Publication information: Journal of Hepatology (ISSN 0168-8278). For 2023, volumes 78 and 79 are scheduled for publication. Subscription prices are available upon request from the Publisher or from the Elsevier Customer Service Department nearest you or from this journal's website (http://www.elsevier.com/locate/jhep). Further information is available on this journal and other Elsevier products through Elsevier's website: (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Orders, claims, and journal enquiries: Please visit our Support Hub page https://service.elsevier.com for assistance.

Advertising information: Advertising orders and enquiries can be sent to: **USA, Canada and South America:** Elsevier Inc., 360 Park Avenue, Suite 800, New York, NY 10169-0901, USA; phone: (+1) (212) 989 5800. **Europe and ROW:** Robert Bayliss, Pharma Solutions, Elsevier Ltd., 125 London Wall, London EC2Y 5AS, UK; phone: (+44) 207 424 4454; e-mail: r.bayliss@elsevier.com.

Author enquiries: Visit the Elsevier Support Center (https://service.elsevier.com/app/home/supporthub/publishing) to find the answers you need. Here you will find everything from Frequently Asked Questions to ways to get in touch.
You can also check the status of your submitted article via https://service.elsevier.com/app/answers/detail/a_id/29155/ or find out when your accepted article will be published via https://service.elsevier.com/app/answers/detail/a_id/5981/.

Funding body agreements and policies: Elsevier has established agreements and developed policies to allow authors whose articles appear in journals published by Elsevier, to comply with potential manuscript archiving requirements as specified as conditions of their grant awards. To learn more about existing agreements and policies please visit http://www.elsevier.com/fundingbodies.

Special regulations for authors: Upon acceptance of an article by the journal, the author(s) will be asked to transfer copyright of the article to EASL. Transfer will ensure the widest possible dissemination of information.

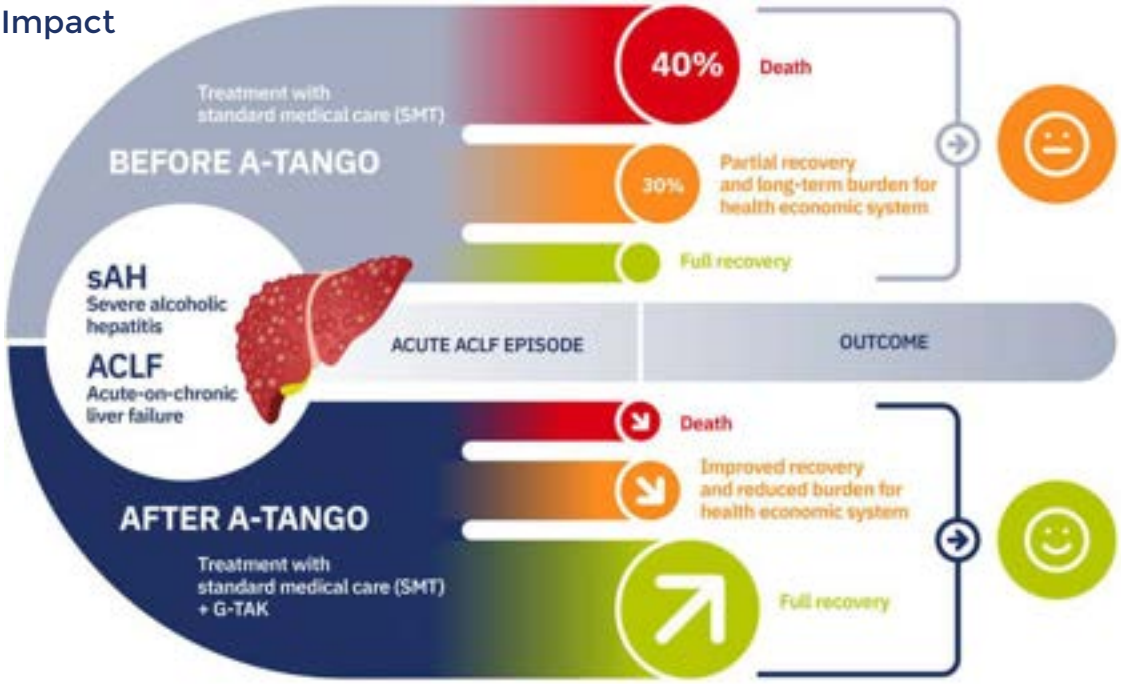
The A-TANGO project - featuring G-TAK, a novel combinatorial therapy for acute-on-chronic liver failure (ACLF)

Expected Impact



- More than **10 million people** suffer from **decompensated cirrhosis** worldwide.
- Effective treatment of ACLF is an urgent and unmet need.
- A-TANGO performs **Phase II clinical studies of G-TAK,** a novel and innovative therapeutic strategy that aims to **reduce inflammation** and **improve hepatocyte proliferation.**
- A-TANGO also strives to identify **reliable biomarkers** for better patient stratification and increased survival.

decision-project

The objective of DECISION is to better understand the pathophysiology of decompensated cirrhosis leading to acute-on-chronic liver failure (ACLF) or death. This consortium will take advantage of already existing large and clinically well-characterised patient cohorts to develop reliable prognostic and response tests and combinatorial therapies tailored to the needs of individual patients to decrease the risk of short-term death.

- Pathophysiologic elucidation of acute decompensated cirrhosis at the systems level (genetics, epigenetics, transcriptomics, metabolomics, lipidomics, miR, and analysis of extracellular vesicles)
- Integration of existing clinical data and new multi-omics data from 2,200 patients with more than 8,600 measurements
- Development of new combinatorial therapies
- Optimization of therapies using existing and new animal models
- Development of novel and robust tests for prediction of outcome following traditional treatment versus response to new therapies
- Phase II clinical trials to test new combination therapies
- Creation of new guidelines for outcome prediction and personalized treatment of acute decompensated cirrhosis to prevent ACLF to death

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 847949.

Registration of Clinical Trials
The *Journal of Hepatology* endorses the policy of the WHO and the International Committee of Medical Journal Editors (ICMJE) on the registration of clinical trials. Therefore, any trial that starts recruiting on or after July 1, 2005 should be registered in a publicly owned, publicly accessible registry and should satisfy a minimal standard dataset. Trials that started recruiting before that date will be considered for publication if registered before September 13, 2005.
More detailed information regarding clinical trials and registration can be found in New Engl J Med 2004; 351:1250–1251 and New Engl J Med 2005; 352:2437–2438.

Gene ENvironment Interaction in ALcohol-related hepatocellular carcinoma

Understanding **G**ene **EN**vironment **I**nteraction in **AL**cohol-related hepatocellular carcinoma

A project that will use AI models to integrate genetic and non-genetic information, including digital imaging, to develop novel cost-effective strategies towards prevention and early-stage detection of ALD-HCC

AIM:

- **To portray genetic and environmental determinants promoting ALD-HCC;**
- **To evaluate how they interact at cellular level in human samples and preclinical models to get novel insights into liver carcinogenesis and identify chemopreventive targets; and**
- **To assess how they modulate the risk of ALD-HCC in several retrospective and prospective cohorts of patients included in HCC surveillance programs.**

The GENIAL Project is funded by the European Union within the Horizon Europe programme under grant agreement No 101096312.

MICROB-PREDICT will investigate the human microbiome to identify predictors and mechanisms associated with the development of decompensation of cirrhosis and progression to acute-on-chronic liver failure (ACLF) and death.

- → New microbiome-based tests for better stratification of cirrhosis patients
- → Personalized prediction and prevention of decompensation and ACLF
- → Clinical trial to predict response to treatment
- → Modern, effective nanobiosensors as clinical tools with improved specificity
- → More personalized treatment
- → Increased survival times
- → Decreased costs for the health systems

GS-001

Primary results from MAESTRO-NASH a pivotal phase 3 52-week serial liver biopsy study in 966 patients with NASH and fibrosis

Stephen Harrison[1], Pierre Bedossa[2], Cynthia Guy[3], Jörn Schattenberg[4,5,6], Rohit Loomba[7], Rebecca Taub[8], Dominic Labriola[8], Sam Moussa[9], Guy Neff[10], Arun Sanyal[11], Mazen Noureddin[12], Meena Bansal[13], Naim Alkhouri[14], Vlad Ratziu[15]. *[1]Pinnacle Research, United States; [2]LiverPat, France; [3]Duke University, United States; [4]Mainz University, Germany; [5]Metabolic Liver Research Program, I. Department of Medicine, University Medical Center Mainz, Mainz, Germany; [6]Department of Internal Medicine I, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, Germany; [7]UCSD, United States; [8]Madrigal Pharmaceuticals, United States; [9]Adobe Research, United States; [10]Covenant Research, United States; [11]VCU, United States; [12]CSHS, United States; [13]Mount Sinai, United States; [14]AZ Liver, United States; [15]Inserm, France*
Email: rebeccataub@yahoo.com

Background and aims: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, Phase 3, registrational double blind, placebo-controlled NASH clinical trial to study the effect of once daily 80 mg or 100 mg resmetirom as compared with placebo in patients with NASH and liver fibrosis. Eligibility required: presence of ≥3 metabolic risk factors, FibroScan VCTE ≥8.5 kPa, baseline MRI-PDFF ≥8% and biopsy-proven NASH with fibrosis stage 1B, 2, or 3 and NAFLD activity score (NAS) ≥4 with at least 1 in each NAS component. An analysis of the Week 52 primary end points of MAESTRO-NASH were conducted and presented here. Week 52 dual primary end points included resolution of NASH (ballooning 0, inflammation 0, 1 with at least a 2-pt reduction in NAS) with no worsening of fibrosis OR ≥1 stage reduction in fibrosis with no worsening of NAS. The key secondary end point was % reduction in LDL-C at Week 24.
Method: 966 patients were enrolled at ~200 global sites. Liver biopsies were read by two central pathologists using glass slides (primary analysis) with results combined using a statistical algorithm to generate a single treatment effect; if readers disagreed on the response for either primary end point, a supportive consensus read using digitized images was conducted. The mITT population excluded 11 patients with liver biopsies after Week 60 due to COVID site issues.
Results: Baseline characteristics included age 57 (11) (mean (SD)), female 56%, white 90%, BMI 36 (7), type 2 diabetes 67%, hypertension 78%, dyslipidemia 71%, FibroScan VCTE 13 kPa (7), CAP 348 (38), MRI-PDFF 18 (7)% fat fraction, baseline liver biopsy NAS ≥5 84%, baseline fibrosis stage: F3-62%, F2-33%, F1B-5%. Both primary histologic end points and the key secondary end point (LDL cholesterol lowering) were met at both doses (table); consensus review confirmed results. Similar results for both end points were obtained by both central pathologists, and results were independent of diabetes status or baseline fibrosis stage. Multiple other liver biopsy end points were met including NASH resolution and fibrosis reduction (combined) and a 2-stage reduction in fibrosis. Biomarker end points including reduction in ALT, AST and GGT, ELF, MRI-PDFF, CAP and FibroScan VCTE were met. Resmetirom appeared generally safe and well-tolerated with similar numbers of SAEs across groups and an increase in the incidence of diarrhea and nausea in resmetirom treatment groups only at the beginning of therapy.

Figure.

End points	Resmetirom 80 mg (n = 316)	p value	Resmetirom 100 mg (n = 321)	p value	Placebo (n = 318)
Primary End points (Dual)					
NASH resolution (ballooning 0, inflammation 0, 1) with ≥2-point reduction in NAS and no worsening of fibrosis	26%	<0.0001	30%	<0.0001	10%
≥1-stage improvement in fibrosis with no worsening of NAS	24%	0.0002	26%	<0.0001	14%
Key Secondary End point					
LDL-C lowering (24 weeks)	−12%	<0.0001	−16%	<0.0001	1%

Conclusion: NASH resolution and fibrosis reduction end points on liver biopsy were achieved at both resmetirom doses in a large Phase 3 pivotal clinical trial. Resmetirom appeared safe and was generally well-tolerated. These data support the potential for resmetirom treatment to provide benefit to patients with NASH and liver fibrosis.

GS-002-YI

Myeloid IL-8 enrichment associates with immunotherapy resistance in advanced hepatocellular carcinoma

Tsz Tung Kwong[1], Zhewen Xiong[2], Yiling Zhang[2], Patrick Pak-Chun Wong[2], Jingying Zhou[2], Alfred Sze-Lok Cheng[2], Stephen Chan[1]. *[1]The Chinese University of Hong Kong, Department of Clinical Oncology, Hong Kong; [2]The Chinese University of Hong Kong, School of Biomedical Sciences, Hong Kong*
Email: tsztungkwong@cuhk.edu.hk

Background and aims: Despite the therapeutic options with immunotherapy have been emerging in advanced hepatocellular carcinoma (HCC), durable response is confined to a small fraction of patients. Thereby, ineffectiveness of immune checkpoint blockade (ICB) and resistance acquisition caused by the immunosuppressive drivers including inflammatory cytokines and myeloid cells within the liver tumor microenvironment (TME) had to be tackled urgently. In this study, we analyzed the immune contexture of advanced HCC patients before and after pembrolizumab treatment to investigate the role of myeloid IL-8 in ICB-resistance mechanism and aim to intervene the IL-8 pathway through inhibition of its receptor by a clinical in-use CXCR2 antagonist.

ELSEVIER

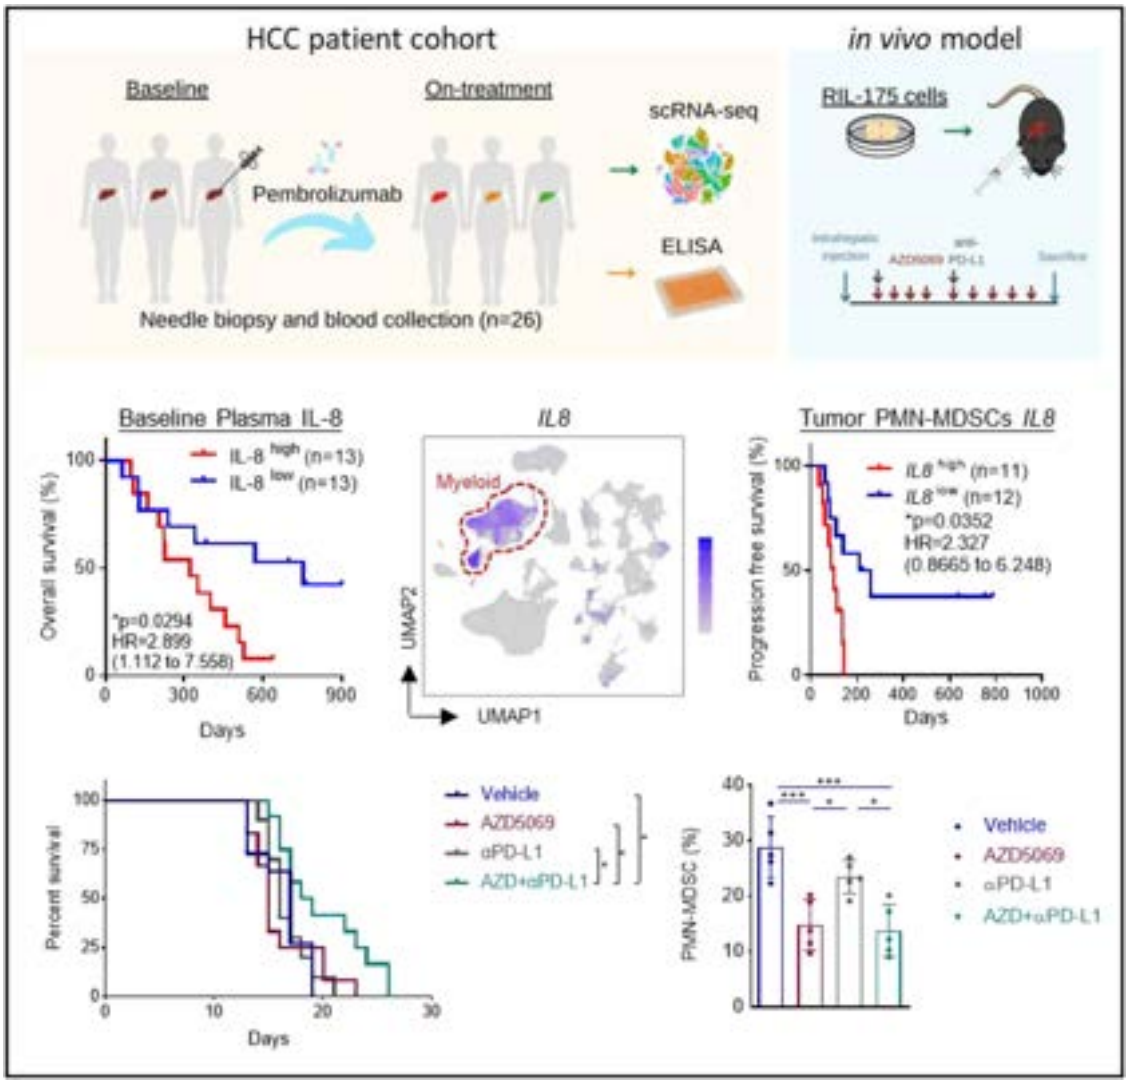

Figure: (abstract: 002).

Method: Patients with advanced HCC (n = 26) were enrolled prior to pembrolizumab therapy with their baseline and on-treatment biopsies collected to perform single cell RNA transcriptomic analysis. Simultaneously, circulating IL-8 level was quantified in the paired peripheral blood samples. Therapeutic efficacy of CXCR2 pathway inhibition by AZD5069 in potentiating ICB response was evaluated in our ICB-resistant orthotopic mouse model which is generated by serial *in vivo* passaging of anti-PD-L1 residual tumor. Profiling of immune landscape in the TME were assessed by high-parameter flow cytometry.

Results: In our advanced HCC cohort with anti-PD-1 treatment, patients with higher baseline plasma IL-8 had worse overall survival compared to those with lower IL-8 level (hazard ratio (HR), 2.899, 95% confidence interval (CI), 1.112–7.558; p = 0.0294). Single cell RNA sequencing further revealed that IL-8 was originated from myeloid cell cluster in tissue biopsies. In particular, the upregulated expression of *IL8* on polymorphonucler myeloid-derived suppressor cells (PMN-MDSCs) were strongly linked with poorer progressive free survival (HR, 2.327; 95% CI, 0.867–6.248; p = 0.0352). Inhibition of the IL-8 receptor with a CXCR2 antagonist (AZD5069) improved the survival benefit of anti-PD-L1 treatment in our ICB-resistant orthotopic pre-clinical HCC model. Mechanistically, the suppression of CXCR2 signaling hindered the MDSC recruitment to tumor site, in turn reverted the immunosuppression in the TME which favors ICB treatment.

Conclusion: We demonstrated the importance of myeloid IL-8/CXCR2 pathway in ICB-resistance from our advanced HCC cohort which paved way for IL-8 to become a novel prognostic target for immunotherapy. Blocking CXCR2 could reduce MDSC trafficking and overcome ICB-resistance in our pre-clinical HCC model, suggesting a promising combination regimen in future development. This work is supported by the Collaborative Research Fund C4045-18W.

GS-003

Rivaroxaban improves survival and decompensation in cirrhotic patients with moderate liver dysfunction. Double-blind, placebo-controlled trial

Email: angelapuente@hotmail.com

Background and aims: Observational studies and a non-double-blind non-placebo randomized study suggested that anticoagulation decreases the probability of developing portal hypertension (PHT) complications and improves survival in cirrhotic patients. However, anticoagulation is not routinely used in these patients showing that stronger evidence is required. Our study aimed to evaluate the efficacy/safety of the direct anticoagulant Rivaroxaban (Rban) in patients with cirrhosis.

Method: Randomized, double-blind, placebo-controlled multicenter trial (EudraCT: 2014-005523-27) in cirrhotic patients with PHT and moderate liver dysfunction (Child-Pugh:7–10) of Rban 10 mg/24 hours vs. placebo for 24 months. Primary composite end point: development of a PHT complication (grade>II ascites, grade>II encephalopathy, or PHT related bleeding) or death/transplantation whatever occurred first. An intention-to-treat (mITT) and per-protocol (PP) analysis was performed.

Results: 90 patients were included (Age: 58.1 ± 7.6 years; 82.2% male; Child-Pugh:7.4 ± 0.8; MELD:12.4 ± 2.5; 86.7% alcoholic cirrhosis), median follow-up: 10.1 (0.4–24) months. 49 received placebo (P) and 41 Rban. In the mITT analysis, 34 patients developed the primary end point, 23 (46.9%) in the P vs 11 (26.8%) in the Rban group, with an actuarial cumulative probability of primary end point at 1 and 2 years of 40.1% and 60.9% in P vs 21.6 and 33.2% in Rban (Log-rank; p = 0.069). This difference reached statistical significance (HR = 0.466 [95% CI 0.222–0.980] p = 0.044) when adjusted by Child-Pugh. This beneficial effect of Rban was especially relevant in the subgroup of Child-Pugh B7 (n = 66) (HR: 0.292 [95% CI 0.098–0.870] p = 0.017). The main benefit relies in the prevention of ascites (Log-rank; p = 0.056). Twelve patients had a protocol deviation due to therapeutic non-compliance. In the PP analysis (41 P and 37 Rban), the main event was reached in 19 P (38.7%) vs. 9 (21.9%) in the Rban group (Log-rank; p = 0.05). Figure.

Thirty-one non-PHT bleeding events were registered in twenty four patients (26.6%) [placebo (n = 10) vs Rban (n = 22), OR 3.34 (95% CI 1.36–7.74) p = 0.008]. However, no differences were observed in major bleeding events: P (n = 2) vs Rban (n = 6): OR 4.02. (95% CI 0.767–21.167, p = NS)]. One death associated with major bleeding (hemoperitoneum) was recorded in the P group.

Conclusion: In cirrhotic patients with moderate liver dysfunction, rivaroxaban improves PHT complication-free survival without significantly increasing major bleeding events.

GS-004-YI

Vulnerable offspring: a nationwide Danish cohort study of adverse health outcomes in offspring of parents with alcohol-related liver disease compared to controls

Peter Jepsen[1], Joe West[2,3], Frederik Kraglund[1], Colin Crooks[2], Anna Emilie Kann[4], Joanne Morling[2], Gro Askgaard[1]. [1]*Aarhus Universitetshospital, Aarhus, Denmark;* [2]*University of Nottingham, United Kingdom;* [3]*Nottingham University Hospitals NHS Trust and the University of Nottingham, NIHR Nottingham Biomedical Research Centre (BRC), United Kingdom;* [4]*Zealand University Hospital, Køge, Denmark*
Email: gask@dadlnet.dk

Background and aims: Offspring of parents with alcohol-related liver disease (ALD) likely grow up in families with significant exposure and access to alcohol and may themselves be vulnerable to adverse health outcomes. We compared the risk of adverse health outcomes in such offspring to that of controls.

Method: We used nationwide healthcare registries to identify offspring of parents diagnosed with ALD (ICD-10: K70.x) in Denmark 1996–2018 and age- and gender-matched controls (20:1). We compared the incidence rates of: diagnosis of ALD, any alcohol-related hospital contacts, emergency room visits for fractures or injury, hospital contacts for intentional or accidental poisoning, and

Figure 1. Incidence rate ratios of alcohol-related outcomes in offspring of individuals with ALD (n = 60,708) compared to age-and sex matched controls (n = 1,213,380), overall and stratified by gender and ALD parent´s educational level. Outcomes are: Alcohol-related liver disease (black), any alcohol-related hospital contact (red), fracture or injury (green), intentional or accidental poisoning (blue) and death (purple).

The figure shows that the risk of alcohol-related hospital contacts is higher in offspring of individuals with ALD of primary [incidence rate ratio, 2.63 (95%CI: 2.58-2.68)] than of higher educational level [incidence rate ratio, 1.60 (95%CI: 2.58-2.68)] compared to controls.

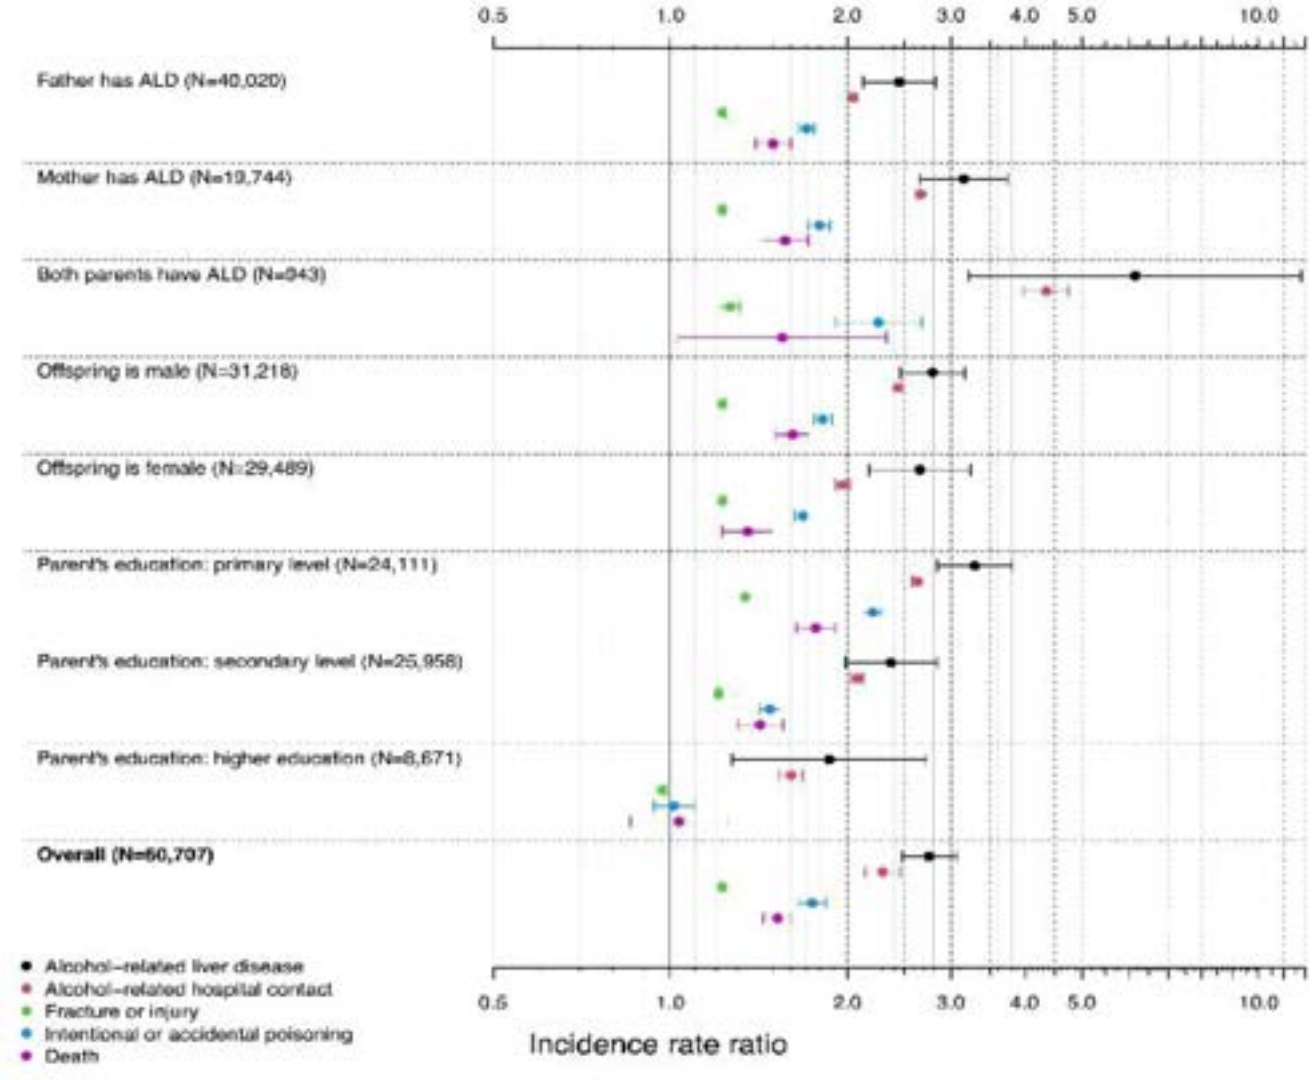

Figure: (abstract: 004).

all-cause death in offspring of parents with ALD with that of the matched controls, overall and within subgroups. We used a self-controlled case series design to examine whether hospitalization for poisoning was more likely to occur during the first year after the parent's ALD diagnosis vs. at any other time among offspring aged 13–25 years.

Results: There were 60,708 offspring of parents with ALD and 1,213,380 matched controls. Offspring had a median age of 31 years (IQR 23–39) when their parent was diagnosed with ALD; 51% were male. Offspring had a higher incidence rate of ALD, any alcohol-related hospital contacts, fractures or injury, poisoning, and all-cause death compared to controls (Figure 1). Offspring whose ALD parent had only primary education experienced higher risks compared to controls, than offspring whose parents had a higher education [incidence rate ratios (IRR) for an alcohol-related hospital contact compared to controls were 2.63 (95%CI: 2.58–2.68) vs 1.60 (95%CI: 1.53–1.68) respectively]. Offspring aged 13–25 years were most likely to have their first admission for poisoning in the first year after their parent's ALD diagnosis than at any other time (IRR = 1.25, 95% CI: 1.01–1.55), suggesting that the event of the parent´s diagnosis of ALD might cause the offspring to self-harm.

Conclusion: Offspring of parents with ALD have a higher risk of adverse health outcomes; only the minority with well-educated parents are partially protected from those consequences. The first year after a parent's ALD diagnosis is a particularly vulnerable time for the offspring of a young age with respect to hospitalization with poisoning.

GS-005

Selective activation of the IL-2 pathway in CD8+ T cells drives antiviral activity to Hepatitis B Virus (HBV)

Francesco Andreata[1], Kelly Moynihan[2], Pietro Di Lucia[1], Danielle Peppas[2], Irene Ni[2], Henri Nguyen[2], Chiara Perucchini[1], Mike Chin[2], Elisa Bono[1], Leonardo Giustini[1], Paul Bessette[2], Andy Yeung[2], Craig Gibbs[2], Ivana Djuretic[2], Matteo Iannacone[1]. *[1]San Raffaele Scientific Institute, Division of Immunology, Transplantation and Infectious Diseases, Milan, Italy; [2]Asher Biotherapeutics, San Francisco, United States*
Email: iannacone.matteo@hsr.it

Background and aims: CD8+ T cells are critical for mediating anti-viral activity against Hepatitis B virus (HBV); however, CD8+ T cell responses against HBV antigens may be deficient in chronically infected HBV patients.[1–3] In murine HBV models that recapitulate key features of HBV-induced CD8+ T cell dysfunction, IL-2-based therapy (but not PD-1 checkpoint blockade) successfully rescued CD8+ T cell function and anti-viral immunity[4], suggesting that the IL-2 pathway may be a promising approach to reinvigorate CD8+ T cell immunity. Unfortunately, IL-2-based therapeutics are limited by pleiotropy, as IL-2 receptors are expressed broadly on many cell types, including regulatory T cells (Tregs) and natural killer (NK) cells, which may oppose anti-viral responses or contribute to toxicity, respectively. We developed a cis-targeted IL-2 fusion protein called AB359 that selectively acts on CD8+ T cells in order to evaluate its potential for the treatment of chronic HBV.

Method: AB359 was generated by fusing an attenuated IL-2 mutein to an anti-CD8 antibody, and activity was characterized on human cells. Cynomolgus monkeys were dosed with AB359 and peripheral blood pharmacodynamics were assessed by flow cytometry. AB359's murine surrogate, muAB359, was tested in a murine HBV model5.

Results: In a murine HBV model[5], muAB359 significantly increased the number of HBV-reactive CD8+ T cells in the liver without substantial changes to NK and Treg numbers. The expanded HBV-specific CD8+ T cells following muAB359 treatment showed enhanced expression of IFNγ and granzyme B relative to controls. Therapy with muAB359 resulted in strong anti-HBV activity: a single dose of muAB359 demonstrated over 100-fold reduction in serum HBV core DNA and a 79% decrease in serum Hepatitis B surface antigen (HBsAg) levels. In contrast, an untargeted not-α IL-2 (CTRL-IL2) demonstrated preferential expansion of IL-2Rβγ^{high} NK cells, modest CD8+ T cell expansion, and minimal changes to IFNγ and granzyme B expression by HBV-reactive CD8+ T cells following therapy. As a result, less robust viral control was observed with CTRL-IL2; a 9.5-fold reduction in HBV core DNA and a 37% decrease in HBsAg were observed. In cynomolgus monkeys, AB359 induced the selective expansion of peripheral blood CD8+ T cells by approximately 20-fold without substantial changes to NK and Treg numbers.

Conclusion: Selectively providing an IL-2 signal to CD8+ T cells via cis-targeting shows considerable anti-viral activity in a preclinical model of HBV, with superior performance to an untargeted IL-2. These data support the development of AB359 as a therapy for the treatment of chronic HBV.

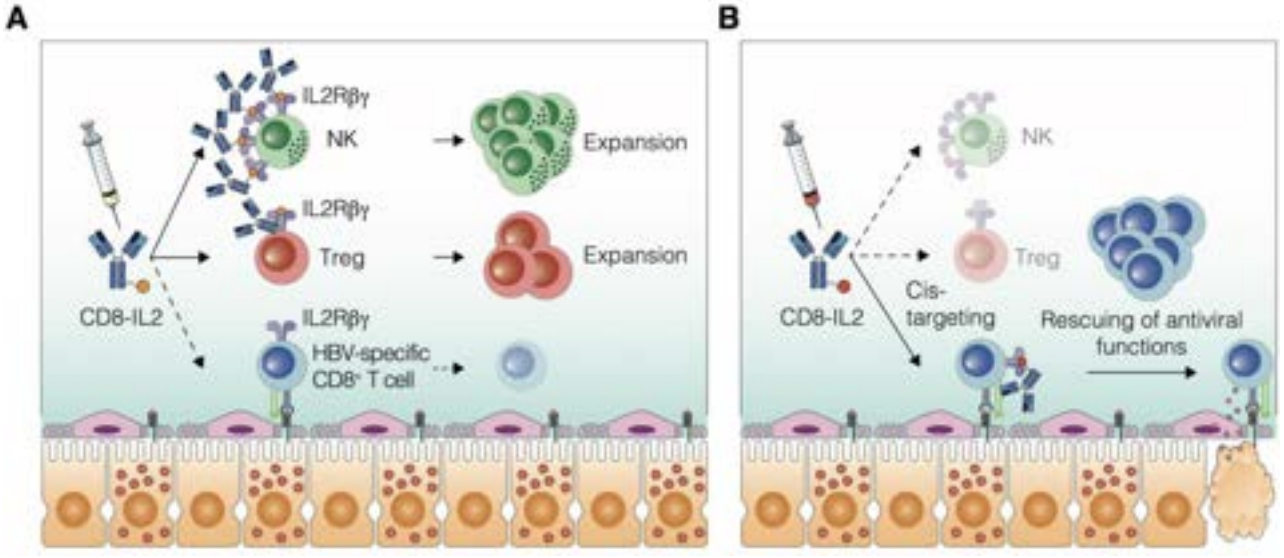

Figure: (abstract: 005): "Cis-targeting of IL-2 to CD8$^+$ T cells avoids the pleiotropy associated with untargeted IL-2 therapy and drives potent anti-HBV immunity"

GS-006

Randomised controlled trial of ceftriaxone versus no antibiotic to prevent infection in patients with Child-Pugh A cirrhosis with acute variceal bleeding

Anany Gupta[1,1], Samagra Agarwal[1], Sanchit Sharma[2], Deepak Gunjan[3], Srikanth Gopi[3], Jamshed Nayer[4], Anoop Saraya[1]. Email: ansaraya@yahoo.com

Background and aims: Administering antibiotics reduce the risk of bacterial infections and improve survival in advanced decompensated cirrhosis presenting with acute variceal bleeding. However, their role in patients with Child-Pugh A cirrhosis with variceal bleed is not clearly defined. We studied the impact of antibiotic prophylaxis on outcomes in patients with Child-A cirrhosis.
Method: We conducted a single centre open label randomised controlled trial with a non-inferiority study design. Eligible patients of Child-A cirrhosis with suspected variceal bleeding were randomly assignedat presentation to receive either 5-day course of intravenous Ceftriaxone (active control) or no antibiotic (test regimen). Patients were otherwise managed as per Baveno-VI recommendations for variceal bleeding. The primary outcome was incidence of infection at day-5 in both arms. Secondary outcomes were incidence of early rebleeding and mortality at day-5, new onset decompensation at 6 weeks and 6-week mortality in both arms.
Results: One hundred eighty patients of Child-A cirrhosis with variceal bleeding (Mean age 45.1+–13.1 years, 76.9%males) of

	Overall N=180	Ceftriaxone N=90	No antibiotic N=90	P value

Figure: (abstract: 006).

predominant non-viral aetiology (alcohol 43.4%; NAFLD 21.7%) were randomised. Baseline characteristics including MELD score were comparable between two arms. The incidence of 5-day infection in Ceftriaxone arm and no antibiotic arm was 7% (95%CI: 2.8–15.1%) and 12% (6.02–20.8%)respectively (p = 0.397; non-inferiority margin met). Spontaneous bacterial peritonitis following early decompensation was the most common site of infection in both groups (10/16; 66.7%). The incidence of rebleeding at day-5 (4.9 vs 0; p = 0.117), in hospital mortality (2.5% vs 0%; p = 0.456), new onset decompensation at 6-weeks (16.0% vs 11.8%; p = 0.566) and 6-week mortality (2.5% vs 1.4%; p = 0.93) were comparable across both the arms although non-inferiority could not be established.

Conclusion: Among patients with Child-A cirrhosis with acute variceal bleeding, the incidence of post-bleed infectionsand other outcomes in those receiving no antibiotics was comparable to those receiving ceftriaxone (CTRI/2021/06/033939).

Email: lindsey.edwards@kcl.ac.uk

Background and aims: Patients with cirrhosis have reduced gut bacterial diversity, and a gut microbiome over-represented by pathobionts. This, coupled with gut barrier damage and bacterial translocation, increases susceptibility to infection and death. Bacterial translocation is a significant driver of cirrhosis-associated immune dysfunction which increases the susceptibility to developing infection. Faecal microbiota transplant [FMT] has been shown to restore gut diversity and improve hepatic encephalopathy (HE) in 10 patients with cirrhosis. We hypothesised that modifying the gut microbiota with FMT may alter intestinal barrier function, mucosal immunity and microbial ammonia metabolism in patients with cirrhosis.

Method: We performed a placebo-controlled randomised single-blinded feasibility trial of FMT transplanted in 32 patients with advanced cirrhosis (MELD score 10–16) [NCT02862249]. 50 grams of liquid frozen FMT *versus* placebo [allocated in a 3:1 ratio] was administered into the jejunum *via* endoscopy. To assess efficacy in modulating the patient's own microbiome and inflammatory status: blood and stool were collected at baseline and day 7, 30 and 90 post-FMT/placebo. Cytokine production, markers of barrier integrity (electrochemiluminescence/ELISA), global metabolite profile (^{1}H-NMR) and faecal proteomics (LC-MS/MS) were assessed.

Results: Deep metagenomic sequencing confirmed FMT increased recipient species richness with significant donor engraftment. FMT significantly reduced stool carriage of *E. faecalis* and other pathobionts. FMT reduced biomarkers of inflammation and increased markers associated with gut barrier repair. FMT led to a reduction at 30-days in plasma ammonia (p = 0.0006). Faecal ammonia was higher in the FMT group *versus* placebo at days 30 (p = 0.011) and 90 (p = 0.025). Faecal proteomics quantified 301 proteins, 154 proteins found were of human origin and 147 were of bacterial origin. Many of these proteins were found to be both human and microbial enzymes. In converse to the enzymes found reduced in blood, increases in the abundance of microbial enzymes involved in denitrification and ammonification were observed in the stool [enzyme EC.4.3.1.1 (aspartate ammonia-lyase), with 17 high-confident peptides, was enhanced in patients administered FMT *versus* placebo (p = 0.031)]. Enzymes required for nitrogen assimilation and excretion *via* the urea cycle were enhanced, with enhanced secretion of urinary hippurate (*p = 0.0299*) at day 30 in FMT *versus* placebo.

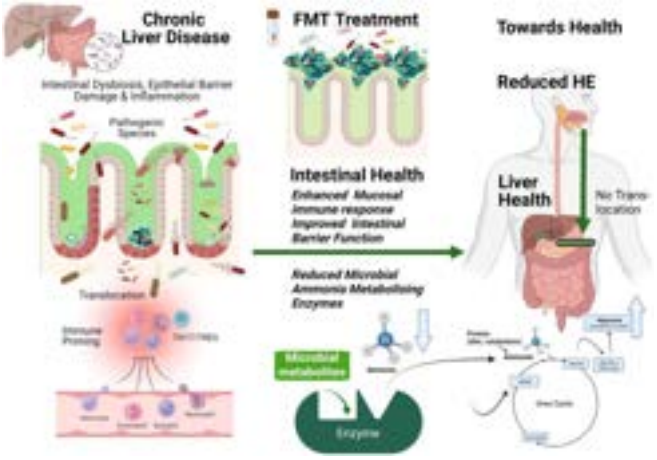

Figure:

Conclusion: These data support FMT as playing an important role in enteric pathogen reduction, altering the gut-microbiota to promote inflammatory restoration of the gut barrier. FMT reduced microbial-associated ammonia production in the blood and upregulated ammonia excretion in stool and augmenting the anaerobic metabolism of L-aspartate providing proof of concept that FMT augments ammonia metabolism, central in the pathogenesis of HE.

GS-008-YI

Naltrexone is safe and effective in achieving abstinence and reducing alcohol craving in cirrhotic patients: a double blind randomized placebo controlled trial

Manasa Alla[1], S Muralikrishna Shasthry[1], Mohit Varshney[1], Vinod Arora[1], Shiv Kumar Sarin[1]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India*
Email: shivsarin@gmail.com

Background and aims: Continued alcohol use is the single important driver of long term outcomes in alcohol associated liver diseases. But there are no FDA approved drugs for alcohol use disorder (AUD) that have been approved in patients with liver cirrhosis. Considering the importance of maintaining abstinence and the positive effect on survival in patients with alcohol liver disease, this study assumes importance in establishing safety and efficacy of naltrexone in patients with alcohol related liver disease.

Method: This is a single centre double blind placebo controlled randomized trial conducted in ILBS hospital (April 2020–July 2022) in patients with compensated cirrhosis with AUD. 147 patients were screened and 100 consecutive patients with compensated cirrhosis fulfilling the DSM -5 criteria for AUD as per inclusion and exclusion criteria of the study were enrolled and randomized between Naltrexone or placebo, given for 12 weeks. The primary objective was proportion of patients achieving and maintaining alcohol abstinence at 12 weeks and secondary obectives were proportion of patients maintaining abstinence at 6 months and 12 months, adverse effects, lapses and relapses at 3, 6 and 12 months. Behavioural therapy and counselling was offered to both the groups.

Results: Baseline demographics, clinical characteristics, AUDIT and OCDS scores were comparable between the groups. Significantly higher number of patients i.e., 32/50 (64%) achieved abstinence with Naltrexone compared to placebo at 12 weeks {11/50 (22%)}, P < 0.001}. Similarly maintenance of abstinence after 6 months of follow-up was higher with Naltrexone {22% vs. 8%, P = 0.09}. Number of lapses at 12 weeks {14/50 (28%) vs. 27/50 (54%), P = 0.01} were significantly lower in Naltrexone group. Relapses were higher with the placebo {14/50 (28%) vs. 6/50 (12%), P = 0.07}. Mean craving scores were significantly lower with Naltrexone by 12 weeks- OCDS-O score (6.63 ± 1.16 vs 9.29 ± 1.78, P < 0.01) and OCDS-C score (6.35 ± 1.23 vs 9.02 ± 1.86, P < 0.01). Significant difference in visual analog scale for craving was also noted between the groups in comparison of means values (4.27 ± 1.301 vs 6.51 ± 1.27, P < 0.01). Adverse events were comparable in both the groups and none required discontinuation of drug. Mild abdominal discomfort was the most common adverse effect noted in 5/50 (10%) patients in Naltrexone group vs. 3/50 (6%) in placebo, P = 0.71. 2/50 (4%) patients in naltrexone group developed jaundice with bilirubin values >3 mg/dl, likely due to continued alcohol consumption and as a part of disease progression.

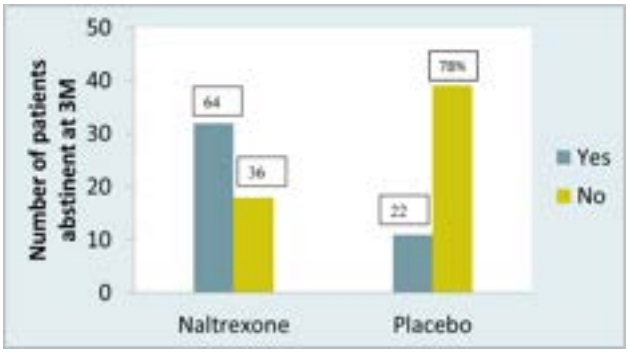

Figure:

Conclusion: Naltrexone can be safely administered for AUD in patients with compensated cirrhosis and is effective in achieving abstinence and as well as decreasing the craving scores at 3 months.

GS-009

Endoscopy sleeve gastroplasty is an effective treatment in steatohepatitis patients: a prospective, multicenter, randomized trial

Javier Abad Guerra[1], Elba Llop[1], María Teresa Arias Loste[2], Diego Burgos Santamaria[3], José Luis Martínez Porras[1], Javier Graus[3], Paula Iruzubieta[2], Belén Ruiz Antoran[1], Manuel Romero Gomez[4], Agustin Albillos[3], Javier Crespo[2], José Luis Calleja Panero[1]. *[1]Puerta de Hierro Hospital, Spain; [2]Marques de Valdecilla Hospital, Spain; [3]Ramon y Cajal Hospital, Spain; [4]Virgen del Rocio Hospital, Spain*
Email: javiabad83@gmail.com

Background and aims: Non-alcoholic steatohepatitis (NASH) affect over 5% of the population, and patients are at risk of progressing to cirrhosis. Life-style intervention with diet and exercise achieving a weight loss >10% promotes NASH resolution, but this goal is only achieved by <25% of the patients. Endoscopic sleeve gastroplasty (ESG) with Overstitch® system has recently emerged as a safe and effective option to promote weight loss in patients with obesity. We report the results of a multicenter, randomized, controlled and double-blind study to evaluate the efficacy and safety of ESG in NASH patients.

Method: 40 patients were 1:1 randomized to ESG with OverStitch® (Apollo Endosurgery) plus lifestyle modification vs. endoscopic simulated intervention (ESI) with upper endoscopy plus lifestyle modification. Inclusion criteria included biopsy proven NASH with NAS ≥ 3 and fibrosis stage from F1 to F3. 18 patients from the ESG group and 19 from the ESI group completed follow-up. (72 weeks). We evaluated changes from baseline to end of follow-up in body weight, liver function tests, liver stiffness by Fibroscan® and liver histology.

Results: (mean ± SD) Both groups had similar clinical characteristics at baseline. 55% of the patients were men, with a median age of 56.5 years (23–69). The mean BMI was 37.85. Half of patients had type 2 diabetes. Total body weight loss (TBWL) was 9.47% (± 9.38) in ESG group vs 3.91% (± 5.43) in ESI group (p < 0.05). Only patients in the ESG group achieved more than 15% of their body weight (22.2%). Liver stiffness decreased 5.63 (± 7.17) KPa in ESG group vs 0.2 (± 5.38) KPa in ESI group (p < 0.05). Steatosis was significantly reduced in ESG group (−0.94 ± 0.87) vs ESI group (−0.26 ± 0.99). NAS score, but not fibrosis stage, was reduced in patients achieving weight loss >10% (−4 ± 0.94 vs. −0.81 ± 1.62, p < 0.01). Only 2 patients of the ESG group had adverse events that required admission (perigastric hematoma and perigastric collection), that resolved conservatively in 72 hours.

Table 1:

WEIGHT CHANGES (n)	ESI (19)	ESG (18)	p
N° patients weight lost% (SD)	11 (57.9)	17 (94.4)	0.010
TBWL% (SD)	−3.91 (5.43)	−9.47 (9.38)	0.025
LIVER STIFFNESS CHANGES (n)	ESI (18)	ESG (16)	p
LS KPa (SD)	−0.2 (5.38)	−5.63 (7.17)	0.017
HISTOLOGICAL CHANGES (n)	ESI (19)	ESG (18)	p
NAS score (SD)	−1.47 (2.01)	−1.89 (2.11)	0.544
Steatosis (SD)	−0.26 (0.99)	−0.94 (0.87)	0.033
Lobulillar inflammation (SD)	−0.53 (0.84)	−0.44 (0.86)	0.771
Ballooning (SD)	−0.68 (0.75)	−0.50 (0.86)	0.490
HISTOLOGICAL BY WEIGHT CHANGES (n)	No weight loss (9)	Weight loss (28)	p
NAS score (SD)	−0.22 (1.48)	−2.14 (2)	0.012
HISTOLOGICAL BY WEIGHT CHANGES (n)	Weight loss<10% (27)	Weight loss>10% (10)	p
NAS score (SD)	−0.81 (1.62)	−4 (0.94)	<0.001
Steatosis (SD)	−0.22 (0.75)	−1.60 (0.84)	<0.001
Lobulillar inflammation (SD)	−0.26 (0.86)	−1.10 (0.32)	0.005
Ballooning (SD)	−0.33 (0.68)	−1.30 (0.67)	<0.001
Fibrosis (SD)	−0.48 (1.22)	−0.30 (0.95)	0.674

Conclusion: ESG is an effective and safe method to promote weight reduction associated with significant improvement in liver stiffness and histological parameters in patients with NASH and obesity that achieve a significant weight loss. ESG could be an option in the management of obese patients with NASH failing to lose weight by life-style intervention.

GS-010

An integrative multi-omic approach defines therapeutic pathways associated with altered cell state and chromatin organisation in human liver fibrosis

Elliot Jokl[1], Aoibheann Mullan[1], Varinder Athwal[1], Kara Simpson[1], Nigel Hammond[2], Sokratia Georgaka[2], Syed Murtuza-Baker[2], Oliver Street[2], Neil Hanley[1], Karen Piper Hanley[1]. *[1]The University of Manchester, Division of Diabetes, Endocrinology and Gastroenterology, Manchester, United Kingdom; [2]The University of Manchester, United Kingdom*

Email: karen.piperhanley@manchester.ac.uk

Background and aims: Liver fibrosis is characterised by the deposition of pathological extracellular matrix from myofibroblasts, leading to progressive scarring and loss of organ function. As a progressive step in most chronic liver diseases, fibrosis is almost always diagnosed too late with limited treatment options. There is a massive unmet clinical need to halt tissue damaging fibrosis. In this study we have utilised a multi-omic integrative approach to define a novel targetable pathway driving profibrotic myofibroblasts.

Method: In human liver cirrhosis, we carried out single cell RNA and Assay for Transposase-Accessible Chromatin (ATAC) sequencing to deconvolute our multi-cell spatial transcriptomic (ST) using the Visium platform. Molecular mechanisms were validated in vitro and in vivo through genetic manipulation of the actin cytoskeleton and modelling in fibrosis.

Results: Through an integrative approach using RNA, ATAC and ST sequencing we defined molecular signatures associated with human liver myofibroblasts. Computational approaches identified altered cell state driven by nuclear lamina proteins in scar associated myofibroblasts (Figure). In cell biology, the nuclear lamina provides nuclear elasticity and chromatin organisation. Through in vitro and in vivo interrogation, we investigated how physical tension from increasing scar alters spatial organisation of the genome and transcription in liver fibrosis. We uncovered that when myofibroblasts encounter a stiffer environment (e.g. due to fibrosis) the nuclear response is to soften. Significantly, this is in parallel to a radical shift in cytoskeletal cell shape and pro-fibrotic gene expression. Through uncoupling the actin cytoskeleton by *Pak1*-loss (P21-activated kinase 1 associated with actomyosin signalling) we highlight a functional mechanoresponse of myofibroblasts driven by nuclear deformation and H3K9me3-mediated chromatin remodelling. These findings are consistent with a profound switch in profibrotic gene expression and one that further permits their migratory, contractile phenotype. By integrating chromatin accessibility profiles (ATAC and RNA sequencing) we provide insight into the transcription network and open chromatin landscape underlying the switch in profibrotic myofibroblast states, emphasizing mechanoadaptive pathways linked to PAK1 as key drivers. In addition, we demonstrated increased chromatin accessibility parallels loss of heterochromatin H3K9me3 marks in profibrotic myofibroblasts. The correlation with enhanced nuclear adaptation, measured by atomic force microscopy (AFM), and pro-fibrotic gene expression as myofibroblasts switch to an activated pro-fibrotic phenotype supports the idea that H3K9me3 compacts chromatin structure and restricts gene expression programmes.

Figure: Spatial trancriptomics and data integration of human cirrhotic liver. Human cirrhotic liver. Sections were stained for HandE for visual landmarks and localisation of Visium spots defined by spatially-significant gene clusters. Gene expression of lamin A (LMNA) located in the tissue section representing scar associated myofibroblast spatial clusters.

Conclusion: This study provides insight into the chromatin landscape and nuclear mechanics driving pro-fibrotic myofibroblasts and highlights actomyosin-dependent mechanisms linked to chromatin state as urgently needed therapeutic targets in liver disease.

GS-011

IMbrave050: Efficacy, safety and patient-reported outcomes (PROs) for adjuvant atezolizumab (atezo) + bevacizumab (bev) vs active surveillance in hepatocellular carcinoma (HCC) patients at high risk of disease recurrence after resection or ablation

Ahmed Kaseb[1], Minshan Chen[2], Pierce Chow[3], Masatoshi Kudo[4], Han Chu Lee[5], Adam Yopp[6], Lars Becker[7], Sairy Hernandez[8], Bruno Kovic[9], Qinshu Lian[8], Ning Ma[8], Chun Wu[10], Shukui Qin[11], Ann-Lii Cheng[12]. *[1]MD Anderson Cancer Center, Houston, TX, United States; [2]Sun Yat-sen University Cancer Center, Guangdong Province, China, China; [3]National Cancer Centre Singapore, Singapore and Duke-NUS Medical School Singapore, Singapore, Singapore; [4]Kindai University, Osaka, Japan, Japan; [5]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, Korea, Dem. Background and aims: In IMbrave050, adjuvant atezo + bev demonstrated a statistically significant and clinically meaningful improvement in recurrence-free survival (RFS) vs active surveillance in patients (pts) at high risk of HCC recurrence following resection or ablation with curative intent. Further, the safety of atezo + bev was generally manageable. Here, we additionally report PRO data from IMbrave050.

Method: IMbrave050 (NCT04102098) enrolled pts HCC pts at high risk of recurrence following resection or ablation. Pts were randomized to Arm A (atezo + bev) or Arm B (active surveillance). Pts in Arm A received atezo 1200 mg + bev 15 mg/kg IV q3w for a period of one year (17 cycles). Pts in Arm B underwent active surveillance for one year and were eligible to crossover to atezo + bev following independent review facility (IRF) confirmation of recurrence. The primary end point was IRF-assessed RFS. Pre-specified exploratory analyses included change from baseline in global health status (GHS)/quality of life (QoL), physical functioning, role functioning, emotional functioning, and social functioning. Clinically meaningful deterioration was defined as a ≥10-point decrease. Pts completed the IL42-EORTC QLQ-C30 (reduced) questionnaire at baseline and then at every odd treatment/surveillance visit through Cycle 17.

Results: The ITT population included 334 pts in both Arms A and B. With a median follow-up time of 17.4 mo (clinical cutoff date: 21 Oct 2022), IRF-RFS HR was 0.72 (95% CI: 0.56, 0.93; $p = 0.0120$). In the safety population, Grade 3 or 4 adverse events occurred in 41% of 332 Arm A pts and 13% of 330 Arm B pts. In ITT pts, IL42 completion rates remained ≥93% in both arms from baseline through treatment/surveillance Cycle 17. Mean scores at baseline in both arms were high and similar, as measured by the GHS/QoL and physical, role, emotional and social functioning scales. Mean changes from baseline were not considerable through Cycle 17 and were similar between arms as evidenced by overlapping 95% CIs. Pts' GHS/QoL and functioning was maintained through Cycle 17, with no clinically meaningful deterioration observed at any time.

Conclusion: Statistically significant and clinically meaningful improvement in RFS was seen in pts receiving atezo + bev vs active surveillance. Atezo + bev safety was generally manageable, and consistent with the established safety profiles of each therapeutic agent and with the underlying disease. PRO outcome analyses

revealed similar overall health-related QoL (HRQoL) and functioning between atezo + bev and active surveillance, and that treating high-risk pts with HCC with adjuvant atezo + bev following procedures with curative intent did not result in a clinically meaningful deterioration in HRQoL or function.

Email: ohadet34@yahoo.com

Background and aims: Chronic hepatitis delta (CHD) is the most severe form of human viral hepatitis for which there is no FDA approved therapy. Lonafarnib (LNF) is a farnesyl transferase inhibitor that interferes with HDV virion assembly through inhibition of the interaction of the large delta antigen with hepatitis B surface antigen. The purpose of this study is to evaluate the safety and efficacy of LNF boosted with ritonavir (RTV) ± peginterferon alfa-2a (Alfa) for the treatment of CHD.
Method: *D-LIVR* (NCT03719313) is a randomized, double-blind, placebo-controlled, parallel-group clinical trial. Adults with CHD and compensated liver disease were enrolled and randomized (7:5:2:2) to receive LNF 50 mg BID + RTV 100 mg BID (oral), LNF 50 mg BID + RTV 100 mg BID + Alfa 180 mcg QW (combo), Alfa 180 mcg QW (Alfa), or placebo for 48 weeks, followed by 24 weeks post-treatment. All patients were on background entecavir or tenofovir throughout the study. Paired liver biopsies were obtained at baseline (BL) and Week 48. The primary end point was a composite response of HDV RNA decline ≥2 log IU/ml and ALT normalization in the LNF arms compared to placebo at Week 48. Key secondary end points included the components of the primary end point and the rate of patients achieving >2 point improvement in histology activity index score without worsening of fibrosis (histology end point) at Week 48 compared to BL.
Results: A total of 407 patients (mean age 42.7 years, 69% male, 73% white) were enrolled, of whom 405 were randomized to the oral (n = 178), combo (n = 125), Alfa (n = 52) and placebo arms (n = 52). At BL, mean ALT, total bilirubin, albumin, platelets and HDV RNA levels were comparable across the four arms. 27% of patients had evidence of cirrhosis per investigator assessment. At Week 48, by intention to treat analysis, composite response rate was 10.1% (oral), 19.2% (combo), 9.6% (Alfa) and 1.9% (placebo). Composite response rates for both LNF-based arms were statistically significant vs placebo arm (p = 0.0044, oral; p < 0.001, combo). HDV RNA decline of ≥2 log IU/ml was observed in 14.6% (p = 0.0026, oral) and 32% (p < 0.001, combo), vs 3.8% (placebo). ALT normalization was achieved in 24.7% (p = 0.003, oral) and 34.4% (p < 0.001, combo), vs 7.7% in placebo. Of the 229 evaluable paired liver biopsies, statistically significant improvement in the histology end point was seen between the combo (35/66, 53%, p = 0.0139) and placebo arms (8/30, 27%), but not between the oral or Alfa and the placebo arms. Overall, both LNF-based regimens were well-tolerated, with comparable rates of treatment discontinuations across all arms.

Table:

Endpoint	Oral (n=178)	Combo (n=125)	Alfa (n=52)	Placebo (n=52)
Primary Endpoint[1]	10.1% p=0.0044[2]	19.2% p<0.0001[2]	9.6%	1.9%
≥2 Log Decline in HDV RNA	14.6% p=0.0026[2]	32% p<0.0001[2]	36.5%	3.8%
ALT Normalization	24.7% p=0.003[2]	34.4% p<0.001[2]	11.5%	7.7%
	Oral (n=107)	**Combo (n=66)**	**Alfa (n=26)**	**Placebo (n=38)**
Histology Endpoint[3]	33% (35) p=0.61[2]	53% (35) p=0.0139[2]	38% (10) p=0.46[2]	27% (8)

[1] ≥2 log decline in HDV RNA + ALT normalization
[2] Compared to placebo
[3] >2 point improvement in histology activity index score without worsening of fibrosis

Conclusion: The Phase 3 *D-LIVR* trial achieved the primary efficacy end point for both LNF-based regimens compared to placebo with oral arm matching and combo arm doubling the Alfa response rate. Encouragingly, statistically significant histologic improvement was observed in the combo arm. Week 72 results of this trial are awaited.

Background and aims: Atezolizumab-bevacizumab combination therapy is the standard of care for advanced hepatocellular carcinoma (HCC). Objective responses are however observed only in a minority of patients and the development of predictive biomarkers is critical to improve patient stratification and outcomes. The ABRS gene signature has been previously developed to this aim[1], however, molecular profiling techniques remain very challenging to

implement into clinical practice as they require expertise in molecular biology and bioinformatics. Our goal was to develop a regression based deep-learning model to estimate the ABRS expression value directly from HCC histological digital slides, and determine if this model could predict progression-free survival (PFS) in treated patients.

Method: We trained our model (ABRS-P) using the public TCGA dataset (n = 336). Image features extracted from whole-slide images were fed along with ABRS gene signature expression as the label, into a model fit for gene expression prediction/regression analysis. The model was externally validated on two independent datasets: a resection series (n = 225, Henri Mondor University Hospital) and a biopsy series (n = 157, Henri Mondor and Avicenne University Hospitals), which differed significantly from the discovery dataset in gene profiling technology (3' RNA sequencing) and slide staining and encoding formats. The predictive value was then tested on an multicentric series of 122 biopsy samples from patients treated by atezolizumab-bevacizumab. A control series of patients (n = 44) treated by other systemic therapies was also investigated. Finally, to obtain insights into the biological features of areas that significantly impact ABRS-P predictions, we performed spatial transcriptomics on HCC samples and matched prediction heatmaps with *in situ* gene expression profiles.

Results: Using cross-validation, the mean Pearson correlation coefficient (r) of ABRS-P was 0.62 (0.46-0.72), with a median p value of 9.37E-09. The ABRS-P generalised well on the resection external validation series with a r = 0.60, p = 1.81E-23. A small drop in performance (r = 0.53) was observed in the biopsy validation set, but the correlation was still highly significant (p = 1.52E-12). Patients with ABRS-P High tumors showed prolonged PFS (p = 0.014) after initiation of atezolizumab-bevacizumab treatment. No impact of the ABRS-P prediction was observed on PFS in patients treated with other systemic therapies. Spatial transcriptomics showed significantly higher ABRS gene expression, along with upregulation of various other immune effectors, in tumor areas with high ABRS-P predicted values.

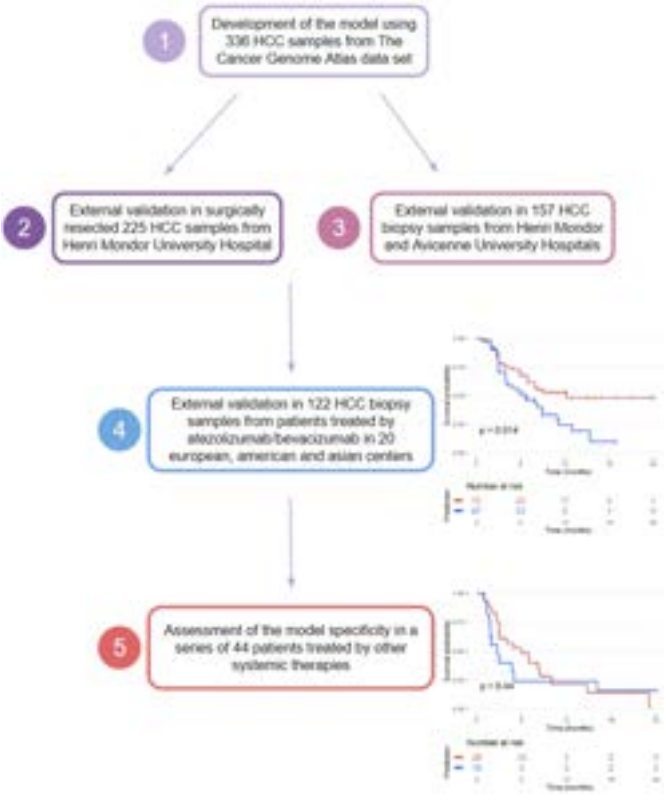

Figure:

Conclusion: Our study demonstrates that AI applied on HCC digital slides is able to predict PFS in patients treated by atezolizumab-bevacizumab. These approaches pave the way for the development of inexpensive and fast biomarkers of sensitivity to targeted therapies that could be easily implemented in clinical practice. Finally, we also show that the combination of AI prediction heat maps with spatial transcriptomics provides insights on the molecular features associated with areas with high predictive value. This could be applied to other cancers or diseases and improve our understanding of the biological mechanisms that drive outcomes or responses to treatments.

Refractory ascites in cirrhosis is associated with a major psychological burden in patients with cirrhosis and caregivers

Ana Belen Rubio Garcia[1,2], Rebeca Moreira[3], Marta Carol[2,3], Martina Perez[2,3], Marta Cervera[2,3], Ruth Nadal[3], Jordi Gratacos[3], Anita Arslanow[3], Adria Juanola[3], Anna Soria[3], Elisa Pose[3], Isabel Graupera[3], Pere Ginès[2,3], Núria Fabrellas[4]. *[1]Hospital Clinic of*

Barcelona, Hepatology, Spain, [2]Faculty of Medicine and Health Sciences, Spain, [3]Hospital Clinic of Barcelona, Spain, [4]Faculty of Medicine and Health Sciences, University of Barcelona, Spain
Email: anabrubio96@gmail.com

Background and aims: Refractory ascites is common in patients with cirrhosis and represents a major challenge for nurses caring for patients with liver diseases. The management of refractory ascites has been investigated extensively. However, there is very little information on the psychological impact of this condition in patients and the burden for their caregivers. The aim of this study was to investigate the psychological burden of refractory ascites in patients and effects on caregivers.
Method: Qualitative phenomenological study, the study population included outpatients with cirrhosis and refractory ascites. Sociodemographic and clinical data was collected from all patients. Psychological experiences were collected through semi-structured individual interviews to patients and caregivers. The analysis of the interviews was carried out by transcription and subsequent reading and re-reading of the description of the interpretative experiences. Subsequently, the content was analyzed to code the obtained information and grouped into categories. The sample was determined by data saturation. In patients, overall quality of life (QoL) was assessed by the short form survey 36 (SF-36) and liver specific QoL by the Chronic Liver Disease Questionnaire (CLDQ). Caregivers were asked to complete the SF-36 as well as the Zarit Burden Interview to measure caregiving burden.
Results: A total of 26 patients were included in the study (13 patients and 13 main caregivers). The mean age of the patients was 65 years. Nine patients (69%) were male and the main etiologic factor was alcohol consumption. Patients had a marked impairment in QoL in both physical and mental components. Main clinical symptoms were related to loss of appetite and weight loss, exhaustion, and insomnia. Patients reported a marked psychological impact mainly due to their decreased ability to move and reduced social activity ("*I am very tired, I am always very tired*"). Patients frequently reported mood swings ("*I can open the window and disappear and that's it...*") and symptoms of depression, yet some patients also expressed feelings of acceptance and resilience. The psychological impact was also very high in caregivers who had a major burden, as assessed by a median Zarit score of 57 (SD ± 12).
Conclusion: Refractory ascites has a profound psychological impact on patients and their informal caregivers. This psychological impact should be evaluated and treated to help improve patients and caregivers wellbeing.

OS-002

Pharmacist led telemonitoring and titration of carvedilol for ambulatory patients with compensated cirrhosis and clinically significant portal hypertension

Sheridan Rodda[1,2], Chloe McAinch[1,2], Aparna Morgan[2,3], Eliza Flanagan[2,3,4], Edward Saxby[2,3], Jo Hunter[1,2], Sue Kirsa[1,2], Sally Bell[3,4], Suong Le[2,3,5]. *[1]Monash Health, Pharmacy Department, Melbourne, Australia; [2]Monash University, Monash Digital Therapeutics and Innovation Laboratory, Melbourne, Australia; [3]Monash Health, Department of Gastroenterology and Hepatology, Melbourne, Australia; [4]Monash University, Department of Medicine, Melbourne, Australia; [5]Monash University, School of Clinical Sciences, Melbourne, Australia*
Email: roths2@hotmail.com

Background and aims: Carvedilol is frequently under-prescribed and under-dosed in patients with compensated cirrhosis and clinically significant portal hypertension (CSPH), despite significant mortality benefits. We aimed to investigate the feasibility, safety, and patient acceptability of a novel pharmacist led telemonitoring and titration service for achieving guideline directed carvedilol therapy (GDCT).
Method: We conducted a mixed methods study to prospectively evaluate the Optimising One Medication for Patients with Cirrhosis (OOMPa-C) clinic. A new model of care and GDCT titration protocol was developed by Pharmacy, Hospital in the Home and the Department of Gastroenterology and Hepatology at Monash Health Australia. During April to December 2022, 22 ambulatory adult patients with compensated cirrhosis and CSPH were trained to self-record daily blood pressure (BP) using a Bluetooth machine paired to a smartphone application. Pharmacists reviewed the results on a web-based platform and conducted twice weekly video consultations with patients. Doses were titrated per GDCT up to 12.5 mg daily as tolerated. Semi-structured interviews were conducted by the OOMPa-C pharmacist at the final consult.
Results: Of 22 participants, 20 (91%) were successfully titrated over a median of 14 days (interquartile range (IQR):12.5–17) with a median of 4 (IQR:3–5) pharmacist consults. Overall 18 (82%) participants took 12.5 mg per day at completion and 20 (91%) adhered to monitoring on at least 90% of enrolled days. One participant (4.5%) experienced respiratory adverse effects requiring treatment cessation. The figure summarises the themes identified from the 21 participants that completed interviews. The BP machine and app were reported as easy to use. Convenience was the most cited benefit; saving time, money and effort by receiving care in the privacy and comfort of home. Participants were happy to use the service again and recommend it to others. Clinical safety and data security were not a concern.

Table:

Theme	Barriers	Facilitators
Perceived ease of use	Issues with app, phone, BP machine Work routines Illness Telehealth application	Regular routines Alerts/reminders Family/carers Use of familiar video call method Flexible review times Accessibility of pharmacist via phone
Perceived usefulness	Little perceptible benefit (preventive medication)	More information and visibility for BP and pulse Respectful communication More education on carvedilol
Intention to use the service	Medication adverse effects	Referring doctor Altruism (research setting) Perceived trustworthiness of staff
Perceptions of technology	Low self-esteem Apprehension	Family/carers

Conclusion: A virtual carvedilol dose titration service (telemonitoring combined with pharmacist telehealth reviews) achieved GDCT and was feasible, safe and acceptable to patients with compensated cirrhosis and CSPH.

OS-003

Feasibility of a home-based, virtually-delivered, group exercise intervention in older patients with liver cancer (TELEX-Liver Cancer)

Kate Hallsworth[1,2], Sam Orange[1,3], Misti McCain[1,3], Roisin Fallen-bailey[1], Helen Louise Reeves[1,2,3]. *[1]Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [2]The Liver Unit, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [3]Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, United Kingdom*
Email: kate.hallsworth@ncl.ac.uk

Background and aims: Hepatocellular carcinoma (HCC) is often diagnosed at an intermediate/advanced stage; less than a third of patients are offered potentially curative treatments. For many,

maintaining quality-of-life (QoL) and independence throughout cancer treatment (s) and beyond is a core objective of clinical care. Strong evidence supports supervised exercise as an effective way to improve QoL in older adults with cancer and age-related comorbidities. Multiple barriers to the implementation of system-wide exercise programmes exist on both an organisational and individual patient level.

The aim of the study was to investigate whether it is feasible and safe to deliver supervised group exercise via videoconferencing to patients with HCC in their own home.

Method: TELEX-Liver Cancer was a non-randomised feasibility study for patients with HCC aged ≥60 years. Primary outcomes focussed on recruitment, retention, exercise adherence, and safety. Patients were asked to attend exercise classes, twice-weekly for ~45 minutes via online videoconferencing for 10 weeks in their own home. Each class included both aerobic and resistance training. Physical function was assessed pre-/post-intervention and patient-reported outcomes were collected via postal questionnaire.

Results: From November 2021 to September 2022, 45 patients were invited to participate and 19 provided consent (recruitment rate 42%). Participants had a mean age of 74 years, were on average 22 months post-diagnosis and 11 months post-treatment. Participants completed 76% of planned exercise sessions. 15/19 (79%) patients completed assessments of physical function and 14/19 (74%) patients returned study questionnaires. Hand grip strength ($p = 0.002$), Liver Frailty Index ($p < 0.001$) and 5-times chair stand ability ($p = 0.002$) significantly improved from pre- to post-intervention. No adverse events occurred during exercise sessions.

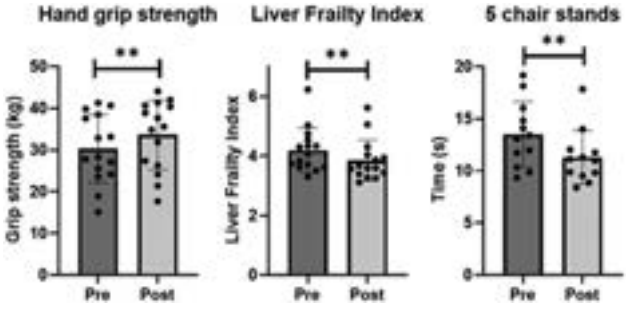

Figure:

Conclusion: It is feasible and safe to deliver supervised group exercise via videoconferencing to patients with HCC in their own home. Patients also benefited from improvements in physical functional. These findings will inform the design of a future, adequately-powered randomised controlled trial to evaluate the efficacy of the intervention.

OS-004-YI

Community dispensed hepatitis C virus treatment for 'hard to reach' opiate substitution treatment service users in Dublin: an intervention to address HCV infection eradication

Gillian Farrell[1], Kieran Harkin[2], Miriam Coghlan[1], Nessa Quinn[1], Colm Bergin[1]. [1]*St. James's Hospital, GUIDe Clinic, Dublin, Ireland;* [2]*Merchants Quay Ireland, Ireland*
Email: gilfarrell@stjames.ie

Background and aims: The GUIDe Clinic is Irelands largest hospital-based infectious diseases' clinic. We run a very successful HCV treatment clinic; however, a number of our target patient group were regularly failing to attend clinic appointments, of which a disproportionate number were homeless. With the ambition of becoming 'HCV Free by 2023' we developed an alternative 'linkage to treatment' pathway. In September 2020 we established a partnership with Merchants Quay Ireland (MQI)-a not for profit organisation that provides services for people who are homeless and those with addiction issues. The aim of the programme was to link otherwise 'hard to reach' populations to HCV DAA curative treatment.

Method: GUIDE Nurse and MQI General Practitioner (GP) set up and ran a fortnightly HCV clinic for patients who attended the opiate substitution treatment (OST) clinic based in MQI. This service offered a 'one-stop-shop' service where patients with HCV were assessed, educated, baseline bloods collected, fibroscan performed, drug-drug-interaction (DDI) checked and registered for treatment all within one clinical visit-as they attended for their OST review. DAAs were prescribed within this clinic and patients received their DAAs from the community pharmacy. Data was retrospectively collected using Electronic Patient Record (EPR) and Excel spreadsheet.

Results: 283 patients were registered to GP in MQI for OST (Opiate Substitution Treatment), of whom 239 (84%) had blood borne viral (BBV) screening. 89 (37%) of these patients were HCV Ag or PCR positive and were referred for DAA workup.

Of this patient group (N = 89).

- 40 were linked to our community dispensed DAA treatment
- 21 were linked to DAA treatment elsewhere (e.g. hospital based clinic, drug treatment centre or prison HCV treatment programme)
- 14 disengaged from MQI service
- 11 subsequently tested HCV RNA negative
- 3 died.

40 patients were treated in our programme and eligible for inclusion for analysis. All were HIV negative, fibroscan score <12 KPa.

- 40 patients (7 (17.5%) female, 33 (88.5%) male) received 42 courses of DAA treatment.
- 6 patients received >1 DAA course, having been previously treated elsewhere, or else requiring re-treatment.
- Regimens Prescribed: SOF/VLP (Epclusa) 26; G/P (Maviret) 14, SOF/VLP/VOX (Vosevi) 1, SOF/GP 1.

DAA Treatment Outcome Data (N = 42):
On Treatment Analysis:

24 (57%) SVR12 achieved
10 (24%) Failed to attend for SVR bloods: either lost to follow-up (LTFU) or declining bloods
3 (7%) treatment failure (2 successfully re-treated, 1 early discontinuation and now LTFU)
4 (10%) Re-infection (1 patient successfully re-treated, 1 linked to re-treatment elsewhere, 1 in prison and listed for DAA re-treatment with Prison in-reach service, 1 still actively trying to link with re-treatment
1 (2%) RIP

Conclusion: This model of care and treatment delivery programme has proved to be very successful to date, with many patients that failed to be treated in standard clinics, now successfully treated and cured. Many other patients were successfully linked to alternative treatment programmes. Although absolute numbers are small the high re-infection rate is concerning, and highlights the need for ongoing BBV molecular screening and rapid access to re-treatments in this high risk population group. The next challenge is to offer HCV screening and treatment to persons sleeping rough or living in unstable accommodation in a community based setting to optimise patient engagement and compliance and outcomes.

THURSDAY 22 JUNE

Alcohol-related liver disease and drug-induced liver injury

OS-005-YI
Clinical course of biopsy-controlled alcohol-related liver disease

Stine Johansen[1,2], Mads Israelsen[1], Nikolaj Torp[1,2], Katrine Thorhauge[1,2], Johanne Kragh Hansen[1,2], Katrine Prier Lindvig[1,2], Peter Andersen[1], Emil Deleuran Hansen[1,2], Camilla Dalby Hansen[1,2], Ida Ziegler Spedtsberg[1,2], Ida Villesen[1,2], Katrine Bech[1], Sönke Detlefsen[2,3], Helene Bæk Juel[4], Ditlev Rasmussen[1], Torben Hansen[4], Aleksander Krag[1,2], Maja Thiele[1,2]. *[1]Odense University Hospital, Fibrosis, fatty liver and steatohepatitis research center Odense (FLASH), Denmark; [2]University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Denmark; [3]Odense University Hospital, Department of Pathology, Denmark; [4]University of Copenhagen, Novo Nordisk Foundation Center for Basic Metabolic Research, Denmark*
Email: stine.johansen@rsyd.dk

Background and aims: Alcohol-related liver disease (ArLD) is associated with high morbidity and mortality but there is a lack of good prospective studies characterising the natural history of ArLD in more detail than epidemiological studies. We aimed to investigate the clinical course of biopsy-controlled ArLD according to baseline fibrosis stage including the risk of progression to decompensation and death.
Method: We prospectively followed a cohort of patients with a history of excessive alcohol intake (≥36 g/day for men and ≥24 g/day for women) and no prior decompensation. At baseline, we performed liver biopsies, genotyping of four single nucleotide polymorphisms in PNPLA3, MBOAT7, TM6SF2, HSD17B13, and clinical investigations. During follow-up, we manually reviewed patients' medical health records for all hospital contacts, new diagnoses/complications, reports of alcohol intake and all-cause mortality. First and further decompensation were defined according to the Baveno VII recommendations.
Results: We followed a total of 459 ArLD patients for a median of 5.9 years (IQR 4.5–7.8). Mean age at baseline was 57 ± 10 years, 76% male, fibrosis stage F0-1/F2/F3-4 = 57%/23%/20%. Patients reported a median of 15.5 years of excessive drinking. During follow-up, 67 patients decompensated of whom 46 developed at least one further decompensation, and 101 patients died (figure). All-cause mortality increased with higher fibrosis stage from 1.4 deaths per 100 person-years for stage F0-1, to 5.0 deaths per 100 person-years for stage F2, and 9.3 deaths per 100 person-years for stage F3-4. The cause of death was hepatic in 38%, non-hepatic in 43% and unknown in 20% of cases. The most frequent type of first decompensation was ascites (60%) followed by hepatic encephalopathy (25%) and variceal bleeding (15%). The incidence of decompensations during follow-up increased with baseline fibrosis stage: 5 out of 260 = 1.9% for stage F0-1, 17 out of 107 = 15.9% for stage F2, and 45 out of 91 = 49.5% for stage F3-4. Baseline fibrosis stage (hazard ratio, HR = 3.11; 95%CI 1.54–6.30) and excessive drinking during follow-up (HR = 4.80; 95%CI 3.28–7.02) were independent predictors of a first decompensation. PNPLA3 and TM6SF2 were predictors of decompensation in univariable regression but did not exhibit independent prognostic information.

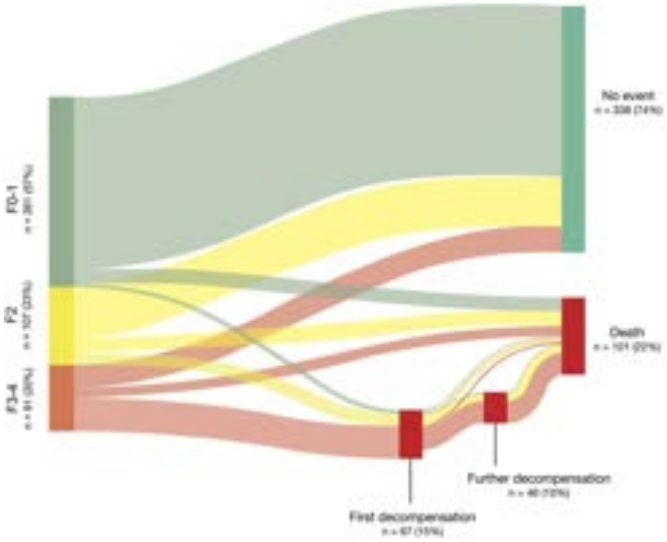

Figure:
Hepatocellular carcinoma occurred in 14 patients (3%) after a median of 3 years (IQR 1.3–6.4) with eight of the cases detected prior to first decompensation.

Conclusion: In this prospective cohort with 5.9 years of follow-up, patients with alcohol-related liver disease experienced a high 5-year risk of decompensation and death, even in patients with only moderate fibrosis (F2) at baseline. Continuous excessive drinking predicted decompensation independent of fibrosis stage.

OS-006-YI
Plasma multi-omics outlines association of urobilinogen with corticosteroid non-response, inflammation, intestinal permeability and outcome in severe alcoholic hepatitis

Jaswinder Maras[1], Manisha Yadav[1], Babu Mathew[1], Sadam H Bhat[1], Neha Sharma[1], Gaurav Tripathi[1], Nupur Sharma[1], Vasundhra Bindal[1], Sushmita Pandey[1], Jitendra Kumar[1], Pushpa Yadav[1], Ravinder Singh[1], Mojahidul Islam[1], Ashima Bhaskar[2], Ved Dwivedi[2], Nirupma Trehanpati[1], Shvetank Sharma[1], Shiv Kumar Sarin[3]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]International Centre For Genetic Engineering And Biotechnology, New Delhi, India; [3]Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Severe alcoholic hepatitis (SAH) has a high mortality and corticosteroid therapy is effective in 60% patients. Reliable indicators of response to therapy and mortality in SAH are needed.
Method: Altogether 223 SAH patients, 70 in derivative [50 responders (R) and 20 non-responders (NR)] and 153 in validation cohort [136 R, 17 NR] were included. Plasma metabolic and meta-proteomic phenotype was studied using UHPLC-HRMS and validated using Machine-Learning (ML). Temporal metabolic changes were assessed using Weighted Metabolome Correlation Network Analysis (WMCNA). Functional properties (inflammatory nature, effect on membrane integrity, effect on glucocorticoid receptor expression and downstream signaling) of nonresponse indicator were assessed in-vitro on primary healthy neutrophils and primary mice enterocytes.
Results: Baseline plasma metabolomics discriminated NR ($p < 0.05$) with significant increase in urobilinogen (3.6-fold), cholesterol sulfate (6.9-fold), Adenosine monophosphate (4.7-fold) levels. Baseline plasma meta-proteome showed increase in alpha, beta diversity and clusters of orthologous groups of protein functions; biosynthesis of secondary metabolites, and others as a characteristic feature of NR ($p < 0.05$). Temporal change in the metabolite expression post- corticosteroid therapy was higher in responders ($p < 0.05$) whereas NR remained metabolically inactive. Plasma

urobilinogen predicted non-response [AUC = 0.94] with a hazard-ratio of 1.5 (1.2–1.6) and cut-off >0.07 mg/ml segregated non-survivors (p < 0.01, log-rank) and showed >98% accuracy using ML. Plasma urobilinogen expression correlated with circulating bacterial peptide known for converting bilirubin to urobilinogen (r2 > 0.7; p < 0.05). A significant increase in neutrophil activation marker (CXCR1, NGAL), oxidative stress (NOXO1, NOXA1, NOX1, and NOX4), and pro-inflammatory cytokine genes (IL15, IL7, TNFα, IL6, IL8, and IL11) was observed post-treatment of primary healthy neutrophils with urobilinogen. Additionally, urobilinogen promoted corticosteroid resistance by enhancing the expression of GRß, trans-repression genes under GRα (inflammatory genes- NFkB, MAPK-MAP, IRF) and downregulating the expression of GRα, and transactivation (anti-inflammatory genes- NFkB-IkB) genes. Urobilinogen also dysregulated intestinal membrane junction proteins (gap junction protein 1, occludin and desmoglein) which promoted leaky gut.

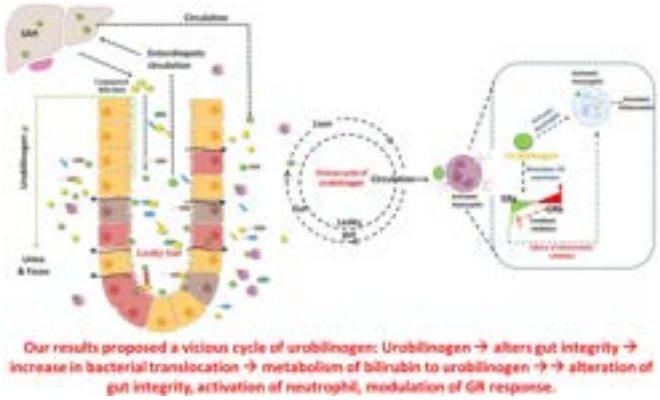

Figure:

Conclusion: Plasma metabolome/meta-proteome can stratify pre-therapy steroid response. Increase in plasma Urobilinogen modulates gut integrity and increases bacterial translocation. Increase in circulatory bacteria increases metabolism of circulatory bilirubin to urobilinogen. This vicious cycle of increase in urobilinogen again modulate gut integrity, increases activation of neutrophil and modulate glucocorticoid receptor activity thereby contributing to Non-response.

OS-007
Prior drug allergies are associated with worse outcome in patients with idiosyncratic drug-induced liver injury: an analysis from the Spanish DILI registry

Pablo Solis-Munoz[1,2], Inmaculada Medina-Cáliz[1], Rocio Romero Flores[1], Miguel Zoubek[1], Judith Sanabria-Cabrera[1], M Robles-Díaz[1,3], Miren Garcia Cortes[1,3], Aida Ortega-Alonso[1,3], Jose Pinazo Bandera[1,3], MR Cabello[1], Raul J. Andrade[1,3], Maria Isabel Lucena[1,3], Hao Niu[1,3], Ismael Alvarez-Alvarez[1,3]. [1]*UGC de Aparato Digestivo, Servicio de Farmacología Clínica, Instituto de Investigación Biomédica de Málaga y Plataforma en Nanomedicina-IBIMA Plataforma BIONAND, Hospital Universitario Virgen de la Victoria, Universidad de Málaga, Málaga, Spain;* [2]*Unidad de Investigación, Hospital Universitario Santa Cristina, Instituto de Investigación Sanitaria La Princesa, Madrid, Spain;* [3]*Centro de Investigación Biomédica en Red, Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain*
Email: andrade@uma.es

Background and aims: Drug allergies encompass a plethora of hypersensitivity reactions with heterogeneous mechanisms. Whether the presence of prior drug allergies (PDA) is related with the outcome in patients that develop idiosyncratic drug-induced liver injury (DILI) remains uncertain. We aimed to determine the differences in clinical phenotype and outcomes of DILI patients according to the presence or absence of PDA.

Method: The demographics, clinical, biochemical and outcome information of patients included in the Spanish DILI Registry was analyzed, and the previous history of PDA was carefully examined. Cases of non-drug allergies, other types of adverse drug reactions, or insufficiently documented allergies were not considered PDA. Drugs were classified according to the Anatomical Therapeutic Chemical (ATC) Classification System. Differences between groups were tested with the Mann-Whitney U test, or the chi-square test or Fisher's exact test, as appropriate.

Results: Of 913 cases with a first episode of DILI, 62 (6.8%) patients presented with well-documented PDA (6.8%). Patients with PDA exhibited an older age (60 vs. 54 years, respectively; p = 0.011). Although hepatocellular injury predominated in both groups, compared to patients with no history of drug allergies, cases with PDA showed significantly lower median values of alkaline phosphatase (1.6 vs 1.4 × ULN; p = 0.027) and platelet count (226 vs. 189 x103/ml; p = 0.011), while aspartate aminotransferase (AST) showed a trend towards increased levels in patients with PDA (6.2 vs. 8.7 × ULN; p = 0.049). Fatal outcome was more common in patients with PDA (15% vs. 3.1%; p < 0.001). Indeed, seven cases (11%) developed a liver-related death compared to 1.6% who did not suffer from drug allergy (p < 0.001). Fatal cases with PDA were predominantly women (78% vs. 55% in non-fatal cases; p = 0.282), and all of them presented with hepatocellular injury, jaundice, and required hospitalization. Moreover, fatal cases with PDA had increased total bilirubin levels (14 vs. 4.1 × ULN in non-fatal cases; p < 0.001), but lower platelet count (189 vs. 226 × 103/ml in non-fatal cases; p = 0.013). The most common pharmacological groups implicated in PDA were anti-infectives (53%), central nervous system agents and musculoskeletal system drugs (14% each). The most frequent drugs implicated in PDA were penicillin (31%), acetylsalicylic acid and codeine (4% each). In 16 patients with PDA (26%), the drugs that caused the allergy and the DILI belonged to the same ATC group, and in five cases (8.1%), they belonged to the same drug class.

Conclusion: Our findings support the hypothesis that a previous history of an immunoallergic reaction related to drugs is associated with a worse outcome in patients with DILI. Patients with PDA presenting with hepatocellular damage, jaundice and lower platelet count were more likely to develop a fatal outcome.

OS-008-YI
Tumor necrosis factor-inducible gene 6 protein suppresses release of cluster of differentiation 44 intracellular domain, and attenuates alcohol-induced liver damages and activation of hepatic stellate cells

Jinsol Han[1], Chanbin Lee[1,2], Youngmi Jung[1,3]. [1]*Pusan National University, Department of Integrated Biological Science, Pusan, Korea, Rep. of South;* [2]*Pusan National University, Institute of Systems Biology, Pusan, Korea, Rep. of South;* [3]*Pusan National University, Department of Biological Sciences, Pusan, Korea, Rep. of South*
Email: y.jung@pusan.ac.kr

Background and aims: Alcohol-related liver disease (ALD) is global prevalent chronic liver disease caused by excessive and/or habitual alcohol consumption. However, the effective and practical treatment against ALD has not been developed. Previously, we have demonstrated that tumor necrosis factor-inducible gene 6 protein (TSG-6), one of cytokines released from mesenchymal stem cells, reduces liver fibrosis and induces successful liver repair in mice with chronically damaged liver. TSG-6 was also shown to attenuate activation of hepatic stellate cells (HSCs), a main player in liver fibrosis, by interacting with cluster of differentiation 44 (CD44). CD44 is cleaved and releases its intracellular domain (ICD) fragment, which translocates into the nuclear and turn on fibrotic genes, contributing to liver fibrosis. However, it remains unclear whether and how TSG-6 has protective function in ALD. Hence, we investigated therapeutic effect of TSG-6 and its underlying mechanism in mice with ALD.

Method: 7-week-old male C57BL/6 mice were fed isocaloric pair diet (the CON group) or 5% (v/v) ethanol-containing Lieber-DeCarli liquid diet (EtOH group) for 12 weeks. At 9 weeks after the liquid diet, 50 ng of TSG-6 (EtOH + TSG-6) or saline (EtOH + Veh) as vehicle was intraperitoneally injected every other day along with feeding liquid diet for 3 additional weeks. These experimental mice were sacrificed 12 weeks after the diet feeding to collect blood and liver samples. Human primary HSCs at 70% confluence were serum starved overnight and cultured in medium containing 2% FBS with 20 ng/ml of TSG-6 or saline for 6 hr, 12 hr and 24 hr.
Results: Chronic alcohol feeding increased liver weight/body weight (LW/BW) ratio and caused severe liver damage including fat accumulation, hepatocyte death, inflammation and fibrosis. However, the EtOH + TSG-6 group had significantly lower LW/BW ratio and less alcohol-induced liver damage than the EtOH +Veh group had. Moreover, TSG-6 treatment remarkably reduced liver fibrosis in EtOH treated mice. The both levels of full-length CD44 and ICD significantly increased in the EtOH + Veh group compared with the EtOH + TSG-6 group. The nuclear translocation of CD44ICD was also significantly reduced in TSG-6-treated alcohol-fed mice. Immunostaining for CD44 showed that CD44-positive HSCs-looking cells were more apparent in the EtOH + Veh group than the TSG-6 treated group. In addition, TSG-6 treatment significantly alleviated expression of CD44ICD and suppressed its nuclear accumulation in human primary HSCs, leading to HSC inactivation.
Conclusion: These findings demonstrate that TSG-6 attenuates alcohol-induced liver damage and fibrosis, by blocking cleavage of CD44 to CD44ICD, and suggest that TSG-6 has therapeutic potential for ALD with fibrosis.

OS-009
Efficacy of N-acetylcysteine to prevent anti-tuberculosis drug-induced liver injury: a randomized controlled trial

Supot Nimanong[1], Kittichai Samaithongcharoen[1], Watcharasak Chotiyaputta[1], Suppareark Disayabutr[2], Phunchai Charatcharoenwitthaya[1], Siwaporn Chainuvati[1], Tawesak Tanwandee[1]. *[1]Division of Gastroenterology, Department of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand; [2]Division of Respiratory Disease and Tuberculosis, Department of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand*
Email: supotgi@gmail.com

Background and aims: Hepatitis is a common complication of anti-tuberculosis therapy, especially from isoniazid. Slow acetylator status in the N-acetyltransferase 2 (NAT2) genotype is a significant risk factor of anti-tuberculosis drug-induced liver injury (AT-DILI). There is scanty data of N-acetylcysteine (NAC) to prevent AT-DILI. This study was aimed to explore the efficacy of NAC to prevent clinically significant AT-DILI.
Method: We conducted a randomized, open-labeled, controlled trial in patients with newly diagnosed tuberculosis (TB) who received standard anti-TB regimen. Patients with HIV infection or chronic liver disease were excluded. The enrolled patients were randomized to using NAC 1,200 mg/day for 2 months (NAC group) or anti-TB drugs alone (control group). Acetylator status of NAT2 was determined and liver function tests were assessed at baseline, 2 weeks, 2 and 6 months. Clinically significant hepatitis was defined as elevated aspartate aminotransferase (AST) or alanine aminotransferase (ALT) more than 5 times of baseline levels.
Results: Among 82 enrolled patients, the mean age was 54 years, 53.7% were male, 30% were NAT2 slow acetylator, mean AST was 25 IU/ml, mean ALT was 22 IU/ml which were not significantly different between NAC (n = 40) and control group (n = 42). The prevalence of clinically significant hepatitis was 19.5%. All events occurred within 2 months and 50% occurred within 2 weeks. The number of patients in NAC group who had clinically significant hepatitis were 5% and 15% at 2 weeks and 2 months respectively, compared with 14.3% and 23.8% in control group, which were not significantly different. Among NAT2 slow acetylator patients (n = 24), there was no hepatitis in NAC group, whereas 50% of control group had hepatitis at 2 months, which was significantly different (p = 0.02). No adverse effect of NAC was observed. Multivariate analysis revealed NAT2 slow acetylator was the only predictor of AT-DILI (hazard ratio 3.60 [1.07–12.15]; p = 0.039).

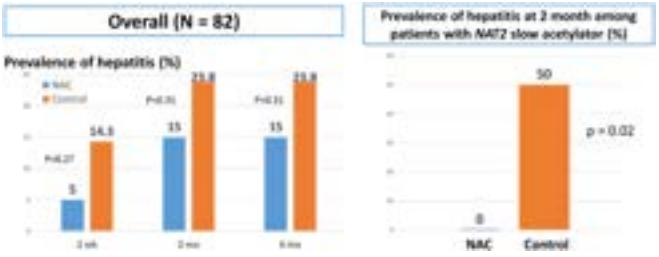

Figure:

Conclusion: Hepatitis is a common complication within 2 months of anti-TB therapy. NAC is safe and can prevent AT-DILI in patients with NAT2 slow acetylator.

Cirrhosis Experimental

OS-010-YI
Dysregulation of the FXR-FGF19 pathway indicates impaired gut-liver axis signalling in patients with cirrhosis

Benedikt Simbrunner[1], Benedikt Hofer[1], Philipp Schwabl[1], Kerstin Zinober[1], Oleksandr Petrenko[1], Claudia Fuchs[1], Georg Semmler[1], Rodrig Marculescu[2], Mattias Mandorfer[1], Christian Datz[3], Michael Trauner[1], Thomas Reiberger[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Austria; [2]Department of Laboratory Medicine, Medical University of Vienna, Austria, Austria; [3]Department of Internal Medicine, General Hospital Oberndorf, Teaching Hospital of the Paracelsus Medical University Salzburg, Salzburg, Austria, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Experimental studies demonstrated impaired Farnesoid X receptor (FXR)-fibroblast growth factor 19 (FGF19) signalling in liver disease. This study aimed to characterize the FXR-FGF19 pathway along the gut-liver axis in patients with cirrhosis and investigate associations with disease severity.
Method: Patients with cirrhosis undergoing hepatic venous pressure gradient measurement with or without transjugular liver biopsy (n = 107, n = 53 liver biopsy; n = 5 control livers without background disease) or colonoscopy with ileum biopsy (n = 37; n = 6 liver-healthy controls) were included. Expression of genes reflecting hepatic and intestinal FXR activation and intestinal barrier integrity was assessed by qPCR. Bile acid (BA) and FGF19 levels in the systemic circulation were measured.
Results: Systemic BA correlated with FGF19 levels ($r = 0.461$; $p < 0.001$) and were significantly higher in patients with decompensated vs. compensated cirrhosis. Hepatic SHP expression was significantly lower in patients with cirrhosis than in controls ($p < 0.001$), reflecting reduced hepatic FXR activation. FGF19 ($r = 0.512$, $p < 0.001$) and BA ($r = -0.487$, $p < 0.001$) levels in the systemic circulation correlated negatively with CYP7A1 expression in the liver, but not with hepatic SHP or CYP8B1, indicating dysfunctional FXR-dependent BA feedback signalling in the liver. Furthermore, decreased expression of FXR, SHP and FGF19 was observed in the ileum of patients with cirrhosis. Surprisingly, intestinal FGF19 gene expression was not linked to systemic FGF19 levels. The expression of intestinal barrier proteins

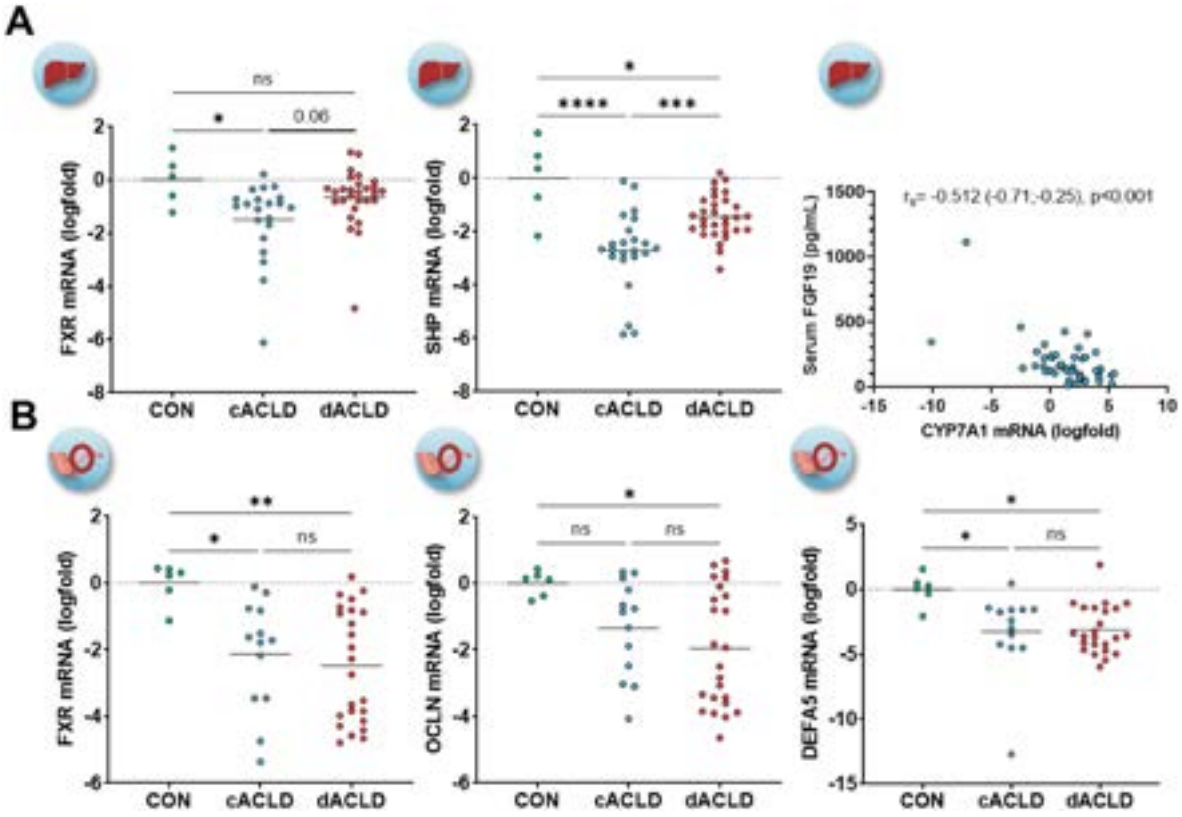

Figure: (abstract: OS-010-YI).

zonula occludens-1, occludin, and alpha-5-defensin correlated with SHP and decreased in patients with decompensated cirrhosis as compared to controls.
Conclusion: FXR signalling is dysregulated at key intersections of the gut-liver axis in patients with cirrhosis. Decreased FXR activation in the ileum was associated with reduced expression of intestinal barrier proteins in patients with cirrhosis. These translational data are highly relevant for ongoing efforts investigating whether targeting the FXR-FGF19 pathway in the gut-liver axis may ameliorate bacterial translocation in cirrhosis.

OS-011-YI

Restoration of epithelial and vascular intestinal barriers and splanchnic macrophage function mediates the halting of bacterial translocation by propranolol in cirrhotic rats with ascites

Elisa Castillo[1,2], Lorena Paule[1,2], Leticia Munoz[1,2], Manuel Ponce-Alonso[3,4], Rosa del Campo[3,4], Oscar Pastor[4], Miguel A Ortega[1,5], Melchor Álvarez-Mon[1,2,6], Agustin Albillos[1,2,4].

Email: elisa.castillo@uah.es

Background and aims: It has been hypothesized, but not proven, that restoration of the intestinal barrier damaged in cirrhosis could mediate the non-hemodynamic effects of propranolol (Prop). Prop has also been suggested to be associated with improved survival in acute-on-chronic liver failure (ACLF). We aimed to i) study the effects of Prop on the epithelial and vascular intestinal barriers, microbiota, and immune system of cirrhotic rats with ascites, and ii) explore whether any effect is also present in cirrhotic rats with ACLF.
Method: Cirrhosis was induced in Wistar rats by CCl4 gavage or bile duct ligation (BDL). Prop (Prop) (30 mg/kg/d, p.o.) or vehicle (Veh) was administered for 2 weeks from ascites development (Cirrhosis group, n = 40). ACLF was induced by LPS (6 microg/kg, i.p., 7 and 3 days before sacrifice) in rats already on Prop or Veh (ACLF group, n = 37). In the ileum, we evaluated the epithelial and vascular intestinal barriers, the microbiota adhering to the mucosa, bacterial translocation (BT), and peritoneal macrophage activation and function.
Results: Prop normalized the ileal microbiota of CCl4-cirrhotic rats by reducing the elevated proportions of Gammaproteobacteria, Verrucomicrobium, and Bacteroidota. BT was reduced 2.5-fold by Prop (Table). Compared to Veh, Prop increased ileal mucus thickness and ZO-1 and occludin expression and reduced the expression of TNF-alpha, IFN-gamma, and IL-23. Prop improved the ileal vascular barrier, as shown by reductions in the PV1/CD34 ratio and liver detection of dextran in an intestinal loop assay. Prop exerted similar effects in BDL cirrhotic rats. In peritoneal macrophages, Prop ameliorated the increased RT1B expression (mean ± SD: from 33.8% ± 5.4% to 18.5% ± 3.2%, $p < 0.01$) and TNF-alpha production (from 24.4% ± 6.9% to 5.8% ± 2.7%, $p < 0.01$) and restored the phagocytosis (from 8.3% ± 2.4% to 29.9% ± 5.3%, $p < 0.01$). BT (89% vs. 91%), ileal mucous thickness (9.5 ± 3.4 vs. 10.1 ± 4.6 µm), ZO-1 expression (0.09 vs. 0.11 R.E.), and PV1/CD34 (0.83 ± 0.13 vs. 0.75 ± 0.17) were similar in ACLF rats on Prop or Veh.

Table:

	Controls n = 5	CCl_4 cirrhosis	
		Vehicle n = 7	Propranolol n = 6
Small intestine (ileum)			
Mucus thickness (microm)	87 ± 6	13 ± 7*	40 ± 15†
ZO-1 (R.E.)	1	0.15*	0.65*†
Occludin (R.E.)	1	0.22*	0.59*†
TNF-alpha (R.E.)	1	121.6*	73.8*†
IFN-gamma (R.E.)	1	3.6*	1.9*†
IL-23 (R.E.)	1	2.2*	1.6*†
PV1/CD34	0.04 ± 0.03	0.81 ± 0.11*	0.52 ± 0.09*†
4KDa-dextran in liver	0	11 ± 3*	3 ± 1*†
Bacterial translocation			
Mesenteric lymph nodes (%)	0	86*	33*†
Ascites (%)	0	57*	0†

*p < 0.001 vs. healthy controls;
†p < 0.05 vs. vehicle; R.E., relative expression.

Conclusion: Prop halts gut and hepatic BT in cirrhotic rats with ascites, but not in those with ACLF. Prop mediates these effects by restoring the integrity of the epithelial and vascular intestinal barriers and the activity of the splanchnic innate immune system.

OS-012-YI
Novel insights on liver endothelial mechanobiology in cirrhosis: role of calcium integrin-binding protein 1

Cong Wang[1], Sonia Selicean[1], Eric Felli[1], Yeldos Nulan[1], Sergi Guixe-Muntet[2], Juanjo Lozano[2], Jaime Bosch[1], Annalisa Berzigotti[1], Jordi Gracia-Sancho[1,2]. [1]*University of Berne and Inselspital, Department of Visceral Surgery and Medicine, Berne, Switzerland;* [2]*IDIBAPS-Hospital Clinic Barcelona-CIBEREHD, Liver Vascular Biology, Barcelona, Spain*
Email: jgracia@recerca.clinic.cat

Background and aims: Liver microcirculatory malfunction is a key event in liver cirrhosis and portal hypertension, being liver sinusoidal endothelial cells (LSECs) central players in this pathological situation. We previously delineated how increased liver stiffness *per se* dysregulates sinusoidal cells phenotype by altering cells nuclear morphology. Reversing this mechanism may open novel therapeutic approaches based on targeting stiffness-modulated molecular factors (SMMFs). A possible SMMFs is calcium and integrin-binding protein-1 (CIB1), a small, ubiquitously expressed protein involved in many processes, and dysregulated in liver cancer and fibrosis. This study aimed at investigating the mechanotransduction mechanisms promoting endothelial dedifferentiation in cirrhosis, with a particular focus on CIB1 mechanobiology.
Method: Primary LSECs were cultured 48 h on tunable stiffness polyacrylamide gels (healthy, soft stiffness: 0.5 kPa vs. pathologic: 30 kPa). RNAseq was performed and dysregulated pathways were determined by Ingenuity Pathway Analysis. CIB1 expression and cellular localization was measured in healthy and cirrhotic human and rat liver tissues and cells. The effects of depleting CIB1 using siRNA were investigated in endothelial cells cultured at pathologic stiffness.
Results: Pathologic stiffness (30 kPa) induced significant changes in LSECs transcriptome as demonstrated by the dysregulation of 224 genes in comparison to soft substrate ($p < 0.05$; FC 1.5). Top dysregulated pathways were related to CIB1 functions, involving integrin, sirtuin, hepatic fibrosis, actin cytoskeleton and mTOR signaling. Immunofluorescence on healthy LSECs and HUVECs cultured at 0.5 and 30 kPa confirmed that CIB1 significantly translocates to the cytoplasm on a stiff substrate (+46.7% and +93.3% respectively), which was prevented using nuclear mechanotransduction inhibitors (cytochalasin D plus nocodazol). Importantly, overexpression and translocation of CIB1 were confirmed in human cirrhotic liver (+20%) and primary cirrhotic LSEC (+40.8%). Cirrhotic rat LSECs showed significant re-translocation into the nucleus when cultured on healthy-like substrate (−231.6%) (all $p < 0.05$). Finally, CIB1 knock-down reversed LSECs nuclear morphology to a healthy spherical shape on 30 kPa, which was associated with improved LSECs phenotype as demonstrated by the amelioration of pathways related to LSECs dysfunction such as inflammation, DNA damage and repair, nitric oxide signal transduction, ROS scavenging activity, as well as a reduced nuclear membrane trafficking.
Conclusion: We demonstrate that CIB1 is a key regulator of LSECs mechanotransduction and dysfunction in liver cirrhosis. The reversibility of the effects of CIB1 makes it, or its downstream molecular pathways, potential novel therapeutic targets for chronic liver disease and portal hypertension.

ETS2 alleviates HMGB1 and LPS triggered excessive inflammation in acute-on-chronic liver failure

Lulu He[1], Xi Liang[2], Jiaojiao Xin[1], Dongyan Shi[1], Jinjin Luo[1], Jiaqi Li[1], Jing Jiang[1], Jun Li[1]. [1]*The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China;* [2]*Taizhou Central Hospital (Taizhou University Hospital), Precision Medicine Center, Taizhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) is characterized by rapid deterioration of liver function with pre-existing chronic liver diseases (CLDs), and shows high short-term mortality. This study aims to identify potential biomarkers in ACLF pathogenesis and clarify the potential mechanisms.
Method: Peripheral blood mononuclear cells from patients with HBV-ACLF (n = 50), patients with chronic liver disease (n = 19) and healthy subjects (n = 14) were subjected to transcriptome analysis. The potential biomarkers ETS2 were subsequently validated in vivo and in vitro with myeloid-specific ETS2 deficiency mice and ETS2 deficient macrophages.
Results: Transcriptome analysis identified ETS2 as the top differentially expressed genes. ETS2 expression levels were significantly higher in ACLF patients than patients with chronic liver disease and normal controls (all $p < 0.001$). High accuracy of ETS2 for ACLF short-term mortality (28-/90-day) prediction were observed (AuROC value: 0.9083/0.7725) (all $p < 0.001$). The activation of innate immune and the suppression of adaptive immune were observed in ACLF patients with high ETS2 expression. In vivo studies showed that myeloid-specific ETS2 deficiency aggravates the impairment of liver function, promotes the induction of pro-inflammatory cytokines and hepatocyte apoptosis. Ablation of ETS2 in macrophages increased the levels of high-mobility group box 1 (HMGB1) and LPS-induced IL-6 and IL-1 beta significantly ($p < 0.05$), and nuclear factor-kappa B inhibitor abolished the suppressive effect of ETS2.

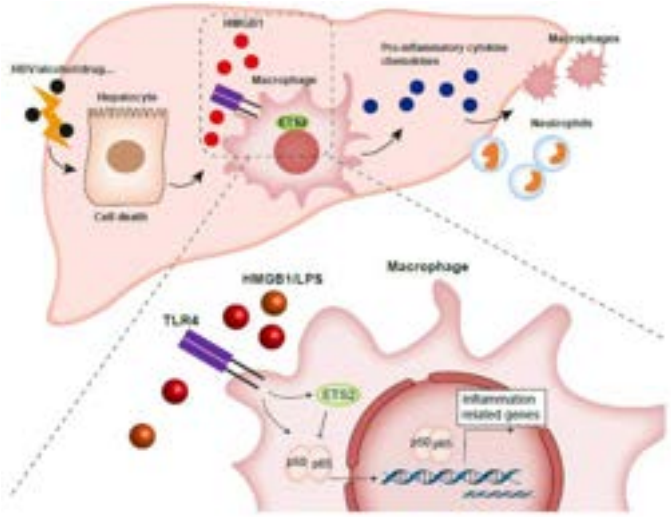

Figure:

Conclusion: Our study describes the role of ETS2 as a prognostic biomarker of ACLF patients. ETS2 protect mice from liver failure via alleviation of HMGB1-/lipopolysaccharide-triggered inflammation response in macrophages, and serve as a potential therapeutic target for ACLF.

OS-014-YI

Longitudinal change in the plasma metabotype indicates therapeutic plasma exchange in acute-on chronic liver failure patients should be done every 12 hours

Jaswinder Maras[1], Gaurav Tripathi[1], Vasundhra Bindal[1], Babu Mathew[1], Manisha Yadav[1], Nupur Sharma[1], Sadam H Bhat[1], Neha Sharma[1], Sushmita Pandey[1], Abhishak Gupta[1], Meenu Bajpai[2], Shiv Kumar Sarin[3], Rakhi Maiwall[3]. *[1]Institute of Liver and Biliary Sciences, Department of molecular and cellular medicines, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Department of Transfusion Medicine, Institute of Liver and Biliary Sciences, New Delhi, India; [3]Institute of Liver and Biliary Sciences, Department of hepatology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Therapeutic plasma exchange (TPE) has shown some benefits in ACLF patients as it reduces inflammatory cytokines, albumin/water-bound toxins and improves the survival of ACLF patients. Analogous changes in the plasma metabolic landscape post-TPE in ACLF patients are unknown and could predict non-survival or TPE requirements.
Method: In this study, TPE was performed on ACLF patients (N = 42), and plasma samples of patients were collected at pre-therapy (baseline), mid-therapy, post-therapy, and at 6hrs and 12hrs post-therapy, respectively. A total of 250 plasma samples were subjected to untargeted metabolomics using HRMS. Temporal change in the plasma metabolic profile of non-survivors was compared to survivors

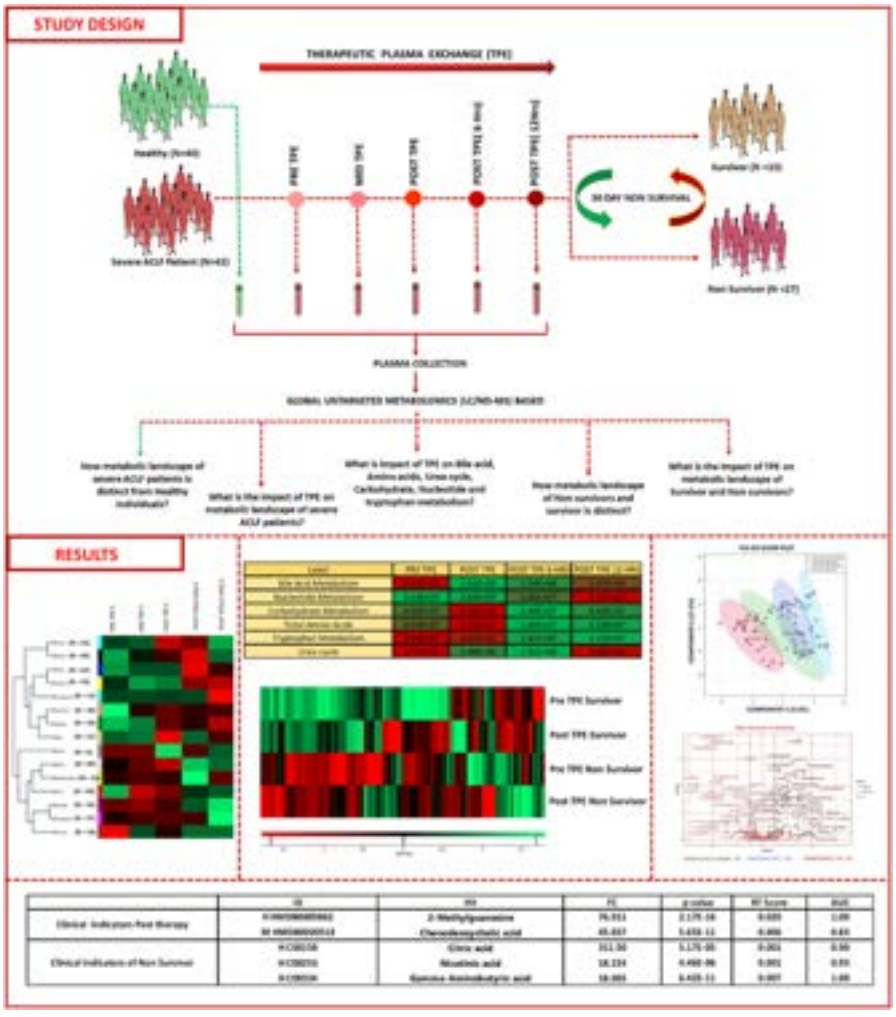

Figure: (abstract: OS-014-YI).

(30 days) using weighted metabolome correlation network analysis (WMCNA). Non-survivor-specific metabolites were identified (baseline) and subjected to clinical correlation and outcome prediction.
Results: Plasma metabolomics identified 620 features. ACLF patients, as compared to healthy, showed 142 metabolites (Up-77; Down-65 (FC >1.5, $p < 0.05$)). Partial Least Square-Discriminant Analysis (PLS-DA) analysis and hierarchical clustering segregated ACLF patients. ACLF patients showed dysregulated energy, nucleotide, amino acid metabolism, and others. Analysis of Post TPE compared to pre-TPE showed 130 metabolites (Up-63; Down-67 (FC >1.5, $p < 0.05$)) differentially expressed. PLSDA and hierarchical clustering showed clear distinction in the post-therapy metabolic landscape of ACLF patients. TPE specifically remodelled Tryptophan, Carbohydrate, Urea, and bile acid metabolism. Post-therapy levels of chenodeoxycholic acid and others (FC >76, AUC >0.9, $p < 0.05$) were responsible for the segregation of post-therapy metabotype. WMCNA and pathway enrichment analysis revealed a temporal post-TPE decrease in the urea cycle, bile acids, and tryptophan metabolism, whereas amino acids and carbohydrate metabolism-linked metabolites were increased. Interestingly the metabolic profile of ACLF showed a reversal of metabotype in 6 hrs which got prominent by 12 hrs suggesting an urgent need for another TPE. The plasma of non-survivors was highly enriched for DAMPS/PAMPS compared to survivors. Further, single TPE very effectively clears the plasma of survivors but was found ineffective for non-survivors. Non-survivors showed a significant increase in Citric acid, Nicotinic acid, and others (FC >10, AUC >0.99, $p < 0.05$), which directly correlated with the severity and clinical factors (MELD, SOFA, and others, R2 >0.7, $p < 0.05$) and can be used as a putative indicator for non-survival or requirement of TPE.
Conclusion: Temporal change in the metabolic phenotype of ACLF patients is predictive of TPE response, and an increase in plasma level of Citric acid, Nicotinic acid, and others by 12 hrs post TPE warrants an urgent need for another TPE in ACLF patients.

Gut microbiome/organ crosstalk

OS-015
Unexpected function of the cell cycle kinase Cyclin E/CDK2 for control of intestinal barrier: implications for gut-liver communication, liver fibrosis and liver cancer

Anna Verwaayen[1], Julia Hennings[1], Christian Penners[1], Adrien Guillot[2], Tobias Otto[1], Nicole Treichel[3], Thomas Clavel[3], Christian Trautwein[1], Yulia Nevzorova[4], Christian Liedtke[1]. [1]*University Hospital RWTH Aachen, Department of Medicine III, Germany;* [2]*Charité Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Germany;* [3]*Institute of Medical Microbiology, Functional Microbiome Research Group, University Hospital RWTH Aachen, Germany, Germany;* [4]*Department of Immunology, Ophthalmology and ENT, Complutense University School of Medicine, Madrid, Spain, Spain*
Email: cliedtke@ukaachen.de

Background and aims: E-type Cyclins (*i.e.* CCNE1, CCNE2) and their associated Cyclin-dependent kinase 2 (CDK2) control the transition from quiescence to the S-phase of the cell cycle. In addition, recent data point to several non-canonical functions of E-cyclins. In previous work, we demonstrated that constitutive deletion of the Cyclin E1 gene (*Ccne1*) in mice protected from liver fibrosis and hepatocellular carcinoma (HCC), while the underlying mechanisms are incompletely understood. In the present study, we tested the hypothesis that *Ccne1* expression contributes to liver fibrosis and hepatocarcinogenesis through modulation of the gut-liver axis and activation of Hepatic Stellate Cells (HSCs).
Method: We generated mice deficient for the whole Cyclin E/CDK2 complex in intestinal epithelial cells (*i.e. Ccne1*, *Ccne2*, and *Cdk2*, referred to as TKO mice). TKO mice at the age of twelve weeks were analysed for intestinal proliferation, gut barrier function, microbiota profiles and liver phenotypes. We also generated mice with deletion of *Ccne1* in Lecithin retinol acyltransferase (*Lrat*)-expressing cells ($Ccne1^{DHSC}$) targeting HSCs. $Ccne1^{DHSC}$ mice were either subjected to the Carbon tetrachloride/Diethylnitrosamine (DEN/CCl_4) model to induce liver fibrosis and HCC, or fed with the Lieber-DeCarli alcohol liquid diet to challenge the intestinal barrier. Identification of *Lrat*-expressing cells in the gut was performed using *Lrat-cre* reporter mice and multiplex immunostaining.
Results: Unexpectedly, TKO mice were characterized by enhanced gut barrier and up-regulation of Tight junction protein 1 (*Tjp1*), which was associated with reduced gene expression of Toll-like receptor 4 (*Tlr4*) in the liver. Additionally, TKO mice showed changes in microbial composition. $Ccne1^{DHSC}$ mice had significantly reduced liver fibrosis and HCC burden after DEN/CCl_4 treatment, which was related to impaired HSC activation and reduced hepatic *Tlr4* signaling. Importantly, *Lrat-cre* driven gene deletion did not only target HSCs, but also intestinal myofibroblasts and subpopulations of epithelial cells in the gut. Accordingly, $Ccne1^{DHSC}$ mice had reduced intestinal permeability and improved liver injury after chronic ethanol feeding.
Conclusion: Cyclin E1 is an important driver of liver fibrosis and HCC. These functions are mediated at least in part through HSC activation. We provide unexpected evidence that the Cyclin E/CDK2 complex is involved in the control of intestinal permeability. Thus, reduced liver fibrosis and HCC as found in $Ccne1^{-/-}$ or $Ccne1^{DHSC}$ mice might be supported by enhanced intestinal barrier and modulation of the gut-liver crosstalk.

OS-016
Association of gut microbiome with prospective risk of hepatocellular carcinoma in chronic hepatitis B patients: a prospective nested case-control study

Zhixian Lan[1], Qiuhong You[1], Kaifeng Wang[1], Rui Deng[1], Rong Fan[1], Xieer Liang[1], Dekai Zheng[1], Jinlin Hou[1], Jian Sun[1]. [1]*State Key Laboratory of Organ Failure Research, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, China*
Email: doctorsunjian@qq.com

Background and aims: Case-control studies showed a possible relationship between gut microbiome and hepatocellular carcinoma (HCC), but longitudinal study was lacking. Here, we aimed to prospectively investigate the association of gut microbiome with subsequent risk of HCC in chronic hepatitis B (CHB) patient.
Method: SEARCH-B Study (NCT02167503) was conducted to evaluate the effect of anti-viral treatment on long-term outcome on patients with CHB, which have included 3798 patients so far. Fecal samples have been collected when patients were enrolled in this cohort. A total of 70 incident HCC cases were ascertained after a median follow-up of 2.9 years. Using a prospective nested case-control design, 70 incident HCC cases and 280 controls were selected at a ratio of 1:4 by propensity score matching. 16S rRNA gene sequencing was performed to characterize the composition of gut microbiota. Cox proportional hazards models were used for the association of different taxonomies as well as KEGG pathways with overall HCC risk adjusted for age, gender, albumin, platelet and body mass index (BMI). Spearman correlation analysis was performed on different taxonomies and KEGG pathways to assess their correlations. The significant threshold is $p < 0.05$.
Results: At the order level, we found that *Gemellales* was associated with an increased risk of HCC with an HR (95% CI) of 1.22 (1.05–1.42). At the family level, a higher risk of HCC was also linked to greater richness of *Gemellaceae* and *Peptostreptococcaceae* with HR (95% CI) of 1.19 (1.02–1.37) and 1.18 (1.03–1.35) respectively. At the genus level, *Blautia* was significantly associated with higher risk of HCC (HR (95%

CI): 1.27 (1.03–1.57)). However, genus *Roseburia* and *Ralstonia* were significantly linked to a decreased incidence of HCC with HR (95% CI) of 0.61 (0.38–0.99) and 0 (0.00–0.64) respectively. The analysis of microbial functional characteristics showed that secondary bile acid biosynthesis pathway was related with a higher risk of developing HCC (HR (95% CI): 1.32 (1.04–1.67)). Furthermore, risky order *Gemellales*, family *Gemellaceae*, family *Peptostreptococcaceae* and genus *Blautia* were positively correlated with the risky secondary bile acid biosynthesis pathway, with which protective genus *Roseburia* were negatively correlated.

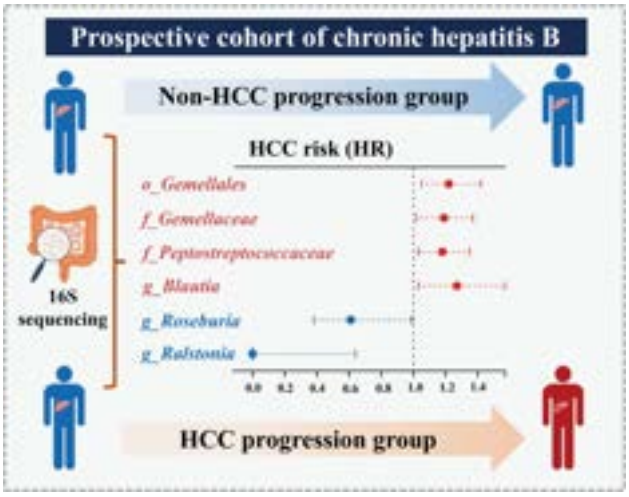

Figure:

Conclusion: This study demonstrated that several gut bacterial taxa were prospectively associated with HCC risk in our CHB cohort, which indicated that gut microbiome may play a significant role in the etiology of HCC in CHB patients, but more experiments are needed to clarify the causal relationships.

Serum villin-1 level-a tell-tale sign of gut barrier failure in patients with cirrhosis and acute decompensation

David Tornai[1], Boglárka Balogh[1], Aniko Csillag[1], Budai András[2], András Kiss[2], Péter Antal-Szalmás[3], Gábor Méhes[4], Lukács Baráth[4], Tamas Tornai[5], Istvan Tornai[1], Zsuzsanna Vitális[1], Nóra Sipeki[1,6], Patricia Kovats[1], Jonel Trebicka[7,8], Maria Papp[1]. [1]*University of Debrecen, Division of Gastroenterology, Department of Internal Medicine, Faculty of Medicine, Debrecen, Hungary;* [2]*Semmelweis University, Department of Pathology, Forensic and Insurance Medicine, Faculty of Medicine, Budapest, Hungary;* [3]*University of Debrecen, Department of Laboratory Medicine, Faculty of Medicine, Debrecen, Hungary;* [4]*University of Debrecen, Department of Pathology, Faculty of Medicine, Debrecen, Hungary;* [5]*Semmelweis University, Institute of Pancreatic Diseases, Budapest, Hungary;* [6]*Faculty of Medicine, University of Debrecen, Division of Gastroenterology, Department of Internal Medicine, Debrecen, Hungary;* [7]*University of Münster, Department of Internal Medicine B, Münster, Germany;* [8]*European Foundation for Study of Chronic Liver Failure, EF-CLIF, Barcelona, Spain*
Email: papp.maria@med.unideb.hu

Background and aims: Dysfunctional and leaky gut barrier are characteristics of cirrhosis and associated with disease progression and mortality. Utility of biomarkers, indicating the presence and extent of intestinal barrier dysfunction, remains a controversial issue in the prognosis and risk stratification of decompensated cirrhosis. Villin-1 (VIL1) is an actin-bundling protein, present in the intestinal, renal and biliary brush border. VIL1 is downregulated in response to chronic injury and diverse cellular stressors, including the microbiome, while during acute stress it is redistributed from the brush border to the basolateral membrane, which facilitates its release into the blood. We investigated clinical significance of serum VIL1 levels in patients with cirrhosis and acute decompensation (AD).
Method: Patients (n = 86) and healthy controls (HC; n = 50) from the MICROB-PREDICT cohort were tested for serum VIL1 by ELISA. Four patient severity sub-groups were defined according to the PREDICT study (stable AD (SDC), unstable AD (UDC), pre-ACLF and ACLF [acute-on-chronic liver failure]). VIL1 immunohistochemistry (IHC) evaluation of duodenum biopsy was performed in a sub-cohort of the patients (n = 13) and controls (n = 11).
Results: Serum VIL1 levels were decreased in SDC patients (median [IQR]: 6.5 [4.9–10.4] vs 12 [8.4–14.9] ng/ml, p < 0.001) compared to controls and increased in more severe disease. This difference was confirmed in duodenum tissue by IHC. Significantly higher serum VIL1 levels were detected in pre-ACLF patients compared to those who did not develop ACLF (10.7 [7.8–22.9] vs 6.9 [5.0–10.5] ng/ml, p = 0.004), while in ACLF survivors decreased VIL1 levels were observed on day-7 compared to day-0 (9.8 [7.3–14.6] vs 12.7 [9.7–18.1] ng/ml, p = 0.010). High serum VIL1 levels (≥16.17 ng/ml) predicted 90-day mortality (AUROC:0.73, 95%CI: 0.563–0.888, p = 0.013) and in combination with high (≥50) CLIF-C AD score the prediction accuracy was excellent (both is high: 75%; all other together: 8% mortality, LogRank p < 0.001). High serum VIL1 level was able to predict mortality both in the presence (20% vs 62% LogRank p = 0.030) and absence (14% vs 40% LogRank p = 0.008) of renal failure.
Conclusion: Besides the six organ failures included in CLIF-SOFA, patients with cirrhosis and AD may also develop intestinal failure, as an additional organ failure. Serum VIL1 level could reliably indicate this organ failure and made the mortality risk stratification performed by CLIF-C OF score more accurate.
The MICROB-PREDICT project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 825694. Offspring of obese mothers have a higher risk for hepatocellular carcinoma through the transmission of an altered gut microbiome

Beat Moeckli[1,2], Vaihere Delaune[1], Benoit Gilbert[3], Andrea Peloso[1], Graziano Oldani[1], Sofia El Hajji[2], Florence Slits[2], Quentin Gex[2], Stéphanie Lacotte[2], Christian Toso[1,2]. [1]*Geneva University Hospitals, Departement of Surgery, Geneva, Switzerland;* [2]*University of Geneva, Transplantation and hepatology laboratory, Genève, Switzerland;* [3]*University of Geneva, Departement of rhumatology, Genève, Switzerland*
Email: beat.moeckli@gmail.com

Background and aims: The obesity pandemic leads to rising number of obese women of reproductive age. Emerging evidence suggests that maternal obesity has a negative impact on the long-term health of offspring. Additionally, obesity is an independent risk factor for malignancies and particularly hepatocellular carcinoma (HCC). The aim of our study is to investigate the impact of maternal obesity on the risk for HCC in the offspring and identify potential mechanisms of transmission.
Method: Female mice were fed either a high fat (HFD) or a normal diet (ND) before mating. Offspring received ND throughout life. In the offspring we studied the gut microbiome, liver histology, inflammatory patterns and tumor load in a diethylnitrosamine induced HCC mouse model. To normalize the gut microbiome, we co-housed offspring of HFD and ND mothers after weaning. The composition of the gut microbiota was assessed through 16S rRNA sequencing.
Results: Maternal obesity induced a distinguishable shift in the microbial composition towards decreased microbial diversity (2.56 vs. 2.92, p = 0.0089), increased proportions of Firmicutes and decreased abundance of Bacteroidota. Only at 40 weeks female HFD offspring developed steatosis (9.43 vs 3.09%, p = 0.0023) and a higher

number of inflammatory infiltrates (4.8 vs 1.0, p = 0.018) compared to ND offspring. Additionally inflammatory markers such as *TLR4*, *MHCII*, *iNOS* and *CXCL16* were overexpressed in offspring of obese mothers. A higher proportion of female HFD offspring developed liver tumors after DEN induction (79.8 vs 37.5%, p = 0.0084) with a higher total tumor volume at 36 weeks (234 vs 3 μm^3, p = 0.0041). Co-housing offspring of obese and lean mothers corrected the gut microbiome composition and co-housing normalized the tumor number and volume to the level of ND offspring. Abundance of Erysipelotrichaceae was positively ($R = 0.46$, $p = 0.003$) and Lachnospiraceae negatively ($R = -0.35$, $p = 0.029$) correlated with tumor load.

Conclusion: Maternal obesity increases the susceptibility for chronic liver disease and HCC in the offspring. The transmission of an altered gut microbiome appears to play an important role in this increased risk profile.

OS-019

Lactobacillus protects against leaky gut, future decompensation, and hepatic encephalopathy in patients with cirrhosis

Patricia Bloom[1], Vincent B. Young[1], Anna Lok[1]. [1]*University of Michigan, United States*
Email: ppbloom@med.umich.edu

Background and aims: Several complications of cirrhosis result from the translocation of bacteria or their products across a leaky gut; however, little is known about how mucosal bacteria (lining the intestinal epithelia) influence intestinal permeability and clinical cirrhosis outcomes. We aimed to assess if mucosal bacteria associate with intestinal permeability and predict future hospitalization for hepatic decompensation.

Method: We obtained duodenum, ileum, and colon tissue biopsies from patients with cirrhosis. Patients were excluded if they recently used non-rifaximin antibiotics or immunosuppression. Composition of the mucosal microbiota was determined via 16S rRNA gene sequencing and epithelial permeability assessed by measuring transepithelial electrical resistance (TEER). Patients were followed until they met the primary outcome of hospitalization for cirrhosis decompensation or were censored at last visit, liver transplantation, or death. Associations between microbiota relative abundance and clinical outcomes were assessed in a beta binomial model with a false discovery rate of 0.05.

Results: We studied 58 patients with cirrhosis and obtained biopsies from 49 duodenums, 16 ileums, and 20 colons. Patients had median MELD 8 (IQR 7, 10), 62% were male, 16 (28%) had a history of hepatic encephalopathy (HE) and 28 (49%) had a history of ascites. In follow-up of median 192 days (IQR 79, 548), 14 were hospitalized for cirrhosis decompensation after median 90 days (IQR 50, 173), 7 of which were due to overt HE (2 of these patients had prior HE, 5 did not).

Including all gut segments, a beta binomial model found 37 mucosal bacteria were associated with future hospitalization for decompensation (5 positively associated, 32 protective) and 28 were associated with future overt HE episodes (5 positively associated, 23 protective). Of the taxa identified in these models, a *Lactobacillus* was significantly correlated with higher TEER (less leaky gut; $r^2 = 0.23$, $p = 0.05$), and protective of future overt HE and hospitalization for decompensation (Figure).

Sensitivity analyses were performed on duodenal samples only, the gut segment with the largest number of samples. A beta binomial model found 17 mucosal bacteria were associated with hospitalization for decompensation and 15 with future overt HE. Duodenal *Lactobacillus* was protective of future overt HE and decompensation.

Conclusion: Certain mucosal bacteria are associated with future cirrhosis decompensation hospitalizations and overt HE. *Lactobacillus*, a known probiotic, was associated with intact epithelial permeability and protected against HE and cirrhosis decompensation. Targeting mucosal microbiota and intestinal permeability may prevent HE and hospitalization among patients with cirrhosis.

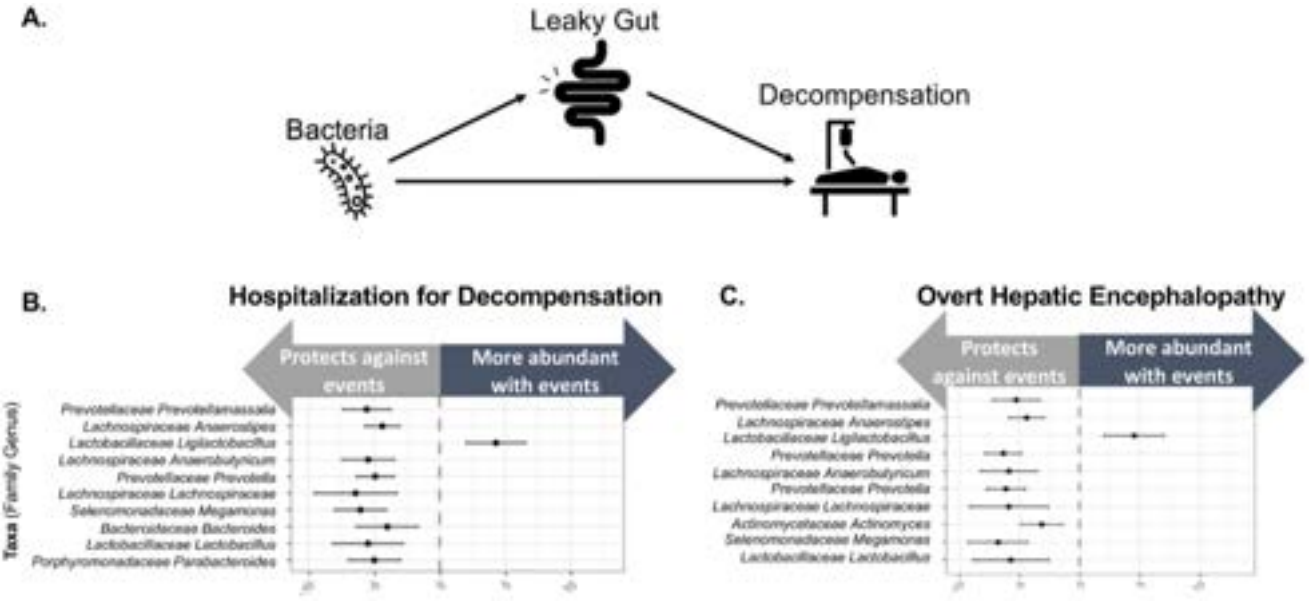

Figure: (abstract: OS-019): (A) Proposed causative pathway to cirrhosis decompensation; (B) Top 10 taxa that predicted hospitalization for decompensation; (C) Top 10 taxa that predicted overt hepatic encephalopathy

Liver tumours – Basic

Multiplatform single cell spatial dissection of the invasive front of hepatocellular carcinoma (HCC) reveals molecular insights into tumor progression

Josephine Zhang[1], Nia Adeniji[2], Akanksha Suresh[3], Lea Lemaitre[1], Vivek Charu[4], Brendan Visser[5], C. Andrew Bonham[6], Renumathy Dhanasekaran[1]. [1]*Stanford University School of Medicine, Medicine- Division of Gastroenterology and Hepatology, Stanford, United States;* [2]*UCSF School of Medicine, Medicine, San Francisco, United States;* [3]*The Johns Hopkins University School of Medicine, Medicine, Baltimore, United States;* [4]*Stanford University School of Medicine, Pathology, Stanford, United States;* [5]*Stanford University School of Medicine, Surgery- General Surgery, Stanford, United States;* [6]*Stanford University School of Medicine, Surgery- Multi-Organ Transplantation, Stanford, United States*
Email: dhanaser@stanford.edu

Background and aims: Cells at the invasive edge of a tumor evade immune surveillance and drive tumor progression. However, characterization of HCC cells along the tumor edge has remained elusive. Here, we used three powerful spatial technologies to perform multiregional profiling of primary HCC lesions and identify how heterogenous tumor evolution from the central core to the invasive edge drives disease progression.
Method: We prospectively obtained 30 tissue samples from HCC tumor specimens of 7 patients undergoing surgical resection, under appropriate IRB approval. We generated a tissue microarray of these samples to analyze 48,458 cells from three distinct regions: tumor core (7 samples, 15,668 cells), invasive edge (14 samples, 23,234 cells), and uninvolved liver (10 samples, 9,556 cells). We used CODEX, a 42-plex immunofluorescent imaging approach, to identify cell

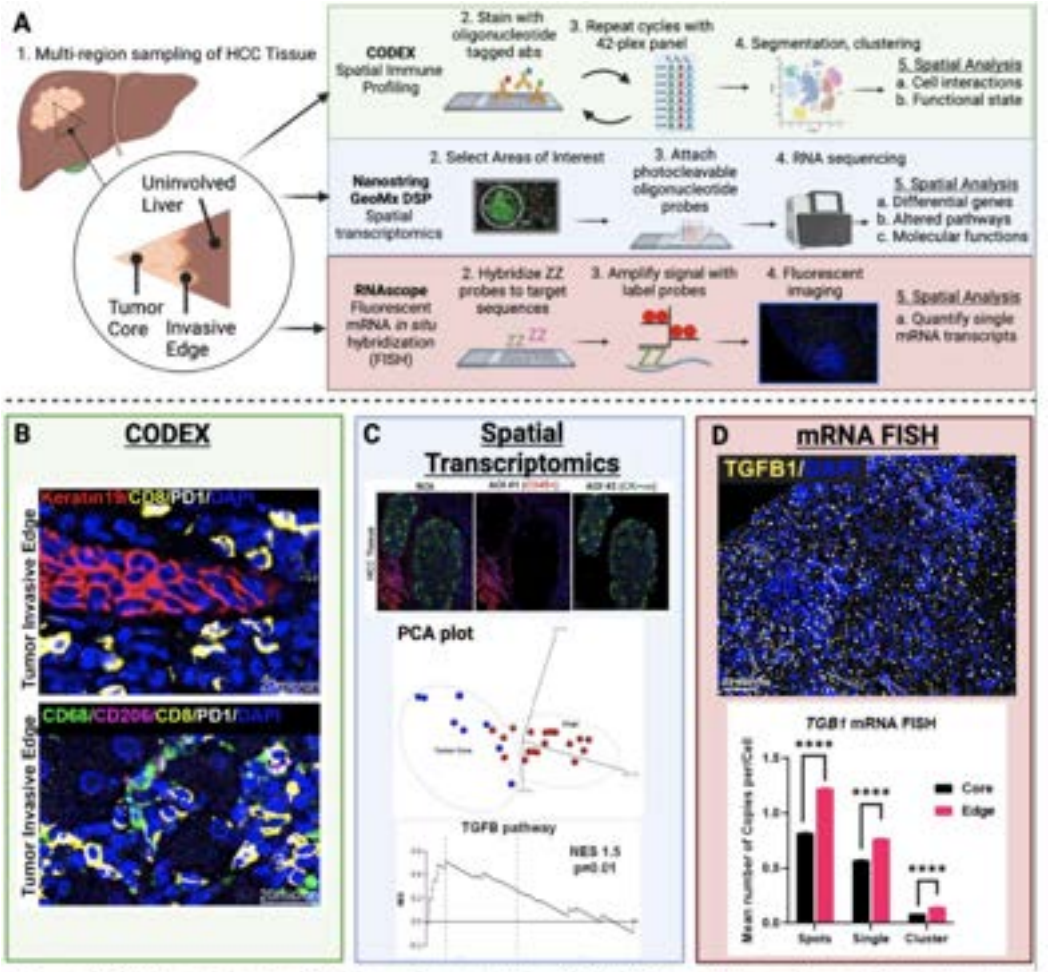

Figure 1. A) Study design: Multi-region sampling of HCC tissue followed by single cell spatial analysis. We use three powerful technologies : CODEX, a 42-plex immunofluorescent imaging approach; Nanostring GeoMx, a spatial transcriptomic platform; and RNAscope, an mRNA FISH assay. B) CODEX reveals enrichment of CK 19+ cancer stem-like cells at the invasive edge and their interaction with exhausted CD8+ T cells. C) Spatial transcriptomics determines gene expression in the CK+ tumor compartment and CK-/CD45+ TME. PCA plot indicates separate clusters between tumor core and invasive edge . The TGFβ pathway is the most upregulated pathway along the edge. D) mRNA FISH validates TGFβ upregulation, showing that TGFB1 transcripts are more abundant at the invasive edge than in the tumor core

Figure: (abstract: OS-020-YI).

populations and interactions. A spatial transcriptomic platform, Nanostring GeoMx, determined gene expression and molecular pathway involvement of 1,812 genes in regions of interest classified into tumor (CK+) and microenvironment (TME) (CK-/CD45+). We used fluorescent RNA *in situ* hybridization (mRNA FISH) to validate gene expression at the single-cell level (Fig. 1A).

Results: We identified 20 unique tumor, immune, and stromal cell types in our samples with CODEX. The invasive edge had a higher proportion of endothelial cells ($p = 0.003$), CD4+ T cells ($p = 0.01$), exhausted CD8+ T cells ($p = 0.04$), and fibroblasts ($p = 0.04$) than the uninvolved liver. Moreover, the edge had a higher proportion of CK19 + cancer stem-like cells ($p = 0.03$) than the tumor core. The CK19+ cancer stem-like cells interacted with exhausted CD8+ T cells ($p = 0.01$), CD4+ T cells ($p = 0.02$), and fibroblasts ($p = 0.04$) more frequently at the invasive edge than at the core (Fig. 1B). We also observed more frequent interactions between CD206+ and PDL1+ M2-like macrophages and CD8+ T cells ($p = 0.02$). Spatially resolved transcriptomics identified 141 genes that were differentially expressed in the CK+ tumor compartment of invasive edge vs the core, including upregulation of several genes which promote pro-tumoral inflammation (*SERPING1*, *IL6ST, CD81*, *NCOR1*, *PSEN1*). The TME of the invasive edge vs the core showed differential expression of 38 genes including upregulation of immune modulating genes (*CD164*, *ST6GAL1*, *ITCH*) (Fig. 1C). Enrichment analysis revealed that TGF-beta pathway was the top upregulated pathway in the invasive edge (NES 1.46, $p = 0.01$). Through mRNA FISH, we validated that *TGFB1* mRNA transcripts, both as single copies and clusters per cell, were indeed more abundant in the invasive edge than the core (47% of cells in the edge vs. 36% in the core ($p < 2810^{-16}$) (Fig. 1D).

Conclusion: We integrate multiplatform single cell spatial data from multi-region sampling of HCC and demonstrate dramatic remodelling of the immune microenvironment along the invasive edge of the tumor. Compared to the core, the invasive edge of the tumor is enriched in aggressive CK19+ cancer stem-like cells and exhausted CD8+ T cells which interact with each other and with M2-like macrophages. Further, we determine and validate TGF-beta pathway activation as the master regulator of cancer stemness and anti-tumor immunity along the invasive edge. Collectively, our spatial analysis provides mechanistic insights into how molecular events along the edge fuel tumor progression and identifies molecular targets for therapy.

OS-021-YI

Myeloid-derived cells suppress CD8+ T cells by arginase-1 through interaction with stellate cells in the microenvironment of hepatocellular carcinoma

Sung Eun Choi[1], Jong-Min Jeong[1], Kyurae Kim[1], Won-il Jeong[1,2]. [1]*Korea Advanced Institute of Science and Technology (KAIST), Graduate School of Medical Science and Engineering (GSMSE), Daejeon, Korea, Rep. of South;* [2]*Center for the Hepatic Glutamate and Its Function, KAIST, Daejeon, Korea, Rep. of South*
Email: wijeong@kaist.ac.kr

Background and aims: Hepatocellular carcinoma (HCC) is one of the leading causes of deaths worldwide and its occurrence relies heavily on the onset of liver cirrhosis. Various hepatic and immune cells, namely hepatic stellate cells and macrophages, are reported to be activated near the tumour area during HCC development, and yet their mechanisms of migration or intercellular interaction have not been fully elucidated. Here, we aim to investigate the mechanism regulating the migration of pro-tumorigenic immature macrophages and their interaction with activated HSCs (aHSCs) in the HCC microenvironment.

Method: 2-week-old male mice were intraperitoneally injected with 20 mg/kg diethylnitrosamine (DEN) for HCC induction and bred for 40 weeks for tumour formation. $eGFP^+$, $CX_3CR1GFP/GFP$, or Arg1-YFP $Ly6C^+$ bone marrow (BM) cells were adoptive transferred to observe the migration of immature macrophages and their interaction with aHSCs via arginase-1 (Arg1) expression. Mice with myeloid-specific depletion of Arg1 ($LyzM^{\Delta Arg1}$) were utilised to observe the changes in $CD8^+$ T cell proliferation and HCC progression. *In vitro* co-culture system was adopted to further confirm the findings *in vivo*.

Results: The frequency of $CD14^+CD11b^+HLA\text{-}DR^-$ and $CD11b^+Ly6G^-Ly6C^{high}$ macrophages was elevated in blood and liver tissues of clinical and DEN-induced HCC, respectively, whereas the frequency of hepatic $CD8^+$ T cells was decreased compared to healthy controls. From the adoptive transfer of eGFP+ BM cells, we found that $CD11b^+Ly6G^-Ly6C^{high}$ macrophages were located particularly near the aHSCs in the peritumour area, expressing high level of CX_3CR1, Arg1, and iNOS. In CX_3CR1-depleted HCC-bearing mice, the expression of Arg1, iNOS and IL-10 was reduced in hepatic immune cells along with markedly reduced interaction of $Ly6C^+$ cells with CX_3CL1^+ aHSCs.$Ly6C^+$ BM cells co-cultured with aHSCs revealed that immature $Ly6C^+$ BM cells highly expressed Arg1 while the expression of genes related to retinoid metabolism (Raldh1, RARα/β, RXRα/β) was elevated in aHSCs, indicating that Arg1 expression in immature macrophages may have been induced by retinoids produced from aHSCs. In fact, co-incubation of $CD8^+$ T cells with $Ly6C^+$ BM cells pre-co-cultured with aHSCs exhibited suppressed proliferation of CD8+ T cells, supporting the acceleration of HCC. These findings in vitro were further confirmed by reduced hepatic tumourigenesis in $LyzM^{\Delta Arg1}$ mice compared to controls.

Conclusion: We showed that CX_3CR1-expressing $CD11b^+Ly6G^-Ly6C^{high}$ cells migrate and interact with aHSCs in the peritumour region. Retinoids produced from the aHSCs induce Arg1 expression in the migrated immature macrophages, subsequently depriving $CD8^+$ T cells of arginine to be used for proliferation and promoting the progression of HCC. By proposing the abovementioned mechanism, we suggest CX_3CR1 and Arg1 as potential therapeutic targets of HCC.

Email: leonardkaps@googlemail.com

Background and aims: Cancer associated fibroblasts (CAF) support tumor growth and metastasis in the tumor microenvironment (TME) and are therefore promising target cells for anti-stromal therapy in solid tumors [Kaps, Schuppan; Cells 2020]. We have designed a novel polypeptoide nanoparticle (NP) with improved endosomal escape for small interfering RNA (siRNA) delivery into stroma cells of hepatocellular carcinoma (HCC) [Birke et al., Prog. Polym. Sci. 2018]. NPs loaded with CAF targeting siRNA were tested in a murine model of primary liver cancer.

Method: In vitro screening for CAF relevant target genes revealed that the CAF derived microfibrillar-associated protein 5 (MFAP-5) was highly upregulated in fibroblasts (3T3 fibroblasts and MHSC-SV40 hepatic stellate cells) when co-cultured with HCC cells (Dt81Hepa1-6). NPs have been designed utilizing the triblock copolymer polysarcosine-b-poly(-benzyl glutamic acid)-b-polylysine, which enables co-loading of siRNA and desloratidin, an antihistamine that triggers endosomal release of siRNA after cell

uptake. NPs loaded with Cy-5.5 labeled control siRNA were efficiently taken up by fibroblasts and induced a robust knockdown (<50%) at low siRNA concentrations (≤5 nM) in these cell lines as assessed by FACS and qPCR analysis, respectively. For the HCC model, B6 mice were intrasplenically injected with 500.000 HCC cells to develop macroscopic tumor lesions exclusively in their livers after 28 days. In vivo studies using NPs loaded with Cy5.5 labeled control siRNA were performed in healthy and HCC mice. After intravenous injection, NPs distributed preferentially to the liver (>80%), while biodistribution did not differ between healthy versus tumor mice. Ex vivo FACS analysis of digested livers confirmed a cellular uptake of NPs in CAF (FAP+) >macrophages (CD45+, F4/80+, CD11b+) >dendritic cells (CD45+, F4/80+, CD11c+). For in vivo anti-stromal therapy, tumor mice (n = 5) received three intravenous injections of NPs loaded with anti-MFAP-5 siRNA (corresponding to 0.5 or 1 mg/kg siRNA) in week four, while controls received equal concentrations of NPs loaded with non-targeting scrambled siRNA (scsiRNA).

Results: Liver weights of mice treated with anti-MFAP-5 siRNA were significantly (*$p < 0.05$) lower compared to mice treated with encapsulated scsiRNA, indicating less hepatic tumor burden. Efficient vivo knockdown of MFAP-5 was confirmed on RNA and protein level by qPCR and FACS analysis, respectively, while controls had similar MFAP-5 levels like healthy mice. The treatment was well tolerated by the mice and serum parameters for liver- and nephrotoxicity were in the normal range. Histological analysis of liver sections revealed that markers of tumor vascularization (e.g. CD34, CD105) were downregulated by the siRNA treatment in the TME, suggesting that the knockdown of MFAP-5 may inhibit angiogenesis.

Conclusion: Liver targeting NPs loaded with siRNA induced a gene specific knockdown of CAF derived MFAP-5 and demonstrated a convincing antitumor effect by interference with angiogenesis in the TME of HCC.

OS-023-YI

Remodeling of myeloid cells during hepatocellular carcinoma driven by beta-catenin activation

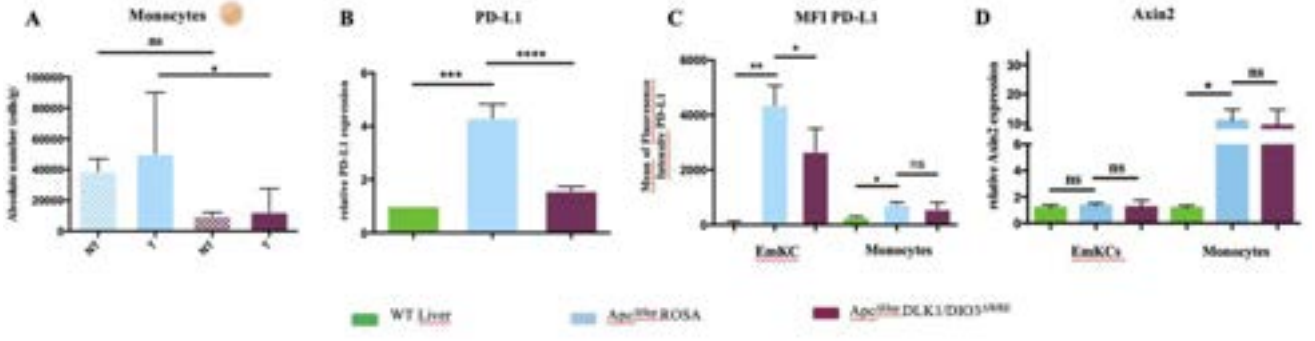
Camille Joubel[1,2], Lucie Poupel[1], Julie Sanceau[1], Sabine Colnot[1], Angélique Gougelet[1]. [1]*INSERM UMRS 1138 Cordeliers Research Center, Team "Oncogenic functions of beta-catenin in the liver", Paris, France;* [2]*Université Paris Cité, Doctoral School 561 HOB, Paris, France*
Email: camille.joubel@inserm.fr

Background and aims: Hepatocellular Carcinoma (HCC) is the paradigm of inflammation-associated tumors and is one of the deadliest cancers in the world. Recently, immunotherapies (IT) give promising results in almost 30% of HCC, while mutations in beta-catenin signaling detected in 30% of HCCs appear to be associated with resistance to IT. In the liver, coexist resident Kupffer cells (emKCs), able to self-renew, and inflammatory monocyte-derived macrophages (moKCs) recruited and differentiated from circulating monocytes upon liver injuries. Our work aims at exploring how an oncogenic beta-catenin signal in hepatocytes gives rise to a switch from protective emKCs to inflammatory moKCs permissive to HCC and how it affects response to IT.

Method: We have created relevant murine models, targeted Apc or Ctnnb1, that closely recapitulate human HCC features and enables kinetic studies from early pre-neoplastic states to advanced tumors (Loesch et al, JHep, 2022; Gougelet et al. Gastroenterology, 2019). Non-parenchymal cells (NPCs) are freshly isolated together with pre-neoplastic hepatocytes by liver perfusion or from murine tumors. They are either analyzed by flow cytometry or cultured, alone or with hepatocytes, for further analyses. In parallel, cell supernatants were collected to study exosome content after their purification by ultracentrifugation.

Results: Tumorigenesis driven by beta-catenin is associated with a strong infiltration of monocytes and a gradual replacement of emKCs by moKCs in both tumors and adjacent non-tumor tissues. We showed that beta-catenin activation in pre-neoplastic hepatocytes leads to an activation of this pathway at distance in emKCs and monocytes. More strikingly, the expression of the immune check-point inhibitor PD-L1 on both cells is induced in both preneoplastic livers and tumors. We additionally highlighted that non-coding RNAs (ncRNAs) produced from the DlK1/Dio3 locus, a positive target of the beta-catenin that we recently found to be involved in liver tumorigenesis, are encapsulated into exosomes and oversecreted by preneoplastic hepatocytes and NPCs activated for the beta-catenin pathway. The impairment of the Dlk1/Dio3 locus by CRISPR/Cas9 significantly impaired the proportions of monocytes in tumors and non-tumors tissues as well as PD-L1 expression.

Conclusion: During early steps of liver tumorigenesis, pre-neoplastic hepatocytes with beta-catenin overactivation educate surrounding myeloid cells through their subsequent activation for beta-catenin signaling and the downstream induction of ncRNAs produced from the Dlk1/Dio3 locus in favor of HCC progression. These ncRNAs seems to participate to myeloid cell education, in part through exosomal transfer communication and PD-L1 dysregulation. We are now exploring their potential implication in the resistance to IT of this group of HCC.



The impairment of the Dlk1/Dio3 locus (DLK1/DIO3$^{\Delta WRE}$) in Apc$^{\Delta Hep}$ livers limits the recruitment of monocytes in tumors and non-tumor tissues (A). It also decreases the induction of Cd274 (PD-L1), seen in RT-qPCR in Apc$^{\Delta Hep}$ tumors (B). PD-L1 expression was mainly detected by cytometry on monocytes and emKCs (C). The activation of beta-catenin signaling in Apc$^{\Delta Hep}$ hepatocytes induces Axin2 expression in monocytes (D).

Figure: (abstract: OS-023-YI): Beta-catenin overactivated hepatocytes reprogram myeloid cells during HCC progression.

OS-024-YI

Scavenger receptor MARCO is associated with an immunosuppressive microenvironment and tumor progression in intrahepatic cholangiocarcinoma

Email: matxus.perugorria@biodonostia.org

Background and aims: Cholangiocarcinoma (CCA) comprises a heterogeneous group of malignant tumours with dismal prognosis. During the last years, different studies have highlighted the key role of the immune system in the development of intrahepatic CCA (iCCA) and several combinational therapies targeting the tumour microenvironment (TME) have shown promising results for anti-cancer therapy. In this regard, the macrophage receptor with collagenous structure (MARCO) is a class A scavenger receptor found on particular subsets of macrophages that has been described to play a determining role in macrophage polarization and consequently in adaptive immune responses in many solid tumours. However, its role in iCCA is still unknown. This study aims to unravel the role of MARCO in iCCA development and progression.

Method: The cell-type specific *MARCO* expression was examined in iCCA human tumours by using publicly available single-cell RNA sequencing data from different studies and *MARCO*-expressing tumour-associated macrophages (TAMs) were phenotypically characterized. *MARCO* mRNA expression was analyzed in human control and iCCA liver tissue samples and associated to different immune cell types and immune-functionality scores employing state-of-the-art technologies as ConsensusTME, Tumour Immune Dysfunction and Exclusion (TIDE) tool and Tumour Immunophenotype Profiling (TIP). To study the role of MARCO in murine cholangiocarcinogenesis, wild type (WT) and *Marco*$^{-/-}$ mice were subjected to 3 different iCCA murine models and flow cytometry analysis of the TME was carried out to characterize different lymphocytic and myeloid populations.

Results: Single-cell RNA sequencing data indicate that *MARCO* is expressed in a specific subtype of TAMs in patients with iCCA. Besides, high *MARCO* expression levels in the liver samples of patients with iCCA are linked with worse clinical outcome. In line with this, *MARCO* expression in human iCCA tumours is associated to cell types involved in tumour progression such as M2 macrophages, and related with T cell dysfunction. Regarding the potential role of MARCO in murine models of iCCA, *Marco*$^{-/-}$ mice show a trend to be protected from iCCA development, the mechanisms behind this effect being likely associated to a reduction of the innate immune cells such as CD9^{+}Ly6C^{-}F4/80^{+} resident macrophages and type-2 innate lymphoid cells (ILC2). Noteworthy, in a context of a syngeneic orthotopic experimental model, *Marco*$^{-/-}$ mice exhibit a reduced presence of immune checkpoint molecules in innate and adaptive immune cells, including a lower percentage of PD-L1^{+}Ly6C^{-}F4/80^{+} resident macrophages and, PD-1^{+} and CTLA-4^{+} cytotoxic CD8^{+} T cells in comparison to WT mice. In addition, MARCO deficiency significantly improves the overall survival of mice subjected to the orthotopic injection of syngeneic CCA cells into the liver. This was associated with a reduction of the tumour metastasis in the lungs.

Conclusion: High *MARCO* expression is associated to a worse outcome in patients with iCCA and is associated to an immunosuppressive TME. Importantly, *Marco*$^{-/-}$ mice display a reduced presence of immunosuppressive cell populations and present an increased overall survival. Therefore, MARCO arises as a novel therapeutic target for iCCA.

NAFLD: Diagnostics and non-invasive assessment

A clinical care pathway to detect advanced liver disease in patients with type 2 diabetes through automated fibrosis score calculation and electronic reminder messages: a randomised controlled trial

Xinrong Zhang[1], Terry Cheuk-Fung Yip[1], Grace Lai-Hung Wong[1], Wei-Xuan Leow[2], Yan Liang[1], Lee-Ling Lim[3], Guanlin Li[1], Luqman Ibrahim[3], Huapeng Lin[1], Che To Lai[1], Henry LY Chan[1], Alice Pik-Shan Kong[1], Wah-Kheong Chan[2], Vincent Wai-Sun Wong[1].
[1]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong; [2]University of Malaya, Gastroenterology and Hepatology Unit, Malaysia; [3]University of Malaya, Endocrinology Unit, Malaysia
Email: wongv@cuhk.edu.hk

Background and aims: The majority of patients with non-alcoholic fatty liver disease (NAFLD) are seen at primary care and non-hepatology settings. Although several studies have demonstrated the successful implementation of clinical care pathways with the involvement of highly motivated clinicians, the findings may not be generalised. We aimed to test the hypothesis that automated fibrosis score calculation and electronic reminder messages could increase the detection of advanced liver disease in patients with type 2 diabetes.

Method: In this pragmatic, single-blind, randomised controlled trial at 5 general medical or diabetes clinics in Hong Kong and Malaysia, we randomly assigned patients in a 1:1 ratio to the intervention group with Fibrosis-4 index and aspartate aminotransferase-to-platelet ratio index automatically calculated based on routine blood tests followed by electronic reminder messages to alert clinicians of abnormal results, or the control group with usual care. The primary outcome was the proportion of patients with increased fibrosis scores who received appropriate care (referred for hepatology care or specific fibrosis assessment) within 1 year. This trial is registered with ClinicalTrails.gov, number NCT04241575.

Results: Between May 19, 2020, and Oct 14, 2021, 1379 patients were screened, of whom 533 and 528 were assigned to the intervention and control groups, respectively. A total of 55 out of 165 (33.3%) patients with increased fibrosis scores in the intervention group received appropriate care, compared with 4 of 131 (3.1%) patients in the control group ($p < 0.001$) (Table). Overall, 11 of 533 (2.1%) patients in the intervention group and 1 of 528 (0.2%) patients in the control group were confirmed to have advanced liver disease (liver stiffness ≥10 kPa and/or cirrhotic complications) ($p = 0.006$). Among patients attending hepatology care, 33 had NAFLD, and 22 had no liver disease identified.

	Intervention group	Control group	p value
Primary outcome			
Proportion of patients with high fibrosis scores who were referred for hepatology care or further fibrosis assessment	55/165 (33.3)	4/131 (3.1)	<0.001
Secondary outcomes			
Proportion of patients in the entire cohort who were referred for hepatology care or further fibrosis assessment	57/533 (10.7)	6/526 (1.1)	<0.001
Proportion of patients with low fibrosis score who were referred for hepatology care	1/368 (0.3)	2/397 (0.5)	>0.999
Proportion of patients confirmed to have advanced liver disease*	11/533 (2.1)	1/526 (0.2)	0.006

Data are number (%).
*Advanced liver disease was defined as liver stiffness measurement ≥10 kPa and/or development of cirrhotic complications.

Figure:

Conclusion: Automated fibrosis score calculation and electronic reminders can increase identification of advanced liver disease in patients with type 2 diabetes at non-hepatology settings. However, over half of patients with increased fibrosis scores did not receive appropriate care, and a minority of referred patients actually had advanced liver disease. The findings of this trial serve as the basis to further refine the clinical care pathway.

OS-026

Performance of the AGA clinical care pathway in identifying patients with at-risk non-alcoholic steatohepatitis: combined data from multiple therapeutic clinical trials including more than 5,000 patients (in collaboration with NAIL-NIT consortium)

Naim Alkhouri[1], Julie Dubourg[2], Stephen Harrison[3], Michael Charlton[4], Vlad Ratziu[5], Jörn Schattenberg[6], Sophie Jeannin Megnien[2], Mazen Noureddin[7]. *[1]Arizona Liver Health, Chandler, United States; [2]Summit Clinical Research, San Antonio, United States; [3]University of Oxford, United Kingdom; [4]UChicago Medicine, Chicago, United States; [5]Institute for Cardiometabolism and Nutrition, France; [6]University medicine at the Johannes Gutenberg University in Mainz, Mainz, Germany; [7]Houston Methodist Hospital, Houston, United States*
Email: jdubourg@summitclinicalresearch.com

Background and aims: The American Gastroenterological Association (AGA) has released guidelines in 2021 to identify non-alcoholic steatohepatitis (NASH) patients with at least stage 2 fibrosis (at-risk NASH) that will benefit from referral to hepatology and potential use of pharmacologic agents. We aimed to assess the utility of the recommended score-based parts of these algorithms (FIB-4 and Vibration Controlled Transient Elastography (VCTE)) in the setting of non-cirrhotic NASH clinical trials in the United States.
Method: We combined screening data from 6 ongoing non-cirrhotic NASH phase 2 trials (>5,000 patients). We assessed the proportion of NASH patients with at least stage 2 fibrosis for each risk-category based on FIB-4 and liver stiffness measurement (LSM) by VCTE. We also assessed the proportion of at-risk NASH with a non-alcoholic fatty liver disease activity score (NAS) of at least 4 and excluding fibrosis 4.
Results: 2,119 patients with histology results were included for final analysis, with 2,119 (100%) of those having FIB-4 data and with 1,105 (52%) of those having LSM data. The table shows the proportion of patients in each risk-category meeting AGA target population as well as the classic non-cirrhotic NASH trial population. 1,254 patients with FIB-4 <1.3 would not have been referred to hepatology clinic but 430 (30%) of those had at-risk NASH on liver biopsy (missed cases). 388 patients with FIB-4 >1.3 had LSM on VCTE of <8 kPa but 16 (76%) of those had at-risk NASH on biopsy. In patients with FIB-4 >2.67, 65% had at-risk NASH on biopsy and in those with LSM of 8–12 kPa and >12 kPa, 67% and 65% had at risk NASH, respectively.

AGA Guidelines				Clinical trial Target
AGA Guidelines Criteria		N of patients with data	N of NASH patients with at least fibrosis stage 2	NASH-NAS ≥4 Fibrosis 2 or 3
Low risk Group FIB-4 <1.3		1, 254	430 (34%)	380 (30%)
Intermediate Risk Group FIB-4 ≥ 1.3 to 2.67	LSM <8 kPa	21	16 (76%)	15 (71%)
	LSM 8 to 12 kPa	212	142 (67%)	135 (64%)
	LSM >12 kPa	255	201 (79%)	171 (67%)
High risk group FIB-4 ≥ 2.67		80	63 (79%)	52 (65%)

Figure:

Conclusion: Using the AGA clinical care pathway in the setting of clinical trial may lead to missing patients with biopsy-proven at-risk NASH. In patients considered high-risk based on the pathway, two thirds have at-risk NASH and will potentially benefit from clinical trial and future pharmacologic treatments.

OS-027

Performance of vibration controlled transient elastography and related scores to identify at-risk non-alcoholic steatohepatitis patients: combined data from multiple trials including more than 5,000 patients (in collaboration with NAIL-NIT consortium)

Mazen Noureddin[1], Julie Dubourg[2], Stephen Harrison[3], Sophie Jeannin Megnien[2], Vlad Ratziu[4], Michael Charlton[5], Naim Alkhouri[6], Jörn Schattenberg[7]. *[1]Houston Methodist Hospital, Houston, United States; [2]Summit Clinical Research, San Antonio, United States; [3]University of Oxford, United Kingdom; [4]Institute for Cardiometabolism and Nutrition, France; [5]UChicago Medicine, Chicago, United States; [6]Arizona Liver Health, Chandler, United States; [7]University medicine at the Johannes Gutenberg University in Mainz, Mainz, Germany*
Email: jdubourg@summitclinicalresearch.com

Background and aims: Non-alcoholic steatohepatitis (NASH) with Fibrosis (F) F2-F3 patients is the target population for phase 2b/3 NASH clinical trials. High screening failure (SF) rate on biopsy has slowed down enrollment and drug development. Subsequently non-invasive tests (NITs) have been developed to reduce SF rate on biopsy. We aim to assess composite scores related to vibration-controlled transient elastography (VCTE), namely FAST and Agile 3+ and compare them to traditional VCTE cut offs to identify NASH patients with F2 and F3 in clinical trial settings.
Method: We combined screening data from 6 ongoing biopsy-proven therapeutic NASH trials (>5,000 patients). Liver histology data were read centrally. We assessed the diagnostic accuracy of FAST and liver stiffness measurements (LSM) on VCTE, using published cut-offs (0.5 for FAST and 8.2 kPa for LSM) to identify NASH patients with F2-F3. We also assessed the diagnostic accuracy of Agile 3+ and LSM on VCTE, using published cut-offs (0.6 for Agile 3+ and 9.7 kPa for LSM) to identify NASH patients with F3. Patients with F4 were excluded. We calculated the following diagnostic performance indices: sensitivity (Se), specificity (Sp), negative predictive value (NPV), positive predictive value (PPV), positive likelihood ratio (LR+), negative likelihood ratio (LR-) and the correct classification (CC).
Results: 1,048 patients with liver histology and NIT data were included, with a fibrosis prevalence of: 92 (9%) for F0, 231 (22%) for F1, 290 (28%) for F2, and 435 (42%) for F3. The average age was 54.7 years, 644 (61%) were females and 439 (42%) were Hispanics. The Se, Sp, NPV, PPV and CC are shown in the table. Overall, FAST had better Sp, NPV, PPV, LR+ and CC than the traditional LSM value of 8.2 kPa for patients with NASH F2-F3. Agile 3+ had better Sp, PPV, LR+, LR- and CC than the traditional LSM value of 9.7 kPa for patients with NASH F3.

NASH F2-F3								
NIT	Published Cut-offs	Se	Sp	NPV	PPV	Correct Classification	LR+	LR-
FAST	0.5	76.7	51.7	58.2	71.7	0.67	1.59	0.45
LSM	8.2	94.4	8.4	48.6	62.2	0.61	1.03	0.66
NASH F3								
Agile 3+	0.6	67.6	62.0	76.2	51.6	0.64	1.78	0.52
LSM	9.7	82.9	35.7	77.7	43.5	0.53	1.29	0.48

Figure:

Conclusion: In a pooled data analysis from a large cohort of NASH patients enrolled in Phase 2 clinical trials we showed that FAST and Agile 3+ are better screening tests than liver stiffness alone for patients with NASH F2-F3 and, NASH F3, respectively. We recommend using these scores as screening criteria in phase 2b/3 NASH trials.

OS-028

Prediction of outcomes in patients with non-alcoholic fatty liver disease by initial measurements and subsequent changes in magnetic resonance elastography

Takashi Kobayashi[1], Michihiro Iwaki[1], Asako Nogami[1], Masato Yoneda[1], Satoru Saito[1], Atsushi Nakajima[1]. [1]*Yokohama city university graduate school of medicine, Department of gastroenterology and hepatology, Japan*
Email: yoneda@yokohama-cu.ac.jp

Background and aims: Liver fibrosis is strongly correlated with prognosis in non-alcoholic fatty liver disease (NAFLD). We investigated whether liver stiffness measured (LSM) by magnetic resonance elastography (MRE) and its changes can predict clinical outcomes in patients with NAFLD.
Method: A retrospective analysis of 405 NAFLD patients who had undergone at least two magnetic resonance elastography (MRE) was conducted. The patients were divided into five groups corresponding to fibrosis stages 0–4 based on their initial LSM. Additionally, based on the difference between two LSMs (ΔLSM), the patients were classified as progressors (ΔLSM ≥+19%) and non-progressors (ΔLSM < +19%). Cumulative outcomes were calculated using Kaplan-Meier analysis and compared by log-rank test.
Results: The mean duration from the initial MRE to the end of follow-up was 72.64 ± 25.80 months. In the interval between serial MREs (mean: 23.51 ± 0.47 months), 52 (12.8%) were progressors and 353 (87.2%) were non-progressors. According to the groups based on initial LSM, there were significant differences in the cumulative incidence of decompensated cirrhosis ($p < 0.001$), hepatocellular carcinoma (HCC) ($p < 0.001$), liver-related events ($p < 0.001$), extrahepatic malignancies ($p = 0.049$) and overall mortality ($p < 0.001$), but no significant differences in cardiovascular disease ($p = 0.203$). Hazard ratios (HRs) for progressors to non-progressors were significantly higher for decompensated cirrhosis (HR = 12.08, $p = 0.009$), HCC (HR = 25.02, $p = 0.008$), and liver-related events (HR = 12.79, $p = 0.012$), but not for extrahepatic malignancies (HR = 2.66, $p = 0.179$), cardiovascular disease (HR = 5.396, $p = 0.317$), or overall mortality (HR = 1.207, $p = 0.821$) (Figure A–F). Among patients with no clinical evidence of cirrhosis (n = 385), the HR of cirrhosis development for progressors versus non-progressors was 60.15 ($p < 0.001$), which was significant. Even within the subgroup with low initial LSM (n = 296), corresponding to fibrosis stages 0–2, which has been considered a good prognosis, the HR for progressors versus non-progressors was significantly high for liver-related events (HR = 77.45, $p = 0.009$) and overall clinical events (HR = 10.32, $p = 0.012$).
Conclusion: In addition to initial LSM, ΔLSM can predict liver-related events in patients with NAFLD, even for low initial LSM. Their integrated evaluation can provide more detailed risk stratification and sort out high-risk patients with NAFLD from those previously considered low-risk.

Background and aims: The gold standard for participant enrollment and end point assessment in NASH clinical trials is manual histologic

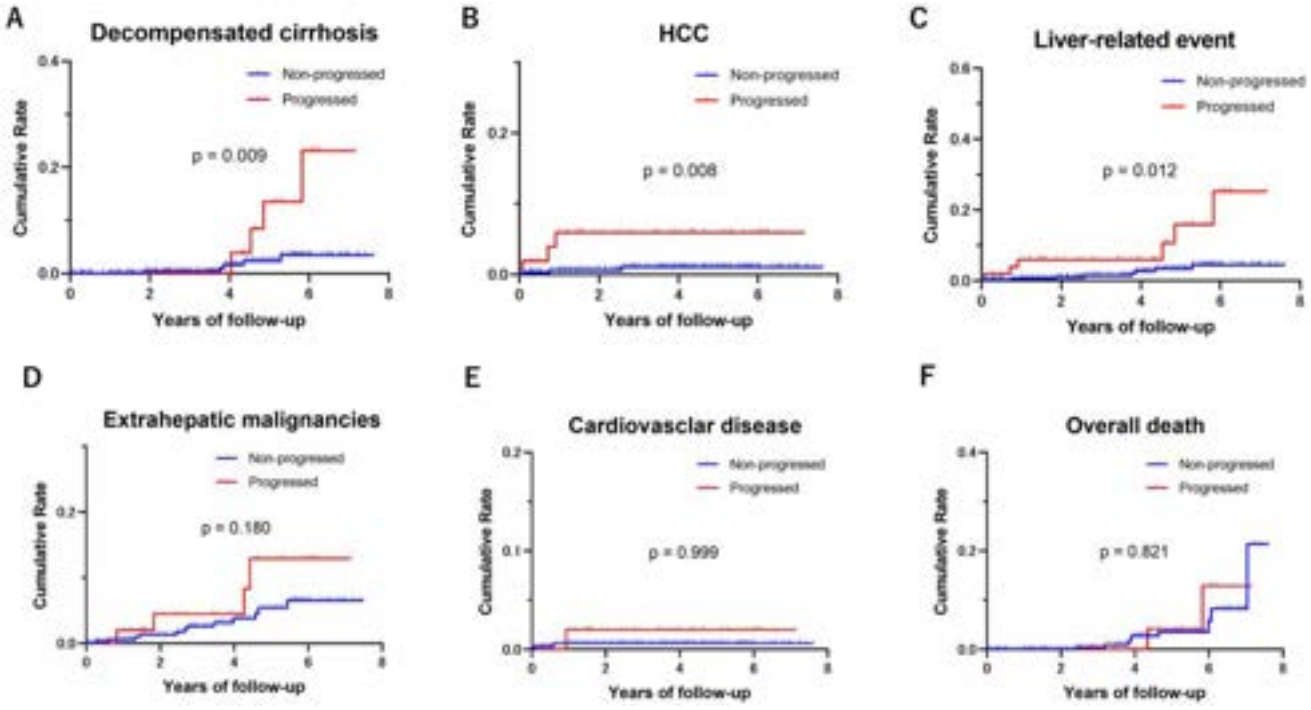

Figure: (abstract: OS-028).

assessment of a liver biopsy. The NASH CRN scoring system has suboptimal reproducibility, even amongst expert hepatopathologists (HPs). High variability limits assessment of change over time and therapeutic response. Here, we describe the validation of AIM-NASH (AI-based Measurement of NASH Histology) (PathAI, *v1.1.0*), an AI-powered, assistive digital pathology tool that detects and scores the key histologic features of NASH ((steatosis (ST), lobular inflammation (LI), hepatocellular ballooning (HB), and fibrosis)). Analytical Validation (AV), Overlay Validation (OV) and Clinical Validation (CV) studies were conducted to determine the accuracy and precision of AIM-NASH as an aid to HPs in NASH scoring.

Method: Ground Truth: (GT) NASH CRN scores for AV/CV were determined via consensus by a panel of 3 experts. AV: The AIM-NASH algorithm alone was evaluated for non-inferior accuracy to HPs manual reads (MRs) (Figure 1). Algorithm repeatability (at one site) and reproducibility (at 3 sites) with Leica AT2 scanners was evaluated against a target agreement of >85%. OV: Assessed the accuracy of AI-derived heatmap overlays, per visual feature, with target true positive and false positive success (TPS/FPS) rates of ≥85%. CV: HPs' AI-assisted performance was assessed for non-inferior accuracy to MRs within a NASH clinical trial workflow, totaling 1501 anonymized biopsies from 3 trials.

Results: AV: [Accuracy] AIM-NASH was superior to MRs for HB (weighted kappa (κ_w) difference 0.17; $p < 0.0001$) and non-inferior (margin of 0.1) for ST, LI, and fibrosis ((κ_w) differences 0.05, 0.01, and 0.02; all $p < 0.02$). [Repeatability] Mean intra-scanner overall percent agreement (OPA) rates for ST, LI, HB, and fibrosis were 0.93, 0.96, 0.96, and 0.93 (all $p < 0.0001$). [Reproducibility]: Mean inter-site OPAs between scans for ST, LI, HB, and fibrosis were 0.86, 0.85, 0.91, and 0.87 ($p = 0.002$-0.53). OV: All overlays met TPS/FPS criteria of ≥85%. CV: AI-assisted reads were superior to MRs for LI and HB (κ_w improvements 0.12 and 0.15; both $p < 0.0001$) and non-inferior for ST and fibrosis (κ_w differences 0.003 and -0.009). The AI-assist workflow also showed superior accuracy over MRs when evaluating for NASH

Reference: 1. Davison BA, Harrison SA, Cotter G, Alkhouri N, Sanyal A, Edwards C, et al. Suboptimal reliability of liver biopsy evaluation has implications for randomized clinical trials. J Hepatol. 2020;73(6).

*NASH Assessment defined as NAS ≥4 and each H&E component ≥1

**NASH Resolution defined as ballooning=0, inflammation of 0 or 1, and any steatosis

***Unweighted kappa, all others reported are weighted.

Table: (abstract: OS-029).

resolution (HB = 0, LI = 0, 1) with a κ_w difference 0.16 ($p < 0.01$) (Table 1).
Conclusion: AIM-NASH is highly repeatable and reproducible, with accuracy ranging from comparable to superior relative to HPs. AIM-NASH-assisted HPs are superior to unaided HPs in assessing NASH resolution, HB, and LI. These results are notable given high HP disagreement in HB and LI evaluation. The data suggest AIM-NASH may reduce the impact of rater variability on NASH clinical trial end points and subsequently allow for a more consistent and reliable assessment of therapeutics being developed in the field.

Viral hepatitis B/D - New treatments

Email: wedemeyer.heiner@mh-hannover.de

Background and aims: Hepatitis D virus (HDV) requires hepatitis B surface antigen (HBsAg) to form infectious viral particles. The siRNA JNJ-73763989 (JNJ-3989) has been shown to profoundly reduce HBsAg in chronic hepatitis B patients. In the REEF-D study, the antiviral effect of JNJ-3989 was evaluated for the first time in patients with CHD to investigate whether reduction of HBsAg would lead to reduction of HDV replication, resulting in a therapeutic benefit of JNJ-3989 for patients with CHD.
Method: REEF-D, a 2-part, phase 2, multicenter, randomized, double-blind, placebo-controlled study, included adults with CHD, including compensated cirrhosis. Patients were randomized 4:1 to receive JNJ-3989 (100 mg subcutaneously every 4 weeks) + NA for 144 weeks (active arm) or placebo + NA for 52 weeks followed by JNJ-3989 + NA for 96 weeks (deferred treatment arm) with 48 weeks of off-treatment follow-up. Changes in serum viral markers (HBsAg and HDV RNA) and safety (alanine aminotransferase [ALT] levels) were assessed. The primary composite end point was the proportion of patients with HDV RNA decline from baseline of ≥ 2 $\log_{10}$ IU/ml (or undetectable) and normal ALT at Week 48. Antiviral activity in Part 1 was used to expand the study (Part 2). Data from Part 1, Week 48 interim analysis are reported here.
Results: Of 22 patients enrolled in REEF-D Part 1, 17 and 5 were randomized to the active and deferred treatment arms, respectively. Treatment with JNJ-3989 led to robust reductions in HBsAg, and subsequently, HDV RNA. Twelve of 17 (70.6%) patients in the active arm had treatment-emergent ALT elevations ($\geq 3 \times$ upper limit of normal [ULN] and $\geq 2 \times$ nadir) between Weeks 8 and 20, which were associated with HDV RNA rebound, limited transient HBV DNA increase in most patients, but no clear impact on HBsAg decline, and resulted in early treatment discontinuation in 8 patients. Grade 3/4 ALT elevations were observed, with no cases of decompensation. In general, ALT levels returned to baseline values after treatment discontinuation in those patients. Among the 9 JNJ-3989-treated patients still on-treatment at Week 48, mean (standard error [SE]) HBsAg change from baseline was −1.75 (0.29) $\log_{10}$ IU/ml in the active arm vs −0.07 (0.04) $\log_{10}$ IU/ml for the 5 patients in the deferred treatment arm. Mean (SE) change from baseline in HDV RNA was −1.52 (0.38) $\log_{10}$ IU/ml and −0.23 (0.15) $\log_{10}$ IU/ml in the active and deferred treatment arms, respectively. Four of 17 (23.5%) patients in the active arm achieved the primary composite end point vs none from the deferred treatment arm. Among the 5 patients without ALT elevations, 4 (80.0%) achieved the primary composite end point, 2 (40.0%) of whom had HDV RNA <lower limit of quantification of the assay. Aside from ALT elevations, safety outcomes were unremarkable. Predefined antiviral criteria to initiate Part 2 of the study were met and the observation of ALT flares predominantly in patients with high HBsAg and HDV RNA levels at baseline led to exclusion of patients with cirrhosis or HBsAg >10,000 IU/ml and HDV RNA >100,000 IU/ml.
Conclusion: This is the first proof-of-concept study showing that an HBsAg-targeting agent leads to simultaneous reduction of HBsAg and HDV RNA in patients with CHD. Clinically relevant ALT elevations were frequent and associated with increases in HDV RNA and led to treatment discontinuation. However, patients without ALT elevations generally had a continuous reduction of HDV RNA, 4/5 of whom met the primary efficacy end point.

Email: edgane@adhb.govt.nz

Background and aims: There is an unmet need for a finite, curative, and well-tolerated treatment regimen for chronic hepatitis B virus (HBV) infection. VIR-2218 is an investigational small interfering ribonucleic acid (siRNA) targeting the HBx region of HBV genome, and VIR-3434 is an investigational fragment crystallizable (Fc)-engineered human monoclonal antibody targeting the conserved antigenic loop of HBsAg. This phase 2 open-label trial (MARCH) evaluated the safety, tolerability, and antiviral activity of short-duration combination regimens of VIR-2218 and VIR-3434 for the

treatment of chronic HBV infection. Here, we report data through 24-week post-treatment follow-up from the first cohorts of the MARCH study.

Method: This open-label study included adults with chronic HBV infection who received continuous nucleos (t)ide reverse transcriptase inhibitor therapy for ≥2 months. Cohorts 2 and 3 were restricted to participants with HBsAg <3,000 IU/ml at screening. Participants in Cohort 1 received VIR-2218 200 mg on day 1 and on weeks 4, 8, 12, 16, and 20, plus 5 weekly (QW) doses of VIR-3434 75 mg between weeks 16 and 20. Participants in Cohorts 2 and 3 received 3 doses of VIR-2218 200 mg on day 1 and weeks 4 and 8, plus 12 QW doses of VIR-3434 18 mg (Cohort 2) or 75 mg (Cohort 3) from day 1 through week 11. The primary end points were the proportion of participants with treatment-emergent adverse events (TEAEs), serious adverse events (SAEs), and HBsAg loss at EOT and at 24 weeks post-EOT.

Results: A total of 40 participants were enrolled across Cohorts 1 (n = 17), 2 (n = 4), and 3 (n = 19). Mean HBsAg change from baseline over time by cohort is presented in the Figure. HBsAg gradually rebounded after EOT but remained >1 $\log_{10}$ IU/ml below baseline on average in all cohorts at time of last available follow-up (24 weeks post-EOT for Cohort 1 and 28 weeks post-EOT for Cohorts 2 and 3). No participants achieved HBsAg loss or functional cure. TEAEs were observed in 50% (20/40) of participants overall. All TEAEs were mild or moderate except for one Grade 3 TEAE of creatine kinase elevation observed in Cohort 3. No TEAEs led to treatment discontinuation.

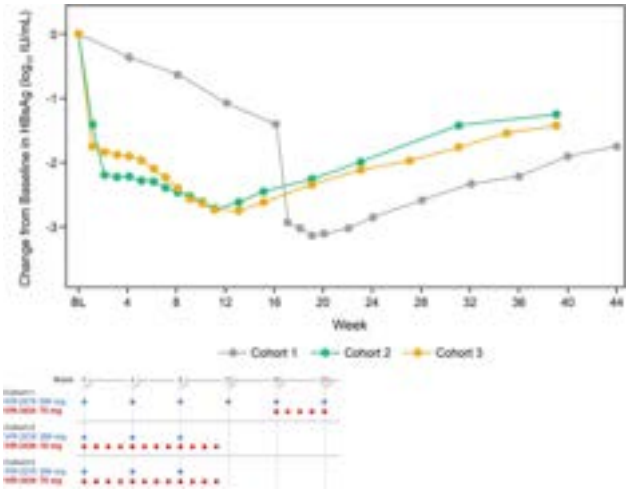

Figure: Mean HBsAg Change from Baseline by Cohort ($\log_{10}$ IU/ml)

Conclusion: By 24 weeks post-EOT, HBsAg levels rebounded in all treatment groups but remained >1 $\log_{10}$ IU/ml below baseline on average. Combination therapy with VIR-2218 and VIR-3434 was generally well tolerated with no safety signals observed to date. Regimens evaluating 24 or 48 weeks of VIR-2218 and VIR-3434, with and without PEG-IFNα, are ongoing.

A PKA-associated liver-tissue rheostat curbs T cell receptor signalling and effector function of virus-specific CD8 T cells in chronic viral hepatitis

Miriam Bosch[1], Nina Kallin[1], Donakonda Sainitin[1], Hannah Wintersteller[1], Anna Fürst[1], Jitao David Zhang[2], Carlos Ramirez[3], Carl Herrmann[3], Maike Hofmann[4], Robert Thimme[4], Ulrike Protzer[5], Jan Boettcher[1], Dirk Wohlleber[1], Souphalone Luangsay[2], Percy A. Knolle[1]. *[1]Institute of Molecular Immunology, School of Medicine, Technical University of Munich (TUM), Munich, Germany; [2]Roche Pharmaceutical Research and Early Development, Switzerland; [3]Health Data Science Unit, Medical Faculty Heidelberg and BioQuant, Germany; [4]Klinik für Innere Medizin II, University Hospital Freiburg, Germany; [5]Institute of Virology, Technical University of Munich, Germany*
Email: miriam.bosch@tum.de

Background and aims: Antigen-specific CD8 T cell immunity is crucial for clearance of viral liver infections such as Hepatitis B virus (HBV) infection. During persistent HBV infection, however, a functional CD8 T cell response is missing and to date cannot be induced by immune therapies. We aimed at determining the mechanisms determining the functional inhibition of CD8 T cells during persistent viral infection of the liver.

Method: We used a preclinical model system with adenoviral gene transfer of the HBV genome or ovalbumin to investigate virus-specific immunity during persistent or acute-resolving viral liver infection. Antigen-specific CD8 T cells from liver and spleen were analyzed by flow cytometry, RNAseq and tissue sections by confocal microscopy. HBV-specific CD8 T cells from patients with chronic HBV infection were compared to the results from preclinical models.

Results: Hepatic CXCR6$^+$CD69$^+$ virus-specific CD8 T cells during persistent viral liver infection had a liver-resident phenotype in transcriptome and flow cytometry analysis. However, T cells did not respond to cognate stimulation with cytokine production and cytotoxicity. Transcriptional network analysis of dysfunctional compared to cytotoxic CXCR6$^+$CD8T cells revealed elevated cAMP signaling indicated by increased Crem (cAMP responsive element modulator) activity as single differentiating transcription factor in persistent infection. We did not observe a rescue of anti-viral T cell immunity in mice lacking the inhibitory Crem isoform ICER in T cells, and therefore searched for post-translational mechanisms influencing T cell immunity. Strikingly, PKA phosphorylation at S114 was elevated in dysfunctional CXCR6$^+$CD8T cells confirming increased cAMP signaling. Pharmacologically induced cAMP signaling caused loss of functionality in previously highly cytotoxic CXCR6$^+$CD8T cells isolated after resolved infection. Importantly, increased cAMP signaling curbed T cell receptor signaling shown by reduced phosphorylation of Lck, Akt and Erk rendering virus-specific CXCR6$^+$CD8T cells unable to respond to cognate stimulation. Confocal microscopy revealed increased contact between prostanoid-producing liver sinusoidal endothelial cells (LSECs) and dysfunctional CXCR6$^+$CD8T cells recognizing peptide presented on infected hepatocytes, and coculture with LSECs led to increased cAMP-signaling in T cells pointing at spatially regulated cAMP signaling in persistent viral infection.

Conclusion: We identify a liver-tissue rheostat enforced by LSECs increasing cAMP-signaling in virus-specific CXCR6$^+$CD8T cells during persistent hepatotropic infection that renders T cells non-responsive to stimulation through TCR signaling. Our results further identify molecular markers for identification of T cells influenced by the liver tissue rheostat and allow to explore novel targeted immune therapies to reconstitute virus-specific immunity in chronic hepatitis B.

Email: jlhousmu@163.com

Background and aims: Current hepatocellular carcinoma (HCC) risk scores do not reflect changes in the risk assessment of HCC resulting from liver disease progression/regression over time. Moreover, majority of HCC risk scores perform unsatisfactorily among cirrhotic patients. Therefore, we aimed to develop and validate novel prediction models by using multivariate longitudinal data with or without incorporating cell-free DNA (cfDNA) signatures.
Method: A total of 13,728 patients from 2 nationwide multicentre prospective cohorts (Search-B CHB cohort and PreCar cirrhotic cohort) were enrolled in the study. aMAP HCC risk score [J Hepatol, 2020], calculated by age, sex, platelets, albumin and total bilirubin, was evaluated for each patient using baseline data. Low-pass whole genome sequencing was used to derive multi-modal cfDNA fragmentomics features for PreCar cirrhotic patients. Longitudinal Discriminant Analysis algorithm was used to estimate the risk of HCC development.
Results: We developed and externally validated two novel HCC prediction models with greater accuracy called aMAP-2 and aMAP-2 Plus scores. The aMAP-2 score, calculated with longitudinal data of aMAP score, AFP and ALT during up to 8-year follow-up, performed superbly in the Search-B training (N = 3,706, AUC: 0.84) and external validation (N = 5,796, AUC: 0.85) CHB cohorts, and performed moderately in PreCar cirrhotic cohort (N = 4226; AUC: 0.73). In Search-B training cohort, aMAP-2 score could clearly divide patients into low-risk (3191, 86.1%), and high-risk (514, 13.9%), with 5-year cumulative incidences of 1.4% and 15.7% ($p < 0.0001$), respectively. The significant difference of future HCC incidence between aMAP-2 score identified low-and high-risk groups were also demonstrated in Search-B validation and PreCar cohorts. The aMAP-2 Plus score, developed by incorporating cfDNA signatures (Nucleosome, Fragment and Motif scores) based on aMAP-2 score, could further optimize the performance in predicting HCC development, especially for cirrhotic patients (AUC: 0.86–0.89). These two HCC prediction models both exhibited broadly better performance than the other existing HCC risk scores. Moreover, the aMAP-2 Plus score also played a potential role in very-early diagnosis of HCC, by alarming HCC occurrence 3.5 months earlier, on average. More importantly, among the PreCar cirrhotic patients, the application of stepwise approach (aMAP ->aMAP-2 ->aMAP-2 Plus) could identify 90.9% and 9.0% of

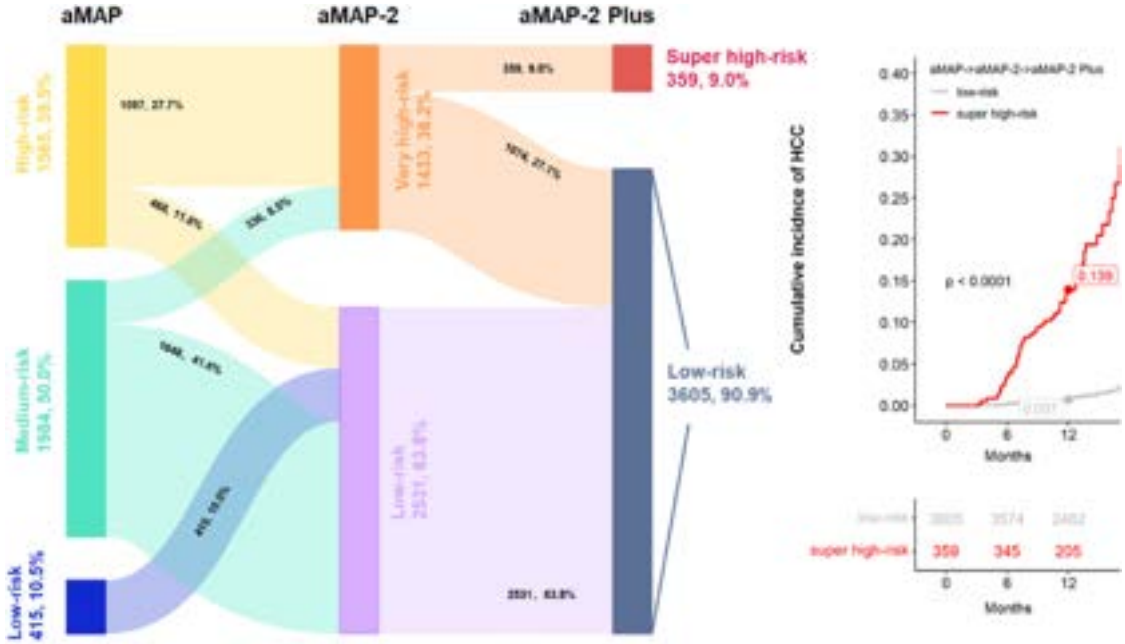

Figure: (abstract: OS-033).

cirrhotic patients with annual HCC incidence of 0.7% and 13.9%, respectively (p < 0.0001, Figure).
Conclusion: aMAP-2 and aMAP-2 Plus scores represent more accurate models in predicting HCC for patients with or without cirrhosis. The stepwise application of aMAP scores (aMAP ->aMAP-2 ->aMAP-2 Plus) provides an improved enrichment strategy of super high-risk HCC patients, which could effectively guide nationwide individualized HCC surveillance.

OS-034
A gene editing approach for chronic hepatitis B: elimination of hepatitis B virus in vivo by targeting cccDNA and integrated viral genomes with a sequence-specific ARCUS nuclease
Cassandra Gorsuch[1], Paige Nemec[1], Mei Yu[2], Simin Xu[2], Dong Han[2], Jeff Smith[1], Janel Lape[1], Nicholas Van Buuren[2], Ricardo Ramirez[2], Robert Muench[2], Meghan Holdorf[2], Becket Feierbach[2], Greg Falls[1], Jason Holt[2], Wendy Shoop[1], Emma Sevigny[1], Forrest Karriker[1], Robert Brown[1], Amod Joshi[1], Tyler Goodwin[1], Ying Tam[3], Paulo Lin[3], Sean Semple[3], Neil Leatherbury[1], William E. Delaney[2], Derek Jantz[1], Emily Harrison[1], Amy Rhoden Smith[1]. *[1]Precision BioSciences, United States; [2]Gilead Sciences, United States; [3]Acuitas Therapeutics, Canada*
Email: cassie.gorsuch@precisionbiosciences.com

Background and aims: ARCUS nucleases can be engineered to recognize conserved DNA sequences in the Hepatitis B virus (HBV) genome and provide a strategy for chronic hepatitis B (CHB) treatment. Persistence of CHB is attributed to maintenance of the intrahepatic pool of viral covalently closed circular DNA (cccDNA) and expression of immunosuppressive Hepatitis B surface antigen (HBsAg) from integrated HBV. Current therapies have no direct impact on cccDNA or expression of HBsAg from integrated virus. ARCUS nucleases expressed in hepatocytes can cut both cccDNA and integrated viral genomes leading to removal of cccDNA and inhibition of viral gene expression. We describe a potential curative approach for CHB using a highly specific engineered ARCUS nuclease (ARCUS-POL) targeting the HBV genome.
Method: Through iterative rounds of protein engineering, ARCUS-POL nucleases were optimized to exhibit high levels of on-target editing with minimal off-target activity. Efficacy and specificity were then tested *in vitro* in primary human hepatocytes (PHHs) infected with HBV and a HepG2 cell line with an integrated partial HBV genome. To evaluate ARCUS-POL in vivo, novel episomal adeno-associated virus (AAV) mouse and non-human primate (NHP) models were developed containing a portion of the HBV genome serving as a surrogate for cccDNA. Clinically relevant delivery was achieved through systemic administration of lipid nanoparticles (LNPs) containing ARCUS-POL mRNA.
Results: ARCUS-POL mRNA was transfected into HBV-infected PHHs, resulting in >75% reductions of both cccDNA and HBsAg. Importantly, ARCUS-POL produced no detectable translocations in PHHs using hybrid capture followed by long-read sequencing. After transient delivery of ARCUS-POL into cells containing integrated HBV DNA, >80% on-target editing was achieved with subsequent HBsAg reductions. In both mouse and NHP AAV models, a significant decrease in total AAV copy number and high on-target indel frequency was observed after LNP delivery of ARCUS-POL mRNA. In the case of the mouse model, which supports HBsAg expression, circulating surface antigen was durably reduced by 96%.

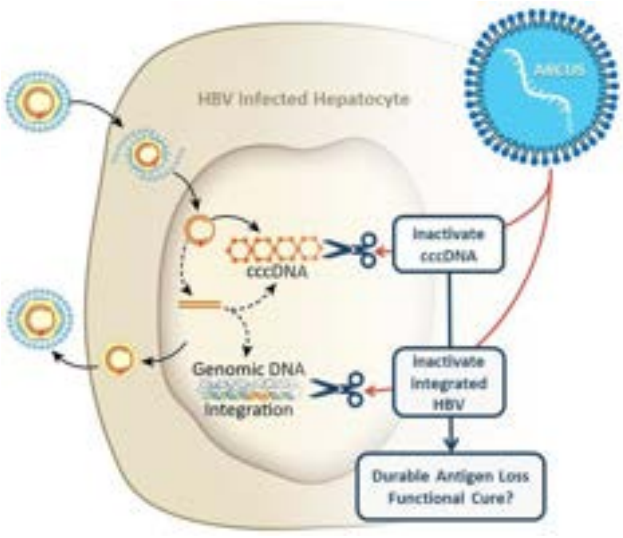

Figure:

Conclusion: ARCUS-Pol nucleases were able to eliminate cccDNA and reduce HBsAg expression from integrated HBV without inducing translocations. Together, these data support a potential gene editing approach and cure for CHB.

Cirrhosis and its complications: Clinical

OS-035-YI
Development and validation of the AMMON-OHE model to risk stratify cirrhotic outpatients for ocurrence of overt hepatic encephalopathy
María Pilar Ballester[1,2], Thomas Tranah[3], Lorenz Balcar[4], Alessandra Fiorillo[2], Javier Ampuero[5], Annarein Kerbert[6,7], Karen Louise Thomsen[6,7], Desamparados Escudero-García[1], Mattias Mandorfer[4], Thomas Reiberger[4], Debbie L. Shawcross[3], Manuel Romero Gomez[5], Carmina Montoliu[2], Juan Antonio Carbonell-Asins[2], Rajiv Jalan[7]. *[1]Hospital Clínico Universitario de Valencia, Digestive Disease, Spain; [2]INCLIVA Biomedical Research Institute, Spain; [3]King's College London, Institute for Liver Studies, United Kingdom; [4]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Austria; [5]Virgen del Rocio University Hospital, Digestive Disease Department, Spain; [6]Aarhus University Hospital, Denmark; [7]University College London, Liver Failure Group, United Kingdom*
Email: mapibafe@gmail.com

Background and aims: Neuropsychological and psychophysical tests are recommended for the risk assessment for overt hepatic encephalopathy (OHE), but their accuracy is limited. Hyperammonaemia is central in the pathogenesis of OHE, but its predictive utility is unknown. This study aimed to determine the role of neuropsychological or psychophysical tests and ammonia and to develop the AMMON-OHE model for risk stratification regarding subsequent OHE development in outpatients with liver cirrhosis.
Method: This observational, prospective study included 426 out-patients without previous OHE from 3 liver units followed for a median of 2.5 years. Psychometric hepatic encephalopathy score (PHES) <–4 or critical flicker frequency (CFF) <39 was considered abnormal. Ammonia was normalized to upper limit of normal (AMM-

ULN) at the respective reference laboratory. Multivariable frailty competing risk analyses and fast unified random forest were performed to predict future OHE and to develop the AMMON-OHE model. External validation of the model was carried out using 267 and 381 patients from two independent liver units.
Results: Significant differences were found in time-to-OHE (log-rank $p < 0.001$) according to PHES and CFF tests and ammonia, with the highest risk in patients with abnormal PHES plus high AMM-ULN (HR: 4.4; 95% CI: 2.4–8.1, $p < 0.001$ compared with normal PHES and AMM-ULN) (Figure 1). On multivariable analysis, AMM-ULN but not PHES or CFF was an independent predictor for development of OHE (HR: 1.4; 95% CI: 1.1–1.9; $p = 0.015$). The AMMON-OHE model included sex, diabetes, albumin, creatinine and AMM-ULN, and showed a C-index of 0.844 and 0.728 in the two validation cohorts, respectively.

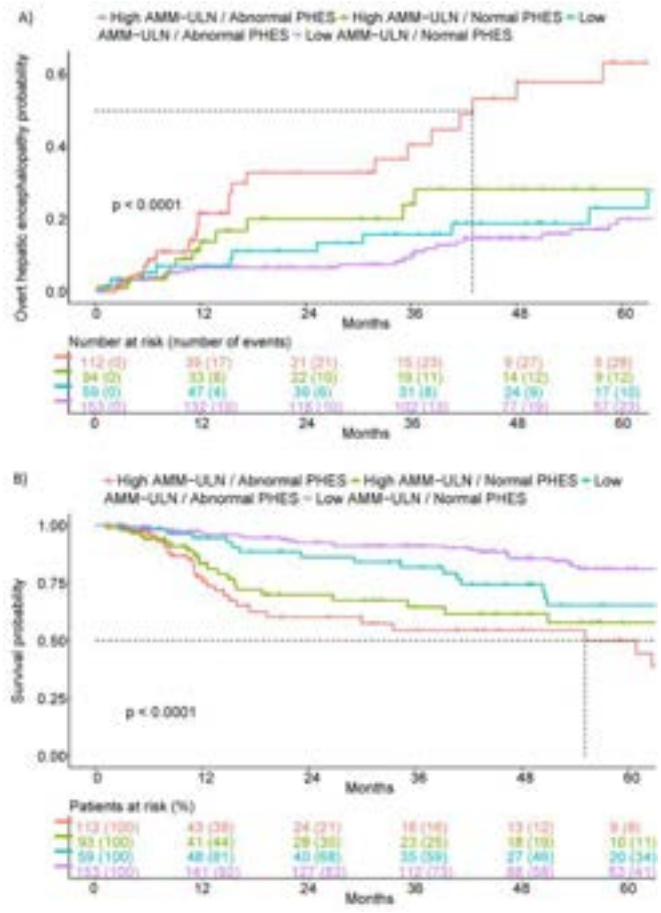

Figure:

Conclusion: This study developed and validated the AMMON-OHE model, comprising readily available clinical and biochemical variables that can be used to identify outpatients with cirrhosis at highest risk for developing a first episode of OHE.

OS-036
Efficacy and safety of lusutrombopag in a real-world Italian series of cirrhotic patients with severe thrombocytopenia undergoing invasive procedures: the Reality study
Paolo Gallo[1], Antonio De Vincentis[1], Valeria Pace Palitti[2], Maurizio Russello[3], Anthony Vignone[4,5,5], Domenico Alvaro[4], Raffaella Tortora[6], Marco Biolato[7], Maurizio Pompili[7], Vincenza Calvaruso[8], Marzia Veneziano[8], Valerio Rosato[9], Ernesto Claar[9], Rosanna Villani[10], Antonio Izzi[11], Raffaele Cozzolongo[12], Marco Distefano[13], Vincenzo Messina[14], Enrico Ragone[15], Rodolfo Sacco[10], Pierluigi Cacciatore[2], Alessandra Moretti[16], Francesca Terracciani[1], Antonio Picardi[1], Umberto Vespasiani Gentilucci[1]. *[1]Fondazione Policlinico Campus Biomedico Rome, Italy; [2]ASL Pescara, Italy; [3]Arnas Garibaldi Catania, Italy; [4]Sapienza University of Rome, Italy; [5]Policlinico Umberto I, Rome, Italy; [6]5.AORN Cardarelli, Naples, Italy; [7]Fondazione Policlinico Universitario Gemelli Rome, Italy; [8]University of Palermo, Italy; [9]Betania Hospital Naples, Italy; [10]University of Foggia, Italy; [11]D. Sebastiano Hospital Caserta, Italy; [15]Monaldi Hospital Naples, Italy; [16]San Filippo Neri Hospital Rome, Italy*
Email: paolo.gallo@policlinicocampus.it

Background and aims: Severe thrombocytopenia (platelet count less than 50.000/μL) complicates the management of patients with chronic liver disease by increasing the risk of bleeding for invasive procedures and sometimes delaying lifesaving treatments. In the last years, thrombopoietin (TPO) receptor agonists such as lusutrombopag have been developed in order to avoid platelet transfusion and associated concerns. Real-world data on the efficacy and safety of the drug are limited to sparse reports or administrative databases. We aimed to evaluate the first post-marketing European cohort of cirrhotic patients treated with lusotrombopag in order to verify efficacy and safety of the drug in a real-world setting.
Method: In the REAl-world Lusutrombopag treatment in ITalY (REALITY) study, we collected data of consecutive cirrhotic patients receiving lusotrombopag before invasive procedures between March 2021 and November 2022 from 15 Italian hepatologic centers, mostly belonging to the "Club Epatologi Ospedalieri" (CLEO). Efficacy, i.e., the capability of lusutrombopag to raise platelet count to ≥50.000/μL and avoid transfusions, as well as treatment-related adverse events, were captured and analyzed.
Results: Fifty patients were enrolled (median age 66 years, female 30%, Child-Pugh A/B/C 67/27/6%). Ten patients (20%) had a previous medical history of portal vein thrombosis. Chronic viral hepatitis was the most common cause of liver disease (42%), followed by the non-alcoholic fatty liver disease (28%). Interventional radiology (44%) and endoscopic (32%) were the most common procedures involved: thermal ablation (14%) and transarterial chemoembolization (14%) of liver cancer, liver biopsy (15%), endoscopic band ligation (18%), other endoscopic operative procedures (14%). Lusutrombopag induced a significant increase in platelet count [from 36.500 (33.000–43000/μL) to 61.500 (52.000–80.750), $p < 0.01$]. The efficacy of lusotrombopag was 78%, while 11 patients (22%) did not reach the platelet threshold of 50.000/μL and required platelet transfusions before the invasive procedure. Notably, the efficacy of lusutrombopag was significantly lower in the 9 patients with a baseline platelet count ≤30.000/μL compared to the 41 patients with a baseline count >30.000/μL (4% *Vs* 85%, respectively, $p < 0.01$). There were no hemorrhagic events in this series. *De novo* portal vein thrombosis was observed in 2 patients.
Conclusion: In this first real-world European series of cirrhotic patients with severe thrombocytopenia treated with lusutrombopag before invasive procedures, the drug confirmed efficacy and safety profiles in line with those observed in registrative trials. According to our results, patients with baseline platelets ≤30.000/μL are unlikely to respond to the drug.

OS-037
Pregnancy outcomes in women with liver cirrhosis: a prospective UK obstetric surveillance system national cohort study
Melanie Nana[1], Agata Majewska[1], Mussarat Rahim[2], Victoria Geenes[1], Paul Seed[1], Caroline Ovadia[1], Marian Knight[3], Michael Heneghan[2], Catherine Williamson[1]. *[1]King's College London, Women's Health, London, United Kingdom; [2]Institute of Hepatology, King's College London, United Kingdom; [3]National Perinatal Epidemiology Unit, United Kingdom*
Email: melanie.nana@kcl.ac.uk

Background and aims: The number of women entering pregnancy with cirrhosis is increasing, yet there is a paucity of data to inform

evidence-based management and counselling of these patients. In the first prospective study of cirrhosis in pregnancy we aimed to determine its national incidence and management, and to describe maternal and fetal outcomes in this group.

Method: A prospective, national cohort study was performed using the UK Obstetric Surveillance System between 2017 and 2020. Rates of adverse perinatal outcomes were compared with published rates of adverse perinatal outcomes in uncomplicated pregnancies or at population level using logistic regression, and prediction of adverse pregnancy outcomes by ALBI score was determined by calculating the area under the receiver operating characteristic curve (AUROC) (Stata 17.0 and GraphPad Prism v9).

Results: In total, 52 eligible cases were reported (denominators were determined by available data for specific adverse outcomes. The causes of cirrhosis are illustrated in Figure 1.

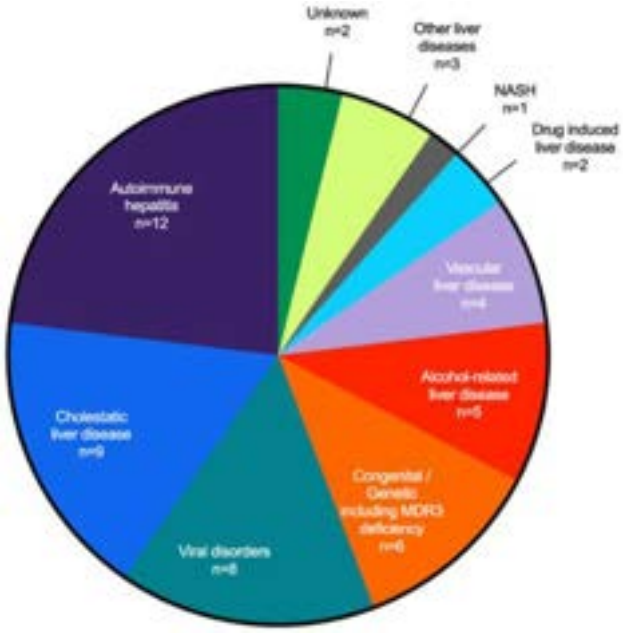

Figure: Underlying causes of cirrhosis. Abbreviations: NASH-non-alcoholic steatohepatitis; MDR3-multidrug resistance protein 3.

Only 17/42 (40.5%) of women received pre-pregnancy counselling. In total, 49/52 (94.2%) conceived spontaneously; three miscarried. Maternal decompensation occurred in seven women, defined by jaundice (n = 2), ascites (n = 3) and encephalopathy (n = 1). The worst ALBI score in pregnancy predicted maternal decompensation AUROC 0.80 (p = 0.03). During the pregnancy 26/49 (53.0%) had an endoscopy, of which 34.6% had uncomplicated variceal banding. Untreated varices were associated with increased rates of variceal bleed (p = 0.01). In total, 9/52 (17.3%) women developed cholestasis. Four women required intensive care unit (ICU) admission, none required liver transplant, and none died. There were 42 live births: 51.2% were preterm, 44.2% had low-birth-weight; there was one stillbirth; and two neonatal deaths (both a consequence of extreme prematurity). The worst ALBI score in pregnancy predicted pre-term birth AUROC 0.74 (p = 0.03). When compared to a healthy reference population, cirrhotic women were at increased risk of cholestasis in pregnancy (OR 29.4, 95% CI 13.8–61.6, p < 0.001), ICU admission (OR 42.5, 95% CI 15.2–118.8, p < 0.001), pre-term birth (OR 13.2, 95% CI 71.2–24.4, p < 0.001), low-birth-weight (OR 12.0, 95% CI 6.5–22.0, p < 0.001), neonatal intensive care unit admission (OR 4.4, 95% CI 2.4–8.2, p < 0.001) and neonatal death (OR 31.795% CI 7.6–131.4, p < 0.001).

Conclusion: High numbers of women with cirrhosis in pregnancy conceive spontaneously. Pre-pregnancy counselling is paramount to ensuring that women are optimised for pregnancy, including having screening and appropriate management of varices and being counselled regarding the increased rates of maternal and neonatal complications. The ALBI score predicts maternal decompensation and pre-term birth.

OS-038

Substitution of even one non-vegetarian meal with plant-based alternatives associate with lower ammoniagenesis in patients with cirrhosis who follow a western diet: a randomized clinical trial

Andrew Fagan[1], Bryan Badal[1], Victoria Tate[1], Travis Mousel[1], Mary Leslie Gallagher[1], Puneet Puri[1], Michael Fuchs[1], Brian Davis[1], Jennifer Miller[1], Jasmohan S Bajaj[1]. [1]*Virginia Commonwealth University and Richmond VAMC, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Dietary preferences (Vegetarian, vegan, meat) could differentially influence ammoniagenesis in cirrhosis and hepatic encephalopathy (HE). Most Western populations follow meat-based diets but the impact of intermittent diet substitution on ammoniageneis is unclear. Aim: Determine impact of substituting one meal with equicaloric and protein containing vegan, vegetarian or meat on ammonia levels in outpatients with cirrhosis on a Western non-vegetarian diet.

Method: Outpatients with cirrhosis with/without prior HE (on stable lactulose/rifaximin) on a stable Western meat-based diet were enrolled. We excluded those with MELD>23, unclear cirrhosis diagnosis, BMI (<18.5 or >40), prior TIPS, recent antibiotic/probiotic use, HE treatment<2 months, or valproate/steroid use.

Subjects were randomized 1:1:1 into the 3 meals which had equivalent protein (20 gm) and calories. Meals were freshly prepared by our dietician. These consisted of a burger (meat substitute patty for vegan, bean-burger for vegetarian and pork/beef patty for meat) with bun and low-salt potato chips and water. Baseline dietary history, cirrhosis details, MELD-Na were collected, after overnight fasting, all patients ate the entire meal under observation. They remained fasting for the remaining 3 hours, where they were kept under observation. Venous ammonia levels were drawn at baseline and hourly for 3 hours post-meal (Fig 1A). Baseline characteristics and changes in ammonia levels were compared within and between groups.

Results: We enrolled 30 men; ten each were randomized per meal group. All subjects finished the meals and none developed HE symptoms or confusion during the observation period. There were no baseline differences in age, MELD-Na, prior HE, lactulose, rifaximin, PPI and ascites (Fig 1B) between the groups.

Ammonia levels: At baseline, no significant differences in ammonia levels were observed (Figure 1B). However, the ammonia levels over time increased significantly from baseline (p = 0.007) only in the meat-based group but not the vegan (p = 0.45) or vegetarian (p = 0.84) group. As shown in figure 1C, serum ammonia levels between groups were significantly higher in the meat group compared to the other 2 groups at hours 1, 2 and 3 post-meal. There were no differences between the ammonia level changes at any timepoint between the vegan and vegetarian groups.

Conclusion: Substitution of even one meat-based meal with vegan or vegetarian alternatives has the potential to reduce ammoniagenesis in outpatients with cirrhosis regardless of prior HE. Intermittent plant-based options for protein could be considered in patients with cirrhosis who usually follow a Western diet.

OS-039-YI

Head-to-head comparison of the prognostic performance of the hepatic venous pressure gradient and non-invasive tests in compensated advanced chronic liver disease

Mathias Jachs[1], Lukas Hartl[1], Benedikt Simbrunner[1], Georg Semmler[1], Lorenz Balcar[1], Benedikt Hofer[1], Michael Schwarz[1], David JM Bauer[1], Albert Stättermayer[1], Matthias Pinter[1], Michael Trauner[1], Thomas Reiberger[1], Mattias Mandorfer[1]. [1]*Medical University of Vienna, Austria*
Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Models based on platelet count (PLT) and liver stiffness measurement (LSM; ANTICIPATE) or von Willebrand factor antigen (VWF) to PLT ratio (VITRO) are applied to estimate the probability of/rule in- or rule-out clinically significant portal hypertension (CSPH), and thus, stratify risk and guide NSBB therapy in patients with compensated advanced chronic liver disease (cACLD). However, head-to-head comparisons of their prognostic utility for first hepatic decompensation and comparisons with the minimally invasive hepatic venous pressure gradient (HVPG) are lacking.

Method: Patients with cACLD, defined by LSM ≥10 kPa, who underwent same-day assessment of HVPG, LSM, and VITRO between 2007 and 2022 were included. Patients' individual ANTICIPATE-derived probability for CSPH was calculated based on PLT and LSM according to the published formula. Long-term follow-up data on first hepatic decompensation was recorded. Time-dependent AUROC analyses and competing risk regressions were performed.

Results: We included 445 cACLD patients: median age: 54.1 years; 66.7% male; etiology: 51.7% viral, 20.8% ALD, 18.9% NAFLD/cryptogenic, while 8.8% other. The median HVPG was 12 (IQR: 8–17) mmHg with a CSPH prevalence of 61.5%. The median PLT, VWF, and VITRO levels were 109 (80–156) G/L, 243 (188–306) %, and 2.24 (1.29–3.52), respectively. The median estimated probability of CSPH based on the ANTICIPATE model was 80.0 (47.0–94.2) %. The cumulative incidences of first hepatic decompensation were 4.4%, 7.6%, and 13.3% at 1, 2, and 3 years of follow-up. HVPG, VITRO, and CSPH-probability according to ANTICIPATE conferred similar time-dependent prognostic value in AUROC analyses (Figure; panel A), with VITRO showing the numerically highest values over time. In competing risk analyses adjusted for model for end-stage liver disease (MELD) score and serum albumin levels, HVPG (adjusted subdistribution hazard ratio [aSHR]: 1.092 [95%CI:1.048–1.140) per mmHg; p < 0.001), VITRO (aSHR: 1.138 [1.066–1.210] per unit; p < 0.001), and ANTICIPATE-CSPH probability (aSHR: 1.022 [1.010–1.034] per %; p < 0.001) all predicted first decompensation during follow-up. When stratifying the cohort by previously proposed decision rules (HVPG ≥10 mmHg vs. <10 mmHg, VITRO ≥2.5 vs. <2.5, and ANTICIPATE-CSPH probability ≥60% vs. <60%), all biomarkers accurately discriminated between patients at negligible risk and those at substantial risk of hepatic decompensation, as shown in the Figure (panels B–D).

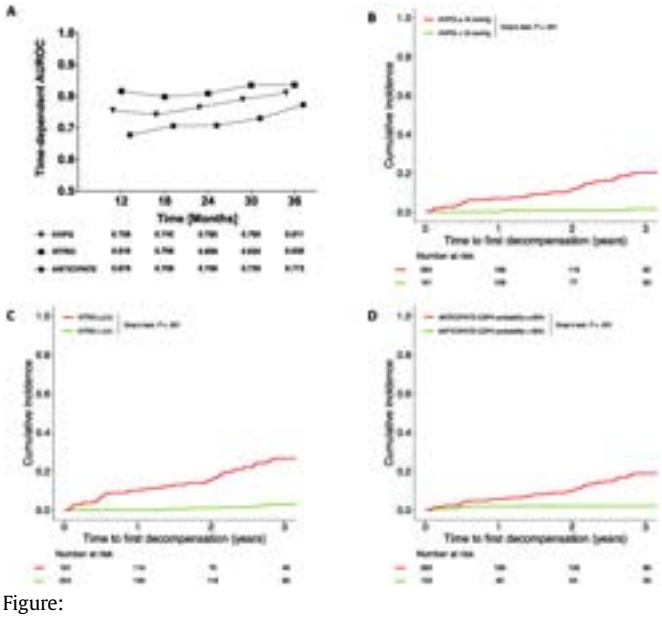

Figure:

Conclusion: Non-invasive CSPH surrogates, i.e., the ANTICIPATE-CSPH probability, and even more, VITRO, have a high prognostic performance that is similar to minimally invasive HVPG-measurement. Thus, they provide clinically meaningful information and accurately identify candidates for medical therapies to prevent first hepatic decompensation.

Email: hangwu@ucm.es

Background and aims: Hepatic fibrosis is a pathogenic condition triggered by persistent inflammation, in which hepatic stellate cells (HSC) are the main cell type responsible for the overexpression of extracellular matrix (ECM) proteins. Recently, it was reported that myeloid-specific XBP1 deficiency or pharmacological inhibition of XBP1 protected the liver against fibrosis. In this study, we aimed to investigate the role of XBP1 in HSCs.
Method: Mice harboring a conditional floxed allele of *Xbp1* (*Xbp1$^{f/f}$*), were crossed with Lrat-Cre mice to obtain a HSC-specific knockout of *Xbp1* (*Xbp1$^{\Delta HSC}$*). Overnight-fasted 8–12 week-old male *Xbp1$^{f/f}$* and *Xbp1$^{\Delta HSC}$* mice were either fed a MCD diet, challenged with carbon tetrachloride (CCl_4) [0,6 ml/kg] or corn oil for 4 weeks, or given a Western diet (WD) in combination with CCl_4 [0,2 ml/kg] for 12 weeks- the FAT-NASH model. Upon sacrifice, qRT-PCR, Western blot, and IF analysis, were performed. In addition, functional experiments were carried out in primary isolated XBP1-deficient HSC and in LX2 cells treated with TGFß (0–24 h) or vehicle. Finally, scRNA-seq of HSC from fibrotic mouse liver induced by 19 injections of CCl_4 and HSCs from normal and cirrhotic human livers was used.
Results: Interestingly, *Xbp1$^{\Delta HSC}$* mice exhibited significantly increased lipid accumulation (Oil Red O) and steatosis as well as cell death (TUNEL, CC3) and compensatory proliferation (Ki-67), compared with *Xbp1$^{f/f}$* knockout mice, after 4 weeks of MCD diet. Moreover, one month of CCl_4 challenge triggered elevated serum markers of liver damage (ALT, AST) in *Xbp1$^{\Delta HSC}$*. These changes were accompanied with aggravated periportal fibrosis (HandE, Sirius red), a robust overexpression of αSMA expression- a marker of HSC activation-, and other ECM components (Vimentin, Desmin), and the production of proinflammatory proteins (*Tnfα, IL-6, Tgfβ*). Finally, the FAT-NASH preclinical model exacerbated liver injury, periportal fibrosis and inflammation in *Xbp1$^{\Delta HSC}$* compared with *Xbp1$^{f/f}$* mice. Additionally, LX2 cells challenged with TGFß exhibited increased markers of the IRE1-XBP1. Finally, enrichment of XBP1 in HSCs was found in fibrotic murine and cirrhotic human livers.

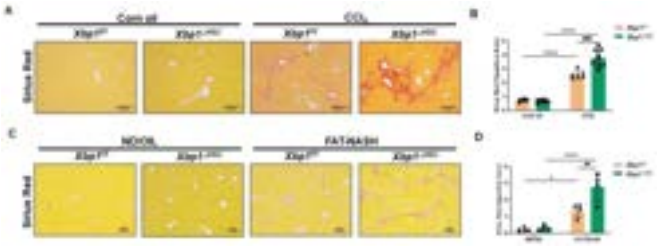

Figure:

Conclusion: Our data highlighted a novel function of *Xbp1* specifically in HSCs in NAFLD/NASH models by mitigating NAFLD/NASH-induced injury. Thus ER stress modulation specifically in HSC could potentially be used clinically to satisfy the current lack of effective treatments against hepatic fibrosis.

Novel insights on the contribution of collagen degradative macrophages to liver fibrosis resolution

Maria Fernandez-Fernandez[1,2], Paloma Ruiz-Blazquez[1,2], Valeria Pistorio[1,3,4], Celia Martinez-Sanchez[2,5], Michele Costanzo[4], Paula Iruzubieta[6], Susana Núñez[2], Ekaterina Zhuravleva[7], Jesper Andersen[7], Margherita Ruoppolo[4], Javier Crespo[6], M. Email: anna.moles.fernandez@gmail.com

Background and aims: Liver fibrosis is caused by an excessive accumulation of extracellular matrix (ECM) proteins. Macrophages are important effectors for ECM remodelling through recycling of the ECM within acidic compartments and can contribute to liver fibrosis resolution. Proteases, such as cathepsins, are essential for lysosomal proteolytic activity; however, their contribution to ECM remodelling within the macrophages is unknown. Thus, the aim of this study was to investigate the proteolytic and degradative signalling pathways associated to macrophages during liver fibrosis.
Method: A novel macrophage-cathepsin D KO mouse strain (CtsD$^{\Delta Myel}$) was generated by breeding LysMCre (macrophages) with CtsD-floxed mice. Fibrosis was established by chronic CCl_4 administration and bile duct ligation in CtsD$^{F/F}$ or CtsD$^{\Delta Myel}$ mice and determined by hydroxyproline, Sirius Red, α-SMA, Col1A1 and TGF-β RT-PCR. Proteomic profile was determined by LC-MS/MS in fibrotic livers. Reversion was assessed 72 h post-challenge in a 4-week CCl_4 model. Collagen degradation in liver was determined by R-CHP staining. Macrophage polarization and proteolytic secretome was assessed by RT-PCR and protease array, respectively. Collagen degradation and endocytosis was determined by FACS in Kupffer cells (KC). Single-cell RNA sequencing analysis was performed using GSE136103 dataset.

Results: ScRNAseq analysis and CtsD IHP demonstrated high expression of CtsD in liver macrophages from cirrhotic patients. Next, CtsD$^{\Delta Myel}$ mouse was validated by FACS and WB in KC and dual IHP (F4/80-CtsD) in liver. CtsD deletion in macrophages enhanced liver fibrosis with enriched matrisome proteomic signatures in chronic CCl_4 and BDL models. Analysis of KC isolated from 72h-CCl_4-treated livers demonstrated significantly lower expression of markers associated with resolutive macrophages (CD206, TREM-2 and TGF-β) and defective proteolytic secretome profile in CtsD$^{\Delta Myel}$ KC. In addition, CtsD$^{\Delta Myel}$ KC displayed defective proteolytic processing of collagen I without impairment of the Endo180 receptor-mediated endocytosis demonstrated by FACS. Analysis of CtsD macrophage subclusters in control and cirrhotic human livers, confirmed cirrhotic CtsD-expressing subclusters were differentially enriched in ECM degradation and organization signalling pathways. In addition, it revealed a decrease in the number of CtsD-expressing macrophage subclusters in cirrhotic livers, which could contribute to inadequate ECM recycling, perpetuating fibrosis and hampering resolution. Indeed, CtsD$^{\Delta Myel}$ mouse was unable to remodel collagen in vivo when subjected to a fibrosis reversion model determined by both percentage of HP and fluorescent intensity of collagen hybridizing peptide (CHP) binding to liver tissue.
Conclusion: CtsD is essential in regulating the collagenolytic activity of macrophages during liver fibrosis and is part of a novel and currently unknown degradome landscape of restorative macrophages.

Atypical Chemokine receptors regulate the induction of 'disease-associated' LSEC by modulating Endothelial-to-Mesenchymal transition (EndMT) during liver fibrosis

Christina Gkantsinikoudi[1], Antal Rot[1], William Alazawi[1], Neil Dufton[1].
[1]*Queen Mary University of London, United Kingdom*
Email: n.dufton@qmul.ac.uk

Background and aims: Single cell RNA sequencing of cirrhosis patients (Ramachandran et al., 2019) and murine models of fibrosis (Su *et al.,* 2020 and Ruan *et al.,* 2021) have revealed the induction of 'disease-associated' Liver Sinusoidal Endothelial Cells (LSEC) correlate with liver fibrosis. Meta-analysis of these datasets shows that loss of endothelial identity and acquisition of mesenchymal characteristics, a process termed endothelial-to-mesenchymal transition (EndMT), are a common trait of 'disease-associated' LSEC. Our research was the first study to establish EndMT correlates with progressive fibrosis in murine models and human end-stage liver disease (Dufton et al., 2017). We aim to determine the contribution of EndMT to 'disease-associated' LSEC during fibrogenesis. Secondly, we noted that LSEC undergo a switch in expression of Atypical Chemokine Receptors (ACKRs), from ACKR4 in healthy liver to ACKR1 during injury. Our study assessed the role of ACKRs in the regulation of EndMT during liver injury using ACKR1 and ACKR4-deficient mice.
Method: Carbon tetrachloride (CCl_4) was administered for 2, 4 and 8 weeks in ACKR4$^{egfp-KO}$ and ACKR1^{KO} mice. To characterise LSEC subtypes we assessed 12 phenotypic markers by spectral flow cytometry. LSEC where gated using live cells, singlets and CD31^{+} CD45^{-} populations and analyzed by tSNE using the co-expression of LSEC markers with mesenchymal markers (e.g. Thy-1, TAGLN, and PDGFRa) to identify EndMT following CCl_4. Histograms show the expression of individual markers within each cluster corresponding to their colour. Localisation of LSEC subtypes were confirmed by immunofluorescent microscopy (IF).
Results: Healthy LSEC were distributed in four clusters 1: Lyve1^{hi} EMCN^{hi}, 2: CD31^{hi} Thbd^{hi}, 3:CD31^{lo} EMCN^{lo} and 4: CD31^{lo} ICAM1^{lo} (Fig. 1A). 8-weeks CCl_4 significantly reduced the number and composition of LSEC in clusters 1–4 and gave rise to three unique populations of EndMT cells 5: Thy-1^{hi} PDGFRa^{hi} CD34^{neg} 6: TAGLN^{hi} CD34^{med} and 7: Thy-1^{hi} PDGFRa^{mid} CD34^{hi} (Fig. 1B). IF revealed these EndMT populations predominantly arise in peri-central LSEC.
ACKR4$^{egfp-KO}$ reporter mice revealed ACKR4 expression in peri-central LSEC in healthy tissue. ACKR4 gene expression was significantly downregulated in WT following CCl_4. Conversely, ACKR1 expression was absent in healthy LSEC but markedly upregulated in peri-central regions following CCl_4. CCl_4 treated ACKR1-deficient mice maintained their vascular architecture with reduced collagen deposition and reduced number of cells undergoing EndMT compared to WT. ACKR4-deficient mice displayed augmented fibrogenesis at all time points characterized by increased collagen-deposition, significant disruption of EC identity and increased EndMT.
Conclusion: We observed three distinct 'disease-associated' LSEC subtypes arose with characterised features of EndMT. These clusters may represent different stages of EndMT that occur with LSEC transitioning from Cluster 3, to acquire mesenchymal traits in Cluster 6 before reaching complete EndMT (Cluster 5 and 7). ACKR1^{KO} mice were protected from both EndMT and fibrogenesis while ACKR4$^{eGFP-KO}$ mice displayed an opposite phenotype suggesting regulation of ACKRs during liver injury is a crucial determinant of vascular health and liver fibrosis.

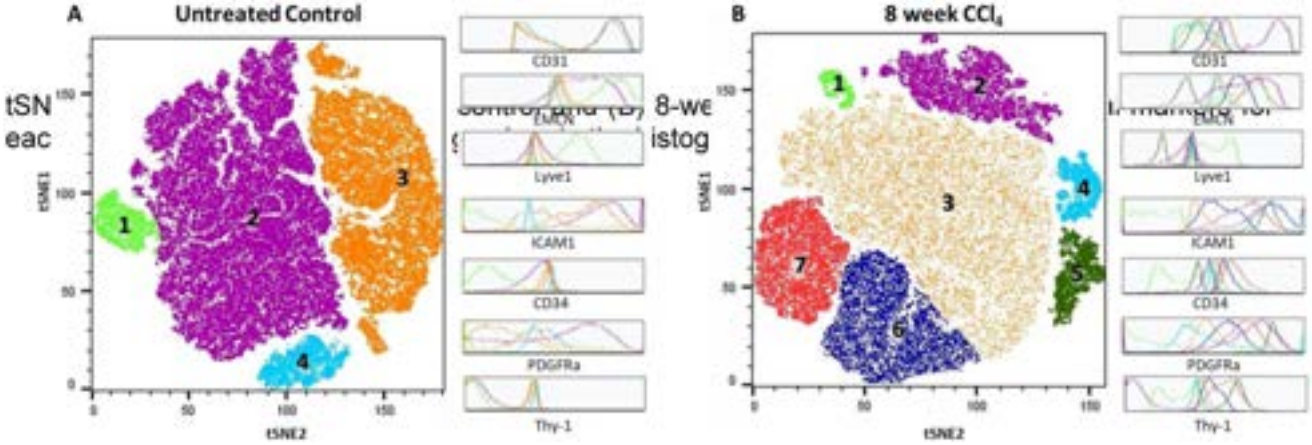

Figure: (abstract: OS-043): tSNEs plots display LSEC from (A) control and (B) 8-week CCl_4 WT mice with individual markers for each cluster shown by corresponding colour in the histograms.

OS-044-YI

Single-cell multiomics defines candidate transcription factors regulating pathogenic macrophage differentiation in murine liver fibrosis

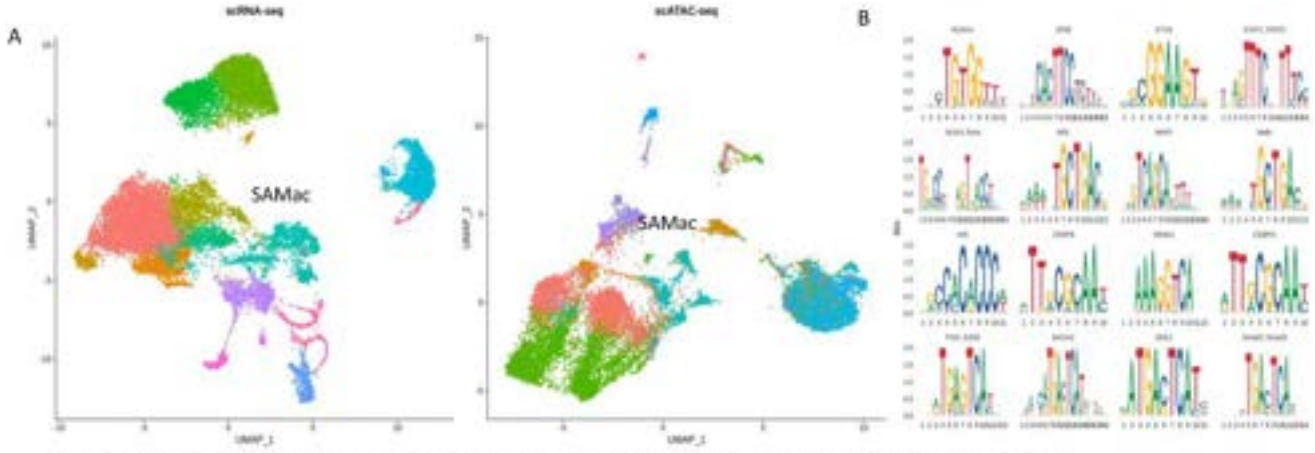
Eleni Papachritoforou[1], Elena Sutherland[1], Neil Henderson[1], Prakash Ramachandran[1]. [1]*University of Edinburgh, Centre for Inflammation Research, United Kingdom*
Email: eleni.papachristoforou@ed.ac.uk

Background and aims: Hepatic macrophages are key regulators of fibrosis progression and regression. Recent work using single-cell RNA-sequencing (scRNAseq) has identified a subpopulation of TREM2+CD9+ scar-associated monocyte-derived macrophages (SAMac) which expand in fibrotic human and murine liver tissue and regulate fibrosis. However, whilst the transcriptome of this macrophage population has now been well defined, the key transcriptional regulators of SAMac differentiation and phenotype remain unknown. To address this, we aimed to apply scRNAseq and single-cell ATAC-seq (scATACseq) in a murine model of liver fibrosis, to study transcription factor (TF) enrichment in monocyte and macrophage subpopulations at single-cell resolution.

Method: Liver injury was induced in C57BL/6J mice by carbon tetrachloride (CCl_4) twice weekly for 4 weeks. Age matched uninjured mice were controls. ScRNAseq and scATACseq was performed on FACS-purified immune cells from blood and liver tissue of CCl_4 injury (n = 6 scRNAseq; n = 4 scATACseq) and controls (n = 6 scRNAseq; n = 4 scATACseq) using the 10X Genomics Chromium platform. Computational analysis was performed in R.

Results: Unsupervised clustering of scRNAseq data enabled atlassing of populations of immune cells. Mononuclear phagocytes (MP) were reclustered, identifying 17 distinct subpopulations (Fig) including Trem2+Cd9+Gpnmb+ macrophages which expanded in fibrotic liver tissue and were transcriptionally similar to the corollary SAMac population in human fibrotic livers. Trajectory inference performed using Scvelo, demonstrated that murine SAMac derived from the recruitment and differentiation of circulating Ly-6C^{hi} monocytes. Having defined macrophage heterogeneity and differentiation kinetics using the scRNAseq data, scATACseq cell type clusters were then annotated by employing Seurat label transfer methodology (Fig). Differential TF motif enrichment was assessed in annotated scATACseq MP subpopulations using SIGNAC (Fig). We identified enrichment for previously described TFs such as the *Cebp* family in Ly-6C^{hi} blood monocytes, *Nr4a1* in Ly-6C^{lo} monocytes, *Runx1* in dendritic cells and *Nr1h3 (Lxra)* in resident Kupffer cells. Focussing on SAMac, this population was enriched for *AP-1* family members, *Nfe2, Batf, Smad2/3* as well as the transcriptional repressor *Bach2* and the antioxidant regulator *Nfe2l2*. Hence, the differentiation of monocytes into SAMac results in a distinct motif profile, suggesting that complex signals within the fibrotic niche are crucial to determining SAMac phenotype.

Conclusion: Single-cell multiomics identifies novel candidate transcriptional regulators of SAMac differentiation and expansion in the fibrotic liver. These data provide a framework for future functional studies aiming to selectively target and modulate SAMac transcription as an antifibrotic strategy for liver disease.



(A) UMAP of MP lineages with annotated SAMacs. (B) Differential TF motifs in the dendritic cells (DC), Kupffer cells (KC), Ly6Clo Monocytes and SAMac clusters of scATACseq data.

Email: f.terracciani@unicampus.it

Background and aims: Primary biliary cholangitis (PBC) is a chronic inflammatory and autoimmune cholestatic liver disease, which, if left untreated, can lead to cirrhosis and the need for liver transplantation. A variable percentage of patients (25–40%) are non-responder to first-line therapy with ursodeoxycholic acid (UDCA). In 2016, obeticholic acid (OCA) has been approved for patients non-responder or intolerant to UDCA. A number of studies have already reported post-marketing experiences with OCA; however, they are limited by small sample sizes and short follow-up. Aim of the RECAPITULATE study is to provide long-term results concerning real-world treatment with OCA in a large Italian cohort of PBC patients.
Method: Centres belonging to the "Italian PBC registry," the PBC task force of "Club Epatologi Ospedalieri" (CLEO) and "Associazione Italiana Gastroenterologi Ospedalieri" (AIGO), the "Sicilian PBC Network" and the "PBC Project Piemonte-Liguria-Valle D'Aosta" partecipated to data collection. Data from all patients followed at those centres receiving at least one dose of OCA, and with a follow-up of at least 6 months, were captured. Cumulative incidences of OCA response and discontinuation were evaluated through Aalen-Johansen (taking into account the competing risk of discontinuation) and Kaplan-Meier estimators, respectively.
Results: Data on 441 PBC patients (median age 58 years, women 88%, median time on OCA therapy 24 months), enrolled from 50 Italian centres, were analyzed. 153 patients (34%) were cirrhotics and 59 (13%) were PBC/autoimmune hepatitis (AIH) overlap. Observed response probabilities according to POISE criteria at 12/24/36 months were 37.5/43.5/47.2%, respectively. OCA was discontinued in 86 patients (19%). Discontinuation probabilities at 12/24/36 months were 12.8/17.7/22.9%, respectively. Leading causes of discontinuation were pruritus (41 patients, 48%), and hepatic events (19 patients, 21%). Cirrhotics showed lower response probabilities (25.9/27.7/34.8% at 12/24/36 months; $p < 0.01$ *Vs* non-cirrhotics), and higher discontinuation probabilities (19.9/27.6/34.6% at 12/24/36 months; $p < 0.01$ *Vs* non-cirrhotics). Response and discontinuation probabilities in PBC/AIH overlap were not significantly different to those observed in "pure PBC" ($p = 0.20$). Liver stiffness measurements (LSM) by vibration-controlled-transient-elastography (VCTE) were available for 309/114/69 patients at 0/12/24 months. LSMs were not different at 12 months compared with baseline either in Poise non-responders or responders. Conversely, at 24 months, LSMs were significantly reduced with respect to baseline in Poise responders [7.5 (5.4–9.5) *Vs* 7.9 (6.1–11.3), $p = 0.01$], but not in non-responders ($p = 0.96$).
Conclusion: Results from the Italian RECAPITULATE study confirm in a real-world setting the long-term efficacy and safety of second-line PBC treatment with OCA. These first data concerning LSM variation over time under OCA treatment suggest a reduction only in Poise responders, but need to be verified in a larger sample size.

OS-046

Results from a planned interim analysis of a randomized, double-blind, active-controlled trial evaluating the effects of obeticholic acid and bezafibrate on serum biomarkers in primary biliary cholangitis

Vaclav Hejda[1], Alexandre Louvet[2], Antonio Civitarese[3], Lynda Szczech[3], Heng Zou[3], Frederik Nevens[4]. *[1]University Hospital in Pilsen, Pilsen, Czech Republic; [2]University Hospital of Lille, Lille, France; [3]Intercept Pharmaceuticals Inc, Morristown, United States; [4]University Hospital KU Leuven, Belgium*
Email: antonio.civitarese@interceptpharma.com

Background and aims: Bezafibrate (BZF), a pan-agonist of the peroxisome proliferator-activated receptors, benefits patients with primary biliary cholangitis (PBC) who have an inadequate response to ursodeoxycholic acid (UDCA). Obeticholic acid (OCA), a potent farnesoid X receptor agonist, was approved as second-line treatment for PBC in 2016. This planned interim analysis of an ongoing phase 2, randomized, active-controlled trial assessed whether a combination of OCA and BZF may improve serum biomarkers for PBC more than BZF monotherapy, while also monitoring the safety and tolerability of the novel combination.

Method: While continuing their UDCA treatment (if any), subjects with PBC were randomized 1:1:1:1 to receive 12 weeks of once daily oral BZF 200 mg + placebo (B200), BZF 400 mg + placebo (B400), BZF 200 mg + OCA 5 mg titrated to 10 mg at week 4 (OCA/B200), or BZF 400 mg + OCA 5 mg titrated to 10 mg at week 4 (OCA/B400). End points included comparisons of serum biomarker levels of PBC-induced liver damage: alkaline phosphatase (ALP), alanine transaminase (ALT), aspartate aminotransferase (AST), gamma-glutamyl transferase (GGT), and total bilirubin (TB). Safety was assessed by monitoring of adverse events (AEs) and laboratory values.

Results: This planned interim analysis from the first 45 of the anticipated 72 subjects focused on short-term changes in biochemical indicators of improved outcomes in PBC. Relative to baseline values, only subjects receiving OCA/B400 showed a highly significant reduction in ALP to within normal range (60% of subjects) at week 4, which continued to improve through week 12 (**Figure**). Subjects receiving OCA/B400 also exhibited the greatest reductions in biomarkers and normalized levels of total bilirubin (100%), ALT (100%), and GGT (70%) by week 12. Two events of pruritus (20%) were reported in B200, 3 (25%) in B400, 2 (17%) in OCA/B200, and none in OCA/B400. Five of 23 (22%) subjects who received OCA discontinued the study: 2 withdrew consent (one in each combination group), 2 experienced treatment-emergent AEs (TEAEs; OCA/B400), and 1 violated the inclusion/exclusion criteria (OCA/B200). Four subjects experienced severe or serious TEAEs deemed non-drug related (atrial fibrillation [2 events], breast cancer, and pleural mesothelioma malignant). No deaths occurred in this study.

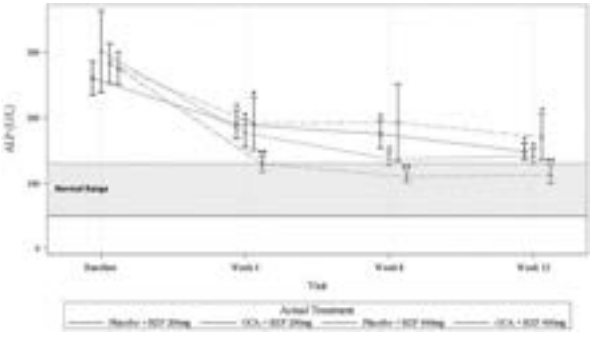

Figure: Effect of BZF (200 or 400 mg) and placebo or BZF (200 or 400 mg) and OCA (5–10 mg) on ALP levels in subjects with PBC. All treatment groups showed reductions from baseline in ALP, but only the highest dose combination (BZF 400 mg + OCA 5–10 mg) reduced the mean ALP levels to within normal range. Data are shown as mean values ± standard error of the mean. $^{*}p < 0.05$, $^{**}p < 0.0001$.

Conclusion: The results of this planned interim analysis suggest that short-term combination of BZF and OCA was well tolerated and has therapeutic potential in the reduction of biomarkers of PBC-related liver damage.

Email: i.schregel@uke.de

Background and aims: Prospective multicentre data on the treatment and outcome of adult autoimmune hepatitis (AIH) patients is lacking. The European Reference Network for Hepatological Diseases (ERN RARE-LIVER) launched the prospective, quality-controlled R-LIVER registry on rare liver diseases including data from newly diagnosed patients with autoimmune liver diseases. The aim of this study was to assess presentation, treatment heterogeneity and outcome under real-world conditions to describe the landscape of AIH in Europe.

Method: Data was collected prospectively between 01/2015 and 10/2022 at time of diagnosis of AIH, and after 6- and 12-months follow-up. Patients with concomitant liver diseases other than fatty liver disease at diagnosis were excluded. Treatment response was defined as normalization of ALT since in our cohort, correlation of ALT with histological activity could not be improved by the addition of serum IgG levels.

Results: 227 patients from six centres were included in the final analysis (81.5% female) with a median age at diagnosis of 55 years. Liver biopsy was performed in 96%, of whom 81.3% presented with a moderate to severe mHAI and 25.4% with severe Fibrosis (F3/F4). 24/227 patients presented with acute-severe AIH (including three patients receiving liver transplantation who were further excluded). After six months ALT was below ULN in 58% (130/224) and after 12 months, in 69.2% (155/224) of patients. In 36.6% steroids were withdrawn within the first year resulting in a steroid-free response in 29.4% (66/224) of patients.

