Background and aims: Bacterial translocation (BT), and Pathogen Associated Molecular Patterns (PAMPS), propagate a pro-inflammatory response in chronic liver diseases. However, the role of BT, the immune system, and their interaction, is as-yet incompletely characterised in Biliary Atresia (BA). We aimed to characterise the association of immune markers in BA, before and after Kasai portoenterostomy (KPE), with fibrosis and BT, and clinical outcomes.
Method: Plasma samples were prospectively collected from BA infants (n = 55) pre-KPE, 6weeks-, 3months-, and 6months-post-KPE. Th1- (IL-2, IFNy), Th2- (IL-4, IL-10), TH17- (IL-17, 1Lβ-23), macrophage-associated (IL-6, IL-8, TNFα, IL-1β) cytokines, and cellular adhesion molecules (ICAM-1, VCAM-1), BT biomarkers (LBP and D-lactate) were measured. Clinical outcomes: 6month-JC (jaundice clearance), 1year-LT (liver transplantation), cholangitis by 6month-post-KPE, fibrosis biomarkers [Aspartate Aminotransferase-to-platelet ratio index (APRi); Liver Stiffness Measurement (LSM)]. Additionally, we investigated the course of the assessed immune markers via longitudinal analysis, using generalised estimating equations.
Results: Pre-KPE, immune markers were similar between clinical outcome groups. By 6weeks-post-KPE, increased IL-4, IL-8, IL-1β and ICAM-1 were associated with 1-year-LT. ICAM-1 was associated with poor 6month-JC and with fibrosis biomarkers [APRi;rs = 0.6, p < 0.001:LSM;rs = 0.6, p < 0.001]. By 3months-post-KPE, further increases in macrophage-associated cytokines in non-favourable outcome groups (1year-LT and poor 6month-JC), were evident. VCAM-1/ICAM-1, IL-8 and IL-1β positively correlated with APRi and LSM. We found an increased rise of IL-17 [1.14 ng/L/month], IFN-y [4.04 ng/L/month] ICAM-1 [76 ug/L/month] and VCAM-1 [142 ug/L/month] over the 6month-period, in 1yr-LT group. IL-17, 6weeks-post-KPE, associated with cholangitis [p = 0.03]. At early-post-KPE time-points, macrophage markers (IL-6, IL-8, TNFa) and ICAM-1/VCAM-1 positively correlated with LBP levels; macrophage markers/TH2/Th17 and adhesion molecules, positively correlated with D-lactate.
Conclusion: Divergence of innate (macrophage) and adaptive (Th1/Th2/Th17) immune pathways early post-KPE, strongly discriminates BA infants with non-favourable clinical outcomes. This novel data provides convincing evidence for BT in macrophage activation, upregulation of adhesion molecules, and fibrosis. Consequently, targeted microbiota-modulatory therapy, early-post-KPE, could dampen PAMP-associated damage in BA.

THU-308

Chronic hepatitis B infection and porto-sinusoidal vascular disorder, a non-negligible coexistence

Pol Olivas Alberch[1,2,3], Sabela Lens[3,4], Genís Campreciós[3,5], Carla Montirioni[6], Marta Magaz[2,3,4], Valeria Perez[2,3,7], Lara Orts[3,8], Anna Baiges[2,3,4], Fanny Turon[2,3,4], Juan Carlos, Garcia Pagan[2,3,9], Virginia Hernandez-Gea[2,3,10]. Email: olivas.alberch@gmail.com

Background and aims: Porto-sinusoidal vascular disorder (PSVD) diagnostic criteria have recently been redefined (Baveno VII). An important novelty is that the presence of other liver disease etiology does not exclude PSVD diagnosis in absence of cirrhosis. Coexistence of HBV chronic infection (HBVci) and PSVD-like vascular alterations have anecdotally been reported. Our aim is to evaluate the prevalence of this coexistence and its clinical impact.
Method: Retrospective unicentric study. Inclusion of patients meeting Baveno VII PSVD criteria. Detailed characterization of HBV biology. Collection of clinical data at diagnosis and follow-up (11 ± 9

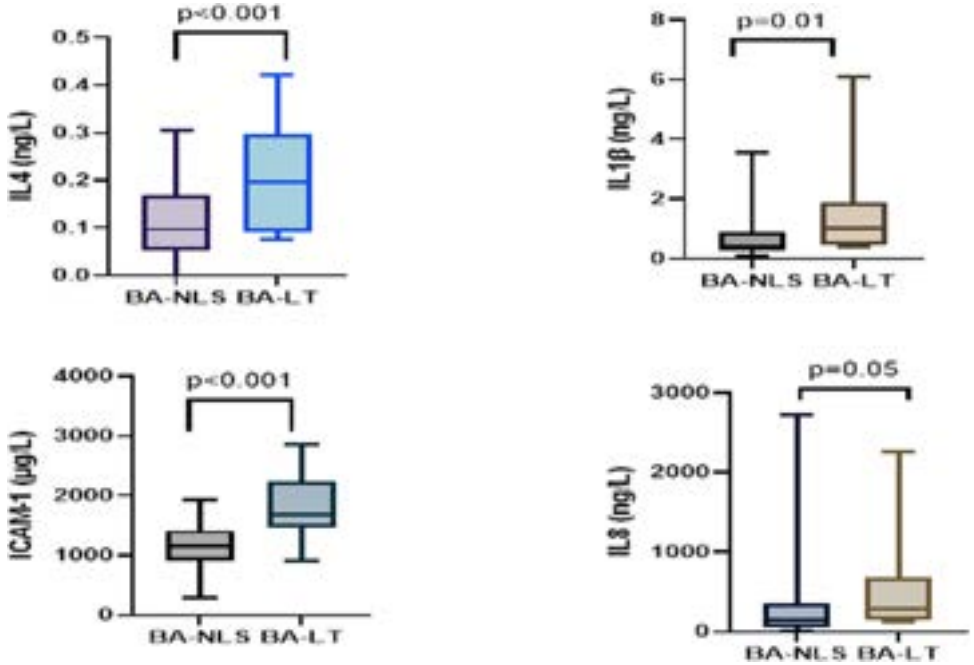

Figure: (abstract: THU-307).

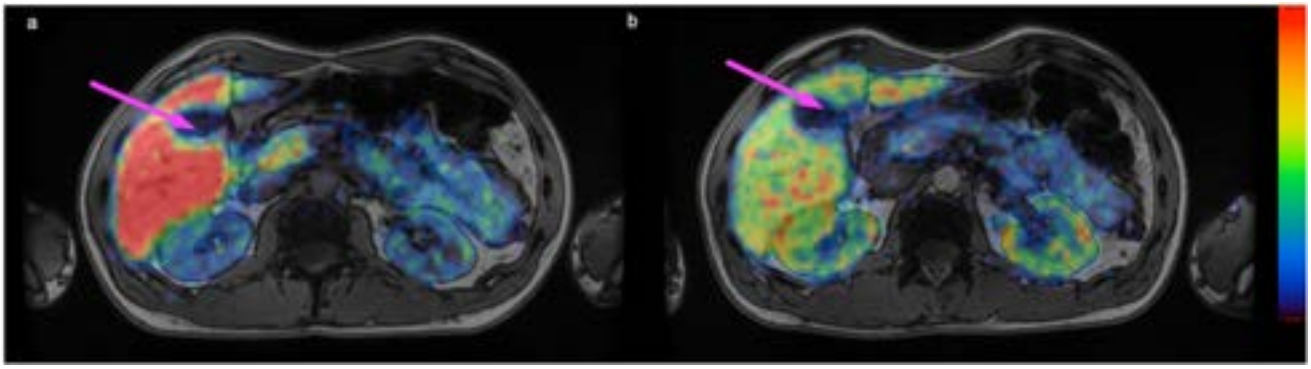

Figure: (abstract: THU-300): Fused axial abdominal PET/MRI showing the liver, kidneys and gallbladder (magenta arrow), 6 hours after i.v. ^{64}Cu injection. a) Pre-treatment after a 3 day pause of treatment with penicillamine. b) After 7 days of treatment with TTM. 64Cu concentration is expressed as Standard uptake Value (SUV). Scale 2.5 (black)-20 (red).

years). Definitions: HBVci (AgHBs + more than 6months), HBV past infection (HBsAg- and anti-HBc+), Non-exposed (HBsAg- and anti-HBc-).

Results: We included 173 patients with PSVD: 151 had a complete HBV biology characterization (HBsAg, anti-HBs, anti-HBc), the other 22 only had HBsAg- information and so, they were only used to calculate prevalence. Prevalence of HBVci was higher in the PSVD cohort than in the general Spanish population (4,49% vs 0,8% p < 0,001), as well as the prevalence of past HBV infection (16,85% vs 12,3% p 0,064). As HBV and HIV infection may coexist, we analyzed our cohort and did not find differences in HIV infection prevalence in patients with PSVD and HBVci compared to the whole PSVD cohort. The presence of underlying associated conditions (50%) and the biopsy findings were similar in all the HBV serology groups. According to HBV status, patients with HBVci had a significant delay in the diagnosis of PSVD (14 vs 1 year) compared to non-infected ones (Past HBV infection and non-exposed), and the most common misdiagnosis was cirrhosis. At time of PSVD diagnosis HBVci patients had more advanced liver disease with worse hepatic function (MELD 12 (9–16) vs 9 (7–11) p 0,062) and slightly higher rate of decompensation (50% vs 38,5% p 0,712) and further decompensation (37,5% vs 14,7% p 0,115) conditioning higher need of liver transplantation than non-infected patients (25% vs 2, 1% p 0,023) and worse liver transplant free survival at one year of diagnosis (75% vs 95, 8%; log-rank 0,002).

Conclusion: HBV chronic infection and PSVD can coexist. Patients with PSVD and HBVci had a more advanced disease at diagnosis and higher need of liver transplantation than non-infected patients. Increased awareness is needed to reduce misdiagnosis and delay in diagnosis reinforcing the idea of managing patients at centers of expertise.

THU-309

Effects of tetrathiomolybdate on copper distribution and biliary excretion: a controlled 64CuCl2 PET/MRI

Frederik Teicher Kirk[1], Ditte Emilie Munk[1], Eugene Scott Swenson[2], Adam Quicquaro[2], Mikkel Holm Vendelbo[3], Michael Schilsky[4], Peter Ott[1], Thomas Damgaard Sandahl[1]. *[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark; [2]Alexion, AstraZeneca Rare Disease, United States; [3]Aarhus University Hospital, Department of Nuclear Medicine and PET-center, Denmark; [4]Yale School of Medicine, Department of Medicine, Section of Digestive Diseases, and Department of Surgery, Section of Transplant and Immunology, United States*
Email: frkirk@rm.dk

Background and aims: Patients with Wilson Disease (WD) experience pathologic hepatic copper accumulation due to reduced biliary copper excretion. Bis-choline tetrathiomolybdate (TTM) is a high affinity copper chelator with therapeutic potential in WD. Reports in rodents that TTM stimulates hepatic copper excretion into the bile have not been confirmed in humans. In this study, to better understand its mechanism of action, we used ^{64}Cu PET imaging to examine the effects of TTM on copper distribution and hepatic excretion in patients with WD.

Method: Copper distribution and biliary excretion after an intravenous ^{64}Cu dose was investigated in four WD patients on stable chelation therapy using ^{64}Cu PET/MRI. Samples of venous blood were also taken for radiocopper measurement. Patients were scanned 20 minutes post ^{64}Cu dose and 7 more times until 68 h post dose. We compared PET/MRI recordings without treatment (baseline) and after TTM treatment, with each patient serving as their own control.

Results: TTM significantly increased ^{64}Cu levels by 5–700% in venous blood samples and in aorta (measured by PET) during the first 6H after the ^{64}Cu administration. Hepatic levels of ^{64}Cu were significantly decreased from baseline by TTM by 59%-27% (20 min-68 h post dose, respectively). These observations suggested immediate strong binding of ^{64}Cu in blood by TTM with retention of ^{64}Cu in plasma, leading to reduced uptake in organs.

Gallbladder ^{64}Cu levels were below or near detection limit at all time points and did not increase on TTM treatment during the 68 h timeframe, suggesting no induction of biliary radiocopper excretion (Figure). Radiocopper in the kidneys followed a different pattern. Initially, TTM inhibited renal ^{64}Cu accumulation, but from 20 h onwards renal ^{64}Cu was higher after TTM ($p < 0.03$). However, this was not followed by increased ^{64}Cu levels in the bladder.

Conclusion: PET/MRI is a useful tool for examining copper metabolism and mechanism of action of copper chelation therapy. TTM did not enhance biliary excretion of ^{64}Cu after TTM administration to patients with WD, in contrast to earlier reports in rodents, suggesting an alternative mechanism of action for this drug. TTM initially acted to reduce exposure of the liver and other organs to Cu by retaining ^{64}Cu in the plasma, but with time the copper may be redistributed. Further study is needed to delineate the multimodal effect of TTM on copper metabolism.

THU-310

Targeting CCL24 in primary sclerosing cholangitis with CM101: rationale and study design

Douglas Thorburn[1], Massimo Pinzani[2], Palak Trivedi[3], Christopher Bowlus[4], Rifaat Safadi[5], Christina Crater[6], John Lawler[6,7], Adi Mor[6], Chris Cirillo[6], Matthew Frankel[6]. *[1]The Royal Free Hospital, United Kingdom; [2]University College London, United Kingdom; [3]University of Birmingham, United Kingdom; [4]University of California, Davis, United States; [5]Hadassah Hebrew University Hospital, Israel; [6]Chemomab Therapeutics, Ltd, United States; [7]Chemomab Therpeautics, INC, Clinical, Israel*
Email: douglas.thorburn@nhs.net

Background and aims: Primary sclerosing cholangitis (PSC) is a rare, chronic cholestatic liver disease characterized by progressive inflammation, fibrosis, and destruction of the intrahepatic and extra-hepatic bile ducts. Animal models of PSC have shown that cytokines and chemokines may be important pathogenetic mediators of liver inflammation and fibrosis. CCL24 (eotaxin-2) is a chemokine that promotes cell trafficking and regulates inflammatory and fibrotic activities through the CCR3 receptor. Blockade of CCL24 with CM101, a humanized anti-CCL24 monoclonal antibody, has been shown in pre-clinical models to significantly reduce migration and activation of immune cells and fibroblasts, including hepatic stellate cells. In four PSC relevant mouse models (MDR2 knockout, chronic ANIT-induced cholestasis, bile duct ligation, and thioacetamide-induced liver fibrosis), CM101 consistently demonstrated both anti-inflammatory and antifibrotic effects. CM101 was found to reduce alkaline phosphatase (ALP), bile acid and liver fibrosis in the MDR2 knock out mouse model. CM101 was also observed to be safe and well tolerated in healthy subjects and in subjects with non-alcoholic fatty liver disease and patients with non-alcoholic steatohepatitis. Based on the pre-clinical evidence, the safety and tolerability profile of CM101 in phase 1 studies, and the high unmet medical need for patients with PSC, further evaluation of CM101 safety and efficacy is warranted.
Method: A phase 2a biomarker and clinical study was designed to understand the role of CCL24 in the pathogenesis of PSC and the effects of blockade of CCL24 with CM101 in patients with PSC.
Results: This is a Phase 2a, randomized, double-blind, placebo-controlled, multiple-dose, international study evaluating the safety and efficacy of CM101 in patients with PSC (NCT04595825). The overall study design is shown in Figure 1. Up to 93 patients with large duct PSC disease of >24 weeks duration, ALp >1.5 upper limit of normal, and any patients with concurrent stable inflammatory bowel disease will be randomized. The primary end point of the study is safety and tolerability. The pharmacodynamic effects of CM101 will be assessed by changes in CCL24 serum levels, serum inflammatory markers, and immune cell sub-populations. The clinical activity of CM101 will be assessed by changes in ALP, enhanced liver fibrosis (ELF) score, liver enzymes, liver elastography and liver fibrosis markers (e.g. PRO-C3, and PRO-C5). Patient reported outcomes will also be assessed. An independent Data Monitoring Committee has recently reviewed all safety data and had no safety concerns. They endorsed the plan for the next dose escalation per protocol.
Conclusion: Results from this study will provide early evidence of the role of CCL24 in inflammatory and fibrotic disease pathology and the clinical impact of neutralizing CCL24 with CM101, which will guide future development of CM101 in PSC.

THU-311

Intrahepatic cholestasis of pregnancy: genetic testing and genotype-phenotype relations in a cohort from a Danish tertiary liver center

Henning Grønbæk[1], Ida Paulsen[1], Jens Fuglsang[2], Ida Vogel[3], Naja Becher[4]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark, Aarhus N, Denmark;* [2]*Aarhus University Hospital, Department of Obstetrics and Gynaecology, Aarhus N, Denmark;* [3]*Aarhus University Hospital, Department of Obstetrics and Gynaecology, Aarhus N, Denmark;* [4]*Aarhus University Hospital, Department of Clinical Genetics, Aarhuis N, Denmark*
Email: henning.gronbaek@dadlnet.dk

Background and aims: Intrahepatic cholestasis of pregnancy (ICP) affects 0.5–1% of all pregnancies in Denmark. In pregnancy, women present with symptoms of pruritus, elevated liver enzymes and bile acids, and hepatic dysfunction. In severe cases, ICP increases the risk of preterm birth and stillbirth. We aimed to investigate genetic variants related to the development of ICP and describe the genotype-phenotype associations.
Method: We included 34 women (median age 28 years) with ICP and genetic testing of disease causing variants. Thirteen (38%) had a history of cholestatic disease prior to their pregnancy. Patients were screened for disease-causing variants in *ABCB11, ABCB4, ABCG5, ABCC2, ATP8B1, JAG1, NOTCH2, TJP2* and *UGT1A1* using a gene panel approach.
Results: Symptoms of cholestatic pruritus occurred in 5 (15%) patients in the 1st trimester, 13 (38%) in the 2nd trimester and in 16 (47%) patients in the 3rd trimester. At first visit the majority presented with elevated ALT (94%), bilirubin (91%), GGT (44%), and bile acids (53%). Thirty-three patients (97%) received treatment; 21 (62%) received monotherapy with Ursodeoxycholic acid, while 12 (35%) patients also received Rifampicin and/or Cholestyramine. In 20 of 34 (59%) patients we identified disease-causing variants, with highest prevalence in *ABCB11* and *ABCB4*. A genotype/phenotype correlation was detected in 21 (62%) women. A total of 13 (38%) women gave birth prematurely (<37 weeks); 7 patients with planned induced labor, and 6 gave birth spontaneously. Four women had an intrauterine foetal demise. Fourteen (41%) had recurrence of ICP in their subsequent pregnancy with one foetal demise.

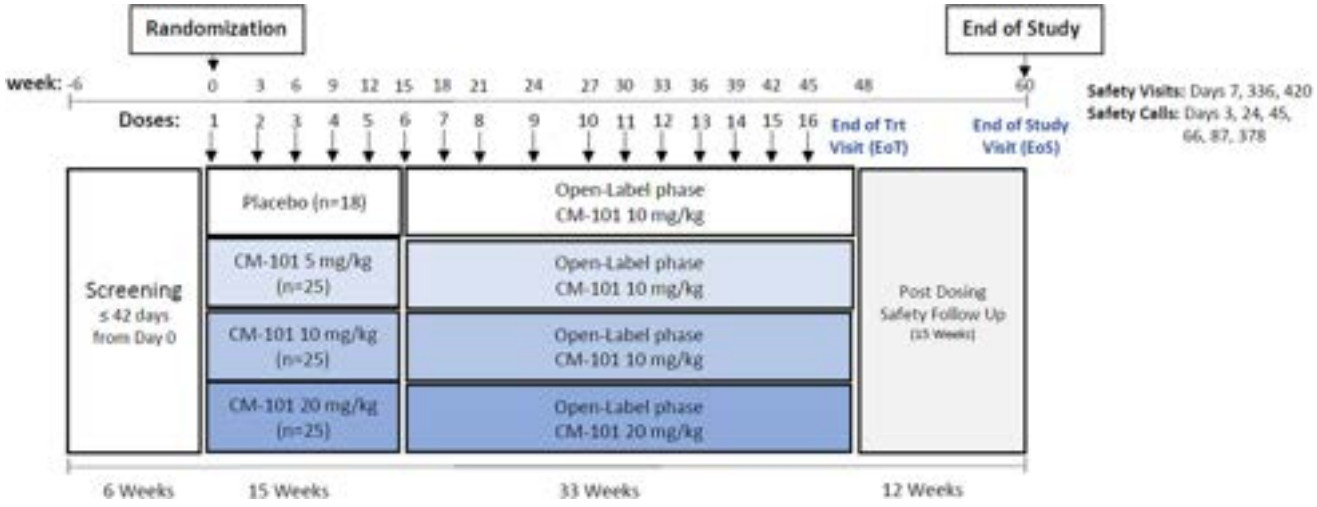

Figure: (abstract: THU-310).

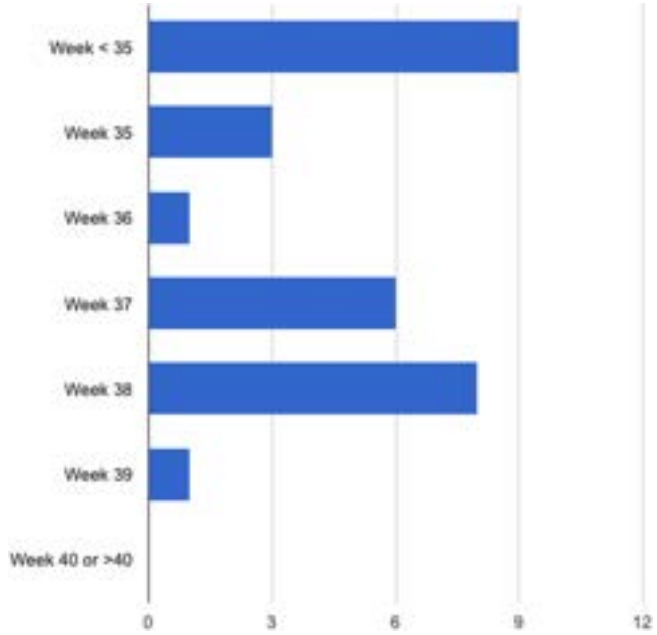

Figure: Overview of gestational week at delivery for patients with ICP.

Conclusion: We detected a genotype/phenotype correlation in 21 (62%) women with ICP. This illustrates the importance of the combination of genetic testing and clinical work-up among women with ICP and may guide handling and treatment of future pregnancies in these women.

THU-312

Longitudinal assessment of gut microbiota, metabolome and intestinal barrier dysfunction in biliary atresia

Vandana Jain[1], Charlotte Burford[1], Emma Alexander[1], Konstantinos Gerasimidis[2], Anita Verma[1], Mark Davenport[1], Matthew Dalby[3], Lindsay Hall[3], Anil Dhawan[1]. [1]*King's College Hospital, United Kingdom;* [2]*University of Glasgow, United Kingdom;* [3]*Quadram Institute, United Kingdom*
Email: vjain@nhs.net

Background and aims: Adjuvant therapy post-Kasai Portoenterostomy (KPE), has not reduced liver transplantation (LT) in Biliary Atresia (BA). Increasingly, a gut microbiota (GM)-host interplay, in chronic liver disease, is being described. We aimed to characterise GM, stool short chain fatty acids (SCFAs) and intestinal barrier (IB) markers, in BA, and association with clinical outcomes.
Method: Stool, plasma, were prospectively collected, in BA infants (n = 55) pre-KPE, and 6weeks-, 3months-, 6months-post-KPE. Age-matched healthy (HC;n = 19) and cholestatic control (CC;n = 21) stool was collected. Stool 16S rRNA sequencing (GM) and gas chromatography (SCFAs), were performed. IB markers included plasma Claudin-3 and stool calprotectin (SC). Clinical outcomes: 6month-JC (jaundice clearance), 1year-LT, cholangitis by 6month-post-KPE, fibrosis biomarkers [Aspartate Aminotransferase-to-platelet ratio index (APRi); Liver Stiffness Measurement (LSM)]
Results: Pre-KPE, beta-diversity revealed differences in genus-level-clustering, between BA vs HC [p < 0.03], not CC [p = 0.5] (Fig1). BA incorporated ↓*Bifidobacterium [p = 0.01]*, ↑*Enterococcus [p = 0.01]*, ↑*Clostridium [p = 0.04]*, compared to HC. 6weeks-post-KPE, increased alpha-diversity [p < 0.001], increased genus-level-clustering variation [BA:↓*Bifidobacterium, p < 0.001;* ↑*Enterococcus, p = 0.02]*, and reduced acetate [p < 0.001], was shown in BA vs HC. Pre-KPE, increased alpha-diversity [p = 0.04], and reduced acetate [p = 0.004], was associated with 1year-LT. Increased propionate was associated with poor 6month-JC [p = 0.02]; *Clostridium* positively correlated with propionate [rs = 0.5;p = 0.01]. Early-post-KPE, increased alpha-diversity [p = 0.01], ↑*Streptococcus [p < 0.001]*, ↓*Blautia [p = 0.03]*, were associated with poor 6month-JC. APRi positively and negatively correlated with *Streptococcus [rs = 0.4; p = 0.03] and Bifidobacterium [rs = – 0.5;p = 0.01]*. ↓*Bifidobacterium*, 6weeks-post-KPE, was associated with cholangitis development [p = 0.03]. Butyrate, 6weeks-post-KPE, inversely correlated with total bilirubin [rs = – 0.3;p = 0.02]. Increased Claudin-3, early-post-KPE, was associated with poor 6month-JC [p = 0.01] and 1year-LT [p = 0.001]. 6months-post-KPE, ↓*Blautia [p = 0.01]*, ↓SCFAs [p = 0.04], ↑SC [p = 0.05], were associated with 1year-LT; *Bifidobacterium* inversely correlated with LSM [rs = – 0.5;p = 0.02].

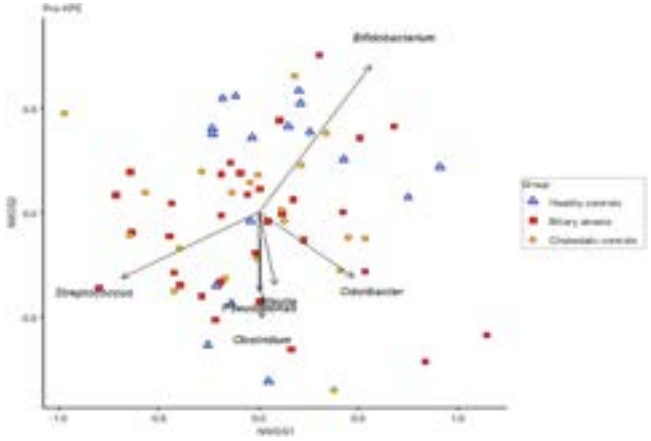

Figure:

Conclusion: Dysbiosis, characterised by pathobiont enrichment and 'probiotic' (*Blautia, Bifidobacterium) deficiency, and subsequent SCFA dysregulation*, in pre- and early-post-KPE BA, are associated with non-favourable clinical outcomes. Increased intestinal permeability early-post-KPE, is a likely a key factor in GM-BA-pathogenesis. Early microbiota-modulatory therapy may reduce LT in BA.

THU-313

Odevixibat therapy following liver transplantation in patients with FIC1-deficient progressive familial intrahepatic cholestasis: a retrospective case series

Georg-Friedrich Vogel[1,2], Simone Kathemann[3], Andrea Pietrobattista[4], Giuseppe Maggiore[4], Denise Aldrian[1], Marco Sciveres[5], Henkjan J. Verkade[6], Peter Rauschkolb[7], Christof Maucksch[7], Velichka Valcheva[7], Christine Clemson[7], Elke Lainka[3]. Email: georg.vogel@i-med.ac.at

Background and aims: *ATP8B1*, encoding FIC1, is expressed in multiple organs such as the liver and small intestine. Mutations in this gene can result in progressive familial intrahepatic cholestasis type 1 (PFIC1), which is characterized by hepatic and extrahepatic manifestations that can ultimately necessitate liver transplantation (LT). Following LT, patients with PFIC1 may develop complications that include graft injury (hepatic steatosis), liver fibrosis, and/or exacerbated diarrhoea, which may impair patients' ability to perform daily activities and reduce their quality of life (QoL). These complications are thought to result from the interplay between physiologic bile acid secretion from the transplanted liver and the native, FIC1-deficient bowel. In this case series, we present clinical

Table: (abstract: THU-313).

Clinical Features, Quality of Life, and Liver Pathology Before and Following Odevixibat Initiation in Patients With PFIC1 And Liver Transplantation

	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Patient 6
Before LT						
Symptoms leading to LT	• Refractory pruritus • Cholestasis • Dystrophy • Feeding disorder	• Electrolyte imbalance • Dystrophy • Pruritus • Infections with hospitalization	• Intractable pruritus • Decreasing liver function	• 1st LT: o Cholestasis o Jaundice o Failure to thrive o Severe pruritus • 2nd LT: o Hepatic artery thrombosis	• 1st LT: o Cholestasis o Failure to thrive o Severe pruritus • 2nd LT[a]: o Acidosis o Failure to thrive o Progressive liver damage	• Refractory pruritus and cholestasis • Jaundice • Fatigue
After LT But Before Odevixibat Initiation						
Description of impact on QoL	• Diapers needed during day and/or night	• Diapers needed during day and/or night	• Wearing diapers unacceptable to patient, so diarrhoea impacted school and family's ability to travel	• Diarrhoea frequency negatively impacted the patient's QoL	• Diarrhoea frequency negatively impacted the patient's QoL	• N/A
Biopsy findings[b]	• 10% macrovesicular and 5% microvesicular fatty degeneration • Liver fibrosis, stage 1	• 25% macrovesicular and 50% microvesicular fatty degeneration • Liver fibrosis, stage 3 • Steatohepatitis and ductular proliferation	• N/A[c]	• 15% micro-macrovesicular steatosis • Expanded portal spaces due to mild fibrosis	• 40% steatosis • Moderate portal and mild central fibrosis	• N/A
Current daily odevixibat dose (treatment duration)	~ 30 µg/kg (11 months)	~ 100 µg/kg (17 months)	~ 80 µg/kg (13 months)	40 µg/kg (5 months)	40 µg/kg (8 months)	120 µg/kg (16 months[d])
With Odevixibat						
Description of impact on QoL	• No diarrhoea • Diapers not needed as frequently	• No diarrhoea and no nocturnal stools • Daytime diapers no longer necessary • Reduced fatigue and better concentration at school	• Better able to participate in school and leisure activities	• No diarrhoea • First time in patient's life with normal stool consistency; improved QoL	• Reduced frequency of diarrhoea	• N/A
Biopsy findings[e]	• Liver fibrosis, stage 1–2 • Portal inflammation • Slight ductular proliferation	• < 5% microvesicular fatty degeneration • Liver fibrosis, stage 1–2	• N/A	• 25% to 30% micro-macrovesicular steatosis • Expanded portal spaces due to mild fibrosis	• 40% steatosis • Fibrosis, stage 3–6	• N/A

[a]Patient underwent a complete bilocolonic diversion at the same time as the second LT; [b]Last available data before initiating odevixibat; [c]Patient developed steatosis and hepatic inflammation shortly after LT. The patient received surgical biliary diversion approximately 4 years after LT, which resolved the steatosis and liver inflammation; [d]Patient was previously treated with odevixibat for approximately 15 months before undergoing LT on 18 November 2022. Odevixibat was restarted approximately 4 days after LT. Available data are limited due to recent surgery; [e]Data from last available assessment. LT, liver transplantation; N/A, not available; PFIC, progressive familial intrahepatic cholestasis; QoL, quality of life.

details of patients with PFIC1 who received odevixibat, an ileal bile acid transporter inhibitor (IBATi), after LT.
Method: Patient demographic, clinical, and treatment data were collected retrospectively using standardised case report forms.
Results: This case series comprises 6 male patients. Common indications for LT included intractable pruritus, cholestasis, and/or growth issues or dystrophy; a second LT was performed in patients 4 and 5 (Table). After LT, 5 patients had fatty degeneration, steatohepatitis, or hepatic steatosis, and patients 1, 2, 4, and 5 had hepatic fibrosis (stage 1–3; Table). Following LT, all patients had diarrhoea (up to 7 stools/day). As a result, QoL and/or school functioning were negatively impacted for these patients and/or their families (Table). Five of 6 physicians cited steatosis and/or unresolved diarrhoea as a reason for initiating odevixibat; in patient 6, who had prolonged episodic cholestasis prior to LT, the drug was prophylactically re-initiated. In patient 5, odevixibat was withdrawn after 8 months due to unchanged steatosis and progression of liver disease despite mild improvement in stool frequency (4–7 to 2–4 stools/day). In other patients with available data who received odevixibat post LT, diarrhoea resolved and/or patients had less frequent bowel movements (approximately 2 stools/day) or improved stool consistency (eg, Bristol Stool Chart type 7 to type 4–5). These patients had improvements in QoL (Table). Changes in liver pathology before and following odevixibat initiation are shown in the Table.
Conclusion: In patients with PFIC1, diarrhoea and hepatic steatosis after LT are frequent and severe, impacting QoL. The real-world data presented here indicate that odevixibat can improve diarrhoea and QoL after LT in patients with PFIC1. In addition, 2 of 4 patients where biopsy was performed following odevixibat initiation had improved steatosis (odevixibat duration: 11 and 17 months, respectively, at last data collection). More studies are needed to determine the role of IBATi treatment in long-term graft survival.

THU-314
A longitudinal study of epidemiology and treatment management of Wilson disease in France based on the French national claims database SNDS

Bernard Benichou[1], Thomas Daniel Robin[1], Jean Philippe Combal[1], Claire Leboucher[2]. [1]*Vivet Therapeutics, France;* [2]*Putnam Inizio Advisory, France*
Email: bbenichou@vivet-therapeutics.com

Background and aims: The aim of this study was to evaluate longitudinal trends in the epidemiology and management of patients with WD (Wilson disease) identified in the French national health insurance database (SNDS).
Method: The study included all patients with at least one medical claim for hospitalisation with the ICD-10 diagnostic code for WD (E83.0*: copper metabolism disorder) or eligible for ALD status for WD between 1st January 2009 to 31st December 2019. For each patient, data were extracted on age, gender, hospitalisations, liver transplantation, mortality, WD-specific treatments (D-penicillamine, trientine and zinc), disability status and sick leave.
Results: 1,928 patients with WD were identified, of whom 1,520 (78.8%) were analysed. Prevalence of WD in 2019 was estimated as 2.2 cases per 100,000. The median age of the total cohort at inclusion was 39 years and 48% of patients were women. At inclusion, 67% of patients were symptomatic, with a spectrum of hepatic, neurological or psychiatric symptoms. In the first year, 995 patients (65.6%) were hospitalised at least once for a mean duration of 4.4 ± 10.9 days. In the following year, the proportion declined to 41.7% and remained around 40% for the remainder of the follow-up period. 152 patients (10.0%) underwent liver transplantation and 205 died (13.5%). The mean age at death was 57.9 ± 23.1 years. 665 patients (43.8%) received a WD-specific treatment at least once. 167 patients (17.1%) received a government disability pension and 624 (41.1%) benefited from long-term illness status due to WD.
Conclusion: Unexpectedly, less than half of French patients with WD ICD-10 diagnostic code received continuous treatment as recommended in practice guidelines, which with reduce compliance may contribute to a high disease burden in terms of hospitalizations, disability and reduced life expectancy. Interestingly similar results from other countries have been observed (Choe et al. Nature Scientific Reports 2020; Czlonkowska et al. Eur J Neurol 2022) either from national healthcare databases or from large cohort of WD patients followed in reference center. Raising awareness around the limitations of current disease management, patients awareness and improving treatment rates with new transformative treatment alternatives could help reduce the burden of patients living with WD.

THU-315
Impact of suffering Wilson disease in Spain: an observational cross-sectional multicenter study

Zoe Mariño[1,2], Marina Berenguer[3,4], Luis Peña[5], Antonio Olveira Martin[6], Anna Miralpeix[1], Clara Pérez[7], Anna Anguera[8]. Background and aims: Wilson disease (WD) can negatively impact health-related quality of life (HRQoL) as well as emotional/social health, two aspects, which have been little explored to date. We aimed to assess the impact of WD on HRQoL, treatment adherence, use of healthcare resources utilization (HRU), and its associated costs.
Method: An observational cross-sectional multicenter study was conducted. Patients with WD aged ≥12 years; at least 1 year of previous follow-up and signed informed consent were included. Sociodemographic, clinical and treatment data were collected. The following questionnaires were administered: 1) EQ-5D-5L: HRQoL questionnaire, 2) ad-hoc questionnaire on social/emotional impact of WD, and 3) SMAQ: medication adherence questionnaire. Also, HRU in the last year and productivity were collected, and the costs per patient/month (€) were estimated. A descriptive analysis was performed on 2 subgroups of patients: 1) isolated liver involvement (group H, n = 83, 81.4%) and 2) hepatic and extrahepatic involvement (group EH, n = 19, 18.6%). Data analysis was performed with STATA v.14. Variables were expressed as % or median (IQR_{25-75}).
Results: We included 102 patients: median age of 35 (22–47) years, 57.8% were male, median time since diagnosis 16.2 (10.6–29.4) years, 14.7% with cirrhosis (93.3% Child-Pugh A; 33.3% with esophageal varices), mainly treated with zinc salts (48%) or D-Penicillamine (32.4%). 46.1% received concomitant treatment, especially neuropsychiatric drugs (46.8%). Group H showed better median EQVAS score (88 [75–92]) than EH group (76 [50–85]), with higher scores in mobility, self-care, activities of daily living or pain items. However, up to 42% of patients had some degree of anxiety/depression in both groups. Group EH reported greater impairment in daily activities and executive function. EH group had more difficulty in making friends (42.2% EH vs 16.9% H) or dating (57.9% EH vs 13.2% H). Although emotional affectation was greater in the EH group (47%), up to 30% of the H group reported sadness, anxiety, frustration, or anger related to WD. According to the SMAQ, only 18.1% of the H group showed total treatment adherence vs 42.1% of the EH group. In the last year, patients had a median of 4 outpatient visits to specialists (3 to hepatology). EH group used more extra NHS health resources than the H group (31.6% physiotherapist, 21.1% speech therapist). Overall,

the median cost/patient per month was 59.6 (32.4–96.1) € in H group vs 114.9 (76.4–1752) € in EH group.
Conclusion: Patients with extrahepatic involvement showed worse HRQoL, and higher HRU and costs than the hepatic group. Despite the fact that H patients had less general impairment, they showed significant percentages of anxiety/depression and reported difficulties in emotional/social aspects. Treatment adherence was poor, highlighting that there is room for improvement in this area in WD.

THU-316
Role of transient elastography to identify Fontan-associated liver disease (FALD) and novel risk-score to predict failing Fontan
Luisa Cavalletto[1], Roberta Biffanti[2], Giovanni Di Salvo[2], Massimo Padalino[3], Chiara Giraudo[1], Liliana Chemello[1]. *[1]University of Padova, Department of Medicine-DIMED, Padova, Italy; [2]University of Padova, Department of woman and child's health, Padova, Italy; [3]University of Padova, Department of cardiac, thoracic and vascular sciences and public health, Padova, Italy*
Email: liliana.chemello@unipd.it

Background and aims: The single ventricle (SV) heart is a rare congenital heart disease (CHD) (7/1000 cases, born alive, with major heart defects) corrected with the palliative Fontan's intervention (cavo-pulmonary shunt) that restores the survival of most child and young patients up to adultwood. Unlikely, these patients develop a series of complications, among all, the Fontan associated liver disease (FALD), which is particularly due to chronic systemic venous hypertension, that causes the occurrence of liver cirrhosis and other severe complications, that negatively impacts the life expectancy in the majority of cases. Our primary aim was to characterize these patients by liver fibrosis and portal hypertension scores (FORNS, LSPS and SSPS) and by liver (LS) and spleen (SS) stiffness measurement in relation to time since Fontan, secondarly to define the risk profile of major complications tailored to the individual patient by selective criteria.
Method: One-hundred and twenty outpatients (68 m/52 f, mean age 24.8 ± 11.6 years) born with SV corrected with Fontan circuit have been recruited prospectively from 2019 to 2022 (mean FU 18.5 ± 13.1 months). Each patient underwent a complete anamnesis, physical examination and specific lab-test profile, and an instrumental evaluation with abdominal US-Doppler or CT/MRI and the LS and SS by transient elastography (VCTE, Fibroscan, Echosens, Paris).
Results: Based on the time elapsed since Fontan's surgery 3 groups, each of 40 cases (group: A <15; B 15–25 and C >25 yrs), were formed to compare the clinical, biochemical and imaging features. ROC curves were built to select the scores cut-off proved to be the most accurate to diagnose FALD (Fig.1). The worsening of the hepatic, renal and cardiac function in relation to time since Fontan surgery appeared in 58/120 cases (group A, B and, C in 17.5%, 47.5% and 80% of cases, respectively; $p < 0.01$). Ten patients (8.3%) died, need OHT or had HCC occurrence. Moreover by identification of advanced liver disease and of portal hypertension selective criteria, we applied a novel risk-score of failing-Fontan, that has predicted a low-moderate risk profile (HR 0.30; CI 0.18–0.52) in 66 patients (55%) and a high risk profile (HR 3, 29, CI 1.93–5.60) in 54 (45%).

Score	Cut-off	Sens. Spec. (%)	AUC ± SE	CI 95%	p-value
FORNS	≥ 4,0	91,2/86,0	0,931±0,021	0,866-0,971	< 0,0001
LSPS	≥ 1,4	91,2/86,2	0,928±0,021	0,877-0,971	< 0,0001
SSPS	≥ 2,3	91,2/91,1	0,960±0,016	0,906-0,988	< 0,0001
LS	≥ 20,2	84,5/79,0	0,907±0,025	0,840-0,952	< 0,0001
SS	≥ 30,7	84,2/85,7	0,915±0,025	0,847-0,959	< 0,0001

Figure 1:

Conclusion: All the scores (Fig.1) showed the capability to improve the FALD diagnosis and the hepatologic management of these young and adult subjects with SV and Fontan circuit. This novel risk score proposed may help to predict the development of major complication and targeting individual surveillance in Fontan patients, to better guide some decision-making process (i.e., the need of surgical interventions or OHT).
LSPS or SSPS, liver or spleen-platelet-score.

THU-317
Real-world experience of Odevixibat in adults with genetic disorders of cholestasis
Palak Trivedi[1,2], Alberto Borghi[3], Cornelius Engelmann[4], Vinod Hegade[5], Simon Hohenester[6], Deepak Joshi[7], Jan F. Monkelbaan[8], Anna Morgando[9], Praneeta Nagraj[10], Velichka Valcheva[10]. *[1]National Institute for Health Research Birmingham Biomedical Research Centre, University of Birmingham, Birmingham, United Kingdom; [2]Liver Unit, University Hospitals Birmingham, Birmingham, United Kingdom; [3]Internal Medicine Unit, Faenza Hospital, Italy; [4]Medizinische Klinik m. Email: p.j.trivedi@bham.ac.uk

Background and aims: Genetic disorders of cholestasis, including progressive familial intrahepatic cholestasis (PFIC), typically present in infancy or early childhood. The ileal bile acid transporter inhibitor odevixibat is approved for the treatment of PFIC in patients aged 6 months or older in the European Union and for treatment of pruritus in patients aged 3 months and older with PFIC in the United States. The overarching goal of this study was to seek experience with odevixibat in adult patients with genetic disorders of cholestasis with regard to safety, tolerability, and efficacy.
Method: Data were collected from adults harbouring suspected or confirmed genetic variants associated with cholestasis who initiated odevixibat therapy at age >16 years. Details regarding symptoms and on-treatment biochemical changes are presented.
Results: We accrued data from 10 patients across 8 treatment centres (50% men; age range at diagnosis: 6 months-35 years; current age range, 22–48 years); 6 patients were diagnosed in adulthood (Table). Prior to odevixibat initiation, median serum bile acid (sBA), total bilirubin, and alanine aminotransferase (ALT) values were 138 µmol/L, 18 µmol/L, and 56 U/L, respectively. In most patients, presenting features included pruritus and jaundice, alongside impaired sleep and attention and overall diminished quality of life. Nine patients experienced improvement in pruritus with odevixibat over a median of 3.4 months follow-up (range: 0.9–25.5 months), with 8 patients reporting complete absence of pruritus at the last available assessment. Median (quartile 1, quartile 3) reduction in sBA values was −73 (−174, −38) µmol/L ($p = 0.012$ [Wilcoxon signed-rank test]). Median changes in total bilirubin and ALT values were minimal ($p \geq 0.16$). Two patients experienced gastrointestinal adverse events (increased defecation frequency that resolved with dosage adjustment in 1 patient; mild diarrhoea modifiable with dietary changes in another patient) during treatment with odevixibat; no new safety signals were reported.
Conclusion: In adults with genetic disorders of cholestasis, odevixibat treatment appears to be safe, well tolerated, and associated with a reduction in pruritus intensity.

Table: (abstract: THU-317).

Table. Outcomes in Adult Patients With Genetic Disorders of Cholestasis Treated With Odevixibat

	Age at Diagnosis	Current Age	Sex	Affected Gene(s)	Presenting Features	Dosage (Treatment Duration)	Outcomes With Odevixibat
Patients 1–6: Diagnosed in Adulthood							
Patient 1	35 years	38 years	F	*ABCB4*[a]	• Cholangitis and fibrosis • Impaired QoL • No pruritus • sBAs: 10 µmol/L	2400 µg/day (1.7 months)	• No change in pruritus, sleep, ALT or TB • Mild diarrhoea modifiable with dietary changes • sBAs: 5 µmol/L at month 1
Patient 2	34 years[b]	48 years	M	*ABCB11*[c]	• Pruritus and recurrent jaundice • Elevated GGT • sBAs: 69 µmol/L	2400 µg/day (1.3 months)	• Improved pruritus (no itch within 1 month) • Decreased TB • sBAs: 76 µmol/L at month 1
Patient 3	32 years	32 years	M	ND[d]	• Pruritus • Jaundice • Abdominal pain • sBAs: 96 µmol/L	3600 µg/day (4.6 months)	• Improved pruritus (VAS=0 by month 2) • Decreased ALT, TB • Improved sleep, increased energy • sBAs: 4 µmol/L at month 2
Patient 4	26 years	41 years	F	*ABCB11*[c]	• Pruritus and recurrent jaundice • Elevated GGT • sBAs: 84 µmol/L	2400 µg/day (0.9 months)	• Improved pruritus (no itch within 1 month) • sBAs: 22 µmol/L at month 1
Patient 5	18 years	29 years	F	*ABCB11*[e]	• Pruritus • sBAs: 48 µmol/L	2400 µg/day (4.8 months)	• Improved pruritus (no itch by month 2) • sBAs: 10 µmol/L at month 3 • Able to care for child
Patient 6	18 years	23 years	M	*ABCB11*[f]	• Pruritus • Jaundice • sBAs: 214 µmol/L	2400 µg/day (3.5 months)	• Improved pruritus (absent within 3 months) • No waking up at night • sBAs: 141 µmol/L at month 3
Patients 7–10: Diagnosed in Childhood							
Patient 7	11 years	33 years	M	*ATP8B1*, *ABCB11*, *ABCB4*[g]	• Recurrent pruritus, jaundice, liver dysfunction • Impaired QoL, psychological distress • sBAs: 260 µmol/L	2400 µg/day (1.8 months[h])	• Improved pruritus (absent by month 2) and jaundice • Decreased ALT, TB • Positive psychological impact • sBAs: 6 µmol/L at month 2
Patient 8	9 years	32 years	F	*ABCB11*[i]	• Pruritus • sBAs: 284 µmol/L	2400 µg/day (4.3 months)	• Improved pruritus (no itch by month 3) • Decreased ALT, TB • sBAs: 110 µmol/L at month 3 • Better mood
Patient 9	4 years	22 years	F	ND[j]	• Pruritus, dry skin • Fatigue • Short stature • Poor QoL and attention • sBAs: >180 µmol/L	1600 µg/day (3.4 months)	• Pruritus ~20% reduced • Decreased TB • Eyes are less yellow • More engaged in activities of daily living • sBAs: ND
Patient 10	6 months	25 years	M	ND[k]	• Persistent pruritus • Intermittent cholestasis • Sleep and attention disorders • sBAs: 386 µmol/L	2400 µg/day and 1200 µg/day alternating (25.5 months)	• Improved pruritus (no itch by month 3) • Continued sleep for first time in life • sBAs: 27 µmol/L at month 6 • Increased defecation frequency

[a]Heterozygous c.1445T>C variant; [b]Patient was symptomatic for many years prior to diagnosis; [c]Common variant in *ABCB11* (c.1331T>C); [d]Clinical presentation compatible with PFIC; [e]Homozygous c.1331T>C, heterozygous c.149T>C, and heterozygous c.1568C>G variants; [f]Homozygous c.1546T>C, heterozygous c.3148C>T, and heterozygous c.2599C>T variant s; [g]Homozygous *ATP8B1* variant (p.R952Q), heterozygous *ABCB11* variants (p.A444V and c.3084A>G), and heterozygous *ABCB4* variant (c.787A>T); [h]Treatment was stopped due to significant improvement of symptoms, as well as normalized blood values and liver function; [i]Heterozygous c.1723>T and heterozygous c.1139delT variants; [j]Diagnosis of PFIC type 1; [k]Demonstrated similar haplotype to known patients with recurrent episodic cholestasis.

ALT, alanine aminotransferase; F, female; GGT, gamma-glutamyl transferase; M, male; ND, not determined; PFIC, progressive familial intrahepatic cholestasis; QoL, quality of life; sBAs, serum bile acids; TB, total bilirubin; VAS, visual analogue scale.

THU-318

High diagnostic uptake of a targeted panel sequencing in adult patients with chronic hereditary liver disorders

Luisa Ronzoni[1], Ilaria Marini[1], Serena Pelusi[1], Federica Golfetto[1], Angela Lombardi[1], Jessica Rondena[1], Giulia Periti[1], Cristiana Bianco[1], Giulia Passignani[1], Roberta D'Ambrosio[2], Daniele Prati[3], Luca Valenti[1,4]. [1]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Milano, 1 Precision Medicine-Biological Resource Centre-Department of Transfusion Medicine, Italy;* [2]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Milano, Division of Gastroenterology and Hepatology, Italy;* [3]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Milano, Department of Transfusion Medicine, Italy;* [4]*Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Italy*
Email: luisa.ronzoni@policlinico.mi.it

Background and aims: The pathogenesis of chronic liver diseases (CLD) remains often unexplained despite extended clinical and instrumental evaluations. Next-generation sequencing (Whole Exome [WES] or Targeted Panel Sequencing [TS]) and polygenic risk scores (PRS) determination may improve the diagnostic rate of rare genetic disorders also in adults, but they are not yet widely clinically available. The aim was to evaluate the clinical utility of a TS approach, combined with PRS stratification, in diagnosis CLD in adult patients.
Method: A customized TS including 82 selected liver-diseases genes was performed in 57 unrelated adult patients with CLD of suspected hereditary etiology. For each patient, the genetic predisposition to progressive fatty liver disease was evaluated (PRS based on *PNPLA3* rs738409, *TM6SF2* rs58542926, *MBOAT7* rs641738, *GCKR* rs1260326 and *HSD17B13* rs72613567 variants combination).
Results: Patients' phenotypes were divided into four categories: iron overload, dyslipidemia, cholestatic diseases and fatty liver diseases. Overall, TS allowed to reach a definitive genetic diagnosis in 16 patients (diagnostic yield: 28%). Heterozygous likely pathogenic variants or rare variants of unknown significance (VUS), but with a high likelihood of altering protein function, were identified in 26 patients, providing a diagnostic rate of 46% for genetic contribution to the phenotype. A total of 15 cases (26%) remained undiagnosed. Stratifying according to the clinical phenotypes, the higher diagnostic yield was obtained in patients with dyslipidemia (36%) and iron overload (35%). Overall, PRS values were over the positive threshold (fixed at 0.495) in 13 patients, 7 of whom (54%) had fatty liver diseases (Figure 1).
Conclusion: TS proved to be a useful first-tier genetic test for the diagnosis of selected adult patients with CLD, mainly if the clinical phenotype is well defined, as in dyslipidemia or iron overload cases. Moreover, TS allowed to identify genetic variants possibly contributing to disease phenotype in a high number of patients, expanding disease pathogenesis understanding. PRS stratification was a useful analysis, mainly in patients with fatty liver diseases, contributing to the diagnosis and allowing to set up a personalized follow-up.

Phytoestrogens as a possible hidden driver of cysts proliferation in polycystic liver disease in men and women after menopause

Miki Scaravaglio[1], Antonio Ciaccio[2,3], Martina Manna[2], Giacomo Mulinacci[1], Pietro Invernizzi[1,2,3]. [1]*University of Milano-Bicocca, Department of Medicine and Surgery, Italy;* [2]*Fondazione IRCCS San Gerardo dei Tintori, Gastroenterology Unit, Italy;* [3]*European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Italy*
Email: antonio.ciaccio@unimib.it

Background and aims: Polycystic liver disease (PLD) is characterized by the presence of multiple liver cysts with a potential for progressive liver enlargement and cysts growth that may result in visceral compression and poor quality of life, requiring surgery or liver

Figure 1. Diagnostic rate of a customized targeted panel for the analysis of 57 unrelated adult patients with CLD, divided in four disease categories

Clinical Phenotype (number of cases)	Genetic diagnosis		Likely genetic diagnosis		Undiagnosed cases	High PRS (>0.495)

Figure: (abstract: THU-318).

transplantation in some cases. Female sex hormones have been identified as major drivers of liver cysts growth and among them estrogens have been recently pointed as a promising target for new treatment strategies. Phytoestrogens (PEs) are plant-derived non-steroidal compounds mimicking the effects of estrogens by binding estrogen receptors. They are found in plant foods, mainly soy and red clover, and in many dietary supplements prescribed for postmenopausal symptoms and prostate conditions. Nonetheless, possible concerns related to PEs exposure in patients with PLD have been overlooked so far. We aimed to investigate whether PEs-containing supplements might have a role in the progression of liver cysts growth in PLD patients.

Method: We retrospectively assessed the exposure to PEs in all consecutive men and postmenopausal women with a diagnosis of PLD evaluated at the Gastroenterology Unit of Fondazione IRCCS San Gerardo, Monza. Patients with a follow-up less than 12 months were excluded from the analysis.

Results: Of 68 patients diagnosed with PLD, 45 satisfied the study criteria and were included in the analysis, with a median follow-up of 64 months (interquartile range [IQR], 39 to 101 months). Most patients were female after menopause (73.3%) and had a diagnosis of autosomal dominant polycystic kidney disease (51.1%). During the study period, a growth of liver cysts of any grade was reported in 10 out of 45 patients (23.8%), while 7 patients (16.7%) had a significant growth of liver cysts, as defined by an increase of at least 25% per year of the diameter of any cyst and/or the development of signs or symptoms of liver enlargement. Cyst complications, including cyst hemorrhage, cyst infection and cyst rupture, occurred in 8 patients (17.8%). Nobody required liver transplantation. Only one patient died during the study period, for causes unrelated to liver disease. A documented exposure to over-the-counter PEs supplements was identified in 6 out of 41 patients (14.6%). PEs exposure was associated with a higher risk of significant growth of liver cysts (OR 8.3, CI 2.1–42.8, p = 0.005). No associations were found when assessing sex, type of PLD, exposure to estrogen-containing drugs before menopause, metabolic comorbidities.

Conclusion: PEs exposure is associated with a significant risk of liver cysts growth in PLD resulting in a higher burden of symptoms. Pending confirmatory results in larger prospective studies, this pilot study supports the key role of estrogens signaling in the progression of PLD and highlights the need to establish a proper dietary counselling to minimize the risk of exposure to PEs and improve PLD patients care.

Patient experience with acute hepatic porphyria before and after long-term givosiran treatment: a qualitative interview study

Stephen Lombardelli[1], Michelle Brown[2], Stephen Meninger[3], Hetanshi Naik[4]. [1]*Alnylam Pharmaceuticals, Maidenhead, United Kingdom;* [2]*RTI Health Solutions, Research Triangle, United States;* [3]*Alnylam Pharmaceuticals, United States;* [4]*Icahn School of Medicine at Mount Sinai, United States*
Email: slombardelli@alnylam.com

Background and aims: Acute hepatic porphyria (AHP) is a family of genetic disorders associated with disruption of heme biosynthesis, accumulation of neurotoxic heme intermediates, and acute neurovisceral attacks; chronic manifestations may be present. In Phase 1/2 (NCT02949830) and Phase 3 (ENVISION; NCT03338816) studies, givosiran treatment led to sustained improvement in annualized attack rate and other measures. To explore long-term treatment outcomes, qualitative interviews were conducted with study participants.

Method: Patients with AHP (US, Spain, UK) continuing givosiran treatment after completing open-label extension periods of the Phase 1/2 or ENVISION studies participated in 1-hour semistructured telephone interviews. Thematic analysis was conducted.

Results: There were 21 interviewees (86% female; mean [range] age at interview, 39.3 [25–61] years; mean [standard deviation] duration

Table: (abstract: THU-320).

Table. AHP Symptoms, Prestudy and Posttreatment

Symptom	Participant Description of Symptom	
	Prestudy[a]	Posttreatment[b]
Abdominal pain	*It would usually start with severe stomach pain, intractable vomiting, it would expand to a full body, horrible, searing, and indescribable level of pain.*	*The stabbing pain that I used to get in the upper right quadrant is completely gone. Now if it hurts, it's more of an ache. I never have that searing knife-like, sharp pain anymore.*
Other pain		
Neuropathic pain/paresthesia[c]	*I had this spine pain, which was at the base of my neck; it would hurt so bad; I would be at work like laying on tennis balls to relieve the pressure and I just knew that I'd be hospitalized.*	*My pain is completely gone. I don't have it on a day-to-day basis anymore. I don't get attacks of pain or nausea at all. On the very odd occasion I do have some discomfort, [but] it's not anywhere near going towards an attack.*
Limb pain		
Back pain		
Headache		
Body pain		
Gastrointestinal		
Nausea	*[O]nce I started throwing up, I couldn't stop throwing up. Then having thrown up for 3 days and then I'd have to go to the hospital.*	*I don't really vomit anymore though, that has been a big change.*
Vomiting		
Constipation		
Diarrhea		
Mood and emotions		
Anxiety, fear, and worry	*To be honest … I didn't do anything. I didn't want to go outside, I didn't want to speak to anybody, I was angry at life, at the world.*	*The depression has significantly improved. I kind of feel like I'm getting back to my old self.*
Depression and sadness		
Anger, agitation, and aggression		
Other		
Fatigue	*I could barely go up the stairs anymore … when I would get home from work, I felt like I couldn't get up the stairs in my house so I would just stay on the couch the whole night and just keep stuff downstairs.*	*The fatigue is definitely better, and I actually started trying to get my [work] license back. I've started the process to get that back, so it's definitely improved, and it doesn't affect me on a daily basis.*
Sleep (excessive or limited)	*I couldn't sleep at all; I would be up sitting there just staring at the ceiling.*	*I get a better quality of sleep.*
Cognition (eg, concentration, confusion)	*You can tell me something so simple, and I'll forget.*	*I was able to think much clearer.*
Muscle weakness and paralysis	*[I]t feels like you're wearing a lead suit so it's just this heaviness … I couldn't stand up from a seated position.*	*Yeah, so just physically able to do more. Slightly stronger muscle tone, able to walk slightly further. I don't fall over anymore. I just have the residual paralysis that I have, but physically I'm definitely stronger than I was.*

AHP, acute hepatic porphyria.
[a]Prior to Phase 1/2 study or ENVISION.
[b]Prestudy and posttreatment symptom descriptions are not necessarily from the same interviewee.
[c]Neuropathic pain/paresthesia was coded for any mention of neuropathy, burning, or tingling.

of givosiran treatment, 51.8 [7.9] months). When describing their prestudy (ie, prior to Phase 1/2 or ENVISION studies) experience (Table), interviewees reported AHP symptoms in multiple domains, particularly abdominal pain and fatigue (95% for both). The impacts of AHP symptoms were wide-ranging, affecting work/school (100%), family and intimate relationships (95%), and other domains. Most interviewees (19/21; 90%) had used opioids prestudy; relief of acute and/or chronic pain was described as somewhat effective (84%), not effective or mildly effective (26%), and/or effective only in the hospital (intravenous; 21%). Posttreatment, interviewees reported improvement in both symptoms (including abdominal and other types of pain [100%]) and impacts (particularly family and intimate relationships [95%] and work/school [91%]). Most described their attacks as gone (62%) or less frequent/severe (33%). Among 17 interviewees who took opioids, 10 (59%) stopped opioids and 4 (24%) used a lower dose. Pain alleviation was mentioned most frequently as the most important posttreatment improvement (43%). Symptoms that were still present (but less severe) included muscle weakness and paralysis (4/5 interviewees; 80%), fatigue (14/18; 78%), and neuropathic pain and paresthesia (6/9; 67%). All interviewees (100%) were "very satisfied" with givosiran treatment.

Conclusion: Results of these qualitative interviews improve the understanding of the burden of AHP. Interviewees reported meaningful improvements with continuing givosiran treatment.

THU-322

Surveillance of cystic echinococcosis in France: report of the first 103 cases from the French observatory OFREKYS

Solange Bresson-Hadni[1,2], Coralie Barrera[1,2], Louis Bohard[1,3], Noémie Tissot[1,3], Paul Calame[1,4], Alexandre Doussot[1,5], Celia Turco[1,5], Eleonore Brumpt[1,4], Demonmerot Florent[1], Jenny Knapp[1,2], Catherine Chirouze[1,3], Laurence Millon[1,2]. *[1]CNR-Echinococcoses, laboratoire de Parasitologie-Mycologie, CHRU Besançon, Besançon, France; [2]UMR6249 CNRS Chrono-Environnement, Université de Franche-Comté, Besançon, France; [3]Service des Maladies Infectieuses, CHRU Besançon, Besançon, France; [4]Service de radiologie viscérale CHRU Besançon, Besançon, France; [5]Service de chirurgie viscérale et carcinologique, transplantation hépatique, CHRU Besançon, Besançon, France*

Email: dr.bresson.hadni@wanadoo.fr

Background and aims: Cystic echinococcosis (CE) is a zoonosis due to the larval stage development of *Echinococcus granulosus*. The liver is the organ most often concerned. In France, the available data on CE is limited. In 2016, the French Observatory of CE was launched by the National Reference Center for Echinococcosis (NRC-E) at the request of the Agence Santé Publique France. It aims to study the population diagnosed with CE in France, and to provide an overview of current practices in CE patients care.

Method: Patient's enrolment has been mainly performed through clinical advice requests to the multidisciplinary concilium organized monthly by the NRC-E. After obtaining the patient's consent, demographic, epidemiological and clinical data were recorded through a computerized reporting system (Clean WEB®).

Results: From January 2016 to January 2023, 103 patients were included, (53H/50F), median age 42 yrs (range : 5–89). Most of the reports came from infectious diseases specialists (40% of the cases) and hepato-gastroenterologists (25% of the cases). Eighty five patients (83%) were from foreign countries, Maghreb in 52 cases (50%), Turkey in 10 cases (10%), Eastern Europe in 10 cases (10%). This was a primary diagnosis in 60 patients (59%). A past-history of CE was reported in 42 patients, 16 of them having had an incomplete surgery for CE in their native country. Ten patients seem to have been infected in France. CE discovery was incidental in 41% of the cases. Abdominal pain was the most common revealing symptom (56% of the cases). An acute inaugural complication (cyst fissuration or rupture, abscess, compression) involved 24% of the cases and resulted in death in 2 patients. There was a single cyst in 45 patients (44%). The liver was the organ most often affected in 84 patients (82%), either alone (n = 61) or in combination with other sites (n = 23). In 18 cases (17%), it was a primary extra-hepatic CE. Cyst characterization according to the WHO classification had only been assessed in 61 cases (59%). Therapeutic data (available on 90 patients) indicated that surgical treatment concerned 72% of the cases and was associated to albendazole (ABZ) in 79%. Instrumental treatments (per-cutaneous and/or biliary interventional endoscopy) concerned 6 cases. Long-term ABZ alone involved 10 patients (11%). In 13% of the cases, CE was considered as inactive and the « Watch and Wait » option was proposed.

Conclusion: This first report of CE case collection in France indicates that most cases are imported and concerns migrant population. The level of knowledge of French practitioners on CE appears insufficient, both at the diagnostic and therapeutic stages. Percutaneous treatments are not developed in this country. Concerning autochthonous cases, prevention actions and animal investigations in the field will be soon set up in the concerned areas. The continuation of this surveillance should help to optimize the management of CE in France.

THU-323

Role of gut-derived endotoxins in porto-sinusoidal vascular disease

Stefania Gioia[1], Roberto Carnevale[2], Daniele Tavano[1], Diletta Overi[3], Lorenzo Ridola[1], Silvia Nardelli[1], Manuela Merli[1], Giulia d'Amati[4], Adriano Pellicelli[5], Vincenzo Cardinale[1], Valerio Giannelli[5], Andrea Baiocchini[6], Guido Carpino[7], Oliviero Riggio[1], Eugenio Gaudio[3]. *[1]Sapienza, University of Rome, Department of Translational and Precision Medicine, Italy; [2]Sapienza, University of Rome, Department of Medico-Surgical Sciences and Biotechnologies, Latina, Italy; [3]Sapienza, University of Rome, Department of Anatomical, Histological, Forensic Medicine and Orthopedics Sciences, Italy; [4]Sapienza, University of Rome, Department of Radiological, Oncological, and Pathological Sciences, Italy; [5]Azienda Ospedaliera San Camillo, Department of Transplantation and General Surgery, Italy; [6]Azienda Ospedaliera San Camillo, Department of Pathology, Italy; [7]University of Rome "Foro Italico", Department of Movement, Human and Health Sciences, Division of Health Sciences, Italy*

Email: stensgioia@hotmail.com

Background and aims: Porto-sinusoidal vascular disease (PSVD) is characterized by histological lesions involving portal veins and sinusoids in absence of cirrhosis. The pathophysiology of PSVD is unclear. However, its association with immunodeficiency, celiac disease, intestinal bowel disorders and abdominal bacterial infections supports the role of altered intestinal permeability and of gut-derived endotoxins. The study aimed at assessing the association between serological markers of increased intestinal permeability, pro-aggregating/pro-coagulant state and liver injury in patients with PSVD.

Method: 33 patients with biopsy-proven PSVD and clinical signs of portal hypertension and 33 healthy subjects, similar for age and sex, were submitted to a peripheral venous blood sampling for the measurement of zonulin and lipopolysaccharides (LPS) as markers of intestinal permeability, of s-Glycoprotein VI, sP-selectin, ADAMTS13 and von Willebrand factor as markers of platelet aggregation, thrombogenesis and microvascular inflammation, factor VIII and F1 +2 as markers of hypercoagulability. Liver biopsy specimens from a subgroup of PSVD patients (n = 18) were available for histomorphological and immunohistochemical study.

Results: Compared to controls, PSVD patients had higher serum levels of LPS (55.4 ± 15.4 vs 19.1 ± 5.3 pg/ml, p < 0.0001), zonulin (4.3 ± 1.4 vs 1.9 ± 0.8 ng/ml, p < 0.0001), von Willebrand Factor (vWf) (303 ± 88 vs 158 ± 65 U/dl, p < 0.0001), factor VIII (185 ± 77 vs 103 ± 33 U/dl, p < 0.0001), sP-selectin (37.9 ± 11.9 vs 17.7 ± 5.5 ng/ml, p < 0.0001), and F1+2 (158 ± 40 vs 136 ± 27 pmol/l, p = 0.01). ADAMTS13 (259 ± 95 vs 497 ± 110 ng/ml, p < 0.0001) was reduced. Serum LPS correlated with zonulin (r = 0.80, p < 0.0001), sP-selectin (r = 0.85, p < 0.0001), FVIII (r = 0.42, p = 0.02), and vWF (r = 0.53, p = 0.02). Histological analysis showed specific signs of PSVD in all patients; particularly, obliterative portal venopathy (OPV) was associated with clinical features, portal inflammation and fibrosis. Compared to samples from healthy subjects (liver donors), PSVD specimens were characterized by increased Toll-like Receptor-4 (TLR4)-positive macrophages and platelet number, located both in portal and perisinusoidal position. TLR4+ macrophage number was correlated with portal inflammation and fibrosis. Sinusoid dilation, perisinusoidal fibrosis, and sinusoidal capillarization were observed. Bile duct alterations and ductular reaction were also observed in PSVD, and their extent correlated with liver fibrosis.
Conclusion: PSVD patients display an altered intestinal permeability with a concomitant endotoxemia correlated to a pro-aggregating and pro-coagulant state; at histologic level, PSVD was associated with increased TLR4+ cell involvement and platelet aggregation within sinusoids. Our study suggests that LPS-TLR4 pathway could play a role in the pathophysiological basis of OPV (figure).

THU-324
Evaluating pruritus and fatigue in patients with treatment-refractory primary biliary cholangitis

Jörn Schattenberg[1], Betsy Williams[2], France Sowell[2], Peter Serafini[3], Asad Khan[4], Marwan Sleiman[5], Julie Dietrich[6], Carol Addy[6], Dawn Vargas[6], Gail Wright[7], Kris Kowdley[8]. [1]*University Medical Centre of the Johannes Gutenberg-University, Mainz, Germany;* [2]*IQVIA, New York, United States;* [3]*Ipsen, Cambridge, United States;* [4]*Ipsen, Slough, United Kingdom;* [5]*Ipsen, Boulogne, France;* [6]*GENFIT Corp, Cambridge, United States;* [7]*Canadian PBC Society, Toronto, Canada;* [8]*Liver Institute Northwest, Seattle, United States*
Email: marwan.sleiman@ipsen.com

Background and aims: Pruritus and fatigue are common symptoms that negatively impact patients with primary biliary cholangitis (PBC). The PBC Worst Itch Numeric Rating Scale (PBC WI NRS) and PROMIS Fatigue Short Form 7a (PFSF 7a) are being used to assess symptoms in a phase III clinical trial of an investigational therapy for PBC.
Method: Semi-structured qualitative interviews were conducted with adult patients diagnosed with PBC using Institutional Review Board-approved materials. PBC WI NRS asks patients to rate their worst itch over the past 24 hours on a scale ranging from 0 (No itch) to 10 (Worst itch imaginable). The PFSF 7a consists of 7 items that measure both the experience of fatigue and interference of fatigue on daily activities over the past 7 days using a Likert response scale. Patients were asked to evaluate the PBC WI NRS and PFSF 7a on ease of understanding of instructions and items, ease of use of scale/response options, and appropriateness of recall period to capture the patient experience. Interviews were conducted by experienced qualitative researchers, and audio recordings were transcribed and analyzed with coding software.
Results: 20 patients (aged 28–68 years; 19 females) diagnosed with PBC, (mean 10.7 years since diagnosis) experiencing pruritus (mild [30%], moderate [45%] or severe [25%]) were interviewed. For the PBC WI NRS, patients reported that instructions (20/20), item wording (20/20), and response options (19/20) were clear (Figure). Most patients (10/18) reported that a 3-point change on the PBC WI NRS scale would constitute a meaningful improvement, which would be pruritus that is "manageable," and would occur occasionally, for shorter periods of time. This change would lead to less scratching, providing periods of "peace of mind" and less interference with sleep. For the PFSF 7a, all patients asked stated that instructions (18/18), items (18/18), and response options (19/19) were easy to understand. Most patients (12/18) stated a 1-point change on the PFSF 7a would represent a meaningful change in fatigue; this improvement corresponded to changes in alertness and well-being that would be easily noticeable compared to the consistency in their day-to-day experience with fatigue. The energy remaining would also be less fleeting allowing them to accomplish more throughout the day.

Instrument	Instructions were clear	Response options easy to use	Recall period appropriate
PBC WI NRS	20/20	19/20	15/19*
PFSF 7a	18/18**	19/19*	16/20

*One patient was not asked the question
**Two patients were not asked the question

Conclusion: Most patients found the PBC WI NRS and PFSF 7a instruments easy to understand and use for reporting their experience with pruritus and fatigue. These interview results support the content validity of the PBC WI NRS and PFSF 7a instruments in the context of PBC clinical trials; these instruments were selected to measure treatment benefit.

THU-325
Ultrasonographic liver characteristics among patients with Wilson disease

Zoe Mariño[1], Clàudia García[2], Cristina Collazos[2], Anna Miralpeix[2], Xavier Forns[1], Ernest Belmonte[3]. [1]*Liver Unit, Hospital Clínic Barcelona, IDIBAPS, CIBERehd, ERN-RARE Liver, Universitat de Barcelona, Barcelona, Spain;* [2]*Liver Unit, Hospital Clínic Barcelona, Barcelona, Spain;* [3]*Abdominal section, Radiology Department, Hospital Clínic Barcelona, Barcelona, Spain*
Email: zmarino@clinic.cat

Background and aims: Wilson disease (WD) may mimic other prevalent liver diseases. A previous work by *Akhan O et al (Eur J Radiol 2009)* suggested that WD may exert some differential ultrasonographic characteristics, such as the presence of hypoechoic nodules or increased periportal thickness (pPT) (more than 2 mm), that could be used for arising WD suspicion. The aim of this work was to analyze the main characteristics of abdominal ultrasounds (aUS) in a cohort of WD patients and correlate them with clinical and elastographic data.
Method: WD patients followed in our institution with aUS performed between 2018 and 2022 were included. An experienced radiologist blinded to clinical data performed the aUS retrospective analysis. We recorded the closest clinical, elastographic and analytical data for each patient. Statistical analysis was performed with SPSS v.27; variables were expressed as n (%) or mean (IQR_{25-75}).

Results: We included 55 WD patients with aUS: 28 (51%) male, current age 38 (27–47), WD diagnosis done 17 years (11–27) ago, 30 (55%) hepatic phenotype, 14 (25.5%) with cirrhosis (10 at diagnosis, 4 at follow-up), 28 (52.8%) with abnormal ASAT and/or ALAT at US evaluation, elastographic value 5.2 Kpa (4.6–7.4) and CAP 255 dB/m (209–295), available in 47 cases. Transient elastography (TE) was higher in cirrhosis *vs* non-cirrhosis (9.1Kpa *vs*. 4.9KPa, $p < 0.001$). At the aUS, most of the WD patients showed normal hepatic size and morphology (87.3% and 100% respectively). Hepatic contours were normal in 37 (67%). Hepatic parenchyma was heterogeneous in 18 (32.7%), and echogenicity was increased in 31 (56.3%) patients: mild 24 (77.4%), moderate 5 (16.2%), severe 2 (6.4%). The presence of moderate/severe steatosis in aUS (n = 7) was significantly associated with a CAP value >261 dB/m, corresponding to S2-S3 at TE ($p = 0.02$). Eleven patients (20%) presented any solid hepatic lesion (SHL): the majority were hypoechoic nodules (isolated in 2, multiple in 4) or hemangiomas (n = 3). Five out of the 6 cases with hypoechoic nodules had cirrhosis; 1 case was hepatocellular carcinoma. pPT was explored in 40 patients (72.7%) and was increased in 14 cases (40%); abnormal pPT was not associated with the presence of cirrhosis, increased transaminases, or SHL. Up to 19 patients (34.5%) had splenomegaly [spleen diameter: 13 cm (12.7–15.5)]: 52.6% of them had cirrhosis (n = 10) whereas 47.4% (n = 9) had no signs of advanced liver disease ($p < 0.001$). Splenomegaly could only be associated with a reduced platelet count (136 vs 224, $p < 0.001$).

Conclusion: Steatosis showed to be very prevalent in US and correlated with the TE-CAP value among patients with WD. Splenomegaly was observed in one third of the cohort, even in the absence of cirrhosis. The presence of an increased periportal thickness and/or hypoechogenic nodules at the aUS could be helpful for WD diagnosis and should be explored prospectively.

THU-326

Exploring pregnancy, breastfeeding and contraception among women with Wilson disease in Spain: results from the Spanish Wilson registry

Email: m.romero.gutierrez@gmail.com

Background and aims: Recommendations about gestation and breastfeeding in patients with Wilson disease (WD) are heterogeneous. Our aim was to collect data on gestational history, lactation, therapeutic modifications, and contraception in patients with WD in Spain.

Method: Multicenter ambispective study including adult women within the Spanish Wilson Registry. Informed consent was obtained and specific interviews were performed in all cases.

Results: We included 92 women with WD: median age was 43.7 (range: 18–81) years, age at WD diagnosis was 15.7 (3–67) years. Thirty-four women (37%) reported no history of gestation, whereas 58 (63%) referred previous pregnancies [total gestations: 143, median/woman: 2]. WD diagnosis was done during pregnancy in 2 patients (3.4%), before in 41 (70.7%) and after in 15 (25.9%). Up to 35 (33.6%) received no anti-copper therapy while on pregnancy, mostly due to post-gestation diagnosis (91.4%). In those pregnant women with treatment (n = 69), the drugs used were: 52.2% D-Penicillamine (D-P), 5.8% trientine and 42% zinc. The therapeutic attitude during pregnancy was: 62.3% unchanged, 10.1% dose reduction, 7.3% changed D-P to zinc; 7.3% women decided to voluntarily abandon therapy; in 13% it was unknown. Up to 49% of women were followed in high-risk gynecological programs. The age at first delivery was 26.1 (18–40) years. Twenty-three WD patients (39.6%) reported previous history of miscarriage, mainly spontaneous (74%) and most occurring during the first trimester. Data regarding 106 newborns was available: 98 term neonates, 6 pre-term, 2 post-term; pathology was reported in 4 children (3.8%). Breastfeeding data was obtained from 78 pregnancies: 26.9% did natural breastfeeding, 60.3% artificial lactation, mixed in 12.8%. Type of lactation was based on patient's choice in 37.2%, hepatology recommendation in 17.9%, gynecology recommendation in 30.8%, others in 7.7%, not available in 6.4%. The use of artificial lactation was mainly (68%) based on physician's recommendations (hepatology/gynecology). After WD diagnosis, 26.1% did not use any contraception, 29.4% used hormonal contraceptives, 21.7% barrier contraceptives, 5.4% IUDs, 10.9% other/combined, and 6.5% unknown. When we asked specifically, WD women were concerned about pregnancy (48.1%), mostly because of the risk of WD and treatment on the fetus (64.5%). However, information received from physicians was considered to be sufficient in more than a half (53.2%).

Conclusion: Gestational history among women with WD in Spain was shown to be heterogeneous. Almost 50% of the patients reported concerns about being pregnant. Artificial breastfeeding was the most frequent method, mainly due to medical recommendations. A clear guide for physicians and WD patients would be desirable.

THU-327

Hepatic alterations in COVID-19: a comparative autopsy study

Sigurd Lax[1,2], Kristijan Skok[3], Peter Zechner[4], Stephan Aberle[5], Ute Bargfrieder[1], Claudia Grosse[6], Helmut Salzer[7], Thomas Zlamal[8], Lisa Setaffy[1], Harald Kessler[9], Hans-Peter Dienes[10], Michael Trauner[11]. *[1]Hospital Graz II, Pathology, Graz, Austria; [2]Johannes Kepler University, Pathology and Molecular Pathology, Linz, Austria; [3]Hospital Graz II, Pathology, Graz, Austria; [4]Hospital Graz II, Cardiology and Intensive Medicine, Graz, Austria; [5]Medical University Vienna, Virology, Wien, Austria; [6]Kepleruniklinikum, Pathology and Molecular Pathology, Linz, Austria; [7]Kepleruniklinikum Linz, Pulmonary Medicine, Linz, Austria; [8]Hospital Graz II, Cardiology and Intensive Medicine, Graz, Austria; [9]Medical University Graz, Hygiene, Microbiology and Environmental Medicine, Graz, Austria; [10]Medical University Vienna, Gastroenterology and Hepatology, Wien, Austria; [11]Medical University Vienna, Gastroenterology and Hepatology, Vienna, Austria*
Email: sigurd.lax@kages.at

Background and aims: COVID-19 is a systemic disease involving particularly the lungs and, in addition, multiple other organs. Whereas the pulmonary changes have been extensively studied, our knowledge on the impact of SARS-CoV-2 on the liver is limited. The aim of this study was to investigate liver changes of COVID-19 deceased in correlation with the hepatic viral status and to compare

the findings with a control group of non-COVID-19 patients matched for age and underlying medical conditions.
Method: Formalin-fixed, paraffin-embedded liver tissue of 50 COVID-19 and 20 non-COVID deceased was studied histologically, by immunohistochemistry and by PCR for SARS-CoV-2 RNA and correlated with clinical and laboratory information.
Results: Viral RNA was detected in liver tissue of 15/50 (30%) COVID-19 deceased but in none of the controls. Livers of COVID-19 deceased showed significantly more frequently moderate to severe (mostly macrovesicular) steatosis, Kupffer cell proliferation and ductular metaplasia of hepatocytes compared to the control group ($p < 0.01$). Portal T- cell infiltrates were significantly less frequent in the PCR-positive COVID-19 subgroup compared to PCR-negative COVID-19 patients and controls ($p < 0.01$). Other findings such as active cholangitis, ductular proliferation, periductular sclerosis, fibrosis, and congestion were present in both COVID-19 patients and controls, without statistically significant differences. Cholestasis and hepatic thrombosis were only found in COVID-19 deceased.
Conclusion: Severe hepatic steatosis, increased Kupffer cell proliferation, ductular proliferation and ductular metaplasia of hepatocytes in COVID-19 may reflect a reaction to the viral infection and/or associated systemic inflammation. However, other histological findings in the liver of elderly COVID-19 deceased, particularly, periductular sclerosis seem to be potentially age-related.

THU-328

The adequacy and safety of liver biopsy performed during cardiac catheterization in patients with Fontan and non-Fontan heart disease

Edward Cytryn[1], Peizi Li[2], Sara Lewis[3], Maria Isabel Fiel[2], Barry Love[4], Ali Zaidi[5], Thomas Schiano[6], Lauren Grinspan[6]. *[1]Icahn School of Medicine at Mount Sinai, Department of Medicine, New York, United States; [2]Icahn School of Medicine at Mount Sinai, Department of Pathology, New York, United States; [3]Icahn School of Medicine at Mount Sinai, Department of Radiology, New York, United States; [4]Icahn School of Medicine at Mount Sinai, Department of Pediatrics, Division of Cardiology, New York, United States; [5]Icahn School of Medicine at Mount Sinai, Department of Medicine (Cardiology), Department of Pediatrics, New York, United States; [6]Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, Recanati/Miller Transplantation Institute, New York, United States*
Email: edward.cytryn@mountsinai.org

Background and aims: Liver biopsy is the gold standard for diagnosis of hepatic fibrosis and cirrhosis. However, it is an invasive procedure and carries risk of bleeding. The surveillance of Fontan-associated liver disease (FALD), an increasingly recognized complication in the growing number of patients post-Fontan procedure, with biopsy during right heart catheterization (RHC) is a unique approach performed at few centers, in part due to questions of risk of biopsy and sampling error. The role and efficacy of transcaval liver biopsy during RHC warrants further investigation. The aim of this study was to review the indications, outcomes, and adequacy of liver biopsy during RHC, with special attention to patients having FALD.
Method: A multidisciplinary, retrospective review of patients at a single institution who underwent liver biopsy during RHC was performed. 94 liver biopsies taken between December 2011 and October 2022 were analyzed. Patient characteristics, RHC and biopsy indications, hemodynamics, complications, and tissue adequacy were evaluated. Specimens were classified as "adequate" if total biopsy linear length was greater than or equal to 20 mm or the total number of portal tracts was greater than or equal to 10, "limited" if the total length was 10 to 20 mm or total number of tracts was 5 to 10, or "inadequate" if the total length was less than 10 mm and total number of tracts was less than 5.
Results: There were 55 biopsies in non-Fontan patients and 39 in Fontan patients with a median age at RHC of 55.5 years and 30 years, respectively. Indications for RHC were routine hemodynamic assessment (49%), new or progressive heart failure symptoms (47.2%), and arrhythmia (3.6%) in the non-Fontan group and assessment of Fontan circulation (84.6%), heart failure symptoms (10.3%), and arrhythmia (2.6%) in the Fontan group. Indication for liver biopsy in non-Fontan patients was to rule out fibrosis in 92.7% and abnormal LFTs in 7.3%. In Fontan patients, biopsy was indicated to assess FALD in 25.6% with known disease and to rule out fibrosis in 74.4%. Hepatic pressure measurements were obtained in 95.7% of cases (98% non-Fontan, 92.3% Fontan). Average fluoroscopy time was longer in Fontan compared to non-Fontan cases, 12.5 vs 6.4 minutes, with fewer average number of biopsy passes, 2.8 vs 3.6. There were no complications from pain, bleeding, perforation, or infection, and no noted technical difficulties in either group. Average total linear length and number of portal tracts were similar between Fontan and non-Fontan biopsies, 24.3 vs 24.4 mm and 12.7 vs 13.7 portal tracts, respectively. In total, 82/94 (87.2%) were "adequate" and 10/94 (10.6%) were "limited." 4/94 (4.3%) were inadequate by linear length, while 3/94 (3.2%) were inadequate by number of portal tracts, however, only 2/94 (2.1%) met both criteria and were classified as "inadequate." Similar adequacy was noted in sub-analysis of Fontan patients with 34/39 (89.7%) "adequate, " 4/39 (10.3%) "limited, " and 1/39 (2.6%) "inadequate." A definitive diagnosis was reached on pathology review of 92/94 (97.9%) biopsies.
Conclusion: Liver biopsy performed during a clinically warranted RHC can be safely performed with adequate yield and minimal complication risk. It is especially useful and effective in Fontan patients undergoing RHC to assess FALD development and progression. Liver histology is important to analyze during cardiac decompensation and obtaining a liver biopsy concurrently during a RHC should be considered.

THU-329

Deep learning quantification reveals fundamental prognostic role for ductular reaction in biliary atresia

Iiris Nyholm[1], Nelli Sjöblom[2], Maria Hukkinen[1], Marjut Pihlajoki[3], Jouko Lohi[2], Aino Mutka[2], Päivi Heikkilä[2], Mark Davenport[4], Markku Heikinheimo[3], Johanna Arola[2], Mikko Pakarinen[1]. *[1]University of Helsinki and Helsinki University Hospital, Section of Pediatric Surgery, Pediatric Liver and Gut Research Group, Finland; [2]University of Helsinki and Helsinki University Hospital, Department of Pathology, Finland; [3]University of Helsinki and Helsinki University Hospital, Pediatric Research Center, Finland; [4]King's College Hospital, Department of Pediatric Surgery, United Kingdom*
Email: iiris.nyholm@helsinki.fi

Background and aims: Ductular reaction (DR) is a prominent pathological feature of biliary atresia (BA) associating with unsuccessful Kasai portoenterostomy (KPE) and liver fibrosis in previous small studies using conventional histopathology.
Method: Deep learning model was developed and applied to cytokeratin 7 (CK7) stained native liver biopsies ($n = 257$) in BA patients ($n = 136$). The CharBADR model quantified total proportional DR (DR%) composed of CK7 positive portal biliary epithelium (BEL%) and parenchymal intermediate hepatocytes (PIH%). Results were related to clinical data, Sirius Red quantified liver fibrosis, and serum bile acids.
Results: In total, 116 biopsies were obtained at KPE and 141 during postoperative follow-up. 58% of patients cleared their jaundice (COJ, post-KPE serum bilirubin <20 µmol/l) and overall native liver survival (NLS) was 38%. DR% (8.3 vs 5.9%, $p = 0.045$) and PIH% (13.4 vs 6.3%, $p = 0.004$), but not BEL% (6.8 vs 5.1, $p = 0.09$), were increased at KPE in patients without COJ. During follow-up, increased DR% (13.6 vs 2.9%, $p < 0.001$), PIH% (6.4 vs 0.3%, $p < 0.001$) and BEL% (4.4 vs 2.5%, $p < 0.001$) persisted in patients subsequently transplanted. In Cox regression, high DR% predicted inferior NLS both at KPE (HR = 134, $p = 0.02$) and during post-KPE follow-up (HR = 22, $p < 0.001$). DR% correlated with liver fibrosis at KPE ($R = 0.47$, $p < 0.0001$) and follow-up ($R = 0.27$, $p = 0.004$). A close association between DR% and serum

bile acids was observed at follow-up (R = 0.61. p < 0.001). Fibrosis was not prognostic for NLS at KPE (HR = 1.00, p = 0.96) or follow-up (HR = 1.01, p = 0.29).

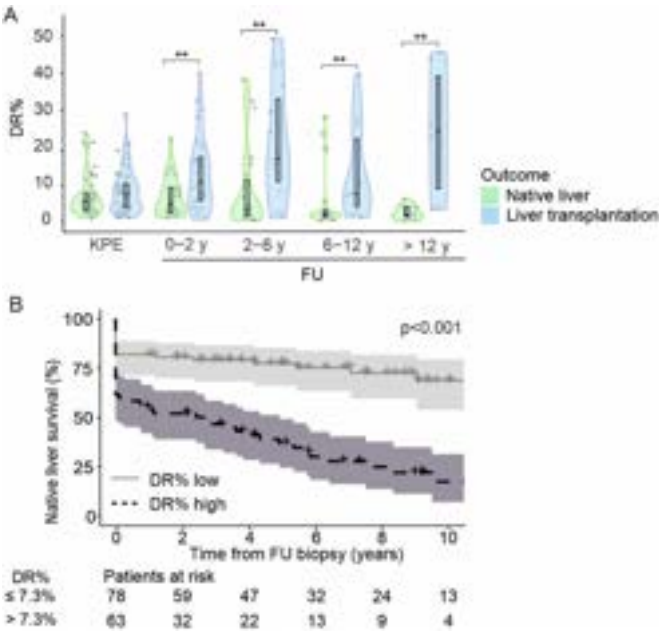

Figure:

Conclusion: DR associated with COJ and, unlike liver fibrosis, predicted need for liver transplantation.

THU-330

Long-term outcomes of patients with Wilson disease: a single center analysis of 361 Korean patients

Hyo Jin Nam[1], Jonggi Choi[1], Won-Mook Choi[1], Danbi Lee[1], Ju Hyun Shim[1], Kang Mo Kim[1], Young-Suk Lim[1], Han Chu Lee[1]. *[1]Asan Medical Center, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and aims: There are few data regarding long-term outcomes and survival of patients with Wilson disease (WD) from large Asian cohorts. We aimed to analyze the clinical long-term data in a large Korean cohort of WD.

Method: Between 2000 and 2022, 361 patients with WD were retrospectively analyzed at Asan Medical Center, Seoul, Republic of Korea. Diagnosis of WD were made on typical symptoms, clinical, biochemical and genetic findings. Primary outcome was liver transplant-free survival. Development of hepatocellular carcinoma (HCC) in the entire patients and progression to liver cirrhosis (LC) in patients without LC at diagnosis were also analyzed. Patients who met the following criteria were excluded: 1) received liver transplantation within 6 months of diagnosis; 2) follow-up period less than 6 months; 3) co-infection with hepatitis B virus; 4) combined alcoholic liver disease. Median follow-up period was 13.0 years.

Results: The mean age was 17.2 years, and 206 (57.1%) of the patients were male. At diagnosis, 146 (40.4%) patients had LC, of which 48 (13.3%) patients showed decompensation. Transplant-free survival rates at 5-, 10-, 15-, and 20-years were 100.0%, 98.4%, 97.9%, and 97.9%, respectively. Cumulative probabilities of HCC development at 5-, 10-, 15-, and 20-years were 0.0%, 0.4%, 1.9%, and 6.1%, respectively. Of the 215 patients without LC at diagnosis, 15 (7.0%) patients showed progression to LC with cumulative risks of 0.0%, 3.0%, 6.1% and 14.1% at 5, 10, 15, and 20 years, respectively. No patients without LC at diagnosis died or developed HCC during the follow-up period. Older age and LC at diagnosis were significantly associated with a worse survival rate (p < 0.05 for all).

Conclusion: Korean patients with WD had a favorable long-term prognosis However, older age and LC at the time of diagnosis increase the risk of death and HCC development.

THU-331

Lessons from population genomics for Wilson disease: Prevalence, penetrance of mutations, clinical implications and design of regional screening programmes

Email: lgarciavillarreal@gmail.com

Background and aims: During the last years several studies have discussed about the prevalence and penetrance of Wilson Disease (WD) mutations with conflicting conclusions. So we decided to compare the estimated data for WD in Spain from genome databases-Lorente et al J Pediatr Gastroenterol Nutr. 2022 Feb 1;74 (2):192–199- with clinical and genetic data obtained from the Spanish Wilson Registry (SWR) by AEEH

Method: We calculated the number of homozygotes of the most frequent mutations in Spain as predicted from the number of carriers found at the Collaborative Spanish Variant Server (assuming that the

	1 (n = 62) Met645Arg	2 (n = 16) Leu708Pro	3 (n = 22) His1069Gln	4 (n = 5) Gly869Arg	
Neurological manifestations	6, 00%	19, 00%	27, 00%	0, 00%	p = 0.05
Hepatic manifestations	72, 00%	81, 00%	31, 00%	60, 00%	p = 0.003
Screening cases	23, 00%	0, 00%	18, 00%	50, 00%	p = 0.023
K-F ring	6, 00%	25, 00%	39, 00%	0, 00%	p = 0.009
Cirrhosis at diagnosis	14, 00%	25, 00%	37, 00%	0, 00%	P < 0.05 1 vs 3

Figure: (abstract: THU-331).

Hardy-Weinberg equilibrium is met), and compared those estimated values with records from the Spanish Wilson Registry (adding late communication from a center not included yet) covering approximately 85% of the Spanish population, and represented mainly by adult cases recruited at digestive services.

Results: The estimated vs real number of homozygotes were as follows: p.Met645Arg (1949 vs 6), p.His1069Gln (20 vs 8), p. Leu708Pro (63 vs 24; only Gran Canaria) and p.Gly869Arg (147 vs 0). Studying homozygous cases from the SWR, the p.Met645Arg homozygous cases compared with those for p.Leu708Pro and p. His1069Gln presented 0% with cirrhosis at diagnosis (vs 40% and 20%, respectively), 20% with extrahepatic disease (vs 46% and 50%, respectively), 20% asymptomatic cases (vs 8% and 0%, respectively), 0% with Kayser-Fleischer (KF) ring (vs 40%, 75% $p < 0.05$ with p. His1069Gln)), and 60% diagnosed after 40 y.o. (vs 0% and 0%, $p < 0.001$). When comparing p.Met645Arg homozygotes vs p.Met645Arg compound heterozygotes, we found that 60% vs 17%, respectively, were diagnosed after 40 yo ($p < 0.05$). Finally we studied these 4 mutations in compound heterozygotes with any other mutation, excluding compounds between the frequent mutations (Table):

Conclusion: Considering the limited recruitment time (only one year) of the registry, not covering all patients and only ¾ of cases with a genetic test, it seems that Met645Arg and Gly869Arg are less penetrant mutations, as homozygote patients presented with less cirrhosis at diagnosis, no KF ring, no neurological manifestations and are diagnosed later. From the estimated values, WD in Spain seems to be underdiagnosed possibly, among other reasons, due to the low penetrance of the most frequent mutations (p.Met645Arg and p. Gly869Arg), low suspicion in some cases and atypical presentation in others. Data like these from population genomic studies and clinical records may help to design better screening strategies that could accelerate and improve WD diagnosis.

THU-332

Endogenous ethanol production in biliary atresia and its association with clinical outcomes, liver disease severity, fibrosis, bacterial translocation and intestinal permeability

Emma Alexander[1], Charlotte Burford[1], Mark Davenport[1], Erica Makin[1], Anita Verma[1], Anil Dhawan[1], Vandana Jain[1]. *[1]King's College Hospital, United Kingdom*
Email: vjain@nhs.net

Background and aims: Altered gut microbiota (GM; dysbiosis), have been implicated in the pathogenesis of chronic liver diseases, including Biliary Atresia (BA), and are a major source of endogenous ethanol production. Plasma ethanol concentration was increased in NASH vs obese/healthy controls, and we have previously described an increase in potential ethanol-producing GM in BA. Aim: To characterise ethanol production in BA, and its association with clinical outcomes, liver disease severity, fibrosis, bacterial translocation (BT) and intestinal permeability (IP).

Method: Stool and plasma samples, were prospectively collected, in BA infants (n = 55) pre-Kasai Portoenterostomy (KPE), 6weeks-, 3months-, and 6months-post-KPE. Plasma ethanol, BT [Lipopolysaccharide-Binding Protein (LBP), D-lactate] and IP [Claudin-3] biomarkers, were measured. Stool 16S-rRNA sequencing was performed for GM genus abundance. Outcomes: 6month jaundice clearance vs 6month jaundice [BA-JC vs BA-J], 1year-liver transplant (LT) status [BA-native liver survivor (NLS) vs BA-LT], Paediatric End Stage Liver Disease (PELD) score, fibrosis [Liver Stiffness Measurement (LSM)].

Results: Plasma ethanol concentration pre-KPE, 6weeks-post-KPE, were not associated with 6month-JC or 1year-LT outcome groups. At 3months-post-KPE, increased ethanol was associated with 1year-LT [BA-NLS, 2.4 mg/L (0, 12.3) vs BA-LT 7 mg/L (1, 140, $p = 0.02$) and predicted the need for LT at 1year-post-KPE, with AUROC of 0.74. At 6months-post-KPE, ethanol was not associated with clinical outcomes. At 3months-post-KPE, ethanol positively correlated with disease severity [PELD, $rs = 0.4$, $p = 0.02$] and fibrosis [LSM, $rs = 0.5$, $p = 0.01$]. Regarding BT, ethanol positively correlated with D-lactate at 6weeks-post-KPE [$rs = 0.4$, $p = 0.02$] and 3months-post-KPE [$rs = 0.5$, $p = 0.01$], but inversely with LBP [3months-post-KPE; $rs = -0.3$, $p = 0.05$; 6months-post-KPE, $rs = -0.5$, $p = 0.01$]. No correlation between ethanol and individual genus abundance or IP (Claudin-3), was identified.

Conclusion: Ethanol, at 3months-post-KPE, is associated with LT in BA. Ethanol and D-lactate production are linked, suggesting a role for GM-ethanol-BA pathogenesis. The inverse correlation between LBP and ethanol may reflect a protective role for LBP in early endotoxemia. Mechanistic pathways for ethanol-BA pathogenesis, warrant further investigation.

THU-333

Digital pathology using stain-free imaging indices as a tool for fibrosis quantification in patients with congestive hepatopathy

Matthew Yeh[1], Hong-Wen Tsai[2], Che-Wei Hsu[2], Cheng-Yi Chen[2], Yayun Ren[3], Kutbuddin Akbary[3], Elaine Chng[3], Dean Tai[3]. *[1]University of Washington, Department of Pathology, United States; [2]National Cheng Kung University Hospital, Taiwan; [3]HistoIndex Pte Ltd, Singapore*
Email: yehmliver@gmail.com

Background and aims: Congestive hepatopathy (CH) is the result of right heart failure from myriads of heart diseases. It causes centrilobular fibrosis and can progress to portal and bridging fibrosis and even cirrhosis. While histological scoring system for fibrosis in congestive hepatopathy exists, the scores are categorical but not continuous. There are also intra- and inter-observer variation among pathologists. Second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy has been demonstrated to provide accurate and reproducible fibrosis quantification in preclinical and clinical liver specimens, including biopsies from patents with viral hepatitis and NAFLD. We aim to test the feasibility using SHG/TPEF microscopy in assessing liver fibrosis in congestive hepatopathy.

Method: Unstained sections from 10 congestive hepatopathy cases with Dai scheme stages 0, 1, 2 and 3 were imaged using SHG/TPEF microscopy. Changes in overall liver fibrosis and in five zonal regions of liver lobules were quantitatively assessed by qFibrosis-a cumulative index based on measuring 184 collagen features on a continuous scale. Using sequential feature selection, 3 parameters were chosen out of 184 fibrosis parameters and a linear regression method was used to construct a congestive hepatopathy index.

Results: 3 parameters chosen for CH fibrosis are all from central vein regions, whereas in NASH, 15 parameters chosen were from total tissue area and portal tract regions. This finding indicates the fibrosis

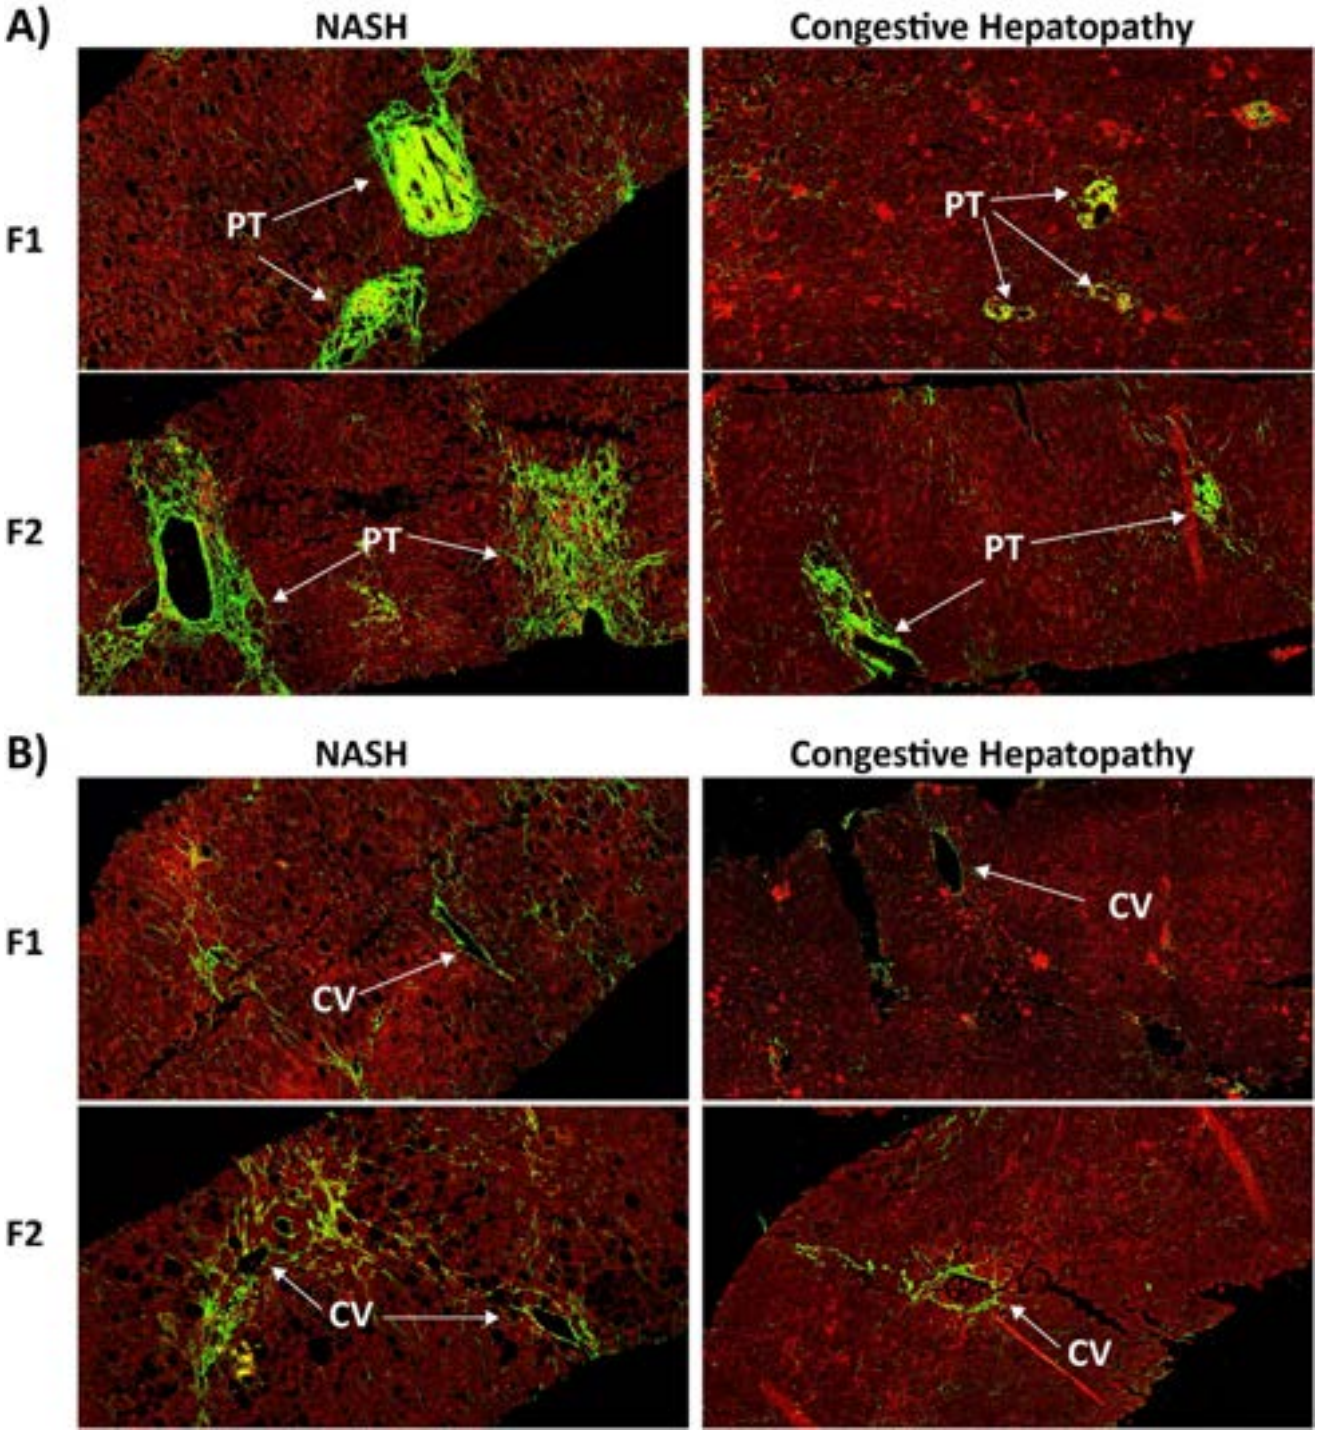

Figure: (abstract: THU-333): Image examples of (A) portal fibrosis and (B) central fibrosis for NASH and CH patients.

progression patterns is quantitatively different in portal tract and central vein regions. This difference can be better visualized in the figures, where SHG/TPEF images shows more fibrosis in NASH comparing to CH. Note that the staging systems used are NASH-CRN and Dai for NASH and CH patients respectively.

Conclusion: This is the first series liver fibrosis in congestive hepatopathy is shown to be assessed using SHG/TPEF microscopy. These data will be expanded and validated in an additional larger number of congestive hepatopathy cohort correlating with clinical and outcome data, and compared with other liver diseases (e.g., NASH and viral hepatitis), which may provide insight evaluating disease severity that aid clinical management plan algorithm and decision-making.

THU-334

Current transition management of adolescents and young adults with liver diseases: an European reference network rare liver survey

Joao Madaleno[1,2,3], Marianne Samyn[3,4], Isabel Gonçalves[3,5], Zoe Mariño[3,6], Ruth de Bruyne[3,7], Deirdre Kelly[3,8]. [1]*Liver Disease Unit,*

Email: joaocarvalhomadaleno@gmail.com

Background and aims: There is an increased risk for medical complications and morbidity surrounding transfer from pediatric to adult hepatology and transplant services. Health care transition (HCT) is the process of moving from a child/family-centered model of care to an adult or patient-centered model of health care. On behalf of the European Reference Network (ERN) RARE-Liver, the Transition Working group conducted a survey within Europe exploring current practice.
Method: A questionnaire was developed and circulated electronically via ERN members and other national/international professional bodies using the EU Survey platform.
Results: A total of 90 responses (44% adult) from 67 centers in 27 countries were collected. A liver HCT programme was available in 61% (n = 41) centres, organized by paediatrics in 29%, adults 11% and jointly in 57%. Lack of resources was the main reason (56%) for not having a liver HCT programme. Transfer to adult services is mainly driven by age, with 71% occurring by their 18th/19th birthday but exceptions are allowed in 57%. Transition readiness assessments were only used by 19%, and 70% of health care providers had not received specific training in the care of adolescents and young adults (AYA). The main barriers to adequate HCT were patient/family's dependence on the pediatric provider and inadequate communication between teams with 76.7% and 68.9% responding strongly agree/agree. No feedback system between pediatric and adult services occurs in 45.5% and no evaluation system is in place in 60%.
Conclusion: HCT is important for AYA with chronic liver diseases, but there are crucial limitations and variations in the current provision of transition services across Europe. Standardization of AYA management and specific training are required. This should improve management and continuity of care during adolescence and into adulthood to achieve the best healthcare outcomes.

