinoma (n = 3902) or decompensated cirrhosis were identified from 2009 to 2019. Algorithms combining ICD and MP identified post-transplant invasive neoplasia at different sites. Cox models including competitive risk, everolimus as time-dependent exposure (tmerge function) and propensity score (weightit pckg) analysed cancer incidence, mortality.

Results: With a median follow-up of 4.6 [2.2, 6.8] years after LT, 1119 (13%) patients developed DNC, of which 232 (2.7%) dysmyelopoiesis, 216 (2.5%) head and neck, 213 (2.5%) skin cancer, 184 (2.1%) metastatic cancer, 180 (2.1%) lung cancer, 100 (1.2%) lymphoma, 88 (3.3%) colorectal cancer, 87 (1.0%) prostate cancer and 50 (0.6%) bladder cancer. Age, tobacco, alcohol, diabetes and cancer before LT were significantly associated to DNC for most studied sites. 5-year survival after DNC was poor: 40% for dysmyelopoiesis or skin, 30% for colorectal or lymphoma, 25% for prostate, 20% for lung, head and neck and metastasis. During the follow-up, 2588 (30%) patients were exposed to everolimus including 997 before the detection of any cancer. In all cases both using landmark analysis or time-dependent exposure, everolimus was associated neither to a lower incidence nor to a better survival after occurrence (Figure).

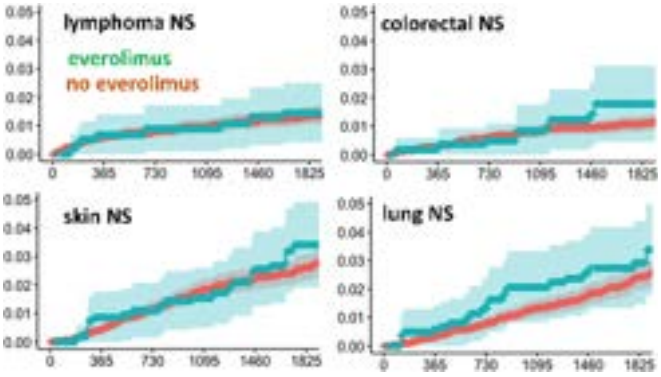

Figure:

Conclusion: DNC occur in at least 13% of adults after LT. Systematic screening is clearly insufficient in view of the poor survival observed after their detection. More surprisingly, the antitumoral action of everolimus recipients to prevent de novo malignancies was not observed for any cancer including skin cancers.

THU-487

Assessment of silent coronary artery disease with functional and anatomic tests in liver transplantation: analysis of the diagnostic and prognostic capacity of a risk-adapted protocol

Giulia Pagano[1], Pablo Ruiz[2], Jordi Colmenero[2], Sergio Rodriguez-Tajes[2], Judit Mestres[2], Julia Martinez-Ocon[2], Salvatore Brugaletta[2], Gonzalo Crespo[2]. [1]*Hospital Clinic, Liver Transplant, Spain;* [2]*Hospital Clinic, Spain*
Email: gpagano@clinic.cat

Background and aims: Cardiovascular (CV) risk burden of liver transplant (LT) candidates is increasing, and CV events (CVE) are a main cause of post-LT death, thus identifying LT candidates at high CV risk is key to improve outcomes. The best strategy to assess silent coronary artery disease (CAD) before LT is controversial. We aimed to evaluate the performance of a risk-adapted protocol that uses functional (stress tests) and anatomical (coronary artery calcification score [CACS] by CT, and CT angiography [CTCA]) explorations, to diagnose pre-LT CAD and predict post-LT CVE.
Method: Single-center, retrospective analysis with patients considered for LT between July 2015 and September 2020. In a pre-specified clinical protocol depending on the accumulation of risk factors, primary CAD assessment included a) no specific test; b) CACS followed by CTCA; or c) stress test. Invasive coronary angiography (ICA) was performed according to the results of non-invasive tests. We investigated the variables, including the diagnostic tests and the clinical risk factors comprised in the CAD-LT score, associated with the presence of significant lesions in ICA; as well as the association between diagnostic tests and the incidence of CVE 2 years after LT.
Results: 634 candidates were evaluated and 351 underwent LT. CACS was performed as primary test in 244 (39%), stress tests in 81 (13%, most dobutamine stress echocardiography [DSE]), and in 309 cases (49%) no specific explorations were indicated. 122 patients eventually underwent ICA. In patients undergoing CACS, the prevalence of CACS = 0 (absence of calcifications) was 22%, while severe coronary calcifications (CACS ≥400) were found in 26%. Most DSE (61%) were non-diagnostic, and very few stress tests resulted positive. The prevalence of significant lesions in ICA was 23%, and it was not associated with either CACS, CTCA findings or stress tests results. In contrast, the incremental presence of CV risk factors in a modified CAD-LT score predicted the presence of significant lesions in ICA ($p < 0.001$). Among LT recipients, the 2-year cumulative incidence of CVE was 12%. Patients without specific exploration indications for silent CAD presented the lowest incidence (7%) of CVE, while those with pre-LT CACS ≥400 ($p < 0.001$) had the highest incidence (37%). In the adjusted multivariate analysis, pre-transplant CACS ≥400 and the indication of stress test were independent predictors of post-LT CVE (Figure).

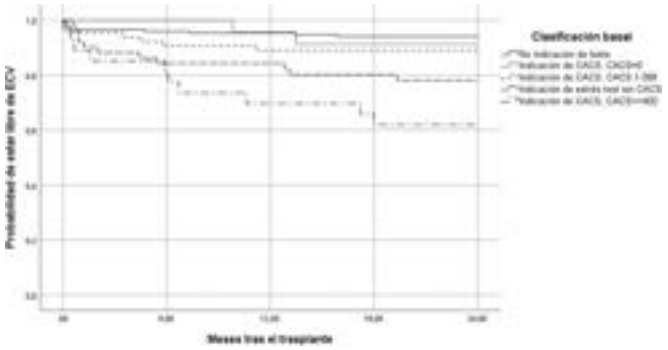

Figure:

Conclusion: A high (≥400) CACS identifies LT candidates at the highest risk of post-LT CVE, despite being poorly associated with the presence of CAD before LT, probably highlighting its value as a biomarker of systemic atherosclerosis. Stress tests are of limited value due to a high rate of unreliable results. The accumulation of clinical risk factors using calculators like the CAD-LT score can be useful to identify LT candidates with more risk of significant lesions in ICA.

THU-488

Sex-based differences and comparative predictive value of MELD 3.0 in simultaneous liver-kidney transplantation waitlist outcomes after standardization of listing criteria in the United States

Emily Leven[1], Ditian Li[2], Emilia Bagiella[2], Lauren Grinspan[3]. [1]*Icahn School of Medicine at Mount Sinai, Gastroenterology, New York, United States;* [2]*Icahn School of Medicine at Mount Sinai, Department of Population Health Science and Policy, New York, United States;* [3]*Recanati/Miller Transplantation Institute, New York, United States*
Email: emily.leven@mountsinai.org

Background and aims: In liver transplantation (LT) in the United States (U.S.), women experience longer waitlist times and higher mortality than men, in part because of the use of a creatinine-based organ allocation score (Model of End-stage Liver Disease-Sodium, or MELD), which underestimates renal dysfunction in women. The newly proposed MELD 3.0 incorporates sex and mitigates LT waitlist disparities in models. In 2017, the United Network for Organ Sharing (UNOS) implemented a new policy requiring either a need for renal replacement therapy or reduced glomerular filtration rate (GFR) for simultaneous liver-kidney (SLK) listing; prior to this, no standardized criteria existed. The impact of this policy on sex-based waitlist disparities has not been reported. We aimed to 1) compare waitlist outcomes by sex before and after SLK listing criteria standardization; and 2) examine the predictive value of the difference in MELD vs. calculated MELD 3.0 at SLK listing on waitlist outcomes.
Method: Publicly available UNOS data were used. Pre- and post-groups included adult SLK listings from 2013 to 2016 and 2018–2021, respectively. 2017 listings (SLK policy change year) were excluded. Data were censored at 3 years. Cox proportional hazards and competing risk analyses were used to compare pre- and post- waitlist outcomes (death, transplantation, delisting due to improvement, delisting due to illness) between sexes and time groups and to estimate the predictive value of MELD vs. MELD 3.0 on waitlist outcomes.
Results: 2633 men (61.1%) and 1676 women (38.9%) were listed pre-policy change; 2610 men (57.6%) and 1921 women (42.4%) were listed post-policy change. Controlling for age, ethnicity, transplant indication, height, and listing MELD, women were less likely than men to undergo transplantation pre-policy change (hazard ratio [HR] = 0.87, 95% confidence interval [CI] = 0.77–0.99, $p = 0.03$). Women post-policy change were significantly more likely to undergo transplantation compared to women in the pre- group ($p = 0.02$);sex-based differences in likelihood of transplantation were no longer significant post-intervention, though there was an increased chance of transplantation for women vs. men in the post- group (HR = 1.11, 95% CI = 0.98–1.23, $p = 0.10$) (Figure). A one-point deficit in MELD vs. MELD 3.0 at SLK listing was associated with a 2% lower chance of transplantation (HR = 0.98, 95% CI = 0.97–0.99, $p = 0.002$).

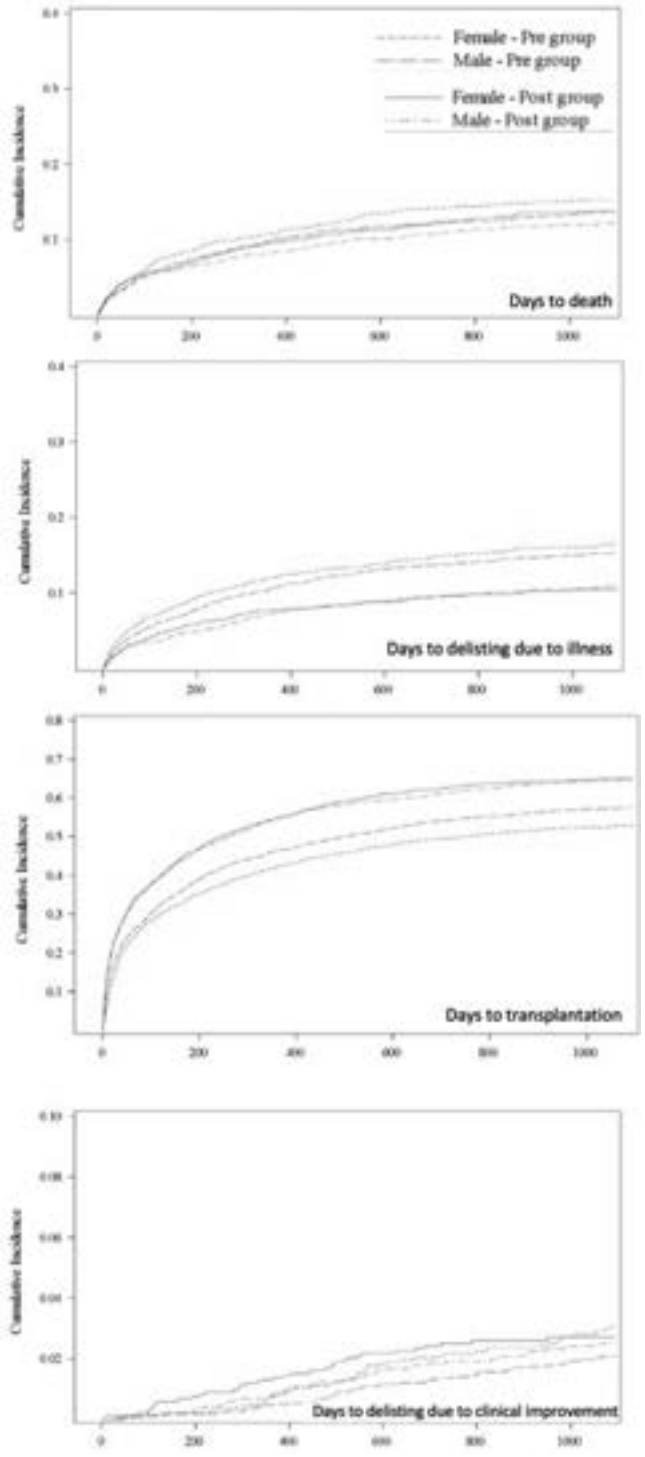

Figure: Competing risk analyses for waitlist outcomes by sex and time group.

Conclusion: Accounting for sex in SLK listing and allocation may reduce health disparities. GFR-based standardization of SLK listing in the U.S. was associated with better chances of transplantation for women and with the mitigation of decreased female vs. male transplantation patterns in this population. The use of MELD 3.0 may also contribute to equity in SLK waitlist outcomes.

THU-489

Increased left ventricular dimensions are the new risk factor for acute kidney injury after living donor liver transplantation (cardio-renal interaction)

Dheapak V[1], Lalita Mitra[2,3]. [1]*Institute of Liver and Biliary Sciences, Organ Transplant Anaesthesia and Critical Care, India;* [2]*homi Bhabha Cancer Hospital and Research Centre, India;* [3]*Institute of Liver and Biliary Sciences, Organ Transplant Anaesthesia and Critical Care, New Delhi, India*
Email: dheapak22@gmail.com

Background and aims: Acute kidney injury (AKI) is a common complication of liver transplant surgery, resulting in lengthy intensive care unit/hospital stays and considerable morbidity with the development of chronic renal failure in liver transplant recipients. AKI after liver transplantation is caused by a variety of factors, including recipient's hepatic decompensation, poor donor graft quality, intraoperative hemodynamic instability, blood loss and blood product transfusions, The cardiac dysfunction could also mediate impairment in renal function (Cardio-renal syndrome). We prospectively evaluated the possible associations between perioperative N-terminal pro B-type natriuretic peptide (NT-proBNP) levels, transthoracic echocardiograph findings and post-transplant AKI in patient undergoing living donor liver transplantation.
Method: Seventy adult cirrhotic patients without endogenous heart or renal disease were included. AKI was defined as increase in serum creatinine by 0.3 mg/dL or more within 48 hours (or) increase in serum creatinine to 1.5 times baseline or more within the last 7 days. Serum NT-proBNP levels were measured immediately after induction of anaesthesia and also at the end of the surgery. We analysed the relationship between NT-proBNP levels, preoperative echocardiographic findings and post-transplant AKI.
Results: The overall incidence of AKI was 38.57%. However, the majority (77.78%) of patients had stage 1 AKI, and none of our patients had stage 3 AKI or required renal replacement therapy during the first week following LT. The patients who developed AKI had significantly higher left ventricular end-diastolic dimension (LVEDD = 49.37 ± 4.48 mm vs 45.6 ± 4.01 mm, p = 0.0005) and left ventricular end-systolic dimension (LVESD = 28.7 ± 3.46 mm vs 26.3 ± 3.44 mm, p = 0.006) in the 2d echocardiography and also had a higher intraprocedural transfusion of platelets. Other echocardiographic parameters were comparable between both groups. In multivariate logistic regression analysis, left ventricular end diastolic dimension [odds ratio (OR): 1.168, 95% confidence interval (CI): 1.011–1.349; p = 0.035] and left ventricular end systolic dimension (OR: 1.196, 95% CI: 1.002–1.428; p = 0.048) were found to be independently associated with the development of AKI. There was a moderately significant correlation between baseline NT-proBNP level and MELD score and amount of ascites drained intraoperatively. There was no significant association between perioperative NT-proBNP levels and post-transplant AKI.

Parameters	Beta coefficient	Standard error	P value	Odds ratio	Odds ratio Lower bound (95%)	Odds ratio Upper bound (95%)
LV ED D (mm)	0.155	0.074	0.035	1.168	1.011	1.349
LV ES D (mm)	0.179	0.090	0.048	1.196	1.002	1.428
SDPC (unit)	0.978	0.555	0.078	2.659	0.895	7.897

Figure: Multivariate logistic regression to identify independent factors associated with the development of AKI.

Conclusion: We confirmed that post-transplant AKI in patients with cirrhosis is related to cardio-renal interactions. The enlarged left ventricle during systole and diastole indicates the state of hyperdynamic circulation with increased cardiac output and blood volume along with decreased systemic vascular resistance. This results in the state of effective hypovolemia and along with latent cardiac dysfunction in cirrhosis causes renal hypoperfusion and abnormal

neurohumoral regulation resulting in renal vasoconstriction and acute kidney injury.

THU-490

Effect of glucagon-like peptide-1 receptor agonists and sodium-glucose cotransporter-2 inhibitors on post-liver transplant mortality and major adverse cardiovascular events

Kelli Kosako Yost[1], Paul Gomez[1], Pooja Rangan[1], Michael Fallon[1], Rohit Nathan[1], Moises Nevah Rubin[1], Mark Wong[1], Karn Wijarnpreecha[1], Ma Ai[1], Thanda Han[1]. [1]*University of Arizona College of Medicine-Phoenix, United States*
Email: kellikosakoyost@gmail.com

Background and aims: Glucagon-like peptide-1 receptor agonists (GLP-1 RA) and Sodium-glucose cotransporter-2 inhibitors (SGLT2i) have shown to have cardiovascular benefit, promote weight loss, and improve glycemic control in patients with type 2 diabetes mellitus (T2DM). Although there is some data of these medications on post-heart and kidney transplant populations, there is no data on their effect on cardiovascular events and mortality in post-transplant population, especially the post-liver and post-simultaneous liver/kidney transplant populations. The aim of our study was to determine the effect of GLP1 RA and SGLT2i on post-liver and post-simultaneous liver/kidney transplant recipients on major adverse cardiovascular events (MACEs) and overall mortality.

Method: A retrospective chart review in a single hospital system reviewing any adult age ≥18-year-old with either solidary liver or simultaneous liver and kidney transplant from January 2012 to March 2022 was completed. GLP1RA or SGLT2i usage was determined. Demographic, clinical characteristics, and outcomes were compared between the two groups. MACE events included myocardial infarction, coronary revascularization (percutaneous intervention, stent placement, coronary artery bypass graphing), cerebrovascular event, or congestive heart failure. The Mann-Whitney test and Fisher's exact or Chi-square test was used for continuous and categorical variables respectively and multivariate logistic regression was used to evaluate for significant differences in outcomes between the two groups.

Results: Of the 776 patients included, 33 (4.25%) were on a SGLT2i or a GLP1 RA. Patients' demographics and comorbidities are shown in the table. Hypertension ($p < 0.001$), hyperlipidemia ($p < 0.001$), and BMI at transplant ($p = 0.021$) were all statistically significant comorbidities between the two groups on univariate analysis. On multivariate analysis, the use of an SGLT2i or a GLP1 RA was associated with significantly lower mortality rate (OR 0.28, CI 95% 0.08–0.97, P = 0.045) and number of MACEs (OR 0.32, CI 95% 0.13–0.79, P = 0.014) after controlling for age at transplant, BMI at transplant, sex, hypertension, T2DM at listing, hyperlipidemia, chronic kidney disease, and tobacco use.

Demographics	Total patients	Patients on SGLT2i or GLP1 RA	Patients not on SGLT2i or GLP1 RA	P-value
Total patients, n (%)	776	33 (4.25%)	743 (95.75%)	
Age at Transplant, Mean ± SD		58.43 ± 7.64	55.63 ± 10.42	0.2132

Mortality	180 (23.44%)	3 (9.09%)	177 (24.08%)	0.027

*Statistically significant

Figure:

Conclusion: This study shows that, after controlling for comorbidities, the use of an SGLT2 inhibitor or a GLP1 agonist post-liver or post-liver/kidney transplant was associated with decreased mortality and decreased number of MACEs. Although this was a small cohort of patients on these medications, this proves promising to this patient population and warrants further studies.

THU-491

Deep learning prediction modeling of major adverse cardiovascular events following liver transplantation

Ahmed Abdelhameed[1], Cui Tao[1,2], Liu Yang[3]. [1]*The University of Texas Health Science Center at Houston, School of Biomedical Informatics, United States;* [2]*University of Texas Health Science Center at Houston, United States;* [3]*Mayo Clinic, United States*
Email: ahmed.m.abdelhameed@uth.tmc.edu

Background and aims: Major adverse cardiovascular events (MACE) are among the leading causes of morbidity and mortality following liver transplantation (LT). The aim was to develop and validate deep learning models' ability to predict post-transplantation MACE among patients undergoing LT

Method: Using data from Optum's de-identified Clinformatics® Data Mart Claims Database, we identified patients who received LT between January 2007 and March 2020 and built multiple predictive models for the risk of developing any of the post-transplantation MACE, including myocardial infarction, atrial fibrillation, pulmonary embolism, heart failure, cardiac arrest, and stroke, as an outcome. A MACE is primarily predicted using the Bidirectional Gated Recurrent Units (BiGRU) deep learning sequence processing model in different prediction interval lengths up to 5 years after the LT index date, using patients' demographics and retrospective diagnosis, medications, and procedures claim data recorded back to 3 years before the LT index date. The performance of the deep learning model against other machine learning models such as Logistic Regression (LR), Random Forest (RF), and Light Gradient-boosting Machine (LGBM) was assessed using a cohort of 18304 liver transplant recipients (mean age 57.4 years [SD 12.76]; 11146 [60.9%] men and 7158 [39.1%] women). Models' optimization was done using five-fold cross-validation on 80% of the cohort (training set) and the performance of the models is assessed using the remaining %20 (testing set) based on the area under the receiver operating characteristic curve (AUC-ROC) and the area under the precision-recall curve (AUC-PR).

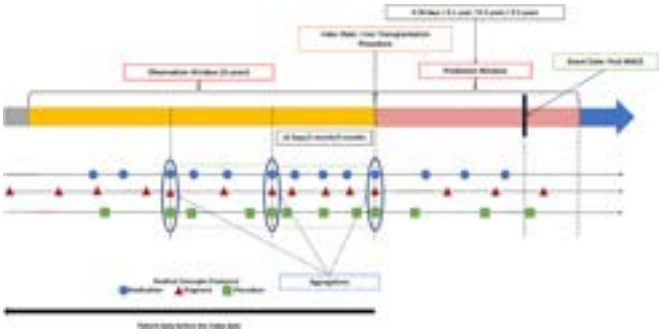

Figure:

Results: Using different prediction intervals (0–30 days, 0–1 year, 0–3 years, and 0–5 years) after the LT index date and compared to the three machine learning models, the top-performing model was the deep learning model, BiGRU, achieved an AUC-ROC of 0.833 (95% confidence interval [CI], 0.8127–0.8522) and AUC-PR of 0.560 (95% CI 0.5205–0.6058) for a 30-day prediction interval after LT.

Conclusion: Using patient longitudinal claims data, deep learning systems can efficiently model and predict outcomes following liver transplantation. This model will help clinicians to identify high-risk candidates for further risk stratification or other management strategies to improve liver transplant outcomes.

THU-492

The growing prevalence and impact of type 2 diabetes among liver transplant candidates in the United States

Zobair Younossi[1,2,3], Katherine Eberly[1,3], Reem Al Shabeeb[1,3], Ameeta Kumar[1,3], Pamela Brandt[1,2], Nagashree Gundu Rao[1,4], Janus Ong[5], Kenneth Cusi[6], Saleh Alqahtani[7,8], Maria Stepanova[1,2,9]. *[1]Inova Health System, Department of Medicine, United States; [2]Beatty Liver and Obesity Research Program, Inova Health System, United States; [3]Inova Health System, Medicine Service Line, United States; [4]Inova Health System, Division of Endocrinology, United States; [5]University of the Philippines, College of Medicine, Philippines; [6]University of Florida, Division of Endocrinology, Diabetes and Metabolism, United States; [7]Johns Hopkins University, Division of Gastroenterology and Hepatology, United States; [8]King Faisal Specialist Hospital and Research Center, Liver Transplant Center and Biostatistics, Epidemiology and Scientific Computing Department, Saudi Arabia; [9]Center for Outcomes Research in Liver Disease, United States*
Email: zobair.younossi@inova.org

Background and aims: Type 2 diabetes (T2D) and superimposed NAFLD can negatively impact outcomes of patients with chronic liver disease (CLD). The aim of this study was to assess the impact of pre-transplant T2D on the outcomes of liver transplantations (LT).
Method: We used Scientific Registry of Transplant Recipients (SRTR) 2008–2020 to collect data for all adult patients ≥18 years of age who received a liver transplant in the U.S. The study outcome was time to post-transplant mortality (cut-off date March 2, 2022).
Results: A total of 86,153 LTs were included: mean age 56 ± 11 years, 71% Caucasian, 66% male, 5.0% re-transplants. Acute liver failure accounted for 4.2% of LTs. Of those transplanted with a CLD, 2% had chronic hepatitis B, 20% chronic hepatitis C, 17% NASH, 24% alcoholic liver disease; 25% also had hepatocellular carcinoma (HCC). Of all LT recipients, 26% had history of pre-transplant T2D; this rate increased from 22% (2008) to 28% (2019). Similar trends were observed in subgroups with acute liver disease (from 10% to 15%), those with HCC (from 26% to 38%), and CLD patients without HCC (from 22% to 27%). During follow-up (median = 61 months, IQR = 30–103 months), 26% of LT recipients died and 5.4% had a graft failure; the cumulative mortality rates were 23% in acute liver disease, 30% in HCC, and 25% in non-HCC subgroups. The 5-year mortality rates were higher in LT recipients with vs. without pre-transplant T2D: 28% vs. 21% in acute liver disease, 27% vs. 24% in HCC, and 24% vs. 20% in non-HCC (all $p < 0.01$). In multivariate survival analysis, pre-transplant T2D was independently associated with a higher risk of post-LT mortality in all subgroups: adjusted hazard ratio (aHR) = 1.26 (1.22–1.30) in all LT patients, aHR = 1.30 (1.05–1.62) in acute liver disease, aHR = 1.20 (1.13–1.28) in HCC, and aHR = 1.28 (1.23–1.34) in non-HCC (all $p < 0.02$). Other risk factors included an earlier calendar year for LT, older age, higher MELD score, lack of college education, coverage by Medicare or Medicaid, and being on life support before LT ($p < 0.01$). However, there was no association between pre-LT T2D and greater the risk of graft failure (one-sided $p > 0.05$).
Conclusion: There is a growing burden of T2D among liver transplant candidates in the United States. The presence of pre-transplant T2D is independently associated with an increased risk of post-transplant mortality in all LT subgroups.

THU-493

The evolution of the muscle compartment from the listing to six-month post-transplantation: a longitudinal monocentric study

Delorme Alicia[1,2], Alexis Goffaux[3], David De Azevedo[4], Colin Dumont[1], Guillaume Henin[3], Marie Philippart[1], Frédéric Braem[1], Olga Ciccarelli[5], Pierre Trefois[6], Nicolas Lanthier[7,8], Géraldine Dahlqvist[1]. *[1]Clinique Universitaire Saint-Luc, Hepatology and Gastroenterology, Bruxelles, Belgium; [2]Clinique Universitaire Saint-Luc, Hepatology, Bruxelles, Belgium; [3]Clinique Universitaire Saint-Luc, Laboratory of Hepatology and Gastroenterology, Bruxelles, Belgium; [4]Clinique Universitaire Saint-Luc IREC/CARD, Cardiovascular Disease, Bruxelles, Belgium; [5]Clinique Universitaire Saint-Luc, Abdominal Surgery and Liver Transplant Department, Bruxelles, Belgium; [6]Clinique Universitaire Saint-Luc, Radiology, Belgium; [7]Cliniques universitaires Saint-Luc (UCLouvain), Service d'Hépato-Gastroentérologie, Bruxelles, Belgium; [8]Université Catholique de Louvain, Laboratory of Hepato-Gastroenterology, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium*
Email: alidelorme0206@gmail.com

Background and aims: Body composition of the cirrhotic patient plays an important role in his prognosis. Skeletal muscle mass (sarcopenia), malnutrition, frailty (liver frailty index LFI) and

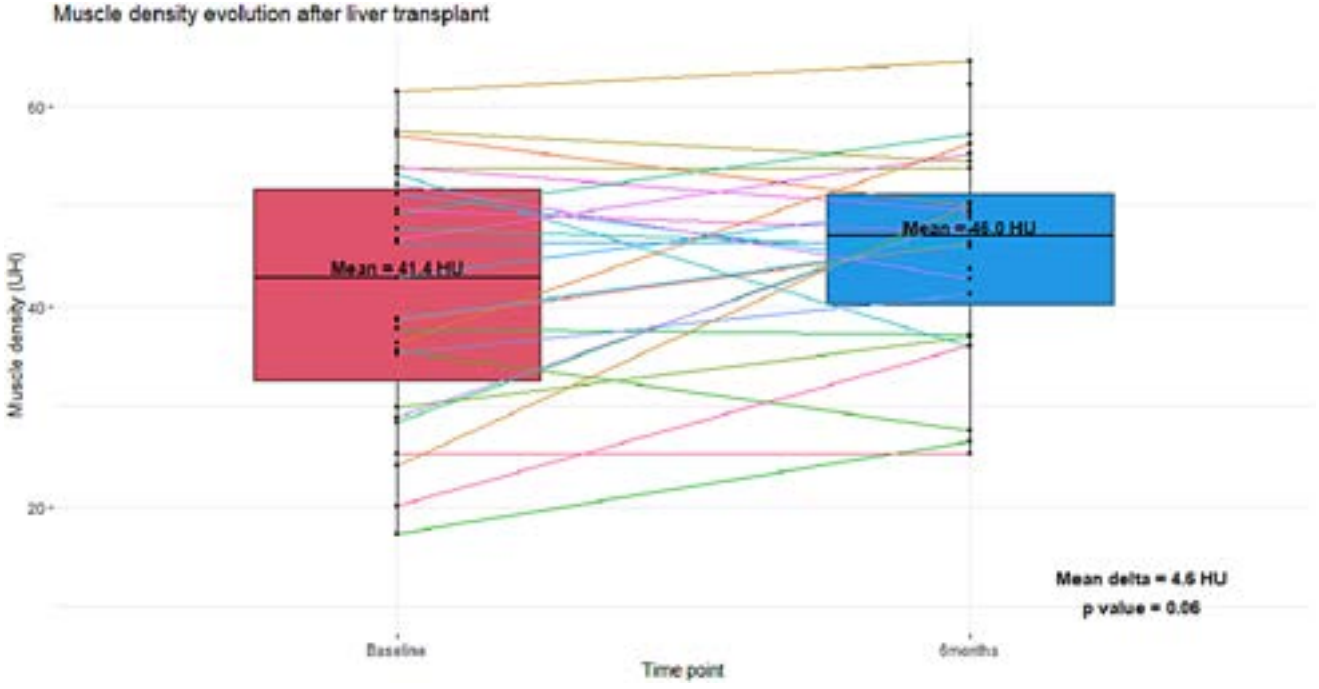

Figure: (abstract: THU-493).

myosteatosis are associated with worse outcome in cirrhotic patients. The aim of this study was to determine the best muscle-related predictor of morbidity and mortality on the waiting list and after LT and to evaluate the evolution of all muscle-related parameters up to six months post-transplant.
Method: This single-center prospective observational study screened adult patients who were candidates for liver transplantation from June 2021 to September 2022. Each candidate received a functional and nutritional assessment during its pre-transplant evaluation. Muscle quantity and quality were assessed using an abdominal CT scan at the third lumbar level (L3). Sarcopenia was defined as skeletal muscle mass index (SMI) <39 cm^2/m^2 in females and <50 cm^2/m^2 in males. Myosteatosis was assessed by skeletal muscle radiodensity attenuation (SM-RA), with cut-offs of SM-RA <41 HU for patients with a BMI <24.9 kg/m^2 and <33 HU for patients with a BMI ≥25 kg/m^2. Frailty was defined using the Liver Frailty Index (LFI). Time-to-event analysis was performed using Kaplan-Meier method to investigate the impact of functional variables on outcome. One-year survival was determined for patients who underwent liver transplant during this period. Univariate and multivariate Cox proportional hazard regressions were computed to identify predictors of morbidity and mortality on the waiting list for LT.
Results: 103 patients were screened, 84 were placed on the Eurotransplant LT waiting list and 49 were transplanted during the study period. The mean age was 54 years and 67.7% were males. The primary etiology of liver disease was alcohol and 38% had a hepatocellular carcinoma. The one-year patient survival probability on the waiting list was 76.9 ± 7.2%. This probability was significantly reduced in patients with myosteatosis compared with patients with higher SM-RA values (43 ± 17% vs 95 ± 4%, $p < 0.001$). Compared with other muscle characteristics, myosteatosis was the strongest predictive factor of mortality. 28 patients had a full 6-months post-LT assessment. Of those liver transplanted patients, 57.7% were frail and 40.7% had myosteatosis before LT. At 6 months post-LT, 53.8% were frail and only 25% had myosteatosis. SMI was not different before and after LT. Compared with pre-LT data, muscle density increased with a mean delta of 4.6 HU ($p = 0.06$) (Figure). The 5 chairs stand test significantly improved after LT (11.6 sec vs 9.0 sec ($p = 0.013$). The other parameters (handgrip, LFI, …) remained stable.
Conclusion: Myosteatosis is significantly associated with negative pre-transplant outcomes. After LT, patients improve in muscle strength but not in muscle quantity or quality evaluated by CT-scan.

THU-494

Endothelial glycocalyx damage marker Syndecan-1 measured during hypothermic oxygenated machine perfusion can predict early allograft dysfunction after liver transplantation

Laurin Rauter[1], Judith Schiefer[2], Pierre Raeven[2], Thomas Öhlinger[2], Marija Spasic[1], Effimia Poumpouridou[1], Jule Dingfelder[1], Andreas Salat[1], Zoltan Mathe[1], Georg Gyoeri[1], Thomas Soliman[1], Dagmar Kollmann[1], Gabriela Berlakovich[1]. *[1]Medical University of Vienna, Department of General Surgery, Division of Transplantation, Austria; [2]Medical University of Vienna, Department of Anesthesia, Intensive Care Medicine and Pain Medicine, Austria*
Email: laurin.rauter@meduniwien.ac.at

Background and aims: During liver transplantation, the graft has to endure an ischemic phase and additional injury after reperfusion (IRI), especially mediated by reactive oxygen species (ROS). The endothelial glycocalyx covers the luminal side of the vascular endothelium and regulates vascular permeability, modulates adhesion of leucocytes onto the vascular wall and transduces mechanical shear stress. It is very sensitive to ROS and therefore degraded during graft preservation and reperfusion. Hypothermic oxygenated machine perfusion (HOPE) is a preservation strategy that can reduce IRI-inflicted graft injury compared to static cold storage (SCS). We aimed to measure glycocalyx degradation after HOPE or SCS alone, to evaluate its viability-assessment potential for liver transplantation.
Method: We measured glycocalyx degradation via ELISA for its main component Syndecan-1, in samples from 77 liver transplant patients. 37 grafts were directly transplanted after SCS, 40 grafts additionally underwent HOPE with the Organ Assist® perfusion system, prior to liver transplantation.
Results: Sdc-1 concentrations in the graft effluent are significantly lower after HOPE [466 (350–1073)] compared to SCS alone [4011 (3382–4683] ($p < 0.001$). Further, Sdc-1 concentrations regenerate faster towards baseline levels on postoperative day 1 [HOPE: 362 (232–880) vs. SCS: 1017 (637–1900) $p < 0.001$], indicating a shorter glycocalyx shedding period. Regarding viability assessment, Sd1-concentrations in the perfusate were elevated in EAD patients after 60 minutes of HOPE compared to non-EAD patients [429 (260–556) vs. 896 (419–1681) $p = 0.018$]. Additionally ROC-analysis indicated a significant discriminatory value of Sdc-1 concentration after 60 minutes of HOPE regarding the occurrence of EAD with an AUC of 74% ($p = 0.018$, sensitivity 66.7% and specificity 84.6%)
Conclusion: HOPE reduces the duration of glycocalyx shedding, evident by Sdc-1 release in recipient serum after liver transplantation. Sdc-1 concentration during HOPE can predict early allograft dysfunction. Therefore, Sdcc-1 could be a potential viability assessment marker in liver transplantation.

THU-495

Use of von Willebrand factor antigen for surgical decision making in patients with hepatocellular carcinoma

David Pereyra[1,2], Lindsey Gregory[3], Aidan Mullan[3], Anna Kern[1], Jule Dingfelder[2], Hubert Hackl[4], Thomas Grünberger[4], Rory L. Smoot[3], Sean Cleary[3], David M. Nagorney[3], Mark Truty[3], Susanne Warner[3], Cornelius Thiels[3], Michael Kendrick[3], Georg Gyoeri[2], Patrick S. Kamath[5], Gabriela Berlakovich[2], Julie Heimbach[6], Patrick Starlinger[1,3]. *[1]Medical University of Vienna, Department of General Surgery, Division of Visceral Surgery, Austria; [2]Medical University of Vienna, Department of General Surgery, Division of Transplantation Surgery, Austria; [3]Mayo Clinic Rochester, Department of Surgery, Division of Hepatobiliary and Pancreatic Surgery, United States; [4]HPB Center, Viennese Health Network, Clinic Favoriten and Sigmund Freud Private University, Department of Surgery, Austria; [5]Mayo Clinic Rochester, Division of Gastroenterology and Hepatology, United States; [6]Mayo Clinic Rochester, Department of Surgery, Division of Transplantation Surgery, United States*
Email: david.pereyra@meduniwien.ac.at

Background and aims: Potential treatment modalities for hepatocellular carcinoma (HCC) are widely varied. Many affected patients undergo transplant or resection with curative intent. While current guidelines aim to clarify appropriate patient selection for liver resection (LR) or transplantation (LTx), both modalities carry significant risk of adverse perioperative outcomes that warrant improvement. We previously reported on von Willebrand factor antigen (vWF-Ag) as a predictor of both post-hepatectomy liver failure (PHLF) and early mortality on the waiting list for LTx. Herein, we explore the use of vWF-Ag as a tool for perioperative decision-making in patients with HCC.
Method: Included patients were diagnosed with HCC within Milan criteria and underwent either LR or listing for LTx at Medical University of Vienna (MUV) and Mayo Clinic Rochester (MCR) between 2004 and 2022. VWF-Ag was evaluated prior to LR or at time of listing for LTx, respectively. The previously evaluated cut-offs at 182% and 291% vWF-Ag were used to divide the cohort into low- (≤182%), intermediate- (183%–291%) and high-risk (>291%) groups. Clinical course and overall survival (OS) were prospectively documented and retrospectively analyzed (chi-squared, Kaplan-Meier).
Results: In total, 443 patients were included: 106 patients underwent LR (MUV: 72, MCR: 34); 337 patients were listed for LTx (MUV: 214, MCR: 123), of those 199 underwent LTx (MUV: 124, MCR: 75).

Patients in intermediate- and high-risk groups undergoing LR displayed significantly higher incidences of PHLF (low = 4.0%, intermediate = 27.5%, high = 53.3%, p < 0.001). Furthermore, post-operative OS was significantly reduced in both these cohorts (median in months: low = 95.5, intermediate = 46.7, high = 13.7, p = 0.006). As previously reported for a cohort of all-comers listed for LTx, HCC patients with increased vWF-Ag had reduced survival on the waiting list (p = 0.01). Yet, no difference in post-LTx OS was observed when comparing risk groups according to vWF-Ag (median in months: low = not reached, intermediate = 130.4, high = 116.6, p = 0.343). Similarly, OS from listing was comparable between vWF-Ag risk groups (median in months: low = 108.7, intermediate = 131.8, high = 90.0, p = 0.390).

Conclusion: Herein, we present an international bicentric evaluation of vWF-Ag as a perioperative decision-making tool for patients with HCC. Patients with high vWF-Ag prior to LR show an increased risk for PHLF and reduced OS and therefore seem to derive limited benefit from surgery. Furthermore, increased vWF-Ag is associated with poor outcome while on the LTx waiting list. Because no difference in post-LTx OS was observed between risk groups according to vWF-Ag, patients presenting with HCC and high vWF-Ag values may benefit from a vWF-Ag risk adjusted LTx listing process. We conclude that vWF-Ag can optimize LR and LTx decision-making for patients with HCC.

THU-496

Incidence and risk factors for de-novo NAFLD after liver transplantation: real-world data

Lea Guetzlaff[1], Alejandro Campos-Murguia[1], Emily Bosselmann[1], Anna Katharina Baumann[1], Björn Hartleben[2], Elmar Jaeckel[3], Richard Taubert[1], Katharina Luise Hupa-Breier[1]. *[1]Hannover Medical School, Gastroenterology Hepatology, and Endocrinology, Germany; [2]Hannover Medical School, Pathology, Hannover, Germany; [3]University of Toronto, Ajmera Transplant Center, Canada*
Email: hupa.katharina@mh-hannover.de

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is not only a leading indication for liver transplantation (LT), but also a frequent complication after LT in patients, who developed graft dysfunction. However, the overall incidence of de-novo NAFLD after LT and its risk factors even in patients without graft dysfunction are unknown. This is the first study to describe the incidence and risk factors of de-novo steatosis and steatohepatitis in a unique cohort of surveillance and indication biopsies from patient after LT.

Method: This was a retrospective single-center study in a post-LT cohort with surveillance (svLbx) and indication biopsies (indLbx). Patients with NAFLD as primary indication for LT were excluded. Risk factors were analyzed with univariant and multivariant analyzes. P values <0, 05 were considered as statistical significant.

Results: After applying the in- and exclusion criteria, we analyzed 255 representative biopsies from patient after LT, where 21% (n = 54) of patient had NAFLD, in which already 43% (n = 23) had non-alcoholic steatohepatitis (NASH) (Figure 1). Interestingly, the incidence of de-novo NAFLD in svLbx was with 18% nearly similar compared to the overall cohort. PSC as primary disease is associated with significant decreased risk of de-novo steatosis after LT

On the multivariant analyses, BMI after LT and Diabetes mellitus are independent risk factors for development of NAFLD and NASH (OR: 1, 09, p = 0, 006 for BMI, OR: 1, 68, p = 0, 033 for diabetes). Furthermore, transaminases were significantly higher in NAFLD and NASH patient compared to control group, although transaminases were still in the normal range. Therefore, even borderline elevations of transaminases should raise suspicion of graft injury including NAFLD, especially in patients with other risk factors.

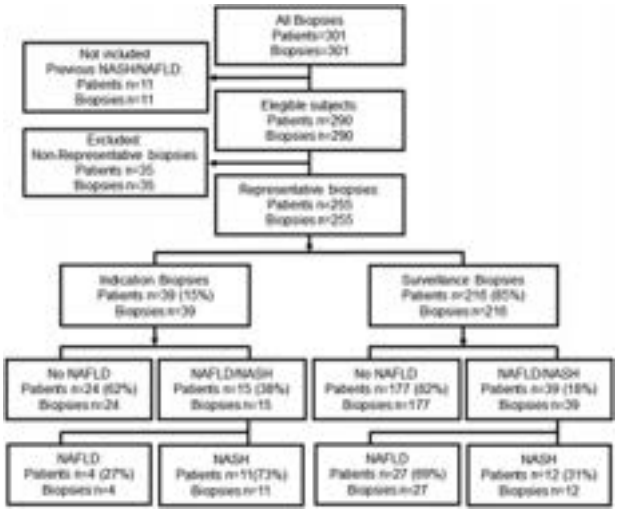

Figure:

Conclusion: To date, this is the first study representing the actual incidence of de-novo NAFLD in the overall post-LT cohort. It demonstrates that de-novo steatosis and steatohepatitis are common findings after LT even in patients without clinical signs of graft dysfunction and therefore supports the indication for post-LT biopsies on a regular basis even without sings of graft dysfunction.

THU-497

Long-term outcomes following donation after cardiac death (DCD) liver transplantation in primary sclerosing cholangitis (PSC)

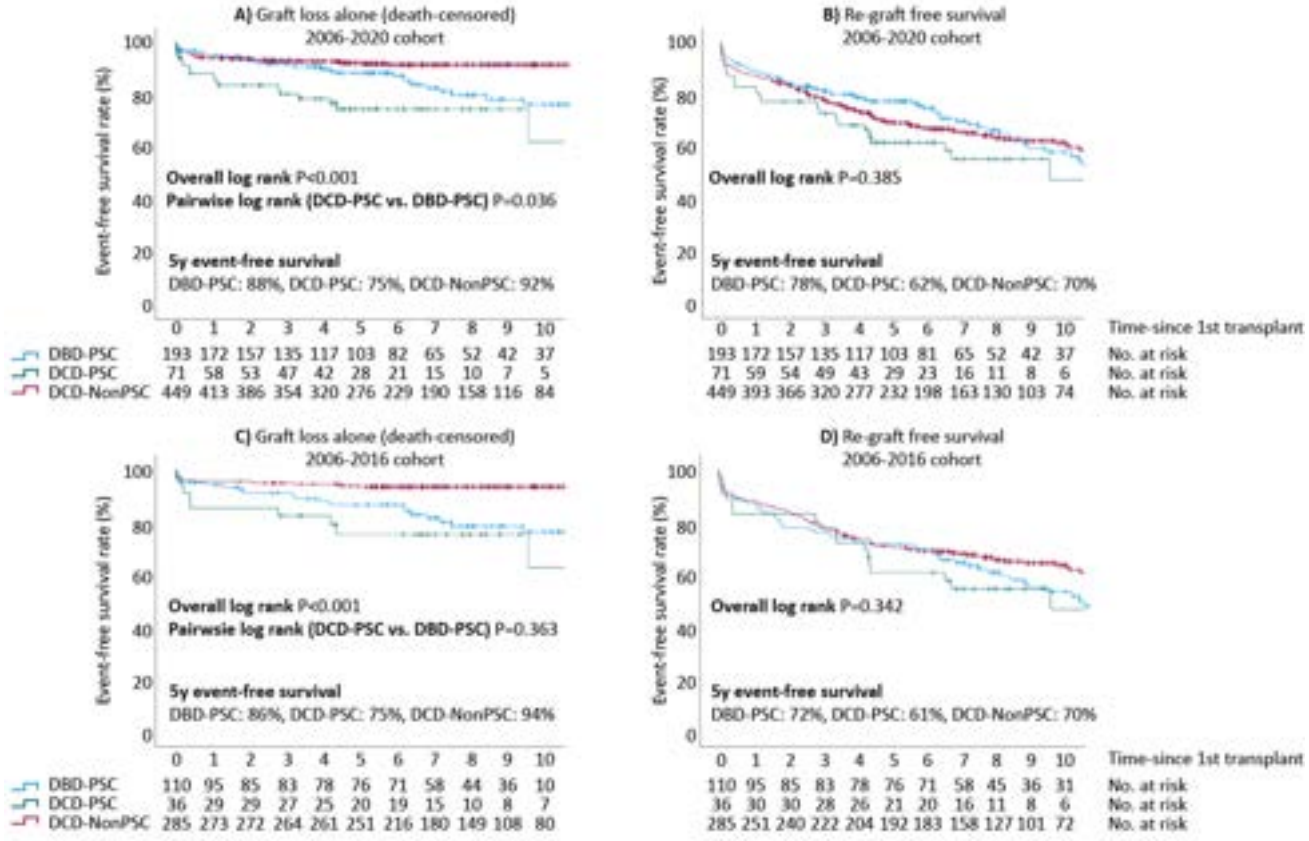
Arul Suthananthan[1], Nadir Abbas[1,2], Graham Caine[1,2], James Ferguson[1,2], Thamara Perera[1], Palak Trivedi[1,2]. *[1]University Hospitals Birmingham, Liver Unit, United Kingdom; [2]University of Birmingham, National Institute for Health Research (NIHR) Birmingham Biomedical Research Centre (BRC), Birmingham, United Kingdom*
Email: p.j.trivedi@bham.ac.uk

Background and aims: Liver transplantation is the only life-extending intervention for individuals with PSC. Whilst donation after brain death (DBD) is the practice of choice, patients may endure prolonged waitlist times due to young age. Equally, outcome data following DCD transplantation are conflicting, particularly with regards long-term follow-up. We have previously published data showing that post-transplant outcomes among PSC patients transplanted with a DCD liver were no different to that of DBD recipients at 1 year (*J Hepatol. 2017;* PMID:28690174). In the current study, we seek to validate prior observations through a contemporary PSC transplant cohort, in parallel to long-term evaluation of graft loss and regraft-free survival among patients with a minimum 5 years since their first transplant.

Method: Long-term outcomes following DCD transplantation in PSC (DCD-PSC) were compared to DBD recipients (DBD-PSC). (A) First, we validated 1y-outcomes presented from our previous study (liver transplants performed 2006–2016) with a contemporary cohort transplanted 2016–2020. (B) Next, we evaluated long-term outcomes in the combined cohort of patients (transplanted 2006–2020), alongside (C) 5y-outcomes specifically in the 2006–2016 cohort, including for non-PSC patients (DCD-nonPSC).

Results: (A) In the 2016–2020 cohort, 1y-risk of death-censored graft loss was not significantly greater in the DCD-PSC vs DBD-PSC group (odds ratio [OR]:2.6; 95% CI: 0.96–7.0), nor was the risk of all-cause mortality (1.14; 0.39–3.38) or regraft-free survival (2.66; 0.79–8.89). (B) In the combined 2006–2020 cohort, a total of 17 patients experienced graft loss in the DCD-PSC group, compared to 30 in the DBD-PSC group (Fig. 1A); 88% of the DCD-PSC graft losses occurred within five years of transplantation vs. 60% in the DBD-PSC group.

Figure 1: Post-transplant outcomes stratified by donor type and underlying disease aetiology



Kaplan-Meier survivorship estimates presented to show rates of first graft loss (**A+C**) and graft loss / death as a combined endpoint (**B+D**) in PSC and non-PSC liver transplant recipients. Data presented for the combined 2006-2020 cohort (**A+B**) and the original derivation cohort (**C+D**; 2006-2016) with >5 years post-transplant follow-up.

Figure 1: (abstract: THU-497).

However, overall regraft-free survival was not significantly different between PSC groups, and both were inferior to DCD-nonPSC (Fig. 1B). (C) On restricting analysis to patients with a minimum 5 y since first transplant, the risks of death-censored graft loss (hazard ratio [HR]: 1.44; 0.66–3.14), all-cause mortality (0.62; 0.29–1.34) and regraft-free survival (1.14; 0.66–1.97) were not significantly greater for DCD-PSC vs. DBD-PSC (Fig. 1C+D).

Conclusion: In an era of organ shortage, regraft-free survival rates are not significantly different for PSC patients transplanted with a DCD vs. DBD liver. Given the heightened risks of graft loss in PSC compared to non-PSC patients, improved understanding of high-risk combinations of donor-recipient factors is essential to maximise outcomes following transplantation.

THU-498

Evaluation of a delayed liver transplant strategy for patients listed for hepatocellular carcinoma treated with resection or thermo-ablation as a bridge to liver transplantation; the DELTAS-HCC study

Catherine Lamarque[1], Lauriane Segaux[1], Armand Abergel[2], Philippe Bachellier[3], Faiza Chermak[4], Audrey Coilly[5], Filomena Conti[6], Thomas Decaens[7], Sebastien Dharancy[8], Vincent Di Martino[9], Jérôme Dumortier[10], Claire Francoz[11], Jean Gugenheim[12], Jean Hardwigsen[13], Fabrice Muscari[14], Sylvie Radenne[15], Ephrem Salamé[16], Thomas Uguen[17], José Ursic Bedoya[18], Corinne Antoine[19], Vincent Leroy[1], Nadia Oubaya[1], Christophe Duvoux[1]. *[1]Henri Mondor Hospital APHP- Paris Est University, France; [2]CHU Estaing, France; [3]Hopitaux Universitaires Strasbourg, France; [4]Bordeaux University Hospital, France; [5]Centre Hépato-Biliaire, Hôpital Paul Brousse, France; [6]APHP, France; [7]HOPITAL ALBERT MICHALLON, France; [8]HOPITAL CLAUDE HURIEZ, France; [9]CHU Jean Minjoz, France; [10]HOPITAL EDOUARD ERRIOT, France; [11]Beaujon University Hospital, France; [12]Department of Digestive Surgery, Archet Hospital, University of Nice-Sophia Antipolis, France; [13]Aix Marseille University, Department of General Surgery and Liver Transplantation, Hopital la Timone, France; [14]Toulouse University Hospital, France; [15]Hospices Civils de Lyon, France; [16]CHU Trousseau, France; [17]HOPITAL PONTCHAILLOU, France; [18]CHU Montpellier, France; [19]Agence de biomedecine, France*
Email: catherine.lamarque@yahoo.fr

Background and aims: To maximize utility and prevent premature liver transplantation (LT), a delayed transplant strategy (DS) was adopted in France in 2015 in patients listed for any single hepatocellular carcinoma (HCC) treated with surgical resection (SR) or thermo-ablation (TA) during the waiting phase, postponing LT until recurrence. It is crucial to make sure that pre and post-LT outcomes of patients entering DS are not negatively impacted. The purpose of this study was to evaluate this DS.

Method: Study population: patients listed for HCC in France between 2015 and 2018, with an AFP score ≤2. After data extraction from the national LT database, Cristal, 2025 patients were classified according to 6 groups: single tumor entering DS, single tumor not entering DS (NDS), multiple tumors (MT), other loco-regional therapies (LRT) with no DS, untreatable HCC (UH) and T1 tumors (T1). 18-months

Kaplan-Meier estimates of drop-out before LT and 5-year post-LT recurrence and survival rates were compared.
Results: The patients' features are shown in the table. Pre-LT drop-out probabilities were 13, 18, 21, 22 and 25% in DS, LRT and MT, UH, NDS and T1, respectively (p = 0.05), significantly lower in DS, and higher in T1. Post- LT 5-year survival and recurrence rates did not differ among groups.

	DS N = 341 (16.8%)	NDS N = 74 (3.7%)	MT N = 238 (11.7%)	LRT N = 879 (43.4%)	UH N = 346 (17.1%)	T1 N = 147 (7.3%)	p
MELD (median)	8.47	10.25	8.95	9.93	15.54	13.21	<0.0001
Tumor size (cm) (median)	2.5	2.55	2.4	3.0	2.3	1.5	0.0005
Number of tumor (median)	1.0	1.0	2.0	2.0	2.0	1.0	0.006
AFP (ng/ml) (median)	7.95	7.00	9.25	9.30	5.71	7.00	1
Time from treatment to LT (days) (median)	910	285	666	442		717	<0.0001

This study benefited from a grant of Agence de la Biomédecine, the French Organ Sharing Organization.

Figure:

Conclusion: The DELTAS HCC study shows that: DS can be considered in around 20% of HCC candidates (DS and NDS groups), DS in patients amenable to curative treatments pre-LT has no negative impact on pre- and post-LT outcomes, DS has the potential to redistribute organs to patients in more urgent need and can reasonably be pursued. The unexpected high drop-out in T1 patients seems related to a combination of purely MELD-based driving rules, with a 15 median MELD at listing, hampering bridging treatments and access to LT. It calls for revision of allocation rules in this subgroup.

THU-499

Use and outcomes of hepatitis B virus positive grafts for renal or heart transplantation in the US (1999–2021)

Ashwani Singal[1], K. Rajender Reddy[2], Mindie Nguyen[3], Zobair M. Younossi[4], Paul Yien Kwo[3], Yong-Fang Kuo[5]. *[1]University of South Dakota-Sioux Falls, Sioux Falls, United States; [2]University of Pennsylvania, Philadelphia, United States; [3]Stanford University, Stanford, United States; [4]Fairfax, Fairfax, United States; [5]UTMB Health-University of Texas Medical Branch at Galveston, Galveston, United States*
Email: ashwanisingal.com@gmail.com

Background and aims: The gap between demand and supply for solid organ transplants continues to widen, requiring strategies to expand the donor pool. The use of hepatitis B virus (HBV) positive grafts in liver transplantation without impacting the graft and patient survival has been reported. However, the outcomes of kidney transplant (KT) or heart transplant (HT) recipients with HBV positive grafts from deceased donors is not known.
Method: We examined the outcomes of recipients undergoing KT or HT with HBV positive grafts (hepatitis B surface antigen and/or HBV nucleic acid test [NAT] positive) from deceased donors using the UNOS database (01/1999 to 06/2021). Propensity score matching (1:5) was done for KT recipients of HBV positive with HBV negative grafts for transplant year, recipient demographics, donor age, and serum creatinine at transplant. Similar matching (1:10) was done among HT recipients for transplant year and recipient demographics.
Results: Among 189,898 potential donors, 448 (0.24%) were HBV positive with 996 kidneys and 448 hearts available for transplantation. Of these, 352 kidneys (35.3%) and 56 hearts (12.5%) were transplanted, with 332 kidneys and 53 hearts in HBV negative recipients. Although, use of HBV positive kidney and heart grafts increased over time (p < 0.001), 60% of kidneys and 94% of heart grafts were discarded in 2020. Among KT recipients of HBV positive and negative grafts, 10-yr. graft survival rates were similar at 47.1% and 49% (log rank P = 0.353), and respective patient survival rates were 58% and 59% (p = 0.999). Similarly, among HT recipients of HBV positive and negative grafts, 10-yr. graft survival rates were 41.9% and 38.9% for graft survival (p = 0.471), and 54.3% and 61.2% for patient survival (p = 0.277). Outcomes were similar in subgroups with HBV grafts matched with HBV negative grafts based on HBsAg, NAT, and anti-HBc serology (Figure).

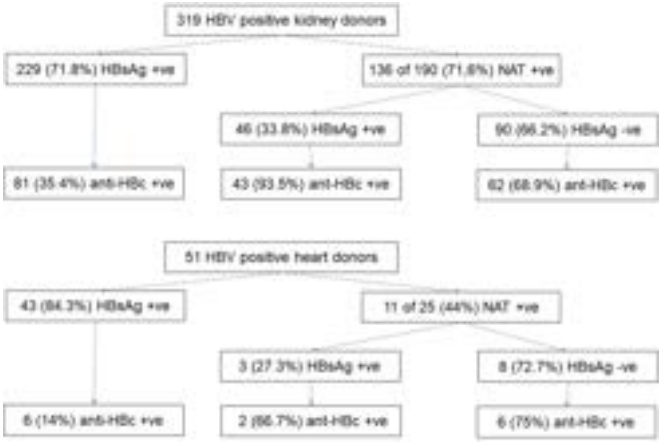


Figure: Hepatitis B surface antigen (HBsAg), nucleic acid test (NAT), and core antibody (anti-HBc) status of hepatitis B positive donor kidneys (A) and hearts (B).

Conclusion: These observations wherein that use of HBV positive donors for KT or HT did not impact the recipient graft or patient survival, suggest that it is a reasonable strategy to expand the donor pool and lower the waitlist mortality rate among candidates waiting for kidney or heart transplant.

Donor outcomes incidence after living-donor liver transplantation: meta-analysis and systematic review

Jieling Xiao[1], Rebecca Wenling Zeng[1], Wen Hui Lim[1], Darren Jun Hao Tan[1], Cheng Han Ng[1], Margaret Teng[2], Eunice Tan[2], Daniel Huang[2], Mohammad Shadab Siddiqui[3], Alfred Kow[2], Mark Muthiah[2]. *[1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore; [2]National University Health System, Singapore; [3]Division of Gastroenterology, Department of Internal Medicine, Virginia Commonwealth University, United States*
Email: margaret.tenglp@gmail.com

Background and aims: Liver transplantation remains a critical means of treatment for end stage liver disease which has increased steadily in the recent decades. The scarcity of liver grafts has prompted developments in living donor liver transplantations (LDLT) with previous literature illustrating similar outcomes in recipients as compared to deceased donor transplants. However, there are concerns regarding living donor morbidity and mortality which has yet to be examined comprehensively. This study aims to provide estimates of the incidence of various outcomes in living liver donors.
Method: In this meta-analysis, Medline and Embase were searched from inception to July 2022 for articles assessing incidence of outcomes in LDLT donors. Analysis of incidence was done using a generalised linear mixed model with Clopper-Pearson intervals in terms of incidence rate per 10, 000 person-days. With regards to risk factors, binary variables were analysed with generalised linear model while meta regression with logit transformation was done for continuous variables.
Results: Of 5074 abstracts, 182 articles involving 60,152 living liver donors were included. The overall pooled incidence rate of complications in LDLT donors was 29.23 (CI: 23.42 to 36.48) per 10,000 person-days. The incidence rate of complications in liver donors in study conducted before and in 2010 was 40.77 (CI: 30.32 to 54.82) while that on study conducted after 2010 was 22.84 (CI: 16.79 to 31.07) per 10,000 person days. The incidence rate of major complications was 5.32 (CI: 4.10 to 6.90) while the incidence rate of

donor mortality was 0.05 (CI: 0.02 to 0.12) per 10,000 person-days. The complications with the highest incidence rate in LDLT donors were respiratory complications (IR: 6.28, CI: 4.40 to 6.95), followed by wound-related (IR: 5.95, CI: 4.64 to 7.62) and biliary complications (IR: 5.59, CI: 4.49 to 6.95) per 10,000 person-days. Additionally, the incidence rate of cardiovascular complications was lowest amongst the subgroups of complications at 0.81 (CI: 0.41 to 1.62) per 10,000 person-days. Duration of ICU stay was significantly associated with greater complications rate in liver donors while preoperative liver volume, donation volume and liver remnant were not.
Conclusion: This study presents the incidence of post-LDLT outcomes in liver donors illustrating the high incidence of respiratory, wound-related and biliary complications. While significant advancements in recent decades have contributed towards decreased morbidity in living liver donors, targeted measures and continued efforts are warranted to ensure the safety and quality of life of liver donors post LDLT.

THU-501
Access to liver transplant for women in Spain: a national registry analysis
Marta Tejedor Bravo[1], Fernando Neria[2], Gloria de la Rosa[3], Carolina Almohalla Alvarez[4], Andrea Boscá[5], Yilliam Fundora[6], Francisco Sánchez-Bueno[7], Marina Berenguer[5]. *[1]Hospital Universitario Infanta Elena, Gastroenterology and Hepatology, Spain; [2]Universidad Francisco de Vitoria, Madrid, Spain; [3]Organización Nacional de Trasplantes, Madrid, Spain; [4]Comité científico del Registro Español Trasplante Hepático, Spain; [5]La Fe University and Polytechnic Hospital, València, Spain; [6]Hospital Clínic de Barcelona, Barcelona, Spain; [7]Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain*
Email: marina.berenguer@uv.es

Background and aims: Gender inequities in liver transplantation (LT) have been documented recently in several studies. Providing national data is crucial as poorer access to liver transplantation for women than men might be explained by different analytical approaches or different national contexts. Our aim was to describe the recipient profile over time in Spain, particularly regarding potential sex-related differences in access to LT.
Method: All adult patients registered in the RETH-Spanish Liver Transplant Registry from 2000 to 2018 for LT were included. Baseline demographics, presence of hepatocellular carcinoma (HCC), cause and severity of liver disease, time on the waiting list (WL), access to transplantation, and reasons for removal from the WL were assessed.
Results: 9427 patients were analyzed (77.6% men, 55.3 ± 8.6 years of age). Mean MELD score was reported for 3404 patients (36.1%), and was 16.5 ± 5.8. Women were less likely to receive a transplant than men (OR 0.84, 95% CI 0.73, 0.97) and more likely to be excluded for deterioration (HR 1.21, 95% CI 1.02, 1.44), despite similar liver disease severity (MELD score 16.6 ± 5.8 vs 16.5 ± 5.8 respectively, N.S) and only a slightly longer mean time on the WL (244 ± 398 days for women vs 213 ± 324 for men, p = 0.001). In recent years, this difference in access to LT was less significant (before 2011 women's HR for exclusion was 1.51 [95% CI 1.01, 2.26] vs 1.17 [95% CI 0.97, 1.41] after 2011) and could be attributed to overall shorter mean WL times after 2011 (398 ± 602 vs 154 ± 217 days respectively, p < 0.001). When analyzed by MELD, WL times were similar by sex for patients with scores under 16 or above 20, but women had significantly longer mean WL times than men with MELD scores 16–20 (270 ± 267 vs 211 ± 207 days respectively, p < 0.001). Women were shorter (170.5 ± 9.7 vs 158.5 ± 9.8 cm) but had a similar BMI compared to men. In women, the main indications for transplant were cholestatic liver diseases, autoimmune hepatitis and NASH, whilst in men it was alcohol (p < 0.001). Women had less HCC than men (27.1 vs 16.6%, p < 0.001).
Conclusion: Shorter WL times contribute to a more equal access to LT by sex, as it prevents women from deteriorating while waiting and therefore being excluded from the list.

THU-502
Body composition and MAFLD are associated with prognosis after resection of intrahepatic cholangiocarcinoma
Isabella Lurje[1], Deniz Uluk[2], Sandra Pavicevic[2], Minh Phan[1], Timo Auer[3], Dominik Modest[4], Frank Tacke[1], Johann Pratschke[2], Georg Lurje[2]. *[1]Charité-Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Campus Charité Mitte | Campus Virchow-Klinikum, Berlin, Germany; [2]Charité-Universitätsmedizin Berlin, Department of Surgery, Campus Charité Mitte | Campus Virchow-Klinikum, Germany; [3]Charité-Universitätsmedizin Berlin, Department of Radiology, Germany; [4]Charité-Universitätsmedizin Berlin, Department of Hematology, Oncology, and Tumor Immunology, Germany*
Email: isabella.lurje@charite.de

Background and aims: Body composition alterations are frequent in patients with cancer or chronic liver disease. We investigated the impact of disease etiology and body composition after surgery for intrahepatic cholangiocarcinoma (iCCA), a rare and understudied cancer entity in European cohorts.
Method: Computer tomography-based assessment of body composition at the level of the third lumbar vertebra was performed in 173 patients undergoing curative-intent liver resection for iCCA. Muscle mass and -quality as well as subcutaneous and visceral adipose tissue quantity were determined semi-automatically. Sarcopenia, sarcopenic obesity, myosteatosis, visceral and subcutaneous obesity were correlated to clinico-pathological data.
Results: Fifty-eight patients (34%) had metabolic (dysfunction)-associated fatty liver disease (MAFLD). Patients with MAFLD had a higher incidence of sarcopenic (p = 0.006), visceral (p < 0.001) and subcutaneous obesity (p < 0.001). At the same time, patients with MAFLD had longer disease-free survival than patients without liver disease or with fibrosis (median: 38 months vs. 12 months, p = 0.025). Sarcopenia was associated with higher postoperative morbidity (intraoperative transfusions [p = 0.027], Clavien-Dindo ≥IIIb complications [p = 0.030], postoperative comprehensive complication index, CCI [p < 0.001]). Inferior overall survival was noted in patients with subcutaneous obesity (median: 35 vs. 23 months, p = 0.042) and myosteatosis (33 vs. 23 months, p = 0.020). Multivariable analysis confirmed only clinical parameters (lymph node invasion, CCI >40) as independently prognostic for overall survival.

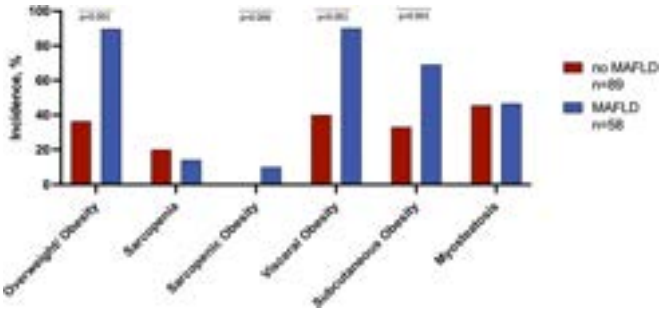

Figure:

Conclusion: This study evidenced a high prevalence of MAFLD in iCCA, suggesting its potential contribution to disease etiology. While being associated with body composition phenotypes regarded as pathological, MAFLD may be associated with improved disease-free survival in patients undergoing surgery for iCCA.

THU-503

Cytomegalovirus reactivation is associated with lower hepatocelullar carcinoma recurrence rates after liver transplantation

Victoria Aguilera Sancho[1,2,3], Sarai Romero Moreno[4], Isabel Conde[1,3,5], Ángel Rubín[1,5,6], Cristina Dopazo[7], Antonio Cuadrado[8], Carmen Bernal[9], Sheila Pereira[10], Magdalena Salcedo[11], Sara Lorente Perez[12], Ana Sánchez Martínez[13], Javier Zamora[14], Sonia Pascual[15], Esteban Fuentes Valenzuela[16], Laura Martínez-Arenas[5], Jose Ignacio Herrero[17], Marina Berenguer[18], Manuel Rodríguez-Perálvarez[3,14]. *[1]La Fe University and Polytechnic Hospital, Hepatology and Liver Transplant Section, Valencia, Spain; [2]Instituto de Investigación Sanitaria La Fe de Valencia, Valencia, Spain; [3]CIBERehd Instituto de Salud Carlos III, Spain; [4]La Fe University and Polytechnic Hospital, Hepatology and Liver Transplant Section, Valencia, Spain; [5]Instituto de Investigación Sanitaria La Fe de Valencia, Valencia, Spain; [6]Ciberehd, Instituto Carlos II, Spain; [7]Hospital Universitario Vall d´Hebron, Barcelona, Spain; [8]Hospital Universitario Marqués de Valdecilla, Department of Gastroenterology and Hepatology, Santander, Spain; [9]Hospital Universitario Virgen del Rocio, Hepato-Biliary-Pancreatic Surgery, Sevilla, Spain; [10]Hospital Universitario Virgen del Rocio, Hepato-Biliary-Pancreatic Surgery Unit and Liver Transplantation, Sevilla, Spain; [11]Hospital General Universitario Gregorio Marañon, Department of Hepatology and Liver Transplantation, Madrid, Spain; [12]Hospital Clinico Universitario Lozano Blesa, Department of Hepatology and Liver Transplantation, Zaragoza, Spain; [13]Hospital Universitario Virgen de la Arrixaca, Liver Transplantation Unit, Murcia, Spain; [14]Hospital Universitario Reina Sofia, Department of Hepatology and Liver Transplantation, Córdoba, Spain; [15]Hospital General Universitario Alicante, Department of Hepatology and Liver Transplantation, Alicante, Spain; [16]Hospital Universitario Rio Hortega, Unit of Hepatology and Liver Transplantation, Valladolid, Spain; [17]Clínica Universitaria de Navarra, Liver Unit, Pamplona, Spain; [18]La Fe University and Polytechnic Hospital, Hepatology and Liver Transplant Section, Valencia, Spain*
Email: toyagui@hotmail.com

Background and aims: CMV reactivation (rCMV) may impact morbidity and mortality after liver transplantation (LT). Immune modulation occurring after rCMV could decrease HCC recurrence rates after LT. Aims: To assess the effect of early rCMV LT-patients with HCC in a multicenter cohort.

Method: We included LT patients with HCC (2010–2015) in a multicenter cohort involving 11 Spanish institutions. Exclusion criteria were: age <18, re-LT, mortality within the first 12 months, and combined organ transplantation. Variables: (i) Donor (D) and recipient (R) demographics, (ii) related with rCMV (reactivation after LT prior to HCC recurrence) DR CMV mismatch, preemptive therapy, CMV disease, (iii)related to HCC: bridging, downstage, vascular invasion, baseline AFP. Prophylaxis with valganciclovir was used in high-risk patients while a preemptive approach was used in low-risk patients.

Results: Out of 621 LT, 543 (87% men, median age 58 [range: 20.5–71.5]) fulfilled inclusion criteria; the main etiology was alcoholic liver disease (n = 313, 50%) followed by hepatitis C (n = 299, 48%) and hepatitis B (n = 57, 9%). MELD at LT was 13 (6–40). Most patients met Milan criteria (87%) or up to seven criteria (97%) before LT; 111 patients (21%) were included after downstaging and 63% received locoregional therapy either for bridging or downstaging. On explant, 11% of patients had microvascular invasion. Median serum AFP at inclusion and at transplantation were 75 ng/ml (range 1–5245) and 64 ng/ml (range 1–764), respectively. High-risk CMV mismatch (D +/R-) occurred in 11% of patients. rCMV occurred in 185 patients (30%); 115 (65%) started early treatment and 25 (14.5%) developed CMV disease. Overall, 81 patients (13%) had HCC recurrence after a median of 2, 6 years (0.3–9.6).In the multivariate Cox regression analysis, microvascular invasion [HR 4.03 (p:0, 0001], absence of rCMV (HR:2, 307, p = 0.028), moderate or poor histological differentiation (HR2.049, p:0.03) and MELD (HR 1.094, p0.005 were associated with HCC recurrence. Survival at 1, 3 and 5 and 7 yrs post-LT were in HCC recurrence vs non HCC recurrence: 85%, 61%, 30% and 14% and 99%, 91%, 86% and 81% respectively.

Conclusion: In a Spanish multicenter series, the absence of rCMV was associated with increased risk of HCC recurrence after controlling for well-established prognostic features.

THU-504

The influence of immunosuppression and recipient geography on non-melanoma skin cancer risk after liver transplantation

Therese Bittermann[1], James Lewis[1], David Goldberg[2]. *[1]University of Pennsylvania, United States; [2]University of Miami, United States*
Email: therese.bittermann@pennmedicine.upenn.edu

Background and aims: Immunosuppression (IS) after liver transplantation (LT) is associated with an increased solid cancer risk, of which the most common is non-melanoma skin cancer (NMSC). The optimal approach to IS management in those at the highest risk for *de novo* NMSC has not been determined, nor has the impact of recipient geography.

Method: Using a merged dataset of Medicare healthcare claims linked to U.S. national transplant registry data, we identified a retrospective cohort of adult first liver-alone transplant recipients who were alive with their native allograft at 1-year post-LT. Patients with a prior history of NMSC were excluded. *De novo* NMSC incidence was computed overall and by latitude of residence at transplant. Patient characteristics were described. Multivariable Cox regression evaluated the association of clinical characteristics, latitude and time-updating maintenance IS regimen with *de novo* NMSC.

Results: The 10,413 LT recipients in the cohort were 62.6% male, 69% non-Hispanic White (NHW) and with median age 60 years. In total, 891 (8.6%) developed *de novo* NMSC, yielding an overall incidence of 23 per 1,000 person-years (PY). Median time from LT to NMSC was 2.6 years (IQR: 1.7–3.9). NMSC incidence increased at lower latitudes: from 17 per 1,000 person-years (PY) for patients residing at ≥40° to 25 per 1,000 PY for those <30° (Northern). In multivariable analyses, factors independently associated with *de novo* NMSC included: female sex (hazard ratio [HR] 0.6 vs male; p < 0.001), NHW race/ethnicity (HR 7.8; p < 0.001), age ≥60 years (HR 2.0 vs <60 years; p < 0.001), lower latitude of residence (HRs of 1.4 and 1.8 for <30° and 30–39° vs ≥40°; p < 0.001) and calcineurin inhibitor plus anti-metabolite (CNI + antiM) maintenance IS (HR 1.5 vs CNI alone; p = 0.003 overall). The interaction of IS with latitude was non-significant (p = 0.967). There was a possible interaction of IS with age (p = 0.096). In stratified analyses, IS was not associated with NMSC for patients <60 years (p = 0.355), but was so in patients ≥60 years (p = 0.002), in whom CNI + antiM and mechanistic target of rapamycin inhibitor regimens were associated with increased NMSC (HRs 1.5 and 1.4, respectively, vs CNI alone; p = 0.002 overall).

Conclusion: *De novo* NMSC is a frequent occurrence among LT recipients with modifiable and non-modifiable risk factors. An individualized approach to post-LT IS has the potential to reduce *de novo* NMSC post-LT.

THU-505

Perfusate composition of transplanted and not transplanted livers during normothermic machine perfusion

Jule Dingfelder[1], David Pereyra[1], Laurin Rauter[1], Sertac Kacar[1], Gerd Silberhumer[1], Andreas Salat[1], Zoltan Mathe[1], Thomas Soliman[1], Dagmar Kollmann[1], Georg Gyoeri[1], Gabriela Berlakovich[1]. *[1]Medical University of Vienna, Department of General Surgery, Division of Transplantation, Vienna, Austria*
Email: jule.dingfelder@meduniwien.ac.at

Background and aims: Dynamic changes in perfusate composition during normothermic machine perfusion (NMP) can reflect on the synthesis capability of the graft and extent of preservation injury. Components of the perfusate are either flushed out of the liver during

perfusion or produced by the liver or endothelial cells. Our aim was to compare perfusate composition during NMP of transplanted livers (tx) with not transplanted livers (non-tx).
Method: During NMP of 27 livers, blood gas analysis (BGA) of perfusate and bile was performed, as well as perfusate analysis for thrombocytes, leukocytes, van Willebrand factor activity (vWF), factor XIII activity (FXIII), fibrinogen, bilirubin, sodium, alkaline phosphatase (AP), alanine-aminotransferase (ALT), aspartate-amino-transferase (AST) gamma-glutamate transferase (gGT) and lactate dehydrogenase (LDH). Liver and bile duct biopsies were taken before and after perfusion. Viability assessment was performed between hours 2 and 4 and included lactate clearing, decreasing perfusate glucose, perfusate and bile pH, bile glucose and bile production.
Results: In total 31 livers underwent NMP, 20 were transplanted following viability assessment while 11 livers did not meet the criteria for transplantation. The two groups did not differ in donor age (p = 0.06) and BMI (p = 0.197), but WIT was significantly longer (p = 0.016) and gGT was higher (p = 0.005) in the non-tx group. BGA of perfusate showed lower sodium and bicarbonate (60 minutes, p = 0.011) levels in non-tx livers after 30 (p = 0.001) and 60 (p = 0.05) minutes. The pH was higher in tx livers at 0 (p = 012), 30 (p = 0.001), and 60 (p = 0.024) minutes. Non-tx livers presented with higher FXIII activity at 5 min (p = 0.041), 60 min (p = 0.07), 120 min (p = 0.084), and 240 min (p = 0.069). FXIII act was increasing in non-tx livers but remained mostly stable in tx livers. Bilirubin (5 min, p = 0.02), AP (5 min, p = 0.027; 60 min, p = 0.049), AST (5 min, p = 0.02; 60 min, p = 0.04; 120 min, p = 0.008; 240 min, p = 0.014), ALT (5 min, p = 0.07; 60 min, p = 0.08; 120 min, p = 0.009; 240 min, p = 0.043), gGT (5 min, 0.002; 60 min, p = 0.013), LDH (5 min, p = 0.05; 60 min, p = 0.011; 120 min, p = 0.009) was significantly higher in non-tx livers. Fibrinogen levels trended higher in tx livers (not significantly) and were increasing over the course of the perfusion in both groups.
Conclusion: Decisions regarding viability assessment were confirmed by damage marker composition in perfusate. Interestingly, FXIII in perfusate was significantly higher in non-tx livers and presented with different dynamics. Fibrinogen was increasing over the course of perfusion in all livers. Transplanted livers presented with higher fibrinogen levels, maybe indicating a higher regenerative capacity.

THU-506
Risk factors associated with surgical morbidities of laparoscopic living liver donors

Jinsoo Rhu[1], Gyu-Seong Choi[1], Jong Man Kim[1], Jae-Won Joh[1].
[1]*Samsung Medical Center, Department of Surgery, Korea, Rep. of South*
Email: jsrrules@gmail.com

Background and aims: This study analyzed incidence and risk factors for surgical morbidities of laparoscopic living donors. Although laparoscopic living donor program has been safely established in leading centers, donor morbidities have not been sufficiently discussed.
Method: Laparoscopic living donors operated during May 2013 to June 2022 were reviewed. Donors' complications were reviewed, and factors related to bile leakage and biliary stricture were analyzed using multivariable logistic regression method.
Results: A total of 636 donors underwent laparoscopic living donor hepatectomy. Open conversion rate was 1.6%. Thirty-day complication rate was 16.8%. (n = 107) Grade IIIa and IIIb complication occurred in 4.4% (n = 28) and 1.9% (n = 12), respectively. The most common complication was bleeding (n = 38, 6.0%). Fourteen donors (2.2%) required reoperation. Portal vein stricture, bile leakage and biliary stricture occurred in 0.6% (n = 4), 3.3% (n = 21), and 1.6% (n = 10) of cases. Readmission rate and reoperation rate was 5.2% (n = 33) and 2.2% (n = 14), respectively. Risk factors related to bile leakage were two hepatic arteries in liver graft (OR = 13.836, CI = 4.092–46.789, P < 0.001), division-free margin <5 mm from main duct (OR = 2.624, CI = 1.030–6.686, P = 0.043) and estimated blood loss during operation (OR = 1.002, CI = 1.001–1.003, P = 0.008) while Pringle maneuver (OR = 0.300, CI = 0.110–0.817, P = 0.018) was protective for leakage. Regarding biliary stricture, only bile leakage was the only significant factor (OR = 11.902, CI = 2.773–51.083, P = 0.001).

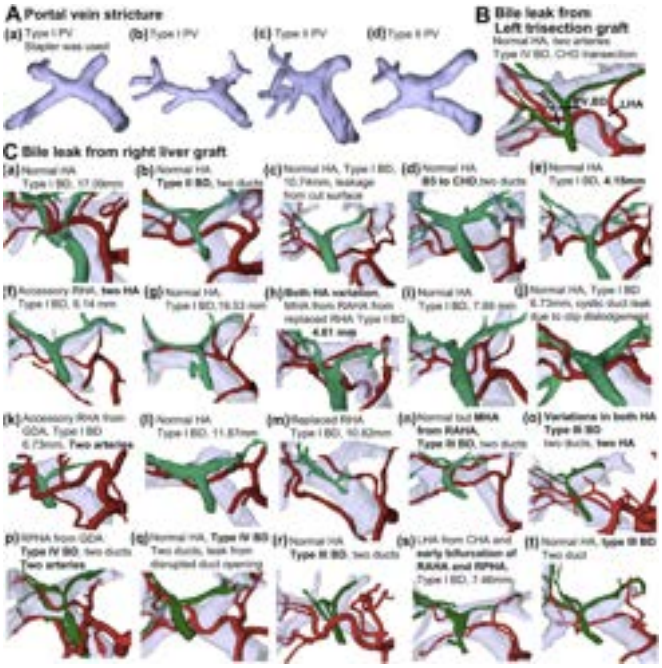

Figure: 3D reconstructed models of donors who experienced portal vein stricture or bile leakage after laparoscopic living donor hepatectomy. (A) Portal vein stricture cases. Two type I portal veins and two type II portal veins. (B) Bile leakage after left trisection graft donation. Right and left hepatic artery was divided at the black line marked, while bile duct was divided at the common hepatic duct level. Portal vein was divided at the common trunk of left and right anterior portal vein. (C) Bile leakage cases after right liver graft donation. Type and number of hepatic artery and bile duct variation are summarized. In type I bile duct cases, length of right hepatic duct common channel is measured. The leakage points are also summarized for cases with reoperation. The bold descriptions emphasize the possible risks for bile leakage.

Conclusion: Laparoscopic living donor showed excellent safety for majority of the donors and critical complications were resolved with proper management. To minimize bile leakage, cautious surgical manipulation should be made on donors with complex hilar anatomy.

THU-507
Clinical impact and treatment of veno-occlusive disease/ sinusoidal obstruction syndrome (VOD/SOS) after liver transplant (LT): the role of transjugular intrahepatic porto-systemic shunt (TIPS)

Michela Triolo[1], Mauro Viganò[1], Francesca Poggi[1], Luisa Pasulo[1], Leonardi Filippo[1], Maria Grazia Lucà[1], Massimo De Giorgio[1], Claudia Iegri[1], Michele Colledan[2], Aurelio Sonzogni[3], Paolo Marra[4,5], Stefania Camagni[2], Domenico Pinelli[2], Stefano Fagiuoli[1]. Email: mik.triolo@gmail.com

Background and aims: veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) after liver transplantation (LT) is a rare complication, and best treatment and long-term outcome is still

undefined. Aim of this monocentric retrospective study is to evaluate the management and outcome of VOD/SOS after LT.
Method: between November 1997–2022, 1123 adult patients underwent LT. In patients who developed portal hypertension with ascites and/or hydrothorax after LT, the diagnosis of VOD/SOS was established by liver biopsy and measurements of hepatic venous pressure gradient (HVPG).
Results: 35/1123 (3%) patients [74% males, median age 51 (18–70) yrs, all treated with steroids plus tacrolimus (94%), plus tacrolimus and mycofenolic acid (3%) or plus cyclosporin and mycofenolic acid (3%)] had histologicallly proven VOD/SOS diagnosis. All patients presented with ascites, associated with hydrothorax in 4 (11%) cases. In 28/35 (80%) HVPG was measured at diagnosis of VOD/SOS. Median HVPG was 14 (7–34) mmHg. Median time of VOD/SOS after LT was 47 (20–220) days. In 6 (17%) patients VOD/SOS developed 24 (13–201) days after acute cellular rejection (ACR), whereas 2 (6%) patients had concomitant ACR and VOD/SOS occurrence. Ten (28%) patients showed spontaneous clinical improvement after a median time of 41 days (17–259), 2 (6%) were treated with defibrotide and 23 (66%) underwent TIPS. HVPG and Meld-Na at VOD/SOS diagnosis were significant higher in patients treated with TIPS compared to those which experienced spontaneous clinical improvement (19 vs 12.5, $p < 0.001$ and 14 vs 10, $p = 0.002$). After TIPS placement, the median HVPG was reduced to 8 mmHg (2–15), 17 (89%) patients resolved ascites ± hydrothorax after a median time of 3 months, 3 (16%) patients developed porto-systemic encephalopathy which resolved with medical therapy in 2 cases and with TIPS caliber reduction in the other one. Two (10%) patients needed TIPS enlargement within one year due to stent dysfunction and ascites relapse. Overall, during a median follow-up of 62 months, 3 (16%) patients needed re-OLT, 1 (3%) for tipsitis, 1 (3%) for hepatic arteria thrombosis and 1 (3%) for delayed dysfunction of graft. The 1, 3, 5 and 10-yr survival of patients having VOD/SOS spontaneous improvement were 100%, 100%, 87% and 73% compared with 95%, 91%, 63% and 29% of those treated with TIPS, respectively ($p = 0.016$).
Conclusion: VOD/SOS is a rare (3%) post LT complication associated with ACR in nearly 25% of cases. Among patients with high HVPG (median 19 mmHg) and without an early spontaneous clinical improvement, TIPS could be a safe and effective treatment option in our case series.

THU-508
Reassessing BCLC stage at transplant to predict risk of mortality and HCC recurrence in HCC liver transplant recipients

Cameron Goff[1], Ronald Samuel[1], Nicole Rich[2], Jihanne Benhammou[3], Ponnadai Somasundar[4], Abbas Rana[1], Hashem El-Serag[1], Fasiha Kanwal[1], George Cholankeril[1]. *[1]Baylor College of Medicine, Houston, United States; [2]UT Southwestern Medical Center, Dallas, United States; [3]Peter Morton Medical Building-UCLA Medical Center, Los Angeles, United States; [4]Boston University School of Medicine, Boston, United States*
Email: george.cholankeril@bcm.edu

Background and aims: The Barcelona Clinic Liver Cancer (BCLC) staging system is widely used for prognostication and treatment-decision making for patients with hepatocellular carcinoma (HCC) at time of diagnosis. However, progression in BCLC stage and change in performance status for HCC liver transplant (LT) recipients is not routinely reassessed at LT, and could predict risk of HCC recurrence and post-LT mortality. The aim of this study is to evaluate BCLC stage at LT as an independent predictor for post-LT mortality and HCC recurrence.
Method: Using the United Network for Organ Sharing (UNOS) database, we retrospectively analyzed all adult T2 HCC exception patients who received LT in the United States from January 1, 2012, to July 1, 2022. BCLC stage at LT was determined for all patients using calculated Child Pugh Score, ECOG Performance Status Scale from reported Karnsofsky performance status, and explant pathology at the time of transplant. Due to poor data quality, performance status of 1 was not used for classification. Cox Hazards regression analyses performed to analyze BCLC as a predictor for mortality, and logistic regression was used to analyze BCLC as a predictor for HCC recurrence.
Results: The study population consisted of 18,534 HCC LT recipients, of which 19.5% (3,808) remained at BCLC stage 0- A and 11.8% (2,188) were BCLC stage B at time of LT. 29.8% of HCC recipients progressed to BCLC stage C and 39.3% (n = 7,279) progressed to BCLC stage D at LT. In recipients with BCLC stage D at LT, 59.1% had ECOG 3–4 and 79.1% were Child Pugh C at time of LT. In addition, 45.7% (n = 3,295) recipients with BCLC stage D at LT had ECOG 0–1 at listing, of which 46.6% (n = 1,536) progressed to ECOG 3–4 at LT. On multivariate analyses accounting for recipient characteristics (age, sex, race and ethnicity), hepatic decompensation, laboratory MELD-Na and AFP at listing, wait time, and donor characteristics, BCLC stage C (Hazard Ratio (HR): 1.48, $p < 0.001$) and stage D (HR: 1.39, $p < 0.001$) at LT were significant predictors for post-LT mortality. For post-LT HCC recurrence, on multivariate analyses, BCLC stage B [Odds Ratio (OR): 1.40, $p = 0.004$), stage C (OR: 1.86, $p < 0.001$), and stage D (OR: 1.42, $p < 0.001$) were also significant predictors of recurrence.

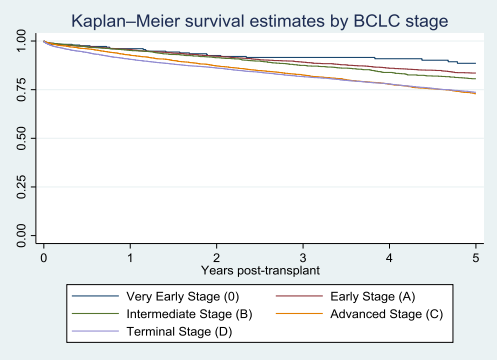

Figure:

Conclusion: These results suggest that BCLC stagie should be reassessed at LT to prognosticate risk of post-LT mortality and HCC recurrence. This can aid clinicians in determining optimal surveillance strategies for disease monitoring and recurrence.

THU-509
Outcomes in patients with new-onset atrial fibrillation after liver transplantation using the national readmission database

Induja Nimma[1], Anand Maligireddy[2], Denise Harnois[1], Rohan Goswami[3]. *[1]Mayo Clinic Florida, Gastroenterology and Hepatology, Jacksonville, United States; [2]Mayo Clinic Arizona, Cardiovascular Medicine, Scottsdale, United States; [3]Mayo Clinic Florida, Cardiology and Heart Transplant, Jacksonville, United States*
Email: nimma.induja@mayo.edu

Background and aims: Atrial fibrillation (AF) increases morbidity and mortality in patients undergoing liver transplantation (LT). Outcomes data is limited on readmission in patients with new-onset AF (NOAF) after LT. We reviewed 90-day outcomes in patients utilizing the National Readmission Database (NRD).
Method: Retrospectively reviewed all adults undergoing LT between 2016 and 2019 using the NRD. Patients readmitted within 90 days were selected based on ICD-10 procedure code for LT (0FY00Z0). Patient data were abstracted from NRD, and descriptive statistics were used to determine significance with a p value of <0.05. All statistical analysis was performed using the Stata version 17.0 (StataCorp LLC, College Station, TX, USA).
Results: 31,557 patients underwent LT during our review period, with 8,449 patients (28%) readmitted within 90 days of the index transplantation hospitalization. 222 patients (2.6%) were found to

have NOAF, with 67 (43.2%) being female. The median age of NOAF LT patients was 63 (58–67) compared to those without NOAF, which was 58 (50–64) p < 0.01. Comparing NOAF to those without NOAF, we found an increased average hospital length of stay (12 days vs. 6 days), p < 0.01 (95% CI 6.2–7.1). Similarly, the average cost of care was greater in NOAF, 87,010.23 vs. 44,033.59 (US Dollars), p = 0.02 (95% CI 11,932–138,860). NOAF was also associated with increased inpatient mortality 13 deceased (6%) vs. 52 deceased (0.7%) using a multivariate mixed effect logistic regression analysis, p < 0.01 (OR 7.6, 95% CI 3–19).
Conclusion: Based on NDR data, patients in the US who undergo LT and are readmitted within 90 days have increased hospital costs and length of, as well as significantly increased risk of death if they develop new-onset AF. This data highlights risk models' potential benefit in predicting NOAF risk after LT. This may prevent adverse outcomes and increased patient mortality in this population.

THU-510
Liver Transplantation outcomes in patients following COVID-19 infection
Dinesh Jothimani[1], Mullai Ezhili[1], Radhika Venugopal[1], Hemalatha Ramachandran[1], Sathish Srinivasan[1], Ramya Paramashivam[1], Mohamed Rela[1]. [1]*Dr Rela Institute and Medical Centre, India*
Email: dinesh.jothimani@relainstitute.com

Background and aims: COVID-19 can be associated with deleterious effects in patients with underlying chronic liver disease. However, the clinical impact of COVID-19 in patients who undergo LT following recovery from the infection is unclear. This study aimed to compare patients who underwent LT following recovery from COVID-19 to those underwent LT without COVID-19.
Method: A retrospective study of patients who underwent LT following recovery from COVID-19 illness between January 2020 and December 2021 carried out and compared with MELD matched LT recipients without COVID in a 1:1 ratio. Demographics, clinical presentation, post-operative events, allograft dysfunction and laboratory parameters at week 1, month 1 and 3 compared between the groups. Data analysis done using SPSS v24.
Results: 35 patients underwent LT after COVID illness with a median time of 94 (IQR 58–153) days, Most common etiology was NASH (N = 31.4% vs 37.14%). Mean age 51.23 vs 52.26, p = 0.620), MELD at the time of LT (18.03 vs 18.03, P = 1). Post-operative variables showed ventilator days (mean 3.2 ± 5.346 vs 2.17 ± 0.707 p = 0.95), ICU (11.14 ± 7.826 vs 8.23 ± 7.42 days, P = 0.097) and hospital stay (mean, 18.34 ± 7.82 vs 11.14 ± 6.28, days; P = 0.045) between COVID-LT and non-COVID-LT groups. Post-operative events showed ACR (5.7%vs 8.6% P = 1), AKI (37.1%vs 25.7%, P = 0.44.), early allograft dysfunction (17.1% vs 22.9%, P = 0.766), pleural effusion (25.7% vs 5.7%, P = 0.045) between two groups, respectively.
Conclusion: Patients who recovered from COVID-19 illness had comparable outcome following LT akin to those with no COVID in MELD matched recipients.

Email: m-meszaros@chu-montpellier.fr

Background and aims: Long-term outcomes of patients with chronic liver disease (CLD) who undergo liver transplantation (LT) in the intensive care unit (ICU) have been poorly reported. We aimed to investigate it and to evaluate the impact on organ utility.
Method: The study was allowed by the French LT organism (Agence de la Biomédecine). All patients with CLD who underwent LT alone between 2008 and 2013 in France were retrospectively included. Data were extracted from the CRISTAL national database. Patients ≤18 years old or who underwent LT in the context of unknown liver disease, secondary malignancy of the liver or primary non-function of the graft were excluded from the analyses. We evaluable organ failure was defined by EASL CLIF-OF criteria.
Results: 5532 patients fulfilled the inclusion criteria including 5236 (94.7%) with CLD and 296 (5.3%) transplanted in the context of fulminant hepatitis (FH). Among them, 708 patients with CLD (12.8%) and 253 (4.6%) with FH were transplanted while in ICU with a median follow-up of 6.1 years. The main causes of LT for CLD-ICU patients were alcohol-related (n = 288, 40.7%) and viral-related cirrhosis (n = 148, 20.9%). Their median age was 54 years old with a median MELD score of 30.8. At the time of LT, 42% were under mechanical ventilation, 31.2% had renal failure (22.0% treated with renal replacement therapy), 63.3% had liver failure and 43.4% had coagulation failure. The 5-year survival was 64.3% in CLD-ICU patients vs. 78.1% in patients with CLD transplanted outside of ICU (CLD-non-ICU, p < 0.0001) and 72.6% in patients with FH (p = 0.09). In CLD-ICU patients, 169/246 deaths (68.7%) occurred within the 1st year following LT. After the 1st year, the annual risk of death was 3.5% vs. 3.1% (p = 0.4) in CLD-ICU and CLD-non-ICU respectively. At the time of LT in CLD-ICU patients, factors independently associated with 5-year survival in multivariable analyses were age (p = 0.04), MELD score (p = 0.05), mechanical ventilation (p = 0.002), and liver failure (p = 0.04). There was a trend toward an independent association of 5-year survival with the timeframe of LT (with better survival observed when LT was performed in the two last years (68% vs. 61.8%, p = 0.06). Causes of death were different between CLD-ICU vs. CLD-non-ICU patients (p < 0.0001) with infection being the leading cause of death (37.2% vs. 20.5%) and cancer being less frequent (9.5% vs. 20.8%).

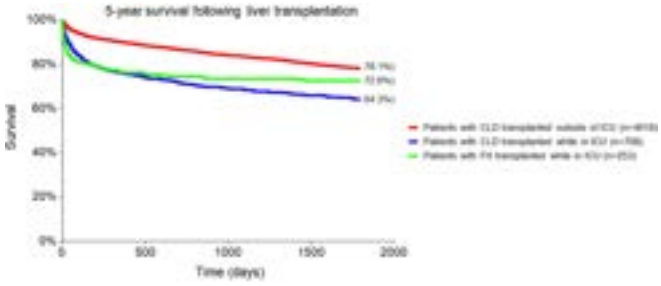

Figure: 5-year survival following liver transplantation according to the presence of chronic liver disease and intensive care hospitalization.

Conclusion: CLD-ICU patients had a poorer 5-year survival rate as compared to CLD-non-ICU patients. This was explained by an increased mortality risk at 1 year with infection being the main driver of mortality. After 1-year the annual risk of death was not different. Research should focus on predictors of early mortality as well as on the prevention of infectious events in these patients to improve organ utility.

THU-512

Validation of MELD3.0 in two centres from different continents

Marta Tejedor Bravo[1], José Bellón[2], Margarita Fernández-de la Varga[3], Peregrina Peralta[4], Eva Montalvá[3], Nazia Selzner[4], Marina Berenguer[3]. [1]*Hospital Infanta Elena, Valdemoro, Spain;* [2]*Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain;* [3]*La Fe University and Polytechnic Hospital, València, Spain;* [4]*Toronto General Hospital, Toronto, Canada*
Email: marina.berenguer@uv.es

Background and aims: A new scoring system, MELD3.0, has been proposed to stratify patients on the liver transplant (LT) waiting list (WL), as it seems to reduce the historical disadvantage of women in accessing LT. Our aim was to validate MELD3.0 in our populations.
Method: a 2 centre retrospective review of medical charts of all adult patients included in the LT WL between 2015 and 2019 was conducted. Variables related to patient's demographics, liver function, etiology of liver disease and survival were collected.
Results: 619 patients were included, 61% were male, mean age 56 years. Mean MELD at inclusion was 18.00 ± 6.88, MELDNa 19.78 ± 7.00, MELD3.0 20.39 ± 7.25 (MELD3.0 only available for 548 patients). AUC to predict mortality on the WL was 0.8791 (95% CI 0.81965, 0.93850) for MELD, 0.9212 (95% CI 0.87571, 0.96661) for MELDNa and 0.9439 (95% CI 0.91160, 0.97611) for MELD3.0. MELDNa and MELD3.0 were better predictors than MELD ($p = 0.06$ and $p = 0.04$ respectively). In women, AUD for MELD was 0.8348 (95% CI 0.74380, 0.92575), for MELDNa 0.8732 (95% CI 0.78544, 0.96104) and for MELD3.0 0.9166 (95% CI 0.86975, 0.96345), differences for the comparison between AUC in women vs men for all 3 scores were non-significant. Better survival was found in the european cohort, attributable to shorter WL times (212 ± 426 vs 649 ± 821 days respectively, $p < 0.001$) and less severely ill patients (patients on pressors or intubated at the time of LT were 0.7 vs 4.4% and 0 vs 5.3% respectively, $p < 0.05$ for both comparisons), although no differences in postLT survival were observed. In particular, no differences in postLT survival between women and men were found. Etiology of liver disease was significantly different between the two cohorts, with a predominance of alcohol (56%) and virus related (34%) liver disease in the European one, and alcoholic (35%) and non-alcoholic (24.6%) fatty liver disease, followed by viral (18%) and primary sclerosing cholangitis (14.7%), being the leading causes in the Canadian cohort.
Conclusion: MELD3.0 has been validated in centers with significant heterogeneity and offers the highest mortality prediction for women on the WL without disadvantaging men.

THU-513

Pre-transplant mycophenolate mofetil may be associated with reduced intrahepatic cholangiopathy in ABO-incompatible liver transplantation

Jinsoo Rhu[1], Gyu-Seong Choi[1], Jong Man Kim[1], Jae-Won Joh[1].
[1]*Samsung Medical Center, Korea, Rep. of South*
Email: jsrrules@gmail.com

Background and aims: Intrahepatic cholangiopathy is a life-threatening sequela of ABO-incompatible liver transplantation. We analyzed the clinical impact of pre-transplant administration of mycophenolate mofetil in reducing intrahepatic cholangiopathy in ABO-incompatible liver transplantation.
Method: Patients who underwent living donor liver transplantation between 2010 and April 2022 were included. Pre-transplant mycophenolate mofetil was started in November 2020. A comparison between patients who experienced intrahepatic cholangiopathy and who did not among ABO-incompatible transplantation was performed. Recipients of ABO-incompatible transplantations were categorized based on donor surgery into open, laparoscopy without pre-transplant mycophenolate mofetil, and laparoscopy with pre-transplant mycophenolate mofetil groups. Cox analysis of intrahepatic cholangiopathy was performed.
Results: A total of 234 ABO-incompatible transplantations were included. Intrahepatic cholangiopathy occurred in 1.1% (n = 1/94), 13.3% (n = 12/90) and 2.0% (n = 1/50) of patients who received an ABO-incompatible liver with open surgery, laparoscopic donor surgery without pre-transplant mycophenolate mofetil and laparoscopic donor surgery with pre-transplant mycophenolate mofetil. ($p = 0.001$) Multivariable analysis showed that transplantations involving a donor who underwent a laparoscopic hepatectomy and a recipient who did not receive pre-transplant mycophenolate mofetil were associated with a higher risk of intrahepatic cholangiopathy (HR = 13.449, CI = 1.710–105.800, $P = 0.02$) compared to transplantations from donors who underwent open surgery. Transplantations involving a donor who underwent laparoscopic donor surgery and a recipient who received pre-transplant mycophenolate mofetil resulted in no increased risk compared to transplantations from donors who underwent open surgery. (HR = 5.307, CI = 0.315–89.366, $P = 0.25$)
Conclusion: Laparoscopic donor hepatectomy was a risk factor for intrahepatic cholangiopathy in ABO-incompatible liver transplantation while pre-transplant mycophenolate mofetil was related to risk reduction of intrahepatic cholangiopathy.

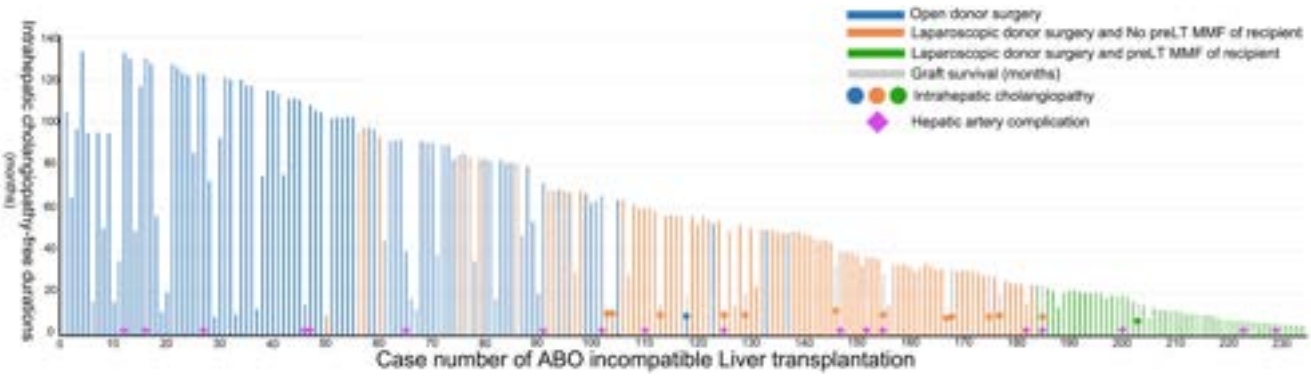

Figure: (abstract: THU-513): Intrahepatic cholangiopathy-free survival according to the case number of ABO-incompatible living donor liver transplantation cases as demonstrated in different groups.

THU-514

Prevalence of renal dysfunction is higher in patients that receive a liver transplant for non-alcoholic steatohepatitis

Rubén Sánchez-Aldehuelo[1,2,3,4], Margarita Papatheodoridi[1,2], Agustin Albillos[3,4], Emmanuel Tsochatzis[1,2]. [1]*Royal Free Hospital, London (United Kingdom), United Kingdom;* [2]*Institute for Digestive and Liver Health. University College London (UCL), United Kingdom;* [3]*Hospital Universitario Ramón y Cajal, Madrid (Spain), Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Spain;* [4]*Universidad de Alcalá, Spain*
Email: ruben.sanchez.aldehuelo@gmail.com

Background and aims: Renal dysfunction (RD) is common among liver transplant (LTx) recipients and is associated with worse long-term outcomes. In patients with non-alcoholic steatohepatitis (NASH), additional well-known risk factors for developing RD are present prior to LTx such as diabetes mellitus, hypertension or obesity. We aimed to: i) Investigate the prevalence of pre-LTx RD; ii) Assess the development of RD post-LTx and iii) Identify predictors of RD in such patients.
Method: Retrospective analysis of prospectively collected data of patients that received a LTx at the Royal Free Hospital (London, United Kingdom) between 01/1995 and 04/2022. Patients were considered as NASH cirrhosis if registered as such in the National Database records or if diagnosed with cryptogenic cirrhosis and a BMI ≥30 kg/m^2 or BMI ≥25 kg/m^2 and diabetes. Patients who died during LTx or early after were excluded. RD was defined as glomerular filtration rate (GFR) <60 ml/min/1.73 m^2. Demographic and clinical features were collected from clinical records. A cohort of non-NASH cirrhotic patients transplanted from 01/1995 to 09/2013 was also considered for the aim of the study.
Results: NASH was the primary etiology of cirrhosis in 140/2090 (6.7%) LTx performed. Sixteen patients (11.4%) were excluded because of early post-LTx death and 14 (10%) were lost to follow-up (FU). Finally, 124 patients were included (76.6% males; mean age 59.2 ± 6.8 years; median FU 49.47 months [22.85–102.35]). Diabetes was present in 75% and hypertension in 34.7% pre-LTx. RD was present in 60% and 65.8% at 1 year and at FU respectively. In the multivariate analysis (Figure) we found age, pre-LTx RD, creatinine, presence of varices, ascites and gastrointestinal (GI) bleeding as predictors of RD at 1 year. The NASH group showed a lower GFR compared with other etiologies of cirrhosis (56 vs 63; p < 0.001 and 63 vs 55 ml/min; p < 0.001) at 1 year and FU, respectively. In the logistic regression, NASH was associated with a higher risk of RD during post-LTx FU (OR = 2.511; p < 0.001). After propensity-score matching (PSM) adjustment for age, sex and presence of diabetes and hypertension, no differences for RD at 1 year or at the end of FU were found between NASH and PSM non-NASH LTx recipients (47.5% vs 40.3%; p = 0.24 and 50.8% vs 50.8%; p = 1, respectively).

	One year OR (95% CI)	p	Last FU OR (95% CI)	p
Age	**1.08 (1.02-1.15)**	**0.01**	1.03 (0.99- 1.06	0.075
Sex	0.64 (0.25-1.65)	0.35	0.71 (0.46-1.11)	0.13

OR: odds ratio; 95% CI: 95% confidence interval; BMI: body mass index; Cr: creatinine.				

Figure: Multivariate analysis showing predictors of renal dysfunction at 1 year and last FU in patients with NASH cirrhosis

Conclusion: RD at 1 year and FU is higher in patients transplanted with NASH-cirrhosis compared to other etiologies. Several pre-LTx factors may predict the development of RD in this group of patients.

THU-515

Comparing clinical outcomes of robot-assisted versus open hepatectomy for liver cancer: a systematic review and meta-analysis

Muhammed Elfaituri[1], Ala Khaled[1], Ahmed BenGhatnsh[2], Ahmed Elfaituri[1], Hazem Faraj[1], Ahmed Msherghi[1]. [1]*University of Tripoli, Faculty of Medicine, Tripoli, Libya;* [2]*National Heart Centre, Tajoura, Libya*
Email: dr.muhammed.khaled.elfaituri@gmail.com

Background and aims: Liver cancer is a major contributor to cancer-related deaths worldwide. Surgical management of liver tumors remains a challenge, with both open hepatectomy and robot-assisted hepatectomy being commonly used. This systematic review and meta-analysis compare the clinical outcomes of these two surgical techniques.
Method: A comprehensive search of electronic databases, including PubMed, Embase, and the Cochrane Library, was conducted to identify eligible studies comparing robot-assisted and open hepatectomy for liver tumors. The search was conducted up to January 2023. The primary outcome measures were operative time, blood loss, length of hospital stay, and overall complications. The meta-analysis was performed using R version 4.0.3 and the metafor and meta packages.
Results: Seven studies with a total of 368 patients who underwent robot-assisted hepatectomy and 648 patients who underwent open hepatectomy met the inclusion criteria and were included in the meta-analysis. The results showed that robot-assisted hepatectomy was associated with longer operative time (SMD 1.65, 95% CI 0.53 to 2.75, p < 0.01, I^2 = 98) but lower blood loss (SMD −0.39, 95% CI −0.55 to −0.25, p < 0.01, I^2 = 0) compared to open hepatectomy. Length of hospital stay was also significantly shorter in the robot-assisted group (SMD −1.7, 95% CI −2.7 to −0.43, p < 0.01, I^2 = 98). There was no significant difference in the need for blood transfusions between the two groups (RR 1.02, 95% CI 0.38 to 2.71, p = 0.98, I^2 = 60%). Resection margins and overall complication rates did not show significant differences between the two approaches (SMD – 0.08, 95% CI −0.25 to 0.102, p = 0.4, I^2 = 0 and RR 0.77, 95% CI 0.56 to 1.05, p = 0.1, I^2 = 6%, respectively).
Conclusion: This systematic review and meta-analysis suggest that robot-assisted hepatectomy is associated with longer operative time, but shorter hospital stays, and lower blood loss compared to open hepatectomy for liver tumors. Further high-quality studies are needed to confirm these findings and assess the long-term outcomes of the two surgical techniques.

Association between waiting time and post-transplant survival in recipients with hepatocellular carcinoma outside Milan criteria after downstaging with locoregional therapy

Zoljargal Lkhagvajav[1], Elliott Haut[2], Uurtsaikh Baatarsuren[3], Betsy King[2]. [1]*Onom foundation-Оном сан, Ulaanbaatar, Mongolia;* [2]*The Johns Hopkins University School of Medicine, Baltimore, United States;* [3]*Onom foundation-Оном сан, Ulaanbaatar, Mongolia[NT1]*
Email: zoljargal.l@onomfoundation.org

Background and aims: Prior studies show conflicting results on the association between waiting time and post-transplant survival among patients with hepatocellular carcinoma (HCC). We aimed to assess the association between waiting time and post-transplant survival in recipients with HCC outside Milan criteria after down-staging with locoregional therapy and identify factors that are associated with higher post-transplant survival.
Method: Using the Scientific Registry of Transplant Recipients (SRTR) database, we retrospectively analyzed 5-years post-transplant survival of all adult patients who had HCC outside Milan criteria and received liver transplantation (LT) between January 1, 2010, and December 31, 2021, after downstaging with LRT and with information about their tumor size and number. According to their waiting time,

recipients were divided into three groups: <6 months, 6–12 months, and >12 months. Kaplan-Meier method and a log-rank test were used to assess survival. Univariable and multivariable Cox regression was used to identify factors associated with post-transplant mortality.

Results: A total of 479, 439, and 307 recipients were included in the waiting time group of <6 months, 6–12 months, and >12 months respectively. We conclude that there is no statistically significant difference among the three waiting time groups in terms of post-transplant survival (HR 1.4; 95% CI 1.03–1.91; p = 0.03; HR 1.17; 95% CI 0.83–1.66; p = 0.37 and log-rank p = 0.12). Waiting time of <6 months prior to LT put the patients at a significantly higher risk of mortality compared to a waiting time of 6–12 months (HR, 1.4; 95% CI 1.03–1.91; p = 0.03). Being in the higher median serum alfa-fetoprotein (AFP) level groups (HR, 1.37; 95% CI 1.02–1.79 and HR, 1.37; 95% CI 1.02–1.79) was associated with a higher risk for post-transplant mortality.

Table 2. Univariate and multivariate Cox regression analysis for 5-year survival in recipients with HCC Outside Milan Criteria After Downstaging with Locoregional Therapy

Conclusion: To our knowledge, there hasn't been any study that measured the association between waiting time and post-transplant survival among recipients who presented HCC outside Milan criteria and downstaged through LRT before receiving LT. Thus, we aimed to evaluate the association among these patients and find factors that are associated with post-transplant survival. Our findings show that a waiting time of <6 months was associated with 1.4 times increased hazard of mortality compared to a waiting time of 6–12 months. We found that a higher median serum AFP level is associated with a higher risk for post-transplant mortality. Although, the generalizability of this study is affected by the small size of the study population and the selection criteria. As we included patients who were responsive to LRT and successfully downstaged within Milan criteria, it can be implied that these patients had good tumor biology and the result of the current study could not be generalized to all patients who present with HCC outside Milan criteria. Our study indicates that it is important to consider the tumor biology for post-transplant survival and serum AFP level can be used as an indicator for tumor biology and subsequently an indicator for post-transplant survival. The result is consistent with the existing literature that the higher serum AFP level is associated with a higher risk for mortality after LT among patients with HCC. Further research is needed to assess the association with a bigger sample size, possibly in another country where the HCC patients are diagnosed at a more progressed stage and the prevalence of HCC outside Milan criteria is higher.

THU-517

CMV reactivation after liver transplantation (LT) in HIV infected is similar to non-HIV patients: a single center comparative study

Sonia García-García[1], Isabel Terol Cháfer[1], Víctor Argumánez Tello[1], Carmen Vinaixa[1,2], Javier Maupoey[1], Marino Blanes Julia[1], Angela Carvalho Gomez[1], Marina Berenguer Haym[1,2,3], Victoria Aguilera Sancho[1,2]. [1]*Hospital Universitario y Politécnico La Fe, Valencia, Spain;* [2]*CIBERehd, Instituto Carlos III, Madrid, Spain;* [3]*Universidad de Valencia, Facultad de Medicina, Spain*
Email: soniagg1995@hotmail.com

Background and aims: Cytomegalovirus (CMV) reactivation after liver transplant (LT) has been associated with poor outcomes. There is no evidence of a higher rate of CMV reactivation or disease in HIV-infected patients. Our aim was to describe the CMV reactivation, primary infection and need of antiviral treatment in HIV-infected LT patients, compared to non-HIV-infected LT patients.

Method: We included patients who underwent LT from June 2004 to December 2020 in a single LT center. Each HIV-infected patient was matched to 2 non-HIV infected controls by age, sex, liver disease etiology, and date of LT. Pre-LT baseline features, HIV related variables, and post-LT outcomes related to CMV were recorded. Patients at donor/recipient (D/R) missmatch high risk (D +/R –) were given prophylaxis with valganciclovir. The rest of the patients were followed with a "preemptive" strategy and received early treatment based on clinical criteria.

Results: A total of 156 LT recipients were included (52 HIV-infected and 104 non-HIV-infected). Baseline characteristics were similar in both groups (see figure 1), except for age and body mass index, which were lower in HIV-infected patients. Mean follow-up post-LT was 7.5 years in the HIV group vs 8.2 years in the non-HIV group. CMV reactivation occurred in 10 (20%) in HIV vs 24 (24%) in non-HIV and CMV disease occurred in 2 (2%) non-HIV and 1 (2%) HIV (p 0.521 and 0.687).The need for preemptive treatment was 11.5% in the HIV group and 14% in the non HIV group (p 0.8).

Mean CMV viral load (VL) at reactivation was 2518 in HIV-patients and 5453 in non-HIV (p 0.47); and mean high CMV VL was 5435 in HIV and 9263 in non-HIV (p 0.36). Time to reactivation was 6, 8 weeks in the HIV-patients group and 8 weeks in non-HIV patients. Factors significantly associated with CMV reactivation were D/R missmatch (p 0.006) and recipient's age (p 0, 037). Factors such as HIV condition, CD4 count, MELD and hepatocarcinoma were not associated with CMV reactivation (p 0.85).

	HIV (n = 52)	Non HIV (n = 104)	p
Age at LT (mean) (years, range)	48 (33-60)	52 (25-70)	0.002
Sex (Men) (%)	88%	87%	0.866
HCV	92%	86%	0.266
HCC	33%	40%	0.350
BMI at LT (mean)	24.8	27.1	0.0016
MELD at LT (mean)	18	17	0.21
Diabetes preLT	22%	18%	0.625
Arterial hypertension preLT	10%	13%	0.489
Dislipidemia preLT	8%	5%	0.466

Figure:

Conclusion: In the post-LT setting, CMV reactivation in HIV-infected patients was similar to non-HIV patients. Variables associated with reactivation were D/R mismatch and recipient's age. Preemptive strategies seem to be effective in both groups.

THU-518

Development of metabolic disorders in transplant recipients

Gizem Erdemir[1], Hale Gokcan[2], Ayşegül Gürsoy Çoruh[3], Basak Gulpinar[3], Zeynep Melekoğlu Ellik[4], Mesut Gümüşsoy[5], Serkan Duman[6], Emin Bodakçi[2], Ramazan Idilman[2]. *[1]Ankara University School of Medicine, Internal Medicine, Turkey; [2]Ankara University School of Medicine, Gastroenterology and Hepatology, Turkey; [3]Ankara University School of Medicine, Radiology, Turkey; [4]Karaman Training and Research Hospital, Gastroenterology and Hepatology, Turkey; [5]Gaziantep Şehitkamil Public Hospital, Gastroenterology and Hepatology, Turkey; [6]Mersin Toros Public Hospital, Gastroenterology and Hepatology, Turkey*
Email: halesumer@yahoo.com

Background and aims: Metabolic syndrome (MS) is the most common long-term complication after liver transplantation. The aim of this study was to assess the prevalence and risk factors for metabolic syndrome (MS) and its component after living donor liver transplantation (LDLT).
Method: A total of 114 adult patients listed for liver transplantation (LT) between 2005 and 2021with a minimum follow-up of one year were included. Demographics, laboratory and computed tomography data were collected pre and post-transplant.
Results: Mean age was 56.0 ± 11.5 and 63% were male. LDLT was performed on 88 (77%) patients. Fourty-six (40%) patients were smokers. HBV infection (36%) was the main indication. The majority of the patients (n = 101, 89%) were on tacrolimus-based treatment. Median follow-up period after LT was 7.5 year (range 1–20 year). In post-transplant period; BMI was 27.8 kg/m^2, 29.7% of them were obese. Thirty-two (28%) patients developed new-onset DM (NODAT), 60.1% hypertension, 40.7% hyperlipidemia, and 51.3% MS (Table 1). The post-transplant median atherosclerotic cardiovascular disease (ASCVD) risk score was 16.5. Sixteen patients (14%) had a history of a cardiac event post-transplant. The mean posttransplant HbA1C, waist and hip circumference were 6.22 ± 1.57, 104.2 ± 15.3 and 109.4 ± 12.5 respectively. Post-transplant hypertension, diabetes, antihypertensive and antidiabetic drug use, ASCVD score and BMI were higher in post-transplant MS. Posttransplant median visseral adipose tissue (VAT), subcutaneous tissue (SAT), total fat area (TFA) and VAT/SAT were 146.8 cm^2 (12.6–484.4), 169.3 cm^2 (22.7–527.5), 348.1 cm^2 (40.9–744.8) and 0.76 (0.1–4.2). In the MS present group, the median VAT, VAT/SAT and TFA were 171.7 cm^2 (29.9–484.4), 0.82 (0.23–4.21) and 400.8 cm^2 (62.3–744.8) respectively, which were higher than in the non-metabolic syndrome group 103.0 cm^2 (12.6–340.8), 0.63 (0.1–4.2) and 314.4 cm^2 (40.9–653.4) (p = 0.002, p = 0.06, and p = 0.005).SAT in the MS and non-MS group were 201.6 cm^2 (32.4–527.5) and 156.1 cm^2 (22.7–448.7) respectively (p = 0.06).
Conclusion: Metabolic disorders are frequent complications after liver transplantation and a high VAT, VAT/SAT and TFA are at increased risk for developing MS. The high incidence of MS and its components in our sample highlights the importance of closely and carefully monitoring for development of MS and its complications.

THU-519

Tailored immunosuppression with LCPT extended release Tacrolimus based on NFAT-regulated gene expression

Judith Kahn[1], Eva Matzhold[2], Petra Ofner-Kopeinig[3], Peter Schlenke[2], Peter Schemmer[4]. *[1]General, Visceral and Transplant Surgery, Graz, Austria; [2]Department of Blood Group Serology and Transfusion Medicine, Graz, Austria; [3]Institute for Medical Informatics, Statistics and Documentation, Graz, Austria; [4]General, Visceral, and Transplant Surgery, Graz, Austria[NT2]*
Email: judith.kahn@medunigraz.at

Background and aims: There is a narrow therapeutic window for immunosuppression (IS) with calcineurin (CNI) inhibitors. The immunosuppressive effect of CNIs differs between individuals. Therefore, the drugs' trough levels do not reflect IS and should be replaced by pharmacodynamic monitoring. Since nuclear factor of activated T-cells (NFAT)-depending gene expression correlates with cyclosporine induced IS, this study was designed to evaluate the effect of LCP extended release tacrolimus (Tac) on NFAT regulated residual gene expression (RGE).
Method: Gene expressions of interleukin-2, interferon-γ and granulocyte-macrophage colony-stimulating factor and three reference genes were measured with droplet digital polymerase chain reaction (ddPCR) in whole blood samples at day 2, 7, 14, month 1 and 6 until 1

Figure: Table 1. Demographics and laboratory data of pre and post transplant period

	Pre-transplant	Post-transplant

Table: (abstract: THU-518).

year after LT in 23 patients transplanted between February 2019 and June 2020. The RGE after Tac intake was calculated as $c_{peak}/c_0 \times 100$, where c_0 is the adjusted number of transcripts at the Tac predose level and c_{peak} is the number of transcripts at peak level. IS consisted of LCPT extended-release Tac introduced directly after LT, mycophenolic acid, and a corticosteroid-taper for 3 months.

Results: Tac peak levels and NFAT-RGE showed a strong inverse correlation ($r = -0, 8$). Our descriptive analysis shows that although patients show a Tac trough level within the targeted therapeutic window, low RGE can result in a higher risk for infection. Mean individual trough effect of Tac on the 3 target genes with all timepoints pooled was 33% (26–56%) in patients without infection and 81% (53–95%) in patients with infection ($p < 0.011$), mean individual peak effect was 48% (44–64%) in patients without infection and 91% (90–94%) in patients with infection ($p < 0.001$).

Conclusion: Tailored IS monitored with NFAT-RGE is promising to decrease infectious complications by optimization of the IS level in LT recipients on LCP extended release Tac.

Long-term survival after liver transplantation in patients with common variable immunodeficiency

Ina Andersen[1,2], Henrik Reims[3], Krzysztof Grzyb[3], Børre Fevang[1,4], Espen Melum[2,5,6], Pål Aukrust[1,7,8], Kristine Wiencke[2], Ingvild Nordøy[1,7], Pål-Dag Line[8,9], Silje Jørgensen[1,7]. *[1]Section of Clinical Immunology and Infectious Diseases, Department of Surgery, Inflammatory Medicine and Transplantation, Oslo, Norway; [2]Section of Gastroenterology, Department of Surgery, Inflammatory Medicine and Transplantation, Oslo, Norway; [3]Oslo universitetssykehus HF, Rikshospitalet, Department of Pathology, Oslo, Norway; [4]Centre of Rare Diseases, National Advisory Unit on Rare Disorders, Oslo, Norway; [5]Norwegian PSC research centre, Department of Surgery, Inflammatory Medicine and Transplantation, Oslo, Norway; [6]Hybrid Technology Hub Centre of Excellence, Institute of Basal Medical Sciences, Oslo, Norway; [7]Research Institute of Internal Medicine, Department of Surgery, Inflammatory Medicine and Transplantation, Oslo, Norway; [8]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo; Norway, [9]Division of Transplant Surgery, Department of Surgery, Inflammatory Medicine and Transplantation, Oslo, Norway*
Email: inaand@ous-hf.no

Background and aims: A considerable proportion of patients with common variable immunodeficiency (CVID) have inflammatory and autoimmune complications. This can include liver disease with development of nodular regenerative hyperplasia (NRH) leading to portal hypertension and end-stage liver disease. We sought to assess the long-term outcome after liver transplantation (LTX) of patients with CVID.

Method: Information was retrieved from the Nordic liver transplant registry and the patients' medical records at Oslo University Hospital (OUH) until December 31st 2021.

Results: Between 2009 and 2021, six patients with CVID underwent LTX at OUH. Patient characteristics and indications for LTX are summarized in table 1. All patients had NRH in the explanted liver and none was hepatitis C positive. All patients received our standard initial immunosuppression after LTX which includes prednisolone, tacrolimus and mycophenolate. Table 1 gives an overview of complications and outcome after LTX. Five of the six patients are still alive after an observational time of 4–12 years with median survival 7.5 years. Of the three patients who underwent LTX due to hepatopulmonary syndrome, one is currently well without need for extra oxygen therapy 4 years after LTX, one underwent a lung-transplantation 6 years after LTX due to relapse of pulmonary shunt-related respiratory failure and one is deceased. Patient 2 died suddenly and unexpectedly 6 years after LTX without signs of liver failure, infection or chronic respiratory failure. Two patients (Patient 1 and 4) have developed signs of increased portal vein pressure including one case of severe upper gastrointestinal bleeding, but no other complications of chronic liver disease have been noted. Four patients have had a graft biopsy, all with findings of de-novo NRH. All patients who are still alive have slightly elevated transaminases and/or cholestatic markers. All six patients have had bacterial infections post-LTX, but based on small numbers it's difficult to conclude if there are more infectious complications in CVID post-LTX compared to other liver recipients. Airway and GI infections may be CVID related, whereas urinary tract infections are not, and none of these infections resulted in severe morbidity or death following LTX. Overall survival rate was 83% after 4–12 years post-transplant observation, which is comparable with overall post LTX survival in the Nordic countries for conventional transplant indications.

Conclusion: Our report shows that CVID patients may obtain overall survival fully comparable to conventional indications for LTX. These patients have a dismal prognosis without transplant. Hence, CVID with severe liver failure should not be considered a contraindication to LTX.

Patient no	Age at LTX	Sex	CVID-related complications	Year of LTX	Cause of LTX	MELD-Na	Infections				Vascular complications	Miscellaneous	Rejection	Survival (years)

Porto-pulmonary hypertension in patients considered for liver transplantation: a cohort study

Ilaria Curro[1], Declan Lewis[2], Tasneem Pirani[3], Robert Loveridge[3], Varuna Aluvihare[4], Krishna Menon[5], William Bernal[3], Christopher Willars[3], Mark Mcphail[3], Julia Wendon[3], Georg Auzinger[3], Sameer Patel[3]. *[1]King's College Hospital, Department of Critical Care, United Kingdom; [2]Institute of Liver Studies, King's College Hospital, Department of Hepatology, United Kingdom; [3]Liver Intensive Therapy Unit, King's College Hospital, Consultant in Critical Care, United Kingdom; [4]Institute of Liver Studies, King's College Hospital, Consultant Transplant Hepatologist, United Kingdom; [5]Institute of Liver Studies, King's College Hospital, Consultant Transplant Surgeon, United Kingdom*

Email: declan.lewis@nhs.net

Background and aims: Porto-pulmonary hypertension (PoPH) is a rare cardiovascular complication of portal hypertension and carries significant morbidity and mortality both in the pre- and post-liver transplant (LT) groups. The aim of this study is to assess the efficacy of therapeutic interventions and outcomes in PoPH patients in transplanted and non-transplanted cohorts.

Method: Retrospective review of health records of adult patients with PoPH in a large tertiary centre over an 18-year period.

Results: Records of twenty adult patients diagnosed with PoPH between January 2005 and December 2022 were analysed. Mean age was 48.8 years (SD: ±10.2); male 14 (70%); MELD and UKELD scores were 16.1 (SD ±7.1) and 53.5 (SD ±5.3) respectively; 18 (90%) had cirrhosis; 6 (30%) carried a dual diagnosis of PoPH and hepatopulmonary syndrome. Ten (50%) patients had severe PoPH at diagnosis (mean pulmonary artery pressures (mPAP) >45 mmHg); 7 (35%) moderate (35–44 mmHg); and 2 (10%) mild (25–34 mmHg). MPAP before initiation of monotherapy was 46.1 mmHg (SD ±12.3), decreasing to 39.8 mmHg (SD ±11.7) post-treatment (6.3% reduction; $p < 0.05$). MPAP prior to dual therapy was 51.8 mmHg (SD ±6.1) decreasing to 35.9 mmHg (SD ±15.5) post-treatment (15.9% reduction; $p < 0.05$). Normalization of mPAP was achieved in 1 (5%) patient following initiation of pharmacological therapy; 8 (47%) patients improved to mPAP <35 mmHg. Overall, 13 (65%) patients were assessed for LT; five (25%) patients were deemed too unwell for formal transplant assessment; transplantation was not indicated in two (10%) patients due to relative preservation of native liver function. Twelve patients were listed (two were de-listed due to the development of contra-indications). One patient was declined for transplant due to prohibitive underlying cardiovascular risk factors. Median transplant free survival was 19 months (IQR 8–28); median survival in transplanted group was 33 months (IQR 19–54), with 1 year survival 69.2% and 71.4%, respectively. No patients died on the waiting list.

Conclusion: Dual therapy strategies appear to be superior to monotherapy for reduction in mean pulmonary artery pressures in patients with PoPH. However, despite improvement in pulmonary haemodynamics post initiation of pharmacological therapy, outcomes in both transplanted and non-transplanted cohorts remain suboptimal. Further studies are required to assess the impact of dual versus monotherapy on post-transplant outcomes.

THU-522

Liver transplantation in patients with cystic fibrosis: 30 years of experience in Australia and New Zealand

Thomas Wilson[1], Toni Illhardt[1], Michael Fink[2,3], Robert Jones[2], Anastasia Volovets[4], Mandy Byrne[2], Mark Oliver[1,3]. [1]*The Royal Children's Hospital Melbourne, Parkville, Australia;* [2]*Austin Hospital, Heidelberg, Australia;* [3]*University of Melbourne, Parkville, Australia;* [4]*Royal Prince Alfred Hospital, Camperdown, Australia*
Email: tom.wilson3@rch.org.au

Background and aims: Liver transplantation has emerged as an effective treatment strategy in patients with Cystic Fibrosis-related liver disease (CFLD) who develop features of hepatic decompensation or intractable variceal bleeding. We aimed to review the outcomes of patients within our region who had undergone liver transplantation for CFLD.
Method: We utilised the Australia and New Zealand Liver and Intestinal Transplant Registry (ANZLITR) to retrospectively review data from all patients in Australia and New Zealand who had undergone liver transplantation for CFLD, including those who underwent liver transplantation as a component of a multi-organ transplantation.
Results: A total of 54 patients (25 children and 29 adults) underwent liver transplantation for CFLD in Australia and New Zealand between January 1989 and July 2022. Mean age at time of transplantation was 12.2 ± 4.3 years and 28.5 ± 6.0 years for the paediatric and adult groups, respectively. Thirty-six patients (67%) underwent isolated liver transplantation (22 of 25 children (88%); 14 of 29 adults (48%)). Eighteen patients (33%) underwent liver transplantation as a component of a multi-organ transplantation (combined liver-heart-lung in 8, combined liver-lung in 5, combined liver-pancreas in 4, and combined liver-pancreas-kidney in 1). Three patients underwent re-transplantation for liver graft failure. Causes of death following transplantation included pulmonary disease (12 patients), sepsis (2 patients), intra-abdominal haemorrhage (1 patient), and multi-organ failure (1 patient). The overall 5-year survival rate for the children was 92.0% (95% confidence interval [CI]: 71.6–97.9%) versus 66.2% (95% CI: 44.8–80.9%) for the adults. The 5-year survival rate for those who underwent isolated liver transplantation was 82.6% (95% CI: 65.3–91.8%) versus 67.7% (95% CI: 38.3–85.3%) for those undergoing multi-organ transplantation. Survival at 5- and 10-years after transplantation for the entire group was 78.1% (95% CI: 63.8–87.3%) and 71.0% (95% CI: 54.3–82.5%), respectively.
Conclusion: Liver transplantation remains a viable treatment option in children and young adults with CFLD. Survival outcomes are comparable to those previously reported in the literature, with superior survival rates observed among both children and those undergoing isolated liver transplantation.

THU-523

Which is the best therapy for not transplantable patients with multinodular early HCC?

Alessandro Vitale[1], Fabrizio Romano[2], Fabio Farinati[1], Franco Trevisani[3], Umberto Cillo[1]. [1]*Azienda Ospedale Università di Padova, Italy;* [2]*Università Milano Bicocca, Italy;* [3]*Università di Bologna, Italy*
Email: alessandro.vitale@unipd.it

Background and aims: The 2022 version of the BCLC staging system recommends a treatment stage migration from liver transplantation (LT) directly to trans-arterial chemo-embolization (TACE) in patients with multinodular early stage HCC, when LT is not feasible. We sought to compare the effectiveness of liver resection (LR), percutaneous radiofrequency ablation (PRA), and TACE in patients with not transplantable but potentially resectable multinodular early HCC.
Method: Only multinodular not transplantable early stage (2 or 3 nodules ≤3 cm) HCC patients were considered. LR patients were obtained from the HE.RC.O.LE.S. register, whereas PRA and TACE patients were obtained from the ITA.LI.CA register. Since the aim of this study was to compare the effectiveness of three potential treatments in resectable patients, the statistical method "matching-adjusted indirect comparison" (MAIC) was used to match the PRA and TACE groups to the LR group.
Results: Between 2008 and 2020, 655 HCC cirrhotic patients were enrolled: 303 in LR, 204 in PRA, and 148 in TACE groups. Age, sex, Charlson Comorbidity index, Child-Pugh grade, MELD, platelets count, etiology of cirrhosis, number, and diameter of nodules, and alpha-fetoprotein were weighted by MAIC to create two PRA and TACE pseudo-populations balanced with the LR group. After MAIC, 1–3–5 years OS was 88%, 71%, 56% for LR (median survival 67 months), 97%, 63%, 22% for PRA (median survival 53 months), and 88%, 58%, 32% for TACE (median survival 41 months) ($p < 0.001$). At Cox multivariable weighted regression, the survival benefit of LR over alternative treatments was confirmed: LR group as the reference; PRA (hazard ratio 1.44; 95% confidence interval 1.19–1.84; $p = 0.0045$); TACE (hazard ratio 1.70; 95% confidence interval 1.25–2.31; $p = 0.0007$).

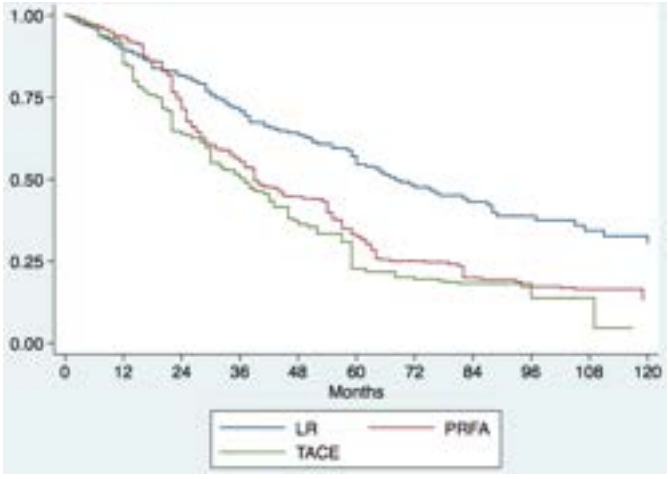

Figure: Comparison of survival curves.

Conclusion: In multinodular early, not transplantable HCC, LR should be the first option, followed by PRA and TACE only when LR is not feasible.

THU-524

Management in hepatology: cost analysis of two oppposite options for pretransplantation evaluation

Irene Peñas Herrero[1], Gloria Sánchez Antolín[1], Carmen Alonso Martin[1], Félix García Pajares[1], Carolina Almohalla Alvarez[1], Beatriz Burgueño[1], Sandra Izquierdo Santervás[2], Isabel Ruiz Núñez[1], Jorge Ruiz Rodríguez[1], Alicia San José Crespo[1], Cristina Martínez Cuevas[1], Esteban Fuentes Valenzuela[1], Soledad Sañudo García[3]. [1]*Hospital Universitario Río Hortega, Hepatology Unit, Valladolid, Spain;* [2]*Hospital Clínico Universitario, Gastrointestinal and Hepatology Department, Valladolid, Spain;* [3]*Hospital Universitario Río Hortega, Admission and Clinical Documentation Department, Valladolid, Spain*
Email: ipenash@saludcastillayleon.es

Background and aims: Pretransplantation evaluation before a liver transplant is a critical step in every liver transplant program. It stablishes the indication of liver transplant in every patient, and it detects any contraindication that risk the life of patients or the survival of liver graft. This evaluation can be done as an inpatient manner or in an outpatient clinic. In our terciary hospital, from 2011 the pretrasplantation evaluation is done in the outpatient setting with an specific hepatology clinic. It includes at least 2 onsite visits. The aim of our study is to compare the cost associating to the

pretrasplantation evaluation between conventional inpatient hospitalization and in an outpatient setting.
Method: Retrospective, single-center, observational comparison between the cost of pretrasplantation evaluation as an inpatient manner before 2011 vs the cost of the same evaluation in an external clinic specifically dedicated to pretrasplantation evaluation. We used in both periods the valid costs in 2022 to avoid introducing a bias.
Results: In total, 1789 patients were evaluated, 78.53% were male, mean age of 56.1 years (SD 7.08). The most frequent etiology of cirrhosis was alcohol-related in 54.16% of patients. Cirrhosis due to HCV infection was the second most frequent etiology in 23.53% of patients. The most common cause for referring the patient was descompensated cirrhosis and hepatocellular carcinoma in 42.29% and 37.28%, respectively. Pretrasplantation evaluation as an inpatient manner implies a length of hospitalization of a mean of 22.97 days (SD 11.75), with a cost of 9388.75 euros by patient. In outpatient clinic, pretrasplantation evaluation results in a mean of 5.1 (SD 3.64) visits of every patient, 2.2 (SD 1.67) of them were onsite visits. The total cost for every patient, including 2 morning stays in a day-hospital was 843.83 euros by patient.
Conclusion: Liver pretrasplantation evaluation in an outpatient setting and with an specific clinic reduce cost of it in a significant manner. It contributes to a better sustainability of sanitary system. Also, it cuts down iatrogenic complications, nosocomial infections, as avoiding long hospital stays. Also, it allows to preserve the usual liver transplantation activity in periods with a high stress in hospital occupancy without interfering with other diseases, like recent example of SARS-CoV-2 pandemia.

Email: afyunquera@gmail.com

Background and aims: Liver transplantation (LT) for primary sclerosing cholangitis (PSC) is conditioned by recurrence of PSC and the course of inflammatory disease (IBD). OBJECTIVES: 1) to analyse the incidence of PSC recurrence and its conditioning factors 2) to analyse the course of IBD after LT and 3) to determine the impact of both (PSC recurrence and IBD) on LT outcomes in southern European population.
Method: Retrospective multicentre study of LT indicated by PSC during 1991–2022. Recurrence of PSC was defined as cholangiopathy with patent hepatic artery and no ischaemic history. IBD activity was assessed by Mayo endoscopic index and histology. Factors associated with recurrence of PSC and outcomes after LT were determined by regression analysis.
Results: 143 patients with LT for PSC were included (68.3% male, median age at LT 46 (37–53), 28 (19.6%) of them with recurrence of PSC after median 4.17 (2–6.99). Before HT, 81 (55.9%) patients had IBD, (66 ulcerative colitis [UC]), with colectomy in 10 patients. In univariate analysis the absence of IBD was associated with a lower risk of recurrence of CEP, OR 0.17 (0.04–0.80). Gender, age, type of donation, immunosuppression (90.6% receiving tacrolimus + mycophenolate), UDCA treatment, study period (before/after 2012), IBD treatment, and colectomy before or after LT were not associated with recurrence. Recurrence of PSC was more frequent in UC vs Crohn's (64.3% vs 3.6%, p = 0.02) and was associated with the development of cholangitis (OR 7.43 (2.87–19.25)), graft liver disease (OR 13.5 (3.31–54.90)), portal hypertension (PHT) (OR 11.84, (3.36–42.41)), and retransplantation (11 vs.4 patients, OR 16.17 (4.61–56.72). In post-LT, de novo IBD was diagnosed in 10 cases (6.9%). The presence of colonic endoscopic activity was more frequent after LT (52.4% vs. 38.4%, p = 0.7) with need for therapeutic escalation in 24.7%. Recurrence of PSC was not associated with endoscopic or histological activity, nor with changes in IBD treatment. 22/143 (15.6%) patients died during follow-up (40.9% due to complications of PSC or IBD). In univariate analysis, age at LT (HR: 1.034 (0.99–1.072)), cholangiocarcinoma (HR 5.763 (1.672–19.861)), PTH (HR 2.843 (1.02–7.92)) and infectious complications (HR 2.376 (0.880–6.365)) were associated with lower survival in univariate analysis, whereas in multivariate only PTH was significant (HR 3.8 (1.3–11.6). p = 0, 015).
Conclusion: The frequency of recurrence of PSC after LT in our country is similar to that described in other series and is associated with worse LT outcomes. The presence of IBD, especially UC, is associated with recurrence of PSC. We observed worse control of IBD after LT, but it was not associated with recurrence of PSC.

THU-526
Liver transplant recipients with autoimmune hepatitis in the Swiss transplant cohort study have a higher risk of graft loss and vascular complications

Aurélie Rosat[1], Benedetta Terziroli[2], Linard Hoessly[3], Susanne Stampf[3], Michael Koller[3], Nicolas Goossens[4], Montserrat Fraga Christinet[1], Annalisa Berzigotti[5], Nasser Semmo[5], Beat Müllhaupt[6], David Semela[7], Markus Heim[3], Simon Brunner[8], Manuel Pascual[1], Darius Moradpour[1], Julien Vionnet[1]. *[1]Lausanne University Hospital, Switzerland; [2]Epatocentro Ticino, Switzerland; [3]University of Basel, Switzerland; [4]Geneva University Hospitals, Switzerland; [5]Inselspital, Switzerland; [6]Universitätsspital Zürich, Switzerland; [7]Kantonsspital St Gallen, Switzerland; [8]Kantonsspital Graubünden, Switzerland*
Email: aurelie.rosat@chuv.ch

Background and aims: Data suggest that patients transplanted for autoimmune hepatitis (AIH) have a higher post-liver transplantation (LT) mortality as compared to other liver diseases. Our aim was to compare patient and graft survival of patients transplanted for AIH included in the Swiss Transplant Cohort Study (STCS) with those of patients transplanted for other indications.
Method: All adult patients who underwent a first LT from May 2008 to December 2020 and who consented to participate in the STCS were classified into seven categories according to their initial indication to LT: AIH, alcohol-related liver disease (ARLD), viral liver disease (VLD), primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC), non-alcoholic steatohepatitis (NASH) and other. Patients with AIH were selected based on clinical, immunological and histopathological criteria; patients with unequivocal etiology were classified in the respective categories, patients with mixed or other diagnoses being classified as "other." Primary outcomes were graft and patient survival; secondary outcomes were post-transplant vascular, biliary and infectious complications. Cumulative incidence of graft loss and death were calculated in the different categories and compared with AIH. The p value was adjusted according to the Bonferroni method. A Cox proportional hazards model was used to investigate the effect of AIH on complications.
Results: A total of 880 LT recipients were included: 23 transplanted for AIH, 254 for ARLD, 303 for VLD, 38 for PBC, 49 for PSC, 61 for NASH, and 152 for other indications. In the AIH group, 65.2% (n = 15)

were women, the median age was 49 (IQR 39–58) years, follow-up time 3.36 (1.69–5.20) years, and MELD score 20 (15–32); graft loss and death rates were 34.8% (n = 8) and 21.7% (n = 5), respectively. There was no significant difference in death rates between AIH and other groups but graft loss was significantly higher in AIH patients (p = 0.002) (Figure). Eighteen (78.3%) AIH patients had a relevant complication, 77.8% (n = 14), 44.4% (n = 8) and 27.7% (n = 5) of them having a vascular, biliary or infectious complication, respectively. In the multivariate analysis, AIH was independently associated with a higher risk of complications (HR 1.693, 95% CI 1.024–2.799, p = 0.040), along with pre-LT MELD score (HR 1.013, 95% CI 1.002–1.024, p = 0.017), living donation (HR 3.165, 95% CI 2.069–4.841, p < 0.005), and rejection (HR 3.452, 95% CI 2.487–4.791, p < 0.005).

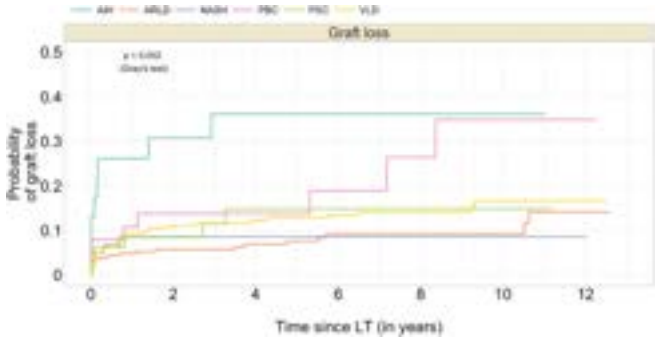

Figure:

Conclusion: Patients transplanted for AIH have a higher risk of early graft loss compared to other etiologies, likely explained by a higher rate of vascular complications.

THU-527

Primary sclerosing cholangitis recurrence after liver transplantation: a nationwide survey in Italy

Email: mariacristina.morelli@aosp.bo.it

Background and aims: Primary sclerosing cholangitis recurrence (rPSC) after liver transplantation (LT) occurs at a variable rate among different studies from different geographical areas; moreover, the impact of rPSC on patient and graft survival has not been fully defined. We aimed to investigate the rate and impact of rPSC after LT in an Italian cohort.
Method: In April 2022, we conducted a nationwide survey of LT in PSC over the past 15 years, including 85% of Italian LT centers. Participating centers were instructed to define rPSC according to established Mayo criteria and were asked to report rPSC rates at 1, 5 and 10 years. In addition, we explored the effect of rPSC on graft and patient survival.
Results: From January 2007 to December 2021, 445 patients with PSC were listed for LT and 411 underwent LT. The median age at LT was 46 years (18–73), with a prevalence of males of 70% (287/411). rPSC was diagnosed in 81 patients (20%), 24% in the first year, 64% in the first three years, and 91% in the first five years. The prevalence of rPSC varied among centers according to surveillance procedures; the one center that performed protocol liver biopsies reported a higher prevalence than those that did not (24% vs. 15%). rPSC was more frequent in recipients with inflammatory bowel disease (66%) than in recipients with isolated PSC. Recurrence was symptomatic in 69% of the cases, and the main symptoms were cholangitis (66%), pruritus (86%) and jaundice (60%). The overall post-LT mortality was 15% (66/441): 24 patients died in the first year (50% from surgical complications and 25% from infection); 33 patients died between 1 and 5 years (36% rPSC, 21% recurrence of occult CCA) and 9 patients after 5 years (56% cancer, 44% rPSC).
22 out of 81 (27%) patients with rPSC were retransplanted, with an overall survival of 72%; three developed early recurrence one year after the second LT.
Conclusion: In our Country, the rate of rPSC was 20% at five years after liver transplantation. Recurrent PSC was a major cause of long-term mortality and the leading cause of retransplantation.

THU-528

Statins and metformin after liver transplantation: a nationwide cohort

Cyrille Feray[1], Christophe Desterke[1], Nathalie Goutte[1], Daniel Azoulay[1], Eric Vibert[1], Didier Samuel[1], Paul Landais[1]. [1]*INSERM 1193, Villejuif, France*
Email: cyrille.feray@gmail.com

Background and aims: LT is the treatment for decompensated cirrhosis or liver cancer. Along with immunosuppressants, drugs such as statins, oral antidiabetics, aspirin, proton pump inhibitors and many others are prescribed over the long term. We studied, in the total population of French 8658 liver transplanted recipients between 2009 and 2018, the influence of non-immunosuppressive drugs on survival and other outcomes.
Method: The French health insurance SNDS database, linked with the national hospital database (PMSI), contains information on at least 99% of the French population: all ICD-10 codes, medical procedures (MP) and prescribed drugs and the vital status. The drugs were evaluated as a time dependent covariate in a cox model using propensity score adapted to studied drug and to the outcome. Outcome on other relevant events were defined by algorithm combining ICD and MP.
Results: Among the 10 most prescribed drugs, statin and oral antidiabetic (OAD) were associated to a favorable survival (HR for statin: 0.53–0.85p = 0.0003, HR for OAD: 0.51–0.89 p < 0.005) (Figure). Statins were associated to less hepatic events and better survival after cardiovascular, renal and infectious events. OAD were associated to less kidney, hepatic and infectious events. None of them

were associated neither to the incidence of *de novo* cancer nor the recurrence of liver cancer. A dose-dependent action was established for both. Hydrophilic more than lipophilic statins and metformin more than other OAD were associated to a better survival. Multivariate analysis showed that the action of statin and OAD were independent each other and to other drugs (including immunosuppression) and was not synergic.

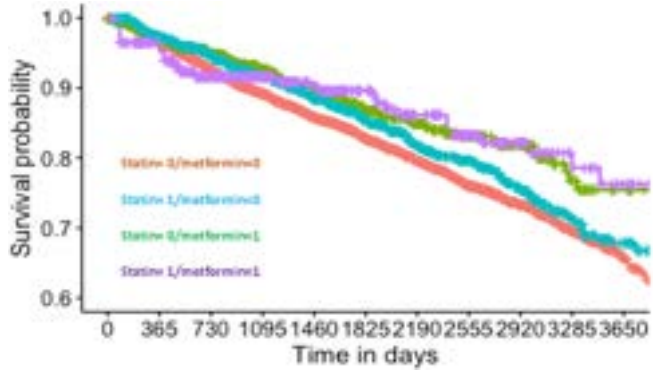

Figure:

Conclusion: In conclusion. Statins and OAD were associated to a favorable effect on survival and important outcomes such as hepatic, cardiovascular and infectious events. The dose-effect observed and the specificity of drug (hydrophilic statins and metformin) suggest that these drugs are directly involved and that their prescription should be extended in the population of patients liver transplanted for cirrhosis or liver cancer.

THU-529

The GALAD score allows early detection of recurrent hepatocellular carcinoma after orthotopic liver transplantation

Magdalena Hahn[1], Adam Herber[1], Janett Fischer[1], Sebastian Rademacher[2], Daniel Seehofer[2], Sebastian Ebel[3], Timm Denecke[3], Thomas Berg[1], Florian van Bömmel[1]. [1]*Leipzig University Medical Center, Division of Hepatology, Department of Medicine II, Leipzig, Germany;* [2]*Leipzig University Medical Center, Department of Visceral, Transplant, Thoracic and Vascular Surgery, Leipzig, Germany;* [3]*Leipzig University Medical Center, Department of Diagnostic and Interventional Radiology, Leipzig, Germany*
Email: magdalena.hahn@medizin.uni-leipzig.de

Background and aims: Recurrence of hepatocellular carcinoma (HCC) after orthotopic liver transplantation (OLT) has an unfavourable prognosis. The potential of novel HCC biomarkers for prediction and early detection of HCC recurrence after OLT is not established. We have assessed the value of the GALAD score for detection and prediction of HCC recurrence after OLT.

Method: In this retrospective monocentric study all patients who underwent OLT due to HCC between 2010 and 2020 in one University Hospital were included. Inclusion criteria were diagnosis of HCC by radiologic or histologic criteria before OLT, availability of serum for biomarker measurement before OLT, 6, 12 and 24 months after OLT, follow-up for at least two years or until HCC recurrence after OLT and written informed consent. AFP, alpha-fetoprotein-L3 (AFP-L3) and des-carboxy-prothrombin (DCP) were measured by μTASWako i30 test system. The GALAD score was calculated as previously published.