In multivariate analysis corrected for centre site, older age at diagnosis (OR = 1.03 [95%CI 1.01–1.05]; p = 0.007), severe fibrosis (OR 0.38 [95% 0.16–0.89]; p = 0.026) and change of treatment between baseline and six-months follow-up (OR 0.40 [95% CI 0.2–0.86]; p = 0.018) were associated with treatment response at 12 month-follow-up.

Change of treatment, mostly due to intolerance, occurred in 30.4% within the first six months and in another 13.4% in the following six months. Of those who had a treatment change within the first six months, in only 57.4% ALT was below ULN at 12 months-follow-up.

After 12 months, 62.9% were still on first-line therapy (azathioprine and/or steroids). Overall, 16 different treatment regimens were administered within the first year of follow-up.

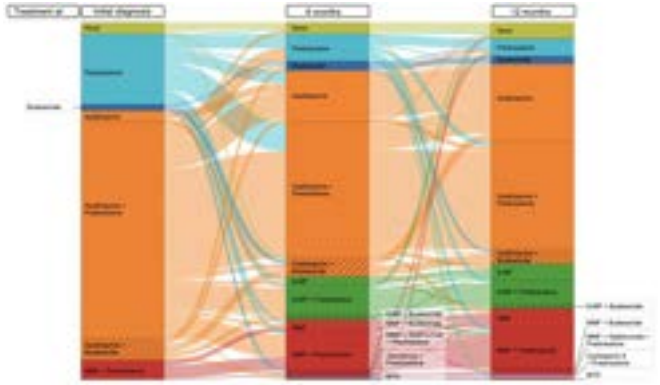

Figure 1: *Sankey diagram showing treatment regimens and flows between treatment regimens at diagnosis, at 6 months and at 12 months (n = 224, 3 patients excluded due to liver transplantation). Steroids: Prednisolone (dotted), budesonide (striped). Immunosuppressive Treatment: Azathioprine (orange), MMF (red), 6-MP (green), tacrolimus (purple), cyclosporine A (pink), MTX (brown).*

Conclusion: The results from this European multicentre prospective registry demonstrate a high rate of drug intolerance within the first six months of AIH therapy leading to change of treatment regime in 30.4%. The landscape of AIH-treatment is heterogenous even in expert centres throughout Europe with nearly one third of patients not reaching normalization of serum ALT levels until 12 months-follow-up and less than one third of patients with steroid-free treatment response. Those high rates of failure highlight the unmet needs in the care of people suffering from AIH.

OS-048-YI

Risk of cancer and subsequent mortality in primary biliary cholangitis: a population-based cohort study of 3,052 patients

Axel Wester[1], Johanna Schönau[2], Jörn Schattenberg[3], Hannes Hagström[1]. *[1]Karolinska Institutet, Department of Medicine Huddinge, Sweden; [2]University Medical Center of the Johannes Gutenberg-University, Germany; [3]Metabolic Liver Research Program, University Medical Center of the Johannes Gutenberg-University Mainz, Germany*
Email: axel.wester@ki.se

Background and aims: Primary biliary cholangitis (PBC) is a rare cholestatic liver disease. Incident cancer is a concern. Previous studies have described an increase in hepatocellular carcinoma (HCC), but the risk of non-hepatic cancer and the cancer risk across subgroups is largely unknown.
Method: We used the Swedish National Patient Register to identify all patients who were newly diagnosed with PBC between 2002 and 2019. Patients were matched for age, sex, and municipality with up to ten reference individuals from the general population. Incident cancer was recorded from the National Cancer Register. Cox regression was used to investigate the rates of cancer and post-cancer mortality, adjusted for potential confounders. The cumulative incidence of cancer was calculated while accounting for the competing risk of death.
Results: We identified 3,052 patients with PBC and 26,792 reference individuals and followed them for a median of 5.5 and 7.0 years, respectively. The median age was 64 years and 85% were women. At ten years of follow-up, the cumulative incidence of any cancer in patients with PBC was 14.3% (95% confidence interval [CI] 12.8–15.9), compared to 11.8% (95% CI 11.3–12.2) in the reference population (adjusted hazard ratio [aHR] 1.4, 95% CI 1.2–1.5). Although the rate of HCC was particularly high (aHR 30.9; 95% CI 14.8–64.6), PBC was also associated with non-HCC cancer (aHR 1.2, 95% CI 1.1–1.4), including gastrointestinal (aHR 1.5, 95% CI 1.1–1.9), lung (aHR 1.5, 95% CI 1.1–2.2) and lymphoma (aHR 2.9, 95% CI 1.9–4.6). The cancer rates were similarly increased across age and sex subgroups, but more prominently increased in patients with cirrhosis (aHR 2.1; 95% CI 1.4–3.0). Following a diagnosis of cancer, patients with PBC had higher one-year mortality rates compared to reference individuals (aHR 1.4, 95% CI 1.1–1.8), which was mainly driven by HCC (non-HCC related mortality: aHR 1.2, 95% CI 0.9–1.6).

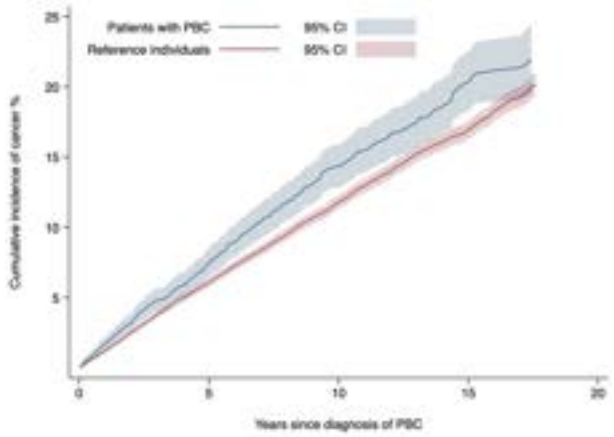

Figure:

Conclusion: Patients with PBC have a significantly higher risk of cancer compared to the general population. PBC was associated with both HCC and non-hepatic cancers as well as higher mortality following a diagnosis of cancer.

OS-049-YI

Lack of biochemical response after diagnosis is associated with cirrhosis development during follow-up in autoimmune hepatitis

Charlotte Slooter[1], Patrick Maisonneuve[2], Francesca Colapietro[3], Floris van den Brand[1], Marco Lenzi[4], Paolo Muratori[4], Nanda Kerkar[5], George Dalekos[6], Kalliopi Zachou[6], Maria Isabel Lucena[7], Mercedes Robles-Díaz[7], Daniel E. Di Zeo-Sánchez[7], Raul J. Andrade[7], Aldo Montano-Loza[8], Ellina Lytvyak[8], Gerd Bouma[1], Rodrigo Liberal[9], Ana Lleo[3], Ynto de Boer[1]. *[1]Amsterdam University Medical Center, Netherlands; [2]European Institute of Oncology, Italy; [3]Humanitas University, Italy; [4]University of Bologna, Italy; [5]Golisano Children's Hospital, University of Rochester Medical Center, United States; [6]University Hospital of Larissa, Greece; [7]Vírgen de Victoria University Hospital, University of Málaga, Spain; [8]University of Alberta Hospital, Edmonton, Canada; [9]Centro Hospitalar Sao Joao, Porto, Portugal*
Email: y.deboer1@amsterdamumc.nl

Background and aims: The aim of treatment in autoimmune hepatitis (AIH) is the achievement of complete biochemical response defined as normalization of aminotransferases and immunoglobulin G (IgG) in order to prevent further progression of the disease and the development of cirrhosis. Studies with enough power that assess prognostic factors are scarce. The aim of this study is to identify prognostic factors in the worlds' largest AIH cohort from the International Autoimmune hepatitis (AIH) Group retrospective registry (IAIHG-RR).

Method: This retrospective, observational, multicentre study included all patients with a clinical diagnosis of AIH and available follow-up data from the IAIHG-RR. Logistic regression and Cox regression were used to identify independent risk factors for lack of biochemical response and development of cirrhosis. Analysis of cirrhosis development was restricted to the four centres that reported date of cirrhosis development.
Results: This analysis included 1700 patients with a median follow-up of 10 (range 0–49) years. In those with available data on response, no normalization of aminotransferases and IgG within 6 months after treatment initiation was observed in 418 (32%) and 153 (22%) patients, respectively. Overall, 224 (32%) patients did not achieve complete biochemical response and 114 (37%) developed cirrhosis after a median of 8 (range 0–33) years. Predictors of lack of biochemical response were cirrhosis at diagnosis (HR 2.6 95% CI 1.7–4.0), anti-smooth muscle antigen (SMA) (HR 0.5 95% CI 0.3–0.7), and the laboratory values alkaline phosphatase (ALP) (HR 1.0 95% CI 1.0–1.0) and IgG (HR 1.1 95% CI 1.0–1.1) at first evaluation. Predictors of cirrhosis development included variant syndromes with primary biliary cholangitis (PBC) (HR 2.0 95% CI 1.0–4.0) and primary sclerosing cholangitis (PSC) (HR 6.7 95% CI 2.6–17.6) as well as lack of biochemical response (HR 4.2 95% CI 2.1–8.2).

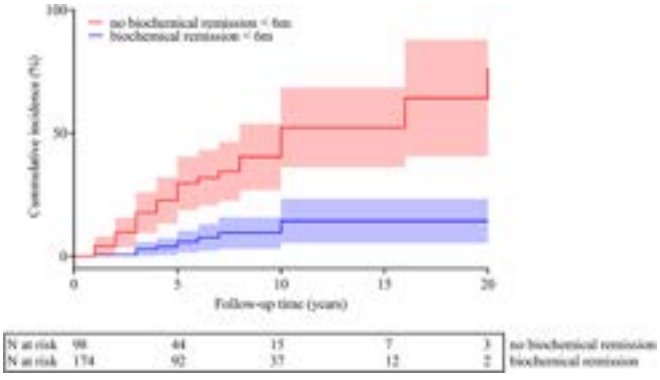

Figure: Cumulative incidence of cirrhosis development according to response to treatment in patient with AIH (p < 0.001 log-rank).

Conclusion: Cirrhosis at diagnosis, SMA, ALP and IgG were associated with lack of biochemical response. Predictors of cirrhosis development after diagnosis were lack of biochemical response and the presence of variant syndromes. This finding supports IAIHG statement that treatment of AIH should aim at complete biochemical response within 6 months, as defined by normalization of both liver enzymes and IgG. Close follow-up and more aggressive treatment of these patients may be warranted.

Liver transplantation and hepatobiliary surgery

OS-050-YI

APRI+ALBI score is superior to Indocyanine Green (ICG) clearance and LiMAx test in the prediction of posthepatectomy liver failure- an international multicenter study of 14581 patients

Email: tellsantol@gmail.com

Background and aims: APRI+ALBI, a score calculated using only aspartate aminotransferase, platelet count, albumin and bilirubin, and dynamic liver function tests like ICG clearance and LiMAx have been evaluated for their predictive potential for posthepatectomy liver failure (PHLF). The aim of this study was to compare the predictive potential of these parameters for PHLF grade B + C and validate our findings using an international multicenter cohort and a logistic regression-based prediction model.
Method: 622 patients undergoing major and minor liver resection with preoperative ICG clearance measurement and 192 patients undergoing hepatic surgery, with preoperative LiMAx test assessment were included from a prospectively maintained database. PHLF grade B + C was defined according to the ISGLS criteria. To form a validation cohort 1906 patients with available preoperative APRI +ALBI score from 8 different international institutions were included. Finally, 12056 patients from the NSQIP database, who underwent hepatic surgery and where a preoperative APRI+ALBI score could be calculated, were included to generate a logistic regression-based prediction model along with generalized additive models to capture non-linearities.
Results: Predictive potential of the APRI+ALBI score for PHLF grade B + C was superior to ICG clearance and LiMAx, when comparing areas under the curve (AUC) (ICG cohort: APRI+ALBI AUC = 0.785, ICG-R15 AUC = 0.643, ICG-PDR AUC = 0.643; LiMAx cohort: APRI+ALBI AUC = 0.868, LiMAx AUC = 0.536). We then defined two cutoffs for APRI +ALBI. A low-risk cutoff of ≥−2.43, to assess which patients could safely be resected (negative predictive value (NPV) = 98%, p < 0.001) and a high-risk cut-off of ≥−0.86, to identify which patients were most likely to develop PHLF B + C (positive predictive value (PPV) = 56%, p < 0.001). Both cutoffs proved independent of other parameters and confounders in two multivariable models (low-risk multivariable

model: low-risk cutoff, p < 0.001, odds ratio (OR), 5.751, 95% confidence interval (CI), 2.193–15.082; high-risk multivariable model: high-risk cutoff, p < 0.001, OR, 20.534, CI, 4.946–85.252) The cutoffs showed similar results in the validation cohort (≥–2.43 NPV = 93%, p < 0.001; ≥–0.86 PPV = 29%, p < 0.001; ≥–0.98 PPV = 33%, p < 0.001). To evaluate dynamic risk increase more precisely, in a next step, we developed a logistic regression based dynamic risk assessment model (Fig. 1). We were able to demonstrate and validate that with a rising APRI+ALBI score a concomitant exponential increase in risk can be observed.

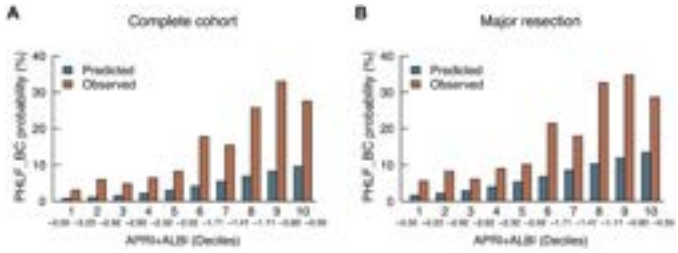

Figure 1: Logistic regression based dynamic risk assessment model, calculated for the whole cohort (A) and for major resections only (B).

Conclusion: APRI+ALBI can be calculated using only routine preoperative laboratory parameters. We can demonstrate that APRI +ALBI is superior to ICG clearance and LiMAx testing, as two frequently used dynamic liver function tests, in the prediction of PHLF grade B + C. Using high- and low-risk cutoffs, we were able to assess which patients could safely undergo surgery and which patients had the highest postoperative risk to develop PHLF B + C. We were able to validate our findings, using an international multicenter validation cohort. Importantly, we could ultimately develop and validate a dynamic risk assessment model for clinically significant PHLF based on simple APRI/ALBI scoring to increase predictive accuracy for the individual patient.

OS-051-YI

MicroRNA based prediction of posthepatectomy liver failure and mortality outperforms established markers of preoperative risk assessment

Anna Kern[1], David Pereyra[2], Hubert Hackl[3], Susanna Skalicky[4], Jonas Santol[5,6], Jeremias Weninger[2], Sarah Brunner[2], Valerie Laferl[2], Yannic Herrmann[2], Thomas Grünberger[5], Matthias Hackl[4], Alice Assinger[6], Patrick Starlinger[7]. [1]*General Hospital of Vienna, Department of General Surgery, Division of Visceral Surgery, Medical University of Vienna, Vienna, Austria;* [2]*General Hospital of Vienna, Department of General Surgery, Division of Visceral Surgery, Medical University of Vienna, Austria;* [3]*Medical University of Innsbruck, Division of Bioinformatics, Austria;* [4]*TAmiRNA GmbH, Austria;* [5]*Clinic Favoriten, Department of Surgery, HPB Center, Vienna Health Network, Austria;* [6]*Institute of Vascular Biology and Thrombosis Research, Center for Physiology and Pharmacology, Medical University of Vienna, Austria;* [7]*Mayo Clinic, Rochester, Department of Surgery, Division of Hepatobiliary and Pancreatic Surgery, Rochester, United States*
Email: tellkern@gmail.com

Background and aims: Posthepatectomy liver failure (PHLF) continues to be the most significant factor determining outcomes after hepatic resection, accounting for nearly half of postoperative mortality. In this study, we evaluated if the simple assessment of circulating microRNAs (miRs) can predict PHLF, and could outperform other liver function tests, such as indocyanine green (ICG) clearance, hepatic venous pressure gradient (HVPG) and liver maximum capacity (LiMAx) test.
Method: A total of 329 patients, all undergoing liver resection in 3 different hospitals in Vienna, Austria, were included and postoperative outcome was assessed. Our previously described miR-Score (HepatomiR) was assessed preoperatively, as well as other well established predictors of PHLF.
Results: HepatomiR was superior to all other analyzed liver function tests in the prediction of PHLF and PHLF grades B and C (PHLF: HepatomiR: area under the curve (AUC) = 0.770, Fig. 1A) (PHLF: plasma disappearance rate (PDR): AUC = 0.569; retention rate at 15 minutes (R15): AUC = 0.618; HVPG: AUC = 0.530; LiMAx: AUC = 0.540, Fig. 1B) (PHLF B+C: HepatomiR: AUC = 0.755, Fig. 1C) (PHLF B+C: PDR: AUC = 0.634; R15: AUC = 0.653; HVPG: AUC = 0.530; LiMAx: AUC = 0.593). Also, strong predictive potential for PHLF was observed when analyzing HepatomiR in the respective tumor subgroups (colorectal cancer liver metastases (mCRC): AUC = 0.799; hepatocellular carcinoma (HCC): AUC = 0.723; cholangiocellular carcinoma (CCa): AUC = 0.701; other: AUC = 0.949, Fig. 1D). We could validate the previously published low-risk cut-off P > 0.59 (negative predictive value = 91.5%) and high-risk cut-off P > 0.68 (positive predictive value = 77%) for PHLF and document a close association with postoperative overall survival. Economic analyses demonstrated a significant reduction of health care costs utilizing improved patient risk-stratification.

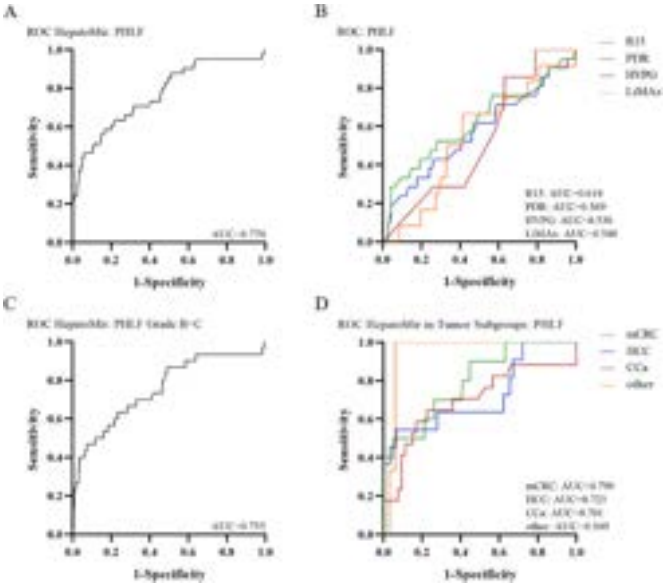

Figure:

Conclusion: The simple assessment of 3 circulating miRs outperforms several liver function tests utilized in daily clinical practice in the prediction of PHLF. Moreover, HepatomiR allowed identification of patients that died rapidly after hepatic resection, which might be better served with alternative treatments. Economic assessment let us to demonstrate, that optimized preoperative risk-assessment lead to a significant reduction of health care costs.

OS-052

Prehabilitation intervention to maximize early recovery (PRIMER) in liver transplantation: a randomized, controlled trial

Marina Serper[1], Lauren Jones[1], Thomas Clement[1], Kristen Dwinnells[2], Derek Zaleski[2], Peter Reese[1]. [1]*University of Pennsylvania, United States;* [2]*Hospital of the University of Pennsylvania, United States*
Email: marinas2@pennmedicine.upenn.edu

Background and aims: Frailty and impaired functional status are associated with adverse outcomes on the liver transplant (LT) waitlist and after transplantation. Prehabilitation prior to LT has rarely been tested. We conducted a two-arm patient randomized trial to evaluate the efficacy of a behavioral intervention to promote exercise and physical activity prior to LT.
Method: This was a 12-week, prospective study comparing enhanced usual care to a home-based, remote monitoring behavioral intervention. A total of 30 patients were randomized 2:1 to intervention (n-

20) vs. control (n = 10). The intervention arm included financial incentives and text-based reminders that were linked to personal fitness trackers (Nokia Go) to gradually increase daily steps by 15% in 2-week intervals (6 in total). Weekly check-ins with study staff were incentivized to promote adherence and assess barriers to physical activity. Both arms received personalized dietary and physical activity recommendations based on a nutrition assessment, short physical performance battery (SPPB), and frailty. The primary outcomes were feasibility and acceptability. Secondary outcomes included mean end-of-study (week 11–12) step counts, SPPB, grip strength, and body composition (PhA). We fit regression models for secondary outcomes with arm as the exposure adjusting for baseline performance using robust standard errors.

Results: Mean age was 61, 47% were female, median MELD-Na was 13. One third were frail or pre-frail by the liver frailty index (LFI), 40% had impaired mobility by SPPB, nearly 40% had sarcopenia by bioimpedance PhA, 23% had prior falls, and 53% had diabetes. Study retention was 27/30 (90%; 2 unenrolled from intervention, 1 lost to follow-up in control arm). Self-reported adherence to exercise during weekly check-ins was about 50%; most common barriers were fatigue, weather, liver-related symptoms. Figure 1 shows mean step counts by arm (Panel A) and % adherence to daily step targets (Panel B) by each 2-week interval. Mean baseline daily steps counts were: overall: M 2186 SD (1166); control: M 2632 SD (1599); intervention: M 1924 SD:758). End of study step counts were nearly 1000 steps higher for intervention vs. control: β = 997, 95% CI 147–1847; p = 0.023). On average, the intervention group achieved daily step targets 51% of the time.

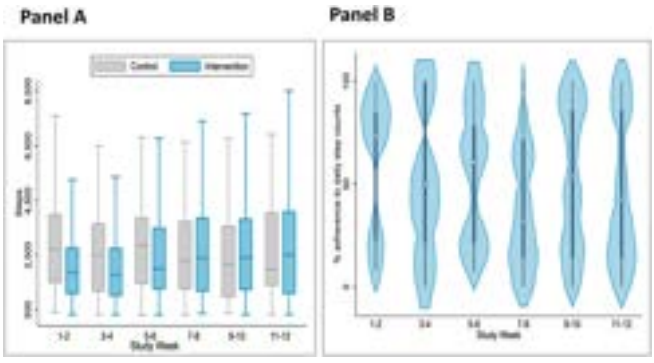

Figure 1: Panel A. Steps counts by arm during each 2-week interval; Panel B. Percent adherence to step count goals during each 2-week interval in the intervention arm.

Conclusion: A home-based intervention with financial incentives and text-based nudges increased walking by one third over baseline in LT candidates with functional impairment and malnutrition. Adherence to physical activity was three-fold higher than reported in recent studies. Home-based prehabilitation is feasible and hold promise for larger trials.

OS-053-YI

Type of calcineurin inhibitor versus long-term outcome following liver transplantation for primary biliary cholangitis-an ELTR study

Email: m.vanhooff@erasmusmc.nl

Background and aims: Tacrolimus is the preferred calcineurin inhibitor (CNI) following liver transplantation (LT). As compared to cyclosporine, however, tacrolimus has been linked to a more frequent recurrence of Primary Biliary Cholangitis (PBC), which was recently shown to negatively impact graft and patient survival. Therefore, the aim of this study was to assess the relation between the type of CNI and long-term graft and patient survival following LT for PBC.

Method: Cox proportional hazard analyses were used to assess the association between the type of CNI and graft or recipient survival among adult patients with PBC in the European Liver Transplant Registry (ELTR) who received a DBD graft between 1990 and 2021. Graft failure was defined as re-transplantation irrespective of the cause, as ELTR contained no data on recurrence PBC. Patients were not included in case of concomitant liver disease or in case they did not reach one year of follow-up with a functioning graft. The type of CNI was based on the registered maintenance immunosuppressive regimen, or in case this was not available, on the initial regimen.

Results: In total, the ELTR included 5306 PBC patients who received a DBD LT between 1990 and 2021. Overall, these patients were followed for a median of 8.3 years (IQR 2.0–15.9), during which 2213 patients lost their graft and/or died. The 5-year cumulative graft and recipient survival rates was 77.7% (95%CI 76.5–78.9) and 82.0% (95%CI 80.8–83.2), respectively. Of the 5306 patients, 443 (8.3%) patients did not (yet) reach one year of follow-up and 797 (15.0%) lost their graft or died during the first year. Among the remaining 4066 patients, there was no information concerning immunosuppressive drugs in 891 (21.9%) patients. The study population for the primary aim thus included 3175 PBC patients; 2764 (87.1%) females, median age at LT of 55.4 years (IQR 48.8–61.4), and a median year of LT of 2001 (IQR 1996–2009). Tacrolimus was used in 2056 (64.8%) patients and cyclosporine in 819 (25.8%), while 283 (8.9%) did not use any CNI and 17 (<0.01%) used both. Among patients using a single CNI, tacrolimus was not associated with higher risk of graft loss (HR 0.95, 95%CI 0.83–1.08, p = 0.397) or death (HR 0.91, 95%CI 0.80–1.04, p = 0.150). Adjusting for age, gender, year of LT, ischemia time and donor age did not change the association between the type of CNI and graft loss (aHR 0.97, 95%CI 0.82–1.15, p = 0.751) or death (aHR 0.96, 95%CI 0.81–1.14, p = 0.636). Findings were consistent in clinically relevant subgroups (e.g. based on age and time of LT) and sensitivity analyses including events in the first year post-LT (range of aHR for type of CNI was 0.83–1.22, p > 0.100 for all).

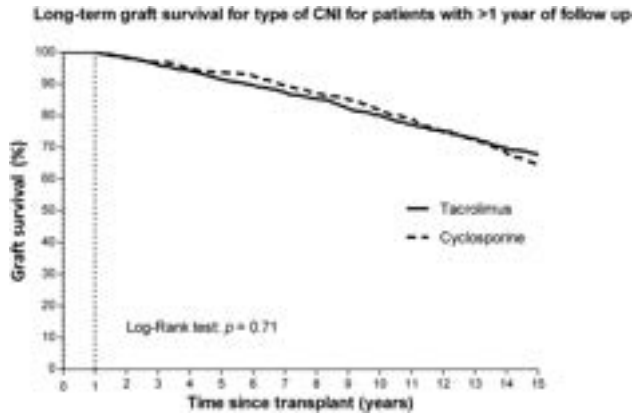

Figure:

Conclusion: Among adult PBC patients transplanted with DBD liver grafts, the type of CNI was not associated with long-term graft survival or recipient survival. These results justify the continued use of tacrolimus after DBD LT in the patients with PBC.

Liver tumours – Therapy

OS-055

Characterization and burden of non-hepatocellular carcinoma focal lesions detected during surveillance of patients with cirrhosis

Pierre Nahon[1], Layese Richard[2], Nathalie Ganne-Carrié[1], Cagnot Carole[3], Etienne Audureau[2], Pierre-André Natella[1]. *[1]APHP Avicenne, France; [2]APHP Henri Mondor, France; [3]ANRS, France*
Email: pierre.nahon@aphp.fr

Background and aims: Hepatocellular carcinoma (HCC) surveillance is challenged by the detection of hepatic focal lesions (HFL) of other types. The aim was to describe the incidence, characteristics and outcomes of non-HCC HFL detected in patients with cirrhosis.
Method: We analyzed data obtained from medical files of French patients with cirrhosis included in protocolized multicentre HCC surveillance programs (prospective ANRS CirVir and CIRRAL cohorts, HCC 2000 trial). Incidences of HFL, applied recall procedures, diagnoses and outcomes were analyzed.
Results: 3295 patients were studied. After a median follow-up of 59.8 months, 1024 (31.1%) patients developed at least one HFL (5-yrs incidence: 33.3%). Following recall procedures 391 (38.2%) were considered as HCCs (5-yrs incidence: 12.1%, Fig1A). The 633 (61.8%) remaining lesions corresponded to non-HCC HFL (5-yrs incidence: 21.1%). These lesions were more frequently detected in younger patients with non-viral cirrhosis, with less severe liver disease and better screening compliance. Rates of uninodular lesions were similar in both groups (66.2% vs 65.7%), as was the examination that enabled detection (ultrasound 62.6% vs 59.7%). 283 (72.6%) HCC patients were classified as BCLC 0 or A. The diagnostic procedures performed for non-HCC HFL were available in 389 patients [median additional cross-sectional examination 1 (min: 0, max: 6), 0.7 exams per year (IQR : 0–1.4)]. Sixty-three/389 (16.1%) non-HCC HFL were not subsequently confirmed by recall procedures. One hundred and four/389 (26.7%) non-HCC HFL remained undetermined. A diagnosis of benign liver tumour was assessed for 206/389 (52.9%) HFL (cyst = 41, angioma = 38, vascular fistula = 37, regeneration nodule = 33, dysplastic nodule = 15, perfusion defect = 15, pseudo-lesion = 4, others = 23). Sixteen/389 (4.1%) malignant tumours (cholangiocarcinoma = 15, metastases = 1) were diagnosed. Overall survival of patients with non-malignant HFL was similar to that of patients who never developed HFL during follow-up (5-year survival 92% vs 88%, $P = 0.07$, Fig1B). Extra-hepatic mortality was the first cause of death in these 2 groups (60.3% and 63.7%).
Conclusion: The incidence of non-HCC HFL reaches 20% at 5 years and corresponds to two-thirds of lesions detected in patients enrolled in screening programs. This burden must be taken into account in cost-effectiveness analyses of future surveillance programs using more sensitive imaging techniques such as abbreviated MRI.

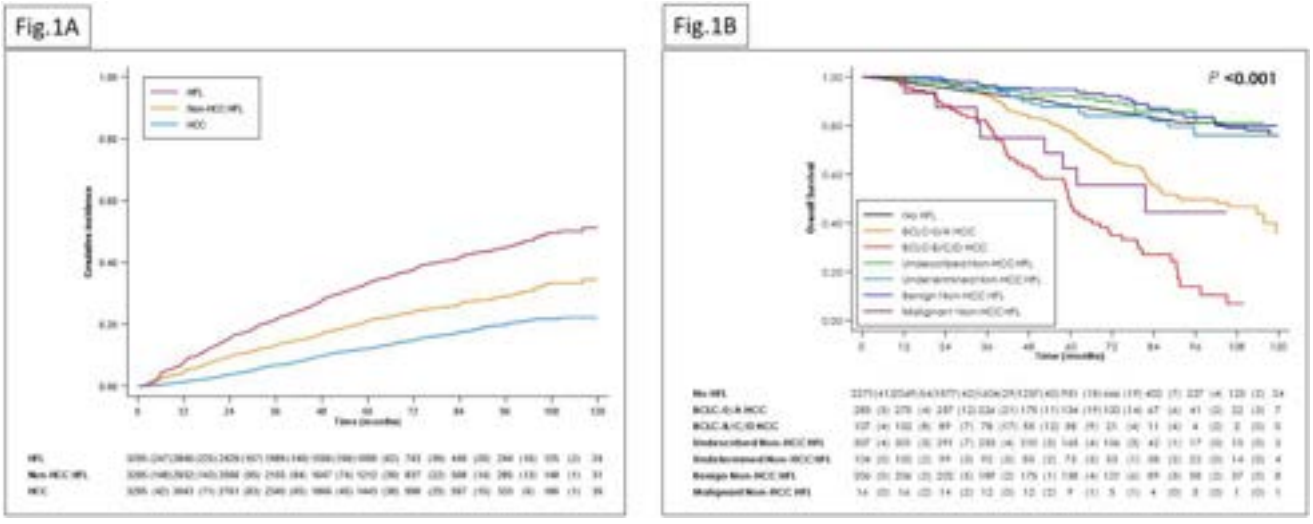

Figure: (abstract: OS-055).

Email: najib.benkhaled@med.uni-muenchen.de

Background and aims: The combination of atezolizumab and bevacizumab demonstrated superiority over the tyrosine kinase inhibitor (TKI) sorafenib in patients with advanced hepatocellular carcinoma (HCC). VEGF-inhibition with bevacizumab or TKI is associated with the risk of bleeding and thromboembolic events, which is of particular concern in HCC patients. In the pivotal IMbrave150 trial, there was a numerically higher rate of bleeding and arterial thromboembolic events with atezolizumab/bevacizumab compared to sorafenib. The current first-line alternative to a treatment with atezolizumab/bevacizumab is lenvatinib, which demonstrated longer progression free survival and higher objective response rates compared to sorafenib. However, data comparing the safety of atezolizumab/bevacizumab and lenvatinib are lacking.
In this study, we evaluated the risk of bleeding and thromboembolic events with atezolizumab/bevacizumab versus lenvatinib in a large, multi-centric real-world population.
Method: Data from HCC cohorts of six tertiary centers in Germany were used for analysis. In total n = 262 patients treated with atezolizumab/bevacizumab (treated between Jun. 2019 and Oct. 2022) and n = 136 patients treated with lenvatinib (treated between Sept. 2018 and Jun. 2022) were evaluated. Occurrence of bleeding or thromboembolic events within 3 months after initiation of therapy was assessed. For statistical analysis, normality of the data was assessed by Shapiro-Wilk test, followed by Student's t test or Mann Whitney test. Fisher's exact test was applied for contingency tables.
Results: Both groups were balanced with respect to demographics, presence of liver cirrhosis and variceal status (see figure). Median length of therapy was not different between groups (atezolizumab/bevacizumab 105 vs. lenvatinib 108 days, p = 0.96). Surrogate markers of portal hypertension such as platelet count (atezolizumab/bevacizumab 195.7 ± 107.9 vs. lenvatinib 187.7 ± 99.8 × 10^9/L; p = 0.75) or spleen size (atezolizumab/bevacizumab 12.5 ± 2.6 vs. lenvatinib 12.6 ± 2.7 cm; p = 0.99) showed no differences between groups.
Bleeding episodes were described in 46 of 262 (17.6%) patients receiving atezolizumab/bevacizumab compared to 16 of 136 (11.8%) patients receiving lenvatinib (p = 0.15, Odds Ratio 1.60, 95% CI 0.86–2.95). Variceal hemorrhage occurred in 8 of 262 (3.0%) patients treated with atezolizumab/bevacizumab versus 5 of 136 (3.6%) patients treated with lenvatinib (p = 0.77, Odds Ratio 0.83, 95% CI 0.26–2.28). Thromboembolic events were reported in 20 of 260 (7.6%) patients in the atezolizumab/bevacizumab cohort compared to 5 of 136 (3.6%) patients in the lenvatinib cohort (p = 0.19, Odds Ratio 2.1, 95% CI 0.81–5.23).

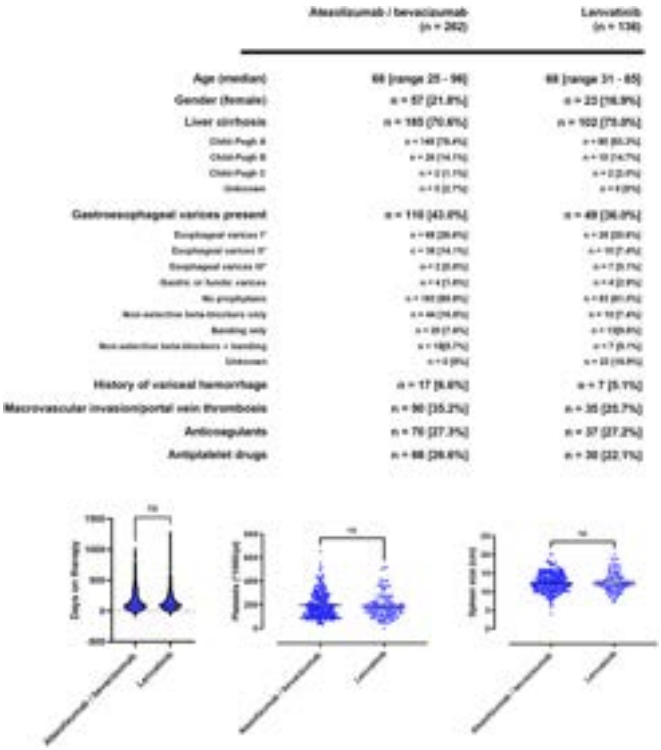

Figure:

Conclusion: Rates of bleeding and thromboembolic events did not differ significantly between atezolizumab/bevacizumab and lenvatinib and may not be helpful in choosing between the two treatments. Future prospective studies are needed to confirm our results.

OS-058

Multimodal integrative genomics and pathology analyses in neoadjuvant nivolumab treatment for borderline resectable HCC

Tan-to Cheung[1], Daniel Ho[1], Shirley Lyu[1], Qingyang Zhang[1], Yu Tsui[1], Tiffany Yu[1], Karen Sze[1], Joyce Lee[1], Vince Lau[1], Yin-Lun Chu[2], Simon Tsang[2], Wong She[1], Roland Leung[2], Thomas Yau[1], Irene Oi-Lin Ng[1]. *[1]The University of Hong Kong, Hong Kong; [2]Queen Mary Hospital, Hong Kong*
Email: iolng@hku.hk

Background and aims: Immunotherapy has resulted in pathologic responses in hepatocellular carcinoma (HCC) but the benefits and molecular mechanisms of neoadjuvant immune checkpoint blockade are largely unknown. In this study, we evaluated the efficacy and safety of pre-operative nivolumab (anti-PD1) in patients with borderline resectable HCC and investigated the molecular determinants for predicting treatment response.
Method: A single-arm study was designed to assess the clinical benefit of neoadjuvant treatment with nivolumab in patients with untreated, borderline resectable HCC. Between July 2020 and November 2021, 20 treatment-naïve HCC patients with intermediate and locally advanced tumors received preoperative nivolumab at 3 mg/kg for 3 cycles prior to surgical resection. Pathological examination of pre- and post-operative tumour specimens, RNA-sequencing to devise the cellular and molecular profiles of patients' HCC tumours, and plasma cell-free DNA and copy number variation (CNV) to derive a non-invasive biomarker anti-PD1 response score were used.

Results: Of the 20 patients, 19 underwent surgical resection on-trial. The majority (90%) of patients had locally advanced stage and 10% had intermediate stage per Hong Kong Liver Cancer (HKLC) staging classification. 70% of the patients were HBV carriers and the remaining 5 had chronic alcohol consumption. Seven (36.8%) of the 19 patients had major pathologic tumor necrosis (≥60%) in the post-nivolumab resection specimens, with 3 having almost complete (>90%) tumor necrosis. The tumor necrosis was hemorrhagic and often accompanied with increased or dense immune cell infiltrate at the border of the tumors. None of the patients developed major adverse reactions contradicting hepatectomy. RNA-sequencing analysis on both pre-nivolumab tumor biopsies and post-nivolumab resected specimens revealed a change in the immune cellular landscape. In the cases with major pathologic necrosis, the proportion of CD8T cells in the HCC tissues predominantly increased after treatment. Immunohistochemistry for CD8 and CD4 T cells showed result consistent with those of the cellular deconvolution. With subsequent gene set enrichment analysis, we detected an overall upregulation of immune response, particularly lymphocyte activation and differentiation, consistent with our findings in the cellular landscape. Moreover, to investigate non-invasive biomarker for nivolumab response, we evaluated, on plasma cell-free DNA of the patients, the copy number variation (CNV) using target-panel sequencing and derived a CNV-based anti-PD1 score. The score correlated with the extent of tumor necrosis, and was validated in a Korean patient cohort with anti-PD1 treatment.

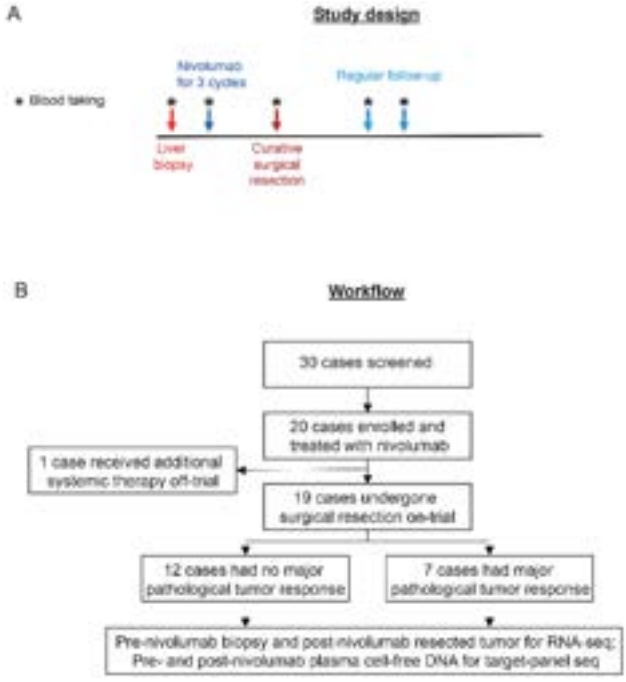

Figure:

Conclusion: Our study demonstrates that neoadjuvant nivolumab is safe and has promising clinical activity in borderline resectable HCC patients. We also identify potentially useful non-invasive biomarker predicting anti-PD1 responsiveness. Significant immune cell-related tumor necrosis observed in the post-nivolumab hepatectomy specimens signifies that successful restoration of cytotoxic immunity is the key determinant for immune checkpoint blockade response.

Predicting response to atezolizumab plus bevacizumab in advanced hepatocellular carcinoma using single-cell RNA-sequencing-derived gene signatures

Sarah Cappuyns[1,2,3,4,5], Marta Piqué-Gili[1,2], Roger Esteban-Fabró[1,2], Gino Philips[4,5], Roser Pinyol[2], Vincent Vandecaveye[6,7], Jordi Abril-Fornaguera[1,2], Philipp Haber[1,8], Chris Verslype[3], Eric Van Cutsem[3], Diether Lambrechts[4,5], Augusto Villanueva[1], Jeroen Dekervel[3], Josep Llovet[1,2,9]. *[1]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, Mount Sinai Liver Cancer Program, Division of Liver Diseases, NY, United States; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Liver Cancer Translational Research Laboratory, Spain; [3]UZ/KU Leuven, Digestive Oncology, Department of Gastroenterology, Belgium; [4]Katholieke Universiteit Leuven, Laboratory for Translational Genetics, Department of Human Genetics, Leuven, Belgium; [5]Vlaams Instituut voor Biotechnologie, Center for Cancer Biology, Leuven, Belgium; [6]UZ Leuven, Radiology Department, Belgium; [7]Katholieke Universiteit Leuven, Laboratory of Translational MRI, Department of Imaging and Pathology, Belgium; [8]Charité Universitätsmedizin Berlin, Germany; [9]Institució Catalana de Recerca i Estudis Avançats, Spain*
Email: sarahcappuyns@hotmail.com

Background and aims: Single-cell transcriptomic profiling (scRNAseq) is a powerful explorative technique that has helped in the characterisation of tumour immune cell infiltration and how it relates to treatment response in advanced HCC (aHCC). Here, we aimed to 1) derive gene expression signatures that recapitulate distinct single-cell derived immune cell types that can be applied to bulk RNAseq data and to 2) evaluate whether these signatures are associated with clinical response in aHCC treated with atezolizumab plus bevacizumab (atezo + bev), current standard of care.
Method: Using scRNAseq data from 31 aHCC tumour biopsies (91.169 single cells), we defined gene signatures for 35 cell phenotypes using a customized bio-informatics pipeline based on differential gene expression analysis. Signatures were validated in an independent, publicly available scRNAseq dataset of 22 HCC patients (Ma *et al.* JHep 2021). To evaluate the power of single-cell derived signatures to capture the presence of specific intra-tumoural cell types in bulk transcriptomic data, we analysed three cohorts comprising a total of 547 HCC tumour samples: 1) 399 early HCCs, 2) 83 anti-PD1-treated aHCCs and 3) 65 aHCCs treated with atezo + bev in frontline. We performed a) single-sample Gene Set Enrichment Analysis (ssGSEA) and b) Nearest Template Prediction (NTP) analysis, and ssGSEA-derived scores and class prediction results were correlated with both known HCC immune subclasses and objective response to therapy (mRECIST).
Results: We successfully generated highly specific gene signatures for 21 out of 35 single-cell derived cell types. As expected, signature enrichment analysis using the bulk transcriptome of 399 early HCCs revealed that the 'immune-active' and 'exhausted' HCC subclasses (Sia *et al.* Gastroenterology 2017) were enriched in both T-cell and myeloid signals. In contrast, the inflamed profile of the 'immune-like' subclass (Montironi *et al.* Gut 2022) was mostly driven by myeloid populations, in particular PDL1$^+$ CXCL10$^+$ macrophages, previously associated with response to immunotherapy at the single-cell level (Cappuyns *et al.* ILC 2022). In aHCC, 12% of tumours (n = 17/148) were enriched in PDL1$^+$ CXCL10$^+$ macrophages in bulk RNAseq (using the NTP-method). Importantly, their presence was associated with response to both anti-PD1 (n = 4/12 responders *vs.* 0/16 non-responders; $p = 0.02$) and atezo + bev (n = 6/18 responders *vs.* 1/39 non-responders; $p = 0.003$), thus identifying responders with a specificity of 100% and 97.5% and a positive predictive value of 100% and 86.6%, respectively.
Conclusion: Using scRNAseq data from immunotherapy-treated aHCC patients, we generated gene signatures representative of 21 distinct cell phenotypes. The presence of PDL1$^+$ CXCL10$^+$

macrophages was associated with response to atezo + bev, confirming their essential role in facilitating the efficacy of immunotherapy in aHCC.

NAFLD: Therapy

OS-060

A Phase 2a, randomized, active-comparator-controlled, open-label study to evaluate the efficacy and safety of efinopegdutide in individuals with non-alcoholic fatty liver disease

Manuel Romero Gomez[1], Eric Lawitz[2], R. Ravi Shankar[3], Eirum Chaudhri[3], Jie Liu[3], Raymond Lam[3], Keith Kaufman[3], Samuel Engel[3]. [1]*University of Seville/Virgen del Rocio University Hospital, Institute of Biomedicine of Seville (HUVR/CSIC/US)/Digestive Diseases Unit and CIBERehd, Sevilla, Spain;* [2]*University of Texas Health Science Center at San Antonio-UT Health San Antonio, Texas Liver Institute, San Antonio, United States;* [3]*Merck and Co Inc, MRL, Rahway, United States*
Email: mromerogomez@us.es

Background and aims: Currently, there are no approved therapies for non-alcoholic steatohepatitis (NASH). This study was conducted to assess the effects of the GLP-1/glucagon receptor co-agonist efinopegdutide (EFI), relative to the selective GLP-1 receptor agonist semaglutide (SEMA), on liver fat content (LFC) in patients with non-alcoholic fatty liver disease (NAFLD), and to inform on the role of EFI as a therapy for NASH.
Method: This was a Phase 2a, randomized, active-comparator-controlled, parallel-group, open-label study in subjects with NAFLD (18–70 years, BMI 25–50 kg/m^2, stable body weight, without type 2 diabetes mellitus (T2DM), or with T2DM with an A1C ≤8.5% controlled by diet ± stable dose of metformin). During a 4-week screening period, an MRI-PDFF was performed to determine LFC. Participants with an LFC of ≥10% were randomized in a 1:1 ratio to open-label SC EFI 10 mg Q1W or SC SEMA 1.0 mg Q1W for 24 weeks, stratified according to concurrent diagnosis of T2DM. Both drugs were titrated to the target dose over an 8-week time period. The primary efficacy end point was the least squares (LS) mean relative reduction from baseline in LFC (%) after 24 weeks of treatment.
Results: Among 145 randomized subjects (EFI n = 72, SEMA n = 73), 55.2% were male, 35.2% were Hispanic and 33.1% had T2DM. At baseline, the mean BMI was 34.3 kg/m^2 and the mean LFC was 20.3%. The LS mean relative reduction from baseline in LFC at Week 24 was significantly ($p < 0.001$) greater with EFI (72.7% [95% CI: 66.8, 78.7]) than with SEMA (42.3% [95% CI: 36.5, 48.1]) (figure). Median relative reductions from baseline in LFC at Week 24 were 83.8% with EFI and 44.4% with SEMA. Greater proportions of participants had relative reductions from baseline at Week 24 in LFC of ≥30%, ≥50% and ≥70% with EFI (81.9%, 77.8%, and 70.8%, respectively) compared with SEMA (67.1%, 43.8%, and 12.3%, respectively) (figure). A greater proportion of participants achieved normal LFC (<5%) at Week 24 with EFI (66.7%) compared with SEMA (17.8%). Both treatment groups had an LS mean relative reduction from baseline in body weight at Week 24 ($p = 0.085$ for EFI 8.5% vs SEMA 7.1%). The relative reductions from baseline in LFC at Week 24 by weight loss category (≤5%, >5% to ≤10%, and >10% reduction in body weight from baseline) were greater in the EFI group (52.4%, 76.6%, and 86.2%, respectively) than in the SEMA group (13.4%, 39.6%, and 64.2%, respectively). There were no meaningful differences between the two treatment groups in the incidence of overall, serious, or drug-related adverse events, including adverse events that led to discontinuation.

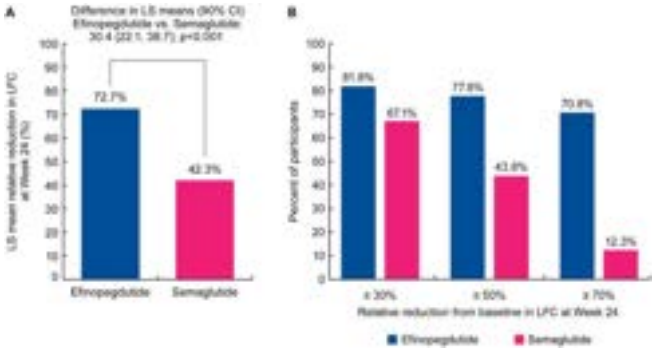

Figure: (A) LS mean relative reduction from baseline in LFC at Week 24 and (B) proportions of participants with relative reductions from baseline in LFC at Week 24 of ≥30%, ≥50% and ≥70%

Conclusion: In this study in patients with NAFLD, treatment with EFI 10 mg weekly led to a significantly greater reduction in LFC than SEMA 1 mg weekly. EFI may offer an effective treatment option for patients with NASH.

OS-061

Multicenter, randomized, double-blind, placebo-controlled trial of Fatty Acid Synthase (FASN) inhibitor, denifanstat, versus placebo in the treatment of biopsy-proven NASH: A 26-week interim analysis of the FASCINATE-2 Phase 2B trial

Marie O'Farrell[1], Katharine Grimmer[1], Alithea Zetter[1], Wen-Wei Tsai[1], George Kemble[1], Rohit Loomba[2], Eduardo Bruno Martins[1], Stephen Harrison[3]. [1]*Sagimet Biosciences, San Mateo, United States;* [2]*University of California, San Diego, Dept of Medicine, NAFLD Research Center, La Jolla, United States;* [3]*Pinnacle Clinical Research, San Antonio, United States*
Email: marie.ofarrell@sagimet.com

Background and aims: Denifanstat (DEN) is a first-in-class FASN inhibitor. In the completed FASCINATE-1 study, patients with NAFLD treated with denifanstat for 12 weeks showed significant reductions of liver fat, ALT, low density lipoprotein cholesterol (LDL) and N-terminal type III collagen propeptide (PRO-C3). DEN exhibited a well-tolerated safety profile. The FASCINATE-2 (NCT04906421) study, is a Ph2b, placebo-controlled, double-blind study of DEN compared to placebo in 168 biopsy-confirmed NASH patients. The primary end points will evaluate safety and histological impact of a 50 mg daily oral dose of DEN compared to placebo after 52 weeks. A planned interim analysis (IA) at Week 26 of treatment was performed using non-invasive assessments including de novo lipogenesis assessment, MRI-PDFF and ALT.
Method: Adults ≥18 years were enrolled in this study with a screening biopsy confirming F2-F3 fibrosis and a NAFLD activity score (NAS) ≥4 with a score of at least 1 in each of the following parameters: steatosis, balloon degeneration and lobular inflammation. In the IA, the first 52 patients on study for 26 weeks with a baseline MRI-PDFF of ≥8% liver fat were evaluated. 30 of these patients received 50 mg of DEN and 22 received placebo; 65% were diabetic; mean ALT 62.7 U/L; mean liver fat by MRI-PDFF 19.3%; and 54% had F3 fibrosis.
Results: DEN inhibited FASN activity as demonstrated by reduction of plasma levels of the saturated fatty acid triglyceride tripalmitin (−42.0% vs +21.5%, $p < 0.002$). FASN inhibition resulted in a relative reduction of liver fat from baseline in DEN-treated patients compared to placebo (−34.1% vs. −1.5%, $p < 0.002$). Importantly, 67% of DEN-treated patients reduced their liver fat by ≥30% (67% vs 18%, $p < 0.002$) and approximately half of these responders decreased liver fat by ≥50%. ALT also dropped significantly in the DEN-treated group (−16.5 U/L vs −4.0 U/L, $p < 0.05$). Recent studies show an MRI-PDFF reduction of ≥30% combined with an ALT reduction of ≥17 U/L highly correlate with histological improvement. The proportion of DEN patients achieving this combined metric was significantly improved (37% vs 9%, $p < 0.05$). Fibrosis markers declined from baseline with DEN

treatment; enhanced liver fibrosis (ELF) score (−0.34 vs −0.02, $p < 0.05$) and PRO-C3 (−4.4 ng/ml vs −0.28 ng/ml, $p < 0.05$). Consistent with Ph2a results, LDL was significantly decreased by DEN (−12.4 mg/dL vs 0.0 mg/dL, $p < 0.05$) while FGF-21 increased (+0.21 vs −0.04 ng/ml, $p < 0.05$), indicating improved metabolism. There were no treatment-related serious adverse events, and the majority of adverse events were mild to moderate in nature (Grade 1 and 2).
Conclusion: Denifanstat showed a strong improvement of key non-invasive disease markers in NASH patients after 26 weeks of treatment. These data suggest that denifanstat will have a positive impact on histological end points in FASCINATE-2.

OS-062
Phase 1 study of the RNA interference therapeutic ALN-HSD in healthy adults and patients with non-alcoholic steatohepatitis
Arun Sanyal[1], Jörg Täubel[2], Prajakta Badri[3], Sarah Bond[3], Nune Makarova[3], Weizhi Zhao[3], Satyajit Karnik[4], Farshad Kajbaf[3], Benjamin Olenchock[4], Joshua Friedman[3], John Gansner[3]. [1]*Virginia Commonwealth University, Division of Gastroenterology, Hepatology and Nutrition, Richmond, VA, United States;* [2]*Richmond Pharmacology and St. George's University of London, London, United Kingdom;* [3]*Alnylam Pharmaceuticals, Cambridge, MA, United States;* [4]*Regeneron Pharmaceuticals, Tarrytown, NY, United States*
Email: jgansner@alnylam.com

Background and aims: Non-alcoholic steatohepatitis (NASH) is a prevalent chronic liver disease that can lead to progressive fibrosis, cirrhosis, and hepatocellular carcinoma. Genome-wide association studies have identified loss-of-function variants in the hydroxysteroid 17-beta dehydrogenase 13 (HSD17B13) gene that are associated with a reduced risk of chronic liver disease and progression from steatosis to steatohepatitis. ALN-HSD is an investigational, subcutaneously administered, N-acetylgalactosamine (GalNAc)-conjugated small interfering RNA (siRNA) targeting liver-expressed HSD17B13 mRNA, in development for the treatment of NASH. Here, we present interim results of the Phase 1 study of ALN-HSD.
Method: ALN-HSD-001 (NCT04565717) is a two-part, randomized, double-blind, placebo-controlled, multi-center, single-ascending dose and multiple-dose study designed to evaluate the safety, tolerability, pharmacokinetic (PK), and pharmacodynamic (PD) effects of ALN-HSD in healthy adults (Part A) and adult patients with NASH (Part B). The primary end point is frequency of adverse events (AEs). Secondary end points include characterization of ALN-HSD plasma and urine PK and change from baseline of liver HSD17B13 mRNA.
Results: In Part A, which is complete, 58 healthy adults were randomized 3:1 to receive a single dose of study drug (ALN-HSD or placebo) in ascending dose groups from 25 to 800 mg. The only AE occurring in at least 10% of subjects treated with ALN-HSD was injection site reaction (n = 5/44; 11%), all mild in severity and transient. One serious AE (SAE) of tonsillitis was reported and deemed unrelated to study drug. Consistent with other GalNAc-conjugated siRNAs, plasma concentrations of ALN-HSD declined rapidly by 24 hours post-dose. ALN-HSD showed a slightly more than dose proportional increase in exposures across doses. Across doses, ALN-HSD showed 17–37% excretion in urine. In Part B, which is ongoing, 46 patients with NASH were randomized 4:1 to receive ALN-HSD (25, 200, or 400 mg) or placebo on Day 1 and Day 85 (12 weeks apart). Liver biopsies were performed at baseline and either Day 169 or Day 337. At data cut-off, 45 patients received at least one dose of study drug. The only AE occurring in at least 10% of all patients was upper respiratory tract infection (13.3%), all deemed unrelated to study drug. Two SAEs, appendicitis and skin laceration, were also deemed unrelated to study drug. There was no evidence of drug-induced liver injury. In the cohorts with Day 169 liver PD data, ALN-HSD was associated with dose-dependent reduction of HSD17B13 mRNA. ALN-HSD was also associated with numerically lower liver enzymes and biopsy-derived non-alcoholic fatty liver disease activity score over six months relative to placebo.

Dose (mg)	N	Change from baseline of liver *HSD17B13* mRNA at Day 169 (%)	
		Mean (SD)	Median [Range]
Placebo	5	4.6 (10.7)	4.7 [-11.7, 18.1]
25	6	-38.7 (24.7)	-39.8 [-67.2, -4.5]
200	6	-68.7 (8.6)	-71.5 [-79.3, -55.8]
400	7	-73.2 (9.7)	-78.3 [-80.9, -53.7]

Figure:

Conclusion: ALN-HSD has exhibited an encouraging safety and tolerability profile to date, with robust reduction in liver HSD17B13 mRNA expression. A Phase 2 study has been initiated to further investigate ALN-HSD in patients with NASH (NCT05519475).
Co-funded by Alnylam Pharmaceuticals and Regeneron Pharmaceuticals, Inc.

OS-063
Pemvidutide, a glp-1/glucagon dual receptor agonist, significantly reduces liver fat, fibro-inflammation, and body weight in patients with non-alcoholic fatty liver disease: a 24-week multicenter, randomized, double-blind, placebo-controlled trial
Stephen Harrison[1], Shaheen Tomah[2], John Suschak[2], Scot Roberts[2], Jay Yang[2], Liang He[2], Bertrand Georges[2], Lakisha Rodwell-Green[2], Randy Brown[2], M. Scott Harris[2], Sarah Browne[2]. [1]*Pinnacle Research, San Antonio, United States;* [2]*Altimmune, Inc, Gaithersburg, United States*
Email: stephenharrison87@gmail.com

Background and aims: Pemvidutide is a long-acting, balanced GLP-1/glucagon (GCG) dual receptor (R) agonist under development for the treatment of NASH and obesity. The balanced 1:1 potency ratio combines the reduced caloric intake effects of GLP-1R agonism with the increased energy expenditure and lipometabolic effects of GCGR agonism. This study assessed the efficacy, safety, and tolerability of pemvidutide on liver fat content (LFC), body weight and non-invasive markers of fibro-inflammation in patients with NAFLD over 24 weeks of treatment.
Method: Subjects were randomized 1:1:1:1 to receive 1.2 mg, 1.8 mg, and 2.4 mg pemvidutide, or placebo weekly for 12 weeks with an optional 12-week extension for a total of 24 weeks of treatment. There was no dose titration at 1.2 mg or 1.8 mg; a brief 4-week titration was used at 2.4 mg. The primary efficacy end point was the reduction in LFC from baseline after 12 and 24 weeks of treatment. Key secondary end points included: reductions in serum alanine aminotransferase (ALT), corrected T1 (cT1) and percent (%) body weight loss from baseline after 12 and 24 weeks of treatment.
Results: 94 subjects were randomized and dosed, and 66 subjects participated in the 12-week extension study. Mean baseline body mass index (BMI), LFC by MRI-PDFF, cT1, and ALT were approximately 36 kg/m^2, 22%, 920 ms and 37 IU/L, respectively. Twenty-seven (29%) participants had type 2 diabetes (T2D), and 71 (75.5%) were of Hispanic ethnicity. The primary end point was met in all pemvidutide treatment groups at both 12 and 24 weeks (Table 1). Significant reductions in absolute and relative LFC were noted at both time-points, with a mean relative LFC reduction of 76.4% at the 2.4 mg dose at 24 weeks, with 100% of subjects achieving ≥30% reduction in LFC and approximately 50% achieving normalization, defined as LFC ≤5%. cT1 decreased significantly from baseline, with 84.6% of subjects across all pemvidutide treatment groups achieving a reduction of ≥80 ms in cT1 at week 24 compared to 0% of subjects receiving placebo. Serum ALT levels decreased significantly in a dose-dependent manner, particularly in subjects with baseline ALT ≥30 IU/L, with all pemvidutide treatment groups achieving mean reductions ≥17 IU/L. Weight loss of 7.2% and 5.3% were achieved in patients without and with T2D at the 1.8 mg dose at 24 weeks. Pemvidutide was well-tolerated, with no serious or severe AEs related to study drug, and low rates of AEs leading to study discontinuation.

Table:

	Week 12				Week 24			
	placebo	pemvi 1.2 mg	pemvi 1.8 mg	pemvi 2.4 mg	placebo	pemvi 1.2 mg	pemvi 1.8 mg	pemvi 2.4 mg
Change in LFC								
Absolute reduction (%)	0.2	8.9	14.7	11.3	1.6	11.2	17.0	15.6
Relative reduction (%)	4.4	46.6	68.5	57.1	14.0	56.3	75.2	76.4
30% reduction (%)	4.2	65.0	94.4	85.0	5.6	76.9	92.3	100
50% reduction (%)	0.0	40.0	72.2	70.0	0.0	61.5	84.6	72.7
Normalization (≤5%)	0.0	20.0	55.6	50.0	0.0	30.8	53.8	45.5
Change in ALT								
All subjects (IU/L)	−6.2	−11.2	−13.8	−13.6	−2.2	−13.3	−13.7	−15.2
Baseline ALT ≥30 (IU/L)	−12.6	−17.8	−20.8	−27.0	−3.1	−17.0	−17.7	−20.6
Change in cT1								
Proportion of subjects with 80 ms reduction in cT1 (%)	0.0	87.5	83.3	85.7	0.0	85.7	75.0	100.0
Weight loss								
Without diabetes (%)	0.2	3.4	4.9	3.5	1.2	5.2	7.2	5.8
With diabetes (%)	0.5	3.3	3.8	4.4	3.4	4.3	5.3	3.5

Conclusion: Pemvidutide led to rapid and potent reductions in LFC, serum ALT, cT1, and body weight, and was well-tolerated without the use of dose titration. These findings support a high likelihood of histopathologic improvement in NASH patients in a forthcoming paired liver biopsy study.

OS-064-YI

Calorie restriction by time restricted intermittent fasting is better than standard calorie restriction in improving the metabolic profile and hepatic fibrosis in patients with non-alcoholic fatty liver disease

Deepankshi Aggarwal[1], Ajay Kumar Duseja[2], Arka De[2], Sanjay Bhadada[3], Naveen Kalra[4], Nancy Sahni[5]. *[1]Post Graduate Institute of Medical Education and Research, Internal Medicine, Chandigarh, India; [2]Post Graduate Institute of Medical Education and Research, Hepatology, Chandigarh, India; [3]Post Graduate Institute of Medical Education and Research, Endocrinology, Chandigarh, India; [4]Post Graduate Institute of Medical Education and Research, Radiodiagnosis and Imaging, Chandigarh, India; [5]Post Graduate Institute of Medical Education and Research, Dietitics, Chandigarh, India*

Background and aims: Lifestyle interventions including diet modification and exercise causing weight-loss are recommended as first line treatment for patients with non-alcoholic fatty liver disease (NAFLD)/non-alcoholic steatohepatitis (NASH) with overweight/obesity. Even though found to be beneficial in weight reduction, efficacy of intermittent fasting (IF) in improving liver disease in patients with NAFLD is still evolving. Aim of the present study was to compare the effectiveness of calorie restriction by intermittent fasting (IF) with standard of care calorie-restriction (SOC) in improving hepatic steatosis, inflammation and fibrosis in patients with NAFLD.
Method: In this open label randomized study, 68 overweight/obese patients [as per Asia-Pacific cut offs-body mass index (BMI) ≥23 Kg/m^2] with NAFLD were randomised to IF and SOC groups. After calculating daily calorie requirement (30–35 kcal/Kg/day), patients in both groups were advised 30% calorie restriction either by IF or SOC. IF regimen was 16:8-IF [time restricted feeding (TRF)], [meals for 8-hours followed by fasting of 16-hours daily]. Changes in anthropometry, components of metabolic syndrome, hepatic steatosis [ultrasound and controlled attenuation parameter (CAP)], hepatic inflammation [liver enzymes and FibroScan-AST (FAST) score] and hepatic fibrosis [APRI, FIB-4, NFS, liver stiffness measurement (LSM) on Fibroscan], were assessed at 6 months with intra-group and inter-group analysis.
Results: Of 68, 6 patients in each group were lost to follow-up; remaining 56 (M: F 1:1) patients (28 in each group, comparable mean age and BMI) were analyzed. Patients in both groups had significant reduction in waist circumference, weight and BMI from baseline [4.3%, 5.88% and 6.1% reduction in IF (p < 0.001) versus 2.7%, 4.71% and 4.6% reduction in SOC group (p < 0.001)] with no difference between the groups. There was significant reduction in mean blood pressure, fasting blood glucose, total cholesterol, low-density lipoprotein levels in IF group in comparison to baseline (p < 0.001) and in comparison to SOC group (p = 0.012). There was significant improvement in hepatic steatosis in both the groups [mean CAP reduction in IF group 316 ± 43.78 to 287.7 ± 46.4 dB/m (p < 0.001); SOC group 323.1 ± 40.34 to 300.89 ± 45.7 dB/m (p < 0.001)] with no difference between the groups. In those with elevated ALT, there was significant reduction in mean ALT in both IF group [(from 74.1 ± 49 to 38.2 ± 26.4 U/ml (p < 0.001)] and SOC group [54.39 ± 36.7 to 37.9 ± 27.3 U/ml (p 0.006)] with no difference between the groups. Similarly, significant reduction in mean FAST score was observed in both IF [from 0.38 ± 0.23 to 0.21 ± 0.18 (p < 0.001)] and in SOC group [from 0.32 ± 0.18 to 0.21 ± 0.19 (p 0.001)] with no difference between the groups. IF group showed significant reduction in mean LSM on Fibroscan in comparison to baseline [6.42 ± 2.28 to 5.89 ± 2.12 kPa (p 0.016)] whereas there was no significant reduction in LSM in SOC group. The proportion of patients having >20% reduction in LSM were also significantly higher in IF [21.4% (n = 6)] compared to SOC group [3.5% (n = 1)] (p 0.04). The mean reduction in APRI, FIB-4 and NFS was not significant in either group.
Conclusion: Calorie restriction by time restricted intermittent fasting is better than standard calorie restriction in improving the metabolic profile and hepatic fibrosis; both IF and SOC are equally effective in causing weight reduction and improving hepatic steatosis and inflammation in NAFLD.

Background and aims: Flares after nucleos (t)ide analogue (NA) cessation are common and potentially harmful. Predictors of severe withdrawal flares are required for risk stratification and to guide off-treatment follow-up.
Method: This is a retrospective, international, multicenter cohort study including patients with chronic hepatitis B (CHB) who were virally suppressed and hepatitis B e antigen (HBeAg) negative at the time of NA cessation. Flares after NA withdrawal were defined as mild, moderate or severe based on a ALT level of 5-, 10- or 20 times or more the upper limit of normal (ULN). Multivariable cox regression analyses (adjusted for age, sex, previous interferon and NA therapy, type of NA, HBsAg- and ALT levels at withdrawal, cirrhosis and HBeAg status at start of treatment) were performed censoring at re-treatment and loss-to-follow-up. A sub-group analysis was performed to investigate the association between HBV DNA levels at 12 weeks after withdrawal and subsequent flare risk, excluding patients with a flare before or at 12 weeks.
Results: Among 1557 included patients, 356 (22.9%) developed a mild flare during follow-up of which 70% occurred within the first year after withdrawal and with a 5-year cumulative incidence of 31.9%. One-year cumulative incidences for ALT flares ≥5×, ≥10×, ≥20× ULN were 18.6%, 10.0% and 3.4%, respectively (see figure). Fifteen (4.2%) patients decompensated after a mild flare of which 9 subsequently developed a severe flare resulting in 1 death.

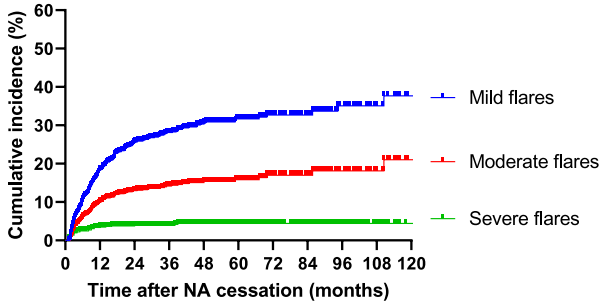

Figure:

Multivariable analyses showed that older age (aHR 1.02, 95%CI 1.01–1.03), male sex (aHR 1.49 95%CI 1.11–1.99), higher HBsAg levels at NA withdrawal (100–1.000 IU/ml; aHR 2.15, 95%CI 1.47–3.16, >1.000 IU/ml; aHR 2.79, 95% CI 1.85–4.22) and Tenofovir (TDF) vs. Entecavir therapy (aHR 2.23, 95%CI 1.76–2.83) were predictive for any flare (≥5x ULN). TDF therapy (aHR 2.50, 95%CI 1.78–3.49), previous NA-therapy (aHR 1.53, 95%CI 1.04–2.25) and a HBsAg level >1.000 IU/ml at withdrawal (aHR 2.41, 95%CI 1.38–4.19) were predictive for moderate flares. Only TDF therapy was associated with an increased risk of severe flares (aHR 4.06, 1.92–8.58).
When focusing on available HBV DNA data from 12 weeks after NA-cessation (n = 685), only levels between 2.000–10.000 IU/ml (aHR 2.15, 95%CI 1.00–4.61) and >10.000 IU/ml (aHR 4.63, 95%CI 2.42–8.86) were associated with an increased risk of mild flares (HBV-DNA <100 IU/ml as reference).
Conclusion: Flares are common after NA withdrawal and were predominantly observed in the first year after NA cessation and could result in liver decompensation or death. Older age, male sex, increased HBsAg levels at end of treatment and TDF therapy before drug withdrawal were associated with a higher risk of flares. HBV DNA kinetics after stopping NA may be used to stratify the risk of flares, with an increased risk observed among patients with an HBV DNA level >2.000 and >10.000 IU/ml 12 weeks after NA withdrawal.

Background and aims: Bulevirtide (BLV) is a lipopeptide inhibiting the HBV/HDV entry into the hepatocytes. Significant HDVRNA decline was observed in HBV/HDV patients who received 48 weeks of BLV in monotherapy or in combination with PEG-interferon α 2a (PEG-IFNα). The aim of this analysis was to evaluate the efficacy of BLV 2 mg daily with or without PEG-IFNa 2a in HDV patients with poor early virologic response in the French BLV early access program.
Method: 118 HDV patients (male 67.8%, mean age 42 years, cirrhosis 52%, median HDV-RNA 6.52 $\log_{10}$ IU/ml) with chronic HDV infection, with compensated cirrhosis/severe fibrosis or moderate fibrosis with elevated ALT levels were included in this analysis. Patients received at least 6 months of BLV 2 mg QD SC alone or in combination with PEG-IFNα once weekly according to physician's choice. Poor response was defined as HDV-RNA decline lower than 1 or 2 $\log_{10}$ IU/ml at M3 or M6. The evaluation at M12 and M18 was performed only in patients who continued treatment during 12 and 18 months respectively.
Results: From baseline, median HDV RNA ($\log_{10}$ IU/ml) and median ALT levels (IU/L) declined overtime: M3 −1.33 and −27, M6 −3.48 and −29, and M12 −3.83 and −33, respectively. Algorithm of virologic response in BLV monotherapy is proposed in Figure. In the BLV group (N = 59), among the 23 patients with HDV-RNA decline <1 log at M3, 8/21 (38%), 2/21 (9.5%), and 11/21 (52.4%) had HDV-RNA decline <1 log, between 1 and 2 log, and >2log at M6, respectively. In the 10 patients who had HDV-RNA <1 log at M6, HDV-RNA decline <1 log, between 1 and 2 log, and >2log at M18 was observed in 6 (60%), 4 (40%), and 0% of patients, respectively. In these patients, ALT <1.5 at M18 was observed in 2/6 (33.3%), 3/4 (75%), and 0% of patients, respectively. In the BLV + PEG-IFN group, at M3, only 4/58 (7%) of patients had HDV-RNA decline <1 log, and 10/58 (17%) had HDV-RNA decline between 1 and 2 log. Among the 6 patients with HDV RNA decline <2 log at M6, 3/5 (60%) had decline <2 log at M18.

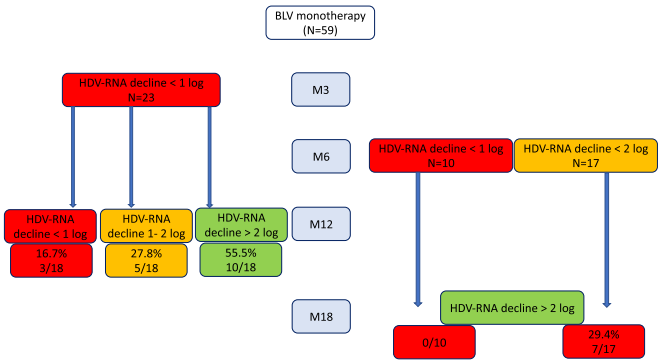

Figure: Algorithm of virologic response in BLV monotherapy

Conclusion: For the first time, in patients receiving BLV monotherapy 2 mg daily, we could define a subgroup of poor-responders with low probability to improve virological response overtime. The data of this real-life cohort suggest that BLV monotherapy should be stopped and another strategy offered in patients with HDV-RNA decline <1 log at M6. This strategy needs to be evaluated in future studies.

Background and aims: In 2 similarly designed double-blind (DB), randomized (2:1), Phase 3 studies (Study 108 in HBeAg-negative patients [N = 425] and Study 110 in HBeAg-positive patients [N = 873]), tenofovir alafenamide (TAF) demonstrated noninferior efficacy relative to tenofovir disoproxil fumarate (TDF) in the blinded assessments. After completing up to 3 years (yr) of DB treatment, all patients were eligible to receive open-label (OL) TAF through week 384 (yr 8). Here we present the final 8-yr results.

Method: Efficacy was assessed for each study by missing equals excluded (M = E) approach of the full analysis set and included serial assessments for viral suppression (HBV DNA <29 IU/ml), ALT normalization by 2018 AASLD criteria, serologic responses, and fibrosis change by serum FibroTest. Resistance analyses, including deep sequencing of HBV pol/RT (at baseline and annually), for those with virologic breakthrough/blip, persistent viremia, or treatment discontinuation with viremia were performed, as was phenotyping of qualifying samples.

Results: Of 1298 randomized and treated patients, 1157 (89%; 775 TAF; 382 TDF) entered the OL phase, including 180 and 202 TDF-treated patients who began OL TAF at week 96 (TDF-OL TAF 6 yr) or week 144 (TDF-OL TAF 5 yr) based on timing of a protocol amendment. Overall, 974 (75%) participants completed OL study treatment. The most common reasons for discontinuation were withdrawal of consent, loss to follow-up, or investigator discretion. Similar high rates of virologic suppression and ALT normalization were achieved and maintained over 8 yr in all treatment groups (Table). Sequence/phenotyping analysis through 6 yr showed no resistance to TAF; resistance analyses at yr 8 are ongoing.

Table.: Results at Yr 8[a].

n/N (%)	TAF 8 yr	TDF-TAF 6 yr	TDF-TAF 5 yr
Study 108			
HBV DNA < 29 IU/ml	201/208 (97)	43/44 (98)	57/58 (98)
Normalized ALT[b]	147/189 (78)	30/41 (73)	44/57 (77)
HBsAg loss/	8/199 (4)	0/41	1/58 (2)
Seroconversion	6/199 (3)	0	0
Mean (SD) $\log_{10}$IU/ml change in HBsAg	−0.62 (0.924)	−0.50 (0.526)	−0.61 (0.758)
Mean change in FibroTest score (SD)	−0.05 (0.142)	−0.04 (0.174)	0.00 (0.158)
Study 110			
HBV DNA < 29 IU/ml	370/392 (94)	74/81 (91)	108/112 (96)
Normalized ALT[b]	295/380 (78)	55/79 (70)	83/103 (81)
HBeAg loss/	171/373 (46)	32/73 (44)	50/108 (46)
Seroconversion	114/373 (31)	20/73 (27)	36/108 (33)
HBsAg loss/	9/384 (2)	4/76 (5)	3/109 (3)
Seroconversion	6/384 (2)	4/76 (5)	3/109 (3)
Mean (SD) $\log_{10}$IU/ml change in HBsAg	−0.89 (1.211)	−1.09 (1.424)	−1.09 (1.268)
Mean change in FibroTest score (SD)	−0.05 (0.155)	−0.04 (0.158)	−0.01 (0.142)

[a]Full analysis set by missing = excluded analysis. [b]Population included only patients with ALT above.
ULN at baseline.

Conclusion: After 8 yr of treatment with TAF or up to 6 yr after switch from TDF, virologic suppression rates remained high across all groups; up to 33% achieved HBeAg/HBeAb seroconversion, while HBsAg loss was low (≤5%).

Background and aims: Bulevirtide (BLV) is a first-in-class, entry inhibitor for chronic hepatitis D (CHD) which was conditionally approved in the EU in July 2020. Results from the Week 48 primary end point analysis for MYR301 (NCT03852719), a phase 3 randomized study, showed monotherapy with BLV at 2 mg/d or 10 mg/d given subcutaneously was superior to no active anti-HDV treatment based on the combined viral and biochemical response. Efficacy was similar at the 2 dose levels and BLV was generally safe and well tolerated. Here, we present findings from the predefined week 96 interim analysis of this ongoing study.
Method: 150 patients with CHD were randomized (1:1:1) and stratified based on the presence/absence of compensated cirrhosis as follows: Arm A: no active anti-HDV treatment for 48 weeks followed by BLV 10 mg/d for 96 weeks (n = 51), and Arms B or C: immediate treatment with BLV at 2 mg/d (n = 49) or 10 mg/d (n = 50), respectively, each for 144 weeks, with follow-up of 96 weeks after end of treatment (i.e. up to Week 240). The combined response was defined as undetectable HDV RNA or decrease by ≥2 $\log_{10}$ IU/ml from baseline and ALT normalization; other end points included viral response (undetectable HDV RNA or decrease by ≥2$\log_{10}$ IU/ml from baseline), ALT normalization, $\log_{10}$ change in HDV RNA and change in liver stiffness (LS) by transient elastography (TE).
Results: Baseline characteristics were similar between groups and included: mean (SD) age 41.8 (8.4) years, 57% males, 83% White, 47% with compensated cirrhosis, mean (SD) HDV RNA 5.05 (1.34) $\log_{10}$ IU/ml, mean (SD) ALT 110.9 (69.0) U/L, mean (SD) LS of 15 (8.9) kPa; and 61% were on concomitant nucleos (t)ide analogues therapy. Of 150 patients, 143 (95%) completed 96 weeks of treatment. Week 96 efficacy responses were improved vs. Week 48 (Table). At Week 96, similar combined responses were seen in arms B and C. Viral and biochemical responses were also similar among arms B and C. BLV was safe and well tolerated; there were no drug discontinuations, serious AE (SAE) or deaths attributed to BLV. Increases in bile acids without a correlation to pruritus or other symptoms were noted with BLV treatment. Injection site reactions occurred in a higher proportion receiving 10 mg/d dosing.
Conclusion: BLV continues to be safe and well tolerated as monotherapy for CHD through Week 96. Virological and biochemical responses increased with longer term therapy.

Email: burra@unipd.it

Background and aims: Discontinuation of hepatitis B (HBV) immune globulin (HBIG) after liver transplantation (LT) for HBV-related cirrhosis with and without hepatocellular carcinoma (HCC) represents a challenging option. The adherence to this option in real-life practice is unknown. In a contemporary cohort of patients transplanted for HBV, with and without HCC, we aimed to; 1) assess the rate of HBV recurrence (HBV-R); 2) evaluate risk factors for HBV-R; 3) evaluate the association between HBV-R and HCC recurrence (HCC-R) and patient survival.
Method: This is a multicentric, retrospective study designed by the "Permanent Transplant Commission" of the Italian Association for the Study of the Liver; 20 LT Italian centres were invited to participate and 17 were finally included. All recipients who underwent LT for HBV-related liver disease were considered for inclusion. Exclusion criteria were: LT prior to January 1, 2010; age < 18 years old; combined transplantation; HIV coinfection; duration of follow-up after LT <12 months. HBV-R was defined by positivity of HBV-DNA and/or HBsAg. Uni and multivariate linear regression analysis were used to identify predictors of HBV/HCC-R.
Results: 1115 patients were included (77% male; median age 57 years old). Indications for LT were HCC (51%), decompensated cirrhosis (41.2%), acute on chronic liver failure (ACLF) (3.4%), and acute liver failure (ALF) (4.2%). Median MELD at LT was 15 (10-21). Data regarding HBV prophylaxis were available in 984 (88%) of patients. Among them, life-long HBIG+nuclos (t)ide analogues (NA) were used in 94.4%; withdrawal HBIG+life-long NA in 2.8%; HBIG alone in 0.5%; NA alone in 2.3%. Overall rate of HBV-R was 2.2% (median time after LT: 7 months [2-15]). Patients who received life-long HBIG+NA had lower rates of HBV-R than those in whom HBIG were withdrawn and those who received NA alone (1.4% vs. 10.7% vs. 13.6%; respectively, p < 0.001). HBV-R was associated with a lower survival after LT (p = 0.008). No association was found between HBV-R and MELD, HBV-DNA positivity or title >2000 UI/L at time of LT, HCC, use of anti-HBc donor. In patients transplanted for HCC (n = 535), the rate of HBV-R was 2.8% and of HCC-R was 10.3% (median time from LT: 17 months). Rate of HBV-R was higher in patients with vs. without HCC-R (14.6% vs. 1.2%; p < 0.001). Vascular invasion, TNM, AFP, and HBV-R were associated with HCC-R. Multivariate analysis showed that HBV-R was the only parameter independently associated with HCC-R (HR: 20; CI95% 5-86; p < 0.001). HCC-R was associated with a significantly reduced survival after LT (5-year survival 36% vs. 94%; p < 0.001).
Conclusion: Life-long HBIG+NA is the most commonly used scheme for HBV-R prophylaxis after LT in Italy, leading to a low risk of HBV-recurrence. In LT recipients, HBV recurrence is associated with an increased risk of death. In patients transplanted for HCC, HBV-R is independently associated with HCC recurrence. Therefore, discontinuation of HBIG in these patients should be considered only in the setting of clinical trials.

Background and aims: Obeticholic acid (OCA) is the only approved second-line treatment for patients with primary biliary cholangitis (PBC), and has been shown to provide an effective biochemical response in around ~40% of patients, according to POISE criteria. We aimed to derive and validate a predictive score (OCA response score, ORS) for predicting response to OCA at 12 and 24 months.
Method: We exploited data from the Italian recapitulate database including centers from the Italian PBC Registry, the Sicilian PBC Network, the PBC Project Piemonte-Liguria-Valle D'Aosta and CLEO/AIGO PBC study group. Multivariable Cox's regressions with backward selection method were applied to obtain parsimonious predictive models, including pre-treatment variables and/or the change of ALP/ULN and total bilirubin after 6 months' therapy. Biochemical response was evaluated according to the POISE (alkaline phosphatase (ALP)/upper limit of normal (ULN) <1.67 with a reduction of at least 15%, and a normal bilirubin) and ALP/ULN <1.67 criteria. Discrimination and calibration were evaluated by c-

statistics and comparing observed and predicted probabilities, and internally validated with bootstrap resampling procedure.
Results: We selected 441 subjects (median age 58, women 88%, cirrhosis 34%, median follow-up 24 months) with at least 6 months' observation after of OCA prescription. The observed response rates were 38%, 47% for POISE and 58%, 67% for ALP/ULN <1.67 criteria at 12 and 24 months. A score including age, pre-treatment pruritus, cirrhosis, ALP/ULN, GGT/ULN and bilirubin (ORS), and one that includes also the relative change of ALP/ULN and total bilirubin after 6 months (ORS+), showed good discrimination for response by POISE (c-statistics = 0.76 and 0.84, for ORS and ORS+, respectively) and by ALP/ULN <1.67 (c-statistics = 0.78 and 0.89, for ORS and ORS+, respectively). Bootstrap validation evidenced modest overfitting (slopes>0.90) and consistent discrimination. The score also disclosed a good calibration (mean absolute errors <0.04 for prediction of POISE and ALP/ULN <1.67 response at 24 months according to ORS and ORS+).
Conclusion: We derived and internally validated the ORS, that accurately predicts OCA response at 12 and 24 months. This could enhance allocation of second-line therapies in PBC with a personalised medicine approach. The present performances will need validation in external cohorts.

OS-071-YI

Laminin 511-E8 is an autoantigen in IgG4-related cholangitis patients that protects cholangiocytes against T lymphocyte-induced epithelial barrier dysfunction

David Trampert[1], Remco Kersten[1], Aldo Jongejan[2], Dagmar Tolenaars[1], Stan van de Graaf[1], Ulrich Beuers[1]. *[1]Tytgat Institute for Liver and Intestinal Research, Amsterdam Gastroenterology Endocrinology Metabolism (AGEM), Amsterdam University Medical Centers, Department of Gastroenterology and Hepatology, Netherlands; [2]Amsterdam University Medical Centers, Department of Clinical Epidemiology, Biostatistics and Bioinformatics, Netherlands*
Email: u.h.beuers@amsterdamumc.nl

Background and aims: IgG4-related disease is a systemic, lymphocyte driven, fibroinflammatory disorder. The most common organ manifestations are autoimmune pancreatitis (AIP) and IgG4-related cholangitis (IRC). Laminin 511-E8 is an extracellular matrix protein and autoantibodies against laminin 511-E8 have been described in AIP. We have previously demonstrated that laminin 511-E8 protects human cholangiocytes against toxic bile acids (J Hepatol. 2022; 77 (S1): 603). Additionally, laminin 511-E8 appears to aid in establishing barrier function and lymphocyte recruitment. Here, we aimed to investigate whether IRC patients have autoantibodies against laminin 511-E8 and via which mechanisms laminin 511-E8 could further contribute to cholangiocyte health.
Method: Anti-laminin 511-E8 autoantibody positivity in patient sera was assessed by ELISA and compared to healthy control and primary sclerosing cholangitis (PSC) sera. *In vitro*, human H69 cholangiocytes were treated with recombinant laminin 511-E8, after which RNA sequencing was performed. For permeability assays, Transwell inserts were coated with recombinant laminin 511-E8 alongside BSA control coating, after which H69 cholangiocytes were seeded onto the inserts. In addition, T lymphocytes were activated *in vitro* and then added to the basolateral compartment of the co-culture system to better mimic the phenotype of IRC. The effect of laminin 511-E8 coating was studied by subjecting confluent H69 monolayers to 4kD FITC-dextran permeability assays.
Results: Seven out of 52 patients (13.5%) with IRC had autoantibodies against laminin 511-E8 confirming that laminin 511-E8 is an autoantigen in patients with IRC. In contrast, no PSC patients and one healthy control had autoantibodies against laminin 511-E8. RNA sequencing of H69 cholangiocytes treated with recombinant laminin 511-E8 compared to controls showed differential expression of genes involved in cell barrier function and inflammation. Permeability assays revealed that laminin 511-E8 reduced leakage of FITC-dextran past the H69 monolayer. When Transwell inserts were coated with recombinant laminin 511-E8 in the co-culture setup, H69 cholangiocytes were protected from T lymphocyte-induced epithelial barrier dysfunction.
Conclusion: In this study we establish that laminin 511-E8 is an autoantigen in a subset of IRC patients. RNA sequencing and FITC-dextran permeability assays indicate that laminin 511-E8 enhances barrier function and protects cholangiocytes against T lymphocyte-induced epithelial barrier dysfunction. In addition to the previously reported effects of laminin 511-E8 protecting cholangiocytes against toxic bile acids, we speculate that autoantibodies against laminin 511-E8 may contribute to the pathogenesis of IRC by impairing cholangiocyte barrier function with increased inflammatory bile duct damage.

Maralixibat leads to significant reductions in bilirubin for patients with progressive familial intrahepatic cholestasis: data from MARCH-PFIC

Lorenzo D'Antiga[1], Alexander Miethke[2], Douglas Mogul[3], Tiago Nunes[3], Will Garner[3], Pamela Vig[3], Richard Thompson[4].
[1]*Hospital Papa Giovanni XXIII, Paediatric Hepatology, Gastroenterology and Transplantation, Bergamo, Italy;* [2]*Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio, United States;* [3]*Mirum Pharmaceuticals, Inc., Foster City, California, United States;* [4]*King's College London, Institute of Liver Studies, London, United Kingdom*
Email: ldantiga@asst-pg23.it

Background and aims: Progressive Familial Intrahepatic Cholestasis (PFIC) refers to inherited disorders of abnormal bile formation causing pruritus, chronic liver disease, and increased serum bile acid (sBA) levels. Evidence exists that elevated serum bilirubin levels portend poor outcomes in PFIC. Ileal bile acid transporter inhibitors (IBATi) interrupt enterohepatic circulation of bile acids. We evaluated the pre-specified secondary end point of the impact of maralixibat (MRX) on bilirubin and a post-hoc analysis of bilirubin normalization in the MARCH-PFIC study.
Method: MARCH-PFIC enrolled patients with a genetic diagnosis of PFIC, pruritus, and elevated sBA. Patients were randomized to MRX 570 µg/kg BID or placebo (PBO) for 26 weeks. Changes were determined as the difference between MRX and PBO groups for Change from Baseline (CFB) to the average of the final 3 measurements (Weeks 18, 22 and 26) using a mixed-effects model with recurrent measurements. Total/direct bilirubin (TB/DB) categories were defined as normal (≤1.2/0.3 mg/dL) or abnormal (>1.2/0.3 mg/dL).
Results: Analysis included 64 patients from the All-PFIC cohort (13 FIC1, 31 nt-BSEP, 9 MDR3, 7 TJP2, and 4 MYO5B); patients were randomized to MRX (n = 33) or PBO (n = 31). Baseline median (Q1, Q3) TB in the MRX and PBO groups were 2.8 (1.4, 5.5) and 2.6 (0.8, 5.5) mg/dL, and DB were 2.1 (0.9, 4.0) mg/dL and 1.9 (0.5, 4.3) mg/dL, respectively. The study achieved significant CFB between MRX vs PBO for TB (−1.1 vs +0.9 mg/dL; group difference: 2.0; p = 0.047) and DB (−0.8 vs +0.8 mg/dL; group difference: 1.5; p = 0.048). Among individuals with abnormal Baseline bilirubin (total: n = 46; direct: n = 56), there was a significant CFB between MRX vs PBO groups for DB (−0.8 vs +1.0 mg/dL; group difference: −1.8; p = 0.042). For the post-hoc analysis assessing bilirubin normalization, pre and post bilirubin values were available for 60 individuals (32 MRX; 28 PBO). For the MRX group, TB normalized in 40% (10/25) of patients with abnormal Baseline values, and no patient went from normal to abnormal TB (0/7). For the PBO group, TB never normalized in those with abnormal Baseline values (0/18) and instead became abnormal for 30% (3/10) of patients. For DB, the MRX group also showed greater frequency of normalization vs PBO (34% vs 7%). Among all individuals that normalized TB, sBA was reduced by 94.9% (95% CI: 68.5%, 98.9%,) whereas for those individuals that did not normalize TB, sBA only decreased by 13.3% (95% CI: 1.4, 34.0); p < 0.0001. For treatment-emergent adverse-event reporting, bilirubin increases were observed less frequently in MRX vs PBO (14.9% vs 19.6%).
Conclusion: MRX is the only IBAT inhibitor to demonstrate significant decreases in TB/DB compared to PBO in children with PFIC and across PFIC types. 40% of MRX patients with abnormal Baseline bilirubin achieved normalization vs none in the PBO group, suggesting that MRX may yield clinically meaningful improvements in liver health in patients with PFIC.

OS-073

Prognostic significance of liver stiffness progression in primary biliary cholangitis

Email: christophe.corpechot@aphp.fr

Background and aims: The prognostic value of point measurement of liver stiffness (LSM) by vibration-controlled transient elastography (VCTE) in patients with primary biliary cholangitis (PBC) has been established. However, the association between LSM progression over time and the occurrence of adverse clinical events in these patients is poorly known. Our aim was to evaluate the risk of adverse clinical events associated with longitudinal changes of LSM in a large cohort of PBC patients.
Method: A large retrospective cohort study (24centres, 13 countries) of patients with PBC, followed-up using VCTE (Fibroscan) over the past 15 years whilst on ursodeoxycholic acid (UDCA) therapy, was performed. Patients with follow-up ≤12 months, those diagnosed

with autoimmune hepatitis overlap syndrome, and those exposed to second-line therapies (i.e., fibrates, obeticholic acid, corticosteroids) at any time were excluded. Unreliable LSM values, defined by an interquartile/median ratio >30%, were excluded from the analysis. Advanced PBC was defined by LSM ≥10 kPa. Biochemical response to UDCA was defined by the Paris-2 criteria. The primary composite end point was time to adverse clinical events, defined as death, liver transplantation, or liver-related complications. Joint models for longitudinal and time-to-event data, adjusted for age and sex, were used to assess the association between changes in LSM and clinical outcomes.

Results: A total of 4408 LSMs performed in 2244 patients (female 90.8%; mean age 58.4 years; advanced disease 25.4%; mean prior treatment with UDCA 5.9 years) were analyzed. A total of 217 adverse clinical events occurred during 10122.3 patient-years (incidence, 21.4 per 1000 patient-years). Any increase in LSM was associated with an increased risk of poor clinical outcomes (Figure), with an overall hazard ratio per 10% increase in LSM/year of 1.47 (95% CI 1.40–1.55, $p < 0.001$). This association was consistent regardless of age (≤45 years; >45 years) and LSM (<8 kPa; >8 kPa and ≤15 kPa; ≥15 kPa) risk groups at baseline. Conversely, LSM progression was significantly higher in patients who met the primary end point than in those who did not ($p < 0.05$). No association was found between LSM progression and baseline values of LSM, except in the youngest patients (≤45 years; $p < 0.05$) and those who did not have an adequate response to UDCA ($p < 0.01$).

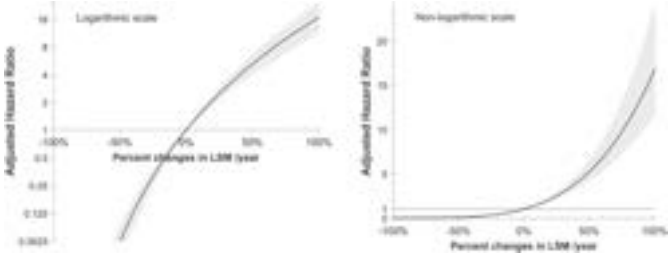

Figure: Adjusted risk of adverse clinical events associated with LSM progression over time.

Conclusion: In patients with PBC treated with UDCA, progression of LSM over time is associated with poorer clinical outcomes regardless of age and LSM values at baseline. LSM values on UDCA are associated with LSM progression in the youngest patients and those with inadequate biochemical response to UDCA.

OS-074-YI

A3907, a systemic ASBT inhibitor, improves cholestasis in mice by inhibiting multi-organ bile acid transport and shows translational relevance to human

Francisco J. Caballero[1,2], Pedro Miguel Rodrigues[2,3,4], Aloña Agirre Lizaso[2], Paula Olaizola[2], Laura Izquierdo-Sánchez[2], María Jesús Perugorria[1,2,3], Luis Bujanda[1,2,3], Bo Angelin[5], Sara Straniero[5], Anna Wallebäck[6], Ingemar Starke[6], Per-Göran Gillberg[6], Ellen Strängberg[6], Fredrik Wangsell[6], Jan Mattsson[6], Henrik B. Hansen[7], Erik Lindström[6], Peter Akerblad[6], Jesus Maria Banales[2,3,4,8]. *[1]University of the Basque Country, Department of Medicine, Faculty of Medicine and Nursing, Spain; [2]Biodonostia Health Research Institute, Liver and Gastrointestinal Diseases, Spain; [3]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd, "Instituto de Salud Carlos III"), Spain; [4]Ikerbasque, Basque Foundation for Science, Spain; [5]Karolinska Institutet at Karolinska University Hospital Huddinge, CardioMetabolic Unit, Department of Medicine and Clinical Department of Endocrinology, Sweden; [6]Albireo AB, Göteborg, Sweden; [7]Gubra, Denmark; [8]University of Navarra, Department of Biochemistry and Genetics, Spain*
Email: jesus.banales@biodonostia.org

Background and aims: Cholestasis is characterized by impaired bile flow leading to intrahepatic accumulation of bile constituents, including bile acids (BAs). Sustained cholestasis can progress to advanced stages of liver disease, increasing the risk of hepatobiliary malignancies and liver failure. The apical sodium-dependent BA transporter (ASBT) is pivotal for BA reabsorption in the ileum, bile ducts and kidneys, contributing to BA overload during cholestasis by preventing BA excretion. Our aim was to explore the therapeutic and translational potential of a novel oral systemic ASBT inhibitor (A3907) for the treatment of cholestasis.

Method: The pharmacological profile of A3907, its therapeutic potential in experimental models of cholestasis, and its translational potential in healthy human subjects was investigated.

Results: A3907 was a potent and selective inhibitor of both mouse and human ASBT displaying significant systemic biodistribution in healthy rodents. Daily oral administration of A3907 for 7 days promoted fecal BA excretion in healthy mice without affecting urine BA levels. A3907 was evaluated in two animal models of cholestasis, *Mdr2*$^{-/-}$ and BDL mice. Daily oral administration of A3907 resulted in high systemic exposure in both models. In the *Mdr2*$^{-/-}$ mice, 4-week oral treatment with A3907 significantly reduced liver-to-body and spleen-to-body weight ratios, serum bile acids, plasma markers of liver injury, and liver markers of inflammation, fibrosis, and ductular reaction. Interestingly, A3907 prevented apoptosis in cultured cholangiocytes exposed to high concentrations of GCDCA (1 mM), also indicating a direct cholangioprotective effect. In the BDL mice, oral A3907 administration for 11 days enhanced renal BA clearance resulting in substantial reduction of serum and biliary BA levels. As a result, the pronounced body weight loss observed in BDL mice was prevented by A3907 administration. Furthermore, A3907 treatment led to marked reduction in serum transaminases (AST and ALT), bilirubin, and urea, and liver histopathological analysis revealed reduced inflammatory cell infiltration and fewer necrotic areas in the treated animals. Finally, the translational potential of A3907 into clinical practice was investigated in a placebo-controlled Phase 1 study, showing that A3907 was well-tolerated in human subjects at pharmacologically active doses.

Conclusion: A3907 is the first oral systemic ASBT inhibitor that acts at the level of the intestine, liver and kidney and robustly attenuates cholestatic liver damage in experimental models. A3907 was well-tolerated in human subjects at doses reaching systemic exposures comparable to those required for therapeutic effects in animal models of cholestasis. Collectively these results highlight the promising translational potential of A3907 for the treatment of cholestatic diseases.

Single-cell atlas of liver myeloid cells with cure of chronic viral hepatitis

Ang Cui[1,2], Bo Li[1,2], Michael Wallace[3], Anna Gonye[3], Christopher Oetheimer[3], Hailey Patel[3], Pierre Tonnerre[3], Jacinta Holmes[3], David Lieb[1], Brianna Yao[1], Aileen Ma[1], Kela Roberts[1], Marcos Damasio[3], Jonathan Chen[1,3], Daphnee Piou[3], Charles Carlton-Smith[3], Joelle Brown[3], Ravi Mylvaganam[3], Jeremy Fung[3], Moshe Sade-Feldman[1,3], Jasneet Aneja[3], Jenna Gustafson[3], Eliana Epstein[3], Shadi Salloum[3], Cynthia Brisac[3], Ashraf Thabet[3], Arthur Kim[3], Georg Lauer[3], Nir Hacohen[1,3], Raymond Chung[3], Nadia Alatrakchi[3]. *[1]Broad Institute of MIT and Harvard, United States; [2]Harvard University, United States; [3]Massachusetts General Hospital and Harvard Medical School, United States*
Email: angcui@broadinstitute.org

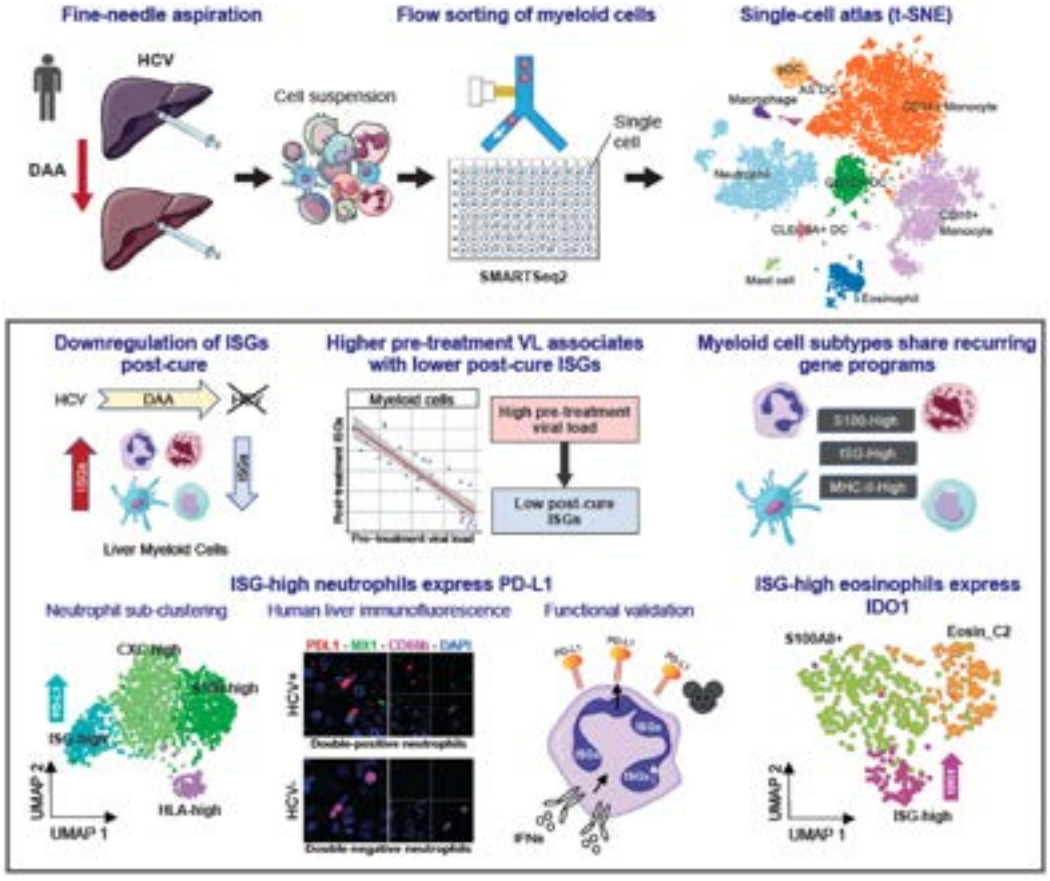

Figure: (abstract: OS-075-YI).

Background and aims: Direct-acting antivirals (DAAs) are now able to cure nearly all patients infected with the hepatitis C virus (HCV), representing the only definitive cure of a human chronic viral infection to date. DAAs provide a valuable opportunity to study immune pathways in the reversal of chronic immune failures in humans.

Method: To leverage this opportunity, we used plate-based single-cell RNA-seq (scRNA-seq) to deeply profile myeloid cells from liver fine needle aspirates (FNAs) in HCV patients before and after DAA treatment. We comprehensively characterized liver neutrophils, eosinophils, mast cells, conventional dendritic cells (cDCs), plasmacytoid dendritic cells (pDCs), classical monocytes, non-classical monocytes, and macrophages, and defined fine-grained subpopulations of several cell types.

Results: We discovered cell-type-specific changes post-cure, including an increase in *MCM7+STMN1+* proliferating CD1C+ cDCs, which may support restoration from chronic exhaustion. We observed an expected downregulation of interferon stimulated genes (ISGs) post-cure as well as an unexpected inverse relationship between pre-treatment viral load and post-cure ISG expression in each cell type, revealing a link between viral loads and sustained modifications of the host's immune system. We found an upregulation of PD-L1/L2 expression in ISG-high neutrophils and IDO1 expression in eosinophils, pinpointing cell subpopulations crucial for immune regulation. We identified three recurring gene programs shared by multiple cell types, distilling core functions of the myeloid compartment.

Conclusion: This comprehensive scRNA-seq atlas of human liver myeloid cells in response to a cure of chronic viral infections reveals principles of liver immunity and provides immunotherapeutic insights.

OS-076

Liver-on-chip platform for studying recruitment and differentiation of circulating monocytes

Aleksandra Aizenshtadt[1], Mathias Busek[1,2], Inger Øynebråten[1,3], Shadab Abadpour[1,4], Anna Katharina Frank[1,5,6,7], Alexey Golovin[1], Justyna Stokowiec[1], Alexandre Corthay[1,3], Espen Melum[1,4,5,6,7], Stefan Krauss[1,2]. *[1]University of Oslo, Hybrid Technology Hub, Institute of Basic Medical Science, Oslo, Norway; [2]Oslo University Hospital, Department of Immunology and Transfusion Medicine, Oslo, Norway; [3]Oslo University Hospital, Department of Pathology, Oslo, Norway; [4]Oslo University Hospital, Department of Transplant Medicine and Institute for Surgical Research, Oslo, Norway; [5]Oslo University Hospital, Norwegian PSC Research Center, Department of Transplantation Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo, Norway; [6]Oslo University Hospital, Research Institute of Internal Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo, Norway; [7]University of Oslo, Institute of Clinical Medicine, Faculty of Medicine, Oslo, Norway*
Email: aleksandra.aizenshtadt@medisin.uio.no

Background and aims: Recent studies based on single-cell and spatial (proteo)genomics uncovered a significant diversity of immune cells in the liver, reflecting metabolic zonation, and might be altered during diseases. For instance, circulating monocytes can be recruited to damaged liver tissue and change fate depending on signals from the microenvironment. An expanded population of recruited macrophages is believed to affect the progression of liver diseases. The exact mechanisms and functions of recruited macrophages are not fully understood, partially due to the absence of relevant human *in vitro* models. The aim of this study was to establish an *in vitro* system for functional studies of circulating immune cells in

the context of their recruitment and interactions with healthy and diseased 3D liver tissue representations with metabolic zonation.
Method: We developed medium compositions for generating and maintaining human pluripotent stem cells-derived periportal (zone 1) and pericentral (zone 3)-like liver organoids (HLO). The zone-specific phenotype of the HLOs was demonstrated by immunofluorescence, gene expression analysis, proteomics. Functional assays included drug metabolism, production of albumin, urea, glutamine and accumulation of glycogen. Using a recently developed pump-less recirculation Organ-on-a-Chip (rOoC) platform, healthy and diseased zonated HLOs were co-cultured with human primary $CD14^+$ monocytes, isolated from peripheral blood mononuclear cells (PBMC). Confocal imaging, flow cytometry and multiplex assay of cytokines were employed for the analysis of interaction between HLOs and monocytes.
Results: We present a novel *in vitro* model for studying interactions between circulating human immune cells and liver tissue representations with metabolic zonal identity (Fig. a) in a rOoC platform (Fig. b). In this setting, HLOs could be cultured for at least 2 weeks while retaining viability and functionality. Moreover, disease phenotype (hepatic steatosis or drug-induced liver injury, DILI) can be induced in HLOs in a rOoC platform in response to free fatty acids or acetaminophen (APAP) (Fig. c), respectively. Monocytes could be circulated in the rOoC platform without trapping, activation or decrease in viability. The functional interactions between zonated HLOs and circulating monocytes were analyzed in control and disease-mimicking conditions. We observed an increased migration of monocytes toward APAP-treated HLOs compared to untreated HLOs (Fig. c). The multiplex analysis of cytokines and *in situ* immunophenotyping enabled a thorough characterization of deployment and disease-dependent alterations of monocytes and liver cells "*on chip*.".

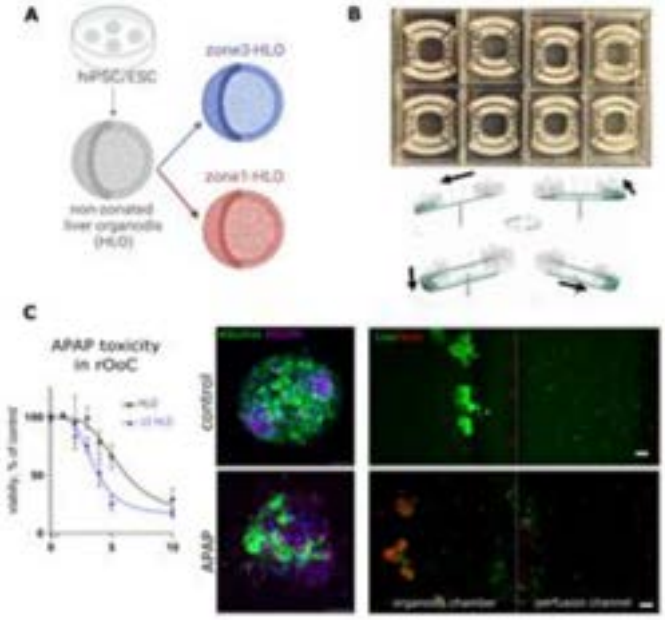

Figure: The Liver-on-chip platform. A) Scheme of generation of zonated HLO. B) rOoC chips in the culture 8-wells format, and scheme of rOoC perfusion. C) Example of disease model in rOoC-APAP-induced liver injury. "On chip" confocal imaging showing expression of albumin (green) and PDGFR (magenta) in control and APAP-treated HLO. Live/dead staining was used for the visualization of monocytes (green dots) migration toward APAP-treated organoids.

Conclusion: In this proof-of-concept study, we developed a novel platform for modelling the interactions between zonated liver 3D representations and circulating immune cells "*on chip*." The platform provides an improved tool for a scalable and personalized evaluation of human liver responses to drug interventions and disease modelling.

Liver immunity index: circulating HBV-specific CXCR6+ CD8T cells mirror intrahepatic anti-viral T cell immunity and predict immune control in models of chronic hepatitis B

Hannah Wintersteller[1], Miriam Bosch[1], Donakonda Sainitin[1], Anna Kosinska[2,3], Edanur Ates-Öz[2,3], Christine Wurmser[4], Dietmar Zehn[4], Ulrike Protzer[2,3], Dirk Wohlleber[1], Percy A. Knolle[1,3].

Email: percy.knolle@tum.de

Background and aims: Persistent hepatic viral infections, such as chronic hepatitis B, are characterized by a scarcity and dysfunction of virus-specific CD8T cells detected in the liver and the circulation. Immunotherapies, such as therapeutic vaccination, thus aim to reinvigorate and expand virus-specific CD8T cell immunity to control viral infection in the liver. Since liver biopsies are difficult to obtain, we sought to identify markers on circulating antigen-specific CD8 T-cells that reflect the immune response at the site of infection in the liver and could be used for immune monitoring of immune therapies.
Method: We used pre-clinical models of adenoviral hepatocyte-specific delivery of nominal antigens and HBV genomes to study the dynamics of virus-specific T cell responses by flow cytometry and single-cell RNA sequencing (scRNAseq).
Results: After adenoviral transduction of hepatocytes, we detected generation of $CXCR6^+$ virus-specific CD8T cells with a liver-resident phenotype that were absent from the spleen. During an acute infection, $CXCR6^+$ CD8T cells were potent effector cells, expressing high levels of Granzyme B and TNF/IFNγ after *ex vivo* stimulation. $CXCR6^+$ CD8T cells in a persistent infection of the liver were rendered dysfunctional. Strikingly, during clearance of hepatic infection, high numbers of circulating $CXCR6^+$ CD8T cells were detected in peripheral blood, whose phenotype and functionality were identical to their counterparts in the liver, and most importantly predicted outcome. Notably, $CXCR6^+$ CD8T cells developed solely when recognizing their antigen in the liver and not after systemic DNA vaccination in the absence of infection, which led to formation of circulating CX_3CR1^+ effector T cells. scRNAseq analysis of sorted, virus-specific CD8T cells confirmed co-clustering of CD8T cells from the liver and blood but not spleen.
Conclusion: Our results reporting the occurrence of HBV-specific $CXCR6^+$CD8T cells in the circulation, that have previously seen their antigen in the liver, provide the basis for using CXCR6 as a predictive marker for intrahepatic immune responses during monitoring of immune therapies, such as therapeutic vaccination, in patients with chronic hepatitis B.

OS-079-YI

2D-interactome of the tumor immune-microenvironment reveals immunosuppressive T cells in primary sclerosing cholangitis-associated cholangiocarcinoma

Email: je.krause@uke.de

Background and aims: Primary Sclerosing Cholangitis (PSC) is the greatest risk factor for Cholangiocarcinoma (CCA), its most feared complication (1, 2). Curative therapeutic options are limited, and its pathogenesis is still only partially understood. Altered T cell function has recently been described in patients with PSC, characterized by a pro-inflammatory $CD4^+$ T_{EM} phenotype dominated by IL-17 producing cells (T_H17) (3–5). In CCA, highly activated immunosuppressive regulatory $Foxp3^+$ T cells ($Foxp3$ T_{REG}) have been linked to unfavourable outcome (6). The tumor immune-microenvironment (TIME) of PSC-associated CCA (PCS-CCA) has never been thoroughly characterized, thus whether T_H17 or $Foxp3^+$ T_{REG} contribute to TIME of PSC-associated CCA remains unknown.
Method: To understand the composition and function of the TIME in PSC-CCA, we applied state-of-the-art single-cell multi-omics, as well as spatial transcriptomics (ST). By using a combination of novel analyses such as interactome and spot deconvolution, we overcame the limitation of 1-dimensional biased morphological experiments, revealing the cellular neighborhood composition and the comprehensive 2D interactome of PSC-CCA TIME.
Results: We provide the first comprehensive characterization of the TIME in PSC-CCA. We developed a new method to elucidate the 2D-immune-interactome based on single-cell multi-omics, and thereby identified immunosuppressive T cell interaction within the PSC-CCA TIME. Trajectory analyses and scTCR-Seq suggests plasticity of $CD4^+$ T_{EM} with a T_H17 polarization-state towards $Foxp3^+$ T_{REG} in PSC-CCA. ST spot deconvolution revealed the neighborhood composition of $Foxp3^+$ T_{REG} within the tumor, showing proximity to CCA cells and cancer associated fibroblasts. Finally, we found *TGFB1,* a cytokine known to promote the conversion of $CD4^+$ T cells to Treg, gene expression increased in tumors when compared to the adjacent liver.
Conclusion: We here generated the first comprehensive multi-omics dataset on the complex TIME of PSC-CCA proposing potential therapeutic targets. By revealing the 2D-immune-interactome, we identified location and cellular network of $Foxp3^+$ T_{REG} and suggested them as a potent mediator of tumor maintenance. We further suggest TGFb1 from the tumor microenvironment to be the potential cytokine able to polarize $CD4^+$ T_{EM} in the liver toward immunosuppressive regulatory T cells in PSC-CCA, and thus impair antitumorigenic function of cytotoxic $CD8^+$ T cells.

Background and aims: Hepatocellular carcinoma (HCC) is the first cause of primary liver cancer, constantly increasing, and the 3rd cause of cancer death worldwide. The objective of the study is to describe the epidemiology and management of HCC in France.
Method: CHIEF is a prospective and nationwide observational cohort initiated in September 2019, with the aim to include all patients with HCC in a real-life situation. The clinical, biological, radiological and therapeutic characteristics of the patients were collected with a follow-up for 5 years for each patient.
Results: 2043 patients were included from September 2019 to September 2021 in 31 centers. The analysis involved 1640 patients, with 68 years of median age, 86% of men, BMI at 26.8 kg/m2. HCC was diagnosed by a screening program in 35.2% of cases, associated with better survival (84.7% at 1 year $p < 0.0001$) compared to those diagnoses during a complication. A diagnostic by liver biopsy was performed in 46.3% of cases. Cirrhosis was present in 70.8% of cases, with median MELD 9 IQR[7;11], Child-Pugh A in 77.8%, median ALBI score at −2.4 [−2.7; −1.9] (ALBI 1: 36.3%, ALBI 3: 7%), esophageal varices of grade ≥2 in 28.4%. The etiologies were at least alcohol in 58.5% of cases, metabolic syndrome in 39%, and viral infection in 23.3% (16.4% HCV). HCC was diagnosed within the Milan criteria in 32.9%, with a median AFP level of 39 ng/ml IQR [7–562], a portal thrombosis in 5.9% and a metastatic condition in 10.7% of cases. The distribution of BCLC stages 0, A, B, C and D was 6.1%, 29.8%, 28.8%, 32.1% and 3.2% respectively. The median follow-up of new cases was 17.8 months 95% CI [17.3;18.5], IQR [13.7;23.3], with 29.1% of death. The survivals at 6 months, 1 year and 18 months were 84.9% 95%CI [82.8;87], 76.7% [74.2;79.2] and 69.3% [66.4; 72.3]. Median overall survival was not reached. First-line therapeutic access was 40.5% for curative treatments, 36.2% for locoregional procedures, 19.2% for systemic treatments and 4% palliative. The 1-year survival rates for BCLC stages 0, A, B, C and D were 95.6%, 89.7%, 81.7%, 54.9% and 40% (log rank test $p < 0.0001$). BCLC 0, A and B median survivals were not reached. They were 14.6 months and 6.1 months for BCLC stages C and D. The 1-year survival rates for curative, locoregional and systemic treatments were 92.9% 82.2% and 57.8% ($p < 0.0001$). Among the systemic treatments, the atezolizumab-bevacizumab combination was used as much as first-line TKIs (18.8% for each treatment), with a median survival of 17.05 months versus 9 months for TKIs ($p < 0.0001$).

Conclusion: The first analysis of the CHIEF cohort provides epidemiological data and recent therapeutic results in real life. In this cohort, the overall survival at 1 year, the survivals observed for the treatments applied, and the access to curative treatments seem interesting. First-line immunotherapy shows comparable survival in real life as in trials.

OS-082

Glycemic control as a modifiable and independent risk factor for the development of liver, biliary tract and pancreatic cancer: a territory-wide study of 273,421 patients with diabetes mellitus

Xianhua Mao[1], Ka Shing Cheung[1,2], Jing Tong Tan[1], Lung-Yi Mak[1], Chi Ho Lee[1], CL Chiang[3], Ho Ming Cheng[1], Rex Wan-Hin Hui[1], Man-Fung Yuen[1], Wai Keung Leung[1], Wai-Kay Seto[1,2]. *[1]The University of Hong Kong, Medicine, Hong Kong; [2]The University of Hong Kong-Shenzhen Hospital, Medicine, China; [3]The University of Hong Kong, Clinical Oncology, Hong Kong*
Email: wkseto@hku.hk

Background and aims: Diabetes mellitus (DM) is an established risk factor for liver, biliary and pancreatic cancer, but the impact of glycemic control on the development of these cancers in patients with DM has not been well-investigated.
Method: We identified adults (age ≥18 years) newly diagnosed with DM between 2000 and 2015 via a territory-wide electronic healthcare registry in Hong Kong. DM was identified by (i) the American Diabetes Association criteria with two abnormal test results of hemoglobin A1c (HbA1c) ≥6.5% or fasting plasma glucose ≥7 mmol/L, (ii) use of antidiabetic medications, or (iii) international classification of diseases (ICD-9) coding. An initial lead-in period of three years from the date of DM diagnosis was used to minimize reverse causality, with optimal glycemic control defined as mean HbA1c <7% from at least two values within the lead-in period. Average successive variabilities of HbA1c were calculated to assess the variability. Outcomes of interest were incident liver, biliary (gallbladder and extrahepatic biliary tract), and pancreatic cancer development. A multivariable Cox regression model was used to calculate the adjusted hazard ratio (aHR) of cancer development with glycemic control. Additional sensitivity analyses (Table 1) were applied to assess robustness of results.
Results: Among 421,818 screened individuals, 273,421 patients with DM (mean age 61.5 ± 11.7 years, 52.6% male) were included. The median follow-up duration was 6.7 (4.4–10.1) years, with the occurrence of 2,018, 517, and 721 liver, biliary and pancreatic cancers respectively. When compared with a mean HbA1c ≥7%, a level <7% was independently associated with a lower risk of liver cancer (aHR: 0.74; 95% CI: 0.67–0.81), biliary tract cancer (0.67; 0.56–0.80), and pancreatic cancer (0.83; 0.71–0.97). The associations remained significant after 1:2 propensity score matching (HR 0.68–0.80), inverse probability of treatment weighting (HR 0.71–0.85), and via other sensitivity analyses (Table 1). A lower risk of liver cancer was observed regardless of presence or absence of obesity (aHR 0.69–0.78); aspirin intake (aHR 0.71–0.75); or viral hepatitis (aHR 0.68, 0.59–0.79; and aHR 0.78, 0.69–0.88 respectively). Significant associations were also demonstrated in biliary tract cancer regardless of smoking, hypertension, and hyperlipidemia (aHR 0.46–0.74). For pancreatic cancer, the association was significant in non-smokers, normotensive and non-dyslipidemia individuals (aHR 0.80–0.82), but became insignificant when these metabolic risk factors were present.
Conclusion: Optimal glycemic control with mean HbA1c <7% was independently associated with a lower risk of cancers of the liver, biliary tract, and pancreas among patients with DM. Glycemic control is a modifiable risk factor which can influence oncoprotective strategies for hepatobiliary and pancreatic cancers.

Mean A1c <6.5% vs. ⩾6.5%	0.69 (0.62-0.77)	0.53 (0.42-0.67)	0.75 (0.62-0.90)
Based on at least three A1c values during lead-in period	0.77 (0.69-0.85)	0.66 (0.53-0.82)	0.86 (0.72-1.02)
A1c ASV <25% quartile vs. ⩾25%	0.74 (0.66-0.83)	0.86 (0.70-1.06)	0.76 (0.63-0.91)

*A multivariable Cox proportional-hazards regression model accounted for the following covariates: baseline characteristics (age, sex, BMI, duration of diabetes, smoking, alcohol abuse, hyperlipidemia, hypertension) and medication use during follow-up (statins, aspirin, NSAID, metformin, sulfonylureas, insulin, SGLT-2i, DPP-4i, GLP-1a).

†Model 3 included model 2 covariates and further adjusted for chronic hepatitis B and C infection, cirrhosis, and liver compensation in liver cancer; gallstone, cholangitis, calculus of bile duct, and cholecystitis in biliary tract cancer; acute and chronic pancreatitis in pancreatic cancer.

ASV, average successive variability; BMI, body mass index; CI, confidence interval; DPP-4i, dipeptidyl peptidase-4 inhibitors; GLP-1a, glucagon-like peptide-1 agonists; HR, hazard ratio; IPTW, inverse probability of treatment weighting; NSAID, non-steroidal anti-inflammatory drug; PS, propensity score; SGLT-2i, sodium-glucose cotransporter-2 inhibitors.

Figure: (abstract: OS-082).

transplant survival. More data on the natural history, clinical presentation, efficacy and safety of treatments are needed to optimize the management of rHCC in the specific context of transplanted patients.
Method: Observational, retrospective study in 9 French transplantation centers, including all patients with rHCC after LT between 01/01/2008 and 31/12/2020. Patients' characteristics at LT and at recurrence were collected. We evaluated factors associated with overall survival (OS) from the date of recurrence, treatment in terms of efficacy and safety, and the impact of immunosuppressive (IS) drug management.
Results: Two-hundred-and-fifty-five patients were included (median age 63 years, HCC/alcohol 55%). The median time between LT and recurrence was 23 months (IQR 11.8–45.4) and was predominantly only extrahepatic (60%), with bone lesions in 35% of cases. AFP at recurrence was only weakly correlated to last AFP before LT (Spearman r = 0.36). Recurrence was very early (<6 months) in 12% of cases and very late (>5 years) in 18% of cases. Early and late recurrences were similar in terms of anatomical sites. Size of the main nodule on the explant pathology (p = 0.01) and the last AFP before LT (p = 0.01) were associated with earlier recurrence.
Median OS was 18.2 months (95%CI: 15.1–21.7) from the date of recurrence. Overall 5-year post-LT survival was 45% (95%CI: 39–52). 31% of patients (n = 78) received a curative treatment (surgery or percutaneous destruction) at the first recurrence, with a subsequent 5-year recurrence-free survival of recurrence of 19% (95% CI; 11–34). When considering systemic treatments, sorafenib was the most commonly used TKI (n = 131, 86%), while the use of the atezolizumab and bevacizumab was limited (n = 6). 10-year OS post-LT was 46% (95% CI; 34–62) for patients who were amenable to curative treatment at recurrence 6% (95% CI; 0.3–12) for non-curative treatment. In multivariate analysis, non-curative treatment (HR 2.76, p < 0.001), recurrence later than 2 years after LT (HR 0.15, p = 0.001), WHO PS 1 (HR 1.69, p = 0.01) or >1 (HR 8.1, p < 0.001), AFP level at recurrence >100 ng/ml (HR 1.83, p = 0.03) and concomitant intra- and extra-hepatic recurrence (HR 1.54, p = 0.04) were associated with OS after HCC recurrence. Change of listing criteria for HCC in France in 2013 (Milan criteria versus AFP model) did not impact on rHCC prognosis.
Forty-nine percent of patients experienced grade 3/4 toxicity, and treatment discontinuation was required in 38%. There was no significant association between mTOR inhibitors, calcineurin inhibitors or mycophenolate mofetil management with survival or safety profile of systemic treatments.
Conclusion: Recurrence HCC after LT is a predominantly extrahepatic disease, and 20% of recurrences occur more than 5 years after LT. OS could be improved by aggressive management in selected patients, resulting in those patients in 46% survival 10 years after LT. Timing of recurrence after LT has a major prognostic impact. TKIs have a manageable toxicity profile, no impact of IS drugs on the prognosis of the disease or on the tolerance of systemic treatments.

OS-084-YI
Weakly supervised intrahepatic tumour classification from routine tumour biopsy: a proof of concept
Paul Emile Zafar[1,2], Aurélie Beaufrère[1,3], Nora Ouzir[2], Miguel Albuquerque[1], Jules Grégory[4], Kévin Mondet[1], Jean Christophe Pesquet[2], Valérie Paradis[1]. *[1]APHP Hôpital Beaujon, Pathology FHU MOSAIC, Clichy, France; [2]CentraleSupélec, France; [3]Curie, U900 CBIO Team, France; [4]APHP Hôpital Beaujon, Radiology FHU MOSAIC, France*
Email: aurelie.beaufrere@aphp.fr

Background and aims: Primary liver malignancies define a wide spectrum of tumours, including hepatocellular carcinoma (HCC), intrahepatic cholangiocarcinoma (iCCA) and combined hepatocholangiocarcinoma (cHCC-CCA) recognised by the presence of HCC and iCCA features. Due to cHCC-CCA's heterogeneity, diagnosis using conventional histology with Hematein Eosin Safran (HES) staining is challenging, especially on biopsy samples. This study aims to automatically classify primary liver malignancies on biopsy samples using a weakly supervised learning method based on deep convolutional neural networks (CNN).
Method: We constituted 119 biopsies of primary liver malignancies (Beaujon Hospital, Clichy, France) divided into training and validation sets of 90 and 29 samples, respectively. Two liver pathologist experts examined each sample's whole slide HES image (WSI). After annotating the tumour/non-tumour areas, tiles of 125 µm2 (256 pixels) were extracted from the WSIs and used to train a ResNet18

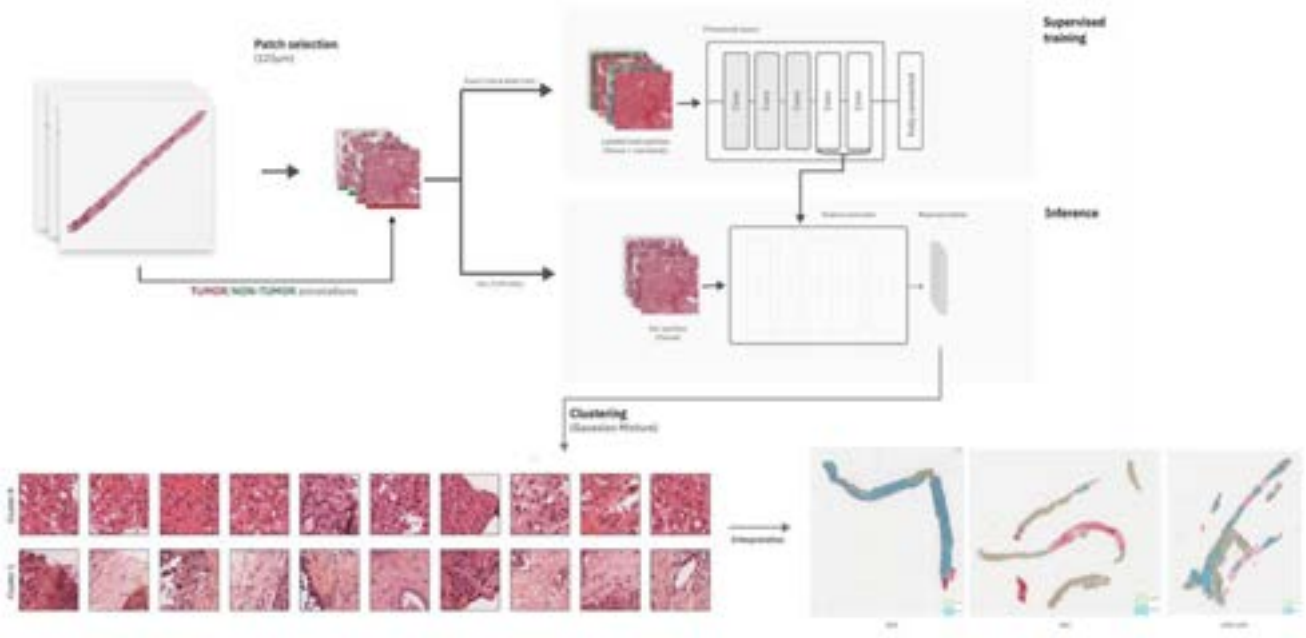

Figure: (abstract: OS-084-YI).

CNN. The tumour/non-tumour annotations of the WSIs served as (weak) labels during training (Figure), while the network's last convolutional layer was used to extract new tumour tile features. Without knowledge of the precise labels of the malignancies, we then applied an unsupervised clustering algorithm to the newly extracted features and explored the results using different numbers of clusters.
Results: First, pathological reviewing classified the training and validation sets into HCC (n = 33 and n = 11), iCCA (n = 28 and n = 9), and cHCC-CCA (n = 29 and n = 9), respectively. We then analysed the results of the proposed weakly supervised method using 2 to 8 clusters. No specific cluster associated with cHCC-CCA was identified. In the case of 2 clusters, cluster 0 contained mainly HCC histological features (76% of the tiles) while cluster 1 contained mainly iCCA features (92% of the tiles) (Figure). This two-clusters model was assessed on the validation set by quantifying the proportion of clusters 0 (representative of HCC) and 1 (representative of iCCA). For HCC and iCCA, the diagnostic agreement between the pathological diagnosis and the model predictions (major contingent) was 100% for HCC (11/11 cases) and 78% for iCCA (7/9 cases). For cHCC-CCA, we observed a highly variable proportion of each cluster type (cluster 0: 5–90%; cluster 1: 9–94%). The diagnostic agreement of the major contingent in pathology predicted by the model was 89% (8/9 cases).
Conclusion: This study shows that a weakly supervised learning method applied to primary liver malignancy biopsy can identify specific morphological features of HCC and iCCA. While no specific features of cHCC-CCA were recognized, assessing the proportion of HCC and iCCA tiles within a slide could improve the identification of cHCC-CCA in biopsies.

NAFLD: Clinical aspects

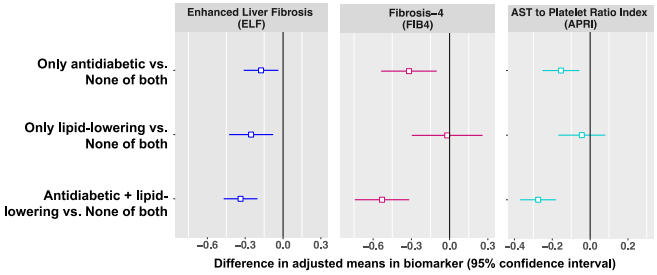
Use of antidiabetic and lipid-lowering medications associated with lower scores of liver fibrosis biomarkers in non-alcoholic steatohepatitis (NASH) patients

Jun Wang[1], Dora Ding[1], Xiaorong Shao[1], Lily Ma[1], Jun Xu[1], Jason Melehani[1], Lisa Boyette[1], Timothy R. Watkins[1], Catherine Jia[1], Vlad Malkov[1], Andrew Billin[1], Shahed Iqbal[1]. [1]*Gilead Sciences, Inc., United States*
Email: jun.wang37@gilead.com

Background and aims: The effects of antidiabetic or lipid-lowering drug use on liver fibrosis biomarkers in NASH patients are not well documented. We investigated the associations between use of antidiabetic or lipid-lowering drugs and blood liver fibrosis biomarkers. Additionally, we assessed if the associations vary by patient's genetic predisposition to NASH.
Method: We conducted a cross-sectional analysis of baseline data from two completed phase III trials of NASH patients with bridging fibrosis (NCT03053050, N = 785) or compensated cirrhosis (NCT03053063, N = 864). Use of antidiabetic (metformin, GLP-1RA, Pioglitazone, SGLT2 inhibitors and DPP4 inhibitors) and lipid-lowering (statins and fibrates) drugs were obtained from trial baseline data. Among patients who provided blood samples for sequencing (N = 1077), a polygenic risk score (PRS) for NASH was derived for those of European ancestry (N = 742) using 6 variants from prior genome-wide association or exome sequencing studies: *PNPLA3*, *TM6SF2*, *HSD17B13*, *GCKR*, *MBOAT7* and *LEPR*. Outcomes included composite scores measured at baseline: Fibrosis 4 (FIB-4), AST to platelet ratio index (APRI) and Enhanced Liver Fibrosis (ELF). Linear regression models were used, adjusting for age, sex, race, BMI, HbA1C and triglyceride.
Results: Study participants (N = 1649) were predominantly ≥50 years old (82%), female (59%) and White (75%). About 61% (N = 1008) of patients used any antidiabetic drugs, most of whom used Metformin alone or in combination (901/1008, 89%). Among patients who used lipid-lowering drugs (N = 750), the majority used statins (657/750, 88%). Overall, use of any antidiabetic or any lipid-lowering drugs was inversely associated with all biomarkers and the associations were stronger among those using both types of drugs (Figure). Compared to patients who used neither drug, patients using both drugs had an average 0.34 (95% Confidence Interval [CI] = −0.47, −0.20) lower ELF, 0.53 (95%CI = −0.74, −0.32) lower FIB-4 and 0.27 (95%CI = −0.37, −0.18) lower APRI scores. Among patients of genetically inferred European ancestry (N = 742), the associations were stronger in those with high PRS (>median PRS; N = 364) than those with low PRS (≤median PRS; N = 378) for FIB-4 (interaction p = 0.01) or APRI (interaction p = 0.004). Use of both drugs was significantly associated with an average 0.50 lower FIB-4 (95%CI = −0.92, −0.07) in patients with high PRS while no such association in patients with low PRS. Similar patterns were seen for APRI. However, there was no statistically significant interaction for ELF.



None of both (none of any antidiabetic and any lipid-lowering drugs): N = 460; only antidiabetic drug: N = 420; only lipid-lowering drug: N = 168; any antidiabetic + any lipid-lowering drugs: N = 561.

Figure:

Conclusion: Use of antidiabetic and lipid-lowering drugs was inversely associated with biomarkers of liver fibrosis. Among patients of European ancestry, stronger associations were observed in those at high genetic risk of NASH development and progression. Prospective studies may provide further insights into potential benefits of these drugs.

OS-086

Stratification of liver fat content in non-alcoholic steatohepatitis patients with significant liver fibrosis using the MEFIB-Index and MRI-PDFF and its association with hepatocellular carcinoma, decompensation, and mortality

Sung Won Lee[1,2], Daniel Huang[1,3], Veeral Ajmera[1], Monica Tincopa[1], Jaclyn Bergstrom[1], Nabil Noureddin[1], Maral Amangurbanova[1], Harris Siddiqi[1], Egbert Madamba[1], Abdul Majzoub[4], Tarek Nayfeh[4], Nobuharu Tamaki[5], Namiki Izumi[5], Atsushi Nakajima[6], Ramazan Idilman[7], Mesut Gumussoy[7], Digdem Kuru Öz[8], Ayse Erden[8], Mazen Noureddin[9], Rohit Loomba[1]. Email: roloomba@health.ucsd.edu

Background and aims: Progression of liver fibrosis in non-alcoholic steatohepatitis (NASH) patients often result in a decrease in hepatic fat to <5%. However, there are limited data on the differences in prognosis according to the liver fat content and fibrosis in NASH patients. Therefore, we aimed to compare the prognosis of patients

stratified by liver fat content and fibrosis using the MEFIB-Index (magnetic resonance elastography [MRE] ≥3.3 Kpa + FIB-4 ≥1.6) and magnetic resonance imaging-derived proton density fat fraction (MRI-PDFF).

Method: A total of 456 patients from three countries with both MRE and MRI-PDFF at baseline were enrolled, and 294 patients with longitudinal follow-up were retrospectively analyzed. MEFIB-negative, MEFIB-positive + MRI-PDFF ≥5, and MEFIB-positive + MRI-PDFF <5 were defined as having no significant liver fibrosis, significant liver fibrosis with higher liver fat content (higher liver fat content group), and significant liver fibrosis with lower liver fat content (lower liver fat content group), respectively. Cox proportional hazards model was used to assess the factors associated with the composite primary outcome of hepatocellular carcinoma (HCC), decompensation, and mortality.

Results: In this meta-analysis of individual participants (IPDMA), the lower liver fat content group consisted of patients with older age, and higher proportion of diabetes and hypertension. Also, compared to the higher liver fat content group, the lower liver fat content group had lower alanine aminotransferase, albumin, platelet counts, and prolonged prothrombin time. The rates of decompensation, HCC, and death were highest in the lower liver fat content group with 1%, 1%, 2% occurrence in the no significant liver fibrosis group; 22%, 13%, 13% in the higher liver fat content group; 32%, 14%, 14% in the lower liver fat content group, respectively. In multivariate analysis, lower liver fat content in patients with significant liver fibrosis was associated [HR = 74.6 (95%CI: 7.2–768.4, p = 0.0003)] with the composite outcome of HCC, decompensation, and mortality.

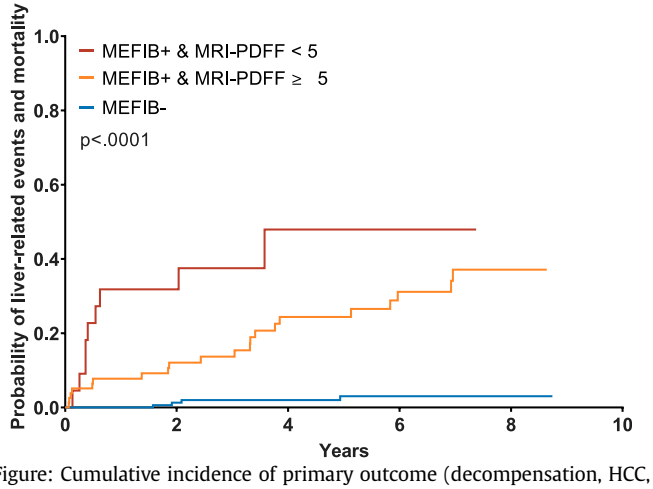

Figure: Cumulative incidence of primary outcome (decompensation, HCC, or death) stratified by MEFIB and MRI-PDFF

Conclusion: The combination of MEFIB-Index and MRI-PDFF is a useful tool to stratify prognosis according to liver fat content and fibrosis in NASH patients. Lower liver fat content in NASH patients with significant fibrosis is associated with an increase in HCC, hepatic decompensation, and mortality.

OS-087

Digital pathology using stain-free imaging indices allows direct prediction of all-cause mortality, hepatic decompensation and hepatocellular carcinoma development in patients with non-alcoholic fatty liver disease

Timothy Kendall[1], Dean Tai[2], Gideon Ho[2], Yayun Ren[2], Elaine Chng[2], Jonathan Fallowfield[1]. [1]*University of Edinburgh, United Kingdom;* [2]*HistoIndex Pte Ltd, Singapore*
Email: tim.kendall@ed.ac.uk

Background and aims: Digital quantification of scarring from either stained liver sections or stain-free imaging reduces observer-related variability in the histological assessment of non-alcoholic fatty liver disease (NAFLD). To date, computational methods have mainly provided ordinal scores analogous to those provided by a pathologist as disease outcomes are strongly correlated with stage. Direct prediction of outcomes from tissue, without using fibrosis stage as a surrogate, has not been possible due to the absence of suitable event-rich cohort data. Using SteatoSITE (https://steatosite.com/), a resource containing integrated clinical and pathological data, we undertook stain-free imaging to generate tools predictive of patient outcomes using architectural features unapparent to human observers.

Method: Unstained sections from a training set of 294 biopsies were imaged using second harmonic generation/two-photon excitation fluorescence microscopy. Using sequential feature selection, 10, 10 and 5 parameters were chosen out of 184 fibrosis parameters and a linear regression method was used to construct individual indices for risk of all-cause mortality, hepatic decompensation and hepatocellular carcinoma (HCC), respectively. Time-to-event analysis was performed using the Kaplan-Meier method, with death as a competing risk for decompensation and HCC, and distributions compared using the log-rank test (Fig. 1). A Cox proportional hazards model was used to estimate hazard ratios (HRs). The predictive power of the risk indices was compared with the assigned NASH-CRN fibrosis stage (F0/1/2 v F3/4) and the stain-free imaging derived qFibrosis stage (qF0/1/2 v qF3/4).

Results: The newly defined "Mortality Index" had greater predictive power for all-cause mortality (index >0.28 vs. </= 0.28, HR 5.33, 95% confidence intervals (CI) 3.00–9.47, p = 0.000) than either NASH-CRN or qFibrosis stage. The "Decompensation Index" had greater predictive power for decompensation events (index >0.421 vs. </=

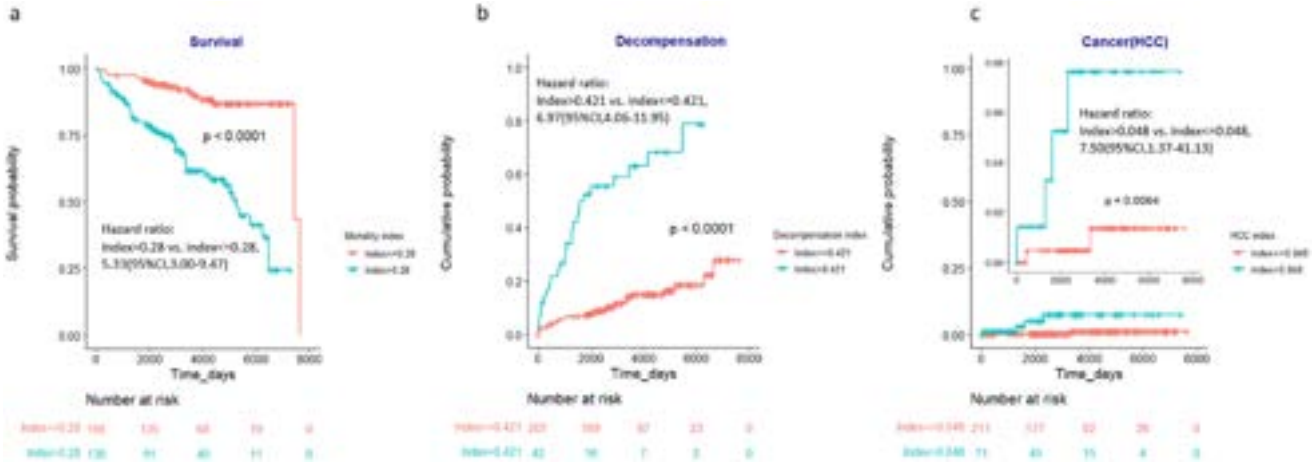

Figure: (abstract: OS-087).

0.421, HR 6.97, 95% CI 4.06–11.95, p = 0.000) than either NASH-CRN stage or qFibrosis stage. Finally, the "HCC Index" had greater predictive power for HCC development (index >0.048 vs. ≤0.048, HR 7.50, 95% CI 1.37–41.13, p = 0.020) than either NASH-CRN stage or qFibrosis stage.

Conclusion: Using liver biopsy material with linked long-term clinical outcome data, we developed tools that directly predict hard end points in patients with NAFLD and do not rely on ordinal fibrosis scores as a surrogate. These tools have greater predictive value than pathologist-assigned NASH-CRN fibrosis stage or computationally-assigned qFibrosis stage. These indices will be validated in an additional NAFLD cohort but may provide direct tissue-to-outcome predictions that aid clinical decision-making, offer more nuanced participant stratification and meaningful end points in clinical trials.

OS-088

Effect of semaglutide 2.4 mg on alanine aminotransferase in adolescents with obesity: a post-hoc analysis of the STEP TEENS trial

Daniel Weghuber[1], Inge Gies[2], Lise Lotte Gluud[3], Aske Thorn Iversen[4], Maximilian Jara[5], Signe Schmidt[6], Rasmus Sørrig[5], Martin Wabitsch[7], Mazen Noureddin[8,9]. *[1]Department of Pediatrics, Paracelsus Medical University, Salzburg, Austria; [2]Department of Pediatrics, Division of Pediatric Endocrinology, Universitair Ziekenhuis Brussel, Brussels, Belgium; [3]Gastro Unit, Copenhagen University Hospital Hvidovre and Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [4]Biostatistics, Novo Nordisk A/S, Søborg, Denmark; [5]Global Medical Affairs, Novo Nordisk A/S, Søborg, Denmark; [6]Medical and Science, Novo Nordisk A/S, Søborg, Denmark; [7]Division of Pediatric Endocrinology and Diabetes, Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, University of Ulm, Ulm, Germany; [8]Sherrie and Alan Conover Center for Liver Disease and Transplantation, Houston Methodist Hospital, Houston, TX, United States; [9]Houston Research Institute, Houston, TX, United States*
Email: NoureddinMD@houstonresearchinstitute.com

Background and aims: Increased body mass index (BMI) is associated with a greater incidence of non-alcoholic fatty liver disease (NAFLD) and its advanced forms, such as steatohepatitis. Weight loss can improve hepatic parameters, such as alanine aminotransferase (ALT) levels, in patients with NAFLD/steatohepatitis. Change in ALT levels is associated with histological response in patients with steatohepatitis. The phase 3, double-blind, placebo-controlled, STEP TEENS trial (NCT04102189) demonstrated the efficacy and safety of semaglutide 2.4 mg once weekly for weight management among adolescents with obesity. This post hoc analysis of the STEP TEENS trial examined the change in ALT levels and presumed NAFLD in adolescents treated with semaglutide 2.4 mg vs placebo.

Method: Adolescents (aged 12 to <18 years) with obesity (BMI ≥95th percentile), or overweight (BMI ≥85th percentile) with ≥1 weight-related comorbidity, were randomised 2:1 after a 12-week lifestyle intervention run-in phase (consisting of diet and physical activity counselling) to receive semaglutide 2.4 mg once weekly (or maximum tolerated dose) or placebo for 68 weeks, plus lifestyle intervention. Change in ALT from baseline to week 68 was a prespecified secondary end point, assessed using a mixed model for repeated measurements using data from the on-treatment period for the trial product estimand (assessed the treatment effect if all participants remained on treatment without using rescue interventions).

Results: Overall, 201 participants were randomised. Mean parameters at baseline were: age 15.4 years, body weight 107.5 kg and BMI 37.0 kg/m^2. Participants were 62% female, 38% had elevated ALT (>25.8 U/L in males, >22.1 U/L in females) and 34% were presumed to have NAFLD (defined as BMI ≥85th percentile, fatty liver index ≥60 [a surrogate index of fatty liver based on BMI, waist circumference, triglycerides and gamma-glutamyl transferase] and elevated ALT). The geometric mean ALT level at baseline was 23 U/L vs 20 U/L in the semaglutide vs placebo groups, respectively. The change from baseline in ALT with semaglutide was significantly greater vs placebo (−18.1% vs −1.1%; estimated treatment difference [95% confidence interval] −17.2%-points [−28.8, −3.6]; p = 0.015). At week 68, mean ALT levels decreased from baseline levels in participants treated with semaglutide who achieved a weight loss of ≥10%, but not in those with <10% weight loss (Table). Estimated ALT changes in participants with presumed NAFLD were −15.5% vs 10.6% with semaglutide vs placebo, respectively (estimated treatment difference −23.7%) (Table). Of participants with elevated baseline ALT levels, 53.8% vs 33.3% had normal levels at week 68 with semaglutide vs placebo, respectively. Participants reporting hepatic-related adverse events (mostly non-serious) were higher in the semaglutide 2.4 mg group (7.5%) than with placebo (1.5%). The imbalance was mainly driven by events reported at the day of randomisation (without exposure to semaglutide) and events in subjects with pre-existing hepatic disorders.

Table Change in ALT parameters

Endpoints	Semaglutide 2.4 mg		Placebo	
Participants with elevated ALT[a]				
Geometric mean ALT level at week 0, U/L (CV)	n = 56 42 (51.2)		n = 20 40 (51.1)	
Mean change from baseline at week 68, %	−20.1		0.50	
Treatment difference, %-points (95% CI)	−20.5 (−38.5, 2.8)			
Participants with presumed NAFLD[b]				
Geometric mean ALT level at week 0, U/L (CV)	n = 50 43 (51.4)		n = 18 39 (48.7)	
Mean change from baseline at week 68, %	−15.5		10.6	
Treatment difference, %-points (95% CI)	−23.7 (−41.7, 0)			
ALT ratio to baseline at week 68 by % body weight loss, geometric mean (CV)				
< 10% weight loss[c]	n = 39 1.00 (56.6)		n = 44 1.04 (43.2)	
≥ 10% weight loss	n = 72 0.67 (65.3)		n = 5 0.99 (36.5)	
≥ 20% weight loss	n = 44 0.62 (67.1)		n = 2 1.22 (57.7)	
ALT levels by % body weight loss, geometric mean, U/L (CV)				
Weight loss at week 68	**Semaglutide**		**Placebo**	
	Baseline	**Week 68**	**Baseline**	**Week 68**
< 10% weight loss[c]	n = 53 24.4 (72.8)	n = 39 27.4 (72.6)	n = 62 19.9 (72.1)	n = 44 21.0 (58.4)
≥ 10% weight loss	n = 81 22.6 (68.3)	n = 72 15.9 (49.9)	n = 5 15.0 (49.5)	n = 5 14.8 (27.2)

Observed data from on-treatment analysis.

[a]Elevated ALT was defined as levels > 25.8 U/L in males and > 22.1 U/L in females.[1]

[b]Presumed NAFLD was defined as BMI ≥ 85th percentile, FLI (a surrogate index of fatty liver based on BMI, waist circumference, triglycerides and gamma-glutamyl transferase) ≥ 60 and elevated ALT.[1,2]

[c]Includes participants who gained weight.

ALT, alanine aminotransferase; BMI, body mass index; CI, confidence interval; CV, coefficient of variation in %; FLI, fatty liver index; n, number of participants with an observation at the visit; NAFLD, non-alcoholic fatty liver disease.

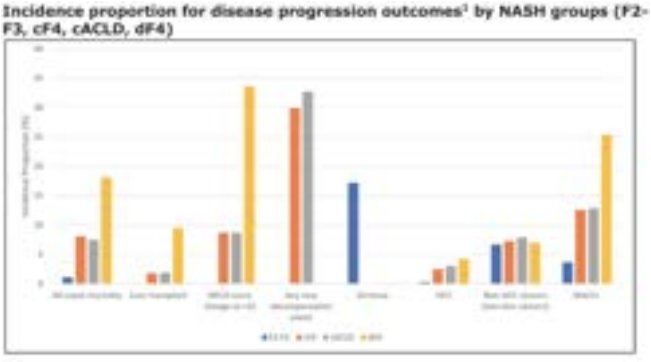
Non-alcoholic steatohepatitis disease progression in participants from the United States TARGET-NASH real world longitudinal observational study

Claudio Sartini[1], Bryan Rudolph[1], Mandy Fraessdorf[2], Heather Morris[3], Derek Gazis[3], Andrea Mospan[3], Michael Fried[3], Michael Roden[4], Brent Tetri[5], Kenneth Cusi[6], Philip N Newsome[7,7].
[1]Boehringer Ingelheim, United States; [2]Boehringer Ingelheim, Germany; [3]Target RWE, United States; [4]German Diabetes Center, Germany; [5]St. Louis University, United States; [6]University of Florida, United States; [7]University of Birmingham, United Kingdom
Email: hmorris@targetrwe.com

Background and aims: Estimating progression rate is essential for understanding the comprehensive burden of disease and informing future clinical trial designs. The aim of this study was to describe demographic and clinical characteristics in a large multi-centre cohort of NASH participants followed in routine clinical practice and determine the occurrence of health outcomes.
Method: Adults from the US TARGET-NASH longitudinal observational study were followed from August 2016-October 2021. Participants had a biopsy or clinical NASH diagnosis with significant fibrosis (stage F2/3/4). Demographic and clinical characteristics were analyzed in 4 groups: non-cirrhotic NASH F2-F3, compensated cirrhosis (cF4), compensated advanced chronic liver disease (cACLD-no signs of decompensation and ≥1 of the following: FibroScan liver stiffness ≥15 kPa, NASH F3/F4 on biopsy, gastric/esophageal varices on endoscopy, or cirrhosis and findings of portal hypertension noted on imaging) and decompensated cirrhosis (dF4). Progression outcomes included all-cause mortality, progression from non-cirrhosis to cirrhosis, compensated to decompensated cirrhosis, and liver-related and cardiovascular events. Incidence rates and incidence proportion for all outcomes were estimated in each group.
Results: Of the 1,852 participants, median age was 59 years, BMI was 34.1 kg/m2, mostly female (59%), and non-Hispanic white (77%). 699 (38%) were classified as F2-F3, 1153 (62%) as F4 (795 cF4, 358 dF4). Among the 1,494 (81%) with no signs of decompensation, 428 (29%) were defined as cACLD. Participants with F4 (vs F2-F3) were 6 years older, had a higher prevalence of diabetes (p = 0.02), and similar BMI; lower ALT, higher GGT, higher glucose levels, and higher FIB-4 score (p < 0.001). The cACLD group was older with a higher FIB-4 (compared to non-cACLD and F2-F3). Over an average follow-up (FU) time of about 4 years, the incidence rate per 1000 person-years (py) for all-cause mortality was 42 per 1000 py in dF4, 18 per 1000 py in cACLD, 19 per 1000 py in cF4, and 3 per 1000 py in F2-F3. In the F2-F3 group, 120 (17%) progressed to cirrhosis (49 per 1000 py, average FU time 3.5 years); in the cF4 group, 238 (30%) progressed to decompensation (89 per 1000 py, average FU time 3.4 years). For completeness, the incidence proportion for all outcomes is summarized in Figure 1.



[1] HCC= Hepatocellular carcinoma; MELD= model for end-stage liver disease; MACE+ = events or procedures indicative of all-cause death, non-fatal MI, non-fatal stroke, coronary revascularization or unstable angina

[2] MELD outcome was only assessed in cirrhotic patients with a MELD ≤12 prior to index

Figure:

Conclusion: This is a large US multi-center study using real-world data to examine NASH disease progression longitudinally. Although rates of progression to cirrhosis were similar compared to previous studies, substantially lower mortality incidence rates were found for participants in dF3/4 subgroups. The real world evidence from our study inform the natural history of NASH and can provide additional rationale and justification in clinical trials design, including enrollment criteria, duration of the trials, and the choice of end points.

Email: clemence.ramier@inserm.fr

Background and aims: Hepatocellular carcinoma (HCC) is the third cancer-related cause of death worldwide and 90% of cases are attributable to either unhealthy alcohol use or viral hepatitis. People infected with hepatitis B virus (HBV) have an increased risk of developing HCC. To date, predictive scores of HCC are mainly based on clinical data and do not include behaviours. We aimed to develop an easy-to use score based on both behaviours and routine medical data predicting HCC in chronic HBV patients.
Method: The study population included chronic HBV patients with no history of HCC enrolled between 2012 and 2018 in the French ANRS CO22 HEPATHER cohort. The study population was randomly split into a training set (70%) and a testing set (30%). A Cox proportional hazards model for time to HCC was estimated on the training set. Variables with a p value <0.20 in univariable analyses were included in the multivariable analysis, then a backward selection procedure based on an alpha error <0.05 was used. Points were assigned to each variable in the final multivariable model by dividing its coefficient by the coefficient associated with a 10-year

increase in age, then rounded. A prediction score for HCC was calculated as the sum of thee points. The optimal cut-off predicting the risk of HCC was computed using Youden index on 1000 bootstrap samples. The score's predictive performance was rated on the testing set and compared to other published scores using the area under the receiver operating characteristic curve (AUROC).

Results: The study population (N = 4,370) was 63% male, 65% were aged <50 years and 3.6% were infected with hepatitis Delta virus (HDV). During the 8-year follow-up (25,900 person-years), 55 patients (1.3%) developed a HCC. In the multivariable model, age, unhealthy alcohol use (>2 and >3 standard units/day for women and men, respectively), tobacco smoking, HDV infection, low platelet count and receiving HBV treatment were associated with increased HCC risk. The ADAPTT score (Age, Delta, Alcohol, Platelet, Tobacco, Treatment) (Table 1) ranged from 0 to 16, a score ≥6 indicating a high risk of HCC. Comparisons with existing scores suggested higher performance for ADAPTT score (AUROC = 0.848) than for PAGE-B (AUROC = 0.783), REAL-B (AUROC = 0.787) and THRI (AUROC = 0.776) scores.

	ADAPTT score
AUROC	0.848
Age: 50–59 years	+1
Age: 60–69 years	+2
Age ≥70 years	+3
HDV infection	+3
Past or current unhealthy alcohol use	+2
Platelet count <200 × 10^9/L	+2
Tobacco smoking ≥20 pack-years	+2
Receiving HBV treatment	+4

Conclusion: Based on easy-to-collect behavioural data and routine medical data, the ADAPTT score shows higher performance than existing scores for predicting HCC in patients with chronic HBV infection. Though further validation on other datasets is needed, this score, implementable in all settings, including primary care and decentralized areas, can facilitate follow-up of at-risk patients.

OS-093-YI

Chronic hepatitis B virus infection and risk of stroke types: a prospective cohort study of 0.5 million Chinese adults

Elizabeth Hamilton[1], Ling Yang[1,2], Iona Millwood[1,2], Zhengming Chen[1,2]. *[1]Clinical Trial Service Unit and Epidemiological Studies Unit (CTSU), Nuffield Department of Population Health, Oxford, United Kingdom; [2]Medical Research Council Population Health Research Unit (MRC PHRU), Nuffield Department of Population Health, Oxford, United Kingdom*

Email: elizabeth.hamilton@univ.ox.ac.uk

Background and aims: Stroke is a leading cause of mortality and permanent disability in China, with large and unexplained geographic variations in rates of different stroke types. Chronic hepatitis B virus (HBV) infection is prevalent among adult Chinese and may play a role in stroke aetiology.

Method: The prospective China Kadoorie Biobank included >0.5 million adults aged 30–79 years who were recruited from ten (five urban and five rural) geographically diverse areas of China during 2004–2008, with measurement of hepatitis B surface antigen (HBsAg) positivity at baseline. During 11-years of follow-up, a total of 59,117 incident stroke cases were recorded (>90% confirmed by neuroimaging), including 11,318 intracerebral haemorrhage (ICH), 49,971 ischaemic stroke (IS), and 995 subarachnoid haemorrhage (SAH) and 3,036 other/unspecified stroke. Cox regression models were used to estimate adjusted hazard ratios (HRs) for risks of stroke types associated with HBsAg positivity. In a subset of 17,833 participants, levels of liver enzymes and lipids were measured and compared between HBsAg positive and negative individuals.

Results: Overall, 3.0% (men: 3.4%; women: 2.8%) of participants were positive for HBsAg at baseline. HBsAg-positivity was associated with an increased risk of ICH (adjusted HR = 1.29, 95% CI 1.16–1.44), similarly for fatal (n = 5,982; 1.36, 1.16–1.59) and non-fatal (n = 5,336; 1.23, 1.06–1.44) ICH. There were no significant associations of HBsAg positivity with risks of IS (0.97, 0.92–1.03), SAH (0.87, 0.57–1.33), or other/unspecified stroke types (1.12, 0.89–1.42). Individuals who were HBsAg-positive, compared to those who were HBsAg-negative, had significantly lower levels of TC (4.41 vs 4.61 mmol/L), LDL-C (2.19 vs 2.32 mmol/L), TG (1.42 vs 1.61 mmol/L) and albumin (41.4 vs 42.1 g/L), and higher levels of ALT (28.0 vs 21.7u/L) and AST (33.2 vs 28.2u/L). The association of HBsAg with ICH was attenuated with adjustment for liver enzymes in the subset (from 1.28, 1.01–1.62 to 1.22, 0.95–1.56).

Figure: Number of events and adjusted HRs for risks of different stroke types associated with HBsAg positivity among 500,991 participants.

	Number of events		Risk of stroke[a]	
Stroke types	HBsAg negative	HBsAg positive	HR (95% CI)	P value
Intracerebral haemorrhage	10,992	326	1.29 (1.16–1.44)	6.3×10^{-6}
Ischaemic stroke	48,817	1,154	0.97 (0.91–1.03)	0.29
Subarachnoid haemorrhage	973	22	0.87 (0.57–1.33)	0.53
Other or unspecified stroke	2,964	72	1.12 (0.89–1.42)	0.34
Total stroke	57,691	1,426	1.02 (0.97–1.07)	0.52

[a]Stratified by (5-year categories), sex, stuy site (10 sites) and adjusted for education (3 levels), smoking, alcohol, physical activity, regular fruit, meat or dairy intake, BMI; systolic blood pressure, prevalent diabetes and cancer. Abbreviations: HBsAg, hepatitis B surface antigen; ICD-10, International Statistical Classification of Diseases and Related Health Problems 10th Revision.

Conclusion: Among Chinese adults, chronic HBV infection is associated with a significantly high risk of ICH, but not other types of stroke and the association with ICH may be mediated through multiple mechanisms, including liver dysfunction and lipid metabolism.

DNA damage induced-senescence shifts the cellular bioenergetics capacity from glycolysis to oxidative phosphorylation in mouse hepatocytes

Pavitra Kumar[1], Mohsin Hassan[1], Frank Tacke[1], Cornelius Engelmann[1,2,3]. *[1]Charité Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany; [2]Berlin Institute of Health (BIH), Berlin, Germany; [3]University College London, Institute for Liver and Digestive Health, London, United Kingdom*
Email: cornelius.engelmann@charite.de

Background and aims: Cellular senescence is a state in which cells become resistant to growth-promoting stimuli and apoptosis, resulting in permanent cessation of cellular proliferation. This leads to a prolonged 'zombie-like' state, which can have detrimental effects on tissues relying on their regenerative capacity for homeostasis, such as the liver. Cells undergo a drastic metabolic shift as they adapt to senescent phenotype, potentially affecting the function of the liver. Therefore, in the present study, we aim to characterize, specifically, the link between DNA-damage-induced senescence and metabolic capacity in primary hepatocytes and hepatocyte-derived liver organoids.

Method: Primary hepatocytes, isolated by collagenase-perfused mouse liver (C57B6/J; 18–23 weeks), were cultured overnight in William's E-medium (+2% FBS, L-glutamine, and hepatocyte growth supplements). Hepatocyte-derived organoids were developed in a 3D matrix for two weeks. Cells or organoids were treated with the DNA damage inducers, cisplatin (DNA cross-linker and alkylating agent), BIBR-1532 (telomerase inhibitor), and 5-azacytidine (DNA-methyl transferase inhibitor) for 24 hours. Senescence was assessed by SA-β galactosidase activity, immunofluorescence, and immunoblotting (p53, p21, and γH2Ax), and senescence-associated secretory phenotype (SASP) candidates. Cellular bioenergetics was measured by XFe Seahorse analyser (substrates: 10 mM glucose, 2 mM pyruvate, and 1 mM glutamine).

Results: Dosages and time of treatment were optimized on the primary hepatocytes (five dosages and four-time points, 12 hours, 24 hours, 48 hours, and 72 hours). The results showed that cisplatin, 5-azacytidine, and BIBR-1532 increased phosphorylation of histone (γH2Ax), a DNA damage marker, by 10-fold ($p < 0.001$), 5-fold ($p < 0.001$), and 10-fold ($p < 0.001$), respectively. Additionally, cisplatin, 5-azacytidine, and BIBR1532 increased SA β-galactosidase activity by 15-fold ($p < 0.001$), 6-fold ($p < 0.001$), and 11-fold ($p < 0.001$), respectively (Fig. 1A). Arrested proliferation is an important feature of senescence cells and the primary hepatocytes have limited proliferation in 2D culture. To overcome this limitation, we validated the results in hepatocyte-derived organoids. Coincided with DNA damage, cisplatin, 5-azacytidine, and BIBR1532 stabilized p53, increased p21 levels, and SASP (CCL2, CXCL2, IL6, IL10, TNFα, and MMP13) among which BIBR-1532 being the most potent to increase p21 and cisplatin is the most potent to stabilize p53 and increase SASP production. DNA damage-associated senescence reduced the basal glycolysis and oxidative phosphorylation. However, in contrast to the studies in immortalized cell lines, DNA damage inducers extended the bioenergetics capacity towards oxidative phosphorylation from glycolysis significantly. Hydroxy urea (a negative control for oxidative phosphorylation) inhibited oxidative phosphorylation and hence it extended the cellular respiration capacity towards glycolysis along with the increased senescent phenotype (Fig. 1B).

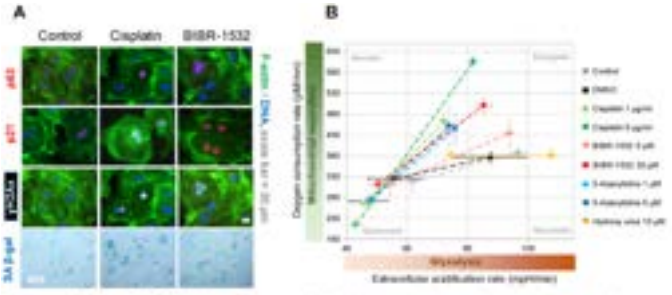

Figure 1. Effect of DNA damage on cellular bioenergetics and senescence markers on mouse hepatocytes treated for 24 hours **A)** senescence markers **B)** cell energy phenotype measured by XFe Seahorse analyser

Figure:

Conclusion: Cisplatin (DNA cross-linker), BIBR-1532 (telomerase inhibitor), and 5-azacytidine (DNA-methyl transferase inhibitor) induce senescence phenotype in mouse primary hepatocytes. DNA damage-induced senescence shifts the cellular bioenergetics capacity from glycolysis to oxidative phosphorylation, which may affect the hepatocytes' response to toxins and inflammation.

OS-097

CLOCKΔ19 circadian disruption primes myofibroblasts for accelerated activation and fibrotic progression

Elliot Jokl[1], Jessica Llewelyn[2], Kara Simpson[1], Oluwatobi Adegboye[1], James Pritchett[3], Leo Zeef[1], Qing-Jun Meng[1], Karen Piper Hanley[1]. *[1]University of Manchester, United Kingdom; [2]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, United States; [3]Manchester Metropolitan University, United Kingdom*
Email: elliot.jokl@manchester.ac.uk

Background and aims: Non-Alcoholic Fatty Liver Disease (NAFLD) is an increasing health burden with an estimated incidence of around 25%. Progressive disease is associated with fibrosis, characterised by

deposition of extracellular matrix (ECM) proteins by hepatic stellate cells (HSCs). Circadian rhythm governs many aspects of liver physiology and its disruption exacerbates chronic disease. However, the impact of disrupted circadian rhythm in pro-fibrotic HSCs remains to be investigated. In this study we investigate whether genetic disruption of circadian homeostasis predisposes HSCs to instigate fibrotic changes in the liver.

Method: Circadian rhythm was disrupted in vitro and in vivo using CLOCK mutant mice (CLOCKΔ19). HSC characteristics were investigated by western blot and genomic analysis. *In vivo* CLOCKΔ19 livers were assessed at basal state and during CCl_4 induced fibrosis. HSC CLOCKΔ19 genomic data was integrated with ATAC-seq from WT HSCs to generate a putative CLOCK regulome.

Results: Livers from CLOCKΔ19 mutant mice showed a higher baseline collagen (COL1) deposition and significantly worse fibrotic injury after CCl_4-induced fibrosis. Mutant livers had significantly increased scar formation (~40%), accumulation of myofibroblasts (~50%) and increased serum liver enzymes compared to control animals. HSCs isolated from PER2:LUC mice (displaying critical circadian rhythm measured by luciferase activity of the Per2 gene) were shown to display an intrinsic circadian rhythm. To investigate the role of circadian rhythm in HSCs further, genomic analysis demonstrated quiescent HSCs from CLOCKΔ19 mice had higher expression of RhoGDI pathway components, a suppression of genes associated with lipid metabolism, and had accelerated *in vitro* activation of pro-fibrotic genes on plastic. Through data integration, we discovered chromatin regions (through ATAC-seq peaks) containing CLOCK binding motifs were differentially accessible during HSC activation. Our data suggested CLOCK may act in qHSCs to supress profibrotic genes involved in focal adhesions and promote the expression of genes involved in lipid metabolism associated with quiescence.

Conclusion: Taken together, our data suggests disrupted circadian rhythm primes HSCs to a profibrotic state associated with dysregulated metabolic and mechanotransduction genes. This promotes an enhanced response to fibrotic-insult, driving more rapid progression of disease. Genes involved in the CLOCK regulome that underlie the HSC primed state include several secreted ECM candidates as urgently needed biomarkers of disease progression in NAFLD.

Gender differences in repair mechanisms of chronic cholangiopathies with progressive fibrosis

Massimiliano Cadamuro[1,2], Labjona Haxhiaj[3], Chiara Montanaro[3], Erica Villa[4], Annarosa Floreani[5], Nora Cazzagon[5], Giovannella Baggio[3], Mario Strazzabosco[6], Paolo Simioni[1,2,7], Luca Fabris[1,6,8]. *[1]Padua University-Hospital, General Internal Medicine Unit, Italy; [2]University of Padua, Department of Medicine (DIMED), Italy; [3]University of Padua, Italy; [4]University of Modena and Reggio Emilia, Gastroenterology, Italy; [5]University of Padua, DISCOG, Italy; [6]Yale University, Digestive Disease Section, Liver Center, United States; [7]University of Padua, Thrombotic and Haemorrhagic Disease Unit and Haemophilia Center, Department of Medicine (DIMED), Italy; [8]University of Padua, Department of Molecular Medicine (DMM), Italy*
Email: massimiliano.cadamuro@unipd.it

Background and aims: In chronic liver disease pathophysiology, gender dimorphism is much less characterized compared with degenerative disorders affecting other organs. Repair mechanisms are instrumental to direct fibrogenesis and progression of chronic inflammatory conditions. Therefore, we investigated the gender-specific differences in tissue repair culminating in liver fibrogenesis and sustained by activation of hepatic progenitor cells (HPC) and ductular ductular reaction (DR) in two models of diseases of the biliary epithelium (cholangiopathies) featuring progressive fibrosis. We considered the Pkhd1$^{del4/del4}$ and the Mdr2$^{-/-}$ mouse models, orthologous of the human congenital hepatic fibrosis/Caroli's disease (CHF/CD) and primary sclerosing cholangitis (PSC), respectively, and in sections of human PSC and CHF/CD.
Method: Serial sections of liver tissue specimens of PSC (n = 9 M/n = 5 F) and CHF/CD (n = 3 M/n = 1 F), along with Pkhd1$^{del4/del4}$ (n = 11 M/n = 23 F), and Mdr2$^{-/-}$ mice (n = 5 M/n = 3 F), were stained with Sirius Red (histological staining) and with immunohistochemistry for myofibroblasts (α-SMA), macrophages (CD68, human samples only), and RDC/DR (K19). Extent of DR, fibrosis, inflammation and number of HPC were evaluated with computer-assisted morphometry.
Results: In both mouse models and human diseases, fibrosis resulted higher in M compared with F, without significant differences in myofibroblast accumulation and HPC activation. In both Mdr2$^{-/-}$ mice and PSC patients, extension of DR was more prominent in M than F, whereas in Pkhd1$^{del4/del4}$ mice, dysgenetic biliary lesions were greater in F than in M. In addition, in PSC samples, the number of CD68+ macrophages was higher in M as respect to F. Similar trends were also found in human CHF/CD samples.
Conclusion: This study shows gender-specific differences in tissue repair mechanisms of the biliary epithelium in both mouse models and human samples of PSC and CHF/CD. In particular, we found more severe fibrogenesis associated with more intense inflammatory infiltrate dominated by macrophages in males compared to females, thereby providing mechanistic evidence of the more severe clinical course of chronic liver diseases affecting men as reported in viral and metabolic etiologies.

Hemodynamic response determines further decompensation and survival in patients with decompensated cirrhosis

Claudia Pujol[1,2], Marta García Guix[1,2], Anna Brujats[1,2], Edilmar Alvarado-Tapias[1,2,3], Anna Huerta[1,2], Berta Cuyas[1,2], Maria Poca[1,2,3], Xavier Torras[1,2], Àngels Escorsell[1,2,3], Càndid Villanueva[1,2,3]. *[1]Hospital Santa Creu i Sant Pau, Department of Gastroenterology, Barcelona, Spain; [2]Institut de Recerca Sant Pau-Universitat Autònoma de Barcelona, Barcelona, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain*
Email: cpujolc@santpau.cat

Background and aims: Different stages can be identified in decompensated cirrhosis, such as bleeding alone or with other concomitant decompensation, and ascites without bleeding. The development of further decompensation determines prognosis in each of these stages. This study investigates the influence of hemodynamic response to β-blockers on the risk of further decompensation and survival in each substage of decompensated cirrhosis.
Method: Patients admitted due to variceal bleeding (VB) were consecutively included, differentiating those who only had VB (VBAlone) from those with concomitant ascites (As) (with or without encephalopathy) (VBPlus). Patients with ascites and varices without previous bleeding (AsAlone) referred during the study period for primary prophylaxis, were also investigated. An

hemodynamic study was performed before starting therapy with β-blockers and was repeated after 1–2 months to assess the response. The risk of outcomes was estimated in a competing risks (CR) framework considering death and liver transplant as competing events.

Results: 476 patients with decompensated cirrhosis were included, 103 with VBAlone, 186 with VBPlus and, 187 with AsAlone. During a mean follow-up of 32 months (IQR 12–58), the risk of death and of further decompensation, were higher in AsAlone group than in VBAlone group and higher in VBPlus than in the other two groups. Survival probability was significantly worse in patients with further decompensation than in those without, in each of the 3 substages (<70% at 3rd-year), and was lower in patients with VBPlus (37% at 3rd-year) than in the other groups. Among patients without further decompensation, survival probability was similar in the 3 substages (≥83% at 3rd-year). HVPG-decrease was an independent predictor of further decompensation and death. An HVPG-decrease ≥10% from baseline (defining HDK-response) was achieved in 43% of patients. Overall, patients with HDK-response vs those without, had lower risk of further decompensation (sHR = 0.31, 95%CI = 0.24–0.39), and lower risk of death (sHR = 0.23, 95%CI = 0.17–0.32). Similar results favoring HDK-responders were observed in each substage separately.

Conclusion: At each decompensation of cirrhosis (bleeding, ascites or both), the risk of death is higher in patients developing further decompensation. With each decompensation, those patients achieving an HVPG-decrease ≥10% have lower risk of further decompensation and better survival. Our results suggest that therapies effectively decreasing HVPG (such TIPS) may be valuable in decompensated patients without HDK-response to β-blockers.

OS-101-YI

Comparison of 1-day vs 3-days intravenous terlipressin in cirrhosis patients with acute variceal bleeding: open-label randomized control trial

Manas Vaishnav[1], Sagnik Biswas[1], Shekhar Swaroop[1], Arnav Aggarwal[1], Abhinav Anand[1], Piyush Pathak[1], Shalimar[1]. *[1]All India Institute of Medical Sciences, New Delhi, India*
Email: drshalimar@yahoo.com

Background and aims: In patients with acute variceal bleeding (AVB), the optimal duration of vasoconstrictor therapy after endoscopic therapy with band ligation is unclear. Expert guidelines recommend vasoconstrictor therapy for 1-day to 5-days. We aimed to compare the efficacy of 1-day terlipressin therapy vs 3-days of terlipressin in cirrhosis patients with AVB post-endoscopic intervention. We also measured HVPG on day 1 and day 3 in both groups. The primary objective was to compare the rebleeding rates at 5-days between the two groups. The secondary objectives were to compare rebleeding and mortality at 6 weeks. We also assessed the change in HVPG between days 1 and 3 (HVPG response rate).

Method: In this open-label, randomized controlled trial, cirrhosis patients with AVB were randomized to receive either 1-day or 3-days of terlipressin therapy post-endoscopic intervention. Rebleeding and mortality were noted on day 5 and after 6 weeks. HVPG measurements were done after the first endoscopy and after 72 hours.

Results: Of the 149 patients randomized, 74 were randomized to the 1-day and 75 to 3-day group. There were no differences in baseline clinical as well as laboratory parameters between the 2 groups. Failure to control bleeding at 24 hours in the 1-day and 3-days [0 vs 2 (2.7%), p = 0.497], 5-days rebleeding rate [3 (4.1%) vs 4 (5.3%), p = 1.000], and 5-day mortality [1 (1.4%) vs 1 (1.3%), p = 1.000] were similar. At 6 weeks, rebleeding [9 (12.2%) vs 10 (13.3%), p = 0.830] and mortality [5 (6.8%) vs 4 (5.3%), p = 0.745] were similar (Figure 1a and b). HVPG response (defined as ≥10% reduction from baseline) was similar in both groups. Patients who received 3-days of terlipressin therapy experienced more adverse effects as compared to 1-day therapy [42 (45%) vs 28 (37.8%), p = 0.026].

Conclusion: As compared to 3 days therapy, 1 day of terlipressin was associated with similar rebleeding rates at 5-days and 6 weeks, 42-days mortality, and HVPG response rate at day 3. One-day terlipressin therapy is associated with fewer adverse effects than 3-days therapy.

OS-102

The new diagnostic criteria of portopulmonary hypertension identify a group of patients with cirrhosis at high risk of death

Luis Téllez[1,2,3,4], Antonio Guerrero[1], Jesus Donate[1], Miguel Ángel Rodríguez-Gandía[1,2,3], Susana del Prado[5], Andrés Tenes[6], Rosa Martin- Mateos[1,2,3], Rosario González Alonso[1,2,3], Javier Martinez[1,2,3,4], Miguel García González[1,2,3], Rubén Sánchez-Aldehuelo[1,2], Diego Burgos Santamaria[1,2,3], Beatriz Mateos Muños[1,2,3], María Torres Guerrero[1,6], Jose Luis Lledo Navarro[1,2,3], Agustin Albillos[1,2,3,4]. *[1]Hospital Universitario Ramón y Cajal, Gastroenterology and Hepatology, Madrid, Spain; [2]Instituto Ramón y Cajal de Investigación Sanitaria-IRYCIS, Madrid, Spain; [3]Universidad de Alcalá: Facultad de Medicina y Ciencias de la Salud, Alcalá de Henares, Spain; [4]CIBER-Center for Biomedical Research Network, Madrid, Spain; [5]Hospital Universitario Ramón y Cajal, Cardiology, Madrid, Spain; [6]Hospital Universitario Ramón y Cajal, Respiratory Diseases, Madrid, Spain*
Email: luistevilla@gmail.com

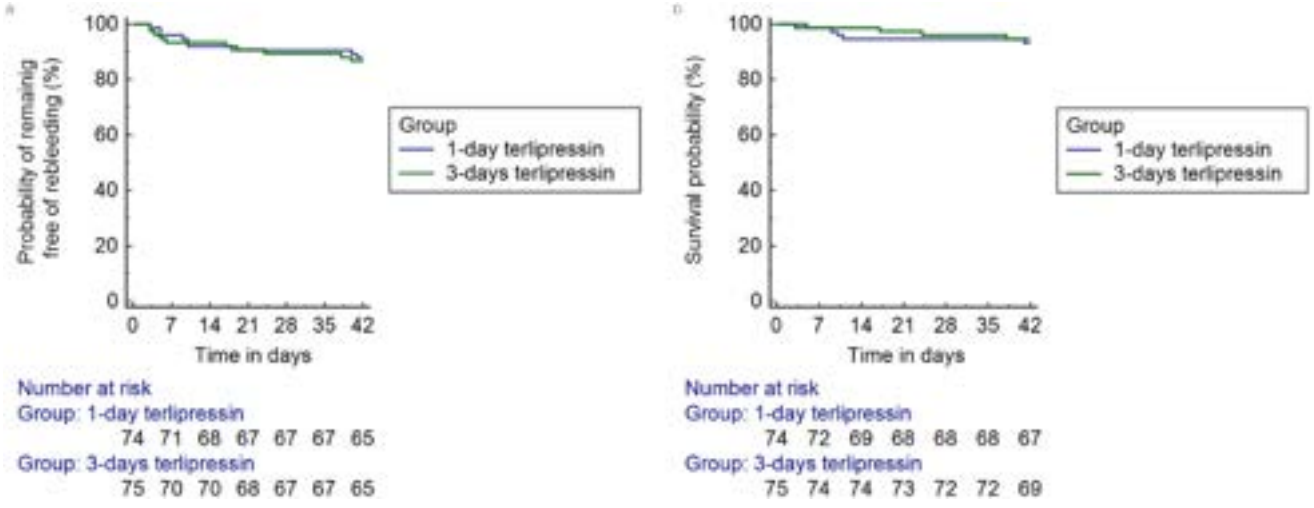

Figure: (abstract: OS-101-YI): (a) Cumulative probability of remaining free of bleeding at 6 weeks (log rank p = 0.820) (b) Cumulative probability of survival at 6 weeks (log rank p = 0.691)

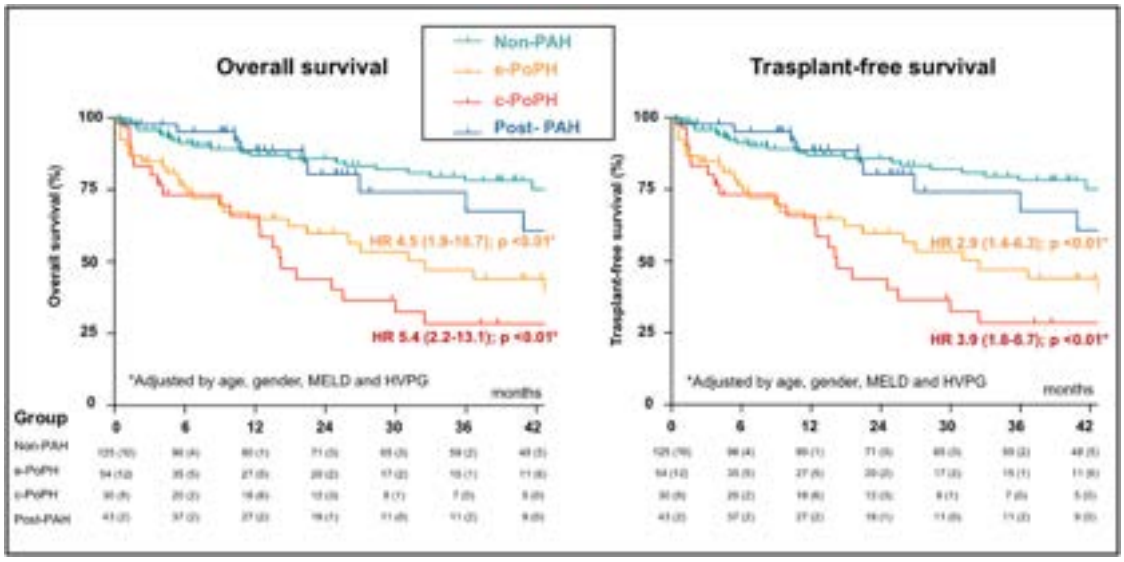

Figure: (abstract: OS-102).

Background and aims: The new diagnostic criteria of pulmonary arterial hypertension (PAH) use lower cut-offs for mean pulmonary arterial pressure (mPAP) (before: 25; now: 20 mmHg) and pulmonary vascular resistance (PVR) (before: 3; now: 2 Woods Units (WU)) to define portopulmonary hypertension (PoPH). Using these criteria, we can identify a group of patients with early precapillary PAH (e-PoPH: mPAP 20–25 mmHg and PVR ≥2 WU), whose prognostic significance in cirrhosis has not been studied. The primary aim was to analyze the impact on the prognosis of the new PAH criteria in patients with cirrhosis and portal hypertension; the secondary objective was to identify non-invasive predictors of PoPH according to new criteria.
Method: Observational study including prospectively all consecutive patients with cirrhosis and HVPG >5 mmHg evaluated by hepatic and right heart catheterization between 2015 and 2022. The patients were classified as Non-PAH (mPAp <20 mmHg); e-PoPH (mPAp = 20–25 mmHg and RVP ≥2 WU); classic PoPH or c-PoPH (mPAP ≥25 mmHg and RVP≥3 WU); postcapillary PAH or post-PAH (mPAP≥20 mmHg and pulmonary artery wedged pressure ≥15 mmHg). The variables associated with a worse prognosis (death or transplantation) were analyzed using Cox regression, and the predictors of HAPoP using binary logistic regression.
Results: (mean, SD). 258 patients were followed-up for 104 (28) months (72.5% male; age 58.6 (9.1) years). Non-PAH: 48.4%; e-PoPH: 20.9%; c-PoPH: 11.6%; post-PAH: 16.7%. Poorer liver function (MELD), higher portal hypertension (HPVG), and the presence of PAH were independently associated with worse overall survival and transplant-free survival ($p < 0.01$).
The prognosis of patients with PoPH, whether early (HR 4.5 (1.9–10.7)) or classic (HR 5.4 (2.2–13.1)), was worse ($p < 0.01$) than that of those without PAH or with post-PAH (overall-survival and transplant-free survival) (Figure). Those with PoPH (early or classic) had higher ($p < 0.05$) levels of C-reactive protein, brain natriuretic peptide (BNP), and uric acid and lower levels of albumin than those without PAH. The variables independently associated with PoPH were the existence of a portosystemic shunt (OR 6.8 (2.0–22.8)) and BNp >80 pg/ml (OR 13.1 (2.7–65.0)). Tricuspid regurgitation velocity (AUC 0.82 (0.7–0.9), $p < 0.01$) and right atrial area (AUC 0.86 (0.8–0.9), $p < 0.01$) were the echocardiographic parameters that best discriminated the presence of PoPH.
Conclusion: The new diagnostic criteria of PAH identify a group of patients with cirrhosis and early PoPH at high risk of death. We have identified clinical and analytical variables that allow us to suspect the existence of PoPH according to new criteria.

OS-103-YI

Outcomes of a therapeutic stepwise approach involving low-dose systemic thrombolysis for managing acute portomesenteric thrombosis

Ahmed Hashim[1], Aashish Pandya[1], Naz Kanani Alviri[1], Hannah Old[1], Jonathan King[1], Louise China[1], Dominic Yu[1], David Patch[1]. [1]*Institute for Liver and Digestive Health, Royal Free Hospital, London, United Kingdom*
Email: ahmed.hashim@nhs.net

Background and aims: Acute non-malignant portomesenteric thrombosis (PMT) is challenging to manage and can often result in bowel infarction leading to high morbidity and mortality. We report a large series of patients presenting with this condition who received our novel step-wise therapeutic protocol, aiming to describe the rates of recanalization, symptom control and complications. Our protocol-published originally in 2019- adopts a step-ladder approach involving the infusion of systemic low-dose tissue plasminogen activator (L-tPa) for 72 hours initially and up to a maximum of 7 days. Depending on the clinical and radiological response, the treatment is escalated to Catheter-Directed Thrombolysis (CDT) followed by Transjugular Intrahepatic Portosystemic Shunt (TIPSS) when indicated.
Method: We conducted a retrospective analysis of clinical records of patients with acute PMT who undertook the stepwise regimen above at Royal Free Hospital between December 2019 and August 2022.
Results: The total number of patients included was 42 patients; 25 (60%) were males. The mean age was 46 (SD = 13). Hereditary thrombophilia was identified in 17 (40%) patients and acquired prothrombotic conditions were observed in 15 (36%) cases (2 had a recent COVID-19 infection and 3 received the ChAdOx1 vaccine). Three patients had underlying chronic liver disease. All patients had thrombosis of the superior mesenteric vein (SMV) on cross-sectional imaging. Main portal vein thrombosis (PVT) was found in 38 (90%) patients whereas thrombosis of all three-vessel (PVT + SMV + splenic vein) was present in 25 (60%). All patients had persistent abdominal pain despite standard anticoagulation prior to the initiation of L-tPa. The median time to initiation of L-tPa (n = 39) was 12 (IQR = 12) days of symptoms and the mean duration of L-tPa infusion was 95 (SD = 48) hours. CDT was undertaken in 21 (50%) patients, of whom, two-thirds (15/21) had the local therapy delivered through EKOS™ endovascular system. TIPSS was inserted in 18 patients (43%) and remained patent at discharge in 16/18 (89%). A degree of recanalization was observed in 33 (79%). Around half of the patients (n = 20) did not require intensive or high-dependency care admission. The

majority 31 (80%) received warfarin as long-term anticoagulation (5 were maintained on Apixaban). At a median follow-up of 10 (IQR = 12) months, complete symptom resolution was achieved in 26/37 (70%). Recanalization was maintained in 26/40 (65%) and TIPSS remained patent in 14/18 (78%). Nine patients required bowel resection within a median duration of 11 (IQR = 10.5) days from presentation. The mean length of small bowel resected was 67 cm (SD = 50). One patient was discharged with a stoma and needed parenteral nutrition and another suffered an intracranial haemorrhage. Minor bleeding occurred in 10 patients. One death was recorded (due to bowel ischemia).

Conclusion: Our stepwise protocol achieved good recanalization and patency rates, and sustained symptom control was observed in the majority of patients. While some patients inevitably required surgical intervention, bowel continuity was eventually achieved in almost all cases.

OS-104

Long-term outcome following liver transplantation for patients with acute on chronic liver failure grade 3 (ACLF-3): a retrospective matched-controlled study

Florent Artru[1,2], Sophie-Caroline Sacleux[3], José Ursic Bedoya[4], Clementine Levy[2], Marion Khaldi[2], Charles Le Goffic[2], Eric Levesque[3], Sébastien Dharancy[2], Emmanuel Boleslawski[2], Gilles Lebuffe[2], Philippe Ichai[3], Audrey Coilly[3], Eleonora De Martin[3], Eric Vibert[3], Samir Jaber[4], Astrid Herrero[4], Magdalena Meszaros[4], Clement Monet[4], Didier Samuel[3], Philippe Mathurin[2], Georges-Philippe Pageaux[4], Faouzi Saliba[3], Alexandre Louvet[2]. *[1]King's College Hospital, United Kingdom; [2]CHU Lille, France; [3]Hopital Paul Brousse, France; [4]CHU Montpellier, France*
Email: florent.artru@kcl.ac.uk

Background and aims: Utility, a major principle for allocation in the context of scarce medical resources, is questioned in patients with acute-on chronic liver failure (ACLF) grade 3 who undergo liver transplantation (LT). Indeed, while the evidence is growing regarding an acceptable 1-year survival after LT, very scarce data reports long-term patients and graft survivals that are the final aim of LT. We aimed to explore long-term outcomes of patients included the 3 center retrospective French experience published in 2017.

Method: All patients with ACLF grade 3 (n = 73) as well as their matched controlled (on sex and age) with ACLF 2 (n = 145), 1 (n = 119) and no ACLF (n = 292) that have participated in the princeps study published in J Hepatol were included. We explored 5- and 10-year patient and graft survivals, causes of death and their predictive factors.

Results: Patients with ACLF grade 3 were male in 70% with a median age of 57 years old. Alcohol was the main cause of cirrhosis (53%) and septic shock (49%) the main primary reason for admission in intensive care unit. At time of LT, MELD score was 40 and CLIF-C ACLF 67. Median follow-up was 9 years. In patients with ACLF 3, 2, 1 and no ACLF, 5- and 10-year patient survivals were respectively 73% vs. 71% vs. 76% vs. 79% (p = 0.3) and 57% vs. 58% vs. 59% vs. 65% (p = 0.3). In cox-regression analysis ACLF grade was not associated with 5- (RR 1.1, 95%CI:0.95–1.29, p = 0.16) and 10-year survival (RR 1.1 95%CI: 0.97–1.22, p = 0.11). 5- and 10-year graft survivals were respectively 67% vs. 68% vs. 74% vs. 73% (p = 0.4) and 50% vs. 53% vs. 58% vs. 60% (p = 0.3). At 10 years in ACLF 3 patients, 30 died and 5 were retransplanted. The leading causes of death were infections (33%), and cardiovascular events (23%) and reasons for retransplantation were chronic rejection (60%) and biliary complications (40%). Multivariable analyses identified Charlson comorbidity index (CCI) (RR 1.59, 95%CI: 1.12–2.26, p = 0.009 and RR 1.37, 95%CI: 1.05–1.78, p = 0.019) at LT and the number of RBC packs transfused (RR 1.18, 95%CI: 1.10–1.34, p = 0.0001 and RR 1.17, 95%CI: 1.07–1.27, p = 0.0003) as independently associated with 5- and 10-year patients' survival while age, etiology of cirrhosis, MELD score, sarcopenia, donor-risk index were not.

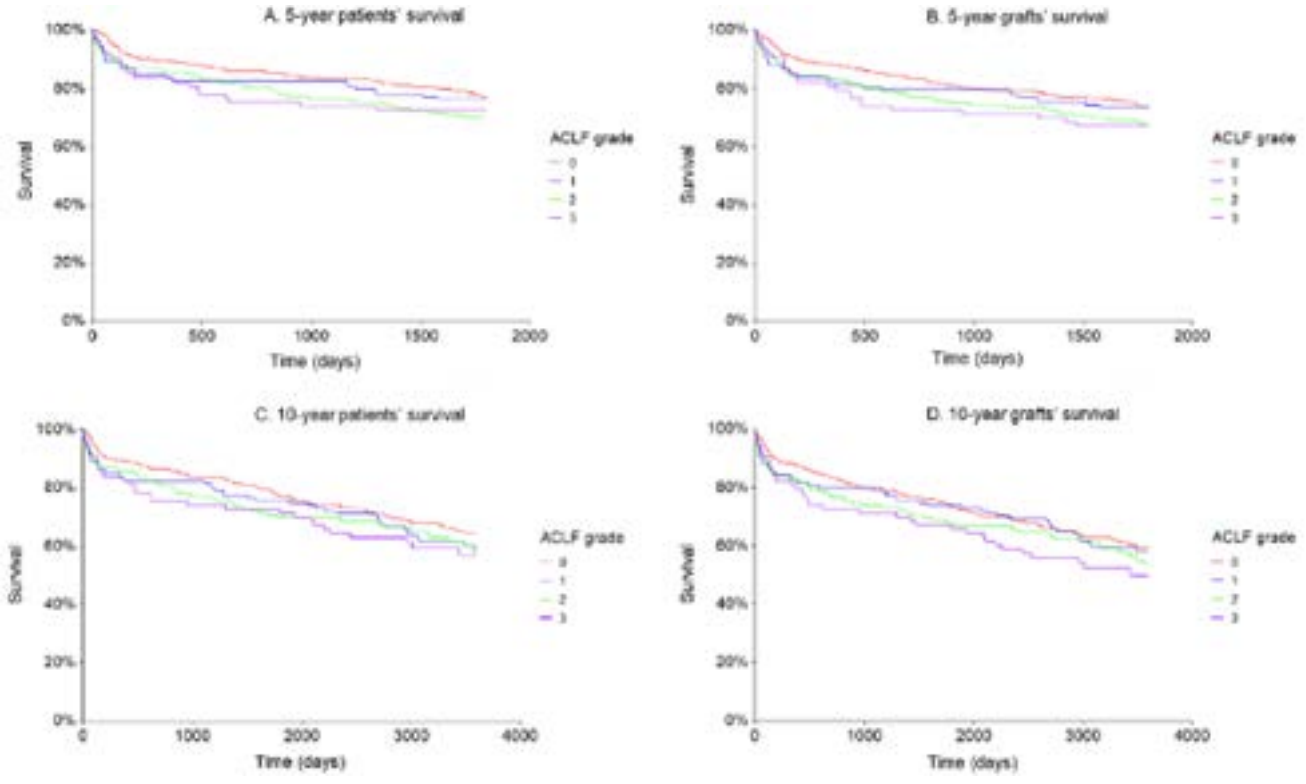

Figure: (abstract: OS-104): 5-year patients (A) and graft (B) survival, and 10-year patients (C) and graft (D) survivals in patients with ACLF 3 (n = 73) and their matched controls with ACLF 2 (n = 145), 1 (n = 119) and no ACLF (n = 292).

Conclusion: 5- and 10-year patients and graft survivals in ACLF 3 patients were not significantly different from their matched controls with lower ACLF grade or absence of ACLF. 5-year patients' survival is higher than that of the 50%–70% threshold defining the utility of liver graft. To further improve outcomes efforts should focus on candidates' selection (CCI associated with long-term survival) and prevention of infection and cardiovascular events standing as the main causes of death.

Liver failure and regeneration

OS-105

Hepatic nerve endings are rewired by cholestatic injury to connect inflamed lymphatics to sites of ductular remodelling

Luke Noon[1,2,3], Anne-Laure Cattin[2], Jemima Burden[2], Luigi Aloia[2], Giulia Casal[2], Marina Berenguer[4], Judith Pérez[4], Alison Lloyd[2]. *[1]CIPF Centro de Investigación Príncipe Felipe, Valencia, Spain; [2]MRC Laboratory for Molecular Cell Biology, United Kingdom; [3]CIBER-Center for Biomedical Research Network, Madrid, Spain; [4]La Fe University and Polytechnic Hospital, València, Spain*
Email: lnoon@cipf.es

Background and aims: Hepatic nerves regulate blood flow, metabolism and regeneration, yet we have almost no understanding of the structure, function, or cell-specificity of nerve endings in liver. In this study we set out to map the "connectome" of peripheral nerves in murine liver, taking a cross-scale approach to visualize, quantify and reconstruct nerve terminals using correlative light and electron microscopy (CLEM) and 3D-electron microscopy (EM).
Method: Plp-EGFP transgenic mice were used to identify hepatic nerves in portal tracts by EGFP fluorescence and hone in on the ultrastructural features of the neural niche by CLEM. Array tomography-based scanning EM (SEM) was then used to scale-up sampling around nerves and compare "healthy" adult liver to that of "injured" mice fed 0.1% 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC). The resulting volume (v)EM image database was annotated, segmented and 3D-rendered using the Webknossos open source platform.
Results: We identified 187 individual axonal contacts in "healthy" liver (n = 3) and 208 in "injured" liver (n = 3) from a total tissue volume of 165835 um^3. Our survey of hepatic nerve endings revealed Schwann cells in portal tracts support a wider network of "naked" axons protruding into the surrounding stroma, making multitude contacts with fibroblasts (21.9% of total), macrophages (6.4%), and the basal lamina of blood vessels (36.9%) and bile ducts (2.7%). Axons also formed prominent varicosity-like contacts abutting hepatocytes of the limiting plate (31.6%). Remarkably, we observed a close physical association between hepatic nerves and lymphatic vessels, that was confirmed in human liver. Nerve terminals contacting lymphatics in healthy liver were rare (0.53%), but their density increased dramatically with injury (8.79-fold) indicating axonal remodelling. Axon tracing also revealed individual nerve fibres connected inflamed lymphatics with hepatocytes of the canals of Hering-the epithelial interface where ductular remodelling occurs upon DDC injury. Moreover, synapse-like structures penetrating the basal lamina of ductular progenitors could be traced back to axons protruding from nearby lymphatic tissue (see figure). Together, our results demonstrate hepatocytes and cholangiocytes of the Canals of Hering are connected in series by nerves emanating from lymphatic tissue.

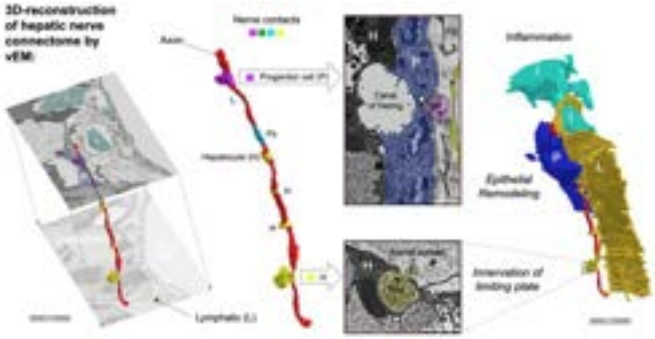

Figure:

Conclusion: We showcase a new workflow that enables quantitative mapping and visualization of peripheral nerve connectomes in liver at the ultrastructural level, revealing multiple novel features of hepatic nerve endings. Our analysis uncovers local circuitry connecting regenerative epithelial surfaces in series with nearby lymphatic tissue, raising the extraordinary possibility that the detection/response to injury is coordinated between inflamed lymphatic tissue and progenitor cells by hepatic nerves.

OS-106-YI

The silencing of Sox9 impairs ductular reaction expansion while enhancing the differentiation of DR cells into hepatocytes

Arthur de Schaetzen[1], Maxime De Rudder[1], Isabelle Leclercq[1]. *[1]Institut de recherche expérimentale et clinique, Pôle d'éhpato-gastro-entérologie, Woluwe Saint Lambert, Belgium*
Email: arthur.deschaetzen@uclouvain.be

Background and aims: After acute damage or liver resection the liver regenerates and each cell compartment proliferates to repopulate the cells that were lost. In chronic liver disease, hepatocytes are found in a state of replicative senescence and are no longer able to duplicate. In such a setting, cholangiocytes proliferate and invade the parenchyma, in a phenomenon called the ductular reaction (DR). Cells of the ductular reaction have the ability to differentiate in hepatocytes, offering an alternative path for regeneration. Observations in animal models show nevertheless that DR cells generate only a modest fraction of hepatocytes. Hence strategies to enhance DR-derived regeneration are needed to significantly support liver function in chronic diseases.
Sox9 is a transcription factor that determines the biliary fate of the bipotential precursor to cholangiocytes and hepatocytes during embryogenesis. Sox9 ectopic expression is proposed to direct liver epithelial cells towards the biliary lineage. Here we hypothesize that the silencing of Sox9 in cells of the ductular reaction will ease their shift towards the hepatocyte lineage, thereby enhancing their contribution to liver regeneration.
Method: We used $Opn^{iCreERT2}$: $Rosa26R^{YFP}$: $Sox9^{floxed}$ transgenic mice in which the injection of Tamoxifen drives the constitutive expression of YFP and the silencing of Sox9 in cholangiocytes alone. Any cell expressing YFP is a cholangiocyte or its progeny. $Sox9^{Chol}$ KO and controls with intact Sox9 expression received carbon tetrachloride (CCl_4) for 6 weeks to cause chronic hepatocellular damage. In a separate experiment, we first treated mice with CCl_4 to induce DR and then operate Sox9 silencing in cholangiocytes, followed by a 2 weeks recovery period before harvest.
Results: In response to tamoxifen injection, we observed expression of YFP in 71% (± 1.9%) of cholangiocytes together with deletion of Sox9 in 100% of them in $Sox9^{chol}$ KO mice. In controls mice 82% (± 3.5%) of cholangiocytes expressed YFP and all of them expressed Sox9. After 6 weeks of CCl_4, the magnitude of the ductular reaction, as measured by the area of $Ck19^{+}$ cells, was significantly lower in $Sox9^{Chol}$ KO than in controls. Patches of YFP^{+}/$HNF4alpha^{+}$ hepatocytes generated from the DR were present in all animals, but similar in density in $Sox9^{Chol}$ KO and in controls, this regardless whether the

ductular reaction was weak (Sox9^{Chol} KO) or vigorous (controls), supporting that Sox9 deletion favors differentiation of DR cells.
To further support this, we silenced Sox9 after the induction of the DR in chronic hepatocellular injury, and examined livers after a 2 weeks recovery period. We confirmed that tamoxifen injection effectively induced YFP expression and silenced Sox9 in 68% and 100% of DR cells respectively in Sox9^{Chol} KO and in 83% and 0% of DR cells in controls. The number of YFP^{+} hepatocytes was significiantly increased in Sox9^{Chol} KO compared to controls (*figure*).

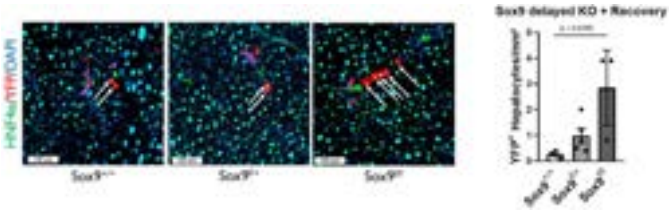

Figure: Livers with homozygous deletion of Sox9 (Sox9$^{f/f}$) and with heterozygous deletion of Sox9 (Sox9$^{f/+}$) are compared with livers with wild type Sox9 alleles (Sox9$^{+/+}$). Statistical analysis: one-way anova

Conclusion: We generated a model for inducible and cholangiocyte-specific YFP expression along with Sox9 silencing: the Opn^{iCreERT2} : Rosa26R^{YFP} : Sox9^{floxed} mice. With this model, we showed that the silencing of Sox9 impairs the expansion of DR cells. Furthermore, the silencing of Sox9 in DR cells enhances their hepatocytic differentiation.

OS-107-YI

Bio-molecular map of albumin identifies signatures of severity and early mortality in acute liver failure

Neha Sharma[1], Jaswinder Maras[1], Sushmita Pandey[1], Manisha Yadav[1], Babu Mathew[1], Vasundhra Bindal[1], Nupur Sharma[1], Gaurav Tripathi[1], Sadam H Bhat[1], Rakhi Maiwall[2], Shvetank Sharma[1], Shiv Kumar Sarin[2]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Acute liver failure (ALF) has high mortality and corresponds to changes in plasma albumin levels and functions. Whether the bio-molecular analysis of albumin could identify signatures of the severity of the hepatic injury and early mortality in ALF is unknown.
Method: A total of 225 subjects (200 ALF and 25 healthy controls) were enrolled in the study protocol. Albumin was purified and analysed in the training cohort (ALF Non-Survivors; n = 32, ALF-survivors; n = 8 and Healthy Controls; n = 5) for modification, functionality, and bounded multi-omics signatures (Proteins, Lipids, Metabolites, and bacterial peptides) followed by validation in a test cohort of 160 ALF patients using machine learning (ML) approach.
Results: Albumin oxidative state, plasma oxidation, and glycosylation were higher in ALF, specifically in ALF-non-survivors ($p < 0.05$). Purified albumin from non-survivors showed significant multi-omics alterations as indicated by multivariate Partial least squares-discriminant analysis (PLS-DA) and alpha/beta-diversity indices ($p < 0.05$). Albumin bio-molecular profile of non-survivors showed a significant ($p < 0.05$) increase in bound biomolecules linked to inflammation, Advance Glycation End-products (AGE) signaling, amino-acid (arginine, proline) metabolism, bile acids, mitochondria breakdown (carnitines and beta-oxidation) and bacterial peptides of phylum Proteobacteria, Firmicutes, Verrucomicrobia, and others. Increased bacterial taxa (Listeria, Clostridium, and others) functionality correlated with serum Triglyceride; TG (4:0/12:0/12:0), Phosphatidylserine; PS (39:0) and metabolites (Porphobilinogen, Nicotinic Acid, and others) in non-survivors s ($R^2 > 0.7$, $p < 0.05$). Multiomics signature-based probability of detection (POD) for non-

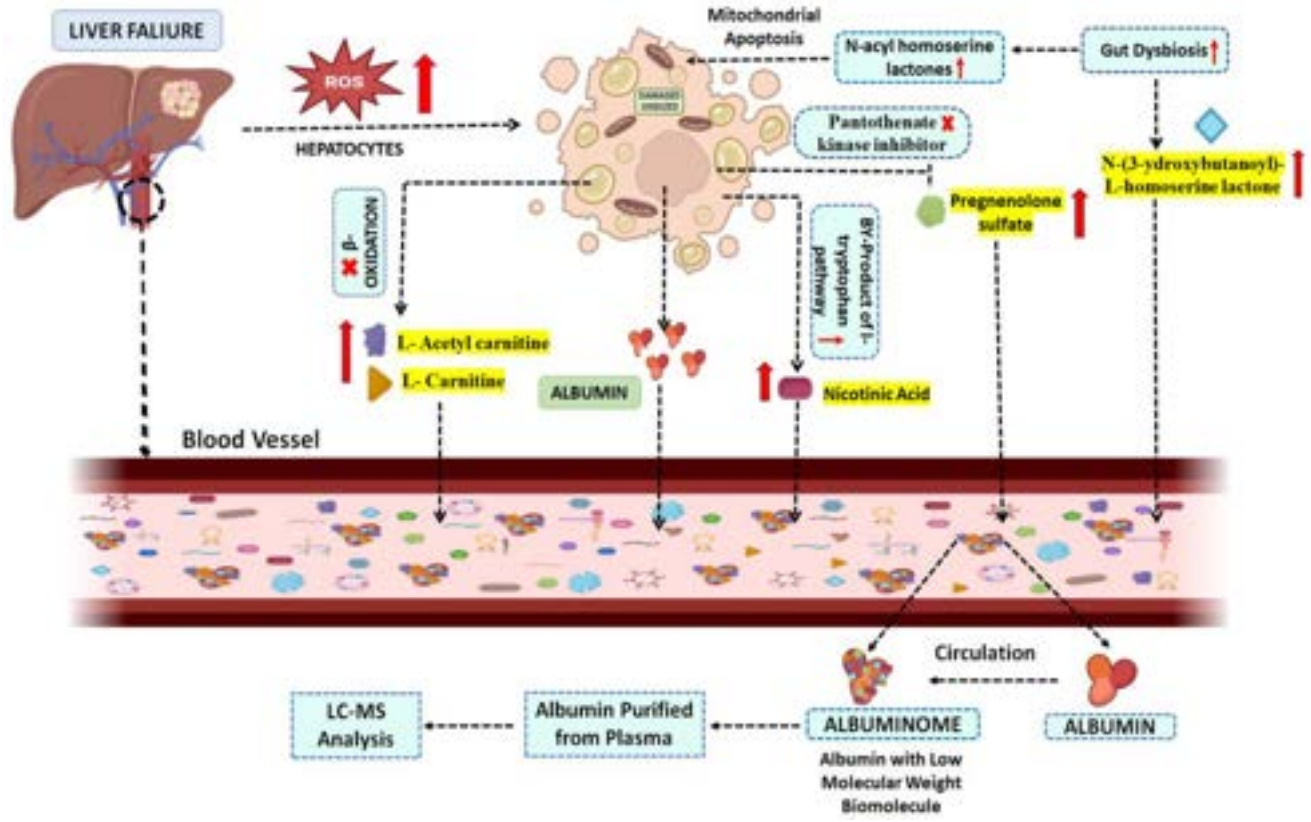

Figure: (abstract: OS-107-YI): Albumin-bounded Biomolecule shows ongoing mitochondrial failure and hyperinflammation state in ALF Patients

survival in ALF was >90% and correlated with albumin functionality and clinical parameters ($R^2 > 0.85$). POD metabolites showed diagnostic efficiency of 98% (AUC = 0.98 [0.95–1.0]) for early mortality prediction in ALF ($p < 0.05$). Specific increase in binding of L-acetylcarnitine, L-carnitine, N-(-3ydroxybutanoyl)-L homoserine lactone (linked to mitochondrial failure), nicotinic acid (a by-product of tryptophan metabolism) and pregnenolone lactone (a pantothenate kinase inhibitor) to albumin were seen in non-survivors. It was validated using five machine learning algorithms in test cohort 1 (plasma and paired one drop blood) and showed >98% accuracy for early mortality prediction.

Conclusion: Albumin bio-molecular composition is hyperoxidized and deranged in ALF patients. Novel albuminome signatures can segregate ALF patients who are likely to have early mortality or require emergency liver transplantation.

OS-108-YI

Investigating the PD-1/PD-L pathway and macrophage responses in acute-on-chronic liver failure

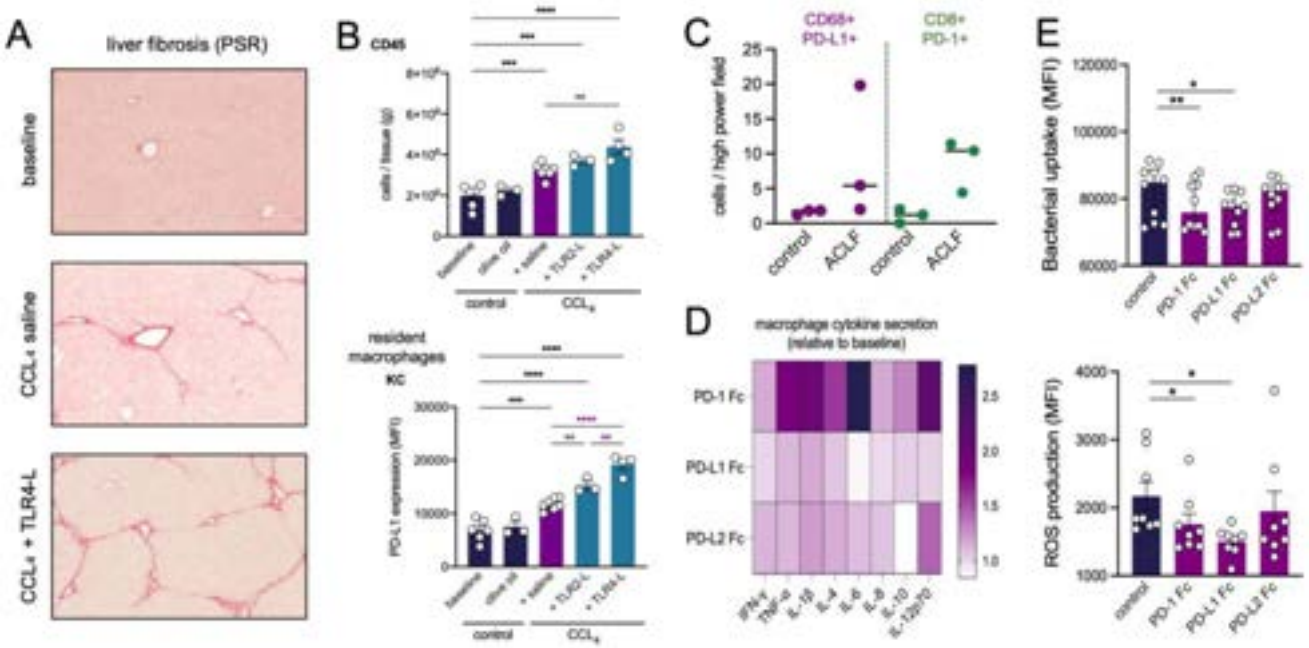
Dimitrios Patseas[1], Eoin Mitchell[1], Emilio Flint[2], Tong Liu[1], Sujit Mukherjee[1], Lucia Possamai[1], Mark J W McPhail[3], Christine Bernsmeier[2], Evangelos Triantafyllou[1]. [1]*Imperial College London, Department of Metabolism, Digestion and Reproduction, London, United Kingdom;* [2]*University of Basel, Department of Biomedicine, Basel, Switzerland;* [3]*King's College London, Department of Inflammation Biology, London, United Kingdom*
Email: e.triantafyllou@imperial.ac.uk

Background and aims: Macrophage dysfunction and bacterial infections are common in acute-on-chronic liver failure (ACLF) and contribute to mortality. PD-1/PD-L related adaptive immune dysfunction has been documented in alcoholic hepatitis, HBV/HCV infection, and anti-PD- (L)1 therapy is approved for HCC. We also found that PD-1/PD-L axis impaired macrophage antimicrobial responses in murine acute liver injury. However which inflammatory cues trigger this axis' upregulation, and how it modulates macrophage function, remain unknown. We explored this using human tissue samples, cell culture, and in vivo models.

Method: WT male mice were intraperitoneally (i.p.) treated with CCl4 (0.4 ml/kg), twice-weekly for 6 weeks, and then were i.p. dosed with saline, TLR2-L (Pam3CSK4; 20 ug) or TLR4-L (LPS; 100 ug) ligand for 24 h before culling. FFPE murine liver tissue was histologically examined, and phenotyping of myeloid cells was performed by flow cytometry. Liver tissue sections of ACLF patients and pathological controls were imaged using multiplex immunofluorescent (mIF) staining. Effects of TLR-ligand (TLR-L) 24 h treatment on human monocyte-derived macrophage (MoMF) PD-L1 were assessed by flow cytometry. In additional experiments, MoMF were primed for 24 h with TLR4-L (100 ng/ml; LPS) and then treated for 24 h with Ig control, PD-1, PD-L1 or PD-L2 Fc proteins (5 ug/ml) to activate the PD-1/PD-L axis. Macrophage *E. coli* pHrodo uptake, ROS production, and cytokine secretion levels were assessed by flow cytometry and Meso Scale Discovery kit.

Results: We found that TLR4-L, TLR5-L and TLR9-L (but not TLR2, TLR3, or TLR7-L) agonism upregulated PD-L1 expression on human MoMF [TLR4: 38,054 vs TLR5: 43,120 vs TLR9: 32,806 vs CTRL: 9,048; (MFI), all $p < 0.05$]. Also, our in vivo analyses revealed that TLR4-L (LPS) treated CCl4 mice were characterized by increased liver inflammation and Kupffer cell (Fig. A–B) or MoMF (not shown) PD-L1 levels, in comparison with TLR2-L and saline treated CCl4 mice (Fig. A–B). Human liver tissue mIF showed that ACLF patients had higher numbers of CD68+ PD-L1+ macrophages and CD8+ PD-1+ cells (Fig. C). We found that PD-1 axis' agonism on human LPS-primed MoMF with PD-1 or PD-L1 proteins (but not PD-L2) resulted in altered pro-inflammatory cytokine secretion (Fig. D) and reduced bacterial uptake and ROS production (Fig. E).

Conclusion: Our findings show that macrophage PD-L1 is differentially induced by microbial toxins (TLR-L) such as LPS, both in vitro and in experimental liver fibrosis and ACLF. Mechanistically, we found that PD-1 axis' activation on LPS-primed macrophages causes negative "back-signaling" by reducing their bactericidal functions.



(A-B) MOUSE MODELS OF FIBROSIS & ACLF. AFTER 6-WEEK I.P. CCL4 (0.4 UL/G) TREATMENT, WT MICE RECEIVED I.P. SALINE OR TLR2-L OR TLR4-L 24H BEFORE CULL. (A) REPRESENTATIVE HISTOLOGICAL STAINS. (B) NUMBER OF CD45+ LIVER CELLS & KUPFFER CELL PD-L1 EXPRESSION. (C) DATA SHOW CD68+ PD-L1+ AND CD8+ PD-1+ CELLS IN HUMAN ACLF & CONTROLS. (D-E) HC MONOCYTE-DERIVED MACROPHAGES (7 DAYS) WERE TREATED FOR 24H WITH RECOMBINANT IG FC CONTROL OR PD-1 FC OR PD-L1 FC OR PD-L2 FC PROTEIN (5 UG/ML) TO ACTIVATE THE PD-1 PATHWAY. CELL BACTERIA PHAGOCYTOSIS (PHRODO) AND REACTIVE OXYGEN SPECIES (ROS) PRODUCTION WERE MEASURED BY FLOW CYTOMETRY. CYTOKINE SECRETION WAS MEASURED BY MSD KIT.

Figure: (abstract: OS-108)

Future work will evaluate PD- (L)1 and/or TLR-directed immunomodulatory therapeutic approaches for improving hepatic macrophage antimicrobial responses in ACLF.

Neutrophils promote chronic liver injury resolution

Silvia Ariño[1], Laura Serrerols-Viñas[1], Beatriz Aguilar-Bravo[1], Raquel A Martínez-García de la Torre[1], Iván Ballesteros[2], Andrea Rubio-Ponce[2], Daniela Cerezo-Wallis[3], Alex Guillamon[1], Juanjo Lozano[4], Andrés Hidalgo[2,3], Pau Sancho-Bru[1,4]. *[1]Institut d'Investigacions Biomèdiques August Pi Sunyer (IDIBAPS), Spain; [2]National Center for Cardiovascular Research Carlos III, Spain; [3]Yale University School of Medicine, United States; [4]Centro de Investigación Biomédica en Red de enfermedades hepáticas y digestivas (CIBERehd), Spain*
Email: sarinom@recerca.clinic.cat

Background and aims: Advanced chronic liver injury is characterized by the loss of hepatocyte function, fibrosis accumulation, ductular reaction expansion and neutrophil recruitment. Previous results from our group have shown that neutrophils participate in chronic liver injury progression. However, neutrophils' contribution to chronic liver damage repair remains elusive. Therefore, the aim of the present study is to investigate the role of neutrophils in chronic liver injury resolution and regeneration.
Method: Injury regression was evaluated by immunohistochemistry and serum transaminase levels in a mouse model treated for 3 weeks with DDC diet which was followed by resolution periods of 1, 3 or 5 days of standard diet administration. To investigate neutrophils' role, neutrophils were depleted using a transgenic mouse in which the diphtheria toxin receptor is expressed under the neutrophil specific promoter Mrp8. Depletion impact was evaluated during 5 days of regression by immunohistochemistry and gene expression. Finally, we performed bulk-sequencing analysis of isolated neutrophils from healthy liver, injured liver after 3 weeks of DDC and injury resolution after 3 days of regression.
Results: We observed an imminent decrease of transaminase levels after 24 hours of DDC diet withdrawal. At histological level, hepatocyte proliferative peak was achieved at 3 days of resolution. However, a significant decrease of neutrophils and ductular reaction and fibrosis regression were not observed until day 5 of resolution. The specific depletion of neutrophils during a 5-days resolution period showed a reduced ductular reaction and fibrosis regression. Moreover, there was a lower number of proliferative hepatocytes in the neutropenic model, suggesting the participation of neutrophils in hepatocyte regeneration in the context of injury resolution. Finally, neutrophil sequencing analysis showed that liver neutrophils from injury resolution recover the expression of pathways related to interferon type I, apoptosis and autophagy, which were lost in DDC liver-injured neutrophils. Moreover, liver neutrophils from injury resolution were enriched in pathways related to LPS-response, cell migration and mitogenic factors (IL6 and TNFa) secretion when compared to healthy and DDC liver neutrophils.
Conclusion: Our study shows the participation of neutrophils in chronic liver injury resolution. Moreover, our data indicate that neutrophils are a plastic cell population and suggest their capacity to acquire a pro-resolutive phenotype and to promote liver regeneration.

NAFLD: Experimental

Spatial proteotranscriptomics identifies macrophage heterogeneity in patients with at-risk non-alcoholic steatohepatitis

Dina Tiniakos[1,2], Asier Antoranz-Martinez[3], Trieu My Van[4], Daniel Newhouse[4], James Clark[1], Ann K Daly[1], Tania Roskams[3], Quentin Anstee[1,5], Olivier Govaere[1,3]. *[1]Newcastle University, Translational and Clinical Research Institute, Faculty of Medical Sciences, United Kingdom; [2]National and Kapodistrian University of Athens, Dept of Pathology, Aretaieio Hospital, Greece; [3]KU Leuven and University Hospitals Leuven, Department of Imaging and Pathology, Translational Cell and Tissue Research, Belgium; [4]NanoString Technologies, United States; [5]Newcastle upon Tyne Hospitals NHS Trust, Newcastle NIHR Biomedical Research Centre, United Kingdom*
Email: olivier.govaere@kuleuven.be

Background and aims: Patients with "at-risk" NASH (NAS ≥ 4 + F ≥ 2) are a key recruitment group for drug trials as they are more likely to progress to cirrhosis. Besides lobular inflammation and hepatocellular ballooning at an advanced fibrosis stage, the biopsies of these patients often exhibit lipogranuloma and monocyte-derived macrophages infiltration in the portal tract. The dynamics between the response of Kupffer cells to parenchymal damage and the influx of circulating immune cells, are still poorly understood. In this study, we aimed to resolve the spatial heterogeneity of the macrophage population in at-risk NASH and their relationship to histopathological features.
Method: GeoMx Human Whole Transcriptome Atlas profiling was performed on 8 biopsies from patients with NASH fibrosis stage 3. Regions of interest were selected based on (1) the presence of portal inflammatory infiltration, (2) steatosis with lobular inflammation and/or lipogranulomas, and (3) parenchyma without steatosis. Fluorescent CD68, CD45 and pan-keratin markers were used to segment the different macrophage, immune cell and epithelial cell populations from each region. A total of 80 segments were processed for high throughput RNA sequencing. The clinical relevance of the identified differentially expressed genes were explored in extant bulk RNA sequencing data from 206 NAFLD patients. Key targets were validated on protein level using the Multiple Iterative Labelling by Antibody Neodeposition method. All samples were scored by an expert liver pathologist according to the semi-quantitative NASH-CRN Scoring System.
Results: Comparison of parenchymal steatohepatitis-associated (SH-) macrophages with portal (PT-) macrophages and Kupffer cells from parenchyma without steatosis identified 352 and 218 differentially expressed genes respectively. PT-macrophages displayed a typical immature/monocyte phenotype, lacking the expression of scavenger receptors (*MSR1*, *CD36*, *CD163*), and expressing lymphocyte-regulatory genes (*CCL19*, *CCL21*, *CD48*, *IL7R*, *CCL5*). Compared to Kupffer cells in areas without steatosis, SH-macrophages showed features of both monocytes (high expression of *LSP1*, glycoprotein NMB and lysozyme) and mature macrophages (high *MSR1* expression). In addition, SH-macrophages displayed an increase in metabolic- and phagocytosis-related genes. Exploring the clinical relevance of key markers in bulk RNASeq data showed that *CCL19* expression was linearly correlated with the fibrosis stage, lobular inflammation and hepatocyte ballooning scores, but not with the steatosis grade. In contrast, *GPNMB* and lysozyme mRNA expression reflected predominantly NASH activity, as it was significantly associated with steatosis, lobular inflammation and hepatocyte ballooning scores, but not with fibrosis. At the protein level, GPNMB-positive macrophages were observed in steatotic areas with active inflammation and lipgranulomas.

Conclusion: This study identified a steatohepatitis-associated macrophage subpopulation in patients with at-risk NASH, with unique characteristics compared to portal macrophages and Kupffer cells from non-steatotic liver parenchyma highlighting macrophage heterogeneity. Furthermore, we showed the clinical relevance of steatohepatitis-associated macrophages in the grading and staging of the NAFLD spectrum.

OS-111

Intestinal Angptl4 perturbs gut barrier function in NAFLD

Damien Chua[1], Hong Sheng Cheng[1], Nguan Soon Tan[1,2]. [1]*Lee Kong Chian School of Medicine, Singapore, Singapore;* [2]*Nanyang Technological University, Singapore, School of Biological Sciences, Singapore*
Email: NSTAN@ntu.edu.sg

Background and aims: The disruption of the gut-liver axis, which involves a complex interplay of intestinal and hepatic processes, contributes to the onset and progression of liver diseases. The gut barrier functions are compromised in NAFLD patients, which increases the exposure of the liver to pathogen-mediated microbial patterns and microbial-derived metabolites. The identification of the elements of the gut-liver axis primarily damaged in NAFLD offers possibilities for intervention. Early studies have implicated angiopoietin-like 4 protein (Angptl4) as a potential link between gut microbiota and adiposity. However, the role of intestinal Angptl4 in the gut-liver axis is poorly understood. Here, we examined the role of intestinal Angptl4 as a prime pathological player of gut-liver axis in NAFLD.

Method: We developed a human-relevant diet-induced NAFLD mouse model based on thermoneutral housing, LIDPAD (Liver Disease Progression Aggravation Diet) and a control diet of defined ingredients. Intestinal epithelium-specific Angptl4 deleted ($Angptl4^{Vil-/-}$) mice were fed NASH-inducing LIDPAD and control diet. Liver histology and CellROX were performed to assess the liver damage and oxidative stress. RNA-seq of liver and intestinal epithelium and gene ontology analyses were performed. Liver histology and CellROX were performed to assess the liver damage and oxidative stress. Gut permeability was assessed using a FITC-dextran permeability assay and qPCR of tight junctions proteins. Whole-mount immunofluorescence imaging was performed to reveal alteration in the spatial distribution of the intestinal structure and vasculature.

Results: $Angptl4^{fl/fl}$ mice developed hepatic steatosis at 1–4 weeks of LIDPAD that progressed to NASH by 8–12 weeks. Fibrosis was prevalent in 90% of LIDPAD-fed $Angptl4^{fl/fl}$ mice from 12 weeks onwards. Hepatic transcriptomic and gene ontology analyses to identify early events that underpin NAFLD onset revealed acute-phase response and hepatic response to LPS between weeks 1–4. Functional hepatic analysis revealed increased hepatocyte oxidative stress and lipid peroxidation in the liver as early as 2 weeks after diet feeding, before the presentation of NASH. Consistently, $Angptl4^{Vil-/-}$ mice had reduced gut permeability and hepatic oxidative stress damages compared with $Angptl4^{fl/fl}$ mice. Furthermore, LIDPAD-fed $Angptl4^{fl/fl}$ mice gained more body weight with larger liver and epididymal adipose tissue than $Angptl4^{Vil-/-}$ mice.

Figure:

Conclusion: Our observations suggest an integral role for intestinal Angptl4 in regulating gut barrier functions associated with early diet-induced liver injury and adiposity associated with diet-induced NAFLD.

OS-112

The transcriptional function of TCF7L2 is spatially restricted in liver and regulates zonated metabolic pathways that contribute to NAFLD

Iriscilla Ayala[1], Skanda Hebbale[1], Christopher Shannon[2], Ivan Valdez[3], Luis Cruz-Moreno[1], Terry Bakewell[1], Marcel Fourcaudot[1], Sami Heikkinen[4], Luke Norton[1]. [1]*University of Texas Health San Antonio (UTHSA), United States;* [2]*University College Dublin, Ireland;* [3]*University of Texas Southwestern Medical Center (UTSW), United States;* [4]*University of Eastern Finland, Finland*
Email: nortonl@uthscsa.edu

Background and aims: The prevalence of non-alcoholic fatty liver disease (NAFLD) is 40–80% in people with Type 2 Diabetes (T2D). Single nucleotide polymorphisms in the transcription factor 7-like 2 (*TCF7L2*) gene are significantly associated with T2D, but the metabolic function of TCF7L2 remains to be fully elucidated. TCF7L2 is a transcriptional effector of the WNT/beta-catenin signaling pathway, and we previously demonstrated that it regulates key zonally expressed metabolic genes in hepatocytes. Here we investigated the spatial transcriptional role of TCF7L2 in mouse liver using multimodal single nuclei genomics, and determined the impact of TCF7L2 transcriptional inactivation on zonated metabolic pathways and the development of severe NAFLD.

Method: Using single nuclei RNA-Seq and ATAC-Seq, we examined the spatial expression and DNA binding activity of TCF7L2 across the mouse liver lobule. We visualized TCF7L2 transcriptional activity in liver using TCF/Wnt signaling reporter mice, which express eGFP downstream of the conserved TCF/LEF DNA binding site. The transcriptional activity of TCF7L2 was ablated in liver by breeding mice with a floxed *Tcf7l2* exon 11, which encodes part of the DNA binding domain (DBD), to albumin-Cre mice to create liver specific TCF7L2 mutant mice ($Hep\text{-}TCF7L2^{DBD}$). The impact of TCF7L2 inactivation on the development of fibrosis in NAFLD was investigated in $Hep\text{-}TCF7L2^{DBD}$ mice fed a choline-deficient amino acid-defined high fat (CDAHFD) diet for 8-weeks. In liver samples harvested from these mice, we examined the disruption to zonated metabolic pathways including cholesterol, bile and glutamine/glutamate metabolism.

Results: Our multimodal single nuclei methodology reliably isolated distinct hepatocyte populations in mouse liver. We found that the expression of *Tcf7l2* mRNA was ubiquitous across the liver lobule, but that the presence of the consensus TCF/LEF DNA binding motif in ATAC peaks was significantly enriched in zone 3 pericentral hepatocytes. Consistent with this, immunofluorescence analysis of TCF/Wnt reporter mice revealed GFP staining that was highly restricted to zone 3 hepatocytes. In $Hep\text{-}TCF7L2^{DBD}$ mice, the expression of zone 3 marker genes was abolished, and was associated with disruptions to cholesterol and bile acid metabolism, and glutamine/glutamate homeostasis. Following the CDAHFD, $Hep\text{-}TCF7L2^{DBD}$ mice developed more severe fibrosis, and expressed elevated levels of genes involved in fibrogenesis, collagen synthesis and TGF-beta signaling.

Conclusion: Our findings suggest that under normal conditions, TCF7L2 activity is spatially regulated in mouse liver, and that its transcriptional activity is required for pericentral hepatocyte function. We also demonstrate that disrupted pericentral zonation may contribute to the development of severe NAFLD by interfering with several zonated metabolic pathways.

OS-113

Macrophage-derived osteopontin protects from non-alcoholic steatohepatitis

Hui Han[1], Xiaodong Ge[1], Sukanta Das[1], Romain Desert[1], Zhuolun Song[1], Dipti Athavale[1], Wei Chen[1], Sai Komakula[1], Daniel Lantvit[1], Grace Guzman[1], Natalia Nieto[1]. [1]*University of Illinois at Chicago, Pathology, Chicago, United States*
Email: nnieto@uic.edu

Background and aims: Osteopontin (OPN, encoded by the *SPP1* gene) is an immunomodulatory protein involved in chronic liver disease. The expression of OPN in macrophages (MFs) from healthy liver is relatively low; however, it markedly increases in non-alcoholic steatohepatitis (NASH). Our aim was to determine whether MF-derived OPN is protective or pathogenic in NASH.
Method: *Spp1* knock-in and knock-out mice in myeloid cells ($Spp1^{KI\ Mye}$ and $Spp1^{\Delta Mye}$) and liver MFs ($Spp1^{KI\ MF}$) were generated. Mice were fed a NASH-inducing or an isocaloric control diet for 6 months. Livers were pathologically evaluated by HandE staining and immunohistochemistry. RNA-seq, lipidomics and metabolomics analyses were done in total liver. MFs were isolated and RNA-seq was performed. Fatty acid metabolism was analyzed with the Seahorse. The crosstalk between MFs and hepatocytes (HEPs) was studied using a co-culture system.
Results: Both genders of $Spp1^{KI\ Mye}$ mice were fully protected from NASH. The NASH activity score, liver triglycerides (TGs) and cholesterol were significantly decreased in $Spp1^{KI\ Mye}$ compared to control and $Spp1^{\Delta Mye}$ mice. The latter presented the worst phenotype. $Spp1^{KI\ MF}$ recapitulated the protection achieved in $Spp1^{KI\ Mye}$ mice. Metabolomics and lipidomics analyses revealed that livers from $Spp1^{KI\ Mye}$ mice showed less saturated fatty acid-containing TGs, which correlated with up-regulation of urea cycle metabolites. Gene expression enrichment analysis revealed that mitochondrial arginase-2 (*Arg2*) but not cytosolic arginase-1 (*Arg1*), was up-regulated mainly in HEPs from $Spp1^{KI\ Mye}$ mice. The increase in ARG2 was associated with higher NAD^+/NADH ratio and ATP levels in total liver. HEPs from $Spp1^{KI\ Mye}$ showed higher mitochondrial respiration and fatty acid oxidation (FAO), which were reduced by ablation of *Arg2* in HEPs. Transcriptomics and gene network analyses revealed that Oncostatin-M (OSM) was induced in $Spp1^{KI\ Mye}$ MFs regardless of diet. Treatment of HEPs with OSM induced *Arg2* and FAO while they were blocked by co-treatment with a STAT3 inhibitor.
Conclusion: MF-derived OPN protects from diet-induced NASH in mice. The ARG2-mediated increase in mitochondrial respiration and FAO is responsible for the protective effect. OSM induced in MFs from $Spp1^{KI\ Mye}$ mice up-regulates ARG2 in HEPs through STAT3. Future work will focus on delineating how OPN induces OSM in MFs.

OS-114-YI

Dissecting NAFLD pathomechanisms using primary mouse liver and blood cells in a microfluidic perfusable compartmentalized liver-on-a-chip model

Hanyang Liu[1], Marlene Kohlhepp[1], Guo Yin[1], Jana Hundertmark[1], Felix Heymann[1], Kehinde Aina[2], Alexander Mosig[2], Frank Tacke[1], Adrien Guillot[1]. [1]*Charité Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany;* [2]*University Hospital Jena, Center for Sepsis Control and Care and Institute of Biochemistry II, Jena, Germany*
Email: hanyang.liu@charite.de

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a chronic liver condition defined by lipid accumulation in liver parenchymal cells (steatosis) associated with varying degrees of lipotoxicity, hepatocellular injury, inflammation and fibrosis. The liver sinusoids are lined by liver sinusoidal endothelial cells (LSECs) and represent the interface between circulating blood and liver resident macrophages (Kupffer cells, KCs) on one hand, liver epithelial cells (mainly hepatocytes) and hepatic stellate cells (HSCs) on the other hand. Thus, the liver sinusoid microenvironment includes all cellular players involved in NAFLD pathogenesis. Current in-vivo mouse NAFLD models present ethical challenges, and traditional in-vitro approaches cannot recapitulate the complex cellular interplay and the involvement of circulating cells. In this project, we aim at establishing and testing a primary cell biochip-based liver sinusoid model for the study of NAFLD driving mechanisms.
Method: Our liver-on-chip model consists of two distinct seeding chambers separated by a porous membrane. A microfluidic system can differentially perfuse both chambers. Primary mouse hepatocytes, HSCs, KCs and LSECs are isolated from fresh liver tissues, while peripheral blood mononuclear cells (PBMCs) were isolated from the vena cava of the same animal. Free fatty acids (palmitic and oleic acids) were used to induce hepatic steatosis. Lipid deposition, cellular lipotoxicity and inflammation were evaluated by lipid droplet and live/dead immunostaining, or immune cell tracking and flow cytometry. NAFLD-relevant markers were measured by qRT-PCR. The pan-PPAR agonist lanifibranor was used to test the relevance of our model for therapeutic agent testing. Acetaminophen (paracetamol) was used as a model of acute drug-induced injury.
Results: Five cell types were successfully isolated from mouse livers, and seeded in the biochip system, followed by PBMC perfusion for 48 hours. We found that FFA stimulation resulted in hepatocelluar lipid deposition, cell injury and immune cell mobilization, as well as the induction of NAFLD-associated inflammatory cytokines. Lanifibranor treatment attenuated the FFA-induced observations. Similarly, acetaminophen induced acute hepatocyte injury and immune cell activation.
Conclusion: Our data demonstrate the relevance of the liver-on-chip model to study NAFLD and acute liver injury, suggesting that it is an innovative tool for functional and molecular studies.

Inreased risk of hepatocellular carcinoma among first-degree relatives of patients with biopsy-proven NAFLD – a multigenerational nationwide cohort study

Fahim Ebrahimi[1,2], Tracey Simon[3], Hannes Hagström[4], Jiangwei Sun[1], David Bergman[1], Bjorn Roelstraete[1], Jonas Ludvigsson[1,5,6]. [1]*Karolinska Institutet, Department of Medical Epidemiology and Biostatistics (MEB), Stockholm, Sweden;* [2]*Clarunis-University Center for Gastrointestinal and Liver Diseases Basel, Gastroenterology and Hepatology, Basel, Switzerland;* [3]*Harvard Medical School, Gastroenterology and Hepatology, Boston, United States;* [4]*Karolinska University Hospital, Division of Hepatology, Stockholm, Sweden;* [5]*Örebro University Hospital, Department of Pediatrics, Örebro, Sweden;* [6]*Columbia University, Department of Medicine, New York, United States*
Email: f.ebrahimi@outlook.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the fastest growing cause of hepatocellular carcinoma (HCC). First-degree relatives (FDR) of patients with NAFLD are at substantially increased risk to develop NAFLD themselves, however little is known about their risk for HCC.
Method: We conducted a nationwide, population-based cohort study including all Swedish adults with biopsy-proven NAFLD in Sweden 1966–2017 (n = 11,924), who were matched to ≤5 population controls (n = 56,634) by age, sex, calendar year and county of residence. Leveraging the Swedish Total Population Register, we identified all first-degree relatives (fathers, mothers, siblings, offspring) (n = 48,032) and spouses (n = 9,406) of patients with NAFLD and of controls (n = 248,463; and n = 47,718 respectively). All first-degree relatives and spouses were followed from the time of NAFLD diagnosis or matching in their relative or from 18 years of age, whichever occurred last. We used Cox proportional hazards model to calculate multivariable adjusted HRs (aHRs) and 95% confidence intervals (CIs) for the risk of incident HCC.
Results: Over a median of 17.2 years, 86 (0.22%) NAFLD FDRs were diagnosed with incident HCC, compared to 285 (0.14%) control FDRs, yielding a significantly increased relative risk (13.0 *vs.* 8.4/100,000 PY; difference = 4.6/100,000 PY; aHR = 1.74, 95% CI = 1.32 to 2.28). The excess risk for HCC did not differ across generations: parents (36.9/100, 000 PY, aHR = 2.01, 95% CI = 1.24 to 3.26), siblings (15.9/100,000 PY, aHR = 1.73, 95% CI = 1.04 to 2.88), offspring (5.3/100,000 PY, aHR = 1.46, 95% CI = 0.84 to 2.56). The risk was highest among FDRs of NAFLD patients with histological confirmation of fibrosis or cirrhosis (aHR = 2.77, 95% CI = 1.50 to 5.14) when compared to FDR of those with simple steatosis or NASH without fibrosis (aHR = 1.56, 95% CI = 1.15 to 2.12). There was no difference in HCC risk between NAFLD spouses and control spouses (17.9 *vs.* 14.4/100,000 PY), aHR = 1.30, 95% CI = 0.80 to 2.12).

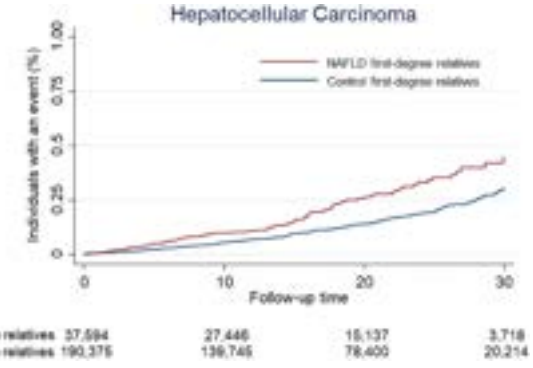

Figure:

Conclusion: First-degree relatives of patients with NAFLD, but not patient spouses were at increased risk of HCC, indicating that shared biological or early environmental factors might contribute to these elevated risks. Screening for risk factors of HCC-such as underlying NAFLD-might be considered in first-degree relatives of patients with NAFLD, especially when the patient already has signs of fibrosis or cirrhosis.

OS-117

Socioeconomic disparities and primary liver cancer incidence between 2006 and 2016: analyze by subtypes, a French population-based study

Nga Nguyen[1], Bertille Comoz[1], Joséphine Bryere[2], Anne-Marie Bouvier[3], Jean Baptiste Nousbaum[4], Guy Launoy[2], Veronique Bouvier[2], Isabelle Ollivier-Hourmand[1]. *[1]CHU de caen, Calvados, Caen, France; [2]Centre Francois Baclesse, Calvados, Caen, France; [3]INSERM UMR 1231, France; [4]CHU de Brest, France*
Email: bertille.comoz@hotmail.fr

Background and aims: Hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (iCCa) are the two most frequent histological subtypes of primary liver cancer (PLC). Despite different risk factors, these two types of cancer are often pooled in most epidemiological studies, as they are coded in databases under the common code C22 according to the ICDO-3 classification. The aim of this study was to measure the association of socio-economic disparities on the incidence of these two subtypes of PLC.
Method: Data provided from FRANCIM the French cancer registry network, which covers 20% of the French territory, between 2006 and 2016. HCC was defined by topographic code C22.0 and morphological codes 8000, 8001 and 8170–8175. iCCa was defined by topographic code C22.1 and morphological codes 8000, 8001, 8050, 8140–8141, 8160–8161, 8260, 8440, 8480–8500 and 8570–8572. Each patient's address was geolocalized and assigned to an IRIS, the smallest geographic unit in France. The socio-economic environment was assessed by the European deprivation index (EDI). The EDI based on the 2011 national census was used for each IRIS. Crude and standardized Incidence rates with 95% confidence intervals (CI) were estimated as the number of newly diagnosed cancer cases per 100, 000 inhabitants. These were given for each IRIS, sex and age group using a 15-year increment: 15–29, 30–44, 45–59, 60–74, 75 and over. Incidence rates by national quintiles were calculated, with quintile 1 (Q1) characterizing the most affluent areas and quintile 5 (Q5) characterizing the most deprived areas. A Poisson regression by subtypes was performed to model the impact of deprivation on the incidence of HCC and iCCa separately, using the continuous EDI.
Results: Between 2006 and 2016, the study population included 22 249 cases of PLC: 17 732 men and 4 517 women, over the period. HCC accounts for 79.64% of PLC with a male/female ratio of 5.6 and a mean age at diagnosis of 69 years. iCCA accounts for 16.97% of PLC with a male/female ratio of 1, 44 and a mean age at diagnosis of 71 years. The overall age- and sex-standardised incidence rates were 11.46 per 100 000 person-years for HCC and 2.39 per 100 000 person-years for iCCa.
There was an over incidence rate of HCC in quintiles 2, 3, 4, and 5 compared to quintile 1: Q1 10.28 [9.9–10.66] per 100 000 person-year, Q2 11.43 [10.48–12.47] (p < 0.0001), Q3 11.81 [10.82–12.89] (p < 0.0001), Q4 12.26 [11.25–13.37] (p < 0.001), Q5 11.53 [10.57–12.57] (p < 0.0001). By contrast there was no difference for iCCa: Q1 2.25 [2.08–2.43] per 100 000 person-year, Q2 2.37 [1.96–2.85] (p 0.3614), Q3 2.44 [2.02–2.95] (p 0.1422), Q4 2.50 [2.07–3.00] (p 0.06), Q5 2.40 [1.99–2.89] (p 0.2506).
Using Poisson regression and analysis of the β1 coefficient, a significant association was found between the deprivation and the risk of HCC (positive and significant β1 coefficients) for both men and women. By contrast, there was no significant association between environment and the risk of iCCa (Table 1).

Table 1. Socioeconomic disparities in liver cancer incidences in French registries between 2006 and 2016 by subtypes.

	Estimated EDI coefficient, β1	CI [95%]	P-value	Exp (β1)
PLC				
Total	0.0112	[0.0079-0.0144]	<.0001	1.01
Men	0.0053	[0.0016-0.0090]	0.0054	1.01
Women	0.0133	[0.0062-0.0204]	0.0002	1.01
HCC				
Total	0.0121	[0.0085-0.0157]	<.0001	1.01
Men	0.0064	[0.0024-0.0104]	0.0018	1.01
Women	0.0150	[0.0062- 0.0239]	0.0009	1.02
iCCA				
Total	0.0015	[-0.0072-0.0102]	0.7407	
Men	0.0054	[-0.0067-0.0175]	0.3823	
Women	-0.0031	[-0.0161-0.0099]	0.6392	

If the β1 coefficient is significantly different from the 0 value and positive, there is an increase in cancer risk for the most deprived areas. If β1 is significant and negative, the risk of cancer is higher for the deprived areas.

Conclusion: This population-based study showed that HCC account for the vast majority of PLC. Its incidence is lower in most affluent areas, and the risk of HCC is related to socioeconomic disparities, contrary to the risk of iCCA. This reinforces the need to study separately, HCC and iCCa, and to adjust public health measures to each subtype of PLC.
Key words: Epidemiology, cancer registries, socioeconomic inequalities, deprivation index, hepatocellular carcinoma, intrahepatic cholangiocarcinoma.

OS-118

Metabolic dysfunction associated fibrosis-5 (MAF-5) score to identify at-risk liver fibrosis and to predict prognosis in a population-based setting

Laurens van Kleef[1], Sven Francque[2], Jhon Prieto-Ortiz[3], Milan Sonneveld[1], Carlos B Sanchez Luque[3], Robin G Prieto-Ortiz[3], Wilhelmus Kwanten[2], Luisa Vonghia[2], An Verrijken[2], Christophe De Block[2], Zouhir Gadi[2], Harry La Janssen[1], Robert De Knegt[1], Willem Pieter Brouwer[1]. *[1]Erasmus MC University Medical Centre Rotterdam, Gastroenterology and Hepatology, Netherlands; [2]UZA, Gastroenterology and Hepatology, Belgium; [3]Center for Liver and Digestive Diseases (CEHYD), Bogota, Colombia*
Email: w.p.brouwer@erasmusmc.nl

Background and aims: There is an unmet need for non-invasive tools to improve case-finding and aid primary care professionals in referring patients at high risk of advanced liver disease.
Method: A metabolic dysfunction associated fibrosis (MAF-5) score was developed: an age-independent anthropometric-based non-invasive test, using the NHANES 2017–2020 as training set. Individuals with metabolic dysfunction were selected with complete data on potential score components (n = 6.333). Fibrosis was defined as liver stiffness (LSM) ≥ 8.0 kPa. Diagnostic accuracy was evaluated in the entire group and clinically relevant subgroups and compared to the FIB-4, NFS and SAFE. The score was externally validated with LSM ≥ 8.0 kPa in an elderly population with metabolic dysfunction (Rotterdam study, N = 2.699), with shear-wave elastography (SWE ≥9 .3 kPa) and biopsy-proven NAFLD according to METAVIR (Bogota cohort, N = 231) and with biopsy-proven NAFLD according to NASH-CRN (Antwerp cohort, N = 562). Finally the score was tested for prognostic performance against all-cause mortality in participants from the NHANES III with metabolic dysfunction (N = 9.679).
Results: The MAF-5 score comprised waist circumference, BMI, diabetes, AST and platelets. With this score, 60.3% was predicted at low risk (MAF-5 < 0), 14.6% at intermediate risk (MAF-5 0–1) and 25.1% at high risk (MAF > 1) of liver fibrosis. The observed fibrosis prevalence in these groups were 3.6%, 9.3% and 29.1%, respectively. The AUC of the MAF-5 (0.81) was significantly higher than the FIB-4 (0.60), NFS (0.70) and SAFE (0.73). The MAF-5 showed similar performance in detecting LSM ≥8 kPa in an elderly population, as

well as for SWE ≥9 .3 kPa. MAF-5 was significantly associated with the presence of liver fibrosis according to both NASH-CRN (median MAF-5 for stages F0F1/F2/F3/F4: 0.8/2.3/3.4/4.2, p < 0.001) and METAVIR (median MAF-5 0.66/1.12/2.57/3.5, p < 0.001). Finally, MAF-5 score >1 was associated with increased risk of all-cause mortality in both unadjusted and adjusted models (HR 1.65, 95% 1.51–1.79).