THU-335
Quality of life in patients with Wilson disease treated with Trientine dihydrochloride: a prospective study

Karl Heinz Weiss[1], Isabelle Mohr[2], Larissa Wijnberg[3], Carlot Kruse[3].
[1]Salem Medical Centre, Internal Medicine, Germany; [2]Heidelberg University Hospital, Gastroenterology, Germany; [3]Univar Solutions, Netherlands
Email: larissa.wijnberg@univarsolutions.com

Background and aims: Wilson disease (WD) is a rare genetic disorder, causing copper accumulation in organs, particularly the liver and brain. Life-long chelation therapy is required to remove excess copper and avoid development or worsening of hepatic and neurological symptoms. Chronic illness is known to impact quality of

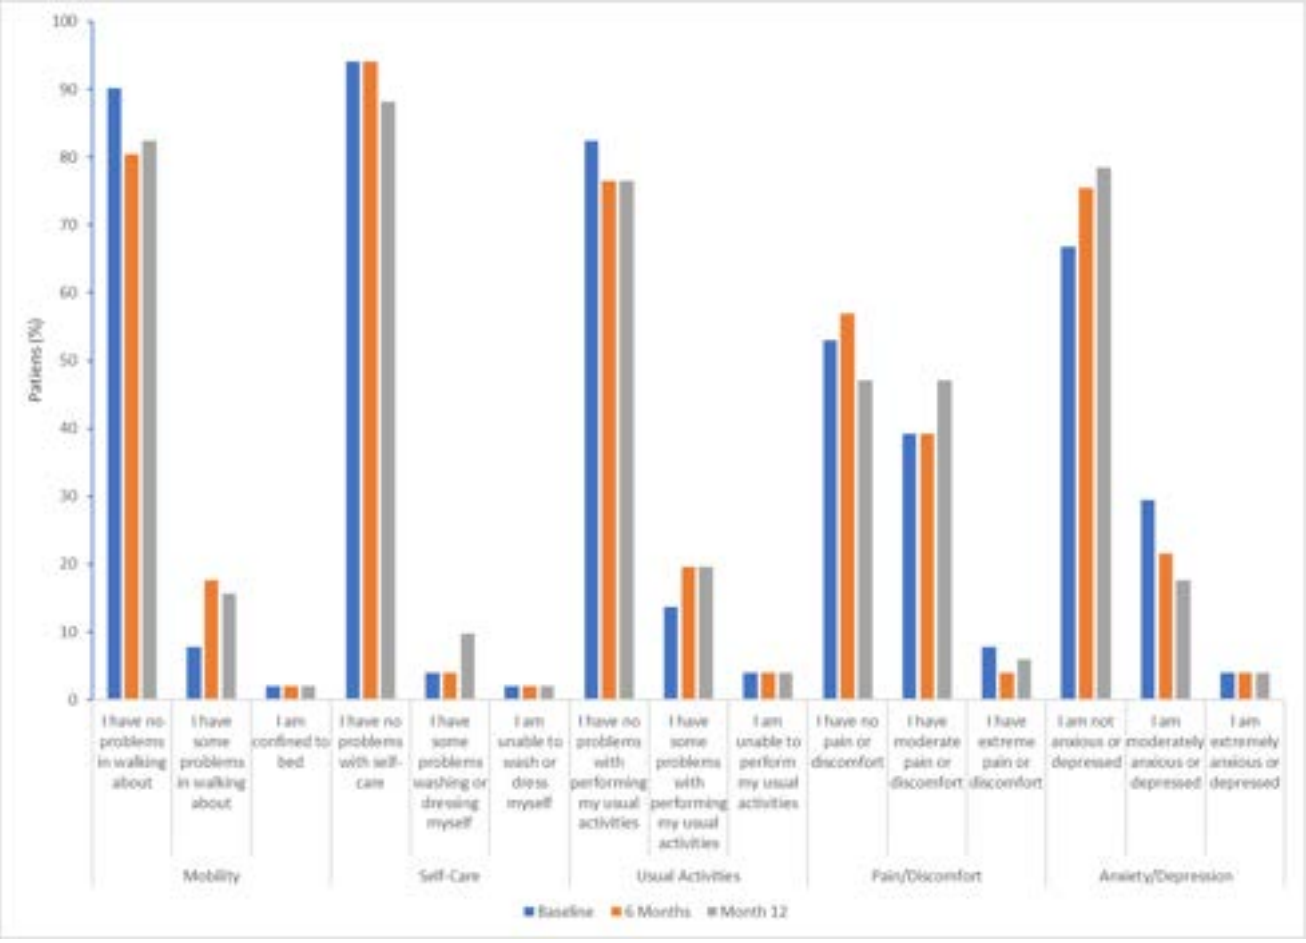

Figure: (abstract: THU-335): Quality of Life (EQ-5D-3L) dimensions at Baseline, Month 6, and Month 12.

life (QoL), with lower QoL and increased risk of depression reported in WD. We report QoL outcomes in a prospective study to assess long-term outcomes in patients with WD treated with Trientine dihydrochloride (TETA-2HCl).

Method: Patients with WD who were withdrawn from therapy with D-penicillamine and treated for at least 6 months with 300 mg capsules of TETA-2HCl (equivalent to 200 mg of trientine base) were eligible for this prospective, observational study. Patients were administered their routine dose of TETA-2HCl and completed the EQ-5D-3L questionnaire at Baseline, Month 6, and Month 12.

Results: EQ-5D-3L questionnaires were completed by all patients (N = 51). The five dimensions of the EQ-5D-3L (mobility, self-care, usual activities, pain/discomfort, anxiety/depression) were stable and generally similar at Months 6 and 12. Most patients had no difficulty in mobility or performing self-care activities while on treatment with TETA-2HCl, however one (2%) patient was confined to bed and not able to perform self-care (unable to wash or self-dress) throughout the study. Some problems in performing usual activities were reported by 7 (13.7%) patients, 10 (19.6%) patients and 10 (19.6%) patients at Baseline, Month 6, and Month 12, respectively, while two (3.9%) patients were completely unable to perform any usual activities during the study. Overall, 20 (39.2%) patients, 20 (39.2%) patients and 24 (47.1%) patients experienced moderate pain or discomfort at Baseline, Month 6, and Month 12, respectively. Extreme pain or discomfort was experienced by 4 (7.8%) patients, 2 (3.9%) patients and 3 (5.9%) patients at Baseline, Month 6 and at Month 12 respectively. Moderate anxiety or depression was noted in 15 (29.4%) patients, 11 (21.6%) patients and 9 (17.6%) patients at Baseline, Month 6, and at Month 12, respectively. Extreme anxiety or depression were experienced by 2 (3.9%) patients at Baseline, Month 6 and at Month 12, respectively.

Conclusion: Patients with WD receiving long-term TETA-2HCl therapy generally reported good mobility, self-care and ability to carry out their usual activities. However, pain or discomfort were reported by almost half of patients. Anxiety or depression also affected up to half of patients at Baseline, although the proportion reporting moderate anxiety or depression decreased substantially during the 12 months of treatment. As a clinical consequence, assessment of anxiety and depression in patients with WD is warranted, even during maintenance therapy.

THU-336

Odevixibat therapy in patients with MYO5B mutations: a retrospective case series

Bertrand Roquelaure[1], Marco Sciveres[2], Tassos Grammatikopoulos[3], Eberhard Lurz[4], Folke Freudenberg[5], Lionel Thevathasan[6], Fatine Elaraki[6], Velichka Valcheva[6], Emmanuel Gonzalès[7]. *[1]CHU, Hospital de la Timone, France; [2]Paediatric Hepatology and Paediatric Liver Transplantation, ISMETT, University of Pittsburgh Medical Center Italy, Palermo, Italy; [3]Institute of Liver Studies, King's College London, London, United Kingdom; [4]Division of Paediatric Gastroenterology und Hepatology, Dr. von Hauner Children's Hospital, University Hospital Munich, LMU, Munich, Germany; [5]Klinikum Dritter Orden, Division of Pediatric Gastroenterology and Hepatology, Munich, Germany; [6]Albireo Pharma Inc., Boston, MA, United States; [7]Hépatologie et Transplantation Hépatique Pédiatriques, Centre de Référence de l'Atrésie des Voies Biliaires et des Cholestases Génétiques, FSMR FILFOIE, ERN RARE LIVER, Hôpital Bicêtre, AP-HP, Université Paris-Saclay, Hépatinov, Inserm U 1193, Paris, France*
Email: bertrand.roquelaure@ap-hm.fr

Background and aims: Progressive familial intrahepatic cholestasis type 6 (PFIC6, recently renamed PFIC10 according to Online Mendelian Inheritance in Man [OMIM; https://www.omim.org/entry/619868]) is a rare liver disease caused by mutations in the *MYO5B* gene and characterised by elevated serum bile acids (sBAs) and severe pruritus. This case series reports the effects of treatment with the ileal bile acid transporter inhibitor odevixibat in children with PFIC10.

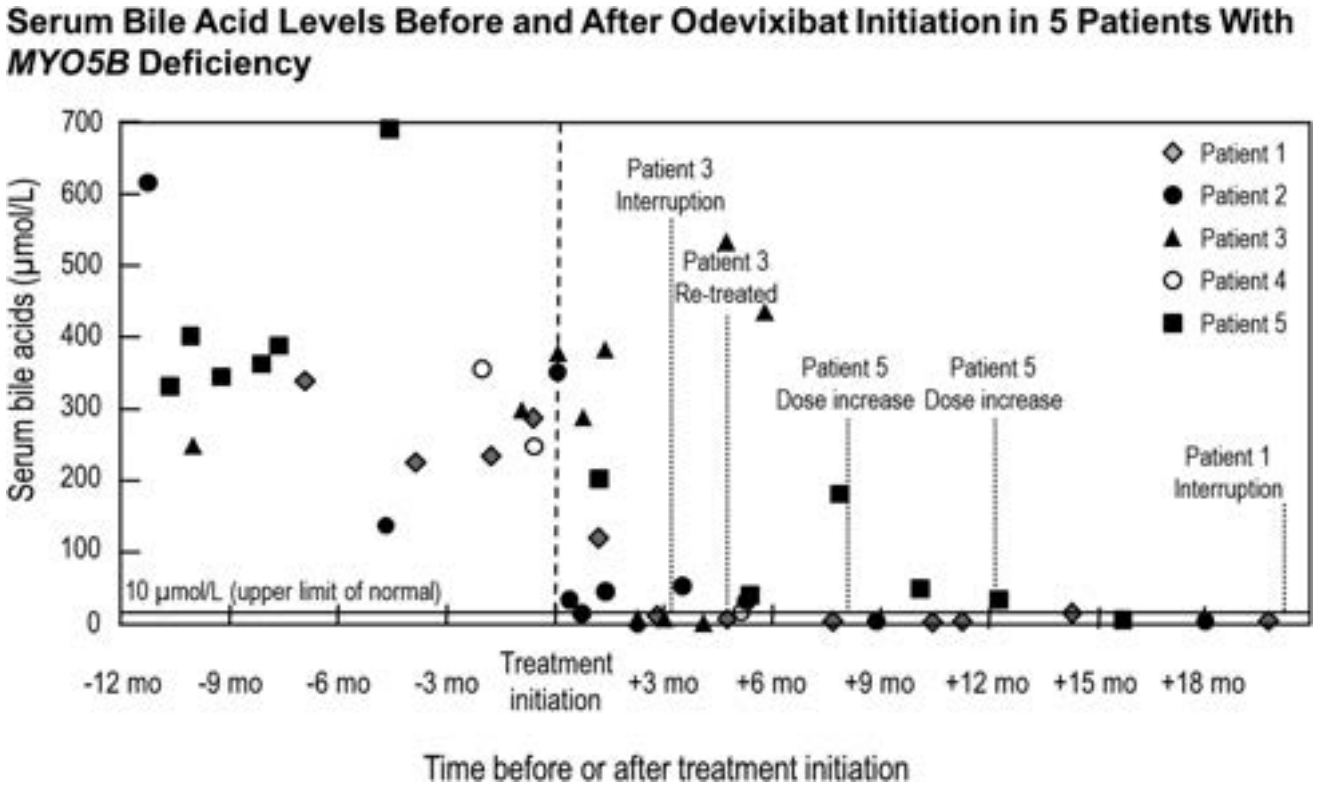

Figure: (abstract: THU-336).

Method: This was a retrospective analysis of 5 children with a diagnosis of MYO5B-related PFIC and pruritus refractory to standard treatment who were treated with odevixibat. Anonymised clinical and laboratory data collected at least quarterly were analysed, including anthropometrics, liver function tests, and treatment history. Pruritus and sleep disorders were rated on a 4-point Likert scale (absent, mild, moderate, or severe).
Results: Odevixibat treatment (40–120 µg/kg/day) was started between 2 and 10 years of age. In the year before starting odevixibat, all patients presented with moderate to severe pruritus despite treatment with rifampicin and ursodeoxycholic acid. Four patients had sleep disturbances. Patient 4 had a history of microvillus inclusion disease and was enterally fed. In the year prior to initiating odevixibat, sBA levels were >150 µmol/L in all patients; total bilirubin levels were >25 µmol/L in 4 patients and <5 µmol/L in Patient 5. In the 3 months after starting odevixibat, sBA levels decreased dramatically (Figure). By 6 months, all patients achieved sBA levels <10 µmol/L and total bilirubin fell to <15 µmol/L. sBA levels remained mostly <10 µmol/L throughout the treatment period (up to 20 months) in 4 patients (Figure). In Patients 3 and 5, compliance and access to treatment were limited, which may explain the fluctuations in sBA levels observed. Pruritus and sleep disturbances improved in the first 3 months and disappeared completely on treatment in all patients (dose increases to 45 µg/kg/day and 65 µg/kg/day were required in Patient 5). In Patients 1 and 3, odevixibat treatment was discontinued following an episode of gastroenteritis associated with a positive test for adenovirus or enteropathogenic *Escherichia coli*. Patient 3 subsequently resumed full-dose odevixibat after 6 weeks of suspension or reduced dosing. Digestive tolerability of odevixibat was good; no new or worsening gastrointestinal symptoms were observed in any child.
Conclusion: Odevixibat treatment in patients with PFIC10 led to a rapid and sustained resolution of pruritus and a significant decrease in or normalisation of sBA levels, supporting the effectiveness of odevixibat. Treatment with odevixibat should be further evaluated in patients with PFIC associated with *MYO5B* gene mutations.

THU-377

Alkaline phosphatase on admission to the intensive care unit as a new early prognostic biomarker for the development of COVID-19-associated secondary sclerosing cholangitis

Lea Aratari[1], Lea Krauß[1], Vlad Pavel[1], Alexander Mehrl[1], Arne Kandulski[1], Karsten Guelow[1], Martina Mueller-Schilling[1], Stephan Schmid[1]. [1]*University Hospital Regensburg, Department of Internal Medicine I, Gastroenterology, Hepatology, Endocrinology, Infectious Diseases and Rheumatology, Regensburg, Germany*
Email: stephan.schmid@ukr.de

Background and aims: In COVID-19, hepatic involvement occurs in up to 53% of patients. Secondary sclerosing cholangitis in critically ill patients (SSC-CIP) is of great importance in the management of critically diseased patients with COVID-19 in the intensive care unit (ICU). In COVID-19 disease cases with SSC-COVID-19-associated SSC-occur. Early detection of this disease and endoscopic treatment is crucial. Therefore, the aim of our study was to identify new and early prognostic biomarkers for developing COVID-19-associated SSC.
Method: 258 patients hospitalized in the ICUs of the University Hospital of Regensburg were analyzed retrospectively. Various clinical, laboratory and intensive care parameters were recorded from the electronic documentation systems. For statistical analyses, IBM SPSS Statistics was used. Receiver operating characteristic (ROC) analysis was conducted, and the area under the curve (AUC) was calculated.
Results: 14 of the 258 patients (5.4%) developed COVID-19-associated SSC during hospitalization in the ICU. 9 of the 14 patients had a high positive end-expiratory pressure (PEEp >10) and were in prone position. In the 9 patients with COVID-19-associated SSC who received Extracorporeal membrane oxygenation (ECMO) therapy, the average duration of ECMO treatment was 55 days. 3 of the 14 patients had a medical history of preexisting liver disease. 8 of the 14 patients survived the hospitalization at the ICU. In the ROC analysis, there was a significant ($p = 0.037$) association between a longer duration of ECMO therapy and the development of SSC. Of note, elevated values of the alkaline phosphatase on admission to the ICU correlated significantly ($p = 0.004$) with the development of COVID-19-associated SSC in the ROC analysis. The area under the curve (AUC) was 0.731.
Conclusion: Elevated alkaline phosphatase on admission was identified as a novel and early prognostic biomarker for the development of COVID-19-associated SSC. Our findings allow optimization of intensive care therapy to reduce the risk of developing COVID-19-associated SSC and early initiation of endoscopic treatment.

THU-378

Outcomes in adult patients with progressive familial intrahepatic cholestasis treated with odevixibat: subgroup analysis from the PEDFIC 2 study

Bertrand Roquelaure[1], Henkjan J. Verkade[2], Kathleen M. Loomes[3], Janis M. Stoll[4], Christine Clemson[5], Tao Gu[5], Jan Mattsson[5], Philip Stein[5]. [1]*CHU, Hospital de la Timone, Marseille, France;* [2]*Department of Paediatrics, University of Groningen, Beatrix Children's Hospital/University Medical Centre Groningen, Groningen, Netherlands;* [3]*Children's Hospital of Philadelphia, Philadelphia, PA, United States;* [4]*Department of Paediatrics, Washington University School of Medicine, St. Louis, MO, United States;* [5]*Albireo Pharma, Inc., Boston, MA, United States*
Email: bertrand.roquelaure@ap-hm.fr

Background and aims: Progressive familial intrahepatic cholestasis (PFIC) is a group of rare genetic liver diseases characterized by cholestasis, pruritus, and progressive liver damage. Symptoms of PFIC typically present in infancy and often progress to end-stage liver disease by early adolescence; however, in some patients, symptom onset may not occur until adulthood. The safety and efficacy of odevixibat, an ileal bile acid transporter inhibitor, was evaluated in patients with PFIC in the phase 3 PEDFIC 1 and PEDFIC 2 studies. To improve our understanding of the effects of odevixibat treatment in adult patients with PFIC, we examined the efficacy and safety of odevixibat in adult patients from PEDFIC 2.
Method: PEDFIC 2 is an ongoing, 72 week, open-label extension study in patients of any age with any type of PFIC; all patients receive odevixibat 120 µg/kg once daily. This analysis includes all adult patients enrolled in PEDFIC 2 and spans from patients' first dose of odevixibat to a data cut-off of 31 January 2022. The following parameters were evaluated: patient-reported pruritus scores (range, 0–4; higher scores indicate worse symptoms), serum bile acid (sBA) levels, hepatic parameters (total bilirubin and alanine aminotransferase [ALT] levels), and treatment-emergent adverse events (TEAEs).
Results: Overall, 5 adult patients with PFIC (mean [range] age, 23.3 [19.5–26] years; 40% female) had enrolled in PEDFIC 2. At baseline, all patients had elevated sBAs and moderate-to-severe pruritus. Of these 5 adult patients, 3 had PFIC1 and 2 had PFIC2. Mean (range) exposure to odevixibat was 36 (24–65) weeks. At the data cut-off, 4 patients were ongoing in the study and 1 patient discontinued the study due to patient withdrawal of consent. From baseline to last assessment, sBA levels varied over time in some patients, but several patients had

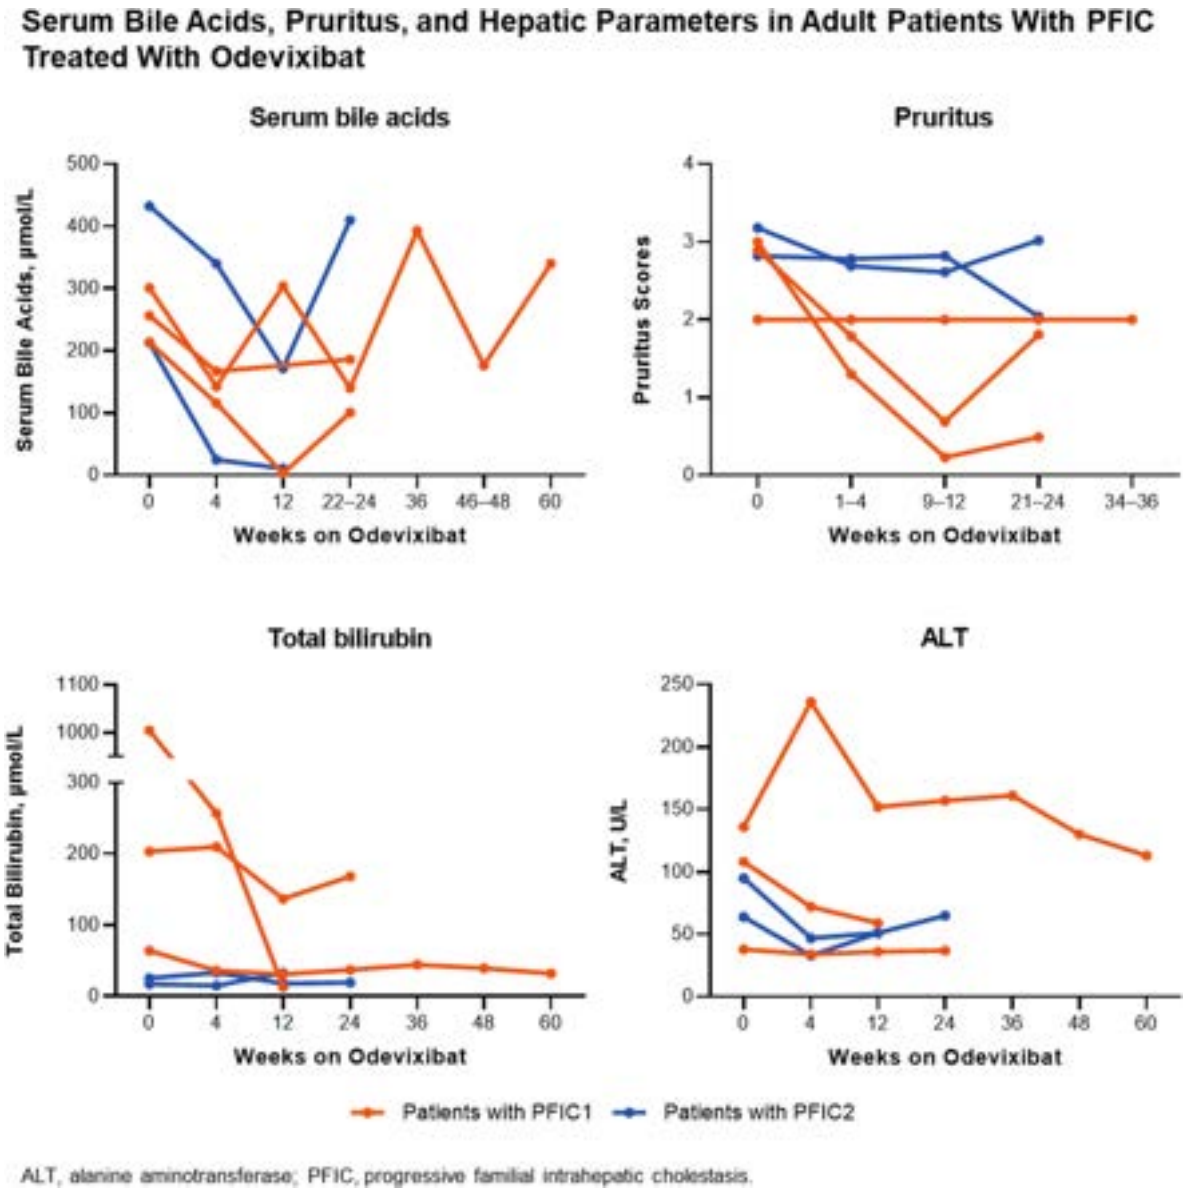

Figure: (abstract: THU-378).

reductions in sBA levels, pruritus scores, total bilirubin levels, and/or ALT (Figure). Three of the 5 patients (60%) had at least 1 TEAE; most were mild to moderate in severity. Two patients experienced a serious TEAE; 1 patient had streptococcal septic arthritis and another patient with a history of pancreatitis experienced acute pancreatitis. None of the TEAEs were considered drug related, and no patient discontinued due to TEAEs.

Conclusion: Several adult patients with PFIC enrolled in the ongoing PEDFIC 2 study have experienced clinical benefits with odevixibat, including reductions in sBAs, pruritus, and/or improvements in hepatic parameters. Odevixibat was generally well tolerated in this adult population.

THU-379

Association of liver injury and prognosis in patients with severe fever with thrombocytopenia syndrome

Rui Huang[1,2,3], Jian Wang[1,2], Huali Wang[4], Qun Zhang[5], Zhiyi Zhang[3], Shaoqiu Zhang[1], Yifan Pan[6], Bei Jia[1], Xiaomin Yan[1], Jie Li[1,2,3], Chao Wu[1,2,3]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, China; [2]Institute of Viruses and Infectious Diseases, Nanjing University, China; [3]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, China; [4]Department of General Practice, Nanjing Second Hospital, Nanjing University of Chinese Medicine, China; [5]Department of Infectious Diseases, Affiliated Zhongda Hospital of Southeast University, China; [6]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing Medical University, China*
Email: dr.wu@nju.edu.cn

Background and aims: Severe fever with thrombocytopenia syndrome (SFTS) is an epidemic emerging infectious disease caused by a novel bunyavirus with high mortality rate (up to 50%). Liver injury have been reported as a common complication of SFTS patients. However, the prevalence of liver injury related to this disease and its clinical significance is not well characterized.

Method: Two hundred and ninety-one hospitalized SFTS patients were retrospectively included from three hospitals in China between October 2010 and August 2022. Presence of at least one of the

following conditions would be diagnosed as liver injury: alanine transaminase (ALT) or aspartate aminotransferase (AST) more than 3 upper limit of normal (ULN), or alkaline phosphatase (ALP) or total bilirubin (Tbil) more than 2 ULN.
Results: The median age of patients was 63.0 years and male accounted for 51.9%. A total of 65 (22.3%) patients were deceased. 60.1% of patients had liver injury, and the median levels of ALT, AST, ALP, and Tbil at admission were 76.4 U/L, 152.3 U/L, 69.8 U/L, and 9.9 μmol/L, respectively. Compared to survivors, non-survivors had higher levels of AST (253.0 U/L vs. 131.1 U/L, $p < 0.001$) and ALP (86.2 U/L vs. 67.9 U/L, $p = 0.006$), higher proportion of the elevated ALP (20.0% vs. 4.4%, $p < 0.001$) and liver injury (78.5% vs. 54.9%, $p = 0.001$) at admission. There were increasing trend of ALT, AST, and ALP in non-survivors, while survivors had stable or decrease trend of these parameters during hospitalization. The presence of liver injury (HR 2.015, 95% CI 1.055–3.848, $p = 0.034$) at admission was an independent risk factor of fatal outcome. Patients with liver injury had significant lower cumulative survival probability than patients without liver injury ($p = 0.003$).

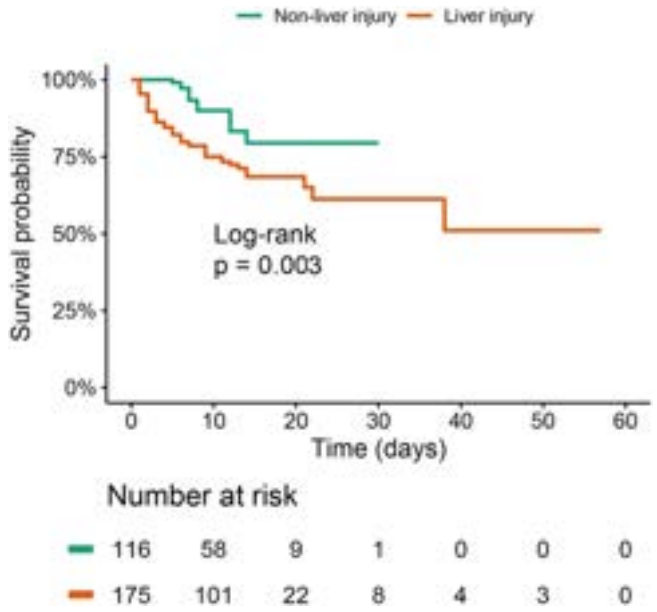

Figure: Cumulative survival probability of SFTS patients with and without liver injury at admission.

Conclusion: Liver injury was common in patients with SFTS. The presence of liver injury is strongly associated with poor prognosis in patients with SFTS, indicating that liver injury indicators should be monitored during hospitalization.

THU-380

State of knowledge of alpha 1 anti-trypsin deficiency among practitioners specialized in liver transplantation in France : a national survey

Manon Evain[1], Ilias Kounis[1], Jérôme Dumortier[2], Sebastien Dharancy[3], Faouzi Saliba[1], Audrey Coilly[1]. [1]*Hôpital Paul-Brousse Ap-Hp, Villejuif, France;* [2]*Edouard Herriot Hospital, Lyon, France;* [3]*Hospital Claude Huriez, Lille, France*
Email: manon.evain@hotmail.fr

Background and aims: Alpha-1 antitrypsin deficiency (AATD) is one of the most common genetic diseases in Europe with a prevalence of heterozygosity of 1.6%. Although it is also responsible for liver damage leading to end stage liver diseases, AATD is not always diagnosed, even in the most severe patients who are candidates for liver transplantation (LT). Considering the recent advances in potential treatment and the understanding of AATD involvement in progression of liver diseases, we aimed to investigate the level of knowledge on AATD and the current practices of liver transplant physicians in France.
Method: A practice survey of 22 multiple-choice questions in the form of a questionnaire created and distributed via GoogleForm was sent by e-mail to the members of the French think tank in LT, GREF2.
Results: Adherence to the survey was 54%, including 89% hepatologists, 7.5% liver surgeons and 3.5% anesthesiologists. 81% of practitioners rated their level of knowledge as very low, low, or average, and only 22% answered the question of disease prevalence correctly. Half of the responders had >15 years of experience in high-volume LT centers. Only 57% of practitioners routinely performed AATD screening before LT. AAT dosage was used in 97% of cases for the screening but 47% knew that it is decreased by hepatocellular insufficiency and 20% by pregnancy. Only 47% knew that heterozygosity status could be a cofactor of liver disease progression. Furthermore, 62% of practitioners with <5 years of experience considered their level of knowledge to be low but systematically screened before LT in 75% of cases compared to 44% for practitioners with between 5 and 15 years of experience and 61% for practitioners with >15 years.
Conclusion: AATD is a poorly known disease among LT practitioners in France. A better knowledge of screening methods, diagnosis and treatment of the disease would allow a better management of the patients and their relatives.

THU-381

Symptom severity measured by polycystic liver disease-specific questionnaire score partly correlates with both total number of liver cysts and the presence of dominant cysts

Avisnata Das[1], Benjamin Giles[1], Aqeel Jamil[1], Joanna Dowman[1], Andrew Fowell[1], Richard Aspinall[1]. [1]*Portsmouth Liver Centre, Portsmouth, United Kingdom*
Email: avisnata@gmail.com

Background and aims: The polycystic liver disease-specific questionnaire (PLD-Q) has been found to be useful in assessing severity of Polycystic Liver Disease (PLD) related symptoms. The PLD-Q score (from 0 to 100) is based on this questionnaire with higher scores indicating more severe symptoms. PLD-Q score has shown some correlation with PLD disease-severity stage (using Gigot's classification) but not liver volume. Scarce literature exists correlating PLD-Q scores with Qian's Grade of PLD and number of dominant cysts. Here we report variations in PLD-Q scores across Qian's grades 2 to 4 and in patients with varying numbers of dominant cysts.
Method: We evaluated PLD-Q scores in a cohort of 39 fully phenotyped PLD patients in a single centre. Patients had 11 or more liver cysts either as isolated PLD or in conjunction with Polycystic Kidney Disease. We studied PLD-Q scores in three different PLD patient groups classified as per Qian's classification-Grade 2 (11–20 cysts), Grade 3 (>20 cysts) and Grade 4 (>20 cysts with symptomatic hepatomegaly). We also looked at PLD-Q scores in three different patient groups according to number of dominant cysts (size >8 cm) with either zero dominant cyst, 1–2 dominant cysts and 3 or more dominant cysts. Cysts were radiologically evaluated using either CT/MRI/Ultrasound scan within 1-year prior to submission of PLD-questionnaire by the patient.
Results: In 7 patients with Qian's Grade 2 disease, the PLD-Q score ranged from 17 to 68 with a mean of 34.7 and median of 33. In 22 Grade 3 patients, PLD-Q score ranged from 6 to 76 with a mean of 32.5 and median of 35. In 10 patients with Grade 4 disease, PLD-Q scores ranged from 31 to 83 with a median of 47 and median of 42.5. However, there was no statistically significant difference between the distributed means of PLD-Q scores within these three groups. (Independent sample t-test, 95% CI). Out of 38 PLD patients with radiologically calculated dominant cyst numbers, 26 had zero dominant cysts (Group A), 10 had 1–2 dominant cysts (Group B) while the remaining two had 3 dominant cysts each (Group C). The mean PLD-Q scores in Groups A, B and C were 36, 44.6 and 33.5

respectively while the median scores were 35, 42.5 and 33.5 respectively. No statistically significant difference exists between the distributed means of PLD-Q scores within these groups.
Conclusion: Qian's Grade 4 patients had the highest median PLD-Q score and highest-recorded score of 83 among all grades. Median PLD-score of Grade 3 exceeded that of Grade 2. Patients with 1–2 dominant cysts had the highest mean and median PLD-Q score, suggesting a greater impact on quality of life and supporting targeted intervention. However, there was no statistically significant difference in distributed means of PLD-Q scores between any two groups within the three different Qian's Grade groups or between any two groups within the three dominant cyst numbers-based groups.

THU-382
Online education yields significant gains in gastroenterologists' knowledge of clinical manifestations of Wilson disease
Sukhbir Bahra[1], Adriana Stan[1], Marinella Calle[1], Maya Khalaf[1], Gill Adair[1], Karl Heinz Weiss[2]. [1]*Medscape, Education, Netherlands;* [2]*Krankenhaus Salem der Evang. Stadtmission Heidelberg, Germany*
Email: astan@medscape.net

Background and aims: WD is a rare disorder in which excessive amounts of copper accumulate in the body, particularly in the liver, brain, and eyes.
We developed an online continuing medical education (CME) activity titled: "Wilson Disease: The Great Masquerader." We hypothesized that participation in this online CME education would lead to improved recognition of the different clinical manifestations of WD.
Method: An online 45 minute video CME activity (www.medscape.org/viewarticle/976141) consisting of a series of 6 expert commentaries was developed. Educational effect was assessed using a repeated-pair design with pre-/post-assessment (3 knowledge questions and 1 confidence question). A paired samples t-test was conducted for significance testing on overall average number of correct responses and for confidence rating, and a McNemar's test was conducted at the question level (5% significance level). Cohen's d with correction for paired samples estimated the effect size of the education (<0.20 modest, 0.20–0.49 small, 0.59–0.79 moderate, ≥.80 large). Data were collected from 6/30/2022 to 9/30/2022.
Results: A total of 465 gastroenterologists outside US participated, of whom 55 completed all the pre-/post-activity questions. Overall 64% improved their knowledge related to the copper metabolism, clinical manifestations of WD and diagnostic strategies for WD ($p < 0.001$) indicating a considerable effect of the education (Cohen's $d = 0.85$). 4 times more physicians answered all questions correctly after education (9% pre, 47% post). 62% of gastroenterologists had a measurable increase in their confidence in their ability to recognize manifestations of WD in clinical practice.
Conclusion: This online CME activity significantly improved gastroenterologists' knowledge of the clinical manifestations of WD and strategies for timely diagnosis of WD in clinical practice.

THU-383
Progressive familial intrahepatic cholestasis: KFSH and RC
Faisal Abaalkhail[1], Fahad Alsohaibani[1], Musthafa Peedikayil[1], Muath Najmi[1]. [1]*King Faisal Specialist Hospital and research center, Saudi Arabia*
Email: faisal.abaalkhail@gmail.com

Background and aims: Progressive Familial intrahepatic cholestasis (PFIC) is a rare genetic disorder that results from defective mechanisms of bile secretion. There have been no studies describing

Parameter	PFIC 2 (N = 31)	PFIC 3 (N = 49)
Male gender %	51.62	55.10
Age (Mean)	10.2	13.5
Months from birth to diagnosis (Mean)	24.7	82.1
Region%		
Central	33.33	22.45
Eastern	10.00	16.33
Northern	6.67	2.04
Southern	16.67	40.82
Western	33.33	18.37
Positive consanguinity %	89.47	85.71
Family members affected %	52.17	69.57

PFIC in Saudi Arabia, Aim: to describe the different types of PFIC and their clinical features, treatment modalities and the outcome in Saudi Arabia.
Method: This is a retrospective study of all patients diagnosed with PFIC at the King Faisal Specialist Hospital and Research Centre in Riyadh from January 1, 2002 to December 31, 2020. All relevant information was
Results: 83 patients were identified with PFIC and type 3 was the commonest (59%), followed by type 2 (37.4%), type 1 (2.4%) and type 4 (1.2%). Males and females were affected equally. Mutation in ATP8B1, ABCB11 and ABCB4 genes were observed in 50% of PFIC type 1, 96% of type 2 and 93% of type 3, respectively. A total of 52 (63.4%) patients underwent liver transplantation; two patients with type 1 (100%), 22/30 (73.3%) with type 2, and 28/49 (57.1%) with type 3. Mean duration of disease before transplantation was 57 ± 71.3 months with a median of 30 months. Following liver transplantation, transplantation, symptomatic control was achieved in 49 patients (94.2%). Recurrence after transplant occurred in 5 (9.61%) patients within average of 41.5 months and a median of 17 months.
Conclusion: PFIC is considered a rare disorder in Saudi Arabia, however early recognition of this disease is important for appropriate management and early referral for liver transplantation evaluation. The overall rate of liver transplantation in our cohort was 63.4% with excellent five-year survival rate.

THU-384
Clinical picture of acute hepatitis in children-single center observations

Anna Mania[1], Paweł Małecki[1], Katarzyna Mazur-Melewska[1], Magdalena Figlerowicz[1]. [1]*Poznan University of Medical Sciences, Department of Infectious Diseases and Child Neurology, Poznań, Poland*
Email: maniaanna@hotmail.com

Background and aims: The aim of the study was to analyze the clinical course and outcome of acute hepatitis in children considering new emerging viral agents.
Method: The study included all children with acute hepatitis admitted to tertiary care centers between 1.10.2021 and 30.11.2022. Clinical data were analysed including potential etiology, clinical and laboratory and imaging tests.
Results: The study included 36 children admitted to the tertiary care center due to acute hepatitis in analysed period. Median (M) age was 13 years (range 3 months-18 years). The most common causing factor was Epstein-Barr virus (EBV) (13/36 cases-13%), autoimmune hepatitis was detected 5/36 children (14%), hemophagocytic lymphohistiocytosis in 3/36 children (8%). SARS-CoV2 infection 2/36 children. Children with EBV-related-hepatitis were older (Median age M = 16 years vs 10 years; p = 0.0001) had significantly lower aspartate aminotransferase activity (Median AST M = 121 IU/l) when compared to non-EBV induced hepatitis (Median AST M = 290 IU/l); p = 0.01. The majority of children recovered from the infection. One fatal case of unknown etiology was detected.
Conclusion: The most common cause of acute hepatitis was EBV infection of self-limiting course. Certain proportion of patients suffered from life-threatening conditions.

THU-385
Differences in the rates of liver-related clinical events in paediatric patients with alpha-1 antitrypsin deficiency-associated liver disease in the United States

May Hagiwara[1], Victoria Divino[2], Swapna Munnangi[2], Mark Delegge[2], Suna Park[1], Ed G. Marins[1], Kaili Ren[1], Charlton Strange[3]. [1]*Takeda Development Center Americas, Inc., Cambridge, MA, USA, United States;* [2]*IQVIA Inc., Falls Church, VA, USA, United States;* [3]*Medical University of South Carolina, Charleston, SC, USA, United States*
Email: ed.marins@takeda.com

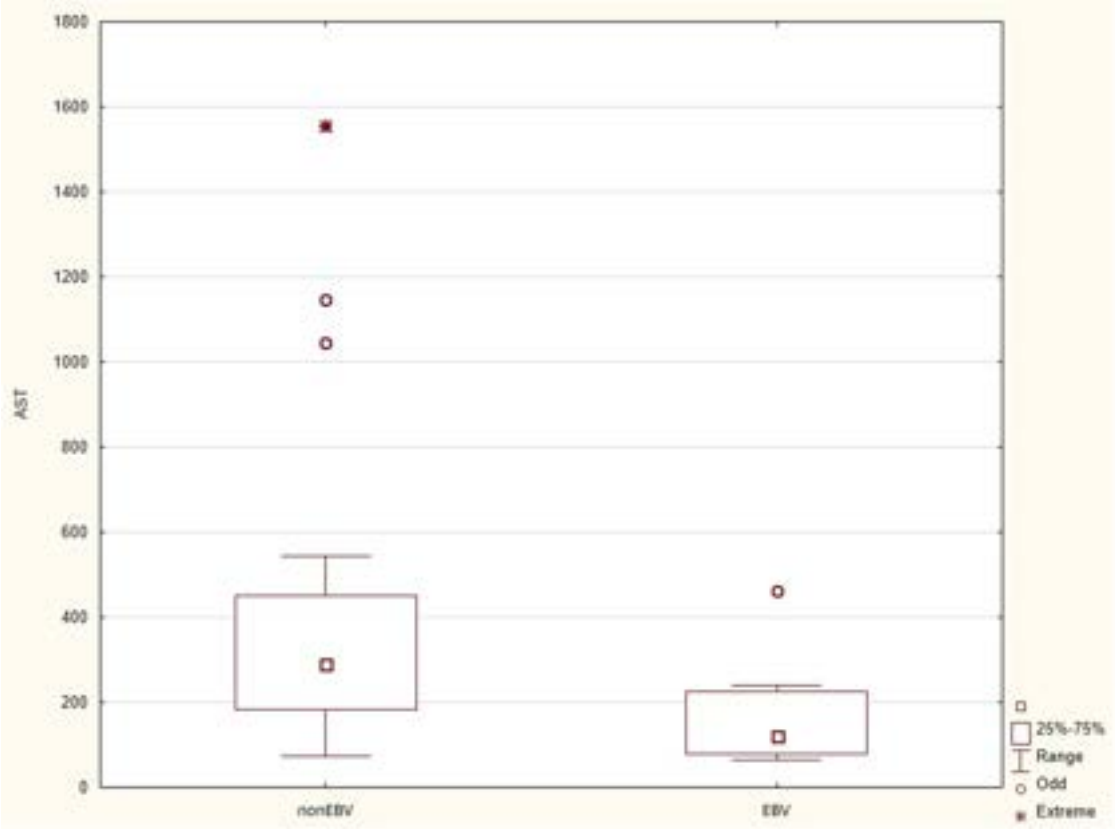

Figure: (abstract: THU-384): Aspartate aminotransferase activity in EBV and non-EBV-related hepatitis.

Figure 1. Liver-related clinical events in the follow-up time of paediatric patients with alpha-1 antitrypsin deficiency-associated liver disease, by age group (event rate per person-year)

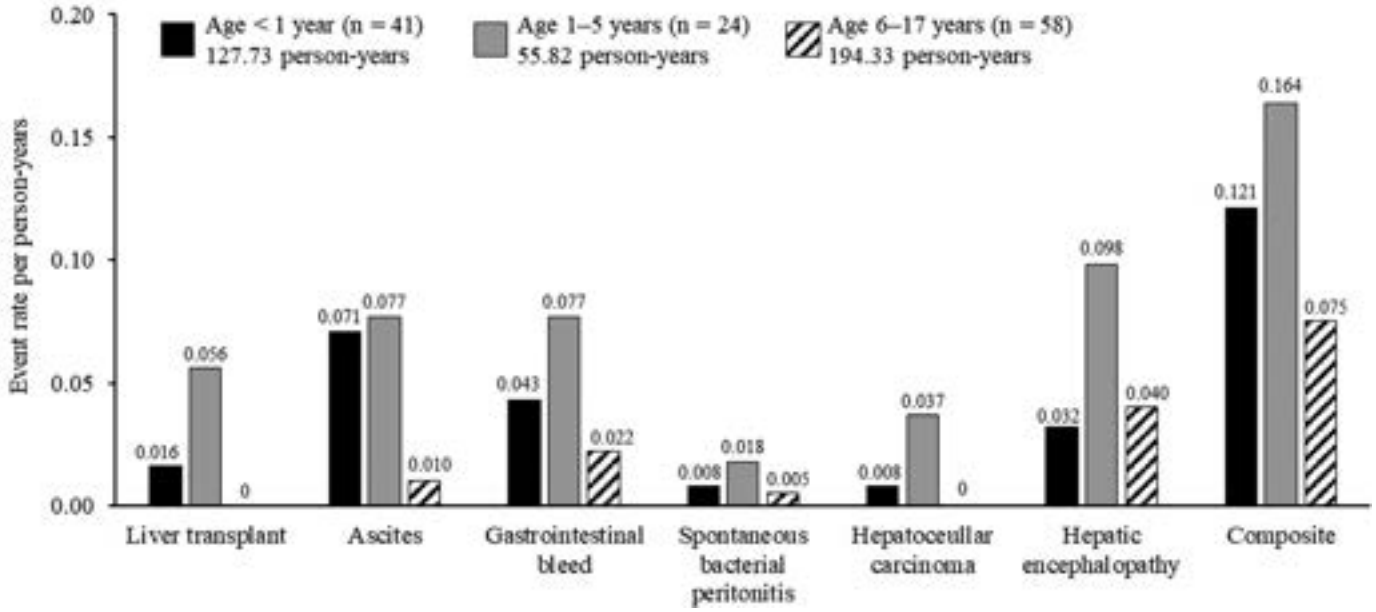

Figure: (abstract: THU-385).

Background and aims: Protease inhibitor (Pi) ZZ genotypes are associated with alpha-1 antitrypsin deficiency (AATD), which affects ~1 per 3000–5000 people in the USA. AATD is characterized by low levels of serum alpha-1 antitrypsin (AAT) and accumulation of misfolded AAT in hepatocytes, which can lead to liver disease in paediatric patients. The burden of liver-related clinical events among paediatric patients with AATD-associated liver disease was investigated by age group using large US claims and Ambulatory Electronic Medical Records (AEMR) databases.
Method: This was a retrospective analysis of administrative claims data from the IQVIA PharMetrics® Plus database linked to the IQVIA AEMR database (selection period: January 2012 to October 2021). PharMetrics Plus comprised 142 million enrollees with medical and pharmacy benefits and ≥1-month enrolment during the selection period. Inclusion criteria were: (1) at least one inpatient or at least two outpatient medical claims ≥90 days apart with a diagnosis of AATD in PharMetrics Plus, or (2) with a PiZZ/PiMZ genotype in AEMR and with linkage to PharMetrics Plus; (3) a liver disease diagnosis. A person-time approach was used to maximize the use of data. Liver-related clinical events of interest (identified by International Classification of Diseases-Ninth/Tenth Revision codes) included liver transplantation, ascites, gastrointestinal bleeds, spontaneous bacterial peritonitis, hepatocellular carcinoma and hepatic encephalopathy. These were evaluated separately and as a composite (defined as the occurrence of ≥1 of the six clinical events), and reported for the overall paediatric population and by age group (<1, 1–5, and 6–17 years).
Results: In total, 123 patients met the eligibility criteria, of whom 41, 24, and 58 were aged <1, 1–5, and 6–17 years, respectively. Median age was 5 years, 60% were male, and the median duration of observation was 31.5 months. Clinical event rates per person-year (PPY) by age group for the liver-related events are shown in Figure 1. Among patients aged <1, 1–5, and 6–17 years, event rates were 0.07, 0.08, and 0.01 PPY for ascites, 0.03, 0.10, and 0.04 PPY for hepatic encephalopathy, 0.04, 0.08, and 0.02 PPY for gastrointestinal bleeds and 0.02, 0.06, and 0 PPY for liver transplant.
Conclusion: Liver-related clinical event rates were generally similar between paediatric patients with AATD-associated liver disease aged <1 year and 1–5 years. In all age groups, ascites, gastrointestinal bleeds, and hepatic encephalopathy were more common than spontaneous bacterial peritonitis and hepatocellular carcinoma. Liver transplantation was more common in paediatric patients aged 1–5 years than in patients aged <1 year and did not occur in patients aged 6–17 years. Among the study patients, no confirmed PiZZ/PiMZ genotype was identified.
Acknowledgments Writing assistance was provided by Elena Sugrue, PhD, of Oxford PharmaGenesis, Oxford, UK and funded by Takeda Development Center Americas, Inc.
Funding: This study was funded by Takeda Development Center Americas, Inc.

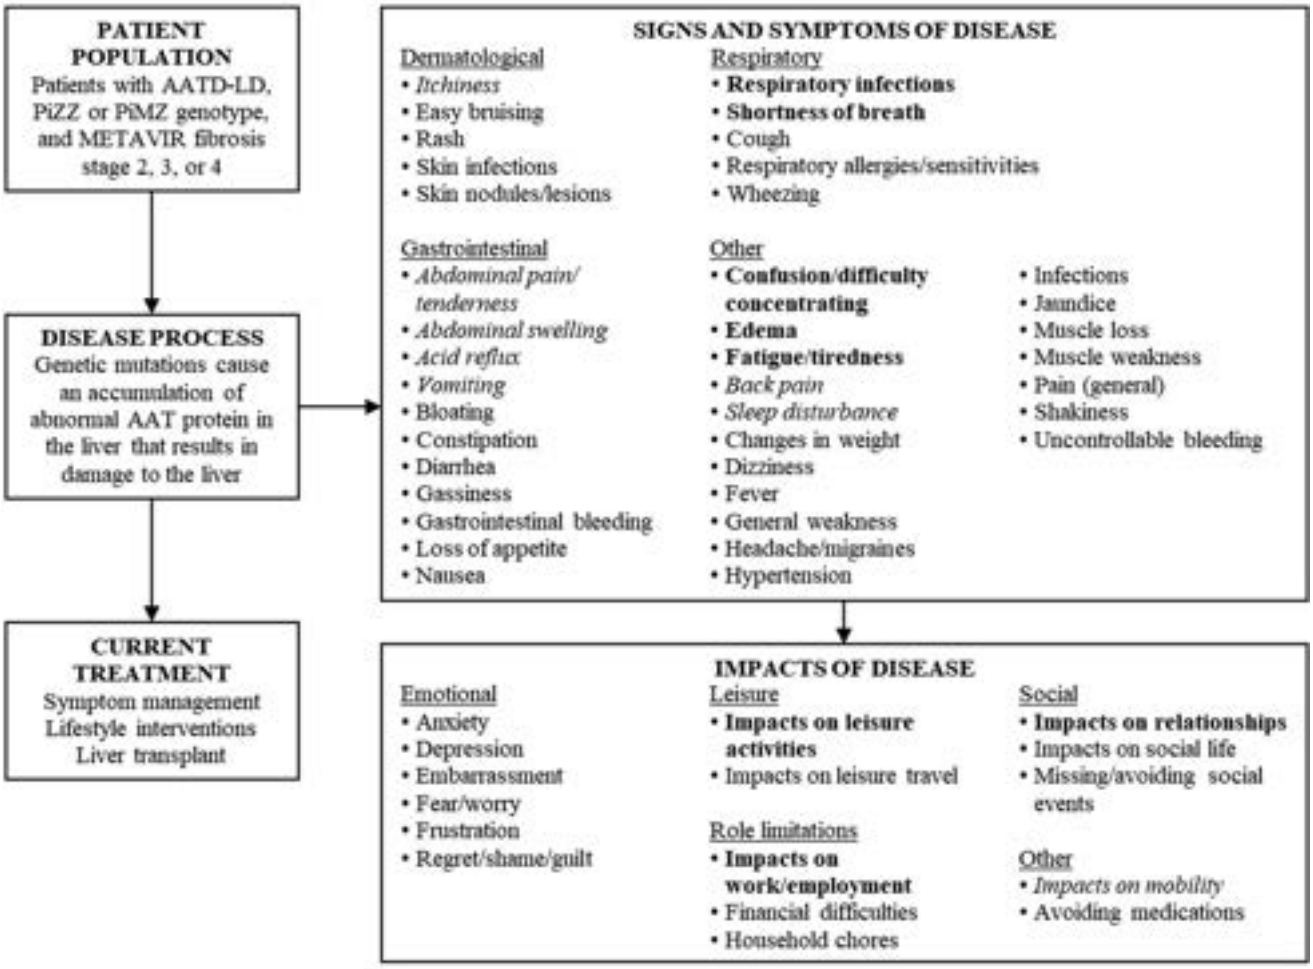
Understanding the experience of patients with alpha-1 antitrypsin deficiency (AATD)-associated liver disease

Virginia Clark[1,2], Suna Park[3], Robert Krupnick[4], Nicole Sparling[4], Jason Ritchie[5], Chitra Karki[3], Justin Reynolds[6]. *[1]University of Florida, Gainesville, FL, United States; [2]University of Florida, Gainesville, United States; [3]Takeda Pharmaceuticals USA, Inc, Cambridge, MA, United States; [4]IQVIA Patient Centered Solutions, Boston, MA, United States; [5]IQVIA Patient Centred Solutions, New York, NY, United States; [6]St. Joseph Hospital Medical Center, Phoenix, AZ; Creighton University School of Medicine, Phoenix, AZ, United States*
Email: virginia.clark@medicine.ufl.edu

Background and aims: Alpha-1 antitrypsin deficiency (AATD) is a genetic disease that affects ~3.4 million people worldwide and manifests clinically as lung and/or liver disease. This study aimed to elicit characteristics of disease signs, symptoms, and impacts from patient interviews, and inform appropriate selection of clinical outcome assessments.

Figure 1. Conceptual model of alpha-1 antitrypsin deficiency-associated liver disease



Concepts in **bold** were 'most salient', defined as being reported by ≥ 50% of patients and with a mean bothersomeness/disturbance rating of ≥ 5. Concepts in *italics* were 'highly salient', defined as being reported by ≥ 40% of patients and with a mean bothersomeness/disturbance rating of ≥ 5.
AATD, alpha-1 antitrypsin deficiency; AATD-LD, alpha-1 antitrypsin deficiency-associated liver disease; METAVIR, Meta-analysis of Histological Data in Viral Hepatitis; Pi, protease inhibitor.

Figure: (abstract: THU-386).

Method: One-to-one telephone interviews involving English-speaking, US adults with AATD-associated liver disease (AATD-LD), with a protease inhibitor (Pi) ZZ or MZ genotype, and without liver cancer were conducted by trained interviewers following a central Institutional Review Board-approved discussion guide. Confirmation of diagnosis was collected for all patients. A preliminary 'concept list' of disease signs, symptoms, and impacts was used to guide the patient interviews and was developed from a targeted literature review, patient blog searches, and clinician interviews with two gastroenterologists, two pulmonologists, and one hepatologist. A conceptual model of AATD-LD was developed based on the findings. Symptoms and impacts of AATD-LD were considered most salient/highly salient if reported by ≥50%/≥40% of patients with a mean bothersomeness/disturbance rating of ≥5 on a 0–10 scale (0, not at all bothersome/disturbing; 10, extremely bothersome/disturbing).
Results: Interviews were conducted with 15 patients (male: n = 8) with a median (range) age of 57 (28–78) years. Twelve patients had PiZZ and three patients had PiMZ genotypes. METAVIR stages were F2 (n = 6), F3 (n = 1), and F4 (n = 8). Eight patients had liver and lung disease; seven had liver disease only. Median time since AATD diagnosis was 12 years. Four patients had received a transplant (liver, n = 3; lung, n = 1). Of the 41 symptoms reported, the most salient were fatigue/tiredness (n = 14), respiratory infections (n = 10), shortness of breath (n = 10), confusion/difficulty concentrating (n = 8), and edema (n = 8; Figure 1). Highly salient symptoms were abdominal swelling (n = 7), acid reflux (n = 7), sleep disturbance (n = 7), vomiting (n = 7), abdominal pain/tenderness (n = 6), itchiness (n = 6), and back pain (n = 6). The most salient impacts were on work and employment, leisure activities, and relationships. Impacts on mobility (n = 6) were highly salient. Overall, emotional impacts were relatively disturbing (mean disturbance rating: 6.3), but each individual impact was reported by few patients.
Conclusion: To our knowledge, this is the first qualitative study of the experience of patients with AATD-LD. Although experiences varied, several concepts were frequently reported and characterized as moderately/highly bothersome/disturbing, even in patients with

earlier fibrosis stages which are presumed to be asymptomatic. Clinical outcome assessments that can capture salient concepts are needed to assess the nuances of each patient's experience.

THU-387

Acute liver failure due neonatal hemochromatosis: case with fatal outcome despite early diagnosis and treatment

Liudmyla Shostakovych-Koretska[1], Viktor Mavrutenkov[1], Tetyana Mavropulo[2]. [1]*Dnipro State Medical University, Infectious Diseases, Dnipro, Ukraine;* [2]*Dnipro State Medical University, Neonatological, Dnipro, Ukraine*
Email: vvmavr@gmail.com

Background and aims: Neonatal hemochromatosis is a very rare, often fatal, iron metabolism disorder in newborns, which is characterized by iron overload of the liver and the development of antenatal acute liver failure. Neonatal hemochromatosis differs from hereditary, although both diseases have similar disorders of iron metabolism. Hereditary hemochromatosis is an autosomal recessive disease while Neonatal hemochromatosis is gestational alloimmune liver disease. The purpose of this study was to show the need to consider the possibility of hemochromatosis diagnosis in all cases of neonatal liver injury.

Method: A descriptive analysis of the features of the presentation and differential diagnosis of neonatal hemochromatosis that developed within the first day after the birth of a child using a wide range of diagnostics and modern approaches to treatment.

Results: The patient (girl) was born from the 2nd pregnancy, 38 weeks of gestation, weight 3500 g, length 55 cm, Apgar score 8 points. The first pregnancy ended in a spontaneous abortion. The girl was on a joint stay with her mother for 13 hours. Then the newborn suddenly had respiratory arrest, cardiac depression, convulsions. In the intensive care unit, the child had signs of acute liver failure with severe jaundice, hepatosplenomegaly, hemorrhagic, hepatorenal syndrome. Laboratory investigation revealed anemia, leukocytosis, thrombocytopenia, hypoglycemia, hypoalbuminemia, moderate increase transaminases, hyperbilirubinemia 343 mg/dl with the predominance of the direct fraction, severe coagulopathy. There were no data on the incompatibility of maternal and fetal blood types. Differential diagnostics was carried out with viral hepatitis, neonatal hepatitis, herpesvirus, congenital pathology of the biliary system, neonatal sepsis. Plasma Ferritin level 6713 ng/ml was very high compare with the normal level. A high level of ferritin was also confirmed during a second study which, after excluding other causes, made it possible to suspect neonatal hemochromatosis. An liver biopsy revealed giant cell transformation of hepatocytes without specific inclusions. The therapy included antibiotics, fresh frozen plasma, albumin, exchange transfusion session followed by intravenous immunoglobulin. After the therapeutic measures the child's condition showed a short-term improvement, but Ferritin level remained high and the subsequent deterioration was accompanied by the progression of multiple organ disorders, which led to the child death at the age of 40 days. Autopsy revealed hepatosplenomegaly, severe jaundice and hemorrhagic syndrome. Histopathology revealed pathognomonic inclusions of hemosiderin in the liver, kidneys and lungs.

Conclusion: Due to the non-specificity of the first symptoms, neonatal hemochromatosis seems to be one of the most difficult for the differential diagnosis of diseases of the neonatal period. According to reports in one third of cases, mothers have a history of miscarriages with an unknown cause of death. In the presented case, a previous pregnancy ended with spontaneous abortion, which may also be related to these mechanisms. In the reported case, the disease manifested itself in the first hours after birth with rapid progression to fatal liver failure. In real practice, it is necessary to include neonatal hemochromatosis in the differential diagnosis in all cases of severe liver damage, any cases of spontaneous abortion, stillbirth or early postnatal death.

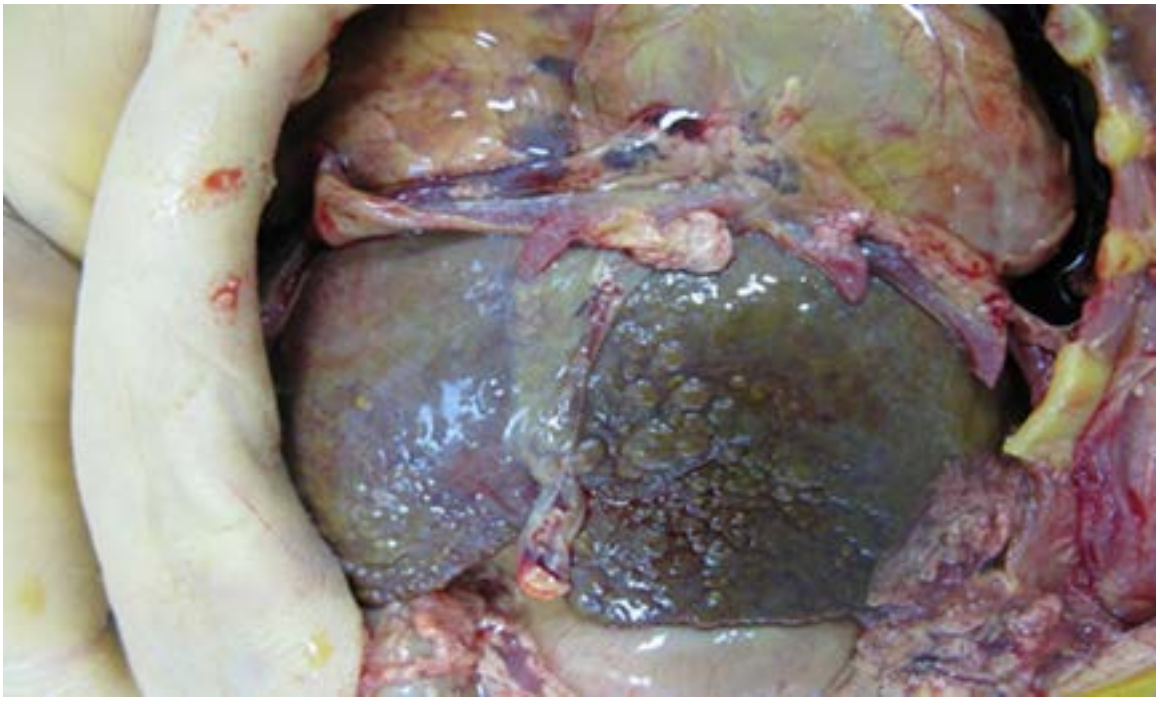

Figure: (abstract: THU-387).

THU-388

Trans-jugular intrahepatic Porto-systemic shunt for Budd Chiari syndrome: single center experience

Amnah Alhanaee[1,2], Hamad Alsuhaibani[1], Faisal Joueidi[3], Ali Albenmousa[1], Ahmad Elhassan[4], Abdullah asir[4], Ahmed Joueidi[3], Saad Alghamdi[1], Waleed Alhamoudi[1], Saad Abualghannam[1], Dieter Clemens Broering[1], Khalid Bzeizi[1]. *[1]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; [2]Tawam Hospital, أبو ظبي, United Arab Emirates; [3]AlFaisal University, Riyadh, Saudi Arabia, Saudi Arabia; [4]Alfaisal University, Riyadh, Saudi Arabia*
Email: amnahalhanaee@gmail.com

Background and aims: Budd-Chiari syndrome (BCS) is a rare and life-threatening disorder secondary to hepatic venous outflow obstruction. It has a significant mortality rate if untreated. The management differs depending on the clinic presentation and usually follows a step-wise approach. Anticoagulation medication may be the only option, however interventional radiology procedures such as the trans-jugular intrahepatic portosystemic shunt (TIPS) and, if necessary, liver transplantation are lately widely applied. TIPS is regarded a relatively safe and effective treatment. We aimed to evaluate the feasibility and safety of TIPS in the management of BCS in Saudi Arabia

Method: All BCS patients presented to King Faisal Specialist hospital and Research Center and had TIPS during the period January 2010 and November 2022 were included in the analysis. The Aetiology, clinical presentation, laboratory and radiological parameters were all included. All patients underwent surveillance for hepatocellular carcinoma.

Results: A total of 71 patients, mostly females (63.3%) were included in the analysis. The mean age at the onset of symptoms was 38 years (range 19–69 years). Abdominal pain and jaundice were the most common presentations (87.3%). Proteins C and S deficiencies were identified in 31 patients (46.6%), JAK2 mutation in 25 patients (35.2%) and Anti Phospholipid Syndrome in 13 patients (18.2%). The mean MELD score was 19 (range: 8–36) and most patients had Child-Pugh score ≥B (56.3%). BCS confirmation was made by doppler ultrasonography and cross-sectional abdominal imaging in all patients. All patients received anticoagulants pre and post TIPSS. None of the patient died post TIPSS. TIPSS revision was performed on 47 patients (52.8%) and 6 patients (12.7) had more than 10 revisions.

Conclusion: TIPS is an effective modality of treatment for this uncommon condition. Morbidity due to TIPSS failure was relatively low in our cohort. TIPSS occlusion and the need for repeat revisions was the main limitation.

THU-389

The ancestral haplotype HLA-A3 does not influence the likelihood of advanced hepatic fibrosis or cirrhosis in C282Y homozygous hemochromatosis

John Olynyk[1,2,3,4], Louise Ramm[5], Richard Grainger[2], Helen Currie[2], Grant Ramm[5]. *[1]Edith Cowan University, Medical and Health Sciences, Joondalup, Australia; [2]Fiona Stanley Hospital, Murdoch, Australia; [3]Curtin University, Bentley, Australia; [4]Curtin University, Medicine, Bentley, Australia; [5]QIMR Berghofer Medical Research Institute, Herston, Australia*
Email: john.olynyk@health.wa.gov.au

Background and aims: Advanced hepatic fibrosis occurs in up to 25% of individuals with C282Y homozygous hemochromatosis as a result of progressive iron overload. The aim of the current study was to determine whether human leukocyte antigen (HLA)-A3 haplotypes act as genetic modifiers of the likelihood of advanced hepatic fibrosis.

Method: Between 1972 and 2013 291 *HFE* C282Y homozygous individuals underwent clinical and biochemical evaluation, liver biopsy for fibrosis staging and phlebotomy treatment. Of these 133 also underwent HLA typing. Hepatic fibrosis was graded using the system of Scheuer as F0-2 (low grade fibrosis), F3-4 (advanced hepatic fibrosis), and F4 cirrhosis. We analysed the association between the severity of fibrosis and HLA-A3 homozygosity, HLA-A3 heterozygosity or absent HLA-A3 haplotype using categorical analysis.

Results: The mean age of HLA-A3 homozygotes (15 male, 9 female), heterozygotes (43 male, 22 female) and HLA-A3 null individuals (34 male, 10 female) was 40 years. There were no significant differences between the groups for mean (± SEM) serum ferritin levels (1320 ± 296, 1217 ± 124, 1348 ± 188ug/L), hepatic iron concentration (178 ± 26, 213 ± 22, 199 ± 29umol/g), mobilizable iron stores (9.9 ± 1.5, 9.5 ± 1.5, 11.5 ± 1.7 g iron removed via phlebotomy), frequency of advanced hepatic fibrosis (5/24[12%], 13/63[19%], 10/42[19%], p = 0.751) or cirrhosis (3/24[21%], 12/63[21%], 4/42[24%], p = 0.922), respectively.

Conclusion: HLA-A3 is not associated with the risk of liver biopsy-proven advanced hepatic fibrosis or cirrhosis in HFE C282Y homozygous haemochromatosis.

THU-390

Demographics, outcomes, and costs of Wilson's disease hospitalizations: a nationwide cohort study

Ankoor Patel[1], Matthew Pelton[1], Carlos Minacapelli[2], Carolyn Catalano[2], Vinod Rustgi[2]. *[1]Rutgers-Robert Wood Johnson Medical School, Medicine, United States; [2]Rutgers-Robert Wood Johnson Medical School, Gastroenterology and Hepatology, United States*
Email: ahp60@rwjms.rutgers.edu

Background and aims: Wilson's disease (WD) is a rare, autosomal recessive disorder. Current treatment is focused on chelators and copper antagonists. Data on hospitalization, outcomes, and costs in patients with WD are scarce Using the National Inpatient Sample (NIS), our study evaluated mortality, length of stay (LOS), and costs among patients with Wilson's Disease in the USA.

Method: We performed a retrospective cohort study using the National Inpatient Sample (NIS) from 2007 to 2017. Wilson's Disease patients were identified using ICD-9/10 codes. Mortality, LOS and costs were primary outcomes A Charlson Comorbidity Index (CCI) score was calculated for each participant using admission records.

Results: Of the 16,950 WD hospitalizations included, a majority were female (57.01%). Liver failure was diagnosed in 4.93%. The prevalence of depression was 2.01%. The mortality rate and mean LOS were 2.49% and 4.81 days, respectively. The average cost of hospitalization was $33,483; however, total charges ranged from $696 to $1,673,546. The number of hospitalizations with a primary diagnosis of WD peaked in 2010 followed by a gradual decrease in number of hospitalizations between 2011 and 2016.

Conclusion: Our study shows clinical characteristics and outcomes of patients with Wilson's Disease in the USA from an inpatient healthcare database. The risk of liver failure was low. Patients with WD are responsible for significant healthcare cost burden with a wide variation likely due to orthotopic liver transplant.

Proteomics for the study of biomarkers in Wilson's disease

Li Li[1], Jie Su[1,1], Amina Abudzi[1,1,1], Rui Hua[1,1]. [1]*The First Hospital of Jilin University, China*
Email: huar@jlu.edu.cn

Background and aims: Wilson's disease (WD), also known as hepatolenticular degeneration, is an autosomal recessive genetic disease caused by ATP7B gene mutation resulting in abnormal copper metabolism and corresponding organ damage. The clinical manifestations are complex and diverse, and genetic, gender, age and other factors make the diagnosis of the disease more difficult. The current diagnostic methods for WD still have some shortcomings: the determination of ceruloplasmin level, 24-hour urinary copper and hepatic copper is easily affected by other factors; Genetic testing is expensive. Therefore, it is particularly important to explore more sensitive and specific markers for the diagnosis of this disease. This study aims to use proteomics tools to search for potential markers of WD and provide diagnostic basis for WD.

Method: We used quantitative proteomics studies to reveal differentially expressed proteins (DEPs) between 20 WD subjects and 10 healthy controls. Then, we used gene ontology (GO), KEGG and other methods to enrich and cluster the differential proteins, so as to obtain

the signal pathway of significant changes in the differential proteins. Aiming at the differential proteins in the signaling pathway, relevant literature was searched to further clarify the relationship between their biological effects and WD, and explore the potential markers of WD.
Results: Angiotensin, lysosome and TNF signaling pathways. A search of relevant literature found that cathepsin A (CTSA), intercellular adhesion molecule 1 (ICAM1), vascular cell adhesion molecule 1 (VCAM1) and matrix metalloproteinase 9 (MMP9) were significantly correlated with the onset of WD, which may be potential markers of WD.
Conclusion: We preliminarily found that CTSA, ICAM-1, VCAM1 and MMP9 could be used as potential markers of WD by proteomics, which still needs further study.

THU-392
Emphysematous pancreatitis: a sporadic sequela of necrotizing pancreatic infections
Audrey Fonkam[1], George Garriss[1]. [1]*Wellstar Kennestone Hospital, United States*
Email: fonkamaudrey@gmail.com

Background and aims: Emphysematous pancreatitis (EP) is a rare, life-threatening complication of acute necrotizing pancreatitis. EP is associated with various forms of bacteria including gas-forming organisms such as Escherichia coli and Clostridium perfringens. An abdominal CT is the imaging of choice given its high sensitivity and specificity when gas is seen within or around the pancreatic parenchyma. We present a case of this rare condition that was successfully treated.
Method: A 64 year old male with a history of CAD, HFrEF, type 2 diabetes mellitus, peripheral vascular disease, hyperlipidemia, essential hypertension, and alcohol and tobacco use presented with one-day history of sudden onset, 5/10 sharp, epigastric abdominal pain that radiated to his back and which began after eating an omelet. The pain was worsened by inspiration. Associated symptoms included nausea and vomiting. He denied any fever, chills, constipation, diarrhea or any other symptoms. On exam, his temperature = 99.8o F, pulse = 119 bpm, Bp = 123/78 mm Hg, RR = 18 bpm, and SpO2 = 94% on room air. Abdominal exam was notable for a non-distended abdomen with normoactive bowel sounds. The abdomen was soft with epigastric tenderness to palpation; there was no guarding or rebound tenderness. Pertinent laboratory studies included: WBC = 7.43 × 109, lipase = 793 U/L, aspartate transaminase = 60 IU/L, alanine transaminase = 102 IU/L, and total bilirubin = 2.4 mg/dL. CT of the abdomen and pelvis with IV contrast showed interstitial edema with hypoenhancement throughout the pancreas and peripancreatic free fluid with gas surrounding the pancreas extending into the retroperitoneum. These findings were suggestive of either an acute gastric ulcer perforation, a fistula, or EP. The patient was admitted, kept n.p.o., and started on intravenous fluids and broad-spectrum antibiotics. Because of the concerns about a possible fistula, the patient underwent a CT of the abdomen with oral contrast and an EGD; neither study supported the diagnosis of fistula or perforation.
Results: Blood cultures grew Proteus Mirabilis and Escherichia Coli. Subsequent imaging demonstrated the progression of extraluminal gas and fluid extending between the pancreas and stomach, which developed into a partially-loculated fluid and gas collections in the lesser sac and greater curve of the stomach. These findings were consistent with the diagnosis of EP with possible pseudocyst. The patient completed a course of IV meropenem and had a drain placed by Interventional Radiology which continued to have high volume output throughout his admission. He ultimately required surgical drainage of his abscess, but eventually made a full recovery.
Conclusion: Due to the rarity of this condition, EP is infrequently described in literature, making its diagnosis and management challenging. An interdisciplinary approach between internal medicine, radiology, gastroenterology, and surgery teams is key for successful treatment of these patients.

Viral Hepatitis Experimental and pathophysiology

Proteomics analysis of HBV cccDNA-bound proteins for therapeutic targeting in liver biopsies from hepatitis B patients
Purnima Tyagi[1], Jitendra Kumar[1], Shiv Kumar Sarin[2], Vijay Kumar[1]. [1]*Institute of Liver and Biliary Sciences, Molecular and cellular medicine, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India*
Email: vijaykumar98@gmail.com

Background and aims: There is a growing need to investigate new therapeutics that could target the hepatitis B virus (HBV) reservoir, the cccDNA, since its silencing may facilitate a functional cure for chronic hepatitis B. (CHB). Present study aims to examine the potential roles of cccDNA-bound proteins in HBV reactivation, silencing and contribution to viral replication in the progression of the infection. Identification of cccDNA-bound proteins in both HBeAg-positive (high replicating group) and HBeAg-negative patients (Low replicating group) may aid in better management of HBV patients.
Method: A total of (n = 14) liver biopsies from chronic hepatitis B patients were collected and were sub-grouped on basis of HBeAg

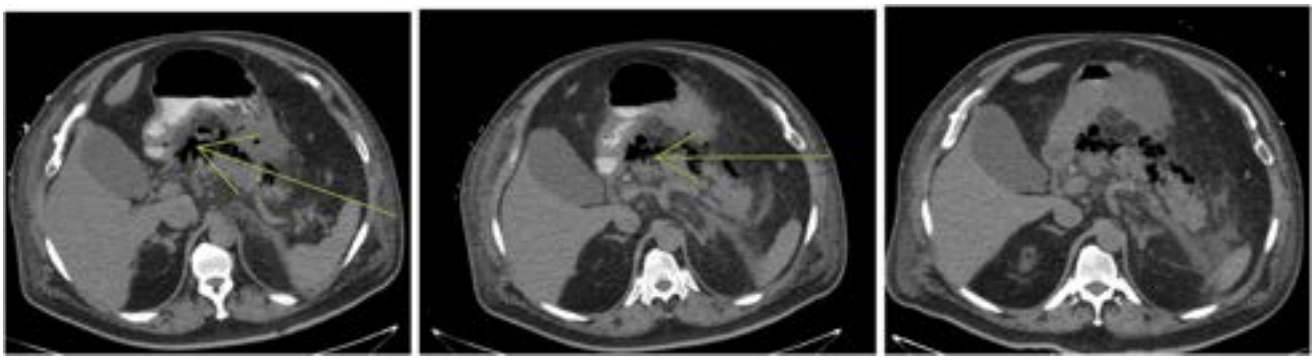

Figure: (abstract: THU-392).

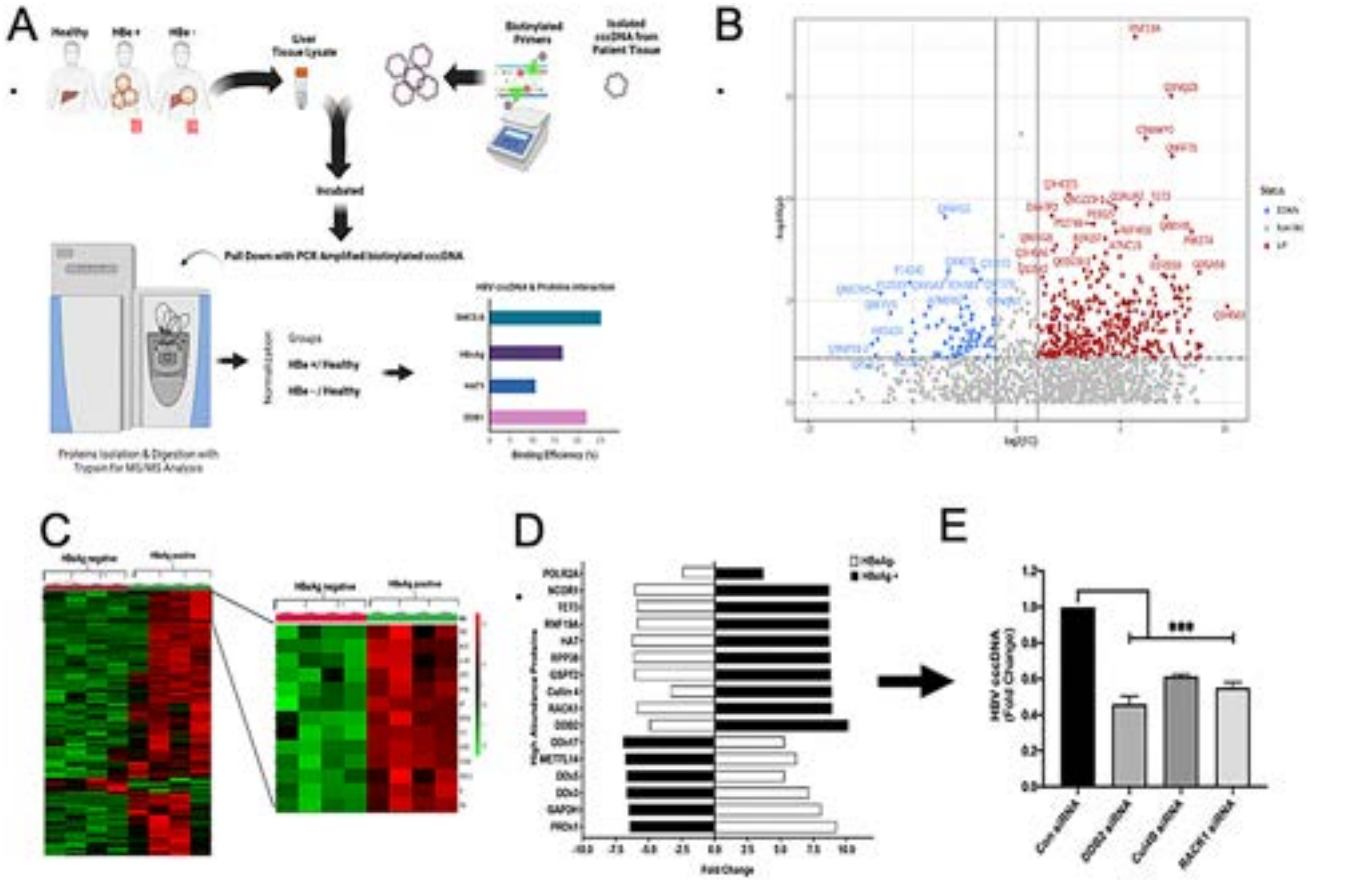

Figure: (abstract: TOP-102): Characterization and identification of HBV cccDNA bound proteins. Illustration of the details study design (A). Volcano plot of the 1350 proteins identified by LC-MS/MS. It shows the fold-change (x-axis) versus the significance (y-axis) of the identified 1350 proteins. The significance (non-adjusted p value) and the fold-change are converted to –Log10 (p value) and Log2 (fold-change) (B). Heat map of HBeAg positive and HBeAg negative liver biopsies identified proteins in hepatitis B (C). HBV cccDNA bound proteins shown in fold change (D). HBV cccDNA levels after knockdown of selected proteins by using SiRNAs in HepG2.2.15 cell lines (E).

negative (n = 7) and HBeAg positive (n = 7) serum HBsAg positive [log10 IU/ml 3.21 ± 1.09 >6 months] and serum HBV DNA [log10 IU/ml 4 ± 1.09]. Biotinylated DNA oligo complimentary to the single stranded region of HBV cccDNA was synthesized. The pull down assay was used to extract cccDNA together along with the binding proteins from both the HBeAg+ and HBeAg- patient's liver tissues, further analysed by nano liquid chromatography coupled with mass spectrometry (nano LC/MS). HepG2.2.15 (with stably integrated HBV genome) was used for the in vitro knockdown studies. After 72 hours of knockdown, the cccDNA levels and the expression pgRNA and HBe and HBsAg proteins were measured by RT-qPCR and ELISA respectively.

Results: cccDNA and the bound proteins were subjected for proteomics analysis. Interestingly, in the HBeAg+, we found total 300 bound proteins significantly upregulated (≥2-fold) and 900 down-regulated (≤0.5-fold). [Culin 4B, RACK1 (Receptor of activated protein C kinase 1), DDB2 (DNA damaging binding protein 2)] significantly upregulated (≥2-fold) and [repressor bound proteins DDx17, DDx5, METTL4 and PRDX1] (≤0.5-fold) were downregulated. We selected top three proteins for knockdown of DDB2, RACK1 and Cul4B using siRNA in vitro (HepG2.2.15) and found the above proteins directly correlated with the expression of HBV parameters like HBsAg ($p < 0.001$), HBeAg ($p < 0.001$), pgRNA ($p < 0.005$), HBV Dna ($p < 0.005$) and cccDNA ($p < 0.005$)

Conclusion: We found cccDNA-bound proteomes correlated with viral load in different patient groups. DDB2, Cul4B and RACK1 were identified as novel nuclear cccDNA-bound proteins in high viral replicating group followed their validation by reduction of cccDNA levels by knockdown. This study provides new insights into the molecular status of cccDNA and potential antiviral targets and for the treatment prognosis of hepatitis B.

The TLR8 agonist Selgantolimod modulates Kupffer cell differentiation status and indirectly impairs HBV entry into hepatocytes via an IL-6-dependent mechanism

Armando Andres Roca Suarez[1,2], Marie-Laure Plissonnier[1,2], Xavier Grand[1,2], Maud Michelet[1,2], Guillaume Giraud[1,2], Simon Fletcher[3], Michel Rivoire[4], Barbara Testoni[1,2], Massimo Levrero[1,2,5], Fabien Zoulim[1,2,5]. *[1]INSERM U1052, CNRS Umr-5286, Cancer Research Center of Lyon (CRCL), Lyon, France; [2]University of Lyon, Université Claude-Bernard (UCBL), Lyon, France; [3]Gilead Sciences Inc., 324 Lakeside Dr., Foster City, CA, 94404, United States; [4]INSERM U1032, Centre Léon Bérard (CLB), Lyon, France; [5]Hospices Civils de Lyon (HCL), Lyon, France*
Email: fabien.zoulim@inserm.fr

Background and aims: Chronic HBV infection affects close to 300 million people worldwide and is one of the major etiologies for the development of cirrhosis and hepatocellular carcinoma. In spite of universal vaccination programs, HBV is still a global burden due to the limited therapeutic options available. Thus, achieving the goal of HBV cure will require a continuous effort in the development of new molecules and combination therapies. In this regard, the TLR8 agonist Selgantolimod (SLGN) has shown promising results during its clinical evaluation as an immunomodulatory agent against HBV. Although the effect of SLGN has been explored in the peripheral immune compartment, little is known regarding its intrahepatic response. Therefore, we aimed to characterize the transcriptomic changes and intercellular communication events associated with the action of SLGN in the liver microenvironment.
Method: We analyzed publicly available single-cell RNA-seq (scRNA-seq) data in order to identify *TLR8*-expressing cell types in the human liver and established a method for their isolation. We characterized the transcriptomic and cytokine profiles of this population in response to SLGN. The indirect effect of SLGN was evaluated by RNA-seq in primary human hepatocytes (PHH) treated with SLGN-conditioned media (CM) and the quantification of viral parameters following HBV infection. Identified signaling pathways mediating this effect were validated by the analysis of liver transcriptomic data from HBV-infected patients.

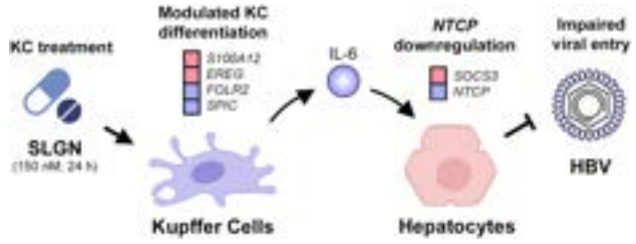

Figure:

Results: Our analysis determined that *TLR8* is primarily expressed in the myeloid compartment of the liver. Therefore, we optimized a method for the isolation of Kupffer cells (KCs) from human liver resections. Using this model, we found that *in vitro* treatment of KCs with SLGN leads to the upregulation of markers that characterize monocyte populations (e.g., *EREG*, *S100A12*) and the downregulation of genes associated with the KC identity (e.g., *SPIC*, *FOLR2*). Interestingly, a similar profile was observed in response to LPS, suggesting this to be part of the general changes associated with an inflammatory response. Moreover, treatment of PHH with SLGN-CM produced in KCs led to the downregulation of NTCP and an impaired HBV entry into hepatocytes. Finally, co-treatment with SLGN-CM and an IL-6-inhibitory antibody identified IL-6 as the cytokine mediating this reduced HBV entry.
Conclusion: Our results suggest that in addition to its previously described therapeutic antiviral activity in HBV-infected hepatocytes, SLGN also has a prophylactic effect via an IL-6-dependent mechanism. Moreover, our characterization of SLGN sheds light into the general transcriptional programs regulating KC activation and underscores the importance of considering cell states when annotating hepatic cell populations based on scRNA-seq data.

Intrahepatic CD8+ T cells correlate with significant declines in HBV viral load and S antigen following a single vaccination with VRON-0200 in an AAV mouse model

Mohadeseh Hasanpourghadi[1], Andrew Luber[2], Sue Currie[2], Xiang Zhou[1], Hildegund Ertl[1]. [1]*The Wistar Institute, United States;* [2]*Virion Therapeutics, United States*
Email: scurrie@viriontx.com

Background and aims: VRON-0200 is a therapeutic vaccine developed to achieve functional cure of chronic HBV. The vaccine contains a genetically encoded checkpoint modifier, glycoprotein D (gD), to enhance, broaden and prolong CD8+ T cell responses to HBV core and polymerase with the goal to eliminate HBV-infected hepatocytes and prevent further viral spread. We hypothesized that, by removing virus-infected hepatocytes, S antigen would decline without being targeted by the vaccine. Here we report on correlations between intrahepatic CD8+ T cell responses and HBV viral load and S antigen declines in an AAV mouse model following a single i.m. injection of VRON-0200 (AdC6-gDHBV2).
Method: C57Bl/6 mice were tested for frequency and epitope specificities of IFN-gamma producing vaccine-insert-specific CD8+ T cells in blood, spleens, and livers, following a single i.m. dose of 1×10^{10} vp of a chimpanzee adenovirus vector (AdC6) expressing sequences of polymerase and core within gD (AdC6-gDHBV2), polymerase and core without gD (AdC6-HBV2) or nothing (controls). Efficacy was assessed in C57Bl/6 mice injected i.v. with an AAV8-1.3HBV vector at doses of 10^9 or 10^{10} genome copies. At week 4, mice with high levels of circulating HBV genome copy numbers were vaccinated (n = 5–10/group) with a single i.m. dose of 1×10^{10} vp of AdC6-gDHBV2, AdC6-HBV2, or nothing (control). HBV DNA viral loads and HBsAg titers in sera were assessed before and after vaccination and relationships between viral parameters and frequencies of IFN-gamma producing CD8+ T cells were assessed by Spearman's rank correlations.
Results: gD significantly enhances and broadens CD8+ T cells response in blood, spleens, and livers. In spleens, gD more than doubles the frequencies and breadth of CD8+ T cells. In AAV8-1.3HBV mice, at week 12, a single injection of AdC6-gDHBV2 achieves an HBV viral load decline of ≥ 3 $\log_{10}$, the same vaccine without gD reduced viral loads ≤ 1 $\log_{10}$. Viral loads increase or remain stable in control mice. HBV DNA copies/ml strongly inversely correlate with the frequency of IFN-gamma CD8+ T cells in livers and spleens (figure); S antigen levels correlate with HBV viral load and inversely correlate with CD8+ T cell frequencies.
Conclusion: VRON-0200 is the first therapeutic vaccine to show significant correlations between intrahepatic CD8+ T cells and HBV viral loads declines. S antigen declines were also observed and directly related to HBV clearance. These data further support the key role of HBV viral load and CD8+ T cells as end points for HBV functional cure and highlight VRON-0200's clinical potential alone or in combination. A VRON-0200 Phase 1b multi-national study is scheduled to begin in 2023.

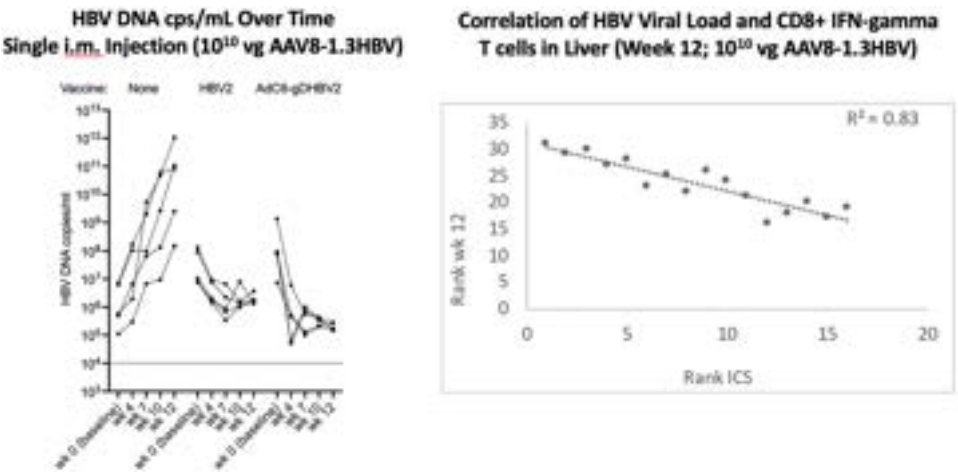

Figure: (abstract: TOP-107).

TOP-108

HBsAg induces mild activation, but not suppression, of intrahepatic immune cells as shown by single-cell RNA sequencing of fine-needle aspirates in chronic HBV patients

Zgjim Osmani[1], Boris Beudeker[1], Gertine Oord[1], Anthony Grooshuismink[1], Robert De Knegt[1], Eric Bindels[2], Harmen van de Werken[3], Andre Boonstra[1]. *[1]Erasmus Mc, Gastroenterology and hepatology, Rotterdam, Netherlands; [2]Erasmus Mc, Hematology, Rotterdam, Netherlands; [3]Erasmus Mc, Immunology, Rotterdam, Netherlands*
Email: z.osmani@erasmusmc.nl

Background and aims: There is no curative treatment for chronic hepatitis B virus (HBV) infection. Circulating hepatitis B surface antigen (HBsAg) is hypothesized to be responsible for the lack of an effective immune response to HBV. So far, previous attempts have failed to provide us with a complete understanding of the effects of HBsAg. To determine the impact of HBsAg on immune subsets, we optimized a workflow to examine circulating and intrahepatic cells from fine-needle aspirates (FNAs) of the liver.
Method: We included 18 HBeAg-negative patients on tenofovir and entecavir treatment with normal transaminases. Isolated cells from blood and paired liver FNAs were sequenced by 10X Genomics single-cell RNA sequencing. Patients were divided into an HBsAg high (920–12447 IU/ml) and HBsAg low group (1–100 IU/ml). Bioinformatic and differential gene expression analyses were performed comparing the two groups.
Results: Clustering identified 36 clusters in blood (166,351 cells; n = 18) and 29 clusters in liver FNAs (35,513 cells; n = 8). Cluster frequencies were comparable between both groups, except for the *KLRC2+ TIGIT+* NK cell cluster which was significantly decreased in the blood of patients with high HBsAg (avgFC 2.9). When comparing the HBsAg high vs. low group, the highest number of differential expressed genes (DEGs) in blood were observed in the *KLRC2+ TIGIT+* NK cell cluster (78 DEGs). Among others, interferon-related genes and inhibitory KIRs were downregulated in the HBsAg high group. This cluster presumably acquires memory-like properties and is often referred to as "adaptive" NK cells. Similar to blood, cluster frequencies in liver FNAs were comparable between groups except for the *TIGIT+* liver-resident NK cell cluster which was significantly increased in patients with high HBsAg (avgFC 1.8). In general, gene expression differences were relatively low in FNAs when comparing the HBsAg high vs. low group. The highest number of DEGs were observed in the *CXCR6+ CD69+* liver-resident CD8 T cell cluster (15 DEGs). The inhibitory receptors *KLRB1, KLRC1*, and more importantly *IFNG* were upregulated by this cluster in the HBsAg high group, pointing towards a more activated cell state. Interestingly, the memory B cell clusters (10–14 DEGs) upregulated activation markers in the HBsAg high group (e.g., *CD69*, *CD83*), whereas the *TIGIT+* liver-resident NK cell cluster (8 DEGs) significantly upregulated *IL32*. IL-32 is known to induce pro-inflammatory cytokines and chemokines, yet, its role in the antiviral immune response against HBV remains unknown.
Conclusion: Our workflow provided us with unique insights into the effects of HBsAg at single-cell resolution. Unbiased analyses show us for the first time, to our knowledge, that relatively high HBsAg levels trigger gene expression changes of immune subsets in blood and liver, collectively pointing towards a more activated cell state; primarily in NK-, B- and intrahepatic CD8 T cells.

TOP-111

Dating the origin and evolution dynamics of hepatitis D virus

Yibo Ding[1], Hongbo Guo[1], Qiudi Li[1], Dan Liu[1], Zhijiang Miao[2], Renxian Tang[1], Kuiyang Zheng[1], Qiuwei Pan[3], Wenshi Wang[1]. *[1]Xuzhou Medical University, Jiangsu Key Laboratory of Immunity and Metabolism, Pathogenic Biology and Immunology, Xuzhou, China; [2]Kunming University of Science and Technology, Kunming, China; [3]Erasmus Medical Center, Department of Gastroenterology and Hepatology, Netherlands*
Email: wenshi.wang@xzhmu.edu.cn

Background and aims: Chronic infection of hepatitis D virus (HDV) causes the most severe form of viral hepatitis. Although discovered more than 40 years ago, the origin and evolutionary landscape of HDV remain elusive. As a satellite virus of hepatitis B virus (HBV), it is poorly understood whether a co-evolution and co-migration relationship exists between HDV and HBV. We aim to map the evolutionary dynamics of HDV geographically and chronologically.
Method: Bayesian coalescent analysis was performed to analyze the phylogenetic relationships, time of origin, the most rapid

dissemination period, area of origin and transmission roadmap of HDV and HBV.
Results: We found the origin time of HDV and HBV and their rapid dissemination period are distantly separated in the timeline. Specifically, HDV jumped into human around 220 years ago and disseminated rapidly since 1990, whereas HBV jumped into human around 37,700 years ago with the most pronounced dissemination period started 4500 years ago. In addition, HDV originated from South America, while HBV originated from Africa. And their propagation roadmaps were also distinct. Moreover, a striking geographic separation of HDV was observed. Both the fitness to HBV genotypes and the adaptation to human lineages contribute to the formation of HDV cladogenesis.
Conclusion: This study has delineated the origin and evolution landscape of HDV. The origin and dispersal of HDV and HBV are distinct both geographically and chronologically. This implies that instead of a co-evolution and co-migration relationship, HDV and HBV evolve in parallel. Nevertheless, the genetic diversity of HDV was driven by multiple factors, including HBV genotypes and human lineages.

FRIDAY 23 JUNE

FRI-215
PD-1 does not suppress effector CD8 T cell differentiation during acute HBV infection and is not required for the induction of HBV-specific CD8 T cell exhaustion in HBV persistent mice

Jia Liu[1]. [1]*Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Infectious Diseases, Wuhan, China*
Email: jialiu77@hust.edu.cn

Background and aims: PD-1 is one of the key inhibitory receptors regulating CD8 T cell exhaustion during chronic viral infection. However, the role of PD-1 in modulating effector T cell differentiation and function during acute HBV infection is not well defined. Moreover, it is unclear whether PD-1 directly causes HBV-specific CD8 T cell exhaustion during chronic HBV infection.
Method: To address these questions, we examined the impact of genetic depletion of PD-1 from HBV-specific CD8 T cells on their differentiation and function in acute self-resolving and persistent HBV replication mouse models.
Results: We observed a sustained increase of PD-1 expression on CD8 T cells in both the spleen and liver in mice with acute self-resolving HBV replication. PD-1+ CD8 T cells demonstrated significantly increased effector T cell differentiation, proliferation, effector cytokine production, and granzyme B expression in compared to PD-1- CD8 T cells. Interestingly, transcriptome sequencing analysis revealed that PD-1+ CD8 T cells also expressed significantly higher inhibitory molecules such as TIGIT, LAG-3, CTLA-4 and CD244 compared to PD-1- CD8 T cells. Next, we generated PD-1 knockout (KO) HBcAg-specific TCR transgenic (C93-TCRtg) mouse strain to further analyze the role of PD-1 in regulating HBV-specific CD8 T differentiation and function. Wild type (WT) and PD-1 KO C93-TCRtg CD8 T cells were transfer to naïve mice, and the mice were then challenged with HBV leading to either self-resolving or persistent replication. In the acute self-resolving HBV replication model, both transferred WT and PD-1 KO C93-TCRtg CD8 T cells proliferated efficiently in a comparable level post HBV exposure. The PD-1 KO C93-TCRtg CD8 T cells also showed similar effector differentiation phenotype, effector cytokine production and cytotoxicity molecule expression compared to the WT C93-TCRtg CD8 T cells. However, the absence of PD-1 led to significant decreases of Tox and Eomes expression in C93-TCRtg CD8 T cells. In HBV persistent mice, the genetic deletion of PD-1 on C93-TCRtg CD8 T cells was insufficient to prevent the development of cell exhaustion. Interestingly, the absence of PD-1 led to significant increases of Tox and Eomes expression and decrease of T-bet expression in C93-TCRtg CD8 T cells in HBV persistent mice.
Conclusion: Our results demonstrate that PD-1 does not suppress effector CD8 T cell differentiation during acute HBV infection and HBV-specific CD8 T cell exhaustion can occur in the absence of PD-1.

FRI-216
Detection and functional analysis of HBV-specific stem cell memory T cells (Tscm)

Hiromi Abe-Chayama[1], Kazuaki Chayama[1]. [1]*Hiroshima University, Graduate School of Biomedical and Health Sciences, Hiroshima-shi, Japan*
Email: habe@hiroshima-u.ac.jp

Background and aims: CD8+ CTLs (Cytotoxic T lymphocytes) play a pivotal role to eliminate HBV. CTLs of chronic HBV patients fail to eliminate infected cells because of exhaustion. Stem cell memory T cells (Tscm) are a rare subset of memory lymphocytes with stem cell-like self-renewal capabilities. Tscm are expected to be useful in cancer therapy. In this study, we detected HBV-specific Tscm in patients with chronic hepatitis and investigated their functions by transferring the Tscm into HBV-infected human hepatocytes transplanted TK-NOG mice.
Method: We isolated CD8+ T cells by MACS technology using PBMCs of HBV patients with HLA-A24. HBV core or pol tetramer+ HBV-specific Tscm were detected using FACSCanto2. Isolated Tscm from 8 HBV patients were labeled with CFSE and injected into 8 HBV-infected HLA-A24 human hepatocyte transplanted TK NOG mice. Serum HBV DNA and human albumin levels were monitored until the mice were sacrificed three or four weeks after the Tscm transfer. Hepatic mononuclear cells and splenocytes were isolated to study cell proliferation and intracellular IL-2 and IFN-gamma production.
Results: Detection of Tscm from patients with hepatitis B. HLA-A24 core and polymerase tetramer-positive Tscm were detected in 15 and 10 of 18 patients with chronic hepatitis B, respectively. The frequency of Tscm in these patients ranged from 0.6 to 38%. Transfer of Tscm to human hepatocyte transplanted TK-NOG mice. To explore a possibility of Tscm administration therapy to treat HBV infection with Tscm, we transferred 10^ 5 Tscm from 8 chronic HBV patients to 8 TK-NOG mice with HLA-A24 hepatocytes after HBV infection. Four mice were sacrificed three weeks after human cell injection and remaining four were sacrificed four weeks after the Tscm transfer. Apparent HBV DNA reduction was seen in 5 of the 8 mice. Human albumin levels also declined in these 5 mice suggesting the elimination of HBV-infected hepatocytes. Histological analysis of mouse liver tissue three and four weeks after human cell transfer revealed mild and severe mononuclear cell infiltration. These infiltrating cells were positive for human CD8-alpa staining, suggesting that the transferred TSCMs had differentiated into CTLs and caused hepatitis. No mice showed signs of GVHD. High levels of human blood cells were recovered from the liver and spleen of the mice three weeks after injection but dramatically decreased one week later. IL-2 and IFN-gamma producing cells were more abundantly detected in mice sacrificed four weeks after T-cell transfer than three weeks. Most of these

cytokine-producing cells were tetramer-positive, suggesting that these cytokines were produced from CTLs reactive to HBV peptides.
Conclusion: We detected Tscm specific to HBV and showed a possibility of Tscm therapy for chronic HBV infection.

FRI-217
RBD1016-a novel anti-HBV GalNAc-siRNA drug resulted in sustained HBsAg reduction and seroconversion in mice models
Li Ming Gan[1], Shuquan Zheng[2], Feng Li[2], Zhaoxu Guo[2], Hong Yu[2], Hongyan Zhang[2], Zicai Liang[2], Shan Gao[2]. [1]*Ribocure Pharmaceuticals Ab, Sweden;* [2]*Ribo Life Science Co., Ltd, China*
Email: ganlm@ribolia.com

Background and aims: RBD1016 is a siRNA drug intended for treatment of chronic HBV infection, by targeting HBV X gene with pan-genotypic coverage. RBD1016 is in Phase 1 clinical stage for the treatment of CHB patients. Here we report the preclinical data from *in vivo* proof of concept studies using RBD1016 in two relevant mouse models of human HBV.
Method: To evaluate the efficacy of RBD1016, C57B/6N-Tg (1.28HBV)/Vst mice (or HBV transgenic mice) and rAAV8-1.3HBV (or AAV-HBV) animal models were used to investigate the anti-HBV effect of RBD1016 administered at different doses and different treatment regimens.
Results: 1. Single dose of RBD1016 resulted in dose-dependent knockdown of HBV viral markers in transgenic mice. An effective reduction of HBsAg by RBD1016 (max reduction 3.33 $\log_{10}$ IU/ml) was observed in HBV transgenic mice, which lasted for at least three months (Figure 1A). RBD1016 could also achieve substantial and durable reduction of HBeAg and HBV DNA (Figure 1B) in a dose-dependent manner. 2. RBD1016 resulted in HBsAg seroconversion and synergistic effect on HBV DNA reduction combined with ETV (spell out ETV). Rather distinct from other assets in this class, RBD1016 caused *de novo* production of HBsAb in the AAV-HBV mouse model, which was detected in up to 62.5% of the experimental animals after repeated RBD1016 (3 mg/kg, qw*3) treatment (Figure 1C). The combination of RBD1016 and ETV demonstrated a synergistic effect on serum HBV DNA inhibition, with serum HBV DNA reduced up to 4.91 $\log_{10}$ IU/ml, and the profound inhibition was maintained even after discontinuation of ETV on Day 29 until the end of the study (Figure 1D). 3. A good PKPD correlation between liver RBD1016 concentration and serum HbsAg. There was a good correlation between RBD1016 liver concentration and HBsAg level in the plasma, supporting the use of HBsAg reduction in estimating drug concentration in the liver in human studies. 4. Pre-clinical safety profile. Based on 13 weeks´ GLP toxicity studies, no observed adverse effect levels (NOAEL) were defined at 600 and 400 mg/kg in mice and monkeys, respectively, which supports large safety windows for ongoing and future studies in man.
Conclusion: The non-clinical studies of RBD1016 showed a significant and dose-dependent reduction of HBsAg on transgenic mouse model and AAV-HBV mouse model, which was further accompanied with HBsAg seroconversion. RBD1016 alone and in combination with drugs of other mode of action have the potential to contribute to functional cure of HBV in patients with chronic HBV.

FRI-218
HBV infection reshapes host chromatin accessibility and affects choline and iron metabolism

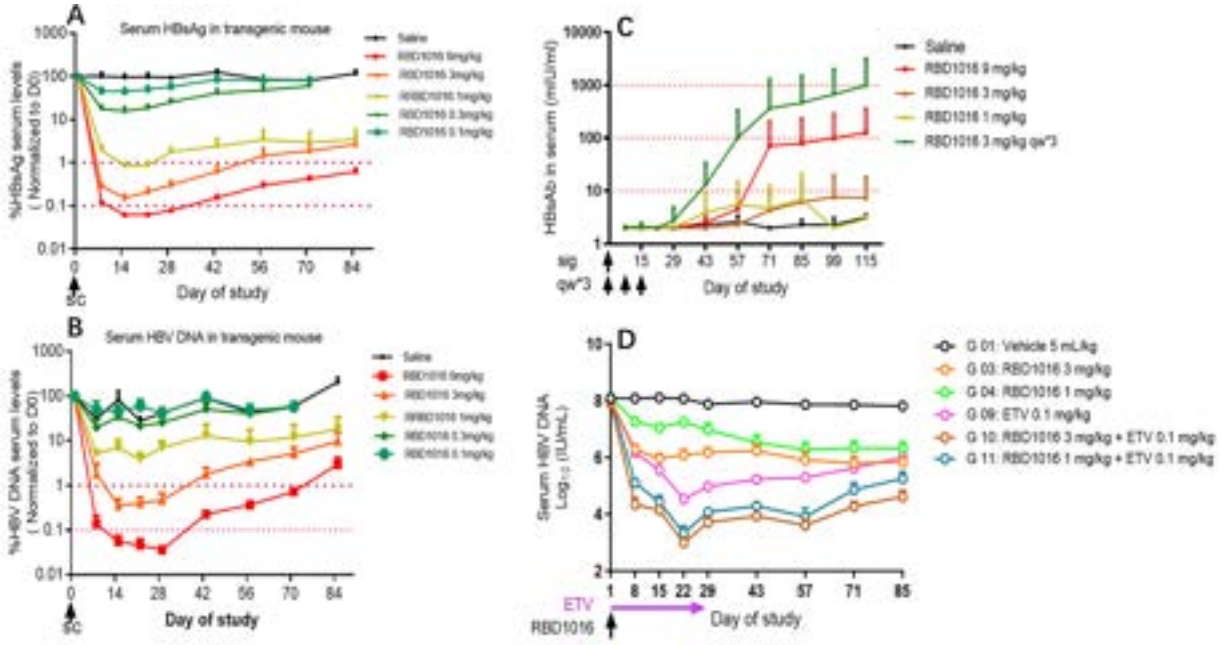
Email: vincenzo.alfano@inserm.fr



Effects of RBD1016 on HBV viral markers in transgenic mice. HBsAg was measured by ELISA, HBV DNA was quantified by qPCR, respectively (A, B); Serum HBsAb can be detected after a singe or repeated dose of RBD1016 in 62.5% AAV mice, HBsAb level was much higher in repeated dose (C); Additive inhibition of serum HBV DNA was observed for RBD1016 in combination with ETV in HBV transgenic mice (D).

Figure: (abstract: FRI-217).

Background and aims: HBV remains a major health problem worldwide with 250 million people chronically infected and at risk to develop liver cirrhosis and HepatoCellular Carcinoma (HCC). A complex host-virus interaction is responsible for both HBV-specific T and B cells dysfunction and the persistence of the viral cccDNA mini-chromosome, the two key challenges for HBV cure. The extent of HBV impact on the liver transcriptome remains controversial. Transcriptional activation in eukaryotic cells has been tightly linked with disruption of nucleosome organization at accessible genomic sites of remodeled chromatin. We used ATAC-seq (Assay for Transposase Accessible Chromatin followed by high throughput sequencing) to probe open chromatin and detect early changes in chromatin accessibility in HBV-infected Primary Human Hepatocytes (PHHs).
Method: HBV-infected PHHs (2 h/72 h) from 2 donors were used for ATAC-seq and analysis. The libraries were sequenced (75 × 2 cycles) on a NextSeq 500 Illumina.
Results: ATAC-seq analysis revealed an average of 2000 and 3500 cellular Differentially Accessible Regions (DARs) at 2 h and 72 h post infection (p.i.) respectively, indicating that after HBV infection an increasing number of genomic sites (including promoters, intragenic and distal intergenic regions) change their chromatin accessibility over time. Overall, the regions with different chromatin accessibility were enriched in genes involved in metabolism (KEGG) and GSEA analysis revealed an important role of the chromatin regulating complex PRC2 complex at 72 h p.i.Interestingly, the 1804 DARs, that are equally impacted by HBV infection in both the donors, enriched the pathway of choline metabolism in cancer, which affects PRC2 function. The integration of the ATAC-seq and RNA-seq data allowed us to identify 614 genes that had significant changes in both the analysis at 72 h p.i.These targets confirmed the impact of HBV infection on liver metabolism, and revealed a strong involvement of the iron metabolism in the cellular response to HBV infection. We validated the expression of iron-related genes and we found that HBV infection significantly upregulated the iron uptake in the cells. Finally, using the iron chelator Ferrostain-1, we showed that lowering the available iron levels results in a drastic inhibition of viral replication.
Conclusion: Altogether these results challenge the commonly accepted concept of HBV as a "stealth" virus and show that HBV infection impacts on host cell chromatin landscape and specific transcriptional programs. In particular, HBV imposes a reshaping of key cell metabolic pathways (e.g., choline and iron metabolism). Finally, we showed that available iron levels impact on HBV replication.