Results: A total of 77 patients was enrolled. The mean observation time was 68 ± 44 (range 2–144) months. HCCR was diagnosed in 20 patients after a mean period of 32 ± 30 (1–104) months. The median recurrence free survival after OLT was 135 months (95% CI: 126, 144 months). The GALAD score before OLT was associated with the number of HCC nodules (p = 0.009), with HCC grading (p = 0.025) and total HCC diameter in the explanted liver (p = 0.004). GALAD score correlated negatively with the time between first diagnosis of HCC recurrence and OLT (p = 0.047). Regular determination of the GALAD score within the first two years after OLT showed a positive score (cut-off value of –1.55) in 8 of the 9 patients with HCC recurrence. GALAD score became positive on average 2.13 ± 3.5 (0–10) months before radiological diagnosis of HCC recurrence. The mean GALAD score was higher before OLT in patients with early HCC recurrence diagnosed within 6 months of OLT (n = 4), as compared to those with late or no HCC recurrence or (2.23 ± 2.1 (0.84–4.61) vs –0.97 ± 2.6 (-5.88–11.21); p = 0.02).

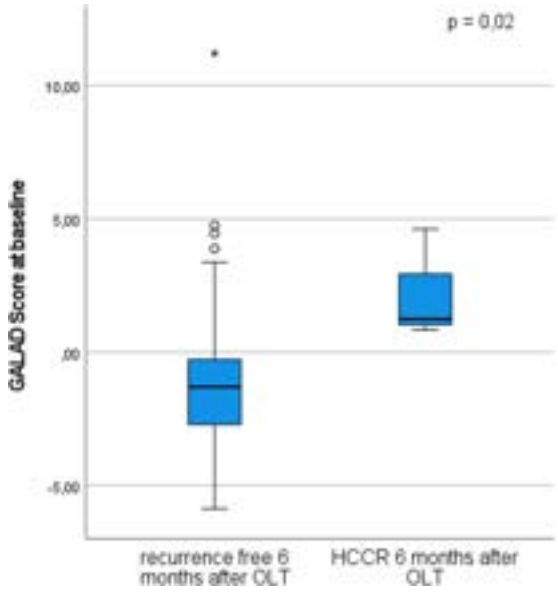

Figure:

Conclusion: The GALAD score may be a useful tool to improve the prediction and early diagnosis of HCC recurrence after OLT.

THU-530

Post reperfusion syndrome in liver transplant after normothermic perfusion: experience of a reference center

Luciano Beltrão Pereira[1], Alice Loughnan[1], Yamen Jabri[1], Lucy Dancy[1], Fionnuala Schwartz[1], Wayel Jassem[1], Juliana Pereira[1], Gudrun Kunst[1], Zoka Milan[1]. [1]*King's College Hospital, Institute of Liver Studies, United Kingdom*
Email: lpereiras@me.com

Background and aims: Post reperfusion syndrome (PRS) is defined as severe haemodynamic instability, with a greater than 30% drop below the anhepatic mean arterial blood pressure (MAP) within 5 minutes of reperfusion sustained for at least 1 minute. It is an important factor in graft survival, morbidity and mortality. Therefore diminishing PRS is essential and the type of donor liver storage could affect it such as preserving the organ in specialised cold storage (CS) reaching 4°C, conventional method, or with normothermic machine perfusion (NMP), modern method, which may reduce ischemic reperfusion liver damage because of its continuous normothermic perfusion of the donor liver.

Method: This was a retrospective case controlled study. Patients were recruited between January 2011 and December 2013. A total of 22 patients were included; 11 patients received a NMP Organ Ox perfused liver (OX), and 11 patients formed a control group, who received liver grafts from CS. Recipient and donor demographics were evenly matched between patients (Table 4). The primary outcome was the incidence of PRS with secondary outcomes being inotrope, blood product and fluid requirements. Data was examined for normality, and compared using Fisher exact test or Mann-Whitney.

Results: PRS occurred in 54% (n = 6) of the CS group compared to 18% (n = 2) of the OX group, p = 0.183. The percentage drop in MAP was significantly lower for the OX (15.8%) compared with the CS group

(40%) p = 0.007 (Figure 2). Total amount of adrenaline used was lower in the OX group compared with the CS group, p = 0.088. Total amount and number of patients on noradrenaline was similar between the groups. Total fluids administered was less for the OX group (5090 mls) compared with the CS group (7419 mls) p = 0.365. The OX group received less blood products in the post reperfusion phase compared to the CS group, however this was also not statistically significant.

Donor parameters		OX	CS	p Value
Donor Sex M/F		7/4	5/6	0.9
Donor age		60.7	57.4	0.63
Donor BMI		25 (22-28.6)	24.6 (16.6-32)	0.57
Inotropic Support		7/12	9/12	0.66
Liver Steatosis	normal	7	6	0.9
	mild	3	4	0.73
	Mild - moderate	1	1	1
	moderate	0	0	1
	Sever	0	0	1

Table 1: Recipient demographics and characteristics
BMI: Body Mass Index; M: male; F: female

Conclusion: A reduced incidence of PRS in patients receiving NMP compared to CS livers was observed, with improved haemodynamics and lower adrenaline requirements.

THU-531

Comorbidities and complications of patients hospitalized for liver transplantation evaluation, transplant and post-LT: a fourteen-year nationwide study in Germany

Wenyi Gu[1], Louisa Schaaf[2], Hannah Hortlik[2], Yasmin Zeleke[2], Maximilian Joseph Brol[1], Andreas Schnitzbauer[2], Wolf Bechstein[2], Alexander Queck[2], Michael Tischendorf[1], Andreas Pascher[1], Michael Praktiknjo[1], Martin Schulz[1], Frank Erhard Uschner[1], Florian Rennebaum[1], Jonel Trebicka[1]. [1]*University Hospital Muenster, Department of Internal Medicine B, Germany;* [2]*University Hospital Frankfurt, Germany*
Email: jonel.trebicka@ukmuenster.de

Background and aims: Liver transplantation (LT) is so far the only cure for end-stage liver disease or progressive acute liver failure (ALF), hepatocellular carcinoma (HCC), as well as other chronic liver diseases. However, LT bears also morbidities and mortality, even post-LT. Different comorbidities may follow, and further increase mortality and morbidity. We investigated the outcomes in hospitalized patients, evaluated for LT and in the post-LT patients in Germany in this study over a period of 14 years.
Method: This German nationwide study investigated 10,787 patients hospitalization for LT evaluation, 14,745 on the waiting list, 12,836 underwent LT and 142,809 admissions of patients after LT on related comorbidities and complications between the year of 2005 and 2018. All data were based on the diagnosis related groups (DRG) system with ICD-10 and procedure key (OPS) codes.
Results: The number of admissions for LT evaluation or waiting list increased approximately three times over the observational years from 2005 to 2018. Balance between LT evaluation and LT waiting list entering reached in 2014. LT number decreased by 2.3% overtime, while waiting-list mortality rate increased by 5%. By contrast, the in-hospital mortality rate decreased over the observational period, especially in ALF patients with a drop by 16%. Interestingly, admissions of post-LT patients for complications almost doubled, driven mainly by complications of immunosuppression (e.g. respiratory diseases, infections, acute kidney injury [AKI], malignant diseases, gastritis and diarrhea), which nearly tripled (from 2,748 to 7,290). Importantly, post-LT patients with AKI and biliodigestive anastomosis showed the highest in-hospital-mortality rate of 20% and 18% of all complications, respectively.

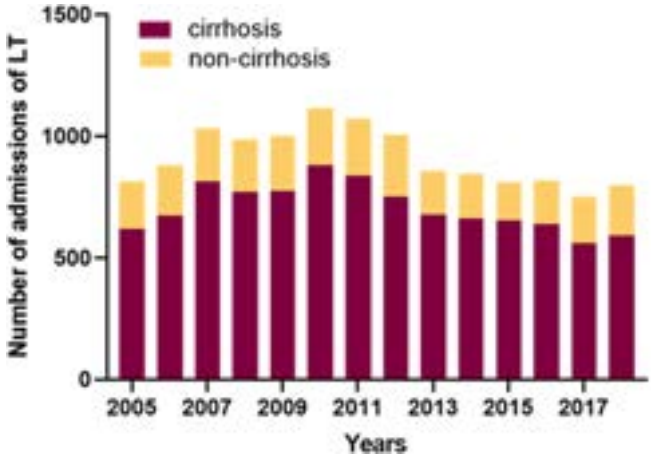

Figure: Number of admissions of liver transplantation patients during the observational year of 2005 to 2018.

Conclusion: In conclusion, the drop of LT leads most probably to the increased in-hospital mortality of patients on the waiting-list. Interestingly, in-hospital mortality decreased in LT patients. An important finding of this study is that post-LT comorbidities requiring hospitalization increased over the observational period. AKI and biliodigestive anastomosis are associated with highest in-hospital mortality and should be addressed.

THU-532

Long-term benefit of mTOR inhibitors for dropping calcineurin inhibitors in liver transplant recipients

Yael Milgrom[1], Ashraf Imam[1], Alaa Jammal[1], Suha Shabaneh[1], Johnny Amer[1], Asher Shafrir[1], Muhammad Massarwa[1], Wadi Hazou[1], Abed Khakayla[1], Rifaat Safadi[1]. [1]*Hadassah-Hebrew University Hospital, Liver Institute, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: Dropping the calcineurin inhibitors (CNi) with an antimetabolite (azathioprine or mycophenolate mofetil (MMF)) or mTOR inhibitor (mTORi) became common practice to protect renal function in liver transplant recipients (LTR). We retrospectively assessed our real-life experience in a trans sectional study 2020–2022.
Method: Long-term follow-up of CNi drop in 169 LTR compared in 4 regiments (study groups): CNi drop that needed an addition of mTORi (n = 44, 26%), MMF (58, 34%), both mTORi and MMF (7, 4%) or no additional therapeutic regimen (60, 36%). ANOVA, Hochberg Multiple Comparisons, Chi-Square Tests used for the comparison analysis.
Results: After post-transplant follow-up of 10.9 ± 8.7 years, the used immunosuppression included steroids in 38.9% of LTR, CNi; usually tacrolimus (81.7%) but also cyclosporine-A (6.5%), MMF in 38.9% and mTORi in 30.2% (usually everolimus in 24.9%, but also sirolimus in 5.3%). All 4 regiments (study groups) share a similar means and distributions of ages, gender, ethnicity, smoking, BMI, post-transplant follow-up, etiologies (except of significantly higher HCV and PBC in mTORi and MMF groups, respectively), HCC, incidence of impaired glucose homeostasis, hypertension, hematology, liver enzymes, eGFR, LDL, HDL, TG, HBA1c, and the incidence for using some medications (glucose lowering agents, cyclosporin-A, and UDCA). Comparing to MMF, mTORi group found with significantly increased serum fasting glucose, lower total bilirubin, increased incidence of using statins, decreased number of immunosuppressants, decreased incidence of steroids (without impact on daily dosages) and of prograf (with reduced dosages and trough levels), and lower death rates along the study follow-up 2020–2022 (2.3% in mTORi, 14.3% in mTORi and MMF, 6.9% in MMF, and none in the no additional therapeutic regimen).
Conclusion: Comparing to MMF, the long term CNi drop with mTORi was safer than MMF in LTR needed an additional therapeutic CNi

sparing. Although mTORi introduced for LTR with higher risk factors (high HCV background and worse metabolic homeostasis of glucose and lipid), it allowed better CNi drop to achieve similar renal outcomes with lower bilirubin levels and favorable survival.

THU-533

Sarcopenia at listing for liver transplantation is a negative predictor for post-transplant survival, but not for graft survival

Guido Stirnimann[1], Anja Beugger[1], Federico Storni[1], Vanessa Banz[1], Annalisa Berzigotti[1], Verena Obmann[2]. [1]*Inselspital, Bern University Hospital, Department of Visceral Surgery and Medicine, Bern, Switzerland;* [2]*Inselspital, Bern University Hospital, Department of Radiology, Bern, Switzerland*
Email: guido.stirnimann@insel.ch

Background and aims: Sarcopenia is a common finding in patients listed for liver transplantation (LT), independent of the underlying liver disease. Sarcopenia has a known influence on wait-list mortality and is associated with an unfavourable outcome after LT including longer intensive care and hospital stay, short-term mortality, higher incidence of infections, and higher overall health care cost. To date, data on the influence of sarcopenia on patient long-term and graft survival is scarce.
Method: In this retrospective tertiary care center analysis, patients with first LT only between 2012 and 2022 and a CT scan ±3 months before/after listing for LT were included. CT slides were analyzed with sliceOmatic, TomoVision, Canada. Total skeletal muscle area was measured at lumbar level L3 and normalized by height to obtain skeletal muscle index (SMI). Sarcopenia was defined by gender-specific cut-offs (<50 cm^2/m^2 in males and <39 cm^2/m^2 in females). Survival was visualized with Kaplan Meier survival curves and assessed with the Breslow (generalized Wilcoxon) test.
Results: In total, 161 patients were included (male = 113, 70.2%). Mean age at listing was 55.8 (±11.8) years. 59 (36.6%) patients were sarcopenic (mean age 57.6 ± 10.9 years), 102 (63.4%) were not sarcopenic (mean age 54.8 ± 12.3 years). Mean wait-list time was 10.1 (±7.9) for sarcopenic and 9.9 (±8.2) months for non-sarcopenic patients. Mean post-LT follow-up time was 49.3 (±36.5; range 0–131) for sarcopenic and 59.8 (±33.4; range 0–130) months for non-sarcopenic patients, respectively. Mean SMI was 43.3 (±5.0) in the sarcopenic group and 54.3 (±10.0) cm/m^2 in the non-sarcopenic group. Kaplan Meier survival curve is displayed in the figure. Overall post-LT survival was significantly shorter for sarcopenic patients compared to non-sarcopenic patients (94.1 (±7.5) versus 107.8 (±4.6) months, p = 0.039 Breslow (generalized Wilcoxon) test). Pre-transplant sarcopenia did not have a relevant effect on graft survival (p = 0.65).

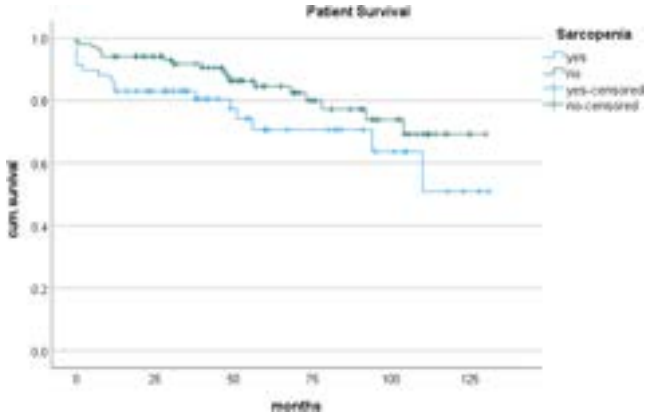

Figure: Post-transplant survival based on pre-transplant nutritional status.

Conclusion: Sarcopenia at listing for LT is a negative predictor for post-transplant survival, but not for graft survival. To what extent counteracting sarcopenia in this patient population improves post-transplant outcome remains to be elucidated.

THU-534

Safety of coronary angiography with consecutive dual antiplatelet therapy in patients with liver cirrhosis and esophageal varices as part of an evaluation for liver transplantation

Moritz Passenberg[1], Aycan Bogazliyan[1], Alexandra Frey[1], Hartmut Schmidt[1], Roxane Authorsen-Grudmann[1], Katharina Willuweit[1], Jassin Rashidi-Alavijeh[1]. [1]*University of Duisburg-Essen, Medical Faculty, Department of Gastroenterology, Hepatology and Transplant Medicine, Essen, Germany*
Email: jassin.rashidi@uk-essen.de

Background and aims: For patients with advanced liver cirrhosis, liver transplantation is the only curative therapeutic option most cases. Inclusion on the waiting list for liver transplantation usually requires extensive evaluation examinations, which in many cases include coronary angiography. Depending on the findings, this may lead to the placement of a stent with subsequent use of dual antiplatelet therapy. To date, there are only limited data on the influence of dual antiplatelet therapy on bleeding events and transplant-free survival.
Method: Clinical data from 228 patients with liver cirrhosis who underwent coronary angiography with or without stenting were collected and statistically analyzed.
Results: Of 228 patients who underwent coronary angiography, 21 (9%) had a bleeding event within 6 months after the intervention, whereas 207 (91%) did not have a bleeding event during the same period. After multivariate analysis, the occurrence of bleeding events was significantly associated with the laboratory parameters INR (HR 15.96 [2.57, 99.10]; P = 0.003), albumin (HR 0.42 [0.19, 0.93]; P = 0.033), and the placement of a stent after coronary angiography (HR 2.68 [1.07, 6.74]; P = 0.036). However, neither platelet count nor the presence of esophageal varices showed an independent and significant association with bleeding events. Furthermore, an analysis was performed to determine the impact of stent placement on the occurrence of ACLF; here, stent placement (HR 2.94 [1.2, 7.18]; P = 0.018) was shown to be an independent risk factor for the occurrence of ACLF, in addition to the parameters bilirubin (HR 1.12 [1.03, 1.21]; P = 0.009) and hemoglobin (HR 0.81 [0.65, 0.99]; P = 0.042).
Conclusion: The performance of coronary angiography with stent placement and consecutive antiplatelet therapy in patients with liver cirrhosis is significantly associated with bleeding events during the period of taking this medication. However, the occurrence of bleeding events is not dependent on the presence of esophageal varices or the extent of thrombocytopenia. Despite increased bleeding events, stenting was not associated with a significantly more frequent occurrence of ACLF or worsening of transplant-free survival.

THU-535

Incidence of de novo tumors after liver transplantation (LT) in HIV infected is similar to non-HIV patients: a single center comparative study

Isabel Terol Cháfer[1], Carmen Vinaixa[1], Sonia García[1], Víctor Argumánez Tello[1], Marina Berenguer[1,2], Victoria Aguilera Sancho[1]. [1]*La Fe University and Polytechnic Hospital, València, Spain;* [2]*Facultat de Medicina i Odontologia, Departamento de Medicina, València, Spain*
Email: vinaixa.carmen@gmail.com

Background and aims: De novo tumors and cardiovascular diseases are one of the leading causes of death after LT. Our aim was to describe the incidence of de novo tumors in a HIV-infected LT patients and compared to non-HIV-infected LT patients.
Method: We conducted a retrospective study based on a prospectively maintained database including patients who underwent liver transplantation (LT) from June 2004 to December 2020 in a single LT center. HIV-infected patients were matched to 2 non-HIV infected controls each by age, sex, liver disease etiology, and date of LT. Pre-LT baseline features, HIV related variables, and post-LT outcomes were recorded.

Results: A total of 156 LT recipients were included (52 HIV-infected and 104 non-HIV-infected). Baseline characteristics were similar in both groups, except for age and body mass index, which were lower in HIV-infected patients. Mean follow-up post-LT was 7, 5 years in the HIV group vs 8, 2 years in the non-HIV group. Incidence of de novo tumors was 17% in HIV patients vs 12%f in non-HIV, pNS. The mean time of appearance de novo tumors since LT was similar in both groups (6, 25 years in HIV-infected patients vs 6, 18 years in non-HIV infected, pNS) (see graph 1). Approximately one third of patients in each group died during follow-up, leading to similar overall survival between groups. De novo tumors were the leading cause of death in both groups (5 HIV patients and 8 on-HIV patients). Smoking after LT was the only factor significantly associated to development of de-novo tumors (p 0, 008).

Figure:

Conclusion: In the post-LT setting, incidence of de-novo tumors in HIV-infected patient was similar to non-HIV patients. Smoking after LT was associated to development of de novo tumors. Larger prospective studies are warranted to validate these results.

THU-536

Biliary strictures in liver trasplant recipients: novel strategies for identifying therapeutic targets of biliary fibrosis

Alex Bofill[1,2], Pablo Ruiz[3], Yilliam Fundora[4], Carla Montironi[5], Manuel Morales-Ruiz[6], Andres Cardenas[7]. *[1]Institute of Digestive Diseases, GI Unit, Spain; [2]ICMDM, GI Unit, Barcelona, Spain; [3]Institute of Digestive Diseases, Liver Unit, Spain; [4]Institute of Digestive Diseases, HBP Surgery, Spain; [5]Pathology Department, Spain; [6]Biochemistry and Molecular Genetics Department, Spain; [7]Institute of Digestive Diseases, GI/Liver Unit, Spain*
Email: acardena@clinic.cat

Background and aims: Biliary anastomotic strictures (BAS) are the most common biliary complication in liver transplant (LT) recipients. The mechanisms of BAS fibrosis are unknown; but overexpression of transforming growth factor beta-1 (TGF-β1) and interleukin-6 (IL-6) is described in animal models. Per-oral digital cholangioscopy (POCS) allows direct visualization of the bile duct and adequate sampling of the biliary epithelium to evaluate factors associated with BAS. We aimed to determine gene expression of TGF-β1 and IL-6 from POCS and from surgical bile duct samples as a potential therapeutic target for local therapies. In addition, confirm the role of POCS for classifying BAS. We present preliminary data of this study.
Method: Prospective and single-center study of patients that developed BAS after LT. Biliary samples were obtained with POCS performing biopsies of the anastomotic stricture, and from surgical bile duct samples. Samples were preserved in RNAlater for subsequent processing and purification of mRNA. Gene expression of TGF-β1 and IL-6 was quantified by quantitative real-time PCR.
Results: Twenty-two recipients have been included, 82% male, median age 62 y (IQR 58–67). The underlying etiology that led to LT was cirrhosis due to alcohol, MAFLD, HCV and HCC. All patients received a cadaveric organ. The median period from LT to POCS or surgery was 12.7 months (IQR 5–48). POCS was successfully performed in 18 patients (4 of them had surgery). Of all patients treated 12 had BAS pattern A (scar), and 6 pattern B (sloughing, ulcer). Molecular studies (mRNA expression of TGF-B1 and IL-6) have been performed in 13 (4 had insufficient RNA) Figure. 2/18 had mild pancreatitis (11%).

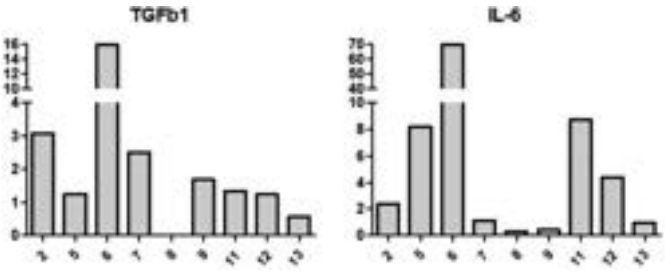

Figure:

Conclusion: Preliminary results indicate mRNA expression of TGF-β1 and IL-6 in BAS of LT recipients. Overexpression of TGF-β1 and IL-6 are potential therapeutic targets for local endoscopic therapy of BAS.

THU-537

Coronary computed tomography angiography in pre-liver transplant cardiac work-up

Chiara Manuli[1], Margherita Saracco[1], Bruna Lavezzo[2], Alessandro Depaoli[3], Fabrizio D'Ascenzo[4], Renato Romagnoli[5], Silvia Martini[1]. *[1]Gastrohepatology Unit, AOU Città della Salute e della Scienza, University of Turin, Italy; [2]Anesthesiology and Intensive Care Unit, AOU Città della Salute e della Scienza, University of Turin, Italy; [3]Department of Imaging Diagnostics and Radiotherapy, AOU Città della Salute e della Scienza, University of Turin, Italy; [4]Cardiology Unit, AOU Città della Salute e della Scienza, University of Turin, Italy; [5]General Surgery 2U, Liver Transplantation Center, AOU Città della Salute e della Scienza, University of Turin, Italy*
Email: chiara.manuli@gmail.com

Background and aims: Controversies persist around the optimal screening of pre-liver transplant (LT) candidates for coronary artery disease (CAD). Dobutamine-stress-echocardiography (DSE) is used in many centers, but real-life studies demonstrated its poor performance. Coronary-computed-tomography-angiography (CCTA) is emerging as a promising non-invasive tool to detect CAD; therefore, we aimed to describe its role in the pre-LT setting.
Method: All patients (pts) who underwent CCTA during the pre-LT work-up from 01/01/2022 to 31/12/2022 in our Centre were included. Pts with previous CAD or with cardiac symptoms underwent per-protocol cardiac catheterization (CATH) and were not included in the study. CCTA was performed in pts with at least one major cardiovascular risk factor (age >65 years, insulin-dependent diabetes, NASH-cirrhosis, severe peripheral vascular disease, previous stroke). Significant CAD (S-CAD) was defined as ≥50% stenosis in major-vessels (left main, left anterior descending or right coronary artery) or ≥70% stenosis in moderate-sized vessels. Pts with S-CAD or non-diagnostic CCTA underwent CATH.
Results: During the study period, 122 pts underwent pre-LT work-up in our Centre. CCTA was performed in 42/122 (34%) pts, who represent our study population. Median age was 65 years (IQR 60–68), 24/42 (57%) pts had diabetes (22 insulin-dependent), 16/42 (38%) had NASH-cirrhosis, 3/42 (7%) peripheral vascular disease, 4/42 (10%) previous stroke. As additional risk factors, 19/42 (45%) suffered from arterial hypertension, 9/42 (21%) dyslipidemia and 15/42 (36%) were active smokers.
CCTA identified S-CAD in 17/42 (40%) pts and was non-diagnostic in 2/42 pts (5%); 15 of these 19 pts (79%) underwent CATH; in 2/19 (10.5%) CATH was not performed after careful evaluation with

cardiology specialist and the remaining 2/19 (10.5%) were excluded from LT for extra-cardiac reasons.
CATH showed S-CAD needing revascularization in 8/15 pts (53%): 7/8 pts (88%) underwent percutaneous coronary intervention (PCI) (one complicated by myocardial infarction), 1/8 (12%) required surgical-bypass. After PCI, the median duration of dual-antiplatelet therapy (DAPT) was 1 month (IQR 1–4.5). After revascularization, 1 patient underwent uneventful LT, 3 were listed for LT, 1 was still in DAPT at the end of the study period, 1 died and 2 were excluded from LT for extra-cardiac reasons.
To date, among the 23 pts without S-CAD on CCTA, 14 (61%) underwent LT without early cardiological events.
Conclusion: During a 1-year study period, 42/122 (34%) pts evaluated for LT listing at our Centre had at least one major cardiovascular risk factor and underwent CCTA which identified S-CAD in 17/42 (40%). 8 pts underwent successful revascularization and the median duration of DAPT was 1 month.

THU-538

Safety and efficacy of glucagon-like peptide-1 receptor agonists and sodium- glucose co-transporter-2 inhibitors compared with the standard of care in a cohort of liver transplanted patients: a retrospective study

Aida Rebiha[1], Alessandra Mazzola[1], Philippe Sultanik[2], Dominique Thabut[2], Olivier Scatton[3], Olivier Bourron[4], Filomena Conti[1]. *[1]APHP-Pitié-Salpêtrière Sorbonne University, Liver Transplant Unit, Hepato-Gastroenterology, France; [2]APHP-Pitié-Salpêtrière Sorbonne University, Hepato-Gastroenterology, Paris, France; [3]APHP-Pitié-Salpêtrière Sorbonne University, Hepatobiliary and Liver Transplantation Surgery, Paris, France; [4]APHP-Pitié-Salpêtrière Sorbonne University, Diabetology, Paris, France*
Email: alessandra.mazzola3@gmail.com

Background and aims: Few data on the safety and efficacy of the use of Glucagon-like peptide-1 receptor agonists (GLP-1RAs) and sodium-glucose co-transporter-2 inhibitors (iSGLT2) are available after liver transplantation (LT). The aims of this study were to evaluate the safety and the efficacy of this treatment 6 months after LT compared to the standard of care treatment.
Method: We performed a retrospective monocentric comparative study on 36 liver recipients with post and/or pre-transplant diabetes treated with GLP1-RAs and/or iSLGT2 after LT. A control group of recipients receiving the standard of care therapy, matched (1:2) according to the time of LT, sex, age and causes of chronic liver disease was performed to compare clinical and biological outcomes. The effectiveness was defined as: glycated hemoglobin (Hb1Ac) target <7% and fasting glycaemia ranged to 0.8–1.3 g/l at 6 months. Side effects were collected. Comparison of the 2 groups was performed using Chi-2.
Results: A total of 36 LT adult patients between 2019 and 2022 were treated in our center with GLP-1RAs and/or iSGLT2 after LT. The majority of patients were male (88.8%, n = 34) with a mean age of 58.91 years old (±8.4). The median MELD score was 14 (IQR 10–21). The most common etiology of liver disease was alcohol in 52.7% of patients (n = 19) and NASH in 44.4% (n = 16). Pre-transplant diabetes was reported in 47.2% of patients (n = 17). After LT 63.9% of patients (n = 23) have GLP1-RAs and 61.1% (n = 22) iSLGT2 therapy. Patients were comparable for clinical and biological characteristics to the control group. Non-serious adverse event was reported in patients receiving GLP1-RAs and/or iSLGT2 treatment. 16.6% (n = 6) of patients had moderate side effects: 4 patients developed gastrointestinal disorders. The hypoglycemia rate was similar between the two groups (p = 0.1). Fasting glycaemia target was achieved in 78.1% (n = 25) and in 61.8% (n = 34) of patients in the GLP1-RA and/or iSLGT2 group compared to the control group (p = 0.1). Hb1Ac <7% was achieved for 81.2% (n = 26) and 75.9% (n = 41) of patients in GLP1-RAs and/or iSLGT2 group and in the control group (p = 0.5), respectively. Fast and slow acting insulin withdrawals were statistically significantly different between the 2 groups, especially in the sub-group of patients with post-transplant diabetes receiving GLP1-RAs and/or iSLGT2 treatment (s) (p < 0.001, p < 0.001).
Conclusion: In our study performed on liver transplant recipients with a higher rate of NASH and alcoholic diseases, the use of GLP1-RAs and SLGT2 treatments for diabetes was safe. The effectiveness was similar to the standard of care with a remarkable benefit of insulin withdrawal in a subgroup of patients with post-transplant diabetes. Futures prospective studies are needed to evaluate the benefit of the GLP1-RAs and SLGT2 treatments on long-term cardiovascular events, obesity, liver steatosis and mortality.

THU-539

Influence of marginal organs on the drug metabolism in liver transplantation

Laura Bütow[1,2], Dominik Schröter[1,2], Uta Dahmen[1], Peter Schlattmann[1], Utz Settmacher[1], Hans-Michael Tautenhahn[1]. *[1]Jena University Hospital-Hospital Lobeda, Jena, Germany; [2]Else Kröner Graduate School for Medical Students "JSAM", Jena University Hospital, Jena, Germany*
Email: hans-michael.tautenhahn@med.uni-jena.de

Background and aims: Metabolic zonation is a phenomenon of the liver that describes the differential distribution of functions between liver lobules. One important liver function is drug degradation, which is realized by cytochrome P450 enzyme (CYP). Alteration of CYP expression and activity is being studied in marginal donor livers to better characterize these high-risk organs and improve the transplant selection process to allow for better risk assessment in the allocation process. We hypothesize that marginal organ factors influence drug metabolism in donor livers of transplanted patients.
Method: The first step of the study is to investigate the influence of marginal organs on drug metabolism, by comparing the steatosis severity, the donor age, and the CIT to the CYP expression and activity. The measurements will be correlated with changes in reperfusion and ischemia-reperfusion-injured grafts. Second, to evaluate the LiMAx assay as a CYP 1A2 point-of-care diagnostic, in vivo and in vitro CYP measurements will be correlated. Experimental results will be correlated with patient outcome, particularly the prevalence of delayed graft function, and validated clinical chemistry parameters. 40 patients undergoing liver transplantation at Jena University Hospital in 2022 who gave informed consent will be studied. For an exploratory approach, 10 subjects per independent variable are needed. With the tissue samples we perform an H.E. staining for the morphological analysis of the donor organs. CYP expression will be visualized using an indirect immunohistochemistry more specifically CYP 1A2, CYP 3A4, CYP 2C19. Additionally, fluorescence assay is performed to measure CYP 1A2 activity in vitro, and a breath assay (LiMAx) to measure CYP activity in vivo.
Results: The CYP enzymes are expressed pericentral in the lobules. Steatosis, age, and CIT are three interrelated factors influencing the CYP expression pattern. We assume that the CYP activity is altered by the reperfusion and the IRI.

Figure:

Conclusion: It is likely that LiMAx can be used to better predict liver regeneration after transplantation.

THU-540

A multi-center, stratification-randomized, double-blind, placebo-controlled, phase III clinical trial of topical recombinant human thrombin for intraoperative hemostasis

Sheng Yan[1], Jun Yu[2], Chaoyong Tu[3], Chengyou Du[4], Jia Luo[5], Jingfeng Liu[6], Tian-Qi Liu[7], Qiang Liu[8], Jun Liu[9], Xuehua Li[10], Lianchen Wang[11], Zheping Fang[12], Weimin Yi[13], Yajin Chen[14], Qinglong Li[15], Yong Ni[16], Jincai Wu[17], Changjiang Qin[18], Yuanlong Gu[19], Zheng Lu[20], Zengjun Lun[21], Lixue Du[22], Gang Chen[23], Qichang Zheng[24], Ling Zhu[25], KeJian Sun[26], Weiqing Han[5]. *[1]The Second Hospital of Zhejiang University School of Medicine, China; [2]The First Hospital of Zhejiang University School of Medicine, China; [3]Lishui Central Hospital, China; [4]The First Affiliated Hospital of Chongqing Medical University, China; [5]Hunan Cancer Hospital, China; [6]Mengchao Hepatobiliary Hospital of Fujian Medical University, China; [7]Jiangbin Hospital of Guangxi Zhuang Autonomous Region, China; [8]Liuzhou People's Hospital, China; [9]Guizhou Provicial People's Hospital, China; [10]Liaocheng People's Hospital, China; [11]The Third People's Hospital of Hainan Province, China; [12]Taizhou Hospital of Zhejiang Province, China; [13]Hunan Provincial People's Hospital, China; [14]Sun Yat-sen Memorial Hospital of Sun Yat-sen University, China; [15]The Second Xiangya Hospital of Central South University, China; [16]Shenzhen Second People's Hospital, China; [17]Hainan Provincial People's Hospital, China; [18]Huaihe Hospital of Henan University, China; [19]The Third People's Hospital of Wuxi, China; [20]The First Affiliated Hospital of Bengbu Medical College, China; [21]Zaozhuang Municipal Hospital, China; [22]Shaanxi Provincial People's Hospital, China; [23]The First People's Hospital of Kunming, China; [24]Union Hospital Affiliated to Tongji Medical College of Huazhong University of Science and Technology, China; [25]Wuhan Central Hospital, China; [26]Zibo Central Hospital, China*
Email: shengyan@zju.edu.cn

Background and aims: Thrombin is a local hemostatic drug commonly used during surgical interventions and can promote blood coagulation by bypassing the initial enzymatic step of the coagulation pathway. Topical recombinant human thrombin is a potentially safer substitute for plasma-derived thrombin and has demonstrated hemostatic activity in a Phase I/II study. This study was designed to evaluate the hemostatic effect of human recombinant thrombin for capillary and venule errhysis after hepatectomy and for any conditions when conventional surgical hemostasis is ineffective or inapplicable.

Method: A total of 510 subjects are expected to be enrolled at 33 study sites in China by the end of the study. Enrolled subjects were randomized to the thrombin group and the placebo group in a 2:1 ratio. An interim analysis was conducted after about 70% of the subjects had completed the observation, and O'Brien Fleming spending function was used to control the total α level at a two-sided significance level of 5%. If the results of the interim analysis supported efficacy, the study was to be terminated early. The primary efficacy end point was the hemostasis rate within 6 min of the evaluable bleeding point. Safety analysis was performed within one month after operation and positive rates of antidrug antibody (ADA) and neutralizing antibody were evaluated.

Results: At the interim analysis, a total of 348 subjects had been randomized and received the study drug, 232 in the thrombin group and 116 in the placebo group, with balanced and comparable demographics and baseline characteristics between the two groups. The hemostasis rate at 6 minutes was 71.6% (95% CI [65.75%, 77.36%]) in the thrombin group and 44.0% (95% CI [34.93%, 53.00%]) in the placebo group, respectively. After adjusting for stratification factors, the difference in hemostasis rate was 27.6% (95% CI [16.92%, 38.36%]), with a significant difference between groups ($p < 0.0001$). The median time to hemostasis was 240.5 s (95% CI [210.00, 297.00]) in the thrombin group and NA (95% CI [341.00, NA]) in the placebo group, respectively. No grade ≥3 drug-related adverse events and no drug-related deaths were reported from the study.No drug-related deaths were reported from the study. No recombinant human thrombin-induced immunologically-enhanced ADA or immunologically-induced ADA was detected after topical use in subjects.

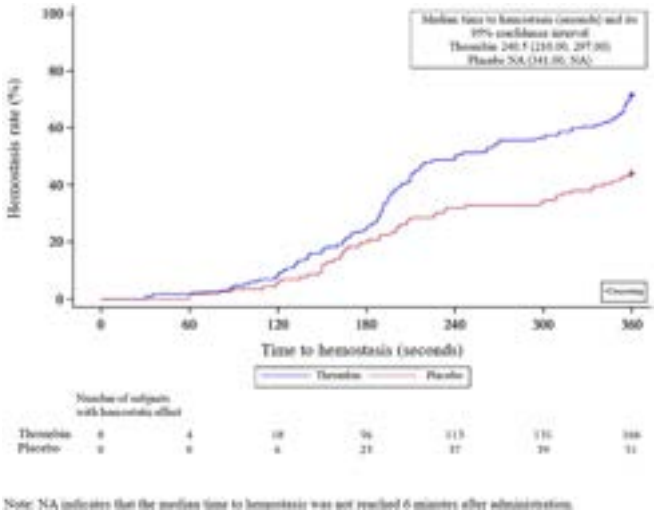

Figure: Hemostasis time curve of evaluable bleeding points

Conclusion: Topical recombinant human thrombin has a significant hemostatic effect for capillary and venule errhysis during surgical operation and has shown good safety and immunogenicity.

THU-544

Liver transplantation for alcohol-related-liver disease in the era of acute on chronic liver failure-single center experience

Dinesh Jothimani[1], Evangeline Simon[1], Hemalatha Ramachandran[1], Rajesh Rajalingam[1], Ilankumaran Kaliamoorthy[1], Gomathy Narasimhan[1], Mohamed Rela[1]. *[1]Dr. Rela Institute and Medical Centre, India*
Email: dinesh.jothimani@relainstitute.com

Background and aims: Liver transplantation (LT) is curative in patients with end stage liver disease (ESLD). Alcohol related liver disease (ALD) is a leading indication for LT. Acute on chronic Liver failure (ACLF) is an increasingly recognised condition requiring LT.

Method: A retrospective analysis of patients who underwent LT from October 2018 to September 2022 was carried out. Patients were stratified as ACLF and ESLD. Demographics, transplant indication, modality (deceased vs Living donor) and survival between the groups were studied.

Results: 114 (19.1%) out of 594 adult patients underwent LT for ALD during the study period; 26 (22.8%) were ACLF and 88 (77.1%) were ESLD. Mean age (52.0 vs 29.31, years. P = 0.13), MELD (22.0 vs 20.6, P = 0.231), diabetes (19.2% vs 22.7%, P = 0.793), LDLT (92.3% vs 97.7%, P = 0.223) did not differ between the groups. Spontaneous bacterial peritonitis (34.6% vs 15.9%, P = 0.05), was significantly higher in the ACLF group. Post-operative parameters such as ICU stay (9.08 vs 8.32, P = 0.733), hospital stay (17.62 vs 18.16, P = 0.862) in days, did not differ between the groups. One and three year post-transplant patient survival was 83.3% vs 95.0%, P = 0.054 and 72.9% vs 95.0%, P = 0.014 between ACLF and ESLD, respectively. Sepsis was significantly higher in the ACLF group (42.3% vs 21.6%, P = 0.044) and was the most common cause of death in both groups. Recidivism showed no difference (3.8% vs 3.4%, P = 1.0).

Conclusion: Compared to ESLD, ACLF patients have lower but acceptable over-all survival in the predominant LDLT set up. Efforts to overcome septic complications in these patients should be implemented.

THU-545

Liver transplantation as treatment option for cholangiocellular carcinoma

Gabriela Berlakovich[1], Georg Gyoeri[1], David Pereyra[1], Jule Dingfelder[2], Thomas Soliman[1]. [1]*Medical University of Vienna, Division of Transplantation, Vienna, Austria;* [2]*University of Vienna, Division of Transplantation, Vienna, Austria*
Email: gabriela.berlakovich@meduniwien.ac.at

Background and aims: The treatment of choice for cholangiocarcinoma is surgery and the most important predictor of outcome is a complete margin-negative resection (R0) with an adequate future liver remnant. This goal is only achieved in 60%-80% of cases with a recurrence rate over 50%. The 90-day postoperative mortality is up to 10% in experienced centers in Europe and ∼48% of patients who die are dying from post-hepatectomy liver failure. Disappointingly, long-term survival following radical resection remains low, ranging from 20% to 40% at 5 years.On the basis of the anatomical site of origin, cholangiocarcinoma is classified into intrahepatic (iCCA), perihilar (pCCA) and distal (dCCA). Surgery is a potential curative option for all subtypes. However, most patients (∼70%) are diagnosed at late stages due to lack of specific symptoms.
Method: Review.
Results: Liver transplantation for pCCA was initially determined to be contraindicated due to a high rate of recurrence (∼50%). However, a multicenter retrospective study analyzed 216 patients with early-stage, unresectable pCCA treated with neoadjuvant chemoradiotherapy and followed by liver transplantation showing 5-year disease-free survival of 72%, in the standard group. Several predictors of a patient dropping out before liver transplantation were identified: mass size >3 cm, positive or suspicious intraluminal brushing or biopsy, elevated CA 19-9 ≥500, and higher MELD score ≥20. The drop-out rate was nearly one third of these already highly selected patients. Of those transplanted, the recurrence rate was 20%. Despite selection and neoadjunvant treatment R1 was diagnosed in 47% of explanted livers.Liver transplantation for iCCA might be of great value for patients with cirrhosis and small tumors. 5-year survival following transplantation in patients with small, incidental iCCA (<2 cm) was 65%. In larger iCCA transplantation is reserved for unresectable cases and should only be performed under strict clinical protocols.
Conclusion: Liver transplantation could be a cure for CCA (1) upfront in patients with very early iCCA (single tumor ≤2 cm) in a cirrhotic liver. (2) Highly selected pCCA patients with a single small tumor <3 cm and treated in a specific protocol with neoadjuvant chemoradiation may be candidates and (3) patients with advanced iCCA in a noncirrhotic liver may become transplant candidates if the disease remains stable after neoadjuvant therapy. In any case, the number of patients with cholangiocarcinoma eligible for liver transplantation is very small.

Liver transplantation in patients with schistosomiasis in a reference hospital in Sao Paulo, Brazil

Martina Zannini[1], Patricia Zitelli[2], Javier Fernandez[3], Alberto Farias[4], Miquel Sanz[5], Isabel Requejo[1], Laia Zamora[1], Laura Lorenzo[1], Miriam Valdivieso[1], Eva Centelles[1], Foix Valles[6], Susana Nieto[1]. [1]*Nurse in Liver Unit ICU Hospital Clinic de Barcelona, Spain;* [2]*Investigation nurse at Hospital das Clínicas de Sao Paulo, Brazil;* [3]*Head of the Liver unit ICU, Spain;* [4]*Hepatologist at Hospital das Clínicas de Sao Paulo, Brazil;* [5]*Nurse coordinator of the Liver unit ICU, Spain;* [6]*Research nurse in Liver unit ICU Hospital Clinic de Barcelona, Spain*
Email: zannini@clinic.cat

Background and aims: Schistosomiasis is a parasitic disease caused by a trematode which belongs to the *Schistosomas* gender. Globally, this illness causes a huge amount of morbimortality (around 240.000 people die every year). Although schistosomiasis is unusual in Europe, globalization increases the risk of facing imported cases in our continent. Hepatosplenic schistosomiasis causes presinusoidal portal hypertension requiring pharmacological, endoscopic or surgical treatment. LT is indicated in refractory cases. LT is a common reality in decompensated hepatosplenic schistosomiasis in Brazil, where the illness is endemic. The aim is to describe prevalence and outcome of patients with schistosomiasis transplanted in Hospital das Clinicas, Universidad de Sao Paulo between years 2010–2021.
Method: Retrospective, descriptive analysis on patients with liver disease caused by *Schistosoma mansoni* requiring LT. Clinical records of 1354 liver transplant patients were reviewed.
Results: Among the investigated population, 24 had an infection by this trematode (2% of the total series of LT). The mean age was 54, 63 ±10, 64 years and 58% were men. In 67% of cases schistosomiasis was associated with other concomitant etiologic factor. Portal vein thrombosis after LT occurred in 33%, whereas portal thrombosis before LT were not relevant. One-year survival rate of LT patients with hepatosplenic schistosomiasis was 75%, figure slightly higher than that observed in the non-schistosomiasis group (72%; p = 1330).
Conclusion: Schistosomiasis was an infrequent cause of LT in Hospital das Clinicas de Sao Paulo. Prognosis of patients requiring LT is good with survival rates similar to those observed in other LT recipients.

Email: judong.yang@cshs.org

Background and aims: Early detection of cancer is imperative to improve dismal outcomes of hepatocellular carcinoma (HCC). Conventional imaging techniques and serologic markers based surveillance have suboptimal accuracy. Recently, several blood-based cell-free DNA (cfDNA) platforms have emerged for early detection of cancers including HCC. However, it still needs to be better understood what type of biomarkers provide the most valuable information for the detection of HCC. In this study, we conducted multidimensional genomic profiling of plasma cell-free (cfDNA) to analyze HCC gene mutations, DNA methylation, copy number variation (CNV), the 5 prime end motif on cfDNAs, and serum protein biomarkers in a phase 2 case-control study.
Method: We applied Mutation Capsule (MC) Screening technology and conducted RACEseq to profile mutations and methylation alterations simultaneously in target genomic regions, and sWGS for CNV and 5 prime end motif analysis. For mutations, we targeted frequently mutated regions of frequently mutated genes. Methylation alterations were predicted by a methylation model we developed

using the methylation values of 19 genes. For analytical modeling, GLM was performed for individual genomic feature-based model construction in the training cohort. Tenfold cross-validation was used in parameter optimization. The probability score of each genomic and serologic feature for each sample was generated by base models, in which a higher score represented a higher probability for cancer.

Results: We analyzed blood samples from a cohort of 175 patients, including 87 HCC patients and 88 non-HCC patients with liver cirrhosis. Individual panels have various accuracy for HCC detection: AUC of 0.849 (95% CI: 0.791–0.907) for mutation, 0.914 (95% CI: 0.870–0.958) for methylation, 0.896 (95% CI: 0.848–0.945) for CNV, 0.768 (95% CI: 0.698–0.838) for 5 prime end motif, 0.839 (95% CI: 0.779–0.899) for serum protein markers (AFP, AFPL3%, DCP). An integrated model, which combined the biomarkers of mutation, methylation, CNV, 5 prime end motif, and protein markers exhibited a consistently strong screening potential, achieving an AUC of 0.971 (95% CI: 0.946–0.997), 93.1% sensitivity and 94.3% specificity. The sensitivity increased with HCC stages: 100% (5/5) for BCLC stage 0, 89.4% (42/47) for stage A, 93.8% (15/16) for stage B, and 100% (19/19) for stage C, respectively. When stratified by etiology, the performance remains excellent: AUC of 0.964 (95% CI: 0.910 1.000), 93.5% sensitivity, 90.9% specificity in alcohol-associated HCC, AUC of 1 (95% CI: 1.000–1.000), 100% sensitivity, 100% specificity in non-alcoholic steatohepatitis associated HCC, AUC of 0.934 (95% CI: 0.861–1.000), 72.7% sensitivity, 93.5% specificity in viral hepatitis associated HCC.

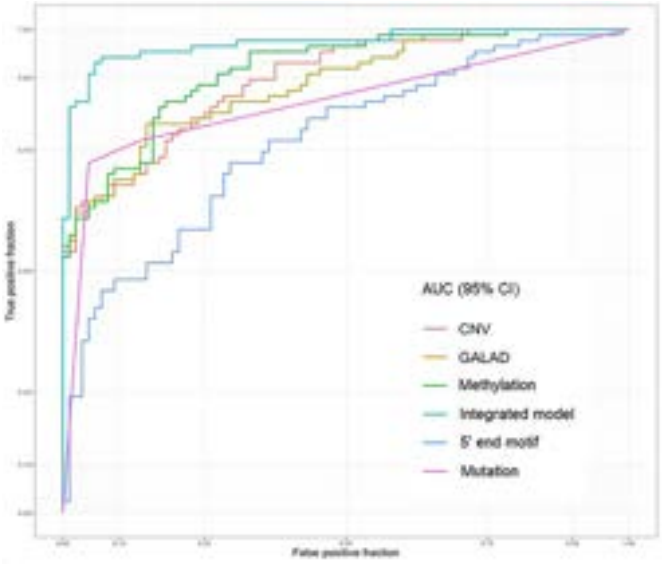

Figure:

Conclusion: Liquid biopsy demonstrates outstanding performance in early detection of HCC with superior performance via multiomics approach. External validation is in progress in a larger phase 2 study.

Deep learning-based model in pre-operative computed tomography for prediction of hepatocellular carcinoma recurrence after curative surgery

Rex Wan-Hin Hui[1], Keith Wan Hang Chiu[2], I-Cheng Lee[3,4], Chenlu Wang[5], Ho Ming Cheng[1], Lok-Ka Lam[1], Lung Yi Loey Mak[1], Nam-Hung Chia[6], Chin-Cheung Cheung[7], Yi-Hsiang Huang[3,4], Man-Fung Yuen[1], Philip Yu[5], Wai-Kay Seto[1]. *[1]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [2]Department of Radiology and Imaging, Queen Elizabeth Hospital, Hong Kong, Hong Kong; [3]Institute of Clinical Medicine, Faculty of Medicine, National Yang Ming Chiao Tung University, Taiwan, Taiwan; [4]Division of Gastroenterology and Hepatology, Taipei Veterans General Hospital, Taiwan, Taiwan; [5]Department of Mathematics and Information Technology, The Education University of Hong Kong, Hong Kong, Hong Kong; [6]Department of Surgery, Queen Elizabeth Hospital, Hong Kong, Hong Kong; [7]Department of Surgery, Tuen Mun Hospital, Hong Kong, Hong Kong*
Email: huirex@connect.hku.hk

Background and aims: Curative surgery is a first-line treatment for early-stage hepatocellular carcinoma (HCC), yet recurrence within 5 years post-resection occurs in over 70% of patients. Early recurrence, particularly within the first year, is associated with worst prognosis. Current risk scores cannot accurately predict recurrence. While histological microvascular invasion (MVI) predicts recurrence, it is only ascertained from surgical specimens and cannot provide pre-treatment prognostication. We developed a deep learning-based model using pre-operative computed tomography (CT) for prediction of early first-year recurrence.

Method: A residual-network deep learning-based model was developed through the training-validation-testing approach. The model utilised both pre-operative CT and clinical data (age, sex, comorbidities and baseline blood tests) to predict HCC recurrence. Chinese patients with resected histology-confirmed HCC were recruited from 5 Hong Kong centers. Patients were randomly divided in a 8:2 ratio to training and internal validation cohorts. The model was then externally tested in an independent cohort from Taiwan. Area-under-curve (AUC) with positive and negative predictive values (PPV/NPV) of the model were calculated, and the AUC of the model was compared with MVI from resected specimens by Delong's test. The 1-year recurrence risk prediction by the model and MVI were compared by survival analysis, with Kaplan Meier curves plotted.

Results: This interim analysis included 1306 patients (83.1% male, age at CT 62.2 ± 10.8 years, median follow-up 5.3 [2.8–8.3] years), with 391 patients (29.9%) developing recurrence within the first year. 564 (43.2%), 141 (10.8%) and 601 (46.0%) patients were included in the training, internal validation and external testing cohorts respectively, and the model was trained for 200 epochs. In the internal validation cohort, the deep learning-based model achieved AUC of 0.783 (95% CI 0.643–0.821; PPV 70.5%; NPV 79.6%) for predicting HCC recurrence at 1-year, which was significantly better than MVI (AUC 0.546 [95% CI 0.446–0.649]; PPV 43.2%; NPV 66.7%) ($p = 0.04$). In the external testing cohort, the deep learning-based model achieved AUC of 0.709 (95% CI 0.546–0.762; PPV 47.8%; NPV 81.0%) for HCC recurrence at 1-year, which was numerically higher than MVI (AUC 0.614 [0.525–0.670]; PPV 34.5%; NPV 86.8%). In both the validation and external testing cohorts, the deep learning-based model had better discriminative ability on 1-year recurrence risk when compared with MVI (Fig 1: 70.5% vs 43.2% and 47.8% vs 34.5% respectively, both $p < 0.05$).

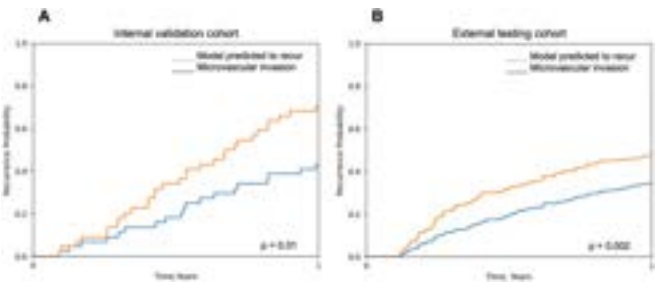

Figure:

Conclusion: A deep learning-based model on pre-treatment CT can accurately predict HCC recurrence within the first year after surgery, outperforming MVI in risk stratification. Our deep learning-based model will be developed, and has potential to become a novel tool for pre-treatment prognostication of short- and long-term outcomes in HCC.

Email: matthias.pinter@meduniwien.ac.at

Background and aims: We recently developed the C-reactive protein (CRP) and alpha-fetoprotein (AFP) in Immunotherapy (CRAFITY) score in patients with hepatocellular carcinoma (HCC) undergoing immune checkpoint inhibitor (ICI) therapy. As CRAFITY was developed in patients undergoing different ICI-based regimens, the score requires validation in patients treated with atezolizumab and bevacizumab (AB), the current standard of care in systemic first-line treatment for advanced HCC.

Method: AB-treated patients with HCC at 15 centers in Europe and Asia between 12/2018 and 01/2023 were included. CRAFITY was derived from serum CRP and AFP values prior to AB initiation by adding one point each for CRP ≥1 mg/dL and AFP ≥100 ng/ml resulting in the following categories: 0 points = CRAFITY-low, 1 point = CRAFITY-intermediate, 2 points = CRAFITY-high. The prognostic (overall survival (OS) and progression-free survival (PFS)) and predictive ability (best radiological response) of the CRAFITY score were assessed using uni- and multivariable analyses.

Results: Overall, 274 patients (66.1 ± 11.0 years; male: n = 224, 82%) were included, of which 208 (76%) had cirrhosis. Most patients had BCLC C (n = 198, 72%). While 97 patients (35%) had CRAFITY-low, n = 113 (41%) and n = 64 (23%) had CRAFITY-intermediate and CRAFITY-high, respectively.

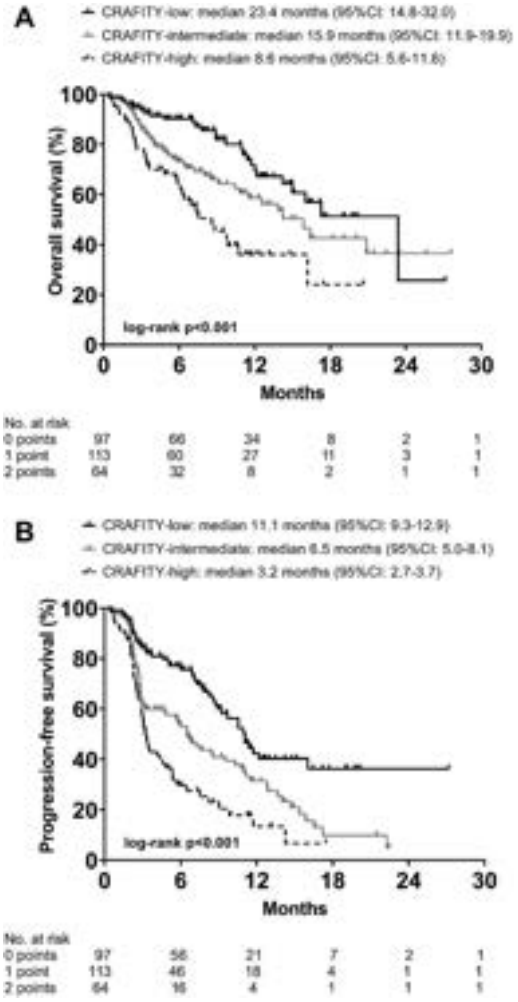

Figure: Comparison of overall (A) and progression-free survival (B) across CRAFITY score

Median OS (Panel A) and PFS (Panel B) were significantly worse in patients with higher CRAFITY scores (OS: low: 23.4 (95%CI: 14.8–32.0) vs. intermediate: 15.9 (95%CI: 11.9–19.9) vs. high: 8.6 (95%CI: 5.6–11.6) months, p < 0.001; PFS: low: 11.1 (95%CI: 9.3–12.9) vs. intermediate: 6.5 (95%CI: 5.0–8.1) vs. high: 3.2 (95%CI: 2.7–3.7) months, p < 0.001). Upon multivariable analyses, CRAFITY was independently associated with OS (aHR: intermediate vs. low: 1.51 (95%CI: 0.92–2.48), p = 0.103; high vs. low: 2.56 (95%CI: 1.52–4.33), p

< 0.001) as well as PFS (aHR: intermediate vs. low: 1.77 (95%CI: 1.21–2.59), p = 0.003; high vs. low: 2.90 (95%CI: 1.91–4.39), p < 0.001). CRAFITY was also significantly associated with radiological response (complete/partial response (CR/PR)/stable disease (SD)/progressive disease (PD), which was evaluable in 245 patients (89%): low: n = 34 (38%)/n = 45 (50%)/n = 11 (12%) vs. intermediate: n = 37 (37%)/n = 28 (28%)/n = 34 (34%) vs. high: n = 12 (21%)/n = 18 (32%)/n = 26 (46%); p < 0.001). Disease control rates (DCR) were 88% vs. 66% vs. 54% (p < 0.001), respectively. Upon multivariable logistic regression, a higher CRAFITY score was independently associated with a lower probability of disease control (aOR: intermediate vs. low: 0.25 (95%CI: 0.11–0.55), p = 0.001; high vs. low: 0.15 (95%CI: 0.06–0.35), p < 0.001).
Conclusion: The CRAFITY score identifies AB treated patients with a favourable prognosis and response and may help with patient counselling.

FRI-274
Baveno VI and VII criteria are not suitable for screening of large size esophageal varices and clinically significant portal hypertension in patients with HCC
Manon Allaire[1], Bertille Campion[1], Edouard Larrey[1], Mathilde Wagner[1], Marika Rudler[1], Charles Roux[1], Lorraine Blaise[2], Nathalie Ganne-Carrié[2], Dominique Thabut[1]. [1]*Hôpital Pitié Salpetière, France;* [2]*Hôpital Avicenne, France*
Email: allama5@hotmail.fr

Background and aims: Baveno VI and VII criteria are used in patients with cirrhosis to rule-out large size varices (EV) and rule-in/out CSPH. Their diagnostic performance is still unclear in patients with HCC.
Method: All Child-Pugh A cirrhotic patients with HCC with endoscopy, liver stiffness measurement (LSM) and platelet count within 6 months were retrospectively included and classified according to the BCLC stage in 2 centers. Favorable Baveno VII criteria were defined by LSM <20 kPa and Plt >150 G/l, favorable Baveno VII criteria if LSM ≤15 kPa and Plt ≥150G/l. Clinical significant portal hypertension (CSPH) was defined by a HVPG ≥10 mmHg or the presence of EV regardless the size.
Results: 185 Child-Pugh A cirrhotic patients were included in the study (male 87%, median age 63 years, etiology of cirrhosis alcohol/metabolic syndrome/hepatitis C/hepatitis B in 46%/36%/20%/31% of cases and mixed for 33% of patients). Esophageal varices (EV) were present in 44% of patients (23% large size EV) and HVPG ≥ 10 mmHg in 41.7% (mean HVPG 8 mmHg). Median platelet count and elastometry were 148 × 103/mm^3 and 25 kPa respectively, 50% had platelet count <150 × 103/mm^3.
In the cohort, 46% of patients were classified as BCLC-0/A, 28% as BCLC-B and 26% as BLCL-C, and 18% had received prior treatment for HCC. A multinodular and infiltrative form was present in 52% and 15% of patients respectively, with a location in the right liver in 78% of cases. Compared to BCLC O-A HCC (21 kPa), elastometry was higher in BCLC-B (25 kPa, p = 0.005) and BCLC-C (27 kPa, p < 0.001) patients. There was no difference in platelet count between the different groups. In patients with favorable Baveno VI criteria, 7.8% in the whole cohort (Se 93%, PNV 82%), 11.1% of BCLC-0-A (Se 89%, PNV 89%) and 10.0% of BCLC-C patients (Se 91%, PNV 90%) had large EV. Among the patients with HVPG < 10 mmHg, i.e. without CSPH, 5.7% had large size EV and 17.1% small EV. CSPH was present in 26.7% of patients with favorable Baveno VII criteria in the whole cohort and in 23.5% of those of the BCLC-0/A subgroup. Specificity of LSM ≥ 25 kPa to rule-in CSPH was of 63%.
Conclusion: Favorable Baveno VI criteria are not appropriate to rule-out the presence of high-risk EV and Baveno VII criteria to rule-in/out CSPH in HCC patients.

FRI-275
Multi-omic large scale risk prediction for hepatocellular carcinoma
Jan Clusmann[1], Kai Markus Schneider[1], Christian Trautwein[1], Carolin V. Schneider[1]. [1]*RWTH Aachen University, Department for Gastroenterology, Metabolic Disorders and Internal Intensive Medicine, Aachen, Germany*
Email: janclusmann@ukaachen.de

Background and aims: Hepatocellular carcinoma (HCC) is the third-leading cause of cancer-related death worldwide and a crucial public health concern. Many patients with HCC are only diagnosed at advanced tumor stages, with low to no chance of curative treatment. Meanwhile, high-risk populations for liver cancer are well known. This highlights the urgent need for improved risk stratification, especially as multi-omics pave the way for personalized medicine.
Method: In a systematic approach we analyzed the population-based UK Biobank with n >500,000 subjects. We assessed population characteristics, electronic health records, death registers, lifestyle, physical and biological measures as well as single nucleotide polymorphisms (SNPs) associated with risk of HCC for ~500 000 subjects (508 with HCC) and nuclear magnetic resonance based (NMR) metabolomics for 106.000 subjects. We train several machine learning algorithms on the different data modalities, to assess relevance for risk stratification (Figure 1A).

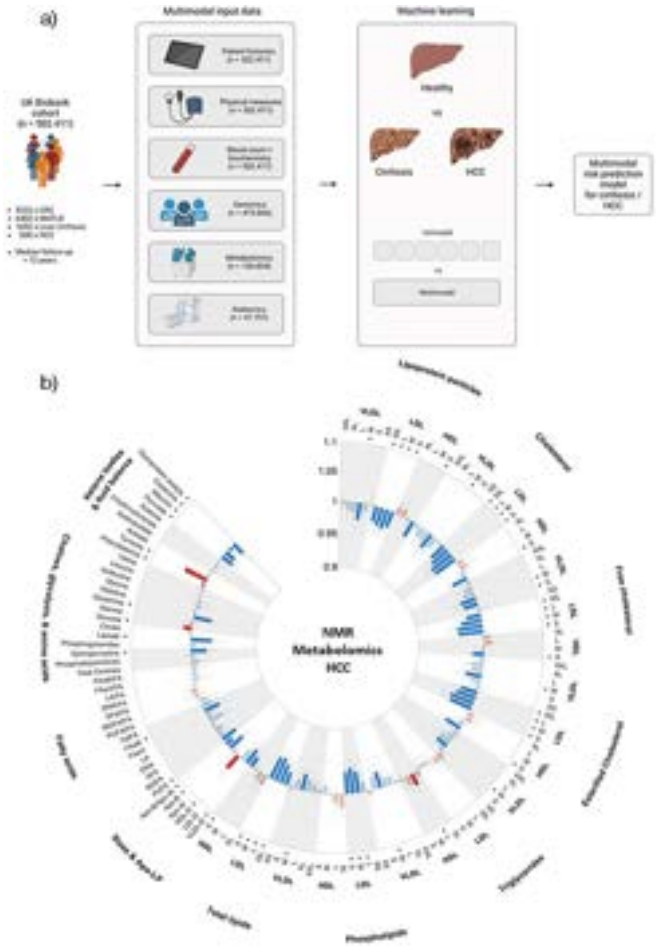

Figure: a) Study design for multimodal risk prediction of HCC (Created with BioRender.com). b) Associations of metabolic biomarkers with development of HCC. Hazard ratios (with 95% confidence intervals) are presented per 1-SD higher metabolic biomarker on the natural log scale, stratified by age, sex, body mass index and previous diagnosis of liver cirrhosis. *False discovery rate-controlled p < 0.01. DHA, docosahexaenoic acid; FA, fatty acids; FAw3/6, omega-3/6 fatty acids; HDL, high-density

lipoprotein; IDL, intermediate-density lipoprotein; LA, linoleic acid; LDL, low-density lipoproteins; LP, lipoprotein; MUFA/PUFA; mono-/polyunsaturated fatty acids; SFA, saturated fatty acids; VLDL, very low-density lipoprotein; (Code adapted from Diego J Aguilar-Ramirez).

Results: Preliminary results show robust validation for known single nucleotide polymorphisms (in TM6SF2, PNPLA3, GCKR, HLA-DP/DQ), risk factors (e.g., male sex and older age), and diagnosis commonly associated with HCC (e.g., cirrhosis). Linear regression models of NMR-metabolomics show a broad spectrum of significant alterations in metabolomic profiles for patients with HCC, even when stratified for liver cirrhosis (Figure 1B). Current benchmarking experiments comparing 25 different classifiers reveal decision-tree based models as highest performing models. As a next step, we are currently building a decision-tree based classifier, step-by-step integrating the multimodal data predicting HCC.
Conclusion: Our study shows significant changes in metabolomic profiles, as well as risk factors in several data modalities for individuals with HCC. Multimodal risk prediction models for HCC may assist clinicians in improving risk stratification.

FRI-276

Macrotrabecular-massive pattern is associated with aggressive factors, but it is not an independent predictor of tumor recurrence and overall survival in patients with hepatocellular carcinoma treated with liver resection

Ezequiel Mauro[1], Carla Fuster[2], Joana Ferrer[3], Berta Caballol[1], Marco Sanduzzi Zamparelli[1], Jordi Bruix[1], Josep Fuster[3], María Reig[1], Alba Díaz[2], Alejandro Forner[1]. *[1]Hospital Clínic de Barcelona, Liver Oncology Unit, Liver Unit, Barcelona Clínic Liver Cancer (BCLC) Group, IDIBAPS, CIBEREHD, University of Barcelona., Barcelona, Spain; [2]Hospital Clínic de Barcelona, Liver Oncology Unit, Pathological Unit, Barcelona Clínic Liver Cancer (BCLC) Group, IDIBAPS, CIBEREHD, University of Barcelona., Barcelona, Spain; [3]Hospital Clínic de Barcelona, Liver Oncology Unit, Unit, Hepatobilioopancreatic and Liver Transplant Department, Barcelona Clínic Liver Cancer (BCLC) Group, IDIBAPS, CIBEREHD, University of Barcelona, Barcelona, Spain*
Email: aforner@clinic.cat

Background and aims: The assessment of recurrence risk after liver resection (LR) is critical, particularly with the advent of effective adjuvant therapy. The presence of macrotrabecular-massive histological pattern (MTM: trabeculae >6 cells thick and whose pattern represents >50% of the tumor) has been recently associated with an increased risk of tumor recurrence and decreased overall survival (OS) after LR in patients with hepatocellular carcinoma (HCC). The aim of the study was to describe the subgroup of patients with HCC-MTM, as well as to evaluate its association with aggressive recurrence and OS after LR.
Method: Retrospective study in which all BCLC-0/single-A patients treated with LR between February 2000 and November 2020 were included. The main clinical variables were recorded at the time of admission, surgery and during follow-up. Histological features were evaluated by two independent pathologists. Aggressive recurrence was defined as those that exceeded the Milan criteria at the 1st recurrence.
Results: A total of 218 patients were included (30% BCLC 0 and 70% BCLC A), the median (interquartile range) age and tumor size were 63 years (54–69) and 28 mm (19–42), respectively. The prevalence of MTM and microvascular invasion and/or satellitosis (mVI/S) was 7.8% and 39%, with a kappa index between the two pathologists of 0.81 and 0.77. The presence of the MTM histological pattern was significantly associated with a higher prevalence of mVI/S (82.4% vs. 35.8%, $p < 0.001$), Edmonson Steiner grade III-IV (82.4% vs 36.8%, $p < 0.001$), and higher AFP values [185 (7–664) vs 6 (3–20) ng/ml, $p < 0.001$]. The median follow-up to the 1st recurrence was 34 (14–59) months and 127 (58%) patients experienced HCC recurrence. The recurrence free survival was 51 (41–61) months. The prevalence of aggressive recurrence was 35% (44/127, advanced stage in 20). The median follow-up was 49 (23–85) months, with a 5-year OS of 81%. The presence of MTM was not significantly associated with recurrence [HR: 1.57 (0.84–2.92), p:0.154] or with aggressive recurrence [HR: 1.57 (0.53–4.43), p:0.154], and the presence of mVI/S was the only independent predictor of aggressive recurrence [HR: 3.31 (1.74–6.29), $p < 0.001$]. Regarding OS, in the univariate analysis the presence of MTM was associated with a higher risk of death [HR: 2.50 (1.19–5.29), p:0.016], but after adjusting for AFP and mVI/S, it was not a predictor of OS [HR: 1.32 (0.49–3.52), p:0.573]. The presence of mVI/S was the only independent predictor of mortality [HR: 2.23 (1.27–3.91), p:0.005].
Conclusion: The MTM pattern is significantly associated with clinical and histological features of poor prognosis (worse degree of differentiation, mVI/S, and elevated AFP values), but it does not represent an independent predictor for recurrence/OS. Finally, the presence of mVI/S was the only independent risk factor of aggressive recurrence or lower OS rate.

FRI-277

GALAD score outperforms aMAP and ALBI scores in the 5- and 10-year prediction of hepatocellular carcinoma (HCC) development in patients with compensated advanced chronic liver disease (cACLD): a 12-year prospective study

Valentina Baldaccini[1], Sara Ascari[1], Rosina Maria Critelli[1], Letizia Pesole[2], Simone Lasagni[1], Sergio Coletta[2], Calogero Claudio Tedesco[2], Giuseppe Pasculli[2], Rossella Donghia[2], Filippo Semellini[1], Erica Villa[1], Gianluigi Giannelli[2]. *[1]Gastroenterology, Chimomo, Italy; [2]National Institute of Gastroenterology "S. De Bellis" Research Hospital, Italy*
Email: erica.villa@unimore.it

Background and aims: Several scores for hepatocellular carcinoma (HCC) prediction have been derived from the analysis of prospective or retrospective patients' cohorts, among these aMAP and ALBI scores. In this study, we have tested the performance of GALAD score alone for predicting 5-year and 10-year HCC risk score from the analysis of a cohort of patients with cACLD of any etiology prospectively enrolled since 2011 vs. aMAP and ALBI scores.
Method: A cohort of 545 patients with cirrhosis was recruited and their GALAD score was calculated. The patients were followed up for a median of 3.60 years at 5 years, and 5.58 years at 10 years. A Cox proportional hazard regression model was used to analyse the predictive ability of GALAD, aMAP and ALBI scores towards the development of HCC at 5 and 10 years.
Results: The results of the study showed that GALAD were all significant predictors of HCC at 5 (HR = 1.373, $p < 0.001$), aMAP (HR = 1.097, $p < 0.001$), and ALBI (HR = 0.162, $p = 0.074$) and at 10 years (HR = 1.315, $p < 0.001$), aMAP (HR = 1.072, $p < 0.001$), and ALBI (HR = 0.389, $p = 0.042$) respectively. Their direct comparison at the same time points showed that GALAD outperformed the other two for the prediction both at 5 and at 10 years (Figure).
Conclusion: We have shown in this study that GALAD score outperforms two other already validated and commonly used scores (aMAP and ALBI) for HCC prediction both at 5 and at 10 years. One possible explanation for GALAD advantage resides in the specific GALAD composition, i.e. the inclusion of AFP as well as AFP-L3 and DCP, whose alteration, especially on the long-term, can be of relevant gain vs. scores including biochemical parameters, more related with liver function than with carcinogenic risk thus opening new opportunities for the clinical management and the decision making of patients with cACLD.

Alternative surveillance using CT/MR improves clinical outcomes by detecting early-stage hepatocellular carcinoma in High-risk patients with chronic hepatitis B

Su Jong Yu[1], Dong Ho Lee[2], Heejin Cho[1]. [1]*Seoul national university hospital, Internal Medicine, Korea, Rep. of South;* [2]*Seoul national university hospital, Radiology, Korea, Rep. of South*
Email: dhlee.rad@gmail.com

Background and aims: This study aimed to evaluate the outcome of alternative hepatocellular carcinoma (HCC) surveillance using CT/MR compared to that of US only in chronic hepatitis B (CHB) patients.
Method: We enrolled consecutive CHB patients undergoing regular HCC surveillance, classifying into two groups: US only group and alternative surveillance group. The risk estimation for HCC in CHB (REACH-B) score was calculated to categorize high and low risk. Outcomes included 10-year overall survival (OS), Size and Barcelona Clinic Liver Cancer (BCLC) stage of HCC, and OS after HCC diagnosis.
Results: A total of 2024 patients were enrolled with 1012 patients in each group. In alternative surveillance group, all of 1012 patients underwent contrast enhanced CT (median number, 3; IQR, 1–6; range, 1–24) instead of scheduled US for HCC surveillance during the follow-up. Contrast enhanced MR was done in 222 patients (median number, 1; IQR, 1–2; range, 1–10). There was no significant difference in OS (96.0% in US only vs. 96.8% in alternative surveillance; P = 0.379). In both groups, HCC occurred in 66 patients. Medium size of HCC in alternative surveillance was significantly smaller than US only (1.6 cm vs. 2.1 cm; P < 0.001). The rate of BCLC 0 stage HCC was also significantly higher in alternative surveillance than US only (71.2% [47/66] vs. 42.4% [28/66]; P = 0.003). OS after HCC diagnosis in alternative surveillance group was significantly better than that in US only group (83.0% vs. 67.0%; P = 0.025). In high risk group including 970 patients, alternative surveillance provided significantly better OS (97.3% vs. 93.6%; P = 0.029) and OS after HCC diagnosis (83.0% vs. 60.6%; P = 0.010) than US only. However, there was no significant difference in both OS (p = 0.202) and OS after HCC diagnosis (p = 0.937) in 1054 patients with low risk.
Conclusion: Alternative surveillance using CT/MR enabled the detection of HCC in earlier stage with smaller size than US only, and had a potential to improve OS after HCC diagnosis, especially for patients with high risk.

FRI-279

Presence of esophageal varices regardless their size is associated with overall survival in patients with advanced HCC treated with Atezolizumab/Bevacizumab

Philippe Sultanik[1], Edouard Larrey[1], Bertille Campion[1], Manon Evain[1], Christine Brochet[2], Héloise Giudicelli[1], Mathilde Wagner[3], Jérome Denis[2], Marika Rudler[1], Dominique Thabut[1], Manon Allaire[1]. Email: philippe.sultanik@aphp.fr

Background and aims: Portal hypertension (PHT) and hepatocellular carcinoma (HCC) are 2 closely related complications of cirrhosis. The presence of PHT is associated with higher mortality with locoregional treatments of HCC. Our objectives were to investigate whether PHT parameters were associated with progression-free survival (PFS) and overall (OS) in HCC patients (pts) treated with Atezolizumab/Bevacizumab (Atezo/Beva).
Method: Data from all pts treated with Atezo/Beva were collected prospectively since August 2020. OS and PFS were assessed using Kaplan Meier. Progression was defined as a composite (progression and/or side effects/hepatic decompensation requiring discontinuation). The influence of baseline characteristics on events during follow-up was assessed by Cox model.
Results: Data from 75 pts treated with Atezo/Beva were analyzed prospectively (median age 65 years, 21% women, 81% cirrhotic pts). Risk factors for cirrhosis were viral infection (57%), excessive alcohol consumption (47%) and metabolic syndrome (35%). 37% had a mixed cause of cirrhosis. At inclusion, 74% of the pts were Child-Pugh A and 49% had esophageal varices (EV) (25% large size EV). On the day of treatment, 65% of pts were BCLC-C and 52% were treatment-naive for

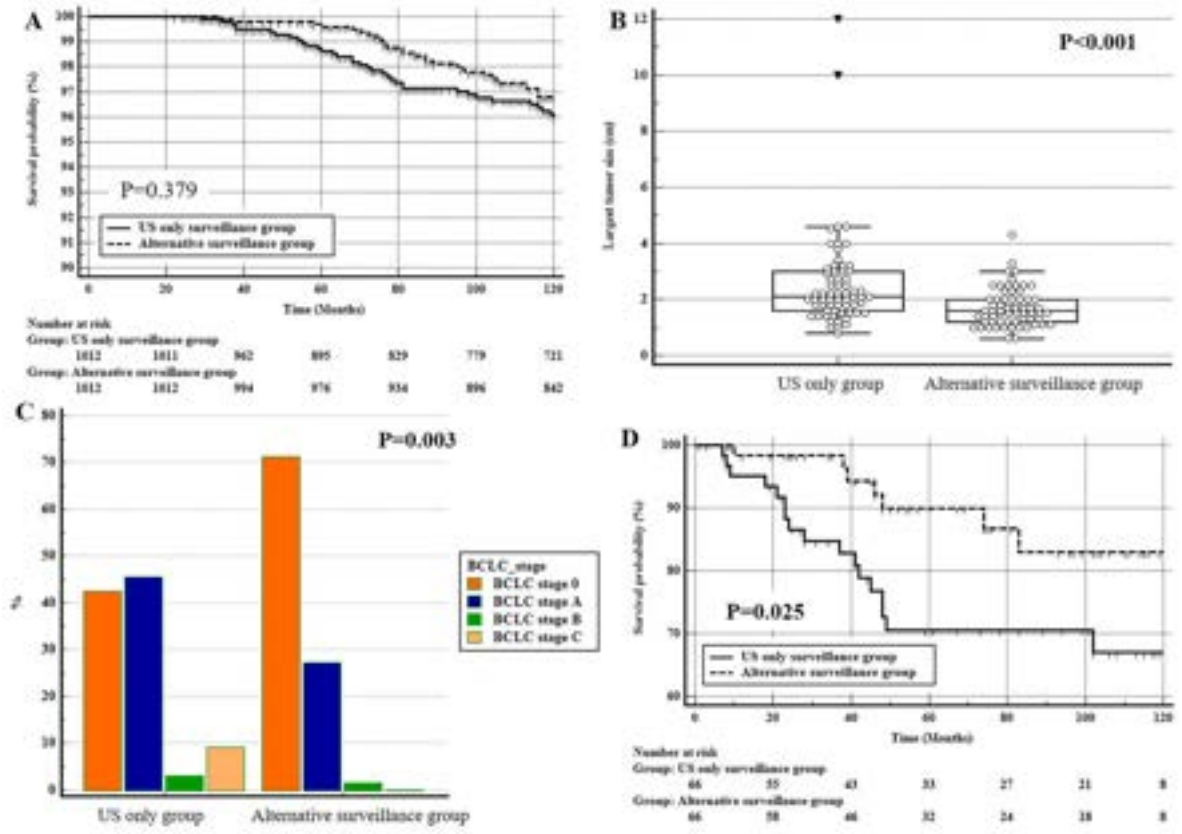

Figure: (abstract: FRI-278): (A) Overall survival in total of 2024 patients with 1012 patients in each group. (B) Size of HCC in total of 132 patients who had HCC. HCC was occurred in 66 patients of both two groups. (C) Distribution of BCLC stage of HCC at the time of diagnosis in total of 132 patients who had HCC. (D) Overall survival after HCC diagnosis in 132 patients who had HCC.

HCC. HCC was multi-nodular in 68%, with a median size of 59 mm for the largest lesion, 33% had infiltrating HCC and 47% vascular invasion. At inclusion, median bilirubin was 14 μM, INR 1.14, albumin 35 g/L, platelets 170,000/mm^3, MELD score 9.0, PIVKA 3.358 and AFP 207 ng/ml. Of the patients, 15% had an ALBI score of 3 and 18% had thrombocytopenia <100,000/mm^3. Median follow-up was 13 months, 33% of pts had a response to treatment (regression or stability). The PFS was 30% at 12 months. In univariate analysis, the presence of ≥3 HCC lesions (HR = 1.4, 95% CI [0.6–3.2], p = 0.02), platelet count (HR = 1.01, 95% CI [1.01–1.1], p = 0.03), albumin level (HR = 0.9, 95% CI [0.89–0.99], p = 0.04), PIVKA (HR = 1.01, 95% CI [1.01–1.1], p = 0.003), AFP (HR = 1.01, 95% CI [1.01–1.1], p = 0.003) and the presence of large EV (HR = 2.2, 95% CI [1.2–4.2], p = 0.02) were associated with PFS. Only the presence of large EV was associated with PFS in multivariate analysis (HR = 3.5, 95% CI [1.5–8.3], p = 0.005). OS was 54% at 12 months. Death was related to HCC in 59%, liver failure in 15%, sepsis in 15% and other causes in 11%. In univariate analysis, BMI (HR = 1.1, 95% CI [1.02–1.2], p = 0.01), presence of ≥3 HCC lesions (HR = 1.1, 95% CI [0.4–2.2], p = 0.001), ALBI grade (HR = 1.9, 95% CI [1.2–3.3], p = 0. 01), PIVKA (HR = 1.01, 95% CI [1.01–1.1], p < 0.001), AFP (HR = 1.01, 95% CI [1.01–1.1], p = 0.001), presence of EV regardless the size (HR = 2.2, 95% CI [1.2–4.2], p = 0.02) were associated with OS. Only the presence of EV regardless of the size was associated with OS in multivariate analysis (HR = 2.2, 95% CI [1.1–6.9], p = 0.03). During the follow-up, 8% of pts presented an acute variceal bleeding (AVB): 60% of them had a history of AVB, 60% small size EV and 40% large size EV at the pre-treatment endoscopy. Primary prophylaxis for AVB was started only in pts with large size EV according to Baveno VI recommendations. None of the pts died secondary to AVB.

Conclusion: The presence of EV regardless of their size is associated with OS in patients with advanced HCC treated with Atezo-Beva. Among the patients who presented AVB under treatment, 60% had small size EV, motivating the implementation of an AVB prophylaxis with beta-blockers in all patients with EV regardless of their size.

FRI-280

A machine learning enabled score based on large varices predicts 5- and 10-year hepatocellular carcinoma (HCC) development in a 12-year prospective cohort of patients with compensated advanced chronic liver disease

Sara Ascari[1], Rodolfo Sardone[2], Fabio Castellana[2], Filippo Schepis[1], Valentina Baldaccini[1], Filippo Semellini[1], Alessandra Pivetti[1], Lorenza Di Marco[1], Barbara Lei[1], Nicola De Maria[1], Francesco Dituri[2], Gianluigi Giannelli[2], Erica Villa[1]. [1]*Gastroenterology, Chimomo, Modena, Italy;* [2]*S. De Bellis Research Hospita, National Institute of Gastroenterology, Italy*
Email: erica.villa@unimore.it

Background and aims: Most scores for HCC prediction can assess at most 3- or 5-year HCC risk, as the observation period of the derivative cohort is usually short. We aimed to develop a 5- and 10-year HCC risk score from a prospective cohort of patients with compensated advanced chronic liver disease (cACLD) of any aetiology followed up for 12 years.

Method: 545 patients with cACLD, HCC-free, prospectively enrolled from 2011 to 2022, using a convenience sampling, underwent at enrolment upper g.i. endoscopy, liver ultrasound/elastography, HVPG measurement, lab tests. Cox proportional models were used to assess the association between esophageal varices, adjusted for all the selected covariates, and HCC incidence. Random Survival Forest (RSF), a machine learning (ML) prediction model, was used as a

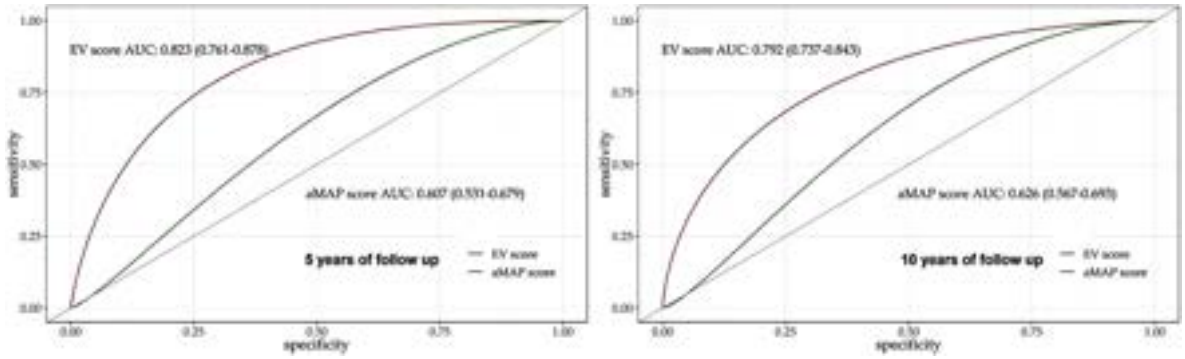

Figure: (abstract: FRI-280).

sensitivity analysis to test prediction power of the same covariates, considering all the possible interactions and non-linear relationships with HCC incidence as the outcome.

Results: Median f-up time was 5.9 years. We observed 78 incident HCCs (14.3%). In the fully adjusted Cox proportional models after the adjustment for covariates, patients with large esophageal varices had 4 times the risk of developing HCC (HR:4.02; 95% C.I.: 2.42–6.68) than patients with small/without varices. The covariates, viral aetiology (HR 2.61;95% C.I.: 1.57–4.35), LSM (for each kPa) (HR: 1.01;95% C.I. 1.01–1.03, male sex (HR:1.94 C.I. 95%: 1.10–3.41), were also meaningfully associated with HCC risk. As a sensitivity analysis we performed the RSF selection algorithm to rank all the variables of the Cox models, according to their prediction power (using minimal depth metric) for the incidence of HCC. Large esophageal varices had the best prediction power for HCC, followed by LSM, viral aetiology, BMI, albumin, and age at the enrolment. Interestingly, RSF prediction power was in line with the magnitude of association with Cox model, but ML further identified BMI and albumin as related and excluded sex. The score built with the RSF-selected variables (Esophageal Varices [EV] score) had excellent discrimination and calibration in assessing both 5- (AUROC 0.823) and 10-year (AUROC 0.792) HCC risk irrespective of aetiology, with a significantly better overall performance at both time points than aMAP score, built on the same data (figure).

Conclusion: The machine learning approach, used to build this score, allowed us to identify large varices as the most important predictor for HCC risk (underlining the critical pathogenetic role of long-standing and severe portal hypertension in HCC development). This score also obtained better prediction for 5- and 10-year HCC development than aMAP score (i.e. the best score so far for HCC prediction independently from aetiology) tested in the same dataset. The proposed score is highly reliable. Being based on routine clinical data of the patients with cACLD it can be easily applied worldwide.

FRI-282

Validation of serum biomarker panels for early HCC detection: results from a large prospective European and Latin American multicenter study

Boris Beudeker[1], Siyu Fu[1], Domingo Balderramo[2], Angelo Z. Mattos[3], Enrique Carrera[4], Javier Diaz-Ferrer[5], Jhon Prieto[6], Marco Arrese[7], Arndt Vogel[8], Jesus Maria Banales[9], Jeffrey Oliveira[1], Anthony Grooshuismink[1], Gertine Oord[1], Robert De Man[1], Jose Debes[10], Andre Boonstra[1]. *[1]Erasmus MC, Gastroenterology and hepatology, Rotterdam, Netherlands; [2]Hospital Privado Universitario de Córdoba, Argentina; [3]Federal University of Health Sciences of Porto Alegre, Brazil; [4]Hospital Eugenio Espejo, Ecuador; [5]Hospital Nacional Edgardo Rebagliati Martins, Peru; [6]Centro de Enfermedades Hepáticas y Digestivas (CEHYD), Colombia; [7]Facultad de Medicina, Chile; [8]Medizinische Hochschule Hannover, Germany; [9]Biodonostia Health Research Institute, Spain; [10]University of Minnesota, United States*
Email: b.beudeker@erasmusmc.nl

Background and aims: HCC is a major cause of cancer death. Guidelines recommend routine 6-month ultrasonography surveillance for high-risk patients, but its effectiveness in early-stage HCC detection is limited. PIVKA-II, AFP, and the GALAD panel of serum biomarkers are linked to HCC, but inconsistent use in guidelines limits their value.

Method: In a multi-center study, 2045 patient samples were retrospectively or prospectively collected from 7 countries and analyzed for cancer diagnosis and liver disease etiology. The performance of multivariable models based on AFP and PIVKA were tested for early stage HCC detection, low AFP HCC, 12 months pre-diagnostic HCC (n = 92, range 9–15 months), and compared to cirrhosis and other liver tumors.

Results: The GALAD model showed excellent ability to differentiate HCC from liver cirrhosis in the prospective Latin American cohort (n = 288), with an AUC of 87.9. A novel multivariable model was developed to detect early-stage HCC with low AFP levels, by combining sex, age, AFP, and PIVKA-II (also called GAAD), with an AUC of 87.3. Both GALAD and GAAD effectively differentiated low AFP HCC from cirrhosis in both European and Latin American patients, with AUCs of 82.8 and 81.6, respectively. Aiming to improve and recalculate the GALAD model in early HCC cirrhotic cases performed similarly to the original. 12 Months prior to HCC diagnosis, GAAD differentiated cirrhosis (n = 193) from pre-diagnostic HCC (n = 92) ($p < 0.0001$), with 59% sensitivity and 85% specificity in those who would develop an advanced HCC in 9–15 months. In addition, GAAD differentiated non-cirrhotic HCC (n = 243) from other malignant and benign liver tumors with an AUC of 91.9, and it was 100% sensitive and specific in hemangioma cases (n = 64).

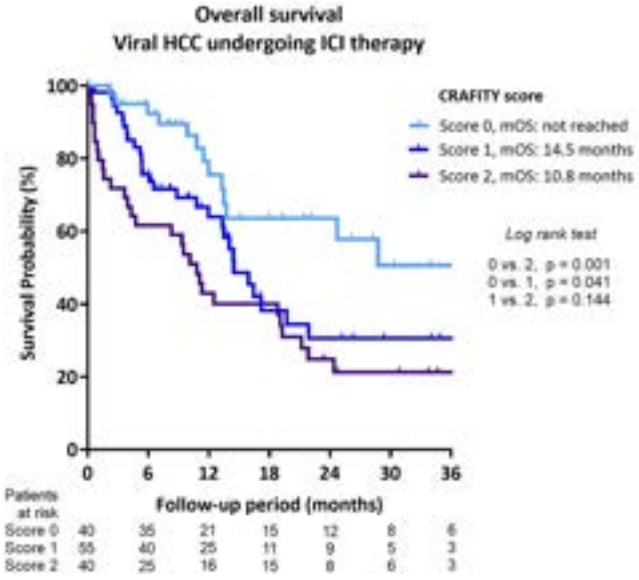
Conclusion: The GALAD model has proven to be robust in early stage HCC and diverse patient populations, and its performance remains consistent even when recalculated using different patient cohorts. Our findings warrant its consideration for inclusion in international guidelines for HCC diagnosis and surveillance. With high accuracy, sensitivity, and specificity, the GAAD models has the potential to revolutionize the routine HCC surveillance and diagnosis, in both high-risk cirrhotic and non-cirrhotic cases patients and in low AFP early stage HCC.

FRI-283

A novel AFP-M2BPGi score has better performance than CRAFITY score in predicting survival for patients with viral hepatocellular carcinoma undergoing immunotherapy

Pei-Chang Lee[1], Chijung Wu[1], Kuo-Wei Huang[2], ChiehJu Lee[1], I-Cheng Lee[1], Ming-Chih Hou[1], Yi-Hsiang Huang[1]. *[1]Taipei Veterans General Hospital, Taiwan; [2]Taipei City Hospital Yang- Ming branch, Taiwan*
Email: yhhuang@vghtpe.gov.tw

Background and aims: CRAFITY score has been developed to predict the clinical outcomes of patients who received immune checkpoint inhibitors (ICI) for unresectable hepatocellular carcinoma (HCC).



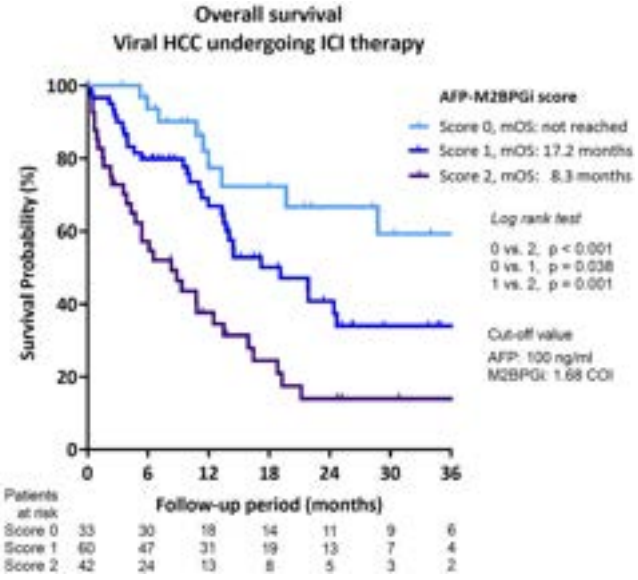


Figure: (abstract: FRI-283).

However, it remains uncertain about the performance of CRAFITY score in patients with viral HCC undergoing ICI-based therapy. Serum Mac-2 binding protein glycosylation isomer (M2BPGi) is a novel biomarker reflecting liver fibrosis for chronic hepatitis B and C. In this study, we aimed to investigate the role of serum M2BPGi in predicting the survival of ICI-treated viral HCC.

Method: From May 2017, 243 consecutive patients had received ICI-based immunotherapy for unresectable HCC in Taipei Veterans General Hospital. The prognostic value of baseline variables, including M2BPGi, on overall survival was analyzed.

Results: During the follow-up period, 140 patients died and the median overall survival (OS) was 13.9 months (95% confidence interval [CI]: 10.6–17.2). Patients with baseline low CRAFITY score had the significantly longest median OS (not yet reached) than the others. However, the OS could not be significantly differentiated between CRAFITY-intermediate and CRAFITY-high patients (median OS: 13.3 vs. 9.5, p = 0.105), particularly in patients with viral HCC (median OS: 14.5 vs. 11.1, p = 0.241). Among patients with viral HCC, blood samples had been prospectively collected from 135 patients at baseline for measuring M2BPGi. A serum level of M2BPGi greater than 1.68 COI acceptably predicted OS in these patients (AUROC: 0.629, hazard ratio: 2.599, 95% CI: 1.594–4.238, p < 0.001). Combined with baseline serum alpha-fetoprotein level (AFP ≥100 ng/ml), a new score including AFP and M2BPGi was developed. Patients who fulfilled no criterion (0 points) had the longest median OS (not yet reached), followed by those fulfilling 1 point (17.2 months, 95% CI: 7.6–26.8), and patients meeting both criteria (8.3 months, 95% CI: 3.8–12.8) (p = 0.038, <0.001, and 0.001 for score 0 vs.1, 0 vs. 2, and 1 vs. 2). Besides, the new AFP-M2BPGi scoring model had a higher homogeneity value (21.85 vs. 11.21) and lower corrected Akaike information criterion value (582.76 vs. 593.41) compared to the CRAFITY score.

Conclusion: A new AFP-M2BPGi score would be superior to CRAFITY score to predict survival in patients receiving ICI-based immunotherapy for viral HCC. This new score may have better clinical application for HCC patients in areas endemic for viral hepatitis.

FRI-284

Implication of patients experience in the liver cancer multidisciplinary approach

Gemma Iserte[1,2,3], Eva Palou[4], Neus Llarch[1,2,3,5], Jessica Farre[4], Maria Ángeles García-Criado[1,2,3,6], Joana Ferrer[1,2,3,7], Alba Díaz[1,2,3,8], Marta Burrel[1,2,3,6], Montse Brañas[9], Antonia Murcia[9], María Reig[1,2,5,10], Joan Escarrabill[4]. *[1]BCLC group. Fundació Clinic per a la Recerca Biomèdica-IDIBAPs, Barcelona, Spain, Spain; [2]CIBERehd, Madrid, Spain; [3]Liver Oncology Unit. Institut de Malalties Digestives i Metabòliques. Hospital Clinic of Barcelona, Barcelona, Spain, Spain; [10]Liver Oncology Unit. Liver Unit, Hospital Clinic of Barcelona, Barcelona, Spain, Spain*
Email: escarrabill@clinic.cat

Background and aims: The three pillars of the Quality of Health Care are efficacy, safety and patients experience (PE). Additionally, it has been demonstrated that the multidisciplinary approach is associated to better outcome. The last version of BCLC staging system includes the chapter on '*clinical decision-making*' showing the multiparametric approach used by physicians when selecting treatments including patient perspective. Aim**:** to evaluate PE in the BCLC group.

Method: The project was divided into 3 parts: 1) The Patient Experience Team (PExT) and professionals from BCLC map the patient journey, the stakeholder map, and identify the patient's archetype; 2) based on the information from part 1, the PExT designed questions. The BCLC nurses, according the archetypes, invited patients for the focal groups/interviews and 3) PExT did the focal groups/interviews. All the interventions were recorded and verbatim transcription was analyzed through MAXQDA software.

Results: A total of 11 patients and 3 caregivers of patients who died due to liver cancer were invited. Eleven patients participated in 3 focal groups and 3 caregivers were interviewed. In the focal groups 91 concepts were identified and were grouped into 23 categories and 6 meta-categories (Figure 1). The most frequent meta-categories were related to the information received, the contact with professionals, the impact of cancer in their life and the support received. The majority of patients did not need to look further information on the internet, they found that the information at diagnosis was clear, precise and enough but they would like to have more time to clarify doubts. The patients were aware of the role of the different professionals and saw them as a coordinated group but some of

them requested more information regarding the 'clinical decision process.' The majority of patients agreed that the diagnosis had affected their lives and most of them commented that the best support was their family despite of the fact that some received external support. In the caregivers interviews the good coordination between the Hospital and palliative home care teams was mentioned. However, they raised the difficulties that they had to openly speak about death with their relatives due to the cultural barrier and the need of support for caregivers in this regard. The PE can be positive even in situations where outcomes worsen, such as in the case of the end of life.

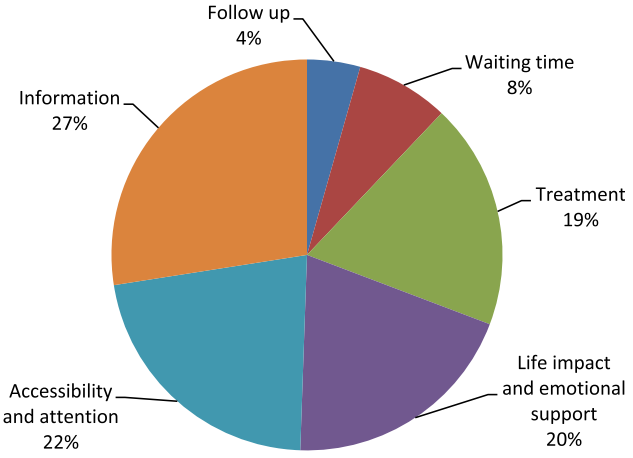

Figure:

Conclusion: Patients and caregivers are interested on aspects related to contact with professionals and the support received. Thus, the evaluation of PE helps the BCLC team to promote Value-based Heath Care. In addition, this study reinforces the need of information given during the follow-up visits or organizing activities not only with patients but also for caregivers as well as developing the PROMs/PREMs to effectively implement 'shared-decision making'.

FRI-285

Management of varices but not anticoagulation is associated with improved outcome in patients with hepatocellular carcinoma and macrovascular tumour invasion

Lorenz Balcar[1,2], Arpad Mrekva[3], Bernhard Scheiner[1,2], Katharina Pomej[1,2], Tobias Meischl[1,2,4], Mattias Mandorfer[1], Thomas Reiberger[1], Michael Trauner[1], Dietmar Tamandl[3], Matthias Pinter[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Liver Cancer (HCC) Study Group Vienna, Vienna, Austria; [3]Medical University of Vienna, Department of Radiology, Vienna, Austria; [4]Hanusch Krankenhaus, 3rd Medical Department (Hematology and Oncology), Vienna, Austria*
Email: lorenz.balcar@meduniwien.ac.at

Background and aims: The value of bleeding prophylaxis and anticoagulation in patients with hepatocellular carcinoma (HCC) and macrovascular tumour invasion (MVI) is unclear. We evaluated the impact of anticoagulation on thrombosis progression, bleeding events, and overall mortality, and assessed the efficacy of adequate management of varices as recommended for patients with cirrhosis.
Method: HCC patients with MVI who had Child-Turcotte-Pugh A-B7 were included between Q4/2002 and Q2/2022. Localization of the tumour thrombus and changes at 3–6 months were evaluated by two radiologists. Univariable and multivariable logistic/Cox regression analyses included time-dependent variables (i.e., anticoagulation, systemic therapy, non-selective beta blocker treatment). The occurrence of portal-hypertension-related complications was recorded.
Results: Of 124 patients included (male: n = 110, 89%), MVI involved the main portal vein in 47 patients (38%), and 49 individuals (40%) had additional non-tumorous thrombus apposition. Fifty of 80 patients (63%) with available endoscopy had varices. Twenty-four individuals (19%) received therapeutic anticoagulation and 94 patients (76%) were treated with effective systemic therapies. The use of therapeutic anticoagulation did not significantly affect the course of the malignant thrombosis at 3–6 months. Systemic therapy (aHR: 0.26 [95%CI: 0.16–0.40]) but not anticoagulation was independently associated with reduced all-cause mortality. In patients with known variceal status, adequate management of varices was independently associated with reduced risk of variceal bleeding (aHR: 0.12 [95%CI: 0.02–0.71]). In the whole cohort, non-selective beta blockers were independently associated with reduced risk of variceal bleeding or death from any cause (aHR: 0.69 [95%CI: 0.50–0.96]).
Conclusion: Adequate bleeding prophylaxis and systemic anti-tumour therapy but not anticoagulation were associated with improved outcomes in patients with HCC and MVI.

FRI-286

Phenotypic characteristics of primary liver cancer in a large French cohort of patients with viral chronic liver disease followed-up before and after viral eradication: an ANRS study

Email: alina_pascale@yahoo.com

Background and aims: Liver cancer is the third leading cause of cancer death and the sixth most commonly diagnosed cancer worldwide. In patients with viral chronic liver disease, the risk of liver cancer diminishes significantly after viral eradication but it does not become null. Our study aims to describe the phenotypic characteristics of primary liver cancer occurring in a large cohort of patients with viral chronic liver disease, followed-up before and after viral eradication or control.
Method: 406 patients with viral chronic liver disease included in the French cohort LICAVIR (partially prospective), who developed a liver cancer, were analyzed. Epidemiological, radiological, histological data were recorded and assessed. Among them, 380 (93.5%) patients had centrally revised radiological data and 128 (31.5%) had centrally revised histological data. The median follow-up was 61 months [IQR: 40–74]. Statistical analysis was performed using SAS software version 9.4 (SAS Institute Inc., Cary, North Carolina).
Results: Most patients were males: 312 (77%) with median age of 61.8 years. 368 patients (90%) had hepatitis C virus (HCV) infection, 33 (8%) had hepatitis B virus (HBV) infection and 5 (1%) were coinfected. The main cofactors for chronic liver disease were: excessive alcohol consumption (37%), diabetes (25%), arterial hypertension (35%). 361

patients (89%) had cirrhosis, among whom 82% had a Child-Pugh A score and a median MELD score of 8.5 [IQR: 7–11]. 28% of cirrhotic patients had a prior history of liver decompensation. The median time between cirrhosis and liver cancer diagnosis was 72 months [IQR: 37–126]. 78% of liver cancers were diagnosed during regular surveillance. 385 patients (97.8%) developed hepatocellular carcinoma (HCC), 7 patients (1.7%) developed cholangiocarcinoma and 2 (0.5%) patients had hepato-cholangiocarcinoma. At diagnosis, 243 of liver cancers (62%) were single tumors, with a mean diameter of 28.5 mm, while 67 (17%) were associated with portal vein thrombosis or invasion and 22 (6%) were metastatic (27% of lung metastasis). Among HCV-infected patients, 126 developed liver cancer after achieving sustained virological response (SVR) and were compared to 215 patients who developed it before SVR. Multinodular HCC were more frequent in HCV-infected patients (43% vs 33%, p < .0001), while single tumors were more frequent in patients who achieved SVR (66% vs 56%, p = 0.0075). The median time between SVR and liver cancer diagnosis was 23 months [IQR: 9–36]; 96% of liver cancers occurred within 5 years after SVR. Multiple treatments were performed: among 364 curative treatments-189 (51%) percutaneous tumor ablations, 112 (31%) liver resections and 63 (17%) liver transplantations; among 501 palliative treatments-217 (43%) trans-arterial chemoembolizations and 128 (26%) systemic therapies. During follow-up, 110 patients died.

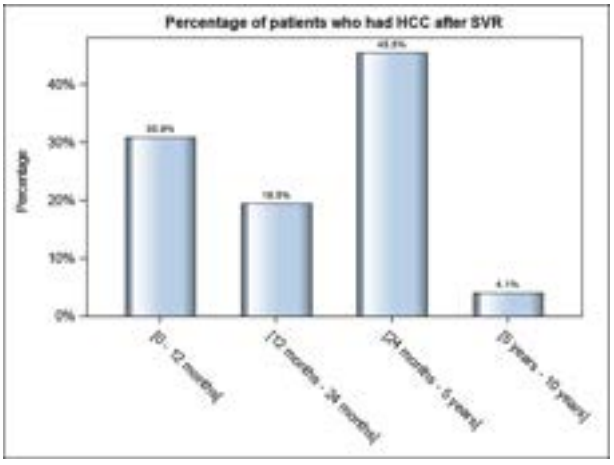

Figure:

Conclusion: In our large cohort of patients with viral chronic liver disease, followed-up before and after viral eradication or control, liver cancers developed mostly in cirrhotic liver. The most frequent type of liver cancer was HCC, which in more than half of patients was a single tumor, detected during a surveillance program. There was no significant phenotypical difference between HCC occurring before or after SVR, except for the multinodular type, which seemed to be more frequent before SVR. In our cohort, most of liver cancers (96%) occurred within the five first years after SVR.

FRI-287

Predicting cardiovascular risk in patients with HCC receiving tyrosine kinase inhibitors: comparison of two different scores

Bernardo Stefanini[1], Francesco Tovoli[1], Alessandro Granito[1], Franco Trevisani[2], Tiziana Pressiani[3], Andrea Casadei Gardini[4], Rodolfo Sacco[5], Fabio Piscaglia[1]. *[1]Division of Internal Medicine, Hepatobiliary and Immunoallergic Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, Italy; [2]Semeiotica Medica, Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italia., Italy; [3]Medical Oncology and Hematology Unit, Humanitas Clinical and Research Center, IRCCS Humanitas Research Hospital, Rozzano (Milan), Italy, Italy; [4]Department of Oncology, IRCCS San Raffaele Scientific Institute Hospital, Milan, Italy, Italy; [5]Gastroenterology Unit, Azienda OspedalieGastroenterology and Digestive Endoscopy Unit, Foggia University Hospital, Foggia, Italy, Italy*
Email: bernardo.stefanini@gmail.com

Background and aims: Antineoplastic agents targeting the VEGF-VEGFR pathway increase the risk of major adverse cardiac and cerebrovascular events (MACE). In the HCC setting these agents include bevacizumab (as part of the first-line combination treatment) and TKIs. The European Society of Cardiology proposed a risk stratification algorithm for cardio-oncology (ESC-2022), never been tested in HCC. The CARDIOSOR score has been also proposed (Carballo-Folgoso, 2021) but lacks external validation in predicting MACE in sorafenib-treated patients.
Method: Retrospective analysis of the ARPES and ITA.LI.CA databases to test the ESC-2022 and CARDIOSOR abilities in predicting MACE in sorafenib-treated HCC patients (2010–2018 timeframe). Evolutive events after sorafenib start (including the occurrence of MACE) were available for all patients. Competing-risk regressions for each score were performed to address the study aim.
Results: This study included 815 patients, 28 suffered at least one MACE (3.4%). The four-tier ESC classification showed an sHR 1.42, (p = 0.015) per every risk-class (1-year risk 1.7%, 2.1%, 4.3%, and 8.0% in the low, medium, high, and very-high-risk tiers, respectively). The dichotomous CARDIOSOR scale identified a high-risk group with a 4-fold increased risk of MACE (sHR 4.12, p = 0.007; 1-year risk 3.2% and 13.1%). Both score had similar predictive ability (Akaike information criterion 360 and 366, respectively.

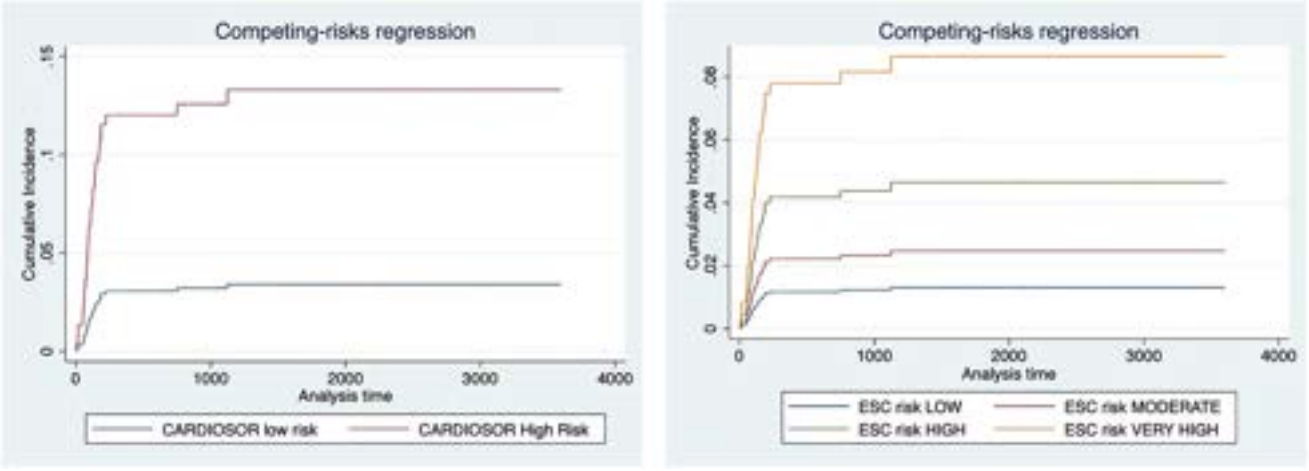

Figure: (abstract: FRI-287).

Conclusion: The risk of MACE in patients receiving TKI for HCC was non-negligible. Both scores discriminated this probability accurately, with different perks and pitfalls. These tools will be useful in the near-future to identify high-risk patients, candidate for anti-VEGF-free regimens (i.e. tremelimumab-durvalumab).

FRI-288

A prospective multicenter study to examine the impact of acquired and genetic predictors on Hepatocellular carcinoma risk in patients with advanced NAFLD: first report

Serena Pelusi[1], Cristiana Bianco[1], Luisa Ronzoni[1], Alessandro Cherubini[1], Ilaria Marini[1], Francesco Malvestiti[1], Roberta D'Ambrosio[1], Anna Ludovica Fracanzani[1], Annalisa Cespiati[1], Giorgio Soardo[2,3], Stephanie Pivetta[2], Luca Miele[4], Antonio Liguori[4], Elisabetta Bugianesi[5], Chiara Rosso[5], Salvatore Petta[6], Grazia Pennisi[6], Umberto Vespasiani Gentilucci[7], Federica Tavaglione[7], Alessandro Federico[8], Francesco Paolo Russo[9], Paola Zanaga[9], Mario Masarone[10], Daniele Prati[1], Luca Valenti[1]. *[1]IRCCS Ca' Granda Ospedale Maggiore Policlinico Milano, Italy; [2]University of Udine, Department of Medicine, Italy; [3]Italian Liver Foundation AREA Science Park, Italy; [4]Università Cattolica del Sacro Cuore, Department of Internal Medicine, Roma, Italy; [5]University of Torino, Department of Medical Sciences, Division of Gastroenterology, Torino, Italy; [6]University of Palermo, Palermo, Italy; [7]University Campus Bio-Medico of Rome, Roma, Italy; [8]University of Campania, Napoli, Italy; [9]University of Padova, Padova, Italy; [10]University of Salerno, Salerno, Italy*
Email: serenapelusi@libero.it

Background and aims: In parallel with the diabesity pandemic, hepatocellular carcinoma (HCC) is increasingly being diagnosed in non-alcoholic fatty liver disease (NAFLD), often at a late stage. Aim was to estimate the impact of acquired and genetic factors on HCC incidence in a prospective multicenter cohort of patients with advanced NAFLD.

Method: Inclusion criteria were NAFLD diagnosis, age 45–75 years, fibrosis stage F3-F4, determined histologically or by non-invasive assessment (stiffness >7.9 kPa by Fibroscan and FIB-4≥1.3), regular 6-months surveillance. Clinical parameters were collected and the cohort was genotyped for rs738409C>G in *PNPLA3*, rs58542926C>T in *TM6SF2*, rs1260326C>T in *GCKR*, rs641738C>T in *MBOAT7* and rs72613567:TA in *HSD17B13* genes. In 276 subjects with complete genetic data, variants were combined to calculate a polygenic risk score (PRS-5). Time of progression to HCC was evaluated by Kaplan-Meier's estimates of cumulative incidence rates and p values were adjusted for confounding factors.

Results: We enrolled 429 individuals (59% male) with median follow-up of 46 months (IQR 34–53). Of these, 213 (49%) showed overt cirrhosis; diabetes was present in 196 (45%), whereas 231 (53%) had hypertension. Twelve patients developed HCC during follow-up. Of these, 11 had cirrhosis and 1 showed F3 fibrosis at liver biopsy. The cumulative 5-year Incidence of HCC was 3.7% (95%CI, 2–6%), 1.2% (95% CI, 0.5–2.5%) in the first year. We registered 6 HCC-related deaths, median survival after HCC diagnosis was 17.5 months (IQR 2–24). At Kaplan-Meier analysis, time of progression to HCC was not influenced by diabetes, sex or hypertension but it was faster in patients with cirrhosis (p = 0.006; fig. 1) and in those homozygous for the *GCKR* P446 variant (Wilcoxon, p = 0.02). At multivariable Cox regression, considering sex, age, diabetes, platelets count, albumin and FIB-4, higher FIB-4 and lower albumin were correlated with faster progression to HCC (p = 0.01; P = 0.005).In this cohort the best FIB-4 cut-off to identify HCC risk was 4.09 (Sn100%, Sp83%, AUC 0.92). Carriage of *PNPLA3* I148M and PRS-5 were associated with cirrhosis (p = 0.007; p = 0.003) but not with HCC risk.

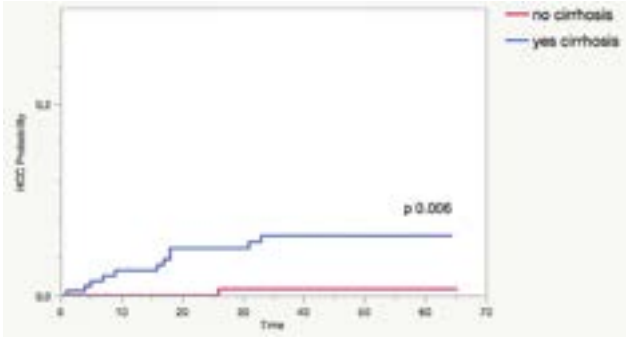

Figure:

Conclusion: In a multicenter prospective cohort of advanced NAFLD, HCC 5-year Incidence was 3.7%, median survival was 17 months. Non-invasive markers of liver fibrosis are useful to identify patients at increased risk of HCC. A longer follow-up is needed to clarify the impact of genetic factors on HCC in advanced NAFLD.

FRI-289

Sex disparities in presentation and outcome of hepatocellular carcinoma: results of a nationwide study in France

Charlotte Costentin[1,2], Mélanie Minoves[3], Sylvain Kotski[3], Nathalie Goutte[4], Olivier Farges[5], Thomas Decaens[1,2], Zuzana Macek-Jílková[1,2], Sébastien Bailly[3]. *[1]Centre Hospitalier Universitaire de Grenoble, Hepatology, gastro-enterology and digestive oncology, La Tronche, France; [2]Institute for Advanced Biosciences, INSERM U1209/CNRS UMR 5309, Grenoble, France, France; [3]Centre Hospitalier Universitaire de Grenoble, HP2 Laboratory, Grenoble Alpes University, INSERM U1300, La Tronche, France; [4]Hôpital Paul-Brousse Ap-Hp, Paris XI University, INSERM UMRS-1193, DHU Hépatinov and centre hépatobiliaire, Villejuif, France; [5]Hospital Beaujon AP-HP, Hepato-biliary surgery department, Clichy, France*
Email: charlotte.costentin.pro@gmail.com

Background and aims: Men are disproportionately affected by hepatocellular carcinoma (HCC) compared to women across the globe. A growing body of evidence also suggests differences in risk factors as well as prognosis. Our aim was to assess sex disparities in HCC in France, leveraging the national French Healthcare Database (PMSI).

Method: Incident cases of HCC were identified between 2009 and 2012. We only retained patients with 1) at least one hospital stay more than 3 months before the diagnosis and 2) one rolling year of follow-up from the first hospital stay preceding the diagnosis to ensure a minimum depth into the patient's history. Etiology was ascertained according to ICD-10 codes.

Results: We identified 26,117 patients (5,458 women and 20,659 men). Women were older at the time of HCC diagnosis (mean 73 years vs 68 years; p < 0.01). The underlying etiology was unclassified in 50.8% of cases in women, while alcohol was retained as the only etiology in 50.1% of cases in men. From patient with unclassified etiology (n = 8664; including 2772 women and 5892 men), metabolic comorbidities and in particular diabetes were less frequent in women than in men (diabetes 22.7% and 36.4% respectively; p < 0.01). Cirrhosis was less often documented in women (45.9% vs. 62.7% in men: p < 0.01), and less often recognized before diagnosis HCC (24.0% vs 28.7% in men: p < 0.01). At the time of diagnosis, liver complications were less frequent in women than in men (ascites: 19.3% vs 23.6%; hepatic failure: 12.9% vs 16.2%; hepatorenal syndrome 1.3% vs 2.4%; varice banding 2.6% vs 4.6%; p < 0.01). Women less often than men received treatment with curative intent (resection, radio-frequency or transplantation: 16.9% vs 20.2%). However, in univariate analysis, 12-month survival was higher for women than for men (p = 0.026).

Conclusion: In a large cohort of patients with HCC identified from the national French Healthcare Database, notable differences were

observed between women and men in terms of risk factors and severity of the underlying liver disease. Interestingly, women experienced higher 12-month survival.

FRI-290

Artificial intelligence assisted qFibrosis as a pathological "biomarker" to evaluate disease severity in patients with hepatocellular carcinoma

Chih-Yang Hsiao[1], Yayun Ren[2], Elaine Chng[2], Kutbuddin Akbary[2], Dean Tai[2], Kai-Wen Huang[1]. [1]*National Taiwan University Hospital, Surgery, Taiwan;* [2]*HistoIndex Pte Ltd, Singapore*
Email: cyhsiao1102@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is highly heterogeneous in both intra-tumoral and inter-patient features and its manifestations in its pathology. Tumor grade is a comprehensive index that is subjectively judged by a pathologist, which does not reflect the local regional differences of tumor cells and different disease characteristics relating with its pathological heterogenicity. Our hypothesis is that collagen features of pathology in HCC analyzed by artificial intelligence assisted qFibrosis could be used as a pathological "biomarker" to evaluate disease severity.
Method: Tumor specimen from 201 patients with HCC who underwent curative treatment were scanned by the second harmonic generation (SHG) microscopy (HistoIndex Pte. Ltd., Singapore). Digital image analysis generated 33 collagen parameters. Patients were grouped into tumor grades ≤2 and tumor grades ≥3 groups. Collagen features of tumor specimen between the two groups were compared, and the features with most significant differences were selected. A combined index was built using the selected collagen features. The usefulness of the combine index to predict survival outcome and the correlation between the combine index and tumor grade were tested. Leave-one-out cross-validation method was utilized.
Results: Total of 5 collagen features has been selected by sequential selection methods to build a combine index model. In addition, the value of each collagen features is shown in the radar map (Figure A), so that the dynamics of the extracellular matrix can be visualized instead of just a single number, tumor grade. These collagen features are further illustrated (Figure B) to help researchers to visualize and investigate the histopathological relevance for further disease studies and treatment efficacy evaluations. With specific cut-off values, the combine index model was significant in distinguishing patients with tumor grades ≤2 and ≥3 ($p < 0.05$), as well as in distinguishing patients with long-term survival and early death ($p < 0.05$). Moreover, it can be seen in the radar map that the features that are relevant include intersections of collagen strings, ratio between distributed and aggregated collagens. This implies the physical characteristics of extracellular matrix (ECM) is correlated to long-term survival of the patients.
Conclusion: Pathological heterogenicity of HCC could be profiled by artificial intelligence assisted qFibrosis. Selected collagen features of HCC could be used as a pathological "biomarker" that has the potential to be a parameter to evaluate disease severity in patients with HCC. Quantitative measurements and the new visualization tools like radar map better reveals dynamic of ECM with other cell types, enhances disease studies and drug development programs in the future.

FRI-291

Cryptogenic non-cirrhotic HCC: clinical, prognostic and immunologic aspects of an emerging HCC etiology

Boris Beudeker[1], Rael Guha[1], Kalina Stoyanova[1], Jan Ijzermans[2], Robert De Man[1], Dave Sprengers[1], Andre Boonstra[1]. [1]*Erasmus MC, Gastroenterology and hepatology, Rotterdam, Netherlands,* [2]*Erasmus MC, Surgery, Rotterdam, Netherlands*
Email: p.a.boonstra@erasmusmc.nl

Background and aims: The incidence of hepatocellular carcinoma (HCC) in non-cirrhotic livers is increasing. In order to better understand this trend, we conducted a comprehensive study to investigate the characteristics of HCC in non-cirrhotic livers in detail.
Method: Data was analyzed of 2304 HCC cases diagnosed at a large referral center in the Netherlands between 2009 and 2020, and 1654 cases with a complete medical record were included for analysis. Patient characteristics, liver disease etiologies, post-diagnosis survival rates, genetic risk factors, and immune profiles were analyzed.
Results: Of the 1654 included HCC cases, 371 (22%) were non-cirrhotic. The incidence of non-cirrhotic HCC rose by 61% between 2009 and 2020, with 39% of cases diagnosed in the absence of underlying liver disease classified as cryptogenic non-cirrhotic HCC. Cryptogenic non-cirrhotic HCC cases were similar to non-cirrhotic NAFLD HCC cases in terms of patient characteristics, but had more advanced tumors, a higher prevalence of symptoms (such as significant weight loss) at the time of diagnosis, and shorter survival times. Overall survival of non-cirrhotic cryptogenic HCC was dismal

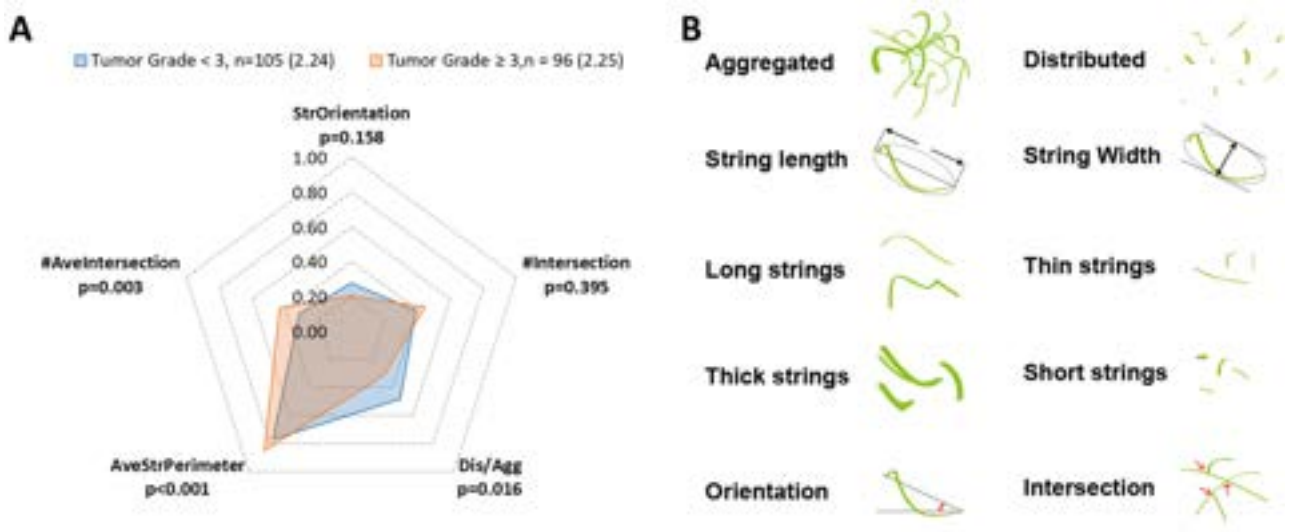

Figure: (abstract: FRI-290): (A) Radar map showing 5 parameters: total orientation of strings (StrOrientation), total number o intersections (#Intersection), the ratio of distributed collagen area and aggregated collagen area (Dis/Agg), average perimeter for one string (AveStrPerimeter) and average number of intersections within each string; (B) graphical illustration of how colleagen strings are defined and measured.

compared to viral and non-viral causes of HCC (figure 1). In a multivariable analysis, cryptogenic etiology was found to be an independent negative prognostic factor (p = 0.037), along with intermediate and advanced tumor stage and older age. More advanced stages of cryptogenic HCC were associated with higher levels of circulating interleukin-6. Analysis of a balanced sub-cohort of non-cirrhotic cryptogenic and NAFLD HCC cases revealed comparable immune profiles and HCC risk gene phenotypes.

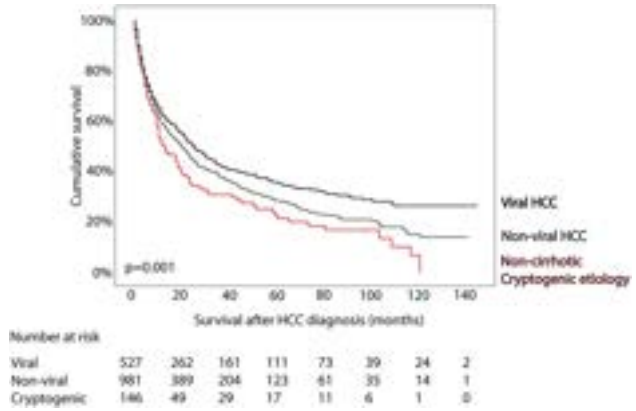

Figure 1: Survival proportion after the diagnosis of de novo hepatocellular carcinoma (HCC) in patients with viral hepatitis-related HCC in cirrhotic or non-cirrhotic liver, non-viral related HCC in cirrhotic and non-cirrhotic liver and in those with cryptogenic HCC.

Conclusion: These findings suggest that cryptogenic non-cirrhotic HCC may represent a unique HCC etiology, with more aggressive traits such as advanced tumors and a pro-inflammatory immune protein signature in the blood. These observations made us postulate that cryptogenic non-cirrhotic HCC may be a group of patients with "burned-out" NAFLD. Further research is needed to identify risk factors and guide better clinical management.

FRI-292

Add-on benefits of AFP-L3, PIVKA-II and GALAD score to ultrasound plus AFP for surveillance of hepatocellular carcinoma

Supot Nimanong[1], Tawesak Tanwandee[1], Punchai Charatcharoenwitthaya[1], Siwaporn Chainuvati[1], Watcharasak Chotiyaputta[1]. [1]*Division of Gastroenterology, Department of Medicine, Siriraj Hospital, Mahidol University, Thailand*
Email: supotgi@gmail.com

Background and aims: Combination of abdominal ultrasound (US) and alpha-fetoprotein (AFP) is widely recommended as a surveillance tool for hepatocellular carcinoma (HCC). Lens culinaris-agglutinin-reactive fraction of AFP (AFP-L3) and protein induced by vitamin K absence or antagonist-II (PIVKA-II) are potential biomarkers for small HCC detection. This study was aimed to determine the add-on benefits of AFP-L3, PIVKA-II and GALAD score to routine use of US plus AFP for HCC surveillance.
Method: This prospective study enrolled patients with cirrhosis or high risk non-cirrhotic chronic hepatitis B (HBV). US and three biomarkers were measured and GALAD score was calculated. Triple phase computed tomography (CT) or dynamic magnetic resonance imaging (MRI) was performed in all patients who had new liver nodule larger than 1 cm or abnormal biomarkers (cutoff: 20 ng/ml for AFP, 10% for AFP-L3, and 40 mAU/ml for PIVKA-II). All patients were followed at 6-month for the missed lesions.
Results: Among 1003 enrolled patients, the mean age was 60 years, 56% were men, 72% had cirrhosis (95% were Child A). The major etiologies of chronic liver disease were HBV (79%), hepatitis C (12%), and alcohol (3%). HCC was diagnosed in 33 patients (3.3%) with the median size of 1.85 cm and all of lesions were within Milan criteria. Among three biomarkers, PIVKA-II showed the highest sensitivity (51.5%) followed by AFP-L3 (24.2%) and AFP (9.1%) for detecting small HCC. The sensitivity and specificity of US plus AFP were 54.5% and 97.5% respectively, whereas the combination of triple markers with US increased the sensitivity to 87.9% but decreased the specificity to 94.6%. The area under the curve (AUC) of US plus AFP and combination of triple markers with US were 0.961 and 0.944 respectively. GALAD score had lower sensitivity than triple markers (48.3% vs 57.6%), and the addition of GALAD score to US did not provide more sensitivity than combined triple markers with US (86.2% vs 87.9%).
Conclusion: Routine use of US plus AFP appears to be suboptimal for detecting small HCC. The addition of AFP-L3 and PIVKA-II to US plus AFP increase the sensitivity for HCC detection at an early stage. GALAD score does not provide superior sensitivity than using of triple markers.

Addition of des-gamma-carboxy prothrombin to standard of care is effective for HCC surveillance among high-risk patients

Grishma Hirode[1,2,3], Hooman Farhang Zangneh[1], Orlando Cerocchi[1], Lima Awad El-Karim[4], Korosh Khalili[4], Harry LA Janssen[1,5], Bettina Hansen[1,6,7], Jordan J. Feld[1,2,3]. Email: grishma.hirode@gmail.com

Background and aims: Despite regular surveillance, several patients are diagnosed with hepatocellular carcinoma (HCC) at an advanced stage. An understanding of the effectiveness of current methods and the development of novel strategies are required to improve early-stage HCC diagnosis. We aim to analyze the utility of each specific biomarker from a study evaluating ultrasound (US) alone compared to US plus serum biomarkers (BM) for HCC surveillance.

Method: Prospective study of patients with cirrhosis or high-risk HBV infection (REACH-B score ≥9) randomized to HCC surveillance with US alone (Group A) or US and BM (Group B) measuring alpha-fetoprotein (AFP), des-gamma-carboxy prothrombin (DCP) and lectin-reactive fraction of AFP (AFP-L3). For all analyses using Group B data, any BM levels above the specified thresholds (AFp >100 ng/ml, DCp >2 ng/ml, AFP-L3 >10%) or a positive US result triggered further imaging for HCC confirmation. US or AFP is the current standard method of surveillance. We examined the incremental value of adding DCP, AFP-L3, or both to US and AFP by comparing sensitivity and specificity between groups; US and AFP was used as the reference group.

Results: Among 603 patients in Group A (mean age at baseline 58 ± 9.8 years, 72% male, 64% with cirrhosis at baseline), 35 patients were diagnosed with HCC (30 early-stage, 5 advanced) with a sensitivity of 80% and specificity of 35% for the detection of early-stage HCCs using US alone. Among 605 patients in Group B (mean age at baseline 58 ± 9.9 years, 72% male, 63% with cirrhosis at baseline), 27 patients were diagnosed with HCC (22 early-stage, 5 advanced). US or AFP had a sensitivity of 78% and specificity of 35% (Figure). The addition of DCP to AFP and US yielded higher sensitivity (81%, p = 0.32) but slightly lower specificity of (34%, p = 0.01) whereas the addition of AFP-L3 to AFP and US did not change the sensitivity (78%) and resulted in lower specificity (32%, p < 0.001). The overall sensitivity and specificity for Group B using US or BM were 81% (p = 0.32) and 31% (p < 0.001), respectively; that is with the addition of both DCP and AFP-L3 to US or AFP. There was no significant difference in sensitivity or specificity between the two study arms. Among the individual biomarkers, AFP-L3 had both low sensitivity and specificity.

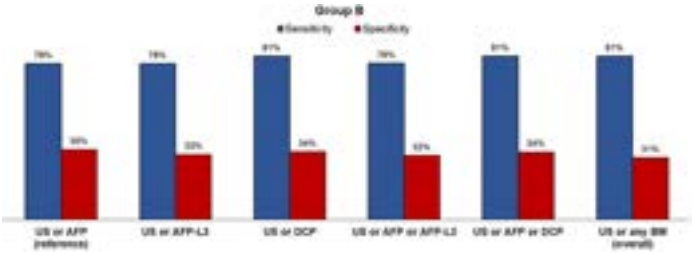

Figure:

Conclusion: In this large study, US and DCP was the most sensitive while US and AFP was the most specific for an early diagnosis of HCC. The addition of DCP to the existing standard of care using US plus AFP would optimize sensitivity and specificity. Lower AFP thresholds may also be beneficial for enhanced HCC surveillance.

FRI-294

A radiogenomics study for hepatocellular carcinoma: distinct transcriptome patterns underlying different radiomics phenotypes in early recurrence

Weijia Liao[1], Liying Ren[2], Dongbo Chen[2], Tingfeng Xu[1], Bigeng Zhao[1], Zhipeng Zhou[3], Yong He[4], Junxiong Yu[5], Minjun Liao[6], Hongsong Chen[2]. Email: liaoweijia288@163.com

Background and aims: The prognosis of early-recurrence (within 2 years) hepatocellular carcinoma (HCC) remains poor. We aim to explore the biological pathway underlying the radiomics phenotypes.

Method: The datasets involved in this study were collected from Guilin Medical University and The Cancer Genome Atlas dataset, with contrast-enhanced CT images and corresponding transcription data. Low and high radiomics phenotypes based on the rad-score were determined to predict early recurrence. Radiomics features were annotated with biological pathways. Then, the most relevant gene modules underlying the radiomics phenotypes were identified and radiomics hub genes were selected.

Results: Rad-score constructed by 6 radiomics features illustrated a predictive value for HCC early recurrence in both training (AUC: 0.915, 95% CI: 0.796–1.033) and external validation datasets (AUC: 0.794 95% CI: 0.731–0.858). Patients with high risk radiomics phenotype were prone to early recurrence. Early recurrence related radiomics features were associated with metabolism, proliferation and immune-related pathways. Further, the red module was considered as the most relevant radiomics gene module, in which the 6 hub genes (ACACA, ACLY, ATRNL1, FADS2, MPV17L, ZNF492) were determined, and the model fitted by the hub genes had the ability to predict early recurrence (AUC: 0.724, 95% CI: 0.509–0.930). There were significant correlations among radiomics features, hub genes, immune cell infiltration, metabolism and immune-related keys genes.

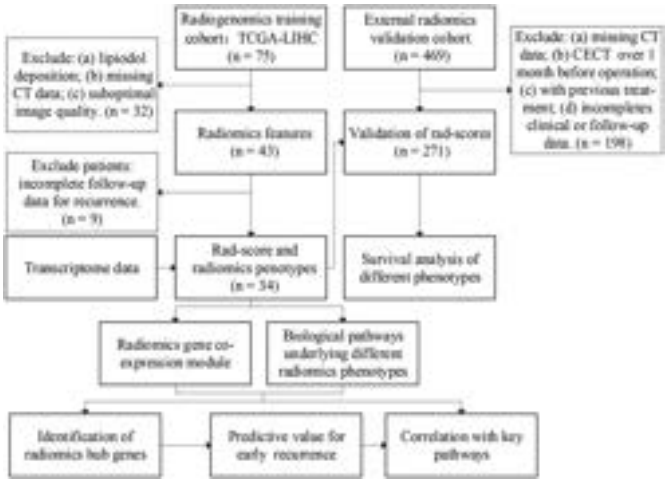

Figure 1: Flowchart of the study cohorts.

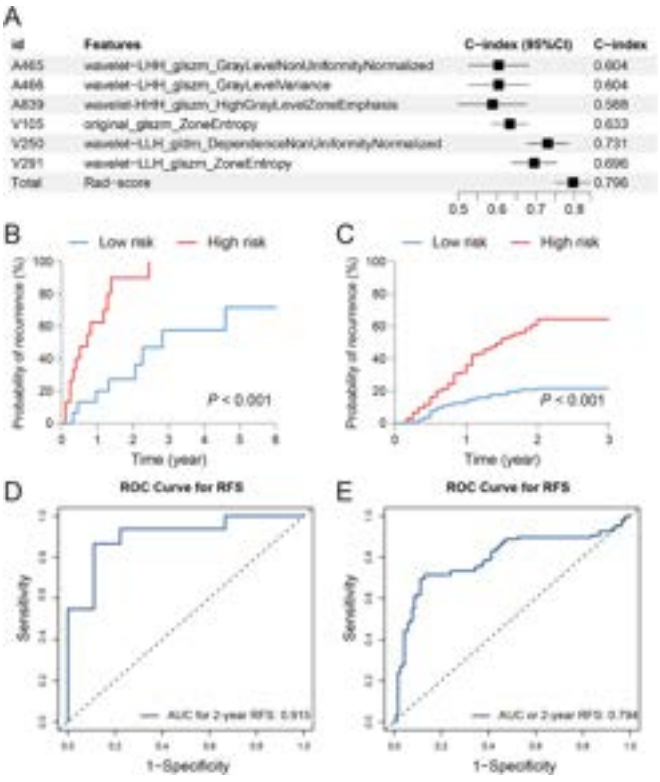

Figure 2: Construction and validation of the rad-score for the early recurrence of HCC.

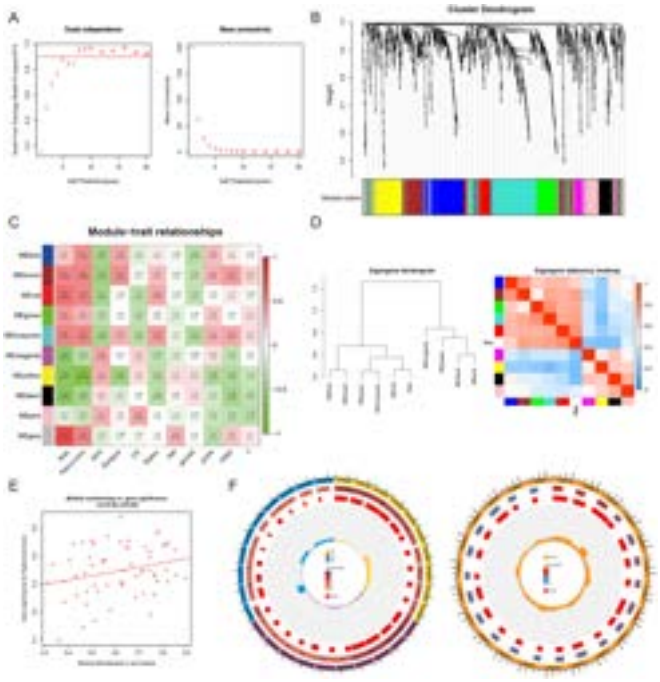

Figure 3: Weighted Correlation Network analysis (WGCNA) of the radiomics gene modules.

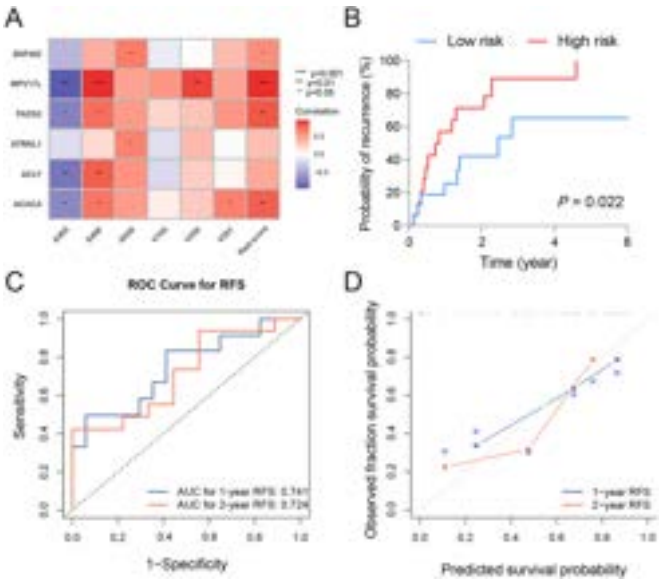

Figure 4: Radiomics hub genes and their predictive value for early recurrence.

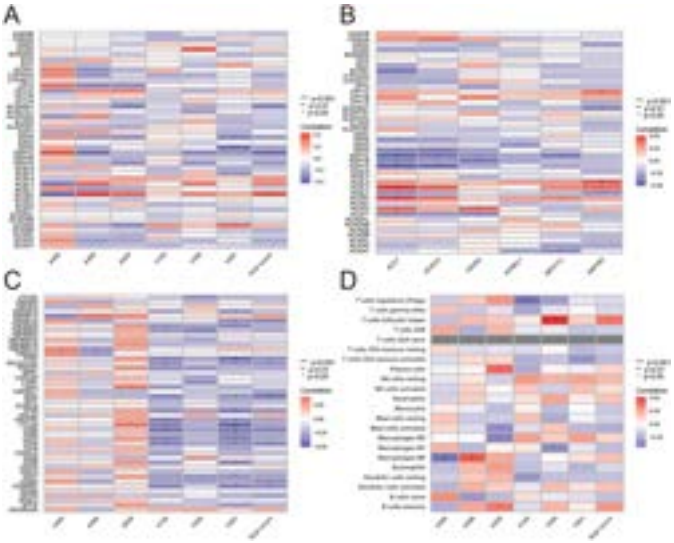

Figure 4: Function and mechanisms related to radiomics features and hub genes.

Conclusion: Rad-score derived from enhanced CT of HCC could effectively predict early recurrence. Metabolic, proliferative and immune-related pathways varied in low and high radiomics phenotypes, in which the hub genes might play an important role.

FRI-295

Transversal psoas muscle thickness measurement is associated with response and survival in patients with hepatocellular carcinoma undergoing immunotherapy

Bernhard Scheiner[1,2,3], Katharina Lampichler[4], Katharina Pomej[1,3], Lucian Beer[4], Lorenz Balcar[1,3], Riccardo Sartoris[5], Mohamed Bouattour[6], Sabrina Sidali[6], Michael Trauner[1], Martina Scharitzer[4], Dietmar Tamandl[4], David J. Pinato[2,7], Maxime Ronot[5,8], Matthias Pinter[1,3]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Austria; [2]Imperial College London, Department of Surgery and Cancer, United Kingdom; [3]Medical University of Vienna, Liver Cancer (HCC) Study Group Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Austria; [4]Medical University of Vienna, Department of Biomedical Imaging and Image-Guided Therapy, Austria; [5]APHP.Nord, Hôpital Beaujon, Department of Radiology, France; [6]APHP.Nord, Hôpital Beaujon, Department of Digestive Oncology, France; [7]University of Piemonte Orientale, Department of Translational Medicine, Division of Oncology, Italy; [8]Université Paris Cité, CRI INSERM U1149, France*
Email: matthias.pinter@meduniwien.ac.at

Background and aims: Sarcopenia is a common problem in patients with hepatocellular carcinoma (HCC) and may be diagnosed using clinical or imaging-based assessments. This study aimed to evaluate the prognostic and predictive value of transversal psoas muscle thickness (TPMT) measurement at baseline in patients with HCC undergoing immunotherapy.

Method: Patients with HCC treated with PD- (L)1-based therapies between 06/2016 and 10/2022 at the Vienna General Hospital (n = 80) and the Hôpital Beaujon Clichy (n = 96) were included. TPMT at the level of the third lumbar vertebrae was measured independently by two radiologists in the Vienna cohort to evaluate inter-reader reliability and by one radiologist in the Clichy cohort. Clinical outcomes were evaluated in the pooled cohort. TPMT <12 mm/m in men and <8 mm/m in women indicated sarcopenia.

Results: Overall, 176 patients (age: 66.3 ± 11.7 years; male: n = 143, 81%)) were included, of which 131 (74%) had cirrhosis. Most patients had BCLC C HCC (n = 121, 69%).

Inter-reader agreement for the diagnosis of sarcopenia based on TPMT was 90% and Cohen's Kappa showed a 'strong agreement' (κ = 0.80 (95%CI: 0.66–0.93)). Sarcopenia was present in 59 patients (34%) and predominantly observed in men (n = 56 (39%) vs. women: n = 3 (9%), p = 0.001). Sarcopenia was associated with shorter overall (median OS, 8.0 (95%CI:4.1–11.9) vs. 24.7 (95%CI:19.1–30.4); p < 0.001, Figure A) and progression-free survival (median PFS, 5.0 (95% CI:0.8–9.2) vs. 9.7 (95%CI:6.0–13.4), p = 0.003), and an independent predictor of overall (HR:1.80 (95%CI:1.10–2.95)) and progression-free mortality (HR:1.54 (95%CI:1.03–2.30)) in multivariable analyses. Radiological response was evaluable in 161 subjects (91.5%). Objective response rate per mRECIST in patients with and without sarcopenia was 20% and 39%, respectively (p = 0.011). Outcomes were worst in patients with sarcopenia and elevated serum C-reactive protein (Figure B).

Conclusion: Evaluation of sarcopenia using TPMT measurement is reliable and identifies HCC patients with a dismal prognosis and response to immunotherapy.

FRI-296

The efficacy of direct-acting antivirals for chronic hepatitis C in patients with the active oncological disease

Maria Dąbrowska[1], Jerzy Jaroszewicz[1], Marek Sitko[2], Janocha-Litwin Justyna[3], Dorota Zarębska-Michaluk[4], Ewa Janczewska[5], Beata Lorenc[6], Magdalena Tudrujek[7], Anna Parfieniuk-Kowerda[8], Jakub Klapaczynski[9], Hanna Berak[10], Łukasz Socha[11], Beata Dobracka[12], Dorota Dybowska[13], Wlodzimierz Mazur[14], Robert Flisiak[8]. *[1]Medical University of Silesia, Department of Infectious Diseases and Hepatology, Poland; [2]Jagiellonian University, Kraków, Poland; [3]Medical University Wroclaw, Poland; [4]Jan Kochanowski University, Kielce, Poland; [5]Medical University of Silesia, Bytom, Poland; [6]Medical University of Gdańsk, Poland, [7]Medical University of Lublin, Poland; [8]Medical University of Białystok, Poland; [9]Central Clinical Hospital of the Ministry of Internal Affairs and Administration, Poland; [10]Hospital for Infectious Diseases in Warsaw, Poland; [11]Pomeranian Medical University, Szczecin, Poland; [12]MED-FIX Medical Center, Poland; [13]Faculty of Medicine, Collegium Medicum Bydgoszcz, Nicolaus Copernicus University, Poland; [14]Specialist Hospital in Chorzów, Medical University of Silesia, Katowice, Poland*
Email: jerzy.jr@gmail.com

Background and aims: The introduction of direct-acting antivirals (DAA) has revolutionized HCV infection treatment and extended possibilities for patients with active malignancies. Data on the safety and efficacy of DAA in this group is limited but often crucial to undertake oncologic therapy. We investigated patients with active solid malignant tumor (SMT), hematooncologic disease (HD), and hepatocellular carcinoma (HCC) treated with DAA.

Method: A total of 203 patients with active oncological disease (SMT n = 62, HD = 67, HCC n = 74) were evaluated and compared to 12,930 subjects without any history of malignancy. All subjects were treated with DAA between 2015 and 2020 and included in the national real word evidence project EPITER.

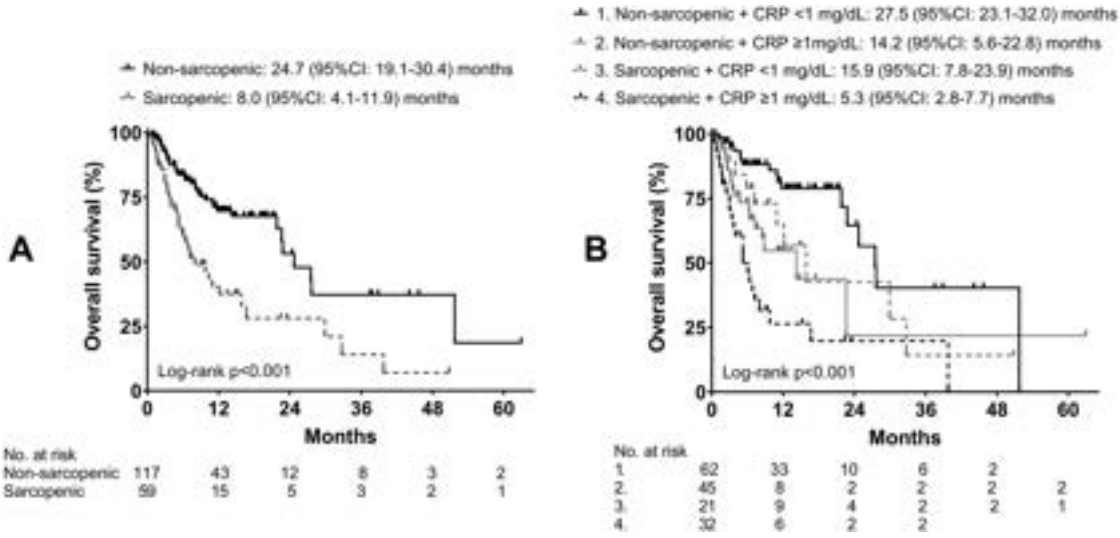

Figure: (abstract: FRI-295).

Results: The proportion of patients suffering from malignancies among chronic hepatitis C patients was lower than in the general population of Poland (any malignancy 1.5% vs 3.1%; HD 0.26% vs 0.49%, data: National Registry of Cancers). The distribution of genotypes was comparable in patients with and without malignancies, while HCV-viral load was significantly higher in hematooncologic patients (HD = 6.2 vs SMT = 5.7 vs HCC = 5.8 log10 IU/ml, P < 0.001). Likewise, the rate of extrahepatic symptoms was more frequent in HD patients (17.2% vs. SMT = 10.3%, HCC = 8.2%, without = 7.8%, p = 0.04). Patients with HCC had higher ALT activity (81 IU/l vs. SMT = 59.5 IU/l, HD = 52 IU/l, controls = 58 IU/l p < 0.001) and more often F4 fibrosis (86.11% vs. SMT = 23.3%, HD = 28.8%, controls = 24.4%, p < 0.001). DAAs were well tolerated with the need for premature discontinuation in 9.4% of HCC patients, only 2.9% of HD and no SMT patients compared to 1.1% in the general population. Sustained virologic response rates were 89.55% in HD, 90.32% in SMT and 77.03% in HCC (ITT analysis), and in 93.6% HD, 90.16% SMT and 80.6% in HCC after exclusion of non-virologic failures.
Conclusion: A lower proportion of active malignancies among patients with chronic hepatitis C than the general population might suggest shortfalls in HCV screening or DAA uptake. Importantly, we claim the high effectiveness and safety profile of the DAAs therapy in solid tumor and hematooncologic malignancies subjects. Patients with HCC remain to be a challenging group not only considering the severity of their liver disease but also struggling to achieve SVR.