Conclusion: The MAF-5 score is an inexpensive tool to identify individuals with metabolic dysfunction at high risk of liver fibrosis and all-cause mortality in a primary care setting, using only easily obtainable variables. Given the MAF-5 outcompetes other first-line non-invasive tests, it can prevent unnecessary referrals and avoid extra diagnostic expenses.

OS-119-YI

Machine learning models are superior to FIB-4 as a first line stratification tool for liver disease in the community

Background and aims: Alpha-1 antitrypsin (AAT) deficiency, caused by homozygous protease inhibitor ZZ (PiZZ) mutations, results in production of mutant Z-proteins (Z-AAT) that aggregate in hepatocytes, leading to progressive liver dysfunction and fibrosis. Fazirsiran, an investigational RNA interference therapeutic, degrades liver Z-AAT messenger RNA to reduce Z-AAT synthesis. This study evaluated safety, pharmacodynamic and histologic effects of fazirsiran in adults with PiZZ AAT deficiency.
Method: This ongoing, placebo (PBO)-controlled, phase 2 study (NCT03945292) randomized participants (PTP) to subcutaneous PBO or fazirsiran 25/100/200 mg doses. The primary end point was change from baseline (BL) in serum Z-AAT concentration at week (wk) 16. PTP with biopsy-proven liver fibrosis underwent liver biopsy at BL and received treatment on day 1, wk 4, and then every 12 wks, and underwent a second liver biopsy at or after wk 48. PTP without liver fibrosis received 2 treatment doses on day 1 and wk 4. Three blinded central pathologists scored and adjudicated histological parameters, including hepatic globule burden (periodic acid-Schiff-diastase [PAS+D] staining (score 0–9), portal inflammation (score 0–3), and fibrosis score (F0-F4 METAVIR staging). Change from BL in serum and total liver Z-AAT concentrations were measured using liquid chromatography-tandem mass spectrometry.
Results: Forty PTP were enrolled (PBO [n = 14]; fazirsiran 25 mg [n = 9], 100 mg [n = 8], 200 mg [n = 9]). Fazirsiran reduced serum Z-AAT levels in a dose-dependent manner at wk 16 compared with PBO ($p < 0.001$), with mean relative reductions of 92% in the 200 mg group. Sustained reductions in serum Z-AAT up to wk 52 were observed with fazirsiran treatment. At post-BL liver biopsy, median reduction in liver Z-AAT was 94% with fazirsiran, compared with a median increase of 26% with PBO. Concomitant reduction from BL in hepatic PAS+D globule burden was observed with fazirsiran (mean [standard deviation (SD)] score of 5.9 [2.24] at BL and 2.3 [2.24] at post-BL visit), compared with no change with PBO (mean [SD] score of 6.9 [1.76] at BL and 6.6 [2.13] at post-BL visit). In PTP with BL score >0, portal inflammation improved in 5/12 PTP in the fazirsiran group vs. 0/8 PTP in the PBO group. In PTP with adjudicated liver fibrosis >F0 at BL, ≥ 1-point improvement in METAVIR score occurred in 7/14 PTP in the fazirsiran group vs. 3/8 PTP in the PBO group. Fazirsiran was well tolerated without any adverse events leading to study/drug discontinuation and no treatment-associated decline in pulmonary function.
Conclusion: Fazirsiran reduced serum and liver concentrations of Z-AAT and hepatic PAS+D globule burden in all treated PTPs compared with PBO, leading to improved liver portal inflammation. These results support further development of fazirsiran in larger phase 3 studies.

Email: lucile.moga@gmail.com

Background and aims: Spleen stiffness is associated with the severity of portal hypertension in patients with cirrhosis. Baveno VII consensus suggests that screening endoscopy can be safely avoided in patients with cirrhosis and a spleen stiffness measurement (SSM) by vibration-controlled transient elastography (VCTE) ≤40 kPa as they have a low probability of high-risk varices (HRV). In porto-sinusoidal vascular disorder (PSVD), endoscopic screening for varices is recommended in all patients. Whether SSM could also avoid endoscopies in patients with PSVD is currently unknown. This study aimed to evaluate the performance of SSM by VCTE to rule out high-risk varices (i.e. large varices, or red spot signs, or previous variceal band ligation) in patients with PSVD.
Method: All the patients with PSVD, according to Baveno VII definition, and at least one sign of portal hypertension, who underwent a liver biopsy between 2012 and 2022 at our center, and SSM by VCTE using FibroScan® performed within two years before or after an endoscopy, have been included. Patients with cavernoma or complete portal vein thrombosis at the time of liver biopsy, prior TIPS, or tense ascites at the time of SSM by TE, have not been included. Performance of SSM by VCTE was externally validated in a cohort of PSVD patients from 21 VALDIG centers, using the same inclusion and non-inclusion criteria.

Results: 154 patients were included in the derivation cohort: 56% men, median age 53, 75% with ≥1 condition known to be associated with PSVD. Median INR was 1.08 (IQR 0.99–1.24), median serum bilirubin 14 µmol/L (IQR 9–22), and median serum creatinine 70 µmol/L (IQR 61–86). A history of variceal bleeding was present in 16% of the patients, and 46% had HRV. Median SSM was 46.8 kPa (IQR 30.0–70.3). By univariate analysis, platelet count, serum bilirubin, serum albumin, spleen size, portosystemic collaterals, partial occlusion of portal venous axis, LSPS, and SSM by VCTE were associated with HRV status. By multivariate logistic regression analysis, only serum bilirubin ($p = 0.003$) and SSM by VCTE ($p < 0.0001$) remained associated with HRV. SSM by VCTE ≤40 kPa had a sensitivity of 87% to rule out HRV. This cutoff would avoid 45% of screening endoscopies, but with 13% of HRV missed, and a negative predictive value (NPV) of 87%. SSM by VCTE ≤40 kPa combined with serum bilirubin <17 µmol/L had a sensitivity of 96% to rule out HRV, and could avoid 34% of screening endoscopies, with 4% of HRV missed, and a NPV of 94%. In the validation cohort including 207 patients with similar characteristics, the combination of SSM and serum bilirubin could avoid 17% of screening endoscopies, with 4.7% of HRV missed, and a NPV of 86% (Fig.). Sensitivity analyses restricted to patients with an interval between SSM and endoscopy <6 months, or to patients without a history of bleeding, gave even better results. We tested SSM ≤40 kPa combined with platelet count ≥150G/L, and observed that HRV missed rate was >5%.
Conclusion: This study gathering a total of 361 patients with PSVD showed that SSM by VCTE ≤40 kPa combined with serum bilirubin <17 µmol/L identifies patients with PSVD with very low risk (<5%) of HRV, in whom screening endoscopy can be avoided.

OS-122
Final results from a phase 1/2, 48-month, open-label extension study of givosiran in patients with acute intermittent porphyria

Background and aims: Acute hepatic porphyrias (AHPs) are rare genetic disorders that can lead to accumulation of the neurotoxic intermediates 5-aminolevulinic acid (ALA) and porphobilinogen (PBG). The clinical presentation of AHPs, including the most common AHP, acute intermittent porphyria (AIP), is characterized by acute neurovisceral attacks, chronic symptoms, and long-term complications. Givosiran is an RNA interference therapeutic for AHP. In a phase 1 study in AIP (NCT02452372), once-monthly givosiran treatment led to sustained reductions in ALA and PBG levels and a lower annualized rate of porphyria attacks and hemin use versus placebo. We report final results from a phase 1/2 open-label extension study (NCT02949830) of the safety and efficacy of up to 48 months of givosiran treatment.
Method: Patient eligibility criteria for this multicenter study were AIP diagnosis, completion of the phase 1 trial, and absence of a prophylactic hemin regimen. Patients received givosiran 2.5 mg/kg once monthly, 5.0 mg/kg once monthly, or 5.0 mg/kg once every 3 months; eventually, all patients transitioned to 2.5 mg/kg once monthly.
Results: Of 16 patients enrolled, 14 completed the study. Mean (SD) age was 37.4 (12.0) years. Most patients were White (81%) and female (88%). Fourteen patients (88%) reported at least 1 adverse event (AE) related to study drug. The most common treatment-related AEs were injection-site erythema (N = 6; 38%) and injection-site pruritus (N = 4; 25%); most were mild or moderate in severity, and none led to treatment discontinuation. One (6%) patient experienced a serious treatment-related AE of anaphylaxis, leading to study withdrawal. Two patients experienced AEs of elevated alanine aminotransferase, and 1 experienced elevated blood homocysteine. Long-term treatment with givosiran 2.5 mg/kg once monthly led to a sustained

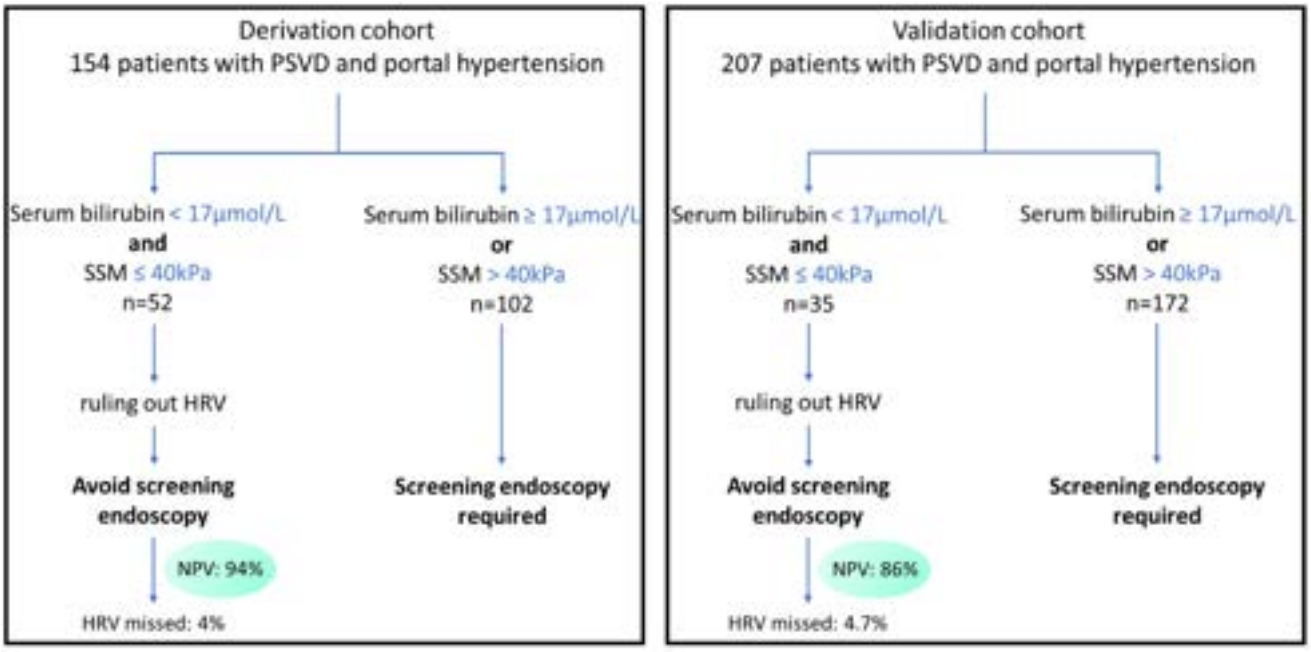

Figure 1. Performance of spleen stiffness measurement by vibration-controlled transient elastography combined with serum bilirubin to rule out high-risk- varices in patients with porto-sinusoidal vascular disorder

Figure: (abstract: OS-121-YI)

reduction in composite porphyria attacks, with a mean annualized attack rate of 0.4 (98% reduction), as well as a decrease in the mean rate of hemin use, from 33.1 doses/year during run-in to 0.9 dose/year (97% reduction) during this study. Sustained reductions in ALA and PBG levels were also observed. Exploratory assessments showed that quality-of-life scores improved over time.

Conclusion: This longest follow-up (up to 48 months) of patients receiving monthly givosiran treatment demonstrated acceptable safety, durable clinical response, and improvements in quality-of-life scores.

Email: martamagazm@gmail.com

Background and aims: The natural history and prognostic factors in portosinusoidal vascular disorder (PSVD) are not well understood. Aim: to describe the natural history of and prognostic factors in PSVD patients with portal hypertension (PH).

Method: Retrospective multicentric study of patients with PSVD and PH prospectively registered in 28 European centres. PSVD patients without an associated condition, or with an associated condition that usually impacts on life expectancy (e.g. autoimmune hypothyroidism), or with a controlled associated condition were classified as having "no or mild associated conditions." The remaining PSVD patients with an active associated condition known to potentially negatively impact life expectancy, (e.g. severe lupus with kidney involvement), were classified as having a "severe associated condition." Cox analysis was performed to identify variables with an independent predictive value for transplant-free survival.

Results: A total of 587 patients (38% women) were identified. At PSVD diagnosis, median age was 47 (33;59) years; 377 (64%) were asymptomatic. 210 patients had a PH complication as first manifestation: 87 (41%) variceal bleeding, 92 (43.8%) ascites, 25 (12%) variceal bleeding plus ascites, 11 (5%) hepatic encephalopathy (HE; 4 of them together with variceal bleeding and in 7 coexistent with ascites) and 13 (6%) dyspnea (seven of them coexisting with ascites). Median Child-Pugh at diagnosis was 5 (5;6), MELD 8 (7;11), total serum bilirubin 1 (0.6;1.4) mg/dL, INR 1.1 (1;1.2). Associated conditions

included: autoimmune (23%), hematologic (9%), HIV (9%), azathioprine (8%), oxaliplatin (7%), prothrombotic (8%), hereditary (4%), others (1%), while 32% had no other conditions (idiopathic). In 157 patients, the associated persistent condition was considered severe. Median follow-up was 68 [1–469] months. Fifty (9%) patients were transplanted and 109 (19%) died (59 non-liver related death). Transplant-free survival was 97%, 93%, 83%, and 72% at 1, 2, 5, and 10 years, respectively. We developed a predictive model based on multivariable Cox regression analyses for transplant free survival including age, ascites, serum bilirubin, creatinine and albumin at diagnosis, and the severity of the associated underlying condition that showed good discrimination and calibration (bootstrapped c-statistic: 0.82, Integrated calibration index at 3 and 6 years: 0.008 and 0.011) (nomogram). An accurate HVPG was available in 327 patients (without vein-vein communications). The median value was 7 mmHg (4;11). In this subgroup of patients, HVPG improved the predictive value of the model.

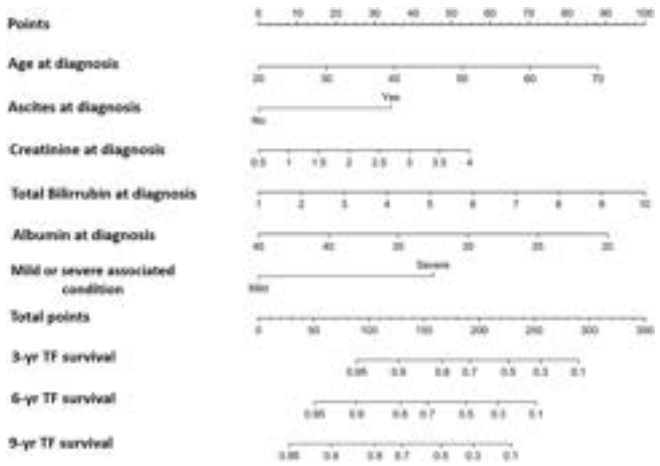

Figure:

Conclusion: Prognosis of patients with PSVD and PH is strongly determined by the presence of associated diseases. If diagnosis is made at the time of preserved liver function, long-term prognosis is good reinforcing the need of early diagnosis and management in centers of expertise.

Background and aims: Sinusoidal obstruction syndrome (SOS), also known as veno-occlusive-disease (VOD), remains a serious complication for patients undergoing hematopoietic stem cell transplantation (HSCT). Improving diagnosis with non-invasive methods needs to be urgently investigated. Consequently, we aimed to evaluate the diagnostic role of the measurement of liver stiffness (LSM), assessed with different ultrasound elastography techniques, for diagnosing SOS.

Method: This interventional prospective multicenter clinical trial, from April 2018 to December 2021, consecutively and prospectively examined 1089 patients from 25 Italian centres undergoing HSCT. Sixty-nine (6.3%) patients were excluded for inadequate data quality; among the remaining 1020 patients, 80 did not perform at least one LSM assessment after HSCT and were consequently excluded. Patients were followed according to the protocol by a dense clinical, laboratory, and imaging program during hospitalization for HSCT and until the diagnosis of SOS, death, or +100-day follow-up. LSM was performed before the HSCT (T0), on days +9/10 (T1), +15/17 (T2), and +22/24 (T3) after the. The diagnosis of SOS was performed clinically by each participating centre. The primary end point of the study was the diagnostic role for SOS by LSM assessed by different elastographic methods (ClinicalTrials.gov-number-NCT03426358)

Results: Among the 941 patients, 774 were adults, and 167 were children. Characteristics of the populations enrolled were reported in Table. Sixty per cent of patients were male with a mean age of 43.7 (SD 20.25) at the time of HSCT; the main HSCT indication was AML (40.3%), ALL (16.9%), NHL (7.1%), and myelofibrosis (6.6%). Most HSCTs

were allogeneic (95%) from peripheral blood stem cell sources (79.2%) and myeloablative intensity conditioning (63.3%). The +100-days overall survival was 96.5% [95%CI 90.2–100] in the whole population and 75.0% [95%CI 53.3–100] in the SOS group (78.6% [95%CI 39.2–100] in mild and moderate and 50.0% [95%CI 18.4–100] in very severe). LSM was measured in kilopascals (kPa) in 90.9% and meter-second (m/sec) in 9.1% of cases and evaluated by transient elastography (FibroScan, Echosens, Paris), 2D shear wave elastography (2D-SWE), and point shear wave elastography (p-SWE) in 76%, 12.9%, and 11.1%, respectively. Median LSM values prior-HSCT (T0) were 4.9 kPa [IQR 3.9–6.13] and 1.18 m/sec [IQR 1.01–1.4] with no significant difference (p value 0.350) according to SOS occurrence both by kPa (4.9vs5.0) and by m/sec (1.19vs1.02). LSM time point by time point (Fig1A), LSM values increased significantly in patients who developed SOS and differed between SOS severity grades (Fig1B). LSM values on the day of clinical diagnosis were significantly ($p < 0.0001$) associated both with SOS (OR 1.424 [95%CI 1.308–1.549]) and showed good diagnostic performance with a c-statistic of 0.975 [95%CI 0.948–1.000]. Comparable results were observed when LSM was evaluated in adults and paediatrics cohorts and by m/sec. Combination of the rule-in (25 kPa) and rule-out (6 kPa) cut-offs with deltaLSM (2x) in a stepwise algorithm achieved high values of PPV (84.2–98) and NPV (95–99) in all cohorts.

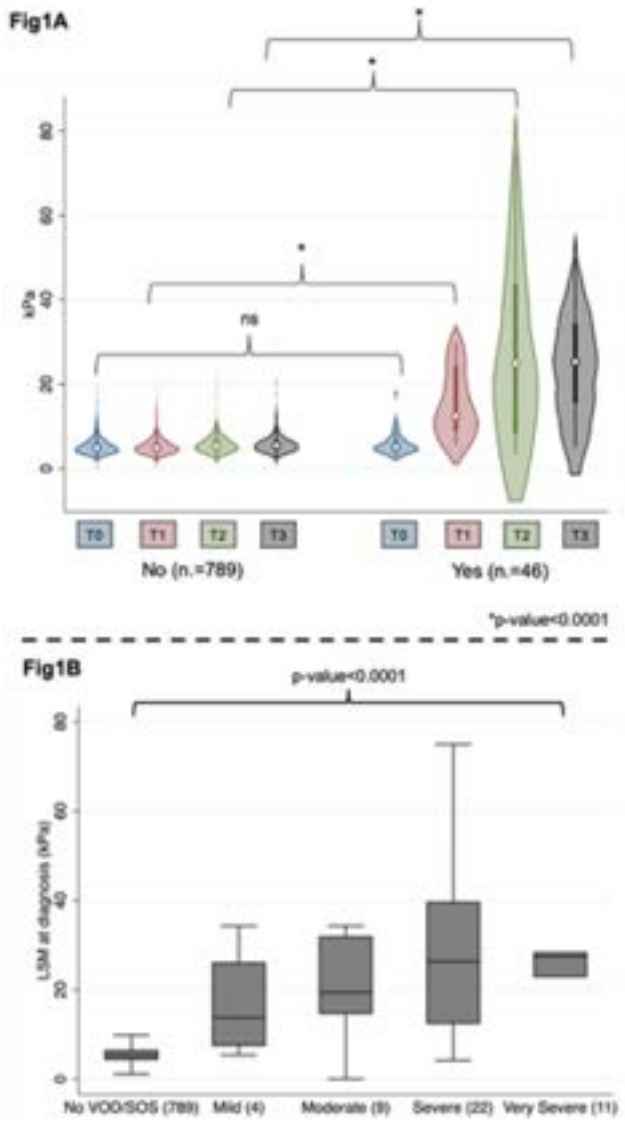

Figure 1:

Conclusion: LSM, regardless of the elastography modality, has proven to be an accurate diagnostic tool for SOS. This non-invasive method can support the multidisciplinary team formed by hepatologists and haematologists and allows for diagnosing SOS/VOD.

Viral hepatitis C

Background and aims: In North America (NA), the ongoing opioid overdose crisis has led to increasing organ transplantation from hepatitis C (HCV)-infected donors to HCV-uninfected recipients (D+/R-). While early treatment is recommended in societal guidelines, the optimal timing of antiviral therapy remains unclear. We compared the safety and efficacy of early vs late HCV treatment initiation in D+/R- non-liver solid organ recipients.
Method: Enrolled patients were treated with direct-acting antiviral (DAA) regimens per local standard of care at 10 NA sites. We compared efficacy and safety of HCV treatment between those who started before/within 7 days of transplant (Early) and those treated >7 days post-transplant (Late). The primary end point is sustained virological response (SVR12), defined as HCV RNA negativity 12 weeks post-treatment completion.
Results: 56 participants received Early treatment which included glecaprevir/pibrentasvir ± ezetimibe (GLE/PIB ± E) (n = 48) and sofosbuvir/velpatasvir (SOF/VEL) (n = 8). Treatment was initiated immediately before transplantation in GLE/PIB ± E, and by median day 5 and 4 in GLE/PIB and SOF/VEL, respectively. 102 participants received Late treatment which included SOF/VEL (n = 45), GLE/PIB (n = 49) and other regimens (n = 6). Two patients in the Late group did not start DAA treatment. Late treatment was initiated a median of 31 (range 8–114) days post-transplant. Median total treatment days was 8 (range 7–93) in Early vs 85 (range 51–111) in Late ($p < 0.0001$). There were 79 kidney, 50 lung, 23 heart, and 6 mixed transplants with similar distribution between groups. The proportion who achieved SVR12 was 92.9% (95% CI:82.7–98.0) in the Early and 91.0% (95%CI: 83.6–95.8) in the Late groups, respectively. No participant in Early treatment group experienced non-response or relapse. In the Late group, 2 patients did not respond to treatment and 3 had post-treatment relapse. Of those with available virologic outcomes (n = 148) 100% (95% CI: 93.2–100.0) in Early and 94.8% (95%CI: 88.3–98.3) in Late groups achieved SVR12, respectively. Acute cellular rejection occurred in 11 (19.6%) recipients in the Early and 25 (25.0%) in the Late group, with 7 (12.5%) and 5 (4.9%) cases of biopsy-proven rejection requiring treatment. There were 11 patient deaths; all unrelated to HCV or HCV therapy: 8 in the Early group (1 during treatment), and 4 in the Late group (1 pre- and 3-post-treatment). HCV treatment was well tolerated in both groups.

Figure: (abstract: OS-125) Recipient characteristics and outcomes

Conclusion: Solid non-liver organ transplantation in D+/R- recipients was safe with excellent graft and patient survival. Early treatment led to a non-significant lower rate of virological failure despite shorter duration treatment with numerically fewer episodes of acute rejection than with delayed therapy, supporting guideline recommendations for prompt treatment initiation.

Email: julia.dietz@em.uni-frankfurt.de

Background and aims: The global HCV elimination targets could be achieved with highly effective direct acting antivirals (DAAs) for treatment of hepatitis C virus (HCV) infection. However, studies showed that unusual HCV genotypes (GT) that are uncommon in industrialised countries are associated with lower SVR (sustained virologic response) rates and second generation DAAs are not available in all countries. This study aimed to describe the prevalence of unusual GT and resistance-associated substitutions (RASs) among European DAA-failure patients.

Method: We have identified 1314 patients who had failed IFN-free DAA treatment in the European Resistance database between 2014 and 2022. NS3, NS5A and NS5B were amplified and population sequenced and RASs that had >2-fold increased DAA susceptibility were analysed. All HCV geno- and subtypes were re-evaluated sequence-based.

Results: Overall, 4% (58/1314) of DAA-failure patients were infected with an unusual subtype. We found different frequencies of unusual GT among DAA treatment failures, namely 46% (27/58) GT4 (4b, 4c 4f, 4n, 4o, 4r, 4v), 24% (14/58) (3b, 3g, 3h, 3i, 3k; 24%), 12% (7/58) GT6 (6e, 6f, 6n, 6r), 10% (6/58) GT1 (1c, 1e, 1l) and 4% (2/58) each of GT2k and GT5a. The majority of patients with unusual GT (79%, 46/58) had failed to first-generation DAAs (LDV/SOF, DCV/SOF, 2D/3D, SOF/RBV, GZR/EBR) and only 21% (12/58) had failed to second-generation DAAs such as VEL/SOF or G/P. Characteristic NS5A RASs at positions 28, 30 and 31 were detected particularly in GT3 (86%, 12/14) and in GT4 (96%, 23/24) after DAA failure, whereas RASs were less frequent in the other GTs. Y93H was rarely detected overall. 76% (44/58) of patients had started retreatment, most with VOX/VEL/SOF (n = 29) and overall 95% (39/41 with completed follow-up after end of retreatment) achieved SVR across all regimens. Two patients with cirrhosis had virological treatment failure. One patient with GT4r had failed to respond to VEL/SOF/RBV and another with GT3b had failed to VOX/VEL/SOF.

Conclusion: We found unusual HCV GT in 4% of DAA failure patients, mainly after failure to first generation DAA regimens. Retreatment with second generation DAAs was effective with 95% SVR. The lack of global availability of second generation DAAs could lead to the global HCV elimination targets not being met.

OS-127-YI

The risks of first hepatic decompensation and HCC remain constant during long-term follow-up and can be stratified by a one-time assessment after HCV-cure

Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: The number of individuals who will be treated for and cured from HCV infection world-wide is expected to exceed 1 million per year for the next decade. In those with compensated advanced chronic liver disease (cACLD), the risks of *de-novo* hepatocellular carcinoma (HCC) and hepatic decompensation are decreased but not completely abolished by HCV-cure. Thus, risk stratification is key to decrease resource utilization by individualizing post-treatment management. We evaluated whether the incidences of HCC and hepatic decompensation decrease with time after HCV-cure and whether the discriminatory ability of a one-time post-treatment assessment is maintained during long-term follow-up.

Method: We retrospectively analyzed cACLD patients with paired liver stiffness measurement (LSM) and platelet count (PLT) before and after HCV-cure by interferon-free therapies from 7 European regions. Cumulative incidence curves were used to estimate the incidence of hepatic decompensation/HCC over time in the overall group and throughout previously defined risk strata (i.e., Baveno VII criteria for clinically significant portal hypertension after HCV-cure and Semmler et al. J Hepatol 2022 for HCC).

Results: 2347 patients (mean age 60 ± 12 years, 60% male, 21% obese, 21% diabetes) with a median LSM of 16.3 kPa (IQR: 12.1–24.5, 25% ≥25 kPa) before HCV-cure were followed for a median of 6.0 years after treatment. Interestingly, the incidence of first hepatic decompensation was strictly linear with 65 patients (2.8%) developing hepatic decompensation before eventually being diagnosed with HCC (incidence rate 0.57/100 patient years, incidence at 6 years: 3.1%, Figure-panel A). Similarly, incidence of HCC was also linear with 184 patients (7.8%) developing HCC (incidence rate 1.60/100 patient years, incidence at 6 years: 8.3%). Stratifying the risks for hepatic decompensation according to Baveno VII (Figure-panel B) and for HCC according to Semmler et al (algorithm based on age, LSM, albumin and alcohol consumption, Figure-panel C) after HCV-cure identified subgroups with a distinct prognosis during long-term follow-up, even after limiting prediction to events occurring >3 years after HCV-cure.

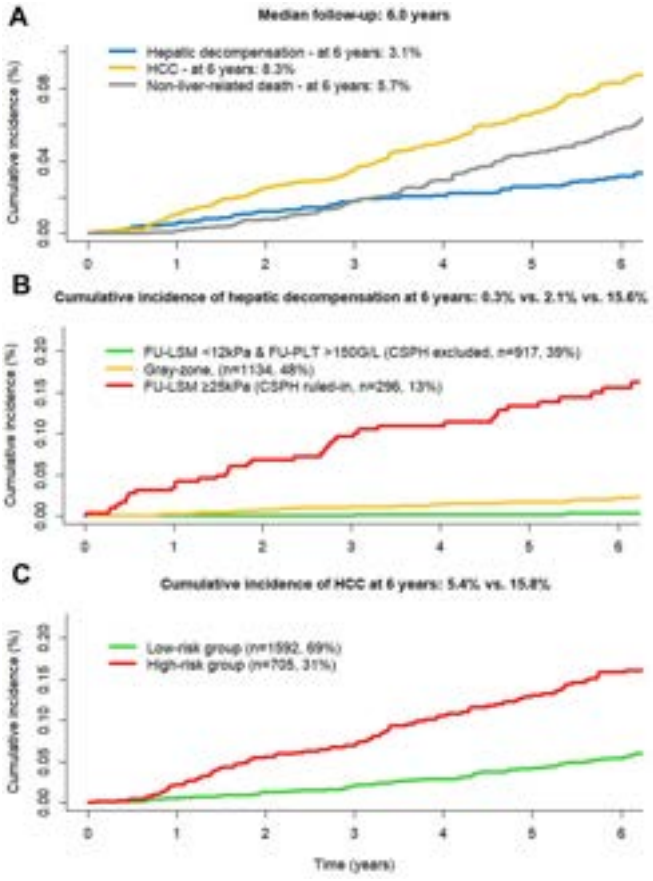

Figure:

Conclusion: In patients with cACLD, the risks of hepatic decompensation, and more importantly, HCC remain constant after HCV-cure, even in the long-term (>3 years). A one-time post-treatment risk stratification based on non-invasive criteria confers important prognostic information that is maintained during long-time follow-up, as the hazards over time remain proportional.

Achieving a hepatitis C cure in those with hepatocellular carcinoma is associated with an improvement in overall survival: real world data

Maria Guerra Veloz[1], Sital Shah[1], James Lok[1], Riham Soliman[1], Almuthana Mohamed[1], Mary D Cannon[1], Paul Ross[2], Ivana Carey[1], Kosh Agarwal[1]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]Guy's and St Thomas' NHS Foundation Trust, Oncology, London, United Kingdom*
Email: maria.guerraveloz@nhs.net

Background and aims: Achieving sustained virological response (SVR) has proved to improve clinical outcomes/survival rates in patients with chronic hepatitis C and HCC. However, the optimal time frame for delivering antiviral therapy in those with active infection remains unclear. The aim of this study was to provide real-world data on virological response and overall survival in patients with hepatitis

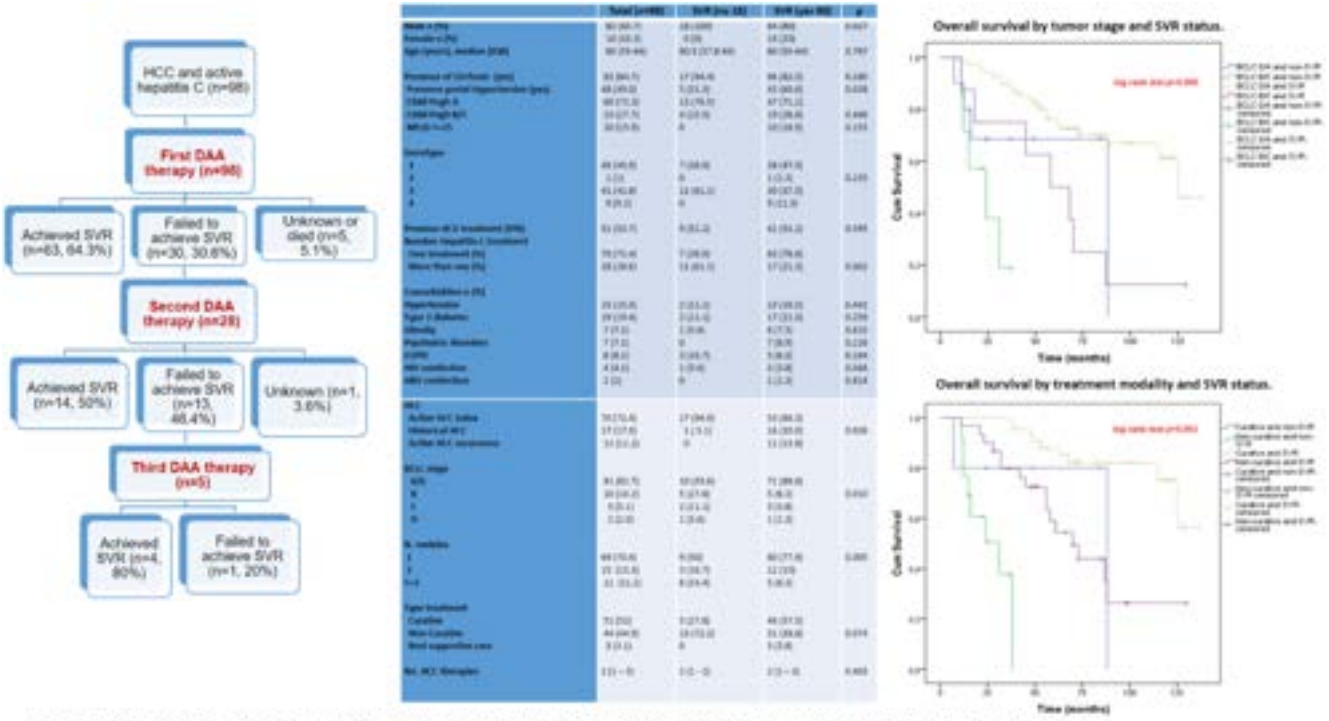

Figure 1: a) Flow chart of number of hepatitis C treatment during the study b) Demographic and clinical outcomes divided by SVR status c) overall survival

Figure: (abstract: OS-128).

C related HCC who were treated with direct acting antiviral (DAA) therapies at different time points.

Method: This retrospective cohort study included hepatitis C virus (HCV) positive patients who were diagnosed with HCC and managed at King's College Hospital between January 2015 and 2020. Follow-up data was collected until death, liver transplantation or April 2022, whichever came first. Patients with historical or active HCC were included and information about tumour stage and treatments modality were collected. The latter was defined as curative (ablation, resection or liver transplantation) or non-curative (TACE, SIRT, SBRT or systemic therapy). The primary outcome was to compare the SVRs in both HCC groups, and the secondary outcome was to measure the overall survival.

Results: Of the 98 patients included, 82.7% (81) had active HCC at the time of DAA therapy and 17.3% (11) had a historical HCC. The majority (84.7%) were cirrhotic with compensated liver disease and 52% received curative HCC therapy. The overall SVR rate was 81.6%, but decreased to 75.7% in patients with active HCC. In the multivariate analysis, the presence of active HCC at the time of HCV therapy (HR, 5.46: 95% CI, 1.25–23.82, p = 0.024) and the number of HCC nodules (2.19 CI 95% 1.08–4.41, p = 0.029) were the only factors associated with not achieving SVR. Failure to achieve SVR (HR, 9.9: 95% CI, 2.16–46.01, p = 0.003), the presence of more advanced chronic liver disease (i.e. Child Pugh B/C HR 3.7: 95% CI 1.46–9.58) and administration of non-curative treatments (HR 3.2: 95% CI 1.19–8.44) were associated with mortality. The overall survival was higher in those who achieved SVR (*130 m 95% CI 85–174*) and this was consistently irrespective of treatment timing (historical HCC 119 m, 95% CI 102–135; active HCC 78 m, 95% CI 67–88), tumor stage (BCLC A 104 m, 95% CI 93–116; BCLC B/C 60 m, 95% CI 63–85) and treatment intent (curative 117 m *(95% CI 107–128) and non-curative 75 m (95% CI 59–91)* (log-rank test *p* = 0.003).

Conclusion: Treating Hepatitis C in patients with HCC is feasible with acceptable SVR rates.

Failure to achieve SVR is one of the main factors associated with mortality. Overall survival was higher in those who achieved SVR and this was independent of tumor stage or treatment modality

Email: makiyama@montefiore.org

Background and aims: Injection drug use is an important risk factor for viral hepatitis in sub-Saharan Africa, but factors associated with seropositivity are poorly understood. Understanding the prevalence and transmission risk factors is critical to reducing prevalence and incidence among people who inject drugs (PWID). We assessed factors associated with hepatitis C antibody (anti-HCV) and hepatitis B (HBV) positivity among PWID in Kenya.
Method: We are recruiting 3,500 PWID from needle and syringe programs sites in Kenya. Participants are recruited using respondent driven sampling, complete biobehavioral surveys and receive HCV, HBV, and HIV testing. We conducted this analysis using chi-square tests for categorical values and t-tests for continuous variables.
Results: Among the 1526 participants enrolled, participants are mainly male (89.9%) and 34.4 years old (SD = ±8.6) on average. Roughly one-fifth, 314 (20.6%) are anti-HCV positive; regional prevalence is highest in the Coast (175/589, 29.7%), followed by Nairobi (137/589, 23.3%), and Western Region (2/348, 0.6%). HBV surface antigen (HBsAg) follows a similar gradation to HCV moving inland. Overall HBsAg prevalence is 1.4%; 13/589 (2.2%), 6/589 (1.0%) and 2/348 (0.6%), respectively. HBV-positive participants were significantly more likely to be female (23.8% vs 9.9%, p = 0.036), which was not the case for HCV (12.7% vs 9.4%, p = 0.09). However, both HCV-positive and HBV-positive PWID were more likely to have a main sexual partner who injects (30.4% vs 19.9%, p = 0.023) and (55.6% vs 21.5%, p = 0.028), respectively. HCV-positive PWID were more likely to have used supplies previously used by others at their last injection; needle (17.8% vs 7.8%, p < 0.001) and cookers (23.3% vs 9.0%, p < 0.001) when compared to their HCV-negative counterparts. Similar supply sharing patterns were identified for HBV status, HBV-positive PWID were more likely to share needles (23.8% vs 9.7%, p = 0.031) and cookers (28.6% vs 11.7%, 0.018). HCV-positivity was also associated with a history of incarceration (52.9% vs 43.9%, p = 0.004), more years injecting (9.7 vs 5.4, p < 0.001), and exchanging sex to be injected in the last 30 days (0.25% vs. 1.61%, p = 0.011).
Conclusion: Rising anti-HCV prevalence in Kenya (20.6% vs 13.0% in our previous survey) could be attributable to high engagement in risk behaviours such as shared injection equipment, suggesting a need to expand harm reduction interventions and include targeted approaches among PWID with sexual partners who also inject. Due to differing risk factors for HCV and HBV, once size fits all intervention may not be optimal. While preliminary, we anticipate these data will inform policy makers and programs on identifying viral hepatitis elimination and prevention strategies among PWID. Next steps include performing next generation HCV sequencing and phylogenetic analysis to characterize transmission networks and determine factors associated with transmission and cluster membership. We anticipate the latter will be leveraged for targeted elimination strategies to reduce viral hepatitis among PWID with potential for generalizability to other resource limited settings.

LBP-02

Using FIB-4's parameters an explainable black-box machine learning model outperforms FIB-4 index on the diagnosis of advanced fibrosis of non alcohol related fatty liver disease patients in three cohorts from China, Malaysia and India

Athanasios Angelakis[1,2,3], Tianlu Chen[4,5]. [1]*Amsterdam Public Health Research Institute, Netherlands;* [2]*University of Amsterdam, Netherlands;* [3]*Amsterdam University Medical Centers, Netherlands;* [4]*Shanghai Jiao Tong University, China;* [5]*Sixth People's Hospital, China*
Email: a.angelakis@amsterdamumc.nl

Background and aims: Non-alcoholic fatty liver disease (NAFLD) affects over 25% of the general population. FIB-4 index for liver fibrosis is an important non-invasive test which can be used to distinguish advanced fibrosis (F012 vs. F34 in metavir score). Our aim is to tune an explainable machine learning model using as features FIB-4's variables which outperforms FIB-4 on the diagnosis of early/advanced fibrosis of patients with NAFLD.
Method: We use three cohorts from China (train), Malaysia (test1) and India (test2) consisting of 540 (early/advanced fibrosis) 391/149, 147 (116/31) and 97 (65/32) patients with liver biopsy validated hepatic fibrosis. The features of the datasets are: age, sex, alanine transaminase (ALT), aspartate transaminase (AST), platelet (PLT), the ratio AST/PLT and the FIB-4 score. For training the machine learning model on the train dataset and we test it on the test1 and on the test2. For tuning we use 10-fold cross validation (10CV) in order to gain more confidence in our machine learning model regarding its robustness. Even though the number of data instances of our train set is relatively low, we use categorical gradient boosted trees (catboost) which has shown great performance on similar size tabular datasets; it hardly overfits and it is robust. We use feature engineering in order to add more dimensions to our features' space taking powers of products of the initial features. Tuned catboost's parameters' values are: iterators: 111, learning_rate: 0.12 and depth: 16; all other parameters have default values. From explainable artificial intelligence we use shapley values in order to understand the weight of features regarding the predictability of catboost.
Results: We compare our catboost's performance with the FIB-4 score. Catboost on the training set using 10CV, on the test1 and one the test2 achieved the following performance: 10CV: Spec: 0.9301 ± 0.0616 CI95[0.8235, 1.000], Sens: 0.5546 ± 0.1005 CI95[0.3226, 0.75], AUC: 0.7950 ± 0.0649 CI95[0.6809, 0.8902], test1: Spec: 0.9545, Sens: 0.4576, AUC: 0.7976, test2: Spec: 0.7759, Sens: 0.4872, AUC: 0.643. The performance of the FIB-4 using 1.3 as cutoff value was the following on the training set 10CV: Spec: 0.8500 ± 0.0744 CI95 [0.7436, 0.9667], Sens: 0.4893 ± 0.0855 CI95[0.3750, 0.6667], AUC: 0.6997 ± 0.0692 CI95[0.5691, 0.7871], test1: Spec: 0.9109, Sens: 0.4783, AUC: 0.7514, test2: Spec: 0.7414, Sens: 0.4359, AUC: 0.5964.

ELSEVIER

Using our method we observe a relative big improvement of the AUC on the train, test1 and test2 datasets regarding the performance of FIB-4, namely: 13.41%, 6.15% and 7.81%. Using shapley values we observe that the ten most important features regarding the predictability of catboost are: PLT^11, PLT^8, ALT^11, PLT^9, ALT^10, FIB4^3, Age^11, FIB4^2, FIB4^7, FIB4^5. None of this belongs to the initial features.

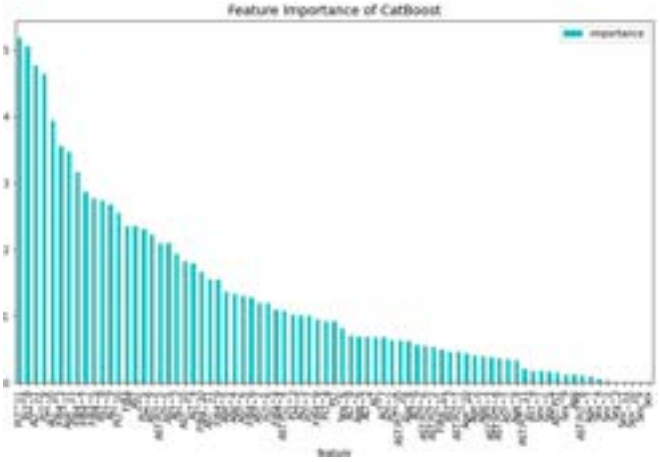

Figure:

Conclusion: Using data science approach, catboost, feature engineering and as features sex and FIB-4's variables, we achieve better performance and more robust solution, than the FIB-4. Using explainable artificial intelligence we identify the importance of powers of the variables of FIB-4 which could lead to an improved version of FIB-4. In addition, we think we should start considering that the classification of NAFLD patients to early versus advanced fibrosis is not a problem which could be approached by linear cut-off values only. It is a more complicated problem and data science using explainable artificial intelligence could help.

LBP-03

Safety and efficacy of continuous infusion terlipressin (BIV201) in patients with decompensated cirrhosis and refractory ascites: a phase 2, randomized, controlled, open-label study

Jasmohan Bajaj[1], Ethan Weinberg[2], K. Rajender Reddy[2], Andrew Keaveny[3], Michael Porayko[4], David Koch[5], Paul Thuluvath[6], Douglas Simonetto[7], Paolo Angeli[8], Sujit Janardhan[9], Eric Orman[10], Sammy Saab[11], Jeffrey Zhang[12], Susan Clausen[13], Joseph Palumbo[13], Penelope Markham[13]. *[1]Richmond VA Medical Center, United States; [2]University of Pennsylvania, United States; [3]Mayo Clinic, Jacksonville, FL, United States; [4]Vanderbilt University, United States; [5]Medical University of South Carolina, United States; [6]Mercy Medical Center, United States; [7]Mayo Clinic, Rochester, United States; [8]University of Padova, Italy; [9]Rush University, United States; [10]Indiana University, United States; [11]David Geffen School of Medicine, University of California, Los Angeles, United States; [12]Princeton Pharmatech, United States; [13]BioVie Inc., United States*
Email: jasmohan.bajaj@va.gov

Background and aims: Patients with cirrhosis and refractory ascites have a poor quality of life. The standard of care (SOC), which includes regular large-volume therapeutic paracentesis (TP), provides only temporary relief and is associated with significant medical complications. Terlipressin, an analog of vasopressin, improves renal perfusion and excretion. BIV201 (terlipressin administered as a continuous infusion by a small ambulatory pump) is being evaluated for reduction of ascites accumulation and related complications in a prospective, phase 2b, open-label, randomized trial.
Method: Fifteen, out of a total of 30, adult patients with diuretic-resistant ascites due to decompensated cirrhosis and 3 to 9 TPs within the previous 60 days were enrolled, monitored for 14-28 days, and randomized 2:1 to receive either continuous infusion of BIV201 (3 mg/day; dose-adjusted to 2-4 mg/day) for two 28-day cycles plus SOC, separated by an up to 56-day washout period, or SOC alone, respectively, for a total of 180 days, followed by a 180-day, long-term follow-up phase. Here we report interim data analysis for safety, change in ascites accumulation (total ascites volume removed by TP), and related parameters.
Results: Mean age of the 15 enrolled patients was 61.3 years, mean MELD-Na was 15.4, and the mean CTP score was 8.7. 10 patients were randomized to receive BIV201 plus SOC and 5 patients received SOC alone. Five (50%) patients in the BIV201 group completed both 28-day infusion cycles; 5 patients discontinued during or at the end of treatment cycle 1. One patient in the SOC-only group withdrew consent at randomization. Patients who completed both treatment cycles of BIV201 plus SOC (n = 5) experienced mean reductions of 43% ($p = 0.063$) in ascites accumulation and 47% ($p = 0.021$) in the mean number of monthly TPs, during the 3 months of treatment, compared with 3 months prior to treatment, vs respective mean reductions of 13% ($p = 0.561$) and 21% ($p = 0.263$) in the SOC-only group. In these patients, after 28 days of treatment, BIV201 treatment was associated with significant improvements in ascites-related symptoms scores ($p = 0.006$), pharmacodynamic measures related to ascites pathophysiology (reduction in serum creatinine [$p = 0.019$] and plasma renin activity [$p = 0.048$]), and health-related quality of life measured by the Chronic Liver Disease Questionnaire ($p = 0.002$), mainly driven by improvements in the abdominal domain. Treatment was generally well tolerated with 1 treatment-related serious adverse event (hyponatremia), which resolved upon treatment withdrawal.
Conclusion: These data indicate that treatment with BIV201 plus SOC may significantly reduce ascites accumulation and its associated symptoms compared with SOC alone. If confirmed in future studies, the current safety profile of BIV201 may support its use for outpatient administration in the treatment of refractory ascites.

Long-term trends of circulating hepatitis B virus RNA and hepatitis B core-related antigen levels in persons with HIV and functional hepatitis B cure during tenofovir therapy

Lorin Begré[1,2], Anders Boyd[3], Marie-Laure Plissonnier[4], Barbara Testoni[4], Franziska Suter-Riniker[5], Charles Béguelin[1], Jürgen Rockstroh[6], Huldrych Günthard[7,8], Alexandra Calmy[9], Matthias Cavassini[10], Hans Hirsch[11], Massimo Levrero[4,12], Gilles Wandeler[1], Fabien Zoulim[4,12], Andri Rauch[1]. *[1]Department of Infectious Diseases, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [2]Graduate School for Health Sciences, University of Bern, Bern, Switzerland; [3]Department of Infectious Diseases, Research and Prevention, Public Health Service of Amsterdam, and stichting hiv monitoring, Amsterdam, Netherlands; [4]UMR Inserm U1052-CNRS 5286, Cancer Research Center of Lyon (CRCL), Lyon, France; [5]Institute for Infectious Diseases, University of Bern, Bern, Switzerland; [6]HIV-Clinic, Department of Medicine I, University Hospital Bonn, Bonn, Germany; [7]Department of Infectious Diseases, University Hospital Zurich, Zurich, Switzerland; [8]Institute of Medical Virology, University of Zurich, Zurich, Switzerland; [9]Division of Infectious Diseases, University Hospital Geneva, University of Geneva, Geneva, Switzerland; [10]Division of Infectious Diseases, Lausanne University Hospital, University of Lausanne, Lausanne, Switzerland; [11]Division of Infectious Diseases and Hospital Epidemiology, University Hospital Basel, University of Basel, Basel, Switzerland; [12]Hepatology Department, Hospices Civils de Lyon and University of Claude Bernard Lyon 1 (UCLB1), Lyon, France*
Email: lorinaaron.begre@insel.ch

Background and aims: Hepatitis B core-related antigen (HBcrAg) and circulating hepatitis B virus (HBV) RNA correlate with intrahepatic covalently closed circular DNA (cccDNA) levels and cccDNA transcriptional activity. Both markers may help improve the understanding of the determinants of functional HBV cure during antiviral

therapy. We aimed to compare long-term trends of HBcrAg and circulating HBV RNA levels in persons with HIV and HBV treated with tenofovir disoproxil fumarate or tenofovir alafenamide in the Swiss HIV Cohort Study.

Method: We included 29 participants experiencing functional HBV cure during tenofovir-containing antiretroviral therapy (ART) and 29 participants without functional HBV cure matched 1:1 based on age, sex, prior treatment with lamivudine and CD4+ T-cell count. We defined functional HBV cure as a quantitative hepatitis B surface antigen (qHBsAg) level <0.05 IU/ml. We measured qHBsAg, HBV DNA, HBcrAg and HBV RNA every six months during the first two years after the initiation of tenofovir and annually thereafter. We assessed the cumulative proportion of participants with undetectable HBV DNA, HBV RNA and HBcrAg levels using Kaplan-Meier estimators in participants with detectable levels at tenofovir start, and compared participants with and without functional HBV cure using Fisher's exact and log-rank tests.

Results: Median follow-up time was 12 years (interquartile range [IQR] 8-14), with functional HBV cure occurring after a median of 4 years (IQR 1-8). Prior to starting tenofovir, 48/58 (83%) participants received lamivudine for a median duration of 6 years (IQR 4-8). At tenofovir start, 15/58 (26%) had HBV DNA levels <20 IU/ml, 7/49 (14%) had HBcrAg levels ≤3 log10 U/ml and 17/49 (35%) had HBV RNA levels <10 copies/ml without significant differences between participants with and without functional HBV cure. All participants with functional HBV cure and 28/29 (97%) without cure achieved HBV DNA <20 IU/ml on tenofovir ($p = 1.00$). Among participants with functional HBV cure, 23/29 (79%) ever achieved HBcrAg ≤3 log10 U/ml and all achieved HBV RNA <10 copies/ml before or at the time of the first qHBsAg <0.05 IU/ml. In comparison, 23/29 (79%) participants without cure achieved HBV RNA <10 copies/ml ($p = 0.02$) and 14/29 (48%) achieved HBcrAg ≤3 log10 U/ml ($p = 0.03$). The cumulative proportions of participants with HBV DNA <20 IU/ml, HBcrAg levels ≤3 log10 U/ml and HBV RNA <10 copies/ml in persons with and without functional HBV cure are depicted in the Figure.

Conclusion: HBV RNA levels decreased to undetectable levels in all persons with HIV and functional HBV cure, whereas a fifth of the persons without cure had detectable HBV RNA levels on long-term tenofovir-containing ART despite HBV DNA suppression. HBcrAg levels decreased during tenofovir therapy, but remained detectable in approximately 20% of persons with and 50% of persons without functional HBV cure.

LBP-05

Dramatic reductions in hepatic steatosis accompanied by improved HbA1c following a 4-week treatment of obese/diabetic/NAFLD patients with DD01, a novel long-acting GLP-1/glucagon receptor agonist

Adam Bell[1], Dennis To[1], Subbu Karanth[1], Svetlana Sosnovtseva[1], Yen-Huei Lin[1], Jaehee Shin[2]. [1]*DandD Pharmatech, Neuraly, Inc, Gaithersburg, United States;* [2]*DandD Pharmatech, Seongnam-si, Korea, Rep. of South*
Email: acbell@neuralymed.com

Background and aims: DD01 is a novel, long-acting dual agonist of the GLP-1 and glucagon receptors. In rodent and non-human primate models, DD01 improved glycemic control, reduced hepatic steatosis, and resulted in weight loss. In rodents the effect on liver fat was more significant than achieved with a comparable dose of semaglutide, consistent with the expected effect of increased hepatic lipolysis achieved through activation of the glucagon receptor. Based on these pharmacologic effects, DD01 was evaluated for safety and its effect on diabetes, obesity, and NAFLD in humans.

Method: A Phase 1 study was conducted in subjects with overweight/obese subjects with type 2 diabetes and NAFLD. Doses from 1-80 mg were evaluated in both single-ascending and multiple-ascending (4 once-weekly doses) cohorts of 8. Safety, tolerability, and PK were assessed for all dose groups. Fasting and post-prandial glucose,

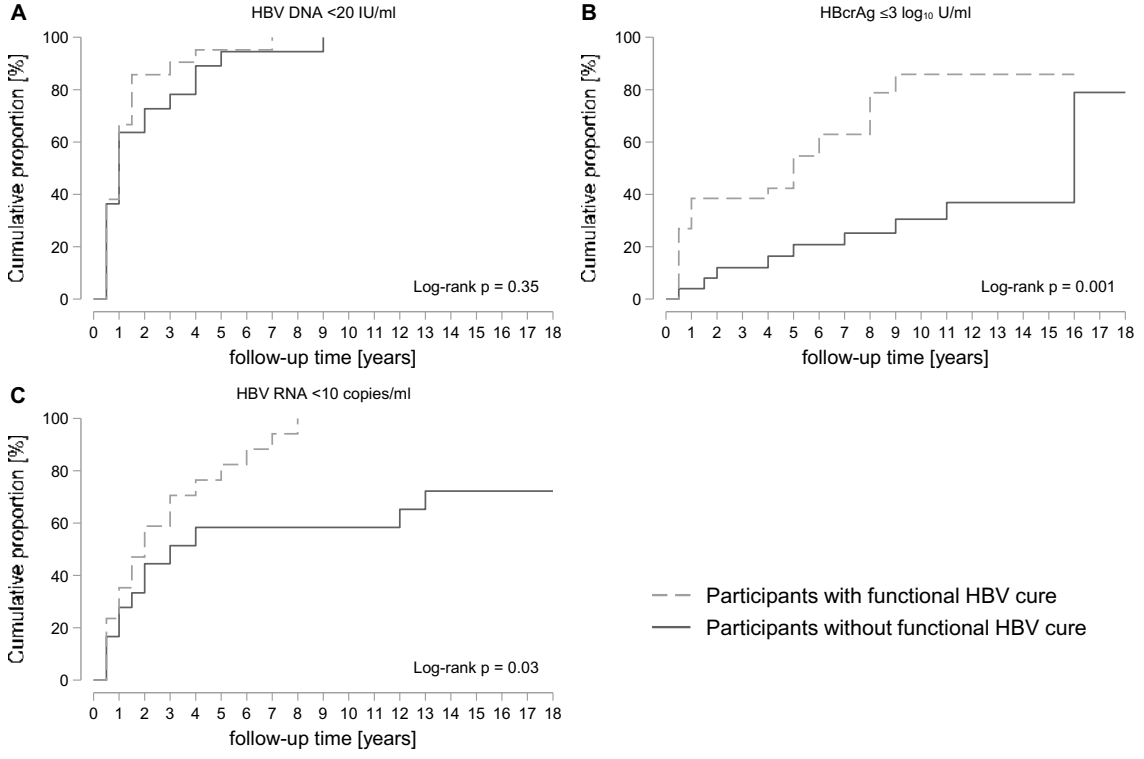

Figure: (abstract: LBP-04): Kaplan Meier curves for cumulative proportions with HBV DNA <20 IU/ml (A), HBcrAg ≤3 log10 U/ml (B) and circulating HBV RNA <10 copies/ml (C) after starting tenofovir-containing antiretroviral therapy, stratified on participants with and without functional HBV cure on tenofovir.

insulin, and glucagon were measured periodically during the dosing period and during a mixed-meal tolerance tests conducted at baseline and after the last dose was administered for each cohort. Liver fat was measured by MRI-PDFF on Day -1 and Day 36. HbA1c and body weight were assessed pre-dose and at the end of 4 weeks dosing.

Results: DD01 treatment resulted in rapid, clinically significant reductions in hepatic steatosis. Reductions in HbA1c were observed at lower and overlapping doses and this was accompanied by reductions in caloric intake and weight loss. DD01 was generally safe and well tolerated. Adverse events were as expected for a GLP-1R agonist and primarily GI-related. DD01 has a half-life of 7-8 days. Following only 4 once-weekly treatments with DD01, up to 100% of patients achieved ≥30% reduction in liver fat as assessed by MRI-PDFF. In the high dose group, all subjects achieved at least a 40% reduction in liver fat with a mean reduction of 52% whereas the change from baseline liver fat in the placebo group was only 2.8%. Substantial reductions in liver fat were observed at doses with minimal effect on body weight underscoring the importance of direct lipogenic action achieved through the glucagon receptor in the liver. Meaningful and rapid improvements in steatosis were observed at well-tolerated doses that did not cause significant weight loss, potentially uncoupling the need for weight loss to precede or coincide with significant improvements in liver health. Over the 4-week treatment period, improved HbA1c, decreased meal-related glucose, and mild weight loss accompanied dose-dependent reductions in hepatic steatosis. DD01 is a dual-pathway GLP-1R agonist augmenting the benefits of the incretin pathway through activation of the glucagon pathway.

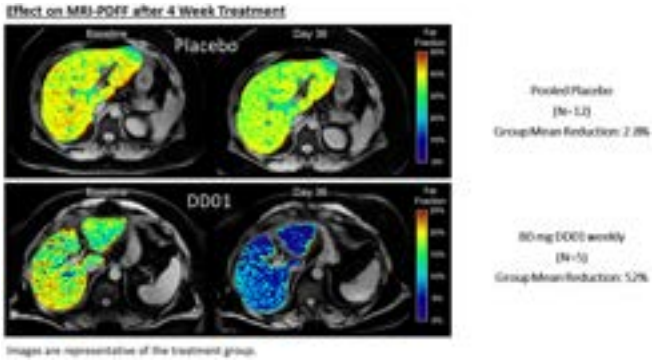

Figure:

Conclusion: DD01 acts through the GLP-1 receptor and glucagon receptor pathways to improve glucose control and rapidly reduce hepatic steatosis. Weight loss is observed at higher doses and it appears that rapid resolution of hepatic steatosis can be achieved independent of weight loss. The combined effects of DD01 may be useful in the treatment of NASH and NAFLD both with and without co-occurring diabetes.

LBP-06

Preventing liver disease with policy measures to tackle alcohol consumption and obesity: a microsimulation study

Email: lise.retat@healthlumen.com

Background and aims: Chronic liver disease (CLD) causes 1.8% of all deaths in Europe. Without policies to mitigate harmful alcohol consumption and obesity, that proportion will continue to increase. This study aims to estimate the impact of policy interventions targeting alcohol and obesity on the incidence of CLD and primary liver cancer in France, the Netherlands, and Romania.

Method: A validated and peer-reviewed microsimulation model was employed using data from online public databases and published literature. Static and dynamic trends in alcohol consumption and body mass index (BMI) respectively were projected from 2022 to 2030. We modeled the incidence of CLD and liver cancer under three policy scenarios versus an inaction scenario. The policies were 1€ minimum unit pricing (MUP) on alcohol; a combination of 0.7€ MUP and a sugar sweetened beverage (SSB) tax; and a combination of 0.7€ MUP, SSB tax, and a volumetric tax on alcohol.

Results: All policies had an important impact ranging from a 2% to 7% reduction in annual incidence of chronic liver disease and liver cancer by 2030. The 1€ MUP policy had the largest predicted impact: In the three countries combined, that policy would result in 11,550 fewer cases of CLD and 7,921 fewer cases of liver cancer by 2030. Policy interventions combining a €0.7 MUP, an SSB tax, and a volumetric tax on alcohol would prevent nearly as many cases: 7,317 cases of CLD and 5,390 cases of liver cancer by 2030 compared with the inaction scenario.

Conclusion: In conclusion, we can reduce the number of Europeans who develop chronic liver disease or liver cancer by up to 7% before 2030 if we introduce a €1 MUP on alcohol, or we introduce complementary public health policies targeting alcohol consumption and obesity.

LBP-07

Validation of the R3-AFP model for risk prediction of HCC recurrence after liver transplantation in the SiLVER clinical trial

Federico Piñero[1], Quirino Lai[2], Charlotte Costentin[3], Andreas Schnitzbauer[4], Helena Degroote[5], Edward Geissler[6], Christophe Duvoux[7]. *[1]Hospital Universitario Austral, Austral University, Liver Unit. Email: fpinerof@cas.austral.edu.ar

Background and aims: Hepatocellular carcinoma (HCC) recurrence risk after liver transplantation (LT) has been evaluated with different prediction models following pathology explant analysis. The inclusion of alpha-feto protein (AFP) in these models, such as the novel R3-AFP score (1), have significantly improved risk stratification of HCC recurrence post-LT. The SiLVER trial (NCT00355862) evaluated the efficacy of mTOR inhibitors (Sirolimus-Group B) compared to mTOR-free based immunosuppression (Group A) to reduce post-LT HCC recurrence (2). Here, we aimed to validate the prognostic and predictive discrimination power of R3-AFP scoring on the

Table: (abstract: LBP-06).

intention-to-treat population (ITT) included in the SiLVER trial (NCT00355862).

Method: We included the intention-to-treat (ITT) patient population from the SiLVER Study. Cox proportional hazard survival analysis was performed, estimating hazard ratios (HR) and 95% confidence intervals (95% CI). Discriminant function was evaluated using the Harrell's c-index. A competing risk regression analysis was also conducted estimating sub-HR. Calibration was conducted through expected versus observed events estimating the baseline hazard.

Results: Overall, 528 patients signed written informed consent of which 20 were excluded for the intention-to-treat analysis (Group A, n = 256; Group B, n = 252). The 5-year recurrence rate in the ITT population was 18.7% (95% CI 15.3-22.6; n = 88 recurrences). The frequency distribution of the R3-AFP score was 42.6% low risk group (n = 216), 35.7% (n = 181) intermediate risk, 19.5% high risk group (n = 99), and 2.2% very high risk group (n = 11). The R3-AFP score correctly stratified HCC recurrence risk (Figure 1) (reference: low risk group): intermediate risk group SHR 1.80 (95% CI 1.02;3.18), high risk group SHR 4.20 (2.41;7.31), and very high risk group SHR 9.55 (3.66;24.92). Discrimination power for the R3_AFP model was 0.75 (95% CI 0.69;0.81) in the ITT population; lower in the mTOR group [Group B 0.67 (0.59-0.75) vs Group A 0.75 (CI 0.69-0.81); P = 0.048]. No significant differences were observed between expected and observed events across R3-AFP strata.

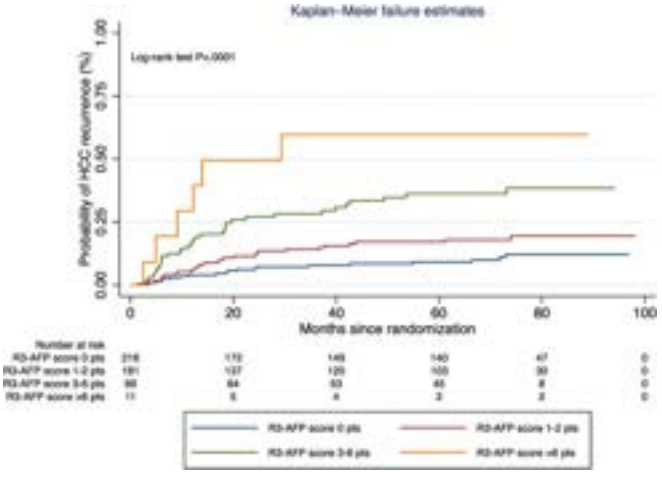

Figure:

Conclusion: The R3-AFP score has been validated in the ITT population of the SiLVER trial, a high-quality evidenced-based data, showing good performance. The model had lower discrimination of the risk of recurrence in exposed subjects with mTOR immunosuppression. This should lead to further hypothesis testing.

LBP-08

High prevalence of short telomeres in patients with idiopathic porto-sinusoidal vascular disorder

Alexander Coukos[1], Chiara Saglietti[2], Monika Haubitz[3], Christine Sempoux[1], Jean-Marc Good[2], Thomas Greuter[2,4], Darius Moradpour[1], Lorenzo Alberio[5], Gabriela Baerlocher[3], Montserrat Fraga Christinet[1]. *[1]Lausanne University Hospital, Gastroenterology and hepatology, Lausanne, Switzerland; [2]Lausanne University Hospital, Lausanne, Switzerland; [3]Department for BioMedical Research of University of Bern (Mu35), Bern, Switzerland; [4]GZO Spital Wetzikon, Wetzikon, Switzerland; [5]Lausanne University Hospital, Hematology and central hematology laboratory, Lausanne, Switzerland*
Email: alexcoukos@gmail.com

Background and aims: Telomeres are repetitive DNA sequences on chromosomal ends which naturally shorten during mitosis, preventing loss of coding DNA. Monogenic loss-of-function mutations in telomere-maintenance genes cause excessive telomeric shortening, leading to cellular senescence and consequently systemic organ dysfunction, a condition referred to as short telomere syndrome (STS). One hepatic manifestation documented in STS is porto-sinusoidal vascular disorder (PSVD). Because the etiology of many cases of PSVD remains unknown, this study aimed to explore the extent to which short telomeres are present in patients with idiopathic PSVD.

Method: This single-center study included patients with idiopathic PSVD and characterized them in depth after histological review and confirmation. Telomere length in six peripheral blood leukocyte subpopulations was assessed by multicolor flow cytometry.

Results: In total, 28 patients were included of whom 19 (68%) had short (12/29) or very short (7/29) telomeres, while nine (32%) had telomere length in the middle part of the age-adjusted reference range (shown as percentiles) calculated from healthy individuals. Seventeen (61%) had clinically significant portal hypertension. The shortest telomeres were found in granulocytes compared to other cell subtypes. Short telomeres were more frequent in males ($p = 0.006$), in patients with portal hypertension ($p = 0.026$) as well as in patients with concomitant interstitial lung disease ($p = 0.001$), chronic kidney disease ($p = 0.002$) and erythrocyte macrocytosis ($p = 0.001$). Low serum albumin ($p = 0.004$), low platelets ($p = 0.048$), hyperbilirubinemia ($p = 0.029$) and a dysmorphic liver on imaging studies ($p = 0.012$) were also associated with short telomeres.

Conclusion: Short telomeres were present at a remarkably high rate in all six cell lines in patients with idiopathic PSVD. This reinforces the hypothesis that they may play a role in the pathogenesis of vascular liver disease. Studies investigating the genetic basis in our patient cohort are ongoing.

Email: gedamico@libero.it

Background and aims: The development of a stage of "further" decompensation in cirrhosis is assumed to be associated with worse survival. However, this has been based on clinical observation rather than on scientific evidence. We investigated the incidence of further decompensation and its impact on mortality in cirrhosis

Method: Multicenter (Europe and Argentina) prospective cohort study. The cumulative incidence of further decompensation was assessed by competing risk analysis in 2028 patients presenting with their first decompensation of cirrhosis (variceal bleeding, ascites, hepatic encephalopathy or jaundice). At inclusion patients' characterization was based on MELD and Child-Pugh scores and on clinical stage defined as follows: stage 3, variceal bleeding alone; stage 4, any non-bleeding event (ascites encephalopathy or jaundice); stage 5, any combination of 2 or more events. Further decompensation was defined as any new ascites, encephalopathy, (re)bleeding or jaundice or complications of ascites (need of large volume paracentesis, spontaneous bacterial peritonitis, acute kidney injury-hepatorenal syndrome). The impact of further decompensation on mortality was assessed by the cause-specific Cox model.

Results: Etiology was viral in 31.5% (mostly untreated), alcoholic 38.6%, alcoholic/viral 10.7%, NASH 8.8%, autoimmune/cholestatic 5.2%. In a mean follow-up of 43 months, 1192 patients developed further decompensation and 649 died. Corresponding 5-year cumulative incidences were: further decompensation 52% and mortality 35%, respectively. The most common further decompensating event was ascites/complications of ascites. Five-year survival was significantly lower in patients with further decompensation compared to the 836 patients who did not develop further decompensation: 35% vs. 50%; P < 0.0001; median survival 273 vs.767 days, p < 0.0001. This significant reduction in survival was observed independent of the stage of first decompensation, including patients whose first decompensation presented with two or more decompensating events. After variceal bleeding further decompensation decreased survival when occurred after 5 days from bleeding. Compared to first decompensation, the hazard ratio for death after further decompensation, adjusted for MELD and other prognostic indicators, was 2.05 (p < 0.001).

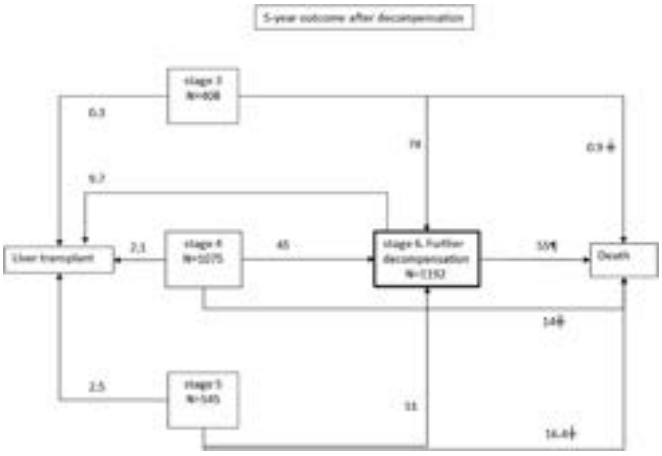

Figure: Summary of 5-year probability of outcome from each decompensated disease stage. Numbers next to the arrows represent the cumulative probability (%) of events from disease stages (3-4-5) at first decompensation or from further decompensation. After first decompensation, most patients develop further decompensation and most deaths occur after further decompensation. Mortality from each decompensation stage (ǂ) was significantly different from mortality after further decompensation (¶) (p < 0.0001 each).

Conclusion: In cirrhosis, further decompensation occurs in approximately 60% of patients after the first decompensating event and significantly increases mortality. We propose that further decompensation be considered a more advanced prognostic stage of cirrhosis, beyond first decompensation.

Prospective direct comparisons of four widespread non-invasive fibrosis tests (NITs) in outpatients with type-2 diabetes (T2D) using EPoS histological staging as reference

Olivier Deckmyn[1], Dominique Valla[2], Valentina Peta[1], Angélique Brzustowski[3], Valérie Paradis[2], Pierre Bedossa[4], Castera Laurent[2], Stanislas Pol[5], Raluca Pais[3], Vlad Ratziu[3], Dominique Thabut[6], Jean-François Gautier[7], Thierry Poynard[1,3,8].

Email: thierry@poynard.com

Background and aims: Very few prospective diagnostic studies have been published, comparing directly non-invasive liver tests (NITs) in T2D only, as well as using recent histological scores and intention to diagnose method. The main end point was to compare the diagnostic performance for the diagnosis of significant fibrosis stage of four NITs: a new FibroTest modified for T2D (FT-T2D), liver stiffness measurement (VCTE), Share-Ware-Elastography stiffness (SWE) and FIB4. The secondary aim was to compare the performance for the diagnostic of significant activity of two NITs: a new NashTest2 modified for T2D (NT2-T2D), and aspartate-aminotransferase (AST) the only NIT combined with VCTE in the FibroScan-AST score (FAST). The third aim was to compare the performance of three NITs for the diagnostic of steatosis ≥30%: a new SteatoTest2 (ST2-T2D), controlled attenuation parameter (CAP) available with VCTE and the hepatorenal gradient available with SWE (SWE-HR).

Method: The reference was a concomitant biopsy, blinded, centralized and scored using EPoS a new seven-tier fibrosis staging system which specifically identifies early versus advanced bridging as two separate stages with more specific bridging definitions than CRN score, and standard SAF/CRN scoring systems for Nash and steatosis (Pais, Hepatology 2022). Main end point was the binary AUROCs (bAUC) for the clinically significant features≥EPoS-F3-stage (Bridging

		Reliability and applicability		In intention to diagnose			Not taking into account reliability and applicability				
Test	Comparator	Test	Comparator	AUC1 Test	AUC2 Comparator	AUC1 - AUC2	AUC1 Test	AUC2 Comparator	AUC1 - AUC2	Standard Error	P-Value
FT-T2D	FIB4	99.8%	99.5%	0.778	0.704	0.074	0.776	0.707	0.071	0.027	0.009

ST2-T2D	CAP	99.8%	93.0%	0.748	0.655	0.093	0.749	0.700	-0.049	-0.042	0.240

Table: (abstract: LBP-10).

fibrosis), ≥SAF-A3-grade activity and ≥SAF-S3-grade steatosis. Obuchowski weighted-AUROC (wAUC) were also compared to take into account the spectrum effects. Intention to diagnose (ITD) was used to adjust the AUCs according to applicability and liability of NITs. Learning and validation subsets of T2D-modified NITs used a k-fold randomization.

Results: Between 2018 to 2022, 713 outpatients were investigated in four diabetes clinics (NCT03634098), and 402 with interpretable biopsy were included, median age 59 years, 63% male, 58% NASH, 39% bridging. Results are detailed in Table1 for the diagnosis of Bridging fibrosis. Due to lower applicability and liability the VCTE performance decrease by more than 5% vs the 3 other NITs when ITD method is used ($p < 0.05$). SWE, FT-T2D and VCTE AUROCs (0.795, 0.778 and 0.758) were not significantly different for Bridging ($p > 0.19$) and all three higher than FIB4 (0.704;$P < 0.01$). For the diagnosis of activity grades≥SAF-A3-grade, the bAUC in ITD of NT2-T2D was 0.759, and 0.709 for AST alone. For the diagnostic of steatosis grades≥SAF-S3-grade, the bAUC in ITD of ST2-T2D was 0.748, 0.718 for SWE-HR and 0.655 for CAP.

Conclusion: For the first time four fibrosis NITs were directly compared in ITD in a prospective study of T2D outpatients using a more specific definition of advanced fibrosis. SWE, new FT-T2D and VCTE performances were not significantly different for the diagnostic of Bridging ($p > 0.19$) and all three higher than FIB4 score.

Email: elisabetta.degasperi@policlinico.mi.it

Background and aims: Bulevirtide (BLV) has been conditionally approved by EMA for treatment of chronic compensated hepatitis D

virus (HDV) infection, however real-life data in large cohorts of cirrhotic patients are lacking.

Method: Consecutive compensated HDV cirrhotic patients starting BLV 2 mg/day since July 2019 were included in a retrospective multicenter real-life European study. Clinical, biochemical and virological features at BLV start and during treatment were collected. Virological response (HDV RNA undetectable or ≥2-log decline vs. baseline), biochemical response (ALT <40 U/L), combined response (biochemical + virological) and adverse events were assessed. HDV RNA was quantified locally. Liver-related events (hepatocellular carcinoma, decompensation, liver transplantation) were recorded.

Results: 176 patients receiving BLV monotherapy up to 96 weeks [median follow-up: 48 (8-96) weeks] were included: at BLV start, age was 50 (19-82) years, 59% men, ALT 77 (23-1, 074) U/L, liver stiffness measurement (LSM) 18.3 (6.4-75.0) kPa (30% with LSM >25kPa), platelets 89 (17-330) G/L (80% with PLT<150 G/L), 100% CPT score A, 9% HIV-positive, 46% with oesophageal varices, 12% with history of previous ascites, 6% with active HCC, 91% on NUC. Median HDV RNA and HBsAg levels were 5.38 (1.18-8.48) Log IU/ml and 3.7 (0.8-4.5) Log IU/ml, respectively. Rates of virological responses at W24, W48 and W96 were 48%, 66% and 77%, respectively; HDV RNA was undetectable in 16%, 33%, and 43% patients. Biochemical response was achieved by 60%, 69% and 73% at W24, W48 and W96, respectively, while rates of combined response were 28%, 48% and 58%. Patients with <1 log HDV RNA decline vs baseline declined from 25% at W24 to 18% at W48. In the 15 HIV-positive patients, HIV-RNA persisted undetectable during treatment without significant changes in CD4 T-cell count; rates of virological response were similar to HIV-negative patients. Bile acids significantly increased, 10% patients reported mild and transient pruritus. Injection site reactions occurred in 3% of cases; 1 patient discontinued BLV due to a grade 3 maculopapular rash with mild eosinophilia. 4 patients were lost to follow-up and 3 discontinued due to primary non response. The W96 cumulative risk of de-novo HCC (7 cases) and decompensation (n = 2 ascites, n = 1 variceal bleeding) was 5.9% (95% CI 2-12%) and 2.4% (95% CI 1-5%), respectively. Six (3%) patients underwent liver transplantation (n = 4 for HCC, n = 2 for end-stage liver disease; BLV stopped at transplant) and 2 patients died of BLV-unrelated causes (pneumonia and intestinal infarction). The overall cumulative survival rate was 93% (95% CI 88-98%) at W96.

Conclusion: BLV 2 mg/day monotherapy up to 96 weeks was safe and effective in patients with HDV-related compensated cirrhosis. Virological and clinical responses increased over time. The risk of decompensation was very low.

LBP-12

Off-label Bulevirtide monotherapy for chronic hepatitis D virus infection in patients with decompensated liver disease

Christopher Dietz-Fricke[1], Elisabetta Degasperi[2], Pietro Lampertico[2], Mathias Jachs[3], Thomas Reiberger[3], Julia Grottenthaler[4], Christoph Berg[4], Toni Herta[5], Florian van Bömmel[5], Johannes Wiegand[5], Thomas Berg[5], Florian P Reiter[6], Andreas Geier[6], Kathrin Sprinzl[7], Stefan Zeuzem[7], Peter Buggisch[8], Benjamin Maasoumy[1], Markus Cornberg[1], Heiner Wedemeyer[1], Katja Deterding[1]. *[1]Hannover Medical School, Dept. of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Germany; [2]University of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Italy; [3]Department of Medicine III, Division of Gastroenterology and Hepatology, Medical University of Vienna, Austria; [4]University Hospital Tuebingen, Tuebingen, Germany, Department of Gastroenterology, Gastrointestinal Oncology, Hepatology, Infectiology, and Geriatrics, Germany; [5]Leipzig University Medical Center, Division of Hepatology, Clinic and Polyclinic for Gastroenterology, Hepatology, Infectiology, and Pneumology, Germany; [6]University Hospital Würzburg, Division of Hepatology, Department of Medicine II, Germany; [7]Goethe University Hospital, Internal Medicine Department, Germany; [8]ifi-Institute for interdisciplinary medicine, Hamburg, Germany*
Email: dietz-fricke.christopher@mh-hannover.de

Background and aims: Chronic hepatitis D virus infection is the most debilitating form of viral hepatitis causing severe hepatic damage consequently leading to liver cirrhosis. Bulevirtide (BLV) has been conditionally approved by the EMA for the treatment of chronic hepatitis D virus infection in patients with compensated liver disease. Its safety and efficacy on HDV viral load and ALT levels has been demonstrated for compensated patients in clinical trials and recently published real world cohorts. However, BLV data in the vulnerable collective of patients with decompensated cirrhosis are still lacking. We thus, aimed to report real-world data obtained from patients with decompensated HDV cirrhosis in whom BLV was used off-label.

Method: We collected anonymized and retrospective data from Austrian, Italian and German centers experienced in the use of BLV. Patients with HDV cirrhosis at Child-Pugh stages B and C or clinical signs of decompensated cirrhosis were included. Virologic response was defined by a decline in HDV-RNA levels by ≥2 log while virologic non-response was defined if HDV-RNA decline was <1 log decline.

Results: We included 15 patients (Child-Pugh A n = 1, Child-Pugh B n = 14) with 10 patients showing ascites at BLV initiation. The patient with Child-Pugh A liver cirrhosis had history of large volume paracentesis due to ascites but resolution of ascites under ongoing diuretics at treatment initiation. However, given the uncontrolled CHD the patient was considered as decompensated following the Baveno VII recommendations. At baseline hypoalbuminemia was present in 9 patients (mean 33 ± 4.6 g/dL), hyperbilirubinemia (>34.2 µmol/l) in 6 patients (mean 36.1 ± 24.6 µmol/l) and thrombocytopenia (platelets <150 G/L) in all patients-indicating portal hypertension.

Virologic response was achieved after a mean of 23 weeks in 10 (66%) patients while viral non-response did not occur. ALT levels significantly decreased under BLV therapy (see figure) and normalized in 7 (47%). Under BLV treatment liver function improved from Child-Pugh B to Child-Pugh A in 4 cases. Ascites improved in 4 patients. Hepatic improvement was associated with virologic and biochemical response. In one case a worsening of liver function to Child-Pugh C occurred after off-label pegylated interferon was added to BLV treatment (data censored after start of interferon). Another case experienced further decompensation after TIPS insertion and incarceration of a hernia. In both cases decompensation was not attributed to BLV therapy. In 3 cases BLV was terminated at liver transplantation.

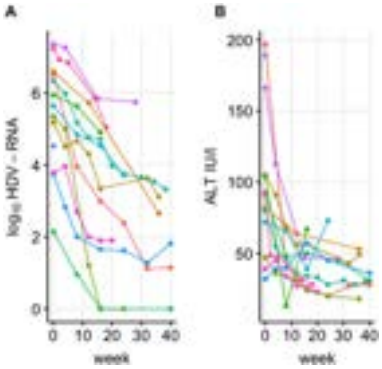

Figure 1. Decline in HDV-RNA (A) and ALT (B) in patients with decompensated liver disease under BLV treatment. Shown are individual data points from patients with complete data sets (n = 13). Viral response was achieved in 10 cases.

Conclusion: The off-label use of BLV in patients with decompensated cirrhosis and impaired liver function results in a decline in HDV-RNA and ALT levels. Improvement of liver function and cirrhosis recompensation may be achieved in selected patients. While some patients developed further decompensation, this was not related to the use of BLV. This case report series supports the antiviral efficacy of BLV also in decompensated cirrhosis. To investigate long term efficacy

of BLV on clinical end points and its safety profile in this highly vulnerable patient population with decompensated cirrhosis, prospective clinical trials are urgently needed.

LBP-13

Safety, pharmacokinetics and antiviral efficacy of freethiadine, a novel capsid assembly modulator, in healthy volunteers and patients with chronic hepatitis B virus infection

Yanhua Ding[1], Xiaojiao Li[2], Jia Xu[3], Jixuan Sun[1], Yingjun Zhang[4], Jing Zhu[5], Yujie Chen[4], Lin Luo[6], Qingyun Ren[6], Yunfu Chen[6], Junqi Niu[7]. *[1]Phase I Clinical Trial Center, The First Hospital of Jilin University, Changchun, China; [2]Phase I Clinical Trial Center, The First Hospital of Jilin University, Changchun; [3]Phase I Clinical Trial Center, The First Hospital of Jilin University, Changchun, China; [4]Sunshine Lake Pharma Co., Ltd., Guangdong, China; [5]Sunshine Lake Pharma Co., Ltd., Guangdong, China; [6]Sunshine Lake Pharma Co., Ltd., Guangdong, China; [7]Department of Hepatology, The First Hospital of Jilin University, Changchun, China*
Email: dingyanh@jlu.edu.cn

Background and aims: Freethiadine is a novel capsid assembly modulator (CAM) developed by Sunshine Lake Pharma Co., Ltd. Here we report the safety, tolerability, pharmacokinetics (PK), and 28-day antiviral activity of freethiadine in two randomized, double-blinded phase I studies in healthy subjects and patients with chronic HBV infection (CHB).

Method: The studies were consisted of two parts. Part 1 was a double-blind, randomized, placebo-controlled single-ascending-dose (SAD, 50-600 mg), multiple-ascending-dose (MAD, 100 mg, 200 mg, or 300 mg, BID) and food effect (200 mg) study. Part 2 was a double-blind, double-dummy, randomized, entecavir controlled, multi-dose escalation study in CHB patients. Patients were randomized 4:1 to freethiadine+ entecavir placebo or entecavir 0.5 mg+ freethiadine placebo across 4 multiple-dose cohorts: freethiadine 100 mg once a day (QD), 200 mg QD, 200 mg twice a day (BID), and 300 mg QD for 28 days.

Results: A total of 88 healthy subjects and 40 CHB patients were enrolled in the study. Freethiadine was safe and well tolerated both in healthy subjects and CHB patients. The paresthesia was occured among both healthy subjects and patients when the freethiadine dose greater than 300 mg. Grade I or II alanine aminotransferase (ALT) elevation was the most common AE (12.5%-50%) among freethiadine treated patients, and the incidence and severity was not related to the dose. Only two grade III ALT elevation occurred at 200 mg QD and 300 mg QD cohorts, respectively. All the ALT elevation was correlated with the decline in the HBV DNA levels, which is "good flare". Absoption and elimination of HEC160208 and active metabolite HEC142106 occurred rapidly in plasma. In the SAD study, median Tmax of HEC160208 and HEC142106 was 1.75-3.0 h, 2.5-4 h, and t1/2 ranged from 0.71-2.02 h, 1.95-5.84 h, respectively. The exposure of HEC160208 and HEC142106 was proportional to dose and was not significantly affected by food intake. The HEC160208 exposure of 100 mg has exceeded that of the the effective dose in the preclinical mouse model. In the MAD study, steady-state was attained on day 3, and there was no apparent plasma accumulation of HEC160208 and HEC142106 after 10-day dosing. (Racc <1.0). The exposure of both analytes was slightly higher in CHB patients than that in the healthy subjects. After 28 days of treatment, the mean maximum HBV DNA declines from baseline were -2.76, -3.47, -3.56, -2.89, and -2.55 log10 IU/ml for the 100 mg QD, 200 mg QD, 200 mg

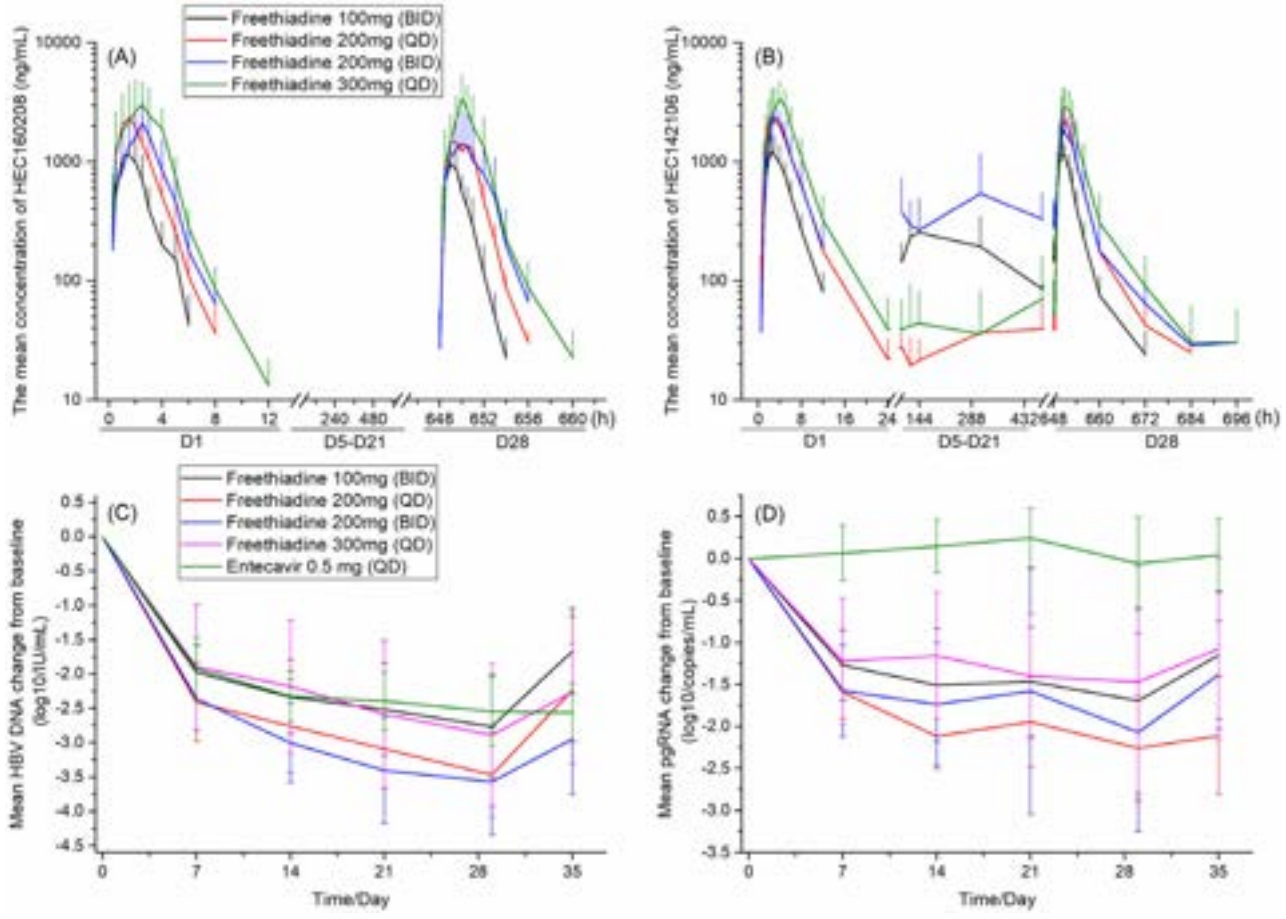

Figure: (abstract: LBP-13).

BID, and 300 mg QD of freethiadine or entecavir control cohorts, respectively; and the mean maximum pregenomic RNA (pgRNA) declines from baseline were -1.69, -2.26, -2.07, -1.47, and -0.06 log10 copies/ml, respectively. The numbers of patients whose HBV DNA level was reduced below the lower limit of quantification (LLOQ) after 28 days of administration were 3 (37.5%), 0, 3 (37.5%), 3 (37.5%), and 3 (37.5%), respectively. HBV DNA decrease did not differ substantially between HBeAg (-) and HBeAg (+) patients, however, the pgRNA decreased more in HBeAg (+) patients than in HBeAg (-) patients after freethiadine treatment, especially in 300 mg QD cohort. There were no significant changes in the levels of HBsAg, HBeAg, and HBcrAg.
Conclusion: Freethiadine showed an acceptable safety profile and efficacious antiviral activity in CHB patients, 200 mg freethiadine (QD or BID) can be considered for further development in treating HBV infection.

LBP-14
Evaluation of 8 non-invasive models in predicting NAFLD severity and progression in a one-year prospective study based on MRI-PDFF

Aruhan Yang[1], Lei Zhang[1], Hong Chen[1], Guoyu Lv[1], Xiaoxue Zhu[1], Yanhua Ding[1]. [1]*First hospital of Jilin University, China*
Email: arh20@mails.jlu.edu.cn

Background and aims: Although biopsy remains the gold standard for assessing NAFLD, several non-invasive models can provide useful estimates. The aim of this prospective study was to compare the accuracy of eight non-invasive methods to predict steatosis and disease progression.
Method: A total of 846 samples were collected, among which 236 samples were collected from participants with two examinations (baseline and 1 year). The liver fat content (LFC, measured by MRI-PDFF) decrease/increase by 20% from baseline was classified as the Improve/Progression group, and the others were referred to as the Keep group. Eight models (FAST, HSI, FLI, KANFLD, BAAT, LAP, Liver Fat Score, Liver Fat Equation) were calculated in agreement with previous studies, and their performances in diagnosing NAFLD and predicting progression were compared based on the MRI-PDFF.
Results: The 8 clinical models performed well in predicting different degrees of NAFLD in this cohort (healthy: N = 146, 17.3%; mild NAFLD: N = 400, 47.3%; moderate NAFLD: N = 257, 30.4%; severe NAFLD: N = 43, 5%), especially KNAFLD (the highest AUC of diagnosis was 0.90). Within the whole cohort, the correlation analysis revealed that KNAFLD was most strongly correlated with LFC ($r = 0.56$, $P < 0.01$, Figure 1), and other clinical models (FAST, liver fat score, BAAT, HSI, FLI, LAP, liver fat equation) also showed weaker but significantly positive correlations with LFC (correlation coefficients: 0.48, 0.48, 0.45, 0.43, 0.38, 0.35, 0.33, respectively; $P < 0.05$ for all).When the KNAFLD score was above 2.935, the LFC was significantly higher (4.4% vs. 19.7%, $P < 0.001$). After 1 year of follow-up, FAST performed best in predicting NAFLD progression (AUC = 0.84), correlation analysis showed that the association between the changes in FAST and LFC was the strongest ($r = 0.42$, $P < 0.01$), followed by KNAFLD ($r = 0.39$, $P < 0.01$) ; when the change in FAST from baseline was lower than -0.012, the LFC significantly decreased (from 11.5% to 8.5%, $P < 0.05$), and when it was higher than -0.012, the LFC increased from 8.6% to 10.9% ($p < 0.05$).
Conclusion: Most non-invasive techniques are correlated with LFC and have acceptable accuracy in estimating the degree and progression of NAFLD, especially KNAFLD. FAST has the best accuracy in predicting NAFLD progression.

Background and aims: Bepirovirsen (BPV) is an investigational novel unconjugated antisense oligonucleotide for treatment of chronic hepatitis B virus (HBV) infection. Data from the Phase 2b B-Clear study (NCT04449029) indicated that a subset of participants (pts) achieved a response at end of BPV treatment, which was sustained for

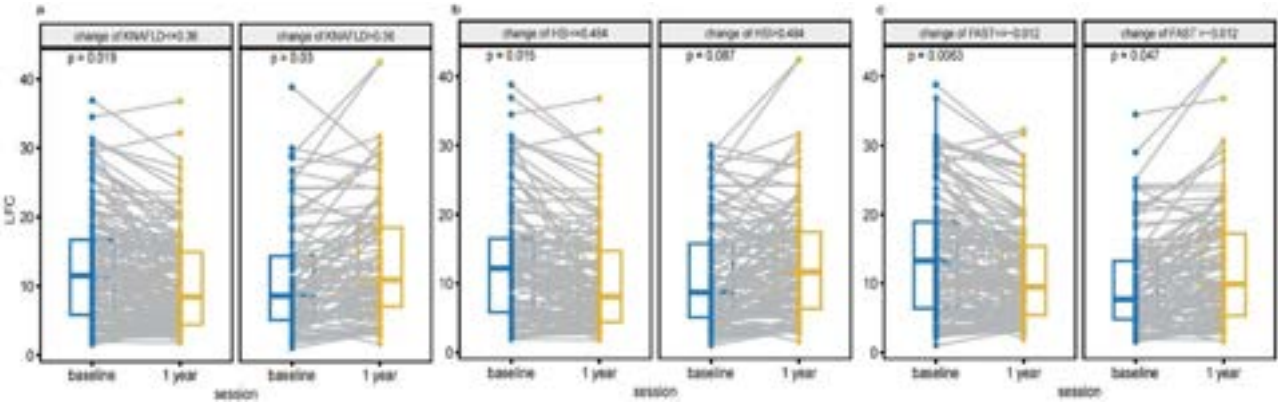

Figure: (abstract: LBP-14).

24 weeks' follow-up. This occurred in pts on and not on nucleos(t)ide analogue (NA) therapy (On-NA and Not-on-NA), in the absence of newly initiated antiviral therapy. Pts who achieved a partial or complete response at the end of study (EoS) visit were eligible for this long-term durability study-B-Sure (NCT04954859). Here we present preliminary data from the first annual review to examine the durability of response for B-Clear On-NA and Not-on-NA complete responders (hepatitis B surface antigen [HBsAg] <0.05 IU/ml and HBV DNA <lower limit of quantification) who enrolled into B-Sure.

Method: Not-on-NA pts will be followed up at Month 3, Month 6, and every 6 months thereafter for up to 36 months after B-Clear EoS. On-NA pts, if eligible, will cease NA 6 months after B-Clear EoS visit and be followed more intensively. Adverse events were recorded, and physical exams and blood tests were performed at each visit to assess safety and response. Durability of response was assessed:

a) On-NA: Time from NA cessation to loss of complete response.

b) Not-on-NA: Time from achieving a B-Clear complete response to loss of response.

Results: 13/16 On-NA and 12/14 Not-on-NA complete responders in B-Clear enrolled into B-Sure (Figure); 12 On-NA and 12 Not-on-NA pts remain in the study at the time of reporting. For On-NA pts (n = 13), 12 (92%) were male, with a mean age of 53.2 years; 6/13 (46%) had chronic HBV infection for ≥20 years, 10/13 (77%) were hepatitis B e antigen (HBeAg) negative and 9/13 (69%) had HBsAg ≤1000 IU/ml at B-Clear study baseline. 9/13 (69%) pts ceased NA as per protocol, 3/13 (23%) were not eligible to cease NA and 1/13 (8%) withdrew prior to NA cessation. 7/9 (78%) of those who ceased NA had complete data with ≥3 months of follow-up, and 6/7 (86%) maintained response 3 months post NA cessation. 4/9 (44%) had complete data with ≥6 months of follow-up post NA cessation, of whom 100% (4/4) maintained response. No pts restarted NAs. For Not-on-NA pts (n = 12), 7 (58%) were male with a mean age of 43.8 years; 3/12 (25%) had chronic HBV infection for ≥20 years, all were HBeAg negative and 7/12 (58%) had HBsAg ≤1000 IU/ml at B-Clear study baseline. 9/12 responders (75%) had complete data with ≥3 months of follow-up and 78% (7/9) maintained response 3 months after enrolling into B-Sure. 3/12 (25%) had complete data with ≥9 months of follow-up, of

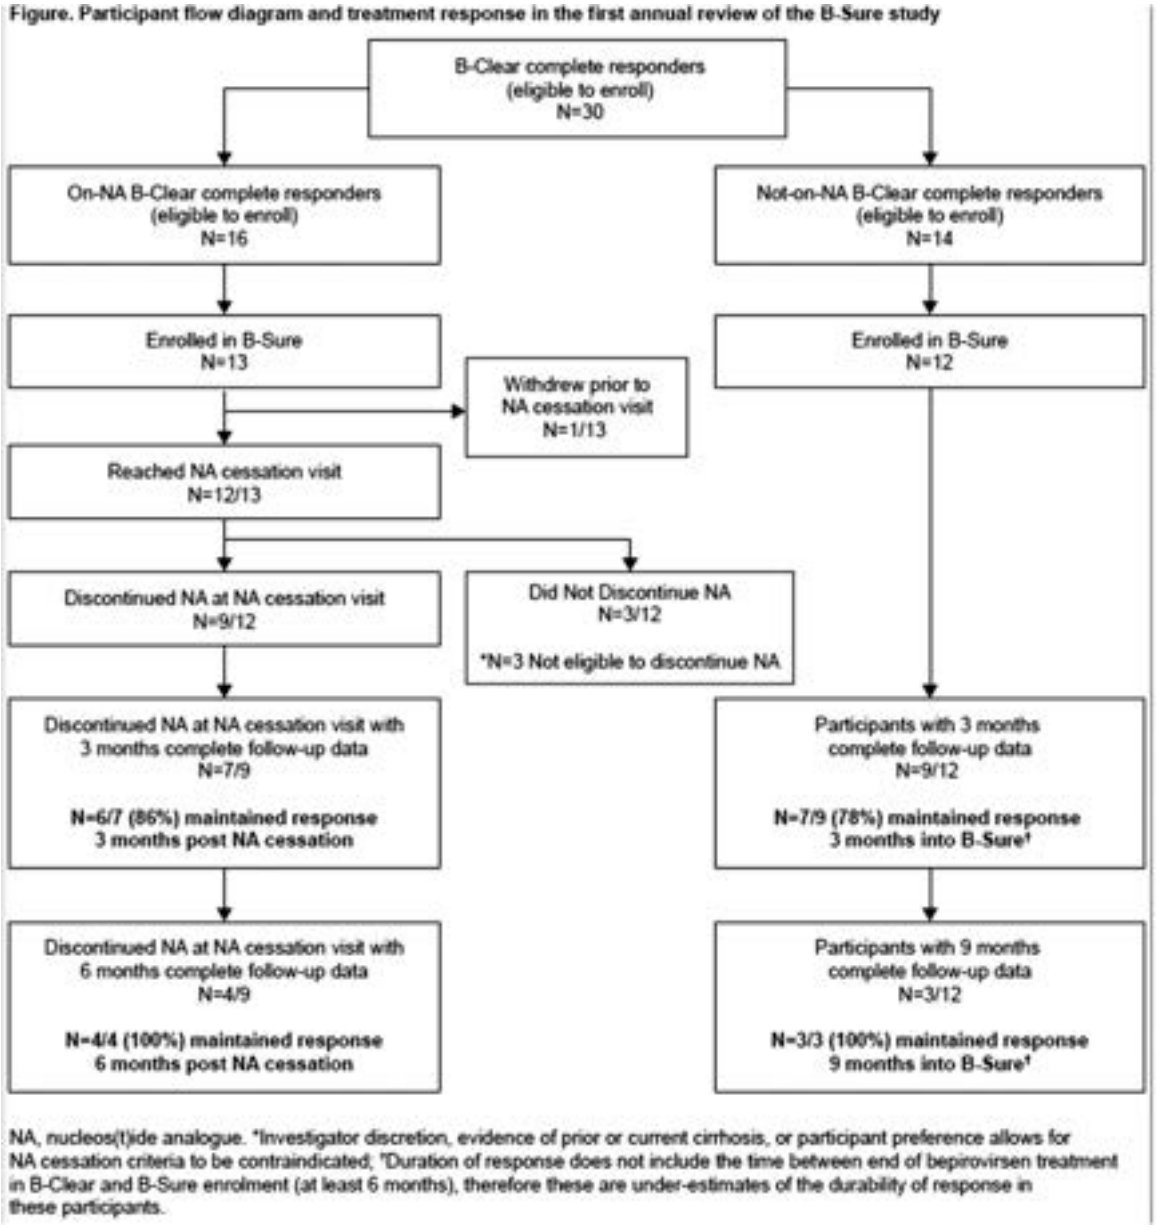

Figure: (abstract: LBP-15).

whom 100% (3/3) maintained response 9 months into B-Sure. There were no safety signals that suggested a latent adverse drug effect following use of BPV.
Conclusion: These data provide early evidence on the durability of response observed with BPV.

LBP-16

Hepatocellular carcinoma surveillance improves early detection and curative treatment in chronic hepatitis C patients treated with direct acting antivirals

Cassia Regina Guedes Leal[1], Carmem Ferguson Theodoro[1], Thais Guaraná[1], Jorge Strogoff-de-Matos[1], Rosângela Teixeira[2], Renata Perez[3], Paulo de Tarso Aparecida Pinto[4], Tatiana Guimaraes[1], Solange Artimos[1]. *[1]Antonio Pedro University Hospital, Fluminense Federal University, Brazil; [2]Minas Gerais Federal University, Brazil; [3]Federal University of Rio de Janeiro, Brazil; [4]Hospital Federal dos Servidores do Estado, Brazil*
Email: cassia.r.g.leal@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is the third leading cause of cancer mortality worldwide. HCC prognosis remains poor, partly because up to 70% of patients are diagnosed with advanced HCC at initial presentation. As with other cancers, surveillance programs aim to detect tumors at an early stage, facilitate curative-intent treatment, and reduce cancer-related mortality. The aim of this study was to evaluate the incidence of HCC and the impact of surveillance on early diagnosis in patients with chronic hepatitis C virus (HCV) treated with direct antiviral agents (DAAs).
Method: A cohort of 1075 HCV patients ≥18 years were treated with DAAS from 2015 to 2019 and followed until 2022. Ultrasonography was performed up to 6 months before DAAs and each 6 months thereafter for patients with advanced fibrosis (F3 and F4 METAVIR). HCC diagnosis was established based on the criteria of the European Association for the Study of the Liver and staging according to the Barcelona Clinic Liver Cancer (BCLC) system.
Results: Of the total, 51/1075 (4.7%) developed HCC in the median of 40 (IQR 25-58) months: 26/51 (51%) male, median age 60 (IQR 54-66) years, alpha-fetoprotein (AFP) 12.2 (IQR 6.1-18.8) ng/ml, 47/51 (92.1%) cirrhotic (78.7%; Child-Pugh (CP) A and 21.3% CP B), 8/51 (15.7%) without sustained virological response (SVR). Cumulative HCC incidence was 6.5%. Overall incidence was 1.46/100 patient-years (PY) (95% CI = 1.09-1.91), being 2.31/100 PY (95% CI = 1.70-3.06), 0.45/100 PY (95% CI = 0.09-1.32) and 0.20/100 PY (95% CI 0.01-1.01) in METAVIR F4, F3 and F2, respectively. According to BCLC, liver tumors were classified as follows: 0 (8/51, 15.6%), A (26/51, 51%), B (11/51, 21.6%), C (5/51, 9.8%) and D (1/51, 2%). Among patients with early HCC diagnosis, 71% received potentially curative treatment.
Conclusion: HCC still occurs after HCV treatment with DAAs, mainly in METAVIR F4 patients. According to our findings, screening favored early diagnosis in approximately 70% of patients, facilitating earlier initiation of potentially curative treatments thus improving the prognosis of these patients.

LBP-17

Artificial intelligence to measure fibrosis change on liver biopsy in MAESTRO-NASH a phase 3 52-week serial liver biopsy study in 966 patients with NASH treated with resmetirom or placebo

Stephen Harrison[1], Rebecca Taub[2], Dominic Labriola[2], Yayun Ren[3], Elaine Chng[3], Dean Tai[3]. *[1]Pinnacle Research, United States; [2]Madrigal Pharmaceuticals, RandD, United States; [3]Histoindex, Singapore*
Email: rebeccataub@yahoo.com

Background and aims: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, Phase 3, registrational double blind, placebo-controlled non-cirrhotic NASH clinical trial to study the effect of once daily 80 mg or 100 mg resmetirom as compared with placebo in 966 patients with NASH and liver fibrosis. NASH resolution and fibrosis reduction end points on liver biopsy at 52 weeks were achieved at both resmetirom doses, including at least a one stage reduction in fibrosis without worsening of NASH of 24%, 26% (mITT) at 80 and 100 mg doses compared with placebo (14%). As an exploratory end point, artificial intelligence slide reading technologies were employed to measure the effect on fibrosis on serial liver biopsy using both continuous and quantitative scoring.
Method: Fibrosis was estimated as a continuous and categorical variable using second harmonic generation (SHG) (qFibrosis)/two photon excited fluorescence of 768 paired biopsy samples from MAESTRO-NASH. A separate unstained slide was analyzed for qFibrosis (normalized by tissue area and then corrected for qSteatosis (tissue area-steatosis area)). Relative changes in 184 fibrosis parameters were determined.
Results: The analyses were based on a total of 768 slide pairs including a baseline and Week 52 slide that were received and met criteria for quality (<10% missing pairs; <3% excluded for quality). Based on a continuous qSteatosis score, the % change from baseline in steatosis was 80 mg, -36%; 100 mg, -46%, placebo, -10%, $p < 0.0001$ for both doses, the continuous change from baseline in corrected qFibrosis score was 80 mg, -22%; 100 mg, -20%; placebo, 3%, $p < 0.0001$ for both doses. The categorical qFibrosis stage aligned with pathologist scoring (F1, F2, F3) with the exception that qFibrosis estimated a high fraction ~20% as F4 stage fibrosis at baseline (F4 stage scored at baseline by central pathologists were excluded from this study). Based on categorical change in qFibrosis score, there was a significant improvement in fibrosis stage (1-stage or 2-stage improvement) at 80 and 100 mg relative to placebo, and less worsening of fibrosis in the resmetirom treatment groups compared with placebo (Table). The percentage showing improvement in qFibrosis (≥1-stage) was higher than scored by pathologists, and identified 90% of resmetirom responders determined by pathologists. Significant correlations were observed between reduction in qFibrosis and reduction in PDFF, ALT, AST, and ELF.

Categorical change in qFibrosis stage						
	≥1-stage improvement	p value	≥2-stage improvement	p value	worsened	p value
80 mg	58%	<0.0001	19%	<0.0001	11%	<0.0001
100 mg	56%	<0.0001	25%	<0.0001	11%	<0.0001
PBO	34%		7%		35%	

Conclusion: Measurements of fibrosis change using qFibrosis on either a continuous or categorical scale demonstrated a clear improvement and less worsening in fibrosis in resmetirom treated NASH patients as compared with placebo after 52 weeks of treatment.

LBP-18

ALG-000184, a capsid assembly modulator, dosed with entecavir for up to 28 weeks is well tolerated and resulted in substantial declines in surface antigen levels in untreated Hepatitis B e antigen positive subjects with chronic hepatitis B

Jinlin Hou[1], Yanhua Ding[2], Junqi Niu[2], Xieer Liang[1], Man-Fung Yuen[3], Edward J. Gane[4], Kosh Agarwal[5], Min Wu[6], Kha Le[7], Meenakshi Venkatraman[7], Christopher Westland[7], Maida Maderazo[7], Sushmita Chanda[7], Leonid Beigelman[7], Lawrence Blatt[7], Tse-I Lin[8], Matt McClure[7], John Fry[9]. *[1]Nanfang Hospital, Southern Medical University, China; [2]Jilin University, the First Hospital, China; [3]University of Hong Kong, Hong Kong; [4]University of Auckland, New Zealand; [5]King's College, United Kingdom; [6]Aligos Therapeutics (Shanghai) Co., Ltd, China; [7]Aligos Therapeutics, United States; [8]Aligos Belgium BV, Belgium; [9]Consultant, United States*
Email: jlhousmu@163.com

Background and aims: To evaluate the safety, pharmacokinetics (PK), and antiviral activity of

ALG-000184, an oral prodrug of ALG-001075, a novel, pan-genotypic capsid assembly modulator with picomolar potency.
Method: ALG-000184-201 is a multi-part, multi-center, double-blind, randomized, placebo-controlled study (NCT04536337). Single and multiple ALG-000184 daily doses have previously been shown in Parts 1-3 to be well tolerated for dosing durations of 1-28 days and have potent antiviral activity in untreated chronic hepatitis B (CHB) subjects. In Part 4, multiple cohorts are evaluating dosing with ALG-000184 (100 mg x 24 weeks in Cohort 1 and 300 mg x 48 weeks in Cohort 2) in combination with entecavir (ETV) in untreated hepatitis B e antigen positive (HBeAg +) CHB subjects. Previously, available data from Cohorts 1 and 2 have shown that ≤300 mg ALG-000184 + ETV for ≤28 weeks is well tolerated and lowers hepatitis B DNA and surface antigen (HBsAg) levels. Here we report newly emerging safety, PK, and antiviral activity data from Cohort 2.
Results: Fifteen subjects were enrolled, all of which were Asian, with 7 (47%) female, mean age 31.4 years and body mass index 22.2 kg/m^2. Baseline alanine aminotransferase (ALT) was elevated in 8 (53%) of subjects and all subjects were genotype B (33%) or C (67%). Mean ($\log_{10}$) baseline HBV DNA, RNA and HBsAg levels were 8.1 IU/ml, 6.7 copies/ml, and 4.4 IU/ml, respectively. 300 mg ALG-000184 + ETV for up to 28 weeks has been well tolerated with no concerning safety findings or trends reported, including no serious or treatment emergent adverse events (TEAEs) leading to discontinuation. Three subjects have experienced Grade ≥3 TEAEs; 1 subject developed Grade 4 neutropenia that was deemed related to an upper respiratory tract infection and 2 subjects experienced aminotransferase elevations (Grade 4 ALT with Grade 2 or 3 aspartate aminotransferase (AST) elevations), both of which were considered by the study ALT Flare Committee to be related to antiviral activity. All of these events resolved or are improving despite continued dosing. The PK profile with longer term dosing is consistent with prior observations with shorter dosing durations. Substantial mean (SEM) DNA (6.4 (0.3) $\log_{10}$ IU/ml) and RNA (4.7 (0.7) $\log_{10}$ copies/ml) declines have been observed for subjects dosed x 28 weeks (N = 5). Additionally, 4 (80%) of these subjects have exhibited continuous HBsAg declines of at least 1.1 $\log_{10}$ IU/ml with a mean (SEM) decline of 1.4 (0.1) $\log_{10}$ IU/ml; 2 of these 4 responders experienced declines of 1.6 and 1.7 $\log_{10}$ IU/ml, respectively.
Conclusion: 300 mg ALG-000184 + ETV was well tolerated and had profound antiviral effects, including lowering HBsAg levels by up to 1.7 $\log_{10}$ IU/ml among subjects dosed for 28 weeks. The observed HBsAg lowering effects indicate oral ALG-000184 may play an important role in combination regimens designed to achieve enhanced functional cure rates.

LBP-19

Assessing progress towards achieving regional hepatitis B control goal-nationwide serosurvey among children, Uzbekistan, 2022

Nino Khetsuriani[1], Dilorom Tursunova[2], Rano Kasimova[3], Said Sharapov[3], Brock Stewart[1], Renat Latipov[4], Liudmila Mosina[5], Bakhodir Yusupaliev[2], Erkin Musabaev[3]. *[1]Centers for Disease Control and Prevention (CDC), United States; [2]Center for Sanitary-Epidemiological Welfare, Ministry of Health, Uzbekistan; [3]Research Institute of Virology, Ministry of Health, Uzbekistan; [4]World Health Organization Country Office for Uzbekistan, Uzbekistan; [5]World Health Organization Regional Office for Europe, Denmark*
Email: nck7@cdc.gov

Background and aims: Uzbekistan, a highly endemic country for hepatitis B virus (HBV), has adopted regional hepatitis B control and global hepatitis B elimination goals. Routine infant vaccination with hepatitis B vaccine (HepB), including a birth dose (HepB-BD), was introduced in the national immunization schedule in 2001. Since 2002, reported immunization coverage in Uzbekistan has been ≥90% for ≥3 doses of HepB (HepB3) and ≥95% for HepB-BD. However, the impact of vaccination and the progress towards achieving the European regional control target of ≤0.5% HBV surface antigen (HBsAg) prevalence in vaccinated age groups had not been assessed. To determine current HBsAg prevalence among children in Uzbekistan, we conducted a serosurvey in 2022.
Method: This nationwide serosurvey included primary school children (ages 6-10 years) and used a stratified, multi-stage cluster design. Participants' basic demographics and HepB immunization information (from clinic records) were obtained. Blood samples were tested for HBsAg using a WHO-prequalified rapid test (Bioline HBsAg WB, Abbott Diagnostics). Samples with positive and indeterminate results were tested for HBsAg by ELISA (Murex HBsAg Version3, Diasorine). Weighted proportions and adjusted 95% confidence intervals (CI) for HBsAg prevalence and for receipt of HepB3, HepB-BD, and timely HepB-BD (given within the first 24 hours of birth), were calculated.
Results: Of 4,119 children enrolled in classes selected from the 148 participating schools, blood was collected from 3,753 (91.1%) and immunization data were available for 3,833 (93.3%). Overall, national HBsAg prevalence was 0.20% (adjusted 95% CI, 0.09%-0.38%). Among children with available immunization data, 3,745 [97.7% (97.2%-98.1%)] received HepB3 and 3,635 [94.9% (94.1%-95.5%)] received HepB-BD. Timely HepB-BD was given to 3,349 [93.7% (92.9%-94.5%)] of 3,592 children with available HepB-BD vaccination age data.
Conclusion: Uzbekistan has most likely achieved the European region hepatitis B control target based on ≥90% HepB-BD and HepB3 vaccine coverage and <0.5% HBsAg seroprevalence among children. To further decrease HBsAg seroprevalence in Uzbekistan to a ≤0.1% level consistent with the elimination of mother-to-child transmission of HBV, additional interventions should be considered, including improving antenatal screening for HBsAg and providing hepatitis B immunoglobulin to infants born to HBsAg-positive mothers and anti-HBV antiviral treatment to eligible HBsAg-positive pregnant women.

Email: pietro.lampertico@unimi.it

Background and aims: Bulevirtide (BLV), a novel entry inhibitor of hepatitis delta virus (HDV), is conditionally approved in the EU for treatment of chronic hepatitis D (CHD) based on surrogate end point results. In clinical studies, virologic responders (VR) to HDV therapy is

defined as achieving undetectability or a ≥2-log_{10} IU/ml decline in HDV RNA from baseline (BL). However, the optimal BLV treatment duration is unknown, and it is also unclear if patients who are early virologic non-responders (NR) will benefit from continued therapy. This analysis aimed to evaluate the efficacy of continued BLV monotherapy in those who were not VR after 24 weeks (W) of treatment.

Method: Data from the ongoing phase 3 study (MYR301; NCT03852719) was analyzed. MYR301 is an open-label, randomized study evaluating three cohorts: BLV 2mg (Arm B) and BLV 10mg (Arm C) for 144W, and a delayed treatment arm (Arm A). Only results from participants on treatment at 96W from Arm B + C were included in this analysis. NR and partial-responders (PR) were defined as HDV RNA declines of <1-log_{10} IU/ml and ≥1 but <2-log_{10} IU/ml, respectively. Rates of participants achieving biochemical response (alanine transaminase [ALT] within normal limits [WNL]), were compared between NR, PR, and VR.

Results: Participants with CHD (N = 94) were included (47 BLV 2mg; 47 BLV 10mg). BL characteristics included: 62% male, 85% white, 48% with cirrhosis, 61% taking concomitant nucleos (t)ide analogues and 55% with prior interferon exposure. Mean (SD) HDV RNA was 5.0 (1.3) log_{10} IU/ml and median (Q1, Q3) ALT was 102 (65, 141) U/ml. At W24, 58 (62%) participants were VR of which 30 had ALT WNL, 22 were PR of which 12 had ALT WNL, and 14 were NR of which 2 had ALT WNL. (Table 1) Of the 36 NR or PR at W24 vs VR, mean (SD) baseline HDV RNA and median (Q1, Q3) ALT at W96 were as follows: VR [5.1 (1.7) log_{10} IU/ml, 77 (58, 113) U/ml], PR [4.9 (1.4) log_{10} IU/ml, 120 (52, 153) U/ml], and NR [4.4 (1.9) log_{10} IU/ml, 156 (133, 196) U/ml]. Of 22 PR participants at W24, 18 became VR by W96 (11-BLV2 mg/7-BLV 10 mg); 15 with ALT WNL) and 3 remained PR (3-BLV 10mg); 2 with ALT WNL. Of 14 NR participants at W24, 6 became VR (3-BLV2 mg/3-BLV10 mg) by W96, and 3 became PR (3-BLV2 mg), with 5 remaining NR. Mean (SD) HDV RNA decline from baseline at W96: VR [−3.6 (1.1) log_{10} IU/ml], PR [−1.5 (0.3) log_{10} IU/ml], and NR [−0.2 (0.5) log_{10} IU/ml]. Median (Q1, Q3) ALT decline from baseline at W96: VR [−48 (−75, −12) U/ml], PR [−42 (−102, 9) U/ml], and NR [−83 (−102, −33) U/ml]. At W96, ALT had declined by >50% from BL in 5 of the 6 NR (1 achieved ALT WNL).

Conclusion: Most patients who were PR (18 of 24; 75%) and a considerable portion who were NR (6 of 14; 43%) to BLV at 24W achieved VR by W96; with ALT improvements occurring in all groups including those who remained a NR. These results provide evidence for continuing BLV therapy despite early (W24) suboptimal virological responses in patients with CHD.

Email: Jeffrey.Lazarus@isglobal.org

Background and aims: Over the past three decades the burden of non-alcoholic fatty liver disease has increased drastically, and globally an estimated 38% of adults and 1 in 10 children and adolescents have the condition. The implications of the disease are profound spanning health, social and economic consequences at both individual and population levels. This study aimed to develop an aligned, prioritised research agenda for the global fatty liver disease community of practice.

Method: Nine study co-chairs drafted initial research priorities which were reviewed by 40 core study members. Following a Delphi methodology, over two rounds a large panel reviewed the priorities, via Qualtrics XM, indicating agreement using a four-point Likert-scale ('agree', 'somewhat agree, 'somewhat disagree', and 'disagree') and providing written feedback. The core members revised the priorities between rounds. In R2, panellists also ranked the priorities within six domains: epidemiology, treatment and care, models of care, patient and community perspectives, education and awareness, and leadership and public health policy.

Table 1: Shift Table for Non- and Partial Responders at Week 24 Through Week 48 and 96

	BLV 2mg Week 24 HDV RNA			BLV 10mg Week 24 HDV RNA			BLV 2mg + 10mg Week 24 HDV RNA		
	NR	PR	VR	NR	PR	VR	NR	PR	VR
	n = 10	n = 12	n = 25	n = 4	n = 10	n = 33	n = 14	n = 22	n = 58

Responder	3 (30)	11 (91.7)	23 (92)	3 (75)	7 (70)	31 (93.9)	6 (42.9)	18 (81.8)	54 (93.1)

Figure: (abstract: LBP-20).

Figure: (abstract: LBP-21). Research priorities agenda for fatty liver disease.

Results: Of the 473 individuals invited to participate in R1, 344 (72.7%) completed the survey. The 344 R1 respondents were invited to participate in R2, with 288 (83.7%) completing the survey. The panel originated from 94 countries and are predominantly employed in the academic sector (66.6%), and work in the field of clinical research (79.4%). In R1, the study presented 31 initial priorities to the panel. In revisions ahead of R2 three priorities were removed, with key components of these being merged with others, leaving 28 for the panel to review in R2. Across rounds, consensus increased in all domains, with the mean percentage of 'agree' responses rising from 78.3 in R1 to 81.1 in R2. In R2, the mean level of combined agreement ('agree' + 'somewhat agree') across all priorities was 97.7% and five received unanimous combined agreement (Figure 1); the remaining 23 priorities exhibited >90% combined agreement. All but one of the priorities exhibited at least a super-majority of agreement (>66.7% 'agree'). Thirteen priorities had <80% 'agree', with reliance on 'somewhat agree' to achieve >90% combined agreement.
Conclusion: Adopting the multidisciplinary consensus research priorities agenda can deliver a step-change in understanding fatty liver disease, from the individual and societal harms to its prevention, identification, treatment, and care. The outcomes of this study should catalyse the global liver health community's efforts to advance and accelerate responses to this widespread and fast-growing public health threat.

Email: roloomba@health.ucsd.edu

Background and aims: BOS-580 is a genetically engineered fusion of IgG1 Fc and fibroblast growth factor 21 (FGF-21) with specificity for FGF receptors 1c/2c/3c allowing for prolonged, balanced pharmacological effects. BOS-580 has a 21-day half-life that enables biweekly and monthly dosing. A growing body of evidence demonstrates that FGF-21 analogues can increase NASH resolution and improve fibrosis in patients with NASH. The aim of this study was to examine pharmacokinetics, safety and efficacy of multiple doses and dose regimens of BOS-580 in patients with phenotypic NASH.
Method: Inclusion criteria for this patient- and investigator-blinded, randomized, placebo-controlled Phase 2A trial were a BMI of 30-45 kg/m^2 hepatic magnetic resonance imaging proton density fat fraction (MRI-PDFF) of ≥10%, vibration controlled transient elastography liver stiffness measurement (VCTE-LSM) of 7.0 to 9.9 kPa, and serum aspartate transaminase (AST) >20 IU/L. Subjects were randomized into 5 dosing cohorts treated for 12 weeks: 75 mg every 4 weeks (Q4W), 75 mg every 2 weeks (Q2W), 150 mg Q4W, 150 mg Q2W and 300 mg Q4W, with a 4:1 ratio of BOS-580 to placebo per cohort. The primary end point was safety/tolerability and pharmacokinetics; exploratory efficacy end points were also evaluated.

	BOS-580					
Baseline Characteristics (Enrolled Analysis Set)	75 mg Q4W N=8	75 mg Q2W N=14	150 mg Q4W N=15	150 mg Q2W N=15	300 mg Q4W N=13	Placebo N=37

Pro-C3 Relative CFB, %	-11	-14*	-6	-24***	-26***	

*p < 0.05, ** p < 0.01, ***p < 0.001 (model adjusted for baseline value and treatment effects)
Pro-C3 – N-terminal type III collagen pro-peptide, ALT – alanine amino transferase, CFB – change from baseline, LS – Least Square

Figure: (abstract: LBP-22).

Results: 102 patients of both sexes, 26-72 years old, with phenotypic NASH were enrolled. Demographic and baseline disease characteristics were evenly balanced across cohorts, with a mean liver steatosis of 19-24% by MRI-PDFF, a mean AST of 29.1-43.1 IU/L and a mean liver stiffness of 8.1-8.4 kPa. BOS-580 was well-tolerated with only a 4.6% discontinuation rate due to treatment emergent adverse events, and with mild, transient gastrointestinal events reported more commonly at higher doses. No deleterious effect was seen on the serum low density lipoprotein. BOS-580 resulted in statistically significant hepatic MRI-PDFF reduction of up to 61% after 12 weeks of treatment. In dosing cohorts of 75mg Q2W to 300mg Q4W, 67% to 72% of patients achieved super-responder status (≥50% MRI-PDFF reduction). Further, multiple NASH biomarkers (ALT, AST, Pro-C3), high-density lipoprotein, and triglycerides significantly improved with a total monthly dose of 300mg.
Conclusion: Our results demonstrate that monthly dosing with BOS-580 can achieve clinically important reductions in liver fat and non-invasive biomarkers of liver injury and fibrosis in patients with phenotypic NASH.

LBP-23

Improving hepatitis B screening and linkage to care rates via the electronic medical record, provider engagement, and patient navigation in a large, urban health system

Anna Mageras[1], Eric Woods[1], Brooke Wyatt[1], Rebecca Roediger[1], Francina Collado[1], Tasnim Bhuiyan[1], Caroline Romano[1], Douglas T Dieterich[1]. [1]*Icahn School of Medicine at Mount Sinai, United States*
Email: anna.mageras@mssm.edu

Background and aims: In March 2023, the United States CDC updated its screening guidelines for hepatitis B virus (HBV) from risk-factor-based to universal one-time screening for adults. The WHO recommends screening where prevalence is ≥2%. In NYC, HBV prevalence is 2.9%, and ~46% of New Yorkers with HBV are undiagnosed. To address this public health issue and in anticipation of the CDC's new guidelines, in October 2022 we implemented universal one-time HBV screening for adults in our large, multi-center hospital system serving metro-NYC. We describe the process of implementing modifications to the electronic medical record (EMR). We also summarize initial changes in screening rates and outcomes from patient navigation for patients identified as HBsAg+.
Method: We met with leadership from population health, ambulatory, EMR IT, and laboratory teams to secure buy-in and to build the EMR modification and provider education materials. The screening consists of three lab orders: HBsAg, anti-HBs, and anti-HBc, in line with updated CDC guidance. In response to PCP concerns, we made several adjustments, including limiting the alert to adults 18-79 rather than 18+, turning off patient-facing alerts, and creating a new panel that orders all three labs in one step. To complement the EMR alert, we conducted outreach to PCPs in three of our five pilot clinics via presentations, feedback reports, broadcast and personalized emails, and a one-page tip sheet. We also implemented patient outreach and navigation via phone, patient portal, and PCP engagement for patients who tested HBsAg+, with the goal of connecting them to liver care.
Results: Since implementation of the EMR alert, the average HBV screening rate has increased from 4% at baseline in September 2022 to 23% in March 2023 across our pilot clinics that received our education (n = 3) and from 3% to 15% in clinics that did not (n = 2). From September 2022 to February 2023, we identified 207 HBsAg+ patients who were screened or had an encounter at one of our pilot clinics. Of these, 17 (8%) were screened for the first time during this period, and 190 (92%) had a previous HBsAg+ test on record. At the time of chart review, 62% of these patients were receiving care for HBV. Of the 78 who were not, 53% attended at least one liver appointment by April 21, 2023, largely due to patient navigation; 27% were still being followed by our patient navigators; and 20% declined care or were lost to follow-up.

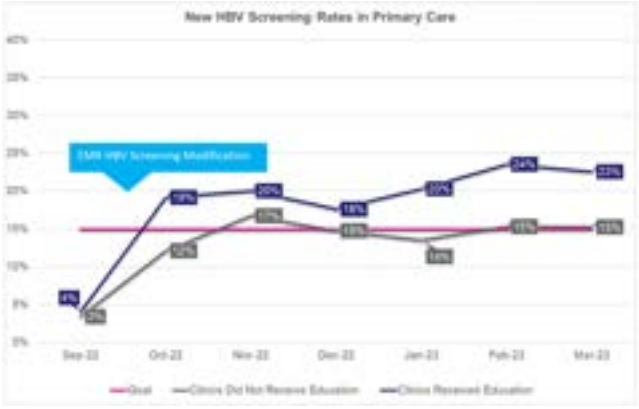

Figure:

Conclusion: Policy changes, automatic prompts in the EMR, and outreach to providers can help promote and streamline universal HBV screening. More research is needed, but preliminary results indicate that provider education enhances the positive effect of EMR alerts on screening rates. This approach is replicable at low cost. Many patients with HBV are undiagnosed or diagnosed but not receiving liver care. Patient navigation and PCP engagement can help link them to life-saving care.

LBP-24

Safety and efficacy of anti-pre-S1 domain monoclonal antibody (HH-003) treatment in patients with co-infection of chronic hepatitis B virus (HBV) and hepatitis D virus (HDV): a single center, open-label, phase 2 trial

Xinrui Wang[1], Xiumei Chi[1], Yingyu Zhang[1], Yumei Gu[2], Long Xiao[2], Yonghe Qi[2], Liangfeng Zou[2], Jiaying Wen[2], Yin Zhang[2], Pan Chen[2], Cong Lei[2], Bin Ye[2], Jianhua Sui[3], Wenhui Li[3], Junqi Niu[3]. *[1]First Hospital of Jilin University, China; [2]Huahui Health Ltd., China; [3]National Institute of Biological Sciences, China*
Email: junqiniu@jlu.edu.cn

Background and aims: HH-003 is a human monoclonal antibody that targets the preS1 domain of the large envelope protein of HBV and HDV. It prevents the binding of preS1 with sodium taurocholate co-transporting polypeptide (NTCP), the cellular receptor for HBV and HDV, and effectively blocks viral infection and re-infection of hepatocytes. This open-label, phase 2 study (NCT05674448) aimed to evaluate the safety and efficacy of HH-003 in patients with chronic HBV and HDV co-infection.

Method: The study included nine participants (aged 18-70 years old) who were serum anti-HDV IgG positive and HDV RNA positive at screening and had a history of HBV for at least 6 months at screening. All participants received intravenous infusion of 20 mg/kg HH-003 once every two weeks for 24 weeks, with a 24-week follow-up. Virological response (a serum HDV RNA level below the limit of detection or a ≥2 log10 IU/ml decline from baseline) and biochemical response (normalization of ALT, normal ALT was defined as ≤33 U/L for women and ≤41 U/L for men) to HH-003 treatment were assessed at week 24 and week 48. Serum HDV RNA level was measured using RoboGene HDV RNA Quantification kit 2.0.

Results: The median (min, max) HDV RNA and ALT levels at baseline were 3.48 (1.58, 5.40) log10 IU/ml and 36.0 (21.0, 86.0) U/L, respectively. After HH-003 treatment, the median (min, max) changes of HDV RNA level from baseline at week 24 and week 48 were -2.18 (-3.88, 0.35) log10 IU/ml and -1.98 (-3.64, 0.72) log10 IU/ml, respectively. At week 24, 77.8% (7/9) of the participants achieved virological response; 3/5 (60%) of the participants with abnormal baseline ALT levels achieved ALT normalization, and the other 4 participants remained to have normal ALT levels (100%, 4/4); and 3/5 (60%) participants achieved combined response of both virological response and ALT normalization. At week 48, 66.7% (6/9), 2/5 (40%) and 2/5 (40%) of participants achieved virological response, ALT normalization and combined response, respectively. One subject (11.1%) experienced treatment-related adverse events (AEs) of abdominal discomfort (Grade 1) and asthenia (Grade 2). No grade 3 or higher AEs or serious AEs occurred, and no participants discontinued treatment due to AEs.

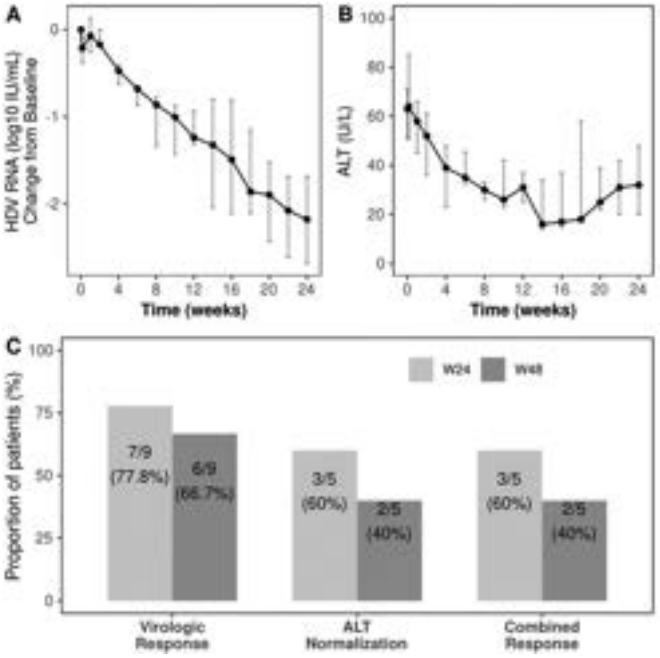

Figure: Efficacy outcomes from the study. (A) Serum HDV RNA level reduction during the HH-003 treatment period. Line plot with median and interquartile range (IQR) showing the log10 change from baseline of the serum HDV RNA level. (B) Line plot with median and IQR showing the dynamics of ALT levels in 5 participants with abnormal baseline ALT levels. (C) The proportions of patients achieved virologic response, ALT normalization and combined response at week 24 and week 48.

Conclusion: HH-003 treatment at a dose of 20 mg/kg demonstrated significant decrease of HDV RNA level and ALT normalization, with a good safety profile in participants co-infected with HBV and HDV. HH-003 might provide a new treatment option for patients with HBV and HDV co-infection, and a large-scale study will be conducted to further demonstrate such a promising anti-viral effect of HH-003 in patients with HBV and HDV co-infection.

LBP-25

Concurrent nivolumab and external beam radiation therapy for patients with advanced hepatocellular carcinoma with vascular invasion: a phase 2, single-arm NEXTRAH trial

Joong-Won Park[1], Bo Hyun Kim[1], Hee Chul Park[2], Young-Hwan Koh[3], Jung Yong Hong[2], Yuri Cho[1], Boram Park[2], Dong Hyun Sinn[4], Tae Hyun Kim[5]. *[1]National Cancer Center, Center for Liver and Pancreatobiliary Cancer Center, Korea, Rep. of South; [2]Samsung Medical Center, Korea, Rep. of South; [3]National Cancer Center, Department of Radiology, Korea, Rep. of South; [4]Samsung Medical Center, Division of Gastroenterology, Department of Medicine, Korea, Rep. of South; [5]National Cancer Center, Center for Proton Therapy, Korea, Rep. of South*
Email: jwpark@ncc.re.kr

Background and aims: Nivolumab (NIV), a PD-1 inhibitor, was the first immune checkpoint inhibitor (ICI) to be used in the systemic treatment of advanced hepatocellular carcinoma (aHCC). ICIs have become the backbone of systemic therapy for HCC; however, their efficacy needs improvement in patients (pts) with far-aHCC with vascular invasion (VI). External beam radiation therapy (EBRT) could potentially enhance the effectiveness of immunotherapy. This study

aimed to investigate the efficacy and safety of concurrent therapy of NIV and EBRT in pts with aHCC with VI.
Method: In this phase 2, single-arm, multicenter, investigator-initiated trial, pts with Child-Pugh class A HCC with VI were treated with intravenous NIV (3 mg/kg every 2 weeks) and EBRT concurrently followed by maintenance NIV until progression or unacceptable toxicity. The primary end point was progression-free survival (PFS) and safety; secondary end points included overall survival (OS), time to progression (TTP), objective response rate (ORR), and disease control rate (DCR). (NCT04611165)
Results: Between January 2020 and June 2021, 50 pts were enrolled from two hospitals in South Korea: 47 (94.0%) had portal vein invasion (Vp) (Vp1/2, n = 21; Vp3, n = 23; Vp4, n = 3), and 13 (26.0%) and 2 (4.0%) had hepatic vein and inferior vena cava invasion, respectively. Also, 5 pts received prior systemic therapy. Pts received EBRT (proton beam RT, n = 26; intensity-modulated RT, n = 24), beginning 2-7 days after the first NIV dose; the median irradiation dose was 50 Gy (range, 21-66 Gy). The median number of NIV doses was 8.5 (interquartile range, 4-26), and 22 pts (44.0%) had at least one dose delay. After the follow-up (median: 29.3 months), the median PFS was 5.55 months (90% confidence interval [CI], 3.58-9.89). Median OS and TTP were 15.24 months (90% CI, 10.81-19.58) and 5.55 months (90% CI, 3.58-9.89), respectively. ORR and DCR were 36.0% and 74.0%, respectively. Any-grade adverse events (AE) and serious AEs were present in 48 (96.0%) and 9 pts (18.0%), respectively. Treatment-related AEs occurred in 40 pts (80.0%); pruritus (38.0%), nausea (10.0%), and pneumonitis (10.0%) were most commonly reported.

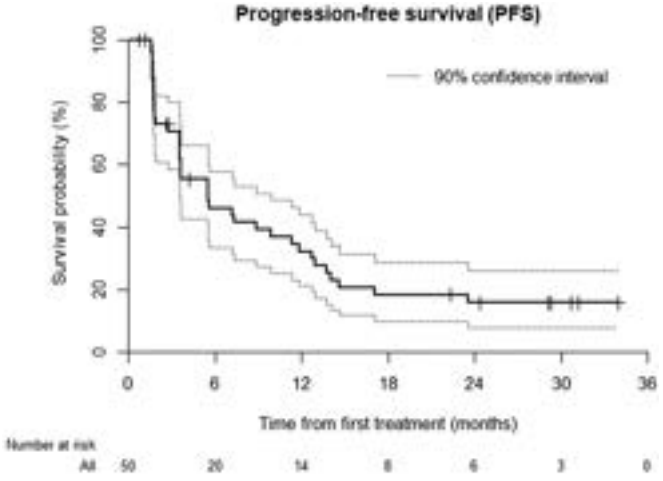

Figure:

Conclusion: Concurrent therapy of NIV and EBRT demonstrates a meaningful PFS and promising clinical outcomes in pts with aHCC with VI. The safety profile was overall acceptable.

LBP-26
Evaluation of non-invasive tests to identify precirrhotic fibrosis due to NASH in patients screened for the phase 3 REGENERATE and REVERSE studies of obeticholic acid

Rohit Loomba[1], Kris Kowdley[2], Quentin Anstee[3], Mazen Noureddin[4], Zobair Younossi[5], Naim Alkhouri[6,7], Jerome Boursier[8], Stephen Harrison[9], Thomas Capozza[10], Jing Li[10], Christopher Gasink[10], Mary Rinella[11]. *[1]University of California, San Diego, La Jolla, United States; [2]Liver Institute Northwest and Elson S. Floyd College of Medicine, Washington State University, Seattle, United States; [3]Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Framlington Place, Newcastle upon Tyne, United Kingdom; [4]Division of Digestive and Liver Diseases, Cedars-Sinai Medical Center, Los Angeles, United States; [5]Beatty Liver and Obesity Research Program, Center for Liver Diseases, Inova Medicine, Falls Church, United States; [6]The Texas Liver Institute, University of Texas Health San Antonio, San Antonio, United States; [7]Arizona Liver Health, Chandler, United States; [8]Angers University Hospital, Angers University, Angers, France; [9]Pinnacle Clinical Research Center, San Antonio, United States; [10]Intercept Pharmaceuticals, Inc., Morristown, United States; [11]University of Chicago, Pritzker School of Medicine, Chicago, United States*
Email: roloomba@health.ucsd.edu

Background and aims: Liver biopsy is the historic basis to identify non-alcoholic steatohepatitis (NASH) fibrosis (F) stage but is limited by complications as well as pathologist read and sampling variability. However, non-invasive tests (NITs) are now widely used in clinical practice and society guidelines to identify and risk-stratify NASH F stage. Potential NASH therapies create a pressing need for NIT-based approaches to specifically identify appropriate patients (pts) with F2/3 (precirrhotic) fibrosis.
Method: Patients (pts) screened for the phase 3 trials of obeticholic acid (n = 6060) were examined based on values for FibroScan (FS), Enhanced Liver Fibrosis (ELF), Fibrosis-4 (Fib-4), direct bilirubin (DB), albumin (ALB), and platelet count (PLT) vs both original single-pathologist and consensus panel pathology reads to identify pts likely to have F2/F3 disease, while excluding F0, F1, and F4. The distribution of each NIT across the spectrum of histologic F stages was used to determine ideal cutoffs, which were then assessed for sensitivity (SENS), specificity (SPEC), and related parameters using NITs alone and in combination.
Results: Among all screened pts, F stage n was F0:658, F1:1160, F2:1088, F3:1619, and F4:1535 (REGENERATE only, n = F0:657, F1:1158, F2:1084, F3:1599, and F4:273). The lower bounds of Fib-4 (1.3), ELF (9.6), and FS (9.6) eliminated most F0/1 pts, while the upper bounds (Fib-4, 2.67; ELF, 11; FS, 18) discriminated between F3 and F4. Results were generally similar in single and consensus pathology reads (Table). Although single NITs had insufficient SPEC, use of 2 sequential tests, ie, Fib-4 (1.3-2.67) followed by either ELF (9.6-11) or FS (9.6-18) with additional exclusion of PLT <150 10^3/μL, DB >0.5 mg/dL, and ALB <3.8 g/dL led to a SPEC of 91% for identification of F2/F3 pts (SENS:31, NPV:35, PPV:89, AUROC:75; for F3: SPEC:85, SENS:38, NPV:66, PPV:65, AUROC:74).
Conclusion: A combined NIT approach using Fib-4 followed by either ELF or FS identified F2/F3 pts with high SPEC and PPV. The addition of PLT, DB, and ALB upper bounds further increased SPEC, ensuring precise identification of pts who would be appropriate for therapies or studies in this population. While low SENS is a limitation, this approach reliably identified precirrhotic fibrosis without liver biopsy in almost 40% of F3 pts. This approach should be validated in an independent cohort of similar pts.

Table: (abstract: LBP-22). Upper Bound Criteria Applied to Original and Consensus Pathology Reads, by Fibrosis Stage.

Background and aims: Finite duration of treatment associated with Hepatis B surface antigen (HBsAg) loss is the current goal for improved therapeutic approaches against chronic hepatitis B virus (HBV) infection, as this indicates elimination or durable inactivation of intrahepatic covalently-closed circular (ccc)DNA. To assist drug development, it will be essential to define early predictive markers of HBsAg loss by assessing their value in reflecting intrahepatic cccDNA levels and transcriptional activity. In this context, fine needle aspirates (FNA) have recently emerged as a less invasive alternative to core liver biopsy (CLB), having already shown to be useful for the characterization of intrahepatic immune responses.The aim of this study was to optimize and validate the use of FNA vs CLB to evaluate the intrahepatic viral reservoir.
Method: Paired FNA/CLB samples were obtained from patients with hepatitis B e antigen (HBeAg)+ chronic hepatitis (n = 4), HBeAg- chronic hepatitis (n = 4) and HBeAg- chronic infection (n = 1). One HBeAg+ patient was undergoing tenofovir treatment. HBV 3.5-kb RNA and cccDNA were quantified by droplet digital (dd)PCR.
Results: cccDNA was quantifiable in all but one FNA/CLB pair, showing the highest levels in untreated HBeAg+ subjects, with exception of the tenofovir-treated patient. Similarly, 3.5-kb RNA was detectable in all but one FNA sample and showed higher levels in HBeAg+ patients. When comparing cccDNA and 3.5-kb RNA quantification in FNA vs CLB samples, no statistically significant differences were identified.

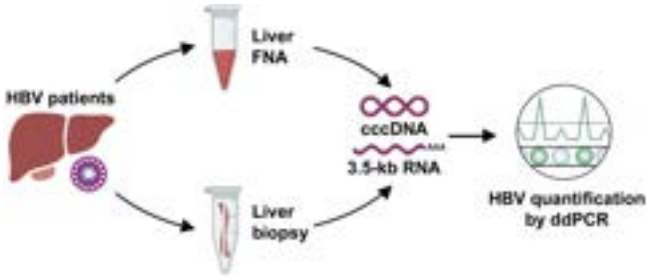

Figure:

Conclusion: These results demonstrate the possibility to quantify cccDNA and assess its transcriptional activity in chronic hepatitis B patients by combining FNA and ddPCR. Moreover, this supports the use of FNA in clinical trials to evaluate the intrahepatic viral reservoir during the development of new antivirals and immunomodulatory agents.

LBP-28

Phase 2a study of CM-101, a CCL24 neutralizing antibody, in patients with non-alcoholic steatohepatitis: a proof-of-concept study

Rifaat Safadi[1], John Lawler[2], Revital Aricha[2], Ilan Vaknin[2], Scott Friedman[3], Adi Mor[2]. [1]*Hadassah Hebrew University Hospital, Israel;* [2]*Chemomab Therapeutics, Ltd, Israel;* [3]*Icahn School of Medicine, United States*
Email: safadi@hadassah.org.il

Background and aims: CCL24 (eotaxin-2) is a chemokine that promotes cell trafficking and regulates inflammatory and fibrotic processes through the CCR3 receptor. CCL24 plays a central role in the development of hepatic fibrosis and liver injury (Segal-Salto M, 2020). Patients with non-alcoholic steatohepatitis (NASH) and advanced non-alcoholic fatty liver diseases (NAFLD) were noted to have elevated levels of CCL24 and CCR3 in liver and blood samples. CM-101 is a humanized IgG1 neutralizing monoclonal antibody to CCL24, which significantly reduced migration and activation of immune cells and fibroblasts, including hepatic stellate cells. CM-101 has been shown to reduce liver damage in three different experimental animal models of liver fibrosis and NASH (Segal-Salto M, 2020). The purpose of study is to evaluate the therapeutic potential of CM-101 in patients with NASH with fibrosis stages 1c, 2 and 3.
Method: This was a single country, multicenter, randomized, double-blind, placebo-controlled, phase 2a study. Patients with liver biopsy confirming NASH within 18 months of randomization or screening were randomized (2:1) to receive either CM-101 5mg/kg or placebo subcutaneously (SQ), every 2 weeks for 14 weeks (8 total administrations) and all patients had a follow-up visit 6 weeks after the end of

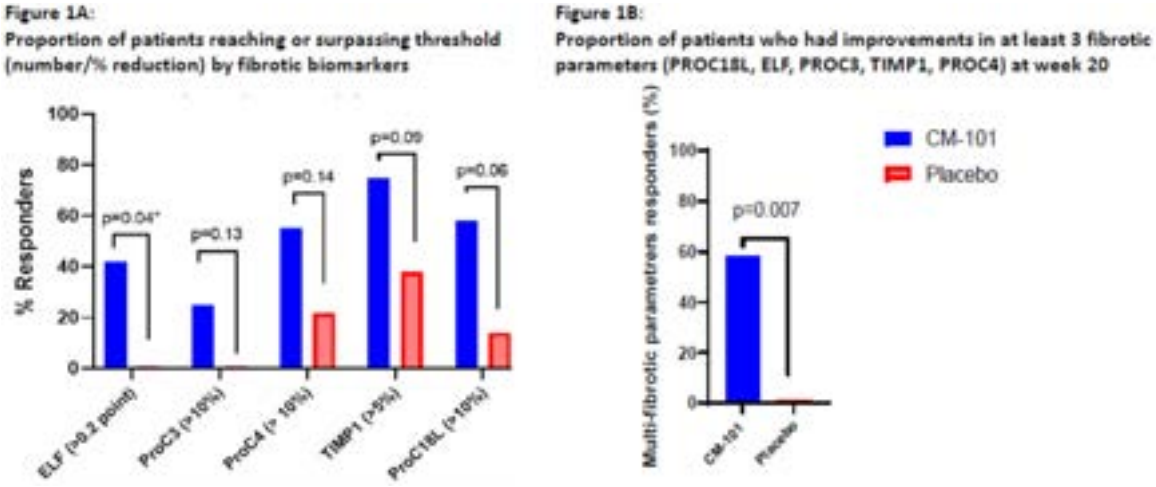

Figure: (abstract: LBP-28).

treatment (total study duration 20 weeks). The primary end point was safety and tolerability at 16 weeks. Secondary and exploratory end points included changes from baseline in various fibrotic and inflammatory serum biomarkers and liver stiffness as assessed by Fibroscan. PK and target engagement profile of CM-101, and the development of anti-drug antibodies (ADAs) were also assessed.

Results: 23 patients (14 CM-101; 9 Placebo) were randomized. The demographic and baseline characteristics were comparable between the groups, except more patients in the CM-101 group had a higher fibrosis stage (36% Stage F3 vs. 0% Stage 3), enhanced liver fibrosis (ELF) score (9.8 vs. 8.7, p = 0.001), and liver stiffness (11.3 kPa vs. 8.1 kPa, p = 0.037) at baseline than patients in placebo group, respectively.

CM-101 5mg/kg SQ every 2 weeks for 14 weeks was safe and well tolerated. Most adverse events (AEs) were mild with one unrelated serious adverse event. There were no significant injection site reactions, and no ADAs were detected at 20 weeks. CM-101 showed a favorable PK and target engagement profile that was consistent with other phase 1 studies. Compared to placebo-treated patients, a higher proportion of CM-101-treated patients showed improvement in liver fibrosis-related biomarkers (ProC-3, ProC-4, ProC-18, TIMP-1, ELF) (Fig 1A). At 20 weeks, 8 (60%) of CM-101-treated patients had improvements in at least 3 fibrotic biomarkers compared to 0 of the placebo-treated patients (Fig 1B). Among CM-101-treated patients, those with higher CCL24 levels at baseline showed greater reductions in fibrosis-related biomarkers than patients with lower CCL24 levels.

Conclusion: CM-101 5mg/kg administered SQ every 2 weeks for a relatively short duration of 14 weeks was safe and well tolerated and provided evidence supporting CCL24 as a potential therapeutic target in NASH. Neutralizing the pro-inflammatory and pro-fibrotic effects of CCL24 with CM-101 at higher doses and for prolonged duration should be further evaluated in a statistically powered, biopsy-based, randomized, placebo-controlled study.

Predictors of long-term mortality after HCV eradication among PLWH

Alessia Siribelli[1], Sara Diotallevi[1], Laura Galli[1], Giulia Morsica[1], Riccardo Lolatto[1], Costanza Bertoni[1], Emanuela Messina[1], Simona Bossolasco[1], Benedetta Trentacapilli[1], Caterina Uberti-Foppa[2], Antonella Castagna[2], Hamid Hasson[1]. *[1]San Raffaele Scientific Institute, Milan, Italy; [2]Vita-Salute San Raffaele University, Italy*
Email: siribelli.alessia@hsr.it

Background and aims: This study aimed to assess the long-term incidence and risk factors of death in HIV-HCV coinfected people treated with direct acting antivirals (DAAs).

Method: Retrospective study in HIV-HCV coinfected people, anti-retroviral-treatment experienced, followed at San Raffaele Hospital, who achieved sustained virological response (SVR) after DAAs. Biochemical and virological data were collected at baseline (BL), defined as end of DAA treatment; follow-up (FU) accrued since BL until death, lost-to FU or last visit. ALBI grade, which reflects the hepatic functional reserve, was calculated with the formula: ($\log_{10}$-bilirubin[µmol/L]× 0.66)+ (albumin[g/L]× −0.0852). Kaplan-Meier curves and the log-rank test were used to estimate cumulative probability of death for any cause according to some BL characteristics. Cox proportional hazard model was used to estimate adjusted hazard ratio (aHR) of death and the corresponding 95% confidence interval (95%CI); BL variables included in the model were: age, diabetes, HCC, α-fetoprotein (AFP), ALBI grade.

Results: Overall, 663 people analyzed; BL characteristics are reported in Table 1. During a median follow-up of 4.41 years (IQR = 3.5-5.5), 49 people died: 35% deaths were liver-related, 51% malignancies of which 16% liver cancers. The overall 3-, 5- and 7-year cumulative probabilities of death were 4.9% (95%CI = 3.2%-6.7%), 8.0% (95%CI = 5.5%-10.4%), 11.4% (95%CI = 7.8%-14.9%), respectively. Cumulative probabilities of death were higher among older individuals (Figure1), in people with vs without cirrhosis (Figure2), with AFP ≥3.4 vs <3.4 ng/ml (Figure3), with ALBI grade ≥2 vs 1 (Figure4), with HCC (log-rank p = 0.002). At multivariate analysis, death was more likely in older people [aHR (5-year older) = 1.46, 95%CI 1.16-1.83, p = 0.0009] and in people with diabetes [aHR = 2.98, 95%CI 1.55-5.71, p = 0.001], ALBI grade ≥2 [aHR = 2.13, 95%CI 1.17-3.90, p = 0.014] and AFP ≥3.4 ng/ml [aHR = 1.96, 95%CI 1.01- 3.84, p = 0.049]; the effect of HCC on the risk of death was marginally significant [aHR = 2.69, 95%CI 0.90-8.05, p = 0.076].

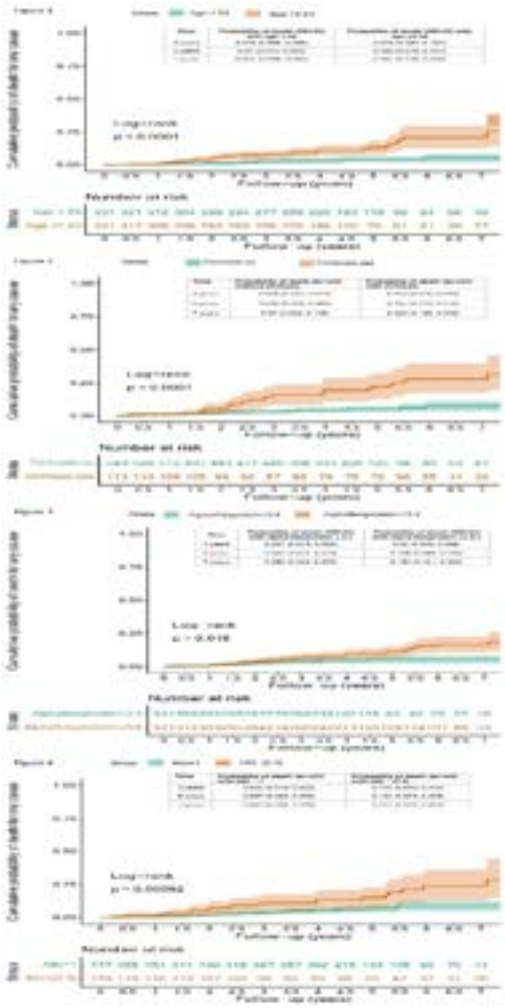

Figure:

Conclusion: HIV-HCV coinfected people who achieved SVR after DAAs showed a higher risk of death in presence of cirrhosis, HCC, diabetes, ALBI grade ≥2 and AFP ≥3.4 ng/L, the latter as possible laboratory predictors of mortality. We observed a high number of liver and non-liver malignancies among died people suggesting that surveillance of non-liver events should be extended to all individuals, regardless of liver disease stage.

LBP-30-YI

A new risk model outperforms FIB-4 when predicting incident cirrhosis in the general population: a cohort study of 504,000 persons

Rickard Strandberg[1], Mats Talbäck[2], Niklas Hammar[2], Hannes Hagström[1,3]. *[1]Karolinska Intitutet, Department of Medicine, Huddinge, Sweden; [2]Karolinska Intitutet, Institute of Environmental Medicine, Solna, Sweden; [3]Karolinska University Hospital, Department of Upper GI, Huddinge, Sweden*
Email: rickard.strandberg@ki.se

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has a high prevalence in the general population, and the incidence of NAFLD-associated cirrhosis is increasing. The Fibrosis-4 score (FIB-4) is a diagnostic model used in patients with NAFLD to estimate the present degree of fibrosis, but the FIB-4 score is inadequate for predicting future events. The aim of this study was to develop a risk score allowing physicians to identify individuals at a high risk of developing cirrhosis. Correct identification would allow for early intervention and preventive measures.

Method: We used a large Swedish population-based cohort, free of known liver diseases other than possibly NAFLD, with available laboratory data, including biomarkers associated with liver disease, and national registry data. Using flexible parametric survival models, a 10-year risk model of cirrhosis or associated complications was created, employing non-liver death as a competing event. The new comprehensive risk score includes age, sex, body mass index (BMI), aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma-glutamyl transferase (GGT), cholesterol, platelet count, albumin, bilirubin, glucose, and triglycerides. The performance was assessed in terms of calibration (calibration curves), discrimination (time-dependent area-under-curve (AUC)), and utility (decision curve analysis). The model was compared to the FIB-4 score.

Results: We used data of 504,309 individuals that were followed over an average follow-up time of 25 years. During follow-up, 7604 liver-related outcomes were observed. The cumulative risk of liver cirrhosis at ten years was 0.22%. The new risk score achieved a 10-year AUC of 81% compared to the FIB-4 AUC of 73% (*Figure*). In total, 4525 individuals had a FIB-4 above the established high-risk cut-off (2.67). Among these, the 10-year positive predictive value (PPV) for incident cirrhosis was 4.6%. Among an equal 4525 individuals with the highest new score (corresponding to >1.62% predicted risk), the 10-year PPV was 7.2%. According to the decision curve analysis, the new score has a positive net benefit for risk thresholds up to 18%, and a higher net benefit than FIB-4 for all thresholds.

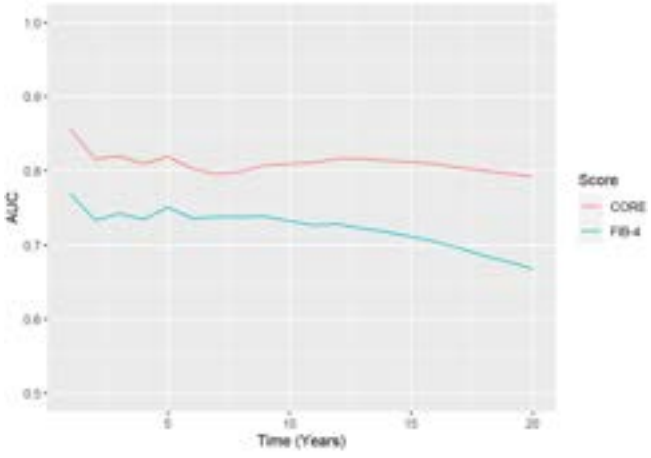

Figure:

Conclusion: The new risk score, the *Cirrhosis Outcome Risk Estimator (CORE)*, based on a flexible modeling approach, and using biomarkers easily accessible in primary care, outperforms FIB-4 when predicting

liver-related outcomes in the general population. External validation is needined before use in primary care.

LBP-33-YI

Investigating the potential of the primary cilium as an immunomodulatory organelle in intrahepatic cholangiocarcinoma

Sara Teles[1], Scott Waddell[1], Kostas Gournopanos[1], Kyle Davies[1], Philippe Gautier[1], Pleasantine Mill[1], Edward Jarman[1], Luke Boulter[1].
[1]*Institute of Genetics and Cancer, University of Edinburgh, MRC Human Genetics Unit, United Kingdom*
Email: sarapteles@gmail.com

Background and aims: Primary cilia (PC) are important organelles that protrude from biliary epithelial cells to sense changes in bile. Although changes in PC have been observed in Intrahepatic Cholangiocarcinoma (iCCA), why these cancers supress their cilia and how the lack of a functioning cilium benefits iCCA progression remains unexplored. Here, we investigate how PC loss shapes the immune microenvironment of iCCA to favour tumour progression.
Method: Using a combination of human iCCA tissue and two transgenic mouse models in which iCCA originates from either ciliated or unciliated cholangiocytes, we used bulk RNA sequencing to analyse the cell-intrinsic transcriptional changes resulting from PC-loss. By deriving organoid cultures from the same ciliated/unciliated cells, we have then functionally investigated how PC status in biliary cells affects the tumour immune microenvironment and how this influences iCCA progression.
Results: Human iCCA lack PC by immunohistochemical analysis; therefore, we developed an *in vivo* mouse model of iCCA in which PC are either lost or remain intact. In this model, iCCA does not develop when PC are present in biliary cells. However, when PC-loss is induced *in vivo* (through deletion of the essential cilia gene *Wdr35*), iCCA rapidly develops. Importantly, unciliated cells do not show increased rates of proliferation. Rather, bulk RNA sequencing showed that PC-loss induced the expression of progenitor transcription factors and immunoregulatory genes. Interestingly, in mice with unciliated iCCA we found lower levels of liver neutrophil infiltration. Using *in vitro* organoid cultures of ciliated and unciliated iCCAs and transwell assays, we found that PC-loss on cancer cells influences neutrophil recruitment and migration, indicating that loss of PC in iCCA has the potential to modulate local tumour immunity and avoid neutrophil-induced clearance.
Conclusion: PC-loss coordinates an inflammatory cell state that affects the recruitment of immune cells to the liver. By directly modulating the chemotaxis and infiltration of neutrophils, PC-loss promotes an immunosuppressive tumour microenvironment, thereby favouring iCCA progression.

LBP-34

Modelling intrahepatic bile duct morphogenesis in vitro using synthetic hydrogels

Ludovic Vallier[1], Iona Thelwall[2], Kevin Chalut[3], Carola Maria Morell[2], Lucia Cabriales[4]. [1]*Berlin Institute of Health, Berlin, Germany;*
[2]*Wellcome-MRC Cambridge Stem Cell Institute, United Kingdom;* [3]*Altos Labs, Great Abington, United Kingdom;* [4]*Lightcast Discovery Ltd, United Kingdom*
Email: igt20@cam.ac.uk

Background and aims: Cholangiopathies account for a third of adult liver transplantations, access to which is limited by a shortage of healthy donor organs. A promising alternative is the use of human induced pluripotent stem cell (hiPSC)-derived cholangiocytes in a therapeutic context. However, lack of knowledge regarding cholangiocyte development limits the generation of fully functional cells. To address this issue, we developed a culture system consisting of tuneable synthetic hydrogels capable of testing the influence of mechanical stimuli on cholangiocyte development, with the aim of generating fully functional cholangiocyte organoids.
Method: Novel 2D polyacrylamide hydrogels developed in the Chalut Lab (*Labouesse et al. 2021*) were optimised for the *in vitro* culture of hiPSC-derived hepatoblast-like-cells using established protocols (*Hannan et al. 2013, Sampaziotis et al. 2017*). Optimised parameters consist of seeding cells at a density of 500,000 cells/cm^2 onto collagen I-coated soft hydrogels. Once seeding was optimised, the hepatoblast-like-cells were differentiated into cholangiocyte-like cells and marker expression was verified. The 2D hydrogel was then used as the base of a novel sandwich culture consisting of two distinct hydrogels, both with a defined extracellular matrix. Production of the sandwich culture involves the differentiation of immature cholangiocyte-like cells on polyacyrlamide and the subsequent application of a proprietary synthetic gel top layer. This provides the encapsulation required for 3D structure formation and enables cholangiocyte morphogenesis into tubular bile duct structures.
Results: We have developed a promising alternative to Matrigel in the form of a novel synthetic hydrogel which enables the production of luminal bile ducts *in vitro* from hiPSCs. Cholangiocytes cultured in this system express biliary markers (KRT7/SOX9) to the same or a greater level than that observed in iPSC-derived intrahepatic bile duct (IHBD) organoids. We found that collagen I-coated hydrogels provide

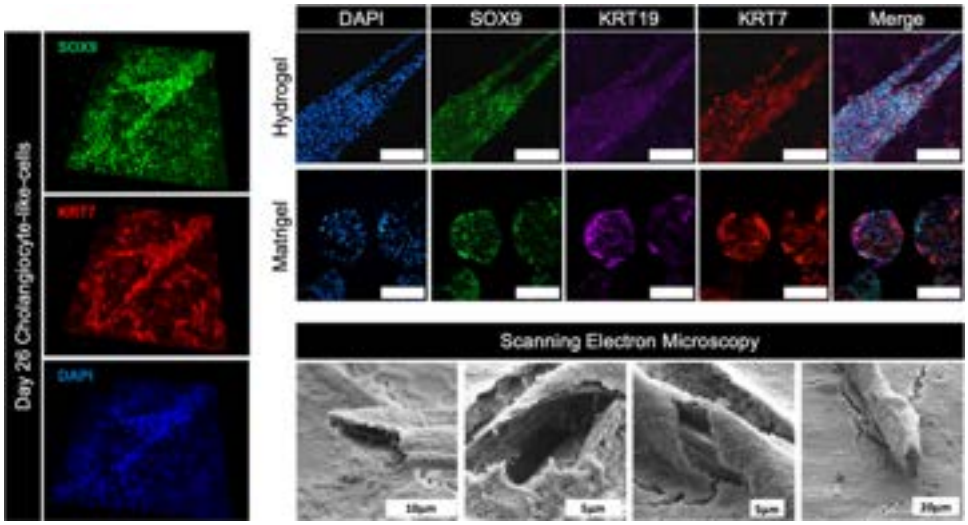

Figure: (abstract: LBP-34): Day 26 hiPSC-derived cholangiocyte-like-cells cultured within a synthetic hydrogel sandwich represented by immunostaining (300um) and scanning electron microscopy.

an excellent substrate for cholangiocyte differentiation, with increased collagen correlated with enhanced biliary (KRT7/SOX9) and reduced hepatic (ALB/AFP) marker expression. Indicating a potential mechanism by which collagen I directs hepatoblast fate choice and subsequent differentiation. This is supported by *in vivo* results showing that foetal IHBDs are surrounded by a localised region of collagen I. We are currently using the hydrogel system as a model to study the role of extracellular matrix composition in the induction of mechanically activated pathways linked to cholangiocyte differentiation (TGF-beta Activin/Nodal and YAP-TAZ) with the end goal of elucidating a mechanism for extracellular matrix-driven hepatoblast zonation.

Conclusion: Overall, these results show that our synthetic hydrogel platform can be used to model bile duct development *in vitro*. Its tunable properties make the hydrogel a novel tool for the investigation of mechanical stimuli on cholangiocyte differentiation and enable the incorporation of good-manufacturing-process compliant reagents for cell therapy applications.

Background and aims: Progressive familial intrahepatic cholestasis (PFIC) is a group of genetic disorders resulting in disrupted bile composition, cholestasis, and pruritus. Maralixibat (MRX) is a minimally absorbed ileal bile acid transporter (IBAT) inhibitor which prevents enterohepatic bile acid recirculation. In the 26-week placebo-controlled MARCH Phase 3 study, MRX at 570 µg/kg BID demonstrated significant improvements in pruritus, serum bile acid (sBA), bilirubin and growth in patients across the broadest range of PFIC types studied to date. MARCH-ON is an open-label long-term extension study for patients who completed the MARCH study. Here, we report on long-term maintenance of effect from MARCH-ON.

Method: Long-term maintenance of response was assessed for patients who were originally randomized to receive MRX in MARCH and continued with treatment in MARCH-ON (MRX-MRX group; n = 33). MRX response was assessed for patients who received PBO in the MARCH study and switched to open-label MRX in MARCH-ON (PBO-MRX group; n = 24). Assessments included: pruritus measured by 0-4 scale of ItchRO[Obs]), sBA, bilirubin, and growth z-scores, as well as incidence of treatment-emergent adverse events (TEAEs). Baseline (BL) was defined as the start of MRX for each group.

Results: For the MRX-MRX group, the median (min, max) time on MRX was 394 days (108, 836). In total, 20 of 33 patients reached week 52 at time of analysis. Significant improvements observed in the first 26 weeks of the MARCH study were sustained from BL through week 52 inMARCH-ON for pruritus severity (-2.13, $p < 0.0001$), sBA (-200 µmol/L, $p = 0.0004$), bilirubin (-2.64 mg/dL, $p = 0.0084$), height z-score (+0.54, $p < 0.0001$), weight z-score (+0.44, $p = 0.0010$). In the PBO-MRX group, the median time on MRX was 256 days (29, 569). In total, 15 of 26 patients reached week 26 at time of analysis. Newly gained statistically significant reductions in pruritus and sBA levels were observed in the key efficacy end points from BL through Week 26 for pruritus (-1.05, $p = 0.0017$) and sBA (-141 µmol/L, $p = 0.0003$), in line with observations from the initial MARCH MRX group. Overall, there were no new safety signals identified. The most frequent TEAEs were GI-related with early onset of diarrhoea (44%) in line with the mechanism of IBAT inhibition, mostly mild and transient. In the MRX-MRX sub-group, fewer patients experienced diarrhoea (n = 2) in MARCH-ON supporting these effects are early and transient in nature.

Conclusion: Significant and sustained responses in pruritus, sBA, bilirubin as well as growth are observed with 52 weeks of MRX treatment across the broadest range of genetic PFIC types studied to date. These data suggest overall improved liver health with MRX treatment which can be maintained over time.

Email: nabilquraishi@gmail.com

Background and aims: Primary Sclerosing Cholangitis (PSC) is the classical hepatobiliary manifestation of inflammatory bowel disease (IBD). The strong association between gut and liver disease has fostered several pathogenic hypotheses, in which enteric dysbiosis is proposed to contribute. We conducted a phase 2A clinical trial of oral vancomycin (OV), a gut-restricted antibiotic, in patients (pts) with

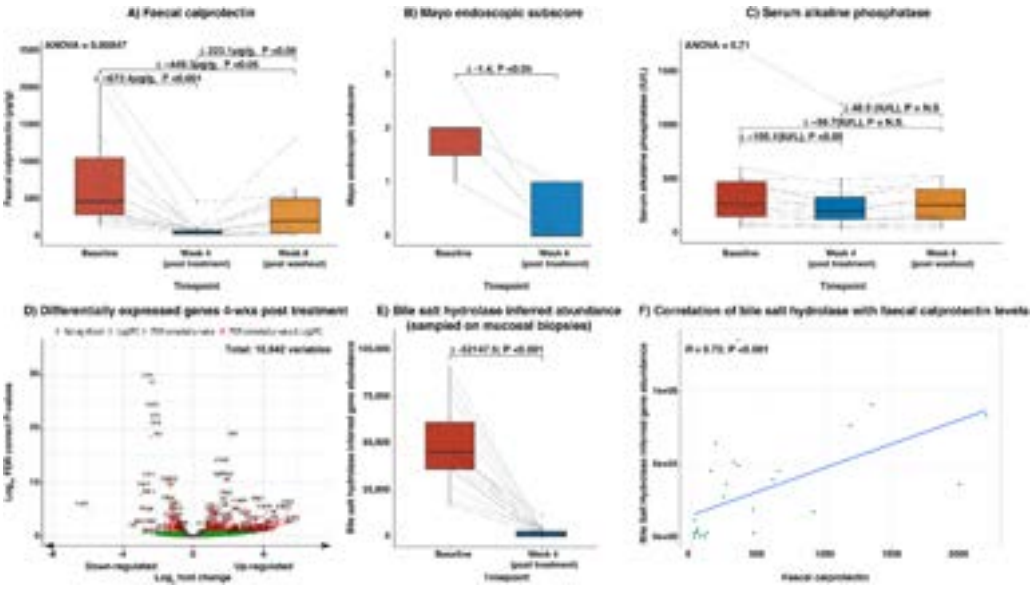

Figure: (abstract: LBP-36). Therapeutic effects and associated gene expression changes following OV treatment

PSC and active colitis. The overarching goal was to identify key mechanistic pathways associated with induction of treatment response.

Method: Study drug was administered at a dose of 125mg QID for 4 weeks (wk) followed by a 4wk washout (total study duration 8 wks). Lower gastrointestinal endoscopies were performed at 0 and 4 wks. Clinical assessment was performed and peripheral blood and stool laboratory tests obtained at 0, 4 and 8 wks. The primary outcome measure was to quantify the magnitude of composite treatment response at 4w, defined as a reduction in faecal calprotectin (fcal), Mayo endoscopic subscore and serum liver biochemistry. Important translational objectives included colonic mucosal microbial profiling along with inferred metagenomics and colonic mucosal host RNA sequencing. The study was registered on clinicaltrials.gov (NCT05376228).

Results: In entirety, 15 patients were recruited to the study, all of whom completed the 4wk treatment course (11 men, 7 previously treated with at least one biological agent). At 4wks, all participants attained response with regards IBD activity (Fig. 1A+B), along with significant reductions in serum ALP (Fig 1C). No significant changes in bilirubin were observed. Paradoxically, a reduction in gut microbial diversity associated with improvement in IBD activity (Δ -1.25 [SD -1.15], P = 0.001), with the Shannon index positively correlating with fcal values (R = 0.53, P = 0.002). This was alongside significant shifts in beta diversity (p <0.001). The latter was characterised by reduced abundance of *Lachnospiraceae, Blautia* and *Bacteriodes,* and enrichment of *Enterbacteriaceae, Veillonella* and *Eschericia.* Differential gene expression of host colonic mucosa demonstrated downregulation of 134 genes and upregulation of 298 genes following treatment with OV (Fig 1D). Reduction in IBD activity strongly correlated with downregulation in the enzymatic activity of several pathways, including copper containing amine oxidases and inferred microbial bile salt hydrolase (Fig 1E-F). No adverse safety events were observed during treatment. However, microbiological analyses captured the emergence of vancomycin resistant Enterococci in 6 pts as early as 1 wk into treatment. During washout, relapse in IBD activity and an increase in serum ALP was observed in 4 pts upon stopping OV therapy.

Conclusion: Oral vancomycin is associated with a reduction in colitis activity, serum ALT and ALP values in PSC-IBD. However, emergence of antimicrobial expression warrants further evaluation. Targeting specific bile acid and amine oxidase metabolic pathways may offer novel avenues for future therapeutic intervention in PSC-IBD. Metagenomic, metatranscriptomic and metabolomic readouts from this study are ongoing.

LBP-37

Intestinal bacterial vesicles cause fibrosis progression and serum albumin levels reduction in cirrhosis

Atsunori Tsuchiya[1], Kazuki Natsui[1], Yui Natsui[1], Nobutaka Takeda[1], Shuji Terai[1]. [1]*Niigata University, Japan*
Email: atsunori@med.niigata-u.ac.jp

Background and aims: Liver fibrosis progression causes portal hypertension and the formation of an edematous intestinal tract with impaired gut barrier function, resulting in bacteria and bacterial components invasion of the host. Lipopolysaccharides and pathogen-associated molecular patterns are well-known bacterial components. This study investigated the role of outer membrane vesicles (OMVs) of *Escherichia coli,* the representative pathogenic gut-derived bacteria in patients with cirrhosis, to assess cirrhosis pathogenesis.

Method: We analyzed the roles of OMVs in humans using human serum and ascites samples and the role of OMVs from *Escherichia coli* in mice using mouse liver-derived cells and a mouse cirrhosis model. The effects of OMVs in immune cells of the cirrhotic mouse liver were also investigated by single-cell RNA-sequencing.

Results: In vitro, OMVs activated inflammatory responses to macrophages and neutrophils especially, with upregulation of C-type lectin domain family 4 member E (Clec4e) and reduction in the albumin production from hepatocytes, but with a relatively little direct effect on hepatic stellate cells. In a mouse cirrhosis model, administration of OMVs led to increased liver inflammation, especially inducing the activation of macrophages, worsening fibrosis, and decreasing serum albumin levels. Albumin administration weakened these inflammatory changes. Human sample analysis showed increased antibodies against bacterial components such as ompA and CirA with a progressing Child-Pugh grade. OMVs were detected in ascites samples of patients with decompensated cirrhosis. The *Clec4e* reported in this study was not present in *Clec4f*-positive Kupffer cells but was abundant in *Cx3cr1*-positive, extrahepatic-derived macrophages that are *Mrc1*-negative and *Cd86*-positive by single-cell RNA-sequencing.

Conclusion: OMVs induce inflammation, fibrosis, and suppression of albumin production, affecting the pathogenesis of cirrhosis. Appropriate albumin administration could reduce these inflammatory changes. This study could pave the way for the future prevention and treatment of cirrhosis.

Email: ksims@arbutusbio.com

Background and aims: AB-729 is an *N*-Acetylgalactosamine (GalNAc)-conjugated single trigger RNA interference therapeutic that targets all HBV RNA transcripts, resulting in suppression of viral replication and all viral antigens. AB-729-201 is an ongoing Phase 2a study assessing 24 weeks of AB-729 followed by 12 or 24 weeks of pegylated interferon alfa-2a (IFN) with or without additional AB-729 doses in virally suppressed, HBeAg-negative CHB subjects. We report interim data through 12 weeks of IFN treatment for the first 12 subjects.

Method: Forty-three CHB subjects, virally suppressed on stable nucleos (t)ide analog (NA) therapy, were all enrolled to receive AB-729 60 mg every 8 weeks for 24 weeks (4 doses) during the lead-in phase. After Week 24, the subjects were randomized to 1 of 4 sub-groups: A1 (24 weeks IFN + AB-729+NA), A2 (24 weeks IFN + NA), B1 (12 weeks IFN + AB-729 + NA) or B2 (12 weeks IFN + NA). After completing IFN ± AB-729 treatment, subjects continued NA therapy only for an additional 24 weeks and were then evaluated for NA discontinuation based on protocol criteria (ALT <2 x upper limit of normal, undetectable HBV DNA, confirmed HBsAg <100 IU/ml). Safety and antiviral assessments were obtained every 2-4 weeks. HBsAg quantification was assessed via Roche Cobas Elecsys HBsAg II quant II assay (lower limit of quantitation [LLOQ] = 0.05 IU/ml).

Results: The median subject age was 46 years, 72% were male, and 79% were Asian. To date, 32 of 43 subjects have been randomized to the 4 IFN sub-groups after completing the 24-week AB-729 lead-in period. The mean (standard error [SE]) baseline HBsAg level for all 43 subjects was 2.98 (0.07) $\log_{10}$ IU/ml and the median (range) was 2.92 (2.7-3.4) $\log_{10}$ IU/ml. The mean (SE) HBsAg decline observed at Week 24 was -1.65 $\log_{10}$ (0.10, n = 34). All subjects had HBsAg declines of approximately 1 $\log_{10}$ or more from baseline, and 28 of the 32 (88%) randomized subjects reached HBsAg <100 IU/ml. After 6 weeks of IFN treatment, mean HBsAg declines from baseline ranged from -1.53 to -2.49 $\log_{10}$ across the 4 sub-groups (3-5 subjects/group), and after 12 weeks of IFN, mean HBsAg declines ranged from -0.74 to -2.20 $\log_{10}$ (2-4 subjects/group). Three subjects had intermittent HBsAg <LLOQ, 2 during the IFN treatment period and 1 at the end of the AB-729 lead-in period. Three subjects have completed the NA follow-up period, and 1 subject met the criteria to stop NA therapy. AB-729 treatment has been well-tolerated with no serious adverse events (AEs) or AEs leading to AB-729 discontinuation. AEs during IFN treatment have been typical, with 4 subjects requiring IFN dose reduction or interruption due to neutropenia and 1 due to Grade 3 ALT elevation.

Conclusion: AB-729 treatment in virally suppressed CHB subjects was well tolerated and led to mean HBsAg declines of >1.6 $\log_{10}$ after 24 weeks of treatment, comparable to other AB-729 studies. HBsAg levels <100 IU/ml were noted in 88% of the subjects. This interim data analysis suggests addition of IFN was well tolerated, and AB-729 + IFN appears to result in continued HBsAg declines in most subjects with 2 subjects reaching HBsAg <LLOQ during IFN treatment, but more data is needed to assess the overall impact on HBsAg responses.

Acute liver failure and drug induced liver injury

WEDNESDAY 21 TO SATURDAY 24 JUNE

Epigenetic modifications implicated in idiosincratic drug-induced liver injury

Marina Villanueva[1], Romina De los Santos Fernández[1], Ismael Alvarez-Alvarez[1], Hao Niu[1], Camilla Stephens[1,2], A González-Jiménez[1], Gonzalo Matilla[1], Maria Isabel Lucena[1,2], Inmaculada Medina-Caliz[1], Raul J. Andrade[1,2]. *[1]Servicios de Aparato Digestivo y Farmacología Clínica, Hospital Universitario Virgen de la Victoria, Instituto de Investigación Biomédica de Málaga y Plataforma en Nanomedicina-IBIMA Plataforma BIONAND, Universidad de Málaga, Malaga, Spain; [2]Centro de Investigación Biomédica en Red, Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain*
Email: lucena@uma.es

Background and aims: Drug-induced liver injury (DILI) is a complex disorder involving pharmacological, genetic, and environmental factors. Among these, genetic factors have been the most studied. Different Human Leucocyte Antigen (HLA) alleles and liver metabolism genes polymorphisms have been associated with an increased risk of DILI. However, the role of epigenetic modifications in DILI has been minimally investigated. Our study aimed to analyse the genome methylation status during an idiosyncratic DILI episode in a cohort of well-defined DILI cases from the Spanish DILI Registry.
Method: DNA from 32 well-characterized DILI cases enrolled in the Spanish DILI Registry and 32 healthy controls were extracted from peripheral blood samples by using the DNeasy Blood and Tissue Kit (Qiagen). For the study of genome-wide methylation analysis, high-quality genomic DNA samples (500 ng) were subjected to bisulfite treatment using the EZ-96 DNA Methylation kit (Zymo Research, Irvine, CA) following the manufacturer's instructions. Subsequently, DNA methylation was analyzed by microarray assays using Infinium Methylation EPIC BeadChip Kit (Illumina, San Diego, CA). Then, whole-genome amplification and hybridization were performed using BeadChip, followed by single-base extension and analysis using the HiScan SQ module (Illumina) to assess the cytosine methylation states. The annotation of CpG islands (CpGIs) used the following categorization: (1) shore, for each of the 2-kb sequences flanking a CpGIs; (2) shelf, for each of the 2-kb sequences next to a shore; and (3) open sea, for DNA not included in any of the previous sequences or in CpGIs. DNA methylation for each CpG site was represented by beta values ranging from 0 to 1, corresponding to fully unmethylated and fully methylated. Finally, an analysis of differentially methylated regions between groups was performed.
Results: Control and DILI groups samples showed a similar density distribution of beta values. A total of 43861 CpG islands were identified (FDR ≤0.05) from which 213 manifested significative differential methylation (delta beta ≥0.1 and FDR ≤0.05) between groups with an overall tendency towards hypomethylation within the DILI cohort. Finally, candidate genes with the most significative differentially methylated CpGIs regions between groups were identified, resulting in 14 hypomethylated genes (*ZNF350-AS1, LOC349408, P2RY13, GPR109B, SUMO1B1, LOC285626, FAM200B, LOC284276, TEX28, STS, KLRK1, LOC101928100, TLR8, CSTA*) and one hypermethylated gen (*FAM163B*) in DILI group compared to the control group.
Conclusion: This exploratory analysis shows a general tendency towards hypomethylation in the DILI cohort compared to the control group. Further, deeper analysis must be conducted to unveil the relationship between DNA methylation and DILI phenotypes, severity, and outcome. Funding: PI19/00883, PEMP-2020-0127, PI21/01248, P18-RT-3364, PI-0310-2018, ISCIII CIBERehd, POSTDOC_21_00780, CD20/00083, CD21/00198.

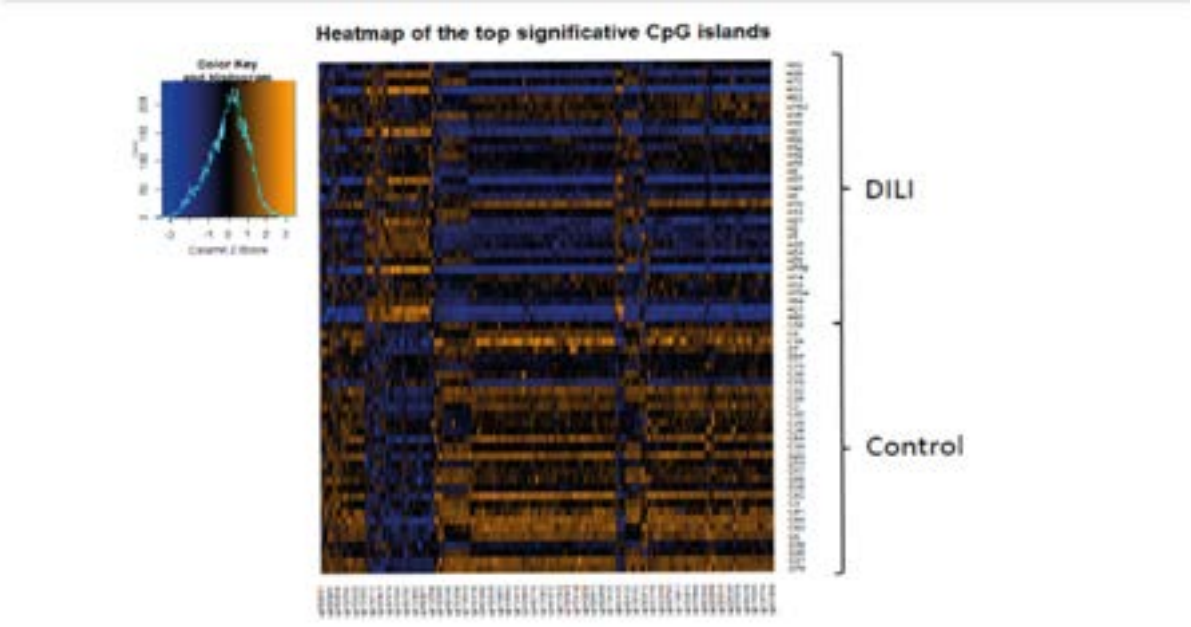

Figure 1: Heatmap of the top significative CpG islands. Significative CpG island hypermethylation and hypomethylation appear in orange and blue respectively. Differential distribution of significative CpG island methylation was observed between DILI and control groups (delta beta ≥ 0.1 and FDR ≤ 0.05).

Distinctive cytokine profiles in checkpoint inhibitor-induced liver injury, idiosyncratic drug-induced liver injury and autoimmune hepatitis: a potential mechanistic biomarker panel

Edmond Atallah[1,2], Stuart Astbury[1,2], Jane I. Grove[1,2], Ankit Rao[3], Hester Franks[3,4], Poulam Patel[3,4], Guruprasad Aithal[1,2]. *[1]Nottingham University Hospitals NHS Trust and the University of Nottingham, National Institute for Health Research (NIHR) Nottingham Biomedical Research Centre, Nottingham, United Kingdom; [2]University of Nottingham, Nottingham Digestive Diseases Centre, Translational Medical Sciences, School of Medicine, Nottingham, United Kingdom; [3]Nottingham University Hospitals NHS Trust, Oncology, Nottingham, United Kingdom; [4]University of Nottingham, Centre for Cancer Sciences, Translational Medical Sciences, Biodiscovery Institute, Nottingham, United Kingdom*
Email: edmond.atallah@nottingham.ac.uk

Background and aims: Immune mechanisms underlie the development of acute liver injury in checkpoint inhibitor-induced liver injury (ChILI) which shares some clinical and histological features with idiosyncratic drug-induced liver injury (DILI) and acute autoimmune hepatitis (AIH). Currently, there are no biomarkers to differentiate between these three aetiologies in individuals presenting with acute liver injury. We aimed to characterise circulating cytokine profiles of well-phenotyped acute cases of ChILI, DILI and de-novo AIH and develop a classification model that distinguishes between the groups.

Method: Consecutive patients with acute liver injury were prospectively enrolled. All met the criteria defined by the DILI International Expert Working Group at the time of sampling. They were evaluated through formal causality assessment and then adjudicated by an independent panel as ChILI (n = 19), DILI (n = 18) or AIH (n = 7) based on International AIH Group criteria. Plasma cytokine profiling was performed using a 20-plex inflammatory panel (Luminex). Kruskal-Wallis test was used to compare cytokine levels between groups and corrected for multiple testing. Linear Discriminant Analysis (LDA) was performed for classification, dimension reduction, and data visualization.

Results: All cytokines except for GM-CSF were quantifiable and included in the analysis. There was a significant difference in the plasma levels of anti-inflammatory cytokine IL-10 (p <0.0001) and pro-inflammatory cytokines CXCL10 (p = 0.006), IL-1 beta (p = 0.01), and CCL3 (p = 0.02) between the groups. Cytokines showed different linear discriminant coefficients separating the groups. Two dimensional LDA model, using 19 cytokines, classified patients into three types of liver injury with high diagnostic accuracy. IL-17A was the key cytokine associated with ChILI indicating a possible role of Th17 cells. IL-1 beta and CXCL10 which recruit T cells and amplify the inflammatory response in checkpoint-induced colitis, were important markers differentiating ChILI from DILI and AIH. CXCL8, a potent chemoattractant to neutrophils, distinguished AIH in combination with IFN gamma and IL-17A. IL-12p70 and TNF-alpha were the most important cytokines identifying DILI from other types of liver injury.

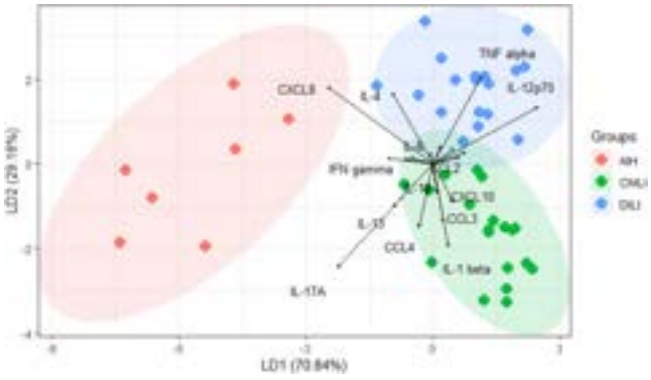

Figure:

Conclusion: Distinct cytokine profiles in ChILI, DILI and AIH point to key immunopathogenic pathways underlying each type of acute liver injury. The profile in ChILI highlights the contribution of pro-inflammatory subsets of CD4+ T cells producing IL-17A (characterizing Th17 subtype), similar to other immune-related organ toxicities. In AIH, CXCL8 release by monocytes and macrophages is distinctive, previously shown to correlate with serum IgG and macrophage accumulation in liver fibrosis. In DILI, IL12p70 stimulates the production of TNF-alpha (which previously showed prognostic value in acute DILI), emphasising the role of Th1 in response to antigenic stimulation.

Using cytokine profiles for LDA classification modelling revealed a high diagnostic accuracy in separating these aetiologies. If validated in a larger number of patients, an algorithm using cytokine profiles may assist in the diagnosis of these conditions.

Soluble and monocyte surface CD206 is a promising indicator of sepsis in patients with acute liver failure

Anna Cavazza[1,2], Evangelos Triantafyllou[3], Roberto Savoldelli[4], Salma Mujib[1,2], Ellen Jerome[1,2], Francesca Trovato[1,2], Florent Artru[1,2], Roosey Sheth[1,2], Rima Abdalla[1,2], Xiaohong Huang[2], Yun Ma[2], Francesco Dazzi[4], Charalambos Gustav Antoniades[1], William M. Lee[5], Mark J W McPhail[1,2], Constantine Karvellas[6]. *[1]Liver Intensive Therapy Unit, Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Institute of Liver Studies, Department of Inflammation Biology, Kings College London, United Kingdom; [3]Section of Hepatology and Gastroenterology, Department of Metabolism, Digestion and Reproduction, Imperial College London, United Kingdom; [4]School of Cardiovascular and Metabolic Medicine and Science, King's College London, London, United Kingdom; [5]Division of Digestive and Liver Diseases, UT Southwestern Medical Center, Dallas, United States; [6]Department of Critical Care Medicine and Division of Gastroenterology (Liver Unit), University of Alberta, Edmonton, Canada*
Email: a.cavazza1@gmail.com

Background and aims: Acute liver failure (ALF) has a high mortality and need for emergency liver transplantation (LT). Deaths are mostly due to septic complications in part due to monocyte-macrophage dysfunction. The role of prophylactic antimicrobials is under debate as most infective complications occur late in the disease. A validated marker of immune dysfunction associated with sepsis is.

Method: Patients from the United States Acute Liver Failure Study Group (USALFG) were recruited and healthy volunteers as controls (HC) and ALF patients were also recruited from Kings College Hospital as a validation cohort. Patient serum samples were analysed for monocyte/macrophage activation markers secretory leukocyte protease inhibitor (SLPI), osteopontin (OPN), soluble Mer tyrosine kinase (sMerTK), CD163 (sCD163), mannose receptor (sMR/CD206) and programmed death ligand 1 (sPD-L1) by enzyme-linked

immunosorbent assay (ELISA). These were correlated to markers of illness severity and 21 day survival (LT was grouped with death). Validation of key markers CD155, CD163, HLA-DR, MerTK, programmed cell death protein 1 (PD1), PD-L1, and CD206 was performed on peripheral blood monocytes using flow cytometry and analysed using an R pipeline (cytofkit) to generate unsupervised and unbiased clustering.

Results: Two hundred and twenty-four patients (79 (36%) male) with a median (range) age of 42 (17–81) and 34 HC were studied from USALFG. Eighty-seven ALF cases (39%) had drug induced liver injury (DILI), 46 (20%) indeterminate ALF, 60 (27%) with APAP-ALF, 15 (7%) autoimmune and 16 (7%) for other aetiologies as vascular or hypoxic hepatitis. All marker serum concentrations were significantly higher in ALF compared to controls (p <0.0001). sMR/CD206 concentration was higher in patients with bacteraemia (p 0.002) and infection (p 0.006). In MELD-adjusted multivariate modelling sMR/Cd206 and sCD163 after day 3 retained statistical significance for survival prediction. There were increases in surface expression ofCD206 (p <0.001) and PD-L1 (p <0.05) on CD14+ monocytes from patients with ALF compared with controls. CD206% were higher in patients with sepsis compared to those without and correlated with SOFA score (p = 0.018).

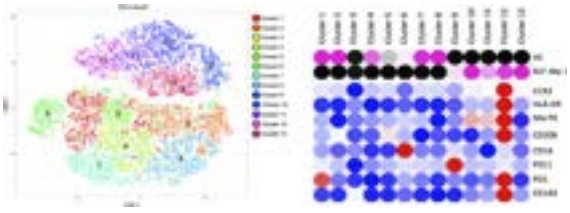

Figure: Surface expression on CD14+ monocytes in acute liver failure (ALF) and healthy controls (HC) measured by Flow Cytometry and analysed via CytofKit demonstrating 13 clusters with a clear division between heathy and ALF patient.

Conclusion: Soluble markers of macrophage activation are upregulated in patients with ALF that died compared to those who survived. sMR/cd206 serum concentrations were higher in patients with infections and those who died. In a validation cohort CD206 and PD-L1 were more highly expressed in ALF monocytes compared to controls. sMR/CD206 should be explored as a biomarker of sepsis in ALF.

THURSDAY 22 JUNE

THU-393

Non-invasive screening for histological features of autoimmune hepatitis and prognosis of patients with antinuclear antibody-positive drug-induced liver injury

Yanhang Gao[1], Feiyu Zhang[1]. [1]*The first hospital of Jilin University, China*
Email: yanhang@mail.jlu.edu.cn

Background and aims: Although useful for distinguishing drug-induced liver injury (DILI) from autoimmune hepatitis (AIH), liver biopsy is an invasive examination, and the high prevalence of antinuclear antibody (ANA) positivity in cases of DILI may lead to excessive use of biopsy. Hence, we aimed to develop a non-invasive screening tool based on histological features for detection of AIH in ANA-positive DILI patients and analyzed their clinical outcomes.

Method: This retrospective study included patients who presented with suspected DILI, were ANA-positive, and underwent liver biopsy between January 2017 and December 2020. Two pathologists determined histological features of AIH. The follow-up period was 1 year after DILI onset.

Results: The final analysis included 93 ANA-positive DILI patients, of which 17 had AIH-like histology and 76 did not. Factors independently associated with AIH-like histology included globulin level (odds ratio [OR] = 1.136, 95% confidence interval [CI]: 1.03–1.27; p = 0.017) and ANA titer ≥1:1000 (OR = 6.363, 95% CI: 1.30–47.44; p = 0.035). The optimal cut-off value for globulin indicating AIH-like histology was 31.5 g/L. This globulin level in combination with ANA titer ≥1:1000 provided a sensitivity of 100% and specificity of 57.9% for indicating histological features of AIH in ANA-positive DILI patients. During the 1-year follow-up, more patients developed AIH in the group with AIH-like histology than in the group without (31.2% vs 0, p < 0.001).

Table: Diagnostic performance of independently associated factors alone, in series, and in parallel.

	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	AUC	95% CI
ANA ≥1:1000	59	82	42	90	0.702	0.574–0.830
Globulin ≥31.5 g/L	88	63	35	96	0.757	0.661–0.853
ANA ≥1:1000 and Globulin ≥31.5 g/L	47	87	44	88	0.670	0.541–0.798
ANA ≥1:1000 or Globulin ≥31.5 g/L	100	58	35	100	0.790	0.734–0.845

Statistical tests: Receiving-operating characteristic curve analysis.
Abbreviations: PPV: positive predictive value; NPV: negative predictive value; AUC: area under the curve; ANA, antinuclear antibody; CI: confidence interval.

Conclusion: For ANA-positive DILI patients who present with an ANA titer ≥1:1000 or globulin ≥31.5 g/L, liver biopsy is indicated to determine the presence of histological features of AIH, and patients who then present with the histological features of AIH should be followed to detect the development of AIH.

THU-394

Outbreak of unexplained acute hepatitis in children: the role of viral infections

Yael Gozlan[1], Lital Goldberg[1], Orith Waisbourd-Zinman[2], Yael Mozar-Glazberg[2], Ronen Arnon[3], Lior Hecht Sagie[4], Michal Mandelboim[1], Merav Weil[1], Sara Dovrat[1], Orna Mor[1], Eyal Shteyer[5]. [1]*Israeli Ministry of Health, Centeral Virology Laboratory, Israel;* [2]*Schneider Children's Medical Center, Gastroenterology, Nutrition and Liver Diseases, Israel;* [3]*Rambam Medical Center, Israel;* [4]*Israeli Ministry of Health, Israel;* [5]*Shaare Zedek Medical Center, The Juliet Keidan Institute of Pediatric Gastroenterology Institute, Jerusalem, Israel*
Email: eyals@szmc.org.il

Background and aims: An increase in the number of cases of acute hepatitis of unknown etiology (AHUA) in children has been observed since October 2021. In view of the SARS-Cov-2 pandemic, adenovirus and adeno-associated virus 2 (AAV2) infections have been suggested as possible triggers in numerous cases. However, the causal relationship between AHUA and any potential etiology is still unclear. Our aim was to characterize the cohort of children with AHUA in Israel.

Method: Subsequent to the WHO/CDC announcement on the AHUA a national registry was established by the Israeli Ministry of health. Retrospective and prospective demographic, clinical data and laboratory results on the children compatible with the CDC criteria for AHUA were collected. In addition, when available, blood and stool were sent to the central virology laboratory (CVL).

Results: A total of 42 children were included in the registry, of them 21 females, median age of 39 months. Past SARS-Cov-2 exposure (infection or vaccination) was observed in 25 children. Median lab values were AST 1164 (IU/L), ALT 1082 (IU/L), total bilirubin 5 (mg/dL) and INR 1.12. Samples from 23 children were further assessed by the CVL. Adenovirus was found in 4/21 of cases. AAV2 was detected in 4/18. Past SARS-Cov-2 exposure (infection or vaccination) could be verified in 16/22 children. Interestingly, HHV6 infection or reactivation was identified in 13/22. Twelve children underwent liver biopsy

Positive
Not tested

Figure 1: (abstract THU-394): Virological results in samples from 23 AUHA patients. Adeno, AAV2 and HHV6 were tested by RT-PCR in whole blood samples (adeno also in stool samples). Anti HHV6 IgG antibodies were measured by immunofluorescence in sera samples. All cases positive for HHV6 in whole blood, with high IgG titer (>1:600) or positive IgM were recorded as having HHV6 infection or reactivation. SARS-Cov-2 exposure status (infected or vaccinated) was retrieved from the Ministry of Health records.

of which 10 showed variable autoimmune features consisting of plasma cells and variable degree of interface hepatitis and two appeared as none-specific hepatitis. Six were treated with steroids. Two underwent liver transplantation.

Conclusion: In view of the SARS-Cov-2 pandemic, it may be that combination of reactivation or active infection with specific viruses is a trigger for this AHUA outbreak. In our cohort HHV6 is the most abundant cause.

THU-396

Determinants of steroid responsiveness in patients with severe acute hepatitis of indeterminate, autoimmune hepatitis and drug induced aetiologies

Mahdi Saeidinejad[1], Andrew Hall[2], Disha Jindal[3], Shashank Ramakrishnan[3], Su Lin[4], Alberto Quaglia[5], Fausto Andreola[1], Rajiv Jalan[1]. *[1]University College London, Liver failure Group, Institute for Liver and Digestive Health, Division of Medicine, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, Department of Cellular Pathology and Sheila Sherlock Liver Centre, United Kingdom; [3]Royal Free London NHS Foundation Trust, Hepatology, United Kingdom; [4]the First Affiliated Hospital, Fujian Medical University, Department of Hepatology, Hepatology Research Institute, Fuzhou, China; [5]Royal Free Hospital and UCL Cancer Institute, Department of Cellular Pathology, London, United Kingdom*
Email: mohammad.saeidinejad@nhs.net

Background and aims: Acute hepatitis (AH) due to autoimmune hepatitis (AIH), drug induced liver injury (DILI) and indeterminate acute hepatitis (IAH) have similar histological features. The role of corticosteroids (CS) in these situations is unclear. The aims of this real-world study were to determine the role of CS in patients with AH due to AIH, DILI and IAH. Furthermore, we aimed to identify prognostic factors and their value in predicting response to CS therapy.

Method: Patients admitted with AH due to AIH, DILI and IAH to Royal Free Hospital, between January 2010 to August 2022, who form part of an ongoing hospital database, the CARNATION cohort. Diagnosis was based on history, routine screening tests and liver biopsy. Response to CS was defined as survival at 90-days without the need for emergency liver transplantation (ELT). Univariate and Multivariate analyses were then performed to identify factors predictive of steroid responsiveness (SR).

Results: 129 patients with AH (76 IAH, 29 AIH, 24 DILI) were included of whom 76 had received CS (38 with IAH, 28 with AIH, 10 with DILI). CS was used more frequently in patients with AIH (96.6%) vs. 51.3% and 45.8% in IAH and DILI respectively. Transplant-free survival amongst patients who received CS was not different compared to those who did (62.8% vs 51.0%; p = 0.18). 29.5% underwent ELT in the CS group compared to 43.1% in the latter (p = 0.11). The baseline MELD-Na (22.9 vs 24.0; p = 0.46) and the infection rates were similar between those that received steroids and those that did not (9.0% vs 7.8%; p = 0.70). SR was 67.9% in those with AIH, 60% in DILI, and 60.5% in IAH (p = 0.57). When comparing those with severe AH (n = 62) [total serum bilirubin of more than 5 times the upper limit of normal, and INR of more than 1.2], the overall SR was found to be lower at 54.8% but still not significantly different across the 3 etiologies (59.1% AIH, 50.0% DILI, 53.1% IAH; p = 0.27). All patients with non-severe AH were that were treated with CS were steroid responsive. In the multivariate analyses only the MELD-Na score was found to be independently predictive of SR.

Competing risk analysis of steroid responsiveness using the binary logistic regression model.

	Univariate analysis			Multivariate analysis		
Variable	HR	95% CI	P value	HR	95% CI	P value
Age	0.981	0.951–1.011	0.238			
MELD-Na	1.298	1.112–1.514	<0.001	1.308	1.043–1.641	0.020
ALF-OF	5.264	1.933–14.332	<0.001	1.516	0.308–7.458	0.609
Albumin	0.921	0.854–0.993	0.033	1.065	0.956–1.187	0.252

Figure:

Conclusion: The results show that administration of CS to patients with AIH, DILI or IAH did not improve the overall transplant free survival and SR was independent of etiology. The baseline MELD-Na score is the single best measure in predicting SR in patients with AH.

THU-397

Clinical and histological features of drug-induced liver injury: a retrospective study in biopsy-based cohort

Ting Zhang[1], Mengqi Li[1], Xingang Zhou[2], Hong Zhao[1], Gang Wan[3], Wen Xie[1]. [1]*Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China;* [2]*Department of Pathology, Beijing Ditan Hospital, Capital Medical University, Beijing, China;* [3]*Department of Biostatistics, Beijing Ditan Hospital, Capital Medical University, Beijing, China*
Email: xiewen6218@163.com

Background and aims: This study aimed to describe the clinical and histological features of drug-induced liver injury (DILI) in a biopsy-based cohort.
Method: Patients diagnosed with DILI and underwent a liver biopsy were included in this retrospective study. We grouped the severity of DILI into 5 grades according to the Chinese guideline for DILI. The logistic regression analysis was performed to assess the associated clinical and histological factors for the severity of DILI.
Results: A total of 1070 hospitalized patients diagnosed with DILI between 2009 and 2012. Among them, 523 patients underwent a liver biopsy. Patients with pre-existing liver disease (n = 139), diagnosed with toxic liver injury (n = 19), undergone liver transplantation (n = 3), unqualified liver biopsy samples (n = 7) and followed up for less than 6 months (n = 14) were excluded. In addition, 40 patients could not be definitively diagnosed DILI were also excluded. Finally, 301 patients were included in this study. The leading single classes of implicated drugs were traditional Chinese medicines or herbal and dietary supplements (50%) and anti-infectious agents (8%). Only 8 (3%) patients with acute liver failure and no one died. Compared grades 3–4 group, grades 1–2 group with higher levels of biochemistry parameters and higher degrees of fibrosis stage, significant inflammation, cholestasis and ductular reaction. But granulomas were more often found in grades 1–2 group. Multivariable logistic regression analysis showed that grades 3–4 were still associated with higher degrees of fibrosis stage, cholangiolar cholestasis, ductular reaction and the presence of granulomas was associated with grades 1–2.

Table 1: Clinical and histological characteristics of DILI patients with different liver injury severity.

Characteristics	Grades 1–2 (n = 157)	Grades 3–4 (n = 144)	*P* value
Age at diagnosis, years	47 (35–55)	46 (35–54)	0.874
Females, n (%)	111 (70.7)	91 (63.2)	0.166
Implicated agents			0.161
Herbal and dietary supplements	70 (44.6)	79 (54.9)	
Western medicine	57 (36.3)	39 (27.1)	
Both	30 (19.1)	26 (18.1)	
ALT at onset (U/L)	517.0 (252.8–892.0)	685.0 (370.0–1120.1)	0.003
AST at onset (U/L)	251.5 (116.6–514.0)	497.4 (238.5–796.3)	<0.001
ALP at onset (U/L)	135.3 (97.9–175.5)	171.4 (132.9–239.8)	<0.001
TBIL at onset (μmol/L)	23.8 (15.5–41.8)	184.0 (122.5–276.4)	<0.001
ALB (g/L)	39.9 (37.6–42.9)	37.4 (33.5–41.3)	<0.001
Cr (μmol/L)	57.0 (51.0–71.0)	58.0 (51.0–68.0)	0.985
INR	0.97 (0.89–1.06)	1.02 (0.93–1.19)	0.006
PLT ($\times 10^9$/L)	192.0 (153.5–240.3)	195.8 (160.5–239.2)	0.447
Clinical pattern of liver injury, n (%)			0.372
Hepatocellular	115 (73.2)	95 (66.0)	
Cholestatic	15 (9.6)	16 (11.1)	
Mixed	27 (17.2)	33 (22.9)	
Granulomas, n (%)	9 (5.7)	2 (1.4)	0.045
Ductular reaction, n (%)	27 (17.2)	47 (32.6)	0.002
Cholangiolar cholestasis, n (%)	17 (10.8)	55 (38.2)	<0.001
IFS ≥1 points, n (%)	18 (11.5)	34 (23.6)	0.005
HAI ≥10 points, n (%)	23 (14.6)	43 (29.9)	0.001

All data are presented as n (%) or median (interquartile range).
DILI: drug-induced liver injury; ALT: alanine aminotransferase; AST: aspartate aminotransferase; ALP: alkaline phosphatase; TBIL: total bilirubin; ALB: albumin; Cr: creatinine; INR: international normalized ratio; PLT: platelet count; IFS: Ishak fibrosis score; HAI: histology activity index.

Conclusion: In this biopsy-based cohort of DILI, severer liver injury was related to higher degrees of fibrosis stage, cholestasis, and ductular reaction, whereas granulomas was associated with milder injury.

THU-398

Clinical characteristics of chronic drug-induced liver injury in mainland China: a multicenter retrospective cross-sectional study

Hong Zhao[1], Chengwei Chen[2], Yimin Mao[3], Wen Xie[1]. [1]*Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China;* [2]*Liver Disease Center of Naval 905 Hospital, Shanghai, China;* [3]*Division of Gastroenterology and Hepatology, Shanghai Institute of Digestive Disease, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China*
Email: xiewen6218@163.com

Background and aims: To investigate the prevalence, clinical characteristics, and risk factors of chronic drug-induced liver injury (DILI) in mainland China.
Method: A multicenter, open, retrospective, non-interventional, epidemiological survey collected the baseline information, medical history, data of laboratory examinations and imaging, examinations and outcomes of the DILI patients from 308 medical centers in mainland China from 2012 to 2014.
Results: A total of 25,927 patients were enrolled in the study, including 22,556 cases with acute DILI and 3,371 cases with chronic DILI. The average age of patients with chronic DILI was higher than that of the acute DILI group ($p < 0.0001$). The proportion of male cases in the acute DILI group was significantly higher as compared to the chronic DILI group ($p < 0.0001$), while the chronic DILI had underlying liver diseases, significantly higher than the chronic DILI group ($p < 0.0001$). ALT, AST, AKP, TBIL, and INR levels in the chronic DILI group were higher than the acute DILI group ($p < 0.0001$). The percentage of patients with fatigue, jaundice, itch, and gastrointestinal symptoms in the chronic DILI group was higher than that in the acute DILI group ($p < 0.0001$). A large subset of chronic DILI group used Chinese herbal medicine or dietary supplements as compared to

the acute DILI group (p < 0.0001). In the chronic DILI group, the percentage of cholestatic liver injury was higher as compared to the acute DILI group (p < 0.0001). Multivariate logistic regression analysis showed that the independent risk factors of chronic DILI included gender (male, p < 0.0001) and history of underlying liver diseases (p < 0.0001).

Table 1: Demographics and clinical characteristics of DILI patients.

Characteristics	Acute DILI (N = 22556)	Chronic DILI (N = 3371)	P value
Age (y), mean ± SD	45.19 ± 17.12	48.00 ± 16.65	<0.0001
Male (%)	11397 (51.51%)	1533 (46.27%)	<0.0001
History of liver disease	4832 (21.42%)	1229 (36.46%)	<0.0001
Cause of liver injury			<0.0001
Herbal medicines	5968 (26.46%)	1227 (36.40%)	
Western medications	15072 (66.82%)	1831 (54.32%)	
Herbal, Western medications and health products	1516 (6.72%)	313 (9.29%)	
Number of drugs for liver injury			<0.0001
1 drug	13491 (59.81%)	2154 (63.90%)	
2 drugs	4106 (18.20%)	618 (18.33%)	
≥3 drugs	4959 (21.99%)	599 (17.77%)	
Days from drug use to symptom appearance, median	33.00	51.00	<0.0001
Clinical symptoms and signs			
Jaundice	3895 (17.27%)	936 (27.77%)	<0.0001
Itching	729 (3.23%)	168 (4.98%)	<0.0001
Digestive symptoms (including inappetence, abdominal distension, nausea, vomiting)	8800 (39.01%)	1669 (49.51%)	<0.0001
Fever	1112 (4.93%)	163 (4.84%)	0.8127
Rash	463 (2.05%)	58 (1.72%)	0.2000
Feeble	8453 (37.48%)	1642 (48.71%)	<0.0001
Hemorrhagic tendency	28 (0.12%)	16 (0.47%)	<0.0001
Others (liver pain, arthralgia, hepatosplenomegaly)	4566 (20.24%)	1010 (50.13%)	<0.0001
No symptoms and signs	8472 (37.56%)	730 (21.66%)	<0.0001
Pattern of DILI			<0.0001
Hepatocellular	10626 (51.21%)	1672 (52.60%)	
Cholestatic	4091 (19.72%)	769 (24.19%)	
Mixed	6033 (29.07%)	738 (23.21%)	

Conclusion: Compared to acute DILI, patients with chronic DILI were older, with a high percentage of female patients. Moreover, liver function-associated indicators and clinical symptoms were severe. Among these, female gender and history of underlying liver diseases were independent risk factors of chronic DILI.

THU-399

Impact of plasma exchange and evolution of intensive care management in patients with acute liver failure in a liver transplant center over the past decade

David Toapanta[1], Octavi Bassegoda[1], Miriam Valdivieso[1], Fatima Aziz[1], Juliana Zapatero[1], Natalia Jimenez-Esquivel[1], Foix Valles[1], Helena Hernandéz Evole[1], Joan Cid[1], Enric Reverter[1], Miquel Lozano[1], Javier Fernandez[1]. [1]*Hospital Clínic de Barcelona, Barcelona, Spain*
Email: bassegoda@clinic.cat

Background and aims: Acute liver failure (ALF) is a rare clinical syndrome characterized by an acute alteration in liver blood test, coagulopathy, and encephalopathy in patients without chronic liver disease. The most common causes are acetaminophen-induced liver injury (AILI) and drug-induced liver injury (DILI). ALF may progress to multiple organ dysfunction and need for an emergent liver transplantation (LT). Plasma exchange (PE) improves transplant-free survival in patients with ALF, mainly in non-candidates to LT. PE was implemented in the standard care of those patients in the recent decade. Our goals were to determine the current management and outcomes of patients with ALF treated with PE in a real-life scenario.
Method: Retrospective cohort study of ALF patients admitted to the Liver Intensive Care Unit of Hospital Clinic of Barcelona during the period 2012–2022. We included all patients with a diagnosis of ALF defined as an acute alteration of liver blood tests, coagulopathy (INR >1.5) and hepatic encephalopathy of any grade without previous chronic liver disease. Listing for emergent LT was applied according to local criteria. PE was initiated at the discretion of the clinical team, mainly when a contraindication for emergent LT was present, or the expected time-to-transplant was above 24 h as a bridge to LT.
Results: A total of 46 patients with ALF were included. The most common etiology was autoimmune hepatitis (26%), followed by DILI (20%) and acetaminophen-induced liver injury (15%). Most patients required organ support with mechanical ventilation (70%), vasoactive drugs (60%) and renal replacement therapy (36%). Neurological monitoring was performed with ultrasonography in 41% of the patients and with intracranial sensor in 28%. Most patients were listed for LT (70%) and 63% were transplanted. Overall, mortality was 30%. Of the total cohort, 35% received PE. Those patients requiring PE were more severely ill as assessed by SOFA score and only 31% were transplanted. Mortality of patients receiving PE was 43% compared to patients who did not receive PE (23%). In the subgroup of non-transplanted patients, mortality in patients who received PE was 54% vs. 45% in those who did not. PE was well tolerated with no serious adverse events.
Conclusion: Mortality of ALF in patients who are not candidates for LT remains high despite the use of PE. Autoimmune hepatitis has replaced AILI and DILI as the main causes of ALF in our environment in the last decade. Neurological monitoring is performed mainly using ultrasonography. More studies addressing the use of PE in ALF patients who are not candidates to emergent LT are needed.

Clinical and histological features of porto-sinusoidal vascular disorder in drug-induced liver injury population: a retrospective study in biopsy-based cohort

Mengqi Li[1], Ting Zhang[1], Xingang Zhou[2], Hong Zhao[1], Gang Wan[3], Wen Xie[1]. [1]*Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China;* [2]*Department of Pathology, Beijing Ditan Hospital, Capital Medical University, Beijing, China;* [3]*Department of Biostatistics, Beijing Ditan Hospital, Capital Medical University, Beijing, China*
Email: xiewen6218@163.com

Background and aims: Porto-sinusoidal vascular disorder (PSVD) has been introduced as a new entity to describe a group of vascular liver diseases with or without portal hypertension (PH)[1]. Drug exposure is related to PSVD. However, the relationship between PSVD and drug-induced liver injury (DILI) is still unclear. This study aimed to describe the clinical and histological features of PSVD in DILI population.
Method: Patients diagnosed with DILI, underwent a liver biopsy at baseline and excluding those with pre-existing liver disease were screened for PSVD criteria in this retrospective study. Diagnosis of PSVD requires liver biopsy and the presence of (i) at least one specific feature for PH or one specific histological sign for PSVD or (ii) at least one unspecific feature for PH together with at least one unspecific histological sign for PSVD[2].
Results: Thirty-six patients with specific or unspecific clinical PH signs were enrolled in this study. Finally, 29 patients diagnosed with PSVD and 4 patients diagnosed with sinusoidal obstruction syndrome. Specific clinical PH signs and specific histological signs were found in 5 (17%) and 9 (31%) of 29 PSVD patients, respectively. Specific clinical PH signs including: (i) gastric, esophageal or ectopic

varices (n = 4); (ii) portal hypertensive bleeding (n = 1); (iii) porto-systemic collaterals at imaging (n = 1). Specific histological signs of PSVD including: (i) obliterative portal venopathy (n = 4); (ii) nodular regenerative hyperplasia (n = 5); (iii) incomplete septal fibrosis (n = 1). Patients with PSVD were mostly female (72%), with a median age of 47 years. Over half patients exposed to Chinese medicines or herbal and dietary supplements, 8 (28%) and 6 (21%) patients exposed to medicine or both of them, respectively. Five (17.2%) patients with persistent abnormalities in liver tests over 12 months.

Figure: PSVD patients (blue background, n = 29) were stratified according to the presence of clinical PH signs and histological signs for PSVD. Red background indicates patients who are not meeting PSVD criteria (n = 3). Four patients diagnosed with sinusoidal obstruction syndrome is not shown in this figure.

Conclusion: It seems that PSVD is not rare in DILI patients. Therefore, clinicians and pathologists should pay more attention to PSVD patients in DILI population.

Stanozolol-induced liver injury: a peculiar biochemical profile in a series of thirteen cases

Vinicius Nunes[1], Isadora Almeida[1], Maria Carolina Campos[1], Bárbara Freire[1], Marcelo Silva[2], Raymundo Parana Filho[1], Fernando Bessone[3], Nélia Hernandez[4], Eduardo Cancado[5], Maria Schinoni[1]. *[1]Hospital Universitário Professor Edgard Santos, Brazil; [2]Hospital Sao Roque, Argentina; [3]Hospital Provincial del Centenario-University of Rosario School of Medicine, Argentina; [4]Clinical Hospital, Uruguay; [5]Hospital das Clínicas of University of São Paulo Medical School, Brazil*
Email: isadora-lins@hotmail.com

Background and aims: Anabolic androgenic steroids (AAS) are synthetic derivatives of testosterone and stanozolol is a AAS 17α-alkylated derivative, often used for the increase of physical strength. However, the AAS process of biotransformation involves the liver and has a large potential toxicity. Frequently, the use of ASS occurs concomitantly with other supplements or anabolic steroids, so it is crucial to understand how the use of each drug presents clinically and laboratory. Also important is knowing other aspects such as latency period and prognosis, aiming to provide the best support for each case. The objective is to characterize patients with hepatotoxicity of stanozolol.

Method: Thirteen patients were evaluated by a group of specialists from the Latin American Dili Registry, configurating an epidemiologic, descriptive, prospective and observational study about hepatotoxic effect of Stanozolol between 2013 and 2022. The data were collected in Brazil (HUPES-BA and HC-USP), Argentina (Hospital Provincial Del Centenario- Rosário), and Uruguay (HC-UdelaR). We declare financial support from the Maria Emilia foundation.

Results: Nine reports of Stanozolol Induced Liver Injury were observed in Brazil, 02 in Argentina and 02 in Uruguay. All patients were males between 21 and 37 years old, and all of them reported use of AAS with the objective of muscular hypertrophy. About the symptons latency period, the average was 63.2 days, and the average resolution time was 141 days. All patients presented with jaundice, pruritus and fatigue. The enzymatic pattern observed was a total bilirrubin (TB) mean of 30.23 mg/dl, with 92.3% of patients presenting values higher than 9 mg/dL, a small increase of aminotransferases, which the aspartate transferase (AST) presented a mean value of 62.75 mg/dL, and the alanine transaminase (ALT), of 117.5 mg/dL. The alkaline phosphatase (ALP) was characterize by an increase in all cases with an average of 311.9 UI/L, and the gama-glutamyl-transferase (GGT) was very close to normal, presenting an average of 52 UI/L, in which all cases presented values bellow 100 IU/L.

Subject	Age years	Sex	Latency period of time days	Duration days	TB mg/dL	AST U/L	ALT U/L	ALP U/L	GGT U/L
1	21	M	45	180	15.2	52	72	258	17
2	31	M	45	60	15	99	147	146	36
3	26	M	180	100	9.7	60	103	217	53
4	29	M	15	180	15.7	53	61	100	75
5	29	M	30	120	45	38	50	139	71
6	25	M	-	90	31	47	49	250	45
7	22	M	-	-	21	48	-	241	80
8	29	M	45	-	36	-	46	319	13
9	37	M	45	180	44.3	105	98	281	89
10	31	M	50	-	32	-	98	775	42
11	37	M	80	-	5, 1	-	355	253	51
12	36	M	99	-	38	-	104	689	52
13	26	M	62	218	49	-	228	387	22

Conclusion: Liver injury induced by stanozolol was found in a population of young men, who have aesthetic purpose. These patients have high levels of total bilirubin, modest aminotransferases elevations. We suppose that genetic mutations such as seen in familial intrahepatic cholestasis may be present. Further studies are needed to confirm this hypothesis.

THU-402

Systematic review: patients with pre-existing chronic liver disease are more vulnerable to the severe sequelae of drug induced liver injury

Georgia Zeng[1,2], Guy Eslick[3], Martin Weltman[1,2]. *[1]Nepean Hospital, Gastroenterology and Hepatology, Australia; [2]The University of Sydney, Nepean Clinical School, Australia; [3]The University of Newcastle, NHMRC Centre of Research Excellence in Digestive Health, Australia*
Email: georgiazeng@icloud.com

Background and aims: Drug-induced liver injury (DILI) is a leading cause of death from acute liver failure (ALF) as well as medication withdrawal from the market. The diagnosis and management of DILI in the context of preexisting chronic liver disease (CLD) remains a controversial and difficult area to navigate, given that the natural

history of certain hepatological conditions involves a spontaneous fluctuation of LFTs. Our systematic review sought to assess the current literature in regard to the diagnosis and prognosis of DILI in CLD patients, and evaluate whether patients with CLD are at higher risk of worse DILI outcomes.
Method: Studies with a minimum of 50 patients adhering to a systematic collection of all DILI cases available to the registry were identified from electronic databases PubMed and EMBASE through to 26 October 2022. Only studies inclusive of patients with pre-existing CLD were included. Data extraction from each study included DILI definition, causality assessment, severity assessment, types of pre-existing CLD included, predominant DILI agents implicated, and incidence of the following outcomes delineated by patients with and without pre-existing CLD where available: ALF, liver-related mortality, liver transplant and chronic DILI.
Results: Overall, 10 studies comprising 36,579 unique patients were included. 6,556 of these patients had CLD, and the most common aetiologies were viral hepatitis, non-alcoholic fatty liver disease and alcoholic liver disease. No studies adopted specialised algorithms proposed to define DILI in CLD patients, based on multiples of their baseline ALT or Bilirubin values rather than the ULN. Only 2 studies compared the spread of DILI agents between patients with and without CLD, of which the multicentre Spanish DILI registry found a significantly higher prevalence of antitubercular drugs in patients with CLD (21% of cases) vs without CLD (7.6% of cases). 6 of 9 studies reported significantly higher rates of mortality in DILI patients with vs without CLD, with adjusted HRs as high as 2.64 (95% CI 1.78–3.93, $p < 0.001$) in a multicentre Taiwanese study, and 2.72 (95% CI 2.33–3.19, $p < 0.001$) in a national population-based Thailand study. 6 studies compared rates of ALF, liver decompensation and/or severity of DILI between DILI patients with and without CLD, 3 of which returned significant results. For example, in a large-scale retrospective Chinese study comprising 25,927 DILI cases, patients with pre-existing CLD consisted of 64% of fatal cases, 29% of cases with jaundice, and only 21% of cases without jaundice. 3 of 4 studies concluded that DILI patients with CLD were not at higher risk of suffering from DILI chronicity.

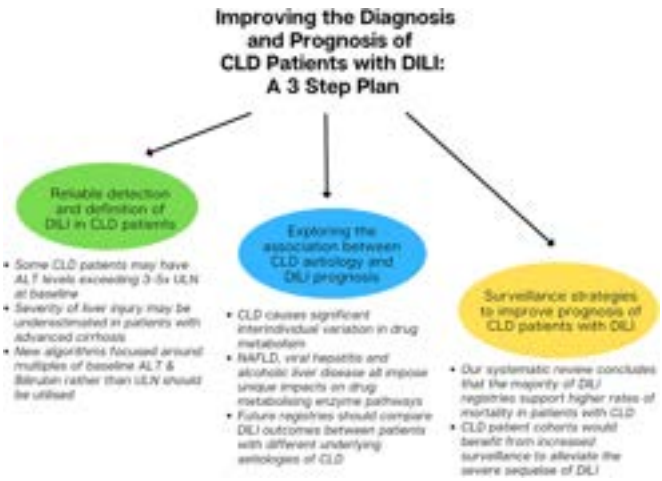

Figure: Improving the Diagnosis and Prognosis of CLD patients with DILI: A 3 Step Plan

Conclusion: Our systematic review demonstrates that a majority of DILI registries support higher rates of mortality in patients with CLD, with a stronger correlation between cirrhotic patients and poor outcomes. Future DILI registries should aim to fully characterize CLD patient cohorts regarding their demographics, clinical characteristics and spread of DILI agents. Our findings suggest that CLD patients who suffer DILI would stand to benefit from increased surveillance and a clear diagnostic strategy.

THU-403

Autoimmune hepatitis (AIH) or drug-Induced liver injury (DILI)-a diagnostic challenge

Yaakov Maor[1,2], Ali Abdallah[1,3], Leore Cohen Mendel[4], Ehud Melzer[1,2], Stephen Malnick[2,3]. [1]*Kaplan Medical Center, Institute of Gastroenterology and Hepatology, Rehovot, Israel;* [2]*The Hebrew University, Hadassah School of Medicine, Jerusalem, Israel;* [3]*Kaplan Medical Center, Department of Medicine C, Rehovot, Israel;* [4]*Kaplan Medical Center, Institute of Gastroenterology and Hepatology, Rehovot, Israel*
Email: halishy@netvision.net.il

Background and aims: AIH and DILI share clinical, biochemical, serological and histopathological characteristics. DILI cause by several medications may simulate AIH, while certain drugs can induce bonne-fide AIH. Therefore, the diagnosis of AIH vs. DILI is often challenging.
Method: Patients evaluated for hepatitis with clinical, biochemical, serological, and liver biopsy with a presumptive diagnosis of AIH or DILI were included in a retrospective attempt to make a definitive diagnosis. All biopsies were reviewed for features compatible with either diagnosis or both. Conventional scores of AIH (simplified criteria) and DILI (RUCAM) were calculated.
Results: 20 patients were enrolled: 75% female; mean age 59 years (age >50 years in 75%). 50% were affected with the metabolic syndrome and 45% with autoimmune disorders. A potential hepatotoxic drug was identified in 90%, mainly statins. Pattern of injury was hepatic in 90%. Bilirubin >10 mg/dL occurred in 25%. IgG >1.5xULN was present in 65% and ANA/ASMA >1:80 in 40%. Histopathology considered typical of AIH in 70%; compatible with or atypical in 15% each. AIH simplified score was: probable (≥6 points) in 15% and definite (≥7 points) in 40%. Histopathology determined suspected of DILI in 55%, consider DILI in 25% and low probability in 20%. RUCAM scored possible (3–5 points) in 60% and probable (6–8 points) in 40%. 75% were treated with corticosteroids ± azathioprine, with 70% response rate.
Conclusion: Distinction between DILI and AIH is still problematic, reflected by significant overlap in immune serology and histopathologic features in HIA and DILI. The majority of patients received corticosteroid treatment for severe or protracted hepatitis. DILI may be the initiating event of a flare of AIH or still unrelated to liver injury in such instances.

THU-404

Gender differences in liver transplantation (LT) for acute liver failure (ALF) in a multicentre ALF-LT Spanish cohort

Isabel Conde[1,2,3], Sara Martinez[1], Andrea Bosca[1,2], Maria Senosiáin[4], Rosa María Martín Mateos[5], Carolina Almohalla Alvarez[6], Maria Luisa Gonzalez Dieguez[7], Sara Lorente Perez[8], Alejandra Otero[9], Maria Rodriguez[10], Jose Ignacio Herrero[3,11,12], Isabel Campos-Varela[13], Ainhoa Fernandez[14], Marina Berenguer[1,2,3,15], Victoria Aguilera Sancho[1,2,3,15]. [1]*Hospital Universitario y Politécnico La Fe, Valencia, Spain;* [2]*Instituto de Investigación Sanitaria La Fe, Valencia, Spain;* [3]*CIBERehd, Instituto Carlos III, Madrid, Spain;* [4]*Hospital Universitario de Cruces, Bilbao, Spain;* [5]*Hospital Universitario Ramón y Cajal, Madrid, Spain;* [6]*Hospital Universitario Río Hortega, Valladolid, Spain;* [7]*Hospital Universitario Central de Asturias, Oviedo, Spain;* [8]*Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain;* [9]*Complejo Hospitalario Universitario A Coruña, A Coruña, Spain;* [10]*Hospital General Universitario de Alicante, Alicante, Spain;* [11]*Clínica Universidad de Navarra, Pamplona, Spain;* [12]*Instituto de Investigación Sanitaria de Navarra, Pamplona, Spain;* [13]*Hospital Universitari Vall d´Hebron, Barcelona, Spain;* [14]*Hospital General Universitario Gregorio Marañón, Madrid, Spain;* [15]*Universitat de València, Department of Medicine, Valencia, Spain*
Email: icondemiel@gmail.com

Background and aims: ALF is a critical illness with high morbi-mortality, improved by LT. There may be potential differences in

clinical presentation and outcome between men and women which we aimed to assess in this Spanish multicenter ALF-LT cohort.
Method: Baseline features, biochemical data, comorbidities, acute complications, early and late outcomes of an ALF-LT retrospective cohort from 11 hospitals (2001–2020) were collected.
Results: We included 217 adults ALF-LT (62% women) with an increasing proportion of women overtime (57% 2001–2005, 54% 2006–2010, 69% 2011–2015, 67% 2016–2020) but similar age (median: men 41, women 41.5yrs). Past history of alcohol, tobacco and drug use was higher in men ($p < 0.05$). Autoimmune and cryptogenic aetiologies were more frequent in women (31% vs 19% and 31 vs 20%) while HBV was more common in men (29% vs 10%) (p 0, 007). Kings College criteria as well as acute kidney injury (AKI) were present more frequently in men (14% vs 5% and 52% vs 29%, respectively). Renal function, ALT, platelets and MELD preLT were worse in men ($p < 0.05$). Early post-LT complications: AKI (73% vs 53%), and haemorrhage (26% vs 14%) were more frequent in men whereas rejection was more common in women (11% vs 22.5%) ($p < 0.05$). Later complications: arterial hypertension-AHT (36% vs 27%), dyslipidaemia (25% vs 11%), chronic kidney disease (24% vs 17%) and biliary complications (32% vs 21%) were all more frequent in men but without reaching statistical significance. AHT, pre-LT AKI and infection were independently associated with poor survival (HR 2.6, $p = 0.031$; HR 3.7, $p = 0.004$ and HR 2.5, $p = 0.03$, respectively) without gender differences. Causes of death, survival and reLT were similar in both groups.

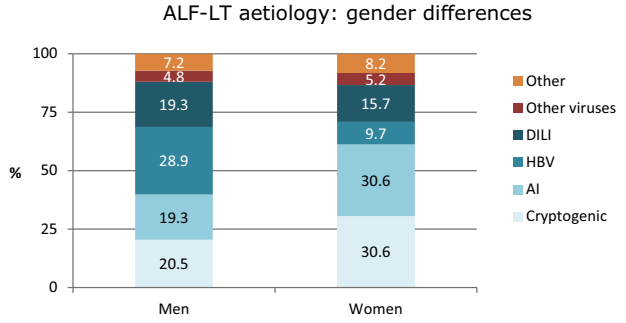

Figure:

Conclusion: Aetiology and history of toxic abuses were different between gender. At time of LT men were in worse clinical condition resulting in a higher rate of early post-LT complications, with the exception of rejection, yet long-term outcome was similar.

THU-405

CDK 4/6 inhibitors induced liver injury: 7 cases from REFHEPS registry

Lucy Meunier[1], Bénédicte Delire[2], Eleonora De Martin[3], Yves Horsmans[2], Dominique Larrey[1]. *[1]CHU Montpellier, Hepatology, Montpellier, France; [2]Cliniques Universitaires Saint-Luc, Gastroenterology, Belgium; [3]Hôpital Paul Brousse, Centre hepato biliaire, France*
Email: lucymeunier66@gmail.com

Background and aims: Cyclin-dependent kinase inhibitors (CDKIs) are the corner-stone of systemic
therapy for patients with hormone-positive (HR+) HER2-negative metastatic breast cancer (MBC). As reported by large randomized clinical trials, grade 3 elevation of alanine and aspartate amino-transferases occurred in up to 11% and 6% of patients receiving ribociclib or abemaciclib. The mechanism of liver toxicity remains unclear.
Method: Seven cases have been retrospectively collected through the French-speaking hepatotoxicity network (REFHEPS).
Results: Of the 87 cases collected by REFHEPS between November 2021 and January 2023, 7 involved CDKIs: ribociclib (n = 5) and abemaciclib (n = 2). All were women, median age 63 yr-old (49–77), treated for metastatic breast cancer. All patients also had concomitant hormonal treatment: letrozole, fulvestran or anastrozole. The median time to onset of hepatitis after introduction of CDKIs was 46 (24–274) days. All liver events exhibited a hepatocellular profile with a CTCAE severity grade 3 (n = 4) or 4 (n = 3). Median peak of liver tests were : AST: 335 IU/L (262–1201); ALT : 698 IU/L (402–2523); ALP : 131 IU/L (87–423). Exhaustive work-up was performed in all patients including viral serologies, liver antibodies and imaging. Only 2 patients had positive anti-nuclear antibodies and one had a slightly elevated immunoglobulin G level (1.1N). Liver biopsy, performed in 3 patients, showed no fibrosis but centro-lobular hepatitis in favor of DILI. RUCAM score was between 3 and 9. For most patients, improvement was spontaneous after CDKI withdrawal, median xx 57.6 days (min:19; max:112). Three patients received steroids (0.5–1 mg/kg) introduced due to a lack of spontaneous resolution followed by complete resolution. No recurrence of hepatitis after stopping steroids or resuming anti-tumor treatment.
Conclusion: CDKIs are frequently used to treat metastatic breast cancer. A few DILI cases have been reported in the literature. The mechanism of toxicity is unknown. However, the interest of corticoids to treat such DILI cases has been outlined but its place remains unknown. Here we reported 7 DILI cases from the REFHEPS registry outlining the interest ant potential limitations of steroid treatment. More data are clearly needed.

(abstract: THU-405): Patients' characteristics,

Case	Sex, age (years)	CDK 4/6	Concomitant medications	Delay treatment-DILI (days)	RUCAM score	Grade DILIN	Delay improvement (between stop drugs and grade 1) (days)	Steroids	Duration of steroids (days)	Delay DILI-steroids (days)

THU-406

Exponential increase of paracetamol liver injury over the last decade in a Spanish referral center

Anna Pocurull[1], Helena Hernandéz Evole[2], Cristina Collazos[1], Elia Canga[2], Ana Martinez-Ibiricu[3], David Toapanta[3], Enric Reverter[3], Xavier Forns[1]. [1]*Liver Unit, Hospital Clínic Barcelona. University of Barcelona. IDIBAPS. CIBEREHD. , Spain;* [2]*Liver Unit, Hospital Clínic Barcelona., Spain;* [3]*Liver ICU, Liver Unit, Hospital Clínic Barcelona, IDIBAPS and CIBERehd, Spain*
Email: apocurull@gmail.com

Background and aims: Paracetamol is one of the most used analgesics worldwide. Despite the fact that paracetamol overdose accounts for most cases of acute liver failure in some countries, this was uncommon in Spain. Since we had the perception that more patients were admitted to our unit due to paracetamol overdose, we analyzed its incidence and characterized the clinical phenotype of patients admitted to our Liver Unit during the last decade.

Method: We retrospectively reviewed all admissions due to paracetamol-associated liver toxicity from January 2010 to August 2022. Demographic data, laboratory test, use of concomitant drugs and psychiatric comorbidities were registered. In addition, the severity of liver injury and the need for support therapy were analyzed.

Results: One hundred and five patients with a median age of 31 (22–34) years were included; 65% were women. From 2010 to 2015 the incidence remained stable with around 5 cases/year, whereas starting in 2016 the incidence increased progressively, reaching 20 cases in 2022. In most patients the overdose was taken with autolytic intention (93%) and was the first attempt (69%). Regarding psychiatric comorbidities, 29% had past medical history of depression, anxiety (25%), or borderline personality disorder (16%). The intake of other medications or drugs during the episode was common (55%): anti-inflammatories (37%), illicit drugs such as cocaine (22%) or benzodiazepines (22%). Regarding the severity of liver injury, 87% required ICU admission due to PT<40%, hepatic encephalopathy or metabolic acidosis. At admission, the median values of ALT and total bilirubin were 1177 (204–4509) IU/L and 1, 55 (0.89–2.5) mg/dl, respectively. Hepatotoxicity resolved with specific treatment (N-Acetylcysteine) in 87% patients; 4% required plasma exchange or renal replacement therapy. One patient (1%) required liver transplantation and six patients died (6%). Variables associated with acute liver failure were overdose with autolytic intent (84% vs 43%) and presence of psychiatric comorbidity (87% vs 69%) (p <0.05).

Figure:

Conclusion: The incidence of hepatitis caused by paracetamol has increased significantly in recent years in Spain. The profile of patients are young women with symptoms of anxiety and/or depression, who attempt suicide. Although most cases resolve with specific treatment, ICU admission is frequent.

THU-407

Liver transplantation in acute liver failure in Slovenia

Marjana Turk Jerovšek[1], Marija Ribnikar[1]. [1]*University medical centre Ljubljana, Department of gastroenterology, Ljubljana, Slovenia*
Email: marjana.tjerovsek@gmail.com

Background and aims: Acute liver failure (ALF) is characterised by sudden onset of hepatic encephalopathy with concomitant coagulopathy, jaundice and multiorgan failure in a patient without previously known liver disease. Most prevalent causes of ALF in developed countries are paracetamol toxicity, drug induced liver injury (DILI), hepatitis B virus infection and autoimmunity. Viral hepatitis A, E and especially B are the main causes of ALF in Eastern countries. Patients with acute liver failure are transplanted urgently if criteria for urgent liver transplantation are met.

Method: 388 patients, of which two thirds' men and one third women, underwent liver transplantation in UMC Ljubljana, Slovenia, between 20.6.1995 and 31.12.2021. The average age at transplantation was 51 years. 31 (8,0%) patients, of which 9 men and 22 women, were transplanted urgently, due to acute liver failure. Their average age at transplantation was 39 years. 6 patients (1 man and 5 women) underwent emergency liver transplantation due to fulminant autoimmune hepatitis (19,4%), which is the most common indication for urgent liver transplantation in Slovenia. 4 patients (2 men and 2 women) each were urgently transplanted for drug-induced liver disease (12,9%) and Budd Chiari syndrome (12,9%) and 4 women for acute Wilsons disease (12,9%). 3 female patients (9,7%) were urgently transplanted due to fulminant hepatitis B. 1 man was urgently transplanted due to liver trauma and 1 female patient each due to mushroom poisoning and liver failure during pregnancy. We were unable to determine the cause of acute liver failure in 3 men and 4 women (22,6%). 41 (10,6%) of all patients and 3 (9,7%) of patients with acute liver failure were re-transplanted.

Results: 1 and 5-year survival of our liver transplanted patients is 84,1% and 76,1% respectively. 1 and 5-year survival of urgently transplanted patients with acute liver failure is 68,0%. 10 out of 31 urgently transplanted patients died, all of them in the first year after transplantation: 3 each because of infection and graft failure and 1 each because of gastric carcinoma and complication of liver transplant procedure. In 2 patients the cause of death is unknown.

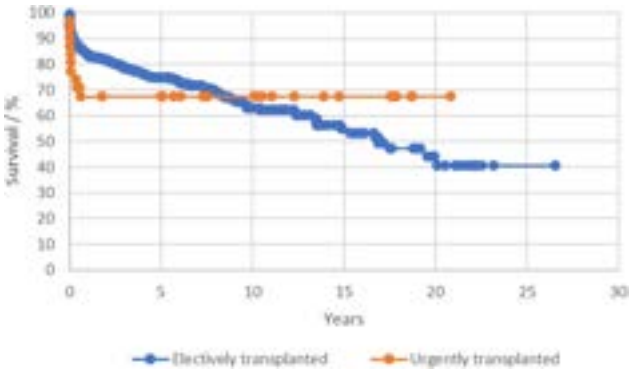

Figure:

Conclusion: Acute liver failure is a rare disease with poor prognosis and high mortality. For critically ill patients, urgent liver transplantation is currently the only effective method of treatment. Urgently transplanted patients are on average younger than electively transplanted patients. Unlike electively transplanted patients, women predominate among them. 1-year survival of urgently transplanted patients is worse than in electively transplanted, that reflects the severity and complexity of acute liver failure. Long-term survival is better due to younger age at transplantation and fewer comorbidities.

THU-408

Chemotherapy-induced hepatotoxic reactions in patients with acute myeloid leukemia: the overweight and obesity role in the pathogenesis

Igor Skrypnyk[1], Ganna Maslova[1], Roman Skrypnyk[1], Tetiana Lymanets[1]. [1]*Poltava State Medical University, Ukraine*
Email: inskrypnyk@gmail.com

Background and aims: To investigate the frequency of development and nature of cytostatic-induced hepatotoxic reactions in patients with acute myeloid leukemia (AML) with overweight and obesity during remission induction chemotherapy (CT).
Method: We examined 25 patients with newly diagnosed acute leukemia (AL), of which 56% (14/25) were men, 44% (11/25) were women. Depending on the body mass index (BMI), patients were divided into groups: I (n = 10)-patients with AML and BMI of 18.5–24.9 kg/m^2; II (n = 15)-patients with AML and BMI ≥25.0 kg/m^2. The biochemical blood analysis was evaluated twice: before and on the 56th day of CT, which included alanine-, aspartate-aminotransferases, gamma-glutamyltranspeptidase (GGT), alkaline phosphatase (ALP), total protein and total bilirubin.
Results: In patients with AML and normal BMI, CT conduction increased the risk of GGT (RR = 3.00; 95% CI = 1.14–7.91; p < 0.05) and ALP activity impairment (RR = 2.67; 95% CI = 0.98–7.22; p > 0.05). The presence of overweight and obesity in patients with AML of group II led to significant risk of increase the GGT (RR = 3.00; 95% CI = 1.46–6.14; p < 0.05) and ALP activity (RR = 4.00; 95% CI = 1.41–11.35; p < 0.05) during CT. GGT and ALP activity in the blood serum of group II patients after CT exceeded the baseline data in 2.4 times (p < 0.0001) and 1.6 times (p = 0.0007), respectively. After two courses of remission induction CT, the biochemical liver tests violations were recorded in 100% (15/15) of group II patients with overweight and obesity, of which cholestatic syndrome was detected in 20% (3/15) of patients and mixed syndrome-in 80% (12/15) of patients.
Conclusion: The remission induction CT of AML is accompanied by the risk of cytostatic-induced liver injury. In patients with AML, regardless of BMI, induction CT was associated with a risk of increased GGT and ALP activity. However, in patients with normal BMI, GGT and ALP activity increase was associated with hyperbilirubinemia, and in overweight and obese patients-with hypoproteinemia development. Moreover, the increased ALT activity after CT compared with the baseline data was observed in AML patients with high BMI.
The presence of overweight, obesity and primary disorders of biochemical liver tests due to the oncohematological disease influence are the risk factors for hepatotoxic reactions development during CT.

THU-409

Clinical determinants of hospital mortality in liver failure: a comprehensive analysis of 62,717 patients

Tobias Eßing[1], Hans Bock[1], Christoph Roderburg[1], Tom Lüdde[1], Sven H Loosen[1]. [1]*University Hospital Düsseldorf, Department of Gastroenterology, Hepatology and Infectious Diseases, Germany*
Email: Sven.Loosen@med.uni-duesseldorf.de

Background and aims: Liver failure (LF) is characterized by a loss of the synthetic and metabolic liver function and is associated with a high mortality. Large-scale data on recent developments and hospital mortality of LF in Germany are missing. A systematic analysis and careful interpretation of these data sets could help to optimize outcomes of LF.
Method: We used standardized hospital discharge data of the Federal Statistical Office to evaluate current trends, hospital mortality and factors associated with an unfavourable course of LF in Germany between 2010 and 2019.
Results: A total of 62,717 hospitalized LF cases were identified. Annual LF frequency decreased from 6,716 (2010) to 5,855 (2019) cases and was higher among males (60.51%). Hospital mortality was 38.08% and significantly declined over the observation period. Mortality significantly correlated with patients' age and was highest among individuals with (sub)acute LF (47.5%). Multivariate regression analyses revealed pulmonary (OR_{ARDS}: 2.91, $OR_{mechanical\ ventilation}$: 8.49) and renal complications ($OR_{acute\ kidney\ failure}$: 2.05, $OR_{hepatorenal\ syndrome}$: 2.99) and sepsis (OR: 1.96) as factors for increased mortality. Liver transplantation reduced mortality in patients with (sub)acute LF. Hospital mortality significantly decreased with the annual LF case volume and ranged from 47.46% to 29.87% in low or high case volume hospitals, respectively.

Figure:

Conclusion: Although incidence rates and hospital mortality of LF in Germany have constantly decreased, hospital mortality has remained at a very high level. We identified a number of variables associated with increased mortality that could help to improve framework conditions for the treatment of LF in the future.

Serum proteomics in American adults with acute liver failure

Katharina Remih[1], Franziska Hufnagel[1], Valerie Durkalski-Mauldin[2], William M. Lee[3], Zemin Su[2], Jody Rule[3], Laura Krieg[4], Isabel Karkossa[4], Kristin Schubert[4], Martin von Bergen[4], Robert Fontana[5], Pavel Strnad[1]. [1]*University Hospital RWTH Aachen, Clinic for Gastroenterology, Metabolic Disorders, and Internal Intensive Medicine, Aachen, Germany;* [2]*Medical University of South Carolina, Department of Public Health Sciences, Charleston, United States;* [3]*UT Southwestern Medical Center, Dallas, United States;* [4]*Helmholtz Centre for Environmental Research, Department of Molecular Systems Biology, Leipzig, Germany;* [5]*University of Michigan Medical Center, Division of Gastroenterology, Ann Arbor, United States*
Email: pstrnad@ukaachen.de

Background and aims: Acute liver failure (ALF) indicates sudden hepatocellular dysfunction with coagulopathy and encephalopathy in patients without known liver disease. Liver transplantation represents the only effective treatment, but the decision for/against transplantation remains challenging. We used mass spectrometry to characterize day 1 proteomic profiles in adult ALF patients of varying aetiology to identify diagnostic and prognostic biomarkers.