FRI-219
Identification of unique liver NK cells in HBV and a new perspective on exhaustion-related NK cell phenotypes by single-cell RNA sequencing
Boris Beudeker[1], Arda Karaoglu[1], Gertine Oord[1], Anthony Grooshuismink[1], Noé Axel Montanari[1], Remco Hoogenboezem[2], Eric Bindels[2], Harmen van de Werken[3], Robert De Knegt[1], Andre Boonstra[1]. *[1]Erasmus Mc, Gastroenterology and hepatology, Rotterdam, Netherlands; [2]Erasmus Mc, Hematology, Rotterdam, Netherlands; [3]Erasmus Mc, Immunology, Rotterdam, Netherlands*
Email: p.a.boonstra@erasmusmc.nl

Background and aims: NK cells play an important role in the body's response to chronic hepatitis B virus (HBV) infection. Understanding the impact of stably suppressed HBV on NK cell activation or inhibition is crucial for improving protective immunity and developing effective HBV cure therapies.
Method: Blood NK cells of HBeAg-negative HBV patients with low viral load were phenotyped and functionally tested. To provide a comprehensive and unbiased profile of the composition and transcriptional states of NK cells, paired blood and fine needle liver aspirates of treated HBV patients were single-cell RNA-sequenced (ScRNAseq) and compared to healthy control datasets.
Results: ScRNAseq analysis revealed distinct NK cell subsets in patients with chronic HBV. We observed a reconfiguration of peripheral NK cells in HBV patients, including a heterogeneous activation-related gene signature and increased TIGIT expression. Contrary to previous hypotheses, we found limited expression of T-cell exhaustion related genes in peripheral NK cells. Our analysis of paired blood and liver NK cells is to date the largest, revealing a unique population of intrahepatic NK cells that clusters with blood NK cells in multidimensional analysis. These intrahepatic cells expressed immediate early genes (*FOS/JUN*), and genes encoding proinflammatory cytokines (*IFNG*). ScRNAseq of unprocessed ex vivo HBV liver aspirates profiled the tissue-resident phenotype of NK cells and revealed pronounced proinflammatory features, accompanied by high expression of the inhibitory factor *TIGIT,* as compared to blood. Our analysis of inhibitory genes in liver-resident NK cells showed a link between TIGIT expression and cytotoxicity and proinflammatory transcriptional profiles in both HBV and healthy liver. Our extensive analysis of NK cell phenotype and function in 101 cases of stably suppressed HBV or healthy patients with spontaneous HBsAg loss showed a link between TIGIT frequency on CD56dim NK cells and the clinical phase of HBeAg-negative HBV, as well as the duration of antiviral therapy. No other well-known activation or inhibitory proteins, such as PD1, TIM-3 KLRG1, HLA-DR or CD38 were found to be associated with these factors.
Conclusion: Blood and liver NK cells of treated HBV patients expressed limited T-cell exhaustion associated features, and expression of TIGIT was linked with favorable clinical outcomes and highly active NK cell subsets. Besides liver-resident NK cells, also activated liver-infiltrating NK cells were observed. In conclusion, our findings demonstrate the potential of targeting blood and liver NK cells as a strategy to cure HBV, especially as novel anti-HBV compounds are being developed in combination with NUC therapy.

FRI-220
Impact of pegylated interferon-alpha in combination with Bulevirtide in HBV/HDV infected humanized mice
Tassilo Volz[1,2], Jonathan Kolbe[1], Annika Volmari[1,2], Lena Allweiss[2,3], Marc Luetgehmann[2,3], Simon Fletcher[4], Meghan Holdorf[4], Robert Muench[4], Maura Dandri[1,2]. *[1]University Medical Center Hamburg-Eppendorf, Internal Medicine, Hamburg, Germany; [2]German Center for Infection Research, DZIF, Hamburg-Lübeck-Borstel-Riems Site, Germany; [3]University Medical Center Hamburg-Eppendorf, Medical Microbiology, Virology and Hygiene, Hamburg, Germany; [4]Gilead Sciences, Foster City, United States*
Email: m.dandri@uke.de

Background and aims: Chronic hepatitis D (CHD) is a complex viral disease for which treatment remains challenging. The entry inhibitor bulevirtide induces a significant decline in HDV RNA and ALT reduction/normalization in CHD patients after 24 weeks, but longer treatment durations and/or combination therapies are needed to accelerate HDV decline and increase cure rates (*Wedemeyer, Lancet Inf Dis 2022*). Pegylated interferon-alpha (pegIFNα) is also used to treat CHD but has high rates of viral relapse. In a small phase II study, the combination of BLV with pegIFNα had superior antiviral efficacy relative to either agent alone (*Wedemeyer, J.Hep 2020*). However, the underlying mechanism (s) by which PEG-IFN-α improves the antiviral response to BLV remains unclear. The aim of this in vivo study was to evaluate the antiviral efficacy of BLV and pegIFNα administered alone or in combination using HBV/HDV infected immunodeficient humanized mice.
Method: uPA/SCID/IL2Rγ$^{-/-}$ (USG) mice reconstituted with adult primary human hepatocytes (PHH), were stably infected with HBV and superinfected with a recently cloned patient-derived HDV viral isolate (GT-1p) (*Giersch, JHEP Rep 2023*). Animals (n = 5–6 per group) received BLV (2μg/g once per day) and pegIFNα (25 ng/g, twice per

week) either alone or in combination for a total of 8 weeks. Virological markers and IFN responsiveness in serum and liver were analyzed by qRT-PCR, ELISA, and immunofluorescence.
Results: At baseline of treatment, mice had a median of 9.7log$_{10}$ HBV DNA copies/ml and a 6.5 log$_{10}$ HDV RNA copies/ml in the serum. Compared to untreated controls, the combination of BLV + pegIFNα resulted in the greatest decrease of serum HDV RNA levels (median –2.4 log$_{10}$), intrahepatic reduction of HDAg-positive cells, and intracellular HDV RNA (median –2.4log$_{10}$). Monotherapies decreased intrahepatic HDV RNA to a lesser extent (BLV: median –0.6log$_{10}$; pegIFNα: median –0.8log$_{10}$). As expected, pegIFNα strongly enhanced the expression of human interferon-stimulated genes (ISGs) in liver of humanized mice. In contrast, HDV-mediated intrahepatic ISG induction (e.g., h-ISG15 and h-Mx1) was lower in mice receiving BLV monotherapy compared to untreated HBV/HDV infected controls.
Conclusion: The combination of BLV + peg-IFN-α reduced intrahepatic HDV levels in humanized immunodeficient mice with high levels of HBV and HDV infection to a greater extent than either agent alone. Despite the lack of adaptive immune responses, the block of new infection events mediated by BLV, together with the activation of innate immune responses in hepatocytes by pegIFNα, provide a rationale for the combination effect of these agents observed in CHD patients.

FRI-221
Automated high-throughput image-based screen discovers members of the Akt serine/threonine kinase family as potential targets for treatment of hepatitis E virus infection
Mara Klöhn[1], Yannick Brüggemann[1], Marc Windisch[2], Daniel Todt[1], Eike Steinmann[1]. [1]*Ruhr Universität Bochum, Molecular and Medical Virology, Bochum, Germany;* [2]*한국파스퇴르연구소, Seongnam-si, Korea, Rep. of South*
Email: eike.steinmann@rub.de

Background and aims: Nearly four-and-a half decades after the discovery of Hepatitis E virus (HEV) as the etiological agent of viral hepatitis in human, treatment options remain limited to the off-label use of the nucleoside-analog ribavirin (RBV) and pegylated interferon-alpha. Although these drugs have made HEV infections manageable for the majority of patients, a considerable number of patients are either not eligible for or do not respond to currently available treatment options. To find substitute antiviral medications against HEV infections, we developed a simple and effective image-based high-throughput screening assay.
Method: We screened up to 9,500 compounds derived from FDA-approved drug-libraries and carried out dose-response assays of up to 170 of the most promising compounds by utilizing subgenomic HEV reporter replicons of genotype 3 expressing a GFP gene as a marker for viral replication in hepatoma cells. Furthermore, we tested the top hits in infection experiments with the human-derived HEV-3 p6 and the wild-boar HEV-3 83-2 virus.
Results: We discovered at least 5 compounds that markedly inhibit viral infection at low micromolar concentrations in hepatoma cells. Finally, infection experiments with HEV-3 p6-FL and HEV-3 83-2 virus identified Capivasertib and Ipatasertib, two pan-inhibitors of the serine/threonine kinase Akt to inhibit virus infection *in vitro*.
Conclusion: In conclusion, screening drug-repurposing libraries proved to be a versatile tool for identifying novel drugs against HEV infections, but most importantly, our results suggest that pan-Akt inhibitors may be promising therapeutic candidates for the treatment of HEV infections.

FRI-222
The hepatitis E virus ORF2 protein forms amyloid-like protein aggregates which may be pathogenic in human neurons
Jungen Hu[1], Giulia Mizzon[2], Chiara Olmeo[3], Ann-Kathrin Mehnert[1], Rebecca Fu[1], Jan Birkel[1], Andrew Freistaedter[1], Claudio Acuna[3], Ralf Bartenschlager[2,4], Viet Loan Dao Thi[1,4]. [1]*Chica and Heinz Schaller Research Group, Department of Infectious Diseases, Virology, Heidelberg University Hospital, Germany;* [2]*Molecular Virology, Center for Integrative Infectious Disease Research, Heidelberg University Hospital, Germany;* [3]*Chica and Heinz Schaller Research Group, Institute for Anatomy and Cell Biology, Medical Faculty Heidelberg, Germany;* [4]*German Centre for Infection Research (DZIF), Partner Site Heidelberg, Germany*
Email: vietloan.daothi@med.uni-heidelberg.de

Background and aims: Hepatitis E virus (HEV) is an important human pathogen. Immunocompromised patients can become chronically HEV-infected and suffer from extrahepatic manifestations, especially neurological disorders. HEV genomic RNA was detected in the cerebrospinal fluid of chronic HEV patients and in the brains of HEV-infected animals. In HEV-infected cells, three different forms of the capsid protein ORF2 have been described: a glycosylated, a cleaved, and an infectious form. How the expression of the different ORF2 forms is regulated, where progeny particles assemble, and how they traffic through the cell is poorly understood. We want to investigate HEV assembly by studying ORF2 in host cells. We also

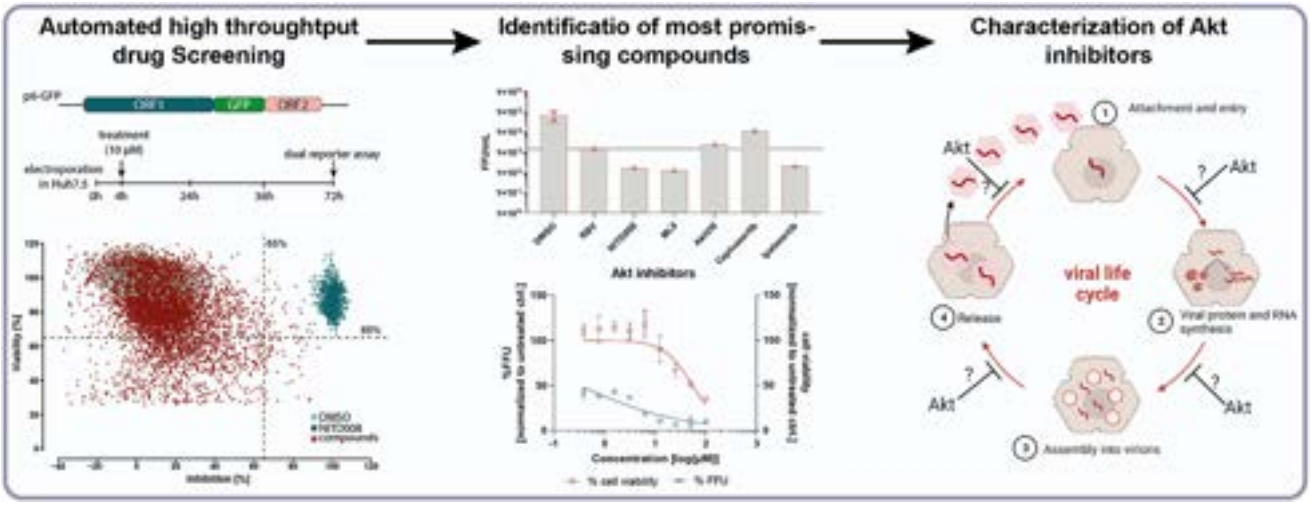


Figure: (abstract: FRI-221).

want to analyze if ORF2 is involved in HEV-induced neuropathogenesis.
Method: We engineered a new full-length fluorescence HEV reporter and derivates by tagging ORF2 using the split GFP system (ORF2-GFP11), which allowed us to perform correlative light-electron microscopy (CLEM) and live-cell imaging studies. We used human induced pluripotent stem cell (iPSC)-derived neurons to study potential HEV-induced neurological disorders.
Results: The ORF2-GFP11 reporter virus replicated to similar levels as WT HEV and made infectious progeny particles. HEV ORF2-GFP11 infection of cells expressing GFP1–10 led to the formation of ~2 μm long rod-shaped GFP-positive ORF2 structures in the cytoplasm. By staining with ORF2 antibodies, we confirmed the formation of these structures in a range of WT HEV-infected cell types, including iPSC-derived hepatocytes and neurons. In HEV WT-infected neurons, calcium concentrations appeared to be lower compared to non-infected neurons. To our surprise, both the supposedly secreted and the infectious ORF2 forms formed large structures in the cytoplasm. Further, ectopically expressed WT ORF2 formed the same structures, suggesting it to be the sole viral determinant. By CLEM and electron tomography analysis, we found that the ORF2 protein formed aggregates composed of orderly stacked tubular filaments with a periodicity of ~35 nm, reminiscent of amyloid fibrils.
Conclusion: We have generated a full-length fluorescence HEV reporter for the first time. The ORF2 protein can form large, cytoplasmic, amyloid-like protein structures which may be involved in the pathogenesis in HEV-infected neurons. We are currently investigating how the structures are formed and if they play a role in progeny HEV assembly processes.

FRI-223.
Hepatitis B virus infected hepatocytes are resistant to cell death induction by virus-specific T cells.
Emely Springer[1], Annika Schneider[1], Joseph Trapani[2], Daniel Hartmann[3], Norbert Hueser[3], Melanie Laschinger[3], Percy A. Knolle[1], Dirk Wohlleber[1]. *[1]Technical University of Munich, Institute of molecular Immunology, Munich, Germany; [2]Peter MacCallum Cancer Centre, Melbourne, Australia; [3]University Hospital München rechts der Isar, Department of Surgery, Munich, Germany*
Email: emely.springer@tum.de

Background and aims: Hepatitis B virus (HBV) infection is considered as global health problem with more than 290 million cases of chronic hepatitis B. Although infection of hepatocytes with HBV induces anti-viral CD8 T cell response, viral clearance by CD8 T cells takes weeks or may develop into persistent infection. The reasons for failure of the immune system are manifold and not entirely understood. We recently identified that viral infections renders hepatocytes more susceptible for immune-mediated cell death induction by reducing the mitochondrial stress resilience. Here we aim to analyze if HBV infection renders HBV infected hepatocytes susceptible for enhanced cell death induction or if HBV infected hepatocytes may escape cell death.
Method: Primary human and murine hepatocytes were infected with hepatotropic HBV or transduced with recombinant adenoviruses delivering HBV genomes. T cell effector function against virus-infected hepatocytes were analyzed by co-culture with antigen-specific CD8 T cells or by T cell-derived effector molecules like Fas-ligand, tumor necrosis factor (TNF) or perforin. Cell death induction was monitored by real-time killing assay and caspase activation assay. In addition, we analyzed the mitochondrial stress resilience by challenging with calcium ions. Proof-of-concept experiments were performed in mice to verify the in vitro results.
Results: We found that viral infection with adenoviruses and lymphocytic choriomeningitis virus (LCMV) sensitized infected hepatocytes towards induction of cell death resulting in higher killing efficiency of virus-specific CD8 T cells though reduced mitochondrial resilience. Strikingly, HBV infected hepatocytes did not display such increased susceptibility for cell death induction by CD8 T cell effector molecules. Consequently, mitochondria from HBV infected hepatocytes showed normal stress resilience. Most importantly, co-infection with HBV reversed the adenovirus-induced sensitivity towards immune-mediated cell death induction leading to reduced killing efficiency of HBV-infected hepatocytes.
Conclusion: Here, we demonstrate that HBV infected hepatocytes do not only escape the non-canonical CTL effector function but are also more resistant towards CD8 T cell mediated killing. This identifies a so far not appreciated immune escape of HBV at the level of immune cell effector function against virus-infected hepatocytes. Overcoming this immune escape bears the promise to help in immune-mediated clearance of HBV-infected hepatocytes.

FRI-224
A novel imaging approach to investigate hepatitis E virus entry
Rebecca Fu[1], Zoe Engels[1], Jasmin Weihs[1], Jungen Hu[1], Viet Loan Dao Thi[1,2]. *[1]Schaller Research Group, Department of Infectious Diseases, Virology, University Hospital Heidelberg, Heidelberg, Germany [2]German Centre for Infection Research (DZIF), Partner Site Heidelberg, Heidelberg, Germany*
Email: vietloan.daothi@med.uni-heidelberg.de

Background and aims: Hepatitis E virus (HEV) is a major causative agent of acute hepatitis and mainly transmitted faecal-orally. HEV particles in faeces are non-enveloped (nHEV) and responsible for host-to-host transmission, while those in the blood possess a cell-derived lipid envelope (eHEV) allowing HEV to disseminate within the host. Studies on nHEV entry pathways have been controversial and no entry receptor has been identified for either form yet. A previous study proposed integrin alpha 3 (ITGA3) as a potential host factor of nHEV entry, but no follow-up studies have been made. In this study, we aimed to develop a new imaging approach, combined with the use of entry inhibitors, to study single HEV particles upon cell entry.
Method: We used fluorescent *in situ* hybridization and immunofluorescence staining to detect the HEV genome and the capsid, respectively. We knocked out (KO) the partner of ITGA3, namely integrin beta 1 (ITGB1), in hepatoma cells. We used chemical inhibitors, siRNAs, GFP-tagged Rab proteins together with their dominant-negative counterparts to study the cell entry pathways used by the two HEV forms.
Results: We successfully established the detection of single incoming HEV particles during early hours of infection (Figure 1A). We found that the binding and infection of nHEV but not eHEV particles was less efficient in ITGB1 KO cells as compared to WT cells. We observed that the genome dissociated from the capsid approximately 7 h post-infection (p.i.), suggesting a rather slow entry process. Endosomal acidification inhibitors led to intracellular capsid accumulation and thus unsuccessful genome release. Affirmingly, these inhibitors decreased both eHEV and nHEV infection in a dose-dependent manner. However, eHEV exhibited higher sensitivity to these inhibitors than nHEV (Figure 1B). For nHEV, knocking down the early endosome marker Rab5 had only a minor effect, while the knockdown of the recycling and late endosome markers Rab11 and Rab7 resulted in strong capsid accumulation and thus unsuccessful cell entry and infection. In contrast, we found eHEV entry to rather depend on the classic endocytic pathway based on Rab5 but not Rab11.

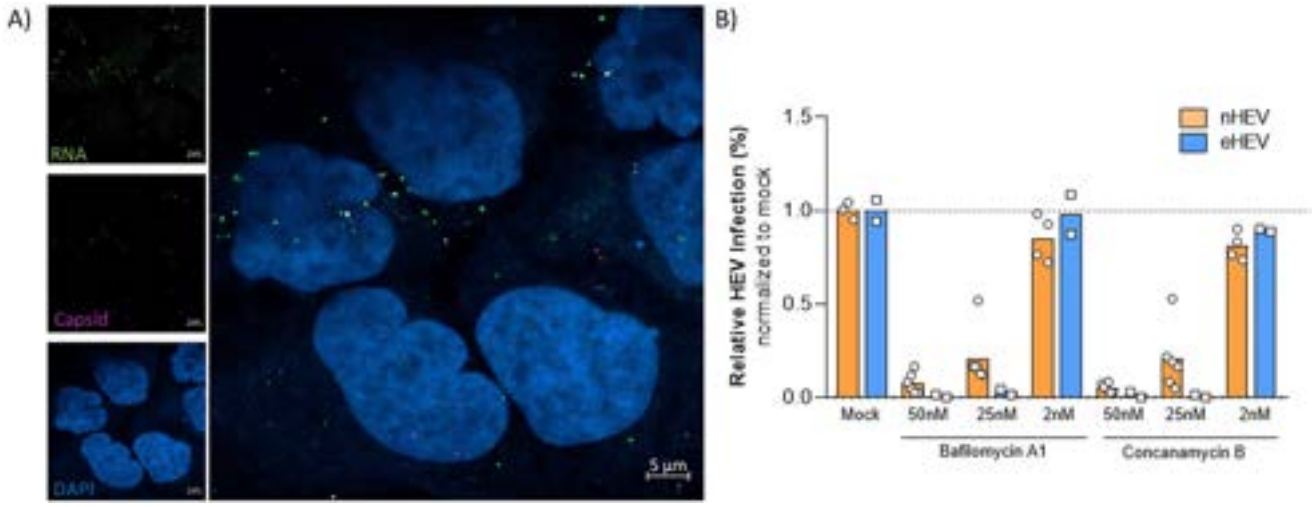

Figure: (abstract: FRI-224): (A) Co-detection of nHEV RNA and capsid 5 hours post-internalization. White arrows indicate co-localized particles. (B) Different sensitivity of nHEV and eHEV to endocytic inhibitors.

Conclusion: Using our novel entry assay, we found that the two HEV forms differentially depend on integrins and that they use likewise differential pathways to enter the cell. Our efforts shall lead to a better understanding of the HEV cell entry mechanism and may ultimately contribute to the development of specific anti-HEV therapies.

FRI-225

CTLA4 inhibits anti-HBs secretion by blocking BCR signaling pathway in chronic hepatitis B infection

Minxin Mao[1], Shengxia Yin[2], Yawen Wan[3], Ming Li[1], Yu Geng[1], Xin Tong[2], Jie Li[2], Chao Wu[1,2]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjing, China; [2]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China; [3]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Xuzhou Medical University, Xuzhou Medical University, Xuzhou, China*
Email: dr.wu@nju.edu.cn

Background and aims: It has been reported that there is no significant change in the number of HBsAg specific B cells in chronic hepatitis B (CHB) patients. However, the vast majority of

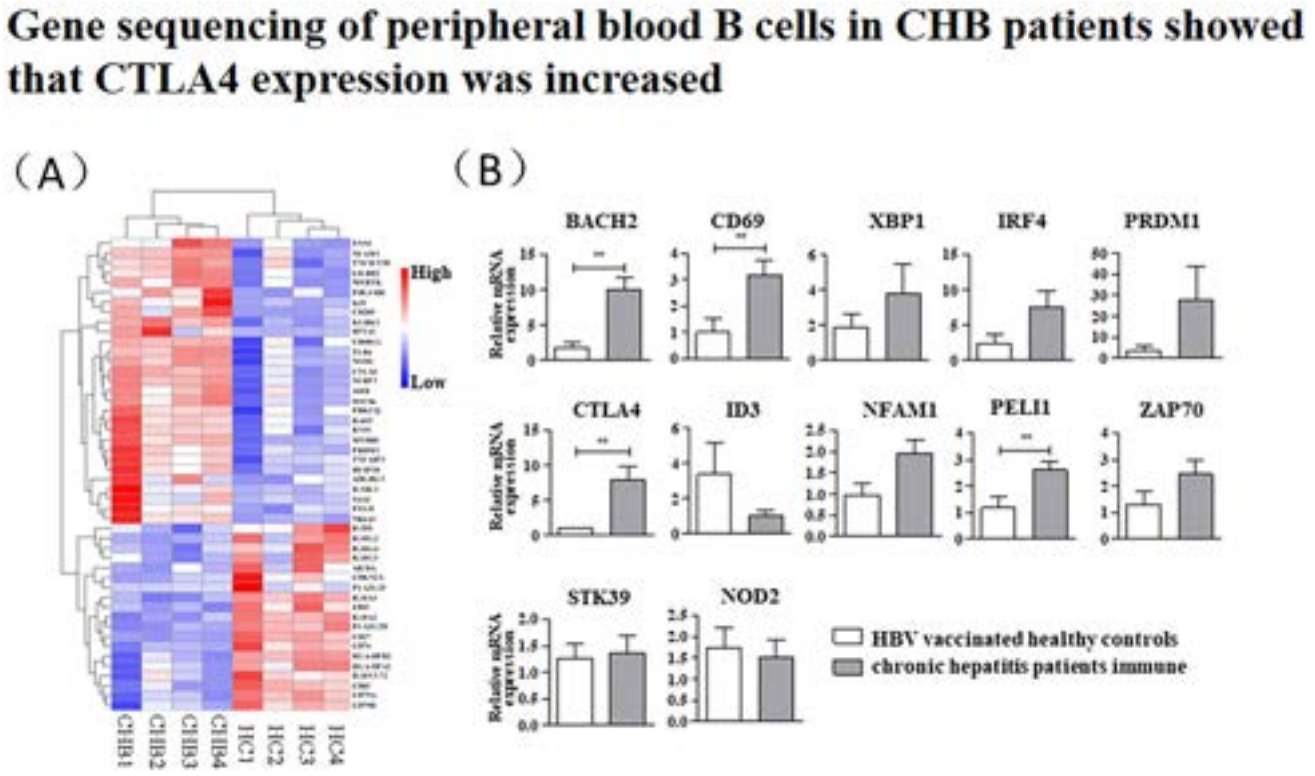

Figure: (abstract: FRI-225).

CHB patients are anti-HBs negative. B cells are the main source of antibodies in humoral immunity against HBV infection. It is believed that the deficiency of anti-HBs is caused by the dysfunction of anti-HBs secretion by HBsAg specific B cells. Therefore, more attention should be paid to the activation of HBsAg specific B cells and the cause of the inhibition of anti-HBs secretion.
Method: Peripheral blood B cells from 4 healthy controls (HC) and 4 CHB patients were collected by flow sorting technology for single cell sequencing, and the sequencing results were analyzed by GO analysis. Blood samples were collected from CHB patients and HC, and the changes in the proportion of peripheral blood B cells were detected by flow cytometry. HBsAg specific B cells were identified by fluorescent dye labeling. Peripheral blood B cells from CHB and HC were sorted by flow cytometry, and B cell cytokines, signaling pathways and antibody secretion by blocking CTLA4 signaling pathway were detected. Using immunocoprecipitation (CO-IP), anti-CTLA4 antibody was used to precipitate CTLA4 protein complex, and the protein complex was analyzed by protein general spectrum to identify the differences in phosphorylation levels of downstream proteins and related proteins bound to the complex.
Results: GO analysis showed that the expression levels of multiple proteins in the BCR signaling pathway of B cells were decreased, suggesting that the BCR signaling pathway was blocked. Flow cytometry analysis of peripheral blood B cells from CHB patients and HC showed that CTLA4 protein was highly expressed in B cells from CHB patients, and the increase of CTLA4 expression was more significant in HBsAg specific B cells. We further phenotyped infiltrating B cells in liver biopsy tissues from 5 CHB patients and found that the expression level of CTLA4 in liver B cells was positively correlated with peripheral blood B cells. ELIspot assay showed that after blocking CTLA4, B cells in some CHB patients recovered the ability to secrete anti-HBs. Calcium flow experiments showed that BCR dependent calcium flow was significantly reduced in HBsAg specific atMBC cells infected with chronic HBV infection, and the conduction of calcium flow was partially restored after the addition of anti-CTLA4. Western Blot test found that HBsAg specific atMBC BCR signaling pathways in cell signal more abnormal protein phosphorylation levels, after adding anti-CTLA4 p-Src, p-BLNK rise obviously, BCR intracellular signal transduction recovered to a certain extent. CO-IP results showed that the phosphorylation level of CTLA4 signaling pathway downstream was inhibited.
Conclusion: High expression of CTLA4 protein in circulating B cells and liver-infiltrating B cells blocks BCR signaling, thereby inhibiting anti-HBs secretion. Therefore, the abnormal expression of CTLA4 protein on B cells may be one of the reasons for the loss of virus specific humoral response during CHB infection.

Background and aims: GS-US-389–5458 is an open label phase1b study of selgantolimod, an oral selective small molecule agonist of Toll-like receptor 8 (TLR8) in special populations of subjects with chronic hepatitis B (CHB). Here we investigate the effect of selgantolimod on the periphery and liver microenvironment in the inactive carrier (IC) population of CHB.
Method: IC CHB subjects (HBV DNA <2000 IU/ml, qHBsAg ≤1000 IU/ml and ALT ≤ULN by AASLD 2018 guidelines) received weekly dosing of 3 mg selgantolimod for 24 doses. Paired core needle liver biopsies were collected from 4 IC participants during screening as well at week 23 2-6 hours post selgantolimod dosing. Matching PBMCs and fixed whole blood samples were collected at the same timepoints. RNA was isolated from the peripheral and liver tissue samples and bulk RNAseq, T-cell receptor (TCR), and B-cell receptor (BCR) sequencing was performed using Illumina TruSeq and Takara SMARTer TCR/BCR Profiling Kits. RNAseq alignment was performed using TopHat and Cufflinks. Differentially expressed genes were identified using a linear mixed effect model (DESeq2). Changes in immune pathways of interest were characterized using single-sample Gene Set Enrichment Analysis (ssGSEA). Immune cell composition was estimated using quanTIseq. Clonotype assembly for BCR and TCR sequencing utilized an MiXCR pipeline. Repertoire diversity was quantified using Inverse Simpson Index.
Results: Transcriptional profiles of paired liver biopsies and matched peripheral blood were compared to evaluate modifications in these compartments after treatment with selgantolimod. While we did not observe consistent alterations to the peripheral transcriptional landscape, there were some notable changes in all subjects within the liver. Specifically, a number of genes had increased expression, including regulation of macrophage chemotaxis (*CSF1*), inflammatory cytokines (*STAT1, IL6, TNFAIP3, MYD88, TLR7*), activation and proliferation of cytotoxic T cells (*CD69, CD44, TAP1*), and mature B cell differentiation (*LYN*). Cell deconvolution analyses showed an increase in the averages of M1 Macrophages (1.7-fold), regulatory T cells (4.6-fold), and B cells (1.9-fold) within the liver. TCR analysis of the liver did not indicate consistent expansion or shifts within the liver microenvironment despite increases in T cell activation-related genes. Analysis of B cell receptor repertoires in liver revealed an increase in clonotypic diversity after treatment (mean 1.8-fold). Additionally, we identified a specific heavy chain V gene family, 3–74 that had expanded in the liver but not the periphery upon treatment in two of the four subjects (ranging from ~1.5–5-fold increase within the liver).
Conclusion: Our data indicate that selgantolimod treatment in CHB patients could drive upregulation of inflammation-associated genes within the liver microenvironment, promoting activation of pro-inflammatory myeloid, B and T lymphocytes. Additionally, subsequent weekly treatment with selgantolimod may drive changes to the B cell compartment to both increase diversity of the immunoglobulin repertoire and enrich specific antibody families that may be specific to HBV.

HBs-directed T cell engager antibodies foster efficient recruitment of T cells and lead to strong reduction of hepatitis B virus infection in livers of human liver chimeric mice

Annika Volmari[1,2], Oliver Quitt[3], Pin Xie[4], Tassilo Volz[1,2], Lena Allweiss[1,2], Ke Zhang[4], Ulrike Protzer[2,3], Maura Dandri[1,2]. [1]*University Medical Center Hamburg-Eppendorf, I. Medical Department, Hamburg, Germany;* [2]*German Center for Infection Research (DZIF), Hamburg-Luebeck-Borstel-Riems and Munich sites, Germany;* [3]*Technical University Munich/Helmholtz Munich, Institute of Virology, School of Medicine, Germany;* [4]*SCG Cell Therapy, Shanghai, China*
Email: a.volmari@uke.de

Background and aims: Current treatment options for chronic Hepatitis B (CHB) efficiently suppress viral replication but rarely achieve a functional cure. Virus-specific adaptive immunity is lacking or dysfunctional in CHB patients and restoration of a functional antiviral T cell response has the potential to promote cure. Recent studies have shown that bispecific antibodies binding HBV envelope proteins (HBVenv) on infected hepatocytes and CD3 and CD28 on T cells target and kill HBV infected cells (*Quitt et al. J Hepatol. 2021*). The aim of this study was to assess liver targeting and antiviral efficacy of these T cell (Tc-)engager antibodies *in vivo* in HBV infected human liver chimeric mice in the presence of high circulating HBsAg levels.
Method: Humanized mice that were stably (12w) or partially (4w) infected with HBV received PBMCs isolated from healthy human

blood at day 0 and 4 of treatment and four i.p. injections of a combination of bispecific Tc-engager antibodies recognizing HBVenv and either CD3 or CD28 (1 mg/kg body weight, every 3 days). Control mice received PBMCs and PBS. Virological markers and cell infiltration were determined by qPCR, ELISA, immunofluorescence, RNA *in situ* hybridization (RNAscope) and flow cytometry.

Results: *In vitro* assays showed high specificity of the Tc-engager antibodies and determined an optimal treatment ratio of 1:1 to induce efficient activation of T cells, elimination of target cells and antiviral effects. Treatment of stably HBV-infected mice (median viremia of 7×10^8 HBV DNA copies/ml; median HBsAg 3×10^3 IU/ml) with Tc-engager antibodies and human PBMCs induced strong intrahepatic recruitment of human CD4+ and CD8+ T cells. Antibody treatment resulted in reduction of viremia (1.4log), circulating HBsAg (0.69log) and HBeAg (0.55log) in only 11 days. Intrahepatic levels of HBV pregenomic (pg)RNA (0.7log), HBV DNA (1.4log) and cccDNA (0.9log) were efficiently reduced. Histology and RNAscope revealed reduced numbers of HBcAg+ cells and substantially lower HBV-RNA in infected hepatocytes. These changes were accompanied by a transient increase of ALT, increased expression of granzyme B, IFN-γ and TNF-α, and reduction of human serum albumin, indicating human hepatocyte killing. Treatment of partially infected mice efficiently reduced intrahepatic levels of HBV RNA (0.7log), HBV DNA (1log) and cccDNA (0.8log), demonstrating specific recognition of infected cells also in livers harboring lower numbers of HBV+ cells.

Conclusion: Treatment of HBV-infected humanized mice with bispecific Tc-engager antibodies after transfer of human PBMCs efficiently reduced HBV viral load *in vivo*, demonstrating their recruitment to the liver and potent recognition of infected hepatocytes despite the presence of high circulating HBsAg levels, as well as induction of both cytolytic and cytokine-mediated HBV-specific T cell immunity.

HBV and HDV interaction and variability in a superinfection mouse model: role of type I interferon

Beatriz Pacín Ruiz[1,2,3], Gracián Camps Ramón[4], Maria Francesca Cortese[1,2,3], Josep Gregori[5], Selene Garcia-Garcia[1,2,3], David Tabernero[1,3], África Vales Aranguren[4], Adrian Najarro[1], Cristina Olague Micheltorena[4], Ariadna Rando-Segura[1], Josep Quer[5], Rafael Esteban[3,6], Mar Riveiro Barciela[3,6], Maria Buti[3,6], Gloria González-Aseguinolaza[4], Francisco Rodríguez-Frías[1,3,5]. *[1]Vall d'Hebron Barcelona Hospital Campus, Microbiology/Liver Unit, Barcelona, Spain; [2]Universitat Autònoma de Barcelona, Biochemistry and Molecular Biology Department, Bellaterra, Spain; [3]Carlos III Health Institute, Network Center For Biomedical Research in Hepatic and Digestive Diseases (CIBERehd), Madrid, Spain; [4]University of Navarra, Center for Applied Medical Research (CIMA), Pamplona, Spain; [5]Vall d'Hebron Barcelona Hospital Campus, Liver Unit, Liver Disease, Laboratory-Viral Hepatitis, Barcelona, Spain; [6]Vall d'Hebron University Hospital, Liver Unit, Department of Internal Medicine, Barcelona, Spain*
Email: beatriz.pacin@vhir.org

Background and aims: The hepatitis delta virus (HDV) inhibits the hepatitis B virus (HBV) replication and, differently from its helper, it activates the interferon pathway, inducing the expression of mutagenic enzymes such as ADAR1. This study aimed to inspect the relation between HDV and HBV variability and the role of type I interferon (IFN-I) by studying both viruses' variability upon HDV superinfection in an HBV-expressing transgenic (HBVtg) mouse model knock-out for the IFNalpha/beta-receptor (HBVtgxIFNAR-KO).

Method: HBVtgxIFNAR-WT and HBVtgxIFNAR-KO mice were infected with 5×10^{10} viral genomes of an adeno-associated vector expressing luciferase or HDV. HBV expression was weekly monitored by quantifying the HBV DNA and RNA in plasma. Intrahepatic viral RNA was extracted at 7- and 21-days post injection (dpi) to quantify the pregenomic RNA (pgRNA) and to study HBV and HDV quasispecies (QS) in respectively HBX (5′-HBX between nucleotide [nt] 1255 to 1611 and 3′-HBX between 1596 and 1936) and HDAG (nt 912–1298 in genome) by next-generation sequencing (NGS). QS variability between the groups was evaluated by identifying the single nucleotide variations (SNVs), whereas HDV editing was quantified by evaluating the percentage of haplotypes with the A281G variation (editing site).

Results: A strong reduction of circulating HBV DNA and RNA was observed in presence of HDV especially at 21 dpi. This effect reverted when the IFN-I pathway was inhibited. This trend was not confirmed in liver tissue, where similar concentrations of pgRNA were observed between groups. Several SNVs, especially C to T transition, were detected in the *HBX* gene over time (CT transition/total mutated positions = 7/15 vs 20/44 at 7 vs 21 dpi, respectively). Some of them were specifically identified in HDV HBVtgxIFNAR-WT mice and involved trans-activation domain of the HBX gene at intrahepatic level. HDV genome editing was low at 7 dpi, and increased at 21 dpi, especially in HDV HBVtgxIFNAR-WT mice ($p = 0.002$). Several SNVs, remarkably A to G transitions, were also spotted in HDAg (75 vs 28 for 7 vs 21 dpi, respectively). Notably, most of the SNVs observed at 7 dpi were also identified at 21 dpi for both HBV and HDV QS.

Conclusion: In our model, the presence of HDV mainly interfered with HBV particle release rather than intrahepatic expression. Of note this effect seems IFN-I dependent. Several transitions, typical of the intracellular mutagenic enzymes, were observed in both HBV and HDV, and some of them were identified at both timepoints, suggesting that these enzymes might contribute to the viral variability by acting on viral mutational hotspot. In HBV, some of these variations specifically interested the trans-activation domain of the HBX gene and could probably contribute to HBV inhibition.

FRI-229

Rapid functional secretome analysis of HBV-specific T cells to guide clinical management of CHB patients

Nina Le Bert[1], Apostolos Koffas[2], Anthony Tan[1], Lung-Yi Mak[2], Sophie Stretch[2], Shou Kit Hang[1], Haiyan Ma[3], Ariel Lee[3], Yun Ji[4], Upkar Gill[2], Qi Chen[1], Qing Zhu[4], Antonio Bertoletti[1], Patrick Kennedy[2]. *[1]Duke-NUS Medical School, Singapore; [2]Queen Mary University of London, United Kingdom; [3]T Cell Diagnostics/Hyris, Singapore; [4]Brii Biosciences Limited, United States*
Email: antonio@duke-nus.edu.sg

Background and aims: Control of Hepatitis B virus (HBV) infection requires functional virus-specific T cells, yet clinical management of patients with chronic HBV infection (CHB) relies exclusively on the assessment of virological and biochemical biomarkers. We aimed to develop a robust rapid assay to measure cytokines secreted or induced by HBV-specific T cells (secretome) with efficient throughput and minimal invasiveness to allow the integration of immunological biomarkers in CHB clinical management.

Method: We designed a rapid HBV-specific T cell test method based on the stimulation of whole blood with customized peptide mixtures covering the envelope, nucleoprotein, polymerase and X protein of different HBV genotypes followed by the quantification of plasma cytokines (IFN-γ, IL-2, IL-10, granzyme B, TNF-α, IL-4). The assay performance was tested in healthy HBs vaccinees ($n = 32$) and in treated ($n = 31$) and treatment naïve ($n = 42$) CHB patients. In selected patients, the sensitivity of the assay was compared with ex vivo and in vitro expansion ELISpot assays and by spiking known numbers of engineered HBV-specific CD8 T cells into whole blood.

Results: Cytokines produced by peptide mixtures covering the different HBV proteins can be individually measured utilizing only 2 ml of whole blood from HBs vaccinees and CHB patients. Sensitivity of the assays was comparable and at times even superior to traditional T cell assays. Spiking known numbers of HBV-specific CD8 T cells into whole blood demonstrated that this assay can detect as little as 50–100 HBV-specific T cells in 400 μl/whole blood, a sensitivity corresponding to an HBV-specific T cell frequency in total T

cells of 0.02–0.04%. The quantity and ratio of cytokines detected in different CHB patients revealed a vast heterogeneity of secretome profiles. Through multiple logistic regression, the measured immunological parameters were capable of accurately (ROC AUC = 0.9363) segregating untreated CHB patients with high or low viral load.
Conclusion: We demonstrated that we can accurately assess quantity and multi-functionality of HBV-specific T cells in patients without complex in-vitro manipulation in a small volume of whole blood. The assay sensitivity is comparable with known frequencies of circulating HBV-specific T cells in CHB. Global measurement of cytokines secreted or induced by HBV-specific T cells provides a novel biomarker for the interpretation of host-viral interactions in different categories of CHB patients and can signpost the selection of novel immunotherapies.

FRI-230
Identification and functional analysis of miR-4461 associated with hepatitis B-derived hepatocellular carcinomas
Aiko Sakai[1], Masaya Sugiyama[1]. [1]*National Center for Global Health and Medicine, Japan*
Email: msugiyama@hosp.ncgm.go.jp

Background and aims: The development of hepatocellular carcinoma (HCC) due to hepatitis B is difficult to predict. One reason is that its pathogenesis is not due to a persistent accumulation of inflammation. The molecular changes that occur in cells persistently infected with hepatitis B virus (HBV) are not clear on a cell-by-cell basis. The impact of those HBV-infected cells on the pathogenesis of the disease is also unknown. In this study, single-cell RNA-seq (scRNA-seq) analysis of HBV-infected cells was performed to investigate changes in gene expression on a single-cell basis. The molecules relating to HCC were identified and their functions were analysed.
Method: After the infection of primary hepatocytes with HBV, their scRNA-seq analysis was performed. scRNA-seq data were compared between HBV RNA-positive and negative hepatocytes (cell populations in the same environment) in one dish. The miR-4461 levels of HuH7 and HepG2 cells with and without HBV were identified and analyzed for cell proliferation, invasion and migratory capacity. Target genes to which miR-4461 bound were explored by in vitro assay. miR-44661 was quantified in HCC and non-HCC areas using resected liver tissue of hepatitis B and non-B/non-C.
Results: Primary hepatocytes were infected with HBV and then scRNA-seq was performed. miR-4461 was significantly reduced in HBV-infected hepatocytes. miR-4461 expression was reduced when HBV replication plasmids were transfected into HuH7 and HepG2 cells. siRNA knockdown of miR-4461 enhanced the proliferation, invasive and migratory capacity of HuH7 and HepG2 cells. miR-4461 expression levels were confirmed in liver tissues from hepatitis B and non-B/non-C HCC patients. In non-B/non-C specimens, no difference of the miR-4461 expression was observed in both HCC and non-HCC areas compared to normal liver tissue. On the other hand, in hepatitis B specimens, the expression of miR-4461 was lower than that of normal liver ($p < 0.05$). in addition, the expression in HCC areas was lower than non-HCC areas ($p < 0.05$). Target genes of miR-4461 were explored using database and in vitro assay. Then, the FGA gene was one of the targets of miR-4461.
Conclusion: The miR-4461 pathway was suggested to be associated with the establishment and pathogenesis of HBV infection. miR-4461 levels were reduced in liver tissue derived from hepatitis B, and a more significant reduction was observed in HCC area, suggesting that this pathway could be a useful biomarker for HBV-derived HCC.

FRI-231
Reduced hepatic bile acid uptake and blocked hepatitis B viral infection after oral administration of novel small molecule inhibitors of the sodium taurocholate co-transporting polypeptide (NTCP)
Kalliopi Pervolaraki[1], Jean-Christophe Vanherck[1], Charlène Marcadet[1], Lieven Verhoye[2], Amse De Meyer[2], Madina Rasulova[3], Heyrhyoung Lyoo[3], Jasmine Paulissen[3], Hendrik Jan Thibaut[3], Kristof De Vos[3], Patrick Chaltin[4], Johan Neyts[3], Pieter Annaert[3], Philip Meuleman[2], Arnaud Marchand[1], Matthias Versele[1], Stan van de Graaf[5]. [1]*CISTIM Leuven vzw, Leuven, Belgium;* [2]*Ghent University, Ghent, Belgium;* [3]*Katholieke Universiteit Leuven, Leuven, Belgium;* [4]*Centre for Drug Design and Discovery, Leuven, Belgium;* [5]*Amsterdam Umc, locatie AMC, Amsterdam, Netherlands*
Email: k.f.vandegraaf@amsterdamumc.nl

Background and aims: The sodium taurocholate co-transporting polypeptide (NTCP, *SLC10A1*) is selectively expressed on the basolateral membrane of hepatocytes and is the main transporter of conjugated bile acids. NTCP also serves as the entry receptor for the hepatitis B virus (HBV) and hepatitis delta virus (HDV). Daily injection with bulevirtide, previously known as Myrcludex-B, a synthetic peptide mimicking the NTCP-binding domain of HBV, is approved in the EU for treatment of patients co-infected with HBV and HDV. Preclinical studies suggest that pharmacological inhibition of hepatic bile salt uptake using bulevirtide ameliorates cholestatic liver injury. Both treatment of viral hepatitis and cholestatic liver diseases require chronic treatment, thus indicating the necessity of orally available small molecule inhibitors for this liver-specific transporter/receptor.
Method: A comprehensive drug discovery effort was conducted to identify and optimize potent and selective small-molecule inhibitors of NTCP-mediated bile acid uptake and HBV/HDV entry with adequate *in vitro* ADME characteristics. Several examples were evaluated for impact on bile acid disposition in sandwich-cultured human hepatocytes. Oatp1a/1b deficient mice were used to determine *in vivo* impact on bile acid kinetics. Finally, effects of a lead compound on HBV infection were determined in a urokinase-type plasminogen activator-severe combined immunodeficiency (uPA-SCID) humanized liver mouse model.
Results: Several new compounds were synthesized with single-digit nM potency for NTCP and high selectivity (>100×) against ASBT and BSEP mediated bile acid uptake. Consistently, derivatives of this series dose-dependently reduced intracellular bile acid levels in sandwich-cultured human hepatocytes. PK/PD experiments in Oatp1a/1b deficient mice and in uPA/SCID humanized liver mice illustrated prolonged target engagement (elevation of serum bile acid levels) allowing for once daily oral dosing schedules. *In vitro* infection studies demonstrated low nM HBV and HDV entry inhibition, similar to bulevirtide. Finally, a lead compound completely blocked HBV infection *in vivo* using once daily oral administration in a humanized liver mouse model.
Conclusion: Here we developed orally bioavailable small molecule inhibitors of NTCP with similar anti-HBV efficacy as bulevirtide. This strategy can also be applied to lower hepatocellular bile acid accumulation in cholestatic disease.

FRI-232
The divergent C-terminus of L-HDAg regulates the dynamic life cycle of HDV and the responses to lonafarnib treatment
Hongbo Guo[1,1], Qiudi Li[1], Yi Ni[2], Kuiyang Zheng[1], Stephan Urban[2], Wenshi Wang[1]. [1]*Jiangsu Key Laboratory of Immunity and Metabolism, Department of Pathogenic Biology and Immunology, Xuzhou Medical University, Xuzhou, China;* [2]*Department of Infectious Diseases, Molecular Virology, University Hospital Heidelberg, Germany*
Email: wenshi.wang@xzhmu.edu.cn

Background and aims: Different life-cycle kinetics of Hepatitis D virus (HDV) genotypes 1–8 were reported previously. C-terminal extension, the only difference between L- and S-HDAg, enables L-HDAg to inhibit HDV replication, but also mediate HDV assembly, thus being the natural drug target of lonafarnib. Strikingly, these residues are highly divergent among genotypes. Therefore, their roles in the life-cycle of HDV and the treatment responses of lonafarnib on HDV were investigated.
Method: Constructs to express chimeric or mutant L-HDAg were created. Their roles in HDV replication and production were investigated using northern blot, reverse-transcription quantitative PCR, and an HDV trans-complementary system established.
Results: C-terminus of L-HDAg of HDV 1–8, although highly divergent, inhibits HDV replication and supports virus production with similar efficacy. The prolines and hydrophobic residues of C-terminus, together with the isoprenylated site, support HBV enveloped HDV, while not needed for non-HBV envelopment. In contrast, the isoprenylated site, but not the prolines and hydrophobic residues, contributes to the trans-inhibitory function of L-HDAg, explaining the double mode-of-actions of lonafarnib on HDV. Besides blocking HDV assembly, lonafarnib promotes intracellular HDV replication solely via inhibiting L-HDAg isoprenylation, while not through an off-target effect on host prenylated proteins.
Conclusion: The divergent C-terminus of L-HDAg *per se* is not the underlying cause to explain the different kinetics of HDV 1–8. During HDV envelopment, the isoprenylated site and the hydrophobic residues of L-HDAg might conduct hydrophobic interactions with the hydrophobic C-terminus of S-HBsAg, while the prolines may extend the C-terminus out of L-HDAg to facilitate this interaction. These findings provide insights into HDV envelopment, and also the usage of lonafarnib against HDV in clinic.

FRI-233

A novel recombinant HBV based selection system allows for a systematic genomic knock-out screening and the identification of host factors involved in HBV infection

Bo-Hung Liao[1], Rupert Öllinger[2], Wen-Min Chou[1], Andreas Puschnik[3], Cho-Chin Cheng[1], Jochen Wettengel[1], Roland Rad[2], Ulrike Protzer[1].
[1]Institute of Virology, Munich, Germany; [2]Institute of Molecular Oncology and Functional Genomics, Germany; [3]The Chan Zuckerberg Biohub, United States
Email: protzer@tum.de

Background and aims: HBV infection is a global health issues with >285 million of humans living with chronic HBV infection. Unfortunately, our knowledge about the early steps of the virus replication cycle up to the establishment of the nuclear HBV persistence form, the covalently closed circular DNA (cccDNA), are limited. HBV infection relies on host factors rendering these prospective therapeutic targets. Wild type HBV infection is widely used to screen for these host factors which, however, precludes an analysis on a single cell level. We therefore designed a recombinant HBV (rHBV) expressing part of Cre recombinase complementing a cellular counterpart to perform a systematic genome wide CRISPR-Cas9 knock-out screening at a single cell level.
Method: Fluorescent microscopy and flow-cytometry were conducted to optimize the infection rate of rHBV. The Cre-lox system consists of a rHBV that encodes the N-terminal Cre and HepG2 cells that stably express the HBV-receptor NTCP and the C-terminal part of Cre recombinase as well as a reporter cassette flanked by *lox*P sites (HepG2-K7-NTCP-CreC Induced Red (CCIR)). Lentivirus transduction system was applied to introduce Cas9 and a genome-wide human sgRNA knock/out library into the cells. Next generation sequencing (NGS) was performed to deeply sequence the sgRNAs in the cells and followed by the calculation of sgRNA enrichment scores by MAGeCK module analysis.
Results: The split Cre-*lox*P rHBV infection system allowed for both, positive and negative selection of infected cells. Positive selection uses a reporter gene that is expressed upon rHBV infection and recombination. Negative selection is achieved by antibiotics as antibiotics resistance is lost due to Cre-*lox*P recombination. Using numerous rounds of infection and subsequent antibiotic selection, we optimized the infection and selection protocol. This allowed us to get around the main drawback of cell-culture HBV infection, its low infection rate. The Cas9 and genome-wide gRNA library introduced into the CCIR cells now allowed to carry out first genome-wide host factors knock-out screenings at the single-cell level. Using NGS, we were able to confirm ZCCHC14 as a top-ranked candidate and identify new host factors involved in HBV infection. We are now validating the discovered candidates and inhibitors that may serve as potential antivirals.
Conclusion: We introduced a novel rHBV infection system that establishes a permanent infection mark via Cre-*lox*P recombination and enables positive and negative selection of infected cells. After optimization of infection and selection, genome-wide host factor knock-out screenings at the single-cell level identified ZCCHC14 and other host factors participating in the HBV infection. This now allows to dive into the mechanism behind these and explore possible inhibitors targeting these as candidate therapeutics.

miR-26a targets USP15 to robustly suppress hepatitis E virus replication via the enhancement of RIG-I-mediated type I interferon response

Jikai Zhang[1], Dan Liu[1], Zijie Wang[1], Renxian Tang[1], Hongbo Guo[1], Wenshi Wang[1]. [1]*Xuzhou Medical University, China*
Email: wenshi.wang@xzhmu.edu.cn

Background and aims: Hepatitis E virus (HEV) infection is the leading cause of acute viral hepatitis globally. However, no specific antivirals are available. Being one of the key host natural antiviral responses, small noncoding RNAs (miRNAs) represent a novel antiviral strategy. Nevertheless, the key miRNAs that regulate HEV life cycle remain largely elusive.
Method: IFN-β promoter activities were determined by dual luciferase reporter (DLR) assay. The mRNA levels of IFN-β, interferon stimulated genes (ISGs) and USP15 or the relative level of HEV RNA were determined by real-time quantitative PCR (qRT-PCR), respectively. The protein levels of USP15, RIG-I, IRF3 and HEV ORF2 were verified by immunoblotting or immunofluorescence assay (IFA). The interaction between USP15 and key elements of IFN pathway or the ubiquitination levels were determined by co-immunoprecipitation (co-IP) and immunoblot analyses.
Results: Herein, we found that miR-26a robustly suppressed HEV replication via the specific inhibition of USP15 expression. Mechanistic investigation revealed that USP15 interacts directly with the retinoic acid-inducible gene I (RIG-I) to deubiquitinate K63-linked RIG-I, thus negatively regulating type I interferon (IFN) signalling. Conversely, miR-26a, by downregulating USP15, promotes RIG-I K63-ubiquitination to enhance type I IFN antiviral responses, resulting in an active antiviral state against HEV. Intriguingly, the activation of type I IFN responses could suppress miR-26a expression, serving as an intrinsic negative feedback loop to maintain balanced activating signals.
Conclusion: This research identified a new anti-HEV miRNA and elucidated the antiviral mode-of-action. miR-26a may serve as a potential antiviral candidate for combating HEV infection.

Altered metabolic program initiates immune activation leading to hepatitis B surface antigen seroconversion in mild and severe hepatitis B reactivation patients

Jayesh Kumar Sevak[1], Mojahidul Islam[1], Anoushka Saxena[1], Gayantika Verma[1], Manoj Kumar[2], Ankur Jindal[2], Gayatri Ramakrishna[1], Shiv Kumar Sarin[2], Nirupma Trehanpati[1]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India*
Email: trehanpati@gmail.com

Background and aims: Rate of seroconversion in hepatitis B reactivation (rHBV) patients is based on the clinical syndrome. Along with elevated bilirubin, coagulopathy, ascites, hepatic encephalopathy, organ failure, systemic immune and metabolic responses play vital role in morbidity and mortality. Therefore, our **aim** was to understand the immune and metabolic responses in mild, sever and ACLF leading to seroconversion.
Method: Total sixty-seven rHBV patients (age 42 ± 13) with raised ALT (>5XULN) and HBV DNA$\log10^{4-8}$ categorized as mild (n = 42, INR < 1.5), severe (n = 10, INR > 1.5, bilirubin >2.5XULN) and ACLF (n = 15) were studied at baseline, week (wk) 12 and 24. Soluble inhibitory molecules and plasma metabolomics was assessed using multiplex bead array and mass spectrometry respectively. High dimensional immune cell profiling was done by flow cytometry.
Results: Of 67 patients, 12 were seroconverted, 7 from mild and five from severe group, but none was seroconverted from ACLF group. At

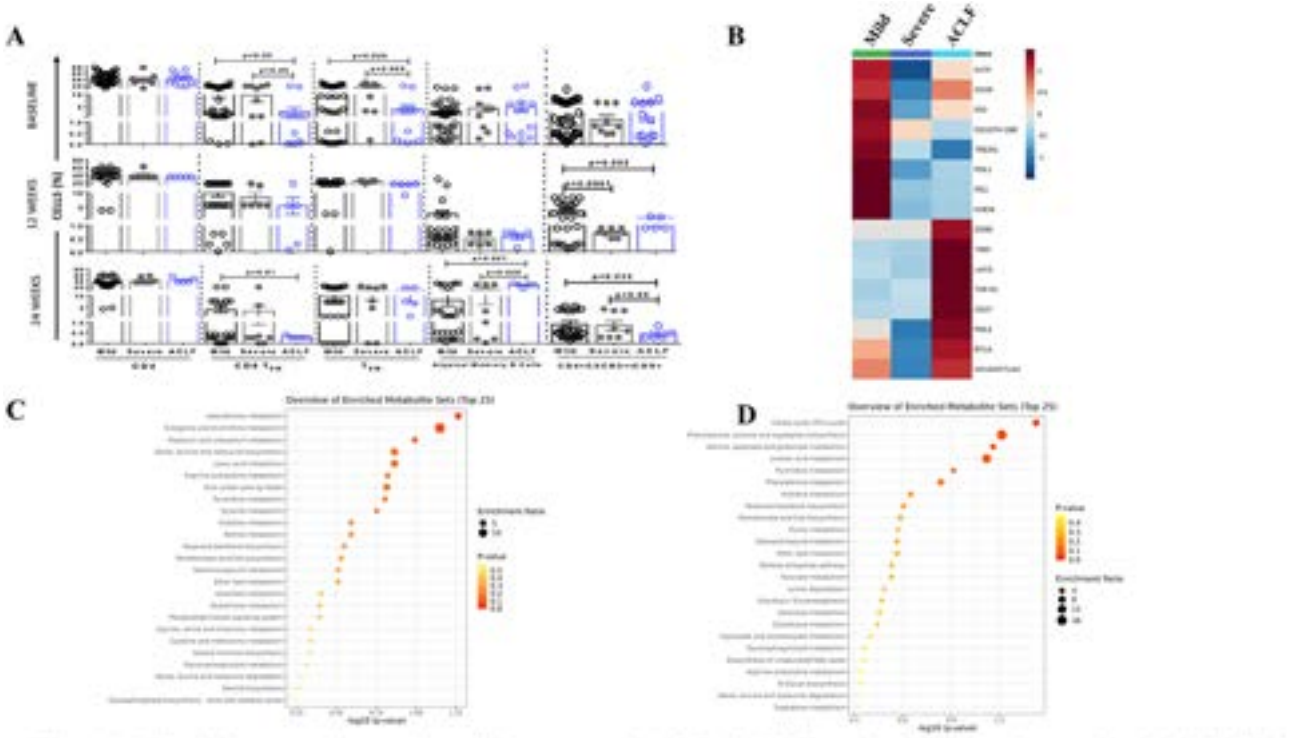

Fig: (A). Kinetic immune changes in mild, severe and ACLF of HBV reactivation. (B). Increased soluble inhibitory molecules in mild, severe and ACLF patients. (C).Pathway enrichment of mild patients at Baseline. (D). Pathway enrichment of ACLF at 24 week.

Figure: (abstract: FRI-235).

baseline, no significant difference was observed in the proportions of total CD4/CD8, central memory (CM), TEMRA, B cells, TFH cells and soluble inhibitory receptors except effector memory (EM) which was significantly compromised in ACLF patients compared to mild and severe. At baseline, metabolomics analysis revealed, 32 commonly expressed metabolites associated with beta alanine, arginine, ornithine, porphyrin, urobilinogen metabolism and valine, leucine and isoleucine biosynthesis in mild and severe groups. Which play critical role in exiting T cells from quiescence and leading to T cell activation and cytokine secretion. At wk 12, all B cell subsets including naïve, mature, activated, classical memory, plasma B cells were significantly increased in mild patients compared to severe and ACLF. In severe and ACLF patients, soluble TIM3, LAG3, PDL2, CD27 and CD80 and atypical memory B cells were significantly appeared more with decline in Tfh cells indicating exhausted B cells and formation of short lived plasma B cells. Further, in severe and ACLF patients, unique metabolites pertaining to purine, taurine, hypotaurine, phenylalanine metabolism were expressed with critical role in immune inhibition and anti-inflammatory response. At wk 24, B cells and TFH were significantly increased in mild and severe but declined in ACLF. In ACLF, 75 unique metabolites associated with TCA cycle, Phenylalanine, tyrosine, tryptophane biosynthesis, alanine, aspartate and glutamate metabolism leading to insulin resistance and metabolic alterations.

Conclusion: Our results show that metabolism of beta alanine, arginine, ornithine, porphyrin and urobilinogen contribute immensely to immune activation. Increase levels of soluble inhibitory molecules in ACLF leads to immune and metabolic dysfunction and multiorgan failure.

FRI-236

HBsAg level defines different clinical phenotypes of chronic HBV infection eAg (-) related to the quality of the HBV-specific CD8 cell response

Jeniffer Martínez[1,2], Henar Calvo Sánchez[2,3], Julia Peña Asensio[2], Alberto Delgado[2], Joaquin Miquel[2], Eduardo Sanz de Villalobos[2], Alejandro González Praetorius[2], Miguel Torralba[2,3], Juan Ramón Larrubia[2,3]. [1]*University of Alcalá, Department of Biology of Systems, Spain;* [2]*University Hospital of Guadalajara, Translational Hepatology Unit., Spain;* [3]*University of Alcalá, Department of Medicine and Medical Specialties, Spain*
Email: juan.larrubia@uah.es

Background and aims: Chronic e-Ag-negative HBV infection (CIBe (-)) is characterized by little progression of liver fibrosis and a vigorous HBV-multispecific CD8+ cell response. The level of HBV surface antigen (HBsAg) could differentiate different subtypes of CIBe (-). Aims: To evaluate whether HBsAg level correlates with different clinical phenotypes of CIBe (-) and with the quality of the HBV-specific CD8+ cell response.

Method: An analytical cross-sectional study was performed in a cohort of 56 patients with CIBe (-) followed-up for at least one year (95% CI: 5.5–7.5) with ALT<50 IU/ml, HBV viral load (VL) <20,000 IU/ml, APRI<0.5 and Fibroscan <7 KPa. HBsAg level (<300 IU/ml, 300–1000 IU/ml, >1000 IU/ml) was correlated with ALT, AST, APRI, liver stiffness by elastography, platelets, HBV VL, percentage of HBV VL measurements >2000 IU/ml, APRI/years of evolution ratio, Fibroscan (KPa)/years of evolution. In HLA-A2 positive patients we also analyzed the proliferation capacity of HBV-specific CD8+ cells against core18–27, polymerase456–63 and envelope183–91 epitopes after antigenic encounter, using pentameric technology by flow cytometry.

Results: A positive linear trend was observed between HBsAg level and APRI level (p = 0.002), Fibroscan (p = 0.004), ALT (p = 0.018), AST (p = 0.009), HBV VL (p = 0.037), frequency of HBV VL > 2000 IU/ml (p = 0.046) and a negative correlation with platelet level (p = 0.024), although all these values were always within the normal range. The frequency of cases with HBV-specific CD8+ cell response against at least two HBV epitopes was significantly higher in cases with HBsAg < 1000 IU/ml (p = 0.037) and this was due to a different response against polymerase456-63 (p = 0.022). This response was decreased in cases with HBsAg > 1000 IU/ml, while the response against HBVcore18–27 was preserved and the response against envelope183-91 was abolished, regardless of HBsAg level. Cases with preserved CD8+ cellular response against HBV polymerase456-63 had lower KPa/duration of infection (p = 0.036) and APRI/duration of infection (p = 0.004). The intensity of specific CD8+ HBV-polymerase456-63 CD8+ response was negatively correlated with Fibroscan (KPa)/years of infection evolution ratio (p = 0.027).

Conclusion: Some CIBe (-) patients with HBsAg > 1000 IU/ml present indirect data of higher degree of inflammation, liver stiffness and speed of fibrosis progression which are related to an altered anti-HBV-polymerase456-63 CD8+ cell response. In cases of CIBe (-) with HBsAg > 1000 IU/ml, the cytotoxic T cell response against polymerase should be evaluated and if absent, a liver biopsy should be performed to evaluate the need for treatment.

FRI-237

Chimeric bio-nanoparticles induce targeted HBeAg seroclearance in a HBV hydrodynamic injection mouse model

Yianni Droungas[1,2], Hugh Mason[1], Chee Leng Lee[1], Rachel Hammond[1], Stephen Locarnini[1], Renae Walsh[1], Hans Netter[1], Peter Revill[1,2]. [1]*Victorian Infectious Diseases Reference Laboratory, Royal Melbourne Hospital at the Peter Doherty Institute for Infection and Immunity, Australia;* [2]*Department of Microbiology and Immunology, The University of Melbourne, Victoria, Australia*
Email: peter.revill@mh.org.au

Background and aims: The hepatitis B e antigen (HBeAg) is a secreted viral protein important for establishing chronic HBV infection. HBeAg seroconversion is a current treatment end point and a preceding step to functional cure. This project utilised HBeAg-epitope expressing bio-nanoparticles (HBeAg-BNP) as immunogens in a hydrodynamic injection (HDI) mouse model of HBV persistent replication. HBeAg clearance was investigated as a novel therapeutic strategy.

Method: HBeAg-BNP candidates were bioengineered using a panel of HBeAg-specific epitopes. Immunogenicity studies were performed in BALB/c mice to identify the most immunogenic HBeAg-BNP candidates, which were then tested using the HDI mouse model. HBV markers of replication, protein expression and antibody production were assessed.

Results: Immunisations of naïve BALB/c mice with HBeAg-BNPs induced HBeAg-specific immune responses against the inserted HBeAg epitopes. Sera from HBeAg-BNP treated BALB/c mice detected HBeAg peptides and native HBeAg by ELISA. Two candidate HBeAg-BNPs (BNP1 and BNP2) were further tested using the HDI mouse model of persistent HBV replication, resulting in 40% (BNP1, 3/7 mice) and 66% (BNP2, 8/12 mice) HBeAg seroclearance. In addition, HBsAg loss was observed almost 20% of the HBeAg-BNP2 group (2/12 mice), with modest (up to 0.9 log) reductions in HBV DNA also observed in some BNP2-treated mice. HBeAg seroclearance, HBsAg loss, or reductions in HBV DNA were not observed in any wild-type BNP control mice (0/7). No difference was observed in the abundance of anti-core positive hepatocytes in BNP treated, or wild-type BNP control mice.

Conclusion: This is the first study to show that HBeAg-BNPs trigger HBeAg-specific immune responses against the native HBeAg and induce its seroclearance. In turn, treatment with HBeAg-BNP2 led to HBsAg loss and HBV DNA reductions in some mice, although did not lead to antibody-mediated clearance of HBV infected hepatocytes. These findings suggest that targeting HBeAg and the induction of anti-HBe antibodies should be further investigated as a novel therapeutic approach.

Pharmacodynamic durability of ALG-125755, a GalNAc-conjugated siRNA, correlated with total and RNA induced complex (RISC) bound siRNA in mouse liver

Kusum Gupta[1], Megan Fitzgerald[1], Jin Hong[1], Cheng Kao[1], Cheng Liu[1], Kha Le[1], Sucheta Mukherjee[1], Dinah Misner[1], Meenakshi Venkatraman[1], Matt McClure[1], Sushmita Chanda[2], John Fry[1], David Smith[1], Julian Symons[1], Lawrence Blatt[1], Leonid Beigelman[1], Tse-I Lin[2]. [1]*Aligos Therapeutics, Inc., United States;* [2]*Aligos Belgium Bv, Leuven, Belgium*
Email: kgupta@aligos.com

Background and aims: For the functional cure of chronic hepatitis B, a sustained loss of hepatitis B surface antigen (HBsAg) is required. Targeted small interfering RNAs (siRNAs) have recently demonstrated significant clinical reduction of HBsAg. ALG-125755 is a novel N-acetylgalactosamine (GalNAc)-conjugated siRNA currently in clinical development. Here we demonstrate its mechanism of action, and correlate the durable pharmacodynamics to total and RNA induced silencing complex (RISC) bound siRNA in mouse liver in the adeno-associated virus (AAV)-HBV mouse efficacy model.
Method: To confirm the mechanism of action of ALG-125755, argonaute-2 (AGO-2) degradation of the target S-region HBV RNA sequence induced by the antisense strand (AS), ALG-125736, was qualitatively measured using denaturing polyacrylamide gel electrophoresis. Total and RISC-bound siRNA quantification was performed in the harvested livers from a previously reported adeno-associated virus (AAV)-HBV mouse efficacy study, where a 10 mg/kg single dose or repeat doses up to 70 days at 5 mg/kg every other week (Q2W) or every four weeks (Q4W) demonstrated significant and durable decline in serum HBsAg. Liver samples (Days 14, 28, 70, each prior to the dose, and postdose timepoints at Days 98 and 168) from the single dose and repeat (Q2W) dose groups were analyzed by liquid chromatography-high resolution accurate mass method for total siRNA and immunoprecipitation/reverse transcription-quantitative polymerase chain reaction method for RISC-bound siRNA.
Results: The AS, ALG-125736, complementary to the highly conserved S-region of the HBV RNA sequence, induced cleavage of the target RNA sequence from the S-region of HBV by AGO-2. The engagement of ALG-125755 with AGO-2 protein was confirmed in vitro and also in vivo in the AAV-HBV mouse. Following a single dose in AAV-HBV mice, the half-life of RISC-bound siRNA (23.5 days) was two times longer than that of the total liver siRNA (11.7 days). Upon repeat Q2W dosing, kinetics of RISC-bound siRNA was similar to the total siRNA. Sustained RISC-bound siRNA concentrations were achieved upon repeat dosing. RISC-bound siRNA was quantifiable through the last study day 168 with the repeat dose (Q2W regimen) and at up to 98 days following a single dose. The durability of HBsAg reduction corresponded with both the total and the RISC-bound siRNA.
Conclusion: Binding of ALG-125755 to AGO-2 was demonstrated in vitro and in vivo, confirming that the mechanism of action for ALG-125755 is consistent with that of an siRNA. Pharmacodynamic response of HBsAg reduction and durability correlated with total siRNA and RISC-bound siRNA in mouse liver. The long half-life of the RISC-bound siRNA indicates that dosing in human could be less frequent than monthly dosing.

FRI-239

A potent human PD-L1 siRNA leads to significant reduction of AAV-HBV infected hepatocytes via immune activation in human PD-1/PD-L1 double knock in mice

Jin Hong[1], Dawei Cai[1], Saul Montero[1], Hua Tan[1], Vivek Rajwanshi[1], Aneerban Bhattacharya[1], Kang Hyunsoon[1], Min Luo[1], Megan Fitzgerald[1], David Smith[1], Lawrence Blatt[1], Julian Symons[1], Leonid Beigelman[1]. [1]*Aligos Therapeutics, South San Francisco, United States*
Email: jhong@aligos.com

Background and aims: T cell exhaustion is characteristic of chronic hepatitis B (CHB) and contributes to the persistence of hepatitis B virus (HBV) infection. PD-1/PD-L1 is the dominant co-inhibitory axis mediating T cell exhaustion in CHB patients. Monoclonal antibodies against PD-1 or PD-L1 have been tested in CHB patients and have shown promising results. However, the dose of antibodies administered were significantly lower in CHB patients than in cancer patients to minimize immune related adverse events. Compared with antibodies, subcutaneously (SC) delivered siRNA have a short half-life in plasma and exposure is mainly concentrated in the liver, thereby reducing the potential for systemic toxicities. We have developed a GalNAc conjugated human PD-L1 (hPD-L1) siRNA lead molecule, ALG-072571, that demonstrated significant reduction of AAV-HBV infected hepatocytes through immune activation in human PD-1/PD-L1 double knock in (KI) mice.
Method: siRNAs were synthesized on a MerMade synthesizer. In vitro human PD-L1 knockdown was evaluated in the SNU-387 cell line by RT-qPCR. GalNAc PD-L1 siRNA pharmacodynamics (PD) were studied by assessing Poly IC induced human PD-L1 levels in double KI mice. In double KI mice chronically infected with AAV-HBV, ALG-072571 and HBV siRNA ALG-125819 were dosed SC as single agents (8 × 7.5 mg/kg QW and 4 × 5 mg/kg QOW respectively) or in combination. Serial serum collections were tested for HBsAg, HBeAg, HBV DNA and ALT. Terminal serum samples were assayed for anti-HBsAg antibody. Mouse livers were stained for HBcAg, HBsAg and CD3 using IHC and scored for positive cells.
Results: Unconjugated ALG-072571 containing novel siRNA stabilization chemistries showed an EC_{50} of 90 pM in reducing hPD-L1 RNA in SNU387 cells. In a PD study, a single SC 7.5 mg/kg dose of ALG-072571 reduced liver hPD-L1 RNA by 71% and protein by 45%. In parallel FACS analysis, the cell surface hPD-L1 level in liver CD45+ immune cells were reduced by 19% and in Kupffer cells by 37%. In an AAV-HBV study using double KI mice, ALG-072571 repeat dosing reduced HBsAg, HBeAg and HBV DNA by 3.3 $\log_{10}$ IU/ml, 1.73 $\log_{10}$ PEIU/ml and 4.5 $\log_{10}$ IU/ml respectively. In the combination group, ALG-072571 and ALG-125819 showed additivity, reducing HBsAg, HBeAg and HBV DNA 4.3 $\log_{10}$ IU/ml, 2.0 $\log_{10}$ PEIU/ml and 6.9 $\log_{10}$ IU/ml respectively. ALT elevation was observed preceding the viral marker reductions. In liver IHC HBcAg staining, the core positive hepatocyte percentages were approximately 60% for the vehicle control and ALG-125819 alone groups, but not detectable in ALG-072571 alone and combination groups. ALG-072571 alone and in combination also showed CD3+ T cell infiltration in the liver and anti HBsAg antibody in the serum of mice with the lowest HBsAg levels.
Conclusion: Liver targeted PD-L1 siRNA therapy may lead to restoration of immune responses against HBV and consequent clearance of HBV infection.

Heatmap showing mean values of normalized SIM that are statistically significant (adjusted p-value <0.05) changed in chronic HCV patients at therapy start compared to controls, separated in patients with and without cirrhosis

Figure: (abstract: FRI-240): Soluble immune markers (SIM) in chronic HCV patients before and after HCV elimination by DAA and in controls.

Background and aims: DAA therapy results in sustained virologic response in over 99% of patients with chronic HCV. However, a proportion of patients remain at risk for long-term sequelae, such as fatigue or development of hepatocellular carcinoma (HCC), suggesting persistent biological alterations. Following our previous results showing the impact of chronic HCV on the inflammatory milieu in the context of short-term follow-up of 12–24 weeks after DAA therapy, we now aim to further investigate the effect of viral elimination in cirrhotic and non-cirrhotic patients at long-term follow-up.
Method: 104 chronic HCV patients, 47 with cirrhosis (age 57.31 ± 9.37, elastography 34.17 ± 17.49), of whom 8 developed HCC, and 57 without cirrhosis (age 57.90 ± 11.70, elastography 7.65 ± 2.50), were treated with DAA. Plasma samples were available at baseline, at the end of treatment, and at long-term follow-up (median: 96 weeks). 40 inactive HBsAg carriers (HBeAg negative, ALT normal) and 16 healthy individuals served as controls. Plasma levels of 92 soluble immune markers (SIM) were measured by Olink Proteomics using a proximity extension assay.
Results: Compared with controls, 43 SIM were statistically significantly altered at baseline in all chronic HCV patients (Welch Two Sample t-test, adjusted p value <0.05). However, an independent comparison between cirrhotic and non-cirrhotic HCV patients revealed very distinct SIM profiles (49 altered SIM in cirrhotics, 24 altered SIM in non-cirrhotics compared to controls). Moreover, SIM dynamics after DAA treatment differed significantly between cirrhotic and non-cirrhotic patients. Compared to controls, no SIM was significantly changed anymore in non-cirrhotics at long-term follow-up, while 39 SIM were still significantly (adjusted p value<0.05) modified in cirrhotics. Of the SIM that were elevated at baseline in both HCV patients with and without cirrhosis, 16 of these "HCV-specific SIM" (including CXCL10, CXCL11, IL-8, PD-L1, IL-15RA, HGF) were still significantly elevated in cirrhotic patients at long-term follow-up in addition to "cirrhosis-specific" SIM (e.g., IL-6, FGF-23, CXCL6, CCL25, MMP-10, MCP-1). Interestingly, some of these "HCV-specific SIM" (e.g., HGF) showed different dynamics in patients who developed HCC compared to matched cirrhotic controls without HCC.
Conclusion: After successful HCV elimination, the HCV specific inflammatory milieu remains altered in cirrhotic patients. Our data suggest that "HCV-specific" and "cirrhosis-specific" changes in the inflammatory milieu can be distinguished. Some of the SIM, known to be associated with carcinogenesis, show different dynamics over time in HCC patients, suggesting a possible link between an altered inflammatory milieu and HCC development.

FRI-241

Preclinical pharmacokinetic, pharmacodynamic and efficacy relationships of ALG-093702, a liver targeted PD-L1 small molecule inhibitor, in different in vivo models

Heleen Roose[1], Qingling Zhang[2], Kha Le[2], Andreas Jekle[2], Kristina Rekstyte-Matiene[1], Sarah Stevens[2], Ruchika Jaisinghani[2], Cheng Liu[2], Sandra Chang[2], Antitsa Stoycheva[2], Lawrence Blatt[2], Leonid Beigelman[2], Julian Symons[2], Sushmita Chanda[2], Francois Gonzalvez[1], Tongfei Wu[1]. *[1]Aligos Belgium Bv, Belgium; [2]Aligos Therapeutics, Inc., United States*
Email: twu@aligos.com

Background and aims: The PD-1/PD-L1 immune checkpoint pathway is an attractive target to reverse immune tolerance in chronic hepatitis B (CHB). However, due to the systemic immune adverse effects associated with antibodies, a lower dose of PD-1/PD-L1 antibodies has been used in CHB vs. the dose used for cancer. ALG-093702 is a liver-targeted PD-L1 small molecule inhibitor that preferentially partitions into the liver and thereby may potentially mitigate extra-hepatic on-target related toxicity. Characterizing the relationship between pharmacokinetics (PK), pharmacodynamics (PD) and the efficacy of ALG-093702 is critical for selecting the dosing strategy of new liver targeted PD-L1 inhibitor drugs.
Method: Biochemical PD-1/PD-L1 interaction was assessed by AlphaLISA®. Cellular activity was measured using a co-culture reporter assay in which NFAT activity of Jurkat T cells was constitutively inhibited by the engagement of PD-1 by PD-L1-expressing CHO cells. HBV-specific T cell activation assays were performed in PBMCs from an HBV-infected patient and assessed by measuring IFN gamma release. Oral dosing of ALG-093701, a prodrug of ALG-093702, was used for in vivo PK/PD/efficacy studies. In vivo PK/PD/efficacy were assessed in humanized-PD-L1 MC38 subcutaneous xenografts and/or a liver metastasis mouse model.
Results: ALG-093702 inhibited PD-1/PD-L1 interaction with picomolar IC_{50} values (IC_{50} = 0.048 nM) and increased TCR signaling in Jurkat cells with an EC_{50} of 5.9 nM. In an ex vivo study, ALG-093702 activated HBV-specific T cells from an HBV-infected patient to a similar extent as durvalumab. In mouse pharmacokinetic studies, ALG-093702 exhibited significantly higher liver concentrations vs. other tested tissues (liver/lung ratio of 10). In a humanized-PD-L1 MC38 subcutaneous mouse model, oral dosing 50 mg/kg of ALG-093701 achieved a similar extent of PD-L1 target occupancy and tumor growth inhibition as durvalumab. This study also demonstrated that the PD-L1 target occupancy was correlated with ALG-093702 tumor concentration.

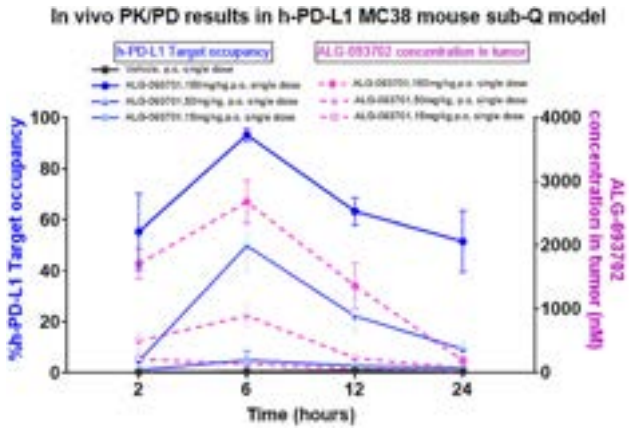

Figure:

Conclusion: We discovered a liver-targeted PD-L1 small molecule inhibitor, ALG-093702, with similar in vitro potency and in vivo PD-L1 target occupancy and tumor growth inhibition as the PD-L1 antibody drug, durvalumab. The preclinical PK/PD/efficacy correlation provides guidance for the efficacious human dose prediction and dosing strategy for clinical studies of oral liver targeted PD-L1 small molecule inhibitor.

FRI-242

The role of gamma delta T cells in chronic hepatitis B virus infection

Katja Steppich[1,2,3], Roni Souleiman[1,2], Elena Bruni[3,4,5], Ximena Leon Lara[4], Katja Deterding[1], Benjamin Maasoumy[1], Heiner Wedemeyer[1], Immo Prinz[3,4,5], Anke Kraft[1,2,3,6,7], Markus Cornberg[1,2,3,6,7]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Germany; [2]TWINCORE Centre for Experimental and Clinical Infection Research GmbH, Germany; [3]Cluster of Excellence RESIST (EXC 2155), Germany; [4]Hannover Medical School, Institute of Immunology, Germany; [5]University Medical Center Hamburg-Eppendorf, Institute of Systems Immunology, Hamburg Center for Translational Immunology (HCTI), Germany; [6]German Centre for Infection Research, Partner-site Hannover-Braunschweig, Germany; [7]Centre for Individualized Infection Medicine (CIIM), Germany*
Email: steppich.katja@mh-hannover.de

Background and aims: Current treatment options for chronic HBV infection can slow disease progression, but "cure" of HBV infection is a rare event. Therefore, several new therapeutic strategies aimed at "functional cure" (HBsAg loss) are currently being developed. Immune responses are thought to be important for HBV disease progression and HBV cure. Human gamma-delta (γδ) T cells have been shown to play a role in various infectious diseases and are enriched in solid tissues such as the liver, suggesting a role in liver-associated diseases. However, their role in chronic HBV infection remains largely unknown. The aim of this study is to investigate the phenotype, function, and T-cell receptor (TCR) repertoire of γδ T cells in patients with chronic HBV infection with different viral and clinical characteristics, including patients discontinuing long-term NA therapy.
Method: We performed in-depth ex vivo phenotyping of 87 chronic HBV patients with different HBsAg and HBcrAg levels and controls using a 28-color full-spectrum flow cytometry panel. In addition, PBMC from selected patients were stimulated with phosphoantigens. In addition, TCR sequencing of TCR gamma and TCR delta from mass-sorted Vγ9+ and Vγ9- γδ T cells was performed using an NGS approach with Illumina MiSeq. In addition, the transcriptome of γδ T cell subsets was analyzed by single-cell sequencing. Intrahepatic γδ T cells from some subjects were examined.
Results: We detected and further characterized two distinct γδ T cell populations (CXCR6+ γδ T cells and CD16+ γδ T cells) that were differentially abundant in patients with high (>3.87 log) and low (<3.87 log) HBcrAg levels, whereas HBsAg levels made no difference. Thus, patients with higher HBcrAg levels had a higher frequency of CXCR6+ γδT cells (similar phenotype to the recently described CXCR6 +CD8+ "autoaggressive" T cells). Analysis of liver tissue samples revealed a higher frequency of CXCR6+ γδ T cells in the liver compared with blood. A pilot study showed that patients with marked ALT flares after discontinuation of NA treatment had an increase in CXCR6+ γδ T cells. Interestingly, two patients with similar CXCR6+ γδ T cell kinetics had similar γδ TCR diversity and showed subsequent HBsAg loss. In contrast, CD16+ γδ T cells were significantly increased in patients with low HBcrAg levels, and after stimulation, CD16+ γδ T cells showed more cytotoxicity (granzyme B) than CD16- γδ T cells. Transcriptome analyses are ongoing.
Conclusion: Our data suggest that γδ T cells may be involved in the immunopathogenesis in chronic HBV infection. We describe two distinct γδ T cell populations that may support viral control in distinct situations but also contribute to hepatitis.

FRI-243

Recombinant hepatitis E viruses harboring a split luciferase tag in the ORF2 capsid protein

Maliki Ankavay[1], Nathalie Da Silva[1], Noémie Oechslin[1], Katja Dinkelborg[2], Patrick Behrendt[2], Darius Moradpour[1], Jérôme Gouttenoire[1]. *[1]Lausanne University Hospital (CHUV) and University of Lausanne, Lausanne, Switzerland, Service of Gastroenterology and Hepatology, Lausanne, Switzerland; [2]TWINCORE Centre for Experimental and Clinical Infection Research, Experimental Virology, Germany*
Email: maliki.ankavay@chuv.ch

Background and aims: Hepatitis E virus (HEV) infection is the most common cause of acute viral hepatitis worldwide. The viral genome harbors three open reading frames (ORF). The ORF2 protein corresponds to the viral capsid. Molecular studies of the HEV life cycle have been hampered by the lack of robust and sensitive cell culture systems. Hence, the main receptor for HEV cell entry is still elusive and there are no specific antiviral drugs against HEV so far. Here, we aimed to develop a convenient, quantitative and potentially scalable reporter system for HEV infection and replication.
Method: Transposon-mediated random insertion was exploited to identify functional insertion sites within the HEV ORF2 protein. Full-length viral genomes with in-frame insertions of a split luciferase (HiBiT) tag in the capsid protein were characterized by immunofluorescence and immunoblot analyses as well as functional assays. Luciferase activity was quantified by luminometry.
Results: Transposon-mediated random insertion and sequencing of viable genomes identified functional insertion sites in the HEV capsid protein. HEV harboring a HiBiT tag in C-terminal sites remained infectious and functional in terms of RNA replication and capsid secretion, allowing for antibody-free detection and quantitation of capsid protein by luciferase assay. As a proof-of-concept, the antiviral effect of ribavirin and sofosbuvir could be assessed in a quantitative manner. Moreover, neutralization of purified quasi-enveloped and naked HEV by convalescent sera and specific monoclonal antibodies could be measured conveniently. Finally, a broad-scale kinase inhibitor screen identified several compounds with potent antiviral activity that are currently being validated and further characterized in terms of mode of action.
Conclusion: Identification of functional insertion sites enabled tagging of the HEV capsid protein with a highly sensitive and quantitative miniaturized luciferase reporter. Tagged HEV allowed for convenient read-out of infection and replication, with a potential to develop large-scale screening assays for entry inhibitors and other

antiviral agents. In addition, the tagged viruses represent a valuable tool for studies aimed at understanding the molecular mechanisms of infection, including the identification of the receptor (s) for HEV cell entry.

Identification of resistance-associated variants after sofosbuvir treatment in chronic hepatitis E patients

Andre Gömer[1], Mara Klöhn[1], Michelle Jagst[1], Maximilian Nocke[1], Thomas Horvatits[2], Julian Schulze zur Wiesch[2], Sven Pischke[2], Svenja Hardtke[2], Tobias Müller[3], Heiner Wedemeyer[4], Markus Cornberg[4], Patrick Behrendt[4], Eike Steinmann[1], Daniel Todt[1]. *[1]Molecular and Medical Virology, Germany; [2]University Medical Center Hamburg-Eppendorf, Germany; [3]Charité-Universitätsmedizin Berlin, Berlin, Germany; [4]Medizinische Hochschule Hannover, Hannover, Germany*
Email: andre.goemer@rub.de

Background and aims: Hepatitis E virus (HEV) infections remain a serious problem in immunocompromised patients, leading to chronic infections in about 50% of cases. As of now, off-label use of Ribavirin is the only treatment option, since no HEV-specific antivirals are available. Recently, the hepatitis C virus polymerase inhibitor sofosbuvir was however evaluated as a potential antiviral against HEV in vitro and in vivo. The most comprehensive investigation was a 24-week multicenter phase II pilot trial, were nine chronically HEV-infected patients were treated with sofosbuvir. HEV RNA transiently decreased by 2 log, but increased back to pre-treatment levels within 24 weeks of treatment onset. We aim to identify the reason for viral recurrence by characterizing changes in the viral population during treatment.
Method: For this, we performed amplicon deep sequencing to characterize viral population dynamics in the nine patients treated with sofosbuvir. In addition, we used an HEV-based reporter cell culture system to characterize high-frequency variants that might affect sensitivity to sofosbuvir.
Results: Most patients had highly divergent HEV populations, which suggest a high adaptability to treatment-related selection pressures, possibly associated with the emergence of treatment-resistant variants. We identified amino acid substitution from different time points and singled out substitutions that had become dominant in multiple patients (A1343V, K1383N, D1384N, V1479I, G1634R). These were then cloned into an HEV-3 replicon system to assess their effect on replication fitness and sensitivity to sofosbuvir. The half maximal effective concentration (EC50) was up to 20-fold higher than control, suggesting that variants associated with lower susceptibility were selected during sofosbuvir treatment. In particular, substitution A1343V, which occurred in eight of nine patients during treatment but was not present at baseline, showed a strong increase both in combination with V1479I (20-fold) and as a single substitution (10-fold).
Conclusion: In conclusion, viral population dynamics play a critical role during antiviral treatment. High population diversity during sofosbuvir treatment led to the selection of variants with higher fitness. In particular, the A1343V substitution selected in most patients showed an increased sofosbuvir resistance in vitro, which may have led to treatment failure in vivo.

FRI-245

HBsAg kinetics at month 9 after analogue treatment discontinuation in chronic hepatitis B eAg (-) predicts long-term HBV control

Henar Calvo Sánchez[1,2], Julia Peña Asensio[1], Jeniffer Martínez[1,3], Alberto Delgado[1], Joaquin Miquel[1], Eduardo Sanz de Villalobos[1], Alejandro González Praetorius[1], Miguel Torralba[1,2], Juan Ramón Larrubia[1,2]. *[1]University Hospital of Guadalajara, Translational Hepatology Unit, Spain; [2]University of Alcalá, Department of Medicine and Medical Specialties, Spain; [3]University of Alcalá, Department of Biology, Spain*
Email: juan.larrubia@uah.es

Background and aims: Withdrawal of nucleos (t)ide analogue (NUC) treatment in eAg (-) chronic hepatitis B (CHBeAg (-)) may lead to HBV control. However, there are no markers that predict who benefits from this strategy. Objective: To assess whether HBsAg kinetics after NUC suspension is associated with long-term HBV control.
Method: A longitudinal study of 22 CHBeAg (-) patients previously treated with NUCs for more than 3.5 years and with liver fibrosis <F3 was performed. After discontinuation of treatment, patients were followed monthly in the first quarter and quarterly thereafter, with a follow-up of three years. HBV viral load, HBsAg level and serum alanine aminotransferase (ALT) level were quantified at each follow-up visit. At the end of follow-up (month 36), a patient was considered to be HBV infection controller if the viral load (HBV36) was <2000 IU/ml and the ALT level (ALT36) was normal. We analyzed whether the decrease in HBsAg at month 9 after treatment discontinuation correlated with HBV control at month 36 post-suspension and with the probability of having a multi-specific HBV-functional CD8+ cell response, according to the predictive logistic regression model previously described by our group (Peña-Asensio et al. Aliment Pharm Ther 2022).
Results: After discontinuation of treatment with NUCs, an overall decrease in HBsAg level was observed after 36 months of follow-up ($p < 0.001$), which was greater in the group with HBV36 < 2000 IU/ml ($p = 0.004$). The percentage of HBsAg level decrease after 9 months of NUC treatment discontinuation correlated with the presence of HBV36 < 2000 IU/ml and normal ALT36 (Area under ROC curve.- 95% CI: 0.58–0.92, $p = 0.037$). The absence of HBsAg decline at month 9 after NUC suspension presented a 100% negative predictive value of viral control at month 36, while a decline ≥40% was associated with a 100% predictive positive value of HBV36<2000 IU/ml. The level of HBsAg decline at month 9 correlated positively with the probability of having a functional HBV-multispecific CD8+ cell response at the end of treatment, ($r = 0.566$, $p = 0.009$). Percentage of HBsAg variation after 6-month NUC stop correlated with the clinical status at end of follow-up (HBsAg loss, inactive carrier, grey zone, re-treatment), ($p = 0.002$).
Conclusion: A decrease in HBsAg level ≥40% at month 9 after NUC discontinuation in CHBeAg (-) is associated with long-term HBV control, while the absence of decrease implies reactivation of infection during follow-up. The level of HBsAg decline at month 9 correlates positively with the likelihood of having recovered a functional HBV-multispecific CD8+ cell response.

FRI-246

Nucleotide analogue therapy does not reverse the hyperexpression of innate-like markers on activated T cells consistent with immunopathology in chronic hepatitis B

Lung Yi Loey Mak[1,2], Apostolos Koffas[2], Sabina Wellington[2], Sophie Stretch[2], Anna Riddell[3], Man-Fung Yuen[1], Patrick Kennedy[2], Upkar Gill[2]. [1]*The University of Hong Kong, School of Clinical Medicine, Hong Kong;* [2]*Blizard Institute, Barts and The London, School of Medicine and Dentistry, QMUL, Centre for Immunobiology, London, United Kingdom;* [3]*Barts Health NHS Trust, Virology, United Kingdom*
Email: u.gill@qmul.ac.uk

Background and aims: There is renewed focus on the importance of non-specific bystander T cells as major contributors to hepatic immunopathology in chronic hepatitis B (CHB). It is key to ascertain details on this understudied immune cell population to provide further insights into the reasons for immunological failure of novel therapies for CHB cure. We studied the phenotypic innate-like properties of global CD4 and CD8 T cells in treatment naïve and experienced patients with CHB compared to healthy controls (HC) to determine any differences and correlated these with clinical parameters.

Method: Forty-six subjects (47.8% male, median age 39.5 years) were studied [CHB; 20, HC; 26]. The proportion of activated (HLA-DR+) T cells was determined along with the expression of NK cell receptors (NKRs), markers of T cell differentiation and residency by multi-parameter flow cytometry. The impact of antiviral therapy in a cohort of CHB subjects was also analysed [median tenofovir treatment duration 7.6 years; median ALT: 43 (range: 31–72) U/L; median HBV DNA: 7.1 log IU/ml at treatment initiation].

Results: The overall proportion of HLA-DR+ T cells was higher in CHB patients compared to HCs, and significantly higher on CD4T cells (3.1% vs 1.3%, $p = 0.041$). T cell expression of CXCR6 (0.7% vs 0.3%, $p = 0.010$) and the NKRs, NKG2A (4.4% vs 1.7%, $p = 0.015$) and NKp30 (2.0% vs 0.9%, $p = 0.023$) was increased in CHB, consistent with immunopathology. We noted augmented expression of NKG2A and CD56 (both $p < 0.0001$) on the activated (HLA-DR+) proportion of CD8 T cells compared to their HLA-DR- counterparts. On analysing CHB subjects undergoing antiviral therapy, the expression of NKRs [NKG2A: CD4; 35.4% vs 2.2% and CD8; 28.4% vs 3.6% (both $p < 0.001$); NKG2D: CD4; 79.6% vs. 2.4% and CD8; 20% vs 5.9% (both $p < 0.01$); NKp30: CD4; 2.9% vs 0.7% and CD8; 3.3% vs 0.5% (both $p < 0.01$)] and the residency marker CXCR6 (CD4; 10.6% vs 0.4%, $p < 0.0001$, CD8; 2.4% vs 0.3%, $p = 0.011$) remained significantly higher in those on antiviral therapy, despite undetectable HBV DNA and ALT normalisation, compared to those with CHB treatment naïve patients with bona-fide immune control, indicating that the bystander innate like immune defects are not recovered by current antiviral therapy.

Conclusion: CHB is associated with increased non-specific innate like activated T-cells, potentially causing immunopathology. Antiviral therapy is unable to reverse these immune cell defects suggesting the need for earlier treatment or add on therapies to achieve CHB cure.

FRI-247

Baseline plasma lipidome correlates with direct-acting antiviral therapy non-response for HCV in HIV-HCV coinfected patients

Jaswinder Maras[1], Vasundhra Bindal[1], Gaurav Tripathi[1], Manisha Yadav[1], Nupur Sharma[1], Babu Mathew[1], Sadam H Bhat[1], Abhishak Gupta[1], Neha Sharma[1], Sushmita Pandey[1], Ekta Gupta[2]. [1]*Institute of Liver and Biliary Sciences, Department of molecular and cellular medicines, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Department of Clinical Virology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Direct-acting antivirals have increased the SVR attainment rate to 95%; however, still, there is an HIV-HCV coinfected population that is non-responders to DAA therapy. As both HIV and HCV co-infection is tightly associated with dyslipidemia characterizing specific alterations in the lipidome of HIV-HCV coinfected patients will give important pathophysiological insights. The primary aim of the present study is to identify baseline lipid species that could be used for the early stratification of HIV-HCV coinfected non-responders of the DAA therapy at baseline.

Method: This study identified N = 43 of N = 2064 HCV patients as HIV-HCV coinfected. These patients received Sofosbuvir and Daclatasvir as standard HCV therapy. Based on the post-therapy HCV RNA status, these patients were further segregated as responders (n = 10) and non-responders (n = 10) to standard DAA therapy. Amongst them, 20 paired patient samples were identified, and their baseline and post-therapy (3 months) plasma samples were subjected to untargeted lipidomics analysis using LC-MS/MS.

Results: HCV-HIC coinfected patients had dyslipidemia; comparative lipid analysis at baseline of DAA non-responders with responders identified 198 differentially expressed lipids ((DEL-90 Up; 108 Down; $FC > 1.5$, $p < 0.05$). The class with the maximum number of (DELs) was PE (Phosphatidylethanolamine-45 Up; 41 Down), PC (Phosphatidylcholine 20 Up; 21 Down), and others. Comparative analysis of the post-therapy lipidome profile of non-responders with responders revealed 261 DEL (96 UP and 165 Down; $FC > 1.5$, $p < 0.05$). Among 198 DEL, the class with the maximum number of DEL were PE (30 Up and 66 Down), PC (22 Up;27 Down), and others. We found that post-therapy downregulation of 27 lipids (Major classes altered PC and PE) and upregulation of 41 lipid species (Major classes altered PC and PE and DG) is linked with DAA therapy response. Surprisingly, non-responders at baseline have very high levels of PE and PC, which decreases post-therapy, suggesting their role in negating the DAA response. DAA therapy induces a net 60X reduction of PE in non-responders and a 12 × reduction in PC. Finally, non-responders at baseline have a very high abundance of lipid species like ((PC (20:1/18.3); $FC > 122$; $p < 0.05$; $AUC > 0.99$), ((PE (18:0) p); $FC > 589$; $p < 0.05$; $AUC > 0.99$) and, all the selected clinical indicators positively correlated with HCV viral load AST, ALT and APRI score suggesting their role in Viral replication.

Conclusion: The lipidome profile of DAA non-responders and responders is distinct and crucial in determining DAA response. Increase in plasma PE [PE (18:0) p] and PC [PC (20:1/18.3)] are the two major classes that negate DAA response and are key lipid indicator for non-response.

Background and aims: Treatment of chronic hepatitis B (CHB) patients with the siRNA JNJ-73763989 (JNJ-3989) and nucleos (t)ide analogs (NAs) ± the CAM-E JNJ-56136379 (JNJ-6379), has shown profound reductions in hepatitis B viral serum markers. The INSIGHT study (NCT04585789) aims to assess intrahepatic and peripheral changes in immunologic and virologic markers in response to JNJ-3989 based combination regimens in participants with CHB.
Method: INSIGHT is a phase 2, open-label, parallel-group, multicenter study across 9 countries in Europe, North America, and Oceania, in CHB participants who are hepatitis B e-antigen (HBeAg)-positive and not currently treated (NCT; Group 1) or HBeAg-negative and virologically suppressed (VS) by NA (Group 2). Patients are receiving JNJ-3989 + NA ± JNJ-6379 for 48 weeks. Paired percutaneous core liver biopsies as well as fine needle aspiration biopsies (FNABs; uniform protocol across sites) are being collected to investigate potential differences and changes in hepatitis B viral markers and intrahepatic immune status. Viral markers are assessed by immunofluorescent (IF) staining combined with single cell digital droplet PCR from fresh frozen tissue sections; immune cells are characterized by single cell RNA sequencing from FNABs. This analysis focuses on baseline biopsies and the comparison of the two distinct subgroups of CHB participants.

Figure. Baseline serum viral marker levels and frequency of HBV-positive liver cells* by viral marker for Groups 1 and 2.

Range per group (min - max)	Group 1 NCT HBeAg-positive (n = 4)	Group 2 VS HBeAg-negative (n = 4)
Serum viral markers		
HBsAg, log_{10} IU/mL	3.5 – 4.9	2.4 – 4.3
HBcrAg, log_{10} U/mL	6.7 – 9.9	2.7 – 5.7
HBV RNA, log_{10} copies/mL	5.3 – 8.6	1.1 – 2.1
HBeAg, log_{10} IU/mL	1.5 – 3.0	–
Liver viral markers, %		
HBsAg-positive cells†	50.8 – 98.4	17.4 – 49.5
HBcAg -positive cells†	40.4 – 92.7	0.02 – 28.3
cccDNA-positive cells‡	16.9 – 87.5	35.7 – 58.3
HBV RNA-positive cells‡	88.8 –100.0	8.0 – 30.2
cccDNA positive/HBV RNA negative	0 – 7.4	33.3 – 48.2

Limit of detection = 1.6 copies/cells for both the cccDNA and HBV RNA assay.
*Minimum and maximum fraction of positive cells per sample.
†Based on entire section.
‡Targeting 90 individual cells/sample.

Results: Baseline liver samples were collected from 20 out of 24 enrolled participants, 10 per group. Currently, analysis of four core liver biopsies from each group has been completed. Ranges of serum viral marker levels were numerically higher for participants in Group 1 vs Group 2, consistent with the higher proportion of HBsAg- and HBcAg-positive hepatocytes in Group 1 vs Group 2 (Figure). Out of individually isolated hepatocytes, a numerically higher frequency of cccDNA positive/HBV RNA positive cells and a lower frequency of cccDNA positive/HBV RNA negative hepatocytes was observed in Group 1 vs Group 2, in line with the difference in liver IF and serum viral markers between the two groups. 19/20 FNAB samples collected at baseline were successfully profiled with approximately 2000 genes/cell quantified (Group 1: n = 9; 15,828 liver resident cells; Group 2: n = 10; 21,925 liver resident cells). On average, 1988 cells per sample were profiled, varying from 282 to 5200 cells. Differential expression of interferon stimulated genes between Groups 1 and 2 was observed in liver CD8+ T-cells, mucosal-associated invariant T-cells (MAIT), and natural killer (NK) cells. A few markers in intrahepatic immune cells were associated with peripheral HBsAg levels, including overexpression of TNF in MAIT cells in participants with HBsAg <1000 IU/ml across both groups.
Conclusion: The INSIGHT study successfully employed a harmonized approach of multicenter biopsy collection with central sample analysis of liver resident cells at the single cell level. At baseline, NCT HBeAg-positive participants had numerically higher serum viral biomarker levels reflected by greater proportions of HBsAg-, HBcAg-, and HBV RNA-positive hepatocytes than VS HBeAg-negative participants. Interestingly, differences in immune cell RNA expression were modest between groups, with 14 genes significantly differentially expressed in MAIT/CD8+ T-cells or NK cells (associated with False Discovery Rate <10%).

FRI-249

Epigenetic modulation by DNA methyltransferase inhibition may enhance the effect of immune checkpoint inhibitors to restore HBV-specific T cell responses

Melanie Urbanek-Quaing[1,2,3], Carlos Oltmanns[1,2,3,4], Jasmin Mischke[1,2,3], Heiner Wedemeyer[3,5], Cheng-Jian Xu[1,2,4], Anke Kraft[1,2,3,4], Markus Cornberg[1,2,3,4]. *[1]Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Germany; [2]TWINCORE, Hannover, Germany; [3]German Center for Infection Research (DZIF), Hannover, Germany; [4]Center for Individualized Infection Medicine (CiiM), Hannover, Germany; [5]Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany*
Email: urbanek-quaing.melanie@mh-hannover.de

Background and aims: Functional cure of chronic hepatitis B virus (HBV) infection (defined by loss of HBsAg) is rarely achieved, emphasizing the need for novel therapeutic approaches. A hallmark of chronic infection is a dysfunctional immune system and the presence of exhausted T cells with a distinct epigenetic signature. There are several approaches to improve their function, such as checkpoint inhibition with anti-PDL1. However, anti-PDL1 alone is unable to remodel the epigenetic patterns associated with exhaustion and thus may prevent durable improvement of the immune response. Our goal is to target these epigenetic imprints of exhaustion in chronic HBV infection to improve the effect of anti-PDL1 on HBV-specific immune responses.
Method: We performed a 10-day stimulation culture with peripheral blood mononuclear cells (PBMC) from 44 individual chronic HBV patients with varying levels of HBsAg and HBcrAg. PBMCs were stimulated with HBV core or polymerase overlapping peptide pools (42 patients) or HLA-restricted peptides HBV $core_{18}$ or pol_{455} (13 patients). In addition, cells were treated with the checkpoint inhibitor anti-PDL1 alone or in combination with the DNA methyltransferase inhibitor (DNMTi) decitabine. HBV-specific immune responses were analyzed by multicolor flow cytometry. In addition, DNA methylation was analyzed using the Illumina Human MethylationEpic Beadchip Array.
Results: After pretreatment with DNMTi followed by anti-PDL1 treatment on day 3 post-stimulation, we observed a markedly improved IFNgamma$^+$ response of HBV-specific CD4$^+$ T cells and CD8$^+$ T cells in some patients. This effect was heterogeneous, with some patients showing a 2- to 100-fold increase compared with anti-PDL1 treatment alone. For example, the combination of anti-PDL1 and DNMTi increased total HBV core-specific CD4$^+$ and CD8$^+$ T cell responses in 42% and 39% of cases, respectively, compared with anti-PDL1 alone. HLA-restricted HBV peptide-specific CD8$^+$ T cell responses were improved in 46% of cases, with a more pronounced effect on pol_{455}-specific responses. Correlation with methylation data and HBV antigen levels is ongoing.

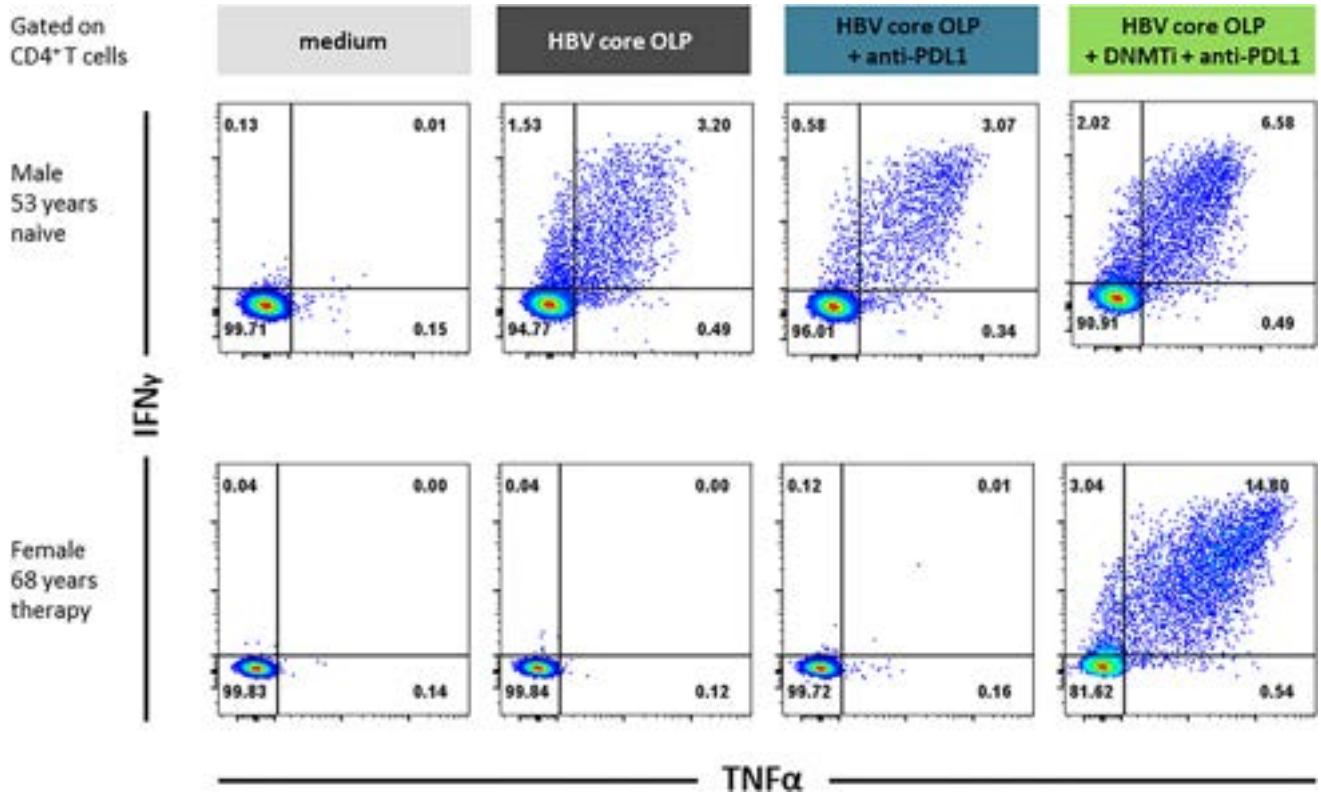

Figure: (abstract: FRI-249): Heterogeneous effect of checkpoint inhibitor anti-PDL1 and DNA methyltransferase inhibitor on HBV core-specific CD4+ T cell responses.

Conclusion: The results confirm that epigenetic signatures of T cells may play an important role in the immune response to HBV. Targeting epigenetic modifications by combining DNMTi and checkpoint inhibitors has not been tested in chronic HBV, but seems to be a promising concept to improve HBV-specific immune responses.

FRI-250

Reduction in quantity and function of HBcAg-specific B cells indicates the response to anti-viral therapy in chronic HBV-infected patients receiving ETV or TDF treatment

Li Wang[1], Ning Ling[1], Wenhui Peng[1], Gaoli Zhang[1], Min Chen[1]. [1]*Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, The Second Affiliated Hospital, Chongqing Medical University, China*
Email: mchen@hospital.cqmu.edu.cn

Background and aims: Recently, hepatitis B virus core antigen (HBcAg)-specific B cells have been reported to be associated with the disease phase of chronic hepatitis B virus (HBV) infection, but their changes and roles in anti-viral therapy remains unknown yet. Here, features of HBcAg-specific B cells were investigated in chronic HBV-infected (CHB) patients during entecavir (ETV) or tenofovir disoproxil fumarate (TDF) treatment.

Method: Fifty-six treatment-naïve, fifty-one ETV-treated, and twenty-nine TDF-treated CHB patients were enrolled in this study. The frequency and phenotype of circulating HBcAg-specific B cells were examined by flow cytometry using fluorescently labeled HBcAg and surface markers. The function of antibody-secretion of HBcAg-specific B cells was assessed by HBcAg-specific enzyme-linked immunospot (ELISpot) assays.