FRI-297

Abbreviated magnetic resonance imaging for secondary surveillance of recurrent hepatocellular carcinoma after curative treatment

Sun Kyung Jeon[1], Dong Ho Lee[1], Bo-Yun Hur[1], Juil Park[2], Se Woo Kim[1], Junghoan Park[1]. *[1]Seoul National University Hospital, Korea, Rep. of South; [2]Severance hospital, Korea, Rep. of South*
Email: dhlee.rad@snu.ac.kr

Background and aims: Given the high hepatocellular carcinoma (HCC) recurrence rate even after a long recurrence-free year following HCC treatment and the risk of developing de novo secondary HCC, long-term continued secondary surveillance (i.e., follow-up after HCC treatment) is needed. However, there is no consensus regarding the ideal imaging modality for the secondary surveillance of HCC. Recently proposed abbreviated magnetic resonance imaging (AMRI) protocols can be a promising imaging modality, however, little is known about the performance of AMRI for secondary surveillance of HCC. This study aimed to evaluate the detection performance of abbreviated MRI (AMRI) for secondary surveillance of HCC after curative treatment, including surgical resection or radiofrequency ablation (RFA).
Method: This retrospective study analysed 243 patients who underwent secondary surveillance for HCC using gadoxetic acid-enhanced MRI after more than two year of disease-free period following curative treatment, including surgical resection or RFA, between January 2015 and December 2017 in tertiary academic center. Four abdominal radiologists with different experience level in liver imaging independently reviewed non-contrast AMRI (NC-AMRI) (T2-weighted, T1-weighted, and diffusion-weighted images), hepatobiliary phase AMRI (HBP-AMRI) (T2-weigted, diffusion-weighted, and HBP images), and full-sequence MRI sets. HCC was confirmed based on either histopathological confirmation or imaging-based diagnosis. Per-lesion sensitivity, per-patient sensitivity and specificity for HCC detection were compared among three image sets using generalized estimating equation.
Results: A total of 42 recurred HCCs were confirmed in the 39 patients. The per-lesion and per-patient sensitivities did not show significant differences among the three image sets for all reviewers (p ≥0 .358): per-lesion sensitivity, 59.5–83.3%, 59.5–85.7%, and 59.5–83.3% for NC-AMRI, HBP-AMRI, and full-sequence MRI, respectively, and per-patient sensitivity: 53.9–83.3%, 56.4–85.7%, and 53.9–83.3% for NC-AMRI, HBP-AMRI, and full-sequence MRI, respectively. Per-patient specificity was not significantly different among the three image sets for all reviewers (95.6–97.1%, 95.6–97.1%, and 97.6–98.5% for NC-AMRI, HBP-AMRI, and full-sequence MRI, respectively; p ≥0 .117).

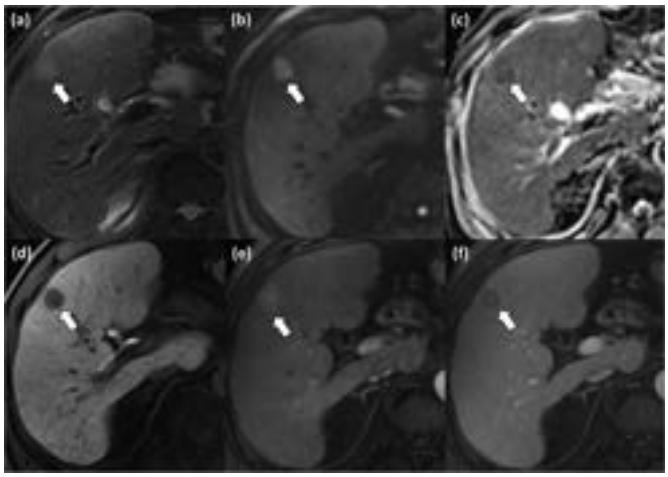

Figure: A case of recurrent HCC 33 months after left lateral sectionectomy in a 66-year-old man, which was detected by reviewers on NC-AMRI (a-c), HBP-AMRI (a-d), and full-sequence MRI (a-f).

Conclusion: NC-AMRI and HBP-AMRI had comparable detection performance to that of full-sequence gadoxetic acid-enhanced MRI during secondary surveillance for HCC after more than 2-year disease free interval following curative treatment. Based on its good detection performance, short scan time, and lack of contrast agent-associated risks, NC-AMRI can be a promising option for the secondary surveillance of HCC, and further prospective validation is needed.

FRI-298

A new biomarker panel for differential diagnosis of cholangiocarcinoma: results from an exploratory analysis

Bruno Köhler[1], Marta Bes[2], Henry LY Chan[3], Juan Ignacio Esteban Mur[4], Teerha Piratvisuth[5], Wattana Sukeepaisarnjaroen[6], Tawesak Tanwandee[7], Anika Mang[8], David Morgenstern[9], Magdalena Swiatek-de Lange[8], Farshid Dayyani[10]. *[1]University Hospital Heidelberg, Germany; [2]Instituto de Salud Carlos III, Spain; [3]The Chinese University of Hong Kong, Hong Kong; [4]Hospital Universitari Vall d'Hebron, Spain; [5]Songklanagarind Hospital, Thailand; [6]Srinagarind Hospital, Thailand; [7]Siriraj Hospital, Thailand; [8]Roche Diagnostics GmbH, Germany; [9]Roche Diagnostics Operations, United States; [10]University of California in Irvine, United States*
Email: magdalena.swiatek-de_lange@roche.com

Background and aims: Accurate diagnosis of cholangiocarcinoma (CCA) can be challenging due to unclear diagnostic imaging criteria and difficulty obtaining adequate tissue biopsy. Although serum cancer antigen 19-9 and carcinoembryonic antigen have been proposed as potential diagnostic aids, they have insufficient sensitivity and specificity. This exploratory analysis aimed to identify individual and combinations of serum tumour biomarkers that could distinguish CCA from hepatocellular carcinoma (HCC) and benign chronic liver disease (CLD) controls using samples obtained from a previously published study.
Method: This prospective, multicentre, case-control study included patients ≥18 years who were at high risk of HCC. Serum and ethylene diamine tetraacetic acid-plasma samples were collected prior to any treatment and a confirmed diagnosis of HCC or CCA. A panel of 14 electrochemiluminescence immunoassays or enzyme-linked immunosorbent assays were used; 14 biomarkers were subjected to

univariate analysis and 13 to multivariate analysis (per selected combinations and exhaustive search).
Results: Overall, 55 CCA (22 intrahepatic CCA; 11 perihilar CCA), 306 HCC and 733 CLD control samples were analysed. The biomarkers with the best individual performance were alpha-fetoprotein and matrix metalloproteinase-2 (MMP-2) (area under the curve [AUC] 86.6% and 84.4%, respectively) for distinguishing CCA from HCC, and tissue inhibitor of metalloproteinase-1 (TIMP-1) for distinguishing CCA from CLD (AUC 94.5%) and HCC + CLD (AUC 88.6%). MMP-2 and TIMP-1 combination was the best performing two-marker panel (Table), with AUC >90% for all comparisons. Carbohydrate antigen 19-9 (CA 19-9) and carcinoembryonic antigen (CEA) performed relatively poorly as individual biomarkers (Table).

Table: Performance of individual biomarkers and of the TIMP-1 and MMP-2 two-biomarker panel for distinguishing CCA from HCC and/or benign CLD controls.

	CCA vs HCC.	CCA vs benign CLD.	CCA vs HCC + benign CLD.
Individual biomarkers (univariate analysis).			
AFP.	86.6 (81.4–91.8).	53.2 (44.1–62.2).	63.0 (55.4–70.6).
CA19-9.	67.5 (58.2–76.8).	78.4 (70.6–86.2).	75.2 (67.1–83.2).
CEA.	60.5 (50.7–70.3).	48.3 (38.9–57.7).	51.9 (42.5–61.3).
MMP-2.	84.4 (78.9–89.9).	72.4 (64.6–80.2).	75.9 (68.9–82.9).
TIMP-1.	74.5 (68.2–80.8).	94.5 (92.1–96.9).	88.6 (85.3–91.9).
Two-biomarker panel (multivariate analysis).			
TIMP-1 and MMP-2.	91.8 (88.3–95.3).	97.9 (96.6–99.2).	95.6 (93.7–97.6).

All results shown as AUC, % (95% CI).

Conclusion: MMP-2 and TIMP-1 are promising non-invasive biomarkers that could rapidly provide additional diagnostic information to help differentiate CCA from HCC and CLD.

FRI-299
CRAFITY score is associated with overall survival in patients with hepatocellular carcinoma treated with transarterial chemoembolisation

Rhea Veelken[1,1], Anne Olbrich[1], Aaron Schindler[1], Sabine Lieb[1], Janett Fischer[1], Sebastian Ebel[2], Timm Denecke[2], Thomas Berg[1], Florian van Bömmel[1]. *[1]University Hospital of Leipzig, Division of Hepatology, Department of Medicine II, Germany; [2]University Hospital of Leipzig, Department of Diagnostic and Interventional Radiology, Germany*
Email: rhea.veelken@medizin.uni-leipzig.de

Background and aims: The CRAFITY score is based on alpha fetoprotein (AFP ≥100 ng/ml) and C-reactive protein (CRP ≥1 mg/dL), and it stratifies patients by the likelihood of increased overall survival (OS) and treatment response to subsequent immunotherapy containing systemic treatment for hepatocellular carcinomas (HCC). We aimed to investigate the association of the CRAFITY score with survival and treatment response to transarterial chemoembolisation (TACE).
Method: A total cohort of 546 patients with HCC was treated with TACE as first-line therapy at our center between 2010 and 2020. Patients were retrospectively enrolled in our study if follow-up was documented over at least 3 months, and if CRP and AFP were available from baseline. We investigated the association of baseline variables on overall survival using Kaplan-Meier estimation and a Cox regression model.
Results: A total of 113 patients was included in the analysis (15 (13%) female). All patients suffered from HCC (BCLC stages A (n = 64), B (n = 37), C (n = 10) and D (n = 2)) with a median age of 63 years (range 31–85 years). Eighty-eight (78%) patients had compensated liver cirrhosis, 25 (22%) patients showed no clear signs of liver cirrhosis on imaging. Patients with a GRAFITY score 0 (n = 67) had the longest median OS of 46.82 (range, 0–140) months followed by patients with 1 point (n = 38), who had a median OS of 24.71 (range, 0–121) months and patients with 2 points (n = 8), who had a median OS of 19.38 (range, 0–67) months (p < 0.001) (Figure). In Cox regression analyses, the CRAFITY score 1 was associated with significantly increased risk of mortality with a hazard ratio (HR) of 2.4 (95% CI 1.23–4.55, p = 0.01) Moreover, patients with a CRAFITY score of 2 had a 6 times higher risk of mortality (HR = 5.9 [95% CI 2.44–14.14] p < 0.001) compared to patients with a score of 0. Interestingly, 62% of the responders at week 12 had a CRAFITY score of 0 and 33% of the responders at week 12 had a CRAFITY score of 1.

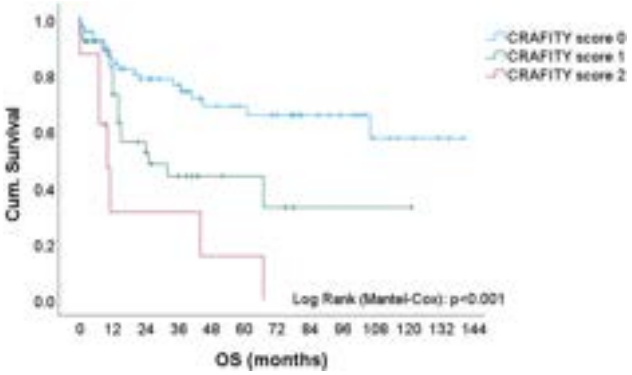

Figure: Kaplan-Meier estimation for overall survival according to the CRAFITY score

Conclusion: The CRAFITY score is a potential tool for the identification of patients who benefit from TACE. The potential of the CRAFITY score for the personalisation of multimodal treatment of HCCs needs to be assessed in future studies.

FRI-300
Development, clinical validation and implementation of a novel algorithmic score (GAAD) for the detection of early-stage hepatocellular carcinoma

Teerha Piratvisuth[1], Jinlin Hou[2], Tawesak Tanwandee[3], Thomas Berg[4], Arndt Vogel[5], Jörg Trojan[6], Enrico de Toni[7], Masatoshi Kudo[8], Anja Eiblmaier[9], Hanns-Georg Klein[10], Johannes Kolja Hegel[11], Kairat Madin[12], Konstantin Kroeniger[12], Ashish Sharma[13], Henry Ly Chan[14]. *[1]Prince of Songkia University, Thailand; [2]Southern Medical University, China; [3]Mahidol University, Thailand; [4]Universitätsklinikum Leizig, Germany; [5]Medizinische Hochschule Hannover, Germany; [6]Goethe Universität Frankfurt, Germany; [7]Ludwig Maximilian University of Munich, Germany; [8]Kindai University, Japan; [9]Microcoat Biotechnologie GmbH, Germany; [10]Zentrum für Humangenetik und Laboratoriumsdiagnostik, Germany; [11]Labor Berlin Charité Vivantes Services GmbH, Germany; [12]Roche Diagnostics GmbH, Germany; [13]Roche Diagnostics International AG, Switzerland; [14]The Chinese University of Hong Kong, Hong Kong*
Email: teerha.p@psu.ac.th

Background and aims: Protein induced by vitamin K absence-II (PIVKA-II) and alpha-fetoprotein (AFP) are serum biomarkers that can support the diagnosis of hepatocellular carcinoma (HCC). The GAAD algorithm is a novel in vitro diagnostic combining quantitative measurements of Elecsys® PIVKA-II assay and Elecsys AFP assay, plus age and gender to generate a semi-quantitative result. This study aimed to establish and train the algorithm coefficients, and clinically validate clinical performance of the GAAD algorithm in differentiating HCC and benign chronic liver disease (CLD), across different regions and aetiologies.
Method: Participants aged ≥18 years were prospectively enrolled across China, Hong Kong Special Administrative Region, Spain, Germany, Japan and Thailand for Algorithm development and clinical validation studies. The HCC group had a first-time diagnosis of HCC confirmed by imaging or biopsy. The CLD control group had an

absence of HCC confirmed by imaging ≤12 months before, and diagnosis of cirrhosis or non-cirrhotic liver disease (viral or non-viral). Serum samples were analysed using the Elecsys PIVKA-II and AFP assays on a cobas e 601 analyser. The established cut-off for the detection of HCC was a GAAD score of 2.57 (range 0–10). Cut-off for detection of HCC in the Elecsys AFP assay was 20 ng/ml.

Results: In the HCC group (n = 366) and CLD control group (n = 303), 176 (48.1%)/136 (44.9%) were from China, 142 (38.8%)/124 (40.9%) from Europe and 48 (13.1%)/43 (14.2%) from Asia-Pacific, respectively. In the HCC group, 287 (78.4%) had cirrhosis, of which 222 (60.7%) had viral liver disease aetiology, and 174 (47.6%) had early-stage HCC (Barcelona Clinic Liver Cancer [BCLC] 0 and A). In the control group, 112 (37%) had cirrhosis including 76 (25.1%) with viral disease. GAAD performed well for differentiating both early- and all-stage HCC from benign disease controls across disease aetiologies and regions (Figure). Sensitivity for detecting early- and all-stage HCC, respectively, was 67.4% and 81.9% in cirrhotic CLD (specificity, 86.6%) and 79.5% and 87.3% in non-cirrhotic CLD (specificity, 97.9%); all sensitivity rates were higher than for AFP alone. Sensitivity was similar across China (67.3% for early-stage HCC/77.3% for all-stage HCC), Europe (76.9%/90.8%) and Asia-Pacific (72%/81.3%), with >85% specificity for CLD controls for all regions; all sensitivity rates were higher than for AFP alone. Two independent workflow options: (a) website solution with user login and manual data entry and (2) an automated integrated solution via the NAVIFY® Algorithm suite were implemented for the GAAD algorithm.

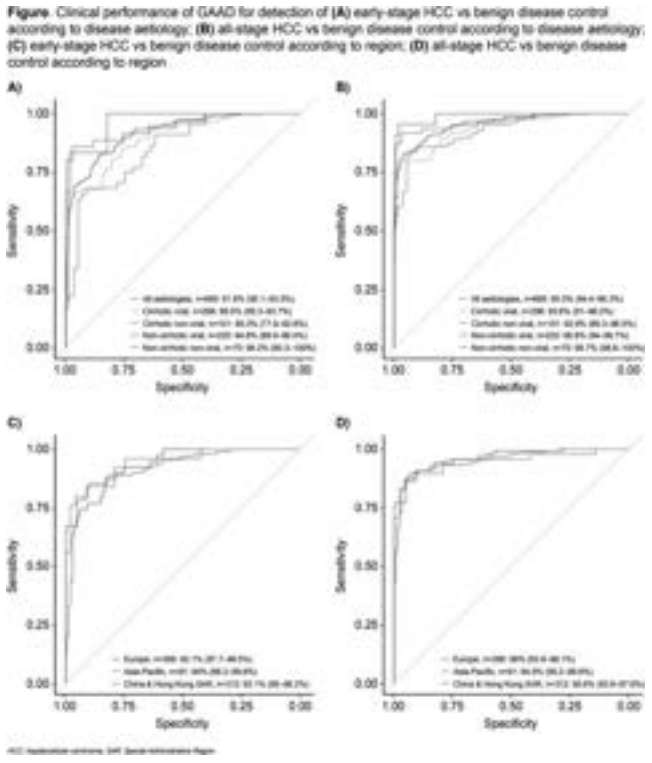

Figure:

Conclusion: The GAAD algorithm, combining PIVKA II and AFP, plus age and gender, demonstrated good clinical performance in differentiating HCC and benign CLD, across all regions and aetiologies.

FRI-301

Gadoxetic acid-enhanced MRI-based risk scoring system development and validation for the recurrence-free survival of a single hepatocellular carcinoma after curative surgery

Bohyun Kim[1], So Hyun Park[2], Joon-Il Choi[1]. [1]*Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Korea, Rep. of South;* [2]*Gil Medical Center, Gachon University College of Medicine, Korea, Rep. of South*
Email: baboojum@naver.com

Background and aims: To develop and validate risk scoring systems using gadoxetic acid-enhanced liver MRI features and clinical factors that predict recurrence-free survival (RFS) of a single hepatocellular carcinoma (HCC).

Method: Consecutive 295 patients with treatment-naïve single HCC who underwent curative surgery and preoperative gadoxetic acid-enhanced MRI were retrospectively enrolled from two centers. Cox proportional hazard models developed risk scoring systems whose discriminatory powers were validated using external data and compared to the Barcelona Clinic Liver Cancer (BCLC) or American Joint Committee on Cancer (AJCC) staging systems using Harrell's C-index.

Results: Independent variables—tumor size (per cm; hazard ratio [HR], 1.07; 95% confidence interval [CI]: 1.02–1.13; p = 0.005), targetoid appearance (HR, 1.74; 95% CI: 1.07–2.83; p = 0.025), radiologic tumor in vein or tumor vascular invasion (HR, 2.59; 95% CI: 1.69–3.97; p < 0.001), the presence of a nonhypervascular hypointense nodule on the hepatobiliary phase (HR, 4.65; 95% CI: 3.03–7.14; p < 0.001), and pathologic macrovascular invasion (HR, 2.60; 95% CI: 1.51–4.48; p = 0.001)—with tumor markers (AFP ≥206 ng/ml or PIVKA-II ≥419 mAU/ml) derived pre- and post-operative risk scoring systems. The risk scores showed comparably good discriminatory powers in the validation set (C-index, 0.75–0.82) and outperformed the BCLC (C-index, 0.61) and AJCC staging systems (C-index, 0.58; p s <0.05). The preoperative scoring system stratified the patients into low-, intermediate-, and high-risk for recurrence, whose 2-year recurrence rate was 3.3%, 31.8%, and 85.7%, respectively.

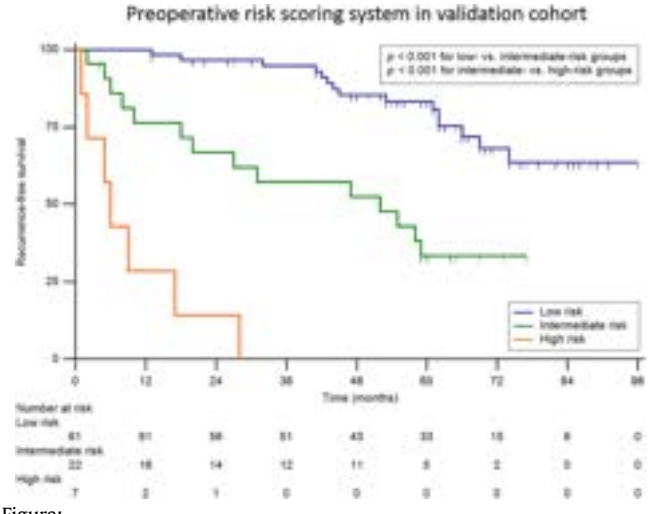

Figure:

Conclusion: The developed and validated pre- and postoperative risk scoring systems can estimate RFS after surgery for a single HCC.

FRI-302

The apparent diffusion coefficient values predict prognosis and Ki67 expression in intrahepatic cholangiocarcinoma on diffusion-weighted magnetic resonance imaging

Daiki Hokkoku[1], Kazuki Sasaki[1], Shogo Kobayashi[1], Yoshifumi Iwagami[1], Daisaku Yamada[1], Yoshito Tomimaru[1], Takehiro Noda[1], Hidenori Takahashi[1], Yuichiro Doki[1], Hidetoshi Eguchi[1]. [1]*Osaka University, Graduate School of Medicine, Department of Gastroenterological Surgery, Suita, Japan*
Email: hokkokudaiki@gmail.com

Background and aims: Intrahepatic cholangiocarcinoma (ICC) is a primary liver cancer with high aggressiveness and an extremely poor prognosis. A poor prognosis with a 5-year survival rate is about 40% after radical resection. Previous reports have indicated that lymph node metastasis and multiple tumors are poor prognostic factors in ICC. However, definite evidence regarding the lymph node dissection for ICC does not exist at present. Therefore, selecting the poor prognosis group and the group that does not require lymph node dissection based on preoperative imaging is necessary. Diffusion-weighted image (DWI) of magnetic resonance imaging (MRI) is a promising functional imaging tool for detecting and characterizing tumors. In biologic tissue, the DWI signal is derived from the motion of water molecules. The apparent diffusion coefficient (ADC) values were calculated based on water protons experiencing different restrictions to diffusion inside cellular compartments. In hepatocellular carcinoma and breast cancer, it has been reported that ADC values obtained from DWI-MRI, especially minimum ADC values (ADC_{min}), are associated with prognosis and Ki67, but there have been few reports focusing on ADC values in ICC. The aim of this study is to investigate the correlation of ADC_{min} and Ki67 expression in ICC.
Method: A total of 39 ICC cases confirmed by surgical pathology were analyzed retrospectively. Subjects underwent MRI at 1.5 or 3.0 T and calculated their minimum ADC_{min} using DWI MRI (b:0, 50, 200, 1000, 1500 seconds/mm^2). Patients were divided into ADC_{min} high group and ADC_{min} low group. The cut-off value for ADC_{min} was obtained using the receiver operating characteristic curve. We compared clinicopathological factors between two groups. Immunohistochemical analysis of Ki67 expression in tumor tissues was performed, and its expression was determined as low (less than 10% immunopositive cells) or high (more than 10% immunopositive cells). We evaluated the relationship between the ADC_{min} and Ki67 expression.
Results: The overall survival rate of the ADC_{min} low group was significantly lower than that of the ADC_{min} high group (p = 0.0404). Univariate analysis revealed that CEA (>5 ng/ml), CA19-9 (>35 U/ml), microvascular invasion, lymph node metastasis, and low ADC_{min} were prognostic factors. Multivariate analysis identified low ADC_{min} as an independent prognostic factor (p = 0.0202). Furthermore, the ADC_{min} low group more frequently expressed high levels of Ki67 than the ADC_{min} high group (75.0% vs. 26.1%, p = 0.0038).

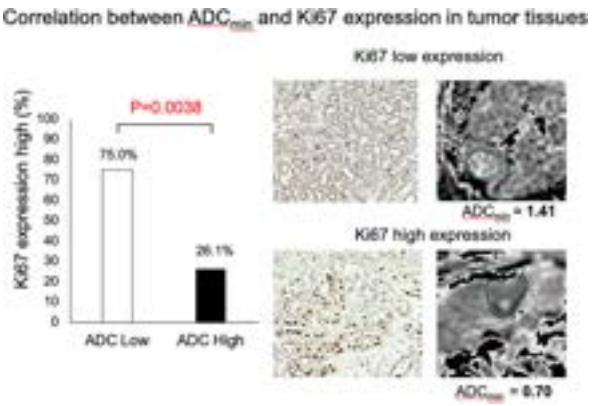

Figure:

Conclusion: Low ADC_{min} was an independent prognostic factor of ICC and correlated with Ki67 expression.

FRI-303

The Kupffer phase of Sonazoid-enhanced ultrasound as the major imaging feature for diagnosing hepatocellular carcinoma in at-risk individuals

Hyo-Jin Kang[1], Jeong Min Lee[1], Jeong Hee Yoon[1], Jeongin Yoo[1]. [1]*Seoul National University Hospital, Radiology, Seoul, Korea, Rep. of South*
Email: jmsh@snu.ac.kr

Background and aims: Sonazoid has different physiologic characteristics from blood-pool ultrasound contrast agents, but there has been no consensus about the diagnostic criteria of HCC. We aimed to investigate whether the Kupffer phase (KP) can be used as a major feature without lowering specificity for diagnosing HCC in high-risk individuals.
Method: Participants at risk of HCC with treatment-naïve solid hepatic lesions (≥1 cm) who underwent PFB-US from March 2019 to June 2022 were prospectively recruited. Three radiologists reviewed the enhancement pattern in the arterial phase, washout time and degrees, and echogenicity in the KP. All malignancies were pathologically confirmed. The pooled per-lesion diagnostic performance for diagnosing HCC using five different diagnostic criteria were compared by McNemar test: Criteria 1) any arterial phase hyperenhancement (APHE) with hypoechogenicity in KP, Criteria 2) nonrim APHE with hypoechogenicity in KP, Criteria 3) following criteria 2, but exclude early (<60 s postcontrast) and marked washout, Criteria 4) nonrim APHE with mild and late (≥60 s postcontrast) washout within 5 min, Criteria 5) nonrim APHE with mild and late washout within 5 min or hypoechogenicity in KP. Criteria 4 was identical to the diagnostic criteria of blood-pool agent-enhanced ultrasound.
Results: In total, 204 individuals with 213 lesions (mean size 32.5 ± 3.2 mm; HCC [n = 122], non-HCC malignancies [n = 21], and benign [n = 46]) were evaluated. For HCC diagnosis, the specificity of criteria 1 and 2 were significantly lower (42.9% and 72.2%) than criteria 3 (91.9%, p < .001) and 4 (p < .001). The sensitivity (63.7%) of criteria 5 was higher than criteria 3 (61.5%) and 4 (63.4%), and specificity (94.1%) of criteria 4 was higher than criteria 3 (91.9%) and 5 (91.9%), but both fail to meet the statistical significance (p = .59 and .93).

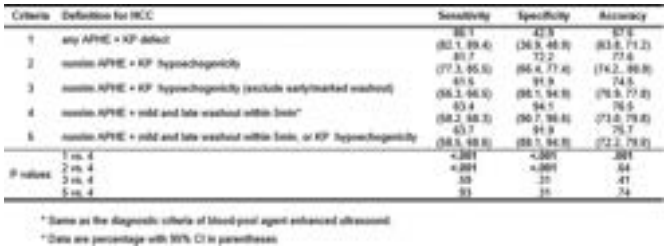

Figure:

Conclusion: Precluding early or marked washout and including nonrim APHE reinforced the specificity when KP was used as a major feature for diagnosing HCC. The KP imaging can be alternative to the 2–5 min postcontrast imaging without significant change in diagnostic performance.

FRI-304

It takes a team for HCC: improvement of outcome with the multidisciplinary ambulatory for systemic therapy

Andrea Dalbeni[1], Alessandra Auriemma[2], Marco Vicardi[1], andrea ruzzenente[3], Alfredo Guglielmi[3], Michele Milella[2], David Sacerdoti[1]. [1]*AOUI Verona, University of Verona, Medice Department, Liver Unit, Italy;* [2]*AOUI Verona, University of Verona, Oncology, Italy;* [3]*AOUI Verona, University of Verona, Surgery Department, Italy*
Email: andrea.dalbeni@aovr.veneto.it

Background and aims: Hepatocellular carcinoma (HCC) is the major cause of liver-related death worldwide. In the last years, a new approach with tyrosine kinase inhibitors (TKIs) and immune checkpoint inhibitors (ICIs) started to gain attention in HCC setting. With these new therapies multidisciplinary team (MDT) discussion becomes necessary due to increased curative treatments, frequency of stage migration, higher treatment rates and reduced mortality. In Verona Hospital, in addition to MDT discussion, a LIVER-MDT ambulatory was created, to our knowledge the first in the Italian health system, with an oncologist, an hepatologist, a surgeon, and an internist. Aim of this study was to verify if the LIVER-MDT ambulatory is useful to reduce adverse effects and mortality compared to a traditional ambulatory (ELEVETOR cohort, Liver cancer 2022).
Method: we collected data from patients attending the LIVER-MDT ambulatory. Major and minor adverse effects (MAE and mAE) and antitumoral doses were collected. Death and progression free survival (PFS) were also recorded.
Results: Among 834 patients evaluated at the MDT discussion from 2021, 40 patients were referred to the LIVER-MDT ambulatory to start systemic treatment. Median age was 69.5 (53–82), 82.5% were male. Cirrhosis etiology was 45% viral (HCV/HBV), 37.5% MAFLD and 10% alcohol. Compared to ELEVATOR cohort, less MAE were recorded (20% vs 32.7%, $p < 0.01$). In addition, MAE strictly due to the systemic therapy developed in 7.5%. No patients developed uncontrolled and resistant arterial hypertension or heart failure during the treatment. 32.5% died, with a median PFS of 8.85 ± 6.03 (median in ELEVATOR 6.4). Only 15% of patients needed a reduction of antitumoral drug dose, compared to 50% in ELEVATOR.
Conclusion: LIVER-MDT ambulatory improves the outcome of HCC patients on systemic therapy, reducing MAEs and mAEs, in particular cardiovascular complications, and seems the best approach for the increasing number of HCC patients.

FRI-305

Developing an aptamer biomarker model for the diagnosis of hepatocellular carcinoma

Mikkel Breinholt Kjær[1], Stine Karlsen Oversoe[1], Søren Fjelstrup[2], Daniel Miotto Dupont[2], Jens Kelsen[1], Jørgen Kjems[2], Henning Grønbæk[1]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Denmark;* [2]*Aarhus University, Interdisciplinary Nanoscience Centre (iNANO), Department of Molecular Biology and Genetics, Denmark*
Email: mikj@clin.au.dk

Background and aims: Hepatocellular carcinoma (HCC) is the fourth leading cause of cancer-related death globally and most tumors are detected at late stages of disease. The current screening method for HCC in risk populations relies on abdominal ultrasound. While ultrasound exhibits acceptable sensitivity for detection of HCC at any stage, the sensitivity to detect early stages of disease is less so. Coupled with the fact that the chance of cure diminishes with later stages of disease warrants novel methods for detection of HCC, herein biomarkers of early-stage HCC.
Thus, the aim of this study is to explore the clinical potential of aptamer technology to distinguish patients with HCC regarding early and late-stage disease.
Method: In this study we utilize APTA-SHAPE, an unbiased biomarker discovery platform based on aptamer technology. Aptamers are short chemically stabilized RNA strands often termed "chemical antibodies." The aptamers form defined 3D shapes capable of specific recognition of a biological target. Through consecutive trainings with plasma from patients with HCC we build a library specifically able to detect thousands of plasma molecules in HCC. In subsequent analysis, aptamers associated with disease stage in HCC are identified and the protein targets of these aptamers are identified by mass spectrometry.
Data for this study was generated by aptamer analysis performed on plasma samples from a cohort of 104 HCC patients and 24 healthy controls collected at the Department of Hepatology and Gastroenterology, Aarhus University Hospital from 2016 to 2018. The material was divided to generate a training set and a validation set for the constructed models. Disease severity groups were defined by TNM staging or Barcelona Clinic Liver Cancer (BCLC) score.
Results: An aptamer-based model for detection of HCC defined by TNM-staging was able to discriminate between healthy and early-stage disease (TNM stages 1A, 1B and 2) with an AUC in the validation set of 0.85 (95% CI: 0.73–0.97). Furthermore, the model was able to discriminate between healthy and late-stage disease (TNM stages 3A, 3B, 4A and 4B) with an AUC of 0.93 in the validation set (95% CI: 0.84–1.00). A second model based on BCLC scores were able to discriminate between healthy controls and patients with early (stages 0, A or B) or late-stage disease (stages 3 and 4) with AUCs of 0.8 (95% CI: 0.64–0.95) and 0.94 (95% CI: 0.87–1.00).
Conclusion: The APTA-SHAPE technology is a promising and unbiased tool to identify novel biomarkers for HCC. We developed a model capable of identifying HCC patients as well as grouping patients with regards to their disease stage and severity of disease. Future studies will aim to identify the protein plasma biomarkers discovered in this study.

FRI-306

The association between alcohol consumption and the risk of hepatocellular carcinoma according to glycemic status: a nationwide population-based study

Eun Ju Cho[1], Goh Eun Chung[2], Jeong-Ju Yoo[3], Yuri Cho[4], Dong Wook Shin[5], Yoon Jun Kim[1], Jung-Hwan Yoon[1], Kyungdo Han[6], Su Jong Yu[7]. [1]*Seoul National University College of Medicine, Korea, Rep. of South;* [2]*Seoul National University Hospital Healthcare System Gangnam Center, Korea, Rep. of South;* [3]*Soonchunhyang University Bucheon Hospital, Korea, Rep. of South;* [4]*National Cancer Center, Korea, Rep. of South;* [5]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Korea, Rep. of South;* [6]*Soongsil University, Korea, Rep. of South;* [7]*Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Korea, Rep. of South*
Email: ydoctor2@snu.ac.kr

Background and aims: Alcohol and diabetes are known risk factors for hepatocellular carcinoma (HCC), however, it is unclear whether the association between alcohol consumption and HCC risk differs by fasting serum glucose level and diabetes. We investigated the dose-response relationship between alcohol consumption and the risk of HCC according to glycemic status.
Method: We included patients who underwent general health checkups in 2009 linked with death certificate data using the Korean National Health Insurance Service Database. Cox proportional hazard regression analysis was performed to estimate the relationship between alcohol consumption and HCC risk according to glycemic status.
Results: A total of 39,798 patients newly diagnosed with HCC were observed in the 8.3 years median follow-up period. Mild-to-moderate alcohol consumption increased the risk of HCC in all glycemic status (normoglycemia: hazard ratio [HR], 1.06; 95% CI, 1.02 to 1.10; prediabetes: HR, 1.14; 95% CI, 1.09–1.20 and diabetes: HR, 1.23; 95% CI, 1.17–1.29). Heavy alcohol consumption also increased the risk of HCC in all glycemic statuses (normoglycemia: HR, 1.39; 95% CI, 1.32–1.44; Prediabetes: HR, 1.60; 95% CI, 1.51–1.71, and diabetes: HR,

2.01; 95% CI, 1.89–2.14). The increased risk in mild-to-moderate or heavy alcohol consumption was the greatest in the diabetes group, followed by prediabetes and normoglycemia (P for interaction <0.001).
Conclusion: Mild-to-moderate alcohol consumption was associated with an increased risk of HCC in all glycemic status groups. The increased risk of HCC was the highest in the diabetes group, suggesting that more intensive alcohol abstinence is required for patients with diabetes.

FRI-307
Combined hepatocellular-cholangiocarcinoma : epidemiological, radiological and survival data from a retrospective single-center study
Guillaume Henin[1], Ivan Borbath[1], Bénédicte Delire[1]. [1]*Cliniques Universitaires Saint-Luc, Hepato-gastro-enterology, Belgium*
Email: ghenin1993@gmail.com

Background and aims: Combined hepatocellular-cholangiocarcinoma (cHCC-CCA) is a rare primary liver malignancy with a poor prognosis and very few available data in terms of pathophysiology, risk factors, imaging features and no current consensus in terms of treatment recommendations. Therefore, our aims were to assess the risk factors, imaging-pathology correlation and survival of these patients in a real-life cohort.
Method: All patients with histologically-confirmed or with imaging-based suspicion of cHCC-CCA (classified Li-Rads M) treated between 2016 and 2021 were screened in a retrospective single-center study. Other histological subtypes of liver tumor in the absence of radiological suspicion of mixed tumor by magnetic resonance imaging (MRI) were excluded. MRI data of transplanted patients were not recorded considering the artifacts due to waiting treatments. All data were recorded based on medical records.
Results: Among 761 screened patients, 69 were included among which 38 patients (55.1%) had a cHCC-CCA lesion (cHCC-CCA group). A hepatocellular carcinoma was confirmed in 18 patients (HCC group-26.1%) and a cholangiocarcinoma in 9 patients (CCA group-13.0%). 4 patients had a benign tumor (5.8%). In terms of risk factors for the onset of cHCC-CCA, alcohol-related liver disease and pre-existing liver lesions were correlated to this risk (OR 4.67, p = 0.024 and OR 4.16, p = 0.043 respectively). In terms of imaging diagnostic accury in the HCC-CCA group (N = 26, liver transplant recipients excluded in this analysis), 17 patients had a positive MRI for HCC-CCA (65.4%) and 9 had a negative MRI (34.6%). In the non-HCC-CCA group (HCC, CCA, benign tumors and non-histologically investigated patients-N = 735), 31 patients had a positive MRI (4.2%) and 704 had a negative MRI (95.8%) (Sensitivity = 0.65; Specificity = 0.96; positive predictive value = 0.35 (PPV); negative predictive value = 0.99 (NPV); p < 0.0001). In terms of tumor biomarkers profiles, there was no significant differences between the 3 histological subtypes of malignant lesions (cHCC-CCA, HCC, CCA) for CA19.9 (p = 0.43), AFP (p = 0.28) and DCP (p = 0.22). In terms of survival analysis, no significant differences were observed in terms of overall survival between histological subgroups (cHCC-CCA : 44.77; CCA : undefined; HCC : 37.61 months-P = 0.81). No significant differences were also observed in the cHCC-CCA group depending on treatment modality (liver directed therapy : 44.8; systemic treatment : 26.86 months-p = 0.06).

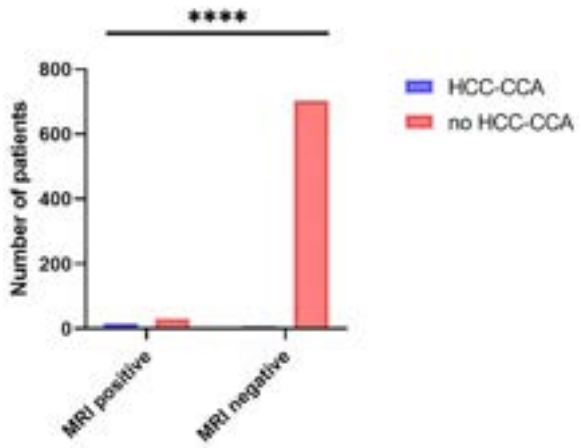

Figure:

Conclusion: We highlighted alcohol-related liver disease and pre-existing liver tumor prior to histological diagnosis as risk factors for the onset of cHCC-CCA (OR 4.67, p = 0.024 and OR 4.16, p = 0.043). we also highlighted an excellent NPV of liver MRI for the diagnosis of cHCC-CCA but a poor PPV (PPV = 0.35; NPV = 0.99-p < 0.0001) confirming the necessity to perform a tumor biopsy in case of diagnostic uncertainty. Further well-conducted prospective studies are required to establish systemic treatment guidelines, systemic treatment regimens being currently chosen based on expert opinion.

FRI-308
Predictors of extrahepatic recurrence after transarterial chemoembolization as first-line therapy for hepatocellular carcinoma
Elisa Pinto[1], Filippo Pelizzaro[1], Alessandro Vitale[1], Edoardo Giannini[2], Franco Trevisani[3], Fabio Farinati[1]. [1]*University of Padua, Italy;* [2]*University of Genova, Italy;* [3]*University of Bologna, Italy*
Email: pintoelisa93@gmail.com

Background and aims: The literature regarding the risk of progression to extrahepatic disease and clinical factors associated with the development of metastases in patients with hepatocellular carcinoma (HCC) treated with transarterial chemoembolization (TACE) is sparse. We aimed to assess the incidence of extrahepatic recurrence and to identify clinically relevant risk factors for the development of metastases in patients with HCC treated with TACE as first-line treatment.
Method: From the Italian Liver Cancer (ITA.LI.CA) database, data of 981 HCC patients undergoing TACE as first-line treatment were retrieved and retrospectively analyzed. Incidence of extrahepatic recurrence was compared between two groups according to the diameter of the largest liver lesion at the time of TACE (HCC ≤3 cm vs. HCC >3 cm). Multivariate Cox regression was used to identify predictor of extrahepatic recurrence.
Results: During a median follow-up of 27.0 months (IQR, 13.2–49.0) the overall recurrence rate was 75.4%. Only 78/981 patients (8.0%) had an extrahepatic tumor localization at first recurrence (5.4% in the ≤3 cm group and 10.7% in the >3 group; p = 0.002), while the overall extrahepatic recurrence rate was 26.0% (21.2% and 31.0% patients in the ≤3 cm and >3 cm groups, respectively; p = 0.0006) (Figure 1). Compared to those with larger tumors, patients with HCC ≤3 cm had a significantly longer recurrence-free survival (12.0 [95% CI 10.7–13.3] vs. 9.7 [95% CI 8.2–11.2] months; p = 0.02) and overall survival (52.5 [95% CI 45.5–59.4] vs. 34.7 [95% CI 30.7–38.7] months; p < 0.0001). HCC size ≥3 cm, multifocality and AFP levels were independent predictors of extrahepatic recurrence.

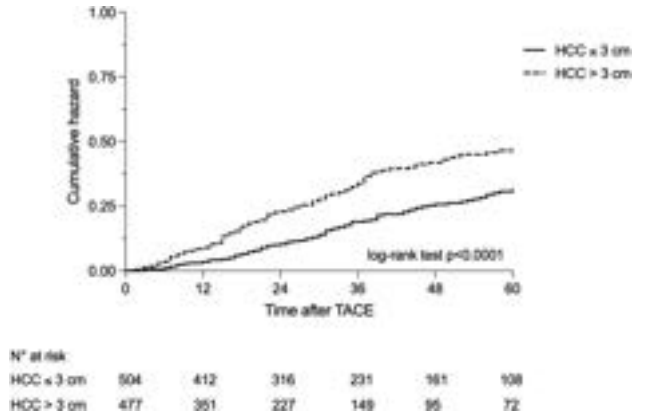

Figure 1: Cumulative hazard of extrahepatic recurrence among patients with HCC ≤3 cm and >3 cm treated with first-line TACE.

Conclusion: Although the majority of patients treated with TACE do not develop metastases during their lifespan, knowledge of risk factors for extrahepatic recurrence (HCC size, multifocality, AFP levels) may help to assess patient prognosis and to identify patients deserving closer follow-up in order to start early systemic therapy.

Associations of pathologic features with integrated genomic and clinical characteristics of cholangiocarcinoma

Keun Soo Ahn[1], Koo Jeong Kang[2], Tae-Seok Kim[2], Yong Hoon Kim[2].
[1]*Keimyung University Dongsan Hospital, Surgery, Korea, Rep. of South;*
[2]*Keimyung University Dongsan Hospital, Korea, Rep. of South*
Email: ahnksmd@gmail.com

Background and aims: Pathologically, cholangiocarcinoma (CCA) can be divided as two pathological subtype; large duct type and small duct type. It represents different origin and carcinogenesis of CCA. However, its clinical impact and molecular characteristics are not well known yet, and we evaluated clinical and molecular features according to pathological subtype.

Method: On 3 different cohort (Korea; Keimyung University Dongsan Hospital, USA; Mayo clinic, TCGA), 107 cases of CCA were included which had available clinical and molecular data (RNA sequencing with mutation). For Korea and USA data, we performed next generation RNA sequencing and RNA expression, variants and fusions were analyzed. For TCGA data, we downloaded clinical and genetic information from TCGA serve. We analyzed clinical and molecular features for them.

Results: On large duct type, frequency of extrahepatic CCA (Klatskin and distal bile duct ca), periductal infiltrating type, history of cholangitis or IHD stone, and N1 stage were significantly high compared to small duct type. In addition, level of serum CEA and CA 19-9 were significantly high in large duct type. In small duct type, history of hepatitis was significantly frequent than large duct type. In both type, frequency of mass forming type was similar. Patients with large duct type showed significant poor disease-free and overall survival than those with small duct type. On multivariate analysis, large duct type, lymph node metastasis and vascular invasion were independent poor prognostic factors. On mutation analysis, KRAS, PIK3CA gene mutation was common in large duct type, whether IDH1/2 mutation and FGFR2 fusion were common in small duct type. On pathway analysis, inflammation related, AKT, Wnt and KRAS related signalling were enriched in large duct type, while metabolism and EMT related pathways were enriched in small duct type.

Conclusion: Two pathological subtypes of intrahepatic CCA with distinct clinical, biological and prognostic differences were identified. Therefore, molecular characteristic of CCA can be predicted based on pathological subtype, and it may lead to more rational targeted approaches to treatment.

Classification of microvascular invasion of hepatocellular carcinoma: correlation with prognosis and MR imaging

Dong Ho Lee[1], Haeryoung Kim[2], Yoon Jung Hwang[3], Jae Seok Bae[3].
[1]*Seoul National University Hospital, Radiology, Korea, Rep. of South;*
[2]*Seoul National University College of Medicine, Korea, Rep. of South;*
[3]*Seoul National University Hospital, Korea, Rep. of South*
Email: dhlee.rad@gmail.com

Background and aims: This study aimed to evaluate the prognostic value of classification of microvascular invasion (MVI) in hepatocellular carcinoma (HCC) and to analyze the radiologic features predictive of MVI.

Method: Total 506 consecutive patients with surgically resected solitary HCCs were enrolled for this study. We retrospectively reviewed the histological and MR imaging features of MVI. Univariable and multivariable logistic regression analyses were performed to identify factor associated with the degree of MVI. Kaplan-Meier curves were calculated to assess prognostic impact of MR imaging features on overall survival (OS) and beyond-Milan recurrence-free survival (RFS).

Results: We identified MVI-positive HCCs with invasion of ≥5 vessels or those with ≥50 invaded tumor cells were significantly associated with decreased OS ($p < 0.001$ and 0.001, respectively). Based on these findings, the number of invaded vessels and the number of invaded tumor cells were decided to be reliable risk factors, and we classified HCCs into three group; severe MVI (presence of all two risk factors; n = 110), mild MVI (presence of one or none of the risk factors; n = 85), and no MVI (n = 311). OS and beyond Milan RFS in severe MVI group were significantly poorer than that in mild or no MVI group ($p < 0.001$). On multivariate analysis, severe MVI was a significant independent predictive factor for OS and beyond Milan RFS. For MRI findings, non-smooth tumor margin (OR, 2.224; p = 0.023) and satellite nodule (OR, 3.264; $p < 0.001$) were independently associated with severe-MVI group in multivariate analysis. Both non-smooth tumor margin and satellite nodule were associated with worse 5-year OS rate and beyond-Milan RFS rate (Ps ≤0 .039).

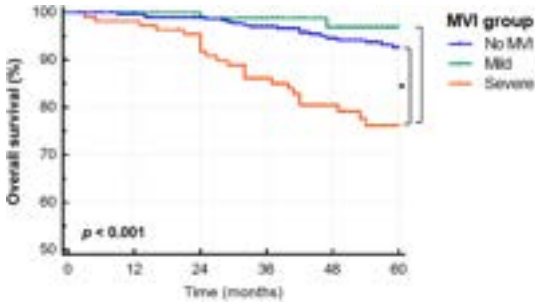

Figure: Overall survival of hepatocellular carcinoma patients, stratified by MVI classification.

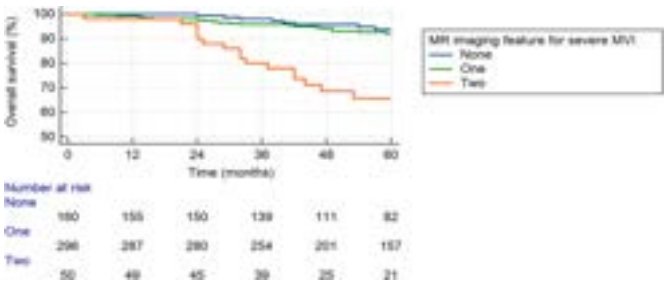

Figure: Overall survival of hepatocellular carcinoma patients, stratified by MR imaging feature for severe MVI.

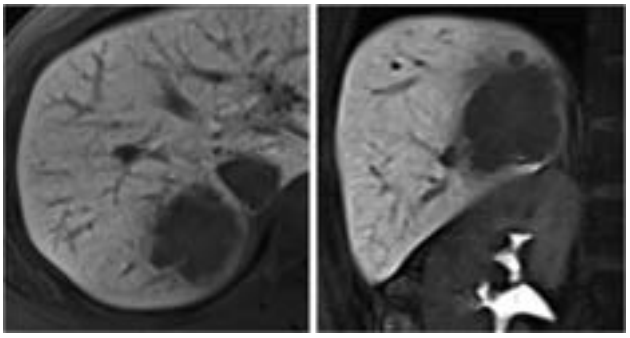

Figure: A representative example of gadoxetic acid-enhanced MRI obtained from a 47-year-old woman with hepatocellular carcinoma with severe-MVI. On the axial image of hepatobiliary phase, there is a tumor with a non-smooth margin (arrows) in segment 7 of the liver. On coronal image, there is a satellite nodule (arrowhead) at the superior aspect of the tumor. After surgical resection, severe MVI was identified by pathological examination. Twenty-five months after surgical resection, this patient experienced recurrence with inferior vena cava invasion, and died 42 months after resection.

Conclusion: Our study revealed the histologic risk classification of MVI according to the number of invaded microvessels and invading carcinoma cells is valuable for predicting prognosis in HCC patients. Non-smooth tumor margin and satellite nodules were sigfinicantly associated with both severe MVI and poor prognosis.

FRI-311

Liver function is a predictor of survival in patients with hepatocellular carcinoma in best supportive care

Claudia Campani[1], Laura Bucci[2], Martina Rosi[1], Valentina Adotti[1], Tancredi Li Cavoli[1], Umberto Arena[1], Franco Trevisani[2], Fabio Marra[1] and Ita.Li.Ca. Study Group[2]. [1]*University of Florence, Italy;* [2]*University of Bologna, Italy*
Email: fabio.marra@unifi.it

Background and aims: The prognosis of patients with hepatocellular carcinoma (HCC) is very variable, and the relative contribution of tumor burden and liver dysfunction to survival is uncertain. Median overall survival (OS) of patients managed with best supportive care is around 3–6 months, although longer values may be observed in clinical practice. Aim of this study was to identify the factors linked to tumor or liver dysfunction associated with survival in patients with HCC treated with BSC.
Method: We retrospectively evaluated the clinical characteristics of 1414 patients who had an indication for BSC recorded in the Ita.Li.Ca. database between 2000 and 2020. We analyzed both patient and tumor characteristics to identify predictors of OS.
Results: Median age was 69y and 76% of patients were male. Etiology included chronic viral infection (68.3%), alcohol use disorder (30.9%) and non-alcoholic steatohepatitis (8.3%). 67.4% of patients had a performance status 0–1 and 41.4% were in Child-Pugh B class. Median MELD was 13. 60% of patients had a multifocal HCC with a median number of 3 lesions and a median size of 33 mm. 533 patients had vascular invasion. Median alpha-fetoprotein was 49.25 ng/ml. 111 patients were classified as BCLC-A, 148 as BCLC-B, 791 as BCLC-C and 325 as BCLC-D (12 unknown). No differences in terms of OS were observed considering the etiology of liver disease or the presence of cirrhosis. Among comorbidities, obesity (p < 0.001), hypercholesterolemia (p = 0.036) and hypertriglyceridemia (p = 0.034) were associated with lower OS. Absence of symptoms (6 vs 10 months, p < 0.001), lack of vascular invasion (9.1 vs 5.03, p < 0.001), and absence of metastasis (8.167 vs 4.733 p < 0.001) were associated with a better OS. Median OS in BCLC-A (14.37 months) patients was longer than in stages B (9.20) or C (7.13). Survival progressively declined according to severity of liver function using three different scores (CPS, ALBI, pALBI, p < 001). Women tended to survive longer 23 vs. 19 months, p = 0.053). Comparing patients surviving more or less than 12 months (398 vs. 1016), age, size of lesions, albumin, bilirubin, alpha-fetoprotein, and MELD were significantly different. At Cox univariate analysis presence of cirrhosis (HR: 1.201 CI 95%CI 0.998–1.445 p = 0.052), number of lesion (HR: 1.02 CI 95%CI 1.01–1.04 p = 0.013), median size (HR: 1.02 CI 95%CI 1.01–1.03 p < 0.001), vascular invasion (HR: 1.80 CI 95%CI 1.59–2.02 p p < 0.001), metastasis (HR: 1.48 CI 95% CI 1.28–1.72 p < 0.001), ALBI grade (ALBI 2 HR: 1.25 CI 95%CI 1.04–1.50 p = 0.015 ALBI 3 HR :1.75 CI 95% 1.43–2.14 p < 0.001), pALBI grade (pALBI 2 HR: 0.99 CI 95%CI 0.8241.202p = 0.960 pALBI 3 HR :1.49 CI 95% 1.25–1.78 p < 0.001), MELD (HR: 1.04 CI 95%CI 1.04–1.05 p p < 0.001) and CPS (HR: 1.13 CI 95%CI 1.10–1.165 p < 0.001) were significantly associated with OS. Using different models to avoid colinearity ALBI, pALBI, and CPS maintained an independent prognostic role on OS (ALBI HR 1.58 CI 1.26–1.98 p < 0.001, pALBI 1.22 CI 1.01–1.49 p = 0.43, CPS 1.12 CI 1.85–1.16 p < 0.001).
Conclusion: In a large series of patients with HCC in BSC, parameters of liver function are strongly associated with survival.

FRI-312

Similar recurrence after curative treatment of HBV-related HCC regardless of HBV replication activity

Mi Na Kim[1], Beom Kyung Kim[2], Heejin Cho[3], Myungji Goh[4], Su Jong Yu[3], Dong Hyun Sinn[4], Soo Young Park[5], Seung Up Kim[2]. [1]*Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South;* [2]*Yonsei University College of Medicine, Korea, Rep. of South;* [3]*Seoul National University College of Medicine, Korea, Rep. of South;* [4]*Sungkyunkwan University School of Medicine, Korea, Rep. of South;* [5]*Kyungpook National University Hospital, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: Antiviral therapy (AVT) is required for patients with newly diagnosed hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC), if HBV DNA is detectable. We compared the risk of recurrence according to HBV replication activity at curative treatment of HBV-related HCC.
Method: Patients with HBV-related HCC who received surgical resection or radiofrequency ablation between 2013 and 2018 were enrolled in this retrospective cohort study. Patients were categorized into two groups according to HBV replication activity at curative treatment of HBV-related HCC (group 1: patients who met AVT indication for HBV-related HCC due to detectable HBV DNA, but did not meet AVT indication for HBV if without HCC; group 2: patients who met AVT indication for HBV regardless of HCC).
Results: In the entire cohort (n = 911), HCC recurred in 303 (33.3%) patients during a median follow-up of 4.7 years. After multivariate adjustment for the key covariates, group 2 showed a statistically similar risk of HCC recurrence (adjusted hazard ratio [aHR] = 1.18, 95% confidence interval [CI] = 0.85–1.64; *P* = 0.332) compared to group 1. In addition, group 2 showed statistically similar risks of early (<2 years) (aHR = 1.31, 95% CI = 0.88–1.95), and late (≥2 years) (aHR = 0.83, 95% CI = 0.45–1.55) recurrence compared to group 1. Propensity score matching and inverse probability of treatment weighting analysis also yielded similar risks of HCC recurrence between the two groups (all *P* > 0.05, log-rank tests).

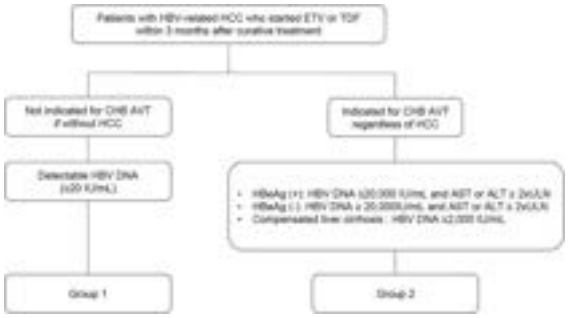

Figure: Definitions of groups according to HBV replication activity

Conclusion: The risk of HCC recurrence in patients who received curative treatment for newly diagnosed HBV-related HCC was comparable, regardless of HBV replication activity at curative treatment of HCC.

Loss of mucosal tolerance to glycoprotein 2 isoform 1 is a novel diagnostic biomarker for cholangiocarcinoma without underlying PSC

Chang-sheng Xia[1], Marcin Krawczyk[2,3], Chun Di[1], Łukasz Krupa[4], Beata Kruk[3], Wacław Hołówko[5], Piotr Milkiewicz[6,7], Huizhang Bao[1], Xiao He[1], Daming Liu[1], Chunhong Fan[1], Abdullah Nasser[8], Steffi Lopens[8,9], Peter Schierack[9,10], Dirk Roggenbuck[8,9,10], Yudong Liu[11]. *[1]Department of Clinical Laboratory, Peking University People's Hospital, Beijing, China; [2]Department of Medicine II, Saarland University Medical Center, Homburg, Germany; [3]Laboratory of Metabolic Liver Diseases, Medical University of Warsaw, Warsaw, Poland; [4]Department of Gastroenterology and Hepatology with Internal Disease Unit, Medical Department, University of Rzeszów, Rzeszów, Poland; [5]Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland; [6]Liver and Internal Medicine Unit, Medical University of Warsaw, Warsaw, Poland; [7]Translational Medicine Group, Pomeranian Medical University, Szczecin, Poland; [8]Medipan GmbH, R/D Department, Dahlewitz, Germany; [9]Institute of Biotechnology, Faculty Environment and Natural Sciences, Brandenburg University of Technology Cottbus-Senftenberg, Senftenberg, Germany; [10]Faculty of Health Sciences Brandenburg, Brandenburg University of Technology Cottbus- Senftenberg, Senftenberg, Germany; [11]The Key Laboratory of Geriatrics, Beijing Institute of Geriatrics, Beijing Hospital, Beijing, China*
Email: marcin.krawczyk@uks.eu

Background and aims: Cholangiocarcinoma (CCA) is a very aggressive tumor with dismal prognosis. In our previous studies we showed that the anti-glycoprotein 2 (anti-GP2) IgA and antineutrophil-cytoplasmic antibodies to proteinase 3 (PR3-ANCA) are predictive for CCA development in patients with primary sclerosing cholangitis (PSC). Here we investigate these antibodies in two independent cohorts of patients with CCA without underlying PSC and in patients with other hepatobiliary tumors.
Method: The PR3-ANCA, IgA and IgG to large (anti- $GP2_1$) and short (anti-$GP2_4$) GP2 isoforms were measured in sera of prospectively collected patients with hepatobiliary-tumors and in controls. The discovery (118 Chinese patients) and validation (38 Polish patients) cohorts with CCA without PSC were compared with patients with pancreatic ductal adenocarcinoma (PDAC, n = 49), patients with hepatocellular carcinoma (HCC, n = 45), patients with benign pancreatic neoplasms (BPN, n = 21). The control cohort consisted of 75 healthy individuals.
Results: Among testes antibodies, anti-$GP2_1$ IgA was the most prevalent one in the CCA cohorts (Chinese cohort: 65/118, 52.6%; Polish cohort: 17/38, 44.7%) and its levels were significantly elevated as compared to other cohorts included in the analysis, except the PDAC patients. The anti-$GP2_4$ IgA levels were, in turn, significantly higher in the individuals with CCA patients as compared to HC and PDAC patients. Neither of the IgA autoantibody corelated with the CCA differentiation or CA19-9 in serum. Among analyzed autoantibodies, the anti-$GP2_1$ IgA demonstrated the best diagnostic performance for the differentiation of CCA from disease controls and HC (AUC = 0.82, 95% CI 0.77–0.86, p < 0.01). Logistic regression including GGT, patients age and anti-GP2 IgG_4 as confounders showed that anti-$GP2_1$ IgA was an independent predictor of CCA occurrence.
Conclusion: Analysis of patients with hepatobiliary tumors demonstrated that the anti-$GP2_1$ IgA is prevalent in patients with cholangiocarcinoma. Mucosal loss of tolerance in the form of anti-$GP2_1$ IgA distinguishes patients with CCA from ones with hepatocellular carcinoma and benign pancreatic neoplasms.

FRI-314

Baseline cirrhosis in addition to the aMAP score, increased the risk of developing hepatocellular carcinoma in patients with hepatitis B

Supakorn Chaiwiriyawong[1], Pimsiri Sripongpun[1], Naichaya Chamroonkul[1], Apichat Kaewdech[1]. *[1]Prince of Songkla University, Thailand*
Email: apichatka@hotmail.com

Background and aims: Hepatocellular carcinoma (HCC) is a major global problem impacting patients' survival with liver diseases. With a few external validation studies, the aMAP score (age, male sex, and ALBI score) was recently developed to predict the risk of HCC development. We aim to externally validate this score in patients with chronic hepatitis B (CHB) infection as well as study the additional predictive factor for HCC development.
Method: We identified all CHB patients who were followed up between January 2007 and December 2021 at our hospital. Patients with CHB infection who were over the age of 18 were eligible. The exclusion criteria were being diagnosed with HCC within 6 months of the baseline visit, coinfection with another viral infection, or other causes of chronic liver disease. Baseline data from the initial diagnosis was retrieved and tracked until the occurrence of HCC.
Results: There were 866 eligible patients among the 902 CHB patients who were followed up on, with a median follow-up time of 7.7 years. Ninety-two (10.62%) patients developed HCC. HCC patients had significantly higher age, male sex, HBeAg-negative status, cirrhosis, total bilirubin, aspartate aminotransferase (AST), and alanine aminotransferase (ALT) levels than non-HCC patients. Serum albumin and platelet count were lower in HCC patients than in non-HCC patients. Multivariate analysis showed that the presence of cirrhosis at baseline [aHR 14.9 (5.62, 39.49), $p < 0.001$] and a high aMAP score at baseline [aHR 2.94 (1.38, 6.26), $p = 0.005$] were associated with HCC development. The cumulative incidence of HCC in patients with cirrhosis and a high aMAP score is higher than in patients with medium or low aMAP score and non-cirrhotic patients, as shown in the figure.
Conclusion: Cirrhosis status at the initial diagnosis of CLD is the strongest predictive factor for HCC development. Patients with cirrhosis and high aMAP were at the highest risk of developing HCC in the future. This group of patients should undergo intensive surveillance.

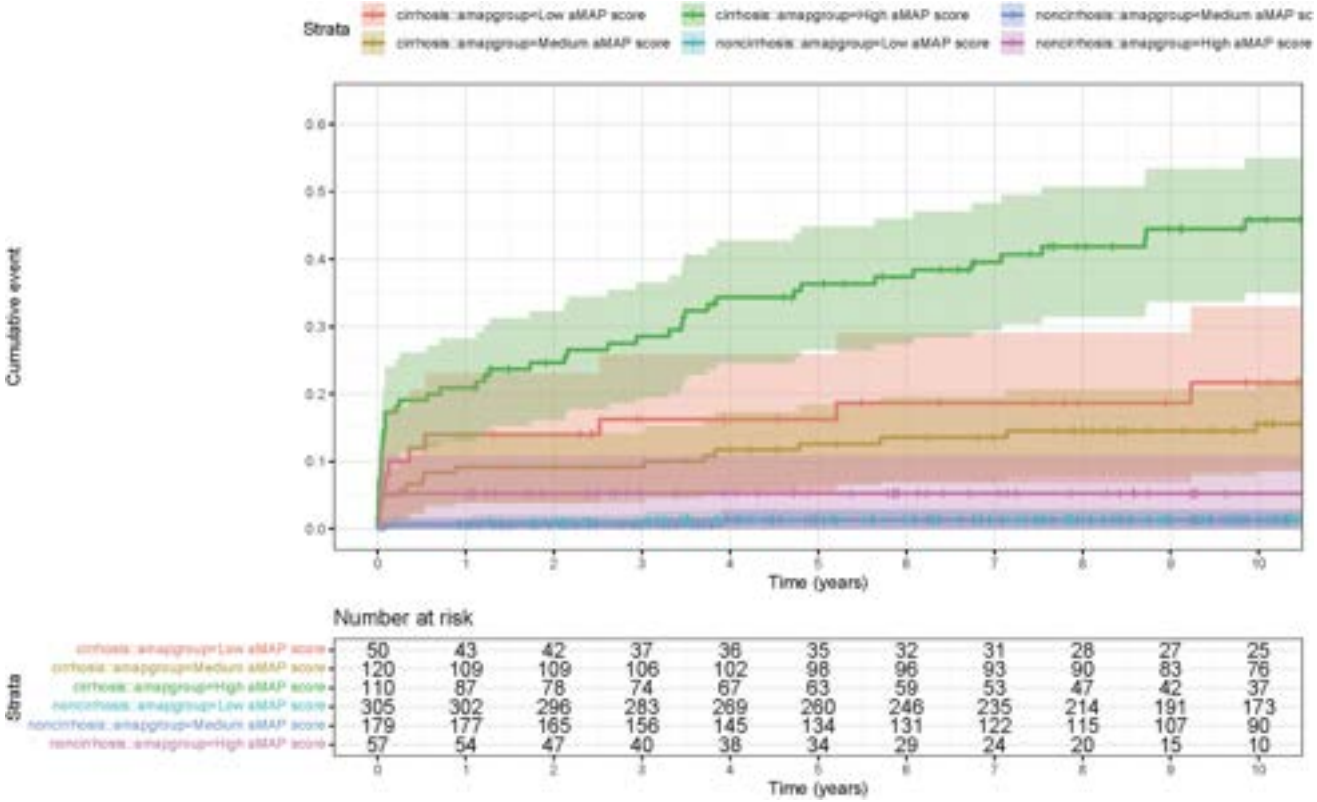

Figure: (abstract: FRI-314): Cumulative probability of development of HCC according to the combination of cirrhosis and aMAP score among CHB patients.

FRI-315

Comparative study of scoring systems predicting outcome of transarterial chemoembolization for hepatocellular carcinoma: a nationwide cohort study

Myeong Jun Song[1], Hae Lim Lee[1], Seok-Hwan Kim[1]. [1]*the Catholic university of Korea, Korea, Rep. of South*
Email: mjsong95@catholic.ac.kr

Background and aims: Several scoring systems have been proposed to predict the outcome of transarterial chemoembolization (TACE) in patients with hepatocellular carcinoma (HCC). However, the application of the albumin-bilirubin (ALBI) grades to TACE candidates is poorly validated. Evaluation of the applicability of prognostic factors for patients performing TACE is necessary. We aimed to develop new scoring system including ALBI grade.
Method: 3,069 patients with unresectable HCC, child class A/B and ECOG 0-1 performing TACE were included from national cohort of the Korean Central Cancer Registry between 2008 and 2017. Patients were randomly divided into training (n = 1,507) and validation cohort (n = 1,562). A prognostic model was developed and validated. We compared with previous scoring models.
Results: In entire cohort, the patient's mean age was 62 years. The patients were hepatitis B virus (57.1%) and child class A (83.2%). The prognostic model of TACE was "largest tumor diameter+ tumor number, AFP, and ALBI grade," which consistently outperformed other currently available models in both training and validation datasets. Patients were assigned points according to sum of tumor burden (≤5, 5–10, ≥10), AFP or ALBI grade. Patients were divided into four risk groups based on their TACE-prognostic (TP) scores: A, B, C and D. The median survival for the groups A, B, C and D was 80.1, 53, 35.2 and 19.4 months, respectively.
Conclusion: This new TP scoring system may prove a favorable tool to stratify ideal candidates of TACE and predict OS with favorable performance and discrimination. Further external validation is needed.

FRI-316

Liver Frailty Index is associated with progression-free survival in patients with advanced HCC treated with Atezolizumab/ Bevacizumab

Philippe Sultanik[1], Edouard Larrey[1], Manon Evain[1], Bertille Campion[1], Amandine Ait Oufella[1], Héloise Giudicelli[1], Mathilde Wagner[2], Dominique Thabut[1], Manon Allaire[1]. [1]*Hôpital Pitié-Salpétrière, Liver Unit, Paris, France;* [2]*Hôpital Pitié-Salpétrière, Radiology Department, Paris, France*
Email: philippe.sultanik@aphp.fr

Background and aims: Prognostic factors of response to immunotherapy (IT) for advanced hepatocellular carcinoma (HCC) are not all established. Sarcopenia is associated with poor prognosis in patients (pts) under tyrosine kinase inhibitors, but its impacts on pts treated with IT is not known. The Liver Frailty Index (LFI) is a simple bedside tool for sarcopenia evaluation and is closely related to morbi-mortality in cirrhotic pts awaiting for liver transplantation. Our objective was to investigate whether LFI was associated with progression-free survival (PFS) and overall (OS) in advanced HCC pts treated with Atezolizumab/Bevacizumab (Atezo-Beva).
Method: From all pts treated with Atezo-Beva in our center, we performed a prospective study with baseline LFI measurement from January 2022. Baseline sarcopenia was asserted using BMI, albumin (ALB) and LFI (as continuous [LFI_c] and categorical [LFI_{gr}] variable-defined as frail [LFI > 4.5] or no-frail [LFI < 4.5] pts). Progression was defined as a composite (progression and/or side effects/hepatic decompensation requiring discontinuation). OS and PFS were assessed using Kaplan Meier. The influence of baseline characteristics on events during follow-up was assessed by Cox model.
Results: 23 pts treated with Atezo-Beva had a baseline LFI measurement from January to August 2022, 74% men, median age at 68 years. 17 (77%) pts had cirrhosis (heavy drinking 62%, NASH 43%, HCV 33%, HBV 10%, mixed causes 48%). At inclusion, Child-Pugh class was A for 45%, B for 45% and C for 10%, with a median MELD score at

$11_{[8-15]}$. On the day of treatment, HCC characteristics were a median size of CHC at $60_{[40-76]}$ mm for the largest lesion, infiltrative for 19% and vascular invasion for 38% pts. Pts'characteristics were: BMI $25.7_{[23.9-28.2]}$ kg/m^2, bilirubin $17_{[10-33]}$ µM, INR $1.25_{[1.13-1.41]}$, ALB $31_{[26-36]}$ g/l, creatinin $74_{[66-87]}$ µM, platelets $133_{[91-202]}$ G/mm^3, AFP $126_{[11-2525]}$ ng/ml, ALBI score : 1 in 14%-2 in 48%-3 in 38%, LFI_c $4.25_{[3.99-4.68]}$. Overall, 10 (43%) pts displayed frailty (LFI_{gr} frail). The median follow-up was $5.3_{[1.9-6.8]}$ months. Median PFS was 5.9 months, and 11 (48%) pts were alive without progression. In Cox univariate analysis, platelets (p = 0.01), AFP (p = 0.03), LFI_c (p = 0.01) and being LFI_{gr} frail (p = 0.02) were associated with PFS. Overall, 9 (69%) no-frail and 2 (20%) frail pts (median PFS at 4.2 months) were alive without progression, log-rank = 0.01 (Figure). AUROC of LFI_c for PFS was 0.77. Only LFI_c (aHR 4.49, p = 0.01) and LFI_{gr} frail (aHR 4.66, p = 0.03) were associated with PFS in multivariate analysis. Overall, 9 (39%) pts died. 10 (77%) no-frail pts and 4 (40%) frail pts (median PFS at 5.6 months) were alive, log-rank = 0.09. In multivariate analysis, platelets (aHR 1.01, p = 0.04) and ALB (aHR 0.79, p = 0.03) associated with OS but not LFI.

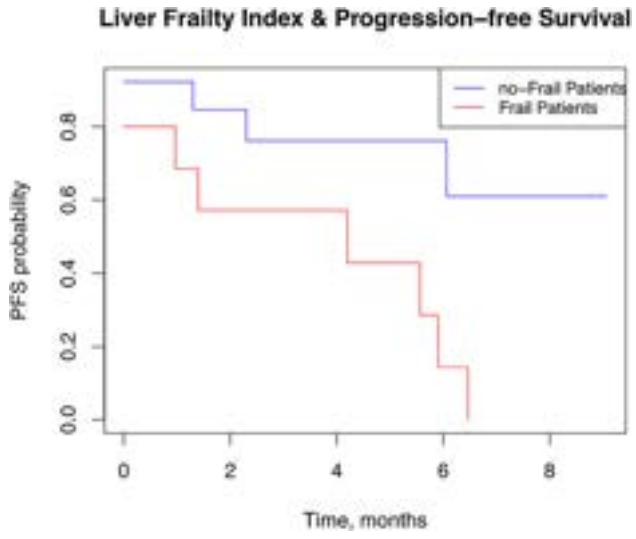

Figure:

Conclusion: The Liver Frailty Index is an easy tool for sarcopenia assessment which is associated with PFS in patients with advanced HCC treated with Atezo-Beva. Sarcopenia screening and treatment including nutritional and physical strengthening should be performed for all patients.

FRI-317

Characterization of the imaging signature of hepatocellular carcinoma with enhancement pattern mapping

Newsha Nikzad[1], David Fuentes[2], Millicent Roach[2], Tasadduk Chowdhury[2], Matthew Cagley[2], Mohamed Badawy[2], Manal Hassan[2], Khaled Elsayes[2], Laura Beretta[2], Eugene Koay[2], Prasun Jalal[1]. *[1]Baylor College of Medicine, Houston, United States; [2]MD Anderson Cancer Center, Houston, United States*
Email: newshanikzad@gmail.com

Background and aims: Limited methods exist to accurately characterize risk of malignant progression of liver lesions in patients undergoing surveillance for hepatocellular carcinoma (HCC). Enhancement pattern mapping (EPM) measures voxel-based root mean square deviation (RMSD) and improves the contrast to noise ratio (CNR) of liver lesions on standard of care imaging. This study investigates the utilization of EPM to differentiate between malignant versus non-malignant lesions.
Method: Patients with liver cirrhosis undergoing MRI surveillance were studied retrospectively. Controls (n = 99) were patients without lesions during surveillance. Cases (n = 48) were defined as patients with LI-RADS 3 and 4 lesions who developed HCC within the study period. RMSD measured with EPM was compared to the signal from MRI arterial and portovenous phases. EPM signals of liver parenchyma between cases and controls were compared.
Results: With EPM, RMSD of 0.37 was identified as a quantitative cutoff for distinguishing HCC from background cirrhotic parenchyma on pre-diagnostic scans with an AUC of 0.83 (CI: 0.73–0.94). EPM RMSD signals of background parenchyma in cases and controls were similar (case EPM: 0.22 ± 0.08, control EPM: 0.22 ± 0.09, p = 0.8).

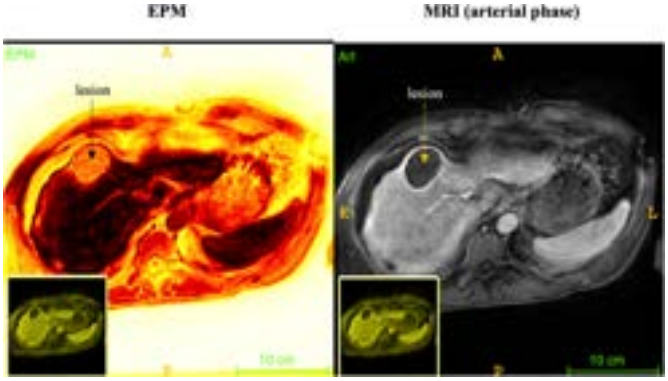

Figure:

Conclusion: EPM differentiates between HCC and non-cancerous parenchyma in a surveillance population. Future directions may involve applying EPM for early detection of HCC and risk stratification of indeterminate lesions.

FRI-318

Initial treatment response and short-term mortality of spontaneous bacterial peritonitis in cirrhotic patients with hepatocellular carcinoma

Chang Hun Lee[1], Hye Jin Kang[1], Seung Young Seo[1], Seong-Hun Kim[1], Sang Wook Kim[1], Seung Ok Lee[1], Soo Teik Lee[1], In Hee Kim[1]. *[1]Research Institute of Clinical Medicine of Jeonbuk National University-Biomedical Research Institute of Jeonbuk National University Hospital, Internal Medicine, Jeonju, Korea, Rep. of South*
Email: ihkimmd@jbnu.ac.kr

Background and aims: This study aimed to investigate the initial treatment response and short-term mortality of spontaneous bacterial peritonitis (SBP) in cirrhotic patients with hepatocellular carcinoma (HCC) compared with those without HCC.
Method: A total of 245 patients with liver cirrhosis diagnosed with SBP between January 2004 and December 2020 were included. Of these, 107 (43.7%) were diagnosed with HCC.
Results: Overall, the rates of initial treatment failure, 7-day and 30-day mortality were 91 (37.1%), 42 (17.1%), and 89 (36.3%), respectively. While the baseline CTP score, MELD score, culture-positive rate, and rates of antibiotic resistance did not differ between both groups, patients with HCC had a higher rate of initial treatment failure than those without HCC patients (52.3% vs. 25.4%, p < 0.001). Similarly, 30-day mortality was also significantly higher in patients with HCC (53.3% vs. 23.2%, p < 0.001). In the multivariate analysis, HCC, renal impairment, CTP grade C, and antibiotic resistance were independent factors for initial treatment failure. Furthermore, HCC, hepatic encephalopathy, MELD score, and initial treatment failure were independent risk factors for 30-day mortality, with statistically significant poor survival outcomes in patients with HCC and initial treatment failure (p < 0.001 and p < 0.001, respectively).
Conclusion: HCC is an independent risk factor for initial treatment failure and high short-term mortality in patients with cirrhosis with SBP. It has been suggested that more attentive therapeutic strategies are required to improve the prognosis of patients with HCC and SBP.

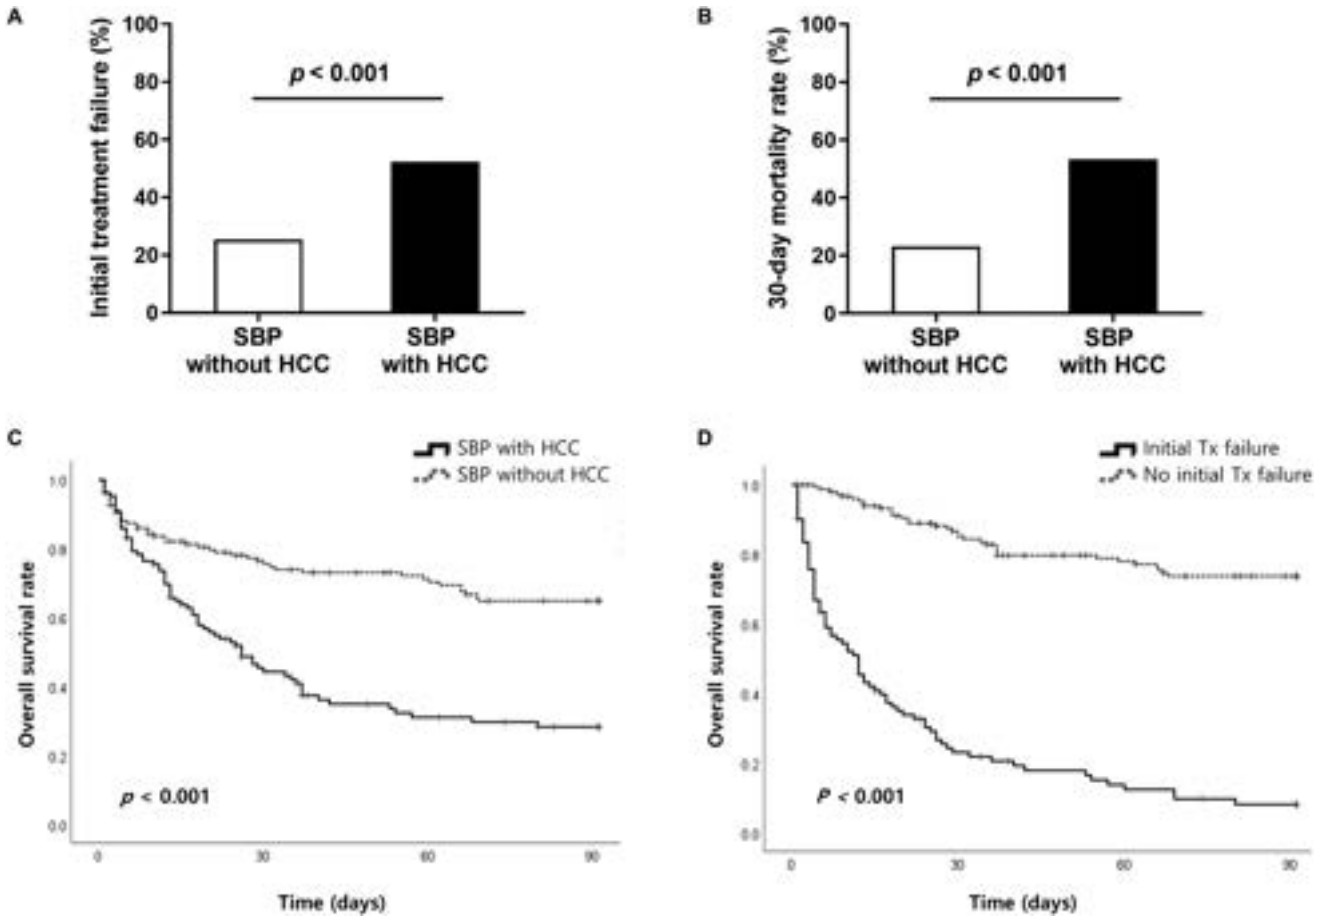

Figure: (abstract: FRI-318).

FRI-319

Effect of different radiologic modalities for surveillance of hepatocellular carcinoma on survival of high risk cirrhotic patients

Ahmed El Sabagh[1], Islam Mohamed[1,2], Megha Bhongade[1], Nikita Rao[1], Eunji Jo[3], Susan Hilsenbeck[3], Prasun Jalal[1]. [1]*Baylor College of Medicine, Houston, United States;* [2]*Ain Shams University, Medicine, Cairo, Egypt;* [3]*Dan L Duncan Comprehensive Cancer Center at Baylor St. Luke's Medical Center, Houston, United States*
Email: ahmed.elsabagh@bcm.edu

Background and aims: European association for the study of the liver (EASL) recommends that patients with high risk of developing hepatocellular carcinoma (HCC) undergo regular surveillance with ultrasonography (US) every 6 months. However, compared to cross-sectional imaging modalities -Computed tomography (CT) and Magnetic resonance imaging (MRI)-US has lower efficacy for detection of early HCC. To our knowledge, there are no studies evaluating the overall survival and receipt of curative treatment for patients who received surveillance using the different imaging modalities.

Method: We retrospectively reviewed all patients who were diagnosed with HCC at Baylor Saint Luke's Medical Center Hospital between January 2011 and June 2021. Patients who underwent regular surveillance were identified. Data retrieved from electronic medical records and radiology reports included demographic and laboratory features, surveillance modality, tumour characteristics, treatments received and survival data. We estimated survival using the Kaplan-Meier method and compared the different modalities using the Log Rank test. We used univariate and multivariate Cox model to evaluate factors affecting survival.

Results: A total of 183 patients developed HCC while on biannual surveillance program (115 with MRI, 34 with CT and 34 with US). Patients were similar regarding with respect to age, sex, comorbid diseases. However, our cohort shoed statistically significant differences regarding race and ethnicity, with more African American and Hispanic population undergoing surveillance with US. The initial survival analysis showed that compared to other modalities MRI had statistically significant association with longer survival (p value = 0.034). However, cox-multivariate regression model with adjustment for race, ethnicity, MELD score and total tumor size at time of diagnosis shows that surveillance modality has no statistically significant association with survival (MRI: HR 1.80, p value = 0.095) (CT: HR 0.71, p value = 0.26).

Conclusion: For cirrhotic patients with high risk for HCC, surveillance with MRI or CT was not associated with higher survival rate compared. This result shed the light on importance of adherence to surveillance irrespective of modality. Additionally, racial and ethnic disparities may affect the access to the HCC surveillance.

Comparison of clinical manifestations and outcomes between non-viral-related and viral hepatitis-related hepatocellular carcinoma

Sih-Han Liao[1], Shang-Chin Huang[2], Tung-Hung Su[3], Shih-Jer Hsu[3], Jia-Horng Kao[3]. *[1]National Taiwan University Cancer Center, Taipei, Taiwan; [2]National Taiwan University Hospital Bei-Hu Branch, Taipei, Taiwan; [3]National Taiwan University Hospital, Taipei, Taiwan*
Email: winterreise0810@gmail.com

Background and aims: After the provision of hepatitis B vaccination and antiviral therapy, the incidence and mortality of viral-related HCC, including hepatitis B (HBV) or C (HCV) virus, have improved. In contrast, the disease burden of non-viral HCC increased. Here we investigated the differences of clinical manifestations and outcomes between non-viral HCC and viral-related HCC.

Method: From 1996 to 2016, a total of 2,781 patients with complete information were identified from the Cancer Registry Database and Integrated Medical Database of National Taiwan University Hospital. Based on the information of viral hepatitis profiles, the patients were categorized into five groups as follows: group 1, non-viral HCC (triple negative for HBsAg, anti-HCV, and anti-HBc); group 2, occult HBV-HCC (only positive for anti-HBc); group 3, HBV-HCC (positive for HBsAg and negative for anti-HCV); group 4, HCV-HCC (positive for anti-HCV and negative for HBsAg); group 5, dual infection-HCC (both positive for HBsAg and anti-HCV). Overall survivals were examined using Kaplan-Meier method. Prognostic factors were explored using Cox proportional hazards regression model.

Results: The proportions of women were more in the group of non-viral HCC (48.0%) and HCV-HCC (45.3%) than other three groups ($p < 0.0001$). The median age at diagnosis were older in the non-viral HCC group than the groups of viral-related HCC ($p < 0.0001$). The maximal tumor size was larger in the non-viral HCC group ($p < 0.0001$). The baseline AFP level of the non-viral HCC group was significantly lower than the groups of viral-related HCC ($p = 0.01$). The estimated 1-, 3-, and 5-year overall survival rates were 42.5%, 20.5%, and 8.2% for non-viral HCC group; 20.9%, 24.9%, and 8.7% for occult HBV-HCC group; 55.9%, 28.1%, and 13.3% for HBV-HCC group; 63.1%, 31.5%, and 13.0% for HCV-HCC group; 63.4%, 33.0%, and 16.1% for dual infection-HCC group. The BCLC stage could be used to predict the prognosis for HCC with various etiologies, including non-viral and viral-related HCC (all log-rank $p < 0.0001$). In the multivariable analysis of overall survival for all patients, four independent prognostic predictors were identified, including HCV-HCC group, advanced BCLC stage, larger tumor size, and higher FIB-4 score.

Variable	HR	95% CI	p value
Sex (Men vs. Women)	1.20	0.93-1.56	0.16
Age (per year increase)			
BMI (others vs. normal)			
Underweight (BMI<18.5 kg/m^2)	1.03	0.61-1.73	0.93
Overweight (BMI≥24 kg/m^2)	0.98	0.80-1.21	0.85
Alcohol consumption (others vs. no abuse)			
Quit	0.91	0.69-1.20	0.49
Abuser	0.91	0.64-1.28	0.57
Group (others vs. group 1, n = 73)			
Group 2 (n = 481)	0.58	0.32-1.05	0.07
Group 3 (n = 1400)	0.72	0.41-1.28	0.27
Group 4 (n = 715)	0.48	0.26-0.88	0.02
Group 5 (n = 112)	0.64	0.30-1.41	0.27
BCLC stage (others vs. stage 0+A)			
Stage B	2.25	1.63-3.10	<.0001
Stage C	9.10	6.47-12.71	<.0001
Stage D	15.33	9.90-23.73	<.0001
Tumor size (per 1 cm increase)	1.06	1.04-1.08	<.0001
Fibrosis-4 score (per 1 increase)	1.07	1.05-1.09	<.0001

Figure: Multivariable Cox proportional hazards regression model for overall survival

Conclusion: The patients of the non-viral HCC were older and more women. The baseline AFP level of the patients with non-viral HCC was lower. Additionally, the overall survival of the patients with non-viral HCC was significantly worse than that of the patients with HCV-HCC, but was similar as that of the patients with other etiologies.

FRI-321

Impact of obesity on outcome of hepatocellular carcinoma in an Asian cohort: when should we consider obesity treatment?

Wei-Lun Liou[1,2], Kaina Chen[1], Ravishankar Asokkumar[1], Chee-Kiat Tan[1]. [1]*Singapore General Hospital, Singapore;* [2]*Singapore General Hospital, Gastroenterology and Hepatology, Singapore*
Email: liouweilun@gmail.com

Background and aims: Obesity is associated with increased risk of hepatocellular carcinoma (HCC) development. There is however conflicting data on impact of obesity on HCC outcome and prognosis. We studied the influence of obesity on clinical characteristics of HCC and on survival in a cohort of Asians.

Method: The study cohort comprised of patients with HCC seen in our centre from 2005 to 2020. We studied and compared HCC characteristics and survival between the non-obese group (body mass index: BMI <27.5) and the obese group (BMI >27.5). Survival analysis was censored on 28 November 2022.

Results: There were 271 HCC patients in this study, 202 (74.8%) were male. 73 (27%) patients were obese. Median age of the patients was 65 (IQR 14). Non-alcoholic steatohepatitis (NASH) or cryptogenic cirrhosis was more common in the obese group (47.9% vs 32.8%, p = 0.02). Tumours median diameter was significantly larger in the non-obese group (25 mm vs 21 mm, p = 0.045). There was no statistically significant difference in Barcelona Clinic Liver Cancer (BCLC) staging: BCLC 0/A, 130 patients (65.7%) in non-obese group vs 49 patients (67.1%) in obese group, p = 0.83). HCC treatment modality was similar between the two groups (curative 61.1% vs 64.4%, non-curative 20.2% vs 21.9%, palliative 18.7% vs 13.7%, p = 0.55). For the cohort of patient receiving curative treatment, there was no significant difference in HCC recurrence rate between the two groups (65.3% vs 74.5%, p = 0.28). 1, 5, 10-year survival were similar between the two groups (non-obese group 75%, 43%, 23% vs obese group 82%, 51%, 23%, p = 0.59). Multivariable analysis confirmed that patient's BMI had no influence on overall survival (Hazard ratio 1.09, 95% C.I. 0.78–1.51). Patients with underlying NASH or cryptogenic cirrhosis had worse survival outcome than patients with HCC of other aetiologies (1, 5, 10-year survival of 73%, 32%, 9% vs 80%, 52%, 30%, p < 0.001), HCC secondary to NASH or cryptogenic cirrhosis was also a predictor for poorer survival (hazard ratio 1.76, 95% C.I. 1.31–2.37).

	1 Year (%)	5 Years (%)	10 Years (%)	p value
Overall	77	45	23	-
BMI				
<27.5	75	43	23	0.59
>27.5	82	51	23	
Aetiology				
NASH/Cryptogenic	73	32	9	<0.001
Others	80	52	30	
Resection				
BMI <27.5	96	68	56	0.91
BMI >27.5	100	89	48	
Ablation				
BMI <27.5	92	57	21	0.59
BMI >27.5	93	62	20	

Figure: Comparison of 1, 5, 10-year survival of patients with hepatocellular carcinoma.

Conclusion: In this cohort of Asian patients with HCC of all etiologies, obesity does not affect the outcome of HCC nor patients' survival. Patients with NASH or cryptogenic cirrhosis had poorer outcome than patients with HCC of other aetiology. Early preventive measures and therapeutic interventions to treat obesity remain vital to prevent development of non-alcoholic fatty liver disease which carries poorer HCC outcome.

FRI-322

Collagen proportionate area (CPA) measurement of liver parenchyma and hepatocellular carcinoma (HCC) can predict HCC recurrence after liver resection

Federico Ravaioli[1,2], Mattia Riefolo[2], Chiara Sicuro[1], Benedetta Rossini[2], Elton Dajti[2], Matteo Serenari[2], Matteo Cescon[2], Maria Antonietta D'Errico[2], Antonio Colecchia[1], Francesco Vasuri[2]. [1]*Gastroenterology Unit, Department of Medical Specialities, University Hospital of Modena, University of Modena and Reggio Emilia, Modena, Italy;* [2]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy*
Email: f.ravaioli@unibo.it

Background and aims: Hepatocellular carcinoma (HCC) is a frequent complication in patients with advanced chronic liver disease (ACLD) with an HCC recurrence (HCC-r) rate of around 70% after liver resection (LR) at five years. Previous studies have found several predictive variables for HCC-r mainly related to the primary tumour characteristics (such as degree of histological differentiation and extent of vascular invasion, satellite nodules, size and the number of nodules) or related to the stage of liver disease and the degree of portal hypertension (as Metavir score, liver (LSM) and spleen stiffness (SSM) measurements). Collagen proportionate area (CPA) measurement is a quantitative automated method for estimating fibrous tissue in liver biopsies by determining the collagen deposition percentage of the total biopsy area. Recently it has been proposed as a reliable tool to predict hepatic decompensation and mortality in patients with ACLD. Thus, we aimed to evaluate the predictive role of CPA in HCC-r after curative LR.

Method: From a cohort of 175 patients with primary HCC eligible for LR prospectively enrolled and followed for at least 30 months or until HCC-r, we analysed the biopsy specimen sampled obtained during LR surgery of 54 patients with a 3:2 ratio of HCC-r. For each patient, ten images of liver sections stained with Sirius red for collagen fibres were acquired from the non-neoplastic liver parenchyma adjacent to the tumour (liver-CPA; Fig. 1A) and HCC tissue (HCC-CPA; Fig. 1B) with an Axiocam 305 colours mounted on a Zeiss Axioscope AX10 microscope, attached to a close-up copy stand with flicker-free backlight. Liver biopsy specimens were reviewed centrally by an expert pathologist. CPA was measured by free public-domain software developed by the National Institutes of Health (NIH-ImageJ). For analyses, the median CPA values were evaluated. Logistic regression analyses were performed to evaluate the prediction of HCC-r.

Results: 35 out of 54 (65%) patients developed HCC-r, 25 (46.3%) patients developed an early (≤24 months) HCC-r, and 10 (18.5%) patients developed late (>24 months) HCC-r. Patients were mainly males (88.9%), with a median age at HCC diagnosis of 73 [68–85] years; the prevalent etiology was viral (81.5%). 47 (87%) median MELD score was 8 (7–9). 98.15% was Child-Pugh A with median alpha-fetoprotein values of 6 (3–38) ng/ml. Liver and HCC-CPA were significantly higher in patients with HCC-r than those without HCC-r (Fig. 1). Liver-CPA significantly correlates with LSM (R = 0.703; p = 0.05). Among all variables evaluated, HCC-r was significantly predicted by liver-CPA (OR 2.672 [95%CI 1.142–6.255] p = 0.002) and HCC-CPA (OR 1.0002 [95%CI 1.000–1.0004]; p = 0.021), number of HCC nodules (OR 2.489 [95%CI 1.876–7.071]; p = 0.054), microvascular invasion (OR 3.611 [95%CI 1.088–11.039]; p = 0.036), and macrovascular invasion (OR 8.609 [95%CI 1.014–73.024]; p = 0.048).

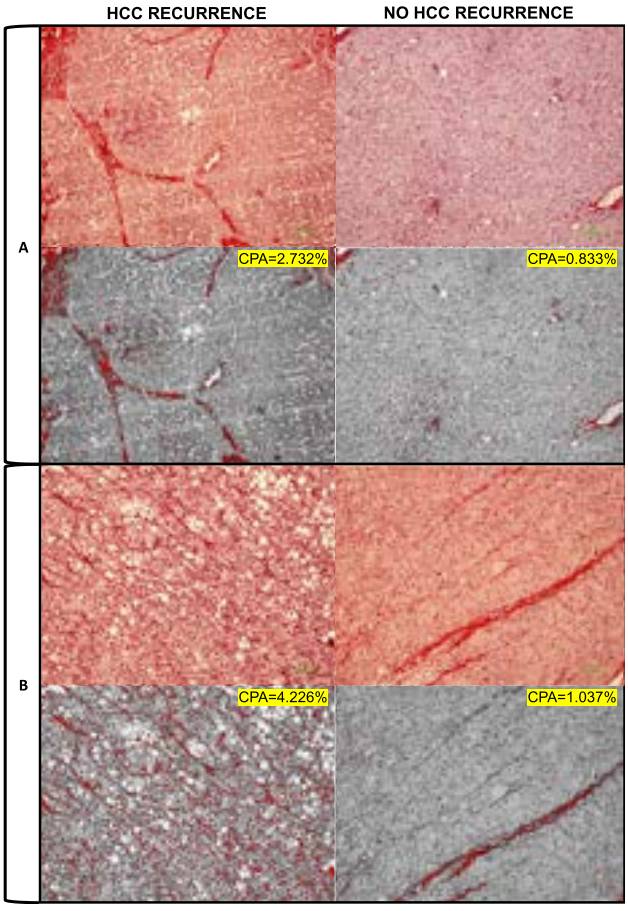

Figure:

Conclusion: CPA is a good quantitative and automated method for estimating fibrosis tissue, and together with already known predictive factors (such as histological differentiation and extent of invasion, satellite nodules, size and the number of nodules, Metavir score, LSM and SSM) can predict the recurrence of HCC after liver resection. Further studies should confirm our results to recommend adding CPA to the standard pathological analysis of liver resected HCC patients.

FRI-323

Exploration of a holistic management procedure for liver cancer surveillance to improve the early diagnosis of liver cancer in Chinese population

Yong Li[1], Ligong Lu[1], Qing Yang[1], Manhua Zhong[1], Xiaofeng Wang[1], Linfang Li[1], Yanhong Chen[1], Xiaolei Zhou[1], Chao Yang[1], Jie Dong[1].
[1]*Zhuhai people's hospital (zhuhai hospital affiliated with jinan university), Zhuhai, China*
Email: lu_ligong@163.com

Background and aims: China accounts for nearly half of all new hepatocellular carcinoma (HCC) cases and death worldwide each year, and over 80% of them suffer from chronic hepatitis B (CHB). In China, up to 80% of the HCC cases are diagnosed at an advanced stage, lost the chance of radical treatment. The 5-year survival rate is only 12.1%. Therefore, it is urgent to enhance HCC screening in China and improve the level of early diagnosis. Accordingly, here we aim to develop a stratified management procedure of HCC screening and surveillance for CHB patients at Zhuhai People Hospital.
Method: CHB patients, without previous HCC diagnosis, visiting the Department of Hepatology and Infectious Disease were recommended for enrollment by the attending physician since Jan 2022. We have established a digital platform and procedure that can collect and synthesize all-round information of enrolled patients, including comprehensive medical history, as well as laboratory and imaging examination results. Dashboards were generated for dedicated liver disease management. Each enrolled patient first took an initial HCC screening (step 2 in the figure), including abdominal ultrasound, and serum tests for AFP and PIVKA-II. Patients with abnormal results will follow standard HCC diagnostic work-up, while other patients who are not currently suspected of HCC will be classified into different risk groups (step 3 in the figure) according to local guidelines, in-house standards (Zhuhai model), and published risk stratification models (such as aMAP). These patients were thereafter matched with a risk-dependent follow-up plan for HCC surveillance. The early diagnosis rate of HCC defined as stage Ia, Ib, and IIa according to the Chinese National Liver Cancer (CNLC) standards, was evaluated and compared to the historical baseline as 30% using one-side binomial test.
Results: 2071 patients were enrolled in 2022. So far, 8 patients have been diagnosed with HCC during either initial screening or surveillance follow-up, of which 7 (87.5%) were at an early stage (CNLC Stage Ia), showing a significant increase as compared to baseline (p value = 0.001). A total of 2030 CHB patients were risk-

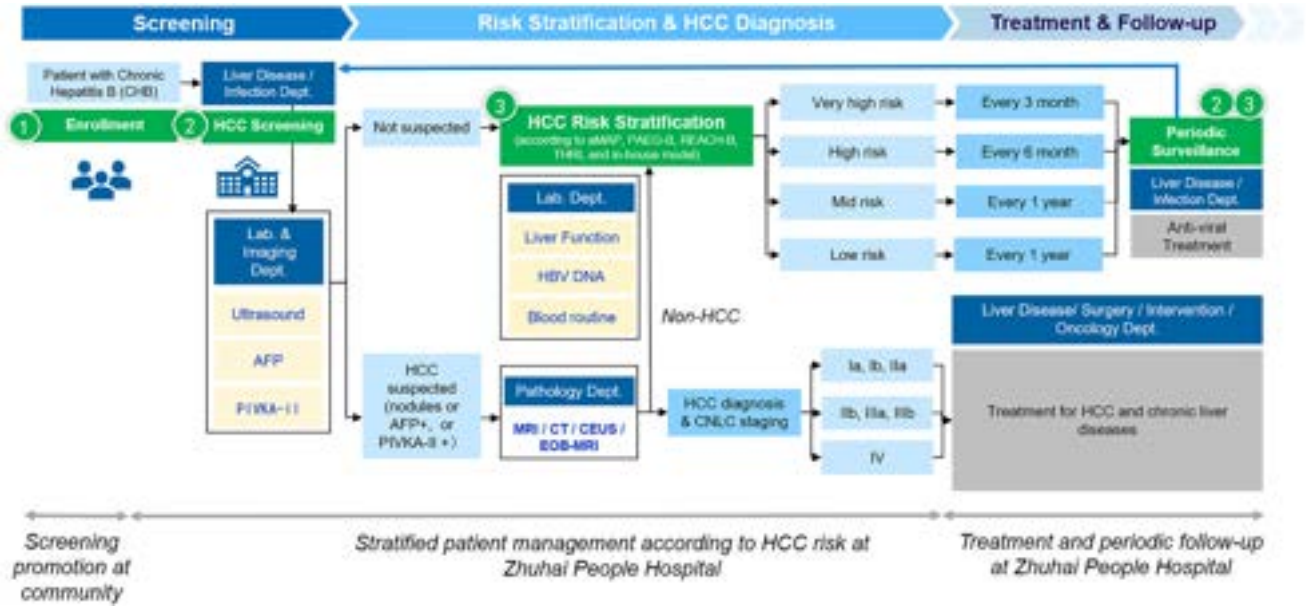

Figure: (abstract: FRI-323): We have established a digitalized management system for HCC screening and surveillance at our hospital.

stratified, 14.2% of whom were classified as high-risk for HCC, and subsequently matched with a well-designed periodic surveillance plan. Our management system has also enabled a significant increase in patient compliance to 71%.
Conclusion: The standardized screening and management system established has so far significantly improved the early diagnosis rate of HCC among the enrolled patients. The stratified management strategy embedded has also considerably improved the management efficiency and follow-up compliance of high-risk patients. The established system warrant further validation and promotion.

FRI-324
Chemerin protein in hepatocellular carcinomas is related to disease severity in European patients
Christa Büchler[1], Kirsten Utpatel[2], Katja Evert[2], Oliver Treeck[3], Florian Weber[2]. [1]*Regensburg University Hospital, Department of Internal Medicine, Germany;* [2]*Regensburg University Hospital, Institute of Pathology, Germany;* [3]*Regensburg University Hospital, Department of Gynaecology and Obstetrics, Germany*
Email: christa.buechler@klinik.uni-regensburg.de

Background and aims: The chemoattractant protein chemerin is protective in experimental hepatocellular carcinoma (HCC), and high expression in HCC tissues of Asian patients leads to a better prognosis. In the present study, immunohistochemistry was used to find out whether higher chemerin in HCC is associated with less severe disease in European patients.
Method: Chemerin and chemokine like receptor 1 (CMKLR1) protein expressions were determined by immunohistochemistry in HCC tissues of 383 patients.
Results: Chemerin protein expression was low in 24%, medium in 49% and high in 27% of the tissues. Chemerin protein in the HCC tissues relates positively to T-stage, vessel invasion, higher histologic grade, Union for International Cancer Control (UICC) stage and tumour size. Chemokine like receptor 1 (CMKLR1) is a functional chemerin receptor. CMKLR1 protein was low expressed in 36%, medium expressed in 32% and high expressed in 32% of the HCCs. Tumour CMKLR1 was positively related to T-stage, vessel invasion, higher histologic grade and UICC stage. Associations of tumour chemerin and CMKLR1 protein with steatosis, inflammation and fibrosis were not observed. In summary, chemerin as well as CMKLR1 protein, were positively related to disease severity of European HCC patients. This is in contrast to Asian patients where higher tumour chemerin was protective.

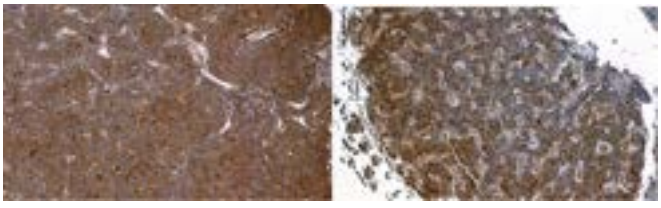

Figure: Chemerin (left) and its receptor CMKLR1 (right) in the liver

Conclusion: Current analysis provides evidence for ethnicity-related differences of HCC expressed chemerin and HCC severity.

Email: amina.abdulle.md@gmail.com

Background and aims: Hepatocellular Carcinoma (HCC) represents a major clinical event in the cirrhotic population, leading to a significant incidence of morbidity and mortality. The aim of our study is to assess the prognostic value of simple non-invasive tests (NITs) for the stratification of the risk of HCC development in a Non-Alcoholic Fatty Liver Disease (NAFLD) cirrhotic population on long-term follow-up (FU).
Method: A total of 122 patients with NAFLD-cirrhosis (median age: 62 years; males 52.5%; median BMI 30.5 kg/m^2; prevalence of type-2 diabetes: 57.4%) were retrospectively analyzed. Cirrhosis diagnosis was achieved by either liver histology, instrumental findings and/or clinical evidence of portal hypertension. Clinical and biochemical data were collected at the time of diagnosis; the following NITs were calculated: FIB-4, AST to Platelet Ratio Index (APRI) gamma-glutamyl transpeptidase-to-platelet ratio (GPR), BARD.
Results: During a median FU of 6 (IQR 3.2–9.3) years, 13 (10.7%) patients developed HCC. Baseline FIB-4 (HR = 1.27, 95%CI 1.03–1.58, p = 0.027) and GPR (HR = 1.44, 95%CI 1.11–1.85, p = 0.005) values resulted significantly associated to HCC occurrence. Conversely, no association was observed for APRI and BARD. Conventional FIB-4 cut-off values allowed a proper patients' stratification into 3 risk categories with different HCC incidence: FIB-4 < 1.3 = 0/18 (0%), FIB-4 between 1.3–3.25 = 7/73 (9.6%), and FIB-4 > 3.25 = 6/31 (19.4%) (Log-rank test: p = 0.009). Likewise, the cumulative HCC incidence according to GPR tertiles risk groups was: 3/41 (7.3%), 4/40 (10.0%) and 6/41 (14.6%) (Log-rank test: p = 0.041).
Conclusion: Baseline FIB-4 could stratify patients with NAFLD-cirrhosis on long-term FU according to their individual risk of HCC development. In such patients, this simple NITs may be useful to optimize tailored HCC surveillance strategies.
The research has been supported by the Italian Ministry for Education, University and Research (MIUR) under the programme "Dipartimenti di Eccellenza 2018–2022" Project code D15D18000410001

FRI-326
Exploration of the lack of systematic surveillance for hepatocellular carcinoma for patients with non-alcoholic fatty liver disease
Theresa Hydes[1,2], Connor Henry Blake[1,2], Mohamed Kassab[2], Charmaine Matthews[2], Vinay Kumar[2], Elizabeth Baggus[1,2], Nick Stern[2], Daniel Cuthbertson[1,2], Daniel Palmer[1], Philip Johnson[1], Tim Cross[1,2]. [1]*University of Liverpool, United Kingdom;* [2]*Liverpool University NHS Hospitals Foundation Trust, United Kingdom*
Email: therasa@doctors.org.uk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is emerging as a leading cause of hepatocellular carcinoma (HCC). We aimed to compare the frequencies of HCC detected in those not under systematic surveillance for people with NAFLD *vs.* other aetiologies of liver disease, to explore possible underlying reasons and determine impact on survival.
Method: A prospective dataset of 623 patients with HCC seen at a large hospital trust in Northwest England from 2007 to 2022 was examined. A diagnosis of NAFLD was made based on radiological evidence of steatosis or cryptogenic cirrhosis in the presence of the metabolic syndrome, without significant alcohol intake or other causes of chronic liver disease. Group comparisons were made using

Mann Whitney *U*-test where data was continuous and Chi-squared test was used to compare categorical data.

Results: Within this cohort 76.2% (n = 475) of patients were male, with a median age of 68 years. In total, 30.3% (n = 189) had NAFLD, 31.9% (n = 199) alcohol-related liver disease, and 19.6% (n = 122) hepatitis C infection. People with NAFLD HCC were less likely to have been enrolled in HCC surveillance (25.4% *vs.* 43.3% for other aetiologies of liver disease, p < 0.0001) and more likely to have a diagnosis of HCC based on symptoms (Table 1). We explored why people with NAFLD HCC presented outside of surveillance. Fewer people with NAFLD were known to secondary liver services prior to developing HCC (26.0% *vs.* 48.3% of people without NAFLD, p < 0.0001). We also noted more people with NAFLD developed HCC without pre-existing cirrhosis (33.9% *vs.* 14.8% without NAFLD, p < 0.0001). Patients with NAFLD HCC presented with a greater median diameter of their largest tumour (43 *vs.* 30 mm, p = 0.0009). While there was an observation that a lower frequency of patients with NAFLD met Barcelona Clinic Liver Cancer (BCLC) staging 0/A (NAFLD 32.6% *vs.* non-NAFLD HCC 37.6%, p = 0.2419) and were less likely to receive curative treatment (resection/transplant/ablation) (NAFLD 31.2% *vs.* non-NAFLD HCC 38.7%, p = 0.0802), no significant difference was detected between the groups. Patients with NAFLD HCC had similar severity of liver disease than people with non-NAFLD HCC according to the model for end stage liver disease (MELD) score (9.8% *vs.* 9.4% had a MELD ≤6 , p = 0.8766), although patients with NAFLD HCC were less likely to have ascites (20.6% *vs.* 28.5%, p = 0.0406) and displayed lower median levels of bilirubin (13 *vs.* 18 mg/dl, p < 0.0001). Performance status was comparable (performance status 0, 64.6% NAFLD *vs.* 63.5% for people without NAFLD, p = 0.8830), despite people with NAFLD being older (median age 75 *vs.* 65 years, p < 0.0001) and more likely to have cardiovascular disease (37.7% *vs.* 21.1%, p = 0.0002). Overall median survival was comparable between groups (NAFLD HCC 484 days *vs.* non-NAFLD HCC 475 days, p = 0.8489).

Indication	NAFLD (%) N=189	Non-NAFLD aetiology of liver disease (%) N=411
HCC Surveillance	16.9	33.9
Abnormal liver biochemistry	26.8	24.4
Rising Alpha fetoprotein	5.5	8.5
Incidental finding on other imaging	25.1	14.7
Abdominal pain	8.2	5.4
Weight loss	6.0	2.3
Clinical ascites	0.5	3.6
Hepatomegaly	1.1	0.5
Anaemia	1.1	0.5
Variceal bleed	3.3	1.0
Other	6.0	5.1

Table 1: Clinical indications for imaging resulting in a diagnosis of HCC.

Conclusion: Patients with NAFLD are more likely to present with HCC outside of surveillance because they are not known to secondary care, or do not have cirrhosis at the time of HCC diagnosis. While patients with NAFLD do not appear to be significantly disadvantaged in terms of overall survival, there may be scope to optimise outcomes for this group via implementation of more widespread screening for advanced NAFLD in the community and the development of better HCC risk stratification models.

FRI-327

Aetiology and outcomes of cirrhosis and hepatocellular carcinoma in Blantyre, Malawi

Email: a.stockdale@liverpool.ac.uk

Background and aims: Age-standardised mortality from liver disease is highest in African countries. We studied the aetiology and outcomes of patients with cirrhosis and hepatocellular

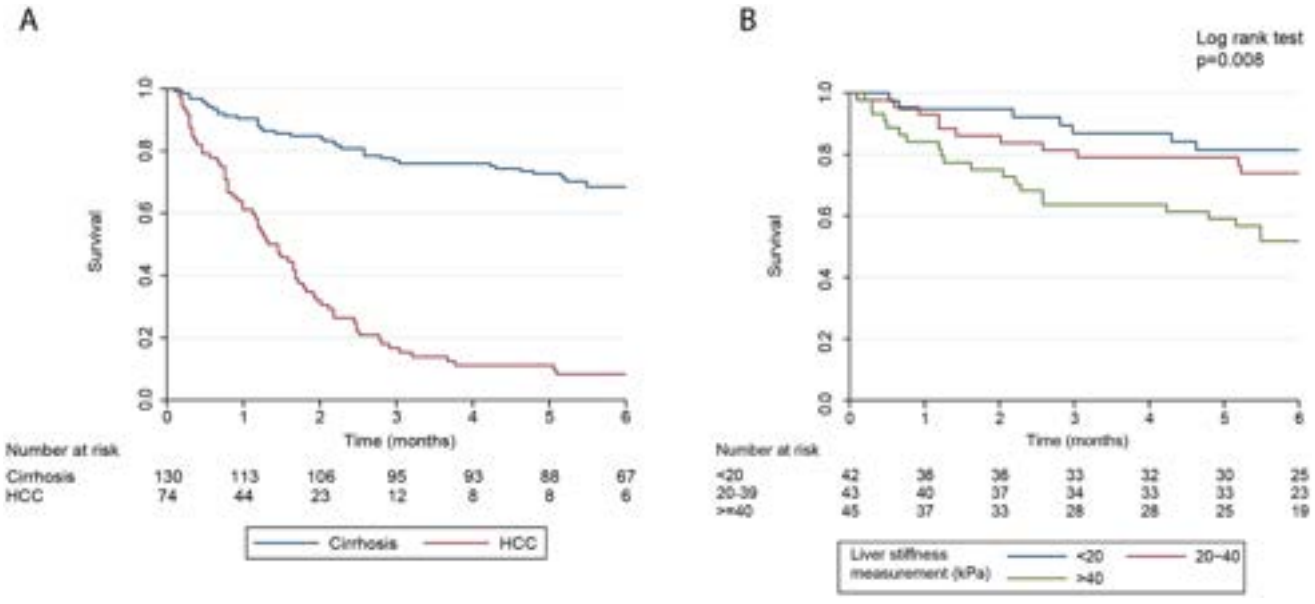

Figure: (abstract: FRI-327): Kaplan Meier curve. A: All participants; B: Cirrhosis stratified by liver stiffness

carcinoma (HCC) presenting to a tertiary hospital in southern Africa, to identify interventions to address liver-related mortality.
Method: We prospectively screened 708 patients over 18 months using transient elastography (>12 kPa) and ultrasound, diagnosing 138 patients with cirrhosis and 78 with HCC. We excluded patients with non-liver-related disease. We estimated population attributable fractions (PAF) using randomly-sampled community controls (n = 3258 for hepatitis B; n = 120 for other exposures) using binomial logistic regression with robust standard errors, with PAF represented by 1- the ratio between the logit of the baseline likelihood and a zero exposure scenario. We tested for hepatitis B (HBsAg), anti-HCV and HCV RNA, anti-HDV, HDV RNA, HEV IgG and RNA, HIV, autoimmune serology, schistosomiasis Ag and PCR in cases and controls.
Results: Patients with HCC were median 40 (IQR 35–50) years old; tumour size was 13.2 cm (IQR 10.2–17.3) with median survival 40 days (95% CI:30–51). Hepatitis B (HBsAg) was attributable for 25.5% (95% CI 17.1–33.1) of cirrhosis and 73.2% (61.0–81.6) of HCC cases. HIV was the second most important cause with PAF 23.6% (13.5–32.5) for cirrhosis and 20.2 (7.4–31.2) for HCC); the association persisted after adjusting for HBV/C co-infection. Hepatitis C was attributable for <5% of liver disease; 6% with cirrhosis had autoimmune liver disease, and no active hepatitis D or E was diagnosed. Alcohol and smoking were attributable for 14.0% (−2.3–27.7) and 23.6% (8.4–36.3) of cases of HCC respectively, but were not associated with cirrhosis. Schistosomiasis was diagnosed in cirrhosis patients by urine antigen (30.4%)) or PCR (36.2%); 12.5% had ultrasound signs of S. mansoni. Liver stiffness (hazard ratio 1.13 (1.05–1.20) per 5 kPa increase, p < 0.001) and presence of ascites (HR 9.09 (2.80–29.5), p < 0.001) were predictors of 6-month cirrhosis mortality.
Conclusion: Hepatitis B and HIV are the principal causes of liver disease in southern Malawi. Patients with HCC are diagnosed at an advanced stage, with a dismal prognosis. There is an urgent need for community HBV screening and treatment programmes to address liver-related mortality.

FRI-328
Survival outcomes of patients with non-alcoholic fatty liver disease-related HCC: a retrospective cohort study
Anders Mellemkjær[1], Josefine Lahn[2], Linda Skibsted Kornerup[2], Gerda Elisabeth Villadsen[2], Henning Groenbaek[2]. *[1]Aarhus University Hospital, Dept. of Gastroenterology and Hepatology, Aarhus N, Denmark; [2]Aarhus University Hospital, Gastroenterology and Hepatology, Aarhus N, Denmark*
Email: anders.mellemkjaer@clin.au.dk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is emerging as a leading cause of hepatocellular carcinoma (HCC) in many Western countries. The aim of this study was to compare survival outcomes of NAFLD-related HCC to HCC by other etiologies in Danish patients with newly diagnosed HCC.
Method: We retrospectively included all patients diagnosed with HCC at the tertiary liver center at Aarhus University Hospital, Denmark in 2018 and 2019. Data was derived from patients' electronic records and follow-up was carried out until death or December 1st, 2022. To identify cases of NAFLD-related HCC, a strict definition was applied, comprising either: 1) previous NAFLD diagnosis, 2) evidence of steatosis on biopsy, ultrasonography, or computer tomography, or 3) presence of three or more features of the metabolic syndrome. Further, patients with alternative causes of HCC or current or previous record of alcohol abuse were excluded from the case definition.
Results: A total of 133 patients diagnosed with HCC were identified. Of these, 29 (21.8%) fulfilled our criteria for NAFLD-related HCC. Remaining etiologies included alcohol (n = 67, 50%), viral hepatitis B and C (n = 22, 17%), cholestatic liver disease (n = 4, 3%) and other or unknown etiology (n = 15, 11%). Patients with NAFLD-related HCC were older (median 76 vs. 67 years, p <0.001), fewer had cirrhosis (41% vs. 73%, p = 0.001), and fewer were smokers (7% vs. 38%, p = 0.002) compared to non-cases. Barcelona Clinic Liver Cancer (BCLC) stages was similar in the two groups (p = 0.49). The Kaplan-Meier plot (Fig. 1) revealed no differences in the survival functions (p = 0.46) or median survival time between NAFLD-related HCC cases (19.8 months) and non-cases (17.8 months). The proportional hazards model adjusted for BCLC stage and age showed no difference in hazards rates between the two groups (Hazard Ratio (HR) = 1.20, 95% CI: 0.74–1.95, p = 0.47).

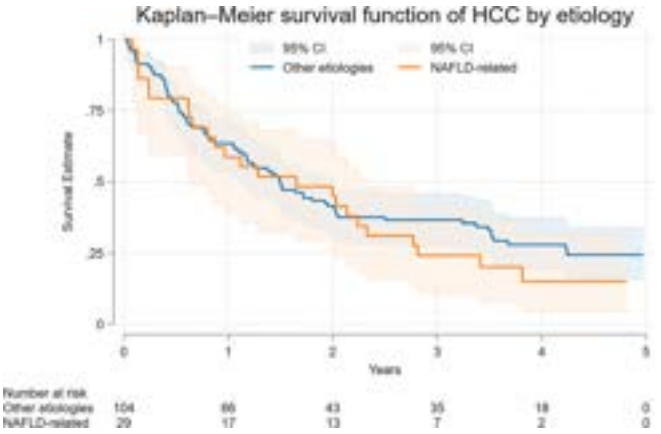

Figure 1: Kaplan-Meier plot of the survival function for patients with newly diagnosed HCC by etiology.

Conclusion: NAFLD-related HCCs were more often diagnosed in older patients and in patients without cirrhosis compared to other etiologies. However, disease stage at diagnosis and overall prognosis was comparable in patients with and without NAFLD-related HCC. Larger cohort studies are needed to substantiate these findings.

FRI-329
Targeted surveillance for hepatocellular carcinoma is cost effective in Australia: evidence from a microsimulation study
Barbara de Graaff[1], Le Tuan Anh Nguyen[1], Lei Si[2], John Lubel[3,4], Nicholas Shackel[5], Kwang Chien Yee[6], Mark Wilson[7], Jane Bradshaw[7], Kerry Hardy[7], Andrew Palmer[1], Christopher Leigh Blizzard[1]. *[1]University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; [2]Western Sydney University, School of Health Sciences, Campbelltown, Australia; [3]Alfred Hospital, Gastroenterology Department, Melbourne, Australia; [4]Monash University, School of Medicine, Melbourne, Australia; [5]Launceston General Hospital, Launceston, Australia; [6]University of Tasmania, School of Medicine, Hobart, Australia; [7]Royal Hobart Hospital, Gastroenterology Department, Hobart, Australia*
Email: barbara.degraaff@utas.edu.au

Background and aims: In Australia and many other Western counties, hepatocellular carcinoma (HCC) is one of the fastest increasing causes of cancer mortality. Recently published Australian Consensus Guidelines recommend HCC surveillance for all patients with liver cirrhosis and high-risk groups living with non-cirrhotic chronic hepatitis B (CHB) (i.e. Aboriginal and Torres Strait Islanders aged <50 years, Asian males >40 years, Asian females >50 years, people born in sub-Saharan Africa aged >20 years). The aim of this study was to assess the cost-effectiveness of these recommendations.
Method: A microsimulation model was developed. Three strategies were evaluated: biannual ultrasound scan (USS), biannual USS+ alpha-fetoprotein (AFP), and usual care (i.e. no formal surveillance). A hypothetical cohort aged 40–80 years with one of the conditions: non-cirrhotic CHB, compensated cirrhosis (CC) or decompensated cirrhosis (DC), was simulated. Face, internal and external validity were assessed. One-way, probabilistic sensitivity analyses were conducted. To account for uncertainties, scenario and threshold analyses were carried out. Scenarios included surveillance of each

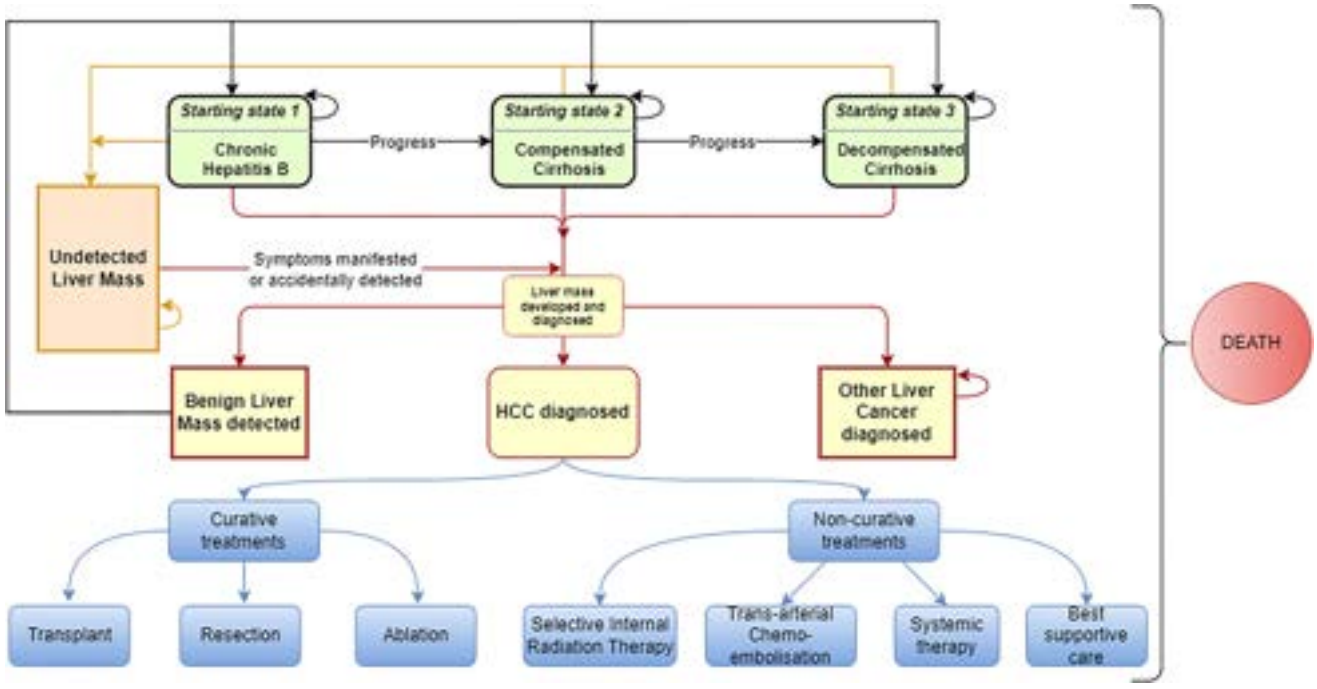

Figure 1: (abstract: FRI-329): Structure of the state-transition individual-level model.

disease individually (CHB, CC, DC), reduced sensitivity of USS due to central adiposity and real-world adherence rates.

Results: The validation analyses indicated that the model is highly accurate in terms of reflecting observed real-world data. For a range of HCC surveillance scenarios for combined CHB, CC and DC patients, USS + AFP was the most cost-effective with an incremental cost-effectiveness ratios (ICER) compared to usual care less than the willingness-to-pay threshold of A$50,000 per quality-adjusted life year (QALY). Whilst USS alone was also cost-effective, it was dominated by USS+AFP. When evaluating cost-effectiveness by groups, surveillance was cost-effective in CC and DC groups (ICERs <$30,000), but not for CHB alone (ICERs >$100,000). Central adiposity decreased the performance of USS, however USS ± AFP surveillance remained cost-effective.

Conclusion: HCC surveillance using USS ± AFP for combined target populations is cost-effective. Surveillance limited to CC and DC groups is also cost-effective. Whilst surveillance for CHB patients alone was not cost-effective, this may be due to an important limitation of this model. As there is a lack of published data for model parameters on CHB and Indigenous status, region of birth, age and sex, our model was simplified and assumed that HCC risk was the same for all CHB patients. Our model will be updated with these data as they become available. Nonetheless, HCC surveillance based on Australian recommendations for all three groups is highly likely to be cost-effective in the Australian setting.

PD1-negative CD45RA effector-memory CD8 T-cells are essential for response to checkpoint inhibition in advanced hepatocellular carcinoma

Sarah Cappuyns[1,2,3,4], Gino Philips[3,4], Vincent Vandecaveye[5,6], Bram Boeckx[3,4], Rogier Schepers[3,4], Thomas Van Brussel[3,4], Ingrid Arijs[3,4], Aurelie Mechels[3,4], Ayse Bassez[3,4], Francesca Lodi[3,4], Joris Jaekers[7], Halit Topal[7], Baki Topal[7], Orian Bricard[3,4], Junbin Qian[8,9], Eric Van Cutsem[1,2], Chris Verslype[1,2], Diether Lambrechts[3,4], Jeroen Dekervel[1,2]. *[1]University Hospitals Leuven, Digestive Oncology, Department of Gastroenterology, Belgium, [2]Katholieke Universiteit Leuven, Laboratory of Clinical Digestive Oncology, Department of Oncology, Belgium, [3]Katholieke Universiteit Leuven, Laboratory for Translational Genetics, Department of Human Genetics, Belgium, [4]Vlaams Instituut voor Biotechnologie, Centre for Cancer Biology, Leuven, Belgium, [5]University Hospitals Leuven, Department of Radiology, Belgium, [6]Katholieke Universiteit Leuven, Laboratory of Translational MRI, Department of Imaging and Pathology, Belgium, [7]University Hospitals Leuven, Hepatobiliary- and pancreas Surgery, Department of Abdominal Surgery, Belgium, [8]Zhejiang University School of Medicine, Zhejiang Provincial Key Laboratory of Precision Diagnosis and Therapy for Major Gynaecological Diseases, Women's Hospital, China, [9]Zhejiang University School of Medicine, Institute of Genetics, China*
Email: sarahcappuyns@hotmail.com

Background and aims: Checkpoint inhibitors (CPI) have dramatically changed the treatment landscape of advanced HCC (aHCC). While PD1-expressing CD8 T-cells have repeatedly been linked to response to CPI, their role in aHCC is controversial. Using single-cell profiling,

we aimed to characterize the intra-tumoural and peripheral immune context of aHCC patients treated with CPI to identify features associated with response and/or resistance.
Method: Both pre-treatment tissue biopsies and serial peripheral blood mononuclear cell (PBMC) samples of aHCC patients (n = 37) treated with systemic therapy were subjected to single-cell transcriptome (scRNAseq) and T-cell receptor sequencing (scTCRseq). Patients (n = 30) treated with PD (L)1 inhibition were stratified according to clinical response and various single-cell readouts were correlated with response and clinical outcome.
Results: Tumours with durable response were enriched for PDL1-expressing CXCL10+ macrophages and, based on cell-cell interaction, expressed high levels of *CXCL9/10/11* to attract peripheral CXCR3+ effector-memory T-cells (CD8 T_{EM}) into the tumour. Furthermore, based on TCR sharing and pseudotime trajectory analysis, CD8 T_{EM} preferentially differentiated into clonally-expanded PD1-negative, CD45RA effector-memory CD8 T-cells (CD8 T_{EMRA}) with pronounced cytotoxicity. In contrast, in non-responders, CD8 T_{EM} remained frozen in their effector-memory state. Finally, in responders, CD8 T_{EMRA} displayed a high degree of T-cell receptor sharing with blood, consistent with their patrolling activity.
Conclusion: In conclusion, we propose a novel paradigm, where response to checkpoint inhibition in aHCC is driven by clonally expanded, cytotoxic CD45RA effector-memory CD8 T-cells, characterized by a high degree of TCR sharing with peripheral blood and present in the tumour prior to therapy. PDL1-expressing CXCL10+ macrophages are positioned as essential gatekeepers in the TME, interacting with the peripheral T-cell compartment to ensure effective T-cell recruitment into the TME.

Email: s.huber@uke.de

Background and aims: Liver metastasis is one of the most common causes of cancer-associated mortality. A presence of liver metastasis was reported to be responsible for an immunosuppressive microenvironment and a diminished immunotherapy efficacy. As a master regulator of the immune system, interleukin-10 (IL-10) targets both innate and adaptive immune cells and orchestrates immunosuppressive functions. Interestingly, IL-10 is upregulated in both human and murine liver metastasis. We aimed here to decipher the source, regulation and function of IL-10 in liver metastasis. Our long-term aim is to improve the outcome of patients with liver metastasis.
Method: To induce spontaneous or forced liver metastasis on mice, murine cancer cells (MC38) were injected into cecum or spleen, respectively. Cell-specific IL-10 and IL-10 receptor (IL-10R) deficient mice were used to identify source and target of IL-10 during metastasis formation. PD-L1 deficient mice were used to test the role of this check point. 3–4 weeks post injection, livers were harvested and metastatic burden including liver weight and number of metastatic sites were analyzed. Immune composition characterization was performed in IL-10-reporter mice using flow cytometry. To investigate the underlying mechanisms, hepatic myeloid cells were sorted for RNA sequencing. Hepatic CD8+ T cells were cocultured with MC38 to measure changes in antitumor immunity using flow cytometry.
Results: In our liver metastasis mouse models, IL-10 blockade as well as IL-10 deficient mice were protected from metastasis formation. Furthermore, by using IL-10 reporter mice, we could demonstrate that Foxp3+ regulatory T cells (Tregs) are the major cellular source of IL-10 in the liver metastatic sites. Deletion of IL-10 expression in Foxp3+ Tregs led to reduced liver metastatic sites, a finding that underlines the importance of this cytokine during metastasis formation. Ablation of IL-10R on myeloid cells, but not DCs, resulted in less liver metastatic burden, suggesting that IL-10 signaling in myeloid cells regulated liver metastasis formation. Nevertheless, Tregs themselves were shown to respond to IL-10 by highly boosting its production, which in turn triggered monocytes to upregulate the immune checkpoint mediator PD-L1. Accordingly, deletion of PD-L1 let to decreased liver metastasis. Coculture with hepatic infiltrating CD8+ T cells and MC38 cells showed that the PD-L1/PD-1 axis attenuates the CD8-dependent cytotoxicity against metastatic lesions.

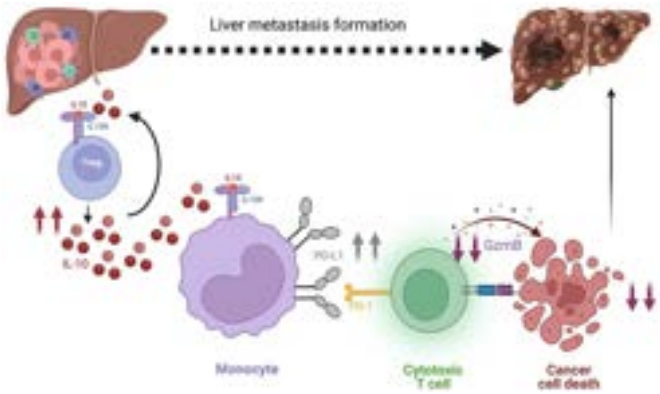

Figure:

Conclusion: Our data provides evidence that Treg- produced IL-10 upregulates PD-L1 expression in monocytes, which in turn reduces CD8+ T cell infiltration and related antitumor immunity, thereby promoting liver metastasis formation. These findings highlight the potential therapeutic benefit of a novel combined anti-IL-10R and anti-PD-L1 approach against liver metastasis.

Constitutive signaling from an engineered IL-21 receptor programs long-lived effector TCR-T cells for HCC therapy

Wei Zhu[1], Zhiming Zhang[1], Jinzhang Chen[1], Xiaolan Chen[1], Xuan Huang[1], Weikang Xu[1], Xuan Yi[1], Xinyu Lu[1], Sha Wu[2], Yongyin Li[1], Jinlin Hou[1]. [1]*Nanfang Hospital, Southern Medical University, China,* [2]*School of Basic Medical Sciences, Southern Medical University, China*
Email: jlhousmu@163.com

Background and aims: Strategies to improve T cell therapy efficacy in solid tumours such as hepatocellular carcinoma (HCC) are urgently needed. The common cytokine receptor γ chain (γ_c) family cytokines such as IL-2, IL-7, IL-15 and IL-21 play fundamental roles in T cells development, differentiation and effector phase. The aim of this study is to determine the effect of IL-21 combination in T cell therapy against HCC and investigate optimized strategies to utilize the effect of IL-21 signal in T cell therapy.
Method: The contributions of IL-7, IL-15 and L-21 in human alpha fetoprotein (AFP) specific TCR engineered T cells (TCR-T) against HCC were evaluated in vitro and in vivo. The phenotypic and transcriptome alteration in AFP-specific TCR-T cells was further determined by flow cytometry and RNA sequencing. A novel IL-21 receptor transmitting IL-21 signal without exogenous IL-21 supplement was designed and expressed in AFP-specific TCR-T cells. The antitumor function of TCR-T cells expressing novel IL-21 receptor (IL-21R-TCR-T)

was evaluated in vitro and in vivo, the phenotypic and transcriptome alteration induced by engineered IL-21 receptor was investigated by flow cytometry and single-cell RNA sequencing.
Results: The antitumor function of AFP-specific TCR-T cells was augmented by exogenous IL-21 both in coculture assay and xenograft model. IL-21 enhanced TCR-T cells proliferation capacity both after CD3/CD28 and tumor antigen stimulation. Phenotypic analysis revealed that IL-21 promoted memory differentiation, downregulated PD-1 expression and alleviated apoptosis in TCR-T cells after activation. IL-21R-TCR-T showed upregulated STAT3 phosphorylation level compared with conventional TCR-T in the absence of IL-21. Superior antitumor function and proliferation capacity after activation was found in IL-21R-TCR-T cells compared with conventional TCR-T cells in vitro and in vivo. Phenotypic analysis revealed that IL-21R-TCR-T cells showed lower apoptosis level, less differentiated and exhausted phenotype and higher effector function after repetitive tumor antigen stimulation.

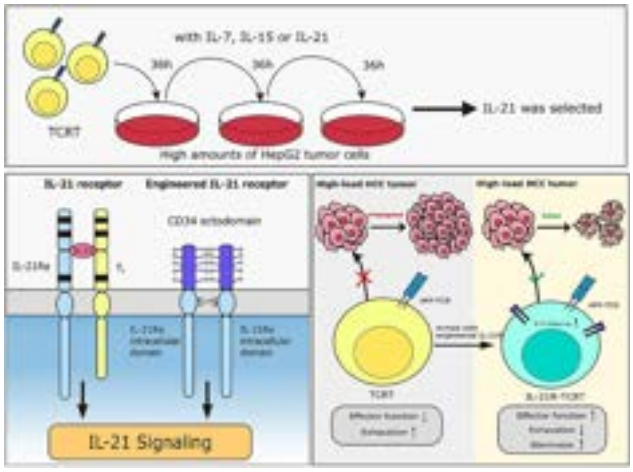

Figure:

Conclusion: We designed a novel IL-21 receptor which programs long-lived effector TCR-T cells and avoids side effects induced by systemic utilization of IL-21. The novel IL-21 receptor creates new opportunities for next generation TCR-T cells against HCC.

Antitumoral activity of the G9a inhibitor EZM8266 in hepatocellular carcinoma: potential for combination with immune checkpoint inhibitors
Maite G Fernandez-Barrena[1,2], José María Herranz[1,2], Elena Adan-Villaescusa[1], Borja Castello[1], Felipe Prosper[3,4], Bruno Sangro[5,6], Maria Arechederra[1,6,7], Carmen Berasain[1,7], Jennifer Totman[8], Veronica Gibaja[8], Matías A Avila[1,6,7]. *[1]CIMA-University of Navarra, Hepatology Program, PAMPLONA, Spain, [2]Carlos III Health Institute, National Institute for the Study of Liver and Gastrointestinal Diseases, CiberEHD, Madrid, Spain, [3]CIMA, CCUN, University of Navarra, Hemato-Oncology Program, PAMPLONA, Spain, [4]Instituto de Investigacion Sanitaria de Navarra, Hemato-Oncology Program, Spain, [5]Liver Unit, Clinica Universidad de Navarra, CCUN, Hepatology Unit, Spain, [6]Instituto de Investigacion Sanitaria de Navarra, IdiSNA., Spain, [2]Carlos III Health Institute, National Institute for the Study of Liver and Gastrointestinal Diseases, CiberEHD, Madrid, Spain, [8]Epizyme, An Ipsen Company, United States*
Email: maavila@unav.es

Background and aims: Advanced hepatocellular carcinoma (HCC) treatment has radically changed with the advent of immune-checkpoint inhibitors (ICIs). Still, a significant proportion of patients show innate or acquired resistance to ICI-based therapies. Therefore, new strategies to overcome resistance and increase efficacy are needed. Epigenetic alterations are increasingly recognized to participate in hepatocarcinogenesis. Moreover, these mechanisms are known to repress the expression of chemokines that promote tumor lymphocyte infiltration, as well as that of immunogenic neoantigens, such as cancer testis antigens (CTAs). As we previously showed, one attractive epigenetic target in HCC is the histone-methyltransferase G9a. In this study, we tested the in vitro and in vivo anti-HCC activity of EZM8266, a highly specific G9a inhibitor with favorable pharmacokinetic properties.
Method: We performed a comprehensive transcriptomic analysis of 180 epigenetic modifiers and validated *in silico* the upregulation of *G9a* expression in a combined cohort including 292 HCC tissue samples, and explored its association with the different immune tumor tissue signatures. We examined the effects of EZM8266 on the growth of human (Hep3B, HuH7, PLC/PRF5, HepG2, SNU449) and mouse (PM299L) HCC cell lines. We performed colony formation, migration, invasion and anchorage-independent growth assays. EZM8266 was tested on the basal and IFNγ-triggered expression of *CXCL9* and *CXCL10* chemokines and CTAs in HCC cells. The effects of EZM8266 on the growth of PM299L cells orthotopically implanted in immunocompetent mice, alone and in combination with α-PD1 antibodies, were also evaluated.
Results: *G9a* is consistently overexpressed in HCCs, positioned as one of the most highly deregulated epigenetic modifiers in HCC patients and most prominently in the "non-inflammed" transcriptomic subclasses. EZM8266 inhibited HCC cells proliferation and all malignant traits tested *in vitro*. EZM8266 induced the expression of CTAs, *CXCL9* and *CXCL10*, potentiating the effect of IFNγ on these chemokines. *In vivo*, EZM8266 inhibited the growth of PM299L cells, and enhanced the effects of α-PD1 resulting in a remarkable antitumoral activity. No signs of systemic or liver toxicity were observed.
Conclusion: G9a is confirmed as an effective druggable target in HCC. Pharmacological inhibition of G9a with EZM8266 antagonizes HCC cells growth and leverages the efficacy of ICIs. Our findings provide strong support for the combination immunotherapy with epigenetic drugs such as EZM8266 for HCC treatment.

Oncostatin M promotes a pro-tumorigenic inflammatory response in NASH-related HCC
Beatrice Foglia[1], Salvatore Sutti[2], Jessica Nurcis[1], Chiara Rosso[3], Marina Maggiora[1], Claudia Bocca[1], Patrizia Carucci[4], Silvia Gaia[4], Elisabetta Bugianesi[3], Emanuele Albano[2], Maurizio Parola[1], Stefania Cannito[1]. *[1]University of Torino, Clinical and Biological Sciences, Torino, Italy, [2]University Amedeo Avogadro of East Piedmont, Health Sciences and Interdisciplinary Research Center for Autoimmune Diseases, Novara, Italy, [3]University of Torino, Medical Sciences, Torino, Italy, [4]Città della Salute e della Scienza University-Hospital, Division of Gastroenterology, Torino, Italy*
Email: beatrice.foglia@unito.it

Background and aims: Oncostatin M (OSM) is a pleiotropic cytokine belonging to the interleukin (IL)-6 family that acts on a large variety of cells involving two distinct heterodimeric receptor complexes: leukemia inhibitory factor receptor beta (LIFRbeta) and OSM receptor beta (OSMRbeta) that is the receptor able to mediate the most relevant biological effects of OSM in mice. OSM has been proposed to contribute to the progression of chronic liver diseases, hepatocellular carcinoma (HCC) development and metastasis. High levels of OSM were found in cirrhotic patients with different etiology carrying HCC. In particular we observed that OSM serum levels are significantly higher in patients carrying non-alcoholic steatohepatitis (NASH)-related HCC, as compared to those whit viral etiologies, and their

increase paralleles the disease progression from simple steatosis to HCC. Noteworthy, OSM serum levels are significantly higher in patients with intermediate/advanced HCC and correlate with poor survival. This work discusses the role of OSM in relation to the development of HCC in a NASH background.
Method: We investigated the role of OSM in NASH-related HCC taking advantage of: a) cohort of NASH patients with HCC; b) human THP1 macrophage cell lines exposed to human recombinant OSM (hrOSM); c) Wild type (wt) mice fed with a control diet (CSAA) or a lipogenic diet (CDAA) for 24 weeks in order to reproduce the non-alcoholic fatty acid disease (NAFLD)/NASH pathogenic phenotype (CSAA-CDAA protocol); d) Wild type (wt) and OSMRbeta knock out (OSMRbeta-/-) mice treated with a protocol of NASH-related liver carcinogenesis (DEN/CDAA protocol).
Results: In patients with NASH-related HCC, OSM is expressed in cancer cells in relation to CD68+ macrophages infiltrating tumour. In in vitro experiments, conducted on human THP1 macrophages exposed to hrOSM, we found that OSM is able to promote an M2 pro-tumorigenic phenotype, which is due to the activation of STAT3 and PI-3K/Akt signaling pathways. Accordingly, OSM expression, which was found increased in NASH-related liver tumours of wt mice during the progression of NAFLD/NASH towards HCC, correlates with F4/80 gene expression. This data suggests an interplay between OSM and macrophages recruitment/functions in the tumor microenvironment. In particular, wt mice treated with the DEN-CDAA protocol show a stronger promotion of the M2 phenotype compared with the M1 and in these mice OSM transcript levels correlate better with M2 macrophage polarization markers. As OSMRbeta is fundamental for the activation of the OSM-related STAT3 and PI-3K/Akt signaling pathways, the OSMRbeta-/- murine model was employed to exploit the role of OSM in this regard. In this respect, the data obtained in the OSMRbeta-/- murine models shows that the livers of these animals develop smaller tumours. This event appears to be due to: i) a decreased amount of M2 Tumor Associated Macrophages (TAMs) in the nodules as revealed by the reduction of transcription levels of CD163, PDL1, CD206 and CCR2 compared with wt mice; ii) a impairment of the angiogenic process as shown by lower transcript levels of VE-cadherin, VEGFR2 and CD105 compared with wt mice.
Conclusion: Experimental data highlight a pro-carcinogenic contribution for OSM in NASH, by promoting pro-tumorigenic inflammation, suggesting a possible role for the OSM-OSMRbeta axes as therapeutic target for NASH-related HCC.

SAT-212

Novel platinum-based chemotherapeutic agents halt cholangiocarcinoma progression through the induction of inter-strand DNA breaks, preventing DNA repair mechanisms

Irene Olaizola[1], Mikel Odriozola[2], Maitane Asensio[3,4], Paula Olaizola[1,4], Ivan Rivilla[2,5], Amanda Guimaraes[2], Francisco J. Caballero[1], Elisa Herraez[3,4], Oscar Briz[3,4], Pedro Miguel Rodrigues[1,4,5], María Jesús Perugorria[1,4,6], Luis Bujanda[1,4], Jose Marin[3,4], Fernando Pedro Cossío[2], Jesus Maria Banales[1,4,5,7]. *[1]Department of Liver and Gastrointestinal Diseases, Biodonostia Health Research Institute-Donostia University Hospital - University of the Basque Country (UPV/EHU), Spain, [2]Department of Organic Chemistry I, Center of Innovation in Advanced Chemistry (ORFEO-CINQA), Faculty of Chemistry, University of the Basque Country (UPV/EHU) and Donostia International Physics Center (DIPC), Spain, [3]Experimental Hepatology and Drug Targeting (HEVEPHARM), Institute of Biomedical Research of Salamanca (IBSAL), University of Salamanca, Spain, [4]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd, "Instituto de Salud Carlos III"), Spain, [5]IKERBASQUE, Basque Foundation for Science, Spain, [6]Department of Medicine, Faculty of Medicine and Nursing, University of the Basque Country (UPV/EHU), Spain, [7]Department of Biochemistry and Genetics, School of Sciences, University of Navarra, Spain*
Email: jesus.banales@biodonostia.org

Background and aims: Cholangiocarcinoma (CCA) comprises a heterogeneous group of biliary malignant tumors characterized by dismal prognosis. The first-line treatment for advanced CCA [cisplatin (CisPt) and gemcitabine] is considered palliative due to the high chemoresistance of this cancer, barely impacting on patients' overall survival. Here, we aimed to design, synthesize and study a new generation of platinum (Pt)-derived chemotherapeutic drugs that produce inter-strand DNA breaks (*vs* classical single-strand breaks induced by CisPt and related compounds) and thus, prevent the development of DNA repair mechanisms in cancer cells.
Method: Ten Pt-derivatives (Aurki-Pt#s) were designed and synthesized. Atomic Force Microscopy (AFM) and Transmission Electron Microscopy (TEM) were used to characterize the binding of Aurki-Pt#s to DNA. The antitumoral effect of the two best candidates (Aurki-Pt#1 and #2) was evaluated by measuring the viability of human CCA cells (EGI-1 and HUCCT1), newly generated CisPt-resistant EGI-1 CCA cells, normal human cholangiocytes (NHC) and cancer-associated fibroblasts (CAFs). The DNA damage induced by Aurki-Pt#1 and #2 was assessed using the comet assay. To ascertain the internalization mechanism of Aurki-Pt#1 and #2, substrate competition studies through flow cytometry and accumulation studies using HPLC-MS/MS were carried out. Finally, the effect of Aurki-Pt#1 and #2 was also tested *in vivo* on a subcutaneous xenograft model of CCA.
Results: Aurki-Pt#s induced inter-strand DNA breaks, and the subsequent DNA fragmentation, contrary to CisPt. Aurki-Pt#1 and #2 significantly reduced CCA cell viability. Both compounds triggered increased DNA damage in CCA cells when compared to CisPt, augmenting the reactive oxygen species levels and being more effective when inducing apoptosis *in vitro*. Additionally, Aurki-Pt#1 and #2 decreased the proliferative capacity of those CCA cells that survived. Importantly, Aurki-Pt#1 and #2 also promoted cell death in CisPt-resistant CCA cells. Moreover, Aurki-Pt#1 and Aurki-Pt#2 caused CCA spheroid shrinkage. On the contrary, Aurki-Pt#1 and #2 did not induce a lethal effect in NHC in culture, but promoted cell cycle arrest. Besides, Aurki-Pt#1 and Aurki-Pt#2 had an impact on the survival of CAFs. Aurki-Pt#1 and #2 were transported into cells through OCT1, OCT3, CTR1 and OATP1A2, which did not transport CisPt. Finally, Aurki-Pt markedly hampered tumor growth on a subcutaneous xenograft model of CCA in comparison with CisPt or vehicle control.
Conclusion: This new generation of Pt-derived chemotherapeutic drugs selectively diminishes CCA cell viability through the induction of inter-strand DNA breaks, and has an impact on its tumor microenvironment, representing a promising therapeutic tool for naïve or CisPt-resistant CCA tumors.