Method: Serum proteomic patterns were compared in 200 and 119 (discovery/validation cohort) adult patients with ALF, ~50% of them acetaminophen (APAP)-related, as well as in 30 healthy controls without liver disease. The former were randomly selected from admission samples (<48 h) of the US ALF study group database. Non-survivors were defined as patients who passed away or required liver transplantation within 21 days. Ingenuity pathway analysis (*Qiagen*) was used to obtain mechanistic insights.
Results: In the discovery cohort, 187 proteins were detected in ≥70% of subjects and most differed between ALF cases and controls. The key altered pathways were IL-6 signalling, acute phase response and prothrombin activation. 158 proteins differed between 95 APAP and 105 non-APAP cases. Three proteins reproducibly discriminated between the groups (AUROCs >0.9 in both cohorts) and were superior to other available markers.
In the discovery cohort, 46 proteins significantly differed between 21-day survivors and non-survivors. The most significantly enriched pathways were activated immune and acute-phase response which coincided with a better outcome. In particular, higher alpha1-antitrypsin (SERPINA1) and leucine-rich alpha-2 glycoprotein 1 (LRG1) levels were associated with better prognosis in the overall group (see figure, panel A). In both cohorts, they constituted the best discriminators (AUROCs >0.7) and were comparable to MELD score (see figure, panel B).
Conclusion: Unbiased proteomics may help identify a panel of new diagnostic and prognostic biomarkers with biological plausibility in ALF.

FRI-394

An in silico designed receptor antagonizing peptide targeting C-C motif chemokine receptor 8 attenuates monocyte/macrophage recruitment in vitro and in vivo

Eline Geervliet[1,2], Ralf Weiskirchen[2], Ruchi Bansal[1]. [1]*University of Twente, Medical cell biophysics, Enschede, Netherlands;* [2]*RWTH Aachen, Institute of Molecular Pathobiochemistry, Experimental Gene Therapy and Clinical Chemistry, Aachen, Germany*
Email: ekgeervliet@gmail.com

Background and aims: Acute liver injury is the most common cause of acute liver failure in the western world. Infiltrating monocytes/macrophages play a crucial role of liver inflammation, one of the hallmarks of acute liver injury. The macrophage compartment of the liver upon acute liver injury is augmented by the infiltrating monocytes driven by C-C motif chemokine receptor/C-C motif chemokine ligand (CCR/CCL) axis. Besides CCL2-CCR2, CCL1-CCR8 is involved in mediating monocyte recruitment which subsequently shapes the inflammatory microenvironment during liver injury. Several small molecular receptor-antagonists have been developed for CCR8 however failed in clinical translation possibly due to poor pharmacokinetic profile, serum stability, and lack of efficacy. Here, using in silico modelling approach, we have designed an antagonizing peptide for CCR8 (AP8) to inhibit liver inflammation and ameliorate acute liver injury.
Method: Efficacy of AP8 on CCL1-driven chemotaxis was examined *in vitro* in mouse RAW 264.7 macrophages and human THP-1 monocytes using transwell assays, and *in vivo* in an acute carbon tetrachloride (CCl_4)-induced acute liver injury mouse model. To assess intrahepatic monocyte infiltration *in vivo*, liver tissues were mechanically dissociated using Tissue Grinder, and the monocyte-derived macrophage (MoMF) population, characterized by CD11b and F4/80 expression levels, was analyzed using flow cytometry. Furthermore, effects of AP8 on disease progression (inflammation and fibrosis) were assessed using immunohistochemistry and mRNA analysis The effects of AP8 were compared with R243, a selective CCR8 antagonist, *in vitro* and *in vivo*.
Results: AP8 showed favorable inhibition of CCL1-driven macrophage and monocyte chemotaxis in both murine RAW264.7 macrophages and human THP1 monocytes while R243 only showed reduced infiltration of mouse macrophages and not human monocytes. *In vivo* in CCl_4-induced acute liver injury mouse model, flow cytometric analysis revealed a decrease in monocytes-derived macrophages (CD11b++/F4/80+) following AP8 treatment, but not R243 treatment. Immunohistochemical analysis evidenced decreased inflammation (F4/80 expression), fibrosis (collagen-I and alpha-smooth muscle actin expression), and increased liver regeneration (Ki-67 and HNF4alpha expression) in the AP8 treated mouse livers. Our data shows effective amelioration of inflammation and fibrosis using a CCR8-antagonizing peptide.
Conclusion: Our CCR8-antagonizing peptide inhibited migration of macrophages/monocytes *in vitro* and *in vivo* and ameliorated inflammation and fibrosis *in vivo* in an acute liver injury mouse model.

FRI-395

E2F2 deficiency protects from acetaminophen-induced hepatotoxicity while E2F1 is required to prevent the devastating effects

Email: patricia.aspichueta@ehu.eus

Background and aims: Acetaminophen (APAP) is one of the most commonly used pain relievers and antipyretics. APAP overdose, the leading cause of drug-induced hepatotoxicity in Western countries, entails a complex, time- and dose-dependent signaling network involving liver metabolism, immune response and liver regeneration. Available therapies are very limited; thus, new therapeutic targets need to be discovered. E2F1 and E2F2 proteins are cell cycle regulators involved in liver regeneration and mitochondrial metabolism. Additionally, they participate in the activation and maturation of T cells and macrophages. Therefore, the aims were: 1) to investigate if E2F1 and/or E2F2 are involved in APAP-induced liver injury and if so 2) to identify the mechanism.
Method: *E2f1*$^{-/-}$, *E2f2*$^{-/-}$, *E2f1*/*E2f2* double knockout (DKO) and wild-type (WT) mice were used.CD45.1 WT mice were used for bone marrow (BM) transplant. APAP-induced liver injury was achieved through the intraperitoneal injection of 750 mg/kg or 360 mg/kg of APAP and mice were monitored up to 6, 24 and 48 h after overdose. Survival and metabolic studies, anatomopathological evaluation of necrosis and immune infiltrate, immunohistochemistry, and protein and lipid levels analysis were performed.
Results: Lack of E2F1 worsens APAP overdose while that of E2F2 has a protective effect. Accordingly, APAP-treated *E2f1*$^{-/-}$ mice showed less survival and higher liver necrosis 24 h post-overdose. E2F2 deficiency ameliorated transaminases levels and improved the resolution of

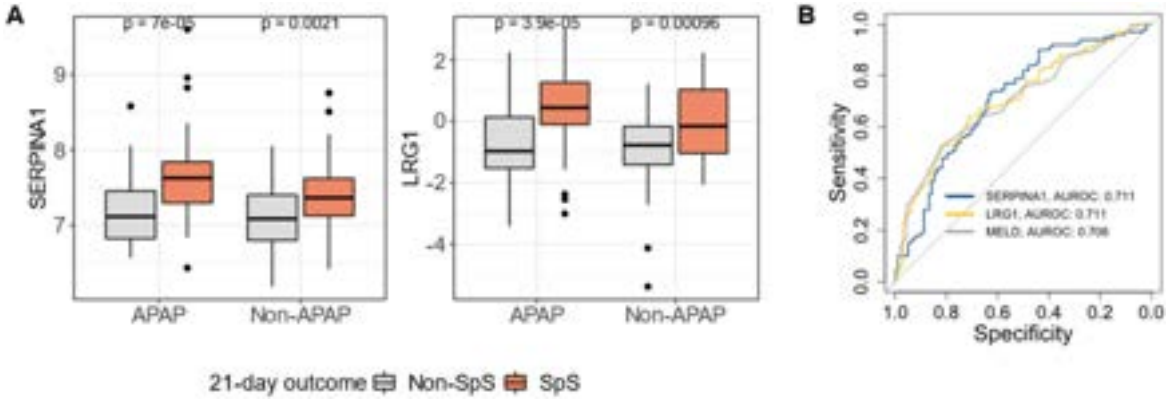

Figure: (abstract: FRI-393): A) The two strongest discriminating parameters for 21-day survival, SERPINA1 and LRG1, grouped by aetiology and survival status. Boxplots display median with first and third quartile and whiskers indicate smallest and largest nonoutlier observations. Outliers are depicted by black circles. APAP/non-APAP refers to the ALF aetiology (acetaminophen-related or not). SpS describes spontaneous survivors, non-SpS individuals who either died or required a liver transplant within 21 days of enrollment. B) Logistic regression analysis of SERPINA1 and LRG1 in comparison to the MELD-Score (discovery cohort).

liver necrosis by 48 h post-APAP. The anatomopathological evaluation post-APAP showed increased inflammatory component linked to necrotic areas in *E2f1*$^{-/-}$ mice, with neutrophils as the main recruited cells, while in *E2f2*$^{-/-}$ mice it was lower than that found in WT mice. The higher immune infiltrate in *E2f1*$^{-/-}$ mice was reinforced with the immunofluorescence determination of CD45^{+}, CD11b^{+} and F4/80^{+} cells in the whole liver, inflammation markers that also demonstrated the resistance conferred by *E2f2* deficiency. BM transplant showed that the protection of *E2f2*$^{-/-}$ mice or vulnerability of *E2f1*$^{-/-}$ mice were associated with the effect of its lack in liver rather than to changes in myeloid cell activity. Liver content of neutral lipids indicated a worse metabolic adaptation of *E2f1*$^{-/-}$ mice to APAP overdose, which together with changes in mitochondrial complexes contributed to their susceptibility. Ultimately, APAP-treated DKO demonstrated similar phenotype to that of *E2f2*$^{-/-}$ mice despite being deficient in both factors simultaneously showing the potent protective predominant role of E2F2 deficiency over the negative E2F1 deficient effect.
Conclusion: *E2f1* deficiency increases vulnerability to APAP-induced liver injury by altering liver metabolic adaptation. However, the inhibition of E2F2 arise as a potential therapeutic approach.

FRI-396

Mesenchymal stem cell-derived small extracellular vesicles ameliorate liver injury via attenuating macrophage extracellular traps

Zhihui Li[1], Zhang Jing[1], Meng Shibo[1], Bingliang Lin[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, The department of infectious disease, Guangzhou, China*
Email: lamikin@126.com

Background and aims: Acute liver failure (ALF) is characterized by massive hepatocyte necrosis and by systemic inflammation. The formation of macrophage extracellular traps (METs) has been associated with immune-mediated diseases. Small extracellular vesicles (sEVs) may act as mediators in the inhibition of inflammation by mesenchymal stem cells (MSCs). In this study, we aimed to investigate the mechanism of bone marrow MSC-derived sEVs (BMSC-sEVs) in treating mice with ALF.
Method: Small EVs and sEV-free BMSC concentrated medium were injected into mice with LPS/D-GalN-induced ALF to assess survival, changes in serology, liver pathology, and the yield of METs in different phases. The results were further verified in vitro in hydrogen peroxide injured L-02 and THLE-2 cells which were co-cultured with METs-induced macrophages THP-1. And Cl-amidine, an inhibitor of METs was used to evaluate the role and mechanism of BMSC-sEVs in METs-mediated liver injury.
Results: Treatment of BMSC-sEVs led to higher 24 h mouse survival rates and significant reductions in METs formation and liver injury compared to treatment with sEV-free concentrated medium. METs increased when macrophages were subjected to hypoxia/reoxygenation, and when METs were co-cultured with hepatocytes, apoptosis increased (Fig) and proliferation decreased, which were reversed by the inhibition of METs. Additionally, the Hippo/YAP pathway was activated in the METs-treated group.

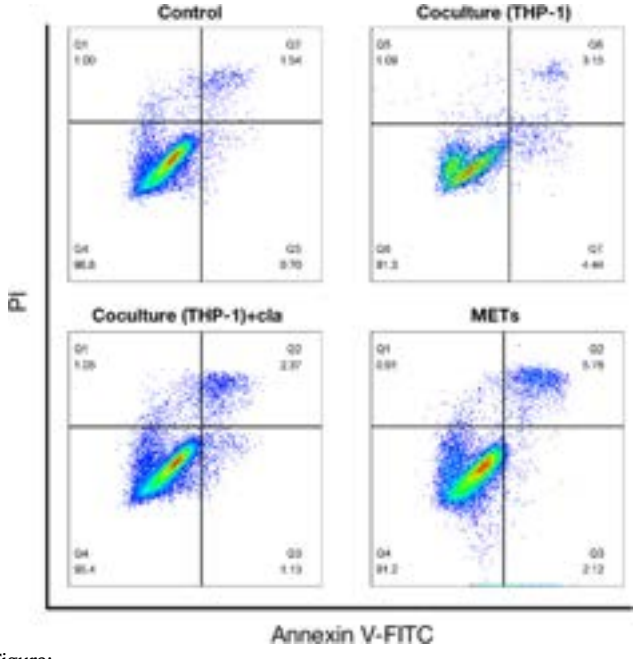

Figure:

Conclusion: Our results reveal that BMSC-sEVs play in suppressing METs formation and highlight the therapeutic potential of METs inhibition in reducing liver injury.

SRT-015, best-in-class apoptosis signal-regulating kinase 1 inhibitor, demonstrates preclinical efficacy in acute models of liver injury

Kathleen Elias[1], S. David Brown[1], Daniel Burge[1], Neil D. McDonnell[1], Artur Plonowski[1]. [1]*Seal Rock Therapeutics, United States*
Email: kelias@sealrocktx.com

Background and aims: SRT-015, a best-in-class apoptosis signal-regulating kinase 1 (ASK1) inhibitor, has demonstrated preclinical efficacy in a chronic therapeutic DIO-NASH mouse model with biopsy verifed steatosis and fibrosis. In vitro studies have demostrated dose-dependent direct anti-apoptotic, anti-inflammatory and anti-fibrotic effects with SRT-015 treatment. Clinical safety was demonstrated and human pharmacokinetic profile was established in Phase 1 trials with SRT-015. Here we evaluate the efficacy of SRT-015 in two acute preclinical models of liver injury for alcoholic hepatitis (AH) and acetamenophen (APAP) overdose.
Method: C57BL/6 male mice were used for both models. In the acute AH model, pyrazole induces high cyp2E1 levels emulating the effect of alcohol and LPS administration the gut bacterial toxins. Cyp2E1 was induced by two consecutive days of pyrazole administration (150 mg/kg, i.p.). On day 3 LPS (4 mg/kg i.p.), vehicle or SRT-015 (1, 3, 10 mg/kg, BID p.o.) was administered (n = 6–9/group). Plasma ALT was measured 24 hr. post LPS treatment. APAP overdose was induced (300 mg, i.p.) and 1 hr. later SRT-015 (0.3–10 mg/kg, p.o.) or vehicle administered. Six hours after APAP treatment plasma ALT was determined and liver analyzed for mitogen-activated protein kinases (MAPK) including ASK1, p38 and JNK by Western blots.
Results: In the AH model, serum ALT level was increased significantly ($p < 0.05$; 6-fold) in pyrazole plus LPS group compared to vehicle control at 24 hr. SRT-015 dose-dependently decreased ALT (marker of liver injury) elevated by pyrazole plus LPS treatment in the AH model. SRT-015 treatment at 1, 3 and 10 mg/kg decreased ALT levels 63%, 71% and 80% respectively compared to pyrazole plus LPS alone. APAP treatment significantly increased ALT over 30-fold and SRT-015 treatment dose-dependently decreased ALT with 1, 3, and 10 mg/kg treatments restoring ALT to control levels. Western blots demonstrated activation of phospho-JNK, phospho-ASK1 and phospho-p38 after APAP administration and all phospho-MAPKs were inhibited with SRT-015 treatment in a dose-dependent manner.
Conclusion: SRT-015 treatment significantly, and dose-dependently, decreased the liver injury marker ALT in two models of acute hepatotoxicity. These data support the advancement of SRT-015 to chronic AH models and suggest that SRT-015 is a promising therapeutic for both APAP overdose and AH.

FRI-398

Microbiome and metabolome analysis outlines circulatory predictors of poor outcomes in ALF

Jaswinder Maras[1], Sushmita Pandey[1], Neha Sharma[1], Nupur Sharma[1], Gaurav Tripathi[1], Babu Mathew[1], Manisha Yadav[1], Vasundhra Bindal[1], Sadam H Bhat[1], Rakhi Maiwall[2]. [1]*Institute of Liver and Biliary Sciences, Molecular and cellular medicine, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Acute liver failure (ALF) is severe hepatic dysfunction associated with early mortality. Exact mechanisms associated to severity and early mortality in ALF are obscure, but are thought to be driven by microbial and metabolic factors.
Method: Baseline plasma samples of 40 ALF patients and 5 healthy controls were subjected for albumin depletion followed by metabolome and meta-proteome (microbiome) analysis (labelled as training cohort). The results were validated on test cohort; plasma and paired one drop blood; in a 160 ALF patients using machine learning (ML). Albumin was depleted to enrich low abundant microbial peptide and metabolites. Circulating predictor of non-survival was identified and correlated with clinical parameters and outcome of ALF patients.
Results: Metabolomic profile of ALF-Non-Survival was distinct and showed significantly alteration in bile acid, sphingolipid, tryptophan metabolism, tyrosine metabolism and others already linked to inflammation, cell death, nutrient absorption, and response to stresses ($p < 0.05$). ALF-Non-Survival plasma showed significant increase in the bacterial diversity as shown by the Alpha and Beta

diversity indices ($p < 0.05$). ALF-Non-Survival were majorly linked to the phylum Proteobacteria, Firmicutes, Actinobacteria and others ($p < 0.05$) which documented significant increase in the bacterial functionality linked to energy, amino acids, xenobiotic metabolism and, others as compared to other groups ($p < 0.05$). Interestingly the increase in the bacterial taxa and functionality correlated with the metabolites Chenodeoxycholic acid, 4-(2-Aminophenyl)-2,4-dioxobutanoate and L-Tyrosine and others in ALF-NS ($R^2 < 0.7$). Multiomics signature-based probability of detection (POD) for non-survival in ALF was greater than 80% and correlated with clinical parameters ($R^2 > 0.85$). POD metabolites (AUC = 0.98) directly associated with early mortality ($p < 0.05$). Specific increase in L-Tyrosine, 4-(2-Aminophenyl)-2, 4-dioxobutanoate (linked to cell death and inflammation), Carnosine (linked to negate oxidative stress effect), Chenodeoxycholic acid (linked to bile acid synthesis), and alanyl-tyrosine (linked to removal of tyrosine) validated in different cohort five machine learning algorithms showed >98% accuracy/sensitivity/specificity for early mortality prediction.

Conclusion: Our findings demonstrated that changes in the plasma microbiome correlates to metabolome in ALF patients. Baseline increase in plasma metabolite signature could be offered as universal utility to serve as biomarker for ALF patients predisposed to early mortality.

FRI-399

Neddylation inhibition recovers drug-induced liver injury through the stabilization of Tamm41

Claudia Gil-Pitarch[1], Marina Serrano-Macia[1], Jorge Simón Espinosa[1], Rubén Rodríguez Agudo[1], Sofia Lachiondo-Ortega[1], Maria Mercado-Gómez[1], Irene González-Recio[1], Naroa Goikoetxea[1], Teresa Cardoso Delgado[1], Luis Alfonso Martinez-Cruz[1], Ruben Nogueiras[2], Paula Iruzubieta[3], Javier Crespo[3], Steven Masson[4,5], Misti McCain[5], Helen Louise Reeves[4,5], María Luz Martínez-Chantar[1]. *[1]CIC bioGUNE, Liver disease lab, DERIO, Spain; [2]Department of Physiology, School of Medicine-Instituto de Investigaciones Sanitarias, University of Santiago de Compostela, Spain; [3]Gastroenterology and Hepatology Department, Marqués de Valdecilla University Hospital, Clinical and Translational Digestive Research Group, IDIVAL, Spain; [4]The Liver Unit, Newcastle-upon-Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne NE7 7DN, United Kingdom; [5]Newcastle University Translational and Clinical Research Institute, The Medical School, Newcastle University, Newcastle upon Tyne, NE2 4HH, United Kingdom*
Email: mlmartinez@cicbiogune.es

Background and aims: In Western countries, acute liver failure is a serious disorder, being the majority cases caused by drug-induced liver injury (DILI), commonly associated to acetaminophen (APAP) overdose. DILI does not have an effective late stage treatment. Neddylation is an ubiquitin-like post-translational modification, usually associated to protein stabilization. It is upregulated in several liver diseases. The accumulation of Cullin-Ring E3 ligase (CRL) substrates induce cell-cycle arrest, senescence and apoptosis, thus, its proteolytic degradation is needed and occurs with posttranslational neddylation of CRL impulsed by Nedd8-activating enzyme (NAE). MLN4924 is an anticancer small molecule, which is currently in phase I trials. MLN4924 inhibits NAE, therefore, blocks cullin neddylation allowing CRL substrates accumulation and triggering cell-cycle arrest, senescence and apoptosis in cancer cells. Studying neddylation role in DILI offers an attracting approach to improve DILI treatment. Tamm41 catalyzes the formation of CDP-diacylglycerol (CDP-DAG) which is central in phospholipid biosynthesis pathways in cells. Those are branched into several pathways, one of which chiefs to the synthesis of Cardiolipin (CL). CL is an essential lipid for the activity of key mitochondrial enzymes that are involved in the cellular energy metabolism. Tamm41 has been identified when inhibiting neddylation, thus, it is accurate to elucidate the relation Tamm41 might have with the neddylation pathway, and, as a consequence, with a possible treatment for DILI.

Method: Nedd8 was measured immunohistochemically and in serum by ELISA assay in clinical DILI samples. The effects of APAP overdose and its treatment with the neddylation inhibitor MLN4924 were evaluated in isolated mouse hepatocytes and pre-clinical three months mice models C57BL/6 and two BirA transgenic mice models, ^{Bio}NEDD8, and ^{Bio}UB. Serum and liver samples were cryopreserved, and part of the liver tissue was embedded in paraffin for histological procedures. Neddylation was inhibited to study its implication in cell death, mitochondrial dynamics and respiration, redox balance, endoplasmic reticulum stress, proteome homeostasis and metabolic pathways. Tamm41 was silenced to study its effect and relation along with neddylation pathway.

Results: Neddylation was induced in DILI. Its inhibition reduced cell death and inflammation and promoted regeneration mitochondrial activity. The proteomic analysis of ^{Bio}NEDD8, and ^{Bio}UB transgenic mice liver reflected the stabilization of Tamm41. Tamm41 silencing resulted in the abolition of the positive effects caused by neddylation inhibition.

Conclusion: Neddylation was upregulated in DILI causing cell damage. Inhibiting neddylation in DILI, returning it at the normal basal activity, restored the correct functioning of the cell by the stabilization of Tamm41.

FRI-400

Forward programming to produce hepatocytes organoids for cell based therapy

Fabian Bachinger[1], Ludovic Vallier[2]. *[1]Cambridge, Department of Hematology, Cambridge, United Kingdom; [2]Berlin Institute of Health, BIH Centre for Regenerative Therapies, Berlin, Germany*
Email: fb520@cam.ac.uk

Background and aims: Organ transplantation remains the only treatment for end stage liver diseases. Alternative therapies like hepatocyte cell transplantation have been developed in the recent years. However, availability and quality of primary hepatocytes represents a major limitation. Human induced pluripotent stem cells (hiPSCs) could provide an alternative source for the production of large quantity of hepatocytes in vitro. However current differentiation protocols are lengthy, complex, technically challenging and produce cells with foetal-like characteristics. The goal of this project is to create a rapid and robust approach to create high quality and large quantity of hepatocytes organoid with increased functional characteristics when compared to cells derived using directed differentiation in 2D.

Method: Here, we take advantage of Forward Programming (FoP), an approach relying on the overexpression of cell specific transcription factors, to generate hepatocytes for cell-based therapy. Factors to drive differentiation of hiPSCs to hepatocytes were identified by comparing primary cells with in vitro generate hepatocytes. The Opti-OX system was then used in hiPSCs to stably overexpress these transcription factors. Forward programming was further increased by optimising 3D culture conditions in suspension such as seeding density and media composition. Functionality was evaluated by direct comparison with directed differentiation derived and primary hepatocytes. Assays include CYP3A4 enzyme activity, qPCR, Immunofluorescence staining and flow cytometry for hepatocyte specific markers.

Results: Hepatocytes generated using FoP (FoP-Heps) display CYP3A4 activity 10-fold higher than cells generated using directed differentiation. Thus, Fop-Heps have detoxification property close to primary cells. Alb secretion and Urea cycle activity were also very similar between in vitro produced and freshly plated hepatocytes. qPCR analyses confirm expression of hepatocyte markers including

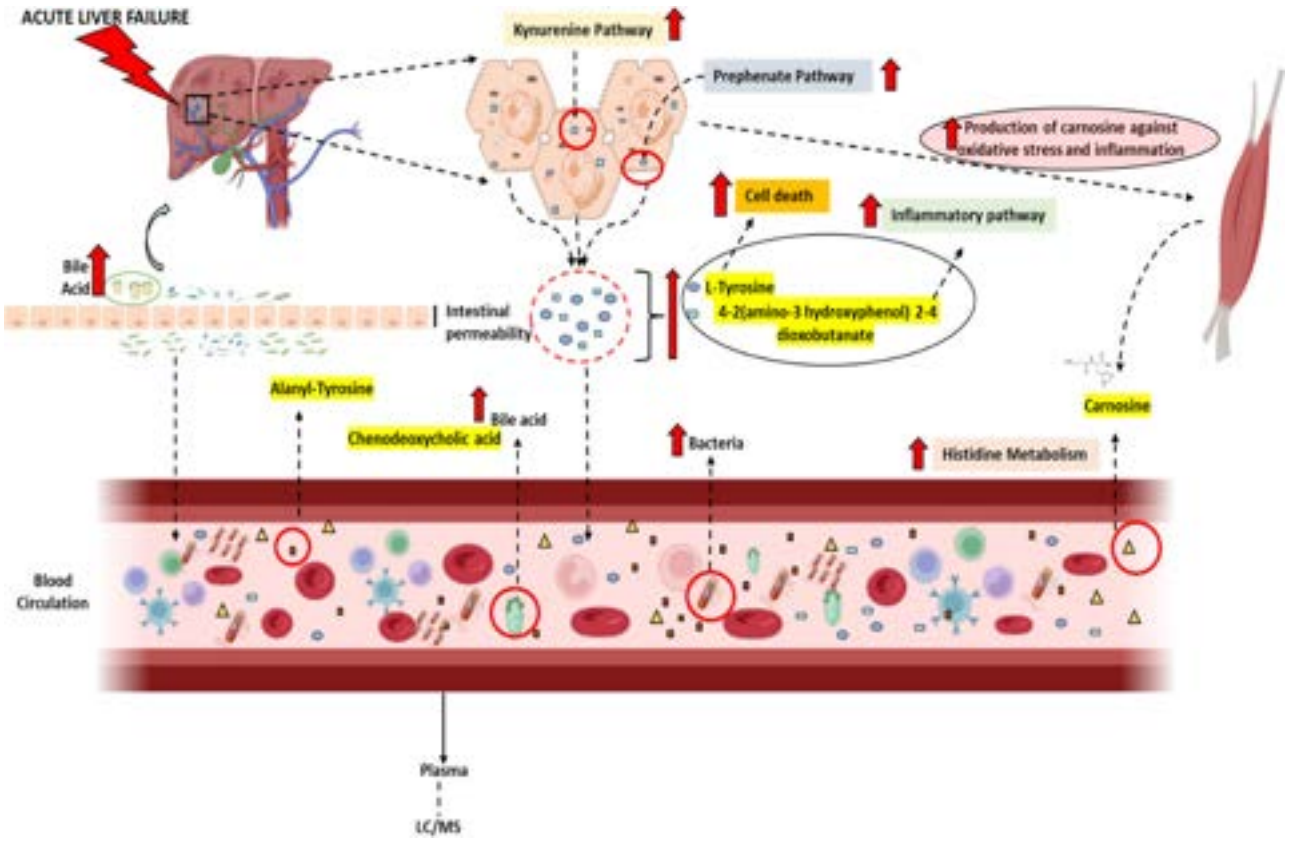

Figure: (abstract: FRI-398): Showing the baseline effect on metabolic pathway in acute liver failure patients.

Albumin, A1AT, PCK1, HNF4A and hFVII at values comparable to primary hepatocytes. Flow cytometry showed expression near homogenous expression of Albumin (90%), A1AT (99.8%) and ASGR1 (85%). Finally, FoP is a 2-step process taking 20 days compared to 30 days for directed differentiation while allowing the production of 10 hepatocytes from 1 hIPSC.

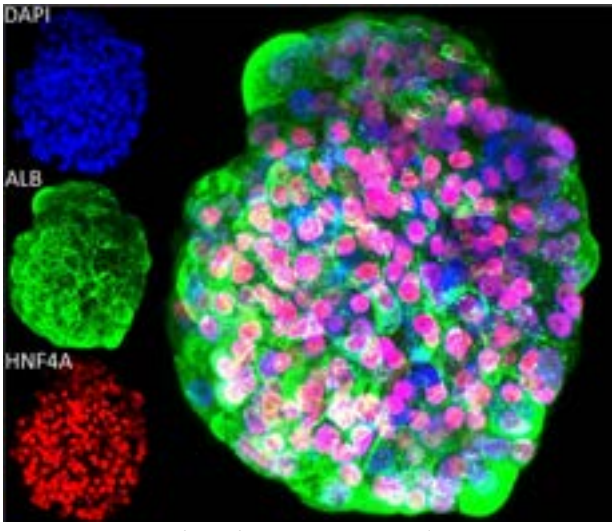

Figure 1: Hepatocytes derived in 3D suspension culture.

Conclusion: Forward Programming in 3D can be used to produce hepatocytes more rapidly and robustly than directed differentiation. In addition, FoP-Heps share key characteristics with their primary counterpart. Finally, this approach is compatible with GMP and large-scale production necessary for future cell-based therapies in the context of liver diseases.

FRI-401

Stress-driven suppression of the hippo pathway accelerates liver injury

Na Young Lee[1], Ari Kwon[1], Jae-Hyun Yu[1], Myeung Gi Choi[1], Ja Hyun Koo[1]. [1]*Seoul National University, Korea, Rep. of South*
Email: jhkoo@snu.ac.kr

Background and aims: The Hippo pathway signals actively represses Yes-associated protein (YAP) and its homolog transcriptional coactivator with PDZ-binding motif (TAZ) to suppress overgrowth of organs and maintain homeostasis. Upon activation, YAP/TAZ translocate into the nucleus and bind to TEAD transcription factors to promote transcriptional programs for proliferation or mitochondrial quality control.

Method: YAP/TAZ activity was analyzed in hepatocytes from patients with cirrhosis using single-cell transcriptomic data. The impact on Hippo pathway regulation following hepatocyte stress was analyzed using RNA sequencing. Phos-tag immunoblotting, immunocytochemistry, and qRT-PCR were used to assess YAP activity. CRISPR-mediated knockout or knock-in cells were used for mechanistic studies. Mice with hepatocyte-specific disruption of Yap and Taz were used to examine their role in hepatocyte death upon damage.

Results: Here, we report that liver damage activates YAP/TAZ in hepatocytes that in turn contributes to promoting hepatitis. Hepatocyte stress suppressed phosphorylation of YAP, increased nuclear translocation and target gene expression of YAP/TAZ. In

addition, global changes in the transcriptome by cellular stress was significantly reversed by YAP/TAZ knockout. Mechanistically, the regulation was occurred through both Hippo-dependent and Hippo-independent pathway, largely requiring a phosphatase activity. Furthermore, hepatic deletion of YAP/TAZ in vivo suppressed liver injury and steatohepatitis progression.
Conclusion: These reveal a pathological role of YAP/TAZ in promoting steatohepatitis progression, which provides an insight into therapeutic intervention of the disease.

FRI-402
Dysregulated lipolysis increases intrahepatic concentrations of non-esterified fatty acids in chemotherapy-associated steatohepatitis
Martina Derler[1], Eva Waich[2], Elisabeth Ableitner[2], Julia Sturm[2], Patrick Starlinger[3], Anton Stift[3], Alice Assinger[4], Marion Mussbacher[2]. *[1]Institute of Pharmaceutical Sciences, University of Graz, Department of Pharmacology and Toxicology, Graz, Austria; [2]Institute of Pharmaceutical Sciences, University of Graz, Graz, Austria; [3]Department of General Surgery, Division of Visceral Surgery, Medical University of Vienna, Vienna, Austria; [4]Institute of Vascular Biology and Thrombosis Research, Medical University Vienna, Vienna, Austria*
Email: martina.derler@uni-graz.at

Background and aims: Up to 50% of colorectal carcinoma patients receiving the chemotherapeutic drug irinotecan develop chemotherapy-associated steatohepatitis (CASH). Typical CASH symptoms include intrahepatic accumulation of lipids and hepatic inflammation. CASH impairs liver regeneration after surgical resection of hepatic metastasis and thereby drastically increases mortality. The biochemical mechanisms leading to CASH are still unknown, and treatment options are lacking. This project aims to investigate the effect of irinotecan on hepatocyte lipid metabolism.
Method: The murine hepatocyte cell line AML-12 was treated with increasing doses of irinotecan (10–60 µM), and extra- and intracellular concentrations of non-esterified fatty acids (NEFA) were quantified. Additionally, the expression of enzymes involved in fatty acid oxidation, *de novo* lipogenesis, and lipolysis was analyzed on mRNA- and protein levels by quantitative PCR and western blotting, respectively. The content of adenosine triphosphate was investigated using high-performance liquid chromatography, and oxidative stress levels were determined by flow cytometry. For mechanistic experiments, AML-12 cells were treated with irinotecan in the presence and absence of 200 µM oleic acid, the lipase inhibitor Atglistatin (40 µM), and under serum-free conditions.
Results: Irinotecan treatment of AML-12 cells led to a significant accumulation of intracellular non-esterified fatty acids, whereas triglyceride and cholesterol levels remained unchanged. Protein expression of adipocyte triglyceride lipase (ATGL), which catalyzes the rate-limiting step of intracellular lipolysis, increased with rising doses of irinotecan by 7-fold. However, key proteins of *de novo* lipogenesis were reduced in irinotecan-treated AML-12 cells. Intracellular levels of adenosine triphosphate and mRNA of enzymes catalyzing fatty acid oxidation were significantly decreased upon irinotecan treatment. This was associated with elevated levels of oxidative stress and increased expression of the oxidative stress marker haemoxygenase-1. Despite increased oxidative stress and NEFA levels, mRNA levels of the peroxisomal biogenesis factor 2 (Pex2) were significantly decreased.
Conclusion: Irinotecan leads to a dysregulation of ATGL-mediated lipolysis, which results in a massive intracellular accumulation of NEFA. These metabolic changes might contribute to hepatocyte lipotoxicity and foster the pathogenesis of CASH.

The University of Edinburg (UK), United Kingdom*
Email: andrade@uma.es

Background and aims: Idiosyncratic Drug-Induced Liver Injury (DILI) encompasses the unpredictable damage that drugs, herbs, and dietary supplements may cause to the liver. When studying the prediction of DILI at preclinical stages, the choice of a validated system is decisive. The present study seeks to provide a list of both DILI positive and negative control compounds. This list arises from a systematic analysis of the existing literature, supported by clinical evidence collected in both national and international DILI registries and endorsed by a committee of experts from the ProEuroDILI Network (COST Action 17112).
Method: This systematic review was conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines. Eligible literature published to June 1st, 2022 was identified through a search in PubMed, Embase, Web of Science, and Scopus. Only peer-reviewed original articles focused on studying the onset of DILI by using preclinical *in vitro* human models were included. The reliability of the studies was assessed using a modified version of the software-based "Toxicological data Reliability Assessment Tool" (ToxRTool). Drugs most commonly used as DILI-positive and negative controls in the literature were selected for in-depth analysis.
Results: The search strategy retrieved 2936 studies from the above-mentioned databases. After screening, 2885 studies were excluded, as they were duplicates or did not meet the inclusion criteria. 51 articles were finally included. Most studies were categorized as reliable without restrictions (58.6%). The mean number of drugs tested was 55 DILI-positive and 30 DILI-negative compounds. Diclofenac was the drug most used as DILI-positive control (88%), followed by troglitazone (80%) and flutamide (71%). Regarding DILI-negative controls, buspirone (49%), dexamethasone (41%), and diphenhydramine (35%) were the most tested compounds. Acetylsalicylic acid, fluoxetine, or warfarin were widely used as DILI-negative controls (33%, 25%, and 22%, respectively), but also as DILI-positive compounds (22%, 20%, and 16%). Moreover, up to 19% of the drugs used as DILI-negative controls had clinical hepatotoxicity cases reported within different DILI registries. The drug concentrations used varied remarkably. Although 49% of studies chose the drug concentrations based on the C_{max} values, the C_{max} assumed for the

same drug in different studies diverged. Most studies assessed drug effects in the short term (≤72 h; 71%). Cytotoxicity was the end point most evaluated (82%). Nevertheless, several studies included the assessment of functional parameters, such as biotransformation activity (20%), albumin (20%), or urea secretion (12%). A few studies included mechanistic end points such as cholestasis (24%) or mitochondrial damage (22%).

	COMPOUND	N° articles using it as DILI positive (%)	N° articles using it as DILI negative (%)
COMPOUNDS MOST USED AS DILI POSITIVE CONTROLS	Diclofenac	45 (88.2%)	0 (0%)
	Troglitazone	41 (80.4%)	0 (0%)
	Flutamide	36 (70.6%)	0 (0%)
	Amiodarone	35 (68.6%)	0 (0%)
	Acetaminophen (APAP)/ Paracetamol	33 (64.7%)	0 (0%)
	Ketoconazole	33 (64.7%)	0 (0%)
	Nefazodone	29 (56.9%)	0 (0%)
	Tamoxifen	29 (56.9%)	0 (0%)
	Chlorpromazine	27 (52.9%)	1 (1.9%)
	Isoniazid	27 (52.9%)	1 (1.9%)
COMPOUNDS MOST USED AS DILI NEGATIVE CONTROLS	Buspirone	3 (5.9%)	25 (49%)
	Dexamethasone	0 (0%)	21 (41.2%)
	Diphenhydramine	0 (0%)	18 (35.3%)

	Primidone	0 (0%)	14 (27.5%)
	Streptomycin	0 (0%)	14 (27.5%)

Figure:

Conclusion: This systematic study has shown a lack of consensus in terms of in vitro DILI modelling. Since no single system serves as a universal test for the multifactorial process of DILI, a portfolio of robust and well-characterized predictive platforms with a well-defined purpose is required. Moreover, there is a need for consensus about the reference drugs to be used for the DILI assay validations, including recommendations about the concentrations to test and criteria for interpreting the data. Email: estefania.huergo.iglesias@navarra.es

Background and aims: Patients with acute decompensation (AD) of cirrhosis have a high short-term mortality due to a lack of a complete understanding of the pathophysiology of the disease and the wide heterogeneity of patients. Hence, it is necessary to better understand the disease at a systems level. Therefore, the aim of this work was to understand at systems level the pathophysiology of AD cirrhosis by using a systems approach to integrate multi-omic profiling with clinical data.

Method: Clinical and omics data from three well-characterized cohorts of patients with AD cirrhosis -CANONIC (572 patients), PREDICT (766 patients) and ACLARA (580 patients)- were used to perform a multi-omic analysis applying a systems medicine framework to characterize AD (Figure), as part of the H2020 funded project DECISION. A multi-state survival analysis was performed using bootstrapping and permutation test to estimate confidence intervals and permuted p values for each feature. Non-Parametric Combination (NPC) analysis was conducted using custom gene-gene and gene-CpG maps (among others) and the STATegRA R package. Network analysis was conducted using custom methods, FEM and Cytoscape available tools. MXM R package was used to identify subsets of variables with maximal predictive power.

Results: We conducted the five-step analysis described in the Method section in the PREDICT cohort. In the first step, we explored the coordination between omics, observing a low coordination in general, but metabolites and RNA-Seq as specific candidates. Secondly, we conducted an uni-omic analysis for each feature of each omic, that allowed us to identify, among thousands of features, statistically robust candidate biomarkers. However, we identified limited features of interest, so that we required to leverage over the multi-omic profiling of each individual. To this end, as a third step, we used an NPC analysis, so the number of features identified was increased. As a result, we gathered enough statistical power to conduct the fourth step: a network analysis. From this analysis, we identified systems-based feature combinations that are associated with ACLF, mortality and/or liver transplant. As a final step, using the identified features, we generated predictive models for prognosis in AD patients, which are being validated in the two additional cohorts, CANONIC and ACLARA.

Conclusion: Our study shows that, while AD patients are very heterogeneous explaining why classical statistical analysis are very limited in power, the use of multi-omic approaches can overcome partly such limitation. We observed that making use of feature-feature connections, systems medicine allows for increased power in the identification of disease mechanisms, but even more important, may allow for candidate biomarkers discovery.

Kelch-like ECH-associated protein-1 deletion rescues cell death associated with glutathione-glutathione peroxidase 4 knockdown in hepatocytes in acute models of liver injury

Julia Grube[1], Leticia Colyn[1], Chaochao Wang[1], Christian Trautwein[1]. *[1]University Hospital RWTH, Internal Medicine III, Aachen, Germany*
Email: ctrautwein@ukaachen.de

Background and aims: Recently, acute liver injury (ALI) has been described to be mediated by ferroptosis in mice models. Ferroptosis is a type of cell death initiated by iron accumulation, reactive oxygen species (ROS) generation, and subsequent lipid peroxidation leading to membrane damage and cell death. The Kelch-like ECH-associated protein-1 (KEAP1)/erythroid 2-related factor 2 (NRF2) axis is of major relevance for ferroptosis, modulating the expression of genes associated with iron metabolism and inducing the cellular response to ROS through the activation of enzymes such as glutathione peroxidases (GPXs). Among them, GPX4 plays a crucial role in ferroptosis, as its inactivation leads to lipid peroxidation. Here, we sought to define the effect of NRF2 activation during acute liver injury in a model of ferroptosis.

Method: We generated a genetic model of ferroptosis by hepatocyte-specific deletion of GPX4 (GPX4^{deltahepa}). To study the activation of the NRF2 axis, we crossed GPX4^{deltahepa} mice with mice in which KEAP1 was specifically deleted in hepatocytes (KEAP1^{deltahepa}), generating GPX4^{deltahepa}/KEAP1^{deltahepa} mice. We performed acute models of liver injury-CCl_4 injection and bile duct ligation (BDL) for 48 hours.
Results: Hepatocyte-specific deletion of GPX4 results in increased liver injury associated with elevated serum transaminase levels and increased macrophage recruitment. Interestingly, histological analysis of GPX4^{Deltahepa} livers showed no evidence of ferroptosis as indicated by immunohistochemical staining for 4-hidroxinonenal. They also showed no evidence of necroptosis or pyroptosis, but we found a strong increase in apoptosis. Deletion of KEAP1 in hepatocytes leads to activation of the NRF2 pathway, as confirmed by its upregulation and activation of target genes. In CCl_4-challenged GPX4^{deltahepa}/KEAP1^{deltahepa} mice, the damage observed in GPX4^{deltahepa} mice is reversed, as evidenced by serum transaminase levels and liver histology. KEAP1 deletion markedly inhibits apoptosis-mediated cell death as indicated by TUNEL assay, cleaved caspase-3 staining, and gamma-H2AX protein levels. We also observed an upregulation of the anti-apoptotic protein BCL2 in GPX4^{deltahepa}/KEAP1^{deltahepa} livers.
Conclusion: Our results indicate that in the GPX4^{deltahepa} mice challenged with CCl_4 injection and bile duct ligation for 48 hours, there is no evidence of ferroptosis, although we observed extensive tissue damage associated with increased apoptosis. Activation of the NRF2 pathway by deletion of KEAP1 rescues acute liver injury. This effect may be mediated by the upregulation of the anti-apoptotic protein BCL2.

Background and aims: The disruption of the intestinal barrier might be a major contributor to the pathogenesis of various liver disorders, including drug-induced liver injury (DILI), through impairment of hepatic immunotolerance. It has been speculated that pathogen-associated molecular patterns (PAMPs) may reach the liver as a consequence of an increase in intestinal permeability caused by alterations in the intestinal microbiota. Consequently, innate immune cells would initiate an inflammatory response that can be lethal to hepatocytes or trigger an adaptive immune response. LBP (lipopolysaccharide binding protein), CD14 and CD163 have been linked to intestinal permeability, as they play a key role in the innate immune response to bacterial endotoxins (e.g., LPS), by binding to them or by exerting an immunomodulatory role. Our aim was to conduct an exploratory study to assess the intestinal permeability status of DILI patients by quantification of LBP, CD14 and CD163 proteins in serum.
Method: Peripheral blood serum was collected from 8 healthy volunteers, 8 DILI patients and 8 patients with acute liver injury (ALI) other than DILI and stored at −80°C until analysis. The drugs responsible for toxic liver injury were antibiotics, antitumor drugs, dietary supplements and statins; whilst ALI cases were mostly viral hepatitis. Patients were followed from the detection of the acute episode (visit 1) until >30 days after detection (visit 3). Serum levels of LBP, CD14 and CD163 were measured by Luminex (RandD Systems) and results were statistically analyzed using Kruskal-Wallis, Dunn and Friedman tests.
Results: The concentration (mean ± standard deviation) of LBP, CD14 and CD163 proteins was >300-fold higher in DILI (LBP: $1.14 \times 10^7 \pm 4.3 \times 10^6$; CD14: $1.98 \times 10^6 \pm 5.8 \times 10^5$ and CD163: $2.8 \times 10^6 \pm 1.1 \times 10^6$ pg/ml) and ALI (LBP: $1.15 \times 10^7 \pm 5.1 \times 10^6$; CD14: $1.96 \times 10^6 \pm 6.8 \times 10^5$ and CD163: $3.2 \times 10^6 \pm 1.1 \times 10^6$ pg/ml) compared to healthy controls (LBP: $3.8 \times 10^4 \pm 9790$; CD14: 6369 ± 950 and CD163: 6273 ± 125 pg/ml) at visit 1 ($p < 0.001$). The levels of these proteins decreased significantly at visit 3, although they remained elevated compared to controls ($p < 0.05$). No significant differences were detected between DILI and ALI.
Conclusion: The elevated concentration of LBP and CD14 proteins detected in DILI patients could be indicative of increased translocation of bacterial products due to an altered intestinal permeability. This theory is further supported by the elevated levels of CD163 protein, which has been considered a marker of macrophage activation, associated with intestinal permeability and dysbiosis.

Email: mhdeztejero@hotmail.com

Background and aims: Alcohol-associated hepatitis (AH) is a severe condition that needs novel targeted therapies. We recently showed by integrated multi-OMICs that severe AH is characterized by profound deregulation of glucose metabolism (Massey et al, Gastroenterology 2021). The polyol pathway is an alternative and potential harmful way to metabolize glucose and is governed by AKR1B10 and other aldose reductases. AKR1B10 metabolizes glucose to produce sorbitol that is oxidized by SORD to produce fructose. This study aimed at analyzing whether this pathway is deregulated in AH.

Method: 55 patients with probable and definite diagnosis of AH according to the NIAAA were included. We also included 10 healthy controls and 45 diseased controls (15 alcohol-associated cirrhosis, 15 NASH and 15 chronic hepatitis C). Hepatic gene expression profiling was assessed by DNA microarray. qPCR and RNAseq was performed to confirm results. To assess the expression of ductular reaction genes, microdissection of KT7 positive and negative areas was performed in 6 AH patients. Protein expression was assessed by IHC and western blotting. scRNAseq were performed in 12 patients including healthy controls, AH, PSC, alcohol-associated and NASH cirrhosis.
Results: AKR1B10 was found to be the most upregulated gene in livers with AH (>400-fold). The expression of SORD, another gene of the polyol pathway that metabolizes sorbitol, was downregulated by 2-fold compared to normal livers. AKR1B10 gene expression correlated with AST ($p = 0.009$), bilirubin ($p = 0.008$), and glucose ($p = 0.01$) levels at admission in patients with AH. AKR1B10 expression also correlated with severity of liver disease according to MELD ($p = 0.004$), portal hypertension ($p = 0.01$), and increased the mortality at 180 days ($p = 0.02$). AKR1B10 mRNA expression was increased in DR cells from patients with AH ($p = 0.0059$). Density plots stratified by severity showed an inverse correlation between disease severity and the AKR1B1/SORD ratio. In addition, IHC indicates that AKR1B10 overexpression is predominantly in hepatocytes. scRNAseq studies demonstrated that AKR1B10 is expressed in hepatocyte and cholangiocyte cell populations compared. Figure 1.
Conclusion: The polyol pathway is dysregulated in AH and correlated with disease severity. Targeting key genes such as AKR1B10 and SORDs represents a potential novel therapy for AH. Further studies should evaluate the use of aldose reductase inhibitors in models of AH.

Pyroptotic MAITs link microbial translocation with severity of alcohol-related liver disease

Li-Ping Zhang[1], Hui-Fang Wang[1], Xing-Ran Zhai[2], Chun-Bao Zhou[2], Jin-Hong Yuan[2], Ye-Nv Ma[2], Zeng-Tao Yao[2], Shuo Huang[2], Wei-Zhe Li[2], Yan-Mei Jiao[2], Fu-Sheng Wang[2], Zhengsheng Zou[3], Ji-Yuan Zhang[2], Qing-Lei Zeng[1]. *[1]The First Affiliated Hospital of Zhengzhou University, Department of Infectious Diseases and Hepatology, China; [2]The Fifth Medical Center of Chinese PLA General Hospital, Treatment and Research Center for Infectious Diseases, China; [3]The Fifth Medical Center of Chinese PLA General Hospital, Department of Liver Disease, Senior Department of Hepatology, China*
Email: zengqinglei2009@163.com

Background and aims: Mucosal-associated invariant T cells (MAITs) are markedly reduced in patients with alcohol-related liver disease (ALD); however, the potential mechanism underlying MAITs loss

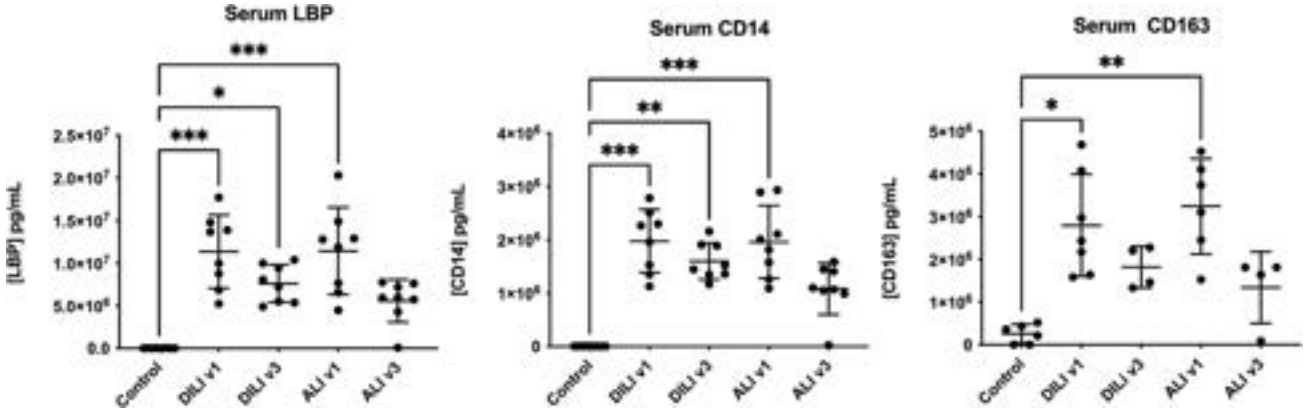

Figure: (abstract: FRI-406).

remains elusive. Hence, we aimed to explore what induced MAITs loss and its clinical significance.
Method: The characteristics of pyroptotic MAITs were evaluated in a cohort of patients with ALD, including 41 patients with alcoholic liver cirrhosis (ALC) and 21 patients with ALC complicated with severe alcoholic hepatitis (ALC+SAH).
Results: In patients with ALD, blood MAITs were significantly decreased, hyperactivated and displayed enhanced cell death through pyroptosis. The frequencies of pyroptotic MAITs increased with disease severity in patients with ALC and patients with ALC +SAH. These frequencies were negatively associated with the frequencies of MAITs and positively correlated with the levels of MAITs activation, plasma levels of intestinal fatty acid-binding protein (a marker of intestinal enterocyte damage), soluble CD14, lipopolysaccharide binding protein and peptidoglycan-recognition proteins (surrogate markers of microbial translocation). Pyroptotic MAITs were also found in the liver of patients with ALD. Interestingly, MAITs underwent further activation and pyroptosis *in vitro* under stimulation by *Escherichia coli* or direct bilirubin. Notably, blocking interleukin-18 signaling could reduced the activation and frequencies of pyroptotic MAITs.
Conclusion: The loss of MAITs in patients with ALD is, at least in part, due to cell death from pyroptosis and is closely associated with the severity of ALD. Such increased pyroptosis may be affected by dysregulated inflammatory responses to intestinal microbial translocation or direct bilirubin.

FRIDAY 23 JUNE

Platelets proteome dynamics and its association with liver severity in severe alcoholic hepatitis

Rupinder Kalra[1], Jaswinder Maras[1], Abhishak Gupta[1], Nupur Sharma[1], Gaurav Tripathi[1], Manisha Yadav[1], Babu Mathew[1], Vasundhra Bindal[1], Neha Sharma[1], Sushmita Pandey[1], Sadam H. Bhat[1]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Platelet activation mediates inflammation, oxidative stress, and contributes to disease severity in patients with SAH. Molecular cargo of platelet may differ between the healthy and SAH patients, which may be the reason for the increase in severity in SAH patients. Temporal change (Baseline, Day1, Day3 and Day7) in the molecular cargo in SAH patients is distinct and could help in stratifying patients with early mortality.
Method: Platelet proteomics was performed in (n = 20) SAH patients and (n = 20) controls at baseline, Day1, Day3, Day7 respectively. Weighted Protein Correlation Network Analysis (WPCNA) identified the temporal increase in SAH specific proteins clusters which were correlated to clinical parameters and outcome. Most prominent predictors of early mortality were identified and validated in a separate cohort of (n = 60) SAH patients.
Results: Platelet activation (PF4, TSP1 and p-selectin) were significantly higher in SAH patients as compared to controls ($p < 0.05$). Temporal proteomics evaluation identified 1236 proteins of them (baseline) 468 were differentially expressed (206-up, 262 down-regulated) in SAH as compared to controls ($p < 0.05$). Proteins cargo significantly increased were linked to platelet activation, ATP synthesis, oxidative phosphorylation and others whereas those significantly decreased were linked to Detoxification of Reactive Oxygen Species, Protein processing, Antigen Presentation and others ($p < 0.05$). Proteomic analysis at Day 1 (196 up- and 311 Dn), Day3 (279 up- and 469 Dn) and Day7 (207 up- and 562 Dn) showed significant change in DEP counts ($p < 0.05$, FC>1.5, FDR<0.01). Venn integration identified 42 proteins commonly up- linked to platelet activation, degranulation, complement activation, dissolution of fibrin clot and others and 32 proteins downregulated linked to Detoxification of Reactive Oxygen Species, cGMP-PKG signalling pathway, Signalling by NGF and others ($p < 0.05$). WPCNA of platelets identified 18 proteins clusters ($p < 0.05$), which correlated to the severity indices (MELD, DF) and provided insight in to inflammation and severity of SAH patients ($p < 0.05$, $R2 > 0.5$). Protein Family analysis showed linear decrease in the energy pathways (ATP-synthase, NADH-dehydrogenase), liver functions (coagulation) and others in SAH patients ($p < 0.05$, $R2 > 0.5$). Blood transcriptome module (BTM) enrichment analysis showed that platelets in SAH patients are activated and carry inflammatory cargo of activated neutrophils, myloid cells and monocytes, coagulation and TGF beta signalling and others ($p < 0.05$). Interestingly, proteins linked to TGF Beta such as Fibulin-5 (FBLN5), Peroxiredoxin-2 (PRDX-2) and others were temporally increased in SAH platelets. Validation experiments confirmed that platelets PRDX2 level increase with time showed direct correlation with the severity indices (MELD, mDF) and inhibit development of PDGF levels altering the molecular regeneration capacity of platelet in SAH patients.
Conclusion: Platelets in SAH are activated; energy deprived and carries inflammatory mediators and was able to stratify SAH patients with early mortality. Temporally these platelets accumulate PRDX2 which inhibit development of PDGF and regenerative support. Our proteomics study underlines PRDX2 as a novel target for therapeutic intervention for hyper-inflammation in SAH patients.

FRI-408
Characterization of fibrogenesis in severe alcohol-related hepatitis using a 3D model of coculture of organoids and fibroblasts from patients

Line Carolle Ntandja Wandji[1,2], Mohamed Bou Saleh[2], Cyril Sobolewski[2], Viviane Gnemmi[3], Emmanuel Boleslawski[4], Fabrice Bray[5], Christian Rolando[5], Philippe Mathurin[1,2], Laurent Dubuquoy[2], Alexandre Louvet[1,2]. *[1]CHU Lille, Service des maladies de l'appareil digestif et de la nutrition, Lille, France; [2]Univ. Background and aims: Since few data are available on liver fibrogenesis during alcohol-related hepatitis (AH), the interplay between injured hepatocytes and fibrogenic cells needs to be studied into more details. Indeed, YAP-mediated impaired hepatocyte regeneration plays an important role in AH but its impact on fibrogenesis remains unknown. Our objectives were to characterize fibrosis during AH and to evaluate the impact of YAP in hepatocytes on the fibrogenic process observed in AH.
Method: Using PCR, immunohistochemistry and proteomic analysis, we characterized the molecular profile of fibrosis in liver explants from patients with AH not responding to steroids (n = 22) or alcohol-related cirrhosis (Cirrh, n = 24), and healthy livers (Ctrl, n = 15). From the explants, we also generated organoids which were cocultured with hepatic myofibroblasts to study their activation, their production of cytokines and their proliferation. We also transduced organoids from Cirrh liver with an active YAP and cocultured them with myofibroblasts to evaluate their contribution to fibrogenesis.
Results: In AH livers, standard histology and immunohistochemistry showed a specific intralobular fibrosis associated with specific markers (alpha-SMA, PDGFR alpha, COL1A1, lamininA2 etc.). PCR and proteomic analysis showed a specific extracellular matrix (ECM) signature (Figure 1) and an increased expression of fibroblast

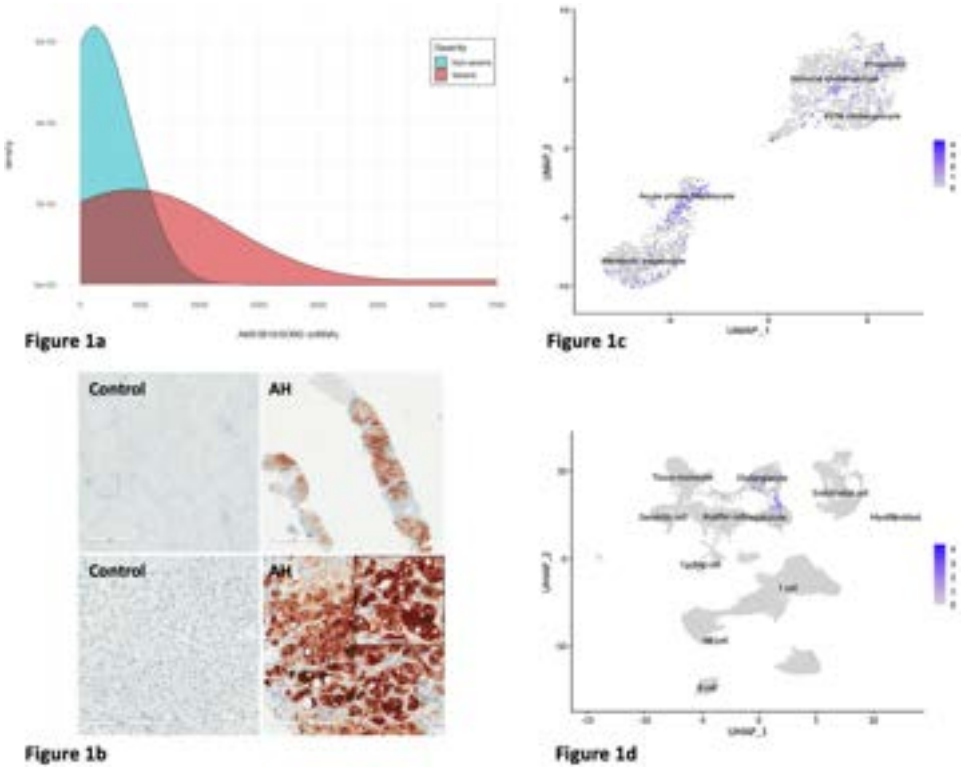

Figure 1: (abstract: TOP-073): (a) Density plot AKR1B10: SORD stratified by severity (MELD ≥21). (b) IHC results indicate that AKR1B10 is predominantly overexpressed in hepatocytes. (c) AKR1B10 is expressed in hepatocyte and cholangiocyte single cell populations. (d) AKR1B10 expression is increased in different hepatocyte and cholangiocyte profiles of liver diseases.

activation markers (alpha-SMA, PDGFR alpha), fibrillar collagens (COL1A1, COL3A1), lamininA2, cytokines (PDGFα, CCL5, MCP1), and a dysregulation of TIMP1 and MMP9. Ex vivo, the mRNA expression of alpha-SMA, PDGFR alpha, COL1A1, TIMP1, PDGF alpha, CCL5, MCP1 were higher in myofibroblasts cocultured with AH organoids as compared to fibroblasts cocultured with Cirrh organoids. Proliferation of myofibroblasts was also increased when cocultured with AH organoids. Compared to non-transduced Cirrh organoids, transduction of YAP in Cirrh organoids led to a greater proliferation of myofibroblasts and increased alpha-SMA, PDGFR alpha, COL1A1, TIMP1, PDGF alpha, CCL5 and MCP1, a profile which mimics coculture with AH organoids.

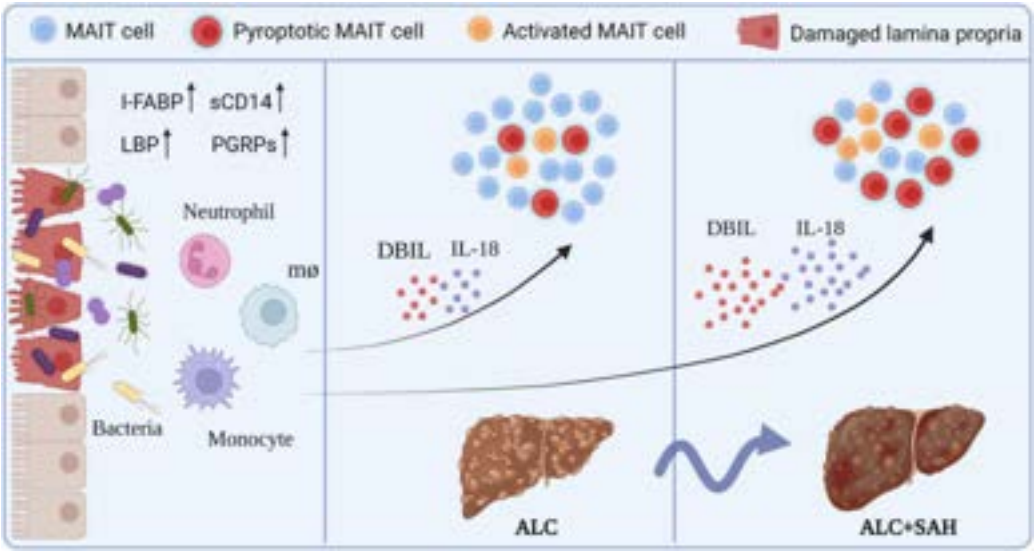

Figure: (abstract: TOP-078).

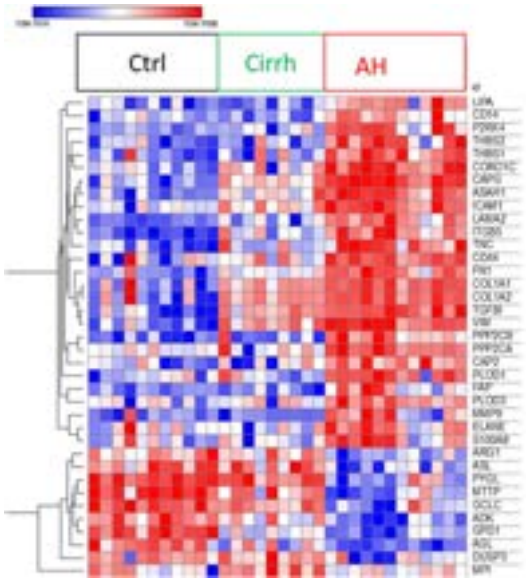

Figure:

Conclusion: AH is characterized by a specific fibrosis profile and organoids from AH patients induce activation, proliferation and release of inflammatory cytokines in myofibroblasts. Hepatocytic YAP appears to play an important role in the fibrogenesis during AH.

FRI-409

An increase in the number of activated regulatory T cells is associated with an improvement in liver function of patients with severe alcoholic hepatitis after steroid therapy

Soon Kyu Lee[1,2], Minwoo Kang[2], Ji Won Han[2,3], Jung Hyun Kwon[1,2], Soon Woo Nam[1,2], Jong Young Choi[2,3], Jeong Won Jang[2,3], Seung Kew Yoon[2,3], Pil Soo Sung[2,3]. *[1]Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Division of gastroenterology and hepatology, Department of Internal Medicine, Korea, Rep. of South; [2]College of Medicine, The Catholic University of Korea, The Catholic University Liver Research Centre, Korea, Rep. of South; [3]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Korea, Rep. of South*
Email: pssung@catholic.ac.kr

Background and aims: Alcoholic liver disease is one of major cause of acute and chronic liver failure worldwide. Although steroid therapy is treatment of choice in severe alcoholic hepatitis, there has been limitation in the treatment of alcohol-related liver disease because of no improvement in the long-term survival after steroid therapy. Moreover, the role of regulatory T (Treg) cells, inhibiting T cell proliferation and cytokine production, in patients with alcoholic liver disease remains unclear. Here, we investigated the population and potential roles of activated Treg cells in patients with alcohol-related liver disease including severe alcoholic hepatitis using steroid treatment.

Method: A total of 30 patients with alcoholic liver disease were consecutively enrolled from two academic hospitals in our study. Among 30 patients, 11 patients had severe alcoholic hepatitis treated with steroid (steroid group) and the others (n = 19) had mild alcohol-induced liver injury without steroid treatment (no steroid group). Peripheral blood mononuclear cells (PBMCs) were isolated from patients at the time of enrollment and 7 days after treatment. Frequency of $CD4^{+}CD25^{+}Foxp3^{high}CD45RA^{-}$ Treg cell was examined by flow cytometry and compared between the steroid and no steroid group. Moreover, we evaluated the population of Treg according to the steroid treatment response. Single cell RNA sequencing analysis using paired PBMCs was also performed and compared between patients with steroid responder and non-responder.

Results: Among 30 included patients, the steroid group (n = 11) had significant higher score of model for end-stage liver disease (MELD) than in the no steroid group (n = 19) (median MELD score, 24.0 vs.

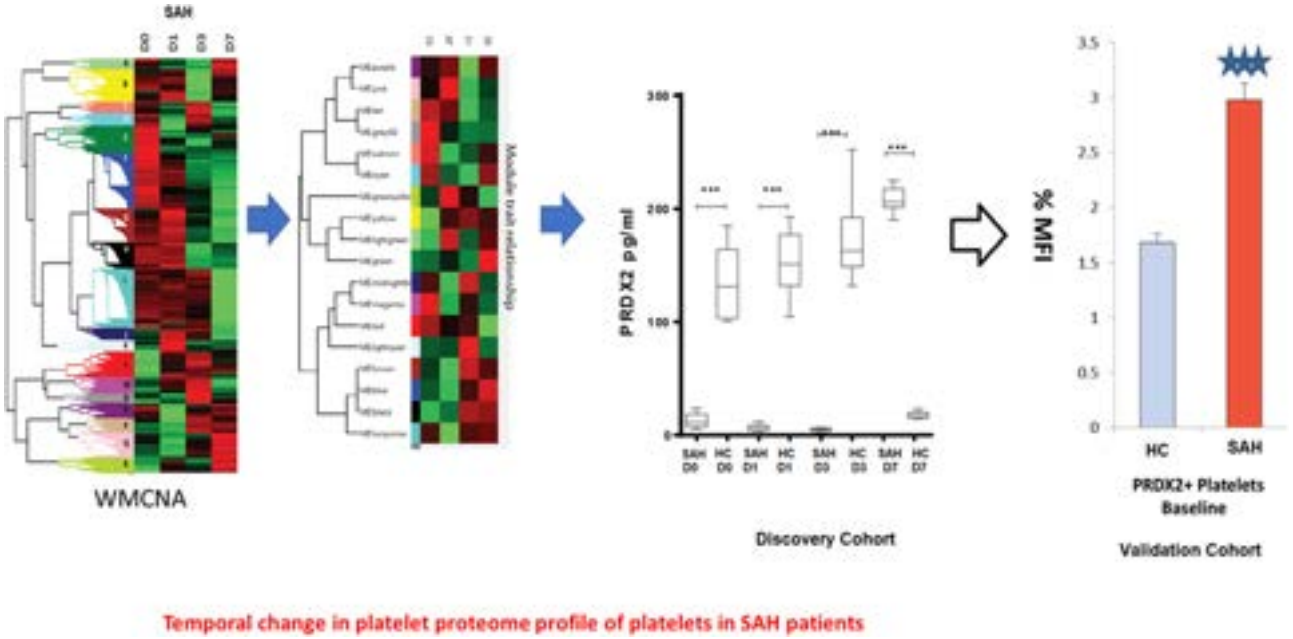

Figure: (abstract: FRI-407).

12.0, respectively; $p < 0.001$). Although initial frequency of Treg cells were marginally lower in the steroid group, the population of Treg cells were significantly increased in the steroid group (p = 0.019, Figure 1A). Of the steroid group, steroid responder (n = 9) showed significant increase in the population of Treg cells after steroid therapy (p = 0.020, Figure 1B). Moreover, there was significant positive correlation between the decrease in MELD score and increase in Treg cells (R = 0.43; $p = 0.019$). In the single cell RNA sequencing analysis using paired PBMCs (pre- and post- steroid therapy), we found that cytokine production and type I IFN gene signature in CD4 T cells were downregulated after steroid therapy, suggesting the possible protective roles of expanded activated Treg cells.

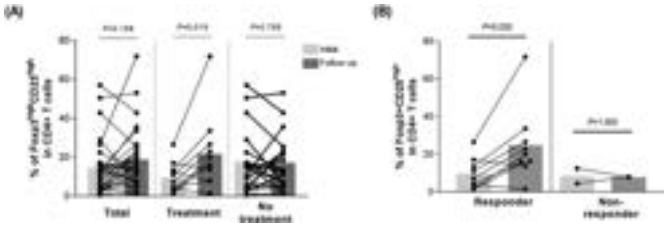

Figure: Changes in regulatory T cells according to steroid treatment (A) and response (B).

Conclusion: Our data suggest that an increase in the number of activated regulatory T cells is associated with an improvement in the liver function of patients with severe alcoholic hepatitis after steroid therapy.

FRI-410

Plasma lipidomics and meta-proteomics analysis classifies lipid species and microbial peptides associated with poor outcome in SAH patients

Jaswinder Maras[1], Manisha Yadav[1], Nupur Sharma[1], Gaurav Tripathi[1], Babu Mathew[1], Vasundhra Bindal[1], Neha Sharma[1], Sushmita Pandey[1].
[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India
Email: jassi2param@gmail.com

Background and aims: Severe alcoholic hepatitis (SAH) has a high mortality and corticosteroid therapy non-response is seen in ~ 60% patients. Corticosteroid therapy is known to cause lipid profile abnormalities. Thus we speculated that lipidomics may represent a useful tool to characterise responders (R) and non-responders (NR) to corticosteroid therapy and outcome.

Method: Plasma lipidomics and metaproteome (metagenomics) was performed in 80 SAH (R = 55 and NR = 25) at baseline, day 4 and day 7 to identify signatures capable of early detection of nonresponse. Temporal change in lipidome was assessed by Weighted Lipid Correlation Network Analysis (WLCNA). Baseline Metaproteome and lipidome profiles were subjected to cross correlation network analysis followed by correlation with clinical parameters. Bacterial specific lipid species which could predict severity and outcome were identified and validated in a test cohort of (n = 100) SAH patients using Machine learning approach.

Results: Plasma samples showed significant alteration of lipidome and microbiome as indicated by multivariate PLS-regression analysis and alpha, beta diversity indices (p < 0.05). Significant reduction of lipid species and increase in bacterial taxa (baseline) were observed in NR (p < 0.05, LogFC > 1.5, FDR < 0.01). Baseline plasma level of TG 48:4 was higher whereas level of PS and PE (known for maintaining body cortisol level) were lower in NR (p < 0.05). Temporal analysis of lipidomic profile showed significant increase in lipid metabolism in R, whereas the NR showed specific increase in triglycerides already reported for promoting steatosis and inflammation (p < 0.05). NR specific Meta-proteomic signatures/functionality directly correlated with lipid species and clinical parameters; severity indices (mDF, MELD and others; p < 0.05). Baseline increase in TG 48:4 showed direct correlation with increased bacterial taxa; Escherichia coli, Bacillales, Streptococcus, Enterobacteriaceae and their functionality in NR (r2 > 0.5, p < 0.05). Baseline reduction of PS and PE were associated Lactobacillus, Nocardiopsaceae and others along with their functionality in NR (r2 > 0.5, p < 0.05). Lipidomic and metaproteomic signature based probability of detection of NR was >90% (p < 0.05). Baseline decrease in PS ((PS a41:5, PS a43:6, PS a43:4, PS a43:5, PS a41:0) with (AUC > 0.89, p <0.05) predicted Non-response and segregated Non survivors (HR = 0.80 (0.75–0.90), p < 0.05) in SAH patients. Validation of 5 lipid species using 5 machine learning algorithms in the validation cohort (n = 100; R = 80, NR = 20) showed accuracy (99%), sensitivity/specificity > (98%) for NR detection in SAH.

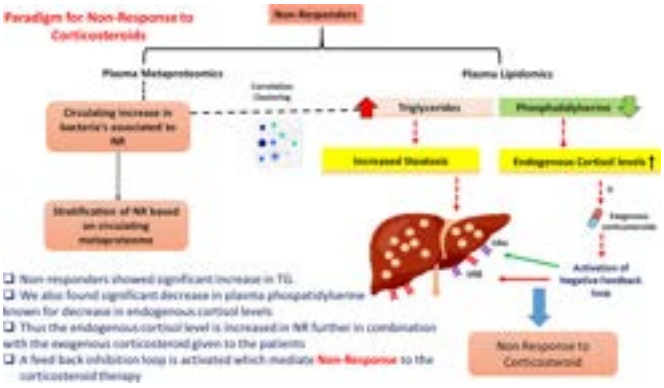

Figure:

Conclusion: Plasma sample of NR show significant reduction in lipid species and increase in bacterial taxa. We, report a core set of plasma lipidome and meta-proteome signature which could be used for early diagnosis of non-response and outcome prediction in SAH patients.

FRI-411

In-silico identification and ex-vivo validation in humans of distinct oncogenic potential of aldo-keto reductase AKR1B10 in hepatocellular carcinoma from alcohol induced liver injury

Email: puneet.puri@vcuhealth.org

Background and aims: Development of hepatocellular carcinoma (HCC) is complex. It is a major cause of cancer-related mortality with a minority diagnosed at an early stage. Chronic alcohol abuse, and hepatitis B and C viral (HBV and HCV) infections are major risk factors. However, pre-cancer alterations which also affect the prognosis are not well known. We aimed to investigate (i) the *in-silico*

transcriptional alterations among HCC patients induced by alcohol liver injury compared to those with hepatitis B and C, (ii) to identify the gene classifier for better prognosis of the disease and validate *ex-vivo* in human samples.

Method: We systemically interrogated The Cancer Genome Atlas (TCGA, n = 433) to search for genes that contribute to HCC. First, we compared the survival of HCC patients who had a history of alcohol abuse vs. Hepatitis B or C alone via Kaplan-Meier analysis. Next, we tested the differential gene expression utilizing dataset, GSE28619, containing healthy (n = 7) and alcohol associated cirrhosis (AAC, n = 15). Gene dysregulation was determined using the 'characteristic direction method' of the EnrichR algorithm. Using GEO database we performed a machine learning technique nearest-shrunken centroid analysis. Further, AKR1B10 expression was validated on human liver tissue from AAC (AAC, n = 5), hepatitis C related HCC (HCC-HCV, n = 5), alcohol cirrhosis related HCC (HCC-AC, n = 5) and normal tissue (control, n = 5) using immunohistochemistry (IHC).

Results: Patients with HCC due to chronic alcohol abuse had worse prognosis than patients with hepatitis B or C related infection (p = 0.011). Gene enrichment analysis showed 500 differentially expressed genes. The family of aldo-keto reductase (AKR) enzymes were statistically enriched in patients with alcohol associated hepatitis (AAH). Using machine learning, a singular gene classifier of AAH was identified as aldo-keto reductase AKR1B10. This is widely expressed in the gastrointestinal tract. However, it is virtually undetectable in normal liver tissue. Then we performed GSEx microarrays analysis between healthy and cirrhotic livers. AKR1B10 was the 5th most statistically upregulated gene. Further, we confirmed that AKR1B10 is upregulated in HCC using unbiased IHC samples from the Human Protein Atlas (Figure A). Additionally, AKR1B10 was an independent marker for poor patient survival in the large TCGA sample (n = 433). Importantly, in patients with HCC and an initial alpha fetoprotein (AFP) value of greater than 400, poor survival was associated with AKR1B10 expression (Figure B, red line). Alcohol associated HCC had higher AKR1B10 expression than those without a history of alcohol abuse (RR = 1.6, p = 0.0076, Figure C). We confirmed this in human liver tissues. There was no expression in controls and >2-fold increase in AAC. This was further increased in HCC-AC in contrast to minimal expression in HCC-HCV.

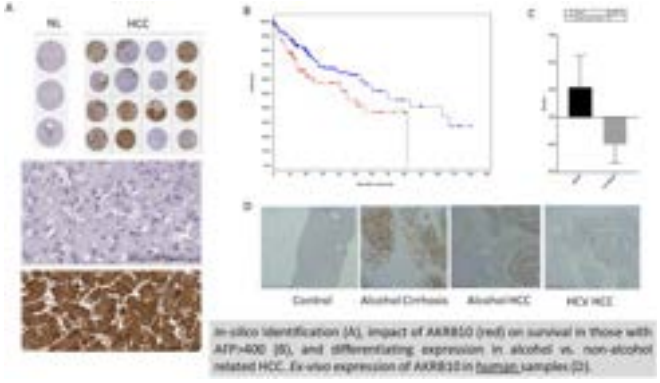

Figure:

Conclusion: Alcohol associated HCC are more aggressive than viral hepatitis infected patients. We identified a novel classifier AKR1B10, as precancerous marker of alcohol induced liver injury, alcohol associated cirrhosis and HCC. Additionally, AKRB10 prognosticated HCC. This promising marker provides a platform to understand mechanism of alcohol induced hepatocarcinogenesis and merits further validation.

FRI-412

The beneficial effects of the diet withdrawal and physical exercise on steatohepatitis of DUAL etiology

Olga Estévez[1], Raquel Benedé[1,2], Hector Leal[1], Jeanne Fabre[3], Johanna Reißing[4], Marina Mazariegos[1], Tony Bruns[4], Javier Vaquero[5,6,7], Rafael Bañares[6,8,9], Francisco Javier Cubero[1,8,10], Yulia Nevzorova[1,8,10]. *[1]Complutense University of Madrid, Immunology, Ophthalmology and ENT, Madrid, Spain; [2]Complutense University of Madrid, Physiology, Genetics and Microbiology, Madrid, Spain; [3]Polytech Angers, Génie Biologique et Santé, France; [4]University Hospital RWTH Aachen, Internal Medicine III, Aachen, Germany; [5]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERHED), Spain; [6]Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain; [7]Gregorio Marañón General University Hospital, Servicio de Aparato Digestivo, Madrid, Spain; [8]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Spain; [9]Hospital General Universitario Gregorio Marañón, Servicio de Aparato Digestivo, Spain; [10]Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Spain*
Email: olgaeste@ucm.es

Background and aims: Along with the increase of obesity and type 2 diabetes (T2D), steatohepatitis incidence is tremendously escalating and becoming a significant burden of liver-related outcomes. Dietary changes and physical activity are recommendable therapeutic strategies. Whether steatohepatitis is reversible remains a relevant clinical question and is a constant matter of debate.

In the present study, we used a synergistic DUAL murine model of NASH and alcohol consumption, and studied the biological impact of physical exercise and dietary changes on the progression of steatohepatitis and fibrosis.

Method: C57BL/6 male mice received 10% alcohol in sweetened drinking water together with a Western diet (DUAL model) for short (10 weeks) and long (23 weeks) period followed by either (i) the replacement with chow diet and normal water for 21 days; or (ii). chow diet/normal water plus treadmill sessions for 21 days. Metabolic syndrome (MS), serum parameters, liver and e-WAT (epididymal white adipose tissue, WAT) histology, were analysed in detail.

Results: Compared to the 10 weeks DUAL-fed mice, all animals in the diet withdrawal (DW) and withdrawal plus exercise (DW+EXER) groups showed significant decrease in body mass, liver and fat weight, remarkable improvement in liver and fat morphology, attenuated hepatic steatosis with reduced hepatic triglyceride (TG) content, diminished hepatic injury and inflammation. Nevertheless, as the long-term DUAL feeding (23 weeks) leads to the significant steatohepatitis and advanced fibrosis, the diet replacement with or without physical exercise resulted only in slightly decrease of the body and liver weight, faintly diminished hepatic steatosis and TG content in the liver and the significant improvement of serum parameters of liver damage. Importantly, long-term DUAL feeding, e-WAT cellular hypertrophy, central markers of the hepatic inflammation (CD45 and F4/80 levels) and fibrosis (alfa-SMA) were reversible only in the group of the diet withdrawal in combination with physical exercises.

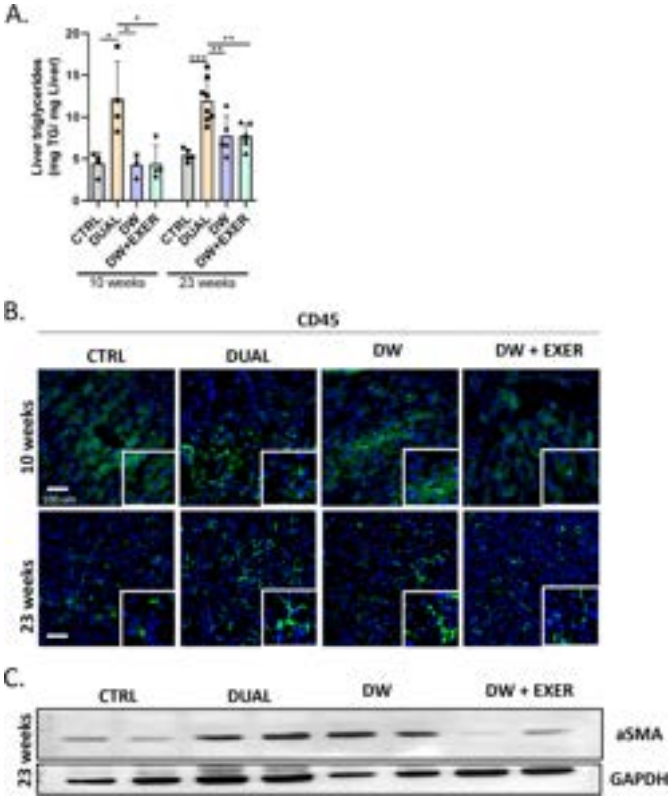

Figure: DUAL diet withdrawal only in combination with intensive physical activity attenuates hepatic inflammation and fibrosis even after long term DUAL feeding. DUAL mice manifest enhanced hepatic inflammation and fibrosis. (i) DUAL diet withdrawal for 21 days, (ii) DUAL diet withdrawal in combination with treadmill for 21 days. A. Quantification of hepatic triglycerides after 10 and 23 weeks feeding B. Illustrative CD45 staining in liver sections of mice fed for 10 and 23 weeks. Positive immune cells are stained in green. Nuclei are stained in blue using DAPI as a counterstain. Scale = 100 μm C. alpha-SMA western blot using GAPDH as a loading control.

Conclusion: Dietary modification, alone or combination with physical exercisers in patients with the initial stages of steatohepatitis might be considered as an efficient non-pharmacological therapy, reducing body weight, hepatomegaly, steatosis and liver inflammation. However, only a combination of dietary changes and physical activity can lead to the clinical improvement at the advance stages of steatohepatitis.

FRI-413

When is the optimal time to collect baseline data for calculating the Lille score in severe alcoholic hepatitis?

Mina Ignat[1,2], Adelina Horhat[3], Andreea Barb[1,2], Irina Dragomir[1], Andreea Fodor[1,2], Fischer Petra[1,2], Oana Nicoara-Farcau[1,2,3], Indre Madalina Gabriela[1,2,3], Vlad Taru[1,2,3], Corina Radu[1,3], Bogdan Procopet[1,2,3], Horia Stefanescu[1,2]. *[1]Regional Institute of Gastroenterology and Hepatology "Prof. Dr. O. Fodor," Cluj-Napoca, Romania," Hepatology, Cluj-Napoca, Romania; [2]Liver Research Club, Hepatology, Cluj-Napoca, Romania; [3]University of Medicine and Pharmacy "Iuliu Hatieganu," Cluj Napoca, Romania, 3rd Medical Clinic, Hepatology, Cluj-Napoca, Romania*
Email: ignat.mina@gmail.com

Background and aims: Treatment of severe alcoholic hepatitis relies on corticosteroids. Lille score is used to identify patients with severe alcoholic hepatitis receiving corticosteroids, that respond or not to treatment. This model uses baseline data and the change in bilirubin level at day 7. However, many patients receive corticotherapy after several days of hospitalization because they need screening for infections or treatment for a severe infection. In this time frame, the level of serum bilirubin can change in both ways compared with the level at admission time. There is no clear recommendation about the specific moment when baseline data needs to be collected in order to calculate the Lille score.
Our aim is to determine how important is the time interval between admission and first day of corticosteroids in the dynamics of Lille score and to evaluate the accuracy of different scores to predict short term mortality.
Method: We retrospectively analysed all consecutive patients with a history of alcoholism, suggestive liver chemistry, biopsy proven AH, Maddrey score >32, treated with corticosteroids, were included between January 2016–December 2022. Biological data was recorded at admission (T0) and prospectively at day 1 (T1), day 7 (T7) of corticosteroid therapy. We excluded patients who didn't receive corticosteroids because of uncontrolled infections, recent gastrointestinal hemorrhage. 40 mg Prednisone or 32 mg Methylprednisolone was given for 28 days for all patients.
Results: One hundred sixty-four patients were included, mean age was 52 ± 9, 76.4% were males. 89.1% were decompensated (ascites 83.6%, hepatic encephalopathy 35.2%), 32.1% had infection at admission, 98% had an AHHS score >3. Out of all patients, 81.0% responded to the corticotherapy treatment, assessed by Lille score at day 7. The survival of these patients was 77.6% at one month, 69.7% at three months, 42.7% overall. Out of all patients, one hundred had the blood analysis required to assess both the Lille T0 and Lille T1. There are no significantly differences regarding Meld score, Maddrey score and serum bilirubin at T0 compared to T1, p > 0.05. AUROC curve for survival at 1 month for Lille7 T0 was 0.84 ± 0.04 (95%CI: 0.74–0.93), Lille7 T1 0.85 ± 0.04 (95%CI: 0.75–0.93), Meld T0 0.73 ± 0.06 (95%CI: 0.61–0.85), Meld T1 0.76 ± 0.05 (95%CI: 0.66–0.87), Maddrey T0 0.62 ± 0.71 (95%CI: 0.48–0.76) and Maddrey T1 0.72 ± 0.06 (95%CI: 0.60–0.84). Lille T0 is significantly higher than Maddrey T0. AUROC for survival at 3 and 6 months is not significantly different between Lille T0 and Lille T1. Survival at one month in the group of patients who responded to corticotherapy according to Lille T1 was 83.0%, at three months 74.6% and at six months 72.4%. In comparison, the responders to Lille T0 survival at one month was 80.5%, at three months 72.2% and at six month 71.4%. The median follow-up duration was 13 months (varying between 0 and 78 months, range 78), 55% of the patients died at the end of the follow-up. Corticosteroids response assessed by Lille T1 predicts better overall survival than Lille T0, HR: 2.26 (95%CI: 1.19–4.29), p = 0.01, respectively HR: 2.03 (95%CI: 1.05–3.91), p = 0.03.
Conclusion: Therefore, our data showed that the time between admission and corticosteroid initiation does not significantly change the dynamic of Lille score and does not impact the prognostic and survival. However, further studies need to be done with larger number of patients.

FRI-414

Low doses of different hepatotoxins induce alcohol-related liver disease and drive hepatocellular carcinoma

Brisa Rodope Alarcón-Sánchez[1,2], Osiris German Idelfonso García[2], Verónica Rocío Vásquez-Garzón[3], Pablo Muriel[4], Julio Isael Pérez-Carreón[2], Saúl Villa-Treviño[1], Jaime Arellanes-Robledo[2,5]. *[1]Center for Research and Advanced Studies of the National Polytechnic Institute, Department of Cell Biology, Mexico City, Mexico; [2]National Institute of Genomic Medicine-INMEGEN, Laboratory of Liver Diseases, Mexico City, Mexico; [3]Faculty of Medicine and Surgery, 'Benito Juárez' Autonomous University of Oaxaca-UABJO, Laboratory of Fibrosis and Cancer, Oaxaca, Mexico; [4]Center for Research and Advanced Studies of the National Polytechnic Institute, Laboratory of Experimental Hepatology, Mexico City, Mexico; [5]National Council of Science and Technology-CONACYT, Directorate of Cátedras, Mexico City, Mexico*
Email: brisa.alarcon@cinvestav.mx

Background and aims: Chronic alcohol abuse is one of the main causes of morbidity and mortality since promotes alcohol-related liver disease (ALD) worldwide This condition may be attributed to multiple hits driving several liver alterations. Excessive ethanol intake promotes the production of reactive oxygen species (ROS) and increases both portal and systemic circulation of lipopolysaccharides (LPS), which exacerbate ROS and potentiate the liver damage. Since hepatocellular carcinoma (HCC) may be the late ALD stage, the synergistic effect of ethanol and diethylnitrosamine (DEN), a hepatic carcinogen, also has been tested. The aim of this work was to determine if the simultaneous administration of ethanol and low doses of LPS and DEN induces HCC as an *in vivo* multi-hit ALD model, as occurs in humans.
Method: C57BL/6J female mice were administered with ethanol and low doses of LPS and DEN. Firstly, after an ethanol adaptation period, mice were allowed to drink *ad libitum* a mixture of 20% (w/v) sucrose containing 20% ethanol for 18 weeks as the only source of drinking fluid, and DEN and LPS were dissolved in PBS and intraperitoneally injected twice a week. While DEN was administered at 7 mg/kg body weight (BW) for 15 weeks during ethanol consumption, LPS was administered at 1 mg/kg BW alongside the period of time of ethanol consumption. In addition to animals subjected to ethanol, LPS and DEN (ELD group), another group was administered with 20% sucrose as controls (C) or DEN plus 20% sucrose as DEN control (DEN). ELD groups were euthanized at 6, 9, 12, 15, 18 and 25 weeks; and C and DEN groups were euthanized at 18 and 25 weeks.
Results: We showed that ELD scheme interfered with BW gain and induced liver structural disarrangement, inflammatory infiltration, steatosis, and fibrosis, as illustrated in the figure (images from C, DEN and ELD groups treated for 18 weeks); which was accompanied by increased levels of the proliferation markers proliferating cell nuclear antigen (PCNA) and Ki-67, those of ethanol metabolism cytochrome P450 2E1 (CYP2E1) and alcohol dehydrogenase (ADH), that of hepatocarcinogenesis glutathione S-transferase P 1 (GSTP1), as well as, that of LPS-inducible myeloid differentiation primary response protein MyD88 (MYD88) and toll-like receptor 4 (TLR4), and that of inflammation interleukin-6 (IL6).

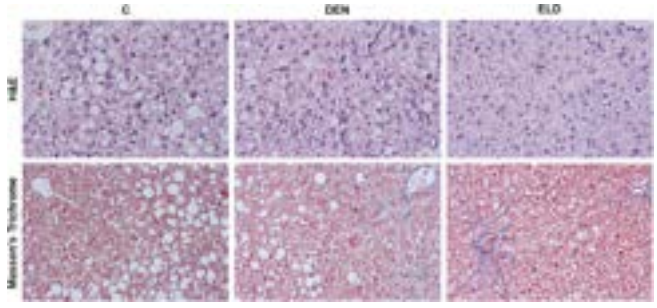

Figure:

Conclusion: Considering that ALD progression naturally occurs as the result of combined effects of multiples hits, we provide evidence showing that the simultaneous administration of ethanol, and low doses of LPS and DEN exacerbates ALD-associated alterations by inducing more deleterious effects on the liver and HCC as compared with those induced by DEN alone. Thus, here we introduce a promising multi-hit ALD model to better recapitulate ALD-associated pathogenesis and eventually, to identify therapeutic targets for the treatment of ALD stages.

FRI-415
Systemic dyslipidemia in Ldlr mice accelerates hepatic fibrosis after chronic-binge ethanol feeding
Constanze Hoebinger[1], Dragana Rajcic[2], Tim Hendrikx[2]. [1]*Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria,* [2]*Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria*
Email: constanze.hoebinger@meduniwien.ac.at

Background and aims: Chronic ethanol consumption is known to cause alcohol-associated liver disease, which poses a global health concern as almost a quarter of heavy drinkers develop severe liver damage. Alcohol-induced liver disease ranges from a mild, reversible steatotic liver to alcoholic steatohepatitis and irreversible liver fibrosis and cirrhosis, ultimately requiring liver transplantation. Although ethanol consumption is associated with dysregulated lipid metabolism, the impact of pre-existing dyslipidemia on the development of alcohol-related liver disease is still unknown. In this study, we investigated the contribution of pre-existing dyslipidemia and particularly hypercholesterolemia to the progression of alcohol-related liver disease.
Method: To address the influence of systemic dyslipidemia on ethanol-induced liver disease, chronic-binge ethanol feeding (NIAAA model) was applied to female C57BL/6J (wild type) mice and mice deficient for the low density lipoprotein receptor ($Ldlr^{-/-}$), which display a human-like lipoprotein profile with elevated cholesterol and triglyceride levels in circulation. Respective control groups were pair-fed with an isocaloric diet.
Results: Chronic-binge ethanol feeding did not alter systemic lipid levels in wild type mice. While increased systemic cholesterol levels in $Ldlr^{-/-}$ mice were not affected by ethanol feeding, chronic-binge ethanol diet aggravated elevated plasma triglyceride levels in $Ldlr^{-/-}$ mice. Despite higher circulatory triglyceride levels in $Ldlr^{-/-}$ mice, hepatic lipid levels and the development of hepatic steatosis were not different from wild type mice after ethanol diet. Immunohistochemical assessment indicated a lower induction of infiltrating neutrophils in the livers of ethanol-fed $Ldlr^{-/-}$ mice compared to wild type mice. In line, hepatic mRNA levels of the pro-inflammatory genes Ly6 g, Cd11b, Ccr2, and Cxcl1 were reduced, indicating less inflammation in the livers of $Ldlr^{-/-}$ mice. In contrast, Ldlr-deficient mice developed more liver fibrosis after ethanol diet than wild type mice, as indicated by increased levels of Sirius Red staining and higher expression of pro-fibrotic genes Tgfb and Col1a1. $Ldlr^{-/-}$ and wild type mice had similar plasma ethanol levels and did not show differences in the hepatic mRNA levels of Adh1 and Cyp2e1, important for ethanol metabolism.
Conclusion: Our results show that chronic-binge ethanol feeding aggravates systemic dyslipidemia in $Ldlr^{-/-}$ mice, resulting in an accelerated development of ethanol-induced hepatic fibrosis.

FRI-416
Dynamics of oxidized albumin and cognate metabolites are associated with severe inflammation in experimental model of alcohol related liver disease
Babu Mathew[1], Jaswinder Maras[1], Sadam H. Bhat[1], Nupur Sharma[1], Manisha Yadav[1], Gaurav Tripathi[1], Vasundhra Bindal[1], Neha Sharma[1], Sushmita Pandey[1], Abhishak Gupta[1], Shiv Kumar Sarin[2]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Alcohol related liver diseases (ALD) result from progressive hepatocellular injury, inflammation and oxidative stress. Albumin therapy is often recommended for ALD patients to improve survival. Albumin exists in 3 major forms: reduced Human Mercaptoalbumin (HMA), oxidized Human Nonmercaptoalbumin 1 (HNA1) and oxidized Human Nonmercaptoalbumin 2 (HNA2). Due to increase in systemic oxidative stress in ALD, oxidation of HMA to

HNA1/HNA2 increases. However, the time at which the infused albumin (HMA) undergoes oxidative modification and changes in cognate circulating metabolites are not known. Our study aims to decipher the time dynamics of oxidized albumin and associated changes in the circulating metabolome in a rat model of ALD.

Method: ALD model was developed by feeding Lieber-DeCarli liquid diet (40% ethanol) to Long Evans rats for 28 weeks. Liver histology (ballooning, steatosis and neutrophil infiltration) and AST/ALT levels confirmed active ALD. HMA, *in-vitro* modified HNA1 and *in-vitro* modified HNA2 (2.5 g/kg) were injected intraperitoneally to the ALD rats (n = 3 each) at three time points: baseline, 24 hours and 48 hours. Plasma was collected at baseline, 5 minutes, 15 minutes, 30 minutes, 1 hour, 24 hours, 48 hours, 72 hours and post euthanasia. Oxidized albumin measurement and untargeted metabolomics was performed.

Results: At baseline (before injection), the ALD rats showed significant increase in HNA1 (42.61%) and HNA2 (24.99%). HMA infused ALD rats showed temporal increase in HMA levels (15%) (5 min to 72 hours) with a slight dip between 5 minutes and 1 hour. HNA1 levels decreased by 18% and there was no significant change in HNA2 levels. Untargeted metabolomics also showed temporal increase in histidine (anti-inflammatory), purine/pyrimidine, glutathione and pantothenate metabolism ($p < 0.05$) indicating the protective and anti-inflammatory activity of HMA. Interestingly, Infusion of HNA1 to ALD rats showed significant temporal increase (5 minutes to 72 hours) in HNA2 (10% to 32%) with simultaneous decrease in the HMA (10%) levels suggesting that HNA1 infusion increases the irreversible oxidation of HMA/HNA1 to HNA2. Metabolomics also showed temporal increase in spermidine synthesis (pro-inflammatory polyamines), ammonia recycling and phosphatidylcholine synthesis (pro-apoptotic phospholipids) ($p < 0.05$) documenting the pro-inflammatory and pro-apoptotic activity of HNA1. Unfortunately, HNA2 infused ALD rats died after 4 hours. We observed significant temporal increase of HNA2 (15%) (5 minutes to 4 hours) with significant and apparent decrease in HNA1 and HMA. Results of metabolomics analysis revealed an increase in fatty acid, amino-sugar, tryptophan, fructose, mannose and sphingolipid metabolism suggesting the increase of inflammatory metabolites in HNA2 infused ALD rats. The advanced oxidative state (AOS) of albumin was highest in HNA2 infused rats ($p < 0.05$).

Conclusion: Our results show that HMA infusion temporally decreases HNA1 levels with simultaneous increase in anti-inflammatory metabolites. HNA1/HNA2 infusion causes irreversible oxidation of albumin to HNA2 and increase in pro-inflammatory/pro-apoptotic metabolites in the circulation. Albumin modification time dynamics significantly correlate with their cognate plasma metabotype and could be used as putative indicators of increasing inflammation and severity over time.

Multi-omics analysis reveals the therapeutic effect and mechanism of the Chinese herbal JiGuCao capsule on acute alcoholic hepatitis in mice

Yue Chen[1], Hening Chen[1], Wenying Qi[1], Xu Cao[1], Ruijia Liu[1], Zao Xiaobin[1,2], Yong'an Ye[1,3]. *[1]Dongzhimen Hospital, Beijing University of Chinese Medicine, China; [2]Key Laboratory of Chinese Internal Medicine of Ministry of Education and Beijing, Dongzhimen Hospital, Beijing University of Chinese Medicine, China; [3]Institute of Liver Diseases, Beijing University of Chinese Medicine, China*
Email: chen.yue123456@163.com

Background and aims: Alcoholic hepatitis (AH) is a kind of alcohol-related liver disease (ALD), caused by alcohol abuse, with high morbidity and mortality, which increases the risk of liver falure, liver cirrhosis and hepatocellular carcinoma, and the current treatment methods are still limited. Its pathogenesis is closely related to inflammatory response, intestinal mucosal permeability changes, bile acid circulation disorders, and other mechanisms. Traditional Chinese medicine (TCM) has shown a therapeutic effect to treat AH. JiGuCao capsule (JGC) is a commonly used marketed TCM for the treatment of acute and chronic hepatitis. However, the therapeutic effect and mechanism of JGC in the prevention and treatment of AH are still unclear and need further study.

Method: A mouse model of AH was established with 14 days of 5% (v/v) ethanol liquid diet and a single dose of 31.5% (v/v) ethanol liquid diet gavage (Figure A). At the same time, the treatment group was given by gavage of an aqueous solution of JGC. The therapeutic effect of JGC on AH was determined by serological analysis of liver function and histopathological examination of hematoxylin-eosin (HE) and oil red (OR) staining. At the same time, transcriptomics and non-target metabolomics of liver tissues, and 16S ribosomal DNA sequencing (16S seq) of gut microbiota were used to investigate the protective effects of JGC on AH. The differently expressed genes (DEGs) and differently expressed metabolites (DEMs) between the model and the JGC groups were screed out to perform further enrichment analyses including the Gene Ontology (GO) and the Kyoto Encyclopedia of Genes and Genomes (KEGG).

Results: Compared with the model group, the intervention of JGC reduced serum levels of alanine aminotransferase and aspartate aminotransferase (Figure B). In histology and pathology, HE and OR staining showed that ethanol exposure significantly increased the number of steatosis and necrotic cells in the liver of the model group, and a large number of fat vacuoles appeared. Meanwhile, the villi structure of the small intestine was scattered, the cells were shed, and the small intestinal glands were increased. Compared with the model group, JGC alleviated hepatic steatosis and restored the integrity of the intestinal structure (Figure C). The enrichment analyses of DEGs showed that JGC may affect KEGG pathways of Bile secretion, retinol metabolism, fatty acid degradation, Gastric cancer and GO pathway of cellular response to interferon-beta, response to cytokine, symbiont-containing vacuole membrane, endoplasmic reticulum membrane, GTPase activity, GTP binding (Figure D–F). The enrichment analyses of DEMs showed that JGC could regulate amino acid metabolism, protein digestion and absorption, and ABC transporter pathways (Figure H–J). And in the gut microbiota level, the results of 16S seq showed that at the genus level, the JGC treatment restored the reduction of Lactobacillus content caused by alcohol, and increased the content of norank_f_Muribaculaceae and Prevotellaceae_UCG-001 (Figure K–L).

Conclusion: Histopathological and multi-omics analysis studies showed that JGC could have good preventive and therapeutic effect on AH.It could restore the normal function of the gut-liver axis by regulating the transport of bile acids and the ecological structure of intestinal flora. And JGC could effectively alleviate liver inflammation, restore the liver and intestinal injury caused by alcohol.

FRI-418

Strategies are needed to support people with alcohol use disorder and alcohol-related liver disease to take part in randomised clinical trials: results from the MIRAGE pilot trial of functional imagery training

Ashwin Dhanda[1,2], Victoria Allgar[1], Jackie Andrade[1], Lynne Callaghan[1], Benjamin Hudson[3], Wendy Ingram[1], Angela King[1], Victoria Lavers[4], Joe Lomax[1], Anne McCune[5], Crispin Musicha[1], Richard Parker[6], Christopher Rollinson[7], Siobhan Creanor[8].

[1]*University of Plymouth, Faculty of Health, Plymouth, United Kingdom;* [2]*University Hospitals Plymouth NHS Trust, South West Liver Unit, Plymouth, United Kingdom;* [3]*Royal Devon University Hospitals NHS Foundation Trust, United Kingdom;* [4]*Unaffiliated, United Kingdom;* [5]*University Hospitals Bristol and Weston NHS Foundation Trust, Department of Liver Medicine, United Kingdom;* [6]*Leeds Teaching Hospitals NHS Trust, United Kingdom;* [7]*University Hospitals Plymouth NHS Trust, Research Development and Innovation, United Kingdom;* [8]*University of Exeter, Exeter Clinical Trials Unit, United Kingdom*
Email: ashwin.dhanda@nhs.net

Background and aims: Treatment of alcohol use disorder (AUD) in people with alcohol-related liver disease (ARLD) reduces the risk of disease progression and mortality. However, there are no effective evidence-based therapies. Functional Imagery Training (FIT) is a novel therapy combining motivational interviewing techniques with imagery to strengthen motivation for behaviour change. We conducted a pilot trial of FIT to test whether people with AUD and ARLD could be recruited and retained in a trial and how well FIT could be delivered within the UK National Health Service (NHS).
Method: We conducted a multicentre randomised pilot trial of FIT with treatment as usual (TAU) versus TAU alone in patients with unplanned hospital admissions with AUD and ARLD. Primary outcomes were recruitment and retention rates. Secondary outcomes included self-reported alcohol use by timeline follow-back. Alcohol liaison nurses were trained to deliver FIT to participants who received the first session in hospital and a further 8 sessions over 6 months by phone. Follow-up of all participants was by phone for Days 28 and 90 and in-person at Day 180 (D180), the primary end point. To help retention, participants were asked to provide contact details for a nominated second person and offered a financial incentive at the final trial visit.
Results: Of 121 patients approached, 54 were recruited (45% recruitment rate) and randomised (TAU: 28; FIT+TAU: 26): mean (SD) age 49 (11), 63% male, 52% had cirrhosis with mean MELD 24 (6.5). Non-participation was mainly due to ineligibility (n = 11), lack of interest (n = 17) and logistical challenges (n = 28). 14 (26%) participants were not retained to D180 due to death (n = 5) and withdrawal (n = 9). Of the remaining 40 participants, 23 (58%) attended the D180 visit. 9, 17 and 17 participants did not attend trial visits at Days 28, 90 and 180, respectively. Most alcohol liaison nurses delivered FIT with adequate fidelity. 50% of participants randomised to FIT+TAU received the first 2 sessions (considered an adequate dose of the intervention). Based on all available data, median alcohol use per week fell from 1568 g (range 788, 2128) pure ethanol at baseline to 0 g (0, 180) at D180 and from 1120 g (610, 1784) to 0 g (0, 196) in TAU and FIT+TAU groups, respectively.
Conclusion: This study demonstrates the importance and challenges of recruitment and retention. Although we showed that alcohol workers in the UK NHS could successfully deliver FIT to people with AUD and ARLD, low retention limited interpretation of clinical outcomes. The implemented retention plan was inadequate as participants frequently changed phone number or did not respond to calls. Robust strategies to support recruitment and retention of people with AUD and ARLD must be incorporated in future clinical trials to enable the evaluation of new interventions in this under-served patient population.

FRI-419
Supplementation of choline attenuates the onset of alcohol-related liver disease

Victor Sánchez[1], Anja Baumann[1], Franziska Kromm[1], Annette Brandt[1], Ina Bergheim[1]. [1]*University of Vienna, Department of Nutritional Sciences, Austria*
Email: ina.bergheim@univie.ac.at

Background and aims: Alcohol-related liver disease (ALD) is still one of the most common liver diseases worldwide. Besides altering liver

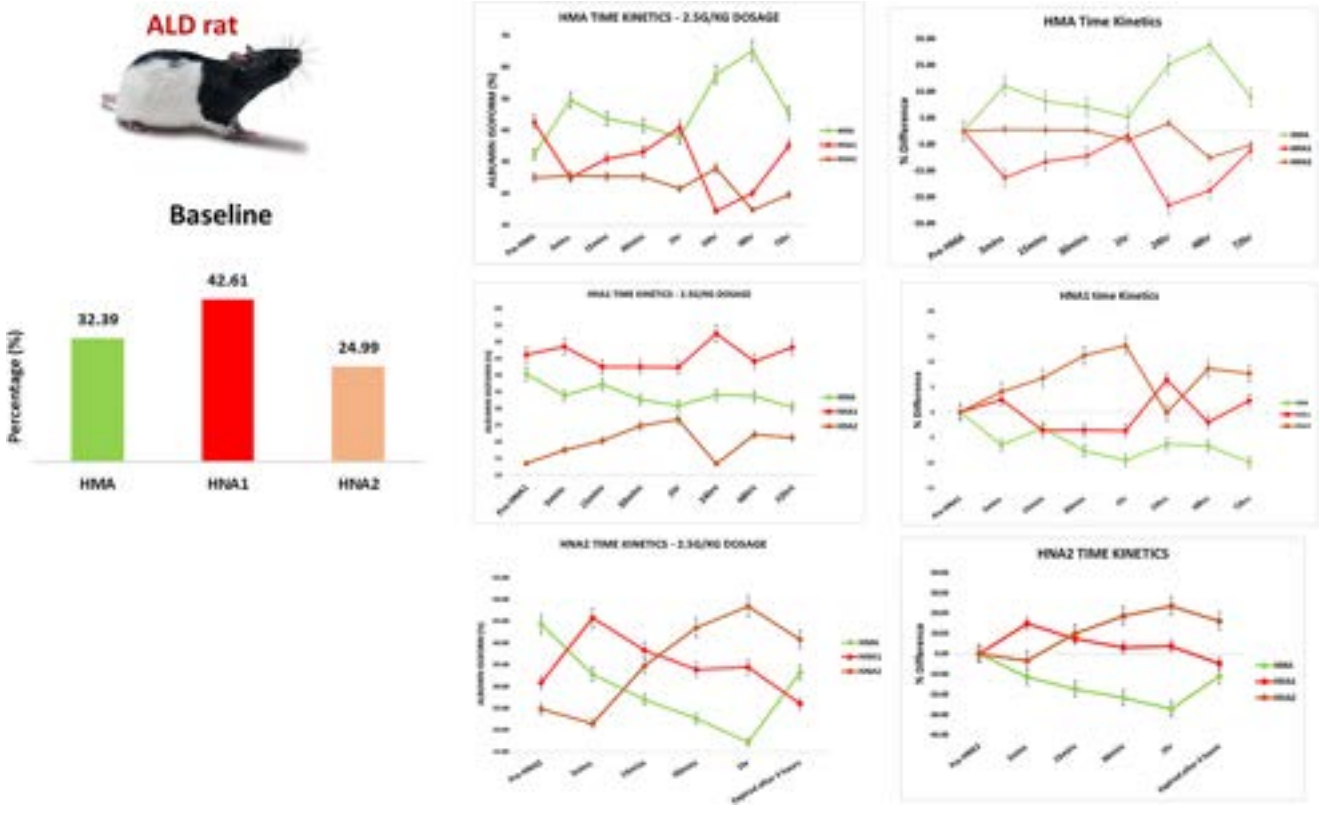

Figure: (abstract: FRI-416).

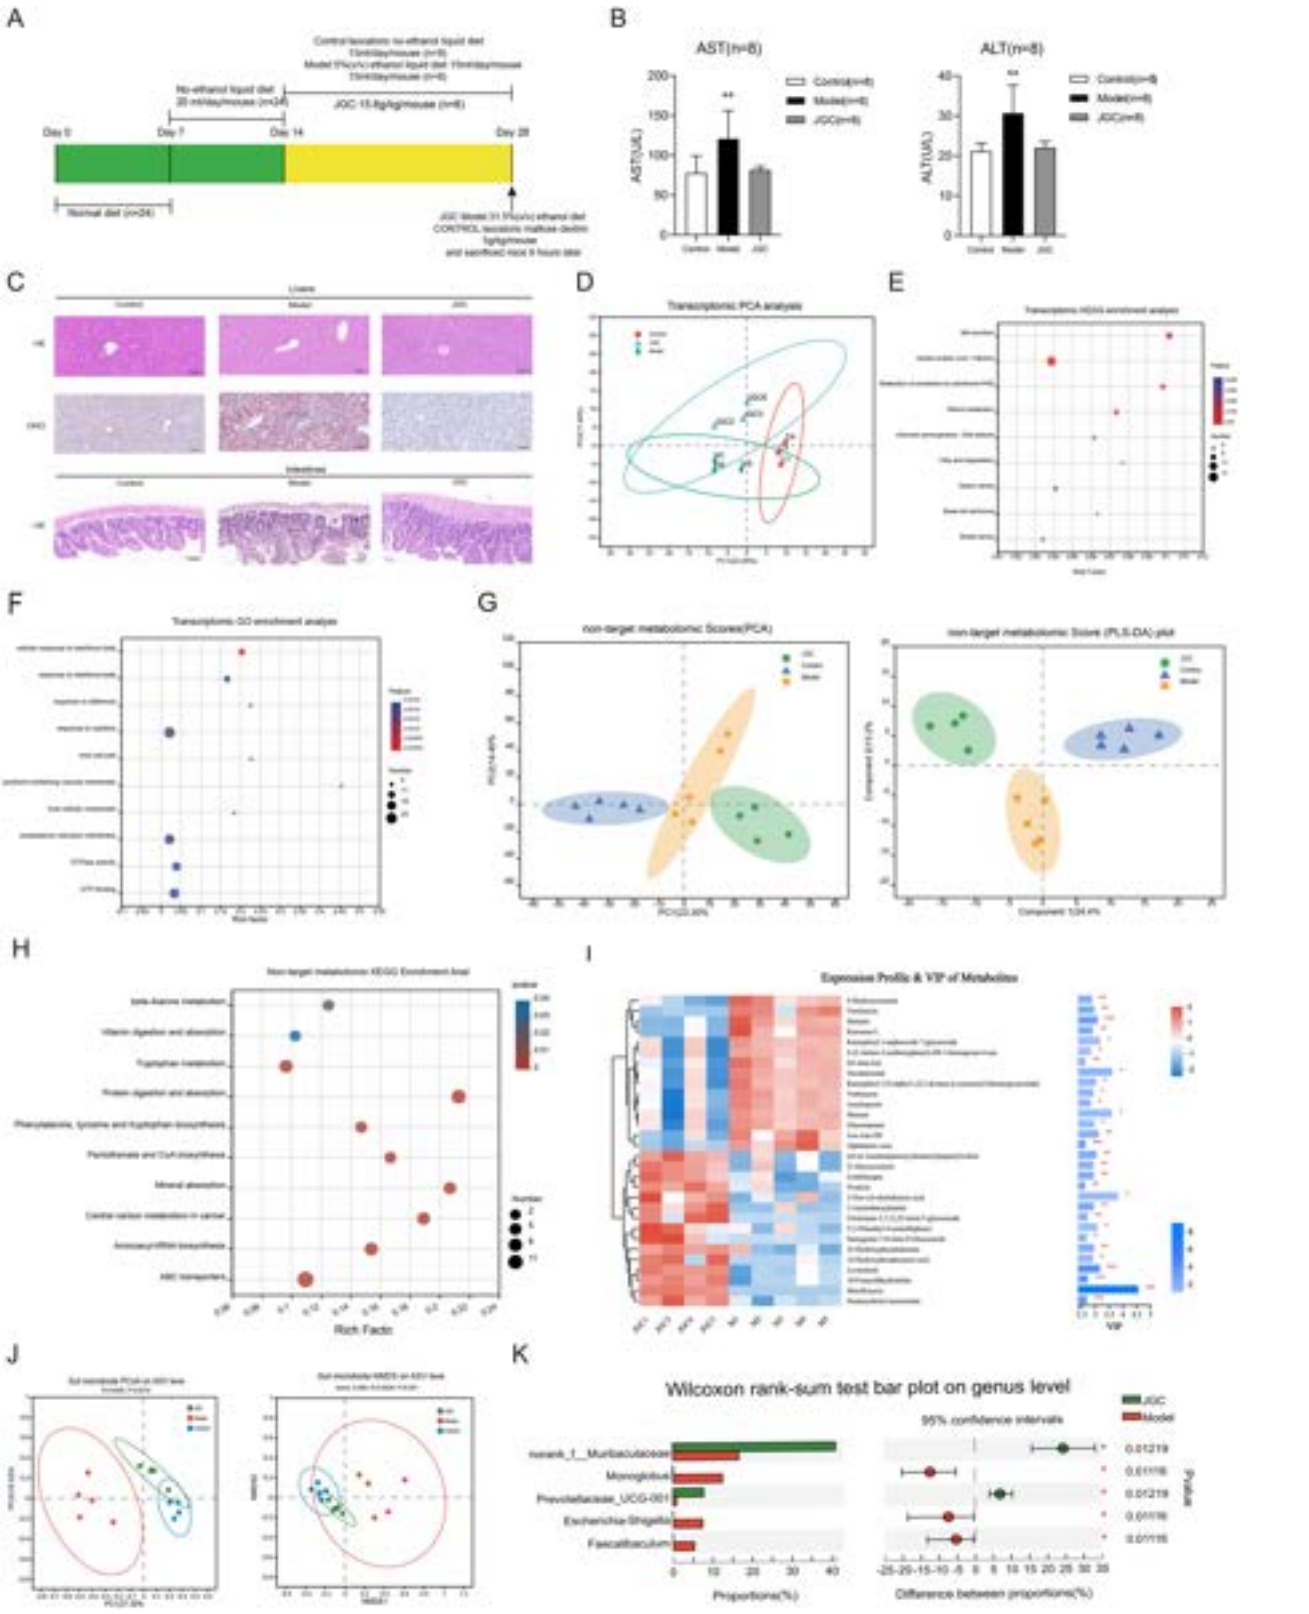

Figure: (abstract: FRI-417).

metabolism due to its metabolism, chronic elevated ethanol intake has also been shown to be accompanied with alterations of intestinal microbiota composition and intestinal barrier dysfunction. Despite intense research efforts, molecular mechanisms involved in the damaging effects of ethanol on intestinal barrier function are not fully understood. Chronic alcohol intake has also been shown to be associated with alterations of choline metabolism in the liver. Here, we assessed the effects of an oral choline supplementation on the

development of a diet-induced ALD in C57BL/6J mice and determined associated molecular mechanisms.
Method: After an adaptation phase, female C57BL/6J mice (n = 8/group) were either pair-fed a liquid control diet (C), or a Lieber deCarli liquid diet (E, 5% ethanol) ± 2.7 g choline/kg diet for 29 days. Markers of liver damage and intestinal permeability were determined. Additionally, effects of choline on ethanol-induced intestinal permeability were assessed *ex vivo* in an everted tissue sac model.
Results: As expected, chronic intake of ethanol was associated with the development of liver steatosis and early signs of inflammation as determined by liver histology, number of neutrophils, NOx concentration in liver tissue and ALT activity in plasma ($p < 0.05$ for all parameters compared to C-fed mice). Supplementing the ethanol diet with choline significantly attenuated the development of ALD with markers of inflammation, steatosis, number of neutrophils and NOx concentration in the liver all being significantly lower in E + choline-fed mice compared to E-fed mice ($p < 0.05$). The protective effects of choline were associated with significantly lower permeability of small intestinal tissue. In line with the *in vivo* findings, choline also significantly attenuated the ethanol-induced intestinal barrier dysfunction in small intestinal everted tissue sacs *ex vivo*, while the concomitant treatment with a choline oxidase inhibitor (dimbunol) almost completely abolished these protective effects of choline.
Conclusion: Our results indicate that an oral supplementation of choline may attenuate the development of ALD in mice and that this at least in part is related to a protection against ethanol-induced intestinal barrier dysfunction.

FRI-420
Increased concentration of 4-hydroxyphenyllactic acid in patients with alcohol-related liver disease could promote the growth of Lactobacillus spp

Jin-Ju Jeong[1], Satya Priya Sharma[1], Raja Ganesan[1], Haripriya Gupta[1], Sung-Min Won[1], Ki Kwang Oh[1], Mi Ran Choi[1], Younglim Ham[2], Ki Tae Suk[1]. *[1]Institute for Liver and Digestive Diseases, Hallym University College of Medicine, Korea, Rep. of South; [2]Department of Nursing, Daewon University College, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Alcoholic liver disease (ALD) is caused by excessive alcohol consumption. It is increasing in prevalence. ALD is a progressive disease that is dangerous and can eventually lead to death. However, no specific treatment has been found to date. In the past decade, studies on the microbiome and metabolites have been conducted to develop disease mechanisms and medicines. Therefore, in this study, to identify metabolites and microorganisms related to alcoholic liver disease metabolites and microorganisms from feces of patients with alcoholic liver disease and healthy subjects will be analyzed. In addition, the correlation between the metabolite and intestinal bacteria that identified in this study will be analyzed.
Method: Stools were sampled from 17 healthy subjects, 26 subjects with alcoholic hepatitis, and 17 patients with more than alcoholic cirrhosis. Metabolites were analyzed using a Q-Exactive Plus Orbitrap MS-connected Ultimate-3000 UPLC system. The obtained data were analyzed using Metaboanalyst 5.0. For analysis of microbiome, the Illumina MiSeq platform was used. The obtained data was analyzed using the comparative microbiome taxonomic profiling analyzer of EZBioCloud. Based on metabolite and microbiome data, *Lactobacillus* spp. were pre-cultured in RCM media and subcultured to same media containing 4-HPA or containing SDW. After 2 days, colony forming unit was assessed by smearing on RCM agar medium.
Results: As alcoholic liver disease progressed, 4-HPA was increased. The family *Lactobacillaceae* was elevated in the microbiome of liver disease patients identified as having this substance. On the other hand, no increase in *Lactobacillaceae* was observed in patients without an increase of 4-HPA. Co-cultured with 4-HPA and *Lactobacillus* spp. *in vitro*, colony forming units were increased compared to without 4HPA.
Conclusion: In this study, 4-HPA, a metabolite that is increased followed by the process of alcoholic liver disease, can increase the population of *Lactobacillus* spp. Research on the 4-HPA and correlation between the microbiome might be helpful to develop the mechanisms and treatments for alcoholic liver disease.

FRI-421
Granulocyte monocyte/macrophage apheresis for corticosteroid-nonresponsive or -intolerant severe alcohol-associated hepatitis: a nonrandomized controlled study

Ryosuke Kasuga[1], Po-sung Chu[1], Nobuhito Taniki[1], Rei Morikawa[1], Takaya Tabuchi[1], Fumie Noguchi[1], Karin Yamataka[1], Yukie Nakadai[1], Mayuko Kondo[1], Takanori Kanai[1], Nobuhiro Nakamoto[1]. *[1]Keio University School of Medicine, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Japan*
Email: pschu0928@icloud.com

Background and aims: Short-term mortality rate of patients with severe alcohol-associated hepatitis (SAH) remains as high as approximately 40–50%. Unmet needs exist in patients who are refractory to corticosteroids (CS) or are ineligible for early liver transplantation. In the current study, we aimed to investigate whether granulocyte and monocyte/macrophage apheresis (GMA) improves 180-day overall survival in CS-nonresponsive or CS-intolerant patients with SAH.
Method: This was a prospective, open-label, nonrandomized, historically controlled study conducted at a liver transplant center in Tokyo since October 2015. Lille model- and Model for End-stage Liver Disease (MELD) score-defined CS nonresponsive or CS-intolerant SAH patients who fulfilled inclusive criteria (leukocytosis over 10,000/μL, etc.) were enrolled. GMA was performed with Adacolumn®, twice per week, for 5 to 10 times per session. Primary outcome was overall survival at 180 days. Secondary outcomes included changes in prognostic parameters, overall survival, cumulative rate of discharge and alcohol relapse. Correlations between cytokines or growth factors and prognostic parameters were also explored. Overall survival at 180 days was compared to SAH patients who were treated with CS and demonstrated nonresponse to CS in previous clinical trials (historical controls). Only patients who were not treated with any medication of interest other than CS, were pooled. This study was registered as UMIN000019351, and jRCT No. 032180221. This study was supported by grants-in-aid from Japan Society for the Promotion of Science (JSPS) KAKENHI (Grant Number 120K16999). Adacolumn was kindly provided by the manufacturer. The funders of the study had no role in study design, data collection, data analysis, data interpretation, or writing of this report.
Results: From October 2015 to December 2021, 13 GMA sessions were conducted on 11 patients. The Maddrey's Discriminant Function was 53.2 ± 17.7 at admission. The overall survival rate of the GMA group was 90.9% at 180 days, which was significantly better than that of the historical controls (51.7%) ($p = 0.0128$). Clinical parameters, including MELD scores, improved significantly ($p < 0.0001$). Estimated mortality risks using the Lille model and MELD scores at two and six months also significantly improved (both $p < 0.01$) and were internally validated. All patients recovered and discharged after a median of 25 days. The cumulative rate of first alcohol relapse was 35.9% per year. Four patients died from liver failure after alcohol relapse. No severe adverse events were observed. Granulocyte colony-stimulating factor levels were significantly inversely correlated with all prognostic scores surveyed after GMA (all $p < 0.05$).

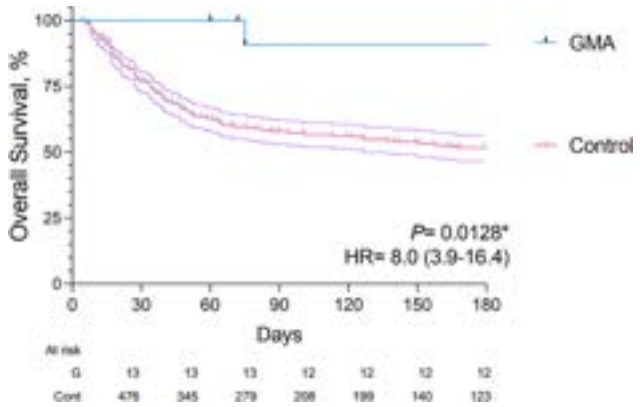

Figure:

Conclusion: Compared to historical controls, GMA significantly improved overall survival at 180 days in patients with CS-non-responsive or CS-intolerant SAH. As GMA has already been applied to other diseases with good safety profiles, immediate needs may be met as a salvage therapy following CS. Further investigations are warranted.

Email: marktheo@doctors.org.uk

Background and aims: Diabetes Mellitus (DM) is a significant risk factor for metabolic associated fatty liver disease (MAFLD), and increases the risk of adverse outcomes. There have been multiple studies looking at the relationship between alcohol intake and the relative risk of developing diabetes, but few of these look specifically at the effect of DM on persons with alcohol-related liver disease (ArLD). This study explored the relationship between ArLD and DM.
Method: The WALDO study is an international multi-centre collaboration to gather a cohort of patients with biopsy proven ArLD and associated outcome data. The presence of DM at baseline or during follow-up was noted. Clinical events after index biopsy were noted retrospectively. Liver-associated clinical events (LACE) were defined as transplant, *de novo* decompensated cirrhosis or hepatocellular carcinoma. Mortality was sub-classified as liver-related or non-liver related. Risks for adverse outcomes was assessed with cox proportional hazards with the presence of diabetes treated as a time-dependent variable to reflect periods of time without or with diabetes. Analysis was done using the survival package in R.
Results: Seven hundred and four patients were included (median age 51.09 + standard error (SE) 0.44, 269 females, mean BMI 28.7, (range 16.3–48.9). During follow-up there were 215 episodes of LACE and 407 patients died (n = 380; 54.0%) and 47 had a liver transplant. At baseline 106 patients had DM (15.1%), and 246 (34.9%) had at least one previous decompensation episode. Median follow-up was 1591.5 days + SE 87.28, during which a further 51 patients (7.24%) developed DM (total diabetes n = 157 (22%)).
In univariable analysis DM was a significant risk factor for all-cause mortality (HR 1.38, 1.01–1.89, p = 0.041) and for incident cardiovascular disease (HR 2.29, 1.33–2.94, p <0.001), and associated with increased risk of LACE, although this did not reach statistical significance (HR 1.48, 0.96–2.27, p = 0.074). In multivariable analysis controlling for fibrosis stage, decompensation at baseline, obesity and abstinence, DM remained significantly associated with all-cause mortality (HR = 2.08, 1.41–3.05, p < 0.001).

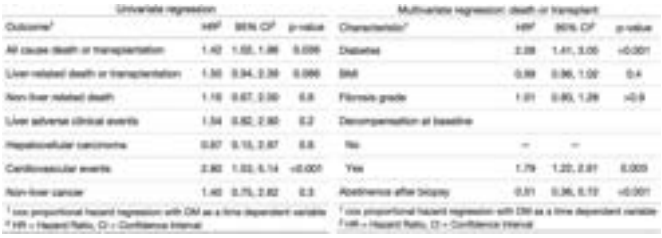

Figure: Cox-proportional hazard regression with diabetes as time dependent variable.

Conclusion: DM is a frequent co-morbidity in persons with ArLD and is associated with a higher risk of mortality. Clinicians managing those with ArLD should actively review diabetic status and ensure adequate treatment as required.

FRI-423

Pharmacological therapy for alcohol use disorder is effective and safe in patients with cirrhosis. Systematic review and meta-analysis

Jordi Gratacos[1,2,3], Pol Bruguera[2,4,5], Martina Perez[1], Ana Lopez Lazcano[2,4], Helena Hernandéz Evole[1], Ramon Bataller[1,2,3,6], Pere Ginès[1,2,3,6], Hugo Lopez[2,4,5,6], Elisa Pose[1,2,3,6]. *[1]Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Centro de Investigación Biomédica En Red en Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain; [4]Hospital Clínic de Barcelona, Psychiatry, Barcelona, Spain; [5]Centro de Investigación Biomédica En Red de Salud Mental (CIBERSAM), Madrid, Spain; [6]Facultat de Medicina i Ciències de la Salut, Universitat de Barcelona, Barcelona, Spain*
Email: EPOSE@clinic.cat

Background and aims: alcohol abstinence is the main prognostic factor in patients with alcohol-related liver disease. Most studies that have assessed the efficacy of pharmacological treatment for alcohol use disorder (AUD) have excluded patients with liver disease. The aim of this study was to perform a systematic review and meta-analysis on the efficacy and safety of pharmacological treatment for AUD in patients with cirrhosis.
Method: we retrieved all studies published in PubMed, Embase and Scopus until May 2022. PRISMA guidelines were used to design the study protocol, which was published in Prospero. We included randomized controlled trials (RCT), cohort studies and case-control studies using any pharmacological treatment for AUD in patients with cirrhosis. We used platform Rayyan® for the selection process, which was divided in a screening phase (evaluation of title/abstract) and an eligibility phase (full-text examination). Records were reviewed by four independent investigators divided in pairs. Data collection was performed by the same reviewers. The primary outcome was defined as percentage of alcohol abstinence (AA). Secondary outcomes were related to safety, amount of consumption and time to lapse/relapse. The meta-analysis was based on a random-effects model and heterogeneity was quantified using I^2.
Results: we identified 4095 studies after duplicates removal. Ten studies (4 RCT and 6 observational) met the inclusion criteria and none of the exclusion criteria. A total of 950 patients were included; 562 patients (59%) had a diagnosis of cirrhosis. The investigated treatments included baclofen (n = 6 studies), metadoxine (n = 2), acamprosate (n = 2), naltrexone (n = 1) and fecal microbiota transplantation (n = 1). Duration of treatment and follow-up ranged from 1 to 12 months. In the observational studies with no control group, abstinence rates varied from 51 to 85%. Two of the 4 RCT (1 on baclofen and 1 on metadoxine) found increased AA in the treatment groups. The random-effects model analysis conducted showed that the pharmacological treatment for AUD reduces the risk of active alcohol consumption with an overall increase in AA of 26% (risk ratio 0.74; CI 0.57–0.96; I^2 = 57%). Concerning individual treatments, we were only able to perform an analysis for baclofen, which did not reach significance (risk ratio 0.72; CI 0.46–1.13; I^2 = 76%). With respect to safety, none of the studies reported higher incidence of severe adverse events in the treatment groups.

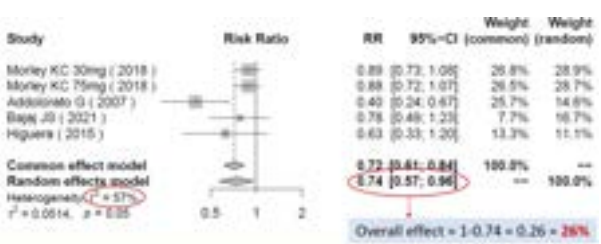

Figure: Random-effects model analysis of the relative risk of active alcohol consumption in patients with cirrhosis treated with pharmacological treatments for AUD or control therapy.

Conclusion: pharmacological treatment for AUD in patients with cirrhosis increases the probability of AA by 26% and has a good safety profile. Further prospective, high-quality studies are needed to establish a robust recommendation for the use of these treatments in patients with liver disease.

FRI-424

Binge drinking acutely induces fatty liver with increased liver stiffness which is readily reversed

Kristoffer Kjærgaard[1], Jeppe Yeoman[1], Anne Catrine Daugaard Mikkelsen[1], Peter Lykke Eriksen[1], Emilie Eifer Møller[1], Ann-Sophie Wietz[1], Lars Gormsen[2], Sara Heeboll[3], Hendrik Vilstrup[1], Karen Louise Thomsen[1]. *[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Denmark; [2]Aarhus University Hospital, Department of Nuclear Medicine and PET, Denmark; [3]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Denmark*
Email: krikje@clin.au.dk

Background and aims: Alcohol-related liver disease is the leading cause of liver-related morbidity and mortality worldwide. Excessive alcohol consumption in a short period of time, also known as 'binge drinking', is a highly prevalent modus of alcohol intake. Binge drinking is often considered particularly harmful, however, the immediate effects on the development of a fatty liver representing the earliest alcohol-related liver injury, are not well established. The aim of this study was to investigate the acute effects of binge drinking on the liver and reversibility.
Method: We performed a cohort study of healthy adults attending a three-day music festival in June 2022 with the intention to binge drink. The participants were examined before, the day after, and 10 days after the festival. The participants were alcohol abstinent one week prior to the first visit and between the two last. Each visit included Magnetic Resonance Imaging (MRI) with measurement of liver fat content (Proton Density Fat Fraction; MRI-PDFF), liver stiffness (MR Elastography), and blood samples. During the festival, the participants were monitored with breathalyzer blood alcohol concentrations and app-based self-reported alcohol and food intake.
Results: Fifteen participants (9 male, 6 female) aged 35 ± 5 years with a BMI of 23.4 ± 2.7 kg/m^2 completed the study. The participants consumed on average 18.6 ± 5.6 units (186 ± 56 g alcohol) per day. Binge drinking induced a 2.5-fold increase in the hepatic fat fraction from 1.9% (IQR 1.6%-2.5%) to 4.6% (IQR 2.4%-5.7%; p <0.0001) resulting in definitive steatosis (>5%) in six participants. This was accompanied by an elevation of liver stiffness from 2.5 ± 0.3 kPa to 2.7 ± 0.3 kPa (p = 0.04). Also, binge drinking caused increased AST/ALT ratio and GGT, and a decrease in LDL-cholesterol. There was no change in plasma triglycerides or glucometabolic measurements. 10 days after binge drinking, all outcome measures were normalized.

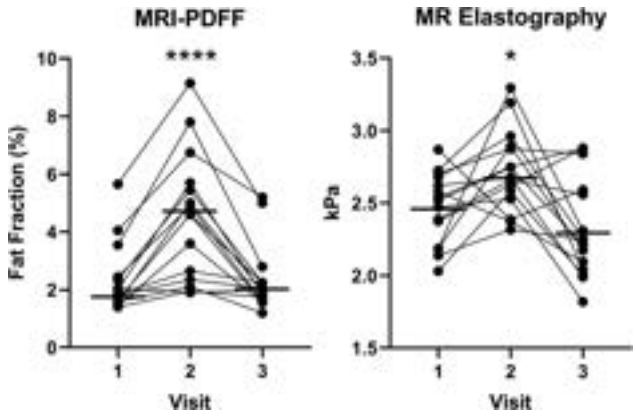

Figure:

Conclusion: In almost all of the healthy participants, a three-day bout of binge drinking caused unambiguous hepatic fat accumulation, which was accompanied by increased liver stiffness. This early alcohol liver injury was readily reversible upon only 10 days of alcohol abstinence. The study demonstrates a definite and potentially harmful fat accumulation in the liver caused by binge drinking. However, our findings imply that binge drinking is possibly not as dangerous as often assumed if binges are separated by a period of alcohol abstinence.

FRI-425

Disentangling the contributions of alcohol and alcohol-related liver disease towards dementia

Sixian Zhao[1], Linnea Widman[1], Hannes Hagström[1], Ying Shang[1].
[1]Karolinska Institutet, Sweden
Email: ying.shang@ki.se

Background and aims: Previous studies have shown an association between alcohol use disorder (AUD) and dementia. However, both alcohol itself and alcohol-related liver disease (ALD) can have detrimental impacts on the brain, yet the relative weights of their contributions remain unknown. We aimed to disentangle the contributions of alcohol and ALD towards dementia by independently assessing the association between AUD alone or combined with ALD, and dementia.
Method: We identified patients with ALD or AUD from the DELIVER dataset, an ongoing nationwide register-based cohort including all patients diagnosed with chronic liver disease and up to ten matched controls from the general population in Sweden between 1987 and 2020. Three groups were identified through the linkage to the National Patient Register (NPR): AUD alone, ALD with co-existing AUD, and controls without any of these two diseases. The NPR and the Cause of Death Register were used to identify diagnoses of dementia. Cox regression models were used to assess the associations between AUD alone, or ALD, with dementia and dementia subtypes. Cumulative incidences were calculated accounting for competing risks of death.
Results: 128,884 individuals with AUD alone, 17,754 with ALD and 2,479,049 controls were identified. During a median follow-up of 8.9 years, 13,395 (10.4%), 2,187 (12.3%), and 138,925 (5.6%) dementia cases were identified in these groups. This translated into an increased dementia rate in the AUD alone group (adjusted HR [aHR] = 4.6, 95% CI 4.5–4.6), and a greater rate was observed in the ALD group (aHR = 8.6, 8.3–9.0) compared to the controls. AUD alone was also associated with a significantly increased rate of vascular (aHR = 2.3, 2.2–2.5) and Alzheimer's dementia (aHR = 1.4, 1.3–1.4), while ALD was associated with an increased rate of vascular (aHR = 2.7, 2.3–3.2) but not with Alzheimer's dementia (aHR = 0.9, 0.7–1.2). On average, the age at dementia diagnosis was younger in patients with AUD alone (67 years, IQR 56–76) and ALD (63 years, IQR 56–71) compared to controls (85 years, IQR 79–89). After stratifying by age at baseline, both AUD alone and ALD had disproportionately increased rates of dementia in the younger <40 yrs and 45–65 yrs groups. Both AUD and ALD had higher cumulative incidences of dementia, but not Alzheimer's or vascular dementia (Figure).

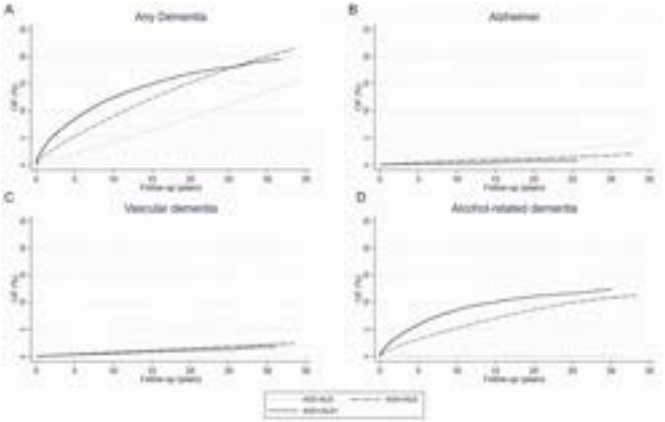

Figure: Cumulative incidence of dementia for AUD, ALD and controls from the general population.

Conclusion: AUD alone increased the risk of developing dementia, but additional ALD further exacerbates this risk. Dementia associated with AUD or ALD tended to be diagnosed at a younger age. These findings emphasize the importance of screening for cognitive impairment individuals with AUD to allow for earlier diagnoses and management of further cognitive decline and dementia. This may be of particular importance in younger patients.

FRI-426

Nucleoredoxin-dependent functioning is dysregulated by chronic alcohol consumption and is associated with the establishment of cellular senescence in the liver of aged mice

Osiris German Idelfonso García[1,2], Brisa Rodope Alarcón-Sánchez[1,3], Verónica Rocío Vásquez-Garzón[4,5], Saúl Villa-Treviño[3], Pablo Muriel[6], Héctor Serrano[2], Julio Isael Pérez-Carreón[1], Jaime Arellanes-Robledo[1,5]. *[1]National Institute of Genomic Medicine-INMEGEN, Mexico; [2]Metropolitan Autonomous University-Iztapalapa Campus, Department of Health Sciences, Mexico; [3]Center for Research and Advanced Studies of the National Polytechnic Institute-CINVESTAV-IPN, Department of Cell Biology, Mexico; [4]Faculty of Medicine and Surgery, 'Benito Juárez' Autonomous University of Oaxaca-UABJO, Mexico; [5]National Council of Science and Technology-CONACYT, Mexico; [6]Center for Research and Advanced Studies of the National Polytechnic Institute-CINVESTAV-IPN, Department of Pharmacology, Mexico*
Email: oidelfonso@inmegen.edu.mx

Background and aims: Aging, a natural process associated with abnormal oxidative stress production, involves several cellular and molecular changes that ultimately compromise the well-functioning of organs and systems in multicellular complex organisms. Aging is associated with a progressive and generalized deterioration of cellular functions, e.g., liver function is declined and involves alterations in hepatic structure, and function, thereby leading to the development of age-related liver disease. Aging also declines the liver metabolic capability and as a consequence, the efficiency to eliminate toxic agents is significantly decreased. These alterations are closely related with an increased production of reactive oxygen species (ROS) which is exacerbated by the chronic alcohol consumption; however, the underlying mechanisms had not been clarified. Nucleoredoxin (NXN) is both an oxidoreductase that targets ROS and a redox-sensitive enzyme that regulates key cellular processes trough redox protein-protein interactions; however, the role of NXN during aging has not been investigated. Here, we aimed to determine the involvement of NXN in alcoholic liver disease (ALD) during aging in the mouse liver.
Method: ALD was recapitulated in 7-week-old (young) C57BL/6J female mice, 12-month-old (adult) and 18-month-old (aged) by the chronic ethanol consumption (20%) in 20% of sucrose for eight weeks and a single dose of lipopolysaccharide (1 mg/kg). We evaluated histological and cellular alterations, cellular senescence markers, NXN protein level and NXN-dependent protein-protein interaction status, as well as, the gene expression profile changes.
Results: During aging, chronic alcohol consumption exacerbated liver structural disarrangement, steatosis and inflammatory infiltration which was accompanied by increased levels of proliferation markers namely proliferating cell nuclear antigen (PCNA) and Ki67, as well as, cellular senescence markers such as senescence-associated beta-galactosidase, H2A.X, Poly ADP ribose and interleukin 6. Interestingly, the level of oxidized proteins was significantly increased, and protein level of NXN and that of its interacting proteins FLII, MYD88, DVL and PP2A were also modified; as well as, the ratio of NXN/FLII interaction complex was significantly disrupted by the chronic alcohol consumption during aging. A RNA-seq analysis revealed that chronic alcohol consumption modified the expression of genes related with cell cycle arrest, oxidative stress regulator, induction of cellular senescence and lipid metabolism in aged mice.
Conclusion: Our results indicate that chronic alcohol consumption exacerbates both the structural and physiological damage, as well as, the cell proliferation and senescence in aged livers. Of note, the level of NXN redox-sensitive enzyme was decreased in the liver of mice subjected to ALD model during aging, but more interestingly, the interaction ratio of NXN-regulated proteins such as FLII was modified, likely, due to the increased protein oxidation induced by the ALD model. Thus, this evidence strongly suggests that ROS produced by the chronic alcohol consumption oxidize proteins and sensitize the liver cells and as a result, the NXN-dependent regulation is altered, a phenomenon that might accelerate the establishment of cellular senescence in the liver of aged mice.

FRI-427

Risk of alcohol-related liver disease in offspring of individuals with alcohol-related liver disease: a nationwide cohort study in Denmark

Peter Jepsen[1], Colin Crooks[2], Joanne Morling[2], Frederik Kraglund[1], Anna Emilie Kann[3], Joe West[2], Gro Askgaard[1]. *[1]Aarhus Universitetshospital, Aarhus, Denmark; [2]University of Nottingham, United Kingdom, [3]Zealand University Hospital, Køge, Denmark*
Email: gask@dadlnet.dk

Background and aims: Offspring of individuals with alcohol-related liver disease (ALD) may have an increased risk of ALD and therefore be potential candidates for screening for liver fibrosis. We compared the risk of ALD and the survival after ALD diagnosis in offspring of individuals with ALD to that of matched controls.
Method: We used nationwide healthcare registries to identify offspring of individuals diagnosed with ALD (ICD-10: K70.x) in Denmark from 1996 to 2018 and age- and gender-matched controls (20:1). Offspring and controls were followed for ALD diagnosis through 2018. We used landmark competing risk analyses to estimate the 10-year absolute and relative risk of ALD according to current age. To compare survival from ALD diagnosis between offspring and controls who developed ALD, we used Cox regression with adjustment for confounders of gender, age, and calendar year of ALD diagnosis.
Results: During the follow-up, ALD was diagnosed in 385 of 60,708 offspring and 2838 of 1,213,380 controls with an incidence rate ratio of 2.7 (95% CI 2.4–3.0). Offspring were slightly younger than controls at the time of ALD diagnosis (median age of 47 vs. 49 years) and the proportion who had cirrhosis at ALD diagnosis was similar in offspring and controls (57% vs. 56%). The 10-year absolute risk of ALD increased with age in both offspring and controls, peaking at 0.17% (95%CI: 0.09–0.28) for offspring aged 55 years and at 0.06% (95%CI 0.04–0.07) for controls aged 57 years (Figure 1, top). ALD was more frequent in offspring than controls at the younger ages, resulting in a very high relative 10-year risk before age 35 years, however, the absolute ALD risk was very low at these ages (Figure 1, bottom). There was no difference in ALD risk according to the gender of the offspring or the ALD parent, but offspring with both parents diagnosed with ALD had the highest risk [10-year absolute risk of 2.04% (95%CI: 0.17–9.40) at

age 57 years]. Survival after diagnosis of ALD was similar in offspring and controls, with an adjusted hazard ratio of 1.02 (95% CI 0.87–1.20).

Figure 1. Risk of alcohol-related liver disease (ALD) in offspring of individuals with ALD and age and sex-matched matched controls in Denmark from 1996 to 2018.

The top figure shows that the 10-year risk of ALD is 0.10% in offspring of individuals diagnosed with ALD compared to 0.04% in controls at the age of 50 years.
The bottom figure shows that the relative risk for ALD in offspring of individuals with ALD compared to controls is 2.1 at age 50 years.

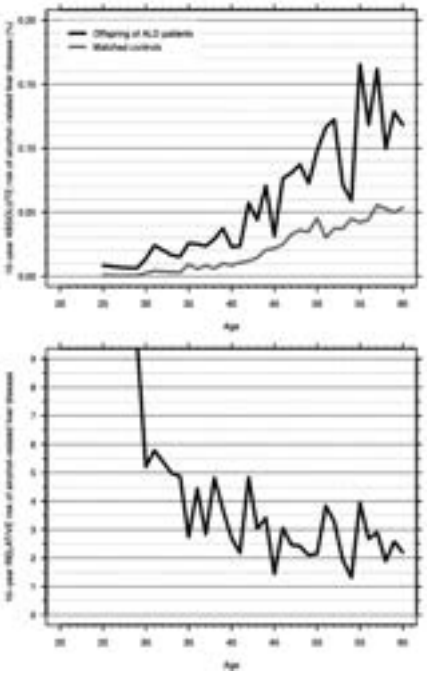

Figure:

Conclusion: Offspring of individuals with ALD had an increased relative risk of ALD, but their absolute risk was low. Their survival after ALD diagnosis was similar to that of controls. These findings indicate that screening may not be cost-effective; only 1 in 1000 offspring aged 50 years was diagnosed with ALD during the subsequent ten years.

FRI-428

US trends and contribution of metabolic syndrome in alcohol-associated liver disease from 1999 to 2018

Brian Lee[1], Jennifer Dodge[1], Norah Terrault[1]. [1]*University of Southern California, United States*
Email: brian.lee@med.usc.edu

Background and aims: Mortality from alcohol-associated liver disease (ALD) has surged in recent years for unclear reasons. We aimed to examine the hypothesis that metabolic syndrome (MetS) may be an important contributor to ALD trends.
Method: Using the National Health and Nutrition Examination Survey (NHANES), an annual nationally-representative sample of the noninstitutionalized United States population, we assessed trends in MetS among ALD and non-ALD, in 4-year intervals (1999–2002, 2003–2006, 2007–2010, 2011–2014, 2015–2018). ALD was defined as average alcohol use >28 g/d in women and >42 g/d for men in the past 12 months, with AST or ALT >25 U/L in women and >35 U/L in men, excluding viral hepatitis. MetS was defined using National Cholesterol Education Program Adult Treatment Panel III criteria. High Fibrosis-4 (FIB-4) was defined as >2.67. Linear regression was used to assess prevalence of MetS among key subgroups and calculate absolute differences in prevalences with 95% confidence intervals. Multivariable logistic regression was used to assess odds of ALD associated with MetS adjusted for age, sex, race, alcohol intake.
Results: Among 36,349 respondents, 479 were with ALD (mean age 45, 70% male, 73% non-Hispanic White). The prevalence of ALD was stable throughout (1999–2002: 1.4% [95CI 1.1–1.8%]; 2015–2018: 1.4% [95CI 1.0–1.9%]). The prevalence of MetS among ALD increased (1999–2002: 36.4% [95CI 27.7–46.1%]; 2015–2018: 52.7% [95CI 38.6–66.3%] vs. non-ALD (1999–2002: 30.4% [95CI 28.6–32.2%]; 2015–2018: 40.4% [95CI 38.0–42.9%]). Increases in MetS among ALD were observed among all demographic subgroups (age, sex, race) (Figure). Increases in MetS were driven by increases in high waist circumference, hypertension, and diabetes, not hypertriglyceridemia or low HDL. The prevalence of ALD with high FIB-4 increased significantly (1999–2002: 0.08% [95CI 0.03–0.2%); 2015–2018: 0.25% [95CI 0.14–0.45%; absolute difference: +0.17% [95CI +0.005 to +0.34%] p = 0.04), but was stable when excluding ALD with MetS (1999–2002: 0.06% [95CI 0.02–0.19%]; 2015–2018: 0.10% [95CI 0.03–0.29%], absolute difference: +0.04% [95CI −0.08 to +0.17%] p = 0.52). In multivariable regression, ALD was associated with female sex (aOR 1.73, p = 0.004), increasing alcohol use (aOR 1.97 per +10 g/day, p < 0.001), and MetS (aOR 1.93, p < 0.001). The association between ALD and alcohol use was 27% higher among those with MetS (interaction p < 0.001).
Conclusion: Between 1999–2018, while the national prevalence of ALD has been stable, the prevalence of ALD with advanced fibrosis has increased significantly, which was no longer apparent when cases with concomitant MetS were excluded. Thus, the rise in MetS among ALD may be an important contributor to the surge in ALD-related mortality observed in the last decade. Interventions to screen and treat MetS among patients with ALD may be relevant to clinicians and policymakers addressing the ALD epidemic.

FRI-429

Alcohol rehabilitation after alcoholic hepatitis is associated with reduced mortality: results of a 2012–2021 National retrospective study

Vincent Mallet[1,2], Eric Nguyen Khac[3,4], Lucia Parlati[1,2,5], Samir Bouam[6], Anoisa Courtois[4], Alexandre Louvet[7], Marcq Ingrid[4], Olivier Ganry[8], Stanislas Pol[1,2], Philippe Sogni[1,2]. Email: vincent.mallet@aphp.fr

Background and aims: There is a lack of knowledge on the long-term prognosis of patients with alcoholic hepatitis. We measured multivariate risks and protective factors, including alcohol rehabilitation, after alcoholic hepatitis.
Method: We selected, among all patients recorded with alcohol use disorders in French hospitals in 2012–2021 (N = 1,438,236), those with alcoholic hepatitis. The primary exposure was alcohol rehabilitation ≥1 month after alcoholic hepatitis. The main outcome was death or liver transplantation. Adjusted hazard ratios were computed with Cox models with age as time scale, stratified on age at cohort inception, sex, severe comorbidities and deprivation.
Results: 65,814 (4.6%) patients were included. Median (interquartile range) age was 52.0 (44.0, 60.0) years and 71.5% were men. 7,141 (10.9%) patients underwent alcohol rehabilitation ≥1 month after alcoholic hepatitis. In-hospital death or liver transplantation were

recorded in 19,363 (29.4%) patients. Alcohol rehabilitation ≥1 month after alcoholic hepatitis was associated with death or liver transplantation (p < 0.001 with the log-rank test, see Figure). Alcohol rehabilitation [aHR 0.73, (95% CI 0.70, 0.77) p < 0.001] and liver disease progression to a liver-related complication [aHR 2.14, (95% CI 1.61, 2.84) p < 0.001] were protective and risk factors for death or liver transplantation, respectively.

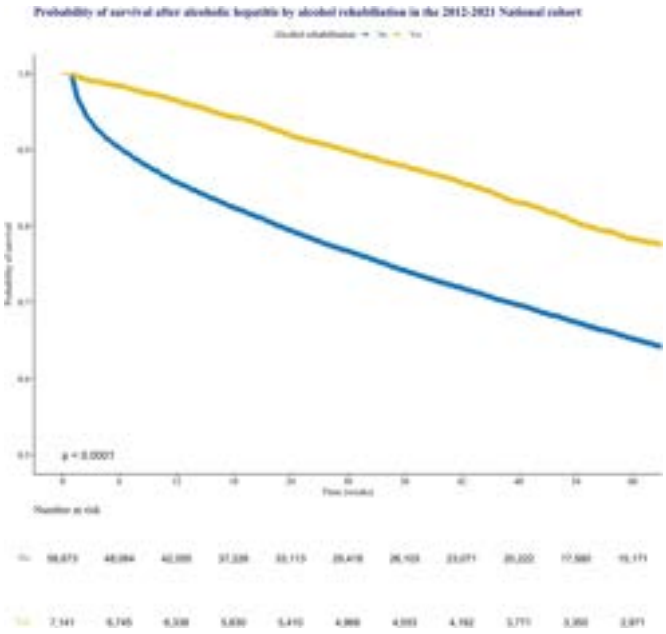

Figure:

Conclusion: Alcohol rehabilitation is the most critical clinical intervention to reduce mortality or liver transplantation from 1 month after alcoholic hepatitis. Currently only ~10% of patients have access to this treatment in France.

FRI-430

The role of HSD17B13 and MBOAT7 during alcohol detoxification: different effects on fibrosis and inflammation

Johannes Mueller[1], Vanessa Rausch[1], Phillippe Brosi[2], Sascha Müller[2], Peter Studer[2], Mathias Worni[2], Felix Stickel[2,3], Sebastian Mueller[1,2].

Background and aims: In genome wide association studies *PNPLA3*, *MBOAT7*, *TM6SF2* and *HSD17B13* were identified as important risk genes for the development of alcohol-related cirrhosis, however, their functions and molecular mechanisms are still incompletely understood. We here present first data on the role of these genotypes on liver stiffness (LS), steatosis (CAP) and inflammation during alcohol withdrawal.

Method: Patients with alcohol use disorders and heavy active alcohol consumption (n = 550) hospitalized for alcohol withdrawal were prospectively enrolled and genotyped for *PNPLA3* rs738409, *MBOAT7* rs626283, *TM6SF2* rs58542926 and *HSD17B13* rs72613567 variants. The Hardy-Weinberg-equilibrium was fulfilled for all loci. All patients had routine laboratory, abdominal ultrasound and measurement of liver stiffness (LS) and hepatic steatosis by controlled attenuation parameter (CAP) both using FibroScan platform (Echosens, Paris) at admission. For 415 patients, additional follow-up data after 6.3 days of alcohol withdrawal were available for analysis.

Results: Patients were predominantly male (72%), with a mean age of 51 (±12) years, mean BMI of 25.3 kg/m^2 and mean alcohol consumption of 199 (±147) g/day. At admission, no difference between the genotypes of the four genes was seen regarding age, BMI, gender, alcohol consumption or serum transaminase levels. Subjects with *MBOAT7* CC genotype had significantly higher LS values than those with the GG variant (22.5 kPa vs 10.4 kPa, p < 0.0001). The *HSD17B13* TA/TA variant had non-significantly lower levels of AST and LS. After detoxification, *PNPLA3* GG had significantly higher inflammation as reflected by higher AST levels (p < 0.05) and more steatosis (CAP 320 vs 280 dB/m, p < 0.01). *MBOAT7* CC carriers had significantly higher LS measurements (15 vs 9 kPa). *HSD17B13* TA/TA had significantly less inflammation (AST 69 vs 125 U/L) and lower LS (7 vs 12 kPa). The results were confirmed in a multivariate model using values after withdrawal. *HSD17B13* T and *PNPLA3* G alleles were

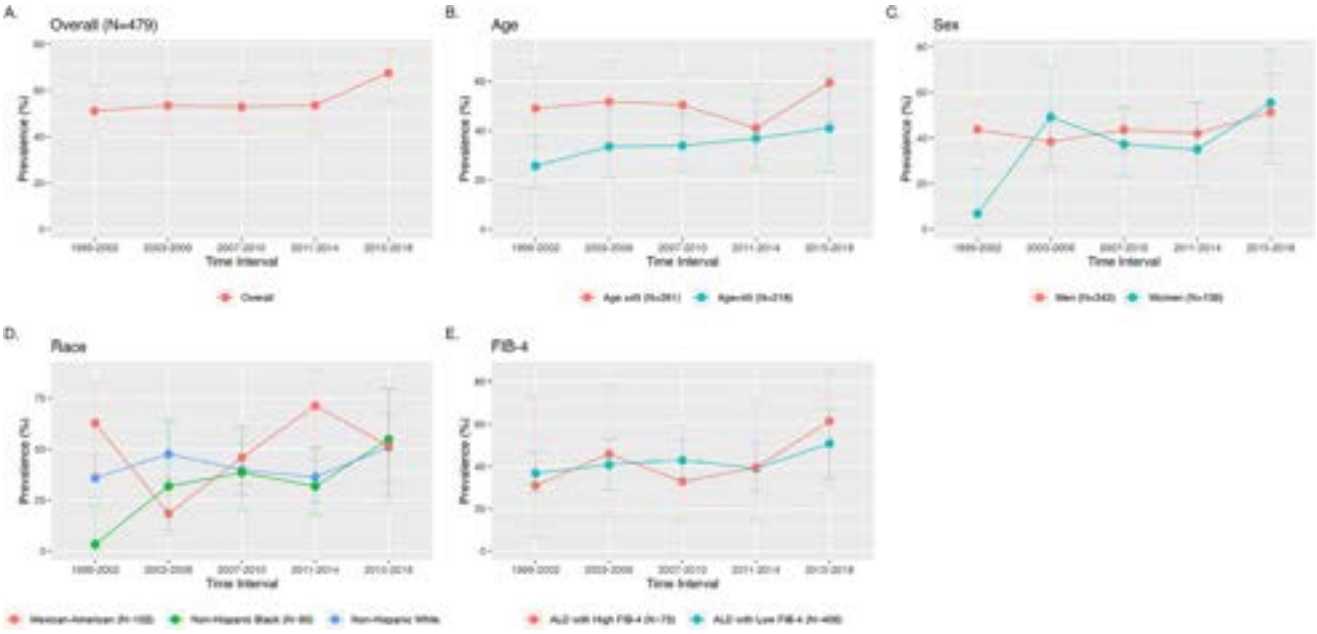

Figure: (abstract: FRI-428).

associated with increased inflammation (AST >50 U/L) (OR = 0.53, p < 0.001 and OR = 1.33, p = 0.08, respectively). Best association with steatosis (CAp >250 dB/m) was seen for *PNPLA3* G (OR = 1.39, p = 0.09). *HSD17B13* T and *MBOAT7* C were both significantly associated with elevated LS (LS >6 kPa) (OR = 0.57, p < 0.001 and OR = 1.41, p < 0.05, respectively). No associations were seen for *TM6SF2*.
Conclusion: We found important differences between the studied genes during the alcohol detoxification phase. The *PNPLA3* G allele seems to be associated with steatosis and inflammation. The *MBOAT7* C allele seems to affect fibrosis without inflammation while *HSD17B13* TA appears to be protective against inflammation and fibrosis.

FRI-431

Patients with alcohol-related cirrhosis who recompensate on follow-up have a characteristic metabolomic profile with differential concentrations of lipid and amino-acid metabolites

Helena Hernàndez-Èvole[1], Jordi Gratacos[1], Emma Avitabile[1], Juanjo Lozano[2], Martina Perez[1], Julia Sidorova[2], Alex Guillamon Thiery[3], Adria Juanola[1], Anna Soria[1], Isabel Graupera[1], Ana Belén Rubio[1], Marta Cervera[1], Marta Carol[1], Núria Fabrellas[4], Pere Ginès[1,4], Elisa Pose[1]. Email: hernandez.ievole@gmail.com

Background and aims: A notable proportion of patients with alcohol-related decompensated cirrhosis will experience resolution of clinical decompensations, which is a relevant phenomenon for prognosis of this population. The mechanisms and metabolic pathways involved in the recompensation of alcohol-related cirrhosis (ArC) are unknown. The aim of this study was to define the metabolomic profile of patients with ArC that will recompensate in the follow-up.
Method: Patients with ArC were selected from a prospective cohort collected between 2016 and 2020 and classified into 4 groups: 0) patients compensated at inclusion and during follow-up, 1) decompensated at inclusion but with subsequent recompensation, 2) decompensated at inclusion and during follow-up and 3) decompensated at inclusion who died the first 3 months of follow-up. Recompensation was defined as the absence of clinical decompensation without requiring specific treatment for ascites or encephalopathy during the year prior to the end of follow-up. Plasma samples were analyzed at baseline for metabolomic profile assessment by high-performance liquid chromatography-tandem mass spectroscopy.
Results: 63 patients with ArC were included: 18 in group 0, 15 in group 1, 15 in group 2 and 15 in group 3. Groups were comparable in terms of age and sex. Baseline MELD score was 8, 17, 16 and 27, respectively. Regarding alcohol follow-up, 11/18 (61%), 7/15 (47%) and 3/15 (20%) patients maintained abstinence at follow-up (p = 0.04). Median follow-up was similar between groups 1 and 2 (3.5 and 3.3 years). Patients in the 4 groups presented a differentiated metabolomic profile. When comparing group 1 and 2 (recompensated vs. decompensated patients) different concentrations in 32 metabolites were identified: 20 lipids were at higher concentrations in recompensated patients: 12 polyunsaturated fatty acids (docosahenoic acid and docosapanthenoic acid at concentrations 2. 1 and 2.6 times higher (p < 0.05)) and 7 acylcarnitine and acylcholine metabolism compounds; 7 amino acids, including phenyl-lactate (3.1 times lower concentrations in the recompensated group (p = 0.04)); and 5 vitamins.

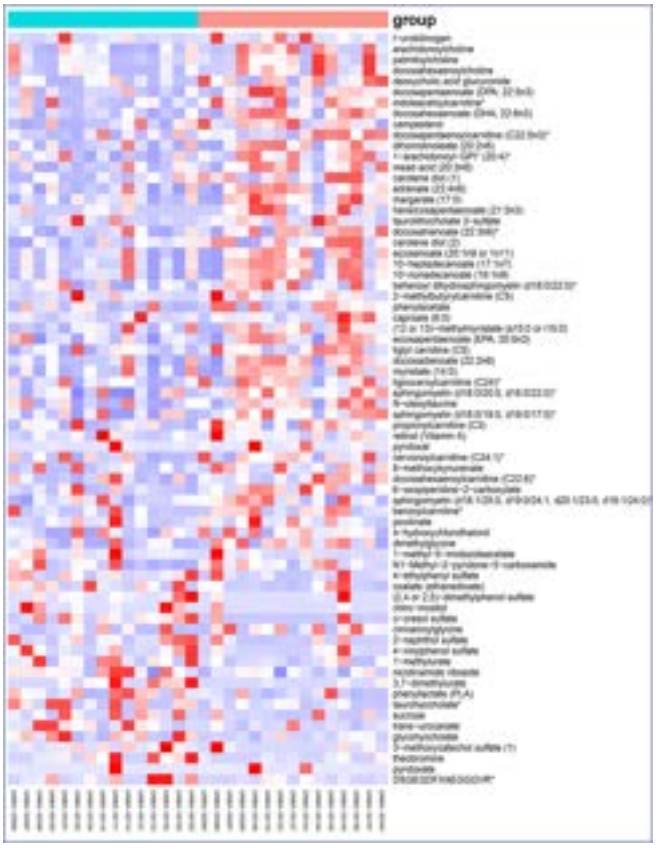

Figure: Heatmap representation of the top metabolites found at different concentrations in the group of patients recompensated during follow-up (group 1) vs those that remained decompensated (group 2).

Conclusion: Patients with ArC who were recompensated at follow-up presented a differentiated metabolomic regarding compounds involved in the metabolism of polyunsaturated fatty acids, acylcarnitines and amino acids such as phenyl-lactate. It is likely, therefore, that these metabolic pathways play a role in the recompensation of ArC.

FRI-432

A cost-comparison of the LiverPRO score with FIB-4, ELF, and FibroScan in 6,032 study participants

Katrine Prier Lindvig[1,2,3], Maria Kjærgaard[1,2], Katrine Thorhauge[1,2], Ellen Jensen[1,2], Johanne Kragh Hansen[1,2], Camilla Dalby Hansen[1,2], Stine Johansen[1,2], Mads Israelsen[1,2], Peter Andersen[1], Nikolaj Torp[1,2], Helle Lindholm Schnefeld[1,2], Sönke Detlefsen[4,5], Mathias Posselt[6], Nanna Kastrup[7], Taus Holtug[3], Aleksander Krag[1,2], Maja Thiele[1,2]. Email: katrine.prier.lindvig@rsyd.dk

Background and aims: Fatty liver disease is an increasing burden to the healthcare system. A key challenge is that most patients go undetected until the disease reaches its end stage. Therefore, an urgent need for cost-effective referral pathway from primary to secondary care is needed. LiverPRO is a diagnostic prediction model for liver fibrosis developed for primary care based on routine blood samples. We aimed to perform a cost analysis to assess the short-term

impact of implementing LiverPRO as a first-tier diagnostic test and compare it to other non-invasive tests.

Method: We conducted a prospective cohort study from 2017 to 2022. Participants were Danish residents with and without risk factors for alcohol-related liver disease (ArLD) and non-alcoholic fatty liver disease (NAFLD). The following referral pathways were evaluated: a) FIB-4 (>1.3) followed by FibroScan, b) ELF test (>9.8) followed by FibroScan, c) LiverPRO (>20%) followed by FibroScan or d) LiverPRO (>20%) followed by FibroScan, and if indeterminate then confirmation by ELF test (adapted from the EASL guideline). This cost analysis applies a hospital perspective and a mixed gross- and micro-costing approach. The analysis includes diagnosis-related costs for LiverPRO (€21 per test), FIB-4 (€7 per test), ELF (67€ per test), and FibroScan (€253 per test), targeting the identification of significant fibrosis (≥F2), defined as TE>8 kPa. Costs for missed cases are not included. We reported the results as mean cost per patient on each pathway.

Results: This cost analysis is based on a study with 6,032 participants screened for chronic liver disease. Here, 48% were male, and the median age was 57 years (52–63 IQR). 30% were at risk of ArLD, 44% of NAFLD and 26% had no risk factors. The four pathways correctly classified patients according to the risk of significant fibrosis (≥F2, defined as TE>8 kPa); a) at 65%, b) at 85%, c) at 93%, and d) at 95%, respectively (Figure). For advanced fibrosis (≥F3, defined as TE>12 kPa) the pathways correctly classified; a) 65% b) 96% c) 95%, and d) 99%, respectively. According to the pathway, the mean cost per patient when diagnosing significant fibrosis (≥F2) was a) € 97 b) € 103 c) € 36, and d) € 38 for the four pathways, respectively. The pathway c) consisting of LiverPRO followed FibroScan has the lowest cost compared to the other pathways.

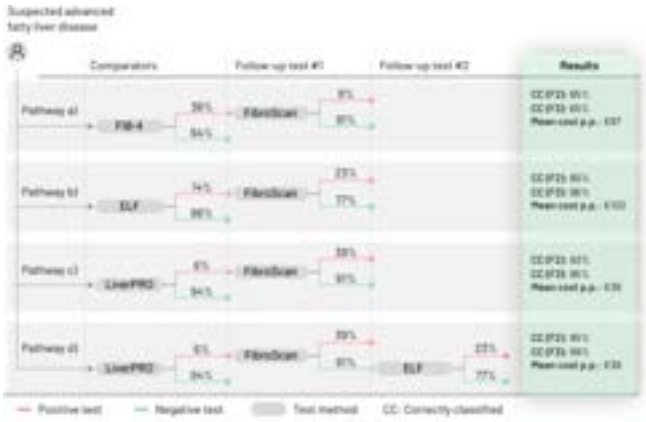

Figure:

Conclusion: This cost analysis shows that using LiverPRO followed by FibroScan has the lowest cost compared to other pathways including FIB-4 and ELF. At the same time, LiverPRO followed by FibroScan correctly classifies 93% of patients with significant fibrosis. This is a notable increase compared to the pathways using FIB-4 and ELF as the initial tests.

Email: ealvaradot@santpau.cat

Background and aims: Alcohol use disorder has been described in patients undergoing bariatric surgery, but its impact on long-term outcomes is unknown. The aim of this study is to evaluate the prevalence, associated factors, and clinical impact of AUD prior to bariatric surgery.

Method: Prospective study of patients undergoing bariatric surgery and included in the LABS-2 (Long-term effect of Bariatric Surgery) registry. The study cohort was completed at 10 hospitals in the United States between 2006 and 2009 (Coordinated by University of Pittsburgh: ClinicalTrials.gov: NCT00465829). All cases with AUDIT performed prior to surgery and at least 7 years of follow-up after the bariatric procedure were included. AUD was defined as an AUDIT score ≥of 8 points. Cases with liver biopsy were histologically evaluated with the NASH-CRN system and Scheuer score to grade iron deposits. Survival analysis was performed with Kaplan-Meier curves and Cox regression adjusted for age, sex, BMI, smoking, diabetes, and cardiovascular events.

Results: A total of 2,271 patients were included (71% Y-De Roux, 25% gastric band, 4% other procedures), of which 16% had AUD prior to surgery. The factors associated with AUD were female gender (72.8% vs 27.2%; p = 0.006), age (40 ± 11 vs. 47 ± 11 years; p < 0.001), smoking (4.8% vs. 2.1%; p = 0.005) and the consumption of other drugs (15% vs. 4%; p < 0.001). Patients without AUD had higher prevalence of metabolic syndrome (57.1% vs. 44.1%; p < 0.001), arterial hypertension (73.4% vs. 60.3%; p < 0.001), diabetes (37.4% vs. 21.2%, p < 0.001), dyslipidemia (38.6% vs. 26.4%; p < 0.001), and cardiovascular events (10% vs. 5.1%; p = 0.003). Liver biopsy was performed in 286 subjects, 42% of whom had AUD. Patients with AUD had higher iron stores (41.7% vs. 22.6%; p = 0.02), with no differences in the presence of significant fibrosis (15.2% vs. 24.6%; p = 0.17) and steatohepatitis (21.7% vs. 32.5%; p = 0.15). Cases with AUD had a higher risk of mortality during follow-up (4.5% vs. 2.4%; log rank p = 0.026) (Figure 1). The factors associated with lower survival in Cox regression were: AUD (HR: 2.90 [95%CI 1.59–5.29] p < 0.001), age (HR: 1.04 [95%CI 1.01–1.07] p = 0.002), diabetes (HR: 2.22 [95%CI 1.30–3.79] p = 0.003), and BMI (HR: 1.03 [95%CI 1.01–1, 06] p = 0.001).

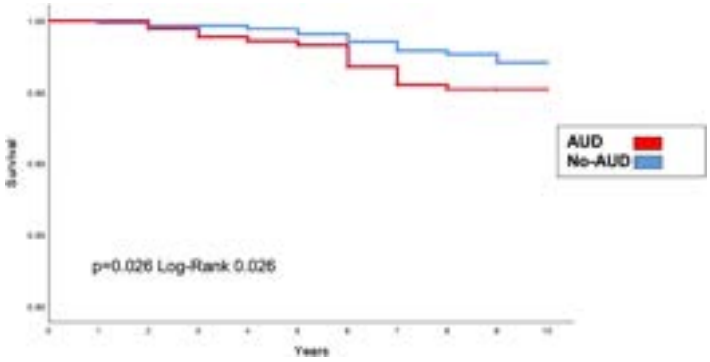

Figure:

Conclusion: The prevalence of AUD in patients undergoing bariatric surgery is high and is associated with increased long-term mortality.

FRI-434

Low sphingolipid levels indicate poor survival in patients with alcohol-related liver disease

Thit Mynster Kronborg[1], Qian Gao[2], Kajetan Trost[2], Henriette Ytting[3], Malene Barfod O'Connell[1], Mikkel Werge[3], Mira Thing[1], Lise Lotte Gluud[1], Søren Møller[4], Thomas Moritz[2], Flemming Bendtsen[3], Nina Kimer[3]. [1]*Hvidovre University Hospital, Gastro Unit, Medical section, Denmark;* [2]*Center for Basic Metabolic Research, Copenhagen University, Denmark;* [3]*Hvidovre University Hospital, Gastro Unit, Medical Section, Hvidovre, Denmark;* [4]*Hvidovre University Hospital, Clinical Physiology and Nuclear Medicine, Denmark*
Email: thit.mynster.kronborg@regionh.dk

Background and aims: Alcohol-related hepatitis (AH) and alcohol-related cirrhosis are grave conditions with poor prognoses. Altered hepatic lipid metabolism may differentiate between different alcohol-related liver diseases. Therefore, assessment of individual lipidomic and/or metabolomic factors might help to predict short-term mortality. We aimed to investigate the influence of lipidomics and metabolomics on different stages of alcohol-related liver diseases and their impact on survival.
Method: Patients with newly diagnosed alcohol-related cirrhosis with current alcohol use (ALC-A), alcohol-related cirrhosis without current alcohol use (ALC) and AH were compared to each other and to liver-healthy individuals (HC). Circulating lipids and metabolites were analysed using high-performance liquid chromatography and mass spectrometry detection. Concentrations were measured as relative values compared to HC.
Results: Plasma samples from 207 patients were analysed; 40 patients with ALC; 95 patients with ALC-A; 30 patients with AH; and 42 HC. Lipidomics showed significant differences among patient groups and the healthy controls; most lipids decreased in patients compared to healthy. Nine of ten analysed free fatty acids differentiated the cirrhosis groups by increases with a relative change of 0.12–0.66 in the ALC group compared to the ALC-A group (p values <0.0005). For metabolomics, total bile acids increased significantly with a relative change of 19.73 in the ALC group, 31.29 in the ALC-A group and 80.38 in the AH group compared to HC (all p values <0.0001). Low sphingolipid (d42:1) and (d41:1) levels in the three patient groups had a high accuracy in predicting 90 days mortality (AUC = 0.922, 0.893; p = 0.007, 0.008) and performed better than MELD score (AUC = 0.700, p = 0.19).

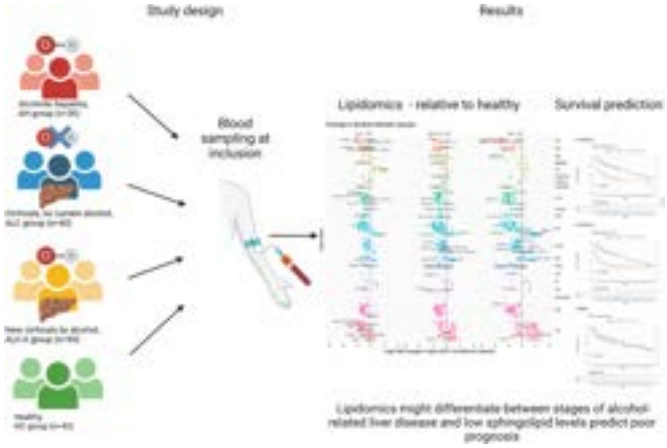

Figure:

Conclusion: Lipidomics classes decrease between stages of alcohol-related liver disease, and low sphingolipid levels predict poor prognosis.

FRI-435

Cause-specific mortality in patients with alcohol-related liver disease: a nationwide Danish cohort study

Anna Emilie Kann[1,2,3], Peter Jepsen[2], Lone Madsen[1], Joe West[4,5], Gro Askgaard[1,2,3]. [1]*Zealand University Hospital, Section of Gastroenterology and Hepatology, Køge, Denmark;* [2]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark;* [3]*Bispebjerg and Frederiksberg Hospital, Center for Clinical Research and Prevention, Frederiksberg, Denmark;* [4]*Nottingham University Hospitals NHS Trust and the University of Nottingham, NIHR Nottingham Biomedical Research Centre (BRC), United Kingdom;* [5]*University of Nottingham, Population and Lifespan Sciences, United Kingdom*
Email: aeka@regionsjaelland.dk

Background and aims: Knowledge of the pattern of causes of death is essential to prevent premature death in alcohol-related liver disease (ALD). We examined cause-specific mortality, including death due to specific cancers, in 15 years after diagnosis of ALD.
Method: We used the nationwide health registries to identify individuals diagnosed with ALD from 2002 to 2017 in Denmark and followed them for the underlying cause of death through 2019. We calculated the cause-specific mortality and investigated whether the pattern of cause-specific mortality differed by age (<60 and >60 years), gender, and ALD stage at diagnosis (cirrhotic and non-cirrhotic).
Results: The study included 23,385 individuals newly diagnosed with ALD with a median age of 58 years; 68% were men, and 64% had cirrhosis. During 110,322 person-years of follow-up, 15,692 (67%) died. Liver disease (Figure 1, red area) was the leading cause of death during the first five years after ALD diagnosis, and 26.0% (95%CI 25.5–26.6%) of patients died from liver disease within five years. Beyond five years of ALD diagnosis, cancer (orange and yellow area), alcohol abuse disorder (green area), and cardiovascular disease (blue area) became more important. The 10-year risk of death from cancer other than hepatocellular carcinoma (HCC) (orange area) was 8.5% (95%CI: 8.1–8.9%). HCC (yellow area) was the dominant cause of cancer death, followed by lung cancer, with 10-year risks of 2.5% (95%CI: 2.3–2.7%) and 1.9% (95%CI: 1.7–2.1), respectively. Alcohol abuse disorder (green area) continued to cause death even many years after ALD diagnosis, with a 10-year risk of 5.6% (95%CI 5.3–6.0). Death due to liver disease was similar according to age and gender but lower for those diagnosed with non-cirrhotic rather than cirrhotic ALD (10-year risk of death due to liver disease of 20.2% vs. 38.4%). Individuals aged >60 years were more likely to die due to extrahepatic causes

compared to younger individuals (10-year risk of death due to extrahepatic causes of 48% vs. 32%).

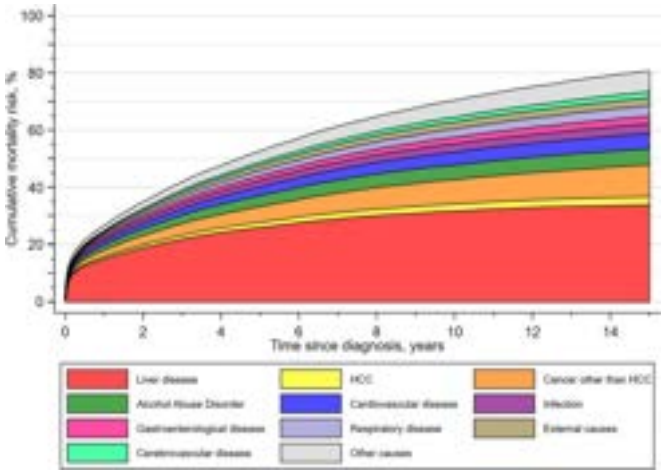

Figure: The cumulative risk of cause-specific death according to time since diagnosis of alcohol-related liver disease from 2002 to 2017 in Denmark, n = 23,385. Each color represents an underlying cause of death. The figure shows that liver disease is the leading cause of death in the first five years after diagnosis. Beyond five years, deaths due to cancer, alcohol abuse disorder, and cardiovascular disease rose.

Conclusion: In the first five years after the ALD diagnosis, liver disease caused the majority of deaths. Beyond five years, death caused by cancer, alcohol abuse disorder, and cardiovascular disease became more important. However, the risk of death due to specific cancers, including HCC, each contributed minimally to the total mortality in individuals with ALD.

FRI-436

Risk of primary liver cancer in alcohol-related cirrhosis-Danish and English cohort studies

Morten Daniel Jensen[1], Joe West[1,2,3], Peter Jepsen[1,2]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark;* [2]*University of Nottingham, Lifespan and Population Health, School of Medicine, United Kingdom;* [3]*Nottingham University Hospitals NHS Trust and the University of Nottingham, NIHR Nottingham Biomedical Research Centre (BRC), United Kingdom*
Email: moje@clin.au.dk

Background and aims: Patients with alcohol-related cirrhosis (ALD cirrhosis) have an increased risk of primary liver cancer (PLC), i.e., hepatocellular carcinoma (HCC) or intrahepatic cholangiocarcinoma (iCCA). Screening for HCC may identify both cancers but is only recommended in England, not in Denmark. We set out to identify the risk and the high-risk-groups among patients with ALD cirrhosis in a Danish and English cohort.
Method: We included all Danish patients (N = 20,265) with ALD cirrhosis in the Danish National Patient Registry (1994–2021) and all English patients (N = 16,763) with ALD cirrhosis in the Clinical Practice Research Datalink (CPRD) (2000–2016). We computed incidence rates (IR) and cumulative incidence (CI) of PLC with death and transplantation as competing risks, stratifying by decompensation, age, and sex.
Results: The IR of PLC per 10,000 person-years was 66 (95% CI 61–71) in Denmark and 62 (95% CI 56–68) in England. The 5-year risk of PLC was 2.24% (95% CI 2.03–2.46) in Denmark and 2.18% (95% CI 1.95–2.43) in England. The 5-year risk of iCCA and HCC was, respectively, 0.04% (95% CI 0.02–0.07) and 2.20% (95% CI 2.00–2.42) in Denmark vs. 0.07% (95% CI 0.04–0.13) and 2.11% (95% CI 1.88–2.36) in England. In both countries, the risk of PLC was higher in men than in women and increased with increasing age; this pattern was seen for both iCCA and HCC. Men had a 5-year PLC risk of 2.92% (95% CI 2.63–3.23) in Denmark and 2.80% (95% CI 2.48–3.15) in England, while men or women aged 70–79 year had a 5-year PLC risk of 3.91% (95% CI 3.04–4.94) in Denmark and 3.94% (95% CI 2.91–5.19) in England. No clear association was found with decompensation. In all patient subsets, HCC constituted the vast majority of PLCs (>96% of PLCs among men, >95% among women).
Conclusion: The risk of PLC is the same in Danish and English patients with ALD cirrhosis indicating that few PLCs are overlooked in Denmark, and that despite guidance recommending HCC screening in England this has not led to higher risks being observed. Male sex and older age were risk factors for both PLCs, while the effect of decompensation was uncertain. In both countries HCCs constituted >96% of PLCs, so the potential for overlooking iCCAs is likely to be small when discussions about moving from imaging-based to blood-based HCC surveillance are undertaken.

FRI-437

Beneficial effects of a screening programme for alcohol-related liver fibrosis with transient elastography in people with alcohol use disorder promoting alcohol abstinence

Emma Avitabile[1,2], Helena Hernandéz Evole[1], Jordi Gratacos[1,2,3], Pol Bruguera[4], Lluisa Ortega[4], Anna Lligoña[4], Martina Perez[1,2,3], Ana Belén Rubio[1,2,3], Ramon Bataller[1,3], Pere Ginès[1,2,3,5], Hugo Lopez[4], Elisa Pose[1,3,5]. [1]*Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain;* [2]*Universitat de Barcelona, Barcelona, Spain;* [3]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain;* [4]*Hospital Clínic de Barcelona, Psychiatry, Barcelona, Spain;* [5]*CIBER-Center for Biomedical Research Network, Madrid, Spain*
Email: EPOSE@clinic.cat

Background and aims: There are few screening programmes for detection of liver fibrosis in at-risk population of alcohol-related liver disease. The aims of this study were 1) to investigate risk factors of liver fibrosis in a population with high-risk alcohol consumption studied with Transient Elastography (TE); 2) to investigate the effect of the screening on alcohol consumption.
Method: Subjects attending the Addiction Unit of the Hospital Clínic of Barcelona for alcohol use disorder (AUD) between 2019 and 2022 were prospectively included (study cohort), excluding those with known liver disease or current alcohol consumption <21 or 14 SU/week in men and women, respectively, considering 1 SU = 10 g of alcohol. Subjects underwent a first visit in the Hepatology Clinic with collection of medical history and blood tests + TE with *Liver Stiffness* (LS) and a second visit to explain tests' results and for a brief intervention on healthy daily habits. Subjects with increased liver stiffness (LS ≥8 kPa) underwent follow-up in the Hepatology Clinic. Abstinence was defined as a minimum of 2-months negative follow-up according to medical records and/or negative ethylglucuronide (ETG) in urine or discharge due to abstinence. Results were compared with a matched control cohort attending the Addiction Unit for AUD treated immediately before the study period between 2017 and 2019.
Results: 314/345 subjects (91%) accepted to enter the study cohort, 68% were men with average 70 SU/week of alcohol consumption. Prevalence of increased LS was 12% (38/315). Presence of diabetes, male gender and higher ferritin and GGT values were independently associated with increased LS at the multivariate analysis. At 6 months, 142/314 (45%) subjects were abstinent based on medical records (n = 52) or medical records and ETG (n = 90). There was a non-significant trend to higher abstinence between subjects with significant fibrosis (55% vs 44%, p = 0.125). The study and control cohort (n = 148) were comparable in terms of baseline characteristics. At 6 months follow-up, abstinence was higher in the study cohort (45% vs 32%, p = 0.01) and median consumption among active consumers was lower (18 vs 21 SU/week, p = 0.008). Factors independently associated with abstinence in the two cohorts considered together (n = 463) were older age (OR = .97 p = 0.001) and being part of the study cohort (OR = 1.69 p = 0.01).

Conclusion: a screening program of liver fibrosis in subjects with high-risk alcohol consumption and AUD appears to have an added beneficial effect to the alcohological treatment for achievement of alcohol abstinence.

FRI-438

Epidemic within pandemic: alcohol-related hepatitis and COVID-19

Natalie Marlowe[1], David Lam[2], Suthat Liangpunsakul[3]. [1]*DURECT Corporation, United States;* [2]*Pharma Analytics, United States;* [3]*Indiana University, United States*
Email: natalie.marlowe@durect.com

Background and aims: We recently reported a steady increase in the total number of hospitalized alcohol-related hepatitis (AH) patients in the US; approximately 5.4% annually between 2015 and 2019. Alcohol consumption is a common coping mechanism for psychological distress. Alcoholic beverage sales increased significantly during the peak of the COVID-19 pandemic in the US. As a result, a rise in alcohol-associated liver disease cases was reported, however there is no published nationwide data on the prevalence of hospitalized AH cases in the US during the COVID-19 pandemic. In this study, we investigated the rate of AH hospitalizations in 2020 during the peak of the COVID-19 pandemic and its impact on patient outcomes and healthcare burden.
Method: We analyzed the US Nationwide Inpatient Sample data from 2019–2020. Patients with a primary or secondary diagnosis of AH were identified using International Classification of Diseases-10. We described associated comorbidities such as ascites, cirrhosis, hepatic encephalopathy (HE), acute renal failure (ARF), GI bleeding, pneumonia, and sepsis in AH patients, with or without COVID-19. The in-hospital mortality, length of stay (LOS), and hospital charges during the study period were calculated and compared.
Results: We observed ~16% annual increase in cases of hospitalized AH patients from 136,620 in 2019 to 157,885 in 2020, a significant increase from an average of 5.4% per annum. The overall US hospitalizations declined by 8.7% in 2020. Men younger than 40 comprised the fastest growing AH group (23% increase) in 2020. There were 154,985 (98.2%) AH hospitalizations without COVID-19 and 2,900 (1.8%) AH with COVID-19. In-hospital mortality was 4.1% for AH+COVID (−) vs. 11.37% for AH+COVID (+) patients. Average LOS was 2.5 days longer for AH+COVID (+) patients (8.6 vs. 6.1 days). Mean hospital charges were 41.3% higher ($93,670) for AH+COVID (+) patients compared to $66,283 for AH+COVID (−) patients. The most common comorbidities in AH+COVID (−) patients were cirrhosis (38.9%), ascites (27.5%), ARF (24.7%), coagulopathy (17%), HE (14.7%), GI bleeding (11.1%), sepsis (10%) and pneumonia (1.5%). In contrast, pneumonia (275% increase) and sepsis (50% increase) were the most common comorbidities in AH+COVID (+) patients followed by GI bleeding (24%), ARF (37%), and HE (27.1%).

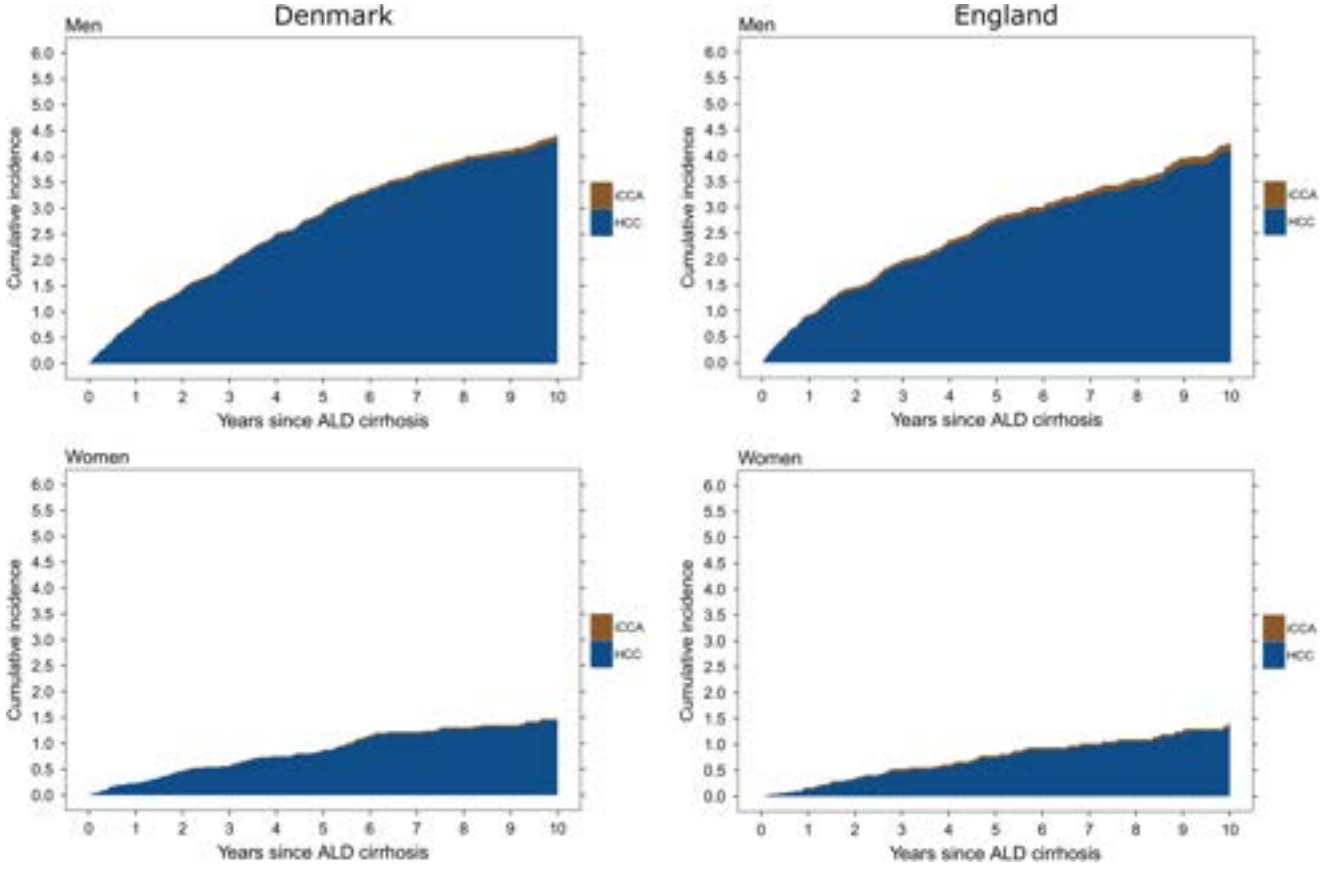

Figure: (abstract: FRI-436).

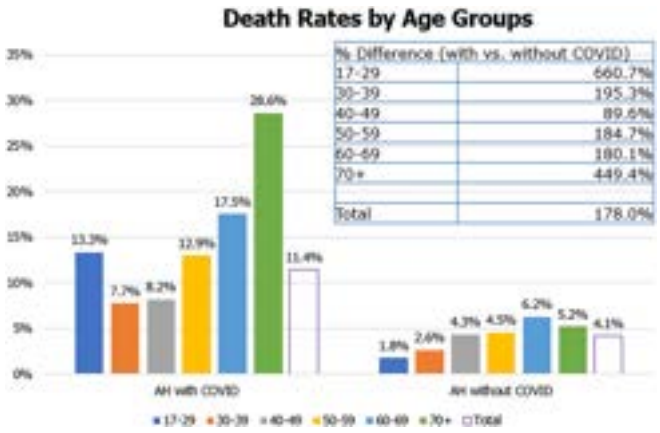

Figure:

Conclusion: Our study documented a significant increase in AH hospitalizations, in-hospital mortality, and healthcare cost and utilization among hospitalized AH patients, notably in those who were infected with SARS-CoV2. Our results underscore an unmet and urgent medical need to identify effective therapies for hospitalized AH patients.

FRI-439

Alcohol use disorder among patients admitted with non-alcohol related conditions: a retrospective cohort study in secondary care

Mohsan Subhani[1,2], Shamas Ul Haq[3], Guruprasad Aithal[1,2], Stephen Ryder[1,2], Joanne Morling[1,2,4]. *[1]Nottingham Digestive Diseases Biomedical Research Centre (NDDC), School of Medicine, University of Nottingham, United Kingdom; [2]NIHR Nottingham Biomedical Research Centre, Nottingham University Hospitals NHS Trust and the University of Nottingham, Nottingham, United Kingdom; [3]Nottingham University Hospitals, United Kingdom; [4]Division of Epidemiology and Public Health, Nottingham University Hospitals NHS Trust and the University of Nottingham, Nottingham, United Kingdom*
Email: mohsan.subhani@nottingham.ac.uk

Background and aims: A substantial number of hospitalised patients drink alcohol harmfully. Only a proportion of those people at risk will have an ICD-10 diagnosis of alcohol-specific or alcohol-related disorders. We aim to determine the prevalence of alcohol use disorder (AUD) in patients admitted with non-alcohol related conditions and ascertain the shared high-risk characteristics.
Method: Retrospective cohort included adult patients admitted to Nottingham University Hospitals (NUH) between 1st-April-2019 to 31st-March-2020 with non-alcohol related disorders. Data were analysed to determine the epidemiology of alcohol use disorder (AUD), identify associated high-risk characteristics, and describe the distribution of AUD in non-alcohol related ICD-10 discharge diagnosis group as defined by an alcohol-attributable fraction.
Results: A total of 36,121 patients presented with a non-alcohol related condition of them 35,080 (97.1%) who had alcohol assessment by AUDIT-C score were included. The mean age of the cohort was 62.2 years (SD ± 20.4), 18,595 (53.0%) were male, and 24,939 (90.6%) were white. Based on AUDIT-C 5, 626 (16.0%) had AUD (increased risk n = 3,559, 63.3%, high risk n = 1,482, 26.3%, possible dependence n = 585, 10.4%). Patients with AUD compared to those without AUD were significantly younger (mean age difference 8.7 years ±0.29, $p < 0.001$), were more likely to be male ($p < 0.001$), white ($p < 0.001$), not in a relationship (<0.001), admitted as an emergency ($p = 0.048$), and cared for by surgical specialities ($p < 0.001$). A significant ($p < 0.001$) higher proportion of patients with possible alcohol dependence compared to other AUD risk groups were from the most deprived areas (Table 1). General medicine, trauma and orthopaedics, general surgery, urology, and respiratory medicine were top five inpatient specialities of care for patients with AUD. Injury, poisoning, diseases of musculoskeletal and connective tissues, neoplasms, and diseases of the digestive system were the most common ICD-10 diagnosis groups for patients with AUD.

Table 1: Characteristics of AUD individual risk groups compared to no AUD (low risk)

	Low risk (n=29,454)	Increased risk (n=3,559)	High Risk (n= 1,482)	Possible dependence (n=585)	p

Data is n (%), mean (SD) or median (range).
AUDIT-C score: 0-4 (low risk), 5-7 (increased risk), 8-10 (high risk), 11-12 (alcohol dependent)
*In a relationship includes married, in a civil partnership or in a long-term relationship
†Not in a relationship includes single, divorced, separated, dissolved civil partnership, widowed, or surviving civil partner

Figure:

Conclusion: One in six admitted patients with anon-alcohol related conditions had AUD. Majority of these patients had either increased or high-risk AUD and were cared for by surgical specialities. Efforts to identify AUD and unidentified liver disease early should be focused on areas of high burden which are outside the specialist wards and units.

FRI-440

Histological inflammation in severe alcohol-related hepatitis is the main pre-treatment factor associated to glucocorticoid response

Mialy Randrianarisoa[1], Laetitia Oertel[2], Pierre Mayer[1], Lucile Heroin[1], Simona Tripon[1,3], François Habersetzer[1,3], Lawrence Serfaty[1], Thomas Baumert[1,3,4], Antonio Saviano[1,3]. *[1]Service d'hépato-gastroentérologie, Institut Hospitalo-Universitaire, Pôle hépato-digestif, Hôpitaux Universitaires de Strasbourg, Université de Strasbourg, France; [2]Service d'anatomo-pathologie, Hôpitaux Universitaires de Strasbourg, Université de Strasbourg, France; [3]Institut de recherche sur les maladies virales et hépatiques, Inserm UMR_S1110, Strasbourg, France; [4]Institut Universitaire de France, France*
Email: saviano@unistra.fr

Background and aims: Severe alcohol-related hepatitis is a condition associated with a significant mortality. Apart from liver transplantation, glucocorticoid is the only validated treatment. Treatment response is usually evaluated at day 7 by the Lille score. Clinical and histological pre-treatment features that could predict this response are unknown. The alcoholic hepatitis histological score, based on pre-treatment liver biopsy and developed to predict outcomes of patients with severe alcohol-related hepatitis, was not able to predict

glucocorticoid response and its prognostic value was not confirmed in an independent cohort.
The aim of this study was to characterize histological inflammation in severe alcohol-related hepatitis and to assess its predictive value of glucocorticoid response.
Method: This retrospective study included patients with histologically proven severe alcohol-related hepatitis treated with glucocorticoids at Strasbourg University Hospital, France, between 2014 and 2021. Pre-treatment liver biopsies stained with HandE were analyzed by QuPath v 0.3.2 to identify and quantify immune cells. Portal spaces, porto-lobular interfaces and lobules were annotated to describe the distribution of the immune cells.
The predictive value for glucocorticoids non-response (Lille score at day 7 >0.56) was evaluated by univariate and multivariate logistic regression analysis.
Results: Among the 61 patients included, 18 (29.5%) were non-responders and 43 (70.5%) were complete or partial responder. Most of the patients were cirrhotic in both groups (respectively 72.2% and 76.7%, p = 0.962). Liver disease was more severe in non-responders (median MELD 30 vs 24 p < 0.001; median Maddrey score 82.36 vs 61.74, p = 0.003). Total inflammatory cell infiltration was significantly lower in non-responders (median 3170 cells/mm^2, range 815–3906, p = 0.018) than in responders (median 3539 cells/mm^2, range 1779–5198).
The multivariate logistic regression analysis using pre-treatment clinical and histological variables, identified the following factors associated with glucocorticoids non-response: a high level of bilirubin (OR 1.02, CI 95% 1.01–1.03, p = 0.016), a high IGSII score (OR 1.19 CI 95% 1.07–1.46, p = 0.012) and a low total inflammatory infiltration (OR 38.9, 95% CI 2.54–3056, p = 0.031). Regarding the localization of the inflammation, portal immune cells were significantly lower in non-responders [1604/mm^2 (range 965–2370) vs 2273/mm^2 (range 1653–2766), p = 0.012] as well as in portal interface [341/mm^2 (range 269–397) vs 487/mm^2 (range 315–603), p = 0.012]. There was no difference between the two groups in terms of intralobular infiltration.

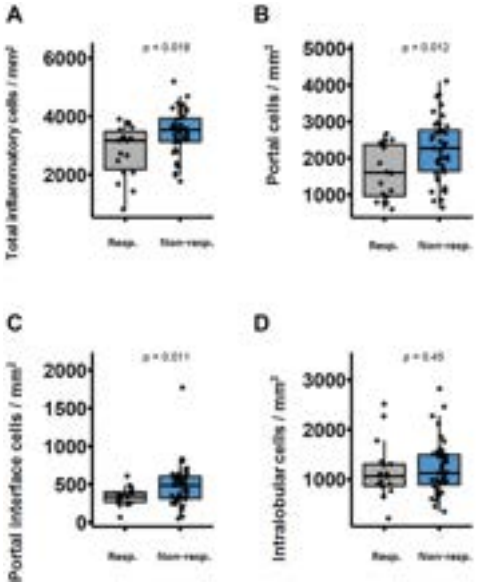

Figure:

Conclusion: Low histological inflammation is the strongest pre-treatment factor associated to glucocorticoids non-response in severe alcohol-related hepatitis. Automatic quantification of inflammatory cells from conventional HandE slides could be used for early detection of patients with a high risk of treatment failure in whom alternative medical therapies should be evaluated and early liver transplantation should be discussed.

FRI-441

The synergistic impact of food insecurity and alcohol use on mortality in adults with significant liver fibrosis

Ani Kardashian[1], Jennifer Dodge[1,2], Norah Terrault[1], Brian Lee[1].
[1]*Division of Gastrointestinal and Liver Diseases, University of Southern California, United States;* [2]*Department of Population and Public Health Sciences, University of Southern California, United States*
Email: ani.kardashian@med.usc.edu

Background and aims: Food insecurity is highly prevalent and associated with significant liver fibrosis. Food insecurity is also associated with adverse health behaviors, including heavy drinking, but the synergistic impact of the two on mortality among people with liver fibrosis is unknown.
Method: We performed a cross-sectional analysis of adult participants (age ≥20 years) with significant liver fibrosis from the National Health and Nutrition Examination Survey (NHANES) between 1999 and 2018. Fibrosis was defined using: NAFLD fibrosis score >0.675 (if subjects had NAFLD as defined by the U.S. Fatty Liver Index), AST-to-platelet ratio index >1.5, or Fibrosis-4 Index >2.67. Food insecurity was measured using the U.S. Department of Agriculture Food Security Survey Module. Alcohol use was self-reported in the prior 12 months and categorized as none versus any use. Mortality from all causes was ascertained through data linkage to the National Death Index through December 31, 2019. We used multivariable Cox proportional hazards regression to estimate hazard ratios (HRs) and 95% confidence intervals (CI) of all-cause mortality according to alcohol use and food security status. We further examined interactions between poverty and food security status/alcohol use given the known associations between these variables.
Results: In total, 1757 participants with significant fibrosis were included with mean follow-up of 6.4 years (SE: 0.10), of whom 443 (25%) were food insecure and 1080 (61%) reported any alcohol use. Participants with (vs. without) alcohol use were more likely to be younger (mean 66 vs 71 years) and male (62% vs 55%) and less likely to be living in poverty (11% vs 15%). Among those with alcohol use, all-cause age-standardized mortality per 1000 person-years was 22.6 among food secure and 30.4 among food insecure persons. In the multivariable model, mortality risk was elevated for food insecurity among participants with alcohol use (HR = 1.41, 95% CI: 1.002–1.98, p = 0.049) but not those without alcohol use (HR = 0.96, 95% CI: 0.68–1.37, p = 0.84; interaction p = 0.11). Furthermore, these effects differed by poverty. The combined effect of food insecurity and alcohol use (vs food secure without alcohol use) was 2.41-fold greater for those with poverty (p = 0.01). Among people without poverty, there was no difference in mortality among alcohol users by food security status (Figure).

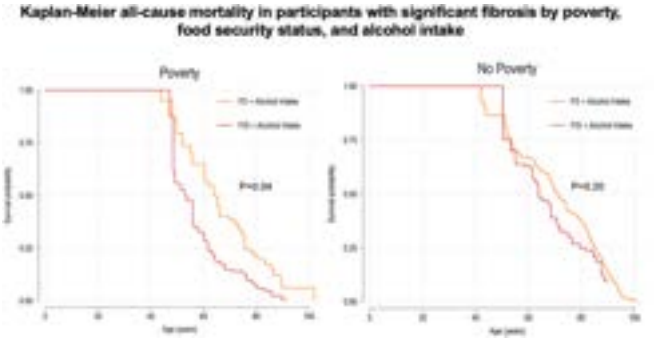

Figure:

Conclusion: Alcohol use disorder and food insecurity are comorbid conditions that have a more detrimental impact on liver health outcomes compared to either condition alone, particularly among people experiencing poverty. Greater efforts are needed to screen

low-income patients for food insecurity and alcohol use in clinical practice and refer them to appropriate resources.

FRI-442

Baclofen is effective on abstinence and improvement of Child-Pugh score in patients with cirrhosis: results of a meta-analysis

Gildas Fantognon[1], Jean-François Cadranel[1], Honoré Zougmoré[1], Mourad Medmoun[1], Ryad Smadhi[1], Philippe Pulwermacher[1], Jean Rene Ngele Efole[1], Camille Barrault[2], Oumarou Nabi[3]. *[1]GHPSO, CREIL, France; [2]CH INTERCOMMUNAL de CRETEIL, Digestuve Disease and Addiction Unit, Creteil, France; [3]Washington University School of MedicineETA, United States*
Email: honoretz87@gmail.com

Background and aims: Baclofen is one of the treatments recommended for abstinence (withdrawal) in patients (pts) with alcoholic cirrhosis (1). A few randomized and observational studies suggest a positive effect on abstinence and improvement of liver function in cirrhotic patients (2). However, despite obtaning marketing authorization in 2021, its impact on alcohol abstinence and liver function improvement remais debated. The aim of this meta-analysis was to evaluate the effect of baclofen in patients with alcoholic cirrhosis on abstinence and improvement of the Child Pugh score.

Method: Analysis studies on baclofen treatment in alcoholic cirrhotic patients published in extenso between January 1, 2020 and August 31, 2022. Randomized controlled studies and observational studies studies involving a large number of patients followed over a period of 12 months were included (for observational studies) were selected for analysis. analysis. The search for publications was based on a systematic search of in MEDLINE, PubMed, Google Scholar, Web of Sciences, Academic Search Premier, Cochrane Library and SCOPUS. We have collected and analyzed the individual data of the patients included in the different studies to assess the effects of baclofen on abstinence and improvement of the Child Pugh score in patients with alcoholic cirrhosis. The size of the effects of of baclofen on abstinence and Child Pugh score was assessed using relative relative risks (RR) and their 95% confidence intervals. We considered that there was improvement in the Child Pugh score when there was a change from a Child Pugh score from C at inclusion to stage A at the end of follow-up. Otherwise, it was, it was considered no benefit. Assessment of bias and heterogeneity were using the I2 and funell plot. A p value <0.05 was considered statistically significant.

Results: Six studies were included in the final analysis, including four randomized trials (318 cirrhotic patients treated with baclofen and 147 patients treated with placebo) and two observational studies (100 pts). The median dose of baclofen was 30 mg per day.

In despite the hight heterogeneity (I2 = 79%), our results show a positive effect of baclofen on alcohol withdrawal and abstinence (RR 1.48, CI95% 1.25–1.76, p = 0.003 and 1.76, CI95% p = 0.0083 respectively). Similarly, baclofen showed a beneficial effect on improvement on the severity of liver injury as assessed by the Child Pugh score score (RR 2.50, CI95% 1.48–4.18, p < 0.0001).

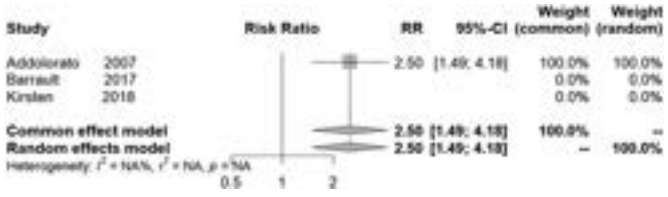

Figure:

Conclusion: Global improvement of the Pugh child.

This meta-analysis shows that baclofen is an interesting treatment for abstinence from alcohol consumption in patients with alcoholic cirrhosis and could improve liver functions in patients with alcoholic cirrhosis. alcoholic cirrhosis.

FRI-443

Hemoglobin is a short-term prognostic factor in decompensated alcohol-associated cirrhosis: a multicenter prospective study

José Ursic Bedoya[1], Claire Espérance[2], Safia Aouinti[2], Ludovic Caillo[3], Magdalena Meszaros[2], Marie Pierre Ripault[4], Laura Jaubert[2], Adrien Ardavan Prost[3], Lucy Meunier[2], Stéphanie Faure[2], Cathy Soulayrac[2], Hélène Donnadieu[2], Boris Guiu[2], Nicolas Molinari[2], Jérôme Dumortier[5], Georges-Philippe Pageaux[2]. *[1]CHU Montpellier, Montpellier, France; [2]CHU Montpellier, France; [3]CHU de Nîmes, France; [4]CH Narbonne, France; [5]Edouard Herriot Hospital, Lyon, France*
Email: jose.ursicbedoya@chu-montpellier.fr

Background and aims: Acute decompensation of alcohol-associated cirrhosis can lead to acute-on-chronic liver failure development or death without liver transplantation (LT). LT can be avoided in some patients who spontaneously recover. Classic prognostic scores (such as Meld) are insufficient to discriminate between patients who recover and those needing LT. We aimed to identify new prognostic factors in the setting of acute decompensation (AD) of alcohol-associated cirrhosis.

Method: This prospective observational study included patients from two tertiary care centers (one with a LT team) and a secondary care center. Inclusion period ranged from 01/04/2018 to 30/09/2019 and patients were followed for a minimum of 12 months. Adults admitted for an AD of alcohol-associated cirrhosis, without hepatocellular carcinoma, previous TIPS placement or active viral hepatitis were included. Primary end points were overall and 3-month transplant-free survival (TFS).

Results: 131 patients were included (mean [SD] age, 58.4 [9.3] years; 96 men [73.3%]); median follow-up was 15 months. 3 and 12-month TFS were 74.8% and 64.1% respectively. Main etiologies for decompensation were alcohol-associated hepatitis (n = 52, 39.7%) and ascites flare (n = 35, 26.7%). Multivariate Cox regression identified baseline hemoglobin ([HR]: 0.558, [95% CI: 0.383; 0.813]) and Meld score ([HR]: 1.307, [95% CI: 1.171; 1.457]) as the variables associated with 3-month TFS. We constructed a score combining hemoglobin and Meld score with an AUROC of 0.91 (95%CI: 0.84; 0.98), showing higher prognostic performance than Meld, Meld-sodium and ACLF-AD scores. Our model was validated in an independent cohort of 49 patients.

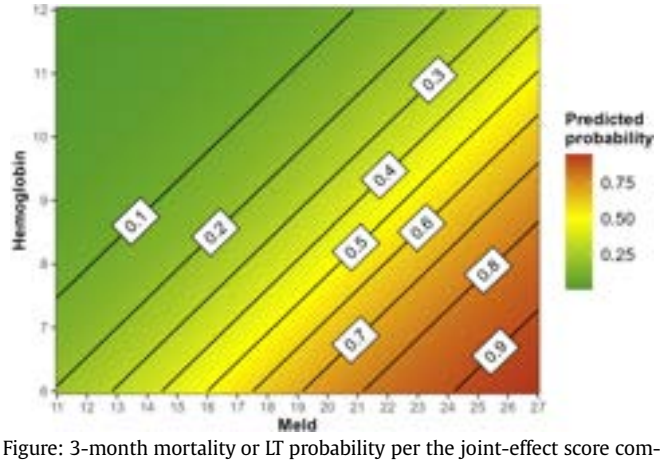

Figure: 3-month mortality or LT probability per the joint-effect score combining baseline Meld and hemoglobin.

Conclusion: Baseline hemoglobin shows potential short-term prognostic value in patients admitted for AD of alcohol-associated cirrhosis (Clinical Trials number 03508388).

FRI-444

Impact of heavy alcohol consumption on mitochondrial metabolism

Scott Minchenberg[1], Margery A. Connelly[2], Naga Chalasani[3], Arun Sanyal[4], Vijay Shah[5], Z. Gordon Jiang[1], Eduardo Vilar Gomez[3]. [1]*Beth Israel Deaconess Medical Center, Division of Gastroenterology and Hepatology, Boston, United States;* [2]*LabCorp Corporate Office, Diagnostics Research and Development, Morrisville, United States;* [3]*Indiana University School of Medicine, Division of Gastroenterology and Hepatology, Indianapolis, United States;* [4]*VCU School of Medicine, Division of Gastroenterology and Hepatology, Richmond, United States;* [5]*Mayo Clinic, Department of Internal Medicine, Rochester, United States*
Email: sminchen@bidmc.harvard.edu

Background and aims: Excessive alcohol consumption results in cumulative damage to mitochondria which has profound implications for cellular metabolism. Changes in mitochondria metabolism result in altered circulating metabolites, such as citrate and ketone bodies. We have previously demonstrated that high levels of circulating ketone bodies and citrate are associated with increased mortality. Herein, we hypothesize that excessive alcohol consumption and alcoholic hepatitis are associated with elevated ketone bodies and Krebs cycle metabolites due to mitochondria injury.

Method: Translational Research and Evolving Alcoholic Hepatitis Treatment (TREAT) was a prospective observational study of patients with alcoholic hepatitis (AH) (n = 196) and matched heavy drinkers (n = 169). Study participants were evaluated at baseline, 6 months, and 12 months. Metabolite levels were quantified from baseline plasma samples using nuclear magnetic resonance profiling. The relationship between metabolites and patient outcome was analyzed using multivariable regression and Cox proportional hazard models.

Results: Heavy drinkers have lower levels of citrate (88.1 ± 26.6 μM), but higher levels of ketone bodies (344 ± 578 μM) compared to healthy controls. Patients with AH have significantly increased levels of ketone bodies and citrate when compared to heavy drinkers (Figure). The increase in citrate and ketone body levels positively correlated with both Maddrey and MELD scores, suggesting liver injury in AH is directly linked to maladaptive mitochondria metabolism. In Cox proportional hazard models, the Citrate level is strongly associated with mortality at 90 days with HR ratio of 2.9 (95% CI 1.5–5.4, p < 0.01), while no significant association was observed with ketone bodies.

Variables	Heavy drinkers N = 169	Alcoholic hepatitis N = 196	P value*
Age, years	44.42 ± 12.40	45.53 ± 10.90	0.437
Gender (male), n (%)	110 (65)	117 (60)	0.28
ALT (U/L)	26.52 ± 12.36	62.15 ± 63.78	<0.001
AST (U/L)	28.45 ± 10.65	136.75 ± 83.50	<0.001
ALP (U/L)	76.52 ± 31.14	188.0 ± 137.07	<0.001
Creatinine (mg/dl)	0.88 ± 0.27	1.01 ± 0.91	0.170
Maddrey score	2.83 ± 9.60	42.97	<0.001
MELD score	7.30 ± 2.35	22.55 ± 6.75	<0.001
Ketone bodies (KB)			
Total KB	344.1 ± 577.7	608.5 ± 517.6	<0.01
Beta-hydroxy-butyrate	237.1 ± 407.8	449.3 ± 354.2	<0.01
Acetoacetate	71.3 ± 124.4	64.5 ± 85.9	0.29
Acetone	35.6 ± 58.7	94.6 ± 188.7	<0.01
Small molecule metabolites			
Glucose	92.2 ± 80.9	104.7 ± 43.4	<0.01
Citrate	88.1 ± 26.6	166.3 ± 196.0	<0.01

*Mann-Whitney U test for continuous and chi square for categorical.

Conclusion: Heavy alcohol use and AH are associated with elevated levels of ketone bodies, while an increase in circulating citrate level is associated with mortality in 90 days in AH, potentially indicative of mitochondrial biogenetic failure. Mitochondrial damage may trigger a buildup of Krebs cycle metabolites that would shift acetyl-CoA to ketone body production. This study is the first to describe the changes in mitochondria metabolites in alcohol-related liver disease.

FRI-445

Recompensation following an episode of alcohol-associated hepatitis mostly occurs in the first year of follow-up and is related to Child-Pugh score, levels of GGT and platelets, and alcohol abstinence

Email: EPOSE@clinic.cat

Background and aims: several studies have recently described the phenomenon of resolution of clinical complications in patients with decompensated cirrhosis. There is currently no evidence regarding the incidence of this event following an episode of alcohol-associated hepatitis (AH), nor the factors associated to its occurrence.

Method: we collected data from a retrospective cohort of patients from 30 Spanish hospitals with a clinical diagnosis of AH between 2014 and 2021. We selected all patients that met the following criteria: 1) were alive after first hospitalization; 2) presented with a decompensation of cirrhosis at diagnosis or had a Model for End-stage Liver Disease (MELD) score >20. Recompensation was defined as: 1) compensated liver disease over the previous 3 months; 2) no specific treatment (diuretics, laxatives or rifaximin) over the previous 3 months; 3) improvement of liver function defined by MELD <12. We evaluated the percentage of recompensated patients at 1 and 3 years, and we performed a logistic regression to assess factors associated to recompensation.

Results: five hundred forty-eight patients were included. The majority were men (72%), with a median age of 52 years and a median MELD score of 22 at diagnosis. At 3-year follow-up, 105 patients (19%) met criteria for recompensation; of those, 74 patients (70%) already met the same criteria at 1-year follow-up. A lower Child-Pugh (CP) score (OR 1.66, CI [1.27–2.19]) at diagnosis, higher

levels of platelets (OR 1.04, CI [1.01–1.08]) and GGT (OR 1.07, CI [1.07–1.12]), and total alcohol abstinence during follow-up (OR 2.72, CI [1.48–5.00]), were the only factors associated to recompensation at 1 year. Baseline probability of recompensation at 1 year ranged from 6.6% in patients with Cp >9 and low platelets (<75.5 × 10^9/L) and GGT (<172 U/L), up to 28.3% in patients with Cp <9 and high platelets and GGT levels.

Figure: Probability of recompensation at 1 year according to baseline Child-Pugh score and levels of platelets and GGT.

Conclusion: a significant percentage of patients diagnosed with AH achieve recompensation of cirrhosis, mainly during the first year after discharge. Recompensation is associated to alcohol abstinence, CP score and levels of platelets and GGT.

FRI-446

A prospective study of hepatic fibrosis evaluation in an alcohol withdrawal unit of an university hospital center: role of FIB-4 and elastometry. Fibr'addict study

Armand Abergel[1], Benjamin Buchard[1], Leon Muti[1], Dominique Boulier[1], Maud Leautaud[1], Brigitte Chanteranne[1], Carine Nicolas[1], Sylvie Massoulier[1], Frédéric Faure[1], Anne Audrey Schmitt-Dischamp[2], Georges Brousse[2]. *[1]CHU Clermont-Ferrand, Medecine Digestive, Clermont-Ferrand, France; [2]CHU Clermont-Ferrand, Service d'addictologie, Clermont-Ferrand, France*
Email: aabergel@chu-clermontferrand.fr

Background and aims: Excessive alcohol consumption is the major cause of liver-related death and the leading cause of liver transplantation in France. Many patients are seen too late, at a decompensated stage. Early diagnosis of cirrhosis would allow early diagnosis for esophageal varices, screening for hepatocellular carcinoma and reinforcement of addictive behaviour care. This project is part of a process of screening for hepatic fibrosis, by elastography, in patients hospitalized in an addictology unit for alcohol withdrawal.
Method: 216 patients benefited from measurement of liver stiffness (LS) (Fibroscan®) upon entering in the unit (day 0 = D0). This measurement was repeated before the patients had left the unit (21 days on average). A LS>25 kPa ruled in advanced fibrosis (15 patients), and a LS<10 kPa ruled out advanced fibrosis (183 patients) (Legros et al. CGEH 2022). If the patients had a LS of between 10 and 25 kPa at D0, the status was determined by the second LS realised at the end of hospitalisation. If the patient had LS>10 kPa, they were considered to have advanced fibrosis (7 patients). Five patients had LS<10 kPa (no advanced fibrosis) and six patients had no second measurement, they were excluded from the analysis. Then 22 patients had an advanced fibrosis (F3 or F4 METAVIR) and 188 patients had no advanced fibrosis (F0F1F2). We also studied the diagnostic performance of FIB-4, prothrombin time and ASAT/ALAT>1 with the objective to reduce the number of LS measurements.
Results: In the total population (210 patients), mean age of the patients was 49+12 years and sex ratio was 2.81. The percentage of patients with a FIB-4 less than 2.6, a prothrombin time (expressed in %) higher than 85% and ASAT/ALAT<1 were respectively 78% (161/206), 83% (164/198), 58% (121/208). For the patients with an advanced fibrosis at D0, the mean LS was 34+18 kPa and the number of patients with CAp >275 kPa was 8/22 (36%). The average alcohol consumption over the last 5 years was 189 + 147 g/day. For the patients without advanced fibrosis, LS was 5 + 2 kPa and the CAp >275 was 35/188 (17%) at D0. The average alcohol consumption over 5 years was 206 + 162 g/day. For FIB-4 > 2.6, sensitivity, specificity, positive predictive value and negative predictive value were respectively 77%, 85%, 38% and 97%. Negative predictive value were also excellent for prothrombin time<85% (97%) and ASAT/ALAT>1 (97%).
Conclusion: Ten percent (22/210) of patients admitted to an addictology unit had an advanced fibrosis. A FIB-4 less than 2.6 had an excellent negative predictive value to exclude advanced fibrosis and then could be able to reduce the number of LS measurements (up to 80% of the patients). The combination of FIB-4 and LS should be studied on a larger number of patients to validate this algorithm, preferably within the framework of a multicentre study. This study suggests that screening for advanced fibrosis should be performed in all hospital units for alcohol withdrawal.

FRI-447

The prevalence and prognostic impact of bariatric surgery in patients hospitalized with alcoholic liver disease

Louis Onghena[1,2,3], Sander Lefere[2,3], Laurissa Demeulenaere[2], Yves Van Nieuwenhove[1], Anja Geerts[2,3]. *[1]Ghent University Hospital, Department for Human Repair and Structure, Department of Gastrointestinal Surgery, Gent, Belgium; [2]Ghent University Hospital, Liver Research Center Ghent, Ghent University, Ghent University Hospital, Gent, Belgium; [3]Ghent University Hospital, Department of Internal Medicine and Paediatrics, Hepatology Research Unit, Gent, Belgium*
Email: Louis.onghena@ugent.be

Background and aims: Patients with a history of bariatric surgery (BS) are susceptible to developing alcohol use disorder. We and others have previously shown that these patients can develop severe alcohol-related liver disease (ARLD), often at a younger age and despite lower cumulative alcohol intake when compared to ALRD patients without BS. However, there is still a paucity of data. Our aim was to describe the demographics and mortality of a hospitalized population diagnosed with alcohol-related liver disease, in relation to BS.
Method: We included patients hospitalized at the University Hospital in Ghent between 1/1/2018 and 31/12/2022 with ARLD. Data were retrieved retrospectively from the most recent hospitalization. Statistical analysis was performed using Mann-Whitney U and Chi^2 tests.
Results: 12.3% (35/284) of patients admitted with ARLD had a history of bariatric surgery, of which 28 (80.0%) underwent Roux-en-Y gastric bypass. Pre-BS BMI was 41.3 ± 5.6 on average, with a one-year post-BS BMI of 27.0 ± 4.7. Patients with a history of BS were predominantly female (77.1%), in contrast to the non-BS population (30.1%) ($p < 0.0001$) and despite being significantly younger (52.0 (45.0, 60.0) vs 63.0 (53.0, 69.0) years old) ($p < 0.0001$), had a similar survival (68.6%

vs 61.0%) and a higher likelihood of transplant listing (25.7% vs 14.2%) (p = 0.085). The cause of death was acute-on-chronic liver failure in 77.8% of BS patients, compared to only 15.9% of those without a history of BS (p < 0.0001). Conversely, and in keeping with the younger age, no BS patients died of non-hepatological causes or HCC. There were no differences in comorbidities (diabetes, ischemic heart disease), complications of liver disease (ascites, spontaneous bacterial peritonitis, esophageal varices, and hepatic encephalopathy), nor in BMI at the time of the latest hospitalization. ALT (p = 0.043) and AST (p = 0.012) were significantly elevated in the BS group, whereas the MELD score was comparable (p = 0.727). More than half of the BS cohort suffered from psychiatric illness, compared to a quarter of the non-BS population (51.4% vs 28.1%) (p = 0.010), paralleled by the number of patients currently treated with psychological counseling (51.4% vs 21.0%) (p < 0.0001). Alcohol abstinence was near identical with 57.6% vs 57.9%. The weekly amount of alcohol consumed during drinking periods (40.0 (25.0, 50.0) vs 50.0 (35.0, 79.0) units/week) (p = 0.060) and duration of use (8.0 (5.0, 15.0) vs 20.0 (10.0, 29.8) years) was significantly lower in the BS population (p < 0.0001).
Conclusion: BS patients hospitalized with ARLD are predominantly young females with a lower cumulative alcohol consumption compared to those without prior BS. Despite this, mortality due to liver disease was higher. There is a need for prospective research to substantiate stricter pre-BS patient selection guidelines.

FRI-448

Prognostic role of serum alpha-1 antitrypsin levels for waitlist mortality in patients with alcohol-associated liver disease

Ronald Samuel[1], Basim Ali[2], Scott Berger[2], Richard Bui[2], Kadon Caskey[2], Cameron Goff[2], Norvin Hernandez[2], Seulgi Kim[2], Christo Mathew[2], Ankur Patel[2], Marguerite Poche[2], Prisca Pungwe[2], Anjiya Shaikh[3], Vinh Tran[2], Ryan Ward[2], Ruben Hernaez[1], Saira Khaderi[1], Tzu-hao Lee[1], Fasiha Kanwal[1], George Cholankeril[1].
[1]Baylor College of Medicine, Gastroenterology and Hepatology, United States; [2]Baylor College of Medicine, United States; [3]University of Connecticut, United States
Email: ronald.e.samuel1@gmail.com

Background and aims: Alcohol-associated liver disease (ALD) is the leading cause of end-stage liver disease, and is commonly associated with protein malnutrition. Although prevalent in ALD patients, the effect of serum zinc, ceruloplasmin and alpha-1 antitrypsin (A1AT), potential surrogates of protein nutritional deficiencies, on liver transplant (LT) waitlist dropout has yet to be examined. The primary aim of our study was to evaluate the variables and predictors of waitlist dropout among ALD patients listed for LT.
Method: A retrospective cohort study was performed of all adult patients (age >18 years) added to the liver transplant waitlist at Baylor St Luke's Medical Center from January 2017 to August 2018. Patients with alcohol use as a primary or secondary etiology of liver disease were included. Multiple demographics, nutrition, alcohol, decompensation, and laboratory variables were collected using manual medical record review. Nutritional labs at waitlist date included albumin (low <2.5 g/dL), zinc (low <60 μg/ml), ceruloplasmin (low <20 mg/dL) and A1AT (low <100 mg/dL) levels. In patients with low ceruloplasmin and A1AT levels, 24 hour urine copper and A1AT phenotypes were obtained, and concomitant Wilsons Disease and genetic A1AT deficiency were excluded from the ALD cohort. Logistic regression was performed to assess the independent effect of nutrient deficiencies on waitlist dropout due to death or removal due to medical deterioration. The institutional review board of Baylor College of Medicine, Houston, Texas approved the research project. Data were analyzed using Stata version 13 (Stata Corp, College Station, TX).
Results: A total of 122 patients were listed with ALD, of which, 69% of patients were male and 61% were Caucasian, with median MELD at listing of 27 [IQR, 13–32]. With regards to hepatic decompensation, 66% had hepatic encephalopathy (HE), 84% had ascites, and 38% had a history of gastroesophageal variceal bleeding and/or required variceal ligation. Overall, 16% of ALD patients died or were removed due to medical deterioration and median time from waitlisting to dropout was 56 days. At the time of listing, 14% of patients had low albumin ([mean] 3.1 g/dL). 70% of patients had low zinc (46.1 μg/ml), 19% had low ceruloplasmin (23.5 mg/dL), and 7% had low A1AT (149.6 mg/dL) levels. As a continuous predictor (increments of 1 mg/dL), higher A1AT levels was associated with reduced risk of waitlist dropout on univariate analysis (odds ratio [OR] 0.98, 95% confidence interval [CI]: 0.96–0.99) (Table 1). After adjusting for age, sex, and MELD score at listing, the association between serum A1AT level and waitlist dropout remained significant (adjusted OR 0.97, 95% CI: 0.95–0.996). As a categorical variable, low A1AT levels (<100 mg/dL) was observed to increased risk of dropout, but did not meet statistical significance (OR 3.32, 95% CI: 0.99–11.16) on univariate analysis. Serum ceruloplasmin and zinc levels, and deficiencies were also not found to be associated with waitlist dropout.

Table 1. Univariate and Multivariate Analysis of Continuous and Categorical Predictors of Waitlist Dropout Due to Medical Deterioration Among ALD Patients Listed for LT

	Univariate		Multivariate	
Variable	Odds Ratio (95 % CI)	P-value	Odds Ratio (95 % CI)	P-value
Continuous				
Zinc	0.98 (0.94 – 1.01)	0.17	0.99 (0.95 – 1.03)	0.52
Ceruloplasmin	0.94 (0.88 – 1.05)	0.37	0.96 (0.89 – 1.08)	0.69
A1AT	0.98 (0.96 – 0.99)	0.01	0.97 (0.95 – 0.996)	0.02
Albumin	0.55 (0.24 – 1.23)	0.14	0.61 (0.27 – 1.40)	0.3
Categorical				
Zinc < 60 μg/mL	2.51 (0.68 – 9.23)	0.17	1.98 (0.51 – 7.65)	0.32
Ceruloplasmin < 20 mg/dL	0.78 (0.21 – 2.93)	0.71	0.66 (0.17 – 2.59)	0.56
A1AT < 100 mg/dL	3.32 (0.99 – 11.16)	0.052	2.81 (0.77 – 10.2)	0.12
Albumin < 2.5 g/dL	2.71 (0.83 – 8.87)	0.1	2.49 (0.71 – 8.04)	0.16

Conclusion: Among patients with ALD listed for LT, A1AT levels were independently associated with waitlist dropout, and may have prognostic value in assessing the severity of liver disease for LT. Additional studies are needed to evaluate the effect of protein nutrition deficiency in patients with ALD to identify and intervene on those at risk for waitlist dropout.

FRI-449

Type VII collagen degradation biomarker (C7M): a new marker of alcohol-induced gut injury and bacterial translocation in steatotic liver disease

Emil Deleuran Hansen[1,2], Nikolaj Torp[1,2], Ida Lønsmann[2,3], Evelina Stankevic[4], Stine Johansen[1,2], Camilla Dalby Hansen[1,2], Bjørn Stæhr Madsen[1], Helene Bæk Juel[4], Katrine Lindvig[1,2], Katrine Thorhauge[1,2], Katrine Bech[1,2], Ellen Jensen[1,2], Peter Andersen[1], Ida Ziegler Spedtsberg[1,2], Johanne Kragh Hansen[1,2], Charlotte Wernberg[2], Ida Villesen[1,2], Morten Karsdal[3], Maja Thiele[1,2], Torben Hansen[4], Diana Leeming[3], Mads Israelsen[1], Aleksander Krag[1,2].

Email: emil.deleuran.hansen@rsyd.dk

Background and aims: The gut barrier is a treatment target in alcohol-related liver disease (ALD) and non-alcoholic fatty liver disease (NAFLD), but biomarkers to assess gut injury and bacterial translocation are lacking. Alcohol induces gut injury and bacterial translocation. Type VII collagen is abundant in the extracellular matrix (ECM) of the gut wall, which may be affected during gut injury. IL-6 is secreted by the Kupffer cells in response to microbial products. We aimed to investigate circulating markers of type VII collagen and IL-6 in response to acute alcohol intoxication as markers of gut injury and bacterial translocation.

Method: We performed a pathophysiological intervention study including 39 patients with three different hepatic phenotypes; healthy controls (HC), ALD and NAFLD. The intervention was 2.5 ml/kg of 40% ethanol in 9 mg/ml NaCl administrated through a nasogastric tube for over 30 minutes. After the intervention, blood samples were collected simultaneously through the hepatic vein at eight-time points during a 180-minute study period. Markers of type VII collagen degradation (C7M) and formation (PRO-C7) were measured using competitive ELISA. IL-6 was measured using O-link technology.

Results: Mean age was 53 (±11) years, 61.4% were males and the median transient elastography was 4.5 (3.9–5.0)/8.9 (5.9–11.0)/10.4 (9.5–11.4) kPa (HC/ALD/NAFLD). At baseline, the hepatic venous mean concentration of C7M was 7.8 (±6.8)/16.6 (±11.0)/10.9 (±8.9) ng/ml (HC/ALD/NAFLD). A significant difference of C7M between ALD and HC was observed at baseline ($p = 0.026$). Baseline PRO-C7 was comparable between groups with a mean of 39.1 (±27.3)/41.6 (±30.2)/37 (±26.6) ng/ml (HC/ALD/NAFLD), $p = 0.73$. In all groups, the hepatic venous concentration of C7M increased gradually during the first 90 minutes and decreased to near baseline values after 180 minutes (Figure). The area under the curve (AUC) for C7M was 1,659 (±1,225)/3,330 (±1,460)/2,456 (±1729) ng/ml (HC/ALD/NAFLD) during the 180 minutes (Figure). AUC^{ALD} for C7M was significantly higher than AUC^{HC} ($p = 0.0074$, 95% CI: 495–2846) but not AUC^{NAFLD} ($p = 0.15$, 95% CI: −350–2098). The difference between AUC^{NAFLD} and AUC^{HC} was not significant ($p = 0.22$, 95% CI: −513–2107). Hepatic and systemic IL-6 was significantly increased after 180 min (mean Normalized Protein eXpression (NPX) 0.62, 95% CI: 0.02–0.80, $p = 0.03$ and mean NPX 0.41, 95% CI 0.62, 95% CI: 0.24–1.01, $p < 0.001$, respectively). No change was observed in the hepatic venous concentration of PRO-C7 (Figure).

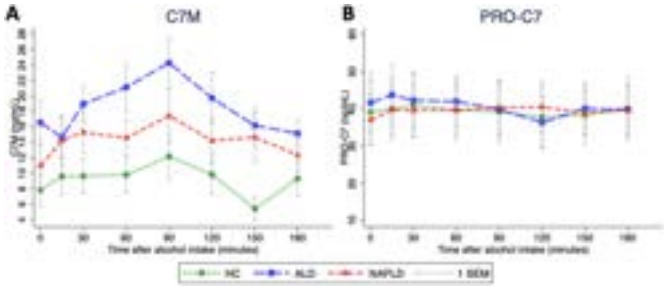

Figure: Change in hepatic A) C7M and B) PRO-C7 after alcohol intervention in patients with alcohol-related liver disease, non-alcoholic fatty liver disease and healthy controls.

Conclusion: Acute alcohol intake induces a rapid increase in hepatic type VII collagen degradation assessed by C7M, indicative of gut-driven ECM damage. The associated IL-6 increase, suggests elevated inflammatory activity from a potential increased bacterial translocation.

FRI-450

Implementation and outcomes of liver health check clinics in community alcohol services

Islam Nassar[1], Michael Griffiths[1], Susan Kemp[1], Douglas Macdonald[1].
[1]*Royal Free Hospital London, Hepatology, London, United Kingdom*
Email: islam.nassar@nhs.net

Background and aims: According to the English National Drug Treatment Monitoring Service, 3105 clients drinking more than 50 units of alcohol a week are engaged in community alcohol services across Hertfordshire and North Central London. These services do not provide an assessment of liver disease. The earlier identification of cirrhosis in this group may facilitate detection of hepatocellular carcinoma (HCC) at a curable stage through surveillance and risk mitigation of complications of portal hypertension.

Method: As part of a National Cancer Program service evaluation, we implemented "Liver Health Check Clinics" (LHCC) in 9 community alcohol services in this region. These were delivered by clinician assistants who provided Fibroscan liver stiffness measurement (LSM) to pre-booked, self-booked and walk-in patients. Individuals with an LSM between 8.5 and 11.4 kPa were offered repeat elastography in 1 year. Those with an LSM >11.4 were offered immediate blood tests including a full liver screen and onward referral to local hepatology services with a liver ultrasound before their first appointment. All patients were given an information sheet with their LSM and an explanation of its significance.

Results: 344 clients attended LHCC for assessment between 15/09/2022 and 27/01/2023. 60% were pre-booked and 40% were walk-ins. 100% gave a history of drinking at least 50 units of alcohol for at least 1 month. A further 120 clients were booked but did not attend (36%). Figure 1 shows the distribution of valid LSM results. 37 patients (10.8%) had LSM >15 kPa and may benefit from long-term HCC surveillance. 24 patients (7%) met Baveno VI criteria for varices assessment (LSM >20 kpa or platelets <150), 15 (4.3%) patients had an LSM >25 kPa predictive of a high risk of decompensation and 10 patients (3%) had biochemical evidence of decompensation (low albumin, raised bilirubin and/or INR). The cumulative non-attendance rate at the first booked liver ultrasound was 8%.

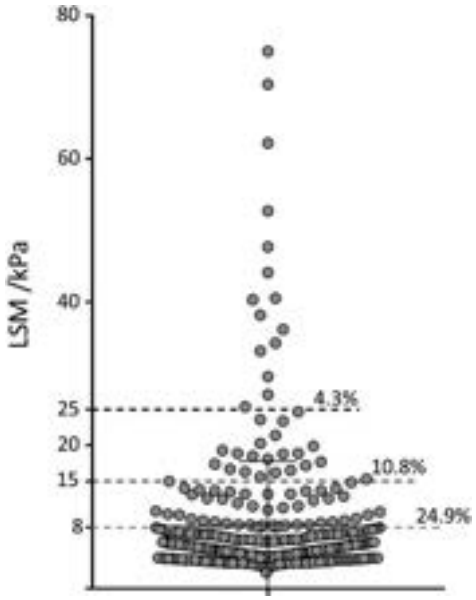

Figure 1: Distribution of LSM by Fibroscan of 344 clients assessed in Liver Health Check Clinics across 9 community drug and alcohol services. The percentage figure gives the proportions of those with a median kPa above the value shown by the dotted line

Conclusion: Although there is a substantial non-attendance rate in LHCC, these slots can be readily filled by walk-in clients. Subsequent engagement in follow-up ultrasound has been high. 11% of clients have an LSM with a high predictive value for cirrhosis and may benefit from long-term HCC surveillance. A significant minority have evidence of clinically significant portal hypertension requiring varices assessment and/or prophylactic beta blockade. The impact of LHCC assessment and feedback on harmful alcohol use and repeat LSM will be assessed prospectively.

FRI-451

Detrimental association between COVID-19 pandemic stages and alcoholic hepatitis admissions: a Canadian population-based study

Abdel-Aziz Shaheen[1], Mark G. Swain[1], Mayur Brahmania[1], Juan G. Abraldes[2]. [1]*University of Calgary, Canada;* [2]*University of Alberta, Canada*
Email: az.shaheen@ucalgary.ca

Background and aims: Increased alcohol sales during the COVID-19 pandemic restrictions have led to a significant increase of alcoholic hepatitis (AH) admissions in Alberta early in the pandemic. We aimed to evaluate the impact of the COVID-19 pandemic on hospitalizations in patients with AH in Alberta, Canada.
Method: We used the definition of the National Institute of Alcohol Abuse and Alcoholism (NIAAA) to identify patients admitted with AH in the province of Alberta between March 2018 and March 2022. We divided admissions into three stages: pre-pandemic (March 2018–March 2020), first year of the pandemic (April 2020–March 2021), and second year of the pandemic (April 2021–March 2022). We calculated AH hospitalization monthly rates compared to overall hospitalizations. We compared demographic and clinical characteristics of AH admissions between the three pandemic stages.
Results: We identified 1,413 hospitalizations for AH (552 pre-pandemic, 462 during the first year, and 399 during the second year of the pandemic). Women admissions were similar during these stages (40.2%, 39.8%, and 45.1%, respectively, p = 0.22). AH admissions were more likely in younger patients (median age: 48, 44, and 44 years old, respectively, p < 0.001) and those living in rural areas (22.5%, 39.2%, and 31.8%, respectively, p < 0.001). Average MELD-Na was similar between the three stages (24, 25, and 25, respectively, p = 0.39). The hospitalization rates significantly increased during the first year of the pandemic (133/100,000 hospitalizations) and second year of the pandemic (102/100,000), compared to pre-pandemic (65/100,000) p < 0.001, Figure 1.

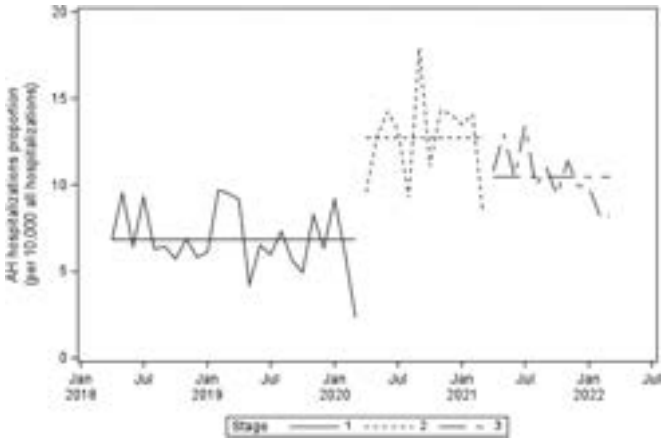

Figure: Monthly AH Hospitalization Rates to All-Hospitalizations Between 2018 and 2022 According to the Pandemic Stage

Conclusion: Since the beginning of the COVID-19 pandemic, AH admissions have particularly involved younger patients living in rural areas. Furthermore, admissions for AH peaked during the first year of the pandemic but remained elevated during the second year compared to pre-pandemic rates.

FRI-452

Cardiovascular events in patients with alcohol-related liver disease and the prognostic value of endotrophin assessed by PRO-C6

Ida Ziegler Spedtsberg[1,2], Ida Villesen[1], Stine Johansen[1,2], Johanne Kragh Hansen[1,2], Katrine Prier Lindvig[1,2], Peter Andersen[1], Nikolaj Torp[1,2], Mads Israelsen[1], Camilla Dalby Hansen[1,2], Katrine Thorhauge[1,2], Katrine Bech[1], Emil Deleuran Hansen[1,2], Sönke Detlefsen[2,3], Diana Leeming[4], Morten Karsdal[4], Aleksander Krag[1,2], Maja Thiele[1,2]. [1]*Odense University Hospital, Department of Gastroenterology and Hepatology, Odense, Denmark;* [2]*University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Odense, Denmark;* [3]*Odense University Hospital, Department of Pathology, Odense, Denmark;* [4]*Nordic Bioscience A/S, Herlev, Denmark*
Email: ida.katharina.ziegler.spedtsberg@rsyd.dk

Background and aims: Patients with alcohol-related liver disease (ALD) are at high risk of developing cardiovascular disease (CVD), however there is a lack of accurate biomarkers prognostic for cardiovascular events. Hence, a prognostic biomarker for early identification and risk stratification among these patients is needed. Fibrosis accumulation is a key pathophysiological process in both liver disease and CVD and can be measured by collagen formation. PRO-C3, a measure of type III collagen formation, strongly predicts fibrosis stage and risk of liver-related events in ALD patients. In contrast, PRO-C6, a type VI collagen formation marker, known as endotrophin, has been suggested to be a marker of cardiovascular events in patients with heart failure. However, the correlation between PRO-C6 and CVD events within ALD is not known. We, therefore, investigated the incidence of CVD in a cohort of ALD patients, and the prognostic value of PRO-C6.
Method: A prospective study of 459 patients with early, biopsy-proven ALD was collected. We obtained data on CVD, liver-related events, and all-cause mortality from patients' electronic medical records. At inclusion, PRO-C6, PRO-C3, and fibrosis stage by histology, along with a general panel of liver function tests were obtained. The following events defined CVD: coronary heart disease, cerebrovascular disease, peripheral arterial disease, hypertension, deep vein thrombosis, and pulmonary embolism. The risk of CVD according to liver fibrosis severity was evaluated using cumulative incidences and competing risk multivariable regression with all-cause mortality as competing risk. Furthermore, we evaluated the prognostic value of PRO-C6 on new CVD events.
Results: Included patients covered the full disease spectrum of ALD (F0-1/2/3-4 = 55.3%/22.8%/21.6%) and were followed for a median of 4.4 years (IQR 2.8–6.2). Patients in the CVD group were older; 61.5 ± 8.6 vs 55.5 ± 10.5, p = <0.001). Liver fibrosis stage, body mass index, and liver biochemistry did not differ between CVD vs. no-CVD patients. In total, 73 patients (15.9%) developed at least one CVD event during the follow-up period. Baseline PRO-C6 were significantly higher in patients who developed a CVD event as compared to patients who did not: 10.0 ng/ml (IQR 8.4–14.6) vs 9.2 ng/ml (IQR 7.2–12.7), p = 0.05. PRO-C3 did not differ between the two groups: 15.1 ng/ml (IQR 10.9–21.6) vs. 12.9 ng/ml (IQR 9.6–21.0), p = 0.19. A competing risk multivariable regression, with all-cause mortality as a competing risk, showed no correlation between CVD incidence and fibrosis stages. Furthermore, PRO-C6 did not show prognostic correlation with the development of a CVD event in the multivariable analysis.

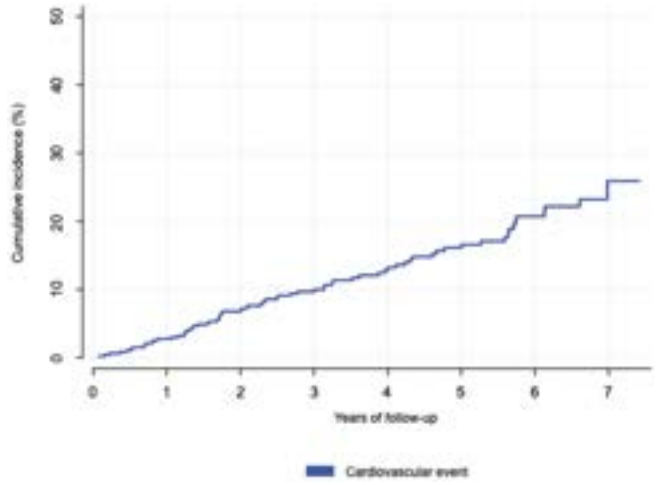

Figure:

Conclusion: ALD patients showed a marked risk of developing CVD. While those who developed CVD had a significantly higher PRO-C6 at baseline, PRO-C6 did not show good prognostic accuracy in the current population.

Bariatric surgery in alcohol dependence and alcohol-related liver disease

Thomas Williams[1,2], Andrew Palmer[1,2,3], Gerald Holtmann[1,2], Jason Connor[2,3], Paul Clark[1,2,3]. [1]*Princess Alexandra Hospital, Department of Gastroenterology and Hepatology, Brisbane, Australia;* [2]*University of Queensland, School of Medicine, Brisbane, Australia;* [3]*Princess Alexandra Hospital, Alcohol and Drug Assessment Unit, Brisbane, Australia*
Email: thomasjwilliams42@gmail.com

Background and aims: Increased risk of alcohol dependence (AD) is recognised following bariatric surgery. Altered gastrointestinal anatomy and alcohol metabolism leads to more rapid increases and higher peaks of blood alcohol concentration. Such changes may enhance reward circuits, reinforcing alcohol ingestion and tolerance. Interactions of AD on liver disease has not been well-characterised using validated measures. We aimed to assess changes in AD and liver fibrosis, using validated tools, following bariatric surgery in patients reviewed within our quaternary Alcohol and Drug Assessment Unit (ADAU).
Method: Treatment seeking patients attending the ADAU with prior sleeve gastrectomy (SG) or Roux-en-Y gastric bypass (RYGB) were retrospectively identified. Patient demographics, comorbidities and surgical details were collected. Validated measures of AD, including Alcohol Use Disorders Identification Test (AUDIT) and brief Michigan Alcohol Screening Test (bMAST), were assessed pre- and post-surgery. FIB4 and APRI non-invasively assessed liver fibrosis before and after surgery.
Results: 20 patients with SG and 10 with RYGB were identified. Mean age at review was 49.0 years with 73.3% female. Mean reduction in body mass index (BMI) post-surgery was 14.5 ± SD 9.2 ($d = 1.5$, $p < 0.001$). Metabolic comorbidities were less frequent following surgery. Overall, mean AUDIT scores were low pre-operatively (10.2, SD 8.9), though 9 patients met criteria for AD (AUDIT score ≥13 in females, ≥15 in males). Mean AUDIT increased significantly post-surgery (18.1, SD 11.6; $d = 1.6$, $p < 0.001$). Interestingly, 29 patients met criteria for AD post-operatively. In those with pre-operative dependent-level AUDIT scores (mean AUDIT 22.5, SD 5.2), the mean AUDIT increased by 8.4 ($p < 0.05$). Patients with low risk AUDIT scores before surgery (mean 4.9, SD 2.6), observed more marked increases in mean AUDIT score post-surgery (mean change in AUDIT 26.8, $p < 0.001$). Changes in bMAST post-operatively reflected the AUDIT. Despite lower metabolic risk after surgery, mean FIB4 increased (mean change 0.98, SD 1.8; $d = 0.5$, $p = 0.003$). The mean increase in APRI score was 0.41 ± SD 0.83 ($d = 0.49$, $p = 0.006$).
Conclusion: Post-bariatric surgery, significant increases in AD were observed in patients seeking treatment. While validated scores of dependence worsened in those with likely unrecognised AD, larger increases in dependent-level AUDIT score occurred in those with low pre-operative AUDIT-screened risk. Liver fibrosis scores increased for many despite reduction in metabolic risk factors, suggesting an alternate driver of disease progression. This suggests *de novo* AD may be important in explaining poor liver outcomes for some after surgery. Our work supports more intensive assessment and possibly lower thresholds of risk screening for AD and liver disease pre-bariatric surgery.