Results: Compared to treatment-naïve patients, ETV/TDF-treated CHB patients displayed lower frequencies of total HBcAg-specific B cells, and their memory and class-switched subsets, especially in HBeAg- negative patients. Meanwhile, the proportion and antibody-producing ability of HBcAg-specific B cells progressively declined with the prolonged duration of antiviral therapy. The number of antibody-producing HBcAg-specific B cells positively correlated with the serum level of HBV DNA, HBsAg, or HBeAg. Notably, HBcAg-specific B cells from CHB patients with maintained virological response (MVR) showed significantly lower percentages of total and classic memory population, lower expression of CXCR5 and CD38, while higher expression of CXCR3 than those with low-level viremia (LLV).

Conclusion: Long-term ETV/TDF treatment led to a gradual reduction in the quantity and function of HBcAg-specific B cells. A lower proportion of HBcAg-specific B cells was potential to predict a better response to antiviral therapy.

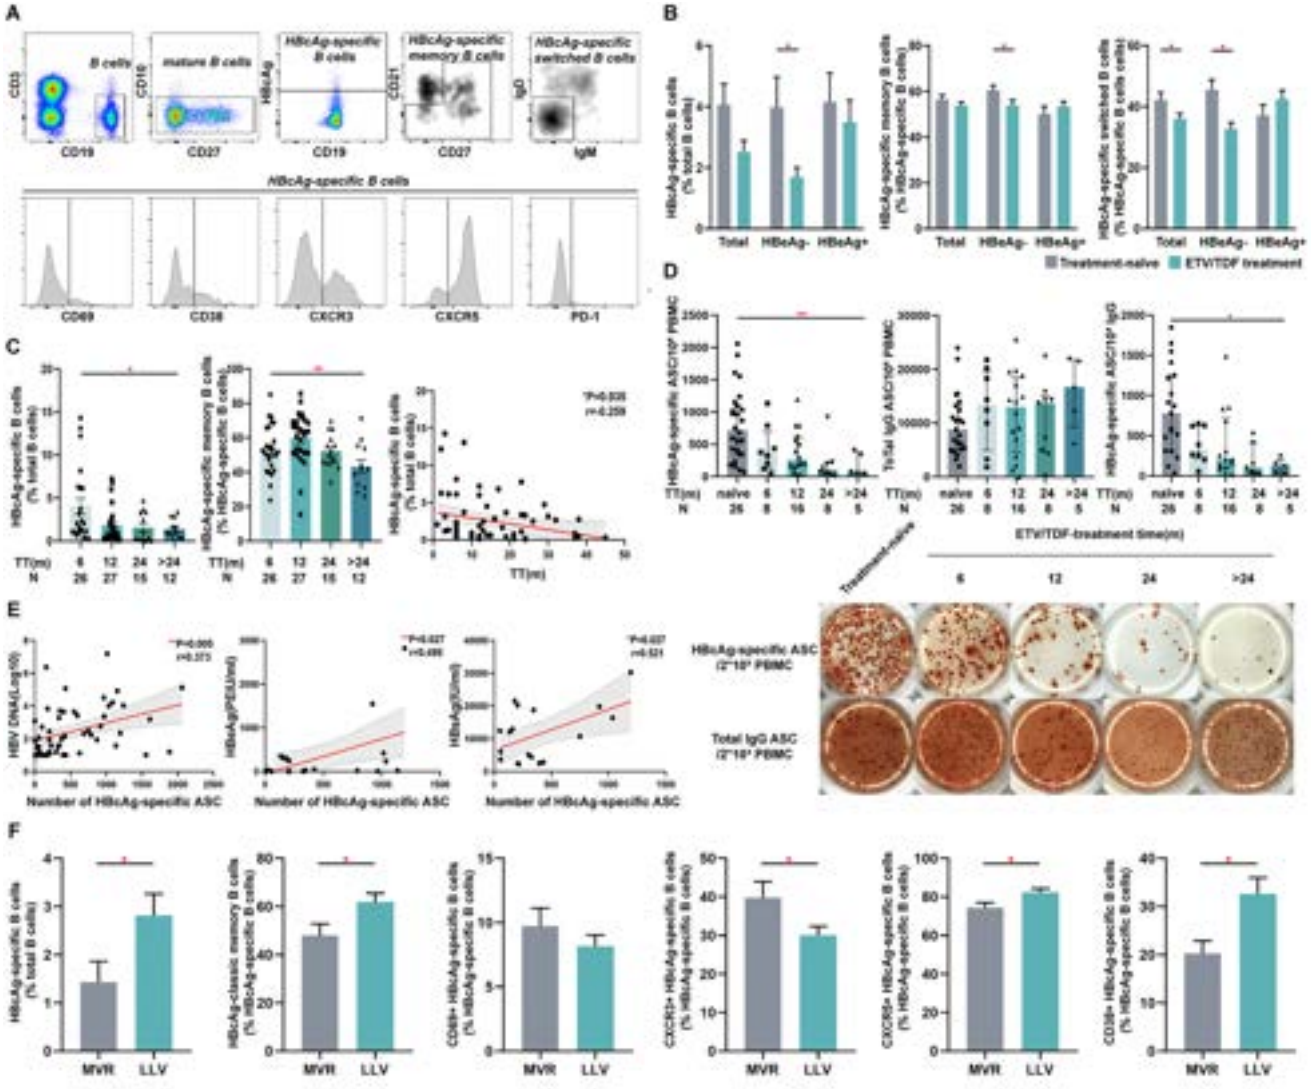

Figure1. Reduction in quantity and function of HBcAg-specific B cells in chronic HBV infected patients on ETV or TDF treatment. (A) representative FACS plots of HBcAg-specific B cells in CHB patients. (B) decreased percentages of total and memory HBcAg-specific B cells in CHB patients after ETV/TDF treatment. (C) dynamic changes in total and memory HBcAg-specific B cells in ETV/TDF-treated CHB patients at different time-points. (D) gradually decreased antibody-secreting memory HBcAg-specific B cells with the prolongation of ETV/TDF treatment time. (E) a positive correlation of antibody-producing memory HBcAg-specific B cells with serum HBV DNA load, or level of HBeAg or HBsAg. (F) fewer HBcAg-specific B cells in CHB patients with better respond to ETV/TDF therapy. TT, treatment time. ASC, antibody-secreting cells. m, month. N, number of cases analyzed. MVR, maintained virological response (defined by persistently undetectable HBV DNA). LLV, low-level viremia (defined by either persistent or intermittent episodes of <2,000 IU/mL detectable HBV DNA). *p<0.05, **p<0.01.

Figure: (abstract: FRI-250).

Extracellular vesicle-derived microRNA signature in chronic hepatitis C patients with different stages of liver fibrosis

Victoria Cairoli[1], Daniel Valle Millares[2], Pablo Ryan[3], Luz Martin Carbonero[4], Ignacio De Los Santos[5], Elena De Matteo[1], Marcela De Sousa[6], Veronica Briz[2], María Victoria Preciado[1], Pamela Valva[1], Amanda Fernández Rodríguez[2]. *[1]IMIPP-CONICET, Buenos Aires, Argentina; [2]ISCIII, Majadahonda, Spain; [3]Hospital Universitario Infanta Leonor, Madrid, Spain; [4]La Paz University Hospital, Madrid, Spain; [5]Hospital de La Princesa, Madrid, Spain; [6]Hospital General de Agudos J. M. Ramos Mejía, Buenos Aires, Argentina*
Email: amandafr@isciii.es

Background and aims: In the context of chronic hepatitis C (CHC), co-infection with HIV has a negative impact on liver damage progression. Recently, extracellular vesicles (EVs) have gained relevance in liver diseases as intercellular communicators thus mediating pathological processes. HCV and HIV have been described to modify the microRNA (miRNA) content of EVs, but little is known about their impact on pathogenesis or their possible role as liver damage biomarkers. We aimed to characterize the plasma derived-EVs miRNA signature of HCV+ and HCV+/HIV+ patients and to explore their expression regarding the severity of liver fibrosis, to assess its impact on pathogenesis.

Method: EVs were purified and characterized from 50 CHC plasma samples [36% significant fibrosis (F ≥ 2)] [21 HCV+ (52.4% F ≥ 2) and 29 HCV+/HIV+ (22.6% F ≥ 2)]. EVs-derived total RNA was extracted and massively sequenced. Then, miRNA identification, significant differential expression (SDE) analysis [fold change (FC) ≥ 1.5; adjusted p value (p.adj) ≤ 0.2], target gene prediction and pathway enrichment analysis (p.adj ≤ 0.5) were performed. The diagnostic value of SDE miRNAs was assessed by ROC curves analysis.

Results: Differential expression analysis of plasma EVs-miRNAs according to severity of liver fibrosis demonstrated 2 SDE miRNAs

(miR-122-5p and miR-92a-3p, up- and down-regulated in the F ≥ 2 group, respectively) which *in silico* regulate genes involved in cytoskeleton organization. Within HCV+ subgroup, 4 up- (miR-122-5p, miR-320c, miR-3615, miR-320a-3p), and 4 down-regulated miRNAs (miR-374b-5p, let-7a-3p, miR-199a-5p, miR-142-5p) were found in F ≥ 2 patients. Together, they regulate genes involved in macrophage activity and cell growth/death regulation. In turn, the HCV+/HIV+ subgroup displayed 11 up- (miR-4508, miR-122-5p, miR-451a, miR-1290, miR-1246, miR-107, miR-15b-5p, miR-194-5p, miR-22-5p, miR-20b-5p, miR-142-5p) and 7 down-regulated miRNAs (miR-328-3p, miR-335-3p, miR-125a-5p, miR-423-3p, let-7d-3p, miR-128-3p, miR-10a-5p). These miRNAs regulate the expression of genes involved in the RNA silencing machinery. Regarding diagnostic performance of SDE miRNAs to discriminate F ≥ 2 cases (AUROC ≥ 0.800) in each group different miRNAs were identified: HCV+: miR-3615 miR-374b-5p, let-7a-3p, miR-142-5p, miR-320a-3p and miR-320c and HCV+/HIV+: miR-423-3p, miR-128-3p, miR-194-5p, miR-10a-5p, miR-328-3p, miR-22-5p, miR-125a-5p, let-7d-3p, miR-335-3p, miR-451a, miR-122-5p and miR-1246.

Conclusion: chronic HCV+ and HCV+/HIV+ patients with different stages of liver fibrosis present a differential profile of EVs-derived miRNAs. This specific miRNA signature would allow elucidation of possible mechanisms involved in clinical evolution and identification of biomarkers of unfavorable progression specific for each group, plausible to be used in a diagnostic panel.

FRI-252
Prophylactic vaccine against hepatitis D virus (HDV) superinfection

Matti Sällberg[1], Lars Frelin[1], Gustaf Ahlén[1], Jingyi Yan[1], Panagiota Maravelia[1], Philip Cunnah[2], Ana-Rita Ricardo[2], Nico Mertens[3], Richard Bethell[4]. *[1]Karolinska Institutet, Laboratory Medicine, Stockholm, Sweden; [2]Rodon Biologics, Portugal; [3]Bionmer, Netherlands; [4]SVF Vaccin, Sweden*
Email: matti.sallberg@ki.se

Background and aims: Chronic infection with HDV caused by a superinfection of a chronic HBV infection is a major cause for severe liver disease. There is currently no vaccine that can protect patients with chronic HBV infection against a superinfection with HDV. We are therefore developing such a vaccine.

Method: A fusion protein containing multiple PreS1 genotypes and hepatitis D virus antigen (HDAg) of genotypes 1 and 2 was previously generated and to protect against HDV superinfection in vitro and in vivo. To generate a protein suitable for large scape production according to good manufacturing practice, protein variants were generated that were optimized for protein expression and stability and were tested for immunogenicity.

Results: The original protein described in Burm et al (Gut 2022; 10.1136/gutjnl-2022-327216) was found to be unstable when produced in large scale. Modified versions yielded proteins that were more stable and that were able to be produced at much higher expression levels in E.coli. Importantly, the modified proteins were equal, or even more immunogenic in mice with respect to both PreS1-specific antibodies and PreS1 and HDAg specific T cells.

Conclusion: We have now developed a potential protein-based prophylactic vaccine candidate against HDV superinfection that can be produced at high expression levels and with a good stability for large scale production according to GMP for phase1, 2, and 3 clinical trials. This may be the first prophylactic vaccine against HDV superinfection.

FRI-253
Rat hepatitis E virus infection in a rat model has multiphasic viral replication kinetics

Zhenzhen Shi[1], Xin Zhang[2], Niels Cremers[2], Johan Neyts[2], Harel Dahari[1], Suzanne Kaptein[2]. *[1]Loyola University Chicago, Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, United States; [2]KU Leuven Department of Microbiology and Immunology and Transplantation, Rega Institute, Laboratory of Virology and Chemotherapy, Belgium*
Email: suzanne.kaptein@kuleuven.be

Background and aims: Hepatitis E virus (HEV) is the causative agent of hepatitis E in humans and a leading cause of acute viral hepatitis. It is also responsible for chronic hepatitis in immunosuppressed patients worldwide. The virus is mainly transmitted fecal-orally, through the consumption of contaminated drinking water or infected undercooked meat of pigs. Additionally, HEV can also be transmitted via blood transfusions. Previously, we reported that athymic nude rats support the productive replication of rat HEV when injected

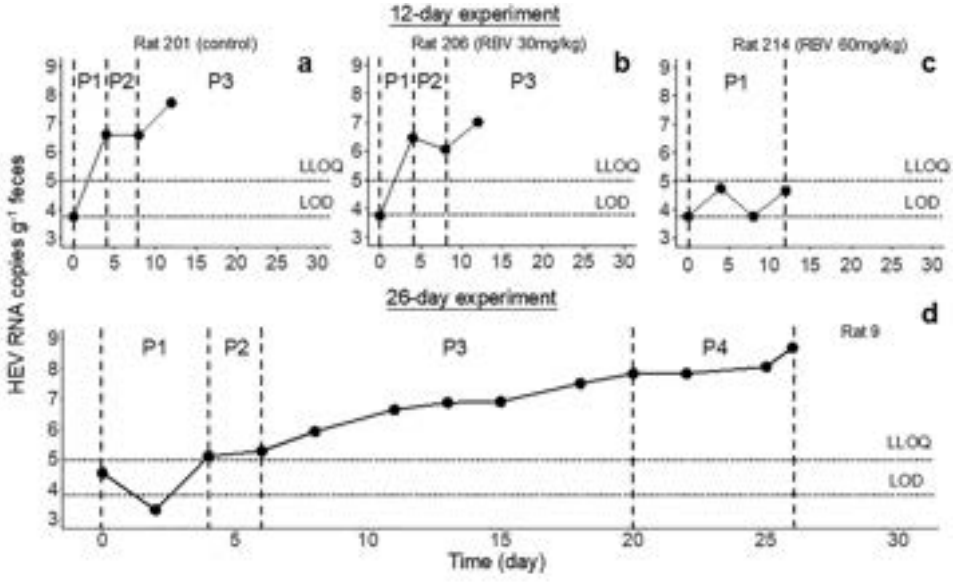

Figure 1. Representative HEV kinetic patterns in the 12-day and 26-day experiments. Solid lines between each experimental data are shown to highlight the trajectory. P1, P2, P3, P4 represent phase 1, phase 2, phase 3, and phase 4, respectively. LLOQ and LOD represent lower limit of quantification and limit of detection, respectively. RBV: ribavirin.

Figure: (abstract: FRI-253).

intravenously with diluted liver homogenate from HEV-infected rats, causing a chronic infection, which resembles the situation in immunocompromised individuals with chronic HEV (PMID: 27483350). Here, we aim to characterize HEV kinetics from infection to steady state in the rat model.

Method: Rat HEV LA-B350 (containing approximately 2×10^7 viral RNA copies) was injected in the tail vein of athymic nude rats in both the 12-day and 26-day experiments (n = 25). In the 12-day experiment, rats were treated once daily by oral gavage with either vehicle (n = 5) or ribavirin at a dose of 30 mg/kg (n = 5) or 60 mg/kg (n = 5) for 12 days. In the 26-day experiment, rats were left untreated (n = 10) for 26 days. Feces were collected at various time points after infection and analyzed for the presence of viral RNA by quantitative PCR.

Results: In the 12-day experiment, there is no difference in HEV replication kinetics between the control group and the group treated with ribavirin (30 mg/kg, once daily oral administration) (Fig. 1a and b). Three main viral phases were identified in these rats: a LLOQ phase that lasts ~4 days (4.8 ± 1.7 days) (phase 1: P1), a plateau phase that lasts ~4 days (phase 2: P2), and the beginning of a rapid ascension phase (phase 3: P3). In the rats treated with ribavirin 60 mg/kg, the viral load remained in the LLOQ (P1) phase (Fig. 1c). In the 26-day experiment, similar P1 and P2 phases were seen (Fig. 1d) as in the 12-day experiment (Fig. 1a and b). The 26-day experiment helped to fully characterize phase 3 (P3) that lasted until ~day 18 post infection (with viral doubling time of ~5 days) that was followed by a high viral plateau (7.9 ± 0.5 $\log_{10}$ copies g^{-1} feces) (phase 4: P4) (Fig. 1d).

Conclusion: The rat HEV infection kinetics presented here is an important step in characterizing this experimental model system so that it can be effectively used to elucidate the dynamics of the HEV life cycle and possibly to predict the efficacy of (novel) antiviral therapeutics or vaccine candidates. Future studies need to reveal whether the viral kinetics in the feces reflect that in the liver and/or blood.

FRI-254

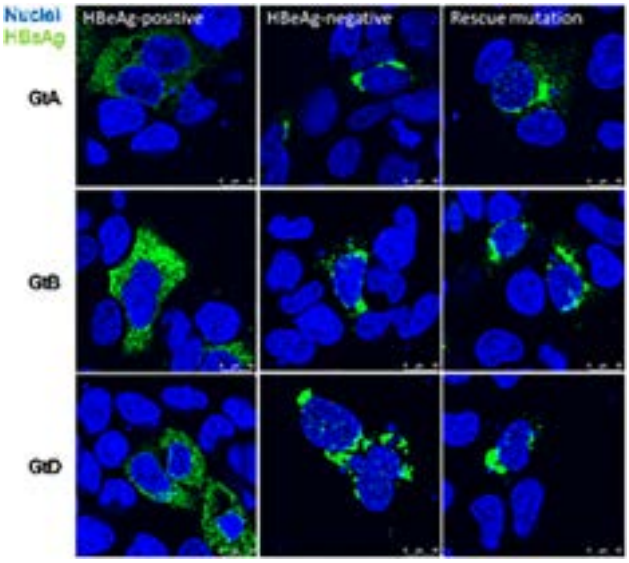
(N)one size fits all: Genotype-matched analysis of different disease phases of chronic hepatitis B virus infection

Michael Basic[1,2], Keerthihan Keerthihan Thiyagarajah[1,2], Mirco Glitscher[1], Anja Schollmeier[1], Qingyan Wu[1], Esra Görgülü[1,2], Julia Dietz[2], Fabian Finkelmeier[2], Jonel Trebicka[3], Stefan Zeuzem[2], Christoph Sarrazin[2,4], Eberhard Hildt[1], Kai-Henrik Peiffer[1,2,3]. [1]*Paul Ehrlich-Institute, Virology, Langen, Germany;* [2]*University Hospital Frankfurt, Department of Gastroenterology and Hepatology, Frankfurt, Germany;* [3]*University Hospital Münster, Medial Clinic B, Münster, Germany;* [4]*St. Josefs-Hospital, Department of Internal Medicine and Liver Center, Wiesbaden, Germany*
Email: kai-henrik.peiffer@kgu.de

Background and aims: Based on the current EASL guideline chronic HBV infections are divided in five phases. Among others, quantitative (q)HBsAg levels and composition of HBsAg are used for phase-assignment, but depend also on the viral genotype. We aimed to analyse the impact of the disease phase on the clinical and molecular phenotype in a genotype-stratified approach.

Method: Sera of 503 patients, infected with HBV genotype A and D from disease phases 1–4 were analysed for HBV-DNA and qHBsAg levels, HBsAg composition and density of HBsAg-particles. Molecular characteristics of genotype A, B and D HBeAg-negative patient isolates with Precore (PC) mutation G1896A from phase 3 were investigated in comparison to respective HBeAg-positive genomes via WB, RT-PCR, oxyblot, immunofluorescence microscopy, density-, reportergen-, infectivity- and kinase-assay. HBeAg-impact was determined by site-directed mutagenesis of PC G1896A.

Results: When stratified by the genotype, no major impact on particle density and HBsAg composition was observed among disease phases 1–4 in the analysed sera of patients infected with genotype A or D. However, in vitro significant differences between HBeAg negative genomes (genotypes A, B and D) from disease phase 3 were observed in comparison to HBeAg positive wildtype genomes. In HBeAg-negative genomes a strong decrease of intracellular and especially extracellular HBsAg amounts in combination with a HBsAg-retention in the endoplasmic reticulum (Figure) was detected. Interestingly, rescue of HBeAg increased HBsAg amount but not release. However, infectivity of secreted viral particles was unaffected. In addition, the HBV-induced expression of the Nrf2/ARE-dependently regulated gene NQO1 was more pronounced and strikingly ROS/Ras-related signaling was homogeneously deregulated leading to less active MAPK8 and MAPK10 in HBeAg-negative genomes. Sequence analysis revealed no conserved mutations between the HBeAg-negative genomes, which could explain these observations.



Conclusion: Our study indicates limited specificity of HBsAg composition for phase-discrimination when stratified by the viral genotype. In contrast, our in vivo data revealed evidence for a diminished HBsAg synthesis and release in HBeAg-negative genomes isolated from patients of the chronic infection phase. While presence of HBeAg increases HBsAg expression, it does not affect HBsAg release. Through regulation of ARE regulated genes and interference with ROS- and Ras-related pathways including MAPK8 and MAPK10, as key kinases of TNF alpha induced apoptosis, cytoprotective and possible immune escape mechanisms were found to be enhanced in the HBeAg-negative genomes. These changes are caused by an interplay of multiple polymorphisms, which occur naturally over the different phases of the disease, suggesting an evolutionary process.

Background and aims: Bepirovirsen (BPV; GSK3228836) and GSK3389404, a GalNAc conjugated BPV, are anti-sense oligonucleotides (ASO) that target a conserved 20 nucleotide sequence present

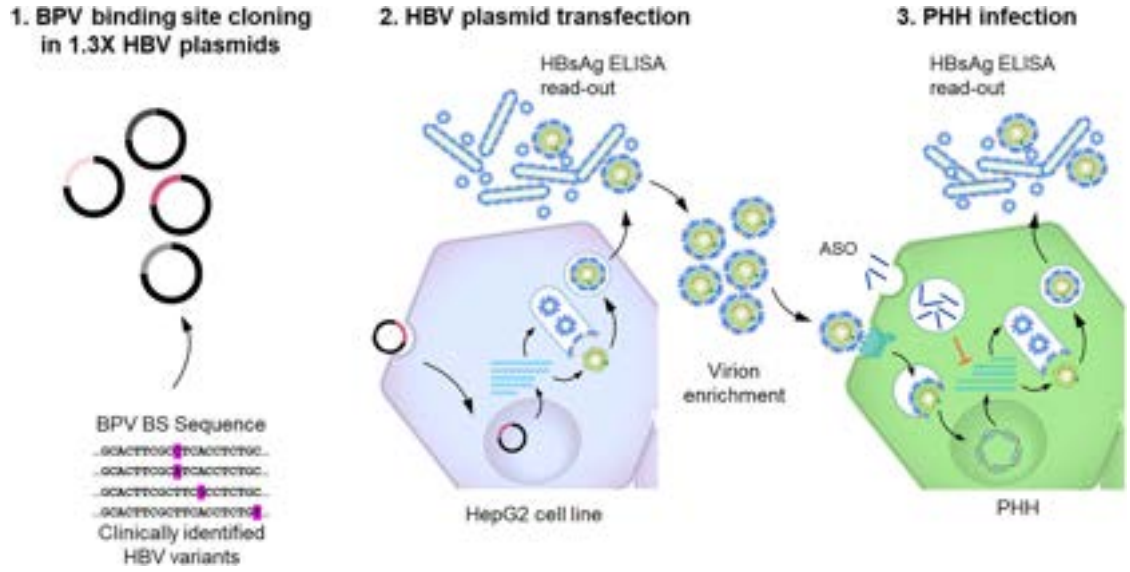

Figure: (abstract: FRI-255).

within all hepatitis B virus (HBV) mRNAs, including pgRNA. Despite the conserved nature of the binding site, single nucleotide polymorphisms (SNPs) within the binding site were identified in a limited number of pre-treatment clinical isolates from BPV B-Clear Phase 2b trial (NCT04449029) or within a publicly available database of sequences derived from clinical isolates. The goal of this study was to develop an *in vitro* system to evaluate the replicative fitness of HBV variants containing SNPs in the BPV/GSK3389404 binding site and to test the susceptibility of progeny virus to ASO treatment.

Method: Clinically identified BPV binding site SNPs, including C7A, C9A, C9T, T10G, A13C, were introduced into genotype D 1.3X HBV genome plasmids that enabled production of infectious viral stocks upon transient transfection in HepG2 cells. Primary human hepatocytes (PHH) were infected with wildtype (WT) HBV or HBV variants for 7 days followed by treatment with ASO GSK3389404 every 3–4 days. Secreted HBsAg levels were measured by ELISA on day 21 post infection. HBsAg levels secreted from mock-treated PHH served as a marker for transcriptional activity of the variants relative to HBV WT. The susceptibility of HBV variants to tool ASO GSK3389404 was evaluated by dose response analysis.

Results: Transfection of each of the 1.3X HBV variant genome plasmids resulted in comparable HBsAg production relative to HBV WT showing successful transfection and that the tested SNPs in the BPV binding site did not appreciably impact plasmid-driven HBsAg levels from HepG2 cells. In PHH, HBV WT and variants C9A, C9T, and T10G collected from HepG2 cells showed comparable infectivity as detected HBsAg levels were similar. In contrast, A13C and C7A variants displayed a several fold reduction of HBsAg, indicating reduced replicative fitness which impedes the interpretation of ASO susceptibility assessments. Among the variants with proportionate fitness to infect PHH and produce HBsAg, dose-response assessment provided evidence that the C9A variant exhibited reduced susceptibility to GSK3389404 compared to HBV WT.

Conclusion: We have developed a two-step *in vitro* model to provide an estimate of replicative fitness and evaluate ASO susceptibility of HBV variants with a SNP in the BPV binding site. Using this system, a few HBV variants identified from B-Clear baseline samples were evaluated. Clinical relevance of HBV variants with reduced susceptibility is under investigation.

Application of magnetic nanoparticle on boosting HBV infection system effectiveness

Bo-Hung Liao[1], Olga Mykhailyk[2], Cho-Chin Cheng[1], Christian Plank[2,3], Ulrike Protzer[1,4]. [1]*Institute of Virology, Munich, Germany;* [2]*Ethris GmbH, Planegg, Germany;* [3]*Institute of Molecular Immunology, Germany;* [4]*Helmholtz Zentrum München, Germany*
Email: protzer@tum.de

Background and aims: Infections with HBV in cell culture is a routine procedure to understand the virus life cycle and to evaluate antiviral strategies. The general drawback in HBV research, however, is its ineffective infection rate, which produces considerable noise effects in downstream analyses and limits its applicability. In contrast to other viruses, HBV infection requires a very high multiplicity of infection (MOI) and still infection rates are limited. To overcome this problem, we used SO-Mag6–11 magnetic nanoparticle (MNP), which have been proven to enhance the potency of lentivirus transduction, to increase the infection rate of HBV and broaden the applicability of the infection system.

Method: We used purified recombinant HBV (rHBV) expressing a red fluorescent protein (rHBV-RFP) to determine infection rates by fluorescence microscopy and flow-cytometry. Incucyte® live-cell imaging was applied to observe the dynamics of HBV infection. Quantitative analysis was conducted according to the expression level of fluorescent protein upon rHBV infection.

Results: We first used rHBV-RFP to titrate the optimal ratio of MNP to viral particles using MOI 1, 2, 5, 10, 20 and Incucyte® analysis from day 1 to 14. The comparison of RFP expression level indicates that 2 fg iron of MNP per virus particle is optimal. Transgene expression levels positively correlated to the applied MOI. Subsequently, rHBV infection was observed via fluorescent microscopy, and followed by flow-cytometry analysis to determine the infection rate. The infection rates indicated that MNP enabled us to use 1/10 the virus amount to obtain infection rates comparable to that using extremely high MOIs. Furthermore, an additional 10–15% increase in infection rates was achieved by complexing high MOI with MNP. Physical and biochemical validation of MNP and HBV complex are in progress. On one hand, high resolution microscopy is utilized to visualize the complex, and profile conversion upon complex formation will be determined. On the other hand, a spatial-temporal study will be performed to examine if the MNPs alter the kinetics of HBV infection, which step of

virus uptake is enhanced by MNP and how MNP revive less infectious HBV particles.

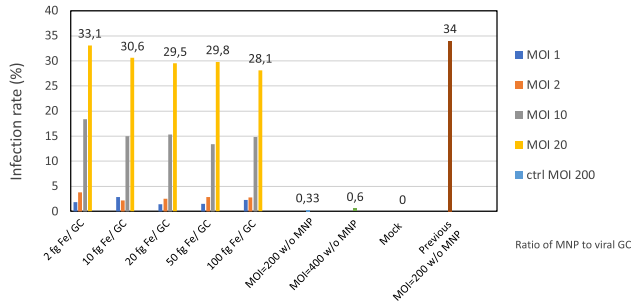

Figure:

Conclusion: The study is the first one reporting the enhancing effect of suitable MNPs on a HBV virus infection system, which is characterized by very low infection rates. We took advantage of the properties of the rHBV infection system that allows visualization of infection and determined the optimal ratio of MNP to viral particles. This increased infection efficacy will allow to extend screening activities in HBV cell culture infection models and provide insights into the limiting steps in these systems.

FRI-257

A new glyco-biomarker for measuring infectious hepatitis B virus targeting surface antigen glycan isomer (HBsAgGi)

Kiyohiko Angata[1], Maki Sogabe[1], Hisashi Narimatsu[1], Ayato Murata[2], Takuya Genda[2]. [1]*RCMG Inc., Japan,* [2]*Juntendo University Shizuoka Hospital, Department of Gastroenterology and Hepatology, Japan*
Email: angata@medglyco.com

Background and aims: Hepatitis B virus surface antigen (HBsAg) is a central marker to point-out HBV infection. However, HBsAg test does not always distinguish infectious and non-infectious subviral particles, as it uses antibodies to S-HBs. We aimed to develop a new marker to measure infectious particles more effective than conventional HBsAg. We previously found that DNA-containing particle was enriched by a lectin recognizing *O*-glycans and then generated a new monoclonal antibody against *O*-glycosylated PreS2 domain of M-HBs [HBsAg glycan isomer (HBsAgGi)]. Here we show the biochemical characteristics and pilot clinical results of HBsAgGi.
Method: To characterize the HBsAgGi antibody, Western blotting, immunoprecipitation (IP) and immunostaining assays were performed. To investigate clinical utility of the HBsAgGi antibody, we established a new ELISA system and measured sera of chronic hepatitis B (CHB) patients before and after nucleos(t)ide analog (NA) treatment. Reverse-transcription PCR was also performed to detect HBV RNA in HBV particles immunoprecipitated by HBsAgGi antibody.
Results: Biochemical analysis demonstrated that the HBsAgGi antibody recognizes M-HBs but not L-HBs, which is not modified with *O*-glycan on the PreS2. Mutations in antigenic loop in S-HBs did not affect the binding of HBsAgGi antibody so far tested. HBsAgGi localized in ER to Golgi in M-HBs-expressing cells, suggesting generation of HBsAgGi through glycosylation pathway. ELISA assay showed HBsAgGi antibody specifically bound to M-HBs of genotype C. In treatment naïve CHB patients, serum HBsAgGi level was higher in HBe-positive patients compared to HBe-negative patients at baseline. HBsAgGi levels were significantly correlated with the HBV DNA level ($p = 0.002$, $n = 32$). After 48 weeks, HBV DNA was significantly decreased. In contrast, HBsAg level did not show a significant reduction while HBsAgGi level was significantly decreased. Immunoprecipitation experiments confirmed that both HBV DNA- and HBV RNA-containing particles were collected by HBsAgGi antibody.
Conclusion: HBsAgGi specifically presents in minor fraction of HBV particles containing M-HBs of genotype C, and less so in subviral particles, indicating that HBsAgGi antibody can properly detect infectious particles. Since both HBV DNA and HBV RNA were detected in HBsAgGi-bound fraction, HBsAgGi would be a new glyco-biomarker to monitor viral kinetics in CHB patients during NA therapy.

FRI-258

Pregnancy zone protein as a promising biomarker for HEV-related acute liver failure

Jian Wu[1,2], Ze Xiang[3]. [1]*Department of Clinical Laboratory, The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou Municipal Hospital, Gusu School, Nanjing Medical University, 242 Guangji Road, Suzhou 215008, Jiangsu, China;* [2]*The Chinese Consortium for the Study of Hepatitis E (CCSHE)., China;* [3]*Zhejiang University School of Medicine, Hangzhou 310009, Zhejiang, China*
Email: wujianglinxing@163.com

Background and aims: Timely and effective prognostic biomarkers for hepatitis E virus (HEV)-related acute liver failure (ALF) are urgently needed.
Method: We performed four tandem mass tag (TMT)-labeled quantitative proteomic and targeted proteomics parallel reaction monitoring (PRM) studies on cross-sectional cohort 1 and 2 including 20 acute hepatitis E and 20 HEV-ALF patients respectively.
Results: Pregnancy zone protein (PZP) is a potential prognostic biomarker for HEV-ALF. PZP was identified by TMT and PRM quantitative proteomics. In the derivation cohort, PZP levels of the HEV-ALF patients in survival group were significantly higher than those of the dead group. According to the median level of PZP, HEV-ALF patients in the retrospective cohort 1 were divided into the high PZP (>1316.18 ng/L) and low PZP (≤1316.18 ng/L) groups. the survival time of the high PZP group was significantly longer than that of the low PZP group. Decreasing PZP levels were also correlated with the increasing number of failed organs. Compared with PZP levels at admission, levels at discharge increased significantly in the improvement group, and decreased significantly in both the fluctuation and deterioration groups. PZP levels were significantly negatively correlated with alanine aminotransferase, total bilirubin, and international normalized ratio levels. It was revealed that PZP level was highly correlated with survival time, clinical course and organ failure in HEV-ALF patients. Besides, multivariate logistic regression showed that laminin, hepatic encephalopathy, TBil, and PZP were independent factors affecting the prognosis of HEV-ALF patients, which were used to establish a novel prognostic model (ePLT). The assessment in the derivation and validation cohorts showed that the ePLT score was significantly superior to the MELD, KCH and Child-Pugh scores.
Conclusion: PZP is a promising prognostic biomarker, and ePLT is a high-performance prognostic score for HEV-ALF patients, which contribute to clinical decision-making in the management of HEV-ALF.

Quadruple mutation GCAC1809-1812TTCT leads to a better prognosis by decreasing HBV-mediated fibrogenic activity

Esra Görgülü[1,2], Michael Basic[2], Mirco Glitscher[2], Keerthihan Keerthihan Thiyagarajah[2], Anja Schollmeier[2], Alica Kubesch[3], Julia Dietz[3], Stefan Zeuzem[1], Christoph Sarrazin[4], Kai-Henrik Peiffer[1,2,5], Eberhard Hildt[2,6]. *[1]University Hospital Frankfurt, Department of Gastroenterology and Hepatology, Germany; [2]Paul Ehrlich-Institute, Virology, Germany; [3]University Hospital Frankfurt, Germany; [4]St. Josefs Hospital, Germany; [5]University Hospital Muenster, Department of Internal Medicine B, Germany; [6]German Center for Infection Research (DZIF), Germany*
Email: esra.goerguelue@kgu.de

Background and aims: The quadruple mutation GCAC1809-1812TTCT (TTCT), which coexists with the basal core promoter double mutation A1762T-G1764A (BCP) and is localized in the basal core promoter and/or HBx, is prevalent in inactive carriers and is associated with significantly lower HBV DNA levels and inactive carrier status and thus a better prognosis. In vitro, GCAC1809-1812TTCT leads to decreased replication activity and significantly reduced HBeAg levels. This study aimed to further investigate the underlying mechanism by which the TTCT mutation impacts HBV pathogenesis, leading to a favorable course of the disease.

Method: Supergenomic constructs harboring BCP and TTCT mutation in different positions localized in the core promoter gene, the HBx gene or both were used to analyze their regulatory activity via reporter gene assays, western blots and qPCR analysis. Reactive oxygen species (ROS) levels were analyzed by oxyblot analyses and flow cytometry. Kinome profiling was performed to investigate the influence of the presence or absence of TTCT on kinase activity.

Results: In our analyses, the TTCT mutation in HBx and basal core promotor leads to a slightly higher induction of the Nrf2/ARE-dependent regulated gene NQO1 as well as lower ROS levels compared to the BCP mutation without TTCT or the wild-type. Strikingly, the presence of the TTCT mutation in HBx and basal core promotor shows downregulation of the serine/threonine kinases PKA, PKG2, and PRKX that contribute to liver fibrosis and upregulation of ERK5 and p38-gamma, which play important roles in hepatic inflammation, whereas the BCP mutation without TTCT enhances the adverse effects in comparison to wild-type HBV.

Conclusion: One potential explanatory approach to the better prognosis in the presence of TTCT mutation is the induction of

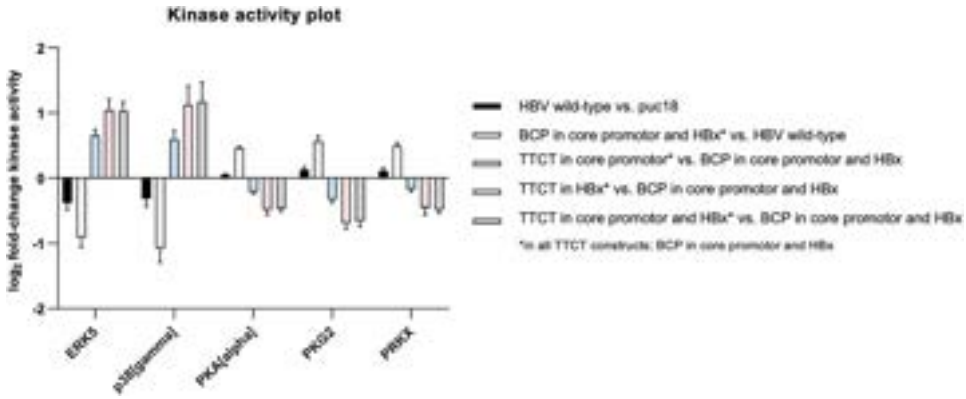

Figure: (abstract: FRI-259).

cytoprotective gene expression and downregulation of major kinases contributing to liver fibrosis.

FRI-260

Growth factor stimulation enhances NTCP expression and improves in vitro HBV infection in hepatoma cells

Rodrigue Kamga Wouambo[1], Maria Pfefferkorn[1], Janett Fischer[1], Jonathan Seltmann[1], Madlen Matz-Soja[1,2], Thomas Berg[1], Florian van Bömmel[1]. *[1]Leipzig University Medical Center, Division of Hepatology, Department of Medicine Ii, Leipzig, Germany; [2]Rudolf-Schönheimer-Institute for Biochemistry, University of Leipzig, Leipzig, Germany*
Email: Maria.pfefferkorn@medizin.uni-leipzig.de

Background and aims: Cell culture systems supporting sustained and stable hepatitis B virus (HBV) infection represent an important tool for studying HBV replication and drug efficacy. However, many cell culture models lack stable HBV replication with sufficient expression of replication markers due to an increasing loss of the HBV entry receptor NTCP on the hepatocyte surface. Our study aimed at improving NTCP expression and HBV replication in a cell culture system by using a growth factor stimulation medium.
Method: HepG2-hNTCP-sec+ cells (kindly provided by M. Windisch) were seeded separately and in equal amounts in either Cellartis® hepatocytes maintenance medium (HMM; TaKaRa Bio, Ann Arbor, USA) (n = 6) or seeding medium (SM; DMEM with 10%FBS, 1%L-Glutamine, 1%Pen/Strep, 2.7%DMSO) (n = 6) for 24 h prior HBV inoculation. Consecutively, cells were infected with cell culture derived HBV (ccHBV, genotype D, MOI 10.000) for 18 h. Supernatant was collected every 2 days during 21 days post infection (dpi). HBV biomarkers HBeAg, HBV DNA, HBV RNA, HBsAg, large (LHBs), and middle (MHBs) antigen were quantified from supernatants. NTCP expression of HBV infected cells in HMM and SM media was quantified by qPCR relative to a stable housekeeping gene (TATABox binding protein-TBP).
Results: The cell growth of HepG2-hNTCP-sec+ cells cultivated with either SM or HMM showed no difference at 6 dpi (p = ns). However, at 14 dpi, cells cultivated in HMM revealed a 2-fold higher NTCP expression compared to cells cultivated in SM. *De novo* secretion of HBV DNA and RNA began 2 dpi in cells cultivated in HMM vs. 2–4 dpi in SM and remained stable over the course of infection. Moreover, levels of HBsAg (ng/ml) increased from day 0 (24.5 ± 6.5 for HMM and 5.6 ± 0.5 for SM, $p < 0.0001$) to day 2 (157.0 ± 24.6 for HMM and 26.9 ± 4.8 for SM, $p < 0.0001$) with highest expression after 4 dpi (171.8 ± 31.9 for HMM and 40.8 ± 6.9 for SM, $p < 0.0001$). Similar to HBsAg levels, HBeAg levels (PEIU/ml) increased in HMM and SM cultivated cells from day 0 (2.6 ± 2.5 vs.0.6 ± 0.5, p = n.s) to day 3 (22.9 ± 4.4 vs.5.8 ± 2.2, $p = 0.004$), and were highest at 5 dpi (26.1 ± 4 vs 6.1 ± 0.8, $p = 0.001$), respectively. Interestingly, in HMM or SM cultivated cells, ratios of MHBs (12.0 ± 4.2% vs. 12.9 ± 3.3%, p = n.s.) and LHBs (11.0 ± 6.2% vs. 11.8 ± 6.5%, p = n.s.) were similar and stable over the course of infection.
Conclusion: Using HMM increases NTCP expression and improves *in vitro* HBV infection and biomarker secretion in HepG2-hNTCP-sec+ cell culture models.

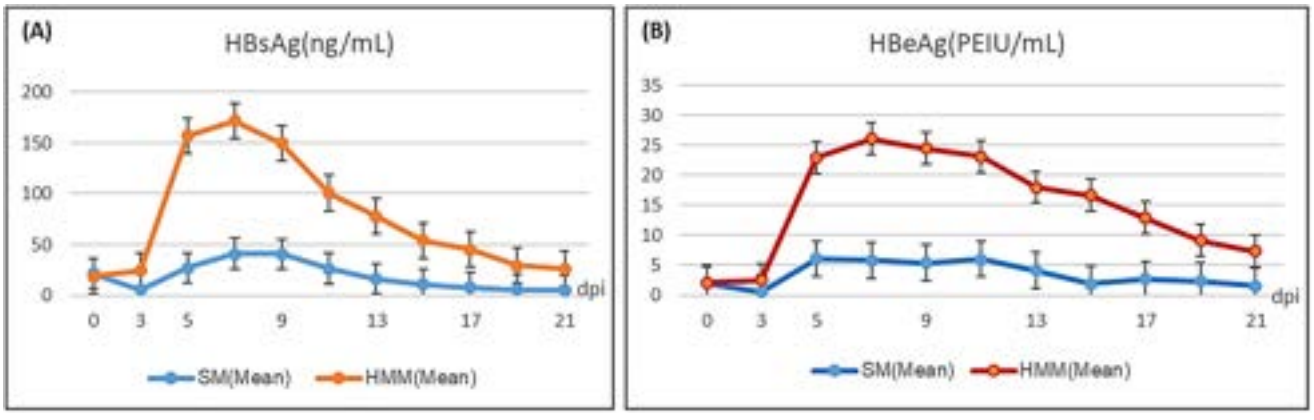

Figure: (abstract: FRI-260).

FRI-261

Hepatitis B virus antigens induce a dramatic LPS-like activation of inflammasome dependent on viral variability

Théophile Cocherie[1], Elisa Teyssou[1,1], Adélie Gothland[1], Sophie Sayon[1], Alessandre Mazzola[2], Anne-Genevieve Marcelin[1], Vincent Calvez[1], Eve Todesco[1]. *[1]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, AP-HP, Hôpitaux Universitaires Pitié Salpêtrière-Charles Foix, laboratoire de virologie, F-75013, Paris, France; [2]Sorbonne Université, Unité médicale de transplantation hépatique, AP-HP, Hôpital Pitié-Salpêtrière, 75013, Paris, France*

Email: eve.todesco@aphp.fr

Background and aims: Inflammation mediated by inflammasome activation leads to pyroptosis, an important innate programmed cell death to control pathogens that could also be associated with multi-organ disturbances. Pyroptosis occurs in two steps. The first, called priming, increases the expression of gene of interests and the second signal leads to activation of caspases and pore formation on the membrane surface, followed by the release of pro-inflammatory cytokines such as IL-1-ß and IL-18. Hepatitis B virus (HBV) role regarding pyroptosis is highly disputed and may depend on HBV disease stage, antigens, strains and even on the immune cells studied and their localization.

The aim of this study was to assess the role of HBV antigens on priming step in monocyte-derived cells and to assess the impact of the different serotypes.

Method: The effect of 3 purified proteins {HBsAg (adr, adw and ayw serotypes), HBeAg and HBcAg antigens; Prospect protein specialists, Ness Ziona, Israel} on priming step was assessed on macrophage-like cells. THP-1 circulating monocytes were cultured with RPMI-hepes 10% FBS-0.05 mM 2-mercaptoethanol, plated in 96-wells plates and differentiated to macrophages with 10nM of PMA for 24 h. HBV proteins were added at 10ug/ml on the differenciated-THP-1. IL-1β was measured by luminescence in the supernatant after 18 h of incubation and the addition of the signal 2-activator Nigericin at 10 µg/ml for 1 h. Controls included mock, cells primed by LPS at 1 µg/ml for 3 h only and cells primed by LPS at 1 µg/ml for 3 h and then activated by Nigericin. Comparison of IL-1β secretions were performed by Turkey's multiple comparisons test after validation by Shapiro test of normality.

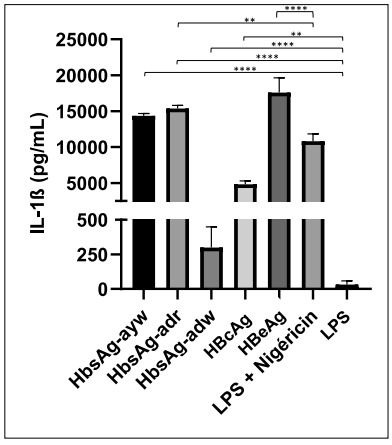

Figure: IL-1ß secretion induced by HBV antigens

The graph represents measure of IL-1ß secretion in supernatants of differenciated-THP-1 cells after incubation with different HBV proteins or LPS only (priming activator) or LPS following by the addition of Nigericin (activator of Signal 2). **p < 0.001; ****p < 0.0001.

Results: We observed that THP-1 cells incubated with HBeAg, HBsAg-adr and ayw serotypes and HBcAg induced a significantly higher IL-1β secretion than the negative controls. Notably, HBeAg and HBsAg-adr incubation led to huge IL-1β concentrations in the supernatant (median 17.6 ng/ml IQR [15.0–19.6] and median 15.4 ng/ml IQR [15.1–15.8], respectively), significantly higher than the positive control (cf. Figure 1). Moreover, among HBsAg, a dramatic difference was observed between the adr/ayw and adw serotypes, the latter inducing a much lower secretion than HBsAg derived from adr/ayw serotypes (median 0.3 ng/ml [1.5–4.5], not significantly different from the negative controls).

Conclusion: We observed a very high priming activation for some HBV antigens on monocyte-derived cells, evoking a large and diffuse pyroptosis involvement during HBV infection. Interestingly, HBsAg-adw serotype poorly induced priming. These results suggest that the innate immunity response and, precisely, IL-1β secretion pathways are influenced by HBV variability. The impact on clinical outcomes should be further studied, particularly regarding the rate of infection chronicity, already reported as high for adw-serotype/genotype A HBV, and the putative impact on systemic inflammation.

Host Sequence snatching identified in-vivo enhances hepatitis E viral replication

Maximilian Nocke[1], Michael Wissing[1], Paula Biedermann[2], Patrick Behrendt[3], C.-Thomas Bock[2], Heiner Wedemeyer[3], Eike Steinmann[1], Daniel Todt[1,4]. *[1]Ruhr University Bochum, Molecular and Medical Virology, Germany; [2]Robert Koch Institute, Germany; [3]Hannover Medical School, Germany; [4]European Virus Bioinformatics Center (EVBC), Germany*

Email: daniel.todt@rub.de

Background and aims: Hepatitis E virus (HEV) infections are usually asymptomatic and self-limiting, while in immunocompromised or other risk group patients may develop chronic courses. Recent data suggest that HEV has a very heterogeneous hypervariable region (HVR), tolerating major genomic rearrangements, which are mainly observed in chronic patients. Those insertions are correlated with replication fitness *in vitro* and chronicity *in vivo*. We provide a time efficient bioinformatics pipeline tool that automates identification and validation of insertions in high-throughput sequencing (HTS) data, while offering an easy to use graphical user interface (GUI) to simplify accessibility.

Method: Cutadapt and Trimmomatic were used to trim reads in an automated manner. Blastn was integrated in diverse variations to reduce runtime, while assigning reads to genes deposited at NCBI nucleotide database. To receive full insertion sequences, the *de novo* assembler Trinity was introduced into the pipeline. Identified insertions in longitudinal samples of a treatment resistant patient, as well as in public databases were analysed for their influence on viral replication kinetics, virus production capacity and treatment resistance using state-of-the-art HEV cell-culture methods.

Results: During development, runtime was drastically reduced and the need for extended command line usage was bypassed by implementing a GUI. We validated the pipeline by monitoring dynamic rearrangements in the HVR of a chronically HEV infected patient over time. Here, we identify insertions of critical impact for viral fitness while not affecting the sensitivity towards Ribavirin in a sub genomic replicon system and gain further insight into content and distribution of insertions and duplications.

Conclusion: Our pipeline has been designed as a user-friendly tool for detecting insertions of human or viral origin in the HVR of HEV from HTS data using computers with limited RAM and processing power, and includes a graphical user interface to help users interpret and validate the output. This study linked insertions in the HVR to an

increased replication capacity and identified determinants of viral replication *in vitro* and *in vivo*.

FRI-263

Thiourea derivatives exhibit antiviral property by inhibiting hepatitis B virus DNA replication and HBx-induced gene transcription

Jitendra Kumar[1], Purnima Tyagi[1], Shiv Kumar Sarin[2], Vijay Kumar[1].
[1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, India;* [2]*Institute of Liver and Biliary Sciences, Department of Hepatology, India*
Email: vijaykumar98@gmail.com

Background and aims: The transactivator HBx protein plays an important role in HBV replication and viral gene expression and has also been implicated in the development of hepatocellular carcinoma (HCC). The current antiviral therapies based on nucleos(t)ide analogs are effective at reducing viral replication but have no impact on the oncogenic functions of HBx. Therefore, HBx is considered as an important therapeutic target to control HBV and HCC. Earlier, we have shown that thiourea derivatives can suppress the expression of HBV DNA and viral antigens. Now we show that the antiviral property of thiourea derivatives is mediated at the Core promoter level resulting in the inhibition of HBx-dependent HBV replication as well as viral gene transcription.

Method: For viral replication studies, HepG2.2.15 cells were transiently transfected with the eukaryotic expression vector for viral HBx (X0) and treated with 10 µM of thiourea derivatives (DSA-00, DSA-02, and DSA-09) for 48 h. Total RNA was isolated and quantitated for pre-genomic (pgRNA) expression by RT-qPCR. To HBx-dependent viral gene transcription, HepG2 cells were transiently transfected with either X0 or its three deletion mutants (X5, X12, and X15) along with a luciferase reporter construct for HBV core promoter (nucleotides 1636 to 1851) (Fig. A). Transfected cells were treated with thiourea derivatives (DSA-00, DSA-02, and DSA-09) (10 µM each) and luciferase activity was measured in cell extracts.

Results: The enhancement in the expression of HBV pre-genomic RNA in the presence of HBx was inhibited to a significant level following treatment with DSA-00, DSA-02, and DSA-09 (Fig. 1B). Further, the HBV core promoter activity induced by HBx was also suppressed by all three thiourea derivatives (Fig. 1C). Interestingly, the three thiourea derivatives also inhibited the core promoter activity induced by two HBx deletion mutants X5 (ΔA) and X12 (partial (ΔE) but not X15 (ΔA, B, F) (Fig. 1D).

Conclusion: The thiourea derivatives DSA-00, DSA-02, and DSA-09 were effective at suppressing the HBV pgRNA to significant levels. Further, these compounds also inhibited the HBx-induced HBV core promoter activity. The presence of A and B regions at N-terminus and C-terminal C region appeared to be crucial for the antiviral activity as the transactivation function of X15 mutant could not be suppressed in the presence of these molecules. Alternatively, thiourea derivatives which dock onto HBx *in silico*, are unable to bind to X15 mutant due to the absence of one or more interacting sites. This study suggests that thiourea derivatives specifically target HBx to exhibit its antiviral activity and thus, has the potential to be developed as a new class of HBV therapeutic.

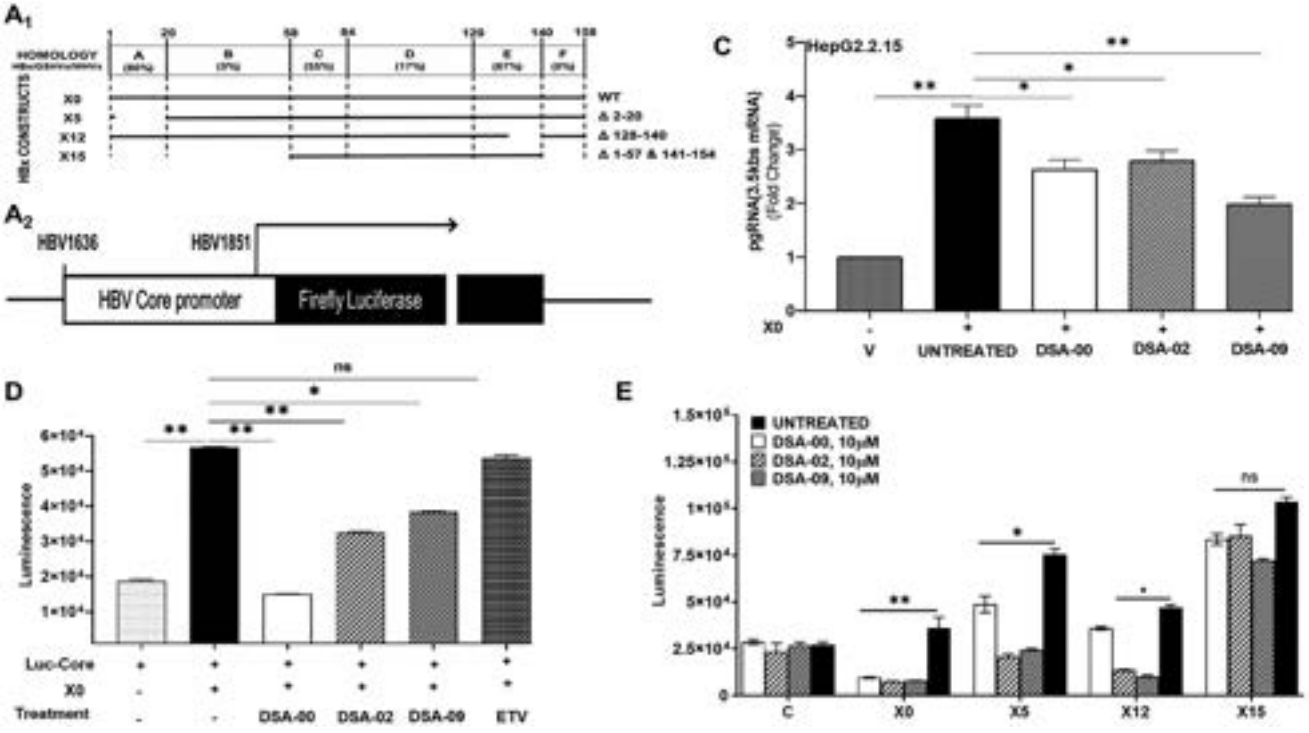

Figure: (abstract: FRI-263): Inhibition of HBV replication and viral gene transcription by Thiourea derivatives. Illustration of HBx wild-type and deletion mutant constructs (A_1). Transient transfection with X-0 and luc-core (A_2) (1 µg each), the pre-genomic RNAs levels measured by RT-qPCR and calculated by Fold changes in HepG2.2.15 cells treated with thiourea derivatives for 24 hours (B). HBV Core promoter activity with ectopic expression of HBx in HepG2, followed by treatment with thiourea derivatives for 24 hours measured by luciferase assay (C). HBV core promoter activity measured by luciferase assay with HBx wild-type and deletion mutants followed by thiourea derivatives treatment for 24 hours (D). (*p < 0.05; **p < 0.001).

Fas/Fas-ligand induced apoptosis of CD8 (+) lymphocytes in the placenta of women with chronic hepatitis B plays a twofold role in the protection of fetus

Dionysia Mandilara[1], Spyridon Pantzios[1], Georgia Barla[1], Antonia Syriha[1], Ioannis Elefsiniotis[1]. [1]*General Oncological Hospital of Kifisia Oi Agioi Anargyroi, Kifisia, Greece*
Email: deniaa96mand@gmail.com

Background and aims: During pregnancy immunological changes, including the reduction of CD8 (+) T-cells, occur, creating an immunotolerant placental environment. Fas/Fas ligand pathway is responsible for maintaining placental homeostasis. Our study examined the role of Fas/Fas ligand induced apoptosis of CD8 (+) lymphocytes in the protection of fetus, from both HBV infection and CD8 (+) T-cell's cytotoxic effect.
Method: Our study included 50 HBsAg (+)/HBV DNA (+) pregnant women that gave birth with vaginal delivery. Peripheral and umbilical cord blood was collected and placental tissue was examined using hematoxylin-eosin staining, immunochemistry and double immunofluorescence in order to identify the T-cell's sub-populations in the decidua and the chorionic villi and detect apoptotic activity.
Results: Umbilical cord HBV-DNA positivity was correlated with high levels of maternal viremia ($p < 0.0001$). Decidua's CD8 (+) lymphocyte count was higher in women with low viral load (LVL) versus women with high viral load (HVL) (11.25 ± 7.23 versus 6.46 ± 3.84 per High Power Field (HPF), $p = 0.043$) and in women with absence of HBV-DNA in contrast with women with positive HBV-DNA in umbilical cord blood (11.00 ± 6.45 versus 4.86 ± 3.02 per HPF, $p = 0.011$). Decidua's CD8 (+)/CD28 (+) and CD8 (+)/Fas-Ligand (+) T-cells' percentage was higher in the LVL group (13 ± 1% vs 9 ± 1%, $p = 0.026$/51 ± 1% vs 45 ± 1%, $p = 0.006$), while the percentage of CD8 (+)/Fas (+) was higher in the HVL group (68 ± 1% vs 73 ± 1%, $p = 0.035$). The percentage of CD8 (+)/CD28 (+) lymphocytes was statistically lower than the percentage of CD8 (+)/Fas (+) and CD8 (+)/Fas-ligand (+) T-cells in both groups ($p < 0.05$).
Conclusion: High levels of maternal viremia relate to lower levels of CD8 (+) lymphocytes in the decidua probably due to activation of Fas/Fas-ligand apoptotic pathway resulting in the fetus protection both from CD8 (+) lymphocytes cytotoxic effect and HBV transmission.

FRI-265

Intrahepatic hepatitis B virus cccDNA amount and transcriptional activity in a well-characterized cohort of Gambian chronically infected patients: correlation with emerging serum viral markers

Anaëlle Dubois[1], Sarah Heintz[1], Damien Cohen[1], Marie-Laure Plissonnier[1], Françoise Berby[1], Marintha Heil[2], Massimo Levrero[1,3,4], Fabien Zoulim[1,3,5], Yusuke Shimakawa[6], Maud Lemoine[7], Dalessandro Umberto[8], Isabelle Chemin[1], Barbara Testoni[1]. Email: barbara.testoni@inserm.fr

Background and aims: Hepatitis B virus (HBV) is highly prevalent in Sub-Saharan Africa, where 80 million people are chronically infected with the virus. One of the most common cancers in the region, hepatocellular carcinoma, is mainly attributable to HBV infection. Natural history of HBV infection has mostly been studied in European and Asian cohorts, thus leaving completely unmet the need of data for the Sub-Saharan Africa, where mode of transmission, age of infection, and various genetic and environmental factors differ completely. Therefore, data relating to the natural history of HBV infection in these patients are much needed.
Method: 96 untreated chronically HBV infected (CHB) patients were retrospectively selected from samples collected in The Gambia in the frame of the PROLIFICA program. Paired liver biopsy and serum samples were analyzed for serum HBV DNA, quantitative (q)HBsAg, HBcrAg (Lumipulse CLEIA Assay) and alanine aminotransferase (ALT) levels. Liver total HBV DNA (tHBV DNA), cccDNA and 3.5Kb RNA were assessed by droplet digital PCR (ddPCR) and cccDNA transcriptional activity was calculated as 3.5Kb RNA/cccDNA ratio. Liver histology scores were also available. Serum HBV RNA (cirB-RNA) was quantified by the Roche HBV RNA investigational assay for use on the cobas® 6800 System (LLOQ 10 cp/ml; linearity range 10 to 10^7 cp/ml; LLOD ~3 cp/ml-Scholtès, J Clin Virol 2022).
Results: The large majority of patients were HBeAg (-), HBV genotype E and only 10% of them had ALT levels above twice the upper limit of normal. Median levels of serum HBV DNA were 2.9 (2.1–4.2) Log IU/ml and qHBsAg were 3.7 (2.5–4.9) Log IU/ml. All patients had quantifiable tHBV DNA in their liver 0.4 (0.1–0.7) copies/cell, 90% had quantifiable cccDNA 0.02 (0.006–0.6) cp/cell and 85% quantifiable 3.5Kb RNA 0.09 (0.02–0.9). cccDNA amount was positively correlated with intrahepatic tHBV DNA, 3.5Kb RNA and serum HBV DNA, but not serum qHBsAg. Moreover, the results clearly indicated the presence of two groups of patients with comparable cccDNA levels, but different transcriptional activity, which was not reflected in differences in the serum HBV DNA or qHBsAg levels. Eighty-five serum samples were available for HBcrAg and cirB-RNA quantification, which were detectable in 35 and 33 samples, respectively. Both markers were highly correlated with intrahepatic HBV markers and in particular with cccDNA levels ($R = 0.7$, $p = 0.0006$ for HBcrAg and $R = 0.6$, $p = 0.02$ for ciirB-RNA), which was confirmed also in the group of patients with low cccDNA transcriptional activity.

Table: T-cell's subpopulations in the decidua and chorionic villi in the LVL vs the HVL group

T-CELL SUBTYPE/PLACENTA'S HISTOLOGICAL AREA	LVL (HPF)	HVL (HPF)	P VALUE
CD3 (+) CHORIONIC VILLI	4.80 ± 8.61	2.38 ± 1.50	0.598
CD3 (+) DECIDUA	11.1 ± 6.58	10.00 ± 6.45	0.548
CD4 (+) CHORIONIC VILLI	4.85 ± 4.80	1.00 ± 1.00	0.762
CD4 (+) DECIDUA	6.05 ± 6.31	5.00 ± 1.00	1.00
CD8 (+) CHORIONIC VILLI	6.25 ± 1.07	3.54 ± 5.14	0.265
CD8 (+) DECIDUA	11.25 ± 7.23	6.46 ± 3.84	0.043

Figure: (abstract: FRI-264).

Conclusion: To the best of our knowledge, this is the most comprehensive study evaluating the correlations between intrahepatic and serum HBV activity in people living with CHB in Sub-Saharan Africa. These data will contribute to a better understanding of the natural history of CHB and thus improve the management of African CHB patients.

Hepatitis B pre-genomic RNA level has a prospective supporting role for predicting the outcomes of the hepatitis B virus inactive carrier phase

Prooksa Ananchuensook[1], Pakkapon Rattanachaisit[1], Sirinporn Suksawatamnuay[1], Panarat Thaimai[1], Supachaya Sriphoosanaphan[1], Kessarin Thanapirom[1], Piyawat Komolmit[1]. *[1]Chulalongkorn University, Division of Gastroenterology, Department of Internal Medicine, Bangkok, Thailand*
Email: pkomolmit@yahoo.co.uk

Background and aims: Hepatitis B viral (HBV) DNA and quantitative hepatitis B surface antigen (qHBsAg) have been used as biomarkers to classify and predict complications in patients with chronic hepatitis B (CHB) infection. Pregenomic-RNA (pgRNA), the biomarker representing covalently closed circular DNA (cccDNA) activity in hepatocytes, has been associated with viral rebound after cessation of nucleotide analog (NA) treatment. However, the role of pgRNA in the inactive carrier (IC) phase is unclear. Therefore, our study aims to evaluate the utility of pgRNA in IC.

Method: Patients with CHB infection were included in this study and classified into IC and chronic hepatitis (CH) groups according to the European Association for the Study of the Liver (EASL) guidelines. The serum HBV pgRNA, qHBsAg, and HBV viral loads (VL) were quantified using digital polymerase chain reaction (PCR), immunoassay methods, and real-time PCR, respectively. The HBV pgRNA levels and percentage of patients with undetectable HBV pgRNA in each phase were analyzed using the Mann-Whitney *U* test and chi-square test. The outcomes, including spontaneous HBsAg loss defined as qHBsAg < 0.05 IU/ml and initiation of antiviral therapy in compliance with the indications outlined in the EASL guidelines, were reviewed. The factors associated with the outcomes were assessed using the Cox regression model.

Results: A total of 309 patients with CHB infection were enrolled. Of these, 154 (49.8%) were in the IC phase and 42 (27.1%) were HBeAg-positive. PgRNA quantity was detectable in 120 patients (38.83%). The log pgRNA showed a moderate correlation with log HBV DNA (r 0.376, p < 0.001) and qHBsAg (0.416, p < 0.001). The proportion of patients with detectable pgRNA was significantly lower in the IC group (24.0%) than that in the CH group (53.5%). In the IC group, 126 (81.82%) patients were prospectively observed with a median follow-up time of 26 months (IQR 22.75–29.00). Six (3.9%) patients had spontaneous HBsAg loss, and all of them had qHBsAg <1,000 IU/ml and undetectable pgRNA. On the other hand, three (1.9%) patients required treatment. Of these, pgRNA was detected in all three (100%), while one (33.3%) had qHBsAg ≥1,000 IU/ml. On univariate analysis, log pgRNA was the only significant factor predicting the need for antiviral therapy, with an odds ratio of 2.85 (95% CI 1.04–7.76).

Conclusion: IC had a lower proportion of detectable pgRNA than the CH group. Furthermore, all patients with spontaneous HBsAg loss had undetectable pgRNA, while all subsequently required treatments had detectable pgRNA. Therefore, pgRNA may be a supporting biomarker that can be added to qHBsAg to improve the accuracy of predicted prognoses for patients in the IC phase of patients in IC.

Figure: (abstract: FRI-266).

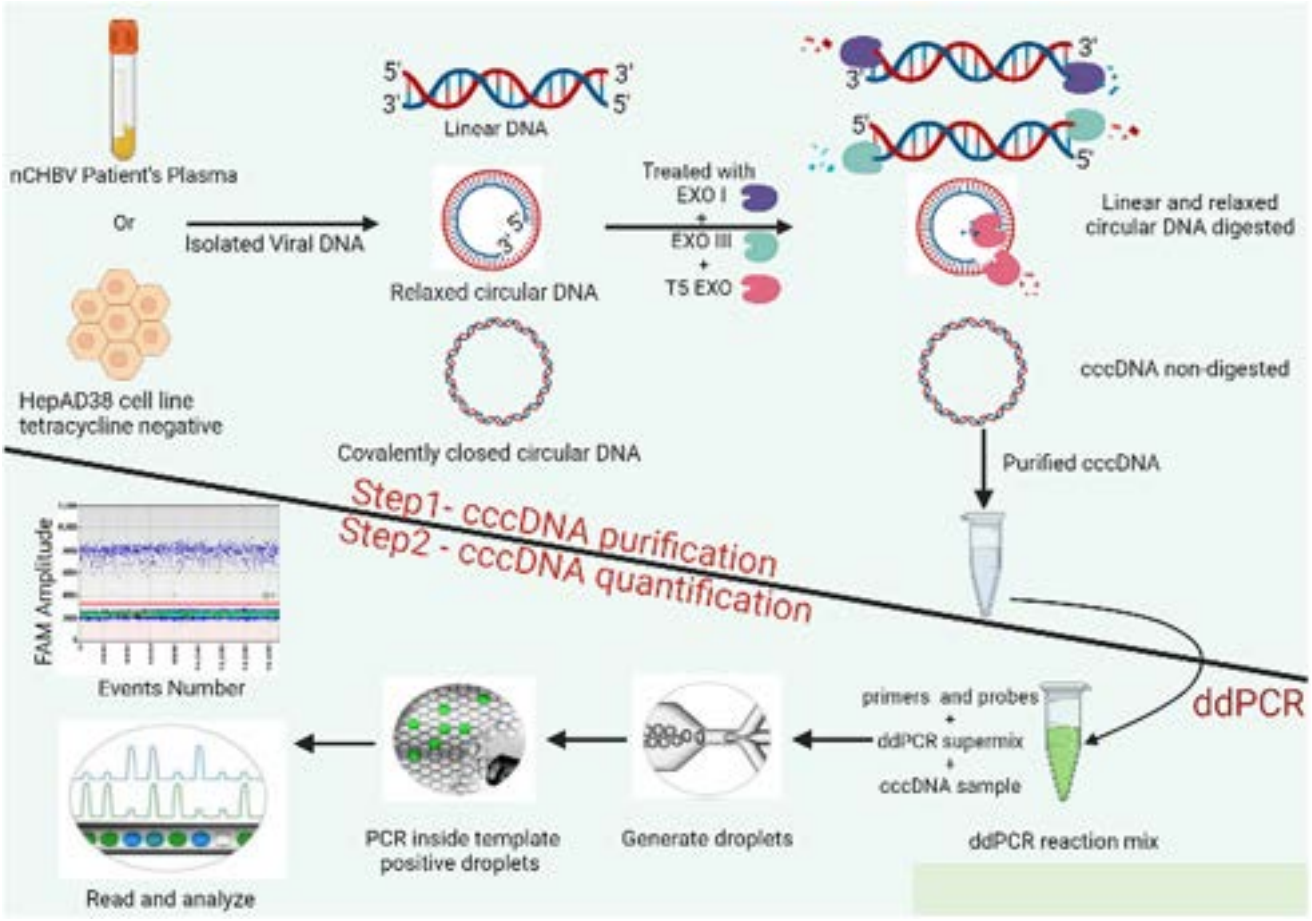

Figure: (abstract: FRI-267): Graphical abstract.

Background and aims: The intranuclear episomal form of HBV DNA i. e., covalently closed circular DNA (cccDNA) is the main replicative and transcriptional unit of HBV. The cccDNA quantification can reflect the transcriptome, active replicon, and persistence of HBV and is done in liver biopsy tissue. There is no sensitive assay for the precise detection of cccDNA in circulation. We aimed to quantify cccDNA in the plasma of chronic HBV (CHBV) patients using three exonucleases followed by droplet digital PCR (ddPCR).
Method: Thirty-six treatment naïve CHBV (nCHBV) patients with low HBsAg (<2,000 IU/ml, HBsAg^{lo}, Gr. I, n = 9) and high HBsAg (>2,000 IU/ml, HBsAg^{hi}, Gr. II, n = 27) with HBV DNA (<2,000 IU/ml or >2,000 IU/ml) with ALT level >1.2 × ULN (ULN = 40 IU/L). To standardize the assay, an HBV genome integrated, tetracycline (tet) regulated HepAD 38 cell line was used as a positive control. Total viral DNA was isolated from tet-off HepAD38 cells and the patient's plasma using Qiagen viral DNA isolation kit. Isolated viral DNA was treated with EXOI and EXO III enzymes to remove linear DNA and T5 exonuclease to remove relaxed circular HBV DNA and got purified cccDNA by phenol:chloroform: isoamyl alcohol (P:C:I) method. Further, to quantitate cccDNA, specific primers with FAM-tagged probe were used in a highly accurate and sensitive droplet digital PCR machine that can detect a single copy of cccDNA. Analysis was done by QuantaSoft Software using the Poisson correction method.
Results: Without enzyme treatment, the tet-off HepAD 38 cell line showed 2210 copies/µl including all three, linear, relaxed circular, and cccDNA forms of HBV DNA. After enzyme treatment, linear and relaxed circular forms were digested and 15 copies/µl cccDNA was evident. Similarly treated viral DNA from chronic HBV patients, showed a median of 9 cccDNA copies (range 1–255)/µl from Gr. I (HBsAg^{lo}) patients and 11 cccDNA copies (range 2 to 555)/µl from Gr. II (HBsAg^{hi}) patients.
Conclusion: This is the first sensitive and efficient protocol for cccDNA quantification in plasma. Using three exonucleases (EXOI, EXO III, and T5 exonuclease), this assay accurately and specifically quantifies cccDNA by droplet digital PCR even in patients with low HBsAg.

FRI-268
COVID-19 vaccination alters NK cell dynamics and transiently reduces HBsAg titers among patients with chronic hepatitis B
Hyunjae Shin[1], Ha Seok Lee[2], Ji Yun Noh[3], June-Young Koh[2], So-Young Kim[2], Jeayeon Park[4], Sungwon Chung[4], Moon Haeng Hur[4], Min Kyung Park[4], Yun Bin Lee[4], Yoon Jun Kim[4], Jung-Hwan Yoon[4], Jae-Hoon Ko[5], Kyong Ran Peck[5], Joon Young Song[3], Eui-Cheol Shin[2], Jeong-Hoon Lee[4]. *[1]Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South; [2]Korea Advanced Institute of Science and Technology, Korea, Rep. of South; [3]Korea University Guro Hospital, Korea, Rep. of South; [4]Seoul National University College of Medicine, Korea, Rep. of South; [5]Sungkyunkwan University School of Medicine, Korea, Rep. of South*
Email: pindra@empas.com

Background and aims: COVID-19 vaccination may non-specifically alter the host immune system. This study aimed to evaluate the effect of COVID-19 vaccination on HBsAg titer and host immunity in chronic hepatitis B (CHB) patients.
Method: Consecutive CHB patients who had serial HBsAg measurements during antiviral treatment were included in this study.

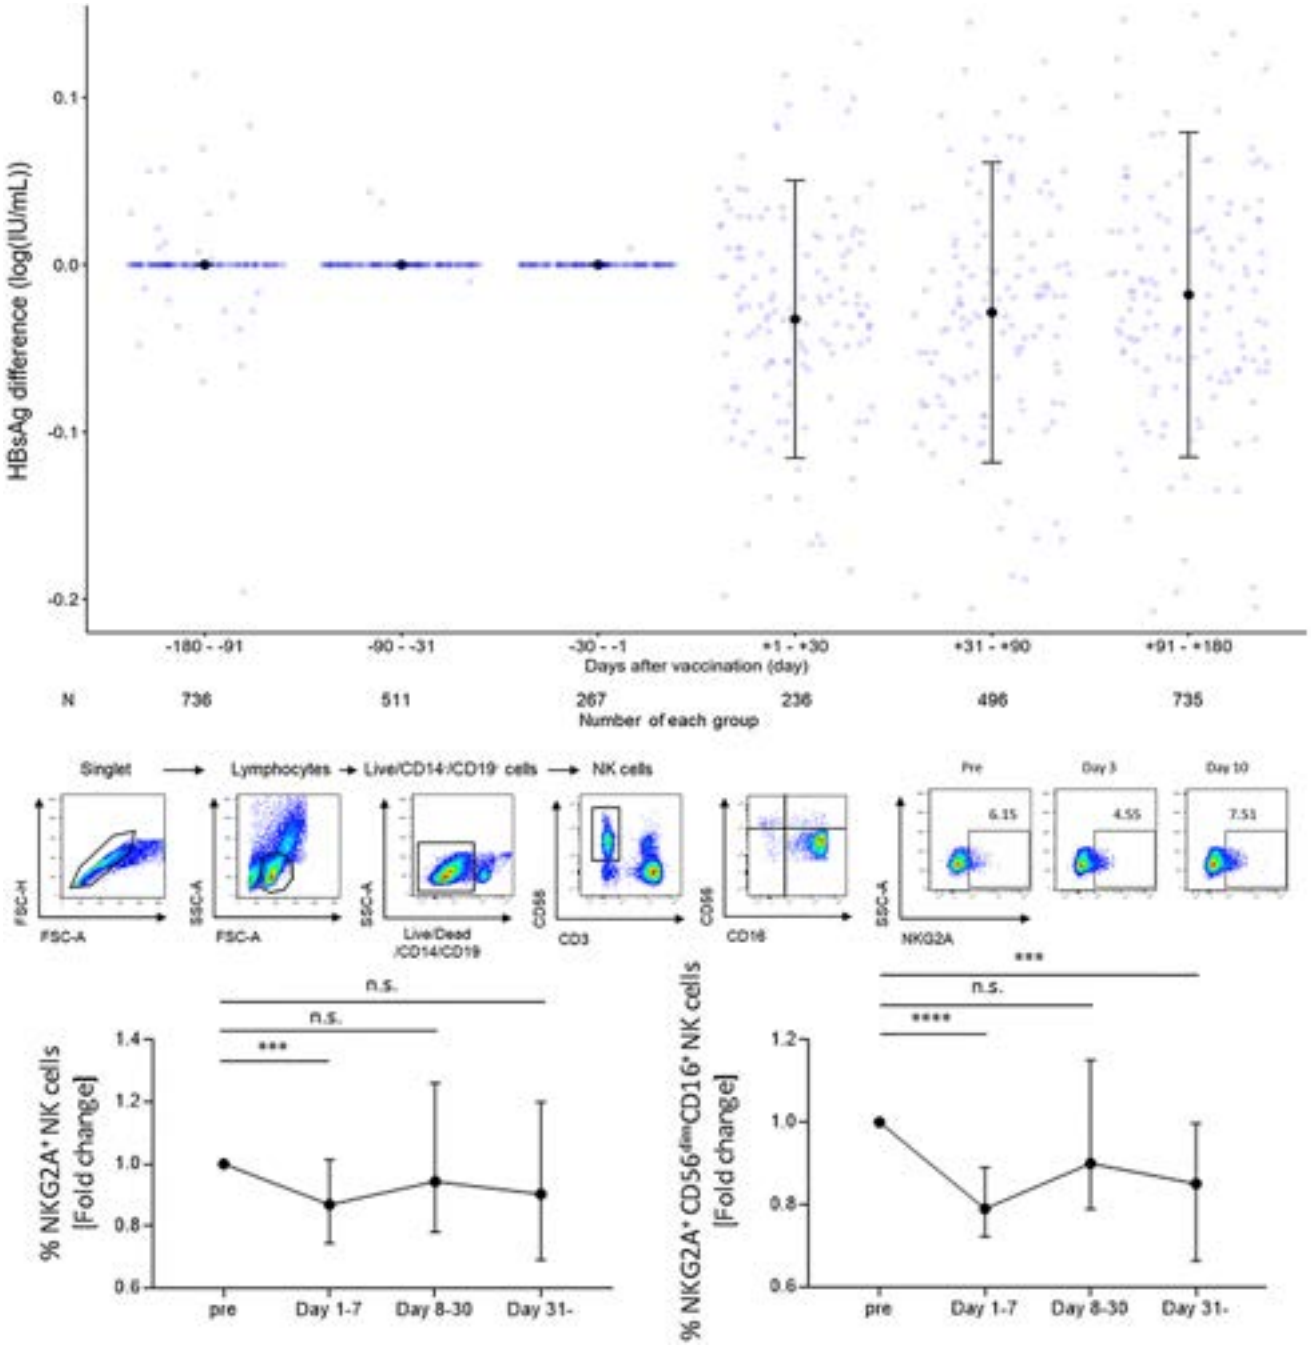

Figure: (abstract: FRI-268).

Changes in the HBsAg levels after COVID-19 vaccination were analyzed. The dynamics of natural killer (NK) cells following COVID-19 vaccination were also examined using serial blood samples collected prospectively from 25 healthy volunteers.

Results: Vaccinated CHB patients (n = 2,329) had significantly lower HBsAg levels 1–30 days post-vaccination compared to baseline (median, −21.4 IU/ml from baseline), but the levels reverted to baseline by 91–180 days (median, −3.8 IU/ml). The velocity of the HBsAg decline was transiently accelerated within 30 days after vaccination (median velocity: −0.06, −0.39, and −0.04 $\log_{10}$ IU/ml/year in pre-vaccination period, days 1–30, and days 31–90, respectively). In contrast, unvaccinated patients (n = 468) had no change in HBsAg levels. Flow cytometric analysis showed that the frequency of NK cells expressing NKG2A, an NK inhibitory receptor, significantly decreased within 7 days after the first dose of COVID-19 vaccine (median, −13.1% from baseline; $p < 0.001$). The decrease in the frequency of $NKG2A^+$ NK cells was observed in the $CD56^{dim}CD16^+$ NK cell population regardless of type of COVID-19 vaccine.

Conclusion: COVID-19 vaccination leads to a rapid, transient decline in HBsAg titer, which may be attributed to a decrease in the frequency of $NKG2A^+$ NK cells.

FRI-269

Serum metabolite revel mirochondrial dysfunction and energy metablism disruption in chronic hepatitis C virus infection

Amar Deep[1], Sumit Rungta[1], Durgesh Dubey[2], Ajay Kumar[3], Amit Goel[2], Dhananjay Kumar[4]. [1]*King george's Medical University Lucknow, Chowk, Medical Gatsroenterology, Lucknow, India;* [2]*SGPGIMS, Gatsroenterology, Lucknow, India;* [3]*King george's Medical University Lucknow, Chowk, Internal Medicine, Lucknow, India;* [4]*ILBS, Hepatology, New Delhi, India*
Email: jsa.amardeep@gmail.com

Background and aims: Hepatitis C virus (HCV) infection is a major public health problem worldwide, with an estimated 170 million people chronically infected. This study aimed to identify patients with HCV infection through an analysis of the 1H NMR spectra of serum samples using multivariate statistical data reduction tools.
Method: The study was a retrospective analysis of 83 chronic hepatitis C patients consecutively treated. To generate an overview of the variations between serological HCV samples and normal controls, an exploratory principal component analysis (PCA) model was created to compare the 800 MHz 1H NMR profiled metabolite concentrations.
Results: The PC1 vs. PC2 scores scatter plot indicated an unsupervised separation trend between HCV and normal controls. A partial least squares discriminant analysis (PLS-DA) model was subsequently constructed, and the corresponding score plot confirmed a conclusive separation between the serum values between the HCV patient and the normal controls. The metabolites were ranked by their contribution to distinguish the HCV from the controls. 10-fold cross-validation was used to assess the statistical robustness of the analysis, and Q2 and R2 values were calculated. Based on the VIP values and p values, 16 serum metabolites were selected for further study as potential biomarkers related to HCV. Compared with the normal control group, the serum contents of several metabolites such as 3-hydroxybutyrate, betaine, carnitine, fucose, glycerol, isopropanol, lysine, mannose, methanol, methionine, and ornithine significantly increased in HCV group, whereas the contents of creatinine, glutamine, proline, serine, and valine decreased significantly. Based on the area under the curve ROC, metabolites were found to have an area under the curve (AUC) greater than 0.8. carnitine can play a role in the transport of fatty acids into the mitochondria for energy production. Proline, serine, and valine are non-essential amino acids that play a role in energy production. They can be converted into intermediates in the TCA cycle and glycolysis. Proline is converted into glutamate, an intermediate in the TCA cycle. Serine can be converted into pyruvate, an intermediate in both the TCA cycle and glycolysis, and also into glucose via gluconeogenesis. Valine can be converted into pyruvate or acetyl-CoA, which can then enter the TCA cycle for energy production. Additionally, Acetyl-CoA is also used in fatty acid biosynthesis. However, none of these amino acids are involved in the PPE (Pentose Phosphate Pathway). These amino acids play an important role in maintaining energy balance in the cells. based on the metabolic signature, mitochondrial damage occurs in CLD-HCV, and the resultant further compromised cellular function, and disease progression occurs.
Conclusion: The study's results indicate a correlation between HCV and mitochondrial damage, as well as potential biomarkers for the disease. it's important to note that the study sample is relatively small, and the findings need to be validated in larger studies to confirm the correlation and biomarkers found in this study.

FRI-270

Characterization of biomarker kinetics in a novel in vitro HBV infection model with the cell line HepG2-hNTCP-sec+ revealed stable HBsAg composition during short- and long-term infection up to four weeks

Lukas Rotter[1], Maria Pfefferkorn[1], Jonathan Seltmann[1], Thomas Berg[1], Florian van Bömmel[1]. [1]*Division of Hepatology, Department of Medicine Ii, Leipzig University Medical Center, Leipzig, Germany*
Email: Maria.pfefferkorn@medizin.uni-leipzig.de

Background and aims: New reliable HBV infection models are needed, since in existing models a low biomarker secretion *in vitro* often impedes biomarker analysis. The previously reported clone HepG2-hNTCP-sec+ promises to support the viral life cycle of HBV fully and stably for prolonged periods of time. The aim of the study was an extensive characterization of the biomarker pattern *in vitro* during an infection of up to 28 days.
Method: HepG2-hNTCP-sec+ cells (kindly provided by M. Windisch) were seeded and infected with cell culture derived HBV (ccHBV), obtained from HepAD38 cells, at different multiplicities of infection (MOI, copies per cell) ranging from 50 to 10 000. Supernatant was collected after varying intervals of time from every day, every 2 days, every 3 days to every 7 days for a period of 7–28 days. To increase the volume of supernatant for extensive biomarker analysis the infection model was upscaled from an initial 384-well format to a 24-well format. HBV biomarkers (HBV DNA, HBV RNA, HBsAg composition) were measured using our published and validated in-house assays.
Results: After upscaling of the infection model cells were seeded and successfully infected with ccHBV in 96-, 48- and 24-well at MOIs >500. Maximum levels of HBsAg were measured in 24-well (MOI 10 000) at supernatant collection every 3 days with a peak concentration of 404.73 ng/ml at 6 dpi. HBsAg levels were significantly lower (136.46 ng/ml), when intensively washed after infection, compared to the standard protocol. However, the composition of HBsAg was not affected by changed washing or collection protocols. In 24-well (MOI 10000, medium change every 2 days) levels of MHBs and LHBs were 0.79 ng/ml (16.99% of total HBsAg) and 0.31 ng/ml (6.49%) at day 0 and increased to 20.23 ng/ml (13.15%) and 17.74 ng/ml (11.52%) after 6 dpi. In comparison, changing medium every 3 days showed concentrations of MHBs at 3.06 ng/ml (11.72%) and LHBs at 3.28 ng/ml (12.6%) at day 0 and 34, 9 ng/ml (8.57%) and 53, 42 ng/ml (13.08%) after 6 dpi, respectively. Long-term infection revealed a stable HBsAg composition despite a gradual decline of HBsAg to 2.61 ng/ml after 28 dpi. Depending on the protocol, HBV DNA and RNA showed an increase after 2–4 dpi and remained stable during the course of infection.
Conclusion: The new infection model with the cell line HepG2-hNTCP-sec+ was reproducible in several scale-sizes and protocol settings without influencing the HBV biomarker kinetics and might be basis for further studies e.g. regarding new surrogate markers for cccDNA.

FRI-271

Low intraindividual viral evolution is linked to disease progression and need of antiviral treatment initiation in chronic hepatitis B

Magnus Illum Dalegaard[1,2], Ulrik Fahnøe[1,2], Anni Winckelmann[1,2], Signe Bollerup[1], Jens Bukh[1,2,3], Nina Weis[1,2,3]. Email: magnus.illum.dalegaard.01@regionh.dk

Background and aims: Treatment of chronic hepatitis B (CHB), that is initiated based on factors associated with disease progression, such as viremia, HBeAg status, fibrosis/cirrhosis status and/or family history of hepatocellular carcinoma, is with a nucleoside analogue (NA), and often lifelong. The hepatitis B virus (HBV) genome is relatively short, however quite diverse and can accumulate mutations over time. The impact of viral diversity and evolution on disease progression is not well-established. The objective of this study was to compare intraindividual viral evolution between two groups of CHB

patients over time, using treatment initiation as a measure of disease progression and lack of immunological control.
Method: We included 25 CHB patients; 14 who did (treated group)- and 11 who did not (non-treated group)-initiate NA treatment during the study period, dating back to the establishment of the Danish Database for Hepatitis B and C (DANHEP) biobank in 2004 until 2019. For each patient we obtained three longitudinal plasma/serum samples taken before potential NA treatment initiation, from the DANHEP biobank. HBV DNA was extracted and amplified by PCR before full-length HBV genomes were obtained by deep sequencing. We analyzed the number of mutations that evolved during the study period and calculated the mutation rates using linear regression.
Results: There was no difference between the two groups regarding age, sex, country of origin, genotype and follow-up time (median 60 versus (vs) 57 months) but there was a significant difference in HBV DNA value (median 40, 237, 179 vs 19, 028 IU/ml), HBeAg+ at baseline (n = 9 vs n = 0) and level of alanine aminotransferase (ALT) (median 43 vs 28 IU/ml). Four patients from the non-treated group were excluded from further analysis after quality control of the sequencing data. We found significantly lower mutation rates in the treated group compared to the non-treated (figure 1A). Regrouping the participants by HBeAg status showed a significantly lower mutation rate in the HBeAg+ group (figure 1B). Furthermore, log (HBV DNA) was significantly negatively correlated with mutation rates (Figure 1C).

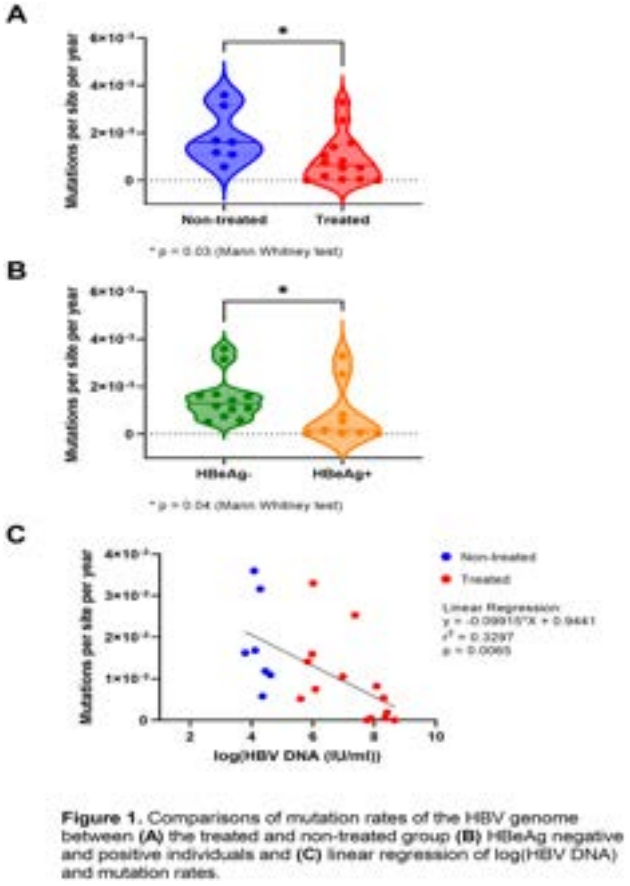

Figure 1. Comparisons of mutation rates of the HBV genome between **(A)** the treated and non-treated group **(B)** HBeAg negative and positive individuals and **(C)** linear regression of log(HBV DNA) and mutation rates.

Conclusion: CHB patients who initiate antiviral treatment have a significantly lower mutation rate prior to treatment initiation compared to patients without treatment indication. This suggests that HBV in individuals with poor immunological control mutates less frequently, which could be due to a lower immune selective pressure. High HBV DNA and HBeAg positivity are good correlates of lower mutation rates.

FRI-272

An in vivo duck hepatitis B virus model recapitulates key aspects of nucleic acid polymer treatment outcomes in chronic hepatitis B patients

Yannick Debing[1], Hannah Vanrusselt[1], Lars Degrauwe[1,2], Daniel Apolônio Silva de Oliveira[2], Christopher Kariuki[2], Ebanja Joseph Ebwanga[2], Shahbaz Bashir[2], Wouter Merckx[3], Santhosh Thatikonda[4], Vikrant Gohil[4], David Smith[4], Pierre Raboisson[1], Saul Montero[4], Jin Hong[4], Abel Acosta Sanchez[5], Lawrence Blatt[4], Julian Symons[4], Tse-I Lin[1], Leonid Beigelman[4], Jan Paeshuyse[2]. *[1]Aligos Belgium BV, Belgium; [2]KU Leuven, Host-Pathogen Interaction Lab, Belgium; [3]KU Leuven, TransFARM, Belgium; [4]Aligos Therapeutics, Inc., United States; [5]Novalix, Belgium*
Email: ydebing@aligos.com

Background and aims: Nucleic acid polymers (NAPs) are an attractive treatment modality for chronic hepatitis B (CHB), with REP2139 and REP2165 having shown efficacy in CHB patients. A significant proportion of patients achieve functional cure, whereas the others exhibit a moderate response or are non-responders. NAP efficacy has been difficult to recapitulate in animal models, with the duck hepatitis B virus (DHBV) model showing some promise but remaining underexplored for NAP efficacy testing. Here we report on an optimized in vivo DHBV duck model and explore several characteristics of NAP treatment in this model.
Method: Pekin ducks (*Anas platyrhynchos domesticus*) were intravenously injected with DHBV-containing serum shortly after hatching. After establishment of infection, animals were treated with entecavir, REP2139 and/or REP2165 and serum DHBV DNA and DHBV surface antigen (DHBsAg) levels were determined weekly. Animals were followed up for several weeks after end of treatment. NAP liver concentrations were determined by mass spectrometry.
Results: REP2139 was efficacious in reducing DHBV DNA and DHBsAg levels in approximately 50% of ducks, both when administered intraperitoneally or subcutaneously. Efficacy was only observed in experimentally infected ducks, not in endogenously infected ducks (vertical transmission). REP2165 showed a different activity profile with a more homogenous antiviral response followed by a faster rebound. Intrahepatic NAP concentrations did not correlate with efficacy. Entecavir pretreatment prior to REP2139 treatment add-on further improved response rates.
Conclusion: Subcutaneous administration of NAPs in the DHBV duck model provides a useful tool for in vivo evaluation of NAPs, recapitulating many aspects of this class of compound's efficacy in CHB patients.

Hepatitis A hospitalisations in the United States and risk factors for inpatient mortality: a nationwide population study, 1998–2020

Paul Wasuwanich[1], Joshua So[1], Megan Hofmeister[2], Saleem Kamili[2], Songyos Rajborirug[3], Wikrom Karnsakul[4]. *[1]University of Florida College of Medicine, Department of Medicine, Gainesville, United States; [2]Centers for Disease Control and Prevention, Division of Viral Hepatitis, National Center for HIV, Viral Hepatitis, STD and TB Prevention, Atlanta, United States; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States; [4]The Johns Hopkins University School of Medicine, Division of Pediatric Gastroenterology, Hepatology, and Nutrition, Department of Pediatrics, Baltimore, United States*
Email: p.wasuwanich@ufl.edu

Background and aims: Hepatitis A virus infections in the United States have been declining due to improvements in sanitation and the introduction of hepatitis A vaccines. However, recent widespread outbreaks associated with person-to-person transmission brought the disease back into the spotlight. We aim to describe the epidemiology of hepatitis A hospitalizations from 1998 to 2020 in the United States and investigate risk factors that increase inpatient mortality.
Method: We utilized the National Inpatient Sample database from the Healthcare Cost and Utilization Project which collects nationwide US hospitalization data. We identified hepatitis A-related hospitalizations using ICD-9 and ICD-10 diagnosis codes. Demographic and geographic data were extracted, as well as clinical data including death, coinfections, comorbidities, pregnancy status, and substance use. Data were analyzed by logistic and Poisson regression. Significance was defined as $p < 0.01$.
Results: We identified a total of 160,661 hepatitis A-related hospitalizations between 1998 and 2020, with the lowest hospitalization rate in 2015 (21.8 per 1,000,000 people), and the highest in 2019 (62.9 per 1,000,000 people). Hospitalization rates decreased overall during 1998–2015 (Incidence Rate Ratio [IRR] = 0.98; 95% CI = 0.98–0.98; $p < 0.001$) and increased during 2015–2020 (IRR = 1.25; 95% CI = 1.24–1.27; $p < 0.001$). The inpatient mortality rate ranged from 1.7% in 2005 to 3.8% in 2020. Most hospitalizations occurred among males (56.9%), non-Hispanic White persons (72.0%), and in the Southern region (51.2%). Age >55 years (OR = 2.81; 95% CI = 2.27–3.49; $p < 0.001$), alcoholic cirrhosis (OR = 4.00; 95% CI = 3.00–5.32; $p < 0.001$), autoimmune hepatitis (OR = 3.44; 95% CI = 1.48–8.00; $p = 0.004$), chronic kidney disease (OR = 2.56; 95% CI = 2.02–3.25; $p < 0.001$), heart failure (OR = 2.68; 95% CI = 2.11–3.40; $p < 0.001$), hepatorenal syndrome (OR = 18.32; 95% CI = 13.31–25.22; $p < 0.001$), and portal hypertension (OR = 3.95; 95% CI = 2.97–5.26; $p < 0.001$) increased the odds of inpatient mortality. Hepatitis C virus coinfection (OR = 0.67; 95% CI = 0.51–0.88; $p = 0.004$), tobacco use disorder (OR = 0.38; 95% CI = 0.30–0.49; $p < 0.001$), and intravenous drug use (OR = 0.38; 95% CI = 0.28–0.53; $p < 0.001$) were associated with decreased odds of inpatient mortality. Diabetes, obesity, hepatitis B virus coinfection, fatty liver disease, and solid organ transplantation were not associated with mortality ($p > 0.01$). None of the pregnant women hospitalized with hepatitis A died.
Conclusion: Hepatitis A hospitalizations declined from 1998 to 2015 and then increased rapidly from 2015 to 2020, coinciding with widespread outbreaks associated with person-to-person transmission. Concerningly, inpatient mortality rates also increased. Certain risk factors can be used to predict prognosis of patients hospitalized with hepatitis A.

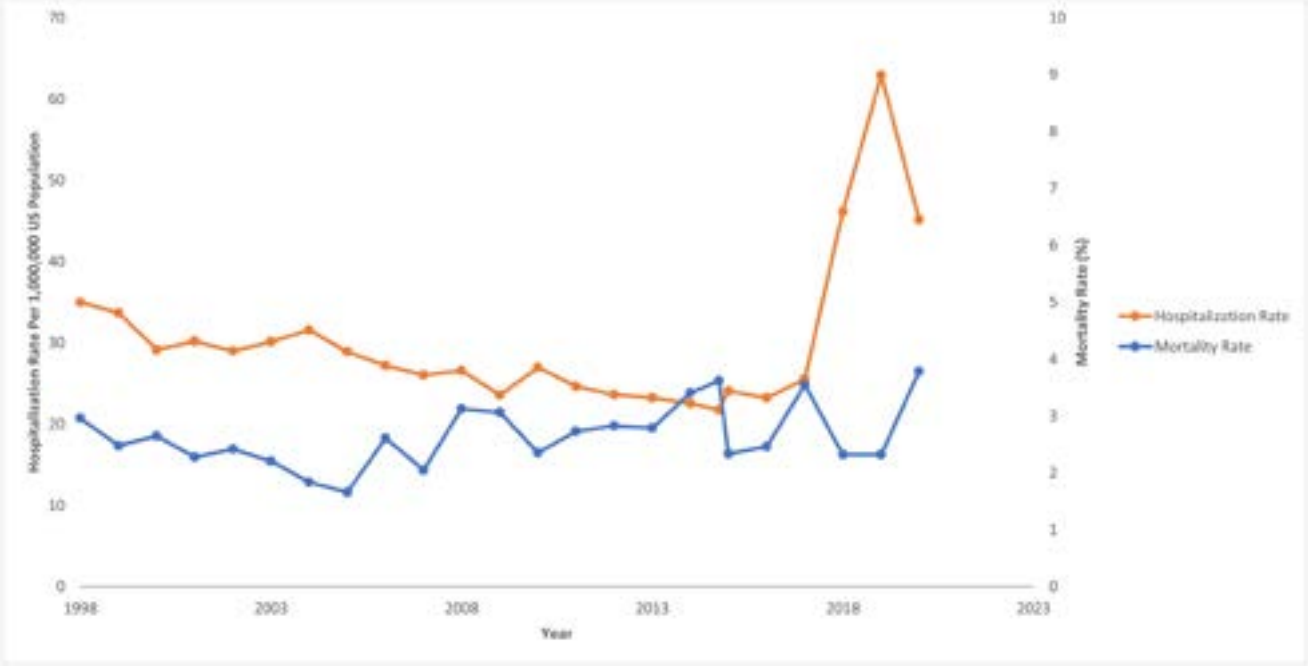

Figure: (abstract: SAT-141): Hospitalization rate and mortality rate of hepatitis A in the United States, 1998–2020.

SAT-142

High prevalence of HEV related to the progression and prognosis of patients with acute pancreatitis: a multicentre cross-sectional and cohort study in China

Jian Wu[1,2], Ze Xiang[2,3], Lan Huang[4], Ce Gao[4], Ling Tong[5]. *[1]The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou Municipal Hospital, Gusu School, Nanjing Medical University, Department of Clinical Laboratory, Suzhou, China; [2]The Chinese Consortium for the Study of Hepatitis E (CCSHE), China; [3]Zhejiang University School of Medicine, China; [4]The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou Municipal Hospital, Gusu School, Nanjing Medical University, China; [5]The First Affiliated Hospital, Zhejiang University School of Medicine, China*
Email: wujianglinxing@163.com

Background and aims: The role of HEV infection in acute pancreatitis (AP) patients remains unclear.
Method: 1000 eligible patients with AP, 1000 healthy controls (HCs) and 300 patients with AHE were recruited from 8 hospitals in China from January 1, 2016 to May 31, 2021.
Results: The positive rates of anti-HEV IgG, anti-HEV IgM and HEV RNA in the AP group were all significantly higher than HCs group. With the increase of the severity of AP, the percentage of HEV infection also increased significantly. According to whether infected with HEV, 1000 AP patients were divided into patients without HEV infection (AP- group, n = 977) and those with HEV infection (AP+AHE group, n = 23). The percentage of patients with severe AP in the AP +AHE group was significantly higher than the AP- group, and the percentage of patients with mild AP in the AP+AHE group was significantly lower than that in the AP- group. In the AP+AHE group, 12 AP cases were potentially associated with HEV infection, the severity of whom were associated with high level of HEV titre. Moreover, HEV infection was one of the main independent risk factors and owned the high predictive power for the outcome of AP, suggesting that HEV infection was related to poorer outcome of AP. High level of HEV titre would prolong the hospital stay of AP patients, and HEV infection was associated with the higher risk of recurrent AP. In addition, AP+AHE patients receiving conservative treatment showed better prognosis. Among 300 AHE patients, 5 patients were diagnosed with AP. After excluding common AP causes, 2 patients with AP were considered to be potentially associated with HEV infection.
Conclusion: HEV infection plays an important role in the occurrence, development and prognosis of AP, which would have implications for management of AP patients complicated with AHE.

Email: petra.dinjar@gmail.com

Background and aims: Liver transplant (LT) recipients have an increased risk of developing chronic hepatitis E virus (HEV) infection, which may rapidly progress to graft failure if not treated. The prevalence of HEV infection after LT is unclear and varies geographically. This study aimed to investigate the HEV seroprevalence, acquired risk factors, and the incidence of acute HEV infection in the early post-LT period.
Method: From 2017 to 2019, 766 LT recipients (cohort 1) enrolled in a cross-sectional study during routine post-transplant outpatient visits, and 152 newly transplanted (cohort 2) were prospectively screened at the time of LT assessment and 6- and 12-months post-LT. Cohort 2 was subclassified into three groups according to established HEV IgG status during follow-up: anti-HEV IgG negative (SN), anti-HEV IgG positive (SP), and de novo anti-HEV IgG positive (SP+). Blood samples were tested for anti-HEV IgG and HEV RNA. Medical records and a risk factor assessment questionnaire were reviewed.
Results: The overall anti-HEV IgG seroprevalence in LT recipients was 19.9%, and no HEV RNA was detected. The IgG prevalence was significantly associated with increasing age ($p = 0.033$), however no significant HEV seroprevalence differences were observed regarding gender, the etiology of liver disease listed for LT, place of residence, specific factors within a household (a farm, number of household members, type of drinking water, type of sewage system), production or consummation of cured meat, occupational exposure, blood transfusions in the post-LT period or any of laboratory parameters including level or type of immunosuppressive therapy. A lower risk of infection was observed among recipients with a higher level of education (OR = 0.33; 95%CI = 0.15–0.74), whilst older age was identified as a risk factor for HEV seropositivity (OR = 1.03; 95%CI = 1.01–1.05). In cohort 2, no patient tested HEV RNA positive. Six patients (3.9%) developed seroconversion in the follow-up period. According to anti-HEV IgG status, there were 115 patients in the SN group, 31 in the SP group, and 6 in the SP+ group. No difference between the groups was observed regarding liver tests at 0, 6, and 12 months, respectively.
Conclusion: In Croatia, a substantial proportion of LT recipients are at risk of acquiring HEV infection. The results highlight high HEV seroprevalence among LT recipients (19.9%) but a low risk of developing an acute or chronic HEV infection with the adverse effect of liver graft in the posttransplant period. The source and routes of HEV infection remain unclear in LT recipients.

Email: wedemeyer.heiner@mh-hannover.de

Background and aims: Chronic delta hepatitis represents a major global health burden. Clinical features of HDV infection vary largely between different regions world-wide. Moreover, treatment approaches may differ and depend on drugs approved and financial resources. However, factors determining disease progression are poorly defined. The Hepatitis Delta International Network (HDIN) was established in 2011 to compile a comprehensive database to facilitate clinical research on chronic hepatitis delta.
Method: The HDIN registry was developed by the HepNet Study-House of the German Liver Foundation in collaboration with researchers from Europe, Asia, North- and South America. A structured questionnaire specifically developed for hepatitis delta long-term follow-up was implemented. We here report data of 547 patients from 13 centers in 10 countries with ongoing or past HDV infection included until December 2022.
Results: The majority of patients were male (n = 335, 61%) and the mean age was 41 years (range 1–79). Most patients were HBeAg-negative (87%). Patients were divided according to the country of birth into Eastern Mediterranean (EM; 26%), Eastern Europe and Central Asia (EE; 38%), Central and Southern Europe (CE; 15%), South Asian (SAS (mainly Pakistan); 16%) and Africa (2%). The median follow-up varied from 9.1 (range 0.6–28) years (EM) to 3.2 (0.6–18) years (SAS) ($p = 0.01$). Liver cirrhosis at baseline was reported in 42% of cases, varying from 41% in EE to 49% in SAS. During follow-up 31% developed a liver-related end point (n = 168) after 3.2–4.5 years. Ascites was the most frequent decompensation (22%), followed by encephalopathy (8.8%) and variceal bleeding (7.1%). Hepatocellular carcinoma developed in 47 patients (8.6%) and 68 patients (12%) underwent liver transplantation. Sixty-four patients died (12%), 47% were HDV-related. Clinical liver-related end points developed more frequently in EM patients (42%), compared to 28% in EE patients, 26% in EM patients and 27% in SAS patients ($p < 0.01$). However SAS patients developed end points earlier ($p < 0.01$) and had the highest mortality (Kaplan Meier $p < 0.01$). Additionally, they had lowest Albumin levels and were younger ($p < 0.01$). Antiviral therapy during follow-up was administered to 350 patients (highest treatment uptake in EM and SAS patients, lowest in CE), including 225 patients being treated with IFNa (SAS 59%, EM 49%, EE 35%, CE 23%). Patients who received IFNa-based therapies developed clinical end points less frequently, which was significant in both chi-square and Kaplan-Meier analysis. End points occurred more frequently in patients with positive HDV RNA (at baseline or at end of follow-up) ($p = 0.01$).
Conclusion: The HDIN registry confirmed the particular severity of hepatitis delta. There is an urgent need to generate global data to determine the incidence, the differences in access to care and treatment and consecutively the liver related outcomes.

TOP-101

Identification of liver-associated gene signatures from serum exosomes in patients with chronic hepatitis B

Mario Cortese[1], Liao Zhang[2], David Pan[2], Jeffrey Wallin[1], Bryan Downie[2]. [1]*Gilead Sciences, Biomarkers, Foster City, United States;* [2]*Gilead Sciences, CBEA, Foster City, United States*
Email: mario.cortese@gilead.com

Background and aims: The invasive nature and high costs of liver biopsies pose significant challenges in HBV clinical studies. Serum-based exosome profiling may be an alternative method to profile liver gene expression differences associated with HBV treatment or cure. Here, we generated RNA sequencing data derived from isolated exosomes (Exosome-seq) and peripheral blood to investigate the gene expression characteristics associated with response to pegylated interferon alpha-2a (PEG-IFN) treatment in patients with chronic hepatitis B (CHB).
Method: Clinical study GS-US-174–0149 evaluated PEG-IFN alone or in combination with tenofovir disoproxil fumarate (ClinicalTrials.gov Identifier: NCT01277601). Exosome-seq data was generated from baseline and on-treatment (week 4) samples for study subjects with (n = 14) and without (n = 26) hepatitis B surface antigen (HBsAg) loss at week 48. Additionally, RNA-seq data was obtained from whole blood samples collected at baseline and week 48 from a total of n = 22 CHB patients (n = 13 with and n = 9 without HBsAg loss) in the study. Biological pathway scores were generated using the ssGSEA methodology. Treatment-induced transcriptional signatures were determined using voom-limma or mixed effects models between the two response groups (HBsAg loss vs. no HBsAg loss). Liver specific genes were determined by comparing count-per-million (CPM) expression profiles of liver tissues compared to non-liver tissues using a Wilcoxon-ranked sum test in the Genotype-Tissue Expression (GTEx) dataset.
Results: Exosome profiling revealed broad transcriptional changes 4 weeks following the start of treatment with PEG-IFN. These changes included immune signatures associated with IFN signaling and T cell activation, similarly to those observed in whole blood. Additionally, an increase in liver-specific genes was observed in exosome-seq following PEG-IFN treatment, suggesting that exosome profiling may provide insight into the cellular response of hepatocytes and liver-resident cells elicited by PEG-IFN. Genes encoding markers of liver inflammation (ALB, complement activation (CFHR2, CFHR5), enzymes involved in metabolic pathways (UGT1A3, UGT1A4, HAO1), and coagulation factors (F9, F13B) were among the most enriched liver-specific genes during treatment with PEG-IFN. Despite a large transcriptional overlap, 570 genes demonstrated trending differences after 4 weeks in transcriptional profile (nominal $p < 0.05$) between Week 48 clinical responders (HBsAg loss) and non-responders. Finally, associations were observed between exosome-derived liver-specific genes and clinical characteristics of HBV disease status, such as HBsAg loss.
Conclusion: Serum-based Exosome-seq revealed liver-associated signatures of response to PEG-IFN treatment in CHB patients. These findings suggest that transcriptional profiling of exosomes has potential as a non-invasive method to profile liver-derived immune responses in HBV clinical studies.