SAT-213

Dynamic evolution of the serum metabolome reflects human hepatocarcinogenesis

Johann von Felden[1], Tim Rose[2], Lorenz Adlung[1], Manuela Peschka[1], Thorben Fruendt[1], Ismail Labgaa[3], Philipp Haber[4], Carolin Zimpel[5], Darko Castven[5], Arndt Weinmann[6], Teresa Garcia-Lezana[4], Moritz Waldmann[1], Thomas Renne[1], Hannah Voß[1], Manuela Moritz[1], Dorian Orlikowski[1], Helmut Schlüter[1], Myron Schwartz[4], Jan Baumbach[7], Ansgar W. Lohse[1], Samuel Huber[1], Henning Wege[1], Jens Marquardt[5], Augusto Villanueva[4], Josch Pauling[2], Kornelius Schulze[1]. *[1]University Medical Center Hamburg Eppendorf, Germany, [2]Technical University Munich, Germany, [3]Lausanne University Hospital (CHUV), Switzerland, [4]Mount Sinai, United States, [5]University Medical Center Schleswig Holstein, Germany, [6]University Medical Center Mainz, Germany, [7]University Hamburg, Germany*
Email: j.von-felden@uke.de

Background and aims: Liver cancer is associated with rising incidence and mortality rates. Mechanisms of hepatocarcinogenesis are poorly understood and current tools for early detection of hepatocellular carcinoma (HCC) remain suboptimal. The aim of this

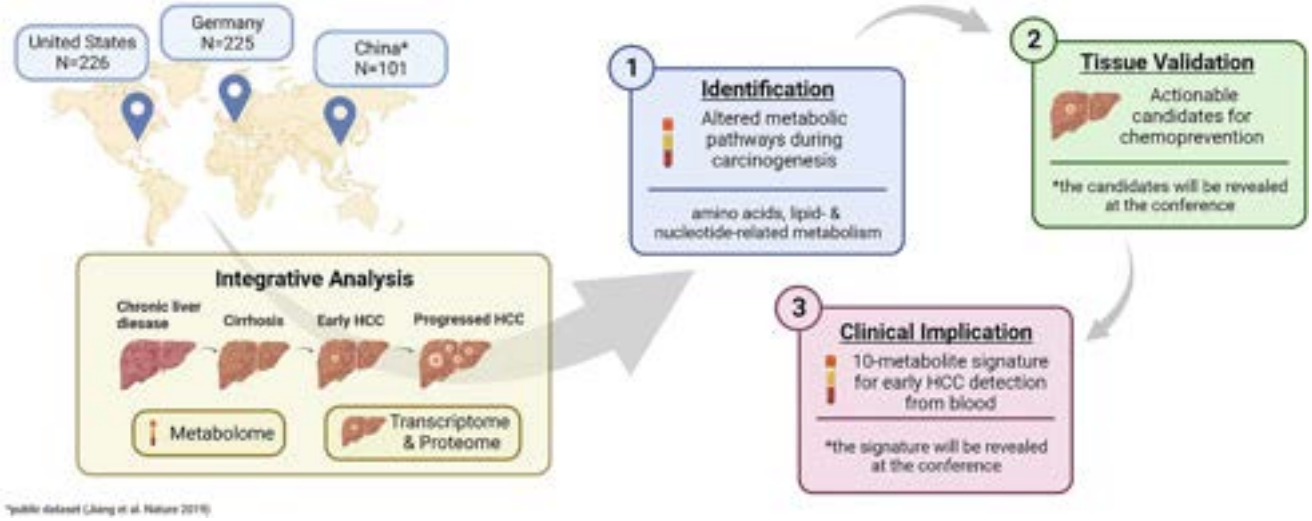

Figure: (abstract: SAT-213).

study was to confirm that the human serum metabolome undergoes significant alterations during hepatocarcinogenesis.
Method: This global, multicenter study included a total of N = 552 patients and n = 691 biospecimens from United States, Germany, and China. We performed targeted metabolomics by ultra-high pressure liquid chromatography coupled to tandem mass spectrometry in sera of N = 406 patients across the spectrum of hepatocarcinogenesis. Deregulated metabolites and respective pathways were identified by differential abundance, unsupervised biclustering using MoSBi, lipid network analysis with LINEX2, and pathway enrichment analysis. Findings were validated by mRNA sequencing and proteome profiling of primary HCC tissue and adjacent non-tumoral tissue in two independent cohorts (n = 285 specimens), including a publicly available dataset (*Jiang et al. Nature 2019*). Finally, we performed a phase 2 biomarker case-control study for early-stage HCC detection using blood samples (N = 375).
Results: Aspartic acid, glutamic acid, taurine, and hypoxanthine were among the top differentially abundant metabolites in the serum across chronic liver disease, cirrhosis, early HCC, and progressed HCC, independent of sex, age, and etiology (all $p < 2*10^{-16}$, n = 406). Unsupervised biclustering (FDR < 0.05), lipid network analysis (>1.5-log2 fold change, FDR < $1*10^{-5}$), and pathway enrichment analysis (up to 30% impact, FDR = $1.43*10^{-2}$) further confirmed alterations in amino acids, lipid-, and nucleotide-related pathways. In tissue, these pathways were significantly deregulated on gene expression and protein abundance levels in two independent datasets, including upregulation of *DUT*, *GMPS*, *NME6*, and *RRM2* (purine metabolism and/or nucleotide metabolism), *BCAT1* and *PYCR2* (biosynthesis of amino acids), and *NEU1* (sphingolipid metabolism) (all FDR < 0.05, n = 285). Finally, a phase 2 biomarker case-control study yielded high accuracy for a 10-metabolite signature from serum to discriminate between early HCC and cirrhotic controls (AUC 92%, n = 330).
Conclusion: Our findings demonstrate that serum metabolome profiling reflects deregulated metabolites and pathways during human hepatocarcinogenesis and identifies actionable candidates for chemoprevention. In addition, this liquid biopsy approach accurately detects early-stage HCC.

SAT-214
TAK1 deficiency promotes liver injury and tumorigenesis via ferroptosis and macrophage cGAS-STING signaling
Haoming Zhou[1], Wantong Su[1], Qi Wang[1], Xun Wang[1], Ling Lu[1]. [1]*The First Affiliated Hospital of Nanjing Medical University, Hepatobiliary Center, China*
Email: lvling@njmu.edu.cn

Background and aims: Oxidative stress-mediated ferroptosis and macrophage-related inflammation play an important role in various

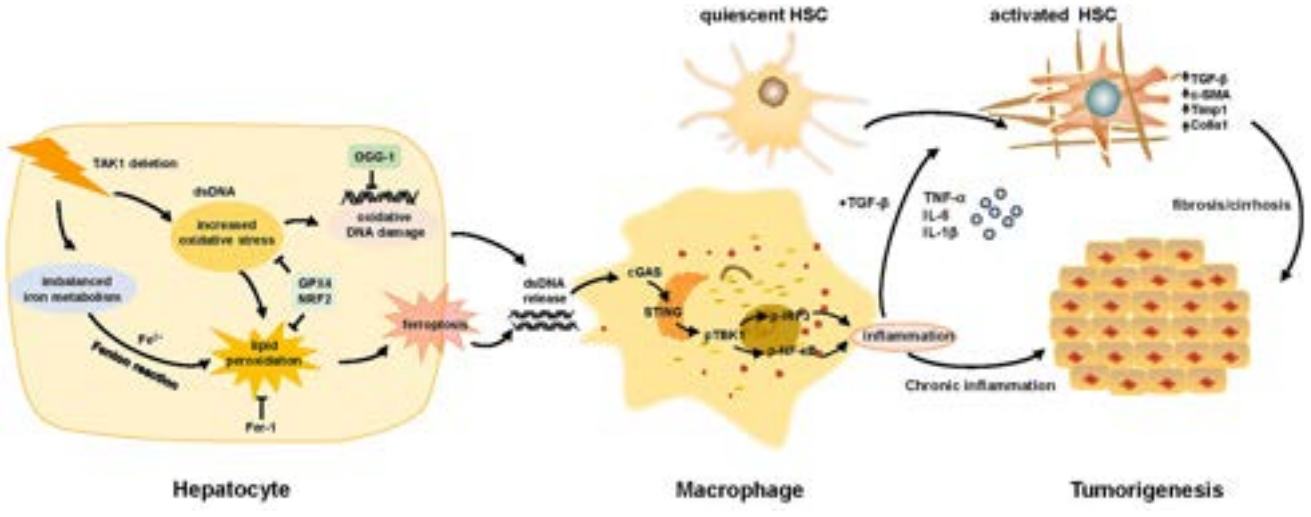

Figure: (abstract: SAT-214).

liver diseases. Here, we explored if and how hepatocyte ferroptosis regulates macrophage STING activation in the development of spontaneous liver damage, fibrosis, and tumorigenesis.
Method: We used TAK1 deficiency-induced liver spontaneous damage, fibrosis, and tumorigenesis model to investigate hepatocyte ferroptosis and its impact on macrophage STING signaling. Primary hepatocytes and macrophages were used for *in vitro* experiments.
Results: Significant liver injury and increased numbers of intrahepatic M1 macrophages were found in hepatocyte-specific TAK1-deficient (TAK1$^{\Delta HEP}$) mice, peaking at 4 w and gradually decreasing at 8 w and 12 w. Meanwhile, activation of STING signaling was observed in livers from TAK1$^{\Delta HEP}$ mice at 4 w and had decreased at 8 w and 12 w. Treatment with a STING inhibitor promoted macrophage M2 polarization and alleviated liver injury, fibrosis, and tumor burden. TAK1 deficiency exacerbated liver iron metabolism in mice with a high-iron diet. Moreover, consistent with the results from single-cell RNA-Seq dataset, TAK1$^{\Delta HEP}$ mice demonstrated an increased oxidative response and hepatocellular ferroptosis, which could be inhibited by ROS scavenging. Suppression of ferroptosis by ferrostatin-1 inhibited the activation of macrophage STING signaling, leading to attenuated liver injury and fibrosis and a reduced tumor burden. Mechanistically, increased intrahepatic and serum levels of 8-OHdG were detected in TAK1$^{\Delta HEP}$ mice, which was suppressed by ferroptosis inhibition. Treatment with 8-OHdG antibody inhibited macrophage STING activation in TAK1$^{\Delta HEP}$ mice.
Conclusion: Hepatocellular ferroptosis-derived oxidative DNA damage promotes macrophage STING activation to facilitate the development of liver injury, fibrosis, and tumorigenesis. Inhibition of macrophage STING may represent a novel therapeutic approach for the prevention of chronic liver disease.

SAT-215

Targeting the E2F/MCM axis in cholangiocarcinoma halts disease progression in experimental models by rewiring lipid metabolism

Email: patricia.aspichueta@ehu.eus

Background and aims: Cholangiocarcinoma (CCA) comprises a heterogeneous group of biliary cancers with dismal prognosis. E2F1 and E2F2, transcription factors that regulate cell cycle and metabolism, are upregulated in metabolic associated fatty liver disease (MAFLD), which is a risk factor of CCA. E2F1/2 drive MAFLD-related hepatocellular carcinoma (HCC) development, sustaining a pro-carcinogenic lipid-rich environment. Minichromosome maintenance (MCM) proteins, helicases involved in DNA replication and cell cycle, are recognized targets of E2Fs that have been linked to different cancers. Thus, the aims were: 1) to evaluate the involvement of the E2F/MCM axis in CCA, and 2) to investigate the potential therapeutic regulatory value of E2F/MCM axis in the rewiring of the cancer lipid metabolism.
Method: *Akt1* and *Yap* or *Taz* were overexpressed in the liver of wild type (WT) or *E2f1*$^{-/-}$ mice as models of CCA. CCA cancer associated fibroblasts (CAFs) were isolated from patients. Triglyceride (TG) concentration was measured in liver samples of the mouse models of CCA and in cell lines *in vitro*. Cell viability, proliferation, spheroid growth and fatty acid oxidation (FAO) rate were measured in EGI1 and HUCCT1 CCA cell lines in the presence or absence of ciprofloxacin (CPX), an antibiotic that inhibits the MCM2-7 helicase activity. The effect on CCA cell viability, proliferation and spheroid growth of an inhibitor of E2F activity (HLM006474) was also tested. Data from human CCA tumours from the TCGA-CHOL cohort were analysed.
Results: Expression (mRNA) of E2F1 and E2F2 was upregulated in human CCA tumours, patient-derived CAFs, and in cellular and mouse models of CCA compared to controls; consequently, expression levels of MCM2-7 were also found elevated, and correlated positively with E2F1/2 expression. Experimental overexpression of *Akt1* and *Yap*, or *Akt1* and *Taz*, in *E2f1*$^{-/-}$ mice resulted in significantly reduced tumour development compared to WT mice. The upregulation of E2F1/2 and MCM2-7 in CCA cells and tumours in mice was accompanied by increased TG content. Inhibition of MCM activity in human CCA cells with CPX induced a dose-dependent decrease in tumour cell viability, proliferation and spheroid growth. CPX also reduced the TG content and the FAO of CCA cells (EGI1) *in vitro*, which we had previously shown to be highly dependent on FAO for proliferation, and incubation with HLM006474 also decreased CCA cell viability, proliferation and spheroid size *in vitro*. Combination of CPX and HLM006474 induced a higher reduction of CCA cell viability *in vitro* than CPX or HLM006474 alone, suggesting that E2F activity promotes CCA progression not only by modulating MCM expression.
Conclusion: The E2F/MCM axis is upregulated in CCA and is required for tumour cell survival and proliferation, potentially by affecting, among other mechanisms, the increased TG content, FAO rate and the tumour microenvironment, arising as a novel target for therapy in this cancer.

SAT-216

MAP17 promotes an epithelial-mesenchymal-amoeboid transition in hepatocellular carcinoma by switching one-carbon metabolism

Background and aims: Epithelial-mesenchymal transition (EMT), a key process during embryonic development, promotes cell migration and resistance to apoptosis during tumour invasion and metastasis. In hepatocellular carcinoma (HCC) an amoeboid behaviour tends to increase the aggressiveness and metastatic capacity of epithelial tumours. MAP17 is a 17 kDa membrane protein expressed during embryogenesis, absent in most adult organs. The presence of MAP17 correlates with an inflammatory environment, hypoxia and increased reactive oxygen species (ROS). MAP17 has been identified in several types of cancer, including HCC. Modulation of EMT and amoeboid behaviour via MAP17 offers an attractive approach to prevent metastasis.
Method: Two HCC patient cohorts were used to characterise MAP17 levels. *In vitro*, expression of MAP17 was measured in mesenchymal and epithelial hepatoma cells, and its levels were modulated to study cell proliferation, drug resistance, mitochondrial dynamics, metabolic rewiring, and proteome homeostasis. *In vivo*, the role of MAP17 in the metastatic capacity was evaluated using orthotopic HCC mouse models.
Results: A positive correlation between MAP17 and mesenchymal markers, RAC/RHO family genes and markers of amoeboid movement was established in 751 HCC patients by *in silico* studies and by mRNA expression analysis in 246 HCC patients. MAP17 overexpression in 3D epithelial cell experiments let to the formation of rosette invadopodia, proinvasive structures with high metastatic capacity. MAP17 overexpression *in vitro* induced a reprogramming of energy metabolism in hepatoma cells with epithelial phenotype, increasing mitochondrial dynamics and Warburg effect-mediated lactic acidosis, which support a tumour microenvironment conducive to cancer cell proliferation. ROS generation was increased as a protective mechanism to avoid apoptotic and senescence processes. Rewiring of the one-carbon metabolic pathway was identified, proving an accelerated metabolism of the cell. There was a faster methionine degradation fuelling the folate cycle, which is the source of purines and pyrimidines, supporting a higher proliferative state. Thus, MAP17 could be involved in the methionine cycle, specially affecting the folate cycle. Accordingly, overexpression of MAP17 in PLC/PRF/5 cells led to the formation of multiple tumour foci when orthotopically implanted in the mouse liver. MAP17 silencing in hepatoma cells with mesenchymal phenotype led to the opposite results, regressing the tumour phenotype and slowing down the cell metabolism and proliferation.
Conclusion: Modulation of MAP17 in epithelial and mesenchymal HCC cells leads to the reprogramming of the transitional genes that define each phenotype. Our findings have identified the metastatic potential of MAP17 in liver cancer, as it triggers the mesenchymal phenotype and amoeboid behaviour in HCC.

Deciphering the cellular and molecular determinants of immunotherapy resistance in NASH-associated hepatocellular carcinoma by single-cell analysis

Lingyun Zhang[1,2], Yiling Zhang[1], Wenshu Tang[1], Zhewen Xiong[1], Xiaoyu Liu[1], Zhixian Liang[1], Weiqin Yang[1], Alfred Sze-Lok Cheng[1]. *[1]The Chinese University of Hong Kong, School of Biomedical Sciences, Hong Kong, [2]The Chinese University of Hong Kong, Hong Kong*
Email: alfredcheng@cuhk.edu.hk

Background and aims: Non-alcoholic steatohepatitis (NASH) has become a prominent risk and the fastest growing cause of hepatocellular carcinoma (HCC). Although immune checkpoint blockade (ICB) therapy, such as anti-programmed cell death-ligand 1 (anti-PD-L1) has exhibited effect in a subset of HCC patients, recent studies unveiled that NASH limited anti-tumor surveillance in ICB-treated HCC. Here we aimed to delineate the mechanisms underlying ICB resistance in NASH-HCC at single-cell resolution.
Method: Orthotopic NASH-HCC mouse models were established through intrahepatic inoculation of liver cancer cell line in NASH mouse induced by methionine-and choline-deficient diet (MCD) or choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD). Multi-color flow cytometry and single-cell RNA-sequencing (scRNA-seq) were utilized to dissect the liver and tumor immune microenvironment upon anti-PD-L1 treatment.
Results: Both MCD-HCC and CDAHFD-HCC mouse models showed no response to anti-PD-L1 therapy. Compared to control liver, multi-color flow cytometry demonstrated that CD11b+F4/80+CD206+M2 macrophages accumulated in NASH and further increased in liver and tumor upon anti-PD-L1 treatment. Notably, significantly positive correlations were identified among hepatic, intratumoral M2 macrophages and tumor weight. Moreover, tumor-infiltrating PD-1-expressing CD8+ T cells positively correlated with tumor weight and intratumoral M2 macrophages. Furthermore, scRNA-seq analysis of tumor-infiltrating immune cells demonstrated remarkably distinct pattern of monocyte/macrophage subclusters compositions which enriched in NASH-HCC development and anti-PD-L1 resistance.
Conclusion: The results provide insights into the importance of monocyte/macrophage reprogramming in ICB-resistance in NASH-HCC. Further investigation is warranted to determine the molecular determinants of these subclusters and identify potential targeted strategy for immunotherapeutic enhancement.

SAT-218
Differential hepatoprotective effects of semaglutide and lanifibranor in the GAN diet-induced obese and biopsy-confirmed mouse model of NASH with advanced fibrosis and HCC

Malte H. Nielsen[1], Susanne Pors[1], Jacob Nøhr-Meldgaard[1], Andreas Nygaard Madsen[1], Mathias Bonde Møllerhøj[1], Denise Oró[1], Mogens Vyberg[2], Henrik B. Hansen[1], Michael Feigh[1]. *[1]Gubra, Hørsholm, Denmark, [2]Center for RNA Medicine, Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*
Email: mni@gubra.dk

Background and aims: Non-alcoholic steatohepatitis (NASH) increases the risk for the development of liver fibrosis which may progress to cirrhosis and hepatocellular carcinoma (HCC). Semaglutide (glucagon-like-receptor (GLP)-1 agonist) and lanifibranor (pan-peroxisome proliferator-activated receptor agonist) are currently in late-stage clinical development for NASH. The present study aimed to evaluate the efficacy of semaglutide and lanifibranor monotherapy on disease progression in the translational Gubra Amylin NASH (GAN) diet-induced obese (DIO) and biopsy-confirmed mouse model of advanced fibrosing NASH and HCC.
Method: Male C57BL/6J mice were fed the GAN diet high in fat, fructose, and cholesterol for 54 weeks prior to treatment intervention. Only animals with liver biopsy-confirmed NAFLD Activity Score (NAS $\geq$ 5) and advanced fibrosis (stage F3) were included and stratified into study groups. DIO-NASH-HCC mice received vehicle (SC, QD, n = 16), semaglutide (SC, QD, 30 nmol/kg, n = 15), or lanifibranor (PO, QD, 30 mg/kg, n = 15) for 14 weeks. Vehicle-dosed chow-fed C57BL/6J mice (SC, QD, n = 9) served as lean healthy controls. Untreated DIO-NASH-HCC mice (n = 10) were terminated at baseline. Tumor histopathological classification was performed by a clinical histopathologist. Within-subject (pre-to-post) change in non-alcoholic fatty liver disease (NAFLD) Activity Score (NAS), fibrosis stage, and collagen deposition (PSR % area) was evaluated using automated deep learning-based image analysis (GHOST). Other end points included terminal blood biochemistry and quantitative histomorphometry.
Results: DIO-NASH-HCC mice demonstrated progressive HCC burden over the 14-week study period. Tumors showed consistent

architectural and cytologic features of HCC with a marked loss of reticulin-stained fibers. Both semaglutide and lanifibranor significantly improved individual histopathological NAS ≥ 2 point, supported by beneficial changes in quantitative histological markers of steatosis (lipids and hepatocytes with lipid droplets) and inflammation (number of inflammatory foci, galectin-3). While both compounds did not improve fibrosis stage, lanifibranor significantly reduced individual pre-to-post quantitative fibrosis levels after 14 weeks. Notably, though, both compounds reduced histological marker of fibrogenesis (α-SMA). In contrast, semaglutide, but not lanifibranor, completely prevented progression in macroscopic tumor numbers, accompanied by reduced quantitative histological markers of proliferation (Ki67) and progenitor cell activation (CK19).
Conclusion: Consistent with recent clinical trials, lanifibranor and semaglutide improves NASH, while only lanifibranor promoted fibrosis regression in GAN DIO-NASH-HCC mice. Notably, semaglutide also improves HCC burden in the model. Deep learning-based image analysis is advantageous to assess within-subject changes in histopathological scores and quantitative fibrosis histology following drug treatment. Collectively, our data highlights the suitability of GAN DIO-NASH-HCC mice for profiling novel drug therapies targeting NASH with advanced fibrosis and HCC.

Capillarization of tumor endothelial cells within tumor associated with T cell exclusion in an autochthonous mouse HCC model

Pin-Hung Lin[1], Tai-Chung Tseng[2], Hung-Chih Yang[2], Ian Liau[3].
[1]*National Taiwan University College of Medicine, Taiwan,* [2]*National Taiwan University Hospital, Taiwan,* [3]*National Yang Ming Chiao Tung University, Taiwan*
Email: tctsenghbv@gmail.com

Background and aims: Liver sinusoidal endothelial cells (LSEC) is featured by the presence of fenestrae and lack of basal lamina and tight junctions between cells, which is different from the capillary EC. Such unique characteristics make LSEC where the surveillance and infiltration of T cells occurs. Recent studies have shown that persistent inflammation in liver results in sinusoidal capillarization, which is featured by overexpression of CD31, CD34, plasmalemmal vesicle associated protein-1 (PLVAP), and collagen IV, a major component of basal lamina. However, little is known about whether sinusoidal capillarization is present in hepatocellular carcinoma (HCC) and how it affects the T cell infiltration.
Method: We generated a spontaneous HCC mouse model via transposon-based delivery of oncogenes and CRISPR/Cas9-mediated knockout of tumor suppressor genes to transform primary hepatocytes through hydrodynamic injection (HDI). In addition, the oncogene was conjugated with a tumor antigen (OVA $_{257-264}$), a fluorescence protein for intravital imaging, and a secretory HiBiT for tumor marker.
Results: In our autochthonous mouse HCC model, the HiBiT level was first shown to correlate well with the tumor cell number and size *in vitro* and *in vivo*, respectively. We then found that the serum Hibit level remained stable and the tumor size increased slowly within 3–5 weeks after HDI (early tumor, <100 μm in diameter) but increased rapidly after week 7 (advanced tumor). The IHC staining showed that T cells were present within the early tumor but were excluded at the border of advanced tumor. The transferred OT-I T cells were shown to infiltrate into the tumor from the LSEC surrounding the early tumor using intravital imaging. In contrast, these cells were shown to be stay mostly at the peripheral part, but not the core of advanced tumor using clear tissue imaging ($n = 8$, $P < 0.01$). We then studied the difference between tumor endothelial cells (TEC) and LSEC, the key to affect T cell infiltration. We found that TEC expressed more CD31, CD34, and PLVAP than LSEC, and the specific component of basement membrane, collagen IV, was only present around the TEC in advanced tumor, but no LSEC via clear tissue imaging. In human HCC, we also found that the increased expression of CD34 and PLVAP was present in TEC, but not LSEC, of human HCC either using IHC of human samples or RNAseq data of TCGA database. All these data suggest that the capillarization of TEC in HCC, which may be the key to block T cell infiltration into advanced tumor.

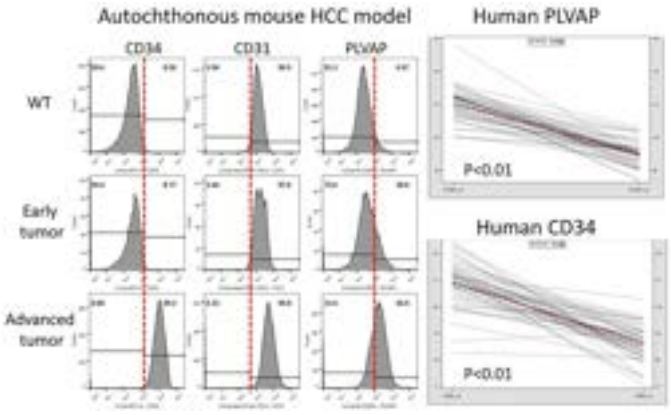

Figure:

Conclusion: Capillarization of tumor endothelial cells in HCC is not only present in our HCC model and human HCC samples. As our intravital imaging shows that the tumor-specific T cells infiltrate into the tumor from the surrounding LSEC, but not the capillarized TEC, it is critical to design a new strategy to delay or reverse the TEC development, which facilitates the T cell infiltration and improves immunotherapy response in HCC.

Anti-CD122 antibody restores specific CD8+ T cell response in non-alcoholic steatohepatitis and prevents hepatocellular carcinoma growth

Stéphanie Lacotte[1], Florence Slits[1], Beat Moeckli[1], Andrea Peloso[2], Stéphane Konig[3], Matthiew Tihi[2], Sofia El Hajji[1], Laura Rubbia-Brandt[2], Christian Toso[1,2]. [1]*University of Geneva, Surgery, Geneva, Switzerland,* [2]*Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland,* [3]*University of Geneva, Geneva, Switzerland*
Email: stephanie.lacotte@unige.ch

Background and aims: Non-alcoholic steatohepatitis (NASH) can lead to hepatocellular carcinoma (HCC). Although immunotherapy is used as first-line treatment for advanced HCC, the impact of NASH on anticancer immunity is only partially characterized. We aimed at assessing the tumor-specific T cell immune response in the context of NASH in a mouse model of recurrent HCC.
Method: We engineered an HCC cell line (RIL-175) with cytoplasmic expression of ovalbumin (OVA). C57BL/6N mice fed a high-fat (HFD) or a control diet (ND) for 35 weeks were injected with 1.5 × 105 RIL-175-LV-OVA-GFP cells into the portal vein. The immune cell subsets and their phenotype were assessed in the blood, in the liver and in the tumors. A dataset of human gene expression in healthy liver, NASH, NASH-adjacent to HCC and HCC was also analyzed.
Results: After 35 weeks of HFD, the mice were obese and developed severe steatosis with inflammation. We observed an increase of the $CD8^+$ T cell subset in the livers of HFD-fed mice, which corresponded to an expansion of the population of $CD44^+$ $CXCR6^+$ $PD\text{-}1^+$ $CD8^+$ T cells known to promote NASH lesions. 14 days after injection of RIL-175-LV-OVA-GFP cells, HFD-fed mice had a higher percentage of peripheral OVA-specific $CD8^+$ T cells than ND-fed mice (8.31 vs 3.67%; $p = 0.010$), but these cells did not prevent HCC growth as the tumors were larger in HFD-fed mice (620 vs 1603 mm^3, $p = 0.051$). In the liver, OVA-specific $CD44^+$ $CXCR6^+$ $CD8^+$ cells were present at similar levels in ND- and HFD-fed mice, but the expression of PD-1 was higher in HFD-fed mice suggesting lowered immune activity (MFI 12605 vs. 16083, $p = 0.0159$). Treating mice with an anti-CD122

antibody, which reduced the number of CXCR6$^+$ PD-1$^+$ cells, we restored OVA-specific CD8 activity (MFI 16406 vs. 10516, p = 0.0571), and reduced HCC growth compared to untreated HFD-fed mice (p = 0.0286). The human dataset confirmed that NASH-affected livers, NASH tissues adjacent to HCC and HCC in patients with NASH exhibited similar expression of a panel of genes.
Conclusion: The immune system is altered and fails to prevent HCC growth in HFD-fed mice. This effect is primarily linked to a higher representation of CD44$^+$ CXCR6$^+$ PD-1$^+$ CD8$^+$ T cells. Treatment with anti-CD122 antibody reduces the number of these cells and prevents HCC growth.

Email: ngoikoetxea@cicbiogune.es

Background and aims: Recent evidence supporting the need of a mitochondria-based metabolism for tumor growth prompted us to study the role of MCJ, an endogenous negative regulator of mitochondrial complex I, in the context of hepatocellular carcinoma (HCC). The tumor microenvironment imposes various metabolic regulations to hamper the antitumor immunity of infiltrating immune cells, therefore, modulating the metabolic rewiring may help recover the antitumor immune potential. This work aims to prove increased malignancy in mitochondria-based tumors and to analyze the differential immune response driven by metabolic changes.
Method: Two different experimental models of HCC were used. Firstly, Wt and whole-body *Mcj*$^{-/-}$ mice were treated with diethylnitrosamine (DEN) for 5, 8 or 12 months. Secondly, C57/BL6 mice were injected with MYC-luc;sgp53 plasmid combination and *Mcj* was specifically silenced in the hepatocytes. Tumor progression, liver metabolism, mitochondrial activity and tumor infiltrating cells were assessed in both models.
Results: An in silico approach using UALCAN revealed reduced Mcj expression in patients at stage IV HCC. In vivo, the absence of MCJ increased tumorigenesis and mortality after DEN treatment. A strong oxidative phenotype was confirmed in Mcj$^{-/-}$ tumors, as mitochondrial respiration was significantly higher, with increased intracellular ATP, NAD$^+$, and NADPH levels. Examination of immune cells infiltrating the tumor showed a reduction in effector T lymphocytes (CD44$^+$ CD62L$^-$) and neutrophils (GR1$^+$CD11b$^+$) in Mcj$^{-/-}$ mice. Serum and liver cytokine analysis showed a decrease in inflammatory IFNg and TNF in Mcj$^{-/-}$ mice. Significantly increased PDL-1 levels in Mcj$^{-/-}$ mice indicated possible immunosuppression. On the other hand, liver-specific silencing of Mcj enhanced tumorigenesis in the MYC-luc;sgp53 model, along with reduced inflammatory IFNg and TNF and increased PDL-1. Interestingly, 20% of *Mcj*-silenced mice developed brain metastases. Mechanistically, increased expression of ectoenzymes *Cd39* and *Cd73* was found in Mcj$^{-/-}$ mice, along with higher hepatic adenosine levels, which may promote immunosuppression in T cells via adenosine receptor signaling cascades.

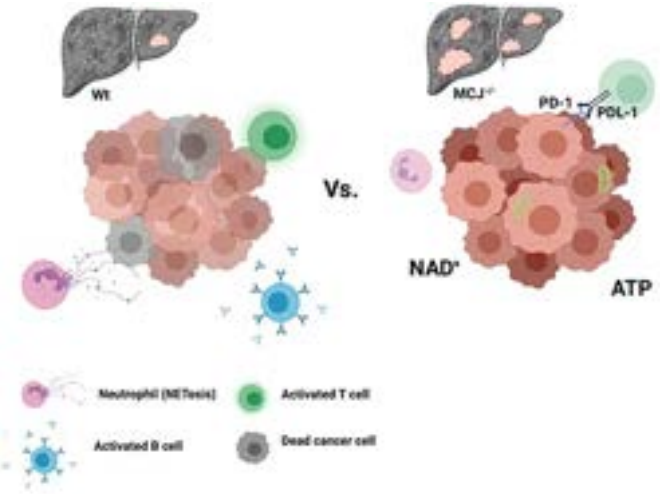

Figure:

Conclusion: Overall, decreased MCJ levels in the liver, which are also seen in advanced HCC patients, promote oxidative respiration and lead to metabolic rewiring that impedes antitumor immune potential via ATP-ectoenzyme-adenosine signaling and promotes tumorigenesis and even metastasis. Therefore, measurement of MCJ levels along with characterization of glycolytic versus oxidative respiration could help determine the most appropriate treatment, such as blockade of the adenosine axis in combination with immunotherapy.

SAT-222
Drug screening for hepatocellular carcinoma: automating and miniaturizing organoid assays for drug screening
Tijmen Booij[1], Sandro Nuciforo[2], David Keller[1], Eva Riegler[2], Diego Calabrese[3], Markus Heim[2]. *[1]ETH Zurich, NEXUS Personalized Health Technologies, Zurich, Switzerland, [2]University of Basel, Department of Biomedicine, Basel, Switzerland, [3]University Hospital Basel, Histology Core Facility, Basel, Switzerland*
Email: booij@nexus.ethz.ch

Background and aims: The past decades have shown an enormous increase in the popularity of using organoids for *in vitro* drug evaluation due to their improved physiological relevance. This is in turn expected to reduce the number, and size, of *in vivo* studies required to select drugs. Due to technological restraints and practical limitations, drug screens with patient-derived organoids have traditionally been performed on a small scale, and these experiments are often used to validate results from earlier *in vitro* drug screens. To enable large-scale drug screes with hepatocellular carcinoma (HCC) organoids derived from patient biopsies, we aimed to automate and miniaturize the drug screening methodology.
Method: The core facility NEXUS Personalized Health Technologies of ETH Zurich operates a lab-automation platform (HighRes Biosolutions). Using this platform, we optimized the liquid handling of organoids and eliminated the requirement for the use of animal-derived hydrogels for 3D culturing. Instead, we optimized the culture conditions with GrowDex and GrowDex-T (UPM Biomedicals), which could be pre-mixed with organoids and dispensed into 1536 well plates using a Certus Flex (Fritz Gyger AG). Using acoustic dispensing technology (Beckman), we could dispense test compounds in nanoliter range to eliminate the requirement for pipette tips. Drug efficacy was measured using cell viability measurement (CellTiterGlo

3D, Promega) and the developed methodology was evaluated in two patient-derived HCC organoid lines.
Results: Here we report the development of a robust organoid high-throughput drug screening platform for hepatocellular carcinoma organoids that is compatible with 1536 well plates and uses the nanocellulose based hydrogel GrowDex-T rather than its animal-derived alternatives as a matrix. We used the newly developed methodology to screen a library of approximately 1′200 FDA-approved drugs in a technical duplicate, and additionally screened a panel of 1′250 novel chemicals in a biological duplicate (performed more than one year apart). For both screens we report high reproducibility and robustness. Furthermore, due to the miniaturization to 1536 well plate format and the elimination of animal-derived matrices, no pipette tips are required at any step in the screening procedure, thereby dramatically reducing the experimental cost and improving assay quality.

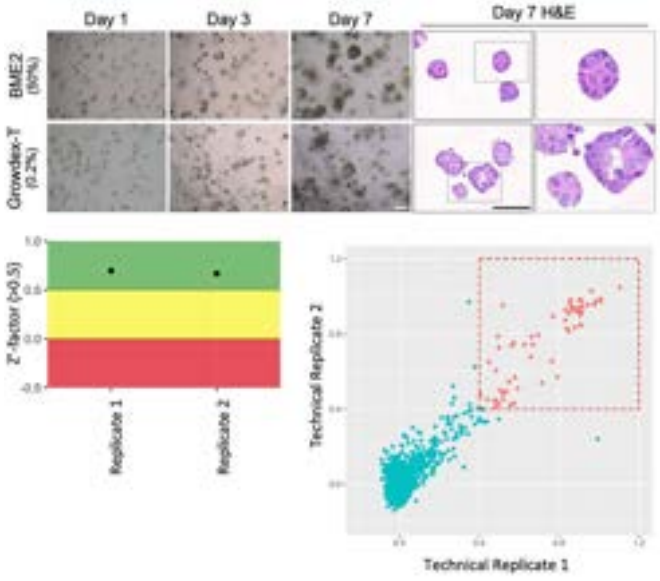

Figure:

Conclusion: We have developed a screening platform for HCC that uses biopsy-derived organoids in a 1536 well plate format. The developed methodology is automation-compatible and vastly the costs of testing drugs while delivering high-quality and robust screening results.

Email: jesus.banales@biodonostia.org

Background and aims: cholangiocarcinoma (CCA) comprises a heterogeneous group of malignant tumors with dismal prognosis. Alterations in post-translational modifications (PTMs), including SUMOylation, result in abnormal protein dynamics, cell disturbances and disease. Here, we investigate the role of SUMOylation in CCA development and progression.
Method: levels and function of SUMOylation, together with response to S-adenosylmethionine (SAMe) and ML792 (SUMOylation inhibitors) or CRISPR/Cas9 against *UBE2I* were evaluated *in vitro*, *in vivo* and/or in patients with CCA. The impact of SUMOylation in CCA cells on tumor-stroma crosstalk was assessed performing co-culture experiments with CCA-derived cancer-associated fibroblasts (CAFs), human endothelial cells and monocytes. Proteomic analyses were carried out by mass spectrometry.
Results: the SUMOylation machinery was found overexpressed and overactivated in human CCA cells and tumors, correlating with poor prognosis. Most SUMOylated proteins found upregulated in CCA cells, after SUMO1-immunoprecipitation and further proteomics, participate in cell proliferation, survival or cell homeostasis. Genetic (CRISPR/Cas9-*UBE2I*) and pharmacological (SAMe and ML792) inhibition of SUMOylation reduced CCA cell proliferation and impeded colony formation *in vitro*. Moreover, both SAMe and ML792 induced apoptotic cell death in CCA cells *in vitro*. SUMOylation depletion (SAMe, ML792 or CRISPR/Cas9-*UBE2I*) halted tumorigenesis in subcutaneous models of CCA *in vivo*. Furthermore, SUMOylation deficiency in CCA cells reduced cancer-associated fibroblast and endothelial cell proliferation and impaired macrophage polarization towards an anti-inflammatory M2-like phenotype.
Conclusion: Aberrant protein SUMOylation contributes to cholangiocarcinogenesis by promoting cell survival and proliferation. Moreover, SUMOylation impacts the CCA-stroma crosstalk. Impaired SUMOylation halts CCA growth and, thus, may represent a potential new therapeutic strategy for patients with CCA.

SAT-224

Cytokine levels and circulating DNA profiling in plasma as biomarkers of response to immunotherapy in hepatocellular carcinoma

Elena Vargas Accarino[1], Monica Higuera[1], María Bermúdez[1], Monica Pons[1], Maria Torrens[1], Ana María Aransay[2], Jose Ezequiel Martín[2], Xavier Merino[3], Beatriz Minguez[1]. *[1]Vall d'Hebron Universitary Hospital, Liver Unit, Spain, [2]CIC bioGUNE, Spain, [3]Vall d'Hebron Universitary Hospital, Radiology Department, Spain*
Email: bminguez@vhebron.net

Background and aims: Immune checkpoint inhibitors (ICIs) have revolutionized the therapeutic landscape for advanced hepatocellular carcinoma (HCC). The combinations anti-PD-L1 antibody (atezolizumab) and VEGF-neutralizing antibody (bevacizumab) and anti-PD-L1 antibody (durvalumab) and anti-CTLA-4 (tremelimumab) have become first line options. Our aim was to identify potential serological markers of response to ICIs.
Method: Prospective cohort of 25 patients treated with ICIs (Nivolumab (n = 14), Atezolizumab/Bevacizumab (n = 8), Durvalumab/Tremelimumab (n = 2) and Lenvatinib/Pembrolizumab

(n = 1)). Plasma samples were collected at the beginning and after 3 months of ICI treatment. 24 inflammatory cytokine levels were analyzed by ELISA as well as the levels of circulating cell free DNA (cfDNA), circulating tumor DNA (ctDNA) and percentage of TERT mutation by ddPCR, at baseline and after 3 months of treatment. Basal cfDNA profiling from 21 of these patients was analyzed by Onco-500 TruSight.

Results: 84% of patients were male, median age was 71 years and 76% were BCLC-C at the beginning of ICIs treatment. 76% had underlying liver disease, being HCV infection the most frequent etiology (52%). Median follow-up was 17 months. 8% presented complete radiological response (CR), 20% partial radiological response (PR), 44% stable disease (SD) and 28% radiological progression (PD) as best radiological outcome (RECIST 1.1). Baseline CTLA-4 levels were significantly higher in patients presenting radiological progression [mean (SD)] [76.55 (150.84) in PD and 0.15 (0.67) pg/ml in no PD] ($p < 0.05$). 3 months post-treatment, MCP-1 levels were significantly lower in patients presenting PD [49.25 (25.73)] than in patients presenting CR/PR/SD [73.73 (86.34) pg/ml] ($p < 0.05$) and TNF-α levels were significantly higher in those patients [110.4 (239.7) vs 49.9 (189.43) pg/ml] ($p < 0.05$). Baseline cfDNA levels were significantly different between patients presenting radiological response (CR/PR) [2.3 (0.58) ng/ul] vs patients (SD/PD) [8.95 (6.89) ng/ul]. These differences were also present after 3 months under therapy [CR/PR 2.12 (0.92) vs SD/PD 10.1 (10) ng/ul]. Higher levels of cfDNA than 3.04 ng/ul were associated with a poorer overall survival ($p < 0.005$). ctDNA levels after 3 months of treatment were also significantly different [0.55 (0.35) in CR/PR and 4.34 (5.5)ng/ul in SD/PD] ($p < 0.005$). Regarding sequencing of baseline cfDNA patients with radiological response (CR/PR) had significantly more copy number variation (CNV) than those without it (97 vs 1) ($p < 0.05$). Pathogenic mutations in CTNNB1 were present in 100% of patients showing PD, but only in 53% of those presenting stable disease or radiological response, and patients presenting PD had significantly more pathological mutations in CDKN2A (67% vs 7%) ($p < 0.05$).

Conclusion: Basal levels of cfDNA, CTLA-4, CDKN2A mutations and CNV are significantly different between patients with and without radiological response to ICIs treatment. Levels of MCP-1, TNF-α and total amount of cfDNA and ctDNA after three months of ICIs treatment are significantly different in patients presenting radiological response. Analysis of cfDNA and cytokines could help to identify HCC patients benefiting more of immunotherapies. Deeper molecular analysis are currently ongoing.

SAT-225

Fibroblast growth factor 19 cooperates with Myc to promote liver carcinogenesis

José Ursic Bedoya[1,2], Guillaume Desandré[2], Carine Chavey[2], Pauline Marie[2], Benjamin Riviere[1], Anthony Lozano[2], Eric Assenat[1,2], Urszula Hibner[2], Damien Gregoire[2]. *[1]CHU Montpellier, Montpellier, France, [2]Institute of Molecular Genetics of Montpellier, CNRS-UMR 5535, Montpellier, France*
Email: jose.ursicbedoya@chu-montpellier.fr

Background and aims: Increased expression of the fibroblast growth factor (FGF19), a hormone whose physiological function is the regulation of bile acids and glucose homeostasis, is a hallmark of a sub-group of aggressive hepatocellular carcinoma (HCC). Analogs have been developed to mimic the hepatoprotective metabolic effects of FGF19, while being theoretically devoid of its oncogenic effects. FGF19 analogs, as well as inhibitors of its signaling, are under investigation for treatment of metabolic disorders and HCC, respectively. Our work investigates oncogenic cooperation between FGF19, or its analogs, and pathways frequently mutated in HCC.

Method: We performed hydrodynamic gene transfer (HGT) in C57BL/6J mice to combine overexpression of FGF19, FGF15, FGF21, FGF19 analog (aldafermin) or constitutively active FGFR4 mutant ($FGFR4^{V547L}$) with oncogenic events commonly found in HCC (p53 inactivation, MYC overexpression, Wnt/ beta-catenin pathway activation). Sequential HGT experiments were used to transfect distinct sets of hepatocytes. Tumors were analyzed by RT-qPCR, RNA-seq, immunohistochemistry (IHC) and phospho-proteome assays. In addition, tumors were dissociated to establish cells lines, which were used for orthotopic xenografts. Transcriptomic datasets from patients with NASH and healthy controls were analyzed to detect Myc pathway activation.

Results: We report that while FGF19 is by itself a weak oncogene, it efficiently cooperates with several oncogenic events characteristic of HCC, such as activation of the Wnt/beta-catenin pathway or increased Myc expression. Sequential HGT experiments demonstrate that FGF19 cooperates with Myc in a non-cell autonomous, paracrine fashion. Transcriptomic and IHC analyses show that FGF19+ tumors display increased neoangiogenesis. Oncogenic cooperation was also observed when Myc was co-expressed with FGF15, FGF21 or $FGFR4^{V547L}$. Surprisingly, similar results were obtained with a plasmid coding for aldafermin, notwithstanding the reported lack of oncogenic activity of this analog. Human datasets from NASH patients display frequent Myc pathway activation compared to healthy controls.

Conclusion: Our findings indicate that FGF19/FGFR4 pathway activation cooperates with Myc to promote aggressive HCC. Moreover, we suggest that aldafermin might keep oncogenic properties in this context. Since Myc pathway is often deregulated in patients with NASH or cirrhosis, our results suggest a precautionary approach with regard to the potential adverse effects of FGF analogs in these patients.

Email: pedro.rodrigues@biodonostia.org

Background and aims: Cholangiocarcinoma (CCA) comprises a heterogeneous group of malignant tumors with poor prognosis. Krüppel-like factors (KLF) are a family of transcription factors involved in large variety of biological processes, including organogenesis, differentiation and cellular homeostasis. Here, we investigated the role of KLF5 in cholangiocarcinogenesis and evaluated the therapeutic potential of its inhibition during CCA tumorigenesis.

Method: *KLF5* expression was determined in human CCA tissues [Copenhagen (n = 210), TCGA (n = 36), Job (n = 78), TIGER-LC (n = 90) and San Sebastian cohorts (n = 12)] and cell lines. $KLF5^{-/-}$ CCA cells were generated by CRISPR/Cas9. Proteomic analyses were carried out by mass spectrometry and the functional effects of KLF5 genetic ablation or chemical inhibition with ML264 were evaluated *in vitro* and *in vivo*.

Results: KLF5 expression was upregulated in human CCA tissues from 5 different patient cohorts compared to surrounding normal liver tissue. High KLF5 levels correlated with lymph node invasion and worse overall survival. In vitro, KLF5 protein and mRNA levels were found upregulated in human CCA cells compared to normal human cholangiocytes. Proteomic analysis of KLF5-/- CCA cells revealed that most of the altered pathways are related with the modulation of cell cycle, proliferation, survival and migration. In agreement, KLF5-/- CCA cells displayed decreased cell proliferation, colony formation and migration while promoting cell cycle arrest at G1/S and apoptosis in vitro, when compared with CCA control cells. Instead, no signs of tumor development were evident after subcutaneous or orthotopic injection in a xenograft animal model of CCA. Likewise, pharmacological inhibition of KLF5 with ML264 hampered CCA cells proliferation and migration in vitro and blocked tumor growth in vivo in distinct animal models. Lastly, both genetic and pharmacological inhibition of KLF5 sensitized CCA cells to chemotherapy-induced apoptosis in vitro, and the combination of the standard of care chemotherapy (gemcitabine + cisplatin) and ML264 completely halted CCA tumor growth in mice.
Conclusion: Increased KLF5 is a general event in CCA, contributing to cancer progression by promoting cell survival and proliferation, as well as, chemoresistance. KLF5 inhibition with ML264 may represent a potential therapeutic strategy for CCA.

SAT-227

NLRP3 and IL-1, but not IL-18, are drivers of hepatocellular carcinoma in two independent murine models

Mona Peltzer[1], Antje Mohs[1], Jan G. Hengstler[2], Serena Pelusi[3], Luca Valenti[3,4], Carolin V. Schneider[1], Kai Markus Schneider[1], Christian Trautwein[1]. *[1]University Hospital RWTH Aachen, Department of Internal Medicine III, Aachen, Germany, [2]Leibniz Research Centre for Working Environment and Human Factors, Toxikologie/ Systemtoxikologie, Dortmund, Germany, [3]Biological Resource Center, Fondazione IRCCS Ca' Granda Policlinico, Milan, Italy, [4]Department of Pathophysiology and Transplantation, Università degli Studi Milano, Milan, Italy*
Email: mpeltzer@ukaachen.de

Background and aims: Hepatocellular carcinoma (HCC) occurs as a consequence of malignant transformation of hepatocytes frequently triggered during chronic inflammation. The NLR Family Pyrin Domain containing 3 (NLRP3) inflammasome plays a crucial role in inflammation related liver disease but its contribution to hepatocyte malignant transformation remains unclear. After the two-step activation of the NLRP3 inflammasome by Pathogen-/Damage-associated molecular patterns (PAMPs/DAMPs), secretion of the pro-inflammatory cytokines Interleukin 1 beta (IL-1beta) and Interleukin 18 (IL-18) is initiated. In the present study, we aimed to understand the role of the NLRP3 inflammasome and its downstream targets (IL-1beta and IL-18) in inflammation- and primary sclerosing cholangitis (PSC) -related hepatocarcinogenesis.
Method: Prevalence of NLRP3, Interleukin 1 receptor (IL1R) and Interleukin 18 receptor (IL18R) as well as inherited variants determining alterations in protein sequence were analyzed in HCC patients. In mice, HCC was induced by the N-nitrosodiethylamine/carbon tetrachloride (DEN/CCl_4) model in wild-type (WT), *Nlrp3*$^{-/-}$, *Il1r*$^{-/-}$ and *Il18r*$^{-/-}$ mice. To study PSC related carcinogenesis, *Nlrp3*$^{-/-}$ mice were crossed to multidrug resistance gene 2 (Mdr2) knockout mice (*Mdr2*$^{-/-}$/*Nlr3*$^{-/-}$) and were analyzed at the age of 64 weeks. In both models, tumor development, immune cell infiltration and proliferation were analyzed.
Results: Analysis of human data sets revealed an overexpression of inflammasome-related proteins in HCC tissue and an overrepresentation of inflammasome-associated protein-coding variants. In two murine tumor models (DEN/CCl_4 and genetic modified *Mdr2*$^{-/-}$) NLRP3 deletion reduced tumor burden and inflammation compared to their respective controls. Reduced inflammation was evidenced by decreased immune cell infiltration via FACS, especially monocyte-derived macrophages and neutrophils. In addition, NLRP3 deletion significantly reduced proliferation in both models, as demonstrated by Western Blot analysis and stainings. To further dissect the downstream pathway, *Il1r*$^{-/-}$ and *Il18r*$^{-/-}$ mice were treated with DEN/CCl_4. Interestingly, tumor bearing *Il1r*$^{-/-}$ but not *Il18r*$^{-/-}$ mice showed a reduced tumor burden and inflammation, mainly of monocyte-derived macrophages and neutrophils. Surprisingly, whereas in tumor-bearing *Nlrp3*$^{-/-}$ mice $CD8^+$/$PD1^+$ T cells were downregulated in tumor-bearing *Il1r*$^{-/-}$ mice these cells were upregulated. Thus, the deletion of NLRP3 or IL1R, but not of IL18R showed protective effects for HCC development.
Conclusion: Our results demonstrate that in human HCC tissue NLRP3, IL-1R and IL18R is overexpressed and an overrepresentation of inflammasome-associated protein-coding variants are present. In two independent murine models NLRP3 and IL-1, but not IL-18 were identified as driver of malignant hepatic tumor development.

SAT-228

Infiltrating suppressive myeloid cells dominate the pediatric hepatoblastoma tumor immune microenvironment

Danielle Krijgsman[1], Lianne Kraaier[2], Meggy Verdonschot[1], Jeanette Leusen[3], Weng Chuan Peng[2], Yvonne Vercoulen[1]. *[1]UMC Utrecht, Center for Molecular Medicine, Utrecht, Netherlands, [2]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands, [3]UMC Utrecht, Center for Translational Immunology, Utrecht, Netherlands*
Email: y.vercoulen@umcutrecht.nl

Background and aims: Pediatric hepatoblastoma is a rare disease, affecting approximately 1/million children. Pediatric liver tumors likely originate from immature hepatocyte precursors and show low mutational burden. Until now, the pathobiology of pediatric liver cancer is poorly understood due to their low incidence. Currently, pediatric hepatoblastoma patients are treated with chemotherapeutics followed by tumor resection. Although this treatment results in a clinical response in most patients, it associates with high toxicity. Better understanding of the pathogenesis and effects of chemotherapy in pediatric hepatoblastoma is crucial to optimize treatment decisions. In adult liver cancer, the immune system plays a pivotal role in tumor development and progression. Tumor-associated macrophages (TAM) and myeloid-derived suppressor cells (MDSC) potently suppress the immune system while supporting tumor growth. We here set out to investigate the role of the myeloid immune infiltrate in pediatric hepatoblastoma.
Method: Tissue samples of pediatric hepatoblastoma were included from pre-treatment biopsies, and post-chemotherapeutic resections containing both tumor tissue and adjacent normal tissue. A custom developed antibody panel was used for high-plex imaging mass cytometry (Hyperion). Data analysis for single-cell spatial profiling was performed, using the 'MATISSE' pipeline which identified both immune cell subsets, and tumor cells. Spatial neighborhood analysis was performed using CytoMap.
Results: Principal Component Analysis revealed that while lymphocyte markers associate with normal tissue, myeloid markers associate with tumor, regardless of treatment. T cell markers CD8a and CD4, and pro-inflammatory proteins IFNg and NFkb were significantly elevated in normal tissue compared to tumor. Moreover, chemotherapy induced an increased expression of CD68 (macrophages) and HLA-DR (MHC-II) in the tumor. We identified diverse myeloid populations: The abundance of macrophage cluster 1, and a cluster of cytotoxic ($CD8^+$) T cells and Macrophages was increased in the tumor upon chemotherapy. Detailed characterization revealed that these macrophages were suppressive, reflected by high expression of CD163, iNOS, and arginase. Moreover, chemotherapy reduced CD33 expression reflecting maturation of infiltrating macrophages upon treatment. Finally, neighborhood analysis revealed that overall, the immune cells avoided tumor and stromal cells, while lymphocytes

and myeloid cells clearly interacted, suggesting immune cell exclusion.

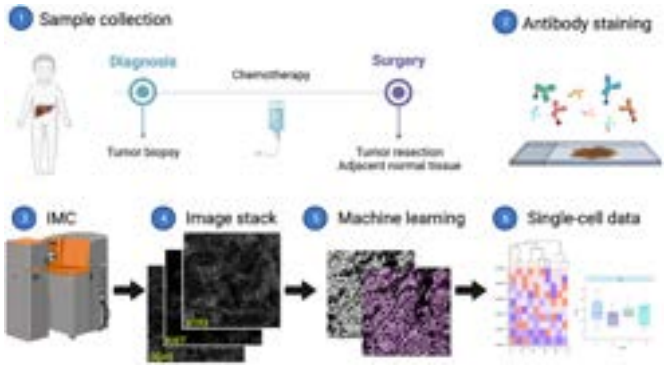

Figure:

Conclusion: We demonstrate here the first in-depth immune infiltrate characterization of pediatric hepatoblastoma and reveal that the myeloid compartment dominates the immune infiltrate in the tumor compared to normal tissue. Moreover, the infiltrating macrophages numbers increased upon chemotherapy and showed a suppressive phenotype upon chemotherapy, indicating that the chemotherapy itself modulates the immune microenvironment in the tumor. The low numbers of infiltrating lymphocytes and reduced expression of pro-inflammatory proteins, and low interaction between immune cells and tumor indicate an immune-cold tumor microenvironment in hepatoblastoma. Our results suggests that these tumors will likely not benefit from T-cell directed therapeutic strategies and that the myeloid compartment would serve as a more relevant target for alternative treatments to chemotherapy.

Fatty Acid Synthase expression promotes the malignant features of cholangiocarcinoma cells and predicts shorter survival in patients

Giulia Lori[1], Chiara Raggi[1], Benedetta Piombanti[1], Mirella Pastore[1], Elisabetta Rovida[1], Jesper Andersen[2], Monika Lewinska[2], Amalia Gastaldelli[3], Fabio Marra[1]. *[1]University of Florence, Italy, [2]University of Copenhagen, Denmark, [3]CNR, Italy*
Email: fabio.marra@unifi.it

Background and aims: Cancer cells are exposed to a metabolically challenging environment with scarce availability of nutrients, and alterations in lipid metabolism may affect the cellular response to drugs. We hypothesize that fatty acids (FA) modulate the biology of cholangiocarcinoma (CCA) cells and the development of stemness features.
Method: CCA cells (HuCCT-1 or CCLP1) were treated with monounsaturated FAs (132 μM oleic or 100 μM palmitoleic acid). Self-renewal ability was tested with a colony formation assay. Cancer stem cell-(CSC)-enriched spheres were obtained growing cells in anchorage-independent conditions and selective medium. Five-year overall survival (OS) was analyzed in 34 patients with CCA sub-grouped based on fatty acid synthase (FASN) expression. Desaturation index and triglyceride de novo synthesis were performed by lipidomic analysis. NSG mice were injected with CCLP1 spheres and treated with the FASN inhibitor orlistat (240 mg/Kg). Tumor volume was measured with Vevo LAZR-X imaging station. RTPCR array on tumor masses was performed using the QuantiNova LNA PCR Panel.
Results: Exposure of CCA cell lines to FAs increased cell proliferation and activated growth and survival pathways, including AKT and ERK1/2. Exposure to FA made CCA cells less sensitive to the toxic effects of chemotherapeutic agents, and modulated the expression of ABC transporters involved in drug resistance. The colony forming ability of CCA cells was increased by FAs, and was associated with upregulation of genes controlling epithelial-mesenchymal transition and stemness. Expression levels of genes involved in lipid metabolism were upregulated in CSC-enriched spheres as well as the percentage of desaturated TGs. FASN inhibition by orlistat decreased cell proliferation and CSC or EMT markers. In a xenograft model of CCA, tumor volume was significantly lower in mice treated with orlistat. Accordingly, expression of genes involved in cell proliferation was downregulated while the one of tumor suppressor genes increased. In a series of CCA patients, the expression of FASN correlated with OS.
Conclusion: FA promote malignant features of CCA and increase CSC markers. FASN expression levels correlate with survival in patients with CCA and promote CCA growth in mice. Lipid metabolism could be a new target to block CCA progression.

SAT-230

Positive effects of PARP-1 inhibition in KRAS-mutated intrahepatic cholangiocarcinoma is mediated by CHK1 kinase

Darko Castven[1], Friederike Keggenhoff[2], Stojan Stojkovic[1], Diana Becker[2], Jovana Castven[1], Carolin Zimpel[1], Beate Straub[2], Harald Langer[1], Patrizia Hähnel[2], Thomas Kindler[2], Jörg Fahrer[3], Colm O Rourke[4], Lichun Ma[5], Xin W. Wang[5], Timo Gaiser[6], Matthias Matter[7], Christian Sina[1], Stefanie Derer[1], Stephanie Roessler[8], Bernd Kaina[2], Jesper Andersen[4], Peter Galle[2], Jens Marquardt[1]. *[1]Universitätsklinikum Schleswig-Holstein, Campus Lübeck, Lübeck, Germany, [2]University medicine at the Johannes Gutenberg University in Mainz, Mainz, Germany, [3]Technical University of Kaiserslautern, Kaiserslautern, Germany, [4]Biotech Research and Innovation Centre, København, Denmark, [5]National Cancer Institute, NIH, Bethesda, United States, [6]UNIVERSITÄTSMEDIZIN MANNHEIM, Mannheim, Germany, [7]Universitätsspital Basel, Basel, Switzerland, [8]Heidelberg University, Heidelberg, Germany*
Email: castvendarko@gmail.com

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is the second most common primary liver cancer with an increasing incidence over recent years. Due to the complexity of iCCA pathogenesis and the pronounced genetic heterogeneity treatment options are still limited. Activating KRAS mutations are among the most abundant genetic alterations in iCCA and are associated with early recurrence, poor response to chemotherapy, and reduced overall survival, highlighting the need for novel therapeutic approaches. Poly (ADP-ribose)polymerase-1 (PARP-1) is frequently observed to be upregulated in iCCA. Evidence indicate potential therapeutic relevance for PARP-1 inhibition in iCCA that preferentially affects KRAS-mutated cancers, but exact mechanisms remain unknown.
Method: PARP-1 depletion was generated by siRNA and CRISPR/Cas9-mediated knockdown/knockout in KRAS-mutated and non-mutated iCCA cell lines. Functional assessment of PARP-1 knockout and inhibition of tumorigenic potential was analyzed by viability assay and colony and sphere formation. RNA sequencing was employed to further decipher PARP-1 regulation. To investigate the impact of PARP-1 deficiency in KRAS-driven tumorigenesis, PARP-1 knockout mice were combined with an inducible KRAS-driven mouse model using hydrodynamic tail vein injection. Molecular analyses including transcriptome profiling were employed to further investigate molecular mechanisms.
Results: Significant upregulation of PARP-1, as well as enrichment of genes related to PARP-1 activation, was observed in iCCA tissue and KRAS-mutated cell lines. Knockout of PARP-1 in KRAS-mutated cells led to a reduction in colony and sphere formation. Moreover, KRAS-mutated cell lines showed higher sensitivity to PARP-1 inhibition. In vivo PARP-1 deficiency considerably impaired biliary carcinogenesis and induced a shift from dominant iCCA towards HCC phenotype in a KRAS-dependent manner. Transcriptome analyses of CRISPR/Cas9 PARP-1 knockout clones and in vivo tumors revealed differential expression of DNA damage response pathways (e.g. CHK1) as well as cellular pathways affected by PARP-1, (inflammation, oxidative stress,

cell death signaling). The most prominent candidate regulating PARP1 in KRAS cell lines and tumors appeared to be CHK1 kinase, further validated by qRT-PCR, western blot, and drug-screening assays.
Conclusion: Together, these findings suggest an unrecognized prognostic and therapeutic role of PARP-1 in iCCA patients with oncogenic KRAS signaling and unveil the potential mechanism of PARP-1 regulation by CHK1 kinase.

SAT-231
Sortilin-driven cancer secretome enhances self-renewal and metastasis of hepatocellular carcinoma via de novo lipogenesis
Kwan Shuen Chan[1], Kwan Yung Au[1], Bernice Leung[1], Cheuk Yan Wong[1], Clive Yik Sham Chung[2], Regina Cheuk Lam Lo[3].
[1]The University of Hong Kong, Pathology, School of Clinical Medicine, LKS Faculty of Medicine, Hong Kong, [2]The University of Hong Kong, School of Biomedical Sciences, LKS Faculty of Medicine, Hong Kong, [3]The University of Hong Kong, Pathology, School of Clinical Medicine, LKS Faculty of Medicine; State Key Laboratory of Liver Research (The University of Hong Kong), Hong Kong
Email: kristykc@hku.hk

Background and aims: De novo lipogenesis (DNL) is a key metabolic pathway to fuel tumorigenesis. Increased free fatty acid uptake and DNL is consistently observed in chronic liver disease and genes related to DNL are universally upregulated in hepatocellular carcinoma (HCC). Yet, the upstream regulatory events triggering DNL in HCC remains to be delineated. Sortilin (*SORT1*) is reported as a regulator to transport a wide range of proteins intra/extracellularly. Association between sortilin and lipid metabolism has been established as reported by genome-wide association studies and animal models. In the present study, we aimed at investigating the functional roles of sortilin-driven cancer secretome in HCC.
Method: Sortilin expression in HCC and paired non-tumoral liver tissues was compared using The Cancer Genome Atlas Liver Hepatocellular Carcinoma dataset and public dataset (GSE89377). Conditioned medium collected from stable sortilin-overexpressing HCC cells was deployed to study the effect of sortilin-driven secretome in HCC using in vitro and in vivo assays. Proteomic profiling of sortilin-driven secretome was analyzed using liquid chromatography-tandem mass spectrometry.
Results: Sortilin was overexpressed in HCC. Overexpression of sortilin was correlated with poorer survival outcome. Functional studies showed that sortilin-driven secretome conferred self-renewal ability and metastatic potential in HCC cells. Fatty acid metabolism was highlighted as a potential molecular pathway associated with sortilin-driven secretome by proteomic profiling. Lipid content and fatty acid synthase (FASN) was increased in HCC cells treated with sortilin-driven secretome. The enhanced tumorigenic phenotypes endowed by sortilin-driven secretome were partially abrogated by co-administration of FASN inhibitor C75. Stabilization of FASN upon treatment with sortilin-driven secretome might be mediated through O-GlcNAcylation.

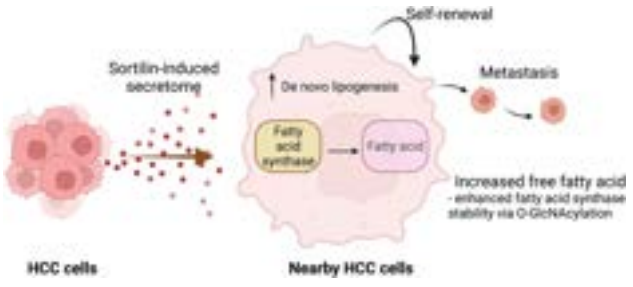

Figure:

Conclusion: Our study uncovered the role of sortilin in contributing to hepatocarcinogenesis via modulation of cancer secretome and deregulated lipid metabolism.

Email: maavila@unav.es

Background and aims: Hepatoblastoma (HB) is the most frequent childhood liver cancer. Surgical resection is the mainstay treatment which frequently is preceded by neoadjuvant chemotherapy (cisplatin or doxorubicin). However, patients with aggressive tumors have limited therapeutic options; therefore, a better understanding of HB pathogenesis is needed to improve treatment. HB have a very low mutational burden; however, epigenetic alterations are increasingly recognized. We aimed to identify epigenetic regulators consistently dysregulated in HB and to evaluate the therapeutic efficacy of their targeting in clinically relevant models.
Method: We performed a comprehensive transcriptomic analysis of 180 epigenetic genes. Data from fetal, pediatric, adult, peritumoral (n = 72) and tumoral (n = 91) tissues were integrated. Selected epigenetic drugs were tested in HB cells. The most relevant epigenetic target identified was validated in primary HB cells, HB organoids, a PDX model, and a genetic mouse model. Transcriptomic, proteomic and metabolomic mechanistic analyses were implemented.
Results: Altered expression of genes regulating DNA methylation and histones modifications was consistently observed in association with molecular and clinical features of poor prognosis. The histone methyl-transferase G9a was markedly upregulated in tumors with epigenetic and transcriptomic traits of increased malignancy. Pharmacological targeting of G9a significantly inhibited HB cells, organoids and PDX's growth. Development of HB induced by oncogenic forms of β-catenin and YAP1 was ablated in mice with hepatocyte-specific deletion of *G9a*. We observed that HB undergo significant transcriptional rewiring in genes involved in amino acids metabolism and ribosomal biogenesis. G9a inhibition counteracted these pro-tumorigenic adaptations. Mechanistically, G9a targeting potently repressed the expression of c-MYC and ATF4, master regulators of HB metabolic reprogramming.

Conclusion: HB display a profound dysregulation of the epigenetic machinery. Among them, G9a is upregulated in association with tumor aggressiveness. Pharmacological targeting of G9a potently quells HB growth. Inhibition of G9a abrogates the c-MYC and ATF4-mediated metabolic reprogramming that supports cancer cell survival. Pharmacological targeting of key epigenetic effectors exposes metabolic vulnerabilities that can be leveraged to improve the treatment of these patients.

SAT-233

Tumor-extrinsic Axl expression shapes an inflammatory microenvironment independent of tumor-cell promoting Axl signaling

Kristina Breitenecker[1], Denise Heiden[1], Gerhard Weber[1], Iros Barozzi[1], Thomas Grünberger[2], Patrick Starlinger[3,4], Wolfgang Mikulits[1].
[1]Center for Cancer Research, Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria, [2]Department of Surgery, HPB Center, Viennese Health Network, Clinic Favoriten and Sigmund Freud Private University, Vienna, Austria, [3]Department of General Surgery, Division of Visceral Surgery, Medical University of Vienna, Vienna, Austria, [4]Department of Surgery, Division of Hepatobiliary and Pancreatic Surgery, Mayo Clinic, Rochester, United States
Email: kristina.breitenecker@meduniwien.ac.at

Background and aims: Signaling of the receptor tyrosine kinase Axl activated by its ligand Gas6 is a major driver of cancer progression. In hepatocellular carcinoma (HCC), patients show upregulation of Axl expression correlating with vascular invasion and poor prognosis. In pre-malignant stages of HCC, Gas6/Axl is crucially involved in developing hepatic fibrosis. Although recent insights into the role of Gas6/Axl in liver disease, a deep understanding of tumor-intrinsic and tumor-extrinsic functions of Axl in HCC is lacking. In this study, we focused on Axl in HCC development by employing novel mouse models and translating experimental data into the HCC patient situation.
Method: Liver tumors were induced by diethylnitrosamine (DEN) and carbon tetrachloride (CCl_4) in systemic $Axl^{-/-}$ and in $Axl^{delta\ hep/delta\ hep}$ mice lacking Axl expression in hepatocytes. Oncogenic-transformed $p19^{ARF-/-}$ hepatocytes were used to study tumor-intrinsic Axl expression. Invasive abilities of cells were examined *in vitro* and *in vivo*. Mouse tumors were subjected to immune cell profiling by FACS and immunohistochemistry. HCC patient samples (n = 47) were analyzed by multiplex immunohistochemistry.
Results: DEN/CCl_4 -induced liver tumor burden of systemic $Axl^{-/-}$ mice was enhanced showing higher proliferation rates including lower infiltration of cytotoxic CD8 + T cells and granzyme B+ cells. PD-L1 levels did not vary between $Axl^{-/-}$ and $Axl^{+/+}$ tumors indicating alternative escape mechanisms. Interestingly, livers of CCl_4 -treated $Axl^{-/-}$ mice were increasingly infiltrated with pro-inflammatory monocytes and neutrophils prior to tumor formation, potentially fostering tumor-promoting inflammation and therefore enhancing tumorigenesis. Most notably, tumor burden and infiltration of CD8 + T cells did not differ between $Axl^{delta\ hep/delta\ hep}$ and $Axl^{fl/fl}$ mice suggesting that hepatocyte-intrinsic Axl expression does not alter proliferation and cytotoxic immune cell infiltration. However, we observed that tumor-intrinsic Axl expression augments invasive abilities *in vitro* and decreases overall survival of mice by increasing pulmonary metastasis. The Axl-driven invasive phenotype was accompanied by upregulation of Snai1/Snai2 and downregulation of E-Cadherin indicating changes in epithelial plasticity.
Conclusion: In an inflammatory setting, tumor-extrinsic Axl expression shapes the liver immune environment which curbs cancer development. Tumor-intrinsic Axl expression promotes the cancer-progressive phenotype of HCC by fostering cell invasion and reprogramming of epithelial organization. These findings highlight the versatile functions of Axl in tumor-stroma interaction which are highly relevant for anti-cancer strategies.

Immunotherapy resistance in NASH-HCC is driven by the dysfunctional liver microenvironment of NASH

Daniel Geh[1], Erik Ramon Gil[1], Maja Laszczewska[1], Amy Collins[1], Saimir Luli[1], Rainie Cameron[1], Fiona Oakley[1], Jack Leslie[1], Helen Louise Reeves[2,3], Derek A Mann[1]. *[1]Newcastle University-Newcastle Fibrosis Research Group, Biosciences Institute, Faculty of Medical Sciences, United Kingdom, [2]Newcastle University-Translational and Clinical Research Institute, Faculty of Medical Sciences, United Kingdom, [3]Freeman Hospital-Hepatopancreatobiliary Multidisciplinary Team, Newcastle upon Tyne Hospitals NHS Foundation Trust, United Kingdom*
Email: daniel.geh@newcastle.ac.uk

Background and aims: There is growing evidence suggesting that anti-programmed death ligand 1 (PDL1)/anti-vascular endothelial growth factor (VEGF) combination therapy in hepatocellular carcinoma (HCC) with underlying non-alcoholic steatohepatitis (NASH) is less effective compared to other aetiologies. Previous work suggests that a subgroup of exhausted CD8+PD1+EOMES+CXCR6+ T cells is responsible in the context of anti-PD1 monotherapy. We aim to explore this further in the context of anti-PDL1/VEGF combination therapy.
Method: C57BL/6J mice were fed either a western diet to induce NASH or fed control diet (lean mice) followed by either intrahepatic or subcutaneous implantation of tumours (Hep 53.4 line). After 2 weeks of tumour growth mice were treated with either anti-PDL1/VEGF or IgG isotype control. Tumour burden was measured and immune characterisation conducted using flow cytometry.
Results: NASH mice with intrahepatic tumours had a poor response to anti-PDL1/VEGF therapy compared to lean mice (figure 1a–c). Analysis showed an influx of CD8T cells into anti-PDL1/VEGF treated intrahepatic tumours but with a preferential recruitment of CD8+PD1+EOMES+CXCR6+ T cells in NASH intrahepatic tumours (figure 1d–e). On the other hand, both NASH and lean mice with subcutaneous tumours had a good response to anti-PDL1/VEGF therapy (figure 2a–c). Analysis demonstrated an influx of CD8T cells into the subcutaneous tumours of anti-PDL1/VEGF treated mice. Unlike in the intrahepatic tumours, the proportion of recruited CD8+PD1+ cells were similar in NASH and lean mice (figure 2 d–e).
Conclusion: In our model of NASH-HCC intrahepatic tumours have a poor response to anti-PDL1/VEGF therapy whereas subcutaneous tumours have a good response. This was likely due to a higher proportion of exhausted CD8+PD1+EOMES+CXCR6+ T cells being recruited into intrahepatic tumours due to their expansion in the pre-cancerous NASH hepatic microenvironment. This suggests that the NASH hepatic microenvironment is the key determinant to treatment response in NASH-HCC.

SAT-235

PSMP inhibits HCC progression by regulating the polarization of tumor-associated macrophages via the PI3K/Akt pathway

Shaoping She[1], Liying Ren[1], Dongbo Chen[1], Hongsong Chen[1]. [1]*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, China*
Email: chenhongsong@bjmu.edu.cn

Background and aims: Hepatocellular carcinoma (HCC) is one of the malignant tumors with high morbidity and high mortality, which is prone to metastasis and recurrence and has a poor prognosis. PC3 secreted microprotein (PSMP) or microprotamine (MSMP) is a novel chemotactic cytokine discovered through genome-wide bioinformatics analysis and chemoattractant platform screening, which can act as a CCR2 ligand to recruit peripheral blood monocytes and lymphocytes. Our previous study found that PSMP was significantly highly expressed in human and mouse liver fibrosis/cirrhosis tissues induced by different causes. PSMP can promote the progression of liver fibrosis by regulating the infiltration, activation and polarization of macrophages. However, the relationship between PSMP and the development and prognosis of HCC remains unclear.
Method: The expression of PSMP was detected in two independent HCC patients cohorts and its correlation with patients' prognosis was analyzed. *In vivo*: In PSMP knockout and wild-type mice, two mouse HCC cell lines (Hepa1-6, H22) were used to construct the subcutaneous tumorigenesis models and the liver orthotopic tumorigenesis models; In nude mice, two human HCC cell lines (BEL-7402, BEL-7405) were used to construct the subcutaneous tumorigenesis models. The direct effects of PSMP on the polarization of macrophages (human THP-1 cell line and mouse bone marrow-derived macrophages (BMDMs) were studied *in vitro*. In addition, we performed RNA sequencing of BMDMs from WT and PSMP gene knockout mice.
Results: Through the detection of clinical HCC patient samples, we found that PSMP is downregulated in human HCC tissues, and its expression level is positively correlated with the prognosis of HCC patients. *In vivo*, we found that knockout of PSMP promotes subcutaneous and liver orthotopic tumor growth in mice; Overexpression of PSMP inhibits the formation of subcutaneous tumors in nude mice. Further, knockout of PSMP significantly inhibits the infiltration of $CD8^+$ tumor-infiltrating lymphocytes (TILs) and promotes the infiltration and polarization of M2-type tumor-associated macrophages (TAMs) in mice. *In vitro*, we found that PSMP could directly promote M1-polarization and inhibit M2-polarization of human THP-1 cells and mouse BMDMs. In addition, analysis of RNA sequencing results showed that PSMP may mediate the polarization of macrophages by regulating the PI3K/Akt signaling pathway.

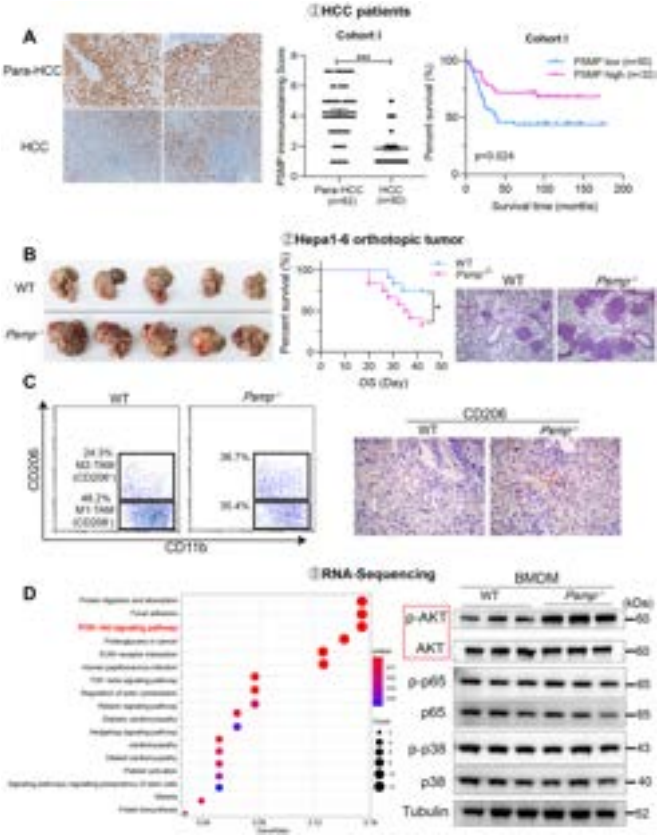

Figure:

Conclusion: Taken together, PSMP may inhibit the M2 polarization of tumor-associated macrophages through the PI3K/Akt signaling pathway, and then promote the anti-tumor immune response of CD8+ T cells, and ultimately inhibit the progression of HCC. The results are expected to clarify the role and mechanism of PSMP in the liver tumor microenvironment for the first time, which has important theoretical significance, and may also provide new targets for the treatment of HCC, with potential application value.

SAT-236

Macrophage STING signaling promotes NK cell to suppress colorectal cancer liver metastasis via 4-1BBL/4-1BB co-stimulation

Haoming Zhou[1], Yu Sun[1], Haoran Hu[1], Jian Xu[1], Yiyun Gao[1], Xinyu Zhan[1], Shun Zhou[1], Weizhe Zhong[1], Dongming Wu[1], Ping Wang[1], Lianbao Kong[1], Zhuqing Rao[1]. [1]*The First Affiliated Hospital of Nanjing Medical University, China*
Email: zhuqingrao_njmu@163.com

Background and aims: Macrophage innate immune response plays an important role in tumorigenesis. However, the role and mechanism of macrophage STING signaling in modulating tumor microenvironment to suppress tumor growth at secondary sites remains largely unclear.
Method: STING expression was assessed in liver samples from patients with colorectal cancer (CRC) liver metastasis. Global or myeloid STING-deficient mice, myeloid NLRP3-deficient mice, and wild-type mice were subjected to a mouse model of CRC liver metastasis by intrasplenic injection of murine colon carcinoma cells (MC38). Liver non-parenchymal cells including macrophages and NK cells were isolated for flow cytometry analysis. Bone marrow-derived macrophages pretreated with MC38 were co-cultured with splenic NK cells for in vitro studies.
Results: Significant activation of STING signaling were detected in adjacent and tumor tissues and intrahepatic macrophages. Global or

myeloid STING-deficient mice had exacerbated CRC liver metastasis and shorten survival, with decreased intrahepatic infiltration and impaired antitumor function of NK cells. Depletion of NK cells in WT animals increased their metastatic burden, while no significant effects were observed in myeloid STING-deficient mice. STING activation contributed to the secretion of IL-18 and IL-1β by macrophages, which optimized antitumor activity of NK cells by promoting the expression of 4-1BBL in macrophages and 4-1BB in NK cells, respectively. Moreover, MC38 treatment activated macrophage NLRP3 signaling, which was inhibited by STING depletion. Myeloid NLRP3 deficiency increased tumor burden and suppressed activation of NK cells. NLRP3 activation by its agonist effectively suppressed CRC liver metastasis in myeloid-SITNG deficient mice.
Conclusion: We demonstrated that STING signaling promoted NLRP3-mediated IL-18 and IL-1β production of macrophages to optimize the anti-tumor function of NK cells via the co-stimulation signaling of 4-1BBL/4-1BB.

A patient-derived hepatocellular carcinoma multicellular spheroid system modeling the tumor microenvironment for drug development and precision medicine

Emilie Crouchet[1], Nuno Almeida[1], Sarah Durand[1], Sara Cherradi[1], Antonio Saviano[1,2], Fabio Giannone[1,2,3], Emanuele Felli[1,2,3], Patrick Pessaux[1,2,3], François H.T. Duong[1], Thomas Baumert[1,2], Catherine Schuster[1]. *[1]Université de Strasbourg, Inserm, Institut de Recherche sur les Maladies Virales et Hépatiques UMR_S1110, Strasbourg, France, [2]Hôpitaux Universitaires de Strasbourg, Service d'hépato-gastroentérologie, Strasbourg, France, [3]Institut hospitalo-universitaire (IHU), Institute for Minimally Invasive Hybrid Image-Guided Surgery, Strasbourg, France*
Email: ecrouchet@unistra.fr

Background and aims: Hepatocellular carcinoma (HCC) is the third leading and fastest rising cause of cancer-related death worldwide. Despite recently approved therapies, the response to treatments remains limited and prognosis of patients with advanced HCC is poor. Preclinical and high-throughput screening of approved drugs or candidate compounds for treatment of HCC is hampered by the absence of tractable model systems recapitulating heterogeneity of HCC tumors and tumor microenvironment.
Method: We established a patient-derived multicellular spheroid model based on liver tumor resections following enzymatic and mechanical dissociation. Cells were grown in 3D in presence of growth factors and autologous patient-derived serum to maintain cell phenotypes. Characterization of the tumorspheroid cellular populations was performed by flow cytometry. As a proof of concept, we treated patient-derived spheroids with FDA approved anti-HCC compounds and assessed treatment response by measuring cell viability and by assessing the effect of drugs on the key signaling pathways by single cell RNA-Seq (scRNA-Seq) and Western blot analysis. Moreover, the 3D tumorspheroid system was used in preclinical proof-of-concept studies to understand the mechanism of action of approved and investigational therapeutics.
Results: The model was successfully established in a highly reproducible manner, independently from the donors and from cancer etiology. The spheroids maintained a high cellular viability during at least 8 days and include epithelial cancer cells as well as all major cell populations that are present in the tumor microenvironment (TME), such as myofibroblasts, immune cells (macrophages and T cells) and endothelial cells. Cell type proportions were variable between spheroids representing the different HCC existing subtypes and patient heterogeneity. We observed differential responses to FDA HCC approved drugs (targeted- and immune-based treatments) between donors. Moreover, treatment response could be correlated to the proportion of the different cell types present in the patient derived spheroids. Finally, using scRNA-Seq we show that the 3D tumorspheroid system enables to study the effect of therapeutics on TME including T cell responses, which offers new perspectives for preclinical drug evaluation compared to the liver organoid model based on epithelial cell differentiation.
Conclusion: Our patient-derived spheroid model may be used to predict clinical treatment response in patients enabling precision medicine. The 3D tumorspheroid system is a powerful tool to monitor anti-tumor treatment responses and uncover the mechanism of action of novel compounds in research and development. Collectively, this model will accelerate clinical translation of personalized liver cancer therapies based on functional screening including the TME.

SAT-238

Liquid biopsy protein biomarkers of cholangiocarcinoma risk, early diagnosis and survival mirroring tumor cells

Email: ainhoa.lapitz@biodonostia.org

Background and aims: Cholangiocarcinoma (CCA), heterogeneous biliary tumors with dismal prognosis, lacks accurate early-diagnostic methods, especially important for individuals at high-risk (i.e., primary sclerosing cholangitis (PSC)). Here, we searched for protein biomarkers in serum extracellular vesicles (EVs).
Method: EVs from patients with isolated PSC (n = 45), concomitant PSC-CCA (n = 44), PSC who developed CCA during follow-up (PSC to CCA; n = 25), CCAs from non-PSC etiology (n = 56), hepatocellular carcinoma (n = 34) and healthy individuals (n = 56) were characterized by mass-spectrometry. Diagnostic biomarkers for PSC-CCA, non-PSC CCA or CCAs regardless etiology (pan-CCAs) were defined and validated by ELISA. Their expression was evaluated in CCA tumors at single-cell level. Prognostic EV-biomarkers for CCA were investigated.
Results: High-throughput proteomics of EVs identified diagnostic biomarkers for PSC-CCA, non-PSC CCA or pan-CCA, and for the differential diagnosis of intrahepatic CCA and HCC, that were cross-validated by ELISA using total serum. Machine learning-based algorithms disclosed CRP/FIBRINOGEN/FRIL for the diagnosis of PSC-CCA (local disease (LD)) vs isolated PSC (AUC = 0.947;OR = 36.9), and when combined with CA19-9, overpowers CA19-9 alone. CRP/PIGR/VWF combination allowed the diagnosis of LD non-PSC CCAs vs healthy individuals (AUC = 0.992;OR = 387.5). Noteworthy, CRP/FRIL accurately diagnosed LD pan-CCA (AUC = 0.941;OR = 89.4). Levels of CRP/FIBRINOGEN/FRIL/PIGR showed predictive capacity for CCA development in PSC before clinical evidences of malignancy. Multi-organ transcriptomic analysis revealed that serum EV-biomarkers were mostly expressed in hepatobiliary tissues, and scRNA-seq and immunofluorescence analysis of CCA tumors showed their presence mainly in malignant cholangiocytes. Multivariable analysis

unveiled EV-prognostic biomarkers, with COMP/GNAI2/CFAI and ACTN1/MYCT1/PF4V associated negatively or positively to patients' survival, respectively.
Conclusion: Serum EVs contain protein biomarkers for the prediction, early diagnosis and prognosis estimation of CCA detectable using total serum, representing a tumor cell-derived liquid biopsy tool for personalized medicine.

SAT-239
Neutrophil degranulation and ageing as potential therapeutic targets in hepatocellular carcinoma?
Daniel Geh[1], Erik Ramon Gil[1], Maja Laszczewska[1], Amy Collins[1], Saimir Luli[1], Rainie Cameron[1], Fiona Oakley[1], Helen Louise Reeves[2,3], Derek A Mann[1], Jack Leslie[1]. *[1]Newcastle University-Newcastle Fibrosis Research Group, Biosciences Institute, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom, [2]Newcastle University-Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom, [3]Freeman Hospital-Hepatopancreatobiliary Multidisciplinary Team, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*
Email: daniel.geh@newcastle.ac.uk

Background and aims: Neutrophils are recognised to play a vital role in hepatocellular carcinoma (HCC) progression through pro-tumour functions such as creating an immunosuppressive tumour microenvironment. This makes them potential therapeutic targets. Aims; 1. To characterise neutrophil phenotype and heterogenicity in HCC using patient samples and an *in vivo* model. 2. Manipulate HCC specific neutrophil changes in our *in vivo* model in order to develop novel neutrophil directed therapies for HCC.
Method: *Patient study.* Circulating neutrophils were isolated from HCC and chronic liver disease patients using density centrifugation. *In vivo model.* C57BL/6J mice underwent orthotopic tumour implantation. Both patient and mouse neutrophils were characterised using flow cytometry and functional assays.
Results: HCC patient blood samples were identified as having an increase in low density (LD) $CD16^{high}$ neutrophils compared to healthy controls. Flow cytometry analysis revealed LD $CD16^{hi}$ neutrophils as being more activated, degranulated and aged compared to normal density (ND) neutrophils as demonstrated by differing expression of CXCR2, CXCR4, CD11b, CD62L, CD10 and CD66b. In addition, LD $CD16^{hi}$ neutrophils expressed markers associated with pro-tumour neutrophils such as CD36 and LOX-1. Tumour bearing mice also developed an increase in LD neutrophil frequency compared to controls with their phenotypic features being highly conserved compared to human. Functionally LD neutrophils were less phagocytic, had reduced migration to CXCL2 and had increased basal reactive oxygen species (ROS) production but a blunted stimulated ROS response further supporting them as being aged and degranulated neutrophils. This highlights circulating LD neutrophils and neutrophil ageing and degranulation as potential therapeutic targets. We used TGF-β and JAK2/STAT3 inhibition in our in vivo model in order to test this. ALK5 (TGF-β receptor 1) inhibition failed to significantly impact tumour burden however did significantly reduce the frequency of circulating LD neutrophils, increase the frequency of tumour associated neutrophils and increase CD62L expression indicating reduced ageing/degranulation (figure 1a–f). JAK2 inhibition significantly reduced tumour burden and altered neutrophil phenotype with an increase in neutrophil CD62L expression (figure 2a–d).

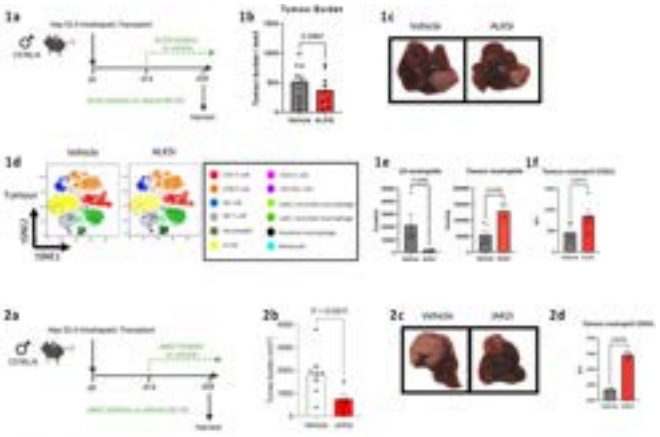

Figure:

Conclusion: We have identified an increase in frequency of circulating LD neutrophils with a degranulated, aged and pro-tumour phenotype in HCC that are highly conserved between HCC patients and tumour bearing mice. Inhibition of the TGF-β and JAK2/STAT3 pathway using ALK5 and JAK2 inhibitors resulted in alterations of neutrophil phenotype suggesting reduced degranulation and ageing. Further studies investigating these therapeutic agents in combination with immune checkpoint inhibitors is warranted.

SAT-240
Carbohydrate restriction inhibits tumor progression in a hepatocellular carcinoma mouse model
Merve Erdem[1], Sraddha Bharadwaj[2], Ana Izcue[2], Frank Schaap[3], Eray Sahin[4], Thorsten Cramer[1]. *[1]University Hospital RWTH Aachen, Molecular Tumor Biology, Department of General, Visceral and Transplantation Surgery, Aachen, Germany, [2]University Hospital RWTH Aachen, Institute of Molecular Medicine, Aachen, Germany, [3]Maastricht University, Department of Surgery, NUTRIM School of Nutrition and Translational Research in Metabolism, Netherlands, [4]Acibadem Mehmet Ali Aydinlar University, Department of Biostatistics and Medical Informatics, School of Medicine, Turkey*
Email: merdem@ukaachen.de

Background and aims: Hepatocellular carcinoma (HCC) is characterized by robust therapy resistance and poor prognosis. Dietary approaches and modifications are actively investigated regarding their impact on tumor metabolism and potential inhibitory effects on cancer progression. Dietary carbohydrate restriction (DCR) is considered to have an anti-tumor effect, conceivably due to the reduced glucose supply to cancer cells. We investigated different DCR approaches in a therapy-resistant HCC mouse model to analyze the effect of dietary carbohydrate restriction on tumor growth.
Method: We used a transgenic mouse model of hepatocellular carcinoma (HCC), termed ASV-B. These mice develop HCC via the T oncogene of SV40. In this study, ASV-B mice were placed under two different DCR regimens, precisely a "low carb high fat" (LCHF, ketogenic diet) and a "low carb high protein" (LCHP) chow. The consequences of the different DCR approaches on the composition of the tumor immune microenvironment, bile acids in blood and the gut microbiome were analyzed.
Results: Both DCR approaches significantly reduced tumor growth in ASV-B mice. However, the effect of LCHF and LCHP diets were variable in subsequent analyses, suggesting different underlying molecular mechanisms for the tumor-inhibiting effects. In the tumor microenvironment, the ketogenic diet resulted in significant accumulation of interleukin-17-producing lymphocytes, while no such observation was made in the LCHP diet group. In this group, on the other hand, enhanced oxidative stress was observed in tumor cells, contrary to LCHF diet feeding. In line, the anti-oxidant N-acetyl cysteine reversed the tumor-inhibiting effect of LCHP diet but not of LCHF diet. The

systemic effects of diet application were further investigated at different levels. In the gut microbiome, carbohydrate restricted-diet highly modified the bacterial composition, where fat and protein content had modest impact. Additionally, bile acid composition also changed upon diet even though total bile acid amount was not significantly affected.

Conclusion: The effect of dietary intervention is especially intriguing due to the fact that ASV-B mice demonstrate resistance to various therapeutic approaches, e.g. sorafenib and conventional chemotherapy drugs such as etoposide and doxorubicin. These results also suggest that macronutrient composition, especially carbohydrate availability, is crucial for murine HCC progression. With the safe use of diets in the clinical application, dietary interventions may provide a promising approach especially in the adjuvant setting.

SAT-241

Efficacy of HBV-TCR T cell therapy to eliminate circulating HBV-HCC cells in immunosuppressed whole blood

Meiyin Lin[1,2], Sebastian Chakrit Bhakdi[3,4], Damien Tan[2], Andrea Pavesi[2,5], Joycelyn Lee[6,7], David Tai[6,7], Antonio Bertoletti[1,8], Anthony Tan[1]. *[1]Duke-NUS Medical School, Emerging Infectious Diseases, Singapore, Singapore, [2]Institute of Molecular and Cell Biology (IMCB), Singapore, Singapore, [3]Mahidol University, Department of Pathobiology, Faculty of Science, Bangkok, Thailand, [4]X-ZELL Biotech Pte Ltd., Singapore, Singapore, [5]National University of Singapore, Mechanobiology Institute, Singapore, [6]National Cancer Centre Singapore, Division of Medical Oncology, Singapore, Singapore, [7]Duke-NUS Medical School, Oncology Academic Programme, Singapore, Singapore, [8]Agency for Science, Technology and Research (A*STAR), Singapore Immunology Network, Singapore, Singapore*
Email: anthony.tan@duke-nus.edu.sg

Background and aims: Recurrence of Hepatitis B virus-related hepatocellular carcinoma (HBV-HCC) after liver transplant (LT) is mediated by circulating tumour cells (CTCs) and exacerbated by the immunosuppression required to prevent graft rejection. In a murine model of HBV-HCC, we have shown the ability of HBV-TCR T cells to prevent HCC cell seeding and subsequent tumour development, demonstrating its potential use in a prophylactic setting. However, it is unclear whether HBV-targeting T cell therapy can eliminate HBV-HCC CTCs in the blood of immunosuppressed liver-transplanted patients.

Method: Here we first developed a microscopy-based assay to quantify CTCs in whole blood. The assay was then utilised to evaluate the cytolytic ability of our previously developed immunosuppressive drug-resistant HBV-TCR T cells (IDRA HBV-TCR) against HBV-HCC CTCs by quantifying the number of spiked HepG2.215 (an HCC cell line) targets recovered after an overnight culture with whole blood containing autologous IDRA HBV-TCR T cells in the presence of Tacrolimus and MMF to mimic the immunosuppressive peripheral blood of LT patients.

Results: Using 6 HCC cell lines (HepG2.2.15, Hep3B, SNU354, SNU368, SNU387 and SNU475) and the peripheral blood of patients with advanced metastatic liver cancer (n = 5), we optimised and validated an immunofluorescence panel containing seven markers: pan-Cytokeratin, vimentin, glypican-3, alpha-fetoprotein, CD34, CD45 and DRAQ5, that can effectively differentiate HCC-CTCs from immune cells. In the presence of immunosuppressants, conventional HBV-TCR T cells had reduced effector function while IDRA HBV-TCR T cells were robustly activated by the spiked HCC cells to produce TNFα and IFNγ. More importantly, we observed a dose-dependent clearance of spiked HepG2.215 targets with a reduction of 60–80% of the targets using 20,000 IDRA HBV-TCRT cells/ml of blood.

Conclusion: Our results demonstrate the ability of IDRA HBV-TCR T cells to effectively eliminate HBV-HCC CTCs in the presence of immunosuppressive drugs and support their use as prophylaxis against HCC relapse after LT.

Email: yongyinli@foxmail.com

Background and aims: Drug resistance of hepatocellular carcinoma (HCC) is primarily attributed to cancer stem cells (CSCs). RBCK1, a component of linear ubiquitin chain assembly complex, has been reported to participate in the progression of HCC; however, its role and the underlying mechanisms in regulating the therapeutic response of HCC remain poorly understood. Herein, we investigated the role of RBCK1 in regulating sorafenib resistance and the CSC properties of HCC.

Method: The association between RBCK1 expression and the therapeutic response was evaluated by half-maximal inhibitory concentration of sorafenib and patient-derived xenografts models. The role of RBCK1 in promoting sorafenib resistance and the CSCs properties of HCC was investigated *in vitro* and *in vivo*. The underlying mechanism of RBCK1 in regulating Numb/Notch1 axis was explored using mass spectrometry, co-immunoprecipitation and western blot.

Results: Upregulated RBCK1 expression was associated with sorafenib resistance in HCC patients and mouse models. Functional studies revealed that RBCK1 promoted sorafenib resistance of HCC cells independently of its ubiquitin ligase activity, and acted as an oncogene that sustained the CSC properties of HCC. Gene set enrichment analysis and serials of assays confirmed that Notch1 signaling was necessary for RBCK1 mediated sorafenib resistance and CSC properties of HCC. Notably, RBCK1 competed with Notch1 for Numb binding, thereby impairing Numb-mediated Notch1 lysosomal degradation, but exerted no significant effects on Numb ubiquitin degradation. Further study indicated that the A64 and Q65 residues of RBCK1 were proven as the key pockets for the oncogenic effects by forming hydrogen bonds with K78 residue of Numb.

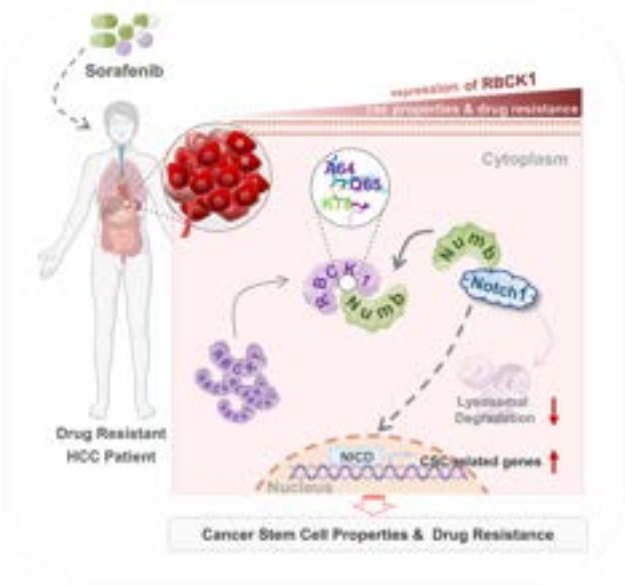

Figure:

Conclusion: RBCK1 is critical in promoting CSC properties of HCC to drive sorafenib resistance through Notch1 signaling, independently of its ubiquitin ligase activity. Our study highlights that RBCK1 is a potential target to reverse sorafenib resistance of HCC, and pave the way for RBCK1-targeted drugs development.

SAT-243

Pegozafermin inhibits NASH-induced hepatocellular carcinoma in the STAM™ mouse model

Maya Margalit[1], Moti Rosenstock[1], Leo Tseng[2], Taishi Hashiguchi[3], Yuka Shirakata[3], Hank Mansbach[2]. *[1]89bio Inc., Rehovot, Israel, [2]89bio Inc., San Francisco, CA, United States, [3]SMC Laboratories Inc., Japan*
Email: mayamargalitmd@gmail.com

Background and aims: Pegozafermin (PGZ), a long-acting glycoPEGylated recombinant human FGF21 analog, led to marked histological and other liver-related benefits, as well as cardiometabolic benefits, with favorable safety and tolerability, in a Phase 1b/2a study in NASH. PGZ does not activate FGFR4, and is not mitogenic. NASH- associated HCC, previously viewed as a complication of cirrhotic NASH, is increasingly diagnosed in pre-cirrhotic NASH. In the STAM™ model, which recapitulates the human NASH-HCC sequence; HCC appears at ~16 weeks of age and develops universally at ~20 weeks of age. In HCC prevention studies in this model, treatment typically begins between 6 and 12 weeks of age. PGZ led to significant improvements in features of NASH, including liver histology, liver transaminases and various metabolic parameters in STAM™ mice. The objective of this study was to evaluate its effect on development of HCC in this model.
Method: STAM™ mice (12 or 13 weeks old, male, N = 20 per group) were treated by vehicle, pegozafermin (previous name BIO89-100), (0.3 mg/kg, 1.0 mg/kg or 3.0 mg/kg) 3 times a week or a positive control, sorafenib (30 mg/kg once daily) for 9 weeks, starting at Week 12 (N = 16 per group) or Week 13 (N = 4 per group). Sorafenib slows tumor progression and decreases tumor burden in HCC mouse models. All surviving animals were sacrificed at 20 or 21 weeks of age. At time of sacrifice, number of surviving animals, liver weight, liver weight/body weight ratio and the number of visible tumor nodules on the surface of the liver in surviving mice were assessed.
Results: PGZ led to a dose-dependent decrease in the number of macroscopic tumor nodules; the mean (± SD) number of visible tumor nodules per mouse was 9 ± 7, 10 ± 4, 7 ± 4, 2 ± 2 and 5 ± 4 in the vehicle, PGZ 0.3 mg/kg, PGZ 1.0 mg/kg and sorafenib groups, respectively (Figure 1; $p < 0.05$ for PGZ 3 mg/kg). A decrease in liver weight and liver/body weight ratio was observed in PGZ-treated animals; mean liver weight and liver/body weight ratios were 2391 ± 473 mg and 9.6 ± 2.2; 2498 ± 1120 mg and 11.0 ± 4.6; 1802 ± 391 mg and 7.8 ± 1.7; 1252 ± 210 mg and 6.2 ± 1.1; and 2013 ± 916 mg and 8.4 ± 3.8 for the vehicle, PGZ 0.3 mg/kg, PGZ 1.0 mg/kg and sorafenib groups, respectively ($p < 0.05$ for liver weight and liver/body weight ratio for PGZ 3 mg/kg). Survival was 4/20, 4/20, 9/20, 8/20 and 12/20 in the vehicle, PGZ 0.3 mg/kg, PGZ 1.0 mg/kg and sorafenib groups, respectively; effect on survival was not statistically significant with either PGZ or sorafenib treatment.

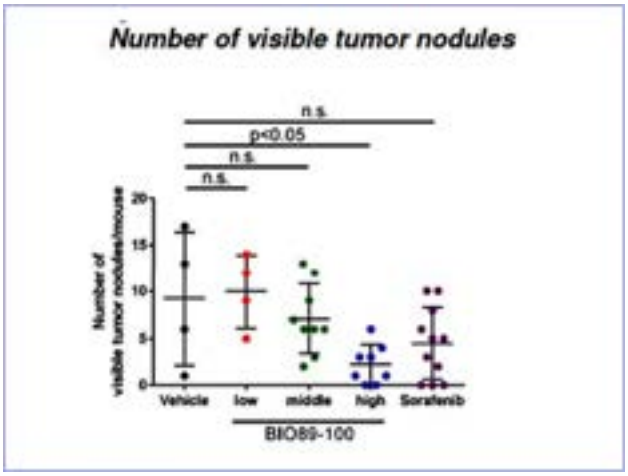

Figure: Number of visible tumor nodules in STAM™ male mice treated with vehicle, pegozafermin or sorafenib

Conclusion: In STAM™ mice, PGZ treatment led to a decrease in the development of HCC tumor nodules and tumor burden, that was comparable to that achieved with sorafenib. These data suggest that in addition to its beneficial effects on NASH and fibrosis and significant metabolic benefits, which render PGZ a promising treatment for NASH, should these pre-clinical data translate to human use, reducing the risk of HCC may be an additional benefit of PGZ treatment. The mechanism of this anti-tumor effect remains to be elucidated. PGZ is currently being studied in the ENLIVEN Phase 2b clinical trial in NASH.

SAT-244

Silencing CNNM4 in cholangiocarcinoma inhibits tumoral progression by means of non-canonical ferroptosis

Maria Mercado-Gómez[1], Alvaro Eguilero Giné[1], Miren Bravo[1], Mikel Azkargorta[2,3], Marina Serrano-Macia[1], Naroa Goikoetxea[1], Irene González-Recio[1], Sofia Lachiondo-Ortega[1], Claudia Gil-Pitarch[1], Marta Romero[3,4], Judit Domenech Omella[5], Rubén Rodríguez Agudo[1], Leidy Estefanía Zapata-Pavas[1], Patricia Peña-San Felix[1], Paula Olaizola[3,6], Pedro Miguel Rodrigues[3,6,7], Luis Alfonso Martinez-Cruz[1], Angela Lamarca[8,9], Victor Moreno[10], Jesus Maria Banales[3,6,7,11], Teresa Cardoso Delgado[1], Felix Elortza[2,3], Matías A Avila[3,12], Francisco Javier Cubero[3,13,14], Cesar Augusto Martín[15], Miguel Angel Merlos Rodrigo[16], Diego Calvisi[17], Jose Marin[3,4], María Luz Martínez-Chantar[1,3]. *[1]CIC bioGUNE, Basque Research and Technology Alliance (BRTA), Liver Disease Lab, Derio, Spain, [2]CIC bioGUNE, Basque Research and Technology Alliance (BRTA), Proteomics Platform, Derio, Spain, [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Carlos III National Institute of Health, Madrid, Spain, [4]University of Salamanca, IBSAL, Experimental Hepatology and Drug Targeting (HEVEPHARM) Group, Salamanca, Spain, [5]KU Leuven, Laboratory of Protein Phosphorylation and Proteomics, Dept. Background and aims: Cholangiocarcinoma (CCA) is a heterogeneous neoplasm of biliary ducts that represents the second most common primary hepatic cancer, after hepatocellular carcinoma. Due to its aggressiveness, late diagnosis and immunoregulatory capacity of the disease, CCA outcomes are poor, with a median overall survival of less than 12 months. Currently, the only curative treatment is surgical resection, but this only applies to 25% of cases and despite this tumoral recurrence is frequent. For that reason, the study of new therapies is of utmost importance. Recent studies show that the isocitrate dehydrogenase 1 (*IDH1*) inhibitor, used to treat patients with irresectable iCCA harboring *IDH1* mutations, reduces cell proliferation, invasion and metastasis by promoting, ferroptosis, a programed cell death caused by iron-dependent lipid peroxidation.
Method: In this study, we analyze the role of CNNM4 (*Cyclin and CBS Domain Divalent Metal Cation Transport Mediator 4*), a Mg^{2+} effluxer, that is overexpressed in CCA in *in silico*, at transcriptional levels and also in human biopsies.
Results: Silencing CNNM4 in CCA human cell lines, EGI-1 and TFK-1, which show high expression of CNNM4, not only increases intracellular Mg^{2+} but also reduces cellular proliferation and sensitizes cells to chemotherapeutic drugs. Key metastasis steps (intravasation, extravasation and invasion in other organs) were also slowed down when CNNM4 is silenced, as seen by 3D spheroid experiments and in *ex ovo* and *in ovo* chicken embryo chorioallantoic membrane assay. Proteomic analysis reveals a metabolic shift into a less glycolytic phenotype in CNNM4-silenced cells, also indicating a role of this transporter in the Warburg effect. Alteration of iron metabolism after CNNM4 modulation in both cell lines is associated with a decrease of NUPR-1 levels, a ferroptosis inhibitor, that can be a possible mechanism of those effects. In a CCA murine model (myr-AKT/Yap^{S127A}), silencing CNNM4 after tumoral development, via a liver-specific molecule, produces its reversion.
Conclusion: In conclusion, silencing CNNM4 is a potential therapeutic target in CCA whose effect could be mediated by iron-dependent cell death.

SAT-245
Exploiting RuvBL1 as a target to improve mTOR -driven hepatocarcinogenesis in mice

Alice Guida[1], Irene Simeone[2], Simone Polvani[2], Gabriele Dragoni[2], Elisabetta Ceni[2], Lucia Picariello[2], Andrea Galli[2], Tommaso Mello[2]. *[1]GenOMeC Doctorate, University of Siena, Siena, Italy, Siena, Italy, [2]University of Florence, Department of Clinical and Experimental Biomedical Sciences "Mario Serio", Italy*
Email: tommaso.mello@unifi.it

Background and aims: RuvBL1 belongs to the highly conserved ATPases associated with several cellular activities (AAA^+) including DNA repair, telomerase complex assembly and mTOR pathway activity. It is deregulated in various human cancers and its expression correlates with a worse prognosis in HCC patients. We have previously demonstrated that RuvBL1 haploinsufficiency impairs insulin signalling affecting the PI3K/Akt/mTOR pathway in vivo. Given the relevance of mTOR pathway hyperactivation in HCC, we hypothesized that RuVBL1 genetic targeting could reduce mTOR driven hepatocarcinogenesis in $Pten^{hep-/-}$ mice.
Method: $Pten^{hep-/-}$ and $Ruvbl1^{hep\pm}$ mice were crossed to generate $Pten^{hep-/-}Ruvbl1^{hep\pm}$ mice. The impact of RuvBL1 haploinsufficiency on NASH development was assessed by histology at 12 weeks of age. Metabolic and inflammatory markers were evaluated by qPCR and IHC. mTOR pathway was analysed by WB of liver lysates. PPARalpha transcriptional activity was evaluated by luciferase reporter assay. The identification of RuvBL1-protein interactions was achieved by MS proteomics analysis of RuvBL1 immunoprecipitation. The impact of RuvBL1 haploinsufficiency on HCC development was assessed by multiplicity evaluation of macroscopic tumours and by histological classification by Edmondson-Steiner grading system at 15 months of age.
Results: Oil red, Sirius red and F4/80 staining revealed a significant reduction of steatosis, fibrosis, and inflammation in $Pten^{hep-/-}Ruvbl1^{hep\pm}$ compared to $Pten^{hep-/-}$ mice. Similar mRNA expression of mTOR-driven lipogenic targets was found in the two mice models. However, expression of *Ppara* and its target CPT1 was increased in $Pten^{hep-/-}Ruvbl1^{hep\pm}$, indicating a lipid-lowering action mediated by PPARalpha in this mouse model. Moreover, promoter reporter experiments revealed that inhibition of RuvBL1 activity by CB-6644 increases PPARalpha transcriptional activity in AML-12 hepatocytic cell line. Next, MS proteomics analysis of RuvBL1-IP in murine AML-12 and Hepa1-6 cells revealed that RuvBL1 interacts with members of the lysosomal AMPK complex (V-ATPase, LAMTOR1, LAMTOR4, Rag C). Furthermore, p-AMPK and p-RAPTOR were increased in $Pten^{hep-/-}Ruvbl1^{hep\pm}$ compared to $Pten^{hep-/-}$mice, suggesting a role of RuvBL1 at the interplay between mTOR and AMPK in hepatic lipid metabolism. Finally, $Pten^{hep-/-}Ruvbl1^{hep\pm}$mice aged to 15 months showed better survival than $Pten^{hep-/-}$ which developed significantly more HCC and of higher grade. qPCR analysis showed a significant upregulation of key lipolytic genes, such as *Cpt1a, Acadl, Acadvl* and *Ppara,* in $Pten^{hep-/-}Ruvbl1^{hep\pm}$ at 15 months of age.
Conclusion: RuvBL1 targeting reduces mTOR pathway hyperactivation hampering NASH-HCC progression in $Pten^{hep-/-}$ mice, likely promoting the switch from mTOR-driven lipogenesis to AMPK-induced fatty acid catabolism.

SAT-246
Determination of human polyploid hepatocellular carcinoma by pathological image diagnosis utilizing artificial intelligence

Tomonori Matsumoto[1], Takanori Matsuura[2], Masatoshi Abe[3], Masahiro Kido[4], Hajime Nagahara[5], Eiji Hara[1], Hirohiko Niioka[6], Yoshihide Ueda[2]. *[1]Research Institute for Microbial Diseases, Osaka University, Department of Molecular Microbiology, Suita, Japan, [2]Kobe University Graduate School of Medicine, Division of Gastroenterology, Department of Internal Medicine, Japan, [3]Faculty of Medicine, Osaka University, Japan, [4]Kobe University Graduate School of Medicine, Department of Surgery, Division of Hepato-Biliary-Pancreatic Surgery, Japan, [5]Osaka University Institute for Datability Science, Japan, [6]Graduate School of Information Science and Technology, Osaka University, Department of Information and Physical Sciences, Japan*
Email: tomomatsumoto@biken.osaka-u.ac.jp

Background and aims: Cancer genomic analysis has revealed that a subset of hepatocellular carcinomas (HCCs) are polyploid. Importantly, polyploidy in HCCs has been suggested to be associated with poor prognosis, and polyploidy may serve as a new prognostic marker for HCC. In our previous study, we established a method to assess ploidy in HCC by multicolored fluorescence in situ hybridization (FISH) for chromosomes in formalin-fixed paraffin-embedded (FFPE) sections and showed that polyploid HCC exhibited a worse prognosis after surgical resection than diploid HCC. However, in routine practice, it is difficult to evaluate chromosome duplications in

HCC by FISH, and a simpler method applicable to high-throughput testing is desired. In the present study, we aimed to establish a novel method for determining polyploidy in HCC by developing an artificial intelligence (AI)-based pathological image model.

Method: Whole-slide images of hematoxylin and eosin (HE) staining were captured by a digital slide scanner and divided into small non-overlapping patches for analysis. The ploidy status of 49 HCCs that underwent hepatectomy at our institution between 2017 and 2021 was determined by multicolored FISH for chromosomes, and their HE images were used for training. EfficientNetB0, a convolutional neural network model of deep learning, to determine HCC ploidy was trained, and its usefulness was examined on images derived from 192 HCCs that were not used for training.

Results: We constructed a model to diagnose HCC ploidy, and its area under the receiver operating characteristic curve was 0.931 in cross-validation with training data. In the test dataset, the model identified 76 polyploid HCCs, accounting for 39.6% of cases. Consistent with our previous finding that macrotrabecular-massive (MTM) architectures were significantly more common in polyploid HCCs than diploid HCCs, the prevalence of MTM architecture was significantly higher ($p < 0.05$) in the polyploid HCCs determined by our model than their counterparts. Moreover, polyploid HCCs determined by our model had significantly higher serum alpha-fetoprotein levels, suggesting that this model can efficiently determine polyploid HCCs with aggressive features. Importantly, the polyploid HCCs showed a significantly poorer prognosis than their counterparts, indicating the possible utility of AI-based ploidy classification in the prediction of HCC prognosis.

Conclusion: An AI-based model diagnosing pathological images could determine HCC ploidy and predict a subset of HCC with poor prognosis. Classification of HCC ploidy utilizing AI-based pathological image diagnosis would be a useful new method for HCC practice.

SAT-247

Pediatric liver cancer: Hepatoblastoma and Neddylation post-translational modification

Leidy Estefanía Zapata-Pavas[1], Marina Serrano-Macia[1], Miguel Angel Merlos Rodrigo[2], Patricia Peña-San Felix[1], Claudia Gil-Pitarch[1], Naroa Goikoetxea[1], Hana Michalkova[2], Zbynek Heger[2], Alvaro del Rio[3], Montserrat Domingo-Sàbat[3], Laura Royo[3], Jon Ander Barrenechea-Barrenechea[1], Maria Mercado-Gómez[1], Sofia Lachiondo-Ortega[1], Teresa Cardoso Delgado[1], Dimitris Xirodimas[4], Jose Marin[5,6], Maite G Fernandez-Barrena[6,7], Matías A Avila[6,7], Carolina Armengol[3], María Luz Martínez-Chantar[1,6]. *[1]Center for Cooperative Research in Biosciences (CIC bioGUNE), Basque Research and Technology Alliance (BRTA), Liver Disease Lab, Spain; [2]Mendel University in Brno, Department of Chemistry and Biochemistry, Czech Republic; [3]Germans Trias i Pujol Research Institute (IGTP), Program for Predictive and Personalized Medicine of Cancer (PMPPC), Childhood Liver Oncology Group, Badalona, Spain; [4]Univ. Email: mlmartinez@cicbiogune.es

Background and aims: Hepatoblastoma (HB), although a rare disease, is the most common form of childhood primary liver cancer. Current therapeutic options are limited or inadequate and involve significant side effects; they include surgical resection with chemotherapeutic agents such as cisplatin or doxorubicin. Ongoing research has uncovered molecular, genetic, and epigenetic mechanisms that have expanded the understanding of HB, but it is an open field with many unknowns. The identification of neddylation, a post-translational modification regulated by NEDD8, widely involved in several signalling pathways and in modulation of protein homeostasis, as a mechanism associated with the development of HB, has opened the doors to new therapeutic strategies. In this sense, the implications of this post-translational modification in the tumour context of HB and its modulation as a potential therapy was evaluated.

Method: A cohort of HB patients, preclinical animal model and in vitro model in tumour cells were used to characterise NEDDylation pathway in HB. Besides the modulation of NEDP1 levels using an in vitro approach was made to study cell proliferation, cell cycle, drug resistance, proteome homeostasis, and metabolic status. In vivo, the implications of NEDP1 overexpression in metastatic capability and its tumour suppressor capacity was evaluated.

Results: Transcriptomic analysis of HB patient samples has demonstrated modulation of the neddylation cycle, and NEDD8 levels correlate with the degree of tumour stratification. The preclinical models of HB, as well as the vitro models in tumour cells, shows an increase in NEDD8 and NAE1, related to an increase in global neddylation, in addition to a significant reduction of NEDP1, demonstrating the importance of this process in the development and progression of this pathology. Moreover, the silencing of NEDP1 in human hepatocytes results in a proliferative phenotype. In contrast, its overexpression in HB tumour lines (HepT1 and HepG2) results in the induction of apoptosis, modulation of migratory and proliferative capacity, metabolic reprogramming, sensitization to chemotherapeutic treatments, and regulation of cellular stress mechanisms and immune and inflammatory responses, with an important modulation of proteins such as LIN28. Similarly, its overexpression in patient-derived xenografts (PDX) from a distal metastasis showed modulation of proliferation and migration, in addition to the metabolic reprogramming like the observed in HB tumour lines. In vivo, in Ovo and ex Ovo experiments showed reduced tumorigenicity and decreased metastatic phenotype, and animal models of HB in mice in which NEDP1 overexpression has been carried out showed a reduction in proliferation and tumorigenesis at the histological level, with modulation of some key proteins like HOOK2.

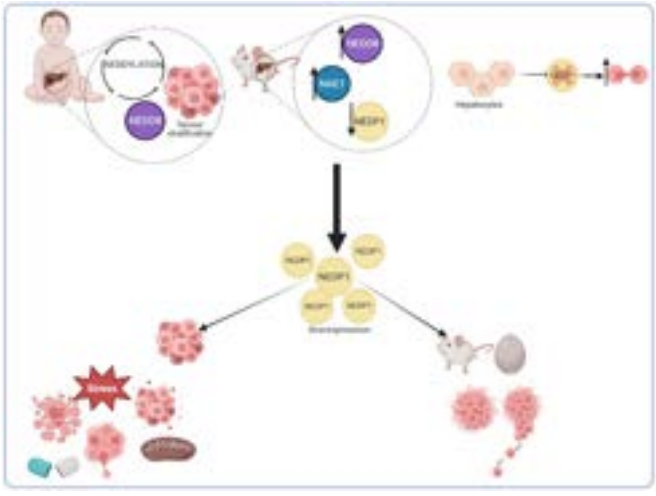

Figure:

Conclusion: Therefore, it is noteworthy that the effect observed with NEDP1 overexpression points to the importance of post-translational modifications in pathologies such as HB and highlights the relevance of neddylation, not only in the molecular characterization of HB, but also in the development of new specific treatments.

Chromosome engineering and CRISPR-Cas9 viability screening reveals increased metastatic capacity targetable by patient-specific synthetic lethality

Thorben Huth[1], Emely Dreher[1], Steffen Lemke[2], Sarah Fritzsche[1], Raisatun Sugiyanto[1], Darko Castven[3], David Ibberson[4], Carsten Sticht[5], Eva Eiteneuer[1], Anna Jauch[6], Stefan Pusch[7], Thomas Albrecht[1], Benjamin Goeppert[1], Jens Marquardt[3], Sven Nahnsen[2], Peter Schirmacher[1], Stephanie Roessler[1]. *[1]Institute of Pathology, University Hospital Heidelberg, Germany, [2]Quantitative Biology Center (QBiC), University of Tübingen, Germany, [3]Department of Medicine I, University Medical Center Schleswig Holstein, Germany, [4]Deep Sequencing Core Facility, University of Heidelberg, Germany, [5]NGS Core Facility, Medical Faculty Mannheim, Germany, [6]Institute of Human Genetics, University of Heidelberg, Germany, [7]Department of Neuropathology, University Hospital Heidelberg, Germany*
Email: stephanie.roessler@med.uni-heidelberg.de

Background and aims: Chromosomal aberrations are a frequent event in a majority of tumor entities and a hallmark of cancer. In hepatocellular carcinoma (HCC), chromosome 8p (chr8p) loss of heterozygosity (chr8pLOH) can be foundis overserved predominantly and is correlated with poor overall patient survival. However, no single chr8p tumor suppressor gene reveals strong pro-tumorigenic effects and can account for the increased mortality alone. Given the extent and complexity of chr8pLOH, this suggests that co-suppression of multiple genes can concomitantly promote tumor growth.
Method: In this study, we use chromosomal engineering and CRISPR-Cas9 viability screens to investigate the effects of concurrent loss of multiple chr8p genes. Chromosomal deletions were introduced by a dual guide CRISPR-Cas9 approach. Single cell clones with chr8pLOH were obtained by FACS sorting. PCR, Sanger Sequencing, fluorescence in situ hybridization (FISH) and RNA sequencing (RNAseq) were used to validate effective chr8p deletions. Functional effects were analyzed by viability, proliferation, migration and invasion assays. Gene dependencies were investigated by genome-wide CRISPR-Cas9 screens in chr8pLOH clones and validated by RNAi-mediated knockdown.
Results: Chromosomal deletions were introduced into different HCC cell lines and stable single clones with chr8pLOH were obtained. PCR, FISH and sequencing confirmed loss of heterozygosity in single cell clones. Genome-wide mRNA abundance was significantly altered and gene set enrichment revealed deregulations in migration and tumor microenvironment. Metastasizing potential of chr8pLOH cells was further investigated in vitro and in vivo and goes in line with increased patient mortality. Subsequently, several metastasis suppressor genes were identified on chr8p in an RNAi migration screen. In addition, by performing a genome-wide knockout screen, we discovered and independently validated dependencies specific for chr8pLOH patients with decreased survival. These include novel synthetic lethality of the Nudix hydrolase NUDT17 in chr8pLOH cells but not in wildtype cells.
Conclusion: We developed a new approach and cell model to study large scale genomic aberrations and chr8pLOH in cancer. State-of-the-art genomic technologies were integrated to explain increased patient mortality by the loss of cooperating metastasis suppressors. Extending the view to patient treatment, we identified novel synthetic lethalities as potential targets and therapeutic options in patients with chr8pLOH.

SAT-249

Expression and role of the metabotropic glutamate receptor type 3 in hepatocarcinoma

Isabel Méndez[1], Andy Hernández-Abrego[1], Ana Cristina García-Gaytán[1], Dalia De Ita-Pérez[1], Ericka de los Ríos-Arellano[1], Isaías Turrubiate[1], Emanuel Gámez[2], Mauricio Díaz-Muñoz[1]. *[1]UNAM Institute of Neurobiology, Querétaro, Mexico, [2]Centro Médico Nacional de Occidente, Instituto Mexicano del Seguro Social, Mexico*
Email: isabelcm@unam.mx

Background and aims: Glutamate acts on metabotropic glutamate receptors (mGluRs) to exert a variety of regulatory effects through the recruitment of second messengers. It has been demonstrated that mGluRs are expressed in various types of cancer cells and contribute to cancer development, such as increased proliferation and metastasis. mGluR type 3 (mGluR3) is a seven transmembrane Gi-protein coupled receptor that inhibits cAMP, and it could positively regulate the pro-inflammatory cytokine interleukin 6 via the transcription factor NF-kappa B. We aim to evaluate the expression of mGluR3 and the glutamate transporter xCT, which exports glutamate from the cell, in hepatocarcinoma (HCC) induced by DEN in rats and the role of the mGluR3 on survival through cAMP and NF-kappa B in the HCC-derived cell line HepG2.
Method: Male Wistar rats received weekly intraperitoneal injections of diethylnitrosamine (DEN- 50 mg/kg body weight) to induce the progressive pathologies fibrosis, cirrhosis, and HCC. Control rats received saline solution at the same intervals. Histopathological and biochemical analyses were achieved to corroborate the establishment of each pathology. Intrahepatic glutamate concentrations were evaluated using a commercial kit. Expression of mGluR3 and xCT mRNA was analyzed in tissue samples by RT-qPCR. Expression of mGluR3 protein was analyzed on cells (HepG2 and C9 normal hepatocytes cell line) by Western Blot and immunocytochemistry. The effect of the activation of mGluR3 was analyzed under the treatment with glutamate or the selective agonist LY354740, in the presence or the absence of the selective antagonist LY341495 in HepG2. Live and dead cells were quantified by tripan blue assay. cAMP generation and translocation of NF-kappa B to the nucleus were analyzed by immunocytochemistry. Activation of NF-kappa B was evaluated using the inhibitor BAY 11-7082.
Results: Overexpression of mGluR3 was observed according to the progression from normal condition to HCC in rats. This observation was corroborated in HepG2 compared to C9 normal hepatocytes. Both, intrahepatic glutamate and xCT expression increased in HCC. The activation of mGluR3 by glutamate and by the mGluR3 agonist inhibited intracellular cAMP induced by forskolin. Glutamate and the mGluR3 agonist increased live cells in a dose-dependent manner and did not affect cellular death. This effect over the live cells was reverted by the mGluR3 antagonist and by the NF-kappa B inhibitor. Cell death was increased in the presence of the mGluR3 antagonist and the NF-kappa B inhibitor.

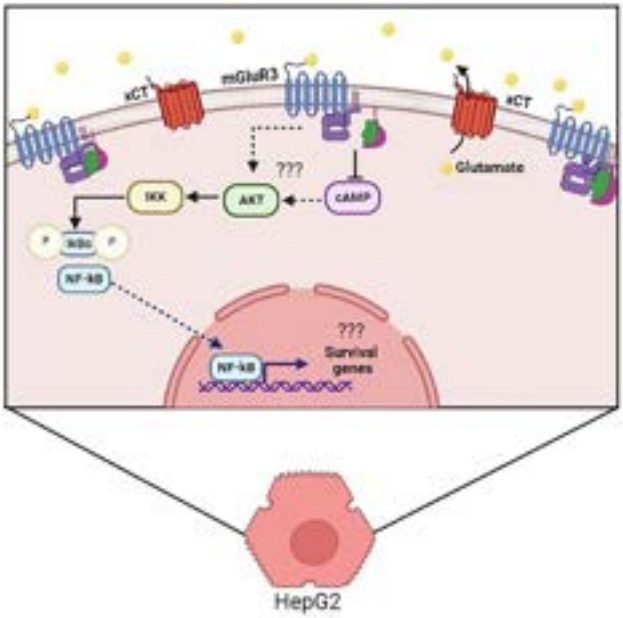

Figure: A suggested mechanism in which mGluR3 could contribute to hepatocarcinoma cell survival

Conclusion: Our data demonstrate that mGluR3 and the transporter xCT are overexpressed in HCC. Moreover, mGluR3 has a role in the survival of HCC cells by inhibiting cAMP and activating the NF-kappa B pathway. This study suggests that the overexpressed mGluR3 could be activated by the enhanced glutamate exported to the extracellular milieu by xCT and may contribute to the survival of HCC. As well, mGluR3 could serve as a possible biomarker and therapeutic target in this pathology.

The rs72613567: TA polymorphism in hydroxysteroid 17-beta dehydrogenase 13 (HSD17B13) is associated with survival benefit after development of hepatocellular carcinoma

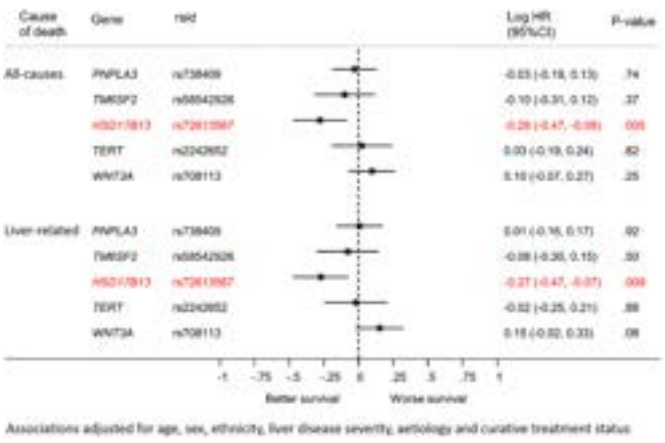
Hamish Innes[1], Marsha Morgan[2], Felix Stickel[3], Jochen Hampe[4], Stephan Buch[4]. [1]*Glasgow Caledonian University, School of Health and Life Sciences, Glasgow, United Kingdom,* [2]*University College London, UCL Institute for Liver and Digestive Health, London, United Kingdom,* [3]*University Hospital of Zurich, Department of Gastroenterology and Hepatology, Zurich, Switzerland,* [4]*University Hospital Dresden, TU Dresden, Medical Department 1, Dresden, Germany*
Email: stephan.buch@uniklinikum-dresden.de

Background and aims: Genetic risk factors play an important role in determining the susceptibility to develop hepatocellular carcinoma (HCC) in people with chronic liver disease. It is unclear whether these same genetic risk factors influence survival following diagnosis. This study aimed to determine whether genetic polymorphisms influencing susceptibility to HCC are also associated with HCC prognosis.

Method: United Kingdom (UKB) Biobank participants diagnosed with HCC after study enrolment were included. The primary outcome event was all-cause mortality. Patients were followed from the date of HCC diagnosis to death or the registry completion date. Five HCC susceptibility polymorphisms were considered: rs738409 (*PNPLA3*), rs58542926 (*TM6SF2*); rs72613567 (*HSD17B13*); rs2242652 (*TERT*) and rs708113 (*WNT3A*). Non-HCC UKB participants (n = 467,673) served as controls. Cox regression was used to determine the independent association between these genetic loci and HCC mortality risk. All associations were adjusted for age, sex, ethnicity, aetiology and severity of the underlying liver disease and receipt of curative HCC treatment.

Results: The final sample included 439 participants (mean [±1SD] age 69.2 ± 6.9 years; men 77.5%; white British ancestry 84.3%); non-alcohol-related fatty liver disease (NAFLD) was the most common underlying liver disease (41%) followed by alcohol-related liver disease (33%) and chronic viral hepatitis (11%). Patients were followed for a median of 1.9 years; a total of 321 patients died. Of the 321 deaths, 295 (92%) were 'liver-related' deaths, of which 235 were attributed to HCC and 60 to liver-disease per se. The median time to death from all-causes was 1.30 years (95%CI: 0.89–1.59). Kaplan Meier survival estimates at 1, 3 and 5 years were 53.2%, 31.2%, and 22.6%, respectively. In multivariate analysis, rs72613567:TA (*HSD17B13*) was associated with a significant reduction in both overall mortality (aHR:0.75; 95%CI:0.63–0.92; p = 0.005) and liver-related mortality risk (aHR: 0.76; 95%CI: 0.63–0.93; p = 0.009); no other genetic associations with mortality risk were identified (Figure 1). Treatment of HCC with curative intent was also associated with a significant reduction in mortality risk (aHR: 0.25; 95%CI: 0.17–0.37; p < 0.001) while Baveno 3–4 staging was associated with an increased risk (aHR: 1.65; 95%CI:1.06–2.59; p = 0.03).

Figure 1. association between genetic variants and mortality risk.



Associations adjusted for age, sex, ethnicity, liver disease severity, aetiology and curative treatment status

Conclusion: The rs72613567 polymorphism in *HSD17B13* is not only associated with a reduction in the risk of developing HCC but is associated with survival benefit in HCC once established. HSD17B13 might be a potential therapeutic target for HCC prevention and outcome.

Selective inhibition of human β-catenin DNA transactivation activity using splice switching oligonucleotides for an improved therapeutic window in treating hepatocellular carcinoma

Jin Hong[1], Vera Huang[1], Laxman Eltepu[1], Hua Tan[1], Vivek Rajwanshi[1], Aneerban Bhattacharya[1], Elen Rosler[1], Kang Hyunsoon[1], Min Luo[1], Saul Montero[1], John Cortez[1], Dana Cho[1], David Smith[1], Lawrence Blatt[1], Julian Symons[1], Leonid Beigelman[1]. [1]*Aligos Therapeutics, South San Francisco, United States*
Email: jhong@aligos.com

Background and aims: Wnt/β-catenin plays a critical role in embryonic development, tissue homeostasis and repair after injury. Aberrations in this pathway are implicated in many human diseases including cancers. Dysregulation of the Wnt/β-catenin pathway may play a key role in the pathogenesis of HCC. Reducing β-catenin by siRNAs or ASOs in an HCC mouse model has shown significant inhibition of liver tumor growth. Due to the importance of Wnt/β-catenin in normal cellular function, many drugs targeting this pathway have failed due to toxicity. We designed splice switching oligonucleotides (SSO) targeting the DNA transactivation domain of β-catenin to reduce the downstream proteins responsible for HCC

development, while leaving intact the domains interacting with α-catenin and E-cadherin that are important for cell adhesion.
Method: The HepG2 Topflash cell line was used to assay the SSO inhibition of β-catenin transcriptional activity. Anti-proliferative assays with SSO were carried out in Huh-6, HepG2 and Hep3B cell lines using CellTiterGlow. SSO effects on different regions of the β-catenin transcript were analysed by qPCR or Western blot. Effects of SSO on downstream gene expression such as c-Myc, CCND1 and AXIN2 were analysed by qPCR. SSO in vivo efficacy (10 × 15 mg/kg or 10 × 30 mg/kg, SC, QOD) was carried out in a Hep3B-luc orthotopic mouse model with the positive control sorafenib (20 × 60 mg/kg, PO, QD).
Results: A lead SSO, ALG-135041 inhibited the transcriptional activity of β-catenin with an EC_{50} of 4.1 nM in the HepG2 TopFlash cell line. In the Huh-6 cell line, ALG-135041 reduced the 3′ transcript while maintaining the 5′ transcript. After a 72-hour treatment in Huh-6, ALG-135041 significantly reduced c-Myc, CCND1 and AXIN2 as measured by qPCR. Western blot with an N-terminal β-catenin antibody showed a truncated protein of ~81 kD in ALG-135041 treated Huh-6 cells. In three cell lines used in the orthotopic HCC mouse model, HepG2, Hep3B and Hep3B-Luc, the anti-proliferative EC_{50} values were 142, 86 and 119 nM respectively. In the Hep3B-luc orthotopic mouse model, ALG-135041 showed a dose response with the high dose group achieving tumor growth inhibition (TGI) of 66% by bioluminescence and 84% by tumor weight at the end of study, similar to the results of sorafenib group. There was no difference in body weight between the high dose of ALG-135041 and the vehicle group, while the sorafenib group lost significant body weight. When compared with representative β-catenin siRNAs or ASOs, ALG-135041 demonstrated a significantly better therapeutic window.
Conclusion: ALG-135041, a human β-catenin SSO, selectively inhibits DNA transactivation activity in the nucleus and showed a better therapeutic window than either siRNAs or ASOs. We therefore significantly improved the therapeutic window by precision targeting of only the disease-causing region of the multifunctional protein β-catenin.

SAT-252

Ductular reaction is mediated by CD24 and regulated by miR-122

Nofar Rosenberg[1], Matthias Van Haele[2], Maytal Gefen[1], Tomer Freemann[1], Tania Roskams[2], Rifaat Safadi2[3], Hilken Marko[4], Christoph Schramm[4], Hilla Giladi[1], Mathias Heikenwalder[5], Eithan Galun[1]. *[1]The Goldyne Savad Institute of Gene and Cell Therapy, Jerusalem, Israel, [2]University of Leuven, Department of translational cell and tissue Research, Leuven, Belgium, [3]Hadassah Hebrew University Hospital, The Liver Institute, Israel, [4]University Medical Center Hamburg-Eppendorf, Dept. of Medicine and Martin Zeitz Center for Rare Diseases, Germany, [5]DFKZ, chronic Inflammation and Cancer, Ghana*
Email: nofar.ros@gmail.com

Background and aims: Ductular Reaction (DR) is associated with chronic liver inflammations, liver fibrosis and presides liver cancer development. DR is characterized by cholangiocytes and hepatic progenitor cells (HPCs) proliferation. CD24, (a marker of HPC) is expressed on cholangiocytes in DR and is overexpressed in HCC and in combined-mixed HCC-Cholangiocarcinoma (CCA). CD24 is essential for self-renewal, proliferation, migration, invasion, and drug resistance of HCC and HCC-CCA tumors through activation of pSTAT3. However, the mechanism of DR is still unknown. We aimed to determine the molecular mechanism regulating DR.
Method: We analyzed bioinformatic data of clinical samples from human with chronic liver diseases as well as samples from mice with acute and chronic liver diseases. We performed transcriptomic investigations including single cell analysis. We have generated numerous genetically modified cell lines and we generated a miR-122 KO mice and we also used the CD24 KO mice model.
Results: Our bioinformatic analysis revealed that CD24 is a target gene of the liver-specific miR-122, which we have also proven by numerous *in vitro* studies both for the human and mouse miR-122 and CD24. A significant negative correlation was found between CD24 and miR-122 in livers of four human clinical diseases manifesting DR, including CAH, PBC, NASH and PSC. In addition, we identified a strong negative correlation between CD24 and miR-122 in a set of human HCC samples. Similarly, we observed a negative correlation between miR-122 and CD24 in a mouse model of acute and chronic liver inflammation. Our *in-vitro* studies showed that over-expression of CD24 resulted with increased cell proliferation via pSTAT3 protein. *In vitro*, HCC cell proliferation was attenuated upon miR-122 supplementation only in cells with CD24 bearing an authentic miR-122 seed at its 3′-UTR but was not attenuated when the miR-122 seed was mutated. In miR-122 KO mice, CD24 expression increases significantly, and DR is enhanced.
Conclusion: DR is mediated by CD24 expression and regulated by miR-122.

SAT-253

Hepatitis B surface antigen impairs endoplasmic reticulum stress-related autophagic flux via down-regulation of LAMP2, thereby participating in hepatocarcinogenesis

Yaojie Liang[1], Stefan Schefczyk[1], Xufeng Luo[1,2], Lorraine Muungani[1], Baoju Wang[3], Hui Deng[3], Hideo Baba[4], Mengji Lu[5], Heiner Wedemeyer[6], Hartmut Schmidt[1], Ruth Broering[1]. *[1]University of Duisburg-Essen, Dept of Gastroenterology, Hepatology and Transplant Medicine, Germany, [2]The Affiliated Cancer Hospital of Zhengzhou University, Institute for Lymphoma Research, China, [3]Huazhong University of Science and Technology, Union Hospital, Tongji Medical College, China, [4]University Duisburg-Essen, Institute of Pathology, Germany, [5]University Duisburg-Essen, Institute for Virology, Germany, [6]Hannover Medical School, Dept. of Gastroenterology, Hepatology and Endocrinology, Germany*
Email: ruth.broering@uni-due.de

Background and aims: Hepatitis B virus surface antigen (HBsAg) drives hepatocarcinogenesis. Factors and mechanisms being involved in this progression remain poorly defined, thus hindering the development of effective therapeutic strategies. Therefore, mechanisms involved in HBsAg-induced transformation of normal liver into hepatocellular carcinoma were explored.
Method: Hemizygous Tg (Alb1HBV)44Bri/J mice were investigated for this HBsAg-driven carcinogenic events by data mining, western blotting, immunohistochemical and immunocytochemical staining. Findings were verified in HBsAg-overexpressing Hepa1-6 cells and validated in human liver specimens.
Results: Gene set enrichment analysis identified significant signatures in HBsAg-transgenic mice correlating with endoplasmic reticulum (ER) stress, unfolded protein response (UPR), autophagy, and proliferation. These events were further investigated in 2-, 8- and 12-month-old HBsAg-transgenic mice. Increased BiP expression in HBsAg-transgenic mice indicated induction of UPR. Furthermore, in HBsAg-transgenic mice, autophagy was enhanced at the early stage (increased BECN1 and LC3B) and blocked at the late stage (increased p62). Finally, HBsAg changed lysosomal acidification by down-regulating LAMP2 expression. In patients, HBV-related HCC and adjacent tissue showed increased BiP, p62 and down-regulated LAMP2, compared to uninfected controls. *In vitro*, use of ER stress inhibitors reversed the HBsAg-related suppression of LAMP2. Furthermore, HBsAg promoted hepatocellular proliferation, indicated by I) Ki67, AFP and cleaved caspase 3 staining in paraffin-embedded HBsAg-transgenic mice liver sections and II) colony formation assay in HBsAg-expressing Hepa1-6 cells. Interestingly, ER stress inhibition in HBsAg-overexpressing Hepa1-6 cells suppressed HBsAg-mediated cell proliferation.
Conclusion: These findings revealed that HBsAg directly induces ER stress, impairs autophagy and promotes proliferation thereby driving hepatocarcinogenesis. Moreover, this study expanded the understanding of HBsAg-mediated intracellular events in carcinogenesis.

SAT-254

RuvBL1 is required for mitochondrial integrity and supports the metabolic reprogramming of HCC cells

Irene Simeone[1], Alice Guida[1,2], Simone Polvani[1], Elisabetta Ceni[1], Daniele Bani[3], Patrizia Nardini[3], Daniele Guasti[3], Massimo Bonora[4], Alice Santi[1], Andrea Galli[1], Tommaso Mello[1]. *[1]University of Florence, Experimental and Clinical Biomedical Sciences, Italy, [2]University of Siena, GenOMeC Doctorate, Italy, [3]University of Florence, Clinical and Experimental Medicine, Italy, [4]University of Ferrara, Department of Medical Sciences, Italy*
Email: tommaso.mello@unifi.it

Background and aims: RuvBL1 is a AAA+ ATPase involved in multiple cellular activities, including proliferation, chromatin remodeling, DNA repair, transcription/translation and mTOR pathway activity. High RuvBL1 expression in hepatocellular carcinoma (HCC) correlates with poor prognosis. We have previously shown that hepatic RuvBL1 haploinsufficiency impairs mTORC1 signaling thereby altering liver metabolism and glucose homeostasis, suggesting that RuvBL1 overexpression may support the metabolic rewiring of HCC. We therefore aimed at dissecting RuvBL1 role in HCC cell metabolism.
Method: Experiments were performed in human HCC cell lines (HepG2, Hep3B, Huh7), mouse HCC cell line (Hepa1-6) and mouse normal hepatocytes (AML-12 and freshly isolated hepatocytes). RuvBL1 was targeted either by RNAi or by inhibiting its ATPase activity with CB-6644. Metabolomics analysis was performed by untargeted GC/MS or by 13C-glucose and 13C-glutamine metabolic tracing. OXPHOS was evaluated by Seahorse analyzer. Mitochondria morphology and potential were evaluated by fluorescence microscopy/HCS and TEM. RuvBL1 localization was assessed via STED microscopy and immunogold labelling. RuvBL1 mitochondrial interactome was evaluated by co-immunoprecipitation coupled with MS. Correlative analysis in human HCC samples was performed on the TCGA_LIHC dataset.
Results: RuvBL1 silencing in Huh7 cells altered many mitochondrial metabolites central to glucose, TCA and aminoacid metabolism, and significantly associated with processes such as cancer metabolic reprogramming by pathway enrichment analysis. Metabolic tracing with 13C-glucose and 13C-glutamine in CB-6644 treated Huh7 revealed alterations in glycolysis and TCA. Targeting RuvBL1 by RNAi or by inhibition with CB-6644 significantly impaired mitochondrial respiration in normal hepatocytes and HCC cell lines. ATP production by OXPHOS and glycolysis was inhibited by CB-6644 treatment in a dose- and time-dependent manner. Interestingly, CB-6644 treatment increased mitochondrial membrane potential, as assessed by JC-1 and by TMRM staining in high content microscopy analysis, eventually disrupting mitochondria structure as shown by the reduced matrix density and disarranged cristae. By super-resolution microscopy and immunogold-TEM we were able to localize RuvBL1 within mitochondria. Gene ontology analysis of mitochondrial RuvBL1-interactome revealed that this ATPase impact on TCA, aminoacid and lipid metabolism, mito-ribosome assembly, and mitochondrial membrane organization. Analysis of human HCC samples in the TCGA-LIHC cohort revealed that high RuvBL1 expression was significantly associated with an enrichment of mitochondria-related GO terms.
Conclusion: Our data uncover a novel localization and function of RuvBL1 in mitochondria, suggesting that RuvBL1 overexpression is exploited in HCC to support mitochondria-related metabolic processes.

SAT-255

Combining non-selective beta-blockers with sorafenib in HCC: targeting the culprits of metastasis

Tasnim Mahmoud[1], Olfat Hammam[2], Mahmoud Khattab[3], Aiman El-Khatib[3], Yasmeen Attia[1]. *[1]Faculty of Pharmacy, The British University in Egypt, Department of Pharmacology and Biochemistry, Cairo, Egypt, [2]Theodor Bilharz Research Institute, Department of Pathology, Egypt, [3]Faculty of pharmacy, Cairo University, Department of Pharmacology and Toxicology, Cairo, Egypt*
Email: Tasnim120764@bue.edu.eg

Background and aims: Hepatocellular carcinoma (HCC) is the most prevalent type of liver cancer and the fifth most common cancer worldwide. For unresectable HCC, sorafenib (SOR), an oral multi-tyrosine kinase inhibitor, is used as first-line therapy, however, acquired resistance towards SOR develops leading to treatment failure. The underlying mechanisms of SOR resistance are not clearly understood, yet strong evidence suggests a role of epithelial-to-mesenchymal transition (EMT), the main culprit of metastasis, in its development. Meanwhile, non-selective beta-blockers (NSBB) were shown to improve outcomes and responsiveness in HCC. The detailed mechanism remains elusive though. This study aims at deciphering whether using carvedilol (CAR), as a NSBB, can enhance HCC responsiveness to SOR. Further, it unravels the potential interception of CAR with EMT at the glycogen synthase kinase (GSK)- 3 beta/Wnt signaling.
Method: Male Sprague Dawley rats were injected intraperitoneally with diethyl nitrosamine (DEN) at a dose of 50 mg/kg, once a week. After a 16 -week period of DEN treatment, the rats underwent a one-week washout period followed by a 4 -week period of oral treatment with SOR at a dose of 30 mg/kg/day, CAR at a dose of 10 mg/kg/day, each alone and combined. By the end of week 20, the rats were sacrificed and livers were collected for further analyses which included histopathological examination, gene expression analysis of Axin- 1 by qRT-PCR along with estimating protein levels of GSK- 3 beta, snail- 1 and twist- 1 by ELISA. One-way ANOVA followed by Tukey Kramer's for multiple comparisons was used for statistical analysis. p values less than 0.05 were considered statistically significant.
Results: In hematoxylin and eosin (HandE)-stained sections, histopathological examination revealed fewer sheets of malignant cells with areas of necrosis and fewer cells showing high nucleocytoplasmic ratios in the SOR+CAR-treated group compared to SOR alone. The combination group also showed lower levels of the EMT markers, snail- 1 and twist- 1, as compared to the HCC group. The latter was also significantly lower with SOR+CAR than with SOR alone (Fig 1A). Axin- 1, the negative regulator of the Wnt signaling, was noticeably upregulated in the combination group compared to the positive control group. This was paralleled with an increase in GSK- 3 beta levels in the SOR+CAR group relative to both control and SOR groups (Fig 1B).

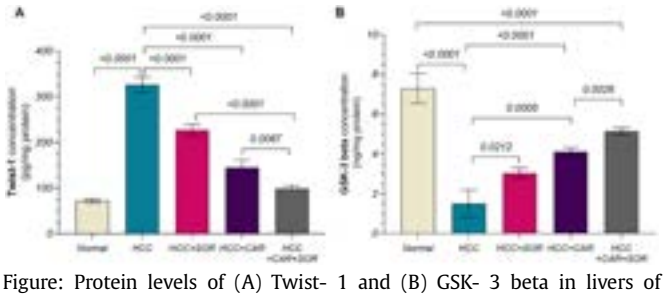

Figure: Protein levels of (A) Twist- 1 and (B) GSK- 3 beta in livers of normal, positive control (HCC), sorafenib (SOR)-treated, carvedilol (CAR)-treated, and SOR+CAR-treated groups, as estimated by ELISA.

Conclusion: Overall, the present findings demonstrated the ability of CAR to impede the EMT program in HCC enhancing SOR efficacy. These results might also suggest the potential inclusion in therapeutic regimens of HCC patients.

SAT-256

Investigation of novel hepatoblastoma chemosensitizers based on the inhibition of ABC pumps-mediated drug efflux

Candela Cives-Losada[1], Oscar Briz[1,2], Stefano Cairo[3], Emilie Indersie[4], Thomas Efferth[5], María Luz Martínez-Chantar[2,6], Matías A Avila[2,7], Carolina Armengol[2,8], Elisa Lozano[1,2], Jose Marin[1,2], Rocio Ir Macias[1,2]. *[1]University of Salamanca, IBSAL, Spain, [2]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd), Spain, [3]Champions Oncology, United States, [4]XenTech, France, [5]Johannes Gutenberg University, Germany, [6]Center for Cooperative Research in Biosciences (CIC bioGUNE), Spain, [7]Cima-University of Navarra, Spain, [8]Germans Trias i Pujol Health Sciences Research Institute (IGTP), Spain*
Email: rociorm@usal.es

Background and aims: The poor prognosis of about one-third of patients with hepatoblastoma (HB) is mainly due to the refractoriness of this cancer to neoadjuvant chemotherapy, which is commonly based on cisplatin and doxorubicin. In previous studies, we have demonstrated that the high expression of drug export pumps belonging to the ABC superfamily of proteins, mainly MDR1, MRP1, and MRP2, plays a primary role in HB chemoresistance. The aim of this study was to search for non-toxic inhibitors of these transporters and to evaluate in vitro their ability to sensitize HB cells to antitumor chemotherapy.
Method: Cell lines with endogenous or chemically induced high expression of MDR1 (HepG2/DR) or MRP1/MRP2 (HB-282) were used. Gene expression was determined by RT-qPCR, Western blot, and immunofluorescence. ABC-mediated transport activity was determined by flow cytometry using fluorescent substrates and specific inhibitors. Known inhibitors of ABC pumps were used as controls. In silico analysis by molecular docking was performed to look for potential ABC inhibitors using homology models for these proteins and a library of 40,000 natural or semi-synthetic compounds. Potentially harmful compounds were discarded based on toxicity prediction using the online tool ProTox-II. Cell viability was determined by the MTT-formazan and sulforhodamine B assays. SynergyFinder 3.0 was used to assess drug combination synergy.
Results: Besides known MDR1 inhibitors (verapamil, elacridar, and tariquidar), 11 novel compounds, among 40 potential inhibitors studied, significantly reduced rhodamine-123 efflux from HepG2/DR cells. Among these with no cytotoxic effect, only CCL-40 was able to slightly increase the sensitivity of cells to doxorubicin. However, CCL-17 and CCL-24, both tyrosine kinase inhibitors, markedly enhanced the cytostatic effect of doxorubicin, which was due to a synergistic mechanism. Regarding MRP1 and MRP2, the molecular docking study identified 1,000 compounds with potential interaction with these pumps. Among them, the best eight compounds, based on low binding energy to both proteins, low predicted toxicity, and commercial availability, were further studied. The results revealed that two of them, CCL-45 and CCL-46, significantly reduced MRP1/MRP2-mediated calcein efflux in HB-282 cells. The chemosensitizing potency of CCL-45 was even stronger than the typical MRP1/MRP2 inhibitor MK-571.
Conclusion: Inhibition of ABC drug export pumps, such as MDR1, MRP1, and MRP2, by several non-toxic natural compounds and drugs commonly used in the clinic for other purposes, could be a helpful strategy to overcome the lack of response to chemotherapy in HB patients.