FRI-454

Risk factors for acute myocardial infarction in patients with alcohol-related liver cirrhosis-a nationwide register-based nested case-control study

Emma Celia Herting[1], Konstantin Kazankov[1], Peter Jepsen[1]. [1]*Aarhus University Hospital, Hepatology and Gastroenterology, Aarhus, Denmark*
Email: ec.herting@gmail.com

Background and aims: Alcohol-related cirrhosis (ALD cirrhosis) predisposes patients to bleeding as well as to thrombosis. Its effect on acute myocardial infarction (MI) is weaker than its effect on other arterial or venous thromboses, and the reasons for this pattern are unclear. The aim of this study was to describe risk factors of MI amongst patients with ALD cirrhosis.
Method: This nationwide register-based nested case-control study included all Danish patients diagnosed with ALD cirrhosis in 2000–2019. Patients with first-time MI after the diagnosis of ALD cirrhosis were identified as cases. Per case, 10 ALD cirrhosis patients with no history of MI were selected as controls, using risk-set sampling. Controls were matched on time since cirrhosis diagnosis and calendar year. We used conditional logistic regression to study the association between risk factors and incidence rate ratio (IRR) of MI. Risk factors included gender, age, comorbidities, and events occurring less than 30 days before MI.
Results: 373 cases with MI were included and matched with 3, 730 controls. The median age was 59.0 years in cases and 56.0 years in controls. 76.4% of cases and 65.2% of controls were male (adjusted IRR 1.65 [95% CI 1.27–2.15]). We identified the following risk factors for MI: history of atherosclerosis (26.5% of cases versus 11.0% of controls, aIRR 1.93 [95% CI 1.43–2.61]), history of cardiac ischemia (23.1% of cases versus 3.1% of controls, aIRR 6.99 [95% CI 4.93–9.90]), hospitalization for infection (aIRR 2.09 [95% CI 1.27–3.43]), recent surgery (aIRR 1.83 [95% CI 1.19–2.82]) or recent out-of-hospital treatment with antibiotics (aIRR 1.46 [95% CI 1.00–2.75]).

Figure: Associations between potential risk factors and incidence rate ratio of acute myocardial infarction

	Crude IRR	95% CI	Adjusted IRR	95% CI
Male	1.72	1.35–2.21	1.65	1.27–2.15
Age, pr year	1.04	1.03–1.06	1.03	1.02–1.04
Events in the previous 30 days				
Hospitalization of infection	2.69	1.74–4.15	2.09	1.27–3.43
Hospitalization of complication of liver disease				
Ascites	1.39	0.86–2.26	1.18	0.69–2.00
Spontaneous bacterial peritonitis	2.00	0.23–17.12	1.12	0.12–10.50
Gastrointestinal bleeding	2.11	1.18–3.75	1.42	0.74–2.75
Prescribed Antibiotics	1.83	1.30–2.58	1.46	1.00–2.14
Surgery	2.95	2.02–4.31	1.83	1.19–2.82
Comorbidities				
Atherosclerosis	3.12	2.40–4.06	1.93	1.43–2.61
Cardiac ischemia	10.58	7.62–14.68	6.99	4.93–9.90
Chronic obstructive pulmonary disease	2.89	2.13–3.92	2.20	1.58–3.08
Diabetes	1.67	1.29–2.16	1.15	0.86–1.55

Conclusion: Among patients the ALD cirrhosis, the incidence rate of MI was higher for those who had history of atherosclerosis or cardiac ischemia, were hospitalized because of infection, had surgery, or received antibiotics treatment in the community in the previous 30 days. Our findings contribute to the understanding of risk factors for MI in patients with ALD cirrhosis. They may have clinical implications e.g., for the decision to offer thromboprophylaxis.

FRI-455

Opportunistic cirrhosis casefinding in alcohol dependent inpatients through alcohol specialist nurse assessment and transient elastography: early detection in a high risk group

Ann Archer[1,2], Molly Thorpe[1], Saswata Roy[1], Charlotte E. Davies[1], Rosie Parnham[1], Grace Cameron[1], Lucy Krouma[1], Fiona Gordon[1], Kushala Abeysekera[1,2]. [1]*University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, UK, Liver Medicine, Bristol, United Kingdom;* [2]*University of Bristol, Population Health Science, Bristol, United Kingdom*
Email: ann.archer@uhbw.nhs.uk

Background and aims: Europe has the highest per capita alcohol consumption and alcohol-related loss of disability adjusted life years compared with other WHO regions, with many countries seeing a rapid rise in alcohol related harms. Despite this, there is still widespread failure to recognise alcohol-related liver disease early before patients present with decompensation. Many patients with alcohol use disorder present frequently with unscheduled admissions to hospital, providing an opportunity for engagement with addiction and hepatology services. We sought to evaluate opportunistic testing for cirrhosis in this vulnerable patient group who often experience barriers to accessing healthcare.

Method: Our transient elastography (TE)-trained alcohol specialist nurses (ASNs) offered TE to patients with alcohol dependence and no previous diagnosis of cirrhosis. Those with elevated liver stiffness measurements (LSM) of ≥12 kPa were offered follow-up in hepatology clinic or assessed during their admission by a hepatologist. Paired t-test was used to assess mean differences between groups pre- and post- intervention.

Results: Between April and December 2022, 94 patients at the Bristol Royal Infirmary, UK were offered TE during emergency admissions by ASNs (23% F; median age 55 (IQR 18.5)). 27 people (30.8%) with LSM of ≥12 kPa (median IQR/M 11.5%) were identified as having probable alcohol related cirrhosis. Of these, 9 had LSM ≥25 kPa suggestive of clinically significant portal hypertension (CSPH). 27% (n = 25/94) of patients post-TE subsequently engaged with outpatient addiction services. Of those who had recorded alcohol consumption (n = 38/94), a trend towards lower units consumed post ASN review and TE assessment was observed; pre admission mean alcohol consumption was 31 units/day (SD: 25.8) falling to 20.5 units/day (SD: 25; t (37) = 3.2; p = 0.003) post admission. Of the 94 patients screened, 4 patients died within the nine month period, 2 of whom had been identified with cirrhosis.

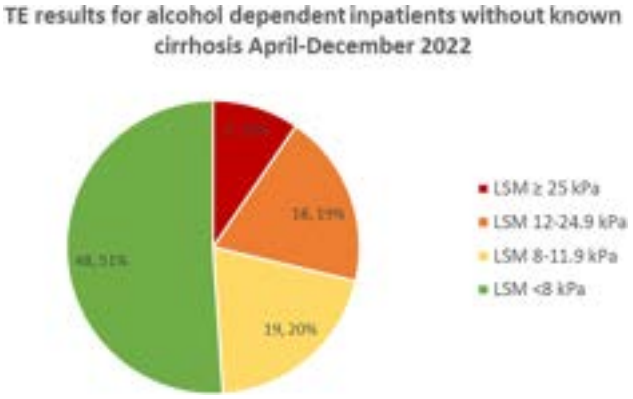

Figure:

Conclusion: Opportunistic testing for liver disease in people with alcohol use disorder is important and high yield to identify patients with cirrhosis and clinically significant portal hypertension. Crucially this is a socially disadvantaged patient cohort who experience barriers to accessing traditional healthcare. Prospective work is needed to establish whether diagnosis has a lasting impact on drinking behavior, engagement with addiction services, liver related morbidity and mortality.

FRI-456

Potential gut microbial biomarkers for detection of sarcopenia in alcohol-related liver disease patients

Haripriya Gupta[1], Sang Joon Yoon[2], Jin-Ju Jeong[2], Satya Priya Sharma[2], Raja Ganesan[2], Sung-Min Won[2], Ki Tae Suk[2,3]. [1]*Hallym University, Institute for Liver and Digestive Diseases, Korea, Rep. of South;* [2]*Institute for Liver and Digestive Diseases, Hallym University, Korea, Rep. of South;* [3]*Institute for Liver and Digestive Diseases, Hallym University College of Medicine, Department of Internal Medicine, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Sarcopenia and alcohol-related liver disease (ALD) are closely related. Not only the liver, but excessive intake of alcohol also increases the catabolism of proteins under stress and inflammation conditions affecting function of skeletal muscles. Gut dysbiosis is thoroughly studied in ALD, however gut dysbiosis under sarcopenia condition in ALD is not well known. So, we aim to determine predictors of sarcopenia using gut microbiota and correlation with the sarcopenia indices in patients with ALD with or without sarcopenia.

Method: Total 177 subjects (healthy control (HC), sarcopenia control (SC) and ALD patients) were enrolled for this study. ALD patients were further categorized under non-sarcopenia (HC, n = 48 and ALD, n = 68) and sarcopenia groups (SC, n = 11 and S-ALD, n = 50) according to the appendicular skeletal mass (ASM) divided by height (meter) squared index. Liver function test, sarcopenia indices were performed, and stool microbiome analysis by 16S rRNA-based sequencing were examined through EzBioCloud Database.

Results: Analysis of variance of sarcopenia indices (subcutaneous, visceral, and appendicular skeletal muscle, ASM/Ht2 index) between the four groups (HC, SC, ALD and S-ALD) revealed significant decreased in S-ALD vs ALD group ($p < 0.01$). In gut microbiome analysis revealed significant shifts in the gut microbiome in sarcopenia group vs non-sarcopenia groups in ALD. Relative abundance of phylum *Bacteroides* and *Proteobacteria* was found to significantly decrease ($p < 0.001$) and increase ($p < 0.05$) respectively in S-ALD vs ALD group. Species *Phocaeicola dorei*, *Phocaeicola*

vulgatus, *Escherichia coli* and *Pantoea agglomerans* were found to be distinctive abundant in S-ALD group vs ALD group with LDA score >2 and AUC >0.60 (p < 0.001 and q < 0.05). Correlating all the four groups together, the aforementioned 4 species were shown to be significantly correlated with sarcopenia indices (p < 0.05).

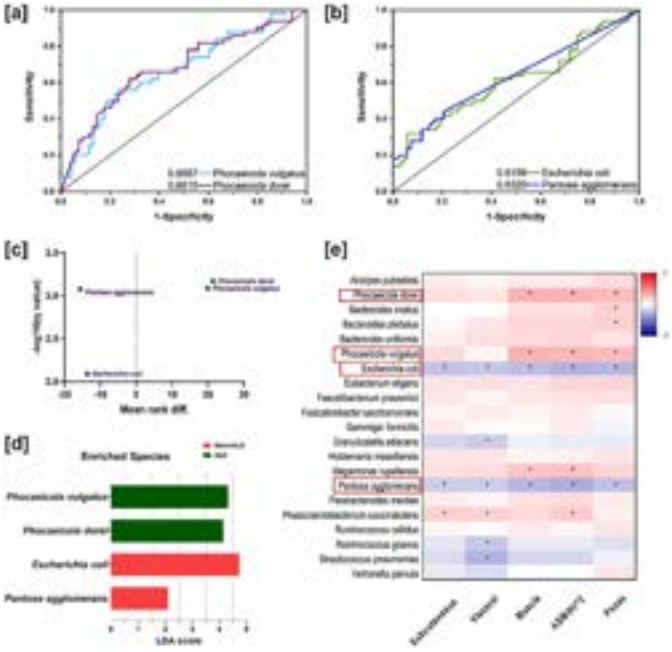

Figure: Identified distinctive gut microbiota in S-ALD vs ALD patients. (a) and (b) AUROC curves, (c) False Discovery Rate, (d) LDA score and (e) Spearman's rank correlation between identified distinctive gut microbiota and sarcopenia indices.

Conclusion: These findings provide preliminary data that *Bacteroides* abundance is severely impacted causing known pathobiont from *Proteobacteria* to grow in abundance. Aiming *Bacteroides* to *Proteobacteria* ratio might be beneficial for the ALD patients having sarcopenia complication which may improve quality of life.

FRI-457

Validation of the Lille 4 score on a cohort of romanian severe alcoholic hepatitis patients

Bumbu Andreea Livia[1], Adelina Horhat[2], Mina Ignat[3], Horia Stefanescu[4], Bogdan Procopet[2,3]. [1]*Iuliu Haţieganu University of Medicine and Pharmacy, Gastroenterology, Cluj-Napoca, Romania;* [2]*University of Medicine and Pharmacy, Cluj Napoca, Romania;* [3]*Regional Institute of Gastroenterology and Hepatology, Cluj Napoca, Romania;* [4]*Regional Institute of Gastroenterology and Hepatology, Liver Unit and Clinical Ultrasound Department, Cluj Napoca, Romania*
Email: andreea_bumbu@yahoo.com

Background and aims: Severe alcoholic hepatitis (sAH) has a high mortality rate. Corticoids are the only pharmacological means to improve short term survival, though burdened by their side effects. We aimed to validate the Lille 4 score on a population of sAH from our center in Cluj-Napoca, Romania.

Method: We enrolled 103 consecutive patients with a clinical suspicion of sAH (Maddrey DF>32). All patients underwent transjugular liver biopsy. The indication of prednisone was based on histological criteria, i.e. AHHS>6. The Lille 4 and Lille 7 scores were calculated and the correlation between these and the short (1 month) and medium/long term survival was analysed. Secondly, we analysed the benefit of subdividing the cut-off values into the intervals proposed by Mathurin *et al* in 2011- complete responders (Lille score ≤0.16), partial responders (Lille score 0.16–0.56) and null responders (Lille score ≥0.56).

Results: The bivariate analysis showed a high correlation between the responders at day 4 (Lille <0.45) and the ones at day 7 (Pearson coefficient 0.766, p < 0.001) and a very high correlation between the responders at day 7 and the ones at day 4 (Pearson coefficient 1, p < 0.001), respectively.
In the Lille 7 responder group, 12 patients (11.6%) died in the first month (p = 0.047), while in the Lille 4 responder group, 8 patients (7.7%) died in the first month (p = 0.041). The analysis of the Lille subgroups showed that out of 103 patients, 43 (41.74%) were situated in the complete responder group (Lille score ≤0.16), 39 (37.86%) in the partial responders group (Lille score 0.16–0.56) and 21 (20.38%) in the null responders group (Lille score ≥0.56), respectively. The mean survival of complete responders was 19.3 months (14.4–24.2; 95% CI), of partial responders was 18.6 months (12.6–24.7; 95% CI) and of null responders was 2.2 months (0.5–4.0; 95% CI) (Figure).

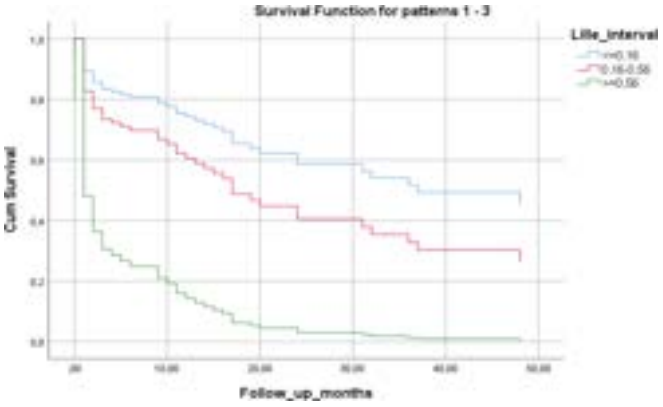

Figure:

Conclusion: The Lille 4 score is a good substitute for Lille 7, and it's validation has the potential to lower the infectious and bleeding events rate. The responder status correlates with the short term survival, but doesn't influence the long term. The subdivision into the proposed intervals highlights a group of patients-the partial responders- that have a similar survival to the complete responders. The null responders have a significantly lower survival.

FRI-458

Evaluation of histological differences between cirrhosis due to alcoholic-related liver disease and non-alcoholic steatohepatitis using automated fibrosis phenotyping of liver histology

Masanori Fukushima[1], Hisamitsu Miyaaki[1], Yasuhiko Nakao[1], Ryu Sasaki[1], Satoshi Miuma[1], Shinji Okano[2], Kazuhiko Nakao[1]. [1]*Nagasaki University Graduate School of Biomedical Sciences, Department of Gastroenterology and Hepatology, Japan;* [2]*Nagasaki University Graduate School of Biomedical Sciences, Department of Pathology, Japan*
Email: ma-fukushima@nagasaki-u.ac.jp

Background and aims: Cirrhosis due to alcoholic-related liver disease (ALD) and non-alcoholic steatohepatitis (NASH) are different diseases with similar histopathology, and histological discrimination can be difficult. Although the distinction between ALD and NASH is defined by the amount of alcohol consumed, there is no sufficient consensus because of individual differences in the effects of alcohol. Therefore, it is desirable to establish new diagnostic criteria to objectively diagnose ALD and NASH. In recent years, digital analysis of pathology has become possible with whole slide imaging systems, which can convert pathology specimens into high-resolution digital images, enabling comprehensive quantitative analysis of pathological parameters using AI. The purpose of this study was to find histological differences between ALD and NASH by analysing more than 300 histological fibrosis phenotypic features.

Method: Thirty-six patients with cirrhosis due to ALD and 17 patients with cirrhosis due to NASH who underwent liver transplantation at Nagasaki University Hospital between January 2000 and December 2020 were included. Tissues of recipient-extracted livers were stained with SiriusRed and imported for digital pathology imaging. The FibroNest™ quantitative digital pathology platform (PharmaNest, Princeton, NJ, USA) was used to quantify the histological phenotype of fibrosis, including collagen amount and structure (12 traits), morphometric traits of the collagen fibres (13 traits), and architecture of fibrosis (7 traits). Each traits considers mean, variance, skewness, kurtosis and progression, for a total of over 300 parameters to compare differences in histological features between ASH and NASH.
Results: The 36 patients with ALD and 17 patients with NASH did not differ in terms of age, BMI, MELD score, or serum hyaluronic acid level. There were significantly more males in the ALD group. Analysis using FibroNest showed no significant differences in collagen amount, structure, and architecture of fibrosis between the two groups. However, morphometric traits of the collagen fibres were significantly different between the two groups. As for morphological traits, the NASH group was characterized by assembled collagen, which defined a complex skeleton with a high number of nodes and branches, were short in length, thin, and small in area. On the other hand, the ALD group had significantly more fine collagen than the NASH group. Using the Phenotypic Fibrosis Composite score (Ph-FCS) created from 350 quantitative fibrosis traits normalized to their maximum value in the group and then averaged, a diagnosis of ALD/NASH was possible with a sensitivity of 86% and specificity of 94% when the cut-off value was set at 4.35 (Figure).

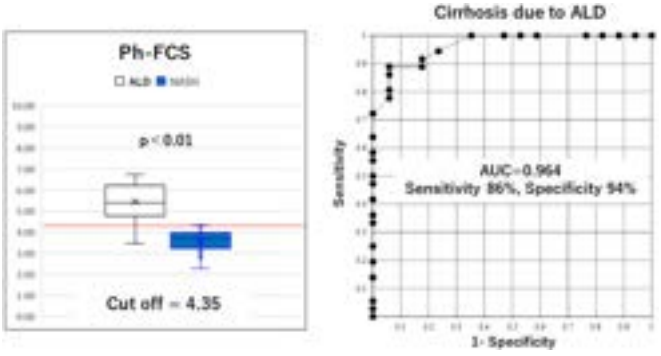

Figure:

Conclusion: The analysis of fibrosis patterns by digital pathology suggested the possibility of discriminating the histological diagnosis of ALD/NASH by differences in fibrosis morphology.

FRI-459

Radiomic data can define phenotypes of acute alcoholic hepatitis

Nawaz Safdar[1], Amy Hicks[2], Yun Chew[2], Craig Roe[3], Sabina Choudhry[4], Ashwani Singal[5], Richard Parker[2]. *[1]University of Leeds, School of Medicine, Leeds, United Kingdom; [2]Leeds Teaching Hospital Trust, Leeds Liver Unit, Leeds, United Kingdom; [3]Leeds Teaching Hospital Trust, Radiology, United Kingdom; [4]Avera Medical Grop, Radiology, Sioux Falls, United States; [5]University of South Dakota, Sioux Falls, United States*
Email: richardparker@nhs.net

Background and aims: Alcohol associated-hepatitis (AAH) is an acute manifestation of alcohol-related liver disease with a 90-day mortality of ~30%. This study aimed to identify phenotypes of AAH based on radiological measures of hepatic volume and steatosis.
Method: Consecutive patients with a clinical diagnosis of AAH based on the NIAAA definition who had undergone computed tomography (CT) imaging of the abdomen within 10 days of admission were included. AAH phenotypes were defined using hepatic steatosis (HS), calculated using a liver/spleen attenuation ratio, and adjusted liver volume (aLV) calculated as a ratio of observed: predicted liver volume using the formula published by Vauthey et al (2002). Radiological anthropometric data were collected using Hepatic VCAR (GE HealthCare, UK) and Vitrea (Canon, USA), and biochemical data were collected from electronic health records. Patients were assigned to three distinct phenotypes: small non-fatty (SNF), intermediate, and large fatty (LF) based on tertiles for HS and aLV (Figure 1). No specific study procedures were performed, and individual patient consent was not sought. All analyses were performed using R.

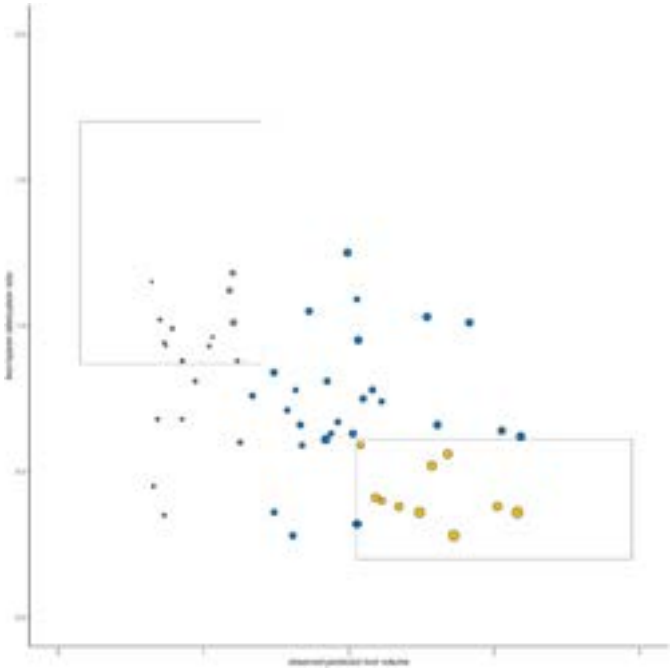

Figure:

Results: Fifty-six patients were included. The median patient age was 47 (IQR 41–53), of whom 62% were male. Twelve patients (21%) were categorised as having SNF livers, and 10 (18%) categorised as having LF livers. Thirty-four (61%) of patients had an intermediate phenotype. LV and HS varied considerably: SNF [LV: 1582 (1406–2086) cm^3 and HS: 1.00 (0.94–1.13)], and LF [LV: 5112 (4564–6744) cm^3 and HS: 0.39 (0.37–0.49)]. Patients with LF livers had significantly lower international normalised ratio (INR; 1.3 vs. 1.6 vs. 2.1 in LF vs. intermediate vs. SNF, respectively, ANOVA $p < 0.001$), significantly higher bilirubin (350 vs. 171 vs. 156 mmol/L in LF vs. intermediate vs. SNF respectively, ANOVA $p = 0.02$), and tended to have higher ALT, although this was not statistically significant (88 vs. 46 vs. 34 IU/ml in LF vs. intermediate vs. SNF, respectively). Overall survival was 73.2% at 90 days. Compared to the intermediate phenotype, both extremes of size and fat had worse mortality at 90 days: 40% and 33% in LF and SNF respectively vs. 21% in intermediate; this was not statistically significant (Log-rank $p = 0.31$). Infection was common and occurred more frequently in patients with LF livers: 75% of patients suffered infection vs. 52% and 26% in intermediate and SNF livers, respectively. Only a minority of patients received corticosteroids in this retrospective cohort, but response to treatment (Lille score <0.45) was seen only with LF livers and not with other phenotypes.
Conclusion: Liver volume and steatosis assessed by CT varied significantly between patients admitted to hospital with acute AAH and were associated with clinical findings. A larger cohort is required to further investigate these findings.

FRI-460

New patient referrals and alcohol consumption data in an Irish hepatology outpatient setting

Aoife Moriarty[1], Paul Armstrong[1], Caroline Walsh[1], Jennifer Russell[1], Eleanor Ryan[1], Stephen Stewart[1]. [1]*Mater Misericordiae University Hospital, The Liver Centre, Dublin, Ireland*
Email: aoifemoriarty@eril.ie

Background and aims: New patient referrals to specialist hepatology clinics are increasing. Alcohol remains a common problem for Irish healthcare. Concentrated efforts are required to establish which patients referred can be managed in primary care, thus improving specialist access for more complex cases. The aims of this prospective study were to evaluate new referrals to hepatology clinic in MMUH and to assess the impact of a hepatology nurse specialist. We also aimed to evaluate patterns of alcohol consumption in these new referrals and the correlation with phosphatidylethanol levels (PEth) testing.

Method: New patients to clinic were reviewed by a hepatology nurse specialist. A questionnaire was completed including referral details, basic demographics and alcohol consumption data. Bloods including PEth and transient elastography (TE) were performed. Following review by a consultant hepatologist, patients with alcohol or non-alcohol related steatosis with low TE scores (<6kPa) were discharged to their GP with lifestyle advice.

Results: 380 new patients were reviewed over 7 months, 53.75% male with a mean age 50.69 years (±15.29). Mean BMI was 28.98 kg/m^2 (±6.77) with a median TE score of 6.9kPa (IQR 5.63), and median CAP of 263.58 (IQR 90). 69.5% of referrals were made from primary care. 29% of patients were discharged following review at nurse led clinic. There was a 6% DNA rate of these patients at the subsequent doctor led clinic. 67.4% of patients consumed alcohol. The majority (18.4%) consumed alcohol on 2–3 occasions/week, with 11% drinking daily. Beer was most frequently consumed (39.2%), with the majority of patients (47.5%) drinking at home. Patients were separated into 3 groups; non-drinkers (33.68%), low risk drinkers (35%) and hazardous drinkers (31.32%), which was defined as >11units/week for females and >17units/week for males. Hazardous drinkers had statistically significantly higher PEth levels than non-drinkers and low risk drinkers (Kruskall Wallis $p < 0.05$) but no difference was observed in TE kPa, CAP or BMI. A strong correlation was observed between documented units of alcohol consumed and PEth levels (0.805 Spearman's rho $p < 0.001$). 2.1% of patients who reported never consuming alcohol had a positive PEth test, the majority (75%) at low levels (<50 ug/L).

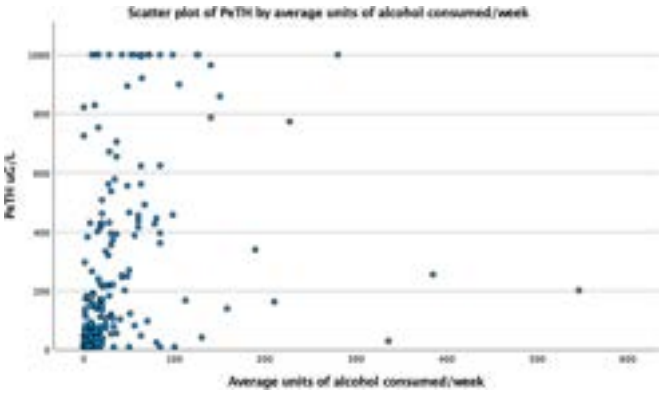

Figure:

Conclusion: Our study shows that the initial nurse led clinic is a useful adjunct in identifying which patients can be managed in a primary care setting after appropriate screening investigations, thus freeing up space in the doctor clinic to manage more advanced patients. Two thirds of our patients consume alcohol, with one third at hazardous levels with PEth testing being a useful tool in identifying these patients. Equally, in patients who report alcohol abstinence, their history is generally very reliable without the need for further confirmatory PEth testing.

FRI-461

Carbohydrate-deficient transferrin is a suitable drinking marker for patients with metabolic dysfunction-associated fatty liver disease

Kazuyoshi Kon[1], Maki Morinaga[1], Akira Uchiyama[1], Hiroo Fukada[1], Toshifumi Sato[1], Shunhei Yamashina[1], Kenichi Ikejima[1]. [1]*Juntendo University School of Medicine, Department of Gastroenterology, Japan*
Email: kazukon@juntendo.ac.jp

Background and aims: In 2020, an international expert group newly proposed the definition of metabolic dysfunction-associated fatty liver disease (MAFLD). MAFLD focuses on obesity and metabolic syndrome-related diseases, not exclude alcohol-related steatohepatitis; it is essential to objectively evaluate alcohol consumption as well as glycolipid metabolism in clinical practice. In this study, we examined the usefulness of measurement of carbohydrate-deficient transferrin/total transferrin ratio (%CDT) in patients with MAFLD.

Method: A total 121 patients who visited our hospital from September 2018 to November 2021 and were diagnosed with fatty-related liver disease, including alcohol-related liver disease and non-alcoholic fatty liver disease, were evaluated according to MAFLD diagnostic criteria of the International Consensus Panel. They were classified into a MAFLD group (n = 95) and a non-MAFLD group (n = 26). Controlled attenuation parameter (CAP) value of ≥220 dB/m was defined as fatty liver. ROC analysis was performed to evaluate the diagnostic usefulness of %CDT, mean corpuscular volume (MCV), and gamma-glutamyl transpeptidase (γGT) as drinking markers for non- to light-drinkers (<210 g/week for men, <140 g/week for women) and heavy drinking (≥420 g/week). In addition, we analyzed the effects of alcohol consumption, age, gender, hepatic enzymes, lipids, blood glucose levels, CAP levels, and liver stiffness on each marker by multiple regression analysis.

Results: In the MAFLD group, the diagnostic power of non- to light-drinking by %CDT was higher than AUROC 0.78 (cut-off 1.78%: sensitivity 73%, specificity 76%), which was higher than AUROC 0.71 in MCV and AUROC 0.69 in γGT. AUROC for %CDT was 0.78 (cut-off 2.08%: sensitivity 55%, specificity 88%), which was higher than 0.69 in AUROC for MCV or AUROC 0.66 in AUROC for γGT. Even in the non-MAFLD group, the %CDT value remained high AUROC values, 0.88 for non- to light- drinking detection and AUROC 0.83 for heavy drinking, whereas other markers tended to increase in the non-MAFLD group more markedly than in the MAFLD group. (MCV: non- to light-drinker 0.90, heavy drinker 0.81, γGT: non- to light-drinker 0.78, heavy drinker 0.74). In the multiple regression analysis, only alcohol consumption was an independent factor for %CDT in both the MAFLD and non-MAFLD groups. In contrast in γGT, alcohol consumption was not a significant factor in either the MAFLD group or the non-MAFLD group, and serum triglycerides levels were detected as significant factors in the non-MAFLD group, and AST and triglycerides levels were detected as significant factors in the MAFLD group.

Conclusion: Measurement of %CDT showed high AUROC values in the detection of non- to light- drinkers and heavy drinkers regardless of MAFLD or non-MAFLD. MCV and γGT values were affected by dyslipidemia and liver damage, and rather favorable AUROC values were shown in the non-MAFLD group. %CDT was shown to be a very useful marker for the objective evaluation of alcohol consumption in the diagnosis and treatment of MAFLD.

FRI-462

Early liver transplantation for acute alcoholic hepatitis In a spanish liver transplant center

Victoria Aguilera Sancho[1,2,3], Sonia García-García[3], Sarai Romero Moreno[3], María García Eliz[1,4], Isabel Conde[1,5], Javier del Hoyo[4], Carmen Castillo[6], Sagrario Gutierrez[6],

Marina Berenguer[1,2,5]. [1]*Instituto de Investigación Sanitaria La Fe de Valencia, Valencia, Spain;* [2]*University of Valencia, Spain;* [3]*La Fe University and Polytechnic Hospital, Hepatology and Liver Transplant Section, Valencia, Spain;* [4]*La Fe University and Polytechnic Hospital, Valencia, Spain;* [5]*La Fe University and Polytechnic Hospital, Hepatoloogy and Liver Transplant Section, Valencia, Spain;* [6]*La Fe University and Polytechnic Hospital, Social Work Department, Valencia, Spain*
Email: toyagui@hotmail.com

Background and aims: Liver Transplantation (LT) for acute alcoholic hepatitis (AAH) has become an accepted treatment for selected patients. However, the inclusion in the waiting list and access to LT remains limited in our country.
Aims: (i) To describe the number of patients admitted due to AAH during 2015–2021 divided in 3 temporal cohorts and (ii) to evaluate access to LT and reasons for not been included.
Method: Patients admitted due to AAH during 2015–2021 were recorded and divided in 3 temporal cohorts (1:2015–2017, 2:2018–2019, 3:2020–2021). The demographics, social features, NIAAA criteria and severity of AAH assessed by Maddrey and MELD were recorded. Access to LT and reasons for not being included were recorded.
Results: 61 patients were admitted during these years (NIAAA probable criteria in 87%). There was a trend towards higher admissions in last cohort (1:33%, 2:16% and 3:51%). Mean age was 55 years, 75% were men, 73% were from Spain and rest were from foreign countries. Only 25% were married. Social risk was moderate-high in 77% of patients. 61% had cirrhosis at admission, median MELD was 21 and Maddrey 43. Treatment with corticoids was indicated in 38 (62%) but only 31 received treatment and 17 patients were considered non-responders at 7 day (Lille score). 24 patients (non-responders to corticoids (n = 17) and those who did not received them (n = 7)), were evaluated as potential early LT candidates for AAH. Reasons for not been included in the waiting list were: addiction risk (n = 8), high social risk (n = 4), improvement in liver function (n = 4), contraindication due to medical condition (n = 5). Only 1 patient (1.6%) was included on the waiting list due to AAH but died before LT and 2 patients were included after 6 months of abstinence. 1, 3 and 5 year survival was 69, 44 and 41%. High social risk and non-maintained abstinence were associated with mortality.

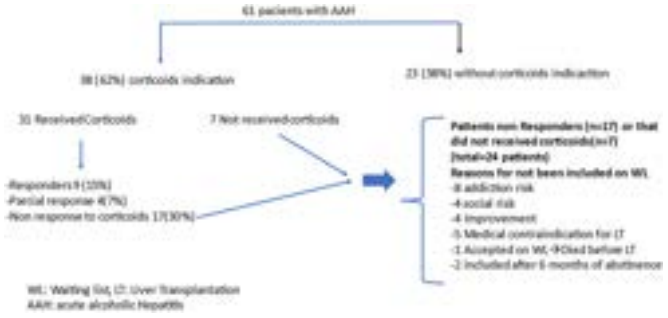

Figure:

Conclusion: Admissions due to AAH has increased during the las years, potentially related to COVID pandemia. Acces to LT is very limited (<2%) at our center, mainly due contraindiations related to social or addiction comorbidities. Both aspects should be managed intensively in order to improve the prognosis of those patients.

FRI-463

Identification of risk factors for alcohol relapse in liver transplant patients with alcohol-related liver disease

Dilara Turan[1], Fulya Günsar[2], Murat Harputluoglu[3], Gökhan Kabaçam[4], Hale Gokcan[5], Murat Akyildiz[6], Mesut Akarsu[7], Gupse Adali[8], Derya Ari[1], Ilker Turan[2], Nilay Danis[7], Ulus Akarca[2], Esra Durmazer[2], Genco Gencdal[6], Murat Aladag[3], Murat Taner Gulsen[9], Ozan Sarikaya[2], Volkan Yılmaz[5], Zeki Karasu[2], Ramazan Idilman[5], Meral Akdogan Kayhan[1]. [1]*Ankara Bilkent City Hospital, University of Health Science, Department of Gastroenterology and Hepatology, Turkey;* [2]*Ege University, School of Medicine, Department of Gastroenterology and Hepatology, Turkey;* [3]*Inonu University, School of Medicine, Department of Gastroenterology and Hepatology, Turkey;* [4]*Yuksek Ihtisas University, School of Medicine, Department of Gastroenterology and Hepatology, Turkey;* [5]*Ankara University, School of Medicine, Department of Gastroenterology and Hepatology, Turkey;* [6]*Koc University Hospital, School of Medicine, Department of Gastroenterology and Hepatology, Turkey;* [7]*Dokuz Eylül University, School of Medicine, Department of Gastroenterology and Hepatology, Turkey;* [8]*Umraniye Training and Research Hospital, University of Health Science, Department of Gastroenterology and Hepatology, Turkey;* [9]*Gaziantep University, School of Medicine, Department of Gastroenterology and Hepatology, Turkey*
Email: akdmeral@yahoo.com

Background and aims: Alcohol-related liver disease (ALD) is one of the most common causes of liver transplantation (LT). Although alcohol relapse after LT negatively impacts the graft and patient survival rates, predictors for alcohol relapse are not yet well defined. This study aimed to determine risk factors for alcohol relapse after LT.
Method: Patients with ALD who underwent LT from 9 different transplantation centres were assessed. Demographic and clinical features such as family support, alcohol consumption habits, educational level, whom the patient resided with, length of abstinence of alcohol before LT, marital status, age at transplantation, and smoking habits were evaluated and statistically analyzed. The chi-square test was used to evaluate categorical variables.
Results: A total of 124 patients with ALD, consisting of all males (100%) with and mean age of 52.9 ± 9.6 years, were recruited for evaluation of the alcohol relapse. The mean follow-up time was 65 ± 54.2 months (range: 6 months–238 months). The mean MELD-Na score before LT was 21.6 ± 5.7. Twenty and eight patients reported consumption of alcohol following LT: all patients began drinking alcohol within the first 5 years of the posttransplant period (mean relapse time: 18.5 ± 3.2 months). Most patients had heavy alcohol consumption (53%, >210 g/day). there was no relationship between alcohol relapse and being a heavy drinker (p = 0.254). While fifty patients (40%) did not adhere to the "6-month rule" of alcohol abstinence before LT, it was found that their rate of alcohol relapse did not statistically increase after LT (p = 0.405). Approximately 30% of the patients reported strict adherence to alcohol abstinence during Ramadan time. Remarkably, marital status was related to higher rates of posttransplant alcohol abstinence success (p = 0.010).

Table 1: Risk factors of alcohol relapse after LT evaluated in patients (n = 124)

n, (%)	Relapse (n = 28)	No Relapse (n = 96)	p value
Age <50 years at Tx	11 (39.2)	29 (30.2)	0.248
Married	16 (57.1)	77 (80.2)	0.010
Social support	19 (67.8)	78 (81.2)	0.060
Family history of alcohol use	15 (53.5)	51 (53.1)	0.340
Smoker	20 (71.4)	53 (55.2)	0.110
Pre-LT abstinence <6 months	10 (35.7)	39 (40.6)	0.405
Alcohol consumption during Ramadan (Yes)	5 (17.8)	32 (33.3)	0.102
Donor (Living Liver Donor)	19 (67.8)	64 (66.6)	0.550

Conclusion: In our study, being married was linked to a lower rate of relapsing back to drinking. There was no increase in the rate of relapsing back to drinking among patients who had transplants without following the 6-month rule. The results of this study indicated that multifactorial predictors strongly influenced post-transplantation alcohol consumption among patients. All patients

should be comprehensively assessed in regard to multiple factors to determine whether or not the patient is eligible for LT.

FRI-464

Costs of hospital management of acute alcoholic hepatitis

Lucy Turner[1], Richard Parker[1], Kath Chapman[2]. [1]*Leeds Teaching Hospital Trust, Leeds Liver Unit, Leeds, United Kingdom;* [2]*Leeds Teaching Hospital Trust, Finance, Leeds, United Kingdom*
Email: richardparker@nhs.net

Background and aims: Alcoholic hepatitis is an acute manifestation of alcohol related liver disease (ARLD) with a high short-term mortality. Patients with AH are often very unwell and require significant healthcare resources.
Method: We used the ALLHEAL observational study of patients with ARLD to derive the cost of admissions to hospital with AH or other types of liver disease for individual patients. The cause of admission was recorded as per hospital discharge coding using ICD-10 codes. Validation of coded diagnoses was done by reviewing hospital records and laboratory values. Costs are reported in pounds sterling (£) with Euro (€, 1 GBp = 1.12 EUR) and US dollar ($, 1 GBp = 1.22 USD) equivalent values. Hospital episode statistic (HES) reports for the NHS in England were used to estimate the costs of alcoholic hepatitis to the health service in England.
Results: Two hundred and sixteen patients recruited into ALLHEAL had a total of 2, 947 hospital admissions over a five year period including 124 (4%) due to primary diagnosis of AH, and a further 183 admissions (6%) had AH as a secondary diagnosis. The average cost of a primary admission with alcoholic hepatitis was £3,880 (SD 3369) (€4377, $4745). Secondary admissions with AH cost an average of £3461 (SD 2901), (€3904, $4232). The average costs of non-AH admissions with ARLD was £1,004. HES data showed that in 2021–22 there were 2749 primary admissions to hospital in England with AH and 10,022 secondary admissions, with a clear increase in both types of admission over the past decade. Scaling up ALLHEAL costs based on HES data showed that costs to the health service in England in 2021–22 were £10,666,120 for primary admissions and £34,686,142 for secondary admissions.
Conclusion: Hospital admissions with AH are expensive, costing on average three times as much as admissions with other diagnoses. The cost to the health service is considerable: based on the admissions in this series, we estimate that the NHS in England spent a total of nearly £45 million on caring for patients with AH in the last financial year. Better treatments are urgently required to address this significant burden to the healthcare system.

FRI-465

Adverse childhood experiences as a background for alcoholic liver disease-cohort analysis of risk score in ALD and non-ALD cirrhosis patients in comparison with the control group

Karolina Sulejova[1]. [1]*University Hospital F.D. Roosevelt Banska Bystrica, Department of Internal Medicine Div Hepatology, Gastroenterology and Liver Transplantation, Banska Bystrica, Slovakia*
Email: sulejovakarolina@gmail.com

Background and aims: The alcoholic liver disease represents the main cause of liver cirrhosis in the Slovak republic. An important position in the development of addiction has childhood trauma. Child abuse, neglect, and other traumatic experiences contribute to the development of risky patterns of behavior leading to the evolution of cirrhosis. The Adverse Childhood Experience Questionnaire is a rating scale evaluating the main risky domains for the development of addiction, and it could play as an indicator for cirrhosis development.
Method: In the following period, we evaluated adverse childhood experiences by the 10-item questionnaire in all patients enrolled in the local register of cirrhosis. The end point of this study was to assess the risk score for ALD and non-ALD groups in contrast with the cut-off value for the peril of addiction. According to the questionnaire, we tried to analyze the high-risk domain for the development of alcoholic liver disease. Finally, we compared the ACE risk score in ALD, non-ALD, and control groups, which were represented by university students.
Results: ACE score in a cohort of patients with alcohol cirrhosis reached 3,21 points (2,88-3,54 points). In comparison, the ACE score in non-ALD cirrhosis was 1,26 points, and in the cohort of university students 1,32 points. The main domains of ACE for ALD were sexual and physical abuse, alcohol addiction, and depression in the family.

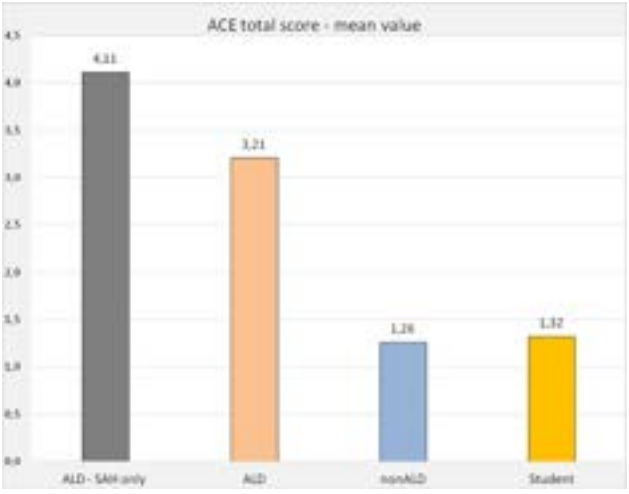

Figure:

Conclusion: The higher score in ACE-Q reflects grave childhood trauma which represents the risk for addiction and correlates with the prevalence of ALD-cirrhosis in our local register. We assume that a higher number of points from ACE-Q could predict the development of alcoholic hepatitis and alcoholic cirrhosis and simultaneously could be a useful predictive tool for recurrence of thy abuse after liver transplantation.

Cirrhosis and its complications ACLF and Critical illness

Evaluation of albumin and midodrine versus albumin alone in the outcome of refractory ascites in patients with decompensated cirrhosis: a randomized controlled trial (NCT04816240)

Rakhi Maiwall[1], Priti Jain[1], Shiv Kumar Sarin[1], Manoj Kumar[1], Deepak Tempe[1], Shalini Thapar[1], Anupam Kumar[1], Vijayraghavan Rajan[1], Prashant Agrawal[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: rakhi_2011@yahoo.co.in

Background and aims: Long term albumin has been recently shown to improve outcomes of uncomplicated ascites. Refractory ascites (RA) is a severe form of ascites wherein the hemodynamic alterations are further impaired and patients have marked vasodilatation and impaired renal perfusion. Midodrine acts on the alpha-adrenergic receptors, producing an increase in vascular tone and elevation of blood pressure. There are no studies on using combination of midodrine and albumin compared to albumin alone in improving liver related outcomes in RA. We studied efficacy of combining

midodrine with intravenous albumin (A-MIDO) versus albumin alone (A-PLAC) in 6-month mortality in RA.
Method: We conducted an open-label randomized controlled trial of 112 patients. A-MIDO group (55 patients) received albumin started at 80 gm/week for 2 weeks followed by 40 gm/week and midodrine started at 15 mg and increased up to 45 mg a day with target mean arterial pressure (MAP) of >75 and <90 mm Hg, while Group 2 (57 patients) received albumin and placebo. Competing risk survival analysis was performed with liver transplant (LT) and transjugular intrahepatic portosystemic shunt (TIPS) placement as competing events. Primary end point was survival free of LT and TIPS at 6 months and secondary end points were liver-related complications, impact on frailty and renal hemodynamics.
Results: Cirrhosis patients with RA [54 years age, 86.6% males, 48.2% alcohol] in both the groups were comparable at baseline; MELD Na [24.25 ± 5.85 vs. 25.95 ± 5.86; p = 0.13], MAP (mmHg) [72.18 ± 4.91 vs. 73.26 ± 5.51; p = 0.23], serum albumin (g/dL) [2.66 ± 0.39 vs. 2.69 ± 0.36; p = 0.53] and eGFR [79.68 ± 25.29 vs. 81.63 ± 26.51; p > 0.05]. Mean dosage of midodrine was 22.30 ± 5.15 mg at 6 months in A-MIDO. LT and TIPS free survival were significantly better in A-MIDO [74.5% vs 54.4%; p = 0.01]. On competing risk survival analysis, hazard ratio [2.29 (95% CI 1.09–4.48)]. Cumulative incidence of paracentesis induced circulatory dysfunction and therapeutic paracentesis were high in A-PLAC [20% vs. 35.1%; p = 0.07, 3.69 ± 1.90 vs. 5.16 ± 2.18; p = 0.00]. Liver related events were high in A-PLAC, hepatic encephalopathy [p = 0.01], acute variceal bleed [p = 0.04]. A significant decline in renal functions was seen in A-PLAC; hepatorenal syndrome (HRS)-acute kidney disease [18.2% vs. 7%; p = 0.07] while HRS-chronic kidney disease [10.9% vs. 26.3%; p = 0.03]. Similar results were observed in the per-protocol analysis.

Events in 6 months	A-MIDO	A-PLAC	p value
Number of hospitalizations (%)	35.1	60	0.03
MELD Na (mean ± SD)	20.92 ± 9.89	30.17 ± 10.09	0.00
Frailty index	1.91 ± 0.78	2.53 ± 0.57	0.00
Reintroduction of beta-blockers (%)	54.54	17.5	0.00
MAP at 6 months (mmHg)	77.47 ± 4.43	73.16 ± 5.18	0.00

Conclusion: The combination of Midodrine and albumin is better for LT and TIPS free survival and lesser liver related complications by improving hemodynamics and renal functions in RA.

Increased level of presepsin in patients with acutely decompensated cirrhosis predicts development of acute-on-chronic liver failure
Alberto Zanetto[1], Monica Mion[2], Alberto Ferrarese[3], Sarah Shalaby[1], Giacomo Germani[1], Martina Gambato[1], Francesco Paolo Russo[1], Fabio Farinati[1], Daniela Basso[2], Patrizia Burra[1], Marco Senzolo[1].
[1]Gastroenterology and Multivisceral Transplant Unit, Surgery, Oncology, and Gastroenterology, Padova University Hospital, Padova, Italy; [2]Laboratory Medicine, Padova University Hospital, Padova, Italy; [3]Unit of Gastroenterology, Borgo Trento University Hospital of Verona, Italy
Email: alberto.zanetto@yahoo.it

Background and aims: The clinical course of acutely decompensated cirrhosis (AD) is heterogeneous. Presepsin (PSP) is a soluble CD14-subtype biomarker that reflects Toll-like receptor activity as the immune response to endotoxemia and bacterial infections, and it has regulatory properties of the adaptive immune system. We conducted a prospective study to assess whether, in hospitalized patients with AD, plasmatic level of PSP could predict development of ACLF.
Method: Hospitalized patients with AD were prospectively recruited at admission and underwent determination of PSP (chemiluminescent immunoassay). All patients were then followed for 1 year, and predictors of ACLF were assessed by Cox regression analysis.
Results: 99 patients with AD were included (male; 66%; median age: 61 years; 65% had alcohol-related cirrhosis). The main reasons for AD were bacterial infections and alcoholic hepatitis (52% and 22%, respectively). Median MELD and CLIF-C AD scores were 18 and 54, respectively. Median PCP was 674 U/L (308–1700). Thirty-six patients developed ACLF (median time from inclusion to development of ACLF was 88 days). Baseline level of PSP was significantly higher in patients who experienced ACLF vs those who did not (1253 [670–2562] vs 375 [245–722], respectively; p < 0.0001). Among patients who didn't develop ACLF, PSP was comparable between those who were re-hospitalized due to cirrhosis complications and those who were not re-hospitalized (432 vs 355, respectively). Cox regression analysis demonstrated that PSP was independently associated with development of ACLF (Table). AUROC of PSP was good and comparable to that of CLIF-C AD score (0.78 vs 0.79, respectively). A PSP value >660 U/L had 77% sensitivity and 70% specificity for the development of ACLF. In a sub-analysis including patients at lower risk of ACLF (i.e. CLIF-C AD score ≤50 and Child B), PSP was significantly higher in those who developed ACLF than in those who did not (1054 vs 250, respectively).

Table. Variables associated with development of ACLF (Cox-regression analyses).

Variables	HR	95%CI	P value
Univariate			
CLIF-C AD score (>54)	4.8	2.3-10.1	<0.0001
Presepsin, ng/L (>674)	3.9	1.9-8.5	<0.0001
MELD score (>18)	3.1	1.5-6.0	0.002
Child class C vs B	5.7	2.4-13.7	<0.0001
C-reactive protein, mg/dL (>21)	3.4	1.6-7.1	0.001
Infection (YES/NO)	1.8	0.93-3.45	0.08
Hemoglobin, mg/dL	0.9	0.8-1.2	0.8
Multivariate model#1			
Presepsin, ng/L (>674)	2.7	1.2-5.9	0.01
CLIF-C AD score (>54)	2.4	1.1-5.5	0.03
C-reactive protein, mg/dL (>21)	1.6	0.7-3.5	0.2
Child class C vs B	2.9	1.2-7.4	0.02
Multivariate model#2			
Presepsin, ng/L (>674)	2.5	1.1-5.6	0.02
CLIF-C AD score (>54)	3.1	1.4-6.8	<0.01
C-reactive protein, mg/dL (>21)	1.6	0.7-3.5	0.2
MELD score (>18)	1.5	0.7-3.1	0.3
Multivariate model #3			
Infection (YES/NO)	1.2	0.6-2.6	0.4
Presepsin, ng/L (>674)	2.5	1.1-5.6	0.02
CLIF-C AD score (>54)	3.2	1.5-7.2	0.003
MELD score (>18)	1.6	0.7-3.5	0.2

Figure:

Conclusion: PSP can be a useful, single and independent biomarker to identify trajectories of AD, even in patients who would be considered at lower risk of ACLF, if this is confirmed in larger cohorts.

FRIDAY 23 JUNE

FRI-339
Disparities in hospital outcomes among patients with end- stage liver disease with palliative care collaboration: a nationwide cohort analysis (2016–2020)
Sheza Malik[1], Mohammed Faisaluddin[1], Jay Bapaye[1], Ali Jaan[1], Yasir Rajwana[2]. *[1]Rochester General Hospital, United States, [2]Stanford Medicine, United States*
Email: sheza.malik@rochesterregional.org

Background and aims: Despite the very high symptom burden, palliative care (PC) services are underutilized in patients with end-stage liver disease (ESLD). In addition, previous studies have shown that there are significant racial disparities in PC utilization for these ESLD patients in the United States. Herein, we investigated the

disparities in the utilization of PC services among patients with ESLD hospitalized in the United States.

Method: We conducted a retrospective cohort analysis by utilizing Nationwide Inpatient Sample from 2016 to 2020. All patients greater than 18 years old admitted with ESLD, defined as having at least two hepatic decompensation events, were included in the analysis. A multivariate logistic regression model predicting referral to PC was created.

Results: The mean age of ESLD patients at the time seeking palliative care services was 62.25. PC consultation was performed in only 17% of ESLD patients. Hispanic patients were significantly less likely than White and Black patients to receive palliative care services (15.83% compared to 17.26% and 17.23% for White and Black patients respectively ($p < 0.01$). Our analysis also revealed that compared to Whites, Blacks, and other ethnicities, Hispanics are also less likely to be referred to other hospitals or skilled nursing facilities. This patient population also had significantly higher lengths of stay in the hospital (22 days in Hispanics versus 20 days in the White population, $p < 0.01$). Total hospitalization cost was also statistically significantly higher ($p < 0.01$) in Hispanics (76104 United States Dollars) compared to the White (66737 United States Dollars) and Black population (67209 United States Dollars). Furthermore, the mortality rate was significantly higher in the PC group than no-PC group among all racial groups (52.76% vs 13.95%, $p < 0.01$ for Whites, 55.45% vs 19.95%, $p < 0.01$ for Black and 55.19% vs 19.03%, $p < 0.01$ for Hispanics).

Conclusion: There are significant racial disparities in the use of palliative care services. Further research on the causes of racial disparities is needed to improve access to palliative care services for the vulnerable ESLD population.

FRI-340

ACLF grade is not independently associated with 1-year mortality after hospital discharge in cirrhotic patients admitted to ICUs in the Netherlands

Jubi de Haan[1], Fabian Termorshuizen[2,3], Nicolette de Keizer[2,3], Diederik Gommers[1], den Hoed Caroline [4]. *[1]Erasmus University Medical Center, Department of Adult Intensive Care, Rotterdam, Netherlands; [2]National Intensive Care Evaluation (NICE) foundation, Amsterdam, Netherlands; [3]Amsterdam Public Health Institute, Amsterdam UMC, University of Amsterdam, Department of Medical Informatics, Amsterdam, Netherlands; [4]Erasmus MC Transplant Institute, Erasmus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: j.dehaan@erasmusmc.nl

Background and aims: Patients with acute decompensated liver cirrhosis or Acute-on-chronic liver failure (ACLF) often require intensive care unit (ICU) admission for organ support. Nonetheless data addressing the outcomes of these patients remains scarce, is mainly limited to studies conducted in specialized liver transplant centres and has predominantly focused on short-term outcomes, such as ICU and hospital mortality. The aim of this study was to evaluate the influence of ACLF grade on the outcomes of cirrhotic patients admitted to all ICUs in the Netherlands.

Method: We conducted a nationwide observational cohort study using data from the Dutch ICU quality registry, the National Intensive Care Evaluation (NICE). Adult patients with an history of cirrhosis or first complications of cirrhotic portal hypertension admitted to all 82 ICUs in the Netherlands between 2012 and 2020 were included. Admission for elective or cardio-thoracic surgery or primary neurologic events were excluded. We identified 7779 cirrhotic patients; complete data to classify ACLF grade according to EASL-CLIF criteria was available in 2917 patients. The influence of ACLF grade on in-hospital mortality was evaluated using multivariate logistic regression (LR) to adjust for factors including demographics, GI bleeding, infection, APACHE IV probability and MELD score. Subsequently the influence of ACLF grade on 1-year mortality after hospital discharge among survivors of hospital admission was evaluated using unadjusted Kaplan-Meier (KM) survival curve and adjusted Cox proportional hazard model.

Results: In-hospital mortality rate according to ACLF grade is shown in figure 1A. The adjusted OR of in-hospital death among those with ACLF-1 vs no ACLF was 1.18 [95% CI 0.65–2.16], ACLF-2 vs no ACLF 1.92 [95% CI 1.16–3.16] and ACLF-3 vs no ACLF 1.99 [95% CI 1.2–3.3] ($p = 0.008$). In KM analysis among hospital survivors, a higher ACLF grade appeared to be associated with a lower survival following discharge ($N = 1318$) (Figure 1B; Logrank $p < 0.0001$). However, this association vanished after adjustment for factors including age, comorbidities, malignancy status, APACHE IV probability and MELD score ($p = 0.1715$), factors that appeared to have a more important influence on 1-year mortality than ACLF grade.

Figure 1A

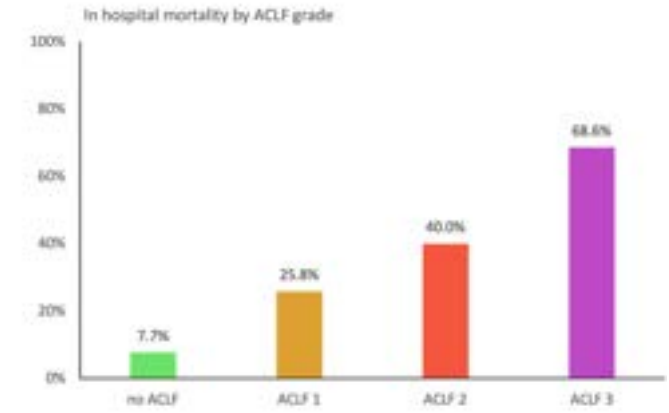

Figure 1B

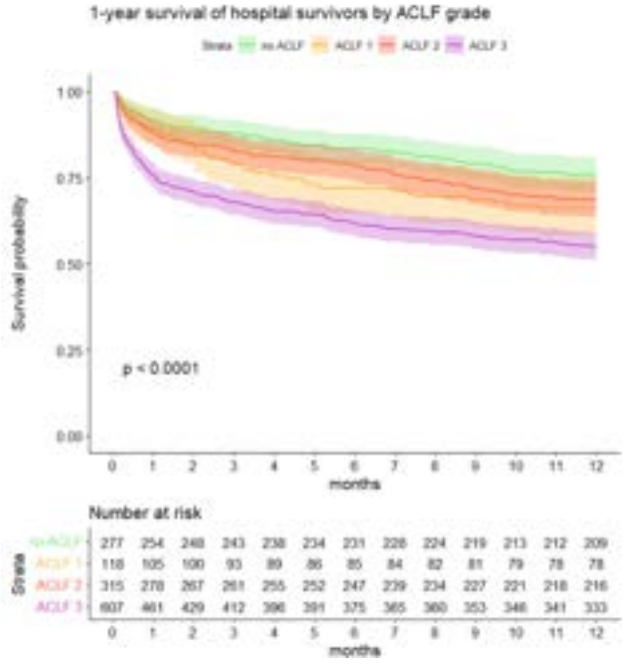

Figure:

Conclusion: In this nationwide cohort study ACLF grade was associated with in-hospital mortality of cirrhotic patients admitted to ICUs in the Netherlands. In those surviving hospital admission, ACLF grade was not an independent risk factor for 1-year mortality after hospital discharge.

FRI-341

Outcomes, clinical trajectories and risk factors of acute kidney injury (AKI) in critically-ill patients with liver cirrhosis

Martin Schulz[1], Georg Guttenberg[2], Wenyi Gu[1], Jan Mengers[2], Nora Ackermann[2], Frank Erhard Uschner[1], Maximilian Joseph Brol[1,1], Philip Ferstl[2], Michael Tischendorf[2], Christiana Graf[2], Salvatore Piano[3], Paolo Angeli[3], Stefan Zeuzem[2], Michael Praktiknjo[1], Alexander Zarbock[4], Christoph Welsch[2], Hermann Pavenstaedt[5], Kai-Henrik Peiffer[1], Jonel Trebicka[1,6]. *[1]Münster, Department of Internal Medicine B, Münster, Germany; [2]Frankfurt, Department of Internal Medicine I, Frankfurt am Main, Germany; [3]University of Padova, Unit of Internal Medicine and Hepatology, Dept. of Medicine, DIMED, Padova, Italy; [4]University of Münster, Department of Anesthesiology, Intensive Care and Pain Medicine, Münster, Germany; [5]University of Münster, Department of Internal Medicine D, Münster, Germany; [6]European Foundation for Study of Chronic Liver Failure, EF-Clif, Barcelona, Spain*
Email: jonel.trebicka@ukmuenster.de

Background and aims: In critically-ill patients with cirrhosis (CIC), AKI is a frequent and severe complication, associated with high mortality rates. This study aimed to assess the detailed impact of AKI in patients' clinical trajectory and identify risk factors for AKI development.

Method: In this observational study, data from 498 patients with liver cirrhosis and admission to IMC or ICU were retrospectively analysed. Risk factors for increased short-term mortality and AKI development were analysed by multivariable Cox regression. Decision tree analysis was performed to derive a risk stratification for AKI development. Clinical trajectories were visualized by Sankey plots dependent on AKI subtypes.

Results: At index IMC/ICU admission, AKI was observed in 208/498 CIC patients. Median age was 60 years, 71.5% of patients were male, 176/498 patients presented ACLF. AKI at index ICU admission was associated with a 28-day mortality of 43.3%. After IMC/ICU discharge, 21.4% of patients developed an AKI within a median of 30 days (IQR 13.8–93.3). Patients without full AKI resolution were observed as a highly vulnerable subgroup in case of AKI recurrence. In these patients, recurrent AKI was associated with a massive mortality increase compared to patients with regular AKI at readmission (90d-mortality 75.0% vs. 39.7%, $p < 0.05$). Multivariable Cox regression showed bilirubin (HR 1.06, 95%CI 1.01–1.10, $p < 0.05$) and tense ascites requiring paracentesis at ICU/IMC admission (HR 1.84, 95%CI 1.07–3.17, $p < 0.05$) are risk factors for AKI development. In decision tree analysis, bilirubin ≥6 mg/dl and tense ascites allowed a risk stratification into three distinct groups: Patients with none of these clinical features (n = 65) showed a relatively low risk of AKI development (26.2%), while patients meeting one criterion (intermediate risk, n = 83) or both criteria (high risk, n = 19) developed AKI in 51.2% and 73.7%, respectively. Intermediate and high risk patients showed significantly higher mortality rates (90d-mortality 47.6% vs 12.9%, $p < 0.001$) and higher rate of renal replacement therapy (21.4% vs 9.7%, $p < 0.05$). High-risk patients also developed AKI significantly faster with a median time to AKI of 15 days ($p < 0.05$).

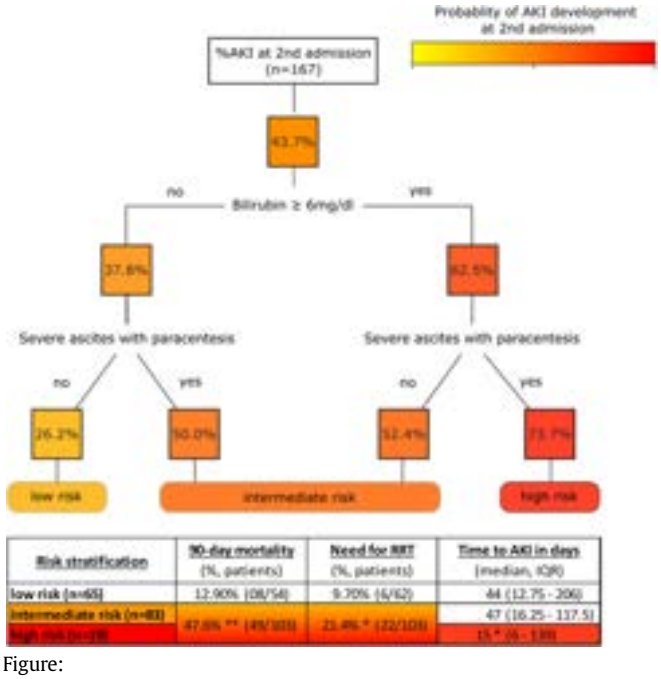

Figure:

Conclusion: Patients without full AKI resolution and persisting renal dysfunction emerge as a novel and profoundly vulnerable subgroup

in case of AKI recurrence as a second hit. Thus, full restoration of renal function should be closely monitored to identify recurrent AKI and initiate rapid treatment. Consequently, this data underscores the urgent clinical need for further evaluation of secondary prophylaxis for selected patients at risk.

FRI-342

VSIG4 as a biomarker for the diagnosis and prognosis of HBV-ACLF

Xi Liang[1], Peng Li[2], Jing Jiang[2], Jiaojiao Xin[2], Xin Chen[3], Dongyan Shi[2], Jun Li[2]. [1]*Taizhou Central Hospital (Taizhou University Hospital), Precision Medicine Center, Taizhou, China;* [2]*The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Hangzhou, China;* [3]*Zhejiang University School of Medicine, Institute of Pharmaceutical Biotechnology and the First Affiliated Hospital, Department of Radiation Oncology, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) is a complex syndrome with high short-term mortality. This study aims to reveal the molecular basis and identify novel HBV-ACLF biomarkers.

Method: Transcriptome sequencing was performed using peripheral blood mononuclear cells (PBMCs) of HBV-ACLF patients in the derivation (n = 20) and validation cohorts (n = 50). Candidate biomarkers were confirmed in two external cohorts using enzyme-linked immunosorbent assay.

Results: Cellular composition analysis with PBMC transcriptomics from the derivation cohort showed that the proportions of monocytes, T cells and NK cells were significantly correlated with ACLF 28-day mortality. A significant upregulation of myeloid lineage modules and metabolic dysregulation with lipid, carbohydrate and energy metabolism were observed in ACLF nonsurvivors. External sequencing confirmed the above results. V-set and immunoglobulin domain-containing 4 (VSIG4) was the most robust predictor of ACLF patient survival (adjusted p = 1.4 × 10 – 6/1.7 × 10 – 7; VIPpred = 1.28/1.92; area under the receiver operating characteristic curve (AUROC) = 0.91/0.88) and was linked to T-cell activation/differentiation and inflammatory response. Plasma VSIG4 analysis externally validated its diagnostic value for ACLF patients (compared with chronic liver disease and healthy groups, AUROC = 0.983). The prognostic performance for 28-/90-day mortality (AUROCs = 0.769/0.767) was comparable to that of 5 commonly used scores (COSSH-ACLF IIs, 0.876/0.878; COSSH-ACLFs, 0.867/0.884; CLIF-C ACLFs, 0.840/0.835; MELD, 0.721/0.750; MELD-Na, 0.710/0.737). Risk stratification of the VSIG4 expression level (>122 μg/ml) specifically identified ACLF patients with a high risk of death. The generality of VSIG4 in other etiologies was validated.

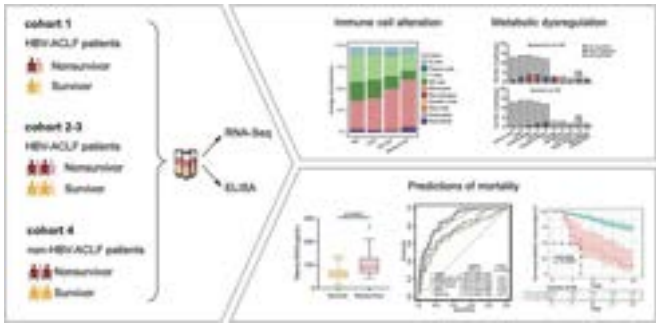

Figure:

Conclusion: This study reveals immune-metabolism disorder underlying poor ACLF outcomes. VSIG4, as a biomarker for the diagnosis and prognosis of HBV-ACLF, may be helpful in clinical practice.

FRI-343

The prognostic impact of each organ failure is different than that of acute-on-chronic liver failure according to the major clinical presentation in acutely decompensated cirrhosis

Email: sekim@hallym.or.kr

Background and aims: The acute-on-chronic liver failure (ACLF) is major poor prognosis factor in acute decompensation (AD) of chronic liver disease (CLD) or liver cirrhosis (LC). Main pathogenic mechanism of AD has been speculated systemic inflammation and portal hypertension. The effects of not only ACLF but also each organ failure may be different depending on the major pathogenesis in AD patients, but studies for this have not yet been investigated. Therefore, we aimed to investigate whether significant differences of adverse outcomes (death or LT) show or not according to main clinical presentation in AD cirrhotic patients in prospective Korean Acute-On-Chronic Liver Failure (KACLiF) cohort. Also, we intend to reveal risk factor including ACLF and each organ failure for adverse outcomes.

Method: The prospective KACLiF cohort consisted of 1773 patients who were hospitalized with AD of CLD, from July 2015 to August 2018. We enrolled a total of 1,416 patients with AD after excluding non-LC patients. Patients were then regularly evaluated for 3 months outcomes (liver transplantation and death) at 1 year were also recorded.

Results: According to clinical presentation, patients were analyzed: gastrointestinal bleeding (GIB) (n = 490), ascites (n = 355), bacterial infection (n = 103), hepatic encephalopathy (HEP) (n = 178), and jaundice (n = 290). The adverse outcomes rate for subgroups of AD were differed as followed; 28-day adverse outcome (total = 8.1%, GIB = 4.9%, ascites = 9.6%, bacterial infection = 13.6%, HEp = 10.1%, and jaundice = 8.3%; p = 0.011), 90-day adverse outcome (total = 13.5%, GIB = 8.4%, ascites = 15.2%, bacterial infection = 19.4%, HEp = 17.4%, and jaundice = 15.5%; p = 0.001), and 1-year adverse outcome (total 21.9%, GIB = 14.7%, ascites = 25.1%, bacterial infection = 31.1%, HEp = 27%, and jaundice = 23.8%; p < 0.001). After multivariate cox regression analysis, MELD was most important risk factor for adverse outcome in total or subgroup of AD patients if it were analyzed with ACLF. As a result of analysis with each organ failure as a variable other than ACLF, cardiac failure in GIB patients, coagulation failure in ascites patients, coagulation failure and brain failure in BI patients, liver failure in HEP patients, and MELD and DM in jaundice patients were the main factors.

Conclusion: According to main clinical presentation, cirrhotic patients with AD showed different 28-days, 90-days, and 1-year adverse outcomes. Although ACLF is a factor influencing the patient's adverse outcomes, the relevant organ failure may differ depending on the patient's major clinical presentation upon admission. Especially, AD patients with bacterial infection showed poorer adverse outcomes compared to patients with other clinical presentation. Each organ failure rather than ACLF tends to have a direct impact on the

Incidence, risk factors and outcomes of acute kidney disease in cirrhosis patients with sepsis-related acute kidney injury

Rakhi Maiwall[1], Ashini Hidam[1], Neha Chauchan[1], Shiv Kumar Sarin[1].
[1]*Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India*
Email: shivsarin@gmail.com

Background and aims: Cirrhosis patients frequently have sepsis related acute kidney injury (S-AKI). Persistence of kidney dysfunction in S-AKI is reported to have sustained inflammatory and procoagulant responses. Patients with acute kidney disease (AKD) in the context of sepsis may have worse outcomes compared to those with recovery. We aimed to investigate in a prospective cohort of patients with S-AKI the incidence, spectrum, risk factors, and outcomes of AKD.
Method: Prospective cohort of cirrhosis patients admitted to the liver intensive care unit with S-AKI (n = 254) were enrolled. AKD was defined as acute or subacute damage and/or loss of kidney function for a duration between 7 and 90 days after AKI. A detailed biochemistry, urine sediment and neutrophil gelatinase-associated lipocalin (NGAL) was performed for all patients at enrolment and day 7. A urine microscopy score (UMS) was derived based on the observed quantification of renal tubular cells (RTC) and casts in the sediment. Our primary outcome was development of AKD. Secondary outcomes included need of dialysis, recovery from AKD and death. The stages of AKD at day 90 or last follow-up were defined in accordance with Levey et. al (Nephron 2022).
Results: Patients with S-AKI, mean age 45.6 ± 9.6 years, 91% males, mean MELD 27.3 ± 11.3, and CTP score 12.3 ± 1.6, 43% alcoholics, 44% obese, 29% diabetics, and 19% with grade 3 ascites were enrolled. The median urine NGAL was 1865.5 (1276.7–2863.5) ng/ml. Pneumonia was the most common infection in 67% and septic shock was seen in 58%. AKI stage at enrolment (KDIGO Stage 1:2:3 26%vs 33%.vs 41%). The cause of AKI was acute tubular necrosis in 60% followed by hepatorenal syndrome in 24% and remaining had prerenal volume-responsive AKI. A total of 115 (45%) developed AKD at day 90. Patients

who developed AKD had significantly higher urine spot sodium (mEq/L) (27.6 ± 15.9 vs. 18.2 ± 8.7; p < 0.001), urine protein-to-creatinine ratio (2.0 ± 1.3 vs. 1.18 ± 0.89; p < 0.001), and NGAL at enrolment and day 7 (Figure). These patients also had higher UMS for granular casts and RTCs. On multivariate analysis, higher NGAL at enrolment (log transformed) (OR 2.9, 1.8–4.7), UMS (OR 3.2, 1.6–6.3), presence of metabolic syndrome (OR 1.9, 1.2–3.4) were risk factors for AKD. At last follow-up, 9% had stage 0, 4% had stage 1, 16% had stage 2, 18% had stage 3 AKD and 54% were on dialysis. In the proportion of patients with recovery (n = 9), 44% had stage C, 22% stage B and 33% stage A AKD. Development of AKD was an independent predictor of 90-day mortality (OR 6.4, 3.7–11.1)

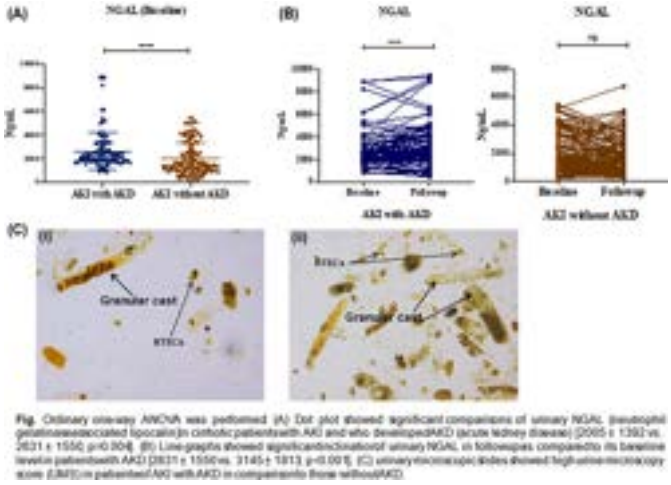

Fig. Ordinary one-way ANOVA was performed. (A) Dot plot showed significant comparisons of urinary NGAL (neutrophil gelatinase-associated lipocalin) in cohorts: patients with AKI and who developed AKD (acute kidney disease) (2065 ± 1392 vs. 2821 ± 1556; p=0.004). (B) Line graphs showed significant increase of urinary NGAL in follow-ups compared to its baseline level in patients with AKD (2831 ± 1556 vs. 3145 ± 1813; p=0.001). (C) urinary microscopic slides showed high urine microscopy score (UMS) in patients' AKI with AKD in comparison to those without AKD.

Figure:

Conclusion: Almost 60% of patients with S-AKI have acute tubular necrosis and one in two develops AKD. AKD after S-AKI is associated with worse outcomes, recovers in only 9%, and progresses to dialysis in one-half. Of patients with recovery only 33% have return to normal renal functions. Higher NGAL, urine sediment score and presence of metabolic syndrome predict risk of AKD in patients with S-AKI. Novel therapeutic modalities are an unmet need for preventing AKD in S-AKI.

FRI-534
Machine learning-based model is superior to CLIF-C ACLF score for predicting ICU mortality in critically ill patients with acute-on-chronic liver failure

Maike Rebecca Pollmanns[1], Bastian Kister[2], Samira Abu Jhaisha[1], Jonathan Frederik Brozat[1], Philipp Hohlstein[1], Tony Bruns[1], Lars Küpfer[2], Christian Trautwein[1], Alexander Koch[1], Theresa Hildegard Wirtz[1]. *[1]University Hospital RWTH Aachen, Medical Department III, Aachen, Germany; [2]University Hospital RWTH Aachen, Institute for Systems Medicine with Focus on Organ Interaction, Aachen, Germany*
Email: mpollmanns@ukaachen.de

Background and aims: Acute-on-chronic liver failure (ACLF) defines a highly heterogeneous syndrome characterized by acute decompensation in patients with pre-existing liver disease accompanied by multiple organ failure. Available prognostic scores predict overall mortality. The aim of the presented study was to establish a simply applicable scoring system that could reliably predict mortality of ACLF patients during intensive care unit (ICU) treatment.
Method: A retrospective analysis of 206 patients with ACLF who were admitted to the medical ICU at the University Hospital RWTH Aachen between 2015 and 2021 was conducted. To develop a machine-learning model for predicting ICU mortality a training and validation dataset were defined and model development was performed by logistic regression. Various metrics were assessed to evaluate the calculated model and compare its predictive performance to existing scoring systems, including the chronic liver failure consortium (CLIF-C) ACLF score, the ACLF grade as well as CLIF-C OF, SOFA, MELD, APACHE-II, and SAPS score.
Results: The ICU mortality in this cohort was 60.2%. All evaluated scoring systems were able to distinguish between ICU survivors and non-survivors. The CLIF-C ACLF scoring system had the highest area under the receiver operating characteristics curve (AUROC) at 0.79 (95% CI) in the cohort. Machine learning resulted in seven different models using five up to thirteen features. The prognostic accuracy of CLIF-C ACLF score could be significantly improved by adding the number of organ failures, Horovitz quotient (FiO_2/PaO_2), FiO_2 and lactate (validation cohort AUROC 0.96, "model" in Fig. 1). Moreover, this model was superior to the existing 'gold-standard' CLIF-C ACLF score in predicting ICU mortality as well as 90-days transplant-free mortality.

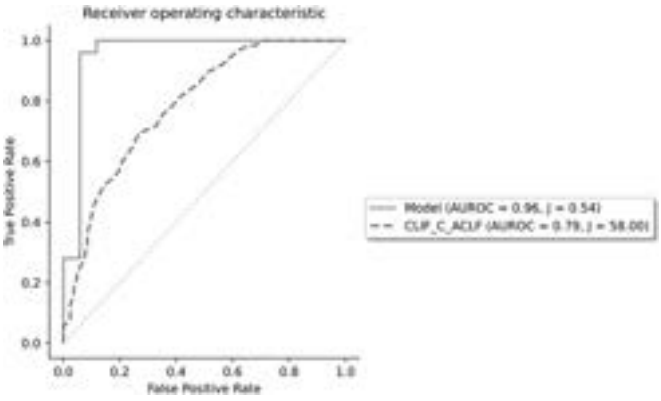

Figure: ROC curve analysis for the discrimination between ICU-survivors and non-survivors by our developed model including CLIF-C ACLF score, number of organ failures, Horovitz quotient (FiO_2/PaO_2), FiO_2 and lactate in comparison to CLIF-C ACLF score only. *Abbreviations:* AUROC, area under the receiver operating characteristic curve; J, Youdeńs J Index.

Conclusion: Our findings indicate that this novel model can effectively predict ICU mortality in critically ill patients with ACLF, highlighting its potential for practical use in clinical settings.

FRI-535
Albumin use in acute-on-chronic liver failure in a large national cohort

Nadim Mahmud[1], Tamar Taddei[2], David Kaplan[1], Elisabet Viayna[3], Thomas Ardiles[4], Marina Serper[1]. *[1]University of Pennsylvania, United States; [2]Yale University, United States; [3]Grifols, SA, Spain; [4]Grifols, SA, United States*
Email: marinas2@pennmedicine.upenn.edu

Background and aims: Acute-on-chronic liver failure (ACLF) is associated with high short-term mortality. Common ACLF triggers include hepatorenal syndrome (HRS) acute kidney injury (AKI) and as spontaneous bacterial peritonitis (SBP); conditions where albumin is indicated for treatment. Albumin use in ACLF hospitalizations has not been studied in detail in large cohorts. We aimed to investigate use of albumin in ACLF by severity and identify factors associated with its use in a large national cohort of patients with cirrhosis in the U.S. Veterans Health Administration Affairs (VHA).
Method: We identified all hospitalizations of patients with cirrhosis between 2008 and 2021 and classified them based on the EASL criteria from ACLF 0 (no ACLF) to 3 (severe ACLF) using validated methods. All inpatient albumin use was captured via inpatient pharmacy files; we also obtained demographic, comorbidity, and admission laboratory data. Average days of albumin administration were presented by length of hospital stay (LOS), stratified by ACLF grade. We subsequently fit multivariable logistic regression models for albumin use adjusting for characteristics at hospital admission: patient demographics, liver disease etiology, Child Pugh score, MELD-

Na, medical comorbidities, ACLF grade, and guideline-recommended albumin indication (HRS, SBP).
Results: Among 47,290 hospitalizations; 4.3% were ACLF-3, 6.6% ACLF-2, 12.1% ACLF-1, and 77.0% ACLF-0. Any albumin use was significantly associated with ACLF grade, for example 78.9% of ACLF-3 hospitalizations versus 22.8% of ACLF-0 (p < 0.001); these associations were also apparent when visualized as cumulative days of albumin use for hospitalizations of different LOS (Figure 1). In adjusted models, factors independently associated with lower odds of albumin use were: Black race (OR 0.78, 95% CI 0.72–0.84) and Hispanic ethnicity (OR 0.80, 95% CI 0.72–0.90) (relative to White race): congestive heart failure (OR 0.77, 95% CI 0.72–0.82), atrial fibrillation (OR 0.72, 95% CI 0.66–0.78), and diabetes (OR 0.72, 95% CI 0.67–0.76). Factors associated with higher use were: HRS-AKI (OR 2.48, 95% CI 2.16–2.85), SBP (OR 2.89, 95% CI 2.57–3.25), and ACLF grade [relative to ACLF-0]: (ACLF-1: OR 1.72, 95% CI 1.59–1.85; ACLF-2: OR 1.95 95% CI 1.78–2.15, ACLF-3: OR 4.25, 95% CI 3.73–4.84). Among liver disease etiologies, hepatocellular carcinoma was associated with higher albumin use (OR 1.22, 95% CI 1.13–1.32).

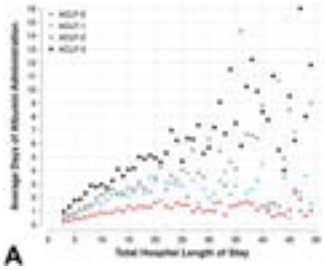

Figure 1: Albumin Use by ACLF Grade and Hospital Length of Stay

Conclusion: In this national cohort study, we show that inpatient albumin utilization is substantial in high-grade ACLF and in the setting of SBP and HRS-AKI. After adjusting for medical factors, we found variation in use by race/ethnicity suggesting practice variation and health inequity. These findings highlight the need to identify causes of practice variation to improve use of guideline recommended therapies; this is particularly important in ACLF, which carries very high mortality risk.

FRI-536

Microbial cell-free DNA next-generation sequencing of ascites in acutely decompensated cirrhosis patients: a proof-of-concept study

Beiling Li[1], Yanhang Gao[2], Yan Huang[3], wei yuan[4], Zuxiong Huang[5], Qintao Lai[1], Qinjun He[1], Ling Zhou[1], Miaoxia Liu[1], Jinjun Chen[1,6].

Email: chjj@smu.edu.cn

Background and aims: Targeted anti-microbial treatment therapy in patients with spontaneous bacterial peritonitis (SBP) is currently not possible as pathogens are identified in only 5%-20% patients. Metagenome next-generation sequencing (mNGS) test can provide rapid diagnosis of a comprehensive spectrum of pathogens. The aim is to evaluate the performance of microbial mNGS of ascites and its clinical effect in the decompensated cirrhosis patients.

Method: Decompensated cirrhosis patients with ascites were prospectively recruited at 5 teaching hospitals between 2019 and 2020 (NCT04125654). Patients were underwent microbial mNGS detection of ascites and clinical characteristics as well as outcomes were recorded accordingly. The association between the microorganisms detected by mNGS and clinical outcomes was assessed.
Results: In this study, 165 decompensated cirrhosis patients with ascites were included. Twenty patients were diagnosed with SBP and 14 patients had positive ascites culture. By microbial mNGS of ascites testing, 149 microorganisms were detected in 52 (31.5%) patients, including bacteria (65.8%), fungi (4.0%), virus (30.2%). Fever was more frequent in patients with positive ascites mNGS detection than those without (30.8% vs.15.0% p = 0.019). The prevalence of new-onset SBP and acute kidney injury were much higher in the positive ascites mNGS group than the negative group (25.6% vs. 3.9%, p < 0.001; 30.8% vs. 14.2%, p = 0.012).

	Ascites mNGS positive (n = 52)	Ascites mNGS negative (n = 113)	P value

Laboratory measurements			
Bilirubin (μmol/L)-median (IQR)	86.9 (42.3–210.2)	70 (27.9–216.6)	0.203
INR -mean (SD)	1.9 (1.2)	1.7 (0.9)	0.242
Serum creatinine (μmol/L)-median (IQR)	71.0 (61.0–95.6)	81.8 (62.0–101.0)	0.405
Leukocytes counts ($\times10^9$/L)-median (IQR)	6.8 (3.8–9.9)	5.3 (3.9–7.7)	0.126
C-reactive protein (mg/L)-median (IQR)	14.7 (8.8–35.6)	11.4 (6.3–23.7)	0.107
28-day mortality- n (%)	2 (3.8)	5 (4.4)	0.864

Conclusion: Microbial mNGS detection may improve the pathogen diagnosis of infected ascites in acutely decompensated cirrhosis. The positive detection by ascites mNGS was correlated with the progression of SBP and future studies need to be further validated.

FRI-537

Performances of the CLIF-consortium acute-on-chronic liver failure (ACLF) score are gender specific

Sophie-Caroline Sacleux[1], Thomas Mangana Del Rio[2], Philippe Ichai[1], Julien Vionnet[2], Audrey Coilly[1], Jean-Daniel Chiche[2], Faouzi Saliba[1], Constantine Karvellas[3], Florent Artru[2,4]. *[1]Hopital Paul Brousse, France; [2]Lausanne University Hospital, Switzerland; [3]Department of Critical Care Medicine and Division of Gastroenterology (Liver Unit), University of Alberta, Edmonton, Canada; [4]King's College Hospital, United Kingdom*
Email: florent.artru@kcl.ac.uk

Background and aims: CLIF consortium acute-on-chronic liver failure (CLIF-C ACLF) score is the current gold standard for the

prediction of outcomes in ACLF. This score was derived from cohorts comprising mainly male participants, as women are underrepresented in studies on critically ill patients with ACLF. Our aim was to investigate whether the performance of CLIF-C ACLF is gender-specific in a large multicentric and international cohort of critically ill patients with ACLF.

Method: Three cohorts of consecutive patients with ACLF hospitalised in intensive care units (ICU) were included in the present study: Lausanne-Switzerland (2010 to 2020, n = 428), Paul Brousse-France (2017 to 2019, n = 200) and Edmonton- Canada (2001–2015, n = 308) cohorts. CLIF-C ACLF score was calculated using its original formula. Performances were evaluated by discrimination ability estimated by the area under the receiver operating characteristics (AUROC) curve and calibration.

Results: A total of 936 patients fulfilled the inclusion criteria: median age was 59 years (IQR 50–66 years), 268 (29%) were women, and 568 (61%) had alcohol-related cirrhosis. The main causes of admission were sepsis (n = 359, 33%) and bleeding (n = 243, 26%). On day 1, the median MELD score was 24, the median ACLF grade was 3, and the median CLIF-C ACLF score was 63. Forty-five patients (5%) underwent LT within the first 28 days of ICU admission. The 28-day transplant-free survival (TFS) was 56% and was not different between women (57%) and men (55%) (p = 0.71). The distribution of ACLF grades on day 1 between women and men was not different (p = 0.31), but there was a trend to an increased prevalence of ACLF grade 3 with 4 or more OFs in women vs. men (48.6% vs. 37.4%, p = 0.09). The AUROC of CLIF-C ACLF score on days 1 and 3 was greater in women (0.74 and 0.83) than in men (0.61 and 0.72) (p = 0.002 and p = 0.006, respectively). In sensitivity analyses, the AUROC of CLIF-C ACLF on days 1 and 3 remained greater in women at each of the three centers. Calibration according to the quintile of the population on days 1 and 3 had a maximum delta of 3% in women and 8% in men between observed and predicted 28-day TFS. We then explored whether variables included in the CLIF-C ACLF score had a different association with 28-day TFS in women vs. men. All the variables included in the CLIF-C ACLF score apart from leukocyte count and cerebral failure were associated with 28-day TFS in multivariable analyses in women. In men, leukocytes count, cerebral failure, and age were not associated with 28 -day TFS. Besides, the probability of recovery was diminished in women. It was illustrated by a less dynamic course of organ failure (OF) as compared to men with 39% showing a different ACLF grade between days 1 and 3 vs. 49% in men (p = 0.04).

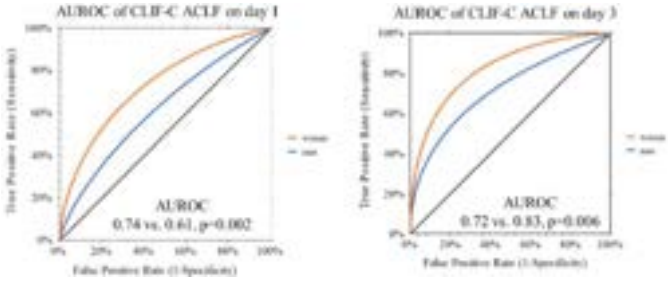

Figure: AUROC of CLIF-C ACLF on days 1 and 3 in women (orange) and men (blue)

Conclusion: CLIF-C ACLF score better predicts 28-day TFS of critically ill women with ACLF, likely due to a lower discriminant ability of age in men as well as a lower chance of recovery in women where ACLF is less dynamic. In women, based on its excellent performance, especially on day 3, CLIF-C ACLF allows identifying patients with the lowest chance of survival to adapt critical care management toward LT or withdrawal of intensive care. CLIF-C ACLF score should be optimised in men.

FRI-538

The risk factors for poor prognosis according to the clinical course after first acute decompensation in cirrhotic patients

Jung Hee Kim[1,2], Sung-Eun Kim[1,2], Do Seon Song[3], Eileen Yoon[4], Hyoung Su Kim[1,2], Jang Han Jung[1,2], Tae Hyung Kim[5], Young Kul Jung[5], Ki Tae Suk[1,2], Won Kim[6], Jae Young Jang[7], Dong Joon Kim[1,2]. *[1]Hallym University College of Medicine, Internal Medicine, Korea, Rep. of South; [2]Institute for Liver and Digestive Diseases, Hallym University, Korea, Rep. of South; [3]College of Medicine, The Catholic University of Korea, Korea, Rep. of South; [4]Hanyang University College of Medicine, Korea, Rep. of South; [5]Korea University Ansan Hospital, Korea, Rep. of South; [6]Seoul Metropolitan Government Seoul National University Boramae Medical Center, Korea, Rep. of South; [7]Soonchunhyang University College of Medicine, Korea, Rep. of South*
Email: sekim@hallym.or.kr

Background and aims: The acute on chronic liver failure (ACLF) is well known poor prognosis in acute decompensation (AD) of chronic liver disease or liver cirrhosis. Recently the European Foundation for the Study of Chronic Liver Failure (EF-CLIF) consortium suggested that four clinical course within 3 months after first AD stratified the long term prognosis: stable decompensate cirrhosis (SDC), unstable decompensated cirrhosis (UDC) and pre-ACLF and ACLF. We verify the outcomes of these subgroups and analysis the initial factors for affecting these clinical course in Korean prospective cohort of AD.

Method: The prospective Korean Acute-On-Chronic Liver Failure (KACLiF) cohort consisted of 1773 patients who were hospitalized with AD of CLD, including either LC or non-cirrhotic CLD, from July 2015 to August 2018. We enrolled the first AD patient on LC after excluding as followed: previous history of decompensation (n = 902), previous diagnosis of HCC (n = 26) and non LC (n = 133). After exclusion, a total of 746 patients with AD were enrolled. Patients were then closely followed up and evaluated for 3 months outcomes (liver transplantation and death) at 1 year were also recorded.

Results: The subgroups consisted with SDC (n = 565), UDC (n = 29), Pre ACLF (n = 28) and ACLF n = 124). The subgroups of AD stratified the 90 days and 1-year mortality as followed. (90 days' mortality: SDC = 5.3%, UDC = 10.3% and pre ACLF = 42.9%, 1year mortality: SDC = 13.5%, UDC = 34.5% and pre ACLF = 57.1%). And ACLF group showed favorable 90 days and 1year mortality (29.0% and 33.9%) compared with pre ACLF group. The initial factors that affected to occurrence of UDC or pre ACLF within 3 months were age [Odd ratio (OR) = 1.027, p = 0.042], non-variceal GI bleeding (OR = 3.031, p = 0.008), hepatic encephalopathy (HEP) (OR = 2.457, p = 0.033) and MELD (OR = 1.106, p < 0.001).

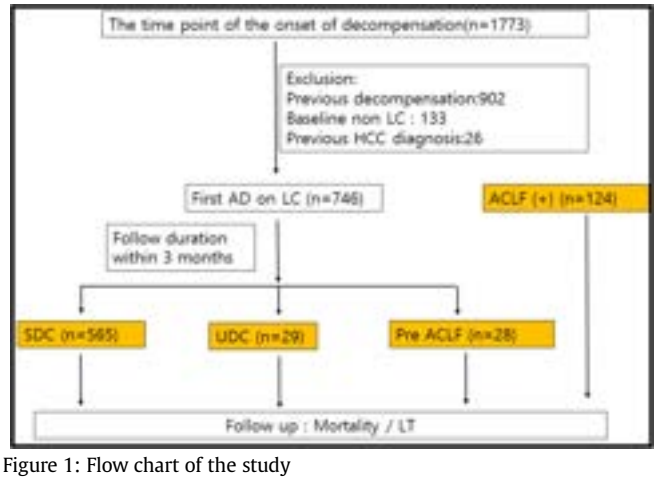

Figure 1: Flow chart of the study

	SDC (N=565)	UDC (N=29)	PreACLF (N=28)	P value	ACLF (n=124)

Table 1. Baseline characteristics of enrolled patients according to clinical course

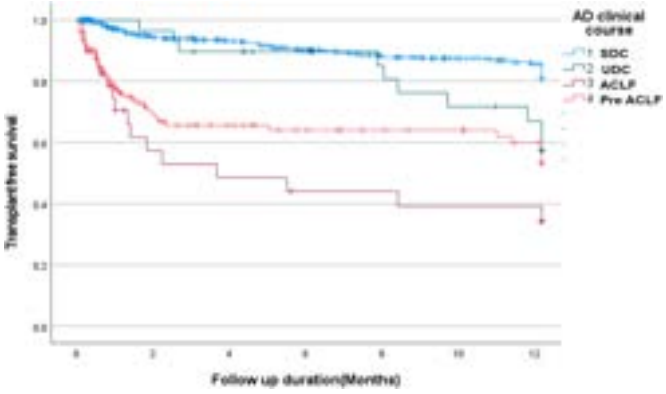

Figure 2: Clinical outcome according to clinical course

Conclusion: The prognostic groups of EF-CLIF are also verified in Asian cohort of cirrhosis. The accumulation of hepatic injury caused by recurrent symptom and progression to ACLF after first AD cause the dismal prognosis. Specially, the symptoms of first AD which were difficult to control and easily reproducible such as non-variceal bleeding and HEP are the sign of recurrent hepatic insult and should be care for prevention from the occurrence

FRI-539

Prediction of sepsis in patient of acute on chronic liver failure (ACLF)-a machine learning approach

Ashok Choudhury[1], Vinod Arora[1], Shiv Kumar Sarin[1], Vikash Dubey[1] and APASL ACLF Research Consortium Aarc Consortium[1]. [1]*Institute of liver and billiary sciences New Delhi, India*
Email: doctor.ashokchoudhury@gmail.com

Background and aims: ACLF is syndrome rapid worsening liver failure with poor outcome. The survival is confounded by organ failure often with or without sepsis. Early sepsis identification is crucial. The machine learning using big data is could precisely and accurately predict the development of sepsis. Aim is to develop a machine learning based prediction model for development of sepsis among hospitalized patients of ACLF who had no sepsis at presentation.

Method: We analysed the prospective collected data from AARC registry. Clinical data, laboratory parameters and sepsis were serially noted. AI-modelling was done after appropriate mining, feature engineering, splitted randomly into train and test-sets (70:30). The models created on the train-set were (XGB), Random Forest, K-Nearest Neighbours Classifier, Decision Trees (DT), Logistic Regression (LR), Adaptive Boosting (adaBoost) Model. We evaluated area under the curve (AUC), accuracy, sensitivity, specificity, and precision of models for predicting the outcomes in the test-set for any definite sepsis within first 7days of hospitalization who had none at baseline. AUC was the primary selection criteria; confusion matrix was used to compare AUCs between AI-models and calibration plot created to evaluate the observed and predicted risk.

Results: Of 4990 ACLF patients [mean age 44.8 ± 11.6 years, 86% male], sepsis at presentation was detected in 1180 (23.6%) patients. New onset sepsis developed in 9.4% (358) within first week and is considered as the event. Initial 54 features reduced to 45 after data cleaning and preparation and followed by selection of the top 14 features to prepare the basic model representing the sepsis development. The XGB-CV model had the best accuracy among other tested models for prediction in train-set: 0.94 ± 5%, validation-set: 0.90 ± 5% and overall-dataset 0.86 with an AUROC of 0.954. The top five features critical for the XGB-CV model were baseline GGT, and day 4 parameters i.e., Heart rate, systolic and diastolic blood pressure and AARC score. New onset sepsis was associated with significantly higher 30-day mortality [56.4% versus 38.1%, OR = 2.07 (95 CI 1.77–3.61), p = 0.01].

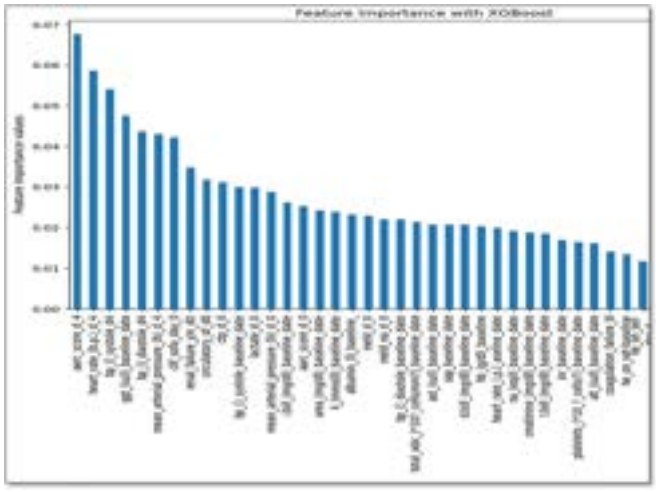

Figure:

Conclusion: New onset definite sepsis developed in one tenth of hospitalized ACLF patients within first week. The baseline GGT and fourth day AARC score along with simple heart rate and blood pressure dynamicity can predict sepsis. This may be a simple guide for decision regarding early prevention of sepsis and may improve survival.

FRI-540

Predictors of clinical courses in patients wih acutely decompensated cirrhosis. An external validation of the PREDICT study

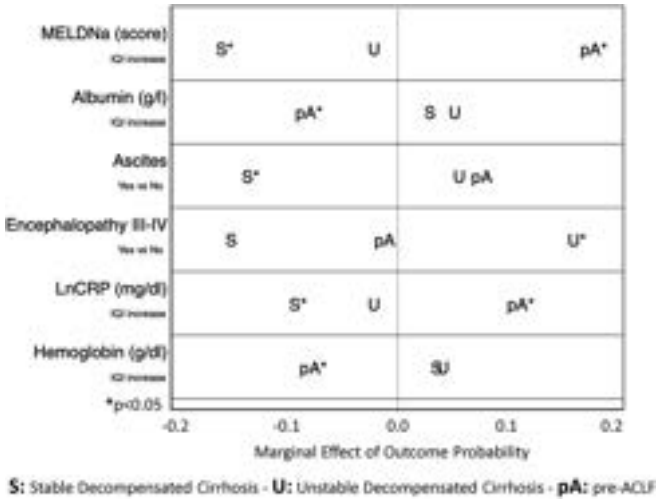
Enrico Pompili[1,2], Maurizio Baldassarre[1,3], Giorgio Bedogni[1,4], Giacomo Zaccherini[1], Giulia Iannone[1,2], Clara De Venuto[1,2], Francesco Palmese[1,4], Manuel Tufoni[2], Marco Domenicali[1,4], Paolo Caraceni[1,2]. [1]*Alma Mater Studiorum-University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy;* [2]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Unit of Semeiotics, Liver and Alcohol-related diseases, Bologna, Italy;* [3]*Alma Mater Studiorum-University of Bologna, Centre for Applied Biomedical Research (CRBA), Bologna, Italy;* [4]*AUSL Romagna, Department of Primary Health Care, Internal Medicine, Frailty and Aging, Ravenna, Italy*
Email: paolo.caraceni@unibo.it

Background and aims: The PREDICT study recently showed that acutely decompensated (AD) cirrhotic patients without acute-on-chronic liver failure (ACLF) at admission present three different clinical trajectories and mortality rates: pre-ACLF, developing ACLF

within 90 days; Unstable Decompensated Cirrhosis (UDC), who were readmitted within 90-days or die without prior ACLF; and Stable Decompensated Cirrhosis (SDC), without ACLF or readmissions. This study aimed to i) validate the existence of three distinct trajectories in AD patients and compare their 1-year mortality rate; and ii) identify predictors for the occurrence of each trajectory.

Method: We performed a secondary analysis in a prospectively cohort of patients admitted to hospital for AD. Laboratory and clinical data at admission, development of ACLF and readmission up to 3 months and 1-year mortality were recorded. Patients were classified as pre-ACLF, UDC or SDC according to the PREDICT criteria. A pre-specified multinomial multivariable model (MNM) was used to evaluate the association between baseline features and the occurrence of pre-ACLF, SDC or UDC. Marginal estimates of the probability of pre-ACLF, SDC or UDC made by the MNM were calculated for one interquartile interval (IQI) increase for continuous predictors and for presence vs absence for binary predictors.

Results: Of the 311 patients included, 169 (55%) met the criteria for SDC, 57 (18%) for UDC, and 85 (27%) for pre-ACLF. The 1-year mortality was significantly different between the three groups: pre-ACLF 65%, UDC 46% and SDC 21% ($p < 0.001$). Marginal changes of the probability of pre-ACLF, SDC and UDC attributable to the predictors are reported in Figure 1. Among clinical parameters, the presence of hepatic encephalopathy was associated to UDC ($p = 0.043$), while the absence of ascites to SDC ($p = 0.017$). Among laboratory parameters, the increase in MELD-Na ($p = 0.000$) and C-Reactive Protein ($p = 0.009$) and the decrease in hemoglobin ($p = 0.004$) and albumin ($p = 0.008$) levels were associated to pre-ACLF.



S: Stable Decompensated Cirrhosis - **U:** Unstable Decompensated Cirrhosis - **pA:** pre-ACLF

Figure:

Conclusion: The present study confirms that patients with AD have 3 different clinical trajectories associated to different mortality rates. Besides severity of cirrhosis, the association with CRP supports the predominant role of systemic inflammation in ACLF development. Finally, HE is associated to the UDC trajectory highlighting the need of a better management of this complication after discharge.

Email: andreivoiosu@gmail.com

Background and aims: We hypothesized that the inflammation underpinning many cases of acute decompensation (AD) in cirrhosis leads to impaired cardiac function increasing the risk of evolving towards Acute on Chronic Liver Failure (ACLF) or death. We aimed to explore the relationship between a panel of relevant inflammatory biomarkers and functional cardiac parameters in patients with AD of cirrhosis.

Method: This is a retrospective analysis of a prospective database of 70 patients with AD of cirrhosis who had echocardiography performed within 48 hours of admission and for whom follow-up was available. A single investigator examined all patients with according to a pre specified echocardiography protocol and measured parameters of systolic and diastolic function. Cardiac dysfunction was diagnosed by echocardiograpy according to current algorithms and cut-off values based on parameters available from the corresponding recorded examinations. We measured serum concentrations of inflammatory (IL-6, IL-8, TNF-α, CD206) and cardiac biomarkers (pro Brain Natriuretic Peptide -proBNP, Troponin T) from frozen samples stored in our biobank. Patients were divided into a low and a high-risk group by using a cut-off CLIF-C AD score of 50 [1]. We analyzed associations between the echocardiographic parameters of cardiac dysfunction, concentrations of biomarkers, CLIF-C AD score, and outcome.

Results: We included 70 patients (mean age 58 ± 10 years, 28 women) admitted for AD of cirrhosis and followed-up for 17 ± 7 months. 3 patients had ACLF at enrollment and the mean CLIF-C AD score was 47 ± 7. 13 patients fulfilled the echocardiographic criteria for systolic dysfunction and 29 patients those for diastolic dysfunction, but there were no significant correlations with the concentrations of serum IL-6, IL-8, TNF- α or CD206. Of the echocardiographic parameters, increased left atrial volume and mitral A wave, both indicators of left ventricular diastolic dysfunction, positively associated with markers of inflammation: IL-6 ($r = 0.404$, $p < 0.001$), and, respectively, IL-8 ($r = 0.368$, $p = 0.002$). In univariate analysis, patients with higher CLIF-C AD score had higher levels of IL-6 ($r = 0.284$, $p = 0.02$) and IL-8 ($r = 0.307$, $p = 0.01$), but were not more likely to have cardiac dysfunction. 18/70 patients died during follow-up. Patients with higher concentrations of proBNP ($p = 0.01$), IL-6 ($p = 0.01$), IL-8 ($p = 0.008$), and higher CLIF-C AD score ($p = 0.02$) were more likely to die.

Conclusion: We found associations between inflammatory biomarkers and echocardiographic indicators of diastolic dysfunction. Cardiac dysfunction was not more prevalent in patients with AD of cirrhosis at higher risk of developing ACLF or death during follow-up.

Email: sekim@hallym.or.kr

Background and aims: Gastrointestinal bleeding (GIB) including variceal bleeding (VB) and non-variceal gastrointestinal bleeding

(NVB) is a major complication in patient with chronic liver disease, especially liver cirrhosis. Recent studies reported that there were no differences in clinical outcomes between VB and NVB. However, larger scale, multicenter, prospective studies were warranted to confirm these results because there was different pathogenic mechanism of development between VB and NVB. We aimed to investigate differences of clinical outcomes and risk factor in cirrhotic patients with GIB.

Method: The prospective Korean Acute-On-Chronic Liver Failure (KACLiF) cohort consisted of 1, 773 patients who were hospitalized with acute decompensation of chronic liver disease, from July 2015 to August 2018. We enrolled a total of 490 cirrhotic patient with GIB after excluding non-cirrhotic patients. Patients were then regularly evaluated for adverse outcomes (liver transplantation and death) every 3 month during follow-up period.

Results: A total of 490 cirrhotic patient with GIB were included, 414 with VB and 76 with NVB. Patients with NVB had poorer underlying liver function than those with VB (bilirubin 4.49 ± 3.96 vs 2.86 ± 3.64 mg/dL, $p < 0.001$; Child-Pugh score 8 (5–14) vs 7 (5–15), $p < 0.001$; MELD 16.6 (7–41) vs 13.6 (7–54), $p = 0.004$; MELD-Na 19.2 (8–41) vs 15.3 (7–50), $p < 0.001$). Patients with VB and NVB had similar 28-day adverse outcome (death or liver transplantation) (4.6% vs 6.6%, $p = 0.460$), 90-day adverse outcome (7.5% vs 13.2%, $p = 0.101$), 1-year adverse outcome (18.4% vs 19.7%, $p = 0.177$). MELD was only one predictor for 28-day, 90-day, and 1-year adverse outcome in patients with VB if factors were analysed with ACLF. However, cardiac failure and/or respiratory failure were additional risk factors for 28-day, 90-day, and 1-year adverse outcomes in patients with VB if factors were analysed each statistically important organ failure. Compared to results in patients with VB, MELD was an important predictor for 28-day and 90-day adverse outcomes in patients with NVB.

Conclusion: Our results showed no statistically difference of adverse outcomes in cirrhotic patients with VB and NVB. However, there were differences of major predictor for short-term and long-term adverse outcomes between patients with VB and NVB.

FRI-543

Trajectory of outcome from acute-on-chronic liver failure is determined beyond 48 hours of admission to intensive care

Thomas Dixon[1], Laura White[1], Sherif Ghabina[1], Agnieszka Walecka[1], Phyllis Keen[1], Paul Bassett[2], Rajiv Jalan[1], Banwari Agarwal[1], Gautam Mehta[1,3]. [1]*Royal Free Hospital, United Kingdom;* [2]*Statsconsultancy LTD, Amersham, United Kingdom;* [3]*Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom*
Email: thomasdixon@nhs.net

Background and aims: Acute-on-chronic liver failure (ACLF) represents the most severe form of acute decompensation of cirrhosis, associated with multi-organ failure and high mortality. The CLIF-C ACLF score has been shown as a predictor of outcome in Intensive Care Unit (ICU) settings, and to determine futility of ICU care in certain cases (Engelmann et al., 2018). Change in ACLF grade over time (between 3 and 7 days) has been noted to correlate with outcome (Gustot et al., 2015). The aim of this study was to determine if change in CLIF-C ACLF score from ICU admission baseline to day 2 and day 7 were predictive of survival up to 3 months.

Method: Data for consecutive patients admitted to Royal Free London ICU with a complication of cirrhosis, between 2016 and 2017, were contemporaneously maintained on a research database (Research Ethics committee: 21/NI/0175). Additional clinical metadata was entered retrospectively. CLIF-C ACLF scores were calculated at days 0, 2 and 7 following ICU admission, and survival assessed at ICU discharge and 3 months. Differences between CLIF-C ACLF score were compared using unpaired t-test. The relationship between CLIF-C ACLF Score, age, sex and survival at ICU discharge and 3 months were analysed by logistic regression.

Results: The cohort comprised of 102 patients with complete data available at baseline; 64% were males and a median age 55. 63 patients (62%) survived to ICU discharge. Baseline CLIF-C ACLF score was a significant predictor of ICU mortality and survival at 3 months. Change in CLIF-C ACLF score from baseline to day 7, but not day 2, was a significant predictor of survival at ICU discharge and 3-months (Table 1). Logistic regression for survival at 3 months demonstrated an odds ratio of 3.61 (1.04–12.5, $p = 0.04$) for 3-month mortality for every 10-point increase in CLIF-C ACLF score between days 0 and 7; changes at day 2 were not significant.

Conclusion: Although preliminary, the data presented here suggests that re-assessment of clinical status at day 2 following ICU admission is an insufficient time to determine prognosis in ACLF patients. The optimal duration is likely between 3 and 7 days. These data have implications for resource allocation in ICU care of liver patients and merit validation in larger cohorts.

FRI-544

Serum Cytokine and Chemokine profiles and disease prognosis in hepatitis B virus-related acute-on-chronic liver failure

Bingbing Zhu[1], Fangyuan Gao[1], Yuxin Li[1], Ke Shi[1], Yixin Hou[1], Jialiang Chen[1], Qun Zhang[1], Xianbo Wang[1]. [1]*Capital Medical University Affiliated Beijing Ditan Hospital, Center of Integrative Medicine, China*
Email: wangxb@ccmu.edu.cn

Background and aims: Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) has significant morbidity and mortality and is associated with the induction of cytokines/chemokines, which might contribute to the pathogenesis of liver injury. This study aims to explore the cytokines/chemokines profiles of HBV-ACLF patients and develop a composite clinical prognostic model.

Method: We prospectively collected blood samples and clinical data of 107 HBV-ACLF patients admitted to the Beijing Ditan Hospital. The concentration of 40-plex cytokines/chemokines were measured by the Luminex assay in 86 survivors and 21 non-survivors. Discrimination between cytokine/chemokine profiles in different prognosis groups were analyzed using the multivariate statistical technique of principal component analysis (PCA) and partial least square discriminant analysis (PLS-DA). The immune-clinical prognostic model was obtained using multivariate logistic regression analysis.

Results: The PCA and PLS-DA method indicated that the cytokine/chemokine profiling could distinguish patients with different prognosis clearly. 14 cytokines including IL-1β, IL-6, IL-8, IL-10, TNF-α, IFN-γ, CXCL1, CXCL2, CXCL9, CXCL13, CX3CL1, GM-SCF, CCL21 and CCL23 were significantly correlated with disease prognosis. Multivariate analysis identified CXCL2, IL-8, total bilirubin, and age as independent risk factors that constituted the immune-clinical prognostic model, which showed the strongest predictive value of 0.938 compared with the CLIF-C ACLFs (0.785), MELD (0.669), and MELD-Na (0.723) ($p < 0.05$ for all).

Conclusion: Serum cytokine/chemokine profiles correlated with 90-day prognosis of patients with HBV-ACLF. The composite immune-clinical prognostic model we proposed resulted in more accurate prognostic estimates than CLIF-C ACLFs, MELD, and MELD-Na.

Email: thomas.reiberger@meduniwien.ac.at

Background and aims: A low free triiodothyronine (fT3) phenotype has been described in patients with advanced chronic liver disease (ACLD). While conversion, transport and metabolism of thyroid hormones is dependent on hepatic function, thyroid hormones in turn affect hepatic metabolism. We aimed to characterize the pituitary-thyroid axis and the prognostic value of low fT3 in ACLD.
Method: Patients with ACLD, i.e. liver stiffness measurement (LSM) ≥10 kPa or HVPG ≥6 mmHg, undergoing hepatic venous pressure gradient (HVPG) measurement between 04/2007 and 09/2022 with available thyroid stimulating hormone (TSH) levels were considered. Patients with hepatocellular carcinoma (HCC), vascular liver disease, portal vein thrombosis, infections, liver transplantation (LT) or intake of thyroid hormones were excluded. Clinical stages were defined as: probable ACLD (pACLD): LSM ≥10 kPa and HVPG <6 mmHg, S0: mild portal hypertension (PH; i.e. HVPG 6–9 mmHg), S1: clinically significant PH (CSPH) without varices, S2: CSPH with varices, S3: previous variceal bleeding, S4: previous non-bleeding hepatic decompensation and S5: further decompensation.
Results: A total of 648 ACLD patients (median age: 54.7 years; 65.9% male; main etiologies: alcohol-related 50.2% and viral liver disease 22.7%) were included. 316 were compensated (pACLD: n = 31; S0: n = 35; S1: n = 85; S2: n = 165), while 332 had decompensated ACLD (S3: n = 33; S4: n = 170; S5: n = 129). Median levels of TSH (p < 0.001) and C-reactive protein (CRP; p < 0.001) increased with progressive ACLD stages and fT3 (available in n = 298 patients; p < 0.001) declined, while free thyroxin (fT4) levels did not change significantly (available in n = 329 patients; p = 0.368; see Figure). 38 patients showed low fT3 levels with a higher prevalence among dACLD patients (cACLD: 7.0% vs. dACLD: 17.2%; p = 0.009) fT3 correlated with ACLD severity (Child score; rho = −0.52), portal hypertension (HVPG; rho = −0.30) endothelial dysfunction (von Willebrand factor antigen; rho = −0.36) and systemic inflammation (CRP; rho = −0.35). In multivariate linear regression analysis, CRP per mg/dL was associated with TSH (aB: 0.49; p < 0.001), as well as with fT3 (aB: −0.21; p = 0.016) after adjustment for HVPG, Child score and creatinine. Low fT3 was associated with a higher risk of acute-on-chronic liver failure (ACLF; aHR: 4.7; p = 0.004) and liver-related death (aHR: 5.5; p < 0.001), considering etiological cure, HCC, LT and non-liver-related death as competing risks.

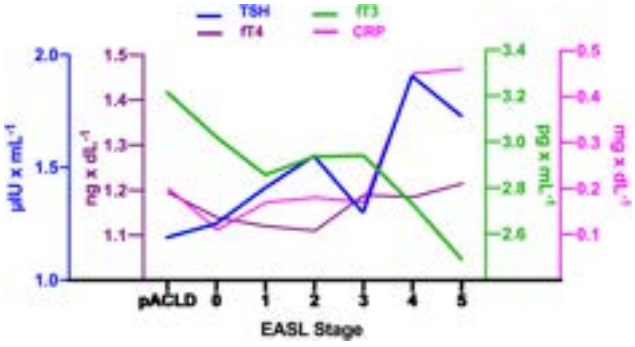

Figure:

Conclusion: The pituitary-thyroid axis is impacted by progressive severity of ACLD. Increasing TSH and declining fT3 levels in more advanced ACLD stages might be indicative of a low T3 (i.e. euthyroid sick) syndrome. In ACLD, low fT3 was associated with key disease driving mechanisms such as systemic inflammation. Importantly, low fT3 in patients with ACLD represents an independent risk factor for ACLF and liver-related death.

Background and aim: Define determinants, predictors, and variations in NI across a global population of cirrhosis inpatients.
Method: CLEARED Consortium prospectively recruited cirrhotic inpatients from 6 continents. Data were collected at baseline and patients followed during their hospitalization. Infections on admission, and NI (diagnosed >48 hrs after admission) were recorded. Comparisons were made between NI vs no-NI variables and between regions. Multivariable (MV) analysis for NI was performed using admission variables.
Results: 3884 patients from 95 centers identified 474 pts (12%) with NIs. Major NIs were respiratory (RTI 32%), UTI (18%), SBP (15%) and spontaneous bacteremia (11%). Most did not have an organism isolated (42%), then gram negative (29%), positive (16%) and fungal (6%). 16% had drug-resistant organisms (DRO) and 20% were 2nd infections. NI vs No-NI admission variables: NI pts were mostly female (p = 0.05), with alcohol as etiology (45% vs 40%, p = 0.05) and higher MELD-Na (26 vs 20, p < 0.0001). NI patients had ↑prior infections (28 vs 19%, p < 0.0001) and AKI (23 vs 15%, p < 0.0001), prior transplant listing (13 vs 9%, p = 0.005), admission lactulose use (48 vs 40% p = 0.006) and lower antivirals (14 vs 19% p = 0.02) use. NI pts had more often admissions due to infections (42 vs 32%, p = 0.006) and lower GI bleed (20 vs 26%, p = 0.008). Rest of the admission causes were similar. Of admission infections, sites were not different between those who developed NI or not. Outcomes: NI pts had higher mortality (32 vs 9%), ICU transfer (42 vs 15%), AKI development (59 vs 32%) [all p < 0.001]. MV analysis for NI had a low AUC (0.67) but was significant for ↑MELD-Na (OR 1.07, p < 0.0001) and infections in past 6 months (1.43, p = 0.002). Male gender (0.71, p = 0.001) was protective. Regional variations: Highest rate of NIs were in India, South America, Asia, and Europe (Fig A). Most common NIs were SBP, RTI and UTIs (Fig B). RTI was highest in Africa, Australia and Asia while UTIs were highest in Mexico and Turkey (Fig C). SBP was highest in China, Turkey and India. Most pts in Africa did not have culture positivity followed by China, Europe and Australia. Gram negatives were higher in Asia and Turkey while Gram positives were relatively similar. Fungal infections were higher in China and Asia. DROs were highest in Asia, Mexico, and USA/Canada (Fig D) but similar overall since many regions did not have enough culture positive isolates.

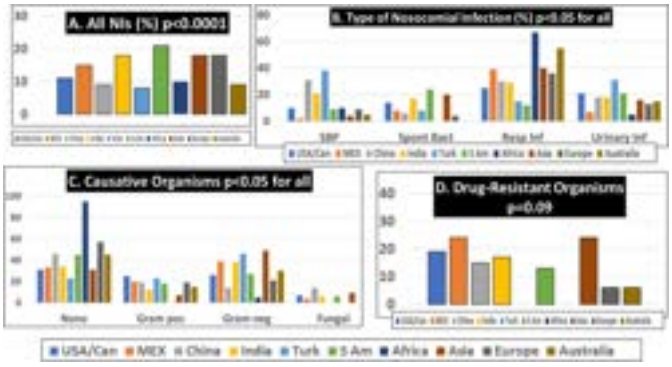

Figure:

Conclusion: In a global consortium of in-patients with cirrhosis, 12% developed NI, mostly women with alcohol cirrhosis, which led to poor outcomes and were difficult to predict. Most NIs were respiratory, UTI and SBP. NI sites, culture positivity rates and resultant DROs were substantially different across regions.

FRI-547
Metabolic biomarkers significantly enhance the prediction of HBV-related acute-on-chronic liver failure prognosis

Background and aims: Acute-on-chronic liver failure (ACLF) is a clinical syndrome of high short-term mortality in patients with chronic liver disease. Early diagnosis and accurate prognosis are needed to improve disease management and survivals for ACLF patients. We aimed to discover novel ACLF biomarkers using metabolomics and assess if the biomarkers can be used to enhance ACLF diagnosis and prognosis.
Method: We performed a metabolomics profiling of 1,024 serum samples collected from HBV-related chronic liver disease patients with acute exacerbation at hospital admission in a multi-year and multi-center prospective study (367 ACLF and 657 non-ACLF). The samples were randomly separated into equal halves as a discovery set and a validation set. We identified metabolites associated with 90-

day mortality in the ACLF group and the progression to ACLF within 28 days in the non-ACLF group (pre-ACLF) using statistical analysis and random forest analysis. We developed diagnostic algorithms in the discovery set and assessed the findings in the validation set.

Results: ACLF significantly altered the serum metabolome, particularly in membrane lipid metabolism, steroid hormone metabolism, oxidative stress pathways, and energy metabolism. Numerous metabolites were significantly associated with 90-day mortality in the ACLF group and/or pre-ACLF in the non-ACLF group. We trained and validated machine learning algorithms for the prediction of ACLF 90-day mortality (area under curve, AUC: 0.87) and the diagnosis of pre-ACLF (AUC: 0.94). To translate our discoveries into practical clinical tests, we developed targeted assays on selected metabolites using liquid chromatography mass spectrometry (LCMS).

Figure:

Conclusion: Based on biomarkers uncovered by metabolomics analysis of a large cohort of HBV related ACLF and non-ACLF serum samples, we developed novel tests with improved accuracy for ACLF prognosis and early diagnosis. The in-depth analysis of metabolic perturbations caused by ACLF could provide new insights on ACLF pathogenesis and therapeutics development, and the novel ACLF tests could be used to improve the clinical management for ACLF patients.

FRI-548

Combination of CLIF-C ACLF and ammonia levels as a predictor of in-hospital outcomes in patients with acute-on-chronic liver failure

Sagnik Biswas[1], Manas Vaishnav[1], Shekhar Swaroop[1], Umang Arora[1], Shalimar Shalimar[1]. *[1]All India Institute of Medical Sciences, New Delhi, India*
Email: drshalimar@gmail.com

Background and aims: The chronic liver failure consortium acute-on-chronic liver failure (CLIF-C ACLF) score performs significantly better than Child-Pugh-Turcotte (CTP), model for end-stage liver disease (MELD) and MELD-Na scores in predicting outcome in patients with ACLF. It also defines futility of care to enable withdrawal of support in patients with irreversible organ failures. Elevated ammonia levels have pleiotropic detrimental effects in multiple organ systems and constitute an independent risk factor to predict hospitalization due to liver related complications and mortality in cirrhotics. We explored the effect of addition of ammonia levels to existing prognostic scores in predicting outcomes in patients with ACLF.

Method: All consecutive ACLF patients with available ammonia values at admission evaluated between January 2011 to June 2022 were included. ACLF was defined as per the EASL-CLIF definition. Prognostic scores including CLIF-C ACLF, MELD-Na, CTP were calculated at baseline. A new model was generated which included CLIF-C ACLF and ammonia levels. Receiver operator characteristic (ROC) curve was used to assess the performance of the prognostic model. Comparison of the area under ROC curves was performed using DeLong method.

Results: A total of 568 patients with ACLF were included, mean (± SD) age 42.4 ± 12.8 years, 456 (80.3%) males. Overall, 160 (28.2%) patients survived. Active alcohol consumption was the most common aetiology, both for the chronic liver disease and the acute insult (57.7% and 43.1% respectively). The mean (± SD) values of prognostic scores on day 1 were as follows: CTP (12.9 ± 1.5), MELD-Na (33.2 ± 6.3), CLIF-C ACLF (51.5 ± 10.0) and serum ammonia 108 (82–140) micromoles/L. The area under curve (AUC) for CLIF-C ACLF score was 0.75 (0.71–0.79) followed by CTP, MELD-Na, and ammonia at 0.71 (0.67–0.75), 0.64 (0.60–0.68) and 0.63 (0.59–0.67) respectively ($p = 0.02$). The model based on combination of CLIF-C ACLF and serum ammonia levels at admission had numerically highest AUC 0.76 (0.72–0.79), and performed significantly better than the CTP ($p = 0.050$), MELD-Na ($p = 0.001$) and serum ammonia ($p < 0.001$) alone, but was equivalent to CLIF-C ACLF score in predicting survival.

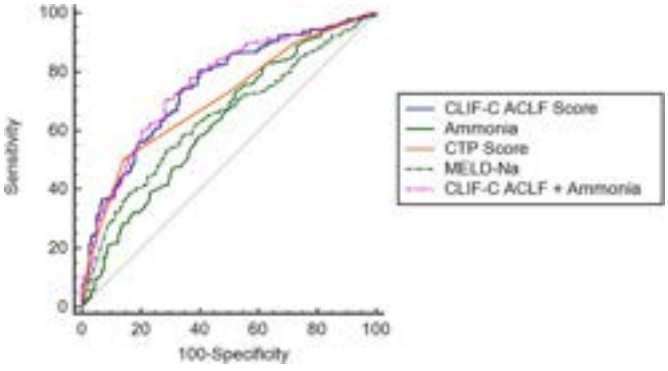

Figure: Receiver operating characteristic (ROC) curves of various prognostic variables and in-hospital mortality.

Conclusion: Addition of ammonia to CLIF-C ACLF score does not improve the overall diagnostic accuracy of CLIF-C ACLF score in predicting in-hospital mortality.

FRI-549

Soluble urokinase plasminogen activator receptor is a biomarker for outcome in decompensated liver cirrhosis and acute-on-chronic liver failure

Sven Lamatsch[1], Mohsin Hassan[1], Carlos de la Peña-Ramirez[2], Kai Kappert[3,4], Raphael Mohr[1], Münevver Demir[1], Minh Phan[1], Fausto Andreola[5], Rhea Veelken[6,7], Niklas F Aehling[6], Janett Fischer[6], Raj Mookerjee[5], Thomas Berg[6], Rajiv Jalan[5], Frank Tacke[1], Cornelius Engelmann[1]. *[1]Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and HumboldtUniversität zu Berlin, Medizinische Klinik mit Schwerpunkt Hepatologie und Gastroenterologie, Berlin, Germany; [2]EF CLIF, Barcelona, Spain; [3]Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and HumboldtUniversität zu Berlin, Institut für Laboratoriumsmedizin, Klinische Chemie und Pathobiochemie, Berlin, Germany; [4]LABOR BERLIN-CHARITÉ VIVANTES GMBH, Fachbereich Laboratoriumsmedizin and Toxikologie, Berlin, Germany; [5]University College London, Royal Free Campus, Liver Failure Group, Institute for Liver and Digestive Health, London, United Kingdom; [6]Universitätsklinikum Leipzig, Klinik und Poliklinik für Onkologie, Gastroenterologie, Hepatologie, Pneumologie und Infektiologie Bereich Hepatologie, Leipzig, Germany; [7]University Hospital of Leipzig, Division of Hepatology, Department of Medicine II, Germany*
Email: cornelius.engelmann@charite.de

Background and aims: Liver cirrhosis represents a major health burden and decompensation may lead to acute-on-chronic liver failure (ACLF) with high morbidity and mortality. Reliable biomarkers predicting the course of the disease are urgently needed in order to

tailor treatment strategies. Expression of urokinase plasminogen activator receptor (uPAR, CD87) and the release of its soluble variant, the cleaved soluble uPAR (suPAR), showed to be related to systemic inflammation in liver disease. Therefore, we were seeking to evaluate suPAR as a predictive marker for the outcome in ACLF.

Method: In a retrospective study plasma suPAR concentrations were measured in two different academic centers in a derivation cohort (n = 178 (healthy controls (n = 6), compensated cirrhosis (n = 17), decompensated cirrhosis (n = 120) or ACLF (n = 35)) and a validation cohort (n = 197 (decompensated cirrhosis (n = 135) or ACLF (n = 62)). SuPAR levels were analyzed with suPARnostic® TurbiLatex (Nr. T004, suPARnostic, ViroGates, Birkerød, Denmark) on a Cobas c501/502 clinical chemistry analyzer (Roche Diagnostics Ltd., Burgess Hill, UK). Clinical data was obtained from patients medical records. Primary end point were death and disease dynamics during hospitalization.

Results: In the derivation cohort, 60.1% of patients were male, 36.5% female and in 3.4% no information on gender was provided. Alcohol related liver disease was the most common etiology before NASH and viral hepatitis. Median suPAR levels were significantly higher in patients with decompensated cirrhosis (13.7 ng/ml) and ACLF (20.0 ng/ml) compared to compensated cirrhosis (6.65 ng/ml) and healthy controls (1.9 ng/ml) ($p < 0.001$). Mortality during hospitalization was 13.7% in decompensated cirrhosis and 34.3% in ACLF. SuPAR levels showed a statistical significant correlation with other parameters indicating disease severity: Creatinine ($r = 0.209$, $p < 0.012$), Bilirubin ($r = 0.473$, $p < 0.001$), Albumin ($r = -0.247$, $p < 0.02$), INR ($r = 0.323$, $p < 0.001$), ALT ($r = 0.273$, $p = 0.001$) as well as disease severity scores such as MELD score ($r = 0.486$, $p < 0.001$) and CLIF-C ACLF score in ACLF patients ($r = 0.454$, $p < 0.001$) and duration of hospitalization ($r = 0.361$, $p < 0.001$). SuPAR levels ≥14.1 ng/ml were associated with a higher in hospital mortality ($p = 0.020$, sensitivity: 75.0%, specificity: 50.8%, AUC = 0.641), need for ICU treatment ($p < 0.001$) and 90 days mortality ($p = 0.003$) and in patients with decompensated cirrhosis higher suPAR levels indicated a higher risk of developing ACLF ($p = 0.014$). These findings were validated in our second cohort: higher suPAR levels indicated a higher 28 days mortality ($p < 0.001$) as well as 90 days mortality ($p < 0.001$) and in Cox-Regression a lower survival ($p < 0.001$, HR = 1.012).

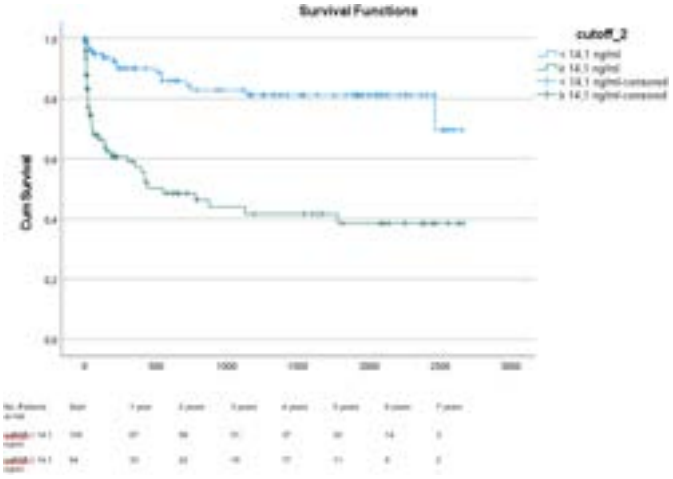

Figure:

Conclusion: SuPAR might be used as biomarker for outcomes in patients with ACLF and acute decompensated liver cirrhosis indicating disease severity.

FRI-550

ACLF course profiles over screening period in the phase IIb DHELIVER study

Email: etienne.sokal@cellaion.com

Background and aims: Acute-on-chronic liver failure (ACLF) is a syndrome characterised by acute decompensation of cirrhosis associated with organ failures and high mortality. ACLF exhibits dynamic clinical course with final ACLF grade (G) defined 3 to 7 days after initial diagnosis in 81% of patients (Gustot, 2015). DHELIVER study is an ongoing Phase IIb RCT double-blinded POC trial that aims to demonstrate the efficacy of HepaStem® on overall survival in patients with persistent ACLF G1 and G2. The purpose of current analysis is to study evolution of ACLF during screening and to describe patients' characteristics.

Method: Consented patients were re-assessed at the end of screening period, 3 to 7 days after initial ACLF diagnosis (according to EASL-CLIF definition). Only patients with confirmed G1 and G2 were randomized.

Results: Up to 26-JAN-2023, 96 patients with ACLF (69 M/27 F), aged 52.5 years (range: 25–73), were screened in 23 sites in 11 European countries: 61 G1 and 35 G2. During screening (3 to 7-days) ACLF recovered or improved in 27 patients (28.1%), stable clinical course was in 57 patients (59.4%) and 12 patients worsened (12.5%). By ACLF grade: among G1, ACLF resolved in 39.3%, was stable in 49.2%, and worsened in 11.5% (9.8% to G2 and 1.6% died); while among G2, clinical course of ACLF was stable in 77.1%, worsened in 14.3% (2.9% to G3 and 11.4% died), and improved in 8.6% (2.9% to G0 and 5.7% to G1). Fifty-five patients (34 G1 and 21 G2) were enrolled; 41 (27 G1 and 14

G2) were screen failures, mostly because their condition resolved (61.0%, 24 G1 and 1 G2) or worsened/died (14.6%; 1 G1 and 4 G2 died, 1 G2 to G3). Enrollment criteria were not met for 10 patients (24.4%). The etiology of cirrhosis was mainly alcohol (88.5%). Other etiologies included NASH (2.1%), a combination of alcohol with viral (HCV or HBV) infection, hemochromatosis, or NASH (5.2%) or were unknown (4.2%). Patients with alcohol etiology were slightly younger compared to other etiologies (52.0 vs 56.3 years) and had more pronounced biochemical (e.g., total bilirubin: 20.2 vs 9.4 mg/dL) or hematological (e.g., WBC: 12.7 vs 10.0 G/L) alterations. Precipitating events of ACLF were mostly acute alcoholic hepatitis/active alcoholism (71.0%; 43.8% of them were on steroids) and bacterial infection (29.3%). Other trigger events were GI bleeding (3.1%), DILI (2.1%), or unknown (13.5%). Organ failures affected mainly the liver (68.8%), coagulation (46.9%), and kidney (8.3%). Most patients with G1 had liver failure (57.4%), primarily associated with mild or moderate hepatic encephalopathy (HE) (85.7%).

	Randomized		Screen failures	
N	55		41	
Age	52.0 ± 10.7		53.1 ± 9.5	
M/F	42/13		27/14	
	G1	G2	G1	G2
Initial ACLF grade	34	21	27	14
Stable	28 (82.4%)	19 (90.5%)	2 (7.4%)	8 (57.1%)
Improved	-	2 (9.5%)	24 (88.9%)	1 (7.1%)
Worsened	6 (17.6%)	-	1 (3.7%)	5 (35.7%)
T-BIL (mg/dL)	21.5 ± 10.5[2]		15.9 ± 9.0≥	
WBC (G/L)	13.8 ± 7.7[1]		10.4 ± 5.9≥	
CRP (mg/L)	36.6 ± 26.1[2]		33.4 ± 38.6[10]	
INR	2.3 ± 0.7		2.5 ± 0.8[4]	
CLIF-ACLF score	49.8 ± 5.2		47.5 ± 8.0≥	

[x]: information missing for x patients

Figure:

Conclusion: This prospective study confirms the variable and highly dynamic course of the disease in patients with ACLF G1 and G2 over the 3 to 7-day period post initial diagnosis. Improvement was most commonly observed in patients with ACLF G1 (39.3% vs 8.6% in G2). The most common etiology of cirrhosis was alcohol-related liver disease. Hepatic failure represented the most common type of organ failure, characterized by high level of bilirubin associated with HE.

FRI-551

Lower free and total serum cortisol levels are associated with higher risk of bacterial infection and acute-on-chronic liver failure in stable outpatients with advanced chronic liver disease

Lukas Hartl[1,2], Benedikt Simbrunner[1,2,3], Mathias Jachs[1,2], Peter Wolf[4], David Jm Bauer[1,2], Bernhard Scheiner[1,2], Lorenz Balcar[1,2], Georg Semmler[1,2], Michael Schwarz[1], Rodrig Marculescu[5], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2,3].

Email: thomas.reiberger@meduniwien.ac.at

Background and aims: We aimed to evaluate the prognostic value of free (f-Cort) and total serum cortisol (t-Cort) in a cohort of stable outpatients with advanced chronic liver disease (ACLD).
Method: We included consecutive outpatients with ACLD and hepatic venous pressure gradient (HVPG) measurement within the prospective VICIS (NCT03267615) study. Exclusion criteria were HVPG <6 mmHg, hepatocellular carcinoma, vascular liver disease, occlusive portal vein thrombosis, a history of liver transplantation, evidence of infection and intake of corticosteroids. Competing risk regression was performed considering liver transplantation and death (or non-liver-related death, as appropriate) as competing events.
Results: In total, 151 patients (compensated ACLD: n = 61; decompensated ACLD: n = 90) were included. There was a strong correlation between f-Cort and t-Cort (Spearman's rho: 0.893).
Lower levels of f-Cort and t-Cort independently predicted bacterial infections (f-Cort: aHR per ng/ml: 0.89; p = 0.014/t-Cort: aHR per µg/dL: 0.91, p = 0.003) and acute-on-chronic liver failure (ACLF; f-Cort: aHR per ng/ml: 0.84; p = 0.003/t-Cort: aHR per µg/dL: 0.90, p = 0.001). Youden's index determined f-Cort <4.8 ng/ml and t-Cort level <12.0 µg/dL as ideal cutoffs for the prediction of ACLF. Overall, 69/146 (47.3%) and n = 95/151 (62.9%) patients exhibited f-Cort <4.8 ng/ml and t-Cort <12 µg/dL, respectively. Patients with f-Cort <4.8 ng/ml tended to exhibit a more advanced clinical stage of ACLD (p = 0.095) and patients with t-Cort <12 µg/dL tendentially had more severe ACLD (CTP score: ≥12 µg/dL: 6.0 points vs. <12 µg/dL: 7.0 points; p = 0.053) and more pronounced portal hypertension (HVPG: ≥12 µg/dL: 15 mmHg vs. <12 µg/dL: 18 mmHg; p = 0.073). With low t-Cort (i.e. <12 µg/dL), the cumulative incidences of bacterial infections (p = 0.026), (further) decompensation (p = 0.028), and ACLF (p = 0.005) were significantly higher (Figure), with similar-but non-significant-trends observed for low f-Cort <4.8 ng/ml. Both f-Cort <4.8 ng/ml and t-Cort <12 µg/dL were independently linked to increased risk of bacterial infections (f-Cort <4.8 ng/ml: aHR: 2.11; 95%CI: 1.06–4.23; p = 0.034/t-Cort <12 µg/dL: aHR: 2.91; 95%CI: 1.12–7.00; p = 0.017), (further) decompensation (f-Cort <4.8 ng/ml: aHR: 2.23; 95%CI: 1.27–3.91; p = 0.005/t-Cort <12 µg/dL: aHR: 1.87; 95%CI: 1.06–3.30; p = 0.032) and ACLF (f-Cort <4.8 ng/ml: aHR: 2.45; 95%CI: 1.16–5.19; p = 0.019/t-Cort <12 µg/dL: aHR: 3.51; 95%CI: 1.35–9.10; p = 0.009).

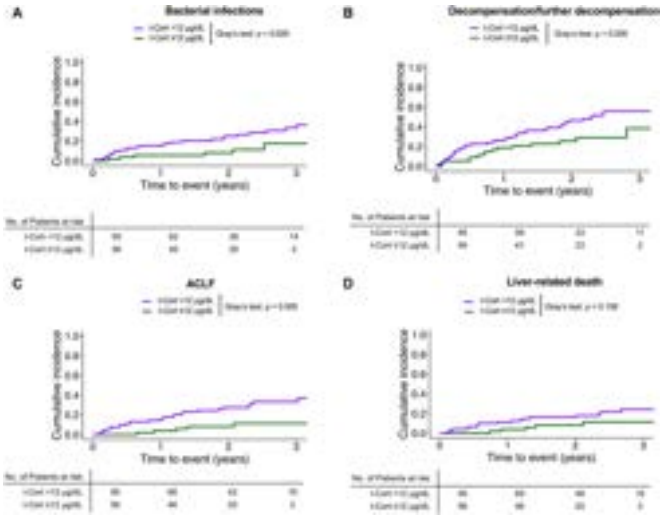

Figure:

Conclusion: Lower levels of both f-Cort and t-Cort are independently linked to bacterial infections and ACLF in patients with ACLD, possibly due to an impaired stress response. Moreover, f-Cort <4.8 ng/ml and t-Cort <12 µg/dL identify stable patients with ACLD with a particularly high risk of adverse outcomes.

FRI-552

Acute on chronic liver failure is associated with prolonged clot initiation in rotational thromboelastometry as compared to acute decompensation, but clot formation time and firmness are similar

Tian Yu Qiu[1], Louis Wang[1], Chin Kimg Tan[1], Eugene Wong[1], Kenneth Lin[1], Andrew Kwek[1], James Weiquan Li[1], Tiing Leong Ang[1], Roshni Sahashiv[2], Louis Ng[3], Prasanna Tirukonda[4], Rahul Kumar[1].

Email: rahul.kumar@singhealth.com.sg

Background and aims: Viscoelastic Test (VET) such as Rotational Thromboelastometry (ROTEM) is increasingly used in cirrhosis to guide blood product transfusion strategies as compared to conventional coagulation tests (CCT). Although ROTEM successfully reduced transfusion requirements, there is little clarity around changes in ROTEM parameters with severity of presentation i.e., Acute Decompensation (AD) or Acute on Chronic Liver Failure (ACLF). We aim to compare coagulation panel amongst AD and ACLF population using ROTEM.

Method: This is a single-center observational study conducted from August 2021 to December 2022 which included all patients admitted for AD or ACLF (defined based on EASL-CLIF classification). ROTEM, CCT and severity of liver disease (Child-Pugh score and MELD score) of both groups were collected and compared. Data was analyzed using standard statistical tests in SPSS.

Results: A total of 54 participants were included (38 in AD and 16 in ACLF group). The results are shown in Table 1. The mean age was 60.3 ± 10.5 years and 77.8% were males. Child-Pugh score and MELD scores among AD vs ACLF were (10.0 vs 10.5; p = 0.227) and (15.82 vs 23.25; p = <0.001) respectively. CCT showed marked derangements in PT (15.05 seconds (s) vs 18.20 s; p = 0.012) and aPTT (35.29 s vs 51.12 s; p = <0.001) but platelet and fibrinogen levels were comparable. (p = NS). Comparison of ROTEM parameters between groups showed initiation of clot formation was delayed in ACLF patients as evidenced by statistically significant prolongation of clotting time (CT) in INTEM (205.86 s vs 258.13 s; p = <0.001), EXTEM (73.39 s vs 91.06 s; p = 0.022) and FIBTEM (78.00 s vs 139.13 s; p = 0.013). However, interestingly clot formation time (CFT) in INTEM (132.83 s vs 165.44 s) and EXTEM (121.36 s vs 156.63 s) were similar between groups (p = NS), as was maximal clot firmness (MCF) in INTEM (48.75 millimeter (mm) vs 48.31 mm), EXTEM (50.25 mm vs 49.75 mm) and FIBTEM (11.69 mm vs 12.44 mm), (p = NS).

This data suggests that although there is a significant delay in clot initiation in ACLF patients, clot formation is not affected and the clot is as strong as in patients with AD. These findings have practical implications for ACLF patients undergoing either elective procedures or actively bleeding, as they should not be over transfused just to correct the delayed clot initiation. Another novel finding is although low fibrinogen levels were detected in AD, patients with ACLF had normal levels (p = NS). We cannot fully explain this finding mechanistically and it will require further exploration.

Table 1: Comparison of baseline characteristics, CCT and ROTEM parameters between AD and ACLF patients

	Normal values/ranges	All Patients (N=54)	AD (n=38)	ACLF (n=16)	P value

SD = mean (SD)
IQR = median (IQR)
% = number (%)

Figure:

Conclusion: Our prospective exploratory study shows that in patients with ACLF as compared to AD, based on ROTEM parameters, although clot initiation is delayed, clot formation and strength of clot remains similar. Further studies are needed to validate our findings.

FRI-553

Even small amounts of alcohol consumption can worsen the prognosis in acutely decompensated patients with viral hepatitis

Jung Hee Kim[1], Sung-Eun Kim[1], Jang Han Jung[1], Hyoung Su Kim[1], Eileen Yoon[2], Jae Young Jang[3], Dong Joon Kim[1]. [1]*Hallym University College of Medicine, Korea, Rep. of South;* [2]*Hanyang University College of Medicine, Korea, Rep. of South;* [3]*Soonchunhyang University College of Medicine, Korea, Rep. of South*
Email: sekim@hallym.or.kr

Background and aims: Acute decompensation (AD), especially accompanied by dysfunction of other organs, is a common cause of death or liver transplantation (LT) in chronic liver disease (CLD). However, when comparing the aetiology of CLD, little is known about how aetiology affects the adverse outcomes of AD in CLD.

Method: The prospective Korean Acute-on-Chronic Liver Failure (KACLiF) cohort consisted of 1,501 patients who were hospitalized with AD of CLD, including either liver cirrhosis (LC) or noncirrhotic CLD, from July 2015 to August 2018. We compared their clinical characteristics and analysed 28-day/overall adverse outcomes according to the aetiology of CLD.

Results: There was a median follow-up of 8.0 months (1.0–16.0 months), the mean age was 54.7 years, and 74.5% of patients were male. Cirrhosis was confirmed in 93.2% of patients. The most common aetiology of CLD was alcohol-related CLD (n = 1021), followed by viral hepatitis CLD (n = 206), viral hepatitis with alcohol-related CLD (n = 129), cryptogenic CLD (n = 108) and autoimmune-related CLD (n = 37). Viral hepatitis with alcohol-related CLD showed a poor liver function profile and a high frequency of acute-on-chronic liver failure (ACLF) (22.1%), with worse 28-day/overall adverse outcomes than other aetiologies. The difference in aetiology was a significant factor for 28-day adverse outcomes in multivariate analysis. In the subgroup analysis according to MELD, the differences in aetiology were stratified into 28-day adverse outcomes among patients with a high MELD score (≥15) (p = 0.001). Patients who

consumed alcohol or more than a small amount of alcohol (males, >20 g/day, females, >40 g/day) showed the most increased 28-day adverse outcomes of viral hepatitis with alcohol-related CLD. In addition, patients who did not drink or drank small amounts of alcohol showed increased overall adverse outcomes of viral hepatitis with alcohol-related CLD compared with viral hepatitis or alcohol-related hepatitis.

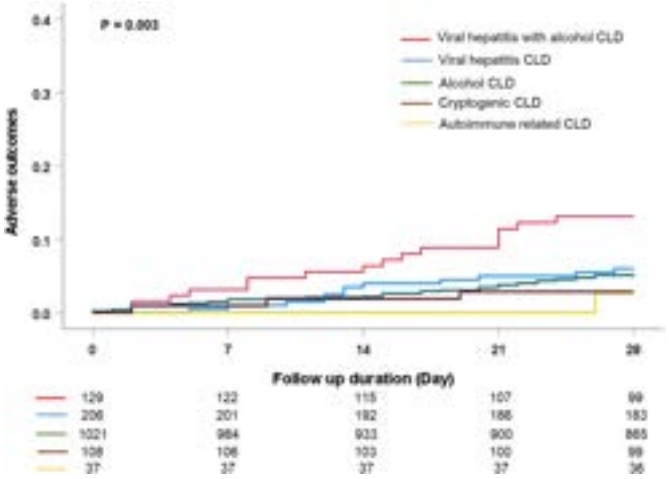

Figure: 28-days adverse outcome according to etiology of CLD

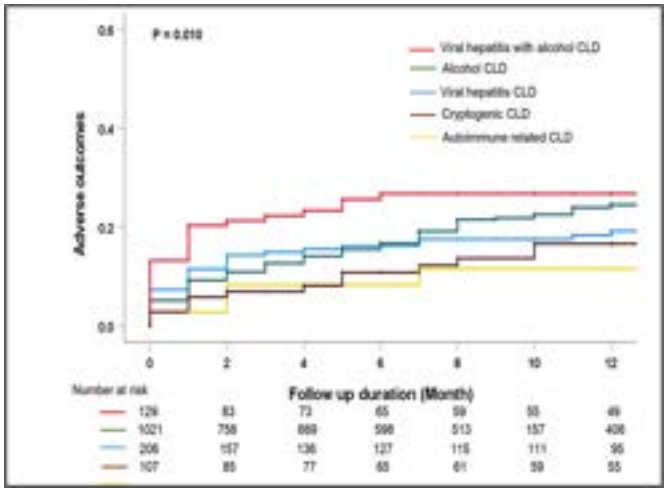

Figure: Overall adverse outcome according to etiology of CLD

Table. Association with alcoholic intake and adverse outcomes

Conclusion: The aetiology of CLD is a valuable factor that affects short- and long-term adverse outcomes of AD in CLD, even among patients with high MELD scores. Thus, the aetiology of CLD, especially viral hepatitis with alcohol related CLD, should be considered when determining the priority of LT together with the MELD system for patients with AD of CLD. Additionally, patients with viral hepatitis should be careful even with small amounts of alcohol intake, which can cause aggravating adverse outcomes of AD.

FRI-554

High histamine levels associate with acute-on-chronic liver failure and liver-related death in patients with advanced chronic liver disease

Michael Schwarz[1,2], Benedikt Simbrunner[1,2], Mathias Jachs[1,2], Lukas Hartl[1,2], Bernhard Scheiner[1,2], Rafael Paternostro[1,2], David Jm Bauer[1,2], Matthias Pinter[1,2], Albert Stättermayer[1,2], Michael Trauner[1], Thomas Reiberger[1,2], Mattias Mandorfer[1,2].
[1]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Austria; [2]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna Hepatic Hemodynamic Lab, Austria
Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Mast cells have been implicated in liver disease progression. The role of plasma histamine in advanced chronic liver disease (ACLD) is not fully understood, but may pose a potential target for pharmacological intervention.
Method: Patients (pts) included in the prospective VIenna CIrrhosis Study (VICIS) who underwent hepatic venous pressure gradient (HVPG) measurement (=baseline, BL) from April 2017 until March 2020 were considered. Inclusion criteria were portal hypertension (HVPG ≥6 mmHg) and/or a liver stiffness measurement by vibration-controlled transient elastography ≥10 kPa.
Results: Of the 251 included pts, 167 (66.5%) were male and median age was 58.5 years (IQR 49.8–67.0). The most common etiologies were alcohol-related liver disease (102 pts, 40.6%) and viral hepatitis (51 pts, 20.3%). Child-Turcotte Pugh (CTP) stages were: A 142 pts (56.6%), B 84 pts (33.5%), and C 25 pts (10.0%). A quarter of pts (67, 26.7%) had a model for end-stage liver disease (MELD) score ≥15 and half of pts were decompensated at BL (135 pts, 53.8%).
Median plasma histamine was 8.5 nmol/L (IQR 6.3–11.5) and 37.1% of patients had values above the upper normal limit (i.e., 9.9 nmol/L). Interestingly, histamine levels did not differ significantly across CTP, MELD, or HVPG strata. However, histamine concentrations showed weak positive correlations with markers of circulatory dysfunction (i.e., plasma renin and serum sodium).
During a median follow-up of 28.9 months, 69 patients developed acute-on-chronic liver failure (ACLF) or liver-related death. In univariate Cox proportional-hazards model, BL plasma histamine levels were predictive of overall mortality (hazard ratio [HR]: 1.021 per nmol/L; 95% confidence interval [95%CI]: 1.005–1.038]; p = 0.010) as well as ACLF or liver-related death (HR: 1.023; 95%CI: 1.007–1.039]; p = 0.004). When adjusting for either MELD, clinical stage, and serum albumin or CTP and serum sodium as well as age, sex, and HVPG, histamine levels remained associated with ACLF or liver-related death: CTP-based model: 1.033 (95%CI 1.014–1.053), p < 0.001; MELD-based model: 1.030 (95%CI 1.010–1.050), p 0.003 (Figure).
Conclusion: High plasma levels of histamine were linked to circulatory dysfunction and associated with increased risks of ACLF and liver-related death during follow-up. Further studies investigating the underlying mechanism (i.e., mast cell activation vs. decreased degradation) and the implications of histamine for hyperdynamic circulation and ACLF development are warranted.

FRI-555

Detection of 1,3-beta-D-glucan increases with the severity of decompensation stages in liver cirrhosis and is associated with lower survival in patients with acute on chronic liver failure

Adam Herber[1], Janett Fischer[1], Cornelius Engelmann[2], Niklas F Aehling[1], Rhea Veelken[1], Sirak Petros[3], Lorenz Weidhase[3], Thomas Berg[1], Florian van Bömmel[1]. *[1]Leipzig University Medical Center, Division of Hepatology, Department of Medicine II, Leipzig, Germany; [2]Campus Charité Mitte/Campus Virchow-Klinikum, Department of Hepatology and Gastroenterology, Germany; [3]University Hospital Leipzig, Medical Intensive Care Unit, Germany*
Email: adam.herber@medizin.uni-leipzig.de

Background and aims: Increased intestinal permeability (IP) and translocation of pathogen associated molecular patterns (PAMPs) are factors contributing to the pathogenesis and outcomes of acute-on-chronic liver failure (ACLF). The polysaccharide 1,3-β-D-glucan (BDG) is a potential marker for increased IP. We have studied the correlation of BDG in patients with different stages of chronic liver disease.
Method: A total 230 individuals including 98 CLIF-ACLF patients (mean MELD score 27 ± 8, ACLF grade 1: n = 59, grade 2: n = 23, grade 3: n = 16), 84 patients with decompensated cirrhosis with ascites (mean MELD score 16 ± 6), 24 with compensated cirrhosis (mean MELD 12 ± 6) (76% male, mean age 57 ± 9 years, 77% alcohol related liver disease), and 24 controls were prospectively enrolled. Blood samples from patients were collected during the hospital stay and stored at −20°C. BDG levels were measured in the serum (n = 230) and, if available, in corresponding duodenal fluids samples (n = 125) by Kinetic Turbidimetric Assay (FUJIFILM Wako, Japan, LLOD = 2.57 pg/ml) and correlated with outcomes.
Results: BDG was more frequently detected in serum samples from ACLF patients (42/98, (43%)) than in patients with decompensated cirrhosis (23/84 (27%), p = 0.03), compensated cirrhosis (3/24, (12%), p = 0.008) or healthy controls (2/24 (8%), p = 0.002). The BDG-detection rate correlated with the ACLF grade (ACLF 1: 120/59 (34%), ACLF 2: 10/23 (43%) and ACLF 3: 12/16 (75%); ACLF 1 vs. ACLF 3 p = 0.0004). The mean serum BDG concentration was higher in ACLF 3 than in ACLF 1 patients (22.6 ± 19.1 vs. 16.2 ± 27.31 pg/ml, p = 0.0003). In contrast, in duodenal fluid samples the frequency of BDG detection was similar across all groups (79–100%). Within the ACLF group, mean 60-day, 90-day (31.7 ± 8.3% vs. 59.5 ± 6.9%; p = 0.012) and overall survival were significantly lower in patients with detectable BDG compared to those without BDG. In a multivariate Cox-regression analysis for 90-day mortality adjusted for ACLF grade and MELD, the detection of BDG in serum showed an OR of 19.0 (95% CI 4.0–90.9), p = 0.0002. In all patients, there was one microbiologically proven fungal infection in blood samples.
Conclusion: The serum BDG detection rate increases with increasing severity of chronic advanced liver disease and this serum marker is associated with significantly reduced survival in patients with ACLF. Serum BDG might be a marker of intestinal permeability and its potential for personalized patient management should be addressed in further studies.

FRI-556

Parvovirus B19 infection associated with adverse outcomes in decompensated cirrhosis patients

Changze Hong[1], Beiling Li[1], xiaojing wang[2], Yanhang Gao[3], wei yuan[4], Qinjun He[1], Xiaoqin Lan[1], Qintao Lai[1], Wenfan Luo[1], Tingting Qi[1], Jinjun Chen[1,5]. *[1]Hepatology Unit, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, China; [2]Centre of Integrative Medicine, Beijing Ditan Hospital, Capital Medical University, Beijing, China, China; [3]Department of Hepatology, The First Hospital of Jilin University, Jilin University, Changchun, China, China; [4]Department of Liver Intensive Care Unit, Shanghai Public Health Clinical Centre, Fudan University, Shanghai, China., China; [5]Hepatology Unit, Zengcheng Branch, Nanfang Hospital, Southern Medical University, Guangzhou, China, China*
Email: chjj@smu.edu.cn

Background and aims: Cirrhotic patients are characterized by cirrhosis associated immune dysfunction and have a non-hepatotropic viral signature which correlates with clinical progression and poor outcomes. Human parvovirus B19 (B19V), a non-hepatotropic virus, is rarely reported in cirrhotic patients and its potential pathogenic role remains unknown. This study aims to assess the clinical characteristics and outcomes of B19V infection in decompensated cirrhosis.
Method: Acutely decompensated cirrhosis patients were recruited from two prospective, multi-center cohort study (from 2015 to 2020 and from 2021 to 2022, respectively). Demographics, laboratory data, antibiotic treatment and outcomes (death or transplant) were recorded. Metagenomic next-generation sequencing (mNGS) for plasma microbial cell-free DNA was performed in this study. According to the detection of plasma mNGS, patients with B19V or without any pathogens detectable (including only HBV detected) were included in analysis and were divided into "B19V positive" and "B19V negative" groups. Outcomes of patients with and without B19V infection were compared for transplant censored 28-day mortality by Log-rank test.
Results: Totally, 273 patients were enrolled. The mean age was 52 ± 11 years and male (81.3%) were predominant. HBV (71.1%) was the common etiology of cirrhosis. B19V were detectable in 10 (3.7%) patients by plasma mNGS testing, who were defined as the "B19V positive" group. Furthermore, 83 (30.4%) patients with complete

Figure: (abstract: FRI-554): Cox proportional-hazard models for ACLF or liver-related death. Univariate and multivariate models adjusted for MELD as well as for CTP are shown. Histamine was found to be an (independent) predictor of ACLF or liver-related death in the univariate model as well as in both multivariate models, which were adjusted for established prognostic indicators. HR = hazard ratio, aHR = adjusted hazard ratio, CI = confidence interval.

absence of pathogens and 28 (10.3%) only with HBV detectable were defined as the "B19V negative" group.
Compared to the "B19V negative" group, fever was more common in the "B19V positive" group (Figure A). The level of haemoglobin (73.8 ± 18.6 g/L vs 104.2 ± 25.3 g/L, p < 0.001) was significantly lower in the "B19V positive" group. Higher proportion of severe anaemia (Figure B) was observed in the "B19V positive" group, while the incidence of acute bleeding did not significantly differ between two groups (20.0% vs 14.4%, p = 0.991). Further, the percentage of unproven infection was significantly higher in "B19V positive" group compared to "B19V negative" group (60.0% vs 23.1%, p = 0.048). In "B19V positive" group, empirical antibiotic therapy was less effective (Figure C), and the resolution rate of infections was significantly lower (Figure C). Moreover, incidence of acute kidney failure was more frequent in "B19V positive" patients than that of the "B19V negative" (50.0% vs 14.4%, p = 0.016). Survival analysis showed that those with B19V infection had significantly higher 28-day mortality than those without B19V infection (Figure D).

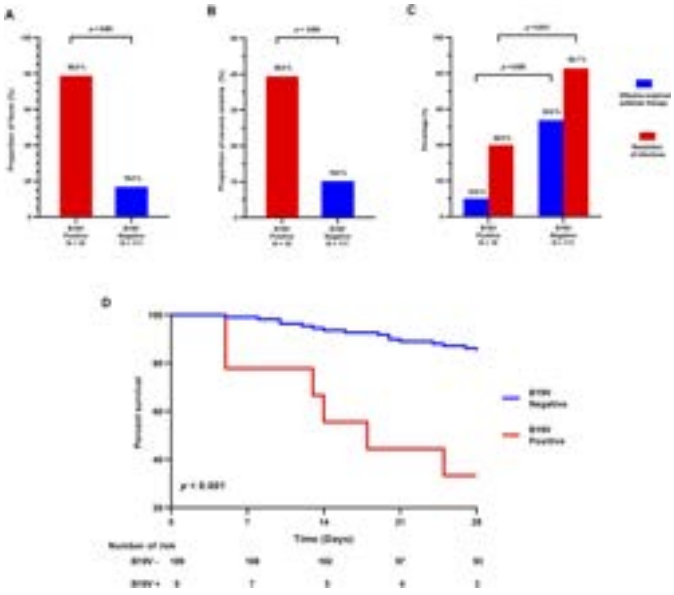

Figure:

Conclusion: B19V infection may have a pathogenic role in the adverse outcomes of cirrhotic patients, with clinical manifestations of recurrent fever, anemia and poor response of antibiotic therapy. This suggests that routine screening for B19V may benefit the management for the decompensated cirrhosis.

FRI-557

Real-world evidence of reversibility in patients with acute-on-chronic liver failure that survive hospitalization

Ahmed Elshabrawi[1,2], Kohilan Gananandan[1], Alexandra Phillips[1], Raj Mookerjee[1,3], Rajiv Jalan[1]. *[1]The Liver Failure Group, UCL Institute for Liver and Digestive Health, London, United Kingdom; [2]Mansoura University, Endemic Hepatology and Gastroenterology, Mansoura, Egypt; [3]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark*
Email: r.jalan@ucl.ac.uk

Background and aims: Acute-on-Chronic Liver Failure (ACLF) is characterized by rapid deterioration of liver function and high short-term mortality rates. Although previous studies have hypothesized potential reversibility of ACLF, real-world data are lacking. In this study, we aimed to evaluate the clinical course and survival of hospitalized cirrhosis patients with ACLF in comparison to those with no ACLF.
Method: Consecutive patients with acute decompensation (AD) of cirrhosis with and without ACLF admitted to a single hepatology and transplantation center, between October 2018 and February 2021 were studied. Clinical and biochemical data, survival times and need for rehospitalization were collected at specified time points (index admission, discharge, 3, 6 and 12 months). ACLF was defined according to the EASL-CLIF criteria. The analyses were performed using data from the time of hospital discharge.
Results: 387 (67.4% males; mean age 58 years) cirrhosis patients were admitted with liver-related decompensation over the 29-month study period. Survivors were classified at discharge into ACLF group (n = 48) and no ACLF (AD) group (n = 283). Higher level of diuretic use at discharge was noted in the AD subgroup (p = 0.039) but no other significant differences were noted with regards to organ function parameters. During follow-up, serum albumin, bilirubin, INR, serum creatinine, severity of hepatic encephalopathy, portal hypertension related gastrointestinal bleeding and disease severity scores were similar in the two groups. There were no significant differences in the mean survival at 3, 6 and 12 months between the ACLF and the AD groups. Over the 12 months following discharge, there was no difference in the rate of re-hospitalizations with liver related complications between the ACLF group [0.35 (range, 0–5)] and the AD group [0.54 (range, 0–7)]; per patient, p = 0.264. To identify predictive factors of 90-day survival post-discharge of the whole cohort, univariate logistic regression analysis was conducted, showing that total serum bilirubin (OR = 0.996, 95% CI, 0.994–0.999; p = 0.003), INR (OR = 0.47, 95% CI, 0.231–0.954; p = 0.037), WBCs (OR = 0.91, 95% CI, 0.856–0.967; p = 0.003) and need for beta blockers at discharge (OR = 0.375, 95% CI, 0.168–0.834; p = 0.016), were significant predictors of survival, with only beta blockers remaining significant in a multivariate analysis (p = 0.023).
Conclusion: These real-world data show for the first time that patients surviving an episode of ACLF or AD are comparable in terms of re-hospitalizations and survival arguing strongly for the potential reversibility of ACLF. These data provide a strong rationale for rapid access of ACLF patients to intensive care to allow recovery and planning the need for liver transplantation.

FRI-558

Spur cells in liver cirrhosis are predictive of ACLF and liver-related mortality regardless of severe anaemia

Michele Bevilacqua[1], Leonardo De Marco[2], Roberta Stupia[2], Francesco Dima[3], Filippo Cattazzo[2], Veronica Paon[4], Donatella Ieluzzi[4], Andrea Dalbeni[2], David Sacerdoti[4]. *[1]Azienda Ospedaliera Universitaria Integrata, Verona, General Medicine C and Liver Unit, Verona, Italy; [2]General Medicine C and Liver Unit, Italy; [3]Laboratory section, AOUI Verona, Italy; [4]Liver Unit, Italy*
Email: bevilacqua.michele@yahoo.com

Background and aims: Chronic anaemia in advanced liver disease is a frequent finding that need to be carefully evaluated. The aim was to explore the clinical impact of spur cells anaemia, a rare form of non-immune haemolytic anaemia in which red blood cells are spiky-like and that is typically associated with end-stage cirrhosis with poor outcome in absence of etiological therapy.
Method: 119 consecutive patients (73.9% males; 43.7% alcoholic, 35.7% viral, 10.1% autoimmune, 10.9% metabolic) referring to our Liver Unit outpatient clinic were enrolled. Inclusion criteria were consistent with a diagnosis of liver cirrhosis of any aetiology and disease severity but without hepatocellular carcinoma. Patients with bone marrow diseases or nutrients deficiencies (iron, folates, vitamin B12) were excluded. In all patients a blood smear was performed in order to assess red blood cells morphology and quantify spur cells (achantocytes and echinocytes). A complete blood biochemical panel was recorded together with Child-Pugh (CPS) and MELD score. For each patients clinical data (acute decompensation and acute-on chronic liver failure, ACLF) and 1-year liver-related mortality were obtained. A cut-off of 5% of spur cell was considered as a threshold for clinical significance.
Results: 11 out of 119 patients (9.2%) had more than 5% of spur cells in blood smear, 7 out of 11 had alcoholic cirrhosis and 2 out of 11 had

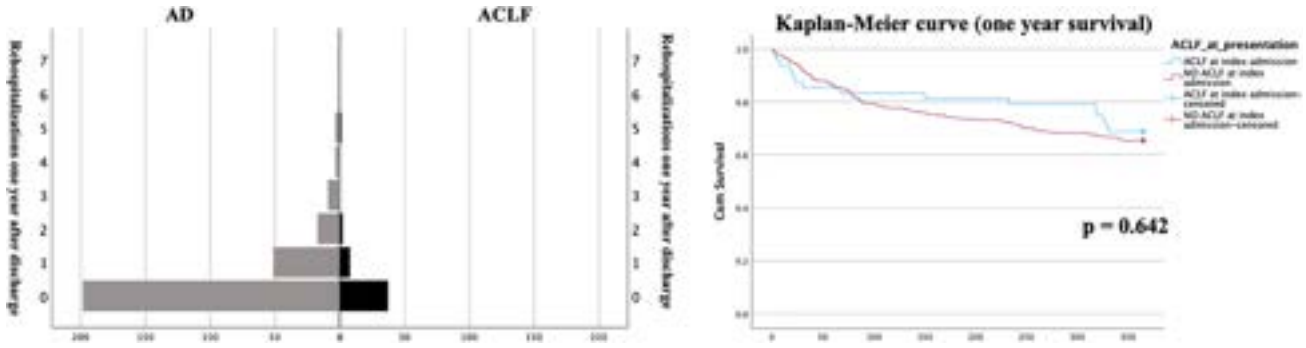

Figure: (abstract: FRI-557): Re-hospitalization and survival of patients with AD and ACLF post discharge

evidence of haemolysis; 33.6% (40/119) had more than 1%. In patients with more than 5% of spur cells, haemoglobin was lower compared with the other sub-group, while CPS, MELD score, prothrombin time, creatinine and unconjugated bilirubin were higher; no differences were shown in ferritin, folates, B12 vitamin, albumin and total bilirubin. Patients with more spur cells were more frequently decompensated, had more ascites (100% vs 55.1%, p = 0.002) and hepatic encephalopathy (63.6% vs 20.8%, p = 0.008). The median follow-up was 10 months (IQR 8–12 months). In multivariate Cox-regression analysis, CPS (HR 1.4 95% I.C.[1.2–1.7], p = 0.001) and spur cells >5% (HR 3.4 95% I.C.[1.5–8.0], p = 0.005), but not age, sex and MELD score, were independently related with ACLF development during follow-up. Similarly, the presence of more than 5% of spur cells (HR 3.3 95% I.C.[1.4–7.8], p < 0.001), together with CPS and MELD score, was independently associated with 1-year liver-related mortality.

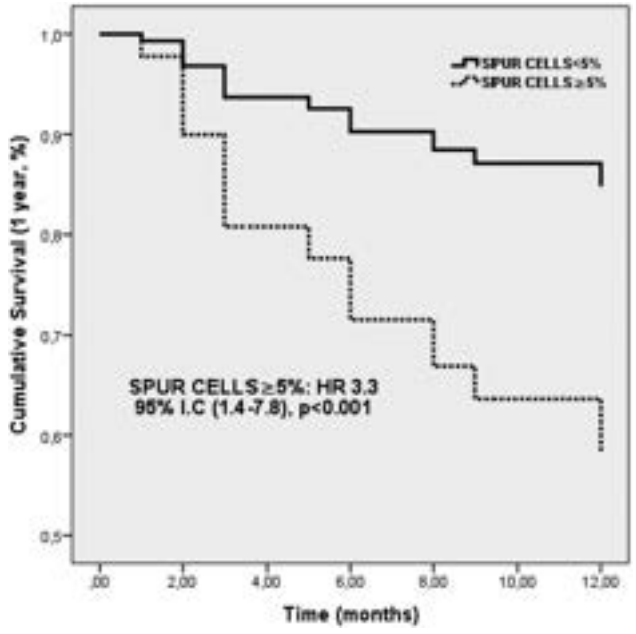

Figure:

Conclusion: Our results are consistent with a fairly high prevalence of spur cells in blood smear of cirrhotic patients. Despite not always associated with clinically overt haemolytic anaemia, the presence of spur red cells is associated *per se* with more severe disease, ACLF development and worse liver-related outcomes, underlining the role of blood smear in better stratifying prognosis and eventually prioritize patients for liver transplant.

FRI-559

Plasma thrombomodulin as a candidate biomarker for the diagnosis and prognosis of HBV-related acute-on-chronic liver failure

Xingping Zhou[1], Jinjin Luo[1], Xi Liang[2], Peng Li[1], Jiaojiao Xin[1], Jing Jiang[1], Dongyan Shi[1], Jun Li[1]. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Hangzhou, China; [2]Taizhou Central Hospital (Taizhou University Hospital), Precision Medicine Center, Taizhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) is a complicated syndrome with high short-term mortality. Effective biomarkers for early diagnosis and prognosis of HBV-ACLF are needed. This study aimed to assess the diagnostic and prognostic value of thrombomodulin (THBD) in HBV-ACLF patients.
Method: The expression of THBD during disease progression was evaluated analyzed through transcriptomics analysis. Plasma THBD levels in 393 subjects with HBV-ACLF (n = 213), acute on-chronic hepatic dysfunction (ACHD, n = 50), liver cirrhosis (LC, n = 50), chronic hepatitis B (CHB, n = 50) and normal controls (NC, n = 30) from a prospective multi-center cohort were measured to validate the diagnostic and prognostic significance of THBD for HBV-ACLF patients by enzyme-linked immunosorbent assay (ELISA).
Results: THBD mRNA level was highly expressed in the HBV-ACLF group (compared with other groups, AUROC = 0.887). High expression of THBD predicted poor prognosis for HBV-ACLF patients in 28/90 days (AUROCs = 0.823/0.788). Functional analysis showed that THBD was significantly associated with complement activation and inflammatory signaling pathway. External validation confirmed its high diagnostic accuracy for HBV-ACLF patients (AUROC = 0.931). Plasma THBD levels were correlated with organ failure, including coagulation and kidney failure. Plasma THBD levels showed a potential prognostic value for 28-day mortality (AUROC = 0.702). Risk stratification of the THBD expression level (>8.4 ng/ml) specifically identified HBV-ACLF patients with a high risk of death.
Conclusion: This study reveals THBD could serve as a candidate biomarker for the diagnosis and prognosis of HBV-ACLF, which might play a crucial role in the coagulation and inflammatory response.

FRI-560

Frequency of ACLF and predictors of in-hospital mortality in cirrhotic patients in a tertiary care hospital of Pakistan

Marium Fatima Waqar[1], Sulhera Khan[1], Zeeshan Junejo[1]. *[1]Jinnah Postgraduate Medical Centre Karachi, Internal Medicine, Karachi, Pakistan*
Email: sulherahussain@gmail.com

Background and aims: Acute on chronic liver failure (ACLF) is characterised by acute decompensation of the liver in patients with chronic liver disease (CLD). This condition presents as jaundice, deranged (international normalised ratio) INR or liver failure. To grade patients, we need to utilise liver-failure-adapted organ assessment scores such as the European Association for the Study of the Liver-Chronic Liver Failure (EASL-CLIF) criteria. Our study focuses on determining the frequency of ACLF in our population and correlating different scoring systems to predict in-hospital mortality.
Method: This study is conducted on cirrhotic patients admitted to Jinnah Postgraduate Medical Centre. The organ failure was assessed with the CLIF-C score. Demographics, baseline characteristics and laboratory investigations were recorded. The severity of cirrhosis was assessed by using the Child-Pugh (CTP), Model for End Stage Liver Disease (MELD) and MELD sodium (Na) scores.
Results: Out of 148 patients, 29.1% (n = 43) of participants met the diagnosis of ACLF according to the EASL-CLIF criteria. 55.4% of the participants were males. The in-hospital mortality rate of the enrolled cirrhotic patients was found to be 20.1% (n = 23). It was observed the mortality in the ACLF (23.3%, n = 10) group was twice that of the non-ACLF (12.4%, n = 13) group. The highest mortality was seen in the ACLF grade 3 group (100%, n = 6), whereas the combined mortality of ACLF grades 2 and 1 (10.8%, n = 4) was almost equivalent to the non-ACLF (12.4%, n = 13) group. The most common reason for admission was hepatic encephalopathy (44%). Renal (60.5%) and cerebral failure (23.8%) were identified as the most common organ failure in the ACLF and non-ACLF groups respectively. AUROC were 0.620 (CI95% 0.48–0.75), 0.646 (CI95% 0.52–0.77), 0.668 (CI95% 0.53–0.79) and 0.653 (CI95% 0.52–0.77) for MELD, MELD-Na, CLIF-C Organ Failure and CLIF-C ACLF scores, respectively. MELD, MELD-Na, and CLIF-C ACLF scores were independent predictors of mortality. Among these scores, the CLIF-C Organ Failure score was the strongest independent predictor of mortality (OR = 3.64, CI 95% = 2.34–5.65, p = 0.01). On ROC curve analysis, the maximum area (66.8%) under the curve was obtained for the CLIF consortium organ failure score (p = 0.01).

Parameters	Univariate analysis Odds Ratio (95% C.I)	Multivariate analysis Odds Ratio (95% C.I)
Blood Pressure Diastolic	**0.9 (0.92–0.99)**	0.9 (0.8–1.0)
Pulse	**1.0 (1.0–1.06)**	1.0 (0.9–1.0)
Total Bilirubin	**1.1 (1.0–1.2)**	1.0 (0.9–1.2)
PT	**1.0 (1.0–1.1)**	1.0 (0.8–1.1)
INR	**2.8 (1.3–6.0)**	1.7 (0.3–10)
Urea	**1.0 (1.0–1.04)**	**1.0 (1.0–1.04)**
Creatinine	**5.0 (2.7–9.2)**	**3.7 (1.4–9.4)**
MELD Score	**1.3 (1.20–1.44)**	**1.2 (1.08–1.33)**
CTP Grade B	3.9 (0.8–18.0)	62 (1.7–230)
CTP Grade C	**5.8 (1.2–27.0)**	9.5 (0.3–287)
Liver failure	**6.6 (1.6–26.)**	2.7 (0.01–86)
Cerebral failure	**2.7 (1.3–5.8)**	2.1 (0.5–8.8)
Circulation failure	**10.0 (1.9–50.)**	**2.5 (2.2–285)**
Use of Vasopressors	**8.9 (2.3–35.)**	**1.0 (1.1–916)**
MELD-Na Score	**1.2 (1.16–1.36)**	
CLIF-C ACLF Score	**1.1 (1.06–1.17)**	

Figure: Risk estimation of ACLF using binary logistic regression

Conclusion: It is important to promptly identify ACLF, as the patients identified early with two or more organ failures at presentation in resource-poor settings can be planned for aggressive management to reduce mortality. Upon analysis, it is seen that MELD Na, CLIF-C ACLF score, and EASL-CLIF organ failure score are superior to the MELD score and highly significant in predicting mortality in patients with ACLF.

Yaq-001, a non-absorbable, engineered carbon beads of controlled porosity impacts on gut dysbiosis, gut permeability, organ function and reduces mortality in rodent models of cirrhosis and ACLF

Jinxia Liu[1,2], Jane Macnaughtan[1], Yi Jin[3], Frederick Clasen[3], Francesco De Chiara[1], Ganesh Ingavle[4], Paul Cordero[1], Junpei Soeda[1], Jude A. Oben[1], Jia Li[5], I. Jane Cox[6], Susan Sandeman[4], Nathan Davies[1], Raj Mookerjee[1], Saeed Shoaie[7], Rajiv Jalan[1]. *[1]UCL Institute for Liver and Digestive Health, Upper third floor, Royal Free Campus, Rowland Hill Street, Hampstead, London, NW3 2PF, United Kingdom; [2]Department of Gastroenterology, Affiliated Hospital of Nantong University, Nantong, 226001, China; [3]Centre for Host-Microbiome Interactions, Faculty of Dentistry, Oral and Craniofacial Sciences, King's College London, SE1 9RT, United Kingdom; [4]Pharmacy and Biomolecular Sciences, University of Brighton, Moulsecoomb, Brighton, BN2 4GJ, United Kingdom; [5]Department of Surgery and Cancer, Faculty of Medicine, Imperial College London, Sir Alexander Fleming Building, Imperial College Road, South Kensington, London, SW7 2AZ, United Kingdom; [6]Roger Williams Institute of Hepatology, United Kingdom; [7]Centre for Host-Microbiome Interactions, Faculty of Dentistry, Oral and Craniofacial Sciences, King's College London, SE1 9RT, United Kingdom*
Email: r.jalan@ucl.ac.uk

Background and aims: Dysbiosis and translocation of bacterial lipopolysaccharide (LPS) stimulates a systemic inflammation in cirrhosis resulting in multiple organ dysfunction and acute on chronic liver failure (ACLF). Current strategies to target bacterial translocation in cirrhosis are limited to antibiotics with risk of resistance. Yaq-001 is a non-absorbable, engineered carbon bead that has been designed to adsorb small molecules such as ammonia and larger molecules such as LPS and bile acids from the gut. The aims of this study were to explore its therapeutic potential in models of cirrhosis and ACLF.
Method: Two rodent models of cirrhosis (4w, bile duct ligation, BDL) and ACLF (BDL+LPS). Eight groups: Sham (n = 36); Sham+Yaq-001 (n = 30); BDL (n = 36); BDL+Yaq-001 (n = 44); Sham+LPS (n = 9); Sham +LPS+Yaq-001 (n = 10); BDL+LPS (n = 16); BDL+LPS+Yaq-001 (n = 12). Yaq-001 was administered for 2-weeks prior to sacrifice. Portal pressure, organ function and transcriptome analysis of liver, colon, brain and kidney were performed. Stool in BDL rats was collected for 16 s microbiome study.
Results: *In vitro* studies: Yaq-001 exhibited rapid adsorption kinetics for endotoxin, ammonia and bile acids without exerting an antibiotic effect. *In vivo*, Yaq-001 supplementation resulted in a significant improvement in ALT, liver cell death (TUNEL stain), portal pressure, markers of systemic inflammation (TNFa, IL-8; white cell count) and renal function (creatinine) in BDL animals. ACLF animals treated with Yaq-001 had significantly better survival compared with controls, with significantly reduced ALT, portal pressure, brain water and creatinine. In addition to improvement in *in vivo* LPS sensitivity, ex-vivo LPS-induced reactive oxygen species production in both portal venous monocytes and Kupffer cell populations was diminished with Yaq-001 treatment. Transcriptomic analysis demonstrated a significant modulation of inflammation, cell death and senescence pathways in the liver, kidneys, brain and colon of Yaq-001-treated BDL rats compared to untreated controls. Abundance of *Family Porphyromonadaceae* and *Genus_Barnesiella* were also significantly reduced with Yaq-001 treatment.

Conclusion: Yaq-001 acts as a non-antibiotic enterosorbant of LPS, restores gut dysbiosis, reduces bacteria translocation, systemic inflammation and multiple organ dysfunction composition resulting in attenuation of LPS-driven oxidative injury, cell death and senescence pathways in the colon, liver, brain and kidneys.

The role of Toll-like receptor 4 in ammonia metabolism and as a therapeutic target for hyperammonemia

Annarein Kerbert[1], Anna Curto[2], Cornelius Engelmann[3], Pavitra Kumar[3], Mohsin Hassan[3], Abeba Habtesion[1], Ferran Aguilar[2], Steven Olde Damink[4], Celine Chollet[5], Ludovic Brunet[5], Joan Clària[6], Richard Moreau[2], Florence Castelli[5], Francois Fenaille[5], Fausto Andreola[1], Rajiv Jalan[1]. *[1]University College London, Institute for Liver and Digestive Health, United Kingdom; [2]European Foundation for the Study of Chronic Liver Failure, Spain; [3]Campus Virchow-Klinikum, Charite-Universitätsmedizin Berlin, Medical Department, Division of Hepatology and Gastroenterology, Germany; [4]Maastricht University, Department of Surgery, NUTRIM School of Nutrition and Translational Research in Metabolism, Netherlands; [5]CEA, INRA, Université Paris Saclay, MetaboHUB, Service de Pharmacologie et Immuno-Analyse (SPI), Laboratoire d'Etude du Métabolisme des Médicaments, France; [6]Hospital Clínic de Barcelona, Spain*
Email: j.c.kerbert@lumc.nl

Background and aims: Novel effective therapies for hyperammonemia are an unmet clinical need. The key enzymes that regulate the urea cycle and therefore ammonia metabolism are in the mitochondria. Hyperammonemia induces oxidative stress and is thought to activate the toll-like receptor 4 (TLR4) pathway inducing mitochondrial dysfunction. This study explored the role of the TLR4 pathway in ammonia metabolism and its modulation as a potential treatment for hyperammonemia.

Method: Hyperammonemia was induced by a 14-day amino acid (AA) diet in wild type (WT) and TLR4 knock-out (TLR4KO) mice. Two mouse models were studied: (1) WT mice ± AA diet with or without treatment with ornithine phenylacetate (OP, 300 mg/kg i.p.) or the TLR4 antagonist TAK-242 (10 mg/kg i.p.), (2) TLR4KO mice ± AA diet. Two other clinically relevant models of hyperammonemia were studied: (1) mice with genetic ornithine-transcarbamylase deficiency ($OTC^{spf\text{-}ash}$) with or without treatment with sodium phenylacetate or TAK-242, (d) rats with bile-duct ligation (BDL)-induced liver cirrhosis with or without TAK-242 treatment. Plasma ammonia, urea and

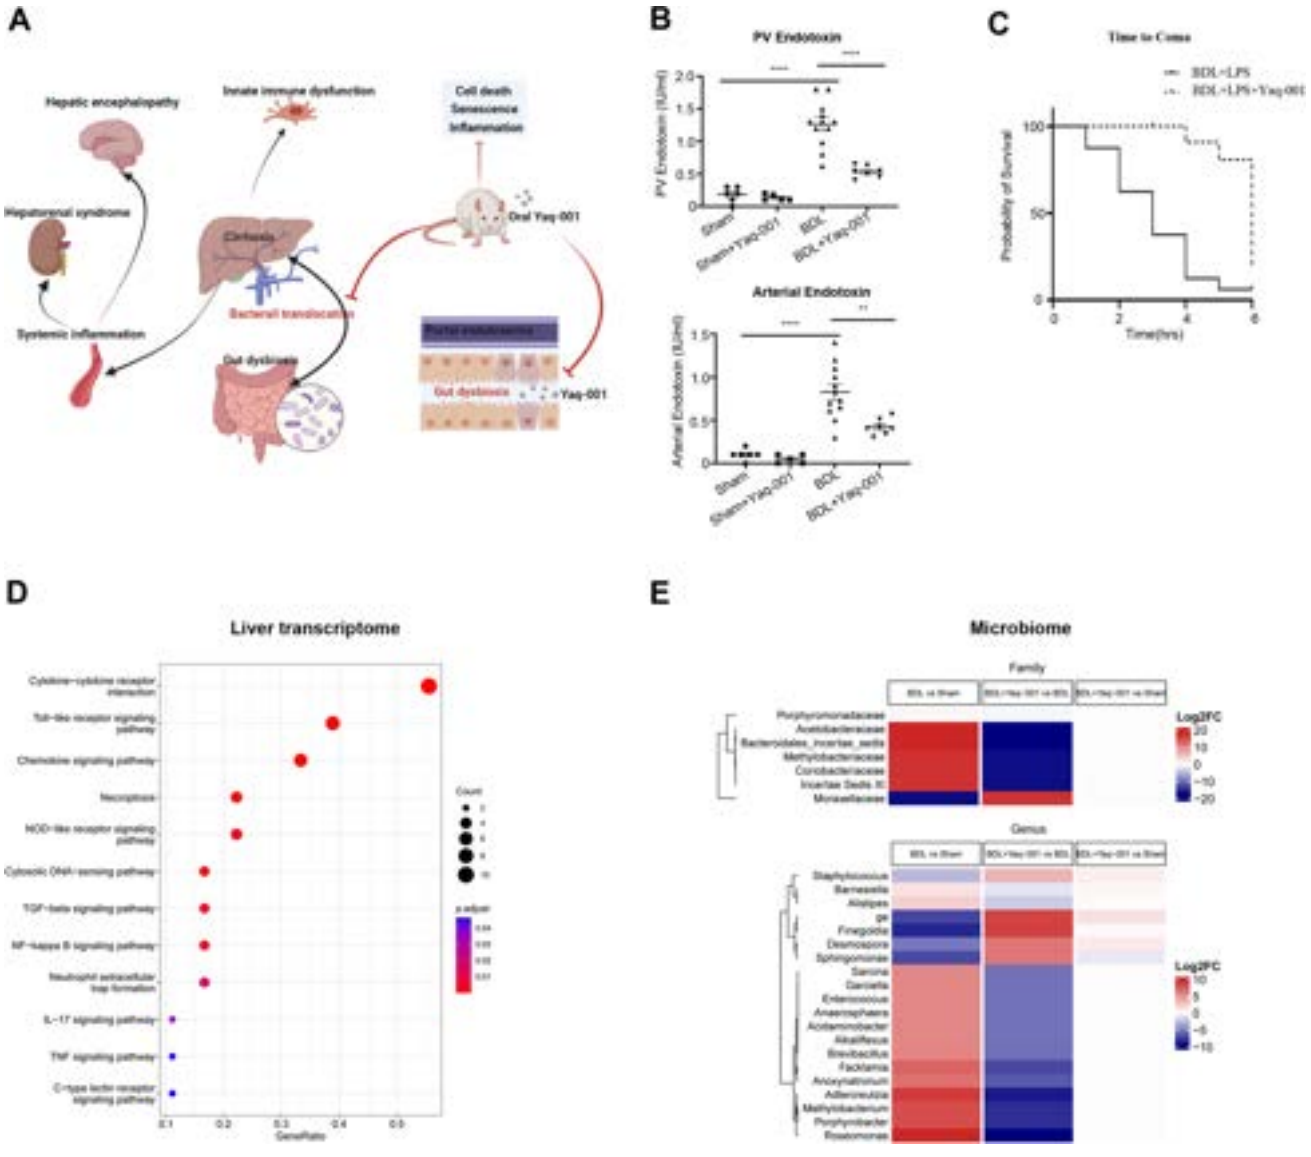

Figure: (abstract: TOP-042).

amino acids concentrations, liver multiplex immunofluorescence (IF) staining for the urea cycle enzymes (UCEs) and liver transcriptomics and metabolomics were studied.
Results: In WT mice, the AA-diet led to a significant increase in circulating ammonia levels ($p < 0.0001$), which was prevented by treatment with OP and TAK-242 (Fig.). Liver metabolomic analysis showed a distinct metabolic fingerprint in hyperammonemia with accumulation of metabolites related to the urea cycle, Krebs cycle and mitochondrial beta-oxidation. Comparative transcriptomics revealed that urea cycle-related pathways were downregulated in hyperammonemia, and oxidative stress related pathways were upregulated. IF confirmed downregulation of hepatic UCE expression in hyperammonemia, whereas the mitochondrial number was preserved. Hyperammonemia-induced changes in metabolomics, transcriptomics and IF were prevented by OP, TAK-242 and TLR4 deficiency. In hyperammonemia induced by OTC-deficiency and BDL, TAK-242 significantly reduced circulating ammonia levels.
Conclusion: These data point towards a novel mechanism of hyperammonemia-induced UCE dysfunction which is associated with a change in the metabolomic fingerprint, primarily involving mitochondrial metabolism. Inhibition of the TLR4 pathway protects against hyperammonemia and is a potential novel therapy for hyperammonemia associated with liver disease and UCE disorders.

Email: sanalmg@gmail.com

Background and aims: Adipose tissue also functions as an endocrine organ. Like bone-marrow, it's derived from embryonic mesenchyme and is a rich source of mesenchymal stem cells. Adipose tissue has more mesenchymal stromal stem cells (MSC) than bone marrow. Lungs, kidneys, and brain are affected in cirrhosis but we don't known about adipose tissue. In cirrhosis, the risk of both thrombosis and bleeding increases, however, the risk of thrombosis is less appreciated. Factor VIII (F8) levels are raised in cirrhosis, not lowered, despite shrinking liver. Liver makes most of the F8, but we know little, how much extra-hepatic sources contribute to F8 levels. Bone marrow transplantation studies showed marrow MSCs could synthesize factor F8 and ameliorate bleeding in hemophilic mice. Considering the total adipose tissue mass in the human body the total contribution of F8 from adipose tissue could be significant. Here we compared the expression of F8 in adipose tissue in health and cirrhosis.
Method: Adipose tissue was harvested from 15 liver cirrhosis patients (recipients) and same number of healthy adults (donors) during Living Donor Liver Transplantation (LDLT). We adapted an MSC isolation protocol for liposuction samples. We confirmed F8 by immunohistochemistry (IHC)/immunofluorescence (IF), western-blot and flowcytometry. F8 'functional assay' was used to estimate F8 activity in plasma. Isolated MSC were transplanted to an immunodeficient F8 knock-out mouse model (factor VIII, *Prkdc*^{scid} double knock-out). One million MSC suspended in PBS (isolated from adipose tissue of cirrhosis patients or healthy controls) were i.v. administered to animals (n = 9, in each test group). C57BL and the double knock-out animals (n = 5, in each control group) were injected PBS. The blood was collected at baseline and after 10 days and 3–6 months post-transplantation. Animals were sacrificed, various tissues were preserved in formalin/liquid nitrogen. T-test/ANOVA was used to calculate the statistical significance.
Results: Of the 15 cirrhosis patients eleven were males and 4 were females. Mean age was 45.5 years (Range:11–59 years). Mean BMI was 23.2 kg/m^2. Mean MELD score was 22.2. Of the 15 donors, 2 were men and 13 were women. Mean age was 39.2 years (Range:19–50 years) and the mean BMI was 23.7 kg/m^2. We found higher expression of F8 in adipose tissue in cirrhosis compared to healthy. For the first time we demonstrated the contribution of F8 from adipose tissue to the body pool. Further we transplanted adipose derived MSC from healthy people and cirrhosis patients into F8 knock-out, immune-compromised mice. Transplanted cells seems to survive in these animals as shown by Real Time PCR in various tissues (Figure-1F-a) and IF (Figure-1F-b-e). F8 functional assay showed small but significant levels of F8 in all animals which received MSC treatment (Figure-1F-f). There is a small and insignificant increase in F8 in animals which received MSC from cirrhosis patients compared to the healthy controls.
Conclusion: We have demonstrated that adipose tissue contributes to F8 production, and this could be significant considering the total

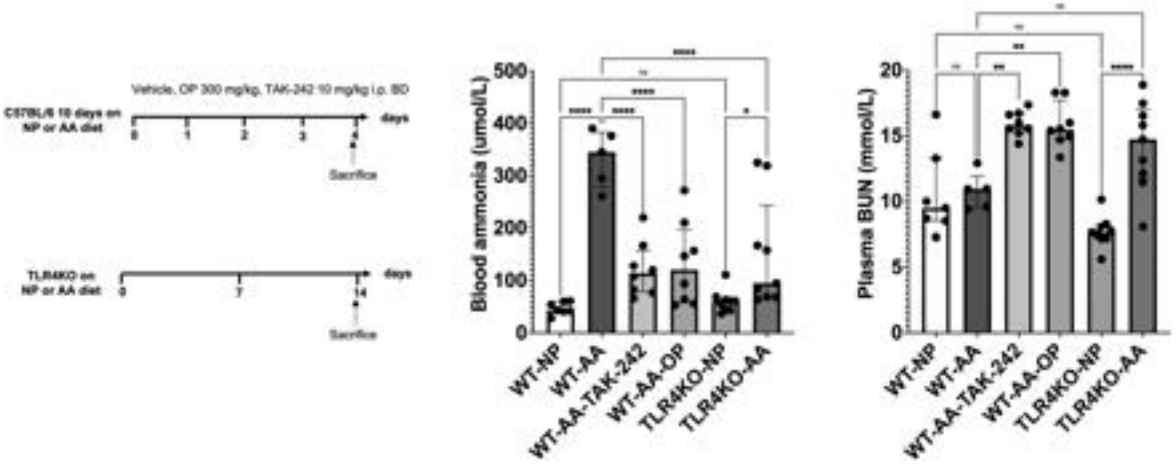

Figure: (abstract: TOP-046).

mass of adipose tissue in the human body. The MSC from adipose tissue upon transplantation to F8 knock-out animals produce F8. It is a less appreciated fact that chronic liver disease is thrombotic condition and the adipose tissue derived F8 could be a contributing factor in keeping delicate balance between bleeding and clotting in cirrhosis.

ε-Lysine-melittin reduces pathological bacterial translocation and enhances gut immunity in experimental decompensated cirrhosis

Deepika Jakhar[1], Pinky Juneja[1], Aarti Sharma[1], Impreet Kaur[1], Dinesh Mani Tripathi[1], Lakshminarayanan Rajamani[2], Savneet Kaur[1].
[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Singapore Eye Research Institute, Singapore
Email: savykaur@gmail.com

Background and aims: Pathological bacterial translocation from intestine to mesenteric lymph nodes (MLN) is an important mechanism in development of systemic infections in liver cirrhosis. Melittin, major component of bee venom is cationic amphipathic peptide that has anti-microbial and cytolytic properties. We modified mellitin by replacing alpha-lysine with ε-lysine at multiple sites to enhance its selective bactericidal properties and reduce its *in vivo* toxicity and evaluated effects of modified mellitin on bacterial translocation, MLN immune responses and intestinal and liver inflammation in experimental cirrhosis with ascites.

Method: Rat models of cirrhosis were prepared by i.p injections of CCl_4 for 8–10 weeks. Mellitin was administered i.p, 0.2 mg/kg, twice a week for 2 weeks in CCl_4 rats. CCl_4 rats given saline served as vehicle. Bacterial load was studied in MLNs. Intestinal permeability in ileum was assessed by immunohistochemistry of occludin protein. Immune cells were quantified in MLNs, portal and peripheral blood by flow cytometry. Gene expression of inflammatory markers in liver and ileum tissues was examined by RT-PCR.

Results: Modified mellitin did not result in adverse effects in mellitin treated CCl_4 rats. Bacterial load in MLNs of cirrhotic (<18 000 CFU/g of

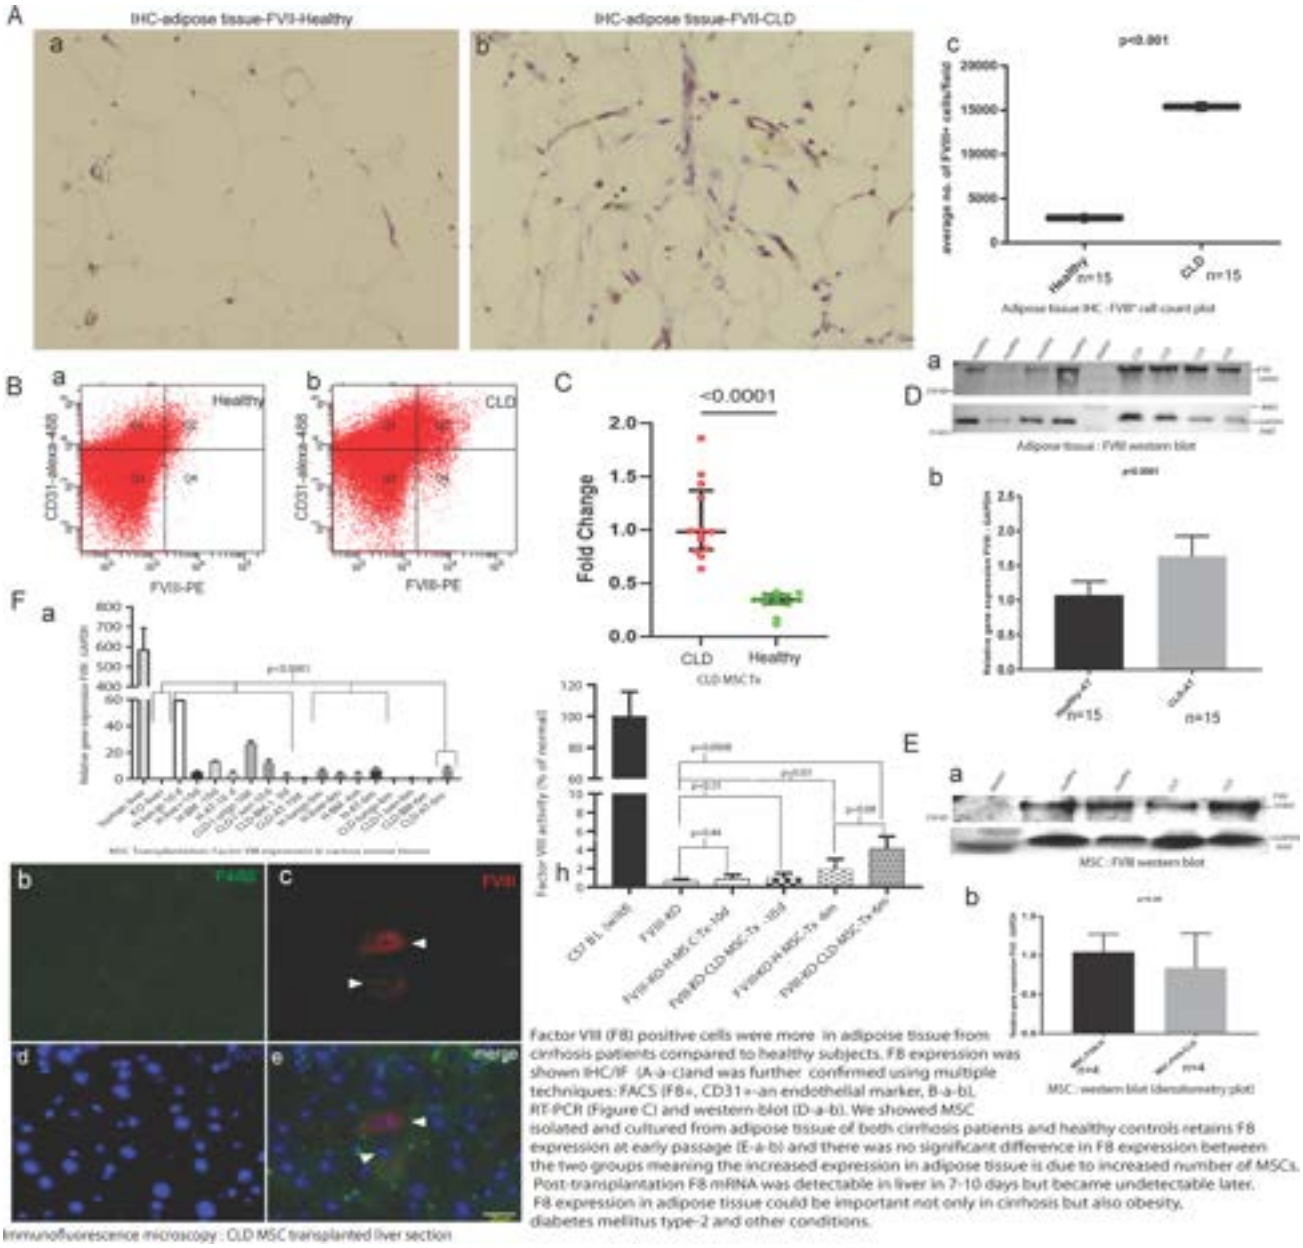

Figure: (abstract: THU-337).

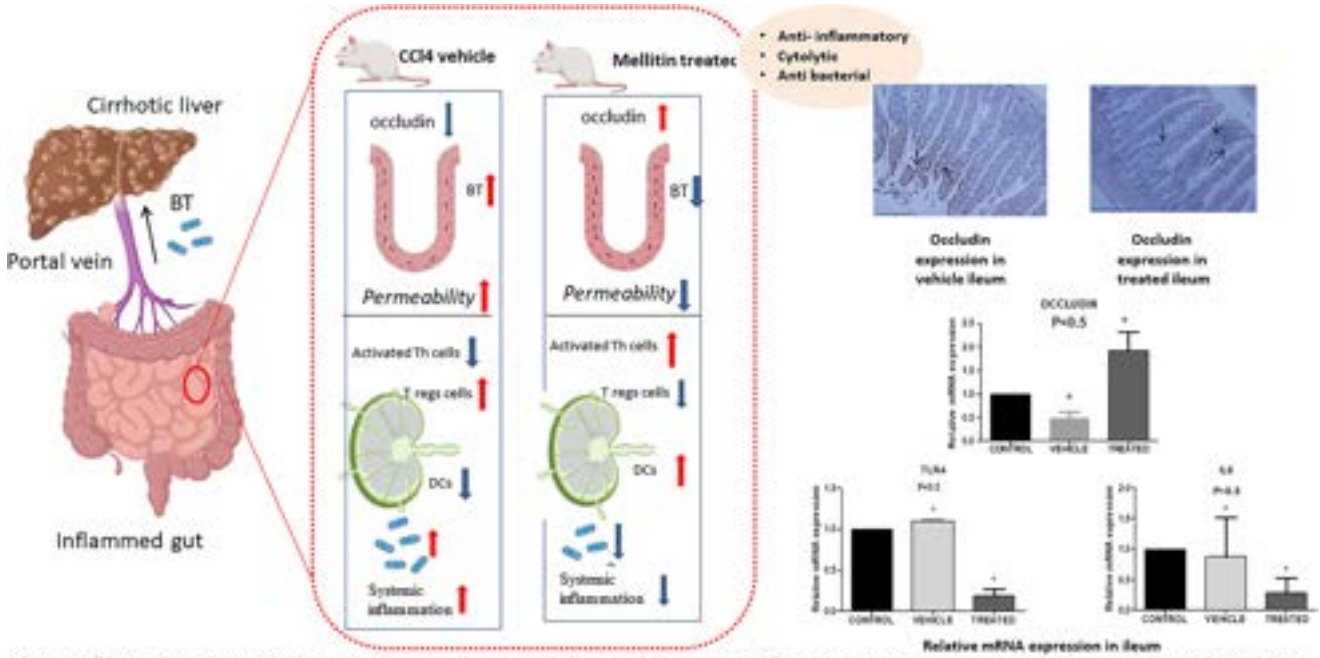

Figure: Effect of ε-Lysine-Mellitin on intestinal permeability and intestinal inflammation in Experimental Decompensated Cirrhosis. (BT- Bacterial Translocation, TLR4- Toll like receptor 4, IL-6 – Interleukin 6)

Figure: (abstract: THU-338).

tissue) was significantly reduced (>10 000CFU/g) in MLNs of melittin-treated ($p < 0.01$) suggesting increased bacterial killing in MLNs. In treated rats, percentage of CD4+ (65.4 ± 0.6 vs 33.2 ± 0.7), CD8+ T (24.9 ± 1.3 vs 19.3 ± 1.5) and activated CD134+Th (34.6 ± 0.9 vs 30.1 ± 1.1) ($p < 0.05$) cells increased and CD25+Treg (3.20 ± 0.8vs56.1 ± 1.2, $p < 0.05$) cells decreased compared to vehicle, decreased inflammatory monocytes (CD43-low) (33.5 ± 1.5 vs 44.2 ± 1.7, $p < 0.05$) and increased dendritic cells (61.5 ± 0.3 vs 43.4 ± 0.5, $p < 0.05$) in treated compared to vehicle. In portal and peripheral blood, there was increased CD8+T (23.57 ± 1.4 vs 19.10 ± 1.1) and CD134+Th (34.13 ± 1.9vs 24.25 ± 1.7) ($p < 0.05$ s) in treated compared to vehicle. In treated rats, occludin protein expression significantly increased (3.2-fold, $p < 0.5$) in epithelial cells of intestinal villi and crypts compared to vehicle. A significant decrease in gene expression of pro-inflammatory markers such as IL6 and TLR4 in both ileum (IL6: 3.5-fold, $p < 0.5$, TLR4: 10 fold, $p < 0.5$) and liver (IL6: 8 fold, $p < 0.5$, TLR4: 9 fold, $p < 0.5$) of treated rats compared to vehicle. There was no change in liver fibrosis after mellitin treatment (Fig).

Conclusion: In decompensated cirrhosis, treatment with modified melittin reduces bacterial load in MLNs by decreasing intestinal permeability and enhancing adaptive T cell immunity in MLNs. It also attenuates inflammation in both gut and liver. Modified ε-lysine mellitin thus holds relevance as an emerging adjunct antimicrobial therapy for combating development of infections in cirrhosis.

THU-339

Combination of weekly albumin infusion, personalized nutrition and home-based exercise programme improves outcomes of patients with end stage liver disease (Al-Fit study)

Chandan Kedarisetty[1], Sasanka Vangara[1,1], Sridhar Reddy Chappidi[2], Malleswari Naga[3], Rami Reddy Yalaka[4], Sameer Godey[4]. *[1]Gleneagles global hospital, Department of hepatology and liver transplant, Hyderabad, India; [2]Gleneagles global hospital, Department of Radiology, Hyderabad, India; [3]Gleneagles global hospital, Department of Nutrition, Hyderabad, India; [4]Gleneagles global hospital, Department of Medical Gastroenterology, Hyderabad, India*

Email: sasanka58v@gmail.com

Background and aims: Cirrhotic patients have progressive deterioration of liver functions and development of sarcopenia and frailty. Frailty has emerged as independent critical determinant of mortality and assessed by Liver Frailty index (LFI). We assumed improvement of LFI through weekly albumin supplementation, personalized nutritional counselling and monitored home based physiotherapy improves outcomes and quality of life in cirrhotic patients. We aimed to study the efficacy of combination therapy in improving physical performance assessed by LFI, reduction in decompensating events and improving quality of life.

Method: We randomized 60 cirrhotics with Model for end stage liver disease (MELD) score ≥ 15 in 1:1 ratio into 2 groups, A and B. Group A received combination therapy in the form of weekly once 20% 100 ml recombinant human albumin infusion, weekly diet recall ensuring calories 30–35 kcal/kg/day and proteins 1.2–1.5 g/kg/d and home-based rehabilitation exercises. Group B received only standard medical care. We assessed liver frailty index, MELD score, quality of life by chronic liver disease questionnaire (CLDQ) at baseline and at follow-up of 3 months.

Results: Mean age in the cohort was 49 ± 9.8 years, predominant etiology was alcohol related liver disease and more than 80% were male gender. Baseline LFI in Group A was 4.42 ± 0.4 vs. 4.3 ± 0.3 in Group B. There was a statistically significant reduction in LFI at 3 months compared to baseline in Group A (4.42 ± 0.4 to 4.3 ± 0.37), compared to an increase in Group B (4.3 ± 0.3 to 4.5 ± 0.45) (p-0.007). The MELD score significantly reduced in Group A (17.5 ± 4.6 at baseline to 16.2 ± 2.6 at 3 months), compared to an increase in Group B (18 ± 3.2 at baseline to 19.7 ± 6.4 at 3 months) (p – 0.009). There was significant improvement of CLDQ score in Group A (23.7 ± 3.5 at baseline to 26.5 ± 4.4 at 3 months) compared to Group B (22.9 ± 2.7 at baseline to 21.7 ± 3.07 at 3 months) (p-0.00001). There was no difference in number of hospital admissions in between the two groups (p-0.19).

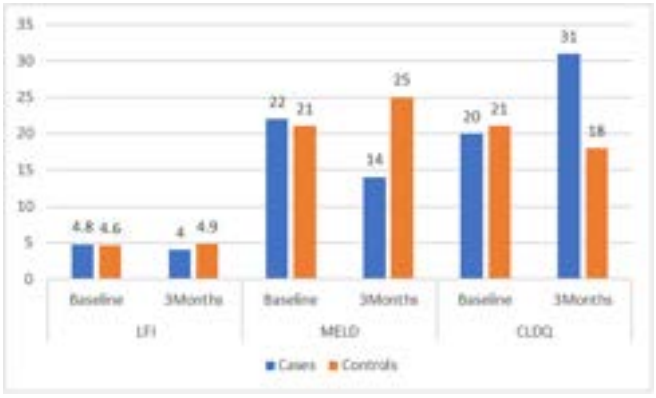

Figure:

Conclusion: Liver transplantation offers improved long-term survival for these patients but is negatively influenced by deceased donor availability and progression of disease in the wait-list. The combination of weekly albumin infusion, personalized nutritional counselling and monitored home-based physiotherapy is first kind of study in patients with high MELD score more than or equal to 15 to show significant improvement in liver frailty index, reduces MELD score and overall improves quality of life. My study trial enrolement details are as follows-CTRI No : REF/2023/02/063149.

THU-340

Imperfect maturation in erythroid progenitors leads to severe anemia in cirrhotic patients

Deepika[1], Chhagan Bihari[2], Jaswinder Maras[1], Rakhi Maiwall[3], Anupam Kumar[1], Shiv Kumar Sarin[1,3]. [1]*Institute of liver and biliary sciences, Department of Molecular and cellular medicine, New delhi, India;* [2]*Institute of liver and biliary sciences, Department of pathology, New delhi, India;* [3]*Institute of liver and biliary sciences, Department of hepatology, New delhi, India*
Email: dr.anupamkumar.ilbs@gmail.com

Background and aims: Anemia is seen in nearly >70% patients with cirrhosis. It is often non responsive to nutritional supplements known as refractory anemia. Therefore, to understand the unknown cause, we assessed the erythropoiesis process and associated alteration in bone marrow of cirrhotic patients.
Method: Flow cytometry was done to assess hematopoietic stem cells (HSCs) and erythroid population (EP) status in bone marrow (BM) of cirrhotic patients (N = 60) compared with Non cirrhotic portal fibrosis (N = 8) and healthy control (N = 3). Proteomics was done of pure CD71 erythroid population of cirrhotics to decipher the internal abnormalities supported by validation experiments Real Time-Polymerase chain reaction, colony assay and heme quantification. Cytokine array and ELISA were done to assess for erythropoietic stimulating agents (ESA), inflammatory cytokines and growth factors as an external factor affecting erythropoiesis.
Results: BM aspirates were collected from cirrhotic and NCPF patients having anemia with mean haemoglobin (8.73 ± 2.02 and 9.54 ± 1.02) with no nutritional deficiency and also from healthy control. We found significant decrease in CD34+ HSCs and intermediate [IEP; CD71+CD235a+], conversely early [EEP; CD71+ CD235a-] and late [LEP; CD71– CD235a+] were significantly increased in cirrhotic and NCPF as compared to control ($p < 0.05$) [figure A], suggesting increase in stress induced erythropoiesis in both cirrhotic and non-cirrhotic (NCPF) injury. Unlike NCPF, cirrhotic BM EP showed significant ($p < 0.05$) decrease in expression of CD71+ Transferrin receptors (TfR1; for iron uptake) [Figure B] with increase in percentage of immature CD71+ erythroids (by 1.17%) in peripheral blood suggesting defective maturation of EP in cirrhosis. In compare to healthy control and NCPF, cirrhotic EP showed significant ($p < 0.05$) increase in protein associated with hypoxia, metabolism dysregulation and oxidative stress and decrease in proteins associated with haemoglobin synthesis, ROS detoxification, Translation, mitochondrial activity ($p < 0.05$)[Figure C]. Further, cirrhotic EP showed decrease in intracellular heme and decreased expression of genes related to erythropoiesis and haemoglobin synthesis (>0.5 folds)[figure D, E]. They also showed significantly reduce number of erythroid colonies (BFU-E) as compared to control ($p < 0.05$). We found significant ($p < 0.05$) increase in inflammatory cytokines such as IL-5, TRAIL-R2, TGF-alfa and TGF-beta in cirrhotic BM plasma. Surprisingly, ESA required facilitating normal erythropoiesis such as erythropoietin, transferrin and growth factors IL-3, IL-6, FLT3 and SCF were also significantly increased in cirrhosis as compared to NCPF and control [Figure F].
Conclusion: In cirrhosis, increased inflammatory cytokines in BM and altered erythroids intracellular physiological pathways involved in hemoglobin synthesis and erythroid cell development as well as decreased transferrin receptors leads to defective erythroid maturation.

THU-341

Study of epigenetic control of LSECtin in hepatic antigen presenting cells during experimental cirrhosis

Enrique Angel[1,2], Sebastian Martinez[1,2], Isabel Gómez-Hurtado[2,3], Paula Boix[1,2], Esther Caparrós[1,2], Rubén Francés[1,2,3]. [1]*Hepatic and intestinal immunobiology group. Miguel Hernandez University, Clinical Medicine Departament, San Juan, Spain;* [2]*IIS Isabial. Hospital general universitario dr. Balmis, Alicante, Spain;* [3]*Carlos III health institute, CIBERehd, Madrid, Spain*
Email: eangel@umh.es

Background and aims: LSECtin, a C-type lectin that acts as Pattern Recognition Receptor and T-cell ligand, is expressed in Liver Sinusoidal Endothelial Cells (LSECs) and Kupffer Cells (KCs). The progressive reduction in the expression of LSECtin in animal models of experimental cirrhosis inhibits inflammatory response control associated to advanced chronic liver disease progression. The main aim of this work is to characterize the epigenetic control of LSECtin's expression during cirrhosis (attending to DNA methylation and histone proteins post-translational modifications, HPTMs) in order to evaluate new potential strategies that could contribute to the recovery of its expression.
Method: C57BL/6 mice were treated by oral gavage of carbon tetrachloride (CCl_4) or olive oil for 16 weeks, for cirrhotic and control groups, respectively. After laparotomy and liver perfusion, KCs and LSECs were isolated by cell sorting. DNA methylation analysis (*Infinium Mouse Methylattion BeadChip Array-Illumina*) and chromatin immunoprecipitation followed by sequencing (ChIP-Seq) experiments were carried out in both APCs subpopulations.
Results: Analysis of DNA methylation allowed the identification of differentially methylated probes in pairwise comparisons using a Benjamini-Hochberg adjusted p value <0.05, distributed over gene body and proximal promoter of *Clec4g*, the gene that encodes LSECtin (Figure 1A). ChIP-Seq experiment for HPTMs associated to gene expression silencing showed a differential binding profile for all control vs CCl_4 comparisons (KCs, $H_3K_{27}Me_3$: 1099/300; $H_3K_9Me_3$: 11594/4571; LSECs, $H_3K_{27}Me_3$: 346/455; $H_3K_9Me_3$: 2573/5802). Specific peak profile of *Clec4g* flanking region for the aforementioned comparisons is depicted in Figure 1B.
Conclusion: The promoter region of LSECtin contains specific epigenetic marks in hepatic APCs during cirrhosis that include changes in DNA methylation and differences in the post-translational modification profile of histone proteins related to gene silencing, specifically $H_3K_9Me_3$ and $H_3K_{27}Me3$.

Nitazoxanide counteracts lipopolysaccharide-induced hepatic and renal transcriptomic profile changes to improve systemic inflammation and organ damage in a disease model of acute-on-chronic liver failure

Vanessa Legry[1], Marie Bobowski-Gerard[1], Nicolas Stankovic Valentin[1], Philippe Delataille[1], Valérie Daix[1], Remy Hanf[1], Dean Hum[1], Bart Staels[2]. [1]*Genfit, RandD, Loos, France;* [2]*Inserm U1011, University Lille, Inserm, CHU de Lille, U1011-EGID, LILLE, France*
Email: vanessa.legry@genfit.com

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by multiple organ failures in patients with cirrhosis and is associated with high short-term mortality. Systemic inflammation, triggered by bacteria or endotoxins, such as lipopolysaccharide (LPS), is a primary driver of ACLF and a potential therapeutic target (Arroyo *et al. Journal of Hepatology*, 2021). The FDA-approved antiparasitic drug nitazoxanide (NTZ) has shown promising effect in disease models of systemic inflammation and ACLF (*Journal of Hepatology* 2022 vol. 77, THU528). To characterize the early mechanism of action of NTZ, transcriptomic analyses were performed on liver and kidney from ACLF rats.
Method: ACLF was triggered through an acute injection of LPS (1 μg/kg, i.p.) in rats displaying cirrhosis induced by bile duct ligation (BDL). NTZ (100 mg/kg) or vehicle were orally administered concomitant to LPS injection. Serum and tissues were collected 3 hours after LPS injection. Transcriptomes were assessed using RNA sequencing from 5 animals per group and pairwise comparisons were performed to identify differentially expressed genes. To evaluate tissue damages, serum levels of cystatin C, Ripk3 and cerebral edema were measured.
Results: LPS injection in cirrhotic rats induced systemic inflammation as shown by elevated serum pro-inflammatory cytokines levels, which were significantly reduced upon NTZ treatment: –99% for IL6 ($p = 0.001$) and –94% for TNF alpha ($p = 0.006$). This was associated with a significant remodeling of the hepatic and renal transcriptome in ACLF compared to cirrhotic rats (Figure). Enrichment analysis revealed that differentially expressed genes mainly related to innate immune response and pro-inflammatory signaling pathways. Treatment of rats with NTZ reversed the inflammatory gene signature both in liver and kidney (Figure). Interestingly, the anti-inflammatory effect of NTZ was associated with a reduction of organ damages as shown by decreased serum, hepatic and renal levels of Ripk3, a marker of necroptosis associated with organ failure and ACLF severity (Kondo *et al. Cell Death and Disease*, 2022). Moreover, the level of cystatin C, a renal function marker ($p = 0.004$), and cerebral water content ($p = 0.003$) were resolved following NTZ treatment.

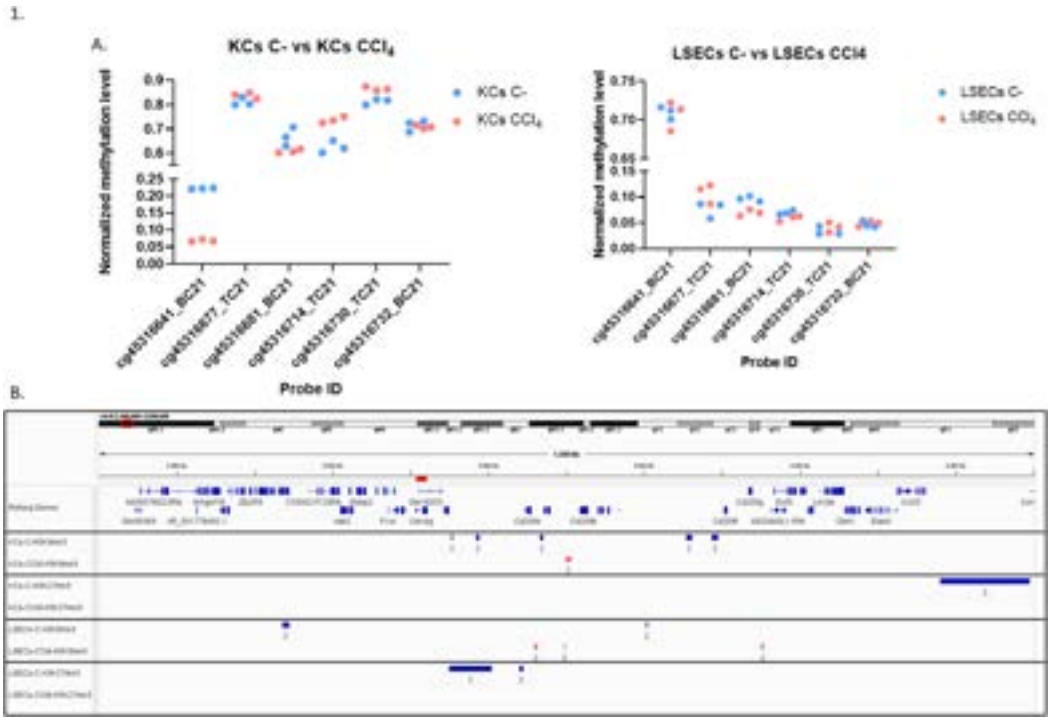

Figure: (abstract: THU-341).

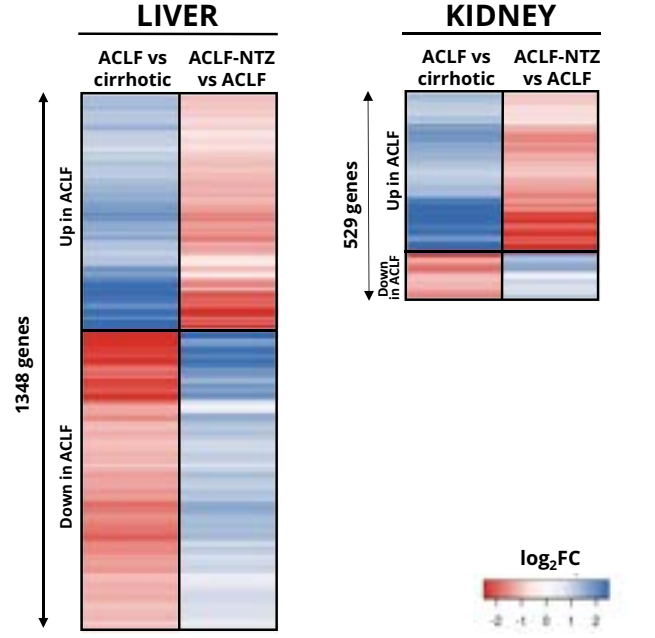

Figure: Heatmap displaying (log_2) fold changes (FC) of genes differentially expressed in the liver and the kidney between ACLF and cirrhotic rats (adjusted $p < 0.01$ and FC >2). Genes strongly induced by LPS injection (column 1, blue lines) were found to be repressed by NTZ treatment (column 2, red lines) and vice-versa in both liver and kidney.

Conclusion: A single oral administration of nitazoxanide rapidly counteracted LPS-induced systemic and tissue inflammation and protected against organ damage in a pre-clinical model of ACLF.

THU-343

Metabolic Derangements in Hematopoietic Stem and Progenitor Cells (HSPCs) underlie monocyte-macrophage dysfunction in cirrhosis

Deepanshu Maheshwari[1], Nidhi Nautiyal[1], Anupama Parasar[1], Rakhi Maiwall[2], Nirupma Trehanpati[1], Archana Rastogi[3], Shiv Kumar Sarin[1,2], Anupam Kumar[1]. *[1]Institute of Liver and Biliary Sciences, Department of Molecular and Cellular Medicine, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India; [3]Institute of Liver and Biliary Sciences, Department of Pathology, New Delhi, India*
Email: dr.anupamkumar.ilbs@gmail.com

Background and aims: Myeloid-biased hematopoiesis play a key-role in promotion and resolution of injury and infection. Bioenergetic flexibility and metabolic adaptation in response to injury govern the balance between self-renewal and differentiation of hematopoietic stem and progenitor cells (HSPCs). In cirrhosis, this process gets dysregulated with poor resolution of infection and injury. We investigated the changes in energy metabolism of HSPCs and its impact on haematopoiesis to decipher the underlying cause of poor resolution of injury in cirrhosis.
Method: Cirrhosis was induced in C57Bl/6 mice (n = 35, 8–10 weeks) by i.p. injection of CCl4 for 18 weeks till the development of decompensated cirrhosis. Mice were sacrificed at week 3 (W3), 6 (W6), 10 (W10) and 18 (W18) to study kinetic changes in liver bone marrow derived macrophages (BMDMs), their function and bone marrow (BM) haematopoiesis. Bioenergetics of HSPCs was determined using Extracellular Flux Analyzer. Mitochondrial properties were studied using MitoTracker dyes and MitoSOX assay. Glucose uptake (GU) was measured by NBDG-GU kit.
Results: Histology of liver showed inflammation with development of portal fibrosis at W3, bridging fibrosis at W6, cirrhosis at W10, ascites {SAAG 1.8 (1.21–2) g/dL} and jaundice by W18. With increase in liver injury there was a reduction in percentage ($p < 0.0001$) and phagocytic function ($p < 0.05$) of liver macrophages from W6 (Fig. 1A). Compared to age matched healthy animals, the cirrhotic animals showed significant loss of Long-term HSC ($p < 0.0001$) with increase in myeloid progenitor ($p < 0.0001$) from W6 (i.e., in

transition from fibrosis to cirrhosis and thereafter, Fig. 1B). Increase in myeloid progenitor in chronic liver injury was mainly contributed by neutrophil ($p < 0.0001$), with monocyte production being compromised ($p < 0.01$) (Fig. 1C). Bioenergetic analysis of HSPCs showed reduction in glycolysis ($p < 0.01$) due to compromised glucose uptake ($p < 0.0001$) (Fig. 1D) and increase in mitochondrial respiration (Fig. 1E) from W6. Interestingly while basal respiration was increased, there was a reduction in mitochondrial spare reserve ($p < 0.05$) with loss of total ($p < 0.0001$) and functional mitochondria. ($p < 0.0001$) in transition from fibrosis to cirrhosis and thereafter (Fig. 1E and F). In-vitro differentiation of HSPCs to BMDMs showed defects in their maturation ($p < 0.001$) and function ($p < 0.01$). These cells also showed metabolic defects with defective glycolysis and OXPHOS ($p < 0.01$).

Conclusion: Increased OXPHOS with loss of glycolysis disrupts the balance between HSC self-renewal and differentiation, leading to increased myelopoiesis and loss of Long-term HSC reserve in chronic liver injury. Further, increased mitochondrial dysfunction in HSPCs leads to production of defective myeloid cells particularly monocyte-macrophages in chronic liver injury. This may underlie for poor monocyte-macrophage driven resolution during chronic liver injury.

THU-344

Constant alcohol consumption exacerbates hepatic encephalopathy and leads to neuronal loss in rats with chronic liver disease

Farzaneh Tamnanloo[1,2], Xiaoru Chen[1], Mariana M. Oliveira[1], Mélanie Tremblay[1], Christopher F Rose[1,2]. [1]*CRCHUM, Hepato-neuro lab, Montréal, Canada;* [2]*Université de Montréal, Medicine, Montréal, Canada*
Email: farzaneh.tamnanloo@gmail.com

Background and aims: Hepatic encephalopathy (HE) is a debilitating neurological complication of chronic liver disease. Alcohol is a major etiological factor known to induce liver injury and disease. However, excessive alcohol consumption has been shown to also induce atrophy of the cerebellum and cerebellar degeneration. To date, the role of alcohol in the development of HE remains unclear. Here we examined the effects of constant alcohol consumption on the neurological decline in rats with chronic liver disease induced following bile duct ligation (BDL).

Method: 5-week BDL rats and Sham-operated controls (Sham) were used. Starting day 7 after surgery, rats were gavaged twice a day (3 hours apart) with alcohol at a dose of 3 g/kg (51% v/v), 5 days per week, for 4 weeks. Motor coordination was assessed using Rotarod every week until week 5. At the end of the model (day 40), anxiety-like behavior was assessed using the open field (OF) and elevated plus maze (EPM). Upon sacrifice, brains were collected, and western blot and immunohistochemical (IHC) analyses were used to investigate the neuronal integrity as well as assess apoptosis and necroptosis pathways in the cerebellum.

Results: Alcohol worsened motor coordination performance in weeks 2, 3, 4, and 5 in BDL-alcohol rats ($p < 0.01$ vs respective shams). Anxiety-like behavior significantly increased in BDL-alcohol rats, with an increase in time spent in the closed arms of EPM and a decrease in time spent in the center of the open field ($p < 0.05$ vs respective shams). These impairments were associated with decreased neuronal markers of NeuN and SMI311 ($p < 0.01$ and $p < 0.05$, respectively), increased apoptotic markers of cleaved/pro-Caspase3 and Bax/Bcl2 ratio ($p < 0.001$ and $p < 0.01$ respectively), increased necroptosis markers of pRIP3 and pMLKL ($p < 0.01$ and $p < 0.001$, respectively), decreased total antioxidant capacity ($p < 0.001$) and increased oxidative stress marker of 4-HNE ($p < 0.05$) in the cerebellum of BDL-alcohol rats when compared to respective controls. IHC results confirmed the colocalization of apoptotic marker (cleaved Caspase3) and necroptosis marker (pMLKL) in the granular and Purkinje layer neurons of the cerebellum of BDL-alcohol rats.

Conclusion: Constant alcohol consumption exacerbates HE by worsening motor coordination impairment and increasing anxiety

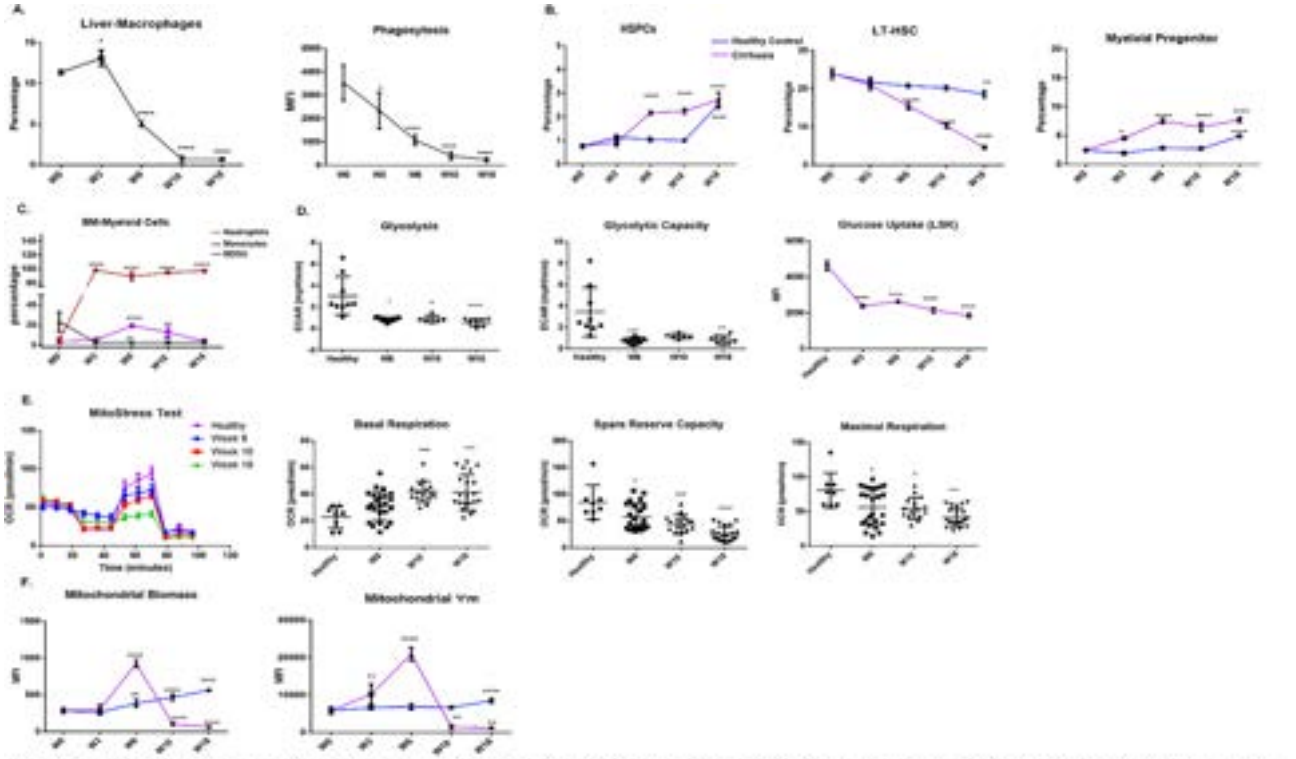

Figure1: Metabolic Derangement in Hematopoietic Stem and Progenitor Cells (HSPCs) may underlie monocyte-macrophage dysfunction in cirrhosis: Kinetic changes in (A.) liver macrophages and their phagocytosis (B. Hematopoietic Stem and Progenitor Cells (HSPCs), LT-HSCs and Myeloid progenitors and (D.) BM-Myeloid Cells (Neutrophils, Monocytes and MDSCs) during chronic liver injury. (D.) Changes in glycolysis, glycolytic capacity abd glucose uptake and (E.) Real time changes in oxygen consumption rate of HSPCs during chronic liver injury. (F.) Changes in mitochondrial biomass and potential of HSPCs during chronic liver injury

Figure: (abstract: THU-343).

in BDL rats. Furthermore, our results show neuronal loss through apoptosis and necroptosis in the cerebellum of BDL-alcohol rats. Additionally, higher levels of oxidative stress marker of 4-HNE and decreased total antioxidant capacity in the cerebellum of BDL-alcohol rats suggest that oxidative stress is the triggering factor of apoptosis and necroptosis pathway leading to neuronal loss/injury. These results demonstrate the adverse effect of constant alcohol consumption on the development of HE and neuronal integrity in chronic liver disease.

THU-345

Targeting myeloid-derived suppressor cells in a carbon tetrachloride-induced murine model of chronic liver injury

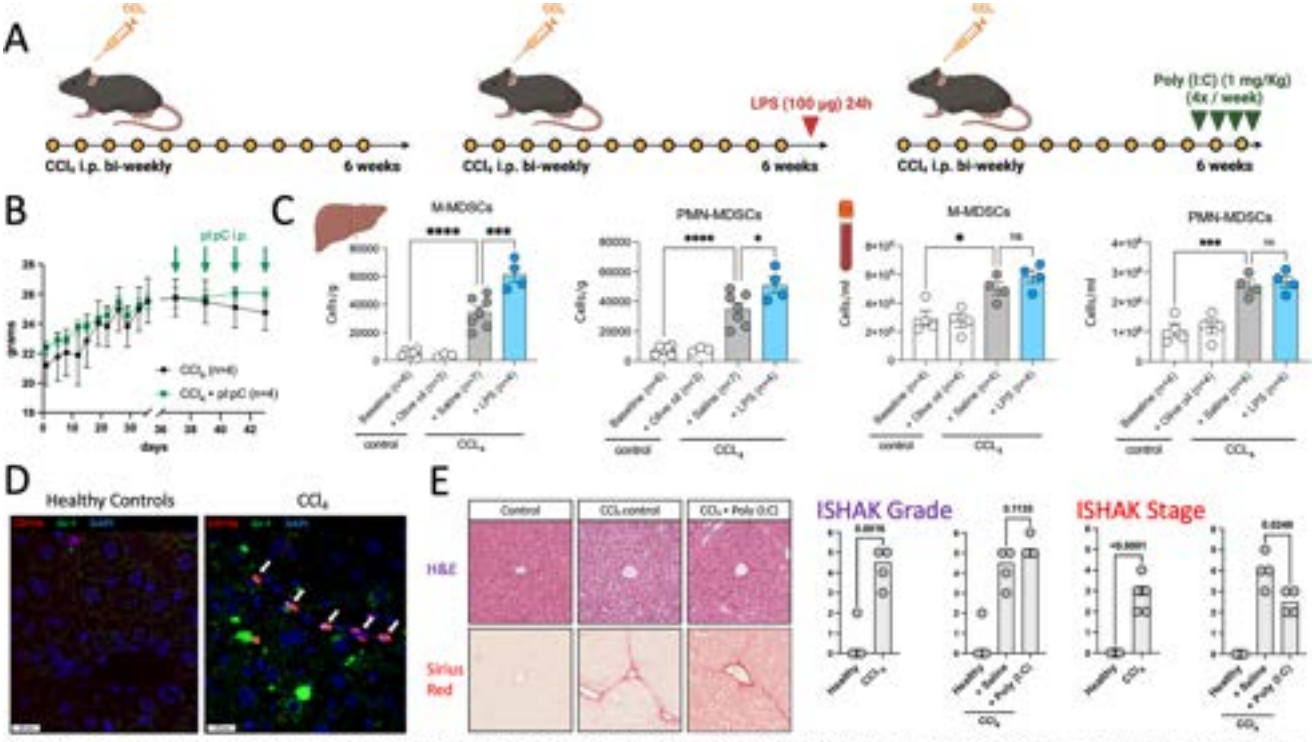
Emilio Flint[1], Caner Ercan[2], Lucia Possamai[3], Evangelos Triantafyllou[3], Christine Bernsmeier[1], Emilio Flint[1], Caner Ercan[3], Lucia Possamai[4], Evangelos Triantafyllou[4], Christine Bernsmeier[1,2]. *[1]University of Basel, Department of Biomedicine, Basel, Switzerland; [2]University Hospital Basel, Institute of Medical Genetics and Pathology, Basel, Switzerland; [3]Imperial College, Department of Metabolism, Digestion and Reproduction, London, United Kingdom [1]Department of Biomedicine, University of Basel (CH); [2]University Centre for Gastrointestinal and Liver Disease, Basel; [3]Institute of Medical Genetics and Pathology, University Hospital Basel (CH); [4]Department of Metabolism, Digestion and Reproduction, Imperial College London, UK*
Email: emilio.flint@unibas.ch

Background and aims: Previously, we identified immunosuppressive monocytic myeloid-derived suppressor cells (M-MDSC) in the circulation of patients with cirrhosis and liver failure. These cells increased with disease severity and were associated with distinct impaired innate and adaptive immune responses, increased infection susceptibility and mortality. Impaired immune responses and M-MDSC expansion were reversed by TLR3 agonism *in vitro*. Thus, we aimed to identify MDSC in murine models of fibrosis and assess the safety and efficacy of polyinosinic:polycytidylic acid (pI:pC) administration *in vivo*.

Methods: C57BL/6C mice were intraperitoneally (i.p.) administered carbon tetrachloride (CCl_4) for 6 weeks. To mimic an acute bacterial challenge, a group of CCl_4 mice was injected lipopolysaccharide (LPS) 24 hours prior to sacrifice. In another group, pI:pC (1 mg/Kg, i.p.) was administered 4 times for one week prior to sacrifice (A-B). Blood and liver cells were isolated and characterised with flow cytometry. Immunofluorescent stainings of CD11b+Gr-1+ identified MDSC in liver sections. Liver histopathology was evaluated on HandE or SiriusRed with Ishak Grade and Ishak Stage scores, plasma markers were quantified.

Results: CCl_4-treated mice displayed liver inflammation, fibrosis, increased plasma ALT levels and changes in frequency of myeloid cells in both the circulation and the liver. Phenotypically distinct polymorphonuclear (PMN)-MDSC and M-MDSC expanded in the blood (2-fold per ml, $p = 0.001$, $p < 0.0001$) and liver (7-fold per gram, $p < 0.0001$ and $p < 0.0001$) in the CCl_4 model (C). Moreover, LPS challenge significantly increased numbers of hepatic MDSC compared to saline-treated CCl_4 controls (C). MDSC expansion in the liver of CCl_4 mice was confirmed with immunofluorescent stainings (D). Both PMN-MDSC and M-MDSC expressed distinct markers Axl and Mertk, while M-MDSC expressed PD-L1. No changes in body weight were observed in CCl_4 mice with or without pI:pC (B), and pI:pC did not reduce MDSC numbers in the current therapeutic protocol. In addition, liver damage, function and necroinflammation (Ishak-Grade) were unvaried following pI:pC administration, while liver fibrosis (Ishak-Stage) was reduced ($p = 0.0240$) (E).

Conclusion: We identified MDSC in the circulation and liver in murine models of fibrosis (CCl_4 and CCl_4 with LPS). Our data support the liver-related safety of pI:pC therapy, although MDSC numbers were unchanged. Yet, pI:pC alleviated fibrosis. Novel approaches targeting MDSC *in vivo* merit further evaluation.



(A) Schematic of carbon tetrachloride model involving bi-weekly administration of CCl_4 (i.p. 0.4 ml/Kg) for 6 weeks, as well as LPS challenge or pI:pC immunomodulation. **(B)** Weight of mice (grams) from CCl_4 controls and CCl_4 + pI:pC treated mice. **(C)** Cell numbers of MDSC subsets per gram of liver tissue or millilitre of blood in CCl_4 alone or CCl_4 + LPS models. **(D)** Representative immunofluorescent image of CD11b+Gr-1+ MDSC in liver sections of CCl_4-treated mice. **(E)** H&E or SiriusRed stainings from FFPE liver sections, ISHAK grade and ISHAK stage scores. Unpaired t-tests or Ordinary one-way ANOVA test (> 2 groups).

THU-346

Cirrhosis alters receptor mediated clearance of therapeutic antibodies by hepatic sinusoidal endothelial cells

Bethany James[1], Louise Gliddon[2], Matthew Gardener[2], Chris J Weston[1], Patricia Lalor[1]. [1]*University of Birmingham, Centre for Liver and Gastroenterology Research and National Institute for Health Research (NIHR) Birmingham Biomedical Research Centre, Institute of Immunology and Immunotherapy., Birmingham, United Kingdom;* [2]*Antibody Pharmacology, Biopharm Discovery, Glaxo Smith Kline Research and Development, Hertfordshire, United Kingdom*
Email: bhj711@student.bham.ac.uk

Background and aims: Fully human or humanized monoclonal antibodies (mAbs) are increasingly used for immunotherapy; but the design of these molecules is complicated by the need to bypass normal antibody clearance mechanisms. The liver plays a key role in the internalisation and catabolic clearance of biological therapies via interactions with scavenger and Fc-receptors within the hepatic reticuloendothelial system. Liver sinusoidal endothelial cells (LSECs) express many of these receptors and play key roles in clearance of immune complexes and regulation of antibody pharmacokinetics. However, changes in the expression of key membrane receptors involved in antibody clearance in chronic disease are not well characterized and may impact on drug efficacy in target patients. Therefore, we wanted to investigate the impact of cirrhosis on the expression of key receptors by human LSEC and assess how this impacts on the uptake and clearance of varying formats of monoclonal antibodies.

Method: LSEC were isolated from diseased and normal human liver tissue; as well as use of whole liver for extraction of RNA and protein lysates. A novel recycling assay was designed using primary cells from both diseased and healthy livers in which the binding and internalisation of chimeric, human/humanised and bispecifics were visualised through immunofluorescence confocal imaging, flow cytometry and quantification of antibody within cells over 4 and 8hours time periods via meso-scale discovery (MSD) assay. Furthermore, whole liver tissue wedges were used for antibody perfusion over a 4-hour period after which the wedges were either fixed for chromogen staining or mechanically digested to generate cell suspensions for flow cytometric analysis of antibody localisation. Fluorescence intensity and MFI was obtained using ImageJ and Flowjo and one-way ANOVA and student T tests were used to statistically analyse the data.

Results: Our results confirm that expression of three important receptors known for antibody clearance by human LSEC (CD32b, DC-SIGN and Mannose Receptor) is significantly altered at the protein level in cirrhosis. Importantly confocal imaging, MSD, flow cytometry and novel recycling assays on isolated diseased and healthy LSEC confirm that LSEC can bind and internalize therapeutic mAbs. We found that the binding capacity is altered on cells that originated from cirrhotic livers with immunofluorescent staining revealing a statistically significant difference between healthy and cirrhotic LSEC at 4 hours (Figure). Cells from cirrhotic livers also lacked the ability to process therapeutic biomolecules as evidenced by the retention of fluorescent signal at the 8-hour time point when compared to cells from donor tissue.

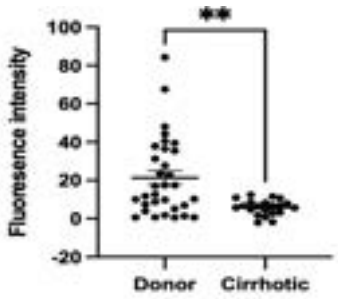

Figure 1: LSEC were isolated from either donor (n=32) or explanted cirrhotic livers (n=21). Once confluent these cells were seeded into 6 chamber ibidis and were treated with a monoclonal antibody X for 4hours. Here the cells were fixed with 4% PFA and permeabilised with 0.1% triton before being stained with an Alexa fluor anti-mouse IgG 488 secondary. Fluorescence intensity was determined using ImageJ and statistical significance determined by an unpair T test (p<0.0001). Data shown as mean ±SEM. Each point corresponds to an individual liver.

Figure:

Conclusion: Our novel assays using human LSEC have demonstrated that changes in LSEC phenotype accompanying chronic disease may explain altered drug pharmacokinetics and toxicity observed in early trials. Therefore, future antibody development pathways should incorporate testing in models representative of the target patient demographic to address issues of poor kinetics, unexpected toxicity and poor predictive ability.

THU-347

Evaluation of the effect of glucocorticoids on cardiac chronotropic dysfunction in cirrhotic rats, do dopamine receptors also play a role?

Mohadese Shokrian Zeini[1,2], Maryam Shokrian Zeini[1,2], Qamar Niaz[1,3], Sania Mehreen[4], Farahnaz Jazaeri[1]. [1]*Department of Pharmacology, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran;* [2]*Experimental Medicine Research Center, Tehran University of Medical Sciences, Tehran, Iran;* [3]*Department of Pharmacology and Toxicology, Faculty of Bio-Sciences, University of Veterinary and Animal Sciences, Lahore, Pakistan;* [4]*Department of Zoology, Faculty of Fisheries and Wildlife, University of Veterinary and Animal Sciences, Lahore, Pakistan*
Email: fjazaeri@yahoo.com

Background and aims: Liver cirrhosis is defined by the regenerative nodules and fibrous septa formation, often causing a complication called cirrhotic cardiomyopathy (CCM) with chronotropic dysfunction. β-adrenergic receptors (β-ARs) are down-regulated in CCM. Glucocorticoids and the dopamine receptor's downstream signaling affect this pathway. Thus, we investigated the dexamethasone treatment effect on chronotropic dysfunction and the possible involved pathways in cirrhotic rats.

Method: Bile duct ligation (BDL) or Sham surgery was performed on male *Wistar* rats to induce cirrhosis or used as control groups and grouped as BDL/NS (normal saline) and BDL/dexamethasone [2.2 mg/kg/day through intramuscular injection, a short term treatment for the last three days of 4 weeks of BDL (28 days)], Sham/NS, and Sham/dexamethasone groups. *In vivo*, chronotropic responses and corrected QT (QTc) interval were studied through electrocardiography (ECG) before and after stimulation with different concentrations of isoproterenol, each concentration for 5 minutes. The tumor necrosis factor-alpha (TNF-α) and interleukin-1β (IL-1β) in heart ventricles were investigated through ELISA. Immunohistochemistry was performed to investigate the dopamine receptor D1 (DRD1) and D2 (DRD2) protein expression levels in the heart ventricles. Real-time polymerase chain reaction (real-time PCR) was conducted to investigate the expression of DRD1, DRD2, and Guanine nucleotide-binding protein G (olf) subunit alpha L (GNAL) receptors (relative to GAPDH) in the heart atria.

Results: The chronotropic responses decreased in BDL/NS and increased in BDL/dexamethasone group. The QTc interval and

ventricular TNF-α level were increased in BDL/NS and decreased in BDL/dexamethasone group. The IL-1β level increased in BDL/NS group and was not affected in BDL/dexamethasone group. The atrial DRD1 mRNA expression level was not affected in BDL/NS group, while the DRD2 and GNAL mRNA expression levels were decreased in atria. The atrial DRD1 mRNA expression level was decreased in the BDL/dexamethasone group without affecting the DRD2 and GNAL mRNA expression levels in atria. The ventricular DRD1 and DRD2 protein expression levels were down-regulated in BDL/NS group, while the DRD1 protein expression level was up-regulated in the BDL/dexamethasone group without affecting the DRD2 protein expression level in ventricles.

Conclusion: Dexamethasone effectively treats the chronotropic hypo-responsiveness and decreases the QTc interval in CCM by affecting the inflammation and the DRD1 expression level in the cirrhotic rat's hearts.