Background and aims: Hepatitis Delta virus (HDV) is a 1.7 kb RNA virus that requires Hepatitis B virus (HBV) envelope proteins for hepatocyte entry and virion release. HDV causes the most severe form of viral hepatitis. Evolutionary analysis of nucleotide sequence diversity groups HDV into eight major genotypes (HDV-1 to HDV-8) and HBV into eight major genotypes (GTA to GTH). Most HDV and HBV genotypes have distinct geographical distributions; however, to date, limited HDV and HBV sequencing data is available from HDV/HBV co-infected patients.
Method: HDV and HBV sequencing were attempted for 391 HDV/HBV co-infected patients from 15 countries of birth. For HDV sequencing, full genome (FG) amplification followed by next generation sequencing (NGS) or total RNA sequencing of plasma was used. HDV consensus sequences from NGS were used to determine genotype based on BLAST analyses against a diverse set of HDV sequences representing all HDV genotypes. For HBV sequencing, FG amplification or an ultrasensitive assay using both HBV RNA and DNA amplification of five small fragments across large hepatitis B surface antigen followed by NGS was performed. HBV consensus sequences from NGS were used to determine HBV genotypes based on BLAST analyses against an HBV reference sequence library. If amplification was unsuccessful, HBV genotype was determined using an enzyme immunoassay.

Table. HBV/HDV Genotypes from Co-infected Patients

Results: The majority of patients were from Eastern Europe (n = 264), Western Europe (n = 71) and West Africa (n = 43). HDV and HBV sequencing were successful for 331 (85%) and 277 (71%) of 391 patients, respectively, while paired HBV/HDV genotypes were determined for 341 (87%) patients. Regarding individual genotypes, HBV GTD and HDV-1 were the most prevalent with 320 (82%) and 327 (84%) of 391 patients, respectively. Paired HBV/HDV genotypes were as follows: D/1 86%, 24 (7%) A/1, 5 (1%) D/5, 5 (1%) E/5, 4 (1%) A/2, 3 (1%) E/1, 2 (1%) D/2, and 1 (<1%) patient each had A/5, A/6, B/1, and C/1 combinations. HBV GTD and HDV-1 were observed in patients from 12/15 and 13/15 countries, respectively while most HBV GTE (11/16) and HDV-5 (9/14) patients were from West Africa. Phylogenetic analyses revealed distinct clusters of sequences within HDV-1 from the same country supported by high bootstrap proportions. Therefore, potential new HDV-1 subtypes can be assigned with the addition of these data to the public domain.
Conclusion: Sequencing and genotyping of HDV and HBV from 391 patients across 15 countries were determined here with HBV/HDV genotypes D/1 being most prevalent. Phylogenetic analyses showed new HDV-1 subtypes that have not been previously reported. To date, this is the largest published dataset of paired HBV/HDV clinical sequences and genotype determinations.

Email: rsalpini@yahoo.it

Background and aims: HDV exploits HBV surface glycoproteins (HBsAg) for viral morphogenesis and de novo entry into hepatocytes. The interplay between the two viruses is poorly understood and has been mainly evaluated in peripheral blood. We investigated HBV and HDV replicative activity and interplay by analysing a well-defined set of liver biopsies from patients with chronic HBV/HDV co-infection.
Method: Liver tissue was analysed from 22 patients (63.6% NUC-treated; 95% HBeAg negative). Intrahepatic levels of covalently closed circular DNA (cccDNA), pregenomic HBV-RNA (pgRNA), total HBV-DNA (itHBV-DNA) and HDV-RNA were quantified by highly sensitive droplet digital PCR (ddPCR). ddPCR assays were also set up to quantify total HBs transcripts and to distinguish HBs transcripts deriving from cccDNA and from integrated HBV-DNA (iDNA-derived HBs) according to Grudda, 2022.
Results: Patients had median (IQR) serum HBsAg, HBV-DNA and HDV-RNA levels of 14,460 (8,868–20,551) IU/ml, 34 (23–65) IU/ml, and 7.3 (3.7–7.7) $\log_{10}$ IU/ml, respectively. Median (IQR) ALT was 75

(64–245) U/L; half of patients has a fibrosis score ≥F5. Intrahepatic HDV-RNA load was median (IQR) 813 (0.3–4266) copies/1000 cells and positively correlated with serum HDV-RNA (Rho = 0.68, P = 0.03). Regarding HBV intrahepatic reservoir, median (IQR) cccDNA load was 4 (0.04–16) copies/1000 cells, pgRNA load was 10 (2–139) copies/1000 cells and itHBV-DNA load was 185 (61–417) copies/1000 cells. Total HBs transcripts showed a load of median (IQR) 6,257 (591–16,636) copies/1000 cells. Notably, iDNA-derived HBs transcripts exceed by >2 log cccDNA-derived HBs transcripts (p = 0.01), supporting an intensive HBs production from integrated HBV-DNA in the setting of HBV/HDV chronic infection. cccDNA load tightly correlated with pgRNA and itHBV-DNA load (Rho = 0.79 and 0.74 respectively; P < 0.01). Notably, a positive correlation was observed between cccDNA load and total HBs transcripts (Rho = 0.63; P = 0.007), which was even stronger for cccDNA-derived HBs transcripts (Rho = 0.9). Conversely, no correlation was observed between intrahepatic HDV-RNA load and intrahepatic HBV markers (Rho<0.36; p > 0.15 for all), supporting independent replicative pathways for the two viruses.

Conclusion: Pathways underlying the persistence of intrahepatic HDV-RNA act independently from the intrahepatic HBV reservoir and are fueled by an abundant production of HBs transcripts, particularly from integrated HBV-DNA. These issues are crucial for understanding mechanisms underlying HDV persistence and for the identification of therapeutic approaches aiming to achieve HDV cure.

Programmed cell death protein 1/ligand 1 inhibitor versus tyrosine kinase inhibitor in the efficacy of HBsAg reduction in chronic hepatitis B patients with hepatocellular carcinoma

Te-Wei Tseng[1], Wei Teng[1,2], Po-Ting Lin[1,2], Rachel Wen-Juei Jeng[1,2], Chun-yen Lin[1,2]. *[1]Linkou Chang Gung Memorial Hospital, Department of Hepatogastroenterology, Taoyuan City, Taiwan; [2]Chang Gung University, College of Medicine, Taiwan*
Email: rachel.jeng@gmail.com

Background and aims: Recent phase I clinical trial revealed chronic hepatitis B (CHB) patients receiving 0.3 mg/kg/dose Nivolumab, a PD1 inhibitor, had mean HBV surface antigen (HBsAg) decline of 0.30 $\log_{10}$ IU/ml on week 12 and 4.5% HBsAg loss by 6 months follow-up. Whether HBsAg reduction magnitude and HBsAg loss rate will be increased in CHB patients receiving higher dose of PD1 inhibitor remained unknown. We aim to investigate this issue by comparing the HBsAg kinetics between CHB patients with hepatocellular carcinoma (HCC) receiving anti-cancer treatment with either PD1 inhibitor (ICI) or tyrosine kinase inhibitor (TKI).

Method: CHB patients with HCC receiving either [Nivolumab (2–3 mg/kg/dose) or Atezolizumab (1200 mg/dose) plus Bevacizumab (5–10 mg/kg/dose), as ICI group] or [Sorafenib (400–800 mg/day), as TKI group] at least 4 weeks during 2012 to 2023 were retrospectively recruited. All patients were followed for at least 3 months after receiving anti-cancer therapy. Propensity score matching (PSM) was done to adjust baseline characteristics differences (including age, gender, ALT, BCLC stage, HBV DNA level, and nucleotide analogues (NUC) coadministration status) between two groups at a 1:1 ratio. Serial HBsAg levels at 3 months before study entry, at the start of ICI or TKI treatment, and 3 months after treatment were assayed. HBsAg decline and HBsAg loss rate were compared between both groups.

Results: After PSM, there were 36 patients in each group. The median duration of ICI or TKI treatment was 3.32 months and 4.93 months, respectively. Characteristics at study entry were comparable between both groups. The HBsAg reduction magnitude [median: 0.10 vs – 0.03 $\log_{10}$ (IU/ml/year), p = 0.514)], proportion of rapid HBsAg decline (>0.5 $\log_{10}$ IU/ml/year) 8/34 vs 11/34, p = 0.418) and HBsAg loss rate (2/36 vs 0/36, p = 0.493) after ICI or TKI treatment were all comparable.

Conclusion: CHB patients with HCC receiving anti-cancer dosage of immunotherapy failed to achieve greater HBsAg reduction magnitude nor higher HBsAg loss probability than those receiving TKI. Immunotherapy alone, even with higher dose, may not be potent enough to achieve functional cure.

Table (abstract: TOP-112).

The performance of the cobas® HBV RNA assay for use on the cobas® 5800/6800/8800 Systems (RUO) against genomic variants and transcript heterogeneity

Thomas Meister[1], Victoria Innocent[1], Debra Liggett[1], Dax Javier[1], Alan Blair[1], Zih-Hua Chen[1], Abdellali Kelil[1], Sneha Nishtala[1], Caroline Scholtes[2], Barbara Testoni[2], Marie-Laure Plissonnier[2], Massimo Levrero[3], Fabien Zoulim[2], Marintha Heil[1], Aaron Hamilton[1]. [1]*Roche Molecular Systems, United States;* [2]*INSERM, France;* [3]*Italy*
Email: aaron.hamilton@roche.com

Background and aims: Circulating HBV RNA has emerged as a novel biomarker reflecting cccDNA presence and transcriptional activity, and is being explored for use as a PCR diagnostic target in monitoring viral clearance and informing treatment decisions. The cobas® HBV RNA assay for use on the cobas® 5800/6800/8800 Systems (RUO) is a quantitative test targeting the 3′ poly-A junction of HBV RNA. This allows differentiation from other nucleic acids including products of integrated viral DNA. In this study, HBV genomic polymorphisms and transcript variants were characterized, and the impact on assay performance was assessed.
Method: HBV sequence and transcript diversity were assessed with an *in silico* analysis and an HBV RNA sequencing workflow. For genomic analysis, NCBI and in-house databases were analyzed with a custom algorithm. For assessing HBV RNA sequences, a panel of HBeAg ± samples from genotypes A-E were collected at the Hospices Civils de Lyon. The cobas HBV RNA RUO assay performance was assessed with varying concentrations of *in vitro transcribed* (IVT) RNAs.
Results: Inspection of the polyadenylation cleavage site revealed the most common polymorphism was an A/T at the penultimate nucleotide. Rare genomic variants were present in 4% of the public database. The next six most reported variants had 0.1–1% frequency. A panel of HBeAg ± samples were sequenced. The penultimate A/T variations were observed but none of the rare variants. Analysis of viral RNA revealed that heterogeneity at the HBV poly-A start site varied in a genotype dependent manner. The major variant found alongside the standard poly-A junction is a −2 poly-A start site, which occurs at higher frequencies (30–50%) in genotypes A, D, and E, likely related to the T > A polymorphism at the penultimate nucleotide commonly observed in these genotypes. In contrast, total poly-A alternative start sites in genotypes B and C ranged from 2 to 25%. When the cobas HBV RNA RUO assay was tested with IVT mixtures, the assay performance against the −2 transcript variant was equivalent to the canonical transcript. The next six most reported genomic variants (0.1–1% frequency) were experimentally tested with *in vitro* transcript templates. Additional primers were assessed to mitigate rare mismatches that may affect quantitation of the assay.
Conclusion: The HBV polyadenylation cleavage site was assessed for genomic and transcriptional variation. The major genomic variation was an A/T polymorphism at the penultimate nucleotide of the cleavage site. Alternative poly-A start sites were identified within patient samples, with the major variant being a −2 poly-A start. The detected levels of poly-A heterogeneity had minimal impact on the cobas HBV RNA RUO assay. The assay design was improved with additional primers matching rare genomic mismatches. This diagnostic assay will fulfill a critical unmet need for monitoring chronic HBV infection.

WED-114

Next generation core inhibitors ABI-H3733 and ABI-4334 have significantly improved potency and target coverage for both antiviral and cccDNA formation activities compared to first-generation core inhibitors

Nuruddin Unchwaniwala[1], Katie Zomorodi[1], Michael Shen[1], Ran Yan[1], Xuman Tang[1], Xiang Xu[1], Michel Perron[1], William E. Delaney[1], Kathryn M. Kitrinos[1]. [1]*Assembly Biosciences, United States*
Email: kkitrinos@assemblybio.com

Background and aims: Core inhibitors (CIs) are a novel class of HBV antivirals with the potential to improve cure rates. CIs have multiple mechanisms of action (MOA), including (1) inhibition of pgRNA encapsidation which prevents formation of new viral particles (antiviral activity), and (2) disruption of incoming capsids which prevents de novo formation of cccDNA (cccDNA activity). CIs typically have greater potency against MOA1 (antiviral) than MOA2 (cccDNA). However, we believe that sufficient target coverage for both MOAs is needed for optimal clinical activity. Assembly Bio has two next generation CI candidates in Phase 1 clinical studies: ABI-H3733 (3733) and ABI-4334 (4334), which have improved potency against both MOAs compared to first-generation CIs including vebicorvir (VBR). Here, we compare human plasma and liver concentrations for VBR, 3733, and 4334 relative to protein adjusted EC_{50}s ($paEC_{50}$s) for each MOA.
Method: Plasma concentrations of VBR, 3733, and 4334 were measured in ongoing Phase 1a/b studies. Trough concentration (C_{min}) values for 3733 and 4334 at 300 mg once daily (QD) were projected assuming dose proportional exposure using 3733 50 mg (Phase 1b) and 4334 30 mg (Phase 1a) cohort data, respectively. In vitro EC_{50}s for antiviral activity (HBV DNA end point) and cccDNA activity (HBeAg end point) were measured in primary human hepatocytes (PHH) by branched DNA and ELISA, respectively. $paEC_{50}$s were determined in HepAD38 cells cultured in medium containing physiologic concentrations of human serum albumin and alpha acidic glycoprotein. Liver concentrations relative to plasma were estimated from nonclinical pharmacokinetic (PK) studies.
Results: The PK and antiviral properties of VBR, 3733, and 4334 are summarized in the Table. VBR achieved C_{min} values 1.4- and 0.1-fold above antiviral and cccDNA $paEC_{50}$s, respectively, at the 300 mg QD clinical dose. Based on the projected C_{min} values at 300 mg QD, 3733 and 4334 are predicted to have C_{min} values >100-fold over $paEC_{50}$ for antiviral activity and >10-fold over $paEC_{50}$ for cccDNA activity, with 4334 having an additional 3 to 4 times greater target coverage compared to 3733. VBR, 3733, and 4334 are predicted to have enriched exposure in the liver by 18, 6, and 7-fold, respectively.

Parameter	VBR 300 mg QD	3733 300 mg QD	4334 300 mg QD
Antiviral EC_{50} (nM)	281	8.8	0.5
cccDNA EC_{50} (nM)	3032	61	2.6
Protein adjustment (fold)	8	9.6	5.5
Plasma $C_{min}/paEC_{50}$ (antiviral)	1.4	127	360
Plasma $C_{min}/paEC_{50}$ (cccDNA)	0.1	18	69
Liver:plasma ratio	18	6	7

Figure: Summary of Key PK and Antiviral Properties for VBR, 3733, and 4334

Conclusion: Next generation CIs 3733 and 4334 have significantly improved coverage for both antiviral and cccDNA formation activities compared to first generation CIs. 3733 and 4334 are currently completing Phase 1b and Phase 1a studies, respectively.

WED-116

A retrospective observational cohort study of liver-related events among individuals with hepatitis B virus infection with and without hepatitis delta virus infection

Laura Telep[1], Amanda Singer[1], Ben Da[1], Ankita Kaushik[1], Chong Kim[1], Fang Xia[1], Anand Chokkalingam[1], Tatyana Kushner[2]. *[1]Gilead Sciences, Inc., Foster City, United States; [2]Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, New York, United States*
Email: laura.telep@gilead.com

Background and aims: Hepatitis delta virus (HDV) is considered the most severe form of viral hepatitis infection. Among commercially insured patients, there are limited mixed data regarding rates of liver-related events in individuals infected with HDV vs. individuals with HBV mono-infection. The goal of this study is to characterize patients with HDV infection in United States (US) administrative claims data and assess the incidence of liver-related events in this population compared to individuals with HBV mono-infection.
Method: This was a retrospective observational cohort study using data from the IQVIA PharMetrics Plus™ database which contains adjudicated medical and pharmacy claims from commercially insured individuals in the US. All included individuals were age 18+ years at cohort entry with no pauses in enrollment >1 month prior to index or during follow-up. Index date for each cohort (HDV and HBV mono-infected) occurred between January 2007 and September 2021 at either first inpatient, or the first of two outpatient diagnosis codes at least 30 days apart with a 365-day baseline period and follow-up for ≥1 day. Four liver-related events were investigated (cirrhosis/fibrosis, hepatocellular carcinoma (HCC), liver decompensation, or liver transplant) using previously validated definitions. In each analysis, patients with baseline evidence of the outcome or coinfection with hepatitis C virus (HCV) or human immunodeficiency virus (HIV), were excluded. A unique propensity score (PS) model was constructed using baseline demographic and clinical characteristics including the other three outcomes, nucleot (s)ide analogue (NA) and interferon (IFN) treatment history. Variables with standardized mean differences (SMD) between the exposure groups that were within 0.1 after weighting were considered balanced. Hazard ratios (HR) comparing risk of liver-related events in those with HBV mono-infection vs. HDV infection were estimated using Cox proportional hazards methods after PS weighting.
Results: During the study period, 46,474 individuals with HBV mono-infection and 1,805 with HDV infection were identified. Individuals with HDV were more likely to be older at cohort entry, male, and take NA or IFN treatment than those with HBV mono-infection (Table 1). In addition, baseline prevalence of diabetes, hypertension, hyperlipidemia, and liver-related conditions including HCV coinfection and end stage liver disease (ESLD) was higher in those infected with HDV. After PS weighting, there were no variables with |SMD| >0.1, and individuals infected with HDV had a higher risk for each clinical outcome than those mono-infected with HBV (cirrhosis [HR: 1.44, CI: 1.22–1.70]; liver decompensation [HR: 1.58, CI: 1.34–1.88]; HCC [HR: 1.41, CI: 1.06–1.88]; liver transplant [HR: 2.08, CI: 1.35–3.21]).
Conclusion: In this real-world study of commercially insured individuals with HBV infection in the US, those diagnosed with HDV infection had a higher prevalence of metabolic comorbidities, HCV coinfection, and ESLD at baseline, and an increased risk of liver-related outcomes before and after PS weighting compared to those with HBV mono-infection.

Email: louise.downs@exeter.ox.ac.uk

Background and aims: Chronic hepatitis B infection (CHB) has diverse clinical phenotypes. Hepatitis B core related antigen (HBcrAg) and pre-genomic RNA (pgRNA) are novel serum biomarkers that provide a proxy signal for cccDNA transcription. We aimed to (i) explore the role of HBcrAg and pgRNA as markers of treatment eligibility in treatment naive patients, and (ii) determine any associations with tissue or immunological phenotypes in patients on nucleoside analogue (NA) treatment.

Method: Serum samples (n = 137) were obtained from adults with CHB at Oxford University Hospitals, UK, including those on and off NA therapy (n = 95 and n = 42 respectively), and HBeAg positive and negative (n = 17 and n = 120 respectively) (Oxford Research Ethics Committee A, reference 09/H0604/20). HBV DNA, Quantitative HBcrAg and HBV pgRNA were measured along with a panel of immune biomarkers. Patient metadata were recorded from the Electronic Health Record (EHR). In untreated patients, we calculated the sensitivity and specificity of previously defined HBcrAg thresholds (>5.3, >4.8 and >3.6 $\log_{10}$ IU/ml) to predict HBV DNA levels relevant to treatment decisions (>200, 000, >20, 000 and >2000 IU/ml). We compared this with the predictive value of HBeAg status. For those on treatment, we examined the relationship between HBcrAg, pgRNA, ALT, and a panel of ten host immunological markers to reflect liver inflammation and immune phenotype.

Results: (i) In the untreated population, HBcrAg ≥5.3 $\log_{10}$ IU/ml was a highly sensitive and specific predictor of HBV DNA >200 000 IU/ml (both 100%). However HBcrAg performed poorly at lower thresholds (e.g. HBcrAg ≥4.8 $\log_{10}$ IU/ml had a sensitivity and specificity of 67% and 98% for predicting HBV VL >20 000 IU/ml). HBcrAg was marginally better at predicting both HBV DNA of >200 000 IU/ml and >20 000 IU/ml than HBeAg (HBeAg sens/spec = 100% and 97% for HBV DNA >200 000 IU/ml and 62% and 96% for VL >20 000 IU/ml). In the untreated population with HBV DNA <200 000, the correlation between HBV DNA and HBcrAg is lost, demonstrating a poor correlation between peripheral DNA levels and hepatic reservoir. (ii) In the treated population, mean treatment duration was 24 months at the time of sample collection (range 0–84 months, IQR = 31.5). Median serum HBV DNA levels were below the limit of quantification but HBcrAg and pgRNA were persistent (median 3.6 $\log_{10}$ IU/ml, and 1.7 $\log_{10}$U/ml respectively). Neither of these biomarkers correlated with ALT (p = 0.4 and 0.8 respectively), or with any of a panel of host immunological biomarkers (p > 0.2 in all cases).

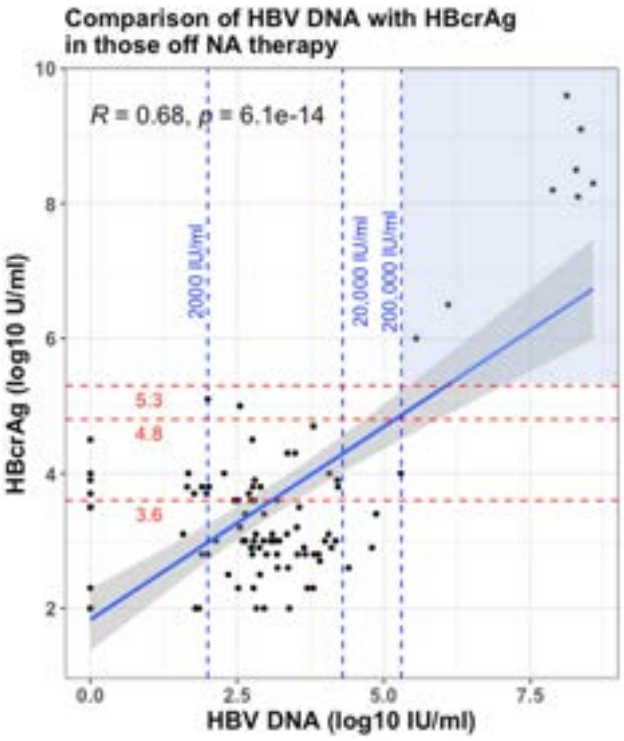

Figure: HBV DNA and HBcrAg levels with HBcrAg thresholds (red dashed lines) and HBV DNA levels used for treatment eligibility (blue dashed lines). Blue shading represents those with HBcrAg >5.3 $\log_{10}$U/ml and HBV DNA >200 000 IU/ml.

Conclusion: In settings where HBV DNA quantification is not available, HBcrAg could support treatment decisions, particularly in pregnancy to prevent MTCT (based on WHO thresholds). However, HBcrAg tests are not yet widely available, have cost implications, and may be only marginally better than existing HBeAg testing. In patients on NA therapy, HBcrAg or pgRNA represent quantifiable serum markers of the HBV cccDNA pool and transcriptional activity years after HBV DNA is undetectable in serum. This offers new opportunities for disease stratification. Further longitudinal work in larger cohorts will help determine the use of HBcrAg and pgRNA in prediction of long-term disease outcomes.

WED-118

Long-term outcomes of untreated chronic hepatitis B patients with persistent HBsAg <100 IU/ml

Rachel Wen-Juei Jeng[1,2], Mei-Hung Pan[3], Chien-Jen Chen[3], Hwai-I Yang[3]. *[1]Linkou Chang Gung Memorial Hospital, Gastroenterology and Hepatology, Taoyuan, Taiwan; [2]Chang Gung University, College of Medicine, Taoyuan, Taiwan; [3]Academia Sinica, Genomic Research Center, Taipei, Taiwan*
Email: hiyang@gate.sinica.edu.tw

Background and aims: Chronic hepatitis B patients (CHB) with HBsAg seroclearance had the most favorable outcomes. However, long-term outcomes of CHB patients who had persistent HBsAg <100 IU/ml in natural history remained unknown. This study aimed to investigate HCC incidence and liver-related mortality of CHB patients with persistent HBsAg <100 IU/ml, and to compare with the other population without HBV nor HCV infection (non-HBV).
Method: From the REVEAL cohort, non-cirrhotic CHB subjects with at least two HBsAg assessments were enrolled into the analysis (N = 2708). Subjects with anti-HCV seropositivity, unavailable baseline HBsAg levels or lack of follow-up data, and cirrhosis at study entry were excluded. CHB subjects were categorized into 3 groups by at least two consecutive assessments of HBsAg with a median (Q1-Q3) interval of 1.49 (1.13–3.95) years: persistent HBsAg <100 IU/ml, drop from >100 to persistent <100 IU/ml, and persistent >100 IU/ml. Non-HBV subjects (N = 18960) without cirrhosis at study entry were used for comparison. Propensity score matching (PSM) was performed in a 1:3 ratio between CHB and non-HBV subjects to adjust for characteristics differences including age, gender, levels of ALT, TG, cholesterol, uric acid, smoking, alcohol drinking and DM history. Outcomes including incident HCC and liver-related death were ascertained by data linkage to the national cancer registry and national death database by the end of 2018.
Results: There were 2441 CHB subjects and 7323 non-HBV subjects in the PSM matched cohort, the characteristics were comparable except that the CHB subjects have higher baseline ALT (11 vs. 10 U/L, P < 0.0001) and BMI (median: 23.7 vs. 23.6, P = 0.0349). During a median follow-up of 26.7 years, the annual incidence of HCC and liver-related death were lowest in non-HBV subjects (0.05% and 0.04%), followed by persistent HBsAg <100 IU/ml (0.09% and 0.09%), HBsAg drop from >100 to persistent <100 IU/ml (0.2% and 0.1%) and highest in persistent HBsAg >100 IU/ml (0.4% and 0.3%). Multivariate Cox regression analysis revealed CHB patients with persistent HBsAg <100 IU/ml did not have a significantly higher risk of HCC or liver-related death than non-HBV (adjusted hazard ratio (aHR): 1.486, P = 0.1426 and aHR: 1.675, P = 0.0699, respectively). However, a significantly increased relative risk of HCC and liver-related death could be observed for patients with HBsAg drop from >100 to persistent <100 (aHR: 3.775, P < 0.0001 and 2.097, P = 0.0365, respectively) and persistent >100 IU/ml (aHR: 9.619, P < 0.0001 and 9.819, P < 0.0001, respectively), when compared with non-HBV.
Conclusion: CHB subjects with persistent HBsAg <100 IU/ml have comparable HCC and liver-related death risk as non-HBV subjects, which may be a good end point for clinical use.

WED-119

HBcrAg-based risk score predicts HCC better than HBV DNA-based risk scores in HBeAg-negative grey zone patients

Tai-Chung Tseng[1], Tetsuya Hosaka[2], Chun-Jen Liu[1], Fumitaka Suzuki[2], Chun-Ming Hong[3], Hiromitsu Kumada[2], Tung-Hung Su[3], Hung-Chih Yang[3], Chen-Hua Liu[1], Pei-Jer Chen[3], Jia-Horng Kao[3].

Email: kaojh@ntu.edu.tw

Background and aims: Risk scores have been designed to predict the risk of hepatocellular carcinoma (HCC) in treatment-naïve chronic hepatitis B (CHB) patients. Little is known about their prediction accuracy in hepatitis B e antigen (HBeAg)-negative patients in grey zone (GZ). We aimed to develop a hepatitis B core-related antigen (HBcrAg)-based HCC risk score and explore whether it outperforms other risk scores in GZ patients.
Method: Two retrospective cohorts of HBeAg-negative patients with AASLD-defined GZ were established for derivation and validation (Taiwanese N = 911, Japanese N = 806). All of them were non-cirrhotic at baseline and remained treatment-free during the follow-up. The primary end point was HCC development.
Results: In a median follow-up period of 15.5 years, 85 patients developed HCC in the derivation cohort. We found that age, sex, ALT, platelet count, and HBcrAg, but not HBV DNA levels, were independent predictors and a 20-point GZ-HCC score was developed accordingly. The predicted risk was well calibrated with Kaplan-Meier observed HCC risk. The 10-year and 15-year AUROC was 0.86 (95% CI: 0.80–0.90) and 0.83 (95% CI: 0.78–0.89), respectively, which outperformed other HBV DNA-based HCC risk scores, including REACH-B and GAG-HCC scores (AUROC ranging from 0.63–0.74). There was a consistent finding in the validation cohort that the AUROC of GZ-HCC score was 0.92 (95% CI: 0.88–0.97) and 0.90 (95% CI: 0.83–0.97) at 10-year and 15-year of follow-up, respectively, while the AUROC ranged from 0.66–0.80 in HBV DNA-based risk scores. The better performance was also validated in EASL- and APASL-defined GZ patients. Finally, the low-risk and high-risk GZ patients (stratified by score of 8) had HCC risk close to inactive CHB and immune-active CHB patients, respectively, in both cohorts.
Conclusion: The HBcrAg-based GZ-HCC score predicts HCC better than other HBV DNA-based risk scores in HBeAg-negative GZ patients, which helps optimize their clinical management.

Extrahepatic malignancies and antiviral drugs for chronic hepatitis B: a nationwide cohort study

Moon Haeng Hur[1], Donghyeon Lee[1,2], Jeonghoon Lee[1], Misook Kim[3], Jeayeon Park[1], Hyunjae Shin[1], Sungwon Chung[1], Heejin Cho[1], Min Kyung Park[1], Heejoon Jang[2], Yun Bin Lee[1], Su Jong Yu[1], Won Kim[2], Yong Jin Jung[2], Yoon Jun Kim[1], Jung-Hwan Yoon[1]. *[1]Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South; [2]Seoul Metropolitan Government Seoul National University Boramae Medical Center, Department of Internal Medicine, Seoul, Korea, Rep. of South; [3]Seoul National University Hospital, Medical Research Collaborating Center, Seoul, Korea, Rep. of South*
Email: pindra@empal.com

Background and aims: Many previous studies comparing tenofovir disoproxil fumarate (TDF) and entecavir (ETV) reported that TDF is superior, or at least comparable, to ETV in terms of hepatocellular carcinoma prevention in patients with chronic hepatitis B (CHB). In addition, our recent study suggested that CHB is associated with an increased risk of extrahepatic malignancy (EHM), which normalized with antiviral treatment. We aimed to compare the risk of EHM as well as intrahepatic malignancy (IHM) associated with ETV versus TDF.

Method: Based on claims data of the National Health Insurance Service of Korea, this nationwide cohort study included treatment-naïve CHB patients who initiated antiviral therapy either with ETV (ETV group: n = 24,287) or with TDF (TDF group: n = 29,199) between 2012 and 2014. The primary outcome was the development of any primary EHM. Secondary outcomes were the development of the 10 most prevalent EHMs in Korea and overall IHM.

Results: During median follow-up of 5.9 years, 822 (3.4%) and 706 (2.9%) patients in the ETV and TDF groups, respectively, developed EHM. EHM incidence rate differed significantly between within 3 years and beyond 3 years in both groups (both P < 0.01, Davies test). During the first 3 years, there was no difference in EHM risk between groups in the propensity score-matched cohort (subdistribution hazard ratio [SHR] = 1.01, 95% confidence interval [CI] = 0.88–1.17, P = 0.84). After year 3, however, TDF was associated with a significantly lower EHM incidence, compared to ETV (SHR = 0.70, 95% CI = 0.60–0.81, P < 0.01; Figure). Various sensitivity and subgroup analyses reproduced these results. The TDF group showed a significantly lower incidence of stomach cancer (SHR = 0.57), breast cancer (SHR = 0.53), and non-Hodgkin lymphoma (SHR = 0.34) than the ETV group after 3 years. Regarding the incidence of IHM, the superiority of TDF over ETV was maintained both before year 3 (SHR = 0.88, 95% CI = 0.81–0.95, P < 0.01) and after year 3 (SHR = 0.68, 95% CI = 0.62–0.75, P < 0.01), with the latter being more prominent.

Conclusion: TDF was associated with about 30% lower risk of EHM as well as IHM than ETV in CHB patients after 3 years of antiviral therapy.

WED-121

Prediction of hepatocellular carcinoma in chronic hepatitis B patients following HBsAg seroclearance: Lage score

Jonggi Choi[1], Eunju Kim[2], Won-Mook Choi[1], Danbi Lee[1], Kang Mo Kim[1], Ju Hyun Shim[1], Young-Suk Lim[1], Han Chu Lee[1]. *[1]Asan Medical Center, Department of Gastroenterology, Korea, Rep. of South; [2]Chung-Ang University Gwangmyeong Hospital, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and aims: Risk of hepatocellular carcinoma (HCC) decreases but remains after HBsAg seroclearance in patients with chronic hepatitis B (CHB). Previous studies focused on predicting the development of HCC in CHB patients without HBsAg seroclearance. The aim of this study was to determine the risk factors for HCC development and develop a prediction model to stratify the risk of HCC after HBsAg seroclearance.

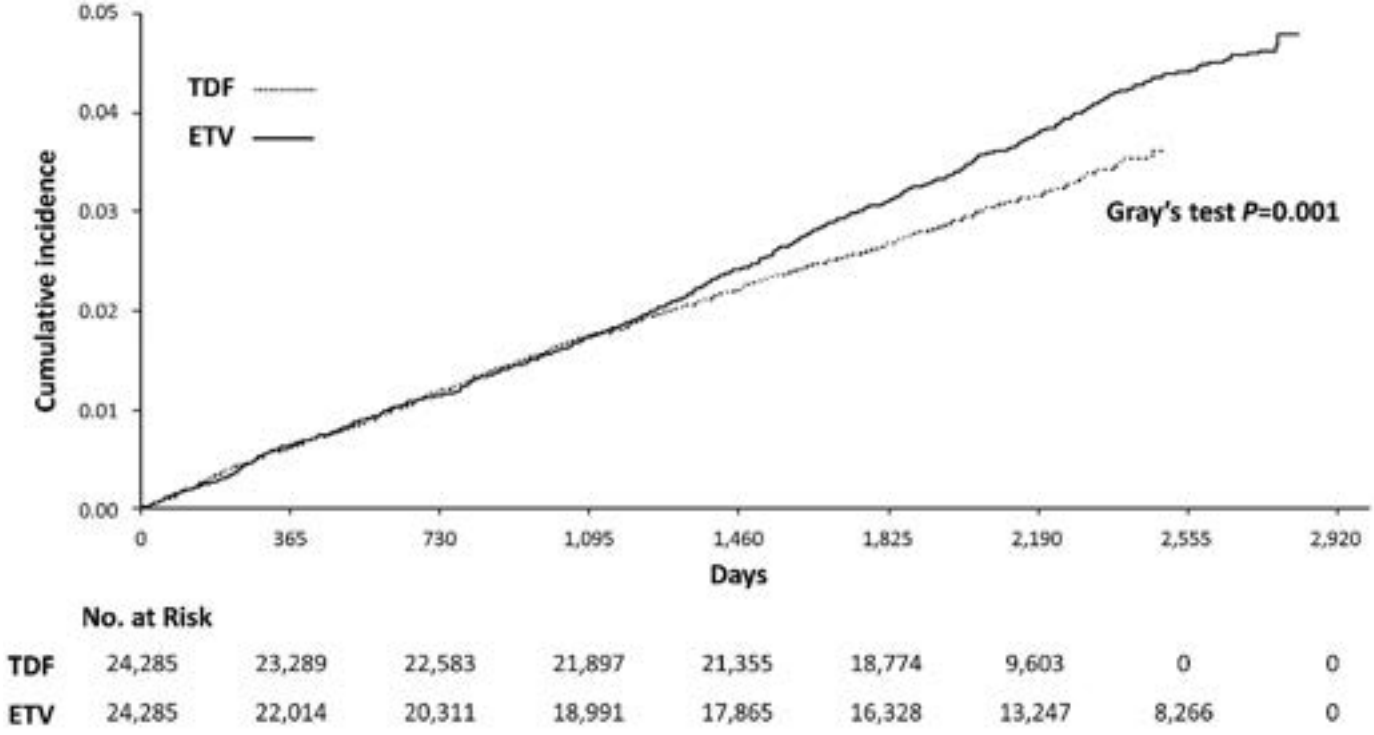

Figure: (abstract: WED-120).

Prediction model (LAGE score) for HCC development after HBsAg seroclearance in 2,421 patients with chronic hepatitis B

	Factors		Assigned score
L	Liver cirrhosis	Present	2
A	Age	50≤ age <60 Age ≥60	1 2
GE	Gender	Male	1
Risk group	**Number of patients**	**Observation period**	**Annual incidence of HCC**
Low	753	5,667	0.035
Intermediate	986	7,471	0.281
High	682	3,901	1.180

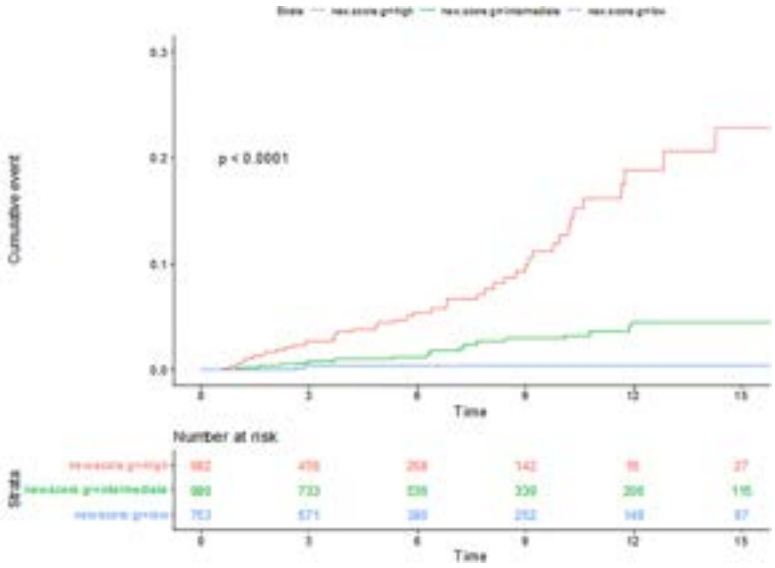

Figure: (abstract: WED-121).

Method: We analyzed 2,421 CHB patients with HBsAg seroclearance at Asan Medical Center in Seoul, Republic of Korea, between 1997 and 2022. HBsAg seroclearance was defined as the HBsAg negativity at least two consecutive tests, 6 months apart, regardless of anti-HBs positivity. The primary outcome was HCC development following HBsAg seroclearance. Cox model was used to determine the factors associated with HCC development. Points were assigned to each risk factor based on the Cox model. Median follow-up period was 5.8 years.
Results: The mean age was 54.6 years, and 64.5% of the patients were male. At the time of HBsAg seroclearance, 414 (17.1%) of patients had liver cirrhosis (LC). During the 17,039 person-years (PYs), 69 of 2421 patients developed HCC, with an annual incidence of 0.41%/100 PYs. At 5, 10, and 15 years, the cumulative incidence of HCC was 1.7%, 4.3%, and 6.8%, respectively. LC [L] (adjusted hazard ration [AHR]: 6.2), age [A] over 60 years (AHR: 3.9), and male gender [GE] (9.2) were independently associated with an increased risk of HCC in multivariable analysis. Risk scores were assigned to age ≥60 years (2 points), 50≤age <60 (1 point), LC (2 points), male sex (3 points). Low risk (0–2), intermediate risk (3–4), and high risk (5–7) were categorized based on the sum of each point. In the low (n = 753), intermediate (n = 986), and high risk groups (n = 682), the incidence of HCC was 0.04, 0.28, and 1.18/100PYs, respectively. Time-dependent AUROCs of the LAGE score for predicting HCC development at 5-, 10-, and 15-years were 0.808, 0.856, and 0.879, respectively.
Conclusion: LC (L), older age (A), and male gender (GE) at the time of HBsAg seroclearance were highly associated factors with HCC development after HBsAg seroclearance. LAGE score may easily be applicable in real world and aid in stratifying the risk of HCC after HBsAg seroclearance in CHB patients.

WED-122
Eight weeks or less of tenofovir alafenamide to prevent the perinatal hepatitis B transmission: a multicenter, prospective, randomized study

Qing-Lei Zeng[1], Xiao-Ping Dong[2], Hongxu Zhang[3], Wei Li[4], Ji-Yuan Zhang[5], Zu-Jiang Yu[6]. *[1]The First Affiliated Hospital of Zhengzhou University, Department of Infectious Diseases and Hepatology, Zhengzhou, China; [2]Sanmenxia Central Hospital, Department of Infectious Diseases, China; [3]Luohe Central Hospital, Department of Infectious Diseases, China; [4]Henan Provincial People's Hospital, Department of Infectious Diseases, China; [5]The Fifth Medical Center of Chinese PLA General Hospital, National Clinical Research Center for Infectious Diseases, Treatment and Research Center for Infectious Diseases, China; [6]The First Affiliated Hospital of Zhengzhou University, Department of Infectious Diseases and Hepatology, China*
Email: zengqinglei2009@163.com

Background and aims: Four weeks of tenofovir alafenamide fumarate (TAF) therapy can lead to 3–4 logs IU/ml of hepatitis B virus (HBV) DNA decrease in clinical practice; meanwhile, young immune tolerant pregnant women commonly have 7–8 logs IU/ml of HBV DNA levels, there was no infant's breakthrough infection reported when the maternal HBV DNA level was below 5.3 logs IU/ml (200 000 IU/ml) after timely standard immunoprophylaxis for the newborns; additionally, the very (gestational weeks [GW] 28–31), moderate (GW 32–33), and late (GW 34–36) preterm rates of singleton pregnancies are 0.6%, 0.7%, 4.3% in China. This study aimed to investigate the feasibility as well as the safety and efficacy of 8 weeks or less of TAF therapy (from GW 33 to delivery date) to prevent mother-to-child transmission of HBV (HBV-MTCT).
Method: In this multicenter, prospective, randomized study, pregnant women with HBV DNA levels ranged from >5.3 logs to <9 logs IU/ml who received TAF from GW 33 to delivery date (group 1) or postpartum month 1 (group 2) were 1:1 enrolled randomly and followed until postpartum month 6, respectively. All infants received standard immunoprophylaxis. The primary end point was the safety of mothers and infants. The secondary end point was the rate of HBV DNA level less than 5.3 logs IU/ml at delivery for mothers, and the hepatitis B surface antigen (HBsAg)-positive rate at 7 months for infants.
Results: In total, 96 and 93 mothers were enrolled, and 96 and 93 infants were born, in groups 1 and 2, respectively (Figure). TAF was well tolerated during a mean treatment duration of 6.5 and 10.3 weeks in groups 1 and 2, respectively. The most common maternal adverse event was nausea (12.5% vs 14.0%), followed by anorexia (7.3% vs 8.6%) and fatigue (6.3% vs 6.5%) in groups 1 and 2, respectively. Only few mothers had abnormal alanine aminotransferase levels at delivery (1[1.0%] vs 0[0%]) and at postpartum months 3 (3[3.1%] vs 3 [3.2%]) and 6 (8[8.3%] vs 7[7.5%]), respectively, and no one had alanine aminotransferase levels higher than 100 U/ml. No infants had birth defects in either group. The infants' physical and neurological development at birth and at 7 months were comparable and

normal in the two groups. The HBsAg positive rate was 0% at 7 months in all 189 infants.

Characteristics of the mothers at baseline	Group 1 (n=96)	Group 2 (n=93)
Age, years	28.7 ± 5.3	29.1 ± 4.9
Gestational age, weeks	33.2 ± 0.3	33.3 ± 0.3
Hepatitis B e antigen positivity	96 (100)	93 (100)
HBV DNA, $\log_{10}$ IU/mL	7.7 ± 0.4	7.8 ± 0.3
Alanine aminotransferase, U/L	20.2 ± 11.0	22.5 ± 10.5
Treatment duration, weeks	6.5 ± 1.0	10.3 ± 0.9
Most common maternal adverse events		
Nausea	12 (12.5)	13 (14.0)
Anorexia	7 (7.3)	8 (8.6)
Fatigue	6 (6.3)	6 (6.5)
Most common maternal complications		
Premature rupture of membranes	8 (8.3)	9 (9.7)
Preterm labor	1 (1.0)	1 (1.1)
Gestational hypertension	1 (1.0)	1 (1.1)
Maternal HBV DNA at delivery, $\log_{10}$ IU/ml	4.2 ± 0.6	4.1 ± 0.6
< 5.3 $\log_{10}$ IU/mL	94 (97.9)	91 (97.8)
Characteristics of the infants at birth		
Gestational age, weeks	39.2 ± 1.2	39.3 ± 1.2
Apgar score at 1 minute	9.6 ± 0.5	9.6 ± 0.5
Congenital defects or malformations	0 (0)	0 (0)
Anthropometric indexes	Normal	Normal
At postpartum month 6 for the mothers		
HBV DNA, $\log_{10}$ IU/mL	7.6 ± 0.3	7.5 ± 0.3
Alanine aminotransferase ≥ 40 U/L	8 (8.3)	7 (7.5)
At 7 months of age for the infants		
Anthropometric indexes	Normal	Normal
HBsAg positive infants	0 (0)	0 (0)

Data are presented as the mean ± standard deviation or n (%).

Figure:

Conclusion: Eight weeks or less of TAF regimen during late pregnancy (from GW 33 to delivery date) to prevent HBV-MTCT are generally safe for both mothers and infants and obtained 0% of HBV-MTCT rate. Future large-scale validation studies are warranted.

WED-123

HBsAg seroclearance decreases risk of hepatocellular carcinoma but not hepatic decompensation in nucleos (t)ide analogue-treated cirrhotic patients with complete hepatitis B virus suppression: a territory-wide cohort study

Terry Cheuk-Fung Yip[1], Vicki Wing-Ki Hui[1], Vincent Wai-Sun Wong[1], Tsz Fai Yam[1], Che To Lai[1], Yan Liang[1], Yee-Kit Tse[1], Henry LY Chan[2], Grace Lai-Hung Wong[1]. [1]*The Chinese University of Hong Kong (CUHK), Department of Medicine and Therapeutics, Hong Kong;* [2]*Union Hospital, Department of Internal Medicine, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: We compared the incidence of hepatocellular carcinoma (HCC) and first and further hepatic decompensation in nucleos (t)ide analogue (NA)-treated chronic hepatitis B (CHB) patients with cirrhosis who achieved complete viral suppression alone or hepatitis B surface antigen (HBsAg) seroclearance.
Method: A retrospective cohort study was performed using data from the Clinical Data Analysis and Reporting System, an electronic healthcare database managed by the Hospital Authority, Hong Kong. All adult monoinfected CHB patients with cirrhosis who received entecavir or tenofovir between 1 January 2005 and 30 September 2020 were identified. Baseline date was the start of entecavir or tenofovir treatment. Patients with HCC before or within the first 6 months of baseline, other cancers or liver transplantation before baseline, liver transplantation before HBsAg loss, without hepatitis B virus DNA measurement, and without complete viral suppression were excluded. 1-year landmark analyses were performed; patients with clinical outcome or follow-up ended within 1 year were excluded. The primary outcome was HCC. The secondary outcome was first and further hepatic decompensation, defined as any new occurrence of ascites, spontaneous bacterial peritonitis, variceal bleeding, hepatic encephalopathy, hepatorenal syndrome, liver transplantation, and/or liver-related death.
Results: Of 5,149 patients (mean age 60.1 ± 12.6 years, 66.3% male, 8.0% decompensated cirrhosis) included in the 1-year landmark analysis, 161 (3.1%) achieved HBsAg seroclearance. At a median (25th-75th percentile) follow-up of 4.1 (2.5–5.0) years, 456 (9.1%) and 5

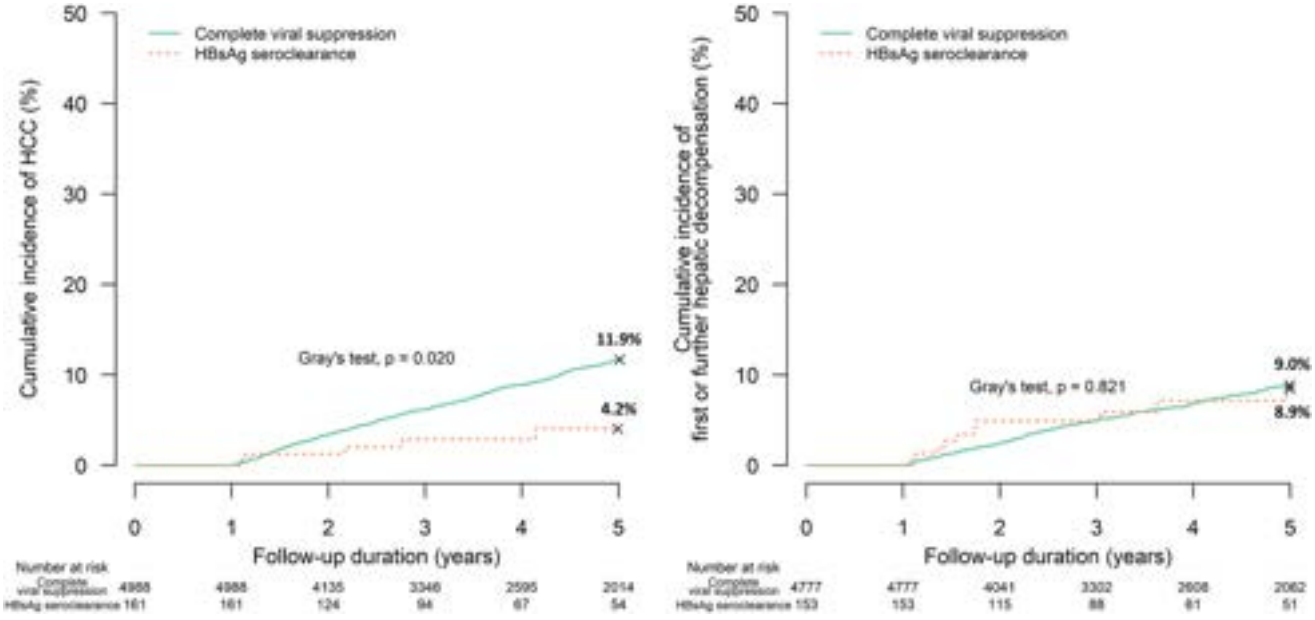

Figure: (abstract: WED-123).

(3.1%) patients with complete viral suppression and HBsAg loss developed HCC respectively; 334/4777 (7.0%) and 10/153 (6.5%) patients with complete viral suppression and HBsAg loss developed first and further hepatic decompensation (Figure). In multivariable analysis, HBsAg seroclearance was associated with a lower risk of HCC (adjusted subdistribution hazard ratio [aSHR] 0.37, 95% confidence interval [CI] 0.15–0.91, p = 0.030) but not first and further hepatic decompensation (aSHR 1.01, 95% CI 0.52–1.95, p = 0.988) than complete viral suppression, after adjusting for age, gender, decompensated cirrhosis, diabetes, platelets, albumin, total bilirubin, alanine aminotransferase, international normalised ratio, hepatitis B e antigen status, and use of other NAs. Similar results on HCC were observed in using cause-specific (CS) hazard model (adjusted CSHR [95% CI] 0.40 [0.16–0.96]), patients with compensated cirrhosis (aSHR 0.36 [0.13–0.98]), and 2-year landmark analysis (aSHR 0.37 [0.14–1.04]).

Conclusion: HBsAg seroclearance is associated with a lower risk of HCC but not first and further hepatic decompensation in a territory-wide cohort of NA-treated CHB cirrhotic patients with complete viral suppression.

WED-124

Influence of viral load and fibrotic burden on hepatocellular carcinoma risk at phase change to immune-active phase in chronic hepatitis B

Ho Soo Chun[1], Minjong Lee[1], Hye Ah Lee[2], Jihye Kim[3], Han Ah Lee[1], Hwi Young Kim[1], Tae Hun Kim[1], Eileen Yoon[4], Dae Won Jun[4], Sang Hoon Ahn[5], Seung Up Kim[5], Yoon Jun Kim[3]. *[1]Department of Internal Medicine, Ewha Womans University College of Medicine, Korea, Rep. of South; [2]Clinical Trial Center, Ewha Womans University Seoul Hospital, Korea, Rep. of South; [3]Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Korea, Rep. of South; [4]Department of Internal Medicine, Hanyang University College of Medicine, Korea, Rep. of South; [5]Department of Internal Medicine, Yonsei University College of Medicine, Korea, Rep. of South*

Email: ksukorea@yuhs.ac

Background and aims: Recent studies reported that moderate hepatitis B virus (HBV) DNA levels are significantly associated with hepatocellular carcinoma (HCC) risk in hepatitis B e antigen (HBeAg)-positive, non-cirrhotic patients with chronic hepatitis B (CHB). We assessed the association of baseline viral load and fibrotic burden with the risk of HCC development in CHB patients entering the immune-active (IA) phase.

Method: This multicenter cohort study recruited 3,589 HBeAg-positive, non-cirrhotic CHB patients who started antiviral treatment with entecavir or tenofovir disoproxil fumarate at IA phase transitioned from immune-tolerant (IT) phase in twenty-three tertiary university-affiliated hospitals of South Korea (2012–2020). Significant liver fibrosis was defined as fibrosis-4 index (FIB-4) >3.25. Multivariable analysis using the Cox proportional hazards model was performed.

Results: Sixty (1.7%) patients developed HCC (median follow-up, 5.4 years). Patients who developed HCC were significantly older and showed a significantly higher proportion of diabetes, lower platelet counts, and higher FIB-4 levels than those who did not (n = 3,525, 98.3%) (all p < 0.05). The HCC risk was highest at moderate HBV DNA levels (5.00–7.99 $\log_{10}$ IU/ml) and significant liver fibrosis. In

Table. (abstract: WED-124): Predictors of HCC development

	Multivariable			Multivariable using FIB-4		
	aHR	95% CI	*P* value	aHR	95% CI	*P* value
Demographic variables						
Age, years	1.04	1.02–1.07	<0.001	-	-	-
Male gender	3.58	1.79–7.17	<0.001	3.65	1.84–7.25	<0.001

Antiviral agents						
ETV	-	-	-	-	-	-
TDF	-	-	-	-	-	-
Laboratory variables						
Platelet count, 10^9/L	0.99	0.98–0.99	<0.001	-	-	-
Aspartate aminotransferase, IU/L	-	-	-	-	-	-
Alanine aminotransferase, IU/L	-	-	-	-	-	-
Total bilirubin, mg/dL	-	-	-	-	-	-
Serum albumin, g/dL	0.92	0.57–1.48	0.725	0.88	0.53–1.47	0.625
Serum creatinine, mg/dL	-	-	-	-	-	-
FIB-4 index						
<1.45	-	-	-	1 (reference)		
1.45–3.25	-	-	-	5.36	2.33–12.33	<0.001
>3.25	-	-	-	7.63	3.05–19.09	<0.001
HBV DNA levels, $\log_{10}$ IU/ml						
≥8.00	-	-	-	-	-	-
7.00–7.99	-	-	-	-	-	-
6.00–6.99	-	-	-	-	-	-
5.00–5.99	-	-	-	-	-	-
<5.00	-	-	-	-	-	-
HBV DNA levels, $\log_{10}$ IU/ml						
≥8.00	1 (reference)			1 (reference)		
5.00–7.99	2.55	1.32–4.91	0.005	2.68	1.40–5.13	0.003
<5.00	1.25	0.50–3.13	0.629	1.77	0.71–4.40	0.221

multivariable analysis, moderate HBV DNA levels was independently associated with the increased risk of HCC development (adjusted hazard ratio [aHR] = 2.55, 95% confidence interval [CI] = 1.32–4.91, p = 0.005). After adjustment for FIB-4 levels, similar result was maintained (moderate HBV DNA levels: aHR = 2.68, 95% CI = 1.40–5.13; FIB-4 >3.25: aHR = 7.63, 95% CI = 3.05–19.09; all p < 0.05).
Conclusion: Moderate HBV DNA levels and significant liver fibrosis at the time of phase change from IT to IA phase was significantly associated with the risk of HCC development during potent antiviral therapy in patients with CHB.

WED-125

IP10 and anti-HBc can predict virological relapase and HBsAg loss for chronic hepatitis B patients after nucleos (t)ide analogue discontinuation

Yandi Xie[1], Minghui Li[2], Xiaojuan Ou[3], Sujun Zheng[4], Yinjie Gao[5], Xiaoyuan Xu[6], Ying Yang[7], Anlin Ma[8], JIA Li[9], Yuemin Nan[10], Huanwei Zheng[11,11], Juan Liu[12], Lai Wei[13], Bo Feng[1]. *[1]Peking University People's Hospital, Peking University Hepatology Institute, China; [2]Department of Hepatology Division Beijing Ditan Hospital, Capital Medical University, China; [3]Liver Research Center, Beijing Friendship*

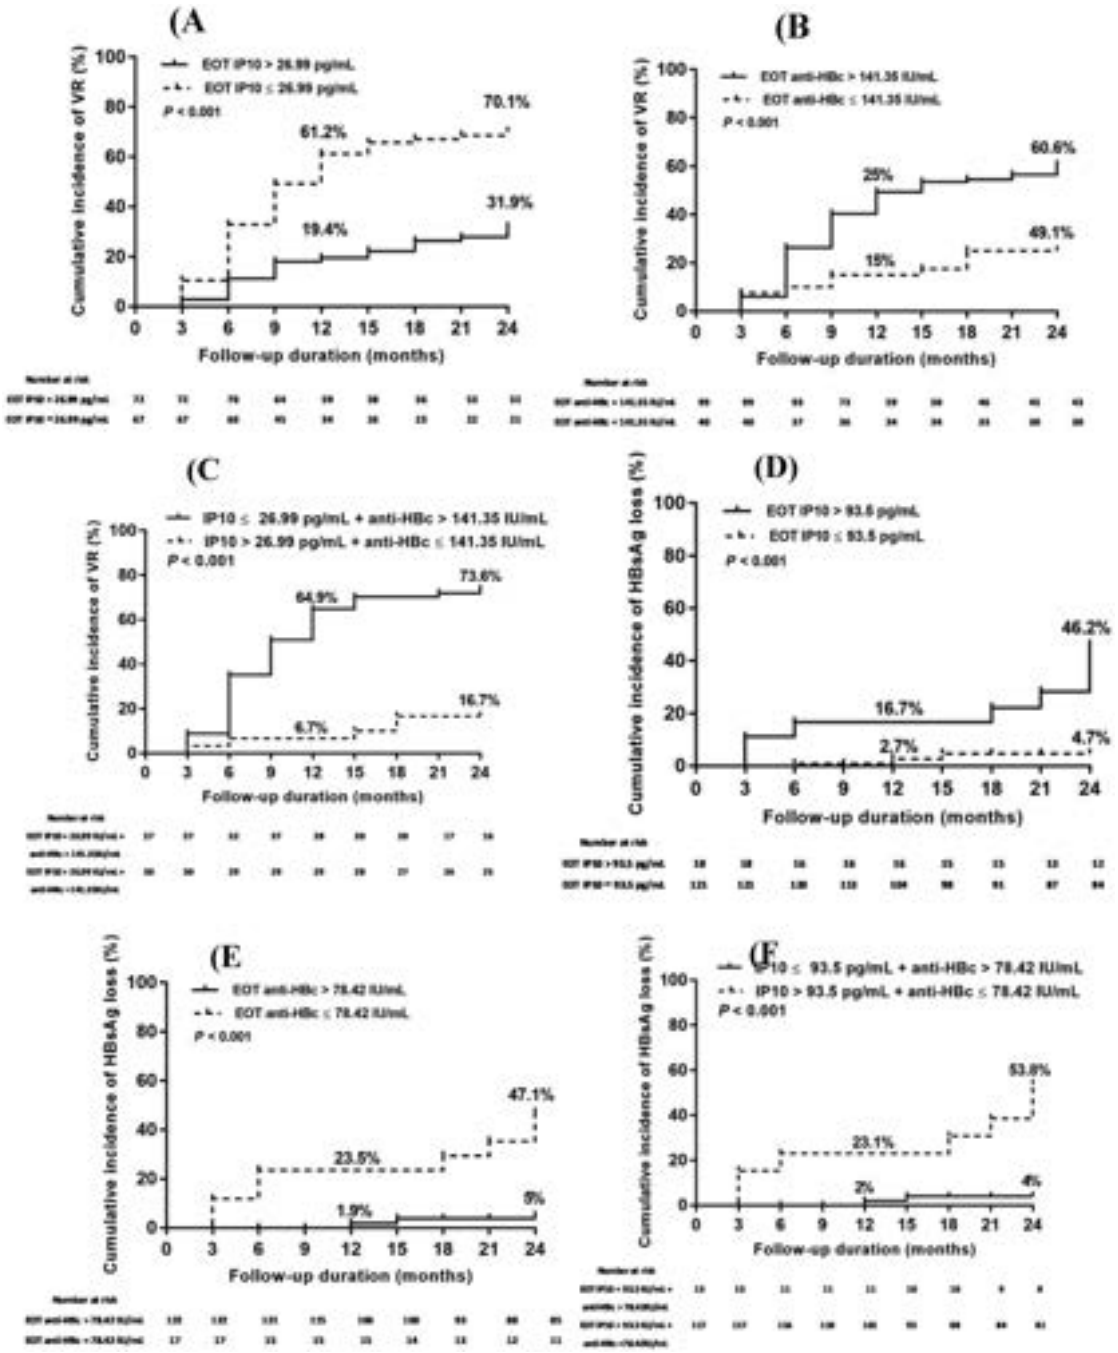

Figure: (abstract: WED-125): Cumulative incidences of virological relapse (VR) and HBsAg loss stratified by end of treatment (EOT) IP10 and anti-HBc. (A)-(C), Cumulative incidences of VR in patients by EOT IP10, anti-HBc or combined two parameters. (D)- (F), Cumulative incidences of HBsAg loss in patients by EOT IP10, anti-HBc or combined two parameters.

Email: xyfyfb_1@sina.com

Background and aims: To assess predictive ability of serum interferon-inducible protein 10 (IP10) and hepatitis B core antibody (anti-HBc) levels for virological relapse (VR) and hepatitis B surface antigen (HBsAg) loss after nucleos (t)ide analogue (NA) discontinuation.
Method: In this multicenter prospective study, overall 139 initially hepatitis virus B e antigen-positive patients were followed up for 24 months after NA discontinuation or until clinical relapse.
Results: End of treatment (EOT) IP10 and anti-HBc were 29.2 (5.1–66.4) pg/ml and 193.6 (136.9–221.4) IU/ml. By Cox regression analysis, EOT IP10 (hazard ratio [HR] 0.976, $p < 0.001$) and anti-HBc (HR 1.011, $p < 0.001$) were independent predictors for VR. EOT IP10 (HR, 1.026, $p < 0.001$) and anti-HBc (HR, 0.981, $p < 0.001$) also were independent predictors for HBsAg loss. Until 24 months after NA discontinuation, cumulative rates of VR in patients with EOT IP10 >26.99 pg/ml and ≤26.99 pg/ml were 31.9% and 70.1%, respectively (HR 2.998, $p < 0.001$). Cumulative incidences of VR in patients with EOT anti-HBc ≤141.35 IU/ml and >141.35 IU/ml were 49.1% and 60.6%, respectively (HR 2.99, $p < 0.001$). Cumulative probability of VR was 16.7% in patients with EOT IP10 >26.99 pg/ml plus anti-HBc ≤141.35 IU/ml, which was significant lower than 73.6% (HR 6.464, $p < 0.001$). Cumulative probabilities of HBsAg loss in patients with EOT IP10 >93.5 pg/ml and ≤93.5 pg/ml were 46.2% and 4.7%, respectively (HR 10.94, $p < 0.001$). Cumulative probabilities of HBsAg loss in patients with EOT anti-HBc ≤78.42 IU/ml and >78.42 IU/ml were 47.1% and 5%, respectively (HR 12.27, $p < 0.001$). Patients with EOT IP10 >93.5 pg/ml plus anti-HBc ≤78.42 IU/ml, had the highest 24-month cumulative HBsAg loss rate (53.8% vs 4%, HR 16.83, $p < 0.001$).
Conclusion: High EOT IP10 and low EOT anti-HBc levels were related to both lower risk of VR and higher probability of HBsAg loss.

WED-126

Off-therapy events in hepatitis B e antigen-negative patients with sustained HBV surface antigen <100 and <50 IU/ml

Yen-Chun Liu[1,2], Rachel Wen-Juei Jeng[1,2], Rong-Nan Chien[1,2]. [1]*Chang Gung Memorial Hospital, Linkou branch, Taiwan, Taiwan;* [2]*College of Medicine, Chang Gung University, Taiwan*
Email: rachel.jeng@gmail.com

Background and aims: Partial cure is defined as sustained low or undetectable HBV DNA level with low HBsAg level. It has not been well studied that if the long-term durability be different between HBeAg negative chronic hepatitis B (CHB) patients who stop nucleos (t)ide analogue (Nuc) with sustained HBsAg level <100 versus <50 IU/ml for 24 weeks from end-of-treatment (EOT). The study aimed to investigate the off-Nuc events incidence in HBeAg negative CHB patients who had achieved sustained qHBsAg <100 and <50 IU/ml.
Method: HBeAg-negative CHB patients who stopped Entecavir (ETV) or Tenofovir (TDF) after consecutive undetectable HBV DNA ≥ 1 year were enrolled. Virological relapse (VR) was defined as HBV DNA ≥ 2000 IU/ml. Clinical relapse (CR) and hepatitis flare were defined as alanine aminotransferase (ALT) levels ≥ 2× ULN and ≥ 5× ULN with VR. Sustained remission (SR) defined as ALT<2X and HBV DNA less than 2000 IU/ml. Sustained qHBsAg <100 or <50 IU/ml was defined as qHBsAg levels persist below 100 or 50 IU/ml for 24 weeks after Nuc discontinuation. Patients who had encountered off-Nuc events within 6 months from EOT were censored from the analysis.
Results: Among 1320 patients, 238 patients (18%) achieved qHBsAg at EOT <100 IU/ml with mean age of 57 year-old, 87% were male and 37% had liver cirrhosis. Of 238 EOT<100 IU/ml patients, 144 achieved EOT HBsAg <50 IU/ml. After excluding 25 patients whose qHBsAg at EOT 6 months being unavailable, 183 patients and 114 patients had achieved SR and sustained EOT <100 and <50 IU/ml by EOT week 24, respectively. The 2-year cumulative incidence of VR, CR, hepatitis flare and retreatment showed comparably low in patients with sustained qHBsAg <100 IU/ml and those with sustained qHBsAg <50 IU/ml [VR: 46% vs. 37%, CR: 22% (annual incidence, IR:6%) vs. 19% (IR:5%), figure A, flare: 11% vs. 10%, retreatment: 19% vs. 19%, all p > 0.1]. Patients who achieved sustained EOT HBsAg <100 or <50 IU/ml had comparably high 5-year cumulative HBsAg loss incidences [35% (IR:8%) vs. 44% (IR: 10%), figure B].
Conclusion: HBeAg negative CHB patients who achieved SR and qHBsAg <100 IU/ml longer than 6 months from EOT showed similarly good off-Nuc durability and high probability for subsequent functional cure compared to those with sustained qHBsAg <50 IU/ml.

WED-127

Improved prediction for liver fibrosis of Fibrosis-4 using machine learning in patients with chronic hepatitis B

Zhiyi Zhang[1], Jian Wang[2,3], Shaoqiu Zhang[2], Yifan Pan[4], Li Zhu[5], Yiguang Li[6], Weimao Ding[7], Jie Li[1,2,3,4], Yuanwang Qiu[6], Rui Huang[1,2,3,4], Chao Wu[1,2,3,4], Chuanwu Zhu[5]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China; [2]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China; [3]Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, Jiangsu, China; [4]Department of Infectious Diseases, Nanjing Drum Tower Hospital, Clinical College of Nanjing Medical University, Nanjing, China; [5]Department of Infectious Diseases, The Affiliated Infectious Diseases Hospital of Soochow University, Suzhou, Jiangsu, China; [6]Department of Infectious Diseases, The Fifth People's Hospital of Wuxi, Wuxi, Jiangsu, China; [7]Department of Hepatology, Huai'an No. 4 People's Hospital, Huai'an, Jiangsu, China*
Email: zhuchw@126.com

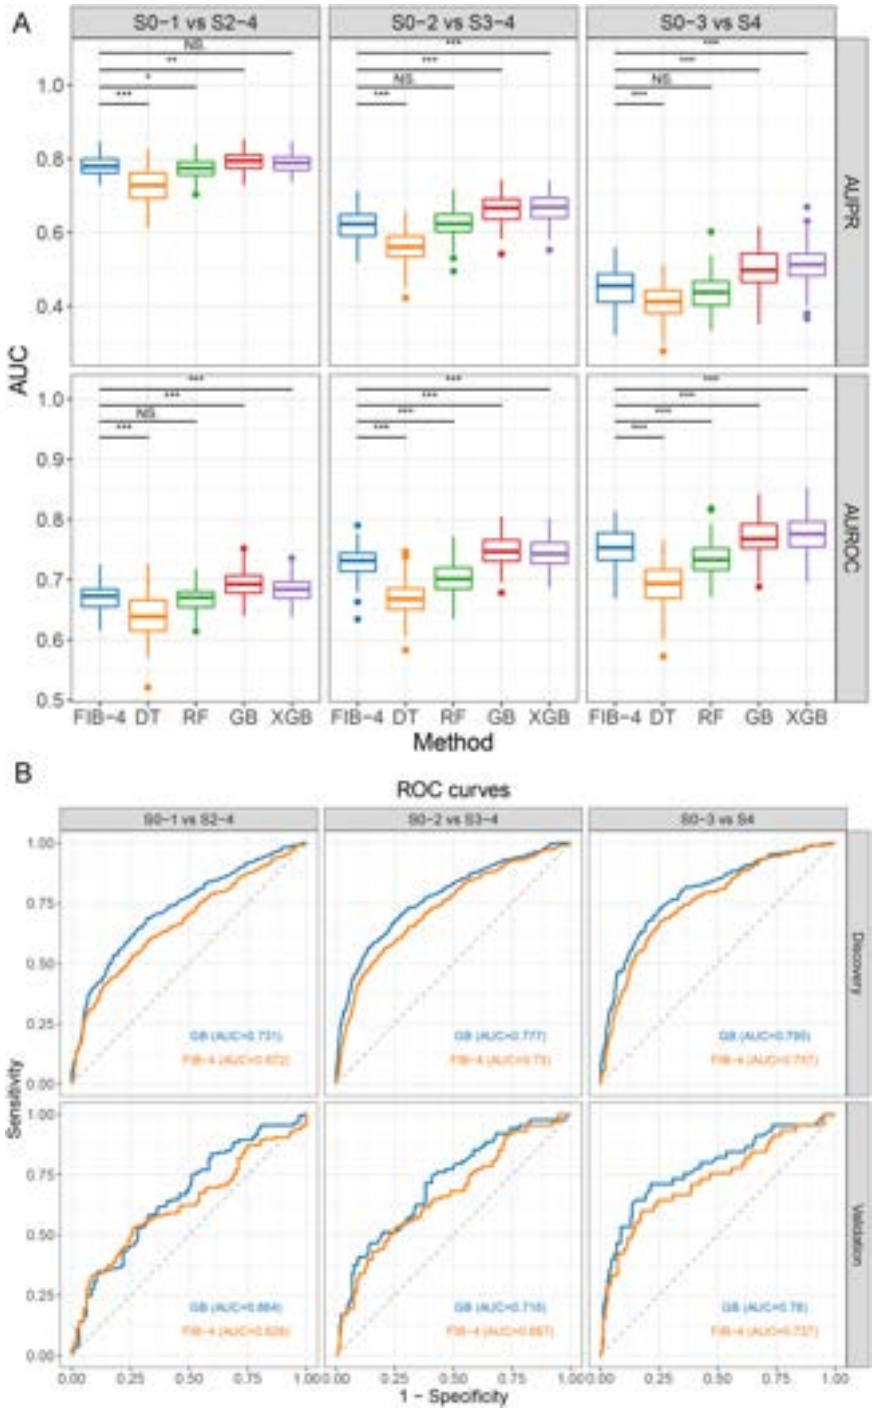

Figure: (abstract: WED-127): Boxplots of AUPR and AUROC on testing sets for five different methods (A) and ROC curves of GB and FIB-4 in fibrosis detection (B).

Background and aims: Fibrosis-4 (FIB-4) index is widely used for predicting liver fibrosis and cirrhosis in patients with chronic hepatitis B (CHB). However, the predictive value of FIB-4 for liver fibrosis and cirrhosis is moderate in CHB. Using cutting-edge machine learning approaches, we aimed to reconstruct FIB-4 for improved prediction of liver fibrosis and cirrhosis.
Method: We included 1231 CHB patients who underwent liver biopsies from four hospitals in this study. To compare the performance of machine learning methods with the FIB-4 index, a discovery set of 957 patients from three hospitals was used. We randomly divided the set into training (70%) and testing (30%) sets 100 times to determine the final model and was externally validated in an independent cohort (n = 274), with comparisons to FIB-4 in terms of the area under the receiver-operating-characteristic curve (AUROC).
Results: In predicting significant fibrosis, advanced fibrosis, and cirrhosis, the AUROC of gradient boosting (GB) outperformed other methods and the FIB-4 index (p <0.001). In the validation set, GB performed better than the FIB-4 index for the classification between significant and non-significant fibrosis (AUROC of 0.664 vs. 0.626, p = 0.09), significantly greater than the FIB-4 index for the classification between non-advanced and advanced fibrosis (AUROC of 0.716 vs. 0.667, P = 0.04) and non-cirrhosis and cirrhosis (AUROC of 0.780 vs 0.727, p = 0.01).
Conclusion: By using the same parameters as FIB-4, the novel GB-based model showed consistent improvements in predicting liver fibrosis and cirrhosis compared to FIB-4 in CHB patients.

WED-128
Passive transfer of hepatitis B core antibody after intravenous immunoglobulin administration in adult patients: a retrospective review

Sital Shah[1], Sophie Mungai[1], Shelley Jones[1]. [1]*King's College Hospital, London, United Kingdom*
Email: sitalshah@nhs.net

Background and aims: After intravenous administration of human normal immunoglobulin (HNIg), patients often test positive for the presence of hepatitis B core antibody (HBcAb). As baseline testing is not common, it is unclear if this is genuine hepatitis B (HBV) exposure or passive transfer during the IV administration of HNIg. Consequently, when patients test positive for HBcAb during screening prior to commencing immunosuppressive therapy, an antiviral to prevent HBV reactivation is commonly prescribed irrespective of true exposure or not. The objective of this study is to highlight the importance of HBcAb testing prior to commencing HNIg infusion, to prevent wrong diagnosis of HBV exposure and incorrect therapeutic decisions.
Method: A retrospective, single center study was carried out at Kings College Hospital, London. Electronic prescription records, dispensing systems and a national HNIg database was used to obtain demographic, clinical information and HNIg specific data of patients receiving long term (>3 months) HNIg treatment during 2011–2021.
Results: Of 493 patients identified, only 71 (14%) received HbcAb testing prior to immunoglobulin administration. 2 were seropositive before infusion, 38 (55%) remained core antibody negative post-infusion, and 31 (45%) became core antibody positive. Those positive for HBcAb, were all hepatitis B surface antigen negative. Because of uncertainly and poor knowledge around baseline testing, all received antiviral treatment consisting of either tenofovir (10%), entecavir (13%) or lamivudine (77%), prior to being initiated on immunosuppressive therapy. After the initial positive test, only 5 (16%) were re-tested either twice or three times afterwards, where all remained positive. The average number of days between their positive HBcAb test and last infusion was 21 days. The average number of doses between baseline and seropositivity was 5 doses. The most common HNIg used was Privigen/Hizentra with 30 patients (38%) for both seronegative and seropositive patients. Many patients changed to subcutaneous immunoglobulin (SCIg) administration of HNIg during the Covid-19 pandemic, which included Hizentra and Cuvitru. Only 2 (6%) patients on SCIg became seropositive.
Conclusion: Passive transfer of hepatitis B core antibody is common after HNIg infusions. Hepatitis B core antibody screening should be considered standard practice for each human normal immunoglobulin administration, effectively improving therapeutic decisions by preventing wrong diagnosis of hepatitis B exposure and therefore preventing unnecessary anti-viral use.

WED-129
Secular trends of newly diagnosed chronic hepatitis B in 2000–2022-a territory-wide study

Grace Lai-Hung Wong[1], Vicki Wing-Ki Hui[1], Terry Cheuk-Fung Yip[1], Yee-Kit Tse[1], Che To Lai[1], Vincent Wai-Sun Wong[1]. [1]*The Chinese University of Hong Kong, Medical Data Analytic Centre (MDAC) and Department of Medicine and Therapeutics, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: The World Health Organization (WHO) proposed targets for the reduction of chronic viral hepatitis incidence and mortality of 90% and 65% respectively by 2030. A comprehensive review of the disease burden of chronic viral hepatitis would provide pivotal data to guide strategies to achieve the goals set by WHO. We aimed to estimate the disease burden of newly diagnosed chronic hepatitis B in 2000 to 2022.
Method: This was a territory-wide retrospective cohort study of all patients with chronic hepatitis B who have been under the care at primary, secondary and tertiary medical centres in Hong Kong. Comprehensive virologic parameters related to chronic hepatitis B from the Hospital Authority were analysed. The number of patients with chronic hepatitis B first diagnosed were evaluated according to calendar year.
Results: Between 1 January 2000 and 31 December 2022, 2,120,008 people patients were tested for chronic hepatitis B, of whom 251,987 (11.88%) tested positive. Annually 6623 to 15,075 people were first diagnosed with chronic hepatitis B; the number of new diagnosis peaked in 2009 then gradually dropped similarly in both genders (Figure A). The drop was more prominent in young adults aged below 30 years old and 50 years old or above, whereas the number of new diagnoses remained high in adults aged 30–49 (Figure B).
Conclusion: Newly diagnosed chronic hepatitis B dropped over the last two decades in young adults but remained high in adults aged 30–49. More resources should be allocated to assess the need of antiviral treatment and complication surveillance for patients with chronic hepatitis B in order to meet the WHO targets of 65% reduction in mortality.

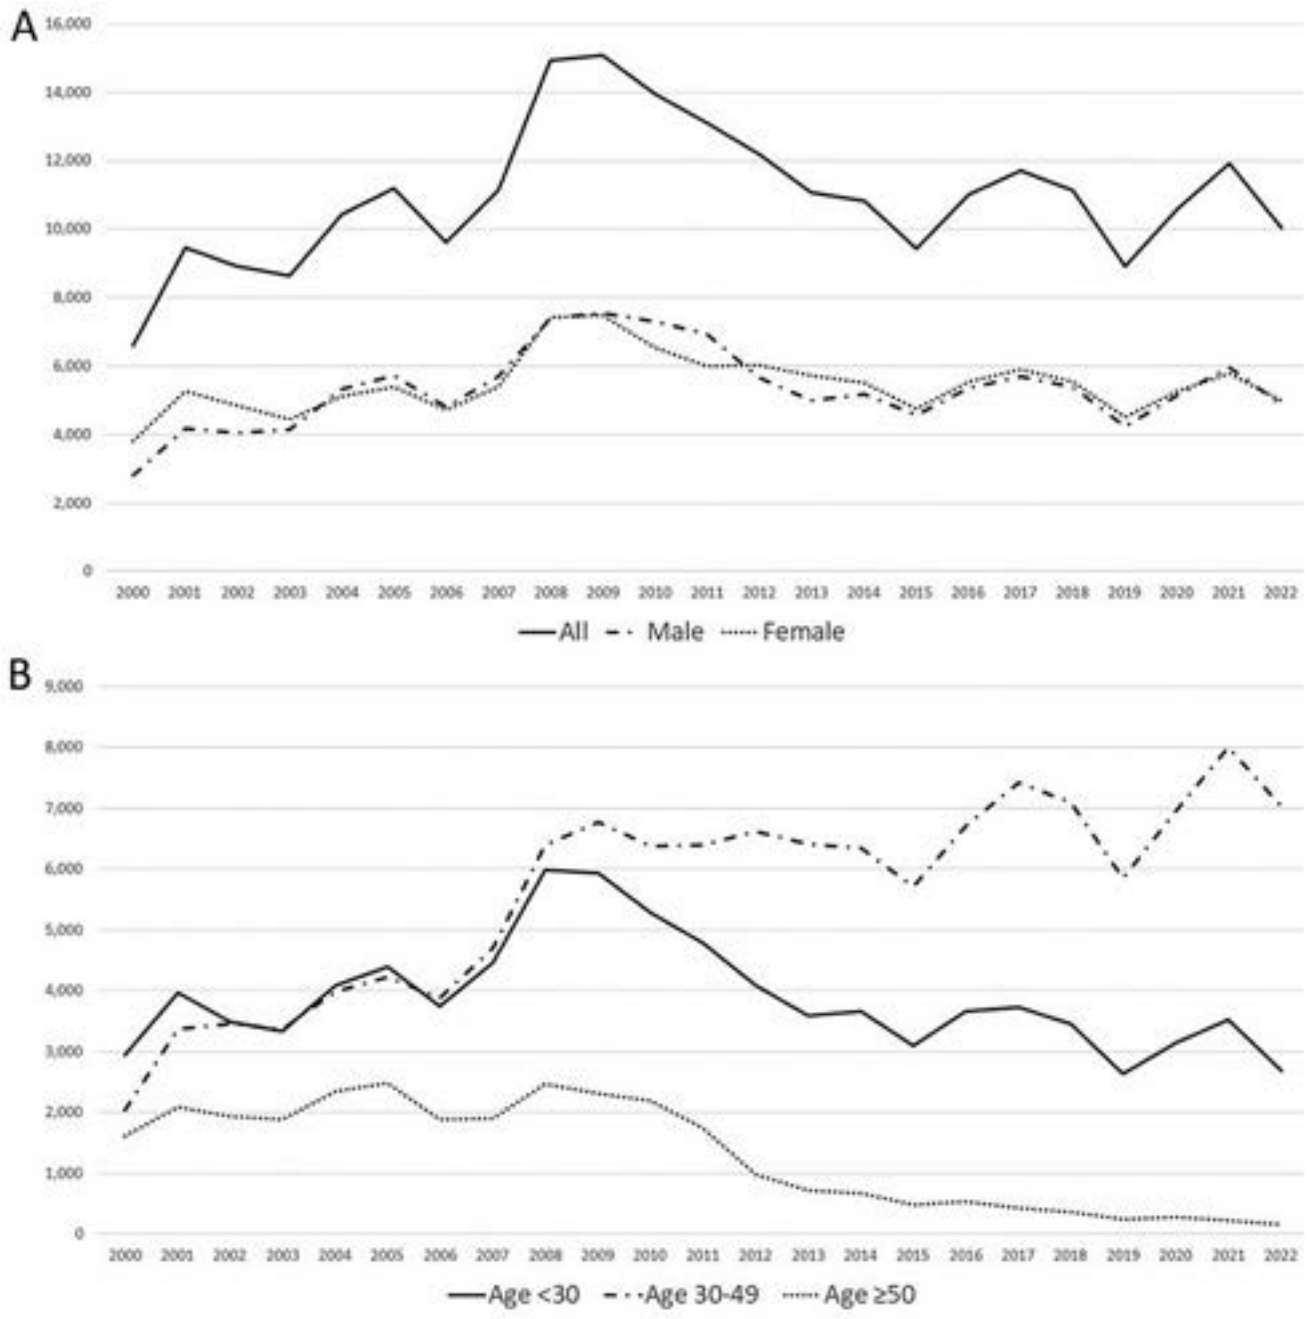

Figure: (abstract: WED-129): Age and gender distribution of patients who were first diagnosed for chronic hepatitis B in 2000 to 2022.

WED-130

Patients with chronic hepatitis delta virus coinfections have higher risk of disease progression than chronic hepatitis B virus monoinfection-results from a Spanish national hospital database

Maria Buti[1], Ankita Kaushik[2], Mertixell Ascanio[3], Josep Darba[4], Chong Kim[2]. *[1]Hospital Universitario Valle Hebron, Liver Unit, Barcelona, Spain; [2]Gilead Sciences, Inc., HEOR-Global Value and Access, Foster City, United States; [3]BCN Health Economics and Outcomes Research SL, Barcelona, Spain; [4]University of Barcelona, Department of Economics, Barcelona, Spain*

Email: ankita.kaushik@gilead.com

Background and aims: Patients with chronic hepatitis delta (CHD) infection are at greater risk of developing liver complications than those with chronic hepatitis B (CHB) monoinfection. This retrospective study compares the rate of disease progression among adult patients with CHD infection vs CHB monoinfection in a national hospital database in Spain.

Method: The study population included patients aged ≥18 years having ≥1 ICD-9/10-CM diagnosis code for HDV or HBV in the Spanish National Health System's Hospital Discharge Records Database (Conjunto Mínimo Básico de Datos) from 1 Jan 2000 to 31 Dec 2019 (study period). HDV-infected and HBV-monoinfected patients were identified from 1 Jan 2001 to 31 Dec 2018 (identification period) with their first diagnosis defined as the diagnosis date, having ≥12 months of continuous enrollment before and after the diagnosis date. Baseline (BL) characteristics including demographics, comorbidities, region, and payer channel were assessed over the entire duration

prior to diagnosis date. HDV-infected and HBV monoinfected patients were propensity score matched (1:5) on BL demographic and clinical characteristics. Multivariable cox proportional hazard regression was performed to assess the differences in risk of compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), liver transplantation (LT), and death between the HDV-infected and HBV-monoinfected patients, adjusting for demographics, comorbidities, region, and payer channel.
Results: The study reported 12,317 patients diagnosed with HDV or HBV, of whom 756 matched patients met the inclusion criteria—126 HDV infected and 630 HBV monoinfected. Among HDV-infected vs HBV-monoinfected patients, mean (SD) age was 41.7 (11.8) vs 41.2 (9.9), p = .581, and the male to female ratio (roughly 9:1) was similar between cohorts. HDV-infected patients were more likely to transition from noncirrhotic disease (NCD) to CC (HR = 1.89; 95% CI, 1.56, 2.29), CC to DCC (HR = 2.44; 95% CI, 1.74, 4.33), DCC to HCC (HR = 2.80; 95% CI, 1.11, 4.66), HCC to LT (HR = 1.83; 95% CI, 1.18, 3.91), and DCC to death (HR = 5.04; 95% CI, 2.40, 32.44) compared to HBV-monoinfected patients.
Conclusion: In a Spanish national hospital database, HDV-infected patients had significantly greater risk of progressing to greater liver disease severity than HBV-monoinfected patients. These findings underscore the need for early screening, diagnosis, and eventual treatment of HDV to mitigate future disease progression.

WED-131

Dynamic monitoring of HBsAg-specific B cells in CHB patients and its clinical significance in predicting interferon therapy efficacy

Yu Geng[1], Yawen Wan[1], Shengxia Yin[1], Jie Li[1], Chao Wu[1]. *[1]Nanjing Drum Tower Hospital, Department of Infectious Diseases, Nan Jing Shi, China*
Email: dr.wu@nju.edu.cn

Background and aims: The guidelines for the treatment of chronic hepatitis B virus (CHB) patients currently recommend two categories of antiviral drugs: nucleoside analogs and interferons. In comparison to nucleoside analogs, interferons have a higher rate of HBsAg and HBeAg clearance, but their medical compliance, cost, and side effects may hinder clinical application. As a result, the identification of reliable predictive biomarkers to maximize benefits is essential. In HBV infection, the damage and recovery of surface antigen (HBsAg) specific B cells is linked to HBsAg serological conversion. However, current understanding of HBsAg specific B cell immunity is limited, and there are no specific and sensitive methods to detect HBsAg specific B cells. This study presents a method for single-cell level detection of HBsAg specific B cells using an optimized ELISPOT (Enzyme-Linked ImmunoSpot) method. This approach can explore the HBsAg specific B cell responses during different stages of chronic HBV infection and the effect of these responses on the efficacy of interferon treatment in CHB patients.
Method: This study included 142 CHB patients at various stages of immunity, 90 of whom were untreated (21 HBeAg positive patients in the chronic hepatitis stage, 5 HBeAg negative patients in the chronic hepatitis stage, 9 HBeAg positive patients in the chronic infection stage, and 55 HBeAg negative patients in the chronic infection stage). 52 patients received antiviral therapy. Peripheral blood lymphocytes were stimulated over a 5-day period, and the frequency of peripheral blood HBsAg-specific B cells was monitored using ELISPOT. The correlation between serum HBsAb levels and peripheral blood HBsAg-specific B cells was analyzed, and preliminary observations of the dynamic changes of HBsAg-specific B cells before and after interferon treatment were made.
Results: In the chronic hepatitis phase, 6 patients (28.6%) who were HBeAg positive showed positive results in ELISPOT, indicating the presence of peripheral blood HBsAg-specific B cells, while no (0%) HBeAg negative patients in the chronic hepatitis phase showed positive results. Among patients in the chronic infection phase, 3 (30%) who were HBeAg positive and 14 (25.5%) who were HBeAg negative showed positive results in ELISPOT. The number of peripheral blood-secreting HBsAb-specific B cells was significantly higher in the HBeAg-positive chronic hepatitis group than in the HBeAg-negative chronic infection group ($p < 0.05$). The proportion of "functional cure" in the ELISPOT-positive group was higher after interferon treatment compared to the baseline state (50% in positive group vs. 17.2% in negative group, $P < 0.05$). After interferon treatment, 10 (52.6%) patients showed an increase in HBsAg-specific B cells, with 4 (21.1%) patients achieving "functional cure." Meanwhile, 4 (21.1%) patients with decreased HBsAg-specific B cells and 5 (26.3%) patients with no change in HBsAg-specific B cells did not achieve "functional cure."
Conclusion: In CHB patients in varying immune states, peripheral blood contains HBsAb-secreting B cells that exhibit differing proportions. The peripheral blood's presence of HBsAb-secreting B cells before interferon treatment may be a significant immunological indicator for forecasting interferon therapy efficacy.

WED-132

Association of TLR7 polymorphisms in Caucasians with disease stages and HBsAg loss in hepatitis virus B infections

Janett Fischer[1], Kai-Uwe Kraps[1], Tobias Müller[2], Heyne Renate[3], Thomas Berg[1], Florian van Bömmel[1]. *[1]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Germany; [2]Department of Gastroenterology and Hepatology, Charité-Universitätsmedizin Berlin, Berlin, Germany; [3]Liver and Study Center Checkpoint, Berlin, Germany*
Email: janett.fischer@medizin.uni-leipzig.de

Background and aims: Toll-like receptor 7 (TLR7) activation is major step during innate immune responses against hepatitis B virus (HBV) infections. TLR7 detects single stranded RNA and induces both type 1 interferon and inflammatory responses. Recently, TLR7-directed therapies are under investigation for the treatment of chronic hepatitis B (CHB). Nonetheless, polymorphisms within the *TLR7* gene might affect immune responses and treatment efficacy. Thus, we aimed to evaluate the impact of common *TLR7* polymorphisms (SNPs) on the course of HBV infection and liver disease progression in a Caucasian population.
Method: The study cohort included 519 Caucasian individuals with CHB (60% male, mean age 58 ± 15 years) and 193 with spontaneous HBV surface antigen (HBsAg) seroclearance (SC) with available full blood samples stored at −20°C who had given informed consent for participation in the study. In the CHB group, 206 patients had HBeAg-negative HBV infection and 90 HBeAg-positive and 223 HBeAg-negative CHB. Host genomic DNA extraction and genotyping of the *TLR7* SNPs rs179008, rs864058 and rs2302267 were performed from full blood samples. Serum levels of pro- and anti-inflammatory cytokines were measured in corresponding serum samples from 193 patients.
Results: Genotype distribution of the *TLR7* rs179008 was different between patients with CHB and spontaneous HBsAg SC ($p = 0.0003$). After sex stratification, this difference in genotype distribution only remained significant in female patients ($p = 0.007$). Here, the AT/TT genotypes were associated with an increased likelihood of spontaneous HBsAg SC in adjusted analysis (OR = 1.78 [95% CI: 1.02–3.10], $p = 0.041$). In the HBsAg SC group, female patients carrying the rs179008 AT/TT genotypes showed lower serum levels of interferon (IFN) alpha ($p = 0.028$), IFN beta ($p = 0.016$), IFN gamma ($p = 0.032$) and interleukin (IL)-10 ($p = 0.017$) than carriers of the AA genotype. Furthermore, we found a significant association of *TLR7* rs2302267 TG/GG genotypes with HBeAg-negative infection (OR = 1.51, $p = 0.039$), and an association of *TLR7* rs864058 GG genotype with an increased frequency of liver cirrhosis (OR = 3.48, $p = 0.019$).
Conclusion: In this retrospective study, we confirmed the association of the *TLR7* rs178009 polymorphism with disease stages and functional cure in HBV infected Caucasian patients, and we identified new effects of additional *TLR7* variants on disease progression. Our

findings further emphasise the relevance of the genetic and sex predisposition in personalized management of HBV infections and potentially for new TLR7-directed treatment strategies.

WED-133

Higher levels of three HBsAg forms (Large, Middle and Small HBsAg) are associated with HDV replication and with the degree of disease and liver damage

Leonardo Duca[1], Antonella Olivero[2], Lorenzo Piermatteo[1,3], Stefano D'Anna[1], Giulia Torre[1], Elisabetta Teti[4], Andrea Di Lorenzo[4], Vincenzo Malagnino[4], Marco Iannetta[4], Leonardo Baiocchi[5], Simona Francioso[5], Ilaria Lenci[5], Francesca Ceccherini Silberstein[1], Michele Milella[6], Annalisa Saracino[6], Alessia Ciancio[2], Loredana Sarmati[4], Mario Rizzetto[2], Gian Paolo Caviglia[2], Valentina Svicher[1,3], Romina Salpini[1]. *[1]University of Rome "Tor Vergata", Experimental Medicine, Rome, Italy; [2]University of Turin, Department of Medical Sciences, Italy; [3]University of Rome "Tor Vergata", Biology, Rome, Italy; [4]University of Rome "Tor Vergata", Department of Systems Medicine, Infectious Disease Clinic, Italy; [5]Policlinico Tor Vergata, Hepatology Unit, Italy; [6]University of Bari "Aldo Moro", Italy*
Email: duca.leonardo@hotmail.it

Background and aims: HBV surface proteins (HBsAg) enable the morphogenesis of HDV progeny and entry into hepatocytes. Total HBsAg is composed by 3 different forms: Large-HBs (L-HBs), Middle-HBs (M-HBs), and Small-HBs (S-HBs). Here, we investigate the still unexplored levels of the different HBs forms in the setting of HDV coinfection and their correlation with ALT and the status of cirrhosis.
Method: This study includes 160 plasma samples from patients with HDV-HBV chronic infection classified as high-replicating HDV (HDV-RNA >3 log IU/ml, N = 130) and low-replicating HDV (HDV-RNA<3 log IU/ml, N = 30). Total HBsAg is measured by COBAS HBsAgII assays (Roche Diagnostics) while ad-hoc designed ELISAs are used to quantify L-HBs, M-HBs, S-HBs (Beacle Inc).
Results: Patients have a median (IQR) serum HDV-RNA and total HBsAg of 5.1 (3.4–6.1) log IU/ml and 5716 (1372–10 887) IU/ml, respectively. ALT >40 U/L is observed in 76.9% (median [IQR]: 87 [67–136) U/L] and 63.8% is cirrhotic. The median (IQR) levels of HBs-S, HBs-M and HBs-L are 3,984 (637–6993), 1,147 (141–2299) and 2.3 (0.2–6.5) ng/ml, respectively.
Notably, significantly higher levels of all the 3 HBs forms are observed in patients with high-replicating HDV compared to low-replicating HDV (median [IQR] levels: 4638 [1560–7467] vs 272 [61–3523] ng/ml for S-HBs; 1,409 [228–2647] vs 103 [7.2–615] ng/ml for M-HBs; 3.5 [0.3–9.1] vs 0.3 [0.04–1.2] ng/ml for L-HBs, P < 0.001 for all). A positive correlation is also revealed for the 3 HBs forms with HDV-RNA levels (Rho = 0.42, 0.46 and 0.39 for S-, M- and L-HBs, respectively; P < 0.001 for all).
In low-replicating HDV patients, 51.9% has altered transaminases (median [IQR]: 78 [61–117] U/L). Notably, in this set of patients, M-HBs>200 ng/ml is the best cut-off predicting altered ALT >40 U/L (75% of patients with M-HBs>200 ng/ml vs 37.5% of those with M-HBs<200 ng/ml, PPV = 75%, NPV = 62.5%; P = 0.049), supporting the role of M-HBs in reflecting cytolytic activity even in the setting of a low HDV replication.
Serum HDV-RNA levels were comparable between cirrhotic and non-cirrhotic patients (median [IQR]: 5.1 [4.1–5.9] vs 4.2 [1.2–5.7] log IU/ml; P = 0.11). Nevertheless, a higher ratio of L-HBs/M-HBs (reflecting unbalanced release towards L-HBs) is observed in cirrhotic vs non-cirrhotic patients (median [IQR] % ratio of L-HBs/M-HBs: 0.41 [0.16–1.45] vs 0.18 [0.06–0.45]; P = 0.05). In particular, a % ratio of L-HBs/M-HBs >0.5 correlates with the status of cirrhosis (83.3% with vs 37.3% without L-HBs/M-HBs >0.5 is cirrhotic; P = 0.037).
Conclusion: In chronic HDV coinfection, higher levels of the 3 HBs forms support an enhanced burden of HDV replication and their composition correlates with the degree of cytolytic activity and liver damage. Thus, the quantification of 3 HBs forms can provide an added value in identifying patients with a more advanced disease, in which treatment should be prioritized.

WED-134

Hepatitis delta treatment utilization in the United States: an analysis of commercially insured adults with hepatitis delta virus infection

Robert Wong[1,2], Robert G. Gish[3], Joseph Lim[4], Ankita Kaushik[5], Chong Kim[5], Gary Leung[6], Ira M Jacobson[7]. *[1]Stanford University School of Medicine, Stanford, United States; [2]VA Palo Alto Healthcare System, Palo Alto, United States; [3]Hepatitis B Foundation, Doylestown, United States; [4]Yale University School of Medicine, New Haven, United States; [5]Gilead Sciences, Inc., HEOR-Global Value and Access, Foster City, United States; [6]Gilead Sciences, Inc., RWE-Epidemiology, Foster City, United States; [7]NYU Grossman School of Medicine, New York, United States*
Email: rwong123@stanford.edu

Background and aims: Hepatitis delta virus (HDV) infection is associated with more rapid liver disease progression than hepatitis B (HBV) infection alone. Compared with HBV monoinfection, if left untreated, HDV is associated with earlier onset of liver-related complications, such as cirrhosis, liver failure, and liver cancer. While pegylated-interferon (Peg-IFN) is used off-label as a treatment option for HDV, treatment utilization for HDV coinfected patients in the US are not well understood. This study aims to describe HDV treatment utilization among a large population-based cohort of commercially insured adults with HDV in the US.
Method: Adult patients with ≥1 HDV or HBV diagnosis (ICD-9/10-CM) were identified retrospectively from 1 Jan 2013 to 31 Dec 2021 (study period) using the IQVIA PharMetrics Plus database covering ~210 million patients from primarily commercial payers. HDV patients were identified from 1 Jan 2014 to 31 Dec 2020 (identification period) and defined as those who had ≥1 inpatient or ≥2 outpatient claims ≥30 days apart with an ICD-9/10-CM diagnosis code (070.21, 070.23, 070.31, 070.33, 070.42, 070.52, B160, B170, B161, B180) for HDV during the identification period (earliest date of diagnosis considered index date), ≥1 claim of HBV diagnosis during BL (12-month period prior to index date), and no claims with HDV diagnosis during BL. Continuous enrollment for ≥12 months before and after the index date was required, and patients aged ≥18 years at index with commercial health plans were included. Utilization of antiviral therapies including pegylated interferon, interferon alfa, interferon alfa N3, interferon gamma, tenofovir disoproxil fumarate, tenofovir alafenamide, entecavir, adefovir, telbivudine, and lamivudine were assessed over the entire post-index period (follow-up).
Results: Among 6,002 patients with HDV identified during the identification period, 440 met inclusion criteria. Only five patients (1.1%) received treatment with pegylated interferon (Peg-IFN) within the follow-up period. Fewer than 40% of patients with concurrent HDV infection (n = 175; 39.8%) were receiving HBV-specific antiviral therapy, including tenofovir disoproxil fumarate (91; 20.7%), entecavir (65; 14.8%), tenofovir alafenamide (46; 10.5%), adefovir (7; 1.6%), and lamivudine (2; <0.5%). The majority of patients with HDV were not on any interferon or HBV-related treatments (263; 59.8%).
Conclusion: In a large US national, primarily commercial, healthcare claims database, fewer than 40% of patients with HDV were treated with HBV-specific antiviral therapies, and very few patients (1.1%) were treated with Peg-IFN, the current off label standard of care for HDV infection. Greater awareness of the importance of timely

initiation of antiviral therapy for patients with combined HBV/HDV infection is urgently needed.

Comparison of HCC incidence between entecavir and tenofovir in a chronic hepatitis B cohort with balanced censoring

Jang Han Jung[1], Eileen Yoon[2], Dae Won Jun[2], Hyunwoo Oh[3], Hyo Young Lee[3], Sung Eun Kim[4], Sung-Eun Kim[5,6], Soung Won Jeong[7], Gi-Ae Kim[8], Jihyun An[2], Joo Hyun Sohn[2], Won Sohn[9], Yong Kyun Cho[9], Sang Bong Ahn[10]. *[1]Dongtan Sacred Heart Hospital of Hallym University Medical Center, Korea, Rep. of South; [2]Hanyang University, College of Medicine, Department of Internal Medicine, Korea, Rep. of South; [3]Uijeongbu Eulji Medical Center, Eulji University College of Medicine, Korea, Rep. of South; [4]Hallym University Sacred Heart Hospital, Hallym University College of Medicine, Korea, Rep. of South; [5]Kangdong Sacred Heart Hospital, Hallym University College of Medicine, Korea, Rep. of South; [6]Hallym University College of Medicine, Internal Medicine, Korea, Rep. of South; [7]Soonchunhyang University College of Medicine, Soonchunhyang University Seoul Hospital, Korea, Rep. of South; [8]Kyung Hee University School of Medicine, Korea, Rep. of South; [9]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Korea, Rep. of South; [10]Eulji university college of medicine, Korea, Rep. of South*
Email: noshin@hanyang.ac.kr

Background and aims: The risk of hepatocellular carcinoma (HCC) in patients treated with either entecavir or tenofovir disoproxil fumarate (tenofovir DF) for chronic hepatitis B (CHB) has not been elucidated. Distinct characteristics of patients tend to be treated with tenofovir DF, shorter observation periods for tenofovir DF, and imbalanced rate of censoring between the two drugs have led to contradictory results. Minimizing and balancing the censored data, we aimed to compare the risk of HCC in treatment-naïve patients who were treated with either entecavir or tenofovir DF over the same follow-up duration.
Method: The de-identified data of 9-centered cohort were linked to the record of HCC development in the National Health Insurance Service. To prove the robustness of this analysis, variable subgroup analyses were done on the propensity-score matched with inverse probability of treatment weighting.
Results: We treated 1698 patients (male, 65.3%; mean age, 47.2 ± 11.5 years) with either entecavir (n = 845) or tenofovir DF (n = 853). The mean follow-up duration was 8.7 (IQR 7.9–10.3) years for entecavir and 7.4 years (IQR 6.7–8.4) for tenofovir DF. Sixty-nine and sixty-five patients developed HCC in entecavir group (8.2%) and tenofovir DF group (7.6%), respectively (p = 0.562). Similarly, the incidence of HCC did not differ between the groups (p = 0.268) in 751-pair propensity score-matched patients.
Conclusion: In a retrospective review of 1,698 treatment-naïve patients with CHB, there was no difference in the HCC incidence between the two groups treated with either entecavir or tenofovir DF, over 7-years for both the medications.

WED-136

Serum CXCL16 serves as the predictor for liver inflammation functioning through a NKT cell-depend way in chronic hepatitis B patients

Yawen Wan[1], Shengxia Yin[2], Ming Li[3], Minxin Mao[3], Jiacheng Liu[2], Xin Tong[2], Jian Wang[2], Jie Li[2], Chao Wu[1,2]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Xuzhou Medical University, Xuzhou Medical University, Xuzhou, China; [2]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China; [3]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjing, China*
Email: dr.wu@nju.edu.cn

Background and aims: Significant liver inflammation is an important indication for initiating antiviral therapy in chronic hepatitis B (CHB) patients. Liver biopsy has always been regarded as the golden standard for assessing the liver inflammation, while its invasive nature limited the application. The level of alanine aminotransferase (ALT) is currently the most commonly used serum indicator. However, the severity of liver inflammation is not always consistent with ALT levels. Therefore, We aimed to find more effective and non-invasive markers for predicting liver inflammation.
Method: We conducted a cross-sectional study that retrospectively included 120 CHB patients who had underwent liver biopsy and 31 volunteers as health control. Liver inflammation were staged by Scheuer's classification. The expression level of CXC motif chemokine ligand 16 (CXCL16) in peripheral blood of patients with CHB was determined by ELISA and the relationship between CXCL16 and liver inflammation was further analyzed. In addition, the mechanism of CXCL16 affecting liver inflammation was explored by using a mouse model infected with hepatitis B virus (HBV).
Results: We found that the serum level of CXCL16 in CHB patients was much higher than that in healthy subjects. Furthermore, serum CXCL16 was severe significantly higher in severe inflammation group ($G \geq 3$, n = 26) than in non-severe inflammation group ($G < 3$, n = 96) [(median, IQR), 0.42 (0.24–0.71) ng/ml VS 1.01 (0.25–2.09) ng/ml, $P < 0.001$]. We combined CXCL16 with platelet, ALT and albumin to build a model, which is more effective in predicting severe inflammation than ALT (ROC, 0.92 VS 0.81, P = 0.015). Additionally, by using HBV infected mice model, we found a decreased level of liver inflammation after CXCL16 blockage. A failure of liver infiltration and decreased inflammatory function of natural killer T (NKT) and natural killer (NK) cells were discovered.
Conclusion: CXCL16 could be developed as a promising non-invasive liver inflammation marker for patients with chronic HBV infection. And it could accelerate the hepatic inflammation by a NKT and NK cell depend way.

Background and aims: The longitudinal patterns of HBV DNA viral load (VL) of chronic hepatitis B (CHB) patients on treatment are not well characterised in the UK population. However, understanding the phenotypes of treatment responses is crucial for patient stratification for better care.
Method: We studied a cohort of 8,028 CHB patients from 6 large teaching hospitals in England with longitudinal follow-up, established by the National Institute for Health Research (NIHR) Health Informatics Collaborative (HIC) from electronic patient record systems. We included adults who had two or more VL measurements with >6 months of follow-up on VL for analysis. We applied latent class mixed models to investigate the patterns of VL trajectories since the earliest treatment date recorded (defined as baseline). Repeated and various number of measurements at different time points for patients were considered in the approach, by including fixed effects, and random effects and slope for individuals. The number of VL classes was determined by the Bayesian information criteria, the Akaike information criteria, the discrimination, the odds of correct classification, the relative entropy, and the interpretability of the model. We performed multinomial logistic regressions to assess the determinants of VL trajectories at baseline.
Results: We identified 740 patients on nucleos/tide analogue (NA) treatment with longitudinal VL data, with a median follow-up duration of 3.3 years (interquartile range [IQR], 1.6–5.2 years). The total number of VL measurements was 4,642 (median [IQR], 5 [3–8] measurements per patient). Five mutually exclusive patterns of VL trajectories were identified (Figure), i.e., class 1 (N = 557, 75.3%)-'VL long term suppressed', class 2 (N = 53, 7.2%)-'persistent viraemia with moderate VL', class 3 (N = 74, 10.0%)-'VL suppressed as expected', class 4 (N = 24, 3.2%)-'VL non-suppressing with high VL', and class 5 (N = 32, 4.3%)-'VL slowly suppressed'. Univariable analysis showed that baseline age, sex, ethnicity, HBeAg status, ALT, albumin, urea, and treatment regimens, were associated with the VL classes identified. After multivariable analysis, the following independent determinants (all p <0.05) measured at baseline were identified (the reference was class 1): i) age, sex, Mixed or Other ethnicity, albumin, ALT for class 2, ii) sex, HBeAg status, ALT, urea for class 3, iii) age, HBeAg status for class 4, and iv) age, HBeAg status, ALT, combination treatment drugs of entecavir and tenofovir disoproxil for class 5.
Conclusion: There is heterogeneity in virologic response to antiviral treatment with NA agents, and complete virologic suppression for CHB patients on current standard antiviral treatment can be slow. Some of this variability is statistically associated with demographics and laboratory parameters. Enhanced understanding of treatment response can be used to inform better risk-stratification, improved patient-centric clinical care, and as a foundation to understand the impact of novel therapies as these become available.