SAT-257

Dual effects of brown-fat activation limit hepatocellular carcinoma (HCC) progress in steatotic liver

Juan Gao[1,2]. *[1]Karolinska Institute, Sweden, [2]Third Affiliated Hospital of Sun Yat-sen University, China*
Email: gaoj59@mail2.sysu.edu.cn

Background and aims: Obesity, a metabolism abnormal disease with increasing incidence, also is a high-risk factor for various tumors. It is often associated with Non-alcoholic fatty liver disease (NAFLD), which could show steatosis, hepatitis, cirrhosis, and finally lead to cancer. Accumulating free fatty acids (FFAs) may contribute to cancerogenesis due to lipid metabolic disorders. Our previous studies suggested that cancer lipid metabolism confers antiangiogenic drug resistance (Iwamoto et al., 2018, Cell Metabolism 28, 104–117), and cold exposure suppresses tumor growth by brown fat activation alters global metabolism (Seki et al., 2022, Nature 608). We are interested in how the host metabolism reshapes the hepatocellular carcinoma (HCC) microenvironment and affects their response to drugs. We also gain insight into the potential mechanisms of the combination of metabolic stimulators and existing drug therapies.
Method: To establish metabolic abnormalities in animal models, adult male C57BL/6N mice were fed with high-fat diet (HFD) for more than 3 months to induce obesity and liver steatosis. Hepa1-6 hepatocarcinoma cells were implanted in the mice's liver under inhaling anaesthetization as the orthotopic HCC model. Approximately 1 week after tumor implantation, mice were randomly grouped and treated with different temperatures exposure for the next three weeks. 4 degree celsius (4 °C) environmental temperature as the cold exposure group, and 30 degree celsius (30 °C) environmental temperature as the control group. Glucose tolerance test (GTT) and insulin tolerance test (ITT) were performed during the treatment. Then mice were sacrificed, blood, liver with tumor and fat tissue were collected for histological and biochemistry analysis. Data presented as mean determinants ± SEM. Statistical computations were performed using the standard two-tailed Student t-test, $^{*}p < 0.05$, $^{**}p < 0.01$, and $^{***}p < 0.001$ were considered statistically significant.
Results: The body weight of obese mice showed a decrease in the 4 °C group in the first week, with noticeable differences between the two groups after three weeks of treatment ($p < 0.001$, Figure A). Both GTT and ITT suggested host metabolic disorders were improved in the 4 °C group (AUC, $p < 0.05$). The tumor volumes of the orthotopically implanted HCC were limited in the 4°C group than in the 30 °C group ($p < 0.001$, Figure B). Furthermore, qPCR indicated that metabolic-related genes were downregulated in the tumors of the 4 °C group, such as *cd36*, *fabp4*, *plin2* and *glut1* (both $p < 0.01$, Figure C). Besides, histopathology showed that the liver steatosis was relieved in the 4°C group compared to the 30 °C group ($p < 0.05$). And both proliferation and metabolism of the tumor were limited in the 4 °C group, showed by IHC staining of KI67 and COX4 (both $p < 0.01$, Figure D).
Conclusion: The dual effect of activating brown-fat relieves liver steatosis and HCC progress in the steatotic liver. The combination of brown-fat activators and drug therapies may contribute to better outcomes in HCC patients with metabolic disorders.

Development of new personalized therapies targeting VDAC1 in intrahepatic cholangiocarcinoma using patient-derived liver organoids

Silvia De Siervi[1], Stefano Conti Nibali[1], Stefania Mantovani[2], Barbara Oliviero[2], Mario Mondelli[2,3], Laura Giuseppina Di Pasqua[3], Davide Ronchi[4], Marco Gaetano Lolicato[1], Cristian Turato[1]. [1]*University of Pavia, Molecular Medicine, Pavia, Italy,* [2]*Division of Clinical Immunology and Infectious Diseases, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy,* [3]*University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy,* [4]*University of Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy*
Email: cristianturato@gmail.com

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is characterized by a very poor outcome, and reliable biomarkers as well as new therapeutic strategies are urgently needed. Voltage Dependence Anion Selective Channel isoform 1 (VDAC1) has emerged as a prominent drug target because it plays a key role in the regulation of mitochondria-mediated cell death and survival signalling pathways. There have been several compounds developed, but none of them have been widely employed to treat patients due to promiscuity and side effects. The aim of this study was to test a new class of small molecules targeting VDAC1 to induce activation of the apoptotic pathway in iCCA patient-derived liver cells and organoids.
Method: We minced tumour and paired non-tumour samples, shortly digested in small cell clusters, and then seeded into Matrigel in order to develop organoids. Following immunofluorescence and qPCR analysis, we treated primary cell cultures and organoids with different concentrations of small molecules targeting VDAC1, detecting cell viability and ROS levels release, to verify the *in vitro* effects and the efficiency of these compounds on cells.
Results: We generated and characterized a biobank of human iCCA-derived organoids, analyzing the morphological characteristics and performing a mathematical tool that allow to simulate tumour progression. We also examined the presence of specific CCA markers, such as CK19, CK7, EpCAM, E-Cadherin, Ki67. In addition, we highlighted the increased levels of VDAC1 expression in iCCA cells compared to non-tumor cells ($p < 0, 005$). The impact of novel small compounds targeting VDAC1 was then investigated at different times points and concentrations, both in patient-derived cell cultures and organoids. In particular, we showed a significant decrease of viability in tumor cells and a modulation in ROS production.
Conclusion: We established and characterized a reliable in vitro iCCA model that allowed us to study the impact of small molecules targeting VDAC1 as a new personalized treatment.

Email: drpjy@yuhs.ac

Background and aims: Organoid models using patient-derived cancer tissues has allowed a better understanding of human cancer as well as development of precision medicine. We evaluated the potential differential sensitivity of HCC organoids (HCOs) to lenvatinib and analyzed the relationship between the resistance group of lenvatinib and intracellular signaling pathways.

Method: Patient-derived tumor tissue was digested at 37 °C and mixed with Matrigel. After polymerization of Matrigel, medium was added and changed twice a week. To evaluate whether HCO exhibit different sensitivity to drugs, we tested its sensitivity and analyzed the sensitivity in HCO lines with the difference in gene expression.
Results: We successfully established HCO lines at a 76% success rate, presenting as two different morphological types: solid-type and mixed-type. Heterogeneous morphological features of HCOs exhibited differential gene expression and response to lenvatinib, showing highly expressed EGFR, GSK3-beta and FOXO3 with lower sensitivity to lenvatinib in solid type HCOs, compared to mixed type HCOs. To confirm the association of morphological classification with GSK3-beta activation and lenvatinib sensitivity, we generated a rHCO from re-biopsied tissue from a patient with advanced HCC progression after lenvatinib treatment and compared it with a HCO from first biopsied tissue. Specifically, the lenvatinib-resistant rHCO expressed much lower levels of the inactive form of GSK3-beta and higher levels of the active form of GSK3β compared with the original HCO, suggesting higher GSK3-beta activity and Ki-67 levels in resistant cells. Knockdown of GSK3-beta with selective GSK3-beta inhibitor and siRNA restores sensitivity to lenvatinib in association with GSK3-beta activity and morphological features.

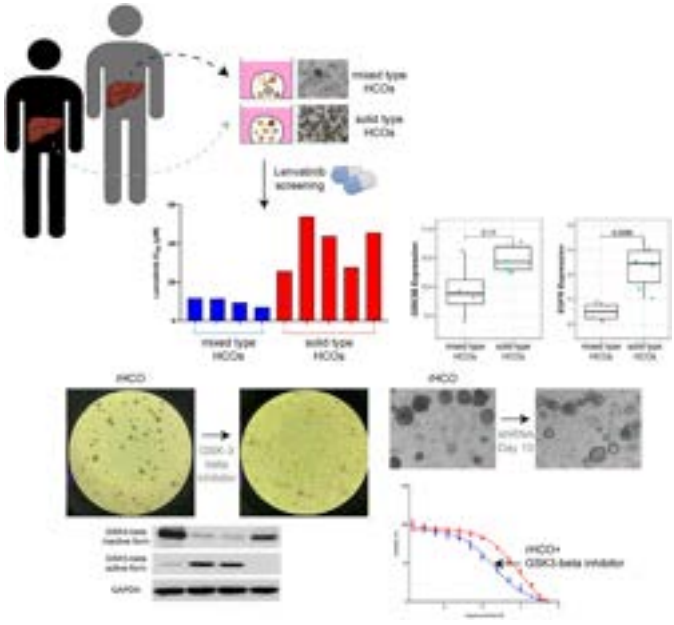

Figure:

Conclusion: Our work demonstrates the relationship between lenvatinib sensitivity and morphological features with GSK3-beta expression and identifies regulators of GSK3-beta activity as potential novel therapeutic agents for restoring lenvatinib sensitivity.

SAT-260
Immunomagnetic enrichment of hepatocyte-specific extracellular vesicles using magnetic beads and click chemistry

Sven Mentink[1], Richell Booijink[1], Maureen Brusse[1], Ruchi Bansal[1].
[1]University of Twente, Netherlands
Email: r.s.booijink@utwente.nl

Background and aims: Extracellular vesicles (EVs) are cell-derived nano- and micro-sized vesicles that are abundantly present in body fluids emphasizing their potential utility in liquid biopsies. EVs have great potential as early hepatocellular carcinoma biomarkers since tumor-derived EVs are found at an early stage, and their inherent stability guarantees the integrity of biomolecular cargos. Unfortunately, conventional EV isolation techniques including ultracentrifugation and/or size exclusion chromatography are based on EVs' density or size respectively, and are incapable of separating tumor-derived EVs from total EVs. Here, we present an unique approach of isolating hepatocellular derived EVs by immunomagnetic enrichment using surface antibodies, magnetic beads and click chemistry.
Method: We developed an EV enrichment system whereby magnetic beads (1–5 µm) were functionalized with tetrazine (Tz). Antibodies [EpCAM (epithelial-specific), CD9 (EV specific) and ASGPR1 (hepatocyte specific)] used to capture EVs was functionalized with trans-cyclooctene (TCO). EVs isolated from the conditioned medium obtained from serum-starved HepG2 cells were captured using antibody-TCO conjugate and the EV-antibody-TCO conjugate was incubated with the magnetic beads-Tz, creating a click reaction between the Tz and the TCO, leading to capture of the hepatocyte specific EVs to the magnetic beads. Magnetic beads were enriched using magnets; and EV release from the magnetic beads was achieved using 1,4-dithiothreitol (DTT, by cleavage of disulfide bonds incorporated during Tz conjugation). Characterization of efficiency of conjugation, click reaction and EV release was performed using flow cytometric analysis.
Results: To validate the efficiency of the EV isolation, EVs were fluorescently labelled with Calcein-AM prior to conjugation, and the EVs captured using magnetic beads were analyzed through a flow cytometer. We confirmed a successful enrichment of the EVs using magnetic beads. Similar results were obtained with EpCAM or ASGPR1 antibodies suggesting antibody-specific EV-capture can be achieved using different antibodies. Hepatocyte-specific EVs (bound to magnetic beads) were separated from other particles in suspension using magnetic enrichment. Finally, DTT treatment released the captured EVs from the magnetic beads for downstream analysis.
Conclusion: We confirm the successful immunomagnetic enrichment of specific hepatocyte-derived EVs by combining cell specific antibodies, magnetic beads and click chemistry. We present an attractive and unique approach for the isolation and analysis of cell-specific EVs. This approach can be extended to other cell types i.e., HSCs, endothelial cells, immune cells based on the availability of the antibodies. We believe this approach will pave the way to the identification of early circulating biomarkers for HCC.

Circular RNA hsa_circ_0062682 promotes oncogenesis in hepatocellular carcinoma and binds to YBX1

Rok Razpotnik[1], Hana Trček[1], Martin Zaplotnik[2], Blaž Trotovšek[3], Mihajlo Djokić[3], Miha Petrič[3], Boštjan Plešnik[3], Irena Plahuta[4], Arpad Ivanecz[4], Linda Cellner[2], Rado Janša[2], Petra Hudler[5], Robert Vidmar[6], Marko Fonovič[6], Uršula Prosenc Zmrzljak[7], Damjana Rozman[1], Tadeja Rezen[1]. *[1]University of Ljubljana, Faculty of Medicine, CFGBC, IBKMG, Slovenia, [2]University Medical Centre Ljubljana, Department of Gastroenterology, Slovenia, [3]University Medical Center Ljubljana, Department of Abdominal Surgery, Slovenia, [4]University Medical Center Maribor, Department of Abdominal and General Surgery, Slovenia, [5]University of Ljubljana, Faculty of Medicine, MCMB, IBKMG, Slovenia, [6]Jožef Stefan Institute, Department of Biochemistry and Molecular and Structural Biology, Slovenia, [7]BIA Separations CRO, Labena d.o.o, Slovenia*
Email: tadeja.rezen@mf.uni-lj.si

Background and aims: Circular RNAs (circRNAs) have gained increasing interest in recent years and have been shown to play an important role in cancer. Although increased efforts have been made to identify their role and differential expression in cancer, the role of most dysregulated circRNAs is unknown, and their function in cancer pathogenesis remains to be assessed. Here, we report the characterization of a circRNA hsa_circ_0062682 with oncogenic properties in hepatocellular carcinoma (HCC) and evaluate its expression and diagnostic potential in HCC patients.
Method: We identified differentially expressed circRNAs in HCC tumors by reanalyzing published microarray datasets. We

investigated the oncogenic potential of circRNA hsa_circ_0062682 in cell lines using various functional cell-based assays, including proliferation, migration, invasion, and colony formation assays. We used microarrays to analyze systemic changes in the transcriptome after modulation of circRNA expression in HCC cell lines. In addition, biotinylated oligonucleotide pulldown coupled with mass spectrometry was used to identify binding partners and RNA immunoprecipitation to confirm binding partners. We analyzed circRNA expression in paired liver tumor and paratumor samples from the Slovenian HCC cohort with metabolism-associated and alcohol-related etiologies. We measured the presence of circRNA in plasma from the same patients by RT-qPCR and ddPCR to evaluate its diagnostic potential.

Results: By analyzing available microarray datasets, published at the time of analysis, we identified 32 upregulated and 6 downregulated circRNAs in HCC tumors. We overexpressed and knocked down the expression of hsa_circ_0062682 in various HCC cell lines and confirmed its oncogenic potential using several functional assays. By integrating pathway enrichment analysis and gene set enrichment analysis, we uncovered systemic changes triggered by perturbations of hsa_circ_0062682 expression and we identified enriched transcription factors (E2F1, Sp1, HIF-1α, and NFκB), known to be oncogenic regulators in HCC, as well as signaling pathways previously associated with HCC that could explain the observed phenotype. Using the proteomics approach, we uncovered protein binding partners of hsa_circ_0062682 and confirmed an interaction with YBX1, a known oncogene, by RNA immunoprecipitation. A cell type-specific role of hsa_circ_0062682 was detected based on differential sorafenib sensitivity, migratory ability and differential localization of the studied proteins in stably transduced cell lines. Interestingly, the expression of this circRNA was downregulated in our cohort, which has a metabolic and alcohol-associated etiology. In our opinion, this discrepancy could be due to different etiologies and molecular subtypes of the HCC cohorts used in the microarray datasets. Furthermore, we evaluated the diagnostic potential of hsa_circ_0062682 as a non-invasive biomarker in plasma by measuring its expression in plasma and comparing it with its expression in liver.

Conclusion: Our data suggest that hsa_circ_0062682 promotes oncogenesis in HCC, binds to YBX1, affects multiple signaling pathways involved in oncogenesis, and may act in a cell type specific context.

SAT-262

The mutated ENTPD6 as neoantigen in hepatocellular carcinoma

Dongbo Chen[1], Pu Chen[1], Hongsong Chen[1]. [1]*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Disease, Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis, China*
Email: chenhongsong2999@163.com

Background and aims: Tumor neoantigens, new peptides generated by somatic mutations from tumor tissues but not normal tissues, have good tumor specificity and strong immunogenicity. Though Clinical trials testing neoantigen immunotherapy have yielded encouraging results in patients with hepatocellular carcinoma (HCC) worldwide, it's hard to know which neoantigens are dominant in determining the responsiveness to immunotherapy treatment. In this study, we used the Co-HA system, a single-plasmid system co-expressing patient HLA and antigen, to detect the immunogenicity of neoantigens and identify new dominant hepatocellular carcinoma (HCC) neoantigens.

Method: First, we enrolled 14 HCC patients for next-generation sequencing for variation calling and predicting potential neoantigens. Then, the specific cytotoxicity generated by this neoantigen was shown using the Co-HA system. Finally, potential HCC-dominant neoantigens were screened out by tetramer staining and validated by the Co-HA system using methods including flow cytometry, ELISPOT, ELISA and sequencing.

Results: First, 2875 somatic mutations were identified in 14 HCC patients. The main base substitutions were C > T/G > A transitions, and the main mutational signatures were 4, 1 and 16. The high-frequency mutated genes included HMCN1, TTN and TP53. Then, 541 potential neoantigens were predicted. Moreover, 37 predicted neoantigens restricted by HLA-A*11:01, HLA-A*24:02 or HLA-A*02:01 were assayed by tetramer staining to screen out potential HCC-dominant neoantigens. Furthermore, the Co-HA system identified that the HLA-A*24:02-restricted epitope 5′-FYAFSCYYDL-3′, produced by the mutated ectonucleoside triphosphate diphosphohydrolase 6 (ENTPD6) had strong immunogenicity in HCC. Finally, Huh-7 cells co-expressing HLA-A*24:02 and ENTPD6 neoantigen were selected as the target cells and implanted into the B-NDG-B2m^{tm1}Fcrn$^{tm1\ (mB2m)}$/Bcgen mouse model. When tumor size was approximately 150 ± 50 mm^3, they were treated with the neoantigen-specific T cells through intratumor injection every 2 days. After 3 times of treatment, the volume and weight of tumors with neoantigens were both smaller than those of WT type.

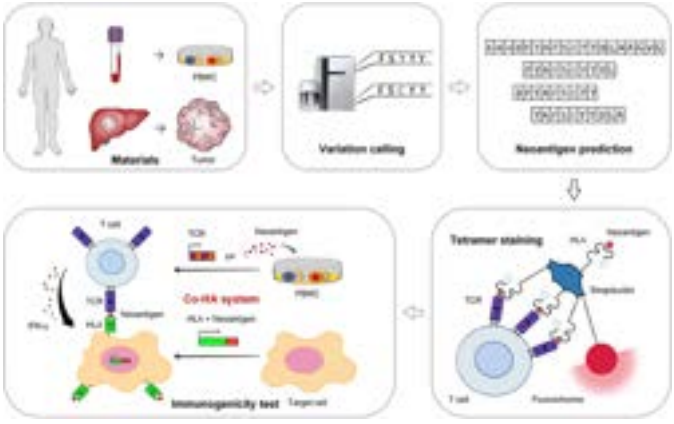

Figure:

Conclusion: The HLA-A*24:02-restricted epitope 5′-FYAFSCYYDL-3′, produced by the mutated ENTPD6, was the dominant neoantigen with high immunogenicity in HCC.

SAT-263

Relevance of hypoxia-inducible factor 1 alpha in hepatocellular carcinoma: clinical and pre-clinical analysis

Tania Payo-Serafín[1,2], Paula Fernández-Palanca[1,2], Carolina Méndez-Blanco[1,2], Jennifer Martínez-Geijo[1,2], Beatriz San Miguel de Vega[1,2], Andrés García-Palomo[3], Juan José Ortiz de Urbina[4], Javier González-Gállego[1,2], María Jesús, Tuñón González[1,2], José Luís Mauriz[1,2]. Email: jl.mauriz@unileon.es

Background and aims: Hepatocellular carcinoma (HCC), the main type of liver cancer, stands as one of the deadliest type of cancer with an increasing prevalence worldwide. Hypoxia plays a major role in tumorigenesis and in the development of chemotherapy-resistant tumor cells. The adaptive cell response to this condition is mainly mediated by the hypoxia-inducible factors 1 and 2 alpha (HIF-1alpha and HIF-2alpha, respectively), which triggers the activation of several cellular pathways contributing to cell survival and the loss of sensitivity to chemotherapy, and leading to tumor progression.

Therefore, our aim was to assess the role of HIF-1alpha on HCC patients' outcome and tumor cell survival.
Method: We analyzed HIF-1alpha gene expression and RNA-seq data in several HCC repositories such as The Cancer Genome Atlas (TCGA), the European Genome-Phenome Archive (EGA), Genotype-Tissue Expression (GTEx) and GSE14520. Data were obtained from UALCAN, Gene Expression Profiling Interactive Analysis (GEPIA) and Gene Expression Omnibus (GEO) databases. We performed a screening of HIF-1alpha expression in eight different human HCC cell lines, employing $CoCl_2$ to simulate a cell response to hypoxia. Western blot and immunofluorescence with laser confocal imaging were used to analyze protein expression, while qRT-PCR was used to assess gene expression. Moreover, HIF-1alpha gene knockdown was performed using siRNA transfection. MTT assay and nuclear Ki67 protein levels assessment were used to determine cell viability and proliferation, respectively. Image-iT Red Hypoxia Reagent was employed to monitor hypoxia in the 3D models of HCC. GraphPad Prism 8 software was used to conduct statistical analysis, considering significant differences when $p < 0.05$.
Results: HIF-1alpha was found to be overexpressed in HCC tissues, being also associated with higher tumor grades and a poor survival rate in HCC patients. Huh-7 and PLC/PRF/5 cell lines showed a higher expression of HIF-1alpha under hypoxia conditions. For this reason, these cell lines were selected to perform HIF-1alpha gene silencing and to generate two spheroid models of HCC showing a physiological hypoxia. A decrease in viability and Ki67 protein levels was detected after gene knockdown, suggesting a pro-survival ability associated with HIF-1alpha. Moreover, HIF-1alpha-silenced cells showed higher levels of pro-apoptotic proteins under hypoxic conditions, revealing the potential effect of HIF-1alpha in HCC cell survival through apoptosis evasion.
Conclusion: Altogether, these findings suggest that HIF-1alpha expression and stabilization plays a key role in HCC progression and patients' outcome, leading to tumor cell survival through apoptosis evasion under a hypoxic environment, highlighting HIF-1alpha activity blockage as a potential therapeutic strategy to restrain HCC progression.

SAT-264
Therapeutic targets associated with conserved subtypes of hepatocellular carcinoma

Ju-Seog Lee[1], Yun Seong Jeong[1], Sun Young Yim[2], Sung-Hwan Lee[3], Sang Hee Kang[2]. [1]*The University of Texas MD Anderson Cancer Center, Systems Biology, Houston, United States,* [2]*Korea University College of Medicine, Korea, Rep. of South,* [3]*Cha University Bundang medical center, Korea, Rep. of South*
Email: jlee@mdanderson.org

Background and aims: While many studies revealed clinically relevant conserved subtypes of hepatocellular carcinoma (HCC), their discovery is not translated to the clinic yet due to lack of associated therapeutic intervention for subtypes. We aim to examine consensus of discovered subtypes and uncover their clinical significance and to identify potential therapeutic targets for each subtype.
Method: We integrated 16 previously established transcriptomic signatures for HCC to uncover consensus subtypes. We also developed and validated a robust predictor of consensus subtype with 100 genes (PICS100). Informatics and statistics approaches were applied to find clinical relevant association of genomic features. Patient derived xenograft (PDX) models were used for testing hypothesis from analysis of transcriptomic data.
Results: Integrative analysis of genomic and proteomic data uncovered five subtypes of HCC with substantial difference in clinical outcomes. STM (STeM) is characterized by high stem cell features, vascular invasion, and poor prognosis. CIN (Chromosomal INstability) has moderate stem cell features but high genomic instability and low immune activity. High expression of IGF2 is another unique feature of CIN subtype, suggesting that CIN subtype might have benefit of treatment targeting IGF2/IGFR pathway. IMH (IMmune High) is best characterized by its high TCR diversity and high baseline immune activity. BCM (Beta-Catenin with high Male predominance) is characterized by prominent beta-catenin activation, low miRNA expression, hypomethylation, and high sensitivity to sorafenib. Interestingly, subtype BCM had a significantly higher male-to-female ratio than the other subtypes. Another unique molecular characteristic of subtype D was miRNA downregulation. DLP (Differentiated and Low Proliferation) is differentiated with high HNF4A activity. We also identified potential serum biomarkers that can stratify patients into 5 subtypes. Our PICS100 predictor is available in the website (https://kasaha1.shinyapps.io/pics100/) with test data set for those who wish to run genomic predictor. Multistep analysis of genomic and proteomic data identified therapeutic targets for poorest prognostic STM subtype and their therapeutic potential was further validated in cell line and mouse models.
Conclusion: Newly discovered subtypes are associated with response to standard and experimental treatments and highly conserved in pre-clinical models such as cell lines and PDX tumors. Therefore, our study may provide a framework for selecting the most appropriate models for preclinical studies of new drugs and potentially for future clinical trials.

SAT-265
In vivo MRI characterization of pathological changes in liver microstructures

Xiaoyu Jiang[1], Manhal Izzy[2], Kay Washington[2], John Gore[2], Junzhong Xu[2]. [1]*Vanderbilt University Medical Center, Radiology, United States,* [2]*Vanderbilt University Medical Center, United States*
Email: xiaoyu.jiang@vumc.org

Background and aims: Cell volume, cell density, and their variations are fundamental concepts in liver pathology. Currently, cell volume and cell density measurements are possible via assessing liver biopsies, which are subject to sampling bias and may not reliably reflect the spatial heterogeneity in the liver as a whole. In vivo MRI cytometry may provide means to overcome this limitation. This study aims to 1) prove the feasibility of in vivo mapping of non-fat cell volume (or equivalent cell size) and cell density in the liver using clinical 3T scanners 2) histologically validate MRI measurements using human liver specimens.
Method: MRI cytometry combines measurements of water diffusion rates over different time scales corresponding to probing cellular microstructure over different distances. The range of sizes of most interest in liver tissues is from 5 um to 25 µm (e.g., hepatocytes ~ 15–25 µm, inflammatory cells ~ 5–10 µm, cancer cells ~ 10–5 µm). These correspond to diffusion times of order 5–70 ms which can be achieved using a combination of OGSE (oscillating gradient spin echo) and PGSE (pulsed gradient spin echo) measurements on clinical scanners. Microstructural properties are derived by fitting multi-b value-multi-diffusion time fat-suppressed diffusion-weighted MRI signals to a three-compartment (blood, intra and extracellular water) signal model. Details of the signal model and imaging protocol have been published previously. ex vivo validation: Microstructures of fixed human liver specimens, including normal liver tissues, cirrhosis, steatosis, hepatocellular carcinoma (HCC), cirrhotic regenerative nodules (CRN), and intrahepatic cholangiocarcinoma (iCCA), were quantified using MRI ex vivo and histology. in vivo feasibility: MRI cytometry was performed in a healthy subject and an HCC patient using a Phillips 3T scanner.
Results: For ex vivo experiments, MRI-based assessment of HCC and iCCA showed that tissues have significantly smaller cell volumes and higher cell densities than normal liver and CRN without steatosis. Cell sizes for fatty areas and CRN with steatosis are smaller than those for normal liver and CRN without steatosis (note that our MRI-derived cell sizes are converted from non-fat cell volumes). These

observations matched histological assessment of microstructures. For in vivo experiments, MRI cytometry demonstrated that the HCC tumor has decreased cell sizes and ~×2 higher cell densities than the healthy subject.

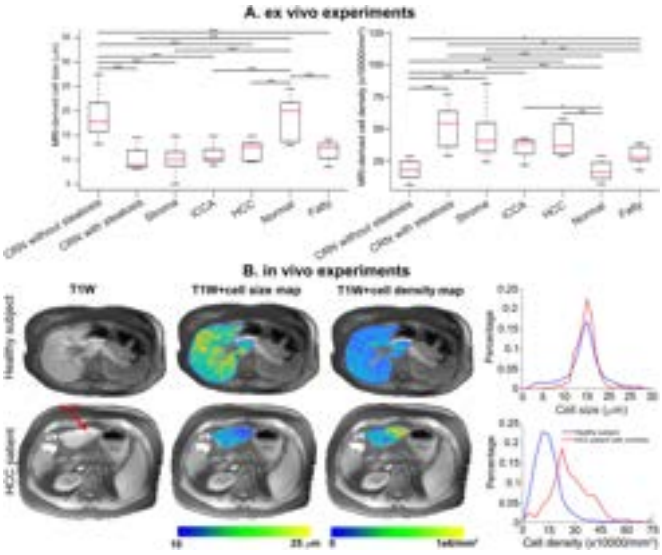

Figure: A. Box-and-whisker plots of MRI-derived cell sizes and cell densities for liver ROIs with different pathologies. For all the Box-and-whisker plots, the 25th–75th percentiles are blocked by the box, the red bands inside the box are the mean values, and the whiskers mark the SD. *P < 0.05, **P < 0.01, ***P < 0.001, and ****P < 0.0001 as measured by one-way analysis of variance (ANOVA) with Bonferroni correction. B. in vivo MR cell size and cell density imaging for a healthy subject and an HCC patient. The in-plane resolution is $4 \times 4\ mm^2$ and the slice thickness is 10 mm.

Conclusion: This study demonstrates that the novel MRI cytometry can characterize pathological changes in liver microstructures using clinical 3T scanners in <12 minutes. These findings provide a solid foundation for future investigation of the role of non-invasive evaluation of liver cellular characteristics in diagnosing liver disease aiming to further decrease the need for liver biopsy.

SAT-266

Prognostic and genomic portrait of hepatocellular carcinomas with bi-allelic inactivation of RB1 gene

Jihyun An[1], Bora Oh[2], Jin-Sung Ju[2], Ju Hyun Shim[2]. [1]*Hanyang University College of Medicine, Korea, Rep. of South,* [2]*Asan Medical Center, Korea, Rep. of South*
Email: starlit1@naver.com

Background and aims: Although *RB1* gene loss have been correlated with progression of HCC, its molecular and pathogenic makeups are poorly defined. We comprehensively characterized a genomic subtype of HCC with true loss-of-function alteration of *RB*1.
Method: We performed integrative analysis of DNA and RNA sequencing data from 561 HCCs included in our hospital and TCGA projects. We classified the tumors according to the presence of *RB1* bi-allelic inactivation (Bi) such as deep deletion and copy-loss/neutral loss-of-heterozygosity: RB1-Bi and RB1-nonBi groups. Their impacts on clinical and genomic features of HCC were investigated.
Results: Among the entire samples, 82 (14.6%) corresponded to the RB1-Bi group, with deep deletion in 58 and copy-loss or copy-neutral loss-of-heterozygosity in 24. RB1-Bi tumors were independently associated with poorer disease-free survival and overall survival after hepatectomy, irrespective of RB1 alteration type. poorly differentiated tumors were more frequently observed in the RB1-Bi group (48.8% vs. 34.6%, $P < 0.05$). The RB1-Bi group was enriched for cell cycle-regulated, replication stress, and DNA damage repair-associated genes, while downregulated for CD8+ T cell markers. RB1 alteration events occurring in the RB1-Bi group were mostly clonal, and completely arose before whole genome doubling that was more frequent in the subset.
Conclusion: Bi-allelic *RB1* loss in the HCC confers worse prognosis through relevant functional and genomic aberrations. Tailored therapies for the disease that might be resistant to immunotherapy should be developed and tested.

SAT-267

Bacterial exosomes cargo vaccine with EpCAM aptamers for targeting hepatocellular carcinoma

Pushpa Yadav[1], Preedia Babu E[1], Nuno Viegas[2], Anupama Parasar[1], Riddhi Sharma[1], Gayatri Ramakrishna[1], Nirupma Trehanpati[1], Shiv Kumar Sarin[3]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India,* [2]*Mantis Pharmaceuticals, Leiden, Netherlands,* [3]*Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: shivsarin@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is the fourth most cause of cancer-associated mortality and leads to approximately 700,000 deaths worldwide annually and is expected to increase over 1 million by 2030. HCC is a highly heterogenous tumor with extensively proliferating and differentiating EpCAM or CD133 positive cancer stem cells. Despite existing chemo, radiation, and immune therapies for non-resectable tumours, 5-year survival rate is quite low with high recurrence rate. Therefore, our aim was to develop anti-EpCAM aptamer equipped bacterial outer membrane vesicles (OMVs) loaded with the chemotherapeutic drug, doxorubicin (DOX) as vaccine for specific targeting of cancer stem cells.
Method: We have designed EpCAM specific DNA (EP166 and SyL3C) and RNA-DNA hybrid aptamers and analysed their in vitro binding efficiency in HepG2, HuH7 cell lines as well as their spheroids and toxicity using MTT assay at 24, 48 and 72 hours of treatment. *Salmonella typhimurium* has the potential to kill tumor cells, therefore isolated and purified outer membrane vesicles (OMVs) were used to load DOX by incubating them together at an appropriate mass ratio for 4 hours at 37°C. As the aptamer cannot bind to the OMVs on its own, carbodiimide (EDC/NHS) coupling chemistry was applied for conjugating the carboxylic group of DSPE-PEG-COOH linker to the amine group of anti-EpCAM aptamer. The linker conjugated aptamer was then mixed with the bacterial exosomes cargo to develop anti-EpCAM aptamer equipped DOX loaded OMVs.
These novel OMVs were then used for testing in vivo efficacy in HepG2 cells derived subcutaneous xenograft model. Apt- conjugated DOX or DOX alone was used as control treatment.
Results: All the aptamers analysed for binding with HepG2 cells with flow cytometry showed maximum binding at 150 nM with SyL3C showing 47.3% binding (Fig1A).
In vivo experiments showed decreased tumor burden as compared to tumor control after treatment with DOX alone, Apt-DOX and Apt-DOX-OMVs (Average tumor volume: 448.26, 307.58, 168.29, 112.85 mm^3) after 12 days of treatment. Apt-DOX conjugate also showed increased specific DOX toxicity and reduced tumor burden in comparison to DOX alone (Average tumor size: 4.8 g and 2.7 g respectively).
Conclusion: Apt-DOX-OMVs and Apt-DOX conjugate and are more efficient in specifically targeting cancer cells in comparison to DOX alone or tumor control.

SAT-268

Poor sorafenib response in hepatocellular carcinoma patients is mediated by hypoxia-related 14-3-3 scaffolding proteins and induces a shift in tumor immune micromilieu

Jovana Castven[1], Diana Becker[2], Sophia Heinrich[3], Carolin Zimpel[1], Darko Castven[1], Beate Straub[2], Peter Grimminger[2], Peter Galle[2], Arndt Weinmann[2], Jens Marquardt[1]. [1]*Universitätsklinikum Schleswig-Holstein, Campus Lübeck, Germany,* [2]*Universitätsmedizin Mainz, Germany,* [3]*Medizinische Hochschule Hannover, Germany*
Email: hajdukjovana@gmail.com

Background and aims: Advanced stage of hepatocellular carcinoma (HCC) is frequently accompanied by poor response to the drug treatment or relapse quickly after initial remission. Therefore, identification of molecular drivers of poor response to sorafenib with large focus on novel prognostic markers associated with observed distinct tumor immune landscapes was our ultimate goal.
Method: From a cohort of 91 patients treated with sorafenib, we identified 17 HCC patients with particularly good or bad response. Integrative RNA sequencing and whole-exome sequencing analyses were performed to identify predictive markers of sorafenib resistance. *In vitro* validation of defined targets were performed in a model of sorafenib resistance, followed by subsequent functional and mechanistic validation.
Results: Patients with worst response (n = 7) were characterized by significantly shorter treatment duration and poor overall survival than good responders (n = 10). Molecular analyses revealed that acquisition of drug resistance observed in poor responder group was associated with upregulation of hypoxia-related targets from 14-3-3 scaffolding protein family. WST-1 viability assay displayed that hypoxia contributes to sorafenib resistance. Specific peptide inhibition of this protein family, in combination with sorafenib, showed synergistic effects and efficiently reduced cell proliferation and viability. Dual inhibition consequently reversed sorafenib resistance under both conditions, normoxia and hypoxia, with predominant effects noticed in normoxia. Furthermore, a shift in immune-cell composition with predominant enrichment of M2-immunosuppressive macrophages in worst responders was observed.
Conclusion: Defining the actionable targets of resistance and their subsequent inhibition might greatly help delineate molecular alterations driving drug resistance. In our model, specific peptide inhibition of 14-3-3 scaffolding proteins, when combined with sorafenib, showed a positive correlation in reversing sorafenib resistance. Importantly, synergistic effects of this dual inhibition influenced sorafenib resistance in normoxic and hypoxic microenvironments, but with different potency. This highlights the significance of the tumor microenvironment in modulating the therapy response. Further, characterization of the immune micromilieu in different subgroups of patients could be of particular importance to depict treatment resistance and warrants further investigations.

SAT-269

RBCK1 promotes the stabilization of HBx by linear ubiquitination to drive the progression of HBV-associated hepatocellular carcinoma

Zheyu Dong[1], Peng Chen[1], Yuxin Zhou[1], Qiuyue Ye[1], Junling Chen[1], Jianzhong Cai[1,2], Yiyan Huang[1,1,2,2], Jiayue Yang[1,2], Yaoting Feng[1,2], Liangxing Chen[1,2], Libo Tang[1], Yongyin Li[1]. [1]*State Key Laboratory of Organ Failure Research, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, China,* [2]*The First School of Clinical Medicine, Southern Medical University, Guangzhou, 510515, China, China*
Email: yongyinli@foxmail.com

Background and aims: Linear ubiquitin chain assembly complex (LUBAC) has been reported to participate in cancer progression, but its role in hepatocellular carcinoma (HCC) remains unknown. This study aimed to investigate the functions and potential tumorigenic mechanisms of LUBAC components in HBV-associated HCC.

Method: The expression of LUBAC components (RBCK1, RNF31, and Sharpin) and Met1-linked ubiquitination (M1-Ubi) and their correlation with prognosis were detected. The biological functions of RBCK1 in HBV-associated HCC were investigated in vitro and in vivo. The regulation of RBCK1 on the HBx protein expression was analyzed by cycloheximide chase assays, coimmunoprecipitation, and ubiquitin assays.
Results: We found that the expression of LUBAC components and M1-Ubi was significantly upregulated in HCC and correlated with poor prognosis. Interestingly, subgroup analysis revealed that RBCK1, not RNF31 or Sharpin, was exclusively overexpressed in HBV-associated HCC compared to non-HBV-associated HCC. Upregulated RBCK1 expression was associated with larger tumor size, higher AFP level, and poor prognosis in HBV-associated HCC cohort. Functionally, RBCK1-knockdown suppressed cell growth and migration, and also inhibited the progression of xenografted tumors in HBV-associated HCC mouse model. Mechanistically, RBCK1 interacted with HBx to promote its stabilization by increasing M1-Ubi ubiquitination and reducing K48-linked ubiquitination. Furthermore, clinical analysis confirmed a positive correlation between RBCK1 and HBx, and the co-expression of which predicted poor prognosis for HCC patients.

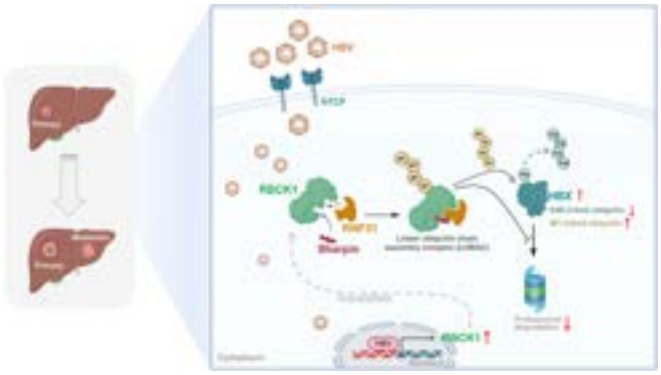

Figure:

Conclusion: RBCK1 is an oncogenic gene to promote tumor progression and may serve as a potential target for HBV-associated HCC.

SAT-270

Molecular determinants of period-specific recurrences in patients with surgically resected hepatocellular carcinoma

Jihyun An[1], Bora Oh[2], Jin-Sung Ju[2], Ju Hyun Shim[2]. [1]*Hanyang University College of Medicine, Korea, Rep. of South,* [2]*Asan Medical Center, Korea, Rep. of South*
Email: starlit1@naver.com

Background and aims: Postsurgical early-phase recurrence is associated with poorer clinical outcomes of patients with hepatocellular carcinoma (HCC). We hypothesized that the immune environments of the early- and late-recurrent HCCs differ, and investigated whether molecular changes differed according to the time of cancer recurrence by a cut-off of 5 years after resection.
Method: We included 253 patients who had HCCs initially without any gross vascular invasion or metastatic lesion, and received curative hepatectomy at the Asan Medical Center. RNA sequencing data and paraffin-embedded tissues derived from the resected tumors were available for all patients. The distributions of molecular subtypes as classified by Hoshida et al. and Boyault et al. were compared according to time of HCC recurrence using *MS.liverK*. For gene set enrichment and pathway analyses by GSEA v4.03, we used the gene sets in the Molecular Signatures Database (MSigDB) and the published literature. Immune phenotypes were classified based on previously defined immune and stromal classifiers. Immunohistochemical staining were performed with antibody against PD-L1 using DAKO 22c3 assays.
Results: Among the entire 253 patients, 134 cases (53.0%) experienced recurrence episodes, with 109 and 25 within (early) and beyond 5 years (late) after resection, respectively. The proportions of the three mRNA expression-based HCC subclasses according to Hoshida et al. (termed S1, S2, and S3) were significantly different in the two recurrence groups: the S2 subclass was enriched in the early recurrence group, and S1 in the late recurrence group (S1, 24.8% vs. 52.0%; S2, 30.3% vs. 8.0%; and S3, 45.0% vs. 40.0%, $P < 0.05$). The G2 subtype of Boyault et al. was exclusively observed in the early recurrence cases (19.3% vs. 0%, $P < 0.05$). In terms of immune and stromal classification, the immune-desert types were more abundant in the former (50.5% vs. 32.0%) and the exhausted types in the latter (32.1% vs. 52.0%). These findings are in agreement with the disproportionate enrichment of PD-L1 determined by combined positive score in the late recurrence group (5.5% vs. 24.0%, $P < 0.05$). Gene set enrichment analyses revealed that most of the gene expression signatures associated with immune responses were down-regulated in the early-period recurrence group (all Ps < 0.001).
Conclusion: We found that early-period recurrence events after resection are strongly associated with immune-silent HCCs and the scarcity of PD-L1 expression of the disease. Together with closer surveillance, adjuvant therapies should be tested in combination with immune system boosters in selective patients with such tumors.

SAT-271

Monitoring the local HCC immune landscape by fine needle aspiration

Gloryanne Aidoo-Micah[1,2], Stephanie Kucykowicz[1], Nathalie Schmidt[1], Amy Trinh[3], Laura J Pallett[1], Daniel Brown Romero[1], Vishnu Naidu[4], Rushabh Shah[4], Upkar Gill[5], Edward Green[4], Tim Meyer[2,3], Mala Maini[1]. [1]*University College London, Institute of Immunity and Transplantation, London, United Kingdom,* [2]*UCL, Cancer Institute, United Kingdom,* [3]*Royal Free Hospital London, Oncology, London, United Kingdom,* [4]*Royal Free London, Radiology, London, United Kingdom,* [5]*Queen Mary University of London, United Kingdom*
Email: m.maini@ucl.ac.uk

Background and aims: Accumulating data underscore the importance of harnessing local tissue-resident immunity in tumour immunotherapy. Sampling immune responses sequestered in tumours that cannot be sampled in blood could provide vital insights to improve immunotherapy. Diagnostic biopsies contain a mixture of immune cells from HCC and surrounding liver and their invasive nature precludes longitudinal monitoring. We postulated that fine needle aspirates (FNA) would provide a minimally invasive approach suitable for repetitive sampling of the tissue-resident HCC immune landscape.
Method: Patients with HCC undergoing systemic therapy with anti-PD-L1 and anti-VEGF consented to provide matched blood, FNA and biopsy samples for *ex vivo* multiparameter flow cytometric analysis of effector and regulatory immune populations.
Results: FNA reproducibly yielded viable leukocytes with all the major myeloid and lymphocyte populations detectable and an immune landscape distinct from blood. In the myeloid compartment, granulocytic myeloid suppressor cells (gMDSC/PMN-MDSC) were strikingly enriched in tumour FNA compared to blood, whereas dendritic cells were reduced. Amongst lymphocytes, FNA contained a significantly lower proportion of CD4 T cells and B cells than blood. Crucially FNA were able to detect tissue-resident T cells ($T_{RM,}$ $CD69^+CD103^+CD8$ and $CD69^{hi}CD4$) and liver-resident NK cells ($CXCR6^+CD69^+$) in HCC that cannot be sampled in blood, albeit at lower frequencies than were detected in matched core biopsies. The majority of tumour $CD8^+T_{RM}$ sampled by FNA or biopsy before immunotherapy expressed checkpoints like PD-1, Tim-3 and 2B4, accounting for significantly higher expression of these therapeutic

targets on the global CD8$^+$T cells extracted from FNA or biopsies than from blood.
Conclusion: Blood sampling can grossly underestimate the expression of key immunotherapeutic targets including checkpoints on T cells and gMDSC that can be detected on populations sequestered within HCC, sampled by either FNA or biopsy. FNA have the capacity to comprehensively monitor the HCC immune landscape to enhance the selection and development of targeted immunotherapy.

SAT-272
Clinicopathological analysis of polyploidization in human hepatocellular carcinoma and the development of an evaluation methodology
Takanori Matsuura[1], Yoshihide Ueda[1], Yoshiyuki Harada[1], Kazuki Hayashi[2], Kisara Horisaka[2], Yoshihiko Yano[1], Shinichi So[3], Masahiro Kido[3], Takumi Fukumoto[3], Yuzo Kodama[1], Eiji Hara[2], Tomonori Matsumoto[2]. *[1]Kobe University Graduate School of Medicine, School of Medicine, Division of Gastroenterology, Department of Internal Medicine, Kobe, Japan, [2]Research Institute for Microbial Diseases, Osaka University, Department of Molecular Microbiology, Osaka, Japan, [3]Kobe University Graduate School of Medicine, School of Medicine, Department of Surgery, Division of Hepato-Biliary-Pancreatic Surgery, Kobe, Japan*
Email: tomomatsumoto@biken.osaka-u.ac.jp

Background and aims: The cross-organ examination of cancer genomes has revealed that polyploidization, the acquisition of multiple sets of chromosomes, is a prevalent phenomenon in various neoplasms, including hepatocellular carcinoma (HCC). This suggests that polyploidization plays a significant role in carcinogenesis and tumor progression. However, the significance of polyploidization in HCC remains largely unknown. To address this, we aimed to establish a methodology for evaluating polyploidization in HCC using pathological specimens and to ascertain the clinicopathological characteristics of polyploid HCC.
Method: We performed multicolored fluorescence in situ hybridization (FISH) on paraffin-embedded, formalin-fixed pathology specimens from 56 HCC patients who underwent hepatectomy between 2017 and 2021 at our institution and determine the ploidy of HCC. Polyploid and diploid HCCs were compared to investigate the clinicopathological characteristics of polyploid HCC. We also explored a surrogate marker for polyploid HCC based on the transcriptome data of human hepatoma cell line Huh7 and verified its overexpression in polyploid HCC by immunostaining.
Results: Determination of tumor ploidy by FISH for three chromosomes revealed that 35.7% of HCCs (20/56 cases) were polyploid. There was no significant difference between polyploid and diploid HCCs in terms of tumor size and fibrosis of the non-tumor region. Notably, however, polyploid HCCs exhibited high serum alpha-fetoprotein levels ($p = 0.026$), poor differentiation ($p = 0.013$), and poor overall survival rates ($p = 0.013$). Moreover, polyploid HCCs contained polyploid giant cancer cells within the tumor at a significantly higher frequency than diploid HCCs. Among some genes that were significantly highly expressed in polyploid Huh7 cells compared to their diploid counterparts, we identified that ubiquitin-conjugating enzymes 2C (UBE2C) was significantly overexpressed in human polyploid HCCs. The abundance of polyploid giant cancer cells and overexpression of UBE2C could efficiently indicate polyploid HCC and predict their poor prognosis in combination.
Conclusion: Polyploidy in HCC was associated with tumor aggressiveness and exhibited a poor prognosis compared to diploid HCC. The assessment of ploidy in HCC utilizing FFPE tissue samples may serve as a novel prognostic marker of HCC.

SAT-273
Epigenetic reprogramming synergizes with PD-1/PD-L1 inhibition for cell-targeted therapy in hepatocellular carcinoma
Caecilia Sukowati[1,2], Loraine Kay Cabral[2,3], Beatrice Anfuso[4], Claudio Tiribelli[2]. *[1]National Research and Innovation Agency of Indonesia, Eijkman Research Center for Molecular Biology, Indonesia, [2]Fondazione Italiana Fegato ONLUS, Italy, [3]University of Trieste, Doctoral School in Molecular Biomedicine, Italy, [4]University of Trieste, Department of Life Science, Italy*
Email: caecilia.sukowati@fegato.it

Background and aims: Hepatocellular carcinoma (HCC) is a heterogenous cancer characterized with various cellular and molecular subtypes. HCC is one of the major causes of cancer-related mortality worldwide with poor prognosis and limited therapeutic options. This study aimed to investigate whether combination strategy between immunotherapy (against PD-L1) and epigenetic reprogramming (DNA demethylation inhibition) would be a potential therapy against heterogenous HCC.
Method: This study used *in vivo* animal model and *in vitro* manipulations. To assess the dynamics of PD-1/PD-L1, hepatic samples were taken from HBV-transgenic mouse C57BL/6J-TG (ALB1HBV)44BRI/J with age: 3 (inflammation), 6 and 9 (dysplasia; pretumoral), and 12 (tumor) together with its wild type counterpart. DNA methylation status of the PD-L1 was checked using the methylation-specific polymerase chain reaction (MSP). PD-L1 RNA silencing was performed by siRNA in several human HCC cell lines consisting of S1/TGFβ-Wnt subtype (HLE, HLF, and JHH6) and S2/progenitor subtype (HepG2 and Huh7). The combination therapy was performed in a co-culture system between HCC cells and immortalized lymphocytes, using a long-term treatment with non-toxic DNA methylation inhibitor 5-Azacytidine (5-AZA) and an antibody against PD-L1.
Results: In the mouse model, during the development of HCC, the gene expressions of both PD-L1 and its receptor PD-1, as well as Dnmt1 (DNA methylation marker) were significantly higher in HCC mouse compared to normal mouse ($p < 0.01$). Analysis of PD-L1 methylation status by MSP showed that the methylation of PD-L1 DNA was significantly higher in HCC mice compared to normal mice ($p < 0.001$). This implied double-targeting combining epigenetic and immunotherapy would be favorable. For *in vitro* data, the knockdown of PD-L1 gene was accompanied with that of DNMT1 gene, mostly noted in aggressive HCC cell lines. The reduction of PD-L1 was also followed by dysregulation of cancer stem marker EpCAM in all cell lines expressing this marker. By combination therapy in a co-culture system between HCC cells and lymphocytes, using a long-term treatment with non-toxic DNA methylation inhibitor 5-AZA and antibody against PD-L1, the growth of lymphocytes was limited by the PD-L1 antibody, and it was furtherly reduced in the presence of 5-AZA for up to 20% ($p < 0.001$). For HCC cells, however, the PD-L1 antibody reduced the cells growth, but the addition of 5-AZA was not significant.
Conclusion: To conclude, we propose that a combination therapy between DNA methylation inhibition and PD-L1 blocking can be potential strategy for the treatment of heterogeneous HCCs.

SAT-274

Lysosomotropic PIP5K inhibitors sensitize hepatic cancer to reative oxygen species by inhibiting proliferative and adaptive pathway

P.A. Shantanu[1], Sameer Panda[1], Bishal rajdev[1], Sai Balaji Andugulapati[2], N.P Syamprasad[1], Akash Kumar Mourya[3], Ramakrishna Sistla[2], Savneet Kaur[3], Vegi Naidu[1], Dinesh Mani Tripathi[3]. Email: dineshmanitripathi@gmail.com

Background and aims: The complex interplay between ROS-molecular signaling governs proliferation, adaptation, and death. To date, how cancer cells modulate PIP5K levels to control proliferative and adaptive signaling is not known.
Method: Firstly, we investigated the protein expression of PIP5K isoforms, Beclin-1 (autophagy marker), and Nrf2 (antioxidant master regulator) in 36 HCC patients and immortalized cells viz PRF5, SNU-387, Skhep-1 and HepG2. To understand ROS-mediated effect on PIP5K, autophagy, and antioxidants, HCC cells exposed to H2O2. Further, effect on cell viability, mitochondrial superoxide, lysosome turnover, expression of PIP5K isoforms, autophagy and antioxidant enzymes through MTT, MitoSOX, lysotracker was evaluated. The effect of PIP5K inhibition on the cancer cells sensitization was investigated with novel investigational molecules NG-TZ-17 and IITZ01 and finding was confirmed with standard PIP5K1A inhibitor ISA-2011B. Also, the Autophagy inhibition of NG-TZ-17 and IITZ01 was examined with respect to autophagy inhibitor Chloroquine and NRF2 inhibitor ML-385. In vivo GFP-HepG2 induced hepatic cancer model in SCID mice was developed for exploring therapeutic efficacy. In HCC Mice, 50 mg/kg NG-TZ-17 and IITZ01 and compared with 60 mg/kg Sorafenib administered orally for seven days.
Results: We observed a positive correlation between PIP5K isoforms, Beclin-1 and Nrf2 in hepatocellular carcinoma liver tissue and cell lines. Cytotoxicity and Protein expression showed a concentration-dependant starvation-induced proliferation, resisted cell death by increasing PIP5K isoforms, Nrf2, HO-1, and SOD2 levels. At cytotoxic concentration resulted in autophagic cell death as indicated by the decrease in PIP5K isoforms, Akt, Nrf2, HO-1, and SOD2 expression however an increase in SRC and Beclin-1was observed. The inhibition of PIP5K with lysosomotropic NG-TZ-17, IITZ01, and ISA-2011B (standard) sensitized HCC cells showed proliferative, autophagy and Nrf2 pathway downregulation compared to HCC cells exposed to mild stress. We observed the PIP5K inhibitors (both) was superior to Chloroquine and ML385. In vivo we observed 50 mg/kg NG-TZ-17 ($p < 0.001$) and IITZ01 ($p < 0.001$) reduced the tumor burden in the HepG2-xenograft SCID mice model ($p < 0.001$ compared to tumor control). The treatment was equipotent to standard sorafenib 60 mg/kg ($p < 0.001$ vs tumor control).

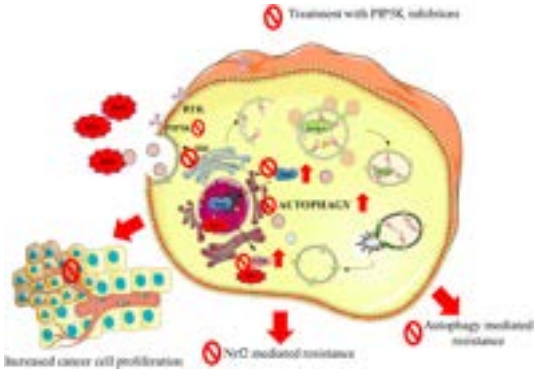

Figure:

Conclusion: HCC clinical and in vitro data showed that PIP5K isoforms involved switching of cancer cells from adaptive to proliferative state vice-versa in response to ROS levels. PIP5K inhibitors sensitized cancer cells to mild ROS. Thus, targeting PIP5K will overcome limitations of standard RTK, autophagy and Nrf2 inhibitors. This study also confers the therapeutic efficacy of novel PIP5K inhibitor viz NG-TZ-17 and IITZ01 in Hepatic cancer.

Background and aims: Cholangiocarcinoma (CCA) constitutes a cluster of highly heterogeneous biliary malignant tumors that can arise at any point of the biliary tree. The silent presentation of these tumors combined with their highly aggressive nature and refractoriness to chemotherapy contribute to their alarming mortality (2% of all cancer-related deaths worldwide yearly). Long non-coding RNAs (lncRNA) can interact with DNA, RNA and proteins to regulate global gene expression patterns. They are remarkably versatile regulators, influencing multiple biological processes and playing key roles in the pathogenesis of several disorders. Their function in cholangiocarcinoma development, however, remains largely unexplored. In this proposal, our main aim is to examine the biological function and mechanism of action of the lncRNA-A1.
Method: We have studied the expression of LncRNA-A1 in samples from patients with primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC), and in mice models of cholestasis, ans several cholangiocarcinoma cell lines (CCA). Finally, we have performed functional analysis by *in vitro* targeting of lncRNA-A1.
Results: In key preliminary experiments, we have observed that LncRNA-A_1 was significantly upregulated in liver samples from patients with primary biliary cirrhosis (PBC) and primary sclerosing

cholangitis (PSC), and that its expression was consistently elevated in three different mice models of cholestasis at different time points: bile duct ligation (BDL), mice fed with a cholic acid diet and MDR2-KO mice. Surprisingly, we did not observe any change in its expression in livers from NAFLD models or CCl_4 intoxicated mice, suggesting that the upregulation of this gene could be restricted to cholestatic liver injury. At cellular level, we observed that LncRNA-A_1 was upregulated specifically in the biliary tree from MDR2-KO mice, but was not significantly altered in hepatocytes, Kupffer, endothelial or hepatic stellate cells. Remarkably, LncRNA-A_1 was generally observed upregulated in CCA cells with KRAS or BRAF mutations (KKU-213, RBE, EGI-1, SK-ChA-1) or in EGF-treated human cholangiocytes (MMNK1), in comparison with CCA cells without KRAS or BRAF mutations (TFK-1, SG231) or with untreated MMNK1 cells. In addition, we found that LNCRNA-A_1 was consistently elevated in tumoral liver from three different animal models of CCA (SB1-Singeneic, AKT-NICD and AKT-YAP) in comparison with non-tumoral liver. Next, we performed *in vitro* targeting of lncRNA-A1 and examined its effects in CCA cell lines and immmortalized cholangiocytes (MMNK1). Silencing of this lncRNA induced cell death and reduced the expression of proliferative genes in CCA cell lines but not in MMNK1 cells.

Conclusion: Altogether these data suggest that hepatic upregulation of lncRNA-A_1 in liver could be involved in CCA survival, although the physiological and mechanistic relevance of this upregulation is still under further investigation.

Identification of hepatocyte-restricted antigens, epitopes, and T cell receptors to treat recurrent hepatocellular carcinoma after liver transplantation

Yannick Rakké[1], Dian Kortleve[2], Astrid Oostvogels[2], Robbie Luijten[3], Monique de Beijer[2,3], Stijn De Man[3], Michael Doukas[4], Jan Ijzermans[1], Sonja Buschow[3], Reno Debets[2], Dave Sprengers[3]. *[1]Erasmus MC-Transplant Institute, University Medical Centre Rotterdam, Rotterdam, the Netherlands, Department of Surgery, Division of HPB and Transplant Surgery, Netherlands, [2]Erasmus MC-Cancer Institute, University Medical Centre Rotterdam, Rotterdam, the Netherlands, Laboratory of Tumor Immunology, Department of Medical Oncology, Netherlands, [3]Erasmus MC-Cancer Institute, University Medical Centre Rotterdam, Rotterdam, the Netherlands, Department of Gastroenterology and Hepatology, Netherlands, [4]Erasmus MC-Cancer Institute, University Medical Centre Rotterdam, Rotterdam, the Netherlands, Department of Pathology, Netherlands*
Email: y.rakke@erasmusmc.nl

Target antigens, epitopes, and T cell receptors are not disclosed due to patent filing.

Background and aims: HCC recurrence in the context of an HLA-mismatched donor liver provides the unique setting that liver antigens from HCC versus the liver allograft are presented by different alleles of Human Leukocyte Antigen (HLA). Here, we present the development of an adoptive therapy with T cell receptor (TCR)-engineered T cells directed against hepatocyte-restricted antigens (HRAs) presented by the recipient, but not donor HLA.

Method: We have applied an integrative approach of *in silico* antigen and epitope prediction, immunopeptidomics, and *in vitro* laboratory tools to stringently select and validate HRAs, their immunogenic epitopes, as well as corresponding TCRs.

Results: 58 presumed liver antigens retrieved from the human protein ATLAS were further evaluated for liver-restricted expression in 6 public RNA databases and 1 protein database (HIPED), short-listing 14 candidate HRAs. 3/14 HRAs did not show RNA expression in healthy tissues, except for liver, in another five tissue datasets (n = 1,709) and validated using qPCR. Two HRAs demonstrated RNA expression in >70% of HCC patients (n = 421). Immunopeptidomics of HCC-derived hepatocytes (n = 12), together with *in silico* predictions of immunogenicity, revealed 36 HLA-A2-restricted epitopes. These epitopes were tested and ranked according to *in vitro* HLA-A2 binding ability. Epitope-specific T cells were enriched from healthy donors for 6 of these epitopes using an *in vitro* co-culture with autologous antigen presenting cells. Eleven TCRαβs directed against 4 HRA-derived epitopes were selected following epitope-MHC-directed fluorescence-activated sorting of T cells. Five TCRs were functionally expressed upon gene transfer into T cells and recognized their cognate peptide, of which 4 TCRs harboured a stringent safety profile according to amino acid scanning, and are expected to mediate no to negligible cross-reactivity.

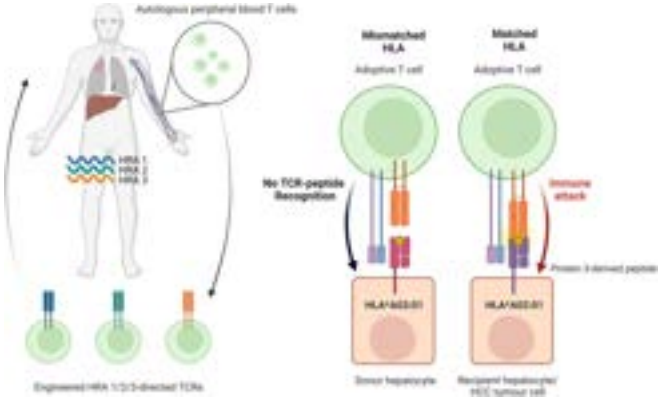

Figure: Concept of TCR-engineered T cells to exclusively target recipient-derived hepatocytes and hepatocellular carcinoma. In the current study, hepatocyte-restricted antigens (HRA) and their epitopes are identified following which HRA-specific T cell receptors (TCRs) are obtained with reactivity towards hepatocytes/HCC tumour cells but not to donor hepatocytes. These TCRs, when used to gene-engineer autologous, peripheral blood T cells, constitute a therapeutic to treat HCC recurrence after liver transplantation leaving the liver allograft unaffected.

Conclusion: We have identified HRAs, epitopes and corresponding TCRs, of which the lead TCRs will be further exploited for the treatment of recurrent HCC after liver transplantation with adoptive therapy of TCR-engineered T cells.

Characterization of the immune tumor microenvironment in HCC

Charlotte Hoffmann[1], Simon Peter[1], Valery Volk[1], Melanie Bathon[1], Tanja Reineke-Plaaß[1], Nadine Schaadt[1], Friedrich Feuerhake[1], Arndt Vogel[1], Anna Saborowski[1]. *[1]Medizinische Hochschule Hannover, Germany*
Email: hoffmann.charlotte@mh-hannover.de

Background and aims: Current frontline therapy for hepatocellular carcinoma (HCC) is based on immune checkpoint inhibitors (ICIs) targeting the programmed cell death protein 1/-ligand 1 (PD-1/PD-L1) axis, but alternative ICIs are under preclinical and clinical investigation. A more granular understanding of the immune contexture of HCC will be critical to determine recurrent patterns of the HCC immune tumormicroenvironment (iTME) and identify potential biomarkers that may ultimately allow for a more stratified approach to using immunomodulatory cancer therapies. We employed multiplex immunohistochemistry (mIHC) to spatially resolve and clinically annotate the iTME in HCC in the context of the underlying etiologies.

Method: FFPE tissues from 95 resected and clinically annotated HCCs were selected, and attention was paid that both tumor- and surrounding non-tumoral liver tissue were represented on a single section. Using a mIHC platform (Phenoptics system, Akoya Bioscience) the sections were stained for the following markers: CD3, CD20, CD68, Perforin, PD-L1, TIM3, LAG3 and Arginase, and regions of interests for subsequent multispectral high-resolution image acquisition were placed i) within the tumor, ii) the margin (tumor invasive front) and iii) the adjacent non-tumoral liver. The

tissue samples were stratified according to the respective underlying diagnosis, ASH (n = 28), NASH (n = 40) and viral (HBV or HCV, n = 27).
Results: No significant etiology-dependent differences were evident in immune cell densities detected by our marker panel across all tumor areas and adjacent liver. According to the intratumoral localization, CD3 and CD20 positive cells were lowest within the tumor compared to margin and surrounding liver. Quantitative assessment of immune checkpoint expression revealed a striking dominance of PD-L1 over LAG3 and TIM3 in tumoral and non-tumoral regions, with a comparatively pronounced relative contribution of TIM3 signals in the margin area. Total PD-L1 signal was increased in HCCs with viral etiology, compared to those arising in the ASH context, but not to NASH-related HCC. Clinical correlations are currently under investigation and will be presented.
Conclusion: The iTME of human HCCs exhibits not only spatial dependencies, but also segregates with the respective underlying etiology. Distinct marker expression in NASH vs. ASH argues in favor of a more differentiated view of "non-viral" subgroups of HCCs. In addition, we posit that instead of quantitative assessments of single markers, a deeper understanding of the spatially resolved and "etiologically" annotated iTME will be required to identify translationally relevant markers, especially in the context of immunotherapy clinical trials.

SAT-278
Nuclear translocation of YAP drives BMI1-associated hepatocarcinogenesis in hepatitis B virus infection
Xufeng Luo[1], Rui Zhang[2], Stefan Schefczyk[3], Shi Liu[4], Yaojie Liang[3], Hideo Baba[5], Christian M. Lange[6], Heiner Wedemeyer[7], Mengji Lu[8], Ruth Broering[3]. *[1]The Affiliated Cancer Hospital of Zhengzhou UniversityandHenan Cancer Hospital, Institute for Lymphoma Research, China, [2]Sun Yat-sen University, Dept. of Biliary-Pancreatic Surgery, China, [3]University Duisburg-Essen, Dept. of Gastroenterology, Hepatology and Transplant Medicine, Germany, [4]College of Life Sciences, Wuhan University, State Key Laboratory of Virology, China, [5]University Duisburg-Essen, Institute of Pathology, Germany, [6]LMU University Hospital Munich, Dept. of Internal Medicine II, Germany, [7]Hannover Medical School, Dept. of Gastroenterology, Hepatology and Endocrinology, Germany, [8]University Duisburg-Essen, Institute for Virology, Germany*
Email: ruth.broering@uni-due.de

Background and aims: Hepatitis B virus (HBV) infection is a major cause of hepatocellular carcinoma (HCC) development and progression. The aim of this study was to mechanistically investigate the involvement of Hippo signalling in HBsAg-dependent neoplastic transformation.
Method: Liver tissue and hepatocytes from HBsAg-transgenic mice were examined for the Hippo cascade and proliferative events. Functional experiments in mouse hepatoma cells included knockdown, overexpression, luciferase reporter assays and chromatin immunoprecipitation. Results were validated in HBV-related HCC biopsies.
Results: Hepatic expression signatures in HBsAg-transgenic mice correlated with YAP responses, cell cycle control, DNA damage and spindle events. Polyploidy and aneuploidy occurred in HBsAg-transgenic hepatocytes. Suppression and inactivation of MST1/2 led to the loss of YAP phosphorylation and the induction of BMI1 expression *in vivo* and *in vitro*. Increased BMI1 directly mediated cell proliferation associated with decreased level of p16INKA4, p19ARF, p53 and Caspase 3 as well as increased Cyclin D1 and γ-H2AX expression. Chromatin immunoprecipitation and the analysis of mutated binding sites in DLR assays confirmed that the YAP/TEAD4 transcription factor complex bound and activated the Bmi1 promoter. In chronic hepatitis B patients, paired liver biopsies of non-tumour and tumour tissue indicated a correlation between YAP expression and the abundance of BMI1. In a proof-of-concept, treatment of HBsAg-transgenic mice with YAP inhibitor verteporfin directly suppressed the BMI1-related cell cycle.
Conclusion: HBsAg-mediated inhibition of Hippo signalling pathway was shown to be responsible for BMI1-mediated cell proliferation by controlling cell cycle check points. YAP and BMI1 might be important factors linking HBV infection and the development of proliferative hepatocellular carcinoma. HBV-associated proliferative HCC might be related to the HBsAg-YAP-BMI1 axis and offer a potential target for the development of new therapeutic approaches.

SAT-279
Nonresolving inflammation in liver cancer; differential regulation of miR-122 signaling by BMP6 and TGFβ
Martha Paluschinski[1], Mihael Vucur[1], Philipp Lang[2], Tom Lüdde[1], Mirco Castoldi[3]. *[1]University Hospital Dusseldorf, Gastroenterology, Hepatology and Infectious Diseases, Düsseldorf, Germany, [2]University Hospital Dusseldorf, Institute for Molecular Medicine II, Düsseldorf, Germany, [1]University Hospital Dusseldorf, Gastroenterology, Hepatology and Infectious Diseases, Düsseldorf, Germany*
Email: mirco.castoldi@med.uni-duesseldorf.de

Background and aims: Persistent inflammation is known to promote and exacerbate malignancy. The identification of key inflammatory signaling pathways causing transition from acute to chronic liver injury and from dysplasia to hepatocellular carcinoma (HCC) could depict novel predictive biomarkers and targets to identify and treat patients with chronic liver inflammation. microRNAs (miRNAs) are sequence-specific inhibitor of gene expression, which control cellular processes, whereas cellular signals and pathological conditions alter miRNA expression. With the aim of identifying miRNAs and mRNAs associated with nonresolving inflammation, genome-wide miRnomic and transcriptomic analyses were performed in the livers of animal models characterized by inflammation-driven liver cancer.
Method: Low density and Affymetrix arrays were used to identify miRNAs and mRNAs altered in animal model with inflammation-driven liver cancer. Expression of genes of interest was independently validated by qPCR in animal models and in cohort of HCC patients. Luciferase vectors carrying the promoter region of human or murine *MIR122* were transfected into tumor cell lines or primary hepatocytes, and the activity of selected cytokines was evaluated.
Results: The liver enriched miR-122 was identified as the most significantly downregulated microRNA in the liver of animal models with inflammation-driven liver cancer. Compelling evidence indicate that miR-122 is required for maintaining hepatic functionality, However, it remains unclear whether the observed phenotype is the trigger or consequence of ongoing diseases. Through this study, analysis of *in-vitro* and *in-vivo* experimental models, identified that miR-122 transcription is tightly interlinked with inflammation. We discovered that Lymphocytic choriomeningitis virus (LCMV) induced acute hepatitis in wild-type mice correlated with decreased level of hepatic miR-122. We identified that miR-122 transcription is differentially modulated by the immunoregulatory cytokines TGFβ and BMP6. We show that Smad4 is required for mediating TGFβ activity.
Conclusion: Collectively, our study provides new insights into the molecular mechanisms that potentially lead to downregulation of miR-122 in liver disease. As a result, new regulatory networks linking inflammation to the modulation of miR-122 expression have been identified. We propose that metabolic overload of regulatory networks driving cytokine-mediated deregulation of miR-122 expression may contribute to the development of chronic liver disease.
Model 1; positive feedback loop; In this model the role of miR-122 is to fine-tune HAMP transcription via inhibiting HJV and HFE translation. Model 2; negative feedback loop; In this model, the role of miR-122 down-regulation is to activate inflammatory response via release of miR-122 inhibitions on its target genes.

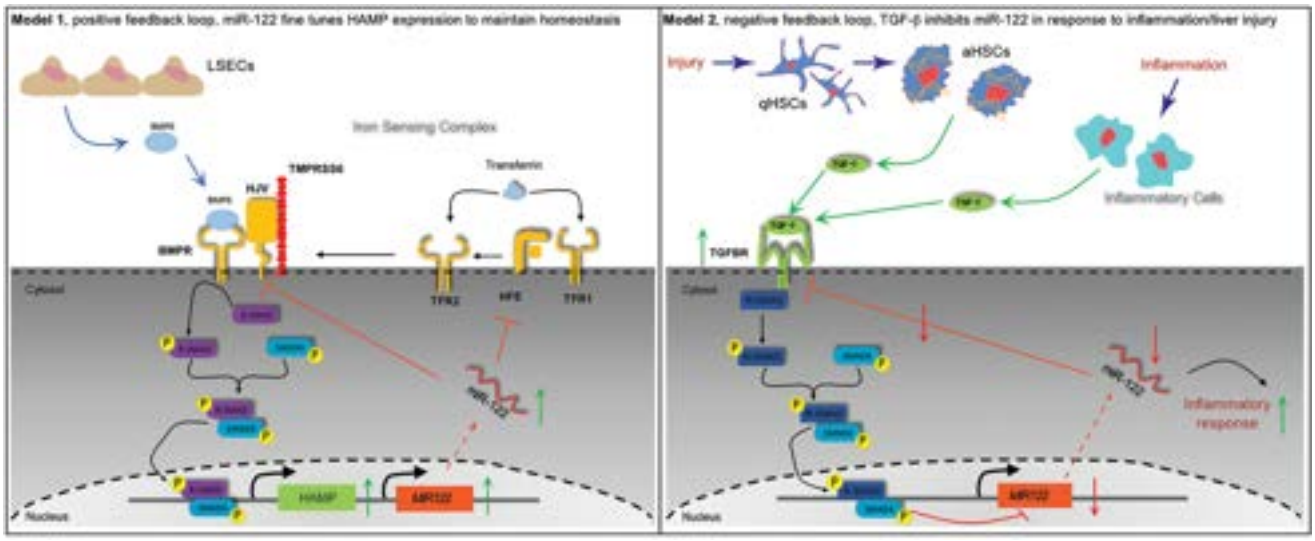

Figure: (abstract: SAT-279): Proposed models for regulatory networks up-steam to miR-122.

Email: marcin.krawczyk@uks.eu

Background and aims: Gallstone disease (GD) is one of the most common hepatobiliary conditions in Europe. In most cases gallstones remain asymptomatic. However, they might also cause complications like choledocholithiasis or gallbladder cancer in case of a long-lasting GD. Here, we analyse the common genetic risk modifier of GD (p. D19H variant in the sterol transporter *ABCG8*) in patients scheduled for bariatric surgery as well as in patients with gallbladder cancer and with recurrent common bile duct stones.
Method: Prospectively, we recruited three Polish cohorts of patients: 170 obese individuals scheduled for bariatric surgery (115 women, age range 19–65 years, 40 with GD), 65 patients with gallbladder cancer (49 women, age range 31–77 years), and 72 patients who underwent ERCP due to *de novo* stones that developed at least six months after cholecystectomy (49 females, age range 26–94 years). The control cohort comprised 172 gallstone-free adults. The *ABCG8* p. D19H variant was genotyped in all cases and controls using TaqMan assays. In addition, we genotyped the c.711 (rs2109505) variant in the hepatic phospholipid transporter *ABCB4* given the potential involvement of the *ABCB4* locus in gallbladder cancer risk (Mhatre et al. *Lancet Oncol* 2017).
Results: Significantly more individuals carried at least one copy of the *ABCG8* p.D19H risk allele among cases with either gallstones or gallbladder cancer (16.5%) as compared to controls (7.5%, p = 0.016). In particular, this variant was associated with an increased risk of developing gallbladder cancer (common OR 2.24, p = 0.017). It also increased the risk of GD in the obese scheduled for bariatric surgery (OR = 2.85, 95%CI 0.98–8.23, p = 0.045). On the other hand, it was not linked with *de novo* choledocholithiasis after cholecystectomy. We also did not find any significant link between the tested *ABCB4* variant and the risk of gallbladder cancer either.
Conclusion: To the best of our knowledge, this is one of the first studies showing that the common *ABCG8* risk variant increases the risk of gallbladder cancer in central Europeans. Moreover, this variant seems to increase the risk of gallstones in obese patients. Given the dismal prognosis of gallbladder cancer as well as the potential difficulties of treating symptomatic gallstones in obese patients, we reckon that carriers of this variant might profit from personalized diagnostic and therapeutic strategies to prevent both conditions.

SAT-281

CRISPR-engineered cholangiocarcinoma tumoroids generation from chemically-derived hepatic progenitor organoid for disease modelling

Michael Adisasmita[1,2], Hyomin Lee[3], Myounghoi Kim[1,2], Hayoon Kim[1,2], Elsy Soraya Salas Silva[1,2], Ji Hyun Shin[1,2], Woochang Hwang[4], Junho Hur[3], Dongho Choi[1,2]. *[1]Hanyang University College of Medicine, Surgery, Korea, Rep. of South, [2]Research Institute of Regenerative Medicine and Stem Cells, Hanyang University, Korea, Rep. of South, [3]Hanyang University College of Medicine, Genetics, Korea, Rep. of South, [4]Hanyang University College of Medicine, Pre-Medicine, Korea, Rep. of South*
Email: crane87@hanyang.ac.kr

Background and aims: Intrahepatic cholangiocarcinoma (iCC) is a deadly malignancy of the liver's biliary epithelial cells. This cancer has a high degree of heterogeneity, is extremely difficult to treat, and has a severely low survival rate. A vital discovery that significantly advances cancer research is the development of cancer organoid technique. These organoids can be derived from iCC patients' specimens but with very limited efficiency due to its insufficient sample cell size and quality. In addition, cancer organoids can be derived from normal adult stem cells edited by CRISPR technology to emulate the gene mutation that occurred during early carcinogenesis.
Method: To generate the iCC tumoroid model, we transfected normal human chemically-derived hepatic progenitor cells (hCdHs) with

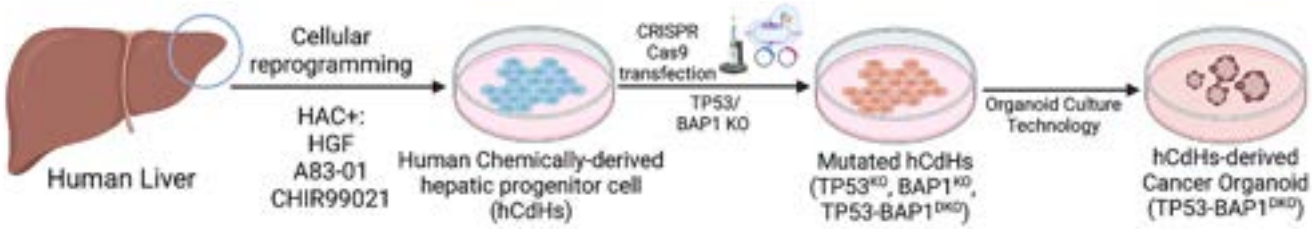

Figure: (abstract: SAT-281).

CRISPR-Cas9 plasmid and gRNA plasmids for TP53 and BAP1 by electroporation. Following the transfection, we generated tumoroids in matrigel dome from these mutated progenitor cells and performed various analyses of this tumoroids.

Results: To overcome the current limitation of the patient-derived cancer organoid, we successfully generated tumoroids from hCdHs that can be robustly expanded from a relatively small cell number. Then, we introduced the double knock-out mutation of TP53 and BAP1 genes, a well-established iCC cancer driver gene. These CRISPR-engineered hCdHs-derived cancer organoids showed comparable phenotypes with the iCC tumour malignant features. We observed pathological features of biliary adenocarcinoma on these tumoroids and confirmed the presence of mucus including mucin in the tumoroids lumen.

Conclusion: These results demonstrated the capability of our CRISPR-engineered hCdHs-derived cancer organoid as a powerful cancer disease modelling platform.

This research is funded by grants Korean Fund for Regenerative Medicine funded by Ministry of Science and ICT, and Ministry of Health and Welfare (21A0401L1). MA is supported by Hyundai Motor Chung Mong-Koo Global Scholarship.

Immunological impact of Axl/TGF-beta signaling in hepatocellular carcinoma

Gregor Ortmayr[1], Viola Hedrich[2], Patrick Starlinger[3], Thomas Grünberger[4], Doris Chen[5], Wolfgang Mikulits[2]. *[1]Medical University of Vienna, Center for Cancer Research, Wien, Austria, [1]Medical University of Vienna, Center for Cancer Research, Wien, Austria, [3]Mayo Clinic Rochester, Department of Surgery, Division of Hepatobiliary and Pancreatic Surgery, Rochester, Minnesota, United States, [4]Clinic Favoriten, Viennese Health Network, Department of Surgery, HPB Center, Vienna, Austria, [5]University of Vienna, Max Perutz Labs, Department of Chromosome Biology, Center for Integrative Bioinformatics Vienna, Vienna, Austria*
Email: gregor.ortmayr@gmail.com

Background and aims: A minority of hepatocellular carcinoma (HCC) patients is susceptible to conventional immune checkpoint blockade (ICB) as determined by immunological subtyping. The majority about 80% of HCC cases present an immunosuppressive or immune-excluded tumor microenvironment (TME). Interestingly, the class of immune-exhausted HCC, which is associated with poor response to ICB and prognosis, is also linked to "highly activated," aberrant TGF-beta signaling. In HCC, the receptor tyrosine kinase Axl collaborates with TGF-beta by the phosphorylation of Smad3 at serine 213 in the linker region (Smad3L-Ser213) causing an aberrant, tumor-promoting TGF-beta signaling, which most likely also translates into the TME. As underlying mechanisms remain unclear, we aim to assess how Smad3L-Ser213-linked TGF-beta signatures shape an immunosuppressive TME.

Method: We used RNA-seq analysis and VENN relations of HCC models to identify targets of the Axl/TGF-beta signaling. Modulation of Axl/TGF-beta activity and analyses in publicly available data sets of HCC patients were employed to verify target expression.

Results: HCC cells showing aberrant TGF-beta signaling together with either proficiency or deficiency in Axl expression, the latter in the absence or presence of Axl reconstitution, were subjected to Gas6 and TGF-beta stimulation and subsequent RNA-seq analysis. Bioinformatics and VENN relations revealed uridine phosphorylases (UPP)1 as the most promising target since upregulation is associated with poor prognosis and immune evasion of HCC patients. Interference with Smad3L-Ser213 phosphorylation by inhibition of 14-3-3ζ or c-JNK confirmed UPP1 as a target of aberrant TGF-beta signaling. Genetic intervention with UPP1 reduced cell invasion and migration, while proliferation and survival of HCC cells remained unaffected. In line, cells exhibiting mesenchymal characteristics showed strong UPP1 expression.

Conclusion: We identified UPP1 as a target of Axl-driven, aberrant TGF-beta signaling in HCC cells. The link to immune escape and poor prognosis provides a clear rationale for further assessing its impact in reshaping the TME based on in vivo models and analyses in prospective HCC patient samples.

Email: massimiliano.cadamuro@unipd.it

Background and aims: Metabolic syndrome (MetS) is a common condition closely associated with non-alcoholic fatty liver disease/non-alcoholic steatohepatitis (NAFLD/NASH). Recent meta-analyses show that MetS can be prodromal to intrahepatic cholangiocarcinoma (iCCA) development, a liver tumor with features of biliary differentiation characterized by dense extracellular matrix (ECM) deposition. Since ECM remodeling is a key event in the vascular complications of MetS, we aimed at evaluating whether MetS patients with iCCA present qualitative and quantitative changes in the ECM able to incite biliary tumorigenesis.

Method: Serial sections of liver tissue specimens of iCCA on a background of MetS (n = 22) and without MetS (non-MetS, n = 44), and relative peritumoral areas, were stained with Masson's Trichrome (histological staining for fibrosis) and with immunohistochemistry to highlight ductular reaction (DR) and hepatic

progenitor cells (keratin 7), and to depict the ECM proteins Osteopontin (OPN), Tenascin C (TnC) and Periostin (POSTN). Type and extent of DR, HPC, and fibrosis was evaluated by histological analysis, while extent of OPN; TnC and POSTN was assessed with computer-assisted morphometry. Patients were divided between the two cohorts based on biochemical and radiological data (CT scan for abdominal fat accumulation).

Results: In iCCAs with MetS patients undergoing surgical resection, we found a significant increased deposition of OPN, TnC, and POSTN compared to the matched peritumoral areas. Moreover, OPN deposition in MetS iCCAs was also significantly increased when compared to iCCA samples without MetS (non-MetS iCCAs). Using an *in vitro* approach, we have seen that OPN, TnC and POSTN treatment significantly stimulated cell motility and cancer stem cell-like phenotype in HuCCT-1.

Conclusion: In MetS iCCAs, fibrosis distribution and components differed quantitatively and qualitatively from non-MetS iCCAs. We therefore propose overexpression of OPN as a distinctive trait of MetS iCCA. Since OPN stimulate malignant properties of iCCA cells, it may provide an interesting predictive biomarker and a putative therapeutic target in MetS patients with iCCA.

SAT-284

Modelling hepatocellular carcinoma in precision-cut liver slices for therapeutic screening and as a precision medicine tool

Amy Collins[1,2], Jack Leslie[1,2], Daniel Geh[1,2], Erik Ramon Gil[1,2], Maja Laszczewska[1,2], Glyn Nelson[3], Rainie Cameron[1], Kenny Dalgarno[4], Helen Louise Reeves[2,5], Derek A Mann[1,2], Fiona Oakley[1,2]. *[1]Newcastle Fibrosis Research Group, Newcastle University, Newcastle upon Tyne, United Kingdom, [2]The Newcastle University Centre for Cancer, Newcastle University, Newcastle upon Tyne, United Kingdom, [3]Bioimaging Unit, Newcastle University, Newcastle upon Tyne, United Kingdom, [4]School of Engineering, Newcastle University, Newcastle upon Tyne, United Kingdom, [5]Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, United Kingdom*
Email: a.l.collins1@newcastle.ac.uk

Background and aims: Liver cancer is one of the most common causes of cancer-related death worldwide, and hepatocellular carcinoma (HCC) accounts for approximately 90% of cases. Recent therapeutic advances extend overall survival by a few months, but only for a minority of patients. Realistic HCC models are necessary in order to bridge the gap between preclinical research and *in situ* human disease, and provide valuable insight into disease pathogenesis and drug discovery. Here we describe the development of two HCC models in precision-cut liver slices (PCLS): a murine precision-cut tumour slice (PCTS) model utilising the Hep-53.4 cell line, and a spheroid-engrafted human PCLS model.

Method: Hep-53.4 PCTSs were generated from orthotopic tumours 21 days after an intrahepatic injection of 1 million cells in C57BL/6 mice, and subsequently treated in the presence of absence of the receptor tyrosine kinase (RTK) inhibitors sorafenib or lenvatinib. An *ex vivo* human HCC model was developed by engrafting spheroids generated from HuH7 cells that express a secreted luciferase, onto human PCLSs. The spheroid-engrafted PCLS were then cultured in the presence or absence of the RTK inhibitors sorafenib, lenvatinib or regorafenib. Primary HCC cell lines derived from patient biopsies were expanded and lentiviral-transduced to express mCherry, and spheroids generated from these cells were also implanted onto human PCLSs. All tissue was cultured in a bioreactor system capable of maintaining the viability of the tissue for 7 days.

Results: Treatment of Hep-53.4 PCTSs with the RTK inhibitors sorafenib and lenvatinib results in decreased proliferation (Ki-67) and increased apoptosis (active caspase-3). Immunohistochemical characterisation of the PCTSs determined that they maintain a rich immune profile in culture, and treatment with anti-PD-1 immunotherapy results in significantly higher CD3 T-cell numbers, as well as increased HCC apoptosis. In relation to the human spheroid-PCLS model, complete invasion of the spheroids into the PCLSs was confirmed via multiphoton imaging. Measurement of luciferase secreted following treatment with RTK inhibitors indicated a significant and dose-dependent reduction in cancer growth, whilst the PCLSs remained viable. Primary HCC spheroids implanted onto human PCLS also displayed complete engraftment and invasion into the tissue (Figure 1).

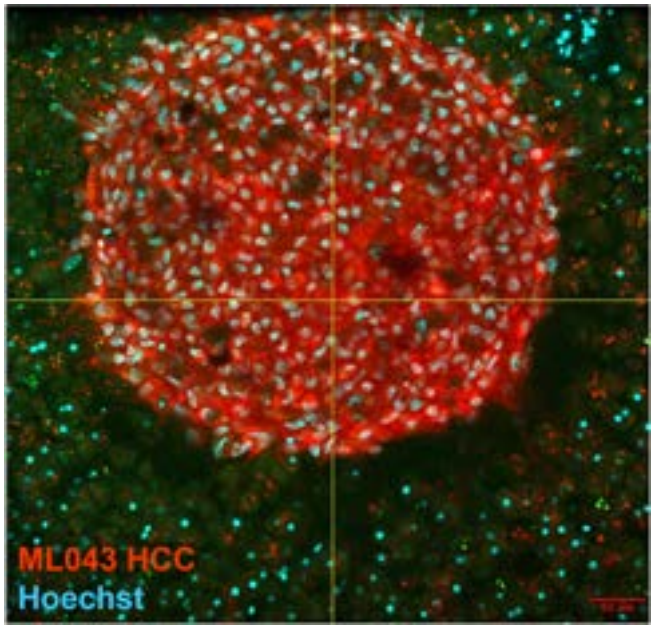

Figure:

Conclusion: The two models described potentially provide unique tools for discovery biology and precision medicine, where therapies can be tested on both PCTSs and patient-derived HCC cells in the context of the tumour microenvironment.

SAT-285

Investigation of optimization model for predicting ICI treatment efficacy on contrast-enhanced CT images of hepatocellular carcinoma using AI

Yasuhiko Nakao[1], Ryu Sasaki[1], Masanori Fukushima[1], Satoshi Miuma[1], Hisamitsu Miyaaki[1], Kazuhiko Nakao[1]. *[1]Nagasaki University Hospital, Gastroenterology and Hepatology, Nagasaki, Japan*
Email: yasu.nakao@nagasaki-u.ac.jp

Background and aims: The introduction of immune checkpoint inhibitors (ICIs) for unresectable hepatocellular carcinoma (HCC) is expected to improve prognosis. However, since the introduction of ICI, it has been found that there are individual differences in treatment efficacy, and studies have been reported to examine the factors associated with treatment failure based on the contrast effect of the hepatocellular phase of EOB-MRI prior to the introduction of ICI. ICI may improve the prognosis of patients. In this study, we developed an AI-based prediction model to predict treatment efficacy based on the characteristics of contrast-enhanced CT scan before ICI introduction, including hepatocellular carcinoma (HCC) and contrast effect of the background liver.

Method: We evaluated the efficacy of atezolizumab and bevacizumab in 43 patients at Nagasaki University Hospital from 2020 to November 2022 using mRECIST. 197 PD (9 patients), 271 PR (14 patients), 342 SD (20 patients) contrast CT images of liver cancer including the background liver were used as a learning dataset. ResNet18 as the Convolutional Neural Network (CNN) model and YOLOv7 as the You Only Look Once (YOLO) model was used to learn to predict the treatment effect. Precision-Recall curves were used to

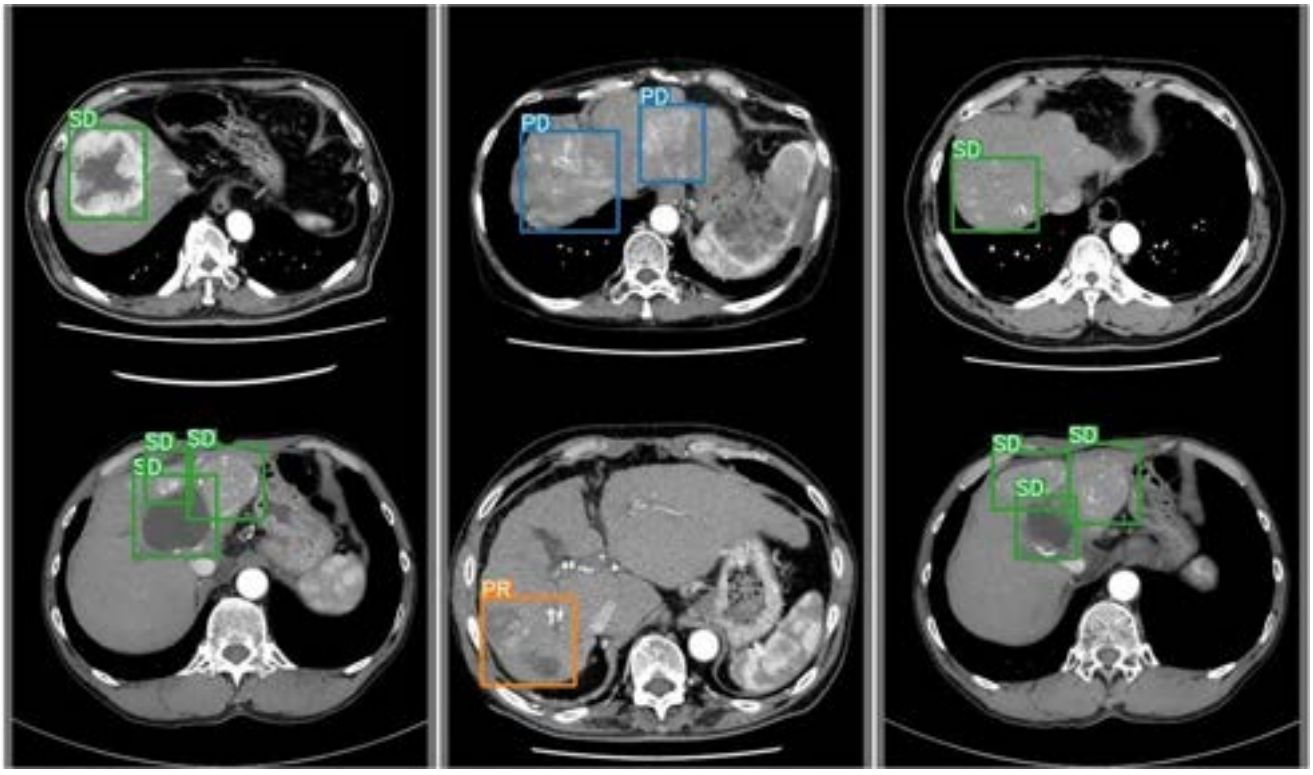

Figure: (abstract: SAT-285).

evaluate diagnostic performance, and class activation maps (CAM) were used to interpret the CNN models. The tSNE was used for feature analysis of the entire image.

Results: (1) The CNN model had a PD prediction sensitivity of 84%. Due to the interpretation of the model, the sites indicated by CAM did not correspond to the tumors. tSNE analysis showed that they were clustered for each case. Although the accuracy of prediction by the CNN model was high, it was expected to over-learn the CT image features of each case other than the tumor site. (2) In the analysis using the YOLO model, the AUC of the Precision-Recall curve for PD was 0.995. The prediction by the YOLO model is not only accurate but also has high clinical versatility because it can identify the point that led to the decision (Figure).

Conclusion: Since it is difficult to prepare a large amount of training data for a drug effect prediction model for tumors compared to a general tumor diagnosis model, a large-scale validation using a more efficient YOLO model is expected.

SAT-286

CD40 expression in liver cancer cells is upregulated by CD4+T cells through IFN-gamma and ERK 1/2 pathway

Norifumi Kawada[1], Hanh Ngo Vinh[1], Le Thi Thanh Thuy[1], Hieu Vu[2], Hai Hoang[1], Akihiro Tamori[1], Masaru Enomoto[1], Sawako Uchida-Kobayashi[1]. [1]*Osaka Metropolitan University, Japan,* [2]*Hanoi Medical University, Viet Nam*
Email: kawadanori@omu.ac.jp

Background and aims: Hepatocellular carcinoma (HCC) is one of the most common primary liver cancers which is a leading cause of cancer-related death worldwide. CD40 is a costimulatory receptor essential for the survival and activation of antigen-presenting cells while its functional role in cancer remains controversial. This study aimed to examine the biological role of CD40 in liver tumor progression.

Method: 168 hepatitis C virus (HCV) -infected patients including 47 HCC and 121 non-HCC were enrolled in this study. The level of soluble (s) and membrane-bound (m) CD40 were examined in plasma and human liver tissues, respectively. Immunoblot and quantitative RT-PCR were performed to assess the expression of CD40 in five human HCC cell lines. The methylation index of the CD40 promoter region was examined. $CD4^+$T cells isolated from the peripheral blood of healthy donors were stimulated to express CD40 ligand (CD40L). Human recombinant IFN-gamma was used to induce CD40 expression in HCC cells.

Results: The plasma level of sCD40 was increased significantly in HCC patients compared to non-HCC patients at baseline ($p = 0.0003$), end of HCV treatment ($p = 0.047$), sustained viral response ($p = 0.035$), end point (time of HCC occurrence, $p = 0.011$), and correlated with HCC accumulation. Immunohistochemistry revealed a dominant mCD40 expression in poorly differentiated HCC tissues compared with non-tumor areas. Consistent with the observations in human samples, CD40 was highly expressed in poorly differentiated HCC cells (SNU387, HLE, and HLF) while well-differentiated HCC cells (Huh7 and HepG2) showed no or weak signal. CD40 promoter region exhibited a low methylation index (all 5%) in SNU387, HLE, and HLF cells compared to a higher one (Huh7: 57.5%, HepG2: 27.5%) in the well-differentiated group. $CD4^+$T cells isolated from healthy donors and activated by culturing on the anti-CD3-coated dish (5 microgram/ml) for 12 hours exhibited marked CD40L expression under flow cytometry analysis. The elevation of CD40 at both RNA and protein levels was noted in HLFs when cocultured with activated $CD4^+$T cells compared to single-culture in both ratio- and time-dependent manners. Coculturing with unactivated $TCD4^+$ cells that lack CD40L induces lower CD40 expression on HLF than with activated $TCD4^+$ cells. Alternatively, this increase was partially canceled when a linkage between HLFs and $CD4^+$T cells was disturbed by using a trans-well culture, denoting the involvement of their both direct and indirect interaction in CD40 expression in HLFs. RNA sequencing from HLF co-cultured with activated $TCD4^+$ cells from healthy donors revealed top three upregulated pathways including interferon response, immune response, and Jak-Stat signaling compared with

single cultured HLF. We then stimulated HLFs with IFN-gamma (5 ng/ml) for 24 hours resulting in the phosphorylation of p65, Jak1 and ERK1/2 pathways, but not p38 nor Akt pathways, and the upregulation of CD40 at both mRNA and protein levels in HLFs. Jak1 inhibitor, CYT387 (2–16 micromolar), and ERK1/2 inhibitor, U0126 (5–80 micromolar), reduced CD40 expression in HLF cells under IFN-gamma stimulation.
Conclusion: CD40 expression in poorly differentiated HCC cells is possibly regulated by $CD4^{+}$T cells and IFN-gamma. A high level of soluble CD40 in the plasma of HCV-SVR patients may indicate the risk of HCC development.

SAT-287
Potential biomarkers predicting ferroptosis sensitivity in hepatocellular carcinoma
Hyun Young Kim[1], Wan Seob Shim[1], Ga Hee Baek[2], Sang Kyum Kim[2], Keon Wook Kang[1]. [1]*Seoul National University, College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul, Korea, Rep. of South,* [2]*Chungnam National University Daedeok Campus, College of Pharmacy, Daejeon, Korea, Rep. of South*
Email: kwkang@snu.ac.kr

Background and aims: Hepatocellular carcinoma (HCC) is one of the most common and aggressive forms of liver cancer characterized by high morbidity and mortality. Despite recent advances in understanding the mechanism underlying HCC progression, there are still limited treatment options in the clinical field. Ferroptosis, a typical form of regulated cell death induced by iron-mediated oxidative stress, has been proposed as a new strategy to treat HCC. Indeed, erastin-a ferroptosis inducer-has been shown to effectively inhibit the growth of tumour cells in preclinical studies. Herein, we aim to suggest potential biomarker (s) of erastin sensitivity to HCC.
Method: Ferroptosis-inducing effects of erastin in various HCC cell lines were examined using C11 BOBIPY™ 581/591 dye, which is a lipid peroxidation sensor. HCC cells were treated with erastin in phenol-red free, serum-containing media. The integrated intensity of green fluorescence and confluency of the cells were calculated automatically in Incucyte™ Live-Cell Imaging System. For stable isotope tracing, HCC cells were incubated with cystine- and methionine-free media supplemented with 0.2 mM ^{34}S-methionine. Metabolites were analyzed by sample injection using an autosampler and separated by an AQUASIL C18 column. Protein and mRNA expressions were examined by Western blot and qPCR, respectively.
Results: The ferroptosis-inducing efficacy of erastin in nine HCC cell lines was cell-type dependent. Among these cell lines, HepG2, Huh7, and SKHep1 were selected for further experiments. Western blot and qPCR analyses revealed that expression of cancer stemness markers, enzymes for transsulfuration pathway and iron metabolism-related proteins were significantly correlated with erastin sensitivity. Next, stable isotope tracing confirmed that the activation of the transsulfuration pathway protects HCC cells from erastin-induced ferroptosis. Finally, the biomarkers listed above were validated by survival analysis using the Kaplan-Meier curve from public datasets.
Conclusion: Ferroptosis, an iron-dependent, reactive oxygen species-mediated cell death has been proposed as a promising strategy in treating HCC. To successfully clarify erastin-sensitive HCC, we propose several genes as predictive biomarkers related to cancer stemness, transsulfuration pathway and iron metabolism. Identifying these phenotypic signatures in HCC would help predict the efficacy of erastin-induced ferroptosis.

Background and aims: Sorafenib, a multitarget tyrosine kinase inhibitor (TKI) which exerts a strong antiangiogenic effect, is now one of the first-line treatments for patients with advanced hepatocellular carcinoma (HCC). Although sorafenib is well tolerated, a significant proportion of HCC patients do not respond to sorafenib treatment. It is increasingly necessary to find suitable biomarkers to predict interindividual response variability to sorafenib in HCC. Patient stratification based on genomic variations may help guide physicians in treatment selection.
Method: Thirty-four patients with advanced HCC, treated for the first time with sorafenib, were enrolled in our study. Patients came from 5 Sicilian hospital centers. Based on published data, five single nucleotide polymorphisms (SNPs) in angiogenesis-related genes, including rs2010963 (VEGF-A), rs4604006 (VEGF-C), rs12434438 (HIF-1alpha), rs55633437 (ANGPT2) and rs2070744 (NOS3), were tested for in 34 HCC patients, of which 9 were responders and 25 were non-responders to sorafenib. Additionally, a subgroup of 23 patients was genotyped for 1,931 SNPs and 5 copy number variations (CNVs) using the DMET Plus microarray platform.
Results: Analyzing the SNPs associated with angiogenesis, we found that only in VEGF-A (rs2010963) was the frequency of the G allele and CG/GG genotypes, compared to CC genotype, significantly associated with response to sorafenib. However, when we examined the cumulative effects of selected angiogenesis-related SNPs, developing a genetic response score (GRS), a higher mean GRS was significantly associated with responders compared to non-responders when the sum of the five scores for the rs2010963, rs4604006, rs12434438, rs55633437, and rs2070744 variants was considered for each patient ($p = 0.042$). The predictive performance of GRS was confirmed in vitro using HCC cells that displayed different responsiveness to sorafenib. ADME-related gene analysis allowed the identification of 10 predictive polymorphic variants in ADH1A (rs6811453), ADH6 (rs10008281), SULT1A2 (rs11401), CYP26A1 (rs7905939), DPYD (rs2297595 and rs1801265), FMO2 (rs2020863) and SLC22A14 (rs149738, rs171248 and rs183574) that were significantly associated with response to sorafenib. Pathway enrichment analysis (PEA) showed that the analyzed genes are associated in several key common biological pathways correlated to sorafenib and HCC.
Conclusion: We identified 15 SNPs associated with angiogenesis and ADME genes, inserted in key points of several biological pathways, as potential predictive biomarkers for response to sorafenib which could be considered as a proof of concept to be further validated in follow-up studies for the definition of a better treatment options to promote better outcomes in HCC patients.

SAT-289

Association between gadoxetic acid-enhanced MR imaging, organic anion transporters, and farnesoid X receptor in benign focal liver lesions

Belle van Rosmalen[1,2], Michele Visentin[3], Alicia Furumaya[1,2], Otto van Delden[1,2], Geert Kazemier[4,5], Thomas Van Gulik[1,2], Joanne Verheij[1,2], Bruno Stieger[3]. *[1]Amsterdam Gastroenterology Endocrinology Metabolism, Netherlands, [2]Amsterdam UMC, University of Amsterdam, Netherlands, [3]University Hospital Zurich, Switzerland, [4]Amsterdam UMC, location VUmc, Netherlands, [5]Cancer Center Amsterdam, Netherlands*
Email: b.v.vanrosmalen@gmail.com

Background and aims: Organic anion uptake and efflux transporters (OATP1B1, OATP1B3, MRP2 and MRP3) are direct or indirect targets of the farnesoid X receptor (FXR) pathway, influencing homeostasis of lipids and bile acids. In benign liver tumours, FXR is not yet characterized. We investigated the expression of FXR and its targets in hepatocellular adenoma (HCA) and focal nodular hyperplasia (FNH) and its correlation with gadoxetic acid (Gd-EOB-DTPA) MRI.
Method: Gd-EOB-DTPA MRI were assessed by an expert radiologist and correlated to mRNA expression levels of OATP1B1, OATP1B3, MRP2, MRP3, FXR and SHP in fresh surgical specimens of patients with FNH or HCA subtypes. Transporter expression was profiled with respect to the FXR pathway in the explorative part of this study, in search of novel molecular markers for HCA subclassification.
Results: Normal and tumour sample pairs of 43 HCA and 15 FNH were included. Of 58 patients, 48 had an Gd-EOB-DTPA MRI. FNH was detected with 100% sensitivity and 82% specificity. HCA was detected with 82% sensitivity and 100% specificity. Of patients who underwent Gd-EOB-DTPA MRI, 28/48 lesions were hypointense and 20/48 lesions were hyperintense. OATP1B3 was downregulated in 23 hypointense tumours, by approximately a 5-fold compared to normal surrounding liver tissue (2.77 ± 3.59 vs 12.9 ± 15.6, $p < 0.001$). Hyperintense HCA showed upregulation in 5/6 patients. OATP1B1, OATP1B3 and MRP2 were significantly downregulated in HNF-1α-mutated HCA (H-HCA). A significant positive correlation between FXR expression and activation and OATP1B3 expression level in HCA was found.

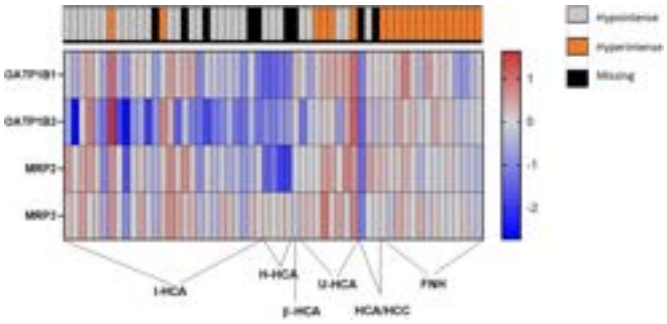

Figure:

Conclusion: A central role for OATP1B3 in Gd-EOB-DTPA uptake in HCA was confirmed. The MRI relative signal may reflect expression level of FXR and SHP. HNF1α may be a regulator of SHP expression in vivo.

SAT-290

Comprehensive analysis of single-cell and bulk RNA sequencing data identifies antioxidant-1 as a novel immune biomarker associated with immune cell infiltration in hepatocellular carcinoma metastasis

Ruijia Liu[1], Xudong Yu[1], Zao Xiaobin[1], Xu Cao[1], Yong'an Ye[1,2].
[1]*Dongzhimen hospital, Beijing university of Chinese medicine, China,* [2]*Beijing University of Chinese Medicine, Liver Diseases Academy of Traditional Chinese Medicine, Beijing, China*
Email: yeyongan@vip.163.com

Background and aims: Copper is involved in cancer progression by affecting biological processes such as cell proliferation, invasion, metastasis, and angiogenesis. Antioxidant-1 (ATOX1) is aberrantly expressed as a copper chaperone protein in several cancers, but its function and mechanism in hepatocellular carcinoma (HCC) are unknown and were the purpose of this study.
Method: The expression, diagnostic, prognostic, clinical features, functional enrichment, and immune characteristics of ATOX1 in HCC were explored through R software using data from multiple

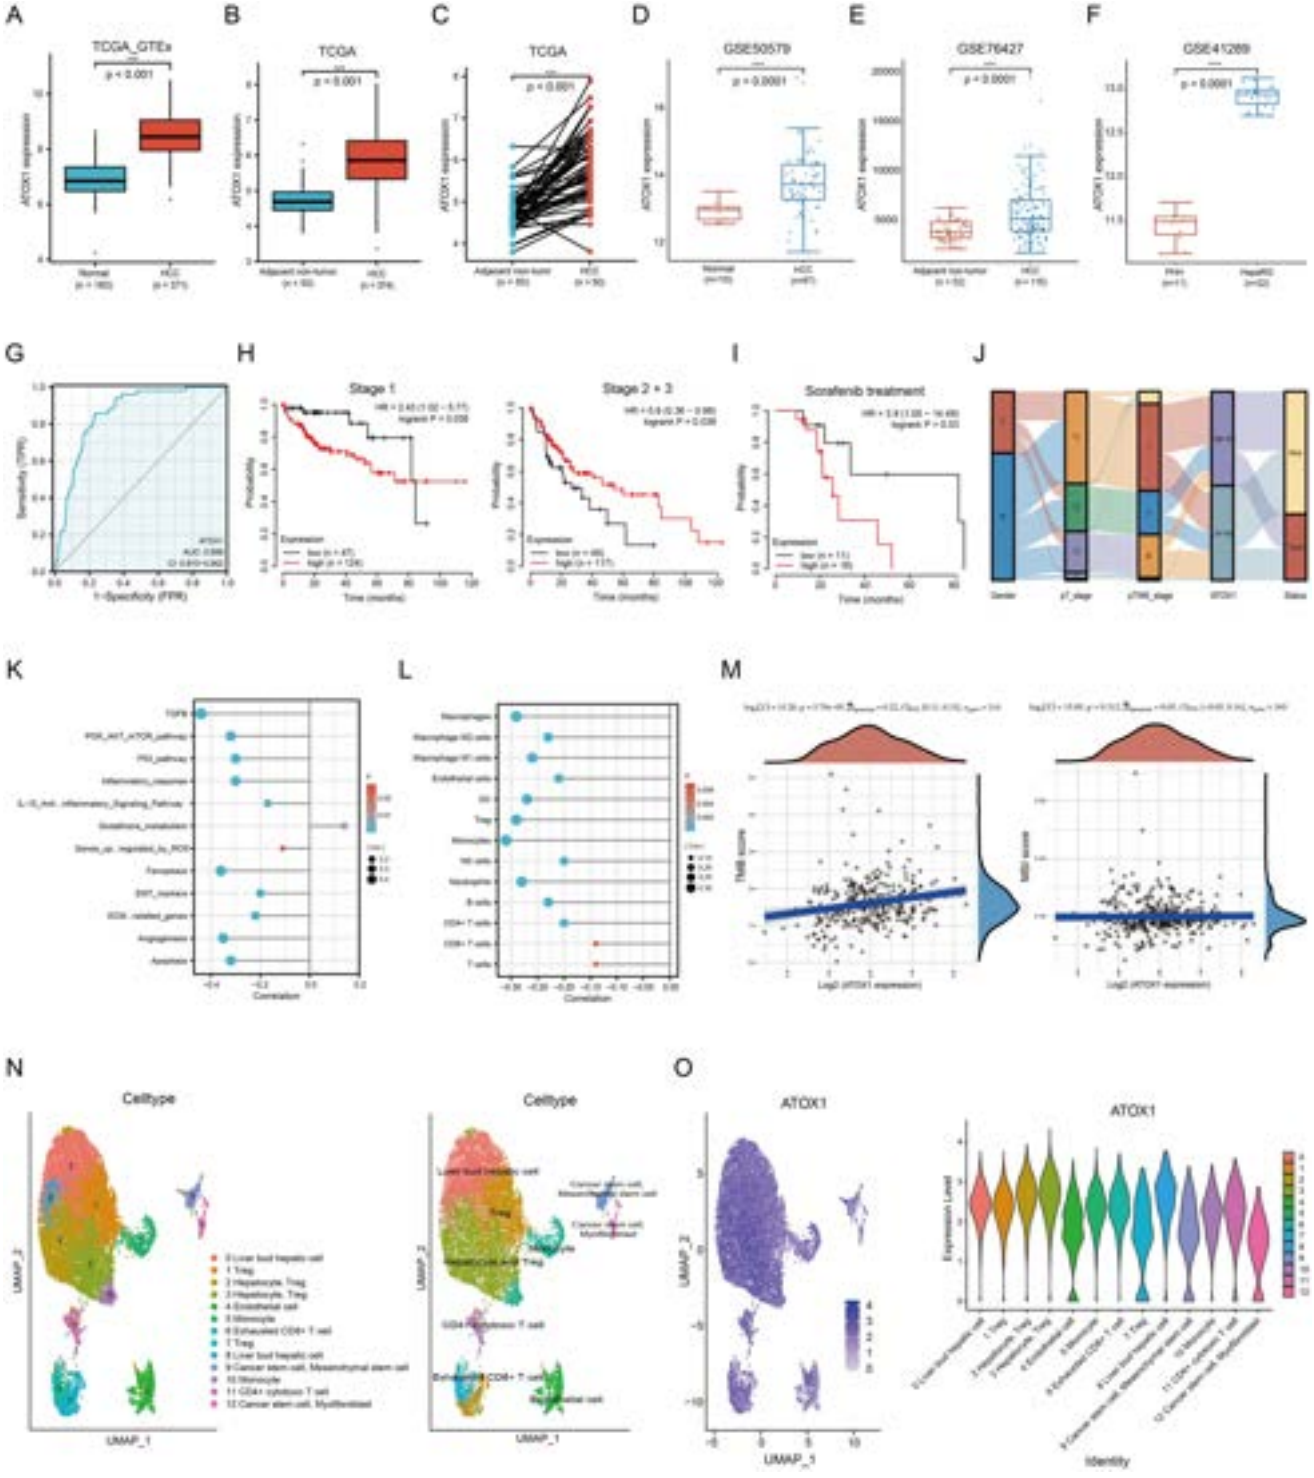

Figure: (abstract: SAT-290).

databases. ATOX1 expression in HCC cells and stromal cells was observed by single cell sequencing analysis.
Results: Compared with the non-tumor tissues, ATOX1 was significantly upregulated in HCC tissues. The GSE50579 and GSE76427 datasets validated this conclusion. And ATOX1 mRNA in HCC cells was also significantly higher than that in primary human hepatocytes. Meanwhile, ATOX1 expression had a certain accuracy for HCC diagnosis, and lower expression predicted better prognosis in the stage 1 and sorafenib treatment subgroups. Enrichment analysis showed that ATOX1 was markedly negatively associated with most cancer-related pathways, such as PI3K-AKT-mTOR, EMT, ECM, Angiogenesis, Apoptosis, Ferroptosis, Reactive oxygen species and Inflammatory response. ATOX1 was significantly negatively associated with immune cell infiltration (ICI) in the tumor microenvironment (TME), including macrophages, monocytes, endothelial cells, dendritic cells, neutrophils, B cells, T cells, CD4+ T cells, CD8+ T cells, regulatory T cells (Treg) and natural killer cells. And it was remarkably positively correlated with tumor mutational burden. Single-cell sequencing showed that ATOX1 was highly expressed on HCC cells and stromal cells, especially Treg, endothelial cells, monocytes, T cell subsets and hepatocytes.
Conclusion: Our results revealed that ATOX1 activity was closely associated with cellular redox status and might play an important role in HCC invasion and migration by regulating ICI in TME. In conclusion, ATOX1 might be a promising predictive biomarker for immunotherapy of HCC.

Email: hend.saber@guc.edu.eg

Background and aims: The numerous side effects of chemotherapy, such as paclitaxel, in Hepatocellular Carcinoma (HCC) have triggered the development of novel treatment approaches. Combining immunotherapy with chemotherapy has become one of the most prevalent treatment modalities recently. Since 2018, small molecule inhibitors (SMIs) as immune checkpoint inhibitors have received the spotlight in immunotherapy research due to their safety and low cost of production. Specifically, programmed cell death 1 and its ligand (PD-1/PD-L1) inhibitors have shown promising results on a myriad of cancers including HCC in clinical trials. In HCC tumor microenvironment (TME), tumor associated macrophages (TAMs) were found to be a major contributor in several molecular pathways involved in HCC progression. CCL5 protein was reported to be upregulated in TAMs and a key molecule in downstream signalling of several molecular pathways that lead to HCC progression along with regulating the activity of multiple immune cells as CD8+ cells. The aim of our study

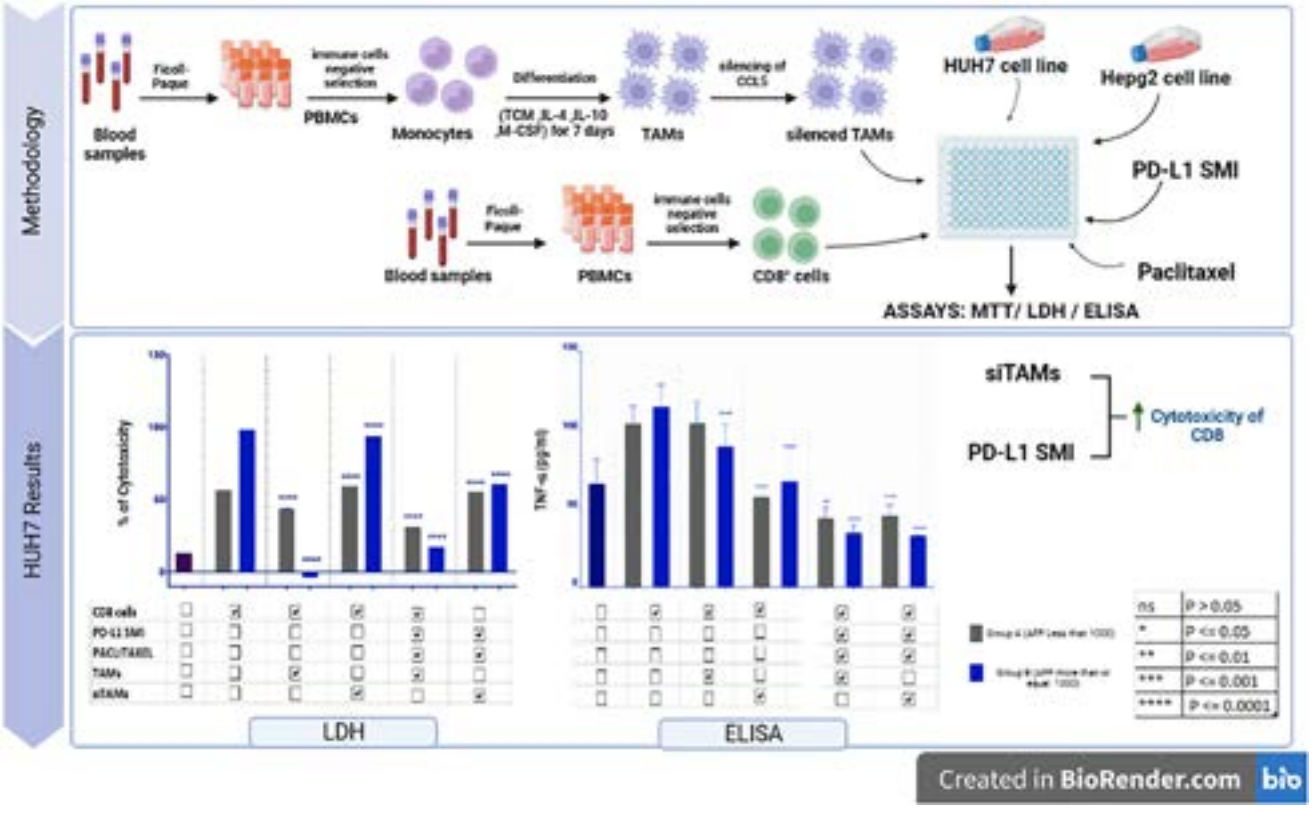

Figure: (abstract: SAT-291).

is investigating the synergistic effect of tuning TAMs by silencing CCL5 along with PD-L1 SMIs on activating the anti-tumor response exerted by CD8+ cells in presence of paclitaxel as a combinational therapy approach. PD-L1 SMI used in this study is obtained through a virtual screening protocol, of commercial databases, that is reported by our group in a previous study.
Method: Monocytes were isolated from whole blood samples of 45 HCC patients (classified according to their alpha fetoprotein levels into two groups), differentiated into TAMs where finally CCL5 was silenced by siRNAs. Silenced TAMs (siTAMs) were co-cultured with CD8+ cells from HCC patients, HCC cell lines (Huh7 and HepG2 as a confirmatory cell line), PD-L1 SMI and paclitaxel. Cell cytotoxicity was performed to assess the effect of regulation of TAMs on CD8+ cytotoxicity after coculturing (LDH assay). Cell viability assays were performed to assess the effect of all conditions on HCC cell lines (MTT assay). Tumor Necrosis Factor alpha (TNF-α), a pro-inflammatory cytokine, was measured in tumor-cultured media (TCM) using Enzyme-linked immunosorbent assay.
Results: The presented data in the figure attached is showing the experiments done on Huh7 cells: CD8+ tumor cytotoxicity showed a significant increase upon CCL5 knockdown in TAMs in the coculture with and without the combined therapy. TNF-α expression significantly declined upon CCL5 knockdown in TAMs and addition of combined therapy. Cell viability of HCC cell lines declined consequent to the knockdown of CCL5 in TAMs, also with combined therapy. Consistent results were observed in HepG2 cells as confirmation.
Conclusion: Combining the PD-L1 SMI with the siTAMs showed a synergistic effect on the activity of CD8+ cells. Combinational approach is more effective than either alone. The development of PD-1/PD-L1 immune checkpoint SMI opens a new avenue for alternative treatment modalities with less immune related adverse events.

Intermittent fasting improves tumor-directed drug delivery by caveolar-mediated endocytosis
Svea Becker[1], Ilaria Biancacci[2], Diana Möckel[2], Qingbi Wang[1], Jan-Niklas May[2], Huan Su[1], Jeffrey Momoh[2], Lena Susanna Candels[1], Marie-Luise Berres[1], Fabian Kiessling[2], Maximilian Hatting[1], Twan Lammers[2], Christian Trautwein[1]. *[1]Medical Department III, Germany, [2]Experimentelle Molekulare Bildgebung, Germany*
Email: svbecker@ukaachen.de

Background and aims: Tumor cells rely on the Warburg effect to maintain their high proliferative activity, making them dependent on external glucose supply for cell metabolism and proliferation. Therefore, fasting may have health benefits to combat tumor growth. Furthermore, it can reduce toxicity and improve the efficacy of chemotherapy. This makes it a beneficial approach for cancers with limited systemic and local ablative therapies, such as hepatocellular carcinoma (HCC).
Method: The effects of intermittent (IF) fasting were investigated on tumor growth, development of the tumor microenvironment (TME) and tumor-targeted drug delivery in an intrahepatic murine hepatocellular carcinoma model and were subsequently subjected to IF for 24 days. Cy7-labeled liposomes were applied *i.v.* and their biodistribution and tumor accumulation was examined via combined micro-CT and fluorescence tomography (μCT-FLT). These effects were validated using immunohistochemistry staining and fluorescence microscopy. *In vitro* studies were performed with the hepatoma cancer cell line Hep-55.1C to identify the effect of liposome uptake under fasting conditions on a cellular level. The cells were stimulated with forskolin and inhibitors of endocytic mechanisms. Uptake was then analysed by flow-cytometry and fluorescence microscopy.
Results: Analyses of MRI-scans demonstrated that IF decreased intrahepatic tumor growth compared to animals fed ad libitum. Fluorescence microscopy and two-photon laser microscopy images revealed significant changes in TME as evidenced by decreased extracellular matrix e.g. collagen production, and increased angiogenesis e.g. lectin-perfused vessels. These changes contributed to increased tumor-directed liposome accumulation and uptake in IF treated animals.
In vitro, Hep-55.1C were stimulated to fast and liposome uptake was analysed via flow cytometry and immunofluorescence microscopy. Together, the *in vitro* data demonstrate that the fasting equivalent forskolin causes a significant increase in liposome uptake, which could be reversed specifically by nystatin inhibition. These results identified that the increase in liposome uptake in HCC cells is mediated by caveolar endocytosis.
Conclusion: Intermittent fasting improves tumor-directed targeting by modifying the TME, due to increased angiogenesis and decreased collagen abundance, and modifying intracellular mechanisms using a caveolar-mediated endocytosis-dependent mechanism. These influences make IF a promising approach when applied concomitantly to HCC targeted therapy.

A simple characterization of dynamic changes in circulating CD8+PD1+ lymphocytes early predicts response to atezolizumab-bevacizumab in hepatocellular carcinoma
Fabio Piscaglia[1,2,3], Fabrizia Suzzi[1,4], Francesco Tovoli[1,2], Mariangela Bruccoleri[5], Mariarosaria Marseglia[2], Eleonora Alimenti[5], Francesca Fornari[3,6], Massimo Iavarone[5], Laura Gramantieri[2,4], Catia Giovannini[1,4]. *[1]University of Bologna, Department of Medical and Surgical Science, Italy; [2]Division of Internal Medicine, Hepatobiliary and Immunoallergic Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Italy; [3]Centre for Applied Biomedical Research-CRBA, University of Bologna, Italy; [4]Centre for Applied Biomedical Research-CRBA, University of Bologna, Italy; [5]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico di Milano. Division of Gastroenterology and Hepatology Milan, Italy; [6]University of Bologna, Department for Life Quality Studies, Italy*
Email: fabio.piscaglia@unibo.it.

Background and aims: Atezolizumab+bevacizumab improves survival of patients with advanced Hepatocarcinoma (HCC) in comparison to Sorafenib. No biomarker predicts responders from non-responders to atezolizumab+bevacizumab or patients who benefit from this combination instead of TKIs. To identify early on treatment predictive biomarkers, we investigated whether baseline and early on treatment variation of CD8+, PD1+, PD-L1+, CD8+PD1+, CD8+PDL1+ peripheral lymphocytes might offer a non-invasive, cheap and feasible assay.
Method: A prospective cohort of 31 patients treated with atezolizumab+bevacizumab and a control prospective cohort of 15 patients treated with sorafenib or lenvatinib were subjected to repeated blood tests, at baseline and during the course of treatments. At first imaging re-evaluation, 11 patients receiving atezolizumab+bevacizumab showed objective response, 13 stable disease, accounting for the responder group, while 7 patients displayed tumor progression, corresponding to primary non-response. Baseline and early on treatment variation of CD8+, PD1+, PD-L1+, CD8+PD1+, CD8+PDL1+ peripheral lymphocytes were tested by cytofluorimetric analysis and compared in responders and non-responders.
Results: Baseline CD8+ and CD8+PDL1+ peripheral lymphocytes were lower in responders versus non-responders (mean ± SD CD8+: 68 ±

30 vs 95 ± 5; T-test, p < 0.0001; mean ± SD CD8+PD-L1+: 77 ± 9.4 vs 82 ± 4.6; T-test: p = 0.004 respectively). Dynamic changes in CD8 +PD1+ lymphocytes assessed at 3-weeks, before the second drug infusion, were the most informative test: 22 of 24 responders displayed a rise of CD8+PD1+ peripheral lymphocytes with a positive mean fold change of 4.63 (±5.5 SD). Conversely, 6 of 7 non-responders displayed a negative mean fold change of 0.89 (±0.84 SD) of CD8+PD1 + lymphocytes. These changes were restricted to patients treated with atezolizumab+bevacizumab, while they were not documented in TKI patients, irrespective of the response.

Conclusion: Early changes in circulating PD1+CD8+ lymphocytes predict the type of response to atezolizumab+bevacizumab and encourage evaluating this minimally invasive, cheap, easy and repeatable test in a larger cohort of patients to confirm its informativeness in this setting.

TOP-071

Impact of statin on the survival of patients with advanced hepatocellular carcinoma treated with sorafenib or lenvatinib

Hyo Jung Cho[1], Ji Eun Han[1], Jae Youn Cheong[1], Soon Sun Kim[1]. [1]*Ajou university school of medicine, Gastroenterology, Korea, Rep. of South*
Email: pilgrim8107@hanmail.net.

Background and aims: To overcome drug resistance to multityrosine kinase inhibitors (TKI) such as sorafenib and lenvatinib is major challenging issue for systemic treatment of hepatocellular carcinoma (HCC). Statin reduced the risk of developing HCC in patients with hepatitis B, C and diabetes mellitus and was also reported to potentiate anticancer effect of the TKIs. We aimed to verify the potential survival benefit of statin combined with the TKIs in patients with advanced HCC. Further, we investigated the impact of timing of statin administration, optimal statin type and dose on survival outcome of patients with HCC treated with the TKIs.

Method: Using large-scale data from 2010 to 2020 provided by National Health Insurance Service in Korea, we identified the effect of statin use on the patients with advanced HCC treated with the TKIs. Statin user was defined as 28 cumulative defined daily dose (cDDD) ≥28 of filled statin prescriptions. After propensity score matching (PSM), 1,534 statin users were 1:4 matched with 6,136 non-users. Primary and secondary outcome were defined as overall survival (OS) and progression-free survival (PFS), respectively. Multivariate cox regression analyses were performed to identify the risk factors associated with survival outcome.

Results: Statin use improved both OS (Hazard ratio [HR] = 0.77, 95% Confidence interval [CI] = 0.72–0.82; p < 0.0001) and PFS (HR = 0.78, 95% CI = 0.74–0.84, p < 0.0001). Regarding the timing of statin use, continuous statin use without interruption from before TKI treatment (HR = 0.87, 95% CI = 0.80–0.95; p = 0.0016), post-TKI statin use (HR = 0.87, 95% CI = 0.80–0.95; p < 0.0001) significantly improved OS, while pre-TKIs statin use but stop after TKI prescription (HR = 1.33, 95% CI = 1.14–1.54; p = 0.0002) was independent risk factor of poor OS. Lipophilic statin use improved OS (HR = 0.75, 95% CI = 0.69–0.81, p < 0.0001) and PFS (HR = 0.74, 95% CI = 0.69–0.80, p < 0.0001). Hydrophilic statin use also improved OS (HR = 0.59, 95% CI = 0.53–0.66, p < 0.0001) and PFS (HR = 0.63, 95% CI = 0.57–0.69, p < 0.0001). 730 or higher cDDD of statin use was significantly associated with greater survival outcome.

Conclusion: In a nation-wide retrospective study, statin offered substantial survival benefit for overall death and tumor progression in dose and duration dependent manner, upon co-administration with the TKIs in patients with advanced HCC. Our study emphasizes the importance of continuous statin administration without interruption even after the TKI treatment.

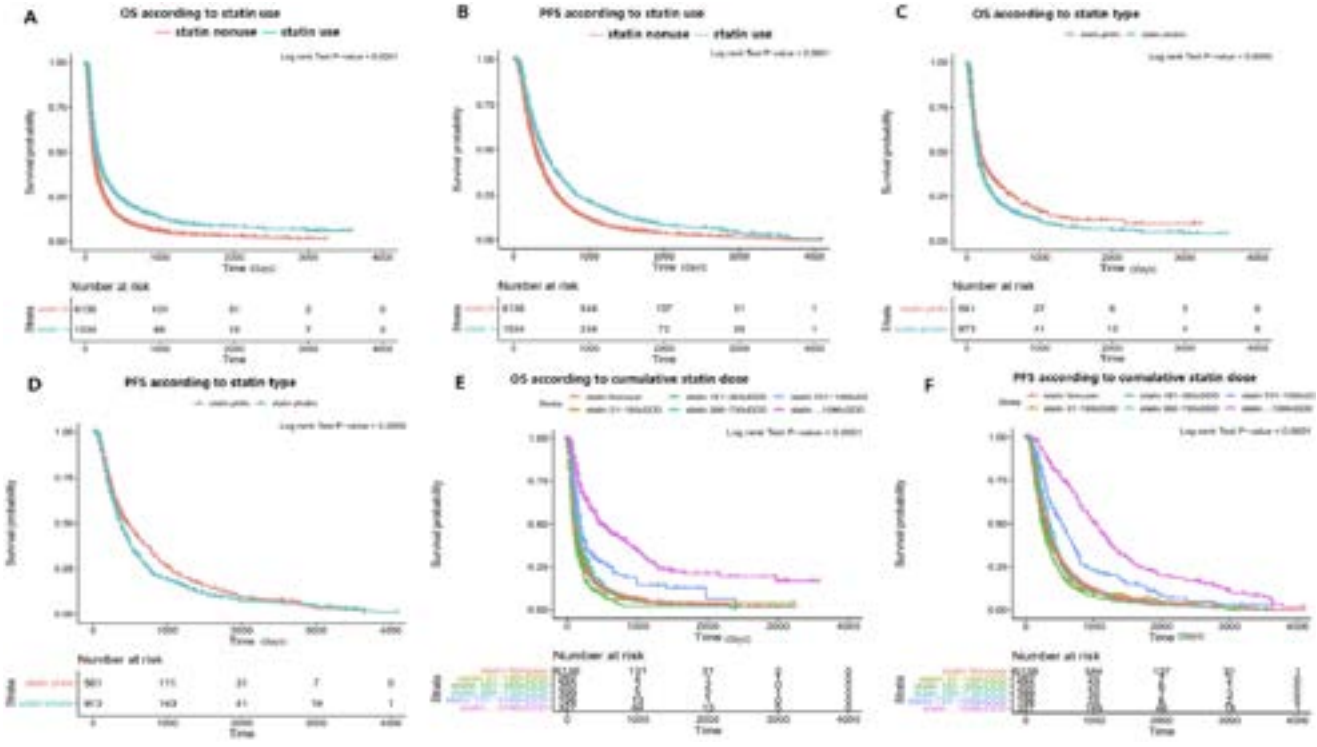

Figure: (abstract: TOP-071): Comparison of OS and PFS according to statin use, statin type and cumulative statin dose through Kaplan-Meier analysis in the entire PS-matched cohort

THU-113

Prediction for gastrointestinal bleeding in patients receiving atezolizumab and bevacizumab for hepatocellular carcinoma

Kanghee Park[1], Euichang Kim[1], Ji won Yang[1], Won-Mook Choi[1], Danbi Lee[1], Ju Hyun Shim[1], Kang Mo Kim[1], Young-Suk Lim[1], Han Chu Lee[1], Jonggi Choi[1]. [1]*Asan Medical Center, Korea, Rep. of South*
Email: jkchoi0803@gmail.com.

Background and aims: The IMbrave 150 phase 3 trial did not include patients with a variceal bleeding history or a high-risk varix. Little is known regarding the actual risk of gastrointestinal bleeding (GIB) in hepatocellular carcinoma (HCC) patients receiving atezolizumab with bevacizumab (A/B). Therefore, we sought factors associated with GIB in these patients.
Method: We performed a retrospective analysis of 321 HCC patients who underwent endoscopy prior to A/B treatment at Asan Medical Center, Seoul, Republic of Korea between 2018 and 2022. GIB was defined as documented hematemesis, melena, or hematochezia, or performing endoscopic hemostasis between the start of A/B treatment and 3 months following the last dose of A/B treatment. Using multivariable logistic regression analysis, GIB-associated factors were sought. A prediction model was developed based on this multivariable analysis. Our model's performance was displayed as the area under the receiver operating curve (AUROC).
Results: The median age was 60.9 years, and 82.6% of the patients were male. At the time of A/B treatment, 29 (9.0%) and 292 (91.0%) patients were in BCLC stage of B and C, respectively. Of the 321 patients, 287 (89.4%) patients were classified as Child-Pugh class A. A total of 20 patients experienced GIB with a median onset of 3.0 months after the first dose of A/B. Cumulative incidence rates of GIB at 3, 6, 9, and 12 months were 3.2%, 7.3%, 8.0%, 9.6%, respectively. No patient died because of GIB. Variceal bleeding was the most common cause of GIB in 12 (60.0%) patients, followed by unknown origin of GIB (n = 6), and benign gastric ulcer (n = 2). Platelet count <100,000/mm^3, prothrombin time (PT) with INR ≥1.3, portal vein invasion (PVI), and endoscopic variceal categorization ≥F2 were significantly associated with an increased risk of GIB in multivariable analysis. Risk scores were assigned to platelet <100,000 (1 point), PT INR ≥1.3 (1 point), PVI (1 point), and EV ≥F2 (3 points). Our prediction model had an AUROC of 0.839 (95% confidence interval: 0.765–0.914). Patients categorized as low (0–1 points), intermediate (2–3 points), and high-risk group (≥4 points) showed an estimated risk of GIB of 1–2%, 2–4%, and 5–11%, respectively, after receiving A/B treatment.

Factors	score	*Applying the prediction model*			
Platelet <100,000	1	Group	Range of estimated GIB risk	Score	Estimated GIB risk
Prothrombin time, INR ≥1.3	1	Low	1-2%	0 1	1.1% 1.7%
Portal vein invasion	1	Intermediate	2-4%	2 3	2.5% 3.6%
Esophageal varix ≥F2	3	High	5-11%	4 5 6	5.3% 7.7% 11.1%

Figure:

Conclusion: Factors associated with GIB after A/B treatment for HCC were lower platelet, prolonged PT, PVI, and EV ≥F2 by endoscopic findings. Our prediction model has a high predictive performance when estimating the real GIB risk following A/B treatment in patients with advanced HCC.

THU-114

Quality of life in patients with unresectable hepatocellular carcinoma treated with selective internal radiation therapy (SIRT) and Nivolumab: a sub-analysis of the NASIR-HCC trial

Background and aims: Patient reported outcomes (PRO) are increasingly recognized as key end points in clinical trials in addition to safety and efficacy. The aim of this study was to assess health related quality of life (HRQoL) of patients with unresectable hepatocellular carcinoma (uHCC) during treatment with SIRT and the anti-programmed cell death-1 (PD1) agent nivolumab.
Method: NASIR-HCC is a single-arm, multicenter, phase 2 trial (NCT03380130) that recruited patients with uHCC free from distant metastasis but not good candidates for chemoembolization. Patients with large single tumors, multinodular disease or predominantly unilobar tumors with segmental or lobar portal vein invasion were treated with SIRT using SIR-Spheres resin microspheres followed 3 weeks later by 240 mg of nivolumab given every 2 weeks until 24 doses, disease progression or unacceptable toxicity. HRQoL was assessed as an exploratory end point using EQ-5D-3L, the 3-level version of EQ-5D, and the FACT-Hep questionnaires at baseline and at day 1 of every treatment cycle thereafter (every 6 weeks, approximately) and during follow-up. Analyses were performed of all patients with a valid baseline assessment and at least one other post-baseline assessment and were limited to the treatment period of 8 cycles. Thresholds for clinically meaningful change were prespecified based on published minimal important differences (MIDs). Time to deterioration (TTD) was evaluated for all HRQoL scores and was defined as the time from treatment initiation to the first date of a worsening meeting or exceeding the MID.
Results: 42 patients received SIRT and 10 patients with no baseline measurement or only one measurement were excluded from the analyses. PRO analysis population therefore included 32 patients. At most timepoints (62%) completion rates were above 70%, the expected threshold for meaningful interpretation, and in 98% it was above 60%. All FACT-Hep scores remained within the limits established by MIDs over the time frame analysed, with only a clinically meaningful decline in social well-being. A statistically significant decrease in scores that did not reach the MIDs was observed for physical well being, FACT-General total and FACT-Hep total scores. EQ5D utility index score showed a slight decline (mean change per cycle, −0.011, $p < 0.05$) while EQ5D VAS remained stable (mean change per cycle, −0.102, $p = 0.778$). The inclusion of age and ECOG as covariates for adjustment did not have a substantial impact on results. Median TTD in FACT-Hep Total Score was 5.5 months (95% CI 5.5-NR) while median TTD in HCS was not reached.

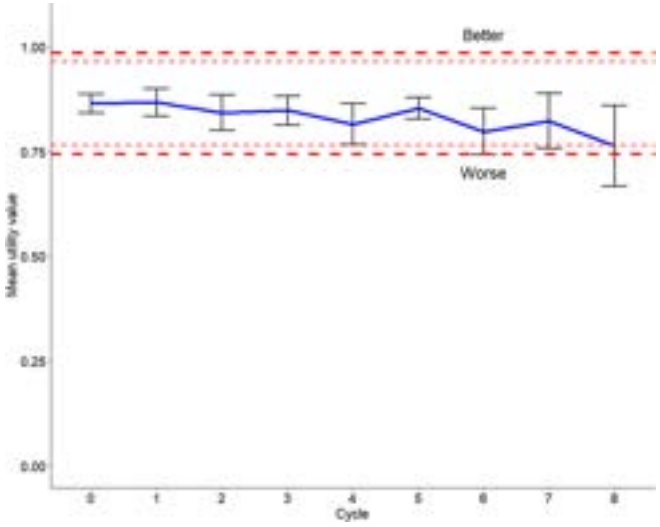

Figure 1: EQ5D VAS.

Conclusion: No clinically meaningful decline in HRQoL was observed in the vast majority of evaluable time points during treatment with nivolumab following SIRT. This combination does not compromise quality of life for this difficult-to-treat population of patients with uHCC.

THU-115

Impact of baseline liver function on overall survival (OS) and safety in patients (pts) with unresectable hepatocellular carcinoma (HCC) treated with first-line (1L) tislelizumab (TIS): results from the RATIONALE-301 study

Masatoshi Kudo[1], Arndt Vogel[2], Tim Meyer[3], Frederic Boisserie[4], Songzi Li[5], Ramil Abdrashitov[6], Yaxi Chen[7], Andrew X. Zhu[8,9], Shukui Qin[10], Richard S. Finn[11]. *[1]Kindai University Faculty of Medicine, Department of Gastroenterology and Hepatology, Osaka, Japan; [2]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [3]Royal Free Hospital NHS Trust and University College London, Academic Department of Oncology, London, United Kingdom; [4]BeiGene Ltd., Ridgefield Park, Clinical Science, NJ, United States; [5]BeiGene Ltd., Ridgefield Park, Biometrics, NJ, United States; [6]BeiGene USA, Inc., Clinical Development, Fulton, MD, United States; [7]BeiGene (Beijing) Co., Ltd., Clinical Development, Beijing, China; [8]Jiahui Health, Jiahui International Cancer Center, Shanghai, China; [9]Harvard Medical School, Massachusetts General Hospital, MA, United States; [10]Cancer Center of General Hospital of Eastern Theater of PLA, Nanjing, China; [11]Geffen School of Medicine, University of California Los Angeles, Department of Medicine, Division of Hematology/Oncology, Los Angeles, CA, United States*
Email: m-kudo@med.kindai.ac.jp.

Background and aims: TIS is a monoclonal antibody with high binding affinity to programmed cell death protein 1. The phase 3 RATIONALE-301 study (NCT03412773) demonstrated non-inferior OS with TIS versus sorafenib (SOR) (median [m] OS 15.9 vs 14.1 months [mo], respectively; HR: 0.85 [95% CI: 0.71, 1.02]) in 1L treatment of pts with unresectable HCC; OS superiority versus SOR was not met. As liver function is a known predictor of survival in pts with HCC, we evaluated baseline liver function and its impact on OS and safety in pts enrolled in RATIONALE-301.

Method: Systemic therapy-naïve adults with histologically confirmed HCC were randomized (1:1) to receive TIS (200 mg intravenously every 3 weeks) or SOR (400 mg orally twice daily) until disease progression, intolerable toxicity, or withdrawal. The primary end point was OS. In this exploratory analysis, OS and safety were assessed by Child-Pugh score (CPS; 5 vs 6) and albumin-bilirubin (ALBI) grade (1 vs 2).

Results: In pts randomized to TIS (n = 342), at baseline, 76.9% and 22.5% had a CPS of 5 and 6, respectively, and 74.9% and 23.7% had an ALBI grade of 1 and 2, respectively. In pts randomized to SOR (n = 332), 74.7% and 25.3% had a CPS of 5 and 6, respectively, and 68.1% and 29.5% had an ALBI grade 1 and 2, respectively. At data cutoff (July 11, 2022; minimum study follow-up 33 mo), mOS was similar in pts treated with TIS and SOR, and numerically longer in pts with CPS 5 vs 6, and ALBI grade 1 vs 2, regardless of treatment arm (Table). Incidence of any grade and grade ≥3 treatment-emergent adverse events (TEAEs) and treatment-related adverse events (TRAEs) were lower in pts treated with TIS versus SOR across CPS and ALBI grades (Table).

Conclusion: Survival was similar between arms, and TIS showed a favorable safety profile compared with SOR, regardless of CPS or ALBI grade, supporting the primary analysis. Pts with CPS 6 and ALBI grade 2 had poorer mOS than those with CPS 5 and ALBI grade 1, regardless of treatment arm, affirming that pts with better liver function have improved outcomes.

Table (abstract: THU-115).

Background and aims: The combination of atezolizumab plus bevacizumab (A+B) is the current standard of care for Child-Pugh A (CP-A) unresectable or metastatic hepatocellular carcinoma (HCC) and is being evaluated in CP-B patients. Whilst highly effective, A+B can lead to potentially life-threatening adverse events (AEs), including bleeding. We investigated whether liver dysfunction as measured by the albumin-bilirubin (ALBI) grade is associated with survival and adverse events (AEs) following A+B.

Method: We performed a multi-centre, retrospective study on patients consecutively treated with A+B in 15 tertiary referral centres. Patients exposed to systemic treatments or Child-Pugh (CP) C liver function were excluded. We correlated baseline ALBI grade with overall survival (OS) and progression-free survival (PFS) with the Kaplan-Meier method and we estimated predictors of survival with the Cox regression model. We assessed the predictive value for 6-months OS landmark with ROC curves. Association with treatment-related (tr)AEs was assessed with the chi^2 test.

Results: From the initial cohort of 433 patients, 368 were included in the analysis, mostly with underlying viral hepatitis (37.5% HBV, 24.2% HCV) and a diagnosis of cirrhosis (78.8%). 295 patients (80.2%) were in CP-A functional class and 73 (19.8%) CP-B. 163 patients (44.3%) were graded as ALBI 1, 192 (52.2%) ALBI 2, and 13 (3.5%) ALBI 3. After a median follow-up of 9.7 months (95% CI, 9.2–10.3), ALBI 1 patients did not reach a median OS (mOS), ALBI 2 achieved a mOS of 9.7 months (95% CI, 6.98–12.29) compared to 5.6 months of ALBI 3 (95% CI, 0.1–12.0, $p < 0.001$, Fig. 1). Similarly, ALBI grade was associated with improved mPFS: 8.1 months (95% CI, 6.0–10.2) for ALBI 1, 4.5 months (95% CI, 3.7–5.3) for ALBI 2, and 1.2 months (95% CI, 0.1–3.6) for ALBI 3 patients ($p < 0.001$). ALBI was independently associated with OS and PFS in multivariable models ($p < 0.001$) and outranked CP for 6-months OS prediction, with an area under the curve of 0.79 (95% CI, 0.73–0.85) for ALBI score and 0.71 (95% CI, 0.63–0.78) for CP score ($p = 0.013$). Whilst rates of bevacizumab-related gastrointestinal bleeding events of any grade were similar according to CP class (6.8% in CP-A vs 8.2% in CP-B, $p = 0.67$), pre-treatment ALBI was associated with a 3-fold increase in risk of bleeding (3.1% in ALBI 1 vs 10.2% in ALBI 2/3, $p = 0.008$). Neither ALBI grade nor CP score were associated with atezolizumab-related AEs. At treatment discontinuation ($n = 252$, 68.5%) all patients were either ALBI 2 or 3. ALBI score predicted for worse OS after discontinuing A+B, with ALBI 2 patients achieving a post-treatment mOS of 6.8 months (95% CI, 4.4–9.2) while ALBI 3 reached 1.6 months (95% CI, 0.6–2.7, $p < 0.001$).

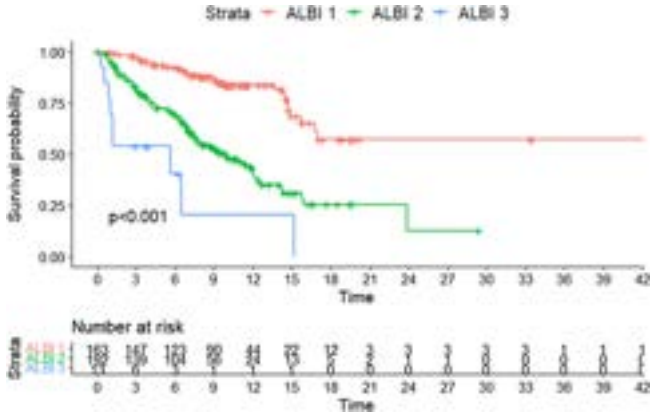

Figure:

Conclusion: ALBI grade identifies a subset of patients with higher probability of achieving an improved survival. Further studies should validate the role of ALBI as a predictor of bleeding events following A+B.

THU-117

Dipeptidyl-peptidase 4 inhibitors improve survival of patients with diabetes mellitus and hepatocellular carcinoma receiving immunotherapy

Dorothy Cheuk-Yan Yiu[1,2], Huapeng Lin[1,2], Terry Cheuk-Fung Yip[1,2], Mandy Sze-Man Lai[1,2], Vincent Wai-Sun Wong[1,2], Ken Liu[3], Grace Lai-Hung Wong[1,2]. *[1]The Chinese University of Hong Kong, Medical Data Analytics Centre, Hong Kong; [2]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong; [3]Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Centre, Sydney, Australia*
Email: wonglaihung@cuhk.edu.hk.

Background and aims: Preclinical studies suggest that dipeptidyl-peptidase 4 inhibitors (DPP4i) improve anti-tumor immunity in

hepatocellular carcinoma (HCC). By enhancing intrahepatic inflammatory cell infiltration, DPP4i may enhance response to immunotherapy regimens. This study aimed to investigate the impact of dipeptidyl-peptidase 4 inhibitors (DPP4i) on survival of patients who had advanced HCC undergoing immunotherapy in a real-world setting.

Method: This was a multi-center retrospective cohort study in Hong Kong and Australia. All patients with advanced HCC who had received at least one dose of immunotherapy were identified. Clinical, biochemical and medication data were collected and analyzed. The primary outcome was overall survival. The analysis was performed using Cox proportional hazards models.

Results: Among 451 patients with advanced HCC on immunotherapy, the mean age was 62.3 ± 12.4 years old. The cohort was predominantly male (n = 373, 82.7%) and the main etiology of HCC was chronic viral hepatitis (n = 331, 78.1%). 169 (37.5%) patients had diabetes and of which, 38 (22.5%) were treated with DPP4i. In diabetic patients, DPP4i use was associated with better survival (hazard ratio [HR] = 0.60 [95% CI 0.38–0.95], p = 0.029) in univariate analysis. After adjusting for patient demographics (age, sex) and pathologic variables (HCC etiology, albumin-bilirubin [ALBI]-grade, alpha-fetoprotein, platelets, alanine aminotransferase), the survival advantage of DDP4i remained similar in patients with diabetes (HR = 0.57 [0.35–0.92], p = 0.022). Within 23 DPP4i users who died, 17 (73.9%) died of cancer, 1 (4.3%) died of sepsis and 1 (4.3%) died of pneumonia.

Table 1. Univariate and multivariable analyses on the association between dipeptidyl-peptidase 4 inhibitor use and overall survival in all patients and diabetes subgroup.

	No. of subjects	Univariate analysis		Multivariable model 1		Multivariable model 2	
		HR (95% CI)	*p*	Adjusted HR (95% CI)	*p*	Adjusted HR (95% CI)	*p*
DPP4i use in all patients	451	0.75 (0.49-1.14)	0.177	0.72 (0.47-1.12)	0.148	0.70 (0.44-1.09)	0.110
DPP4i use in diabetes subgroup	169	0.60 (0.38-0.95)	0.029	0.60 (0.37-0.95)	0.031	0.57 (0.35-0.92)	0.022

Multivariable model 1: adjusted for age, sex, HCC etiology (viral vs non-viral cause)
Multivariable model 2: adjusted for age, sex, HCC etiology, ALBI-grade, alpha-fetoprotein, platelet, alanine aminotransferase
CI = confidence interval, HR = hazard ratio, ALBI = Albumin-Bilirubin.