THU-348

Distinct changes in the inflammatory profile of patients with EASL-CLIF- versus APASL-acute-on-chronic liver failure

Mona-May Langer[1,2], Sabrina Guckenbiehl[2], Alina Bauschen[2], Gerald Denk[1], Christian M. Lange[1,2]. [1]*Department for Internal medicine II, LMU hospital, Munich, Germany;* [2]*Department for gastroenterology and hepatology, University hospital Essen, Essen, Germany*
Email: monamay.langer@med.uni-muenchen.de

Background and aims: Definitions of acute-on-chronic liver failure (ACLF) are heterogeneous. Whereas in APASL-definition the liver is the most important organ failure, EASL-CLIF- and NACSELD-definitions focus on extrahepatic organ failures. In the present study, we

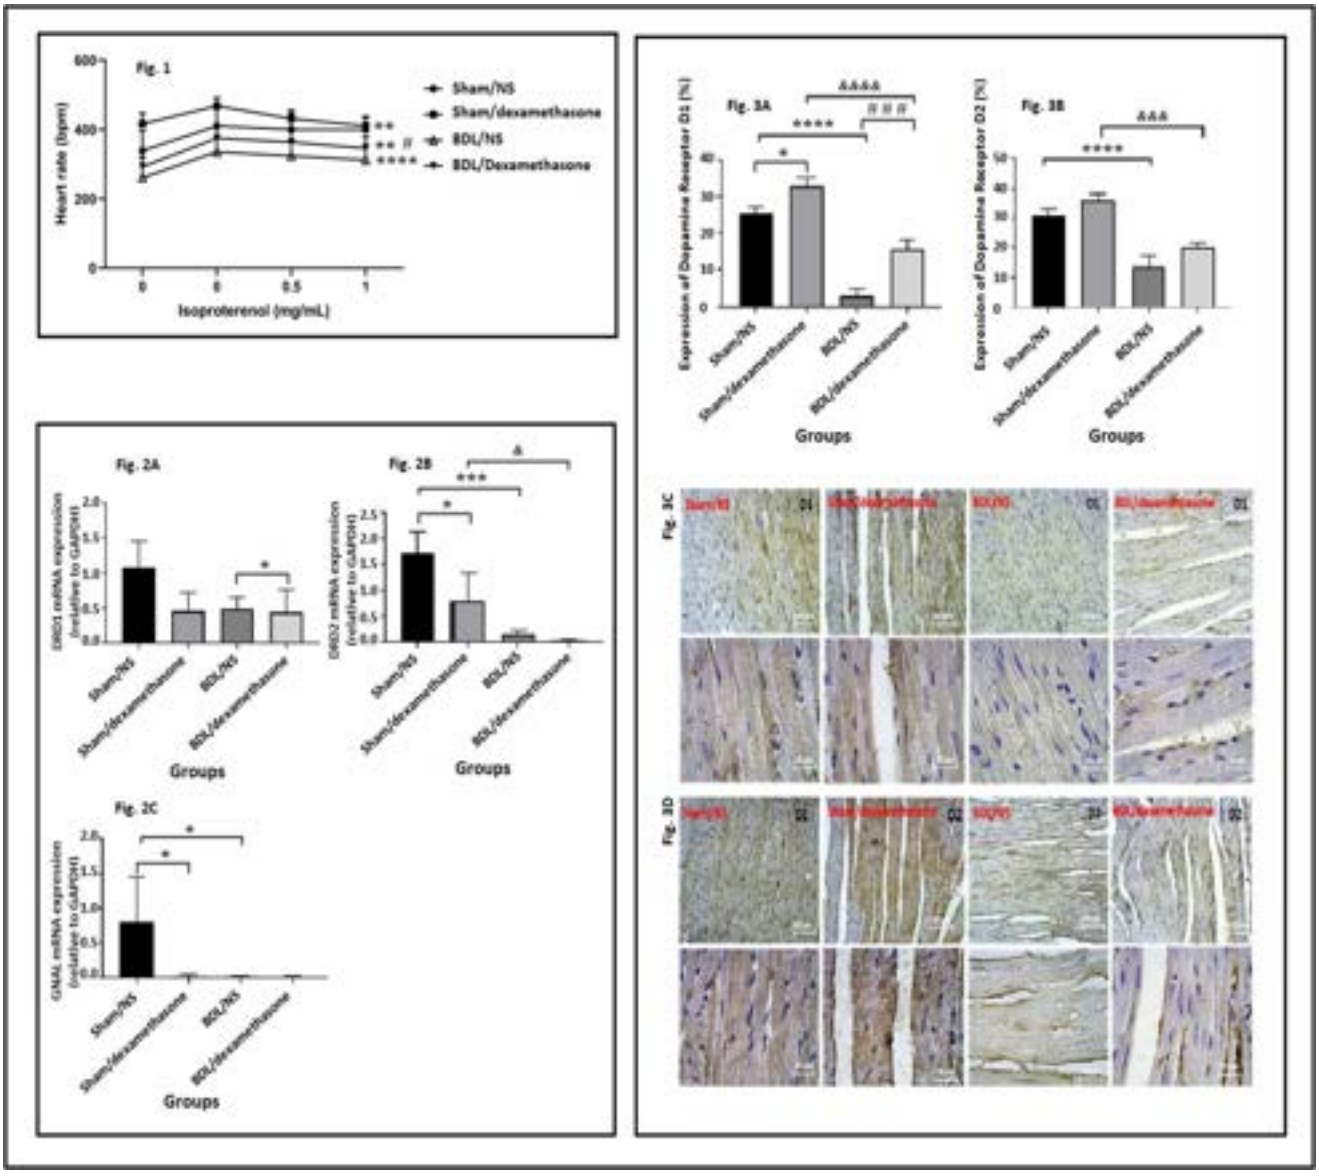

Figure: (abstract: THU-347): *In vivo* average heart beating rates (Fig. 1), DRD1, DRD2, and GNAL mRNAs expression in atria (Fig. 2), and DRD1 and DRD2 proteins expression in ventricles (Fig. 3) of Sham (Sham-operated) and BDL (cirrhotic) rats quantified through ECG, real-time PCR, and IHC, respectively. The data are shown after treatment with saline or dexamethasone (2.2 mg/kg/day) for 3 consecutive days. The average heart beating rates data were analyzed through two-way ANOVA with post-hoc Tukeys' test and the mRNAs and proteins expression data through one-way ANOVA with post-hoc Tukeys' test and presented as mean ± SEM. Total 6 animals were included in each experimental group. Fig. 1: $^{**}p < 0.01$ Sham/dexamethasone and BDL/dexamethasone groups compared to Sham/NS group; $^{****}p < 0.0001$ BDL/NS group compared to Sham/NS group; and $^{\#}p < 0.05$ BDL/dexamethasone group compared to BDL/NS group.

therefore determined associations between the presence and absence of ACLF and correlate these with inflammatory molecules, clinical parameters and outcome.
Method: 208 hospitalized patients with liver cirrhosis with or without ACLF were recruited from a prospective cohort study. 76 inflammatory molecules were quantified by proximity extension analysis assay (Olink, Uppsala, Sweden). Associations between inflammatory profiles and types of ACLF were determined. Moreover, surface expression profiles of immune cells were analyzed by flow cytometry.
Results: Of 208 patients, 127 had no ACLF at all, while 81 had any ACLF. Of patients with ACLF, 20 had ACLF based on the APASL-definition only, while 30 had ACLF exclusively based on the EASL-CLIF-definition. All 12 patients with NACSELD-ACLF also fulfilled the EASL-CLIF criteria. A differential expression of inflammatory molecules according to the type of ACLF was observed. Overall, patients with APASL-ACLF (but without EASL/NACSELD-ACLF) had rather moderate changes of inflammatory mediators compared to patients with acute decompensation without ACLF, whereas patients who met the EASL- or NACSELD-definition of ACLF showed signatures of substantial systemic inflammation. Furthermore, a differential increase of mediators between EASL-CLIF- and APASL-ACLF was observed, as for example FGF-19 and HGF were particularly increased in APASL-ACLF while VEGFA, FGF-23, TNF-beta or IL-17 are significantly upregulated in EASL-CLIF. Data on immune cell phenotypes will be presented.
Conclusion: Patients with APASL- versus EASL-CLIF-ACLF have partially distinct inflammatory profiles, which may point towards distinct pathophysiological mechanisms in different types of ACLF.

THU-349
Bacterial DNA translocation-induced systemic inflammation is associated with overt hepatic encephalopathy and predicts mortality in patients with cirrhosis

Kessarin Thanapirom[1,2,3], Sirinporn Suksawatamnuay[1,2,3], Salisa Wejnaruemarn[1,2,3], Panarat Thaimai[1,2,3], Nipaporn Siripon[1,2,3], Prooksa Ananchuensook[1,2,3], Supachaya Sriphoosanaphan[1,3], Sombat Treeprasertsuk[1], Piyawat Komolmit[1,2,3]. *[1]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Medicine, Bangkok, Thailand; [2]Liver Fibrosis and Cirrhosis Research Unit, Chulalongkorn University, Bangkok, Thailand; [3]Excellence Center in Liver Diseases, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand*
Email: pkomolmit@yahoo.co.uk

Background and aims: There is mounting evidence that bacterial translocation (BT) and systemic inflammation play a key role in the pathogenesis of cirrhotic complications. However, the data on the relationship between BT, hepatic encephalopathy (HE), and mortality is limited. Therefore, we aimed to assess the association between bacterial DNA (bactDNA) translocation, inflammatory markers, ammonia level, and the presence of HE in patients with cirrhosis. In addition, we prospectively assessed the prognostic role of bactDNA translocation in predicting mortality and liver-related complication (LRC) within six months.
Method: Cirrhotic patients without bacterial infection were enrolled at Chulalongkorn University, Bangkok, Thailand, from June 2021 to October 2022. Grading of HE was classified by the West Haven Criteria and Psychometric hepatic encephalopathy score (PHES) ≤-5. BactDNA, lipopolysaccharide-binding protein (LBP), tumor necrosis factor-alpha (TNF-alpha), interleukin-6 (IL-6), soluble CD14 (sCD14), and venous ammonia were evaluated. LRC was a composite end point of bacterial infection, variceal bleeding, overt HE, or new onset ascites.
Results: Overall, 294 cirrhotic patients were enrolled. Of these, 92 (31.3%) and 58 (19.7%) had covert and overt HE, respectively. Patients with overt HE had more bactDNA translocation (48.3% vs. 31.3%. p = 0.02), higher serum LBP (13,480.0 ± 9,469.3 vs. 10,788.5 ± 7,339.4 ng/ml, p = 0.01), IL-6 (105.9 ± 302.2 vs. 10.9 ± 25.6 pg/ml, p = 0.001), and ammonia level (92.7 ± 41.3 vs. 62.2 ± 26.8 ug/dL, p < 0.001) than those without HE. While these tests revealed no differences between patients with covert HE and those without HE. Patients with bactDNA detection exhibited a greater white cell count, serum LBP, and IL-6 than those without bactDNA. During the 6-month follow-up, 40 patients (13.6%) died, and 65 patients (22.1%) developed at least one of the LRC. The multivariate Cox regression analysis showed bactDNA translocation (aHR = 2.14, 95%CI: 1.01–4.51. p = 0.04), MELD (aHR = 1.11, 95%CI: 1.07–1.16, p < 0.001), age (aHR = 1.07, 95%CI: 1.04–1.11, p < 0.001) and serum IL-6 (aHR = 1.002, 95%CI: 1.000–1.003, p = 0.03) were independent predictors of the 6-month mortality. Only the MELD score (aHR = 1.10, 95%CI: 1.06–1.15, p < 0.001) was an independent predictor of LRC development.
Conclusion: Apart from hyperammonemia, bactDNA translocation-related systemic inflammation is a potential pathophysiological mechanism of overt HE in patients with cirrhosis. In addition, the detection of bactDNA translocation and IL-6 elevation are independent predictors of 6-month mortality in patients with cirrhosis.

THU-350
Platelets from patients with decompensated cirrhosis display pro-inflammatory features

Simone Di Cola[1], Lucia Stefanini[1,2], Ludovica Lombardi[1], Stefano Fonte[1], Francesca Maiorca[1], Davide Pallucci[1], Ramona Marrapodi[1], Annamaria Sabetta[1], Marzia Miglionico[1], Roberto Cangemi[1], Marcella Visentini[1], Oliviero Riggio[1], Manuela Merli[1], Stefania Basili[1]. *[1]Department of Translational and Precision Medicine, Sapienza University, Rome, Italy, Italy; [2]Istituto Pasteur Italia-Fondazione Cenci Bolognetti, Rome, Italy, Italy*
Email: simone.dicola@uniroma1.it

Background and aims: Changes in platelet structure and function occur in chronic liver disease. These changes have also been implicated in progression of liver disease. Cirrhotic patients have a. lower platelet count and a heightened risk of thrombosis. However, the functional state of circulating platelets in cirrhotic patients is debated and poorly understood. Thus, we aim to characterize the phenotypical and functional features of circulating platelets of cirrhotic patients.
Method: We here report the preliminary analysis of an ongoing interventional longitudinal study.
(PVTRIFA2017-EudraCT 2017-000488-34). We analyzed the platelet phenotype at baseline of patients with cirrhosis (Child-Pugh score B and C) in comparison to healthy donors matched by age and sex. Exclusion criteria were assumption of aspirin or other non-steroidal anti-inflammatory drugs at the time of enrollment. Phenotype, function, and immune interactions of platelets were studied by multiparameter flow cytometry within 1 hour from blood withdrawal. The study was approved by the Ethics Committee of the Hospital Umberto I (Rome, Italy).
Results: Decompensated cirrhotic patients had a significantly lower platelet count compared to healthy controls. The platelet size was larger than controls, but the immature platelet fraction (i.e. the fraction of platelets that are younger) was not increased, suggesting that there may be a higher platelet turnover, followed by a near-immediate platelet consumption. Circulating platelets from cirrhotic patients displayed higher levels of receptors implicated in immune-like functions (P-selectin, GPIba, FcgRIIA) compared to controls and had a higher propensity to bind monocytes and lymphocytes in peripheral blood. Moreover, platelets from cirrhotic patients exhibited a higher platelet responsiveness to agonists of Immunoreceptor Tyrosine-based Activation Motif (ITAM)-coupled receptors, but a lower responsiveness to the thrombin-receptor agonist peptide (TRAP) signaling through G protein-coupled receptors (GPCRs) (Figure 1).

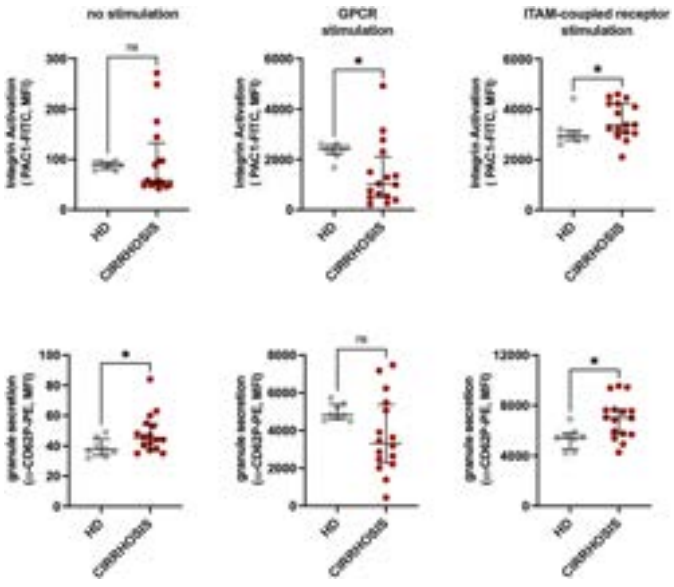

Figure: Activation of circulating platelets determined by multicolour flow cytometry. Citrated blood from healthy donors (HD, grey) or decompensated cirrhotic patients (cirrhosis, red) was diluted 1:10 and incubated with PAC1-FITC (that recognizes the active conformation of integrin αIIbβ3) and α- CD62P-PE (that is a marker of α granules secretion) in resting (no stimulation) or stimulated conditions with agonists specific for platelet-specific G protein-coupled receptor (GPCRs) or Immunoreceptor Tyrosine-based Activation Motif (ITAM)-coupled receptors. Samples were acquired on a BD Accuri C6 Plus and analysed with FlowJo version 10.8. Mann-Whitney test was performed for statistical analysis. *p < 0.05.

Conclusion: The study identified novel pro-inflammatory features that characterize platelets from decompensated cirrhotic patients. These may represent novel molecular targets to prevent thrombotic complications and potentially to decelerate the progression of liver disease.

THU-351

Single-cell RNA transcriptomics of peripheral blood mononuclear cells revealed altered gene expressions in monocyte and HLA variations in decompensated liver cirrhosis patients with sepsis

Nirupma Trehanpati[1], Rashi Sehgal[1], Pramod Gautam[2], Mojahidul Islam[2], Jayesh Kumar Sevak[2], Navkiran Kaur[3], Gayatri Ramakrishna[2], Rakhi Maiwall[2], Shiv Kumar Sarin[2]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Institute of Liver and Biliary Sciences, New Delhi, India; [3]Amity University Noida, Noida, India*
Email: trehanpati@gmail.com

Background and aims: Immune dysfunction and systemic inflammation are the hall marks of decompensated liver cirrhosis (DLC) patients, which gets aggravated with the development of sepsis. The molecular and cellular basis of rapid immune deterioration in cirrhotic patients is not well understood. We investigated immune responses in peripheral blood mononuclear cells (PBMCs) in DLC patients with sepsis using single-cell RNA (scRNA) transcriptomic).
Method: Twenty one DLC patients (age 42+7Yr, all males) with sepsis (n = 10) and without sepsis (n = 11) along with ten healthy controls were recruited. Isolated PBMCs from seven DLC patients were subjected to scRNA transcriptomics using BD Rhapsody (BD Biosciences, #633701). After quality control, raw fastq files were aligned to reference Human genome (GRCh38). Following normalization, a count matrix was generated and then using Seurat (v4.0), this count matrix was filtered and processed further for dimensionality reduction, batch correction, differential gene expression, clustering, gene set enrichment analysis (GSEA) and cell-type identification. Further, HLA DRB1 alleles typing was analysed in DLC patients by Sequence Specific Primer method in Luminex PCR.
Results: Cells with high proportion of mitochondrial and low proportion of ribosomal reads were removed. Single cell sequencing technology have revealed 10 clusters and 7 cell types with significant heterogeneity in monocytes. GSEA revealed, that in DLC patients, there was significant (p > 0.05) decrease in gene expression associated with O^6-methylguanine-DNA methyltransferase (MGMT) mediated DNA damage reversal, Mitochondrial transcription termination and Melanin biosynthesis, but upregulated expression of genes belonging to lactose synthesis, hydroxycarboxylic-acid, FGFR1b and FGFR1c ligand binding and receptors compared to HC. Cluster pertaining to classical monocytes in DLC patients with sepsis, had significant down-regulation of genes related to NF-kB signaling, TNF-α signaling, IL-17 signaling compared to without sepsis group. scRNA technology also revealed that along with decreased HLA-DR expression other HLA markers like HLA-A, HLA-B and HLA-DQA1 were also decreased in sepsis but with unique increased expression of HLA-DRB1, HLA-C, HLA-E, HLA-DRA, and HLA-DQA2. Genotyping of HLA-DRB1 by luminex assay revealed presence of HLADRB1*11 allele in DLC patients with sepsis (HLA-DRB1*07DRB1*11, HLA-DRB1*11 DRB1*14, HLA-DRB1*11 DRB1*13) than without sepsis.
Conclusion: Our study indicated possible reason for sepsis development in DLC patients due to defects in NF-kB, TNF-α and IL-17 signaling in classical monocytes. Increased frequency of HLA-DRB1*11 in monocytes enhanced the potential of sepsis development in DLC patients.

THU-352

Role of extracellular vesicles in sarcopenia associated to chronic liver diseases

Simone Di Cola[1], Laura Barberi[1,2,2], Cristiana Porcu[3], Lucia Lapenna[1], Stefano Fonte[1], Lorenzo Ridola[1], Antonio Musarò[3], Manuela Merli[1]. *[1]Department of translational and precision medicine, Sapienza university of Rome, Italy, Italy; [2]Sapienza University of Rome, Department of translational and precision medicine, Rome, Italy; [3]2 DAHFMO, Unit of histology and medical embryology, Sapienza university of Rome, Italy*
Email: simone.dicola@uniroma1.it

Background and aims: Sarcopenia is a condition of reduced skeletal muscle mass, quality and strength highly prevalent in patients with chronic liver disease and associated with adverse clinical outcomes. Its pathogenesis is multifactorial and mainly resulting from an imbalance between muscle protein synthesis and degradation; however, mechanisms underlying sarcopenia in liver disease are still not completely understood as the mediators of the liver-muscle axis have not yet been identified. Given the emerging role of extracellular vesicles (EVs) in mediating intercellular communication and the metabolic cross-talk between skeletal muscle and liver, we aimed to evaluate whether circulating EVs in liver disease could vehicle to skeletal muscle bioactive molecules, such as microRNAs, able to induce sarcopenia.
Method: Primary human muscle cells were exposed to EVs isolated from serum of healthy (H-EVs; n = 9) and cirrhotic individuals with sarcopenia (C-EVs; n = 13) at different times of muscle culture. Finally, they were examined, by immunofluorescence analysis, for their ability to differentiate in myotubes and, by western blotting, for the expression of markers of protein synthesis and degradation. Moreover, miRNA cargo of serum cirrhotic patients derived-EVs were analysed and compared with that of healthy subjects derived-EVs, examining the expression levels of some microRNAs involved both in liver disease and in muscle development.
Results: We showed that serum EVs were efficiently internalized by skeletal muscle cells and that EVs isolated from cirrhotic individuals were able to cause in vitro muscle atrophy. Indeed, they induced a decrease in muscle differentiation, as revealed by a reduced size of

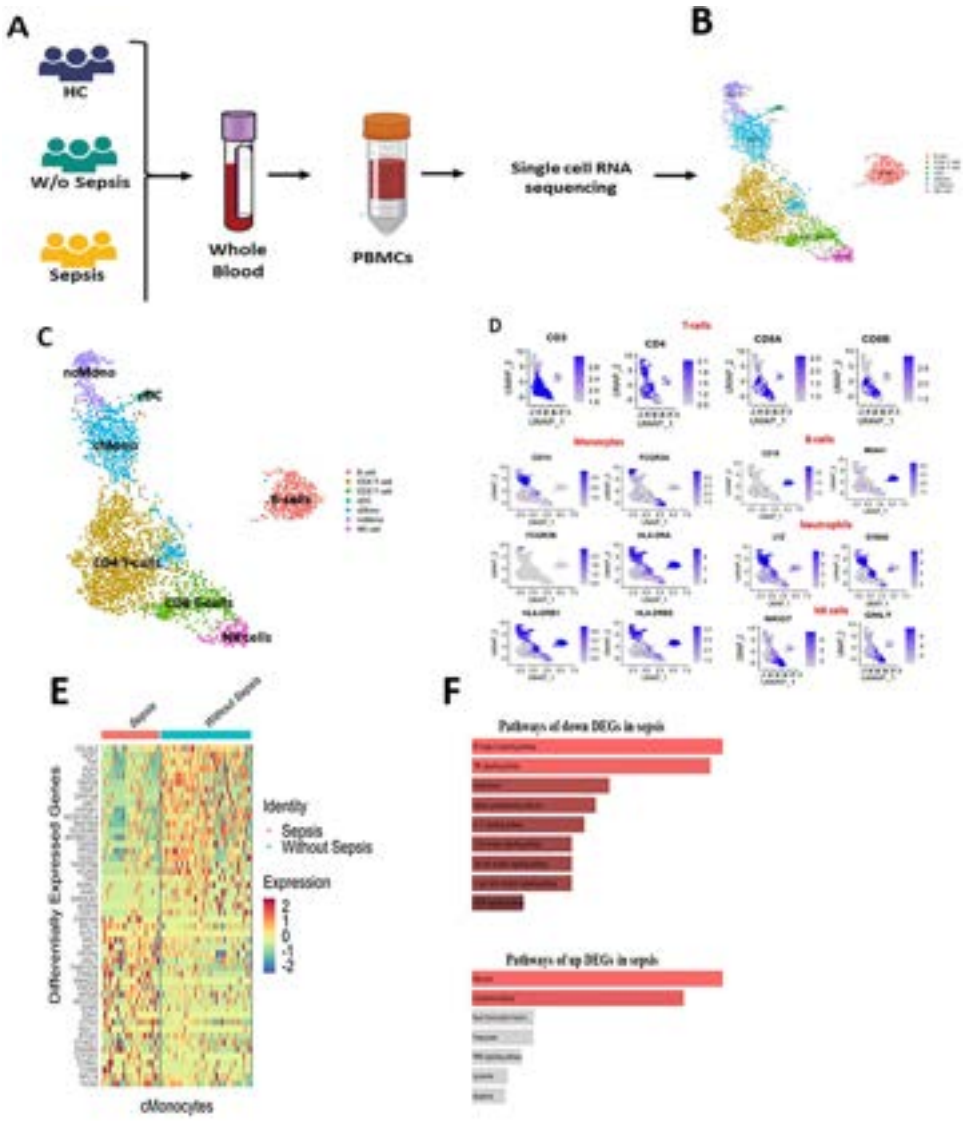

Figure: (abstract: THU-351).

myotubes in culture, and downregulated expression of myosin protein (p <0.05), and an increase in protein degradation, as showed by an upregulation of Murf-1 and Atrogin-1 mRNA expression levels (p <0.05), compared with serum EVs from healthy individuals. Moreover, EVs from cirrhotic patients exhibited significant higher expression levels (p <0.05) of microRNAs, such as miR-223, –133a, –29a, –128a, –21, and –199a-3p, targeting the two most important signaling pathways in muscle tissue: the TGF-β/myostatin/BMP and PI3K/AKT/mTOR pathways, regulating protein synthesis and degradation respectively.

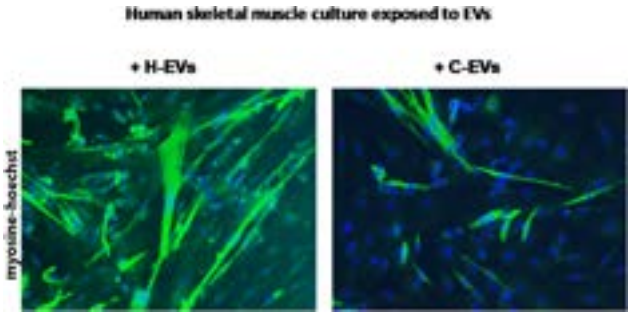

Figure:

Conclusion: Serum EVs in cirrhotic patients, likely released by damaged liver, could affect skeletal muscle homeostasis and mediate sarcopenic processes by delivering to muscle cells a specific miRNA cargo. Therefore, circulating EVs could be key players of the liver-muscle axis in sarcopenia associated to liver disease.

THU-353

Effects of β-adrenergic hyperstimulation, liver cirrhosis and acute-on-chronic liver failure (ACLF) on the small intestinal gut-vascular barrier (GVB)

Marco Felber[1], Reiner Wiest[1]. [1]*Institute for Visceral Surgery and Medicine, Gastroenterology, Bern, Switzerland*
Email: marco.felber@unibe.ch

Background and aims: Acute on chronic liver failure (ACLF) is often characterized by precipitating events of which pathological bacterial translocation (BT) from the gut and/or bacterial infections have been proposed to be of particular pathophysiological relevance. In ACLF i) excessive adrenergic drive has been shown by markedly increased serum levels of norepinephrine (Jalan et al. (2015) *Liver international*) and ii) non-selective beta-blocker therapy appears to improve short-term mortality (Mookerjee et al. (2016) *Journal of Hepatology*). The only treatment in advanced ACLF is liver transplantation. ACLF patients even after transplantation present with up to 10% mortality within the first 60 months being most frequently caused by sepsis (Sundaram et al (2020) *Liver transplantation*). (Sundaram et al (2020) *Liver transplantation*). The gut-vascular-barrier (GVB) is fundamental for limiting access of pathological BT to the gut-liver-axis but has not been addressed as for changes induced by adrenergic drive and/or ACLF. Thus, we aimed to characterize the small intestinal GVB in terms of function, structure and integrity in dependency on beta-adrenergic stimulation, blockade (by propranolol) and/or presence of liver cirrhosis and ACLF.
Method: ACLF was induced in C57Bl/6 cirrhotic mice (bile-duct-ligation) via LPS i.p. and beta-adrenergic hyperactivity was induced by chronic intraperitoneal delivery of isoproterenol (by osmotic mini pump) for 7 days. Duodenal GVB-function was determined in-vivo by confocal laser endomicrosopy assessing extravasation of FITC-albumin. Endothelial intercellular junctions (VE-cadherin, claudin-5) were evaluated by immunofluorescence.
Results: Chronic beta-adrenergic hyperstimulation caused pathological increases in FITC-albumin extravasation into the duodenal lamina propria being even more pronounced in cirrhotic and ACLF mice. Moreover, propranolol-treatment ameliorated FITC-albumin-extravasation in beta-adrenergic stimulated mice. Changes in GVB-function induced by beta-adrenergic stimulation were associated with significant reductions in VE-cadherin and claudin-5 in duodenal capillaries.

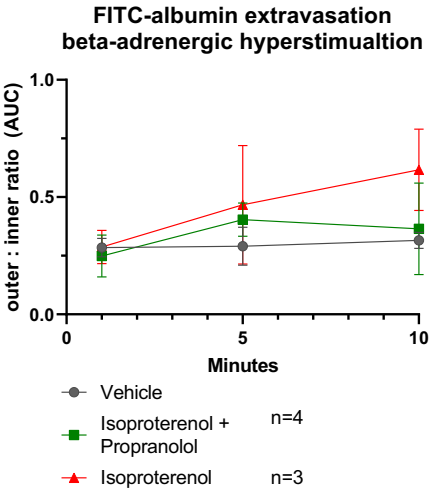

Figure:

Conclusion: Beta-adrenergic hyperstimulation modulates intercellular junctions impairing vascular barrier integrity and function of small intestinal GVB. This GVB-dysfunction may be a leading cause of pathological loss of albumin as well as pathological BT fueling the gut-liver-axis in ACLF.

THU-354

Identification of complication- dependent gut microbial biomarkers for early detection of decompensated cirrhosis

Ki Tae Suk[1], Satya Priya Sharma[1], Haripriya Gupta[1], Sung-Min Won[1], Jin-Ju Jeong[1], Raja Ganesan[1], Dong Joon Kim[1]. [1]*Institute for Liver and Digestive Diseases, Hallym University, Chuncheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Change in gut microbiome is closely associated with liver cirrhosis progression from compensated to decompensated phase. Therefore, gut microbial compositional shift in cirrhosis progression is significantly important to identifying the potential biomarkers for two cirrhotic clinical phases. Here, we have compared the gut microbiome in compensated and decompensated cirrhosis patients based on the complications, to identify the gut composition specific gut microbial biomarkers. Additionally, we have evaluated cirrhosis-dependent gut microbial and metabolic markers.
Method: Stool samples were collected prospectively from 142 cirrhosis patients and 52 healthy controls. 16S-based Microbiome Taxonomic Profiling was performed to discover the gut microbial biomarkers based on cirrhosis severity progression and complications. Next, total 51 samples (control (n = 17) + cirrhosis patients ((n = 34)) were randomly selected for fecal samples metabolites profiling.
Results: Out of total 142 cirrhosis, 33% were females (n = 47) and overall mortality rate was 24% (n = 34), whereas higher mortality rate was found in male (74%) in comparison to female (26%). All 142 patients were classified in major two groups: compensated cirrhosis (n = 10), and decomposed cirrhosis (n = 132), decomposed cirrhosis group further classified based on the occurring and non-occurring decomposed-associated complications. A prominent difference in gut microbial composition has been observed in healthy controls, cirrhosis, and cirrhosis+ complications patients. Whereas 3 species found high in cirrhosis (*Clostridium clostridioforme*, *Bacteroides ovatus*, *Hungatella_uc*) compared to cirrhosis+ complications and combinedly showed ROAUC up to 0.807. Furthermore, 4 species found high in cirrhosis+ complications (*Bacteroides coprocola*, *Bacteroides coprophilus*, *Alistipes finegoldii*, *Parabacteroides goldsteinii*) and combinedly showed ROAUC up to 0.847. We have also identified, 10 species high in healthy control and 8 species high in cirrhosis. Additionally, 8 metabolites found high in healthy and 11 in cirrhosis. Theses microbial and metabolic biomarkers showed significant correlation with clinical markers.
Conclusion: We have identified multiple bacterial species and metabolites which has the potential to become biomarkers for the cirrhosis. Also, we discovered bacterial species which can be used to detected early stage of decompensated cirrhosis. However, further studies are required to establishment a robust pathophysiological mechanism between identified gut microbial species and liver cirrhosis.

THU-355

Pathophysiological biomarkers associated with resolution of ACLF in patients treated with the liver dialysis device, DIALIVE

Background and aims: Acute on chronic liver failure (ACLF) is characterized by severe systemic inflammation and high mortality rates. Its treatment is an urgent unmet need. DIALIVE is a novel liver dialysis device that aims to exchange dysfunctional albumin and remove damage and pathogen associated molecular patterns. In a recently completed clinical trial in patients with ACLF, its safety was confirmed and its use was associated with significantly faster resolution of ACLF (NCT03065699). The aim of this study was to evaluate pathophysiological factors associated with ACLF resolution in patients treated with DIALIVE or standard of care (SOC).

Method: 32 patients with ACLF grades 1-3a were included and randomized. Patients evaluated in the DIALIVE group had at least 3-treatment sessions. The main end point was resolution of ACLF at

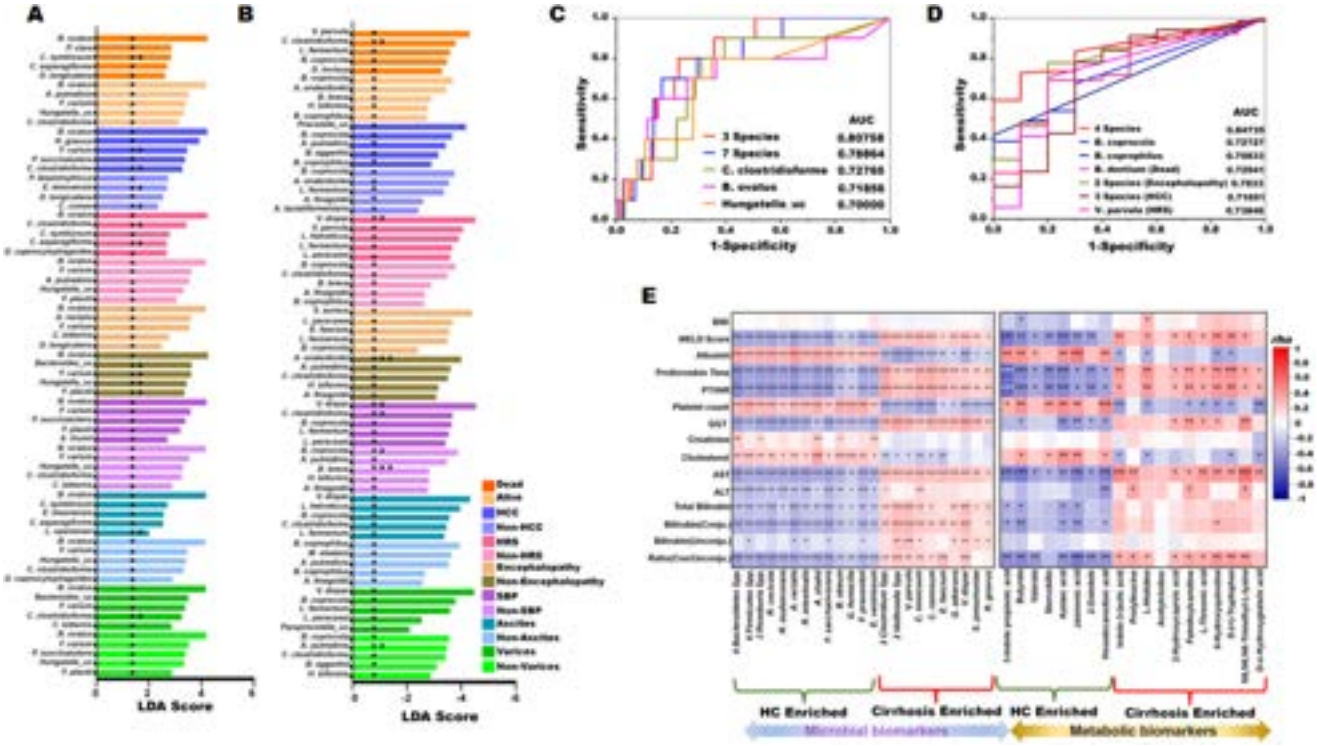

Figure: (abstract: THU-354): Figure (A) LDA score high in cirrhosis and, (B) LDA score high in complications, (C) cirrhosis-dependent species ROAUC (D) complications-dependent species ROAU, (D) Correlation between microbial and metabolic markers with clinical markers.

Day-10. A range of biomarkers of albumin function, pathogen and damage associated molecular patterns, cytokines, endothelial function and ligands for toll-like receptors and inflammasome were measured prior to randomization and then at days 5 and 10. Mixed Models for Repeated Measurements (MMRM) analysis was performed to evaluate the statistically significant differences between groups.

Results: 60% patients in the DIALIVE group resolved ACLF compared with 33% in the SOC group. Resolution of ACLF in the DIALIVE group was associated with significant improvement in albumin function, reduction in endotoxin activity, coagulation factor VIII, IL-18, M30 component of cytokeratin-18 (p = 0.018) and RIPK3 (p = 0.031). In the SOC group, there was an apparently paradoxical relationship with CCL5/Rantes (p = 0.004) and M65 component of cytokeratin-18 (p = 0.029). When both groups were combined, the data showed that a reduction in coagulation factor VIII (p = 0.018), IL-7 (p = 0.027), IL-18 (p = 0.030), RIPK3 (p = 0.034) and INR (p = 0.011) and, an increase in CCL5/Rantes (p = 0.003) were associated with resolution of ACLF.

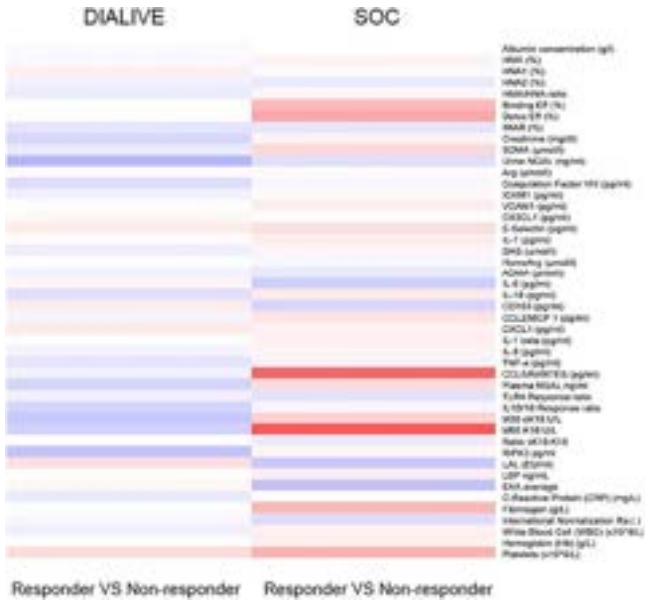

Figure:

Conclusion: ACLF resolution is associated with modulation of each of the pathways known to be associated with the pathogenesis of ACLF rather than predominance of any single pathway both in patients with DIALIVE and in the combined dataset. These data confirm the complex underlying pathophysiological mechanisms of ACLF and the requirement of therapies that target multiple pathways.

THU-356

Development and characterization of novel rodent ACLF models

Frank Erhard Uschner[1,2], Roger Flores Costa[3], Nico Kraus[2], Magnus Moeslein[2], Robert Schierwagen[1,2], Wenyi Gu[1,2], Maximilian Joseph Brol[1,2], Sophie Lotersztajn[4], Pierre-Emmanuel Rautou[5], Joan Clària[3,6], Jonel Trebicka[1,2,6].

Email: frankerhard.uschner@ukmuenster.de

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by systemic inflammation and organ failure and has very high short-term mortality. Bacterial infections and severe alcoholic hepatitis are the most relevant precipitants, inducing acute decompensation and subsequently ACLF in patients with liver cirrhosis. Still, comprehensively tested and validated ACLF animal models for preclinical studies are missing. The aim of this study was to characterize novel ACLF models in rodents that combine (i) different aetiologies of liver cirrhosis and (ii) clinically relevant precipitants leading to acute decompensation and ACLF.

Method: Liver cirrhosis was induced in rats using bile duct ligation (BDL) or CCl_4 intoxication alone and in combination with western diet or ethanol in drinking water. When rats had ascites, as a sign of acute decompensation, ACLF was induced. Precipitants for ACLF were lipopolysaccharid (LPS) i.v. injections to mimic sterile inflammation, transnasal stool inoculation (TNI) or cecal ligation and puncture (CLP) to simulate bacterial infections and alcohol binge mimicking severe alcoholic hepatitis. Hemodynamic measurements *in vivo*, blood and organ sampling was performed three days after ACLF induction. Markers for organ failure were assessed using standard blood analysis, colorimetric assays and animal behavioural tests. Histology, cRNA Microarray, multiplex-based immuno-assay, western blot and qPCR were used to further analyse markers of systemic inflammation and organ dysfunction.

Results: The BDL and CCl_4 with western diet treated animals had earlier acute decompensation compared to CCl_4 alone or CCl_4 with ethanol. ACLF induction caused a high mortality rate in all tested groups. LPS, TNI, CLP and alcohol binge led to significant organ impairment shown by reduced mean arterial pressure, renal perfusion and increased blood creatinine, increased bilirubin and INR as well as reduced oxygen saturation and worse performance in behavioural tests. Of note, all animals had high levels of systemic inflammation, as attested by upregulated expression levels of pro-inflammatory cytokines in organs corresponding to ACLF development and significantly increased levels of circulating pro-inflammatory cytokines. Nevertheless, not all groups had similar severity and manifestation of organ dysfunction.

Conclusion: These novel experimental models in rats show typical characteristics of human ACLF. The obtained detailed characterization of organ dysfunction, organ- and systemic inflammation may be useful as a guide to choose an appropriate model for therapeutic preclinical ACLF studies.

Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Systemic inflammation is a known driver of disease progression in advanced chronic liver disease (ACLD). Nevertheless, aetiology-specific characteristics of inflammation during disease progression and regression require further investigation. Thus, we analysed (i) hepatic inflammatory gene signatures in

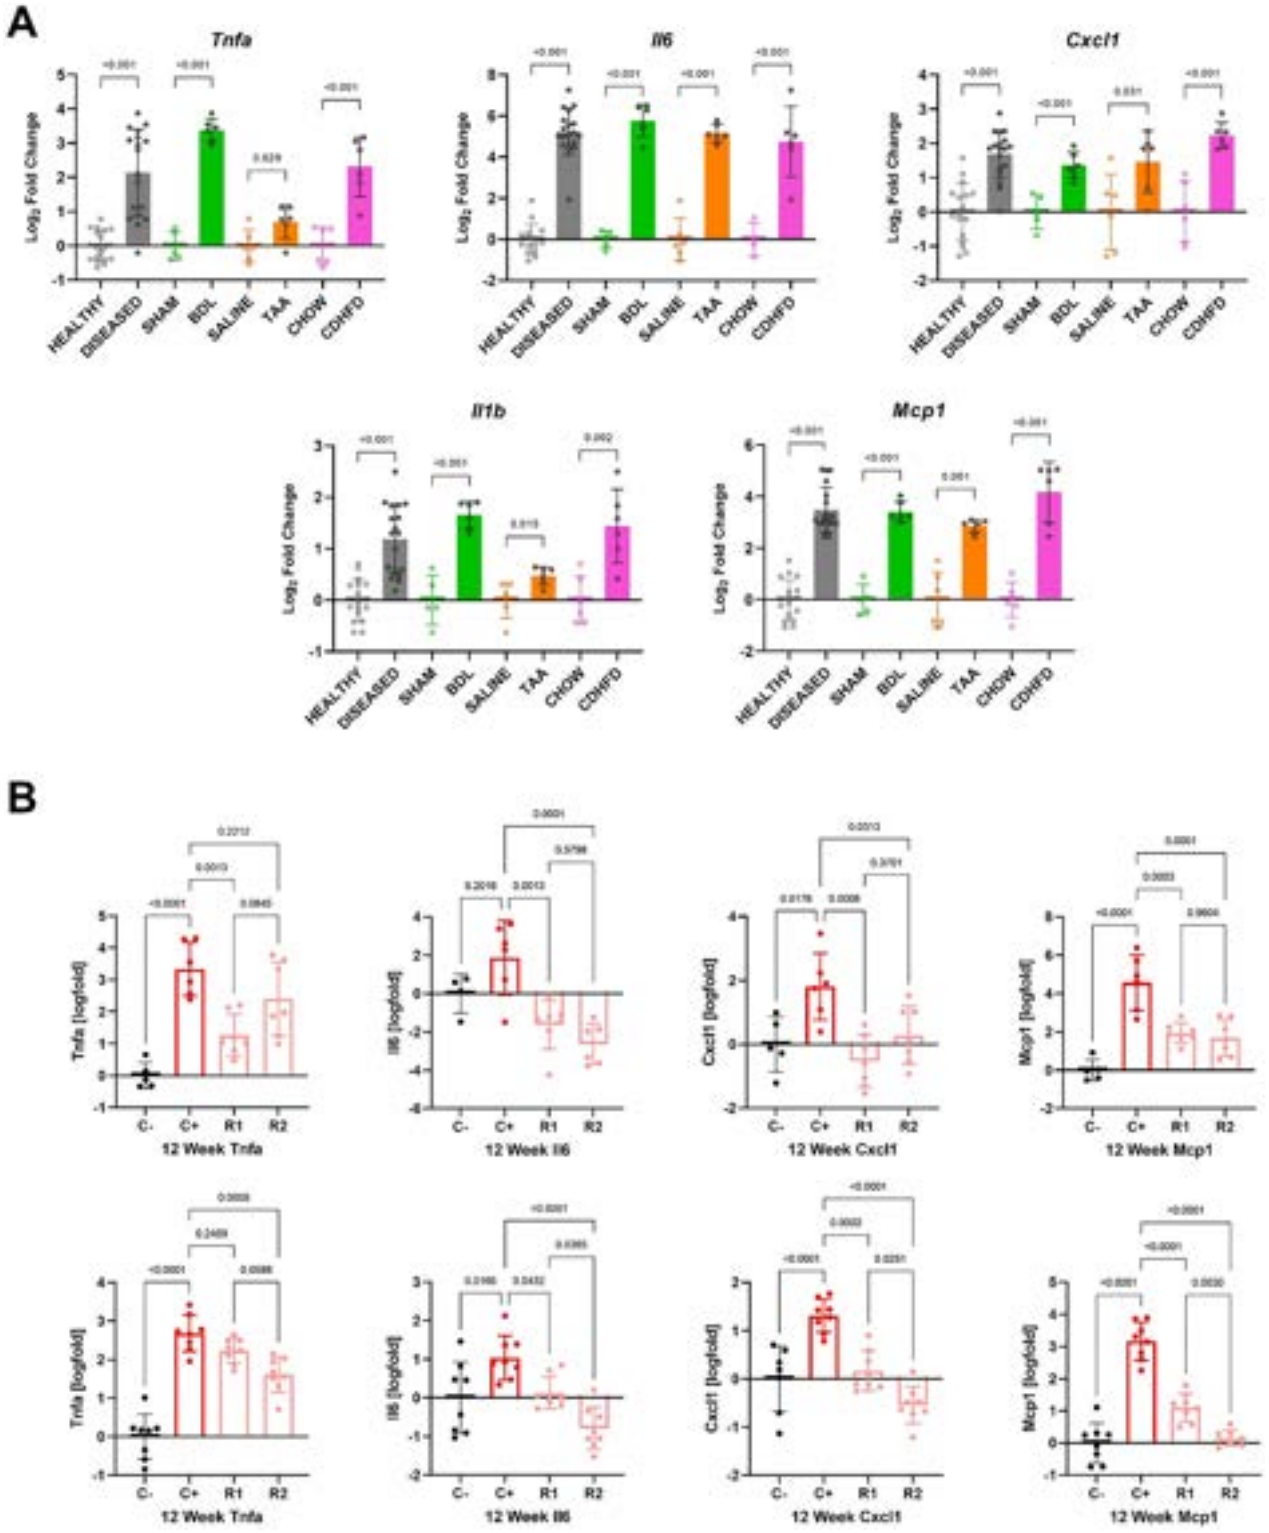

Figure: (abstract: THU-357).

animal models of different types of liver injury and (ii) systemic inflammation in ACLD patients with different liver disease aetiologies.

Method: Intrahepatic gene expression of TNF-alpha, IL-6, CXCL1, IL-1beta and MCP1 was investigated in rat cirrhosis models induced by thioacetamide (TAA, n = 12), choline-deficient high fat diet (CDHFD, n = 12), or bile duct ligation (BDL, n = 12). Inflammatory gene expression was also analysed in two mouse models at 12 weeks of disease induction by TAA or carbon tetrachloride (CCl4) (i.e. peak fibrosis)-but also after regression for 1 (R1) or 2 (R2) weeks after withdrawing the toxic stimulus. In ACLD patients with different liver disease aetiologies, i.e., n = 226 alcohol-related liver disease (ALD), n = 40 non-alcoholic steatohepatitis (NASH), n = 21 cholestatic aetiologies (CHOL), systemic inflammation was assessed by white blood cell

count (WBC), CRP and IL-6 levels. Disease regression in human ACLD was explored in a subgroup of ALD patients (n = 181) with sustained abstinence.

Results: In diseased animals (C+), we observed a significant upregulation of intrahepatic proinflammatory genes across all aetiologies when compared to the respective healthy control group (C-) ($p < 0.05$ for all; Fig. 1A). Particularly intrahepatic IL-6 (log2 fold changes; TAA: 5.18; CDHFD: 4.75; BDL: 5.77; $p < 0.001$ for all) and MCP1 (TAA: 2.85; CDHFD: 4.18; BDL: 3.41; $p < 0.001$ for all) showed a pronounced upregulation. Similarly, in ACLD patients, there was a significant positive correlation between IL6 and MELD in ALD (Spearman's rho: 0.50, $p < 0.001$), NASH (r: 0.54, $p < 0.001$) and CHOL (r: 0.67, $p < 0.001$). For CRP, a comparable correlation was observed in ALD (r: 0.27, $p < 0.001$) and CHOL (r: 0.59, $p = 0.005$), but not in NASH (r: 0.08, $p = 0.618$). With regard to disease regression, we observed a significant decrease in intrahepatic inflammation during the regression period in the TAA and CCl4 models (Fig. 1B), with an immediate (R1) and sustained (R2) decrease of hepatic IL6 and CXCL1, but with a delayed (R2) decrease of TNF-alpha and MCP1. Accordingly, in abstinent ALD patients (n = 181), the duration of abstinence was negatively correlated to WBC (r: −0.26, $p < 0.001$), CRP (r: −0.23, $p = 0.002$) and IL-6 (r: −0.21, $p = 0.004$).

Conclusion: In animal models, the upregulation of hepatic proinflammatory genes follows a liver-injury-specific pattern. In ACLD patients, systemic inflammation is increased across all aetiologies of cirrhosis, and regresses gradually with sustained abstinence in ALD patients. In regressive toxic liver disease models, there is a time-dependent down-regulation of key proinflammatory genes.

THU-358

Extracellular vesicles carrying oxidation-specific epitopes as effectors in acute hepatic decompensation and acute-on-chronic liver failure-a pilot study

Benedikt Simbrunner[1], Taras Afonyushkin[2], Benedikt Hofer[1], Philipp Königshofer[1], Georg Semmler[1], Lorenz Balcar[1], Soreen Taqi[2], Michael Trauner[1], Mattias Mandorfer[1], Christoph Binder[2], Thomas Reiberger[1]. [1]*Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Austria;* [2]*Department of Laboratory Medicine, Medical University of Vienna, Austria, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Extracellular vesicles (EV) can act as mediators of intra- and extrahepatic cellular crosstalk. Oxidation-specific epitopes (OSE) may act as danger-associated molecular patterns (DAMPs) in the context of liver disease. This pilot study aimed to investigate whether circulating hepatocyte-derived EVs carrying OSE in patients with acute decompensation (AD) and acute-on-chronic liver failure (ACLF) are linked to liver injury/dysfunction and induce endothelial activation.

Method: Patients with AD (n = 9) and ACLF (n = 4) admitted at the University Hospital Vienna, Austria, were included. EVs were isolated from platelet poor plasma by differential centrifugation and characterized by flow cytometry. Annexin V (AnV) positivity and a size range of 0.2 to 1.1 µM was used to define larger EVs. Antibodies recognizing hepatocyte-specific ASGPR1 protein and LR04 for the immunodominant OSE, malondialdehyde (MDA), were used to define EVs of hepatocellular origin carrying OSE (ASGPR1+ LR04+ EV). EVs from healthy individuals (n = 8) served as controls. Human umbilical vein endothelial cells (HUVEC) were stimulated with EVs isolated from patients and healthy controls, in the presence or absence of LR04 antibodies.

Results: Patients had a median MELD of 20 (14–24) points, 53% had male sex, and alcohol-related liver disease was the most common liver disease etiology (46%). ASGPR1+LR04+ EVs were significantly more frequent in patients with higher MELD ≥20 (vs. <20) and in those with elevated ALT (vs. normal ALT values; both $p < 0.05$), while overall EVs of either hepatocyte origin or carrying MDA epitopes were not significantly different across these patient strata. In contrast to EVs from healthy controls, EVs from patients with AD/ACLF robustly induced the expression of the cytokine IL-8 and the adhesion molecule VCAM in HUVECs (all $p < 0.001$; Figure). To assess whether this effect was primarily mediated by OSE-carrying EVs, HUVECs were stimulated with EVs either in the presence of LR04 or isotype control antibodies. Notably, the induction of VCAM and IL-8 expression in HUVECs was significantly blunted in the presence of LR04 antibodies (Figure).

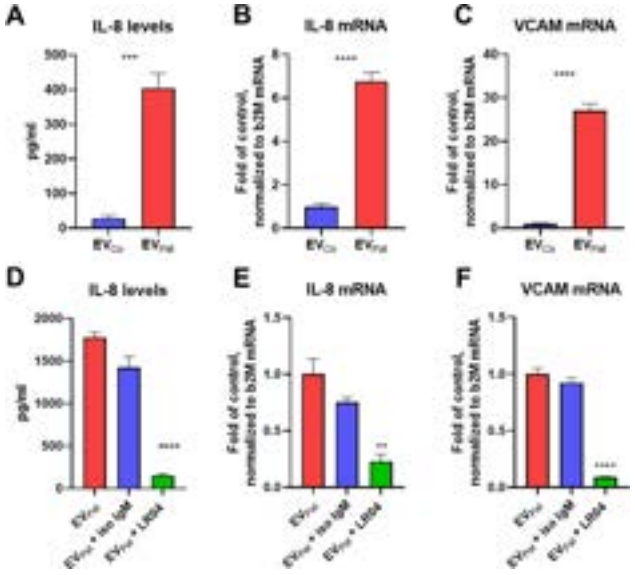

Figure:

Conclusion: Circulating OSE+ EVs from patients with AD/ACLF reflect liver dysfunction and liver injury and induce a pro-inflammatory state in ECs, suggesting them as propagators of systemic inflammation. Further studies should investigate the prognostic role of OSE+ MV in AD and ACLF and the therapeutic potential of OSE+MV-neutralizing antibodies.

Multi-omics reveals the regulation mechanism of the Chinese herbal AnLuoHuaXian formula on reversing liver cirrhosis in the rat

RuiJia Liu[1], Xu Cao[1], Zao Xiaobin[1], Yijun Liang[1], Yong'an Ye[1,2]. [1]*Dongzhimen hospital, Beijing university of Chinese medicine, China;* [2]*Beijing University of Chinese Medicine, Liver Diseases Academy of Traditional Chinese Medicine, China*
Email: yeyongan@vip.163.com

Background and aims: Liver cirrhosis is a common disease that seriously endangers human health. The efficacy of the Chinese herbal AnLuoHuaXian formula (ALHX) in reversing liver cirrhosis is definite, but its specific mechanism of action is not yet perfected and needs further study, which is the purpose of this study.

Method: In this study, a rat model of liver cirrhosis was constructed by intraperitoneal injection of diethylnitrosamine for 12 weeks, with a gavage of ALHX granule aqueous solution starting at week 9. The therapeutic effects of ALHX in cirrhosis were investigated by basic situation analysis, histopathology, and serological analysis. Transcriptomics and non-target metabolomics of liver tissues, and 16S ribosomal DNA gene polymerase chain reaction analysis of gut microbiota were used to investigate the protective effects of ALHX on cirrhosis.

Results: Compared to the control, the hepatic and splenic indices were significantly higher in the model and significantly lower after the ALHX intervention. HE and Masson staining showed that the histopathological changes in the liver of ALHX rats were significantly

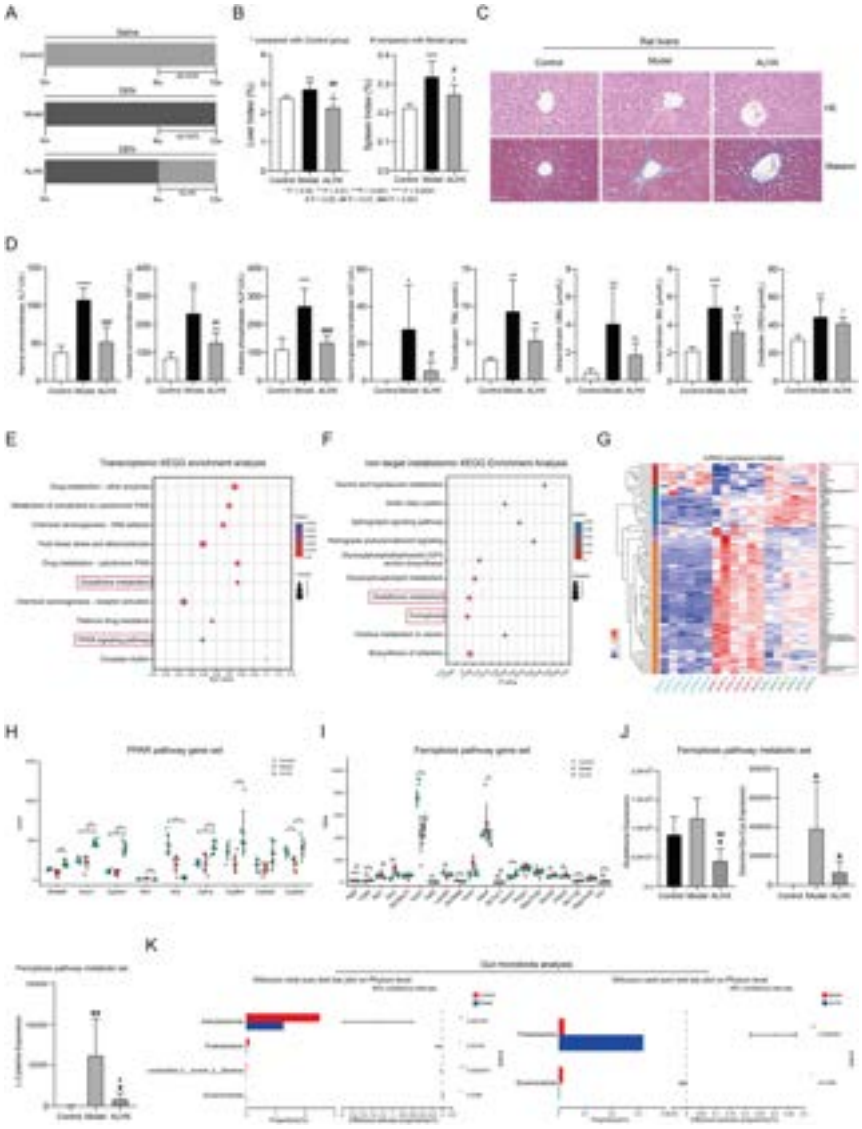

Figure: (abstract: THU-359).

better than those in the model, with less fibroplasia, hepatocyte inflammation, and necrosis, and less collagen deposition and heterotypic proliferation. Meanwhile, the serological indexes of the model were significantly reduced after ALHX intervention, especially the liver function of ALT, AST, ALP, and GGT were significantly improved. Transcriptomics and non-target metabolomics enrichment analyses indicated that ALHX inhibited rat cirrhosis possibly through regulation of Glutathione metabolism, Ferroptosis, and PPAR signaling pathways. In addition, the transcriptomic analysis also showed that ALHX could restore the abnormal expression trend of several genes to normal in model rat hepatocytes, such as Slc7a11, Cyp4a3, Cyp8b1, Gsta2, Gsta3, and Gsta5. The above findings were supported by differentially expressed genes in the PPAR and Ferroptosis pathway gene sets, and by three representative Ferroptosis pathway metabolites with significant intergroup variability. Moreover, gut microbiota analysis suggested that ALHX altered the overall structure of gut microbiota in cirrhotic rats, particularly proteobacteria and elusimicrobiota.

Conclusion: Multi-omics analysis showed that ALHX might effectively inhibit the progression of cirrhosis in rats by regulating Ferroptosis and PPAR signaling pathways, as well as the ecological structure of gut microbiota.

THU-360

MCC950 reduces glial cell activation and neuroinflammation in an animal model of thioacetamide-induced hepatic encephalopathy

Syed Afroz Ali[1], Ashok Kumar Datusalia[1]. [1]*National Institute of Pharmaceutical Education and Research-Raebareli (NIPER-R), Pharmacology and Toxicology, Lucknow, India*
Email: ashok.datusalia@niperraebareli.edu.in

Background and aims: Hepatic encephalopathy (HE) a complex neurological disorder, characterized by increased levels of ammonia and inflammation resulting in glial cells activation and astrocyte swelling in individuals with liver disease. Despite past substantial investigations, the mechanisms regulating the neuroinflammation and pathogenies of HE remains unclear reflecting higher mortality rates and unsuccessful therapeutic strategies. This study aims to explore the role of inflammasome signalling in HE and to investigate the effects of NLRP3 inhibitor (MCC950), against neuroinflammation and its associated mortality in an animal model of HE.

Method: The effects of MCC950 were evaluated in a rat model of acute liver failure induced HE. HE was induced by administering thioacetamide (TAA 300 mg/kg, 3 doses i.p., n = 10). The MCC950 was concurrently administered for 3 days to explore its effects in HE and various biochemical parameters (serum and plasma), BBB

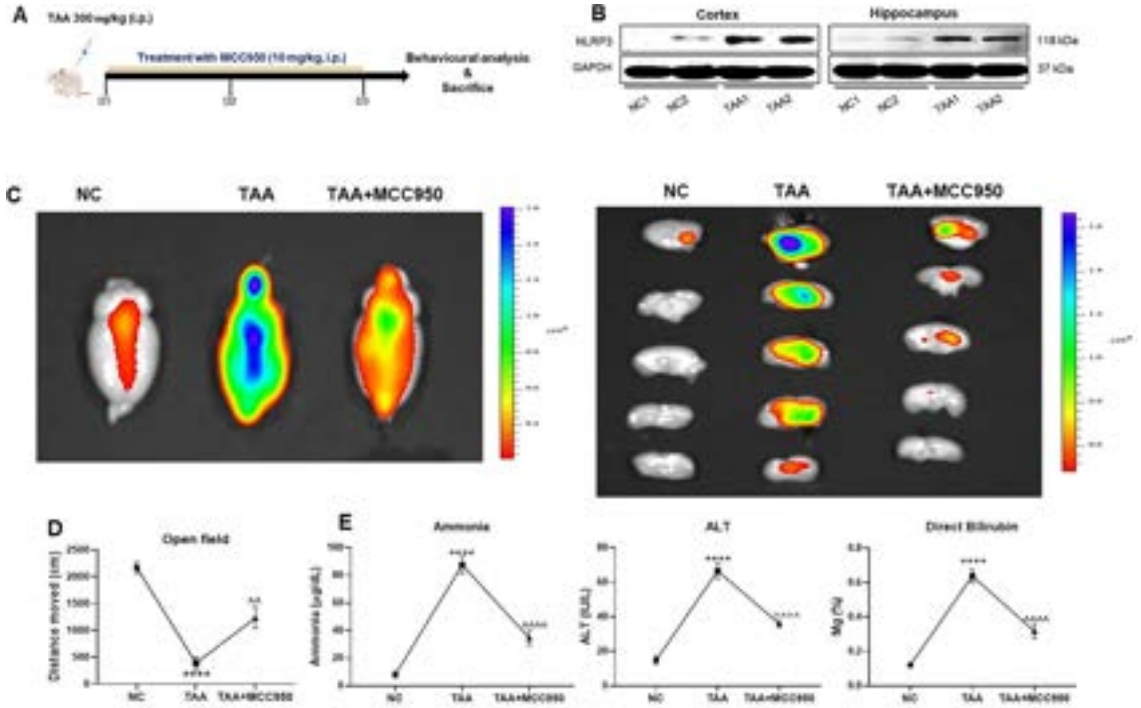

Figure: Effects of MCC950 in HE rats. A) Experimental design, **B)** Representative immunoblots of NLRP3 in cortex and hippocampus, C) Blood brain permeability, the increase in the colour intensity shows altered BBB in TAA rats compared to TAA+MCC950 treated rats. **D)** Open field test and **E)** Plasma ammonia and serum LFT markers among the groups. Data are expressed as mean ± SEM, ****p < 0.0001 vs NC; ^^p < 0.01, ^^^^p < 0.0001 vs TAA.

Figure: (abstract: THU-360).

permeability (IVIS), behavioural, molecular and histological changes in cortex and hippocampus (neuroinflammation and glial cell markers) and liver (inflammatory and fibrotic markers) were studied.
Results: HE rats demonstrate reduced performance in the open field task, while MCC950 prevented the behavioural alterations. Plasma ammonia and serum LFT markers (ALT, AST, ALP, bilirubin and albumin) were induced in TAA rats and the treatment with MCC950 reduced the aberrations and prevented mortality. The increase in the levels of ammonia correlated well with the induced neuronal cell injury (BBB damage and astrocyte swelling), neuroinflammation (NLRP3 downstream) and hepatic cell death (Figure). Whereas, the treatment with MCC950 prevented BBB leakage, astrocyte swelling, hepatic cell death and induction of inflammation associated with IL-1β, caspse-1, IL-18 and NF-κβ in cortex, hippocampus and liver. While on the other end treatment with MCC950 mitigated the microglial and astrocyte activation (IBA-1/GFAP) in cortex and hippocampus of TAA rats.
Conclusion: The findings from the current study for the first time demonstrated that treatment with MCC950 a direct inhibitor of NLRP3 inflammasome reduced hepatic injury, neuroinflammation, increased integrity of tight junction proteins and survival rate in HE rats. Altogether, these findings suggest that inhibition of NLRP3 inflammasome may be considered as a novel potential target for HE in the future.

THU-361

The pan-PPAR agonist lanifibranor decreases portal pressure in models of both hepatic and prehepatic portal hypertension

Anneleen Heldens[1,2], Christophe Casteleyn[3], Louis Onghena[1,2,4], Milton Antwi[1,2,5], Benedicte Descamps[6], Christian Vanhove[6], Xavier Verhelst[1,2], Hans Van Vlierberghe[1,2], Lindsey Devisscher[2,5], Jean-Louis Junien[7], Anja Geerts[1,2], Guillaume Wettstein[7], Sander Lefere[1,2]. *[1]Ghent University, Internal Medicine and Pediatrics, Ghent, Belgium; [2]Ghent University Hospital, Liver Research Center Ghent, Ghent, Belgium; [3]Ghent University, Morphology, Imaging, Orthopedics, Rehabilitation and Nutrition, Merelbeke, Belgium; [4]Ghent University, Gastrointestinal Surgery, Ghent, Belgium; [5]Ghent University, Basic and Applied Medical Sciences, Ghent, Belgium; [6]Ghent University, Electronics and Information Systems, Ghent, Belgium; [7]Inventiva, France*
Email: anneleen.heldens@ugent.be

Background and aims: Portal hypertension (PHT) can cause severe complications in patients with advanced chronic liver disease (ACLD). Studies have indicated that the pan-peroxisome proliferator-activated receptor (pan-PPAR) agonist lanifibranor reduces portal pressure in preclinical models of ACLD. However, as lanifibranor simultaneously improves the underlying fibrosis, the effect on PHT might be secondary. Angiogenesis and liver sinusoidal endothelial cell (LSEC) dysfunction play a major role in the pathogenesis of PHT. Using a combination of prehepatic and pre-cirrhotic PHT mouse models, we investigated the effect of lanifibranor on PHT, LSEC dysfunction, hepatic and splanchnic angiogenesis.
Method: Mice with prehepatic PHT (partial portal vein ligation; PPVL) and fibrotic mice with PHT (common bile duct ligation; cBDL) received daily lanifibranor (10 mg/kg or 30 mg/kg) or vehicle in a therapeutic setting for 7 or 14 days, respectively. The effect of lanifibranor on PHT, angiogenesis and LSEC was evaluated by analyzing hepatic and systemic hemodynamics, serum, hepatic and mesenteric histology, and hepatic, mesenteric and LSEC gene expression levels. Vascular corrosion casts of the venous mesenteric and hepatic vasculature were analyzed using µCT.
Results: Portal pressure was substantially increased in vehicle-treated PPVL mice. 10 and 30 mg/kg lanifibranor reduced the portal pressure by 30–35% compared to vehicle-treated PPVL mice ($p = 0.0048$ and $p = 0.0008$ respectively), without affecting central venous pressure or heart rate. The portal pressure was increased to a lesser extent in the cBDL model, with a non-significant, but dose-dependent trend to decrease by 12–20% with lanifibranor. Lanifibranor significantly alleviated splenomegaly in both models.

Superior mesenteric artery blood flow was significantly increased in vehicle-treated PPVL mice but tended to decrease in PPVL mice treated with 30 mg/kg lanifibranor ($p = 0.07$). Furthermore, the expansion of the venous mesenteric vasculature, as evaluated by µCT, and the increased mesenteric vascular wall thickness (mVWT) caused by PHT were partially reduced by lanifibranor. PPVL did not induce distinct liver damage, with fibrosis, LSEC dysfunction or decreases in serum albumin being absent. In cBDL mice, high-dose lanifibranor treatment reduced fibrosis ($p = 0.0001$) and restored the serum albumin to a level comparable to the sham-operated mice. Hepatic mRNA levels of inflammatory, fibrotic and angiogenic markers and cell adhesion molecules were significantly reduced in lanifibranor-treated cBDL mice compared to vehicle-treated cBDL mice. LSEC dysfunction was improved by lanifibranor treatment, whereas mVWT was not increased in this model.

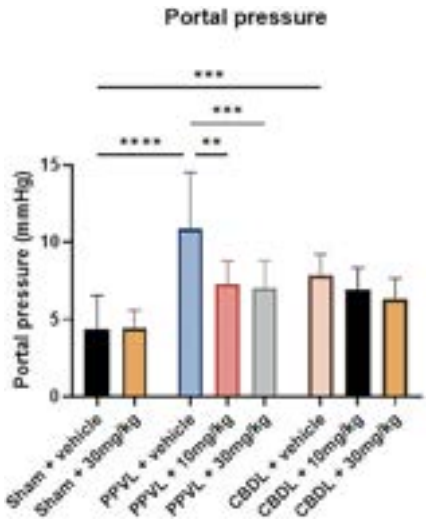

Figure: Portal pressure of sham-operated mice, PPVL mice and cBDL mice treated with vehicle, 10 mg/kg lanifibranor and 30 mg/kg lanifibranor.

Conclusion: Lanifibranor improves PHT, independently from fibrosis reduction, potentially through reducing the venous mesenteric vasculature expansion and intrahepatic angiogenesis, and ameliorating LSEC function.

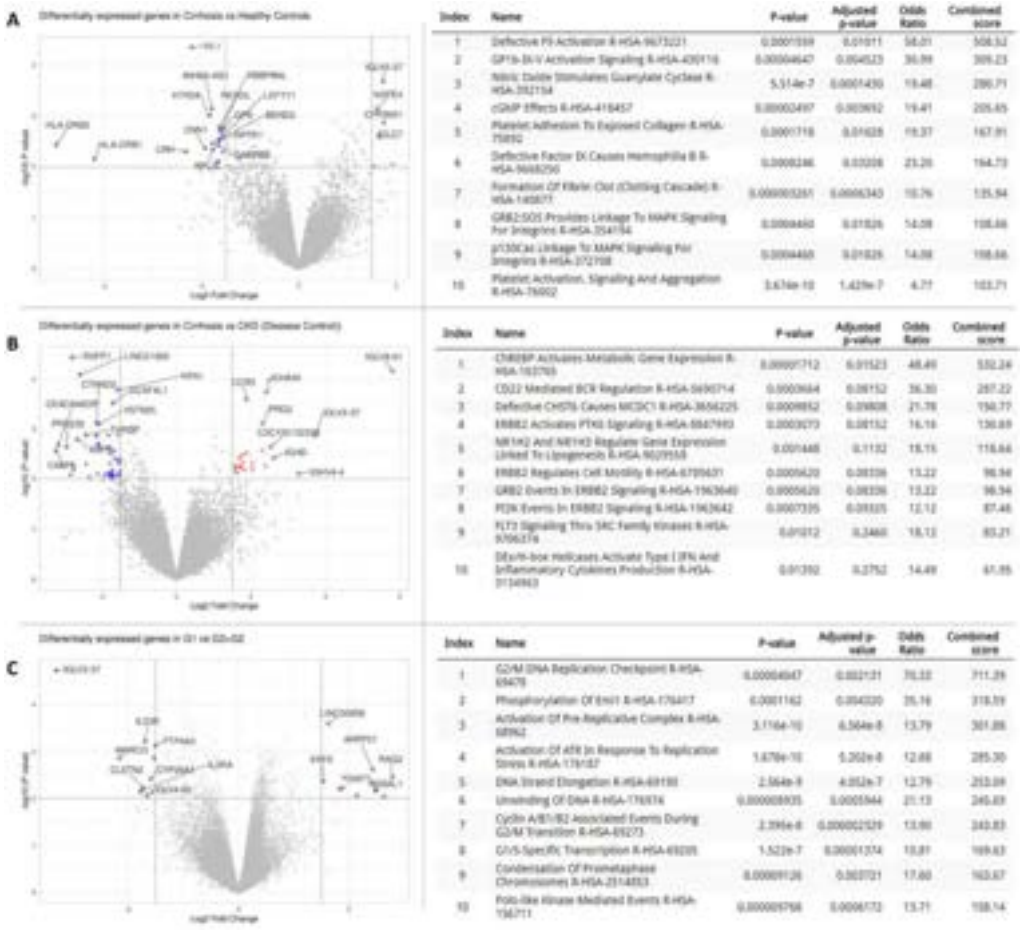

Figure 1. Functional enrichment of DGEs in all three comparisons. A. Between late-stage cirrhosis and healthy controls (HC). B. Between late-stage cirrhosis and disease controls (CKD). C. THU-362

Whole transcriptomic analysis of bone marrow indicates distinct pathways to be at play in different stages of chronic liver disease patients

Pramod Gautam[1], Varun Suroliya[2], Shraddha Singh[3], Prince Garg[1], Pooja Rao[1], Shruti Sureshan[3], Rosmy Babu[3], Shiv Kumar Sarin[4], Chhagan Bihari[3]. *[1]Institute of Liver and Biliary Sciences, Genome Sequencing Laboratory, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Genome Sequencing Laboratory, India; [3]Institute of Liver and Biliary Sciences, 2Department of Pathology, India; [4]Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India*
Email: drcbsharma@gmail.com

Background and aims: Anemia is one of the common complications in liver cirrhosis. We have earlier highlighted the contribution of dyserythropoiesis (DE) in cirrhosis related anemia. We aimed to investigate the possible signatures of dyserythropoiesis in cirrhosis patients.
Method: ere, we have studied the bone marrows of cirrhosis and controls. Patients were divided into four different groups: early-stage cirrhosis (ESC, n = 11), late-stage cirrhosis (LSC, n = 16), non-liver disease controls (C, n = 10) and disease controls (CKD, n = 4). The samples were sequenced with 2 × 150 bp approach using NEBNextUltra-II kit.
Results: Out of 525,569 and 1105 differential gene expression (DGE) in cirrhosis vs HC, cirrhosis vs CKD and ESC vs LSC respectively. Based on fold change (LogFC ± 1.5) we selected and 33 and 13 down- and upregulated gene in cirrhosis vs HC, 84 and 78 down- and upregulated gene in cirrhosis vs CKD and 19 and 17 down- and upregulated gene in ESC vs LSC respectively.
In LSC vs. HC group, taking all the DGEs combined, we observed regulatory pathways related to platelet activation, clotting and Nitric oxide stimulation to be enriched in cirrhosis using both Reactome and MGI database. When looked separately for up- and down-regulated genes, we observed retinoic acid signalling pathway to be significantly enriched among upregulated genes. While downregulated genes showed T-cell mediated immune.
In the comparison between LSC vs. CKD, we observed ERBB2 signalling pathways to be most enriched. Pathways enriched in upregulated genes included positive regulation of neutrophil extravasation and those enriched in downregulated genes included, antimicrobial immune response.
When compared LSC vs. ESC, we found cell-cycle checkpoints activation to be enriched. Terms enriched using MGI database included abnormal erythropoiesis, spleen hypertrophy and reticulocytosis. We found ERFE to be upregulated and BMP6 along with HMOX1 gene to be downregulated in this group. We also found high expression of ANGPTL4 (involved in iron homeostasis) in ESC. Importantly, GATA1 which is a crucial transcription factor in erythropoiesis was found to be moderately downregulated in LSC.
Conclusion: These findings indicate towards a possible mechanism involving retinoic acid signalling with ERFE suppressing hepcidin by inhibiting hepatic BMP/SMAD signalling via BMP subgroup. We believe that the possible role of retinoic acid in modulating erythropoiesis and could serve as a therapeutic target.

THU-363

Resection of mesenteric lymph nodes is associated with increased systemic immunosuppression in experimental cirrhosis following oral salmonella typhimurium challenge

Pinky Juneja[1], Deepika Jakhar[1], Aarti Sharma[1], Akash Kumar Mourya[1], Impreet Kaur[1], Shiv Kumar Sarin[2], Dinesh Mani Tripathi[1], Savneet Kaur[3]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Department of Hepatology, vasant kunj, India; [3]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, vasant kunj, India*
Email: savykaur@gmail.com

Background and aims: Mesenteric lymph nodes (MLN) are immune inductive sites that limit pathogens in gut, preventing their systemic spread. We studied the role of MLN in progression of endotoxemia and systemic inflammation in cirrhosis.
Method: Rat models of liver cirrhosis were prepared using ip CCl_4 administration for 8 wk. MLNs were resected from control (control MLNx) and CCl_4 (CCl_4 MLNx). Post MLN removal, they were allowed to reconstitute lymphatic vessels (LV) connection for next 4 wk. LV in gut were immunostained with LyVE1. Labelled *S. typhimurium* was gavaged and bacterial load was calculated after 48 h. Immune cells were quantified in blood at different time points within 0–48 h after bacterial challenge. Expression of inflammatory genes and proteins were quantified in MLN, gut, liver, spleen and blood after 48 h.
Results: In controls, bacteria were restricted to MLNs, with no bacterial growth seen in other organs and blood while in CCl_4, there was significant increase in bacterial load in lung, liver, spleen and blood at 48 h. Compared to control, there was an increase in percentage of activated CD134+ T cells (22 vs 41), CD25+ Treg (1.3 vs 3.2) and inflammatory cytokine (IL 6 = 2.5 fc, IFN gamma = 1.4 fc) in MLNs of CCl_4 at 48 h ($p < 0.05$ each). Increased percentage of CD134+ (32 vs 19) and CD25+ Treg (2.3 vs 1.8) was observed in blood of CCl_4 vs control. Surgical resection of MLNs from control resulted in regeneration of gut LV within 4 wk, however LV were not restored in CCl_4 MLNx. In contrast to control, there was enhanced bacterial growth in lung and blood of control MLNx 48 h after oral gavage of bacteria, similar to that observed in CCl_4. In gut and liver, there was increased expression of IL 6 (<5 fc) and IFN gamma (<2 fc) in control MLNx in comparison to control ($p < 0.05$ each). In blood of control MLNx vs control, inflammatory cytokines, activated CD134+ T cell (45 vs 30) and CD25+ Treg (4.1 vs 1.8) were increased ($p < 0.05$ each). In CCl_4 MLNx, there was reduced bacterial growth in all organs after bacterial challenge owing to failure of LV conduits restoration post MLN resection. In CCl_4 MLNx, there was significant increase in expression of defence promoting cytokine genes (IL 6 = 10.2 fc, IFN gamma = 3.1 fc, $p < 0.05$) in gut as compared to CCl_4. However, MLN resection in CCl_4 was associated with increased immunosuppressive Treg (5.9 vs 3.2) and decreased expression of IL 6 (<4 fc) and IFN gamma (<3 fc) in liver, spleen, and blood as compared to CCl_4 ($p < 0.05$ each).

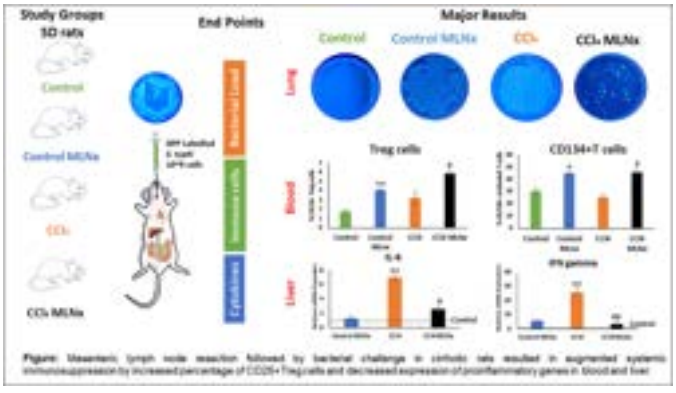

Figure:

Conclusion: In cirrhosis, MLNs mount an increased proinflammatory response to contain exogenous infection in gut, however an underlying immune dysfunction in MLNs fails to contain bacteria, condition that is immunologically similar to control without MLNs. Resection of MLNs in cirrhosis further aggravates systemic immunosuppression. The study provides first evidence of MLNs in maintaining systemic inflammatory responses to bacterial infection in cirrhosis.

THU-364

Glial transcriptional changes in experimental HE arise early and show similarities with established neuroinflammatory disorders

Wouter Claeys[1,2,3,4], Lien Van Hoecke[1,2], Clint De Nolf[1,2], Hannah Lernout[1,5], Griet Van Imschoot[1,2], Elien Van Wonterghem[1,2], Daan Verhaege[1,2], Anja Geerts[3,4,6], Christophe Van Steenkiste[7,8], Roosmarijn Vandenbroucke[1,2]. *[1]VIB-UGent Center for Inflammation Research, Barriers in Inflammation, Zwijnaarde, Belgium; [2]Ghent University, Department of Biomedical Molecular Biology, Zwijnaarde, Belgium; [3]Ghent University, Liver Research Center Ghent, Ghent, Belgium; [4]Hepatology Research Unit, Department of Internal Medicine and Paediatrics, Ghent, Belgium; [5]Ghent Gut Inflammation Group, Department of Internal Medicine and Paediatrics, Ghent, Belgium; [6]Ghent University Hospital, Department of Gastroenterology and Hepatology, Ghent, Belgium; [7]Antwerp University, Department of Gastroenterology and Hepatology, Belgium; [8]Maria Middelares Hospital, Department of Gastroenterology and Hepatology, Ghent, Belgium*
Email: wouter.claeys@ugent.be

Background and aims: Hepatic encephalopathy (HE) is a common complication of liver cirrhosis, associated with poor outcomes. Astrocytes, the primary ammonia-metabolizing cell type in the brain, and microglia, the resident brain macrophages, exhibit altered morphology in the experimental bile duct ligation (BDL) mouse model of HE. Signaling mechanisms underlying these morphological changes remain elusive however. We aim to characterize time-dependent transcriptional changes in glial cells in HE mice.
Method: 10–12 week old male C57Bl/6j mice (n = 6/group/timepoint) underwent BDL/sham surgery for 14 or 28 days. Microglia and astrocytes were isolated using FACS, followed by RNA sequencing. Gene set enrichment analysis (GSEA) and ingenuity pathway (IPA) upstream regulator analysis was performed. Transcriptomic profiles of astrocytes and microglia in the BDL model were compared to gene expression profiles in other acute or chronic neurological diseases.
Results: BDL induces an early and sustained response in microglia, with differential expression of 350 genes 14 days and 448 genes 28 days after induction, and a large overlap (226 genes) between both timepoints. At both timepoints, inflammatory signaling and chemotaxis pathways are significantly enriched. TNF signaling is the top predicted upstream regulator of microglial transcription at both timepoints, along with other cytokines. The microglial transcriptome in BDL mice significantly overlaps at both timepoints with acute LPS-induced changes (14 and 28 days $p = 0.001$ and 0.002, respectively) and Alzheimer's disease related 'disease-associated microglia' (14 and 28 days $p = 0.001$ and 0.02, respectively). In astrocytes, transcriptomic response is less strong, with 171 genes differentially expressed after 14 days, increasing to 495 after 28 days. As a consequence, pathway enrichment is limited at 14 days, while inflammatory signaling pathways are significantly enriched 28 days after BDL surgery. Comparative analysis with published transcriptomic responses shows significant overlap with both LPS-induced ($p < 0.001$ at both timepoints) and ischemia-induced ($p < 0.001$ at both timepoints) astrocyte subtypes. GM-CSF is the top upstream regulator at both timepoints. Corticoid receptor signaling is predicted to drive astrocyte transcription 14 days after BDL, while cytokines and interferon related signaling are mostly found at 28 days after injury.
Conclusion: Glial cells in BDL mice exhibit marked transcriptional changes, with striking similarities to transcriptional phenotypes in other, non-liver-related, brain pathologies. Inflammatory signaling is predicted to drive the observed changes. These data provides useful insights to unravel the sequence of cellular changes in HE and direct future research into the interplay in the neuroimmune compartment in this disease.

Ascites CD8 T cells express a tissue-resident bystander phenotype that may contribute to disease pathogenesis in patients with decompensated liver cirrhosis

Christian Niehaus[1,2,3], Benedikt Strunz[4], Benjamin Maasoumy[1,5], Heiner Wedemeyer[1,5], Niklas Björkström[4], Anke Kraft[1,2,3,5], Markus Cornberg[1,2,3,5]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Germany; [2]Centre for Individualised Infection Medicine (CiiM), Germany; [3]Twincore, Centre for Experimental and Clinical Infection Research, Germany; [4]Karolinska Institutet, Karolinska University Hospital Huddinge, Center for Infectious Medicine (CIM), Department of Medicine Huddinge, Sweden; [5]German Center for Infection Research (DZIF), Partner-site Hannover-Braunschweig, Germany*
Email: niehaus.christian@mh-hannover.de

Background and aims: Liver cirrhosis is the end-stage of many chronic liver diseases. Patients with advanced cirrhosis often develop hepatic decompensation, which is accompanied by systemic inflammation and may ultimately result in acute-on-chronic liver failure. One of the most frequent consequences of hepatic decompensation is the accumulation of substantial amount of ascites in the peritoneal cavity. As liver cirrhosis affects immune cells both in peripheral blood and locally, in this study we aim to investigate the role of $CD8^+$ T cells in the immune compartment ascites.
Method: Matched peripheral blood and ascites fluid were collected from 49 patients with decompensated cirrhosis. Phenotype and function of $CD8^+$ T cells were analyzed using high-dimensional flow cytometry and obtained data were compared to each other as well as to healthy controls and compensated cirrhosis patients (n = 11).
Results: $CD4^+$ as well as $CD8^+$ T cells were decreased in the blood of patients with decompensated liver cirrhosis compared to healthy controls. Intriguingly, $CD8^+$ T cells were enriched in the ascites of patients with liver cirrhosis whereas $CD4^+$ T cells were diminished. This was also in line with a decreased CD4/CD8 T cell ratio in ascites compared to blood indicating a shift towards $CD8^+$ T cells within the ascites T cell compartment. Interestingly, ascites-derived $CD8^+$ T cells expressed an activated tissue-resident memory phenotype with high expression of tissue-homing markers. In addition, high-dimensional data analysis revealed unique ascites-specific (*$CXCR6^+CD69^+$*) clusters of late effector-memory $CD8^+$ T cells that were rarely found in blood. Indeed, *$CXCR6^+CD69^+$* $CD8^+$ T cells were vastly activated, proliferative, and expressed markers of innate-like bystander inflammation. Remarkably, the frequency of ascites *$CXCR6^+CD69^+$* $CD8^+$ T cells correlated significantly with clinical parameters of disease severity ($p = 0.01$ for bilirubin, $p = 0.004$ for International Normalized Ratio). In line with this, peritoneal $CD8^+$ T cells produced high levels of pro-inflammatory cytokines and cytolytic molecules following stimulation with the innate-like cytokines IL-12 + IL-18. Interestingly, the Janus kinase (JAK) inhibitor tofacitinib was effective in inhibiting the pro-inflammatory response by *$CXCR6^+CD69^+$* $CD8^+$ T cells.
Conclusion: $CD8^+$ T cells are abundant in the ascites of patients with liver cirrhosis and exhibit a chronically activated bystander phenotype with innate like functions. Moreover, $CD8^+$ bystander T cells in ascites may potentially contribute to disease progression in patients with decompensated cirrhosis, and JAK inhibitors could be a conceivable therapeutic option to inhibit hyperinflammation (similar to COVID-19) originating from *$CXCR6^+CD69^+$* $CD8^+$ T cells.

Email: johannes.chang@ukbonn.de

Background and aims: Cardiac involvement in patients with end-stage liver disease is frequent. However, pathomechanisms contributing to the development of cirrhotic cardiomyopathy are not fully understood. Moreover, non-invasive biomarkers, including comprehensive imaging data with histopathological correlation are missing. The goal of this study was to explore the presence of cardiac involvement by multiparametric magnetic resonance imaging (MRI) in an experimental model of liver cirrhosis and correlate quantitative MRI biomarkers with parameters of fibrosis and inflammation of the heart-liver axis.
Method: Male Sprague-Dawley rats underwent bile-duct ligation (BDL) to induce cholestatic cirrhosis. Sham-operated rats served as controls. One group received combined liver and heart MRI after 3 weeks (BDL-3w), the other group after 5 weeks (BDL-5w). MRI scans were performed at 3-Tesla MRI. Myocardial function was assessed using cine imaging in standard axes. T1, T2, and extracellular volume fraction (ECV) values of the liver and the heart were assessed using quantitative MRI mapping techniques. After MRI, in-vivo portal pressure was measured. Gene expression studies and histological examinations were performed to evaluate fibrosis and inflammation of the heart and liver.
Results: Clinical and molecular parameters confirmed two distinct stages of liver cirrhosis, especially by portal pressure (4.56 ± 0.25 (sham) vs. 9.93 ± 0.39 (BDL-3w) or 13.29 ± 0.61 (BDL-5w) mmHg; $p < 0.0001$). Histopathological and molecular analyses revealed increased markers of cardiac inflammation and cardiac fibrosis/remodeling in BDL groups vs sham controls. Functional cardiac MRI analyses showed higher cardiac index, elevated left ventricular (LV) end-diastolic volume index and elevated LV mass in BDL groups. Myocardial T1, T2 and ECV values were elevated in BDL groups (T1: 946 ± 29 vs 952 ± 39 vs 987 ± 39 msec; $p = 0.014$; T2: 23 ± 4 vs 32 ± 3 vs 33 ± 4 msec; $p < 0.001$; ECV: 27 ± 3 vs 32 ± 3 vs 37 ± 5; $p < 0.001$; sham vs BDL-3w vs BDL-5w) and correlated with serum NT-proBNP levels and myocardial IL1b, CCL-3 and MMP-9. Interorgan correlations were found between quantitative myocardial imaging parameters and parameters of hepatic fibrosis, inflammation and portal pressure.

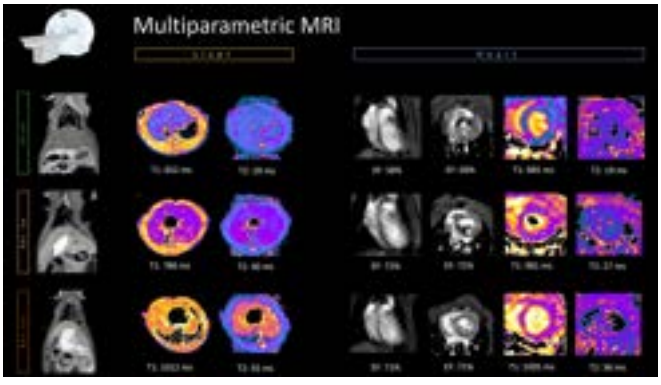

Figure:

Conclusion: Functional cardiac remodeling and elevation of inflammatory and fibrotic biomarkers of the myocardium were found in a preclinical model of cirrhosis. A marked increase in inflammatory gene expression suggests that hepatic cardiomyopathy is predominantly driven by inflammation. Fibrotic myocardial alterations might play a role as another structural component. Quantitative cardiac MRI provides non-invasive, sensitive detection of cirrhotic cardiomyopathy, particularly diffuse myocardial edema/inflammation. This study may lay the groundwork for further clinical application of multiparametric cardio-hepatic MRI in cirrhosis.

THU-367
Peripheral blood metabolite associations with cardiac diastolic dysfunction in advanced chronic liver disease

Madeleine Gill[1,2,3], John O'Sullivan[3,4], Geoff McCaughan[1,2,3], Eugene Slaughter[3], Ren Ping Liu[3], Imre Hunyor[3,4], Stuart Moss[4], Michele McGrady[3,4], Ian Wilcox[3,4], Avik Majumdar[3,5,6]. *[1]Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Centre, Camperdown, Australia; [2]Centenary Institute, Camperdown, Australia; [3]The University of Sydney, Faculty of Medicine and Health, Camperdown, Australia; [4]Royal Prince Alfred Hospital, Cardiology, Camperdown, Australia; [5]Austin Hospital, Liver Transplant Unit, Heidelberg, Australia; [6]University of Melbourne, Parkville, Australia*
Email: madeleine.gill@health.nsw.gov.au

Background and aims: Metabolomics offers the potential to comprehensively screen energetic and other changes in heart failure (HF), including cirrhotic cardiomyopathy (CCM). A burgeoning field in HF involves directly targeting the 'broken energetic machinery', which we aimed to explore with metabolomic screening in CCM, a type of HF with particular metabolic vulnerability.
Method: 47 patients with cirrhosis were included, with frozen plasma samples within six months of transthoracic echocardiogram (TTE), and 9 healthy controls. CCM and systolic dysfunction (SD) were defined by the 2020 CCM consortium criteria. Diastolic dysfunction (DD) was defined as any grade of diastolic impairment. Liquid chromatography tandem mass spectrometry (LC/MS-MS) was used to quantify more than 200 metabolites using two columns; hydrophilic interaction liquid chromatography (HILIC), and amide. Principal component analysis (PCA) was used to explore variation between patient groups. Linear and logistic regression with Benjamini-Hochberg adjustment were used for associations between metabolites, clinical traits and echocardiographic parameters.
Results: The median Model-for-End-Stage-Liver-Disease (MELD) was 16 (IQR 12–22), with median Child-Pugh Score of 10 (IQR 7–12). There were no differences in baseline characteristics of cirrhotic patients with CCM (n = 10) versus without (n = 37). When adjusted for age and sex, moderate to severe ascites was associated with lateral E/e' ($p = 0.006$) and medial E/e' ($p = 0.002$), volume-independent markers of DD. With respect to plasma metabolite profiles, there was clear separation between controls and cirrhotic patients on PCA, but there was no separation between patients with and without CCM. However, there were associations between several metabolites and TTE parameters, when analysed according to type of cardiac dysfunction (see table).

Pathway	Metabolites	Association	FC	Adjusted p value	Type of cardiac dysfunction
NAD	Nicotinate	Increased with medial e'	1.19	0.029	CCM
	Nicotinic acid		0.96	<0.001	SD
	NaAD_B	Decreased with IVRT	0.99	0.048	SD
	N-methyl-2-pyridone-5-carboxamide	Decreased with DT	1.26	0.04	CCM
		Increased with medial e'	1.19	<0.001	All
		Increased with TR velocity	1.39	0.04	CCM
		Increased with medial e'			
ATP	Adenosine	Increased with medial E/e'	1.48	0.026	SD
	Adenosine diphosphate-ribose	Increased with DT	1.01	0.013	DD
Other					

(continued)

(Continued)

Pathway	Metabolites	Association	FC	Adjusted p value	Type of cardiac dysfunction
	Orotate	Increased with TR velocity	1.07	0.006	All
	Uracil		1.08	0.005	All
	Glutarylcarntine	Increased with TR velocity	1.08	0.022	All
	3-Methoxy-4-hydroxyphenylglycol		1.10	0.005	All
	Citraconic acid	Increased with TR velocity	1.18	0.036	CCM
		Increased with TR velocity			
		Increased with medial E/e'			

Metabolite associations with echocardiographic markers of cardiac dysfunction.FC-fold change; NAD-nicotinamide adenine dinucleotide; NaAD_B-nicotinic acid adenine dinuclotide; IVRT-isovolumetric relaxation time; DT-deceleration time; TR-tricuspid regurgitation; CCM-cirrhotic cardiomyopathy; SD-systolic dysfunction; DD-diastolic dysfunction; ATP-adenosine triphosphate.

Figure:

Conclusion: Several NAD pathway intermediates were decreased in association with TTE parameters that indicate DD, while adenosine derivatives were increased. Our data buttress previous findings regarding the emerging NAD^+ target in HF, and for the first time replicate this deficiency in DD associated with chronic liver disease, suggesting NAD^+ repletion may also be a successful strategy in this disease.

THU-368

Biological differences between clinically different muscle wasting phenotypes in patients with decompensated ESLD undergoing assessment for liver transplantation: a UK prospective cohort UK study

Amritpal Dhaliwal[1,2,3], Jonathan Quinlan[1,4], Felicity Williams[1,4], Thomas Nicholson[1,3], Sophie Allen[1,4], Gareth Lavery[5], Simon Jones[1,3,6], Leigh Breen[1,4,6], Carolyn Greig[1,4,6], Ahmed Elsharkawy[1,2], Matthew Armstrong[1,2], Janet Lord[1,3,6].

Email: adhaliwal85@gmail.com

Background and aims: Muscle wasting is an independent predictor of poor outcomes in ESLD, however there is a phenotypic heterogeneity present within these patients. The aim of this study was to determine distinct muscle phenotype and investigate any differences between clinical and biological parameters.

Method: 39 ESLD patients (mean age 55.0 ± 10.5yrs (23 m/16f), mean MELD 13.6 ± 4.7)) were categorised into 4 distinct clinical muscle phenotypes based upon adequate or inadequate lower limb muscle mass (quadricep volume index (QVI)) and function (leg extensor peak torque (PT)), from 18 age-sex matched healthy controls (mean age 50.0 ± 15.2 yrs (11 m/7f). Thresholds for adequate and inadequate mass or function was determined by the >25th quartile and ≤25th quartile control values for QVI and PT respectively. Muscle mass (quadriceps MRI and ultrasound, L3 skeletal muscle index, bioimpedance analysis), muscle function (PT, handgrip strength, composite function tests, accelerometry), and biological parameters (cytokine panel, steroid and vitamin D analytes) were analysed using a principal component analysis (PCA) to identify any clustering between these phenotypes. PCA is used to reduce dimensionality amongst multiple variables to aid in identifying trends within data. Principal components (PC) describe the linear combinations of the original data variables and PC1 describes the maximum variance. The loading plots show the linear coefficients for the PCs shown.

Results: 9 participants (23.1%) had adequate lower limb muscle mass and function, 13 (33.3%) had adequate lower limb muscle mass yet inadequate function and 17 (46.2%) had both inadequate muscle mass and function. No participants had inadequate mass/adequate function. A PCA was performed with: all measures; muscle mass and function only; biochemical parameters only. Figure 1a shows the PCA plot outlining the projections of the biological variables which demonstrated natural clustering between the ESLD and controls. Figure 1b shows those with ESLD, especially those with inadequate muscle mass and function, were separated by loadings from IFN beta, cortisol: DHEA ratio. The control group appear to be separated by loadings from DHEAS, (which has been shown to influence sensitivity to oxidative stress and insulin sensitivity with a positive effect on muscle mass and strength); cortisol to cortisone ratio (a measure of 11βHSD1 activity) and PDGF BB, a potent inducer of proinflammatory cytokines.

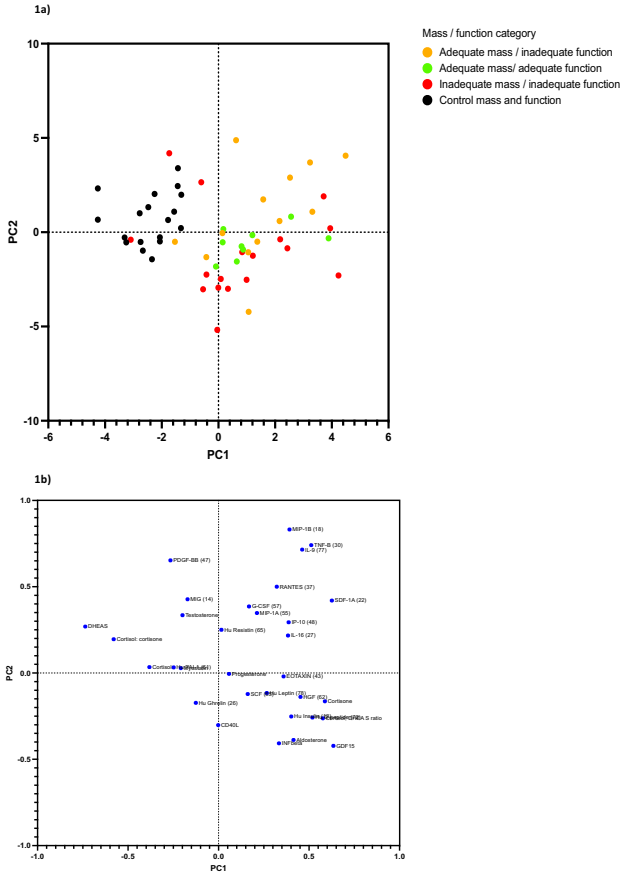

Figure 1a: Principal component (PC) scores for cytokine, steroid hormone and Vitamin D variables for each phenotype of ESLD and healthy controls

Figure 1b: Loading plot for cytokine, steroid hormone and Vitamin D profiles of ESLD and healthy controls

Figure:

Conclusion: This is the first study to consider clinical muscle wasting phenotypes. The data shows there is a difference in clusters between the distinct ESLD groups and controls suggesting there are potential variations in the mechanistic drivers of muscle wasting in each group. Further validation with greater sample sizes are required however there may be potential specific therapeutic targets for clinical muscle wasting phenotypes in ESLD.

THU-369

Effect of fibrinogen substitution in hypofibrinogenaemic CTP class C patients on viscoelastic coagulation tests

Moritz Tobiasch[1], Anna Tobiasch[2], Volker Schäfer[2], Johannes Bösch[2], Mirjam Bachler[3], Philipp Lichtenberger[2], Heinz Zoller[4], Dietmar Fries[2]. [1]*Landeskrankenhaus Hall, Dept. of Medicine, Hall in Tirol, Austria;* [2]*Medical University Innsbruck, Anaesthesiology and Intensive Care Medicine, Innsbruck, Austria;* [3]*UMIT University for Health Sciences, Institute for Sports Medicine, Alpine Medicine and Health Tourism, Hall in Tirol, Austria;* [4]*Medical University Innsbruck, Dept. of Medicine I, Austria*
Email: moritztobiasch@gmail.com

Background and aims: Coagulation deficits in decompensated cirrhosis are complex and usually not reflected in classical coagulation group tests. Therapeutic interventions to optimize the coagulation function are thus difficult to guide. In hypofibrinogenaemic CTP class C patients, viscoelastic test parameters, single factor tests and group tests (INR, aPTT, thrombin time) were assessed in an in-vitro model of fibrinogen substitution.

Method: After obtaining informed consent of all participants, citrated plasma of 17 CTP class C patients with a fibrinogen level below or equal 150 mg/dL and 18 healthy control subjects was tested in classical group tests (prothrombin time/INR, activated partial thromboplastin time (aPTT), thrombin time (TT)), in single factor tests, and in viscoelastic tests (ExTest, InTest, FibTest) with and without addition of fibrinogen, hereby mimicking a therapeutic supplementation of fibrinogen. Fibrinogen levels were determined by Clauss' method and by immunoassay.

Results: Both classical coagulation group tests and viscoelastic test generally performed well in differentiating the CTP class C and the healthy control cohorts. Addition of fibrinogen had only marginal effects on the classical group tests (PT/Quick median absolute difference, −1,5% (IQR −11% to 2%)), whereas particularly FibTest parameters showed a clear and dose-dependent response to fibrinogen concentrations. Elevating the fibrinogen concentration with 200 mg/dL fibrinogen concentrate normalized FibTest clot firmness parameters A5, A10, A20, and maximum clot firmness (MCF) to normal levels (for MCF, R2 0, 38, $p < 0.0001$). The response to fibrinogen augmentation was markedly higher in hypofibrinogenaemic CTP class C patients than in healthy control subjects. All factors synthesized in the liver (F V, VII, IX, X, XI, XII, XIII, and alpha-2-antiplasmin) also showed clear correlations with FibTest parameters in both groups, whereas F VIII, and von Willebrand factor did not influence the response in CTP class C patients.

Conclusion: Viscoelastic tests might provide a better estimate of coagulation function in CTP class C patients than classical coagulation group tests. In hypofibrinogenaemic patients, a significant effect on coagulation function is plausible. With a high robustness in vitro, FibTest parameters might be valid surrogates for fibrinogen substitution in end-stage liver disease.

THU-370

The gene expression profile of skeletal muscle in end-stage liver disease patients undergoing assessment for liver transplantation with muscle wasting

Sophie Allen[1,2], Amritpal Dhaliwal[2,3], Jonathan Quinlan[1,2], Thomas Nicholson[2,3], Felicity Williams[1,2,3], Matthew Armstrong[2,4], Ahmed Elsharkawy[2,4], Simon Jones[2,3,5], Carolyn Greig[1,2,5], Gareth Lavery[2,6], Janet Lord[2,3,5], Leigh Breen[1,2,5]. Email: s.l.allen@bham.ac.uk

Background and aims: Sarcopenia, defined as a loss of muscle mass, strength and physical function is a common condition affecting end-stage liver disease (ESLD) patients. However, the molecular pathways which may underpin the progression of sarcopenia in ESLD are largely unclear. Therefore, the aim of this study was to characterize intracellular signaling pathways that may contribute to sarcopenia progression in ESLD patients with differing levels of muscle mass and physical function.

Method: Fasted muscle and blood samples were obtained from 23 decompensated ESLD patients (aged 54.7 ± 6.4 years, MELD 13.7 ± 4.6). Physical function and body composition assessments were also conducted. ESLD patients were divided into 3 clinically defined groups dependent on muscle mass and function; 1-adequate muscle mass and function (n = 7), 2-adequate muscle mass, inadequate function (n = 5) and 3-inadequate muscle mass and function (n = 11). The skeletal muscle transcriptome was determined by RNA-sequencing using a QuantSeq 2′ kit (Lexogen, Austria) and sequenced on Illumina's NextSeq500. Transcripts were mapped to the human genome (hg38) and were analyzed using Ingenuity Pathway Analysis (Qiagen, UK).

Results: BMI and weight was significantly lower in patients with inadequate muscle mass and function compared to patients with adequate muscle mass and function ($p < 0.05$). Pathway analysis revealed a significant enrichment in canonical pathways related to mitochondrial dysfunction and oxidative phosphorylation in ESLD patients with inadequate muscle mass and function vs. patients with adequate muscle mass and function (Figure A), and patients with adequate muscle mass, with inadequate function (Figure B). A significant enrichment in canonical pathways related to oxidative stress and mTOR related signaling was also identified in patients with inadequate muscle mass and function compared to those with adequate muscle mass and inadequate function. Furthermore,

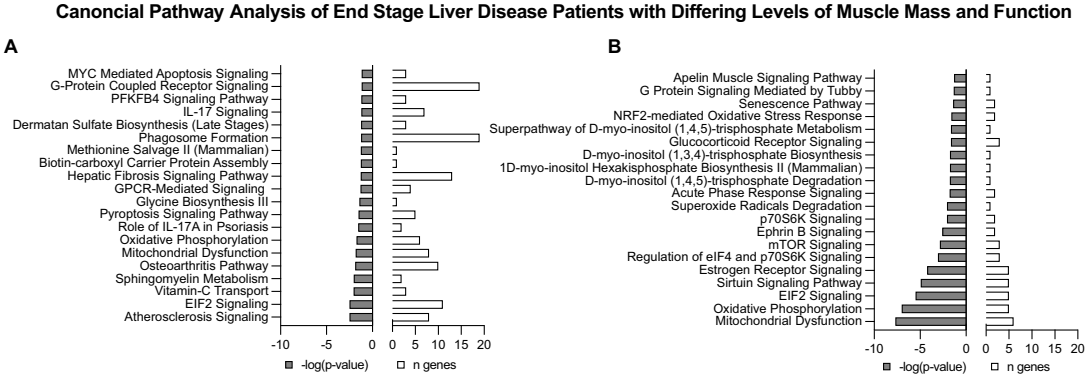

Figure: (abstract: THU-370).

RICTOR and LARP1 were identified as predictive, inhibited upstream regulators in ESLD patients with inadequate muscle mass and function vs. patients with adequate muscle mass and function, and adequate muscle mass and inadequate function.
Conclusion: Collectively, these findings highlight distinct signaling pathways which may underscore alterations in skeletal muscle mass and function in ESLD patients. These findings suggest a number of novel therapeutic targets for future interventions which aim to treat sarcopenia.

Placement of a trans-jugular intrahepatic portosystemic shunt (TIPS) modifies the expression of proinflammatory cytokines in circulating monocytes exposed to lipopolysaccaride

Mirella Pastore[1], Francesco Vizzutti[1], Davide Roccarina[1], Nadia Navari[1], Benedetta Piombanti[2], Valentina Adotti[1], Valentina Cacciato[2], Fabrizio Fanelli[3], Fabio Marra[1]. [1]*University of Florence, Italy;* [2]*Azienda USL Toscana Centro, Italy;* [3]*Azienda Ospedaliero-Universitaria Careggi, Italy*
Email: fabio.marra@unifi.it

Background and aims: Recent data have indicated that decompensated cirrhosis is characterized by an imbalance in the innate immune system, leading to low-grade systemic inflammation. In particular, inflammatory cytokines secreted by monocytes and macrophages have been implicated in the pathogenesis of portal hypertension and its complications. Additionally, MerTK-expressing monocytes participate in the determination of severity of acute liver failure. Transjugular intrahepatic portosystemic shunt (TIPS) is currently used for the treatment of complications of portal hypertension, but whether portosystemic derivation results in changes in the biology of inflammatory cell is currently unknown.
Method: Fifteen patients with severe portal hypertension referred for TIPS placement were enrolled. During the TIPS procedure, blood from the portal and jugular vein was drawn, and at 4 weeks after TIPS placement a sample from a peripheral vein was repeated. Monocytes were isolated from peripheral blood mononuclear cells by adherence after Ficoll-Hypaque purification, and stimulated with LPS (1 μg/ml) for 2, 8 and 24 hours. Gene expression was evaluated by real-time PCR.
Results: Upon exposure to LPS, a significant increase in gene expression of IL-1beta, IL-6, TLR4 and MERTK was observed in monocytes isolated from either the portal or the jugular vein. Basal and LPS-stimulated mRNA levels of these molecules were markedly lower in the post-TIPS compared to pre- TIPS, in particular after exposure to LPS. Expression of the anti-inflammatory cytokine, IL-10, was significantly increased after LPS stimulation for 2 and 8 hours. After TIPS, mRNA levels of IL-10 were reduced in unstimulated conditions but increased after LPS stimulation for 2 hours.
Conclusion: Reduction of portal pressure through TIPS placement is associated with reduced expression of pro-inflammatory mediators and modulation of anti-inflammatory IL-10. Increased portal pressure in cirrhotic patients may be a direct modulator of the complex changes in the inflammatory balance observed in these patients.

Email: alexandre.bourgeois.1@umontreal.ca

Background and aims: Hepatic encephalopathy (HE) is a complex neuropsychiatric syndrome arising from chronic liver disease (CLD). HE manifests with symptoms such as poor memory, impairment in motor coordination, lethargy and coma. The gut microbiota has been shown to influence neurological functions via various mediators such as cytokines or bacterial metabolites, many studies have demonstrated the gut-brain axis is altered in liver disease. Faecal matter transplantation (FMT) in patients with cirrhosis has revealed beneficial effects yet many limitations of these studies render the results inconclusive. The aim of this study is to explore the impact of FMT on gut microbiota and the beneficial effects on neuro behaviour in bile-duct ligated (BDL) rats.
Method: Male Sprague-Dawley rats were randomly assigned to one of three groups; SHAM, BDL-VEH (vehicle) and BDL-FMT (who received FMT daily from pooled faeces from SHAM rats). After five weeks, behaviour tests were performed to evaluate short- and long-term memory (Novel Object Recognition), anxiety (Open Field and Elevated Plus Maze) and motor coordination (Rotarod). Plasmatic parameters such as cytokines, short chain fatty acids (SCFA) and liver impairment markers were measured by ELISA, LC-MS/MS and using Cobas respectively. Finally, faeces were collected for bacterial sequencing and SCFA analysis.
Results: FMT did not alter degree of liver disease in BDL rats. BDL-VEH developed a loss of short/long term memory and motor coordination compared to SHAM rats. However, alterations in neurological dysfunction were prevented in the BDL-FMT group. FMT did not impact microbiota α-diversity in BDL rats and β-diversity of microbiota was significantly different between all groups. The genera *Provotellaceae UCO-001* significantly increased only in SHAM and BDL-FMT rats and *Clostridium Senso Stricto 1* significantly increased only in BDL-VEH compared to SHAMs. Finally, *Rombustia* was only present in SHAM. Plasma pro-inflammatory cytokines (TNF-α and IL-1β) increase in both BDL groups compared to the control group and no difference for the anti-inflammatory cytokine IL-10 was noted. Analysis of short-chain fatty acids in faeces and plasma showed a variation in propionate and butyrate between both BDL groups.
Conclusion: Our results demonstrate that FMT leads to improvement in memory and motor coordination in BDL rats. The microbiota profile was different between BDL-VEH and SHAM, and FMT lead to further alterations on microbiota. The fact that FMT did not normalize microbiota profile compared to SHAM, suggests BDL-FMT leads to a novel specific microbiota profile which in turn protects the brain. The effect of plasma SCFA needs to be further explored to define its impact on the brain and possible therapeutic application.

Cirrhosis and its complications Other clinical complications except ACLF

Randomised controlled trial of intravenous versus oral iron in treatment of iron deficiency anaemia after variceal bleeding in patients with cirrhosis

Tabish Mohammad[1], Sanchit Sharma[2], Samagra Agarwal[1], Srikanth Gopi[1], Randeep Rana[1], Deepak Gunjan[1], Anoop Saraya[1]. [1]*All India Institute Of Medical Sciences, Gastroenterology and Human Nutrition Unit, New Delhi, India,* [2]*Queen Elizabeth Hospital Birmingham, Gastroenterology, United Kingdom*
Email: ansaraya@yahoo.com

Background and aims: There is limited evidence on the optimal strategy to correct iron deficiency anaemia after an episode of variceal bleeding (VB) in patients with cirrhosis. We evaluated the efficacy and safety of intravenous iron in this setting compared to oral iron therapy.

Table:(abstract: TOP-041).

Characteristics	Oral arm (n=39)	IV arm (n=41)	p value
Age (mean (SD) (years)	44.74 (12.17)	46.24 (11.67)	0.63
Male (n%)	33 (84.6%)	37 (90.2%)	
Etiology of cirrhosis			
Alcohol	20(51.3%)	21(51.2%)	0.374
NASH	6(15.4%)	7(17.1%)	
HBV	4(10.3%)	7(17.1%)	
HCV	2(5.1%)	3(7.3%)	
Under evaluation	7(17.9%)	3(7.3%)	
Child-Pugh classification			0.886
A	19(48.7%)	18(43.9%)	
B	13(13.3%)	16(39%)

Moderatehypophosphatemia*	0	0	
Severe hypophosphatemia*	5(12.82%)	NA	
Oral intolerance			

Data is presented as n (%) for qualitative variables and median (IQR) for quantitative variables unless specified. List of abbreviations: VB-variceal bleed, NASH-non-alcoholic steatohepatitis; HBV-hepatitis B virus; hepatitis C virus; ACLF, acute on chronic liver failure; SBP, Spontaneous bacterial peritonitis, SD-standard deviation, IQR- Interquartile range.*Transient hypophosphatemia at 4 week of intervention (Mild: 2-2.5 mg/dL, Moderate: 1-2 gm/dL, Severe: <1gm/dL)

Method: In this single centre randomised controlled trial with superiority study design, eligible patients with cirrhosis with iron deficiency anaemia after VB were randomised to receive either intravenous iron (Ferric carboxymaltose, 2 doses, 7 days apart, haemoglobin and weight-based dose calculation) or oral iron (Carbonyl iron, 100 mg elemental iron per day) for 3 months. The primary outcome was increase in haemoglobin in both arms at 3 months. Secondary outcomes included resolution of anaemia

(haemoglobin >12 g/dL), normalization of iron stores (ferritin >100 ng/dl), liver related outcomes and drug related adverse events. Changes in quality of life was assessed using Chronic Liver Disease Questionnaire at baseline and at 3 months.

Results: Eighty patients (Oral arm n = 39, IV arm n = 41, mean age 45.5 year, 87.5%males) of predominant non-viral aetiology (alcohol, NASH and HBV related 51%, 16%, 13% respectively) were included in this trial. Baseline characteristics including median CTP score7.00 [IQR6.00, 9.00], median MELD score 12.00 [IQR 10.00, 17.00] and degree of anaemia (8.25 ± 1.06 gm/dl) were comparable. The mean increase in haemoglobin in intravenous and oral arm was 3.63 ± 0.35 gm/dl and 1.62 ± 0.35 gm/dl respectively at 3 months (p value <0.001). Resolution of anaemia was seen in 58.3% and 27.3% in intravenous and oral arm (p value <0.009). Normalization of iron stores was seen in 84.4% and 25.9% in intravenous and oral arm respectively (p value <0.001). None of the patient developed drug related serious adverse event in any. There was a significant improvement in quality of life and functional status in intravenous arm.

Conclusion: Intravenous iron replacement is safe and more effective than oral iron in improving haemoglobin, iron stores and quality of life in patients with iron deficiency anaemia after episode of variceal bleed (CTRI/2022/11/47650).

TOP-044

Nutritional therapy improves minimal hepatic encephalopathy in cirrhosis by improvement in sarcopenia, proinflammatory cytokines and myostatin: a double blind randomized controlled trial

Sudhir Maharshi[1], Barjesh Sharma[1], Sanjeev Sachdeva[2], Bhawna Mahajan[2], Ashok Sharma[3], Sushma Bara[2], Siddharth Srivastava[4], Ajay Kumar[2], Ashok Dalal[1], Ujjwal Sonika[1]. *[1]G.B Pant Hospital, Gastroenterology, New Delhi, India, [2]G.B Pant Hospital, New Delhi, India, [3]G.B Pant Hospital, Radiology, New Delhi, India, [4]G. B Pant Hospital, New Delhi, India*
Email: sudhir.maharshi@gmail.com

Background and aims: Minimal hepatic encephalopathy (MHE) impairs health related quality of life (HRQOL), predicts development of overt hepatic encephalopathy (HE) and associated with poor prognosis. We assessed the effects of nutritional therapy on cognitive functions, HRQOL, anthropometry, endotoxins and inflammatory markers in patients of cirrhosis with MHE.

Method: In a double blind randomized controlled trial patient of cirrhosis with MHE were randomized to nutritional therapy (group I: 30–35 kcal/kg/day and 1.0–1.5 gram of protein/kg/day) and no nutritional therapy (group II: diet as patients were taking before) for 6 months. MHE was diagnosed based on psychometry hepatic encephalopathy score (PHES). Anthropometry, ammonia, endotoxins, inflammatory markers, myostatin and HRQOL were assessed at baseline and after 6 months. Primary end points were improvement or worsening in MHE and HRQOL.

Results: A total 150 patients were randomized to group-I (n = 75, age 46.3 ± 12.5 years, 58 men) and group-II (n = 75, age 45.2 ± 9.3 years, 56 men). Baseline PHES (−8.16 ± 1.42 vs −8.24 ± 1.43; p = 0.54) was comparable in both the groups. Reversal of MHE was higher in group I (73.2% vs 21.4%; p = 0·001). Improvement in PHES (ΔPHES 4.0 ± 0.60 vs −4.18 ± 0.40; p = 0·001), HRQOL (Δ SIP 3.24 ± 3.63 vs 0.54 ± 3.58; p = 0·001), anthropometry, ammonia, endotoxins, cytokines and myostatin levels were also significantly higher in group I compared to group II. Overt HE developed in 6 patients in group I and 13 in group II (p = 0·04).

Conclusion: Nutritional therapy is effective in treatment of MHE and associated with improvement in nutritional status, HRQOL, ammonia, endotoxins, inflammatory markers and myostatin levels.

TOP-047

Efficacy of arginine glutamate injection for the treatment of hepatic encephalopathy and hyperammonemia in cirrhosis: a randomized controlled trial

Huaibin Zou[1], Ming Kong[1], Weiwei Kang[1], Rui Zhong[1], Xianshan Yang[1], Lili Feng[1], Yan Ren[1], Yuan Gao[1], Li Zhou[1], Shanshan Li[1], Li Wang[2], Zhongping Duan[1], Yu Chen[1]. *[1]Beijing Youan Hospital Capital Medical University, Beijing, 100069, China., China, [2]School of Basic Medicine Peking Union Medical College, Beijing, 100730, China., China*
Email: chybeyond1071@ccmu.edu.cn

Background and aims: Reducing blood ammonia is essential for treating cirrhotic patients with hepatic encephalopathy (HE). Arginine glutamate injection is a mixture that mainly works through two mechanisms of reducing blood ammonia and adjusting intestinal flora. Its' efficacy for the treatment of HE has not been adequately studied. This study evaluated the therapeutic effects of arginine glutamate injection and L-ornithine L-aspartate (LOLA) on patients with HE.

Method: 108 patients with cirrhosis and HE aged 18–75 years were randomized to receive either intravenous infusions of arginine glutamate injection (experimental group, n = 54), 20 grams daily, or LOLA (control group, n = 54), 20 grams daily for 7 days (stratified factor: West-Haven grading). Standard of care treatment was given in both groups. The primary end point of the study was the improvement rate of HE in patients treated for 7 days. Secondary efficacy measures included the effective rate of ammonia reduction in patients treated for 7 days and the value and rate of ammonia

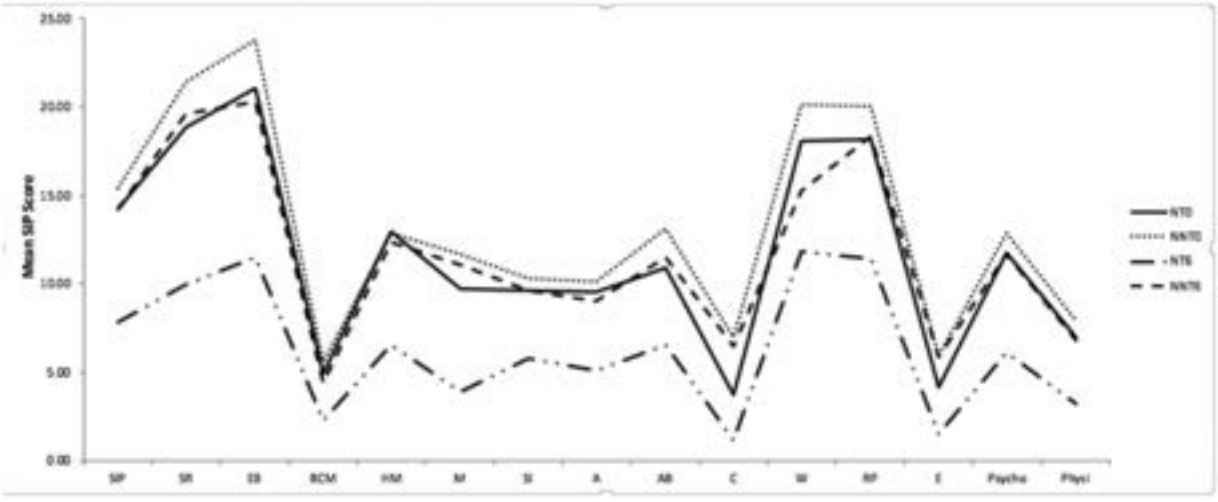

Figure: (abstract: TOP-044).

Table (abstract: TOP-047).

	FAS				PP			
Drug group	N	Number of improvement (%)	Improvement rate difference (95% CI)	p	N	Number of improvement (%)	Improvement rate difference (95% CI)	p
experimental group	54	48 (88.9)	−1.9% (−13.3%, 9.6%)	0.020	49	47 (95.9)	3.5% (−5.6%, 12.5%)	0.0015
control group	54	49 (90.7)			53	49 (92.4)		

Non-inferiority margin = −15.0%.

reduction from baseline at 4 h, 8 h, 24 h, and 7 d after initial administration.

Results: In the analysis of the FAS data set, after 7 days of treatment, the improvement rate of HE in the arginine glutamate injection group was 88.9%, and that in the LOLA group was 90.7%. The improvement rate of HE (non-efficacy threshold = −15.0%, P = 0.020) and the reduction rate of blood ammonia were similar between the two groups. The serum ammonia level of the arginine glutamate injection group was lower than that of the LOLA group at all time points, especially at 4 h and 24 h. The serum ammonia level (4 h p = 0.011, 24 h p < 0.001), the decreased value of serum ammonia from baseline (4 h p = 0.023, 24 h p = 0.005), and the reduced rate of serum ammonia (4 h p = 0.011, 24 h p < 0.001) in the arginine glutamate injection group were significantly superior to that in the LOLA group. When there was no significant difference in blood ammonia reduction rate, the total treatment cost and the cost of reducing blood ammonia value by 1 unit/1% in the arginine glutamate injection group were significantly lower than LOLA, indicating that the economy of arginine glutamate injection was better. No significant difference in the incidence of adverse reactions was seen between the groups.

Conclusion: Compared with intravenous LOLA, arginine glutamate injection reduces blood ammonia faster and has a more significant effect in the early stage. Arginine glutamate injection has lower costs and more pharmacoeconomic advantages.

Rifaximin plus lactulose is more effective than lactulose alone for the prevention of overt hepatic encephalopathy in patients with or without diabetes

Jasmohan S Bajaj[1], Robert Wong[2], Zeev Heimanson[3], Christopher Allen[3], Robert Israel[3], Arun Sanyal[1]. [1]*Virginia Commonwealth University and Central Virginia Veterans Healthcare System, Richmond, United States,* [2]*Stanford University School of Medicine and Veterans Affairs Palo Alto Healthcare System, Palo Alto, United States,* [3]*Salix Pharmaceuticals, Bridgewater, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Rifaximin is approved for reduction in risk of overt hepatic encephalopathy (OHE) recurrence. Diabetes mellitus is a common comorbidity in patients with cirrhosis. Limited published data suggest that it may impact effectiveness of some OHE therapies. The aim was to evaluate the efficacy/safety of rifaximin + lactulose vs lactulose alone in patients with cirrhosis, with/without diabetes.

Method: Data were pooled from 2 randomized trials (1 phase 3 double-blind; 1 phase 4 open-label) of adults with cirrhosis and history of OHE within 6 months (in OHE remission). In phase 3 trial, patients received rifaximin 550 mg BID or placebo, with optional lactulose (2–3 soft stools/d) for 6 months; for phase 4 trial, rifaximin 550 mg BID + lactulose (2–3 soft stools/d) for 6 months. Patients were subgrouped post hoc by baseline diabetes (yes/no). Outcomes assessed included time to onset of OHE episode (Conn score ≥2) and time to first HE-related hospitalization.

Results: 135 patients had diabetes (rifaximin + lactulose [n = 84]; lactulose alone [n = 51]), and 246 had no diabetes (rifaximin + lactulose [n = 152]; lactulose alone [n = 94]) at baseline. At baseline, 78.5% of patients with diabetes had mean MELD scores 11–24 (median, 13.0) and 69.1% without diabetes had MELD scores 11–24 (median, 12.3). Treatment with rifaximin + lactulose resulted in significantly lower percentage of patients with OHE episode vs lactulose alone during 6 months among those with (22.6% vs 51.0%; p < 0.001) and without diabetes (17.1% vs 49.5%; p < 0.0001). Rifaximin + lactulose reduced OHE recurrence risk by 64% (HR, 0.36; 95% CI, 0.20–0.65; number needed to treat [NNT], 3.5) vs lactulose alone during 6 months of treatment in patients with diabetes (Figure); reduction in risk among those without diabetes was 70% (HR, 0.30; 95% CI, 0.18–0.49; NNT, 3.3). Also, significantly fewer patients receiving rifaximin + lactulose vs lactulose alone had an HE-related hospitalization among those with (14.3% vs 29.4%; p = 0.01) and without (10.5% vs 20.2%; p = 0.008) diabetes. Patients with diabetes treated with rifaximin + lactulose had a 60% reduction in risk of first HE-related hospitalization during 6 months vs lactulose alone (HR, 0.40; 95% CI, 0.19–0.86; NNT = 6.6); without diabetes, the risk reduction was 59% (HR, 0.41; 95% CI, 0.21–0.81; NNT = 10.3). Comparing with vs without diabetes, rifaximin + lactulose arms had similar outcomes for rate of OHE episodes (p = 0.31) and HE-related hospitalizations (p = 0.34). Addition of rifaximin to lactulose was well tolerated.

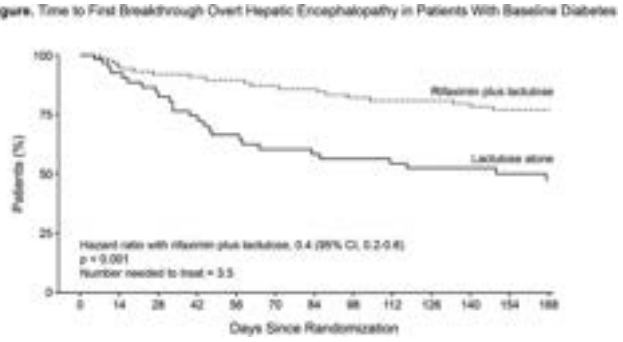

Figure:

Conclusion: Rifaximin + lactulose was more efficacious than lactulose alone for reducing the risk of OHE recurrence and HE-related hospitalization in adults regardless of diabetes status. Thus, both groups would benefit from addition of rifaximin to lactulose for reducing OHE recurrence risk. Also, although the sample size was small, diabetes may not impact rifaximin treatment outcomes; further studies are warranted.

WED-320

Real-word experience of long-term albumin treatment in a large cohort of patients with cirrhosis and ascites (Real-Answer study)

Giulia Iannone[1], Clara De Venuto[1], Salvatore Piano[2], Antonino Lombardo[3], Davide Bitetto[4], Stefania Gioia[5], Giacomo Zaccherini[1], roberta gagliardi[2], Vincenza Calvaruso[3], Enrico Pompili[1], Marta Tonon[2], Maurizio Baldassarre[1], Silvia Nardelli[5], Pierluigi Toniutto[4], Vito Di Marco[3], Paolo Angeli[2], Paolo Caraceni[1,6]. *[1]Alma Mater Studiorum-University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy, [2]University and Hospital of Padova- Unit of Internal Medicine and Hepatology, Department of Medicine-DIMED, Padova, Italy, [3]UOC di Gastroenterologia, Dipartimento di Promozione della Salute, Materno Infantile, Medicina Interna e Specialistica (PROMISE), University of Palermo, Italy, [4]Hepatology and Liver Transplantation Unit, University Academic Hospital of Udine, Udine, Italy, [5]Sapienza University of Rome, Department of Translational and Precision Medicine, Rome, Italy, [6]IRCSS Azienda Ospedaliero-Universitaria di Bologna, Unit of Semeiotics, Liver and Alcohol-related diseases, Bologna, Italy*
Email: paolo.caraceni@unibo.it

Background and aims: Based on the results of the ANSWER randomized clinical trial, long-term albumin treatment (LTA) is now standard of care in patients with decompensated cirrhosis in many Italian liver units. However, several issues (i.e., better characterization of patients amenable to LTA, personalization of albumin infusion, clinical trajectories, stopping rules) should be addressed. Thus, this "real-life" study aimed to increase our knowledge on LTA.

Method: Patients with cirrhosis and ascites receiving albumin for at least one month were enrolled in a multicenter retrospective observational study. Data on patient's characteristics, modalities of albumin treatment, clinical trajectories and outcomes were collected in 5 liver units across Italy.

Results: 326 patients (male 69%, median age 63) were included in the study from January 2016 to January 2022. Alcohol followed by NASH were the predominant etiologies. At baseline, median Child-Pugh score was 9, MELD 15, and MELD-Na 18; serum albumin concentration was 31 (27–35) g/dl. 36% of patients had grade 3 ascites and 27% refractory ascites. About 2/3 of them presented previous or ongoing other major complications of cirrhosis. LTA was started in hospital and then continued after discharge in 34% of patients, while in the outpatient clinic in the remaining cases. Albumin was infused in the outpatient clinic of the referral hospital in 45% of cases, in territorial services in 17% and at home in 38%. Median length of treatment was 401 (196–777) days and median weekly dose was about 40 g. Changes of doses during treatment were made in about 70% of cases. At last observation, albumin was still ongoing in 43% of patients, while it was interrupted due to clinical improvement in 22%, death in 17%, transplantation in 14%, and patient's adherence/logistic barriers in 5%. In the 71 patients who stopped albumin for clinical improvement, median length of treatment was 257 (125–415) days, ascites returned to grade 0–1 in more than 95% of cases (20% of which had baseline diagnosis of refractory ascites), prognostic scores significantly improved (median Child-Pugh: 9 to 7, MELD 14 to 10, MELD-Na 18 to 13; $p < 0.001$) and median serum albumin concentration was 39 (IQR 35–44) g/L. At baseline, these patients were younger and more frequently had alcoholic cirrhosis. Finally, 15% of these patients re-started albumin infusion due to ascites re-accumulation.

Conclusion: These initial results of the Real-ANSWER study indicate that: 1. LTA is frequently added to diuretics as part of medical treatment of ascites in Italy; 2. adherence to treatment in real-life clinical practice is very high; 3. permanent interruption of LTA due to resolution of ascites and improvement of liver function can occur in almost 20% of cases, and 4. besides patients with uncomplicated ascites, also patients with refractory ascites can be responsive to LTA.

WED-321

Efficacy and safety of branched-chain amino acids supplementation on muscle cramps in patients with cirrhosis: a randomized double-blinded controlled trial

Tanongsak Chinaroonchai[1,2], Thanapat Atthakitmongkol[1], Supot Nimanong[1], Watcharasak Chotiyaputta[1], Phunchai Charatcharoenwitthaya[1], Tawesak Tanwandee[1], Siwaporn Chainuvati[1]. *[1]Siriraj Hospital, Mahidol University, Division of Gastroenterology, Department of Medicine, Bangkok, Thailand, [2]Phang Nga Hospital, Department of Medicine, Phangnga, Thailand*
Email: schain111@gmail.com

Background and aims: Patients with cirrhosis commonly experience muscle cramps, which are attributed to poor quality of life. The standard therapies, however, are not effective. This randomized controlled trial aimed to compare the efficacy and safety of branched-chain amino acids (BCAA) versus placebo for treating muscle cramps in cirrhotic patients.

Method: A total of 40 patients with cirrhosis who have experienced muscle cramps at least once per week were randomized to receive either a placebo (n = 21) or 12.45 grams of BCAA (n = 19) orally per day for 12 weeks. Patients were observed at 4-week intervals to monitor any changes in cramping and adverse events. Skeletal muscle index (SMI), handgrip strength, biochemical tests, and the chronic liver disease questionnaire (CLDQ) were assessed at enrollment and study completion. The primary outcome was a relative change in muscle cramp frequency from baseline.

Results: The mean age of the patients was 64.2 ± 9.4 years, with a female predominance of 67% and 90% were Child-Pugh A. Chronic hepatitis B or C was the primary cause of cirrhosis. The two groups were similar in baseline clinical characteristics, severity of liver disease, frequency and duration of muscle cramps, SMI, handgrip strength, and laboratory tests. At the end of the study, no significant difference in the percentage change of muscle cramps was observed between the BCAA group (−68.8%, 95% CI −100% to −46.4%) and the placebo group (−56.3%, 95% CI −75.0% to −20.0%) ($p = 0.235$). There were also no significant differences in the duration and severity of muscle cramps, SMI, hand grip strength, and CLDQ score between both two groups. However, a significant improvement in the activity and worry domains of the CLDQ score was observed in the BCAA group but not in the placebo group. In the subgroup of 30 participants having muscle cramps at least 3 times per week, BCAA supplementation showed a significant reduction in the muscle cramp frequency than the placebo group ($p = 0.010$) after the 12 weeks of treatment. Mild adverse events, including nausea or abdominal discomfort occurred in 31.6% and 23.8% of patients received BCAA and placebo, respectively ($p = 0.583$).

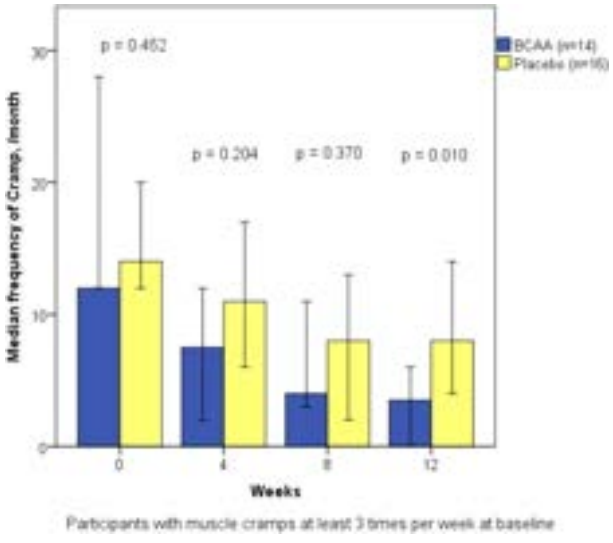

Figure:

Conclusion: A 12-week supplementation of BCAA significantly reduced the frequency of muscle cramps in cirrhotic patients who had cramping at least 3 times per week. However, there was no discernible improvement in skeletal muscle mass or function. Further studies with larger sample sizes and longer duration of BCAA supplementation are needed to validate these findings.

WED-322

Effects of nutritional therapy on Sarcopenia in patient with liver cirrhosis-a randomised controlled trial

Sudhir Maharshi[1], Shyam Sunder Sharma[1]. [1]*SMS Medical College and Hospital, Gastroenterology, Jaipur, India*
Email: sudhir.maharshi@gmail.com

Background and aims: Sarcopenia has been associated with poor survival in patients with cirrhosis. Nutrition may have direct influence on sarcopenia and functional status. There are limited data on nutritional management in cirrhosis with sarcopenia. We assessed the effects of nutritional therapy on sarcopenia in cirrhotic patients.
Method: A randomized controlled trial conducted in a tertiary care setting on patients of cirrhosis with sarcopenia who were randomized to nutritional therapy (group A: 30–35 kcal/kg/day and 1·0–1·5 gram of protein/kg/day) and no nutritional therapy (group B: diet as patients were taking before) for 6 months. Sarcopenia was diagnosed based on computerized tomography psoas muscle index (PMI), hand grip strength (HG) and gait velocity (GV). Primary end points were improvement or worsening in sarcopenia. Secondary end points were improvement of other nutritional parameters and liver functions.
Results: 141 patients were randomized to group-A ($n = 70$, age 42·7 ± 10·1 yr, 58 men) and group-B ($n = 71$, age 42·1 ± 9·8 yr, 57 men). Baseline characteristics including age, body mass index (BMI), hemoglobin, mid arm circumference (MAC), hand grip, gait velocity and PMI were comparable in both the groups. Improvement in MAC (ΔMAC 2.78 ± 0.26 vs −2.13 ± 0.32; p = 0.001), hand grip strength (ΔHG 4.91 ± 1.4 vs −3.1 ± 0.73; p = 0.001), gait velocity (ΔGV 0.98 ± 0.20 vs −0.74 ± 0.32; p < 0.01), PMI (ΔPMI 3.5 ± 0.24 vs −2.7 ± 0.42; p < 0.001) was higher in group A compared to group B at the end of study. Liver functions assessed by Child Turcotte Pugh and Model for end stage liver disease also significantly improved in group A compared to group B, p < 0.001.
Conclusion: Nutritional therapy is effective in the improvement of sarcopenia and liver function in cirrhosis.

WED-323

Real-world treatment of decompensated liver cirrhosis in Italy: a propensity score-matched analysis of long-term versus acute albumin therapy

Wim Laleman[1], Jonel Trebicka[2], Giacomo Zaccherini[3], Paolo Caraceni[4], Dirk Steffen Schmidt[5], Joana Rodrigues[5], Kyle Rodney[6], Sofia Schweiger[7], Paolo Angeli[8]. Background and aims: International guidelines recommend short-term albumin in specific acute conditions related to liver cirrhosis, but clinical trial data (e.g., ANSWER) show long-term albumin (LTA) treatment can be beneficial. We compared real-world outcomes in patients with decompensated cirrhosis receiving LTA or acute albumin therapy (non-LTA).

Method: A retrospective chart analysis was undertaken (Adivo Associates, funded by CSL Behring) to assess adults diagnosed with decompensated cirrhosis presenting ascites and treated in Italy with LTA (≥40 g per infusion per week) or non-LTA (administered at non-regular intervals). The observation period was from 1 Jan 2019 to 31 Dec 2021. In the LTA group, patients must have completed ≥3 months of LTA treatment by the start of the observation period. In the non-LTA group, patients must have received albumin for an acute complication at least once in the 12 months before the observation period. Data collection stopped if the patient received a transplant or switched treatment. The primary end point was the annualised therapeutic paracentesis rate. Propensity score matching (PSM), utilizing sex, Child-Pugh (CP) score and the presence of multiple comorbidities as covariates, was applied for the comparison of the two cohorts. The incidence rates of other cirrhosis-related complications were secondary end points. A negative binomial generalized linear model was used to adjust for the non-normality of the real-world data.
Results: The charts of 311 patients from 14 centres were screened and 125 matched pairs of LTA and non-LTA patients were analysed. In both cohorts, the mean age was 63.5 years, 64% were female, 14.4% had multiple comorbidities, and the mean CP score was 9.0. The mean standard difference between the cohorts for all three covariates included in the PSM model was 0.0% for all matched pairs (100% bias reduction). The mean annual number of therapeutic paracentesis episodes per patient was reduced by 47.8% in the LTA vs the non-LTA cohort (2.21 vs 3.97; p < 0.001; Figure). Statistically significant reductions in refractory ascites (44.2%, p = 0.018), spontaneous bacterial peritonitis (52.7%, p = 0.009), hepatorenal syndrome (62.6%, p = 0.003), hospital admissions (24.6%, p = 0.050) and length of stay for hospitalised patients (35.0%, p = 0.015) were also seen in the LTA cohort vs the non-LTA cohort. Hepatic encephalopathy did not show a statistically significant difference between the groups (13.1% reduction with LTA vs non-LTA, p = 0.605). Transplant and mortality rates were numerically lower in the LTA cohort (7% and 22%) than in the non-LTA cohort (12% and 26%) but were inconclusive due to the limited observation period.

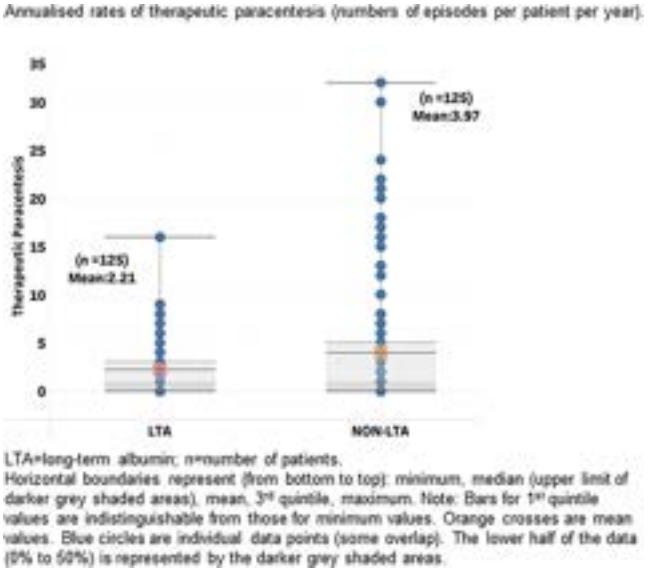

Figure:

Conclusion: These data provide further evidence of the benefits of LTA in patients with cirrhosis. LTA may reduce healthcare resource utilisation and has the potential to be cost-effective in real-world clinical practice.

WED-324

Potentially inappropriate medicine' use and nonadherence in hepatic encephalopathy: a retrospective real-world cohort study

Zhen Howe Hong[1,2], Stephanie Johnson[3], Tina Ha[4], Carolyn McIvor[1], Katherine Stuart[5], Patricia Valery[6,7], Elizabeth Powell[5,7], Kelly Hayward[5,7]. [1]*Logan Hospital, Department of Gastroenterology and Hepatology, Meadowbrook, Australia,* [2]*University of Queensland, Faculty of Medicine, St Lucia, Australia,* [3]*Logan Hospital, Pharmacy Department, Meadowbrook, Australia,* [4]*Princess Alexandra Hospital, Pharmacy Department, Woolloongabba, Australia,* [5]*Princess Alexandra Hospital, Department of Gastroenterology and Hepatology, Woolloongabba, Australia,* [6]*QIMR Berghofer Medial Research Institute, Herston, Australia,* [7]*University of Queensland, Centre for Liver Disease Research, Woolloongabba, Australia*
Email: zhenhowe.hong@health.qld.gov.au

Background and aims: Hepatic encephalopathy (HE) is a complex and debilitating complication of cirrhosis that may be precipitated by use of specific medicines and nonadherence with prophylaxis. We aimed to explore the association between 'potentially inappropriate medicine' use, nonadherence, and hospitalisation with HE in a real-world cohort.

Method: A random sample of 1,318 public hospital encounters among 326 CirCare participants (multi-site, prospective, observational study) with ≥1 admission between July-2017 and August-2019 were selected for review. Clinical and demographic information, comprehensive decompensation history, and medication data including adherence were abstracted from medical records. Encounters without medication documentation were excluded. A multinomial logistic regression model (adjusted for age, current infection, unplanned vs. elective presentation, and taking benzodiazepines, opioids and proton pump inhibitors (PPIs)) was used to calculate the odds of having covert (minimal, grade 1, or suppressed by medication) or grade 2/3 HE compared to no HE at admission. Adjusted odds ratios (OR) and 95% confidence intervals (CI) are reported.

Results: 354 of 1,318 encounters were selected, of which 245 had medication documentation and were included in the study (mean = 1.3 (standard deviation (SD) = 0.6) encounters among 184 patients). Mean age at encounter was 60 (SD = 11) years, and most encounters were unplanned presentations (75.1%) among males (69.4%) with decompensated cirrhosis (58.4%) in a tertiary hospital (69.4%). Nonadherence with ≥1 medicine was documented in 63 (25.7%) encounters. HE was identified in 69 (28.2%) encounters including 13 presentations of new HE. Among 56 encounters with chronic/recurrent HE, patients were prescribed lactulose in 50 (nonadherence rate 42.0%), rifaximin in 27 (nonadherence 7.4%), and other laxatives in 19 (nonadherence 21.5%). Lactulose was prescribed as a laxative in an additional 30 encounters (nonadherence 46.7%), including 8/13 with new HE (4/8 nonadherent). Nonadherence with HE prophylaxis occurred in 31.3% of admissions with grade 2/3 HE and 43.2% with covert HE. 47.8% of people with HE were nonadherent with ≥1 medicine compared to 17.0% without HE (chi-square $p < 0.01$). At least one 'potentially inappropriate medicine' was taken in 60/69 HE encounters (Figure). People taking benzodiazepines (OR = 3.75, 95%CI 1.50–9.35; $p < 0.01$) and those taking opioids (OR = 2.96, 95%CI 1.18–6.12; $p = 0.02$) were more likely to have grade 2/3 HE, and those taking PPIs (OR = 2.28, 95%CI 1.04–4.97; $p = 0.04$) were more likely to have covert HE, than people not taking these medicines. The indication was "unknown" for 30.2% of benzodiazepines, 33.3% of opioids, and 45.8% of PPIs.

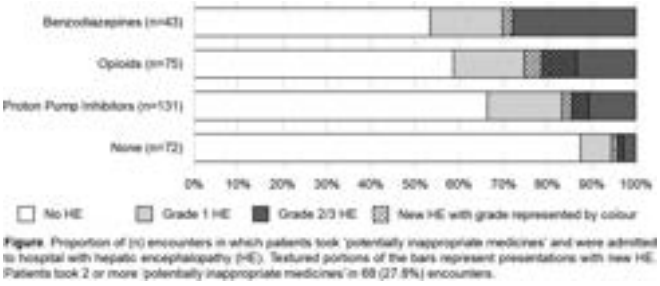

Figure: Proportion of (n) encounters in which patients took 'potentially inappropriate medicines' and were admitted to hospital with hepatic encephalopathy (HE). Textured portions of the bars represent presentations with new HE. Patients took 2 or more 'potentially inappropriate medicines' in 68 (27.8%) encounters.

Conclusion: Nonadherence is common in HE, and people taking opioids and benzodiazepines are at higher risk of grade 2/3 HE. Further exploration of indication and potential alternative therapies is required.

WED-325

Atorvastatin reduces inflammation markers TNF-α, CD62L and MMP2 in a randomised trial

Thit Mynster Kronborg[1], Robert Schierwagen[2], Mette Lehmann Andersen[3], Ane Soegaard Teisner[3], Rasmus Hvidbjerg Gantzel[4], Henning Grønbæk[4], Lise hobolth[1], Søren Møller[5], Flemming Bendtsen[1], Jonel Trebicka[2], Nina Kimer[1]. Email: thit.mynster.kronborg@regionh.dk

Background and aims: In liver cirrhosis with portal hypertension, the mortality and risk of complications are high. Statins may have anti-inflammatory and anti-fibrotic effects in cirrhosis. Hence, statins can potentially reduce the risk of complications and mortality in patients with cirrhosis and portal hypertension. Therefore, we aimed to investigate the effects of Atorvastatin treatment on hospitalisations, mortality and systemic inflammation markers in cirrhosis.

Method: We performed a double-blind, randomised, placebo-controlled clinical trial in patients with liver cirrhosis and portal hypertension ≥10 mm Hg. Atorvastatin 10–20 mg was administered for six months. Invasive hemodynamics were measured at baseline and after six months. Inflammation and cellular markers were analysed in peripheral and liver vein blood samples by bead- and flow-cytometry-based multiplexed immunoassays at baseline and after six months.

Results: 78 patients were randomised. 38 were allocated to Atorvastatin and 40 to placebo. Fifty-eight patients completed six months of intervention. The number of liver-related complications and mortality was similar between groups. Atorvastatin did not significantly affect surrogate hemodynamic (HVPG-decrease 4.1% in Atorvastatin and 2.8% in placebo) or clinical parameters (MELD: 2.4% decrease in Atorvastatin and 7.3% increase in placebo). Interestingly, Atorvastatin significantly decreased the inflammation and extracellular matrix markers TNF-α, CD62L and MMP2 in the Atorvastatin group compared to the placebo group (p values; 0.005, 0.011 and 0.023).

Conclusion: Although six months of Atorvastatin treatment did not change clinical outcomes in this study, probably due to the small sample size, Atorvastatin has significant anti-inflammatory effects in cirrhosis.

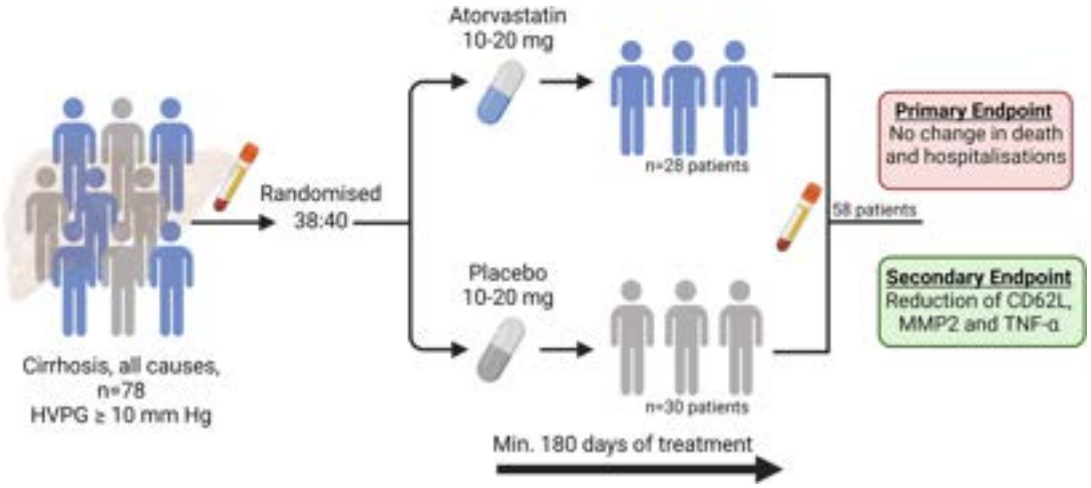

Figure: (abstract: WED-325).

Impact of intrapulmonary vascular dilatations and hepatopulmonary syndrome on the clinical course of patients after transjugular intrahepatic portosystemic shunt insertion

Jim Benjamin Mauz[1], Hannah Schneider[1], Dominik Berliner[2], Anja Tiede[1], Lena Stockhoff[1], Jan Hinrichs[3], Heiner Wedemeyer[1,4], Bernhard Meyer[3], Karen Olsson[5,6], Benjamin Maasoumy[1,4], Tammo Lambert Tergast[1]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany, [2]Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany, [3]Hannover Medical School, Department of Interventional Radiology, Hannover, Germany, [4]German Center for Infection Research (DZIF), Hannover-Braunschweig, Braunschweig, Germany, [5]Hannover Medical School, Department of Respiratory Medicine, Hannover, Germany, [6]German Center for Lung Research (DZL), Gießen, Germany*
Email: mauz.jim@mh-hannover.de

Background and aims: Implantation of a transjugular intrahepatic portosystemic shunt (TIPS) is an established therapy of cirrhosis related complications such as ascites or variceal bleeding. In this setting, data on the impact of TIPS implantation on the clinical course of patients with intrapulmonary vascular dilatations (IPVD) and hepatopulmonary syndrome (HPS) are scarce and only few case reports and case series are available. Some authors suggested that TIPS insertion might exacerbate the hyperdynamic circulatory state that is present in patients with advanced liver disease and could therefore result in a higher incidence of hepatic or cardiac decompensation. Hence, this study aimed to investigate the impact of IPVD and HPS on the course of patients that underwent TIPS implantation.
Method: A number of 366 consecutive patients who received a TIPS between 2009 and 2021 were considered for this study. Contrast-enhanced echocardiography and blood gas analysis (BGA) were conducted to assess the presence of IPVD and HPS. Patients with Budd-Chiari syndrome, relevant lung disease, absence of liver cirrhosis or missing data regarding echocardiography or BGA were excluded from this study. Multivariable competing risk analysis was performed to assess longitudinal end points and adjusted for MELD score, age and refractory ascites as TIPS indication. Patients were followed up for one year after TIPS-insertion and analyzed end points were liver transplant (LTx)-free survival, hepatic decompensation or cardiac decompensation.
Results: Overall, 269 patients were included in the final analysis. A number of 138 patients had IPVD and 72 fulfilled HPS criteria. Patients with IPVD had lower MELD scores (12 ± 4 vs. 13 ± 4, p = 0.028), while ascites as TIPS indication was less frequent than in those without IPVD (75% vs. 90%, p < 0.001). The alveolar-arterial oxygen gradient was higher in the IPVD group (29 ± 15 vs. 21 ± 17, p < 0.001), while arterial-oxygen partial pressure was lower (80 ± 15 vs. 86 ± 17, p = 0.006). Presence of IPVD was not associated with a lower LTx-free survival within one year after TIPS implantation (22% vs. 22%, HR: 1.26, 95%CI: 0.75–2.11, p = 0.380). However, IPVD were linked to cardiac decompensation (28% vs. 18%, HR: 1.78, 95%CI: 1.03–3.07, p = 0.040) and a numerically higher risk of hepatic decompensation (55% vs. 46%, HR: 1.37, 95%CI: 0.98–1.91, p = 0.064) in the follow-up. In those with HPS, LTx-free survival and hepatic decompensation did not differ from those without HPS or IPVD (26% vs. 22%, HR: 1.22, 95% CI: 0.68–2.19, p = 0.510, hepatic decompensation: 54% vs. 46%, HR 1.21, 95% CI: 0.82–1.78, p = 0.340). However, incidence of cardiac decompensation was numerically increased (32% vs. 18%; HR: 1.74, 95%CI: 0.97–3.13, p = 0.061).
Conclusion: Presence of IPVD or HPS increases the risk of cardiac decompensation but does not impact overall mortality after TIPS implantation.

WED-327

Efficacy and safety of nalfurafine hydrochloride for pruritus in patients with chronic liver disease in Japan

Tadamichi Kawano[1], Masanori Atsukawa[1], Akihito Tsubota[2], Kaori Shioda[1], Hiroki Ono[1], Tomomi Okubo[1], Taeang Arai[1], Korenobu Hayama[1], Keiko Kaneko[1], Norio Itokawa[1], Katsuhiko Iwakiri[1]. *[1]Nippon Medical School, Division of Gastroenterology and Hepatology, Tokyo, Japan, [2]Jikei University School of Medicine, Core Research Facilities, Tokyo, Japan*
Email: k-tadamichi@nms.ac.jp

Background and aims: Nalfurafine hydrochloride, a selective κ-opioid receptor agonist has been approved for treatment of pruritus in patients with chronic liver disease. However, not all patients respond to nalfurafine hydrochloride. The aim of this study was to clarify the efficacy and safety of nalfurafine hydrochloride.
Method: The subjects were patients with chronic liver disease complicated by pruritus who were treated with nalfurafine hydrochloride between May, 2015, and May, 2022. The degree of pruritus was evaluated based on the Visual Analog Scale (VAS) score and the Kawashima's pruritus score. Nalfurafine hydrochloride 2.5 μg was orally administered once a day for 12 weeks. A decrease in the VAS score of ≥25 mm or the Kawashima's pruritus score of ≥1 scores was designated as relevant response. The former of ≥50 mm or the latter of ≥2 scores as remarkable response. The 332 patients who were

evaluated the efficacy at 12 weeks. The median time suffering from pruritus to administration of nalfurafine hydrochloride was 4 months.
Results: The median VAS score improved from 70.0 mm before administration to 40.0 and 30.0 mm at 4 and 12 weeks of treatment, respectively. On multivariate analysis, shorter itching period and lower the fibrosis-4 (FIB-4) index value were extracted as the independent factors related to remarkable responder. On multivariate analysis, shorter itching period was extracted as the only independent factor related to relevant responder. The dose escalation (from 2.5 to 5.0 μg/day at 4 weeks of treatment) was performed in 24 patients. Of the 24 patients with dose escalation, 16, 8, and 8 had relevant response, remarkable response, and non-response, respectively.
Conclusion: This study suggested nalfurafine hydrochloride treatment markedly improves pruritus in patients with chronic liver disease. A short pruritus period and less-advanced fibrosis were associated with response to nalfurafine hydrochloride.

WED-328

Safety and efficacy of continuous infusion terlipressin in acute kidney injury-hepatorenal syndrome: the Infuse study

K. Rajender Reddy[1], Ethan Weinberg[1], Stevan Gonzalez[2], Manhal Izzy[3], Douglas Simonetto[4], Richard Frederick[5], Raymond Rubin[6], Zachary Fricker[7], Grace Kim-Lee[1], Sherry Witkiewicz[8], William Tobin[8], Khurram Jamil[9]. Email: reddyr@pennmedicine.upenn.edu

Background and aims: Safety and efficacy of terlipressin for AKI-HRS may be greater with a continuous infusion strategy as opposed to bolus administration (CONFIRM; NCT02770716).
Method: An open-label study of continuous infusion terlipressin (INFUSE; NCT04460560) has been completed in 50 patients with cirrhosis and AKI-HRS. The cohort was enriched with those who were listed/in evaluation/eligible for liver transplantation (LT). Patients with MELD ≥ 35, ACLF-Grade 3, or serum creatinine (SCr) >5.0 mg/dL were excluded. Following a 0.5 mg bolus, terlipressin was administered as a continuous infusion from 2 to 8 mg/day based on SCr response and tolerability. Complete Response (CR): ≥ 30% decrease in SCr with EOT SCr ≤ 1.5, Partial Response (PR): ≥ 30% decrease in SCr with EOT SCr >1.5, Non-Response (NR): <30% decrease in SCr. Follow-up was up to 30 days post-treatment.
Results: (See table) There were no unexpected drug-related serious adverse events. One patient had hypoxic respiratory failure attributed to fluid overload and responded to diuretics. There were 3 deaths (2 progressive liver failure, 1 progressive renal failure). Midodrine and octreotide use prior to enrollment was in 37/50; 74%.

Table:

	All Patients	CR	PR	NR	p value
Mean age 57, 54% male	50	31/50 (62%)	8/50 (16%)	11/50 (22%)	
AKI Stage 1B/2/3	14/50 (28%)	9/31 (29%)	1/8 (12.5%)	4/11 (36%)	NS
	20/50 (40%)	15/31 (48%)	3/8 (37.5%)	2/11 (18%)	
	16/50 (32%)	7/31 (23%)	4/8 (50%)	5/11 (46%)	
Alcohol-Related Liver Disease	26/50 (52%)	18/31 (58%)	3/8 (37.5%)	5/11 (46%)	NS
NASH	15/50 (30%)	8/31 (26%)	4/8 (50%)	3/11 (27%)	
MELD, Baseline	26, 17–34	25, 18–34	27, 17–34	27, 17–33	NS
MELD, EOT	20, 11–32	18, 11–31	20, 14–29	23, 16–32	NS
SCr, Baseline	2.6, 1.5–4.9	2.3, 1.5–3.9	3.0, 2.3–4.4	2.8, 1.7–4.9	0.02
SCr, EOT	1.4, 0.8–4.9	1.2, 0.8–1.5	1.9, 1.7–2.4	2.6, 1.5–4.9	
Days of treatment	8, 1–14	7, 3–14	10, 3–14	4, 1–14	NS
Terlipressin dose (mg)	21, 3–87	21, 3–79	47, 5–87	13, 3–67	NS
Concurrent albumin dose (g)	150, 25–475	175, 50–400	125, 50–475	100, 25–188	0.037
RRT within 30 d	10/50 (20%)	1/31 (3%)	2/8 (25%)	7/11 (64%)	<0.001
Alive at 30 d	47/50 (94%)	30/31 (97%)	7/8 (87.5%)	10/11 (91%)	NS
Transplant candidates	40/50 (80%)	23/31 (74%)	8/8 (100%)	9/11 (82%)	NS
- Waitlist	5/40 (12.5%)	2/23 (9%)	1/8 (12.5%)	2/9 (22%)	
- Evaluation	23/40 (57.5%)	13/23 (57%)	5/8 (62.5%)	5/9 (56%)	
- Eligible	11/40 (27.5%)	8/23 (35%)	1/8 (12.5%)	2/9 (22%)	
LT	15/40 (37.5%)	9/15 (60%)	1/15 (7%)	5/15 (33%)	NS
SLKT	4/40 (10%)	1/4 (25%)	2/4 (50%)	1/4 (25%)	NS

Values are median, range unless otherwise stated.

Conclusion: A high CR of 62% was observed with continuous infusion terlipressin with a favorable safety profile. Fifteen underwent LT alone; 9/15 (60%) were CR, 1/15 (7%) PR, 5/15 (33%) NR, and 4 had simultaneous liver kidney transplants (SLKT). In patients with AKI-HRS, treatment with terlipressin was followed by LT alone in a high proportion of complete responders.

The effects of alfapump on ascites control and quality of life in patients with cirrhosis and recurrent or refractory ascites: pivotal trial results

Florence Wong[1], Hugo Vargas[2], K. Rajender Reddy[3], Mangesh Pagadala[4], Christine Pocha[5], Vinay Sundaram[6], Jasmohan Bajaj[7], Jeroen Capel[8], Patrick S. Kamath[9]. [1]*University of Toronto, ON, Canada,* [2]*Mayo Clinic, Phoenix, AZ, United States,* [3]*University of Pennsylvania, PA, United States,* [4]*Methodist Dallas Medical Center, TX, United States,* [5]*Avera Medical Group, Sioux Falls, United States,* [6]*Cedars-Sinai Comprehensive Transplant Center, Los Angeles, CA, United States,* [7]*Richmond VA Medical Center, United States,* [8]*Sequana Medical NV, Zürich, Switzerland,* [9]*Mayo Clinic, Rochester MN, United States*
Email: florence.wong@utoronto.ca

Background and aims: The standard of care for recurrent or refractory ascites (RA) in cirrhosis is repeat large volume paracentesis (LVP). The alfapump system, providing slow but continuous paracentesis (para) via a subcutaneous pump, has been shown to be a possible alternative in selected patients. The aim was to assess the effects of alfapump on ascites control and quality of life (QoL) in patients with cirrhosis and RA.

Method: Patients with cirrhosis and RA and TIPS contraindications or refusal who had required ≥2 paras in the 30 days prior were enrolled. Patients served as their own controls with ≥5 paras in 3 months (M) before pump implantation. Patients received post-implant prophylactic antibiotics and follow-up was ≥6 M. Data collected were demographics, albumin use, ascites control, safety, QoL and ascites symptoms using SF36 and Ascites Q questionnaires, respectively. The 3 M pre-pump and 4–6 M post-pump data were compared, after initial 3 M post-pump stabilization. Primary efficacy end point was reduction in para requirement; safety end points were pump system adverse events that resulted in intervention, explant or death.

Results: 40 patients with RA, mean age 64 ± 9 yrs, 65% men, mean MELD-Na 15 ± 4, 48% alcohol-related cirrhosis received an alfapump. Efficacy: Para requirement decreased from 3.2 ± 1.5 to 0.2 ± 0.6 times/M ($p < 0.001$) from pre- to post- pump implant period, with 77% of patients having a ≥50% reduction (Figure). Ascites volume removed by para fell from 54.2 ± 23.3 pre- to 2.8 ± 9.1 L/M post-pump ($p < 0.001$). Safety: 6 (17.6%) pumps were explanted, 3 due to pump site skin erosion and 3 due to bladder discomfort. There were 17 serious adverse events (SAEs) in 11 patients in the pre-, and 81 SAEs in 24 patients ($p < 0.001$) in the post-implant period, respectively. Six primary safety events post-implant were related to procedure, device or alfapump therapy. There was no AKI in the pre-, but 23 AKIs in the post-implant period (0–6 M), with 16/24 cases being stage 1, 5 stage 2, and 2 stage 3 AKI. Albumin use was 95 ± 105 g/M in the post-implant vs. 102 ± 127 g/M in the pre-implant period ($p = 0.38$), likely due to AKI treatment. There were 4 SBP SAEs and 1 UTI SAE. There were 5 deaths in the 6 M post-implant period, none related to device or alfapump therapy, renal dysfunction or infection. QoL: Patients reported reductions in ascites related symptoms with an Ascites Q score of 32.2 ± 21.9 at 6 M post- vs. 51.0 ± 19.3 pre-implant (lower value = improvement) ($p < 0.001$). Physical but not mental component of SF36 improved (35.6 ± 9.3 pre-implant to 42.8 ± 8.5 at 6 M [$p < 0.001$]).

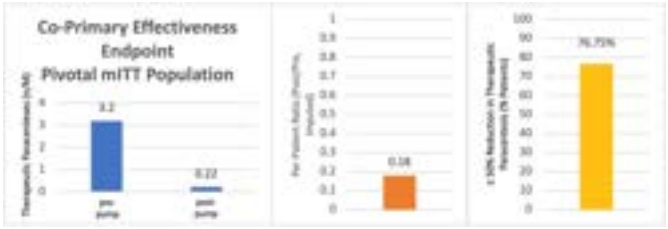

Figure:

Conclusion: The alfapump system was very effective in control of ascites, virtually eliminating the need for LVP. Patients with the alfapump need close monitoring for the development of AKI or infection, which must be treated promptly to prevent adverse outcomes. In carefully selected patients with RA, the alfapump is an alternative to repeat LVP.

WED-331

Quickstroop, an App-based strategy that takes <1 minute, predicts time to overt hepatic encephalopathy development and hospitalizations

Gowthami Kanagalingam[1], Dan Park[1], Bryan Badal[1], Andrew Fagan[1], Leroy Thacker[1], Jasmohan S Bajaj[1]. [1]*Virginia Commonwealth University, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Prediction of overt hepatic encephalopathy (OHE) development needs to be refined beyond current clinical markers. Covert HE (CHE) diagnosis with QuickStroop (1st 2 runs of EncephalApp Off stage) takes <1 min vs the total EncephalApp. Both are comparable cross-sectionally but use of Quickstroop to predict OHE and hospitalizations is unclear. Aim: Determine the ability of QuickStroop to predict OHE and related hospitalizations, other hospitalizations and death in cirrhosis outpatients.

Method: Outpatients with cirrhosis underwent QuickStroop testing and were divided into CHE or not based on age, gender and education adjusted norms. Follow-up for OHE development (grade ≥2 needing Rx changes), OHE-related non-elective hospitalizations, all hospitalizations and death was performed. Demographics, cirrhosis details and medications were recorded. Cox proportional hazard models for CHE by QuickStroop for OHE and hospitalizations were created unadjusted and then adjusted for cirrhosis severity and complications.

Results: 250 pts (62.5 ± 8.2 years, 96% men, education median 12 years) were included. Median MELD-Na (range) was 11 (6, 37) with most pts with NAFLD (33%) then HCV (24%) and alcohol (18%). Prior OHE was seen in 33% (all on lactulose, 29% on rifaximin). 41% had ascites, 37% had varices and 24% were on non-selective beta-blockers (NSBB). Patients were followed a median of 7 (1–107) months from testing. The median time-to-event for those who developed OHE was 5 (1, 47) mths, HE-related hospitalizations was 5 (1, 47) months and all hospitalizations was 6 (1, 72) months post-testing. CHE: CHE on QuickStroop was found in 126 (50%) patients. MELD was higher (14.3 ± 6.4 vs 11.4 ± 5.1, $p < 0.001$), with higher prior OHE (45% vs 23%, $p = 0.002$), higher ascites (51% vs 32%, $p = 0.003$) and lower albumin (3.3 ± 0.7 vs 3.5 vs 0.5, $p = 0.001$) in CHE pts. Outcomes and cox hazards: 60% needed hospitalizations, 16% developed OHE, 10% needed OHE-related hospitalizations and 23% died. On unadjusted comparisons, CHE pts had higher risk of OHE development (24% vs 7%, $p = 0.003$), OHE-related hospitalizations (16% s 5%, $p = 0.004$) and death (31% vs 5%, $p = 0.002$) but similar all-cause hospitalizations (62% vs 57%, p =

Fig 1A	Unadjusted		Adjusted		
Time to OHE Development					
QuickStroop (CHE vs None)	3.99 (1.88, 8.46)	0.0003	QuickStroop (CHE vs No)	2.42 (1.12, 5.23)	0.025
			Prior OHE	1.87 (0.95, 3.68)	0.068
			MELD-Na	1.13 (1.08, 1.19)	<0.0001
Time to OHE Hospitalization					
QuickStroop (CHE vs None)	3.77 (1.51, 9.44)	0.005	QuickStroop(CHE vs No)	2.33 (1.01, 5.99)	0.049
			Prior OHE	1.45 (0.64, 3.30)	0.38
			MELD-Na	1.13 (1.08, 1.20)	<0.0001
Time to All-Cause Hospitalization					
QuickStroop (CHE vs None)	1.39 (1.01, 1.93)	0.04	QuickStroop (CHE vs No)	0.94 (0.66, 1.34)	0.74
			Prior OHE	1.80 (1.26, 2.56)	0.0012
			MELD-Na	1.08 (1.05, 1.11)	<0.0001
Time to Death					
QuickStroop (CHE vs None)	2.44 (1.38, 4.29)	0.002	QuickStroop (CHE vs No)	1.60 (0.87, 2.96)	0.13
			Prior OHE	1.43 (0.82, 2.53)	0.2111
			MELD-Na	1.10 (1.06, 1.15)	<0.0001

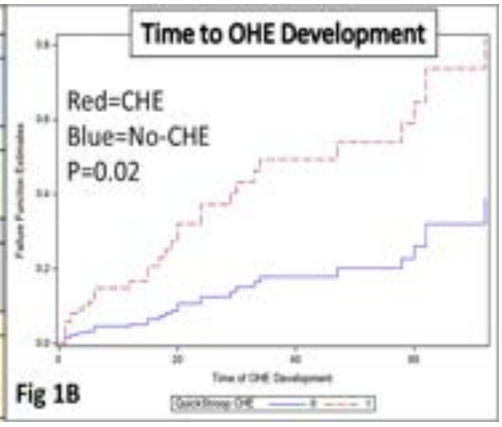

Figure: (abstract: WED-331).

0.45). This pattern was also seen in time-to-event analysis. After adjustment for other variables, CHE on Quickstroop remained significantly linked with lower time to OHE development and hospitalizations but not death or all-cause hospitalizations (Fig 1A/B).
Conclusion: Using the Quickstroop, an App-based strategy providing CHE diagnosis within one minute, is associated with lower time to develop outcomes specific to Overt HE development.

WED-332
On-treatment factors predict recompensation in entecavir-treated hepatitis B patients with decompensated cirrhosis
You Deng[1], Huanwei Zheng[2], Xiang Huiling[3], Yuemin Nan[4], Jinhua Hu[5], Qinghua Meng[6], Hong Zhao[1], Qi Wang[1], Jilian Fang[7], Jie Xu[8], Xiaoming Wang[9], Calvin Q Pan[10], Hong You[9], Xiaoyuan Xu[11], Wen Xie[1], Ji-Dong Jia[9]. *[1]Beijing Ditan Hospital, Capital Medical University, China, [2]Shijiazhuang Fifth Hospital, China, [3]Tianjin Third Central Hospital, China, [4]The Third Hospital of Hebei Medical University, China, [5]The Fifth Medical Centre of Chinese PLA General Hospital, China, [6]Beijing You-an Hospital, Capital Medical University, China, [7]Peking University People's Hospital, China, [8]Peking University Third Hospital, China, [9]Beijing Friendship Hospital, Capital Medical University, China, [10]Division of Gastroenterology and Hepatology, Department of Medicine, NYU Langone Medical Center, NYU School of Medicine, United States, [11]Peking University First Hospital, China*
Email: jia_jd@ccmu.edu.cn

Background and aims: Recompensation is achievable in certain decompensated cirrhotic hepatitis B patients treated with nucleos (t) ide analogues (NAs). However, the prediction factors of recompensation are still unclear. Therefore, we aimed to develop a prognostic model for recompensation prediction in NA-treated hepatitis B patients with decompensated cirrhosis.
Method: In a multi-centre study enrolled decompensated chronic hepatitis B (CHB) patients with ascites and treated with entecavir for 120 weeks, clinical events, viral and biochemical tests were monitored every 12 weeks. The primary outcome was the rate of recompensation as defined by the Baveno VII definition and the criteria of stable improvement in liver function tests reported by us. Multivariate logistic regressions were used to identify the optimal prediction time and to build prediction models.
Results: Of the 320 recruited patients, 283 completed the 120-week entecavir treatment and follow-up, with 56.2% (159/283) of them achieving recompensation at week 120. Treatment week 24 was the optimal time to predict recompensation, with an albumin level of 34 g/L or greater being a reliable threshold for recompensation (AUROC: 0.676) at treatment week 120. Furthermore, a model based on platelet count, serum albumin, and sodium level (Brec-PAS models) at treatment week 24 offered better predictability (AUROC: 0.749) for recompensation at treatment week 120, outperforming the MELD (AUROC: 0.629, p = 0.002) and FIB-4 scores (AUROC: 0.702, p = 0.097).

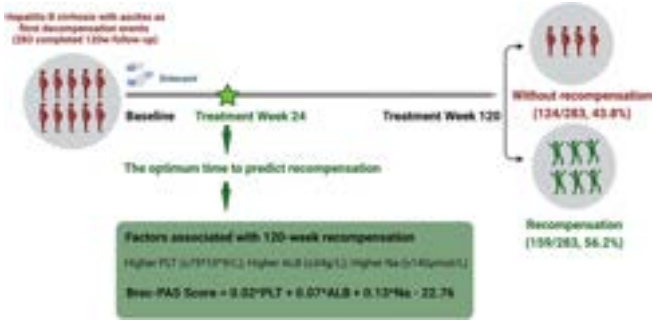

Figure:

Conclusion: At treatment week 24, the serum albumin level of 34 g/L or greater was a simple predictor, whereas Brec-PAS model was a more accurate predictor tool for 120-week recompensation in entecavir-treated CHB patients with decompensated cirrhosis.

WED-333
Temporal trajectory of the model for end-stage liver disease (MELD) score for prediction of mortality among patients with liver cirrhosis
Niv Zmora[1], Lian Bannon[1], Oren Shibolet[1], Liane Rabinowich[1]. *[1]Tel Aviv Sourasky Medical Center-Ichilov, Department of Gastroenterology and Hepatology, Tel Aviv-Yafo, Israel*
Email: nivz@tlvmc.gov.il

Background and aims: The Model for End-Stage Liver Disease (MELD) score and its modification, the MELD-Na score, are important prognostic indicators for patients with liver cirrhosis, as predictors of 3-month survival as well as prioritization and organ allocation in liver transplantation. The scores provide a snapshot of mortality risk at a specific time-point, irrespective of the preceding course of liver disease. Our aim was to assess whether the trajectory in MELD-Na score over time affect mortality rates in patients with liver cirrhosis.
Method: MELD-Na score was retrospectively applied to patients diagnosed with liver cirrhosis who died between the years 2004–2023 at the Tel-Aviv Sourasky Medical Center. Patients with at least 5 records of relevant blood tests required for MELD-Na score calculation (serum bilirubin, creatinine, sodium and international normalized ratio [INR]) within 2 years prior to death were included. The cumulative MELD-Na score was calculated for each patient throughout the study period using incremental area under the MELD-Na curve, and was correlated to patient survival for each MELD-Na score from 9 onwards.

Results: Within the study period there were 1,905 reported deaths among patients diagnosed with liver cirrhosis, of whom 982 were eligible for analysis, encompassing 13,136 calculated MELD-Na scores (average MELD-Na score 19.26 ± 6.88). Observed 3-month mortality rates for each MELD-Na score were higher than predicted by the published model (59.03% for scores in the range of 10–19; 84.14% for scores in the range of 20–29; and 97.27% for scores between 30–39). MELD-Na scores between 9–15 exhibited a statistically significant dependence on MELD-Na history (p values 0–0.05), with an inverse correlation between survival and cumulative MELD-Na scores (correlation coefficient range 0.07–0.20).

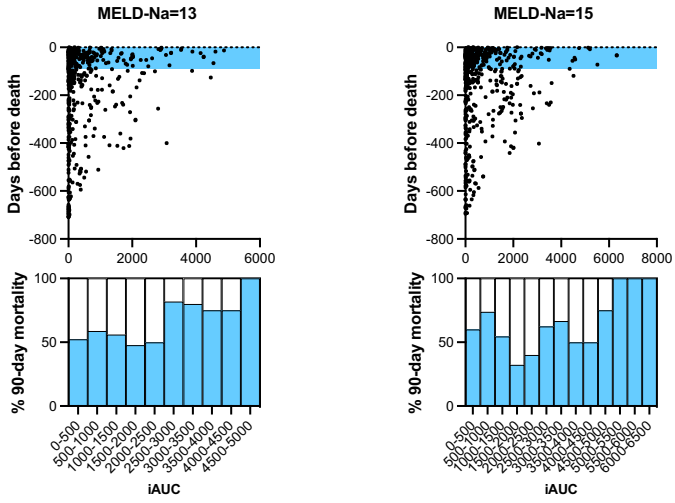

Figure: Top: Correlation between cumulative MELD-Na score to survival in instances where MELD-Na = 13 (left) and 15 (right). Blue fill denotes a 90-day mortality time frame; Bottom: percentage of 90-day mortality binned by iAUC values

Conclusion: In patients with cirrhosis and mild liver dysfunction, temporal trajectories in MELD-Na scores may aid in optimizing prediction of 90-day mortality.

WED-334

Smoking and obesity promote systemic inflammation in patients with compensated and decompensated cirrhosis

Benedikt Hofer[1,2,3], Benedikt Simbrunner[1,2,3], Georg Semmler[1,2], Michael Schwarz[1,2], Lorenz Balcar[1,2], Lukas Hartl[1,2], Mathias Jachs[1,2], Katharina Pomej[1,2], Rafael Paternostro[1,2], Theresa Müllner-Bucsics[1,2], Philipp Schwabl[1,2,3], Bernhard Scheiner[1,2], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2,3]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria, [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria, [3]Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Cigarette smoking and obesity have been linked to systemic inflammation in patients with cardiovascular disease. The relative contribution of these two factors to the proinflammatory state in patients with advanced chronic liver disease (ACLD) remains unknown.

Method: ACLD patients with either compensated (cACLD, n = 284) or decompensated (dACLD, n = 416) disease and available information regarding smoking status and body mass index (BMI) were included. Blood markers of systemic inflammation (white blood cell count [WBC], C-reactive protein [CRP]) were evaluated in groups of "never-smokers" vs "ex-smokers" vs "active smokers" and in BMI strata "BMI < 25" vs "BMI25-30" vs "BMI > 30.".

Results: Overall, 106 cACLD patients (37.3%) and 160 dACLD patients (38.5%) reported active smoking. 84 cACLD patients (29.6%) and 78 dACLD patients (23.5%; grade 3 ascites patients [n = 84] were excluded from all BMI analyses) presented with obesity (i.e., BMI > 30 kg/m2). In cACLD patients, median WBC increased according to smoking status (never: 4.3 vs ex: 5.1 vs active: 6.0 G/L; p < 0.001), with a significant difference between never-smokers and ex-smokers (p = 0.025) or active smokers (p < 0.001), as well as between ex-smokers and active smokers (p = 0.009). No significant difference was observed for CRP (p = 0.649). In dACLD, active smokers and ex-smokers demonstrated a significant increase in WBC (never: 4.4 vs ex: 4.8 vs active: 5.6 G/L; p < 0.001) and a clear trend for CRP (never: 3.9 vs ex: 4.9 vs active: 5.1 mg/L; p = 0.176). Importantly, the link between active smoking and increased WBC remained significant in both cACLD (<0.001) and dACLD (p < 0.001) after adjusting for MELD in a multivariable linear regression model. With regard to obesity, BMI showed a significant positive correlation with CRP both in cACLD (Spearman's r: 0.17; p = 0.004) and dACLD patients (r: 0.11; p = 0.039). Accordingly, CRP was significantly higher in patients with BMI > 30 vs BMI25-30 and BMI < 25 in cACLD patients (2.7 vs 1.6 and 1.8 mg/L; p = 0.035) and in dACLD patients (4.7 vs 3.3 and 3.2 mg/L; p = 0.113). Taking cACLD and dACLD together, active smokers with BMI > 30 (n = 46) showed significantly higher levels of systemic inflammation compared to never-smokers with BMI<25 (n = 79): WBC (6.6 vs 4.3 G/L; p < 0.001), CRP (4.7 vs 2.2 mg/L; p = 0.004). WBC (p = 0.134) and CRP (p = 0.145) in ex-smokers with BMI 25–30 (n = 72) were not significantly different from never-smokers with BMI<25 (Figure).

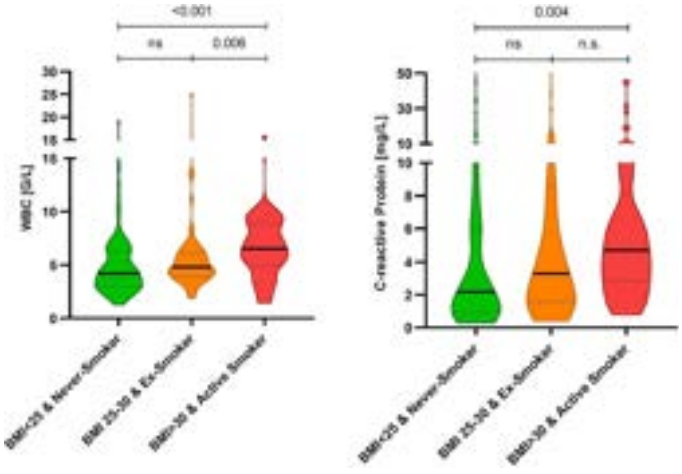

Figure:

Conclusion: In a large cohort of patients with compensated and decompensated cirrhosis, both active smoking and obesity promote a proinflammatory state. Thus, cessation of smoking should be encouraged in all ACLD patients, and weight loss in those with obesity.

WED-335

Association of polymorphisms in genes of the innate immunity with transplant-free survival of patients with decompensated liver cirrhosis

Niclas Selzer[1], Janett Fischer[1], Adam Herber[1], Niklas Aehling[2], Madlen Matz-Soja[1], Thomas Berg[1]. *[1]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Germany, [2]Internal Medicine III-Gastroenterology, University Hospital of Augsburg, Germany*
Email: janett.fischer@medizin.uni-leipzig.de

Background and aims: Liver cirrhosis is associated with severe complications such as acute-on-chronic-liver-failure (ACLF), ascites as well as infections, especially spontaneous bacterial peritonitis (SBP). Several single nucleotide polymorphisms (SNP) have been

reported to affect innate immune responses. In previous studies, some SNPs in patients with liver cirrhosis were associated with altered patient survival, the occurrence of SBPs or cytokine response to bacteria. The aim of our study was to assess the impact of known SNPs in the genes of toll-like receptor 1, 2, 4, 5 and 6, the cluster of differentiation 14 (CD14), nucleotide-binding oligomerization domain-containing protein 2 (NOD2), the farnesoid-X receptor (FXR) and the Mannose-binding lectin 2 (MBL2) on disease progression and transplantation-free survival of patients with liver cirrhosis and ascites in a large, well-characterized cohort.

Method: In our study, we genotyped 409 patients with liver cirrhosis and ascites for 28 SNPs of the innate immune system. We then correlated the genotypes with clinical data from the time of inclusion and with the incidence of infections and survival over a period of 180 days after inclusion. Both the entire cohort and subgroups divided according to a low and high MELD-score (cut-off 17) and sex were examined.

Results: In the main cohort, the genotypes CT and TT of the *TLR4* SNP rs4986791 ($p = 0.039$; OR: 1.881) as well as the genotype CG of the *NOD2* SNP rs2066845 ($p = 0.025$; OR: 2.853) where significantly associated with a reduced transplant-free survival. Additionally, we found an association between CT and TT genotypes of the SNP *FXR* rs386377 and an increased occurrence of SBP ($p = 0.01$; OR: 2.986). Patients with the CC genotype of the *MBL2* SNP rs5030737 survived significantly shorter than other patients ($p = 0.037$; OR: 0.406).

We observed more associations between variants and a worsened course of disease in the females compared to male patients (8,3% vs. 2,4%) as well as in the low-MELD subgroup compared to the high-MELD cohort (4,8% vs. 0%).

Conclusion: We identified several variants in the innate immune system that affect the clinical course of disease in patients with decompensated liver cirrhosis independently from other known risk factors. Thus, panels with different risk genotypes should be implemented into personalized medicine to identify patients with an increased risk of a severe course of the disease.

WED-336

Applicability of EASL clinical guidelines recommendations of empiric antibiotic treatment for spontaneous bacterial infections in patients with cirrhosis in South America

Melisa Dirchwolf[1,2], Marina Agozino[3], Gonzalo Gomez Perdiguero[4], Ivonne Giselle Duarte[5], Maria Dolores Murga[6], Fernando Bessone[7], Sebastian Eduardo Ferretti[8], Diego Arufe[9], Andres Bruno[10], Astrid Smud[4], Diego Giunta[4], Martín Elizondo[11], Hugo Fainboim[12], Adrian Gadano[4], Julia Brutti[13], Josefina Pages[14], German Rojas[15], Esteban Gonzalez Ballerga[15], Alina Zerega[16], Maria Garrido[17], Natalie Vilcinskas Y Botteron[18], Matias Machain[19], Sebastián Marciano[4]. *[1]Hospital Privado de Rosario, Argentina, [2]Hospital Privado de Rosario, Liver Unit, Rosario, Argentina, [3]Sanatorio Guemes, Argentina, [4]Hospital Italiano de Buenos Aires, Argentina, [5]Hospital 4 de Junio, Argentina, [6]Hospital A.C. Padilla, Argentina, [7]Hospital Provincial del Centenario, Argentina, [8]Sanatorio Parque de Rosario, Argentina, [9]Sanatorio Sagrado Corazón, Argentina, [10]Hospital Argerich, Argentina, [11]Unidad Bi-Institucional de Trasplante Hepático: Hospital Militar HCFFAA y Hospital de Clínicas,., Uruguay, [12]Hospital de Infecciosas Francisco Javier Muñiz, Argentina, [13]Hospital Aleman, Argentina, [14]Hospital Universitario Austral, Argentina, [15]Hospital de Clínicas José de San Martín, Argentina, [16]Sanatorio Allende, Argentina, [17]Hospital Central Ramon Carrillo, Argentina, [18]Hospital Central de Mendoza, Argentina, [19]Hospital Privado de la Comunidad de Mar del Plata, Argentina*
Email: marinaagozino@hotmail.com

Background and aims: Clinical practice guidelines of major scientific societies are widely used to choose empiric antibiotic treatment for patients with cirrhosis. It is paramount to assess these recommendations' applicability in each epidemiological setting to guarantee optimal pathogen coverage. We aim to evaluate the applicability of the latest EASL clinical guidelines recommendations for empiric antibiotic treatment for spontaneous bacterial infections according to the acquisition site.

Method: Cross-sectional study on the database of a multicenter prospective cohort study of patients with cirrhosis and bacterial infections in Argentina and Uruguay (NCT03919032). Only culture-positive spontaneous infections were included in this study: spontaneous bacterial peritonitis (SBP), spontaneous bacterial empyema (SBE), and spontaneous bacteremia (SB). We estimated the proportion of antibiotic susceptibility according to where the infection was acquired: community-acquired (CA), healthcare-associated (HCA), or nosocomial (NOS). Regarding applicability, approximately 80% coverage is advisable for empiric treatments in stable patients, and 90% for critically-ill patients.

Results: We included 154 patients: 74 (48%) SBP, 70 (45%) SB, and 10 (7%) SBE. Regarding the site of acquisition, 42% were CA, 34% NOS, and 24% HCA. Gram-positive and negative bacteria were isolated in 53% and 47% of the infections. The prevalence of multidrug-resistant organisms (MDROs) was 34%. Only cefepime and piperacillin-tazobactam offer rational coverage for CA and HCA infections, and imipenem or meropenem for NOS infections. Only meropenem or imipenem combined with vancomycin offer a coverage superior to 90% (table). When considering EASL recommendations for CA that include third generation cephalosporins or piperacillin-tazobactam, empiric coverage ranges from 43–81%; whereas for HCA or nosocomial infections the observed coverage with carbapenems with/without vancomycin ranges from 53–97%, depending on which antibiotic is considered even within the same antibiotic group.

Table: Proportion of isolations that were susceptible to selected antibiotics, according to the site of acquisition of the infection

	Community Acquired (n = 64)	HCA (n = 37)	Nosocomial (n = 53)
Ceftriaxone	34 (53%)	17 (46%)	18 (34%)
Cefepime	47 (75%)	23 (64%)	25 (49%)
Ceftazidime	27 (43%)	11 (31%)	16 (32%)
Piperacillin-tazobactam	52 (81%)	28 (76%)	31 (59%)
Imipenem or meropenem	53 (83%)	29 (78%)	36 (68%)
Imipenem or meropenem + Vancomycin*	63 (100%)	35 (97%)	49 (94%)
Ertapenem	47 (73%)	22 (59%)	28 (53%)

*available in 151 patients.

Conclusion: When considering EASL recommendations for empiric antibiotic treatment in spontaneous infections in cirrhosis according to the site of infection, we observed a wide range of coverage depending on which antibiotic is considered in this cohort of patients from South America. These findings demonstrate that all recommended regimens are not equivalent, even within antibiotic groups, which underlines the urgent need to tailor clinical practice guidelines to local epidemiology to optimize treatment efficacy.

WED-337

Progression of cirrhosis is not associated with clinically significant alterations in hemostasis assessed by thromboelastography

Alina Buliarcă[1], Bogdan Procopet[1,2], Daniela Matei[1,2], Horia Stefanescu[3], Rares Craciun[1], Zeno Sparchez[1,2]. *[1]"Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania, [2]"Prof. Dr. O. Fodor" Regional Institute of Gastroenterology and Hepatology, Cluj-Napoca, Romania, [3]Regional Institute of Gastroenterology and Hepatology, Liver Unit and Clinical Ultrasound Department, Cluj Napoca, Romania*
Email: bogdan.procopet@umfcluj.ro

Background and aims: Standard coagulation tests (SCTs) do not adequately reflect hemostasis in patients with cirrhosis. Thromboelastography (TEG) provides a more balanced overview of coagulation, assessing clotting factors (R-time), fibrinogen (K, alpha

angle), platelet function (maximum amplitude-MA), and fibrinolysis (Ly30). The current study investigated whether abnormal SCTs and liver disease severity are associated with alterations in TEG-based variables in patients with cirrhosis.
Method: Consecutive patients with liver cirrhosis and abnormal SCTs (at least one of International Normalized Ratio-INR >2, platelet count <50.000/µL, fibrinogen <200 mg/dL) were analyzed using native TEG. 19 (17.9%) patients underwent high-risk interventional procedures. The patients were divided according to liver disease severity (group 1-Child A and B, group 2-Child C). SCTs and TEG were compared between the two groups. The TEG abnormalities were assessed in relation to traditional cut-offs for interventional procedures.
Results: Of the 106 patients, 44 (41.5%) were included in group 1 and 62 (58.5%) in group 2. 65.1% of patients had a normal TEG. However, none of the remaining patients fulfilled the TEG-guided transfusion criteria. There were significant differences regarding INR-1.43 (1.25–1.61) vs. 2.57 (1.77–3.37) and fibrinogen levels-248 (189.5–306.5) vs. 155 (90.5–210.5) mg/dL between the two groups. In contrast, there were no significant differences regarding platelet count (p = 0.16) or any of the TEG variables (R-p = 0.51, K-p = 0.28, alpha angle-p = 0.70, MA-p = 0.72, and Ly30-p = 0.74). While there were significant differences in R time between patients with an INR below (n = 56) or above (n = 50) 2 (9.95 ± 4.31 vs. 12.44 ± 5.55, p = 0.01), only two patients (4%) with an INR >2 exceeded the reference values for R. Patients with a platelet count below 50000/µL (n = 36) had a lower MA compared to those (n = 70) exceeding the threshold value (42.38 ± 13.85 vs. 55.02 ± 14.10, p < 0.001). The overall accuracy for the 50000/µL platelet cut-off in predicting platelet dysfunction expressed by MA was 72.64%. Regarding fibrinogen, patients with a value above 200 mg/dL had a higher alpha angle (44.86 ± 15.62 vs. 36.29 ± 16.08, p = 0.01). Nevertheless, only 4 (3.7%) patients had values below the reference range. There were no significant differences regarding the K-time (p = 0.40). No periprocedural bleeding events were recorded.
Conclusion: There is no evidence of progressive worsening of the coagulation status with a more advanced liver disease based on native TEG analysis. Overall, SCTs have poor correspondence with TEG variables.

WED-338
Decreased platelet function is an independent predictor of liver-related and all-cause mortality in patients with advanced chronic liver disease

Benedikt Hofer[1,2,3,4], Ksenia Brusilovskaya[1,3,4], Benedikt Simbrunner[1,2,3,4], Beate Eichelberger[5], Silvia Lee[6], David JM Bauer[1,2], Mattias Mandorfer[1,2], Philipp Schwabl[1,2,3,4], Simon Panzer[5], Thomas Reiberger[1,2,3,4], Thomas Gremmel[6,7,8].
[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria, [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria, [3]Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria, [4]Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria, [5]Medical University of Vienna, Department of Blood Group Serology and Transfusion Medicine, Vienna, Austria, [6]Medical University of Vienna, Department of Internal Medicine II, Vienna, Austria, [7]Karl Landsteiner Society, Institute of Cardiovascular Pharmacotherapy and Interventional Cardiology, St. Pölten, Austria, [8]Landesklinikum Mistelbach-Gänserndorf, Department of Internal Medicine I, Cardiology and Intensive Care Medicine, Mistelbach, Austria
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Patients with advanced chronic liver disease (ACLD) are at an increased risk of both bleeding and thromboembolic events. Thrombocytopenia due to portal hypertension (PH), as well as abnormal platelet activation and function, have been reported in ACLD. We aimed to assess whether alterations in platelet activation predict liver-related events.
Method: Within this prospective study, we included patients with ACLD undergoing a baseline measurement of the hepatic venous pressure gradient (HVPG). Platelet responsiveness was assessed by measuring surface expression of P-selectin by flow cytometry after stimulation with either the protease-activated receptor (PAR)-1 agonist TRAP (thrombin receptor activating peptide), the PAR-4 agonist AYPGKF or epinephrine.
Results: Overall, 107 ACLD patients (71% male; median age: 55.3 [IQR: 46.4–62.9] years; median HVPG: 18 [IQR: 12–21] mmHg) were included. During a median follow-up period of 25.3 (IQR: 15.7–31.2) months, 17 patients (15.8%) died. Of those deaths, 11 were considered liver-related. In univariable analysis, higher platelet surface expression of P-selectin in response to TRAP (HR per 100 MFI [median fluorescence intensity]: 0.92 [95%CI: 0.86–0.97]; p = 0.006) or AYPGKF (HR per 10 MFI: 0.93 [95%CI: 0.87–0.99]; p = 0.034) was significantly linked to a lower risk of all-cause mortality. In addition, a higher surface expression of P-selectin in response to TRAP was also associated with a reduced risk of liver-related mortality within the univariable analysis (HR per 100 MFI: 0.92 [95%CI: 0.85–0.99]; p = 0.026). Importantly, the predictive role of TRAP-inducible P-selectin expression with regard to all-cause mortality remained significant in a multivariable model adjusted for MELD (model for end-stage liver disease) and HVPG (aHR: per 100 MFI: 0.93 [95%CI: 0.87–0.99]; p = 0.019). Six patients presented with de novo portal vein thrombosis (PVT) during follow-up. Interestingly, higher P-selectin expression in response to epinephrine stimulation was significantly linked to a higher risk of developing PVT (HR per 10 MFI: 1.08 [95%CI: 1.03–1.14]; p = 0.004), while no connection was found for other platelet activation parameters.
Conclusion: The assessment of platelet responsiveness provides additional prognostic information in ACLD patients on top of liver disease and PH severity. While higher PAR-1 and PAR-4 mediated platelet activation was linked to a decreased risk of liver-related and all-cause mortality, an increase in epinephrin-inducible platelet activation was associated with de novo PVT development.

WED-339
Thromboelastography-guided coagulopathy correction in cirrhotic patients decreases blood product transfusion: a systematic review and analysis

Hamed Komeylian[1], Carmen Ching[2], Julie Zhu[3]. *[1]Dalhousie University, Gastroenterology, Canada, [2]Dalhousie University, Faculty of Medicine, Canada, [3]Dalhousie University, Gastronetrology, Canada*
Email: h.komeylian@gmail.com

Background and aims: Patients with cirrhosis are a risk factor for coagulopathy and bleeding complications. Thromboelastography (TEG) guided therapy is available to rapidly assess and guide blood product transfusion in this population. This study aims to determine if TEG-guided therapy is able to decrease the administration of blood products and reduce adverse events such as bleeding and mortality compared to standard coagulation testing (SCT).
Method: We performed a systematic review and meta-analysis of literature in PubMed, EMBASE, and The Cochrane Library and pooled six randomized-controlled trials comparing thromboelastography versus standard coagulation testing in patients with cirrhosis. A total of six studies were pooled (n = 386). Primary outcomes were mean platelet transfusion units and fresh frozen plasma (FFP) transfusion units. Secondary outcomes were mortality and bleeding events.
Results: Compared to SCT, there was a significant standard mean decrease in platelet (p < 0.00001) and FFP (p < 0.00001) administration compared to TEG perioperatively prior to a liver transplant. However, there was no significant difference in the pooled odds ratio between TEG and SCT in patients receiving both platelets and FFP (OR 1.40 [95% CI 0.61–3.23, P = 0.42]). Recurrent variceal bleeding was significantly reduced in the TEG group compared to SCT for platelet transfusion (OR 0.05 [95% CI 0.01–0.20, P < 0.0001]) or FFP transfusions (OR 0.18 [95% CI 0.05–0.63, P = 0.007]). With regards to the 5-

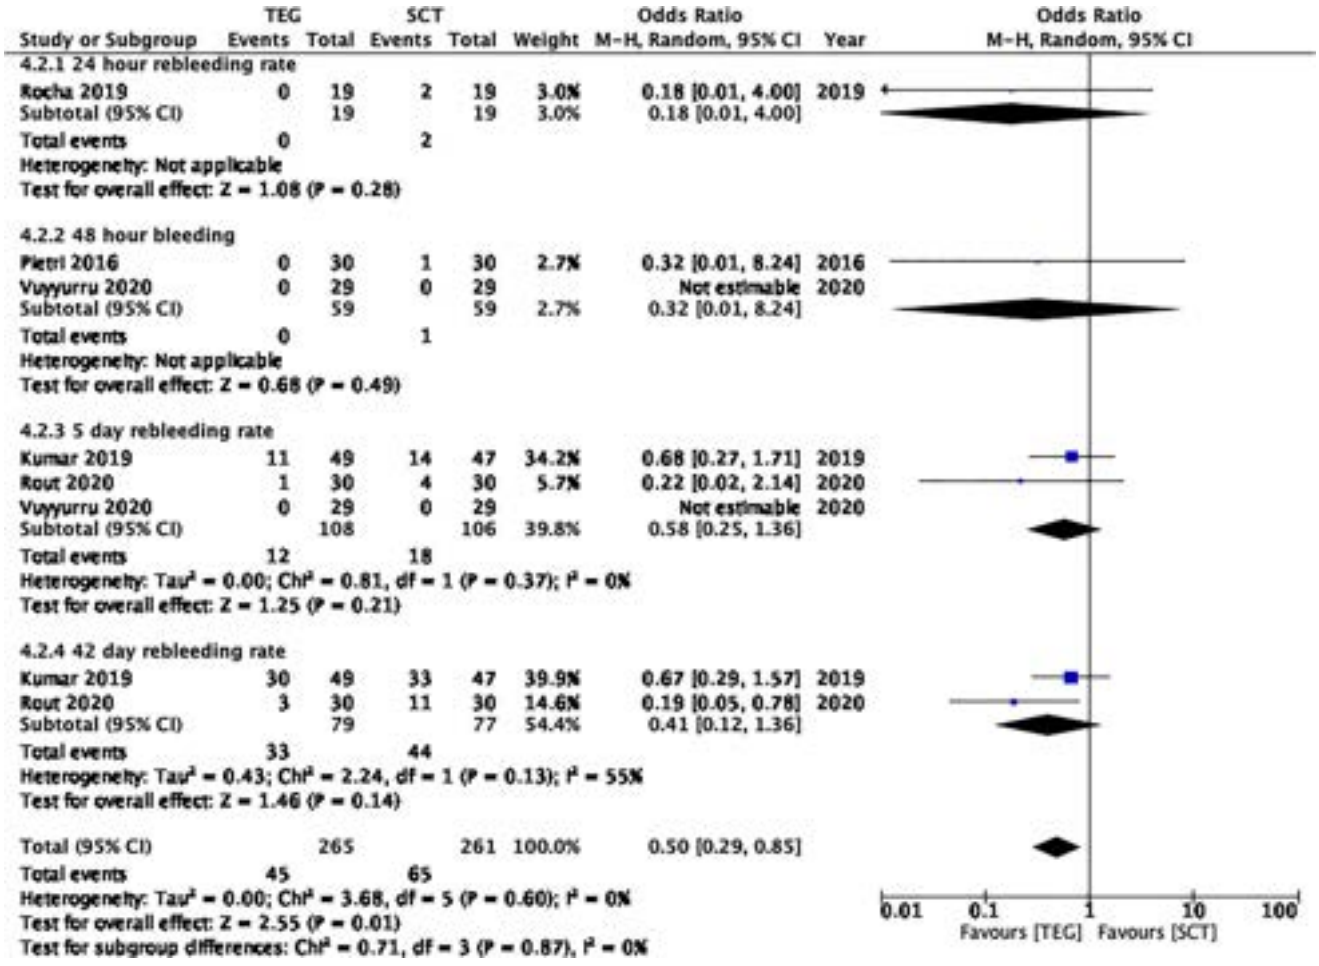

Figure: (abstract: 339).

day, 28-day, 42-day, and 90-day mortality, there was no significant difference between the pooled odds ratio between the TEG and SCT groups (OR 0.69 [95% CI 0.47–1.02, P = 0.06]). The 24-hour, 48-hour, 5-day, and 42-day rebleeding rates were significantly lower in TEG versus SCT groups (OR 0.50 [95% CI 0.29–0.85, p = 0.01)].

Conclusion: The use of TEG-guided therapy favors a reduction in platelet and FFP transfusion compared to SCT in patients with cirrhosis. Additionally, TEG-guided therapy is able to improve patient care by reducing the rebleeding rate of patients with cirrhosis compared to SCT. However, this same effect was not seen for mortality.

WED-340

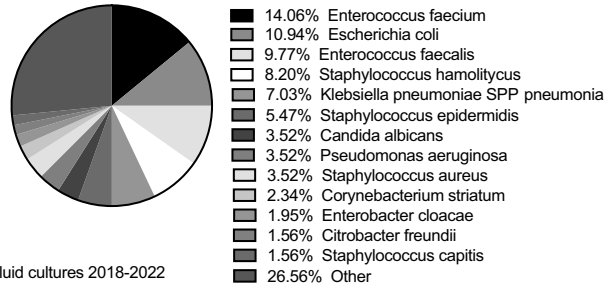
An overview on microbial population in liver cirrhosis : changing paradigm in the known bacteriology of spontaneous bacterial peritonitis

Shirin Demma[1], Bruno Mariani[2], Valerio Giannelli[1], Claudia Telesca[1], Roberto Villani[1], Adriano Pellicelli[1]. [1]*Azienda Ospedaliera San Camillo Forlanini, Dipartimento Interaziendale Trapianti POIT, Italy,* [2]*Azienda Ospedaliera San Camillo Forlanini, Microbiology, Italy*
Email: s.demma@ucl.ac.uk

Background and aims: Liver cirrhosis is a leading cause of death worldwide. Patients with cirrhosis have several biological and immunological alterations that predispose to the development of infections. The spread of multidrug resistant (MDR) infections has been blamed as responsible for the increase in mortality risk in cirrhosis. Therefore, improvement in the management of bacterial infections represents an absolute priority for patients with cirrhosis. We aimed to examine the epidemiology and resistance phenotypes in cirrhotic patients admitted to our liver unit in order to analyse our microbial population and the prevalence of MDR bacteria.

Method: Ascitic fluid cultures from consecutive cirrhotic patients admitted to our liver unit in a tertiary centre in Rome (Italy) over a 4-year period (2018–2022) were analyzed to identify and explore the microbial population and the prevalence of MDR bacteria. Data on organisms culture and proportions of antibiotic resistance were collected. We then compared the results with the results of the ascitic fluid cultures collected over the previous 4-year period (2013–2017) to analyse the trend.

Results: In total 1219 ascitic fluid samples were identified. Organisms were cultured in 256 samples with Enterococcus Faecium as the most represented (14.06%), followed by Escherichia Coli (10.94%) and Enterococcus Faecalis (9.77%). In terms of resistance phenotypes, among the enterococci population, 14.75% were vancomycin resistant enterococci (VRE) and 1.63% were resistant to linezolid (LZD); 27.78% Enterobacteriaceae were extended-spectrum beta-lactamase (ESBL) and 11.11% were carbapenem resistant (CBPEN). All the Acinetobacter Baumannii identified were MDR and CLS-S. Comparing to the previous 4-year period, Candida albicans is less represented while the prevalence of Acinetobacter Baumannii is increasing. Enterococci was confirmed to be the most represented microbial population in our area.



Ascitic fluid cultures 2018-2022

Figure:

Conclusion: Interestingly, in our cohort, gram positive Enterococci were the most representative microbial population in ascitic fluid. This confirms the trend that has been demonstrated in the last years and represent a changing paradigm in the known bacteriology of spontaneous bacterial peritonitis (SBP). This might be related to the long-term quinolone administration, the overuse of extended spectrum antimicrobials or to the increase of invasive intervention. MDR Acinetobacter is a concern as resistance to colistin is increasing worldwide. Knowing the local microbial epidemiology and the resistance rate is fundamental in order to address the best antimicrobial empiric therapy where microbial characterization and antibiogram is not yet available.

WED-341

The combination of LACE index, MELD on discharge and a previous history of decompensation defines risk groups for early readmission in patients with liver cirrhosis

Yolanda Sánchez[1], Jose Miguel Rosales Zabal[2], Isabel Carmona[3], Marta Casado[4], Carlota Jimeno Mate[5], Ana Torres[2], Paula Fernandez Alvarez[3], Miren Garcia Cortes[6], Alberto Garcia Garcia[6], Paloma Alañón[7], Maria Angeles Lopez Garrido[8], Manuel Romero Gomez[1,9], Carmen Sendra[10], Matias Estevez[11], Miguel Jiménez[12], Javier Ampuero[1,9]. *[1]Hospital Universitario Virgen del Rocio, Sevilla, Spain, [2]Hospital Costa del Sol, Marbella, Spain, [3]Hospital Universitario Virgen Macarena, Sevilla, Spain, [4]Hospital Universitario Torrecárdenas, Almería, Spain, [5]Hospital Universitario Valme, Sevilla, Spain, [6]Hospital Universitario Virgen Victoria, Málaga, Spain, [7]Hospital Universitario Reina Sofía, Córdoba, Spain, [8]Hospital Universitario Virgen de las Nieves, Granada, Spain, [9]Instituto de Biomedicina de Sevilla, Sevilla, Spain, [10]Hospital Infanta Elena, Huelva, Spain, [11]Hospital Poniente, El Ejido, Spain, [12]Hospital Regional, Málaga, Spain*
Email: javi.ampuero@gmail.com

Background and aims: Reducing early (<30 days) hospital readmissions is a policy priority to improve the healthcare quality in liver diseases. Thus, we aimed to: a) determine risk factors associated with 30-day hospital readmission in patients with liver cirrhosis; b) identify a subset of patients at risk of 90-day readmission and mortality; c) explore the usefulness of the model in the management of cirrhotic patients in the outpatient clinic.

Method: Multicenter and retrospective study including 885 patients with cirrhosis admitted to the Liver Unit and followed up 90 days after hospital discharge. We collected readmissions and all-cause mortality up to 90 days after discharge. In addition, LACE index was calculated, which comprises Charlson comorbidity index, the number of times in the Emergency Room 6 months before the admission, urgent versus scheduled admission, and length of the hospitalization.

Results: Finally, 818 patients were included in the study, of which 23.2% (190/818) and 42.4% (347/818) required a hospital readmission at 30 and 90 days, respectively, and 13.6% (111/818) died. The main reason for hospitalization was ascites (36%) followed by variceal bleeding (23%), while the leading cause of 30-day readmission was hepatic encephalopathy (35%). LACE index (OR 1.11 (IC95% 1.03–1.20); p = 0.006), MELD on discharge (OR 1.05 (IC95% 1.02–1.08); p = 0.003), and a history of a decompensated event (IC95% 0.99–2.00); p = 0.056) were independently associated with 30-day readmission. Further, according to 90% sensitivity and 90% specificity, this model predicted three risk groups of readmission and survival during the follow-up (Figure). Despite the time to the scheduled outpatient clinic after admission was similar between groups (45 ± 38 vs. 46 ± 40 vs. 50 ± 42 days; p = 0.593), 33% (30/91) of patients belonging to the high-risk group required a hospital readmission before going to the clinic versus 25.7% (148/575) and 14.7% (20/136) (p = 0.002) of intermediate- and low-risk groups, respectively.

Conclusion: The combination between the LACE index, MELD on discharge, and a previous history of decompensation identified different groups at risk of 30-day and 90-day readmission and mortality in patients with liver cirrhosis. This model should be considered for scheduling the outpatient clinic after hospitalization.

WED-342

Factors associated with inpatient albumin administration and center-level variation in a national cohort

Marina Serper[1], Tamar Taddei[2], David Kaplan[1], Thomas Ardiles[3], Elisabet Viayna[3], Nadim Mahmud[1]. *[1]University of Pennsylvania, United States, [2]Yale University, United States, [3]Grifols, United States*
Email: marinas2@pennmedicine.upenn.edu

Background and aims: Guidelines recommend albumin administration in patients with cirrhosis complications including hepatorenal syndrome (HRS), spontaneous bacterial peritonitis (SBP), and in the evaluation and management of acute kidney injury. However, variation in albumin use is not well-characterized. We investigated

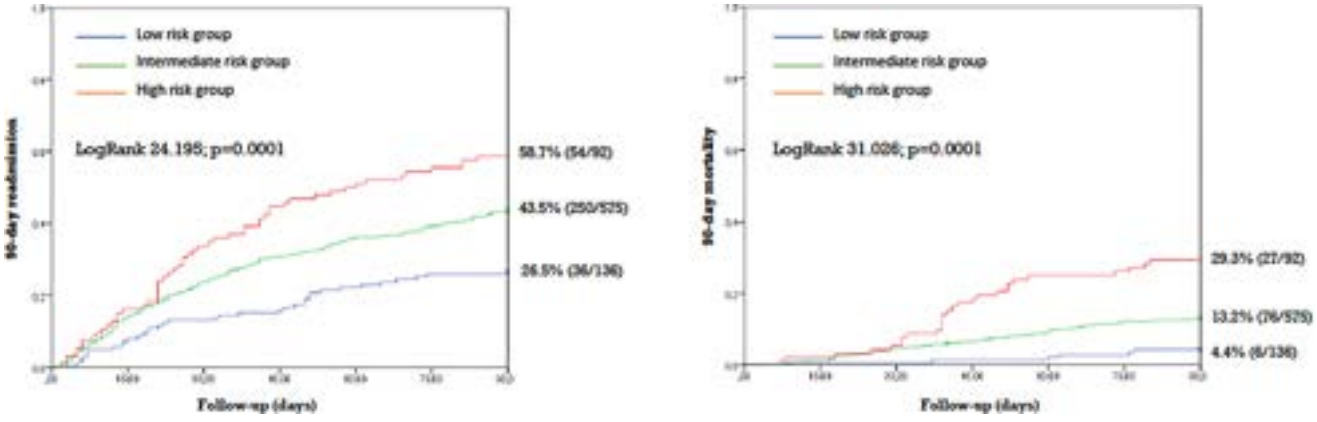


Figure: (abstract: WED-341).

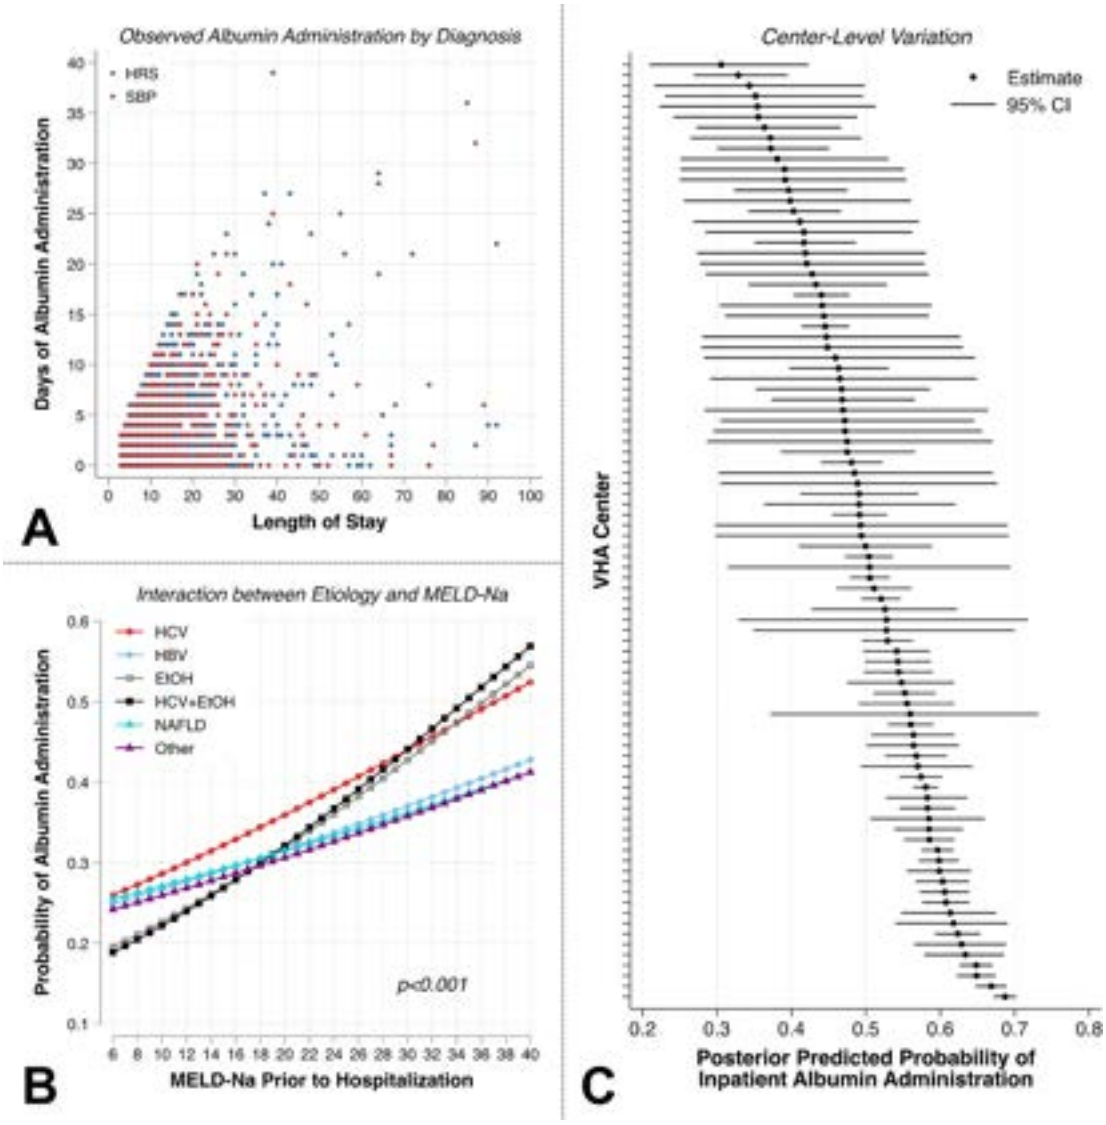

Figure: (abstract: WED-342).

inpatient albumin use, factors associated, and center-level variation in a cirrhosis cohort in the Veterans Affairs (VA) system across all 50 United States.

Method: We performed a retrospective cohort study using a well-characterized cohort of patients in the VA with cirrhosis. We identified all inpatient hospitalizations between 2008 and 2022 and ascertained all inpatient albumin use through via inpatient files. Hospitalizations were excluded for patients with a history of liver transplantation or if the length of stay (LOS) was ≤2 days. Patient baseline characteristics were collected immediately prior hospitalization. Hospitalizations were categorized as due to HRS, SBP, or other. To identify variables associated with inpatient albumin administration we used multivariable logistic regression with *a priori* modeling approaches. To explore variation in the probability of albumin administration across 90 VA centers we used mixed-effects logistic regression.

Results: The cohort included 49,611 hospitalizations among 11,149 patients. Albumin was administered in 14,882 (30.0%) hospitalizations; with a variation in days of albumin administered for different LOS in patients with HRS or SBP (Figure panel A). In multivariable logistic regression, higher odds of albumin use was associated with increased age (OR 1.02 per year, 95% CI 1.01–1.02, $p < 0.001$), HRS (OR 4.30, 95% CI 3.84–4.81, $p < 0.001$), SBP (OR 4.13, 95% CI 3.74–4.56, $p < 0.001$), prior decompensation (OR 1.34, 95% CI 1.27–1.40, $p < 0.001$), and increased LOS (OR 1.01 per day, 95% CI 1.01–1.01, $p < 0.001$). Heart failure was associated with a reduced odds of albumin use (OR 0.65, 95% CI 0.61–0.68, $p < 0.001$). There was a significant interaction between MELD-Na and etiology of liver disease ($p < 0.001$), those with alcohol or hepatitis C-related cirrhosis were more likely to receive albumin at higher MELD-Na scores as compared to other etiologies (Figure panel B). In a mixed-effects logistic regression model adjusted for all variables included in the prior model and accounting for VA center as a random intercept, there was significant adjusted center-level variation in the probability of albumin use ($p < 0.001$; Figure panel C) which ranged from 31% to 69% holding all other clinical factors equal. Larger volume centers were more likely to use inpatient albumin.

Conclusion: In a large VA cohort of patients with cirrhosis, we identify key variables associated with inpatient albumin administration. Substantial center-level variation in albumin use suggests gaps in guideline-recommended care that warrants future studies.

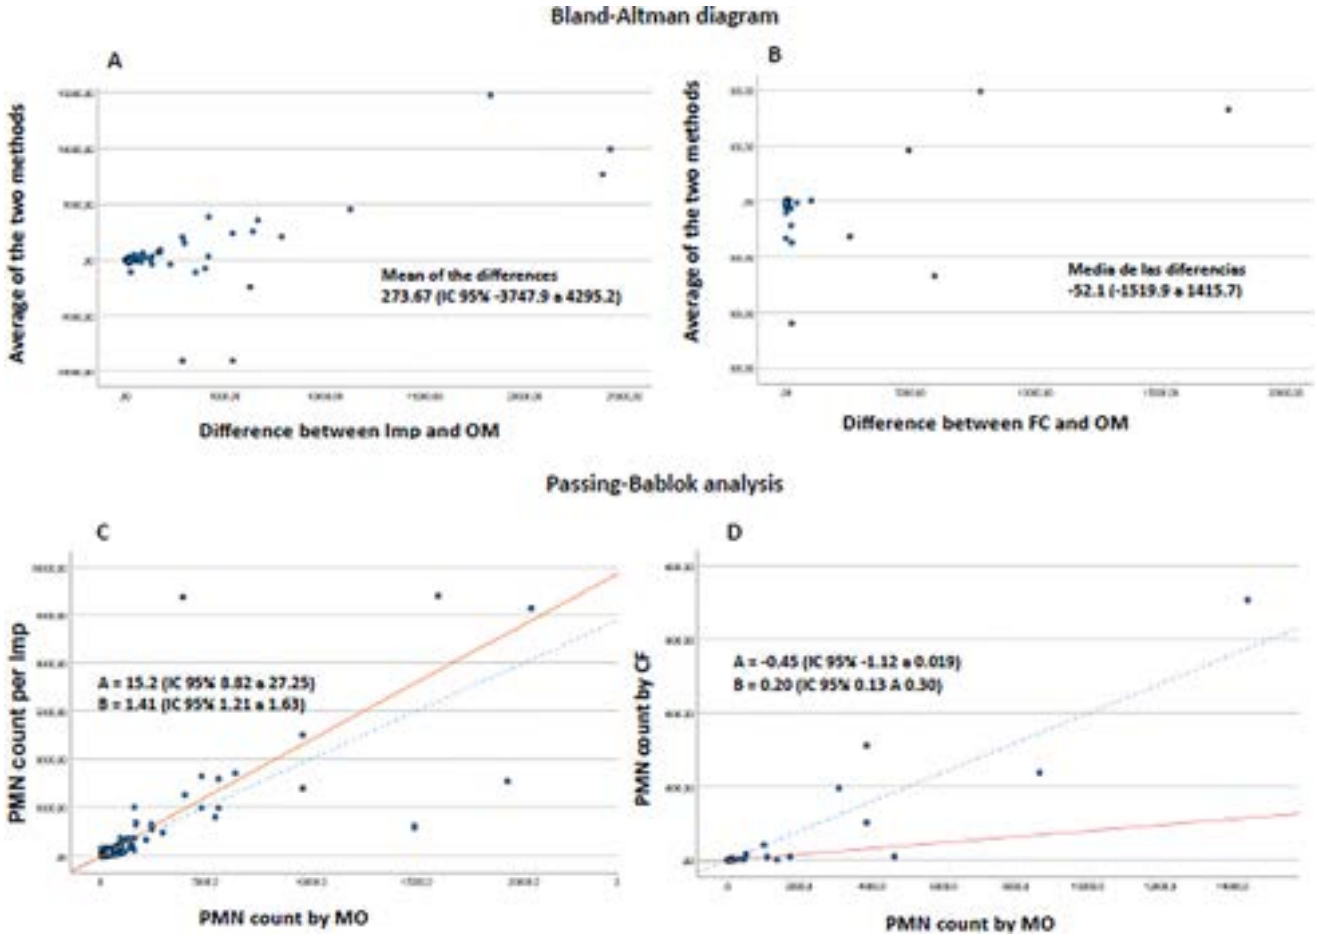

Figure: (abstract: WED-344).

WED-343

Serum PDL1 levels are associated with increased risk of bacterial infections in non-hospitalised patients with cirrhosis

Adria Juanola[1,2,3], Gabriel Mezzano[1], Simone Incicco[4], Elisa Pose[1,2,3], Delia Blaya[2,3], Cristina Solé[1], Natalia Jimenez-Esquivel[1], Joaquin Andrés Castillo[1], Jordi Ribera[2,3,5], Xènia Almodovar[2], Martina Perez[1,2,3], Ana Belen Rubio Garcia[1,2,3], Marta Cervera[2,3], Marta Carol[2,3], Ruth Nadal[1,3], Anita Arslanow[2], Jordi Gratacos[1,2,3], Anna Soria[1,2,3], Núria Fabrellas[2,3,6], Paolo Angeli[4], Manuel Morales-Ruiz[2,3,5,6], Mar Coll[2,3], Isabel Graupera[1,2,3], Salvatore Piano[4], Elsa Solà[7], Pere Ginès[1,2,3,6]. *[1]Liver Unit, Hospital Clínic De Barcelona, Barcelona, Catalonia, Spain, Spain, [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Catalonia, Spain, Spain, [3]Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain, Spain, [4]Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine-DIMED, University of Padova, Padova, Italy, Spain, [5]Biochemistry and Molecular Genetics Department, Hospital Clínic of Barcelona. Email: juanola@clinic.cat

Background and aims: Infections, often recurrent, are a very common complication of cirrhosis and represent a frequent cause of hospitalization, renal failure, ACLF and death. Pathogenic factors responsible for bacterial infections remain largely unknown. Previous data in patients hospitalized for complications of cirrhosis showed that high serum PDL-1 levels are associated with an increased risk of bacterial infections. However, it is not known whether serum PDL-1 levels also correlate with the risk of bacterial infections in decompensated but stable patients with cirrhosis that are not hospitalized. The present study was aimed at assessing the serum levels of PDL1 in stable outpatients with decompensated cirrhosis and its relationship with development of bacterial infections.

Method: Prospective cohort study of 110 patients with cirrhosis (76% men, 53% alcohol etiology, median MELD sodium 11). The serum levels of PDL1, which estimate the soluble form of PDL1 expressed in macrophages, were measured by ELISA. New bacterial infections were recorded during a follow-up period of one year.

Results: During follow-up, 36 patients (33%) developed at least one new episode of infection. The most frequent infections were respiratory tract infections (12, 33%), followed by SBP SBP (6, 17%), urinary infections (5, 14%), bacteremia (5, 14%), skin and soft tissue (2, 6%), colitis (2, 6%) and other (4, 10%). The serum levels of PDL1 in patients who developed infections were higher than those in patients who did not develop infections [135 (108–206) vs. 92 (81–145) pg/ml, respectively; p = 0.030]. In a multivariate analysis, the independent predictive factors of infection development were: MELD score and PDL1 levels [sHR 1.007 (1.001–1.012), p = 0.017].

Conclusion: In decompensated stable patients with cirrhosis, increased serum levels of PDL1 correlate with development of infections. These results, along with those previously reported, suggest that the activation of the PD1-PDL1 system represents a relevant factor in the pathogenesis of bacterial infections in cirrhosis.

WED-344

Validation of automatic cell counting based on impendaciometry and flow cytometry in ascitic fluid

Aitor Odriozola Herrán[1], Ángela Antón[1], Angela Puente Sanchez[1], Romina García Sardina[1], David San Segundo Arribas[1], María Del Barrio Azaceta[1], Sara Alonso[1], Victor Echavarria[1], Andrea González[1], Carmen Ribes[1], Carlos Gutierrez[1], Marcos López-Hoyos[1], Antonio Cuadrado[1], Valeria Adam[1], Javier Crespo[1], Jose Ignacio Fortea[1]. [1]*Hospital Universitario Marqués de Valdecilla, Spain*
Email: aodrihe94@gmail.com

Background and aims: The gold standard test for polymorphonuclear (PMN) cell count in ascitic fluid is manual counting by optical microscopy (OM). A few studies have found a good correlation between OM and the automatic counting based on impedance (Imp) and flow cytometry (FC). Our objective was to evaluate the accuracy of these techniques in PMN cell counting in ascitic fluid and in the diagnosis of spontaneous bacterial peritonitis (SBP) (>250/mm3 PMN).

Method: Prospective single-center study that included patients who underwent paracentesis between January 2020 and August 2022. Cell counts were performed in a Neubauer chamber (MO), DxH 900 Beackman Coulter (Imp), and AQUIOS CL (FC). The concordance between the techniques with OM was evaluated using the intraclass correlation coefficient (ICC) and the Bland-Altman (BA) and Passing-Bablok (PB) methods. The gold standard for the diagnosis of SBP was OM, obtaining the area under the curve (AUC) and the positive (PPV) and negative (NPV) predictive values.

Results: 330 paracenteses of 98 patients were included, 213 (64.5%) of them for diagnostic purposes. The origin of ascites was cirrhosis in 290 (87.9%). The ICC was 0.78 (95% CI, 0.70–0.83; $p < 0.001$) for Imp and 0.92 (0.88–0.94; $p < 0.001$) for FC. The BA diagram showed broader limits of agreement for Imp (Figures A and B) and the PB method showed systematic and proportional differences for Imp (i.e. Imp and MO are not comparable techniques), and only proportional differences for FC (Figures C and D) (i.e. need for calibration adjustment). 33 (10%) patients had SBP. The AUC, PPV and NPV for Imp were 0.96, 79.4% and 97.7%, and for FC 0.98, 100% and 94.8%.

Conclusion: Compared with impedance, flow cytometry showed greater concordance and reliability for the diagnosis of SBP, but its implementation in clinical practice requires evaluating whether a calibration adjustment is needed.

WED-345

Prevalence of minimal hepatic encephalopathy in patients with cirrhosis: a multicenter study

Email: sgairing@uni-mainz.de

Background and aims: Minimal hepatic encephalopathy (MHE) is associated with impaired quality of life, falls, and poorer prognosis. Reliable data on the prevalence of MHE in patients with cirrhosis is lacking with reported prevalence varying from 30% to 70%. Therefore, this study aimed to analyse the prevalence of MHE in a large multicentre cohort of patients with cirrhosis stratified by disease stage.

Method: This retrospective study analyzed data from patients recruited at 10 centers in Europe and the United States, all with experience in detecting MHE. Only patients without clinical signs of HE were included. MHE was detected with PHES according to local norms. Demographic, clinical, and laboratory characteristics were analyzed.

Results: In total, 1868 patients with cirrhosis were enrolled. Most patients were male (66.4%) with a median age of 60 years. Median MELD score was 11 (interquartile range (IQR) 9; 15) and Child-Pugh (CP) stages were as follows: CP A 46.2%, CP B 41.6%, CP C 12.2%. The most frequent etiologies were alcohol (43.2%) and viral hepatitis (23.4%). In the total cohort, MHE was detected by PHES in 650 (34.8%) patients. When excluding patients with a history of overt HE (OHE), the prevalence of MHE was 29.2%. In subgroup analyses of patients without a history of OHE stratified by CP stage, the prevalence of MHE in patients with CP A was low (20.6%), while it was higher in CP B or C (37.7% and 49.2%). In patients without a history of OHE with a MELD score <10, the prevalence of MHE was 22.2%. In contrast, in patients with a MELD score ≥20, the prevalence of MHE was high with 47.7%. Standardised ammonia levels (ammonia level/upper limit of normal of each center) correlated significantly, albeit weakly with PHES (spearman's rho = −0.16, $p < 0.001$). Age, sodium, creatinine, albumin, history of ascites, and history of OHE were associated with the presence of MHE in multivariable logistic regression analysis. After excluding patients with a history of OHE, age, sodium, creatinine, albumin, hemoglobin, and a history of ascites remained associated with MHE.

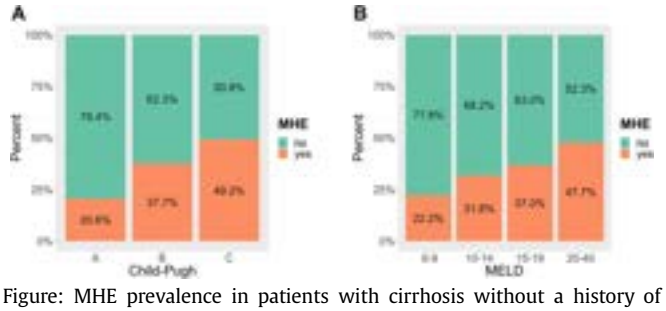

Figure: MHE prevalence in patients with cirrhosis without a history of OHE stratified by Child-Pugh stage (A) and MELD (B).

Conclusion: Roughly one-third of patients with cirrhosis were affected by MHE, but prevalence varied significantly by disease stage. These data may pave the way for more individualized MHE screening approaches.

WED-346

Vitamin D deficiency associates with gut dysbiosis, endotoxemia and the risk of infectious complications in patients with liver cirrhosis

Pei-Chang Lee[1], Kuei-Chuan Lee[1], Hsiao-Sheng Lu[1], Yu-Jen Chen[1], Tsung-Yi Cheng[1], Tsung-Chieh Yang[1], Jen-Jie Chiou[2], Chi-Wei Huang[2], Ueng-Cheng Yang[2], Yi-Hsiang Huang[1], Ming-Chih Hou[1]. *[1]Taipei Veterans General Hospital, Taiwan, [2]National Yang Ming Chiao Tung University, Taiwan*
Email: mchou@vghtpe.gov.tw

Background and aims: Vitamin D deficiency and gut dysbiosis are common problems in patients with liver cirrhosis and both would associate with poorer clinical outcomes. The impacts of vitamin D on gut barrier and microbiota have been demonstrated in cirrhotic rats, but few clinical studies have been reported. In this study, we aimed to investigate the association between vitamin D deficiency and gut microbiota, and the risk of infectious complications in patients with liver cirrhosis.
Method: From September 2018 to December 2020, 80 cirrhotic patients were prospectively enrolled in Taipei Veterans General Hospital. Serum level of 25-hydroxyvitamin D [25 (OH)D], cytokines, fecal microbiota and clinical characteristics were measured and analyzed. The associations between vitamin D deficiency and gut microbiota as well as the development of 1-year cirrhotic infectious complications were investigated.
Results: During the follow-up period of one year, total 41 infectious events and 91 hospitalizations were recorded. Decreased serum level of 25 (OH)D less than 15 ng/ml acceptably predicted development of 1-year infectious complications in these cirrhotic patients (AUROC: 0.818, 95% CI. 0.716–0.895, p = 0.001). A significantly higher Child-Pugh score, neutrophil-to-lymphocyte ratio, prothrombin time, serum levels of lipopolysaccharides (LPS) and TNF-alpha, as well as lower serum albumin level were noted in patients with vitamin D deficiency. Besides, the richness and evenness of fecal microbiota were significantly reduced in vitamin D-deficient cirrhotic patients. A significant microbial dissimilarity could also be identified by unweighted UniFrac analysis according to the presence of vitamin D deficiency. In the feces of vitamin D-deficient cirrhotic patients, a significant prominence of genera Streptococcus and Ruminococcus gnavus were observed. In contrast, Bacteroides was significantly more prominent in patients with higher serum vitamin D. Moreover, the fecal abundance of Streptococcus was significantly positively correlated with serum LPS level, whereas, a significant negative correlation was noted between LPS and Bacteroides. Patients with vitamin D deficiency developed more infectious complications (60.7% vs. 11.5%, p < 0.001) and more numbers of hospitalization (67 vs. 24, p < 0.001) than cirrhotic patients with higher vitamin D. Furthermore, a higher serum 25 (OH)D >15 ng/ml independently decreased the risk of 1-year infectious complications in cirrhotic patients.

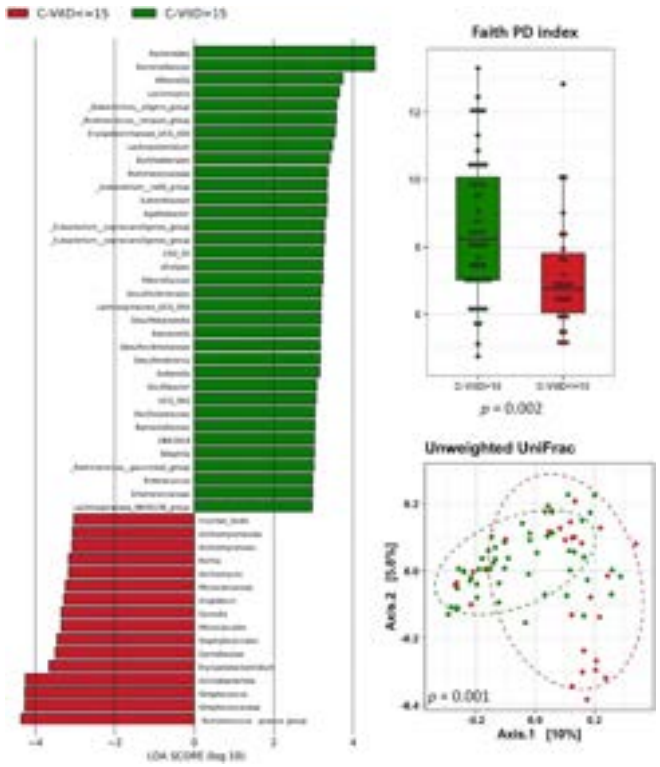

Figure:

Conclusion: Vitamin D deficiency was associated with significant gut dysbiosis, endotoxemia and significant increased risks of infectious complications in patients with liver cirrhosis. These findings potentiate to improve the outcomes of these patients by vitamin D supplementation and also gut microbial modification.

WED-347

Comparison of coagulation parameters as prognostic markers of decompensation and liver-related death in advanced chronic liver disease

Maria Pallozzi[1], Lucia Giuli[1], Francesco Santopaolo[1], Antonio Gasbarrini[1], Raimondo De Cristofaro[2], Maurizio Pompili[1], Francesca Romana Ponziani[1]. *[1]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Internal Medicine and Gastroenterology-Hepatology Unit, Rome, Italy, [2]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Translational Medicine and Surgery Department, Rome, Italy*
Email: mariapallozzi@yahoo.it

Background and aims: Liver cirrhosis has long been considered an acquired bleeding disorder but recent studies have demonstrated that the coagulation balance is associated with disease progression. In patients with advanced chronic liver disease (ACLD) plasma levels of many procoagulant factors (factor VIII [FVIII], von Willebrand Factor [VWF]) are reduced but also the levels of anticoagulant factors (a disintegrin and metalloprotease with thrombospondin 1 repeats number 13 [ADAMTS-13], protein C [PC]) are markedly decreased. A recent study demonstrated that FVIII/PC ratio correlates with the severity of liver disease and with worse liver outcomes [1]. We recently reported that ADAMTS-13/VWF ratio is useful to predict the development of portal vein thrombosis (PVT), but little is known about its role as marker of decompensated ACLD. Based on these previous results, we investigated the prognostic role of ADAMTS13/VWF ratio on the development of dACLD and compared it with FVIII/PC ratio [2].
Method: Consecutive outpatients with ACLD underwent clinical evaluation and were subjected to blood sampling for the assessment of laboratory tests and coagulation parameters. Data from ultrasound

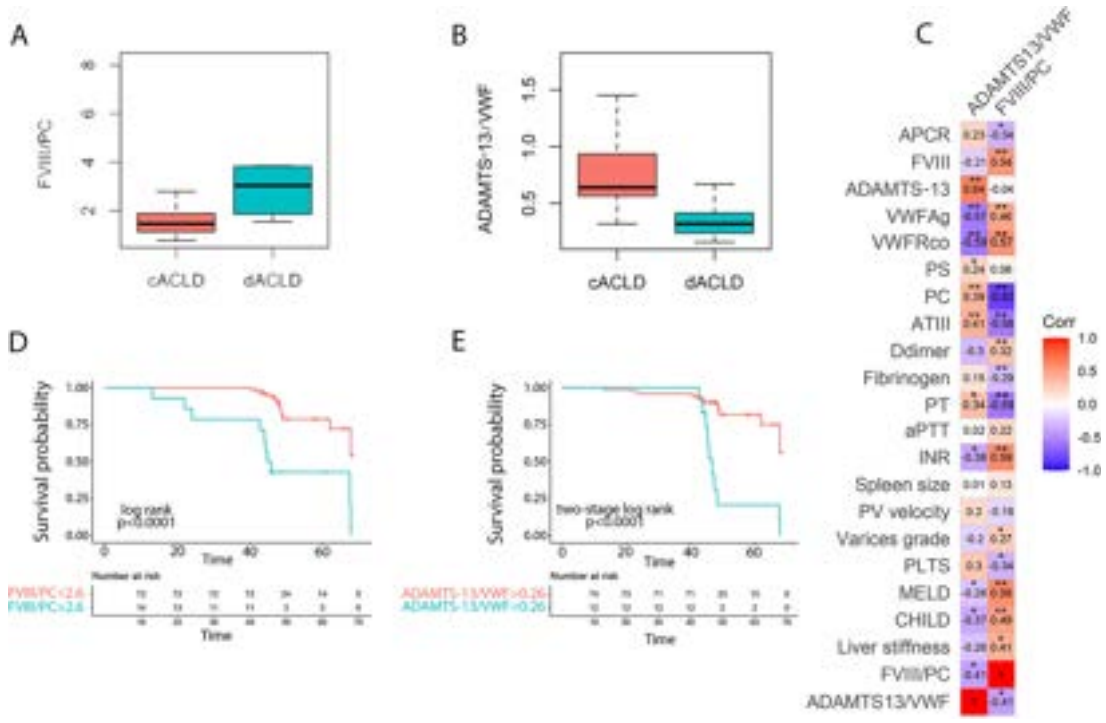

Figure: (abstract: WED-347).

examination and upper endoscopy were also recorded. We compared the FVIII/PC ratio and ADAMTS-13/VWF ratio between patients with compensated and decompensated ACLD and their correlation with the other variables. We finally analyzed survival probability of remaining free of decompensation/liver-related death, stratifying patients according to FVIII/PC ratio or ADAMTS-13/VWF ratio by using the median value of each index in decompensated patients as cut-off. **Results:** We included 86 patients with ACLD (median age 66 (59–72.70) years; 65.47% male; etiology viral/nonviral 50%/50%; Child Pugh A/B/C 80.2%/15.1%/4.7% and median model for end-stage liver disease (MELD) 8 [7–9.20]), 20 (23.25%) developed dACLD after a median follow-up of 48.8 (48–57.30) months. Those patients showed a significantly higher FVIII/PC ratio and a lower ADAMTS-13/VWF ratio compared to their counterparts maintaining cACLD (FVIII/PC 2.62 [1.87–3.81] vs 1.44 [1.13–1.77], $p < 0.0001$ Figure 1A); ADAMTS-13/VWF 0.26 [0.22–0.41] vs 0.52 [0.16–0.62], $p < 0.0001$ Figure 1B). Both the indices correlated with liver disease severity according to Child Pugh score and MELD score (Figure 1C). FVIII/PC ratio showed the strongest correlation with clinical and coagulation parameters. Both FVIII/PC ratio or ADAMTS-13/VWF ratio had a good prognostic ability for ACLD decompensation/liver-related death ($p < 0.0001$, Figure 1D–E); however, when ADAMTS-13/VWF ratio was used the survival curves crossed after 40 months, underlining a limitation in the identification of patients with early events. Finally, the four patients who developed PVT during follow-up showed a lower ADAMTS-13/VWF ratio (0.23 [0.22–0.25] vs 0.58 [0.45–0.73], $p = 0.004$) or a higher FVIII/PC ratio (2.62 [2.45–2.82] vs 1.57 [1.2–2.09], $p = 0.02$) compared to their counterparts who did not experience PVT. **Conclusion:** Coagulation parameters, historically used only for assessing bleeding risk in patients with ACLD, are instead harbingers of important prognostic information. Indeed, ADAMTS13/VWF ratio and FVIII/PC ratio correlate with liver disease severity and can predict liver-related death or decompensation in patients with ACLD.

WED-348

Development and external validation of a model to predict multi-drug resistant bacterial infections in patients with cirrhosis

Sebastián Marciano[1], Salvatore Piano[2], Virendra Singh[3], Paolo Caraceni[4], Rakhi Maiwall[5], Carlo Alessandria[6], Javier Fernandez[7], Dong Joon Kim[8], Sung-Eun Kim[9], Elza Soares[10], Mónica Marino[11], Julio Vorobioff[12], Manuela Merli[13], Laure Elkrief[14], Víctor Manuel Vargas Blasco[15], Aleksander Krag[16], Shivaram Singh[17], Diego Giunta[1], Martín Elizondo[18], Maria Margarita Anders[19], melisa dirchwolf[20], Manuel Mendizabal[21], Rinaldi Lesmana[22], Claudio Toledo[23], Florence Wong[24], François Durand[25], Adrian Gadano[1], Paolo Angeli[2]. *[1]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]University of Padova, Italy, [3]Postgraduate Institute of Medical Education and Research, India, [4]University of Bologna, Italy, [5]Institute of Liver and Biliary Sciences, India, [6]University of Turin, Italy, [7]Hospital Clinic, Spain, [8]Hallym University College of Medicine, Korea, Rep. of South, [9]Hallym Sacred Heart Hospital, Korea, Rep. of South, [10]University of Campinas (UNICAMP), Brazil, [11]Hospital Dr. Carlos B. Email: sebastian.marciano@hospitalitaliano.org.ar

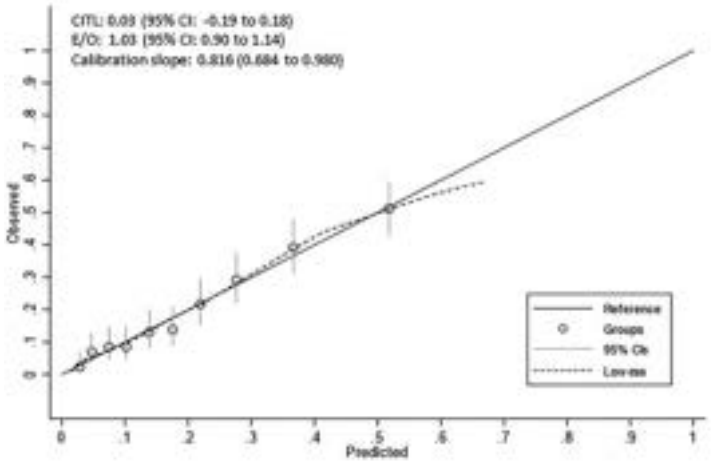
Background and aims: Empirical antibiotic treatment for suspected infections in cirrhosis is crucial. We aimed to develop and validate a model to predict the individual probability of infections by multi-drug resistant organisms (MDRO) at the bedside in patients with cirrhosis to support the selection of appropriate empirical antibiotic treatment.

Figure. Calibration of the model in internal validation and predictors included in the model.

Calibration of the model in internal validation



Perfect calibration occurs when the straight line and the dotted line overlap. CITL: Calibration in the large, which is an average over all individuals (the closer to 0, the better the model calibrates). E/O: expected outcomes by the model over observed outcomes (the closer to 1, the better the model calibrates). Calibration slope is the beta of the model (the closer to 1, the better the model calibrates)

Predictors included in the model

Predictor	OR (95% CI)
Sex	1.29 (0.92 -1.83)
Prior antibiotic treatment	1.79 (1.30 - 2.47)
SBP	0.36 (0.22 - 0.59)
UTI	3.31 (2.19 - 5.02)
Nosocomial infection	2.46 (1.65 - 3.65)
HCA infection	1.81 (1.20 - 2.74)
ACLF at infection	0.54 (0.36 - 0.80)
ICU at infection	2.02 (1.29 - 3.14)
MELD-Na at infection	1.02 (0.99 - 1.04)
Interaction terms	
CA infection * prior isolation of MDRO	4.19 (1.31 - 13.40)
ICU admission * pneumonia	1.80 (1.02 - 3.17)
ICU admission * UTI	0.35 (0.15 - 1.01)
CA infection * penumonia	0.39 (0.15 - 1.01)

OR: odds ratio. CI: confidence interval. MDRO: multidrug-resistant organism. SBP: spontaneous bacterial peritonitis. UTI: urinary tract infection. HCA: health-care associated-infection ACLF: acute-on-chronic liver failure. UCI: intensive care unit. CA: community-aquired, MDRO: multi-drug resistant organism.

Figure: (abstract: WED-348).

Method: Cross-sectional study (NCT05641025) of consecutive in-patients with bacterial infections from two prospective studies. The Global transcontinental study was used for model development and internal validation (n = 1,302), and a study from Argentina and Uruguay (n = 472) was used for external validation. Infection by MDROs was defined as an infection caused by at least one bacteria with acquired resistance to at least one antibiotic of three different families. Multivariable logistic regression with backward stepwise selection of predictors of MDROs was used for model development. Bootstrapping was used for internal validation to adjust for optimism. The optimism-adjusted model was then applied to the external validation dataset. The model's performance diagnosis was explored by applying different cut-off points.
Results: The prevalence of infection by MDROs was 19% in the development and 22% in the external validation dataset. The most frequent etiologies of cirrhosis were alcohol and viral-related, and the most frequent infections were spontaneous bacterial peritonitis (SBP) and urinary tract infection (UTI). Half of the infections were community-acquired, and half were equally distributed among healthcare-associated and nosocomial origin. The model predictors are shown in the figure. Very good calibration was achieved in internal and external validation (Figure). Discrimination was adequate, as shown by the area under the receiver operating characteristic curve (AUROC) of 0.73 (95% CI: 0.69–0.76) in internal validation and 0.67 (95% CI: 0.62–0.74) in external validation. Regarding the clinical utility, when applying a probability cut-off point of 5% or 10%, a negative predictive value (NPV) of 98% (95% CI: 94%–99%) and 94% (95% CI: 91%–96%) was observed in the development dataset, respectively. In the external validation dataset, NPV values for the exact cut-off points were 93% (95% CI: 84%–98%) and 89%, respectively.
Conclusion: This easy-to-implement model achieved adequate performance for predicting infection by MDROs in patients with cirrhosis, offering costless bedside individualized risk estimates that might improve the selection of empiric antibiotics. Its high NPV suggests that it could be used as a rule-out tool, particularly in patients at higher risk of infection by MDROs, to reduce the use of broad-spectrum antibiotics.