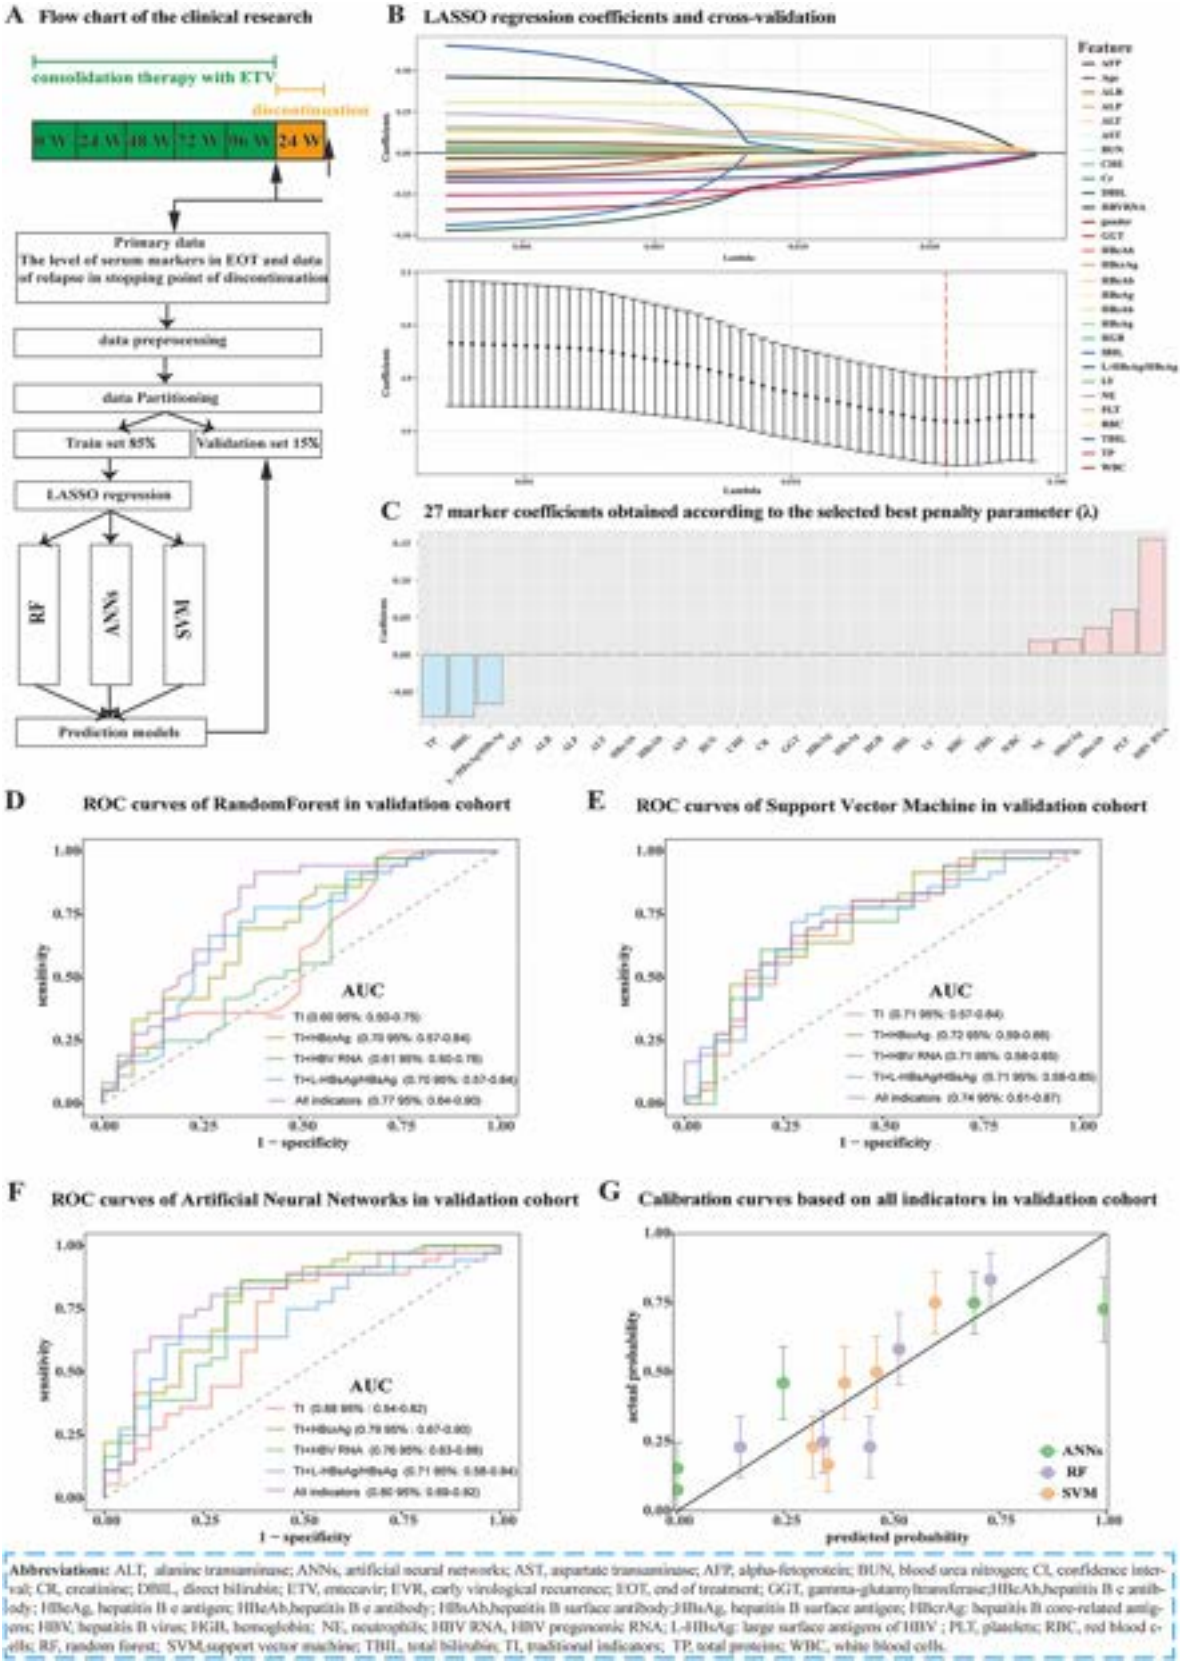
Email: yeyongan@vip.163.com

Background and aims: Although guidelines recommend that chronic hepatitis B (CHB) patients may discontinue nucleos (t)ide analogues (NAs) after consolidation therapy, virological relapses are common. Early virological recurrence (EVR) generally signaling disease flare. However, biomarkers assessing risks of off-treatment virological recurrence are limited. With machine learning techniques, this study aimed to investigate the role of novel biomarkers including hepatitis B virus pregenome RNA (HBV RNA), hepatitis B core-related antigens (HBcrAg), and large surface antigens of HBV (L-HBsAg) in combination with traditional serum assessments such as tests of HBV serological markers, liver enzymes at the end of treatment (EOT) in predicting the risk of EVR in CHB patients within 24 weeks after entecavir (ETV) withdrawal. The study was conducted as part of National Science and Technology Major Project of China, No.2018ZX10725505.
Method: This study was based on data from a prospective multi-center trial in China. In the trial, CHB patients were given a consolidation treatment with ETV for 96 weeks followed by an off-treatment observation for 24 weeks, during which numbers of EVR (defined as serum HBV DNA >10 IU/ml) were counted. With the serological markers collected at the EOT, we developed predictive models to assess the risk of EVR. Multivariable analyses were performed using penalized logistic regression by the LASSO method. Random forest (RF), artificial neural networks (ANNs), and support vector machine (SVM) were used to construct prediction models based on traditional indicators (TI) and novel serum biomarkers, respectively. Area under the curve (AUC) and calibration plots were used to assess the discrimination and calibration.
Results: A total of 420 patients were enrolled in the current study and 172 (40.95%) patients experienced EVR within 24 weeks after ETV withdrawal. LASSO regression revealed that eight variables (levels of



Abbreviations: ALT, alanine transaminase; ANNs, artificial neural networks; AST, aspartate transaminase; AFP, alpha-fetoprotein; BUN, blood urea nitrogen; CI, confidence interval; CR, creatinine; DBIL, direct bilirubin; ETV, entecavir; EVR, early virological recurrence; EOT, end of treatment; GGT, gamma-glutamyltransferase;HBcAb,hepatitis B c antibody; HBeAg, hepatitis B e antigen; HBeAb,hepatitis B e antibody; HBsAb,hepatitis B surface antibody;HBsAg, hepatitis B surface antigen; HBcrAg: hepatitis B core-related antigens; HBV, hepatitis B virus; HGB, hemoglobin; NE, neutrophils; HBV RNA, HBV pregenomic RNA; L-HBsAg: large surface antigens of HBV ; PLT, platelets; RBC, red blood cells; RF, random forest; SVM,support vector machine; TBIL, total bilirubin; TI, traditional indicators; TP, total proteins; WBC, white blood cells.

Figure: (abstract: WED-138).

HBcrAg, HBV RNA, L-HBsAg/HBsAg [hepatitis B surface antigen], platelets [PLT], hepatitis B e antibody [HBeAb], count of neutrophils [NE], direct bilirubin [DBIL] and serum total proteins [TP]) were particularly important features of recurrence. The performance of the SVM model (AUC: 0.71, 95% confidence interval [CI]: 0.57–0.84) based on TI (PLT, HBeAb, NE, DBIL and TP) was superior to RF (AUC: 0.60, 95% CI: 0.50–0.75) and ANNs (AUC: 0.68, 95% CI: 0.54–0.82) models, and the performance of the ANNs (AUC: 0.80, 95% CI: 0.69–0.92) model by integrating TI with all novel serum biomarkers was superior to RF (AUC: 0.77, 95% CI: 0.64–0.90) and SVM (AUC: 0.74, 95% CI: 0.61–0.87) models. Furthermore, the diagnostic efficiency of the combination of TI and all novel serum biomarkers indicators to diagnose EVR was higher than that of a single combined indicator.

Conclusion: Machine learning techniques can be used to create models for predicting EVR following ETV withdrawal in patients with CHB. Patients with certain EOT characteristics, such as high levels of HBcrAg, low L-HBsAg/HBsAg ratio, and detectable serum HBV RNA, are at a higher risk for EVR. These models can assist in identifying patients who are suitable for ETV withdrawal with minimal risk in clinical practice.

WED-139

Extrahepatic mortality in patients with chronic hepatitis B infection: a large population-based cohort study

Young Eun Chon[1], Man Young Park[2], Kwan Sik Lee[1], Dae Won Jun[3].
[1]CHA Bundang Medical Center, CHA University, Korea, Rep. of South; [2]Korea Institue of Oriental Medicine, Korea, Rep. of South; [3]Hanyang University, Korea, Rep. of South
Email: nachivysoo@chamc.co.kr

Background and aims: Accurate statistics on the change in cause of death and mortality in patients with chronic hepatitis B (CHB) are lacking. We investigated the extrahepatic disease-related mortality and its change.

Method: Data of patients who had been newly diagnosed as CHB between 2007 and 2010 (cohort 1, n = 223,424) and between 2012 and 2015 (cohort 2, n = 177,966) from the Korea National Health Insurance Service was used. Mortality and cause of death were obtained from the Statistics Korea. Cause of death were classified as liver-related (hepatic decompensation or HCC) or extrahepatic disease-related (cardiovascular-related, cerebrovascular related, or cancers except HCC).

Results: In cohort 1, death rate was 13.9% yielding overall mortality of 1541/100 000 person-years during 10 years of follow-up. Ten-year overall mortality was 9,234/100 000 person-years in patients with cirrhosis, and 861/100 000 person-years in patients without cirrhosis. Liver-related death in patients with cirrhosis and those without comprised 75.4% and 30.0% of total cause of death, respectively. Most common causes of death in patients with cirrhosis were HCC (62.4%) and liver decompensation (13.0%), whereas those in patients without cirrhosis were cancers except HCC (27.2%) and HCC (22.7%). When 5-year mortality was compared (cohort 1 vs. cohort 2), overall and other mortalities decreased in cohort 2, however, mortality related to cancers except HCC increased (361/100 000 person-years→398/100 000 person-years). Proportion of cancers except HCC as a cause of death has increased (16.7% in cohort→22.4% in cohort 2).

Conclusion: In CHB patients without cirrhosis, extraheptic disease-related mortality overwhelms liver-related mortality. Compared with the past, the mortality rate and proportion due to cancers except HCC are increasing in the recent cohort.

WED-140

Association of liver fibrosis and hypophosphatemia in treatment-naïve patients with chronic hepatitis B

Email: dr.wu@nju.edu.cn

Background and aims: The metabolism disorder of serum phosphate is not uncommon in chronic liver diseases. This study investigated the prevalence of hypophosphatemia and the association between hypophosphatemia and liver fibrosis in treatment-naïve patients with chronic hepatitis B (CHB).
Method: Consecutive treatment-naïve CHB patients were included from three medical institutions between January 2015 and April 2022. Significant liver fibrosis and cirrhosis were identified by the aspartate transaminase (AST) to platelet ratio index (APRI), the fibrosis index based on 4 factors (FIB-4), or ultrasonography. Propensity score matching (PSM) and inverse probability weighting (IPW) measures were conducted to balance variables between patients with and without significant fibrosis or cirrhosis.
Results: Of 6,956 patients with CHB, the median age was 41.0 years and male gender accounted for 58.6%. The overall prevalence of hypophosphatemia was 2.7% in treatment-naïve patients with CHB. Patients with significant liver fibrosis and cirrhosis had higher proportions of hypophosphatemia than patients without significant liver fibrosis (4.4% vs. 1.9%, P < 0.001) and cirrhosis (4.3% vs. 2.2%, P < 0.001). Age ≥50, male sex, and the presence of significant liver fibrosis (OR 1.817, 95% CI 1.291–2.558, P = 0.001) and cirrhosis (OR 1.595, 95% CI 1.116–2.279, P = 0.010) were independent risk factors of hypophosphatemia. After adjusting for age and sex by PSM and IPW, the prevalence of hypophosphatemia remained higher in patients with significant liver fibrosis and cirrhosis.
Conclusion: The proportion of hypophosphatemia was low in treatment-naïve patients with CHB. Hypophosphatemia was related to more severe liver disease, including significant liver fibrosis and cirrhosis. Close monitoring for hypophosphatemia is warranted in patients with CHB who have significant liver fibrosis or cirrhosis.

WED-141

Treatment eligibility and initiation among chronic hepatitis B patients in a real-world setting in the United States

Mark A Schmidt[1], Yihe G Daida[2], Sacha Satram[3], Teresa M Kimes[1], A Gabriela Rosales[1], Sixiang Nie[2], Richard Meenan[1], Judy L Donald[1], Michael Chattergoon[3], Norah Terrault[4]. *[1]Kaiser Permanente Center for Health Research, Portland, OR, United States; [2]Kaiser Permanente Center for Integrated Health Care Research, Honolulu, HI, United States; [3]Vir Biotechnology, San Francisco, CA, United States; [4]University of Southern California, Los Angeles, CA, United States*
Email: mark.a.schmidt@kpchr.org

Background and aims: Current guidelines for chronic hepatitis B (CHB) management recommend using ALT and HBV DNA levels to guide treatment decisions and monitor individuals who are not in a well-defined immunological disease state ("grey area"), but this remains understudied in the real-world setting. We sought to describe the proportion of untreated CHB patients for whom either treatment or continued monitoring ("grey area") would be indicated and the proportion of those patients subsequently receiving treatment within one, two, and five years of cohort entry.
Method: We identified persons with untreated CHB from two integrated healthcare delivery systems in the United States from 1 January 2000 through 31 December 2015. We abstracted demographic, clinical, laboratory, and pharmacy data from the electronic health records. We first classified all individuals with a Fibrosis-4 score-a non-invasive, biomarker-based index of liver fibrosis-of ≥3.25 as *treatment indicated* and then applied the AASLD 2018 Hepatitis B Guidance to classify remaining persons into treatment categories (*grey area, treatment indicated, treatment not indicated,* and *unknown* [i.e. lacked sufficient laboratory and clinical elements required to assign individuals to another category]).
Results: We observed 2,434 individuals with untreated CHB, of whom 1,237 (50.8%) were female and 1,197 (49.2%), male; 1,565 (64.3%) were Asian, 315 (12.9%) White, 279 (11.5%) Native Hawaiian or Other Pacific Islander, and 275 (11.3%) of other or unknown race; and with a mean (median) age of 42.9 (42) years. At the time of cohort entry, we classified 138 (5.6%) as treatment indicated, 364 (15.0%) as treatment not indicated, 450 (18.5%) as grey area; and 1,482 (60.9%) as unknown. The proportion of those with an unknown treatment eligibility decreased from 82.0% in 2000 to 43.5% in 2015 (Figure), with increasing proportions of treatment not indicated and grey area

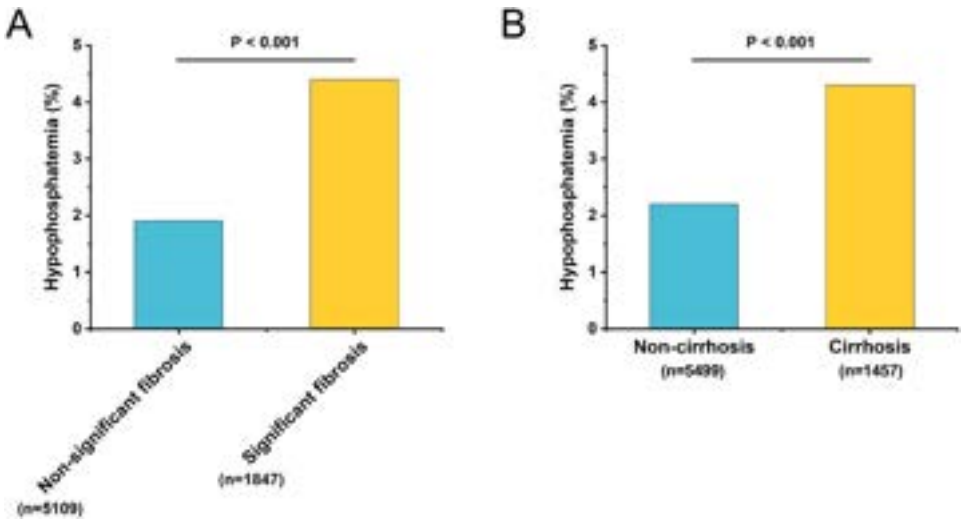

Figure: (abstract: WED-140): The prevalence of hypophosphatemia between patients with and without significant fibrosis/cirrhosis.

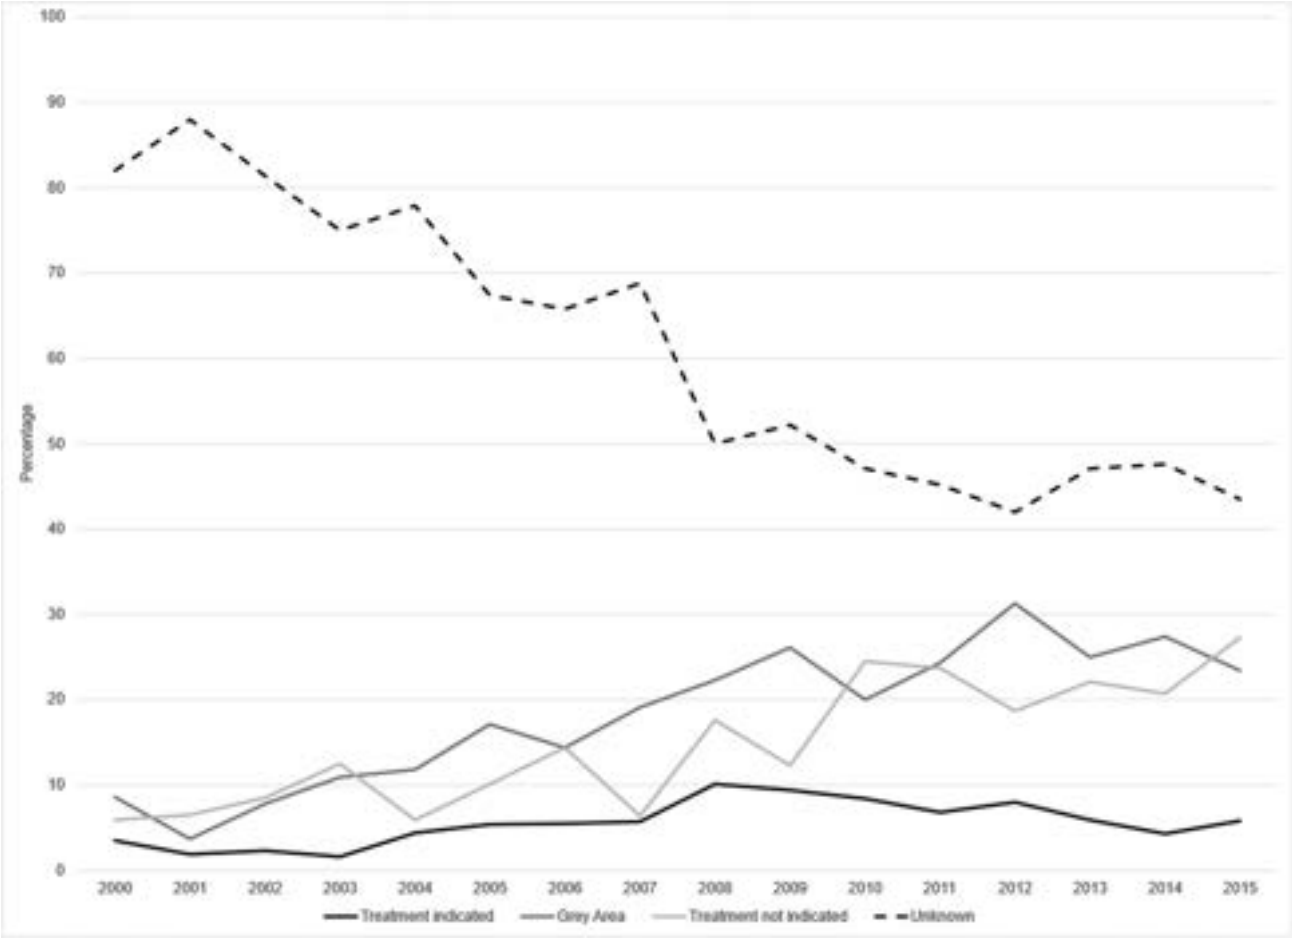

Figure: (abstract: WED-141): Treatment eligibility for individuals with CHB, by year of entry into cohort patients.

patients observed during this time ($p < 0.001$). The proportion of individuals classified as treatment indicated was largely stable. At 1-, 2-, and 5-years of study follow-up, 64 (46.4%), 69 (50.0%), and 75 (54.3%) of treatment indicated had initiated CHB treatment, respectively, as had 46 (10.2%), 59 (13.1%), and 85 (18.9%) of grey area individuals.

Conclusion: The lack of sufficient data to fully characterize treatment eligibility among individuals with CHB is worrisome, especially given that about half of those with treatment eligible CHB are untreated. Although it improved over the course of our study, this proportion has remained over 40%, even in more recent years. The results from this real-world study argue for continued improvement in CHB-related laboratory testing to help clinicians make appropriate treatment decisions for individuals with CHB, especially among those in the grey area who may transition into having active disease.

WED-142

Effects of tenofovir alafenamide fumarate on serum lipids in patients with chronic hepatitis B

Yilin Liu[1], Jian Wang[2,3], Zhiyi Zhang[1], Yao Zhang[1], Weimao Ding[4], Chuanwu Zhu[5], Rui Huang[1,2,3], Chao Wu[1,2,3], Jie Li[1,2,3]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China; [2]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China; [3]Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, Jiangsu, China; [4]Department of Hepatology, Huai'an No. 4 People's Hospital, Huai'an, Jiangsu, China; [5]Department of Infectious Diseases, The Affiliated Infectious Diseases Hospital of Soochow University, Suzhou, Jiangsu, China*
Email: lijier@sina.com

Background and aims: To evaluate the effect of tenofovir alafenamide fumarate (TAF) on lipid metabolism in patients with chronic hepatitis B (CHB).

Method: A total of 298 patients with CHB received antiviral treatment were included between January 2016 to December 2021, including 143 patients treated with TAF and 155 patients treated with tenofovir disoproxil fumarate (TDF). Logistic regression was used to analyze the risk factors for lipid elevation after 24 weeks of antiviral therapy.

Results: Compared to baseline, patients in TAF group had significantly increased total cholesterol (TC) levels (4.22 mmol/l vs. 4.48 mmol/l, $p = 0.009$) after 24 weeks of antiviral treatment, while triglyceride (TG) levels did not change significantly (1.01 mmol/l vs 0.98 mmol/l, $p = 0.710$). Both TG and TC levels decreased significantly from baseline to 24 weeks in TDF group ($p < 0.001$). After propensity score matching on gender, age, BMI, the presence of fatty liver, alanine transaminase (ALT), TG, TC, and HBeAg status at baseline, there was a significant difference in the change of TG and TC levels at 24 weeks of treatment between the TAF and TDF groups ($p < 0.001$). The levels of TG (1.00 mmol/L vs. 0.76 mmol/L, $p = 0.001$) and TC (4.36 mmol/L vs. 3.67 mmol/L, $p < 0.001$) in TAF group were

significantly higher than in TDF group. Multivariate logistic regression analysis indicated that TAF treatment (OR = 3.646, 95% CI: 2.011–6.642, p < 0.001) and ALT level (OR = 1.002, 95% CI: 1.002–1.003, p = 0.014) were independent factors for over 10% increased of TC levels after 24 weeks of antiviral treatment.
Conclusion: TAF treatment was associated with increased TC levels in patients with CHB, while had no significant effect on TG levels.

WED-143
Novel serum markers of cccDNA transcriptional activity-HBcrAg and pre-genomic RNA and CXCL10 pro-inflammatory chemokine levels can reduce uncertainty of HBeAg-negative chronic hepatitis B phases
Ivana Carey[1], Mark Anderson[2], James Lok[1], Christiana Moigboi[1], Bo Wang[1], Gavin Cloherty[2], Geoffrey Dusheiko[1], Kosh Agarwal[1].
[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]Abbott Diagnostics, Department of Infectious Diseases, Chicago, United States
Email: ivana.kraslova@kcl.ac.uk

Background and aims: Two phases of HBeAg-negative chronic hepatitis B are typically determined by HBV DNA and serum ALT concentrations. 'Infection' phase patients have HBV DNA levels <2000 IU/ml and normal ALT (monitoring is recommended), whereas patients in the 'hepatitis' phase have HBV DNA >20000 IU/ml, elevated ALT and moderate-severe liver inflammation on histology, requiring treatment. However up to one third of HBeAg-negative patients fall within a 'grey zone' (HBV DNA 2000–20000 IU/ml and normal ALT) between relatively inactive infection and active disease. Further categorisation of this "grey zone" cohort is required to improve prognostication and treatment indications. Unlike HBsAg, serum levels of hepatitis B core-related antigens (HBcrAg) and pre-genomic HBV RNA (pgRNA) are obligatorily derived from cccDNA, and hence reflect cccDNA transcriptional activity. Thus, these newer markers might be helpful in separating patients with HBeAg-negative infection from patients with more active disease and reduce the number of indeterminate 'grey zone' patients. As HBV disease activity is driven by the interaction of the virus with the host immune system response, serum levels of the pro-inflammatory chemokine CXCL10 could also help in refining 'grey zone' patients. We aimed to compare serum levels of serological, virological and immunological markers in HBeAg negative patients and to determine whether these markers could help in refining HBeAg-negative phases of disease based on HBV DNA and ALT levels (infection, versus grey zone and hepatitis).
Methods: Serum samples from a cross-sectional cohort of 447 HBeAg-negative patients (median age 38 yrs, 170 males) were tested for routine diagnostic markers: HBV DNA (Roche TaqMan, IU/ml), quantitative HBsAg (Abbott ARCHITECT, IU/ml), biochemical (ALT and AST, IU/L) and haematological (INR and platelets counts) and further tests were performed for novel biomarkers-HBcrAg (CLEIA Fujirebio, log_{10}U/ml), pgRNA (Abbott Diagnostics dual-target real-time-PCR assay, LLoQ = 0.48 log_{10}U/ml) and CXCL10 serum levels by ELISA [pg/ml]. FIB-4 and APRI scores were calculated and compared with fibroscan results. The patients were divided into 3 groups based on HBV DNA levels: 'infection' (<2000 IU/ml), 'grey zone' (2000–20 000 IU/ml) and 'hepatitis' (>20 000 IU/ml) phases. The results were compared by AUC-ROC, univariate and multivariate regression analysis.
Results: The levels of all the tested biomarkers were lower in 'infection' phase patients (n = 293) than in 'grey zone' (n = 121) and 'hepatitis' (n = 31) phase patients (Table) by univariate analysis. However, only levels of HBcrAg, pg RNA and CXCL10 differed significantly between groups by multivariate and AUC-ROC analysis (Figure). The proportion of patients with undetectable HBcrAg (<3 log_{10}U/ml) and pgRNA (<0.4 log_{10}U/ml) was highest in 'infection' phase patients than 'grey zone' and 'hepatitis' phase patients (HBcrAg: 64% vs. 25% vs. 6%; pgRNA: 75% vs. 24% vs. 8%, all <0.01).

	Infection phase (n=293)	Grey zone (n=121)	Hepatitis phase (n=31)	p
Median HBV DNA	183 IU/ml	4900 IU/ml	82500 IU/ml	<0.01
Median HBsAg	2387 IU/ml	4830 IU/ml	5931 IU/ml	<0.01
Median HBcrAg	2.6 log_{10}U/ml	3.5 log_{10}U/ml	4.5 log_{10}U/ml	<0.01
Median pg RNA	1.22 log_{10}U/ml	2.13 log_{10}U/ml	2.43 log_{10}U/ml	<0.01
Median CXCL10	125 pg/ml	218 pg/ml	285 pg/ml	<0.01
Median FIB-4	0.85	0.97	1.08	0.02
Median APRI	0.22	0.26	3.79	<0.01
Median fibroscan	4.3	5.1	7.0	0.01

Figure:

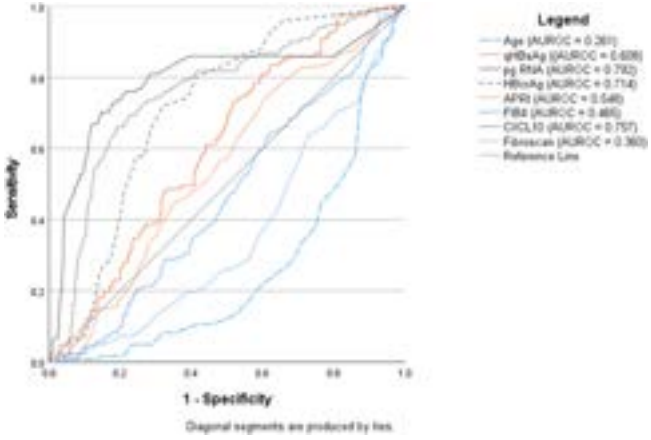

Figure:

Conclusion: Novel serum biomarkers of cccDNA transcriptional activity-HBcrAg and pre-genomic HBV RNA as well as serum CXCL10 levels (<150 pg/ml) can refine active versus inactive HBeAg-negative phases. If larger studies validating these markers confirm their prognostic significance, the finding of undetectable HBcrAg and HBV RNA (by current assay sensitivities) and low CXCL10 levels may qualify a prime group for whom monitoring is appropriate and reduce the uncertainty of 'grey zone' patients.

WED-144
HDV genotypes have an impact on pegylated interferon therapy response and long-term liver disease related outcomes
Ivana Carey[1], Natalie Bolton[1], Mark Anderson[2], James Lok[1], Christiana Moigboi[1], Gavin Cloherty[2], Geoffrey Dusheiko[1], Kosh Agarwal[1]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]Abbott Diagnostics, Department of Infectious Diseases, Chicago, United States*
Email: ivana.kraslova@kcl.ac.uk

Background and aims: Although chronic hepatitis delta (HDV) represents the most severe form of chronic viral hepatitis with accelerated rates of advanced liver fibrosis and hepatocellular carcinoma, it is a diverse disease due to differences between HDV genotypes and their impact on the disease outcome. The long-term follow-up (>5 years) data comparing differences of the outcomes between HDV genotypes are lacking. HDV requires HBsAg for propagation. HBsAg originates from both cccDNA and integrated HBV DNA encoded transcripts. Pre-genomic HBV RNA (pg RNA) and HBcrAg are markers of cccDNA transcriptional activity and there are no data comparing these markers according to HDV genotypes. We aimed to investigate whether different virological (HBV DNA, HDV RNA, HDV genotypes and pg RNA) and serological (HBeAg, HBsAg and HBcrAg) markers at diagnosis are able to predict long-term (>5 years) outcomes (morbidity, mortality, response to pegylated interferon (Peg-IFN) and HBsAg loss) in single centre cohort of HDV RNA positive patients.
Methods: Serum samples of 83 HDV RNA positive patients (median age 38 years, 55 males) at diagnosis were tested for the following markers: HBV DNA (Roche TaqMan, IU/ml), HBeAg status and

quantitative HBsAg (Abbott ARCHITECT, IU/ml), HBcrAg (CLEIA Fujirebio, log_{10}U/ml), pg RNA (Abbott Diagnostics dual-target real-time-PCR assay, LLoD = 0.48 log_{10}U/ml), HDV RNA (in-house real-time PCR, LLoQ = 640 copies/ml) and HDV genotypes by the direct sequencing. All patients had clinical follow-up for at least 5 years (median 6.8 years, range 5.3–17.5). Fifty-three (64%) patients underwent at least 24 weeks of therapy with Peg-IFN (>3 years follow-up results after completing therapy). The liver related complications (cirrhosis, decompensation, variceal bleeding, HCC), liver transplantation, mortality and peg-IFN response including HBsAg loss were recorded and compared between patients according to HDV genotypes.

Results: In our cohort-52 (63%) patients had genotype 1 infection vs. 31 (37%) patients infected with genotype 5. There was no difference in patients' age (38.4 vs 38.2 years, p = 0.89) between genotypes. At diagnosis-cirrhosis was more frequent in genotype 1 than genotype 5 patients (60% vs. 23%, p < 0.01) and genotype 1 patients (n = 30) had poorer response to peg-IFN therapy than genotype 5 (n = 23) patients (7% vs. 61%, p < 0.01) and less likely achieved HBsAg loss (2% vs. 16%, p < 0.01). Only virological markers (HDV RNA and pg RNA) were higher in genotype 1 vs. genotype 5 patients and other markers (HBV DNA, HBeAg status, HBsAg, HBcrAg and ALT levels) were similar at diagnosis between genotypes (Table). While there was no difference between numbers of patients who developed HCC between genotypes (4% vs. 6%, p = 0.621), genotype 1 patients were more likely to have liver related complications-decompensation (32% vs. 10%, p = 0.02), variceal bleeding (6% vs. 3%, p = 0.04) or required liver transplantation (23% vs. 3%, p = 0.003) than genotype 5 patients. The mortality was similar between genotypes (8% vs. 6%, p = 0.646).

	Genotype 1 (n=52)	Genotype 5 (n=31)	p
Median HBV DNA	0 IU/ml	0 IU/ml	0.877
Median HBsAg	9672 IU/ml	10294 IU/ml	0.261
Median HBcrAg	4 log_{10}U/ml	3.5 log_{10}U/ml	0.279
Median pg RNA	2.77 log_{10}U/ml	1.99 log_{10}U/ml	**0.03**
Median HDV RNA	1.29E5 cp/ml	3.24E4 cp/ml	**0.002**
Median ALT	67 IU/L	67 IU/L	0.202
Median fibroscan	13.5 kPa	8.5 kPa	**<0.01**
HBeAg positive [%]	23%	23%	0.958

Figure:

Conclusion: Differences between Peg-IFN responses, liver damage (cirrhosis) and long-term risk of liver disease decompensation were attributed to HDV genotypes in HDV RNA positive patients. Genotype 5 patients were more likely respond to Peg-IFN and had slower progression of liver disease. Lower levels of HDV RNA and pg RNA were more frequent in genotype 5 patients and were linked with better Peg-IFN response and slower disease progression.

Systematic screening for hepatitis B at emergency department and linkage to care in Barcelona, Spain

Juan Carlos Ruíz-Cobo[1], Jordi Llaneras[2], Ariadna Rando-Segura[3], Ana Barreira[1], Francisco Rodríguez-Frías[3], Adriana Palom[1], Anna Feliu-Prius[1], Mar Riveiro Barciela[1,4], Rafael Esteban[1,4], Maria Buti[1,4]. *[1]Vall d'Hebron University Hospital, Hepatology, Barcelona, Spain; [2]Vall d'Hebron University Hospital, Spain; [3]Vall d'Hebron University Hospital, Microbiology, Spain; [4]CIBERehd, Spain*
Email: mbuti@vhebron.net

Background and aims: Spain is considered a low endemicity country for hepatitis B virus (HBV) infection. This is based on a prevalence of HBsAg of 0.22% in the general population attended in primary care centers. Our aim is to perform a screening program for HBV at emergency department where population not attending primary care centers are represented and analyze the barriers to linkage to care of patients with HBV infection.

Method: We implemented FOCUS program for HBV screening at the emergency department of an academic hospital of an area of 450.000 inhabitants. Adults of >16 years old without HBsAg testing in the previous three months who required a phlebotomy for any purpose were screened. Linkage to care was offered to all patients with a positive result.

Results: We screened 20.941 patients between February 2020 and December 2022, detecting 128 (0.61%) HBsAg positive individuals. The majority were men (67.2%), median age of 61.4 years (IQR 28.8), 98.4% were HbeAg negative and 14% patients had cirrhosis. Anti-HDV was positive in 5 (3.9%) patients and 2 of them had detectable HDV-RNA. Only 12.5% had a risk factor for HBV infection screening following Spanish recommendations. At the time of screening 80 (62.5%) patients were not linked to care or lost to follow-up including 51 (63.8%) who were unaware of HBV and 5 patients with cirrhosis. Of them 63 patients were selected for linkage to care, the reason to not be suitable for linkage were low life expectancy or lack of contact information. Among these patients, 54 (85.7%) were successfully linked to care and 43 had HbeAg-negative chronic infection, 8 HbeAg-negative chronic hepatitis and 3 HbeAg-positive chronic hepatitis. Treatment with nucleos (t)ides analogues was initiated in 9 patients without prior HBV care.

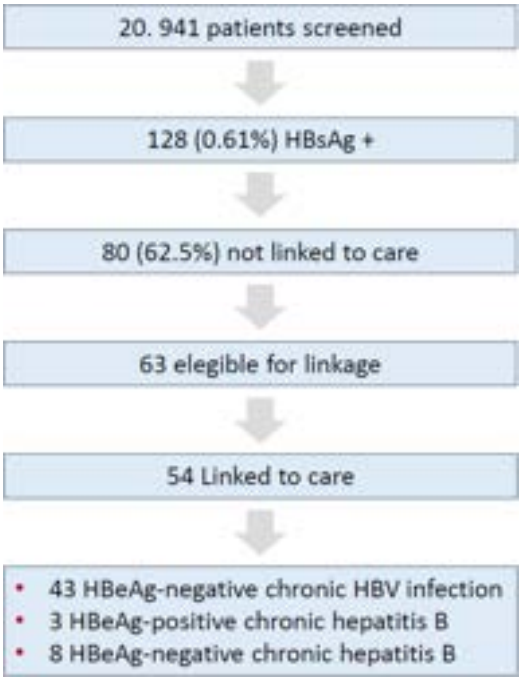

Figure:

Conclusion: The prevalence of HBV in the emergency department is almost three times higher than observed in general population, showing that this strategy allows to identify and link to care a high number of patients without risk factors. In addition, coinfection with HDV is reported in 3.9% of HBsAg positive cases.

WED-146

Epidemiological and clinical profile of HDV infected people in care in Italy: interim analysis from the ongoing PITER cohort

Email: loreta.kondili@iss.it

Background and aims: With the new therapeutic options available for hepatitis delta infection, epidemiological and clinical profile of patients in care are useful to determine better treatment appropriateness. We aimed to describe the updated epidemiological and clinical profile of HDV infected patients in the PITER HBV cohort.
Method: Data from consecutive HBsAg positive patients enrolled from 2019 up to October 2022 by 50 Clinical centers were evaluated.
Results: Of 4729 patients of whom 1010 (21%) were non-Italian natives, the anti-HDV prevalence was 9.3% (343 of 3679 anti-HDV tested patients): 8.3% (median age 57.5; IQR 53–64) Italian, 13.0% (median age 43 years IQR 43–53 years) non-Italian natives ($p < 0.001$); 22% (1050) have never been tested for HDV infection (23% in Italian and 19% in non-Italian; $p < 0.001$), of whom 21% with liver cirrhosis. Of anti-HDV positive patients, 212 (62%) were tested for HDV RNA, of whom 140 (66%) were HDV RNA positive. Of anti-HDV positive patients, transaminase levels were altered in 63%, cirrhosis was present in 70% (57.5% in Italian and 75.5% in non-Italians; $p = 0.001$), of whom portal hypertension signs in 55%, cirrhosis complications and/or HCC development in 37.5%. Liver disease progression cofactors were present as follows: alcohol use 35.6% (similar in Italians and non-Italians), HCV infection in 11.1% (15.5% in Italian and 1.8% in non-Italian, $p < 0.001$), diabetes in 6.1% (7.5% in Italians and 1.9 in non-Italian $p < 0.001$), other features of potential metabolic syndrome in 23.9%. Overall, 52.8% of patients have no comorbidities, 40.8% has 1–2, 6.4% more than 2 comorbidities.
Conclusion: The updated picture of patients in care in Italy confirms the older Italian cohort and significantly younger non-Italian cohort of patients in care with HDV infection, both with significant proportion of liver cirrhosis. The dysmetabolic comorbidities are more represented in Italians, but the overall comorbidity profile is similar between two cohorts.

WED-147

Effect of Tenofovir and Entecavir on occurrence of hepatocellular carcinoma depends on duration of antiviral treatment and hierarchical PAGE-B risk score

Email: yhhuang@vghtpe.gov.tw

Background and aims: The nucleos (t)ide analogues (NUCs) entecavir (ETV) and tenofovir disoproxil fumarate (TDF) have been extensively used for the prevention of hepatocellular carcinoma (HCC) in chronic hepatitis B (CHB) patients. However, their comparative efficacy in this regard remains controversial and requires further investigation.
Method: This retrospective, multicenter, study included CHB patients that have been diagnosed with cirrhosis and received ETV or TDF treatment between January 2008 to December 2018, and 2011 to 2018. Risk factor analysis, 1:1 propensity score matching (PSM), and PAGE-B scores were employed in this investigation. Primary outcome included the evaluation of HCC incidence after treatment with either ETV or TDF.
Results: TDF demonstrated a consistently lower risk of HCC occurrence compared to ETV (HR = 0.65; $p = 0.001$), which was maintained after 1:1 PSM (HR = 0.69, $p = 0.030$). But the 2011–2018 time-adjusted analysis revealed that this positive effect was not significantly observed after 1:1 PSM. A higher proportion of ETV patients with PAGE-B scores ≥18 before PSM might be the confounder that could be eliminated after PSM in both 2008–2018, and time-adjusted cohort. Interestingly, in subgroup patients with

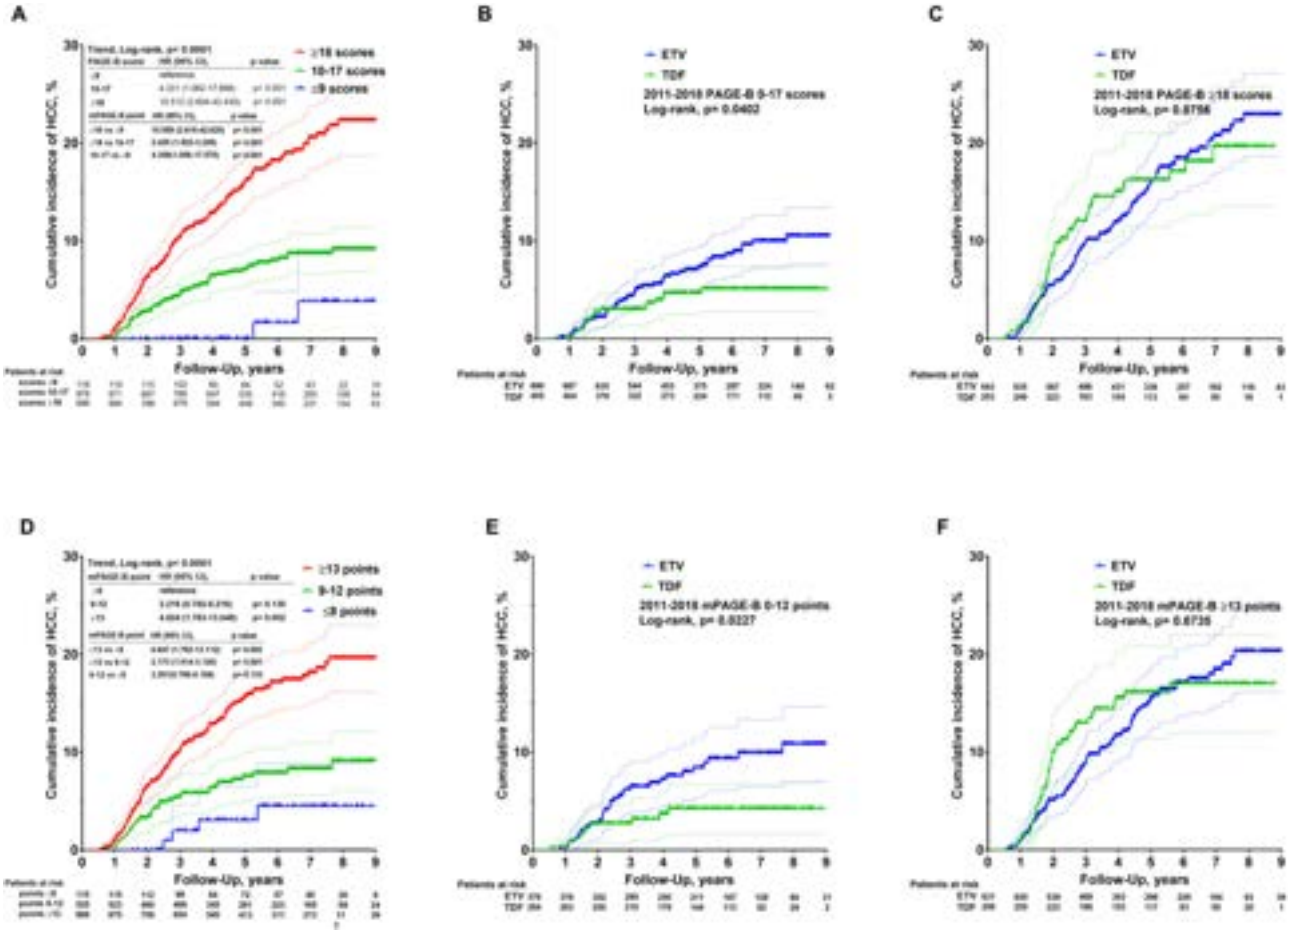

Figure: (abstract: WED-147).

lower PAGE-B scores (0–17), TDF displayed a significantly reduced risk of HCC occurrence than ETV (HR = 0.58, p = 0.043), which was maintained even after the 1:1 PSM adjustment (HR = 0.56, p = 0.048). **Conclusion:** Duration of antiviral treatment and hierarchical risk scores have impact on outcome analysis to compare ETV vs TDF. TDF intervention, when compared to ETV, elicits favorable outcomes by reducing the occurrence of HCC in patients with lower PAGE-B scores.

WED-148

Significant disparities in risk of cirrhosis and hepatocellular carcinoma among non-cirrhotic, treatment naïve, e-antigen negative hepatitis B patients with low levels of serum alanine aminotransferase

Zeyuan Yang[1], Ramsey C. Cheung[2], Robert Wong[2]. *[1]VA Palo Alto Health Care System, Palo Alto, United States; [2]Stanford University School of Medicine, VA Palo Alto Healthcare System, Palo Alto, United States*
Email: rwong123@stanford.edu

Background and aims: The benefit of antiviral therapy in patients with e-antigen (eAg) negative chronic hepatitis B (CHB) with low levels of alanine aminotransferase (ALT) remains unclear given the reported low risk of cirrhosis or hepatocellular carcinoma (HCC). However, it is not clear whether significant heterogeneity in cirrhosis or HCC risk exists, such that certain subsets of this population may benefit from early initiation of antiviral therapy. We evaluated long-term risks of cirrhosis or HCC among non-cirrhotic, treatment-naïve eAg-negative CHB patients with ALT<70 U/L.

Method: Using data from the U.S. National Veterans Affairs database from 2010 to 2022, Veterans with treatment-naïve, e-antigen (eAg) negative CHB with baseline ALT <70 U/L and minimum 12 months of follow-up were identified. Patients with concurrent HIV, hepatitis C, or hepatitis delta infections were excluded. Patients with cirrhosis or HCC at baseline or within 6 months of study entry were excluded. Incidence of cirrhosis or HCC (per 100 person-years) was stratified by patient demographics, clinical characteristics, and baseline HBV DNA (<2000 IU/ml (Low-DNA), 2000–10^5 IU/ml (Intermediate-DNA), and >10^5 IU/ml (High-DNA). Patients were censored at development of cirrhosis or HCC, death, initiation of antiviral therapy, or end of follow-up period. Comparisons of cirrhosis or HCC incidence between groups utilized the z-statistic using standard equations.

Results: Among 1,531 Veterans with treatment-naïve, eAg negative CHB and ALT <70 U/L (91.4% men, 45% African American, 33% non-Hispanic white, 19% Asian, 4% Hispanic, mean age 55 ± 12, 26.6% with diabetes), 77% had Low-DNA, 15% had Intermediate-DNA, and 7% had High-DNA. Overall incidence of cirrhosis was 0.84 per 100 person-years (95% CI 0.67–1.00) and incidence of HCC was 0.21 per 100 person-years (95% CI 0.12–0.29). No significant difference in long-term risk of cirrhosis or HCC was observed by baseline HBV DNA. When stratified by race/ethnicity, the highest risk of cirrhosis was observed in non-Hispanic whites (1.11 per 100 person years) and the lowest risk was observed in Hispanics (0.23 per 100 person-years), whereas the highest risk of HCC was observed in non-Hispanic whites (0.25 per 100 person-years) and the lowest risk of HCC was observed in Asians (0.05 per 100 person-years). Older age, presence of concurrent diabetes, and higher FIB-4 score at baseline were associated with higher risk of cirrhosis and HCC (Figure).

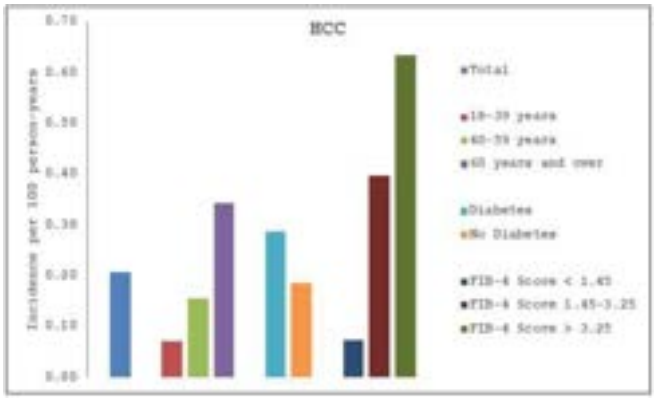

Figure:

Conclusion: Among a large national cohort of treatment-naïve eAg negative patients with non-cirrhotic CHB and baseline ALT <70 U/L, we observed significant heterogeneity in risks of cirrhosis or HCC. Better understanding which sub-populations are at highest risk of disease progression can help guide clinical decisions regarding earlier initiation of antiviral therapy in this group to improve long-term patient outcomes.

WED-149

aMAP score and its combination with liver stiffness measurement accurately assess liver fibrosis in virologically suppressed CHB patients

Background and aims: The changes in liver stiffness measurement (LSM) are unreliable to estimate regression of fibrosis during antiviral

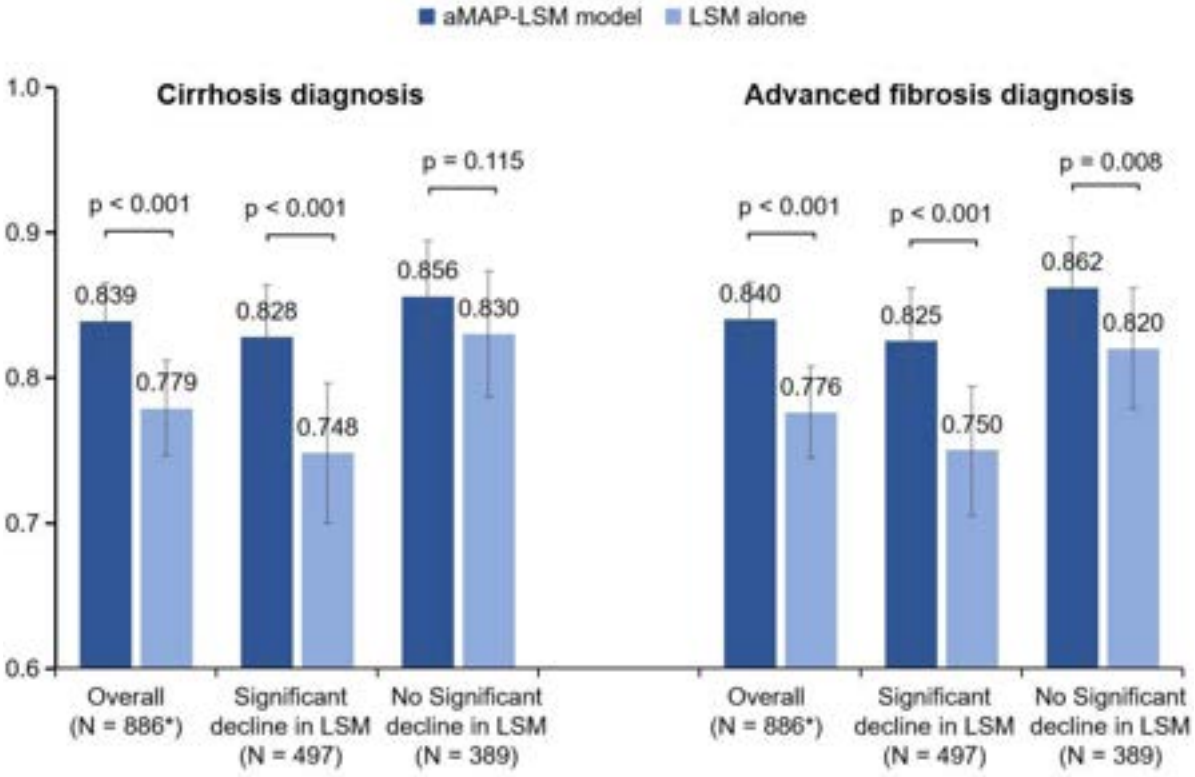

Figure. Comparison between the AUROCs of aMAP-LSM model and LSM alone in diagnosing cirrhosis and advanced fibrosis after treatment among the overall patients and the subgroups of patients stratified by LSM changes during antiviral treatment. *3 patients without available LSM were excluded from the analysis.

Figure: (abstract: WED-149).

treatment for chronic hepatitis B (CHB) patients. aMAP score [J Hepatol, 2020], as an accurate hepatocellular carcinoma risk score, may reflect the liver fibrosis stage. Here, we aimed to evaluate the performance of aMAP for diagnosing liver fibrosis in CHB patients with or without treatment.

Method: 2053 patients with liver biopsy from 2 real-world cohorts and 2 multi-centric randomized controlled trials in China were enrolled, among which 2053 CHB were included in the cross-sectional analysis, and 889 CHB patients with paired liver biopsies before and after 72- or 104-week treatment were included in the longitudinal analysis.

Results: In the cross-sectional analysis, the AUROCs of aMAP in diagnosing cirrhosis and advanced fibrosis were 0.788 and 0.757, which were significantly higher or comparable with those of fibrosis index based on four factors (FIB-4, 0.763, $p = 0.010$; 0.753, $p = 0.694$) and aspartate aminotransferase-platelet ratio (APRI, 0.607, $p < 0.001$; 0.613, $p < 0.001$), respectively. Lower and higher cut-off values for each non-invasive test were selected to obtain sensitivity and specificity of 90% or 95%, respectively. When applying these dual cut-off values, aMAP had a trend toward better performance than FIB-4 and APRI with a numerically smaller uncertainty area (UA) and a higher diagnostic accuracy (DA) in diagnosing cirrhosis. The UA was 68.3% for aMAP with DA of 85.2% in cirrhosis detection (74.2%, 84.5% for FIB-4, and 79.0%, 78.0% for APRI, respectively). Moreover, compared with stepwise approaches using FIB-4 (or APRI) and LSM, the stepwise approach using aMAP and LSM also had the smallest UA and satisfactory DA in both cirrhosis (UA: 29.7%; DA: 82.3%) and advanced fibrosis (UA: 46.2%; DA: 79.8%) detection. In the longitudinal analysis, among patients with significant decline in LSM after anti-HBV treatment (defined as LSM at week 72 or 104 decreased ≥30% from baseline), the performance of LSM at week 72 (or 104) in diagnosing cirrhosis or advanced fibrosis was unsatisfactory, the AUROCs of which were significantly lower than those without significantly decline (cirrhosis: 0.748 vs. 0.830, $p = 0.012$; advanced fibrosis: 0.750 vs. 0.820, $p = 0.024$). We further established a novel model (aMAP-LSM model) comprising aMAP at baseline, LSM at week 72 (or 104) with or without aMAP at week 72 (or 104) by using logistic regression, which had satisfactory performance in diagnosing cirrhosis and advanced fibrosis after treatment (AUROC: 0.839 and 0.840, respectively), especially for those with significant decline in LSM after treatment (vs. LSM alone: 0.828 vs. 0.748, $p < 0.001$ [cirrhosis]; 0.825 vs. 0.750, $p < 0.001$ [advanced fibrosis]) (Figure).

Conclusion: aMAP score is a promising non-invasive tool for diagnosing fibrosis in CHB patients. The aMAP-LSM model could accurately estimate fibrosis stage for treated CHB patients.

WED-150

Systematic review and meta-analysis: the proportion of chronic hepatitis B patients with different alanine transaminase upper limits and significant hepatic histology

Yuhao Yao[1], Jiaxin Zhang[1,2], Xu Cao[1], Xiaoke Li[1,2], Xiaobin Zao[1,2], Yong'an Ye[1,2]. *[1]Dongzhimen Hospital, Beijing University of Chinese Medicine, China; [2]Beijing University of Chinese Medicine, Liver Diseases Academy of Traditional Chinese Medicine, China*

Email: yeyongan@vip.163.com

Background and aims: The proportion of chronic hepatitis B patients (CHB) patients without a history of oral anti-viral medications or interferon use with normal alanine transaminase (ALT) and hepatic histology has been the focus of current research. ALT is one of the most important indicators for initiating antiviral therapy, however, ALT levels alone may not accurately reflect hepatic histology. Furthermore, the current ALT upper limit of normal (ULN) recommended by global guidelines for initiating antiviral therapy varies, leading to controversy on the most appropriate ALT ULN. Thus, this review aims to systematically evaluate the proportion of CHB patients with different ALT upper limits and significant hepatic histology, to provide a reference for the clinical management of this population.

Method: The Medline and EMBASE databases were searched from inception up to November 2022 with the following terms: "Hepatitis B OR "Hepatitis B virus" OR "Hepatitis B, Chronic" OR "chronic hepatitis B" OR "CHB" OR hepatitis B" AND "Alanine Trans-aminase OR "alanine aminotransferase" OR ALT". 'Significant histology' included 'significant fibrosis' and 'significant inflammation'. 'Significant fibrosis' was defined as stage ≥2 (Metavir, Batts-Ludwig, HAI, Scheuer or Ishak staging systems) and 'significant inflammation' was defined as stage ≥2 (Metavir, Batts-Ludwig or Scheuer staging systems) or score ≥4 (Ishak or HAI scoring systems) in the meta-analysis, which was consistent across all studies. Studies with just one of the two outcomes were included in the meta-analysis. Estimation of pooled proportions was calculated using transformed proportions using Freedman-Tukey double arcsine transformation. The protocol was registered at PROSPERO (CRD42021265642, http://www.crd.york.ac.uk/PROSPERO).

Results: Twenty studies with 3,624 CHB patients with ALT ≤ULN were included. All patients had no history of prior antiviral or interferon therapy. Most of the patients had HBV DNA levels >2000–20 000 IU/ml. The pooled rates of significant fibrosis and significant inflammation in CHB patients with ALT ≤40 IU/L were 34.49% (95% CI: 24.31–45.44) and 21.57% (95% CI: 9.20–37.38), respectively. In studies in which ALT upper limits were set below 40IU/L, significant fibrosis and significant inflammation were observed in 25.61% (95% CI: 16.43–36.03) and 16.68% (95% CI: 6.05–31.21) CHB patients, respectively, without limiting the upper limits. Among studies evaluating CHB patients with ALT ≤30 IU/L (males) and 19 IU/L (females), significant fibrosis and significant inflammation were detected in 17% (95% CI: 9.47–26.19) and 14.76% (95% CI: 2.07–36.09), respectively. The comparison of the proportions of CHB patients with significant fibrosis and significant inflammation for different ALT ULN levels was shown in Figure H.

Conclusion: Among untreated CHB patients with normal ALT, a certain percentage of patients still have significant hepatic histology. Approximately one-third of CHB patients with ALT ≤40 IU/L may have significant hepatic fibrosis and one-fifth have significant hepatic inflammation. However, the lower the ALT ULN levels set, the lower the proportion of patients with significant histology. Those CHB patients with normal ALT but significant hepatic histology are of concern to clinicians, and further evaluation and treatment may be warranted. Moreover, our study may be helpful for further negotiation of ALT ULN for initiating antiviral therapy.

Email: rgish@robertgish.com

Background and aims: An estimated 296 million people globally live with chronic hepatitis B (CHB). Stigma against people with CHB is common. Self-stigma (a type of stigma defined as self-induced, internalized negative belief, which affects feelings and function) may negatively impact diagnostics, treatment, and health-related quality of life of people with CHB. We conducted studies to demonstrate the content and psychometric validity of a new patient-reported outcome (PRO) instrument to assess self-stigma in people with CHB, as none currently exists.
Method: Qualitative cognitive debriefing interviews with people living with CHB were conducted to assess the content validity and conceptual coverage of the draft PRO instrument's comprehensiveness and participants' understanding and interpretation of the instructions, items, response scale, and recall period. Quantitative analyses included psychometric evaluation of the PRO instrument using data from the global phase 2b REEF-1 and REEF-2 trials in adults with CHB. The following analyses were conducted: internal consistency and test-retest reliability, known-group validity, exploratory and confirmatory factor analysis, item response theory (IRT), and differential item functioning (DIF).
Results: In the qualitative study, participants in China, Germany, Italy, Japan, and United States (N = 75) informed rephrasing and combining of items for clarity and conceptual overlap, and the addition of a self-stigma definition. Interviews confirmed understanding of the PRO items, instructions, and response scale as intended and confirmed them as relevant and comprehensive. Participants self-reported the frequency with which they experienced each aspect of self-stigma over the past 4 weeks (recall period) and found the response scale appropriate. Quantitative (psychometric) evaluation of responses from participants of REEF-1 (N = 470) and REEF-2 (N = 130) demonstrated that the items possessed good internal consistency (alpha = 0.92) and test-retest reliability (intraclass correlation coefficient [ICC]: summed scores = 0.81; ICC: IRT-based scores = 0.77). Exploratory factor analysis indicated a subset of 9 items that covered important content areas (felt inferior to others, expected others to think less of me, felt people were avoiding me, expected rejection when others found out, worried that people would find out, felt guilty, felt ashamed, avoided social situations, and avoided intimacy) provided a good measurement model fit. Confirmatory factor analysis supported a 1-factor model when fit to these 9 items in the PRO instrument (root mean square error of approximation = 0.04; Tucker-Lewis index = 0.96). The summed scores of the final 9-item scale were supported by results from convergent and discriminant correlations and means of known groups analyses. The 9-item summed scores also detected change over time. DIF analyses indicated no group differences in item performance based on age (≤45 vs >45 years), sex, or race/ethnicity (Asian vs non-Asian). The test reliability function of the final 9-item scale indicated that average to high levels of self-stigma had good reliability (>0.70 at – 0.8 and higher) supporting the suitability of the instrument for future use in clinical trials.
Conclusion: These results support the content and psychometric validity of this new 9-item PRO instrument for use in clinical studies to assess self-stigma in people with CHB.

WED-152

Hepatitis flare appeared to be more severe with poorer outcome in chronic hepatitis B patients with recent COVID vaccination during the COVID pandemic

Jennifer Tai[1], Yen-Chun Liu[1,2], Rachel Wen-Juei Jeng[1,2], Rong-Nan Chien[1,2,3], Yun-Fan Liaw[2,3]. *[1]Chang Gung Memorial Hospital, Linkou Medical Center, Department of Gastroenterology and Hepatology, Taiwan; [2]College of Medicine, Chang Gung University, Taiwan; [3]Chang Gung Memorial Hospital, Linkou Medical Center, Liver research unit, Taiwan*
Email: liveryfl@gmail.com

Background and aims: Immune-mediated hepatitis following COVID vaccination were reported recently. Further, COVID-19 infection has been reported as one of the possible trigger factors for HBV reactivation. This study aims to investigate the characteristics and severity between chronic hepatitis B (CHB) patients who developed severe flare with and without recent COVID vaccination during Nov 2020-Nov 2021.
Method: From the nucleos (t)ide analogues reimbursement application registry system during Nov 2020-Nov 2021 in Chang Gung Memorial Hospital, Linkou medical center, CHB patients with severe flare, defined as ALT ≥1000 U/L or ALT <1000 plus bilirubin ≥3.5 mg/dL and/or international normalized ratio (INR) ≥1.5, and/or hepatic decompensation, defined as ALT ≥5X ULN, bilirubin ≥2 mg/dL and INR ≥1.5, were recruited. Patients with sepsis, biliary tract infection, advanced liver tumor, alcoholism, acute hepatitis B infection and drug-induced liver injury were excluded. Patients' characteristics along with liver biochemistry, viral markers at onset of hepatitis flare event, and the incidence of mortality or liver transplantation were compared between patients with and without history of recent (<6 months) COVID-19 vaccination.

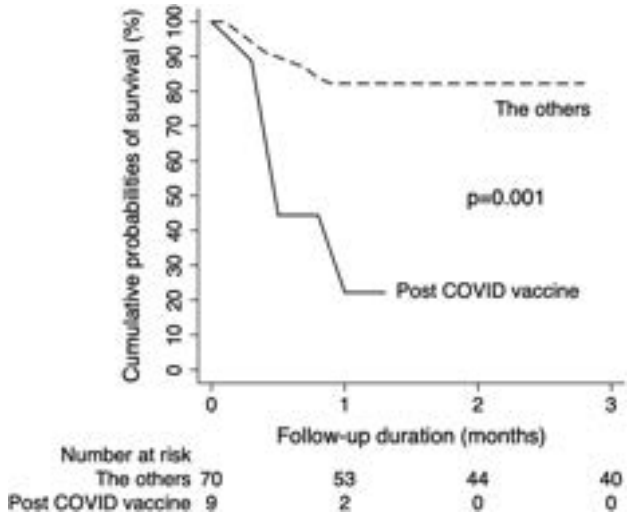

Figure: Kaplan-Meier survival estimates (30-day mortality or liver transplantation).

Results: Among 241 patients registered, 79 patients met the inclusion criteria. Nine patients (11.4%) had history of recent COVID vaccine exposure within 6 months prior to the event (vaccine group), with mean time-to-event of 8 weeks (IQR: 2.9~12.9). The median age, proportion of gender, cirrhosis, and HBeAg positivity were comparable between the vaccine group and non-vaccine group. The median level of HBV DNA at flare was lower in the vaccine group (6.3 vs. 7.0 log10 IU/ml, P = 0.59) and more frequent <5 log10 IU/ml (22.2% vs. 10%, P = 0.29). In addition, the vaccine group had significantly higher

peak INR (median: 3.2 vs 1.7, p = 0.015), AST (median: 1789 vs 808 U/L, p = 0.011), ALT levels (median: 2079 vs 1500 U/L, p = 0.018), more frequent peak ALT >3000 U/L (44.4% vs. 7.1%, P = 0.008) and significantly higher rates of 30-day mortality or liver transplant (66.7% vs 21.4%, log rank test, P < 0.05).
Conclusion: Recent COVID-19 vaccination may exacerbate severe hepatitis flare, probably due to more vigorous immune response or immune mediated hepatitis following COVID-19 vaccination.

WED-153
Increased baseline comorbidity burden among commercially insured patients with hepatitis delta virus infection vs hepatitis B virus monoinfection in the United States
Robert G. Gish[1], Robert Wong[2,3], Chong Kim[4], Gary Leung[5], Ira M Jacobson[6], Joseph Lim[7], Ankita Kaushik[4]. [1]*Hepatitis B Foundation, Doylestown, United States;* [2]*Stanford University School of Medicine, Stanford, United States;* [3]*VA Palo Alto Healthcare System, Palo Alto, United States;* [4]*Gilead Sciences, Inc., HEOR-Global Value and Access, Foster City, United States;* [5]*Gilead Sciences, Inc., RWE-Epidemiology, Foster City, United States;* [6]*NYU Grossman School of Medicine, New York, United States;* [7]*Yale University School of Medicine, New Haven, United States*
Email: rgish@robertgish.com

Background and aims: Compared to hepatitis B virus (HBV) monoinfection, hepatitis D virus (HDV) is associated with more rapid progression to cirrhosis and liver-related complications. Baseline (BL) characteristics of adults with HBV with concurrent HDV infection were compared to those with HBV monoinfection among commercially insured US patients.
Method: Adults with ≥1 HDV or HBV diagnosis (ICD-9/10-CM) were identified retrospectively from 1 Jan 2013 to 31 Dec 2021 (study period) using the IQVIA PharMetrics Plus database covering ~210 million patients from primarily commercial payers. HDV and HBV-monoinfected patients were identified from 1 Jan 2014 to 31 Dec 2020 (identification period). Patients with HDV had ≥1 inpatient or ≥2 outpatient claims ≥30 days apart with an ICD-9/10-CM diagnosis code for HDV during the identification period (earliest date of diagnosis considered index date), ≥1 claim of HBV diagnosis during BL, and no claims with HDV diagnosis during BL (12-month period prior to index date). Patients with HBV monoinfection had ≥1 inpatient or ≥2 outpatient claims ≥30 days apart with a claim for HBV only, no claims with HBV diagnosis during BL, and no ICD codes for HDV diagnosis during study period. At least 12 months of continuous enrollment before and after the index date was required, and patients aged ≥18 years at index with commercial health plans were included. Patient characteristics were assessed over the 12-month BL period, and comparisons between HDV-infected vs HBV-monoinfected cohorts were made.
Results: Of the 186,376 patients diagnosed with HDV or HBV during the study period, 440 HDV and 22,136 HBV-monoinfected patients were included. The HDV cohort was significantly older, mean (SD) age 50.3 (10.50) vs 49.1 (11.72) years, p = .03; had a significantly greater proportion of males, 65.2% vs 55.2%, p <.0001; and had significantly higher mean (SD) Charlson Comorbidity Index scores, 1.97 (2.35) vs 0.91 (1.94), p <.0001 than the HBV-monoinfected cohort. Compared to HBV-monoinfected patients, at BL, HDV patients were more likely to have compensated cirrhosis (13% vs 2%), decompensated cirrhosis (12% vs 3%), hepatocellular carcinoma (5% vs 1%), and liver transplant (4% vs 1%); p <.0001 for all comparisons. Compared to HBV-monoinfected patients, at BL, HDV patients had significantly higher proportions of hypertension (33% vs 25%; p = .0001), obesity (8% vs 5%; p = .002), non-alcoholic steatohepatitis (7% vs 2%; p <.0001), HCV (6% vs 4%; p = .003), and HIV (5% vs 3%; p = .04).
Conclusion: Among a nationally representative cohort of commercially insured US patients, patients with HDV had a greater burden of advanced liver disease and complications and other comorbidities at BL compared to HBV-monoinfected patients. This study underscores the importance of early identification and linkage to treatment of patients with HDV to mitigate disease progression and improve patient outcomes.

WED-154
Can we better characterize HBeAg-negative chronically infected hepatitis B patients using novel biomarkers?
Thais Leonel Couto[1], Sergio Rodriguez-Tajes[1], Ariadna Rando-Segura[2], Ester García-Pras[1], Mirea García-López[1], Sabela Lens[1], Zoe Mariño[1], David Tabernero[2], Maria Francesca Cortese[2], Francisco Rodríguez-Frías[2], Maria Saez-Palma[1], Sofía Pérez-del-Pulgar[1], Xavier Forns[1]. [1]*Liver Unit, Hospital Clínic Barcelona. University of Barcelona. FCRB-IDIBAPS. CIBEREHD, ISCIII, Spain;* [2]*Unitat de Patologia Hepàtica, Departament de Bioquímica i Microbiologia, Hospital Universitari Vall d'Hebron, CIBEREHD, ISCIII, Barcelona, Spain*
Email: xforns@clinic.cat

Background and aims: The natural history of Hepatitis B virus (HBV) infection has different phases that are characterized according to the hepatitis B e antigen (HBeAg) status, HBV-DNA levels and transaminases. Patients with HBeAg-negative chronic infection can be quite heterogeneous, particularly in terms of hepatitis B surface antigen (HBsAg) levels with no apparent association with HBV-DNA levels. In recent years, new biomarkers such as the core-related antigen (HBcrAg) and circulating HBV-RNA (cirB-RNA) have been used as surrogate markers of covalently closed circular DNA (cccDNA) transcriptional activity. Unfortunately, most of these studies focus on patients on nucleos (t)ide analogue (NA) treatment and in the chronic hepatitis phase. The aim of this study was to investigate whether HBcrAg and cirB-RNA could help to better characterize the HBeAg-negative chronic infection phase.
Method: We retrospectively included 184 naive patients with normal ALT divided into 4 groups: HBsAg >10,000 IU/ml and HBV-DNA

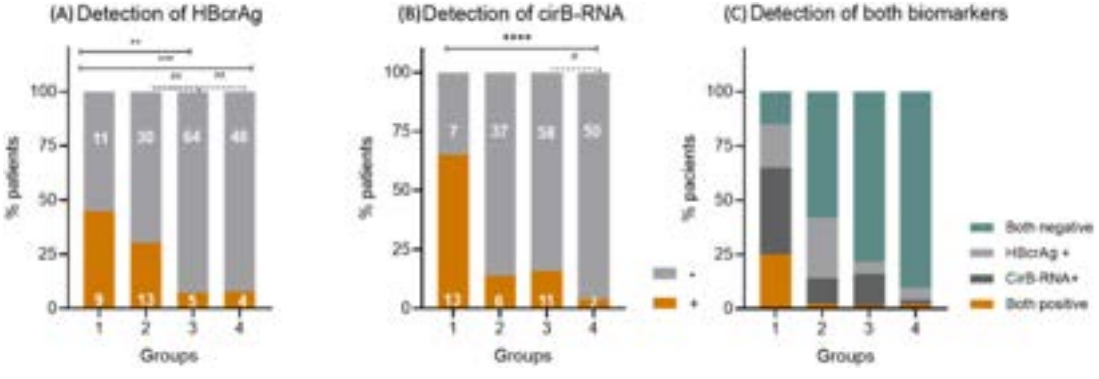

Figure: (abstract: WED-154).

2,000–20,000 IU/ml (Group 1, n = 20); HBsAg >10,000 IU/ml and DNA <2,000 IU/ml (Group 2, n = 43); HBsAg 10,000–100 IU/ml and DNA <2,000 IU/ml (Group 3, n = 69); HBsAg <100 IU/ml and DNA <2,000 IU/ml (Group 4, n = 52). HBV-DNA (LLQ <10 IU/ml), HBsAg (LLQ <0.13 IU/ml), HBcrAg (LLQ<3 LogU/ml) and HBV-RNA (LLQ<10 cp/ml) were quantified in all of them at baseline and in 91 patients during follow-up.

Results: Groups were comparable in sex (55% female) and ethnicity (67% Caucasian); age (median 47 years) was greater in group 4 (54 years). The follow-up period after baseline assessment was similar between groups (2.6 years (1.6–3.9). The presence of HBcrAg and cirB-RNA at baseline varied significantly between groups, ranging from 45% and 65%, respectively, in group 1, to less than 10% in group 4 (Figure). Most of the patients with follow-up remained in the same group (82%) and only 2 patients went from group 2 to group 1 (gray zone). Seventeen patients (18%) achieved functional cure (HBsAg loss) during follow-up (13 from group 4 and 4 from group 3). Neither baseline cirB-RNA detection nor HBcrAg levels predicted change of group or functional cure. Indeed, 2 of the 17 (12%) patients who achieved functional cure had detectable cirB-RNA or HBcrAg at baseline.

Conclusion: In the HBe-negative chronic infection phase, detection of serum HBcrAg and cirB-RNA is not influenced by HBsAg levels, suggesting that it originates from integrated HBV genome. In contrast, HBcrAg and cirB-RNA are frequently detected when HBV-DNA >2000 IU/ml (gray zone), demonstrating increased transcriptional activity of cccDNA. The absence of HBcrAg and cirB-RNA do not predict loss of HBsAg (functional cure). Finally, most patients remain stable overtime and this may indicate that multiple serological marker determination to determine the phase of HBV infection are not required.

WED-155

An online web-based calculator accurately diagnoses immune tolerant phase in chronic HBV-infected patients

Chi Zhang[1], Yiqi Liu[1], Hui Liu[2], Chen Shao[2], Hong Zhao[1], Gui-Qiang Wang[1]. [1]*Peking University First Hospital, Department of Infectious Disease, Center for Liver Disease, China;* [2]*Beijing Youan Hospital, Capital Medical University, Department of Pathology, China*
Email: john131212@126.com

Background and aims: There were different antiviral treatment strategies and prognoses between immune tolerant (IT) and non-IT in chronic hepatitis B (CHB) patients. However, existing non-invasive diagnostics were not precision. We aimed to explore new non-invasive models for diagnosing IT and assessed the risk of hepatocellular carcinoma (HCC) in IT patients.

Method: We included treatment-naive CHB patients with liver biopsy who serological met the diagnostic criteria of IT (HBeAg-positive, HBV DNA>5lgIU/ml, normal ALT). This study included four parts: in step 1, we described the clinical characteristics of IT patients. In step 2, we evaluated the value of non-invasive markers recommended by the guidelines for the diagnosis of IT. In step 3, a new model for the diagnosis of IT with non-invasive markers were developed and validated. In step 4, to assess the risk of developing HCC using 15 HCC prediction models for IT and non-IT.

Results: According to the criteria for the diagnosis of IT by WHO 2015 guidelines, 196 patients were finally included in this study, of which 83 were liver biopsy-proven IT. In the IT group age, qAnti-HBc, ALT, AST and LSM were lower. While, HBV DNA and HBsAg were higher. The risk of non-IT increased 1.2-fold and 3.92-fold in patients aged 30–40 (95%CI 1.00–4.81, P = 0.049) and >40 years (95%CI 2.28–10.60, P < 0.001), respectively, compared to those aged<30 years. Compared to HBV DNA >8 lg IU/ml, the risk of non-IT was increased 4.33-fold and 9.96-fold in patients 7–8 lg IU/ml (p = 0.001) and <8 lg IU/ml (p <0.001), respectively. The accuracy of non-invasive marker combinations for the diagnosis of IT did not exceed 0.800, whether in accordance with EASL2017/APASL2015, AASLD2018 or CHINA2019 criteria (0.709, 0.658 and 0.765, respectively). Using univariate analysis, LASSO regression and multivariate analysis, we created a CALA model (qAnti-HBc, LSM, AST, ALP) to diagnosing IT. The AUROC of CALA model reached 0.890 and 0.892 in training and validation sets, respectively, which were significantly higher than APRI, FIB-4 and LSM. For clinical convenience, we have made CALA model in an online web-based calculator and QR code. We included 15 hepatitis B related HCC prediction models (REACH-B, mREACH-BI, mREACH-BII, GAG-HCC, CU-HCC, LSM-HCC, PAGE-B, mPAGE-B, NGM1-HCC, NGM2-HCC, CAMD, RWS-HCC, AASL-HCC, REAL-B, aMAP) by searching the PubMed database. The risk of HCC was significantly lower in biopsy-proven IT than in biopsy-proven non-IT population (all P < 0.01). Subsequently, the CALA model was used to differentiate IT and the same results were obtained as those confirmed by liver biopsy (all P < 0.01, except CU-HCC model P = 0.066).

Conclusion: Online web-based calculator of CALA model can accurately and conveniently diagnose IT. Patients with liver biopsy or CALA model-proven IT were at a lower risk of developing HCC.

WED-156

Hepatitis D screening in HBsAg positive individuals in Germany: insufficient implementation results in a large number of undiagnosed cases

Toni Herta[1], Anna Joachim-Richter[2], David Petroff[3], Ingmar Wolffram[4], Thomas Berg[1], Jan Kramer[2], Johannes Wiegand[1], Olaf Bätz[2]. [1]*Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany, Germany;* [2]*LADR Laboratory Group Dr. Kramer and Colleagues, Geesthacht, Germany;* [3]*Clinical Trial Centre, University of Leipzig, Leipzig, Germany;* [4]*General Practitioner, Paderborn, Germany*
Email: johannes.wiegand@medizin.uni-leipzig.de

Background and aims: Chronic hepatitis delta (CHD) is the most severe form of viral hepatitis and is caused by hepatitis delta virus (HDV) infection, which can only occur in hepatitis B antigen (HBsAg) positive individuals. Thus, current guidelines recommend an anti-HDV screening in all newly detected HBsAg positive cases. These recommendations received increasing attention after approval of the

Figure: (abstract: WED-155): Online Web-based calculator of CALA model for predicting HBeAg positive chronic hepatitis.

HBV/HDV hepatocyte entry inhibitor bulevirtide as first licensed HDV treatment option in July 2020. We analyzed the implementation of HDV testing in the German health care system during the last 9 years.
Method: We retrospectively searched the database of 11 LADR laboratory sites throughout Germany for HBsAg positive patients detected between the years 2012 and 2021. Request of anti-HDV and HDV RNA testing, origin of laboratory request (primary care, hospital care, occupational medicine, and asylum center), and basic patient characteristics were recorded.
Results: 13,905 HBsAg positive cases were identified (median age 42 ± 15 years, 47% female). They originated from the primary care level, hospitals, occupational medicine, or an asylum center in 84%, 8%, 2%, 5% of cases, respectively. 2,792/13,905 (20%) of HBsAg positive individuals were tested for anti-HDV antibodies with 142/2,792 (5.1%) positive test results. 32% of these anti-HDV positive patients were female with a mean age of 42 ± 13 years. Anti-HDV testing was requested in 2,544/11,679 (22%) of HBsAg-positive individuals at the primary care level, in 218/1,134 (19%) of cases at hospitals, in 18/304 (6%) of cases at occupational medicine, and in 5/711 (1%) of asylum seekers. This observation likely results from differences in reimbursement policy. Testing of HDV RNA was requested in 57/142 (40%) of anti-HDV positive individuals with 26/57 (45%) positive test results. As 80% of HBsAg positive patients were not tested for anti-HDV, a rough estimate suggests that a factor four more patients could benefit from bulevirtide treatment compared to the current situation.
Conclusion: Anti-HDV screening in HBsAg positive individuals and subsequent HDV RNA testing in anti-HDV positive patients is poorly implemented in Germany. One possible solution would be anti-HDV and HDV RNA reflex testing at the laboratory level.

WED-157

HDV RNA levels <1000 IU/ml and total anti-HDV titers <1:1000 identify chronic hepatitis D subjects without active liver disease

Gabriele Ricco[1], Daniela Cavallone[1], Piero Colombatto[1], Filippo Oliveri[1], Barbara Coco[1], Veronica Romagnoli[1], Lidia Surace[1], Antonio Salvati[1], Ferruccio Bonino[2], Maurizia Brunetto[1,2]. Background and aims: To optimize the management and treatment of chronic hepatitis delta (CHD) urges a better clinical/virologic characterization of the patients (pts). We quantified HDV/HBV markers to investigate their correlation with disease activity/stage and response to Interferon (IFN) treatment in a cohort of 146 pts.
Method: One hundred forty-six consecutive untreated anti HDV+ pts admitted at the University Hospital of Pisa were classified according to their baseline clinical, biochemical, histological and imaging data in: 1) Pts without liver disease (no-CHD) [ALT<40U/L; LS<6kPa]; 2) CHD without cirrhosis; 3) CHD with cirrhosis; 4) CHD with advanced cirrhosis [previous or ongoing decompensation/HCC/varices]. HDV and HBV makers (HBV DNA/HBsAg/HBcrAg/IgG anti HBc) were tested at baseline (BL) in the overall cohort and at end of therapy (EOT), 24 weeks after EOT (PT-FU) and end of follow-up (EOF) in 31 (21.2%) IFN-treated pts [median 12.4 (6.0–91.7) mos]. Undetectable HDV RNA at EOT, PT-FU and EOF by in house qualitative PCR defined the virologic response. HDV RNA was quantified by RoboGene 2.0 (Roboscreen Diagnostics, LOD 6 IU/ml). Total anti HDV titer was evaluated by 10-fold end point dilution of serum samples (LiaisonXLmurex Anti HDV, DiaSorin).
Results: Eleven (7.6%) subjects were classified as no-CHD: all were viremic, 10 (90.9%) had quantitative (qt) HDV RNA<1000 IU/ml [2.88 Log (0.82–4.14)] and all had anti HDV titer<1:1000. Among 135 CHD pts, qtHDV RNA was higher in pts with cirrhosis [5.55 Log (0.70–7.73)] compared to those without [4.39 Log (0.70–6.75), p = 0.002], and among cirrhotics was lower in pts with advanced disease [4.81 Log (0.70–6.48), p = 0.008]. Anti HDV≥1:1000 were present in 132 (97.8%) CHD pts. At multivariate analyses HDV RNA [OR = 1.816/p = 0.007], anti HDV [OR = 4.429/p = 0.012] and anti HBc IgG [OR = 3.260/p = 0.041] associated with higher disease activity (ALT>100 U/L); Age [OR = 1.059/p = 0.032] and HDV RNA [OR = 1.643/p = 0.006] with cirrhosis. Among 31 IFN-treated pts, 16 (51.6%) were responders at EOT; 13 (41.9%) maintained a virologic response at PT-FU, 15 (48.4%) were non-responders. Data at EOF [median 4.6 (1.3–18) yrs] were available in 28: 14 (50%) pts maintained undetectable HDV RNA and normal ALT, all had HDV RNA <1000 IU/ml by qtPCR [1.69 Log (0.70–2.34); <LOD in 2 (14%)] and 13/14 (92.8%) had anti HDV <1:1000. Among the remaining 14 PCR positive pts, 12 (85.7%) had ALT>40 U/L, 12 (85.7%) had qtHDV RNA >1000 IU/ml [4.66 Log (1.64–6.65)] and all had anti HDV≥1:1000.
Conclusion: HDV RNA<1000 IU/ml and anti HDV titers <1:1000 identify with high diagnostic accuracy (Table) CHD patients without evidence of active liver disease. In CHD pts HDV viremia independently correlates with biochemical activity and stage of liver disease. Quantification of HDV markers qualifies as a useful tool for clinic-virological classification and treatment monitoring of CHD pts.

Background and aims: The clinical significance of hepatitis D virus (HDV) viral load level in chronic hepatitis D (CHD) is unclear. Unlike infection with hepatitis B virus (HBV), HDV may cause both immune-mediated liver injury as well as direct cytopathic damage to hepatocytes. This study aimed therefore to investigate whether HDV viral load is associated with alanine aminotransferase (ALT)

Figure 1a. Scatter Plot of Baseline HDV RNA (log_{10}) and Baseline ALT in the Total Cohort. Full Analysis Set; Studies MYR203, MYR204 and MYR301

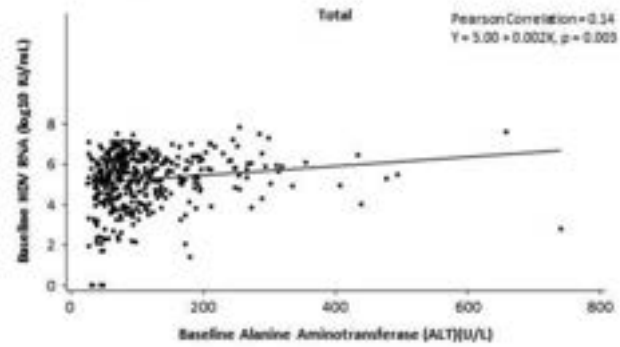

Figure 1b. Scatter Plot of Baseline HDV RNA (log_{10}) and Baseline ALT in Those Without Cirrhosis. Full Analysis Set; Studies MYR203, MYR204 and MYR301

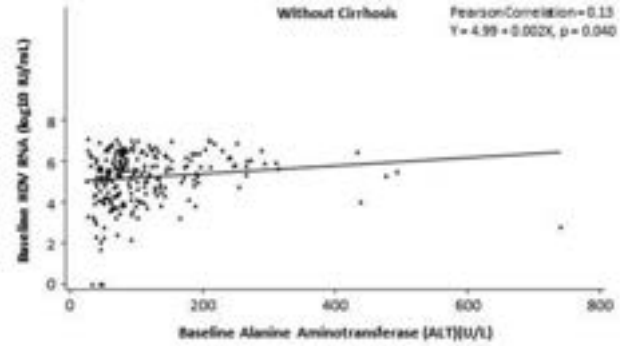

Figure 1c. Baseline HDV RNA (log_{10}) Levels by Baseline ALT (< 2 x ULN, 2-5 x ULN, > 5 x ULN) in the Total Cohort, and Those With/Without Cirrhosis. Full Analysis Set; Studies MYR203, MYR204 and MYR301

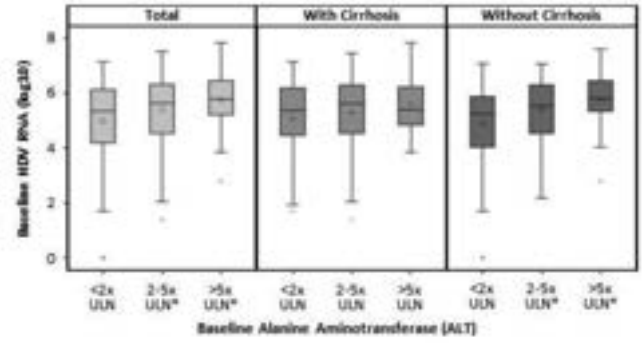

Mean HDV RNA increased with higher ALT subgroup category among the total cohort: ALT <2 x ULN - HDV RNA 5.0 (1.5) log IU/mL; ALT 2-5 x ULN - HDV RNA 5.4 (1.2) log IU/mL; and ALT > 5 x ULN - HDV RNA 5.8 (1.1) log IU/mL.
* Mean HDV RNA of ALT 2-5 x ULN or > 5 x ULN group is significantly different from <2 x ULN ALT group.

Figure: (abstract: WED-158).

levels and liver stiffness (LS) by transient elastography, which are surrogate markers for hepatic inflammation and liver fibrosis.
Method: A cross-sectional analysis was conducted using pooled baseline data from 3 CHD trials: the phase 2 MYR203 (NCT02888106), phase 2 MYR204 (NCT03852433), and phase 3 MYR301 (NCT03852719) studies. Exclusion criteria included a Child-Pugh-Turcotte score B or C and ALT <or ≥10x upper limit of normal (ULN). Correlation between baseline HDV RNA and ALT levels was performed with Pearson's correlation and linear regression analysis. Subjects were further subclassified by ALT levels: <2 × ULN, 2–5 × ULN, >5 × ULN and LS value: <14 vs ≥14 kPa. Additional subgroup analyses were performed by baseline cirrhosis status. T-test was used to compare difference of HDV RNA between ALT subgroups. HDV RNA was quantified by Robogene 2.0 (LLOQ 50 IU/ml).
Results: 414 untreated CHD patients were included; the mean (SD) age was 40 (8.6) years, 64% male, 88% white, 35% with cirrhosis and 33% were on nucleos (t)ide analogues. Median (Q1, Q3) LS was 11.2 (8.1, 15.4) kPa, mean (SD) ALT-114 (118.6), and mean (SD) HDV RNA-5.3 (1.34) log IU/ml which was similar between those with LS <14 vs ≥14 kPa.
Patient distribution across ALT category was: <2 × ULN (N = 180, 43%), 2–5 × ULN (N = 188, 45%), and >5 × ULN (N = 46, 11%). Mean HDV RNA in the total cohort increased with higher ALT subgroup category: ALT <2 × ULN-HDV RNA mean (SD) 5.0 (1.5) log IU/ml, ALT 2–5 × ULN-HDV RNA 5.4 (1.2) log IU/ml, and ALT >5 × ULN-HDV RNA 5.8 (1.1) log IU/ml. Mean HDV RNA was higher among those with ALT 2–5 × ULN (p = 0.003) and >5 × ULN (p < 0.001) compared to those with ALT <2 × ULN. Mean HDV RNA among those without cirrhosis also increased with higher ALT category. A relationship was seen between the baseline HDV RNA level and ALT in the total cohort (p = 0.003, Figure 1a) and non-cirrhotic cohort (p = 0.040, Figure 1b). On further analysis by cirrhosis classification, the significant difference in HDV viral load between ALT subgroups remained only among those without cirrhosis (Figure 1c). Similar results were found using AST and HDV viral load. No correlation was seen with baseline HDV RNA level and baseline LS value, regardless of cirrhosis status.
Conclusion: In a large cohort of untreated HDV patients, higher baseline HDV viral load was significantly associated with increased ALT levels among those without cirrhosis. Whether this is associated with a higher rate of progression to cirrhosis and subsequent liver-related events requires further exploration.

WED-159
B cell phenotype, Toll-Like receptor 9 expression and proinflammatory cytokines profile in patients with chronic hepatitis B with HBsAg loss or persistent

Nour Nasser[1,2], Issam Tout[1], Stephanie Narguet[2], Nathalie Giuly[2], Boyer Nathalie[2], Corinne Castelnau[2], Valérie Paradis[2], Pierre Tonnerre[3], Vassili Soumelis[3], Maria Chartouni[1], Abdel Mansouri[1,2], Tarik Asselah[1,2]. *[1]Université Paris Cité, Centre de Recherche sur l'Inflammation, Inserm U1149, CNRS ERL8252, F-75018 Paris, France; [2]Assistance Publique-Hôpitaux de Paris (AP-HP), Department of Hepatology, Hôpital Beaujon, F-92110 Clichy, France; [3]Université Paris Cité, Human Immunology, Pathophysiology and Immunotherapy (HIPI), team ATIP-Avenir, Inserm UMR 976, F-75010 Paris, France*
Email: nour.nasser@inserm.fr

Background and aims: B cells, especially CD38hi plasma cells play a major role in mediating humoral immune responses to clear HBV infection. Hepatitis B s antigen (HBsAg) loss is associated with a better outcome in patients with chronic hepatitis B (CHB). Toll-like receptor 9 (TLR9) is a sensor of viral DNA motifs and activates B cells to generate effective immune responses against infection. We aimed to characterize the B cells phenotype, TLR9 expression and associated-inflammatory cytokines profile in peripheral blood mononuclear cells (PBMCs) and plasma from patients with CHB who lost HBsAg (HBsAg-) as compared to patients with persistent HBsAg (HBsAg+) and to healthy controls.
Method: HBsAg- patients and HBsAg+ patients (untreated and nucleoside analogues-treated) and healthy controls were included. PBMC and plasma were isolated from the whole patient's blood. B cells phenotype and TLR9 expression were analysed using flow cytometry. Plasma levels of TNFα, IL-10 and IFNγ were analysed using ELISA.
Results: 14 HBsAg-, 40 untreated CHB, and 11 treated CHB with nucleoside analogues patients were recruited and compared to 15 healthy controls. The percent of CD19+, CD27+, CD38hi Plasma B cells was significantly higher in HBsAg+ patients compared to healthy controls (0.76 ± 0.11, n = 49 and 0.50 ± 0.12, n = 14, p < 0.001). However, the proportion of CD19+, CD27+, CD38hi Plasma B cells in HBsAg- patients was like that in healthy controls, whereas it significantly increases in HBsAg+ patients as compared to healthy controls (and 0.83 ± 0.107 n = 12 and 0.502 ± 0.12, p < .0001), indicating a restoration in the percentages of plasma B cells in HBsAg- patients. On the other hand, HBsAg+ patients have shown a significant increase in the percentage of atypical CD19+ CD10+ CD27- CD21- MBC cells when compared to healthy controls (5.68 ± 2.18, n = 38 and 3.13 ± 0.92, n = 14, p < 0.001) or to HBsAg- patients (5.68 ± 2.18and 2.8 ± 0.91 n = 12, p < .0001). The relative TLR9 expression was significantly increased in HBsAg+ patients as compared to healthy controls (0.65 ± 0.15 n = 39 and 0.35 ± 0.11 n = 14, P < 0.0001) or to HBsAg- patients (0.35 ± 0.11 and 0.63 ± 0.19, p < .001 n = 14). Also, plasma TNFα levels significantly increased in HBsAg+ patients compared to healthy controls (15.99 ± 2.83 pg/ml and 11.42 ± 1.67 pg/ml, P < 0.0001) but unchanged in HBsAg- group as compared to controls. However, a significant decrease in the levels of TNFα was observed in HBsAg- patients compared to HBsAg+ patients (15.99 ± 2.83 pg/ml and 12.07 ± 1.46 pg/ml, p < 0.05). Similarly, IL-10 levels increased in HBsAg+ patients in comparison to healthy controls (8.05 ± 1.67 pg/ml and 10.8 ± 2.9 pg/ml, p < 0.05), whereas significantly decreased (10.8 ± 2.9 pg/ml and 8.05 ± 1.67 pg/ml, p < 0.05) in HBsAg- patients compared to HBsAg+.
Conclusion: The normal redistribution of B cell subsets was disrupted in patients with persistent HBsAg while restored in patients who lost HBsAg. A restored cytokine environment in HBsAg- patients characterized by a decrease in TNFα and IL-10 plasma levels was observed in comparison HBsAg+ patients. Finally, TLR9 expression was restored upon HBsAg loss. A study of B cell functionality in all groups of patients will be subsequently conducted to better correlate the B cell response to the HBsAg loss.

WED-160
Healthcare resource use and costs associated with hepatitis delta virus infection compared to hepatitis B virus monoinfection among commercially insured patients in the US

Robert Wong[1,2], Robert G. Gish[3], Chong Kim[4], Gary Leung[5], Ira M Jacobson[6], Joseph Lim[7], Ankita Kaushik[4]. *[1]Stanford University School of Medicine, Stanford, United States; [2]VA Palo Alto Healthcare System, Palo Alto, United States; [3]Hepatitis B Foundation, Doylestown, United States; [4]Gilead Sciences, Inc., HEOR-Global Value and Access, Foster City, United States; [5]Gilead Sciences, Inc., RWE-Epidemiology, Foster City, United States; [6]NYU Grossman School of Medicine, New York, United States; [7]Yale University School of Medicine, New Haven, United States*
Email: ankita.kaushik@gilead.com

Background and aims: Hepatitis delta virus (HDV) infection occurs in patients with underlying hepatitis B virus (HBV) infection and is associated with more rapid liver disease progression. This retrospective study compared baseline (BL) characteristics, healthcare resource use (HCRU), and costs among commercially insured adults in the US with HBV monoinfection and HDV infection.
Method: The study population included commercially insured adults with ≥1 inpatient or ≥2 outpatient claims ≥30 days apart with an

ICD-9/10-CM diagnosis code for HBV in the IQVIA PharMetrics Plus database between 1 Jan 2014 and 31 Dec 2020 (identification period). The HBV index date was the first claim for HBV during the identification period. Patients were required to have ≥12 months of continuous enrollment before and after the HBV index date. Patients with HBV had no HDV diagnosis during the study period. Patients with HDV had ≥1 inpatient or ≥2 outpatient claims ≥30 days apart with an HDV diagnosis on or after the HBV index date and ≥12 months of continuous enrollment before and after HDV diagnosis. Patients with HBV and HDV were matched for geographic region, BL comorbidities, age, sex, and follow-up time. BL characteristics were assessed over the 12-month pre-HBV index period. Mean per patient per year (PPPY) HCRU and costs were assessed over the entire pre- and post-HDV index periods. Descriptive statistics were summarized, and comparisons were made using Mann-Whitney U and chi-square tests.

Results: Of 152,576 commercial patients diagnosed with HBV and/or HDV during the study period, the matched cohorts for analysis included 325 with HBV monoinfection and 325 with HDV infection. There were no significant differences in BL characteristics or comorbidities between the matched cohorts. The mean PPPY numbers of inpatient visits (1.6 vs 0.7; p < .0001), outpatient visits (13.9 vs 7.8; p < .0001), and physician office visits (11.6 vs 9.3; p < .0001) were greater among patients with HDV infection than HBV monoinfection. Mean PPPY length of stay for inpatient visits was higher among patients with HDV infection than HBV monoinfection (4.6 days vs 1.9 days; p < .0001). Patients with HDV infection also had significantly greater total medical costs ($12,319 vs $7619; p < .0001). The greatest differences in HCRU and cost between patients with HDV infection and HBV monoinfection were from outpatient visits, for which patients with HDV had approximately 6 more visits and spent $3,094 more per year vs patients with HBV monoinfection.

Conclusion: Among a large national US commercial healthcare claims database, patients with HDV infection cost $4,700 more in terms of total medical costs annually compared to matched patients with HBV monoinfection. These findings highlight the need for effective screening, diagnosis, and treatment of HDV, which may reduce the clinical and economic burden faced by patients with HDV.

WED-161

Clinical characteristics and phase transition of chronic hepatitis B patients with HBeAg and anti-HBe coexistence

Ruifei Xue[1], Jian Wang[2,3], Jie Zhan[1], Zhiyi Zhang[4], Suling Jiang[1], Juan Xia[2], Weimao Ding[5], Jie Li[1,2,3,4], Rui Huang[1,2,3,4], Chao Wu[1,2,3,4]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing Medical University, Nanjing, Jiangsu, China; [2]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China; [3]Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, Jiangsu, China; [4]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China; [5]Department of Hepatology, Huai'an No. 4 People's Hospital, Huai'an, Jiangsu, China*
Email: dr.wu@nju.edu.cn

Background and aims: The clinical significant of coexistence of hepatitis B e antigen (HBeAg) and antibody against HBeAg (anti-HBe) remains unclear in patients with chronic hepatitis B (CHB). We aimed to explore the clinical characteristics and phase transition of patients with HBeAg/anti-HBe coexistence.

Method: Eight hundred and forty treatment-naïve HBeAg-positive CHB patients from two medical centers were respectively included. Using cox regression to analyze the associated factors of HBeAg clearance and seroconversion.

Results: Eighty-six (10.2%) patients were HBeAg/anti-HBe coexistence. Patients with anti-HBe had older age (39.0 vs. 34.0 years, P = 0.016) and higher FIB-4 value (1.5 vs. 1.0, P < 0.001) than patients without anti-HBe. During a median follow-up of 86.5 weeks, 158 (18.8%) and 118 (14.0%) patients achieved HBeAg clearance and HBeAg seroconversion, respectively. Surprisingly, as high as 39.5% of patients with HBeAg and anti-HBe coexistence transitioned to HBeAg positive and anti-HBe negative status. 4.7% of patients with HBeAg and anti-HBe coexistence transitioned to HBeAg negative and anti-HBe negative status. Patients with anti-HBe had higher cumulative HBeAg clearance and HBeAg seroconversion rate than those without anti-HBe (p < 0.001). HBeAg/anti-HBe coexistence was associated with higher HBeAg clearance (HR 2.960, 95%CI 1.828, 4.791, P < 0.001) and HBeAg seroconversion (HR 4.018, 95% CI 2.372, 6.805, P < 0.001).

Conclusion: HBeAg-positive CHB patients with anti-HBe had higher possibility of HBeAg clearance and seroconversion than those of patients without anti-HBe. The presence of coexistent HBeAg and anti-HBe is a predictor of HBeAg clearance and seroconversion. Close follow-up of patients with HBeAg and anti-HBe coexistence are needed to monitor phase transitions of patients.

WED-162

Lower HBV DNA levels is associated more severe liver fibrosis in chronic hepatitis B with serological immune-tolerant phase

Jian Wang[1,2], Zhiyi Zhang[3], Shaoqiu Zhang[1], Yifan Pan[4], Xiaomin Yan[1], Weihua Wu[1], Weimao Ding[5], Chuanwu Zhu[6], Jie Li[1,2,3,4], Rui Huang[1,2,3,4], Chao Wu[1,2,3,4]. *[1]Department of Infectious Diseases,*

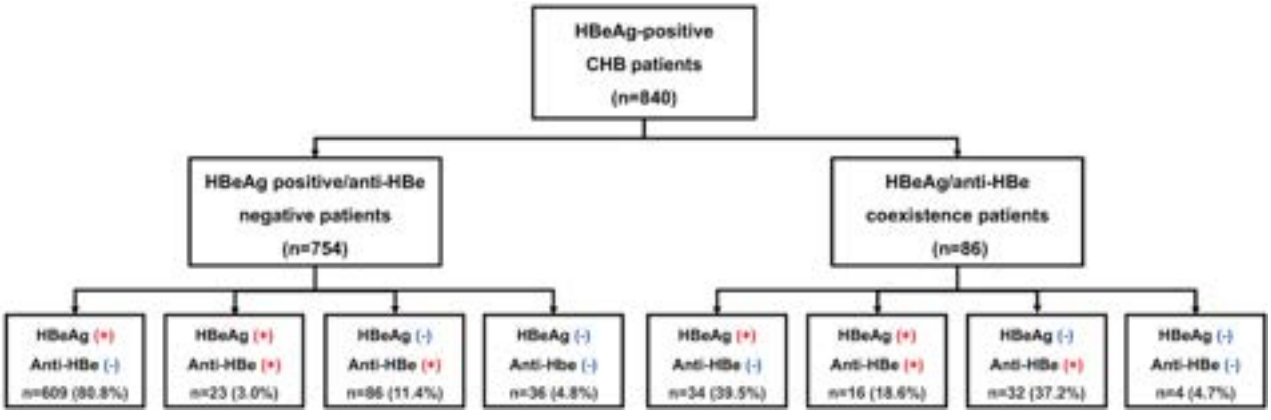

Figure: (abstract: WED-161): Transition of immune status for HBeAg-positive CHB patients with and without anti-HBe.

Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, China; [2]Institute of Viruses and Infectious Diseases, Nanjing University, China; [3]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, China; [4]Department of Infectious Diseases, Nanjing Drum Tower Hospital, Clinical College of Nanjing Medical University, China; [5]Department of Hepatology, Huai'an No. 4 People's Hospital, China; [6]Department of Infectious Diseases, The Affiliated Infectious Diseases Hospital of Soochow University, China
Email: doctor_hr@126.com

Background and aims: Patients with chronic hepatitis B (CHB) in serological immune-tolerant (IT) phase might have significant liver fibrosis. However, the association of hepatitis B virus (HBV) DNA levels and liver fibrosis in patients with serological IT phase of CHB remains unclear. This study aimed to compare the severity of liver fibrosis in serological IT patients with different HBV DNA levels.
Method: Six hundred and twenty-two consecutive treatment-naïve serological IT patients with CHB, defined by criteria of positive serum hepatitis B e antigen, HBV-DNA $\geq 10^6$ IU/ml and normal alanine aminotransferase ($\leq$35 IU/L for male or $\leq$25 IU/L for female), at three different medical centers were included between January 2015 and August 2022. Patients were divided into three groups according to the serum HBV DNA levels: low (6 log10 IU/ml $\leq$HBV DNA <7 log10 IU/ml), moderate (7 log10 IU/ml $\leq$HBV DNA <8 log10 IU/ml), and high (HBV DNA $\geq$8 log10 IU/ml). Significant liver fibrosis and cirrhosis were identified by aspartate transaminase (AST)-to-platelet ratio index (APRI), fibrosis-4 score (FIB-4), transient elastography, or liver biopsy.
Results: The median age of patients was 33.0 years and 57.9% patients were male. The proportion of patients with lower, moderate, and high HBV DNA levels were 18.8%, 52.1%, and 29.1%, respectively. Patients with low HBV DNA were older and had higher AST levels, while lower platelet, albumin, HBsAg levels, compared to patients with moderate, and high HBV DNA levels. The APRI (0.33 vs. 0.26 vs. 0.26, p < 0.001), FIB-4 (1.03 vs. 0.71 vs. 0.68, p < 0.001), and liver stiffness values (7.6 kPa vs. 5.6 kPa vs. 5.5 kPa, p = 0.086) were higher in patients with low HBV DNA levels than other two groups. Patients with low HBV DNA levels had higher proportions of significant fibrosis (24.8% vs. 9.9% vs. 3.3%, p < 0.001) and cirrhosis (7.7% vs. 2.5% vs. 1.1%, p = 0.004) compared to patients with moderate and high HBV DNA levels. Compared to patients with high HBV DNA levels, moderate HBV DNA levels (OR 3.095, 95%CI 1.165–8.222, p = 0.023) and low HBV DNA levels (OR 4.968, 95%CI 1.706–14.473, p = 0.003) were independent risk factors of significant fibrosis, especially for patients aged 30 or older with moderate HBV DNA levels (OR 6.487, 95%CI 1.489–28.255, p = 0.013) and low HBV DNA levels (OR 8.618, 95%CI 1.836–40.458, p = 0.006).
Conclusion: Lower HBV DNA level was associated with more severe liver fibrosis in serological IT patients with CHB. Determination of liver fibrosis by liver biopsy or non-invasive methods should be considered without delay for these patients.