Figure:

Conclusion: The use of DPP4i is associated with improved survival in diabetic HCC patients receiving immunotherapy. The findings should be further validated in prospective studies with larger sample sizes.

THU-118

Application of deep learning auto-segmentation and unsupervised machine learning in developing a radiomic prognostic score to predict disease recurrence post radiofrequency ablation for hepatocellular carcinoma

Background and aims: Disease recurrence after radiofrequency ablation (RFA) for hepatocellular carcinoma (HCC) is 60–85% at five years. Radiological features within the HCC and background liver may predict risk of reoccurrence. Through using a combination of deep-learning (DL) and machine-learning (ML) we developed a radiomic prognostic score to predict disease recurrence in patients undergoing RFA.

Methods: Patients undergoing RFA with or without sorafenib as part of the SORAMIC trial across 12 centers were included. An auto-segmentation tool for whole liver area was developed using DL on post-contrast hepatobiliary MRI sequences, and visually verified by experienced radiologists. Voxel resampling and intensity normalization was applied to segmented areas. 666 radiomic features were extracted using previously validated software (TexLAB 2.0). Least absolute shrinkage and selection operator (LASSO) Cox regression identified radiomic features and coefficients to construct the radiomic prognostic vector (RPV). RPV was evaluated for predicting time-to-recurrence (TTR) in Kaplan-Meier and Cox regression survival analysis.

Results: DL-derived auto-segmentation was applied to pretreatment MRIs in 79 patients undergoing RFA. Four radiomic features were identified from LASSO Cox regression to form the RPV score. Three RPV-associated clusters were identified using unsupervised k-means clustering. Kaplan-Meier survival analysis demonstrated these clusters correlated with low- (median TTR 54.3 months; 95% confidence interval [29.5-*]) medium- (median TTR 20.8 months; 95% CI [8.8–36.6]; log rank cf. low risk p < 0.005) and high- risk (median TTR 10.8 months; 95% CI [4.5–20.7]; p < 0.005) of HCC reoccurrence (Figure 1). In a multivariate Cox regression model including age, Barcelona Clinic Liver Cancer stage and adjuvant sorafenib, RPV was significant in predicting recurrence (Hazard ratio 3.08 [1.94–4.88]; p = <0.005).

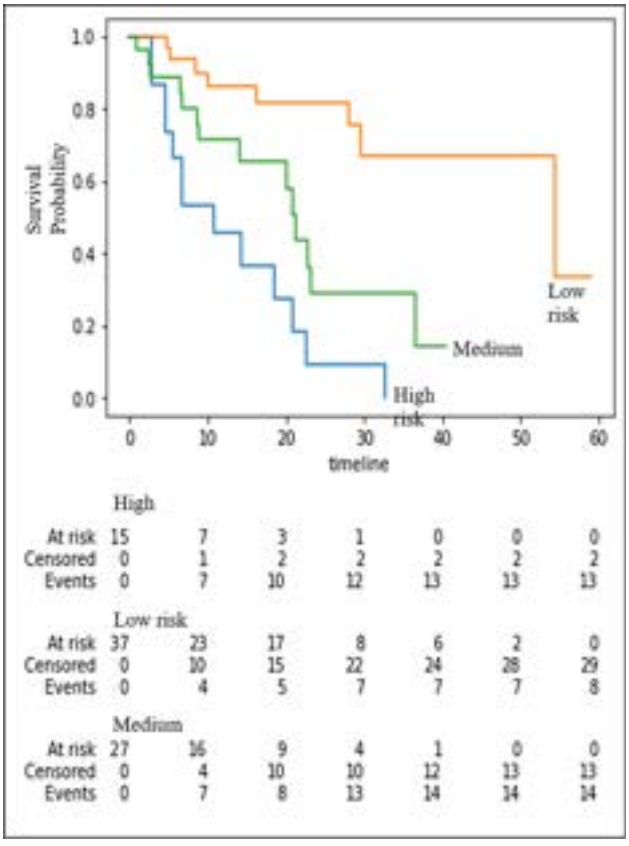

Figure: Kaplan-Meier curves for time-to-recurrence post radiofrequency ablation of HCC for clusters derived from k-means unsupervised learning for radiomic prognostic vectors

Conclusion: DL derived auto-segmentation in combination with pretreatment radiomic feature extraction from whole liver imaging can predict disease recurrence in HCC patients post RFA. Radiomic scores can be used to stratify high-risk patients for post treatment surveillance.

Background and aims: The efficacy of atezolizumab/bevacizumab (AB) had never been reported in patients with metastatic/unresectable combined hepatocellular carcinoma-cholangiocarcinoma (cHCC-CCA). Therefore, the purpose of our study is to describe the effects of atezolizumab/bevacizumab treatment in patients with advanced cHCC-CCA.
Method: We retrospectively included patients with a histological diagnosis of unresectable/metastatic cHCC-CCA and treated by AB (2020 to 2022) in 7 centers. Clinical, and radiological features were collected at the beginning of AB. We reported radiological response using RECIST criteria and overall survival and progression-free survival.
Results: Sixteen patients with cHCC-CCA were included and were predominantly male (75%) with advanced fibrosis/cirrhosis (69%). Nine patients received AB as a first-line systemic treatment, 5 as a second line, one as a third line and one as a fifth line. Severe digestive bleeding occurred in two patients. Among the 9 patients treated in first-line, four experienced radiological progression, three partial response and one had stable disease. Patients treated with AB in first line had a median overall survival of 13 months and a median progression-free survival of 3 months (Figure 1). Among the 7 patients receiving AB as a second line or more, 4 patients harbored a stable disease, two a partial response, and one a progressive disease.

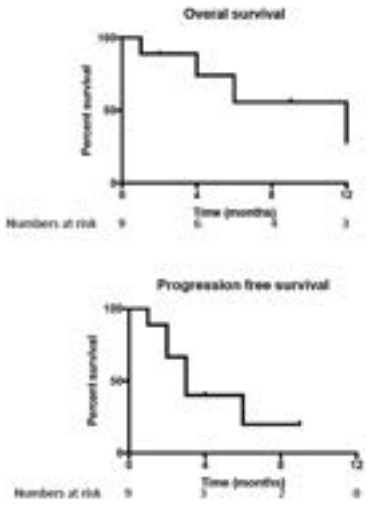

Figure: Overall survival and progression-free survival in patients treated by atezolizumab/bevacizumab as a first line systemic treatment

Overall survival and progression-free survival were represented using Kaplan-Meier curve with the number at risk under the X axis. The median overall survival was 13 months. The median progression-free survival was 3 months.
Conclusion: The combination of atezolizumab and bevacizumab showed signs of anti-tumor efficacy in patients with unresectable/metastatic cHCC-CCA.

THU-120

Fragility index of positive phase 2 and 3 randomized clinical trials of treatment of hepatocellular carcinoma (2002–2022)

Background and aims: The fragility index (FI), i.e., the minimum number of best survivors reassigned to the control group required to revert the statistically significant result of a clinical trial to non-significant, has been developed as a metric to evaluate the robustness of randomized, controlled trials (RCTs). We aimed to assess the FI in the field of HCC.
Method: This is a retrospective analysis of phase 2 and 3 RCTs for the treatment of HCC published between 2002 and 2022. We included two-arm studies with 1:1 randomization and significant positive results for a primary time-to-event end point for the FI calculation, which involves the iterative addition of a best survivor (patients with the longest follow-up time, regardless of having an event or being censored) from the experimental group to the control group, until positive significance ($p < 0, 05$, Log-rank test) is lost.
Results: We identified 51 phase 2 and 3 positive RCTs, of which 29 (57%) were eligible for fragility index calculation. After reconstruction of the Kaplan-Meier curves, 25/29 studies remained significant, among which the analysis was performed. The median (interquartile range (IQR)) FI was 5 (2–10) and Fragility Quotient (FQ) was 3% (1%–6%). Ten trials (40%) had a FI of 2 or less. FI was positively correlated to the blind assessment of the primary end point (median FI 9 with blind assessment *versus* 2 without, $p = 0.01$), the number of reported events in the control arm ($R_S = 0.45$, $p = 0.02$) and to impact factor ($R_S = 0.58$, $p = 0.003$), and negatively correlated to the *p value* ($R_S = -0.83$, $p < 0.0001$).

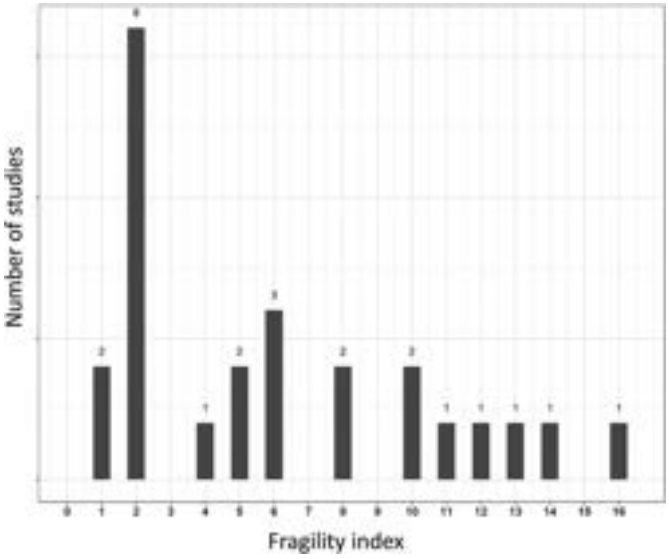

Figure: Distribution of Fragility index across studies (N = 25)

Conclusion: Several phases 2 and 3 RCTs in HCC have a low fragility index, underlying the limited robustness on the conclusion of their superiority over control treatments. The fragility index might provide an additional tool to assess the robustness of clinical trial data in HCC.

Genomic characteristics of hepatocellular carcinoma patients with response to sorafenib

Sun Young Yim[1], Sang-Hee Kang[1], Young-Sun Lee[1], Yoonseok Lee[1], Ji-Hwan Lim[1], Tae Hyung Kim[1], Young Kul Jung[1], Yeon Seok Seo[1], Hyung Joon Yim[1], Jong Eun Yeon[1], Ju-Seog Lee[2], Ji Hoon Kim[1]. [1]*Korea University Hospital, Korea, Rep. of South;* [2]*MD Anderson Cancer Center, United States*
Email: kjhhepar@naver.com.

Background and aims: Sorafenib is a multiple receptor tyrosine kinase inhibitor which is the standard systemic therapy for advanced hepatocellular carcinoma (HCC). However, the objective response rate is low only reaching 10% and since there are other new 1st line treatment options such as lenvatinib and immune checkpoint inhibitors, biomarkers that may predict patients who will respond well to sorafenib is required. We implemented RNA sequencing (RNA-seq) in HCC tumors to identify potential biomarkers that would predict response to sorafenib and uncover underlying biological features associated with better response.
Method: A total of 33 patients who had undergone liver resection prior to sorafenib treatment were enrolled. Matched tumor/surrounding tumor tissues were obtained and RNA-seq was performed with the NextSeq500. Cluster analysis was performed and gene signature associated with sorafenib response was identified. The gene signature was validated in independent Sorafenib as Adjuvant Treatment in the Prevention Of Recurrence of Hepatocellular Carcinoma (STORM) cohort. Gene network analysis by Ingenuity Pathway Analysis (IPA) was performed to uncover activated pathways and key upstream regulators associated with response to sorafenib. The composition of infiltrated immune cells in tumors was also investigated by using the CIBERSORTx algorithm.
Results: The mean age was 58 ± 11 years with male predominance (81.8%), median child pugh score was 5 (range, 5–8) and 57.6% of the patients switched to second-line chemotherapy mostly due to HCC progression. The best response among 33 patients was complete response (CR) observed in 1 patient, partial response (PR) in two patients, stable disease (SD) in 12 patients while 18 patients showed disease progression. Gene signature (721 genes) associated with disease control (SD, PR, CR vs. no response) was derived using cluster analysis and was named as Korea University Sorafenib Response (KUSOR) gene signature. When applied on STORM cohort, KUSOR gene signature was able to predict patients who do not recur on adjuvant setting of sorafenib treatment after HCC resection or ablation with sensitivity of 91% and specificity of 74%. Gene network analysis by IPA revealed that patients who showed disease control were characterized by IL-6 and IL-1ß activation. In contrast, MYC was more activated in HCC tumors showing no benefit of the treatment, suggesting that MYC may trigger resistance of HCC cells to sorafenib. In addition, regulatory T cells (Treg cells) and M2 macrophage fractions were significantly higher in poor response group while the fraction of activated NK cells and CD4 cells were substantially higher in disease control group.
Conclusion: Our study reveals that KUSOR gene signature was able to identify patients who would show disease control when treated with sorafenib. MYC promotes hepatocarcinogenesis in chronic liver disease and overexpression is associated with poor response. Furthermore, it can also be inferred that poor response to sorafenib could be related immune evasion through overexpression of Treg cells and M2 macrophages in tumor microenvironment. Our study is in accord with previous studies where patients with high MYC activation showed poor response to sorafenib indicating that combination therapy such as immune checkpoint blockade should be recommended for these patients.

Efficacy and safety of atezolizumab and bevacizumab in the real-world treatment of Child Pugh B patients with advanced hepatocellular carcinoma

Leonardo Stella[1], Francesca Ponziani[1], Francesco Santopaolo[1], Clemence Hollande[2], Antonio Gasbarrini[1], Sabrina Sidali[2], Maurizio Pompili[1], Mohamed Bouattour[2]. [1]*IRCCS Policlinico Universitario Agostino Gemelli, Italy;* [2]*APHP-Beaujon Hospital, France*
Email: leonardo.dr.stella@gmail.com.

Background and aims: Immunotherapy has changed the prognosis and the treatment paradigm in patients with advanced HCC. Despite the lack of well-designed multicenter studies involving cirrhotic patients with reduced liver function, initial evidence suggests that treatment with atezolizumab plus bevacizumab can be safely administered in patients with Child Pugh B (CP-B) class.
Method: We conducted a 2-years multicenter retrospective study enrolling 132 patients with unresectable or metastatic HCC treated with atezolizumab plus bevacizumab as part of routine clinical care, after a multidisciplinary team evaluation. We evaluated the coprimary end points, more precisely overall survival (OS), progression-free survival (PFS, as assessed at an independent review facility according to Response Evaluation Criteria in Solid Tumors or RECIST 1.1), and decompensation-free survival (defined as "the length of time during and after the treatment, that a patient does not develop new cirrhosis complications"), in CP-B cirrhotic patients compared to CP-A patients. Then, safety has been analyzed as a secondary outcome in the same subgroups of patients.
Results: CP-B patients achieved a median OS of 6.2 months (95% CI 5.0–7.2), which was significantly worse than CP-A patients (HR 2.78, 95%CI 1.34–5.64; $p < 0.0001$). However, there wasn't any difference in PFS between CP-A and CP-B patients (HR 1.68, 95%CI 0.78–3.65, $p = 0.6$). Moreover, disease control rate (DCR) was 69% in CP-A patients and 57% in CP-B patients ($p > 0.5$). Median time to decompensation (TTD) was 7 months (95%CI 5.3–8.7) in CP-B patients, remarkably lower than in CP-A patients (HR 3.27, 95%CI 1.4–7.4, $p < 0.01$). Main predictors of death were performance status, serum platelet count, serum albumin, and signs of portal hypertension. Main predictors of liver decompensation were performance status, signs of portal hypertension, diabetes, and serious adverse events linked to cancer treatment. The only protective factor for death and liver decompensation was chronic treatment with non-selective beta-blockers.

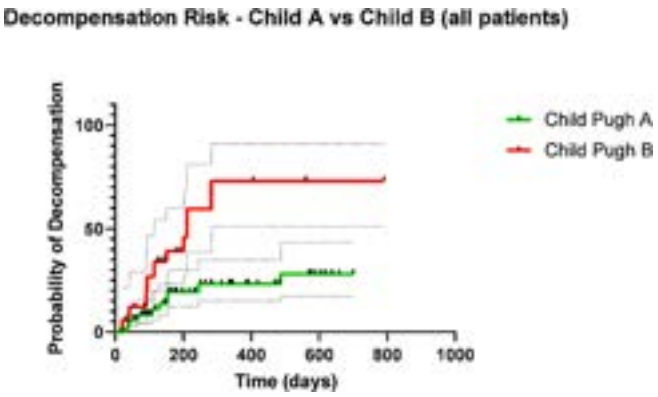

Figure 1: Decompensation risk in CP-A and CP-B patients treated with atezolizumab plus bevacizumab.

Conclusion: CP-B patients receiving treatment with atezolizumab plus bevacizumab showed a worse survival compared with CP-A patients, due to the competing effect of liver dysfunction over tumour progression. Response rates did not seem to differ according to the CP class. Thus, our data confirm that liver decompensation, rather than cancer progression, is the leading cause of death in CP-B patients.

Background and aims: Hepatocellular carcinoma (HCC) develops in patients with autoimmune liver disease (AILD) such as autoimmune hepatitis (AIH) and primary biliary cholangitis (PBC). Due to the low incidence of AILD, this subgroup is regularly underrepresented in HCC clinical trials. Data on treatment tolerability and prognosis in these rare liver patients is scarce. Hence, the aim of this study was to investigate, whether patients with HCC-AILD will equally benefit from systemic treatment with tyrosinkinase inhibitors (TKIs) or transarterial chemoembolization (TACE) and demonstrate a similar safety profile compared to patients with HCC due to viral, or non-/alcoholic liver disease.
Method: For this European retrospective study, conducted by the ERN Rare Liver, we initially enrolled 107 patients with HCC-AILD (55 × AIH, 52 × PBC) treated at 13 centers from 1996 to 2020. Of these, 72 remained for the final analysis (exclusions criteria: treatment other than TACE or TKIs, 38 × AIH, 34 × PBC). Propensity score matching 1:1 with a pool of 347 non-AILD associated HCC patients from Hamburg was conducted to adjust for differences in major clinical confounders between the two groups. Subsequently, comparative analyses of median overall survival (mOS) and treatment tolerability were performed, thereby applying a sequential analysis method for patients having undergone both TACE and systemic treatment.
Results: The final propensity-matched cohort included a total of 130 patients who were treated with TACE and 56 with systemic treatment. HCC-AILD patients demonstrated a comparable mOS for both TACE (19.5 months [10.1–28.3] vs 22.1 months [11.4–30.2], p = 0.9) and systemic treatment with TKIs (15.4 months [5.3-na] vs 15.1 months [9.4–35], p = 0.5). For TACE, adverse events (AE) occurred less frequently in HCC-AILD patients than in controls (e.g. post-TACE embolization syndrome) (≥1 AE: 34% vs 62%, p = 0.003), whereas there was no significant change in rate of AEs for systemic treatment (≥1 AE: 68% vs 82%, p = 0.2).
Conclusion: In conclusion, we present the first study, investigating the outcome and safety profile of rare liver patients with HCC-AILD treated with TACE or TKIs. Patients with HCC-AILD have similar mOS to both local and systemic treatment, and a more favorable tolerability compared to non-AILD associated HCC. Due to the exclusion of HCC-AILD patients in recent immunotherapy trials, systemic treatment with TKIs will continue to be the standard of care for HCC-AILD.

Email: mreig1@clinic.cat.

Background and aims: The landscape of hepatocellular carcinoma (HCC) changed in the last 5 years. Cabozantinib was approved for HCC, but the outcome of HCC patients who received cabozantinib as second- line due to sorafenib intolerance or after discontinuing first line treatment other than sorafenib, mostly come from retrospective analysis. This clinical trial evaluates the safety profile established by the rate of adverse events (AE), rate of related-AEs and rate of death in HCC patients who received cabozantinib in second-line.
Method: Phase II, open label and investigator initiated clinical trial (CT) including HCC patients intolerant to sorafenib or those who discontinued first-line treatment with lenvatinib or atezolizumab-bevacizumab. Cabozantinib was initiated at 60 mg every day, which was modified upon development of AE. Treatment continued until symptomatic tumor progression, unacceptable AEs, patient's decision or death. An interim analysis was planned when 14 patients had a minimum follow-up of 30 days, while the CT would have to be stopped because of futility if there were 8 or more patients with critical AEs according to investigators.
Results: At November 2022, 22 patients had been enrolled: 19 included, 11 on treatment and 8 discontinued cabozantinib. Four patients discontinued due to symptomatic progression, and the other 4 due to anorectal hemorrhage, intestinal ischemia, hand-foot skin reaction grade 3 and investigator decision, respectively. Twelve out of the 14 patients with >30 days follow-up (interim analysis) were sorafenib intolerant, 6 were BCLC-C and all had preserved liver function when starting cabozantinib. Eight patients developed 17 AE >grade 3, 11 of them were cabozantinib-related and 7 meet the definition of serious adverse events (SAE). Table 1 shows the 7 SAEs observed in 5 patients, among which 4 SAEs were cabozantinib-related and occurred in 3 patients.

Table 1: Severe adverse events

Subject PatientID	Sorafenib intolerance	AE description	Start date	End date	Grade (1-5) NCI CTCAE v5.0	Cabozantinib Relationship	Cabozantinib dose (mg)	Action taken (Cabozantinib)	Death
1	Dermatologic adverse event and fatigue	Hypokalemia	2020-09-09	2020-10-07	3	Related	60	Cabozantinib interrupted	Yes
		Gastrointestinal bleeding	2020-12-17	2020-12-22	3	Related	60	None	
2	Rectal ulcer	Ano-rectal Hemorrhage	2020-12-11	2020-12-29	3	Related	60	None	Yes
		Spontaneous bacterial peritonitis	2021-01-28	2021-02-10	3	Not Related	0	None	
3	Dermatologic adverse event	Intestinal ischemia	2021-01-16	2021-01-26	3 (SUSAR)*	Related	60	Cabozantinib interrupted	No
4	Dermatologic adverse event	Fever	2021-04-03	2021-04-09	1	Not related	0	None	No
5	Not reported	Acute cholecystitis	2021-02-04	2021-02-18	3	Not related	0	None	Yes

Table: (abstract: THU-124).

Conclusion: The Data and Safety Monitoring Board concluded that the ACTION trial could continue, since it did not met the safety futility criteria. The final analysis is expected on June 2023.

Association of tumor response with survival in patients with unresectable hepatocellular carcinoma treated with first-line tislelizumab versus sorafenib: results from the RATIONALE-301 study

Tim Meyer[1], Richard S. Finn[2], Masatoshi Kudo[3], Andrew X. Zhu[4,5], Songzi Li[6], Yaxi Chen[7], Frederic Boisserie[8], Ramil Abdrashitov[9], Arndt Vogel[10], Shukui Qin[11]. *[1]Royal Free Hospital NHS Trust and University College London, Academic Department of Oncology, London, United Kingdom; [2]Geffen School of Medicine, University of California Los Angeles, Department of Medicine, Division of Hematology/Oncology, Los Angeles, CA, United States; [3]Kindai University Faculty of Medicine, Department of Gastroenterology and Hepatology, Osaka, Japan; [4]Jiahui Health, Jiahui International Cancer Center, Shanghai, China; [5]Harvard Medical School, Massachusetts General Hospital, MA, United States; [6]BeiGene Ltd., Ridgefield Park, Biometrics, NJ, United States; [7]BeiGene (Beijing) Co., Ltd., Clinical Science, Beijing, China; [8]BeiGene Ltd., Ridgefield Park, Clinical Science, NJ, United States; [9]BeiGene USA, Inc., Clinical Development, Fulton, MD, United States; [10]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [11]Cancer Center of General Hospital of Eastern Theater of PLA, Nanjing, China*
Email: t.meyer@ucl.ac.uk

Background and aims: Tislelizumab (TIS) is a monoclonal antibody with high affinity and binding specificity to programmed cell death protein 1. In RATIONALE-301 (NCT03412773) TIS was non-inferior to sorafenib (SOR) for overall survival (OS) as first-line treatment of patients (pts) with unresectable hepatocellular carcinoma (HCC); OS superiority vs SOR was not met. We evaluated the association of response with survival in pts from the RATIONALE-301 study.
Method: In this phase 3, open-label study, systemic therapy-naïve adult pts with histologically confirmed Barcelona Clinic Liver Cancer Stage B/C HCC were randomized (1:1) to receive TIS (200 mg intravenous every 3 weeks) or SOR (400 mg orally twice daily) until disease progression, intolerable toxicity, or withdrawal. The primary end point was OS; secondary efficacy end points included progression-free survival (PFS) and best overall response (BOR; per RECIST v1.1) by blinded independent review committee. We assessed OS and PFS according to BOR (complete response [CR] vs partial response [PR] vs stable disease [SD] vs progressive disease [PD]). Limitation of this analysis is related to its retrospective nature.
Results: Overall, 674 pts were randomized (TIS: n = 342; SOR: n = 332). At data cutoff (Jul 11, 2022), minimum study follow-up was 33 months. Pt characteristics were generally balanced at baseline in both arms. Survival outcomes across response categories are presented in the table. Response was associated with longer median OS and PFS for both arms. The OS rate at 24 months was higher in responders treated with TIS vs SOR (TIS; OS: 91.7%, 95% CI: 79.4, 96.8; SOR; OS: 72.2%, 95% CI: 45.6, 87.4).
Conclusion: Though there are limitations in the analysis, response achieved on treatment with TIS was associated with better survival vs SOR, in pts with unresectable HCC.

Table: (abstract: THU-125).

Effectiveness and safety of conversion surgery for patients with initially unresectable hepatocellular carcinoma using lenvatinib combined with TACE plus PD-1 inhibitors: a real-world study

Xingzhi Li[1], Xiaobo Wang[1], Tao Bai[1], Jie Chen[1], Zhihong Tang[1], Tao Wei[1], Shaolong Lu[1], Lequn Li[1], Feixiang Wu[1]. [1]*Guangxi Medical University Cancer Hospital, Department of Hepatobiliary Surgery, China*
Email: wufeixiang@gxmu.edu.cn

Background and aims: Conversion surgery for patients with initially unresectable hepatocellular carcinoma (uHCC) using lenvatinib combined with transcatheter arterial chemoembolization (TACE) plus programmed cell death protein-1 (PD-1) inhibitors (LTP) has been promising. However, the effectiveness and safety of conversion surgery for initially uHCC requires additional study. The purpose of this real-world, retrospective study was to compare the effectiveness and safety of conversion surgery for patients with initially uHCC managed with LTP to initial surgery in patients with resectable HCC.
Method: The data of 32 consecutive patients with initially uHCC receiving conversion surgery and 419 consecutive patients with resectable HCC receiving initial surgery from November, 2019, to September, 2022, were analyzed retrospectively. After propensity score matching (PSM) in a 1:2 ratio, 65 patients were selected. The major outcomes were safety of the operation, event-free survival (EFS), overall survival (OS), and clinicopathological factors.

Results: Compared to initial surgery, conversion surgery was safe. Before matching, the conversion surgery group had longer EFS (not reached vs 11.5 months, p = 0.003) and similar OS (not reached vs not reached, p = 0.62) compared with the initial surgery group. Similar results for EFS (p = 0.005) and OS (p = 0.28) were also obtained after matching. Multivariate analysis confirmed that conversion surgery was an independent prognostic factor of EFS. The conversion surgery group had significantly lower incidence of microvascular invasion (MVI) (3.1% vs 50.4%; p < 0.001), grade III/IV tumor differentiation (15.6% vs 45.8%; p < 0.001), and incomplete tumor capsule (12.5% vs 54.7%; p < 0.001). Before matching, patients with MVI-negative in the conversion surgery group had significantly longer EFS than those in the initial surgery group (not reached vs 14 months, p = 0.008). After matching, patients with MVI-negative in both groups had similar EFS (p = 0.39).

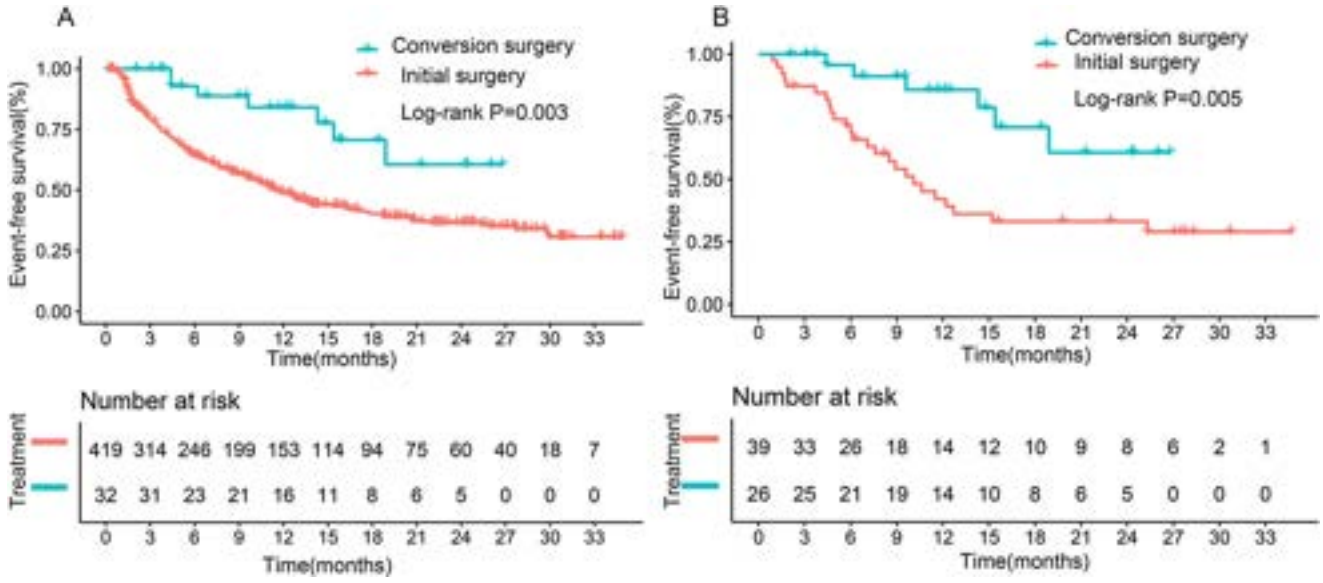

Figure: (abstract: THU-126).

Conclusion: Conversion surgery is effective and safe for patients with initially uHCC receiving LTP. Conversion therapy of LTP has the potential to reduce risk factors for postoperative recurrence, especially MVI, which may change surgical decision-making.

Email: v.joerg@uke.de

Background and aims: Since the introduction of the combination treatment of anti-PD-L1 antibody atezolizumab and anti-VEGF antibody bevacizumab (AB) median overall survival (OS) in hepatocellular carcinoma (HCC) has drastically improved. However, evidence on efficacy and safety of the novel treatment standard in patients with prior exposure to systemic treatment is scarce. Up to now, global positive phase 3 clinical trials for second line treatments are limited to regorafenib, cabozantinib, and ramucirumab following sorafenib treatment. The aim of this global, multi-center, observational study was to evaluate efficacy and safety of AB in patients after previous systemic therapy.

Method: We screened our global, multi-center, prospectively maintained registry database for patients who received any systemic therapy before AB. Primary end point was OS, secondary end points were time-to-progression (TTP), progression-free survival (PFS), objective response rate (ORR), and safety (rate and severity of adverse events).

Results: Among 493 patients who received AB for unresectable HCC, 61 patients received prior systemic therapy and were included in this analysis. Median age of the study population was 66 years, with 91.8% males. Predominant risk factors for HCC were viral hepatitis (59%) and alcohol (23%). OS for AB was 16.2 (95% CI, 14.5–17.9) months, TTP and PFS were 4.1 (95% CI, 1.5–6.6) and 3.1 (95% CI, 1.1–5.1) months, respectively. ORR was 38.2% (7.3% with complete and 30.9% with partial response). Overall survival was not influenced by treatment line (2nd vs >2nd) or previous systemic treatment modality (tyrosin kinase inhibitors (TKI) vs. immune checkpoint inhibitors (ICI)). Treatment-related adverse events (trAE) of any grade according to CTCAE were documented in 42.6% of patients with only 13.1% of grade ≥3, incl. one death.

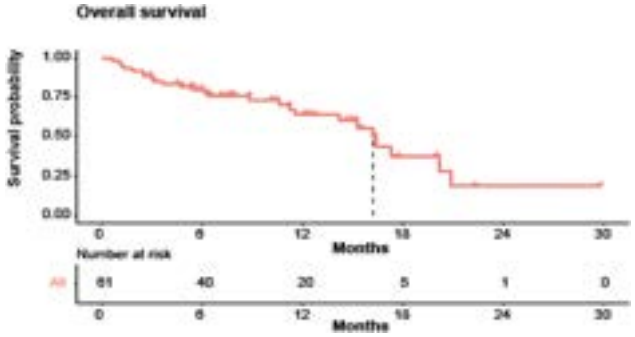

Figure:

Conclusion: In this observational study, AB emerges as a safe and effective treatment option in patients with HCC previously treated with other systemic agents.

THU-129

Survival outcomes of hepatocellular carcinoma after yttrium-90 selective internal radiation therapy in an Asian population stratified by tumour volume and distribution

Kaina Chen[1,2], Fiona Ni Ni Moe[3], Aaron Kian Ti Tong[4], David Chee Eng Ng[4], Richard Hoau Gong Lo[5], Apoorva Gogna[5], Sean Xuexian Yan[4], Sue Ping Thang[4], Kelvin Siu Hoong Loke[4], Karaddi Venkatanarasimha Nanda Kumar[5], Hian Liang Huang[4], Chow Wei Too[5], Weng Yan Ng[3], Marjorie Hoang[2], Pierce Chow[2,6,7]. *[1]Singapore General Hospital, Gastroenterology and Hepatology, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore; [3]National Cancer Centre Singapore, Singapore; [4]Singapore General Hospital, Nuclear Medicine, Singapore, Singapore; [5]Singapore General Hospital, Vascular and Interventional Radiology, Singapore; [6]National Cancer Centre Singapore, Surgical Oncology, Singapore; [7]Singapore General Hospital, Hepato-pancreato-biliary and Transplant Surgery, Singapore, Singapore*
Email: cknworkemail@gmail.com

Background and aims: Selective internal radiation therapy (SIRT) with yttrium-90 (Y90) has been approved by the U.S. Food and Drug Administration (FDA) for solitary hepatocellular carcinoma (HCC) up to 8 cm with preserved liver function. Y90 SIRT is also a widely used locoregional therapy for a wider range of unresectable locally advanced HCC given its favourable safety profile. Our study aims to evaluate the survival outcomes of HCC patients treated with SIRT Y90,

stratified by tumour volume and tumour distribution to improve prognostication.
Method: Included are patients at least 18 years old treated with resin microsphere Y90 SIRT for unresectable HCC between 1st January 2008 and 22nd May 2019 at National Cancer Centre Singapore (NCCS) \Singapore General Hospital (SGH) and had follow-up data. Patients with metastatic HCC, a second primary cancer, or lost to follow-up were excluded. The study cohort was divided into the following subgroups to improve prognostication: 1) within Milan (<Milan); 2) unilobar HCC beyond Milan within Up-To-7 (<UT7-u); 3) bilobar HCC beyond Milan within Up-To-7 (<UT7-b); 4) unilobar HCC beyond Up-To-7 (>UT7-u), 5) bilobar HCC beyond Up-To-7 (>UT7-b), 6) portal vein invasion (PVI) and Child-Pugh class A (PVI-CPA) and 7) PVI and Child-Pugh class B (PVI-CPB).
Results: Among 721 patients treated with Y90 SIRT within the study duration, 413 patients fulfilled inclusion\exclusion criteria. The median follow-up was 16.3 months. The median overall survival (mOS) of the whole cohort was 20.9 months (95% CI 18.2–24.0) and did not significantly differ with age or gender. In patients with HCC without PVI, survival differed significantly with performance status, liver function (Child-Pugh class, Albumin-Bilirubin grade), tumour size and distribution, whereas in patients with PVI, alpha-foetal protein levels and extent of PVI were additional predictors of OS. Of note, patients with solitary HCC (25.3 months, 95% 20.4–37.0) and 2–5 tumours (25.7 months, 95% CI 20.2–31.1) had comparable mOS (p = 0.323). Solitary HCCs with an absorbed Y90 dose above 150Gy tend towards a better mOS (46.4 months, 95% CI 26.2-NE) versus mOS 22.7 months (95% CI 13.7–37) in those with ≤150 Gy (p = 0.085). Median OS of the subgroups is shown in the Figure. Seventy patients (70/413, 16.9%) received curative modalities after Y90 SIRT downstaged the disease with mOS of 79.7 months (95% CI 40.4-NE), versus those who did not receive subsequent curative treatments (mOS 17.1 months; 95% CI 13.5–20.4, p < 0.001), and this was observed among all the subgroups.
Conclusion: Treatment outcomes of Y90 SIRT are favourable for patients with unresectable intermediate-locally advanced HCC. Incorporating tumour distribution improved prognostication of intermediate HCC, whereas the Child-Pugh class can stratify HCC with PVI. Patients downstaged with Y90 SIRT who subsequently received curative therapy had significantly improved mOS.

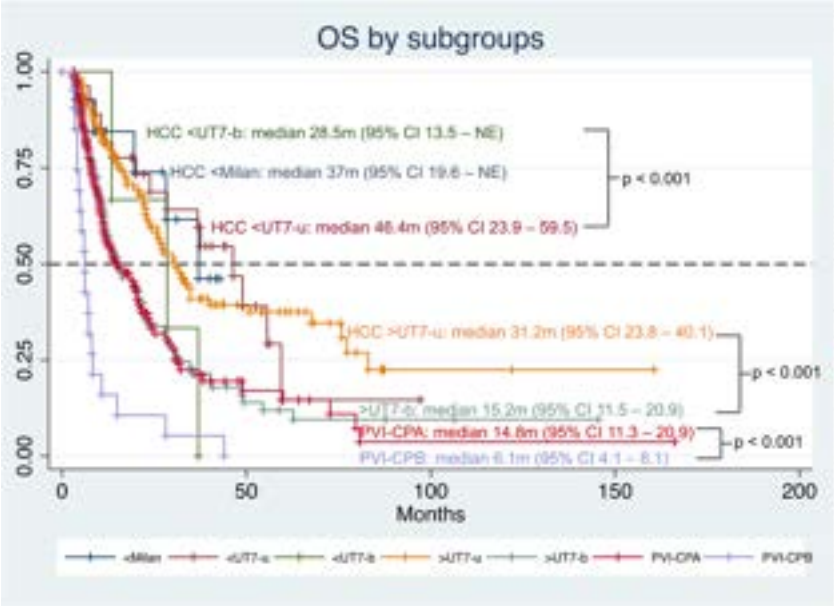
Salvage hepatectomy for recurrent hepatocellular carcinoma after radiofrequency ablation
Jai Young Cho[1], Ho Seong Han[1], Hae Won Lee[1], Boram Lee[1], Yeshong Park[1], MeeYoung Kang[1], Sook-Hyang Jeong[2], Jin-Wook Kim[2], Gwang Hyeon Choi[2]. *[1]Seoul National University Bundang Hopsital, Surgery, Korea, Rep. of South; [2]Seoul National University Bundang Hospital, Internal Medicine, Korea, Rep. of South*
Email: jychogs@gmail.com

Background and aims: Radiofrequency ablation (RFA) is a widely used percutaneous local ablation technique for the treatment of hepatocellular carcinoma (HCC). Yet the optimal treatment for marginal recurrence after RFA is not established, and the role of salvage hepatectomy is still unclear.
Method: A retrospective analysis was performed on 60 patients who underwent salvage hepatectomy (SH) for recurrent HCC after RFA between January 2004 and August 2022 at a single tertiary referral center. Short-term and long-term outcomes were compared to a matched control group (n = 60) of patients who underwent primary hepatectomy (PH) as initial treatment during the same period.
Results: The two groups showed no statistically significant difference in operative extent, operation time, and intraoperative blood loss. Postoperative morbidity rates were similar, and there was no postoperative mortality in either group. After intention-to-treat analysis, recurrence rates were significantly higher in the SH group for both local recurrence (36 [60.0%] vs. 14 [23.3%], p < 0.001) and systemic recurrence (22 [36.7%] vs. 3 [5.0%], p < 0.001). The 1-, 3-, and 5-year DFS rates were significantly worse in the SH group compared to the PH group (83.1% vs. 94.5%, 46.9% vs. 70.4%, and 26.2% vs. 66.9%, respectively; p < 0.001). Cancer-related death showed higher incidence in the SH group (13 [21.7%] vs. 4 [6.7%], p = 0.018). However, the difference in 1-, 3-, and 5-year overall survival rates between the two groups was not statistically significant (93.0% vs. 98.1%, 81.9% vs. 95.8%, and 78.0% vs. 92.2%, respectively; p = 0.091).
Conclusion: Salvage hepatectomy is an acceptable treatment option for recurrence after RFA with short-term outcomes comparable to primary resection. However, treatment should be planned carefully, because recurrent HCC after RFA exhibits more aggressive behavior.



Subgroup	N	median OS	95% CI
<Milan	14	37 months	19.6 – NE
<UT7-u	28	46.4 months	23.9 – 59.5
Solitary	16	46.4 months	10.6 – NE

Email: massimo.iavarone@gmail.com

Background and aims: Lenvatinib (LEN) is among the drugs used in the forefront treatment of patients with advanced hepatocellular carcinoma (HCC) and in the future it could be part of therapeutic combinations with immunotherapy. However, the presence of esophagogastric varices (EGV) and the risk of bleeding might either contraindicate or limit this therapeutic choice. Thus study aimed to assess prevalence, risk factors and clinical consequences of EGV in LEN-treated patients with HCC.

Method: Among 816 patients of a large international cohort of patients treated with LEN for HCC not eligible for other therapies, we selected those with an upper-gastrointestinal endoscopy (UGE) available in the 6 months before treatment starts. Primary end points were: prevalence and risk factors for EGV bleeding during LEN treatment; secondary end points were prevalence and risk factors for presence of high risk EGV at baseline.

Results: We enrolled 535 patients with baseline UGE [median age 72 years, 78% male, 63% viral aetiology, 89% Child-Pugh A, 16% neoplastic portal vein thrombosis (nPVT), 56% BCLC-C]. At baseline, 301 (56%) patients were EGV free. Among the 234 patients with EGV (44%), 206 had esophageal varices (EV), 16 gastric varices (GV) and 12 both; 70/234 (30%) were high-risk EGV (small EV with red signs, medium/large EV, any GV) at baseline and 59 of them were treated with primary prophylaxis (non-selective beta-blockers 25, endoscopic band

ligation 32 and both 2). Child-Pugh B (OR 2.11; 95% CI 1.18–3.77, p = 0.01), platelets <150,000 (OR 3.19; 95% CI 2.17–4.70, p < 0.001) and nPVT (OR 2.44; 95% CI 1.48–4.02, p < 0.001) independently predicted presence of EGV; while Child-Pugh B (OR 2.12; 95% CI 1.08–4.17, p = 0.03), platelets <150,000 (OR 2.47; 95% CI 1.35–4.50, p = 0.003) and nPVT (OR 2.54; 95% CI 1.40–4.61, p = 0.002) independently predicted high risk EGV. During LEN therapy, 17 patients bled from EGV (3 grade 2, 11 grade 3–4 and 3 grade 5): prevalence of EGV bleeding was 3% overall, 7% among patients with EGV and 17% among those with high-risk varices. Among the 234 patients with baseline EGV, the only independent predictor of bleeding was the presence of high-risk varices (HR 6.94; 95% CI 2.23–21.57, p = 0.001). Risk of EGV bleeding can be stratified according to Child-Pugh B, presence of nPVT and platelets <150,000/uL into low (0/3 risk factors, 6-months cumulative incidence 0.77%), intermediate (1/3 risk factors, 6-months cumulative incidence 2.31%) and high (2/3 or 3/3 risk factors, 6-months cumulative incidence 7.40%).

Conclusion: In HCC patients treated with lenvatinib, the risk of EGV bleeding is low but it increases in patients with high-risk EGV at baseline. A risk stratification for high-risk EGV and bleeding can be applied for decision-making, according to liver reserve, platelet count and nPVT.

THU-132

Risk stratification for early recurrence after resection in patients with intermediate stage hepatocellular carcinoma

Han Ah Lee[1], Jeong-Ju Yoo[2], Minjong Lee[1], Ho Soo Chun[1], Hwi Young Kim[1], Tae Hun Kim[1], Yeon Seok Seo[3], Dong Hyun Sinn[4].
[1]Ewha Womans University College of Medicine, Korea, Rep. of South; [2]Soonchunhyang University Bucheon Hospital, Korea, Rep. of South; [3]Korea University College of Medicine, Korea, Rep. of South; [4]Sungkyunkwan University School of Medicine, Korea, Rep. of South
Email: minjonglee2@naver.com

Background and aims: It is unclear which patients will benefit from resection at intermediate stage of hepatocellular carcinoma (HCC). We aimed to identify high-risk patients for early recurrence in patients resectable for intermediate-stage HCC.

Method: This multicenter, retrospective study involved 1,686 patients who underwent resection or transarterial chemoembolization (TACE) for intermediate-stage HCC (2008–2019). Multivariable Cox proportional analysis for identifying high-risk patients treated with resection was performed. A prediction model for 2-year recurrence-free survival (RFS) was developed in the training cohort and validated in the validation cohort. 2-year RFS in each risk group was compared to those treated with TACE after propensity-score matching.

Results: During median follow-up of 31.4 months, 2-year RFS was significantly higher in the resection group (28.5%, n = 480) than in the TACE group (71.5% n = 1,206) (adjusted hazard ratio [aHR] = 1.471, 95% CI = 1.199–1.803, P < 0.001). Higher alpha-fetoprotein (aHR = 0.202), ALBI grade (aHR = 0.709), tumor number (aHR = 0.404), and maximal tumor size (aHR = 0.323) were significant risk factors for 2-year RFS in patients with resection. The newly developed Surgery Risk score in BCLC-B (SR-B score) with four variables showed an area under the curve of 0.801 for 2-year RFS and was externally validated. Based on risk stratification by the SR-B score, low-risk patients had a significantly higher 2-year RFS (training: aHR = 5.834; validation: aHR = 5.675) than high-risk patients (all P < 0.001). In a propensity-score matched cohort, low-risk patients treated with resection had a significantly higher 2-year RFS than those with TACE (aHR = 3.891); high-risk patients had a comparable 2-year RFS than those with TACE (aHR = 0.816).

Conclusion: Resection may be beneficial to resectable patients with intermediate-stage HCC based on the SR-B score.

THU-133

Impact of radiological response and pattern of progression on overall survival in patients with hepatocellular carcinoma treated by atezolizumab-bevacizumab

Background and aims: The combination of atezolizumab and bevacizumab (A-B) is the first-line treatment for patients with unresectable hepatocellular carcinoma (HCC). RECIST 1.1 are the validated criteria used to define the response to systemic therapy in oncology whereas mRECIST criteria have been proposed for the radiological evaluation of patients treated for HCC. Our study aims to assess the radiological response (rR) to A-B therapy using RECIST 1.1 and mRECIST criteria, to define the predictors of rR and radiological progression (rP) for each of the criteria, and the ability of these criteria and of the pattern of progression to predict overall survival (OS).

Method: HCC patients treated with A-B were retrospectively included in two centers between July 2020 and October 2022. A retrospective blinded central analysis was performed using contrast-enhanced liver imaging at 12w after the start of treatment by two radiologists in order to assess RECIST1.1 and mRECIST response. Inter-reader agreement was analyzed using weighted k statistics and logistic regression was used to assess predictors of rR and rP. The association between the variables at the start of A-B treatment, rR, and OS were modelled in univariate and multivariate analysis using the Cox model. Differences in survival between the different categories of rR and according progression pattern were assessed using Kaplan-Meier curves and the log-rank test.

Results: A total of 125 patients were included, median age was 65y and 79% were male. Etiology included hepatitis B (23.2%) and C (39.2%), excessive alcohol consumption (35.2%) and/or NAFLD (25.6%). Cirrhosis was present in 73.6% of the patients including 80.4% Child-Pugh A; 69.6% of the patients were classified as BCLC C. The median OS of the population was 12.4 months (95%CI:9.43–15.37). At the first imaging assessment, according to RECIST 1.1 and mRECIST, 13.6% and 20.8% had response, 39.2% and 35.2% stable disease and 47.2% and 44% progression respectively. Interobserver agreement with weighted k values was substantial with both criteria (0.789 for RECIST 1.1 and 0.790 for mRECIST, p < 0.001). The presence of extrahepatic metastases (HR:4.22, CI95%:1.90–9.32, p < 0.001) was independently associated with a higher risk of rP in RECIST 1.1 in multivariate analysis. No significant predictors of response or

progression were identified using mRECIST criteria. OS was increased in patients with rR in RECIST1.1 (HR:0.38 CI95% 0.15–0.94, p = 0.04) and mRECIST (HR:0.13 CI95%:0.04–0.40, p = 0.037). Conversely, OS was shorter in patients who progressed in RECIST 1.1 (HR:2.67 CI95%:1.59–4.51, p < 0.001) and mRECIST (HR:3.14 CI95%:1.85–5.32, p < 0.001) compared to other. Patients classified as responders, regardless of the criteria used, had not reached median OS, which was 16.20 and 15.87 months with RECIST 1.1 and mRECIST criteria for patients classified as stable and 9.07 months for patients classified as progressors for both criteria (p < 0.001). Among the patterns of progression on A-B, only the appearance of new metastatic lesions was associated with a worse OS (HR:1.93 CI95%:1.04–3.57, p = 0.036)
Conclusion: RECIST 1.1 and mRECIST criteria similarly predict OS in A-B treated HCC patients with more patients identified as responders with mRECIST criteria. Presence of extrahepatic metastases at baseline was associated with a higher risk of radiological progression and the occurrence of new metastatic lesions at progression with a decreased survival.

Background and aims: No randomized controlled trial evidence exists to support use of systemic therapy in patients with hepatocellular carcinoma (HCC) in the setting of liver dysfunction. Although selected patients with Child-Pugh (CP) B cirrhosis can likely be safely treated with immunotherapy, whether systemic anti-cancer therapy (SACT) improves survival in this population is unclear. In this retrospective study, we described outcomes of CP-B patients treated with either sorafenib (Sor), nivolumab (Nivo) or atezolizumab plus bevacizumab (A+B) and compared them to best supportive care (BSC) in a propensity score weighted (PSW) analysis.
Method: From two international consortia, we selected CP-B patients receiving A+B (n = 72), Nivo (n = 46) or Sor (n = 114) as first-line systemic therapy for advanced HCC between 2010 and 2022 and compared outcomes to a cohort of 159 patients receiving BSC in the same timeframe. SACT exposure was evaluated in relationship to OS using propensity score weighted (PSW) multivariate regression models.
Results: In the unmatched population (n = 392), the 233 patients receiving active treatment for HCC had a longer mOS compared to the 159 receiving BSC (6.5 vs. 5.5 months, p = 0.011).
Following PS matching for Barcelona Clinic Liver Cancer (BCLC) stage (A/B vs C), alpha-fetoprotein (AFP) (>400 vs ≤400 ng/ml), CP score (7/8 vs 9) and presence of main portal vein tumor thrombosis (PVTT), 114 couples were left, and receipt of SACT remained associated with improved mOS (7.7 vs 5.8 months, p < 0.001).
PSW univariate regression analyses demonstrated a significant reduction in the risk of death in patients exposed to A+B (HR: 0.6, 95%CI: 0.4–0.8); Nivo (HR: 0.5, 95%CI:0.4–0.8) and Sor (HR: 0.6, 95% CI: 0.5–0.9, p = 0.001). Better OS was observed in patients exposed to A+B (HR: 0.6, 95%CI: 0.4–0.8), Nivo (HR: 0.4, 95%CI:0.3–0.7) and Sor (HR: 0.7, 95%CI: 0.6–0.9, p < 0.001) following adjustment for unbalanced prognostic traits in PSW-multivariate models.
Significantly inferior survival was observed in patients with AFp >400 ng/ml (HR: 1.9, 95%CI: 1.5–2.5); CP score of 9 (HR: 1.7, 95%CI: 1.2–2.4) and in the presence of PVTT (HR: 1.8, 95%CI: 1.4–2.4).
In the SACT-exposed group, incidence of treatment-related adverse events (trAEs) of all grades was 59%. trAEs rates were higher in A+B (69%) and Sor (67.5%) than Nivo (43.2%, p < 0.001).

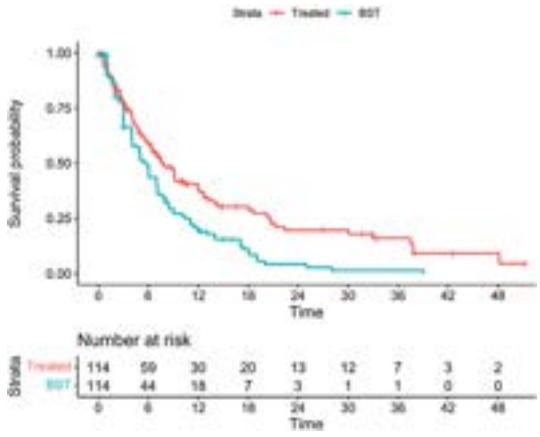

Figure: KM curves for OS in the PS matched population

Conclusion: Receipt of SACT was associated with a small but significant OS improvement in CP-B patients treated with SACT compared to BSC. PS-weighted OS estimates indicate extended survival times in patients with CP 7–8, AFP < 400 ng/ml and no PVTT, identifying a patient sub-population where SACT may be delivered with higher clinical benefit. This retrospective study provides a benchmark for the survival extension potentially associated with SACT delivered in CP-B patients.

Clinical profile and outcomes of hepatocellular carcinoma in primary Budd Chiari syndrome

Ankit Agarwal[1,2], Sagnik Biswas[1], Manas Vaishnav[1], Shekhar Swaroop[1], Rithvik Golla[1], Shubham Mehta[1], Shivanand Gamangatti[2], Subrata Acharya[1], Sashi Paul[2], Shalimar[1].
[1]AIIMS Hospital, Gastroenterology and HNU, New Delhi, India; [2]AIIMS Hospital, New Delhi, India
Email: drshalimar@yahoo.com

Background and aims: There is scant literature on Budd-Chiari syndrome (BCS) in Hepatocellular carcinoma (HCC). Radiological interventions play an important role in the management of BCS and HCC. The feasibility and outcomes of interventions for the management of BCS and HCC in primary BCS-HCC are unclear. We aimed to assess the clinical presentations and outcomes of patients with primary BCS-HCC.
Method: All consecutive patients diagnosed with primary BCS-HCC evaluated between January 1987 and January 2023 were included in this retrospective analysis of a prospectively maintained database. The diagnosis was based on either imaging/liver biopsy with elevated alfa-fetoprotein (AFP). As a protocol, BCS was managed first with endovascular intervention followed by HCC therapy.
Results: Overall, 35/904 (3.8%) BCS patients evaluated had primary BCS-HCC. BCS-HCC patients, when compared to patients with BCS alone, were older (mean age: 32 vs 26 years, P = 0.001), with higher proportion of IVC block, cirrhosis and long-segment vascular obstruction. 18 had HCC at first presentation [prevalence 18/904 (1.99%) and 17 developed HCC (among 886) over a follow-up of 4601 person-years with an incidence of 0.36 (0.22–0.57) per 100 person-years. The median AFP levels in BCS-HCC group was 1310 ng/ml, with higher levels in patients with BCS-HCC at first presentation, compared to those who developed HCC at follow-up (13029 vs 500 ng/ml, P = 0.01). The BCLC presentation included A: 5 (14.28%), B: 17 (60.71%), C: 9 (25.71%) and D: 4 (11.4%). Of the 35 BCS-HCC, 26 (74.3%) underwent radiological interventions for BCS and 22 (62.8%) patients underwent treatment for HCC. Thirteen (37.1%) BCS-HCC patients were not treated for HCC: 7 (53.8%) in group at first presentation and 6 (46.2%) in the BCS-follow-up group. The interventions for HCC included transarterial chemoembolization in 18 (81.8%), oral TKI in 3 (13.6%) and TARE in 1 (4.5%) patient. The response at 1 month based on m-RECIST criteria was available in 15/22 (68.2%). Of these 15, 5/15 (33.3%) showed complete response, 6/15 (40.0%) showed partial response, 4/15 (26.7%) had progressive disease. One patient died within 1 month of TACE. The median number of interventions for HCC were 1 (range, 1–5). The median survival among patients who did not undergo interventions for HCC, compared with those who did, was 3.5 years vs 3.1 months (p = 0.0001) (figure a). The median survival among those who underwent intervention as per BCLC stages A, B, C, D was 172 days, 1352 days, 240 days and 40 days, respectively (figure b).
Conclusion: Hepatocellular carcinoma is not uncommon in patients with BCS. Radiological interventions are feasible in select primary BCS-HCC patients and may improve outcomes.

[21]Hospital Universitario de Canarias, Canarias, Spain; [22]Hospital Universitario Infanta Elena, Madrid, Spain
Email: m.romero.gutierrez@gmail.com

Background and aims: There are scarce data in the literature about liver resection of hepatocellular carcinoma (HCC) in non-cirrhotic patients.
Method: One hundred and forty-one non-cirrhotic patients with HCC diagnosed by histology were included in a Spanish multicenter prospective registry (23 centers, May 2018-October 2022). Surgical resection was performed in 90 patients (63.8%). Liver cirrhosis was excluded by histology. We analyzed the baseline characteristics, evolution and prognostic factors.
Results: Median age was 70.4 (range: 31–86) years. Eighty-three percent were male, 25.6% had other cancers, 2.2% had family history of HCC, 56.7% hypertension and 35.6% diabetes. Toxic habits: non-smoker 27.8%, non-alcohol 52.2%. Etiological study showed hepatopathy in 80%: NASH ± alcohol 26.7%, viral infection ± alcohol 25.5% (HCV 17.7%, HBV 7.8%), alcohol 14.6%, other 8.8% and unknow etiology 4.4%. Twenty percent had no underlying liver disease. Fibrosis stage was mild fibrosis (0–1) in 57.8%, stage 2 in 20%, 3 in 18.9% and unknown in 3.3%. aMAP score had 14.4% in the low-risk group. In 23.3% the diagnosis was made by follow-up ultrasonography, 56.7% was casual and 20% by symptoms. A single nodule was detected in 85.6%. The median size of main nodule was 49 (10–190) mm. Sixty percent had typical hallmark for HCC at least in some of the dynamic imaging explorations performed. Only 2.2% had vascular invasion and 1.1% extrahepatic spread. Median alpha-fetoprotein (AFP) level was 3.6 (range: 0.9–24868) ng/ml (21.1% >20 ng/ml). ECOG 0: 88.9%. The Barcelona Clinic Liver Cancer (BCLC) staging was 0 in 7.8%, A in 80%, B in 10%, C in 2.2%. Resection was anatomical in 85.7% (39.6% laparoscopy/46.1% laparotomy) and non-anatomical in 14.3% (1.1% laparoscopy/13.2% laparotomy), with Pringle maneuver in 46.2%. Surgical piece had: microvascular invasion 25.3%, satellitosis 7.7% and capsule 36.3%. Tumor differentiation: well 29%, moderate 61.1%, poor 4.4%, undifferentiated 1.1%, other histologic variants 4.4%. There were some complications in 15 patients (16.7%): 10 mild and 5 severe, with only 2 cases of perioperative mortality (2.2%). Median follow-up was 31 (range: 2–53) months. Recurrence was 19% at 1 year, 31% at 2 years, 35% at 3 years. AFP > 20 ng/ml was a predictor of relapse. Twenty nine percent received sequential therapy: 6.7% surgery, 2.2% TACE, 13.4% systemic therapy, 2.2% ablation, 4.4% other (1 liver transplantation). The global 1-, 2-, 3- and 4-years survival rate was 95.5%, 84%, 77% and 63.5% respectively. Deaths: 23.3% (71.4% due to liver related causes). BCLC staging, differentiation degree and microvascular invasion were predictors of survival.
Conclusion: This multicenter prospective study showed that surgical resection of non-cirrhotic HCC is an adequate therapeutic approach, with favorable results even in extensive tumors. Less than a third of patients received subsequent therapies. Perioperative morbidity and mortality were low.

THU-137

Real-world experience of atezolizumab plus bevacizumab combination treatment in high risk patients with advanced hepatocellular carcinoma

Sangyoun Hwang[1], Hyun Young Woo[2], Jeong Heo[2], Hyung Jun Kim[1], Young Joo Park[2], Kiyoun Yi[2], Yu Rim Lee[3], Soo Young Park[3], Byoung Kuk Jang[4], Woo Jin Chung[4], Won Young Tak[3]. [1]Dongnam Institute of Radiological and Medical Sciences, Korea, Rep. of South; [2]Pusan National University Hospital, Korea, Rep. of South; [3]Kyungpook National University Hospital, Korea, Rep. of South; [4]Keimyung University Dongsan Hospital, Korea, Rep. of South
Email: jheo@pusan.ac.kr

Background and aims: Atezolimumab plus bevacizumab was established as the first line therapy for patients with advanced Hepatocellular carcinoma through phase 3 clinical trial. However,real world data is lacking in patients who showed poor response to this combination regimen such as high risk patients.
Method: This is a multicenter retrospective study. Between January 2020 to April 2022,215 patients treated for advanced HCC with at atezolizumab plus bevacizumab (ATE+BEV) from four tertiary hospital was analyzed. High risk patients was defined as patients with Vp4 portal vein thrombus, bile duct invasion, or liver infiltration >50%. Tumor response was evaluated with the Response Evaluation Criteria in Solid Tumors (version 1.1.).
Results: Out of 215, 98 (45.6%) was high risk population. Child-Pugh class was A in 186 (86.5%) and B in 29 (13.5%). 128 (59.5%) received neoadjuvant or concomitant radiation treatment. In overall population, objective response rate (ORR) was 21.9% and disease control rate (DCR) was 73.9%. The median progression free survival (PFS) was 8.68 months (95% CI, 7.26–10.10) and median overall survival (OS) was 11.25 months (95% CI, 9.50–13.00). In high risk population, ORR and DCR were 23.5% and 67.3%. The median PFS was 7.32 months (95% CI, 4.78–9.87) and median OS was 10 months (95% CI, 8.19–11.82). Only OS was significantly shorter in high risk population. In total population, neutrophil to lymphocyte (NLR) was common factor associated with both PFS and OS in multivariate analysis. In high risk population,preemptive or concomitant radiation therapy was common factor associated with better PFS and OS in multivariate analysis. Baseline Child-Pugh score was only associated with OS. A total of 92 (42.8%) patients experienced any grade of adverse events (AEs). The most common AEs was proteinuria (14.8%). The rate of grade 3 or higher AE is higher in high risk population (24.5% vs. 11.3%).
Conclusion: ATE+BEV treatment showed consistent efficacy and tolerable safety event including patients with the high risk advanced HCC and Child-Pugh class B. Furthermore, radiation therapy could improve the PFS and OS in the high risk patients.

Atezolizumab plus bevacizumab for patients with unresectable hepatocellular carcinoma and high hepatitis B viral load: focusing on hepatic safety and viral kinetics

San-Chi Chen[1], Hsiao-Hui Sophie Tsou[2], Teng-Yu Lee[3], Hung-Wei Wang[4], Yen-Hao Chen[5], Tseng-En Wang[6], Yung-Yeh Su[2], Shengshun Yang[3], Chang-Fang Chiu[4], Tsang-Wu Liu[2], Ann-Lii Cheng[7], Li-Tzong Chen[8], Chiun Hsu[7]. [1]Taipei Veterans General Hospital, Taiwan; [2]National Health Research Institutes, Taiwan; [3]Taichung Veterans General Hospital, Taiwan; [4]China Medical University Hospital, Taiwan; [5]Chang Gung Medical Foundation, Taiwan; [6]Mackay Memorial Hospital, Taiwan; [7]National Taiwan University Hospital, Taiwan; [8]Kaohsiung Medical University Chung-Ho Memorial, Taiwan
Email: sunkist.chen37@gmail.com

Background and aims: The safety of immune checkpoint inhibitor therapy for hepatitis B (HBV)-related unresectable hepatocellular carcinoma (uHCC) with high viral load was not clear. This study, sponsored by Taiwan Cooperative Oncology Group (ClinicalTrials.gov: NCT04180072), aimed to clarify the liver-related adverse events (AE) of atezolizumab (atezo) plus bevacizumab (bev) for uHCC with high HBV viral load.
Method: Eligible patients were histologically proven uHCC, Child A liver function, HBV DNA >2000 IU/ml, and ≧ 1 measurable tumor by RECIST 1.1. Patients with VP4 portal vein invasion or tumors occupying >50% of liver volume were excluded. Atezo 1200 mg plus bev 15 mg/kg were given on day 1 every 3 weeks until tumor progression or occurrence of unacceptable toxicity. Anti-HBV nucleoside analogs were given prior to start of and during atezo + bev therapy. The primary end point was overall response rate (ORR) by RECIST v1.1. Secondary end points included ≧ grade 3 liver-related AE, HBV reactivation, and patient survival.
Results: Thirty patients were enrolled (mean age 58.6 years, M/F 29/1, macrovascular invasion 11, distant metastasis 11, median baseline HBV DNA 134,500 IU/ml (range 2010–1760000)). Seventeen patients achieved virological response (VR, defined as HBV DNA decrease to

<25 IU/ml). The median time to VR was 2.1 months and was not correlated with baseline viral load. No HBV seroconversion occurred. All-grade liver AE occurred to 13 patients and 6 of them considered immune-related (grade 3, 1 patient; grade 1–2, 5 patients). This grade 3 liver immune-related AE (hepatitis), along with grade 4 Stevens-Johnson syndrome, occurred after 2 cycles of atezo + bev therapy, and resolved after methylprednisolone treatment. No patients experienced HBV reactivation. Five partial responses and 15 stable diseases according to RECIST 1.1 were documented among 28 evaluable patients. One additional patient with documented partial response, after initial progressive disease, that lasted for about 8 months. As of December 31, 2022 (median follow-up 8.21 months, range 1.90–30.03), the median progression-free and overall survival was 6.28 months (95% CI 3.75–8.34) and 19.70 months (95% CI 7.79-NR).
Conclusion: Atezo + bev was generally safe and efficacious in uHCC patients with high HBV viral load (grant support T2219, MOHW112-TDU-B-221-124007).

THU-139

Portal-hypertension parameters are associated with survival and ascites occurrence in patients with hepatocellular carcinoma treated by external radiotherapy

Heloïse Giudicelli-Lett[1], Mickael Andraud[1], Mathilde Wagner[1], Rémi Bourdais[2], Jean-Marc Simon[1], Dominique Thabut[1], Manon Allaire[1]. *[1]Pitié Salpêtrière, France; [2]ICSM 77, France*
Email: heloise.giudicelli@gmail.com

Background and aims: Radiotherapy (RT) appears as a new treatment in the hepatocellular carcinoma (HCC) therapeutic arsenal but can expose to radiation induced liver disease that includes ascites occurrence. We aimed (i) to study the impact of PHT on RT outcome and (ii) to identify predictive factors of ascites occurrence as this could preclude the access to further HCC treatment.
Method: We conducted a retrospective monocentric study in which all cirrhotic patients who received either stereotactic ablation body radiation therapy (SABR) or conventionally fractionated radiotherapy (CFRT) for HCC between 2012 and 2022 were included. PHT was assessed on upper endoscopy and on imaging using the Portal hypertension score (PHT Score) based on the presence on imaging of ascites (0–3), varices (0–3), and spleen size (0–3). Threshold of 6 was chosen according AUROC analyze. Time-to-events data were estimated by Kaplan-Meier method with log-rank test, along with Cox-models.
Results: 60 patients were included (female 27%, median age 49 yrs, Child-Pugh class A 82%, cause of liver diseases alcohol/metabolic syndrome/hepatitis C in 56/40/32%). 40% and 15% presented history of ascites and acute variceal bleeding (AVB) respectively, 26% had large size esophageal varices (EV), median HTP score was 4 and 19% presented a HTP score ≥6. All patients underwent appropriate prophylaxis for AVB when indicated (1 TIPS and 9 NSBB). 92% were BCLC-0/A, median tumor size was 30 mm. An infiltrative form and vascular invasion were present in 2% and 3% respectively. SABR was performed in 39 (48Gy/9 fractions) and CFTR in 21 patients (54Gy/29 fractions). The maximal PTV1 EQD2 (a/b = 10) and PTV1 volumes were 124Gy and 103cc (SABR) and 64Gy ($p < 0.001$) and 173cc ($p = 0.91$) (CFTR). Median EQD2 to uninvolved liver (a/b = 3) were 11Gy and 13Gy ($p = 0.41$) in the SABR and CFTR group respectively. Overall survival (OS) was 75%, 50% and recurrence free survival 54%, 22% at 1 and 3 years after RT, respectively. At six months, progressive disease according to RECIST1.1 was more frequent in patients treated by CFTR vs SABR (18% vs 7%, $p < 0.001$). In univariate but not in multivariate analysis, SABR (HR = 2.65, $p = 0.03$), albumin (HR = 1.00, $p = 0.05$), maximal PTV1 EQD2 (a/b = 10) (HR = 1.02, $p = 0.01$) and PTV1 volume (HR = 0.99, $p = 0.04$) were associated with mortality. In log rank analysis, HTP score ≥6 was associated with lower survival ($p = 0.07$). EV and platelets were not associated with OS in univariate analysis. OS was lower in SABR patients compared to CFTR ($p = 0.03$) and no specific predictor of mortality was identified in Cox analysis. HTP score was similar between both group ($p = 0.68$). Compared to CFTR patients, SABR patients were significantly older (median age: 73 vs 49 yrs, $p < 0.001$) with more metabolic disease (51% vs 19%, $p = 0.02$). Ascites incidence after RT was 24%, 34%, and 38% at 6, 12, and 24 months, respectively. In univariate analysis, platelets count (HR = 1, $p = 0.08$), history of AVB (HR = 2.58, $p = 0.09$) and SABR tended (HR = 2.59, $p = 0.09$) to be associated with ascites but the only significant predictive factor was a HTP score ≥6 (HR = 4.25, $p = 0.007$) and this result was confirmed in log rank analysis ($p = 0.003$). Presence of large size EV was not associated with ascites occurrence ($p = 0.12$). Among 14 patients who developed ascites, 11 were treated with NSBBs.

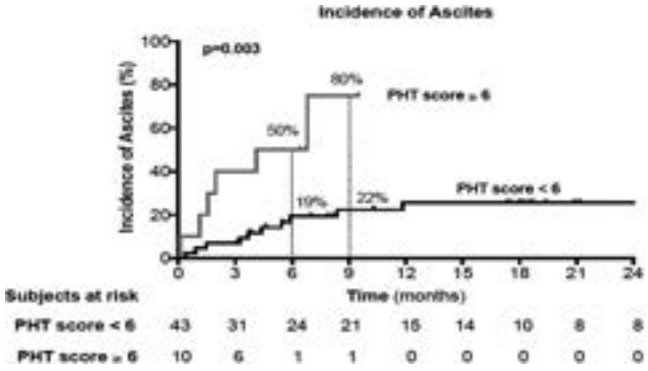

Figure:

Conclusion: This retrospective study suggests that RT should be avoided in patients with a HTP score ≥6 to prevent ascites occurrence that could preclude access to further HCC treatments.

THU-140

Outcomes between surgical resection and transarterial chemoembolization in patients with multifocal BCLC-A and Child-Pugh B

Ji won Yang[1], Won-Mook Choi[1], Danbi Lee[1], Ju Hyun Shim[1], Kang Mo Kim[1], Young-Suk Lim[1], Han Chu Lee[1], Jonggi Choi[1]. *[1]Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Gastroenterology, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and aims: 2022 version of the Barcelona Clinic Liver Cancer (BCLC) system does not recommend resection for multinodular hepatocellular carcinoma (HCC) within Milan criteria. Thus, transarterial chemoembolization (TACE) is regarded the preferred treatment option. In addition, no specific recommendation exists regarding patients with Child-Pugh (CP) class B and this multifocal BCLC stage A of HCC. Therefore, we aimed to compare the outcomes between surgical resection and TACE in patients with multinodular HCC and CP class B.
Method: We retrospectively analyzed 487 patients with multinodular treatment-naïve HCC within Milan criteria and CP class B who received either resection or TACE as an initial therapy at Asan Medical Center, Seoul, the Republic of Korea between 2013 and 2022. Overall survival (OS) was estimated using Kaplan-Meier method and comparison of the OS between resection and TACE was conducted by log-rank test. Propensity-score (PS) matching analysis was also used to minimize biases between the two groups. Cox proportional model was used to identify factors associated with a worse prognosis. Median follow-up period was 5.3 years.
Results: The median age was 68 years, and 85.0% of the patients were men. 72.5% of the patients had two lesions of HCC and the median size of the largest tumor was 2.0 cm. The 3-, 5-year survival rates were 96.2% and 90.0% in the resection group and 82.2% and 68.3% in the TACE group, respectively. Median OS was significantly longer in the resection group than the TACE group ($p < 0.01$). In multivariate

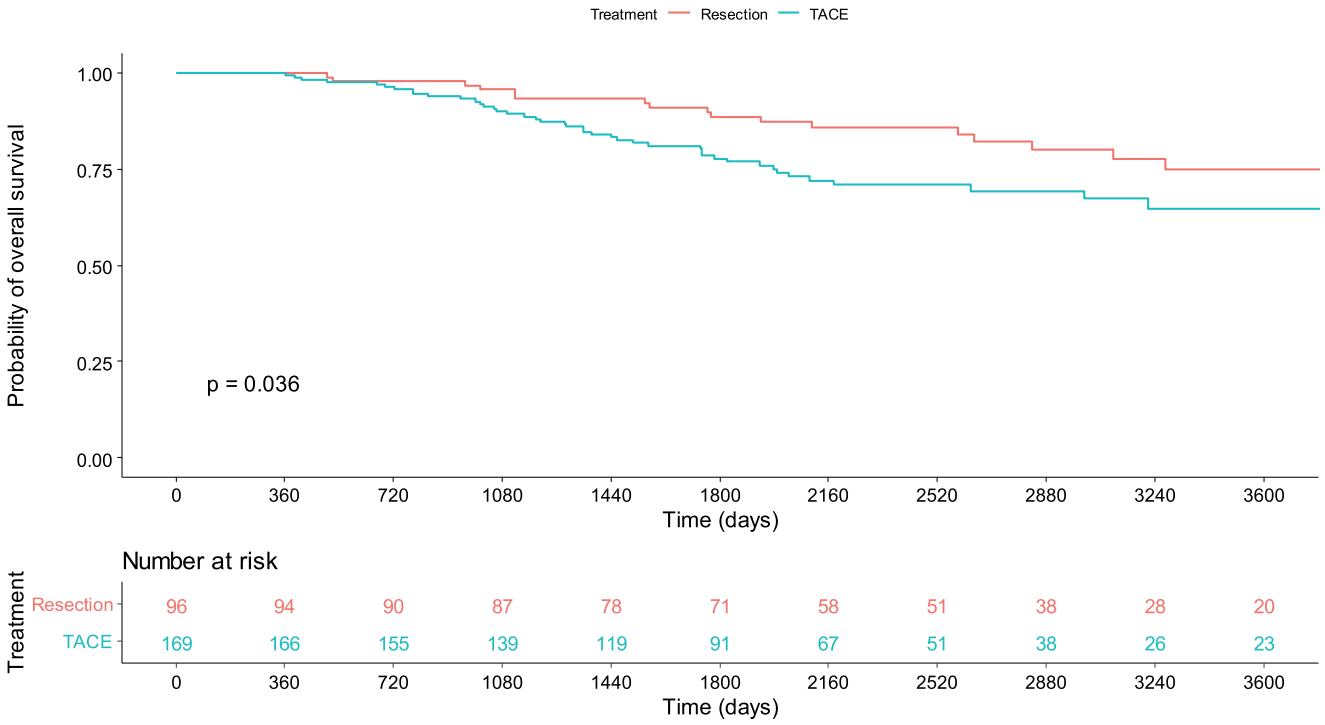

Figure: (abstract: THU-140): Kaplan-Meier curve for overall survival in the resection and TACE groups after applying propensity score matched analysis.

analysis, TACE (hazard ratio [HR]: 1.91, 95% confidence intervals [CIs]: 1.12–3.26, p = 0.02), age (HR: 1.05, 95% CIs: 1.03–1.07, p < 0.01), and tumor size (HR: 1.41, 95% CIs: 1.08–1.83, p = 0.01) were associated with a worse prognosis. PS matched analysis also demonstrated that the resection group had a significantly longer OS than the TACE group (p = 0.036).

Conclusion: In the present study, surgical resection showed a better OS than TACE in patients with multinodular HCC (within Milan criteria) and CP class B. Surgical resection can be considered as an effective treatment option in this category of patients.

THU-141

Downstaging hepatocellular carcinoma with checkpoint inhibitor therapy safely improves access to curative liver transplantation: a case series

Margaret Liu[1], Blanca Lizaola-Mayo[1], Channa Jayasekera[1], Amit Mathur[2], Nitin Katariya[2], Bashar Aqel[1], David Chascsa[1]. *[1]Mayo Clinic Arizona, Gastroenterology and Hepatology, Scottsdale, United States; [2]Mayo Clinic Arizona, Transplant Surgery, United States*
Email: liu.margaret@mayo.edu

Background and aims: Hepatocellular carcinoma (HCC) is the third most common cause of malignancy related mortality globally. Checkpoint inhibitor therapy (CPIT) has traditionally been used as a treatment modality in unresectable HCC, but recent advances have demonstrated the possibility of CPIT as an innovative method of downstaging patients with advanced HCC with the caveat that CPIT prior to transplantation has recognized risks including potentially irreversible graft rejection. The aim of this case series is to report the outcomes of patients at our center who received CPIT in an attempt to shrink the tumor volume of HCC to meet transplant criteria.

Method: A retrospective chart review with descriptive statistics was conducted for all patients at Mayo Clinic Arizona who were diagnosed with HCC who underwent downstaging of HCC with CPIT with the goal of meeting criteria for liver transplantation.

Results: We present 5 cases (mean age 59.4 [40.0–70.0], 100% men) at our center who received CPIT in an attempt to shrink the tumor volume to within Milan criteria to allow candidacy for liver transplantation. All patients were approved and listed for liver transplantation; 3 patients ultimately received a transplant, 1 was delisted due to his exceptional response to therapy and preserved quality of life, and 1 was waitlisted. The etiologies of liver disease included alcohol (n = 1), non-alcoholic steatohepatitis (n = 2), hepatitis C (n = 2), and primary sclerosing cholangitis (n = 1). The average native MELD prior to listing was 13.4 (SD 10.5) with a range of 7–32. All patients received locoregional therapy, including bland or chemoembolization (40%), Y-90 (60%), and/or ablation (60%). Maximum AFP pre-transplant pre-CPIT ranged from 8 to 24 000 ng/ml, which decreased to 5.8–19.6 on CPIT. In addition to CPIT, 2 patients received sorafenib and 1 patient received lenvatinib. CPIT regimens included atezolizumab and bevacizumab (60%), ipilimumab and nivolumab (20%), and pembrolizumab (20%). The median length of time CPIT was held prior to transplant was 3 months, with a range of 2–10 months. Immunosuppression regimens were standard to our center except in 1 patient who received thymoglobulin for induction. There were no cases of rejection upon most recent follow-up, which ranged from 4 months to 2 years post-transplant.

Conclusion: The 5 cases at our center thus far have shown promising outcomes with CPIT as a downstaging tool in order to meet criteria for liver transplantation. The 3 cases who ultimately received a liver transplant demonstrated no evidence of rejection or recurrence up to 2 years post-transplant. Future studies are needed to further assess the outcomes of a larger sample size as well as evaluate areas of interest, such as optimal timing of CPIT discontinuation prior to transplant and to assess whether novel tumor biomarkers may provide insight into which patients will respond to this intervention.

Age (on initial presentation) and sex	Etiology of liver disease (native MELD)	Locoregional therapy	CPIT regimen	Other systemic therapy	Maximum AFP pre-transplant pre-CPIT; maximum AFP on CPIT (ng/mL)	Maximum total tumor diameter prior to CPIT; maximum tumor diameter prior to transplant listing (cm)	Explant residual tumor	Months CPIT was held prior to transplant	Induction immuno-suppression	Time from transplant to last follow up	Recurrence; rejection

Clinical outcomes of surgical resection vs yttrium 90 radioembolization (Y90) in hepatocellular carcinoma (HCC) patients with macrovascular invasion (MVI)

Zhaozhen Zou[1], Brian Goh[2], Peng Chung Cheow[2], Alexander Chung[2], London Lucien Ooi[2], David Chee Eng Ng[3], Richard Hoau Gong Lo[4], Karaddi Venkatanarasimha Nanda Kumar[4], Apoorva Gogna[4], Chow Wei Too[4], Farah Irani[4], Sean Xuexian Yan[3], Kelvin Siu Hoong Loke[3], Sue Ping Thang[3], Aaron Kian Ti Tong[3], Hian Liang Huang[3], Kaina Chen[5], Fiona Ni Ni Moe[6], Weng Yan Ng[6], Siou Sze Chua[6], Jade Shu Qi Goh[6], Pierce Chow[1,2]. *[1]Duke-NUS Medical School, Singapore; [2]Singapore General Hospital, Department of Hepatopancreatobiliary and Transplantation Surgery, Singapore; [3]Singapore General Hospital, Department of Nuclear Medicine and Molecular Imaging, Singapore; [4]Singapore General Hospital, Department of Vascular and Interventional Radiology, Singapore; [5]Singapore General Hospital, Department of Gastroenterology, Singapore; [6]National Cancer Centre Singapore, Singapore*
Email: pierce.chow@duke-nus.edu.sg

Background and aims: Hepatocellular carcinoma (HCC) patients with macrovascular invasion (MVI) have poorer prognosis, and are more challenging to treat due to the increased likelihood of tumour progression and metastasis. The best treatment method for these patients remain unproven and controversial. In this study, we compared the overall survival (OS) and progression free survival (PFS) of HCC patients with MVI treated with surgical resection or with Y90 radioembolization.

Method: The retrospective study included non-metastatic HCC patients with MVI who underwent Y90 radiotherapy or surgical resection at the National Cancer Centre Singapore and Singapore General Hospital between January 2000 and May 2019. The patients were stratified based on the degree of portal vein thrombosis (according to Cheng's classification) and compared using inverse probability of treatment weighting (IPTW) -adjusted Kaplan-Meier analysis.

Results: A total of 209 patients were included, with 68 patients undergoing surgical resection and 141 undergoing Y90. After IPTW, the population was well balanced. The OS and PFS of resection patients and Y90 patients were similar (OS: 15.686 vs 14.93, $p = 0.343$, PFS: 5.907 vs 3.38, $p = 0.132$). Length of hospital stay for Y90 patients was significantly shorter than the resection group (3.94 ± 1.27 vs 13.12 ± 11.55 days, $p = 0.003$). For type I PVTT patients, the IPTW-adjusted Kaplan Meier analysis showed significantly better OS for the Y90 group than the surgical resection group ($p = 0.046$), but PFS did not differ significantly between the two groups ($p = 0.248$). For type II PVTT, there was no significant difference between the two groups in either OS ($p = 0.243$) or PFS ($p = 0.193$).

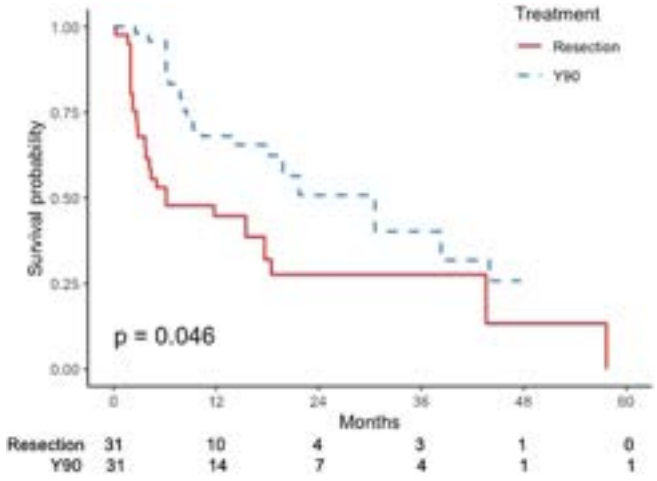

Figure 1: Kaplan–Meier analysis of overall survival in the Y90 group compared with the surgical resection group after IPTW

Conclusion: Compared with surgical resection, Y90 radiotherapy is associated with shorter hospital stay and significantly prolonged overall survival in HCC patients with PVTT and better OS in patients with Type I PVTT.

THU-143

Survival outcomes from Atezolizumab plus Bevacizumab versus Lenvatinib versus Sorafenib in Child Pugh B unresectable hepatocellular carcinoma patients

Margherita Rimini[1], Mara Persano[2], Toshifumi Tada[3], Goki Suda[4], Shimose Shigeo[5], Masatoshi Kudo[6], Jaekyung Cheon[7], Fabian Finkelmeier[8], Ho Yeong Lim[9], José Presa[10], Sara Lonardi[11], Fabio Piscaglia[12], Hong Jae Chon[6], Gianluca Masi[13], Mario Scartozzi[2], Stefano Cascinu[1], Andrea Casadei-Gardini[1]. *[1]Vita-Salute San Raffaele University, Italy; [2]University Hospital of Cagliari, Italy; [3]Japanese Red Cross Himeji Hospital, Japan; [4]Graduate School of Medicine, Japan; [5]Kurume University School of Medicine, Italy; [6]Kindai University Faculty of Medicine, Japan; [7]CHA Bundang Medical Center, Korea, Dem. Email: margherita.rimini@gmail.com

Background and aims: The best first line treatment for patients with advanced hepatocellular carcinoma (HCC) and Child-Pugh (CP) class B remains unknown. The aim of the present study was to perform a real-world analysis on a large sample of patients with unresectable HCC with CP B treated with atezolizumab plus bevacizumab Vs Lenvatinib.

Method: The study population included patients affected by advanced (BCLC-C) or intermediate (BCLC-B) HCC patients not suitable for locoregional therapies from both Western and Eastern world (Italy, Germany, Republic of Korea and Japan), who received atezolizumab plus bevacizumab or Lenvatinib as first line treatment. All the study population presented a CP class of B. The primary end point of the study was overall survival (OS) of CP B patients treated with Lenvatinib compared to atezolizumab plus bevacizumab. Survival curves were estimated using the product-limit method of Kaplan-Meier. The role of stratification factors was analyzed with log-rank tests. Finally, an interaction test was performed for the main baseline clinical characteristics.

Results: 217 CP B HCC patients were enrolled in the study: 65 (30%) received atezolizumab plus bevacizumab, and 152 (70%) received lenvatinib. The mOS for patients receiving Lenvatinib was 13.8 months (95% CI: 11.6–16.0), compared to 8.2 months (95% CI 6.3–10.2) for patients receiving atezolizumab plus bevacizumab as first line treatment (atezolizumab plus bevacizumab Vs Lenvatinib: HR 1.9, 95% CI 1.2–3.0, p = 0.0050). No statistically significant differences were highlighted in terms of mPFS. The multivariate analysis confirmed that patients receiving Lenvatinib as first line treatment has a significantly longer OS compared to patients receiving atezolizumab plus bevacizumab (HR 2.01; 95% CI 1.29–3.25, p = 0.0023). By evaluating the cohort of patients who received atezolizumab plus bevacizumab, we found that Child B patients with ECOG PS 0, or BCLC B stage or ALBI grade 1 were those who had benefit from the treatment thus showing survival outcomes no significantly different compared to those receiving Lenvatinib.

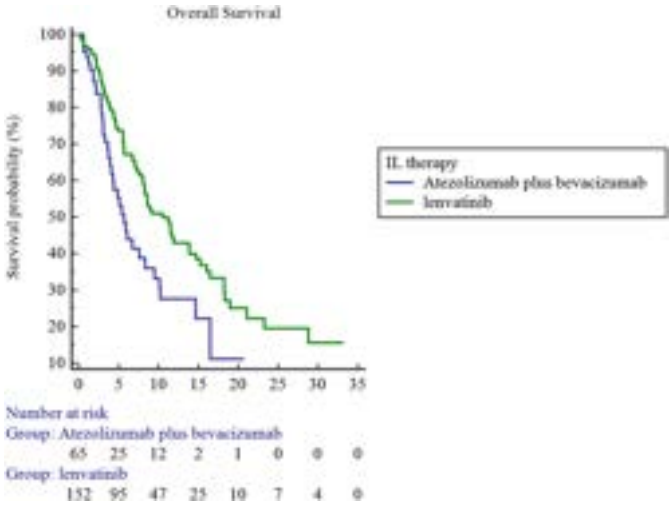

Figure:

Conclusion: The present study suggests for the first time a major benefit from Lenvatinib compared to atezolizumab plus bevacizumab in a large cohort of patients with CP B class HCC.

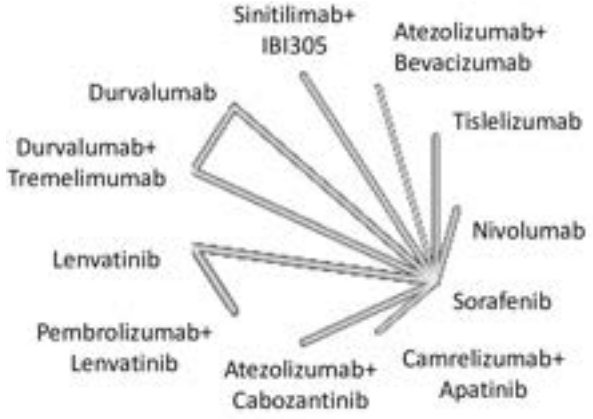
THU-144

Balancing efficacy and tolerability of first-line systemic therapies for advanced hepatocellular carcinoma: a network metanalysis

Ciro Celsa[1], Giuseppe Cabibbo[1], Gabriele Di Maria[1], Marco Vaccaro[2], Salvatore Battaglia[3], Giacomo Emanuele Maria Rizzo[1], Roberta Ciccia[1], Alessandro Grova[1], Mauro Salvato[1], Paolo Giuffrida[1], Marco Giacchetto[1], Gabriele Rancatore[1], Maria Vittoria Grassini[1], Michela Antonucci[4], Piera Morana[1], Marco Enea[1], Calogero Camma[1]. *[1]University of Palermo, Section of Gastroenterology and Hepatology, PROMISE Department, Italy; [2]University of Palermo, Italy; [3]University of Palermo, Dipartimento di Scienze Economiche, Aziendali e Statistiche, Italy; [4]University of Palermo, Department of Biomedicine, Neurosciences and Advanced Diagnostics (BiND), Italy*
Email: celsaciro@gmail.com

Background and aims: Atezolizumab plus Bevacizumab represents the current standard of care for first-line treatment of advanced HCC. However, direct comparison with other combination treatments including immune-checkpoint inhibitors (ICI) plus tyrosine-kinase inhibitors (TKIs) or anti-CTLA4 are lacking. The aim of this network meta-analysis (NMA) is to indirectly compare the efficacy and the safety of first-line systemic treatments.

Method: Literature search of MEDLINE, EMBASE and SCOPUS databases was conducted up to October, 2022. Phase 3 randomized controlled trials (RCTs) testing TKIs, including Sorafenib and Lenvatinib, or ICIs reporting overall survival (OS) and progression-free survival (PFS) were included. Individual survival data were extracted from OS and PFS curves to calculate restricted mean survival time (RMST). A Bayesian NMA was performed to compare treatments in terms of efficacy (15- and 30-month OS, 6-month PFS)



30-month overall survival		6-month progression-free survival	
Treatment	SUCRA	Treatment	SUCRA
Atezolizumab+ Bevacizumab	0.883	Pembrolizumab+ Lenvatinib	0.926
Camrelizumab+ Apatinib	0.865	Lenvatinib	0.858
Pembrolizumab plus Lenvatinib	0.722	Camrelizumab+ Apatinib	0.786
Durvalumab+ Tremelimumab	0.626	Sintilimab+IBI305	0.712
Nivolumab	0.506	Atezolizumab+ Cabozantinib	0.695
Lenvatinib	0.466	Atezolizumab+ Bevacizumab	0.518
Tislelizumab	0.352	Sorafenib	0.347
Durvalumab	0.342	Durvalumab+ Tremelimumab	0.324
Atezolizumab+ Cabozantinib	0.120	Nivolumab	0.153
Sorafenib	0.114	Durvalumab	0.107
-	-	Tislelizumab	0.070

Figure: (abstract: THU-144).

and safety, represented by grade ≥ 3 (severe) adverse events (SAEs). The incremental safety-effectiveness ratio (ISER) as measure of net health benefit was calculated as the difference in probability of SAEs divided by difference in survival between the 2 most effective treatments.

Results: Nine RCTs enrolling 6600 patients were included. Atezolizumab+bevacizumab showed the highest probability (88%) of being the best in 30-month OS. Pembrolizumab+lenvatinib and Lenvatinib showed the highest probability (93% and 86%, respectively) of being the best in terms of PFS. ICI monotherapies were the most safe combination. At a willingness-to-risk threshold of 10% of SAEs for month-year gained, atezolizumab+bevacizumab was favored in 76% of cases, while at a threshold of 30% of SAEs for month-year gained, pembrolizumab+lenvatinib was favored in 72% of cases.

Conclusion: Atezolizumab plus Bevacizumab is the preferred option in unfit patients with high tumor burden, while Lenvatinib with or without Pembrolizumab could be preferred for fit patients with less advanced vascular tumor spread

THU-145

Sequential therapies after atezolizumab plus bevacizumab or lenvatinib first-line treatments

Email: marapersano@alice.it

Background and aims: Today the most used first-line treatments in hepatocellular carcinoma (HCC) patients are lenvatinib (L) and atezolizumab plus bevacizumab (AB). All the data available about second-line therapies derive from trials conducted in patients who progressed to first-line sorafenib (S) therapy. The aim of this retrospective proof-of-concept study is to compare different second-line drugs for HCC patients progressed to first-line L or AB.

Method: The overall cohort included 2225 consecutive patients from 5 countries (Italy, Germany, Portugal, Japan, and Republic of Korea). A total of 1381 patients had progressed disease (PD) at first-line therapy. 917 patients were in L first-line arm, and 464 patients were in AB first-line arm.

Results: 49.6% of PD patients received second-line therapy without any statistical difference in OS between L first-line arm (20.6 months) and AB first-line arm [15.7 months; p = 0.12; hazard ratio (HR) = 0.80]. In L first-line arm, there was a statistical difference between second-line therapy subgroups [p = 0.04; S HR = 1; trans-arterial chemoembolization (TACE) HR = 0.65; immunotherapy (I) HR = 0.69; other therapies (O) HR = 0.85]. 40.1% of patients were treated with S achieving an OS of 15.8 months; 36.8% of patients underwent TACE with an OS of 24.7 months; 13.1% of patients were treated with I not reaching a median OS; 10.0% of patients received O with an OS of 20.8 months. Patients who underwent TACE had a significative longer OS than patients who received S (p < 0.01; HR = 0.64). In AB first-line arm, there was a statistical difference between second-line therapy subgroups [p < 0.01; S HR = 1; L HR = 0.50; cabozantinib (C) HR = 1.34; TACE HR = 0.39; O HR = 0.54]. 18.4% of patients were treated with S achieving an OS of 14.2 months; 36.0% of patients were treated with L with an OS of 17.0 months; 9.9% of patients received C achieving an OS of 12.4 months; 11.6% of patients underwent TACE with an OS of 15.9 months; 24.0% of patients received O not reaching a median OS. Patients who received L had a significative longer OS than patients treated with S (p = 0.01; HR = 0.45). Patients who underwent TACE had a significative longer OS than patients who received S (p < 0.05;

HR = 0.46). No other statistical differences were highlighted between the other subgroups and patients treated with S in both first-line arms.

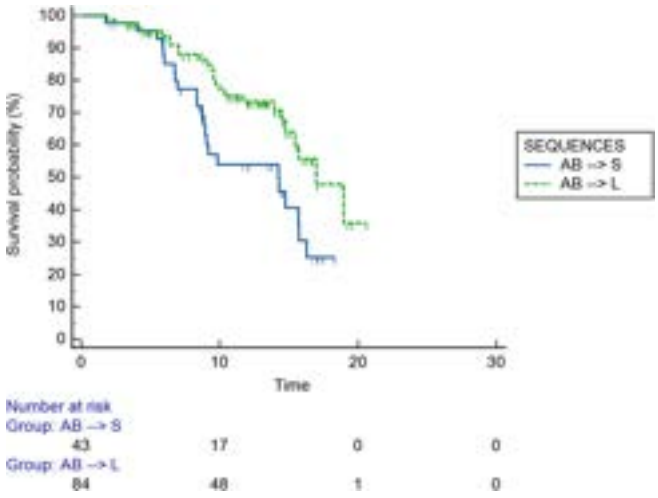

Figure:

Conclusion: The L-I and AB-L sequences are able to achieve the longest median survivals. For patients eligible for locoregional therapy after first-line systemic therapy, TACE has been shown to achieve longer survivals than second-line S in both first-line arms.

THU-146

Prognostic factors of intrahepatic cholangiocarcinoma after radical surgical resection

Keun Soo Ahn[1], Yong Hoon Kim[1], Tae-Seok Kim[1], Koo Jeong Kang[1].
[1]*Keimyung University Dong-San Hospital, Surgery, Daegu, Korea, Rep. of South*
Email: kjkang@dsmc.or.kr

Background and aims: Still it is not clear what status of intrahepatic cholangiocarcinoma shows a good prognosis after surgical resection. We evaluated prognostic factors of intrahepatic cholangiocarcinoma (iCCA) to suggest surgical indications.
Method: Between 2001 and 2020, surgical resection for iCCA was performed in 204 patients. We analyzed demographic factors perioperative results, and long-term prognostic factors.
Results: Mean age of patients was 66.1 ± 9.7. The mass-forming type was most frequent (n = 124), followed by periductal infiltrating (n = 59) and intraductal growing (n = 21). The overall 5-year survival was 33.9%, and the disease-free survival rate was 23%. On univariate analysis, a mass size larger than 5 cm, high CEA level, portal vein invasion, perineural invasion, lymphovascular invasion, and lymph node metastasis were significantly poor prognostic factors. Patients with small less than 5 cm sized had a good prognosis (53.6% of 5-year overall survival). On multivariate analysis, the presence of lymph node metastasis was the only significant independent poor prognostic factor.
Conclusion: Present retrospective study showed that lymph node metastasis shows the only significant prognostic factor. Tumor size, number, and the level of the tumor markers affect survival, but these factors are not barriers to obtaining significantly better survival if it is resected radically.

THU-147

Sequential systemic treatment in patients with hepatocellular carcinoma: real-world data in the era of immune checkpoint inhibition

Email: jana.pauly@med.uni-heidelberg.de

Background and aims: The approval of new systemic therapy (ST) agents for patients with advanced hepatocellular carcinoma (HCC) has increased therapeutic options and allows for sequential ST (SST). Approved agents have generally been tested only in first or second line. The introduction of Atezolizumab/Bevacizumab as novel first-line therapy further led to a shift in ST lines. Data is currently limited to assess how much patients benefit from additional treatment lines. Our aim was to investigate survival parameters using real-world data.
Method: A total of 161 patients with advanced HCC who started ST for HCC at Heidelberg University Hospital between 02/2008 and 03/2022 were included into this retrospective study and follow-up data available until death or data cut-off (12/2022) were included into this retrospective study. To avoid bias, we compared a historical cohort of patients receiving sorafenib (SOR, n = 87) monotherapy with a modern cohort, once multiple systemic agents where available (SST, n = 74), receiving between one to six lines of treatment. Kaplan Meier estimates were performed for assessment of overall survival (OS). Univariate and multivariate cox regression was used to identify favourable survival parameters.
Results: The baseline characteristics between the two cohorts were mostly similar, except the SOR cohort containing significantly more cases of portal vein thrombosis (PVT) than the SST cohort (33% vs 19%, respectively). The SST cohort with up to 6 ST lines had a significant superior median OS (mOS) in comparison to the SOR cohort (8.5 months (SOR) vs 16.9 months (SST), $p < 0.0001$). Among the parameters identified to positively influence OS in the univariate analysis (ECOG ≤1, Child Score ≤6, ALBI score, PVT, AFp <200 ng/ml, pre-treatment, combined loco-regionary treatment (LRT) during or after ST), PVT, AFP, pre-treatment, and LRT remained significant in the multivariate analysis. Accordingly, combined ST and LRT had a significantly positive impact on mOS (8.6 months (ST) vs 25.9 months (ST and LRT), $p < 0.0001$) in all patients with ST. In the SST cohort, 31/74 patients (42%) received immune checkpoint inhibitors (ICI) either in combination (Atezolizumab/Bevacizumab, Ipilimumab/Nivolumab) or as monotherapy (Nivolumab, Pembrolizumab), of which 19 patients (61%) at 2nd line or higher. ICI-therapy, including given as second or higher line, had a significantly positive impact on mOS (9.1 months (non-ICI SST) vs 25.7 months (ICI SST), $p = 0.0002$).
Conclusion: A selection of patients with advanced HCC seem to profit from a combination of ST with LRT indicating a rationale for further investigation in a prospective trial. Patients treated with ICI, also when administered in advanced therapy lines, had a substantial longer OS.

THU-148

Comparison of clinical outcome between Nivolumab and Regorafenib as second-line systemic therapy after Sorafenib failure in patients with advanced hepatocellular carcinoma

Jae Seung Lee[1,2,3], Hong Jun Lee[4], Hye Won Lee[1,2,3], Beom Kyung Kim[1,2,3], Seung Up Kim[1,2,3], Jun Yong Park[1,2,3], Sang Hoon Ahn[1,2,3], Do Young Kim[1,2,3]. *[1]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Yonsei University College of Medicine, Institute of Gastroenterology, Seoul, Korea, Rep. of South; [3]Severance Hospital, Yonsei Liver Center, Seoul, Korea, Rep. of South; [4]Yonsei University College of Medicine, Seoul, Korea, Rep. of South*
Email: dyk1025@yuhs.ac

Background and aims: Nivolumab and regorafenib are used as second-line therapies for patients with advanced hepatocellular carcinoma (HCC). We aimed to compare the effectiveness of nivolumab to regorafenib.
Method: We retrospectively reviewed HCC patients treated with nivolumab or regorafenib after sorafenib failure. Progression-free survival (PFS) and overall survival (OS) were analyzed. Inverse probability of treatment weighting (IPTW) using the propensity score (PS) was conducted to reduce treatment selection bias.
Results: Among the recruited 189 patients, 137 and 52 patients received regorafenib and nivolumab after sorafenib failure, respectively. Nivolumab users showed higher Child-Pugh B patients (42.3% vs. 24.1%) and shorter median sorafenib maintenance (2.2 vs. 3.5 months) compared to regorafenib users. Compared to regorafenib users, nivolumab users showed shorter median OS (4.2 vs. 7.4 months, P = 0.045) and similar median PFS (1.8 vs. 2.7 months, P = 0.070), respectively. However, median OS and PFS were not different between the two treatment groups after 1:1 PS matching yielded 34 pairs (log-rank P = 0.810 and 0.810, respectively), and after stabilized IPTW (log-rank P = 0.445 and 0.878, respectively). In addition, covariate-adjusted Cox regression analyses showed that the nivolumab (vs. regorafenib) use was not significantly associated with the PFS and OS after 1:1 PS matching and stabilized IPTW (all P > 0.05).
Conclusion: Clinical outcomes in patients treated with nivolumab and regorafenib after sorafenib failure did not differ significantly.

THU-149

Efficacy of Atezolizumab/Bevacizumab combination therapy in BCLC-C cirrhotic patients with hepatocellular carcinoma according to the type of disease progression and liver disease severity

Spyridon Pantzios[1], antonia syriha[1], Dionysia Mandilara[1], Ioanna Stathopoulou[1], Georgia Barla[1], Petros Galanis[1], Nikolaos Ptohis[2], Ioannis Elefsiniotis[1]. *[1]General Oncology Hospital of Kifisia "Oi Agioi Anargyroi", Academic Department of Internal Medicine-Hepatogastroenterology Unit, National and Kapodistrian University of Athens, Kifisia, Greece; [2]General Hospital of Athens G.Gennimatas, Department of Interventional Radiology, Athens, Greece*
Email: spiros_pant@hotmail.com

Background and aims: Registrational study (IM BRAVE 150) mainly included hepatocellular carcinoma (HCC) patients at BCLC-C stage, irrespective of the type of progression to this stage, with well compensated liver disease (CPT-A stage). The aim of our study was to retrospectively evaluate, under real life conditions, the overall survival (OS) of patients with advanced HCC (BCLC-C stage), either initially presenting in the advanced stage or migrating from BCLC-A to BCLC-C stage within 2 years after curative LR or RFA, treated either with atezolizumab-bevacizumab (ATZ/BEV) combination or with TKIs sequentially (sorafenib as 1st line and cabozantinib as 2nd line treatment).
Method: Sixty four cirrhotic patients with advanced HCC (56 males, mean age 67y, 22 with diabetes, CPT-A = 45/B = 19, mean MELD/Na = 11, ALBI grade I = 20/grade II = 38, 28 with varices, 18 with extrahepatic metastasis, 24 with macrovascular invasion) who either initially presented on the BCLC-C stage and were treated with ATZ/BEV (group A, N = 23) or TKIs (group B, N = 15) or who migrated from BCLC-A to BCLC-C stage within 2 years after LR or RFA and were treated with ATZ/BEV (group C, N = 12) or TKIs (group D, N = 14) were evaluated.
Results: The four groups were comparable for all the baseline parameters evaluated (age p = 0.9, gender p = 0.08, platelets p = 0.246, chronic liver disease etiology p = 0.408, coexistence of diabetes p = 0.314, presence of varices p = 0.066, CPT stage p = 0.067, ALBI grade p = 0.398) except for CPT score (p = 0.012) and MELD/Na score (p = 0.002). As expected, median OS was significantly higher for group C patients (61 m) compared to group D (27 m), group A (11 m) and group B (8 m) patients (p < 0, 001). Moreover, post-recurrence

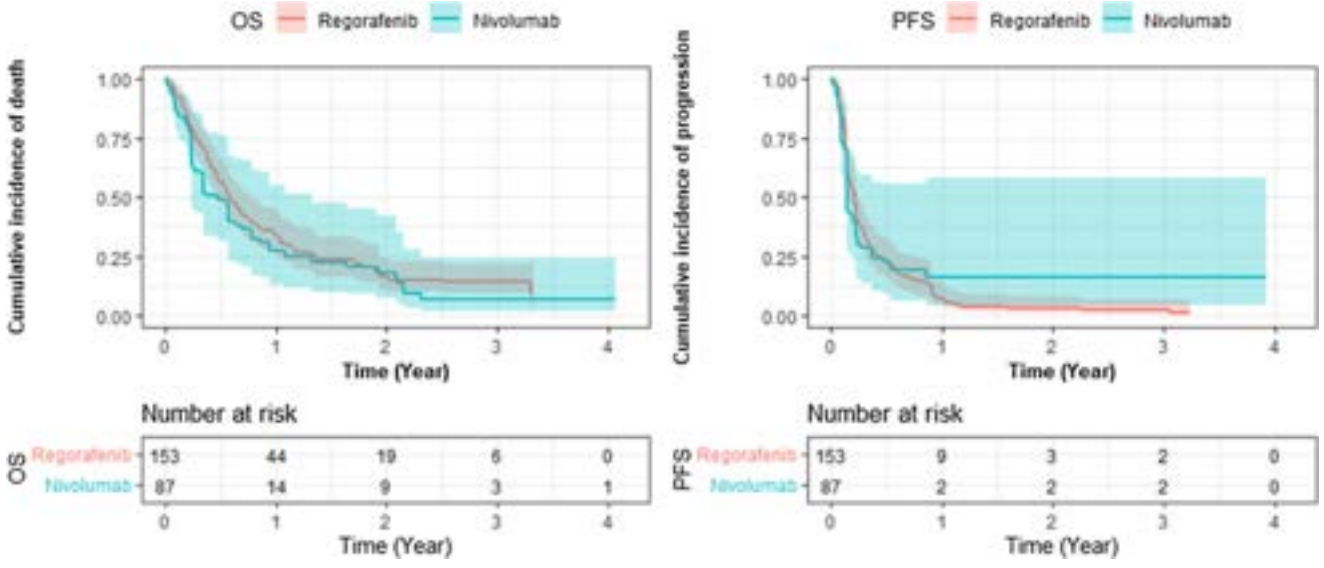

Figure: (abstract: THU-148): Kaplan-Meier curves of overall survival (p = 0.445) and progression free survival (p = 0.878) for regorafenib and nivolumab users using the stabilized inverse probability of treatment weighting.

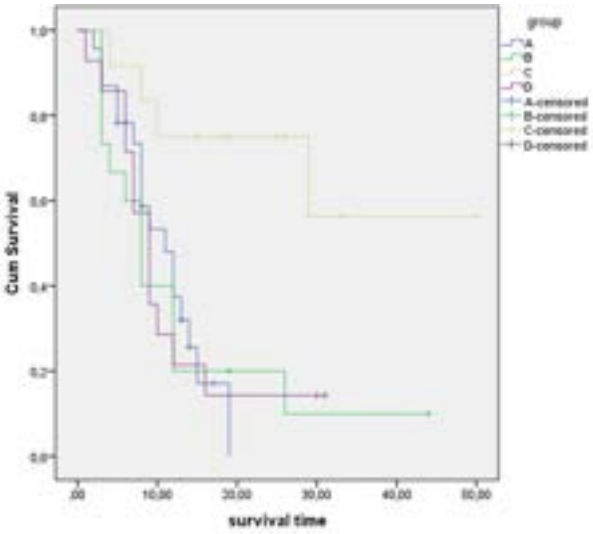
survival for group C patients seems to be significantly higher compared to those of group D (9 m) patients (p = 0.007) as well as for group A and B (figure). Using cox regression analysis, we observe that the OS of group A (HR = 3.71, 1.20–11.46, p = 0.02) was significantly worse than post-recurrence survival of group C, which was comparable to group D (HR = 3.14, 0.95–10.35 p = 0.06), adjusted for CPT, ALBI and MELD/Na score (figure).



Variables	Hazard ratio	95% confidence interval	P-value
Child number	1,03	0,69 to 1,52	0,89
Meld-Na	1,13	0,98 to 1,31	0,09
ALBI	0,86	0,47 to 1,57	0,62
A vs. C	**3,71**	**1,20 to 11,46**	**0,02**
B vs. C	2,89	0,87 to 9,56	0,08
D vs. C	3,14	0,95 to 10,35	0,06

Figure: Survival of group A (blue), B (green), C (yellow) and D (purple) and cox regression analysis for survival after the beginning of systemic therapy comparing group C to the other groups and adjusted for CPT, ALBI and MELD/Na scores.

Conclusion: Median survival of ATZ/BEV or TKI-treated patients who were initially classified in BCLC-C stage is less than 12 m, irrespective of treatment schedule, as was post-recurrence survival of sequentially TKI-treated patients. ATZ/BEV therapy seems to benefit mainly BCLC-C patients who migrate from earlier stages after curative LR or RFA compared to patients initially presented in the advanced stage. Liver disease severity assessed using CPT and MELD/Na scores seems to drive the overall as well as post-recurrence survival.

Changing treatment landscape associated with improved survival in patients with hepatocellular carcinoma: a nationwide, population-based study

Najib Ben Khaled[1], Bernhard Mörtl[2], Dominik Beier[3], Alexander Philipp[1], Andreas Teufel[4], Ilja Kubisch[5], Daniel Schwade[6], Andreas Geier[7], Florian P Reiter[7], Christian M. Lange[1], Julia Mayerle[1], Karin Berger[2], Enrico de Toni[1], Stefan Munker[1]. *[1]University Hospital, Ludwig Maximilian University of Munich, Department of Medicine II, Germany; [2]University Hospital, Ludwig Maximilian University of Munich, Department of Medicine III and Comprehensive Cancer Center (CCC Munich LMU), Germany; [3]InGef-Institute for Applied Health Research Berlin GmbH, Germany; [4]University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Department of Medicine II, Germany; [5]Klinikum Chemnitz, Department of Internal Medicine II, Gastroenterology, Hepatology, Endocrinology, Metabolic Disorders, Oncology, Germany; [6]Technical University Munich, Germany; [7]University Hospital Würzburg, Division of Hepatology, Department of Medicine II, Germany*
Email: najib.benkhaled@med.uni-muenchen.de

Background and aims: The treatment of hepatocellular carcinoma (HCC) is undergoing a historic transformation with the availability of several new systemic therapies. The impact of this changing landscape on patient outcomes has not yet been studied in a German cohort in a nationwide, real-world setting.
Method: This observational, retrospective study is based on a claims data base including anonymized, longitudinal data of around 8.8 million persons (InGef database). A sample of four million persons representative for the German population was drawn. We assessed the implementation and impact of systemic therapies for patients with HCC in nationwide clinical routine in three parts: First, we describe patient characteristics, drug treatments, and associated costs in a large, representative cohort of patients with HCC between 2015 and 2020. Second, we examine the association between drug availability and outcomes comparing survival of HCC patients by date of initiation of systemic therapy. Third, we explore the impact of treatment sequencing based on lenvatinib or sorafenib in the first line setting after the approval of lenvatinib in 2018.
Results: We identified a total of 5586 individuals with a diagnosis of HCC in the study period. Statistically significant developments included an increase in mean age and proportion of patients receiving systemic therapies, and a decrease in chronic hepatitis C virus infection. To investigate the association between systemic therapy availability and survival, we identified patients with HCC started on first line systemic therapy in the study period and grouped them according to time of treatment initiation, defining the cut-off date of the two groups as the approval of lenvatinib into period A (01/2015-07/2018, n = 255) and period B (08/2018-12/2020, n = 205). Baseline characteristics among patients in both periods were similar. Median overall survival (mOS) in the whole cohort was 5.5 months (95% confidence interval (CI) : 4.8–6.9). In period B, a superior mOS of 6.5 months (95% CI : 4.9–8.9) was identified as compared to period A with an mOS of 5.3 months (95% CI : 4.5–6.3) (p = 0.046). Multivariate Cox's regression analysis to adjust for confounders revealed that treatment initiation in period B was an independent, statistically significant factor for a longer survival (period B vs period A hazard ratio 0.77, 95% CI : 0.61–0.96, p = 0.0196). When comparing first line treatment options, lenvatinib showed a significantly longer OS as compared to sorafenib. Median OS with lenvatinib was 9.7 months (n = 103, 95% CI : 6.3–18.4) versus 4.8 months with sorafenib (n = 102, 95% CI : 4.0–7.1, p = 0.008). Patients treated with lenvatinib were younger and had a lower proportion of metastatic disease.

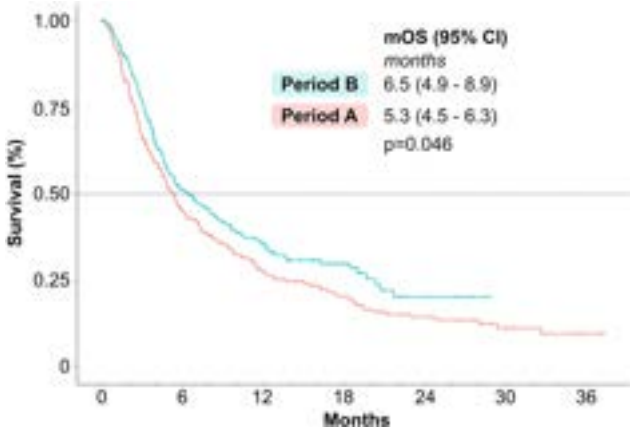

Figure:

Conclusion: The introduction of multiple new treatment options resulted in survival improvements of patients with HCC in Germany.

THU-151

Efficacy and tolerability of stereotactic body radiation therapy in patients with hepatocellular carcinoma: a retrospective cohort study

Dorothy Liu[1], Jennifer Tan[2], Marcus Robertson[1]. [1]*Monash Health, Gastroenterology, Clayton, Australia;* [2]*Peter MacCallum Cancer Centre, Radiation Oncology, Bentleigh East, Australia*
Email: dorothyliu22@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide. There is emerging evidence for the role of stereotactic body radiation therapy (SBRT) as an alternative locoregional therapy in the management of HCC, with high rates of local control and low rates of significant toxicity reported. A multicentre retrospective cohort series was conducted to evaluate the efficacy and safety of SBRT for the treatment of HCC.
Method: A retrospective analysis of a prospective database including adult patients that underwent treatment for HCC with SBRT between July 2012 and September 2021 in Melbourne, Australia, was performed. The primary outcome was local tumour control and secondary outcomes included progression-free survival, overall survival and adverse events (AEs).
Results: 60 patients were included with a median follow-up of 16 months (IQR 7–23). Cirrhosis was documented in 37 (62%) patients with the most common underlying aetiology being alcohol (49%), and a median baseline Child-Pugh grade of A and albumin-bilirubin (ALBI) score of −2.35 (IQR – 2.65–2.15). Forty-seven patients had received prior alternative HCC therapies. A total of 81 lesions were treated (median size 40.5 mm, IQR 30–59 mm) with a median biologically effective dose (BED_{10}) of 86 Gy. The most common reported AE was fatigue. AEs of at least grade 2 severity were reported in 19% of patients. One patient died from radiotherapy induced liver disease 3 months following SBRT. Local control was 76% and 41% at 1 and 2 years, respectively. Progression free survival and overall survival at 1 year were 40% and 75%, respectively. Progression free survival and overall survival at 1 and 2 years were 16% and 42%, respectively.
Conclusion: SBRT can provide durable local control of HCC in the short term with low rates of significant AEs, however disease progression remains common. Thus, larger prospective studies are required to establish the role of SBRT in combination with other therapies in the management of HCC.

THU-153

Prognostic impact of metastatic site in patients receiving first-line sorafenib therapy for advanced hepatocellular carcinoma

Luca Lelasi[1,2], Francesco Tovoli[1,2], Matteo Tonnini[1,2], Bernardo Stefanini[1,2], Raffaella Tortora[3], Giulia Magini[4], Rodolfo Sacco[5,6], Tiziana Pressiani[7], Franco Trevisani[2,8], Fabio Piscaglia[1,2], Alessandro Granito[1,2]. Figure: (abstract: THU-151): Local tumour control following stereotactic body radiation therapy

Gastroenterology Unit, Pisa, Italy; [6]Foggia University Hospital, Gastroenterology and Digestive Endoscopy Unit, Foggia, Italy; [7]IRCCS Humanitas Research Hospital, Humanitas Cancer Center, Rozzano, Italy; [8]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Semeiotica Medica, Bologna, Italy
Email: luca.ielasi.kr@gmail.com

Background and aims: Extrahepatic spread is a well-known negative prognostic factor in patients with advanced hepatocellular carcinoma (HCC). The prognostic role of different metastatic sites and their response rate to systemic treatment is still being debated.
Method: We considered 237 metastatic HCC patients treated with sorafenib as first-line therapy in five different Italian centers from 2010 to 2020.
Results: The most common metastatic sites were lymph nodes, lungs, bone and adrenal glands. In survival analysis, the presence of dissemination to lymph nodes (OS 7.1 vs 10.2 months; $p = 0.007$) and lungs (OS 5.9 vs 40 10.2 months; $p < 0.001$) were significantly related to worse survival rates compared with all other sites. In the subgroup analysis of patients with only a single metastatic site, this prognostic effect remained statistically significant. Palliative radiation therapy on bone metastases significantly prolonged survival in this cohort of patients (OS 19.4 vs 6.5 months; $p < 0.001$). Furthermore, patients with lymph node and lung metastases had worse disease control rates (39.4% and 30.5%, respectively) and shorter radiological progression-free survival (3.4 and 3.1 months, respectively).

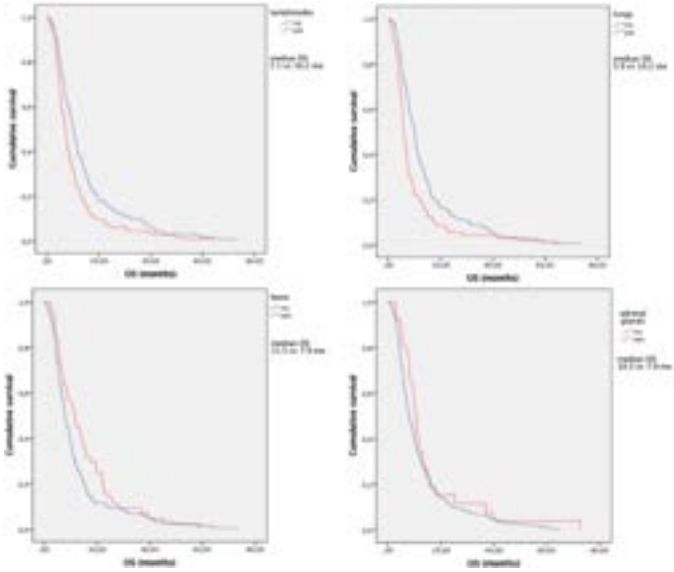

Figure:

Conclusion: In conclusion, some sites of extrahepatic spread of HCC have a prognostic impact on survival in patients treated with sorafenib; in particular, lymph node and lung metastases have worse prognosis and treatment response rate.

THU-154
Improved identification of good candidates for the treatment of intermediate/advanced hepatocellular carcinoma by Yttrium-90 transarterial radioembolization

Carole Vitellius[1], Severine Poulard[1], Julien Fontana[1], Ines Oreistein[1], Pacome Fosse[1], Anita Paisant[1], Laurent Vervueren[1], Frédéric Oberti[1], Christophe Aubé[1], Franck Laceuille[1], Jerome Boursier[1]. *[1]Angers University Hospital, France*
Email: jeboursier@chu-angers.fr

Background and aims: Yttrium-90 transarterial radioembolization (TARE) is a treatment for intermediate/advanced hepatocellular carcinoma (HCC), but its position in the therapeutic arsenal remains poorly defined. We aimed to validate the prognostic score for HCC treated with TARE recently proposed by Spreafico, and to improve prediction by considering also pre-operative dosimetry.
Method: Eighty-six patients with HCC treated by TARE in our center were included. The previsional tumoral dose of 90Yttrium was calculated using images acquired during the work-up. The Spreafico prognostic score was calculated as previously described and delineated three patients groups with "favorable," "intermediate," and "dismal" prognosis (PMID 29331342). The main study outcome was overall survival (OS) and the secondary outcome was progression-free survival (PFS).
Results: Fifty-three patients (62%) were treated with 90Yttrium-glass-microspheres (Therasphere®), and 33 patients (38%) were treated with 90Yttrium-resin-microspheres (Sirsphere®). Sixty-nine patients died during the follow-up. Median OS was 12.0 months (95% CI: 9.0–15.0), and median PFS was 5.0 months (95% CI: 3.5–6.5). OS was 15, 10, and 4 months in the three prognostic groups defined by the Spreafico score ($p < 0.001$, Figure A). Independent predictors of OS were the presence of cirrhosis, an optimal previsional tumoral dose, and the ALBI grade. The CODAG score, developed as the sum of points attributed to these three independent predictors, identified three patient groups: good (0–1 point), intermediate (2 points) and poor (3–4 points) candidates. The CODAG score better discriminated the prognosis with median OS in the three groups being respectively 32, 11, and 4 months ($p < 0.001$, Figure B). Median PFS was respectively 8, 5, and 3 months in the three CODAG groups ($p < 0.001$). The previsional and the received tumoral doses were very well correlated ($Rs = 0.814$, $p < 0.001$).

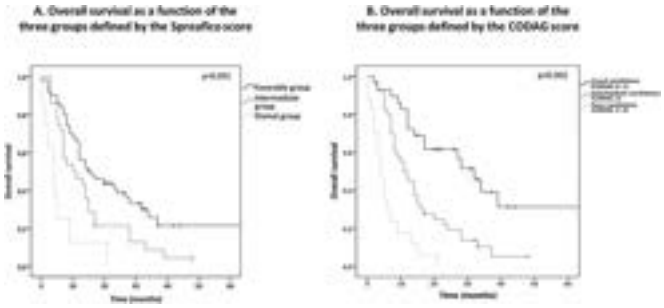

Figure:

Conclusion: The CODAG score improves the identification of good candidates for the treatment of intermediate/advanced hepatocellular carcinoma with transarterial radioembolization.

THU-155
Clinical impact of relative dose intensity over the first four weeks in cabozantinib therapy for unresectable hepatocellular carcinoma

Kaoru Tsuchiya[1], Tsubasa Nobusawa[1], Yutaka Yasui[1], Taisei Keitoku[1], Nobuharu Tamaki[1], Hiroyuki Nakanishi[1], Masayuki Kurosaki[1], Namiki Izumi[1]. *[1]Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology, Tokyo, Japan*
Email: tsuchiyakaoru3@gmail.com

Background and aims: Cabozantinib (CAB) has been used as 2nd or later-line worldwide in patients with unresectable hepatocellular carcinoma (u-HCC). In the phase III study of CAB (CELESTIAL study), the initial dose of CAB was 60 mg/day, while in the phase III study of the combination of atezolizumab plus CAB (COSMIC312 study), the initial dose of CAB was 40 mg/day. Recently the standard first-line therapy for u-HCC is atezolizumab plus bevacizumab or durvalumab plus tremelimumab. We investigated the clinical impact of relative dose intensity over the first four weeks (4W-RDI) in CAB therapy for u-HCC.
Method: A total of 43 u-HCC patients who received CAB between Jan 2021 and Dec 2022 at our institution was included. Tumor

assessments in accordance with RECIST ver1.1 were performed using dynamic CT or MRI within 4–8 weeks and every 8–10 weeks thereafter. The 4W-RDI was calculated as the cumulative dose in the initial 4 weeks divided by the standard dose (60 mg/day), and we evaluated its association with overall survival (OS) and progression-free survival (PFS).
Results: The median age was 74 (24–87) years, and 33 patients were male. Sixteen patients had HBV (n = 7) or HCV (n = 9) infection, and 30 patients were Child-Pugh A. BCLC stage A/B/C were 0/14/29 patients, and 38 patients (88%) were previously treated with atezolizumab plus bevacizumab. CAB was administered as 2nd or 3rd-line in 25 and 4th or later-line in 18 patients. The median follow-up duration was 6.8 months, and the median duration of CAB was 2.7 months. The initial dose of CAB was 60 mg (n = 14), 40 mg (n = 13), and 20 mg/day or less (n = 16). The median PFS and OS were 4.1 and 16.2 months. The objective response rate (ORR) and disease control rate (DCR) was 12.1% and 84.8%. The median 4W-RDI was 33%, and there was no significant difference in PFS and OS between 4W-RDI<40% (n = 27) and ≥40% (n = 16) (3.1 vs. 4.4 months, p = 0.25 and 19.0 vs. 10.2 months, p = 0.78). Adverse events due to CAB were observed in all patients, requiring dose reduction in 35 patients (81%) and interruption of CAB in 32 patients (74%). The rate of molecular targeted therapies after CAB was 62.5%. In a multivariate analysis, the pretreatment ALBI score (HR 7.57, 95% CI 2.09–27.5, P = 0.002) was the only significant factor associated with OS. The 4W-RDI of CAB and treatment -line (CAB as 4–6 line) were not associated with OS. The median OS of the patients who received atezolizumab plus bevacizumab before CAB was 19.1 months.
Conclusion: Maintaining a high 4W-RDI of CAB was not associated with OS and PFS in real-world practice. Prior atezolizumab plus bevacizumab would contribute to prolonged survival in CAB therapy for u-HCC.

THU-156
Tolerability of first line systemic therapy in elderly patients with advanced hepatocellular carcinoma
Giulia Francesca Manfredi[1,2], Davide Di Benedetto[1,2], Antonio Acquaviva[3], Francesca Baorda[1,2], Carla De Benedittis[2], Chiara Gerevini[1,2], Cristina Rigamonti[1,2], Michela Burlone[2], Mario Pirisi[1,2]. *[1]Università degli Studi del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]AOU Maggiore della Carità, Division of Internal Medicine, Novara, Italy; [3]PO Sant'Andrea, Division of Internal Medicine, Vercelli, Italy*
Email: gf.manfredi01@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) accounts for 90% of primary liver cancer. The average age of HCC development is 70, with aging being a known risk factor. Elderly patients should not be excluded from systemic therapy based upon age alone and all available treatments can be recommended for them.
Method: We considered 126 patients affected by advanced HCC, treated with first line systemic therapy. Four patients were excluded from the final analysis due to lack of follow-up (FU) information, 6 patients on atezolizumab/bevacizumab therapy were excluded for less than 3 months of FU at the time of data collection. We studied patients' overall survival (OS), time to progression (TTP) represented as therapy duration and adverse events (AE) secondary to two systemic therapies, namely sorafenib (SB) and lenvatinib (LB).
Results: Patients were predominantly men (80.3%); 84.6% of them suffered from cirrhosis, which the most frequent etiology was hepatitis C (44.4%). Thirty-nine percent of patients carried steatosis and metabolic syndrome. Median age at diagnosis of HCC was 72 [27–88], median age at systemic therapy start was 73 [28–88]. Patients older than 65 years represented the 80.2% of our cohort, over 70 were the 42.2%, while over 80 were 19.8% of the total. The median alpha-fetoprotein value before initiation of therapy was 45 [1.2–83000]. Twenty-six patients were treated with LB and median age at therapy start was 76, 90 patients were treated with SB, median age at therapy start was 72.5 (p = 0.04). Median systemic therapy duration was 11 months in patients treated with LB, 4 months in patients treated with SB (p < 0.05). Median OS was 18.8 months in SB group and 52.7 months in LB group (p < 0.05). No difference was observed in therapy duration considering age >80 years (p = 0.97). No difference was observed in term of OS considering patients younger or older than 80 years (p = 0.72). Most reported AE were fatigue, anorexia and diarrhea, with the latter more common in patients younger than 80 years (p < 0.05). Regarding diarrhea, only 4 patients over 80 (17.4%) had a Common Terminology Criteria for Adverse Events grade >1. Patients over 80 years did not require a dose reduction more than younger ones (p = 0.97). Considering the reason for discontinuing therapy, no difference was observed between patients older than or younger than 80 years of age (p = 0.70).
Conclusion: Our study demonstrates how elderly patients could be treated safely with the same intensity as younger ones. AE didn't represent a crucial factor for discontinuing therapy in elderly. It is essential to know how to manage AE in a timely way, educating the patient to recognize them. Knowing that the epidemiology of HCC will increasingly affect elderly patients, the choice of treatment based on the comorbidity and characteristics of the subject will be decisive, but age alone should not represent a limitation at the beginning of systemic therapy.

Background and aims: Transarterial chemoembolization (TACE) is used most often for the treatment of large unresectable hepatocellular carcinoma (HCC) that are not amenable to other treatments or as a bridging therapy prior to liver transplantation. This procedure is generally well tolerated with an incidence of major complications post-TACE described as 2–7% with a risk of mortality estimated at 1%. Complications contribute to the prognosis of patients which can be associated with several other risk factors. Once these risk factors are identified, clinicians can carefully select, stratify, and prepare patients for TACE. At present, there is a lack of analysis of the risk factors of complications after TACE of patients with HCC. This study investigated the incidence and risk factors in developing infection, acute kidney injury (AKI), and acute liver decompensation in patients with HCC receiving TACE.
Method: A retrospective cohort study of all adult patients with HCC who have undergone TACE from January 2013 to October 2022 was conducted. Incidence and risk factors developing post-TACE complications were analyzed. Univariate and multivariate analyses were performed to identify factors predictive of infection, AKI, and acute liver decompensation.
Results: Out of the total of 318 patients who underwent TACE, 220 TACE sessions were included. Of these, major complications occurred in 56 cases with an incidence rate of 25.45%. Majority were managed as post-embolization syndrome (43.2%), while 11.8% had infections, 9.1% had acute liver decompensation, and 4.5% had AKI. Total of 4 mortalities were seen with a mortality rate of 1.8%. Larger tumor size (OR 0.19, CI 0.05–0.69, p = 0.03) was identified as a risk factor for the development of infection. While older age was a significant risk factor for developing both AKI (OR 1.09, CI 1.00–1.18, p = 0.10) and acute liver decompensation (OR 1.08, CI 1.02–1.14, p = 0.02). Barcelona

Clinic Liver Cancer (BCLC) stage B was also a risk factor in developing AKI (OR 0.08, CI 0.01–0.95, p = 0.09). Over-all multivariate analysis of the major complications showed that older age (OR 1.06, CI 1.02–1.11, p = 0.01), larger tumor size (OR 0.34, CI 0.13–0.90, p = 0.07), multinodular tumor (OR 5.64, CI 1.17–27.18, p = 0.07) and longer prothrombin time (OR 1.50, CI 1.16–1.95, p = 0.01) were independent risk factors of over-all major complications post-TACE.

Table 5. Multivariate logistic regression of risk factors of over-all major complications

Variable	Adjusted OR (90% CI)	p value
Age (years)	1.06 (1.02-1.11)	0.012
Tumor size (cm)	0.34 (0.13-0.90)	0.070
Tumor classification	5.64 (1.17-27.18)	0.070
Baseline prothrombin time (sec)	1.50 (1.16-1.95)	0.011

Figure:

Conclusion: Majority of complications post-TACE consist of minor post-embolization syndrome. The incidence of major complications was notably high at 25% with a mortality rate of 1.8%. Older age poses risk of developing AKI, and acute liver decompensation. Larger tumor size poses risk for infection while BCLC Stage B in developing acute liver decompensation. Risk factors in developing major complications include older age, larger tumor size, multinodular tumor, and longer prothrombin time.

Risk of bacterial infections in non-alcoholic fatty liver disease: a nationwide population-based cohort study

Axel Wester[1], Ying Shang[1], Linnea Widman[1], Fahim Ebrahimi[1], Jonas Ludvigsson[1], Hannes Hagström[1]. [1]*Karolinska Institutet, Sweden*
E-mail: axel.wester@ki.se

Background and aims: Previous literature suggests an association between non-alcoholic fatty liver disease (NAFLD) and bacterial infections. We aimed to determine the rate and risk of severe bacterial infections in NAFLD compared to the general population.
Method: In this population-based cohort study, we used national registers to identify all patients diagnosed with NAFLD in Sweden between 1987 and 2020 (n = 14,869). The patients were matched at the date of diagnosis with up to ten controls from the general population for age, sex, and municipality (n = 137,145). Cox regression was used to estimate hazard ratios (HR) for infections in patients with NAFLD compared to the controls. Cumulative incidences were calculated while accounting for competing risks (non-infection death and liver transplantation).
Results: Severe bacterial infections leading to death or hospitalization occurred in 1990 (13.4 %) patients with NAFLD and 9899 (7.2 %) controls during 94,852 and 1,083,713 person-years of follow-up, respectively. The rate of severe bacterial infections per 1000 person-years was higher in patients with NAFLD (21.0, 95 % CI 20.1–21.9) than controls (9.1, 95 % CI 9.0–9.3) irrespective of comorbidities, including components related to the metabolic syndrome (fully adjusted HR 1.9, 95 % CI 1.8–2.0). The result was similar when additionally including cirrhosis as a time-varying covariate in the model (HR 1.8, 95 % CI 1.7–1.9). Moreover, patients with NAFLD had a higher rate of infections of any severity (fully adjusted HR 1.5, 95 % CI 1.4–1.5) and infection-related mortality (fully adjusted HR 1.8, 95 % CI 1.6–2.2) compared to controls. The ten-year cumulative incidence of severe bacterial infections was 16.6 % (95 % CI 15.8–17.4) in NAFLD and 8.0 % (95 % CI 7.8–8.2) in controls.

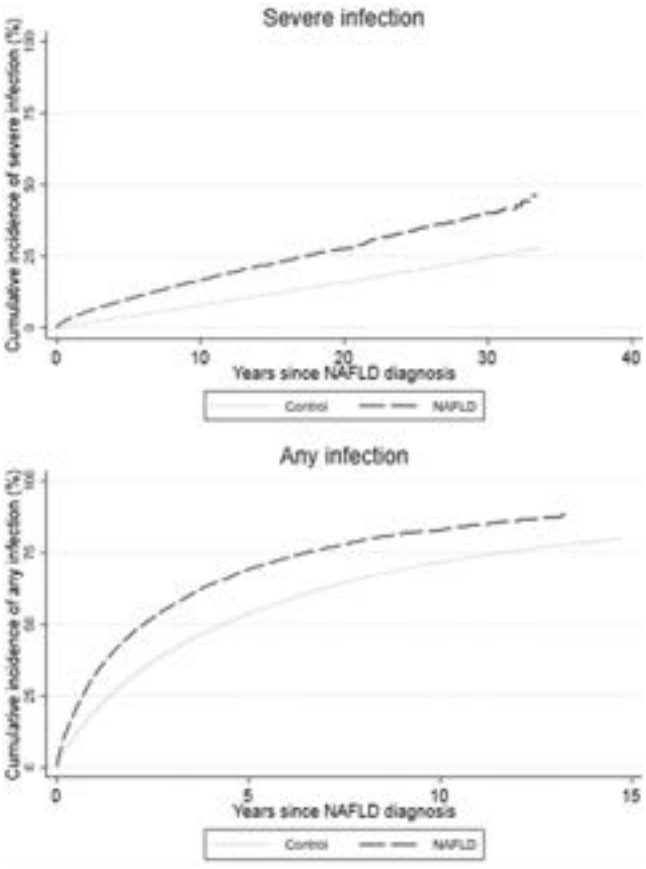

Figure:

Conclusion: NAFLD was associated with incident severe bacterial infections, infections of any severity, and infection-related mortality, independently of components associated with the metabolic syndrome. Increased clinical vigilance of bacterial infections in NAFLD may diminish the risk of premature death.

The growing global burden of non-alcoholic fatty liver disease (NAFLD) among teenagers

Zobair Younossi[1,2,3], James Paik[1,2,4], Shira Zelber-Sagi[5], Jeffrey Lazarus[6], Dipam Shah[1,7], Leyla Deavila[1,2], Huong Pham[1], Pegah Golabi[1,2,3,8], Janus Ong[9], Saleh Alqahtani[10], Linda Henry[1,2,3,8]. [1]*Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States;* [2]*Inova Health System, Inova Medicine, Falls Church, United States;* [3]*The Global NASH Council, Wahington, United States;* [4]*The Global NASH Council, Washington, United States;* [5]*University of Haifa, School of Public Health, Haifa, Israel;* [6]*University of Barcelona, Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain;* [7]*Inova Fairfax Medical Campus, Center for Liver Disease, Department of Medicine, Falls Church, United States;* [7]*Inova Fairfax Medical Campus, Center for Liver Disease, Department of Medicine, Falls Church, United States;* [9]*University of the Philippines, College of Medicine, Manila, Philippines;* [10]*King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia*
E-mail: zobair.younossi@inova.org

Background and aim: NAFLD affects all age groups and all countries. Our aim was to assess NAFLD-related prevalence and liver mortality among teenagers (10–19 years) using the Global Burden of Disease (GBD) dataset.

Method: We analyzed data from 21 GBD regions and countries. GBD modelled NAFLD prevalence based on population-based studies that report NAFLD (ultrasound or imaging). NAFLD-related liver mortality rates (cirrhosis and liver cancer) per 100,000 are reported. The socio-demographic index (SDI) was used as a summary measure as it quantifies each country's rank in the socio-economic development spectrum. Countries are divided into 5 equal groups (quantile) according to their SDI scores. Time trends were assessed by annual percent change (APC) calculated by using Joinpoint regression model.
Results: In 2019, the highest NAFLD prevalence among teenagers was observed in the North Africa and the Middle East region (5.71%), led by Egypt (8.68%), Qatar (8.04%) and Saudi Arabia (7.53%). In this group, the second highest prevalence was observed in Latin America (2.81%), led by Mexico (3.01%) and El Salvador (2.94%). This was followed by Southern Sub-Saharan Africa (2.76%), led by Swaziland (3.17%) and South Africa (3.04%), and East Asia (2.63%), led by Taiwan (3.27%) and China (2.63%). Across SDI quantiles, the prevalence was highest in the middle SDI quintile (2.96%) while the prevalence was lowest in the low SDI quintile (1.70%) groups. In contrast, the liver-death rate (per 100,000) was lowest in the high SDI quintile (0.009) and highest in the low SDI quintile (0.041) groups. From 1990 to 2019, the global NAFLD prevalence increased from 1.84% (19.37 million prevalent cases) to 2.31% (29.16 million prevalent cases) with an APC of +0.80% [95% confidence interval, 0.78%-0.82%]) (Figure). In contrast, during the same period, NAFLD-related liver deaths among teenagers remained low and unchanged (400 to 404 cases). From 2010 to 2019, the highest increase in NAFLD prevalence among teenagers was seen in the low-middle SDI quantile (APC = +1.04% [0.95%–1.14%]), followed by those in low SDI quintile (APC = +0.74% [1.09%–1.28%]) and high SDI quintile (APC = +0.25% [0.17%–0.33%]).

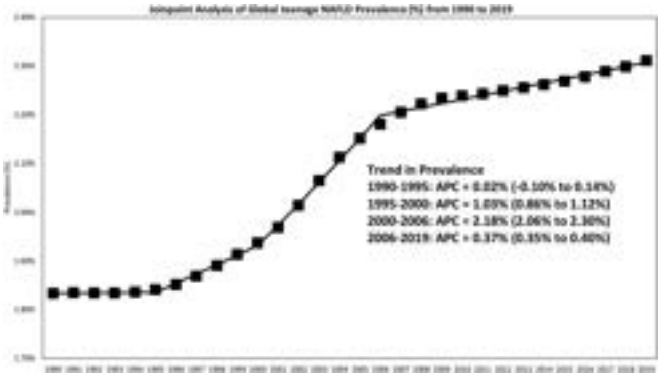

Figure: Joinpoint Analysis of the Global prevalence (%) of NAFLD Among Teenagers

Conclusion: The global prevalence of NAFLD among teenagers is increasing. Although death rates are low, it is expected that the growing prevalence of NAFLD among young populations will drive future liver mortality. Regional and global policies should address NAFLD as an important non-communicable disease.

TOP-082

Identification of a new gene signature that accurately predicts the risk of hepatic decompensation in non-alcoholic fatty liver disease

Maria Jimenez Ramos[1], Timothy Kendall[1], Jessica Minnier[2,3], Lucia Bandiera[4,5], Filippo Menolascina[4,5], Jonathan Fallowfield[1].
[1]*University of Edinburgh, Centre for Inflammation Research, Edinburgh, United Kingdom;* [2]*Oregon Health and Sciences University, OHSU-PSU School of Public Health, Portland, United States;* [3]*Oregon Health and Sciences University, Knight Cancer Institute Biostatistics Shared Resource, Portland, United States;* [4]*Edinburgh University, Institute for Bioengineering, Edinburgh, United Kingdom,* [5]*University of Edinburgh, Centre for Engineering Biology, Edinburgh, United Kingdom*
E-mail: jonathan.fallowfield@ed.ac.uk

Background and aims: The global burden of non-alcoholic fatty liver disease (NAFLD) continues to rise, magnifying the unmet need for tools to enable patient stratification and prognostication. The use of molecular features to predict patient outcomes is unexplored. Using SteatoSITE (https://steatosite.com/), a national-level resource containing integrated time-stamped pathological, transcriptomic and clinical outcome data from NAFLD patients, we aimed to identify genes associated with a higher risk of hepatic decompensation events in patients with advanced fibrotic NAFLD.
Method: Hepatic bulk RNA-sequencing data from needle biopsies showing NASH-CRN stage F3/F4 fibrosis (n = 226) was compared with samples showing stage F0/F1 fibrosis (n = 295). We performed differential gene expression analysis to identify genes with potential to predict a composite outcome of hepatic decompensation events. Ten runs of the 10-fold cross-validated LASSO-penalised Cox regression was used for feature reduction and subsequent development of a model to subdivide patients into high- and low-risk prognostic groups. We evaluated both groups with Kaplan-Meier (K-M) curves and log-rank test. A time-dependent receiver operating characteristic (ROC) curve was used to evaluate the model predictive ability.
Results: Advanced fibrosis stages (F3/F4) were predictive of subsequent decompensation ($p < 0.0001$). We identified 1127 dysregulated genes when comparing F3/F4 and F0/F1 patients. When performing the LASSO Cox regression model with these differentially expressed genes, 15 were associated with decompensation events, some of which could translate to circulating biomarkers based on initial analysis using the TexSEC (Translation of tissue gene expression to secretome) tool. Furthermore, there are biologically plausible links to hepatic decompensation for several of the 15-gene panel such as DPEP1 (implicated in acute kidney injury), CXCL1 (a potential biomarker for acute-on-chronic liver failure), CLEC4M (a pathogen-recognition receptor involved in peripheral immune surveillance in liver) and CTGF (a multiorgan fibrogenic master switch and tractable therapeutic target). The generated risk scores were positively associated with decompensation events and the K-M curves delineate clear prognostic separation into high-risk and low-risk groups ($p < 0.0001$). The measured performance by areas under the ROC curve (AUROCs) were 0.86, 0.81 and 0.83 for 1, 3 and 5 years, respectively.
Conclusion: We have identified a 15-gene signature that predicts the risk of decompensation in patients with advanced NAFLD. Further validation is required in a suitable NAFLD cohort with integrated pathology, transcriptomics and clinical outcomes. This data provides new insights into the pathobiology of NAFLD and sheds light on new potential biomarkers and therapeutic targets.

TOP-088

Altered gut barrier integrity as a mediator of host-microbiome interactions in diabetic patients with advanced Non-alcoholic fatty liver disease

Roberta Forlano[1], Laura Martinez-Gili[1], Jesus Miguens Blanco[1], Charlotte Skinner[1], Mark Thursz[1], Julian Marchesi[1], Benjamin H. Mullish[1], Pinelopi Manousou[1]. [1]*Imperial college london, Liver unit, Department of Metabolism, Digestion and Reproduction, London, United Kingdom*
E-mail: r.forlano@imperial.ac.uk

Background and aims: Aberration of the complex crosstalk between the intestine and the liver, so- called the "gut-liver axis," has been to be a contributory factor in the development and progression of liver disease in patients with Non-alcoholic fatty liver disease (NAFLD).
Method: Consecutive patients with T2DM were screened for liver disease by bloods, ultrasound and liver stiffness measurements (LSM). Elevated LSM was defined as LSM $\geq$ 8.1 kPa. Microbiota composition was analysed in stools by 16S rRNA gene sequencing, while metabolites were measured by liquid chromatography-mass spectrometry. Microbiome signatures were analysed in the whole

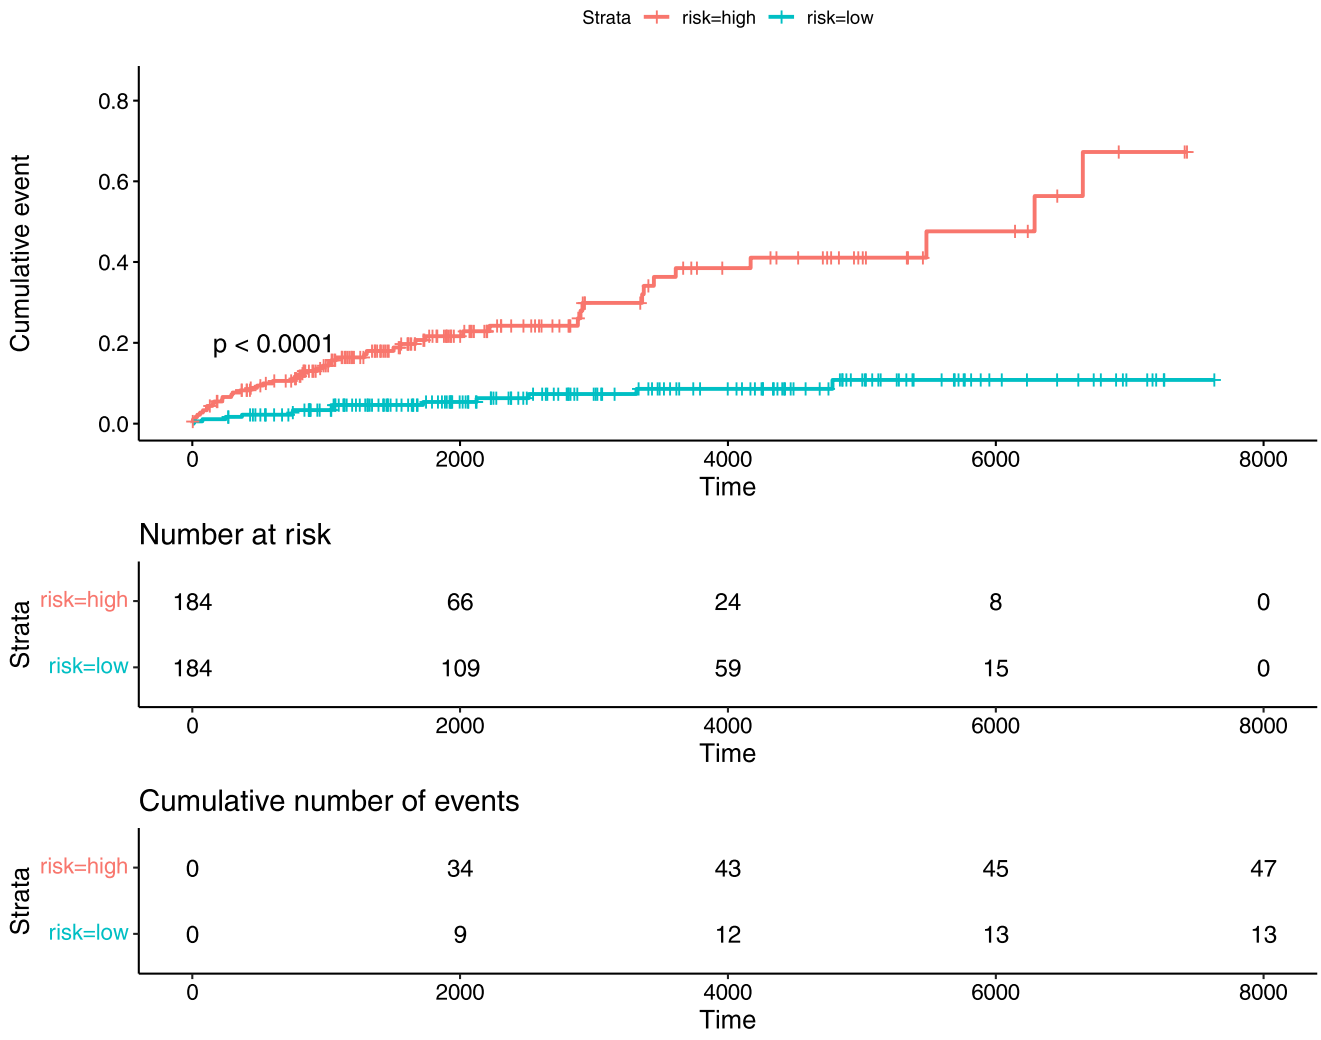

Figure: (abstract: TOP-082).

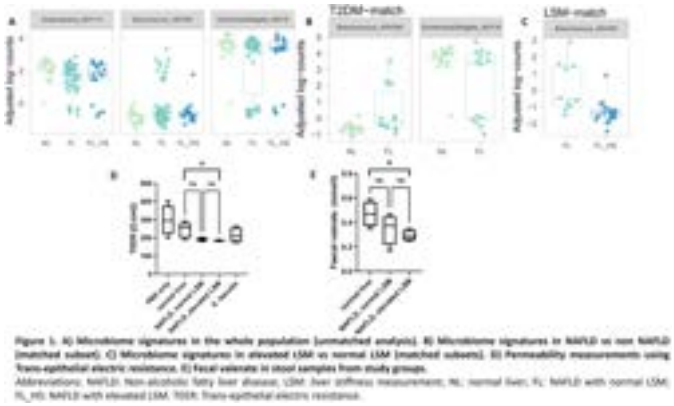
population (unmatched), as well as in subsets matched for metabolic factors (NAFLD vs non-NAFLD and elevated vs normal LSM). An in-vitro model of gut permeability was set up using monolayers of Madin-Darby canine kidney cells. Permeability was estimated by trans-epithelial electric resistance (TEER) on epithelial volt/ohm meter. Faecal water was derived by stool samples, while E. faecalis spent medium and phosphate-buffered saline were used as positive and negative controls.