WED-349
Factors related to a shorter survival in patients with liver disease and followed by a specialized palliative care clinic

Fernando Xavier e Silva[1], Hemant A Shah[2], David Wong[2], Elizabeth Lee[2], Breffni Hannon[3], Kirsten Wentlandt[1], Ebru Kaya[1].
[1]*University of Toronto, Department of Supportive Care-Palliative Care, Toronto, Canada,* [2]*University of Toronto, Toronto Centre for Liver Disease (TCLD), Toronto, Canada,* [3]*University of Toronto, Department of Supportive Care-Palliative Care-Princess Margaret Cancer Centre, Toronto, Canada*
Email: silva.fernandoxavier@gmail.com

Background and aims: Regardless of advances in tools to predict the survival among patients with advanced liver disease and increasing access to palliative care (PC) by this population, literature about their prognosis after referral to PC remains scarce. Considering the risk of rapid clinical deterioration for this population, better predictors of survival may enable more timely access to specialist PC services. This study aims to identify demographic and clinical factors presented at the time of referral to a PC clinic that are related to shorter survival.
Method: We retrospectively reviewed the charts of adult patients with advanced liver disease referred between May 2019 and May 2022 to a specialized PC clinic at a tertiary teaching hospital in Canada. Data collected included demographics, clinical presentation, and length of survival after referral to the clinic. Clinical factors included primary liver disease etiology; functional status (measured using the Palliative Performance Scale (PPS), a discrete numerical scale from 0% to 100%); the intensity of symptoms (using the Edmonton Symptoms Assessment System (ESAS), a discrete numerical scale from 0 to 10 used to grade intensity of common symptoms); candidacy for liver transplant; history of hepatic encephalopathy (HE); and comorbidities. The study was approved by our institutional

research ethics board. Multivariable regression analysis was used to identify variables associated with shorter survival.
Results: Fifty-four patients were included, 24 (44.4%) were female, the median age was 70 (mean 67.6) years, 6 patients (11.1%) were under 50 years and 30 (55.6%) were born outside of Canada. Primary liver disease aetiologies included the following: viral hepatitis (18, 33.3%); alcohol (17, 31.5%), non-alcoholic fatty liver disease (NAFLD; 8, 14.8%), and other (8, 14.8%). 53 (98.1%) patients had cirrhosis and 24 (44.4%) had hepatocellular carcinoma (HCC). 44 patients (81.5%) had more than 2 comorbidities and 20 patients (37%) had extrahepatic organ failure. 22 patients (40.7%) had a history of HE. Regarding functional status, none of the patients had a PPS of 30% or lower, 6 (11.1%) had a PPS of 40%; and 24 patients (44.4%) of 60% or more. The mean sum of ESAS scores for the 12 measured symptoms was 41 (median 35) out of a maximum of 120 points and fatigue was the symptom with the highest isolated score (6.4, median 7). The average survival from the first PC visit was 41.4 weeks (median of 28 weeks or 6.5 months) and 36 patients (66.7%) died within the study timeframe. On multivariable regression, male gender was the only factor statistically associated with shorter survival, with an average of 32.1 weeks (median of 24, compared with 45 weeks among women, p = 0.02) and the survival difference of 21 weeks was considered clinically relevant. Age, type of primary disease, diagnosis of HCC, HE or multiple comorbidities, extrahepatic organ failure, functional status, and severity of symptoms were not associated with the length of survival.
Conclusion: Male patients were more likely to die sooner than female patients in our study of patients with advanced liver disease followed in a PC clinic. Clarity on other prognostic factors for these patients is still needed and new prognostic markers should be explored. Given the size of this study, larger multicenter studies are needed to confirm the findings.

WED-350
Validation of thigh ultrasound for measurement of sarcopenia and fat mass in patient with cirrhosis: correlation with body composition analysis. Higher fat mass, lower muscle mass and reduced functional muscle

Reza Saeidi[1,2], Neasa McGettigan[1,2], Marion Hanley[2], Martina Morrin[1,2], John Ryan[1,2], Karen Boland[1,2]. *[1]RCSI Smurfit Building, Dublin, Ireland, [2]Beaumont Hospital, Dublin, Ireland*
Email: reza_saeidi@hotmail.com

Background and aims: Sarcopenia (low muscle mass, strength, and function) is associated with adverse outcomes in cirrhosis, including hepatic encephalopathy, ascites, infection, and increased hospitalisation. Sarcopenia is measured using cross-sectional CT scanning. Thigh ultrasound (TUS) may be a low-cost tool to identify sarcopenia in cirrhosis. We aim to validate anterior TUS for measurement of total muscle thickness (TMT) and superficial fat thickness (SF) in cirrhosis using bioelectrical impedance analysis (BIA) as a standard.
Method: Patients with cirrhosis were recruited from a tertiary hepatology clinic for this prospective cross-sectional study approved by the local ethics committee. Using thigh ultrasound, muscle mass using B-mode US was recorded. The right thigh muscle thickness was measured using bedside ultrasound. Point at one-half of the total distance from the top of the patella to the iliac crest were marked. Two readings were obtained by feather-weight technique where the probe was held without pressure on the thigh. Mean of measured anterior thigh muscle and superficial fat thickness were calculated. BIA was performed as the validation standard (SECA mBCA 525) using Sergi sarcopenia equation (PMID: 25103151). Validated functional muscle metrics (handgrip and sit-to-stand) and liver-frailty-indices (PMID: 28422306) were calculated. Descriptive statistics and comparisons between controls and patients was analysed in Stata with t-test/Whitney-Mann-test and Pearson-correlation. Using regression analysis, we constructed ROC curves for analysis of TUS.
Results: 69 patients {58% (40) alcohol liver disease, 25% (17) non-alcoholic steatohepatitis, 5% (4) viral, 4% (3) autoimmune and 7% (5) mixed aetiologies} were included. Additionally, 44 healthy controls (HC) were included. Most patients were male (n = 39, 56%), with mean age 58yrs (SD 10), mean Child-Pugh score 6 (IQR = 5–7) and MELD 10 (IQR = 7–12). 14 patients (20%) of patients had clinical ascites at recruitment and 38% (n = 19) were actively drinking alcohol. 23 (33%) male and 1 (3%) female patients with cirrhosis had sarcopenia based on BIA (SECA mBCA).
Using TUS, height-adjusted anterior muscle thickness was lower in cirrhotic cohort compared to HC (female: 1.33 vs 1.52 mm/m2, SD 0.3 and 0.4 respectively, p = 0.03 and male: 1.31 vs 1.53 mm/m2, SD 0.4 and 0.3 respectively, p = 0.03). BIA height-adjusted skeletal muscle mass positively correlated with TUS-measured TMT (male r = 0.71 and female r = 0.43, P < 0.001 and p = 0.001 respectively). TMT > 2.95 mm in men would exclude sarcopenia (sensitivity = 85%, specificity = 64%) with likelihood ratio of 2.4. Intra-rater reliability for TMT was good (p < 0.001). We report lower functional muscle strength and function in cirrhotic patients. Using functional testing, sit-to-stand time was lower in HCs (14.53 vs 9.08 secs, p = 0.001) and hand-grip strength higher in HC (p < 0.001) compared with patients. 13% (n = 5) of male and 30% (n = 9) of female were frail and frailty scores negatively correlated with TMT (r = −0.4, p = 0.003).

Figure:

Conclusion: TUS is a rapid and valid point-of-care test which can identify high-risk patients with systemic sarcopenia in cirrhosis. Furthermore, lower TMT is associated with increased frailty and reduced muscle function in cirrhosis. Further prospective studies are required to determine if this can be used with other biomarkers to identify patients who would benefit from intensive nutrition intervention.

WED-351
Goals of care and end-of-life for patients with advanced liver disease followed by a specialized palliative care clinic

Fernando Xavier e Silva[1], Elizabeth Lee[2], Hemant A Shah[2], David Wong[2], Breffni Hannon[3], Kirsten Wentlandt[1], Ebru Kaya[1]. *[1]University of Toronto, Department of Supportive Care-Palliative Care, Toronto, Canada, [2]University of Toronto, Toronto Centre for Liver Disease (TCLD), Toronto, Canada, [3]University of Toronto, Department of Supportive Care-Palliative Care-Princess Margaret Cancer Centre, Toronto, Canada*
Email: silva.fernandoxavier@gmail.com

Background and aims: Considering the life-limiting nature of advanced liver diseases and the suffering frequently experienced by patients diagnosed with these illness, palliative care (PC) has played an important role in their support, including the assessment of preferences regarding their care and during their end-of-life (EOL) period. This study aims to understand the frequency and possible

barriers to goals-of-care discussions (GOCd), the content of these preferences and how they are reflected on the dying process of these patients.

Method: The authors retrospectively reviewed the charts of adult individuals referred between May 2019 and May 2022 to a specialized PC clinic for patients with liver diseases at a tertiary teaching hospital in Canada and collected data regarding demographics, reason for referral, clinical characteristics including history of hepatic encephalopathy-HE and functional status (measured with Palliative Performance Scale-PPS, a discrete numerical scale from 0% to 100%), frequency and content of goals-of-care discussions (GOCd) during the first 3 appointments with PC, outcome from clinic, mortality and place of death. All personal identifiers were excluded and the study was approved by the research ethical board of the University of Toronto. Descriptive statistics was used to analyze data.

Results: 54 patients were included in the study, 30 (55.6%) were male, median age was 70 years and 24 (44.4%) had a preferred language other than English. GOCd were included in the motivations to refer 46 (85.2%) patients. History of HE was described in 22 (40.7%) patients. No patients had a PPS lower than 40% and 39 (72.2%) had a PPS between 40–60%. GOCd were not performed in the first visit of 11 (20.4%) patients and continued to be missed for 7 patients (13.0%) by the third visit. History of HE was the only barrier significantly related to the absence of GOCd at the first visit (OR 0.18, $p = 0.02$) but not at the third meeting ($p = 0.34$). Full medical management was preferred by 23 patients (42.6%) and 6 (11.7%) decided to exclusively receive comfort measures. Sixteen patients (29.6%) changed their preferences between the first and third visits, mostly (11, 92%) towards a more conservative choice. Most patients (30, 55.6%) decided for a "do not resuscitate" (DNR) status and 20 patients (37.0%) would want standard resuscitation procedures in the case of a cardiac arrest. 24 (44.4%) patients were able to discuss their preferred place of death, 17 (70.8% among them) would rather die at home and 4 (16.7%), in a hospital. For outcomes, 27 (50.0%) patients were referred either to a PC unit or to home visiting PC teams and 36 (66.7%) patients died. Information was available regarding place of death for 17 patients (47.2% of the dead). Among them, 8 (14.8%) patients died at the hospital, 5 (29.4%) at a PCU and 4 (23.5%) at home. Among the ones who discussed their preferences, at least 8 (33.3%) patients died in their place of choice, only 4 (16.7%) were known to die in a different place and data was missing for 10 (41.7%) of them.

Conclusion: GOCd and palliative planning were common reasons to refer patients to PC and HE was a significant initial barrier to this role. Most patients decided for a DNR status and for full medical management and these preferences tended to change towards comfort measures with time. Most patients would rather die at home when discussing the topic. Expanding the understanding about patients' preferences may help to increase the rates of goals-concordant care.

WED-352

Gender differences in the patient-reported outcomes and perception of ascites burden amongst outpatients with decompensated cirrhosis and ascites

Florence Wong[1], K. Rajender Reddy[2], Puneeta Tandon[3], Jennifer Lai[4], Guadalupe Garcia-Tsao[5], Jacqueline O'Leary[6], Scott W Biggins[7], Hugo Vargas[8], Leroy Thacker[9], Jasmohan S Bajaj[10]. *[1]University of Toronto, Medicine, Toronto, Canada, [2]University of Pennsylvania, Medicine, Philadelphia, United States, [3]University of Alberta, Medicine, Edmonton, Canada, [4]University of California- San Francisco, Medicine, San Francisco, United States, [5]Yale University, Medicine, New Haven, United States, [6]Dallas VA Medical Center, Medicine, Dallas, United States, [7]University of Washington, Medicine, Seattle, United States, [8]Mayo Clinic, Scottsdale, Medicine, Phoenix, United States, [9]Virginia Commonwealth University, Biostatistics, Richmond, United States, [10]Virginia Commonwealth University, Internal Medicine, Richmond, United States*

Email: florence.wong@utoronto.ca

Background and aims: The presence of ascites is a health burden to patients with decompensated cirrhosis. They have a poor quality of life (QOL), due to pain from abdominal distension, hernias and attendant frailty with need for repeat large volume paracentesis (LVP). Perception of these issues may be different between the genders. The aim of the study was to assess gender differences in the perception of ascites burden in patients with recurrent or refractory ascites.

Method: The North American Consortium for the Study of End-stage Liver Disease-3 (NACSELD3) prospectively enrolled outpatients with cirrhosis and large ascites who needed repeat LVPs. Data collected were demographics, laboratory results, co-morbidities, medications and frailty measurements. Self-reported questionnaires related to functional status (Duke Status Activity index), physical activities (Godin Leisure Activity Index), overall QOL (SF36, mental and physical), and ascites burden (ascites Q) were compared between genders.

Results: 241 men (60.4 ± 9.9 yrs) and 115 women (58.8 ± 10.7 yrs) of similar MELD (mean = 13) and Child-Pugh (mean = 7) scores were enrolled. Men had significantly more alcoholic cirrhosis (49% vs. 38%), while women had more NASH (29% vs. 23%) and autoimmune diseases (13% vs. 2%) ($p < 0.0001$). Both genders had similar co-morbidities and complications of cirrhosis. Both groups also had a history of median duration of ascites of 3 months ($p = 0.826$), as were the median number of LVPs ($p = 0.587$) and volume of their LVPs in the past 3 months ($p = 0.891$). Despite this, women felt a lot worse about their ascites (Figure) and had a significantly higher total Ascites Q score (67 ± 22 vs. 58 ± 22, $p = 0.0001$) (higher value = feeling worse about their ascites), possibly related to their significantly higher median frailty index of 4.16 versus that of 3.95 in men ($p = 0.023$). 37% of women felt depressed compared to 25% ($p = 0.029$) and women scored lower on their emotional well-being ($p = 0.019$) and social functioning ($p = 0.032$) on SF36 questionnaire, even with 51% of men vs. 34% of women taking chronic beta blockers ($p = 0.003$). Despite this, women were able to conduct their daily activities as adequately as men as indicated by their equal scores on Duke Status Activity index ($p = 0.89$) and their Godin Leisure Activity Index ($p = 0.35$).

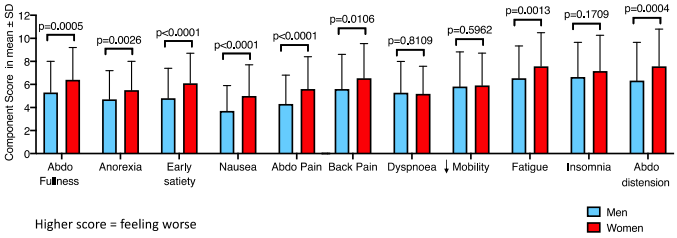


Figure:

Conclusion: The gender difference in the perception of ascites burden is not related to severity of physical illness. Although women felt worse about their ascites-related QOL and emotional health, and were more frail than men, this was not associated with impaired daily function or leisure activity. This may be related to other issues such as cultural/social conditioning, which should be considered when eliciting patient reported outcomes and managing the psychological aspects of ascites care for women.

WED-353

The role of renal impairment on rotational thromboelastometry (ROTEM) parameters in hospitalised patients with cirrhosis-a prospective cohort study

Louis Wang[1], Tianyu Qiu[1], Chin Kimg Tan[1], Eugene Wong[1], Kenneth Lin[1], Andrew Kwek[1], James, Weiquan Li[1], Tiing Leong Ang[1], Roshni Sahashiv[2], Louis Ng[3], Prasanna Tirukonda[4], Rahul Kumar[1].
[1]Changi General Hospital, SingHealth, Gastroenterology, Singapore, [2]Changi General Hospital, SingHealth, General Medicine, Singapore, [3]Changi General Hospital, SingHealth, Anaesthesia, Singapore, [4]Changi General Hospital, SingHealth, Diagnostic Radiology, Singapore
Email: rahul.kumar@singhealth.com.sg

Background and aims: The use of ROTEM has allowed for better understanding of complex haemostatic processes involved in patients with cirrhosis compared to conventional clotting tests (CCT). Renal dysfunction (RD) is a common comorbidity in patients with cirrhosis, but its effect on ROTEM parameters in cirrhosis remains unknown. We conducted a novel study on how ROTEM parameters may be altered by the presence of RD among patients with cirrhosis.
Method: A total of 76 consecutively admitted patients with cirrhosis were prospectively recruited in this study. Patients were classified into 2 groups based on their estimated glomerular filtration rate (eGFR) by the CKD-EPI equation; no-RD (eGFR ≥90, n = 36) and RD (eGFR <90, n = 40). ROTEM parameters (INTEM, EXTEM, FIBTEM and APTEM), CCT (prothrombin time (PT), activated partial thromboplastin time (aPTT), fibrinogen, platelet) and Child- Pugh score were compared between the groups. Standard statistical tools were applied for group comparisons using Student's t-test and Mann-Whitney U test for parametric and non-parametric data, respectively.
Results: The mean age was 60.6 ± 10.0 years and 77.6% were male patients. For severity of liver cirrhosis, MELD scores were significantly higher in the RD group (RD 17.7 ± 7.2 vs non-RD 14.3 ± 6.7, p = 0.04) likely owing to higher serum creatinine levels, while Child-Pugh score were similar (RD 9.4 ± 2.2 vs non-RD 9.0 ± 2.4, p = 0.4). In figure 1, ROTEM parameters in the RD-group showed significantly higher clot amplitudes at A5, A10, A20 and A30 and lower clot formation time (CFT) across INTEM, EXTEM and APTEM analyses (p < 0.05). The RD-group also had a significantly higher maximal clot firmness (MCF) for INTEM, EXTEM, APTEM and FIBTEM (p < 0.05). Difference in clotting time (CT) was not statistically significant between the groups. CCT showed significant differences in platelet (RD 95.9 ± 49.3 vs non-RD 73.2 ± 46.1, p = 0.04) and aPTT (RD 41.1 ± 14.5 vs non-RD 34.7 ± 9.7, p = 0.03), but no difference in PT (RD 15.6 ± 4.7 vs non-RD 14.5 ± 3.2, p = 0.22) and fibrinogen (RD 2.0 ± 1.0 vs non-RD 1.6 ± 0.6, p = 0.07).
Conclusion: The analysis of our data shows that kidney impairment is an important contributor towards the haemostatic processes in cirrhosis and results in an overall hypercoagulable state, as measured using ROTEM parameters. This was not apparent based on traditional clotting tests alone. This is a novel finding as there may be direct implications for patients undergoing procedures where decisions for prophylactic blood product transfusions were previously based on only traditional clotting parameters. By being in a more hypercoagulable state, patients with cirrhosis and renal dysfunction may require less transfusions and experience fewer transfusion-related complications. Further research is needed to elucidate the effect of platelet dysfunction from renal impairment on ROTEM parameters in cirrhosis, and how it contributes towards the complex interplay of various haemostatic mechanisms.

WED-354

Whole body clearance and production of ammonia quantified by constant ammonia infusion-the effects of cirrhosis and ammonia targeting treatments

Peter Lykke Eriksen[1], Lars Djernes[2], Hendrik Vilstrup[1], Peter Ott[1].
[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark, [2]Aarhus University Hospital, Department of Anaesthesiology and Intensive Care, Aarhus, Denmark
Email: ple@clin.au.dk

Background and aims: Hyperammonaemia is a key pathological feature of liver disease and the most important driver of hepatic encephalopathy (HE). However, the relative role of increased ammonia production and reduced clearance is poorly understood, as is the action of ammonia targeting drugs to treat HE. To quantify whole body ammonia metabolism in healthy persons and cirrhosis patients and to validate the method by examination of the effects of glycerol phenylbutyrate and lactulose + rifaximin treatment.
Method: Ten healthy men and 10 male cirrhosis patients were investigated by a 90-minute constant ammonia infusion to achieve plasma ammonia steady-state. Whole body ammonia clearance was calculated as infusion rate divided by steady-state concentration increase and ammonia production as clearance times baseline

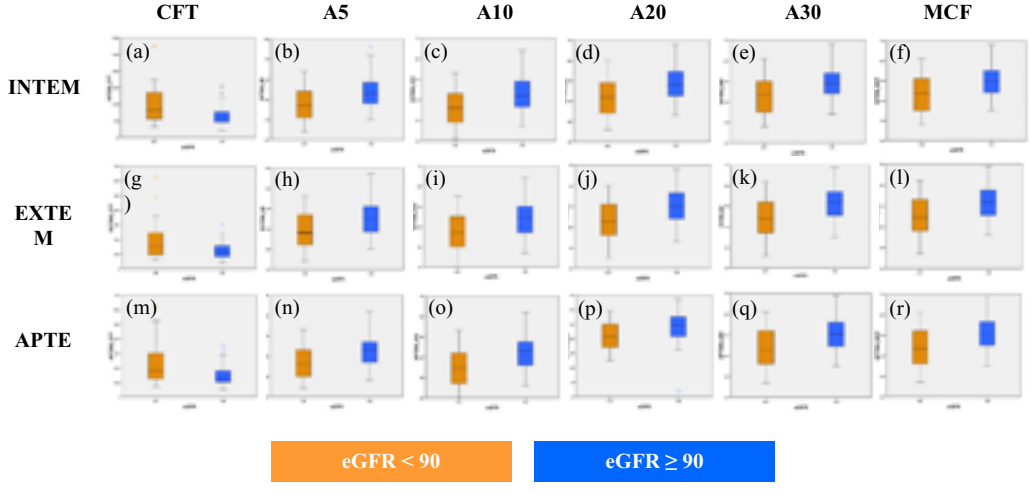

Figure 1 ROTEM parameters were significantly different between cirrhotic patients with or without renal dysfunction (p < 0.05). *(a) INTEM CFT, (b) INTEM A5, (c) INTEM A10, (d) INTEM A20, (e) INTEM A30, (f) INTEM MCF, (g) EXTEM CFT, (h) EXTEM A5, (i) EXTEM A10, (j) EXTEM A20, (k) EXTEM A30, (l) EXTEM MCF, (m) APTEM CFT, (n) APTEM A5, (o) APTEM A10, (p) APTEM A20, (q) APTEM A30, (r) APTEM MCF.*

Figure: (abstract: WED-353).

ammonia concentration. Participants were re-investigated after the ammonia targeting interventions.
Results: In healthy persons, ammonia clearance was 3.5 (3.1–3.9) L/min and production 49 (35–63) μmol/min. Phenylbutyrate increased clearance by 11% (4–19, p = 0.009). Cirrhosis patients had a 20% decreased ammonia clearance of 2.7 (2.1–3.3) L/min (p = 0.02) and a nearly tripled production of 131 (102–159) μmol/min (p < 0.0001). Lactulose + rifaximin reduced production by 20% (2–37%, p = 0.03). The infusion was generally well-tolerated save one hyperammonaemic cirrhosis patient with possible bleeding who developed clinical HE that reverted upon infusion stop.

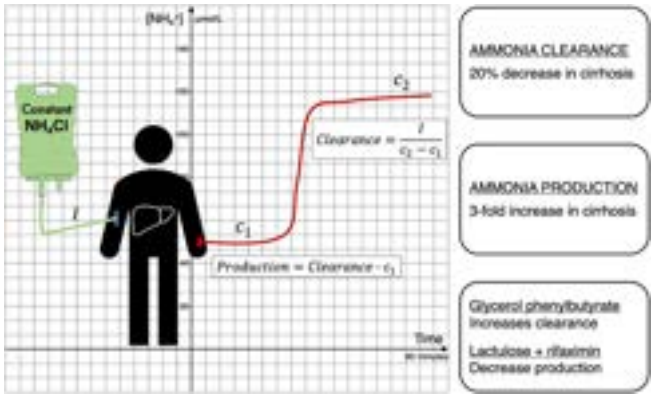

Figure:

Conclusion: Whole body ammonia clearance and production can be separately measured by the technique. The method identified lower clearance and higher production in cirrhosis patients, and showed that phenylbutyrate increases clearance while lactulose + rifaximin decreases production. The method can be used to examine a range of questions on normo-/pathophysiology and ammonia targeting treatment mechanisms.

WED-355
Prognostic significance of individual decompensating events in stable decompensated outpatients with cirrhosis using a multicenter cohort
Jasmohan S Bajaj[1], Guadalupe Garcia-Tsao[2], Puneeta Tandon[3], Jennifer Lai[4], Jacqueline O'Leary[5], Hugo Vargas[6], Scott Biggins[7], Patrick S. Kamath[8], Florence Wong[9], Jawaid Shaw[1], Chimezie Mbachi[2], Jade Ikahihifo-Bender[10], Leroy Thacker[1], K. Rajender Reddy[10].

Email: jasmohan.bajaj@vcuhealth.org

Background and aims: The type/prognostic significance of decompensating events in cirrhosis may be changing given changes in etiology and management of cirrhosis. Ascites, hepatic encephalopathy (HE) and prior variceal bleeding (VB) are considered decompensating events. Aim: to define the prognostic significance (specifically, 3- and 6-month hospitalization, transplant and mortality) in patients with "stable" decompensation.
Method: NACSELD3 (North American Consortium for the Study of End-stage liver Disease) is an ongoing study that enrolls outpatients with cirrhosis and follows them every 3 months (mos) for hospitalizations, transplant and death. Decompensating events prior to enrollment into the study were defined as ascites (requiring diuretics and/or LVP), hepatic encephalopathy (HE; grade ≥2, on specific treatment) and variceal bleed (VB, controlled on EVL/NSBB). Those with alcohol as etiology had an AUDIT score <10 for at least 3 months and those with HCV etiology had achieved eradication. Outcomes (3and 6-month re-hospitalization, transplant and mortality) were compared among those without ascites but with HE ± VB (group 1), those with ascites alone (group 2) and those with ascites and HE ± VB (group 3). Multi-variable analyses were performed.
Results: 437 pts were included: MELD-Na 13.0 (6–33) 71% men, age 59.4 (10.22) with various etiologies (58% alcohol, 20% NASH, 10% HCV, 13% other); 56 were in group 1, 181 in group 2 and 200 in group 3. Only MELD-Na, pre-enrollment hospitalization and WBC count differed at baseline among groups. At 3 and 6 mos, we had data on total 397 pts and 332 pts respectively.
3-mo outcomes: Mortality rates (group 1 4%, group 2 3%, and group 3 3%, p = 0.89) and transplant rates (0% vs 2% vs 4%, p = 1.0) were not different among groups but significant differences in 3 and 6-mo hospitalization rates were noted (Figure). Most (81%) 3-mo hospitalizations were liver-related (21% GI bleed, 19% HE, 12% renal) and were not different among groups. 6-mo outcomes: Mortality rates (group1, 17%, group 2, –9%, and group 3, 11%, p = 0.38) and transplant rates (0% vs 6% vs 8%, p = 0.32) were not different among groups. As per 3-mo outcomes, 6-mo hospitalizations were different among groups ((Figure); 62% were liver-related (17% HE, 10% GI bleed and 19% renal) and were not different among groups. None of the subjects had alcohol misuse during the follow-up.

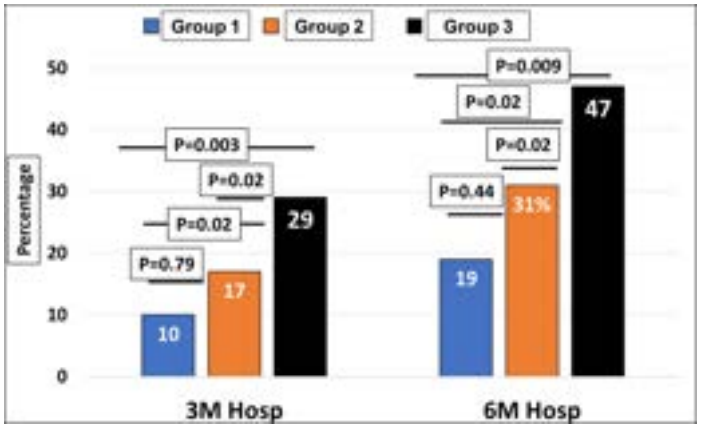

Figure:

MV hospitalization analysis: 3- mo: The only predictors were pre-enrollment hospitalizations (OR 2.95, 1.78–4.87, p < 0.001) and pt group (overall p = 0.02, OR 0.54 group 2 vs. 3 and OR 0.37 group 1 vs. 3). 6-mo: predictors were pre-enrollment hospitalizations (OR 1.97, 1.22–3.20, p = 0.006) and pt group (overall p = 0.005, OR 0.53 group 2 vs. 3 and OR 0.32 group 1 vs. 3).
Conclusion: In a multicenter cohort of North American outpatients with "stable" decompensated cirrhosis, a single decompensating event, regardless of type (ascites, HE or VB) has a better prognosis with respect to hospitalizations at 3 and 6 months compared to those with a combination of decompensating events.

WED-356
Classification of bleeding risk from invasive procedures in patients with cirrhosis: an expert consensus
Alix Riescher-Tuczkiewicz[1], Stephen H Caldwell[2], Erica Villa[3], Pierre-Emmanuel Rautou[1,4]. *[1]Université Paris Cité, Inserm, Centre de recherche sur l'inflammation, UMR 1149, Paris, France, [2]Division of Gastroenterology and Hepatology, University of Virginia Health System, Charlottesville, United States, [3]Gastroenterology Unit, Department of Medical Specialties, University of Modena and Reggio Emilia and Azienda Ospedaliero-Universitaria di Modena, Modena, Italy, [4]Service d'Hépatologie, AP-HP, Hôpital Beaujon, DMU DIGEST, Centre de Référence des Maladies Vasculaires du Foie, FILFOIE, ERN RARE-LIVER, Clichy, France*
Email: perautou@yahoo.fr

Background and aims: Prevention of bleeding complications following invasive procedures in patients with cirrhosis is challenging. A first step in preventing such bleedings is to properly assess the risk of bleeding by considering the patient's history, the risk of the procedure itself and the results of laboratory tests. Several classifications of the bleeding risk have been proposed in recent international guidelines. Several (AGA 2021, AASLD 2021, ISTH 2021, EASL 2022) used the same approach based on the frequency of major bleeding

		Procedure	Voting percentage	
			Low risk	High risk
Digestive endoscopy	ERCP	Without sphincterotomy	**90%**	10%
		With biliary or pancreatic sphincterotomy	12%	**88%**
		With papillary balloon dilatation without sphincterotomy	67%	33%
		With biliary or pancreatic stent placement without sphincterotomy	**80%**	20%
	Upper and lower	Mucosal resection	25%	75%
		Submucosal dissection	8%	**92%**
		Hemostasis with argon plasma coagulation	**92%**	8%
		Radiofrequency ablation	67%	33%
		Video-capsule	**100%**	0%
		Ultrasound without fine-needle aspiration	**98%**	2%
		Ultrasound with fine-needle aspiration	59%	41%
		Stricture dilatation (pneumatic or bougie)	32%	68%
		Stricture dilatation (balloon)	38%	63%
		Enteral stent deployment	**77%**	23%
	Upper	Cystogastrostomy	13%	**87%**
		Polypectomy < 1cm	**76%**	24%
		Polypectomy > 1cm	12%	**88%**
		Diagnostic (with or without biopsy)	**98%**	2%
		Variceal ligation	71%	29%
		Glue injection of gastric varices	54%	46%
		Peroral endoscopic myotomy	7%	**93%**
		Ampullary resection	6%	**94%**
		Percutaneous gastrostomy or jejunostomy placement	22%	**78%**
		Diagnostic balloon assisted enteroscopy	**90%**	10%
		Therapeutic balloon assisted enteroscopy	64%	36%
		Push enteroscopy	**88%**	12%
	Lower	Polypectomy < 1cm	**78%**	22%
		Polypectomy > 1cm	10%	**90%**
		Flexible sigmoidoscopy (with or without biopsy)	**96%**	4%
		Diagnostic colonoscopy (with or without biopsy)	**92%**	8%
Cardiovascular		Central venous catheter placement	**81%**	19%
		Peripherally inserted central catheter line placement	**90%**	10%
		Arterial line placement	73%	27%
		Central line removal	**94%**	6%
		Cardiac catheterization	**82%**	18%
		Transesopheageal echocardiography	**94%**	6%
		Diagnostic coronary angiography	**90%**	10%
		Therapeutic coronary angiography	66%	34%
		Angiography or venography with intervention	60%	40%
		Inferior vena cava filter placement	**87%**	13%

	Procedure	Voting percentage	
		Low risk	High risk
Hepatology	Percutaneous liver biopsy	33%	67%
	Transjugular liver biopsy	**83%**	17%
	Laparoscopic liver biopsy	46%	54%
	Hepatic venous pressure gradient measurement	**92%**	8%
	Portal recanalization	40%	60%
	Transjugular intrahepatic portosystemic shunt	38%	62%
	Transcatheter arterial chemoembolization or radioembolization	62%	38%
	Percutaneous ablation of liver cancer	40%	60%
	Cholecystostomy or percutaneous biliary drain placement	22%	**78%**
	Diagnostic paracentesis	**98%**	2%
	Therapeutic paracentesis	**96%**	4%
	Tunneled ascitic drain placement	59%	41%
Pneumology	Thoracentesis	**78%**	22%
	Bronchoscopy without biopsy	**96%**	4%
	Bronchoscopy with biopsy	29%	71%
	Therapeutic bronchoscopy	26%	74%
	Intrathoracic organ biopsy	9%	**91%**
	Tunneled pleural drain placement	44%	56%
Urology and nephrology	Prostate biopsy	25%	**75%**
	Cystoscopy	**100%**	0%
	Ureteroscopy	**98%**	2%
	Lithotripsy (kidney, bladder, ureter)	59%	41%
	Percutaneous kidney biopsy	10%	**90%**
	Transjugular kidney biopsy	61%	39%
	Nephrostomy tube placement	24%	**76%**
Neurology	Lumbar puncture	41%	59%
	Epidural catheter placement	23%	**77%**
	Central nervous system procedure	2%	**98%**
Gynecology	Colposcopy with cervical biopsy	**79%**	21%
	Diagnostic hysteroscopy	**100%**	0%
	Hysteroscopy with biopsy	64%	36%
	Amniocentesis	38%	62%
Miscellaneous	Dental cleaning	**100%**	0%
	Dental extraction	45%	55%
	Intra-articular puncture	65%	35%
	Intra-articular injection	**77%**	23%
	Lymph node percutaneous biopsy	**83%**	17%
	Nonliver intraabdominal solid-organ biopsy	15%	**85%**
	Skin biopsy	**98%**	2%
	Drainage catheter exchange	**98%**	2%

Consensus for a procedure to be at "low bleeding risk"

Consensus for a procedure to be at "high bleeding risk"

No consensus

Figure: (abstract: WED-356).

events following invasive procedures (threshold at 1.5%). Yet, these guidelines arrived at different conclusions highlighting the need for a broad consensus on this topic. The aim of this study was thus to establish a consensus of experts on the bleeding risk associated with invasive procedure in patients with cirrhosis.

Method: All international experts involved in recent guidelines on the management of invasive procedures in patients with cirrhosis were contacted, namely authors of the AASLD 2021, AASLD 2023, ACG 2020, AGA 2019, AGA 2021, AGA 2021, British Society of Gastroenterology 2020, and the ISTH 2022 guidelines, as well as panel and Delphi panel members of the EASL 2022 guidelines. All were invited to classify 80 procedures frequently performed in patients with cirrhosis as at "high risk" or "low risk" of bleeding. Procedures were considered at high-risk when the estimated bleeding risk is ≥1.5% or when even minor bleeding may lead to severe consequences or death. The predetermined threshold considered as a consensus was 75%.

Results: Out of a total of 72 experts, 52 participated in the study (72%): 35 from Europe, 16 from the USA, 1 from Asia. Of those who specifically declined to respond, 1 was more laboratory oriented, 1 was no longer clinically active and 18 simply declined to respond. Out of the 80 procedures, a consensus could be reached for 51 procedures (64%): 16 procedures were classified as at "high risk," 35 as at "low risk"; a consensus could not be reached for 29 procedures (Figure). Low-risk procedures were mainly diagnostic procedures, while high-risk procedures were mainly therapeutic procedures or procedures involving biopsy/sampling of a particularly high-risk sites (*e.g.*, central nervous system).

Conclusion: A consensus was reached among clinically experienced experts who have published in the field of procedural bleeding risk in cirrhosis for 51 procedures: 16 procedures were classified as "high risk" and 35 as "low risk" for bleeding based on this collective clinical experience. While truly randomized and prospective studies that include various potential interventions would be necessary to be more definitive, this experience-based classification will be helpful to homogenize future study interpretation and in clinical decision making on invasive procedures in patients with cirrhosis.

WED-357

The role of prolonged albumin replacement therapy in correction of its structure and functional properties and management of ascites

Anastasia Turkina[1], Marina Maevskaya[2], Maria Zharkova[2], Vladimir Ivashkin[1]. [1]*Sechenov First Moscow University (Sechenov University), Department of Propaedeutics of Internal Disease, Gastroenterology and Hepatology, Russian Federation,* [2]*Sechenov First Moscow University (Sechenov University), Vasilenko Clinic of Internal Diseases, Gastroenterology and Hepatology, Russian Federation*
Email: daygawa@yandex.ru

Background and aims: Human serum albumin (Alb) undergoes posttranslational changes due to oxidative stress in cirrhotic patients (pts). It leads to "effective albumin" reduction. Alb infusions are widely used not only in short course but also in long term therapy. There is no information about the influence of prolonged Alb therapy on albumin structure and functions. Aim was to access the influence of 3 months albumin replacement therapy on albumin structure and functional properties and management of ascites.

Method: We included 50 eligible pts with decompensated cirrhosis and ascites. Pts were divided into 2 groups: albumin and control-age, gender and clinical presentation matched. Along with standard medical treatment (SMT), Alb group received albumin replacement therapy for 3 months (20%-200 ml per week). Control group-only SMT. On admission and after 3 months of therapy, we performed a standard examination and additionally assessed Alb properties by means of electronic paramagnetic resonance tests. We analyzed the following parameters: DR-an indicator of native albumin conformation, BE -binding efficiency of albumin, RTQ-transport efficiency and DTE-detoxifying ability.

Results: The mean pts's age varied from 31 to 74 years; 2/3 of the patients were female. The main cause of cirrhosis was alcohol-62%. All patients initially had ascites. Only 48% (n = 24) of pts had hypoalbuminemia (<32 g/l). Albumin structure (DR) and functions (BE, RTQ, DTE) were impaired totally in both groups. Those changes didn't depend on albumin serum level ($p < 0.001$). After 3 months of treatment in the Alb group, ascites resolved in 48.4% of pts (n = 15) vs. 7% (n = 1) in the control group ($p = 0.042$). Alb structure and functions also significantly improved in the Alb group vs. controls: DR 42.4% vs. 0%, BE 60.6% vs. 14.3%, RTQ 63.6% vs. 14.3%, DTE 60.6% vs. 28.6% ($p < 0.001$).

Conclusion: Albumin replacement therapy for 3 months induces reduction of ascites, improvement of Alb structure and functional properties. Native conformation and Alb functional properties can be an additional marker for the replacement therapy initiation and withdrawal.

WED-358

A multimodal treatment candidate for sarcopenia in men with decompensated cirrhosis: a randomized, placebo-controlled trial evaluating LPCN 1148

Benjamin Bruno[1], Josh Weavil[1], Jonathan Ogle[1], George Nomikos[1], Anthony DelConte[1,2], Nachaippan Chidambaram[1], Mahesh Patel[1], Jennifer Lai[3], Arun Sanyal[4]. [1]*Lipocine Inc, Salt Lake City, United States,* [2]*Saint Joseph's University, Department of Food, Pharma, and Healthcare, Philadelphia, United States,* [3]*University of California San Francisco, School of Medicine, San Francisco, United States,* [4]*Virginia Commonwealth University, Division of Gastroenterology, Hepatology and Nutrition, Richmond, United States*
Email: bjb@lipocine.com

Background and aims: Sarcopenia affects 30–70% of patients with liver cirrhosis and has been shown to negatively impact outcomes in cirrhosis, including increased hospitalizations, decompensation events (e.g. hepatic encephalopathy [HE] and infections), and deaths. Testosterone (T), a multimodal hormone influencing many organ systems, is low in the majority of cirrhotic men and is an independent predictor of mortality and decompensation events, including ascites, and HE. The aim of this study is to evaluate LPCN 1148, a novel, multimodal, orally available prodrug of T, for treatment of sarcopenia and decompensated cirrhosis. This abstract will present preliminary baseline characteristics for the study population.

Method: Men with cirrhosis and sarcopenia (confirmed by CT scan), who are waiting for a liver transplant, were eligible for this two-stage, randomized (1:1), blinded, placebo-controlled, proof-of-concept clinical trial. In the first stage, participants were assigned to receive either oral LPCN 1148 or placebo twice daily for 24 weeks. At week 24, the second stage open-label extension (OLE) portion of the study begins, where all participants receive LPCN 1148 from weeks 24–52. The primary end point is the change in skeletal muscle index (SMI) at week 24 with additional biochemical, clinical, functional, and PRO end points at 24 and 52 weeks.

Results: Enrollment is complete; at baseline participants (N = 30, mean ± SD for age: 58.8 ± 8.4 yrs, BMI: 29.0 ± 6.9 kg/m2) were sarcopenic (inclusion criterion, L3-SMI 46.4 ± 7.7 cm2/m2) with elevated markers of liver disease (MELD score 16.8 ± 4.2; ALP 147.6 ± 80.6 U/L, AST 45.1 ± 21.5 U/L; AST/ALT 1.69 ± 0.49). Etiology of cirrhosis was ALD (50.0%), followed by NASH (23.3%), hepatitis C (17.3%), PSC (6.7%), and ALD/hepatitis C (3.3%). Major decompensation events present at baseline were HE (72.4%), ascites (53.3%), and varices (46.7%). More than 80% of participants were categorized as frail or pre-frail by the Liver Frailty index. Participants were below the lower limit of normal for androgenic markers (calculated free T 53.5%, IGF-1 62.1%), albumin (56.7%), platelets (89.7%), hematological factors (hemoglobin 63.3%, hematocrit 66.7%), nutritional markers (pre-albumin 89.7%), bicarbonate (66.7%) and lymphocytes (43%).

Additionally, a large portion of participants were above the upper limits of normal for total bile acids (93%), SHBG (63.3%), luteinizing hormone (43.3%), B12 (70.0%), and ammonia (63.3%).
Conclusion: There are trends within this sarcopenic, decompensated cirrhotic population indicating dysfunction in other key physiologic areas, including hematologic, thrombotic, androgenic, metabolic, immunity, and frailty. Potentially related to the failing liver and reduced muscular mass, systemic ammonia levels are high in the majority of the study population which predisposes participants to episodes of overt HE.

WED-359

Clinical effectiveness of human albumin in liver cirrhosis: a meta-analysis update

Huijuan Zhou[1], Ziqiang Li[1], Yuhan Liu[2], Daer Dili[2], Qing Xie[1]. [1]*Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, China,* [2]*Takeda (China) International Trading Co., Ltd, China*
Email: xieqingrjh@163.com

Background and aims: Hyponatremia is a poor prognosis marker and independent predictor of mortality for patients with liver cirrhosis. Albumin infusions from volume expander (VE) treatment group are regarded as an effective strategy for the management of hyponatremia in cirrhosis. Hence, we examined the clinical effectiveness of albumin infusion to resolve hyponatremia and other complications as well as compare the effectiveness of diverse treatment groups in liver cirrhotic patients.
Method: A systematic literature search of PubMed and EMBASE for articles reporting clinical effectiveness of albumin infusion in cirrhotic patients was performed from inception till date. The key primary efficacy outcome was hyponatremia, and the key safety outcomes were peripheral edema, adverse events, and in-hospital mortality. For the main meta-analysis, the studies were pooled, and albumin infusion was compared with control (including VEs, vasoconstrictors, and inactive/standard medical therapy (I/SMT). For subgroup meta-analysis, comparison was performed between albumin infusion and other treatment groups. The odds ratio (OR) and mean difference (MD) estimated the outcome with a 95% confidence interval (CI). The study protocol was prospectively registered at PROSPERO (CRD42022372709).
Results: Twenty-two studies were included in the analysis. Pooled data showed an overall significant low incidence of hyponatremia (OR, 0.33; 95% CI [0.26–0.41]), severe infection (OR, 0.52 [0.29–0.94]), and post paracentesis circulatory dysfunction (PICD) (OR, 0.36 [0.21–0.61]) among albumin treated group compared to control. Among subgroup analysis, statistically significant improvement was observed with albumin infusion vs I/SMT (OR, 0.28 [0.22–0.36]), while favorable improvement was observed with VE (OR, 0.66 [0.38–1.17]) or vasoconstrictor (OR, 0.45 [0.05–3.75]). For PICD, improvement with albumin was significant compared to other VEs (OR, 0.31 [0.15–0.63]), but did not reach statistical significance with vasoconstrictor (OR, 0.63 [0.21–1.91]). Overall subgroup analysis showed albumin infusion lowered the odds of hyponatremia (OR, 0.33 [0.26 to 0.41]) and PICD (OR, 0.38 [0.21 to 0.69]) significantly. Pooled data showed comparable incidences of peripheral edema (OR, 0.97 [0.55, 1.70]) and overall adverse events (OR, 0.98 [0.92, 1.03]) between albumin and control groups. Comparable in-hospital mortality was observed with albumin vs other VE (OR, 1.02 [0.42 to 2.44]) and a favorable improvement when compared to the I/SMT group (OR, 0.58 [0.20 to 1.67]).
Conclusion: Albumin infusion may be beneficial for resolving hyponatremia, PICD and severe infection among cirrhotic patients. However, larger, multi-centered and double-blinded randomized controlled trials with longer follow-up periods are needed to generate more robust data.

WED-360

Effect of kidney injury and hemodynamic effect after moderate abdominal paracentesis: a randomized control study

Sakkarin Chirapongsathorn[1], Sanpolpai Khaoprasert[1], Anuchit Suksamai[1], Amnart Chaiprasert[2]. [1]*Phramongkutklao Hospital, Division of Gastroenterology and Hepatology, Department of Medicine, Bangkok, Thailand,* [2]*Phramongkutklao Hospital, Division of Nephrology, Department of Medicine, Thailand*
Email: sakkarin33@gmail.com

Background and aims: Patients with cirrhosis undergoing therapeutic paracentesis are at risk to develop kidney injury but not well evaluated in non-large volume paracentesis setting. The aims of this study are to determine the risk and consequence of acute kidney injury (AKI) and its progression in patients with decompensated cirrhosis after moderate paracentesis by use of a urine test measuring tissue inhibitor of metalloproteinases-2 (TIMP-2) and insulin-like growth factor-binding protein 7 (IGFBP7), both inducers of G1 cell cycle arrest and represent a key mechanism implicated in AKI and could predict AKI after paracentesis.
Method: A randomized, prospective cohort study was performed during December 2020 to December 2021. All outpatient decompensated cirrhosis with ascites were enrolled and randomized into 3 liters and 5 liters of paracentesis groups. Serial urine samples were analysed for [TIMP-2]*[IGFBP7] concentration before and after paracentesis. The primary outcome measure was kidney injury as defined by raising of Urine [TIMP2]*[IGFBP7] >2 $(ng/ml)^2/1000$ after moderate paracentesis (<5 liters ascites removal).
Results: A total of 90 patients with decompensated cirrhosis with ascites were consecutive enrolled during study period. After screening, 54 patients analyzed, 29 patients underwent in 3 liters paracentesis group and 25 patients underwent in 5 liters paracentesis group. The mean of MELD score was 8 ± 1.2. Of the 17 (31%) patients develop kidney injury after moderate paracentesis. Urine TIMP2.IGFBP7>2, rising urine TIMP2 and rising urine TIMP2/urine Cr were significant higher in patients within 5 liters paracentesis group. Mean arterial pressure were statistically significant decline at 2 hours after paracentesis in both groups. The Urine [TIMP2]*[IGFBP7] predicted hemodynamic event with an area under the curve [95% confidence interval (CI)] of 0.82 [0.72–0.99], an optimal cut-off value of 3.4 $(ng/ml)^2/1000$, a sensitivity 75%, and a specificity of 89%. For predicting severe AKI, hospital admission and death, Urine [TIMP2]*[IGFBP7] was not significantly discriminant. Five of these patients died within 90 days of follow-up.

Table 1: Primary outcome, secondary outcome and urine Biomarker data*

Variables	3 L group (n = 29)	5 L group (n = 25)	p value
Rising Urine TIMP2	3 (10.3%)	8 (32%)	0.049*
Rising Urine IGFBP7	8 (27.6%)	8 (32%)	0.723
Rising Urine TIMP2.IGFBP7	5 (17.2%)	7 (28%)	0.343
Rising Urine TIMP2/Urine Cr	12 (41.4%)	19 (76%)	0.010*
Rising Urine IGFBP7/Urine Cr	12 (41.4%)	13 (52%)	0.435
Rising Urine TIMP2.IGFBP7/ Urine Cr	9 (31%)	12 (48%)	0.202
TIMP2.IGFBP7>2	5 (17.2%)	12 (48%)	0.015*
Hemodynamic event	3 (10.3%)	5 (20%)	0.319
ΔMAP (120–0 mmHg)	−3.1 ± 3.7	−5.2 ± 4.3	0.065
Ascites release times (mins)	4 (3, 6)	6 (4, 6)	0.032*
Rapid decline of GFR	16 (55.2%)	14 (56%)	0.951
Admission within 3 months	7 (24.1%)	8 (32%)	0.520
Death within 3 months	3 (10.3%)	2 (8%)	0.767

*Value presented as n (%). P value corresponds to Independent t test or Pearson Chi-Square test.

Conclusion: Urine [TIMP2]*[IGFBP7] effectively identify patients with risk of kidney injury after moderate paracentesis but could not predict severe AKI. Below a cut-off of 3.4 $(ng/ml)^2/1000$, the risk of kidney injury is low. Kidney injury could occur even less than 5 liters of ascites release in decompensated cirrhosis was performed. Future studies should include a larger sample size to confirm these findings. The nation clinical registration number was TCTR20191116003.

WED-361

Clostridioides difficile infection in patients with liver cirrhosis

Olga Adriana Caliman-Sturdza[1]. [1]*Stefan cel Mare University, Faculty of Medicine and Biological Science, Suceava, Romania*
Email: sturdza_olga@yahoo.com

Background and aims: Clostridiodes difficile is is an infectious agent associated with significant morbidity and mortality in patients with cirrhosis. Our aim is to identify variables that are predictive of poor outcomes and the risk of mortality in this patient population.
Method: We investigated the patients hospitalized in our department in 2022 with the diagnosis of Clostridioides difficile infection (CDI) and liver cirrhosis.
Results: Out of a total of 174 patients diagnosed with enterocolitis with Clostridioides difficile, 28 patients were known to have liver cirrhosis, 4 of viral B and C etiology and 24 of toxic etiology. 21.4% of cirrhotic patients received antibiotics before being diagnosed with CDI and 46.4% were under treatment with proton pump inhibitors. Decompensation of liver disease occurred in 71.4% patients, manifested by confusion, drowsiness, psychomotor agitation (32.1%), jaundice and ascites (39.3%). CDI had an unfavorable evolution towards sepsis with multiple organ failure in a percentage of 17.8% of patients with cirrhosis compared to 2.7% of non-cirrhotic patients, 7.15% developed upper digestive hemorrhage, 11.2% phenomena of hepatic encephalopathy with evolution towards coma. Cirrhotic patients who developed sepsis with Clostridioides difficile had hypoalbuminemia and severe anemia at admission. Mortality was 10.7% in patients with cirrhosis and CDI and only 1.3% in the group of non-cirrhotic patients. Recurrences occurred in 21.4% of cirrhotic patients, compared to 4.2% of non-cirrhotic ones. Diarrhea subsided after 6 days of oral treatment with vancomycin, while in non-cirrhotic patients normalization of intestinal transit was achieved after 3 days of treatment.
Conclusion: Patients with both Clostridioides difficile infection and liver cirrhosis have worse outcomes than patients without cirrhosis, included morbid complications, death and higher rates of hospital readmission. The incidence of CDI in cirrhotic patients is increasing and has become more common in the community. Risk factors of treatment with proton pump inhibitors and antibiotic exposure were associated with the diagnosis of CDI in cirrhosis patients. Hypoalbuminemia and anemia were found to be predictors of increased mortality in cirrhosis patients with CDI.

WED-362

The prevalence and prognostic impact of myosteatosis with and without sarcopenia and its association with age and severity of liver cirrhosis

Eleni Geladari[1], Theodoros Alexopoulos[2], Meropi Kontogianni[3], Larisa Vasilieva[4], Ilianna Mani[5], Roxani Tenta[3], Sofia Manioudaki[6], Vasilis Sevastianos[1], Alexandros-Pantelis Tsigas[3], Ioannis Vlachogiannakos[2], Alexandra Alexopoulou[5]. [1]*Evangelismos General Hospital, 3rd Department of Internal Medicine and Liver Outpatient Clinic, Athens, Greece,* [2]*Laiko General Hospital, Gastroenterology Department, Athens, Greece,* [3]*School of Health Sciences and Education Harokopio University, Nutrition and Dietetics, Athens, Greece,* [4]*Alexandra General Hospital, Gastroenterology, Athens, Greece,* [5]*2nd Department of Internal Medicine and Research Laboratory, National and Kapodistrian University of Athens, Medical School, Hippokration General Hospital, Athens, Greece,* [6]*Intensive Care Unit, Sismanogleio General Hospital of Athens, Greece*
Email: alexandra61@med.uoa.gr

Background and aims: Myosteatosis (MS) is defined as increased fat infiltration in skeletal muscle and implies impaired muscle quality.

MS is different from sarcopenia but part of sarcopenia definition. MS may be considered as a precursor of sarcopenia. The aim of the study was to investigate the prevalence of MS either alone or with sarcopenia and its association with age and severity of liver disease.
Method: Skeletal muscle index (SMI) and MS measured by computed tomography at third lumbar vertebra, muscle strength evaluated by hand dynamometer and functionality by short physical performance battery (SPPB) were used to diagnose sarcopenia according to latest EWGSOP-2 criteria. MS was defined as muscle radiodensity <41 HU for dry body mass index <24, 9 kg/m^2 and <33 HU for ≥25 kg/m^2. Patients' demographics, severity of LC and 360-day mortality were recorded.
Results: 194 consecutive patients were included [age 61 (IQR 52–68); 66.5% male; MELD 10.5 (7.7–16); 60.3% with decompensated LC; 43.8%, 22.7% and 33.5% with alcoholic, viral and other etiology, respectively]. Patients were classified in four groups according to presence of MS and sarcopenia. Neither MS nor sarcopenia was diagnosed in 25.3% (group A), MS without sarcopenia in 30.9% (group B), sarcopenia according to handgrip and MS in 17.5% (group C) and sarcopenia according to handgrip, MS and low SMI in 26.3% (group D). MS was present in all but 3 cases with sarcopenia. There was a significant ascending order across the groups A, B, C and D in age [56 (50–63.5), 57.5 (51.2–66), 62.5 (57–69.5) and 67 (59–72.5) years, respectively, p < 0.001] and severity of LC as it was documented by the increasing rate of decompensated cirrhosis [32.7%, 58.3%, 73.5% and 80.4%, respectively, p < 0.001] and similarly by MELD (p < 0.001) and Child Pugh values (p < 0.001). In contrast, there was a significant descending order across the groups in SMI (p < 0.001) and SPPB (p < 0.001) values. Considering the Kaplan-Meier curve at 360 days, between groups B, C and D (no patient died in A), patients in group D had a higher mortality rate compared to B (log Rank P = 0.001) but not C (log Rank P = 0.068) (log Rank P = 0.002 in overall). In multivariable analysis adjusted for age and sex, mortality was 3.5 times higher in group D compared to B (as reference group) [HR 3.5 (95%CI 1.6–7.3), P = 0.002]. No difference was evident between groups B and C (p = 0.530).
Conclusion: In patients with LC, MS alone is present in earlier stage of LC and younger age and may imply a prodromal phase of muscle degeneration before the development of sarcopenia. MS is present in all but 3 patients with sarcopenia. Furthermore, sarcopenic patients with low SMI are older and have more advanced liver disease compared to sarcopenic with MS but normal SMI, implying that MS predates the decline of muscle strength and performance. Longitudinal data are required to draw solid conclusions about the significance of MS in patients with LC.

WED-363
Comparison of prognostic value of sarcopenia and MELD score in assessing 28 days and 3 months mortality in patients with cirrhosis of liver

Shivam Gupta[1,1]. [1]*Kalinga Institute of Medical Sciences, Gastroenterology and Hepatology, Bhubaneswar, India*
Email: iamdrshivam@gmail.com

Background and aims: Sarcopenia in patients with cirrhosis of liver has been associated with increased mortality, sepsis, hyperammonemia, heart failure, increased length of stay and has been seen to be predictive of waiting list mortality, independent of the Model for End Stage Liver Disease (MELD) score and other possible confounders such as gender and refractory ascites. Sarcopenia and MELD are proven independent prognostic factors for cirrhosis of liver. However, MELD does not take into consideration nutritional and functional status of the patient and has inferior performance in predicting mortality in subgroup with lower MELD scores (≤15). Therefore, a prospective observational study is being carried out to compare sarcopenia and MELD score in assessing 28 days and 3 months mortality in patients with cirrhosis of liver and to study prevalence of sarcopenia in different etiologies of cirrhosis of liver. This study will help in early and better prediction of mortality and therefore better listing of patients in need for liver transplant.
Method: This is an ongoing study on outpatients and inpatients ≥18 years of age and diagnosed with cirrhosis of liver. Patients with underlying co morbidities affecting nutrition such as human immunodeficiency virus, systemic malignancies, chronic kidney disease, neuromuscular disorders causing muscle wasting have been excluded. Also, patients with hepatic encephalopathy or hepatorenal syndrome where complete workup of sarcopenia was not possible have been excluded from this study. Evaluation of sarcopenia was based on combination of strength, assistance with walking, rising from a chair, climbing stairs and falls (SARC-F) questionnaire, hand grip strength test by dynamometer, transverse psoas muscle thickness evaluation for muscle quality and quantity by computerised tomography scan and physical performance by gait speed test. These patients with cirrhosis of liver and sarcopenia are then being followed up at 28 days and 3 months to record mortality.
Results: Out of 256 patients planned for recruitment in this study, 108 patients have been included in this interim analysis. Mortality is seen to be higher in patients with sarcopenia (21%) compared to cirrhotic patients without sarcopenia (11.1%). On assessing 28 days and 3-months mortality, sarcopenia was seen more in patients with lower MELD score (≤15) with higher mortality of 21%. Underlying etiology contributed significantly to development of sarcopenia with maximum sarcopenia seen in patients with Non-alcoholic fatty liver disease (NAFLD) followed by ethanol use related cirrhosis of liver.

Figure:

MELD score	Mean hand grip strength (Male)	Mean transverse psoas muscle thickness (Males)	Mean hand grip strength (female)	Mean transverse psoas muscle thickness (females)	Number of patients died	Percentage
≤15	15.97 kg	7.4 mm/m	11.8 kg	5.7 mm/m	11 (52)	21%
16–25	19.9 kg	8.4 mm/m	13.6 kg	6.9 mm/m	7 (38)	18%
≥26	16.2 kg	8.1 mm/m	13.4 kg	6.3 mm/m	6 (18)	33%

Conclusion: This interim analysis shows high prevalence of sarcopenia in cirrhosis with impact of sarcopenia on mortality seen to be more in patients with lower MELD score (<15) and thus, sarcopenia is seen to be a better predictor of 28 days and 3 months mortality at lower MELD scores in patients with cirrhosis of liver. Interestingly, sarcopenia was seen to be more in patients with NAFLD than those with ethanol use related cirrhosis of liver.

WED-364
Activation of the kynurenine pathway potentially underlies neurodegeneration in patients with covert hepatic encephalopathy

Georgia Zeng[1,2], Shivani Krishnamurthy[3], Ananda Staats Pires[3], Anna Guller[3], Nway Tun[1,2], Joga Chaganti[4], Ian Lockart[1,2], Sara Montagnese[5], Bruce Brew[6], Gilles Guillemin[3], Mark Danta[1,2], Benjamin Heng[3]. [1]*St Vincent's Clinical School, Faculty of Medicine, Australia,* [2]*St Vincent's Hospital, Gastroenterology, Australia,* [3]*Macquarie University, Macquarie Medicine School, Australia,* [4]*St Vincent's Hospital, Medical Imaging, Australia,* [5]*University of Padua, Medicine, Italy,* [6]*St Vincent's Hospital, Neurology and Immunology, Australia*
Email: georgiazeng@icloud.com

Background and aims: Hepatic encephalopathy (HE) is a neuropsychiatric complication of liver disease, characterised by elevated systemic concentrations of ammonia and pro-inflammatory cytokines. These neurotoxins can cross the blood brain barrier and act synergistically to cause neuroinflammation, which can activate the kynurenine pathway (KP). This results in depletion of local tryptophan (TRP) reserves and the production of neuroactive KP metabolites. Specifically, 3-hydroxykynurenine (3-HK) and

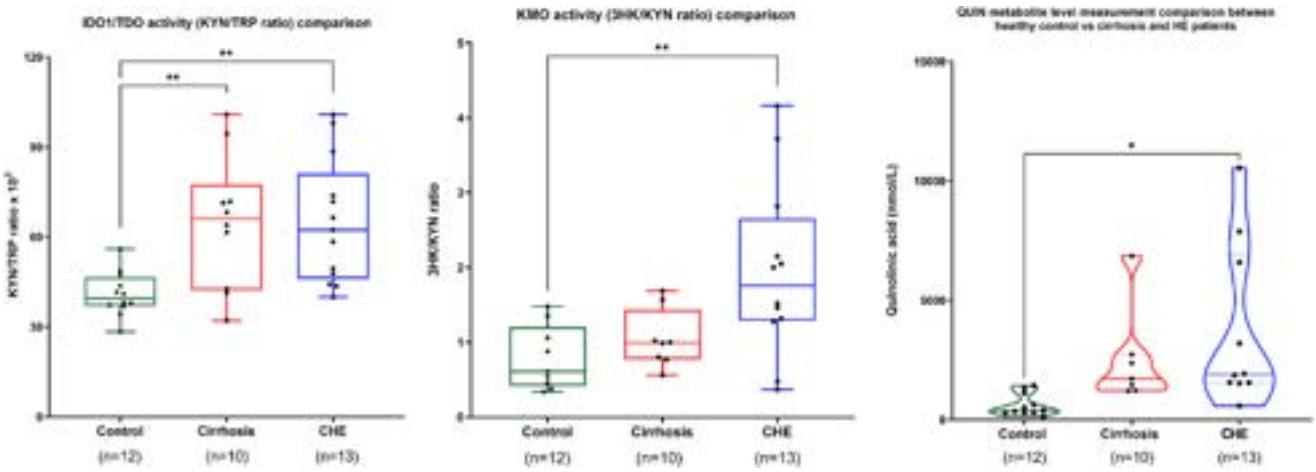

Figure: (abstract: WED-364): Comparison of KP metabolites between CHE patients, non-encephalopathic cirrhosis patients and healthy controls.

quinolinic acid (QUIN) cause astrocyte and neuronal death, while kynurenic acid (KYNA) is a NMDA receptor antagonist with neuroprotective effects. The aim of our study was to compare systemic KP activity between patients with covert HE (CHE), non-encephalopathic cirrhosis patients (NHE) and healthy controls.

Method: This was a single-centre prospective cohort study conducted between 2018–2021 at St Vincent's Hospital in Sydney. Overall, there were 13 CHE patients, 10 NHE patients and 12 healthy controls. Patients with cirrhosis were diagnosed with CHE if they scored ≤–4 on the validated Psychometric Hepatic Encephalopathy Score. Plasma samples were obtained to determine the expression levels of KP enzymes, calculated by a ratio of metabolite product divided by its substrate. TRP, alongside upstream KP metabolites such as kynurenine (KYN), anthranilic acid (AA), KYNA, 3-HK and 3-hydroxyanthranilic acid (3-HAA) were quantified using high-performance liquid chromatography (HPLC) and ultra-HPLC. Downstream KP metabolites, QUIN and picolinic acid (PIC) were quantified using gas-chromatography/mass spectrometry.

Results: KP was highly activated in cirrhosis patients, especially those with CHE, in comparison to healthy controls, as demonstrated by higher KYN/TRP ratios representing elevation of the rate-limiting enzymes, indoleamine-2,3-dioxygenase (IDO-1) and tryptophan-2,3-dioxygenase (TDO). Following catabolism of TRP to KYN, the subsequent kynurenine 3-monooxygenase (KMO) enzyme demonstrated elevation in CHE patients only, skewing the pathway towards production of 3-HK. Levels of KYNA were higher in CHE patients compared to NHE patients and healthy controls. The activation of downstream KP pathways was evident through the higher production of QUIN and PIC metabolites at the final node of the pathway in cirrhosis patients, especially those with CHE.

Conclusion: The activation of KP in patients with cirrhosis results in the dysregulated production of neurotoxic metabolites. The higher levels in the CHE cohort suggest this is potentially contributing to neurodegeneration and clinical course. Dysregulation of the KP pathway appears to already be underway in cirrhosis patients who do not yet show any clinical signs of neurocognitive impairment. Therapeutic agents that modulate KP activity may be able to alleviate symptoms of patients with CHE.

WED-365

A virtual reality-driving test to predict car accidents in patients with cirrhosis

Simon Johannes Gairing[1,2], Eva Maria Schleicher[1,2], Leonard Kaps[1,2], Sophia Schulte-Beerbuehl[1,2], Kristina Steiner[1,2], Joachim Labenz[3], Jörn Schattenberg[4,5], Peter Galle[1,2], Marcus-Alexander Wörns[1,2,6], Christian Labenz[1,2]. *[1]Department of Internal Medicine I, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, Germany, [2]Cirrhosis Center Mainz (CCM), University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, Germany, [3]Department of Medicine, Diakonie Hospital Jung-Stilling, Siegen, Germany, [4]University Medical Center of the Johannes Gutenberg-University, Department of Internal Medicine I, Mainz, Germany, [5]University Medical Center of the Johannes Gutenberg-University, Metabolic Liver Research Program, I. Department of Medicine, Mainz, Germany, [6]Department of Gastroenterology, Hematology, Oncology and Endocrinology, Klinikum Dortmund, Germany, Germany*
Email: sgairing@uni-mainz.de

Background and aims: Patients with cirrhosis and especially those with hepatic encephalopathy (HE) may have impaired driving skills and may be prone to car accidents. Currently, no sufficient tool is available to predict car accidents in these patients. This study aimed to evaluate the usefulness of a virtual reality-based application as a point-of-care tool to predict car accidents.

Method: A driving test using a virtual reality head-mounted-display (HTC Vive Pro eye) was developed to simulate five hazardous situations (e.g., a cyclist suddenly rides on the road). In this test, the car drives automatically on a straight street and events are triggered when an invisible hit box is passed. The patient has to react when he/she has recognized the hazardous situation. The time from triggering the event to pressing the handbrake is recorded as reaction time. Total reaction time (TRT) is defined as the combined reaction time to all five events. Car accidents were assessed retrospectively (previous 12 months) by interview at the day of enrollment. Minimal HE (MHE) was diagnosed using PHES. Patients were recruited in the outpatient clinic.

Results: In total, 112 patients with cirrhosis and 52 controls without cirrhosis were prospectively enrolled. Patients with cirrhosis were in median 61 years and median MELD was 10 (Child-Pugh A/B/C: 74/24/2%). MHE was detected in 14% (n = 15). Regarding safety, no participant had to abort the test; mild forms of motion sickness were present in 16% (n = 27). Patients with cirrhosis showed a worse median TRT compared to controls without cirrhosis (5.15 vs. 4.56 sec, $p < 0.001$). In patients with MHE, median TRT was significantly longer compared to patients without MHE (5.67 vs. 5.02 sec, $p = 0.01$). Seven patients reported a history of car accidents during the twelve months prior to study inclusion. Median TRT tended to be higher in patients with reported car accidents ($p = 0.099$). When patients who stopped driving for HE-related reasons or insecurity (n = 14) were added to the group of patients with accidents (modelled end point), then a longer TRT was significantly associated with the modelled end point in univariable ($p < 0.001$) and multivariable analysis (OR 2.83, $p < 0.001$) after adjusting for age, MELD and PHES.

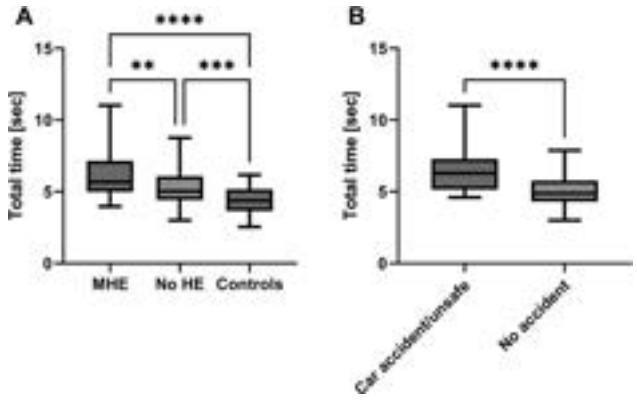

Figure: (A) TRT of patients with cirrhosis and MHE vs. without MHE vs. controls. (B) TRT of patients with the modelled end point (car accidents including patients not driving due to HE-related reasons or insecurity) vs. patients without car accidents. **p < 0.01, ***p < 0.001, ****p < 0.0001.

Conclusion: Virtual reality may be helpful as a point-of-care tool for assessing the risk of future car accidents in patients with cirrhosis.

WED-366

The association between angiotensin converting enzyme inhibitor or angiotensin receptor blocker exposure and key cirrhosis-related outcomes

Roy Wang[1], Marina Serper[2], Tamar H Taddei[3], David Kaplan[2], Nadim Mahmud[2]. [1]*Hospital of the University of Pennsylvania, Philadelphia, United States,* [2]*Hospital of the University of Pennsylvania, Hepatology, Philadelphia, United States,* [3]*Yale University, Digestive Diseases, New Haven, United States*
Email: royxwang88@gmail.com

Background and aims: Current guidelines caution against use of angiotensin converting enzyme inhibitors (ACEi) and angiotensin receptor blockers (ARB) in patients with decompensated cirrhosis. However, recent literature suggests ACEi/ARB may reduce fibrosis and mortality in patients with chronic liver disease or compensated cirrhosis. We explored the real-world association between ACEi/ARB and cirrhosis-related outcomes in a Veterans Affairs cohort.

Method: We performed a retrospective cohort study using an active comparator new user design of patients with cirrhosis newly initiated on ACEi/ARB or calcium channel blockers (CCB, comparator). Kaplan-Meier analysis was used to evaluate unadjusted associations with outcomes of mortality and—in a compensated cirrhosis subgroup—cirrhosis decompensation and hepatocellular carcinoma (HCC). Inverse probability treatment weighting (IPTW) was used to balance key confounders in Cox regression analysis. For the mortality outcome, subgroup analyses explored the impact of baseline Child-Turcotte-Pugh (CTP) class, diabetes, heart failure, and chronic kidney disease (CKD) stage on the primary association. Finally, cause-specific competing risk models were created to evaluate liver-related versus non-liver-related mortality.

Results: The cohort included 1,208 ACEi/ARB and 376 CCB new initiators. ACEi/ARB users were more likely to have higher body mass index (median 29.2 vs. 27.6, p < 0.001), non-alcoholic fatty liver disease (28.5% vs. 19.9%, p = 0.03), and metabolic comorbidities. In

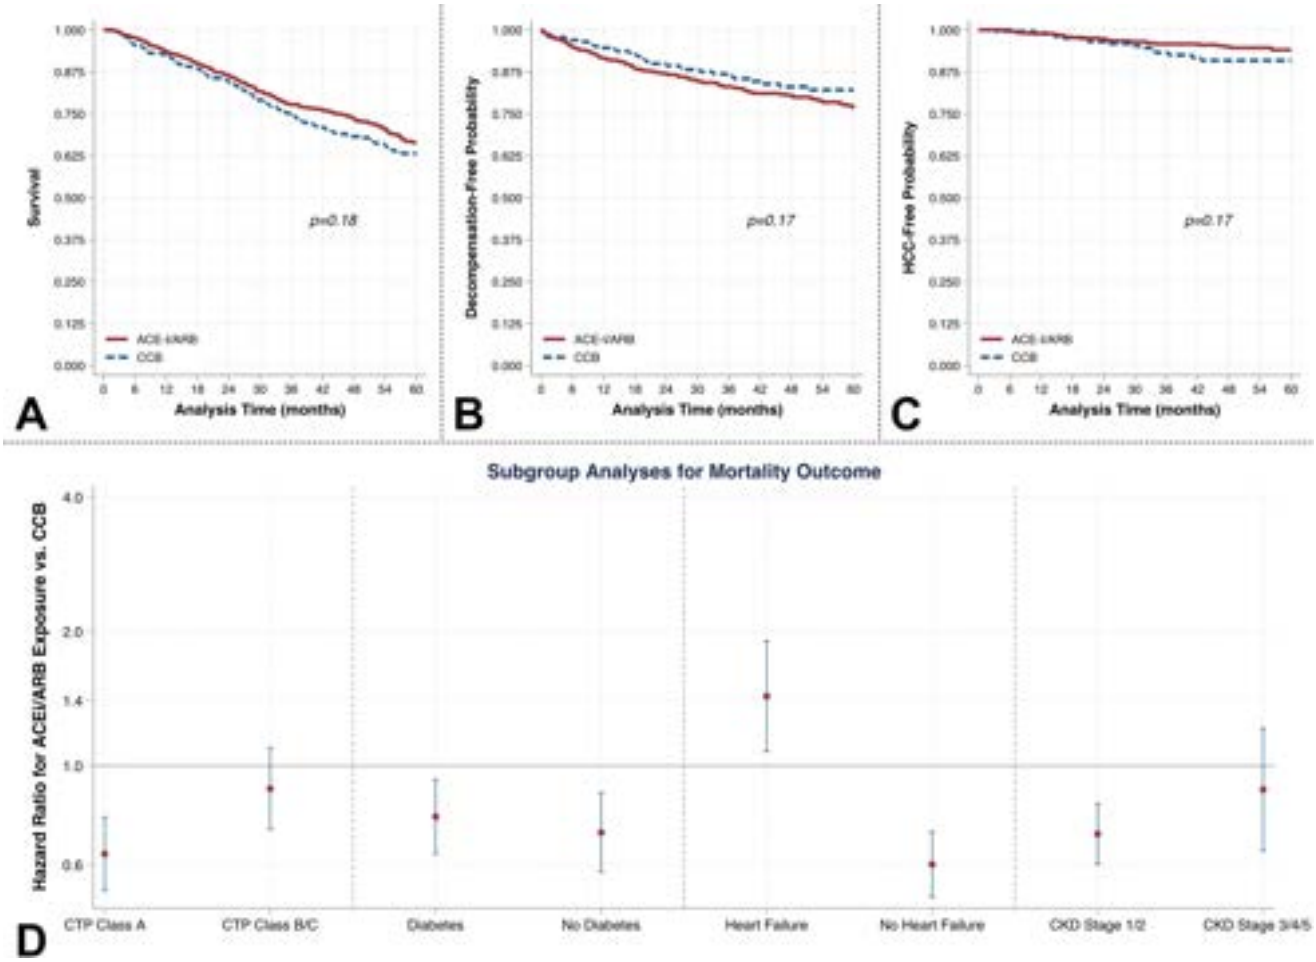

Figure: (abstract: WED-366).

unadjusted Kaplan-Meier analysis, ACEi/ARB exposure was not associated with reduction in mortality, cirrhosis decompensation, or incident HCC (each p > 0.05; Figure A/B/C). In IPTW Cox regression, ACEi/ARB exposure was associated with lower mortality (hazard ratio [HR] 0.74, 95% confidence interval [CI] 0.65–0.85, p < 0.001), increased hazard of cirrhosis decompensation (HR 1.29, 95% CI 1.01–1.65, p = 0.04), and no association with HCC (HR 0.88, 95% CI 0.57–1.37, p = 0.58). In subgroup analyses, the possible mortality benefit with ACEi/ARB exposure was isolated to patients with CTP class A, early-stage CKD, and an absence of heart failure (Figure D). In cause-specific competing risk models, ACEi/ARB exposure was associated with reduction in non-liver-related mortality (cause-specific hazard ratio [csHR] 0.58, 95% CI 0.47–0.71, p < 0.001) but not with liver-related mortality (csHR 0.90, 95% CI 0.75–1.09, p = 0.29).
Conclusion: ACEi/ARB exposure was associated with reduced mortality in patients with cirrhosis; however, this effect may be limited to CTP class A patients and those with early-stage CKD and no heart failure. Furthermore, this effect appears to be mediated through mitigation of non-liver-related mortality. Future research is needed to identify cirrhosis patient subgroups for whom the benefits of ACEi/ARB exposure exceed the risks.

WED-367

Liver nutrition clinic improves nutritional outcomes in patients with advanced cirrhosis

Kylie Matthews-Rensch[1], Elise Treleaven[1], Sharon Forbes[1], Dwayne Garcia[1], Joanne Mina[2], Olivia Cullen[2], Melanie Halford[2], Lucinda Vaux[2], Richard Skoien[2], Barbara Leggett[2], Enoka Gonsalkorala[2]. *[1]Royal Brisbane and Women's Hospital, Dietetics and Food Services, Herston, Australia, [2]Royal Brisbane and Women's Hospital, Gastroenterology and Hepatology, Herston, Australia*
Email: enokag@yahoo.com

Background and aims: Malnutrition and sarcopenia are recognised complications of cirrhosis and are associated with adverse patient outcomes. Current guidelines recommend nutrition assessments for all patients with advanced liver disease. The hepatology service at Royal Brisbane and Women's Hospital (RBWH) service a large catchment area spread over 170,000 km^2 in Queensland, Australia. The Liver Nutrition Clinic (LiNC) was developed to address nutrition requirements of patients with cirrhosis complications attending outpatient or inpatient hepatology services at RBWH. Here we describe the baseline characteristics and longitudinal nutritional outcomes of patients attending this specialist clinic.
Method: All patients attending LiNC were prospectively entered into a secure database and clinical, including nutritional and frailty, data were collected as part of routine clinical care. Descriptive statistics were used to describe demographics and interpret outcomes for patients attending LiNC between April 2021 to January 2023.
Results: Eighty-four patients (67% male, n = 56), median age 59 years (range 22–78 years) were included in this analysis. Indication (s) for referral were ascites (55%, n = 46), clinically significant weight loss (38%, n = 32), peripheral oedema (24%, n = 20), hepatic encephalopathy (14%, n = 12), and/or planned for liver transplant (12%, n = 10). About half (55%, n = 46) had more than one indication for referral. Chronic liver disease aetiology was alcohol (65%, n = 55), metabolic associated fatty liver disease (26%, n = 22), viral hepatitis (24%, n = 20) and other (12%, n = 10). Twenty-one patients had more than one aetiology (25%). Fifty-eight percent (n = 49) had ascites and 27% (n = 23) had peripheral oedema at baseline. Median values (range) for serology results were albumin 30 g/L (15–55), bilirubin 32 µmol/L (3–422), and international normalized ratio 1.3 (0.4–4.8). The median MELD score was 12 (range 6–33). Liver frailty index (LFI) was available for 41 participants (49%) at baseline with 17% (n = 7) robust, 76% (n = 31) pre-frail and 7% (n = 3) considered frail. Baseline LFI was not available for 43 patients due to attendance via virtual appointment (n = 21), inadequate time or administrative issues (n = 13) or being too unwell or unsafe to complete the assessments (n = 7). Only 29% (n = 24) of patients were assessed as having adequate nutritional intake and 51% (n = 43) were well-nourished (per Subjective Global Assessment) at baseline, and this improved at 3- and 6-month follow-up per figure 1.

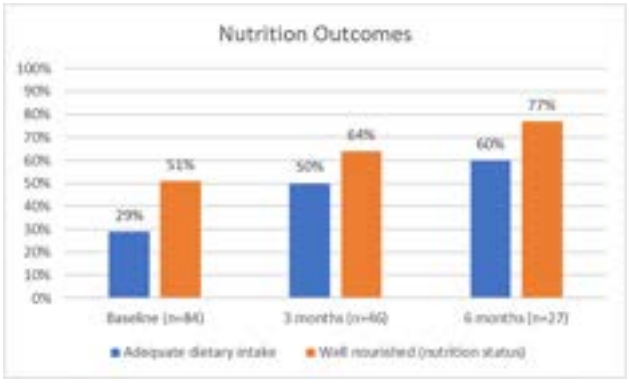

Figure: Nutrition Outcomes

Conclusion: Poor nutritional status (malnutrition) was a common finding in our cohort. Geographic spread and pandemic restrictions affected the ability to complete frailty assessment. This dedicated dietetic service for patients with cirrhosis complications improved dietary intake and nutritional status.

WED-368

Impact of allelic HLA divergence on the risk of bacterial infections in cirrhotic patients awaiting liver transplantation

Clementine Roger[1], Alessandra Mazzola[2], Romain Lhotte[3], Maxime Mallet[2], Dominique Thabut[2], Jean Luc Taupin[3], Filomena Conti[2]. *[1]Hôpital Paul-Brousse Ap-Hp, Villejuif, France, [2]University Hospitals Pitié Salpêtrière-Charles Foix, Paris, France, [3]Saint-Louis Hospital, Paris, France*
Email: clementine9roger@gmail.com

Background and aims: Bacterial infections are frequent in cirrhotic patients and are associated with an increased risk of cirrhosis decompensation and death. The underlying immunologic mechanisms are not well known and the effect of allelic HLA divergence (AHLAD) on the risk of bacterial infections in humans has never been studied. However, higher AHLAD could bestow greater immunocompetence.
Method: We conducted an observational, retrospective, monocentric study. Cirrhotic patients awaiting liver transplantation (LT) in our center from 01/2019 to 02/2022 were included. The primary aim was to assess the impact of class I and class II AHLAD on the risk of bacterial infections. The secondary aim was the evaluation of the impact of AHLAD on the risk of cirrhosis complications.
Results: 269 cirrhotic patients listed for LT were included. The mean age was 56 years old (± 11) and the median MELD score was 14 (IQR 9–19). Overall, 153 bacterial infections were diagnosed in 98 patients. The cumulated incidence of bacterial infections was 36,4%. After multivariate analysis, a greater class II AHLAD was associated with reduced bacterial infections (beta coefficient –0.0057; IC 95% –0.011; –0.0001; p = 0.034) while there was no effect of class I AHLAD (beta coefficient 0.0126; p = 0.074). Independent risk factors of bacterial infections (multivariate analysis) included the realization of invasive procedures (beta coefficient 0.1426; p < 0.001), hospitalization in an intensive care unit (beta coefficient 0.5141; p < 0.001), antibiotic therapy within three months preceding the listing (beta coefficient 0.2014; p = 0.046), rifaximin intake (beta coefficient 0.2066; p = 0, 043) and the occurrence of cirrhosis complications (beta coefficient 0.3266; p = 0.002). There was no effect of class I or II AHLAD on the risk of cirrhosis complications (OR 0.97; p = 0.14 and OR 1; p = 0.63 respectively).

Conclusion: This is the first time that the effect of AHLAD on the risk of bacterial infections was studied in humans. High class II AHLAD appears to be a protective factor from the risk of bacterial infections in cirrhotic patients awaiting LT. There was no impact of AHLAD on the risk of cirrhosis complications. Class II AHLAD could thus be considered as one of the immunological mechanisms underlying the risk of bacterial infections in this population.

WED-369

The impact of a massive transfusion protocol on the outcomes of patients with acute variceal bleeding: propensity score-matched analysis

Aryoung Kim[1], Byeong Geun Song[1], Myungji Goh[1], Dong Hyun Sinn[1], Wonseok Kang[1], Geum-Yon Gwak[1], Yong-Han Paik[1], Moon Seok Choi[1], Joon Hyeok Lee[1]. [1]*Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Korea, Rep. of South*
Email: dh.sinn@samsung.com

Background and aims: A goal-directed massive transfusion protocol (MTP) improved mortality and morbidity in trauma patients with hemorrhagic shock. However, whether MTP can improves outcomes for acute variceal bleeding is not known.
Method: A retrospective cohort of 218 consecutive patients with acute variceal bleeding who visited the emergency room between July 2014 and June 2022 were analyzed. Of those, 19 patients received MTP (8.7%). The 42-days mortality rate and treatment failures (death within 5 days, a 3 g/dL drop in hemoglobin within any 24 hours, and failure of endoscopic hemostasis within the first 24 hours) were compared by MTP use in overall cohort, subgroup stratified by systolic blood pressure (SBP) and the Model for End-Stage Liver Disease (MELD) score, and in 1:4 propensity score matched cohort. Matching variables were age, gender, initial SBP and the MELD score.
Results: In overall cohort, the 42-days mortality rate (42.1% vs 1.5%, p < 0.001), death within 5 days (26.3% vs 0%, p < 0.001), 3 g/dL hemoglobin drop within any 24 hours (21.1% vs 0.5%, p < 0.001), and failure of endoscopic hemostasis within the first 24 hours (15.8% vs 0%, p < 0.001) were higher in MTP group. MTP was associated with increased risk of mortality at 42-days (adjusted hazard ratio: 21.2, 95% confidence interval: 3.0–148.4). When stratified by initial SBP, the 42-days mortality rate was higher in MTP group in patients with SBp < 100 mmHg (46.2% vs 3.7%, p < 0.001), and in patients with SBP ≥100 mmHg (33.3% vs 0.7%, p < 0.001). When stratified by MELD score, the 42-days mortality rate was higher in MTP group in patients with MELD score ≥13 (47.1% vs 3.5%, p < 0.001). In 1:4 propensity matched cohort (n = 56; MTp = 14), the 42-days mortality rate was also higher in MTP group (42.9% vs 2.4%, p < 0.001).

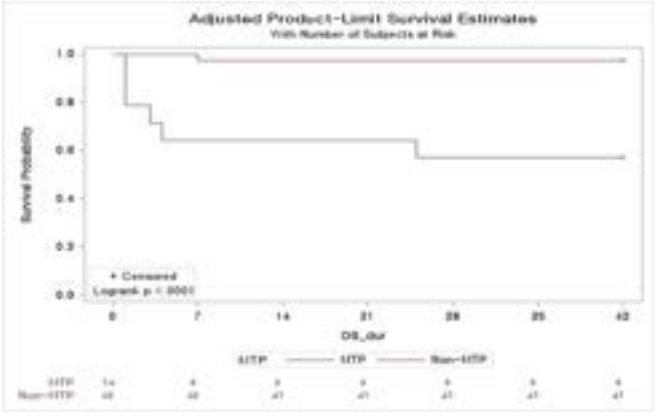

Figure: Kaplan-Meier curves of cumulative probability of 42-days mortality in patients receiving MTP compared to those who did not. (In the matched population)

Conclusion: In patients with acute variceal bleeding, goal-directed MTP was associated with poorer clinical outcomes, including mortality and treatment failure rates. MTP use may not improve, or may even worsen, clinical outcomes in patients with acute variceal bleeding.

WED-370

Acute kidney injury related to metamizole in advanced chronic liver disease patients undergoing major orthopedic surgery

Lidia Canillas[1,2,3], Amalia Pelegrina[2,3,4], Elena Colominas[5], Aina Salis[3], César Jessé Enríquez-Rodríguez[2,3], Antonia Caro[1], Marc Puigvehí[1,2], Teresa Broquetas[1,2], Susana Coll[1,2], NURIA Cañete[1,2], Montserrat García-Retortillo[1,2], Xavier Bessa[1,2,3], Juan Carlos Álvarez[6], Jose A. Carrión[1,2,3]. [1]*Hepatology section, Gastroenterology Department, Hospital del Mar, Barcelona, Spain,* [2]*IMIM (Institut Hospital del Mar d'Investigacions Mèdiques), Barcelona, Spain,* [3]*Departament de Medicina i Ciències de la Vida, Universitat Pompeu Fabra, Spain,* [4]*General Surgery and Digestive Department Hospital del Mar, Barcelona, Spain,* [5]*Pharmacy Department, Hospital del Mar, Barcelona, Spain,* [6]*Anesthesiology Department, Hospital del Mar, Barcelona, Spain*
Email: lidia.canillas.alaves@gmail.com

Background and aims: The use of metamizole and non-steroidal anti-inflammatory drugs (NSAIDs) is common after major orthopedic surgery, but they can lead to acute kidney injury (AKI) in patients with advanced chronic liver disease (ACLD).
Our objectives were to evaluate 1) the prevalence of patients treated with metamizole/NSAIDs and 2) the association with the development of complications (AKI or infections) during hospitalization.
Method: Retrospective, single-center study in patients with ACLD who underwent major orthopedic surgery (large joints and amputations) between 2010 and 2019. We recorded data about ACLD, comorbidities, analgesia, infection and type, development of AKI, hospital stay, and mortality. We defined severe infection if it required ICU admission, and multidrug-resistant microorganism (MDRM) if it presented resistance to ≥2 groups of antibiotics. Differences were compared with Chi-square or U-Mann Whitney tests, and the multivariate analysis was performed using binary logistic regression. Survival curves were contrasted with the Mantel-Cox test.
Results: Of 123 patients with ACLD who underwent major orthopedic surgery, 13 (11%) were excluded due to missing data. The median age (IQR) was 73 (62–82) years, 55% (61/110) were women, and 59 (75%) Child-Pugh A. The ACLD etiology was viral in 52 (47%) and alcohol in 40 (36%) patients. The hospital stay was 11 (5–18) days. Metamizole and/or NSAIDs were administered in 84 (76.4%) patients: 62 (56.4%) metamizole and 39 (35.5%) NSAIDs. Infection was observed in 43 (35%) patients: urinary tract (25/122; 21%), skin/prosthesis (16/122; 13%), and respiratory (14/122; 12%). Severe and MDRM infections were present in 12% (5/43) and 35% (15/43), respectively. Patients who developed infection were older (79 vs. 68 years; p < 0.01) and predominantly women (70% vs. 50%; p = 0.04). During admission, AKI was found in 25 (23%) patients: 20 (80%) AKI-I, 4 (16%) AKI-II, and 1 (4%) AKI-III. AKI was not associated with hypertension, diabetes, chronic kidney disease, Child-Pugh, or portal hypertension (p = ns). Patients with AKI were older (83 vs. 70 years; p < 0.01), had lower albumin values (3.6 vs. 4.1 g/dl; p = 0.03), higher prevalence of infection (60% vs. 31%; p < 0.01) and higher metamizole administration (88% vs. 42%; p < 0.01). In the multivariate analysis, the presence of AKI was related to age >75 years [aOR 5.6 (1.7–17.9) p < 0.01)] and metamizole [aOR 7.0 (1.8–27.2) p < 0.01)]. Postoperative mortality at 30 days was higher in patients with AKI (20% vs. 6%, Log-Rank = 0.03).
Conclusion: In our cohort of patients with ACLD, the use of metamizole after major orthopedic surgery was very frequent and

was associated with the development of acute renal failure during admission. These data suggest the need to optimize perioperative management of patients with ACLD.

WED-371

Racial disparities in COVID-19 clinical outcomes among patients with cirrhosis in North America and Europe-an international registry study

Umar Hayat[1], Saba Afroz[2], Faisal Kamal[3], Muhammad Haseeb[4], Faisal Inayat[5], Muhammad Kamal[6], Andrew Moon[7]. *[1]Geisinger Health, Internal medicine, division of gastroenterology, Wilkes-Barre, United States, [2]Geisinger Health, Internal medicine, Wilkes-Barre, United States, [3]Thomas Jefferson University hospital, Internal medicine, division of gastroenterology, Philadelphia, United States, [4]Beth Israel Deaconess medical center, Internal medicine, Boston, United States, [5]Jinnah hospital Lahore, Internal medicine, Lahore, Pakistan, [6]Essen Health Care, Internal medicine, New York, United States, [7]University of North Carolina, Division of Gastroenterology and Hepatology, Chapel Hill, United States*
Email: umarhayat216@gmail.com

Background and aims: Patients with decompensated cirrhosis have a higher risk of hospitalization, ICU admission, and death from COVID-19. The degree to which these outcomes vary with race and ethnicity is unclear.

Method: We used the SECURE-Liver and COVID-Hep international databases to explore disparities in COVID-19 outcomes among patients with cirrhosis. Patients were stratified by continent (North America and Europe). We defined race/ethnicity as white/non-Hispanic, black/non-Hispanic, and Hispanic for patients from North America. Given the low proportion of black patients in our European cohort, we defined race/ethnicity as white/non-Hispanic and non-white/non-Hispanic for Europe. Bivariate and multivariable logistic regression analyses were performed to determine the association between race/ethnicity and hospitalization, ICU admission, and death. Variables in the multivariable model included age, sex, CTP class, and comorbidity index (CI) (sum of obesity, hypertension, DM, CKD).

Results: Our cohort included 718 patients with cirrhosis and COVID-19 from North America (n = 290) and Europe (n = 428). In the North American subgroup, 51% of patients were white/non-Hispanic, 32% were black/non-Hispanic, and 17% were Hispanic. Black patients had a higher prevalence of comorbidities than white patients (CI 1.86 vs. 1.83, p = 0.007). Compared to white patients, a higher proportion of black patients were hospitalized (77% vs. 85%, p = 0.01), admitted to the ICU (27% vs. 40%, p = 0.05), and died (18% vs. 28%, p = 0.07) (Figure 1). Hispanic patients had the lowest proportions of clinical outcomes in all three groups. In the multivariable analysis, there were no statistically significant differences in the odds of clinical outcomes between white, black, and Hispanic patients. In the European cohort, 82% of patients were white/non-Hispanic, and 17% were non-white/non-Hispanic. White patients had a higher prevalence of comorbidities than non-white patients (CI; 1.63 vs. 1.31, p = 0.02). However, compared to white patients, a higher proportion of non-white patients were hospitalized (82% vs. 67%, p = 0.01) and admitted to the ICU (15% vs. 18%, p = 0.04), but fewer patients died (28% vs. 34%, p = 0.01) (Figure 1). In multivariable analyses, there were no statistically significant differences in the odds of clinical outcomes between the two groups.

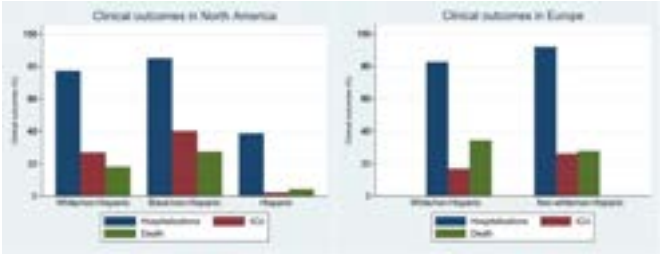

Figure: Clinical outcomes by race/ethnicity in North America and Europe

Conclusion: In conclusion, black patients in North America had a higher risk of hospitalization, ICU admission, and death than white patients. Similar findings were shown in the Europe subgroup; however, white patients had a higher risk of death than non-whites. There were no statistically significant differences for any outcomes after adjusting for potential confounders. The increased likelihood of poor outcomes in non-white patients, particularly in North America, may be driven by non-liver-related comorbidities.

WED-372

Effectiveness and safety of anticoagulant treatment in patients with liver cirrhosis and non-tumoral splenic-portal thrombosis

Nelson Daniel Salazar Parada[1], Elena Gómez Domínguez[1], Sara Pastor Royo[1], Nuria Del Val Huerta[1], Ana Martín Algibez[1], María Luisa Manzano Alonso[1], Maria Amo[1], Berta De las Heras[1], Inmaculada Fernández Vázquez[1]. *[1]Hospital Universitario 12 de Octubre, Gastroenterology and hepatology, Madrid, Spain*
Email: nnspdaniel@hotmail.com

Background and aims: Splenoportal axis thrombosis is a relatively common complication of liver cirrhosis, which can lead to liver function worsening, as well as morbidity and mortality increase after liver transplantation. Furthermore, if thrombosis is extensive, patients might not be able to receive a liver transplant. Although its treatment with anticoagulation is well established, its approaches are heterogeneous and there is not enough evidence about its effectiveness and safety in these patients.

The goal of the current study was to evaluate the effectiveness and safety of anticoagulant treatment in cirrhotic patients with non-tumoral thrombosis of the splenoportal axis in clinical practice.

Method: We retrospectively included all patients with liver cirrhosis and non-tumoral splenic-portal thrombosis who received anticoagulant treatment during 2017 to 2022 in our center. Six months into the treatment, the patient´s response was assessed by partial or complete thrombosis recanalization on imaging tests (US/CT/MRI).

Results: A total of 91 cases were enrolled (64.84% male; median age: 60 ± 13.5 years). At the moment of thrombosis patients were in Child-Pugh classes A: 59.3% (n = 54); B: 28.5% (n = 26) and C: 12% (n = 11). Etiologies of cirrhosis included: alcohol-related liver disease 37.3% (n = 24), followed by chronic HCV infection 28.5% (n = 26), indeterminate 10.9% (n = 10) and MAFLD 5.49% (n = 5). Most common sites of thrombosis were the portal vein 53.8% (n = 49), followed by portal branches 15.3% (n = 14), and 7.6% (n = 11) in both territories. Most frequent type of anticoagulant treatment was low molecular weight heparin (78.2% patients), followed by 22.8% patients who received vitamin K antagonists. Global thrombosis recanalization was achieved in 55% patients (n = 50), being complete in 68% (n = 34) and partial in 32% (n = 16). Univariate and multivariate analysis did not show statistically significant association between response to treatment and baseline patient variables such as etiology, Child-Pugh class, MELD score, or thrombosis extent. During follow-up (42 ± 18.2 months), 13.1% patients (n = 12) died due to non-hemorrhagic complications of their liver disease; 8.7% (n = 8) presented

esophageal variceal bleeding, 0.9% (n = 1) presented bleeding due to portal hypertension gastropathy and 3.2% patients (n = 3) presented minor bleeding in other locations. No patient died due to hemorrhagic complications.
Conclusion: In our study, patients with liver cirrhosis and non-tumor splenic-portal thrombosis responded to anticoagulant treatment effectively. This treatment has achieved global thrombosis recanalization in more than half of cases, with an acceptable safety profile. Finally, in our analysis, we do not find some predictive factors of response to anticoagulation therapy.

WED-373

Normalisation of the psychometric hepatic encephalopathy score in a Nigerian population

Mansur Mohammed[1], Musa Muhammed Borodo[2], Shettima Kagu Mustapha[3]. [1]*University Hospitals of Leicester NHS Trust, Leicester, United Kingdom,* [2]*Aminu Kano Teaching Hospital, Medicine, Kano, Nigeria,* [3]*Ahmadu Bello University Teaching Hospital, Medicine, Zaria, Nigeria*
Email: mansurfm@gmail.com

Background and aims: Minimal hepatic encephalopathy (MHE) is part of the spectrum of hepatic encephalopathy (HE) with subtle cognitive and motor deficits, often not detected by routine clinical examination. The psychometric hepatic encephalopathy score (PHES) has been recommended as gold standard for the diagnosis of MHE, to allow for early diagnosis and treatment, and prevent progression to overt HE. Normalisation studies have been carried out in different countries to determine local norms and cut off values for diagnosis. This study aimed to construct normograms for the PHES test in the Nigerian population, calculate the cut off value for diagnosing MHE, and determine the prevalence of MHE among patients with liver cirrhosis.
Method: Two hundred apparently healthy subjects and 85 patients with liver cirrhosis but without overt hepatic encephalopathy were recruited. They all undertook the PHES test which include Number Connection Test-A (NCT-A), Number Connection Test-B (NCT-B), Digit Symbol Test (DST), Serial Dotting Test (SDT) and Line Tracing Test (LTT). The time taken for each subtest was converted to scores and summed up to give the final score of PHES. The cut off for abnormal PHES score was determined using results from the healthy subjects. Normal range of scores was taken as within mean ± 2 SD. Abnormal PHES was set at PHES score less than-2 SD from the mean. Pearson's correlation coefficient was used to identify variables that confounded the PHES scores. These were then entered into multiple linear regression to construct formulas to remove the effect of these confounders and predict the PHES scores in the cirrhotic group. Using these formulas, PHES score was calculated in the cirrhotic patients and prevalence of MHE was determined. Chi square test was used to test for association between MHE and categorical variables and student t test for quantitative variables. Statistically significant variables (p = <0.05) were entered into logistic regression to identify independent predictors of MHE.
Results: The mean age of the cirrhotic patients was 40.5 ± 11.8, with male to female ratio of 2.4. These were not significantly different from those of the controls. Age and education years were found to affect the PHES score (p = <0.05) while sex did not. The mean PHES in the cirrhotic group was-6 ± 3.7 (range-12 to 3). The cut off for diagnosis of MHE was calculated as <- 5. Hepatitis B was the predominant cause of liver cirrhosis (69.4%) while majority of the patients (62.4%) had decompensated cirrhosis (Child Pugh class B and C). Prevalence of MHE was 51.8%. Prothrombin time, albumin and Child Pugh class were significantly associated with MHE, while Child Pugh class and prothrombin time were independent predictors (O.R 9.3 and 19.5 respectively).

Table 1: Formulas for Predicting the PHES Score

PHES Test	Equation	SD
NCT-A	42.37 + (0.565 × Age)- (1.454 × Education Years)	6.400
NCT-B	100 + (0.677 × Age)- (2.212 × Education Years)	10.635
DST	35- (0.187 × Age) + (0.457 × Education Years)	3.156
SDT	100 + (0.716 × Age)- (1.162 × Education Years)	9.610
LTT	187 + (1.023 × Age)- (1.918 × Education Years)	19.932

Conclusion: This study constructed the Nigerian PHES normograms and determined a local cut-off value for MHE in Nigeria. It identified a high prevalence of MHE, underscoring the need for routine screening in patients with liver cirrhosis. Development of easily accessible online calculators using these normograms will aid easy and accurate diagnosis of MHE in clinical settings.

WED-374

Nutritional status of patients with advanced chronic liver disease: descriptive baseline of a prospective study

Estela Soria López[1], Laura Rey Fernández[2], Jorge Alberto Costa Fernandez[3], Francisco Rivas Ruiz[4], Jose Miguel Rosales Zabal[1]. [1]*Hospital Costa del Sol, Gastroenterology and Hepatology, Marbella (Málaga), Spain,* [2]*Hospital Costa del Sol, Hospital Pharmacy and Nutrition Unit, Spain,* [3]*Hospital Costa del Sol, Radiology Unit, Spain,* [4]*Hospital Costa del Sol, Investigation Unit, Spain*
Email: estelasoria89@gmail.com

Background and aims: Malnutrition in patients with advanced chronic liver disease is a prognostic factor, however, often forgotten in clinical practice. We analyzed the nutritional status of a prospective cohort in our healthcare area.
Method: Baseline descriptive analysis of a prospective study to assess nutritional status and evolution after starting oral supplementation. We included patients from day hospital (ascites unit) and hepatology consultation, identified as at risk or malnourished, with prior informed consent. After nutritional screening with Subjective Global Assessment (SGA), Malnutrition Universal Screening Tool (MUST) and Royal Free Hospital-Nutritional Prioritizing Tool (RFH-NPT), we performed anthropometry, dynamometry (hand pressure strength), blood tests, critical flicker frequency test (CFF), SF-36 health questionnaire and determination of the musculoskeletal index by measuring muscle mass at the L3 level by CT scan.
Results: 37 patients, 81% male. Median time in cirrhosis 2 years. Place of nutritional assessment: 27 day hospital, 9 nutrition consultation, 1 inpatient. Etiology: 1 HBV and 36 alcohol (6 mixed: 4 viral, 1 metabolic, 1 lymphoma). Portal hypertension data: 67.6% portal dilatation, 62.2% splenomegaly, 70% varicose veins. Decompensations: 89% ascites, 24% encephalopathy, 5.4% variceal upper gastrointestinal haemorrhage, 16% spontaneous bacterial peritonitis, 8% hepatorenal syndrome. Functional status: Child-Pugh (9A, 20B, 6C, 2 not listed for anticoagulation), median MELD 13, median MELD-Na 17.

ANALYTIC (medians)				
Lymphocytes 1.180/mcl	INR 1.38	Sodium 131mEq/L	Selenium 54mcg/L	Vitamin D 11.8mg/dl
Hemoglobin 10.5g/dl	Creatinine 0.68mg/dl	Potassium 4mEq/L	Magnesium 1.77mg/dl	Albumin 3g/dl
Platelets 139.000/mcl	Bilirubin 1.5U/L	Zinc 43mcg/dl	Phosphorus 3.5mg/dl	Prealbumin 8.1mg/dl
ANTHROPOMETRY (medians)				
Body mass index 25	Arm circumference 25cm		Calf circumference 34cm	
Triceps skinfold 17mm	Knee-heel length 60cm		Olecranon-styloid length 27cm	
DYNAMOMETRY n=33	27 patients (81%) decreased value (H <30kg, M <20kg)			
CRITICAL FLICKER FREQUENCY n=30	Median 42.3 Hz	Pathologic (<38 Hz) → 3 patients		
MUSCULOSKELETAL INDEX n=30	Median 50.22 cm²/m²			

Nutritional screening test

	MUST low risk	MUST medium risk	MUST high risk
SGA-A well nourished	1	0	0
SGA-B nutritional risk	4	1	2
SGA-B moderately malnourished	1	13	6
SGA-C severely malnourished	0	0	10
	RFH low risk	RFH medium risk	RFH high risk
SGA-A well nourished	0	0	1
SGA-B nutritional risk	1	2	4
SGA-B moderately malnourished	0	8	11
SGA-C severely malnourished	0	0	10

Nutritional diagnosis → 3 nutritional risk, 3 mild malnutrition, 21 moderate, 10 severe malnutrition

CHILD-PUGH Chi squared: 0.303	Moderate malnutrition (* 2 no Child)	Severe malnutrition		
Child-Pugh A	7	1		
Child-Pugh B	9	7		
Child-Pugh C	3	2		
DYNAMOMETRY	Nutritional risk	Mild malnutrition	Moderate malnutrition	Severe malnutrition
Reduced muscle force	2 / 3	3 / 3	14 / 19 * 2 unmeasured	8 / 8 * 2 unmeasured
CFF	Moderate malnutrition	Severe malnutrition		
Pathologic <38Hz → 5 patients	3	2		

Correlation between dynamometry and musculoskeletal index (Pearson 0.515)

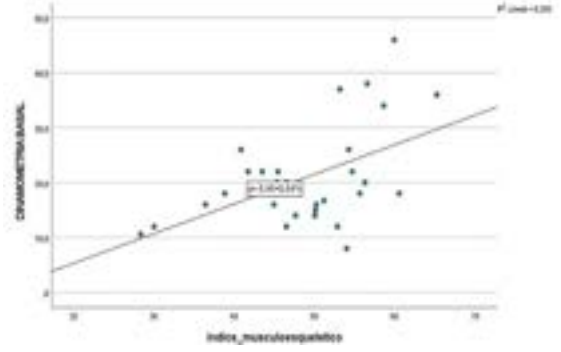

Figure:

Conclusion: Using several tools increases the reliability of nutritional risk assessment. RFH-NPT overestimates the risk of malnutrition in decompensated patients, compared to SGA and MUST, which are comparable. There are no differences in the distribution of malnutrition according to Child-Pugh. Micronutrient deficiency and frailty determined by dynamometry are frequent; sarcopenia is not, but there is a good correlation between dynamometry and CT. Malnutrition does not seem to influence CFF. Currently evaluating the impact of the implementation of a nutritional treatment.

WED-375

Experiences from a palliative care clinic specialized in liver diseases-utilisation, clinical characteristics of patients and outcomes

Fernando Xavier e Silva[1], Elizabeth Lee[2], Hemant A Shah[2], David Wong[2], Breffni Hannon[3], Kirsten Wentlandt[1], Ebru Kaya[1].
[1]*University of Toronto, Department of Supportive Care-Palliative Care, Toronto, Canada,* [2]*University of Toronto, Toronto Centre for Liver Disease (TCLD), Toronto, Canada,* [3]*University of Toronto, Department of Supportive Care-Palliative Care-Princess Margaret Cancer Centre, Toronto, Canada*
Email: silva.fernandoxavier@gmail.com

Background and aims: Despite the significant global increase in liver disease over the last few decades and the high symptom burden for affected patients, access to palliative care (PC) is historically low and referrals happen late in the disease trajectory. Furthermore, the literature on PC in this area is sparse compared to other chronic diseases. This study aims to add to the evidence surrounding the utilization of PC services by this population, and to analyze the underlying reasons for referral as well as the morbidity and outcomes of referred patients.
Method: This study retrospectively reviewed charts of adult patients (18 years or older) with advanced-stage liver disease referred to a specialized PC clinic between May 2019 and May 2022. Data collected included type of primary liver disease, functional status (measured using the Palliative Performance Scale (PPS), a discrete numerical scale from 0% to 100%), and intensity of symptoms at the time of the first visit (using the Edmonton Symptoms Assessment System (ESAS), a discrete numerical scale from 0 to 10 used by patients to grade the intensity of common symptoms), candidacy for liver transplant, comorbidities, outcomes from the clinic (discharge, transfer for other modality of PC, continued care in the clinic, loss of follow-up or death during follow-up) and time and place of death. The study was approved by the research ethics board at University Health Network (UHN). Descriptive statistics were used to analyze data.
Results: Fifty-four patients were included, 30 (55.6%) were male and 70 years was the median age. Cirrhosis secondary to viral hepatitis was the most common diagnosis (18 patients, 33.3%) followed by alcohol-associated liver disease (17, 31.5%). A significant number of patients (24, 44.4%) also had hepatocellular carcinoma and 44 (81.5%) had more than two comorbidities. Forty (64.1%) patients were referred for both symptom management and palliative planning, and 5 patients (9.3%), for symptom management alone. Seven patients (13.0%) were candidates for a liver transplant, of whom 4 (57.1% of candidates) underwent transplantation. Regarding function, 33 patients (61.1%) had a PPS between 50–60% and none had a PPS of 30% or lower. Regarding their symptoms, the overall mean score per symptom on ESAS was 3.6 (median 3) (out of 10) and fatigue had the highest score (6.4, median 7), followed by lack of well-being (average 4.2, median 4) and lack of appetite (3.71, median 4). Patients were followed in the PC clinic for an average of 15.7 weeks (median of 10 weeks) with a mean of 4.6 (median of 3) visits. Outcomes from the clinic were related to clinical deterioration for 36 patients (66.7%) and 19 (35.4%) had their care transferred to home-visiting PC physicians (19, 35.4%) while 8 (14.8%) were referred to PC units. 36 patients (66.7%) died, with a mean survival of 31.2 weeks (median of 24 weeks).

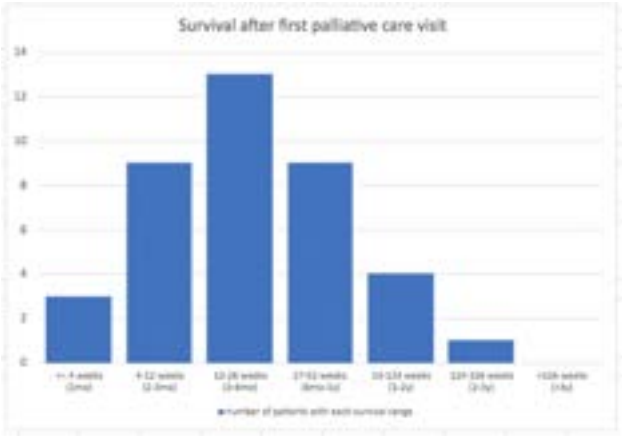

Figure:

Conclusion: Despite being referred for PC when presenting with an intermediate functional capacity and low symptom burden, patients

had high mortality and short follow-up and survival. More flexible criteria for PC referrals may be considered, possibly through a better understanding of prognostic factors for this population, to promote earlier referrals and better and longer support for patients and their families.

WED-376

Booster SARS-CoV-2 vaccination elicits robust antibody response to wild type but not Omicron subvariants BA.4/5 in patients with cirrhosis

Qian Zhu[1], Lu Wang[1], Xiaoxiao Hu[1], Dejuan Xiang[1], Ming-Li Peng[1], Dachuan Cai[1], Xiaofeng Shi[1], Hong Ren[1]. [1]*Institute for Viral Hepatitis, The Second Affiliated Hospital, Chongqing Medical University, China*
Email: renhong0531@cqmu.edu.cn

Background and aims: Our aim is to determine immune efficacy of booster SARS-CoV-2 vaccination in cirrhotic patients who had received the 2-dose inactivated vaccines.
Method: We performed a longitudinal assessment in 48 patients with cirrhosis to continuously track the dynamics of SARS-CoV-2 specific antibodies and memory B cells after receiving the primary 2-dose series and booster dose. Neutralizing antibodies (NAbs) in serum samples were evaluated by capture chemiluminescence immunoassays. Neutralizing activity against Omicron subvariants BA.2.12.1, BA.4 and BA.5 was examined by pseudovirus neutralization assay.
Results: Serum neutralizing antibodies levels in cirrhotic patients were elevated in the early 15–45 days after primary series before rapidly declining and reaching a valley at around 165–195 days. After receiving the booster dose, the NAbs level was re-increased significantly (0.1μg/ml vs. 0.8μg/ml, p = 0.001). 1 month after a booster dose, the serum geometric mean titer (GMT) against Omicron subvariants BA.2.12.1, BA.4 and BA.5 were 1.4-fold, 3.6-fold and 4.3-fold lower than titer against wild type (WT) strains respectively. Compared to 1 month after primary series, cirrhotic patients who received the booster dose did not show an evident improvement of neutralization activity against the Omicron subvariants BA.2.12.1 and BA.4 (BA.2.12.1, 1.9-fold; BA.4, 2.4-fold), and even exhibited a significant lower GMT against the Omicron subvariants BA.5 (3.3-fold, p = 0.042).
Conclusion: Booster SARS-CoV-2 vaccination elicits robust antibody response to wild type but not Omicron subvariants BA.4/5 in patients with cirrhosis. Repeated vaccination of inactivated SARS-CoV-2 vaccine might dampen neutralization activity against newly circulating strains.

WED-377

Poorer results in the clinical frailty scale are associated with covert and overt hepatic encephalopathy in patients with cirrhosis

Eva Maria Schleicher[1,2], Leonard Kaps[1,2], Jörn Schattenberg[1,2], Peter Galle[1,2], Marcus-Alexander Wörns[3], Simon J. Gairing[1,2], Christian Labenz[1,2]. [1]*University Medical Center of the Johannes Gutenberg-University, Department of Internal Medicine I, Mainz, Germany,* [2]*University Medical Center of the Johannes Gutenberg-University, Cirrhosis Center Mainz (CCM), Mainz, Germany,* [3]*Klinikum Dortmund, Department of Gastroenterology, Hematology, Oncology and Endocrinology, Germany*
Email: eva.schleicher@unimedizin-mainz.de

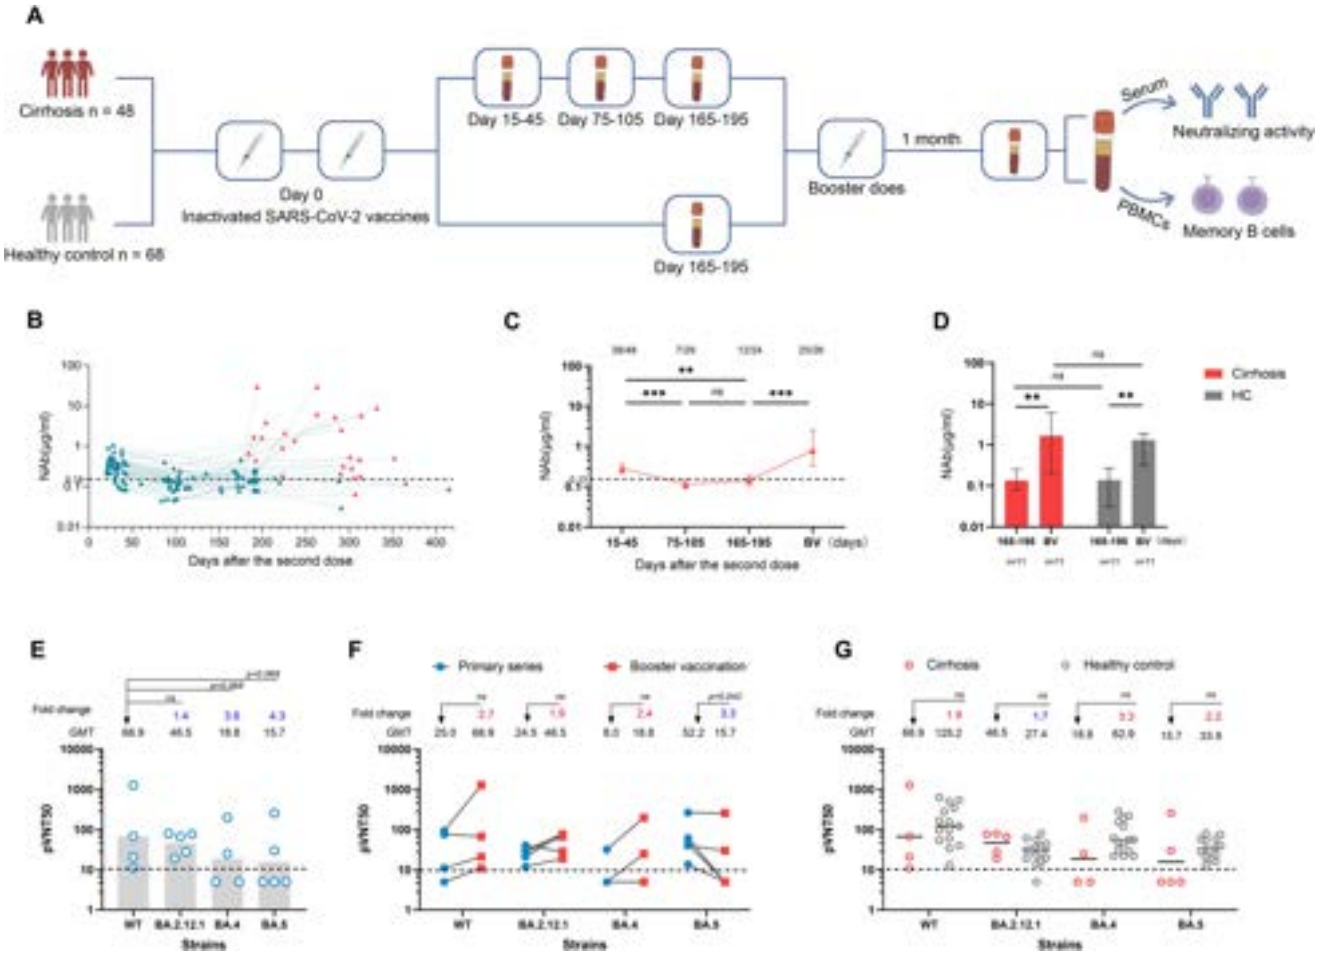

Figure: (abstract: WED-376).

Background and aims: Hepatic encephalopathy (HE) is associated with impaired quality of life, poor prognosis, and frequent hospitalizations in patients with liver cirrhosis. Frailty increases the vulnerability to internal and external stressors and may therefore be an indicator of a higher frequency of cirrhosis complications. We aimed to investigate the association of the rapidly applicable Clinical Frailty Scale (CFS) with covert HE (CHE) and overt HE (OHE) development in patients with cirrhosis.
Method: This study analyzed data from 228 outpatients or electively hospitalized patients with cirrhosis recruited at the Cirrhosis Center Mainz, Germany. Frailty was assessed using the CFS. Patients were examined for the presence of CHE at study inclusion using the West-Haven-Criteria (HE1) and the psychometric hepatic encephalopathy score (PHES). All patients were prospectively followed regarding the development of OHE.
Results: Patients had a median age of 60 years, and the predominant etiology of liver cirrhosis was alcoholism (32.5%), followed by viral hepatitis (19.7%). Median CFS was 3 (IQR 2; 3). 26 (11.4) patients were at least pre-frail (CFS >3) according to CFS. The majority of the patients were in a compensated state of cirrhosis (Child-Pugh A/B/C: 60.5%/30.3%/9.2%), and the median MELD at baseline was 10 (IQR 8; 14). CHE was detected in 71 patients (31.1%), and 33 (14.5%) had a history of OHE. In a multivariable logistic regression analysis that included the subcohort of patients without a history of OHE (n = 195), a higher CFS was independently associated with the presence of CHE at baseline (OR 1.7, 95% CI 1.1–2.6, p = 0.027), whereas age, MELD, sodium, albumin or a history of ascites were not. During a median follow-up of 436 days (IQR 191, 712), 42 (18.4%) patients developed an episode of OHE. In multivariable Cox regression analyses, a higher CFS was independently associated with the development of OHE in the total cohort (HR 2.1, 95% CI 1.5–2.9, p < 0.001) and the subcohort of patients without a history of OHE (HR 1.8, 95% CI 1.2–2.8, p = 0.008) after adjusting for age, MELD, sodium, albumin, CHE or a history of OHE (only in the model including the total cohort).
Conclusion: Frailty, as defined by the CFS, is associated with CHE and OHE development. The CFS appears to be a reliable tool to identify patients at higher risk of HE in whom intensified treatment and monitoring may be justified.

WED-378

Anemia in cirrhotic patients is a risk factor for esophagogastric variceal bleeding and mortality

Elena Santos Perez[1], Elba Llop[1], Marta López-Gómez[1], Marta Hernández Conde[1], Carlos Fernández-Carrillo[1], Esther Maderuelo[1], Jiacheng Cao[1], Natalia Fernández Puga[1], José Luis Martínez Porras[1], Javier Abad Guerra[1], Christie Perelló[1], Maria Trapero[1], Enrique Fraga[1], José Luis Calleja Panero[1]. [1]*Hospital Universitario Puerta de Hierro, Majadahonda (Madrid), Spain*
Email: elenasantosperez8@gmail.com

Background and aims: In liver cirrhosis (LC), anemia has been related to a worsening of the hyperdynamic state associated with portal hypertension, its clinical impact being unknown. There is a lack of longitudinal studies analyzing anemia as a risk factor for relevant outcomes in LC, such as esophagogastric variceal bleeding (EGVB) and mortality.
Method: Cases and controls. A retrospective series of consecutive cases with LC and EGVB (January 2017–December 2021) with laboratory tests in the first year prior to the episode and a historical cohort of control patients with LC without EGVB during their prospective follow-up were included. Demographic, baseline laboratory and clinical data up to death were analyzed.
Results: 556 patients (61 cases, 495 controls) were selected. The mean follow-up time for cases was 24 months (SD 21.7) and for controls 92.3 months (SD 23.1). Given the known influence of age, sex and liver function (Child-Pugh) on variceal bleeding, a 3:1 matching was performed according to these variables, finally including 252 patients (51 cases, 151 controls). In multivariate analysis of the paired data, the only independent factor associated with variceal bleeding was baseline haemoglobin (OR 2.57; p = 0.01). The prevalence of death in the overall cohort was 111 (20.2%). Cox proportional hazards analysis confirmed anemia (Hb < 12gr/dL) as a baseline variable independently related to mortality (HR 2.0;CI 1.3–3.0; p = 0.002), as well as age (HR 1.03; CI 1.02–1.05; p < 0.001), liver function (Child Pugh B/C) (HR 1.8; CI 1.2–2.7; p = 0.03) and variceal bleeding (HR 6.7; CI 3.9–11.6; p < 0.001).
Conclusion: Anemia in cirrhotic patients should be considered as a risk factor for variceal bleeding, is globally associated with higher mortality and it is necessary to study whether it corresponds to a worse hyperdynamic state and to perform close monitoring when it appears.

WED-379

Prucalopride : a novel and safe usage for reducing incidence of hepatic encephalopathy in decompensated cirrhosis

Manasa Alla[1], Vinod Arora[1], Shantan Venishetty[1], Imran Khan[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: shivsarin@gmail.com

Background and aims: Prevention of recurring episodes of hepatic encephalopathy in cirrhotics is vital for improving morbidity and mortality. Previous studies have shown efficacy of lactulose and conflicting results with rifaximin in preventing breakthrough episodes in those with recurrent HE. Prucalopride remains a promising addition and study has been conducted to evaluate its safety and efficacy as a part of secondary prophylaxis in cirrhotic patients
Method: It was a retrospective data analysis with follow-up done at Institute of Liver and Biliary Sciences, New Delhi from Jan 2021–July 2022. Of 144 cirrhotics screened with HE, 78 cirrhotics with ≥2 prior episodes of overt HE despite receiving standard dosage of rifaximin (15–20 mg/kg/day) and lactulose in previous 6 months were analyzed. Patient then received prucalopride (1 mg/day) along with the standard therapy to maintain at least 3 soft stools/day. Number of overt HE episodes and adverse events over 6 months follow-up were recorded.
Results: 78 patients with the mean age 58.42 ± 12.32 years were analyzed. 20/78 (25.6%); 34/78 (43.6%); 24/78 (39.8%) were in CTP A, B and C class respectively. Mean CTP and MELD were 9.42 ± 1.56 and 19.86 ± 4.83 respectively. Alcohol {28/78 (35.9%)} was the most common aetiology of liver cirrhosis followed by NASH {25/78 (32.05%)}. Median number of HE episodes (/6 month) was 2 (0, 3) episodes and stool frequency (/day) at baseline were 1 (0, 2) respectively. 19/78 (24.3%) had presence of porto-systemic shunt. Mean duration of treatment for prucalopride was 90.23 ± 21.65 days. Median number of HE episodes; HE requiring hospitalization (/6 months) and stool frequency (/24 hours)with prucalopride was 1 (0, 2); 1 (1, 3), 3 (2, 5) respectively. Mean reduction in HE episode (/6month) with prucalopride was –0.8 ± 0.3, similarly mean increase in stool frequency (/Day) was noted (+1.2 ± 0.6). HE episode requiring ICU hospitalization was 1 (0, 2). >1 episode and >2 episode HE was seen in 17/78 (21.8%); 9/78 (11.5%) patients. Mortality at 6 months was found to be 12/78 (15.4%). 11/78 (14.1%) patients experienced bloating, abdominal discomfort and diarrhea (>6 episodes/d) was noted in 9/78 (11.5%) patients. 3/78 (3.8%) had worsening liver functions. No adverse events requiring discontinuation were noted. Limitation of the study was intestinal transit time could not be measured.
Conclusion: Our study showed that the addition of prucalopride reduced the incidence of hepatic encephalopathy in addition to lactulose and rifaxamine and can be safely used in advanced cirrhotics.

WED-380

Surgical subtype predicts adverse outcomes and costs among non-alcoholic cirrhotic patients

Christopher Tait[1], Carolyn Catalano[2], Ankoor Patel[2], Carlos Minacapelli[2], You Li[2], Vinod Rustgi[2]. [1]*Rutgers Robert Wood Johnson Medical School, New Brunswick, United States,* [2]*Rutgers Robert Wood Johnson Medical School, United States*
Email: ct662@rwjms.rutgers.edu

Background and aims: Patients with cirrhosis are at increased risk of complications following surgery from multiple factors including portal hypertension and alterations in hemostasis. Gaps remain in our understanding of the cost and morbidity of cirrhotic patients who undergo surgery, particularly with respect to surgical subtype.
Method: We conducted a case-control study using the IBM Electronic health Record (EHR) MarketScan Commercial Claims (MSCC) databases from January 1st 2007 to December 31st 2017. Non-alcoholic cirrhotic patients who underwent surgery were identified based on ICD-9/ICD-10 codes for multiple surgical categories and matched with controls with cirrhosis who did not undergo surgery. Outcomes in the 6-month period following surgery were analyzed between matched groups and a cost analysis was performed. Cirrhotic patients were analyzed for adverse outcomes and cost for 9 different surgical subtypes.
Results: Mortality was increased in the cirrhotic patients undergoing surgery compared with the nonsurgical group (4.68% vs 2.38%, P < 0.001). Among surgical subtypes, mortality was highest in for gastrectomy (6.33%) and colectomy (6.00%), while lowest for total hip replacement (THR) (0%) and cholecystectomy (1.43%).The surgical cirrhotics had higher rates of adverse hepatic outcomes than the nonsurgical cirrhotics, including hepatic encephalopathy (HE) (5.00% vs 2.50%, P < 0.0001), spontaneous bacterial peritonitis (SBP) (0.64% vs 0.25%, P < 0.001), and higher rates of adverse nonhepatic outcomes. Among cirrhotics by surgical subtype (Figure 1), high rates of adverse hepatic outcomes were noted for colectomy and gastrectomy, with lower rates for total knee replacement (THR) and appendectomy. Healthcare utilization analysis revealed significantly increased costs in the surgical cohort ($58,246 vs $26,842, P < 0.0001), largely due to increased inpatient costs ($34,446 vs $10,789, P < 0.0001). Stratifying by surgical subtype, colectomy and gastrectomy had highest total costs ($131,983 and $109,796), with relative high costs from THR ($98,742) and TKR ($98,873).
Conclusion: Non-alcoholic cirrhotics undergoing surgery experienced worse mortality and adverse hepatic and nonhepatic outcomes. Gastrectomy and colectomy had the highest adverse event rates relative to other surgical subtypes. Claims and costs analysis showed significantly increased costs in the surgical group, largely due to the cost of more frequent and longer inpatient admissions.

WED-381

Analysis of surgical risk in patients with advanced chronic liver disease and major orthopedic surgery from a gender perspective

Lidia Canillas[1,2,3], Amalia Pelegrina[2,3,4], Elena Colominas[5], Aina Salis[3], César Jessé Enríquez-Rodríguez[2,3], Antonia Caro[1], Marc Puigvehí[1,2], Teresa Broquetas[1,2], Susana Coll[1,2], NURIA Cañete[1,2], Montserrat García-Retortillo[1,2], Xavier Bessa[1,2,3], Juan Carlos Álvarez[6], Jose A. Carrión[1,2,3]. [1]*Hepatology section, Gastroenterology Department, Hospital del Mar, Barcelona, Spain,* [2]*IMIM (Institut Hospital del Mar d'Investigacions Mèdiques), Barcelona, Spain,* [3]*Departament de Medicina i Ciències de la Vida, Universitat Pompeu Fabra, Spain,* [4]*General Surgery and Digestive Department Hospital del Mar, Barcelona, Spain,* [5]*Pharmacy Department, Hospital del Mar, Barcelona, Spain,* [6]*Anesthesiology Department, Hospital del Mar, Barcelona, Spain*
Email: lidia.canillas.alaves@gmail.com

Background and aims: Improvements in medical care and increased life expectancy have raised the need for major orthopedic surgery in patients with advanced chronic liver disease (ACLD). However, the prevalence of women is underrepresented in the cohort of patients used to create the VOCAL-Penn surgical risk score. Our objective was to assess differences in the risk of surgery, postoperative complications, and mortality in patients with ACLD who underwent major orthopedic surgery from a gender perspective.
Method: Retrospective, single-center study in patients with ACLD who underwent major orthopedic surgery (large joints and amputations) between 2010 and 2019. Comorbidities, data on ACLD, estimated surgical risk, analgesic use with metamizole/non-steroidal anti-inflammatory drugs (NSAIDs), postoperative complications such as acute kidney injury (defined by *Kidney Disease Improving Global Guidelines)* and infections, hospital stay, and mortality were collected. Differences between gender were compared using the Fisher, Chi-square, or U-Mann Whitney tests, as appropriate. Survival curves were contrasted with the Mantel-Cox test.
Results: Of 123 patients, 13 (11%) were excluded from the analysis due to missing data. Women represented 55% (61/110) of the cohort. The median age (IQR) of women was 76 (66–83) years and of men 68 (58–79) ($p = 0.02$). No differences were found in body mass index, diabetes, and chronic kidney disease. However, women had a higher prevalence of hypertension (61% vs. 39%; $p = 0.03$) and a lower prevalence of chronic obstructive pulmonary disease (5% vs 18%; $p = 0.03$). The predominant etiology of ACLD was viral (57%) in women and alcohol (55%) in men ($p = 0.001$). No difference was found between gender in liver function (Child-Pugh A 41% vs. 39%), bilirubin, ASA scale, emergency of surgery, and estimated VOCAL-Penn surgical risk at 30, 90, and 180 days; while women showed lower values of albumin (3.8 vs. 4.1 g/dl; $p = 0.03$) and platelets (108 vs. 143×10^9/L; $p = 0.02$). There were no differences in the

Table (abstract: WED-380).

Patient Outcome	Cholecystectomy (n = 3,994)	Appendectomy (n = 1,984)	Total knee replacement (n = 1,013)	Gastrectomy (n = 1,058)	Colectomy (n = 517)	Hernia repair (n = 264)	Total hip replacement (n = 61)
Death [n (%)]	57 (1.43)	51 (2.57)	24 (2.37)	67 (6.33)	31 (6.00)	8 (3.03)	0
Ascites [n (%)]	232 (5.81)	61 (3.07)	10 (0.99)	111 (10.49)	90 (17.41)	19 (7.20)	4 (6.56)
Hepatic Encephalopathy [n (%)]	52 (1.30)	21 (1.06)	13 (1.28)	137 (12.95)	26 (5.03)	2 (0.76)	1 (1.64)
Average Healthcare Costs (USD/patient)							
Total Cost	33,483	25,059	63,235	68,523	98,057	34,325	99,807
Inpatient Cost	14,361	8,961	43,872	42,772	66,746	8,365	75,768
Average Length of Stay [days]	2.11	1.43	5.01	9.86	10.47	1.43	9.97
Outpatient Cost	14,973	10,475	14,148	19,174	26,302	20,874	17,342

administration of metamizole/NSAIDs or the development of AKI at postoperative admission. But, women developed more infections (48% vs. 25%, p = 0.02), especially in the urinary tract (24% vs. 6%, p < 0.001). No differences were found in the percentage of severe or nosocomial infections, neither related to multiresistant microorganisms. However, postoperative mortality at 30 days (13% vs. 4%; Log-Rank = 0.09) and 180 days (28% vs. 12%; Log-Rank = 0.04) was higher in women than in men.

Conclusion: Age and comorbidities differ in women with ACLD who underwent major orthopedic surgery. Although the VOCAL-Penn surgical risk score does not show significant differences in expected mortality between gender, the percentage of infections and observed mortality was higher in women. These data suggest the need to optimize perioperative management of patients with ACLD from a gender perspective.

WED-382

Availability and affordability of services affects outcome in hospitalized patients with cirrhosis-results from CLEARED consortium

Email: doctor.ashokchoudhury@gmail.com

Background and aims: Treatment of inpatients with **c**irrhosis requires availability of several expensive interventions such as intensive care (ICU) and endoscopy, medications such as rifaximin, terlipressin and IV albumin. Also, the infrastructure and affordability of liver transplant (LT) and palliative care is needed for optimal management. These may vary in access and affordability globally. Aim: evaluate, access and affordability of important resources for inpatient cirrhosis management from Principal Investigators (PIs) from the Chronic Liver disease Evolution And Registry for Events and Decompensation-CLEARED consortium.

Method: CLEARED consortium enrolled in patients with cirrhosis admitted non-electively and followed them for 30-days post-discharge. All PIs were offered a survey regarding availability, access and affordability of their typical population with cirrhosis regarding important services (24 hr endoscopy, ICU care, palliative care), medications (somatostatin, octreotide, terlipressin, rifaximin and albumin). Sites across the world were compared with respect to the PI survey.

Results: We prospectively enrolled 3884 patients from 95 centers in all 6 continents. Of these according to the world bank definition, 34 were high-income, 39 upper middle and rest were low/low-middle income countries. Results summarized in figure. Insurance: Most insurances were national except for centers in India, USA and Mexico where >50% of patients were on private insurances. Services and

Table: Survey of principal investigators regarding availability and affordability for care of cirrhosis patients

Region	No of centre (n=95)	Availability of LT	>50% of pts can afford LT	24 hours Endoscopy service available?	Rifaximin Availability	Terlipressin Availability	>50% can afford Albumin	Palliative care available
China	24	16(67)	2(8)	23(96)	24(100)	23(96)	21(88)	7(26)
India	11	10(91)	0	11(100)	11(100)	11(100)	5(45)	4(36)
Middle East	9	6(67)	4(44)	9(100)	9(100)	9(100)	4(44)	6(67)
Rest of Asia	3	3(100)	2(67)	3(100)	2(67)	3(100)	3(100)	2(67)
North America	23	19(79)	15(65)	22(96)	23(100)	8(35)	16(70)	22(96)
Europe	6	3(50)	3(50)	6(100)	6(100)	6(100)	3(50)	6(100)
Australia	7	1(14)	6(86)	7(100)	7(100)	7(100)	5(71)	7(100)
Africa	5	1(20)	0	1(20)	3(60)	2(40)	1(20)	2(40)
South America	7	7(100)	3(42)	7(100)	7(100)	7(100)	3(43)	7(100)

*: includes USA, Canada, and Mexico, LT: liver transplantation, ICU: intensive care unit, Somatostatin and octreotide are medications needed for treating variceal hemorrhage,() all figure in bracket indicate percentage

Figure: (abstract: WED-382).

Interventions: LT was available in most centers except in Africa. It was only accessible in remaining regions if insured. ICU was unaffordable in regions apart from North America, Australia, and some Asian and European sites. 24-hr endoscopy was available in all centers but not in Africa. Palliative care was least likely to be available in Indian, Chinese, and African sites. Medications: Rifaximin is available in most countries apart from a few in Asia and Africa but was unaffordable for majority of patients in Africa, South America, and Asia. In remaining sites, it was only affordable for 50% of patients. Somatostatin and octreotide were available at all sites except in Africa. This was largely affordable for patients in China, Australia, North America, and Asia but not the rest. Minority of patients in Indian, African, South American, and Middle Eastern sites could afford IV albumin. Terlipressin was not available in USA and Canada. In the remaining sites, Australian, Middle Eastern, Asian, and Chinese patients were more likely to afford terlipressin.

Conclusion: In a prospective global cohort of inpatients with cirrhosis, there are major differences in availability, access, and affordability of services, interventions, and medications needed for optimal inpatient cirrhosis care. In addition to cirrhosis-related variables, these factors should be considered when assessing cirrhosis outcomes.

WED-383

Serum ammonia levels do not correlate with overt hepatic encephalopathy severity and time to resolution in hospitalized patients with cirrhosis

Jasmohan S Bajaj[1], Nikolaos T. Pyrsopoulos[2], Robert Rahimi[3], Zeev Heimanson[4], Christopher Allen[4], Robert Israel[4], Don Rockey[5].
[1]Virginia Commonwealth University and Central Virginia Veterans Healthcare System, United States, [2]Rutgers New Jersey Medical School, United States, [3]Baylor University Medical Center, United States, [4]Salix Pharmaceuticals, United States, [5]Medical University of South Carolina, United States
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Measuring ammonia levels is not considered a diagnostic or prognostic indicator for overt hepatic encephalopathy (OHE) and, per guidelines, OHE is a clinical diagnosis. However, ammonia testing remains a common practice for the assessment of OHE severity/resolution in some practice settings. The current aim was to examine the relationship between ammonia levels and time to OHE resolution in hospitalized patients.

Method: Adults with cirrhosis and OHE (Hepatic Encephalopathy Grading Instrument score [HEGI], 2–3) were included in a phase 2, randomized, double-blind, placebo-controlled, 5-arm multicenter trial of investigational rifaximin soluble solid dispersion (SSD) immediate-release (IR) and sustained extended-release (SER) tablets. Patients were randomly assigned to placebo + lactulose (i.e., lactulose alone) or 1 of 4 rifaximin SSD groups: 1) IR 40 mg once daily (QD) + lactulose; 2) IR 40 mg twice daily (BID) + lactulose; 3) SER 80 mg QD + lactulose; or 4) SER 80 mg BID + lactulose. The primary efficacy end point was time to OHE resolution (HEGI score <2). Serum ammonia levels were measured daily and patients with an ammonia result at Day 1 were pooled (all treatment groups) and included in the analyses. A linear regression analysis (R^2) was conducted to assess the relationship between Day 1 ammonia levels and OHE severity and time to OHE resolution. The trial was terminated after a prespecified interim analysis and not restarted (COVID-19 – related issues). Published data showed that rifaximin SSD 40 mg BID + lactulose significantly reduced time to OHE resolution vs lactulose alone (21.1 h vs 62.7 h; p = 0.02; Bajaj JS, et al. doi: 10.1016/j.cgh.2022.05.042).

Results: 44 patients (median [range] age, 63 y [32–75 y]; 52.3% male) were included (6–13 per 5 groups [all of which included lactulose use]). The median baseline MELD score was 19.0, the median (range) serum ammonia level was 86.4 ug/dL (19.0–272.5 ug/dL), and 65.1% of patients had an HEGI score = 2. There was no relationship between Day 1 ammonia level and Day 1 HEGI score for overall population (R^2 = 0.0255) or when subgrouped by male (R^2 = 0.0095), female (R^2 = 0.1179), aged <65 y (R^2 = 0.1264), or aged ≥65 y (R^2 = 0.0009). Furthermore, there was no relationship between Day 1 ammonia level and time to OHE resolution for the overall population (R^2 = 0.0064; Figure) or when subgrouped by male (R^2 = 0.0479), female (R^2 = 0.0052), aged <65 y (R^2 = 0.0780), or aged ≥65 y (R^2 = 0.0195). There was also no significant difference between dosing regimens in

this analysis, despite the significant reduction in time to OHE resolution with rifaximin SSD 40 mg BID vs lactulose (Bajaj JS, et al.).

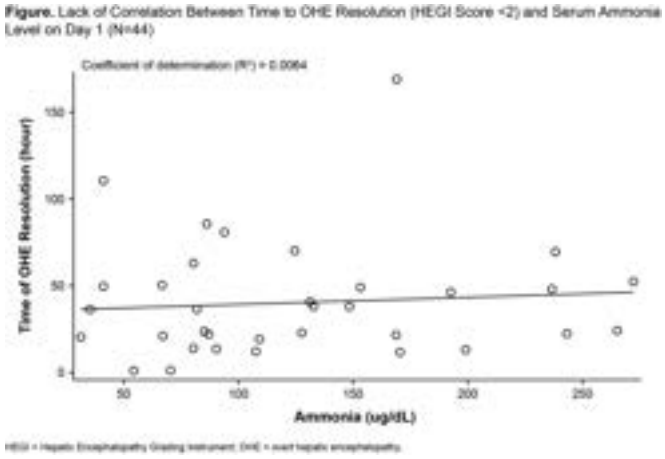

Figure:

Conclusion: This analysis of inpatients with cirrhosis and OHE found no relationship between serum ammonia levels and OHE severity or time to OHE resolution. These data reinforce the limited clinical utility of ammonia levels for the management and prognostication of inpatients with OHE.

WED-384

Six-fold increased rate of chronic kidney disease after acute kidney injury: a population-based cohort study of 46,946 patients with cirrhosis

Anna Cederborg[1,2], Linnea Widman[3], Borje Haraldsson[4], Björn Lindkvist[2,5], Ying Shang[3], Axel Wester[3], Hannes Hagström[3], Hanns-Ulrich Marschall[1]. [1]*Institute of Medicine, Sahlgrenska academy, Gothenburg university, Department of clinical and molecular medicine, Gothenburg, Sweden,* [2]*Department of Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden,* [3]*Karolinska Institutet, Sweden,* [4]*Institute for neuroscience and physiology, Sahlgrenska Academy, Gothenburg university, Sweden,* [5]*Institute of Medicine, Sahlgrenska academy, Gothenburg university, Sweden*
Email: anna.cederborg@vgregion.se

Background and aims: Patients with cirrhosis have a high risk for acute kidney injury (AKI). The risk of developing subsequent chronic kidney disease (CKD) is not well known. Here, we investigated the risk for CKD after an episode of AKI in cirrhosis.
Method: Using Swedish national health registers, we identified all persons diagnosed with cirrhosis between 1988 and 2020. Cox regression was used to assess rates of incident CKD in patients with cirrhosis and an episode of AKI, compared to patients with cirrhosis without AKI. The cumulative incidence of CKD in both groups was calculated considering non-CKD related mortality as a competing event.
Results: We identified 46,946 patients with cirrhosis, 30,082 (64.1%) were men, and the median age was 63 years. The median time to follow-up for all patients was 2.1 (IQR 0.5–5.7) years. AKI was diagnosed in 2,873 (6.1%) patients, of whom 19.6% developed CKD, compared to 5.2% of patients without AKI. The incidence rate of CKD in patients with AKI compared to those without was 133.0 vs. 12.5 per 1,000 person-years (adjusted HR = 6.5, 95%CI = 5.9–7.2) and the cumulative incidence of CKD at 90 days was 9.1% and 0.6%, respectively. Furthermore, the kidney-related mortality rate was also considerably higher (adjusted HR = 7.3, 95%CI = 6.4–8.4) in patients with AKI.

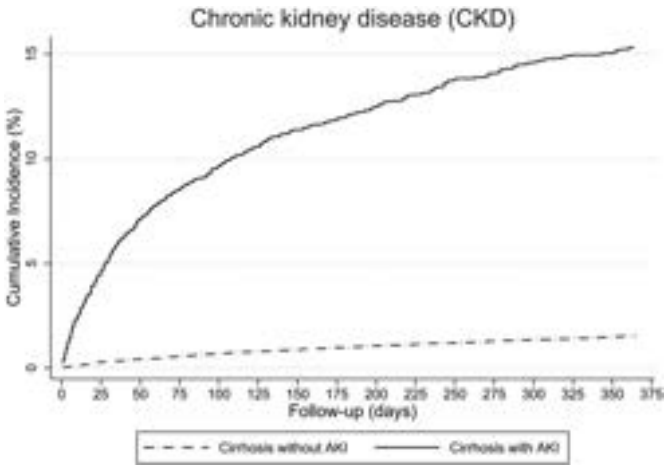

Figure:

Conclusion: Patients with cirrhosis and AKI have a more than six-fold increased rate of CKD, as well as a higher short-term kidney-related mortality compared to cirrhosis patients without AKI.

WED-385

Patients with liver cirrhosis and TIPS are prone to in-hospital falls

Nada Abedin[1], Moritz Hein[1], Christoph Welsch[1], Jörg Bojunga[1], Stefan Zeuzem[1], Georg Dultz[1]. [1]*Department of Internal Medicine I, University Hospital Frankfurt, Goethe University, Frankfurt am Main, Germany*
Email: nada.abedin@kgu.de

Background and aims: In-hospital falls are associated with a high mortality in patients in general and especially in patients with chronic liver disease. Therefore, identifying patients at high risk and implementing safety measures is a major goal in the treatment of hospitalized patients with liver cirrhosis.
Method: In a cohort of hospitalized patients with liver cirrhosis between 2017 and 2019 at the department for gastroenterology at the University Hospital Frankfurt clinical data, treatment courses and follow-up data were assessed retrospectively and statistically analyzed using SPSS.
Results: In the analyzed period there were a total of 1985 hospitalizations of patients with liver cirrhosis. 80 falls were documented with respective complications. Median age significantly differed between the two groups (64 vs. 61 years on admission, $p < 0.001$) and in-hospital mortality was significantly higher in the group of patients with documented falls (27.5% vs. 8.9%, $p < 0.001$). There was no association of etiology and falling incident. 19.9% of the analyzed hospitalizations (n = 396) included patients with an implanted TIPS. 63 of them fell during their hospital stay making up 78.8% of the patients with a documented falling incident. Reasons for admission in the fall-cohort were decompensation (37.5%), hepatic encephalopathy (32.5%), infection (22.5%) and others. While there was a significant difference in all of them, hepatic encephalopathy ($p = 0.006$, OR 2.776, 95% CI) and implanted TIPS ($p < 0.001$, OR 3.146, 95% CI) were the two factors independently associated with in-hospital falls in the uni- and multivariate analysis.
Conclusion: Hospitalized patients with hepatic encephalopathy on admission and patients with a TIPS are at high risk for in-hospital falls. Given the associated increase in in-hospital mortality, these patients require specific safety measurements on admission and continuous monitoring.

WED-386

Correlation between mid-arm circumference and QRS alterations as markers of sarcopenia in patients with decompensated cirrhosis

Background and aims: Sarcopenia is a severe complication of liver disease, associated with a poor prognosis and decreased survival. Early identification and management may improve the patients' outcome. Sarcopenia affects muscle mass and function and may be diagnosed by measuring mid-arm circumference. Cardiac sarcopenia, reflected by electrocardiographic changes, is an important component in the pathogenesis of cirrhotic cardiomyopathy. The aim of this study is to evaluate the relationship between systemic sarcopenia estimated by mid-arm circumference and QRS amplitude and duration.
Method: We performed a cross-sectional observational study including patients with decompensated cirrhosis evaluated in our clinic between January 2022 and December 2022. Patients with cured hepatitis C virus infection or hepatitis B virus infection undergoing treatment with nucleoside analogues and undetectable viremia were considered eligible. Patients with history of cardiovascular disease, malignancies, malabsorption, alcohol-related liver disease, deposit diseases or acute decompensation were excluded from the trial. A total of 161 patients were included and divided into 2 groups, according to Child Pugh classification. We evaluated mid upper arm circumference (MUAC), serum levels of albumin, total cholesterol, INR, as well as QRS mean amplitude and duration in all limb and precordial leads. QRS hypovoltage was defined as less than 0.5 mV in one limb lead and less than 1 mV in one precordial lead.
Results: We included 108 patients with Child B cirrhosis and 53 patients with Child C cirrhosis, with a female predominance in both groups (59.25% and 66.03% respectively). There was no statistically significant difference in age between the groups (56.24 ± 21.32 years versus 59.22 ± 18.3 years, p = 0.8). We noted decreased MUAC in Child C patients, both male and female, compared to Child B patients, as well as decreased QRS amplitude and increased QRS duration within the subgroups (Table). Hypovoltage was present in 9 Child B patients (8.33%) and 41 Child C patients (77.35%). Sarcopenia defined by MUAC was noted in 28 Child B patients (25, 92%) and 49 Child C patients (92.45%). Low MUAC correlated with low QRS amplitude in male (p = 0.02, CI 95%) and female patients (p = 0.01, CI 95%) and also with increased QRS duration (p = 0.03 and p = 0.02 respectively).

Figure: Table: Differences in clinical, biologic and electrocardiographic parameters in Child B and Child C in the male and female population

	Male		P value	Female		P value
	Child B N = 44	Child C N = 18		Child B N = 64	Child C N = 35	
Albumin (g/dL)	3.01 ± 0.52	2.73 ± 1.12	<0.01	3.22 ± 0.82	2.45 ± 0.98	<0.01
Total Cholesterol (mg/dL)	167.88 ± 45.18	97.21 ± 62.46	<0.01	154.29 ± 28.32	102.29 ± 38.13	<0.01
INR	1.37 ± 0.53	1.98 ± 1.09	<0.01	1.64 ± 0.28	2.02 ± 0.87	<0.01
MUAC (cm)	25.12 ± 5.29	21.44 ± 4.12	0.03	26.73 ± 3.98	20.15 ± 4.73	0.02
QRS -A (limbs) (mV)	0.92 ± 0.36	0.61 ± 0.41	0.02	0.89 ± 0.22	0.77 ± 0.35	0.03
QRS- A (precordial) (mV)	2.14 ± 0.76	1.13 ± 0.19	0.04	1.98 ± 0.57	1.01 ± 0.42	0.03
QRS- D (ms)	92.27 ± 7.82	115.28 ± 10.61	0.01	96.35 ± 9.17	122.24 ± 11.85	0.02

Conclusion: MUAC as well as QRS amplitude and duration may serve as markers for sarcopenia in decompensated cirrhosis. The accessibility of these parameters makes them easy to use in clinical practice.

WED-387

Uromodulin serum levels are associated with poorer prognosis in patients with cirrhosis and hepatorenal syndrome

Eva Maria Schleicher[1,2], Simon J. Gairing[1,2], Darko Castven[3], Charlotte Sophie Hock[1], Henrike Dobbermann[3], Raffael Schlüter[3], Sophia Heinrich[4], Leonard Kaps[1,2], Peter Galle[1,2], Julia Weinmann-Menke[1], Marc Nguyen-Tat[1], Jens Marquardt[3], Christian Labenz[1,2]. [1]*University Medical Center of the Johannes Gutenberg-University, Department of Internal Medicine I, Mainz, Germany,* [2]*University Medical Center of the Johannes Gutenberg-University, Cirrhosis Center Mainz (CCM), Mainz, Germany,* [3]*University Hospital Schleswig-Holstein, Lübeck, Department of Medicine I, Germany,* [4]*Hanover Medical School, Clinic for Gastroenterology, Hepatology and Endocrinology, Germany*
Email: eva.schleicher@unimedizin-mainz.de

Background and aims: Hepatorenal syndrome (HRS) is associated with a dismal prognosis in patients with cirrhosis. Biomarkers to identify patients with poor response to therapy with terlipressin and albumin are urgently needed. Uromodulin is a kidney-specific protein and a reliable, early biomarker of impaired renal function. This study aimed to evaluate the predictive value of serum levels of Uromodulin (sUMOD) in patients with cirrhosis and HRS treated with vasopressors.
Method: This study analyzed data of 81 patients with HRS treated with terlipressin and albumin, 39 patients with cirrhosis without kidney injury and 33 patients with cirrhosis with prerenal acute kidney injury (AKI) treated at the Cirrhosis Center Mainz, Germany. sUMOD were analyzed by ELISA and clinical data were collected. Patients with HRS treated with terlipressin were prospectively followed for the composite end point of hemodialysis-/liver transplantation-free survival (HD/LTx-free survival).
Results: Of the 81 patients with HRS, 40 had HRS type 1 and 41 HRS type 2. In the cohort of patients with HRS treated with terlipressin, median sUMOD were 100 ng/ml (interquartile range (IQR) 64; 144). sUMOD differed significantly between patients with HRS compared to patients with no AKI (p = 0.001), but not between patients with HRS and prerenal AKI (p = 0.872). There was a non-significant trend for lower sUMOD in patients with HRS type 2 compared to type 1 (type 2 vs. 1: 99 vs. 106 ng/ml, p = 0.094). Patients with sUMOD in the lowest quartile had significantly lower rates of complete response of HRS after treatment with terlipressin (p = 0.044). During follow-up, a total of 75 patients with HRS reached the end point of HD/LTx-free survival. In multivariable Cox regression analysis, sUMOD in the lowest quartile (<64 ng/ml) (HR 1.747, 95% CI 1.013–3.011, p = 0.045) and MELD (HR 1.081, 95% CI 1.047–1.116, p < 0.001) were independently associated with HD/LTx-free survival during follow-up. In logistic regression analysis, sUMOD in the lowest quartile were independently associated with 90-days HD/LTx-free survival (OR 3.957, 95% CI 1.033–15.163, p = 0.045) after adjusting for MELD (OR 1.179, 95% CI 1.081–1.286, p < 0.001).
Conclusion: sUMOD may be a valuable biomarker to identify patients with HRS treated with terlipressin and poor prognosis.

WED-388

24-Hour urinary creatinine excretion (UCE) a marker of muscle mass is associated with mortality in critically ill patients with cirrhosis

Jaya Benjamin[1], Pallavi Dua[1], Harshita Tripathi[1], Puja Bhatia[1], Varsha Shasthry[1], Saniya Khan[1], Rakhi Maiwall[2], Guresh Kumar[3], Yogendrakumar Joshi[1], Shiv Kumar Sarin[2]. [1]*Institute of Liver and Biliary Sciences, Clinical Nutrition and Hepatology, New Delhi, India,* [2]*Institute of Liver and Biliary Sciences, Hepatology, New delhi, India,* [3]*Institute of Liver and Biliary Sciences, Department of Biostatistics, New delhi, India*
Email: jayabenjaminilbs@gmail.com

Background and aims: Loss of muscle mass is a common feature in cirrhosis which may adversely affect the clinical outcomes in the ICU.

Assessment of muscle mass is a challenge in the critically ill cirrhotics (CIC). The 24 hour urine creatinine excretion (UCE) reflects muscle mass and is a simple method in the ICU settings. To study the relationship of UCE at ICU admission with mortality in critically ill cirrhosis Patients.

Method: In this prospective observational study, CIC meeting the inclusion (age 18–65 yrs, likely ICU stay >24 hours) and exclusion criteria (patients with chronic kidney disease, malignancy, acute kidney injury, anuria or on dialysis) were enrolled. Total duration of ICU stay and mortality were noted. Urinary creatinine concentration was assessed by kinetic modified Jaffe Method. UCE was determined by multiplying the urinary creatinine concentration with the 24 hour urinary volume and expressed in gm/24 hours. An average of first 3 days UCE after admission was taken for analysis. Value of UCE was divided into tertiles (T), and mortality was compared between tertiles using chi-square test. The association of UCE with mortality was analyzed using Kaplan-Meier graph and log-rank test across tertiles.

Results: Altogether, 104 CICs [male-76%; age-48.8 ± 10 yrs; BMI 23.6 ± 4.6 kg/m^2; etiology: alcohol-60%, NASH-15%, others-16%;CTP-10.7 ± 1.5; MELD-27.6 ± 8.1; SOFA-9.5 ± 2.8; APACHE-18.2 ± 6.9; MV- 48 (46%)] were studied. The mean UCE (gm/24 hours) was 0.77 ± 0.4 (range 0.33–2.7) and UCE categorization on the basis of tertiles was T1-≤0.57, T2–0.58–0.82, T3- >0.82. Overall, mortality was seen in 62 (59.6%) patients, which was significantly different between tertiles of UCE [T1:T2:T3 = 26 (41.9%) : 23 (37.1%) : 13 (20.9%); p = 0.030]. Patients in the lowest UCE tertile had an increased mortality compared to those in the highest UCE tertile as depicted in Kaplan Meier graph (fig1).

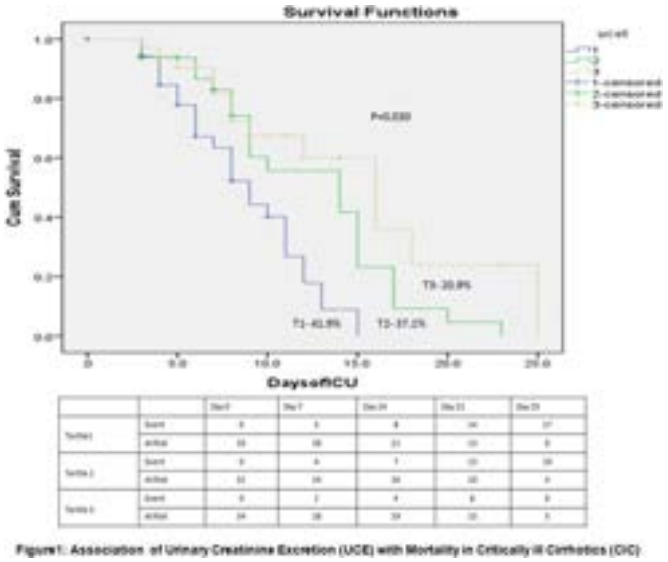

Figure1: Association of Urinary Creatinine Excretion (UCE) with Mortality in Critically ill Cirrhotics (CIC)

Figure:

Conclusion: In critically ill patients with cirrhosis low urinary creatinine excretion is associated with higher mortality, thereby underscoring the role of muscle mass as a risk factor for mortality and UCE as a relevant marker.

WED-389

Rotational Thromboelastometry (ROTEM) reduces need for pre-emptive transfusion in low-moderate risk procedure in cirrhosis: a randomized controlled trial

Chin Kimg Tan[1], Louis Ng[2], Eugene Wong[3], Kenneth Lin[3], Andrew Kwek[3], James, Weiquan Li[3], Tiing Leong Ang[3], Louis Wang[3], Tianyu Qiu[3], Roshni Sahashiv[4], Tirukonda Prasanna Sivanath[4], Rahul Kumar[3]. *[1]Changi General Hospital, Department of Gastroenterology and Hepatology, Singapore, [2]Changi General Hospital, Department of Respiratory Medicine, Singapore, Singapore, [3]Changi General Hospital, Department of Gastroenterology and Hepatology, Singapore, Singapore, [4]Changi General Hospital, Department of Radiology, Singapore, Singapore*
Email: ckimg87@yahoo.com

Background and aims: Viscoelastic tests (VET) like Rotational Thromboelastometry (ROTEM) assess global hemostasis in cirrhosis. We aimed to assess whether ROTEM-guided blood product transfusion results in lower blood product requirement in patients with cirrhosis undergoing elective invasive procedures as compared to standard of care (SOC) based on conventional coagulation tests (CCT).

Method: This is a planned scheduled interim analysis of a single center randomized controlled trial. Patients with cirrhosis and coagulopathy requiring blood product transfusion based on CCT undergoing elective invasive procedure were recruited. Patients were randomized in a 1:1 ratio to receive blood products by either ROTEM-guidance or standard of care (SOC). The primary outcome was the difference in blood products (fresh frozen plasma (FFP) or platelets) transfused between the groups. The secondary outcome was procedure related bleeding or complications within 7 days of the procedure. Haybittle-Peto rule was applied for the interim analysis with p < 0.001 taken as statistically significant.

Results: From August 2021 to January 2023, 40 patients were recruited (20 in each group). The mean age was 57.4 ± 9.3 years. Most patients underwent large volume paracentesis (n = 23, 57.5%) followed by microwave ablation of liver tumor (n = 5, 12%). Other procedures were hepatic venous pressure gradient measurement (n = 4, 10%) and percutaneous liver biopsy (n = 3, 7.5%). More than half of the patients had Child Pugh C liver cirrhosis (n = 24, 64%) with a mean MELD score of 17.38 ± 6.14. Mean platelet count was 75 ± 51 × 10^9/L, mean prothrombin time (PT) was 16.2 ± 2.9 seconds, mean INR 1.55 ± 0.31 and mean activated partial thrombin time was 39.9 ± 12.01 seconds. There was no difference in the baseline demographics, CCT (platelet count, PT, INR and APTT), ROTEM parameters, Child-Pugh and MELD score between the two groups. Overall, 8 (40%) patients in ROTEM-group required pre-emptive blood products compared to all (100%) in SOC group (p < 0.001), Figure 1. The volume of FFP (63 mls ± 160 mls vs 325 mls ± 500 mls, p < 0.001) and platelet (70 mls ± 98 mls vs 110 mls ± 137 mls p = 0.048) transfused were lower in the ROTEM group. None of the patients included in the study had clinically significant bleeding events. One patient (5%) in the SOC group developed allergic reaction but none developed transfusion associated lung injury.

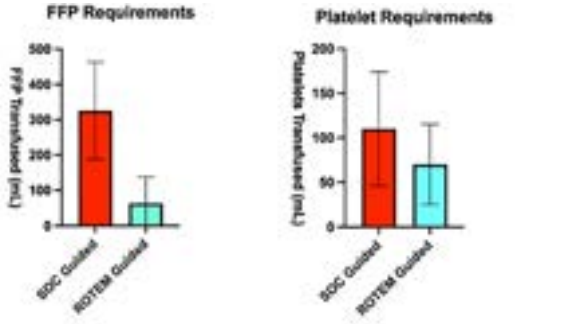

Fig 1: Comparison of Blood product requirements: FFP and Platelets

Figure: Fresh frozen plasma (FFP) and platelet transfusion in ROTEM-guided group and standard of care (SOC) group.

Conclusion: ROTEM-guided transfusion strategy significantly reduces the need for FFP transfusion in patients with cirrhosis undergoing elective procedure without any increased risk of bleeding events. It has important implication as it can reduce transfusion associated adverse events. Trial registration number: NCT05698134.

WED-390

Long-term cellular immune response to COVID-19 vaccination in patients with chronic liver disease

Mariana Moura Henrique[1], Carolina Santos Palma[1], André L. Simão[1], Ana Godinho-Santos[1], Miguel Cardoso[1], Diogo Fernandes[1], Sofia Carvalhana[2], Miguel Moura[2], João Gonçalves[1], Helena Cortez-Pinto[2,3], Rui E. Castro[1]. *[1]Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal, [2]Departamento de Gastrenterologia, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal, [3]Clínica Universitária de Gastrenterologia, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*
Email: ruieduardocastro@ff.ulisboa.pt

Background and aims: Patients with chronic liver disease (CLD), particularly those with cirrhosis, typically present with immune dysregulation, which may lead to a higher risk of adverse outcomes after SARS-CoV-2 infection and a defective immune response after COVID-19 vaccination. Because patients with CLD were not included in COVID-19 vaccine licensing studies, data on effectiveness in this vulnerable population is lacking. Our aim was to evaluate cellular immune responses of CLD patients to COVID-19 vaccines.
Method: Blood from Portuguese CLD patients and healthy volunteers receiving the mRNA-1273, BNT162b2, ChAdOx1 and Ad26.COV2.S vaccines were collected prior to vaccination, six months after vaccination, and one year after vaccination (after 3rd dose). Immunophenotyping of peripheral blood mononuclear cells was performed by flow cytometry with acquisition on a four-laser spectra analyzer, using a panel composed of twenty-two surface markers and a viability dye. After gating, a total of twenty-eight different immune cell subsets were identified.
Results: Prior to and at six months after vaccination, the number of CD4$^+$ T cells was lower in vaccinated patients comparing to vaccinated healthy individuals. During the first six months following vaccination, naïve CD8$^+$ T cells decreased more in CLD patients comparing to healthy individuals, while plasmablasts increased in healthy individuals but not in CLD patients, suggesting a defective production of these antibody secreting B cells in vaccinated patients. In turn, one year after vaccination, the subsets of T and Natural Killer cells were found increased in both groups, suggesting that the booster dose is critical for inducing a strong cellular immune response. Curiously, cirrhotic patients presented with more CD27$^+$ B cells comparing to non-cirrhotic patients. Finally, regarding COVID-19 infection, variations in the percentage of gated cells before and one year after vaccination were similar in almost all cell sub-types, except for TEMRA CD8$^+$ T cells, which showed a more prevalent decrease in non-infected patients.
Conclusion: Patients with more advanced stages of CLD display impaired cellular immune responses to COVID-19 vaccination. Notwithstanding, impaired responses are largely recovered after the administration of a third dose of the vaccine. Studying the response of patients with CLD to recent SARS-CoV-2 variants should elucidate whether novel COVID-19 vaccines are needed.

WED-391

The relation of serum nesfatin-1 levels with disease severity and complications in patients with liver cirrhosis

Özlem Kandemir Alibakan[1], Hasan Eruzun[2], Yasemin Gökden[3], Yücel Arman[1], Tufan Tükek[4]. *[1]Prof. Dr. Cemil Taşçıoğlu City Hospital, Internal Medicine, İstanbul, Turkey, [2]Ondokuz Mayıs University, School of Medicine, Gastroenterology, Samsun, Turkey, [3]Prof. Dr. Cemil Taşçıoğlu City Hospital, Gastroenterology, İstanbul, Turkey, [4]İstanbul University, School of Medicine, Internal Medicine, İstanbul, Turkey*
Email: hasaneruzun@gmail.com

Background and aims: Nesfatin-1 is an anorectic polypeptide that has important roles in the regulation of food intake and energy homeostasis. With the hypothesis that common problems such as cachexia and malnutrition in patients with cirrhosis might be due to the increase in nesfatin-1 protein, we examined the levels of nesfatin-1 peptide in patients with cirrhosis and its relationship with the severity of the disease.
Method: Fifty-one patients with cirrhosis and thirty healthy volunteers were included in the study. Serum samples were collected from the groups and serum nesfatin-1 levels were compared using ELISA. Child-Pugh stages and multifactorial end-stage liver disease (MELD) scores of patients with cirrhosis were calculated and their relationship with nesfatin-1 was examined. In addition, the relationship between the complications of cirrhosis and nesfatin-1 was investigated.
Results: Nesfatin-1 levels were found to be significantly higher in the patients with cirrhosis than in the control group (p = 0.001). Patients with cirrhosis were grouped as compensated and decompensated and compared with the control group. It was determined that the significant difference between these three groups (p = 0.001) was due to the elevation of nesfatin-1 in the compensated cirrhosis group (p = 0.01). When patients with cirrhosis were classified according to Child-Pugh stages and MELD scores, there was no significant relationship between these groups and nesfatin-1 levels.

Nesfatin-1 (ng/ml)	Control A (n = 30)	Compensated cirrhosis B (n = 20)	Decompensated cirrhosis C (n = 31)	A-B-C p value	A-B p value	A-C p value	B-C p value
Median	7.2 (6–10.1)	11.9 (10.2–14.8)	10.4 (6.6–12.6)	0.001	0.010	0.077	0.218
BMI		28.01 (± 4.09)	26.9 (± 4.27)				0.38

Figure:

Conclusion: Nesfatin-1 may be involved in the maintenance of compensation with its antioxidant, anti-inflammatory, and anti-apoptotic effects. The decrease in serum nesfatin-1 levels in decompensated cirrhosis compared with compensated cirrhosis may be due to the defense mechanism and insufficient production.

Email: rafael.paternostro@meduniwien.ac.at

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a leading cause of advanced chronic liver disease (ACLD). Portal hypertension (PH) drives decompensation and is best diagnosed by hepatic venous pressure gradient (HVPG). However, in NAFLD-ACLD decompensation may occur at lower HVPG thresholds than in other ACLD etiologies. Here we investigate the clinical course of strictly compensated NAFLD-ACLD patients (NAFLD-cACLD) according to severity of PH.

Method: In this European multicentre study, NAFLD-cACLD patients were characterized by HVPG at baseline. Patients with any previous decompensation, hepatocellular carcinoma and portal vein thrombosis were excluded. First occurrence of hepatic decompensation (ascites, hepatic encephalopathy, variceal bleeding) or liver-related death defined the composite study end point. Fine and Gray competing risk regression models were used for time-to-event outcome analyses.

Results: 342 patients with NAFLD-cACLD with a median MELD of 8 (7–9) points and a median HVPG of 11 mmHg (11–15) were included; 244 (71.3%) had diabetes. NAFLD diagnosis was made via liver biopsy in 281 (82.2%) and clinical in 61 (17.8%) patients.

CSPH (HVPG≥10 mmHg) was present in 210/342 patients (61.4%) including 71 patients with severe PH (HVPG ≥16mmHg; PH16; 20.8%). Median BMI was 31.7 kg/m^2 (28.0–35.8), with a significantly lower BMI in the CSPH group (31.5 vs. 32.6 kg/m^2, p = 0.011). During a median follow-up of 41.5 (28–66) months, 85 (24.9%) patients developed liver-related events: 36 (10.5%) ascites, 23 (6.7%) hepatic encephalopathy, 16 (4.7%) variceal bleeding and 10 (2.9%) liver-related death.

CSPH (vs. <10 mmHg; subdistribution hazard ratio-SHR: 4.81, p < 0.001) and PH16 (vs. <10 mmHg; SHR: 6.44, p < 0.001) represented significant risk factors for developing decompensation or liver-related death. Importantly, NAFLD-cACLD patients developed decompensation even without CSPH with a rate of 1.5% within the first year (Y1) and 3.3% within Y2. Variceal bleeding did, however, not occur in patients without CSPH. With increasing severity of PH, i.e. with HVPG 10–15 and ≥16 mmHg, respectively, the cumulative incidence rates for developing first hepatic decompensation gradually increased at Y1: 2.2%/8.7%, at Y2: 10.7%/13.5%, and at Y5 36.3%/50.3% (Figure).

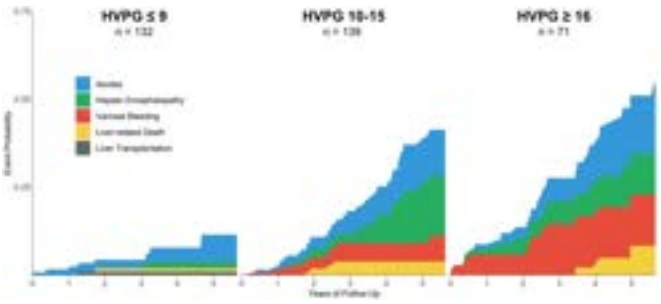

Figure: Stacked incidence curves for the respective first liver-related events during follow-up, stratified according to severity of portal hypertension.

Conclusion: CSPH is strongly linked to the incidence of hepatic decompensation in NAFLD-cACLD. Decompensation, however, may also occur, albeit at low rates, at HVPG<10mmHg, suggesting an underestimation of PH severity by HVPG. Nevertheless, HVPG represents an important risk stratification tool in NAFLD-cACLD patients.

The effect of precipitating factors for hepatorenal syndrome on response to terlipressin treatment: a subgroup analysis of a pooled North American database

Kevin Moore[1], Zunaira Zafar[2], Nikolaos T. Pyrsopoulos[3], Khurram Jamil[4]. *[1]UCL Institute of Liver and Digestive Health, Royal Free Hospital, University College London, London, United Kingdom; [2]St. Mary Medical Center, Langhorne, PA, United States; [3]Rutgers University, New Jersey Medical School, Newark, NJ, United States; [4]Mallinckrodt Pharmaceuticals, Hampton, NJ, United States*
Email: kevin.moore@ucl.ac.uk

Background and aims: Hepatorenal syndrome (HRS) type 1 is a potentially reversible form of acute kidney injury. Terlipressin is approved for the treatment of adult patients (pts) with HRS and rapidly worsening kidney function. This study assessed the efficacy of terlipressin in patient subgroups based on their precipitating factors (PFs) for HRS in a pooled dataset.

Method: Pooled data from 3 North American placebo-controlled Phase III clinical studies (OT-0401, REVERSE, and CONFIRM) of terlipressin to treat pts with HRS type 1 (N = 564), was evaluated for the effect of PFs on efficacy outcomes including renal replacement therapy (RRT) at Day 90, HRS reversal (serum creatinine [SCr] ≤1.5 mg/dL up to 24 hours after the last dose of study drug; SCr values obtained posttransplant or post-RRT were excluded), overall survival, and transplant-free survival (TFS) at Day 90. Significance was determined using a Fisher's exact test.

Results: The most common PF for HRS was hypovolemia due to large volume paracentesis or diuretic therapy (25.2%), followed by infection (18.3%) and gastrointestinal (GI) bleeding (6.2%); no PFs were reported in 50.3% of pts. The incidence of RRT by Day 90 was numerically lower in the terlipressin group versus placebo (overall, 32.2% [109/338] vs 41.2% [93/226]), with the largest difference among those pts with GI bleeding (26.3% vs 43.8%). HRS reversal was higher in the terlipressin versus placebo group, with a significant improvement among pts with no PF or PFs of hypovolemia or infection. Overall survival at Day 90 in pts with GI bleeding was numerically higher in the terlipressin group versus placebo (47% vs 19%; p = .152) and was otherwise similar for the remaining PF subgroups. TFS at Day 90 was numerically higher for the terlipressin group among pts with GI bleeding and hypovolemia (Figure).

Conclusion: Treatment with terlipressin leads to greater HRS reversal and less need for RRT compared with placebo. Across subgroups, HRS reversal in response to terlipressin was significantly greater among pts with no PFs or PFs of infection or hypovolemia.

them with rubber rings (bands). According to current international guidelines, EBL of esophageal varices plays an important therapeutic role in three settings: a) the prevention of a first VH as an alternative to non-selective beta-blockers (NSBB) in patients with contraindications or who cannot tolerate these drugs; b) to achieve hemostasis in combination with vasoactive drugs (somatostatin, octreotide or terlipressin) in patients with acute VH; and c) to prevent recurrent bleeding. In the latter case, patients are treated both with NSBB and EBL. Post-banding ulcer bleeding (PBUB) is an understudied complication of this procedure. The aims of this systematic review with meta-analysis were: to review the reported incidence of PBUB in patients with cirrhosis and varices treated with EBL in primary and secondary prophylaxis or urgent treatment for acute variceal bleeding; to identify predictors of PBUB; and to ascertain strategies to prevent and manage bleeding after PBUB.

Method: A systematic review of articles in English published in 2006–2022 was conducted using the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines. Searches were made in the following electronic databases: Google Scholar, Medline (OVID interface), Embase (OVID interface), PubMed, Cochrane Library, Cochrane Central Register of Controlled Trials (CENTRAL), clinicaltrials.gov, EU clinical Trials. An independent extraction of articles using predefined data fields and quality indicators was used. Random effects meta-analysis was used to determine the incidence, mean interval and predictors of PBUB in cirrhosis. Treatment of PBUB were assessed with qualitative analysis due to the heterogeneity of procedures employed to control bleeding.

Results: Eighteen studies (9034 patients) were included. The incidence of PBUB was overall 5.5% (95% CI, 4.3–7.1%). The mean time for it to occur was 11 days (95% CI 9.94–11.97). Model for End-stage Liver Disease score (OR 1.162, 95% CI 1.047–1.291, p 0.005) and endoscopic band ligation done in emergency setting (OR 4.09, 95% CI 2.99–8.05, p < 0.001) independently predicted PBUB. Patients were treated with a variety of drugs (vasoactive drugs such as somatostatin, octreotide or terlipressin, endovenous proton pump inhibitors) and/or endoscopic procedures (EBL, argon plasma coagulation, esophageal variceal obliteration with sclerotherapy or cyanoacrylate injection, epinephrine injection, hemoclip) and Transjugular

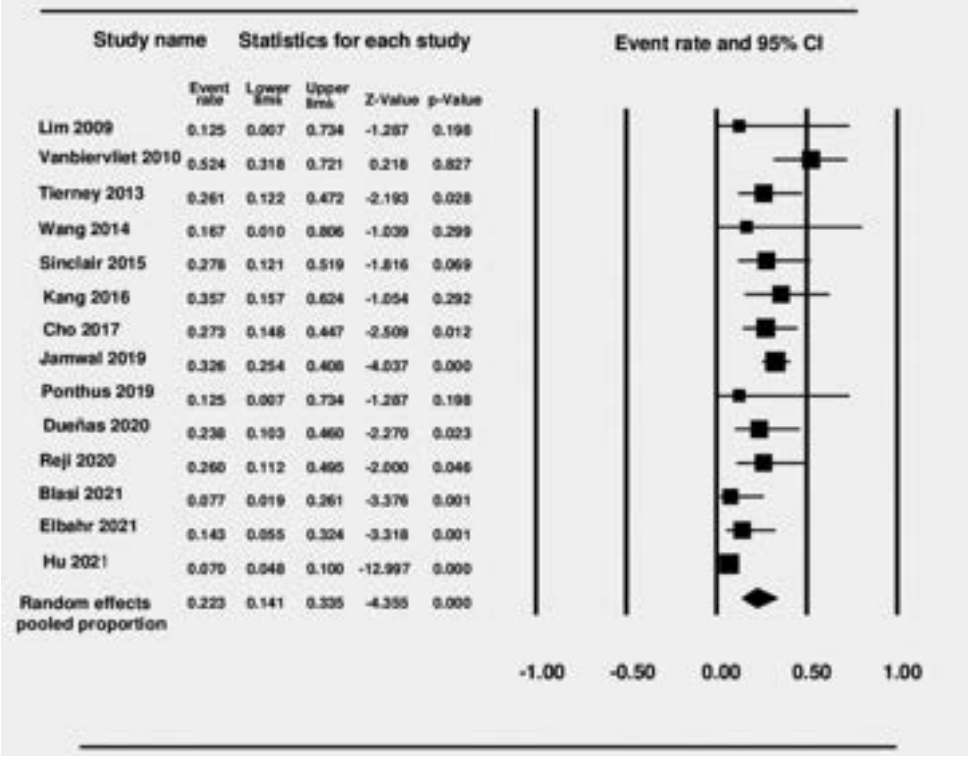

Figure: (abstract: TOP-048): Mortality associated to PBUB

Intrahepatic Portosystemic Shunt (TIPS) for severe bleeding. Refractory bleeding was treated with self-expandable metallic stents and oesophageal balloon tamponade. Treatments had a limited success, as shown by a mortality after PBUB of 22.3% (IC 95%, 14.1–33.6%) (Figure).

Conclusion: Patients more prone to develop PBUB are those with high MELD score, and EBL performed in an emergency context. PBUB carries a severe prognosis with a high mortality despite the variety of treatments used, which calls for prospective, specifically designed studies to improve outcomes of this severe iatrogenic complication. The best therapeutic strategy to address PBUB remains to be ascertained.

Outcome of sucralfate vs proton pump inhibitor vs sucralfate and proton pump inhibitor combination post endoscopic esophageal variceal band ligation-A randomized controlled trial

Arun Vaidya[1], Mayur Satai[1], Abu Aasim Ansari[1], Shashank Pujalwar[1], Gautam Jain[1], Tanmay Laxane[1], Shruti Mehta[1], Aditya Kale[1], Akash Shukla[1]. *[1]Seth GS Medical college and KEM Hospital, Mumbai, Department of Gastroenterology, India*
Email: drakashshukla@yahoo.com

Background and aims: Proton pump inhibitor (PPI) and mucoprotectant like sucralfate are commonly used post variceal band ligation. However, data is sparse in literature on outcome of using them alone or in combination. Therefore, we conducted this trial with the aim to study the outcome of using combination of sucralfate and PPI vs sucralfate alone vs PPI alone vs no treatment post endoscopic variceal band ligation in terms of presence of band ulcers, chest pain, ulcer related bleeding and mortality.

Method: We conducted a single center, single blind randomized trial and included patients above 18 years undergoing esophageal variceal band ligation. Patients already on PPI or sucralfate, pregnant, on anticoagulation, having acute kidney injury or chronic kidney disease and pre-existing esophageal ulcers on endoscopy were excluded. Using simple randomization technique, patients were randomized in 4 arms: Sucralfate plus PPI combination, PPI alone, Sucralfate alone and no treatment. Patients were given these medications for 14 days. We repeated endoscopy after 14 days. Primary end point was post band ulcer bleed and ulcer bleed related mortality at day 28. Secondary end point was to evaluate post band chest pain and presence of band ulcer in each arm.

Results: We randomized 200 patients (50 patients in each arm). Mean age was 43.93 ± 12.8 years. Males were 157 (78.5%). Post band ulcers were seen in 65 (32.5%) patients with mean of maximum ulcer size was 5 mm. Band related chest pain and ulcer bleed were present in 24 (12%) and 2 (1%) patients respectively. Ulcer bleed related mortality at day 28 was 0.5%. There was no significant difference in presence of post band ulcer, chest pain, bleeding or mortality in any trial arm. Serum albumin level was not associated with presence of band ulcer (p = 0.766).

Figure:

Parameters	Sucralfate + PPI (n = 50)	Sucralfate alone (n = 50)	PPI alone (n = 50)	No treatment (n = 50)	p value
Post Band ulcer	17 (34%)	15 (30%)	16 (32%)	17 (34%)	0.969
Chest Pain	5 (10%)	5 (10%)	7 (14%)	7 (14%)	0.568
Ulcer Bleed	1 (2%)	1 (2%)	0	0	0.356
Ulcer bleed related mortality at Day 28	1 (2%)	0	0	0	0.389

Conclusion: Addition of sucralfate, PPI or sucralfate plus PPI combination post variceal band ligation did not reduce post band ulcer bleed or bleed related mortality.

TIPS increases muscle mass in patients with decompensated cirrhosis

Theresa Bucsics[1,2], Katharina Lampichler[2,3], Jakob Kittinger[3], Maria Schoder[3], Konstantin Vierziger[4], Lukas Hartl[1,2], Lukas Reider[3], Florian Wolf[3], David JM Bauer[1,2], Mathias Jachs[1,2], Georg Semmler[1,2], Rafael Paternostro[1,2], Philipp Schwabl[1,2,5], Lorenz Balcar[1,2], Katharina Pomej[1,2], Vinzent Karner[1], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2,5]. *[1]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Wien, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Department of Internal Medicine III, Divison of Gastroenterology and Hepatology, Wien, Austria; [3]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Wien, Austria; [4]Klinik Favoriten-Wiener Gesundheitsverbund, Department of Radiology, Wien, Austria; [5]Medical University of Vienna, Christian Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Wien, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) is used to treat complications of portal hypertension (PH). Sarcopenia is prevalent and associated with poor outcomes in patients with decompensated cirrhosis; however, it may potentially improve after TIPS. We systematically evaluated the evolution of (i) muscle mass and (ii) sarcopenia in patients undergoing TIPS.

Method: Retrospective analysis of the Vienna TIPS cohort. Transversal psoas muscle thickness at the 3rd lumbar vertebra (TPMT) was assessed at CT prior to TIPS, at 3–18 months (FU1) and >18 months (FU2) after TIPS by two independent radiologists. Sarcopenia was defined by height-corrected TPMT <12 mm/m (men) or <8 mm/m (women).

Results: 199 patients with cirrhosis were included (age 55.7 ± 11.0 years; 69.3% men; median MELD 11; Child-C: 12.6%), with 132 (66.3%) undergoing TIPS for ascites. Inter-rater agreement of TPMT readings was excellent (κ = 0.766–0.975). Median TPMT at baseline was 13.4 (IQR: 11.1–15.4) mm/m in men and 12.0 (9.6–13.3) mm/m in women. Sarcopenia was found in 42.7% and correlated with older age (57.7 ± 9.6 vs 53.8 ± 11.7 years, p = 0.012), male sex (50.4% vs 22.7% in women, p < 0.001), alcohol-related liver disease, (49.6% in ALD vs 29.4% in other etiologies, p = 0.006) and Child-C cirrhosis (72.0% vs 36.4% in Child-A/B, p < 0.001). Pre-TIPS portal pressure gradient did not differ between patients with vs. without sarcopenia (20 ± 5 mmHg vs 20 ± 6mmHg, p = 0.472).

Pre-TIPS sarcopenia was further associated with higher risk for post-TIPS overt hepatic encephalopathy (OHE; 56.5% vs 35.1%, log-rank p = 0.024) and persistent ascites (48.2% vs 24.6%, p < 0.001), but not variceal re-bleeding (3.5% vs 5.3%, p = 0.630) and was not identified as an independent risk factor for post-TIPS complications in multivariable analysis.

TPMT improved significantly after TIPS at FU1, with a median relative increase of +18.7% (p < 0.001) at FU1. Sarcopenia resolved in 47.4% of patients with an available CT scan at FU1 and in 72.2% at FU2.

Transplant-free survival (TFS) was significantly shorter in patients with sarcopenia at baseline (median: 21.8 vs 65.9 months; p < 0.001) as well as in those with sarcopenia at FU1 (TFS after FU1: 4 vs 59 months, p < 0.001). When corrected for age, Child-Pugh score, and alcohol-related etiology, sarcopenia at FU1 remained an independent risk factor for mortality afterwards (HR: 6.055, 95% CI: 1.466–25.009, p = 0.013).

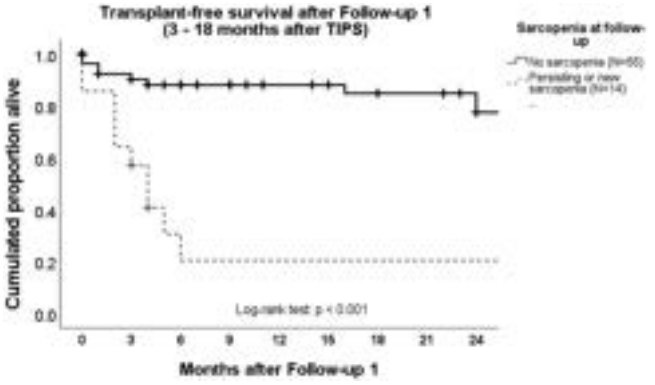

Figure:

Conclusion: Sarcopenia resolves in a considerable share of patients with cirrhosis after TIPS, which is linked to a clear survival benefit. Patients who do not resolve sarcopenia after TIPS remain at considerable risk of mortality and thus should be timely listed for liver transplantation.

SAT-327

Accuracy of spleen stiffness measurement for the diagnosis of clinically significant portal hypertension in patients with advanced chronic liver disease: an individual patient meta-analysis

Background and aims: The identification of patients with clinically significant portal hypertension (CSPH) is of utmost prognostic and therapeutic relevance in patients with compensated advanced chronic liver disease (cACLD). Spleen stiffness measurement (SSM) has been proposed as a direct surrogate of portal hypertension and an accurate non-invasive test for CSPH diagnosis. However, the diagnostic performance and the cut-offs used are very heterogeneous in current literature. Our aim was to perform a systematic review with individual patient data (IPD) meta-analysis to establish the diagnostic performance of SSM and SSM-based algorithms, as measured by different elastography techniques, for the diagnosis of CSPH.
Method: We systematically researched MEDLINE, Ovid Embase, Scopus, and Cochrane Library electronic databases for any study published up to June 2020 and that reported data on hepatic venous pressure gradient (HVPG) and SSM in adult patients. After receiving IPD data, patients with liver stiffness measurement (LSM) <10 kPa, previous decompensation or missing data were excluded. The diagnostic accuracy of the Baveno VII Criteria and the combined Baveno VII-SSM criteria was assessed using a random effect bivariate model. Sensitivity analyses for cACLD definition, center, etiology, and obesity, were conducted. The methodological quality of the included studies was assessed using QUADAS-2 tool.
Results: Of the 44 eligible articles, 17 studies (14 full-texts, 3 abstracts) were included in the meta-analysis. Six hundred patients from six studies were included in the transient elastography cohort. The Baveno VII and the Baveno VII-SSM criteria with a dual cut-off of 21 and 50 kPa were validated, showing adequate (>90%) negative (NPV) and positive predictive values (PPV) in the whole cohort and in all sensitivity analyses. The combined Baveno VII-SSM criteria with a single cut-off (40 kPa) was the most performant in ruling-in CSPH with PPV >90%, while it could rule-out safely CSPH only in viral etiology. The SSM-based algorithms significantly reduced the rate of patients in the "grey zone" from 48% (Baveno VII criteria) to 32% and 9%, respectively. Similar cut-offs showed adequate performance also in the two-dimensional shear-wave elastography (SWE) cohort, compromising 225 patients from five studies. Available data was insufficient to evaluate the performance of SSM assessed by point-shear-wave-elastography.

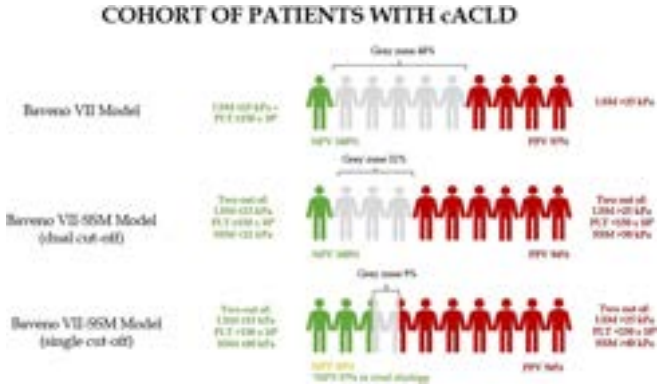

Figure:

Conclusion: The combined Baveno VII-SSM models are highly performant non-invasive algorithms to diagnose CSPH, and were validated in this large, multicenter, international study. Importantly, they significantly reduce the rate of patients in the "grey zone." These criteria can be used in clinical practice to best identify patients that could benefit from carvedilol treatment to reduce the risk of first decompensation.

SAT-328

Effects of renin angiotensin system inhibition on renal function and the clinical course of patients with decompensated liver cirrhosis and ascites

Tammo Lambert Tergast[1], Marie Griemsmann[1], Heiner Wedemeyer[1], Markus Cornberg[1], Benjamin Maasoumy[1]. [1]*Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Germany*
Email: tergast.tammo@mh-hannover.de

Background and aims: Patients with decompensated liver cirrhosis and ascites are at a high risk of developing acute kidney injury (AKI). Studies have suggested that inhibition of the Renin-Angiotensin System (RAS) has certain nephro- and hepatoprotective effects in patients with liver fibrosis and early stages of liver cirrhosis. However, data in patients with decompensated cirrhosis are scarce. This study aimed to investigate the clinical impact of Angiotensin converting

enzyme antagonists and Angiotensin II receptor inhibitors (RAS-Inhibitors) in individuals with decompensated liver cirrhosis.
Method: All hospitalized patients with liver cirrhosis and ascites that underwent paracetensis at Hannover Medical School between 2012 and 2018 were considered for this study. Overall, 667 patients were included of whom 41 (7%) had reported intake of RAS-Inhibitors at baseline. End points were incidences of AKI and severe AKI (i.e. AKI grade III°) within 28-days and long-term need for hemodialysis as well as liver transplant (LTx-) free survival. Patients without RAS-inhibitors were matched via propensity score matching (PPSM) with individuals with RAS-inhibitor intake in a 3:1 manner. Factors included in the matching were glomerular filtration rate, age, mean arterial pressure, leukocyte count, platelet count and presence of type 2 diabetes mellitus. Competing risk analysis was used to analyze longitudinal end points.
Results: After PPSM, 117 patients remained in the No RAS-Inhibitor group and were compared with 39 patients with RAS-inhibitor intake. Baseline characteristics were comparable between both groups and standardized mean differences (SMD) indicated successful matching (SMDs <0.10). Within 28-days, incidence of AKI did not differ between both groups (HR: 0.92, 95%CI 0.49–1.74, P = 0.81). Furthermore, no case of severe AKI was observed in the RAS-Inhibitor group and a significantly increased incidence of severe AKI was observed in those without RAS-Inhibitor intake within 28-days (p < 0.001). Progressive AKI was numerically higher in patients without RAS-Inhibitor intake (RAS-Inhibtor: 25% vs. No RAS-Inhibitor: 46%, P = 0.14). In the long-term follow-up, need for hemodialysis in patients with RAS-Inhibitor intake was significantly decreased compared to patients without RAS-Inhibitors (HR: 0.22, 95%CI: 0.05–0.91 P = 0.03, Figure 1). Furthermore, LTx-free survival was comparable between those with and without RAS-Inhibitor intake (HR: 0.83, 95%CI: 0.48–1.45, P = 0.52). Last, incidence of hepatocellular carcinoma did not differ significantly between patients with or without RAS-Inhibitor intake (HR: 0.81, 95%CI 0.17–3.72 P = 0.71).

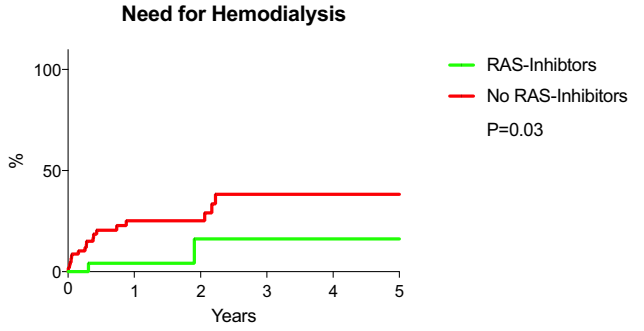

Figure 1: Need for hemodialysis in patients with or without RAS-Inhibitor intake.

Conclusion: RAS-Inhibitor intake is associated with a decreased incidence of severe acute kidney injury and need for hemodialysis in patients with decompensated liver disease.

SAT-329
Adoption of a clinical assessment service in hepatology
Gioia Bratos[1], William Ovenden[1], Arjuna Singanayagam[1], Daniel Forton[1], Metin Yalcin[1], Sarah Hughes[1], Sarah Clark[1]. [1]*St George's Hospital, United Kingdom*
Email: sarah.clark@stgeorges.nhs.uk

Background and aims: The Hepatology Clinical Assessment Service (CAS) was established as a new service at St Georges Hospital in April 2020 during the COVID19 pandemic. It is a novel way to assess new patients referred to the liver outpatient clinic with a view to streamlining the patient pathway, pre-investigation patients prior to a clinic appointment, avoiding inappropriate clinic appointments, rejecting inappropriate referrals and improving the efficiency of the clinic. Hepatology CAS is a weekly consultant-led clinic supported by the Clinical Nurse Specialist (CNS) and the Patient Pathway Coordinator (PPC), the clinic happening virtually without the patient being present at the time of the triage and assessment. On average, every week 35 patients are referred to the Liver Clinic by their GPs or by other clinicians internally or externally to the hospital.
Method: Once the patient's referral has been assessed, the CNS requests the investigations, communicates with the patient and dictates a clinical letter to patient and referrer, while the PPC prioritises the appointments based on their clinical needs. Following this assessment most of the patients then attend a face-to-face appointment, although some patients can be managed entirely virtually if clinically appropriate. With the introduction of the community non-alcoholic fatty liver pathways GP, at a similar time to this service, referrals are rejected if this pathway has not been followed.
Results: Since CAS has been introduced there have been several positive outcomes: in 2021, 18% of the referrals were appropriately repatriated to primary care with advice; 30% of the referrals were managed without needing a face to face appointment; the waiting time reduced from 8 weeks to 5 weeks for a for a clinical review, and from 16 weeks to 15 weeks for a follow-up appointment; from 2020 to 2022 the proportion of patients discharged after the first clinical review has increased from 16% to 29%;

Table 1: Comparison of patients over 6 weeks that were seen and discharged before and after the introduction of CAS.

	2020		2022	
		%		%
Total 'New' appts	190	100	181	100
Total pts seen[1]	134	71	141	78
Total DNAs[2]	56	29	40	22
Breakdown of patients seen[1]				
Total pts seen	134	100	141	100
Of pts seen & F/Up	113	84	100	71
Of pts seen & D/C'd	21	16	41	29
Breakdown of DNAs[2]				
Total DNAs	56	100	40	100
DNA & Reschedule	33	59	25	62.5
DNA & D/C'd	23	41	15	37.5

Conclusion: Hepatology CAS has impacted extremely positively on our service. Following the introduction of the Hepatology CAS service specialist treatment is instigated more quickly, patients can be discharged following their first face to face visit as all information is to hand, it has eliminated unnecessary follow-up and has resulted in a clear and concise pathway to refer the patients into the service, with the diagnostic tests being performed at an earlier stage.

SAT-330
Diabetes impairs the hemodynamic response to non-selective betablockers in compensated cirrhosis and predisposes for hepatic decompensation
Rafael Paternostro[1], Mathias Jachs[1], Lukas Hartl[1], Benedikt Simbrunner[1], Bernhard Scheiner[1], David Jm Bauer[1], Philipp Schwabl[1], Georg Semmler[1], Michael Trauner[1], Mattias Mandorfer[1], Thomas Reiberger[1]. [1]*Medical University of Vienna, Austria*
Email: rafael.paternostro@meduniwien.ac.at

Background and aims: Non-selective betablockers (NSBB) reduce the risk of hepatic decompensation in patients with compensated advanced chronic liver disease (cACLD). The prevalence of metabolic

comorbidities (MetC) in cACLD patients is increasing. We aimed to investigate the impact of MetC on (i) the hemodynamic effects of NSBB and (ii) hepatic decompensation in cACLD.
Method: cACLD patients undergoing paired hepatic venous pressure gradient (HVPG) measurements before/under NSBB-therapy were considered for this study. MetC, i.e. obesity, dyslipidemia, and diabetes (DM) were recorded. Hepatic decompensation and liver-related mortality were evaluated.
Results: Ninety-two patients were included (Child-A n = 80, 87%; Child-B n = 12, 13%). MetC were found in 34 (37%) patients: n = 19 (20.7%) had obesity, n = 14 (15.2%) dyslipidemia, and n = 23 (34.8%) DM. The median baseline-HVPG of 18 (IQR:15–21) mmHg decreased to a median of 15 (IQR:9–12) mmHg under NSBB. HVPG-response (decrease≥10% or to ≤12 mmHg) was achieved in n = 60 (65.2.%) patients. Interestingly, patients with DM (OR: 0.35, p = 0.021) and higher BMI (OR: 0.89 per kg/m2, p = 0.031) were less likely to achieve HVPG-response. During a median follow-up of 2.3 (0.5–4.2) years, 18 (19.5%) patients experienced first hepatic decompensation. Child-B (adjusted subdistribution hazard ratio, aSHR: 4.3 [95%CI:1.5–12.2], p = 0.006), HVPG-response (aSHR: 0.3 [95%CI:0.1–0.9], p = 0.037), and DM (aSHR: 2.8 [95%CI:1.1–7.2], p = 0.036) were independently associated with hepatic decompensation (Table).

Table: (A) Univariate and (B) multivariate competing risk regression analysis modeling the risk for hepatic decompensation during follow-up. Diagnosis of hepatocellular carcinoma, removal of the primary aetiological factor, and non-liver-related death were considered competing events

Model for hepatic decompensation	Univariate regression model			Multivariate regression model		
Parameter	SHR	95% CI	p value	aSHR	95% CI	p value
CTP stage B (vs. A)	3.420	1.330–8.80	**0.011**	4.325	1.536–12.175	**0.006**
HVPG-Response (vs. Non-response)	0.279	0.107–0.728	**0.009**	0.313	0.105–0.934	**0.037**
Age, per year	1.070	1.010–1.140	**0.021**	1.040	0.978–1.105	0.210
Diabetes mellitus, vs. no diabetes mellitus	5.280	1.870–14.900	**0.002**	2.772	1.071–7.175	**0.036**
Dyslipidemia, vs. no dyslipidemia	2.030	0.548–7.530	0.290	–	–	–
Arterial hypertension, vs. no arterial hypertension	0.940	0.309–2.860	0.910	–	–	–
Obesity, vs. normal weight	1.110	0.362–3.390	0.860	–	–	–

Conclusion: In cACLD patients DM and a higher BMI impair the HVPG-response to NSBB. Furthermore, DM-independent from hepatic function and lack of HVPG-response-increases the risk for hepatic decompensation. Thus, DM seems to promote first hepatic decompensation by hemodynamic and non-hemodynamic mechanisms.

SAT-331

Preoperative transjugular intrahepatic portosystemic shunt and in-house mortality in patients with liver cirrhosis undergoing surgery

Felix Piecha[1], Joscha Vonderlin[2], Friederike Frühhaber[1], Julia-Kristin Graß[3], Ann-Kathrin Ozga[4], Aenne Harberts[1], Daniel Benten[1], Peter Huebener[1], Matthias Reeh[3], Christoph Riedel[5], Peter Bannas[5], Jakob R. Izbicki[3], Gerhard Adam[5], Samuel Huber[1], Ansgar W. Lohse[1], Johannes Kluwe[1]. *[1]University Medical Center Hamburg-Eppendorf, I. Email: f.piecha@uke.de

Background and aims: Liver cirrhosis is associated with an increased surgical morbidity and mortality. Portal hypertension and the surgery type have been established as critical determinants of postoperative outcome. We aim to evaluate the hypothesis that preoperative placement of a transjugular intrahepatic portosystemic shunt (TIPS) in patients with liver cirrhosis is associated with a lower in-house mortality after surgery.
Method: A retrospective database search for the years 2010–2020 was carried out. We identified 64 patients with liver cirrhosis who underwent surgery within three months after TIPS-placement and 131 cirrhosis patients who underwent surgery without prior TIPS (control). Surgeries were categorized into low-risk and high-risk procedures. The primary end point was postoperative in-house mortality.
Results: In both the TIPS and the control cohort, most patients presented with a Child-Pugh B stage (37/64, 58% vs. 70/131, 53%) at the time of surgery, but the median MELD score was higher in the TIPS cohort (14 vs. 11 points). Low-risk and high-risk procedures amounted to 47% and 53% in both cohorts. In-house mortality was lower in the TIPS cohort (12/64, 19% vs. 53/131, 41%), also when further subdivided into low-risk (0/30, 0% vs. 11/61, 18%) and high-risk (12/34, 35% vs. 42/70, 60%) surgery. We analyzed the influence of high-risk surgery, preoperative TIPS-placement, age, sex, baseline creatinine, presence of ascites, chronic liver failure consortium-acute decompensation (CLIF-C AD), American Society of Anesthesiologists (ASA) and model for end-stage liver disease (MELD) scores on in-house mortality by multivariable Cox proportional hazards regression. Preoperative TIPS-placement was associated with a lower rate (hazard ratio 0.42, 95%-confidence interval 0.18–0.93) for postoperative in-house mortality.

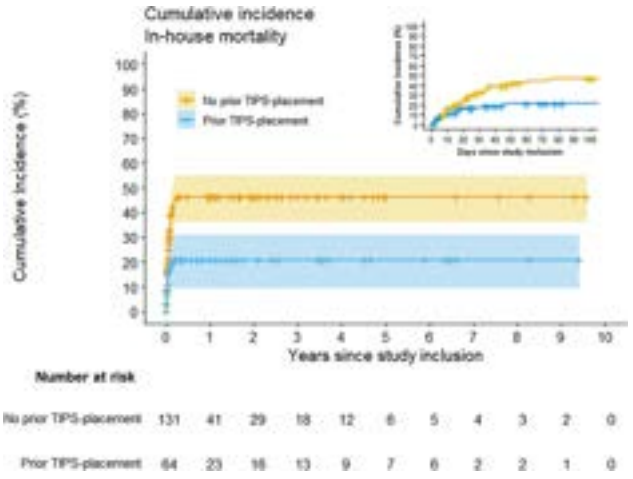

Figure:

Conclusion: A preoperative TIPS might be associated with reduced postoperative in-house mortality in patients with liver cirrhosis, especially after high-risk surgical procedures.

SAT-332

Indocyanine green clearance reflects various pathophysiological mechanisms and independently predicts liver-related events in ACLD

Mathias Jachs[1], Lukas Hartl[1], Benedikt Simbrunner[1], Lorenz Balcar[1], Georg Semmler[1], David Jm Bauer[1], Benedikt Hofer[1], Michael Schwarz[1], Albert Stättermayer[1], Matthias Pinter[1], Michael Trauner[1], Thomas Reiberger[1], Mattias Mandorfer[1]. [1]*Medical University of Vienna, Austria*
Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Indocyanine green (ICG) clearance, determined by venous sampling, has shown a promising diagnostic/prognostic utility for clinically significant portal hypertension (CSPH)/hepatic decompensation in compensated advanced chronic liver disease (cACLD), while the prognostic utility of pulse dye densitometry (PDD)-derived values conveniently measured via a finger clip has primarily been evaluated in the context of hepatectomy or decompensated cirrhosis.
Method: For this retrospective evaluation, patients with ACLD (defined by LSM ≥10 kPa) enrolled in the prospective Vienna Cirrhosis Study (VICIS, NCT03267615) who underwent same-day measurements of the hepatic venous pressure gradient (HVPG) and ICG clearance between 2017 and 2022 were included. ICG retention rate at 15 minutes (R15) was assessed in vivo by PDD. Long-term follow-up data on first hepatic decompensation (cACLD) and the incidence of acute-on-chronic-liver failure (ACLF) or liver-related mortality (decompensated ACLD [dACLD]) was recorded and analysed by competing risk regression.
Results: Two-hundred and sixty-one patients were included: Median age: 56.0 years; 62.8% male; etiology: 55.2% ALD, 18.0% viral, 18.1% NAFLD/cryptogenic, while 10.7% other; Child-Turcotte-Pugh stage A: 49.6%, B: 36.8%, C: 13.8%. The median HVPG was 17 (IQR: 11–20) mmHg. The median ICG-R15 was 24.1 (10.4–41.3) %. Among cACLD patients (n = 115, CSPH prevalence: 62.4%), ICG-R15 correlated moderately with HVPG (Spearman's rho: 0.458, p < 0.001) and yielded a suboptimal diagnostic accuracy for CSPH (AUROC: 0.687 [95% CI: 0.585–0.789]), while a strong correlation with the model for end-stage liver disease (MELD) score (rho: 701, p < 0.001) was found. ICG-R15 also correlated with biomarkers of endothelial dysfunction (von Willebrand factor antigen [VWF]) and inflammation (CRP, IL-6, procalcitonin [PCT]), as shown in the Figure. In dACLD (n = 146), similar correlations were found, however, ICG-R15 correlated only weakly with HVPG (rho: 0.189, p = 0.023). ICG-R15 additionally correlated with renin/mean arterial pressure, i.e., biomarkers of circulatory dysfunction. ICG-R15 was independently associated with hepatic decompensation in cACLD patients in competing risk regression (adjusted subdistribution Hazard Ratio [aSHR]: 1.045 [95%CI: 1.006–1.090] per %, p = 0.024; adjusted for liver stiffness, MELD, and albumin levels). Furthermore, ICG-R15 was an independent predictor for the composite end point ACLF/liver-related mortality in dACLD (aSHR: 1.070 [95%CI: 1.030–1.100] per %, p < 0.001; adjusted for CLIF-C ACLF-D score).
Conclusion: ICG-R15 by PDD correlated with portal hypertension and systemic inflammation as key disease-driving mechanisms in cACLD. Although its diagnostic value for CSPH is insufficient for clinical application, it predicted first hepatic decompensation, even after adjusting for other non-invasive parameters. Moreover, ICG-R15 was independently predictive of ACLF/liver-related death in dACLD.

SAT-333

A multimodal deep learning network for non-invasive prediction of the hepatic decompensation risk in compensated cirrhotic people: a multicentre cohort study (CHESS1701)

Qian Yu[1], Yi Zhou[2], Yuxiang Lai[2], Xiaolong Qi[3], Shenghong Ju[1]. [1]*Department of Radiology, Zhongda Hospital, School of Medicine, Southeast University, China;* [2]*School of Computer Science and Engineering, Southeast University, China;* [3]*Center of Portal Hypertension, Department of Radiology, Zhongda Hospital, School of Medicine, Southeast University, China*
Email: jsh@seu.edu.cn

Background and aims: Assessing the risk of portal hypertension (PHT)-related decompensation aids the prophylactic strategy to improve prognosis of the compensated cirrhotic population. Conventional imaging methods are inadequate to assess this risk, and the usage of specialized screening tools (such as liver stiffness measurement (LSM)) is still limited. Hence, we aimed to develop a multimodal artificial intelligence decompensation prediction system (AIDE) that integrates computed tomography (CT) image-type and clinical context-type information to predict the hepatic decompensation risk non-invasively.
Method: 1,045 compensated cirrhotic patients from seven tertiary medical centres who underwent baseline contrast-enhanced CT imaging were enrolled with a median follow-up of 33 months. A total of 615 patients from the first five centres were treated as the training and validation cohorts, while 430 from other two centres comprised the external test cohort. AIDE's performance was evaluated using concordance index (C-index) and time-dependent area under the curve (tAUC). The risk stratification performance was assessed by Kaplan-Meier analysis and compared with the Baveno VII performance. The classification ability of baseline clinically significant PHT (CSPH) was assessed in 430 persons with or without CSPH to explore the biological mechanisms of AIDE.
Results: In the external test cohort, AIDE achieved a C-index of 0.84 (95% confidence interval (CI): 0.80–0·87) and a 3-year tAUC of 0.87 (0.83–0.92), outperformed the conventional models (Figure 1). The 3-year decompensation rates were 1% (3/230), 25% (47/188), and 59% (23/39) in the low-, moderate-, and high-risk groups, respectively (p <0.05). AIDE reduced the proportion of patients in the grey zone of Baveno VII by 63% and achieved an AUC of 0.82 (0.76–0. 89) for CSPH diagnosis; the PHT progression mechanisms might be captured by the AIDE.
Conclusion: AIDE provided an accurate decompensation risk assessment in compensated cirrhotic patients. It could help guide the prophylactic strategies when HVPG/LSM are not available.

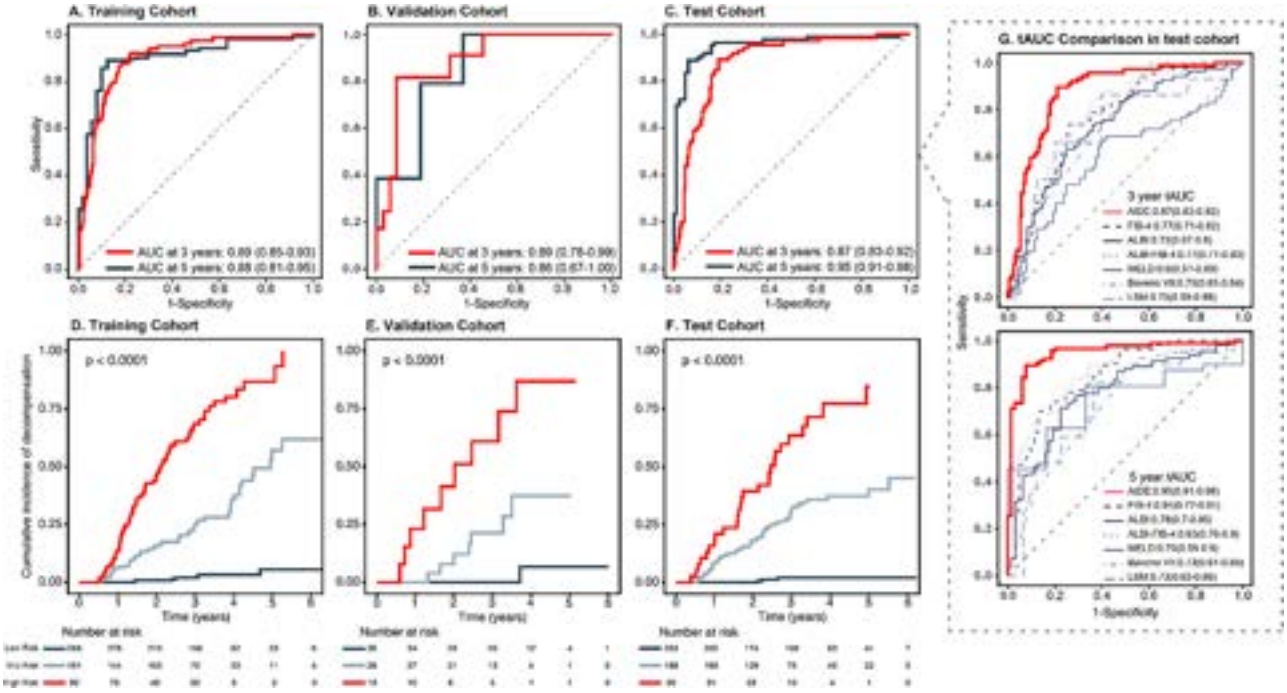

Figure: (abstarct: SAT-333): Performance of the AIDE in predicting the decompensation risk. (A–C) The time-dependent AUC of AIDE at 3 years and 5 years. (D–F) Risk stratification by Kaplan-Meier analysis in the training, validation, and test cohorts. (G) Comparing time-dependent AUC of AIDE to those of other models.

TIPS under-dilation strategy with new controlled expansion endoprosthesis: a hemodynamic and imaging confirmation of its feasibility

Dario Saltini[1,2], Cristian Caporali[2,3], Federica Indulti[1,2], Marcello Bianchini[1,2], Federico Casari[2,3], Francesco Prampolini[2,3], Davide Felaco[2,3], Tomas Guasconi[1], Biagio Cuffari[1], Alberto Zanetto[1,4], Gian Piero Guerrini[5], Nicola De Maria[1,5], Erica Villa[1], Antonio Colecchia[1], Fabrizio Di Benedetto[2,5], Filippo Schepis[1,2].
[1]Gastroenterology Unit, University of Modena and Reggio Emilia and Azienda Ospedaliero-Universitaria of Modena, Italy; [2]TIPS team, Azienda Ospedaliero-Universitaria of Modena, Italy; [3]Interventional Radiology Unit, Azienda Ospedaliero-Universitaria of Modena, Italy; [4]Gastroenterology and Multivisceral Transplant Unit, Azienda Ospedale-Università of Padua, Italy; [5]Hepato-Pancreato-Biliary Surgery and Liver Transplantation Unit, University of Modena and Reggio Emilia, Azienda Ospedaliero-Universitaria of Modena, Italy
Email: fschepis@unimore.it

Background and aims: The use of small caliber (<8 mm) transjugular intrahepatic portosystemic shunt (TIPS) is a promising approach to reduce shunt-related complications. Its feasibility with the new controlled expansion stent-grafts (GORE® VIATORR® CX 8–10 mm or VCX) has not yet been explored. Our aim was twofold: to investigate whether VCX self-expands over time when under-dilated to <8 mm at TIPS placement; to compare VCX under-dilated to 6 mm versus first generation 8 and 10 mm VIATORR® TIPS stent-grafts (VTS).
Method: For the first aim, we prospectively enrolled consecutive patients with cirrhosis who received under-dilated TIPS between June 2020 and September 2022 at our tertiary referral Center in Modena, Italy. All patients underwent hemodynamic measurements a) immediately before and after TIPS placement, b) 6–7 days and c) ≥1 month after the procedure. We measured average pressure values in different sites along the TIPS: portal-vein tract (PV), intra-parenchymal tract (IP), hepatic-vein tract (HV) and inferior vena cava (IVC). A subgroup of patients underwent serial CT scans within 24 h (T0), at 6–7 days (T1) and at ≥1 month after TIPS (T2). Average maximal inner diameter of endoprosthesis was measured at 5 standard sites: PV, PVW, IP, HVW and distal HV. For the second aim, we retrospectively enrolled consecutive patients with cirrhosis who received under-dilated TIPS to 6 mm between January 2015 and September 2022 and underwent a CT scan >1 month after TIPS. Average maximal inner diameter of stent-graft was measured at PVW, IP, and HVW and compared between VCX and VTS-8 or VTS-10. Percentage variations from the dilation diameter were also assessed.
The institutional review board gave approval to collect prospective and retrospective clinical, hemodynamic, and CT data.
Results: For the first aim, 64 patients underwent hemodynamic assessments: 25, 29 and 10 received TIPS under-dilated to 5, 6 and 7 mm, respectively. A significant drop of pressure was observed while crossing PVW and HVW in all under-dilated groups (Figure 1A). Forty-three of these patients underwent CT scans: 17, 19 and 7 were dilated to 5, 6 and 7 mm, respectively. PVW and HVW sites maintained under-dilation overtime (Figure 1B). No TIPS dysfunction occurred during a mean follow-up period of 363 days. For the second aim, 20 patients were enrolled in the VCX, VTS-8 and VTS-10 mm groups, respectively (N = 60). VCX maintained the dilation diameter at PVW and HVW similarly to VTS-8 but significantly better than VTS-10 mm. VCX self-expansion at IP site was significantly inferior than VTS-10 mm (Figure 1C).
Conclusion: Under-dilation TIPS strategy performed with VCX is feasible. Reduced self-expansion in comparison to first generation VTS positively impact the strategy application. Evaluation of clinical outcomes after applying this strategy are awaited.

Figure 1A Average pressure at each standard site in hemodynamic assessment time points (immediate post-TIPS, 6-7 days and ≥ 1 months after TIPS)

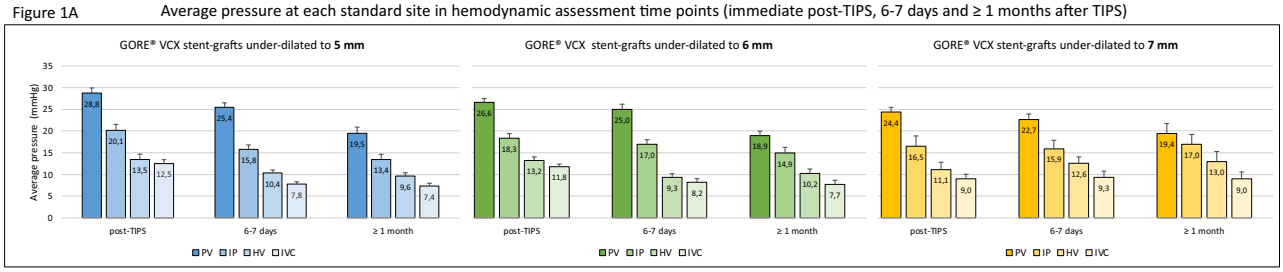

Figure 1B Average maximal inner diameters at each standard site in CTs time points (T0, T1 and T2)

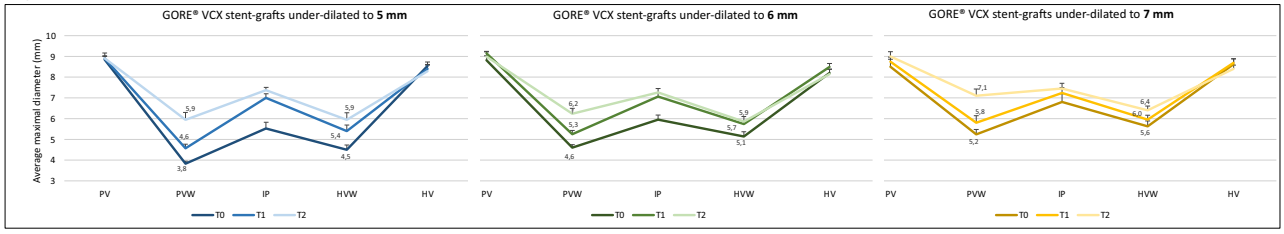

Figure 1C Comparison between GORE® VCX and VTS stent-grafts under-dilated to 6mm

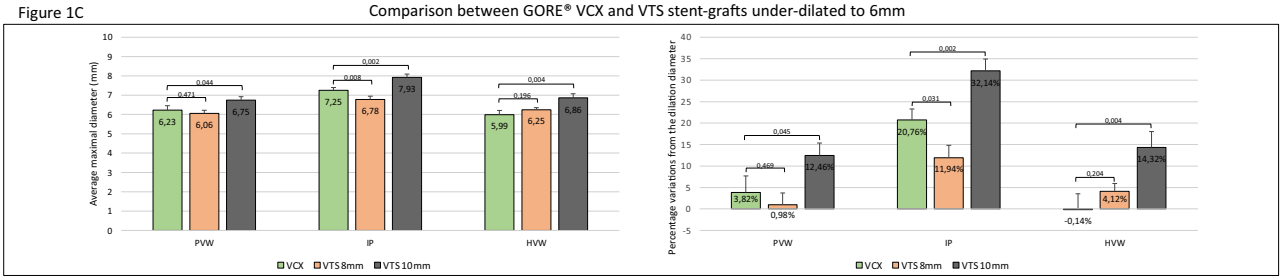

Bars represent mean±SE
HVW, hepatic vein wall; HV, hepatic vein lumen; IP, TIPS intra-parenchymal tract; IVC, inferior vena cava lumen; PV, portal vein lumen; PVW, portal vein wall; VCX, VIATORR® CX 8-10mm stent-grafts; VTS, VIATORR® TIPS stent-grafts.

Is elastography needed for diagnosing cACLD and stratifying CSPH risk?

Georg Semmler[1,2], Lukas Hartl[1,2], Mathias Jachs[1,2], Benedikt Simbrunner[1,2], Benedikt Hofer[1,2], Lorenz Balcar[1,2], Michael Schwarz[1,2], Laurenz Fritz[1,2], Anna Schedlbauer[1,2], Katharina Stopfer[1,2], Daniela Neumayer[1,2], Jurij Maurer[1,2], Robin Szymanski[1,2], Bernhard Scheiner[1,2], Michael Trauner[1,2], Thomas Reiberger[1,2], Mattias Mandorfer[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria*
Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Compensated advanced chronic liver disease (cACLD) identifies the population at risk for liver-related complications and the presence of clinically significant portal hypertension (CSPH) defines the target population for preventing hepatic decompensation. While liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE) has enabled non-invasive identification of these conditions, its availability is mostly restricted to tertiary care. As the reliance on VCTE/referral pathways may impede the identification of cACLD/CSPH in the community, we developed a routine laboratory-based algorithm to identify cACLD patients (by FIB-4) and to subsequently rule-in/rule-out CSPH (by the von Willebrand factor/platelet count ratio [VITRO]).
Method: FIB-4/LSM cohort: To determine a FIB-4 cut-off that reflects cACLD, all patients with (suspected) compensated chronic liver disease undergoing FIB4+LSM at the Medical University Vienna from 2007 to 2022 were characterized and followed for the development of hepatic decompensation. HVPG cohort: To determine VITRO cut-offs for ruling-in/ruling-out CSPH, cACLD patients (as diagnosed by FIB-4) undergoing hepatic venous pressure gradient (HVPG) measurement were analyzed.
Results: FIB-4/LSM cohort: 5646 patients were followed for a median of 54 months during which 248 (4.4%) developed first hepatic decompensation. 1785 (32%) had a LSM ≥10 kPa, which corresponded to a FIB-4 of >1.7. Importantly, both LSM (AUC 0.894) and FIB-4 (AUC 0.900) were similarly accurate in predicting hepatic decompensation within the subsequent 2 years. FIB-4 >1.7 identified patients at risk for first hepatic decompensation (cumulative incidence at 5 years: 11.9%,) while in those below this threshold, risk was negligible (cumulative incidence at 5 years: 0.07%, Figure-panel A). HVPG cohort: 393 cACLD patients (as defined by a FIB-4 >1.7) were included. Among patients with FIB-4 ≥1.7, CSPH prevalence was 61.8% (n = 201/325). VITRO exhibited an excellent performance for diagnosing CSPH (AUC 0.844), which was comparable to LSM (AUC 0.854; DeLong test: p = 0.746) and comparable to the ANTICIPATE model (AUC 0.894; DeLong test: p = 0.073, Figure-panel B). A VITRO <1.0 ruled-out (prevalence: 12.0%; negative predictive value [NPV] 87.2%; sensitivity 97.5%) CSPH, while it was ruled-in (prevalence: 40.9%; positive predictive value [PPV] 91.0%; specificity 90.3%) by VITRO ≥2.5. Importantly, the diagnostic indices were comparable to the Baveno VII cut-offs of LSM ≤15kPa and PLT ≥150G/L (prevalence: 10.8%; NPV 94.3%; sensitivity: 99.0%) and LSM ≥25kPa (prevalence: 43.4%; PPV 90.8%; specificity: 89.5%).

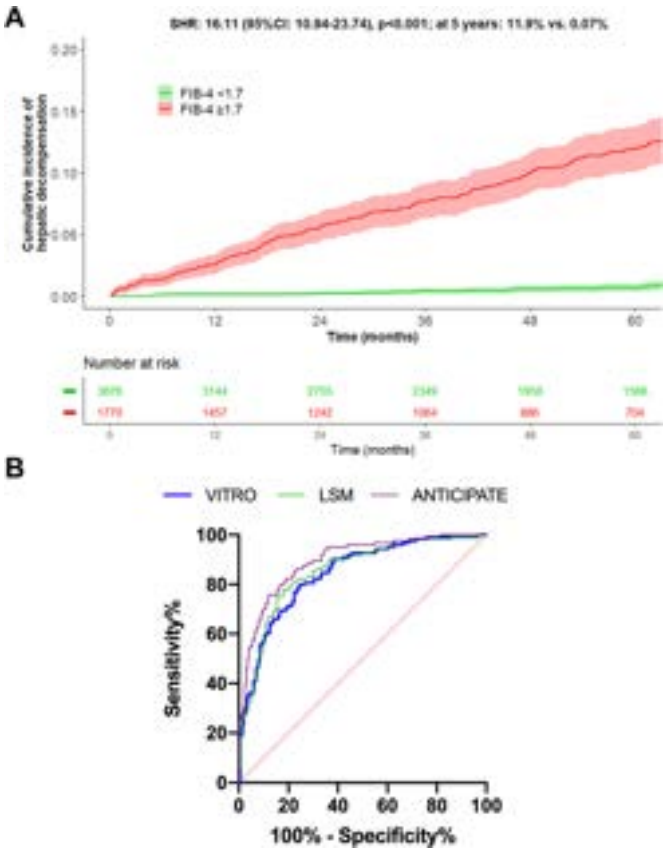

Figure:

Conclusion: FIB-4 >1.7 and VITRO ≥2.5 identify cACLD (defined by risk rather than stage, as endorsed by Baveno VII) and CSPH with a similar diagnostic accuracy as LSM-based criteria, questioning the need for VCTE. Simple laboratory tests which are available in primary/secondary care may broaden the access to risk stratification and early intervention.

SAT-336

Systemic inflammation remains a critical determinant of the dynamic component of portal hypertension in abstinent patients with alcohol-related cirrhosis

Benedikt Hofer[1,2,3,4], Benedikt Simbrunner[1,2,3,4], Kerstin Zinober[1,2,3], Georg Semmler[1,2], Philipp Königshofer[1,3,4], Thomas Sorz[1,3,4], Vlad Taru[1,3], Michael Trauner[1], Philipp Schwabl[1,2,3,4], Mattias Mandorfer[1,2], Thomas Reiberger[1,2,3,4]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [3]Medical University of Vienna, Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria; [4]Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Portal hypertension (PH) drives disease progression in cirrhosis even after removal/suppression of the primary aetiological factor. While the static component of PH is reflected by the degree of liver fibrosis, the assessment of dynamic contributors to PH is particularly challenging. We assessed the impact of hepatic/systemic inflammation on the dynamic component of PH in (i) rodent models of cirrhosis regression and in (ii) abstinent patients with cirrhosis due to alcohol-related liver disease (ALD).

Method: Male C57BL/6JRj mice were exposed to carbon tetrachloride or thioacetamide for 12 weeks to induce cirrhosis before allowing for regression by discontinuing the toxic stimulus for one (R1, n = 15) or two (R2, n = 15) weeks. ALD patients with sustained abstinence (>1 month) undergoing same-day hepatic venous pressure gradient (HVPG) and liver stiffness measurement (LSM) were included. The static component of PH (histological collagen proportionate area [CPA; %] in animals; LSM in patients) was used in a linear model to predict portal pressure (PP). Factors affecting the dynamic component of PH (i.e., the discrepancy between the true PP and the PP predicted by LSM/CPA) were explored using the respective linear model's residuals (Figure).

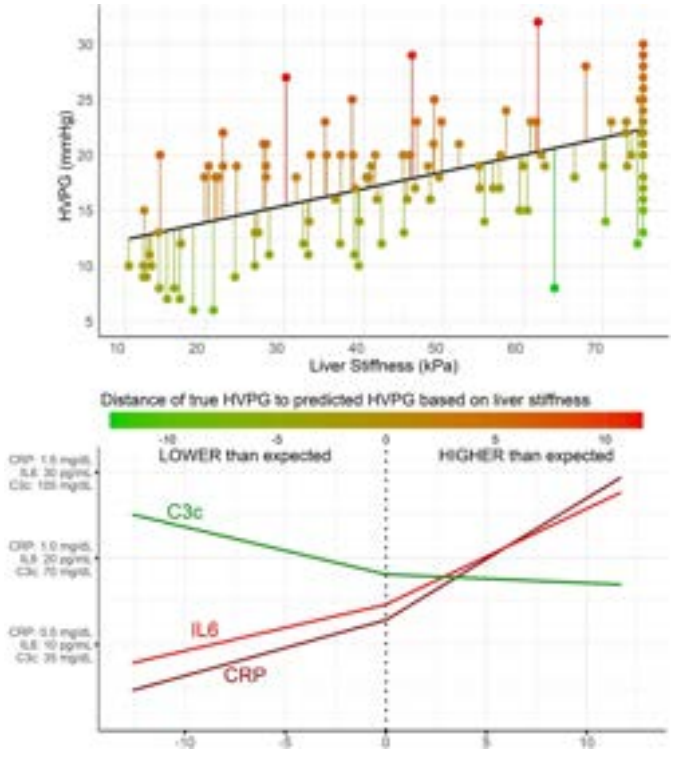

Figure:

Results: In animals, CPA demonstrated a significant positive relationship with PP (beta: 0.20; p <0.001). Hepatic inflammatory gene expression was linked to higher-than-expected PP. Specifically, TNF-alpha (r: 0.46, p = 0.012), CXCL1 (r: 0.36, p = 0.054), IL1-beta (r: 0.46, p = 0.012) and MCP1 (r: 0.35, p = 0.058) were positively correlated with the model's residuals. The impact of intrahepatic inflammation was significantly more pronounced in R2 than R1 animals. In addition to the animal models, 130 ALD patients (median abstinence: 6 [IQR: 10] months) with a median HVPG of 19 (IQR: 8) mmHg and a median LSM of 49 (IQR: 44) kPa were included. In the linear model, LSM showed a significant positive relationship with HVPG (beta: 0.15; p <0.001). Systemic inflammation was significantly upregulated in patients with higher-than-expected HVPG, as demonstrated by a positive correlation of the model's residuals to CRP (Spearman's r: 0.19, p = 0.026) and IL-6 (r: 0.16, p = 0.066). In contrast, complement factors C3c (r: – 0.32, p = 0.005) and C4 (r: – 0.21, p = 0.059) were lower in patients with higher-than-expected HVPG. While the negative correlation of C3c was only found in short-term abstinence (≤6 months), the impact of systemic inflammation was notably more pronounced in long-term abstinence (>6 months).

Conclusion: In animal models of regressive cirrhosis, increased intrahepatic inflammatory gene expression was linked to more pronounced dynamic PH. Similarly, systemic inflammation, as evident from increased CRP and IL-6 and consumption of complement factor C3c, drives the dynamic PH component in abstinent ALD patients.

Robust identification of patient subgroups in acute decompensated cirrhosis

Sara Palomino[1], Estefanía Huergo[1], Eva Uson[2], Cristina Sanchez[2], Vincenzo Lagani[3], Narsis Kiani[4], Nuria Planell[1], Unai Gurbindo[1], Jonel Trebicka[5], Alberto Q. Farias[6], Paolo Caraceni[7], Pierre-Emmanuel Rautou[8], David Gomez-Cabrero[1]. *[1]Navarrabiomed, Unit of Translational Bioinformatics, Pamplona, Spain; [2]European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain; [3]Ilia State University, Institute of Chemical Biology, Georgia; [4]Karolinska Institute, Algorithmic Dynamics lab, Sweden; [5]University of Münster, Department of internal medicine, Münster, Germany; [6]Hospital das Clínicas da Universidade de São Paulo, Department of Gastroenterology, Brazil; [7]University of Bologna, Department of Medical and Surgical Science, Bologna, Italy; [8]Université Paris-Cité, Inserm, Centre de recherche sur l'inflammation, France*
Email: sarapalominoecheve@gmail.com

Background and aims: Understanding patient heterogeneity is essential to better comprehend the mechanisms underlying complex diseases and improve clinical decisions. Therefore, it is necessary to characterize patient diversity by identifying possible sub-types of patients and the clinical features that define them. Classical clustering methods allow patient stratification; however, the intricate nature of clinical data makes the development of more versatile and robust approaches necessary. Here, we developed a tool called *ClustAll* to identify patient subgroups in individuals with acute decompensation of cirrhosis (AD).
Method: In this study, part of the H2020 funded project DECISION, we developed and applied *ClustAll,* an unsupervised clustering strategy capable of identifying all possible robust ways of stratifying a population while addressing high dimensional data, missing values, and correlated features. For each resulting stratification, the sub-groups identified by *ClustAll* were statistically characterized, and the minimal model was found using MXM. Subgroup associations with disease outcomes (ACLF, transplant or death) were explored using survival Kaplan-Meier curves. Then, a supervised classifier was trained to predict the groups obtained by *ClustAll* into additional independent cohorts.
Results: *ClustAll* was first applied to stratify AD patients from the European multicenter PREDICT cohort (n = 766). 74 clinical variables collected at hospital admission were included in the analysis. Five different robust stratifications were identified. Based on clinical expertise, one of the stratifications was selected for further exploration, defining three sub-groups of AD patients: 306 patients were assigned to Cluster 1, presenting the highest rates of organ dysfunction, clinical events, and precipitating events; Cluster 2 (n = 118) included the highest percentage of diabetic patients (51%) and of patients with suffering from hepatic encephalopathy (HE) (89%); Cluster 3 (n = 342) revealed a cluster with similar patterns to Cluster 2, but not afflicted by HE. Regarding the outcomes, patients in Cluster 1 had a poorer outcome (ACLF, transplant requirement or death) compared to the other groups. Cluster 2 and Cluster 3 had similar prognoses. This patient clustering was validated in two independent international cohorts of AD patients (CANONIC, n = 572 and ACLARA, n = 580) as well as in follow-up visits of PREDICT cohort (n = 725). The resulting clustering was robust in all three cohorts, and survival significantly differed in the subgroups identified.
Conclusion: Using a data driven approach, our analysis of three large international prospective cohorts of AD patients robustly identified three clusters of patients with different clinical features and short term outcomes. ClustAll may help improve the characterization of AD complexity.

SAT-338

Clinical profile of porto-sinusoidal vascular disorder : experience from tertiary referral hospital in India

Love Garg[1], Akash Shukla[1], Kashmira Kawli[2], Arun Vaidya[2], Aditya Kale[2], Shashank Pujalwar[2]. *[1]Seth GS Medical College and KEM hospital, Mumbai, Gastroenterology, Mumbai, India; [2]Seth GS Medical College and KEM hospital, Mumbai, India*
Email: drakashshukla@yahoo.com

Background and aims: Porto-sinusoidal vascular disorder (PSVD) is recently described clinical entity encompassing non cirrhotic portal fibrosis, idiopathic portal hypertension, non cirrhotic intrahepatic portal hypertension and various overlapping histologic patterns. We decided to study clinical profile of patients with PSVD at our center.
Method: Prospectively maintained liver clinic database was reviewed to identify 125 patients meeting the inclusion criteria of PSVD proposed in Baveno VII guidelines. Demography, clinical features, endoscopic, radiological and histological findings and associated conditions were noted.
Results: Median age of cohort was 34 years. Females were 80 (64%). Median duration of symptoms at the time of diagnosis was 8 months. Common presentations were gastrointestinal bleed in 59 (47.2%), symptomatic splenomegaly in 45 (36%), transient ascites following bleed in 25 (20%), incidentally detected in 21 (16.8%) patients. Hemogram showed pancytopenia in 101 (80.8%) patients. Portal hypertension was seen in 120 patients (96%). End stage liver disease (ESLD) developed in 18 (14.4%) patients with median follow-up of 110 months (range 30–150 months). Significant ascites was seen in 16 (12.8%) and spontaneous hepatic encephalopathy in 3 (2.4%) patients. Autoantibodies seen in 41 patients {ANA- 29 (23.2%) and ASMA-12 (9.6%)}. IgG elevation was seen in 36 (28.8%) cases. Imaging revealed collaterals and splenomegaly in 113 (90.4%) and 103 (82.4%) patients respectively. Portal vein thrombosis and splenic vein thrombosis was present in 18 (14.4%) and 3 (2.4%) patients respectively. Specific biopsy findings like obliterative portal venopathy, nodular regenerative hyperplasia and incomplete septal fibrosis were seen in 19 (15.2%), 2 (1.6%), 6 (4.8%) patients and combination of obliterative portal venopathy and nodular regenerative hyperplasia in 1 (0.8%). Table 1 shows associated conditions with PSVD. Pancytopenia and IgG elevation was seen significantly more commonly in males than female patients (32 v/s 69 and 7 v/s 29, p value <0.05 for both). Splenomegaly was significantly more common in <35 years age group than >35 years (57 v/s 46, p value <0.005). Devascularization and shunt surgery was performed in 2 patients for refractory bleed. Transjugular intrahepatic portosystemic shunt (TIPS) was performed in 3 patients for recurrent GI bleed and 3 patients for ascites, out of which 2 patients had favourable outcomes.

Table 1: Conditions associated with porto-systemic vascular disorder

Associated disorders	Number of patients	Percentage
Immunological (Autoimmune hepatitis)	7	5.6%
Myeloproliferative disorder	1	0.8%
Hodgkin's lymphoma	1	0.8%
Prothrombotic disorders	10	8%
Protein S deficiency	1	0.8%
Protein C + S deficiency	4	3.2%
Antiphospholipid antibody	2	1.6%
JAK 2 mutation	2	1.6%
Factor V mutation	1	0.8%

Conclusion: PSVD is female predominant entity with varied clinical and histological manifestations. PSVD can present without portal hypertension. Portal vein thrombosis is common. Prothrombotic disorders and autoimmune disorders are less common than reported in western. A proportion of patients developed ESLD (End stage liver disease) with median follow-up of 110 months.

SAT-339

Impact of rifaximin use post-discharge of an overt hepatic encephalopathy (OHE) hospitalization on the annual rates of OHE-related inpatient stays

Arun Jesudian[1], Patrick Gagnon-Sanschagrin[2], Zeev Heimanson[3], Rebecca Bungay[2], Jingyi Chen[4], Annie Guérin[2], Ankur Dashputre[5], Brock Bumpass[5], Danellys Borroto[5], George Joseph[5]. *[1]Weill Cornell Medicine, New York, United States; [2]Analysis Group, Inc., Montreal, Canada; [3]Salix Pharmaceuticals, Bridgewater, United States; [4]Analysis Group, Inc., Boston, United States; [5]Bausch Health Companies Inc., Bridgewater, United States*
Email: brock.bumpass@bauschhealth.com

Background and aims: Overt hepatic encephalopathy (OHE) is a severe neurologic manifestation of cirrhosis, with a wide range of symptoms related to loss of brain function, cognitive impairment, and confusion. Healthcare resource use (HRU) in OHE is substantial, with OHE recurrence as a significant driver. Thus, a key element of OHE treatment is preventing recurrence. Among patients with an initial OHE hospitalization in a real-world setting, literature on the impact of rifaximin use post-discharge on rates of OHE-related inpatient (IP) stays is limited.

Method: Adults (18–64 years) with an OHE index hospitalization were identified from the MarketScan® Commercial claims database (Q4/2015-Q2/2020). Patients were classified into two mutually exclusive cohorts based on treatment following index hospitalization: rifaximin treated (with/without lactulose) and not rifaximin treated. Patients were further classified into four subgroups based on decreasing quality of care (QOC): Type 1 (highest QOC) received rifaximin with no gap in treatment following index hospitalization; Type 2 received rifaximin within 30 days post-discharge; Type 3 received only lactulose within 30 days post-discharge; Type 4 (lowest QOC) received no treatment. The impact of rifaximin use on annual rates of OHE-related IP stays were described and compared by cohort, by QOC subgroup, and by treatment received pre-index hospitalization, accounting for differences in patient characteristics.

Results: At baseline, patients in the rifaximin treated cohort (N = 1,452; Type 1: N = 1,138, Type 2: N = 314) and not rifaximin treated cohort (N = 560; Type 3: N = 337, Type 4: N = 223) had similar demographic characteristics. Specifically, mean age of rifaximin treated and not rifaximin treated patients were 54.2 and 55.2 years, respectively, and 39.3% and 42.7% were female, respectively. Following the index hospitalization, the annual rate of OHE-related IP stays was 59% lower for the rifaximin treated cohort compared to the not rifaximin treated cohort (0.72 vs. 2.04; adjusted incidence rate ratio [IRR] 0.41, $p < 0.01$). Decreasing QOC (from Type 1 to Type 4) after the index hospitalization resulted in higher annual rates of OHE-related IP stays; more specifically, the annual rate for Type 1 was 0.6 whereas it ranged as high as 1.4 for Type 4. Compared to Type 1; the IRRs were 1.61 (Type 2), 2.60 (Type 3), and 2.90 (Type 4) (all $p < 0.01$; Figure). Regardless of whether patients received treatment with rifaximin, lactulose only, or neither prior to the index hospitalization, annual rates of OHE-related IP stays were numerically lower in Type 1 (0.6–0.7) compared to Type 2 (1.1–1.2), Type 3 (1.3–3.7), and Type 4 (1.2–2.6).

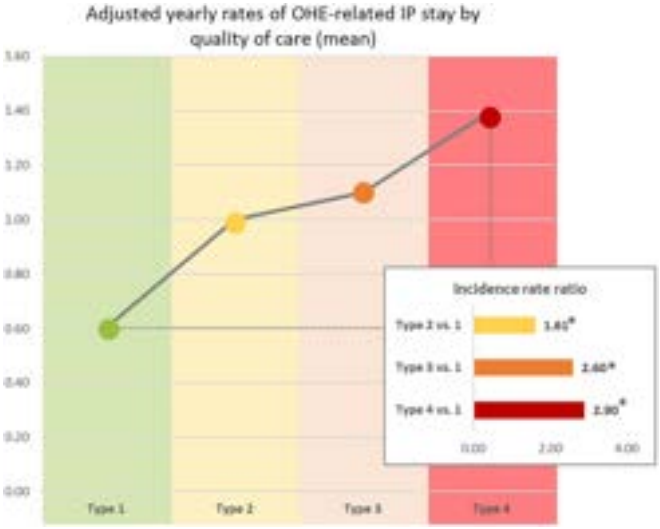

Figure: *Significant at the 5% level Notes: [1] An incident rate ratio greater than 1 indicates that the rate of OHE-related IP stays in patients with Type 2, 3, or 4 care is greater than those of patients with Type 1 care. [2] The four subgroups represent decreasing quality of care and are defined as follows: Type 1 received rifaximin without any gap in treatment following hospitalization; Type 2 received rifaximin within 30 days post-discharge; Type 3 received lactulose within 30 days post-discharge; Type 4 received no treatment.

Conclusion: Patients receiving rifaximin without any gap in treatment following an index OHE hospitalization had lower annual rates of OHE-related IP stays compared with patients who did not receive rifaximin.

SAT-340

MELD-sarcopenia and clinically significant portal hypertension as independent risk factors in the evolution of liver cirrhosis

Elba Llop[1,2,3], Marta Hernández Conde[1,2], Marta López-Gómez[1,2], Christie Perelló[1,2], Carlos Fernández-Carrillo[1,2], Javier Abad[1,2], Jesús Rivera[1,2], José Luis Martínez Porras[1,2], Natalia Fernández Puga[1,2], Maria Trapero[1,2], Enrique Fraga[1], José Luis Calleja Panero[1,2,2,2,3]. *[1]Hospital Universitario Puerta de Hierro Majadahonda, Gastroenterología y Hepatología, Spain; [2]IDIPHISA, Spain; [3]CIBERhd, Spain*
Email: elballop@gmail.com

Background and aims: Clinically significant portal hypertension (CSPH) and MELD-sarcopenia score have been related to the prognosis of liver cirrhosis. Our aim was to evaluate the relationship between both in the evaluation of hepatic decompensation and mortality.

Method: Single-center prospective study that included consecutive patients with liver cirrhosis who underwent baseline laboratory tests, anthropometric and impedance measurements, sarcopenia assessment (by CT scan (SMI <50 cm^2/m^2 in men and <39 cm^2/m^2 in women) or Handgrip (<19.5 kg) and measurement of hepatic venous pressure gradient (HVPG) or Fibroscan® for the evaluation of clinically significant portal hypertension (CSPH;HVPG ≥10 mmHg or Fibroscan®≥25 KPa in the rest). Exclusion criteria were HIV coinfection, hepatocellular carcinoma outside the Milan criteria and TIPS. Hepatitis C had to be cured, hepatitis B controlled with treatment and patients had to demonstrate abstinence of at least 6 months (through AUDIT). Clinical follow-up was carried out until December 2022.

Results: From January 2016 to December 2019, 196 patients were included with a mean follow-up of 47 months (SD 20). Mean age 63 years (SD 10), 67.9% males and predominant HCV etiology 52.6%, CHILD-PUGH A/B/C was 83.2%/5.1%/1.5%. Mean MELD was 9.4 (SD 2.7) and 32.7% had sarcopenia, the mean MELD-sarcopenia was 12.6 (5.1).

46.4% had HPTCS. The presence of sarcopenia showed low correlation with MELD (r = 0.2, p = 0.02). No correlation was found between CSPH and sarcopenia, both in patients with HVPG measurements (n = 60) and in the overall cohort (r = 0.1; p = 0.5, r = 0.05;p = 0.5). During follow-up, 51 (26%) decompensated, 38 (19.4%) died, and 18 (9.3%) underwent liver transplant. Competing risk analysis showed that both CSPH and MELD-sarcopenia were independent predictors of risk of hepatic decompensation during follow-up (SHR 2.2 (CI95 1.2–4.0; p = 0.01); SHR 1.07 (IC95 1.02–1.1; p = 0.01) respectively). Likewise, MELD-sarcopenia was an independent predictor of mortality (SHR 1.1 (95 CI 1.02–1.14); p < 0.01), although CSPH showed a SHR 1.9 (CI95 0.93–3.9, p = 0.07). In the subgroup of CHILD A patients, only CSPH was a predictor of hepatic decompensation (SHR 2.6 (IC95 1.3–5.4; p = 0.03); however, MELD-Sarcopenia obtained a SHR 1.1 (IC95 1–1.12), p = 0.07.
Conclusion: MELD-sarcopenia and CSPH are two independent factors that determine the course of liver cirrhosis. The measurement of both is relevant to know the prognosis of the patient.

SAT-341

Spleen stiffness assessed by point shear-wave elastography predicts portal hypertension better than liver elastography

Vaclav Smid[1], Karel Dvorak[1,2], Barbora Nováková[1,3], Aleš Kuběna[3], Jaromir Petrtyl[1], Radan Bruha[1]. *[1]General University Hospital in Prague, Charles University, 4th Internal Department, Czech Republic; [2]Regional Hospital Liberec, Department of Gastroenterology and Hepatology, Liberec, Czech Republic; [3]General University Hospital in Prague, Charles University, Institute of Medical Biochemistry and Laboratory Diagnostics, Czech Republic*
Email: vaclav.smid@vfn.cz

Background and aims: Severity of portal hypertension is a crucial prognostic factor in patients with liver cirrhosis. The spleen stiffness as compared with liver stiffness might better assess the more advanced stages of portal hypertension. The aim of our study was to assess the usefulness of spleen elastography in the evaluation of portal hypertension in cirrhotic patients and to evaluate the relationship between spleen stiffness measurement and hepatic venous pressure gradient (HVPG).
Method: We examined 138 patients (84 men, 54 women), average age 60.1 ± 12.1 years, with liver cirrhosis (81 ethylic, 15 viral hepatitis, 14 NAFLD, 18 other aetiology). Diagnosis of cirrhosis was confirmed by liver biopsy and/or by ultrasound-based elastography. Every patient underwent standard biochemistry and blood count, abdominal ultrasound and elastography of liver and spleen using point shear-wave elastography (pSWE). HVPG was afterwards measured in every patient.
Results: Clinically significant portal hypertension (HVPG ≥10 mmHg) was diagnosed in 110 patients. The average HVPG was 16.07 ± 7.4 mmHg (median 16.0). The average liver stiffness was 2.7 ± 0.55 m/s (median 2.72), stiffness of the spleen was 3.14 ± 0.47 m/s (median 3.22). HVPG correlated with pSWE liver stiffness measurement (p = 0.001, η^2 = 0.122, “medium effect size”) as well as with pSWE spleen stiffness measurement (p < 0.001, η^2 = 0.219, “large effect size”). However, the liver stiffness correlation worked significantly only for patients with alcoholic liver disease (p < 0.001, η^2 = 0.132, “medium effect size”) but not for a non-alcoholic aetiology (p = 0.248, η^2 = 0.010, “no effect size”). On the contrary, the HVPG correlated with spleen stiffness pSWE measurement independently of aetiology-dependence works for both groups and for both groups statistically in the same way (p < 0.001, η^2 = 0.131, “medium effect size” for an alcoholic aetiology; p = 0.001, η^2 = 0.093, “medium effect size” for a non-alcoholic aetiology). We also analysed our data using a Cox´s regression model (average follow-up period was 43.2 months) and the spleen pSWE emerged as an independent predictor of survival (p = 0.0408, RR = 1.79 per IQr, CI = (1.024, 3.14), whereas liver pSWE did not (p = 0.300).
Conclusion: Spleen stiffness measured using pSWE correlates positively with HVPG independently of aetiology in contrast with liver stiffness. Spleen stiffness also predicts overall survival and may represent a useful additional non-invasive method in the evaluation of portal hypertension in cirrhotic patients. Supported by: MH CZ-DRO-VFN00064165 and KNL VR 180310.