WED-163
Clinical evaluation of highly sensitive iTACT hepatitis B core-related antigen and hepatitis B surface antigen assays in the management of HBV reactivation

Takako Inoue[*,1], Takanori Suzuki[2], Kentaro Matsuura[2], Etsuko Iio[3], Katsuya Nagaoka[3], Masakuni Tateyama[3], Hiroko Setoyama[3], Yoko Yoshimaru[3], Takehisa Watanabe[3], Yasuhito Tanaka[3]. *[1]Nagoya City University Hospital, Department of Clinical Laboratory Medicine, Japan; [2]Nagoya City University Graduate School of Medical Sciences, Department of Gastroenterology and Metabolism, Japan; [3]Kumamoto University, Department of Gastroenterology and Hepatology, Faculty of Life Sciences, Japan*
Email: tinoue@fg8.so-net.ne.jp

Background and aims: We developed a highly sensitive hepatitis B core-related antigen assay (iTACT-HBcrAg) and reported its usefulness for the diagnosis of HBV reactivation (J Hepatol, 2021). In Japan, iTACT-HBcrAg has gained pharmaceutical approval and is now available for clinical use. Meanwhile, hepatitis B surface antigen (HBsAg) assays with a higher sensitivity, such as iTACT-HBsAg, have also been developed as an alternative marker to HBV DNA. In this study, we examined the clinical significance of iTACT-HBcrAg and iTACT-HBsAg in the diagnosis of HBV reactivation.
Method: Between 2012 and 2022, patients who had been assessed for HBV markers prior to the introduction of systemic chemotherapy or immunosuppressive therapy, who were diagnosed with HBV-resolved infection, based on positivity for hepatitis B surface antibody or (and) hepatitis B core antibody, were observed. Among them, 33 patients diagnosed with HBV reactivation and whose serial sera were stored were enrolled in this study. Serial sera were measured with iTACT-HBcrAg (cut-off value: 2.1 log U/ml) and iTACT-HBsAg (cut-off value: 0.0005 IU/ml) and compared to the results of HBV DNA monitoring performed as a part of the medical practice. The diagnostic criterion for HBV reactivation was detection of serum HBV DNA. This study was approved by the ethical review committee of our institute.
Results: Thirty-three patients diagnosed with HBV reactivation during or after systemic chemotherapy or immunosuppressive therapy, and with quantitative detection of HBV DNA during the observation period, were selected. Their underlying diseases were

Variables	Entire patients (n=622)	6 <HBV DNA ≤7 Log 10 IU/ml (n=117)	7 <HBV DNA ≤8 Log 10 IU/ml (n=324)	HBV DNA >8 Log 10 IU/ml (n=181)	P value

Figure: (abstract: WED-162): Comparison of liver fibrosis among CHB patients with low, moderate, and high HBV DNA levels.

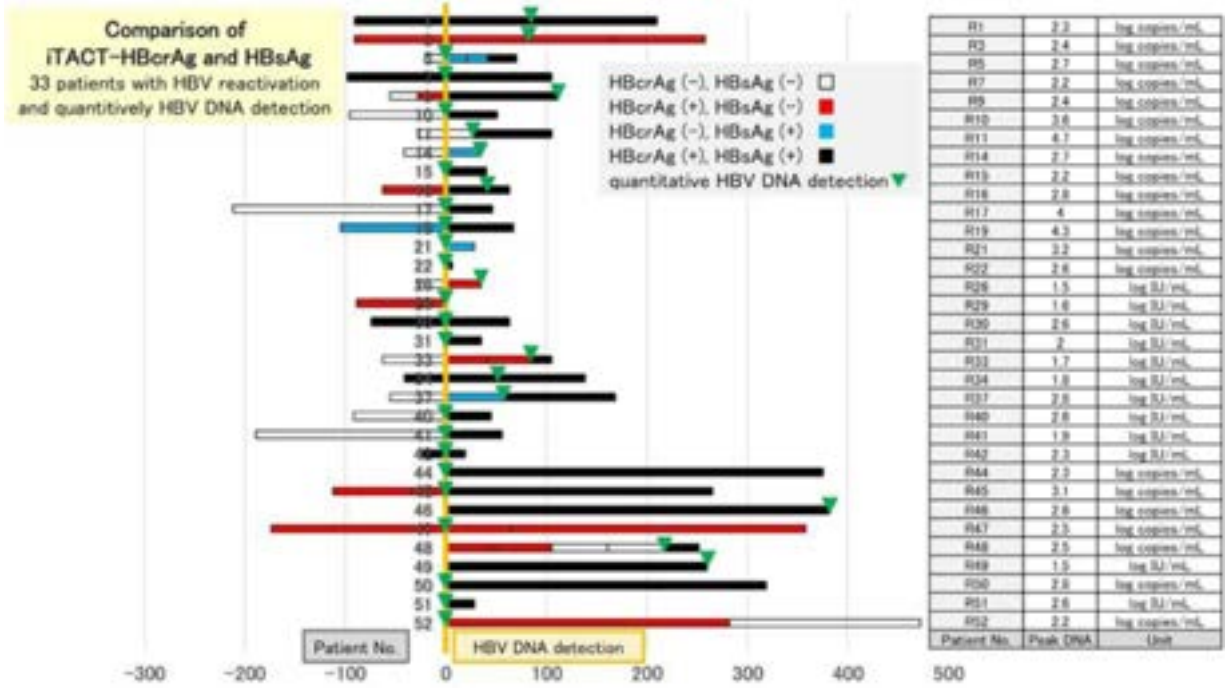

Figure: (abstract: WED-163).

hematopoietic malignancies in 22 patients, non-hematopoietic malignancies in 4 patients, autoimmune diseases in 5 patients, and others in 2 patients. Of the 33 cases in which serum HBV DNA was detected quantitatively, iTACT-HBcrAg was detected early or simultaneously with the diagnosis of HBV reactivation in 85% (28/33), and was detected simultaneously or within 1 month of serum HBV DNA detection quantitatively in 94% (31/33). When iTACT-HBcrAg and iTACT-HBsAg were measured simultaneously, at least one of them was detected earlier or simultaneously with HBV DNA in 100% (33/33).
Conclusion: In the diagnosis of HBV reactivation, a rapid test with comparable sensitivity to quantitative HBV DNA detection, which serves as a guide for administration of nucleos (t)ide analogues, is useful for monitoring outpatients. In this study, the usefulness of iTACT-HBcrAg for the diagnosis of HBV reactivation was reproduced, and the addition of iTACT-HBsAg provided a higher diagnostic performance. iTACT-HBcrAg and iTACT-HBsAg are useful tests for monitoring HBV reactivation because they have the same detection sensitivity as quantitative HBV DNA detection and yield rapid results (within 30 min).

WED-164
Serum thrombospondin-2 for predicting liver fibrosis in patients with chronic hepatitis B virus infection

Yun Chen[1], Yilin Liu[2], Jian Wang[3,4], Zhiyi Zhang[2], Xin Tong[3], Rui Huang[1,2,3,4], Chao Wu[1,2,3,4]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing Medical University, Nanjing, Jiangsu, China; [2]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China; [3]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China; [4]Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, Jiangsu, China*
Email: dr.wu@nju.edu.cn

Background and aims: Thrombospondin 2 (TSP-2) is a secreted glycoprotein belonging to the thrombospondin family, and is involved in collagen/fibrin formation. Serum TSP-2 level has been reported to be associated with liver fibrosis in patients with non-alcoholic fatty liver disease and hepatitis C virus infection. We explored the association between TSP-2 and severity of liver fibrosis in patients with chronic hepatitis B virus (HBV) infection.
Method: Serum samples were collected from 228 patients with chronic HBV infection who underwent liver biopsy. Serum TSP-2 was detected by enzyme-linked immunosorbent assays. The Scheuer scoring system was used to evaluate the liver fibrosis stages. Logistic regression analysis was used to analyze the risk factors for fibrosis. The receiver operating characteristic curve (ROC) was used to evaluate the diagnostic accuracy of significant fibrosis (≥S2) and advanced fibrosis (≥S3).
Results: The median age of patients was 40 years, and 146 patients (64.0%) were men. 69 patients (30.3%) had significant fibrosis (≥S2) and 16 patients (7.0%) had advanced fibrosis (≥S3). The median serum TSP-2 level of patients was 16.7 ng/ml (Interquartile range:13.1–22.1 ng/ml). The serum TSP-2 level increased with fibrosis stages. The aeras under the ROC (AUROCs) of serum TSP-2 for predicting significant fibrosis (≥S2) and advanced fibrosis (≥S3) were 0.643 (95% CI:0.565–0.721, P = 0.001) and 0.855 (95%CI:0.764–0.946, P < 0.001), which was comparable with APRI (0.677 and 0.836) and FIB4 (0.646 and 0.823). Serum TSP-2 level was an independent predictor of advanced fibrosis (Odds ratio:1.042, 95%CI:1.016–1.069, P = 0.002).
Conclusion: Serum TSP-2 correlated with fibrosis stages and could be as a promising predictor of advanced fibrosis in patients with chronic HBV infection.

WED-165
Impact of fatty liver on long-term outcomes in chronic hepatitis B: a systematic review and matched analysis of individual patient data meta-analysis

Background and aims: Chronic hepatitis B (CHB) and fatty liver (FL) often co-exist, but natural history data of this dual condition (CHB-FL) are sparse. Via a systematic review, conventional meta-analysis (MA) and individual patient-level data MA (IPDMA), we compared liver-related outcomes and mortality between CHB-FL and CHB-no FL patients.
Method: We searched 4 databases from inception to December 2021 and pooled study-level estimates using a random-effects model for conventional MA. For IPDMA, we evaluated outcomes after balancing the two study groups with inverse probability treatment weighting (IPTW) on age, sex, cirrhosis, diabetes, ALT, HBeAg, HBV DNA, and antiviral treatment.
Results: We screened 2157 articles and included 19 eligible studies (17 955 patients: 11 908 CHB-no FL; 6047 CHB-FL) in conventional MA, which found severe heterogeneity (I^2 = 88%-95%) and no significant differences in HCC, cirrhosis, mortality, or HBsAg seroclearance incidence (p = 0.27–0.93). IPDMA included 13 262 patients: 8625 CHB-no FL and 4637 CHB-FL patients who differed in several characteristics. The IPTW cohort included 6955 CHB-no FL and 3346 CHB-FL well-matched patients. CHB-FL patients (vs. CHB-no FL) had significantly lower HCC, cirrhosis, mortality and higher HBsAg seroclearance incidence (all $P \leq 0.002$), with consistent results in subgroups. CHB-FL diagnosed by liver biopsy had a higher 10-year cumulative HCC incidence than CHB-FL diagnosed with non-invasive methods (63.6% vs. 4.3%, $P < 0.0001$). On Cox regression, CHB-FL was associated with lower HCC, cirrhosis, mortality and higher HBsAg seroclearance incidence (hazard ratio = 0.68, 0.61, 0.38, 1.35, respectively, all $P \leq 0.004$).
Conclusion: IPDMA data with well-matched CHB patient groups showed that FL (vs. no FL) was associated with significantly lower HCC, cirrhosis, and mortality risk and higher HBsAg seroclearance probability.

Email: slens@clinic.cat

Background and aims: Chronic hepatitis delta (CHD) is the most severe form of chronic viral hepatitis resulting in high morbidity and mortality due to advanced liver disease. The estimated HDV prevalence in Spain is around 5–10% of patients with hepatitis B. However, true prevalence is probably underestimated due to migration and current limitations in screening and diagnosis. The recent approval of bulevertide and the development of other drugs will change the management of the infection. We aimed to characterize the clinical profile of patients with HDV/HBV infection in Spain and current barriers in their management.
Method: Multicenter registry including patients with positive anti-HDV serology actively monitored in 30 Spanish centers. Epidemiological, clinical and virological variables were recorded at the start of follow-up and at the last visit.
Results: A total of 329 patients were included: 59% were male with median age 51 (IQR: 42–56) years (only 5% were >65 years old), the most common geographical origin was Spain (53%) and East Europe (24%). The median follow-up time since diagnosis was 6 (3–12) years. Importantly, patients from Spain were older and had a longer follow-up with higher presence of cirrhosis and HCV and HIV coinfection ($p < 0.01$). HDV-RNA determination was available in 56% of centers (performed externally in the rest) and its quantification only in 16%. During follow-up, HDV-RNA was assessed in 278 (84%) patients, HDV-RNA was undetectable from baseline in 101 (36%). 133 (48%) had active infection throughout follow-up, while 44 (16%) resolved infection (18 spontaneously and 26 after Peg-INF treatment). At diagnosis 33% had liver cirrhosis (LC), 13% portal hypertension (PH) while only 1% had hepatocellular carcinoma (HCC). During follow-up an additional 10% and 6% developed LC and PH, respectively and 2% HCC. The presence of LC and PH was significantly more frequent in HDV-RNA-positive than in HDV-RNA-negative patients (55% and 27%, $p < 0.01$; 30% and 11% $p < 0.01$).
When performing a gender-based analysis we observed higher rate of active infection among women than men (53% vs. 44%, $p < 0.05$). During follow-up, HDV clearance occurred more among men (19% vs. 11%, $p < 0.05$) despite similar Peg-INF treatment. Despite the high rate of active infection, women had a lower prevalence of LC (36% vs 47%, $p < 0.05$) and HCC (0.7% vs 5%, $p < 0.05$).
Conclusion: The burden of HDV-related disease in Spain is high affecting mostly median age people. One-third of the patients already has cirrhosis at diagnosis and this increases up to 43% after less of a decade of follow-up. Despite a greater rate of active viremia, female sex is associated with less advanced liver disease. Importantly we have identified critical barriers for the management of CHD as it is not possible to locally determine or quantify HDV-RNA in most of the centres. The latter is relevant for prognosis and to assess response to new antiviral therapies.

WED-167

Molecular epidemiology of hepatitis B virus and hepatitis delta virus coinfection in-Sudan

Osama Mohamed[1], Birgit Bremer[2], Sabah Ibrahim[3], Sofia Mohamed[3], Petra Dörge[2], Yassir Hamadalnil[4,5], Mohamed Hassan[6], Yasser Mofty[4], Shamsoun Kafi[7], Heiner Wedemeyer[2,8]. *[1]National University Biomedical Research Institute, National University-Sudan, Khartoum, Sudan, Department of Molecular Biology, Sudan; [2]Hannover Medical School, Department for Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [3]National University Biomedical Research Institute, National University-Sudan, Khartoum, Sudan, Department of Bioinformatics and biostatistics, Sudan; [4]faculty of veterinary University of Bahri, Khartoum, Sudan, Department of Molecular Biology and bioinformatics, Sudan; [5]Ibra Hospital, Oman; [6]faculty of medical laboratory science-National University-Sudan, Khartoum, Sudan, Department of hematology, Sudan; [7]Ribat scientific research center, the National Ribat University, Khartoum, Sudan; [8]German Center for Infection Research, Site Hannover-Braunschweig, Germany*
Email: wedemeyer.heiner@mh-hannover.de

Background and aims: Hepatitis D virus (HDV) is dependent on Hepatitis B virus (HBV), and can lead to significant morbidity and mortality. Conflicting data on the impact of hepatitis D have been published for distinct regions in Africa. The aim of this study was to study the molecular epidemiology of HBV/HDV coinfection among a group Sudanese patient.
Method: A total of 324 patient samples (100 patients with hepatocellular carcinoma, 100with liver cirrhosis and 124 with chronic HBV infection were collected in Sudan during the year 2019. The CHB group received therapy Pegylated interferon for 48 weeks and Lamivudine for some of patients HBV markers and HDV total antibody were identified by immunoassays. Extracted HBV-DNA and HDV-RNA was quantified by real-time PCR. HBV genotype was determined by multiplex nested PCR and consecutive PCR gel, 11samples for HBV and 26 samples for HDV were additionally sequenced (Sanger sequencing). Statistical analysis was done using statistical package of social science (IBM SPSS version 20.0) considering a p value ≤ 0.05 as a level of significance.

Figure: (abstract: WED-167).

Results: A total of 319 patients out of 324 were HBsAg positive, were HBV genotyped. the most dominant HBV Genotype was Genotype E in all three groups (52.00%, 44.30%, and 40.30% in HCC, LC and CHB respectively), followed by Genotype D (24.50%, 26.80%, and 31.50% in HCC, LC and CHB respectively). There was a mixed D/E genotypes with 21.40% in HCC group, 24.70% in LC group and 15.30% in CHB group. In addition, some patients possessed genotype A (2.00%, 4.10%, and 7.30% in HCC, LC and CHB respectively). A few Subjects in the CHB group showed a mixed A/E genotype (5.60%) in CHB Individuals with genotype E showed the highest HBV viral load (Median 1550.00, copies/ml, p value = 0.008) with 51.9% of them being HDV RNA positive. Anti-HDV was identified in 54 (16.9%) of HBsAg positive patients. HBV genotypes in HDV coinfected patients were 51.9% E, 27.8% D 20% E/D, while genotype A was not detected. HDV coinfection was more frequent in patients with HCC (27.3%) versus 12.4% of LC, and 17.2% of CHB.

Conclusion: Incidence and existence of HBV and HDV infections in Sudan was documented through the detection of HBV and HDV indicating high prevalence among HCC, LC and chronic HBV patients. Generally, these findings are useful for future studies since there is no information available about HBV and HDV infection in Sudan. HDV coinfected patients in Sudan show a distinct HBV backbone distribution which may contribute to pathogenesis. These findings establish a baseline for future studies of HBV and HDV coinfection in Sudan.

WED-168

In patients with chronic hepatitis D, the decline of ≥2log HDV-RNA levels that remain detectable is associated with better clinical outcomes

Adriana Palom[1,2], Sergio Rodriguez-Tajes[2,3], Ariadna Bono[4], Antonio Madejón[2,5], Mar Riveiro Barciela[1,2], Ângela Carvalho-Gomes[2,4], Sabela Lens[2,3], Marina Berenguer[2,4], Francisco Javier Garcia-Samaniego Rey[2,5], Maria Buti[1,2]. *[1]Liver Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2]Centro de investigación biomédica en red de enfermedades hepáticas y digestivas, Instituto de Salud Carlos III, Madrid, Spain, Spain; [3]Liver Unit, Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain; [4]Hepatology and Liver Transplantation Unit, Hospital Universitario y Politécnico La Fe, Valencia, Spain; [5]Liver Unit, Hospital Universitario La Paz, IdiPAZ, Madrid, Spain*
Email: mariabutiferret@gmail.com

Background and aims: The end point of treatment for chronic hepatitis D (CHD) is HBsAg loss and/or HDV-RNA undetectability, but these end points are difficult to achieve. An intermediate virological end point of ≥2log decline in HDV-RNA has been considered in clinical trials. However, the impact of this response on the progression of the disease remains unknown. The aim of this study was to evaluate the impact of ≥2log declines in HDV-RNA remaining detectable on the development of clinical events in patients with CHD.

Method: Multicenter study including 80 patients with CHD (all with baseline detectable HDV-RNA) who during the follow-up had consecutive HDV-RNA determinations, which allowed to categorize them into three groups according to HDV-RNA kinetics: Group A) persistently stable levels of HDV-RNA, Group B) ≥2 log HDV-RNA decline but remaining detectable (intermediate end point), Group C) achievement of undetectable HDV-RNA. The clinical outcomes (liver decompensation, hepatocellular carcinoma (HCC), transplantation or liver-related death) were analysed. Biochemical (ALT) and virological (HBV-DNA, HDV-RNA) parameters were also compared.

Results: Most patients were male (53.8%), Caucasian (83.8%), median age 46 years and 74% on nucleos (t)ide analogues. Thirty (37.5%) had cirrhosis, and 5 (6%) history of a prior liver decompensation. During a median follow-up of 5.3 (3.1–7.2) years, 42 (52%) subjects had stable HDV-RNA levels, 15 (19%) had a ≥2log decline with detectable HDV-RNA, and 23 (29%) became undetectable. Overall, 19 patients developed clinical events during follow-up. All events occurred while presenting persistently detectable HDV-RNA levels: 13/42 (31%) in HDV-RNA stable subjects (Group A), 3/15 (20%) before reaching ≥2log decline (Group B) and 3/23 (13%) before reaching undetectable HDV-RNA (Group C). After these virological end points, none of the patients with ≥2log decline remaining detectable or undetectable HDV-RNA developed liver-related complications (Figure). Five (13.2%) subjects with undetectable HDV-RNA lost HBsAg during follow-up (p = 0.001). When only the 30 subjects with cirrhosis were analysed, those with a posterior ≥2log decline tended

HDV-RNA end points	N total	Number of patients with a liver-related outcome during follow-up	
		Before end point	After end point
Group A) Persistently detectable	42	13 (31%)* Δ *Follow-up: 6.7 ± 5.4 years*	
Group B) ≥2log decline but detectable	15	3 (20%) *Follow-up: 10.2 ± 7.2 years*	0 (0%)* *Follow-up: 2.1 ± 3.0 years*
Group C) Undetectable	23	3 (13%) *Follow-up: 4.1 ± 4.3 years*	0 (0%) Δ *Follow-up: 0.7 ± 0.8 years*

*Follow-up: mean (SD), *p = 0.01, Δp = 0.002*

Figure: (abstract: WED-168).

to a lower decompensation rate than those with HDV-RNA permanently detectable (1/7 vs 8/17, p = 0.149), although the risk of developing HCC (1/7 vs 2/17, p = 0.664) was similar. Globally, the risk of clinical events in cirrhotic subjects (decompensation, HCC, mortality/transplantation) also tended to be lower in those with a ≥2log decline in HDV-RNA than in stable subjects (2/7 vs 10/17, p = 0.185).

Conclusion: In this cohort, only patients with stable and persistent HDV-RNA levels present clinical events. No clinical events were observed after patients reached a virological end point. More studies with a larger number of patients and a longer follow-up are needed. This project has been financed by Instituto de Salud Carlos III (PI20/01692).

WED-169

Neglible 10-year risk of liver-related events in chronic hepatitis B patients with low liver stiffness

Lesley Patmore[1], Kirsi van Eekhout[2], Ozgur Koc[3], Robert De Knegt[1], Bettina Hansen[4], Harry LA Janssen[1,5], Matthijs Kramer[3], Honkoop Pieter[6], Robert De Man[1], Bart Takkenberg[2], Milan Sonneveld[1]. *[1]Erasmus MC, Gastroenterology and hepatology, Rotterdam, Netherlands; [2]Amsterdam UMC, locatie AMC, Gastroenterology and Hepatology, Amsterdam, Netherlands; [3]Maastricht UMC+, Gastroenterology and Hepatology, Maastricht, Netherlands; [4]Erasmus MC, Epidemiology and Biostatistics, Rotterdam, Netherlands; [5]Toronto General hospital, Toronto Centre for Liver Disease, Canada; [6]Albert Schweitzer Hospital, Gastroenterology and hepatology, Dordrecht, Netherlands*
Email: l.patmore@erasmusmc.nl

Background and aims: Patients with chronic hepatitis B (CHB) are at increased risk of hepatocellular carcinoma (HCC) and liver-related mortality. We aimed to study the long-term risk of HCC development and liver-related mortality in relation to the first liver stiffness measurement (LSM).

Method: We conducted a multicentre retrospective cohort study of all consecutive mono-infected CHB patients who underwent at least one LSM by transient elastograhpy with FibroScan (Echosens, France) whilst off antiviral therapy. We analysed the association between liver stiffness as a continuous variable, and after categorization (<or >9 kPa), with liver-related events, defined as the first of a composite end point of HCC, liver transplantation or liver-related mortality.

Results: We analysed 1102 patients with a median age of 38 years (inter quartile range [IQR] 30–48), predominantly male (53%) and non-Asian (67.5%). The median LSM was 5.3 kPa (IQR 4.3–7.2); 164 patients had an LSM >9 kPa. During a median follow-up of 5.6 years (IQR 2.7–9.3), 12 patients developed an HCC and 10 liver-related deaths were recorded, for a cumulative incidence of 2.3% at 10 years. Higher LSM at study enrolment was associated with an increased risk of liver-related events (hazard ratio [HR] 1.10 per kPa, 95% CI 1.07–1.13, p < 0.001). The cumulative 10-year incidence of liver-related events was 0.7% in patients with a LSM <9 kPa, compared to 9.9% in patients with a LSM >9 kPa (HR 14.62, 95% CI 4.71–45.41, p < 0.001). These results were consistent for patients who subsequently received antiviral therapy (n = 504, p < 0.001) and in patients with an initial HBV DNA >20 000 IU/ml (p = 0.016). LSM >9 kPa was independently associated with an increased risk of liver-related events when adjusting for age, sex, ethnicity, ALT and use of antiviral therapy (adjusted HR 8.9, 95% CI 2.70–29.63, p < 0.001).

Conclusion: An LSM <9 kPa at baseline is associated with negligible 10-year risk of liver-related events in CHB patients. An LSM >9 kPa identifies patients at increased risk of liver-related events who could potentially benefit from treatment with novel antivirals.

WED-170

Steadily decline of HBV DNA load under NAs in lymphoma patients and higher level of qAnti-HBc predict HBV reactivation

Yi-Qi Liu[1], Reyizha Nuersulitan[2], Chi Zhang[1], Wei Ping Liu[2], Hong Zhao[1], Gui-Qiang Wang[1]. *[1]Peking University First Hospital, China; [2]Peking University Cancer Hospital, China*
Email: zhaohong_pufh@bjmu.edu.cn

Background and aims: Patients with lymphoma and hepatitis B virus infection need to be treated with both chemotherapy and nucleotide analogues therapy. However, the dynamic change of HBV DNA level with the increase of chemotherapy cycles is lacking. Quantitative hepatitis B core antibody (qAnti-HBc), HBV RNA, and hepatitis B virus core-related antigen (HBcrAg) are more sensitive markers to evaluate HBV replication in recent years. It is unknown whether these markers are more sensitive to predict HBV reactivation.

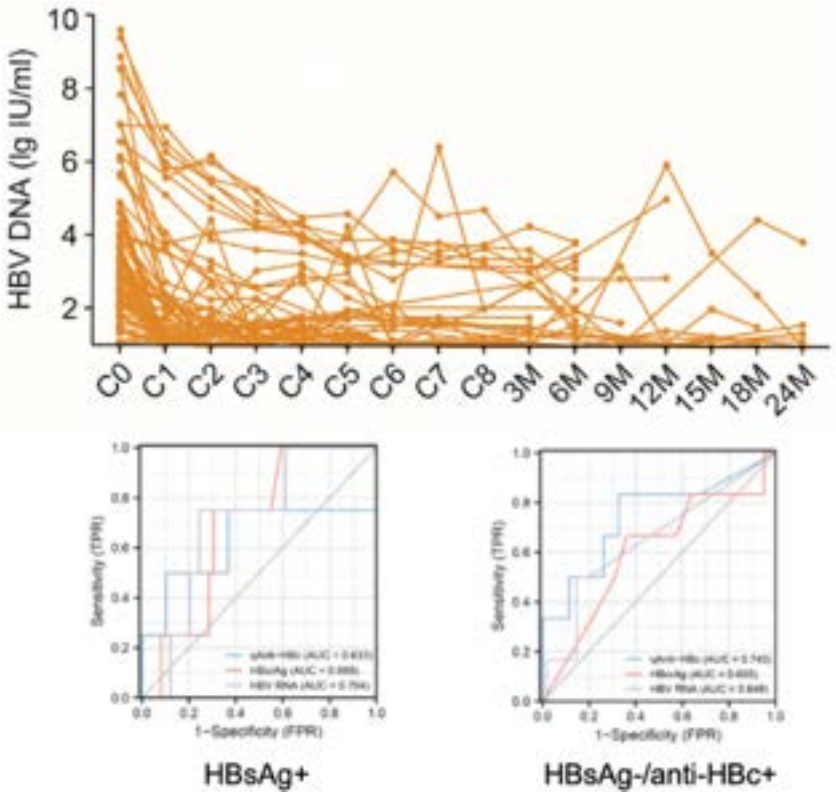

Figure: (abstract: WED-170).

Method: From 29th June 2010 to 6th December 2021, clinical data and serial serum sample were collected from patients with diffuse large B lymphoma and HBV infection. Serum HBV DNA load (real time fluorescent quantitative PCR), qAnti-HBc (developed chemiluminescent particle immunoassay), HBV RNA (simultaneous amplification testing method (HBV-SAT) based on real-time fluorescence detection), and HBcrAg (Lumipulse G HBcrAg assay) were tested before and during chemotherapy. Factors related to HBV DNA reactivation were analyzed by Logistic regression analysis.
Results: Under the NAs, HBV DNA load of 69 with baseline DNA positive HBsAg+ patients declined from 3.15 (2.13–4.73) lg IU/ml at baseline to 1.00 (1.00–1.75) lg IU/ml at the end of chemotherapy, and further declined to 1.00 (1.00–1.04) lg IU/ml at the end of 24-month follow-up. Serum qAnti-HBc level decreased gradually during chemotherapy in HBsAg positive lymphoma patients (F = 7.090, p = 0.009). The levels of serum HBV RNA and HBcrAg stabled under the chemotherapy. Multivariate analysis revealed that a higher level of qAnti-HBc (1.97 ± 1.20 vs. 1.12 ± 0.84 lg IU/ml, OR = 8.367, [95% CI:1.439–48.645], p = 0.018) and a higher level of HBV RNA (0.86 (0.00–1.94) vs. 0.00 (0.00–0.00) lg copies/ml, OR = 3.654, [95% CI:1.208–11.048], p = 0.022) were related to HBV reactivation in HBsAg-/anti-HBc+ lymphoma patients.
Conclusion: The load of HBV DNA declined steadily by NAs under the chemotherapy in all lymphoma patients. In HBsAg – /anti-HBc+ lymphoma patients, higher level of baseline serum qAnti-HBc and HBV RNA predict the HBV reactivation during chemotherapy.

WED-171

Liver stiffness measurement as a non-invasive method for the diagnosis of liver cirrhosis in patients with chronic hepatitis D virus infection

Lisa Sandmann[1,2,3], Kerstin Port[1], Pietro Lampertico[2,4,5], Soo Aleman[2,6,7], Markus Cornberg[1,2,3,8,9], Benjamin Maasoumy[1,8], Heiner Wedemeyer[1,2,3,8], Katja Deterding[1]. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, Milan, Italy;* [6]*Karolinska University Hospital, Department of Infectious Diseases, Stockholm, Sweden;* [7]*Karolinska Institute, Department of Medicine Huddinge, Infectious Diseases, Stockholm, Sweden;* [8]*German Center for Infection Research (DZIF), Hannover/Braunschweig, Germany;* [9]*Center for Individualised Infection Medicine, Helmholtz Center for Infection Research, Germany*
Email: sandmann.lisa@mh-hannover.de

Background and aims: Liver biopsy is the gold standard for the diagnosis of liver cirrhosis. Recently, non-invasive tests (NIT) for determining liver cirrhosis have been proposed as an alternative. Chronic hepatitis D virus infection (CHD) is a rare disease, but associated with high risk of liver cirrhosis. The evidence of NIT for diagnosing liver cirrhosis in this etiology has not been adequately studied due to lack of correlation with histologic findings.
Method: We retrospectively evaluated the diagnostic performance of liver stiffness measurement (LSM) by transient elastography (Fibroscan) for the detection of liver cirrhosis in a cohort of 144 patients with CHD and available liver biopsies. Data was collected from two different German sites and one multicenter clinical trial. LSM was performed within 6 months of liver biopsy, laboratory data was assessed on the day (± 30 days) of LSM. Results were compared to the serological tests AST to ALT ratio (AAR), AST to platelet ratio (APRI), and fibrosis 4 index (FIB-4). Area under the receiver operating characteristic (AUROC) curves was used to assess the performance of NIT, Youden-Index was used to select optimal cut-offs.
Results: Based on histological findings, three groups were defined: Cirrhosis (Metavir 4/Ishak ≥5, n = 22), no cirrhosis (Metavir ≤1/Ishak ≤2, n = 58) or intermediate fibrosis (Metavir 2–3/Ishak 3–4, n = 64).

Mean LSM was significantly higher in patients with liver cirrhosis compared to those without it (23.4 vs 10.2 kPa, $p < 0.0001$) or intermediate fibrosis (23.4 vs 13.5 kPa, $p < 0.0001$). For the detection of liver cirrhosis LSM was superior to other NIT with an AUROC of 0.89 as compared to 0.74 (APRI), 0.73 (FIB-4) and 0.69 (AAR), respectively. The optimal cut-off value of LSM for identifying patients with liver cirrhosis was >15.2 kPa (sensitivity 0.91, specificity 0.84, NPV 0.98, PPV 0.50). With this cut-off, liver cirrhosis was correctly diagnosed in 20 of 22 patients and correctly excluded in 102 of 104 patients. When excluding patients with ALT >5×ULN, the PPV improved slightly to 55.6%. However, the false positive rate remained high as 15.5% of patients without cirrhosis had an LSM of >15.2 kPa. These patients were more likely to have advanced liver disease with histological staging of Metavir 3 (30% vs 14.7%), lower platelet levels (185 vs 137 ×1000/µl, $p < 0.001$) and higher levels of gammaGT (109 vs 44 U/L, $p = 0.015$). The ideal cut-off to exclude advanced fibrosis (Metavir ≥3/Ishak ≥4) was <10.2 kPa (sensitivity 0.55, specificity 0.86, NPV 0.45, PPV 0.90). 56 of 62 patients were correctly identified as having no advanced fibrosis. The six misclassified patients were all Metavir 3.

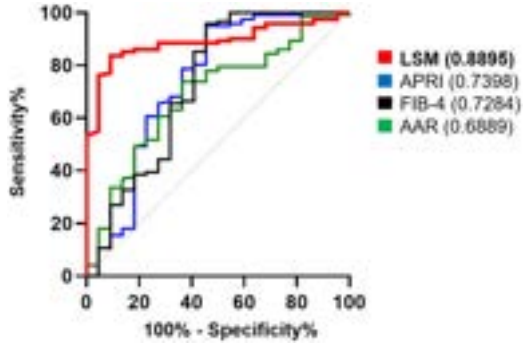

Figure: ROC curves of LSM compared to serological markers for the differentiation of liver cirrhosis defined by histology staging (METAVIR 4/ISHAK 5–6) from absence of liver cirrhosis (n = 144).

Conclusion: LSM is a useful NIT to identify patients at risk for liver cirrhosis and is superior to APRI, FIB-4 and AAR. The cut-off of <10.2 kPa correctly excluded liver cirrhosis in all patients while the cut-off of >15.2 kPa correctly identified liver cirrhosis in 91% of patients.

WED-172

Distribution of the natural history stages of pregnant women with chronic hepatitis B virus infection and its association with pregnancy complications and adverse pregnancy outcomes

Xuelian Zhang[1], Yunfei Gao[2], Jinna Li[3], Xueru Yin[1], Yaohua Hao[1], Shimin Yin[1], Jingran Wu[4], Xiaohuan Jiang[1], Jialin Li[1], Jing Hu[5], Zhihua Liu[1]. *[1]Nanfang Hospital, Southern Medical University, Department of Infectious Diseases, Guangzhou, China; [2]Zengcheng Branch of Nanfang Hospital, Southern Medical University, Department of Obstetrics and Gynaecology, Guangzhou, China; [3]Jiangmen Central Hospital, Department of Infectious Diseases, Jiangmen, China; [4]Nanfang Hospital, Southern Medical University, Department of Obstetrics and Gynaecology, Guangzhou, China; [5]Zhujiang Hospital, Southern Medical University, Department of Nosocomial Infection Administration, Guangzhou, China*
Email: zhihualiu@126.com

Background and aims: A large number of pregnant women are living with Hepatitis B virus (HBV). However, there is limited data on the natural history stages of pregnant women with chronic HBV infection. In this study, we aimed to describe the distribution of natural history stages of HBV infection and explore its relationship to pregnancy complications and adverse pregnancy outcomes.

Method: From Jan. 2015 to Aug. 2022, a total of 1276 pregnant women with chronic HBV infection were enrolled in this study. The natural course stages were defined based on AASLD 2018 Hepatitis B Guidance. Patients who cannot be classified into any of the stages are defined as 'grey zone' (GZ), which was classified into three groups: HBeAg positive, regardless of Alanine aminotransferase (ALT) and HBV DNA levels (GZ-A); HBeAg negative, with normal ALT levels and serum HBV DNA $\geq 2 \times 10^3$ IU/ml (GZ-B); HBeAg negative, with elevated ALT levels and serum HBV DNA $\leq 2 \times 10^3$ IU/ml (GZ-C). Logistic regression analysis was used to examine the relationship between natural course stages and pregnancy complications and adverse pregnancy outcomes.

Results: (1) A total of 1276 pregnant women with CHB were enrolled, with 19.04%, 14.73%, 42%, 4.39%, and19.44% of them in immune-tolerant CHB, HBeAgpositive immune active CHB, inactive CHB and HBeAgnegative immune active CHB, and grey zone CHB, respectively. Among pregnant women in the grey zone, GZ-A, GZ-B and GZ-C accounted for 19.76%, 49.6% and 30.65%, respectively. (2) There were significant differences ($p < 0.05$) in the incidence of thyroid disease in pregnancy, ICP (intrahepatic cholestasis of pregnancy), caesarean section and LGA (greater than gestational age babies) among pregnant women with different natural history stages. The highest incidence of thyroid disease occurred in HBeAg-negative immune active CHB (7.1%); ICP in HBeAg-positive immune active CHB (7.8%); caesarean section in inactive CHB (40.5%); and LGA in the grey zone (12.9%). (3) Analysis of the three groups of "GZ" showed that the incidence of caesarean section was significantly increased in GZ-B compared to GZ-A (43.1% vs 22.4%, $p = 0.014$); the incidence of neonatal weight abnormalities was significantly higher in GZ-C compared to GZ-A (23.7% vs 8.2%, $p = 0.026$); the incidence of GDM (25.0% vs 13.8%), neonatal weight abnormalities (23.7% vs 7.3%) and LGA (21.1% vs 8.9%) were considerably higher in GZ-C compared to GZ-B ($p < 0.05$).

Figure: (abstract: WED-172): Distribution of natural course stages of pregnant women with CHB (a) and distribution of CHB pregnant women of grey zones (b)

Conclusion: Our study showed that inactive CHB was the most common natural course stage among pregnant women, but nearly one-fifth of CHB patients were classified as GZ. The risk of pregnancy complications and adverse pregnancy outcomes varied by natural history stage. Pregnant women with CHB should be closely monitored and managed to further prevent adverse pregnancy outcomes.

WED-173

Comparison of hepatitis B reactivation in patients with resolved hepatitis B infection receiving rituximab or non-rituximab based immunosuppressive therapy: does presence of hepatitis B surface antibody reduce the risk of reactivation?

Wei-Lun Liou[1], Gayathry Morvil[1], Rajneesh Kumar[1]. [1]*Singapore General Hospital, Gastroenterology and Hepatology, Singapore*
Email: liouweilun@gmail.com

Background and aims: Hepatitis B virus (HBV) reactivation and flare may happen in patients with resolved HBV infection (Hepatitis B surface antigen negative, anti-HBc antibody positive) who receive immunosuppressants or chemotherapy. In comparison to Rituximab, most drugs only confer low to medium risk of HBV reactivation to this group of patients. The presence of hepatitis B surface antibody may reduce the risk of HBV reactivation. We compared the outcome of patients with resolved HBV infection who received rituximab or non-Rituximab immunosuppressive therapy and explored the utility of hepatitis B surface antibody in these patients.

Method: We retrospectively collected data of patients who were followed up at HBV immunosuppression clinic at Singapore General Hospital from 2016 to 2022. The lower limit of quantification of HBV DNA was 10 IU/ml. HBV reactivation (HBVr) is defined as a new detectable HBV DNA from previously undetectable DNA. HBV flare is defined as raised alanine aminotransferase of >3 times of upper limit normal in the presence of detectable DNA.

Results: Total 153 patients who did not receive prophylactic nucleoside analogue (NA) were included in the study. There were 70 male patients. The median age of patients was 64 years (IQR 15). The median duration of follow-up following initiation of immunosuppression was 21.4 months (IQR 25.5). 112 patients received non-rituximab therapy, and 41 patients received rituximab therapy. 11 patients in each group developed HBVr. Patients who received rituximab therapy had higher risk of HBVr when compared with non-rituximab group (26.8% vs 9.8%, p = 0.011). HBVr resolved without needing NA in 8 patients in the rituximab group, and 7 patients in the non-rituximab group. No patient developed HBV flare during the follow-up. A baseline hepatitis B surface antibody level of more than 100 IU/L was associated with lower risk of HBVr in patients who received rituximab therapy (6.7% vs 41.7%, p = 0.019), but no statistically significant difference in non-rituximab therapy patients (8.8% vs 9.8%, p = 0.573).

Conclusion: Although the risk of HBVr was higher in patients receiving rituximab therapy, none of the patients developed HBV flare and HBVr resolved spontaneously in the majority. A hepatitis B surface antibody level of more than 100 IU/L may confer additional protection against HBVr in patients receiving rituximab therapy. Regular monitoring instead of prophylactic NA should be considered in this specific group of patients, as well as patients receiving non-rituximab therapy.

Orsola- Malpighi, Infectious Diseases Unit, Bologna, Italy; [15]Bambino Gesu Pediatric Hospital, Rome, Italy
Email: massimo.puoti@ospedaleniguarda.it

Background and aims: HDV causes the most severe liver disease and suppressive antiviral treatment was recently available for this infection. PLWH are at risk of HDV infection. The factors related to HDV infection and its natural history in PLWH have poorly investigated. In order to assess the need for suppressive anti HDV treatment in PLWH, this retrospective case control study investigates the prevalence, risk factors, clinical correlates and the long-term outcome of people with HDV infection in a large prospective cohort of Italian PLWH naïve for antiretroviral therapy the multicenter prospective ICONA cohort (Italian Cohort of Naïve for Antiretrovirals).
Method: We retrieved from the database or measured anti HDV reactivity in all HBsAg pos PLWH with an available serum sample: HDVRNA reactivity was tested by Robogene 2.0 (LOD: 6 IU/ml) in all anti HDV pos with an available serum sample. We compared demographic and clinical data between different groups and calculated Hazard Ratio (HR and Adjusted HR AHR) for Liver Related Hard Outcomes (LRHO: Liver decompensation, HCC, liver transplant or Liver Related Death whatever occurred first) from fitting a Cox regression model.
Results: 152/809 HBsAg pos PLWH (18.8%) showed anti HDV reactivity. They were significantly ($p < 0.01$) less frequently female (7.9% vs 18.1%), more frequently IDU (67.1 vs 15.8%), more frequently anti HCV pos (66 vs 16%), less frequently HCVRNA pos (11 vs 15%) and more frequently showed FIB-4 >3.25 (25 vs 11%). A significantly lower proportion of anti HDV pos pts was still on follow-up in 2022 (23 vs 42%). HDV viremia was detected in 63/95 (68%) anti HDV pos patients. PLWH with HDVRNA reactivity showed more frequently a FIB4>3.25 (34 vs 9.7%) without significant differences in other characteristics. 25/95 were still on follow-up in 2022 (25 HDVRNA+ vs 28% HDVRNA-). HR and aHR for LRHO are reported in the table.

Table: Hazard Ratio (HR) and Adjusted HR (AHR) of developing liver failure (ESLD, HCC or Liver related death) after first HDV screening from fitting a Cox Regression model

		95%				95%		
HDV Status	HR	CI		P	AHR*	CI		P
HDVAb neg	1.00				1.00			
HDVAb pos/HDV-RNA miss	4.68	1.81	12.09	0.001	2.05	0.68	6.15	0.200
HDVAb pos/HDV-RNA neg	3.87	1.28	11.75	0.017	1.53	0.42	5.60	0.523
HDVAb pos/HDV-RNA pos	6.60	3.08	14.14	<0.001	4.08	1.69	9.86	0.002

Conclusion: One out of five HBV/HIV coinfected individuals had been infected with HDV; they were more frequently male IDU with HCV Ab pos/HCV RNA neg, suggesting a suppressive effect of HDV on HCV replication. Globally, 12% showed coinfection with 4 viruses (HIV, HBV, HDV, HCV). Both previous and active HDV infection are related to advanced liver disease. Only active HDV infection is related to a higher incidence of LRHO on follow-up. Pharmacological suppression of HDV replication may improve the prognosis in PLWH with active HDV replication.

WED-175

Detection of hepatitis delta virus in seminal fluid and female genital tract

Oyungerel Lkhagva-Ochir[1], Saruul Enkhjargal[2], Anir Enkhbat[3], Nyamtsengel Vangan[4], Naranjargal Dashdorj[3], Odgerel Oidovsambuu[5]. *[1]Liver center, Ulaanbaatar, Mongolia; [2]National university of mongolia, Ulaanbaatar, Mongolia; [3]Liver center, Ulaanbaatar, Mongolia; [4]Mongolian national university of medical sciences, Ulaanbaatar, Mongolia; [5]National University of Mongolia, Department of Chemical and Biological Engineering, Ulaanbaatar, Mongolia*
Email: l.oyungerel@onomfoundation.org

Background and aims: Mongolia has the highest prevalence of the hepatitis D virus (HDV), leading to high morbidity and mortality from liver diseases and HCC. HDV causes the most severe form of chronic viral hepatitis. In a recent study, it was estimated that anti-HDV prevalence is 67.5% among HBsAg positive population in Mongolia. The prevalence of HDV infection is relatively high among sexually active and young people, thus, the virus might be transmitted during sexual intercourse. Therefore, it is important to confirm the possibility of sexual transmission of HDV by detecting HDV-RNA in the semen and vaginal secretions of patients with chronic hepatitis Delta.
Method: From October 2022 to December 2022, patients from Liver Center, Ulaanbaatar, Mongolia were asked to enroll in this study. A total of 26 patient, (male 18, female 8, aged 23–48 years old) participated in the study. The average age of all participants is 36.5 years and 94% of them are married. The males and females were to refrain from sexual activity for at least 48 hours prior to test. Females also were recommended to do not use any intravaginal products for at least 48 hours prior to the collection of vaginal/cervical swab specimens. The seminal fluids were collected in a sterile container by masturbation. Vaginal/cervical specimens were collected by rubbing with nasopharyngeal swab dedicated for a molecular biology test. Viral RNA was extracted by … and presence of HDV-RNA was detected subsequently by real time RT-PCR analysis.
Results: In male group, 38.8% (7/18) of seminal fluid samples were positive and in female group, 87.5% (7/8) of vaginal/cervical swab samples were positive. This result indicates that HDV is more likely present in genital cavity of female patients than in seminal fluid of male patients. For male group, correlation between HDV RNA existence in seminal fluid and serum RNA level was not observed. In contrast, female group has a correlation between HDV RNA existence in genital tract and serum RNA level. HDV-RNA was not detected in the sample from only one woman, who had low number of HDV RNA in her serum sample (197IU/ml).
Conclusion: HDV RNA can be detected in seminal fluid of male patient and in genital tract of female patient. This result is solid evidence to indicate the possible risk of sexual transmission of HDV. In the future, we need to study in more detail.

HDV RNA in the blood serum, seminal fluid and genital tract of male and female patients

	Participants	Sex	Age	RT-PCR in blood serum		RT-PCR in seminal fluid and genital tract	
				Ct value	IU/mL	Ct value	IU/mL

Email: rsalpini@yahoo.it

Background and aims: Serum HBV-RNA quantification reflects the burden of virions containing pre-genomic RNA (pgRNA) and is used as surrogate marker of cccDNA transcriptional activity. Here, we define HBV-RNA levels across the natural history of HBV infection, including the under studied phase of occult HBV infection (OBI) and the levels after long-term NUC exposure.
Method: This study includes 106 treatment-naive patients (pts) categorized in 17 eAg+ with chronic infection (CI), 7 with eAg+ chronic hepatitis (CH), 50 with eAg- CI and 32 with eAg- CH according to EASL guidelines. 38 eAg- virologically suppressed pts under long-term NUC treatment and 28 Anti-HBc+/HBsAg- pts (HIV-coinfected with a serological status compatible with OBI) are also included. Serum HBV-RNA is quantified by droplet digital PCR (ddPCR) targeting pgRNA (LOQ: 5 copies (cps)/ml).
Results: eAg+ CI and CH have elevated HBV-RNA levels (median [IQR]: 7.5 (4.3–8.3) and 7.1 (6.5–7.5) log cps/ml) in line with high HBV-DNA and HBsAg production (median [IQR] HBV-DNA: 9.2[6.4–9.9] and 8.9 [8.7–9.2] log IU/ml; HBsAg: 20,895 [6,778–72,608] and 52,518 [30,059–80,056] IU/ml).
HBV-RNA undergoes a significant decrease in eAg- phases, achieving the lowest levels in eAg- CI (median [IQR]: 0.6 [0.2–1.4] in eAg- CI vs 2.0 [1.2–2.3] log cps/ml in eAg- CH, $P < 0.001$), paralleling the declining trend of HBV-DNA and HBsAg. In both eAg- phases, HBV-RNA correlates with HBV-DNA (Rho = 0.49, $P < 0.001$ for eAg- CI and Rho = 0.33, $P = 0.06$ for eAg- CHB) while no correlation with HBsAg is revealed (Rho = 0.2 and 0.12, $p > 0.2$), consistent with HBsAg production from integrated HBV-DNA. Notably, by AUROC, HBV-RNA <50 cps/ml shows the best accuracy in predicting the status of eAg- CI (sensitivity: 87.5%, specificity: 71%). In virologically suppressed pts (median [IQR] NUC duration: 6.0 [4.1–9.1] years), HBV-RNA is positive in 78.9% of pts with a median of 1.7 (1.4–2.0) log cps/ml. Notably, the rate of HBV-RNA positivity and HBV-RNA levels remain stable independently from NUC duration, suggesting no decline in intrahepatic HBV activity over prolonged therapy (73.3%, 75% and 90% for NUC duration of <5, 5–9 and ≥9 years, with median [IQR] HBV-RNA of 1.7 [1.5–1.9], 1.4 [1.2–1.4] and 1.8 [1.6–2.3] log cps/ml). Finally, HBV-RNA is also positive in 32.1% of Anti-HBc+/HBsAg- pts (median [IQR]: 1.1 (0.9–1.3) log cps/ml), supporting occult viral activity despite HBsAg negativity.
Conclusion: The production of pgRNA-containing viral particles predominates during the initial phases of chronic infection and decreases after HBeAg-seroconversion. In this context, HBV-RNA can enhance the categorization of chronic HBV infection including the eAg- infection status. The ultra-sensitive HBV-RNA quantification can detect minimal viral activity in the setting of long-term NUC treatment or OBI, providing added value in the identification of patients achieving functional cure.

WED-177

Study of hepatitis delta virus replication markers in anti-HBc positive patients with chronic hepatitis C

Antonio Madejón[1,2], Miriam Romero[1,2], Araceli García-Sánchez[1], Antonio Olveira Martin[1,2], Pilar Castillo[1], José Carlos Erdozaín[1], Francisco Javier Garcia-Samaniego Rey[1,2]. *[1]Hepatology Unit, Hospital Universitario La Paz, Madrid, Spain; [2]Centro de Inverstigación Biomédica en Red (CIBER), Spain*
Email: javiersamaniego@telefonica.net

Background and aims: Recent works have identified antibodies and genome sequences from the hepatitis delta virus (HDV) in patients

with chronic hepatitis C (CHC) in absence of any marker of infection with hepatitis B virus (HBV). The objective of this work was to analyze the prevalence of active HDV infection (positive for HDV genome) in patients with chronic hepatitis C with evidence of past exposure to HBV.

Method: A cohort of 129 anti-HBc positive patients was retrospectively analyzed, 20 of whom (15%) were positive for anti-HBs antibodies. Seventy-seven patients (60%) were Caucasian and 52 (40%) Sub-Saharan. Regarding co-infection markers, 65 (50%) were HIV positive, with HIV-RNA positivity in 20/65 (31%), and 92 (71%) were anti-HCV positive with detectable HCV-RNA in 23/92 (25%) patients. Fibrosis stage (TE) was: F0-F1 in 42/129 (33%), F2 in 16 (12%), F3 in 5 (4%), F4 in 15 (12%) and indetermine in 51 (39%) patients. All patients were analysed for the presence of anti-HDV antibodies and delta antigen (HDAg) using commercial kits. The presence of HDV-RNA was also analyzed by in-house RT-PCR. A longitudinal follow-up was performed in those HDV-RNA positive patients, in order to analyze the evolution of HDV viremia. The complete coding region of HDAg was amplified in at least one sample. The presence of HBsAg and HBV-DNA was also confirmed.

Results: Anti-HDV antibodies were detected in 8 (6%) patients. The prevalence of anti-HDV was higher in anti-HCV positive than in negative patients [7/92 (8%) vs 1/37 (3%), respectively; p = 0.03]; in HIV-negative patients compared to positives [6/64 (9%) vs 2/65 (3%), respectively; p = 0.1); and in Caucasian vs Sub-Saharan patients [7/77 (9%) vs 1/52 (2%), respectively; p = 0.09). HDAg and HDV-RNA were detected in only 1 patient, who was HCV-RNA positive, HIV negative, and from sub-Saharan origin. The entire coding region of HDAg was amplified. HDV-RNA positivity was confirmed in three sequential samples of this patient taken every 6 months, showing slight fluctuations in viral load (2,540, 1,250, and 6,450 copies/ml, respectively). HBV-DNA and HBsAg were not detected.

Conclusion: These results suggest that active HDV viral replication can be detected in patients with detectable HCV-RNA in the absence of any marker of active HBV infection. Whether HDV replication process is sustained by low levels of HBsAg expression or by interaction with HCV must be further investigated.

WED-178

Long-term outcomes of a population-based cohort of chronic hepatitis B (CHB) patients in West Africa

Gibril Ndow[1], Yusuke Shimakawa[2], Damien Leith[3], Sulayman Bah[1], Rohey Bangura[1], Lamin Bojang[1], Amie Ceesay[1], Queen Bola-Lawal[1], Alhagie Touray[1], Abdoulie Jatta[1], Jainaba Barry[1], Fatou Bintou Nyassi[1], Gabriel Lambert[4], Amelia Cook[5], Patrick Ingiliz[6], Sheikh Omar Bittaye[7], Yazan Haddadin[8], Erwan Vo Quang[1], Stéphane Chevaliez[9], Gavin Cloherty[10], Gora Lo[11], Coumba Toure-Kane[11], Isabelle Chemin[12], Ramou Njie[7], Dalessandro Umberto[1], Mark Thursz[4], Maud Lemoine[4]. *[1]MRC Unit The Gambia at LSHTM, Gambia; [2]Institut Pasteur, France; [3]Glasgow Royal Infirmary, United Kingdom; [4]Imperial College London, United Kingdom; [5]Cicely Saunders Institue, United Kingdom; [6]APHP Henri-Mondor University Hospital, France; [7]School of Medicine, University of The Gambia, Gambia; [8]University of Sussex, United Kingdom; [9]Hopital Henri Mondor, France; [10]Abbott Labs, United States; [11]IRESSEF, Senegal; [12]U1052 INSERM, France*
Email: gndow@mrc.gm

Background and aims: Longitudinal data in untreated chronic hepatitis B (CHB) infected patients in Africa who are ineligible for antiviral therapy is scarce and urgently needed to inform treatment and monitoring guidelines adapted to this population.

We assessed the long-term clinical outcomes of a population-based cohort of CHB subjects in West Africa.

Method: Between 2019 and 2021, all CHB patients enrolled in the PROLIFICA cohort between 2011 and 2014 in The Gambia and Senegal were invited for reassessment of liver disease using fasting liver stiffness measurement (LSM) (Fibroscan), abdominal ultrasound, HBV DNA measurement (Abbott, USA), HBsAg and HBeAg serologies, liver enzymes, and full blood count.

This analysis focused on untreated participants in The Gambia who were ineligible for antiviral therapy at baseline according to the 2012 EASL criteria. Number of deaths was collected using death certificates and verbal autopsy to assess mortality rate. Liver disease progression was defined as the proportion of patients who: (i) became eligible for antiviral therapy according to the 2017 EASL treatment criteria; and/or (ii) developed clinically significant fibrosis (LSM≥7.8 kPa) or cirrhosis (LSM≥9.5 kPa); and/or (iii) developed hepatocellular carcinoma (HCC).

Results: At baseline, 93 of 943 participants fulfilled EASL treatment criteria or received antiviral therapy, leaving 850 patients who were ineligible and untreated. After a median follow-up of 6.0 years (IQR: 5.5–6.8), 279 (32.8%) participants were lost to follow-up (LTFU) and 27/850 (3.2%) died, including 10 liver-related deaths, giving an overall mortality rate at 584/100,000 person-years (IQR: 400–852). After adjusting for sex and age, baseline APRI ≥2 was a strong predictor of overall mortality (OR: 7.2 (1.7–31.3), p = 0.008). 544/850 (64.0%) had a full liver reassessment: 321/544 (59.0%) were males, median age: 41 (37–48) years, median BMI: 22.8 (20.1–26.1) kg/m^2, and none reported excessive alcohol intake. Most participants (348/544 (64.0%)) were considered as inactive chronic carriers. 131/544 (24.0%) had viral load ≥2000 IU/ml, 49/541 (9.1%) had an ALT level ≥40 IU/L and 36/540 (6.7%) had significant liver fibrosis including 13 (2.4%) with cirrhosis and 1 with decompensated cirrhosis. Incidence of HBsAg loss was 0.69 (23/544, CI 0.46–1.04) and higher among females (OR: 2.56 (1.03–6.34) p = 0.042). Amongst 544 patients reassessed, no HCC was detected but 39 (7.2%) had liver disease progression: 3.3% newly eligible for treatment and 3.9% had liver fibrosis progression, including 15/540 (2.8%) new cirrhotic patients. Amongst patients with no significant liver fibrosis at baseline, 32/492 (6.5%) had liver disease progression including 13 (2.6%) cases of cirrhosis. In multivariate analysis after adjusting for sex and age, baseline HBV DNA viral load ≥2000 IU/ml was associated liver disease progression (OR 2.8, 95%CI: 0.9–8.5, p = 0.027).

Conclusion: This longitudinal study, the first of its kind in Africa, indicates that the number of liver events is not negligible in ineligible and untreated CHB patients, suggesting that monitoring should be maintained with a special focus on patients with viral load ≥2000 IU/ml.

WED-179

Incidence of hepatitis D virus super-infection in HBsAg positive patients (The Inci-D cohort study)

Patrick Ingiliz[1,2,3], Erwan Vo Quang[1,4], Maud Lemoine[4,5], Amie Ceesay[4,6], Gibril Ndow[4], Marie-Noëlle Hilleret[7], Anne Laure Mazialivoua[1], Yusuke Shimakawa[8], Alhagie Touray[4], Jean-Michel Pawlotsky[2,9], Isabelle Chemin[6], Stéphane Chevaliez[2,9], Vincent Leroy[1,2]. *[1]APHP Henri-Mondor University Hospital, Hepatology, Créteil, France; [2]Inserm U955, Créteil, France; [3]Maison Medicale Chemin Vert, Paris, France; [4]MRC The Gambia Unit @ LSHTM, Gambia; [5]Imperial College London, London, United Kingdom; [6]Cancer Research Center of Lyon (CRCL), INSERM U1052, CNRS UMR-5286, Lyon, France; [7]University Grenoble-Alpes, Grenoble, France; [8]Institut Pasteur, Paris, France; [9]APHP Henri-Mondor University Hospital, Virology, Créteil, France*
Email: patrick.ingiliz@aphp.fr

Background and aims: Super-infection with the hepatitis D virus (HDV) leads to a more aggressive form of chronic hepatitis in patients infected with the hepatitis B virus (HBV). While around 5% of HBsAg-positive individuals are estimated to be HBV-HDV dually infected globally, the timepoint of super-infection is unknown and longitudinal repeated HDV testing is not yet supported by international guidelines. HDV infection occurs most likely parenterally or sexually and depends on the individual's particular risk. In most cases, it remains unclear when super-infection has occured. Inci-D is a collaborative multicenter and longitudinal cohort study that aims

to evaluate the incidence of HDV super-infection in HBsAg chronic carriers from West Africa and Europe.
Method: The Inci-D cohort consists of two distinct HBV cohorts of clinical meta-data and stored clinical specimens including plasma or dried-blood spots (DBS). Cohort A is a West African cohort derived from the PROLIFICA population-based study in The Gambia. Cohort B is a French cohort including out-patients seen in two university hospitals (Grenoble Alpes and Henri Mondor APHP). The HBsAg positive patients' first available stored blood sample was used to calculate the baseline prevalence. HDV-antibody (HDVAb) levels were detected using the Diasorin serology kit (Italy). The incidence rate was calculated using the most recent available blood sample. Here, we present preliminary results from cohort A.
Results: For cohort A, 942 blood samples (915 plasma, 27 DBS) of HBsAg-positive individuals were available at baseline. The median age was 35 years (interquartile range (IQR): 31–43), 592/942 (63%) were male, the median ALT levels were 24 U/L (IQR: 19–31), and the median HBV DNA level was 1.90 Log IU/ml (IQR:1–2.6). At baseline, 14/942 individuals (1.5%) were HDVAb-positive: median age 37 years (IQR: 34–57), 7/14 (50%) male, median ALT levels 21 U/L (IQR: 18–33), and median HBV DNA level 1.2 Log IU/ml (IQR:1–2.2). Among HDVAb-negative patients at baseline, 566 individuals had a follow-up sample available (520 plasma, 46 DBS) with an overall follow-up time of 3363 patient-years. After a median follow-up time of 6.0 years (IQR: 5.5–6.8), 8 individuals were detected to be newly HDVAb-positive, representing an incidence rate of 2.37/1000 patient-years. The HDV prevalence at follow-up was 2.1%, indicating a 40% increase from baseline. Median age at of HDV super-infected patients was 35 years (IQR: 34–57), 88% were male. Analyses on cohort B are ongoing and will be presented.
Conclusion: Hepatitis delta superinfection increases considerably in HBsAg-positive carriers in an intermediate HDV prevalence setting, putting patients at risk for advanced liver disease and death. In order to identify individuals with need for treatment or surveillance, repeated HDV serology testing should be implemented by international guidelines.

WED-180

Significant heterogeneity in long-term risks of cirrhosis or hepatocellular carcinoma among a national cohort of U.S. veterans with non-cirrhotic, treatment naïve chronic hepatitis B in the immune tolerant phase

Zeyuan Yang[1], Ramsey C. Cheung[2], Robert Wong[2]. *[1]VA Palo Alto Health Care System, United States; [2]Stanford University School of Medicine, VA Palo Alto Healthcare System, Palo Alto, United States*
Email: rwong123@stanford.edu

Background and aims: Patients with chronic hepatitis B (CHB) in the "immune-tolerant" phase are not typically recommended for routine antiviral therapy. However, risk of progression to cirrhosis or HCC persists, and debate remains as to whether antiviral therapy is beneficial in certain subsets of this population. We aim to evaluate long-term risks of cirrhosis or HCC among non-cirrhotic, treatment-naïve CHB patients with alanine aminotransferase (ALT) <70 U/L and whether disparities in cirrhosis or HCC risk exist.
Method: Using data from the U.S. National Veterans Affairs database from 2010 to 2022, Veterans with treatment-naïve, e-antigen (eAg) positive CHB with baseline ALT <70 U/L and minimum 12 months of follow-up were identified. Patients with concurrent HIV, hepatitis C, or hepatitis delta infections were excluded. Patients with cirrhosis or HCC at baseline or within 6 months of study entry were excluded. Incidence of cirrhosis or HCC (per 100 person-years) was stratified by patient demographics, clinical characteristics, and baseline HBV DNA (<20 000 IU/ml (Low-DNA), 20 000–10^7 IU/ml (Intermediate-DNA), and >10^7 IU/ml (High-DNA). Patients were censored at development of cirrhosis or HCC, death, initiation of antiviral therapy, or end of follow-up period. Comparisons of cirrhosis or HCC incidence between groups utilized the z-statistic using standard equations.
Results: Among 3,526 Veterans with treatment-naïve CHB and ALT <70 U/L, 19.2% (n = 678) were eAg positive, among whom 91.0% were men, 39.2% African American, 36.6% non-Hispanic white, 20.0% Asian, 4.2% Hispanic, mean age 53 ± 14, 69% had Low-DNA, 13% had Intermediate-DNA, and 18% had High-DNA. Overall incidence of cirrhosis was 1.22 per 100 person-years (95% CI 0.89–1.56) and incidence of HCC was 0.21 per 100 person-years (95% CI 0.07–0.35). Compared to patients with Low-DNA, there was a trend towards higher risk of cirrhosis in patients with Intermediate DNA (2.21 vs. 1.02 per 100 person-years, p = 0.07), but no difference in risk of HCC was observed by baseline HBV DNA. Older age was associated with higher risk of cirrhosis and HCC. Patients with diabetes had significantly higher incidence of cirrhosis (2.49 vs. 0.96 in patients without diabetes, per 100 person-years, p < 0.01). Compared to patients with baseline FIB-4 score <1.45, patients with FIB-4 >3.25 had higher incidence of cirrhosis (5.94 vs. 0.67 per 100 person-years, p < 0.01) and HCC (0.73 vs. 0.27 per 100 person-years, p < 0.05).
Conclusion: Among a national cohort of treatment-naïve, eAg positive patients with non-cirrhotic CHB and baseline ALT <70 U/L, overall long-term risk of cirrhosis or HCC remains low. However, older age, presence of diabetes, and baseline FIB-4 > 3.25 was associated with significantly higher risks of disease progression. Identifying "high risk" features among "immune tolerant" CHB patients may identify individuals that would benefit from earlier treatment initiation.

Contrasting immune fingerprints of chronic hepatitis B Virus infection in adults from South Africa and the United Kingdom

Marion Delphin[1], Louise Downs[2,3], Emily Martyn[1,4], Gavin Kelly[1], Marije Van Schalkwyk[5,6], Susan Hugo[5,7], Elizabeth Waddilove[1], Cori Campbell[2], Tingyan Wang[2,8], Sheila Lumley[2,3], Catherine De Lara[2], Dominique Goedhals[9,10], Christo van Rensburg[5,6], Sue Wareing[3], Polly Fengou[3], Jacqueline Martin[3], Monique Andersson[2,6], Ivana Carey[11], Azim Ansari[2], Wolfgang Preiser[5,7], Shiraaz Gabriel[5,7], Jantjie Taljaard[5,6], Eleanor Barnes[2,3], Tongai Gibson Maponga[12], Philippa Matthews[1,2,13,14]. *[1]The Francis Crick Institute, LONDON, United Kingdom; [2]Nuffield Department of Medicine, Medawar Building for Pathogen Research, University of Oxford, Oxford, United Kingdom; [3]John Radcliffe Hospital, Department of Infectious Diseases and Microbiology, oxford, United Kingdom; [4]London School of Hygiene and Tropical Medicine, United Kingdom; [5]Tygerberg Academic Hospital, South Africa; [6]Stellenbosch University, Faculty of Medicine and Health Sciences, Cape Town, South Africa; [7]Stellenbosch University, South Africa; [8]NIHR Oxford Biomedical Research Centre, University of Oxford, Oxford, United Kingdom; [9]PathCare Vermaak, South Africa; [10]University of the Free State, South Africa; [11]Institute of Liver Studies, King's college Hospital, United Kingdom; [12]Division of Medical Virology, Faculty of Medicine and Health Sciences, Stellenbosch University, South Africa; [13]University College London, Division of Infection and Immunity, United Kingdom; [14]University College London Hospital, Department of Infectious Diseases, United Kingdom*
Email: marion.delphin@crick.ac.uk

Background and aims: Hepatitis B Virus (HBV) interaction with the immune system is a key determinant of infection outcome. As the HBV field advances towards novel therapies (amongst which immunoregulatory drugs), enhanced risk stratification, and cancer prevention, there is a pressing need to better understand the immunological profiles that underlie diverse disease outcomes. Unfortunately, while accounting for almost 70% of all HBV infections worldwide, African populations have been neglected in clinical studies. We set out to compare circulating levels of ten cytokines, alongside host demographics and viral biomarkers, in cohorts based in the United Kingdom (UK) and South Africa (SA).
Method: Serum samples were obtained from adult patients enrolled at Oxford University Hospitals, UK (n = 60), and the Tygerberg Hospital in Cape Town, SA (n = 32) with chronic HBV monoinfection (ethics ref.N17/01/013). HBsAg, HBeAg and HBV VL were estimated using standard clinical laboratory protocols, and HBcrAg were quantified using a chemiluminescent assay (Lumipulse G HBcrAg assay, Fujirebio). GM-CSF, IFNa2a, IL-2, IL-6, IL-8, IL-10, IL-21, IP-10, PD-1 and TNF-a were quantified using multiplex ELISA (K151AEL-1, MesoScaleDelivery). Patient meta-data were recorded at the time of

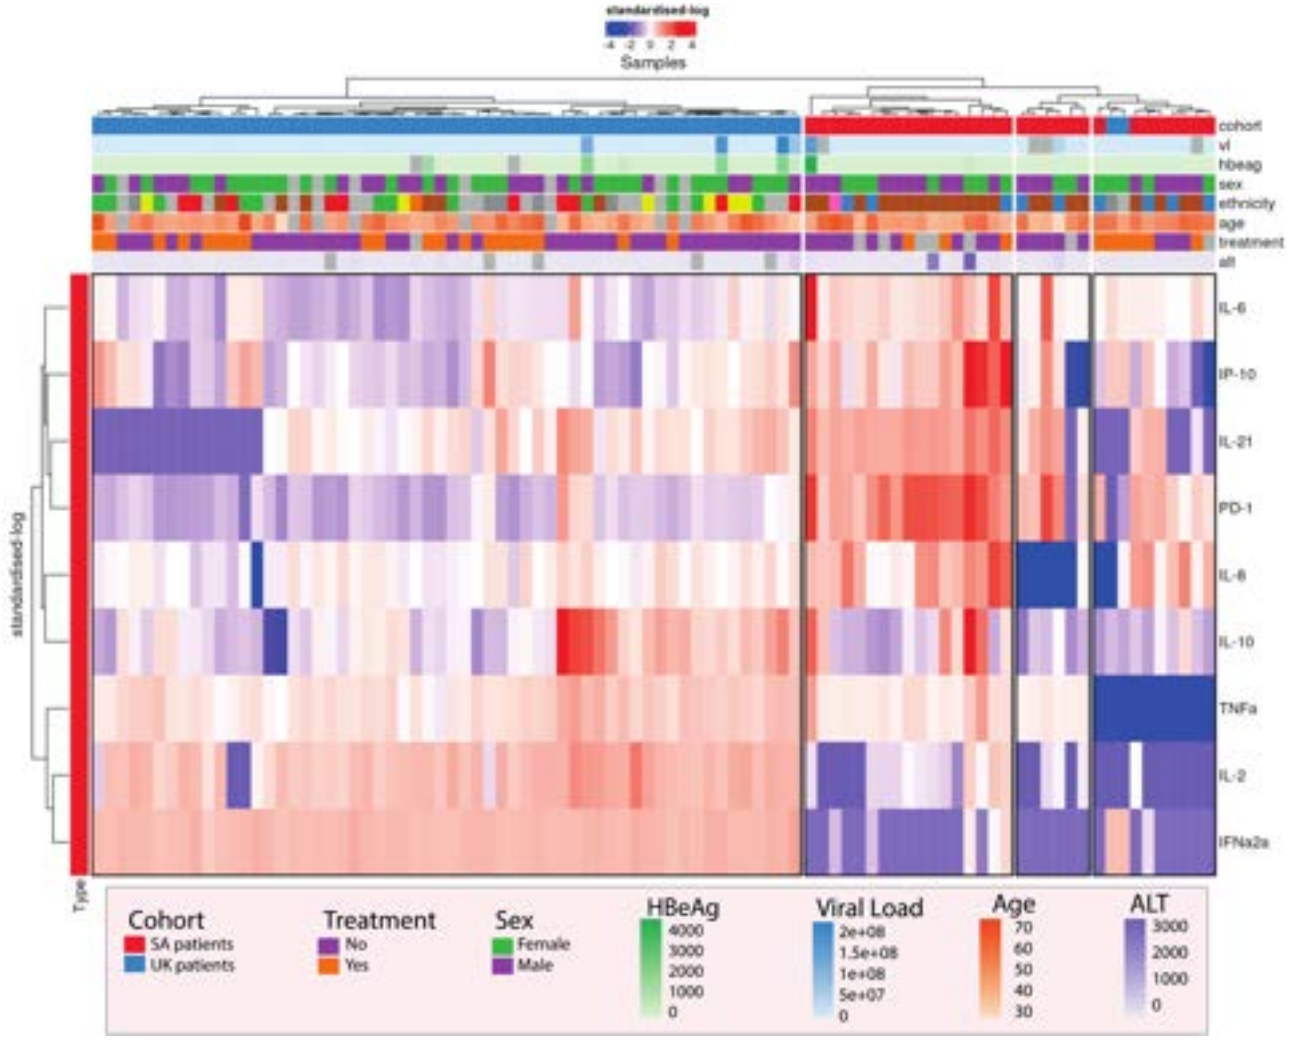

Figure: (abstract: WED-181): Log-standardised heatmap representation of data representing adults with chronic HBV mono- infection (SA cohort in red and UK in blue).

recruitment, supported by Electronic Patient Records where available. For the analysis, using a euclidean distance, samples were hierarchically clustered based purely on standardised log-transformed cytokine measurements using Ward's method for linkage. P values were calculated using Mann Witney test in Prism v. 8.0.
Results: There were no significant differences between the two cohorts in terms of age ($p = 0.09$), sex ($p = 0.07$) or treatment ($p = 0.61$). HBV related biomarkers were comparable between the two cohorts, including HBcrAg ($p = 0.06$), viral load ($p > 0.99$), HBeAg status ($p = 0.74$) and ALT ($p = 0.81$). However, the two cohorts presented distinct immune profiles. The SA cohort is dominated by a decreased level of IL-2, IL-10 and IFNa2a, while IP-10, PD-1 and IL-6 are increased ($p < 0.0001$ for all except IFNa2a, $p = 0.09$) compared to the UK cohort. These clusters did not co-vary with other attributes of the patient, markers of infection or treatment (Figure 1). Of note, the SA cohort could be subdivided into three immune profiles, but without any significant differences.
Conclusion: In this study, CHB patients from SA and the UK have distinct immune profiles, which are not clearly related to other host features or laboratory characteristics of infection. At present, it is unclear if these differences are attributable to host characteristics, viral genetics, exposure to treatment, or other environmental influences. Our data highlight the need for further population-based studies to unravel the diversity in immune profiles. Enhanced understanding of the mechanisms that determine disease outcomes and treatment response are needed to support interventions that reduce the burden of liver disease associated with HBV.

WED-182

Dried blood spot (DBS): a new tool for screening, diagnosis and monitoring of hepatitis D virus (HDV) infection

Rola Matar[1], Alexandre Soulier[1], Valérie Ortonne[1], Olivia Garrigou[1], Pierre Cappy[1], Vincent Leroy[2], Jean-Michel Pawlotsky[1], Stéphane Chevaliez[1]. *[1]French National Reference Center for Viral Hepatitis B, C and delta Department of Virology and INSERM U955, Hôpital Henri Mondor, Université Paris-Est Créteil, France; [2]Department of Hepatology and Inserm U955, Hôpital Henri Mondor, Université Paris-Est Créteil, France*
Email: rola.matar@aphp.fr

Background and aims: Hepatitis D virus (HDV) infection is one of the major public health concerns worldwide. Globally, it is estimated that 5 to 10% of chronic HBsAg carriers are co-infected with HDV. Hepatitis Delta infection can lead to a rapid disease progression towards cirrhosis and hepatocellular carcinoma. The diagnosis of HDV infection is crucial for the management of the disease. Dried blood spot (DBS) sampling is a useful tool for the collection, storage, and shipment of whole blood specimens. The current study was designed to evaluate the performance of standardized HDV diagnostic and monitoring tools in analyzing samples from DBS.
Methods: Paired plasma and whole blood specimens collected using the DBS technique from 110 individuals including 74 patients followed in a tertiary care center and 36 blood donors were tested for virological markers (anti-HD and HDV RNA detection as well as HDV genotype determination) used to diagnose and monitor HDV infection.
Results: Immuological assay detection of anti-HD antibodies in specimens from DBS was reliable after the establishment of a new signal-to-cutoff ratio (0.2545 and 0.2340 using LIAISON XL murex Anti-HDV from DiaSorin and HDV Ab from DIA.PRO assays, respectively). These optimal cutoffs were associated with specificities of 97.5% and 87.5% and sensitivities of 93.1% and 94.2% for the respective assays. HDV RNA viral load was detected from DBS in the vast majority of patients with active replication using the EurobioPlex HDV qRT-PCR assay, but HDV RNA levels were substantially lower than those detected in the corresponding plasma specimens. The mean HDV RNA detected in whole blood was 1.2 Log IU/disk lower compared to plasma. HDV genotype determination using phylogenetic analysis of a part of *R0* region of the delta antigen was achieved in DBS samples with 100% concordance with results obtained from plasma specimens.
Conclusion: This study has shown that whole blood specimens collected on DBS can be used to diagnose and to monitor HDV infection. DBS specimen collection is a clinically relevant tool for improving the access to hepatitis D diagnosis around the world.

WED-183

The role of PAGE-B score in predicting the development of hepatocelular cancer in patients with chronic delta hepatitis

Onur Keskin[1], Cagdas Kalkan[2], Bengi Ozturk[3], Aysun Caliskan[2], Hasan Sahin[4], Mesut Gumussoy[2], Esra Yurdcu[5], Mithat Bozdayi[5], Murat Akyildiz[6], Mujdat Zeybel[6], Ramazan Idilman[5], Cihan Yurdaydin[6]. *[1]Hacettepe University School of Medicine, Gastroenterology, Ankara, Turkey; [2]Ankara University School of Medicine, Gastroenterology, Ankara, Turkey; [3]Hacettepe University School of Medicine, Gastroenterology, Turkey; [4]Hacettepe University School of Medicine, Internal Medicine, Turkey; [5]Ankara University Hepatology Institute, Ankara, Turkey; [6]Koc University School of Medicine, Gastroenterology, Turkey*
Email: onurkeskin81@gmail.com

Background and aims: The aim of this study is to determine the effectiveness of the PAGE-B score in predicting the development of hepatocellular cancer (HCC) in chronic delta hepatitis (CDH) patients.
Method: 124 CDH patients (88 males/36 females; mean age: 40.3 ± 10; 28 cirrhotic-96 noncirrhotic) who received interferon therapy for at least 6 months and had a median follow-up of 115 (12–144) months were included in the study. Patients received median 2 (1–8) episodes of interferon (IFN) therapy. Patients who were found to be HDV RNA negative at the end of 2 years following the end of treatment were considered interferon responsive (n:40). PAGE-B scores of all patients were recorded using previously recorded baseline clinical and laboratory parameters. The clinical and laboratory parameters and PAGE-B scores of the patients who developed and did not develop HCC during the follow-up period were compared and the role of the PAGE-B score in the prediction of HCC in patients with CDH was evaluated.
Results: HCC developed in 21 (18M/3F) patients during the follow-up period. When the patients who developed and did not develop HCC were compared, it was found that the patients who developed HCC were older (47.4 ± 7.5 vs 38.8 ± 10.2; $p < 0.01$) and had higher GGT values (121 ± 68 vs 71 ± 74; $p < 0.01$). It was observed that HCC developed more frequently in patients with cirrhosis and those who did not respond to IFN (55% cirrhotics vs 11% in noncirrhotics; $p < 0.01$ and 7.5% in IFN-responders vs 21% in IFN-non-responders; p:0.04). By multivariate analysis, age, presence of cirrhosis and GGT level were independent predictors of HCC development. Patients who developed HCC had higher PAGE-B scores than patients who did not develop HCC (15.9 ± 3.4 vs 11.3 ± 4.6; $p < 0.01$). Using receiver operating characteristic (ROC) analysis with Youden index, a PAGE-B cut-off score of 13 predicted HCC development with 81% sensitivity, 60% specificity and area under ROC curve of 0.79. Only one patient with a PAGE-B score of <10 developed HCC on a median follow-up of close to 10 years.

Conclusion: PAGE-B score predicts HCC in CDH with a similar strength to that reported for chronic hepatitis B

WED-184

Identification and external validation of the optimal ALT thresholds for ruling in significant histologic disease in chronic hepatitis B

Zhiyi Zhang[1], Jian Wang[2,3], Li Zhu[4], Yilin Liu[1], Xiaomin Yan[2], Yuanwang Qiu[5], Chuanwu Zhu[4], Jie Li[1,2,3], Chao Wu[1,2,3], Rui Huang[1,2,3]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China; [2]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China; [3]Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, Jiangsu, China; [4]Department of Infectious Diseases, The Affiliated Infectious Diseases Hospital of Soochow University, Suzhou, Jiangsu, China; [5]Department of Infectious Diseases, The Fifth People's Hospital of Wuxi, Wuxi, Jiangsu, China*

	> Male/Female: 35/25 (2018 AASLD 1× ULN)	278	30	70.0%	89.2%	30/100 (30.0%)
	Male/Female> 30/19	336	48	52.0%	85.7%	48/100 (48.0%)
	> Male/Female: 70/50 (2018 AASLD 2× ULN)	136	9	91.0%	93.4%	9/100 (9.0%)

Figure: (abstract: WED-184): Scatterplots showing PPVs, specificities (A) and misdiagnosis rates (B) of ALT cut-offs for ruling in significant histologic disease.

of treat-naïve patients with chronic hepatitis B (CHB). We aimed to explore the optimal ALT threshold for ruling in and ruling out significant liver inflammation and fibrosis in CHB patients.
Method: CHB patients underwent liver biopsy were retrospectively included from four hospitals. Patients from two canters were randomly divided into a training and internal validation set, and patients from two other hospitals comprised the external validation set. The grid-search method was used to determine the cut-offs in the training set with the aim of achieving a specificity and positive predictive value (PPV) of at least 90% for ruling in significant histologic disease. Additionally, the cut-off values were aimed to have a sensitivity of 90% and a negative predictive value exceeding 95% for the exclusion of significant histologic disease. Optimal cut-off values were subsequently validated in both the internal and external validation sets for accuracy. Significant histologic disease was defined as liver inflammation ≥G2 or liver fibrosis ≥S2 according to Scheuer scoring system.
Results: In proportions of significant histologic disease in the training set (n = 548), internal validation set (n = 235) and external validation set (n = 483) were 77.9%, 75.7% and 79.3%, respectively. The optimal ALT value of 77.3 U/L had a specificity and PPV of 90.22% and 91.9%, respectively, and misclassified only 12 of 121 (9.9%) patients with non-significant histologic disease in the training set. The performance of the newly optimal cut-off of ALT was significantly better than several previous cut-offs of >40 U/L (2017 EASL ULN), male >35 U/L or female >25 U/L (2018 AASLD 1 × ULN), male>30 U/L or female>19 U/L, slightly better than the cut-off of male >70 U/L or female >50 U/L (2018 AASLD 2 × ULN). The specificity and PPV of the newly optimal cut-off of ALT were all above 90% in two validation sets with a misclassification rate of 7% in the internal validation set, and 8% in the external validation set. Regrettably, the cut-offs of ALT to rule out significant histologic disease could not be found.
Conclusion: The newly identified threshold (≥77.3 U/L) of ALT had high specificity, PPV and low misclassification rate in ruling in CHB patients with significant histologic disease. The well-validated threshold of ALT could help the antiviral treatment decisions for treat-naïve CHB patients by accurately ruling in significant histologic disease.

WED-185
Predominance of genotype 5 hepatitis delta virus infection in a Portuguese centre

Mariana Cardoso[1], Joana Branco[1], Henrique Coelho[1], Sofia Bragança[1], Gonçalo Alexandrino[1], Mariana Costa[1], Rita Carvalho[1], Elizabeth Padua[2], Alexandra Martins[1]. *[1]Hospital Prof. Doutor Fernando Fonseca, Gastroenterology, Portugal; [2]National Health Institute Doutor Ricardo Jorge, Portugal*
Email: marianafcardoso@gmail.com

Background and aims: Hepatitis delta virus (HDV) infection is the most severe form of viral hepatitis. Genotype (GT) 1 is by far the most prevalent in Europe and globally, while GT5 predominates in Western Africa. Data about HDV seroprevalence in Portugal are scarce and no genotyping studies have been performed to date. We aimed to analyse the seroprevalence of HDV in our centre and to characterize seropositive patients, including HDV genotyping.
Method: Patients followed in our Hepatology clinic between 2012 and 2022 for hepatitis B virus (HBV) infection, defined as positive HBsAg (HBV surface antigen), were retrospectively included. Patients seropositive for HDV and actively followed were subjected to cross-sectional analysis, including blood sample collection. RNA was extracted from the patients' plasma and complementary DNA (cDNA) was synthetized before being submitted to PCR amplification of the 3′-terminal part of the HD (hepatitis delta) gene of HDV. The fragments obtained were analysed by electrophoresis, purified, sequenced and genotyped using an international public database. Clinical, laboratory and imaging data from this subgroup were collected.
Results: From a total of 835 HBsAg positive patients (age 48.3 ± 15.2 years; 56.6% male), 665 (79.6%) had been tested for total anti-HDV antibody. Portuguese patients represented 35.9% of total (n = 300), while the majority originated from African countries (57.5%, n = 480). The overall HDV seroprevalence was 43/665 (6.5%). Seroprevalence per country/area of origin was 3.0% in Portugal, 12.0% in Central and Eastern Europe and 8.3% in Africa, being as high as 20.3% in Guinea-Bissau. Seropositive patients were younger than the seronegative (41.3 vs 48.9 years, p < 0.001).
From the 43 seropositive patients, 21 were included in further studies (age 41.2 ± 9.9 years; 57.1% male). Most patients were HBeAg-negative (85.7% at baseline and currently 95.2%). Advanced chronic liver disease was present in 7 patients (33.3%), including 5 with liver stiffness (LS) ≥14 kPa, one with Ishak score of 5/6 and one with imaging findings of cirrhosis and cholangiocarcinoma. Median LS was 7.8 kPa. Most patients (71.4%) were treated with nucleos (t)ide analogs for HBV. One third of patients (7/21) had been treated with peginterferon (HDV clearance: 2; non-response: 4; intolerance: 1). In the current cross-sectional study, HDV RNA was positive in 8/21 (38.0%) patients, 3 of which had previously been classified as RNA negative using a commercial assay. HDV was classified as GT5 in 7 patients (6 from Guinea-Bissau and 1 from Cape Verde), and GT1 in one patient (from Ukraine). Five patients recently started therapy with bulevirtide through the national early access program.
Conclusion: In the largest national cohort to date, seroprevalence and genotype distribution of HDV (with predominance of GT5) were strongly influenced by immigration, notably from African countries.

WED-186
Long-term outcomes of patients with chronic HBsAg positive/HBe-negative infection: differences and transition between inactive carriers and low viremic carriers

Giacomo Emanuele Maria Rizzo[1], Gabriele Rancatore[1], Pietro Graceffa[1], Giuseppe Falco[1], Fabrizio Bronte[2], Donatella Ferraro[3], Vincenza Calvaruso[1], Vito Di Marco[1]. *[1]University of Palermo, Section of Gastroenterology and Hepatology, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, PROMISE, Palermo, Italy; [2]Ospedali Riuniti Villa Sofia-Cervello, Gastroenterology Unit, Palermo, Italy; [3]University of Palermo, Section of Virology, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, PROMISE, Palermo, Italy*
Email: gabriele.rancatore@gmail.com

Background and aims: HBsAg-positive/HBeAg-negative Inactive Carrier (IC) with low viral load levels (<2000 IU/ml) has no indication for antiviral treatment, but HBsAg -/HBeAg-negative Low Viremic Carriers (LVC) with viral load between 2000–20 000 IU/ml, belong to a "grey area" of the HBV natural history. IC have a survival comparable to that of the non-infected general population, but it is not clear whether the status of LVC represents a transient phase of low replication in a patient with chronic hepatitis B or whether it is a transition phase to an inactive infection. In this prospective study we evaluated the natural history of a cohort of HBeAg negative patients with viral load <20 000 IU/ml followed from 2007 to 2022.
Method: At baseline all patients were naïve to antiviral treatment and were evaluated for virus status by quantitative HBsAg (qHBsAg) and serum levels of HBV-DNA, and for disease stage by liver stiffness with FibroScan® and serum transaminase values. Every year patients checked HBV-DNA and transaminase values, performed HBsAg and HBs-Ab tests, and measured liver stiffness by fibroscan. Change of virological status was defined as an increase or decrease in the value of HBV-DNA levels compared to the cut-off of 2000 IU/ml in at least two consecutive evaluations. A negative test for HBsAg and a positive test for HBs-Ab was considered a cure for HBV infection.
Results: After the screening, we identified 130 patients (21.6% of the entire cohort of 602 HBsAg positive patients) with HBsAg positive, HBeAg negative, anti-HDV negative, anti-HCV negative, normal transaminase levels and HBV-DNA levels less than 20 000 IU/ml.

We identified 91 IC and 39 LCV and two group showed no significant differences regarding age (49 vs 44 years), sex (63% vs 51% males), liver stiffness (mean 5.7 vs 5.3 kPa), and ALT values (28 vs 32 IU/ml) at baseline. At the end of follow-up (median 84 months, range 24–180) the mean of liver stiffness was of 5.5 kPa. Only 10% CI transited to LVC status and conversely 51% of LVC transitioned to CI status (p < 0.001). During the follow-up 14 patients (10.7%) lost HBsAg and 9 (7%) showed positive HBs-Ab. Furthermore, the identification of IC status had relevant prognostic implications since 15.4% in these patients lost HBsAg compared to no patients in LCV status (p = 0.01). Finally, 14 (25%) of 56 IC with baseline levels of qHBsAg <1000 IU/ml lost HBsAg compared with none of 31 IC with qHBsAg values >1 000 IU/ml

Conclusion: Our data confirm that both IC and LVC had a good prognosis and no risk of progression to advanced liver disease. HBsAg loss is more frequent in the group of patients with HBV-DNA stably lower than 2000 IU/ml and with quantitative HBsAg values lower than 1000 IU/ml. These evidences can serve as a support in the therapeutic decisions of patients with HBV infection.

WED-187

HBV infected pregnant woman received antiviral treatment and discontinued it postpartum can benefit from retreatment

Qiao Tang[1], Chunrui Wang[1], Peng Hu[1]. [1]*The Second Affiliated Hospital of Chongqing Medical University, China*
Email: hp_cq@163.com

Background and aims: There are limited data on effects of antiviral treatment (AVT) pregnant woman with chronic HBV infection. Previous studies focused on ALT flare but not focused on virological changes. Therefore, we aimed to explore the effects of different antiviral treatments during pregnancy on the mother.

Method: This is a retrospective real-world study on chronic HBV infected pregnant women. We compared the incidences of outcome events (Half decrease in HBsAg, HBV-DNA undetectable and HBeAg clearance) around 1 year postpartum in three groups (Group A: Subjects who started AVT before pregnant and continued it postpartum; Group B: Subjects who who received AVT at 24–28 weeks and continued it postpartum; Group C: Subjects who started AVT at 24–28 weeks and discontinued it postpartum, but retreatment because of abnormal ALT (>40 U/L).

Results: A total of 169 chronic HBV infection pregnant women were enrolled in this study, median follow-up time was 18 months. 131 subjects were HBeAg positive and 8 were HBeAg negative, of whom 109 and 7 subjects started antiviral treatment (AVT) at 24–28 weeks, respectively. For those who started AVT but discontinued it postpartum, ALT flare (ALT >80 U/L) was occurred in 20% (1/5) and 29.8% (28/94) in HBeAg negative and positive, respectively (p > 0.05), which was numerically higher than subjects who continued therapy in HBeAg negative (0%, p > 0.05) and positive (9.1%, p > 0.05). ALT flare occurred in 61.5% in group C, significantly higher than 9.1% in group B and 0% in group A. The proportion of half decrease in HBsAg occured in 77.8% in Group C, significantly higher than 20% in group A and comparable with 71.4% in group B. It seems that the proportion was higher in group B than group A (p = 0.058). The proportion of HBV-DNA undetectable was comparable between three groups. However, the proportion of HBeAg clearance occurred in group C (25%) was significantly lower than group A (66.7%). And the proportion was comparable between groups A and B (28.6%), between groups B and C.

Conclusion: Although higher ALT flare occurred in pregnant woman who received AVT at 24–28 weeks and discontinued it postpartum, they can benefit from retreatment because of more significantly HBsAg decrease.

WED-188

Higher risk of disease progression in the gray zone relative to hepatitis B e antigen negative chronic hepatitis B infection

YunLing Xue[1], Peng Hu[1], Xiaoqing Liu[1], Qiao Tang[1], GuoRui Wang[1], JinSong Wang[1]. [1]*The Second Affiliated Hospital of Chongqing Medical University, Department of Infectious Diseases, Institute for Viral Hepatitis, The Key Laboratory of Molecular Biology for Infectious Diseases, Chinese Ministry of Education, China*
Email: hp_cq@163.com

Background and aims: Chronic hepatitis B (CHB) remains a global healthcare burden. Hepatitis B e antigen (HBeAg)negative CHB infectionthe is the commonest CHB phase. However, there are some patients with normal alanine aminotransferase (ALT)and negative e antigen that cannot be clearly defined by the guidelines, which we call the gray zone (GZ). There is still confusion about the evolution of disease progression in the GZ and controversy about the need for antiviral therapy. So we aimed to study the natural history and antiviral treatment of HBe negative CHB infection and GZ.

Method: The study retrospectively enrolled 321 patients who were HBeAg negative and had normal ALT (<40 U/L) without antiviral therapy and without a diagnosis of cirrhosis and hepatocellular carcinoma at baseline.Patients with normal ALT, negative HBe antigen, DNA <2000 IU/ml and without significant liver fibrosis were diagnosed with HBeAg-negative CHB infection according to the European Liver Association guidelines. Patients who did not meet the above diagnosis were defined as gray zone (GZ). Compared the cumulative incidence of outcome events in GZ and HBeAg-negative CHB infection.

Results: At baseline, 211 (65.73%) of 321 patients were defined as HBeAg negative CHB infection and 110 (34.27%)were defined as GZ. By follow-up, 7 (3.32%) of the total 211 HBeAg negative CHB infection

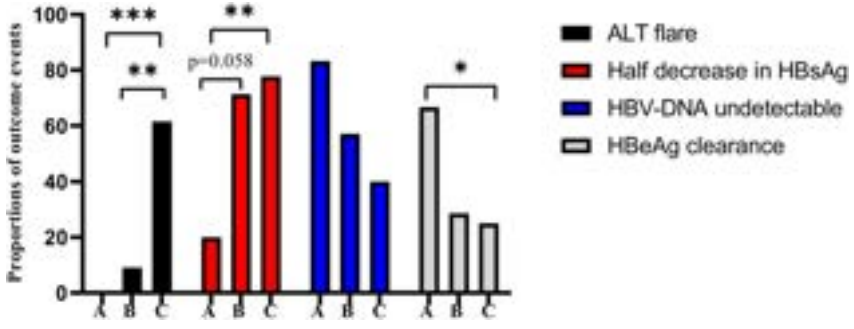

Figure: (abstract: WED-187): X axis represents different groups. Group A: Subjects who started AVT before pregnant and continued it postpartum; Group B: Subjects who who received AVT at 24-28 weeks and continued it postpartum; Group C: Subjects who started AVT at 24-28 weeks and discontinued it post-partum, but retreatment because of abnormal ALT (>40U/L). Y axis represents proportions of different outcome events.

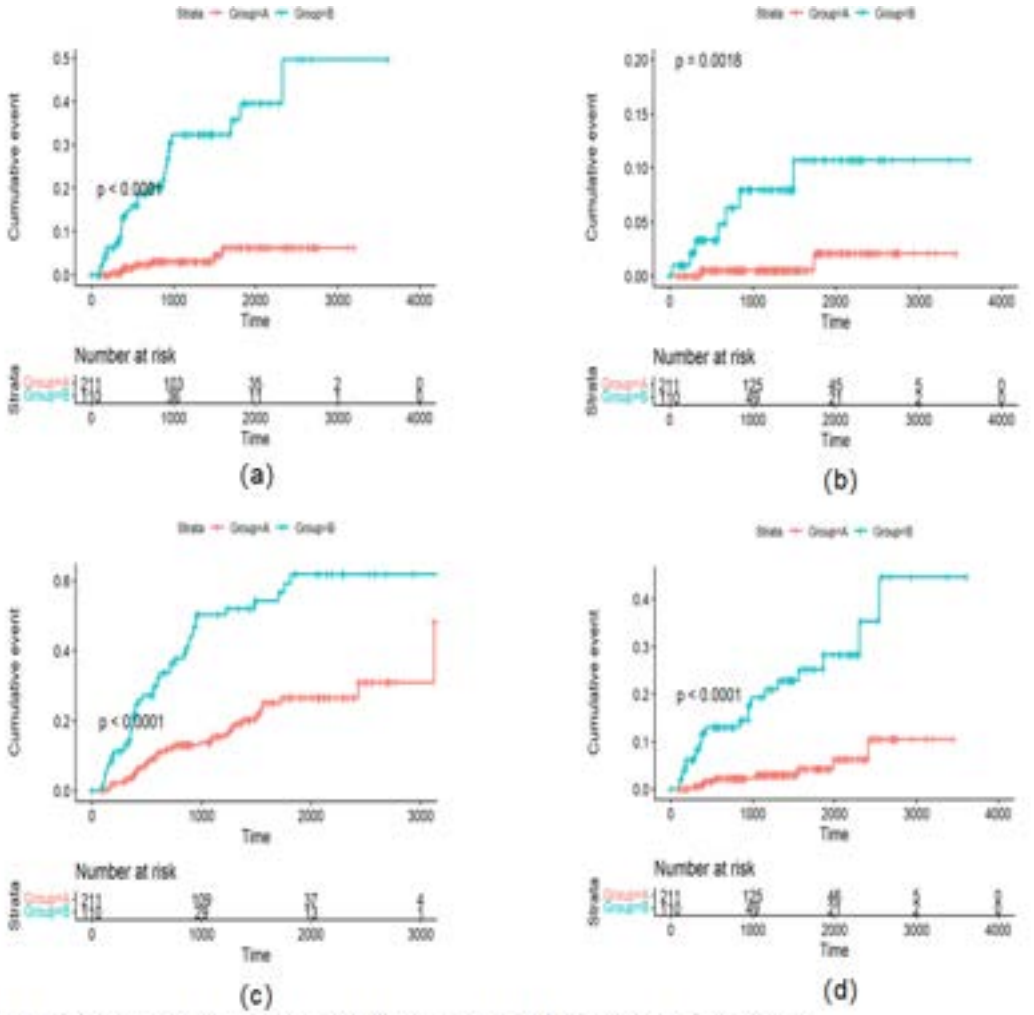

Figure1 The cumulative incidence between Group A(HBeAg-negative CHB infection) and Group B(GZ)
(a)transition to HBeAg-negative chronic hepatitis B and its corresponding gray zone (b)end-stage liver disease (c)elevated ALT (d)antiviral therap

Figure: (abstract: WED-188).

and 27 (24.5%) of the total 110 patients in GZ at baseline transitioned to HBeAg negative chronic hepatitis B and its corresponding gray zone. The cumulative incidence of transitioning was significantly higher in GZ than HBeAg-negative CHB infection ($p < 0.0001$) (Figure 1a). Meanwhile we defined the occurrence of cirrhosis and/or hepatocellular carcinoma suggested by ultrasound as end-stage liver disease. 9 (2.8%) of in our study population (321) had end-stage liver disease events. 7 (77.78%) patients were in GZ and 2 (22.22%) in HBeAg-negative CHB infection. The cumulative incidence of End-stage liver disease was significantly higher in GZ patients than HBeAg negative CHB infection ($p = 0.0018$) (Figure 1b). We also followed up on the occurrence of ALT elevation and antiviral treatment in patients. ALT elevation occurred in 46 (54.8%) patients in GZ and 38 (45.2%) in HBeAg negative CHB infection. Antiviral therapy occurred in 22 (77.3%) patients in GZ and 8 (22.7%)in HBeAg negative CHB infection. The cumulative incidence of ALT elevation and antiviral therapy was significantly higher in GZ than in HBeAg negative CHB infection ($p < 0.001$, $p < 0.0001$) (Figure 1c, Figure 1d).

Conclusion: In summary, we showed that more than 1/3 of of patients were in GZ at baseline. The cumulative incidence of transition to HBeAg negative chronic hepatitis B and its corresponding gray zone, end-stage liver disease, elevated ALT, and initiation of antiviral therapy were all significantly higher in patients with GZ than in HBeAg-negative CHB infection.

WED-189

Analysis of disease progression in patients with chronic hepatitis B using a large nationwide database

Nobuharu Tamaki[1], Masayuki Kurosaki[1], Yutaka Yasui[1], Kaoru Tsuchiya[1], Hiroyuki Nakanishi[1], Namiki Izumi[1]. [1]*Musashino Red Cross Hospital, Japan*
Email: nobuharu.tamaki@gmail.com

Background and aims: Disease progression in patients with chronic hepatitis B remains unclear. In this study, we aimed to investigate disease progression (hepatocellular carcinoma [HCC] development and decompensation) in patients with chronic hepatitis B using a large claims database.

Method: We used a large claims database established by the Japan Medical Data Center (JMDC Co., Ltd. Tokyo, Japan). The database contains monthly claims from medical institutions and pharmacies, thus it includes all ICD code, prescription history, medical practice, etc.. The database contains records of approximately 14 million insured persons. Among these patients, 3 million patients with health examination data from 2016 to 2021 were examined. Of these, 16,676 persons with chronic hepatitis B disease (based on ICD code) were included. The occurrence of new decompensation (encephalopathy, ascites, varices) and HCC during the observation period was examined.

Results: The mean age of the 16676 patients was 51.4 years and 69.2% were male. 3575 (21.4%) were taking nucleic acid analogues (NA). New decompensation occurred in 503 patients (3.0%) and new HCC in 116 patients (0.7%) during the observation period. The 3- and 5-year HCC incidence rates were 0.9% and 1.1%, and the 3- and 5-year decompensation rates were 2.1% and 2.9%. The 5-year HCC incidence was 3.1% and 0.6% in patients with and without NA, respectively. Although patients with NA had a significantly higher incidence of HCC, HCC was also observed in patients without NA. Age, male gender (hazard ratio [HR]:1.7), NA administration (HR:5.3), and alanine aminotransferase (ALT) >20 IU/L (HR:1.5) were significant factors associated with the development of HCC. The 3- and 5-year decompensation rates were 4.1% and 5.2% in patients with NA and 1.5% and 2.1% in patients without NA, respectively. The significant factors associated with decompensation were age, male gender (HR: 1.4), NA administration (HR: 2.4), and ALT >20 IU/L (HR: 1.7). When patients without NA were stratified by ALT level, the 3- and 5-year decompensation rates were 1.3% and 1.8% in patients with ALT ≤20 IU/L and 1.8% and 2.4% in patients with ALT >20 IU/L. The incidence of decompensation was higher in patients with ALT >20 IU/L (p = 0.01).
Conclusion: NA was introduced in high-risk cases for the development of HCC and decompensation. On the other hand, a small number of cases without NA also developed HCC and decompensation, suggesting the need for further verification of the identification of high-risk groups and the criteria for NA administration.

WED-190

The prognosis of hepatitis delta infections in Belgium is poor and determined by the hepatitis delta viremia

Arno Furquim d'Almeida[1,2], Erwin Ho[2], Liesbeth Govaerts[2], Peter Michielsen[2], Thomas Sersté[3], Jean Delwaide[4], Stefan Bourgeois[5], Christophe Moreno[6], Hans Van Vlierberghe[7], Chantal De Galocsy[8], Hans Orlent[9], Michael Peeters[10], Elizaveta Padalko[11], Steven Van Gucht[10], Thomas Vanwolleghem[1,2].

Email: thomas.vanwolleghem@uza.be

Background and aims: Hepatitis B virus (HBV)-hepatitis delta virus (HDV) co-infection is considered the most severe form of chronic viral hepatitis and remains a major global health problem worldwide. Long-term studies that investigate the disease severity are of crucial importance to identify the factors that define the prognosis of this population.
Method: In the present study we retrospectively performed a medical chart review of hepatitis delta patients seen at 8 Belgian hospitals. All relevant data was uniformly collected from July 2001 until January 2023. The inclusion criteria were a) HBsAg or HBV DNA positive at admission; b) anti-HDV or HDV RNA positive; c) at least 1 follow-up visit.
Results: A total of 138 patients were included. The patients were predominantly male (64.5%), had a median age of 36.6 years and had a median follow-up of 5.4 (max 20.4) years. 35.6%, 47.8% and 16.7% of patients respectively were from African, Caucasian and Asian descent. The median AST, ALT and MELD score at admission were 55 (range 9–1735) U/L, 62 (range 13–5463) U/L and 7.9 (range 6–37) respectively. Cirrhosis was diagnosed in 40.6% (52/128) of the patients using liver biopsy (n = 27), liver stiffness measurement (n = 19) or the combination of clinical and radiological findings (n = 6) and did not differ between ethnicity groups (p = 0.06). A total of 33 patients (23.9%) had at least one severe adverse outcome during follow-up: 27 liver decompensations (19.6%), 12 HCC's (8.7%), 10 liver transplantations (7.2%) and 9 deaths (6.5%). Patients of Caucasian ethnicity had more frequently an adverse outcome than the other ethnicities (p = 0.04). The mean age at time of outcome was 48.6 years. The 1-, 5- and 10-year cumulative outcome probability is 8%, 15% and 49% respectively. The last available HDV RNA was positive in 80/120 (66.7%) patients. These patients had a higher AST (89 vs 49 U/L, p <0.001), ALT (121 vs 61 U/L, p <0.001) at admission and had more frequently cirrhosis (46.7% vs 24.3%, p = 0.02) than the patients with a negative last HDV

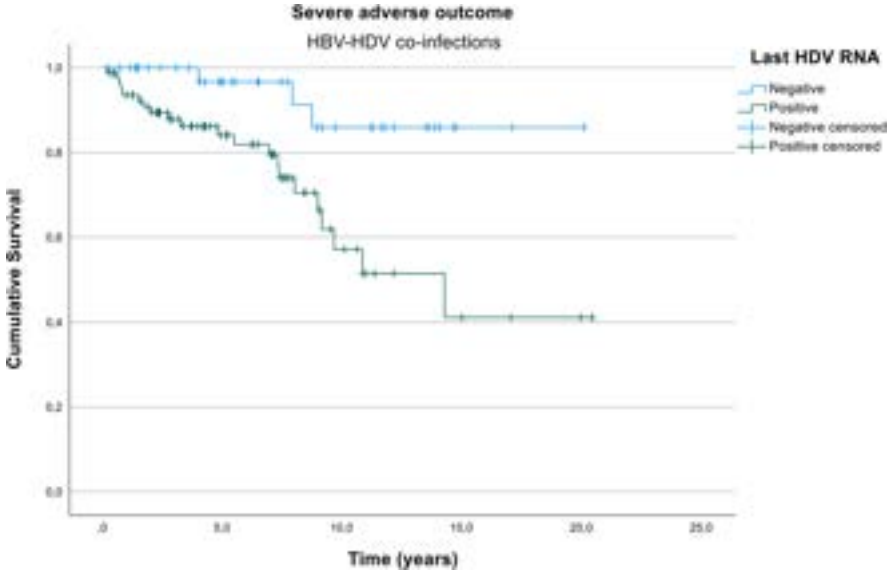

Figure: (abstract: WED-190).

RNA. There was no significant difference in gender (p = 0.11), age (p = 0.74) and MELD score at admission (p = 0.08) between these groups. A detectable HDV viremia at last evaluation was associated with a higher frequency of severe adverse outcomes compared to patients without HDV viremia (1-, 5- and 10-year cumulative outcome probabilities of 10% vs 0%, 18% vs 4% and 59% vs 14% respectively; Kaplan Meier p = 0.005). In addition, having a negative HDV RNA at any point during follow-up was associated with not having an outcome (p = 0.009).

Conclusion: In this real-world national cohort study, approximately half of HBV-HDV co-infected patients develop a severe liver-related outcome within 10 years of diagnosis. Caucasian patients and those with a positive HDV RNA have a worse prognosis during long-term follow-up.

WED-191

Assessment of clinical and patient reported outcome measures in individuals with chronic hepatitis B who clear HBsAg, followed by the Canadian hepatitis B network

Carla Coffin[1,2,3], Magdy Elkhashab[4], Karen Doucette[5], Scott K Fung[6], Alnoor Ramji[7], Hin HIn Ko[7], Carla Osiowy[8], Pamela Crotty[1], Anna Manko[1], Chad Saunders[9], Eric Chan[10], Angelina Villasis Keever[10], TianYan Chen[11], Sebastien Poulin[12], Julie Zhu[13], Mang M[5], Curtis Cooper[14]. *[1]University of Calgary, Department of Medicine, Canada; [2]University of Calgary, Cumming School of Medicine, Calgary, Canada; [3]Cumming School of Medicine, Medicine, Calgary, Canada; [4]Toronto Liver Centre, Canada; [5]University of Alberta, Department of Medicine, Canada; [6]University of Toronto, Department of Medicine, Canada; [7]University of British Columbia, Division of Gastroenterology, Canada; [8]Public Health Agency of Canada, National Microbiology Laboratory, Canada; [9]University of Calgary, Haskayne School of Business, Canada; [10]Janssen Global Services, United States; [11]McGill University Health Centre, Canada; [12]CISSS des Laurentides, Saint-Jérôme, Canada; [13]Dalhousie University, Division of Gastroenterology, Canada; [14]University of Ottawa, Department of Medicine, Canada*
Email: cscoffin@ucalgary.ca

Background and aims: Patient reported outcome measures (PROMs) assessing health-related quality of life (HRQoL) in CHB patients who achieve HBsAg loss compared to untreated HBsAg (+) individuals are not included in most clinical outcome studies.

Method: In this ongoing multi-centre 3-year prospective cohort study we enrolled known CHB patients who achieved HBsAg loss or remained HBsAg (+) but did not require antiviral therapy based on expert guidelines. Subjects consented to serial peripheral blood mononuclear cells and plasma collection for assessment of standard (HBV DNA, qHBsAg, anti-HBs titres) and novel biomarkers, clinical tests (including FibroScan®) and completed a Hepatitis B Quality of Life Questionnaire (HBQOL) and a self-stigma questionnaire at each visit. Data were analyzed using SPSS.