Results: Overall, stools from 89 patients were analysed: 17 (17%) had normal liver, 54 (55%) NAFLD and normal LSM and 17 (17%) NAFLD and elevated LSM. Only three ASV were different across unmatched groups: Anaeroplasma and Escherichia/Shigella ASV were higher, and Butyricicoccus ASV lower in those with normal liver (Fig. 1A). In the matched groups, Butyricicoccus ASV was significantly higher in those with NAFLD vs non NAFLD (Fig. 1B). Among those with NAFLD, Butyricicoccus ASV was significantly higher in those with normal LSM vs those with elevated LSM (Figure 1C). Overall, 12 stool samples were used for the gut permeability. Faecal water from patients with NAFLD and elevated LSM (n = 4) caused the greatest drop in the TEER vs those with normal liver (n = 5), suggesting a leaky monolayer (Fig. 1D). Clinically, TEER correlated inversely with BMI (p = 0.029) and waist (p = 0.019) and positively with LSM (p = 0.009) and AST (p = 0.036). Fecal valerate was significantly lower in those with elevated LSM, compared to normal liver (0.28 vs 0.47 mmol/l, p = 0.007) (Fig. 1E).



Conclusion: In patients with NAFLD, a greater abundance of butyrate-producing bacteria in patients with NAFLD may represent an adaptive response to depleted pectin-degrading bacteria. In those with advanced liver disease, such adaptation may fail and translate into leakier gut and lower production of short-chain fatty acids. Restoring butyrate-producing bacteria could represent a valuable target to treat the disease.

Systematic screening for NAFLD-related advanced fibrosis in high-risk population in diabetology using transient elastography: a prospective study

Amélie Rajot[1], Bruno Vergès[2], Sarah Beland-Bonenfant[2], Valerie Hervieu[3], Dominique Delaunay[1], Marianne Maynard[4,5], Samy Hadjadj[6], Jérémy Thureau[6], Jean-Michel Petit[2], Sybil Charrière[7], Philippe Moulin[7], Massimo Levrero[4,5], Bérénice Ségrestin[1], Emmanuel Disse[1], Bertrand Cariou[6], Cyrielle Caussy[1,8,9]. *[1]Hospices Civils de Lyon, Endocrinology Diabetes and Nutrition, France; [2]Dijon University Hospital, Endocrinology, Diabetes and Metabolic Disorders, Dijon, France; [3]Hospices Civils de Lyon, Biopathology of Tumours, Bon, France; [4]Hospices Civils de Lyon, Hepatology, Lyon, France; [5]Centre de Recherche sur le Cancer de Lyon, Unité 1052, Lyon, France; [6]l'institut du thorax, Nantes, France; [7]Hospices Civils de Lyon, Endocrinology, Diabetes and Nutrition, Bron, France; [8]Université Claude Bernard Lyon 1, France; [9]INSERM, CarMen Laboratory, Pierre-Bénite, France*
E-mail: cyrielle.caussy@chu-lyon.fr

Background and aims: The systematic screening for non-alcoholic fatty liver disease (NAFLD)-related advanced fibrosis (AF) is currently recommended in high-risk population such as patients with type 2 diabetes (T2D) and/or obesity. However, there are limited prospective data from patients enrolled and systematically assessed using transient elastography (TE) in diabetology. Therefore, we aimed to examine the utility of non-invasive tests (NITs) and the prevalence of AF in a prospectively recruited population in diabetology.
Method: This is a multicenter prospective study (NAFLD-Care: NCT04435054), including patients with T2D and/or obesity and NAFLD, age between 40–80 years old and BMI <40 kg/m^2, enrolled in a systematic screening for NAFLD-related AF in four diabetology departments in France from October 2020 to November 2022. All patients underwent a standardized research visit with fasting labs including Fibrotest® and liver assessment by TE using a FibroScan®. All other causes of liver disease were systematically excluded. The presence of AF was determined after assessment in hepatology by either histological fibrosis stage ≥F3 or overt imaging diagnosis of cirrhosis or concordant TE ≥8 kPa and Fibrotest® ≥F3 according to EASL guidelines.
Results: Of 487 patients screened, 461 met eligibility. The mean age and BMI were 59.5 years (± 9.8) and 32.7 kg/m^2 (± 4.1), 46% were female, 75.5% had obesity, 87.4% had T2D, 72.2% were treated for dyslipidemia and 67.9% had hypertension. Among them, 55.5% had a FIB-4 <1.3 and the proportion of participants with TE ≥8 kPa and TE ≥12 kPA was 18.0% and 4.8%, respectively. The presence of AF was ruled out in 71.4% (n = 329) participants based upon concordant TE<8kPa and Fibrotest®<F3 in diabetology. Among participants assessed in hepatology, 82 participants had a determined status of AF including 27 with a confirmed diagnosis of advanced fibrosis and 54 had an undetermined status of AF due to discordant NITs and no liver biopsy results. The prevalence of AF was 6.6% (27/407) among participants with a determined status of AF. A higher BMI was significantly associated with increased odds of AF, OR: 1114 (95% CI: 1.01–1.24, p = 0,040) adjusted for age and sex. FIB-4 <1.3 had a high negative predictive value (NPV) of 98%. Among participants with AF, 15% (n = 4) had a false negative FIB-4 < 1.3. These participants were significantly younger compared to those with AF and FIB-4 > 1.3: mean age 51 (± 6.6) vs 66.1 (± 7.9), p = 0,004. An age below 60 years was significantly associated with false negative FIB-4, p < 0,001.
Conclusion: The estimated prevalence of AF in this multi-center prospective study in high-risk population was 6.6%. FIB-4 < 1.3 had a very high NPV to rule out AF but significantly misclassified patients younger than 60 years. Further analysis, in a larger population will help refine the prevalence of AF and the optimal screening strategy in diabetology.

THU-411

Low-quality muscle mass predicts fibrosis progression in a prospective biopsy-proven non-alcoholic fatty liver disease cohort

Sae Kyung Joo[1], Yong Jin Jung[1], Won Kim[1]. *[1]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Internal Medicine, Seoul, Korea, Rep. of South*
E-mail: wonshiri@yahoo.com

Background and aims: Muscle quality rather than muscle mass has been suggested to play a pivotal role in the deterioration of non-alcoholic fatty liver disease (NAFLD). The muscle quality map developed for computed tomography (CT) images can separately assess normal-quality muscle mass, low-quality muscle mass, and intermuscular adipose tissue. We evaluated the predictive role of each skeletal muscle mass comparted by muscle quality in fibrosis progression up to advanced fibrosis in a NAFLD cohort.
Method: This prospective community-based cohort study included 326 participants who underwent liver biopsy and CT at baseline, with serial vibration-controlled transient elastography (VCTE) every 1 or 2 years. Fibrosis progression was defined as either an increase in liver stiffness measurement (LSM) more than 20% compared to baseline for patients with advanced fibrosis (≥F3) or an LSM more than 9.6kPa for patients with fibrosis stage 0 to 2. Axial muscles of the third lumbar vertebra level CT image were analyzed with DeepCatch software. Skeletal muscle areas (SMAs) were categorized by pre-determined Hounsfield Unit (HU) thresholds as normal-attenuation muscle area (NAMA; +30 to +150 HU), low-attenuation muscle area (LAMA; −29 to +29 HU), and intermuscular adipose tissue (IMAT; −190 to −30 HU). SMAs were normalized by height to obtain the skeletal muscle index (SMI). Cox proportional hazards analysis was performed to determine risk factors for fibrosis progression, and cumulative incidence rates of fibrosis progression was estimated with Cox regression survival curves.
Results: The median time interval between the first and last VCTE was 44 months (IQR, 31–61 months). Baseline histological fibrosis severity was associated with increasing SMI_{LAMA} ($p < 0.001$) and decreasing SMI_{NAMA} ($p = 0.011$). In a multivariable analysis, SMI_{LAMA} and PNPLA3 rs738409 C > G were independently associated with fibrosis progression (HR, 1.05; 95% CI, 1.00–1.11; and HR, 2.24; 95% CI, 1.51–3.33, respectively). After full adjustment of confounders, risk of fibrosis progression increased with increasing SMI_{LAMA} quartiles (HR, 1.45; 95% CI, 1.13–1.87). SMI_{IMAT} also showed an increased dose-dependent risk of progression (HR, 1.37; 95% CI, 1.06–1.77), while SMI_{NAMA} did not (HR, 1.05; 95% CI, 0.78–1.42).
Conclusion: Increased low quality muscle mass, but not decreased normal-quality muscle mass, predicts fibrosis progression in patients with biopsy-proven NAFLD. Evaluation of the severity of myosteatosis may help select subjects requiring closer monitoring and early intervention to alleviate fibrosis progression.

THU-412

Natural history and long-term outcomes of the Newcastle non-alcoholic fatty liver disease cohort

Jenny Gallacher[1,2], Chris Day[1], Stuart Mcpherson[1,2], Quentin Anstee[1,2]. *[1]Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Liver Unit, Newcastle NIHR Biomedical Research Centre, Newcastle upon Tyne Hospitals Foundation Trust, Newcastle upon Tyne, United Kingdom*
E-mail: jennifer.gallacher@nhs.net

Background and aims: NAFLD is a leading cause of chronic liver disease worldwide, affecting >25% of the adult population. Yet, there remains uncertainty regarding disease natural history and long-term outcomes given the competing risks associated with the metabolic syndrome. The Newcastle NAFLD cohort is one of the longest established prospectively recruited, histologically characterised

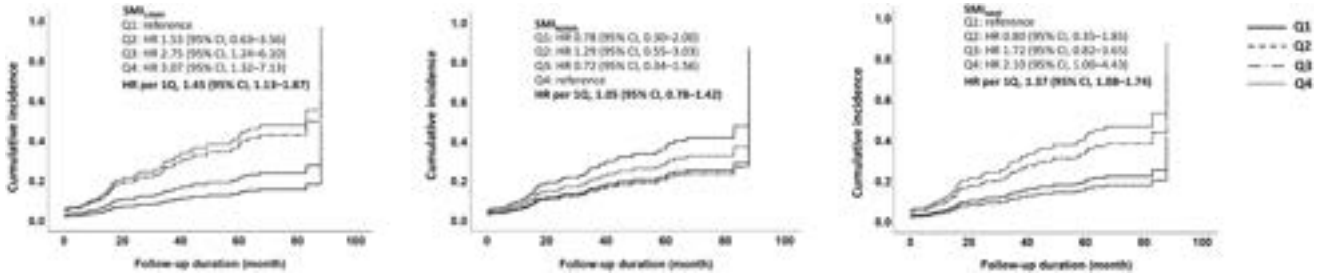

Figure: (abstract: THU-411): Cumulative incidence of fibrosis progression after adjusted for confounders, according to muscle mass comparted by muscle quality.

single-centre patient cohorts. The aim of this study was assess incident comorbidities, and long-term outcomes/mortality in this cohort and seek predictors of adverse outcomes.

Method: Participants with biopsy proven NAFLD with a minimum of 12 months follow-up were recruited from the Newcastle Hospitals between 1990–2018. Data was collected at clinical events and outcomes of interest included co-morbidities, disease progression and adverse liver events such as HCC, liver transplantation and death. Outcomes were explored using Kaplan Meier log-rank test and Cox regression analysis. All cases were censored prior to the COVID19 pandemic to avoid this as a potential confounder.

Results: 605 patients (57% male; age 52 ± 13 years; 47.5% T2DM; BMI 34.7 ± 5.6 kg/m^2) were included with a mean follow-up time of 11.8 ± 7.3 years. 116 (19.2%) had cirrhosis at baseline, with 50 (10.2%) cases progressing to cirrhosis during follow-up (mean time to cirrhosis diagnosis 10.0 ± 7.0 years). Incidence of metabolic co-morbidities (T2DM, HTN and MetS) increased over follow-up. 24 (4.0%) participants were diagnosed with HCC and 10 patients received a liver transplant. 112 patients (18.5%) died (mean age at death 64 ± 13 years and mean time to death 10.1 ± 6.0 years). Liver disease was the most common cause of death (28.6%), followed by cardiovascular disease (20.5%) and extra-hepatic malignancy (20.5%). Factors associated with all-cause mortality included fibrosis stage at baseline (aHR 8.31, 95% CI 4.31–16.01), T2DM (aHR 1.98, 95% CI 1.25–3.14), IHD (aHR 2.31, 95% CI 1.27–4.20) and "high risk" FIB-4 (aHR 10.02, 95% CI 6.14–16.35).

Conclusion: Liver related mortality was found to be the most common cause of death in a large, single centre cohort of NAFLD patients from the U.K. Factors which predicted adverse outcomes included T2DM, IHD, baseline fibrosis stage and "high risk" FIB-4 scores.

THU-413

Deep dive analysis into the screening failure reasons: combined data from multiple therapeutic clinical trials including more than 5000 patients (in collaboration with NAIL-NIT consortium)

Jörn Schattenberg[1], Julie Dubourg[2], Mazen Noureddin[3], Naim Alkhouri[4], Vlad Ratziu[5], Michael Charlton[6], Sophie Jeannin Megnien[2], Stephen Harrison[7]. *[1]Metabolic Liver Research Program, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, Germany; [2]Summit Clinical Research, San Antonio, United States; [3]Houston Methodist Hospital, Houston, United States; [4]Arizona Liver Health, Chandler, United States; [5]Institute for Cardiometabolism and Nutrition, France, [6]UChicago Medicine, Chicago, United States; [7]University of Oxford, United Kingdom*
E-mail: jdubourg@summitclinicalresearch.com

Background and aims: High screen failure (SF) rates in clinical trials for non-alcoholic steatohepatitis (NASH) are a major challenge and pose a high burden for patients, study centers and sponsors. We aimed to describe the main reasons for SF across multiple studies and compare the characteristics of patients meeting the liver biopsy eligibility criteria versus those who failed.

Method: We combined screening data from 7 ongoing non-cirrhotic NASH phase 2 trials. The percentage of patients failing to meet potential eligibility were assessed using common thresholds for non-invasive tests (NITs). Predictors of NASH, non-alcoholic fatty liver disease activity score (NAS) ≥4 and at least fibrosis stage 2, were examined using logistic regression and excluding patients with cirrhosis.

Results: 4808 patients with laboratory results were included. Among them: 1169 (24%) had AST ≤20 IU/L, 248 (5%) had platelets <150 G/L, 189 (4%) had glycated hemoglobin (HbA1c) >9.5%, 185 (4%) had eGFR <60 ml/min, 172 (4%) had total bilirubin >1.3 mg/dL, and 37 (1%) had AST and/or ALT >200 U/L. 2389 patients underwent a magnetic resonance imaging estimated proton density fat fraction (MRI-PDFF).

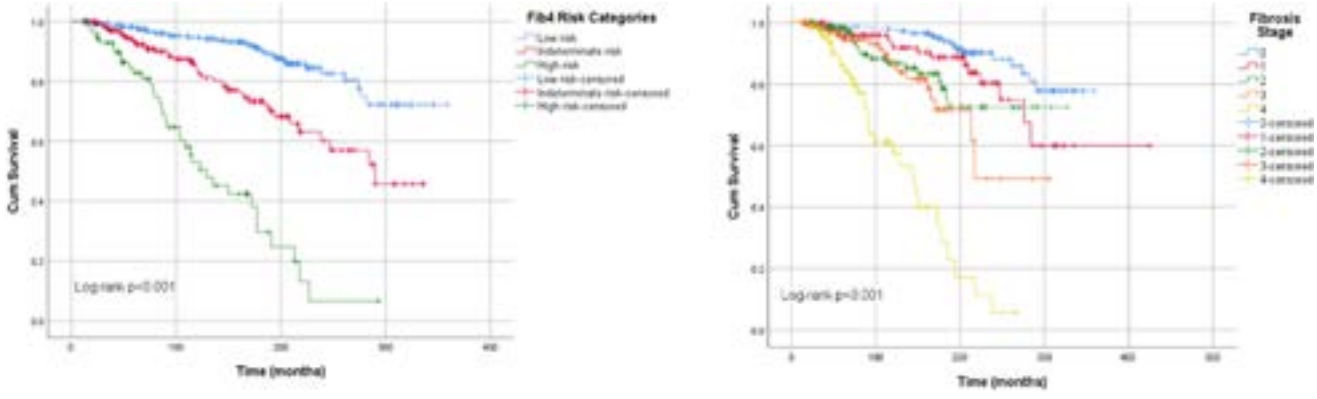

Figure: (abstract: THU-412): Kaplan Meier survival curves exploring the survival of patients across the different risk categories of FIB-4 and different fibrosis stages at baseline.

382 (16%) of them had a liver fat content (LFC) <8%. 2259 patients underwent a biopsy of which 924 (41%) had no NASH with 910 (98%) of those failing the histology criteria for the absence of ballooning. Among the patients with NASH, 135 (10%) had a NAS <4. Among the 2259 patients with biopsy, 1355 (60%) did not meet the common biopsy eligibility criteria (NASH + NAS ≥ 4 + Fibrosis 2 or 3), including 104 (5%) patients with cirrhosis. The patients meeting biopsy eligibility criteria were older with higher HbA1c, liver enzymes, FIB-4 and FAST levels (Table). Among 166 patients with AST <20 IU/L at screening and having underwent a liver biopsy, 147 (89%) did not meet the eligibility criteria.

	Biopsy Fail N = 1251	NASH-NAS ≥4 Fibrosis 2 or 3 N = 904	p value

Figure:

Conclusion: Simple biological or imaging biomarkers such as aminotransferases and elastography were found to be significantly different between patients who screen failed or not based on liver biopsy. Low AST values (<20 IU/L) suggest the absence of at-risk NASH and could help avoid unnecessary biopsies.

THU-414

Causes of death by fibrosis stage in 959 biopsy-proven NAFLD patients

Ying Shang[1], Camilla Akbari[1], Maja Dodd[1], Patrik Nasr[1,2], Johan Vessby[3], Fredrik Rorsman[3], Stergios Kechagias[2], Per Stal[1], Mattias Ekstedt[2], Hannes Hagström[1]. *[1]Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden; [2]Department of Gastroenterology and Hepatology and Department of Health, Medicine, and Caring Sciences, Linköping University, Linköping, Sweden; [3]Dept of Gastroenterology and Hepatology, Uppsala University Hospital, SE-751 85 Uppsala, Sweden*
E-mail: ying.shang@ki.se

Background and aims: Causes of death in patients with non-alcoholic fatty liver disease (NAFLD) may differ based on the fibrosis stage at diagnosis. Our aim was to assess the distribution of different causes of death by fibrosis stage in patients with biopsy-proven NAFLD.

Method: We conducted a retrospective cohort of 959 biopsy-proven patients with NAFLD enrolled from three university hospitals in Sweden between 1974 and 2020. Causes of death were classified by ICD codes from the Swedish Causes of Death Register until the end of 2021. Liver-related deaths were defined as hepatocellular carcinoma, cirrhosis, decompensated cirrhosis, or liver failure.

Results: Among 959 patients (mean age at biopsy 49.5 years, 61.7% male), 335 (34.9%) died during a median follow-up of 17.9 years (IQR 8.0–28.5). Mean age at death was 74.6 years and 52.7% were male. Of these, 75 (33.8%) patients in F0, 120 (32.4%) in F1, 69 (32.7%) in F2, 45 (45%) in F3, and 26 (47.3%) in F4 died. Liver-related mortality was the leading cause of death for patients with F4 (53.9%), followed by extrahepatic cancer (15.4%) and respiratory diseases (11.5%) (Figure). In non-cirrhotic patients with NAFLD (F0-F3), liver-related mortality increased with the severity of fibrosis stage (6.8% in F0, 10.8% in F1, 14.5% in F2, 17.8% in F3). However, these patients' death attributable to cardiovascular diseases and extrahepatic cancers were more common than death in liver-related causes.

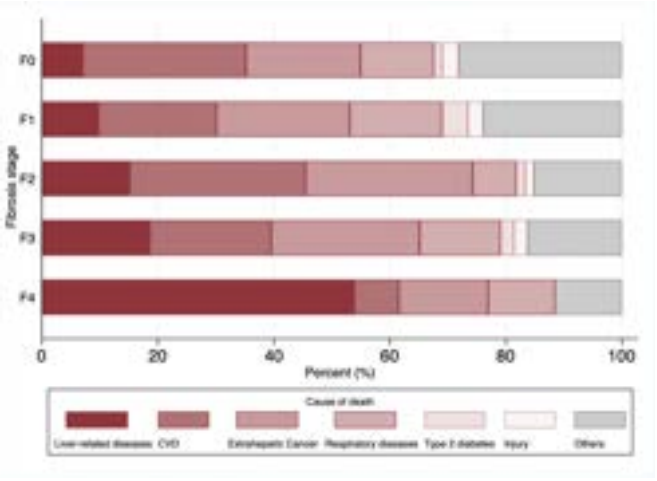

Figure: Proportions of causes of death by fibrosis stage

Conclusion: In patients with NAFLD and cirrhosis at diagnosis, liver disease is the most common cause of death. In patients with no or non-cirrhotic fibrosis, cardiovascular and extrahepatic cancer death were more common than liver-related death. Different management strategies and goals according to fibrosis stage at time of diagnosis can be implemented in patient counselling to improve prognosis.

E-mail: chiara.rosso@unito.it

Background and aims: In subjects with non-alcoholic fatty liver disease (NAFLD), hepatic fat accumulation is the result of insulin resistance (IR) and the impairment of hepatic glucose and lipid metabolism. In addition, the rs738409 C > G patatin-like phospholipase domain-containing 3 (*PNPLA3*) polymorphism is one of the main predisposing factors for the onset and progression of NAFLD and hepatic fibrosis. Here, we aimed to assess if *PNPLA3* rs738409 polymorphism may affect both glucose and lipid metabolism in a

group of non-diabetic subjects with biopsy-proven NAFLD who underwent an oral lipid meal coupled with tracers.
Method: We have studied glucose and lipid metabolism after a lipid load (200 ml dairy cream and egg yolk) in 20 subjects with biopsy proven NAFLD (18 male; median age 41 years, range: 23–57) and 9 healthy controls (CT). Tracers (6, 6–2H2-glucose and 2H5-glycerol) were infused for 120 min before meal, and 240 min after lipid load to evaluate glucose metabolism (endogenous glucose production [EGP] and glucose clearance[GluClear]) and lipolysis. Throughout the test, we measured glucose, insulin (INS), free fatty acids (FFAs) composition, triglyceride (TG) and cholesterol profile. IR components were derived from tracers as follow: hepatic IR (Hep-IR = EGP × INS), adipose tissue IR (Lipo-IR = lipolysis × INS or AT-IR = FFAs × INS). Genotyping was performed by allelic discrimination assay. The mean value of the area under the curve (mAUC) was calculated for each variable.
Results: Prevalence of PNPLA3 rs738409 G minor allele was 75% (15/20) in NAFLD patients and 44% (4/9) in CT (p = 0.116). During fasting EGP, lipolysis and GC were similar in both groups even if NAFLD subjects were more insulin resistant than CT (Hep-IR: 88 vs. 52, p = 0.004; Lipo-IR 24 vs. 13, p = 0.011; AT-IR: 5.1 vs. 4.4, p = 0.043). When we compared NAFLD patients carrying the PNPLA3 G risk allele with those carrying the CC genotype, we showed no differences in fasting EGP, lipolysis, GC and IR components. Conversely, during lipid load, lipolysis was more suppressed in subjects who carried the PNPLA3 CC genotype and in CT. Moreover, lipid meal reduced GluClear with respect to baseline in CC and CG but not in GG carriers. Cholesterol profile did not change during meal in CT vs. NAFLD. Conversely, in all subjects FFAs and TG concentrations increased during the last hour (180–240 min) and TG levels were slightly higher in NAFLD subjects who carried the PNPLA3 CC genotype compared to those carrying the G minor allele, reflecting TG retention in the hepatocytes.
Conclusion: NAFLD patients carrying the PNPLA3 rs738409 G minor allele show an altered lipid but not glucose metabolism after an oral lipid meal. The implications of these results should be further explored.

Patatin-like phospholipase domain-containing 3 (PNPLA3) risk allele increases rate of progression to end-stage liver disease outcomes and decreases survival rate over time irrespective of degree of fibrosis

Javier Armisen[1], Jenny Blau[2], Nellie Fernando[3], Monika Hun[4], Mitra Rauschecker[2], Linda Wernevik[5], Ola Fjellstrom[5], Dirk Paul[6], Björn Carlsson[5], Nils Svangård[4]. *[1]AstraZeneca, Early Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals, RandD, Cambridge, United Kingdom; [2]AstraZeneca, Early Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals, RandD, United States; [3]AstraZeneca, AI and Advanced Analytics, Data Science and Artificial Intelligence, RandD, Cambridge, United Kingdom; [4]AstraZeneca, AI and Advanced Analytics, Data Science and Artificial Intelligence, RandD, Sweden; [5]AstraZeneca, Early Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals, RandD, Sweden; [6]AstraZeneca, Centre for Genomics Research, Discovery Sciences, RandD, United Kingdom*
E-mail: javier.armisengarrido@astrazeneca.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease. Progression to Non-alcoholic steatohepatitis (NASH), can lead to cirrhosis, hepatocellular carcinoma (HCC), end-stage liver disease and death. The severity of hepatic fibrosis is the most important predictor of liver-related mortality. Among known risk factors increasing the risk of progression are genetic factors. The strongest genetic risk factor is a single-nucleotide polymorphism (rs738409) in the *PNPLA3* gene I148M. The 148M allele has been associated with increased hepatic triglyceride accumulation, liver injury and fibrosis. The aim of the study was to evaluate the characteristics and progression rates to outcomes among homozygous *PNPLA3* 148MM risk allele carriers as compared to heterozygous carriers (*PNPLA3* 148IM) and non-risk allele carriers (*PNPLA3* 148II) utilizing the well-characterized longitudinal biopsy-confirmed NashBio cohort.
Method: A Cox proportional hazards model was used to determine the effect of the PNPLA3 risk allele (148MM) on liver outcomes including cirrhosis, HCC and transplant as compared with 148IM and 148II. Survival analysis was performed with adjustments for confounders including age, BMI, gender, T2DM, and fibrosis stage, censored at study drop out or death.
Results: The NashBio cohort (n = 1508 evaluable patients, median age 48) included biopsy-confirmed NAFL or NASH (n = 117 526 271 for Fibrosis stage = 0–1, 2–3, 4 respectively) and PNPLA3 genotypes (n = 133 509 866 PNPLA3 148MM, IM, and II, respectively) with longitudinal electronic health record follow-up over a median of 49 months (range 0–23 years). PNPLA3 148MM had a more rapid progression to end-stage liver disease outcomes when compared to 148IM and 148II individuals with a hazard ratio = 1.6 (95% CI 1.01–2.56; p = 0.05). Predicted survival analyses highlighted nearly a two-fold increase in liver events in PNPLA3 148MM over 148II at 20 years (22% vs 12%, respectively; p = 0.0079). Even after stratification of patients according to fibrosis severity, PNPLA3 148MM patients had an increased risk of liver related events compared to PNPLA3 148II patients.

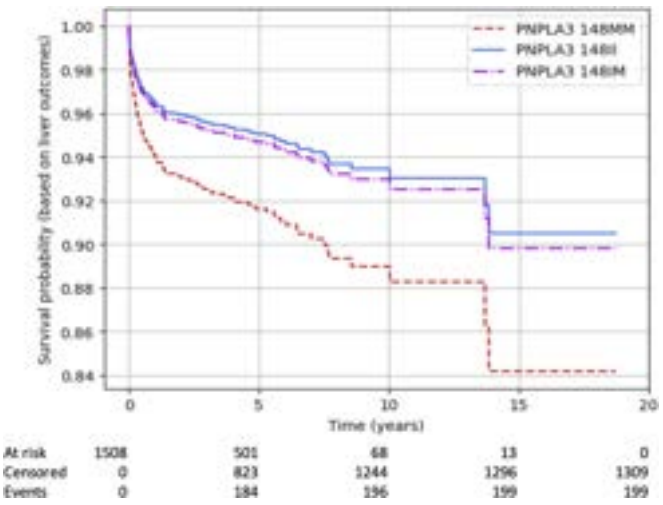

Figure:

Conclusion: Biopsy-confirmed NASH homozygous PNPLA3 148MM risk allele carriers progress to liver-related outcomes significantly faster than PNPLA3 148II and 148IM carriers, adjusted for age, gender, BMI, diabetes status, and fibrosis stage.

THU-417
A risk prediction model for hepatocellular carcinoma for non-alcoholic fatty liver disease without cirrhosis

Gi-Ae Kim[1], Yewan Park[1], Jui Jung[2], Jaeil Kim[3], Han Chu Lee[4]. *[1]Kyung Hee University Hospital, Kyung Hee University, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Korea University, Department of Biostatistics, Korea, Rep. of South; [3]Asan Medical Center, University of Ulsan College of Medicine, Health Screening and Promotion Center, Korea, Rep. of South; [4]Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Korea, Rep. of South*
E-mail: hch@amc.seoul.kr

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is becoming a leading cause of hepatocellular carcinoma (HCC) and burden of NAFLD-related HCC is on the rise. We aimed to develop and validate an HCC risk prediction model for NAFLD patients without cirrhosis using clinical factors widely available.

Method: A nationwide cohort of non-cirrhotic NAFLD patients in Korea were recruited to develop a risk prediction model and its internal validation (n = 409,088, derivation cohort). A model using a simplified point system was developed by Cox proportional hazard model and k-fold cross-validation assessed the accuracy, discrimination, and calibration of the model. The model was externally validated using a hospital cohort recruited from Asan Medical Center (n = 8721, external validation cohort).
Results: The 10-year cumulative HCC incidence rates were 0.21% and 0.20% in the derivation and external validation cohorts. In the derivation cohort, an 11-point HCC risk prediction model for non-cirrhotic NAFLD was developed, using six independent risk factors of age, sex, diabetes, obesity, serum alanine aminotransferase level, and gamma-glutamyl transferase level (c-index 0.75). The average area under receiver operating curves (AUROCs) of the model was 0.72 at 5-year and 0.75 at 10-year. In the external validation cohort, the c-index of the model was 0.82 and the AUROCs were 0.79 [95% confidence interval [CI], 0.59–0.95] at 5-year and 0.84 (95% CI, 0.73–0.94) at 10-year. The calibration was satisfactory. Risk stratification categorized patients into minimal (0–1), low (2–6), and moderate (≥7) risk groups.
Conclusion: A novel HCC risk prediction model targeting non-cirrhotic NAFLD patients was developed and validated with a fair prediction performance. The model is expected to serve as a simple and reliable tool to assess HCC risk.

E-mail: vlad.ratziu@inserm.fr

Background and aims: NASH trials assume that histological classifications predict hepatic events. We evaluated the diagnostic performance of the new European EPoS staging and SAF grading systems.
Method: Pts from 7 European centers biopsied <2011 for suspected NAFLD and with long-term follow-up were scored by the NASHCRN and the EPoS 7 tier (1 minimal fibrosis, 2: portal/periportal fibrosis, 3: early bridging, 4:advanced bridging, 5 early cirrhosis, 6 advanced cirrhosis) fibrosis staging systems by a central pathologist. Activity was scored by NAS and SAF grading. Hepatic morbimortality (HMM) was a composite of liver-related death, occurrence of cirrhosis, cirrhosis decompensation events. Overall mortality, primary liver cancer (PLC), cardiovascular events (CVE) and extrahepatic malignancies (EHM) were recorded. Median follow-up was calculated by reverse Kaplan-Meier. Incidence rates were compared using log-rank test and univariate and multivariate Cox proportional hazard models were used to estimate hazard ratios (HR) for each outcome.
Results: 711 patients were included: 63% males, mean age 52 yrs, BMI 30.1 kg/m², diabetes 36%, arterial hypertension 59%, dyslipidemia 54%, daily alcohol 0–5 g: 84%, 5–20/30 g: 13%, moderate (20/30–50) g: 3%, active smokers 19%. NASH CRN stages were : F0:45%, F1:24%, F2:11%, F3:14%, F4:6%. EPoS stages were: 0:48%, 1:20%, 2:11.5%, 3:6.5%, 4:4%, 5:6%, 6:4%.
Median follow-up was 11.12 yrs (0.1–20). 84 pts died (11.8%), 92 pts developed HMM (12.9%), 32 PLC (4.5%), 72 CVE (10.1%) and 80 EHM (11.3%). The 5 and 10 yr incidence of HMM was 4.8% 95% CI [3.2–6.4] and 12.7% 95% CI [10–15], and that of all-cause death 2.9% 95% CI [1.6–4.1] and 9.3% 95% CI [7–11.5]. In multivariable analysis, age, diabetes, arterial hypertension and moderate alcohol consumption were associated with an increased risk of HMM.
After adjustment for clinical variables and NAS, fibrosis stage was associated with HMM: HRs for NASH CRN: stage 1: 3.06; stage2: 11.04; stage3: 21.1; stage 4: 21.2 vs stage 0. For EPoS: stage 1: 2.3; stage 2: 8.3; stage 3: 19.8; stage 4: 18.1; stage5+6: 21.7 vs stage 0. Both staging systems had similar calibration and discrimination Harrell's C index was 0.84 and AUROCs for cumulative incidence of HMM at 5 yrs was 0.83 and at 10 yrs 0.86. Both were significantly associated with overall survival, PLC, CVE and EHM. Histological activity by SAF was associated with HMM starting grade 2 ($p < 0.001$). Steatohepatitis stage 2–4 (but not 0–1) by EPOS and cirrhosis (5–6 by EPOS) were significantly associated with HMM. Only cirrhosis was associated with CVE. Baseline FIB4 risk strata were significantly associated with HMM, overall survival, PLC, cardiovascular events but not EHM.
Conclusion: This large multicentric cohort demonstrated the prognostic value of the EPoS classification. Fibrosis starting stage 1 (NASH CRN) or stage 2 (EPoS) and activity grade predicted hepatic events. (supported by a grant from Gilead Sciences)

E-mail: rajamannar.thennati@sunpharma.com

Background and aims: GL0034 (GL) is a potent glucagon-like peptide 1 receptor agonist under development for the treatment of metabolic disorders and NAFLD/NASH. In *in-vivo* preclinical studies GL attenuates NAFLD/NASH-relevant pathways of steatosis, liver injury and inflammation. Here, we present NAFLD/NASH relevant pharmacodynamic (PD) and safety results of a multiple ascending dose phase 1 study in healthy individuals.
Method: A randomized, double-blind, placebo (PBO)-controlled study was conducted to evaluate the safety, tolerability and PD of multiple ascending doses of GL. Healthy individuals (N = 12) with BMI 18 to 28 kg/m^2 were randomized (9:3) to subcutaneous GL or PBO. Individuals received weekly dose of GL for a total period of eight weeks. First, they received doses of 450 mcg over two weeks, then 900 mcg over the next two weeks and finally 1520 mcg over four weeks. Biomarker measurements included, body weight, glycated haemoglobin A1c (HbA1c), liver enzymes (alanine transaminase (ALT), aspartate aminotransferase (AST), gamma-glutamyl transferase (GGT)) and lipid profiles (triglycerides (TG), total cholesterol (TC), high-density lipoprotein (HDL) and low-density lipoprotein (LDL)).
Results: GL was generally well tolerated and related adverse effects were mainly gastrointestinal with dose-dependent nausea, vomiting and decreased appetite however adverse events became less frequent over time despite increased dosing. Clinically meaningful changes in the body weight, HbA1c and lipid profile were observed when compared to baseline (Table). HDL increase at EOS (Table) and trends towards lower ALT, AST and GGT were observed vs PBO (Table).

Table:

Treatment Groups	GL0034, 450 mcg × 2, 900 mcg × 2, 1520 mcg × 4 (n = 8)			Placebo (n = 3)

Association between consumption of ultra-processed foods and non-alcoholic fatty liver disease in the Framingham heart study

Natalie Sun[1], Vanessa Xanthakis[2,3], Jiantao Ma[4], Michelle Long[5,6], Maura Walker[2,3,7]. *[1]Boston Medical Center, Boston, United States; [2]Boston University Chobanian and Avedisian School of Medicine, Preventive Medicine and Epidemiology, Boston, United States; [3]Framingham Heart Study, United States; [4]Friedman School of Nutrition Science and Policy, Tufts University, Nutritional Epidemiology, Boston, United States; [5]Novo Nordisk A/S, Clinical Drug Development, Medicine and Science, Denmark; [6]Boston University Chobanian and Avedisian School of Medicine, Medicine, United States; [7]Sargent college of health and rehabilitation sciences nutrition program, Nutrition Programs, Boston, United States*
E-mail: nataliesuneras@gmail.com

Background and aims: Ultra-processed food (UPF) intake is associated with cardiovascular disease, poor metabolic health, and mortality. Consumption of UPFs and prevalent non-alcoholic fatty liver disease (NAFLD) have increased in parallel over recent years, but little is known about the association between the two. We performed a cross-sectional, retrospective, observational study to examine the relationship between consumption of UPFs and presence of liver steatosis and fibrosis in Framingham Heart Study (FHS) participants.
Method: We evaluated FHS participants from the 2016–2019 exam cycle who completed vibration-controlled transient elastography and had valid dietary data (n = 2507, mean age 55 years, 55.6% female). Participants with missing covariate data and excessive alcohol use were excluded from the analysis. Diet was assessed via the self-administered semi-quantitative Harvard food frequency questionnaire and was categorized by level of food processing via the NOVA (not an abbreviation) system, which groups food items by level of industrial processing. We used multivariable-adjusted logistic regression models to evaluate the association of energy-adjusted UPF intake (per 1 standard deviation unit and by quintile) with imaging-defined hepatic steatosis (Controlled Attenuation Parameter [CAP] ≥ 290 dB/m), fibrosis (Liver Stiffness Measurement [LSM] ≥ 8.2 kPa), and hepatic steatosis with fibrosis (CAP ≥ 290 dB/m and LSM ≥ 8.2 kPa); separate models for each outcome. Our primary model adjusted for age, sex, smoking, alcohol intake, physical activity and intake of remaining NOVA levels. Additional models adjusted for diet quality index or body mass index (BMI).
Results: Prevalence of hepatic steatosis, fibrosis, and steatosis with fibrosis was 29.72%, 9.77% and 5.42%, respectively. We observed a statistically significant positive association of UPF consumption with presence of hepatic steatosis (OR 1.33 [95% CI 1.21, 1.46] per SD-increase, i.e. 2.3 servings/day), fibrosis (OR 1.15 [1.01, 1.31]) and hepatic steatosis with fibrosis (OR 1.24 [1.06, 1.47]; Table). Associations were similar when accounting for an index of diet quality (Table). When accounting for BMI, the association between UPF consumption and hepatic steatosis remained significant (OR 1.13

Figure: (abstract: THU-420).

[1.01, 1.27]); however, associations were attenuated for hepatic fibrosis (OR 1.00 [0.87, 1.16]), and for steatosis with fibrosis (OR 0.96 [0.79, 1.18]).
Conclusion: In our community- based sample, we observed associations of UPF consumption with hepatic steatosis. Additional longitudinal studies are needed to determine if UPF consumption contributes to progression of NAFLD and if BMI serves as an intermediate factor in the relationship between the two. Our findings suggest that the consumption of UPFs may be a modifiable risk factor for NAFLD.

THU-421

Presence and severity of esophageal varices drives portal hypertension-related complications in compensated advanced non-alcoholic fatty liver disease

E-mail: graziapennisi901@gmail.com

Background and aims: We aimed to evaluate the impact of esophageal varices (EV) and their changes during follow-up on the risk of developing liver events in patients with compensated advanced chronic liver disease (cACLD) due to NAFLD. We also assessed diagnostic accuracy of non-invasive scores for predicting the development of liver events and for identifying patients at low risk of high-risk EV.
Method: We assessed 629 patients with NAFLD-related cACLD who had baseline and follow-up esophagogastroduodenoscopy (EGD), and clinical follow-up to record decompensation, portal vein thrombosis (PVT) and hepatocellular carcinoma.
Results: Small and large EV were observed at baseline in 30% and 15.9% of patients, respectively. The 4-year rate of EV development from absence at baseline, and of progression from small to large EV were 16.3% and 22.4%, respectively. Presence of diabetes and ≥5% increase in BMI were associated with worsening of EV status. At multivariate Cox regression analysis, small (HR 2.24, 95%C.I. 1.47–3.41) and large (HR 3.86, 95%C.I. 2.34–6.39) EV were independently associated with decompensation. When considering EV status and EV trajectories, baseline and/or follow-up small EV (HR 2.65, 95%C.I. 1.39–5.05), and baseline and/or follow-up large EV (HR 4.90, 95%C.I. 2.49–9.63) were independently associated with decompensation as compared to baseline and/or follow-up absence of EV. Presence of small (HR 2.8 (95%C.I.1.16–6.74) and large (HR 5.29, 95%C.I. 1.96–14.2) EV were also independently associated with PVT occurrence.
Conclusion: In NAFLD-related cACLD, the presence, severity and evolution of EV well stratify the risk of developing decompensation and PVT.

THU-422

PNPLA3 GG genotype is associated with higher incidence of cirrhosis and liver-related events among patients with non-alcoholic fatty liver disease

Karn Wijarnpreecha[1,2], Fang Li[3], Anna Lok[2], Vincent Chen[2]. *[1]University of Arizona College of Medicine-Phoenix, Internal Medicine, United States; [2]University of Michigan Health System, United States; [3]The University of Texas Health Science Center at Houston, United States*
E-mail: dr.karn.wi@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) can develop in persons without obesity. PNPLA3 genetic variant is associated with NAFLD, cirrhosis, and hepatocellular carcinoma (HCC) but its association with non-liver outcomes is unknown. We investigated the association between PNPLA3 genetic variants and mortality and risk of liver and non-liver outcomes among NAFLD patients with and without obesity.
Method: We conducted a retrospective cohort study of NAFLD patients with PNPLA3 data available. NAFLD was defined via imaging, transient elastography, or biopsy without other liver diseases. We excluded patients with baseline cirrhosis or cancer, underweight, bariatric surgery, or missing data on body mass index (BMI). The primary outcome is the association between PNPLA3-rs738409 genotype and incident (hazard ratio [HR] and 95% confidence interval [CI]) cirrhosis, liver-related events (LREs) (ascites, variceal bleeding, hepatic encephalopathy, or HCC), cardiovascular disease (CVD), diabetes (DM), cancers, and mortality among obese and non-obese NAFLD patients without prevalent outcomes. The multivariable model was adjusted for age, sex, and genetic principal components 1–10 to account for race/ethnicity. Analyses of the total population were also adjusted for body mass index category.
Results: A total of 3039 patients with NAFLD: 259 lean, 652 overweight, and 2128 obese, followed for a median of 54.7 months and total follow-up of 15311 person-years were studied. 84.1% were Caucasian, 6.4% African American, and 3.3% Asian. PNPLA3 genotype was CC, CG, and GG in 52.7%, 38.1%, and 9.2% of patients overall; 43.2%, 38.0%, and 8.7% of obese patients; and 51.4%, 38.3%, and 10.3% of lean/overweight patients ($p > 0.05$). NAFLD patients with PNPLA3 GG but not those with CG genotype had higher incidence of cirrhosis compared to patients with CC genotype. PNPLA3 GG was significantly associated with LREs in obese but not in non-obese NAFLD. PNPLA3 genetic variants were not associated with all-cause mortality or incidence of CVD, DM, or cancer.
Conclusion: Among patients with NAFLD, PNPLA3 GG but not CG genotype was associated with higher incidence of cirrhosis in non-obese and obese patients and with LREs in obese patients. Clinical trials of NAFLD treatment should stratify for PNPLA3 genotype.

Table (abstract: THU-422).

Long-term prognosis of patients with non-alcoholic fatty liver disease: a retrospective cohort study to understand the impact of surrogate disease end points on long-term outcomes in South Korea

Sungwon Chung[1], Min Kyung Park[1], Xiao Zhang[2], Tongtog Wang[2], Thomas Jemielita[2], Gail Fernandes[2], Samuel Engel[2], Heejoon Jang[1,3], Yun Bin Lee[1], Eun Ju Cho[1], Jeonghoon Lee[1], Su Jong Yu[1], Jung-Hwan Yoon[1], Yoon Jun Kim[1]. *[1]Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Korea, Rep. of South; [2]Mereck and Co., Inc., Rahway, NJ, United States; [3]Seoul Metropolitan Government Seoul National University Boramae Medical Center, Department of Internal Medicine, Korea, Rep. of South*
E-mail: yoonjun@snu.ac.kr

Background and aims: Prognosis of NAFLD can be difficult to predict without liver biopsy. Previous studies have been focused on assessing the prognostic performance of non-invasive fibrosis scoring systems ascertained at NAFLD diagnosis (baseline). The aim of this study was to examine whether adding time-varying variables for these scores improves prediction of long-term outcomes in NAFLD patients.
Method: This is a retrospective cohort study of 2290 NAFLD patients diagnosed at the Seoul National University Hospital between January 2001 and December 2016. Primary outcomes were overall mortality, composite liver-related outcomes (liver transplant, cirrhosis, hepatocellular carcinoma), and composite cardiovascular outcomes (myocardial infarction, ischemic stroke, heart failure, peripheral artery disease). Multivariable Cox regression models with baseline and time-varying values of the fibrosis scoring systems including fibrosis-4 index (FIB-4) (high risk for advanced fibrosis: >2.67; intermediate risk: 1.30–2.67; low risk<1.30) and NAFLD fibrosis score (NFS) (high-risk: >0.676; intermediate risk: –1.455–0.676; low risk: <–1.455) were fit to the data separately, to assess the association between baseline/current value of these scores at the visit and the primary outcomes.
Results: The median follow-up was 10.4 years. During follow-up, 217 deaths, 132 liver-related outcomes, and 320 cardiovascular events occurred. In the multivariable Cox regression models with baseline score considered, higher baseline NFS (high- versus low-risk group) was associated with higher risk of mortality (adjusted hazard ratio (aHR) = 2.72, 95% Confidence Interval (CI): 1.38–5.37), liver-related outcomes (aHR = 3.49, 95%CI: 1.21–10.07), and cardiovascular events (aHR = 1.12, 95%CI: 0.59–2.12). Similar findings were observed for the association of baseline FIB-4 (high- versus low- risk group) with mortality (aHR = 2.56, 95%CI: 1.48–4.42), liver-related outcomes (aHR = 11.38, 95%CI: 6.04–21.45), and cardiovascular events (aHR = 1.10, 95%CI: 0.62–1.95). In models with time-varying scores considered, stronger association was observed. For NFS, higher current value (high- versus low-risk group) was associated with higher risk of mortality (aHR = 2.89, 95%CI: 1.59–5.26), liver-related outcomes (aHR = 6.36, 95%CI: 2.52–16.09), and cardiovascular events (aHR = 1.18, 95%CI: 0.66–2.10). For FIB-4, higher current value (high- versus low-risk group) was associated with higher mortality (aHR = 2.81, 95%CI: 1.66–4.76), liver-related outcomes (aHR = 14.55, 95%CI: 7.47–28.34), and cardiovascular events (aHR = 1.24, 95%CI: 0.71–2.19).
Conclusion: Current values of FIB-4 and NFS were associated with long-term outcomes. In addition to the baseline measurement, a routine monitoring on these scores is important in predicting prognosis of NAFLD patients.

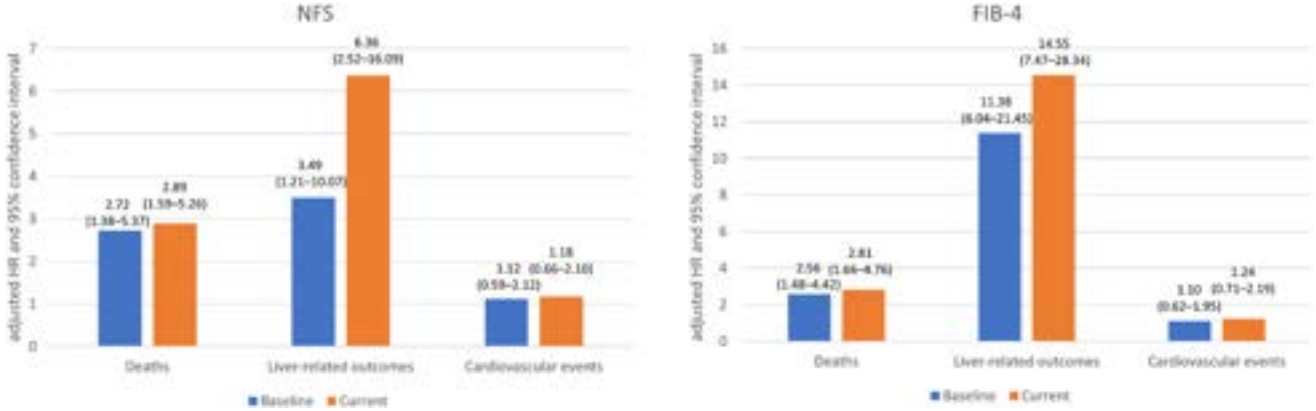

Figure: (abstract: THU-423): Adjusted hazard ratios (aHRs) for primary outcomes comparing high- versus low-risk (for advance fibrosis) group in non-alcoholic fatty liver disease (NAFLD) patients, by scoring system and model (multivariable Cox regression model with baseline measurement considered versus multivariable Cox regression model with current value)

THU-424

Prevalence of extrahepatic manifestations in non-alcoholic fatty liver disease in lean individuals compared to non-lean individuals

Majd Aboona[1], Claire Faulkner[1], Pooja Rangan[2], Vincent Chen[3], Cheng Han Ng[4], Fang Li[5], Karn Wijarnpreecha[6,7]. *[1]The university of arizona college of medicine-phoenix, Phoenix, United States; [2]The university of arizona college of medicine-phoenix, division of clinical data analytics and decision support, Phoenix, United States; [3]University of michigan health system, division of gastroenterology and hepatology, department of internal medicine, Ann arbor, United States; [4]Yong loo lin school of medicine, Singapore, Singapore; [5]The university of texas health science center at houston, school of biomedical informatics, Houston, United States; [6]The university of arizona college of medicine-phoenix, Department of medicine, Division of gastroenterology and hepatology, Phoenix, United States; [7]Banner-university medical center phoenix, Department of internal medicine, Division of gastroenterology and hepatology, Phoenix, United States*
E-mail: aboona@arizona.edu

Background and aims: Non-alcoholic Fatty Liver Disease (NAFLD) has increased in prevalence worldwide in recent years. Data from multi-center study regarding NAFLD in lean individuals are lacking and whether they have higher prevalence of cardiovascular disease (CVD), cirrhosis, and extrahepatic manifestations than non-lean patients with NAFLD still inconclusive. Thus, we conducted a multi-center study to estimate the prevalence of cirrhosis and extrahepatic manifestations among NAFLD.

Method: A multi-state health system based study was conducted on NAFLD patients seen at the Banner Health System, from 2012 to 2022 using ICD Code. Patients with other causes of liver disease, alcohol-related diseases, underweight, baseline decompensated cirrhosis, cancer, prior bariatric surgery, or missing data on race, BMI, aspartate and alanine aminotransferase, and platelet were excluded. Patients were defined as lean, overweight, class obesity I, and class obesity II-III. The primary outcomes are the prevalence of cirrhosis, CVD, diabetes mellitus (DM), and chronic kidney disease (CKD) among lean versus non-lean patients. We performed a multivariate logistic regression analysis to determine the risk of disease prevalence adjusted for multiple confounders.

Results: Of the 51 452 patients in the cohort, 9.60 % were lean, 23.73 % were overweight, 28.97 % were obese class I, and 37.70 % were obese class II-III. The median age was 52 years with 63.33 % White, 27.96 % Hispanic, 3.45 % Black, 2.31 % Native American/Alaskan, and 0.97 % Asian/Pacific Islander. Prevalence of DM was 25.54 % in lean and 40.06 % in non-lean individuals. In the multivariate analysis, patients who were overweight, obese class I, or obese class II-III patients had lower prevalence peripheral vascular disease, coronary artery disease, cerebrovascular disease, and any CVD compared with lean patients (Figure). Moreover, patients with obesity class II-III had significant higher prevalence of cirrhosis and CKD than lean persons.

Conclusion: In this large cohort of patients with NAFLD, lean persons with NAFLD had higher prevalence of CVD than non-lean persons despite lower prevalence of DM. Intervention to optimize CVD risk is warranted in lean patients with NAFLD.

THU-425

De novo lipogenesis discriminates advanced hepatic fibrosis after an oral glucose load in non-obese subjects with non-alcoholic fatty liver disease

Chiara Rosso[1], Fabrizia Carli[2], Angelo Armandi[1], Samantha Pezzica[2], Patrizia Infelise[2], Francesca Saba[1], Gian Paolo Caviglia[1], Marta Guariglia[1], Nuria Pérez Diaz del Campo[1], Gabriele Castelnuovo[1], Amina Abdulle[1], Maria Lorena Abate[1], Federico Salomone[3], Antonella Olivero[1], Giorgio Maria Saracco[1], Roberto Gambino[1], Amalia Gastaldelli[2], Elisabetta Bugianesi[1]. *[1]University of Turin, Department of Medical Sciences, Italy; [2]Institute of Clinical Physiology, CNR, Pisa, Cardiometabolic Risk Unit, Italy; [3]Azienda Sanitaria Provinciale di Catania, U.O.C. of Gastroenterology, Italy*
E-mail: chiara.rosso@unito.it

Background and aims: Elevated free fatty acid (FFA) flux and hepatic triglycerides (TG) accumulation are prominent features in subjects with non-alcoholic fatty liver disease (NAFLD). De novo lipogenesis (DNL) is up to 3-fold higher in NAFLD compared to healthy controls. Under DNL stimulation, the production of saturated FFAs is increased and leads to oxidative stress, inflammation thus enhancing hepatic fibrogenesis. Here, we used a marker of DNL (DNLi) to evaluate its relationship with hepatic fibrosis in a group of non-diabetic subjects with biopsy-proven NAFLD who underwent an oral glucose load.

Method: We have studied glucose and lipid metabolism during fasting in 45 non-diabetic subjects with biopsy proven NAFLD (35 male; median age 41 years, range: 23–57). Among them, 25 patients underwent a double tracers oral glucose tolerance test (dtOGTT). Tracers (6, 6–2H2-glucose and 2H5-glycerol) were used to assess glucose (endogenous glucose production and glucose clearance [GlucClear]) and lipid metabolism (lipolysis). Throughout the study we measured glucose, insulin (INS), free fatty acids (FFAs) composition, triglyceride (TG), oxidized low density lipoprotein (ox-LDL) and cholesterol profile. DNLi was derived as the ratio palmitic/linoleic acid. The area under the curve (AUC) was calculated for each variable.

Results: Overall, fasting DNLi was associated with BMI ($r = 0.31$, $p = 0.04$), TG levels ($r = 0.29$, $p = 0.05$) and FFAs levels ($r = 0.36$, $p = 0.002$). Among FFAs, DNLi significantly correlated with MUFA and SFA concentration ($r = 0.38$, $p = 0.012$ and $r = 0.54$, $p < 0.001$, respectively). Concerning liver histology, fasting DNLi correlated with the degree of hepatic steatosis ($r = 0.34$, $p = 0.027$) and showed a stepwise

Table (abstract: THU-424).

Abbreviations: CI, confidence interval; OR, odds ratio.
[a]OR adjusted for age, sex, race, smoking status, hypertension, dyslipidemia, DM, and aspirin and statin use.
[b]For Type II DM, OR was adjusted with the same confounders excluding DM.

increased from F0/F1 to F2 to F3/F4 (median values from 1.06 to 1.13 to 1.31, respectively). Throughout the OGTT, the AUC-DNLi inversely correlated with AUC-GluClear (r = –0.45, p = 0.05). During the first 60 min of OGTT, TG levels increased by 8% in subjects with F3-F4 compared to those with F0-F2 (p = 0.09) despite elevated insulin levels, suggesting a significant contribution of DNLi. Accordingly, the AUC-DNLi significantly correlated with AUC-INS, AUC-TG and with the AUC-LDLox (r = 0.47, p = 0.044; r = 0.43, p = 0.05; r = 0.44, p = 0.05, respectively) underlying the contribution of oxidative stress in promoting hepatic fibrogenesis

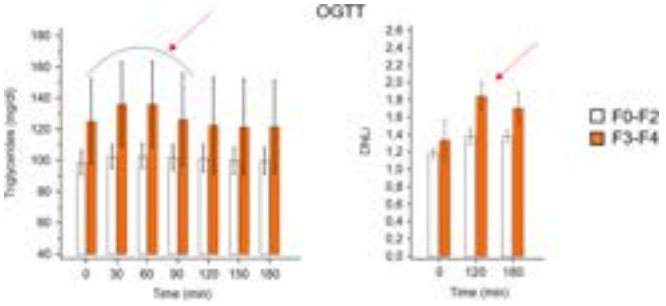

Figure:

Conclusion: Oral glucose load is associated with changes in DNL and hepatic triglyceride synthesis contributing to liver fibrogenesis in patients with NAFLD.

A social media listening study of patients' experiences toward NAFLD (LISTEN-NAFLD)

Jeffrey Lazarus[1,2], William Alazawi[3], Ron Basuroy[4], Laurent Castera[5], Dmitrii Estulin[6], Yiannoula Koulla[7], Preethy Prasad[4], Manuel Romero Gomez[8,9], Vincent Wai-Sun Wong[10], Jörn Schattenberg[11]. *[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain; [2]CUNY Graduate School of Public Health and Health Policy (CUNY SPH), New York, United States; [3]Barts Liver Centre, Blizard Institute, Queen Mary University London, United Kingdom; [4]Novo Nordisk, Copenhagen, Denmark; [5]Hospital Beaujon AP-HP, Paris, France; [6]Novo Nordisk, Zurich, Switzerland; [7]European Liver Patient's Association, Cyprus; [8]Digestive Diseases Department and Ciberehd, Virgen del Rocío University Hospital, Seville, Spain; [9]Institute of Biomedicine of Sevilla (HUVR/CSIC/US), University of Seville, Spain; [10]The Chinese University of Hong Kong, Hong Kong; [11]Metabolic Liver Research Program, Department of Medicine, University Medical Center Mainz, Germany*
E-mail: Jeffrey.Lazarus@isglobal.org

Background and aims: Patients increasingly use social media to share and access health-related information and experiences. Social listening is a mixed-method approach that identifies and assesses what is being said about a topic on social media platforms. This study used social listening to gain patient-centric insights into NAFLD, a liver disease with increasing prevalence and healthcare system burden.

Method: Data from blogs, forums, and social media platforms including Twitter, Facebook, and YouTube were collected using pre-defined keywords through licensed aggregator tools for 8 countries (Brazil, China, France, Germany, Japan, South Korea, Spain, UK), from Nov 2020 to Nov 2022. Manual and automated algorithms were used to filter the dataset, and thematic analysis was used to summarise country-specific data.

Results: Country-specific random samples of data (~10 000 posts for all countries) were manually reviewed to identify a total of 1600 relevant posts for in-depth analysis (balanced for country representation). Patient journey posts (n = 1479) were mainly about ongoing disease management (72%, 1061/1479), diagnosis and tests (50%, 734/1479), and causes and risk factors (36% 534/1479). Dietary changes (55%, 588/1061), exercise (39%, 417/1061) and weight loss methods (25%, 268/1061) were the most frequently discussed management techniques. The key diagnostic tests mentioned were ultrasound (31%, 170/553), blood tests (24%, 130/553) and liver function tests (16%, 91/553). Unhealthy diet (39%, 208/534), overweight/obesity (32%, 169/534) and harmful effects of medication (12%, 65/534) were perceived as the key causes leading to the condition. 12% (192/1600) discussed the impact of the disease on quality of life. Emotional analysis (84%, 1338/1600) revealed patients were worried (20%, 266/1338) and frustrated (19%, 252/1338) about their condition, but they were also hopeful (14%, 186/1338) and determined (20%, 273/1338) to improve their health. In 19% (311/1600) of conversations, an unmet need was highlighted, especially the need to access knowledgeable HCPs (16%, 51/311), driven by European countries. Other needs were better education (25%, 79/311) and management options (13%, 40/311), driven by Asian countries.

Figure:

Conclusion: This social media listening study highlights the experiences of people living with NAFLD, including perceived challenges, coping strategies and unmet needs. Insights from social media can help us improve communication and patient care through education and support.

THU-427

Genetic risk factors for NAFLD and clinically significant fibrosis in persons living with HIV

Eduardo Vilar Gomez[1], Samer Gawrieh[1], Tiebing Liang[1], Jordan Lake[2], Susanna Naggie[3], Tinsay Woreta[4], Jennifer Price[5], Richard Sterling[6], Sonya Heath[7], Holly King[1], Laura Wilson[8], James Tonascia[9], Meena Bansal[10], Kathleen Corey[11], Rohit Loomba[12], Mark S. Sulkowski[13], Naga Chalasani[1]. *[1]Indiana University School of Medicine, Indianapolis, United States; [2]UTHealth Houston (The University of Texas Health Science Center at Houston), Houston, United States; [3]Duke Clinical Research Institute, Durham, United States; [4]Johns Hopkins Hospital, Baltimore, United States; [5]University of California San Francisco Parnassus Campus, San Francisco, United States; [6]Virginia Commonwealth University, Richmond, United States; [7]University of Alabama at Birmingham, Birmingham, United States; [8]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States; [9]Johns Hopkins University, Baltimore, United States; [10]Icahn School of Medicine at Mount Sinai, New York, United States; [11]Harvard Medical School, Boston, United States; [12]Medical Center, San Diego, United States; [13]The Johns Hopkins Hospital, Baltimore, United States*
E-mail: nchalasa@iu.edu

Background and aims: The role of genetic risk variants in modulating the risk and severity of NAFLD has been extensively studied in general populations but not in persons with HIV (PWH) with NAFLD (HIV-NAFLD). We investigated the associations between candidate gene variants and risk of HIV-NAFLD and clinically significant fibrosis (CSF) in PWH.

Method: PWH prospectively enrolled in US multicenter studies underwent detailed phenotyping including VCTE for controlled attenuation parameter (CAP) and liver stiffness measurement (LSM). Participants with history of excessive alcohol use or other

Figure: (abstract: THU-427): Association of genetic variants with NAFLD or CSF. Results based on logistic univariate and multivariable[a] analysis.

	NAFLD				CSF			
	Univariate		Multivariable[a]		Univariate		Multivariable[a]	
	OR (95% CI)	P value	OR (95% CI)	P value	OR (95% CI)	P value	OR (95% CI)	P value
PNPLA3 rs738409	1.7 (1.2–2.3)	<0.01	1.7 (1.2–2.5)	<0.01	1.8 (1.1–3.0)	0.02	1.9 (1.01–3.5)	0.04
TM6SF2 rs58542926	1.5 (0.8–3.1)	0.22	2.1 (1.0–4.6)	0.04	0.3 (0.05–2.6)	0.30	-	-
HSD17B13 rs72613567	1.1 (0.8–1.7)	0.51	-	-	0.7 (0.3–1.6)	0.37	-	-
MBOAT7 rs641738	1.1 (0.8–1.5)	0.58	-	-	2.7 (1.6–4.6)	<0.01	2.8 (1.6–5.1)	<0.01
HFEC282Y rs1800562	1.9 (0.8–4.5)	0.13	-	-	1.1 (0.2–4.8)	0.92	-	-
ADH1B rs1229984	0.8 (0.4–1.8)	0.67	-	-	0.9 (0.2–3.7)	0.90	-	-
GCKR rs1260326	1.4 (1.1–1.9)	0.01	1.5 (1.03–2.1)	0.03	1.1 (0.6–1.9)	0.69	-	-
FKBP5 rs3800373	0.7 (0.5–0.9)	0.04	0.8 (0.6–0.9)	0.05	0.5 (0.3–0.9)	0.02	0.6 (0.3–0.9)	0.04

[a]Covariate-adjusted analysis included age, sex, race/ethnicity, diabetes, and hypertension. All genetic variants were simultaneously included in the multivariable analysis.

liver diseases were excluded. CAP was assessed on a continuous scale and ≥285 dB/m to define steatosis. LSM was assessed on a continuous scale and ≥9.7 kPa to define CSF. The PNPLA3 rs738409, TM6SF2 rs58542926, HSD17B13 rs72613567, MBOAT7-TMC4 rs641738, HFEC282Y rs1800562, ADH1B rs1229984, GCKR rs1260326, FKBP5 rs3800373 were genotyped by TaqMan assay. Associations between CAP and LSM and genetic variants were analyzed with linear and logistic regression models.

Results: 396 participants were evaluated: age 50 years, male 74%, White 28%, Black 44%, Hispanic 24%, BMI 30 kg/m^2, 41% with NAFLD and 8% with CSF. PWH and NAFLD, compared to those without NAFLD, more frequently were White and Hispanic, had hypertension, diabetes, and higher BMI, waist circumference, triglycerides, ALT, and CD4+ cells, higher frequency of PNPLA3 GG (15% vs 4%), GCKR TT (16% vs 8%), and lower frequency of FKBP5 AC/CC (55% vs 67%) ($p < 0.05$ for all). Other HIV-related factors such as duration and level of HIV were not significantly different between the two groups. Variants in PNPLA3, TM6SF2, MBOAT7-TMC4, and GCKR were independently associated with higher whereas FKBP5 with lower odds of NAFLD (Table). PWH with CSF vs those without CSF had higher frequency of PNPLA3 GG (22% vs 7%) and MBOAT7-TMC4 TT (41% vs 11%), and lower frequency of FKBP5 AC/CC (44% vs 62%) ($p < 0.05$ for all). PWH and CSF vs those without CSF had higher frequency of metabolic condition but not HIV-related factors. On multivariable analysis, variants in PNPLA3, and MBOAT7-TMC4 were associated with higher whereas FKBP5 with lower odds of CSF (Table).

Association of genetic variants with NAFLD or CSF. Results based on logistic univariate and multivariable [a] analysis.

Conclusion: Several genetic variants influence risk of NAFLD and CSF in PWH. A novel variant in FKBP5 was protective against NAFLD and clinically significant fibrosis in PWH. Genetic and metabolic but not HIV viral factors are key modifiers of HIV-NAFLD disease risk and severity.

THU-428

Digital pathology with artificial intelligence analyses provides deeper insights into lifestyle intervention-induced fibrosis regression in NASH

Haiyang Yuan[1], Yayun Ren[2], Yangyang Li[3], Xinlei Wang[2], Sui-Dan Chen[3], Xiao-Zhi Jin[1], Fa-Ling Wu[1], Xiao-Yan Pan[4], Wen-Yue Liu[4], Xiaodong Wang[5], Ming-Hua Zheng[1,5]. *[1]the First Affiliated Hospital of Wenzhou Medical University, MAFLD Research Center, Department of Hepatology, China; [2]HistoIndex Pte Ltd, Singapore; [3]the First Affiliated Hospital of Wenzhou Medical University, Department of Pathology, China; [4]the First Affiliated Hospital of Wenzhou Medical University, Department of Endocrinology, China; [5]Key Laboratory of Diagnosis and Treatment for the Development of Chronic Liver Disease in Zhejiang Province, China*

E-mail: zhengmh@wmu.edu.cn

Background and aims: Lifestyle intervention is the basic treatment for non-alcoholic steatohepatitis (NASH) and liver fibrosis is a crucial determinant of clinical outcome in this condition. The second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy with artificial intelligence analyses can provide automated quantitative assessment of fibrosis features on a continuous scale, called qFibrosis. We used this approach to gain insight into the impact of lifestyle intervention intensity on fibrosis in NASH.

Method: Unstained sections from 72 liver biopsies (paired: baseline and end-of-treatment) from 36 NASH patients who received routine lifestyle intervention (RLI, n = 24) or strengthen lifestyle intervention (SLI, n = 12) were examined. Fibrosis regression was determined by pathological reading. Liver fibrosis (qFibrosis) were quantified by SHG/TPEF microscopy. Collagen parameters were quantified from the five regions, including portal tract (PT), peri-PT, Zone 2, central vein (CV) and peri-CV, which were identified from the SHG/TPEF images.

Results: 21% (5/24) and 50% (6/12) of patients had fibrosis regression for RLI group and SLI group, respectively. 50% of patients had fibrosis no change for both RLI and SLI groups. Numerical analysis showed that fibrosis progression tended to no change or regression in NASH patients after lifestyle interventions, and this phenomenon was more pronounced in the SLI group. Among the patients with fibrosis regression, compared with the RLI group, the fibrosis index of SLI group was reduced more ($p < 0.001$) in the PT, peri-CV and CV regions, but increased more ($p < 0.001$) in zone 2 region. In patients with no change in the fibrosis outcome of conventional pathology, we found a more significant regression in zone 2 region in the SLI group than the RLI group.

Table: Average relative difference of parameters in different regions between RLI group and SLI group in regression patients and no change patients.

	Regression patients			No change patients		
Region	RLI (n = 5)	SLI (n = 6)	p value	RLI (n = 12)	SLI (n = 6)	p value
PT	73%	−32%	<0.001	30%	31%	0.452
Peri-PT	13%	−4%	0.053	−31%	1%	<0.001
Zone 2	−17%	18%	<0.001	−14%	−30%	<0.001
Peri-CV	97%	−81%	<0.001	65%	99%	<0.001
CV	84%	−78%	<0.001	92%	79%	0.063

Conclusion: With enhanced lifestyle intervention, we can see a more pronounced regression of fibrosis, mainly in the portal and central vein segments for the regression patients. Digital pathology provides new insights into lifestyle intervention-induced fibrosis regression, which are not captured by current staging systems.

THU-429

Societal costs and labor market affiliation of histologically confirmed non-alcoholic steatohepatitis-a Danish register-based study

Jan Håkon Rudolfsen[1], Lise Lotte Gluud[2], Henning Grønbæk[3,4], Majken Jensen[5], Mogens Vyberg[6,7], Jens Olsen[1], Peter Bo Poulsen[8], Nanna Hovelsø[9], Nikolaj Gregersen[9], Anne Bloch Thomsen[9], Peter Jepsen[3,4]. *[1]Incentive, Holte, Denmark; [2]Copenhagen University Hospital Hvidovre, Gastro Unit, Copenhagen, Denmark; [3]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Denmark; [4]University of Aarhus, Department of Clinical Medicine, Aarhus, Denmark; [5]University of Copenhagen, Department of Public Health, Section of Epidemiology, Copenhagen, Denmark; [6]Aalborg University Campus Copenhagen, Department of Clinical Medicine, Aalborg, Denmark; [7]Copenhagen University Hvidovre, Department of Pathology, Copenhagen, Denmark; [8]Pfizer Denmark Aps, Health and Value, Ballerup, Denmark; [9]Pfizer Denmark Aps, Medical Affairs, Ballerup, Denmark*
E-mail: peterbo.poulsen@pfizer.com

Background and aims: Non-alcoholic steatohepatitis (NASH) is associated with increased risk of cirrhosis, hepatocellular carcinoma, cardiovascular diseases and type 2 diabetes. Evidence on the burden of disease of NASH is limited. This population-based register study examines the healthcare costs, use of healthcare services, labor market affiliation and survival of NASH patients compared to individuals without liver disease.
Method: Patients with biopsy-confirmed NASH and corresponding hospital-diagnosed liver disease from 1997 to 2021 were identified in the Danish National Pathology Register and the Danish National Patient Register. Patients were matched 1:5 with liver disease-free comparators. Outcomes were costs associated with healthcare services, contacts with hospital care, use of home care services, production loss measured by wage differences (NASH patients vs. comparators), incidence of long-term sick leave, weeks of unemployment, early retirement, and survival. All outcomes were estimated based on data from national Danish registers. Patients were followed for 16 years-five years before and 11 years after diagnosis. Excess costs of NASH were calculated as the difference in mean costs for the NASH group and the comparators.
Results: 1039 NASH patients were identified (total population in Denmark (2021): 5 840 000). In the year leading up to diagnosis, a NASH patient generated €6318 in excess costs of healthcare services on average, and total costs in that year were 4.1 times higher than for the average comparator. Within a 10-year window, starting a year before diagnosis, the corresponding excess costs of NASH was €41 998 (2.9 times higher than the comparators) and with 4.4-fold (95% CI 3.18–6.06) higher hazard of early retirement. The NASH patients had significantly lower income than comparators from five year before start of study until nine years after diagnosis (t-test, $p < 0.05$), and 2.4-fold (95% CI 1.80–3.25) higher mortality hazard than comparators.
Conclusion: There are substantial excess societal costs associated with NASH. Patients exit the labour market earlier and have higher mortality than their comparators without liver disease.

THU-430

Prevalence and mortality of non-alcoholic fatty liver disease (NAFLD) in non-diabetics, pre-diabetics, and diabetics in the United States

James Paik[1,1,2], Ameeta Kumar[3], Reem Al-Shabeeb[3], Katherine Eberly[3], Nagashree Gundu Rao[2,4], Zobair Younossi[1,2,3]. *[1]Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States; [2]Inova Health System, Inova Medicine, Falls Church, United States; [3]Inova Fairfax Medical Campus, Center for Liver Disease, Department of Medicine, Falls Church, United States; [4]Inova Health System, Division of Endocrinology, Inova Medicine Services, Falls Church, United States*
E-mail: zobair.younossi@inova.org

Background and aims: Type 2 diabetes (T2D) with NAFLD is associated with adverse outcomes. Lacking is knowledge on the prevalence and outcomes of NAFLD among pre-diabetics (Pre-D) and non-diabetics (ND) which we have assessed here.
Method: NHANES III and mortality data (thru 2019) via National death index were used. NAFLD was defined by ultrasound, absence of other liver diseases, and excess alcohol use. Pre-D was defined as fasting glucose of 100–125 mg/dL or HbA1c level of 5.7%–6.4% without T2D. ND was defined as not having T2D or Pre-D. Metabolically healthy (MH) was defined if all following criteria were absent: waist circumference of ≥102 cm (men) or ≥88 cm (women); blood pressure (BP) ≥130/85 mm Hg or using BP-lowering

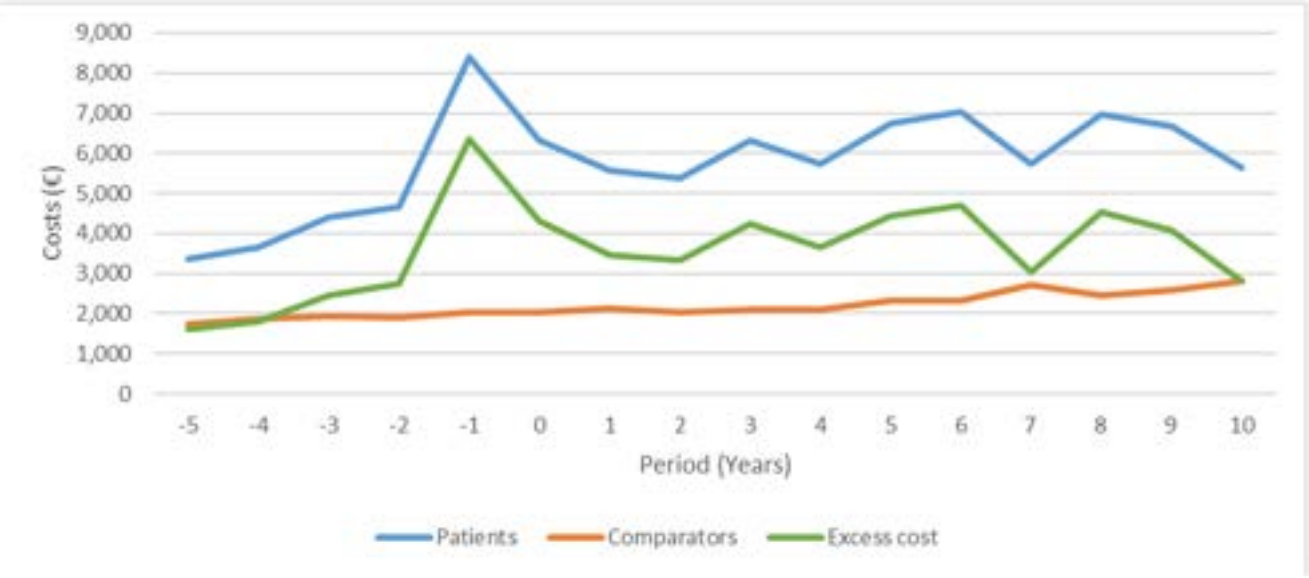

Figure: (abstract: THU-429): Annual total costs healthcare services (hospital care, primary care, prescription medication and home care) for NASH patients and a matched group of liver disease-free comparators. Period 0 start at date of diagnosis; period length was one year. Excess costs are the difference in costs between NASH patients and the comparators

Table: (abstract: THU-430): Factors Associated with Mortality Among NAFLD subjects, Stratified by Diabetes group

	ND with MH HR (95% CI)	ND without MH HR (95% CI)	Prediabetics HR (95% CI)	T2D HR (95% CI)
Hypertension	NA	1.38 (0.90–2.13)	**1.44 (1.08–1.90)**	1.40 (0.82–2.37)

medication; triglyceride ≥150 mg/dL or using lipid-lowering medication; cholesterol level of <40 mg/dL (men) or <50 mg/dL (women); homeostasis model assessment of insulin resistance score ≥2.5; C-reactive protein level of >2 mg/L. Cause-specific competing risk mortality analyses were performed.

Results: Among 11 231 adults (mean age 43.4 years; 43.9% male; 18.9% NAFLD; 6.9% T2D; 25.2% Pre-D; 44.3% ND without MH; and 23.6% ND with MH). Age-standardized NAFLD prevalence among T2D, Pre-D, ND without MH and ND with MH were 40.9%, 23.8%, 19.2% and 5.1%. During mean follow-up of 24.6 years, 3982 died. Age-standardized mortality was higher in NAFLD than in non-NAFLD (32.7% vs. 28.7%, p < .001). Among NAFLD subjects, the highest age-standardized mortality was T2D (43.9%), then Pre-D (34.9%), ND without MH (29.9%), and ND with MH (22.0%) (pairwise p values<.04 vs. ND with MH). Multivariable cox models showed that compared to NAFLD without T2D or Pred-D but with metabolic health, NAFLD with T2D had the highest risk of all-cause and cardiac-specific mortality { ([HR] = 4.79 [95% CI: 2.23–10.24] and HR = 17.41 [3.27–92.6])}, followed by NAFLD with Pre-D { (HR = 2.93 [1.43–6.01] and HR = 9.21 [1.78–47.77])} and then NAFLD without T2D or Pred-D and without metabolic health { (HR = 2.60 [1.27–5.31] and HR = 5.81 [1.07–31.69])}. Independent predictors of mortality varied by groups (Table).

Conclusion: Presence of T2D or Pre-D increased the prevalence and adverse outcomes of subjects with NAFLD.

THU-431

Genetic and metabolic characteristics of lean non-alcoholic fatty liver disease in Asian

Huiyul Park[1], Eileen Yoon[2], Sang Bong Ahn[3], Hye-Lin Kim[4], Jun-Hyuk Lee[5], Mimi Kim[6], Chul-min Lee[6], Bo-Kyeong Kang[6], Joo Hyun Sohn[2], Jihyun An[2], Joo Hyun Oh[3], Hyo Young Lee[7], Hyunwoo Oh[7], Jang Han Jung[8], Dae Won Jun[2], Eun Chul Jang[9].

E-mail: noshin@hanyang.ac.kr

Background and aims: The pathophysiology of lean non-alcoholic fatty liver disease (NAFLD) remains unclear and is associated to have more diverse pathogenic mechanisms than obese NAFLD. We aimed to investigate the characteristics of genetic- or metabolic-associated lean NAFLD in a community-based cohort.

Method: A total of 10 345 health check-up participants enrolled. Lean individuals were categorized according to the body mass index cut-off of 23 kg/m^2. Single nucleotide polymorphism was analyzed using Genotyping Arrays. Anthropometric measurements of waist circumference, total fat mass, and lean mass were included.

Results: The prevalence of lean NAFLD was 21.6% among total NAFLD subjects, and proportion of lean NAFLD was 18.5% in lean subjects (<23 kg/m^2). Prevalence of metabolic syndrome and diabetes among lean NAFLD was 12.4% and 10.4%, respectively. Around 20.1% of lean NAFLD seems to be associated with metabolic-associated. Homozygous minor allele (GG) of PNPLA3 (rs738409) and heterozygous minor allele (CT, TT) of TM6SF2 (rs58542926) associated with lean NAFLD. However, the prevalence of fatty liver was not associated with the genetic variants of MBOAT7 (rs641738), HSD17B13 (rs72613567), MARC1 (rs2642438), or AGXT2 (rs2291702) in lean individuals. Around 32.1% of lean NAFLD seems to be associated with PNPLA3 or TM6SF2 genetic variation. Multivariable risk factor analysis showed that the metabolic risk factors, genetic risk variants, and waist circumference were independent risk factor for lean NAFLD.

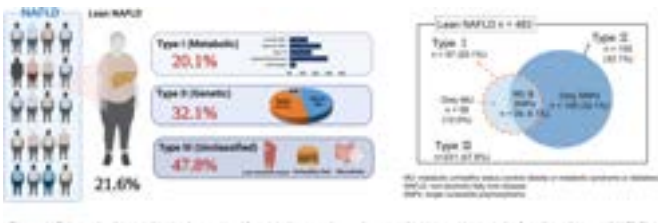

Figure:

Conclusion: Further studies on risk factors beyond central obesity, metabolic syndrome, and genetic risk factors are needed to understanding the pathogenesis of lean NAFLD.

THU-432

PNPLA3 protein levels are increased in liver and decreased in adipose tissue from patients with obesity-associated non-alcoholic steatohepatitis

Helena Castañé[1,2], Andrea Jiménez Franco[1,2], Cristian Martínez Navidad[2], Cristina Placed[1], Jordi Camps Andreu[3], Jorge Joven Maried[3]. [1]*Universitat Rovira i Virgili, Unitat de Recerca Biomèdica, Reus, Spain;* [2]*Fundació IISPV, Unitat de Recerca Biomèdica, Reus, Spain;* [3]*Hospital Universitari Sant Joan, Unitat de Recerca Biomèdica, Reus, Spain*
E-mail: helena.castanev@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most prevalent form of chronic liver disease, affecting 25% of the population. It can progress to non-alcoholic steatohepatitis (NASH), a severe condition characterized by fibrosis, that can lead to cirrhosis, and even liver cancer, requiring a liver transplant. Accurate diagnosis of NAFLD/NASH progression requires a liver biopsy, and there is currently no effective drug treatment. PNPLA3 (patatin-like phospholipase domain-containing 3), an enzyme involved in lipid metabolism, is one of the protein genes linked to NAFLD. The expression of PNPLA3 is associated with NAFLD, and its accumulation leads to larger lipid droplets, a hallmark of NASH steatosis. Finding new targets to halt NAFLD progression is crucial, and PNPLA3 may be a promising candidate, however its role is unknown in other tissues. This study aimed to compare PNPLA3 protein levels in different tissues from patients with and without NASH, including liver, subcutaneous adipose tissue (SAT), and visceral adipose tissue (VAT).
Method: Samples included liver, SAT, and VAT from n = 98 patients with morbid obesity candidates to receive bariatric surgery. During the procedure, tissue biopsies were performed, from which we performed histological analyses, protein extraction and subsequent western blot to explore PNPLA3 protein levels. Semi-targeted lipidomics was performed to quantify the concentration of triglycerides and glycerophospholipids.
Results: We found significative differences in PNPLA3 protein levels in the liver samples of NASH patients compared to those without NASH (Figure A). Also, patients with NASH showed a more prominent expression around the fibrotic areas (Figure B; a: fibrosis, b: PNPLA3 protein shown by immunohistochemistry). Lipid content was significantly higher in the hepatic tissue from patients with NASH (Figure C), triglycerides were significantly increased, meanwhile glycerophospholipids were significantly decreased. Adipose tissue levels of PNPLA3 protein were not significantly different between the studied groups (Figure D), nor the distribution among the tissue (Figure E; a: fibrosis shown by Masson's Trichrome, b: PNPLA3 immunohistochemistry in adipose tissue). On the other side, lipid content in VAT was significantly different between NASH and non-NASH patients, meanwhile in SAT there were no differences in total lipid content between NASH and non-NASH patients (Figure D).

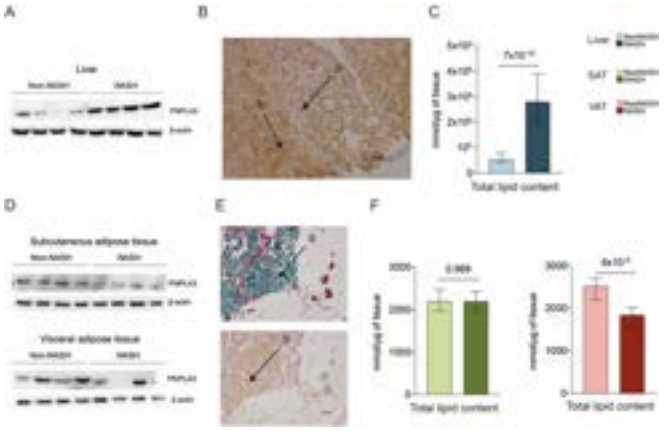

Figure:

Conclusion: PNPLA3 protein levels were significantly increased in the hepatic tissue of patients with NASH and was present in higher quantities around areas of fibrosis. This was correlated with an increased total lipid content. In contrast, no significant differences in PNPLA3 protein levels or localization were observed in adipose tissue between NASH and non-NASH patients, however lipid content in VAT was significantly decreased in NASH patients.

Background and aims: *PNPLA3* rs738409 has been associated with an increased risk of liver-related events in patients with non-alcoholic fatty liver disease (NAFLD). In this study, we investigated the epidemiology of NAFLD and the impact of *PNPLA3* on prognosis in Japan.
Method: A longitudinal multicenter cohort study, the JAGUAR study, includes 1550 patients with biopsy-proven NAFLD in Japan. We performed genetic testing and evaluated outcomes from this cohort. Liver-related events were defined as hepatocellular carcinoma (HCC) and decompensated liver cirrhosis events.
Results: During follow-up (median [range], 7.1 [1.0–24.0] years), 80 patients developed HCC, 104 developed liver-related events, and 59 died of any cause. The 5-year rate of liver-related events for each single-nucleotide polymorphism was 0.5% for CC, 3.8% for CG, and 5.8% for GG. Liver-related deaths were most common (n = 28); only 3 deaths were due to cardiovascular disease. Multivariate analysis identified carriage of PNPLA3 CG/GG (hazard ratio [HR] 16.04, p = 0.006) and FIB-4 index >2.67 (HR 10.70, p < 0.01) as predictors of liver-related event development. No HCC or liver-related death was found among patients with PNPLA3 CC. There was a significantly increased risk of HCC, liver-related events, and mortality for CG/GG versus CC, but no difference between the CG and GG genotypes.

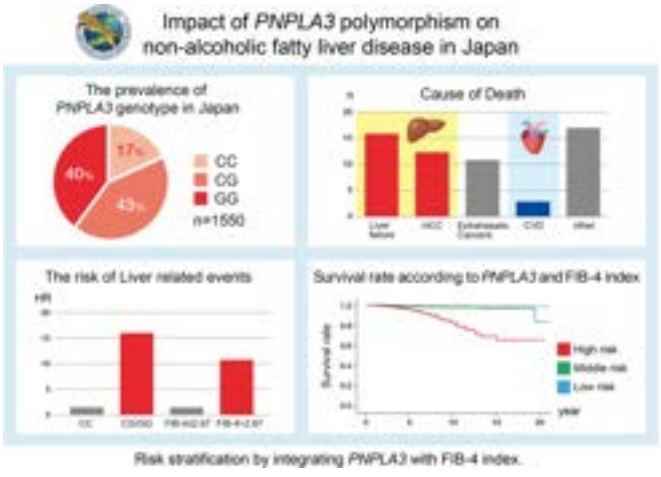

Figure:

Conclusion: In Japanese individuals, the main cause of death from NAFLD is liver-related death. The increased risks of liver-related events incurred by PNPLA3 CG and GG are comparable and

significantly different from the low risk identified with CC. Risk stratification for NAFLD in Japan is best accomplished by integrating PNPLA3 with the FIB-4 index.

THU-434

Pilot results for a multidisciplinary community metabolic liver clinic

Theresa Hydes[1,2], Cyril Sieberhagen[2], Mike Merrimen[3], Louise Millard[3], David Riley[1], Daniel Cuthbertson[1,2]. *[1]University of Liverpool, United Kingdom; [2]Liverpool University NHS Hospitals Foundation Trust, United Kingdom; [3]Millbrook Medical Centre, United Kingdom*
E-mail: therasa@doctors.org.uk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) affects over 1 in 4 people in the UK, with an increased prevalence in areas of deprivation. Most patients with NAFLD do not have significant liver fibrosis and are best managed in the community. Thorough screening and optimisation of cardiometabolic disease is vital, as metabolic disease increases the risk of liver fibrosis and hepatocellular carcinoma, and NAFLD is associated with increased risk of diabetes, chronic kidney disease and cardiovascular disease. We aimed to pilot a community metabolic liver clinic in an area of high deprivation to examine feasibility, burden of undetected disease and the potential for meaningful intervention (lifestyle/pharmacological).

Method: Four pilot clinics ran in a large primary care centre in the Northwest of England October-November 2022. Adults who had type 2 diabetes or a body mass index >25 (without a prior diagnosis of cirrhosis or another cause of chronic liver disease), were invited via text message to book a clinic appointment and attend for bloods. The clinic proforma was designed by a multidisciplinary team (general practitioners/hepatologists/diabetologists/patients) informed by national guidelines, consisting of an assessment (history/anthropometrics/fibroscan/review of bloods) and management section (education/lifestyle/pharmacological). Personalised written feedback using traffic light systems and lifestyle recommendations were integrated into the proforma which was uploaded to the primary care electronic medical records and shared with each patient. Any complex cases were reviewed in a virtual multi-disciplinary team meeting.

Results: Of 24 patients booked in, 19 attended (79.2%). The clinic took 30 minutes including administration time. There was a high burden of known underlying cardiometabolic disease (table 1). In total 73.7% of individuals had a controlled attenuation parameter score >275 dB/m and 31.6% of individuals had a fibroscan score of ≥8 kPa at which point a full liver screen was requested and referral to secondary care was made. The clinic generated the following outputs: (i) Lifestyle intervention: brief alcohol intervention 15.8%; smoking cessation advice 5.3%, referral to community lifestyle hub (free pass to leisure centre/weight management class) offered and accepted by patient 26.3%; (ii) Onward referral: diabetes secondary care clinic 5.3%, hepatology secondary care clinic 31.6%, health care assistant clinic for management of newly diagnosed hypertension 15.8%, or poorly controlled hypertension 42.1%, enhanced weight management services 10.5%; (iii) Pharmacological intervention: escalation of glucose-lowering therapy 57.9%; statin initiation or dose titration 10.5%. Written feedback from patients identified that all patients thought the clinic was useful, 100% said the clinic and written information helped them better understand their results and health conditions and 93% said the clinic and written information would prompt lifestyle changes.

Demographics	
Age (yrs.), median (range)	67 (38-85)
Gender (male), %	42.1
Highest two deciles nationally for multiple deprivation, %	78.9
Audit C score (alcohol) ≥ 8, %	15.8
Metabolic disease	
Body mass index > 25kg/m², %	78.9
Body mass index > 30kg/m², %	63.2
Waist circumference men > 102cm, women > 88cm, %	94.4
Known diagnosis diabetes, %	94.7
HbA1c >48mmol/ml, %	72.2
Known diagnosis of hypertension, %	73.7
Triglycerides >150mg/dl, %	47.4
Cardiorenal morbidity	
Acute coronary syndrome/peripheral vascular disease/stroke, %	47.4
QRISK#2 > 10, or prior acute coronary syndrome, %	94.7
Known chronic kidney disease, %	10.5
Urine albumin creatinine ratio > 3mg/mol, %	26.3

Figure: Table 1. Baseline status of participants

Conclusion: A thorough cardiometabolic assessment for patients with, and at risk of NAFLD, can be performed within 30 minutes in a primary care setting and generates high levels of intervention which is likely to impact future clinical outcomes. A combined form for medical assessment and personalised feedback of individual risk and management is associated with high levels of patient satisfaction.

THU-435

Influence of chronotype and adherence to the mediterranean diet on the risk of liver fibrosis in patients with non-alcoholic fatty liver disease

Gabriele Castelnuovo[1], Gian Paolo Caviglia[1], Chiara Rosso[1], Nuria Pérez Diaz del Campo[1], Angelo Armandi[1,2], Marta Guariglia[1], Amina Abdulle[1], Daphne D'Amato[1], Kamela Gjini[1], Irene Poggiolini[1], Antonella Olivero[1], Maria Lorena Abate[1], Giorgio Maria Saracco[1,3], Elisabetta Bugianesi[1,3]. *[1]University of Turin, Department of Medical Sciences, Turin, Italy; [2]University Medical Center of the Johannes Gutenberg-University, I. Department of Medicine, Mainz, Germany; [3]Città della Salute e della Scienza-Molinette Hospital, Gastroenterology Unit, Turin, Italy*
E-mail: gabriele.castelnuovo@unito.it

Background and aims: Late chronotype, i.e. an individual's aptitude to perform daily activities late in the day, has been associated with low adherence to the mediterranean diet (MedDiet) and metabolic syndrome. The aim of this work was to investigate the potential association between chronotype and adherence to MedDiet with the risk of significant (F≥2) and severe (F≥3) liver fibrosis in individuals with non-alcoholic fatty liver disease (NAFLD).

Method: A total of 156 patients with a diagnosis of NAFLD by ultrasound were consecutively enrolled. All patients underwent liver stiffness measurement (FibroScan ® 530). F≥2 and F≥3 were defined by liver stiffness values ≥7.1 kPa and ≥8.8 kPa, respectively. The chronotype (MSFsc) was defined by the Munich Chronotype Questionnaire (MCTQ) as the mid-sleep on free days (MSF) corrected for sleep debt on working days, and was expressed as h:min. To carry out the analyses, we defined early, intermediate and late chronotype by splitting the MSFsc into tertiles, evaluating the effect of tertile one versus tertile two + three. In addition, mid-sleep on workdays (MSW) was recorded. The adherence to the MedDiet was assessed by the mediterranean diet score (MDS).

Results: Median age was 52 (43–62) years; 60.8 % of participants were male. Median body mass index (BMI) was 29.5 (26–32.5) kg/m^2. The principal comorbidities were type-2 diabetes mellitus (T2DM) (n = 38; 24.3 %), arterial hypertension (n = 79; 50.6 %), dyslipidemia (n = 99; 63.4 %), obstructive sleep apnea (OSAS) (n = 8; 5.1%) and depression (n = 7; 4.4 %). Overall, 22 (13.9 %) patients had F≥2, while 15 (9.5 %) had F≥3. Most subjects (67.9 %) had intermediate or

late chronotype and showed higher MSF (p < 0.001) and MSW (p < 0.001) compared to those with early chronotype. Remarkably, at logistic regression analysis adjusted for MDS, sex, age, BMI, T2DM, OSAS, arterial hypertension, dyslipidemia, and depression, only intermediate+late chronotype (OR = 6.8, 95 % CI 1.3–35.3, p = 0.022), MDS (OR = 0.7, 95 % CI 0.5–0.9, p = 0.025) and T2DM (OR = 6.4, 95 % CI 1.9–20.9, p = 0.002) resulted significantly and independently associated to F≥2. Similarly, in a logistic regression model adjusted for the same variables, only intermediate + late chronotype (OR = 20.4, 95 % CI 1.4–282.9, p = 0.024), MDS (OR = 0.6, 95 % CI 0.4–0.9, p = 0.015) and T2DM (OR = 20.2, 95 % CI 3.9–102.4, p < 0.001) resulted significantly and independently associated to F≥3.

Conclusion: We observed that intermediate/late chronotype and low adherence to MedDiet were associated with both significant and severe liver fibrosis in patients with NAFLD. Future research is needed to better understand the multidisciplinary management of this complex disease.

Italian Ministry for Education, University and Research (MIUR) under the programme "Dipartimenti di Eccellenza 2018–2022" Project code D15D18000410001.

THU-436

Relationship of hepcidin levels to metabolic factors, anthropometric indicators of adiposity and disease severity in NAFLD patients

Claudia Cravo[1], Cristiane Villela-Nogueira[1], Ana Carolina Cardoso[1], Fernanda Calçado[1], Guilherme Rezende[1], Frederico Campos Ferreira[2], Joao Marcello de Araujo Neto[1], Jorge Eduardo Pinto[1,2], Henrique Sergio Coelho[1,3], Renata Perez[1,4], Nathalie Leite[1].

E-mail: nathaliecleite@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) affects approximately 25% of the world's western population. Both iron and lipid metabolism seem to play a role in NAFLD pathogenesis. We aimed to investigate the association between hepcidin levels, ferritin levels and iron overload with body composition indices, metabolic risk factors and the presence of NASH with significant fibrosis (F≥2).

Method: It was a cross-sectional study in a cohort of patients with NAFLD in the outpatient clinic of our tertiary-care University Hospital. All participants gave written informed consent, and the local Ethics Committee had previously approved the study protocol. Inclusion criteria were patients aged between 18 and 70 years, with an ultrasound diagnosis of NAFLD who agreed to undergo percutaneous liver biopsy. Exclusion criteria were NAFLD patients with other etiologies of chronic liver disease, acute or chronic inflammatory diseases, chronic anemia, kidney disease, hemochromatosis, patients using parenteral iron and those with malignant neoplasms. All patients were evaluated by a standard protocol that included anthropometric indices, clinical and laboratory data. Percutaneous liver biopsy was analyzed by an experienced hepatopathologist. Steatohepatitis was defined by NASH-CRN system and iron was graded according to the Scheuer's classification. A multivariate logistic regression analysis was carried on to investigate if hepcidin levels, ferritin levels and iron overload were independently associated with active NASH (NAS≥4) and significant fibrosis (F≥2).

Results: 162 patients were included (73% female (F), age 54 ± 9 y): 78% had type 2 diabetes (T2DM), 66% were obese. Both hepcidin and ferritin levels varied according to gender (F:18.9 vs M: 31.8 p = 0.001; F:131 vs M:280 p < 0.001) and to different anthropometric indicators of adiposity. Higher hepcidin and ferritin levels were found in participants with elevated neck circumference and body adiposity index, whereas lower levels of both iron regulators were found in those with the highest values of visceral adiposity index (VAI). T2DM was the only metabolic risk factor significantly associated with lower hepcidin levels (20.1 vs. 34.3; p = 0.007). On liver biopsy, 24% had NASH (NAS≥4) and significant fibrosis (F≥2); 19% had siderosis. Patients with NASH with F≥2 were less likely to have obesity (51% vs. 71%; p = 0.025) but had higher baseline levels of HbA1c (7.6 vs. 6.6; p = 0.018) and liver enzymes (AST: 31 vs. 25; p = 0.031; ALT 51 vs. 41; p = 0.05; GGT 62 vs. 46; p = 0.001). Regarding iron parameters, those patients with NASH and F ≥2 had significant lower hepcidin levels (18.7 vs 25.4; p = 0.039). On multivariate logistic regression, hepcidin levels were independently associated with NASH with F≥2 (OR: 0.975; 95% CI: 0.955–0.996. p = 0.020) in models hierarchically-adjusted for ferritin levels, iron overload on liver biopsy, age, gender, BMI, diagnosis of arterial hypertension or type 2 diabetes, liver enzymes and parameters of lipid profile and glycemic control.

Conclusion: Our results suggest an association of active and progressing NASH with lower hepcidin levels. There is no association between NAFLD severity with other iron laboratory and histologic parameters. Lower levels of hepcidin are also found in participants with T2DM and those with the highest values of VAI, which, through the mechanisms of insulin resistance and ectopic fat deposition, play an important role in the NAFLD development and progression.

Impairment of health-related quality of life among people with type 2 diabetes and advanced fibrosis

Maurice Michel[1], Michelle Doll[1], Angelo Armandi[1], Christian Labenz[1], Peter Galle[1], Jörn Schattenberg[1]. *[1]Metabolic Liver Research Program, I. Department of Medicine, University Medical Center Mainz, Mainz, Germany*
E-mail: maurice.michel@unimedizin-mainz.de

Background and aims: People living with type 2 diabetes mellitus (T2DM) show a high prevalence of non-alcoholic fatty liver disease (NAFLD) and hepatic fibrosis. Their health-related quality of life (HRQL) is affected by multiple in part overlapping factors and aggravated by metabolic comorbidities and fibrosis stage. However, the association of advanced fibrosis (AF) and HRQL in people with T2DM in secondary care remains poorly established. Therefore, the aim of this prospective study was to investigate the effect of AF on the HRQL in people with T2DM.

Method: A total of 149 individuals with T2DM treated at a secondary care diabetes outpatient clinic within the German disease management program (DMP) were included in the final analysis. Vibration-controlled transient elastography (VCTE) was used to non-invasively define hepatic steatosis (HS) and AF. A controlled attenuation parameter (CAP) of ≥275 dB/m and a liver stiffness measurement (LSM) of ≥12 kPa were used to define HS and AF, respectively. The EQ-5D-3L questionnaire was used to assess HRQL. This questionnaire contains five dimensions, and a visual analogue scale (VAS). Using country-specific value sets, an index value (time trade-off, TTO), that summarises overall HRQL, was obtained. Uni- and multivariable linear regression models were used to identify independent clinical predictors of impaired HRQL (VAS, TTO).

Results: The majority of this cohort was male (63.1%) and the median age was 67 (IQR 59; 71). The prevalence of HS and AF was 77.9% (n = 116) and 12.8% (n = 29), respectively. The majority of these individuals were identified to have NAFLD (n = 104, 89.7%). The mean VAS and TTO index scores in the entire cohort were 71.9 ± 18.4 and 0.85 ± 0.21, respectively. People with T2DM and HS (TTO: 0.92 ± 0.13 vs. 0.83 ± 0.22, p = 0.037) and/or AF (VAS: 74.8 ± 16.4 vs. 59.9 ± 21.3, p < 0.001; TTO: 0.88 ± 0.17 vs. 0.71 ± 0.29, p = 0.001) had an overall lower HRQL in comparison to those without HS and/or AF. The most strongly affected dimensions were mobility (p = 0.001), usual activities (p = 0.032) and pain/discomfort (p = 0.027) in people with T2DM and AF (Figure 1). Obesity (VAS: beta -0.247, p = 0.005; TTO: beta –0.225, p = 0.012), AF (VAS: beta –0.222, p = 0.011; TTO: beta –0.171, p = 0.049) and age (VAS: beta –0.171, p = 0.046) remained independent predictors of a poor HRQL. In turn, T2DM-related comorbidities and HS did not remain predictive of an impaired HRQL.

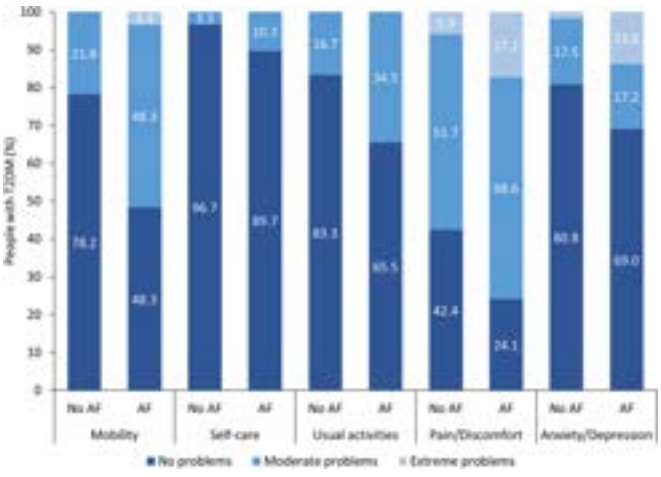

Figure: Distribution (%) of the EQ-5D-3L dimensions in people with T2DM and without advanced fibrosis (no AF) or with advanced fibrosis (AF)

Conclusion: Obesity and AF negatively affect the HRQL in patients with NAFLD and T2DM in secondary care. Interventions aiming at weight reduction may improve patient-reported and liver-related outcomes in people with T2DM.

THU-438

The impact of glycemic control on progressive forms of non-alcoholic fatty liver disease: combined data from multiple clinical trials including more than 5000 patients (in collaboration with NAIL-NIT consortium)

Mazen Noureddin[1], Julie Dubourg[2], Jörn Schattenberg[3], Michael Charlton[4], Stephen Harrison[5], Naim Alkhouri[6], Sophie Jeannin Megnien[7], Vlad Ratziu[8]. *[1]Houston Methodist Hospital, Houston, United States; [2]Summit Clinical Research, San Antonio, United States; [3]University medicine at the Johannes Gutenberg University in Mainz, Mainz, Germany; [4]UChicago Medicine, Chicago, United States; [5]University of Oxford, United Kingdom, [6]Arizona Liver Health, Chandler, United States; [7]Summit Clinical Research, United States; [8]Institute for Cardiometabolism and Nutrition, France*
E-mail: jdubourg@summitclinicalresearch.com

Background and aims: Type 2 diabetes mellitus (T2DM) is a well-known risk factor for non-alcoholic steatohepatitis (NASH) and liver fibrosis but whether glycemic control is an important predictor is not well known. Glycated hemoglobin (HbA1c), a measure of glycemic control has been identified as an independent risk factor of cardiovascular outcomes, independent of T2DM status. We aimed to describe patients' characteristics and liver histology across different groups of HbA1c level.

Method: We combined screening data from 6 ongoing biopsy-proven therapeutic NASH trials (>5000 patients). Patients were classified into 4 groups according to their HbA1c. At-risk NASH was defined as NASH with a non-alcoholic fatty liver disease activity score of at least 4 and a fibrosis stage of 2 (F2) or 3 (F3). The descriptive analyses were repeated in a subset of patients with recorded T2DM status. Patients with HbA1c ≥ 6.5% were reclassified as having undiagnosed T2DM. Univariate linear and logistic regressions were performed.

Results: 2177 patients with liver histology and HbA1c data were included. The liver histology results and patients' characteristics in each group are shown in the Table. The proportion of NASH and at-risk NASH patients increased with each HbA1c group (p < 0.01). Lipid parameters (LDL and triglycerides) were associated with HbA1c level. A subset of 913 T2DM patients with recorded status of T2DM were stratified based on HbA1c levels: Group 1, HbA1c<6.5% (n = 119, 13%); Group 2, HbA1c 6.6%-7.4% (N = 429, 47%), Group 3, HbA1c ≥7.5% (N = 356, 39%). The proportion of NASH increased with higher HbA1c values: 62%, 70% and 74% in groups 1, 2 and 3, respectively (p = 0.01). The proportion of at risk-NASH was significantly higher in T2DM patients with higher HbA1c: 46%, 50% and 56% in groups 1, 2 and 3, respectively (p = 0.02).

	HbA1c <5.7 N = 552	HbA1c [5.7–6.5[N = 785	HbA1c [6.5–7.5[N = 458	HbA1c ≥7.5 N = 382
	n (%) or mean (SD)			
NASH	267 (48%)	408 (52%)	322 (70%)	287 (75%)
NAS	3.8 (1.6)	3.9 (1.6)	4.3 (1.6)	4.5 (1.6)
Fibrosis Stage				
0–1	296 (54%)	385 (49%)	176 (38%)	125 (33%)
2–3	233 (42%)	371 (47%)	254 (56%)	235 (61%)
4	23 (4%)	29 (4%)	28 (6%)	22 (6%)
At-risk NASH	172 (31%)	281 (36%)	213 (47%)	203 (53%)
Age, years	50 (13)	55 (11)	57 (11)	56 (11)
AST, IU/L	41 (26)	40 (23)	42 (25)	43 (27)
ALT, IU/L	57 (37)	53 (33)	54 (31)	54 (32)
GGT, IU/L	59 (60)	56 (53)	69 (78)	70 (73)
LDL, mg/dL	110 (41)	107 (36)	94 (36)	96 (36)
Triglyceride, mg/dL	144 (69)	156 (73)	169 (77)	192 (121)
Liver Stiffness Measurement-transient elastography, kPa	13.4 (5.7)	12.9 (7.1)	13.4 (6.9)	13.6 (5.9)
Liver fat content, %	18 (8)	18 (7)	18 (7)	17 (7)
FIB-4	1.2 (0.7)	1.2 (0.6)	1.4 (0.6)	1.4 (0.7)

Conclusion: HbA1c level as a surrogate of glycemic control appears to be an independent risk factor of NASH and at-risk NASH, in diabetic patients. Additional studies are needed to further confirm the independent association of HbA1c with NASH severity.

THU-439

Glycated hemoglobin as an independent predictor of hepatocyte ballooning in non-alcoholic steatohepatitis: combined data from multiple clinical trials including more than 5000 patients (in collaboration with NAIL-NIT consortium)

Stephen Harrison[1], Julie Dubourg[2], Sophie Jeannin Megnien[2], Jörn Schattenberg[3], Vlad Ratziu[4], Michael Charlton[5], Naim Alkhouri[6], Mazen Noureddin[7]. *[1]University of Oxford, United Kingdom; [2]Summit Clinical Research, United States; [3]University Medical Center Mainz, Germany; [4]Institute for Cardiometabolism and Nutrition, France; [5]UChicago Medicine, Chicago, United States; [6]Arizona Liver Health, Chandler, United States; [7]Houston Methodist Hospital, Houston, United States*
E-mail: jdubourg@summitclinicalresearch.com

Background and aims: One of the major challenges in non-alcoholic steatohepatitis (NASH) drug development is liver histology, serving both as primary end point for conditional approval and as eligibility criteria. The failure to meet the histologic criteria is a major contributor of the high screen failure rate in non-cirrhotic NASH trials. There is a high inter- and intra-reader variability for all histologic features, though the hepatocyte ballooning remains the highest hurdle. We aimed to describe the main reasons for histologic failure across multiple phase 2 trials and to explore the predictors of hepatocyte ballooning.

Method: We combined screening data from 6 ongoing non-cirrhotic NASH phase 2 trials. We detailed the histologic features for NASH and fibrosis (table). Predictors of hepatocyte ballooning were examined using logistic regression in a subset of patients with at least stage 2 fibrosis, a non-alcoholic fatty liver disease activity score (NAS) of at least 3 and at least 1 point in inflammation and 1 point in steatosis (table). This subset was aimed to reduce the biases for the presence or

absence of hepatocyte ballooning in a population susceptible of having more severe NASH.

Histologic results				
Fibrosis Stage	F0-F1 N = 1020	F2- F3 N = 1135	F4 N = 104	All N = 2259
No NASH				
1 histologic feature missing	**739 (72%)**	**159 (14%)**	**26 (25%)**	**924 (41%)**
No ballooning	607 (82%)	148 (93%)	20 (77%)	775 (84%)
No inflammation	4 (1%)	3 (2%)	0	7 (0.5%)
No steatosis	0	3 (2%)	3 (11.5%)	6 (0.5%)
≥2 histologic features missing	128 (17%)	5 (3%)	3 (11.5%)	136 (15%)
NASH	**281 (28%)**	**976 (86%)**	**78 (75%)**	**1335 (59%)**
NAS 3	49 (17%)	72 (7%)	14 (18%)	135 (10%)
NAS 4–5	176 (63%)	515 (53%)	44 (56%)	735 (55%)
NAS 6–8	56 (20%)	389 (40%)	20 (26%)	465 (35%)

Predictors of Ballooning			
	No ballooning (n = 115)	**Ballooning** (n = 1054)	**p value** (Univariate)
Age, years	52 (11)	55 (11)	<0.01
Female	55%	64%	0.06
Hispanic	37%	42%	0.31
AST, IU/L	39 (15)	49 (29)	<0.01
ALT, IU/L	56 (27)	63 (36)	0.04
GGT, IU/L	66 (101)	75 (75)	0.25
HbA1c, %	6.2 (1.0)	6.6 (6.6)	<0.01
LDL, mg/dL	110 (40)	100 (36)	<0.01
Triglyceride, mg/dL	166 (108)	163 (82)	0.79

Figure:

Results: 2259 patients with liver biopsy were included. The absence of hepatocyte ballooning was the main reason for not meeting NASH criteria across all stages of fibrosis. In a specified analysis subset, patients with hepatocyte ballooning were older, had higher levels of AST, ALT, and glycated hemoglobin (HbA1c). After adjustment for fibrosis, inflammation, and steatosis stages, only HbA1c remained significantly different between the groups. For every 1% increase in HbA1c, the adjusted odds of hepatocyte ballooning increased by 1.54 (95% confidence interval: 1.20–1.99).

Conclusion: In this large cohort of centrally read biopsies, HbA1c has been observed as an independent predictor of hepatocyte ballooning, regardless of other histologic features. Further studies are warranted to confirm these results.

THU-440

Liver fibrosis is associated with cardiovascular disease burden amongst patients with non-alcoholic steatohepatitis: the unCoVer-NASH longitudinal cohort study

Kathleen Corey[1], Anurag Mehta[2], Kamal Kant Mangla[3], Abhishek Shankar Chandramouli[4], Ahsan Shoeb Patel[3], Sharat Varma[3], Elisabetta Bugianesi[5]. *[1]MGH Fatty Liver Program, Massachusetts General Hospital, United States; [2]VCU Health Pauley Heart Center, United States; [3]Novo Nordisk A/S, Denmark; [4]NovoNordisk Service Center India Pvt Ltd, India; [5]Department of Medical Sciences, University of Torino, Italy*
E-mail: kknm@novonordisk.com

Background and aims: Cardiovascular (CV) disease (CVD) burden in patients with non-alcoholic steatohepatitis (NASH) is incompletely understood. The unCoVer-NASH longitudinal cohort study assessed baseline CVD burden and subsequent CV events in patients with NASH stratified by Fibrosis-4 Index (FIB-4) using real-world de-identified US healthcare data from a federated network (TriNetX).

Method: Patients were identified using the International Classification of Diseases code (ICD-10-CM) for NASH from October 2015-June 2022 and required ≥1 FIB-4 measurement (s) calculated from data obtained 180 days prior to, or 30 days after, NASH diagnosis (index date) and ≥12 months of data prior to index date (baseline period). FIB-4 score categories were low (<1.3), intermediate (1.30–2.67) and high (≥2.67). Exclusion criteria included baseline evidence of cirrhosis, viral hepatitis, human immunodeficiency virus, liver-related complications and alcohol use disorder. Data analysed were baseline characteristics, CVD prevalence and risk of CV events (s) in follow-up (index date to end of enrolment, death or study end) amongst patients with no history of respective CV event (s) during baseline. For CV risk, cumulative incidence was plotted, incidence rate (IR) was presented per 100 person-years (PY) and hazard ratios (HR) were calculated using Cox proportional hazard models (crude and adjusted for CV risk factors [age, sex, type 2 diabetes (T2D), chronic kidney disease, obesity, hyperlipidaemia, hypertension]).

Results: Of 717 patients included, those with high FIB-4 (N = 102) vs intermediate (N = 201) and low (N = 414) were older (60 vs 57 and 44 years), less likely to have obesity (38% vs 45% and 54%), more likely to have T2D (50% vs 45% and 36%) and be female (71% vs 54% and 57%). The most prevalent CVD phenotypes in all FIB-4 groups (high, intermediate and low FIB-4, respectively) were ischaemic heart disease (18%, 17%, 11%), cerebrovascular disease (16%, 7%, 8%) and heart failure (10%, 9%, 6%). Cumulative incidence of any CV event increased with FIB-4 score (Figure). IRs for any CV event were 24.6, 17.2 and 10.4 per 100 PY for high, intermediate and low FIB-4, respectively. HRs (95% confidence interval) for high and intermediate vs low FIB-4 were 3.43 (2.21, 5.31); p < 0.0001 and 1.53 (1.02, 2.29); p = 0.04 and remained significant for high vs low FIB-4 after adjustment for CV risk factors, similar to results for individual CV events.

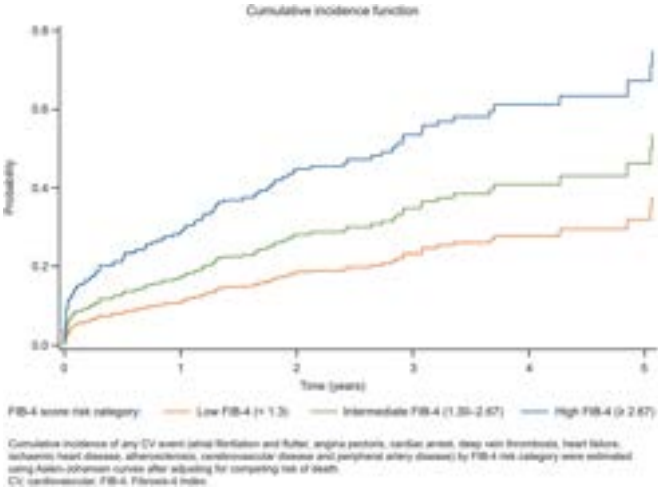

Figure:

Conclusion: CVD prevalence and incidence in patients with NASH was associated with baseline FIB-4 score, indicating higher CV burden as fibrosis worsens. CV risk with high vs low FIB-4 was significantly higher even after adjusting for CV risk factors. Patients with intermediate FIB-4 had an increased incidence of CV event (s) relative to those with low FIB-4 and should be monitored and managed; further research around CV risk in this group may be needed.

THU-441

Low rates of fibrosis scoring in the primary care records of 5987 people living with type 2 diabetes

James Hallimond Brindley[1], Kushala Abeysekera[2,3], Ann Archer[2], Gillian Hood[1], John Moore[1], Michael James[1], Matthew Hickman[2], William Alazawi[1]. [1]*Blizard Institute, Queen Mary University of London, Barts Liver Centre, London, United Kingdom;* [2]*Bristol Medical School, University of Bristol, Population Health Sciences, Bristol, United Kingdom;* [3]*University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, UK, Liver Medicine, Bristol, United Kingdom*
E-mail: halbrindley@gmail.com

Background and aims: Type 2 diabetes (T2D) is an independent risk factor for non-alcoholic fatty liver disease (NAFLD) development, progression to fibrosis and end-stage liver disease. EASL guidelines recommend looking for NAFLD in all people with T2D and calculating surrogate markers of fibrosis for all people with NAFLD. PRELUDE-1 (Trial ID: ISRCTN14585543) is a study evaluating the feasibility and acceptability of adding fibrosis-4 (FIB-4) scoring to the annual T2D review and direct access to community or secondary care transient elastography assessment for individuals with FIB-4 ≥1.3. We sought to determine the extent of liver fibrosis scoring in primary care prior to commencing the study.
Method: We performed an anonymised retrospective data capture of all adults with T2D registered at seven primary care practices in England who were enrolled in PRELUDE-1. Practices were invited to join the study with key inclusion criteria: practice size >4000 and 85% completion of T2D annual review. Patient-level data included selected SNOMED CT codes for demographics, pathology (including alanine transaminase (ALT), aspartate aminotransferase (AST), platelet count and Fib-4 score) and diagnostic data.
Results: Across the initial 7 primary care sites (4 in Bristol and 3 in London), there were a total of 5987 individuals with type 2 diabetes. 47% were female with mean age 60.9 years, 45% of South Asian ethnicity, 32% White, 16% Black and 7% other. NAFLD and NASH were coded for 491 (8.2%) and 12 (0.2%) people with T2D respectively. 65% (n = 3862) of the cohort had a coded ALT result in their primary care record; male mean 35.9 IU/L and female mean 25.5 IU/L. 42% (n = 2535) of the cohort had a platelet count reported, mean value 256 × 10^9/L. 31% (n = 184) had AST values recorded; male mean 39.0IU/L and female mean 30.9 IU/L. Only 26 individuals (0.4%) had a FIB-4 score coded in their primary care records. The complete dataset from the enrolled seven sites will be presented.
Conclusion: Despite current EASL guidance and increasing primary care physician awareness of NAFLD, few people with T2D have a coded diagnosis of NAFLD or surrogate markers of fibrosis despite recognition as an at risk population. New ways of working are needed to raise awareness and recognition of people with T2D and liver disease in primary care.

A machine learning-based classification of adult-onset diabetes identifies patients at risk for liver-related complications

Lukas Otero Sanchez[1], Clara-Yongxiang Zhan[2], Carolina Gomes Da Silveira Cauduro[3], Laurent Crenier[3], Hassane Njimi[4], Gael Englebert[2], Antonella Putignano[2], Antonia Lepida[2], Delphine Degré[2], Nathalie Boon[2], Thierry Gustot[2], Pierre Deltenre[5], Astrid Marot[6], Jacques Deviere[2], Christophe Moreno[2], Miriam Cnop[3], Eric Trépo[2]. [1]*Erasme Hospital, Brussels, Department of Gastroenterology, Hepatopancreatology and digestive Oncology, Brussels, Belgium;* [2]*Erasme Hospital, Department of Gastroenterology, Hepatopancreatology and digestive Oncology, Brussels, Belgium;* [3]*Erasme Hospital, Endocrinology, Belgium;* [4]*Université Libre de Bruxelles, Statistics, Belgium;* [5]*Clinique Saint-Luc, Gastroenterology, Bouge, Belgium;* [6]*Université Catholique de Louvain, Yvoir, Gastroenterology, Belgium*
E-mail: lukas.otero.sanchez@ulb.be

Background and aims: Diabetes mellitus is a major risk factor for fatty liver disease development and progression. A novel machine learning method identified five clusters of patients with diabetes, with different characteristics and risk of diabetic complications using six clinical and biological variables. We evaluated whether this new classification could identify individuals with an increased risk of liver-related complications.
Method: We used a prospective cohort of patients with a diagnosis of type 1 or type 2 diabetes without evidence of advanced fibrosis at baseline recruited between 2000 and 2020. We assessed the risk of each diabetic cluster of developing liver-related complications, using competing risk analyses.
Results: We included 1068 patients, of whom 162 (15.2%) were determined to be in the severe autoimmune diabetes (SAID) subgroup, 266 (24.9%) were severe insulin-deficient diabetes (SIDD), 95 (8.9%) were severe insulin-resistant diabetes (SIRD), 359 (33.6%) were mild obesity-related diabetes (MOD), and 186 (17.4%) were in the mild age-related diabetes (MARD) subgroup. In multivariable analysis, patients in the SIRD cluster and those with excessive alcohol consumption at baseline had the highest risk for liver-related events. The SIRD cluster, excessive alcohol consumption, and hypertension were independently associated with clinically significant fibrosis. Using a simplified classification, patients assigned to severe and mild insulin-resistant groups had a 3- and 2-fold greater risk, respectively, of developing significant fibrosis compared to the insulin-deficient group.

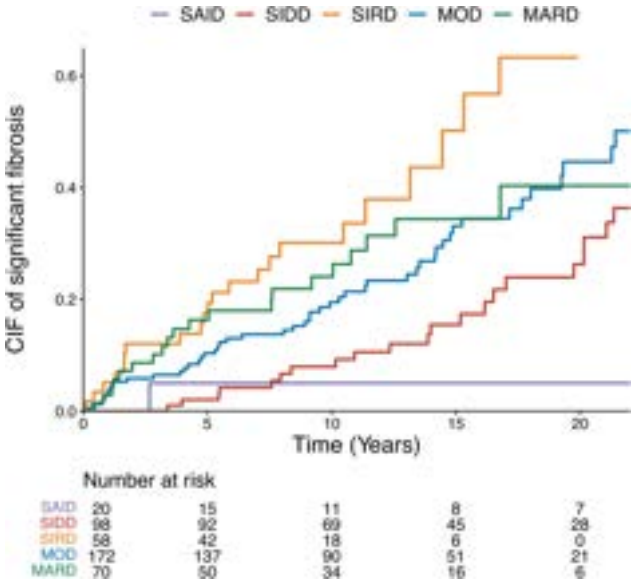

Figure: Time to clinically significant fibrosis by cluster

Conclusion: A novel clustering classification adequately stratifies the risk of liver-related events and liver fibrosis in a diabetes population. Our results also underline the impact of the severity of insulin resistance and alcohol consumption as key prognostic risk factors for liver-related complications.
CIF, cumulative incidence function; SAID, Severe autoimmune diabetes; SIDD, Severe insulin-deficient diabetes; SIRD, Severe insulin-resistant diabetes; MOD, Mild obesity-related diabetes; MARD, Mild age-relate diabetes

THU-443

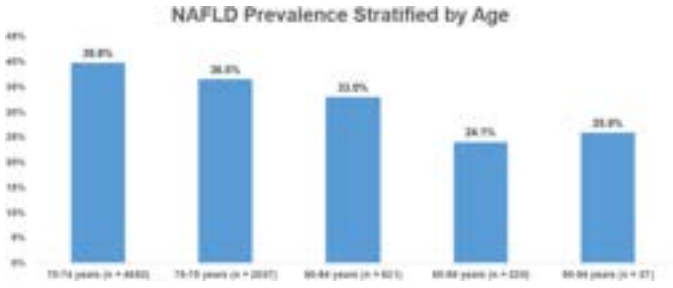
NAFLD prevalence in the elderly declines with age and is associated with increased frailty, reduced physical function and social disadvantage status: results from the ASPREE study

Daniel Clayton-Chubb[1,2,3], Ammar Majeed[1,3], John Lubel[1,3], Robyn Woods[4], Alex Hodge[2,5], Hans Schneider[6], John McNeil[7], William Kemp[1,3], Stuart Roberts[1,3]. *[1]The Alfred, Gastroenterology, Melbourne, Australia; [2]Eastern Health, Gastroenterology, Box Hill, Australia; [3]Monash University-Central Clinical School, Medicine, Melbourne, Australia; [4]Monash University, School of Public Health and Preventive Medicine, Australia; [5]Monash University-Eastern Health Clinical School, Box Hill, Australia; [6]The Alfred, Pathology, Melbourne, Australia; [7]Monash University, School of Public Health and Preventive Medicine, Australia*
E-mail: chubb.daniel@gmail.com

Background and aims: Several global data suggest that Non-Alcoholic Fatty Liver Disease (NAFLD) prevalence increases with age. However, the Rotterdam study showed decreasing prevalence of NAFLD with increasing age among older adults. To further explore NAFLD in older persons we evaluated the prevalence of NAFLD in a large group of older Australians (who were sufficiently healthy to be enrolled in a primary prevention clinical trial). We also aimed to determine factors associated with NAFLD in this group including markers of frailty and social disadvantage.

Method: We included participants involved in the ASPREE (ASPirin in Reducing Events in the Elderly) randomised-controlled trial that enrolled 16 703 community-dwelling Australian participants aged 70 years or older without independence-limiting physical disability, dementia, or cardiovascular disease. Detailed anthropometric, biochemical, and questionnaire data were collected at baseline. We calculated the Fatty Liver Index (FLI), a composite score based on gamma-glutamyl transferase, triglycerides, abdominal circumference, and BMI. Using a score ≥6 0 to define NAFLD, we identified NAFLD prevalence as well as associations via logistic regression analysis.

Results: Data from 7757 (mean age 75.0 ± 4.21 years, 47.1% male) participants were analysed. We excluded 8946 participants for not meeting standard NAFLD inclusion criteria or delayed/missing data. The overall prevalence of NAFLD was 37.7% and this decreased with age (Figure 1) ($p < 0.001$). In logistic regression analysis of NAFLD (FLI ≥6 0, n = 2314) vs no-NAFLD (FLI <30, n = 1755), age (OR 0.93; 95% CI 0.91–0.94; $p < 0.001$), male gender (OR 2.69; 95% CI 2.34–3.09; $p < 0.001$), diabetes (OR 4.19; 95% CI 3.25–5.39; $p < 0.001$), chronic kidney disease (OR 1.51; 95% CI 1.28–1.77), and hypertension (OR 1.75; 95% CI 1.50–2.05; $p < 0.001$) were all significantly associated with NAFLD. Additionally, multiple markers of frailty and social disadvantage were significantly associated with NAFLD, including low gait speed (OR 1.62, 95% CI 1.27–2.07; $p < 0.001$) and worsening frailty using the Fried Frailty Index (OR 1.29; 95% CI 1.10–1.51; $p = 0.002$ for pre-frail participants; OR 2.08; 95% CI 1.19–3.62; $p = 0.01$ for frail participants). Completing more than 12 years of education (OR 0.72; 95% CI 0.63–0.83; $p < 0.001$) and being in the top half of an Australian composite measure of advantage and disadvantage (IRSAD) (OR 0.80; 95% CI 0.70–0.92; $p = 0.002$) appeared to be protective.



Conclusion: Similar to the Rotterdam study we found a decreasing prevalence of NAFLD with increasing age. In addition, our study shows important novel associations between NAFLD in older persons and worsening physical function and frailty, as well as an inverse association between NAFLD and markers of social advantage.

THU-444

Ascites is the most frequent decompensating event in stable And strictly compensated NAFLD with advanced fibrosis

Zouhir Gadi[1,2], Luisa Vonghia[2,3], Jolien Derdeyn[3], Toon Steinhauser[3], Thomas Vanwolleghem[2,3], Sven Francque[2,3], Wilhelmus Kwanten[2,3]. *[1]Antwerp University Hospital, Department of Gastroenterology and Hepatology, Edegem, Belgium; [2]University of Antwerp, Laboratory of Experimental Medicine and Paediatrics (LEMP), Antwerpen, Belgium; [3]Antwerp University Hospital, Gastroenterology and Hepatology, Edegem, Belgium*
E-mail: jolien.derdeyn@uza.be

Background and aims: The natural history of advanced fibrosis in non-alcoholic fatty liver disease (NAFLD) might behave differently compared to other CLD. We aim to describe the natural history of stable and strictly compensated NAFLD patients with advanced fibrosis.

Method: Patients at the Antwerp University Hospital diagnosed between 03/2006 and 11/2021 with a biopsy proven NAFLD and fibrosis F3 or F4 were retrospectively collected. Available clinical follow-up time needed to be ≥12 months after the histological confirmation of advanced fibrosis. Only strictly and stable compensated patients were included, defined as baseline Child Pugh score ≤B7, the absence of prior hepatic decompensation, or development thereof within 12 m after biopsy. Hepatic decompensation was defined as variceal bleed (VB), overt hepatic encephalopathy (HE) or ascites needing large volume paracentesis (LVP). The following clinically relevant events were collected as well: hepatocellular carcinoma (HCC) or death.

Results: 100 out of 185 patients met the inclusion criteria (56 F3; 44 F4), with a mean follow-up time of 264 (56–864) weeks. First decompensation events were noted in 16 (16%) patients during follow-up distributed as LVP/HE/VB with n = 11/6/4 patients respectively (figure 1), 5 patients experienced >1 event. Mean time to first decompensation was respectively 258/195/155 weeks. Compared to patients without decompensation, decompensated patients had at baseline (i.e. at time of biopsy) significantly higher age (64.8 ± 8.6 vs. 58.1 ± 10.3 year; $p = 0.016$), lower platelet count (159 ± 53 vs. 213 ± 80 10^9/L; $p = 0.011$), higher serum GGT (225 ± 155 vs 126 ± 128 U/L; $p = 0.013$), lower serum Na (137.87 ± 2.36 vs. 140.07 ± 2.53 mmol/L; $p = 0.002$), higher Na-MELD (9.88 ± 2.42 vs. 7.85 ± 2.81; $p = 0.008$), higher predicted Hepatic Venous Pressure Gradient (HVPG-3P model) (11.56 ± 1.75 vs.10.01 ± 2.69 mmHg; $p = 0.029$). HVPG (measured in 66/100) was insignificantly higher (9.95 ± 5.33 vs.7.45 ± 3.64 mmHg; $p = 0.106$). Decompensated patients were more frequently on non-selective beta-blockers at baseline (8/16). Interestingly, 5/16 (31.3%) patients with decompensation had F3 fibrosis and 7/15 (46.7%) had a HVPG <10 mmHg. 4 cases developed HCC with a mean follow-up time of 211 (29–473) weeks and 15 deaths (3 liver-related) were noted with a mean follow-up time of 221 (75–733) weeks. Of these cases 1/4 and 8/15 experienced prior decompensation.

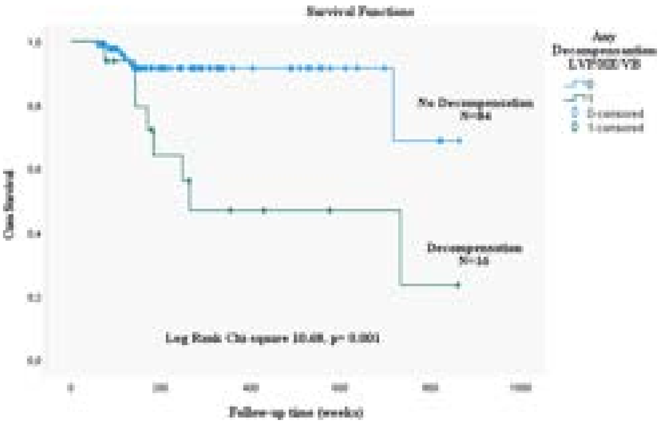


Figure: Kaplan-Meier survival curve patients with and without decompensation after at least 1 year follow-up (p = 0.001, log-rank test)

Conclusion: In this large single centre cohort of NAFLD patients with advanced fibrosis and strictly compensated disease with a mean follow-up of >5 years, roughly 1/6 patients developed a first decompensating event. Ascites needing LVP was the most frequent decompensation event. Age, sodium, platelets and GGT and use of NSBB at baseline were associated with decompensation. About a 1/3 of patients with decompensation had F3 fibrosis and about 1/2 a baseline HVPG of <10 mmHg.

THU-445

The impact of Clostridium difficile on mortality and outcomes in patients with NAFLD vs. NASH

Ankoor Patel[1], Gaurav Pathak[2], Alexander Chen[1], Carlos Minacapelli[2], Carolyn Catalano[2], Vinod Rustgi[2]. [1]*Rutgers-Robert Wood Johnson Medical School, Medicine, New Brunswick, United States,* [2]*Robert Wood Johnson Medical School, Dept of Gastroenterology and Hepatology, New Brunswick, United States*
E-mail: ahp60@rwjms.rutgers.edu

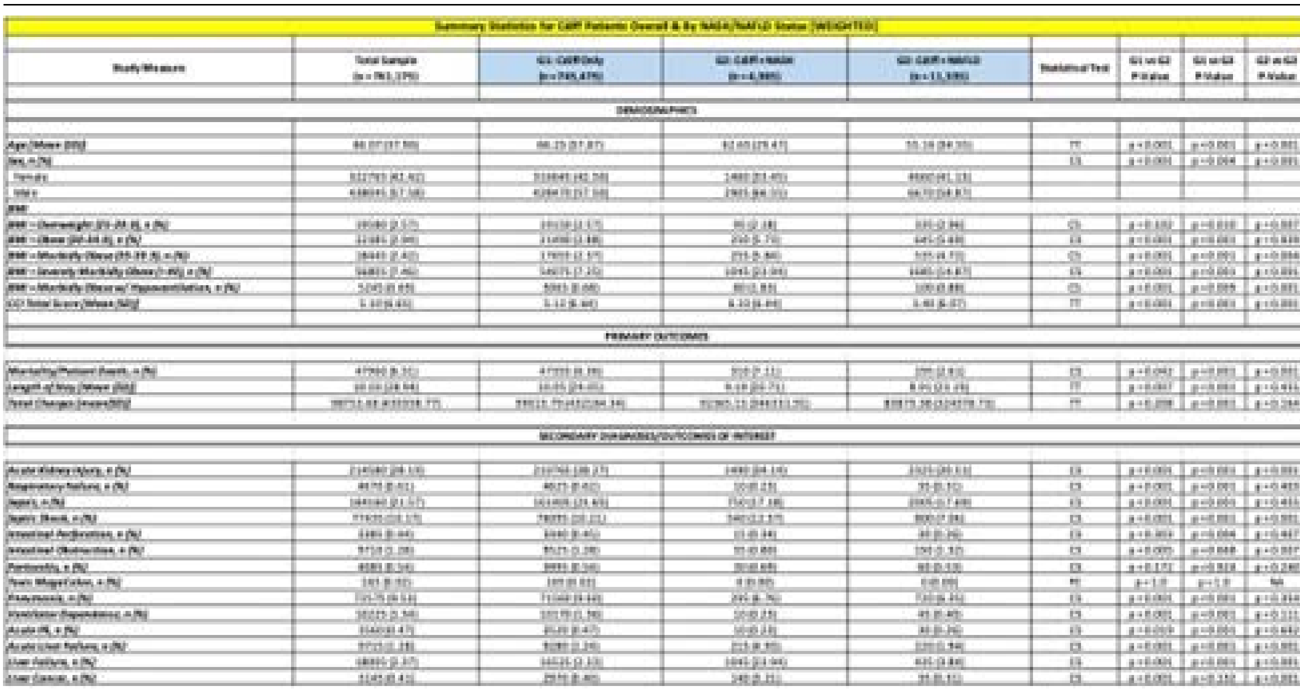
Background and aims: *Clostridium difficile (C. Diff)* infection (CDI) is the most common cause of infectious nosocomial diarrhea among adults in developed countries. The rate of CDI has increased over the last few decades and is associated with significant mortality and morbidity. NAFLD is the most common chronic liver disease due to the increasing prevalence of obesity and other metabolic diseases. Several studies show a correlation between NAFLD and bacterial infections; however, outcomes in patients with NAFLD/NASH and CDI are limited. Using the National Inpatient Sample (NIS), our study evaluated outcomes, including mortality and complications, length of stay (LOS), and costs among patients with NAFLD/NASH and CDI.

Method: We performed a retrospective cohort study using the National Inpatient Sample (NIS) from 2015 to 2017. Patients with C. Difficile infection, NAFLD, and NASH were identified using ICD-10 codes. Patients with diagnoses of both NAFLD and NASH were excluded. Primary outcomes included mortality, length of stay, total hospitalization costs. Secondary outcomes included AKI, pneumonia, respiratory failure, ventilatory dependence, acute pulmonary embolism, intestinal perforation, peritonitis, toxic megacolon, acute liver failure, liver failure, liver cancer. Multivariate logistic regression analysis was used to compare the two groups.

Results: A total of 761 175 patients with CDI were included and 11 335 (1.49%) had NAFLD and 4365 (0.57%) had NASH. The NASH cohort had a higher degree of comorbidities (CCI mean, CDI and NASH, CDI only, CDI and NAFLD, 6.33 vs 5.12 vs 3.40; p < 0.001). Patients hospitalized for CDI with NASH had an increased risk of mortality compared to those with NAFLD and those without NASH or NAFLD (CDI and NASH vs CDI and NAFLD vs CDI only, 7.11% vs 2.61% vs. 6.36%). Patients with CDI and NASH were at increased risk for liver related complications, including liver failure and liver cancer, acute kidney injury, and septic shock (p < 0.001) compared to patients with CDI only.

Conclusion: Patients with NASH have a higher rate of mortality, AKI, septic shock, and liver-related complications following CDI.

Figure: Table 1. (abstract: THU-445): Outcomes of CDI in Patients with NASH, NAFLD, and without NAFLD/NASH.



THU-446

Poor performance at five times sit-to-stand test, but not at handgrip test, is related to significant liver fibrosis and correlates with major cardiovascular events in non-alcoholic fatty liver disease patients

Giordano Sigon[1], Roberta Forlano[1], Benjamin H. Mullish[1], Jian Huang[1], Michael Yee[2], Robert D. Goldin[3], Mark Thursz[1], Pinelopi Manousou[1].
[1]*Liver Unit/Division of Digestive Diseases, Department of Metabolism, Digestion and Reproduction, Faculty of Medicine, Imperial College London, London, United Kingdom, United Kingdom;* [2]*Section of Endocrinology and Metabolic Medicine, St Mary's Hospital, Imperial College NHS Trust, London, United Kingdom, London, United Kingdom;* [3]*Department of Cellular Pathology, Faculty of Medicine, Imperial College London, London, United Kingdom, London, United Kingdom*
E-mail: gio.sigon@virgilio.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) causes both liver and cardiovascular morbidity and mortality. While many studies suggest worse clinical outcomes for sarcopenic patients with cirrhosis, few data are available on sarcopenia in NAFLD patients with early liver disease. Our aim is to assess sarcopenia against fibrosis stage and clinical outcomes in patients with NAFLD.
Method: We consecutively enrolled NAFLD patients followed up in the specialist clinic at Imperial College Healthcare NHS Trust, London, UK. NAFLD was diagnosed either clinically or based on histology. We collected anthropometric, biochemical parameters, medical history and cardiovascular risk factors. For the evaluation of sarcopenia, we performed bioimpedance analysis (BIA), 5 times sit-to-stand test (5STST) and handgrip strength test (HST). As suggested in literature, poor performances were considered 5STST >15 sec, and HST <27 kg for males or <16 kg for females. Patients who were not able to perform the 5STST were included in the 5STST >15 sec category. Major cardiovascular events (MACE) were defined as acute coronary syndrome, transient ischemic attack and stroke. Significant fibrosis was defined as liver stiffness measurement (LSM) >8 kPa, while cirrhosis as a combination of clinical parameters (LSM, bloods and imaging) or on histology.
Results: Overall, 130 NAFLD patients were included, with median age 58 [50–67] years and BMI 29.9 [26.8–34.6] kg/m^2. 86 (67%) were males, 101 (79%) had type 2 diabetes mellitus and 73 (57%) hypertension. BIA and handgrip measurement were available in the whole cohort, while 5STST only in 70 patients (54%). As per BIA, absolute fat mass was 28 [20–40] kg (34 [26–34] %), while muscle mass was 54 [47–65] kg (62 [56–70] %). Furthermore, 22 of 130 (17%) were below the HST cutoff, while 19 out of 70 (28%) had a 5STST >15 sec. Poor HST was associated with lower muscle mass measured with BIA. In terms of severity of liver disease, 51 (41%) showed LSM >8 kPa, while 7 (5%) had cirrhosis. Previous history of MACE was positive in 19 (15%) patients.
On multivariate analysis, 5STST >15sec was significantly associated with LSM >8 kPa (OR 6.7, 95%CI: 1.1–39.9, p = 0.04). Moreover, while no association was found at multivariate analysis between MACE and HST, 5STST >15 was significantly related to history of MACE (OR 5.4, 95%CI: 1.1–26.3, p = 0.04).

	Odds ratio	95% confidence interval	p value
Age	1.1	0.9–1.2	0.52
Male gender	1.2	0.2–9.1	0.83
Type 2 diabetes mellitus	5.8	0.5–60.3	0.14
Statin	3.1	0.5–20.6	0.24
Cirrhosis	3.4	0.4–30.3	0.24
5STST >15	**5.4**	**1.1–26.3**	**0.04**

5STST: five times sit-to-stand test.
Figure: Logistic regression for history of major cardiovascular event

Conclusion: Poor performance at 5STST was associated both with significant liver fibrosis and MACE. In contrast, HST was not related with MACE. The 5STST could be integrated into the cardiovascular risk stratification of NAFLD patients.

THU-447

The national audit of non-alcoholic fatty liver disease (NAFLD) identifies variations and shortfalls in delivery of care in the UK

Wenhao Li[1], David Sheridan[2], Stuart Mcpherson[3], William Alazawi[1].
[1]*Barts Liver Centre, Blizard Institute, Queen Mary University of London, London, United Kingdom;* [2]*University Hospitals Plymouth NHS Trust, United Kingdom;* [3]*The Newcastle upon Tyne Hospitals NHS Foundation Trust, United Kingdom*
E-mail: wenhao.li@doctors.org.uk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a major cause of liver-related morbidity and mortality. The British Association for the Study of the Liver (BASL) and British Society of Gastroenterology (BSG) NAFLD Special Interest Group (SIG) recently published Quality Standards for NAFLD management which includes auditable key performance indicators (KPIs)of good clinical care. This national audit, endorsed by BASL and BSG, aimed to benchmark the care in UK hospitals for people with NAFLD against these KPIs and compared practice in 20129 with 2022.
Method: An electronic survey was designed by BASL/BSG NAFLD SIG and published and distributed via BASL and BSG webpages, mailing lists and twitter accounts. Participating hospitals collected retrospective data from all new NAFLD patients reviewed in outpatient clinic in the month of March 2019 and March 2022.
Results: Data relating to KPIs from 776 NAFLD patients (374 in 2019, 402 in 2022) in 34 hospitals covering all four UK countries were collected (Table 1). Mean age of audited population was 52.7 years, 55.2% were male and 63.4% were of White ethnicity. 85.3% of services reported established local liver disease assessment pathways, yet only 27.9% of patients with suspected NAFLD had non-invasive fibrosis assessment documented at point of referral to secondary care. In secondary care, non-invasive tests were used or liver biopsy was conducted in 79.1% of patients. 34.6% of patients without non-invasive fibrosis assessment at point of referral to secondary care had low-risk of advanced fibrosis (low Fib4 or NAFLD Fibrosis score, Fibroscan <8 kPa). There was considerable variation in the assessment cardiometabolic risk factors including obesity (73.2%), type 2 diabetes [T2DM] (33.0%,), hypertension (19.3%) and smoking (54.9%). Giving appropriate diet and lifestyle advice to address cardiometabolic risk was poorly performed. Only 9.1% of NAFLD patients at increased cardiovascular risk (T2DM and/or QRISK-3 >10%) were advised statin treatment in line with NICE guidelines. Significant improvements in several KPIs were identified between 2019–2022: non-invasive fibrosis assessment at referral increased 20.8% to 35.1% ($p < 0.0001$), statin recommendations increased from 4.3% to 12.5% ($p = 0.012$) and providing patient information material regarding NAFLD increased from 11.6% to 24.5% ($p < 0.001$).
Conclusion: This national audit of NAFLD management in the UK has identified significant variation and areas for improvement, particularly in fibrosis risk assessment prior to secondary care referral and management of associated cardiometabolic risk factors. Improvements from 2019 to 2022 gives cause for optimism but further work is needed to drive changes in service delivery and patient care.

Non-alcoholic fatty liver disease mediates the effect of obesity on arterial hypertension

Carlos Pirola[1], Silvia Sookoian[2]. [1]*Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Systems Biology of Complex Diseases. Centro de Altos Estudios en Ciencias Humanas y de la Salud (CAECIHS), Universidad Abierta Interamericana, Ciudad Autonoma de Buenos Aires, Argentina;* [2]*Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Clinical and Molecular Hepatology. Centro de Altos Estudios en Ciencias Humanas y de la Salud (CAECIHS), Universidad Abierta Interamericana, Argentina*
E-mail: cjpirola@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is highly prevalent among subjects with metabolic syndrome. Obesity, as estimated by body mass index (BMI) is a modifiable risk factor for both NAFLD and cardiovascular disease (CVD), including arterial hypertension (HTN). Herein, we explored to which extent NAFLD mediates the association between obesity and arterial hypertension.
Method: A two-step approach was used. First, we included cross-sectional data (1392 adults aged 29.4 ± 5.1 years) from the Bogalusa Heart Study (BHS) that was designed to assess the early natural history of CVD in a cohort of young adults in a semirural community. NAFLD was assessed using the fatty liver index (FLI). Liver fibrosis was estimated using the NAFLD fibrosis score. To replicate the findings, we included data from the National Health and Nutrition Examination Survey (2017–2018 cycle, NHANES). NAFLD was defined by the controlled attenuation parameter (CAp >268 dB/m) obtained via transient elastography (non-NAFLD = 1876; NAFLD = 1483). Liver fibrosis was defined based on stiffness measurements (n = 3359 subjects). Variables were log-transformed as they showed non-normal distribution according to Q-Q plots. Causal mediation analyses were performed using generalized structural models (GSEM) to examine the causal role of liver steatosis and fibrosis in the relation between obesity and hypertension. Results were adjusted for relevant demographic, anthropometric, clinical, and biochemical variables including age, sex, ethnics, and impaired fasting glucose, or type 2 diabetes.
Results: In the BHS, HTN was associated with NAFLD (OR: 1.70, 95% CI:1.23–2.35, p:1.1E-3) and BMI (OR:1.06, 95%CI: 1.02–1.09, p:2.4E-3) after adjusting for relevant confounders. Significant effects were also found for systolic (SBP) and diastolic (DBP) blood pressure, and heart rate (HR). These findings were replicated in NHANES survey. Specifically, HTN was associated with NAFLD (OR: 1.39, 95%CI: 1.01–1.92) and BMI (OR: 6.43, 95%CI: 2.80–14.8).
In the BHS, causal mediation analysis showed that significant indirect effects of BMI on HTN, SBP, DBP, and HR through FLI gradation explain up to 88%, 91%, 93%, and 100% of the total effect, respectively. In NHANES, these indirect effects also explain a significant proportion of the total effects (HTN = 51%, SBP = 60.4%, HR = 100%, and pulse pressure = 88%). Liver fibrosis mediated the effect of BMI on SBP (52%).
Conclusion: NAFLD mediates a substantial proportion of the effect of obesity on the presence of arterial hypertension. This conclusion has important clinical implications in both NAFLD and hypertension management.

THU-449

Nutritional behavior and food pattern are sex-specific with higher salt intake and consumption of ultra-processed foods in a large cohort of NAFLD patients

Monika Rau[1], Julia Jerzynski[1], Bianca Heller[1], Florian P. Reiter[1], Hans Benno Leicht[1], Ina Bergheim[2], Peter Heuschmann[3], Andreas Geier[1]. E-mail: rau_m@ukw.de

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the leading cause of chronic liver disease. "Western" dietary patterns with high salt content and ultra-processed foods (UPF) are generally linked to hepatic inflammation in NAFLD, but scarce information exists on its particular impact on NAFLD disease stage. Aim of this study is to analyze food pattern and specific nutritional behavior in NAFLD patients as a first step in specific nutritional intervention.
Method: Prospectively, 310 clinically characterized NAFLD patients were included (04/21–11/22) in this single center study at a tertiary hospital. All patients completed a nutrition questionnaire based on FFQ (DEGS[1]) including 53 food groups for the calculation of dietary sodium consumption/day (DSC). UPF consumption was classified by NOVA food classification. Nutritional behavior was assessed by questionnaires such as SINU-Salt[2], the the Intuitive Eating Scale-2[3] and the Adult Eating Behaviour Questionnaire[4].
Results: Slightly more women (57%) than men (43%) were included in this study with an average age of 52.7 for men and 52.3 for women. Men had significantly higher consumption of UPF (708 ± 464 kcal/d) compared to women (478 kcal/d ± 554), but women had higher meal frequency per day. Higher UPF consumption was associated with higher DSC. Mean daily salt intake in the study cohort was 7 g/d. Men had higher DSC (8.3 g/d vs 6.1 g/d in women) and had different behavior with significantly lower salt awareness in everyday life. Furthermore, men had different nutritional behavior with lower agreement to slowness in eating and satiety responsiveness but higher consent to eating for physical rather than emotional reasons. Nutritional behavior with high responsiveness on hunger and satiety cues (as a positive feedback signal) was linked to milder disease phenotype with lower ALT, AST, gGT, Ferritin, and lower DSC in this cohort. NAFLD patients with higher DSC (>5 g/d) had a significantly higher serum ALT, GGT and ferritin compared to low DSC (<5 g/d) (ALT: 165 vs.130U/L; p = 0,001). Patients with high DSC (>5 g/d) had higher weight and more steatosis by CAP (153.2 vs. 116.7 dB/m; p = <0,001) compared to low DSC.
Conclusion: Consumption of ultra-processed food, daily salt intake and nutritional behavior is sex-specific in a large cohort of NAFLD patients. High daily salt intake is linked to higher liver enzymes and more pronounced liver steatosis. The findings of this study represent the basis for a prospective interventional trial.

Prevalence of dysmetabolic iron overload syndrome in non-alcoholic fatty liver disease

Noel Ravindranayagam[1], Monique Fernandez[1], Karl Vaz[1], Julie Lokan[2], Andrew Grigg[3], Marie Sinclair[1,4]. [1]*Austin Health, Victorian Liver Transplant Unit, Heidelberg, Australia;* [2]*Austin Health, Department of Anatomical Pathology, Heidelberg, Australia;* [3]*Austin Health, Department of Haematology, Heidelberg, Australia;* [4]*University of Melbourne, Melbourne, Australia*
Email: noel.ravindranayagam@austin.org.au

Background and aims: Dysmetabolic iron overload syndrome (DIOS) is defined by histologic iron overload in the context of insulin-

resistance. Its occurrence with Non-alcoholic fatty liver disease (NAFLD) has been reported to be associated with more severe fibrosis. Little data is available regarding the prevalence of DIOS in those with NAFLD. This study aimed to evaluate the prevalence of histologic hepatic iron overload in adults with biopsy-proven NAFLD, and to determine the correlation between serum ferritin and hepatic iron overload.