SAT-342

Suppression of the pituitary-adrenal axis in stable outpatients with advanced chronic liver disease increases with disease severity and may be linked to systemic inflammation and bile acids

Lukas Hartl[1,2], Benedikt Simbrunner[1,2,3], Mathias Jachs[1,2], Peter Wolf[4], David Jm Bauer[1,2], Bernhard Scheiner[1,2], Lorenz Balcar[1,2], Georg Semmler[1,2], Michael Schwarz[1], Rodrig Marculescu[5], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2,3]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [3]Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [4]Division of Endocrinology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [5]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Adrenal dysfunction has been described in patients with liver cirrhosis during acute decompensation or infection. Impaired hypothalamus-pituitary signaling may play a role in the adrenal dysfunction of these patients. Mechanistically, elevated bile acid (BA) levels, chronic inflammation and altered cholesterol homeostasis may all impact on adrenal function. We aimed to characterize the pituitary-adrenal axis in a cohort of stable outpatients with advanced chronic liver disease (ACLD).
Method: Consecutive outpatients with ACLD who underwent hepatic venous pressure gradient (HVPG) measurement between June 2018 and March 2020 included in the prospective VICIS (NCT03267615) study were analyzed. Exclusion criteria were HVPG <6 mmHg, occlusive portal vein thrombosis, vascular liver disease, hepatocellular carcinoma, a history of liver transplantation, intake of corticosteroids and evidence of infection at the time of characterization. Patients were stratified into 6 clinical stages: S0: subclinical portal hypertension (PH; HVPG 6–9 mmHg), S1: clinically significant portal hypertension (HVPG ≥10 mmHg) without varices, S2: presence of varices, S3: previous variceal bleeding, S4: previous non-bleeding decompensation and S5: further decompensation.
Results: Overall, 151 patients were included, 61 of which had compensated ACLD (S0: n = 17; S1: n = 15; S2: n = 29), while 90 patients were decompensated (S3: n = 7; S4: n = 50; S5: n = 33). Median levels of ACTH (from S0: 38.0 pg/ml to S5: 20.0 pg/ml; p = 0.001), cortisol binding globulin (from S0: 52.0 µg/ml to S5: 38.9 µg/ml; p < 0.001) and total serum cortisol (t-Cort; from S0: 14.9 µg/dL to S5: 9.2 µg/dL; p = 0.023) decreased with progressive clinical stages. While median levels of free serum cortisol (f-Cort; from S0: 6.6 ng/ml to S5: 5.7 ng/ml; p = 0.379) were non-significantly different across the clinical substages, there was a numerically higher share of patients with particularly low f-Cort levels (i.e. <5.0 ng/ml) with increasing ACLD severity (from S0: 28.6% to S5: 45.5%; p = 0.169). Importantly, there was a significant increase of C-reactive protein (CRP) and BA throughout the clinical substages (see Figure), while no difference in total cholesterol and high-density lipoprotein (HDL) cholesterol was found. Both CRP (ρ = –0.293; p < 0.001) and BA (ρ = –0.186; p = 0.025) negatively correlated with ACTH. In multivariate linear regression analysis, CRP (p = 0.024), but not BA levels (p = 0.859) were independently associated with ACTH (adjusted for HVPG, Child-Pugh score, creatinine and cholesterol).

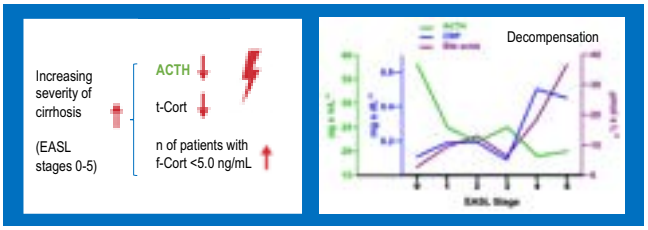

Figure:

Conclusion: With increasing cirrhosis severity, the pituitary-adrenal axis is progressively suppressed in stable outpatients with ACLD. Mechanistically, elevated levels of BA and systemic inflammation in ACLD may explain this clinically relevant suppression of ACTH-cortisol signaling.

SAT-343

Role of non neoplastic portal vein thrombosis in natural history of patients with cirrhosis and hepatocellular carcinoma

Sarah Shalaby[1], Marco Grasso[1], Alessandro Vitale[2], Enrico Pizzirani[3], Alberto Zanetto[1], Paolo Feltracco[4], Paolo Simioni[5], Patrizia Burra[1], Umberto Cillo[2], Marco Senzolo[1]. *[1]Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padova, Italy; [2]Hepatobiliary Surgery and Liver Transplantation Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padova, Italy; [3]Institute of Radiology, Department of Medicine, Padova, Italy; [4]Section of Anesthesiology and Intensive Care, Department of Medicine, Padova, Italy; [5]General Internal Medicine, Hemorrhagic and Thrombotic Diseases Unit, Department of Medicine, Padova, Italy*
Email: sarahshalaby18@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) increases the risk of non-neoplastic portal vein thrombosis (PVT) in cirrhosis. However, data on its natural history and prognostic role in HCC-patients are lacking

Method: Cirrhotic HCC-patients undergoing laparoscopic ablation were consecutively enrolled (2015–2018) and followed until transplantation or up to 36months. HCC and PVT (baseline and incident) characteristics, and their evolution in the first 12months, were reviewed by a single radiologist. PVT evolution was categorized according to changes in occlusion (cut-off 20%) and extension to other segments as: 'complete/progressive': partial-PVT progressing to complete, complete-PVT not improving or, PVT extending to other segments; 'partial/ameliorated': partial-PVT improving or remaining stable, complete-PVT improving. Variables associated with presence of PVT and evolution patterns were analyzed, as well as its impact on survival.

Results: Seven-hundreds-fifty patients were included, 88 with PVT (78.4% partial, 43.2% extended to mesenteric and/or splenic vein). On multivariate analysis, presence of PVT was associated with pre-treatment total-tumor-volume (TTV) (OR1.10, $p < .0001$) and clinically-significant portal hypertension (OR2.90, $p = .0046$). During follow-up, 46 incident PVT occurred, 27/46 (58.7%) in the presence of viable tumor. Among total 115 PVT diagnosed in presence of HCC, 83 had available radiological follow-up (77.1% partial, 41% extended to the mesenteric and/or splenic vein), and 22 were anticoagulated. The 'complete/progressive' evolution pattern was associated with occlusive PVT at diagnosis and absence of anticoagulation in all PVT; whereas to Child C score and non-response to HCC treatment in non-anticoagulated patients. Overall survival was lower in presence of PVT, specifically for 'complete/progressive' PVT [HR3.9, $p < 0.001$]. A higher cumulative risk of death emerged for 'complete/progressive' PVT, both for HCC-related ($p < 0.001$) and non-HCC-related ($p < 0.001$) death.

Conclusion: Non neoplastic PVT in HCC seems to be characterized by a higher risk of progression when not anticoagulated, correlated with the HCC activity. Complete/progressive PVT is an independent factor associated with mortality, regardless of HCC evolution.

SAT-344

To study effect of the combination of midodrine and tolvaptan versus tovalptan alone in patients with severe hyponatremia in cirrhosis-an open label RCT (TOLMINA Trial-NCT05060523)

Srinivasa Reddy Golamari[1,2], Shiv Kumar Sarin[1], Manoj Kumar Sharma[1], Jaya Benjamin[1]. *[1]institute of liver and billiary sciences, hepatology, NEW DELHI, India; [2]Institute of liver and billiary sciences, hepatology, delhi, India*
Email: srinivasareddygolamari@gmail.com

Background and aims: Decreased effective circulating volume secondary to splanchnic vasodilatation plays a central role in the pathogenesis of hyponatremia in patients with cirrhosis Vaptans have shown promise in increasing serum sodium levels in hyponatremia. Vasoconstrictor therapy may improve the diminished effective circulating volume, which in turn would reduce vasopressin release, thereby allowing for more urinary electrolyte-free water excretion. There is no data on combination of vasoconstrictors and tolvaptan till now. Therefore, the current study reports analysis of the efficacy and safety of tolvaptan and midodrine versus tolvapatan alone in patients with cirrhosis and hyponatremia.

Method: Patients [n = 135] with severe chronic hyponatremia (<120 meq/L) who did not respond to albumin infusion [40 gm/day for 48 hours] were randomized to receive Midodrine plus Tolvaptan (n = 70) or Tolvaptan alone (n = 65) for 7 days with a follow-up of 1 month. Tolvaptan was administered as 15–30 mg/d for 7 days and midodrine as 5–15 mg/d to achieve a target Mean Arterial Pressure of –80 mmHg. Primary end point was improvement in serum sodium to 125 mEq/L within 1 week.

Results: 135 patients were included; 85.2% males. Baseline parameters in the two groups were comparable. Grade 3 ascites was seen in 45 (65%) cases in group A and 35 (53%) in group B. There was significant difference in improvement in serum sodium levels from day 1 to day 7 in group A compared to group B ($p = 0.007$). The proportion of patients in group A who improved serum sodium at day 7 was higher, 60/75 (80%) compared to group B 42/65 [$p = 0.001$]. Absolute Change in Serum sodium levels increase at day 5 and 7 was significant in group A $p = 0.001$ ([OR] 4.7021; 95% CI: 3.554–5.432, $p = 0.001$ ([OR] 6.11; 95% CI: 5.238–7.142.5). Urinary sodium excretion significantly increased in both groups after treatment at 7 days as compared to baseline respectively ($p = 0.003$, $p = 0.01$). Absolute change in urine sodium was significantly increased in group A than group B ($p = 0.05$). Plasma renin activity and pro b-type natriuretic peptide (PRO BNP) significantly decreased in both groups at day-7 compared to baseline respectively. ($p = 0.027$, $p = 0.023$). Renal resistivity index significantly decreased in group A at day7 compared to group B ($p = 0.03$). Absolute change in renal resistivity index was also significant in group A than B ($p = 0.027$). Mean arterial pressure (MAP) in group A was higher than group B ($p = 0.004$). Twenty -four -hour urine output was significantly higher in group A than B ($p = 0.03$) when compared to baseline. Mortality was high in group B at 7 and 28 days [$p = 0.005$ ([OR] 6.281; 95% CI: 1.354–29.9, $p = 0.003$ ([OR] 2.121; 95% CI: 0.8–5.5]. Overall adverse events occurred in 30.2% of group A and 24% in group B ($p = 0.39$). Development of acute kidney injury/Hepatic encephalopathy at day 7 and day 28 in group A [16.7%, 12.75%] and B [9.7%, 6%] were not different.

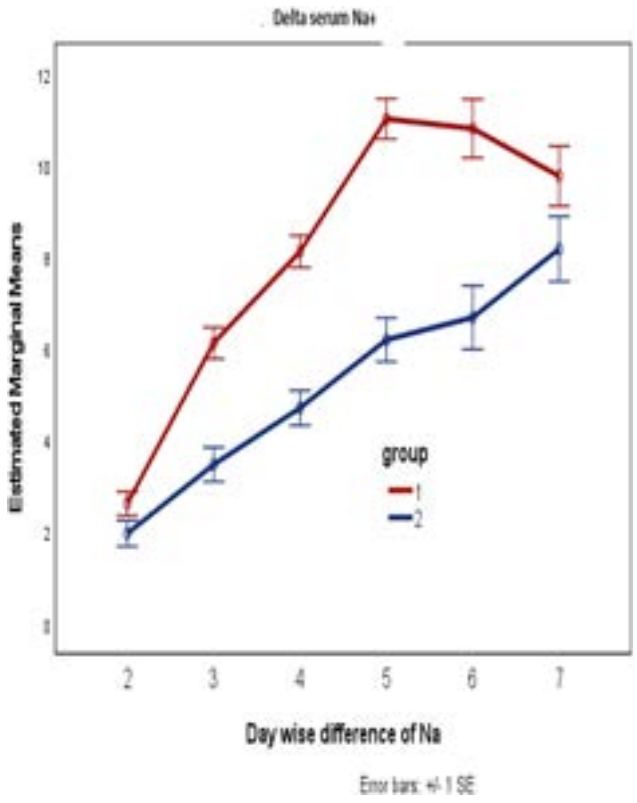

Figure:

Conclusion: Our results clearly demonstrate that combination of tolvapatan and midodrine is superior to Tolvaptan monotherapy in the treatment of severe hyponatremia in cirrhosis patients with ascites.

SAT-345

Bacterial translocation has an early onset in cirrhosis and induces a selective inflammatory response

Benedikt Simbrunner[1], Esther Caparrós[2], Teresa Neuwirth[3], Philipp Schwabl[1], Philipp Königshofer[1], David Jm Bauer[1], Rodrig Marculescu[4], Michael Trauner[1], Bernhard Scheiner[1], Georg Stary[3], Mattias Mandorfer[1], Thomas Reiberger[1,1], Rubén Francés[2]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Austria; [2]CIBEREHD, Instituto de Salud Carlos III, Madrid, Spain, Spain; [3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Austria; [4]Department of Laboratory Medicine, Medical University of Vienna, Austria, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Bacterial translocation (BT) is considered to play an important role in advanced chronic liver disease (ACLD) by promoting systemic inflammation, portal hypertension, and circulatory dysfunction.

Method: Patients with ACLD (n = 249) and absence of acute decompensation or infections undergoing hepatic venous pressure gradient (HVPG) measurement were classified according to EASL stages of compensated and decompensated (c/d) ACLD (cACLD: S0 : HVPG 6–9 mmHg, S1-2 : HVPG ≥10 mmHg/varices; dACLD: S3 : previous variceal bleeding, S4 : one previous non-bleeding decompensation; S5 : 2 or more previous decompensation events). BT biomarkers (lipopolysaccharide, LPS; lipoteichoic acid, LTA; bacterial DNA, bactDNA) and markers of systemic inflammation and circulatory dysfunction were evaluated. Furthermore, T-cell subsets were characterized by flow cytometry in small intestinal biopsies in additional 7 ACLD patients and 4 controls.

Results: The main cohort had a median HVPG of 18 (12–21) mmHg and 56% had dACLD. BT markers were significantly elevated in patients with ACLD compared to healthy controls (n = 40; p < 0.001): The median LPS levels were 0.04 (0.02–0.06) in controls vs. 0.64 (0.30–1.06) EU/ml, LTA 4.53 (3.58–5.97) vs. 43.2 (23.2–109) pg/ml, and bactDNA was detected (≥5 pg/ml) in 5% of controls vs. 41% of patients with ACLD, respectively. Surprisingly, BT markers were similar across the clinical stages of ACLD and not linked to HVPG, systemic hemodynamics, or clinical events during follow-up. LPS was correlated with TNF α and IL-10 (Spearman's r = 0.523, p < 0.001; r = 0.143, p = 0.024). The presence of bactDNA was associated with elevated LPS (0.54, 0.28–0.95, vs. 0.88, 0.32–1.31 EU/ml, p = 0.001) and TNF-α levels (15.3, 6.31–28.1, vs. 20.9, 13.8–32.9, pg/ml). Patients with ACLD displayed a decreased CD4 : CD8-ratio and higher TH1-cells in their intestinal mucosa than liver-healthy controls.

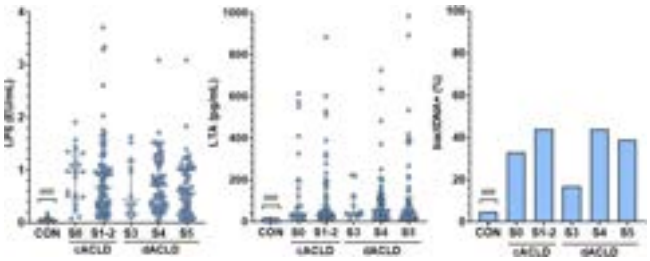

Figure:

Conclusion: BT occurs in early clinical stages of ACLD and linked to a systemic inflammatory response reflected by TNF-α and IL-10. Surprisingly, BT markers were not associated with portal hypertension, circulatory dysfunction, and clinical events in patients with stable ACLD. Changes of the intestinal mucosa immune cell composition may be mechanistically involved in pathological BT of patients with ACLD and should be further investigated by future studies.

SAT-346

Efficacy of long term albumin therapy in treatment of decompensated cirrhosis

Deepanshu Khanna[1,2], Premashis Kar[1], Pabitra Sahu[1]. *[1]Max Super Speciality Hospital, Vaishali, Ghaziabad, India; [2]Max Super Speciality Hospital, Vaishali, Gastroenterology, Ghaziabad, India*
Email: drdeepanshukhanna@gmail.com

Background and aims: Decompensated liver cirrhosis has a poor prognosis, with a median overall survival of 2–4 years, which is worse than for many oncological disorders. These patients are highly susceptible to infections due to increased systemic inflammation leading to kidney failure and death. Aim was to study the efficacy of albumin in reducing episodes of decompensation, preventing bacterial infection, kidney dysfunction and mortality.

Method: Study involved patients with Child B or C cirrhosis with albumin level below 30 g per litre, who were administered 20% human albumin weekly with standard medical treatment for 3 months and compared with age and sex matched controls who received only standard medical treatment. The primary end point was 6 month mortality, and the secondary end points were reduction in infections, kidney dysfunction, ascites recurrence, hepatic encephalopathy, gastrointestinal bleed and complications of cirrhosis.

Results: From September 2021 to January 2023, 88 cases and 86 controls were taken and followed up for 6 months. Overall 6-month survival was not statistically significant between groups (95.1% vs 91.9%; p = 0·330). Incidence of Recurrence of ascites (30.7% v/s 75.6%, P < 0.001), Kidney dysfunction (6.8% v/s 24.4%, P < 0.001) hepatic encephalopathy (18% vs 40%, P < 0.001), Spontaneous bacterial peritonitis (3.4% vs 25.6%, P < 0.001) were significantly less in cases as compared with controls, however infections (8% vs 11.6%, P =

0.603) and Gastrointestinal bleed (14.8% vs 17.4%, P = 0.632) was not statistically significant.

End point	Case	Control	P value
Mortality	4.9%	8.1%	0.330 (NS)
Recurrence of ascites	30.7%	75.6%	<0.001
Refractory ascites	6.8%	16.3%	0.050
Kidney dysfunction	6.8%	24.4%	<0.001
Hepatic encephalopathy	18%	40%	<0.001
Infections	8%	11.6%	0.603 (NS)
SBP	3.4%	25.6%	<0.001
GI Bleed	14.8%	17.4%	0.632 (NS)

NS- Not significant

Conclusion: Long-term Human albumin acts as a disease modifying treatment in patients with decompensated cirrhosis.

SAT-347

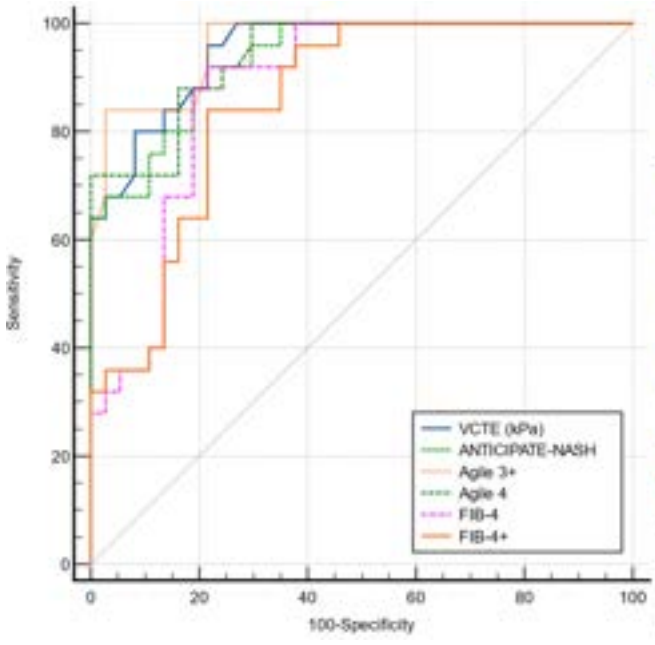
Recently validated non-invasive tests for liver fibrosis assessment have great performance in identifying NASH patients at risk for decompensation

Vlad Taru[1,2,3], Madalina Gabriela Taru[2,4,5], Bobe Petrushev[2], Rusu Ioana[2], Horia Stefanescu[2], Andreea Fodor[2], Mina Dana Ignat[2], Fischer Petra[2], Oana Nicoara-Farcau[1,2], Monica Platon[6,7], Bogdan Procopet[1,2]. *[1]"Iuliu Hatieganu" University of Medicine and Pharmacy, Internal Medicine, Cluj-Napoca, Romania; [2]Regional Institute of Gastroenterology and Hepatology "Octavian Fodor", Hepatology, Cluj-Napoca, Romania; [3]Medical University of Vienna, Medicine III-Division of Gastroenterology and Hepatology, Vienna, Austria; [4]"Iuliu Hatieganu" University of Medicine and Pharmacy, Biochemistry and Molecular Biology, Cluj-Napoca, Romania; [5]University of Bologna, Medical and Surgical Sciences, Bologna, Italy; [6]"Iuliu Hatieganu" University of Medicine and Pharmacy, Medical Imaging, Cluj-Napoca, Romania; [7]Regional Institute of Gastroenterology and Hepatology "Octavian Fodor", Medical Imaging, Cluj-Napoca, Romania*
Email: vlad.taru@lirec.ro

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has become a substantial burden worldwide, with alarmingly increasing prevalence. NAFLD may progress to non-alcoholic steatohepatitis (NASH), NASH-related cirrhosis, and hepatocellular carcinoma. Scientific efforts concentrate on developing non-invasive tests (NITs) to predict clinically significant portal hypertension (CSPH) and reduce the need for invasive, costly investigations. The vibration-controlled transient elastography (VCTE) has become part of many algorithms, including the recent Baveno VII criteria. A new model (ANTICIPATE-NASH) was proposed to identify CSPH in obese patients. Other NITs, such as Agile 3+ and Agile 4, were recently validated for predicting advanced fibrosis and cirrhosis in patients with NAFLD/NASH. Still, their performance in assessing CSPH has not been tested yet. This study aimed to evaluate the performances of Agile3+ and Agile 4 in identifying CSPH in patients with NAFLD/NASH.

Method: Seventy-six consecutive patients with biopsy-proven NAFLD/NASH were included. Hepatic venous pressure gradient (HVPG) was assessed using a 7F-balloon catheter, and a value ≥10 mmHg was considered CSPH. LS was measured by VCTE and fibrosis was assessed histologically using the Metavir scoring system. The statistical analysis was performed in MedCalc v20, using AUROC analysis to assess the performance of NITs and DeLong protocol for comparison of NITs. Differences in classification between NITs were tested using McNemar's test. Continuous variables are expressed as median (interquartile range), and a p value <0.05 was considered statistically significant.

Results: The median HVPG was 7 (4–13) mmHg, and 27 (35.5%) patients had CSPH. The liver histology fibrosis scoring identified 1 (1.3%), 10 (13.2%), 18 (23.7%), 15 (19.7%) respectively 32 (42.1%) patients as F0, F1, F2, F3, respectively F4. The performance of VCTE in identifying CSPH was excellent (AUC = 0.95, 95% CI: 0.86–0.99, p < 0.001). The ANTICIPATE-NASH score had a slightly lower but still excellent performance (AUC = 0.935, 95% CI: 0.84–0.98, p < 0.001). Agile 3+ had the best performance in identifying CSPH (AUC = 0.96, 95% CI: 0.89–9.99, p < 0.001) and was significantly better only compared to FIB-4 (p = 0.04) and FIB-4+ (p = 0.02) The Baveno VII criteria for CSPH had excellent rule-out (Se = 96%, NPV = 96.3%) and rule-in (Sp = 100%, PPV = 100%) performance, with 21 (33.9%) patients left unclassified. Agile 3+ was superior to the Baveno VII criteria in identifying patients with CSPH, with 15 (24.2%) patients still in the "grey zone," and no significant difference in classification (3.17%, CI: –5.59–11.94, p = 0.22).



Performance of NITs in identifying NASH patients with CSPH

Variable	AUC	SE	95% CI
VCTE	0.95	0.0235	0.882 to 0.989
ANTICIPATE-NASH	0.935	0.0281	0.843 to 0.982
Agile 3+	0.961*^	0.0204	0.879 to 0.994
Agile 4	0.941*	0.0266	0.851 to 0.985
FIB-4	0.878	0.0433	0.770 to 0.947
FIB-4+	0.855	0.0464	0.743 to 0.932

*vs FIB-4plus, ^vs FIB-4; p<0.05; other comparisons p>0.05

NITs	Grey zone (n, %total)
BAVENO VII	21 (33.9%)
ANTICIPATE-NASH	19 (30.6%)
Agile 3+	15 (24.2%)
Agile 4	16 (25.8%)

Figure: (abstarct: SAT-347).

Conclusion: Newly developed NITs to assess liver fibrosis in NAFLD/NASH patients, such as Agile 3+ and Agile 4, show good performance in identifying patients with CSPH at risk for decompensation.

SAT-348

Earlier diagnosis of hepatorenal syndrome-acute kidney injury with updated guidelines-review of the Confirm trial

Richard Frederick[1], Florence Wong[2], Hugo Vargas[3], Chris Pappas[4], Khurram Jamil[5]. [1]*California Pacific Medical Center, Department of Transplant, San Francisco, CA, United States;* [2]*University of Toronto, Department of Medicine, Toronto, ON, Canada;* [3]*Mayo Clinic Hospital, Phoenix, AZ, United States;* [4]*Orphan Therapeutics, LLC, Longboat Key, FL, United States;* [5]*Mallinckrodt Pharmaceuticals, Hampton, NJ, United States*
Email: todd.frederick@sutterhealth.org

Background and aims: In 2015, the International Club of Ascites (ICA) published revised consensus recommendations for the diagnosis of acute kidney injury (AKI) and hepatorenal syndrome (HRS) based on a change in serum creatinine (SCr) rather than a required threshold of SCr of 2.5 mg/dL in patients with cirrhosis, to facilitate earlier treatment of HRS Type 1 (HRS-1). Patients receiving vasoconstrictor-based treatment for HRS-AKI respond better and have higher rates of HRS reversal if treatment is started at lower SCr. This study estimated the effect of using the updated ICA-AKI diagnostic criteria on diagnosis and timing of HRS treatment in patients who were enrolled in CONFIRM-a large, prospective, randomized (terlipressin vs placebo) clinical trial.
Method: 2015 HRS-AKI criteria were retrospectively applied to available individual patient's pre-enrollment serial SCr data from CONFIRM. The number of days between meeting current ICA HRS-AKI criteria (for both Stage 1b and Stage 2) and old HRS-1 criteria were determined to estimate the impact of the new criteria on potential earlier treatment. In addition, SCr at HRS-AKI diagnosis using the ICA 2015 criteria was compared to SCr at diagnosis of HRS-1 using the 2007 diagnostic criteria to estimate the effect of the new criteria on SCr at the potential start of vasoconstrictor therapy.
Results: Of 300 patients included in CONFIRM, 297 and 215 subjects had data available for this analysis (Stage 1b and 2, respectively). Compared with the traditional diagnostic criteria used for CONFIRM: the diagnosis of HRS-AKI could be made a median of 4 and 2 days earlier for Stage 1b and Stage 2, respectively; and the absolute median SCr was 1.0 mg/dL and 0.4 mg/dL lower at the time of diagnosis of AKI-HRS Stage 1b and 2, respectively (Figure).

HRS-1 vs HRS-AKI criteria*	Stage 1b (n = 297)	Stage 2 (n = 215)	*P* value*
Change in median time to diagnosis	4 days	2 days	<.0001
Change in median SCr at diagnosis	1.0 mg/dL	0.4 mg/dL	<.0001

*T-test for the change between the 2 diagnostic criteria.

Conclusion: Applying the new 2015 ICA AKI-based criteria for HRS-AKI is estimated to result in earlier diagnosis and treatment of patients by approximately 2–4 days, depending on use of Stage 1b or 2. The SCr at initiation of treatment would be 0.4–1.0 mg/dL lower with use of the updated criteria. Using the new ICA HRS-AKI diagnostic criteria will allow for earlier treatment at lower SCr and the potential for better clinical outcomes.

SAT-349

Predicting esophageal varices and varices needing treatment in patients with compensated advanced chronic liver disease using Baveno VI Criteria, CHESS-ALARM score, FIB-4 score, and recently proposed FIB-5 score

Fares Mashal[1], Nimy John[1,2], Shakshi Sharma[3], Mauricio Garcia Saenz De Sicilia[1], Abhilash Perisetti[4], Ragesh Babu Thandassery[1]. [1]*University of Arkansas for Medical Sciences, Medicine, Division of Gastroenterology, Little Rock, United States;* [2]*UCLA David Geffen School of Medicine, Medicine, Division of Digestive Diseases/Gastroenterology, Los Angeles, United States;* [3]*University of Arkansas for Medical Sciences, Institute of Aging, Little Rock, United States;* [4]*Veteran Affairs Medical Center, Medicine, Division of Gastroenterology, Kansas City, United States*
Email: doc.ragesh@gmail.com

Background and aims: FIB-5 score (FIB-4 and Liver Stiffness, Fibrosis-5 Risk Prediction (fib5.net)) was proposed recently to predict complications of portal hypertension in a US Veteran Cohort. We aim to validate the FIB-5 score in general population with compensated advanced chronic liver disease (cACLD) and compare it with other non-invasive scores for predicting the presence of esophageal varices (EV) and varices needing treatment (VNT).
Method: We studied Baveno VI criteria (BC = liver stiffness >20 kPa and platelet count <150 × 109cells/L), expanded BC (liver stiffness >25 kPa and platelet count <110 × 109cells/L), CHESS-ALARM score (Model = 0.033 × Age-0.598 × Male-0.018 × Platelet+0.032 × liver stiffness), aspartate transaminase platelet count ratio (APRI), FIB-4 score and FIB-5 score in predicting presence of EV and varices needing treatment (VNT), in a cohort of patients with clinical cACLD, in Mid-West United States (Jan 2015-Dec 2021).
Results: 424 patients were studied, mean age 59.2 ± 12.5 years, 57.3% females, 78.3% Caucasian and 14.9% African American. Most common causes of cACLD were non-alcohol associated fatty liver disease (NAFLD, 55.3%), chronic hepatitis C (32.7%) and alcohol (23.1%). EV were present in 126 (29.7%) and VNT in 32 (7.5%). 221 patients (52%) met BC, and 173 (40.7%) met expanded BC.
Among patients with EV seen on EGD, 87.7% met BC, and 77.4% met expanded BC. Of all patients who had VNT (n = 32), 85.7% met expanded BC. BC ($p < 0.001$), expanded BC ($p < 0.001$), CHESS-ALARM score ($p < 0.001$, at cut off >0.37) and FIB-5 score ($p < 0.001$, at cut off >0.75) independently correlated with presence of EV on logistic regression analysis.
The predictive accuracy (AUROC) for EV on EGD was highest for FIB-5 score (0.88, CI = 0.83 to 0.94), followed by CHESS-ALARM score (0.82, CI = 0.76 to 0.86), FIB-4 (0.80, CI = 0.76 to 0.85), APRI (0.76, CI = 0.72 to 0.81), and the lowest for MELD-Na (0.66, CI = 0.60 to 0.72). FIB-5 score at 0.75 had a sensitivity of 73% and specificity of 80% to predict EV. Similarly, the AUROC for predicting VNT on EGD was highest for FIB-5 score (0.85, CI = 0.81 to 0.88), followed by CHESS-ALARM score (0.79, CI = 0.72 to 0.86), FIB-4 (0.78, CI = 0.72 to 0.85), APRI (0.73, CI = 0.66 to 0.81), and the lowest for MELD-Na (0.66, CI = 0.58 to 0.74). FIB-5 score at 1.5 had sensitivity of 81% and specificity of 80% to predict VNT.
Conclusion: Newly proposed FIB-5 score has higher predictive accuracy than most other non-invasive scores for identifying EV and VNT in patients with cACLD. We validate the accuracy of FIB-5 score in predicting EV and VNT in a general (non-veteran) population with cACLD (predominantly from NAFLD).

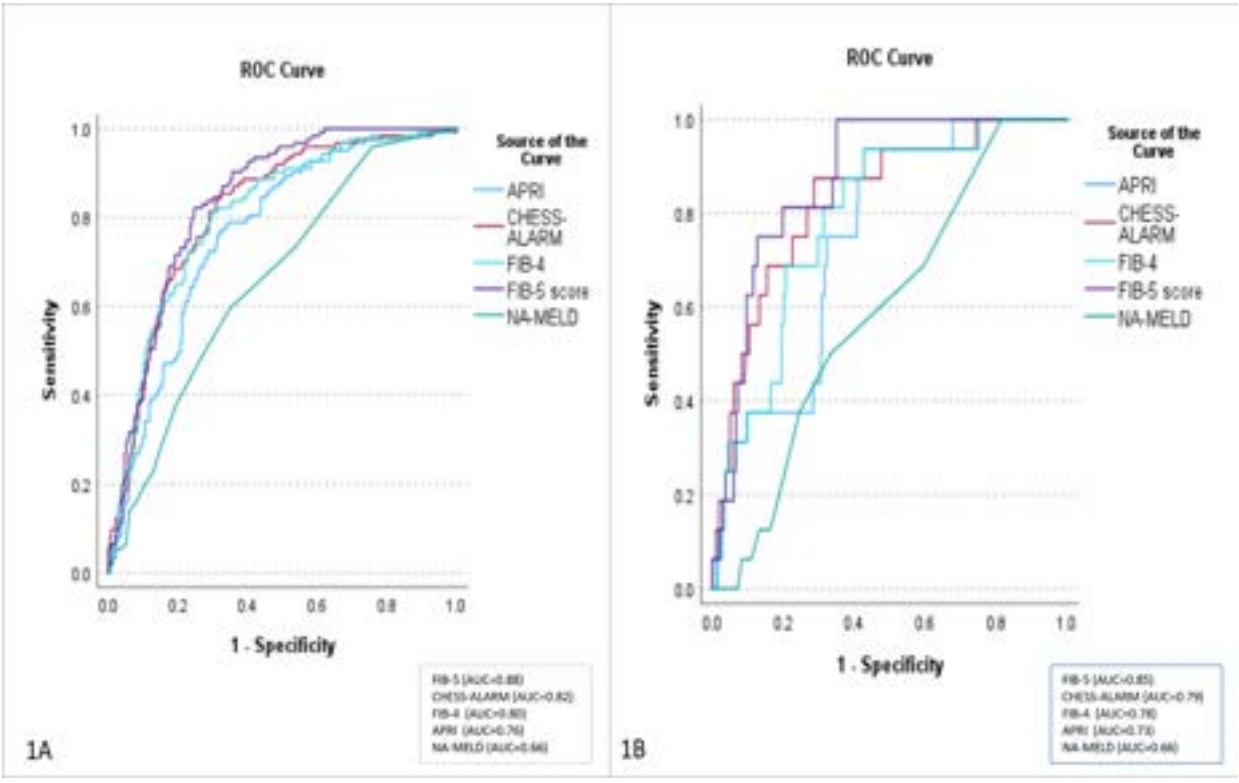


Figure: (abstarct: SAT-349): Comparison of non-invasive scores for predicting esophageal varices and varices needing treatment.

SAT-350

Hepatic venous pressure gradient predicts further decompensation in cirrhosis patients with acute esophageal variceal bleeding

Manas Vaishnav[1], Sagnik Biswas[1], Shekhar Swaroop[1], Arnav Aggarwal[1], Piyush Pathak[1], Abhinav Anand[1], Shalimar[1]. [1]*All India Institute of Medical Sciences, New Delhi, India*
Email: drshalimar@yahoo.com

Background and aims: Portal hypertension is the major driver in the transition from compensated to decompensated cirrhosis. However, the role of hepatic venous pressure gradient (HVPG) in predicting further decompensation in cirrhosis decompensated with acute variceal bleeding (AVB) is not known. We aimed to evaluate the role of HVPG in predicting the risk of further decompensation in cirrhosis patients with AVB.

Method: In a prospective study, 190 patients with cirrhosis with esophageal (n = 103) or gastric AVB (n = 87) were included. HVPG was measured on the day of the AVB, within 8 hours of endotherapy. Decompensating events occurring after 42-day of AVB were considered further decompensation. Multivariate analysis was performed to assess factors associated with further decompensation.

Results: The median age of the study cohort was 45 years with 81.6% male. The predominant etiology of cirrhosis was alcohol in 82 (43.2%), chronic hepatitis B in 27 (14.2%), and chronic hepatitis C in 18 (9.5%). Overall, 53 (27.9%) patients developed further decompensation during a median follow-up duration of 274 days following AVB. New-onset/worsening ascites and GI bleeding were the most common decompensating event in 30 (15.8%). On the multivariate model, HVPG was an independent predictor of any further decompensation in esophageal AVB patients but not in gastric variceal bleeding patients. HVPG cut-off of ≥16 mmHg predicted further decompensation in the esophageal AVB cohort with a sensitivity and specificity of 66.7% and 57.5% respectively. Patients with HVPG ≥16 mmHg compared to <16 mmHg had higher cumulative probability of further decompensation: GI bleed (log-rank p = 0.013) and new-onset/worsening ascites (log-rank p = 0.023). There were no differences in hepatic encephalopathy and jaundice (Figure 1). However, HVPG was not an independent predictor of mortality in the entire, esophageal or gastric AVB cohorts.

Conclusion: HVPG measured during an episode of acute variceal hemorrhage from esophageal varices predicts further decompensating events in patients with liver cirrhosis. For patients with gastric varices, no similar relationship with HVPG could be established. Further studies, including a dynamic evaluation of HVPG in relation to impending decompensation, would shed more light on this matter.

SAT-519

Ultrasound predictors of hemodynamic TIPS dysfunction: friends or foes?

Andreea Fodor[1], Rares Craciun[1], Oana Nicoara-Farcau[1], Fischer Petra[1], Mina Ignat[1], Ionel-Andrei Motofelea[1], Roxana Buda[2], Corina Radu[1], Zeno Sparchez[1], Horia Stefanescu[3], Bogdan Procopet[1]. [1]*"Prof Dr Octavian Fodor" Regional Institute of Gastroenterology and Hepatology, Romania;* [2]*"Iuliu Hatieganu" University of Medicine and Pharmacy, Romania;* [3]*Regional Institute of Gastroenterology and Hepatology, Liver Unit and Clinical Ultrasound Department, Cluj Napoca, Romania*
Email: andreea.fodor11@gmail.com

Background and aims: Although the role of non-invasive tools, namely ultrasound (US) parameters, in the assessment of transjugular intrahepatic portosystemic shunt (TIPS) dysfunction has widely been studied, there is insufficient data regarding clear criteria applicable in current practice.

We primary aimed at evaluating the performance of US parameters for detection of hemodynamic TIPS dysfunction, in the absence of clinical symptoms suggestive for dysfunction. Secondly, we assessed the role of spleen and liver stiffness measured by 2D share wave elastography (2D SWE) and Fibroscan in predicting hemodynamic dysfunction (HD).

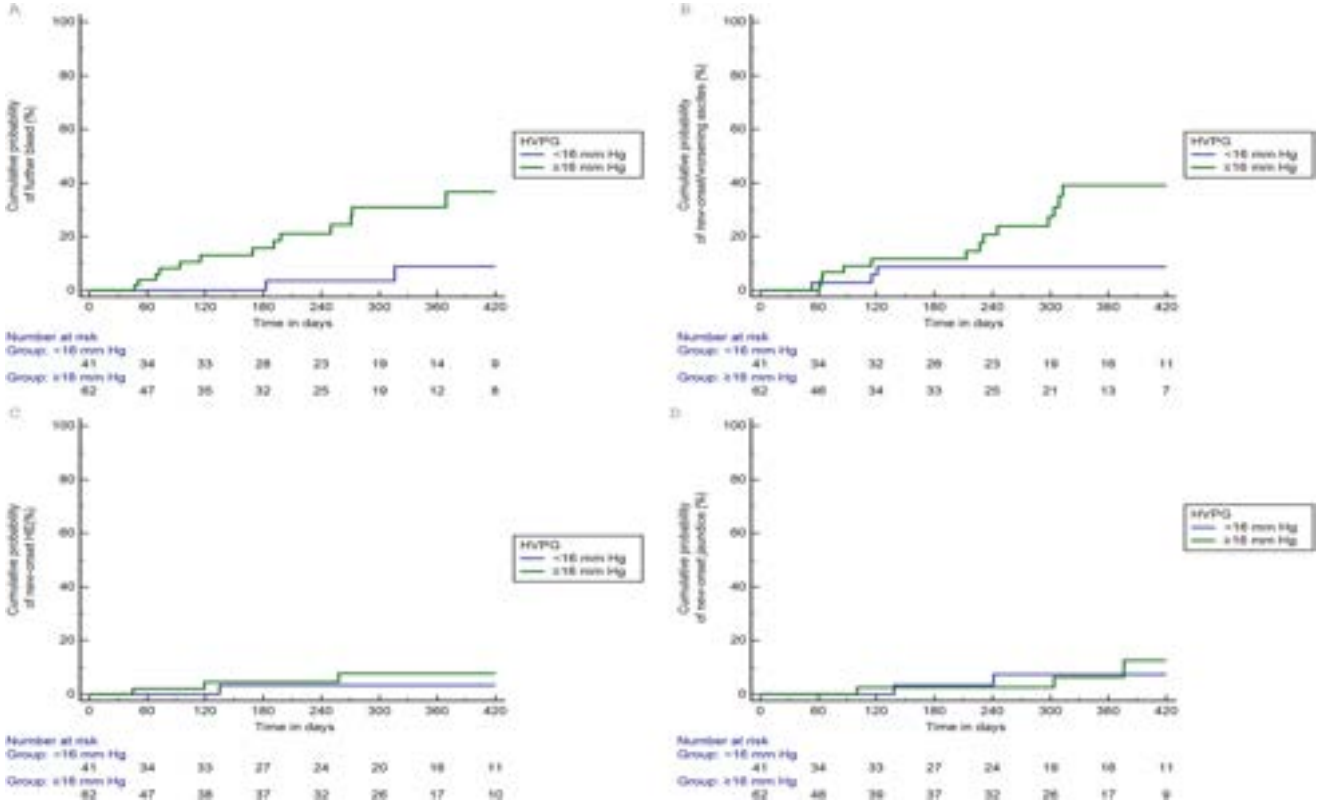

Figure 1: (abstract: SAT-350): Cumulative probability of individual further decompensation in esophageal AVB group based on HVPG: (a) GI bleeding (log-rank p = 0.013), (b) Ascites (log-rank p = 0.023), (c) HE (log-rank p = 0.217), (d) jaundice (log-rank p = 0.812).

Method: All consecutive patients treated with TIPS for portal hypertension-related complications and systematic hemodynamic TIPS revision at 6 weeks after the procedure have been included. Clinical dysfunction was defined as recurrence of variceal bleeding or inadequate control of ascites, whereas HD was defined as revision portal pressure gradient (PPG) ≥12 mmHg. Subgroup analysis was performed on available elastography measurements (initial and at revision) of spleen (delta SSM) and liver (delta LSM).

Results: 86 eligible patients with paired US parameters at TIPS placement and first TIPS revision were analyzed. Recurrent variceal bleeding was the main indication for TIPS placement (82.5%), while 17.5% had refractory ascites. 6 weeks clinical dysfunction rate was 18.6%. Two patients presented with recurrence of PHT-related bleeding and 14 had no clinical improvement of ascites. Median initial and post-TIPS PPG were 16 mmHg (14–19) and 7 mmHg (5.5–8), respectively. A decrease higher than 50% in PPG was achieved in 74.4% of cases. Median 6 weeks systematic PPG was 10 mmHg (7–14). HD occurred in 37 cases (43%). Portal vein velocity had an AUROC of 0.71 for a cut-off of 40.5 cm/s ($p < 0.001$) in detecting HD, with a sensitivity of 0.84 and specificity of 0.50. In subgroup analysis (n = 30), the percentage change in delta 2D SWE SSM predicted HD with a modest AUROC of 0.77 for a cut-off of 40% ($p = 0.03$). However, percentage change in delta LSM in both 2D SWE and Fibroscan, exhibited low performance in discriminating HD (see Figure).

non-invasive marker (cut-off, %)	AUROC	accuracy (%, 95% CI)	p
delta 2D SWE SSM (40%)	0.77 (0.59 – 0.95)	79.0 (60.3 – 91.6)	0.03
delta Fibroscan SSM (40%)	0.58 (0.40 – 0.77)	76.3 (59.7 – 88.5)	0.38
delta 2D SWE LSM (30%)	0.47 (0.26 – 0.69)	59.2 (39.8 – 76.7)	0.83
delta Fibroscan LSM (30%)	0.59 (0.43 – 0.76)	80.4 (66.1 – 90.6)	0.27

Figure:

Conclusion: Doppler US and elastography surveillance cannot replace systematic TIPS revision for diagnosing hemodynamic TIPS dysfunction.

SAT-520

Efficacy of Simvastatin plus non-selective beta blocker in improving survival of cirrhotic patients with variceal bleed: a systematic review and meta analysis

Jemimah Andrea Fajardo[1], Gian Paulo Alberto Soliman[1], Sarah Jean Bellido[1]. [1]*St. Luke's Medical Center Quezon City, Medicine, Quezon City, Philippines*
Email: jemimahpfajardo@gmail.com

Background and aims: Around 60% of patients with decompensated liver cirrhosis have esophageal varices with a high propensity to bleed which is the major cause of death in these patients. Pharmacological treatment in addition to endoscopic intervention has been documented to prevent variceal bleeding. Initial studies exploring the addition of simvastatin, a readily accessible and safe medication, to beta blockers in cirrhotic patients with index variceal bleeding have shown potential benefits in terms of liver generation of

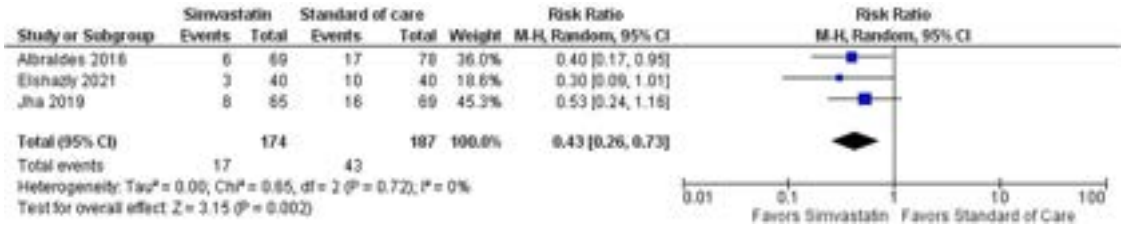

Figure 1: (abstract: SAT-520): Forrest plot on Simvastatin plus non selective beta blocker versus non selective beta blocker alone for survival.

nitric oxide and hepatic endothelial dysfunction. We therefore assessed the efficacy of simvastatin with a non-selective beta blocker in improving survival for cirrhotic patients with variceal bleed through a systematic review and meta-analysis.

Method: A comprehensive systematic search through Pubmed, Cochrane and Google scholar was performed to include clinical studies that examined the use of statin with a beta blocker in improving survival in cirrhotic patients. Two reviewers independently screened and reviewed all abstracts and full text papers available. An inclusion and exclusion criteria was made which was a basis for selection of included studies. The Cochrane Risk of Bias tool was used to assess possible bias in each article. Data was analyzed using RevMan 5.4 and GRADEPro. The dichotomous outcomes were analyzed using relative risk with a confidence interval of 95% and the primary outcome pertained to improvement in survival, with a secondary outcome of rebleeding also noted.

Results: The study included 3 randomized control trials with 361 patients with variceal bleeding. There was significant survival benefit among patients given simvastatin therapy with a risk ratio of 0.43 (95% confidence interval 0.26–0.73; p value (probability value) = 0.002). A secondary outcome of rebleeding was also studied and showed a trend towards benefit with a risk ratio of 0.72. However, the results were not statistically significant (95% confidence interval; 0.47–1.09; p value = 0.12).

Conclusion: Among cirrhotic patients with variceal bleeding, the addition of simvastatin provides a significant benefit in survival, but not in rebleeding. However, there remains a need for larger studies with more participants to strengthen this evidence, and a deeper look into its safety profile in cirrhotic patients specifically.

SAT-521

Validation and refinement of the Baveno VII criteria for risk stratification in compensated advanced chronic liver disease after HCV-cure

Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Baveno VII has established criteria for excluding clinically significant portal hypertension (CSPH) after HCV-cure in compensated advanced chronic liver disease (cACLD), and thus, identifying patients who may be discharged from portal hypertension surveillance (post-treatment liver stiffness measurement (LSM) <12kPa and platelet count (PLT) >150G/L). In contrast, post-treatment LSM values ≥25kPa indicate CSPH and a substantial risk of hepatic decompensation, despite HCV-cure.

However, the long-term prognostic value of these criteria has yet to be independently validated and determinants of decompensation in the gray zone (i.e., in patients meeting none of these criteria) have yet to be identified.

Method: We retrospectively analyzed cACLD patients with paired LSM and PLT before and after HCV-cure by interferon-free therapies from 7 European regions. Fine and Gray competing risk regression models adjusted for clustered data with respective cumulative incidence curves were used to study risk of hepatic decompensation across risk strata. Factors associated with hepatic decompensation in the gray zone were studied using backward elimination. Development of hepatocellular carcinoma and death were considered as competing risks.

Results: 2347 cACLD patients (mean age 60 ± 12 years, 60% male, 21% obese, and 21% diabetes) were followed for a median of 6.0 years during which 65 patients (2.8%) developed hepatic decompensation. In the subgroup of patients who have not been analyzed previously (n = 1527), Baveno VII criteria for excluding CSPH identified patients at a negligible risk of decompensation (at 6 years: 0.5%), while those for ruling-in CSPH identified a high-risk population (at 6 years: 11.4%; Figure-panel A). In the overall study population, decompensation in gray zone patients was uncommon (2.0%, incidence rate 0.4/100 patient years) and was associated with diabetes (adjusted subdistribution hazard ratio (SHR): 2.61 (95%CI: 1.70–4.00), p < 0.001) and post-treatment γ-glutamyltransferase (γ-GT; SHR: 1.38 (95%CI: 1.11–1.73), p = 0.003) independently of LSM, PLT, and albumin. Diabetes or elevated γ-GT identified a subset of gray zone patients (39%) at higher risk (at 6 years: 3.6%; Figure-panel B).

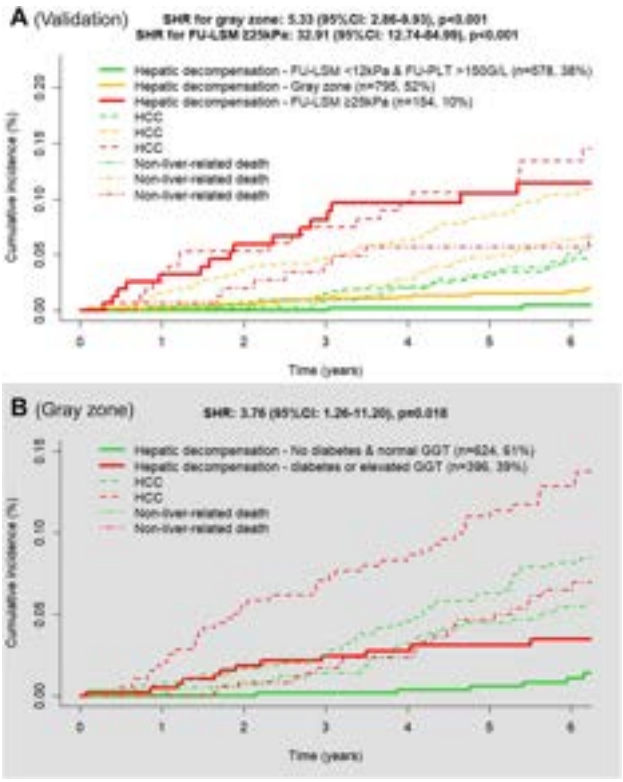

Figure:

Conclusion: Baveno VII criteria for excluding/ruling-in CSPH in HCV-cured patients accurately stratify decompensation risk and may guide patient management. The increased risk of hepatic decompensation in gray zone patients with diabetes and/or elevated γ-GT highlights the importance of managing cofactors. Notably, gray zone patients without diabetes and with normal γ-GT had a negligible risk of hepatic decompensation, despite LSM values of 12–25 kPa and/or thrombocytopenia.

Real-world practice of pre-emptive tipps: an Asia perspective based on Singapore nationwide variceal bleeding audit

Yu Jun Wong[1,2], Margaret Teng[3], Alyssa Sim[4], Marianne De Roza[5], Junhui, Garrett Kang[6], Guan Sen Kew[3], Jia Hong Koh[3], Jonathan Kuang[4], Htay Myat Thet[7], En Xian Sarah Low[7], Pooi Ling Loi[8], Kai Lim[8], Xuhui Teoh[9], Jing Liang Ho[10], Gabriel Cher[9], Kenny Sze[9], Andrew Kwek[1], Guan Wee Wong[11], Wei Lyn Yang[4], Jason Pik, Eu Chang[8]. *[1]Changi General Hospital, Gastroenterology and Hepatology, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore; [3]National University Hospital (NUH)-Singapore, Singapore, Singapore; [4]Tan Tock Seng Hospital, Singapore, Singapore; [5]Sengkang General Hospital, Singapore, Singapore; [6]Changi General Hospital, Singapore, Singapore; [7]Ng Teng Fong General Hospital, Singapore, Singapore; [8]Singapore General Hospital, Gastroenterology and Hepatology, Singapore, Singapore; [9]Khoo Teck Puat Hospital/Dental Department, Gastroenterology and Hepatology, Singapore, Singapore; [10]Woodlands Hospital, Singapore, Gastroenterology and Hepatology, Singapore; [11]Ng Teng Fong General Hospital, Gastroenterology and Hepatology, Singapore, Singapore*
Email: wongyujun1985@gmail.com

Background and aims: The Baveno-VII consensus recommends pre-emptive transjugular intrahepatic portosystemic shunt (pTIPSS) in acute variceal bleeding (AVB) patients with high-risk of rebleeding, ie: *Child-Turcott-Pugh (CTP) class C < 14, or CTP class B > 7 with active bleeding*. Data on the real-world adoption and practice on pTIPSS remains limited, particularly from Asia. To understand the real-world practice on pTIPSS, we aimed to determine: (1) the proportion of patients eligible for pTIPSS, (2) the proportion of patients who underwent pTIPSS based on a Singapore nationwide AVB audit.

Method: We performed a nationwide audit to retrospectively review all adult cirrhosis patients consecutively admitted for AVB from January 2015 to December 2020. Individual patient data on baseline characteristics and clinical outcomes were reviewed and extracted using unified data frame. Eligibility for pTIPSS was based on Baveno-VII consensus; implementation of pTIPSS was based on institutional protocol. We compare the clinical outcomes (5-day rebleeding, 6-week mortality and 1-year mortality) between (1) patients eligible for pTIPSS (vs not eligible), and (2) patients who were eligible and underwent pTIPSS (vs. eligible but no pTIPSS).

Results: This nationwide acute variceal bleeding audit included 910 adult cirrhosis patients with AVB from all 7 public hospitals in Singapore. The mean age was 61 years, 73.7% were male, with ethnicity distribution similar to the general Singapore population. The mean (± SD) MELD score was 13 (± 6). The mean CTP score was 7 (± 1.3), among which 42.2% were CTP-A, 52.1% were CTP-B and 5.7% were CTP-C. At baseline, 18.0% had prior variceal bleeding, 28.7% had ascites requiring diuretics, 34.5% had prior HE, 23.7% had HCC and 18.9% had PVT. Among 14.3% of hospitalized AVB patients who fulfil the eligibility for pTIPSS, only 1.8% underwent pTIPSS. Patients eligible for pTIPSS (vs. not eligible for pTIPSS) had a significantly shorted median (IQR) time to rebleeding [4 (1–15) days vs. 18 (2–111) days, p = 0.025], a higher risk of early rebleeding (19% vs 6%, p < 0.0001) and death at 6 weeks (30% vs 11%, p < 0.0001) and 1 year (45% vs 25%, p < 0.0001), respectively. Yet, only 44% of pTIPSS were performed within 72 hours of AVB. Low uptake of pTIPSS were similar between transplant and non-transplant centers (6.8% vs 3.5%, p = .357). Patients who underwent pTIPSS were more likely to have prior AVB (69% vs 18%, p < 0.001), lower baseline MELD score (11.6 vs 13.5, p = 0.02), lower serum bilirubin (25 vs 41, p < 0.001) and lower AST (47 vs 87, p < 0.001). pTIPSS patients were more likely to be intubated (63% vs 37%, p = 0.025), had early endoscopy <12 hours (100% vs 80.2%, p = 0.03), and had active bleeding during endoscopy (50% vs 17.8%, p = 0.003).

Among patients eligible for pTIPSS, those who underwent pTIPSS (vs. no pTIPSS) had a lower risk of 6-week mortality (17% vs 30%), but a higher risk of HE at 1-year (67% vs 21%, p < 0.001), with a similar risk of early rebleeding within 5 days (17% vs 19%) and 1-year mortality (50% vs 44%).

Conclusion: The Singapore nationwide AVB audit showed that one in seven hospitalized AVB patients were eligible for pTIPSS, but only 1.8% underwent pTIPSS. Future work is needed to identify the barrier for timely pTIPSS implementation among high-risk AVB patients.

SAT-524

Sequential BAVENO VI plus dedicated spleen stiffness measurement or a novel spleen-centered algorithm significantly enlarges non-invasive ruling out of high risk varices: results from an international derivation-validation cohort study

Emma Vanderschueren[1,2], Angelo Armandi[3,4], Wilhelmus Kwanten[5,6], Luisa Vonghia[5,6], Merle Marie Werner[3], Talal Merizian[3], Georg Semmler[7], Thomas Reiberger[7], Thomas Vanwolleghem[5,6], David Cassiman[1,2], Sven Francque[5,6], Jörn Schattenberg[3], Wim Laleman[1,2,8]. *[1]University Hospital Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium; [2]Catholic University of Leuven, Department of Chronic Diseases, Metabolism and Aging (CHROMETA), Leuven, Belgium; [3]University Medical Center of the Johannes Gutenberg University, Metabolic Liver Disease Research Program, I. Background and aims: The BAVENO VI criteria, combining liver stiffness measurement (LSM <20 kPa) and platelet count (>150 × 10^9/L), have set the stage for non-invasive assessment of patients with compensated advanced chronic liver disease (cACLD) who can safely avoid screening endoscopy at the cost of <5% missed varices needing treatment (VNTs). Attempts to expand these two parameters (expanded BAVENO VI) to save a higher proportion of endoscopies resulted in a relevant loss of negative predictive value. For this reason, we aimed to evaluate the potential additive value of spleen stiffness measurement (SSM) using spleen-dedicated vibration-controlled transient elastography (FibroScan® Expert 630, EchoSens) and in addition, to test a novel spleen-centered algorithm combining spleen size and SSM.
Method: We first analyzed in a single-center fashion (Leuven) all consecutive patients with ACLD (LSM ≥10 kPa) from 2020 till 2022 undergoing LSM/SSM and had available reports on upper endoscopy, abdominal ultrasound (spleen size, i.e. craniocaudal diameter) and platelet count. VNTs were defined as grade II or III esophageal varices or varices of any size with red spots. Different models were built in this derivation cohort (see Figure 1). Subsequently, these were tested in an external validation cohort (Mainz, Antwerp) with a higher prevalence of VNTs as this was the downfall of the expanded BAVENO VI criteria.
Results: The derivation cohort included 201 patients (123 men, mean age 58 years, 85.1% Child A-14.9% Child B). Overall prevalence of VNTs was 11.9% (comparable to the ANTICIPATE study). In the derivation cohort, BAVENO VI criteria could spare 33.8% of screening endoscopies which could be doubled to 66.2% by applying sequential BAVENO VI/SSM-criteria (using a SSM cut-off at 43kPa) (Figure 1). A newly developed simple 'spleen size and stiffness' algorithm could save even more patients (71%) from undergoing endoscopy. All applied algorithms missed less than 5% of VNT.
The validation cohort included 176 patients (104 men, mean age 58 years, 70.4% Child A-29.6% Child B). The prevalence of VNTs amounted to 34.7%. Applying the BAVENO VI criteria in this cohort spared a lower amount of screening endoscopies (8.5%). Adding SSM tripled the gain to 27%. The 'spleen stiffness and size' model equally avoided 31% of screening endoscopies, all at the cost of less than 5% of VNT being missed.
Conclusion: The sequential BAVENO VI plus dedicated SSM (<43 kPa) or the more simplified spleen-centred algorithm (size and stiffness) can safely and more extensively "rule out" VNT than the BAVENO VI criteria alone.

SAT-525
Detection of candida species in hospitalized patients with decompensated liver cirrhosis and ascites indicates an unfavorable clinical course and outcome

Marie Griemsmann[1], Tammo Lambert Tergast[1], Michael P. Manns[1], Heiner Wedemeyer[1], Markus Cornberg[1], Benjamin Maasoumy[1].
[1]Medical School Hannover, Germany
Email: griemsmann.marie@mh-hannover.de

Background and aims: Long hospital stays, invasive procedures and antibiotic treatment are major risk factors for fungal colonisation in patients with decompensated liver cirrhosis. However, the general impact of fungal colonisation on outcome and clinical course in patients with decompensated liver cirrhosis has not been investigated, so far. Therefore, we aimed to evaluate the predictive value of the detection of candida species for the further clinical outcome in patients with decompensated liver cirrhosis.

	BAVENO VI criteria	BAVENO VI + SSM	spleen size and stiffness model
			DERIVATION COHORT (n = 201, 11.9% VNTs)			
spared endoscopies	33.8 %	66.2 %	71.1 %
missed VNT	0 %	4.2 %	4.2 %
sensitivity	100 %	95.8 %	95.8 %
specificity	38.4 %	74.6 %	80.2 %
PPV	18.0 %	33.8 %	39.7 %
NPV	100 %	99.2 %	99.3 %
VALIDATION COHORT (n = 176, 34.7% VNTs)			
spared endoscopies	8.5 %	27.3 %	31.3%
missed VNT	0 %	3.3%	4.9%
sensitivity	100 %	96.7 %	95.1 %
specificity	13.0 %	40.0 %	45.2 %
PPV	37.9 %	46.1 %	47.9 %
NPV	100 %	95.8 %	94.5 %

Figure 1. Performance of non-invasive models in the decision for screening endoscopy.
EGD = esophagogastroduodenoscopy, LSM = liver stiffness measurement, NPV = negative predictive value, PPV = positive predictive value, SSM = spleen stiffness measurement, VNT = varices needing treatment

Figure: (abstract: SAT-524).

Method: Overall, 1314 patients, in whom a paracentesis was performed in Hannover Medical School between 2012 and 2018, were retrospectively screened for liver cirrhosis and ascites. After applying in- and exclusion criteria, 667 consecutive patients of the Hannover Ascites Cohort were eligible for further analysis. Patients were followed up for incidence of acute kidney injury (AKI), acute-on-chronic liver failure (ACLF) and death. Multivariate competing risk analysis was performed to adjust for potential confounders (e. g. the MELD score).
Results: Candida species were detected in 81 patients (12%). In the baseline characteristics some significant differences were shown. In the group of patients with detection of candida species was associated with a higher MELD score (22 vs. 18, p < 0.001), proportion of female patients (48% vs. 34%, p = 0.014) and incidence of diabetes (36% vs. 23%, p = 0.011). Of note, most of the detected candida species were candida albicans and were located in urine and respiratory aspirations. Incidence of AKI and incidence of ACLF was significantly higher in the group of patients with detected candida species. Even after adjusting to several confounders spotted candida species was a significant risk factor for development of AKI and ACLF (p = 0.013, HR = 1.57; p = 0.009, HR = 1.84, respectively).
In the univariate competing risk analysis a significant association between detection of candida species and 90-day mortality (p < 0.001) was identified. The 90-day mortality remained significantly influenced by detection of candida species after adjusting to confounders in multivariate competing risk analysis with liver transplantation as competing risk (p = 0.033, HR = 1.66).

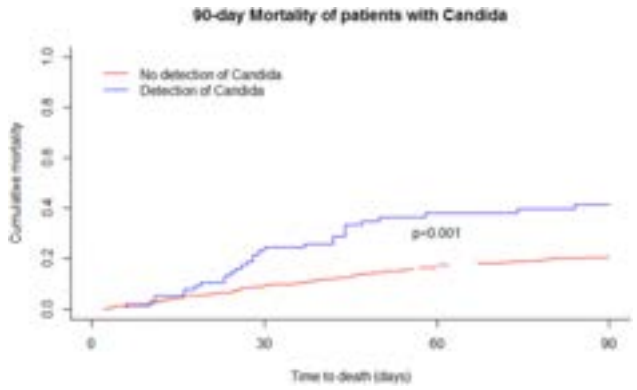

Figure:

Conclusion: Detection of candida species is linked to an impaired short-term mortality and development of severe complications in patients with liver cirrhosis. Further studies may assess if treatment of candida colonisation influences the clinical course and survival in this patient collective or the detection on candida can be used to identify patients that require specific measures to prevent cirrhosis-associated complications.

SAT-526
Clinical utility of liver and spleen elastography in the management of patients living with liver disease
Carmen Lara Romero[1], María Del Barrio[2], Maria Del Carmen Rico[1], Belen Pino[1], Manuel Romero Gomez[1]. *[1]Liver and Digestive Diseases Unit. Virgen del Rocío University Hospital; SeLiver Group, Biomedicine Institute of Seville (HUVR/CSIC/US), Medicine Department, University of Sevilla, CIBEREHD, Sevilla, Spain; [2]Gastroenterology and Hepatology Department, Clinical and Translational Research in Digestive Diseases, Valdecilla Research Institute (IDIVAL), Marqués de Valdecilla University Hospital., Santander, Spain*
Email: carmenlararomero@gmail.com

Background and aims: Portal hypertension (PH) is responsible for the progression of liver diseases and the development of complications. In patients with liver elastography <10 kPa, advanced liver disease is ruled out according to Baveno VII consensus. Our aims are a) To analyze the prevalence of portal hypertension and porto-sinusoidal vascular disease (PSVD) in patients with liver disease; b) Identify non-invasive parameters of suspicion of PSVD and/or hidden PH; c) to Assess the clinical impact of the presence of elevated spleen stiffness in the development of complications.
Method: Prospective cohort of 276 consecutive patients seen in a hepatology consultation who underwent liver and splenic transient elastography (Fibroscan 630, Echosens, France). Thresholds for advanced disease were spleen stiffness measurement (SSM) >45 kPa and Liver stiffness measurements (LSM) >10 kPa. It was evaluated: hepatic, renal, metabolic function, concomitant treatment, ultrasound, endoscopy, liver histology and portal hemodynamic. Statistical analysis: t-student, ANOVA, Chi-square, Spearman's coefficient, U-Mann-Whitney, Wilcoxon, logistic regression, and linear correlation.
Results: SSM > 45 kPa in 23 cases of 154 with LSM < 10 kPa (14.9%) versus 56 of 122 with LSM >10 kPa (45.9%); p < 0.001). The predictive parameters of SSM > 45 kPa in patients with LSM < 10 kPa are collected in the table (platelets, INR, Child-Pugh and MELD3.0). In the multivariate analysis, the platelet count and MELD 3.0 were independently related to SSM > 45kPa and LSM < 10 kPa. The rate of decompensation (hepatic encephalopathy, ascites, or variceal bleeding) was 1.5% in patients with LSM < 10kPa and SSM<45kPa (2/131), versus 13% (3/23) in patients with LSM < 10 kPa and SSM > 45 kPa, 15.4% (10/65) in patients with LSM>10 kPa and SSM < 45 kPa and 44% (24/54) in patients with LSM>10 kPa and SSM > 45 kPa; p < 0. 0001.

Table: Univariate and multivariate analysis

	Univariate analysis			Multivariate analysis	
Variable	SSM≤45kPa (n = 129)	SSM>45kPa (n = 23)	p	HR (IC95%)	p
Platelets	240 ± 83	173 ± 112	<0, 001	0, 982 (0, 973–0, 991)	=0, 008
INR	0, 99 ± 0, 18	1, 13+0, 29	<0, 073		
MELD 3.0	6, 93 ± 0, 98	8, 75 ± 2, 93	<0, 055	1, 335 (1, 002–1, 778)	P = 0, 048
Child-Pugh	5, 0 ± 0, 0	5, 75 ± 1, 36	<0, 082		

Conclusion: The SSM can detect up to 15% of cases of occult PH/PSVD in patients with LSM <10 kPa and SSM>45kPa. In patients with LSM <10kPa, a decrease in platelet count or an increase in MELD 3.0 should lead to suspicion of PH. The presence of altered SSM is associated with an increased risk of liver events. The implementation of SSM will improve the management of patients with liver disease.

SAT-527
Secondary prevention of variceal bleeding is often imperfect: a national, population-based cohort study of 5,018 patients
Hannes Hagström[1], Ying Shang[1], Elliot Tapper[2], Axel Wester[1], Linnea Widman[1]. *[1]Karolinska Institutet, Sweden; [2]University of Michigan, United States*
Email: hannes.hagstrom@ki.se

Background and aims: Secondary prevention of variceal bleeding is important to improve prognosis, but uptake of guidelines is unknown in a real-world setting. Here, we determined the proportion of patients receiving appropriate beta-blocker treatment and repeat upper endoscopy after a first episode of variceal bleeding within a reasonable timeframe.
Method: Population-based registers were used to identify all patients with a first episode of variceal bleeding in Sweden, 2000–2020. Cross-linkage between registers was performed to receive information on the cumulative incidence of patients with a dispensation of beta-blockers within 30 days and repeat upper endoscopy within 120 days from baseline. Overall mortality was investigated using Cox regression.
Results: In total, 5,018 patients were identified, with a median age of 62 years (IQR = 54–71). Of patients not on previous beta-blocker

therapy, the cumulative incidence of a dispensation of beta-blockers within 30 days was 54.3%. The cumulative incidence of repeat endoscopy was 34.5% within 120 days. Overall mortality was high, with 71.2% of patients dying after variceal bleeding during the full follow-up period (median 1.8 years). We observed an improved overall mortality during the later years of the study period (adjusted hazard ratio for the 2016–2020 period compared to the 2000–2005 period:0.84, 95%CI = 0.75–0.93). Patients with beta-blockers and repeat upper endoscopy had better overall survival compared to those without, respectively.

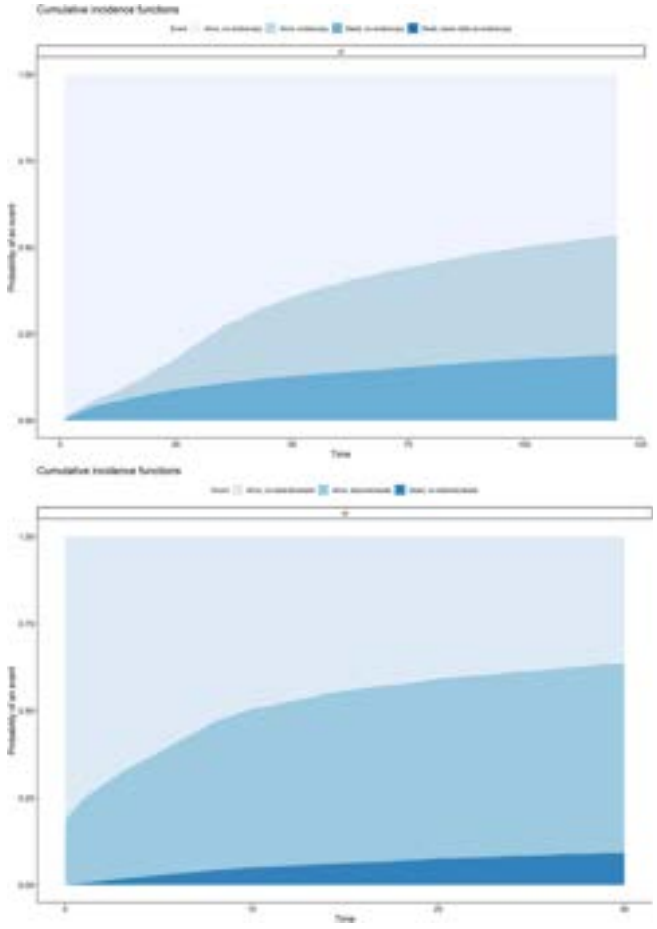

Figure: Probabilities of repeat upper endoscopy within 120 days after bleeding (top panel) and dispensation of beta-blockers 30 days after bleeding (bottom panel).

Conclusion: Secondary prevention of variceal bleeding has not been widely undertaken, with many patients not receiving guideline-supported interventions within a reasonable timeframe. This highlights a need to raise awareness on appropriate prevention strategies to clinicians and patients.

SAT-528

Terlipressin has acute effects on systemic inflammation markers in patients with cirrhosis and ascites

Nikolaj Torp[1,2], Mads Israelsen[1,2], Emil Deleuran Hansen[1,2], Stine Johansen[1,2], Camilla Dalby Hansen[1,2,2], Emilie Dahl[3], Bjørn Stæhr Madsen[1], Johanne Kragh Hansen[1,2], Katrine Prier Lindvig[1,2], Katrine Thorhauge[1,2], Katrine Bech[1], Ida Villesen[1], Ellen Jensen[1,2], Ida Ziegler Spedtsberg[1,2], Peter Andersen[1], Annette Fialla[1], Boye Jensen[2], Maja Thiele[1,2], Sabine Klein[4], Robert Schierwagen[4], Jonel Trebicka[4,5], Aleksander Krag[1,2]. *[1]Odense University Hospital, Department of Gastroenterology and Hepatology, Odense, Denmark; [2]University of Southern Denmark, Faculty of Health Science, Odense, Denmark; [3]Copenhagen University Hospital Herlev, Department of Gastroenterology, Denmark; [4]University of Münster, Department of Internal Medicine B, Germany; [5]European Foundation for the Study of Chronic Liver Failure, Spain*
Email: aleksander.krag@rsyd.dk

Background and aims: Terlipressin is widely used in the management of variceal bleeding and hepatorenal syndrome. However, terlipressin increases the risk of intestinal ischemia, respiratory failure and possibly sepsis and septic shock. The complications are all associated to systemic inflammation, where IL-6 is a pivotal marker. IL-6 is associated to a poor prognosis in patients with cirrhosis, but the immediate effect of terlipressin on IL-6 and other systemic inflammation markers is unknown. We therefore aimed to investigate the acute impact of terlipressin on markers of systemic inflammation in patients with cirrhosis and ascites.

Method: We included 25 stable patients with cirrhosis and ascites from a 2:2:1 cross-over randomized controlled trial of terlipressin with dobutamine as a cardioselective control. The intervention was administered in two treatment periods with A) dobutamine followed by terlipressin (n = 10), B) terlipressin followed by both terlipressin and dobutamine and C) placebo (n = 5). Serial blood and urine samples were available before treatment (baseline) and during both treatment periods. We used the Luminex MAGPIX platform to measure changes of inflammatory markers in blood and urine (CCL2, CCL3, CCL4, CXCL10, IL-1alpha, IL-1beta, IL-1RA, IL-6, IL-10 and IL-18). Urine measurements were corrected for changes in glomerular filtration rate (GFR) as assessed by ^{51}Cr-labeled clearance. All measurements were log-transformed to normalize data.

Results: Mean age was 57 (± 9 years), majority were male (68%) with alcohol-related cirrhosis (92%) as the dominant etiology. Baseline WBC = 6.1 × 10^9/L [5.0–7.7], CRp = 6 mg/L [2–10] and MELD-Na = 10 [9–14]. Before treatment, CRP correlated positively with blood IL-6 ($p = 0.040$) while WBC did not ($p = 0.384$). Relative to placebo and before treatment periods, terlipressin increased blood IL-6 ($p < 0.001$) and urine IL-6 ($p < 0.001$), while dobutamine did not (Figure). Terlipressin also led to increased levels of inflammasome activation markers IL-1alpha ($p < 0.001$) and IL-1beta ($p < 0.01$) in the urine, whereas dobutamine treatment only increased urine IL-1alpha ($p < 0.05$). A significant decrease of differing systemic inflammatory chemokines was observed in blood (CCL2, $p < 0.001$ and CXCL10, $p < 0.001$) and urine (CCL3, $p < 0.001$ and CCL4, $p < 0.01$) following terlipressin. As expected, GFR improved in treatment periods with only terlipressin (+18.8 ml/min/1.73 m^2, 95% CI: +5.7 to +32.0, $p < 0.01$). However, the changes in blood systemic inflammation markers were not associated with the effect of terlipressin on GFR.

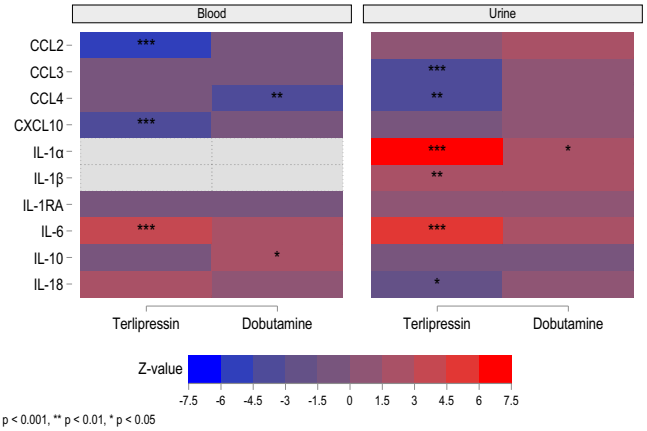

Figure: Heatmap of the effect of terlipressin and dobutamine on systemic inflammatory markers in blood and urine. Z-value changes are relative to placebo and before treatment periods.

Conclusion: Terlipressin induces a rapid changes in systemic inflammation marker, including an increase in IL-6. This increase may likely be a result of intestinal ischemia, since cardioselective dobutamine did not elicit this effect. We did not observe an association between systemic inflammatory changes and the effect of terlipressin on renal function.

SAT-530

Individualized portal pressure gradient threshold based on liver function categories in preventing rebleeding after TIPS

Yifu Xia[1], Jun Tie[2], Guangchuan Wang[3,4], Yuzheng Zhuge[5], Hao Wu[6], Hui Xue[7], Jiao Xu[2], Feng Zhang[5], Lianhui Zhao[1,3], Guangjun Huang[3], Mingyan Zhang[3], Bo Wei[6], Peijie Li[7], Wei Wu[8], Chao Chen[8], Chengwei Tang[6], Chunqing Zhang[1,3]. *[1]Shandong Provincial Hospital Affiliated to Shandong University, China; [2]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, China; [3]Shandong Provincial Hospital Affiliated to Shandong First Medical University, China; [4]Department of Biostatistics, School of Public Health, Shandong University, China; [5]Affiliated Drum Tower Hospital of Nanjing University Medical School, China; [6]West China Hospital, China; [7]First affiliated hospital of xi'an Joao Tong university, China; [8]The First Affiliated Hospital of Wenzhou Medical University, China*
Email: zhangchunqing_sdu@163.com

Background and aims: The evidence in Portal pressure gradient (PPG) <12 mmHg after transjugular intrahepatic portosystemic shunt (TIPS) for preventing rebleeding mostly comes from observations in uncovered stents era. Moreover, association between Child-Pugh classes and post-TIPS hepatic encephalopathy (HE) has indicated that tolerance of PPG reduction depends on liver function.
We aimed to investigate the optimal PPG for covered TIPS and explore the optimal threshold tailored to the Child-Pugh classes to find individualized PPG to balance rebleeding and overt HE.
Method: This multicenter retrospective study analyzed rebleeding, OHE, and mortality of patients associated with post-TIPS PPGs (8, 10, 12, and 14 mmHg) in the entire cohort and among different Child-Pugh classes. Propensity score matching (PSM) and competing risk analyses were performed for sensitivity analyses.
Results: We included 2100 consecutively screened patients undergoing TIPS. In all patients, PPG <12 mmHg reduced rebleeding after TIPS ($p = 0.022$). In Child-Pugh class A, none of the PPG thresholds were discriminative of clinical outcomes. In Child-Pugh class B, 12 mmHg ($p = 0.022$) and 14 mmHg ($p = 0.037$) discriminated rebleeding, but 12 mmHg showed a higher net benefit. In Child-Pugh class C, PPG<14 mmHg had a lower rebleeding incidence ($p = 0.017$), and exhibited more net benefit than 12 mmHg.

Figure:

Conclusion: Different PPG standards may be required for patients with different liver function categories. A PPG threshold <12 mmHg might be suitable for patients in Child-Pugh class B, while <14 mmHg might be optimal for patients in Child-Pugh class C.

SAT-531

Serum procalcitonin and interleukin-6 predict acute-on-chronic liver failure following transjugular intrahepatic portosystemic shunt implantation in patients with refractory ascites

Lukas Sturm[1], Michael Schultheiss[1], Laura Stolz[1], Marlene Reincke[1], Patrick Huber[1], Robert Thimme[1], Dominik Bettinger[1]. *[1]Medical Center University of Freiburg, Germany*
Email: lukas.sturm.med@uniklinik-freiburg.de

Background and aims: As acute-on-chronic liver failure (ACLF) is associated with high morbidity and mortality, early identification of patients who are at risk for developing ACLF is crucial. However, risk factors for ACLF in connection with transjugular intrahepatic portosystemic shunt (TIPS) implantation are only sparsely investigated. Therefore, the present study aimed to evaluate the predictive relevance of inflammatory markers in the context of ACLF development following TIPS implantation.
Method: Sixty-nine patients allocated to TIPS implantation due to refractory ascites were included and blood samples were obtained prior to TIPS placement. Serum levels of high-sensitive c-reactive protein (hsCRP), procalcitonin (PCT) and interleukin-6 (IL-6) were determined. The development of ACLF and death within 90 days after TIPS implantation were recorded. Inflammatory markers were evaluated as predictors of ACLF using uni- and multivariable Fine and Gray competing risk regression models, considering death as competing risk.
Results: Twenty-two patients (31.9%) developed ACLF within 90 days after TIPS implantation, thereof 86.4% ACLF grade 1 and 13.6% ACLF grade 2. ACLF was lethal in 27.3% of cases. Patients developing ACLF had significantly elevated plasma levels of PCT (0.12 [0.09–0.24] ng/ml vs. 0.08 [0.00–0.12] ng/ml, $p = 0.004$) and IL-6 (30.5 [20.2–41.9] pg/ml vs. 21.4 [13.3–39.2] pg/ml, $p = 0.048$) prior to TIPS implantation in comparison to patients without ACLF, while there was no significant difference in levels of hsCRP. Competing risk regression analyses showed that besides the Freiburg Index of Post-TIPS Survival (FIPS; SHR 2.848, 95% CI 1.167–6.948, $p = 0.021$) and elevated serum creatinine (SHR 1.675, 95% CI 1.146–2.450, $p = 0.008$), levels of PCT (SHR 1.129, 95% CI 1.018–1.253, $p = 0.022$) and IL-6 (SHR 1.002, 95% CI 1.001–1.004, $p = 0.015$) were independent predictors of ACLF. ROC-analyses confirmed a high discriminatory performance especially of PCT in the prediction of ACLF (PCT: AUROC 0.715 [0.594–0.836]; IL-6: AUROC 0.648 [0.514–0.782]).
Conclusion: The present results indicate that besides impaired renal function, an inflammatory status predisposes for ACLF development following TIPS implantation in patients with refractory ascites. In this context, the inflammatory markers PCT and IL-6 can help to identify patients at high risk of developing ACLF.

SAT-532

Refractory hepatic hydrothorax is associated with Increased mortality compared to cirrhosis and refractory ascites

Allison Chin[1], Dustin Bastaich[2], Bassam Dahman[2], David Kaplan[3], Tamar Taddei[4], Binu John[5]. *[1]Florida International University, United States; [2]Virginia Commonwealth university, United States; [3]University of Pennsylvania, Philadelphia, United States; [4]Yale School of Medicine and VA Connecticut Healthcare System, West Haven, CT, United States; [5]University of Miami and Miami VA, United States*
Email: binu.john@gmail.com

Background and aims: Refractory hepatic hydrothorax (RH) requiring therapeutic thoracentesis is a serious complication of cirrhosis. Undrained effusions can lead to pulmonary atelectasis, while thoracentesis (particularly multiple), can be complicated by life threatening hemo- or pneumothorax. Patients with RH on the liver transplant list do not receive standardized MELD exemption points because of inadequate evidence to suggest increase mortality. The

aim of this study was to examine liver-related death associated with RH compared to participants with refractory ascites (RA).
Method: This was a retrospective cohort study of patients with cirrhosis from the Veterans Health Administration. Eligibility criteria included patients with RH or RA who underwent at least one therapeutic thoracentesis or paracentesis respectively. The primary outcome was LRD, with non-liver-related-death or liver transplantation as competing risk.
Results: Of 120,952 participants with cirrhosis in the VOCAL cohort, 2,225 met study inclusion criteria. On multivariable analysis, hepatic hydrothorax was associated with a 4.0-fold increased adjusted hazard of LRD compared to refractory ascites (95% CI 3.15–5.07, p < 0.0001). This association of increased LRD with RH was observed across varying levels of MELD-Na from <10 (aHR 3.23, 95% CI 2.10–4.95, p < 0.0001), 10–15 (aHR 4.39, 95% CI 2.78–6.93, p < 0.0001), 15–25 (aHR 4.38, 95% CI 2.96–6.50, p < 0.0001), and ≥25 (aHR 5.81, 95% CI 2.97–11.34, p < 0.0001). Compared to participants requiring a single thoracentesis, LRD was similar for those requiring 2–3 (aHR 1.33, 95% CI 0.75–2.35, p = 0.33), but higher with ≥4 thoracentesis (aHR 2.80, 95% CI 1.52–5.16, p = 0.001). There was no association between number of paracentesis and LRD among participant with RA.

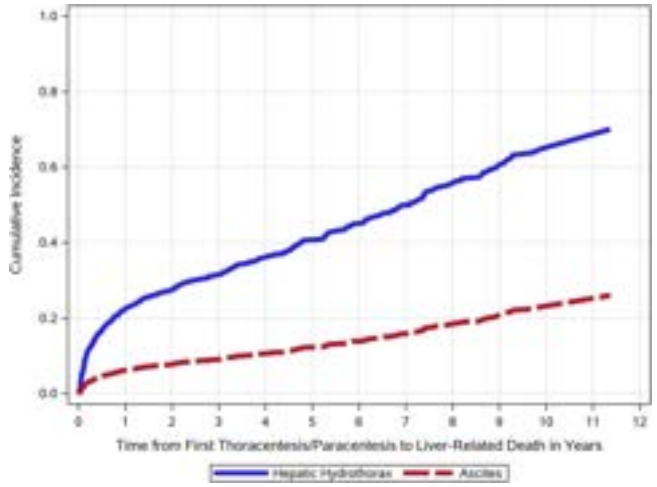

Figure: Cumulative incidence frequency for adjusted hazard ratio of liver-related death with transplantation and non-liver-related death as competing risk Note: The cumulative incidence was estimated from the Fine-Gray competing risk model.

Conclusion: RH is associated with significantly higher LRD compared to participants with ascites across varying levels of MELD. Consideration should be given for a standard MELD exemption in participants with RH listed for transplantation.

SAT-533
Validation of Baveno-VII criteria regarding non-invasive diagnosis of clinically significant portal hypertension

Byeong Geun Song[1], Aryoung Kim[1], Myungji Goh[1], Wonseok Kang[1], Geum-Yon Gwak[1], Yong-Han Paik[1], Moon Seok Choi[1], Joon Hyeok Lee[1], Seung Woon Paik[1], Dong Hyun Sinn[1]. [1]*Samsung Medical Center, Korea, Rep. of South*
Email: sinndhn@hanmail.net

Background and aims: Baveno VII consensus introduced the criteria of clinically significant portal hypertension (CSPH) by non-invasive tools (NITs) using liver stiffness measurement (LSM) and platelet. We aimed to validate the Baveno VII criteria to predict the risk of adverse liver related events in patients with compensated advanced chronic liver disease (cACLD).
Method: We conducted a retrospective cohort study of 1,966 patients with cACLD. Patients were grouped into four subgroups (CSPH excluded (n = 619), grey zone (low probability of CSPH (n = 699), high probability of CSPH (n = 207)), and CSPH included (n = 441)) according to Baveno VII consensus. Risk of decompensation and HCC was estimated using a Fine and Gray competing risk regression analysis, with liver transplantation and death as competing events.
Results: Among 1,966 patients, 178 and 176 patients developed decompensation and HCC over a median follow-up of 3.06 (range, 1.03–6.00) years, respectively. Patients with CSPH had substantially higher risk of decompensation compared to those without CSPH (18%, 21%, 22% vs. 0.69%, 1.1%, 1.4% at 1-year, 2-year, 3-year, respectively). Patients with CSPH had 8-fold higher risk of decompensation (standardized hazard ratio (sHR) 8.00, 95% confidence interval (CI) 4.00–16.0). Also, patients with CSPH had higher risk of HCC compared to those without CSPH (sHR 3.14 (95% CI 1.96–5.04)), yet considerable proportion of patients without CSPH also developed HCC (2.4% at 3-year). Restricted cubic spline curves showed linear relationship between LSM and risk of decompensation. Among patients within the grey zone, alcoholic liver disease, high prothrombin time, high bilirubin, and low albumin was associated with higher risk of decompensation.
Conclusion: Baveno VII criteria for CSPH using NITs can stratify the risk of decompensation and liver related events.

SAT-534
Pressure response to TIPS does not depend on stent diameter

Background and aims: In patients receiving the transjugular intrahepatic portosystemic shunt (TIPS) a greater reduction of the portosystemic pressure gradient (the difference between the portal and right atrial pressure) may harbour a higher risk of shunt-induced complications such as liver failure and hepatic encephalopathy. Prediction of the stent diameter necessary to reach the treatment goal (6–12 mmHg) may reduce the risk of overtreatment with its respective consequences.
Method: We evaluated immediate post-TIPS pressures and stent diameters in 208 patients with liver cirrhosis receiving a TIPS for refractory ascites (69.7%) or variceal bleeding (30.3%). Diameters were determined by planimetry from the angiographic image. Clinical and hemodynamic factors (portal vein diameter, portal vein flow velocity, hepatic resistance) possibly related to response to TIPS were determined before the intervention. Patients were divided into groups with post-TIPS pressure gradients of ≥6 mmHg (low risk; group 1, n = 155) or <6 mmHg (high risk; group 2, n = 53).
Results: Mean post-TIPS pressure gradients, relative reduction of the pre-TIPS gradient, and specific reduction of the pre-TIPS gradient per mm of stent diameter were 10.2 ± 2.3 mmHg, 50.0 ± 12.5%, and 7.1 ± 2.1% per mm in group 1 and 4.5 ± 1.5 mmHg (p < 0.001), 73.6 ± 11.1% (p < 0.001), and 10.1 ± 2.0% per mm in group 2 (p < 0.001), respectively. The stent diameters did not correlate with the reduction of the gradient (r = 0.17) and the pressure changes in group 1 and group 2 were achieved with similar diameters (7.2 ± 1.0 vs 7.4 ± 0.9 mm, p = 0.999). The right atrial pressures, a measure of the preload, increased in group 1 and group 2 by 4.1 ± 3.1 mmHg and 5.0 ± 2.9 mmHg (p = 0.042), and the portal pressures decreased by 6.64 ± 3.9 mmHg and 8.6 ± 4.4 mmHg (p = 0.002), respectively. Prediction of the appropriate stent diameter was not possible.
Conclusion: In most patients, pressure response to TIPS was achieved with real diameters of <8 mm and was not correlated to the measured stent-diameter. The stent diameter was not predictable and a greater response (group 2, ≤6 mmHg) was associated with a greater increase in the right atrial (increased preload) and greater decrease in the portal pressure (decreased afterload) suggesting that systemic hemodynamics and cardiac function may play a role in the response to TIPS.

SAT-535

Single-centre experience of spleen stiffness measurement across the spectrum of chronic liver disease

Sarah Romero[1], Alexander Thompson[1], Jessica Howell[1], Marno Ryan[1], Swee Lin Chen Yi Mei[1], Catherine Croagh[1], Barbara Demediuk[1], David Iser[1], Tim Papaluca[1], Paul Desmond[1], Jacinta Holmes[1]. [1]*St Vincent's Hospital Melbourne, Department of Gastroenterology, Melbourne, Australia*
Email: s.romero.md@gmail.com

Background and aims: Onset of clinically significant portal hypertension (PH) is a critical clinical event, predicting liver-related events and death in cirrhosis[1]. However, HVPG is invasive and inaccessible, and current non-invasive tools are suboptimal. Liver stiffness measurement (LSM) >25 kPa has been suggested to be sufficient to rule in clinically significant PH (CSPH), but LSM <25 kPa remains indeterminate. Spleen stiffness measurement (SSM) correlates strongly with HVPG, where SSM >40kPa rules in CSPH[2]; therefore SSM may be superior to detect CSPH where current algorithms remain indeterminate. However, SSM remains suboptimal due to lack of data regarding optimal procedural technique, quality metrics, and validation with the dedicated spleen probe. We report procedural success and limitations, and clinical correlates of SSM across the spectrum of chronic liver disease (CLD).
Method: Prospective, single-centre study of SSM (100hz) for CLD from January 1 to December 31, 2022, under ultrasound guidance, with paired LSM. Demographics and clinical parameters of PH were collected. Outcomes included: SSM success [10 valid SSM, representing >60% of total SSM, with IQR <30%]; SSM correlation with parameters of PH; factors associated with SSM failure.
Results: 63 patients underwent SSM; 87% (n = 55) had cirrhosis, 62% male, median age 62 yrs [IQR 51–68], median body mass index (BMI) 28 [IQR 24–32]. Child-Pugh A/B/C status was present in 77/16/7% of cirrhotics, respectively, with a median Meld-Na of 10 [IQR 8–14]. Aetiology of liver disease included: viral (35%), alcohol (32%), MAFLD (17%), other (16%). Varices were present on gastroscopy or abdominal imaging in 37% (n = 20). 11% (n = 7) had ascites at time of SSM. SSM was successful in 70% (n = 44); median stiffness 42.6 kPa. SSM failure was due to failure to meet quality criteria or failure to return SSM. Maximum SSM (100 kPa) was reached in 7% (n = 3) and 27% (n = 12) had SSM >75 kPa. SSM was significantly higher in patients who met criteria for CSPH (LSM >25 kPa), 61.3 vs 25.6 kPa ($p = 0.001$), and in patients with thrombocytopaenia (Table). Interestingly, SSM met criteria for CSPH in patients with LSM >15 kPa (median SSM 58.3 kPa (Table)). SSM was significantly higher in patients with non-viral vs viral CLD aetiology (46.6 vs 27.1 kPa, $p = 0.044$) and in those with varices (90.4 vs 29.1 kPa, $p < 0.0001$). SSM failure was more common if LSM <25 kPa ($p = 0.047$). SSM correlated only moderately with platelet count ($r^2 = 0.304$, $p < 0.001$), LSM ($r^2 = 0.190$, $p = 0.006$) and Meld-Na ($r^2 = 0.235$, $p = 0.002$). SSM procedural success was not affected by age, BMI or ascites.

Table:

			P value
SSM (kpa)	LSM <15: 22.3	LSM >15: 58.3	0.0001
	LSM <25: 25.6	LSM >25: 61.3	0.0010
	Plt >150: 26.1	Plt <150: 61.4	0.0012
	Plt >100: 38.2	Plt <100: 90.4	0.0073

Conclusion: In this real-world cohort with mixed liver disease aetiology (treated and untreated), LSM >25 kPa alone was not sufficient to exclude probable CSPH, based on SSM threshold of 40kPa. Furthermore, SSM was significantly higher in non-viral CLD. SSM could not be obtained in 30%. These data have significant implications for wider applicability of LSM in CLD to predict for CSPH. SSM should be considered an adjunct to existing tools for CSPH screening, however further data is required to identify optimum quality criteria, factors associated with SSM failure and optimal SSM cut-offs for degrees of PH according to CLD aetiology, particularly non-viral subgroups.

SAT-536

Adverse outcomes following transjugular intrahepatic portosystemic shunt placement in relation to the underlying cause of portal hypertension

Adriaan Van der Meer[1], Michelle Spaan[1], Adriaan Moelker[2], Willemijn Dijkstra[1], Ellen Werner[1], Diederik Bijdevaate[2], Tychon Geeraedts[2], Milan Sonneveld[1], Sandra Coenen[1], Dave Sprengers[1], Robert De Man[1], Raoel Maan[1,3], Sarwa Darwish Murad[1,3]. Email: s.darwishmurad@erasmusmc.nl

Background and aims: A variety of non-cirrhotic liver diseases, predominantly Budd-Chiari syndrome (BCS) and portal vein thrombosis (PVT), can lead to portal hypertension (PH) with the need for transjugular intrahepatic portosystemic shunt (TIPS). In comparison to cirrhosis-related PH (CPH), non-cirrhotic PH (NCPH) differ in underlying pathophysiological conditions, e.g. in hypercoagulability and residual liver function. Therefore, the aim of this study was to assess TIPS thrombosis and hepatic encephalopathy (HE) in patients with NCPH in comparison to patients with CPH.
Method: Occurrence of TIPS thrombosis (i.e. in-stent or in proximity of TIPS) and HE was assessed in a retrospective mono-center cohort, which included all consecutive patients with PH who received a TIPS with a covered stent between 2007 and 2021. End points were assessed as time-to-event data in Kaplan Meier and Cox proportional hazard analyses, and compared those with NCPH and CPH. Patients were censured at the time of liver transplantation or death.
Results: Overall, 385 patients with PH received a TIPS of which 55 (14.3%) had NCPH and 330 (85.7%) had CPH. Among patients with NCPH, 28 (51%) were male, median age was 51 (range 19–75) years, 26 (47%) had Budd-Chiari syndrome (BSC), 13 (24%) had portal vein thrombosis, and 16 (29%) had other causes of PH. Among patients with cirrhosis, 222 (67%) patients were male, the median age was 57 (range 15–84) years, and the etiology of cirrhosis was viral hepatitis/auto-immune or cholestatic liver disease/(non)alcoholic steatohepatitis or cryptogenic/other in 12/11/71/6%, respectively. Patients with NCPH patients were significantly younger ($p = 0.005$) and more frequently female ($p = 0.019$). NCPH patients developed significantly more TIPS thrombosis than CPH patients (22% vs 8.5%) with 1- and 5-y cumulative incidence of 19.1% (95%CI 13.3–24.9) and 33.2% (95%CI 23.7–42.7) versus 7.1% (95%CI 5.5–8.7) and 12.1% (95%CI 9.4–14.8) ($p = 0.002$). Likewise, the need for re-intervention at 1 and 5 y in NCPH was 33.6% 95%CI 26.4–40.8) and 52.8% (95%CI 43.6–62.0) versus 22.0% (95%CI 19.3–24.7) and 35.4% (95%CI 31.6–39.2) in CPH ($p = 0.026$). BCS patients had the highest 3-year incidence of TIPS thrombosis of 39.6% (95% CI 28.3–50.9) compared to 19.2% in PVT (95%CI 6.6–31.8) and 6.2% for other NCPH (95%CI 0.1–12.3), despite the fact that 92.3% used anticoagulants. HE was more prevalent in CPH (47% vs 31%) with 1- and 5-year cumulative incidence of 46.7% (95%CI 43.6–49.8) and 58.9% (95%CI 55.4–62.4) versus 29.1% (95% CI 22.5–35.7) and 43.6% (95% CI 34.4–52.8) in NCPH ($p = 0.022$).
Conclusion: Post-TIPS complications in patients with PH differ according to the etiology, with a higher risk of TIPS thrombosis in those with NCPH, in particular BCS, despite anticoagulation and a higher risk of HE in those with CPH. Importantly, post-TIPS HE is not uncommon following TIPS in NCPH.

SAT-537

Validation of a discrete event simulation model evaluating the cost-effectiveness of long-term albumin administration in real-world UK patients with recurrent ascites

Kris Bennett[1], Elisabet Viayna[2], Duncan Stacey[3], Matthew Cramp[1].
[1]*University Hospitals Plymouth NHS Trust, South West Liver Unit, Plymouth, United Kingdom;* [2]*Grifols S.A., Sant Cugat del Valles, Spain;* [3]*Grifols UK Ltd., Cambridge, United Kingdom*
Email: kbennett6@nhs.net

Background and aims: The development of cirrhotic ascites is associated with significant complications and costs. We previously developed a discrete event simulation (DES) model to assess the cost-effectiveness of long-term albumin (LTA; 40 g twice/week for 2 weeks, 40 g/week thereafter) in addition to standard medical treatment (SMT) in a UK patient cohort, based on patient characteristics and healthcare resource use (HCRU) from Hospital Episode Statistics (HES) and outcomes from the ANSWER trial. We estimated that treating 30/100 eligible patients with LTA may save up to £264,589/year. We aimed to validate our model and the HES inputs, by performing a detailed notes-based audit of patients undergoing large-volume paracentesis (LVP) for cirrhotic ascites at University Hospitals Plymouth NHS Trust (UHP).
Method: All patients undergoing LVP at UHP between March 2016-June 2018 were identified by OPCS procedure code (T46). Patients were excluded if ascites was not due to cirrhosis or there was insufficient follow-up data. Demographics, cirrhosis aetiology/severity, and 12-month rates for complications and HCRU, was collected by audit of patient records. Patients with recurrent ascites were considered eligible for LTA. The cost-effectiveness of LTA in this cohort was assessed using the previously developed DES by simulating the clinical and economic impact of treating 50% of the cohort with LTA+SMT vs SMT only. Clinical complications and HCRU were transformed into costs using NHS tariffs. Reductions in event probabilities associated with LTA were based on ANSWER trial data.
Results: 87 patients underwent an index LVP for cirrhotic ascites during the study period. 56 were considered ineligible for LTA due to early death (7), rapid ascites resolution (27) or refractory ascites (RA; 22), leaving a sample of 31 patients with recurrent ascites. Patients were predominantly male with alcohol-related liver disease and a median MELD score of 17. 12-month HCRU and complication rates were similar to our HES analysis; on average patients had 4 paracenteses, 5 in- and 10 out-patient encounters. 12-month mortality was 32%, 4 patients were transplanted and 8 developed RA. Hyponatraemia was the most common complication (18/31), followed by HRS (10/31). Our model estimates that treating 15/31 patients with LTA+SMT would avoid 28 inpatient encounters, 2 cases of RA and 3 deaths at 12-months, with an estimated cost-saving of £1,746/patient (Fig. 1).

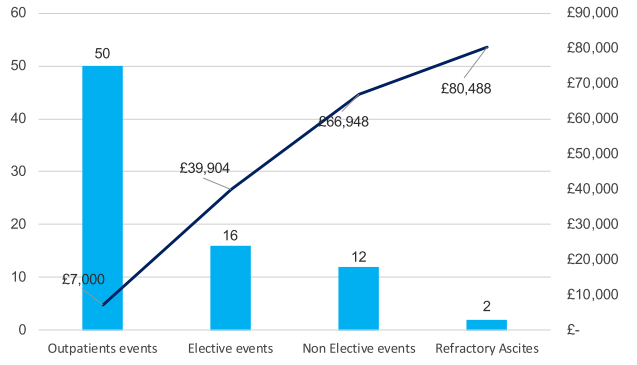

Figure 1. Main events avoided and associated costs savings when adding long-term albumin to standard medical treatment to 15 patients with recurrent ascites out of a cohort 31 patients

Conclusion: This detailed audit of patients with recurrent ascites validates our previous analysis; we found similar HCRU and event rates to previous HES data inputs and this DES model supports the conclusion that treating patients with recurrent ascites with LTA improves survival and leads to cost-savings through reduction of HCRU and complications.

Application of updated diagnostic criteria for cirrhotic cardiomyopathy: evaluation of its clinical impact in liver transplantation candidates

Maxim Khalenkow[1], Francis Voet[1], Michel De Pauw[2], Sander Lefere[1], Helena Degroote[1], Xavier Verhelst[1], Anja Geerts[1], Hans Van Vlierberghe[1], Sarah Raevens[1]. [1]*Ghent University, Gastroenterology and Hepatology, Belgium;* [2]*Ghent University, Cardiology, Belgium*
Email: sarah.raevens@ugent.be

Background and aims: Cirrhotic cardiomyopathy (CCMP) is a liver-related cardiac complication that can occur in patients with cirrhosis, and mainly manifests as diastolic dysfunction (DD). Diagnostic criteria were first established by the Montréal consensus in 2005, however, they substantially lacked specificity. With the application of tissue Doppler imaging, the evaluation of DD has significantly evolved, and diagnostic criteria have been revised since 2019. The prevalence and the clinical impact of DD in liver transplantation (LT) candidates are not well studied.
In this single-center retrospective study, we aimed to estimate the prevalence of DD, applying the 2019 criteria, in our population of LT candidates. We assessed the impact of DD on waitlist mortality and post-LT outcome and explored if DD can improve after LT.
Method: Demographic, clinical, echocardiographic and outcome data of 522 adult patients on the waitlist for LT between 01/01/2005 and 31/03/2017 in the Ghent University Hospital were analyzed. DD was diagnosed based on the diagnostic criteria established in 2019, using tricuspid regurgitation velocity and e' lateral. Data were analyzed using SPSS.
Results: DD was diagnosed in 5.7% of our patients evaluated for LT. Patients with DD were significantly older compared to patients without DD (mean age 65y versus 60y, $P < 0.001$). Other demographic data and clinical characteristics, e.g. etiology and severity of the underlying liver disease, were similar between LT candidates with and without DD. Numerically, more patients with DD (21.1%) died on the waitlist compared to patients without DD (8.9%), although these results did not reach statistical significance. Patients who died on the waitlist were significantly older, had more severe liver disease, and more frequently had pulmonary comorbidities. A similar amount of LT candidates without DD underwent LT as LT candidates with DD (85.4% versus 73.6% respectively). The mean follow-up time in patients with and without DD was 1395 and 988 days ($p = 0,44$) respectively. Post-LT survival was similar in both groups: 14.3% of patients with DD and 15.2% of patients without DD died during follow-up. Pulmonary comorbidities and lower e' lateral were more frequently seen in deceased patients. Follow-up echocardiographic data post-LT were available in 10 patients who were diagnosed with DD before LT: only 1 of them fulfilled the diagnostic criteria of DD post-LT.
Conclusion: This large cohort study indicates that the prevalence of DD among LT candidates is rather low. Our data suggest that the presence of DD could potentially impact waitlist outcome, but does not affect post-LT survival.

SAT-539

Baveno VII algorithm can avoid endoscopic surveillance in patients with cirrhosis

Jinjun Chen[1], Haiyu Wang[1], Jiankang Song[1], Biao Wen[1], Yuanjian Zhang[1]. [1]*Hepatology Unit, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Guangdong Provincial Clinical Research Center For Viral Hepatitis, Guangzhou, China*
Email: chjj@smu.edu.cn

Background and aims: Baveno VI criteria combined with spleen stiffness measurement (SSM) ≤40 kPa (Baveno VII algorithm) can safely rule out high-risk varices (HRV) and avoid esophagogastroduodenoscopy (EGD) screening. With a prospective cohort of cirrhosis patients having paired EGDs assessments, the present study aimed to validate the performance of Baveno VII algorithm in avoiding endoscopic surveillance in cirrhosis patients.
Method: The present study was a prospective study. Patients with cirrhosis were enrolled from April 2019 to February 2020 for endoscopic screening analysis (NCT04123509; NCT04890730). Endoscopic surveillance was performed and recorded in studied patients from June 2020 to April 2022. Liver and spleen transient elastography and EGD were performed within one month. Patients were followed up every 6 months at the clinic, and liver related events including clinical significant ascites, variceal bleeding, overt hepatic encephalopathy, HCC development and death were documented.
Results: Overall 715 patients with compensated cirrhosis were enrolled into screening analysis, of which 287 patients with paired EGDs were further analyzed. At screening, 153 (21.4%) patients had HRVs. Baveno VII algorithm with HRV missing rate at 2.0% (3/153) can avoid more EGDs than Baveno VI criteria (52.0% vs 32.7%, p < 0.001). Of the 287 patients, 27 patients were HRVs, Baveno VII algorithm can avoid 61.3% (176/278) endoscopic screening without (0/27) missing HRV. The distribution of varices at baseline in the 287 patients was as follows: no EV: 111 (38.7%), low-risk varices (grade 1 EV without red sign): 149 (51.9%), and high-risk varices: 27 (9.4%). During 17 (12–24) months follow-up, of the 111 patients without EV at baseline, 35 (31.5%) progressed to low-risk varices at follow-up. In the 149 patients with low-risk varices, varices disappearance of varices at follow-up was found in 19 patients, and 7 cases progressed to HRV. Of the remaining 27 patients with HRV at baseline, 3 regressed to low-risk varices and 24 remained as HRV at follow-up. Eventually, the distribution of varices at follow-up were as follows: no EV: 95 (33.1%), low-risk varices: 161 (56.1%), and HRV: 31 (10.8%). At follow-up, 31 HRV was eventually diagnosed and 27 found in patients with consecutive unfavored Baveno VII status, 3 in worsening Baveno VII status and 1 in consecutive favored Baveno VII status. Baveno VII algorithm spared 63.8% (183/287) EGDs surveillance and only one HRV was missed (3.2%, 1/31). Baveno VII algorithm can avoid more EGDs than Baveno VI criteria both at screening (61.3% vs 40.8%, p < 0.001) and surveillance (63.8% vs 50.5%, p = 0.001). In the whole 715 patients, after 33 months of follow-up, Baveno VII algorithm could be a predictive model to detect patients with low risk of decompensation.
Conclusion: We have validated that the Baveno VI criteria and Baveno VII algorithm (Baveno VI criteria combined with SSM ≤40 kPa) both can safely avoid EGDs surveillance. Baveno VII algorithm is able to avoid more unnecessary EGDs surveillance than Baveno VI criteria in compensated liver cirrhosis patients. The Baveno VII algorithm was able to rule out HRVs safely with HRV missing rate (missed/total) <5%, and over a half of EGD procedures were spared at both screening and surveillance. As well as Baveno VII algorithm was developed to detect cirrhotic patients with low risk of decompensation.

SAT-540

Symptoms from refractory ascites: contributions from both abdominal pressure and the patient

Nikhilesh Mazumder[1], Sardar Ansari[2], Elliot Tapper[1], Anna Lok[1]. [1]*University of Michigan Hospital, Gastroenterology and Hepatology, Ann Arbor, United States;* [2]*University of Michigan Hospital, Emergency Medicine, Ann Arbor, United States*
Email: mazumde@med.umich.edu

Background and aims: Ascites significantly impairs quality of life among patients with cirrhosis. Large volume paracentesis (LVP) can relieve patient symptoms. However, data are limited regarding both the threshold at which a patient experiences symptoms and potential

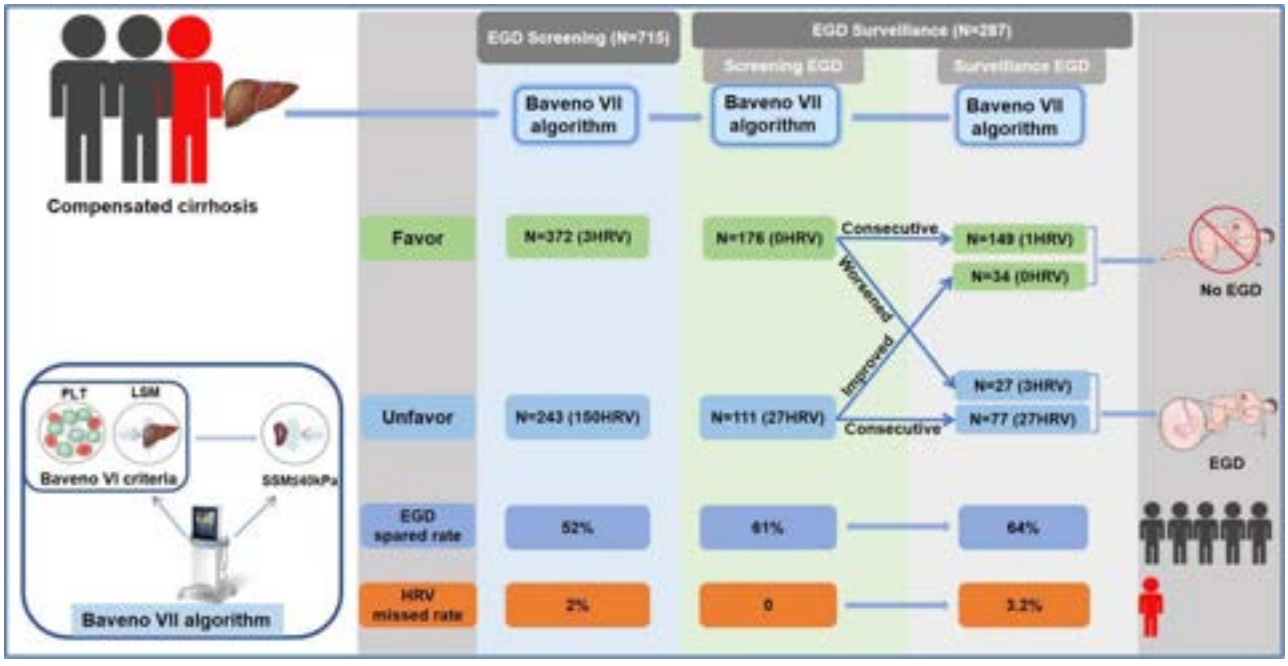

Figure: (abstract SAT-539).

for relief. The objective of this study was to delineate predictors of patient relief and persistence of symptoms after paracentesis.
Method: Patients with cirrhosis undergoing outpatient, therapeutic paracentesis were included. An open-ended manometer was used to measure ascites pressure at 1.5L increments during the procedure. The Ascites Symptom Index-7 (ASI-7), a validated PRO measure that rates seven domains impacted by ascites, was assessed before and at the end of the procedure (0: no symptoms, 35: maximal symptoms). Each component of ASI-7 was also examined separately. Relation between patient-specific responses to ASI-7 and ascites pressure was determined using a random-effects linear mixed model.
Results: 61 LVPs were performed on 21 unique patients (median 2 per patient, IQR 1–3). Opening pressure was 10.7 cmH_2O (IQR 8–13), which dropped to a median of 0 cmH_2O (IQR 0–5) after an average of 7.1 L (SD 2.1L) was removed per procedure. Median ASI-7 score pre-procedure dropped from 25 (IQR 20.5 to 27.5) to 7 (IQR 1–11) immediately after the procedure. Opening pressure was significantly associated with pre-LVP total ASI-7 score ($p = 0.04$). By univariate regression, opening pressure had the strongest association with difficulty moving ($\beta = 0.12$, $p = 0.0016$), bloating/discomfort ($\beta = 0.06$, $p = 0.05$), and dyspnea while walking ($\beta = 0.09$, $p = 0.07$). An ASI-7 score focused on these three questions was more predictive of opening pressure ($p = 0.03$) and closing pressure ($p = 0.04$) than the full survey. Random effects linear modeling suggests that each patient had a unique pressure-symptom relationship ($p < 0.001$). Regression trendlines by patient are plotted denoting the pressure-symptom relationship (Figure). This model also suggests that at abdominal pressure of zero, patients had residual symptoms even using the focused score (7.5 [max 15], 95% CI [5.4, 9.7], $p < 0.006$)

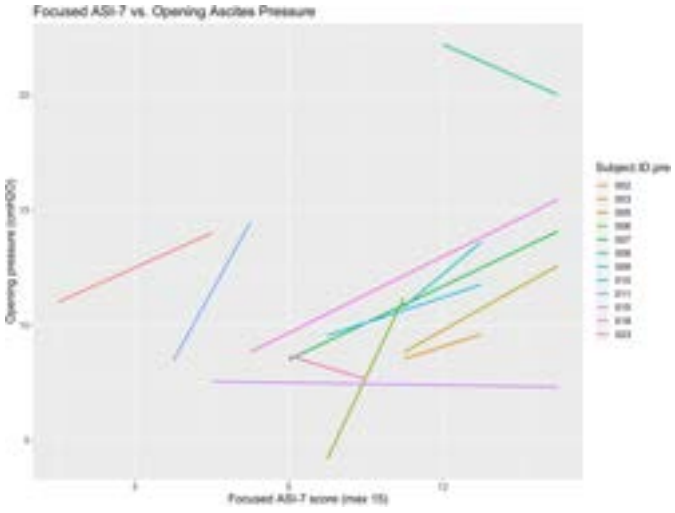

Figure:

Conclusion: Cirrhosis patients seeking relief from ascites-related discomfort typically present with abdominal pressure 10.7 cmH_2O which correlated with specific portions of the ASI-7 score. Each patient had a unique but typically direct relationship between the amount of discomfort experienced and abdominal pressure. However, residual discomfort was reported despite removing attaining zero pressure from ascites. Understanding this relationship will guide when and how much ascitic fluid should be drained for each patient to maximize symptom relief.

SAT-541

A retrospective evaluation of the effectiveness and safety of palliative long-term abdominal drains for the management of refractory ascites in patients with end-stage liver disease, in comparison with large volume paracentesis

Rodrigo Motta[1], Senamjit Kaur[2], Bryony Butler[2], Victoria Wharton[2], Jane Collier[2], Francesca Saffioti[2]. [1]*University of Oxford, Translational Gastroenterology Unit, Nuffield Department of Medicine-Experimental Medicine, United Kingdom;* [2]*Oxford University Hospitals NHS Foundation Trust, United Kingdom*
Email: francesca.saffioti@ouh.nhs.uk

Background and aims: Long term abdominal drains (LTAD) are a cost-effective palliative measure to manage malignant ascites in the community, but their use in patients with end-stage liver disease (ESLD) and refractory ascites (RA) is not routine practice.
We aimed to retrospectively evaluate effectiveness and safety of LTAD in palliative patients with ESLD and RA followed-up at our UK tertiary centre, in 2018–2022, and assess survival and the incidence of peritonitis, acute kidney injury (AKI), drain related complications and relevant hospitalisations, in comparison with a group of palliative patients with ESLD undergoing regular large volume paracentesis (LVP).
Method: Data was collected retrospectively from patients' electronic health records. Fisher's exact tests and Mann-Whitney U Test were used to compare qualitative and quantitative variables, respectively. Significance was set at $p < 0.05$. Kaplan-Meier survival estimates were generated to stratify outcomes according to type of drain.
Results: Thirty patients had LTAD (35 drains, 1–2 litre drained per week). There were no peri-operative complications. Drain displacement occurred in 4 cases (11%), catheter blockage in 2 (6%). Symptoms of shortness of breath and abdominal pain resolved in 70% and anorexia in 50% of patients, following LTAD insertion.
Nineteen patients only underwent regular LVP (median drain frequency 21 days).
Median follow-up (with LTAD in place/undergoing LVP), age, Child-Pugh score, liver disease aetiology, baseline renal function, ascitic protein, and presence of hepatocellular carcinoma were not significantly different between the LTAD and LVP cohort (Table 1). Prophylactic antibiotics were more frequently prescribed in the patients with LTAD ($p = 0.012$), but the incidence of peritonitis did not differ between the two groups ($p = 0.46$). Despite a similar use of diuretics, the incidence of AKI was significantly higher in the LVP group ($p = 0.014$). Ascites/drain related hospital admissions occurred more frequently in the LVP cohort ($p = 0.004$).
Survival was similar in the two groups (log-rank $p = 0.71$). End point-free survival was significantly shorter in the LVP group ($p = 0.004$, $p < 0.001$, $p = 0.018$ for first ascites/drain related hospitalisation, AKI and drain related complications, respectively).
Conclusion: The use of LTAD for the management of RA in palliative patients with ESLD is effective and relatively safe compared to LVP, and may reduce hospital admissions and health resource utilisation. A randomised controlled trial comparing LVP and LTAD is currently recruiting in the UK, to confirm these retrospective findings.

Table 1. Comparison of baseline characteristics and outcomes between the LTAD and the LVP cohort.

	LTAD	LVP	p value
Baseline characteristics			
Age, years (SD)	71 (11)	66 (12)	0.07
Child-Pugh score (IQR)	9 (2)	9 (2)	0.48
Aetiology (NASH/ArLD/viral/other)	9/12/2/7 (30%/40%/7%/23%)	3/10/1/5 (16%/53%/5%/26%)	0.69
HCC	5 (16.6%)	4 (21%)	0.46
Proteins in ascites ≤15 g/L	14 (47%)	9 (53%)	0.76
Prophylactic antibiotics	25 (81%)	8 (44%)	**0.012**
Previous peritonitis	2 (7%)	5 (28%)	0.86
T2DM	12 (40%)	8 (42%)	1.00
AKI	8 (23%)	11 (61%)	**0.014**
Baseline creatinine	104 (68)	84 (143)	0.44
Use of diuretics	23 (66%)	12 (63%)	1.00
Outcomes			
Median follow-up	77 (191)	64 (132)	0.45
Ascites /drain related admissions	11 (31.4%)	17 (73.7%)	**0.004**
Time to first hospitalisation (days)	44 (93)	7.5 (35)	**0.002**
AKI	8 (23%)	11 (61%)	**0.014**
Drain-related complications	14 (40%)	11 (73%)	0.06
Patients with peritonitis	5 (17%)	5 (28%)	0.46
Total n. of peritonitis episodes	10 (28%)	5 (26%)	0.98

Coagulation profile in adult patients with porto-sinusoidal vascular disease

Sidharth Harindranath[1], Ankita Singh[1], Kashmira Kawli[1], Aditya Kale[1], Akash Shukla[1]. [1]*King Edward Memorial Hospital, Gastroenterology, Mumbai, India*
Email: drakashshukla@yahoo.com

Background and aims: Porto-sinusoidal vascular disease is a recently described clinical entity that includes non-cirrhotic portal fibrosis, idiopathic portal hypertension, non-cirrhotic intrahepatic portal hypertension and various overlapping histological patterns. The proposed aetiologies of this conditions is wide including autoimmune conditions, genetic disorders and thrombophilic states. We decided to study the clinical profile and prevalence of thrombophilic conditions in patients with PSVD at our centre.

Method: It was a single centre prospective study conducted over a period of 12 months. 69 consecutive patients were identified meeting the inclusion criteria of PSVD as defined by the recent BAVENO VII guidelines. Clinical, biochemical, and imaging findings were recorded. Thrombophilia profile was done in all patients which included analysis for MTHFR mutation, prothrombin gene mutation, factor V Leiden mutation, JAK2 mutation, estimation of level of homocysteine, Anti-thrombin III, protein C, protein S, APLA and ACLA

antibody levels and flow cytometry for PNH. Bone marrow aspiration with biopsy was done where indicated.
Results: Forty patients (58%) were male with a median age of 37 years (18–61). Common presentations were gastrointestinal bleed in 27 (39.1%), symptomatic splenomegaly in 27 (39.1%) and transient but clinically significant ascites in 20 (28.9%) patients. Twenty two patients (31.8%) were incidentally detected. Evidence of portal hypertension was seen in 62 (89.1%) patients. Portal vein thrombosis was seen in 13 (18.8%) patients. Superior mesenteric vein and splenic vein thrombosis was seen in 4 (5.7%) and 3 (4.3%) patients respectively. Twenty three patients (33.3%) had one or more thrombophilic disorders. Four patients (5.7%) had more than two thrombophilic disorders. Anti-phospholipid antibodies was the most common thrombophilic condition seen in 16 (69.5%), followed by MTHFR mutation in 8 (34.7%), low protein S in 6 (26%), low protein C in 5 (21.7%), prothrombin mutation in 5 (21.7%), JAKV617F mutation in 3 (13%), hyperhomocysteinemia, lupus anticoagulant and antithrombin III deficiency in 1 (4.3%) patient each. Symptomatic splenomegaly was seen significantly more commonly in males than in females (p = 0.003). MTHFR mutation was seen more commonly in patients who presented later (age > 35 years). Patients with one or more thrombophilic disorders had a higher incidence of splanchnic venous thromboses like superior mesenteric vein and/or splenic vein thrombosis (p = 0.034) and had a higher chance of presenting with variceal bleeding (p = 0.07).

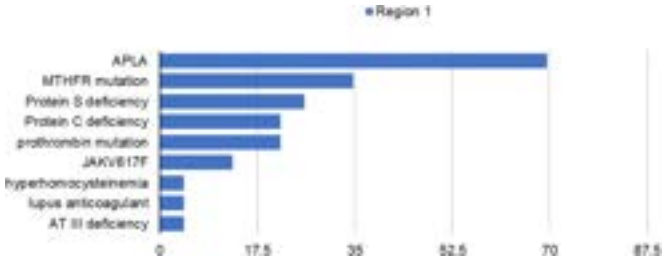

Figure:

Conclusion: PSVD is a distinct and all encompassing clinical entity with varied clinical manifestations. Association of prothrombotic conditions with this disorder has been established. One or more thrombophilic states can be seen in upto 30% of patients. These patients had a higher chance of presenting with splanchnic venous thrombosis and variceal bleeding. Hence all adult patients with PSVD should undergo thrombophilic workup as presence of thrombophilic risk factor like anti-phospholipid antibodies and JAK2 mutation may require additional therapy.

SAT-543

Continuous terlipressin infusion improves muscle function but not muscle mass in patients with cirrhosis and portal hypertension

Ryma Terbah[1,2], Darren Wong[1,2], Paul Gow[1,2], Avik Majumdar[1,2], Brooke Chapman[1,2,3], Adam Testro[1,2], Marie Sinclair[1,2]. [1]*Austin Health, Department of Gastroenterology and Liver Transplant Unit, Melbourne, Australia;* [2]*The University of Melbourne, Department of Medicine, Melbourne, Australia;* [3]*Austin Health, Department of Nutrition and Dietetics, Australia*
Email: rterbah@hotmail.com

Background and aims: Sarcopenia is highly prevalent in patients with cirrhosis and is associated with increased morbidity and mortality both pre- and post-liver transplant. It tends to progress with increasing severity of liver disease and has few treatment options. We have previously shown that terlipressin, a vasopressin analogue, can improve handgrip strength (HGS), but there remains little data on the impact of terlipressin on muscle mass and function.
Method: In this single-centre, prospective study, a continuous infusion of terlipressin 3.4 mg daily was given for 12 weeks to adult patients with cirrhosis, diuretic-refractory ascites, and sarcopenia. Muscle function was assessed using three HGS measurements in the non-dominant hand and the Liver Frailty Index (LFI). Muscle mass was evaluated using dual x-ray absorptiometry (DEXA) appendicular lean mass (APLM) and CT skeletal muscle index (SMI) at the level of the L3 vertebra. Assessments were performed at baseline and at the end of treatment.
Results: Twenty-three patients have completed study to date. The majority were male (n = 15, 65%) and the median age was 62 years (IQR 57–64 years). The most common aetiology of cirrhosis was alcohol (n = 9, 39.1%), followed by NASH (n = 7, 30.4%), chronic hepatitis C (n = 4, 17.4%), cryptogenic (n = 2, 8.7%), and chronic hepatitis B and delta co-infection (n = 1, 4.3%). The median MELD score at enrolment was 16 (12.5–17.5). Muscle function improved after terlipressin therapy. The maximum HGS recording increased from 27.5 kg (21.2–31.6 kg) to 28.4 kg (21.8–34.2 kg), p = 0.012, and the mean HGS increased from 25.9 kg (20–29.6 kg) to 27.8 kg (20.9–31.8 kg) p = 0.021. There was also a significant improvement in the liver frailty index from 4.25 (3.88–4.50) to 4.02 (3.69–4.28), p = 0.01. The SMI increased slightly from 46 cm^2/m^2 (42–54 cm^2/m^2) to 47 cm^2/m^2 (42–51 cm^2/m^2), however this was not significant (p = 0.2). DEXA APLM decreased from 7.53 kg/m^2 (6.22–8.30 kg/m^2) to 7.09 kg/m^2 (6.04–7.78 kg/m^2) but was not significant (p = 0.07). Of the APLM, the DEXA lower limb lean mass decreased from 16.54 kg (14.14–19.96 kg) to 15.58 kg (14.06–17.72 kg) (p = 0.008), but the lean mass in the upper limb, which is less affected by peripheral oedema, increased from 5.13 kg (4.52–5.54 kg) to 5.22 kg (4.64–5.59 kg) (p = 0.4).

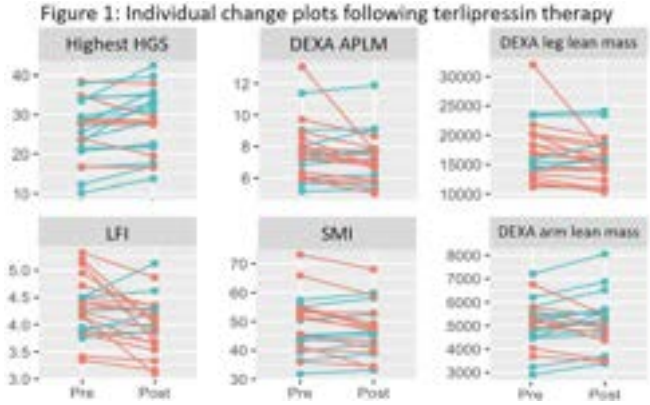

Figure 1:

Conclusion: In a sick cohort of cirrhotics for whom muscle function tends to steadily decline, 12 weeks of terlipressin therapy significantly improved muscle function and reduced frailty. While not statistically significant in this small cohort, the trend towards improvement in SMI and DEXA arm lean mass warrants further investigation with larger and longer studies, given muscle mass tends to take longer to increase than improvements in muscle function. This study provides a promising new therapy for sarcopenia in the sickest cohort of chronic liver disease patients.

SAT-544

Predicting the efficacy of splenic embolization on refractory ascites using a computational model of portal hypertension

Nikhilesh Mazumder[1], Filip Jezek[2], Elliot Tapper[1], Daniel Beard[2]. [1]*University of Michigan Hospital, Gastroenterology and Hepatology, Ann Arbor, United States;* [2]*University of Michigan, Department of Molecular and Integrative Physiology, Ann Arbor, United States*
Email: mazumde@med.umich.edu

Background and aims: Ascites is the most common cause of decompensation among patients with cirrhosis and carries a high morbidity and mortality rate. When refractory, splenic artery

embolization is often offered to patients not eligible for liver transplantation or transjugular intrahepatic portosystemic shunt (TIPS) creation, however its effect on ascites volume varies among patients. The objective of this study was to utilize a computational model of portal hypertension to simulate the effect of splenic embolization on portosystemic gradient (PSG) and ascites volume in different patients.

Method: We developed model of isolated portosplanchnic hemodynamics. This model consists of resistive components in series (intestinal arteries and veins, liver, hepatic vein) and a model of ascites generation (adapted from Levitt and Levitt. *BMC Gastroenterol.* 2012). We then modeled portosystemic collateral shunts with a diameter proportional to its pressure gradient. With increasing luminal diameter, larger amounts of portal flow is shunted, altering the hemodynamics. We then gradually increased intrahepatic resistance to model the progression of liver disease and simulated the steady state ascites volume at each stage. Splenic artery (SA) embolization was simulated by dropping portal inflow by 40% and the resulting effect on portosystemic gradient (PSG) and steady state ascites volume was compared across various levels of portosystemic collateralization.

Results: Representative cases comparing a no-shunt to a shunt case are displayed in the Figure with an end stage marked by the orange line. As liver disease progressed, patients with increased shunting (Fig. A, open red boxes) had a more gradual rise in PSG compared to patients without any shunting (Fig. A, open blue circles). At the same liver resistance (orange line), the end stage of disease resulted in a PSG of 25 vs 18 mmHg. Similarly, patients with shunts had lower ascites volumes at all stages (Fig. B, red crosses) with end stage patients attaining a steady state volume of 6L compared to 12L in the patients without collaterals. PSG was reduced by the same percentage regardless of shunt status, but the absolute drop was greater in patients with fewer shunts (Fig. A). Most notably, in patients with more portosystemic shunting splenic embolization was less effective at improving ascites volume compared to the no shunt case (Fig. C) with an average drop in steady state ascites volume of 3.5 vs 9.6 L.

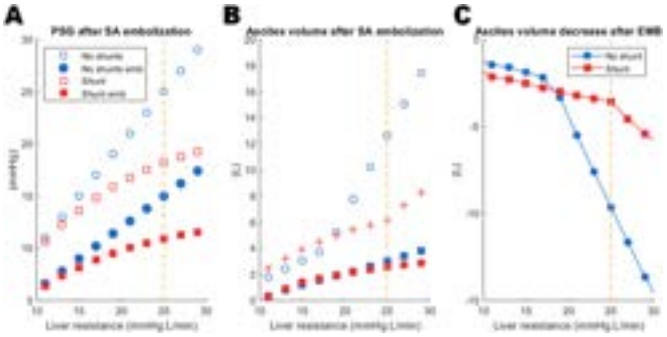

Figure:

Conclusion: We developed a computational model for portal hypertension that demonstrates varying trajectories dependent on the quantity of portosystemic shunting. This model also shows the importance of portosystemic shunting on the severity of ascites and the effectiveness of splenic artery embolization. Such computational models may provide an explanation for heterogenous effects of this intervention in patients with ascites. Future work should seek to fit computational models to individual patients in order to personalize care of portal hypertension.

SAT-545

Administration of Lactulose, Rifaximin, or combination therapy for hepatic encephalopathy is associated with a reduction in gastrointestinal cancers

Ankoor Patel[1], You Li[2], Carlos Minacapelli[2], Carolyn Catalano[2], Vinod Rustgi[2]. *[1]Rutgers-Robert Wood Johnson Medical School, Medicine, New Brunswick, United States; [2]Rutgers-Robert Wood Johnson Medical School, Gastroenterology and Hepatology, United States*
Email: ahp60@rwjms.rutgers.edu

Background and aims: Patients with cirrhosis are frequently administered rifaximin and/or lactulose for prevention and treatment of hepatic encephalopathy (HE). Both rifaximin and lactulose theoretically have anti-cancer effects. The risk of GI cancers in patients with cirrhosis on lactulose, rifaximin, and/or combination therapy has not been evaluated.

Method: A retrospective cohort study was conducted using the Truven Health MarketScan® Commercial Claims database from 2007 to 2017. Patients with cirrhosis were identified using ICD-9/10 codes. An index date was defined for each participant as the earliest date of cirrhosis diagnosis. A baseline period for each participant was defined as the twelve months prior to the first medication date while the study follow-up period represented the period form the first medication date to the last medication date. Patients with history of any cancer before the first medication date were excluded from the study. Student's t tests were used to compare all continuous measures of age and duration of medication. Wald Chi-square tests were performed to test the associations between the study groups.

Results: The rifaximin only cohort had the lowest risk of developing colon cancer (rifaximin only vs lactulose plus rifaximin vs lactulose only (0.28% vs 0.56% vs 0.69%; $p < 0.0001$), esophageal cancer (0.08% vs 0.19% vs 0.27%; $p < 0.0001$), and stomach cancer (0.0% vs 0.15% vs 0.31%; $p < 0.0001$).

Conclusion: Colon, esophageal, and gastric cancers had an incidence reduction in the rifaximin only cohort compared to the lactulose only and lactulose plus rifaximin cohorts. Further studies are required to understand the mechanisms by which rifaximin may exert anti-cancer properties.

Table 1. (abstract: SAT-545): Development of GI cancer in the Lactulose only, Rifaximin only, and Lactulose plus Rifaximin cohorts in the follow-up period.

Development of Cancer:	Total	Lactulose only	Rifaximin only	Lactulose only vs Rifaximin only	Lactulose plus rifaximin combination therapy	Lactulose only vs Rifaximin only vs Lactulose plus rifaximin

Use and impact of transjugular intrahepatic portosystemic shunt: a twelve-year nationwide study in Germany

Wenyi Gu[1], Yasmin Zeleke[2], Hannah Hortlik[2], Louisa Schaaf[2], Frank Erhard Uschner[1], Martin Schulz[1], Michael Tischendorf[1], Kai-Henrik Peiffer[2], Maximilian Joseph Brol[1], Markus Kimmann[1], Thomas Vogl[2], Michael Köhler[1], Carsten Meyer[3], Alexander Gerbes[4], Martin Rössle[5], Wim Laleman[6], Alexander Zipprich[7], Christian Steib[3], Michael Praktiknjo[1], Jonel Trebicka[1]. *[1]University Hospital Muenster, Germany; [2]University Hospital Frankfurt, Germany; [3]University Hospital Bonn, Germany; [4]University Clinic Munich LMU, Germany; [5]Medical Centre University of Freiburg, Germany; [6]University Hospitals Leuven, Germany; [7]Jena University Hospital, Germany*
Email: jonel.trebicka@ukmuenster.de

Background and aims: Portal hypertension (PHT) is the driver of many complications in liver cirrhosis. The number of cirrhosis cases as well as diagnosis of PHT-driven complications have increased over time. Transjugular intrahepatic portosystemic shunt (TIPS) placement is the most effective treatment of PHT. The aim of this study was to analyze the use and impact of TIPS placement in patients with different portal hypertensive complications during the last decade in a German nationwide study.
Method: We analyzed 14,598 admissions of patients for TIPS insertions in Germany from 2007 to 2018 using the DRG system. 1,987,888 admissions of cirrhotic patients did not have TIPS placement and were compared in the analysis as a control group. All diagnoses and procedures were coded according to ICD-10-CM and OPS code. The data were analyzed focusing on the number of admissions and in-hospital mortality in patients admitted for TIPS.
Results: The number of admissions of patients received TIPS insertion increased from 439 in 2007 to 2,037 in 2018. The vast majority ([88.7%] 12,948) of patients received TIPS in the observational 14 years had cirrhosis. The survival of cirrhotic patients with ascites and HRS increased significantly from TIPS insertions by 6.1% and 24.4%, respectively, compared to patients without TIPS. In cirrhotic patients with gastrointestinal bleeding, TIPS significantly decrease their in-hospital mortality with concomitant ascites or hepatorenal syndrome (HRS). 22.6% of patients with TIPS insertion developed hepatic encephalopathy (HE). However, compared to cirrhotic patients without TIPS, TIPS improved the survival of patients with HE grades-1 and -2 as comorbidity by 10% and 33%, respectively. In the logistic regression, higher HE grade (-3 and -4), as well as infection and circulatory diseases (including any forms of diseases of the circulatory system excluded ischemic heart diseases) are found independently associated with in-hospital death in patients with TIPS. Furthermore, TIPS and TIPS revision were independently associated with improved in-hospital survival in cirrhotic patients (Figure).

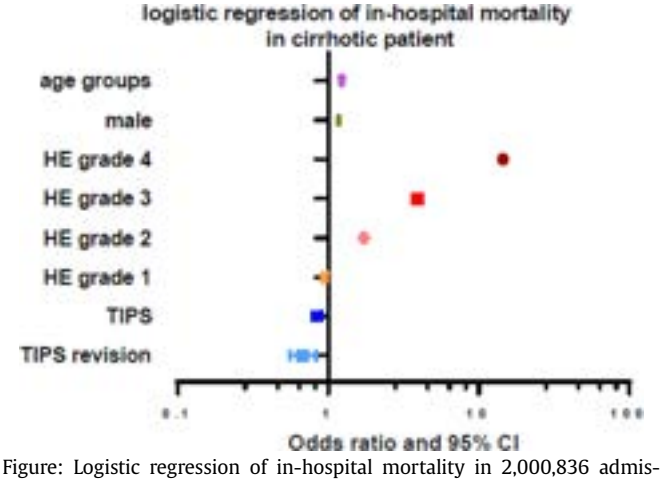

Figure: Logistic regression of in-hospital mortality in 2,000,836 admissions of patients with liver cirrhosis

Conclusion: Our nationwide population-based study demonstrates that TIPS insertion is more frequently used, and it improves outcomes, especially in patients with ascites and HRS. In gastrointestinal bleeding, the effect is significant only when ascites and/or HRS is present. TIPS is beneficial with regard to better survival despite lower HE grades, while higher grade HE, infection and circulatory diseases seem to be associated with risk of in-hospital mortality.

SAT-547

Spontaneous portosystemic shunts (SPSS) regress after transjugular intrahepatic portosystemic shunt (TIPS) implantation

Theresa Bucsics[1,2], Katharina Lampichler[2,3], Maria Schoder[3], Lukas Reider[3], Konstantin Vierziger[4], Lukas Hartl[1,2], David Jm Bauer[1,2], Mathias Jachs[1,2], Georg Semmler[1,2], Rafael Paternostro[1,2], Philipp Schwabl[1,2,5], Lorenz Balcar[1,2], Katharina Pomej[1,2], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2,5]. *[1]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Wien, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Department of Intermal Medicine III, Division of Gastroenterology and Hepatology, Wien, Austria; [3]Medical University of Vienna, Department of Biomedical Imaging and Image-Guided Therapy, Wien, Austria; [4]Klinik Favoriten-Wiener Gesundheitsverbund, Department of Radiology, Vienna, Austria; [5]Medical University of Vienna, Christian-Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Wien, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: The impact of transjugular intrahepatic portosystemic shunt (TIPS) on the evolution of spontaneous portosystemic shunts (SPSS) has not been systematically evaluated.
Method: Ninety-one patients with paired contrast-enhanced CT scans pre and post TIPS were included. The presence of small (S-SPSS, 3–8 mm) and large SPSS (L-SPSS, ≥8 mm) as well as total cross-sectional diameter and area of all SPSS were evaluated. A semiquantitative visual SPSS score was applied: (Coll-0) no, (Coll-1) one S-SPSS, (Coll-2) 2–3 S-SPSS; (Coll-3) ≥4 S-SPSS or 1 L-SPSS.
Results: Median total SPSS diameter and area significantly decreased after TIPS from 14 mm [10–19] to 6 mm [3–10; $p < 0.0001$] and from 69.9 cm^2 [33.8–523.1] to 15.7 cm^2 [7.1–412.3; $p < 0.0001$], respectively. The proportion of patients with pre-TIPS L-SPSS decreased from 45.1% (n = 41/91) to 19.8% (18/91; $p < 0.001$), and the proportion of patients with Coll-3 from 85.7% to 51.6% ($p < 0.001$). Patients with persisting L-SPSS (or a post-TIPS visual SPSS score of 3) showed a significantly shorter transplant-free survival than those with only few S-SPSS or improvement of SPSS (median 30.0 vs 84.0 months, log-rank p = 0.011 and median 53.0 vs 115.0 months, p = 0.037, respectively).

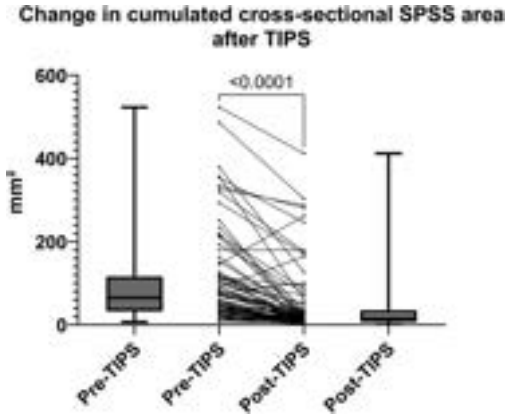

Figure:

Conclusion: TIPS implantation ameliorates the extent of SPSS. While large SPSS regress in a considerable number of patients, their persistence after TIPS is linked to an increased risk of mortality.

SAT-548

Predicting post-TIPSS mortality: external validation of the FIPS score in a Canadian cohort

Shamir Malik[1], Arash Jaberi[2], Sebastian Mafeld[2], Bettina Hansen[3], Morven Cunningham[4], Jordan J. Feld[4], Scott K Fung[4], Aliya Gulamhusein[4], Keyur Patel[4], David Wong[4], Gideon Hirschfield[4], Ann T Ma[4]. *[1]Faculty of Medicine, University of Toronto, Canada; [2]JDMI, University Health Network, Toronto, Canada; [3]Institute of Health Policy, Management and Evaluation, University of Toronto, Canada; [4]Toronto Centre for Liver Disease, University Health Network, Toronto, Canada*
Email: ma.ann.thu@gmail.com

Background and aims: The Model for End-Stage Liver Disease (MELD) score was originally developed to predict mortality post-transjugular intrahepatic portosystemic shunt (TIPSS) insertion. A new prognostic score, the "Freiburg index of post-TIPSS survival" (FIPS) score, has emerged and includes age, serum creatinine, bilirubin and albumin. Preliminary data suggest FIPS outperforms MELD in predicting mortality in certain European and Asian cohorts, while a recent US Veterans Affairs (VA) study did not. We aimed to validate its use in a single-centre cohort in Canada.

Method: This retrospective cohort study included patients who underwent TIPSS insertion between 2010 and 2021 at the University Health Network in Toronto. Prognostic scores including MELD, MELD-Na and FIPS were obtained within 3 months prior to TIPSS insertion. Patients were followed for up to 12 months post-TIPSS. Patients who were lost to follow-up within the first 90 days post-TIPSS were excluded. The performance of prognostic scores at 90 days post-TIPSS was assessed by area under the receiver operating characteristic curve (AUROC).

Results: A total of 129 patients were included (median age 58, 46% male). The indication for TIPSS placement was refractory ascites in 64%, variceal bleeding in 26%, hydrothorax in 5%, hepatorenal syndrome in 4% and portal vein thrombosis in 1%. TIPSS insertion was done in an emergent setting in 19%. The main etiologies of liver disease were alcohol in 46%, autoimmune in 16% and non-alcoholic fatty liver disease in 15%. The median [P25-P75] MELD, MELD-Na and FIPS scores before TIPSS were 15 [12–17], 16 [13–19] and 0.30 [−0.24–0.69], respectively. At 90 days, 6 patients had died (7%), while none had undergone liver transplant. The performance of all prognostic scores to predict 90-day mortality was poor (AUROC 0.54, 0.47 and 0.60 for MELD, MELD-Na and FIPS, respectively). However, using the FIPS cut-off of 0.92 as reported in the original derivation cohort, patients with a high FIPS score had significantly poorer 90-day survival compared to those with a low FIPS score (84% vs 97% respectively, p = 0.04) (Figure).

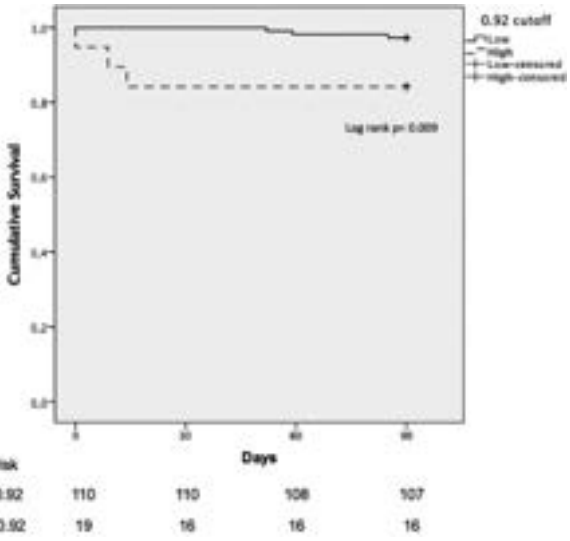

Figure: 90-day survival post TIPSS of patients with high FIPS (≥0.92, dashed line) and low FIPS (<0.92, solid line).

Conclusion: The FIPS score failed to outperform traditional risk scores in predicting post-TIPSS survival in this single-centre Canadian cohort. However, the use of a single FIPS cut-off point was useful in identifying patients at higher risk of mortality. The recent VA study presented important results in a specific population, and further validation of the FIPS score in large, diverse cohorts is still required.

SAT-549

Clinical practice results of the use of intrahepatic portosystemic shunt for the treatment of refractory hepatic hydrothorax

Elena Tenorio González[1], Enrique Pérez-Cuadrado Robles[1], Rocio González-Grande[2], Miguel Jiménez-Pérez[2]. *[1]Georges-Pompidou European Hospital, AP-HP, Paris, France; [2]Regional University Hospital, Málaga, Spain*
Email: etengo89@gmail.com

Background and aims: Technical advances and accumulated experience in the placement of intrahepatic portosystemic shunt (TIPS) in patients with endoscopically uncontrolled gastrointestinal bleeding have allowed their use in other less predominant indications for which there is less data. Refractory hepatic hydrothorax (RHH) is defined as that which either does not respond to treatment with diuretics at maximum doses (spironolactone 400 mg/day and furosemide 160 mg/day) or develops complications derived from their use, and therefore requires periodic thoracentesis for its control. We analyzed the results obtained in terms of clinical success and survival in patients with RHH treated at a tertiary hospital.

Method: Single center cohort retrospective study. Patients who required TIPS placement due to RHH between January 2011 and December 2019 was included, with the last prospective review of the status of the patients being in August 2022. Baseline analytical data and clinical and radiological follow-up data were analyzed at 1, 3, 6, and 12 months after TIPS placement, as well as until death or liver transplantation (if this occurred). Matching techniques were performed for the descriptive analysis of the results, taking into account the cases lost due to loss of follow-up, transplantation or exitus.

Results: Among 83 patients who required TIPS placement during this period of time, 7 were due to HRH. Only one patient required posterior thoracentesis during the first month after TIPS placement due to persistent severe hydrothorax. No patient required further thoracentesis to control hydrothorax after 3, 6, or 12 months (Table 1). However, it should be noted that all the patients had previous ascites, and the ascites resolved in 4 of them (57.1%) during the first year of follow-up. 85.7% of patients (n = 6) required, however, associated diuretics to control hydrothorax. It should be noted that at 6 months

Table 1(abstract: SAT-549).

	Clinical and radiologic (chest X-ray) follow-up							
	1 month		3 months		6 months		12 months	
	Frequency	Percentage	Frequency	Percentage	Frequency	Percentage	Frequency	Percentage
No hydrotorax	0	0	1	16.7	3	75	2	66.7
Mild hydrotorax	0	0	4	66.7	1	25	1	33.3
Moderate hydrotorax	6	85.7	1	16.7	0	0	0	0
Severe hydrotorax	1	14.3	0	0	0	0	0	0
Survival rate								
After liver transplantation	0	0	0	0	1	14.3	1	14.3
Without liver transplantation	7	100	7	100	5	71.4	4	57.1

the best results are observed due to máximum improvement in hyperdynamic circulation thanks to the TIPS. Thus, there is a 12-month survival of 71.4%, being 57.1% without the need for liver transplantation and 14.3% thanks to transplantation.

Conclusion: These data allow us to corroborate that the placement of TIPS is effective and safe in the treatment of RHH, with a gradual improvement in hydrotorax during the first year of follow-up, which is accompanied by an improvement in ascites when associated and, with it, of their MELD score, sometimes avoiding the need for transplantation and increasing their survival.

SAT-550

Detection of minimal hepatic encephalopathy: standardization of psychometric hepatic encephalopathy scale for Israeli population

Nave Firestein[1], Niv Zmora[2,3,4], Nir Bar[2,3], Oren Shibolet[2,3], Helena Katchman[2,3]. *[1]Barzilai Medical Center, Israel; [2]Tel Aviv University, Israel; [3]Tel Aviv Sourasky Medical Center, Israel; [4]Tel Aviv Sourasky Medical Center-Ichilov, Department of Gastroenterology and Hepatology, Tel Aviv-Yafo, Israel*
Email: hkatchman@gmail.com

Background and aims: Minimal hepatic encephalopathy (MHE) is a subclinical form of hepatic encephalopathy (HE) that leads to decreased quality of life and increased incidence of overt HE in cirrhotic patients. Psychometric hepatic encephalopathy scale (PHES) is the gold standard for MHE diagnosis, but its use requires adjustment to population-specific norms of performance. The aim of this study was to construct and validate a set of normal values for PHES in an Israeli population.

Method: PHES tests (NCT-A, NCT-B, DST, SDT and LTT) were performed on 189 healthy volunteers and 63 cirrhotic patients, and possible confounding factors, including age, gender and years of education, were assessed. Linear regression models were computed on the healthy cohort to generate confounder-adjusted equations for each of the PHES components. Reference values were then calculated for the cirrhotic patients with suspected MHE and Z-scores determined. Flicker and ICT tests were also performed in cirrhotic patients and their correlations with PHES results were evaluated.

Results: Age was correlated with all 5 components of PHES and education level was only correlated with NCT-A, NCT-B and DST results. No correlation between gender and test results was noted in our population. Adjusted Z-scores were calculated (figure 1A) and found to be in closest correlation to Chinese scores (figure 1B). Among 45 cirrhotic patients without previous overt HE, MHE was diagnosed in 22 (49%), 17 (38%) and 22 (49%) patients using PHES, ICT or Flicker respectively. There was a statistically significant agreement on MHE diagnosis between Flicker and ICT tests and PHES results (figure 1C). In addition, PHES results correlated to patients' MELD-Na scores (figure 1D).

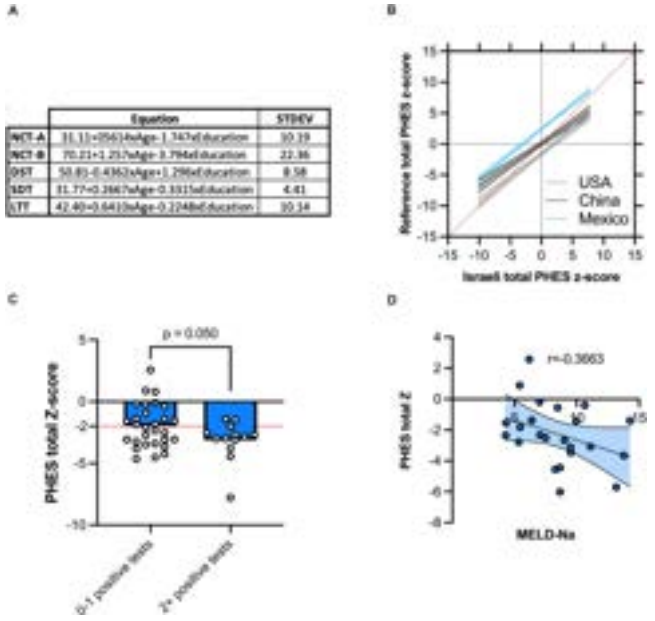

Figure: Calculation of adjusted Z-scores (A) and evaluation of PHES for Israeli population. Correlation to other national PHES norms (B), other MHE tests (C) and MELD-Na score (D).

Conclusion: Norms for PHES tests were generated and validated, demonstrating a good diagnostic capability, a fair agreement with ICT and Flicker tests and a correlation to liver disease severity.

SAT-551

Impact of non-selective beta-blockers on first and further hepatic decompensation after transjugular intrahepatic portosystemic shunt insertion

Anja Tiede[1], Jim Benjamin Mauz[1], Lena Stockhoff[1], Hannah Schneider[1], Bernhard Meyer[2], Heiner Wedemeyer[1,3], Markus Cornberg[1,3,4], Jan Hinrichs[2], Tammo Lambert Tergast[1], Benjamin Maasoumy[1,3]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]Hannover Medical School, Department of Diagnostic and Interventional Radiology, Hannover, Germany; [3]German Center for Infection Research (DZIF), Braunschweig, Germany; [4]Center for Individualised Infection Medicine (CIIM), c/o CRC Hannover, Hannover, Germany*
Email: tiede.anja@mh-hannover.de

Background and aims: Treatment with non-selective beta-blockers (NSBB) is linked to a lower risk of hepatic decompensation in patients with liver cirrhosis and portal hypertension. These positive effects of NSBB do not directly correlate with the decrease of portal pressure and are even present if portal pressure remains unaffected. So far, little is known about the impact of NSBB therapy on the outcome of patients after insertion of a transjugular intrahepatic portosystemic

shunt (TIPS). In this study we aimed to investigate the role of NSBB treatment in preventing first and further hepatic decompensation after TIPS.

Method: A number of 366 consecutive patients receiving a TIPS between 2009 and 2021 were considered. Patients with Budd-Chiari syndrome, absence of liver cirrhosis, history of liver transplantation (LTx), cystic fibrosis, or those receiving a rescue TIPS were excluded. First and further hepatic decompensation (HD) were assessed according to the Baveno VII criteria. After evaluating the impact of NSBB intake at TIPS insertion on the occurrence of periinterventional HD, patients were followed up for one year after hospital discharge with continuous reassessments of NSBB status. Link between NSBB intake and development of HD as well as LTx-free survival was tested using multivariable competing risk and cox regression analysis, adjusting for FIPS score, TIPS indication refractory ascites and Cholinesterase (CHE).

Results: Overall, 176 (57.3%) of the included 307 patients received NSBB therapy prior to TIPS insertion. Patients in the NSBB group had lower FIPS- (−0.25 vs − 0.15, p = 0.001) and MELD scores (11 vs 13, p = 0.008) and a higher CHE (2.63 vs 2.13, p < 0.001). Refractory ascites for TIPS indication was more common in the no-NSBB group (94.7% vs 71.0%, p < 0.001).

In the periinterventional period, NSBB therapy at TIPS insertion had no significant impact on the development of first or further HD (first: n = 34, NSBB/no-NSBB 16/18; p = 0.21; further: n = 77, 38/39, p = 0.10). Most common first and further HD was hepatic encephalopathy (HE, n = 18) and acute kidney injury (n = 46), respectively.

At time of discharge, 132 patients (43.0%) still received NSBB therapy, 37 of whom stopped NSBB therapy before end of follow-up. After discharge, ascites (n = 66/127 first HD) and HE (n = 55/119 further HD) were the respective predominant HD. While NSBB therapy was associated with a lower risk for first and further HD in univariable competing risk analysis (first: HR 0.625, p = 0.01; further: HR 0.588, p = 0.005), this did not remain statistically significant in multivariable analysis (HR 0.787, p = 0.23; HR 0.729, p = 0.12). NSBB intake was also not linked to a higher LTx-free survival in multivariable analysis (HR 0.610, p = 0.16).

Conclusion: NSBB therapy at TIPS insertion and its (dis-)continuation afterwards has no significant impact on the development of first and further hepatic decompensation after TIPS.

SAT-552

Audit assessing real-world incidence of adverse events and mortality rate in patients receiving Terlipressin for hepatorenal syndrome at Royal Free hospital

Naz Kanani Alviri[1], Fatema Jessa[1], David Patch[2]. [1]*Royal Free Hospital, Pharmacy, London, United Kingdom;* [2]*Royal Free Hospital, Hepatology, London, United Kingdom*
Email: naz.kanani@nhs.net

Background and aims: Hepatorenal Syndrome-Acute Kidney Injury (HRS-AKI) involves an acute onset of renal dysfunction on a background of decompensated cirrhosis and ascites, and is associated with high mortality. Terlipressin (TRL), a synthetic vasopressin analogue, is widely used in the management of HRS-AKI to cause vasoconstriction of the splanchnic circulation and improve renal perfusion. In September 2022, the European Medicines Agency issued an alert regarding a higher than previously known risk of respiratory failure and a new risk of sepsis associated with TRL. An audit was carried out in Royal Free Hospital (RFH) in London with the aim of assessing the real-world incidence of adverse events and mortality rate in patients who received TRL for HRS-AKI.

Method: All patients initiated on TRL for HRS-AKI between April 2018 and October 2022 at RFH were investigated retrospectively. Data from electronic dispensing records, clinical documentation, prescription charts and discharge letters were used to determine diagnosis of HRS-AKI, the incidence of respiratory failure, respiratory distress, sepsis and mortality rate within 90 days of receiving the first dose of TRL.

Results: A total of 37 patients received TRL. The mean age was 52.8 years with a Male:Female ratio of 25:12. Within 90 days of the first dose of TRL, respiratory failure was reported in 19% (7), respiratory distress in 14% (5), and sepsis in 11% (4) of patients. Additionally, cardiac rhythm abnormalities were seen in 5% (2). A total of 46% (17) patients experienced adverse reactions; in which 90-day survival was 41% (7). Overall, a mortality rate of 49% (18) was observed. 8% (3) underwent liver transplantation.

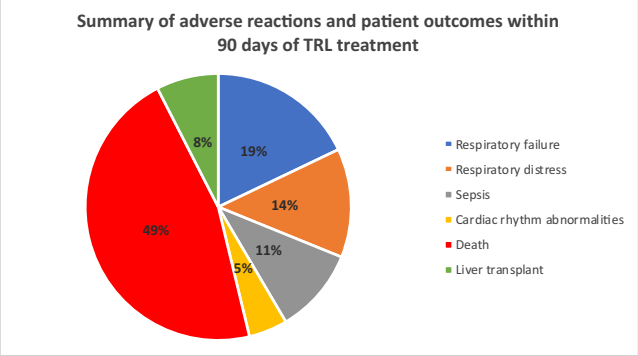

Figure:

Conclusion: Almost half of patients receiving TRL for hepatorenal syndrome experienced adverse reactions within 90 days of the first dose. High mortality was observed at a similar incidence to that in recently published research. Limitations of the audit include varying treatment duration, dosing, method of administration and concomitant human albumin solution. Additionally, severity of clinical presentation and multimorbid state differed within the patient group. Therefore, a larger sample is required to estimate causality, and safety of TRL. Due to risk of sepsis, respiratory failure and respiratory distress, it is advised to monitor patients for signs of infection and stabilise any respiratory symptoms prior to initiating TRL.

SAT-553

Collagen-proportionate area determined by semiautomated histomorphometry correlates with HVPG across different liver disease etiologies

Thomas Sorz[1,2,3], Benedikt Simbrunner[1,2,3,4], Kerstin Zinober[1,3,4], Georg Semmler[1,4], Philipp Königshofer[1,3,4], Christopher Kaltenecker[5], Benedikt Hofer[1,2,3,4], Behrang Mozayani[5], Vlad Taru[1,3], Renate Kain[5], Michael Trauner[1], Mattias Mandorfer[1,4], Philipp Schwabl[1,2,3,4], Thomas Reiberger[1,2,3,4]. [1]*Medical University of Vienna, Department of Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria;* [2]*Center for Molecular Medicine (CeMM), Vienna, Austria;* [3]*Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria;* [4]*Medical University of Vienna, Department of Medicine III, Vienna Hepatic Hemodynamic Laboratory, Vienna, Austria;* [5]*Medical University of Vienna, Department of Pathology, Vienna, Austria*
Email: thomas.sorz@meduniwien.ac.at

Background and aims: Liver fibrosis represents the main static component of portal hypertension (PH). The gold-standard of sinusoidal PH evaluation in advanced chronic liver disease is the measurement of the hepatic venous pressure gradient (HVPG). Digital histomorphometry allows quantification of collagen proportionate area (CPA) on liver biopsies. We aimed (i) to assess the correlation between CPA and HVPG across different etiologies and (ii) to compare the diagnostic performance of CPA and liver stiffness measurement (LSM) for clinically significant portal hypertension (CSPH).

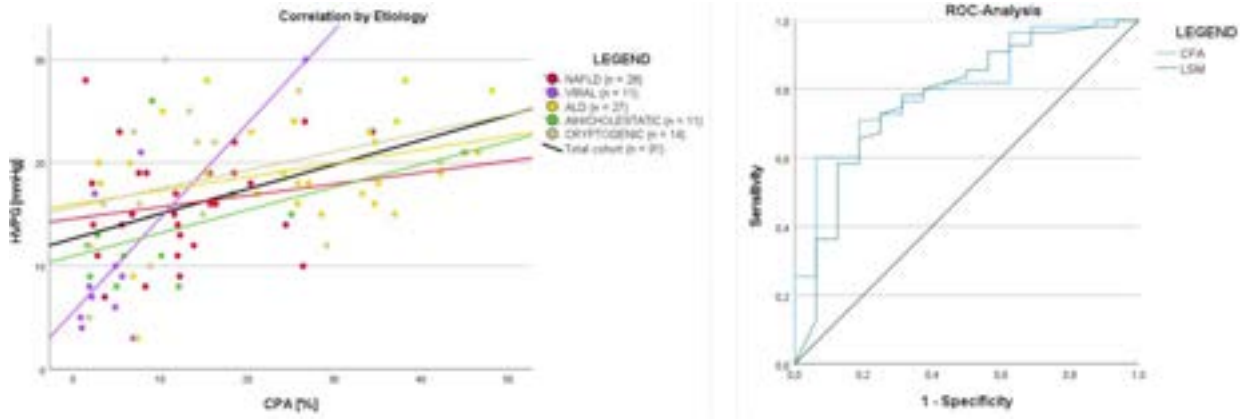

Figure: (abstract: SAT-553).

Method: Patients undergoing liver biopsy with available data on same-day measurement of HVPG were included in this study. The biopsies were stained with picro-sirius-red (PSR) and digitalized with a slide scanner. HALO software (Indica Labs) was used for CPA morphometry. The data for HVPG, LSM, enhanced liver fibrosis (ELF) score, platelet count, MELD and Child-Pugh score were extracted from medical records. Correlations were analyzed using Spearman's Rho (r) coefficient. The performance of CPA to diagnose CSPH was evaluated via ROC analysis and optimal cutoffs were determined by Youden's index.
Results: 91 patients with a median HVPG of 17 (IQR: 10) mmHg (n = 72, 79.1% had CSPH) and a median CPA of 12.1 (IQR: 20) % were included. The liver disease etiologies were: alcohol-related liver disease (ALD; n = 27, 29.7%), non-alcoholic fatty liver disease (NAFLD; n = 28, 30.8%), viral hepatitis (n = 11, 12.1%), cryptogenic fibrosis (n = 14, 15.4%) and AIH/cholestatic disease (n = 11, 12.1%). CPA significantly correlated with HVPG (r = 0.494, p < 0.001), LSM (r = 0.478, p < 0.001), ELF (r = 0.433, p < 0.001) and MELD (r = 0.356, p < 0.001). Importantly, the correlation coefficient of CPA-to-HVPG was distinct for the various etiologies: r = 0.185 for ALD, r = 0.545 for viral hepatitis, r = 0.149 for NAFLD, r = 0.420 for AIH/cholestatic liver disease and r = 0.335 for cryptogenic liver disease. LSM (available in n = 71) showed a similarly high correlation with HVPG (r = 0.410, p < 0.001). CPA diagnosed CSPH with an area under the curve (AUC) of 0.801 (p < 0.001), with a Youden's index-based CPA cutoff at 12.24% (sensitivity: 60%, specificity: 93.75%). LSM yielded a similar AUC of 0.770 (p = 0.003) for diagnosis of CSPH and had a sensitivity of 72.7% and a specificity of 75% using a cut-off at 23.5 kPa.
Conclusion: CPA is a valuable and investigator-independent diagnostic tool for quantification of the static component of PH across different liver disease etiologies. While CPA showed a higher specificity for CSPH diagnosis than LSM, the requirement of invasive liver biopsy limits the broad applicability of CPA.

SAT-554

Impact of new ESC/ERS diagnostic criteria for pulmonary hypertension in cirrhotic patients with portal hypertension on the frequency of portopulmonary hypertension

Hiroki Ono[1], Masanori Atsukawa[1], Kaori Koyano[1], Yuta Hasegawa[1], Tadamichi Kawano[1], Tomohide Tanabe[2], Yuji Yoshida[3], Tomomi Okubo[3], Taeang Arai[1], Korenobu Hayama[3], Norio Itokawa[1], Katsuhiko Iwakiri[1]. *[1]Nippon Medical School Hospital, gastroenterology and hepatology, Bunkyo City, Japan; [2]Nippon Medical School Musashi Kosugi Hospital, gastroenterology, Kawasaki, Japan; [3]Nippon Medical School Chiba Hokusoh Hospital, Inzai, Japan*
Email: h-ono0@nms.ac.jp

Background and aims: Portopulmonary hypertension (PoPH) is categorized as pulmonary arterial hypertension (PAH), which belongs to group 1 of the clinical classification of pulmonary hypertension (PH). In addition, PoPH is defined as PAH associated with portal hypertension. So far, conventional PoPH was defined as a mean pulmonary artery pressure (mPAP) ≥25 mmHg, pulmonary vascular resistance (PVR) >3 Wood units (WU), and pulmonary arterial wedge pressure (PAWP) ≤15 mmHg according the previous diagnostic criteria, whereas in 2022, the European guideline for pulmonary hypertension revised the hemodynamic definition of pulmonary hypertension in pre-capillary PH by lowering the mPAP to >20 mmHg and the PVR to >2 WU. Thus, the purpose of this study is to determine how the diagnosis of PoPH according to the new guideline may change among cirrhotic patients with portal hypertension who underwent hepatic venous catheterization and right heart catheterization that we have previously reported.
Method: One hundred eighty-six patients with liver cirrhosis and portal hypertension were subjected and underwent right heart catheterization in this analysis.
Results: The patients comprised 138 males and 48 females, with a median age of 59 (range, 35–80) years. The etiologies of liver cirrhosis were alcoholic liver disease (n = 61), chronic hepatitis B virus infection (n = 11), chronic hepatitis C virus infection (n = 91), autoimmune hepatitis (n = 2), primary biliary cholangitis (n = 4), non-alcoholic steatohepatitis (n = 7), and others (n = 10). The median Child-Pugh score was 8 (range, 5–13) points. The numbers of patients with Child-Pugh class A, B, and C were 53, 92, and 41, respectively. The median mPAP, PVR and PAWP were 12.9 mmHg (range, 6.6–40.8), 0.8 WU (range, 0.1–4.5) and 7.5 mmHg (range, 2.2–15.4) respectively. For both diagnostic criteria, many of the 186 patients were below the cut-off values for both mPAP and PVR, respectively (conventional, n = 184; new, n = 182). Two (1.1%) patients had conventional PoPH. In addition, two patients that were not diagnosed as PoPH by the conventional diagnostic criteria were included in the PoPH range by the new diagnostic criteria. For each diagnostic criteria, there were no patients that met only one criterion of mPAP and PVR, and were divided into two groups. mPAP and PVR were significantly but weakly correlated (p = 7.44 × 10–5, r = 0.286).
Conclusion: With the new diagnostic criteria of PoPH, there were patients that were not diagnosed with PoPH by conventional diagnostic criteria, resulting in an increase in the number of patients diagnosed with PoPH from 1.1% to 2.2% in this cohort. In particular, it is possible that the change in the cut-off value of PVR was particularly important, since patients with a PVR of 2 to 3 WU were newly diagnosed.

SAT-555

Correlation of lymphangiogenesis and inflammation in patients with ACLD

Florian Offensperger[1], Lukas Sturm[1,2], Elahe Salimi Alizei[1], Patrick Huber[1], Marlene Reincke[1], Maike Hofmann[1], Robert Thimme[1], Michael Schultheiss[1,2], Dominik Bettinger[1]. [1]*Medical Center University of Freiburg, Department of Medicine II, Freiburg, Germany;* [2]*Berta-Ottenstein-Program, Faculty of Medicine, University of Freiburg, Germany*
Email: florian.offensperger@uniklinik-freiburg.de

Background and aims: Lymphangiogenesis plays a major role in fluid homeostasis but its role in the development of ascites is not well studied. There is emerging inflammation during hepatic decompensation, whereas the interaction of lymphangiogenesis and inflammation is poorly understood. Therefore, the aim of our study was to analyze the role of inflammation in the context of lymphangiogenesis in patients with advanced chronic liver disease (ACLD).
Method: Markers of lymphangiogenesis (Vascular endothelial growth factor-D, VEGF-D, and VEGF-C, sVEGF-R3 as main markers of lymphangiogenesis growth factors) and inflammation (IL-6) were analyzed in healthy controls (n = 38), patients with compensated ACLD (cACLD, n = 27) and in patients with decompensated ACLD (dACLD, n = 35) with recurrent ascites. Patients with dACLD were allocated to TIPS implantation and markers of lymphangiogenesis were analyzed before and after TIPS implantation as well as in the portal vein and in peripheral veins.
Results: There was a significant increase in IL-6 along patients with cACLD and dACLD (3.8 vs. 33.3 pg/ml, $p < 0.001$). VEGF-C was significantly lower in patients with ACLD compared to healthy individuals (2825 vs. 1172 pg/ml, $p < 0.001$) and VEGF-R3 was significantly higher in ACLD (165119 vs. 134081 pg/ml, $p < 0.001$). VEGF-D did not differ between patients with ACLD and healthy donors, but was higher in cACLD than in dACLD (985 vs. 381 pg/ml, $p = 0.004$). Further, only VEGF-D showed an increase after compared to before TIPS implantation (467 vs. 381 pg/ml, $p = 0.040$). Importantly, no differences in lymphangiogenesis markers in the portal vein and the peripheral vein were observed. Only moderate correlation was observed between IL-6 and VEGF-C ($r = -0.475$, $p < 0.001$) and VEGF-R3 (0.348, $p < 0.001$).
Conclusion: Inflammation increased in patients with dACLD compared to cACLD. However, there was no concomitant increase in overall lymphangiogenesis. Correlation of lymphangiogenesis and inflammation was only moderate indicating that other co-factors may influence lymphangiogenesis in patients with ACLD.

SAT-556

Current prognosis of gastric variceal bleeding in France: preliminary results from a multicenter prospective cohort of 87 cirrhotic patients

Email: dweil@chu-besancon.fr

Background and aims: Gastric variceal bleeding (GVB) accounts for 10% of portal hypertension related bleedings. Its prognosis is poorer than that of esophageal variceal bleeding, with 1-year mortality up to 43%. This analysis aimed to evaluate the prognosis of GVB in the Transjugular Intrahepatic Portosystemic Shunt (TIPS) era.
Method: We analyzed some preliminary data from an ongoing randomized controlled trial (NCT03705078) that aims to determine the relevance of preemptive TIPS in the management of GVB. Consecutive cirrhotic patients admitted for GVB in 18 university hospitals between 2019 and 2022 were randomized after a first glue obliteration (GO) into a group receiving preemptive TIPS (pTIPS) and another group treated by iterative GO. The primary end point was 1-year survival without rebleeding. The secondary objectives were to analyze the factors associated with GVB and to determine the survival at day 42 (D42) and at 1 year. Analyses were performed using univariate and multivariate Cox models.
Results: 87 cirrhotic patients were followed up to 1 year after GVB. Among them, 84% had alcoholic cirrhosis, 80% were male, with a mean age of 59 years. Cirrhosis was decompensated in 81% of patients (Child-Pugh score B/C). The median MELD score was 14; 5% of patients had hepatocellular carcinoma. Type 2 gastroesophageal varices were the most frequent source of bleeding (55%) followed by type 1 isolated gastric varices (IGV, 52%), and type 2 IGV (1%). Concomitant esophageal varices were present in 51% of cases; band ligation was performed simultaneously with GO in 19% of patients. A complication of the initial GO was observed in 17% of the procedures, including 9% of per procedure bleeding and 7% of glue migration. A total of 41 patients received a TIPS within 72 hours after the initial GO. The overall survival and the survival without rebleeding in the whole cohort were respectively 94% and 86% at D42 and 84% and 65% at 1 year. In univariate analysis, death or rebleeding at 1 year was associated with the MELD score (HR = 1.12; CI95%: 1.03–1.23, $p = 0.01$) and the Maddrey score (HR = 1.04; CI95%: 1.00–1.07, $p = 0.005$) calculated on admission, and with an active bleeding at the time of initial GO (HR = 4.05; CI95%: 1.63–10.1, $p = 0.003$). In multivariate analysis, only the MELD score was associated with death or recurrent bleeding at 1 year (HR = 1.12; CI95%: 1.03–1.23, $p = 0.01$).

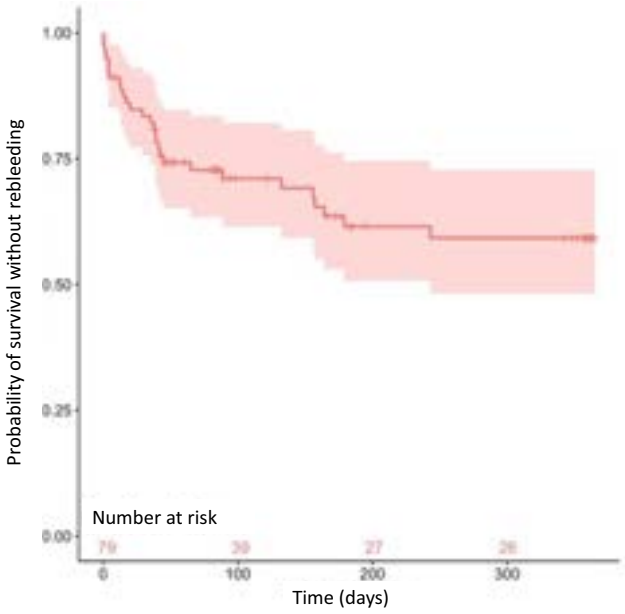

Figure: 1-year survival without rebleeding

Conclusion: The prognosis of GVB treated in expert centers in France between 2019 and 2022 appears to be better than that reported in the literature. The impact of pTIPS on this prognosis will be assessed through the final analysis of the RCT.

SAT-557

MELD 3.0 score in prediction of varices and comparison with its previous versions in patients undergoing esophago-gastro-duodenoscopy for variceal screening or band ligation

Bader Faiyaz Zuberi[1], Faiza Sadaqat Ali[1], Amanullah Abbasi[1], Tazeen Rasheed[1]. [1]*Dow University of Health Sciences, Medicine/ Gastroenterology, Pakistan*
Email: faiza.sadaqat@duhs.edu.pk

Background and aims: For assessing and predicting complications of chronic liver disease, different prognostic scores have been formulated. In a recent validation study MELD 3.0, incorporating serum Albumin (Alb) and female gender, correctly making 8.8% subjects to a higher tier to be eligible for liver transplant especially in women, and lower waiting list deaths in comparison with MELDNa.[4] Although the importance of MELD 3.0 is validated in liver organ transplant allocation, its use for predicting variceal bleed is not yet studied. Aims of this study are to estimate value of MELD 3.0 for predicting small and large varices using AUROC. To compare MELD, MELD Na and MELD 3.0 score values with presence of varices in patients undergoing variceal screening or band ligation.

Method: Cross-sectional ongoing study and is being conducted in Gastroenterology ward and endoscopy unit of Civil hospital Karachi and OMI Hospital, from August 2022 till Jan 2023 on 74 patients of either gender of age between 18 and 60 years undergoing screening endoscopy. Patients with severe cardio-respiratory or psychiatric disease, splenic or portal vein thrombosis, hepatocellular carcinoma, primary biliary cirrhosis, INR ≥5 were excluded from study. Online free calculator was used for calculation of all three scores.[5]. Normal distribution of quantitative variables was checked by Kolmogorov-Smirnov (KS) test and value of ≤.05 determined that variable is not normally distributed. Frequencies of qualitative variables were compared by χ^2 test. Means ± SD of quantitative variables was compared by Student's t-test or ANOVA. AUROC plots were generated for all MELD variants for presence of both small and large varices separately. Sub-group analysis for gender and stage of varices was also done.

Results: Out of Seventy-four patients, 42 (56.8%) were males and 32 (43.2%) were females. Mean age for males was 45.19 ± 9.70 and that for females was 48.19 ± 17.74 years, without statistically significant difference. Significant differences among gender were found between serum sodium levels and MELD Na scores. Varices were found in 66 out of 74 patients as 22 (29.7%) as Small, 42 (56.8%) Large and 2 (2.7%) Gastric varix. Presence of varices correlated positively and significantly with all three MELD score variants with *p* values of <.001. ROC curves were plotted for all three variants of MELD for absence of varices, small varices and large varices. AUC were also calculated for all three variants and options. MELD and MELD Na performed slightly better than MELD 3.0 in prediction of absence of varices with all having significantly high AUCs. For prediction of small varices MELD Na performed the best while simple MELD was non-significant. For prediction of large varices MELD Na performed the best. Details are given in Table 1. ROC Curves are plotted in Figure 1

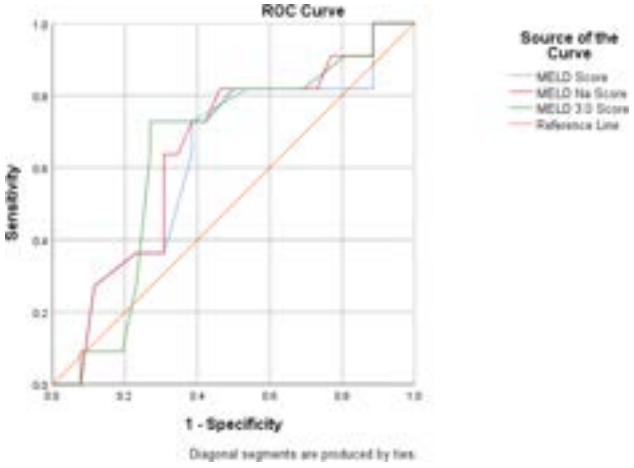

Figure: 1

Table 1: Area under Curve and their significance of MELD variants

	Varices Absent		Small Varices		Large Varices	
Variables	AUC	Sig.	AUC	Sig.	AUC	Sig.
MELD Score	.875	.001*	.626	.089	.704	.003*
MELD Na Score	.875	.001*	.652	.040*	.726	.001*
MELD 3.0 Score	.871	.001*	.649	.044*	.722	.001*

*. Significant values ≤.05
AUC: Area Under Curve

Conclusion: MELD and MELD Na performed slightly better than MELD 3.0 in prediction of presence of all types of varices.
For prediction of small varices MELD Na performed the best while simple MELD was non-significant

SAT-558

Study the effect of serum YKL-40 as a risk of variceal bleeding in Egyptian cirrhotic patients

Abdelfattah Hanno[1], Mohamed Ahmed[2], Reham Aboelwafa[3], Essam Bedewy[2], Aly Elkady[2]. [1]*Alexandria University, Tropical Medicine, Alexandria, Egypt;* [2]*Alexandria University, Tropical Medicine, Alexandria, Egypt;* [3]*Alexandria University, Clinical and chemical pathology, Alexandria, Egypt*
Email: dr_afhanno@yahoo.com

Background and aims: Chronic liver disorders are mostly resulted from HCV infection globally. Esophageal and gastric varices are common in cirrhotic patients due to concomitant portal hypertension. Variceal hemorrhage is a major decompensating event with high morbidity and mortality. The YKL-40 protein is classified as an inflammatory protein that is linked to a variety of factors in

expressing the severity of hepatic fibrosis, including the hepatic venous pressure gradient. The aim of the work was to assess the value of serum YKL-40 as a risk of variceal bleeding in cirrhotic Egyptian patients.

Method: This prospective controlled research was done on 60 HCV induced liver cirrhosis patients visiting the Tropical Medicine Department at the Main University Hospital in Alexandria, Participants were divided into two groups. Group I consisted of thirty patients having grade I, II oesophagheal varices (bleeder and non-bleeder). Group II included thirty patients with grade III, IV oesophagheal varices (bleeder and non-bleeder). Moreover, all participants in groups I and II had post-viral liver cirrhosis. All were due to chronic HCV infection and all of them received treatment for HCV and had a negative Polymerase Chain Reaction for HCV. Serum YKL-40 was measured by ELISA. Patients with sepsis, other causes of liver cirrhosis, portal vein thrombosis, diabetes mellitus, malignancies, acute liver failure and rheumatoid arthritis were excluded from the study.

Results: Table 1 showed that serum YKL-40 was statistically significantly higher in patients who suffered from bleeding varices in group I and II (p = 0.028*) and (p = 0.010*) respectively. Also serum YKL-40 was able to discriminate bleeder form non bleeder patients in group I at a cut of value of (>102.5 ng/dl) with sensitivity of 76.92% and specificity of 52.94%. Additionally, serum YKL-40 was able to discriminate bleeder form non bleeder patients in group II at a cut of value of (>160.1 ng/dl) with sensitivity of 75.0% and specificity of 57.14%. Moreover, a positive correlation between serum YKL-40 and spleen size in patients who suffered from bleeding varices in both groups was found, however there was a negative correlation between serum YKL-40 and platelets count in bleeder patients also in both groups.

	Group I (n = 30)		Group II (n = 30)	
	Non bleeder (n = 17)	Bleeder (n = 13)	Non bleeder (n = 14)	Bleeder (n = 16)
Serum YKL-40				
Min.-Max.	74.0–118.7	85.40–135.2	97.50–180.4	109.1–189.4
Mean ± SD.	99.51 ± 14.88	115.7 ± 16.35	140.2 ± 35.27	166.2 ± 25.33
Median (IQR)	102.5 (88.1–112.4)	114.5 (104.9–133.8)	158.5 (101.4–170.7)	175.9 (150.1–185)
U (p)	U = 58.00*, (p = 0.028*)		U = 51.00*, (p = 0.010*)	

IQR: Inter quartile range; SD: Standard deviation; U: Mann Whitney test
p: p value for comparing between Non bleeder and Bleeder
*: Statistically significant at p ≤0 .05

Conclusion: serum YKL-40 would be useful in prediction of esophageal varices bleeding risk in cirrhotic patients

SAT-559

Progression of portal hypertension in PBC: doppler ultrasound velocity as a non-invasive assessment

Aiymkul Ashimkhanova[1,2], Damesh Orazbayeva[3], Aibar Agynbay[4], Marzhan Zhanasbayeva[4], Kulpash Kaliaskarova[2,4], Gaukhar Kurmanova[1], Nataliya Satlikova[5], Irina Ten[6], Raima Kapiyeva[7]. *[1]Al-Farabi Kazakh National University, School of Medicine and Health, Almaty, Kazakhstan; [2]GastroHepatoTransplant Group, Astana, Kazakhstan; [3]National Research Oncology Center, Radiology, Astana, Kazakhstan; [4]National Research Oncology Center, Oncohepatology and Gastroenterology, Astana, Kazakhstan; [5]UMC, Republican Diagnostic Center, Department of Internal Medicine, Astana, Kazakhstan; [6]UMC, National Research Center for Maternal and Child Health, Interventional Radiology, Astana, Kazakhstan; [7]MEDICAL CENTRE HOSPITAL OF PRESIDENT'S AFFAIRS ADMINISTRATION OF THE REPUBLIC OF KAZAKHSTAN, Radiology, Astana, Kazakhstan*
Email: ashimkhanova.a@kaznu.kz

Background and aims: Primary biliary cholangitis is one of the most common autoimmune diseases worldwide with a female prevalence after age of 45–50's. The natural history of the development of portal hypertension in PBC patients is still not well known. Doppler ultrasound can be routinely used modality to assess non-invasively portal venous system with the additional advantage of determining velocity and flow direction. It has been observed during routine clinical practice that signs of portal hypertension by Doppler ultrasound in Primary biliary cholangitis patients occur faster before the synthetic dysfunction of the liver can be observed or the progression into cirrhosis is established. In order to assess this hypothesis, we decided to analyse the role of ultrasound Doppler characteristics in 23 patients with confirmed diagnosis of primary biliary cholangitis.

Method: Patients admitted from 2018 to 2020 at National Research Oncology Center, Liver Unit were retrospectively analyzed. The chief specialist was a single person assessing the Doppler measurements to keep the validity of the results. Criteria of diagnosis for primary biliary cholangitis: positive AMA- M2 antibodies, Liver histology signs and ALP/GGTp elevation together with bilirubinemia and transaminasemia

Results: Out of 23 patients, female to male ratio was 21:2, AMA-M2 negative, but gp210 and sp100 antibodies positive patients were observed in 6 female patients with confirmatory features of bile duct inflammation and concurrent ALT/AST elevation. Among them there were 3 patients with an Overlap syndrome with IgG increase more than 20 g/L and gamma globulin fraction of more than 20% together with AMA-M2 high titers, and increase of ALT/AST more than 300 IU/ml. Mean age for the onset of disease was 47 ± 8.98 years, mean ALP of 475. ± 289.92 IU/ml, GGTp mean was 315 ± 228.49 IU/ml, mean cholesterol was 6.7 mmol/l ± 2.67 mmol/L, total bilirubin of 33.51 ± 35.17 mcmol/L, direct bilirubin of 26.11 sd ± 32.29 mcmol/L. Ultrasound Doppler characteristics for this cohort was following: mean portal vein size of 1.14 ± 0.2 cm, mean velocity was 21 ± 12.87 cm, V.lienalis diameter mean of 0.8 ± 0.28 cm, with a velocity of 21.31 ± 7.9 cm, the diameter of hepatic artery propria was 0.42 ± 0.06 cm, with a mean velocity of 98.57 ± 25.28 cm, mean IR of 0.67 ± 0.05, splenic artery diameter of 0.56 cm ± 0.1, with an increased velocity of 125 ± 31.5 cm, IR 0.64 ± 0.07, the averaged area of the spleen was calculated to be 66.94cm^2 ± 37.15 and with the following platelet average of 229 × 10^9/L ± 93, WBC average 5.31 × 10^9/L ± 1.34 and a mean hemoglobin of 112 g/L ± 27. Other synthetic function tests measured by total protein (mean = 75.68), albumin (mean = 36.93), fibrinogen (mean = 2.97), INR (mean = 1.07) were not affected despite high inflammatory signs within the liver parenchyma.

Conclusion: According to the results of the Doppler measurements of portal system among patients with confirmed primary biliary cholangitis, there is a tendency in increasing velocity of splenic artery as a first sign of portal hypertension progression in patients without confirmed cirrhosis, Ishak fibrosis stage 3/6. Another finding is the splenomegaly which appears also earlier. Baveno-VII classification stratification might not be ideal for PBC patients, and Portal pressure gradient measurement needs to be applied to stratify these category of patients for future interventions.

SAT-560

Clinical features and analysis of serum BMP9 levels in patients with portal pulmonary hypertension

Ruihua Zhang[1,2], Tengfei Li[1], Yu Tian[2], Xiaoyu Wen[1]. *[1]First Hospital of Jilin University, Department of Hepatology, China; [2]First Hospital of Jilin University, Center of Infectious Diseases and Pathogen Biology, China*
Email: 15804301609@163.com

Background and aims: Portal pulmonary hypertension (POPH) is a serious complication of portal hypertension with low morbidity and high mortality. Bone morphogenetic protein 9 (BMP9), a member of the bone morphogenetic protein family, can protect endothelial integrity and maintain vascular homeostasis. It has been reported

that the BMP9 signaling pathway is involved in the pathogenesis of pulmonary arterial hypertension, and POPH is a sub-group of pulmonary arterial hypertension (PAH). While, it is unclear whether BMP9 is involved in the pathogenesis of POPH. The aim of this study is to collect the clinical data of POPH patients, and to compare the expression levels of BMP9 in POPH and other different forms of PAH.

Method: From January 2018 to July 2022, a total of 3348 patients with liver cirrhosis or portal hypertension were screened underwent Doppler echocardiography in the First Hospital of Jilin University. Finally, 45 patients were considered to have POPH. The clinical data of these patients were collected. Serum samples from 10 patients with POPH, 9 patients with PAH caused by left heart disease, 9 patients with PAH caused by pulmonary disease, and 9 healthy individuals were detected by enzyme-linked immunosorbent assay (ELISA) to detect BMP9 levels.

Results: 1) The prevalence rate of POPH in patients with portal hypertension or liver cirrhosis was rare (1.34%). The basic information of 45 POPH patients selected were listed here, the average age was 60.29 ± 12.10 years old, 40% were female, hemoglobin:95.96 ± 29.67 g/L, platelet:83.96 ± 51.67 × 10^9/L, albumin:28.50 ± 5.66 g/L, creatinine:91.28 ± 69.34 umol/L, prothrombin time:17.46 ± 5.83 s, partial pressure of CO_2:31.31 ± 4.51 mmHg. the most common cause of cirrhosis was alcohol, and the most common complication of cirrhosis patients was gastrointestinal bleeding. 2) The expression levels of BMP9 in each group were detected, and the results were as follows: POPH group:2.345 ± 0 pg/ml (compared with 17.6 ± 8.1 pg/ml in healthy group, $p < 0.0001$); PAH caused by left heart disease:14.9 ± 5.7 pg/ml ml (compared with 2.345 ± 0 pg/ml in POPH group, $p = 0.0002$); PAH caused by pulmonary disease:12.6 ± 7.0 pg/ml (compared with 2.345 ± 0 pg/ml in POPH group, $p < 0.0001$); Healthy control group :17.6 ± 8.1 pg/ml.

Clinical features of portal pulmonary hypertension

	Age	Hemoglobin	Platelet	Creatinine	Prothrombin time	Albumin	Partial pressure of CO_2
Mean	60.29	95.96	83.96	91.28	17.46	28.50	31.31
SD	12.10	29.67	51.67	69.34	5.83	5.66	4.51

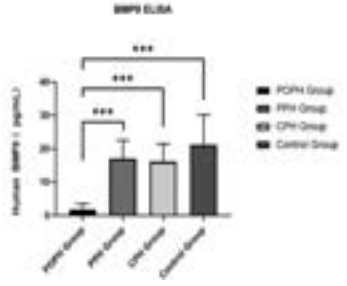

Figure:

Conclusion: 1) Compared with healthy control group, BMP9 in POPH patients was significantly decreased, and the decrease in BMP9 was considered to be related to the pathogenesis of POPH. 2) Compared with patients with PAH caused by left heart disease or by pulmonary disease, BMP9 in POPH group was significantly decreased. Thus, the application of BMP9 is helpful to distinguish POPH from PAH caused by common clinical cardiopulmonary diseases.

Liver cell-type specific molecular signatures marking transition from advanced fibrosis to cirrhosis in human non-alcoholic steatohepatitis

Martin Rønn Madsen[1], Mathias Møllerhøj[1], Mikkel Werge[2], Mikkel Christensen-Dalsgaard[1], Sanne Veidal[3], Lise Rudkjær[1], Elisabeth Galsgaard[3], Lise Lotte Gluud[2], Henrik B. Hansen[1]. *[1]Gubra, Hørsholm, Denmark; [2]Hvidovre Hospital, Hvidovre, Denmark; [3]Novo Nordisk A/S-site Måløv, Måløv, Denmark*
Email: mam@gubra.dk

Background and aims: Hepatic fibrosis is the strongest predictor of morbidity and mortality in non-alcoholic steatohepatitis (NASH), establishing fibrosis as a critical therapeutic target in this disease. To improve treatment outcomes in NASH, the specific roles and molecular signaling mechanisms of hepatic cell types in the progression of fibrosis must be clarified. Here, we developed a transcriptomic map at cellular resolution, defining molecular signatures of parenchymal and non-parenchymal cell types across all stages of fibrosis in human NASH.

Method: Bulk RNA sequencing (RNAseq) was performed on snap-frozen liver biopsies obtained from a patient cohort of 40 obese individuals with NASH (stages F0-F4, n = 4–10 per fibrosis stage) or no/mild NAFLD (macrovesicular steatosis) without fibrosis (control group, n = 7). Paired single-nucleus (sn) RNAseq analysis was performed on a subset of biopsies (control, NASH F0-1, NASH F2-3, NASH F4; n = 4 per group). Cell type deconvolution of differentially expressed genes in bulk RNAseq samples was based on corresponding snRNAseq data.

Results: The transcriptomics platform enabled for paired bulk and single-nucleus (sn) RNAseq analysis on small percutaneous/transjugular human liver biopsies (≤5 mg tissue). The number of differentially expressed genes increased progressively with disease severity. Transcriptome signatures were clearly separated from NASH patients with cirrhosis (fibrosis stage 4), demonstrating perturbations in genes associated with extracellular matrix remodeling and the immune system. Bulk RNAseq data were cross-referenced to public bulk RNAseq data sets for further data validation. snRNAseq yielded data from 33,764 nuclei after quality control, recovering all major liver cell types in both control and disease samples based on cell-specific marker genes. Subclustering of snRNAseq datasets revealed multiple subtypes of hepatic stellate cells (HSCs) relevant in the progression of fibrosis.

Conclusion: We report a state-of-the-art integrative transcriptomics pipeline mapping molecular changes in liver non-parenchymal cell types covering the entire spectrum of fibrosis in NASH patients. Distinct HSC subpopulations and transcriptional programs may play important roles in the transition from advanced fibrosis to cirrhosis in human NASH.

Does sex influence the development of sarcopenia in liver fibrosis?

Katia Sayaf[1], Ilaria Zanotto[2], Daniela Gabbia[2], Gaia Gherardi[3], Rosario Rizzuto[3], Sara De Martin[2], Francesco Paolo Russo[1]. [1]*University of Padova, Department of surgery, oncology and gastroenterology, Italy;* [2]*University of Padova, Department of pharmaceutical and pharmacological sciences, Italy;* [3]*University of Padova, Department of biomedical sciences, Italy*
Email: francescopaolo.russo@unipd.it

Background and aims: Sarcopenia is a debilitating condition affecting 60–70% of patients with liver disease. Interestingly, the incidence of sarcopenia shows sex dimorphisms. In this condition, muscle atrophy is linked to a progressive loss of skeletal muscle function and strength, and correlated to an increased mortality. However, the mechanisms underlying liver-associated sarcopenia, and the role of sex in its the development are still poorly understood. In this study, we investigated sex dimorphism in the development and resolution of sarcopenia in a murine model of liver fibrosis and regeneration.
Method: Progressive stages of liver fibrosis were induced in female and male mice by injecting increasing doses of carbon tetrachloride (CCl4, from 0.17 to 0.72 ml/Kg*bw) for 12 weeks. At the end of the treatment, an 8-week washout period was set to allow liver regeneration. Muscle function and strength were evaluated by the grid hanging and the grip strength test. Mice were sacrificed after 6 and 12 weeks of CCl4-treatment, and after the washout period. Masson's trichrome stain was used to assess liver fibrosis, while hematoxylin and eosin staining was used to calculate the cross-sectional area (CSA) of muscle quadriceps fibers. Muscle pAkt and p4EBP1 protein expression was assessed by western blot, and mRNA expression of Musa, Atrogin-1, Murf-1, and Bnip3 by qRT-PCR. Plasma levels of TNF were measured by means of multiplexed bead-based immunoassay.
Results: After 6 and 12 weeks of CCl4-treatment, mice developed a progressive liver fibrosis that was associated to a significant loss of muscle force in both sexes, as demonstrated by the poor performances on the grid hanging and the grip strength test ($p < 0.05$), and by the reduced CSA of quadriceps fibers ($p < 0.001$). pAkt and p4EBP1 levels, promoters of muscle protein synthesis, were not affected by fibrosis development. However, atrophy-related ubiquitin ligases (Musa, Atrogin-1, Murf-1, and Bnip3), responsible for the breakdown of muscle proteins, were significantly upregulated in fibrotic mice with respect to controls, especially in females ($p < 0.05$). Plasma levels of TNF, responsible for the hepatic-induced muscle damage, were higher in fibrotic mice than in controls. After the washout period, males recovered their physical force and CSA, although liver fibrosis was still present, whereas females were characterized by an amelioration of liver histology and a decrease in the plasma levels of TNF, which was not accompanied by a recovery of muscle function.
Conclusion: CLD-associated sarcopenia is due to an increase of muscle protein degradation, more evident in females, whereas muscle protein synthesis is not affected by liver fibrosis in both sexes. Furthermore, the severity of sarcopenia is not correlated to the severity of liver fibrosis.

WED-215

Dual alpha-v/beta-6 and alpha-v/beta-1 integrin inhibitor bexotegrast attenuates profibrogenic gene expression of myofibroblasts in human liver explant tissue with biliary fibrosis

Steve Ho[1], Chris Her[1], Richard Ahn[1], Vikram Rao[1], Jessie Lau[1], Mahru An[1], Scott Turner[1], Martin Decaris[1], Johanna Schaub[1]. [1]*Pliant Therapeutics, United States*
Email: jschaub@pliantrx.com

Background and aims: Bexotegrast (PLN-74809), a dual inhibitor of TGF-beta-activating integrins alpha-v/beta-6 and alpha-v/beta-1 currently in clinical development for the treatment of primary sclerosing cholangitis (PSC), has previously been shown to reduce fibrosis in the MDR2$^{-/-}$ mouse model of biliary fibrosis. To examine the effects of bexotegrast on individual cell populations in the fibrotic human liver, we combined the precision cut liver slice (PCLivS) platform, a physiologically relevant ex vivo model system, with 10x single nuclei RNA sequencing (snRNA-Seq) to characterize the response of unique cell populations in fibrotic PSC and primary biliary cholangitis (PBC) PCLivS to bexotegrast.
Method: Liver explants were collected from patients with PSC (n = 3) and PBC (n = 1) at the time of transplant. PCLivS were generated and cultured for 2 days in the presence of bexotegrast or vehicle (DMSO). A TGF-beta receptor I kinase inhibitor (ALK5i; R-268712) was also evaluated as a control. Single nuclei were isolated from two pooled slices per treatment and processed for single nuclear barcoding using 10× Chromium Next GEM 3′ HT kits. Resulting libraries were sequenced, processed using CellRanger, and analyzed using Seurat. Custom annotation of cell types was performed using gene markers established from recently published data sets. Differential gene expression was determined using a non-parametric Wilcoxon rank sum test. Pathway enrichment analysis was performed with Enrichr.
Results: snRNA-Seq analysis of human PCLivS identified unique cell populations, including cholangiocytes, mesenchymal cells, hepatocytes, endothelial cells, and leukocytes. Within the overall mesenchymal cell population, we observed clusters of *RGS5*-high cells and *PDGFRA*-high cells, identified as hepatic stellate cells (HSCs) and myofibroblasts, respectively, with the latter myofibroblast cluster having the highest level of type 1 collagen (*COL1A1*) expression. Differential gene expression analysis comparing bexotegrast or ALK5i treatment to vehicle showed significant reductions in type I collagen (*COL1A1*) expression in myofibroblasts (FDR <0.05), with bexotegrast approximately 80% as effective as ALK5i. Gene expression pathways most downregulated by bexotegrast in myofibroblasts were "collagen fibril organization" (GO:0030199) and "extracellular matrix organization" (GO:0030198), driven by reduced expression of genes such as *COL7A1*, *BGN*, and *FBLN*1.
Conclusion: Treatment of human PCLivS with biliary fibrosis with dual alpha-v/beta-6 and alpha-v/beta-1 integrin inhibitor bexotegrast resulted in clear reductions in profibrogenic gene expression within myofibroblasts. The similar degree of effect of bexotegrast compared to ALK5i demonstrates the importance of the integrin-TGF-beta activation pathway in fibrotic biliary disease. These data demonstrate the utility of combining single nuclei transcriptomics with fibrotic human PCLivS to evaluate the mechanism of action of novel anti-fibrotic therapies.

WED-216

TLC-3595, a selective acetyl-CoA carboxylase 2 (ACC2) inhibitor, improves steatosis and fibrosis in murine models of NASH via pleiotropic mechanisms

Archana Vijayakumar[1], Eisuke Murakami[1], Ryan Huss[1], Natalie Sroda[1], Atsuyuki Shimazaki[2], Ippei Morita[2], Hideaki Kato[2], Manami Nakai[2], Naoki Ohyabu[2], Mani Subramanian[1], Robert Myers[1]. [1]*OrsoBio, Inc, Palo Alto, United States;* [2]*Shinogi and Co. Ltd., Osaka, Japan*
Email: archana@orsobio.com

Background and aims: TLC-3595 is a potent (IC_{50} = 14 nM), systemically distributed, allosteric inhibitor of acetyl-CoA carboxylase 2 (ACC2i) that is 76-fold selective over ACC1. By increasing fatty acid oxidation, TLC-3595 has potential for the treatment of metabolic diseases including type 2 diabetes and NASH. Here, we report the pleiotropic benefits of TLC-3595 *in vitro* and in murine models of NASH and fibrosis.
Method: Hepatocyte (HepG2 and H4IIE), hepatic stellate (LX2), or adipocyte (3T3L1) cell lines were treated with TLC-3595 (or a tool compound) for 24–72 hours *in vitro*. High-fat diet (HFD)-fed, diet-induced obese (DIO) mice, Fatty Liver Shionogi-*Lep^{ob}/Lep^{ob}* (FLS-*ob/ob*) mice, or choline-deficient, L-amino acid-defined HFD (CDAHFD)-fed mice were treated with TLC-3595 (5–60 mg/kg BID) or the nonselective, liver-targeted ACC inhibitor firsocostat (FIR, 0.5–1.5 mg/kg BID) for 4–8 weeks. Liver fibrosis was quantified based on picrosirius red-positive (PSR^+) area and hepatic hydroxyproline (HYP) content.
Results: *In vitro*, TLC-3595 or a tool ACC2i dose-dependently reduced apoptosis (27% lower caspase 3/7 activity) and gluconeogenesis (39%) in hepatocytes, decreased procollagen 1 secretion (20%) in LX2 cells, and increased adiponectin in the supernatant (25%) and decreased lipid droplet size (40%) in differentiated adipocytes. In FLS-*ob/ob* mice, TLC-3595 treatment for 4 weeks increased plasma adiponectin (51%; $p \leq 0.0001$) (Fig. A). Additionally, TLC-3595 increased *Fgf21* mRNA expression (4 to 15-fold) in skeletal muscle and intact FGF21 levels (1.5-fold) in plasma of FLS-*ob/ob* mice after a single or repeat doses (10 days to 4 weeks). These changes were associated with significant reductions in liver HYP (58%) and PSR^+ area (38%) in FLS-*ob/ob* mice after 4 weeks of TLC-3595 treatment. In the CDAHFD mouse model, TLC 3595 treatment for 8 weeks significantly reduced liver triglyceride (TG; 20%), hepatic PSR^+ area (28%, Fig. B), and HYP content (36%) vs. vehicle. In contrast, FIR did not increase plasma adiponectin in FLS-*ob/ob* mice (Fig. A) but caused greater liver TG reduction (31%) without impacting hepatic PSR^+ area (Fig. B) or HYP in CDAHFD mice. Lastly, in DIO mice, TLC-3595 reduced liver TG by 35% ($p \leq 0.05$) without effects on plasma TG, unlike FIR, which decreased liver TG by 66% while increasing plasma TG by 168% after 4 weeks of treatment (Fig. C-D).

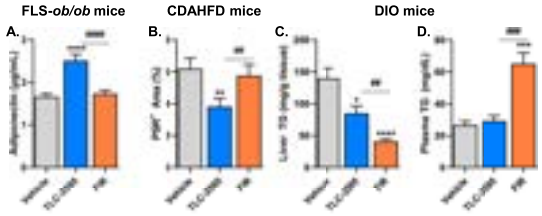

Figure A. Plasma adiponectin levels in FLS-*ob/ob* mice, **B.** Fibrosis assessed by hepatic PSR^+ area in CDAHFD-fed mice, and **C-D.** Liver and plasma TG levels in DIO mice treated with vehicle, TLC-3595 (5-45 mg/kg BID) or firsocostat (FIR, 0.5-1.5 mg/kg BID) for 4-8 weeks. *p≤0.05, **p≤0.01, ***p≤0.001, ****p≤0.0001 vs. vehicle; #p≤0.05, ##p≤0.01, ###p≤0.001, ####p≤0.0001 vs. FIR.

Figure:

Conclusion: TLC-3595 has beneficial effects on steatosis and fibrosis in NASH via multiple mechanisms, including direct effects in hepatocytes, hepatic stellate cells, adipocytes, and skeletal muscle, without causing hypertriglyceridemia as seen with nonselective ACC inhibitors. These data support the development of TLC-3595 in patients with NASH.

WED-217

Spatial lipidomics reveal dysregulated sphingolipid metabolism in liver fibrosis

Aleksandra Gruevska[1], Fiona Oakley[2], Jack Leslie[2], Derek A Mann[2], Matthew Hoare[3], Zoe Hall[1]. [1]*Division of Systems Medicine, Imperial College London, London, United Kingdom;* [2]*Newcastle Fibrosis Research Group, University of Newcastle, Newcastle-upon-Tyne, United Kingdom;* [3]*Early Cancer Institute, University of Cambridge, Cambridge, United Kingdom*
Email: zoe.hall@imperial.ac.uk

Background and aims: Liver fibrosis (LF) represents a major health problem worldwide due to its increasing prevalence and the lack of effective treatments. Although detailed molecular mechanisms are still unclear, during development of fibrosis, specific lipid pathways are re-wired in the liver and may represent candidate therapeutic targets. This is especially relevant for NASH-induced LF where increased hepatic storage of potentially lipotoxic species occurs. The aim of this study is to uncover the complex metabolic adaptations in LF and identify key lipid markers of hepatic fibrosis.
Method: Animal models of liver fibrosis included western diet + CCl4, bile duct ligation (BDL) and chronic CCl4 treatment (all in C57BL/6 male mice). To verify findings in the animal models, background cirrhotic tissue from patients with fatty liver-associated hepatocellular carcinoma (HCC) undergoing liver resection or transplant were analyzed. Lipids were extracted from bulk liver tissue (mice and human) and analysed using liquid chromatography-mass spectrometry (LC-MS) to study metabolic changes. Key lipid-gene transcript correlations were evaluated by performing RNA sequencing on the same set of samples. Pathway analysis and integration of the transcriptomics and lipidomics data was done. Mass spectrometry imaging (MSI) on cryosectioned human liver tissue was used to evaluate the spatial distribution of key altered lipids/metabolites.
Results: RNA sequencing of whole liver samples from mice (n = 5 per group) revealed upregulation of glycosphingolipid metabolism in the fibrotic groups compared to their control groups. Differential gene expression showed an increased expression of the enzymes implicated in ceramide production and these results were confirmed using bulk tissue lipidomics, demonstrating higher amounts of hexose ceramides (HexCer) and sphingomyelins (SM) in the three animal models employed relative to control. Specific lipids such as SM (34:1), SM (42:2), HexCer (34:1) and HexCer (42:2) were able to discriminate fibrotic groups from control. In the human samples (n = 7), pathway analysis and the integration of the transcriptomics and lipidomics data showed strong positive correlation between SM (34:1) lipid abundance and gene expression for transforming growth factor (TGF) beta 1 and bone morphogenetic protein (BMP) receptor 1-both implicated in pro-fibrotic signalling. In addition, spatial lipidomics by MSI revealed a dramatic increase of SM (34:1) and hexose ceramides in fibrotic regions of human cirrhosis (Figure).

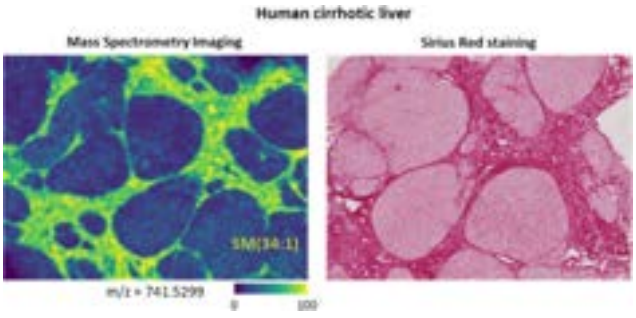

Figure:

Conclusion: Overall, these results have identified several prominent lipid markers for hepatic fibrosis and suggest that altered sphingolipid metabolism is a key process occurring during fibrogenesis.

Targeting these metabolic pathways could be a novel strategy to resolve fibrosis.

WED-218

Cyclophilin inhibition exhibits preventive and curative antifibrotic effects via extracellular matrix remodelling

Sara Campinoti[1,2,3], Una Rastovic[1,2,3], Lai Wei[1,2], Nicola Harris[1,2], Bruna Almeida[1,2], Omolola Ajayi[1,2], Caoimhe Kerins[4], Fiona Kenny[2], Sandra Phillips[1,2], Ane Zamalloa[5], Rosa Miquel[5], Yoh Zen[5], Krishna Menon[5], Eileen Gentleman[4], Tanya Shaw[2], Nigel Heaton[5], Daren Ure[6], Shilpa Chokshi[1,2], Luca Urbani[1,2], Elena Palma[1,2]. *[1]The Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [2]King's College London, Faculty of Life Sciences and Medicine, London, United Kingdom; [3*]equal contribution, United Kingdom; [4]King's College London, Centre for Craniofacial and Regenerative Biology, London, United Kingdom; [5]Institute of Liver Studies, King's College London, London, United Kingdom; [6]Hepion Pharmaceuticals, Edison, United States*
Email: e.palma@researchinliver.org.uk

Background and aims: Fibrosis is caused by persistent liver damage and inflammation and is a central driver for disease progression in chronic liver disease. It is characterised by excessive activation of hepatic stellate cells (HSCs) and altered extracellular matrix (ECM) deposition and remodelling ultimately affecting liver function. Despite enormous research efforts, there are no approved anti-fibrotic drugs. Inhibition of cyclophilins, peptidyl-prolyl isomerases that facilitate protein folding and regulate several biological processes, has been proven beneficial in various disorders, including liver diseases, but the mechanism of action requires further elucidation. Here, we firstly investigate the role of cyclophilins in HSC transdifferentiation, ECM production, composition and 3D organisation and secondly, we tested the efficacy of a pan-cyclophilin inhibitor (rencofilstat) currently in clinical development for NASH, using patient-derived *in vitro* and *ex vivo* models of liver fibrosis.
Method: Patient-matched Precision Cut Liver Slices (PCLS) and primary HSCs were prepared from human liver specimens and exposed to mechanical or chemical insults to induce fibrogenesis, in the presence/absence of 5 μM rencofilstat together (preventive approach) or after the insults (curative approach). Fibrosis and cell activation in HSCs and PCLS were assessed by gene (RNAseq, Quantigene) and protein expression analysis (proteomics, immunofluorescence), and secretion of fibrotic and inflammatory markers by ELISA/Luminex. ECM deposition upon stimulation was characterised for biochemical composition and fibre orientation in cell-derived matrix (CDM) via immunofluorescence, confocal imaging and proteomics. Stiffness of PCLS upon treatment was assessed by atomic force microscopy (AFM).
Results: Rencofilstat profoundly and consistently reduced expression and secretion of pro-fibrogenic markers in both models, independently of insult and treatment regime. Remarkably, cyclophilin inhibition significantly reduced HSC activation and consequent ECM deposition and induced qualitative and quantitative changes in ECM composition (proteomic analysis on CDM and PCLS). The order of organisation of matrix fibres was affected by rencofilstat resulting in significantly less organised bundles, indicating remodelling towards a less stiff 3D matrix structure, which was in line with the AFM analysis performed on PCLS that showed decreased stiffness upon cyclophilin inhibition.
Conclusion: This study confirms the key role of cyclophilins in liver fibrosis and inflammation in patient-derived 3D and multicellular models revealing the remarkable potential of cyclophilin inhibition as anti-fibrotic therapy in relevant models of human disease. We also provide novel insights regarding rencofilstat's mechanism of action in the remodelling of the ECM in liver fibrosis, demonstrating a direct consequence on tissue stiffness.

WED-219

Hepatic stellate cell-derived extracellular matrix to model aetiology-and patient-specific matrix remodelling and fibrosis progression

Lai Wei[1,2], Sara Campinoti[1,2], Bruna Almeida[1,2], Fiona Kenny[3], Rosa Miquel[4], Tanya Shaw[3], Shilpa Chokshi[1,2], Luca Urbani[1,2]. *[1]The Roger Williams Institute of Hepatology, United Kingdom; [2]King's College London, Faculty of Life Sciences and Medicine, United Kingdom; [3]King's College London, Centre for Inflammation Biology and Cancer Immunology, United Kingdom; [4]King's College Hospital, Institute of Liver Studies, United Kingdom*
Email: luca.urbani@researchinliver.org.uk

Background and aims: Liver fibrosis is characterised by aberrant accumulation of extracellular matrix (ECM) secreted by activated hepatic stellate cells (HSCs). Several factors (aetiology, pro-fibrogenic insults, and fibrotic stage) influence the ECM composition, organisation and quantity in fibrosis. However, mechanisms underpinning distinct remodelling processes that affect the ECM biochemical and biophysical properties are elusive, primarily due to the lack of relevant *in vitro* models. Typically, stellate cells are immortalised cells, such as LX-2, and whilst easy to use and unexpensive, they are not patient-specific and the immortalisation process alters their original characteristics. Here, we present the study of the activation potential, metabolic status and specific ECM deposition of patient-derived HSCs as an *in vitro* model to investigate ECM remodelling in chronic liver disease.
Method: Primary human HSCs were isolated from liver tissue collected from patients with different fibrotic stages (METAVIR score): F0 (no fibrosis) to F4 (cirrhosis). Cell activation was induced using different combinations of pro-fibrotic stimuli typically found in non-alcoholic fatty liver disease and steatohepatitis: TGFβ, IL-6, free fatty acids, high glucose and insulin. Cell activation towards myofibroblasts was determined by gene and protein expression analysis. The metabolic activity of activated cells was determined with Seahorse real-time cell metabolic analysis. ECM deposited was characterised for biochemical composition and fibre orientation by decellularisation of cell-derived matrix (CDM) followed by immunofluorescence and confocal imaging and compared to standard LX-2.
Results: Human HSCs were successfully isolated and cultured from liver tissue with different METAVIR fibrotic scores. Upon administration of pro-fibrotic stimuli, HSCs showed clear increased gene and protein expression of activation markers (aSMA, SOX9, collagens), increased proliferation, and high deposition of ECM. Matrix deposition showed remarkable differences between LX-2 and primary HSCs, suggesting substantial limitations in the use of the immortalised HSC line. Various combinations of insults and the fibrotic score of the liver tissue of origin generated different levels of cell activation, metabolic activity and ECM deposition with striking differences in both composition and structure, indicating the suitability of our model to mimic patient- and aetiology-specific fibrotic features.
Conclusion: Here we present the potential of personalised patient-derived cells to investigate ECM remodelling in different fibrotic settings. Our study reveals that patient-derived HSCs, but not LX-2 cells, maintain a unique capacity to produce a highly bundled ECM upon induction of fibrosis. In particular, the use of the CDM analysis allows for mechanistic studies in the field of ECM deposition and remodelling upon different stimuli, an aspect often overlooked in fibrotic models. The information on fibrillar quantity and alignment between patients and upon different pro-fibrotic insults provides new crucial information on the molecular mechanisms of ECM deposition in chronic liver disease and could pave the way to the discovery of novel therapeutic strategies.

WED-220

Selective RNF41 restoration in hepatic macrophages from thioacetamide-induced fibrotic mice reduces liver fibrosis and inflammation

Email: pmelgar@ub.edu

Background and aims: Macrophages play a crucial role during the progression of chronic liver disease. They actively participate in the response to liver damage and in the balance between fibrogenesis and regression. Indeed, macrophage activation is a prognostic of survival in patients with liver cirrhosis. RNF41 E3 ubiquitin ligase has been associated to negative regulation of pro-inflammatory signals and M2 macrophage polarization in muscle injury, but its role in liver fibrosis remains unclear.
Method: RNF41 expression was quantified using real-time PCR in CD11b+ macrophages isolated from the liver of cirrhotic (n = 12) and healthy subjects (n = 8), and from fibrotic (n = 6) and healthy mice (n = 6). Fibrosis was induced in mice with i.p. injections of thioacetamide (200 mg/Kg) twice a week for 9 weeks. Macrophage selective RNF41 induction was achieved with i.v. (50 μg/Kg) injection of dendrimer-graphite nanoparticles delivering a plasmid encoding RNF41 (RNF41-DGNP) or control scrambled plasmid every 3 days for 9 days (n = 12). The therapeutic effect of RNF41 restoration on fibrosis, liver function, and inflammation was evaluated via Real-time PCR and histological techniques.
Results: RNF41 expression was significantly lower in macrophages isolated from the liver of cirrhotic patients regardless of cirrhosis aetiology (1.1 ± 0.2 vs 0.3 ± 0.1, fold change (fc), $p < 0.001$), and from the liver of fibrotic mice (1.0 ± 0.1 vs 0.5 ± 0.1 fc, $p < 0.001$).
Selective restoration of macrophage RNF41 in fibrotic mice using RNF41-DGNP promoted remarkable hepatic repair with 56% reduction in liver fibrosis area, and recovery of parenchymal structure. In concert, macrophage RNF41 restoration reduced the hepatic expression of pro-inflammatory genes and increased the expression of anti-inflammatory genes, denoting a beneficial macrophage switch on liver fibrosis. These anti-fibrotic and anti-inflammatory effects translated into a significant reduction in liver injury (AST: 592.6 ± 93.9 vs. 243 ± 46.15 U/L, $p < 0.01$; ALT: 182.7 ± 22.54 vs. 91.09 ± 12.51 U/L, $p < 0.01$). RNF41-DGNP therapy similarly orchestrated fibrosis regression at cellular level with reduced hepatic stellate cell activation, highlighted by a decrease in the hepatic expression of collagen-I (1.0 ± 0.1 vs. 0.5 ± 0.1 fc, $p < 0.001$), alpha-SMA (1.0 ± 0.1 vs. 0.6 ± 0.1 fc, $p < 0.001$) and TIMP-1 (1.0 ± 0.1 vs. 0.5 ± 0.1 fc, $p < 0.001$). These effects were attributed to a reduction in the hepatic expression of macrophage pro-fibrogenic factors (TGF-beta, PDGFB, and OSM). RNF41-DGNP also promoted an increase in the expression of the collagenase MMP-9, suggesting an active participation of macrophage RNF41 on extracellular matrix remodelling.
Conclusion: RNF41 plays a major role in the regulation of macrophages in hepatic inflammation and fibrosis. This study highlights the potential of macrophage RNF41 as a novel therapeutic target for patients with cirrhosis.

WED-221

Therapeutic effect of recombinant human Cytoglobin against mouse liver fibrosis and stellate cell activation via ROS scavenger function and activation of JAK-STAT1 pathway

Norifumi Kawada[1], Duc Pham Minh[1], Le Thi Thanh Thuy[1], Hai Hoang[1].
[1]*Osaka Metropolitan University, Department of Hepatology, Graduate School of Medicine, Japan*
Email: kawadanori@omu.ac.jp

Background and aims: Cytoglobin (CYGB) is a gas-binding hexacoordinate globin that was originally discovered in the cytoplasm of hepatic stellate cells (HSCs) and has been demonstrated to play a crucial role in maintaining HSCs in a quiescent status. Here we show the promising therapeutic effects of extracellular 6-His tagged recombinant human CYGB (6His-CYGB) against mouse liver fibrosis and activated human HSCs.
Method: Mice with Cygb deficiency or those (TG) with specific overexpression of Cygb in HSCs underwent BDL or CDAA diet-induced liver fibrosis. Synthesized 6His-CYGB was tested for its bio-distribution and function in human HSCs (HHSteCs) and for its therapeutic effects against advanced liver fibrosis in mice induced by TAA, CCl4, or DDC. RNA-Seq, single-cell RNA-Seq and pathway analysis were performed in non-treated or 6His-CYGB-treated HHSteCs and liver tissues exposed to CCl4 or CCl4/6His-CYGB.
Results: Cygb deficiency or overexpression in mice caused marked deterioration or amelioration of liver inflammation and fibrosis, respectively, in both BDL and CDAA-induced liver injuries. In cultured HHSteCs, exogenous 6His-CYGB (~80 μg/ml) was found to be endocytosed and accumulated in endosomes via the clathrin-mediated pathway and gave rise to the attenuated production of reactive oxygen species (ROS), fibrosis-related gene sets including Col 1A1, and alpha-SMA. Besides its ROS-scavenger function, exogenous 6His-CYGB induced interferon (IFN)-gamma secretion by HHSteCs via activating TANK-binding kinase 1, resulting in the activation of JAK-STAT1 pathway. Memolotinib, a JAK1/2 inhibitor, canceled these effects of 6His-CYGB. To assess whether these biological functions of 6His-CYGB was created by the heme holding in CYGB's 3D conformation, we replaced the iron center of the heme with cobalt ions (Co-CYGB). As results, Co-CYGB administration failed to exhibit all 6His-CYGB effects, including the activation of IFN-gamma pathway and the suppression of COL1A1 and alpha-SMA in HHSteCs. In vivo analyses revealed that intravenously injected 6His-CYGB through mouse tail vein reached the liver and, surprisingly, accumulated in sinusoidal cells, dominantly in HSCs and liver sinusoidal endothelial cells (LSECs), but not in Kupffer cells. Administration of 6His-CYGB (2 mg/kg, twice a week) protected mouse liver from ROS-induced DNA damage and histological fibrosis aggravation in TAA, CCl4 or DDC models without any adverse events. We annotated 25 non-parenchymal cell populations in our single-cell RNA-Seq data set obtained from CCl4-mice treated with 6His-CYGB compared with 22 clusters in CCl4 single exposure and identified unique HSC and LSEC subpopulations that responded to fibrosis regression and extracellular matrix degradation pathways.

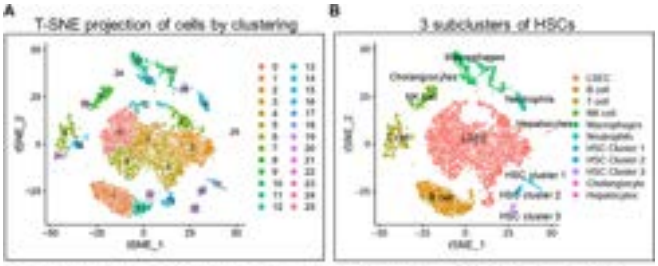

Figure 1. Six weeks of CCL4 treatment with recombinant human CYGB tail vein injection twice a week at the final 4 weeks revealed 25 non-parenchymal cell populations (A) including 3 sub-clusters of HSCs (B) with inactivated phenotype which response to extracellular matrix degradation pathway.

Figure:

Conclusion: Recombinant extracellular 6His-CYGB exhibits a promising anti-fibrotic property for chronic liver diseases.

Hepatic proteomic analysis identifies proteins linked to hepatic sympathetic neuronal degeneration and disorganization which promotes liver fibrosis in bile duct ligation murine model

Sadam H Bhat[1], Nupur Sharma[1], Csaba Adori[2], Anupama Parasar[3], Babu Mathew[1], Manisha Yadav[1], Hami Hemati[4,5], Neha Sharma[1], Gaurav Tripathi[1], Sushmita Pandey[1], Vasundhra Bindal[1], Nilesh Patil[6], Viniyendra Pamecha[7], Savneet Kaur[1], Roshan Koul[8], Manoj Kumar[9], Jaswinder Maras[1], Shiv Kumar Sarin[9]. *[1]Institute of liver and biliary sciences, Molecular and cellular medicine, India; [2]Karolinska institutet, Neuroscience, Sweden; [3]Institute of liver and biliary sciences, Center for comparative medicine, India; [4]University of kentucky, Toxicology, United States; [5]University of Kentucky, Department of Toxicology and Cancer Biology, Lexington, United States; [6]Institute of Liver and Biliary Sciences, Liver Transplant and Hepato Pancreato Biliary Surgery, India; [7]Institute of liver and biliary sciences, Liver transplant and hepato pancreato biliary surgery, India; [8]Institute of liver and biliary sciences, Neurology, India; [9]Institute of liver and biliary sciences, Hepatology, India*
Email: shivsarin@gmail.com

Background and aims: Hepatic sympathetic nerves (HSN) are critically involved in hepatic metabolism. These nerve fibres innervate around hepatic artery, portal vein, and bile duct. Disorganization or degeneration of the HSN is known to alter hepatic metabolism, however, its role in progression of liver disease and the associated molecular changes are not fully elucidated. Our aim is to identify liver proteins that are altered after hepatic sympathetic neuronal damage and are associated with the progression of liver injury.
Method: Liver-specific sympathetic neuronal damage/denervation [sympathectomy (Sx)] was performed by intraportal injection of 6-OHDA hydrobromide on 8–10-week-old male Sprague Dawley rats. Study groups were divided as Group-1 (GR-1), control rats with intact HSN (Veh; n = 9); Group-2 (GR-2) sympathectomized rats (Sx; n = 12); Group-3 (GR-3) Bile duct ligation vehicle with intact HSN; (BDL/Veh; n = 9); and Group-4 (GR-4) sympathectomized rats with BDL (BDL/Sx; n = 9), respectively. All groups were subjected to histological, confocal microscopy, plasma AST/ALT, and proteomic analysis at baseline, Day-7 (D7), D15, and D30.
Results: Liver-specific sympathectomy was validated in GR-2 and GR-4 by observing the change in urine colour (orange red), ptosis (droopy eyelid) and absence of sympathetic nerves marker (tyrosine hydroxylase; TH) in the liver samples. Mild steatosis and inflammation were observed in GR-2 at D7 and D15 with no significant difference in AST and ALT levels when compared to GR-1. Liver histology analysis showed significant increase in liver fibrosis in GR-4 as compared to GR-3 ($p < 0.05$). Interestingly, the level of fibrosis was significantly higher at D15 in GR-4 and it was comparable to the fibrosis seen in D30 in GR-3 ($p < 0.05$). Concordantly, we found significant increase in the AST and ALT values in GR-4, as compared to GR-3 ($p < 0.05$). In GR-3, we observed a significant progressive disorganization of sympathetic nerves that correlated with the severity of fibrosis and inflammation. PLS-DA (Partial least squares-discriminant analysis) analysis of the liver proteome showed clear differences between the study groups. 462 proteins were differentially expressed (227 upregulated and 235 downregulated) in GR-4 as compared to GR-3, showing significant activation of both the fibrogenic (TNFR2, Wnt, FGF) and inflammatory (NLRP3, MAPK, PDGF) pathways ($p < 0.05$). Interestingly, several hepatic secretory proteins [Annexin A2 (Anxa2), Butyrylcholinesterase (Bche), Fibroblast growth factor 5 (Fgf5), Hepatoma-Derived Growth Factor (Hdgf), and Paraoxonase 3 (Pon3)] showed temporal increase in expression (FC > 2, FDR < 0.01, $p < 0.05$) in GR-4 and significantly correlated with the severity of fibrosis ($R2 > 0.7$, $p < 0.05$) in GR-4, suggesting that upregulation of these secretory proteins due to sympathetic neuronal damage could be associated with the progression of liver fibrosis in GR-4.

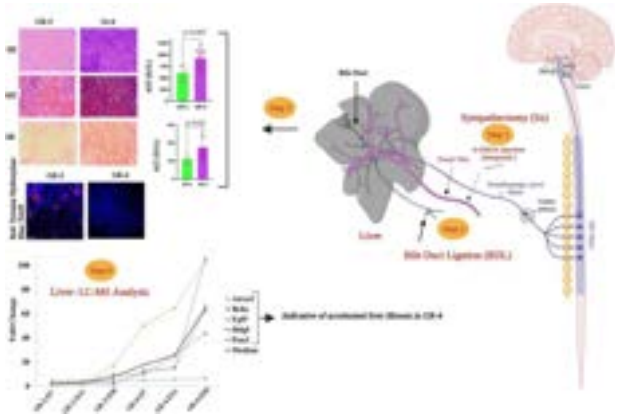

Figure: Graphical abstract

Conclusion: Hepatic sympathetic denervation promotes fibrosis and liver injury. Elevated levels of the secretory proteins, Anxa2, Bche, Fgf5, Hdgf, and Pon3 after hepatic sympathetic neuronal damage/denervation are an indicative of accelerated liver fibrosis in a rat model of bile duct ligation.

WED-223

Functional and mechanistic role of lncRNA-C1 in cholestatic liver diseases

Email: martavarela.rey@usc.es

Background and aims: Liver fibrosis is characterized by complex cellular responses of several hepatic cell types. Long non-coding RNAs (lncRNA) are a class of non-coding RNAs that can interact with DNA, RNA and proteins to regulate global gene expression patterns. They are remarkably versatile regulators, influencing multiple biological processes and playing key roles in the pathogenesis of several disorders. Their function in liver fibrosis however remains largely unexplored.
Method: We have studied the expression of LncRNA-C1 in samples from patients with primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC), in mice models of cholestasis, NAFLD and toxic-induced fibrosis by CCl_4, and in several hepatic cell types after liver injury. Finally, we have performed functional analysis by *in vivo* and *in vitro* targeting of lncRNA-C1.

Results: We have observed that LncRNA-C1 was significantly upregulated in liver samples from patients with primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC), and that its expression was consistently elevated in three different mice models of cholestasis, including bile duct ligation (BDL), mice fed with a cholic acid diet, and MDR2-KO mice. In addition, levels of this lncRNA were also upregulated in other mice models of hepatic fibrosis, including toxic-induced fibrosis by CCl_4 (6 weeks), or mice fed with methionine-choline deficient diet (MCDD), methionine-choline deficient and high fat diet (MCDD-HFD), choline deficient and high fat diet (CD-HFD), and high fructose and high fat diet (HF-HFD). *In vivo* hepatic targeting of lncRNA-C1 a exacerbated liver damage after BDL (as seen by elevated levels of transaminases and enhanced number of necrotic areas), increased NOS2 expression and decreased FXR levels. Using primary cells isolated from MDR2-KO mice, we found that, lncRNA-C1 was upregulated in hepatocytes and in hepatic stellate cells (HSC). Furthermore, both primary hepatocytes isolated from BDL mice, and activated HSC (including LX-2 cells or primary human HSC treated with TGF-beta, or HSC isolated from MCDD, CD-HFD, CCl_4 mice models) showed increased levels of lncRNA-C1. Surprisingly, when lncRNA-C1 was silenced in TGF-beta-treated LX2 cells, phosphorylation levels of Smad2, and the mRNA expression levels of col1a1, col1a2 and acta2 were increased, suggesting an antifibrotic role of lncRNA-C1. Finally, in cholestatic mice models, we observed a positive correlation between the levels of lncRNA-C1 in serum and the hepatic levels of col1a1 and col1a2 mRNA, suggesting the potential role of lncRNA-C1 as non-invasive biomarker for hepatic fibrosis.
Conclusion: Altogether, our data suggest that lncRNA-C1 could play a protective role during liver fibrosis development, and that lncRNA-C1 could represent a clinically relevant novel target in liver fibrosis.

WED-224
Evaluation of anti-fibrotic compounds effect in 3D human NASH model using quantitative digital pathology
Radina Kostadinova[1], Simon Ströbel[1], Louis Petitjean[2], Agnieszka Pawlowska Pawlowska[1], Li Chen[2], Francisco Verdeguer[1], Mathieu Petitjean[2]. *[1]InSphero AG, Liver disease discovery, Schlieren, Switzerland; [2]PharmaNest, Princeton, NJ, United States*
Email: radina.kostadinova@insphero.com

Background and aims: Non-alcoholic steatohepatitis (NASH) is a progressive and severe liver disease characterized by lipid accumulation, inflammation and, later, fibrosis. The development of novel anti-fibrotic therapies has been hindered, in part, by the limitations of existing fibrosis analysis techniques of the histology samples from in vivo and in vitro preclinical models. The novel digital pathology quantitative AI platform, FibroNest, was used previously to generate automatic, and direct fibrosis end points to quantify fibrosis severity and compound treatment response in clinical NASH samples. Here, we established an algorithm for quantification of fibrosis in an in vitro 3D human liver microtissue (hLiMT) NASH model using FibroNest imaging.
Method: The NASH hLiMT model consists of primary human hepatocytes, Kupffer cells, liver endothelial cells and hepatic stellate cells (HSC). Upon exposure to defined lipotoxic and inflammatory stimuli such as free fatty acids and LPS in media containing high levels of sugar and insulin the 3D NASH model displayed key disease pathophysiological features within 10 days of treatment. Quantifiable markers were established for anti-NASH drug efficacy testing such as secretion of pro-collagen type I/III and TIMPs/MMPs as well as quantification of fibrosis using FibroNest platform based on the Sirius Red staining of histology slides. Next generation sequencing (NGS) was also used for the assessment of the gene expression changes and pathways perturbation in the NASH model upon compounds treatment.
Results: The FibroNest algorithm for NASH hLiMTs was first validated using reference anti-fibrotic compounds, ALK5i and anti-TGF-ß antibody. The quantification of fibrosis using the "phenotypic fibrosis quantitative score" demonstrated that both reference compounds decreased the deposition and degradation of fibrosis. An efficacy study extended the evaluation to include clinical compounds, Firsocostat, Selonsertib, and Resmiteron, and a combination of Firsocostat and Selonsertib. When the anti-fibrotic effects of these were evaluated using the same panel of end points, there was a disconnect between the functional assays with gene-expression data and the phenotypic quantification of fibrosis using FibroNest. With few exceptions, none of the clinical single drugs or the combination of Firsocostat and Selonsertib decreased the secretion of pro-collagen type I and III, TIMPs or MMPs. Of the clinical compounds, only 10 µM Selonsertib decreased the pro-collagen type I secretion on day 7. By contrast, the quantification of fibrosis using FibroNest platform demonstrated that all the tested clinical compounds had antifibrotic effects, which were in accordance with clinical observations.
Conclusion: In summary, the use of NASH hLiMTs and FibroNest imaging combined with transcriptomics and functional assays represents a promising drug discovery tool for the evaluation of the efficacy of different modalities of anti-fibrotic drug candidates and their combinatorial treatment.

WED-225
Bulk and single cell RNA sequencing profiling of human hepatic stellate cells and the potential biomarkers for liver cirrhosis
Xu Liu[1,2], Heming Ma[1,2], Qingtian Guan[3], Huan Wang[4], Guangyi Wang[5], Yanhang Gao[1,2], Guoyue Lv[5], Junqi Niu[1,2]. *[1]First Hospital of Jilin University, Department of Hepatology, Changchun, China; [2]First Hospital of Jilin University, Center of Infectious Diseases and Pathogen Biology, China; [3]First Hospital of Jilin University, Bioinformatics Laboratory, Changchun, China; [4]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Infectious Diseases, Wuhan, China; [5]First Hospital of Jilin University, Department of Hepatobiliary and Pancreatic Surgery, Changchun, China*
Email: junqiniu@jlu.edu.cn

Background and aims: Liver cirrhosis, which presents with the distortion of hepatic architecture, is a significant global health burden. However, its exact mechanisms remain incompletely established. Hepatic stellate cells (HSCs) participate in the core regulation of fibrotic occurrence and reversion. Here, we used single-cell and bulk RNA sequencing (RNA-seq) to analyze the changes in the transcriptional patterns of patient-derived HSCs, revealing the diagnostic and therapeutic targets for cirrhosis.
Method: Primary HSCs were isolated from human liver tissues by recirculating perfusion. Bulk mRNA-seq of HSCs was performed by two comparative schemes [scheme A: Group_Cir (n = 9) versus Group_Noncir (n = 6); scheme B: Group_Act (n = 7) versus Group_Fre (n = 7)]. The dysregulated mRNAs of HSCs induced by hepatic cirrhosis were identified, and enrichment analyses were depicted. Protein-protein interaction (PPI) networks were constructed to search for candidates, which were verified by quantitative real time PCR. Then, the upstream transcription factors (TFs) were predicted using the KnockTF database. Cells from seven livers were obtained for single-cell RNA sequencing (scRNA-seq) and myofibroblastic HSCs were identified and analyzed. Ligand-receptor interactions in scRNA-seq were applied to predict the intercellular crosstalk.
Results: In the bulk RNA-seq, we observed 3828 and 2262 differentially expressed genes (DEGs) in scheme A and B, respectively.

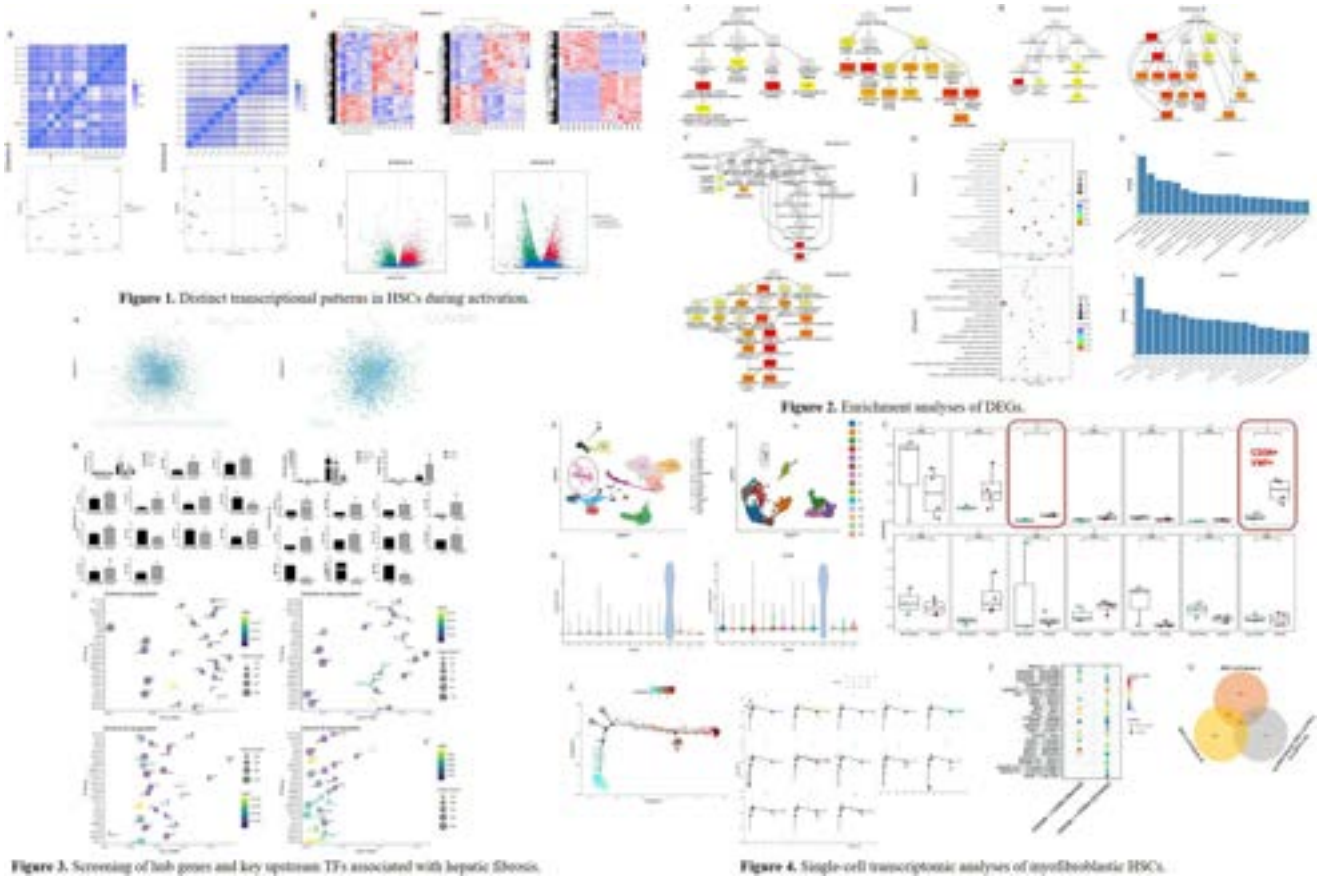

Figure: (abstract: WED-225).

According to the functional annotations of these two schemes, the DEGs were significantly enriched in 'focal adhesion', 'retinol metabolism', and 'formation, assembly, or degradation of collagen or extracellular matrix'. By PPI analysis, CAV1, ESR1, APP, SHC1, BCR, and LPL were screened as hub genes. Through the TFs-DEGs networks, POU5F1, ZFX, RARA, and MXD3 were considered the most important TFs that significantly regulate our DEGs. The scRNA-seq revealed myofibroblastic HSCs were at the end stage of differentiation and were regulated by cirrhosis-related endothelial cells through key ligand-receptor pairs, including PDGFs-PDGFRs, ANGPTL4-SDC2/SDC4/ITGA5+ITGB1, and NAMPT-ITGA5+ITGB1. Finally, we found that 38 upregulated genes of myofibroblastic HSCs in scRNA-seq were shared in bulk RNA-seq.

Conclusion: Our study offers multiple sequencing data; reveals the changing characteristics of human HSCs; and investigates potential targets associated with liver cirrhosis. It therefore sheds light on the molecular mechanisms underlying liver cirrhosis and provides information for its detection and treatment.

WED-226

Novel natural killer cell immunotherapy through synthesized Neuroligin-4 peptides improved liver fibrosis

Baker Saffouri[1], Johnny Amer[1], Ahmad Salhab[1], Rifaat Safadi[1].
[1]*Hadassah-Hebrew University Hospital, Liver Institute, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: NK cells lose their antifibrotic potential in advanced liver fibrosis particularly in patients with non-alcoholic fatty liver disease (NAFLD). Neuroligin-4 (NLGN4) receptor, a postsynaptic neuroinhibitory signalling, recently found overexpressed on NK cells and influence their killing potentials in NAFLD patients with advanced liver fibrosis. NLGN4 and its ligand β-neurexin (β-NRXN) expressed on activated hepatic stellate cells (HSCs) showed to exert a synergistic inhibitory effect on NK cells. β-NRXN overexpression in activated HSCs indicated its role in fibrogenesis. Herein, we developed a newly synthesized NLGN4 peptides to assess their effects on NK cells and HSCs activities in an in vitro and in vivo liver fibrosis model.

Method: Three synthesized peptides were used and incubated for two hours at concentration of 2, 4, 8 μg/ml with LX2 cells prior to co-cultures with NK cells for 24-hours. NK cells were obtained from NAFLD patients with F3/F4 scores. Flow cytometry was used for assessing NK cell activity through CD107a; lysosomal-associated membrane protein-1 and LX2 activations through α-Smooth muscle actin (αSMA expressions). For the in vivo study, C57/Bl mice were i.p injected with CCl_4-induced liver fibrosis (0.5 μl/g body weight) and synthesized peptides (8 μg/mice) twice a week for 6 weeks. Serum and livers were assessed for pro-inflammatory cytokines and histopathological staining, respectively.

Results: In an in vitro setting, HSCs pre-incubated with NLGN4 peptides, reduced their activations (αSMA expressions 1.53 and 1.55-folds in peptide 1 and peptide 2 respectively, $P < 0.001$) with a further prominent reduction in αSMA expressions following incubations with NK cells (2.85 and 2.3-folds in peptide 1 and peptide 2, respectively, $P < 0.001$). Moreover, the studied peptides downregulated expressions of both NLGN4 and β-NRXN in liver extracts isolated from CCl_4 liver fibrosis mice model. NLGN4 peptides showed a delayed progressions of liver fibrosis through improving liver histological findings of inflammatory and fibrotic lesions and reducing liver injury enzymes (ALT). Fibrotic markers (αSMA, Collagen, CREB and MMP4) assessed via western blot and RT-PCR were also alleviated following treatment with peptides, and these results were associated with elevated NK cells activations assessed by the CD107a and F-actin expressions through the flow cytometry and confocal microscopy, respectively.

Conclusion: Interruption of NK/myofibroblast cellular synapse by targeting the NLGN4/β-NRXN axis with NLGN4 peptides achieved a synergistic antifibrotic effects through (1) cytotoxic NK cells stimulation against myofibroblasts; either directly via NLGN4 inhibition and indirectly by blocking the NK inhibitor β-NRXN, (2) directly inhibit β-NRXN of myofibroblasts and decreased their activation. Thus, immunotherapy targeting the NLGN4/β-NRXN axis represent a potential novel immune therapeutic strategy in NK cell-mediated diseases.

WED-227

Multimodal decoding of the mesenchymal landscape of human biliary fibrosis

David Wilson[1], Neil Henderson[1]. [1]*Centre for Inflammation Research, University of Edinburgh, United Kingdom*
Email: d.h.wilson@ed.ac.uk

Background and aims: Primary Biliary Cholangitis (PBC) is a fibrosing cholangiopathy of the liver that is increasing in prevalence globally. Currently, there are no effective antifibrotic therapies available with which to treat patients with liver fibrosis. In end-stage disease, transplantation is the only treatment option, however, less than 10% of global transplantation needs are met. Therefore, effective antifibrotic therapies are urgently required. To advance our understanding of human liver fibrosis and to inform design of antifibrotic therapies, we have used multimodal single cell genomics approaches to generate single-cell, pan-lineage atlases of human primary biliary cholangitis and mouse models of biliary fibrosis.
Method: To deepen our understanding of the cellular and molecular mechanisms driving human biliary fibrosis, and to inform design of effective antifibrotic therapies, we performed single nuclei RNA sequencing (snRNA-seq) of healthy and PBC explant livers to generate a single-cell, multi-lineage atlas of human biliary fibrosis. Following this, we established a single-nuclei pan-lineage atlas of mouse biliary fibrosis and used this mouse model to interrogate the function of corollary subpopulations observed in both human and mouse biliary fibrosis.
Results: We uncovered multiple, disease-associated mesenchymal and cholangiocytes subpopulations in human biliary fibrosis and using newly generated markers we have comprehensively characterised the topography of these subpopulations in the human biliary fibrotic niche. Moreover, ligand-receptor analysis of pathogenic mesenchymal subpopulations has identified a distinct set of putative therapeutic targets, which we are currently functionally interrogating using genetic approaches in mouse biliary injury models, and small molecule approaches in human biliary, multi-lineage organoids.

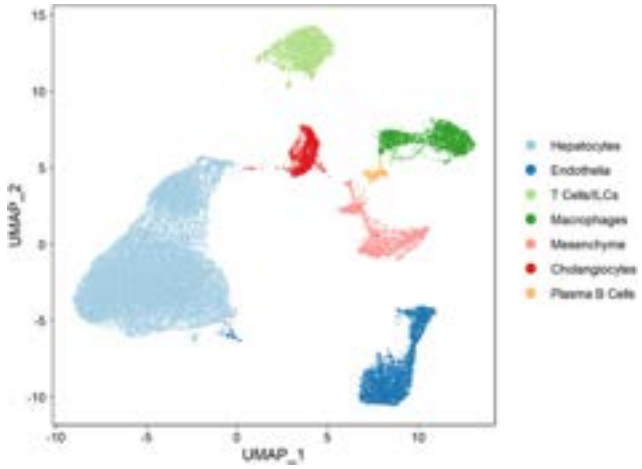

Figure: UMAP delineating a single-nuclei pan-lineage atlas of healthy and PBC human liver (n = 10) showing major cell lineage cluster annotations.

Conclusion: Multimodal single cell genomic approaches, in conjunction with functional interrogation of corollary cellular subpopulations in mouse models of biliary fibrosis, have allowed us to uncover novel cell states and unanticipated aspects of biliary fibrogenesis. Our ongoing work is currently assessing the feasibility and tractability of these newly identified therapeutic targets to treat patients with biliary fibrosis.

Background and aims: Accumulation of hydrophobic bile salts is believed to promote liver fibrosis in human cholestatic liver disease. An important difference between mice and man in regard to liver pathophysiology is their different composition of the bile salt pool with hydrophilic bile salts predominating in mice, and hydrophobic bile salts such as (glyco-) chenodeoxycholate ((G)CDC) in man. We have previously shown that humanization of the bile salt pool by GCDC-feeding is crucial for development of liver fibrosis in chronic hepatocellular cholestasis and hypothesized that direct activation of hepatic stellate cells (HSC) may be involved. Here, we further explored the capability of various bile salts to activate HSC in vitro and tested the role of a humanized bile salt pool in development of CCl_4-induced liver fibrosis.
Method: C57BL/6 mice were fed a control diet or a diet enriched with GCDC (0,1% w/w) for 6 weeks to humanize their bile salt pool. For the last 4 weeks, mice were treated with CCl_4 (0.93 g/kg) 3 times per week. Liver fibrosis was quantified by hydroxyproline measurement and Sirius red staining. The human HSC line LX2 was stimulated with bile salts in standard culture medium at a slightly acidic pH (7.3) to account for the acidic microenvironment known to be present in the perisinusoidal space. Activation of cells was quantified by Western blotting for αSMA (normalized for GAPDH).