Method: This single center, retrospective study included adult patients (≥18 years old) with biopsy-proven NAFLD between 01/01/2010–31/12/2019. The electronic medical record was used to assess detailed data on patient demographics, biochemistry, and clinical parameters. NAFLD is defined as ≥5% steatosis in the absence of any co-factors for liver disease. For the purpose of this study, DIOS is defined by histological evidence of iron deposits on Perl's stain in the presence of any component of the metabolic syndrome (hypertension, type 2 diabetes mellitus, dyslipidemia).

Results: In total 224 patients were included in this study, with mean age 52.3 years and the majority female (64.7%). Forty-one (19.2%) patients had evidence of histologic iron overload, n = 39 (17.4%) fulfilling diagnosis for DIOS. Those with DIOS were more likely to be male (56.4% vs 30.8%, p = 0.002), leaner (body mass index [BMI] 34.9 vs 38.0 kg/m^2, p = 0.01) and had higher serum ferritin (329 vs 94 micrograms/L, p < 0.001) and transferrin saturation (29.7% vs 21.5%, p < 0.001). Ferritin >1000 micrograms/L (odds ratio [OR] 7.60, 95% confidence interval [CI] 1.26–45.86, p = 0.027) and transferrin saturation as continuous variables (OR 1.06, 95% CI 1.01–1.11, p = 0.017) were independent predictors for histological iron overload after adjusting for age, gender, and BMI on multivariate logistic regression analysis. There was a statistically significant but weak correlation between serum ferritin and hepatocellular iron content (Spearman's rho = 0.378, 95% CI 0.213–0.523, p < 0.001) and reticuloendothelial cell compartment iron content (Spearman's rho = 0.341, 95% CI 0.172–0.491, p < 0.001). DIOS was not an independent predictor for fibrosis on multivariable linear regression analysis or F3–4 fibrosis on logistic regression analysis.

Conclusion: Prevalence of DIOS is nearly 20% in those with biopsy-proven NAFLD. While higher levels of ferritin and transferrin saturation were associated with DIOS, most patients with DIOS had ferritin <500 micrograms/L and transferrin saturation <45%, limiting the ability of these parameters to predict DIOS. Hepatic iron overload did not predict presence of advanced fibrosis/cirrhosis in this cohort.

Effect of PNPLA3 (rs738409 C > G) and TM6SF2 (rs58542926 C > T) polymorphisms on the prognosis of non-alcoholic fatty liver disease (NAFLD) in patients with type-2 Diabetes Mellitus

Natália Lavrado[1], Claudia Regina Cardoso[1], Natalia Wajbrot[2], Paulo Henrique França[3], Gil Salles[1], Nathalie Leite[2], Cristiane Villela-Nogueira[1]. *[1]Federal University of Rio de Janeiro, School of Medicine, Internal Medicine Division, Rio de Janeiro, Brazil; [2]Federal University of Rio de Janeiro, Hepatology Division, Brazil; [3]Universidade de Joinville, Brazil*
E-mail: crisvillelanog@gmail.com

Background and aims: The impact of the association of genetic polymorphisms in the progression of liver disease in patients with type-2 Diabetes Mellitus (T2DM) and NAFLD is still under debate. We aimed to evaluate the effect of PNPLA3 and TM6SF2 alleles in the prognosis of liver and extrahepatic outcomes in a cohort of T2DM patients with NAFLD.

Method: T2DM individuals with NAFLD had the PNPLA3 (rs738409 C > G) and TM6SF2 (rs58542926 C > T) genotypes determined. Each polymorphism was categorized into two groups considering the presence of at least one or none risk allele. We evaluated the impact of harbouring at least one risk allele (G or T) from each polymorphism regarding the occurrence of the following outcomes: cirrhosis, esophageal or gastric varices, hepatocellular carcinoma, major cardiovascular events (MACE), extrahepatic cancer and death. Multivariate analysis evaluated the associations between PNPLA3 and TM6SF2 alleles and the outcomes. Several hierarchical models were built to assess the association, independently of confounding factors: model (1) only polymorphism (PNPLA3 or TM6SF2) as the main covariate, (2) model 1 plus age and gender, (3) model 2 plus hypertension, dyslipidaemia, use of insulin, smoking history, alcohol consumption, body mass index, glycated haemoglobin and gamma-glutamyl transpeptidase. Results were presented as odds ratios with their 95% confidence intervals, and a 2-tailed p value <0.05 was regarded as significant.

Results: 407 T2DM with NAFLD (mean age 62 ± 10 years, 67% women) were followed for 66 ± 19 months. Frequencies of the genotypes' categories were: PNPLA3 CC 44.2% and CG+GG 55.8%; TM6SF2 CC 87.5% and CT+TT 12.5%. Forty-seven (11.5%) patients had cirrhosis and esophageal or gastric varices were found in 16 (3.9%) patients. Hepatocellular carcinoma was diagnosed prospectively in 7 (1.7%) patients. Regarding extrahepatic outcomes, 43 (10.6%) patients had extrahepatic cancer, and MACE occurred in 103 (25.3%) patients. Sixty-four (15.7%) participants died during follow-up, the leading causes being cardiovascular (42.2%) and infection (32.8%). Having at least one G allele of PNPLA3 independently increased the risk of developing cirrhosis (OR 12.33/95% CI 3.58–42.38; p < 0.001) and esophageal or gastric varices (OR 13.24/95% CI 1.49–117.52; p = 0.02), and decreased the risk of having extrahepatic cancer (OR 0.41/95% CI 0.18–0.90; p = 0.02). There was no association between the G allele of PNPLA3 and hepatocellular carcinoma, MACE or death. Regarding the T allele of TM6SF2, none of the analyses showed results with statistical significance.

Conclusion: T2DM NAFLD patients harbouring at least one minor allele of PNPLA3 rs738409 polymorphism have a worse prognosis regarding liver disease and should be followed carefully due to the higher odds of disease progression.

Interferon gamma-induced protein 10 levels increase across the spectrum of liver disease and are associated with insuline resistant components in subjects with non-alcoholic fatty liver disease

Marta Guariglia[1], Chiara Rosso[1], Fabrizia Carli[2], Gian Paolo Caviglia[1], Angelo Armandi[1,3], Eleonora Dileo[1], Nuria Pérez Diaz del Campo[1], Gabriele Castelnuovo[1], Maria Lorena Abate[1], Antonella Olivero[1], Daphne D'Amato[1], Amina Abdulle[1], Irene Poggiolini[1], Davide Ribaldone[1,4], Giorgio Maria Saracco[1,4], Amalia Gastaldelli[2], Elisabetta Bugianesi[1,4]. *[1]University of Turin, Department of medical science, Turin, Italy; [2]Institute of Clinical Physiology, CNR, Cardiometabolic Risk Unit, Pisa, Italy; [3]University medical center of the Johannes Gutenberg-University, I.Department of medicine, Mainz, Germany; [4]Città della salute e della scienza- Molinette Hospital, Gastroenterology Unit, Turin, Italy*
E-mail: marta.guariglia@unito.it

Background and aims: The most important determinant of the progression of non-alcoholic fatty liver disease (NAFLD) to non-alcoholic steatohepatitis (NASH) and fibrosis is insulin resistance (IR). Interferon gamma-induced protein 10 (IP-10), a proinflammatory chemokine, plays a crucial role in inflammatory diseases but its interaction with IR in the setting of NAFLD is not clear.

Method: We analysed data from 200 patients with biopsy proven NAFLD (M/F 121/79; mean age 47 ± 12). A subgroup of 46 non-diabetic NAFLD subjects underwent tracers studies (6, 6 -D2-glucose and [2H5] glycerol). Tracers enrichment was determined by GC-MS and data were used to calculate hepatic (Hep)-IR and adipose tissue (AT)-IR components. Serum IP-10 levels were assessed by Bio-Plex (BioRad Laboratories).

Results: Overall, 81/200 (40.5 %) patients had F ≥2 and 151/200 (75.5 %) had NASH. The prevalence of type 2 diabetes was 27.5 % and 47.5 % of the patients were obese. IP-10 levels significantly increased across lean to overweight to obese subjects (p = 0.009), showed a stepwise

increase according to the stages of hepatic fibrosis (p = 0.006) and were significantly higher in patients with NASH compared to those with NAFL (457 pg/ml vs 383 pg/ml, p = 0.039). Moreover, IP-10 levels were increased in diabetic compared to non-diabetic patients (491 pg/ml vs 393 pg/ml, p = 0.021) and showed a significant correlation with HOMA-IR (r = 0.30, p = 0.006). In the subgroup of non-obese, non-diabetic NAFLD patients who underwent tracers' studies, IP-10 levels showed a significant correlation with both Hep-IR and AT-IR (r = 0.32, p = 0.030 and r = 0.33, p = 0.049, respectively). At multivariate analysis, IP-10 was independently associated to the degree of hepatic fibrosis (r_p = 0.3, p = 0.05).

Conclusion: IP-10 may be involved in the complex pathogenesis of NAFLD. Further studies are needed to demonstrate its causality in determining liver damage.

E-mail: zobair.younossi@inova.org

Background and aims: Patients with fatty liver disease may experience stigmatization due to the disease or associated comorbidities. Aim: To understand stigma among NAFLD patients and providers.

Method: Members of the Global NASH Council created two surveys about experiences and attitudes toward NAFLD and related terms: a 68-item patient and a 41-item provider survey.

Results: The surveys were completed by 475 NAFLD patients [12 countries; 58% USA, 20% Middle East/North Africa (MENA), 20% East Asia (EA)] and 555 providers [63% GI/hepatologists, 14 countries; 28% USA, 44% MENA, 25% EA]. Of all patients, 71% ever disclosed having NAFLD/NASH to family/friends; the most used words were "fatty liver" and "NAFLD or NASH" (35–54%), while "metabolic disease" or "MAFLD" were rarely used (never by 83–88%). There were 46% who reported experiencing stigma or discrimination (at least sometimes) due to obesity/overweight vs. 17% due to NAFLD (Figure). The greatest social-emotional burden among NAFLD patients was feeling partially to blame for their liver disease (69% agree) and others believing that they do not eat properly (58% agree). Providers believed that lack of patient motivation (70%) and training in effective communication (62%) were the biggest obstacles to weight loss discussions. Furthermore, provider discomfort was related to perceived patients' lack of willpower for lifestyle changes and taking care of their diabetes (45–49% providers; 13–17% USA vs. 64–70% MENA, 31–67% EA). Regarding how various diagnostic terms are perceived by patients, there were no substantial differences between "NAFLD," "fatty liver disease (FLD)," "NASH," or "MAFLD": the most popular response was being neither comfortable nor uncomfortable with either term (47%-57%), with some greater discomfort with FLD among U.S. patients (45% uncomfortable). Among providers, 42% (49% USA, 43% MENA, 32% EA) believed that the term "fatty" in the name is stigmatizing, while 38% believed that the term "non-alcoholic" is stigmatizing, more commonly in MENA (47%). Also, 38% of the providers reported the term "FLD" as being stigmatizing (47% USA, 40% MENA, 24% EA). Finally, 54% of the providers (GI/hep 58% vs. 42% other specialties; 46% USA, 59% MENA, 51% EA) believe that a name change may reduce stigma.

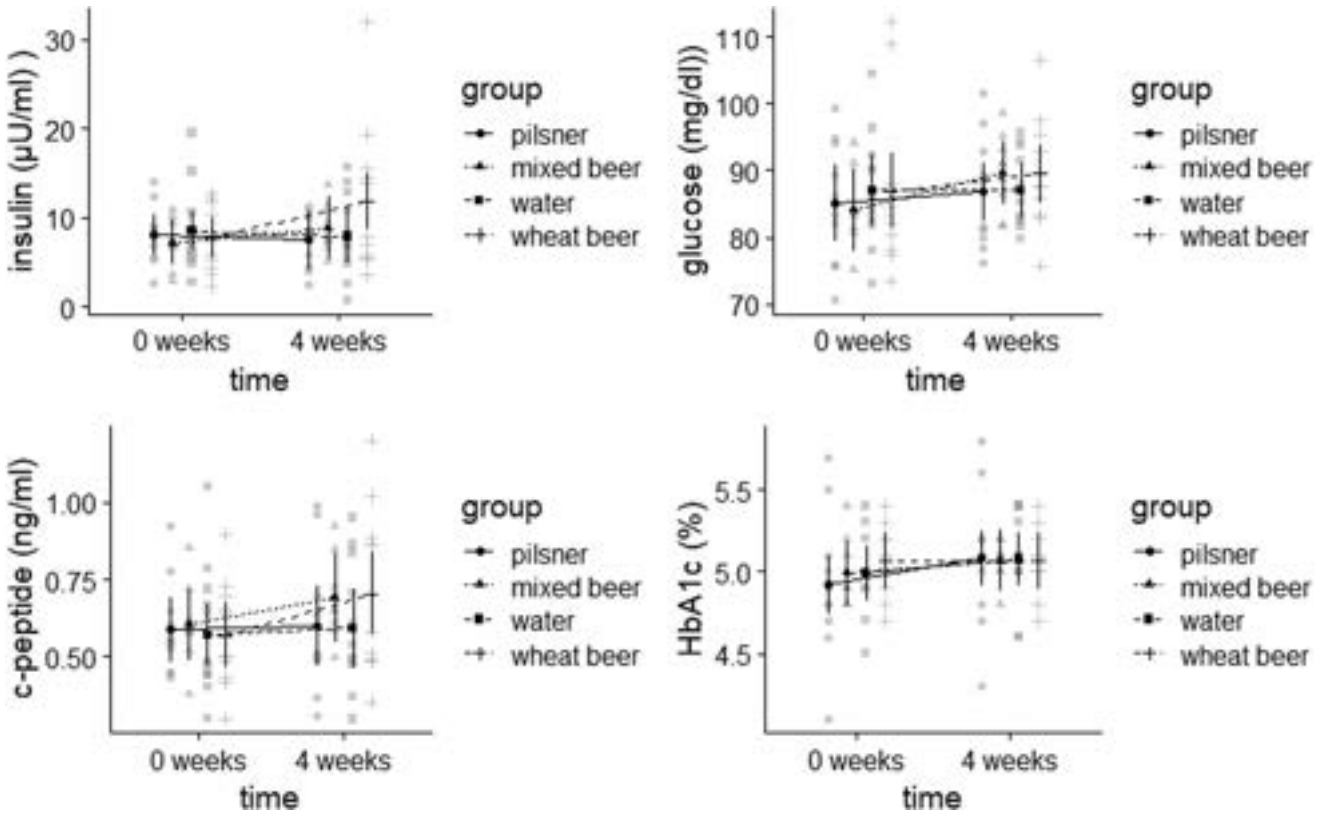

Figure: (abstract: THU-454).

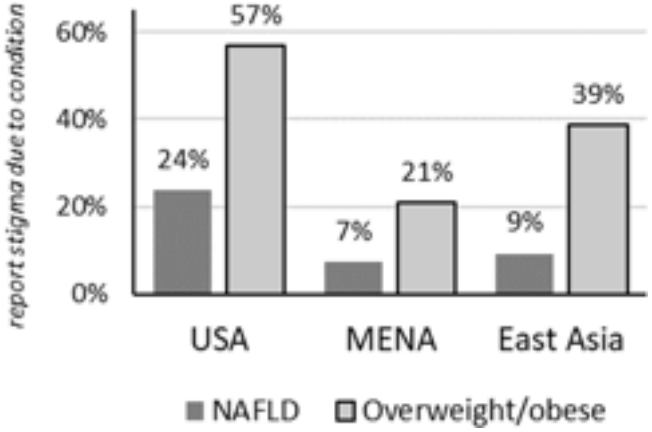

Figure:

Conclusion: Perception of NAFLD stigma varies according to patients, providers, geographic location and sub-specialty. NAFLD patients reported the term obesity to be more stigmatizing than NAFLD.

E-mail: henriette.kreimeyer@gmail.com

Background and aims: The amount of alcohol that can be consumed healthily without causing harm is currently under discussion. Recently, the gender-specific limit for daily alcohol consumption has been further reduced. Non-alcoholic alternatives to regular beer are often promoted. However, data on the effects of non-alcoholic beer on liver health are lacking. We investigated the influence of different non-alcoholic beer beverages [Pilsner (PI), wheat beer (WB), lemon-lime flavored drink/mixed drink (MD), and water (WA) as control] on fatty degeneration and liver damage and effects on glucose and lipid metabolism.

Method: In this monocentric, randomized, multi-arm study, 48 healthy young men were evaluated for serum markers of liver injury, glucose, and lipid metabolism. In addition, liver status was assessed by transient elastography, including measurement of the controlled attenuation parameter (CAP). Blood samples were collected at the beginning and end of a four-week period, during which the subjects were required to consume two 330 ml bottles of each beverage daily.

Results: Deterioration of glucose metabolism markers was observed in all groups compared to controls. Insulin and c-peptide increased significantly in the WB group, while fasting glucose increased in the MB group, and HbA1c increased in the PI group. Triglyceride levels increased in the MB and WB groups and decreased in the WA and PI groups, but not significantly. HDL showed a significant increase in the WA group. Liver enzymes showed a substantial increase in the MB group, while transient elastography results showed no differences. M30, an apoptosis marker, showed a significant decrease in liver damage in the WA and PI groups.

Conclusion: Four weeks of alcohol-free beverage consumption altered several serum parameters associated with glucose, liver, and lipid metabolism in this cohort of healthy young men. In addition, consumption of mixed beer was associated with more significant liver inflammation.

THU-455

Cognitive impairment is frequent in obesity and not restricted to persons with biopsy-proven NAFLD

Charlotte Wernberg[1], Lea Ladegaard Grønkjær[2], Birgitte Jacobsen[2], Vineesh Indira Chandran[3], Jonas Graversen[3], Aleksander Krag[4], Karin Weissenborn[5], Hendrik Vilstrup[6], Mette Munk Lauridsen[2].

E-mail: mettelauridsen@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) may be associated with cognitive dysfunction due to metabolic an micro-ischemic encephalopathy. We aimed to identify the prevalence of cognitive impairment in an obese cohort, assess the association to biopsy-proven NAFLD, and describe the nature of the impairment.
Method: Liver biopsy and basic cognitive testing with Continuous Reaction Time test (CRT), Portosystemic Encephalopathy-Syndrome test (PSE), and Stroop EncephalApp were performed in all. A representative sub-group further underwent Repeatable Battery for the Assessment of Neuropsychological Status (RBANS). 'Cognitive impairment' was defined as ≥2 abnormal basic cognitive tests or abnormal RBANS.
Results: We included 180 persons with BMI >35 kg/m, 72 % women, age 46 ± 12 years, 54 % had NAFLD, and 24 % had steatohepatitis. Eight percent were impaired as defined by CRT, PSE, and Stroop, and 41 % by RBANS. Executive functions and memory were the most affected domains. Male gender, the use of 2 or more psychoactive medications, and low LDL were risk factors (table). There was no correlation to BMI, NAFLD severity, or other metabolic co-morbidities. The few with advanced liver fibrosis performed worse in PSE.
Conclusion: Cognitive impairment was frequent in our obese cohort; not associated with NAFLD severity; and differed from hepatic encephalopathy by severely impacting immediate and late memory. Fibrosis was associated with poor performance in PSE, which might reflect a pre-cirrhosis hepatic encephalopathy.

E-mail: margaret.tenglp@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the fastest growing cause of chronic liver disease globally. Beyond hepatic complications, NAFLD is associated with extra-hepatic disorders such as cardiometabolic diseases, oncological disorders, and other clinical conditions that pose adverse health effects. This study aims to provide an updated meta-analysis on the umbrella of incident clinical complications associated with NAFLD and the effects when stratified by gender and severity of NAFLD.
Method: Medline and Embase databases were searched from inception to 13 November 2022. Search terms included but were not limited to "non-alcoholic fatty liver disease" and "longitudinal outcomes." The DerSimonian and Laird random effects model was used to pool reported effect sizes assessing the longitudinal risks of clinical outcomes associated with NAFLD. Subgroup analyses stratified by NAFLD diagnostic modality, gender, weight class and NAFLD severity were conducted to explore possible heterogeneity.
Results: 129 articles were included in this study. A pooled analysis of 44 articles and 6 151 043 individuals found that NAFLD patients had a greater risk of cardiovascular outcomes (n = 44, HR: 1.43, 95%CI: 1.27–1.60, p < 0.01, I^2 = 97.50%) compared to non-NAFLD individuals. In the assessment of incident metabolic disorders, NAFLD patients were found to have a significantly greater risk of incident hypertension (n

HOMA-IR, homeostatic model assessment for insulin resistance; AST, aspartate aminotransferase; LDL, low-density lipoprotein; HDL, high-density lipoprotein cholesterol; CRP, c-reactive protein; psychoactive medication are antidepressants, antipsychotics, morphine or analogues.

= 9, HR: 1.75, 95%CI: 1.46–2.08, p < 0.01, I^2 = 74.00%), diabetes (n = 37, HR: 2.56, 95%CI: 2.10–3.13, p < 0.01, I^2 = 98.90%), pre-diabetes (n = 4, HR: 1.69, 95%CI: 1.22–2.35, p < 0.01, I^2 = 54.80%), chronic kidney disease (n = 14, HR: 1.38, 95%CI: 1.27–1.50, p < 0.01, I^2 = 80.20%) and metabolic syndrome (n = 5, HR: 2.57, 95%CI: 1.13–5.85, p = 0.02, I^2 = 96.10%). By subgroup analysis, NAFLD patients with advanced liver disease were also found to have a significantly higher risk (p = 0.02) of incident diabetes than those with less severe NAFLD in comparison to non-NAFLD individuals. There was a positive relationship (n = 15, HR: 1.54, 95%CI: 1.35–1.76, p < 0.01, I^2 = 97.30%) between NAFLD and incident cancers when compared to a non-NAFLD cohort. NAFLD was also found to be associated with a significantly greater risk of liver-related outcomes (n = 14, HR: 3.92, 95%CI: 2.05–7.49, p < 0.01, I^2 = 98.50%) and gallstone formation (n = 2, HR: 1.24, 95%CI: 1.16–1.32, p < 0.01, I^2 = 0.00%) when compared to non-NAFLD. No statistical association was found between NAFLD and the risk of incident reflux esophagitis and dementia.

Conclusion: This meta-analysis provides a necessary update on the longitudinal risks of clinical outcomes associated with NAFLD. While this study suggests that NAFLD is associated with an increased risk of disease outcomes and extra-hepatic complications, further research is required to understand the pathophysiology linking NAFLD with development of extra-hepatic disorders.

THU-457

Metabolic dysfunction-associated fatty liver disease is associated with increased risk of extrahepatic malignancies: a nationwide cohort study

Min Kyung Park[1], Hye-Sung Moon[2], Sungwon Chung[1], Sungho Won[2,3], Yun Bin Lee[1], Eun Ju Cho[1], Jeong-Hoon Lee[1], Su Jong Yu[1], Jung-Hwan Yoon[1], Yoon Jun Kim[1]. [1]*Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Korea, Rep. of South;* [2]*RexSoft Inc., Korea, Rep. of South;* [3]*Seoul National University, Department of Public Health Sciences, Graduate School of Public Health, Korea, Rep. of South*
E-mail: yoonjun@snu.ac.kr

Background and aims: Metabolic dysfunction-associated fatty liver disease (MAFLD), a new definition encompassing the entire liver disease associated with metabolic disorders, has been recently proposed. We aimed to analyze the long-term outcome of MAFLD by focusing on extrahepatic malignancy.

Method: We analyzed data from the National Health Insurance Service of Korea that includes 7 454 412 participants who participated health screening program in 2009. MAFLD was defined by an international expert consensus statement previously proposed. Participants were further categorized into four groups followed by the MAFLD definition; non-MAFLD, DM-MAFLD, overweight/obese-MAFLD, and lean-MAFLD. The primary outcome was the development of any primary extrahepatic malignancy. The Cox proportional hazard model was used, including adjustment for competing risks.

Results: Of the study subjects, 2 500 080 (33.5%) had MAFLD. During the median follow-up of 10.3 years (interquartile range, 10.1–10.6), 447 880 patients (6.0%) were diagnosed with primary extrahepatic malignancy. The MAFLD group had a higher overall risk of extrahepatic malignancy than non-MAFLD group (adjusted subdistribution hazard ratio [aSHR] = 1.02; 95% confidence interval [CI] = 1.02–1.03; P < .001). The DM-MAFLD group showed a significantly higher risk of extrahepatic malignancy compared to the non-MAFLD group (aSHR = 1.13; 95% CI = 1.11–1.14; P < .001). Furthermore, the lean-MAFLD group also showed a 1.12-fold higher risk of extrahepatic malignancy than the non-MAFLD group (aSHR = 1.12; 95% CI = 1.10–1.14; P < .001). However, the overweight/obese-MAFLD group showed no significant overall risk of extrahepatic malignancy compared to the non-MAFLD group (aSHR = 1.00; 95% CI = 0.99–1.00; P = 0.42). Sensitivity analysis after excluding underlying liver disease, the MAFLD group maintained a significantly higher extrahepatic malignancy than the non-MAFLD group (aSHR = 1.02; 95% CI = 1.02–1.03; P < .001).

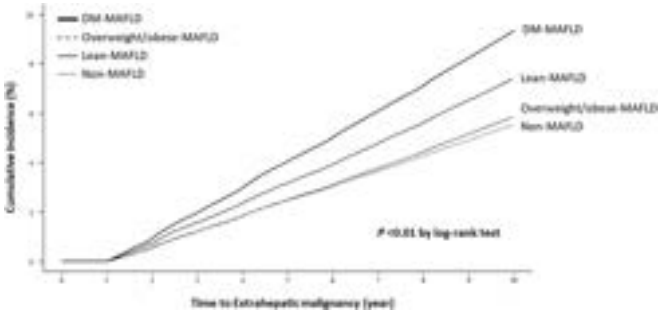

Figure:

Conclusion: MAFLD is associated with developing extrahepatic malignancy, while MAFLD caused by overweight or obese demonstrated no association with developing extrahepatic malignancy. Categorizing MAFLD subgroup according to the positive definition criteria representing the phenotypes of metabolic disorders could help the stratification of the risk of extrahepatic malignancy in MAFLD.

THU-458

Non-alcoholic fatty liver disease (NAFLD) is associated with an increased risk of type 2 diabetes mellitus

Sven H. Loosen[1], Tom Lüdde[1], Christoph Roderburg[1]. [1]*University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University Düsseldorf, Clinic for Gastroenterology, Hepatology and Infectious Diseases, Düsseldorf, Germany*
E-mail: christoph.roderburg@med.uni-duesseldorf.de

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has become the most common liver disease worldwide and represents the leading cause of liver-related morbidity and mortality. Its all cause mortality is often driven by co-existing metabolic disease such as type 2 diabetes mellitus (T2DM), which share many pathophysiological characteristics. The risk of developing T2DM among NAFLD patients in Germany is only poorly described. Here, we evaluated the risk of T2DM development in a large cohort of primary care patients in Germany

Method: A cohort of 17 245 NAFLD patients and a propensity score matched cohort of equal size were identified from the Disease Analyzer database (IQVIA) between 2005 and 2020. The incidence of T2DM was evaluated as a function of NAFLD during a five years study period using Cox-regression models.

Results: Within 5 years of the index date, 18.8% and 11.7% of individuals with and without NAFLD were diagnosed with T2DM (p < 0.001, Figure 1). Regression analysis revealed a Hazard Ratio (HR) of 1.77 (95%CI: 1.68–1.88) for the development of T2DM among NAFLD patients. Subgroup analyses confirmed this association for all age groups (18–50, 51–60, 61–70, and >70 years), male and female patients, as well as normal weight (BMI <25 kg/m^2), overweighted (BMI 25–30 kg/m^2) and obese (BMI >30 kg/m^2) patients.

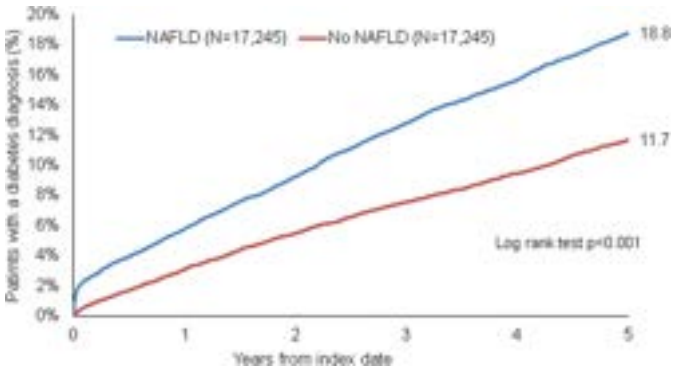

Figure: Kaplan-Meier curves estimating the time to diagnosis of T2DM in patients with and without NAFLD.

Conclusion: Our data revealed a significantly increased incidence of T2DM among NAFLD patients in Germany. Given the dramatically increasing global relevance of NAFLD, we believe that prevention and regular screening programs for T2DM in NAFLD patients could help to reduce its high mortality and morbidity in the future.
NAFLD: Non-alcoholic fatty liver disease, T2DM: Type 2 diabetes mellitus

THU-459

Metabolic dysfunction associated fatty liver disease and the risk of hepatocellular carcinoma

Byeong Geun Song[1], Aryoung Kim[1], Sung Chul Choi[2], Myungji Goh[1], Wonseok Kang[1], Geum-Yon Gwak[1], Yong-Han Paik[1], Moon Seok Choi[1], Joon Hyeok Lee[1], Seung Woon Paik[1], Dong Hyun Sinn[1]. *[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Korea, Rep. of South, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Center for Health Promotion, Korea, Rep. of South*
E-mail: sinndhn@hanmail.net

Background and aims: The metabolic dysfunction-associated fatty liver disease (MAFLD) is a new inclusive term proposed to replace non-alcoholic fatty liver disease (NAFLD). We analysed whether hepatocellular carcinoma (HCC) risk differs by MAFLD or NAFLD status in large asymptomatic adults.
Method: Total of 73 691 adults were followed-up for the development of HCC. NAFLD was diagnosed among participants without other liver disease (n = 65 992).
Results: Participants with MAFLD showed higher incidence of HCC compared with those without MAFLD (0.37 and 0.24 per 1000 person-years, p = 0.006). However, MAFLD was not an independent factor associated with HCC in multivariable analysis [hazard ratio (HR), 1.21; 95% confidence interval (CI), 0.92–1.60]. When stratified according to presence of other liver diseases, MAFLD was not associated with HCC in participants with other liver diseases. In participants without other liver disease, both MAFLD (adjusted HR, 1.84; 95% CI, 1.09–3.11) and NAFLD (adjusted HR, 1.71; 95% CI, 1.01–2.90) was independent factor associated with HCC. When stratified according to NAFLD and MAFLD status, there was no HCC development among NAFLD only participants, but these NAFLD only group comprised 3.4%, and majority with hepatic steatosis fulfilled both NAFLD and MAFLD criteria.
Conclusion: MAFLD could be diagnosed for broader population including participants with other liver diseases, however, MAFLD demonstrated no association with HCC in participants with other liver diseases. The risk of HCC was very low for NAFLD only participants but made up a very small percentage. These findings do not support change in nomenclature from NAFLD to MAFLD.

THU-460

Assessing treatment outcomes in an AIH/NAFLD overlap cohort

Eleanor Belilos[1], Jessica Strzepka[1], Shiriam Jakate[1], Costica Aloman[1], Nancy S Reau[1]. *[1]Rush University Medical Center, United States*
E-mail: eleanor_a_belilos@rush.edu

Background and aims: Overlap between autoimmune hepatitis (AIH) and non-alcoholic fatty liver disease (NAFLD) has become increasingly common in recent years as NAFLD has emerged as the main cause of liver disease worldwide. AIH treatment includes steroids, which have adverse metabolic effects that can worsen NAFLD. No specific treatment guidelines are available to mitigate these effects or redefine treatment goals in the AIH/NAFLD overlap population. Previous data from our study cohort found that AIH/NAFLD overlap patients have lower rates of biochemical remission but have similar clinical outcomes, despite a treatment course that is less likely to adhere to AIH standard of care per AASLD guidelines. This new study aims to expand our understanding of this unique patient cohort by validating previous findings with a larger sample size as well as examining additional outcomes such as time to completion of steroid treatment, Fibrosis-4 (FIB4), and AST to Platelet Ratio Index (APRI) at additional defined time points (three months, one year, two years, and three years).
Method: This was a single-center, retrospective descriptive study examining biopsy proven AIH and AIH/NAFLD patients (2009–2019). Baseline and follow-up clinical and biochemical parameters, FIB-4, APRI and clinical outcomes (if off steroids, all-cause mortality, need for liver transplantation, or decompensated cirrhosis) at three months, one year, two years, and three years were recorded and compared using appropriate statistical testing for continuous (t-tests) and categorical variables (Chi-square, Fisher's exact).
Results: A total of 123 patients (44.7% AIH/NAFLD and 55.3% AIH) were included. AIH patients had higher AST and ALT, FIB4, and APRI at baseline, but also greater improvement from baseline in transaminase levels at all time points ($p < 0.001$). AIH/NAFLD patients were more likely to be in biochemical remission (defined as normalization of AST and ALT) at three months ($p = 0.007$), but less likely at one year ($p < 0.001$), and three years ($p = 0.011$). Although AIH/NAFLD patients less frequently received AIH standard of care treatment ($p < 0.001$), those who did were then less likely to be off steroids ($p = 0.011$) at one year. No significant differences were seen in FIB4, APRI, all-cause mortality, need for liver transplantation, or incidence of decompensated cirrhosis at all future time points (three months, one year, two years, three years).

		AIH	AIH/NAFLD	p value
Biochemical Remission, 3 months (%)	No	30 (46.2%)	37 (71.2)	0.007*
	Yes	35 (53.8)	15 (28.8)	
Biochemical Remission, 1 year (%)	No	8 (13.3)	25 (46.3)	<0.001*
	Yes	52 (86.7)	29 (53.7)	
Biochemical Remission, 2 years (%)	No	6 (12.0)	13 (27.1)	0.059
	Yes	44 (88.0)	35 (72.9)	
Biochemical Remission, 3 years (%)	No	4 (9.3)	14 (31.1)	0.011*
	Yes	39 (90.7)	31 (68.9)	
Off steroids, 3 months (%)	No	49 (84.5)	30 (85.7)	0.872
	Yes	9 (15.5)	5 (14.3)	
Off steroids, 1 year (%)	No	17 (31.5)	20 (58.8)	0.011*
	Yes	37 (68.5)	14 (41.2)	
Off steroids, 2 years (%)	No	9 (20.0)	12 (37.5)	0.089
	Yes	36 (80.0)	20 (62.5)	
Off steroids, 3 years (%)	No	7 (18.4)	10 (31.2)	0.212
	Yes	31 (81.6)	22 (68.8)	

Figure:

Conclusion: The results of this study support that while AIH/NAFLD patients have lower initial biochemical activity than those with AIH alone, biochemical response to treatment appears to be lower. Given that similar clinical outcomes were observed, this may indicate that AIH/NAFLD overlap may benefit from an alternative remission definition as well as unique treatment guidelines.

THU-461

Metabolic associated fatty liver disease: different impact of the three defining criteria on the hepatic and cardiovascular complications

Rosa Lombardi[1,2], Jaqueline Currà[2], Annalisa Cespiati[1,2], Andrea Dalbeni[3,4], Floriana Santomenna[2], Lucia Colavolpe[2], Francesca Alletto[2], Giovanna Oberti[2], Felice Cinque[2], Daniel Smith[2], Erika Fatta[1], Cristina Bertelli[1], Paola Dongiovanni[1], David Sacerdoti[3,4], Silvia Fargion[2], Anna Ludovica Fracanzani[1,2]. *[1]Unit of Medicine and Metabolic Disease, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, Milan, Italy, Italy; [2]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy, Italy; [3]Division of General Medicine C, Department of Medicine, University and Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy, Italy; [4]Liver Unit, Department of Medicine, University and Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy, Italy*
E-mail: rosalombardi@hotmail.it

Background and aims: Metabolic associated fatty liver disease (MAFLD) is defined by the presence of hepatic steatosis and one criteria among: (1) body mass index (BMI)>25 kg/m2; (2) type 2 diabetes (DM); (3) metabolic dysregulation in lean subjects (BMI<25). MAFLD exposes to hepatic and cardiovascular (CV) disease. Aim: to evaluate the different impact of each of the three features of MAFLD on the hepatic and CV disease.
Method: 688 subjects (69% males, mean age 53 ± 12 ys) were classified as MAFLD and enrolled in two Italian liver units. Liver disease was evaluated by ultrasound (US) to detect and grade hepatic steatosis and by Fibroscan to diagnose advanced fibrosis (≥F3) (liver stiffness measurement, LSM>8.2 kPa). CV disease was evaluated by carotid Doppler US and radiofrequency (carotid plaques; carotid stiffness as pulse wave velocity (PWV)),
Results: Eighty% of patients had BMI>25 without other metabolic alterations (obese, group 1), 2% had DM without other metabolic alterations (group 2), 13% had BMI>25+DM (group 3) and 5% had BMI<25 with metabolic dysregulation (lean, group 4). Because of the small number of pure DM, we considered group 2 and 3 together (BMI>25+DM, group 2a). By comparing group 1 and 4, obese and lean patients had the same severity of liver (severe steatosis 16% vs 12%, p = 0.63; advanced fibrosis 8% vs 3%, p = 0.49) and CV disease (plaques 30% vs 44%, p = 0.129; increases EAT 27% vs 33%, p = 0.53; PWV 7.8 ± 1.9 vs 7.9 ± 1.9 m/s, p = 0.77). When comparing patients with BMI>25 +DM with simple obese or lean, an increased prevalence of severe steatosis was evident in this group vs the other two (30% vs 16%, p = 0.006; 30% vs 12%, p = 0.06) and ≥F3 (31% vs 8%, p < 0.001; 31% vs 3%, p = 0.001). As for CV disease, a higher prevalence of increased EAT (40%, p = 0.02), carotid plaques (61% vs 30%, p < 0.001) and increased PWV values (8.7 ± 2 m/s vs 7.8 ± 1.9, p < 0.001) was seen in group BMI>25+DM compared only to pure obese, with superimposable results compared to lean subjects. In multivariate analysis (adjusted for age, sex, smoking and statins use), BMI>25+DM remained an independent risk factor for severe steatosis (OR 2.4, CI 95 1.5–4.1), ≥F3 (OR 3.6, CI 95 1.9–6.6) and carotid plaques (OR 1.8, CI 95 1.1–3.0).
Conclusion: Among all features of MAFLD, lean subjects with metabolic dysregulation present the same hepatic and cardiovascular alterations of obese subjects without DM and even the same CV alterations of patients with coexistence of obesity and DM. As expected, the coexistence of obesity and DM seems to play the major role in the onset of hepatic and CV damage. This stresses on the need of a careful screening for complications and metabolic alterations in MAFLD patients, even if lean.

THU-462

Histological and biopsychosocial predictors of quality of life in Spanish and UK cohorts of patients with non-alcoholic fatty liver disease

Jesús Funuyet-Salas[1], Agustín Martín-Rodríguez[1], María Angeles Pérez-San-Gregorio[1], Luke Vale[2,3,4], Tomos Robinson[2,4], Quentin Anstee[5,6], Manuel Romero Gomez[7], on behalf of the LITMUS consortium investigators. *[1]Department of Personality, Assessment, and Psychological Treatment, Faculty of Psychology, University of Seville, Seville, Spain, Spain; [2]Health Economics Group, Population Health Sciences Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, UK, United Kingdom; [3]National Institute for Health Research (NIHR) Newcastle In vitro Diagnostics Co-operative, Newcastle upon Tyne, UK, United Kingdom; [4]NIHR Applied Research Collaboration North East and North Cumbria, Newcastle University, Newcastle upon Tyne, UK, United Kingdom; [5]Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, UK and Newcastle NIHR Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Trust, Newcastle upon Tyne, UK, United Kingdom; [6]Newcastle NIHR Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Trust, Newcastle upon Tyne, UK, United Kingdom; [7]UCM Digestive Diseases and Ciberehd, Virgen del Rocío University Hospital, Institute of Biomedicine of Seville, University of Seville, Seville, Spain, Spain*
E-mail: jfunuyet1@us.es

Background and aims: It is unclear what biopsychosocial factors affect the impact of non-alcoholic fatty liver disease (NAFLD) on quality of life (QoL), and if these factors are equally important between different nationalities. We sought to: 1) Compare QoL of NAFLD patients based on place of origin and liver severity; and 2) Identify which variables predict QoL in Spanish and UK patient cohorts.
Method: The total sample of 737 biopsy-proven NAFLD patients was evaluated using CLDQ-NAFLD. Five groups (G_1, n = 513, Spain; G_2, n = 224, UK; G_3, n = 370, none/mild fibrosis; G_4, n = 286, moderate fibrosis; G_5, n = 81, severe fibrosis) were formed and a 2 × 3 factorial ANOVA (Snedecor's F) was performed to analyse the influence of place of origin and liver severity on QoL. A logistic regression was used to determine the effects of NASH, fibrosis, body mass index (BMI), gender, age, education and employment status on QoL in both patient cohorts separately. Coheńs d was used as an index of effect size.
Results: The strongest evidence of differences (medium effect size) were that, regardless of fibrosis stage, UK participants (G_2) were more worried ($p < 0.001$, $d = 0.53$) than Spanish participants (G_1). Regardless of place of origin, participants with severe fibrosis (G_5) were more fatigued ($p < 0.001$, $d = 0.54$), had more systemic symptoms ($p < 0.001$, $d = 0.50$), more worry ($p < 0.001$, $d = 0.51$), and lower QoL ($p < 0.001$, $d = 0.64$) than those with none/mild fibrosis (G_5). In addition, for Spanish participants, QoL reduced as fibrosis (OR = 0.29, 95% CI = 0.16–0.51, p < 0.001) and BMI (OR = 0.92, 95% CI = 0.87–0.97, p = 0.002) increased. Lower QoL was also independently associated with female gender (OR = 0.30, 95% CI = 0.18–0.50, p < 0.001). For UK participants, QoL reduced as BMI (OR = 0.94, 95% CI = 0.89–1.00, p = 0.047) increased. Lower QoL was also associated with female gender (OR = 0.45, 95% CI = 0.22–0.91, p = 0.028), non-active employment status (OR = 0.34, 95% CI = 0.15–0.74, p = 0.007) and younger age (OR = 1.06, 95% CI = 1.03–1.10, p < 0.001).
Conclusion: QoL was mainly lower in UK than Spanish participants, and they had more worry about the liver disease. Higher fibrosis stage predicted lower QoL, mainly in the Spanish cohort. Female gender and higher BMI contributed to the impact on QoL in both cohorts and

should be considered in future multinational intervention studies in NAFLD.

THU-463

Clinical features of non-obese NAFLD: analysis of health check-up cohort

Shunsuke Sato[1], Hidehiko Kawai[2], Rifa Omu[3], Yuji Kita[3], Yuji Ikeda[3], Sho Sato[3], Ayato Murata[3], Yuji Shimada[3], Takuya Genda[3]. *[1]Juntendo University Shizuoka Hospital, Gastroenterology and Hepatology, Shizuoka, Japan; [2]Fuji Town Medical Center, Shizuoka, Japan; [1]Juntendo University Shizuoka Hospital, Gastroenterology and Hepatology, Shizuoka, Japan*
E-mail: syusato@juntendo.ac.jp

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is commonly associated with obesity, but it is increasingly being recognized in non-obese individuals, particularly in Asia. We aimed to clarify the frequency and clinical features of non-obese NAFLD using a health check-up cohort.
Method: A total of 1046 subjects underwent a quantitative evaluation of liver steatosis (attenuation: ATT) and fibrosis (shear wave elastography: SWE) using ARIETTA 850SE (Fujifilm Healthcare) in 2020. Among them, 7 with obvious chronic liver disease and 22 who consumed >60 g alcohol/day were excluded. Finally, 1017 subjects were enrolled. Non-obese was defined as BMI <25 kg/m^2. Based on previous studies, cut of values for steatosis were S1 (0.62), S2 (0.67), and S3 (0.73), and NAFLD was defined as ≥0.62 dB/cm/MHz. In addition, cut of values for fibrosis were F1 (1.26), F2 (1.51), and F3 (1.63), and NAFLD with fibrosis was defined as ATT ≥0.62 dB/cm/MHz and SWE ≥1.26 KPa.
Results: The overall prevalence of NAFLD was 36.9%, while those for obese and non-obese subjects were 59.6% and 29.1%, respectively. Despite having a relatively normal BMI, most non-obese NAFLD versus normal liver subjects had a large waist circumference (80.0% vs. 9.9%) and dyslipidemia (59.5% vs, 42.1%). Logistic regression analysis revealed that dyslipidemia (OR = 1.898), ALT level (OR = 1.045), and GGT level (OR = 0.994), and platelet count (OR = 1.037) were significantly associated with liver steatosis. Dyslipidemia was present in 36.7% of the non-obese NAFLD subjects. Many obese NAFLD subjects showed abnormal liver function test (S1, 18.2%; S2 26.4%; S3 48.3%; P = 0.001), whereas most non-obese NAFLD subjects did not (S1, 6.1%; S2, 5.5%; S3, 10.4%; P = 0.241). Among the 220 non-obese NAFLD subjects, 62 (28.1%) presented liver fibrosis (F1, 20.5%; F2, 4.1%; F3, 2.5%) and a large waist circumference (22.6% vs. 10.1%), hypertension (38.7% vs. 25.9%), and diabetes (12.9 vs, 2.5%) versus those without fibrosis. Logistic regression analysis revealed that male sex (OR = 2.328), diabetes (OR = 3.928), and AST level (OR = 1.051) were significantly associated with fibrosis. The non-obese NAFLD subjects with diabetes had a high prevalence of liver fibrosis (52.5% vs. 28.4%). A high FIB-4 index (>1.30) was observed in many obese NAFLD subjects with fibrosis (F1, 26.2%; S2, 16.7%; S3, 55.6%; P = 0.002), but non-obese NAFLD subjects (F1, 33.3%; F2 22.2%; F3 28.6%; P = 0.267).
Conclusion: NAFLD was present in 29.1% of non-obese subjects and fibrosis was present in 28.1% of non-obese NAFLD subjects. Non-obese NAFLD was significantly associated with metabolic disorders. Our study findings suggest that the liver function test and FIB-4 index may be less useful in non-obese NAFLD.

THU-464

Sarcopenia is an independent risk factor for non-alcoholic fatty liver disease regardless of fat mass in men: 1:1 propensity score matching analysis

Jun-Hyuk Lee[1], Yu-Jin Kwon[2], Da-Hye Son[2,3], Eileen Yoon[4], Sang Bong Ahn[5], Dae Won Jun[4]. *[1]Nowon Eulji Medical Center, Eulji University School of Medicine, Family medicine, Seoul, Korea, Rep. of South, [2]Yongin Severance Hospital, Yonsei university college of medicine, Family medicine, Yongin-si, Korea, Rep. of South; [3]Gangnam Severance Hospital, Yonsei university college of medicine, Family medicine, Seoul, Korea, Rep. of South; [4]Hanyang university college of medicine, Internal medicine, Seoul, Korea, Rep. of South; [5]Nowon Eulji Medical Center, Eulji University School of Medicine, Internal medicine, Seoul, Korea, Rep. of South*
E-mail: dr486@eulji.ac.kr

Background and aims: Although sarcopenia is positively related to non-alcoholic fatty liver disease (NAFLD), it is unclear whether patients with sarcopenia is still at higher risk of NAFLD than normal people under the same fat mass. This study aimed to evaluate the association of low skeletal muscle mass index (LSMI) and NAFLD in Korean adults using 1:1 propensity score matching.
Method: Data from 2008–2010 Korean National Health and Nutrition Examination Survey was analyzed. Propensity score matching was applied using logistic regression with covariates including age, height-adjusted waist circumference, height-adjusted body fat mass, height-adjusted bone mass, total energy intake, physical activity, drinking status, and smoking status. LSMI was defined as height-adjusted skeletal muscle mass <7.0 kg/m^2 in men and <5.4 kg/m^2 in women using dual-energy X-ray absorptiometry. NAFLD was defined as NAFLD-liver fat score >−0.640. A total of 3098 adults (497 men with LSMI, 497 men without LSMI, 1052 women with LSMI, and 1052 women without LSMI) included in the study. Logistic regression analysis was performed to estimate odds ratio (OR) with confidence interval (CI) for NAFLD of people with LSMI compared with those without LSMI, separately in men and women.
Results: After propensity score matching, there were no differences in the mean values of age, height-adjusted waist circumference, height-adjusted body fat mass, height-adjusted bone mass, and total energy intake as well as the proportion of regular exerciser, current drinker, and current smokers between LSMI group and non-LSMI group in both men and women, unlike before propensity score matching. The prevalence rate of NAFLD was 33.5% in men and 20.4% in women, respectively. Men with LSMI had higher OR with 95% CI for NAFLD compared with men without LSMI (OR = 1.50; 95% CI: 1.13–1.98, p = 0.005) indicating that the average effect of the LSMI is to increase risk of NAFLD. There was no significant difference in OR with

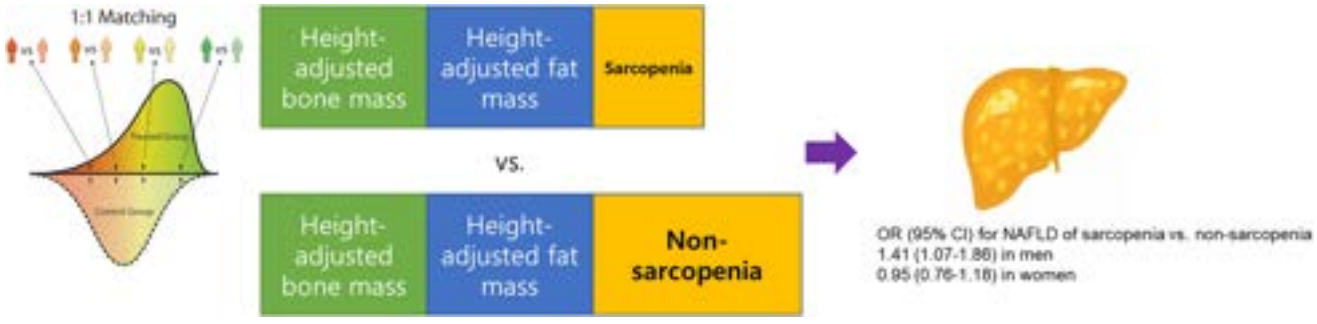

Figure: (abstract: THU-464).

95% CI for NAFLD between women with LSMI and those without LSMI (OR = 1.04; 95% CI: 0.84–1.30, p = 0.721).
Conclusion: LSMI was significantly related to NAFLD in men, not in women. This suggests that risk assessment for NAFLD may differ by gender, and such an assessment is particularly warranted for men with low muscle mass regardless of fat mass.

THU-465
Serum uric acid levels and prognosis of patients with non-alcoholic fatty liver disease
Su Lin[1,1], Yang Xinyi[1], Jiaofeng Huang[1], Chi Yujing[1]. [1]*The first affiliated hospital, Fujian medical university, China*
E-mail: sumer5129@fjmu.edu.cn

Background and aims: Uric acid (UA) is closely associated with non-alcoholic fatty liver disease (NAFLD). Previous studies have shown a significant association between hyperuricaemia and the development of NAFLD. However, it is unclear whether UA plays a predictive role in NAFLD prognosis. This study aimed to explore the relationship between UA levels and mortality in NAFLD patients without severe renal disease.
Method: Data were obtained from the Third National Health and Nutrition Examination Survey (NHANES). The survey was performed in 1988–1994 and all individuals were followed up until December 2015 for survival status. A Kaplan-Meier survival curve was plotted to illustrate mortality between cohorts. X-tile was used to determine the best UA cut-off value to discriminate between survival and death. Time-dependent Cox regression was used to estimate the hazard ratio (HR) and 95% confidence interval (CI) for mortality. Propensity score matching (PSM) was applied to match age and sex, to balance the baseline characteristics between the two study groups.
Results: Overall, 2493 individuals with NAFLD and estimated glomerular filtration rate (eGFR) >60 ml/min/1.73 m^2 were included in this study. The mean age was 44.21 ± 15.03 years and 56.56% were male patients. The median follow-up period was 26.58 years. During this period, 849 (34.06%) deaths were recorded. The mean UA level was 325.63 ± 86.60 in the death group, which was significantly higher than that of the survival group (304.86 ± 84.17, p < 0.001). According

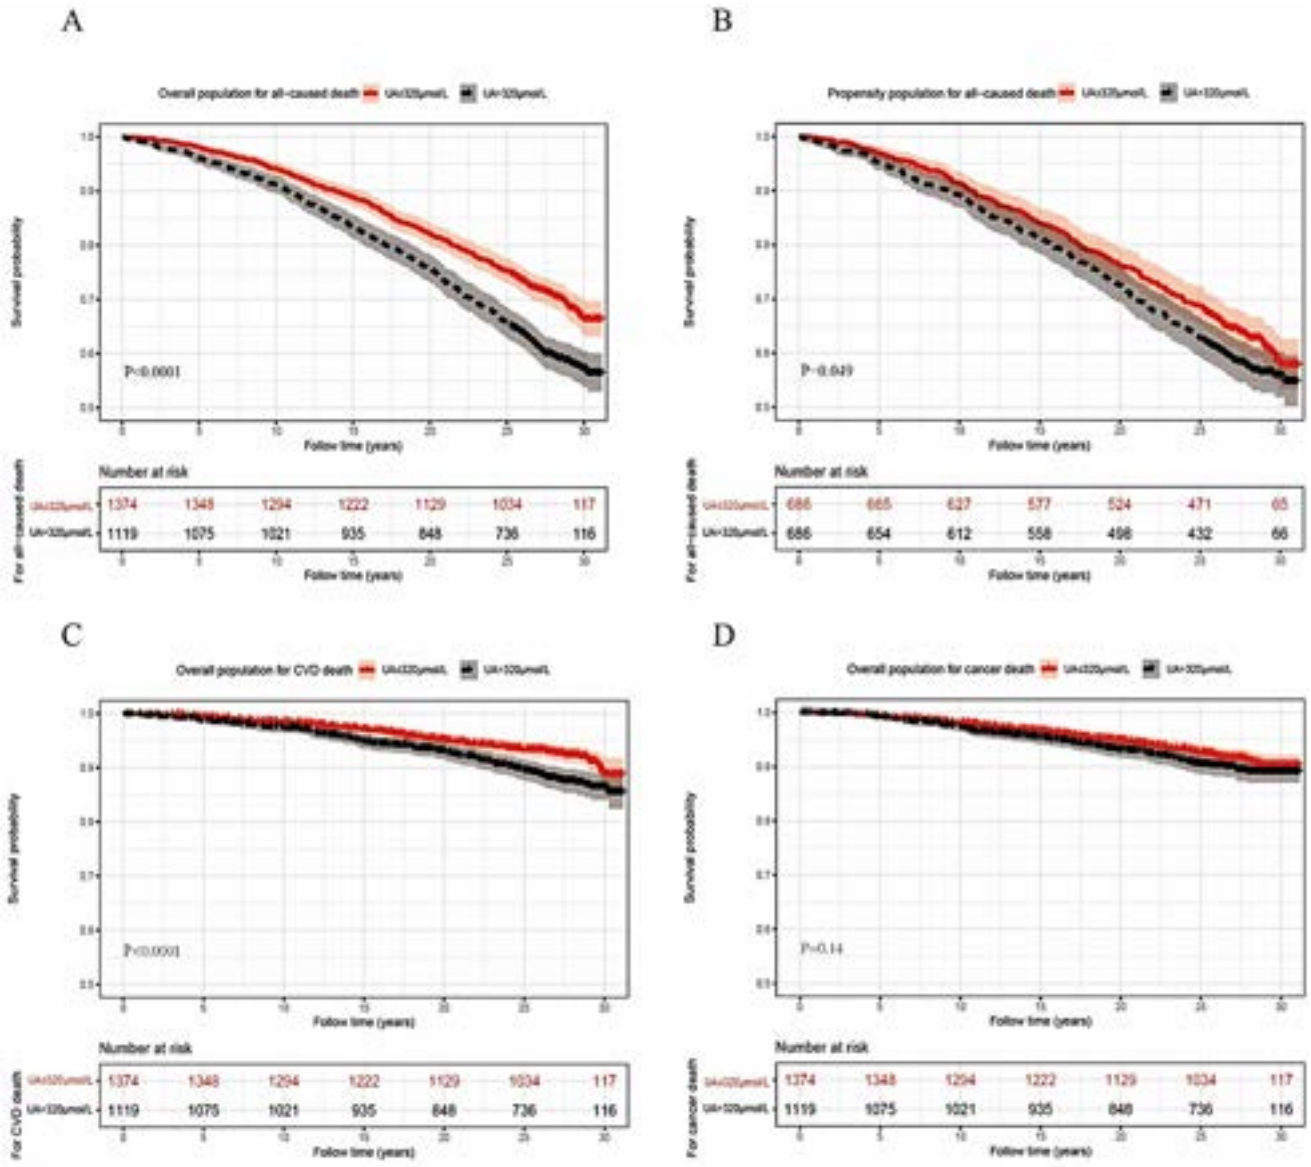

Figure 1: (abstract: THU-465): (A) Kaplan-Meier curve for overall death before PSM. (B) Kaplan-Meier curve for overall death after PSM. (C) Kaplan-Meier curve for cardiovascular-related death. (D) Kaplan-Meier curve for cancer-related death.

to the UA level, participants were classified into high-UA group (UA>320 μmol/L) and low-UA group (=<320 μmol/L). There were 1119 (44.89%) participants had a UA level >320 μmol/L. The high-UA group had a higher BMI level than the low-UA group. The death rate was 39.86% in high-UA group (>320 μmol/L), compared to 29.33% in low-UA group (≤320 μmol/L) ($p < 0.001$). Compared with low-UA group, patients in high-UA group tend to have more severe metabolic dysfunction. The survival probability between the two UA groups is illustrated as a Kaplan-Meier curve in Figure 1, indicating the association between baseline high UA levels and risk of death ($p < 0.001$). However, by the adjustment for the metabolic profiles, the effect of UA level on long-term outcome was no longer significant (All with a p value >0.05). Time-independent Cox regression also showed that UA level was not an independent risk factor for mortality in NAFLD patients without decreased eGFR (>60 ml/min/1.73 m^2) ($p > 0.05$). After matching age and sex by using the propensity score matching method, UA remained not independently associated with death in NAFLD patients ($p > 0.05$). Similar results were found for cardiovascular-related and cancer-related deaths, showing the association between UA level and the risk of cause-specific death was dependent on metabolic confounders.

Conclusion: Although UA is closely related to NAFLD, UA levels are not independently associated with the long-term survival of patients with NAFLD without decreased eGFR. Metabolic disorders may play a mediating role in the relationship between UA level and NAFLD outcome.

THU-466

The risk of liver-related long term outcomes is altered by dynamic changes in metabolic dysfunction-associated fatty liver disease status: a nationwide cohort study

Min Kyung Park[1], Hye-Sung Moon[2], Sungwon Chung[1], Sungho Won[2,3], Yun Bin Lee[1], Eun Ju Cho[1], Jeong-Hoon Lee[1], Su Jong Yu[1], Jung-Hwan Yoon[1], Yoon Jun Kim[1]. *[1]Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Korea, Rep. of South; [2]RexSoft Inc., Korea, Rep. of South; [3]Seoul National University, Department of Public Health Sciences, Graduate School of Public Health, Korea, Rep. of South*
E-mail: yoonjun@snu.ac.kr

Background and aims: Metabolic dysfunction-associated fatty liver disease (MAFLD) status, defined by hepatic steatosis with metabolic dysfunction, could be dynamic changes by treatment such as lifestyle modification. We aimed to evaluate the association between the risk of MALFD long-term outcomes and changes in MAFLD status.

Method: We analyzed data from 4 228 162 participants who participated in health screening programs both in 2009 and 2013

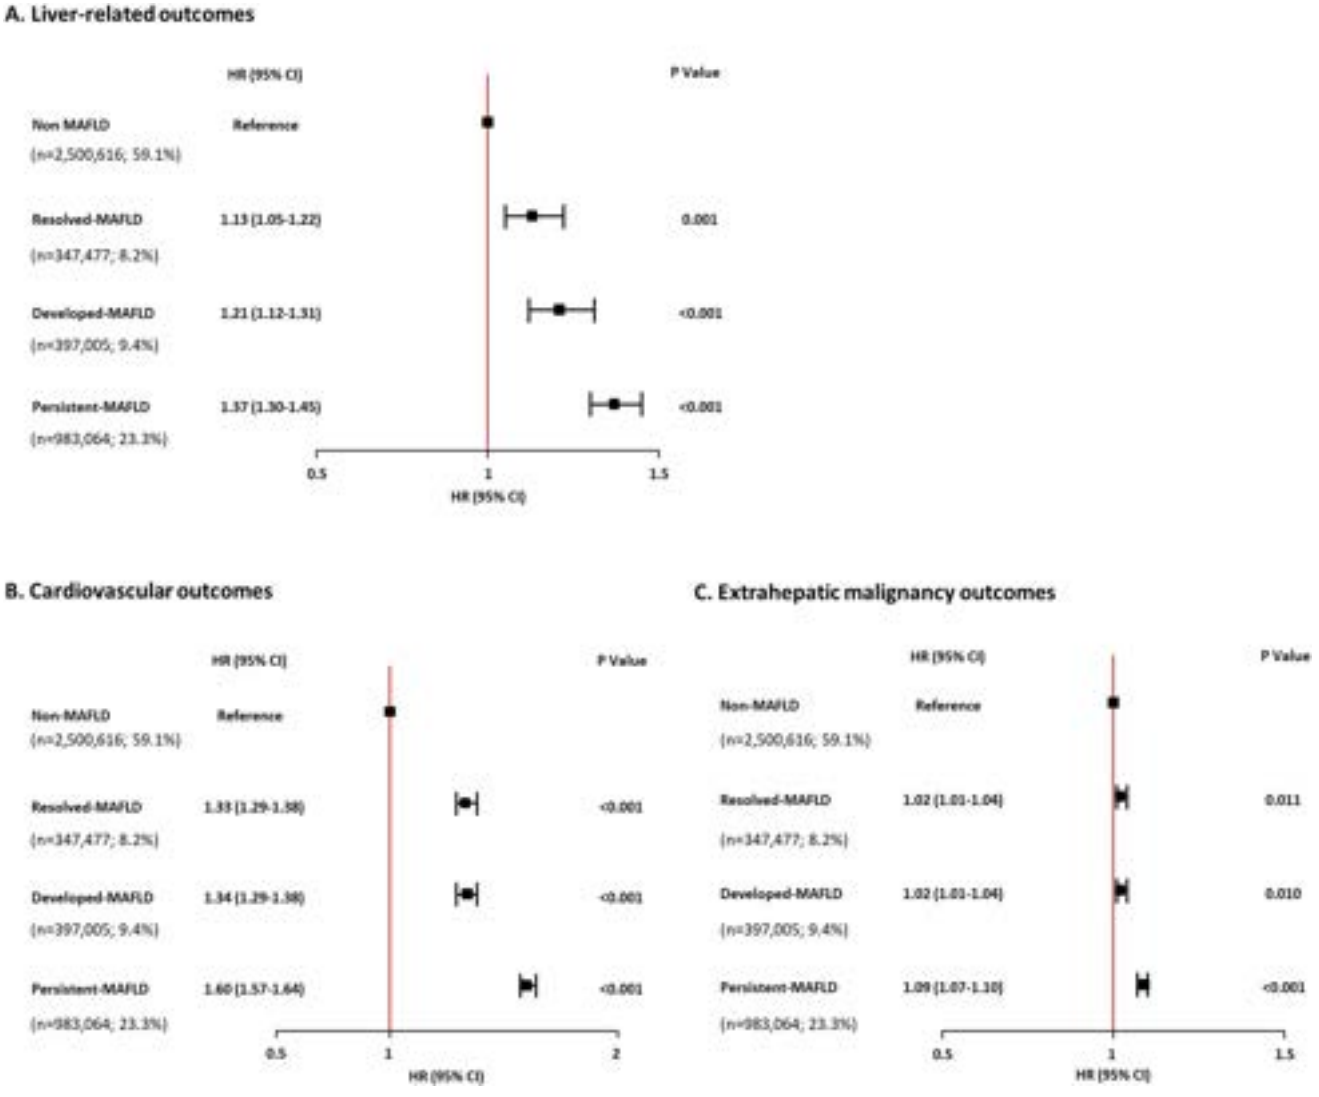

Figure: (abstract: THU-466).

using nationwide claims data from the National Health Insurance Service of South Korea. Participants were divided into four groups based on changes in MAFLD status from 2009 to 2013; non-MAFLD, resolved-MAFLD, developed-MAFLD, and persistent-MAFLD. The primary outcome was the incidence of liver-related complications, and the secondary outcomes were the incidence of cardiovascular complications and primary extrahepatic malignancy.

Results: During the median follow-up of 6.4 years (interquartile range, 6.1–6.6 years), 7828 patients (0.2%) developed liver-related complications. The persistent-MAFLD group had significant higher risk of liver-related complication compared to non-MAFLD group (adjusted hazard ratio [aHR] = 1.37; 95% confidence interval [CI] = 1.30–1.45; P < .001; Figure 1A), followed by the developed-MAFLD group (aHR = 1.21; 95% CI = 1.12–1.31; P < .001; Figure 1A) and resolved-MAFLD group (aHR = 1.13; 95% CI = 1.05–1.22; P < .001; Figure 1A). Interestingly, the recovered MAFLD group showed a significantly lower risk of liver-related outcomes compared to the persistent MAFLD group (aHR = 0.82; 95% CI = 0.76–0.89; P < .001). The risk of cardiovascular complications and the risk of primary extrahepatic malignancy were also higher in the persistent-MAFLD than non-MAFLD group (aHR = 1.60; 95% CI = 1.57–1.64; P < .001; Figure 1B, aHR = 1.09; 95% CI = 1.07–1.10; P < .001; Figure 1C, respectively). On the sensitivity analysis after excluding underlying liver disease, the persistent MAFLD group maintained a significantly higher risk of liver-related complication than the non-MAFLD group (aHR = 1.37; 95% CI = 1.29–1.46; P < .001).

Conclusion: Patients with persistent MAFLD status showed a higher risk of liver-related complications than non-MAFLD patients. Patients with newly developed MAFLD also had a higher risk of liver-related complications than patients who never experienced the MAFLD, while resolved MAFLD status could ameliorate the risk of liver-related complications.

THU-467

Dietary patterns associated with metabolic associated fatty liver disease protection

Simon Schophaus[1], Kate Townsend Creasy[2], Jan Clusmann[1], Alexander Koch[1], Christian Trautwein[1], Kai Markus Schneider[1], Carolin Victoria Schneider[1]. *[1]RWTH Aachen University, Medizinische Klinik III, Aachen, Germany; [2]University of Pennsylvania, Philadelphia, United States*

E-mail: cheimes@ukaachen.de

Background and aims: Metabolic-associated fatty liver disease (MAFLD) is characterised by lipid droplet accumulation in the hepatocytes and affects approximately 20–30% of the general population. High caloric western style diet is a well-established risk factor for MAFLD. However, there is little data that the consumption of specific nutrients might help prevent MAFLD development in the general population.

Method: We analyzed the UK Biobank (ID 71300) dataset and selected our study population based on the availability of nutritional assessment (five questionnaires). We excluded patients with liver diseases diagnosed before the food questionnaires. We investigated the association between nutrients calculated from food questionnaires and MAFLD development during the 11-year follow-up (ICD code and 39 000 MRI images of the liver) in the first nutrient-wide association study-"Nutri-WAS." All analyses are corrected for age, sex, BMI, Townsend index for socioeconomic status, kcal, alcohol, protein intake, fat intake, carbohydrate intake, and for multiple testing.

Results: Data from >210 000 participants demonstrate despite confirming known associations (e.g., Vitamin E or Fructose) that among 50 tested nutrients, manganese showed the strongest protection from liver fat on MRI (Figure 1A). We demonstrate that increased dietary manganese intake was associated with a lower prevalence of MAFLD. Each standard deviation (SD) manganese increase intake reduced the association of MAFLD ICD-10 diagnosis (K76.0) by 14.9% (p < 0.0001) and a reduced MRI diagnosis of MAFLD by 17.2% (p < 0.0001). In addition, there was a significant effect of manganese on metabolomics data, which were available in >49.000 individuals (Figure 1B) and showed an association with reduced VLDL secretion.

Conclusion: Our study showed that increased dietary manganese intake may be beneficial for preventing MAFLD. Randomized clinical trials are needed to confirm the beneficial effects of manganese for MAFLD prevention.

Multivariable Nutrient wide association study for liver fat >5% on MRI.

Manhattan plot of adjusted log10 (P values) for all nutrients (n = 50) comparing liver fat >5% on MRI per SD increase for each nutrient adjusted for age, sex, body mass index, kcal/day, alcohol/day, fat/day, carbohydrates/day, protein/day, and Townsend socioeconomic status index. Highlighted are associations results with P values <10^{-7}.

Associations of metabolic biomarkers with manganese intake among >49 000 participants

Hazard ratios (with 95% confidence intervals) are presented per 1-SD higher metabolic biomarker on the natural log scale, stratified by age, sex, body mass index, alcohol consumption/day, fat/day, carbohydrates/day, protein/day, and Townsend socioeconomic status index. *False discovery rate-controlled p < 0.01. DHA, docosahexaenoic acid; FA, fatty acids; FAw3, omega-3 fatty acids; FAw6, omega-6 fatty acids; HDL-D, high-density lipoprotein particle diameter; LA, linoleic acid; LDL, low-density lipoproteins; LDL-D, low-density lipoprotein particle diameter; LP, lipoprotein; MUFA, monounsaturated fatty acids; PUFA, polyunsaturated fatty acids; SFA, saturated fatty acids; VLDL-D, very low-density lipoprotein particle diameter; (original code by Diego J Aguilar-Ramirez).

THU-468

Rheological properties of bile in patients with non-alcoholic steatohepatitis with and without obesity

Olena Barabanchyk[1], Iryna Biriuchenko[2], Volodymyr Bulda[1].
[1]*Educational and Scientific Centre "Institute of Biology and Medicine" of Taras Shevchenko National University of Kyiv, Internal Medicine, Kyiv, Ukraine;* [2]*Bogomolets National Medical University, Internal Medicine, Ukraine*
E-mail: alenabarabanchyk@gmail.com

Background and aims: Studies have shown that changes in the synthesis and composition of bile acids can potentiate hepatotoxicity through anti-inflammatory mechanisms, membrane damage or cytotoxicity, leading to severe liver fibrosis [1, 2]. Our aim was to assess the changes in bile acids (BA) profile in patients with non-alcoholic steatohepatitis (NASH) with and without obesity compared to healthy controls.
Method: Three study arms were formed: 1st arm-NASH with obesity, 2nd arm-NASH without obesity, 3rd arm-healthy controls. Although liver biopsy is the gold standard for the NASH diagnosis, the vast majority of patients refrained from biopsy. So the diagnosis of NASH was established based on the following criteria: 1) non-alcoholic aetiology (less than 20 g ethanol per day), 2) detection of steatosis by ultrasound imaging, 3) exclusion of other liver diseases. The obesity was considered if BMI was 30 or higher. The bile was obtained after intubation of the duodenum under the ultrasound control. The spectrum of BA and bile properties were assessed using photo-calorimetry. To evaluate the colloidal stability of the bile the cholate-cholesterol ratio (CCR), the ratio of taurochenodeoxycholic acid (TCDCA) and taurodeoxycholic acid (TDCA) to taurocholic acid (TCA) and the ratio of glycochenodeoxycholic acid (GCDCA) and glyco-deoxycholic acid (GDCA) to glycocholic acid (GCA) were calculated.
Results: 67 adult patients (21–55 years, males 26 (38,8%)) were included into the study. Of these, 29 patients were allocated to the 1st arm, 23 patients to the 2nd arm, and 15 healthy controls to the 3rd one. The groups were statistically comparable in age and sex. The bile of healthy patients predominantly consisted of BA conjugated with glycine. The level of tauroconjugates varied between 15–20% of the total amount of BA. Free trihydroxycholanic and dihydroxycholanic BA were presented in approximately the same concentrations. The analysis of BA in patients of the 1 and 2 study groups showed the following: levels of cholic acid (CA) were much increased in patients of the 1 arm, but slightly decreased in case of NASH only. Deoxycholic acid (DCA) was increased both in groups 1 and 2. The levels of TCA were decreased in patients of the 1 arm, but slightly increased in the 2 arm, and the levels of GCA were decreased in both groups compared to the 3 group. Free bile cholesterol which was increased in arms 1 and 2. Cholate-cholesterol ratio (CCR) was significantly decreased in patients with NASH (1 and 2 arms) comparing to the group 3 ($p < 0.001$). But the ratios of TCDCA + TDCA to TCA and GCDCA + GDCA to GCA were decreased only in the 1st group ($p < 0.05$).

Parameters	1 arm mg/%	2 arm mg/%	3 arm mg/%	p
CA	39.65 ± 1.4	7.4 ± 0.8	16.7 ± 1.1	p < 0.05
DCA	48.45 ± 1.9	35.3 ± 8.2	21.5 ± 1.07	p < 0.05
GCA	238.7 ± 4.3	183.5 ± 2.3	347.6 ± 3.9	p < 0.05
TDCA	62.7 ± 2.1	172.3 ± 1.7	115.8 ± 2.5	p < 0.05
Free bile cholesterol	141.3 ± 2.6	98.28 ± 2.20	83.26 ± 2.5	p < 0.001

Figure:

Conclusion: Our data suggest that changes of rheological properties of bile in patients with NASH especially in association with obesity may possibly lead to the increased lithogenicity of bile thus enhancing the risks of gallstones formation.

THU-469

Risk factors for significant fibrosis in non-obese Asian patients with NAFLD

Jae Yoon Jeong[1], Ju-Yeon Cho[2], Jung Hee Kim[3], Yong Kyun Cho[4], Byung Ik Kim[4], Won Sohn[4]. [1]*National Medical Center, Korea, Rep. of South;* [2]*Chosun University Hospital, Korea, Rep. of South;* [3]*Hallym University Dongtan Sacred Heart Hospital, Korea, Rep. of South;* [4]*Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Korea, Rep. of South*
E-mail: hand0827@naver.com

Background and aims: It is unclear which risk factors are associated with hepatic fibrosis in non-obese patients with non-alcoholic fatty liver disease (NAFLD). This study aimed to investigate the risk factors for significant liver fibrosis in in non-obese Asian patients with NAFLD including body mass index (BMI).
Method: A cross-sectional study was conducted using nationally representative samples from the Korean National Health and Nutrition Examination Survey 2012–2019. A total of 1200 Korean patients with NAFLD and BMI <25 kg/m^2 were enrolled in the study. NAFLD was defined as hepatic steatosis index ≥36. Liver fibrosis was assessed using Fibrosis-4 (FIB-4) index. The significant liver fibrosis was defined as FIB-4 index was more than 1.3. We classified into lean NAFLD (BMI <25 kg/m^2) and overweight NAFLD (BMI 23–25 kg/m^2). Univariable and multivariable logistic regression analyses were done to assess the risk factors including lean and overweight for significant liver fibrosis in patients with NAFLD.
Results: The mean age was 51 years and 47% (n = 560) was male sex. The proportion of significant fibrosis was 14% (n = 169). They consisted of 20% (n = 236) of lean NAFLD and 80% (n = 964) of overweight NAFLD. There was no difference in age and sex between two groups. However, the prevalence of hypertension and visceral obesity were higher in overweight NAFLD than in lean NAFLD (all $p < 0.05$). A univariable analysis indicated that overweight NAFLD was associated with significant fibrosis compared to lean NAFLD (odds ratio [OR] 1.86 with 95% confidence interval [CI]: 1.15–3.00, $p = 0.012$). However, a multivariable analysis showed that there was no difference in significant difference between two groups (OR 1.37 with 95% CI: 0.82–2.30, $p = 0.231$). On the other hand, significant fibrosis was associated with other metabolic factors in the multivariable analysis: visceral obesity (OR 2.12 with 95% CI: 1.45–3.09, $p < 0.001$), diabetes mellitus (OR 3.19 with 95% CI: 2.17–4.68, $p < 0.001$), and hypetension (OR 2.91 with 95% CI: 2.01–4.22, p <
Conclusion: BMI is not a risk factor for significant fibrosis in non-obese Asian patients with NAFLD. However, metabolic factors such as visceral obesity, diabetes, and hypertension are associated with liver fibrosis in non-obese Asian patients with NAFLD.

THU-470

Impact of PNPLA3 rs738409 single nucleotide polymorphism and carbohydrate intake for the personalized management of patients with non-alcoholic fatty liver disease

Nuria Pérez Diaz del Campo[1], Eleonora Dileo[1], Gabriele Castelnuovo[1], Chiara Rosso[1], Gian Paolo Caviglia[1], Daphne D'Amato[1], Amina Abdulle[1], Marta Guariglia[1], Angelo Armandi[1,2], Kamela Gjini[1], Irene Poggiolini[1], Antonella Olivero[1], Maria Lorena Abate[1], Giorgio Maria Saracco[1,3], Elisabetta Bugianesi[1,3]. [1]*University of Turin, Department of Medical Sciences, Turin, Italy;* [2]*University Medical Center of the Johannes Gutenberg-University, I. Department of Medicine, Mainz, Germany;* [3]*Città della Salute e della Scienza-Molinette Hospital, Gastroenterology Unit, Turin, Italy*
E-mail: nuria.perezdiazdelcampo@unito.it

Background and aims: The Patatin-like phospholipase domain-containing 3 (*PNPLA3*) rs738409 single nucleotide polymorphism (SNP) is one of the major genetic determinant of non-alcoholic fatty

liver disease (NAFLD) and is strongly regulated by changes in energy balance and dietary factors. We aimed to investigate the association between the *PNPLA3* rs738409 SNP, nutrient intake and NAFLD severity.

Method: PNPLA3-rs738409 SNP was genotyped in 181 patients with NAFLD who completed the EPIC Food Frequency Questionnaire. Liver steatosis was evaluated by Controlled Attenuation Parameter (CAP) (Fibroscan®530, Echosens). According to the established cut-off, a CAP value ≥300 dB/m was used to identify severe steatosis (S3). An independent group of 47 biopsy-proven NAFLD subjects was used as validation cohort.

Results: Overall, median age was 53 years (range 44–62) and 60.2 % of patients were male. Most subjects (56.3 %) had S3 and showed increased liver stiffness (p < 0.001), AST (p = 0.003) and ALT levels (p < 0.001) compared to those with CAp <300 dB/m. At logistic regression analyses we found that the interaction between carbohydrates intake and the carriers of the PNPLA3 G risk allele was significantly associated with S3 (p = 0.001). The same result was confirmed in the validation cohort, were the interaction between high carbohydrate intake (48%) and PNPLA3 SNP was significantly associated with steatosis ≥33% (p = 0.017) and with advanced fibrosis (≥F3) (p = 0.058).

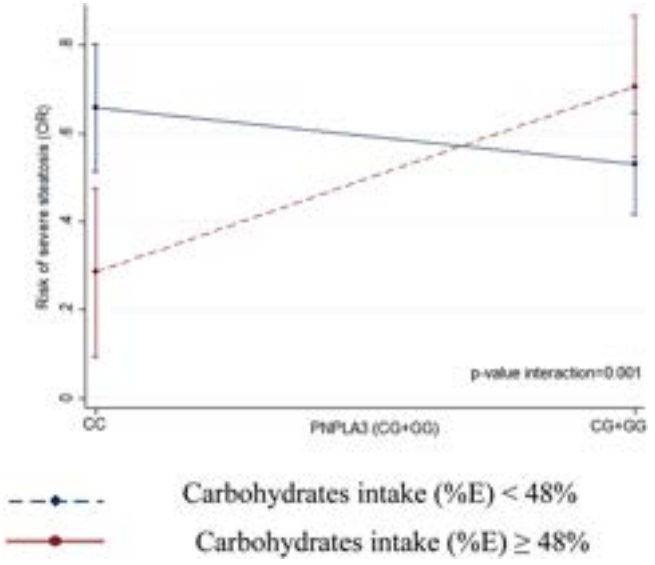

Figure: Impact of the *PNPLA3* rs738409 polymorphism on carbohydrates intake on the risk for severe steatosis (CAP ≥300 dB/m). The model was adjusted by sex, age, energy intake, protein intake, fat intake and diabetes.

Conclusion: The intake of greater than or equal to 48 % carbohydrate in NAFLD patients carriers of the CG/GG allele of PNPLA3 rs738409 may increase the risk of significant steatosis.

Diabetes mellitus (DM) is the strongest risk factor of significant inflammation or fibrosis in chronic hepatitis B (CHB) combined with non-alcoholic fatty liver disease (NAFLD)

Jie Li[1], Fajuan Rui[1], Brian Nguyen[2], Chuanwu Zhu[3], Yuanwang Qiu[4], Weimao Ding[5], Qi Zheng[6], Qing-Lei Zeng[7], Zebao He[8], Junping Shi[9], Chao Wu[1], Mindie Nguyen[2]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China, China; [2]Division of Gastroenterology and Hepatology, Stanford University Medical Center, Palo Alto, CA, USA, United States; [3]Department of Infectious Diseases, The Affiliated Infectious Diseases Hospital of Soochow University, Suzhou, Jiangsu, China, China; [4]Department of Infectious Diseases, The Fifth People's Hospital of Wuxi, Wuxi, Jiangsu, China, China; [5]Department of Hepatology, Huai'an No. 4 People's Hospital, Huai'an, Jiangsu, China, China; [6]Department of Hepatology, Hepatology Research institute, the First Affiliated Hospital, Fujian Medical University, Fuzhou, China, China; [7]Department of Infectious Diseases, The First Affiliated Hospital of Zhengzhou University, Zhenghzhou, Henan, China, China; [8]Department of Infectious Diseases, Taizhou Enze Medical Center (Group) Enze Hospital, Taizhou, Zhejiang, China, China, [9]Department of Infectious Diseases, The Affiliated Hospital of Hangzhou Normal University, Hangzhou, Zhejiang, China, China*
E-mail: mindiehn@stanford.edu

Background and aims: Chronic hepatitis B (CHB) patients and non-alcoholic fatty liver disease (NAFLD) frequently co-exist, but the association of diabetes mellitus (DM) with hepatic inflammation and fibrosis is not well characterized. The aim of this study is to investigate the association of DM with significant hepatic inflammation and/or fibrosis in CHB patients combined with NAFLD.

Method: We enrolled CHB patients with concurrent NAFLD who underwent liver biopsy from eight medical centers of China between April 2004 and October 2020. Univariable and multivariable logistic regression analyses were conducted to explore the association of DM with significant inflammation (grade [G] 2–4) and fibrosis (stage [S] 2–4).

Results: A total of 869 CHB patients with NAFLD with available liver histology data were included in study analysis (mean age 40.6 ± 10.4 years old, 79.9% male), with 71 (8.2%) having DM. The mean body mass index was 24.9 ± 3.3 kg/m^2 and the mean HBV-DNA was 5.3 ± 2.0 log10 IU/ml. About half (380 patients, 46.3%) were HBeAg-positive, and 5.9% (42 patients) were on antiviral therapy. Moderate and severe FLD (grade 2–3) was present in 206 patients (24.3%). The majority (529 patients, 60.9%) had significant inflammation (G2–4), and about half (431, 49.6%) had significant fibrosis (F2–4). Compared with non-DM patients, DM patients more likely had significant inflammation (76.1% vs 59.7%, P = 0.02) or significant fibrosis (76.1% vs 47.3%, P < 0.001). On multivariable logistic analysis adjusting for DM, hepatic steatosis, age, sex, BMI, HBV DNA, and HBeAg, DM was independently associated with significant inflammation (OR: 3.38; 95% CI: 1.46–7.86; P = 0.005) and significant fibrosis (OR: 4.49; 95% CI: 2.08–9.72; P < 0.001) (Table).

Table: Factors associated with hepatic inflammation or fibrosis in hepatitis B patients

	Univariate analysis		Multivariate analysis	
	OR (95% CI)	*P value*	OR (95% CI)	*P value*
Inflammation Grade ≥2				
Diabetes Mellitus (%)	2.15 (1.224–3.774)	0.008	3.38 (1.455–7.858)	0.005

Grade 2–3	0.95 (0.693–1.294)		0.99 (0.657–1.482)	
Age (years)	1.01 (1.001–1.027)	0.032	1.02 (1.002–1.039)	0.031
Sex (%)	0.86 (0.620–1.20)	0.381	1.02 (0.668–1.567)	0.917
Body mass index (kg/m^2)	0.99 (0.950–1.037)	0.736	0.98 (0.928–1.033)	0.434
HBV DNA (Log_{10} IU/ml)	0.99 (0.925–1.065)	0.83	0.85 (0.764–0.954)	0.005
HBeAg positive (%)	1.33 (1.010–1.747)	0.042	2.53 (1.578–4.042)	<0.001

Figure:

Conclusion: CHB patients with DM was more than 3 times more likely to have significant hepatic inflammation and more than 4 times more likely to have significant fibrosis compared to non-DM patients, independent of the presence of hepatitis steatosis, other metabolic (body mass index), viral and demographic factors. DM should be considered as part of the algorithm for CHB management.

THU-472

PNPLA3 I148M polymorphism does not promote liver disease progression in severe alpha1-antitrypsin deficiency

Ines Volkert[1], Malin Fromme[1], Huan Su[2], Nurdan Gueldiken[1], Mohamed Ramadan Mohamed[1], Cecilia Lindhauer[1], Pavel Strnad[3], Christian Trautwein[2]. *[1]RWTH Aachen University hospital, Medical department III, Aachen, Germany; [1]RWTH Aachen University hospital, Medical department III, Aachen, Germany; [1]RWTH Aachen University hospital, Medical department III, Aachen, Germany*
E-mail: ivolkert@ukaachen.de

Background and aims: Alpha-1 antitrypsin (AAT) deficiency (AATD) is one of the most common genetic disorders. A homozygous PiZ mutation in the AAT gene (called PiZZ genotype) is the predominant cause of severe AATD and predisposes to lung and liver damage. Non-alcoholic fatty liver disease (NAFLD) comprises a disease spectrum ranging from steatosis to cirrhosis, inflammation and hepatocellular carcinoma (HCC). The most established genetic risk factor for NAFLD is the patatin-like phospholipase domain containing protein 3 (PNPLA3) I148M that promotes disease progression. This polymorphism is characterized by a substitution of isoleucine to methionine at position 148 (I148M). The aim of the study was to evaluate the interaction between the PNPLA3 and the PiZ variants.
Method: Mice carrying the human PiZ variant and the PNPLA3 I148M polymorphism were generated (PiZ/PNPLA3I148M), characterized at the age of 8 and 52 weeks and compared to WT, PiZ and PNPLA3I148M controls. The mice were subjected to a Western-style Diet (WSD) for 24 weeks to assess the effects on NASH progression. The presence of PNPLA3 I148M polymorphism was evaluated in peripheral blood-derived DNA from 478 Pi*ZZ subjects participating in the European AATD registry.
Results: At weeks 8 and 52, PiZ mice showed higher transaminases than WT and PNPLA3I148M animals, but no difference to PiZ/PNPLA3I148M group was seen. At 52 weeks of age, the PiZ and PiZ/PNPLA3I148M mice showed significantly stronger fibrosis than WT and PNPLA3I148M mice, but no difference between both PiZ subgroups was seen. After WSD, no changes in the liver physiology nor fibrogenesis or inflammatory parameters were noted. Neither PiZ expression nor accumulation was altered by the presence of PNPLA3I148M or through WSD feeding.
In the analyzed Pi*ZZ subjects, PNPLA3 I148M variant was found at the expected Mendelian ratio. The carriers displayed significantly increased GLDH values and more often had elevated ALT and bilirubin levels. However, there was no difference in transient elastography-based liver fibrosis and steatosis measurements.
Conclusion: Our results demonstrate that the presence of the PNPLA3 I148M polymorphism does not play a major role in progression of AATD-associated liver disease in mouse and humans.

THU-473

Frailty in metabolic dysfunction-associated fatty liver disease is related to the presence of diabetes and the severity of liver fibrosis

Alexis Goffaux[1], Guillaume Henin[1,2], Audrey Loumaye[3], Géraldine Dahlqvist[2], Nicolas Lanthier[1,2]. *[1]Université catholique de Louvain, Laboratory of Hepato-Gastroenterology, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium; [2]Cliniques universitaires Saint-Luc (UCLouvain), Service d'Hépato-Gastroentérologie, Bruxelles, Belgium; [3]Cliniques universitaires Saint-Luc (UCLouvain), Service d'Endocrinologie et de nutrition, Brussels, Belgium*
E-mail: nicolas.lanthier@saintluc.uclouvain.be

Background and aims: Frailty is very common in end-stage liver disease, regardless of disease etiology, and has a significant impact on clinical outcome and quality of life, due to impaired skeletal muscle function, quality and quantity. However, there are few data available on the relationship between liver and skeletal muscle, especially in patients with earlier disease stages. Our aims are to evaluate the prevalence of frailty in a prospective cohort of patients with metabolic-dysfunction associated fatty liver disease (MAFLD) according to its severity.
Method: Patients with MAFLD were recruited in a prospective single-center cohort study. Epidemiological, clinical, biological and anthropometric data were collected. All patients underwent a non-invasive assessment for frailty screening, including a dominant hand grip strength test, a balance test, and the time required to do five times sit to stand to calculate the liver frailty index (LFI). The severity of MAFLD was assessed by the fatty liver index (FLI), fibrosis 4 (FIB-4) index, and by transient elastography (elasticity and controlled attenuation parameter).
Results: 92 patients with MAFLD were recruited, including 44 men (47.8 %) and 44 patients with type 2 diabetes (47.8 %). Mean age was 55 years (19–78), mean BMI was 32.7 kg/m² (23.9–47.5) and mean HOMA-IR was 7.6 (0.5–30.1). Regarding the severity of MAFLD, the mean elasticity was 6.45 KPa (3.1–35) and the mean FIB-4 score was 1.33 (0.31–5.61). The mean FLI was 85.1 (28–100) and the mean controlled attenuation parameter (CAP) was 332.3 dB/m (207–400). Regarding frailty parameters, the mean dominant grip strength was 31 kg (8–62), the mean time to do five chair stands was 8.2 seconds (4.25–24.25), the mean balance test score was 9.9 seconds (2.1–10) and the mean LFI was 2.98 (1.13–4.71). 51 patients had an LFI score <3 (robust group, 56 %), 36 had a score between 3 and 4.5 (pre-frail group, 39.6 %), and 4 had a score greater than 4.5 (frail group, 4.4 %). No correlation was observed between the degree of steatosis (assessed by the FLI or CAP values) and frailty. In contrast, a significant increase in the level of frailty is observed in patients with type 2 diabetes ($p = 0.03$) and with a high liver elasticity compatible with an F4 stage (mean LFI: 3.7 vs 2.9, $p = 0.0078$) (Figure), independent of age. Frailty is also significantly higher according to the FIB-4 index with a mean LFI of 3.72 in case of FIB-4 >2.67 vs 2.8 in case of FIB-4 <1.3 ($p = 0.042$) (Figure).

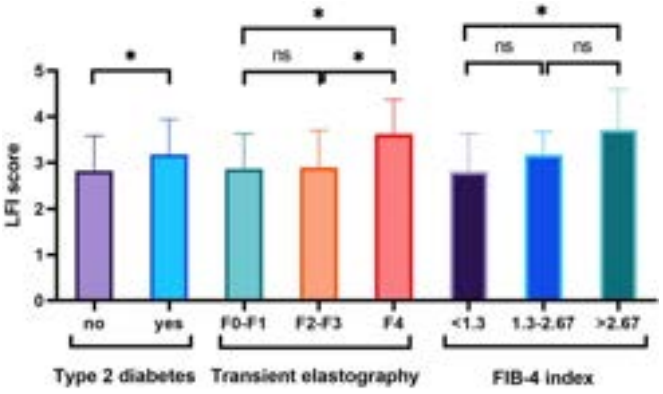

Figure:

Conclusion: 44% of MAFLD patients already have a frail or pre-frail status regardless of age. This reduction of strength is associated with the presence of diabetes and the severity of MAFLD in terms of fibrosis. Further research is needed to determine the cause of this frailty and its potential impact on liver disease severity and prognosis.

THU-474

Significant fibrosis is a risk factor for worse health perception and impaired mental health in people living with HIV

Jesús Funuyet-Salas[1], Maurice Michel[2,3], María Angeles Pérez-San-Gregorio[1], Agustín Martín-Rodríguez[1], Manuel Romero Gomez[4], Peter Galle[2], Martin Sprinzl[2], Jörn Schattenberg[2,3]. *[1]Department of Personality, Assessment, and Psychological Treatment, Faculty of Psychology, University of Seville, Seville, Spain, Spain; [2]I. Department of Medicine, University Medical Center Mainz, Mainz, Germany, Germany; [3]Metabolic Liver Research Program, I. Department of Medicine, University Medical Center Mainz, Mainz, Germany; Germany; [4]Digestive diseases unit, Virgen del Rocío University Hospital. SeLiver group at Institute of Biomedicine of Seville (IBIS). University of Seville, Spain, Spain*
E-mail: jfunuyet1@us.es

Background and aims: Significant fibrosis has been shown to be a critical factor for the biopsychosocial profile of patients with chronic liver disease. However, the role of significant fibrosis in models predicting health perception and mental health in people living with human immunodeficiency virus (PLWH) remains unknown. We aimed to evaluate 1) if health distress and mental health mediated the relationship between unemployment and health perception, 2) if social functioning mediated the relationship between lower education and mental health, and 3) if hepatic steatosis or fibrosis exerted a moderating effect in both relationships.

Method: Two hundred and seven PLWH (147 male and 60 female, mean age 51 ± 12) were evaluated using the MOS-HIV instrument, which assesses ten dimensions of quality of life. Vibration-controlled transient elastography was used to assess hepatic steatosis and significant fibrosis by measuring the controlled attenuation parameter (≥275 dB/m) and liver stiffness measurement (≥8.2 kPa), respectively. Mediation and moderated mediation models were estimated using the SPSS PROCESS macro v3.5. Bootstrapping was used to test the indirect effects estimated, considered significant when the confidence interval (CI) at 95% did not include 0.

Results: Health distress and mental health mediated the association between unemployment and health perception (effect = –3.00, CI = –6.07 to –0.13). Social functioning mediated the association between lower education and mental health (effect = 4.37, CI = 1.31 to 7.82). Significant fibrosis exerted a moderating effect on both relationships (health perception, beta = 0.48, p = 0.001; mental health, beta = 0.48, p = 0.001), but hepatic steatosis did not (Figure). The indirect conditional effects of unemployment and lower education on health perception and mental health, respectively, were higher in patients with significant fibrosis than in those who did not have significant fibrosis.

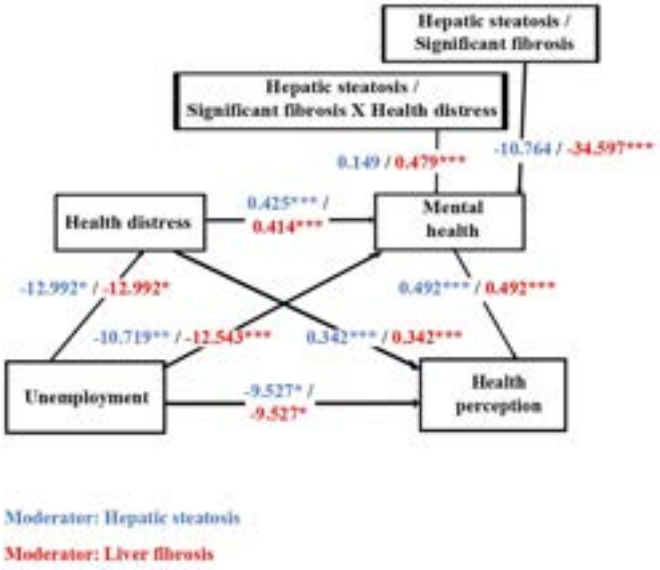

Figure:

Conclusion: Unemployment was related to health distress and poorer mental health, which in turn predicted worse self-perceived health in PLWH. Lower education was linked to lower social functioning, which predicted poorer mental health. Specifically, PLWH with significant fibrosis were more vulnerable to the negative effects of unemployment and lower education on health perception and mental health. Our results confirmed liver fibrosis as a risk factor to be considered in future multidisciplinary interventions in PLWH.

THU-475

Caloric input is inadequate in predicting the presence of liver steatosis and fibrosis in a population adhering to a screening program for metabolic syndrome

Lucia Brodosi[1,2], Michele Stecchi[1], Valentino Osti[1,3], Valeria Guarneri[1], Michela Genovese[1], Francesca Marchignoli[2], Dorina Mita[1], Maximiliano Zioutas[2], Maria Letizia Petroni[1,2], Loris Pironi[1,2]. *[1]University of Bologna, Department of Medical and Surgical Sciences, Italy; [2]IRCCS AOUBO, Clinical Nutrition and Metabolism Unit, Italy; [3]Azienda USL di Bologna, Department of Public Health, Italy*
E-mail: lucia.brodosi2@unibo.it

Background and aims: Non-Alcoholic Fatty Liver Disease (NAFLD) is the liver manifestation of metabolic syndrome (MetS) and can progress to steatohepatitis (NASH). Scores could be calculated to predict the risk of NAFLD and liver fibrosis (LF) in a non-invasive way. The most used ones are Fibrosis-4 (FIB-4), NAFLD Fibrosis Score (NFS), Fatty Liver Index (FLI) and FibroScan·Ast (FAST). In addition, FibroScan® allows evaluating steatosis through Controlled Attenuation Parameter (CAP) and LF. An essential link between NASH and MetS is obesity, resulting from a chronic positive caloric balance due to a caloric input (CI) greater than caloric output (CO). Precise CI assessment represents a challenge in clinical practice and usually requires a 1-to-1 inpatient visit with a dietitian; we previously developed Quanto Mangio Veramente (QMV), a questionnaire that easily allows estimating the daily CI. This work aimed to evaluate a possible link between CI, FibroScan results, and non-invasive steatosis and fibrosis scores.

Method: from 2020 to 2022, we screened patients for MetS according to National Cholesterol Education Program criteria. For each patient, weight, Body Mass Index (BMI), and Basal Metabolic Rate (BMR) were collected. We also administered QMV and performed Fibroscan®. FIB-4, NFS, FLI, FAST and Caloric Surplus (CS, obtained from CI-BMR) were

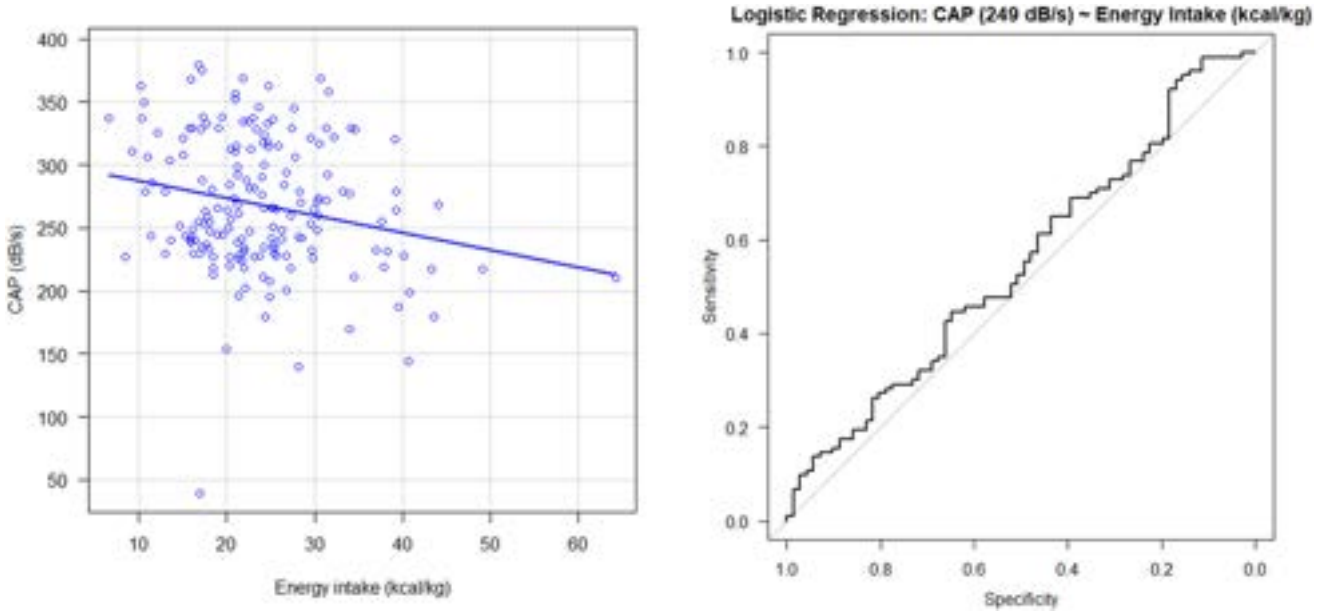

Figure: (abstract: THU-475).

calculated for each patient. For Statistics: median ± IQR, and AUROCs are reported with a 95% confidence interval.

Results: 189 consecutive non-cirrhotic patients were included in the study, 80 with and 99 without MetS. CI and CS, even when normalized by weight or BMI, did not correlate to any of the criteria for MetS, nor to FAST, FIB-4, FLI and NFS, and they did not differ significantly after grouping by MetS diagnosis. We observed a weak inverse correlation between CAP and CI normalized by weight or BMI, by −21.8% ($p < 0.01$) and −18.3% ($p < 0.05$), respectively, suggesting that people with a higher steatosis degree ingested fewer calories (kcal/kg). The same degree of inverse correlation was present after grouping by MetS diagnosis in the group with the syndrome ($p < 0.01$). When considering a cut-off of 249 dB/s for liver steatosis diagnosis, CI and its normalizations did not translate into mathematically appropriate regression models and AUROCs; the same results were obtained after grouping by liver steatosis categories according to CAP.

Conclusion: Our work does not support using QMV to predict NAFLD or LF in healthy and MetS subjects. We hypothesize that adaptive mechanisms, due to weight history, could play a role in disrupting the caloric balance. In addition, QMV did not allow the evaluation of diet quality. Moreover, physical activity levels were not considered. Our study highlights the need for more accurate tools to assess the relationship between the quality and content of the diet and NAFLD parameters.

Disparities in the in-hospital mortality among patients with non-alcoholic fatty liver disease admitted with acute myocardial infarction: a nationwide analysis

Umar Hayat[1], Saba Afroz[2], Muhammad Farhan[3], Atif Nasrullah[4], Naeem Ijaz[4], Faisal Kamal[5], Tariq Ahmad[6]. *[1]Geisinger Wyoming Valley Medical Center, Internal medicine, division of Gastroenterology, Wilkes-Barre, United States; [2]Geisinger Wyoming Valley Medical Center, Internal medicine, Wilkes-Barre, United States; [3]United Regional, Wichita Falls, United States; [4]The Wright Center for Community Health, Internal medicine, Scranton, United States; [5]Thomas Jefferson University Hospitals, Internal medicine, division of Gastroenterology, Philadelphia, United States; [6]Geisinger Wyoming Valley Medical Center, Internal medicine, division of Cardiology, Wilkes-Barre, United States*
E-mail: umarhayat216@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is associated with an increased risk for cardiovascular disease (CVD). Indeed, cardiovascular disease is considered the most common cause of death among NAFLD patients. However, few studies have reported the association between CVD and NAFLD. Therefore, our study aims to assess the association between NAFLD and acute myocardial infarction (AMI) and disparities in in-hospital mortality due to AMI among NAFLD patients by age, gender, and race in the USA.

Method: Hospitalizations with a primary diagnosis of AMI with a concurrent diagnosis of NAFLD were identified in the National Inpatient Sample database (2016–2019) using ICD-10-CM codes. The prevalence and trends over four years were calculated among different sociodemographic groups (Table 1). We stratified the patients into two age groups (>50 years and <50 years). A univariate regression model was used to determine mortality outcomes due to AMI among NAFLD patients by age, gender, and race. A multivariate regression analysis was performed to determine NAFLD as an independent predictor of mortality among patients who had AMI after adjusting for potential confounding factors (sociodemographic and clinical variables).

Results: A total of 5450 patients were admitted to the hospital with AMI and were identified to have a concurrent diagnosis of NAFLD. Among them, 5.11% (279) died in the hospital. Males with NALFD admitted to the hospital due to AMI were more likely to die than females [OR 1.58, 95% CI 1.25–1.91, $p < 0.001$]. Also, patients >50 had higher odds of dying due to AMI if they had NAFLD compared to those <50 [OR 4.29, 95% CI 2.94–6.27, $p < 0.001$]. Compared with the white population, black patients [OR 0.79, 95% CI 0.54–1.15, $p < 0.001$], Hispanics [OR 1.21, 95% CI 0.85–1.74, $p < 0.001$], Asian and Pacific Islanders [OR 0.95, 95% CI 0.45–2.03, $p < 0.001$], and Native Americans [OR 0.58, 95% CI 0.08–4.17, $p < 0.001$] are less likely to die due to AMI if they have NAFLD. The NAFLD patients had higher odds of dying if admitted to the hospital with AMI [OR 1.96, 95% CI 1.74–2.21, $p < 0.001$] (Table 1).

Variables	AMI without NAFLD (n = 24212420)	AMI with NAFLD (n = 5450)	p value
Baseline Patient and Hospital Characteristics			
Age (%)	>50 yrs 15959913 (65.90) <50 yrs 8257626 (34.09)	>50 yrs 4487 (82%) <50 yrs 964 (18%)	p < 0.001
Female (%)	13940284 (57.57)	1150 (49.3)	p < 0.001
Race (%)

Hospital Type (%)			
Urban	2192821 (9.05)	292 (2.0)	p < 0.001
Teaching	16670307 (68.83)	3956 (72.6)	p < 0.001
b) **Logistic regression for AMI mortality (Unadjusted)**			<0.01
	Odds Ratio	**95% CI**	**p value**
Sex			
Female (reference)	-	-	-
Male	1.58	1.25–1.91	p < 0.001
Age			
<50 (reference)	-	-	-
>50	4.29	2.94–6.27	p < 0.001
Race			
White (reference)	-	-	
Black	0.79	0.54–1.15	p < 0.001
Hispanic	1.21	0.85–1.74	p < 0.001
Asian and Pacific Islanders	0.95	0.45–2.03	p < 0.001
Native Americans	0.58	0.08–4.17	p < 0.001
NAFLD and AMI (Adjusted)	1.96	1.74–2.21	p < 0.001

Figure:

Conclusion: Elderly white male patients with NAFLD are more likely to die if admitted to the hospital due to AMI. Moreover, NAFLD was found to be an independent predictor of death among patients who had AMI.

THU-550

Differential risk of 23 specific incident cancers and cancer-related mortality in patients with metabolic dysfunction-associated fatty liver disease: a population-based cohort study with 9.7 million Korean subjects

Goh Eun Chung[1], Su Jong Yu[2], Jeong-Ju Yoo[3], Yuri Cho[4], Kyu-na Lee[5], Dong Wook Shin[6], Yoon Jun Kim[2], Jung-Hwan Yoon[2], Kyungdo Han[7], Eun Ju Cho[2]. *[1]Seoul National University Hospital Healthcare System Gangnam Center, Korea, Rep. of South; [2]Seoul National University College of Medicine, Korea, Rep. of South; [3]Soonchunhyang University Bucheon Hospital, Korea, Rep. of South; [4]National Cancer Center, Korea, Rep. of South; [5]Catholic University of Korea, Korea, Rep. of South; [6]Samsung Medical Center, Sungkyunkwan University School of Medicine, Korea, Rep. of South; [7]Soongsil University, Korea, Rep. of South*
E-mail: creatioex@gmail.com

Background and aims: Although an association between metabolic dysfunction-associated fatty liver disease (MAFLD) and cardiovascular disease or overall mortality has been reported, it is unclear whether MAFLD predicts cancer incidence and mortality. We aimed to investigate the differential risk of all- and specific-cancer incidence and mortality according to MAFLD subgroups categorized by additional etiologies of liver disease.
Method: Using the Korean National Health Insurance Service database, we stratified the participants into three groups: 1) single-etiology MAFLD (S-MAFLD), or MAFLD of pure metabolic origin; 2) mixed-etiology MAFLD (M-MAFLD), or MAFLD with additional etiological factor (s) (i.e., concomitant liver diseases and/or heavy alcohol consumption); and 3) non-MAFLD. Hepatic steatosis and fibrosis were defined using the fatty liver index and the BARD score, respectively.
Results: Among the 9 718 182 participants, the prevalence of S-MAFLD and M-MAFLD was 29.2% and 6.7%, respectively. Compared with non-MAFLD, the risk for all-cancer incidence and mortality was slightly higher among patients with S-MAFLD (incidence, adjusted hazard ratio [aHR] = 1.03; 95% confidence interval [CI]: 1.02–1.04; mortality, aHR = 1.06; 95% CI: 1.04–1.08) and markedly higher among patients with M-MAFLD (incidence, aHR = 1.31; 95% CI: 1.29–1.32; mortality, aHR = 1.45; 95% CI: 1.42–1.48, respectively). The M-MAFLD with fibrosis group (BARD score ≥2) showed the highest risk of all-cancer incidence (aHR = 1.38, 95% CI = 1.36–1.39), followed by the M-MAFLD without fibrosis group (aHR = 1.09, 95% CI = 1.06–1.11). Similar trends were observed for cancer-related mortality.
Conclusion: MAFLD criteria by additional etiology identified a subgroup of people with poor cancer-related outcomes. These criteria may help identify high-risk groups for cancer.

THU-551

The rising burden of non-alcoholic fatty liver disease (NAFLD) related HCC: is time running out to contain this silent epidemic?

Saima Ajaz[1], James Lok[1], Paul Ross[2], Riham Soliman[1], Maria Guerra Veloz[1], Abid Suddle[1], Kosh Agarwal[1]. *[1]King's College Hospital, Institute of Liver studies, London, United Kingdom; [2]Guy's and St Thomas' NHS Foundation Trust, United Kingdom*
E-mail: saima.ajaz@nhs.net

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease due to the exponential increase in obesity and metabolic syndrome. Given this upward trajectory, as well as improvements in viral hepatitis management, NAFLD is predicted to become the leading aetiology of hepatocellular carcinoma (HCC) over the coming years. However, its true oncogenic burden in developed countries remains unclear. The aim of this project was to analyse the prevalence of NAFLD in HCC patients discussed in the HCC multidisciplinary meetings (MDM) at King's College Hospital (KCH).
Method: Data was obtained from patients discussed in the HCC MDM at KCH from 2013 to 2019. A total of 400 patients with a definitive diagnosis of HCC (as per standard radiological and/or histological criteria) were reviewed. The etiologies were grouped as NAFLD, chronic viral hepatitis (Hepatitis B Virus, HBV; Hepatitis C virus, HCV), treated viral hepatitis with co-existent NAFLD, and all other causes. Outcome was measured in terms of the all-cause mortality.
Results: We analysed data from 400 HCC patients. The underlying etiologies were as follows: NAFLD only (n = 116; 29 %), treated HCV with co-existent NAFLD (n = 60; 15 %), chronic HCV without NAFLD (n = 75; 18.5 %), chronic HBV (n = 52; 13 %) and all other etiologies (n = 97; 24.2 %). NAFLD was a contributing factor in 44% of cases (n = 176). The NAFLD patients having HCC had 78 % all-cause mortality and those with treated Chronic Hepatitis C with NAFLD had 83 % all-cause mortality over the follow-up period.
Conclusion: The data suggests that in a tertiary hepatology center in the United Kingdom, NAFLD was the most common underlying cause for HCC. The mortality was high and especially in HCV treated patients with NAFLD. This highlights the importance of early diagnosis and management of NAFLD to reduce the impending burden of NAFLD-related HCC.

THU-552

Comparison of non-alcoholic steatohepatitis severity between Hispanics and non-Hispanics: combined data from multiple therapeutic clinical trials including more than 5000 patients (in collaboration with NAIL-NIT consortium)

Sophie Jeannin Megnien[1], Julie Dubourg[1], Jörn Schattenberg[2], Vlad Ratziu[3], Stephen Harrison[4], Mazen Noureddin[5], Naim Alkhouri[6], Michael Charlton[7]. [1]*Summit Clinical Research, United States;* [2]*University medicine at the Johannes Gutenberg University in Mainz, Mainz, Germany;* [3]*Institute for Cardiometabolism and Nutrition, France,* [4]*University of Oxford, United Kingdom;* [5]*Houston Methodist Hospital, Houston, United States;* [6]*Arizona Liver Health, Chandler, United States;* [7]*UChicago Medicine, Chicago, United States*
E-mail: jdubourg@summitclinicalresearch.com

Background and aims: Hispanic ethnicity has been associated with a higher risk of non-alcoholic steatohepatitis (NASH) with advanced fibrosis. We aimed to describe the demographic, metabolic and histological characteristics, between Hispanics and non-Hispanics, to further delineate the level of disease severity in this group.
Method: We combined screening data from 6 ongoing biopsy-proven therapeutic NASH trials (>5000 patients). Patients were categorized according to their ethnicity. At-risk NASH was defined as NASH with a non-alcoholic fatty liver disease activity score (NAS) of at least 4 and a fibrosis stage of 2 or 3. Screen failure rates were compared between the 2 groups before and after liver biopsy. We performed descriptive statistics, logistic, and linear regressions to compare the 2 groups.

Screening

	Hispanic N = 2213	Non-Hispanic N = 2579	p value
	n (%) or mean (SD)		
Age, years	52 (12)	56 (11)	<0.01
Glycated hemoglobin (HbA1c), %	6.6 (1.5)	6.5 (1.3)	<0.01
Proportion of HbA1c ≥ 6.5%	42%	39%	0.04
Proportion of HbA1c >9.5%	5%	3%	<0.01
AST, IU/L	37 (27)	37 (28)	0.97
ALT, IU/L	50 (39)	48 (35)	0.03
GGT, IU/L	61 (73)	65 (83)	0.13
LDL, mg/dL	102 (38)	102 (38)	0.57
Triglyceride, mg/dL	167 (137)	168 (103)	0.73
Liver Biopsy time point			
	Hispanic N = 980	**Non-Hispanic N = 1223**	**p value**
	n (%) or mean (SD)		
NASH	561 (57%)	750 (61%)	0.06
Fibrosis Stage			
0–1	482 (49%)	505 (41%)	<0.01
2–3	454 (46%)	660 (54%)	
4	44 (4%)	59 (5%)	
At-risk NASH	370 (38%)	516 (42%)	0.04
Age, years	52 (12)	56 (11)	<0.01
Glycated hemoglobin (HbA1c), %	6.4 (1.1)	6.4 (1.0)	0.41
Proportion of HbA1c ≥ 6.5%	376 (39%)	458 (39%)	0.86
AST, IU/L	40 (24)	42 (25)	0.18
ALT, IU/L	55 (34)	54 (33)	0.22
GGT, IU/L	58 (58)	65 (72)	0.01
LDL, mg/dL	103 (38)	103 (38)	0.93
Triglyceride, mg/dL	159 (90)	164 (79)	0.24
Liver Stiffness Measurement-transient elastography, kPa	13.1 (6.9)	13.3 (6.2)	0.59
Liver fat content, %	18 (7)	18 (8)	0.14

Figure:

Results: 4792 patients with ethnicity data were included and 2203 had liver histology data. At screening, 2213 (46%) were Hispanic. Among Hispanic 1233 (56%) screen failed before biopsy compared to 1356 (53%) in non-Hispanic. The table shows the differences in characteristics between groups. At screening Hispanics were younger and had a higher glycated hemoglobin (HbA1c) with a higher proportion of patients with HbA1c >9.5% (considered a screen failure reason in many trials). This difference in HbA1c did not persist in patients who underwent liver biopsy. After adjustment for age, GGT and FIB-4, the non-Hispanic group had more advanced fibrosis (p = 0.02).
Conclusion: Hispanics had less advanced fibrosis compared to non-Hispanics. Enrichment with Hispanic patients in non-cirrhotic NASH clinical trials might not help improve the screen failure rate due to liver histology. Further studies including genotyping are important to further investigate the importance of minority groups in clinical trials of NASH.

THU-553

Study of an association of the serum iron markers, hepatic iron deposition and severity of non-alcoholic fatty liver disease: a single-centered prospective study

Shubham Jain[1], Saurabh Bansal[1], Pankaj Nawghare[1], Anuraag Jena[1], Sanjay Chandnani[1], Pravin Rathi[1]. [1]*Topiwala National Medical College, Mumbai, Gastroenterology, Mumbai, India*
E-mail: dr.shubhamjazz@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is commonly associated with elevated serum ferritin (SF) levels, seen in almost 30% of patients. However, whether this raised serum ferritin is a marker of hepatic inflammation or hepatic iron overload is still debatable. Recent studies have incorporated levels of serum ferritin (SF) to assess the progression of NASH and liver fibrosis. Moreover, the probable relationship between SF, Hepatocellular iron deposition, and stages of NAFLD disease is a pleasing surprise but not fully understood. Therefore we aimed to study the association of hepatic iron deposition in patients with histologically proven NAFLD and the role of serum ferritin as a predictor of the severity of NAFLD.
Method: We prospectively evaluated 103 outpatients with biopsy-proven NAFLD from our tertiary care centre over 2 years. Standard histological and clinical criteria were used for the diagnosis of NAFLD. Complete serum iron profile, hepatic, and metabolic parameters were collected at the time of liver biopsy. Hyperferritenemia was defined when serum ferritin levels were more than 150 ng/ml. Significant fibrosis was defined as F2 fibrosis on histopathology/>8 kpa on transient electrography. Iron deposition in hepatocytes was assessed with staining and graded.
Results: Out of 103 included patients, 60 patients had steatohepatitis (NASH). Among those, 36 (60%) patients had elevated SF levels and iron staining was positive in 18 (30%) patients. however, there was no significant association found between serum hyperferritinemia and the presence of NASH (p = 0.68). Although NASH patients had no significant elevated ferritin levels but hepatic iron deposition was seen significantly higher in NASH vs non-NASH patients (18/60, 30% vs 4/43, 9%, p = 0.014). A total of 64 (62.1%) patients had hyperferritinemia, whereas hepatic iron stain was positive in 22 (21.3%) patients. The association of hyperferritinemia was significant in the early stages of fibrosis F0-F2 (p value- 0.04) whereas advanced stages of fibrosis F3-F4 were noted to have significantly decreased ferritin levels (p = 0.045). The stainable hepatic iron deposition has no significant association with the progression of liver fibrosis as seen in Pre-cirrhotic stage (F0-F2) 11/48, 22.9% vs cirrhotic stage (F3-F4) 11/55, 20%, p value- 0.81

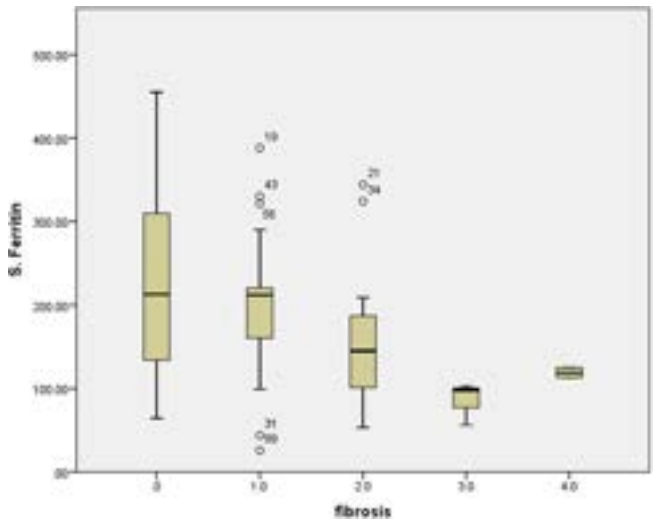

Figure: Relationship between Serum ferritin level (ng/ml) and stages of hepatic fibrosis

Conclusion: Hyperferritenemia is seen in almost two third of NAFLD patients but most of the cases are not associated with hepatic iron deposition and progression of fibrosis. Stainable hepatic iron is more significantly associated with the presence of steatohepatitis (NASH) and less likely to correlate with advanced fibrosis. We conclude that there is no association between hyperferritinemia with hepatic iron deposition and the severity of disease in NAFLD patients. In addition serum, ferritin levels can be supplemented as the non-invasive diagnostic panel in individual NAFLD patients.

THU-554

The importance of regular screening for HCC in non-alcoholic steatohepatitis/non-alcoholic fatty liver disease

Taisei Keitoku[1], Nobuharu Tamaki[1], Masayuki Kurosaki[1], Naoki Uchihara[1], Keito Suzuki[1], Yuki Tanaka[1], Haruka Miyamoto[1], Michiko Yamada[1], Shun Ishido[1], Hiroaki Matsumoto[1], Tsubasa Nobusawa[1], Mayu Higuchi[1], Kenta Takaura[1], Shohei Tanaka[1], Chiaki Maeyashiki[1], Yutaka Yasui[1], Yuka Takahashi[1], Kaoru Tsuchiya[1], Hiroyuki Nakanishi[1], Daniel Huang[2], Namiki Izumi[1]. *[1]Musashino Red Cross Hospital, Gastroenterology and Hepatology, Tokyo, Japan; [2]National University of Singapore, Singapore, Singapore*
E-mail: kurosakim@gmail.com

Background and aims: Although it is necessary to detect HCC at an early stage by appropriate screening, a strategy for screening has not yet been established. Therefore, we decided to investigate the importance of regular screening in patients with NASH/NAFLD.
Method: We studied 317 NASH/NAFLD patients diagnosed with first-episode liver cancer at Musashino Red Cross Hospital and National University of Singapore. We investigated whether these patients had regular imaging screening (AUS/CT/MRI) at least once every 6 months prior to the diagnosis of HCC. The primary outcome was the whether or not curative treatment (curative treatment is defined as RFA or surgery in Barcelona clinic liver cancer (BCLC) Stage0 or A patients) was performed. Survival rates in the patients with or without screening were compared as secondary outcomes.
Results: There were 233 patients without screening and 84 with screening. Patient background without/with screening: age (mean ± standard deviation) was 74 (± 11) vs 72 (± 11) years and BMI (mean ± SD) was 24.7 (± 4.6) vs 26.0 (± 4.4). The number of patients with cirrhosis were 106 (45.5%) vs 57 (67.9%). Among cirrhosis cases, Child-Pugh Class A/B/C: 67.6% vs 75.0%/25.5% vs 22.7%/6.9% vs 2.3% ($p = 0.5$). BCLC Stage 0/A was 10.4% vs 44.6%/48.7% vs 39.8% ($p < 0.001$). Cases with screening were significantly to receive curative treatment (34.8% vs. 64.3%, $p < 0.001$). The 1-, 3-, and 5-year survival rates of the patients without/with screening were 72.5% vs 92.1%/55.1% vs 80.7%/48.0% vs 66.3% ($p < 0.001$), indicating a significantly lower survival rate in patients without screening.
Conclusion: Routine screening for NASH/NAFLD can detect early HCC and provide curative therapeutic intervention.

THU-555

Long-term clinical outcomes of adults with metabolic dysfunction-associated fatty liver disease: a single-centre prospective cohort study with baseline liver biopsy

Wah Loong Chan[1], Shi-En Chong[1], Felicia Chang[1], Kee Huat Chuah[1], Nik Raihan Nik Mustapha[2], Sanjiv Mahadeva[1], Wah-Kheong Chan[1]. *[1]Universiti Malaya, Gastroenterology and Hepatology Unit, Department of Medicine, Faculty of Medicine, Kuala Lumpur, Malaysia; [2]Hospital Sultanah Bahiyah, Department of Pathology, Alor Setar, Malaysia*
E-mail: wljack90@gmail.com

Background and aims: There are limited data on the long-term clinical outcomes of adults with metabolic dysfunction-associated fatty liver disease (MAFLD), especially in Asian population. The primary objective of this study was to provide long-term clinical outcome data of adult patients with MAFLD in Malaysia.
Method: This is a single-centre prospective study of a well-characterized cohort of biopsy-proven MAFLD patients. The patients were followed every 6–12 months for cardiovascular events, liver-related events, malignancy, and mortality. The incidence of clinical outcomes and mortality were compared between patients with and without steatohepatitis and between patients with and without advanced liver fibrosis. Advanced liver fibrosis was defined as histological fibrosis stages 3 or 4. Steatohepatitis was defined as histological presence of steatosis, lobular inflammation, and hepatocyte ballooning (≥grade 1 each). The comparison between groups was performed using Kaplan-Meier curve and log rank test. Significant was assumed when p was <0.05.
Results: The data for 202 patients were analyzed (median age 55.0 years old, 47.5% male, 88.6% obese, 71.3% diabetes mellitus, 76.7% steatohepatitis, 27.2% advanced liver fibrosis). The median follow-up interval was 7 years (range 1–9 years). The rates of cardiovascular events, malignancy, liver-related events, and mortality was 2.49, 0.69, 0.43, and 0.60 per 100 person-years of follow-up, respectively. Liver-related events were only seen in patient with advanced liver fibrosis at 9.1% vs 0% in patient without advanced liver fibrosis ($p = 0.001$). Advanced liver fibrosis was not associated with cardiovascular events, malignancy, or mortality. NASH was not associated with cardiovascular events, malignancy, liver-related events, or mortality.

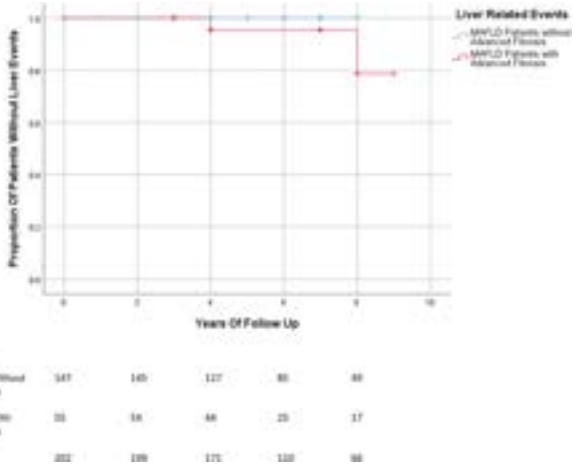

Figure:

Conclusion: The overall liver-related event rate in MAFLD patients is low, but it is significantly higher among patients with advanced liver fibrosis. Cardiovascular disease is the leading cause of mortality in MAFLD patients.

THU-556

Serum vitamin D is strongly associated with liver steatosis but not with liver and spleen stiffness assessed by transient elastography in patients at risk

Gediz Dogay Us[1,2], Ozgur Koc[1,3], Francesco Innocenti[4], İhsan Nuri Akpinar[5], Ger Koek[1,3]. *[1]Maastricht University, School of Nutrition and Translational Research in Metabolism, Maastricht, Netherlands; [2]Pax Clinic, Department of Gastroenterology, Istanbul, Turkey; [3]Maastricht University Medical Center, Division of gastroenterology and hepatology, Maastricht, Netherlands; [4]Maastricht University, Department of Methodology and Statistics, CAPHRI Care and Public Health Research Institute, Maastricht, Netherlands; [5]Pax Clinic, Department of Radiology, Istanbul, Turkey*
E-mail: dogaygediz@gmail.com

Background and aims: Vitamin D exerts a significant role in liver-related pathologies by interacting at multiple steps in development of liver steatosis, steatohepatitis, and liver fibrosis, as well as several related extrahepatic manifestations. Its insufficiency not only associates with obesity and metabolic syndrome but also has been shown to have a causative relationship with the severity and incidence of liver steatosis. However, the association between vitamin D insufficiency (VDI) and the stiffness of liver and spleen is not as well-defined. Therefore, we investigated the relationship between VDI and liver steatosis, liver stiffness (LS) and spleen stiffness (SS) assessed by transient elastography (TE).
Method: We recruited 395 participants for a single-centered prospective study in an outpatient clinic during a one-year period (between 01/2022 and 01/2023). All participants were older than 18 and presented at least with one component of the metabolic syndrome. Body weight, height, and waist circumference (WC) were measured, and body mass index (BMI) was calculated. Vitamin D status was measured as serum 25 (OH)D level and <30 ng/ml was considered as VDI. Liver steatosis by Controlled attenuation parameter (CAP), liver stiffness and spleen stiffness were assessed using a TE device (FibroScan®; Echosens, Paris, France). Multivariable linear regression analyses were used to investigate the association of vitamin D with CAP, LS and SS, adjusting for the following potential confounders: age, sex, WC, BMI, diabetes, hypertension, dyslipidemia, and metabolic syndrome.
Results: VDI was present in 33.4% of the participants. Vitamin D was negatively associated with CAP, with an unadjusted effect on CAP of −0.657 (95% CI: −0.921, −0.392). After adjusting for age, sex, BMI, waist circumference, diabetes, hypertension, dyslipidemia and metabolic syndrome, the association remained statistically significant but the effect of Vitamin D on CAP reduced to −0.342 (95% CI: −0.523, −0.160). There was a very weak and non-statistically significant association between Vitamin D and liver stiffness (−0.01, 95% CI: −0.02, 0.001) and spleen stiffness (−0.046, 95% CI: −0.110, 0.018), which vanishes when controlling for age, BMI, WC, sex, diabetes, hypertension, dyslipidaemia, and metabolic syndrome (−0.004, 95% CI: −0.014, 0.006 and −0.005, 95% CI: −0.071, 0.061, consecutively).
Conclusion: VDI is a predictor of the severity of liver steatosis independently from obesity and all components of metabolic syndrome, however liver and spleen stiffness does not show a significant association with it. Further studies demonstrating the impact of vitamin D in liver-related outcomes are warranted.

THU-557

Hepatic steatosis in people with HIV is associated with lower BMI and more liver fibrosis compared to metabolic dysfunction-associated fatty liver disease

Floriana Santomenna[1], Rosa Lombardi[1,2], Felice Cinque[1,3], Jaqueline Currà[1], Dana Kablawi[4], Annalisa Cespiati[1,2], Luca Marchesi[1], Erika Fatta[2], Cristina Bertelli[2], Giovanna Oberti[2], Wesal Elgretli[3], Bertrand Lebouche[4], Marc Deschenes[4], Thierry Fosind Tadjo[4], Giada Sebastiani[3,4], Anna Ludovica Fracanzani[1,2]. *[1]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy, Italy; [2]Unit of Medicine and Metabolic Disease, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, Milan, Italy, Italy; [3]Division of Experimental Medicine, McGill University, Montreal QC, Canada; [4]Chronic Viral Illness Service, McGill University Health Centre, Montreal QC, Canada*
E-mail: rosalombardi@hotmail.it

Background and aims: People with HIV (PWH) are at risk of hepatic steatosis (HS) possibly evolving to hepatic fibrosis. The pathogenesis of HS in these patients is complex, including HIV-related inflammation, frequent metabolic comorbidities and lifelong exposure to antiretroviral therapy. Recently, a new concept of metabolic dysfunction-associated fatty liver disease (MAFLD) has emerged, defined the presence of HS associated with at least one metabolic alteration. There are limited data whether HIV-associated HS differs in clinical presentation from metabolic dysfunction-associated fatty liver disease (MAFLD). We aimed at comparing severity of metabolic and hepatic dysfunction between PWH with HS and MAFLD patients.
Method: In this international case-control study, 212 consecutive HIV mono-infected patients with HS at McGill University in Montreal were compared to a sex and age matched MAFLD control group at Policlinico Hospital in Milan. Fibroscan with controlled attenuation paremeter (CAP) was used to define HS (CAP ≥248 dB/m), severe HS (CAP > 280 dB/m), and significant liver fibrosis (liver stiffness measurement>7.0 kPa). Serum fibrosis biomarkers APRI, FIB-4 and Fibroscan-AST (FAST) score were also computed.
Results: PWH presented lower median BMI (28[25–31] vs 29[27–32] Kg/m^2, p = 0.002) and lower prevalence of obesity (26% vs 44%, p < 0.001) compared to MAFLD patients, along with a lower prevalence of hypertension (21% vs 38%, p < 0.001). The prevalence of dyslipidemia (41% vs 26%, p < 0.001) and statin prescription (23% vs 11%, p = 0.003), as well as of high triglycerides (26% vs 9%, p < 0.001) and low HDL cholesterol (34% vs 15%, p < 0.001), was higher among PWH compared to MAFLD patients. No difference in cardiovascular events and diabetes prevalence was observed between the two groups. As for liver disease, PWH had a lower prevalence of severe HS (54% vs 74% p < 0.001) but higher prevalence of significant liver fibrosis (15 vs 7%, p = 0.03) by Fibroscan, as well as higher serum fibrosis biomarkers APRI, FIB-4 and FAST score, compared to MAFLD patients.
Conclusion: Despite having lower BMI, PWH seem to have a more severe hepatic and atherogenic presentation of HS than MAFLD patients. Screening and follow-up for HS and especially for liver fibrosis in PWH is recommended, even if lean.

THU-558

Impact of visceral adiposity for coronary artery calcification progression in patients with metabolic dysfunction-associated fatty liver disease; multicenter cohort study

Min Kyu Kang[1], KyeWhon Kim[2], Jung Eun Song[3], Jung Gil Park[1]. *[1]College of Medicine, Yeungnam University, Internal Medicine, Korea, Rep. of South; [2]Yeungnam University Hospital, Korea, Rep. of South; [3]School of Medicine, Daegu Catholic University, Korea, Rep. of South*
E-mail: gsnrs@naver.com

Background and aims: Metabolic dysfunction-associated fatty liver disease (MAFLD) as well as non-alcoholic fatty liver disease (NAFLD) is associated with coronary artery calcification (CAC) progression. Although body composition parameters are emerging as novel

prognostic factors for NAFLD, the clinical significance of those on CAC progression in patients with MAFLD is lacking. We investigated the impact of body composition parameters on the CAC progression in patients with MAFLD.
Method: A cross-sectional analysis of retrospective cohort study was conducted at two health promotion centers, including 457 MAFLD patients who performed ultrasound and abdominal and cardiac CT. Fatty liver was defined using ultrasound and presence of CAC as a CAC score >0 was defined using cardiac CT. The CAC progression was classified by Greenland methods (0, 1 to 100, 101 to 300, and >300) Using cross-sectional CT images of 3rd lumbar vertebra, sarcopenia, visceral adiposity, and myosteatosis were defined.
Results: Median age was 57 years (interquartile range: 52.0–63.0) and 364 (79.6 %) were male. The presence of CAC was 44.6% and the CAC progression groups were identified by 253 (26.3%) in 1 to 100 group, 42 (9.2%) in 101 to 300 group, and 42 (9.2%) in >300 group, respectively. The visceral adiposity progression was correlated with the CAC progression ($p < 0.001$). In the multivariate analysis, visceral adiposity (odds ratio, 1.79; 95% confidence interval; 1.14–2.83, $p = 0.011$) was significant risk factors for presence of CAC, independent of pre-existing prognostic factors.

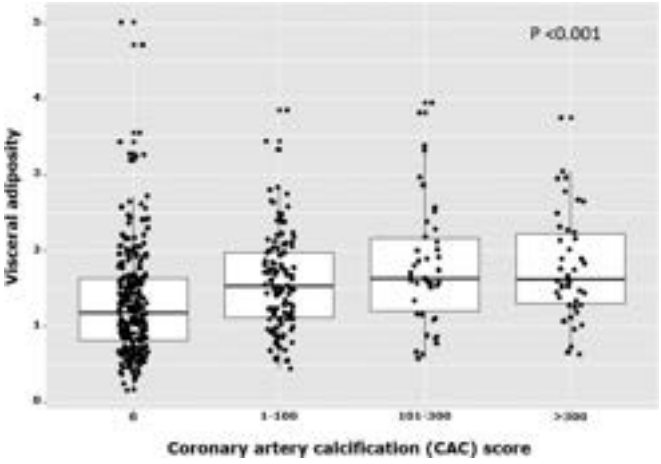

Figure:

Conclusion: Visceral adiposity is associated with an CAC progression in patients with MAFLD, independent of traditional risk factors.

E-mail: andreas.teufel@medma.uni-heidelberg.de

Background and aims: Chronic liver diseases belong to the most common diseases worldwide and are associated with increased morbidity and mortality. Although every fourth adult might be affected by non-alcoholic fatty liver disease (NAFLD), awareness of this condition is low amongst the general public, health care professionals and policy makers. However, meaningful knowledge transfer is essential for raising awareness and improving prevention and treatment of liver disease. Thus, investigating the use of internet search engines might offer valuable insights on how knowledge transfer has evolved and which liver-related issues are currently searched.
Method: We investigated Google search trends by measuring the number of hits relating to liver diseases between 2004 and 2021 in seven languages and European countries but also worldwide. All analyses were performed in R using the R Google trends package gtrendsR.
Results: We found that interest in NAFLD has generally increased over time, but that interest in non-alcoholic steatohepatitis (NASH)-the most severe form of NAFLD-has decreased. Interest in viral hepatitis C has decreased, whereas the number of queries regarding viral hepatitis B have been stable but dominated by interest in vaccination for it. Recent medical developments (in viral hepatitis) did not lead to a noticeable change in overall search behavior. Users preferred searching using their native language and less complex medical terms and acronyms (e.g., fatty liver instead of NAFLD).
Conclusion: In the last two decades, public Google search trends have followed the general changes in hepatology. Searches are dominated by non-healthcare professionals and generally avoid complex and specific medical terms. Awareness and communication strategies around NAFLD should consider these preferences when addressing the general public.

THU-560

Salivary analytical device (SAD) a good tool for monitoring the metabolic status of patients with fatty liver disease

Gaia Sinatti[1], Silvano Junior Santini[1], Giovanni Brienza[1], Marco Lampieri[1], Giovanna Fracassi[1], Clara Balsano[1]. *[1]University of L'Aquila, Department of Life, Health and Environmental Sciences (MESVA), L'Aquila, Italy*
E-mail: gaia.sinatti@graduate.univaq.it

Background and aims: Physical inactivity and sedentary lifestyle have contributed worldwide to the epidemic spread of obesity and non-alcohol related fatty liver disease (NAFLD), the most common cause of chronic liver disease. Besides leading to increased morbidity and mortality due to the possible evolution of the disease into non-alcohol related steatohepatitis (NASH) and/or into advanced fibrosis, NAFLD is also associated with cardiovascular disease (CVD). Monitoring NAFLD patients at risk of developing complications by using a more effective health technology would allow the implementation of preventive health strategies and follow-up programs that would bring considerable benefits to the individual and reduce the burden of this disease on the health care system. Saliva has hundreds of components that can serve as biomarkers of both physiological and pathological status. The purpose of this study was to develop a device, with multiple integrated sensors, that could use saliva to monitor patients with dysmetabolism and derive reliable

detections comparable with blood values to allow and improve telematic control of the patient.
Method: In this study, a small cohort of thirty patients was enrolled. We evaluated and compared each value of lipid profile (total cholesterol, High Density Lipoprotein HDL, triglycerides) and glucose, detected in blood samples, with those identified in saliva samples by using commercial enzymatic kit assay. Besides that, hematological parameters were measured in saliva samples by a lab on chip to validate a prototype of device, with multiple integrated sensors, created in collaboration with electronic engineers and called SAD, Salivary Analytical Device. (Figure)
Results: we obtained a good degree of correlation between blood determinations and salivary values of total cholesterol ($r = 0.65$, $p = 0.04$), HDL ($r = 0.73$, $p = 0.04$), triglycerides ($r = 0.84$, $p = 0.02$) and glucose ($r = 0.98$, $p = 0.003$) both using commercial kits. Moreover, SAD prototype displayed an excellent reliability for salivary parameters evaluation and dosing.

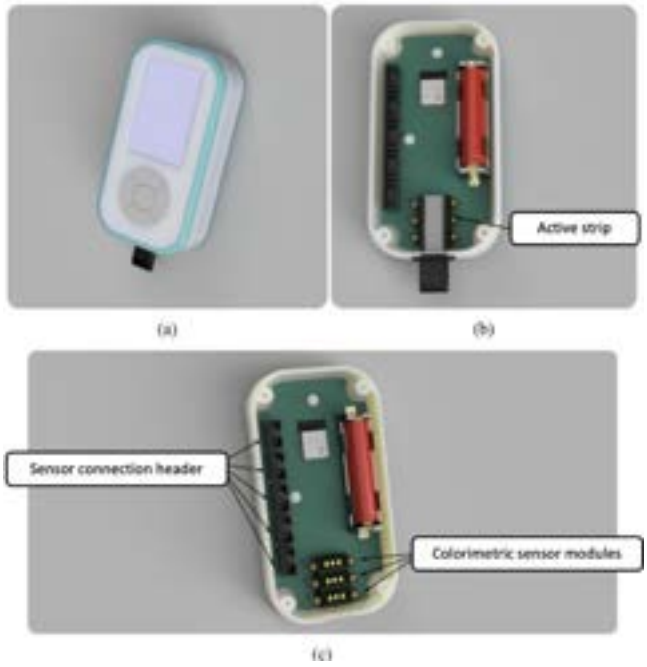

Figure: SAD, Salivary Analytical Device render. a) general view of the device prototype, b) housing arrangement of a commercial strip, c) arrangement of sensor connection header and connector colorimetric sensor modules.

Conclusion: Although our results need to be validated on a larger cohort of patients, our preliminary data confirm that our device SAD can be a good tool for monitoring total cholesterol, HDL, triglycerides, and glucose levels in saliva samples. Offering the possibility of monitoring multiple biochemical parameters with a non-invasive device, in a simple and fast way, capable of analyzing metabolic parameters in a few drops of saliva, is desirable, and would unequivocally implement the performance and reliability of remote telemonitoring.

NAFLD Diagnostics and non-invasive assessment

Significant dose-dependent reduction in liver stiffness using transient elastography in a phase 3 randomized placebo-controlled trial of obeticholic acid over 48 months in patients with pre-cirrhotic fibrosis due to non-alcoholic steatohepatitis

Rohit Loomba[1], Quentin Anstee[2], Stephen Harrison[3], Naim Alkhouri[4], Mary Rinella[5], Thomas Capozza[6], Christopher Gasink[6], Amarita Randhawa[6]. *[1]NAFLD Research Center, University of California, San Diego, La Jolla, United States; [2]Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Framlington Place, Newcastle upon Tyne, United Kingdom; [3]Pinnacle Clinical Research Center, San Antonio, United States; [4]Arizona Liver Health, Chandler, United States; [5]University of Chicago, Pritzker School of Medicine, Chicago, United States; [6]Intercept Pharmaceuticals Inc, Morristown, United States*
Email: thomas.capozza@interceptpharma.com

Background and aims: Transient elastography (TE) may reduce the need for liver biopsies to diagnose and monitor progression of pre-cirrhotic liver fibrosis due to non-alcoholic steatohepatitis (NASH). Interim analyses of the ongoing phase 3 REGENERATE trial showed that obeticholic acid (OCA) significantly improved hepatic fibrosis vs placebo in patients with NASH as assessed by histologic analysis of liver biopsies using individual readers or a consensus panel. Secondary study objectives included non-invasive assessment of the antifibrotic effect of OCA vs placebo. Here, we describe the effect of OCA vs placebo on TE liver stiffness measurement (LSM) over 48 months in patients with pre-cirrhotic fibrosis due to NASH in the REGENERATE study.
Method: TE (FibroScan) was performed every 6 months at study sites where it was available. LSM was analyzed in the intent-to-treat (ITT) population, which included all randomized patients with baseline fibrosis stage 2 or 3 (histologic staging) who received at least 1 dose of placebo, OCA 10 mg, or OCA 25 mg and who had a post-baseline measurement. Fibrosis staging was determined by a consensus method for histologic analysis using NASH Clinical Research Network scoring criteria.
Results: In the ITT population ($N = 2187$), mean (standard deviation) baseline LSM across cohorts was similar (placebo, 12.2 [6.7] kilopascal [kPa]; OCA 10 mg, 12.1 [6.2] kPa; OCA 25 mg, 11.7 [6.4] kPa). Mean LSM in OCA-treated patients decreased relative to those in the placebo group as early as month 6 (about 50% had ≥20% reduction from baseline) and was sustained through month 48 in the OCA 25 mg group (Figure 1A). At month 18, LSM reductions were observed in both OCA groups whereas LSM in the placebo group worsened (OCA 10 mg vs placebo, $p = 0.0006$; OCA 25 mg vs placebo, $p = 0.0015$; Figure 1B). At month 48, there was a dose-dependent reduction of LSM, with OCA 25 mg achieving a −2.32 kPa least-squares mean change from baseline ($p = 0.0172$ vs placebo). In a responder analysis, LSM reductions occurred even in OCA-treated patients whose histologic fibrosis was assessed as unchanged at month 18 by central pathologists (Figure 1C).
Conclusion: Treatment with 48 months of OCA provided a dose-dependent and cumulative benefit in liver stiffness vs placebo in patients with pre-cirrhotic liver fibrosis due to NASH. These findings support the regulatory primary end point of histologic improvement in hepatic fibrosis in the REGENERATE study, which was demonstrated by 2 biopsy-reading methodologies.

Figure: Validation of the AGA Clinical Pathway for NAFLD (A) and an alternate pathway using ELF (B) with MRE as the reference standard in patients with type 2 Diabetes Mellitus

Validation and expansion of the American gastroenterological association clinical care pathway for non-alcoholic fatty liver disease in a prospective cohort of patients with type 2 diabetes

Veeral Ajmera[1], Kaleb Tesfai[1], Scarlett Lopez[1], Vanessa Cervantes[1], Egbert Madamba[1], Ricki Bettencourt[1], Lisa Richards[1], Rohit Loomba[1].
[1]*UCSD NAFLD Research Center, United States*
Email: v1ajmera@ucsd.edu

Background and aims: A multidisciplinary task force commissioned by the American Gastroenterological Association (AGA) recently developed a clinical care pathway with guidance on screening high-risk populations including those with type 2 diabetes (T2DM). We aimed to validate the pathway in a prospectively recruited cohort of patients with T2DM and evaluate the diagnostic performance of an alternate pathway with enhanced liver fibrosis (ELF) testing.
Method: This prospective study enrolled adults age ≥50 years with T2DM recruited from primary care or endocrinology clinics. Participants underwent a standardized clinical research visit with magnetic resonance imaging proton-density-fat-fraction (MRI-PDFF), magnetic resonance elastography (MRE), vibration-controlled transient elastography (VCTE) and controlled attenuation parameter (CAP) and ELF testing. The primary outcome was the diagnostic performance of the AGA clinical pathway and an alternate pathway with ELF for advanced fibrosis using MRE ≥3.63 kPa as the reference.
Results: 417 patients (36% men) with T2DM with FIB-4 and MRE data were included. The mean (± SD) age and BMI were 65 (± 8) years and 30 (± 5) kg/m^2, respectively. The prevalence of NAFLD (MRI-PDFF ≥5% after exclusion of other liver diseases) was 64% and 12% had advanced fibrosis (MRE ≥3.63 kPa). FIB-4 values of <1.3, 1.3–2.67 and ≥2.67 were present in 208 (50%), 183 (44%), and 26 (6%) of patients respectively. VCTE values <8 kPa, 8–12 kPa and ≥12 kPa were present in 309 (77%), 58 (14%), and 36 (9%) of patients respectively. ELF scores of <9.8, 9.8–11.3 and >11.3 were present in 236 (58%), 146 (36%) and 22 (6%) patients respectively. Applying the AGA pathway (N = 403), 202 patients were low risk by FIB-4 and 128 additional patients had VCTE <8 kPa and were classified as low risk. The false negative rate was 3.3% and 18% would qualify for specialty referral (Figure 1A). Applying the alternate pathway with ELF (N = 404), 200 patients were low risk by FIB-4 and 85 additional patients had low ELF and were low

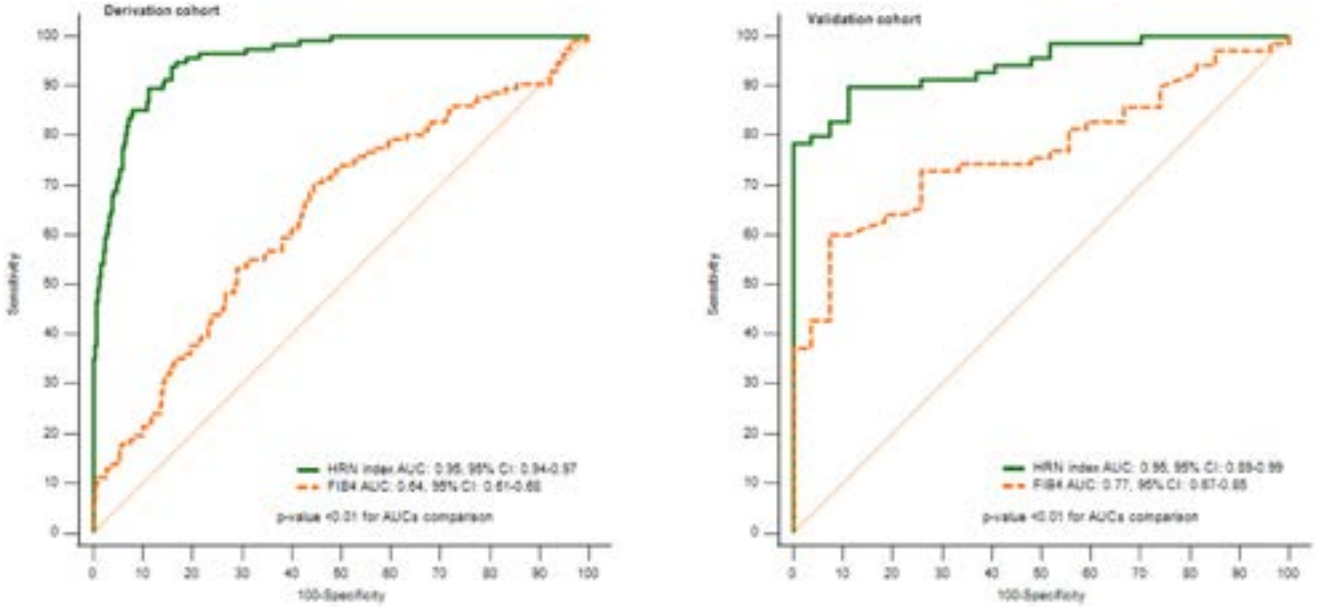

Figure: (abstract: TOP-080).

risk. The false negative rate was 4.8% and 29% would qualify specialty referral (Figure 1B).
Conclusion: Validation of the AGA clinical pathway in a well-phenotyped, prospectively recruited cohort with T2DM revealed a low false negative rate, 3.3% and identified 82% of patients as low-risk. An alternative pathway with FIB-4 + ELF, which does not require VCTE prior to specialty referral, had a low false negative rate and similar performance and may serve as a viable alternative for primary care and endocrinology clinics without access to VCTE.

A validated tool consisting of bedside variables predicts high-risk NASH (HRN) in individuals with type 2 diabetes

Eduardo Vilar Gomez[1], Deven Parmar[2], Niharika Samala[1], Raj Vuppalanchi[1], Samer Gawrieh[1], Oscar Cummings[1], Stephen Harrison[3], Rohit Loomba[4], Naga Chalasani[1]. [1]*Indiana University School of Medicine, Indianapolis, United States;* [2]*Zydus Therapeutics Inc, United States;* [3]*Pinnacle Clinical Research, San Antonio, United States;* [4]*Medical Center, San Diego, United States*
Email: nchalasa@iu.edu

Background and aims: FIB4 is currently recommended to screen patients with NAFLD at increased risk of clinically significant fibrosis (CSF). However, rigorous data are lacking to support screening of CSF via FIB4 in patients with type 2 diabetes (T2D). We developed and externally validated a model to predict the presence of high-risk NASH (HRN) in patients with T2D and compared its performance against FIB4.
Method: 807 T2D participants with vibration-controlled transient elastography (VCTE) in the US population-based National Health and Nutrition Examination Survey (NHANES, 2017–2018) constituted the derivation cohort. 97 T2D screened for a phase 2 clinical trial (NCT05011305) comprised the validation cohort. HRN, defined as NAS ≥4 and fibrosis stage ≥2, was assessed using a FibroScan-AST (FAST) score threshold of ≥0.35 obtained from VCTE and aspartate aminotransferase (AST). Diabetes was defined by HbA1c levels ≥6.5% or fasting plasma glucose of ≥126 mg/dl or current use of glucose-lowering medications. Logistic regression models were used for variable selection and model development in the derivation cohort. The area under the ROC curve (AUC) was computed to determine the diagnostic performance of the final predictive model and Fib-4 and select different thresholds for discriminating participants with HRN.