Results: In 77 participants enrolled to date, 42 completed 1 year follow-up (median age 55.3, 95% CI 52.6, 57.9), 41.6% Female, 61% Asian, 17% Black, 17% White. NAFLD and diabetes occurred in 22% (17/77) and 10.4%, (8/77) respectively. 57% had prior antiviral therapy (mean 5 years, 3.3, 6.7). 68% were born endemic area, 29% infant/childhood acquisition, and ~3% adult acquired (sexual, drug use, work related exposure). At enrolment, 65 (84%) were HBsAg (-) (8/65, 12.3% HBV DNA+, median HBV DNA 0.15 log), 12 (16%) were HBsAg+ (qHBsAg 200 IU/ml; 109.4, 292) (median HBV DNA 2.1 log IU/ml), (p = 0.0001). All tested anti-HBs (+), with higher titres after HBsAg loss (i.e., median 0.7 IU/ml (0.3, 2.0) in HBsAg (+) vs. 18.5 IU/ml (3.9, 46.9) in HBsAg (-) group (p < 0.05). All had low risk of liver disease, mean ALT 23 U/L (20.5, 25.6) and mean FibroScan® 5.1 kpA (4.7, 5.4). Participants with recent HBsAg loss reported 28% improvement in range of HRQoL indicators. The largest improvements were in reducing fear of bad outcomes, and smallest improvement was in productivity gains (Figure 1).

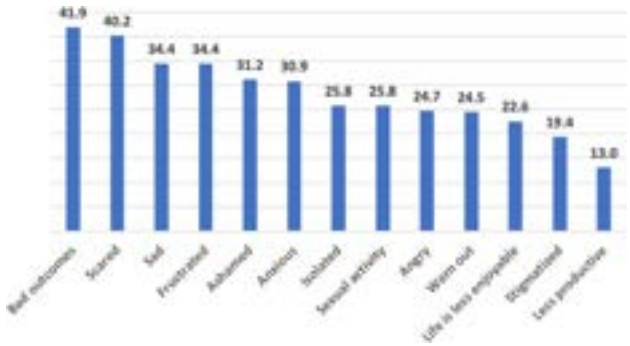

Figure: Participants were asked to report on each of the factors presented on a scale ranging from never to all the time based upon their past experience (prior to HBsAg loss) and current (after HBsAg clearance) (Wilcoxon signed-rank test).

Conclusion: In this prospective cohort study of ethnically diverse CHB patients, participants who achieve HBsAg loss reported improved HRQoL. Patient perspectives are important to consider in assessing benefits of a functional cure.

WED-193

Stability of Hepatitis B virus RNA in plasma and serum under various storage conditions

Valerie Ohlendorf[1], Birgit Bremer[1], Carola Mix[1], Lisa Sandmann[1], Tammo Lambert Tergast[1], Katja Deterding[1], Markus Cornberg[1], Heiner Wedemeyer[1], Benjamin Maasoumy[1]. *[1]Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Germany*
Email: ohlendorf.valerie@mh-hannover.de

Background and aims: Pregenomic hepatitis B virus (HBV) RNA (pgRNA) is intensively investigated as a biomarker in the management of HBV infected patients. However, prior to the use in routine clinical practice potential confounders of test results need to be identified. This study investigates the stability of HBV RNA under various storage conditions.

Method: HBV RNA levels in 26 hepatitis B patients, of whom 15 received NUC treatment, were determined using the Roche cobas® 6800/8800 investigational HBV RNA assay. The lower limit for the quantification of HBV RNA was 10 copies/ml (c/ml). Detectable but not quantifiable HBV RNA level (titer min) were set to 10 c/ml for statistical analyses. Before measurement of HBV RNA, blood samples were stored under the following conditions: baseline (BL) samples were immediately prepared, the supernatant (Su) of plasma (P) and serum (S) samples as well as whole blood (WB) S and P samples of each patient were stored for 6, 48, 169 hours (h) at 4°C, 25°C and 42°C, respectively. HBV RNA level were expressed as median. The unpaired t-test and fishers exact test were performed for statistical analyses.

Results: HBV RNA was detected in 61.5% (N = 16; 122.65 c/ml) of S and 69% (N = 18; 21.9 c/ml) of P samples, respectively. Baseline HBV RNA levels did not differ significantly between P and S samples (p = 0.45). Over all samples, a decrease in HBV RNA was detected over time, with higher declines of mean HBV RNA concentrations with increasing storage temperature (BL 4.87×10^6 c/ml; 169 h: 4°C, 4.61×10^6 c/ml; 25°C, 3.56×10^6 c/ml; 42°C, 4.79×10^5 c/ml). The same trend was observed in further subanalysis: In the subgroup of samples with HBV RNA <titer min (P: 33.3%, N = 6; S: 25.0%, N = 4) the number of all samples with detectable HBV RNA decreased over time. After 48 h of storage at 42°C HBV RNA became undetectable in WB samples and in Su S samples (p = 0.0022 to 0.0286). HBV RNA level of 10–100 c/ml were detected in 22.2% (N = 4; 15.5 c/ml) of P samples and 25.0% (N = 4, 19.45 c/ml) of S samples. Fluctuations in median HBV RNA concentrations ranged from –11.5 to +2.5 c/ml 169 h after BL at 4°C, while at 42°C in WB samples HBV RNA became undetectable after 48–169 h of storage. In samples with HBV RNA level >100 c/ml (P: 44.4%, N = 8, 1.55×10^5 c/ml; S: 50%, N = 8, 1.78×10^5 c/ml) the number of samples with detectable HBV RNA remained stable at all

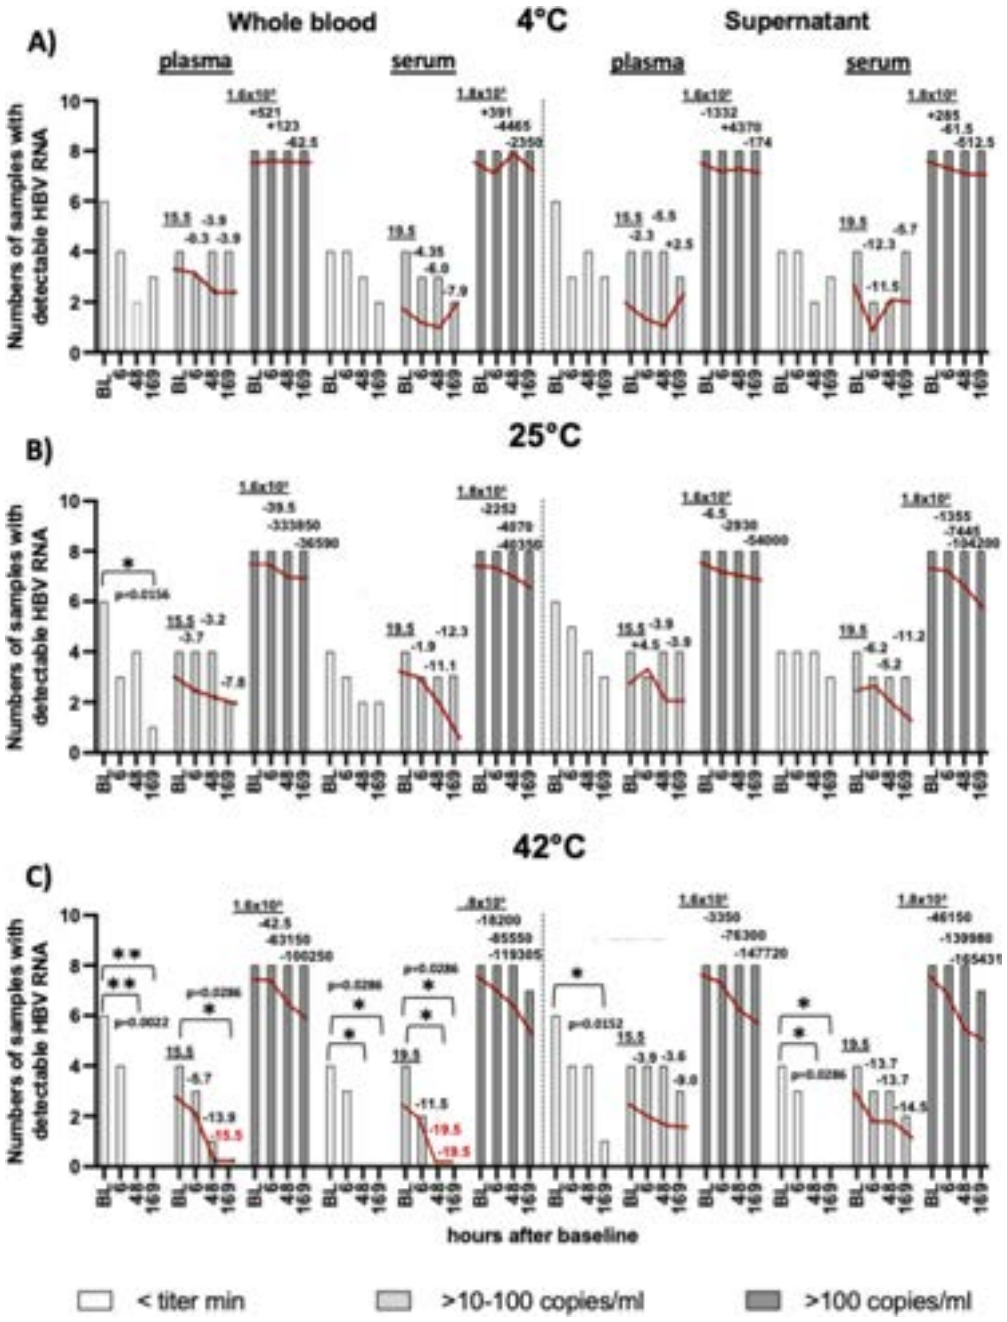

Figure: (abstract: WED-193): Number of samples with detectable HBV RNA (copies/ml) sorted by subgroups of HBV RNA <titer min, HBV RNA levels ≥ 10-100 copies/ml and >100 copies/ml, respectively at A) 4°C, B) 25°C and C) 42°C storage condition. Red lines represent median level of HBV RNA, underlined numbers represent median BL level of HBV RNA in copies/ml, not underlined numbers represent the median change in HBV RNA levels compared to BL. Statistically significant changes of RNA level is expressed in red. Brackets indicate a statistically significant decrease in number of samples with detectable HBV RNA.

storage temperatures, except of S samples stored at 42°C. At 4°C, the most stable HBV RNA concentrations over time occurred in WB P samples (median decrease –62.5 c/ml). The maximum median decrease was –4465 c/ml (169 hours after BL in S samples). In contrast, 169 h after BL the maximum decrease in median HBV RNA level was –104 200 c/ml at 25°C and –165 431 c/ml at 42°C, respectively.

Number of samples with detectable HBV RNA (copies/ml) sorted by subgroups of HBV RNA <titer min, HBV RNA levels ≥ 10–100 copies/ml and >100 copies/ml, respectively at A) 4°C, B) 25°C and C) 42°C storage condition. Red lines represent median level of HBV RNA, underlined numbers represent median BL level of HBV RNA in copies/ml, not underlined numbers represent the median change in HBV RNA levels compared to BL. Statistically significant changes of RNA level is expressed in red. Brackets indicate a statistically significant decrease in number of samples with detectable HBV RNA.

Conclusion: A qualitative detection of HBV RNA is feasible in samples with >100 c/ml up to 48 h under storage temperatures of 4–42°C. For most stable quantitative HBV RNA values storage at 4°C should be preferred.

WED-194

Barriers to hepatitis B treatment from the patient's perspectives: survey study by the Canadian hepatitis B network

Hin Hin Ko[1], Curtis Cooper[2], Anna Manko[3], Alnoor Ramji[1], Chad Saunders[4], Abdel Aziz Shaheen[3], Carla Coffin[3]. *[1]University of British Columbia, Division of Gastroenterology, Canada; [2]University of Ottawa, Department of Medicine, Canada; [3]University of Calgary, Department of Medicine, Canada; [4]University of Calgary, Haskayne School of Business, Canada*
Email: hinnih@gmail.com

Background and aims: Although Canada has a universal health care system, this does not include prescription drug benefits, which vary according to provincial health jurisdiction. There are systemic factors impacting access to treatment leading to poor outcomes. Our previous study has shown undertreatment in patients with chronic hepatitis B who meet treatment guideline criteria. The goal of this survey study is to determine barriers to Hep B treatment from the patient's perspectives.

Method: In this study, an in-person survey was conducted in three specialist hepatology infectious disease clinics for Hep B patients involved in the Canadian HBV Network. Patients' clinical and demographic variables, their knowledge and perception of Hep B and treatment were collected in the survey. Data analyses were performed using SPSS statistics.

Results: Of 83 patient respondents to date from one jurisdiction, 58% (n = 48) were in the 40–59 age group, 50.6% (n = 42) were male. 79.5% (n = 66) were employed and 66.3% (n = 55) worked full time. 25.3% (n = 21) did not have any extended health coverage. 48.2% (n = 40) were currently on treatment and 16.9% (n = 14) sometimes/always had difficulties paying for the anti-viral medication. 44.5% (n = 37) felt 'very knowledgeable/have good knowledge' about Hep B. 30.1% (n = 25) were 'very to extremely worried about developing liver complications' from Hep B. 31.3% (n = 26), 4.8% (4) and 2.4% (2) sometimes, often and always felt stigmatized and isolated because of Hep B, respectively. The percentage of survey respondents who reported challenges in various health related and quality of life factors were summarized in Figure 1. Among those not on treatment (n = 43), 53% (n = 23) 'definitely or probably would accept treatment' if recommended while 18% (n = 8) 'definitely or probably would not accept treatment' despite recommendations. High medication costs, potential medication side effects and needing to take the medication long term were of concern to 30.3% (n = 13), 65.1% (n = 28) and 60.5% (n = 26) of patients, respectively. Before considering treatment, 39.5% (n = 17) would like to try diet and natural remedies, 32.6% (n = 14) would want to be monitored longer and 27.9% (n = 12) would want to know when the treatment can be stopped.

Conclusion: In this ongoing survey study of CHB population in Canada, about one fifth of the patients would not accept treatment despite physician's recommendations. Lower drug costs, treatment with limited side effects and shorter duration might potentially reduce barriers in people willing to accept treatment.

Email: nicholas.riches@lstmed.ac.uk

Background and aims: There are approximately one million new cases of chronic hepatitis B virus (HBV) infection each year in the WHO African region, corresponding to two-thirds of all new infections globally. To achieve global elimination of HBV, Africa must be designated a priority region for future research and interventions. Improved understanding of the natural history of HBV in Africa is needed, since disease patterns may be determined by differences in natural history, circulating genotypes, environmental exposures and coinfections. With seed funding from EASL, the Hepatitis B in Africa collaborative network (HEPSANET) was founded to close gaps in knowledge around HBV in Africa.
Method: A systematic review was conducted to identify established and high-quality HBV cohorts in Africa, and those identified were invited to participate. A modified Delphi exercise was conducted with HBV experts across the region to identify research priorities for the initial period of HEPSANET. Ten research priorities were agreed by consensus, with the leading priority being to establish a longitudinal research cohort of people living with chronic HBV in Africa. Working groups for hepatocellular carcinoma, prevention of mother to child transmission, diagnostics, and data harmonization were formed. Baseline data from participating sites were shared. We described HEPSANET research priorities, site characteristics, patient-level demographics and HBV clinical features.
Results: As of October 2022, 13 cohorts representing sites from eight African countries and three regions (East, West, and Southern) had joined HEPSANET and shared their data. An initial cohort of 4,173 participants was analyzed. Median age of the cohort is 34 years (IQR 28–42), 38.8% are women, with 81.3% of cases identified through asymptomatic testing. 9.6% of the cohort are HBeAg-positive, 33.1% have HBV DNA >2000 IU/ml, and 14.3% are cirrhotic based on transient elastography. Among the 692 with chronic hepatitis (i.e. elevation of both ALT and HBV DNA), the majority (72.8%) were HBeAg-negative.
Conclusion: To address the dearth of longitudinal HBV data in Africa, HEPSANET is combining data from HBV cohorts throughout Africa for the first time. Improved understanding of HBV epidemiology in Africa will lead to better approaches to HBV case finding, care models, and treatment strategies, including with emerging curative therapies. Procedures are now being established to expand this cohort and to allow for collection of longitudinal follow-up data.

WED-196
Risk factors for viral reactivation in patients with overt or occult HepatitisB Virus infection receiving immunosuppressive treatments: a systematic review and meta-analysis

Ciro Celsa[1], Giacomo Emanuele Maria Rizzo[1], Gabriele Rancatore[1], Pietro Graceffa[1], Giuseppe Falco[1], Gabriele Di Maria[1], Marco Vaccaro[1], Marco Enea[1], Vincenza Calvaruso[1], Calogero Camma[1], Vito Di Marco[1].
[1]Section of Gastroenterology and Hepatology, PROMISE Department, University of Palermo, Italy
Email: celsaciro@gmail.com

Background and aims: Patients with Hepatitis B virus (HBV) infection receiving immunosuppressive treatments are at risk of HBV reactivation (rHBV). We performed a systematic review with meta-analysis to estimate the risk of rHBV among patients naïve to antiviral prophylaxis and to identify factors associated with rHBV.
Method: Studies of immunosuppressive treatments in HBV patients were identified through literature search using PubMed, MEDLINE, and EMBASE until October 2022. Pooled estimates were obtained using random-effects model. Subgroup analyses were performed according to viral status, drug class and underlying disease. Decision curve analysis (DCA) was used to identify the threshold probability associated with the best net benefit of administering prophylaxis with nucleos (t)ide analogues (NAs) in HBsAg negative anti-HBc positive patients.
Results: Seventy-nine studies (48 retrospective and 31 prospective) were selected, including 9946 patients (1108 HBsAg positive, 8203 anti-HBc positive and 635 isolated anti-HBs positive). Pooled rHBV rate was 6% (95% CI 5–8%; I^2 79%;$p < 0.001$) with a rate of 23% (95% CI

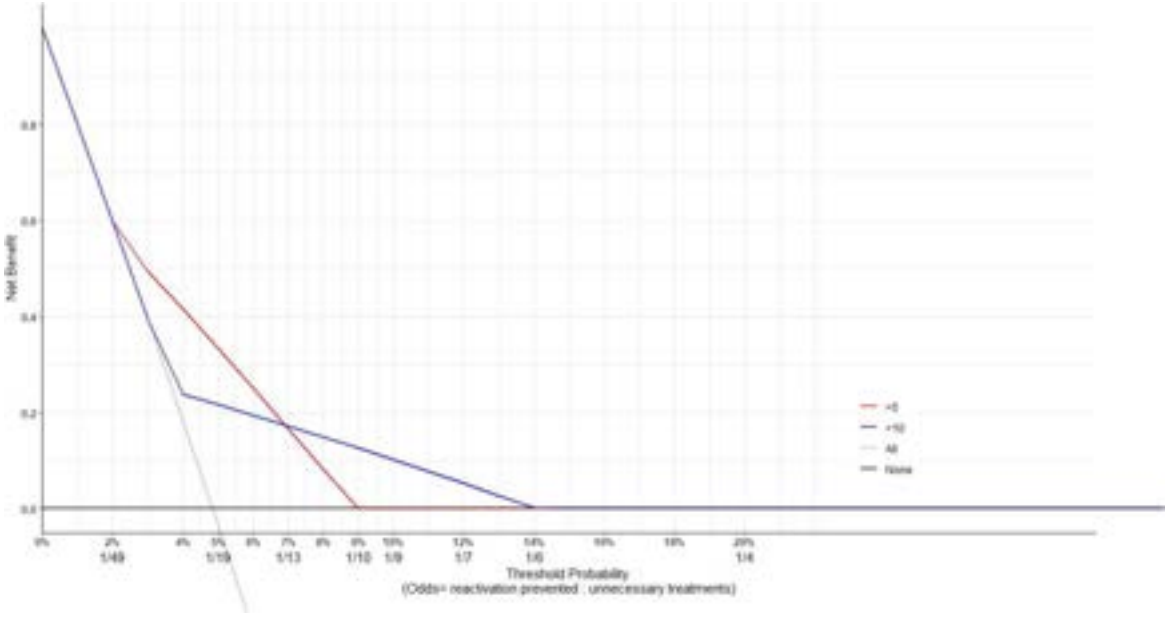

Figure: (abstract: WED-196): Decision curve analysis comparing the net benefit of strategies of administering NAs prophylaxis when HBV reactivation is higher than 5% or 10% with the strategies of treating all or none patients at different threshold probabilities in HBsAg negative anti-HBc positive patients.

16–31%), 4.6% (95% CI, 3.4–6.1%) and 2.9% (95% CI 1.5–10%) in HBsAg positive, anti-HBc positive and isolated anti-HBs positive patients, respectively. In HBsAg positive patients, the risk for rHBV ranged from 22% (95%CI 11–39%) in patients with autoimmune disease receiving immunosuppressants to 30% (95%CI 5–79%) in patients with cancer receiving chemotherapy. In anti-HBc positive patients with cancer, chemotherapy, targeted-therapy and monoclonal antibodies were associated with risk of rHBV of 9% (95%CI 5–15%), 7% (95% CI 1–43%) and 5% (95%CI 2–10%), respectively; in anti-HBc positive with autoimmune diseases, the risk of rHBV was 3% (95% CI 2–4%), 4% (95% CI 2–8%) and 3% (95%CI 1–13%) for anti-TNFα, other monoclonal antibodies and immunosuppressants, respectively. DCA showed that a more aggressive strategy (treating patients with HBV≥5%) was associated with higher net benefit when physicians are willing to successfully prevent one rHBV at the cost of unnecessary treatments ranging from 49 to 13, while a less aggressive strategy (treating patients with HBV≥10%) was better at the cost of unnecessary treatments ranging from 13 to 6.

Conclusion: This meta-analyses provided consistent results that all HBsAg positive patients should receive NAs prophylaxis. Our decision curve analysis in anti-HBc positive patients provided evidence that in patients with cancer treated with chemotherapy, NAs prophylaxis should be recommended, while in patients with cancer treated with targeted therapies either monitoring or NAs prophylaxis could be appropriate. In patients with cancer treated with monoclonal antibodies and in patients with autoimmune diseases, monitoring and on-demand NAs should be recommended.

WED-197

T-cell responses to PreS1 and PreS2 are correlated to anti-HBs antibody titres, which are higher and persist longer in volunteers vaccinated with 3-antigen than with 1-antigen hepatitis B vaccine in the PROTECT Study: 3.5 year follow-up

Francisco Diaz-Mitoma[1], Timo Vesikari[2], Tamara Berthoud[3], Daniel Plaksin[3], David Anderson[3], Vlad Popovic[3]. *[1]VBI Vaccines, Inc, Ottawa, Canada; [2]Tampereen Rautatieasema, Tampere, Finland; [3]VBI Vaccines Inc., Cambridge, United States*
Email: fdiazmitoma@vbivaccines.com

Background and aims: PreHevbri is a 3-antigen hepatitis B vaccine containing S, PreS1 and PreS2 HBV envelope antigens and Engerix is a 1-antigen HBV vaccine containing the S Ag. PreS antigens have CD4+ T-cell epitopes which may mediate the improved antibody response against HBsAg after vaccination with PreHevbri. This study aimed to find the relationship between T-cell activation and induction and persistence of antibody responses after HBV immunization in a Phase 3 study (PROTECT) that compared the immunogenicity of these vaccines and followed volunteers for 3.5 years post vaccination.

Method: Statistical comparisons and correlation analysis between anti-HBs titer and Cultured interferon (IFN)-gamma elispots or stimulation index were measured after the 2nd and 3rd vaccination with PreHevbri or with Engerix in a subset of participants (n = 80) in the PROTECT study (N = 1,607). An additional subset of volunteers (N = 347) was followed with antibody titers 3.5 years postvaccination

Results: Following the third vaccination, there was a statistically significant correlation between anti-HBs titers and T-cell gamma IFN elispot responses to pre-S1 (Pearson's Coefficient = 0.39, p = 0.0137) and pre-S2 (Pearson's Coefficient = 0.33, p = 0.0363), and a trend toward significance between anti-HBs titers and the elispot response to HBsAg (Pearson's Coefficient = 0.31, p = 0.0534) in the PreHevbri arm. In contrast, in Engerix-B-vaccinated subjects, a statistically significant correlation was seen only between anti-HBs titers and elispot responses to HBsAg (Pearson's Coefficient = 0.46, p = 0.0026) and no correlation with ELISPOT responses to pre-S1 or pre-S2. The difference in adjusted mean frequency of IFN-γ-secreting SFU/million PBMCs was statistically significant (p < 0.05) and greater in PreHevbri arm. These responses to pre-S1 and pre-S2 at Day 35 (7 days post second vaccination) in the Sci-B-Vac group correlated with anti-HBs titer at Day 56 (4 wekks post second vaccination), 168 (20 weeks post second vaccination) and 196. (4 weeks post 3rd Vaccination) No such correlations to pre-S1 and pre-S2 were seen in the Engerix-B group. Post third vaccination, the adjusted mean stimulation index was 0.8 (95% CI 0.7, 1.0) in the Engerix-B arm and 1.2 (95% CI 1.0, 1.5) in the PreHevbri arm. In contrast to the Engerix arm, there was a statistically significant correlation of mean stimulation index of pre-S2 with anti-HBs GMT (Pearson's Coefficient = 0.48, p = 0.0149) in the PreHevbri group. 40% (95%CI = 31.9, 48.4) of Engerix and 78% (95%CI = 71.8, 83.7) of PreHevbri recipients had anti-HBs ≥100 mIU/ml at 3.5 years of follow-up post 3rd vaccination.

Conclusion: The 3-antigen Hepatitis B vaccine induces T-cell responses to the PreS domains that are correlated to high and persistent anti-HBs titers observed in the follow-up extension of PROTECT Phase 3 study. Anti-HBs ≥100 mIU/ml at 3.5 years of follow-up post 3rd vaccination were almost double with 3-antigen than the 1-antigen hepatitis B vaccine.

WED-198

Baseline hepatocyte ballooning is a risk factor for adverse events in patients with chronic hepatitis B complicated with non-alcoholic fatty liver disease

Youwen Tan[1], Wang Jiaming[1]. *[1]The Third Hospital of Zhenjiang Affiliated Jiangsu University, China*
Email: tyw915@sina.com

Background and aims: To study the effect of non-alcoholic fatty liver disease (NAFLD) confirmed by liver pathology on the outcome of long-term serious adverse events (cirrhosis, hepatocellular carcinoma (HCC), and death) in patients with chronic hepatitis B (CHB) virus infection.

Method: Patients with chronic hepatitis B virus (HBV) infection who underwent liver biopsy at the Third People's Hospital of Zhenjaing Affiliated Jiangsu University between January 2005 and September 2020 were enrolled. Baseline clinical and pathological data on liver pathology and clinical data at the end of follow-up were collected. Propensity score matching (PSM) was used to balance the baseline parameters, Kaplan-Meier (K-M) survival analysis was used to evaluate the risk of clinical events, and Cox regression was used to analyze the risk factors of events.

Results: Overall, 456 patients with chronic HBV infection were included in the study, of whom 152 (33.3%) had histologically confirmed NAFLD. The median follow-up time of the entire cohort was 70.5 months. Excluding 67 patients with cirrhosis at baseline, 34 developed cirrhosis, which was diagnosed using ultrasound during the follow-up period. K-M survival analysis showed that NAFLD was not significantly associated with the risk of cirrhosis (log-rank test, $p > 0.05$). Patients with CHB with fibrosis at baseline were more prone to cirrhosis (log-rank test, p = 0.046). After PSM, multivariate analysis showed that diabetes mellitus, ballooning deformation (BD), and platelet (PLT) were independent risk factors for cirrhosis diagnosed using ultrasound (p < 0.05). A total of 10 patients (2.2%) developed HCC and six patients were in the combined NAFLD group. The median interval between liver biopsy and HCC diagnosis was 100.5 months. K-M survival analysis showed that the cumulative risk of HCC in the NAFLD group was significantly higher (log-rank test, p < 0.05). Lobular inflammation, hepatocyte ballooning, and severe liver fibrosis were also associated with an increased risk of HCC (log-rank test, all p < 0.05). Cox multivariate analysis revealed that hepatocyte ballooning, liver fibrosis, and diabetes mellitus were independent risk factors for HCC.

Conclusion: There was no significant correlation between chronic HBV infection and risk of cirrhosis in patients with NAFLD. Diabetes mellitus, BD, and PLT were independent risk factors for liver cirrhosis. Patients with chronic HBV infection and non-alcoholic steatohepatitis (NASH) have an increased risk of HCC. BD, liver fibrosis, and diabetes mellitus are independent risk factors for HCC.

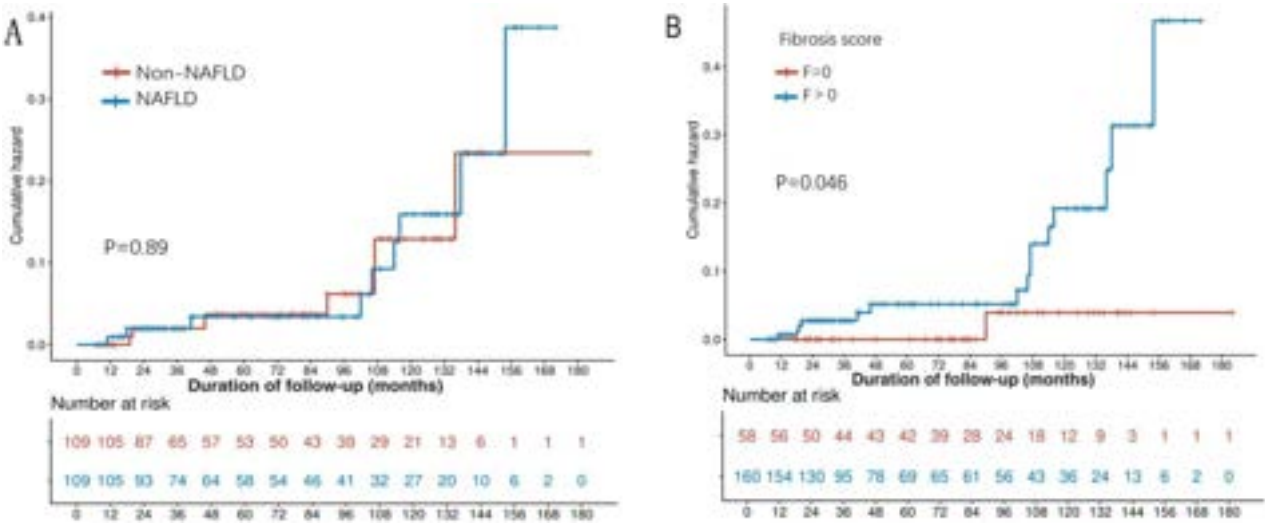

Figure: (abstract: WED-198).

WED-199

Epidemiological landscape and clinical spectrum of chronic hepatitis B in East Africa

Abate Shewaye[1,2], Amir Sultan[1,2], Zebeaman Tibebu Gorfu[2], Rabia Redi[2]. [1]*Addis Ababa University, College of Health Sciences, Department of Internal Medicine, Addis Ababa, Ethiopia;* [2]*Adera Medical andSurgical Center, Department of Internal Medicine, Addis Ababa, Ethiopia*

Email: gzebeaman@gmail.com

Background and aims: According to WHO global report, 296 million people were living with chronic hepatitis B (CHB) infection in 2019, with 1.5 million new infections each year. Nearly 45% of the world's population lives in regions of chronic hepatitis B virus (HBV) endemicity, of which highest percentage is in sub-Saharan Africa including Ethiopia. Fortunately, vaccine and antiviral therapy for CHB has been shown to be effective in preventing the infection and its complications. Thus, this study aims to assess the sociodemographic, clinical and epidemiological pattern of patients with chronic hepatitis B seen at Adera Medical Center, in Addis Ababa, Ethiopia.

Method: Four hundred-three patients were enrolled in this cross-sectional study. Sociodemographic, clinical, and laboratory and imaging parameters were collected and analyzed using SPSS (SPSS, Version 23)

Results: CHB was twice more prevalent amongst males with mean age of 37.96 ± 10.94. Seventeen patients developed HCC, while five patients died; four of whom were HCC patients and one developed Hepatic Encephalopathy. HCV and HIV coinfected patients accounted for 2.2% and 1.7% of the study population. HBeAg seropositivity was only 6.5%. Majority (60%) were from Addis Ababa followed by Jijiga, Zeway, and Harar regions. Poor outcomes were noted among older patients (<65 years) with chronic hepatitis B infection ($p < 0.01$)

Conclusion: Majority of our patients (93.5%) were HBeAg negative indicating childhood chronic HBV infection. Male predominance and clustering of CHB in south east Ethiopia was witnessed in our study. Chronic HBV complications like cirrhosis and HCC are more common among elderly patients (>65 yrs) resulting in poorer outcome ($p < 0.01$).

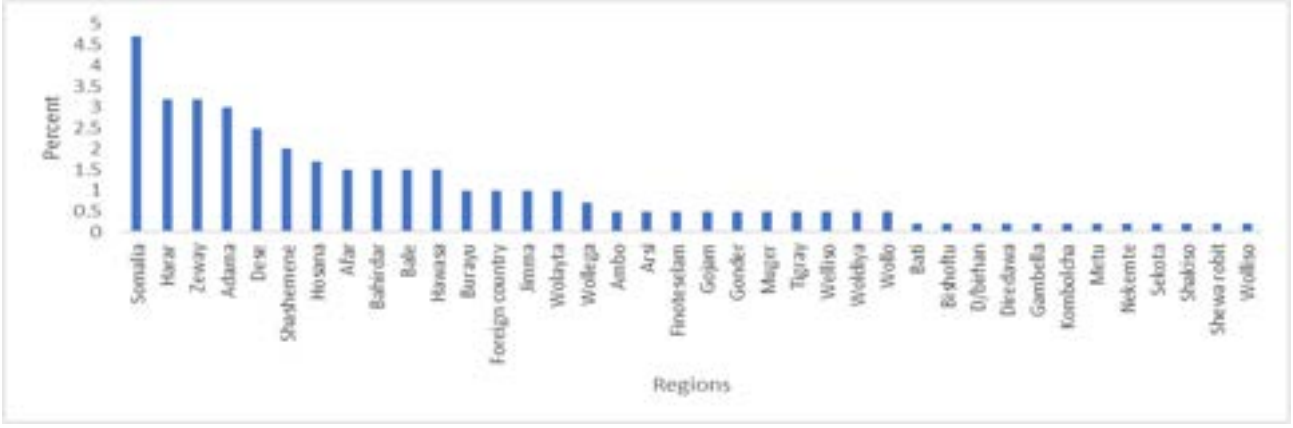

Figure: (abstract: WED-199): Clustering of CHB patients followed at Adera Medical and Surgical Center, Addis Ababa, Ethiopia, 2022.

Significantly higher clinical and economic burden following diagnosis of hepatitis delta virus infection among commercially insured adults with chronic hepatitis B in the United States

Robert Wong[1,2], Robert G. Gish[3], Chong Kim[4], Gary Leung[5], Ira M Jacobson[6], Joseph Lim[7], Ankita Kaushik[4]. *[1]Stanford University School of Medicine, Stanford, United States; [2]VA Palo Alto Healthcare System, Palo Alto, United States; [3]Hepatitis B Foundation, Doylestown, United States; [4]Gilead Sciences, Inc., HEOR-Global Value and Access, Foster City, United States; [5]Gilead Sciences, Inc., RWE-Epidemiology, Foster City, United States; [6]NYU Grossman School of Medicine, New York, United States; [7]Yale University School of Medicine, New Haven, United States*

Email: ankita.kaushik@gilead.com

Background and aims: Hepatitis delta virus (HDV) is associated with more rapid progression to cirrhosis and liver-related complications compared with other hepatitis virus infections. Baseline (BL) characteristics, healthcare resource use (HCRU), and costs among commercially insured adults with HDV infection in the US were examined.

Method: Adult patients with ≥1 HDV or HBV diagnosis (ICD-9/10-CM) were identified retrospectively from 1 Jan 2013 to 31 Dec 2021 (study period) using the IQVIA PharMetrics Plus database covering ~210 million patients from primarily commercial payers. HDV patients were identified from 1 Jan 2014 to 31 Dec 2020 (identification period) and defined as those who had ≥1 inpatient or ≥2 outpatient claims ≥30 days apart with an ICD-9/10-CM diagnosis code for HDV during the identification period (earliest date of diagnosis considered index date), ≥1 claim of HBV diagnosis during BL (12-month period prior to index date), and no claims with HDV diagnosis during BL. Continuous enrollment for ≥12 months before and after the index date was required, and patients aged ≥18 years at index with commercial health plans were included. Patient characteristics were assessed over the BL period and mean per patient per year (PPPY) all-cause HCRU and costs were compared in the 12 months pre- and post-HDV diagnosis.

Results: Among 6,002 patients diagnosed with HDV during the identification period, 440 met inclusion criteria. Baseline characteristics: mean (SD) age, 50.3 (10.50); 65% males; mean (SD) Charlson Comorbidity Index score, 1.97 (2.35). At HDV diagnosis, 13% had compensated cirrhosis, 12% had decompensated cirrhosis, 5% had hepatocellular carcinoma, and 4% had history of liver transplant. Other comorbidities included hypertension (33%), obesity (8%), non-alcoholic steatohepatitis (7%), and hepatitis C (6%). Mean PPPY all-cause total HCRU was significantly greater post-HDV diagnosis vs pre-HDV diagnosis (29.8 vs 24.1, $p < .0001$), driven primarily by significantly increased outpatient visits (8.6 vs 5.5, $p < .0001$), physician office visits (10.8 vs 9.2, $p < .0001$), and pharmacy claims (13.5 vs 11.6, $p < .001$). Mean PPPY all-cause total healthcare costs were significantly greater post-HDV diagnosis vs pre-HDV diagnosis ($11 197 vs $9281, $p < .005$), due to increases in total medical costs, including outpatient ($2471 vs $1650, $p < .0005$) and physician office ($1784 vs $1697, $p < .01$) costs.

Conclusion: Over 20% of commercially insured HDV patients had already developed cirrhosis or liver-related complications at time of diagnosis. Following HDV diagnosis, approximately 6 more visits and claims amounting to $1916 were observed. These findings underscore the need for more effective strategies for screening, diagnosis, linkage to care, and treatment of HDV-infected patients, to decrease the burden of disease for patients and the healthcare system.

WED-201

Aspirin use and risk of hepatocellular carcinoma and gastrointestinal bleeding in patients with HBV-related cirrhosis: a landmark analysis

Mi Na Kim[1], Geun U Park[2], Jae Seung Lee[3], Hye Won Lee[3], Beom Kyung Kim[3], Seung Up Kim[3], Jun Yong Park[3], Do Young Kim[3], Sang Hoon Ahn[3]. *[1]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Clinical and Translational Hepatology Laboratory, Korea, Rep. of South; [3]Yonsei University College of Medicine, Korea, Rep. of South*

Email: ahnsh@yuhs.ac

Background and aims: The use of aspirin in hepatocellular carcinoma (HCC) prevention is still uncertain in patients with hepatitis B virus (HBV)-related cirrhosis. In addition, results regarding whether the risk of gastrointestinal (GI) bleeding is associated with aspirin use in patients with HBV related cirrhosis are controversial. Accordingly, we investigated the association between aspirin use and the risks of HCC and GI bleeding in HBV-related cirrhosis patients using a nationwide cohort.

Method: We conducted a 3-year landmark analysis using nationwide cohort data from the National Health Insurance Service of South Korea. Patients with diagnosed with compensated HBV-related cirrhosis in 2005–2017 were included. Patients who were prescribed aspirin for at least 90 days consecutively during the 3-year exposure period were classified as the aspirin-treated group. A propensity-score matching analysis was applied to balance the aspirin-treated and untreated groups. Using Cox proportional hazard regression analysis, we estimated the risks of HCC and GI bleeding, accounting for competing events.

Results: A total of 12,687 patients (608 aspirin-treated and 12,079 untreated) were included in the analysis. During a median of 7.6 years of follow-up, HCC developed in 219 (36.0%) patients of the aspirin-treated group and 4,265 (35.3%) patients of the untreated group. After multivariate adjustment, the aspirin-treated group showed a significantly lower risk of HCC than the untreated group (adjusted hazard ratio [aHR] = 0.84, 95% confidence interval [CI] = 0.73–0.96; $P = 0.013$). GI bleeding developed in 157 (25.8%) of the aspirin-treated group and 2072 (17.2%) of the untreated group. The aspirin-treated group showed a significantly higher risk of GI bleeding than the untreated group (aHR = 1.21, 95% CI = 1.03–1.43; $P = 0.021$). After propensity-score matching, the cumulative incidence rate of HCC was significantly lower in the aspirin-treated group than the untreated group ($p = 0.013$, log-rank test). Whereas, the cumulative incidence rate of GI bleeding was significantly higher in the aspirin-treated group than the untreated group ($p = 0.025$, log-rank test).

Conclusion: In patients with HBV-related cirrhosis, the aspirin-treated group showed a significantly lower risk of HCC than the untreated group, whereas the risk of GI bleeding was significantly higher in the aspirin-treated group.

WED-202

High prevalence of hepatic steatosis in adults living with hepatitis B, with and without HIV co-infection, in London, UK

Claire Mullender[1,2], Angieszka Kemper[2], Stephen Ogunnaike[2], Sarah Pett[1,3], Irfaan Maan[1], Manik Kohli[1,2], Dimitra Peppa[2,4], Alejandro Arenas-Pinto[1,3], Stuart Flanagan[2], Indrajit Ghosh[2], Richard Gilson[1,2], Philippa Matthews[4,5,6]. *[1]Institute for Global Health, University College London, United Kingdom; [2]Central and North West London NHS Foundation Trust, Department of HIV and Sexual Health, United Kingdom; [3]MRC Clinical Trials Unit at University College Lonon, Institute of Clinical Trials and Methodology, United Kingdom; [4]University College London, Division of Infection and Immunity, United Kingdom; [5]Francis Crick Institute, United Kingdom; [6]University College London, Department of Infectious Diseases, United Kingdom*
Email: claire-marie.mullender1@nhs.net

Background and aims: Hepatic steatosis is likely to become a leading cause of liver related mortality, and can have a significant impact on the progression of liver disease in the setting of chronic hepatitis B (HBV) and HIV/HBV co-infection. It can be measured using controlled attenuation parameter (CAP), a simple non-invasive test, at the same time as fibrosis assessment by transient elastography. We aimed to describe the prevalence of steatosis in a cohort of adults living with HBV and HIV/HBV co-infection, undergoing routine assessment in a central London clinic.

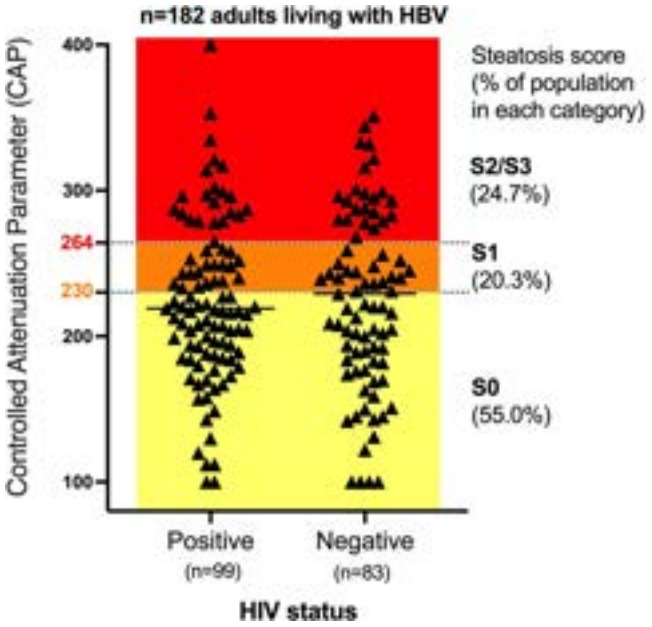

Figure: Distribution of CAP scores in adults living with HBV monoinfection and HBV/HIV co-infection in London. Steatosis graded as S0, S1, S2/3 based on standardised thresholds for HBV. (No difference in distribution between groups, p = 0.82)

Method: We performed a retrospective analysis of adults with HBV (including mono-infected and HIV co-infected) who had had CAP measured by Fibroscan® (Echosens) between 1/2017–10/2022. We used CAP scores to categorise steatosis as: S0 <230 dB/m; S1 230–264 dB/m; S2/3 >264 dB/m; and as a continuous scale in a univariate analysis. We investigated for relationships between CAP scores and liver outcomes (based on alanine transaminase [ALT] and fibrosis score on transient elastography), and age, sex, body mass index (BMI), HIV status and ethnicity.

Results: We reviewed data for 182 patients (80% male; median age 48 years [IQR 39–56]). Ethnicities categorised as 43% White, 30% Black, 10% Asian, remainder mixed/not stated. 99 (54%) had HBV/HIV co-infection. 56% had a BMI ≥25 kg/m^2. Evidence of steatosis was present in 45%, with 20% classified as S1, and 25% stage S2/S3. Median ALT was 23 (IQR 23–41) IU/L. CAP scores were not significantly associated with HIV status (figure 1), sex, or ethnicity, but increased with age ($p = 0.009$) and increased BMI ($p < 0.0001$). Increasing CAP scores were significantly associated with higher ALT ($p = 0.02$) and elevated fibrosis scores ($p = 0.0003$).

Conclusion: We identified a high prevalence of steatosis in our diverse cohort of adults living with HBV, however HIV co-infection was not associated with an increased risk of steatosis in our cohort, which warrants further investigation. We demonstrate that steatosis may contribute to adverse liver outcomes, and as steatosis is a modifiable cause of fibrotic/inflammatory liver disease, further efforts are required to determine its impact and deliver interventions to lower risk in people living with HBV. This is particularly important as people living with HBV and HIV/HBV co-infection are often excluded from therapeutic trials for steatosis.

WED-203

Stable temporal trend of HDV seroprevalence in central Italy across the last two decades with the circulation of HDV sub-genotypes 1 inducing different inflammatory stimuli

Email: lorenzo.piermatteo@uniroma2.it

Background and aims: In Italy, HDV-prevalence and its fluctuations over time are controversial while an extensive characterization of HDV-infected patients (pts) is missing. Here, we assess HDV-seroprevalence in a large cohort of HBsAg-positive pts, followed in Central Italy over time, and the epidemiological/virological characteristics of HDV-infected pts.

Method: This study included 1579 consecutive and well-characterized HBsAg-positive pts, followed in different clinical centers of Central Italy from 2005 to 2022. Factors (demographics, transaminases, HBeAg status) correlated with the lack of HDV screening were defined by multivariable model. HDV sub-genotypes were defined by phylogenetic-analysis.
Results: Most HBsAg-positive pts were male (67%) and Italian (59.4%) with a median (IQR) age of 47 (35–60) years. 75% of pts were HBeAg-negative, median (IQR) serum HBV-DNA and HBsAg were 3.1 (2.8–4.1) IU/ml and 3499 (618–11662) IU/ml, while median ALT was 42 (26–78) U/L. Overall, 45.3% (715/1579) received HDV-screening with an increasing temporal-trend: 17.1% (2005–2010), 43.2% (2011–2015), 56.5% (2016–2019), 75.8% (2020–2022), suggesting a higher awareness towards HDV-screening in recent years. By multivariable model, normal ALT was the only independent factor significantly correlated with the lack of HDV-screening (OR [95%CI]: 1.71 [1.29–2.30], P < 0.001). Notably, 13.4% (96/715) of HDV-screened pts resulted anti-HDV+ with a stable temporal trend: 10.7% (2005–2010), 15.6% (2011–2015), 10.8% (2016–2019), 10% (2020–2022). Among them, 80.5% had detectable HDV-RNA (median [IQR] log: 4.6 [3.6–5.6] copies/ml) with altered ALT in 89.3% (median [IQR]: 92 [62–177] U/L). Anti-HDV positivity was higher in pts from Eastern Europe than from Italy (23.6% vs 12.9%, P = 0.002) and remained stable over time in both groups. Notably, anti-HDV+ pts from Eastern Europe were younger (44 [37–54] vs 53 [47–62] years, P < 0.001) with higher HDV-RNA (4.8 [3.6–5.8] vs 3.9 [1.4–4.9]copies/ml, P = 0.016) and HBsAg (9,461 [4,159–24,532] vs 4,447 [737–13,336] IU/ml), P = 0.032), indicating more pronounced HDV replicative activity. Phylogenetic analysis revealed the circulation of HDV sub-genotype 1a (25.9%), 1b (33.4%), 1c (25.9) and 1d (14.8%). Notably, sub-genotype 1a and 1c correlated with 3xULN ALT compared to 1b and 1d (75% versus 27.3%, P = 0.039).
Conclusion: The awareness to request HDV-screening is increasing over time even if some gaps persist to achieve HDV-screening in all HBsAg-positive pts. The prevalence of HDV infection remains stable in both foreign and Italian pts over time. Notably, immigration from Eastern Europe contributes to fuel the circulation of HDV-strains with enhanced replication. The detection of different sub-genotypes, triggering variable inflammatory stimuli, supports the need to expand HDV molecular characterization.

WED-204
Ten years follow-up of patients with chronic hepatitis B and hepatitis D infection

Andreea Dobroaia[1], Simu Razvan-Ioan[1], Letitia Toma[1], Ioana Tanasie[1], Elena Laura Iliescu[1]. [1]*Fundeni Clinical Institute, Romania*
Email: andreea.dobroaia@gmail.com

Background and aims: Hepatitis B virus (HBV) and hepatitis delta virus (HDV) infection is considered the most severe chronic viral hepatitis, due to the rapid onset of complications, such as cirrhosis and hepatocellular carcinoma. The prevalence of HDV and HBV infection is higher among patients from the Mediterranean basin, especially among those with a history of intravenous drug use. The aim of this study is to observe the evolution of the disease, the survival rate of the patients and to determine the key elements that may aid in rising the life expectancy and quality of life of the patients.
Method: We conducted a retrospective observational study on 110 patients diagnosed in our clinic with chronic HBV and HDV infection between January 2012 and December 2012. We monitored the patients for progression to cirrhosis, hepatocellular carcinoma (HCC), as well as APRI, MELD and FIB-4 scores at diagnosis. The survival rate of those patients was expressed as number of months. We only included patients in which interferon therapy was not tolerated or not indicated due to decompensated liver disease. Patients with hepatitis C or HIV co-infection, as well as patients with malignancies or other significant medical conditions with poor prognosis were excluded from the study.
Results: The mean age at diagnosis was 43.82 ± 22.91 years (range between 21 and 65 years). At the time of diagnosis, 52 patients (47.27%) were already diagnosed with cirrhosis (13 patients Child A, 26 patients Child B and 13 patients Child C), while the rest (52.72%) were classified as chronic hepatitis. 15 patients presented HCC at the

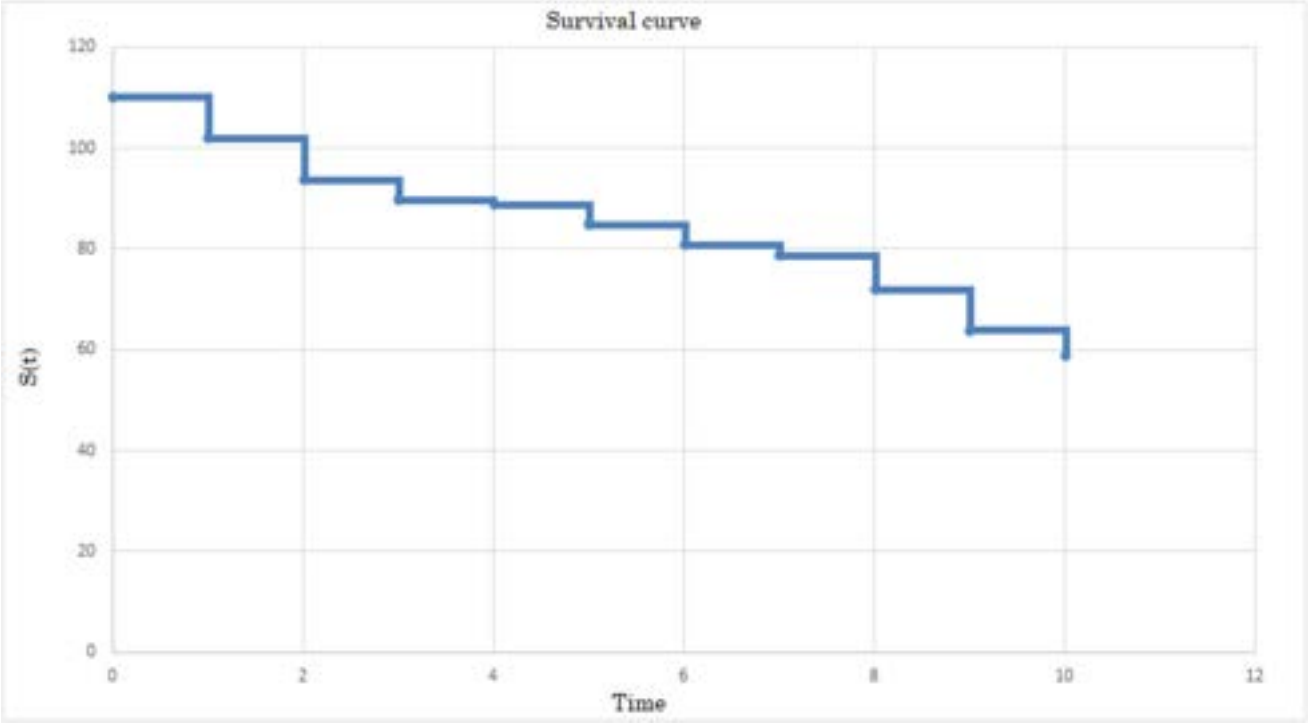

Figure: (abstract: WED-204).

time of diagnosis (10 cirrhotic patients and 5 patients with chronic hepatitis). In cirrhotic patients, mean value of MELD was 16.34 ± 8.16, mean value of APRI was 5.28 ± 1.56, mean value of Fib-4 was 7.27 ± 4.75. During the 10 years follow-up, 70.68% of chronic hepatitis patients developed cirrhosis (41 out of 58 patients). New HCC was diagnosed in 18 patients (11 cirrhotic patients and 7 non-cirrhotic patients). Overall survival was 52.72% at 10 years (25% in the cirrhosis group and 34% in the chronic hepatitis group). Notably, only 9 patients underwent liver transplantation. Carcinogenesis rate was 26.19% in cirrhotic patients and 13.2% in non-cirrhotic patients. Increased APRI score as well as Fib-4 score and MELD at diagnosis were associated with mortality (p = 0.04, p = 0.02, p = 0.01 respectively, CI 95%).
Conclusion: While the survival rate for patients with chronic HBV and HDV infection is low, close monitoring for the development of cirrhosis and frequent HCC screening may increase overall survival and may offer bridging possibilities until liver transplantation.

WED-205
Overcoming barriers to care for Delta infected patients
Ariadna Bono[1], Ângela Carvalho-Gomes[1,2], Maria Dolores Gómez Ruiz[1,3], Susana Sabater Vidal[4], Juan Carlos, Rodríguez Díaz[5], Helena Hernàndez-Èvole[6], Antonio David Palau Canos[4], Ana Forés[4], Maria Rodriguez[5], Maria L Molina[4], Sonia Pascual[5], Martin Prieto[1], Marina Berenguer[1,2,3,7]. *[1]La Fe Health Research Institute, Spain; [2]CIBEREHD, ISCIII, Spain; [3]La Fe Polytechnic and University Hospital, Spain; [4]University General Hospital of Castellon, Spain; [5]University General Hospital of Alicante, Spain; [6]Clinical Hospital of Barcelona, Spain; [7]University of Valencia, Spain*
Email: marina.berenguer@uv.es

Background and aims: Delta hepatitis is a rare infectious disease that affects roughly 15 million people worldwide, unevenly distributed, with endemic such as the Mediterranean basin. Due to increasing worldwide migrations, changes in epidemiology have been highlighted recently. In the current setting of advanced therapies and changing epidemiology, a search and phenotyping of HDV cases are warranted. We aim to better understand the local epidemiology of HDV infection, establishing a registry of delta-infected patients in our region as well as linking to care prior undiagnosed or lost to follow-up (FU) cases.
Method: After a search of all possible HDV cases in a Spanish Region, attempts were made to relink to care those lost to follow-up. Approaches were undertaken to detect all HDV infected patients in a Spanish region: (i) database search of the microbiology units for HBsAg positive results plus anti-HDV in 3 Public Healthcare Departments (those without HDV serology in the last 10 years to be further contacted for anti-HDV determination ± HDV RNA quantitation); (ii) electronic medical records software (ORION program) search from adult patients attending any of the 3 participant Hospitals (Jan 2011–Jun 2021) and codified in the system as HBV HDV.
Results: Two hundred forty-four anti-HDV cases were detected (11% of the chronic HBV patients in our Region), with similar distribution in the three hospital districts. In Hospital 1,133 anti-HDV cases were detected; of these, only 43 were patients that belonged to the Hospital Reference Area. After excluding two possible false positives (only one positive result followed by >5 negative), 41 cases (24 men, 27 European, 12 African, 1 Asian, 1 other) were revised to determine their phenotype and current linkage to care. Four had previously died (2 liver-related), 19 were adequately being followed up in the liver clinic (5 of these had undergone liver transplantation), 11 were no longer followed up in the hospital (2 Africans had left the country, 1 had moved to another city, and 8 were lost to FU; Of the latter 8, 2 out of 3 European and 1 of 5 African were re-linked to care); The reminder 7 anti-HDV + cases had never been studied and linked to care. Of these, 1 of 3 Europeans, 1 of 3 Africans and 0 of 1 Asians were eventually contacted and re-linked to care. Overall, 28% of patients without adequate local FU were relinked to care. Data on Hospital 2 and 3 will be presented at the meeting.
Conclusion: In a reference center hospital, only half of delta-infected patients are being adequately followed up. After an active search, about a third, particularly non-migrant patients can be relinked to care.

WED-206
Clinical phenotypes of hepatocellular carcinoma in patients with chronic hepatitis D compared to patients with chronic hepatitis B
Matthias Jeschke[1], Leonie Steinhoff[1], Leonie Jochheim[1], Benedikt Hild[1], Moritz Passenberg[1], Hartmut Schmidt[1], Christoph Schramm[1]. *[1]University of Duisburg-Essen, Department of gastroenterology, hepatology and transplant medicine, Essen, Germany*
Email: christoph.schramm@uk-essen.de

Background and aims: Patients with chronic hepatitis D (CHD) are at increased risk for developing hepatocellular carcinoma (HCC) compared to patients with chronic hepatitis B (CHB). CHD-associated HCC may feature a distinct molecular profile compared to CHB-associated HCC. We, therefore, aimed to compare the clinical phenotypes of patients with CHD-associated and CHB-associated HCC.
Method: We conducted a retrospective analysis of all patients with CHD-associated HCC from a single tertiary center in Germany between 2012 and 2022. Patients with first diagnosis of CHD-associated HCC were compared to consecutive patients with CHB-associated HCC between October 2017 and November 2021. Patients with previously treated HCC were excluded.
Results: We identified 15 patients with CHD-associated HCC and compared them to 33 patients with CHB-associated HCC. Patients with CHD-associated HCC were significantly younger (median age 56 years, IQR 52–59, vs. 63 years, IQR 53–67.5; p = 0.022), had liver cirrhosis in all cases (100% vs. 62%, p = 0.025) and tended to have worse liver function according to Child-Pugh (CP) stage (CP C 31% vs. 6%, p = 0.080). There were no differences in gender distribution (male gender 80% vs. 88%, p = 0.662), body mass index (median 25.3 vs. 25.3, p = 0.956) and ECOG performance status (median 0 vs. 0, p = 0.577). Method of HCC diagnosis was comparable between both groups (radiologically in 33% vs. 58%, histologically in 67% vs. 42%, p = 0.119). Characteristics of CHD- and CHB-associated HCC are displayed in table 1. HCC in patients with CHD was significantly more likely to be diagnosed in very early (stage 0) and early stages (stage A) according Barcelona Clinic Liver Cancer staging system compared to patients with CHB (67% vs. 21%, p = 0.004).
Conclusion: Patients with CHD-associated HCC are younger and present with more advance liver disease compared to patients with CHB-associated HCC. However, tumor burden is lower and HCC is more likely to be diagnosed in early stages and within Milan criteria, whereas a higher ALBI grade would suggest impaired prognosis.

		CHB-associated HCC n = 33	CHD-associated HCC n = 15	p

WED-207

Risk stratification for hepatocellular carcinoma in patients with chronic hepatitis D

Leonie Steinhoff[1], Matthias Jeschke[1], Leonie Jochheim[1], Benedikt Hild[1], Moritz Passenberg[1], Hartmut Schmidt[1], Christoph Schramm[1]. [1]*University of Duisburg-Essen, Department of gastroenterology, hepatology and transplant medicine, Essen, Germany*
Email: christoph.schramm@uk-essen.de

Background and aims: Surveillance for hepatocellular carcinoma (HCC) is recommended in patients with increased risk. In recent years, scoring systems have been developed and validated in different populations but not in patients with chronic hepatitis D (CHD) to facilitate risk stratification and to identify subgroups in which surveillance can be safely omitted. We aimed to analyze performance of established scoring systems in CHD-patients.

Method: We retrospectively analyzed all patients with CHD presenting to a single tertiary center from Germany between 2012 und 2022. PAGE B, FIB-4, HCC-Rescue, CAMD, and THRI were calculated at baseline, with was defined as time of first presentation, irrespective of treatment with nucleos (t)id analoga. Patients were followed up until diagnosis of HCC, liver transplantation, or last available data, whichever came first. Patients with concomitant chronic liver disease, HCC at first presentation and with follow-up (FU) <12 months were excluded.

Results: Sixty-nine patients were identified (64% male gender, median age 41 years, IQR 36–48). Of these, 42 patients had cirrhosis (61%) and 16 patients had history of decompensation (38% of patients with cirrhosis). In the majority of patients (72.5%), FU was <5 years, whereas only 13% were followed up >10 years. During a median FU of 44 months (IQR 21–64.5), four patients developed HCC (6%) and 14 patients underwent liver transplantation (20%), accounting for an incidence of 1.2 per 100 patient years. Results for risk scores are displayed in table 1. One patient (female, age 56 years at HCC diagnosis, FU 49 months), which was categorized as low risk by all risk scores but THRI, did not have signs of cirrhosis at baseline, but histology revealed cirrhosis at time of HCC diagnosis. She had a long-standing CHD, moderate overweight, and history of kidney transplantation and ulcerative colitis, which may contributed to progression to cirrhosis.

Conclusion: FIB-4 and THRI seem most suitable for risk stratification in CHD. However, short FU and low number of patients limit results.

Risk score	Risk category	n (%)	HCC, n	FU (months), Median (IQR)	Incidence per 100 py	Incidence per 100 py

Email: mm.casado.m@gmail.com

Background and aims: Chronic hepatitis delta (CHD) is the most severe form of chronic hepatitis, associated with high morbidity and mortality due to its high risk of developing cirrhosis and hepatocellular carcinoma. Its prevalence is unknown, but it is believed to affect around 5% of patients with hepatitis B in Spain. However, this percentage may vary, possibly influenced by migration from countries with higher prevalence. The development of new therapeutic alternatives could modify the management of this infection. Our aim was to analyze the current state of diagnosis of CHD in hospitals in the autonomous community of Andalusia and describe the profile of patients with chronic infection by active hepatitis delta virus (HDV).

Method: Multicenter, retrospective study, in which the diagnostic workflow of hepatitis delta in the laboratory information systems (SIL) of the 17 participating centers has been analyzed. HBsAg-positive patients, with anti-delta antibodies and detection of HDV RNA, have been included. In patients with active HDV infection, demographic and clinical variables have been analyzed.

Results: The period between January 2018 to October 2022 has been analyzed. 17,899 HBsAg positive patients have been detected; of these, HDV serology (Ig G anti-HDV) was performed in 3314 patients (18%); 205 patients (6.2%) of those tested were anti-HDV positive; of these, HDV RNA was performed in 158 (77%) and finally, 63 patients (39.9%) were RNA-HDV positive, 1.9% of VHD determinations. Regarding the profile of our 63 viremic patients, 69% were men, with an average age of 50 years, 47% were immigrants, half of them coming from Eastern European countries. 37% had HIV or HCV coinfection and 21% history of drug use. 39% of patients had cirrhosis and of them, 6 patients had developed hepatocellular carcinoma, 21% of all viremic patients had presented some episode of decompensation, most of them ascites. 27% had portal hypertension. 40% of patients had been treated with interferon and 6 patients had been transplanted.

Conclusion: The prevalence of anti-HDV positive patients in Andalusia in HBAgs positive patients is 6% and 40% are viremic patients. However, HDV serology has only been performed in 18% of HBsAg-positive patients. The epidemiological profile of patients with active HDV infection has changed as almost half of the patients are immigrants, however, their morbidity remains high. With the new treatment options for HDV, and considering the benefits that the diagnosis of HDV can currently bring, its implementation in the autonomous community of Andalusia seems necessary.

WED-209

Treatment experience and acceptability in a UK HBV cohort- why personalised regimens may be necessary in chronic hepatitis B

Jane Abbott[1,2], Patrick Kennedy[1,2], Rageshri Dhairyawan[1,2]. [1]*Barts Health NHS Trust, United Kingdom;* [2]*Queen Mary University of London, United Kingdom*
Email: janeabbott85@gmail.com

Background and aims: Nucleos (t)ide analogues (NA) are the mainstay of treatment for Chronic Hepatitis B (CHB) and whilst they offer potent viral suppression, ultimately they are non-curative. In the context of the functional cure program, and expanding access to anti-viral therapy, it is vital to understand patient acceptability and perspective. We present preliminary results of a patient survey from a multi-ethnic CHB patient cohort.
Method: Patients were recruited from the Barts Health viral hepatitis service, London, UK and consented to a self-guided electronic survey. Patient experience and views on treatment were ascertained, and branch logic was used to tailor subsequent questions dependent on treatment status.
Results: Data are presented on the results of 55 individual patient responses. Respondents had a mean age of 42 years; 59% Male. Ethnicity was predominantly from Asian and African backgrounds: 28.3% Chinese, 20.8% Black African, 18.9% Bangladeshi. 44% of respondents had never taken antiviral therapy. Of the treatment experienced patients, n = 2 reported stopping medication due to concerns about side effects. Of patients currently on treatment (n = 34); 44% reported being careless or sometimes forgetting to take their medication. Patients not currently on treatment were asked about the factors that would influence their decision to start NA. 83% stated the 'benefit in terms of risk reduction', but 83% were also concerned about treatment side effects. 66.7% stipulated the potential to stop treatment in the future, whilst 44% were worried about the cost. We asked about willingness to take different forms of treatment; 81.5% were willing to take NA daily, 60.4% were willing to take NA indefinitely. 75.9% were willing to take an approved injectable treatment. We asked "How acceptable is it for you to take a daily NA (tablet) that will control viral replication and reduce the risk of harm but not cure your disease?" 31.5% responded extremely acceptable, 42.6% somewhat acceptable. 16.7% stated neutral stance, 3.7% responded somewhat unacceptable and 5.6% extremely unacceptable. We asked if patients would be open to starting NA therapy if HBV DNA >2000 IU/ml (regardless of ALT level or fibrosis): 20% said yes, 30% said no and 50% were unsure. 66.7% were willing to take part in clinical trials, 61% willing to take an injection as part of a trial, and 74.1% were willing to take a combination of tablets and injections to achieve functional cure. Patients were then asked what duration of this treatment would be acceptable; 3–6 months (27.5%) 6–12 months (37.5%), 12 m-2 yrs (12%) >2 years (25%.)
Conclusion: Our results demonstrate a willingness to participate in clinical trials, and an understanding of potential benefits of treatment, which is paralleled with significant concern about side effects. Cost is also a concern. Most patients are willing to take a combination regimen to achieve functional cure but acceptability of treatment duration varies. Clear information about the rationale for treatment and patient education about drug safety may improve treatment uptake. Consultation with patients in drug development should be a vital component of the functional cure program and may usher in an era of personalised treatment regimens.

WED-210

Eliminating viral hepatitis one island at a time-the Hainan experience

Min Liao[1], Jiao Wang[1], Juan Fu[1], Hui Gao[1], Tao Wu[1], Xuexia Zeng[2], Zhijia Zhao[3], Xingyang Zhou[4], Feng Lin[1], Biao Wu[1]. [1]*Hainan General Hospital, Haikou, China;* [2]*Hainan Provincial Center for Disease Control and Prevention, Haikou, China;* [3]*People's Hospital of Baoting City, Baoting, China;* [4]*Qionghai City Center for Disease Control and Prevention, Qionghai, China*
Email: wubiao@hainmc.edu.cn

Background and aims: Hainan Island has the highest incidence of Hepatocellular carcinoma (HCC) in China. In 2021, HCC was the second most common cancer and the first leading cause of death from cancer in Hainan. Most of them are related to Hepatitis B and Hepatitis C in Hainan. However, low disease awareness among Hainanese and lack of disease knowledge among community Health Care Professionals (HCPs) make achieving the WHO targets a great challenge.
Method: Collaborating with Hainan Medical Association, Preventive Medicine Association and Hainan National Health Commission of the Hainan (NHCH), a series of activities were implemented. Education

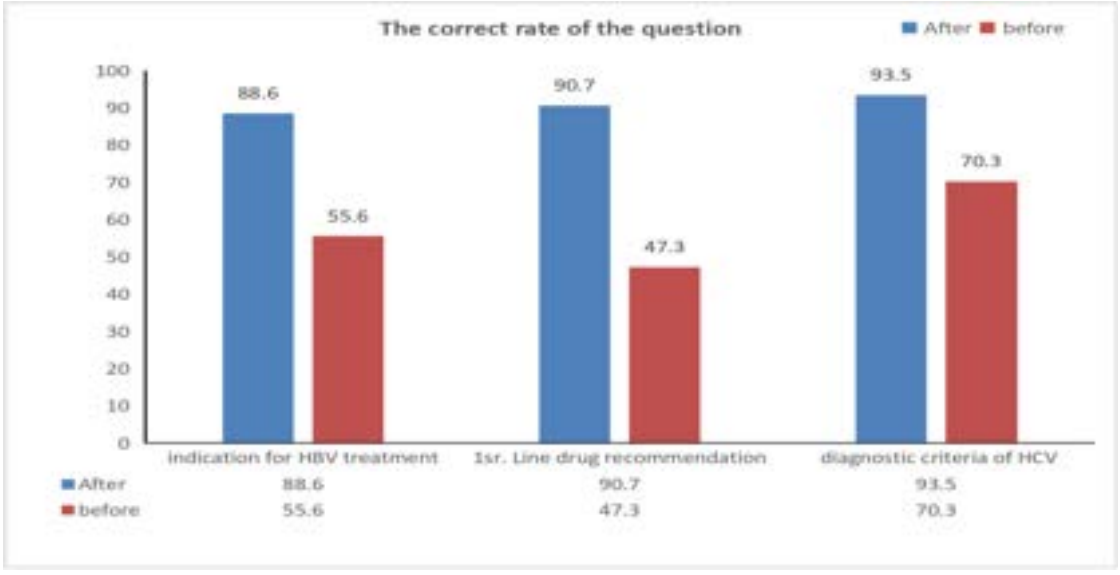

Figure: (abstract: WED-210): The correct rate of the question.

forums to increase awareness of viral hepatitis, screening for HBV in people older than 18 years and HCV in people with high-risk factors were carried out in some cities (Qionghai city, Dongfang city, Baoting city and Haikou city etc) as pilots to create a model of viral hepatitis elimination. It can then be extended to other cities in Hainan to achieve viral hepatitis elimination in Hainan by 2025.
Results: In the past 2 years (2021 Jan-2022 Dec), we have conducted 13 viral hepatitis elimination education conferences in 5 cities for HCPs and a couple of HBV/HCV screening activities in 3 cities. 1683 HCPs were educated and 5, 19733 inhabitants were screened for HBV/HCV, respectively. The prevalence of HBV/HCV was 7.3% and 2.3%, respectively, in Dongfang. After education, awareness of viral hepatitis among HCPs has increased significantly. A total of 918 participants were surveyed, including 73% physicians, 19% nurses, 8% medical technicians. 61%, 21% and 18% of the subjects were from primary, secondary and tertiary hospitals respectively. After the education, awareness of HBV/HCV was increased significantly.
Conclusion: This is an efficient way to achieve viral hepatitis elimination in one island through disease education among HCPs and the public to increase awareness of HBV/HCV and screening for HBV in people older than 18 years and HCV in high-risk individuals.

WED-211

Prevalence and predictors of HDV viremia in anti-HDV positive patients of the HEllenic multicenter ReAl-life CLInical Study (HERACLIS-HDV)

Samonakis[6], Melanie Deutsch[2], Christos Ωeretanos[7], Christos Triantos[8], Konstantinos Mimidis[9], Emmanouil Manesis[10], Ioannis Vlachogiannakos[1], Ioannis Goulis[11], Evangelos Cholongitas[1], Vasilis Sevastianos[7], Andreas Kapatais[12], Nikolaos Papadopoulos[2], Panagiota Ioannidou[1], Georgios Germanidis[13], George Giannoulis[14], Dimitra Lakiotaki[1], Dionisios Kogias[9], Hariklia Kranidioti[2], Konstanitnos Zisimopoulos[8], Maria Mela[7], Georgios Kontos[2], Paraskevi Fytili[1], Chrysanthi Manolaka[3], Polyxeni Agorastou[11], Spyridon Pantzios[4], Margarita Papatheodoridi[1], Eleni Geladari[7], Nikolaos Psychos[4], Kalliopi Zachou[14], Anna Chalkidou[9], Anastasia Spanoudaki[2], Konstantinos Thomopoulos[8], George Dalekos[14]. *[1]General Hospital of Athens "Laiko", Medical School of National and Kapodistrian University of Athens, Greece; [2]General Hospital of Athens "Hippokratio", Medical School of National and Kapodistrian University of Athens, Greece; [3]General Hospital of Rhodes, Greece; [4]General and Oncology Hospital of Kifisia "Agioi Anargyroi," Greece; [5]University General Hospital of Ioannina, Greece; [6]University General Hospital of Heraklion Crete, Greece; [7]General Hospital of Athens "Evangelismos," Greece; [8]University General Hospital of Patras, Greece; [9]University General Hospital of Alexandroupolis, Greece; [10]Euroclinic SA, Athens, Greece; [11]General Hospital of Thessaloniki "Hippokratio," Aristotle University of Thessaloniki, Greece; [12]General Hospital Nikaia-Piraeus "Agios Panteleimon" and General Hospital of Western Attica "Agia Varvara," Greece; [13]University General Hospital of Thessaloniki "AHEPA"; Greece; [14]General University Hospital of Larissa, Greece*
Email: gepapath@med.uoa.gr

Background and aims: HDV underdiagnosis remains common varying widely even among different areas of the same country. HDV diagnosis is based on anti-HDV detectability, but not all anti-HDV+ patients (pts) are diagnosed to have HDV viremia. We assessed the rate and predictors of HDV viremia among anti-HDV+ pts of HERACLIS-HDV cohort.
Method: We included 157 (5.8%) anti-HDV+ pts diagnosed among 2696 HBsAg+ adult pts with anti-HDV screening until 03/2022; all had ≥1 visit within 5 years before 10/2021 at one of the 14 participating clinics of HERACLIS-HDV retrospective-prospective cohort study. Epidemiological, clinical and laboratory patients' characteristics were collected using a specifically designed case report form. Serum HDV RNA was detected by a quantitative real-time polymerase chain reaction assay (Primerdesign Ltd; LLD 400 IU/ml).
Results: Of the 157 anti-HDV+ pts, 135 (86%) could be tested for HDV RNA at screening, while 6 had died and another 16 had been lost to follow-up. At screening, HDV RNA was detected in 85/135 (63%) pts with median levels of 32,000 (range: $10–22 \times 10^6$) IU/ml. All 6 pts who had died and 7/16 pts lost to follow-up had detectable HDV RNA in the past, whereas 8/50 pts with undetectable HDV RNA at screening also had detectable HDV RNA in the past (HDV therapy:4, liver transplantation:2, low fluctuating levels:2). Thus, the overall HDV RNA detectability rate at any time point was 71.6% (106/148 pts tested). HDV RNA at any time point was more frequently detected in anti-HDV+ pts with chronic hepatitis (elevated ALT) than infection (normal ALT) (90/111 or 81.1% vs 16/37 or 43.2%, $P < 0.001$), advanced (cirrhosis or liver transplantation) than non-advanced liver disease (51/60 or 85.0% vs 55/88 or 62.5%, $P = 0.005$) and current/past use than no use of HBV therapy (88/108 or 81.5% vs 18/40 or 45.0%, $P < 0.001$). There was no association between HDV RNA detectability and age, gender, risk group, birth place, center location or size and period of 1st pts visit.
Conclusion: Among anti-HDV+ pts, the probability of serum HDV RNA detectability is significantly higher in those with active and/or advanced liver disease. However, HDV RNA can be frequently detected in all anti-HDV+ subgroups, such as those with normal ALT (>40%), without cirrhosis (>60%) and without a history of HBV therapy (45%).

WED-212

A novel nomogram for predicting HBeAg clearance in HBeAg-positive chronic hepatitis B patients after nucleos (t)ide analogues treatment

Yan Gu[1], Jian Wang[2,3], Zhiyi Zhang[1], Shaoqiu Zhang[2], Yao Zhang[1], Weimao Ding[4], Jie Li[1,2,3], Rui Huang[1,2,3], Chao Wu[1,2,3]. *[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China; [2]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China; [3]Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, Jiangsu, China; [4]Department of Hepatology, Huai'an No. 4 People's Hospital, Huai'an, Jiangsu, China*
Email: dr.wu@nju.edu.cn

Background and aims: Serum biomarkers for the prediction of HBeAg clearance are important for the management of HBeAg-positive chronic hepatitis B (CHB). This study developed and validated a simple nomogram for predicting HBeAg clearance in hepatitis B e antigen (HBeAg)-positive chronic hepatitis B (CHB) patients treated with nucleos (t)ide analogues (NAs).
Method: Five hundred and sixty-nine CHB patients treated with NAs from two medical institutions between July 2016 to November 2021 were included. Patients were randomly assigned to a derivation cohort (n = 374) and a validation cohort (n = 195) in a 2:1 ratio. A predictive nomogram was established based on cox proportional hazards regression analysis. The predictive value of nomogram was evaluated using the area under the receiver operating characteristic curve (AUC), and the calibration curve.
Results: The 3-year cumulative rates of HBeAg clearance were 27.27% and 21.54% in the derivation cohort and validation cohort, respectively. In the derivation cohort, baseline aspartate aminotransferase, gamma-glutamyl transpeptidase, HBeAg levels and hepatitis B core antibody levels were independently associated with HBeAg clearance and were used to establish the nomogram. The calibration curve revealed that the nomogram had a good agreement with actual observation in both two cohorts. The nomogram showed relatively high accuracy for predicting 48 weeks, 96 weeks, and 144 weeks of HBeAg clearance in the derivation cohort (AUCs: 0.782, 0.734 and 0.671) and validation cohort (AUCs: 0.699, 0.718 and 0.689). The

prediction scores of nomogram ranged from 0 to 100, patients with high scores (79.51–100) had significant higher cumulative incidence of HBeAg clearance than patients with low scores (0–79.51) in both cohorts ($p < 0.05$).
Conclusion: The novel nomogram provided an excellent prediction of antiviral efficacy in HBeAg-positive CHB patients after NAs treatment.

WED-213
The benefit of a local hepatitis B reactivation guideline to improve screening and prophylaxis for patients initiated on rituximab
Helen Boothman[1], Kieran Reynolds[1], Zainab Jadawdji[1], Hannah Hesketh[1], Sarah Clark[1]. [1]*St George's Hospital, Hepatology, London, United Kingdom*
Email: helen.boothman@stgeorges.nhs.uk

Background and aims: Immunosuppressant agents, especially rituximab, have the potential to cause flares and reactivation of hepatitis B virus (HBV) in patients who are currently infected or previously exposed to the virus. The European Association for the Study of the Liver (EASL) Hepatitis B guideline 2017[1] and a Drug Safety Update in England 2014[2] advise, prior to initiation of rituximab, HBV surface antigen (HBsAg) and HBV core antibody (HBcAb) should be checked and prophylaxis with tenofovir or entecavir should be initiated for any positive results. Despite national guidance, in 2016 there was a fatal HBV reactivation following rituximab at St George's Hospital (SGH). A local guideline was developed in 2018 to highlight the risk and ensure adequate monitoring and prophylaxis. Prior to its implementation, an audit showed 67% of patients receiving rituximab had adequate HBV serology checked.
Method: Newly initiated rituximab prescriptions over a one year period in 2021/22 were identified. Serology results were reviewed to check if pre-screening and initiation of prophylaxis was completed as per the local policy.
Results: 96% of patients started on rituximab had HBV screening. However, only 82% were checked within 3 months of receiving rituximab. 14% of patients had appropriate serology results performed prior to or on the same day as receiving their first dose of rituximab. 10 patients were found to have positive HBsAg or HBcAb, 9 were initiated on prophylaxis (see Table 1).
Conclusion: The introduction of a local guideline and education sessions for specialties responsible for prescribing rituximab resulted in an improvement in HBV screening from 67% to 96%. This has also empowered clinicians to initiate prophylaxis prior to referral to the hepatology team. Despite this, further work is required to ensure the guideline is adhered to in all cases. All 4 patients with no HBV screening were paediatrics, education sessions were offered and the policy is now implemented by the paediatric teams.

The comparisons of clinical relapse timing and severity after cessation of prophylactic nucleos (t)ide analogue between chronic hepatitis B patients with lymphoma receiving chemotherapy with and without Rituximab
Yen-Chun Liu[1,2], Yu-Jia Shih[1,2], Chao-Wei Hsu[1,2], Rachel Wen-Juei Jeng[1,2]. [1]*Chang Gung Memorial Hospital, Linkou branch, Taiwan, Taiwan;* [2]*College of Medicine, Chang Gung University, Taiwan, Taiwan*
Email: rachel.jeng@gmail.com

Background and aims: Rituximab-based chemotherapy for hematologic malignancies has been well known for high reactivation comparing to other solid tumor chemotherapy regimen. Prophylactic nucleos (t)ide analogues (NUC) treatment is effective to prevent HBV reactivation during chemotherapy. Whether CHB with lymphoma patients will encounter different onset timing or severity of off-Nuc clinical relapse after completion of chemotherapy with and without Rituximab remained unknown. The study aimed to investigate these issues.
Method: HBsAg-positive CHB patients who were diagnosed as lymphoma and had stopped prophylactic Nuc treatment for systemic chemotherapy after at least 12 weeks extended treatment duration were enrolled. In patients with detectable HBV DNA at end-of Nuc treatment (EOT), HBV reactivation was defined at least 2 $\log_{10}$ increase in serum HBV DNA level greater than that at EOT while in patients with undetectable HBV DNA at EOT, reactivation is defined by reappearance of HBV DNA or HBV DNA level $\geq$ 2000 IU/ml. Clinical relapse (CR) was defined as HBV reactivation with ALT elevation to 2 times upper limit of normal. Hepatic decompensation (HD) was defined was bilirubin $\geq$ 2 mg/dL and INR $\geq$ 1.5 with or without clinical syndrome of ascites or hepatic encephalopathy. Cox regressions were analyzed for predictors of off-therapy CR. The cumulative incidence was evaluated by Kaplan-Meier method.
Results: A total of 156 CHB patients with lymphoma were enrolled, mean age of 55-year-old, 51% male, 83% Rituximab-based regimens, and received prophylactic Nuc treatment of a median duration of 48 (range: 29–198) weeks, which the extended Nuc duration of 28 (range: 13–174) weeks. During a median of 56 months follow-up, there were 49 (31%) patients encountered CR with a median time to CR of 24 weeks, and 10 (6%) patients suffering from HD. Compared to patients without Rituximab-based regimens, those receiving Rituximab-based chemotherapy showed numerically higher 2-year cumulative CR incidence (32% vs. 23%, log-rank p = 0.314, Figure), three-fold higher peak ALT level at CR (864 vs. 282 U/L, p = 0.204), two times greater proportion of ALT $\geq$ 1000 U/L (47% vs. 20%, p = 0.362), but comparable HD rate (6% vs. 8%, p = 0.673) and comparable timing to CR (23 vs. 24 weeks, p = 0.574). Multivariate cox regression showed male (adjusted hazard ratio (aHR): 1.855, p = 0.049], use of less potent Nuc rather than ETV or TDF (versus ETV; aHR:2.516, p =

Table 1: (abstract: WED-213): Adherence to local HBV reactivation guideline)

		Receiving rituximab	Adequate screening	Inadequate screening	HBsAg or HBcAb +ve	Prophylaxis initiated
Prior to local guideline	No. pts	228	152	76	13	8
	% pts	100	67	33	6	62
After local guideline	No. pts	106	102	4	10	9
	% pts	100	96	4	9	90

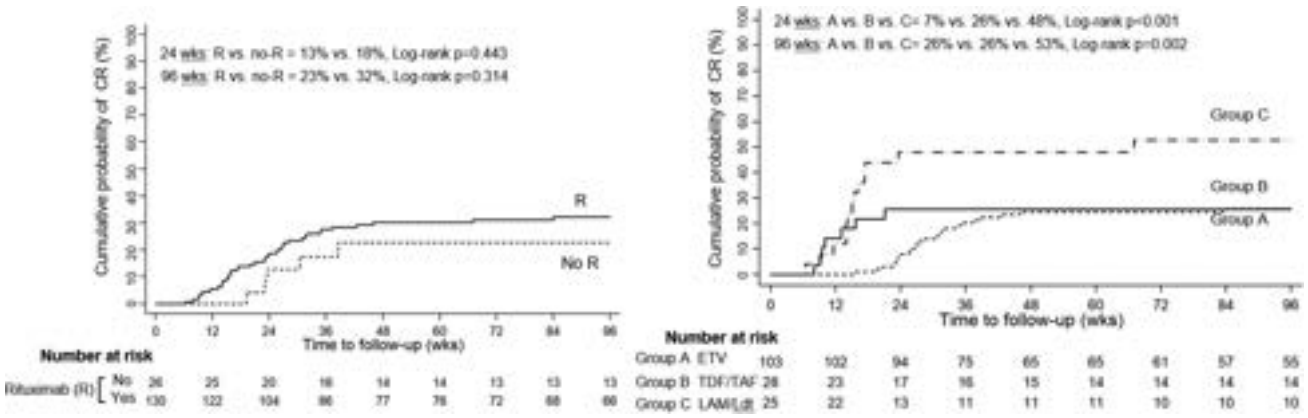

Figure: (abstract: WED-214).

0.007] and pre-treatment HBV DNA ≥ 4 $\log_{10}$ IU/ml (aHR:1.953, p = 0.030] were predictors for CR. Duration of Nuc extension therapy is not an independent factor for CR.
Conclusion: CHB patients who received Rituximab-based regimens for lymphoma had numerically higher off-NUC CR rates and higher ALT level at CR than those without rituximab-based chemotherapy while the timing of CR and hepatic decompensation rate were comparable. Stringent off-therapy monitoring is necessary, especially in patients receiving Rituximab-based regimens.

Tenofovir is associated with a better prognosis of hepatocellular carcinoma compared with entecavir in patients with chronic hepatitis B

Hyun Jun Um[1], Jonggi Choi[1], Young-Suk Lim[1], Won-Mook Choi[1].
[1]*University of Ulsan College of Medicine, Department of Gastroenterology, Liver Center, Asan Medical Center, Korea, Rep. of South*
Email: dr.choi85@gmail.com

Background and aims: Whether tenofovir or entecavir has different effects on the prevention of hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) in secondary and tertiary preventive settings remains controversial. This study was aimed to compare the long-term prognosis of HCC between tenofovir and entecavir in patients with chronic hepatitis B (CHB).
Method: CHB patients who were diagnosed with HCC between November 2008 and December 2018 and were treated with either entecavir (n = 3,469) or tenofovir (n = 3,056) at a tertiary center in Korea were included. The effect of tenofovir vs. entecavir on the prognosis of HBV-related HCC was evaluated in a propensity score (PS)-matched cohort. Various predefined subgroup analyses were performed.

Results: The mean (SD) age was 54.6 (9.1) years, and 4,351 patients (81.1%) of the PS-matched cohort of 5366 patients were male. During a median follow-up period of 3.0 years, entecavir-treated patients had a mortality rate of 43.0%, whereas tenofovir-treated patients had a mortality rate of 33.5%. Overall survival (OS) was better in tenofovir-treated patients compared with entecavir-treated patients (hazard ratio [HR], 0.80; 95% confidence interval [CI], 0.73–0.88). The difference in OS probability between the two groups became more pronounced over time. The magnitude of the risk difference in OS after 3 years of HCC diagnosis (HR, 0.40; 95% CI, 0.30–0.53) was more prominent than that within 3 years (HR, 0.87; 95% CI, 0.79–0.95). In all subgroup analyses, tenofovir was associated with a better OS than entecavir, except for those with advanced or terminal stage HCC. For those who received curative-intent treatment, recurrence-free survival (HR, 0.83; 95% CI 0.73–0.95) and OS (HR, 0.63; 95% CI 0.50–0.79) were better with tenofovir compared with entecavir.

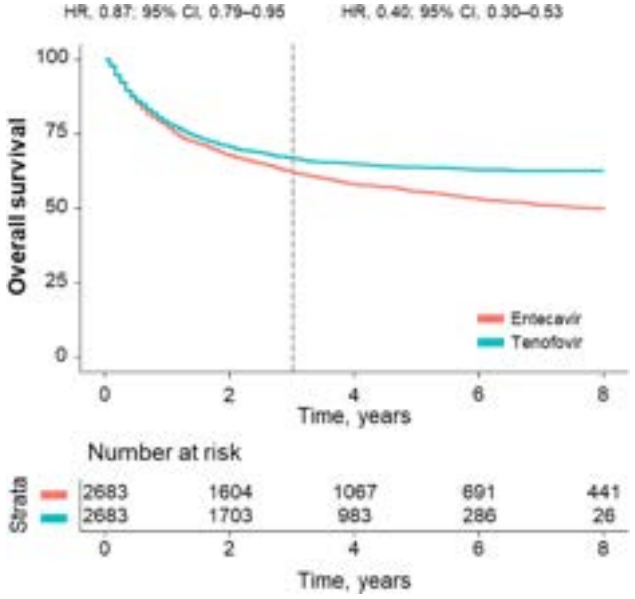

Figure: Survival probability between tenofovir and entecavir in patients with hepatitis B virus-related hepatocellular carcinoma of the propensity score-matched cohort.

Conclusion: In patients with HBV-related HCC, tenofovir showed a better prognosis than ETV, especially in those who survived longer.

SAT-144

Predictors of Baveno VII criteria for recompensation in patients with hepatitis B-related decompensated cirrhosis

Vicki Wing-Ki Hui[1], Terry Cheuk-Fung Yip[1], Vincent Wai-Sun Wong[1], Henry LY Chan[1], Grace Lai-Hung Wong[1]. [1]*Department of Medicine and Therapeutics, Hong Kong*
Email: wonglaihung@mect.cuhk.edu.hk

Background and aims: The latest Baveno VII consensus established the foundation of a new concept of hepatic recompensation. The present study sought to investigate potential predictors for recompensation in individuals diagnosed with hepatitis B-related decompensated cirrhosis.
Method: Individuals diagnosed with both chronic hepatitis B and decompensated liver cirrhosis who were treated with first-line oral nucleos (t)ide analogues from March 2006 to December 2022 were identified from a territory-wide database in Hong Kong. A Fine-Gray subdistribution hazard model, which accounts for competing risks, was employed to identify potential predictors for recompensation.
Results: This study included 2,913 eligible patients, with a mean age of 63.0 ± 11.6 years, of whom 2,184 (75.0%) were male. The baseline Child-Pugh score and MELD score were 7[6, 8] and 8.5 ± 6.4, respectively. During a mean follow-up of 2.1 ± 1.9 years, 435 (14.9%) patients recompensated. High serum albumin correlated with recompensation in cirrhosis (adjusted subdistribution hazard ratio (sHR) 1.03; 95% CI 1.016–1.041; $p < 0.001$), while older age, high alpha-fetoprotein, positive hepatitis B e antigen (HBeAg), and high total bilirubin were associated with a decreased likelihood of recompensation (Age: sHR 0.983; 95% CI 0.975–0.992; $p = 0.001$; Alpha-fetoprotein: sHR 0.697; 95% CI 0.617–0.787; $p < 0.001$; Positive HBeAg: sHR 0.694; 95% CI 0.524–0.919; $p = 0.033$; Total bilirubin: sHR 0.992; 95% CI 0.988–0.996; $p < 0.001$). Patients with recompensation had higher mean serum albumin but lower median AFP, and median total bilirubin compared to those without recompensation over the 5-year follow-up period.
Conclusion: Albumin was an independent protective factor for recompensation, while age, alpha-fetoprotein, positive hepatitis B e antigen, and total bilirubin were identified as risk factors.

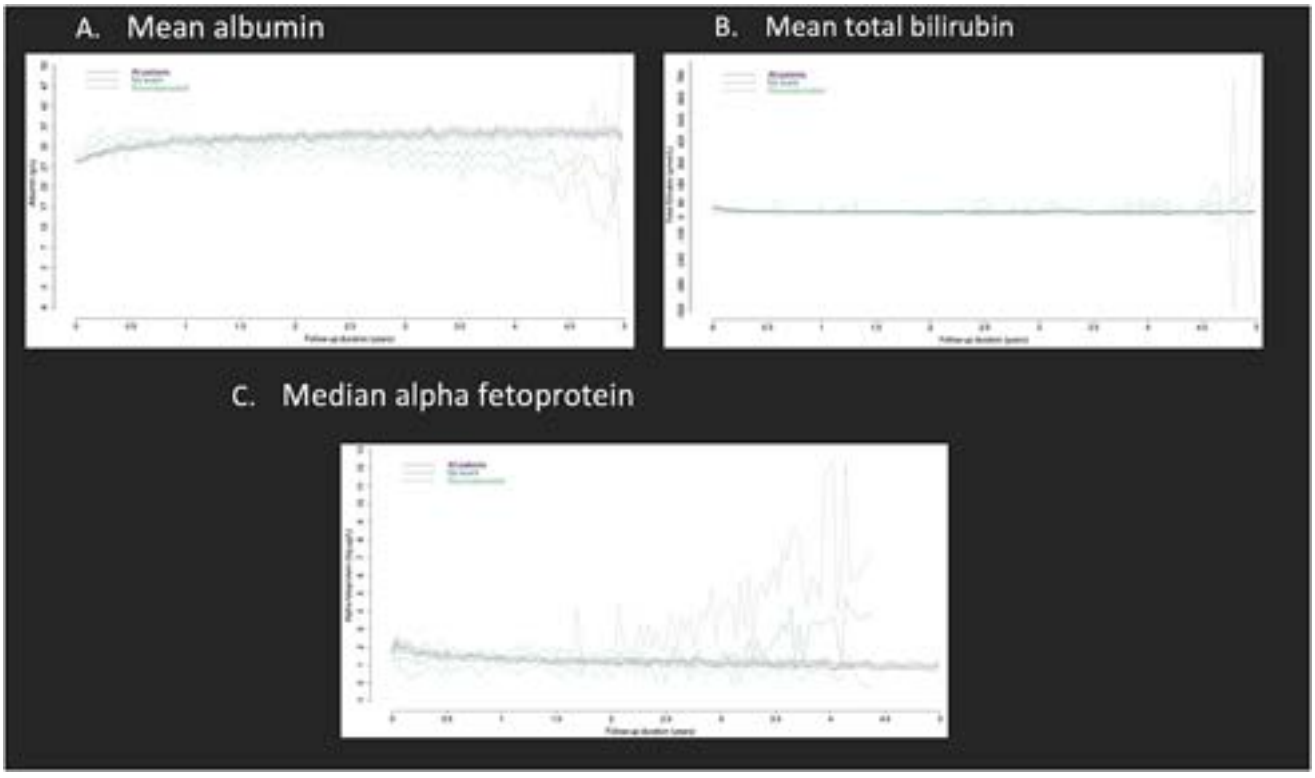

Figure: (abstract: SAT-144).

Email: grishma.hirode@gmail.com

Background and aims: While functional cure or hepatitis B surface antigen (HBsAg) loss remains the optimal end point for chronic hepatitis B (CHB), recent discussions have suggested the use of "partial cure" as a new primary end point, defined as sustained suppression of HBsAg and HBV DNA undetectability for six months off-therapy. We aim to examine the durability of partial cure after nucleos (t)ide (NA) withdrawal.
Method: Retrospective cohort study of CHB patients who stopped NA therapy and were hepatitis B e antigen (HBeAg) negative with undetectable HBV DNA at cessation. We analyzed differences in patient characteristics and outcomes between those who achieved HBsAg loss within six months after NA cessation and those with partial cure defined as sustained HBsAg positivity with levels below 100 IU/ml and HBV DNA ≤20 IU/ml for at least six months after NA cessation. Survival analysis methods were used to analyze off-therapy outcomes that occurred after six months post-cessation.
Results: Among 1,187 included patients (mean age at end of therapy 54 ± 11 years, 74% male, 88% Asian, 20% HBsAg <100 IU/ml at end of therapy, median off-therapy follow-up time 18 months [IQR: 6.6–35]), 1.3% had HBsAg loss (n = 15) and 4.1% achieved partial cure (n = 49) at six months after NA cessation. The partial cure group (vs HBsAg loss group) had a higher proportion of Asian patients (94% vs 60%, p = .001) with a shorter median NA duration (3.0 months [IQR: 3.0–3.1] vs 4.5 months [IQR: 3.0–10], p = .04). At NA cessation, the partial cure group (vs HBsAg loss group) had higher mean HBsAg levels (1.0 ± 0.9 log10 IU/ml vs 0.2 ± 1.8 $\log_{10}$ IU/ml, p = .03), and median ALT levels (0.8x ULN [IQR: 0.5–1.2] vs 0.5x ULN [IQR: 0.4–0.5], p = .04) but within the normal range. At 36 months after NA cessation, among the partial cure group, the cumulative probability of HBsAg loss was 48%, sustained response (HBV DNA <2000 IU/ml and ALT <2× ULN) was 60%, virological relapse (HBV DNA ≥2000 IU/ml) was 18%, ALT flare (≥5x ULN) was 7.7%, and retreatment was 8.4%. Among this group, 1 patient developed hepatic decompensation, 1 patient was diagnosed with HCC, and no patients died during off-therapy follow-up. No patients in the HBsAg loss group experienced relapses or flares and thus none required retreatment. Compared to the group of patients who remained off-therapy without HBsAg loss or partial cure at six months post-cessation, the partial cure group had significantly higher rates of sustained response (p < .001), and lower rates of virological relapse (p < .001) and ALT flare (p = .08) (Figure).
Conclusion: Most patients who achieved partial cure at six months after NA withdrawal, as defined in this study, remained off-therapy thereafter and had favorable outcomes with a high probability of subsequent HBsAg loss. Thus, it may be a viable end point among CHB patients who are well-suppressed and HBeAg negative with low levels of HBsAg at end of therapy.

SAT-146

Effects of tenofovir disoproxil fumarate versus tenofovir alafenamide on risk of osteoporotic fracture in patients with chronic hepatitis B : a nationwide claims study

Eunju Kim[1], Hyun Woong Lee[2], Kwan Sik Lee[3]. *[1]Chung-Ang University Gwangmyeong Hospital, Department of Gastroenterology, Gwangmyeong-si, Korea, Rep. of South; [2]Gangnam Severance Hospital, Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [3]CHA Bundang Medical Center, CHA University, Department of Gastroenterology, Seongnam, Korea, Rep. of South*
Email: leeks519@yuhs.ac

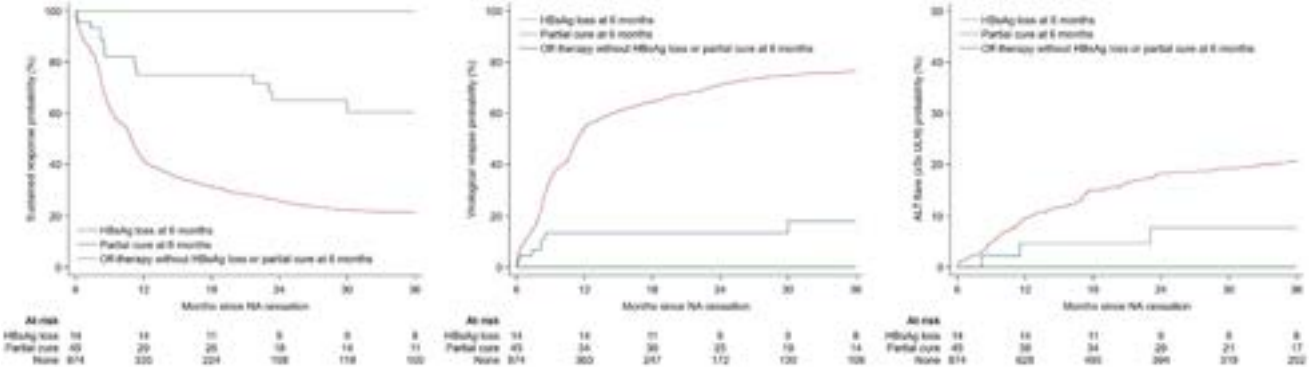

Figure: (abstract: SAT-145).

Background and aims: Since tenofovir disoproxil fumarate (TDF) require long-term use, reduction in bone density should be considered when treating chronic hepatitis B (CHB) patients with aging and systemic diseases. Several studies have shown that patients treated with tenofovir alafenamide (TAF) had less or improved bone mineral density loss compared to patients treated with TDF. However, although improvement in bone density by taking TAF has been reported in previous studies, studies on the actual reduction of fractures are insufficient.
Method: A retrospective cohort study was conducted on 32 582 CHB patients who were initially treated with TDF or TAF from November 2017 to December 2020 using the national claims data of the Health Insurance Review and Assessment Service. The number of patients treated with TDF and TAF was 11 705 and 20 877, respectively. The annual rate of fracture per 100 patients in each group was calculated, and the cox proportional hazard ratio (HR) was analyzed after applying inverse probability treatment weights (IPTW) for both groups.
Results: Among a total of 32 582 patients, the average age was 47.8 ± 11.2 years, males were 64.5%, and the follow-up period was 24.4 ± 11.6 months. The incidence of osteoporotic fractures was 0.78 and 0.49 per 100 person-years in the TDF and TAF groups, respectively. After application of IPTW, HR was 0.68 (95% confidence interval 0.55–0.85, p value = 0.001).

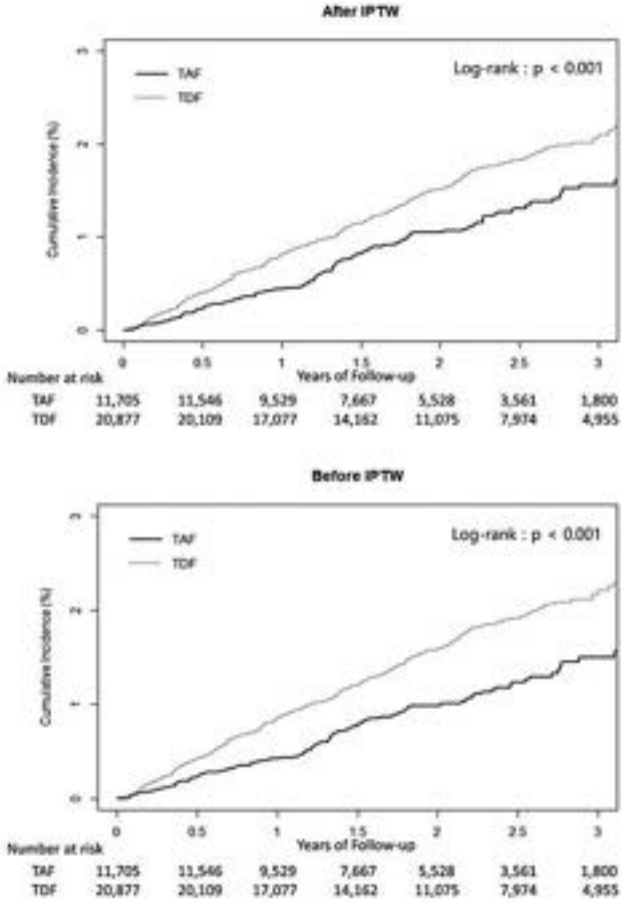

Figure:

Conclusion: In CHB patients, the risk for osteoporotic fracture was significantly lower in the TAF treatment group than the TDF treatment group.

Email: zhangwenhong@fudan.edu.cn

Background and aims: Interferon (IFN)-based therapy (IFN alone or combined with nucleoside analog [Nuc]) is considered as an effective strategy to improve functional cure rate and reduce hepatocellular carcinoma (HCC) risk in patients with chronic hepatitis B (CHB). We aimed to evaluate the effects of interferon-based therapy in CHB patients with different anti-viral treatment history and baseline HBsAg levels in terms of functional cure and HCC risk reduction, based on large scale real-world data from China.
Method: The analysis was conducted in the data from a multi-center, prospective real-world study (OASIS Project) from China. This project recruited treatment-naïve, IFN-treated and Nuc-treated patients from 32 provinces in China. Participants in OASIS Project received either IFN-based therapy (IFN alone or combined with Nuc) or Nuc monotherapy, and would be followed up for five years. We made this analysis at the time-point of 2 years from project initiation. Data on those who have completed 48 weeks of treatment were analyzed for HBsAg-related events, and all subjects included in this project with complete information were analyzed for cumulative HCC incidence.
Results: A total of 24 946 patients with complete baseline information was included in this analysis, of which 17 210 received IFN-based therapy and 7736 received Nuc therapy. A total of 6978 participants reached 48-week follow-up visit at the timepoint of analysis, of which 4590 were with baseline HBsAg <1500 IU/ml and 2388 with baseline HBsAg ≥1500 IU/ml. In patients with HBsAg<1500 IU/ml, the HBsAg loss rates at 48 weeks of IFN-based therapy were high, regardless of treatment history, either in IFN monotherapy (28.0%–33.3%) or in IFN-Nuc combination therapy (18.1%–28.6%) (Figure 1A). In patients with HBsAg≥1500IU/ml, neither IFN monotherapy (2.6%–4.3%) nor IFN-Nuc therapy (1.8%–5.2%) could improve HBsAg loss rates significantly from Nuc monotherapy (0.0%–2.0%) (Figure 1B). The rates of significant HBsAg reduction at 48 weeks (HBsAg decline >1 log10 IU/ml from baseline) were high in patients with IFN-based therapy (26.3%–36.9% in IFN monotherapy and 24.0%–27.8% in IFN-Nuc therapy) (Figure 1C and D). There was significant difference between IFN-based and Nuc treatment, but no significant difference between IFN monotherapy and IFN-Nuc therapy. There were 28 cases developed HCC within 18 months. The cumulative HCC incidence was significantly lower in IFN-based group than Nuc group (0.0301% vs 0.1245%, P < 0.0001). After adjusting covariates including age, cirrhosis status and baseline HBsAg levels by COX regression, the difference between two groups was still significant (p < 0.0001), and the HR of IFN-based therapy for HCC was 0.153 compared with Nuc therapy (Figure 1E).
Conclusion: IFN-based therapy can significantly improve 48-week HBsAg loss rate from Nuc treatment in patients with low baseline

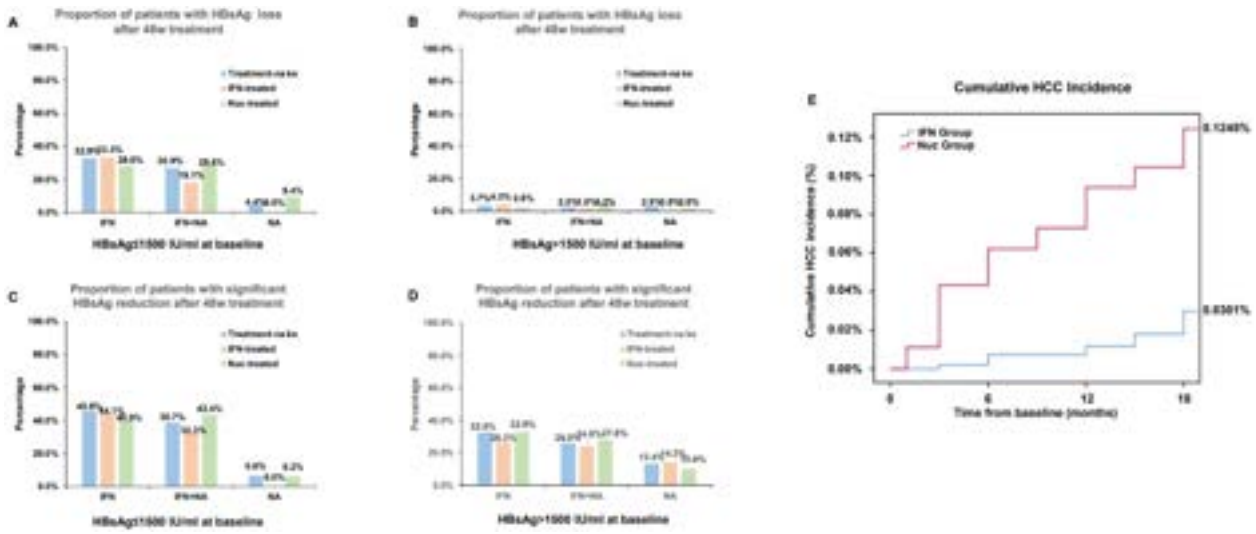

Figure: (abstract: SAT-147).

HBsAg levels, but in patients with high baseline HBsAg levels, HBsAg loss rate is similarly low in either IFN-based or Nuc treatment. However, a high proportion of patients with high baseline HBsAg levels can achieve significant HBsAg reduction after IFN-based therapy, and IFN-treated patients with low HBsAg levels still have relatively high HBsAg loss rates after 48-week IFN based therapy. This suggest that prolonged IFN therapy might be effective for patients with high HBsAg levels to achieve functional cure. Moreover, IFN-based therapy is superior in reducing HCC risks in patients with CHB.

SAT-148

Low HBV DNA and HBsAg levels at 24 weeks off-treatment predict sustained response and HBsAg loss in patients who discontinued antiviral therapy

Milan Sonneveld[1], SM Chiu[2], Jun Yong Park[3], Sylvia Brakenhoff[1], A Kaewdech[4], Wai-Kay Seto[5], Yasuhito Tanaka[6], Ivana Carey[7], Margarita Papatheodoridi[8], Piero Colombatto[9], Florian van Bömmel[10], Thomas Berg[10], Fabien Zoulim[11], Sang Hoon Ahn[3], George Dalekos[12], Nicole Erler[1], Maurizia Brunetto[9], Heiner Wedemeyer[13], Markus Cornberg[13], Man-Fung Yuen[5], Kosh Agarwal[7], Andre Boonstra[1], Maria Buti[14], Teerha Piratvisuth[4], George Papatheodoridis[8], Chien-Hung Chen[2], Benjamin Maasoumy[13].

Email: m.j.sonneveld@erasmusmc.nl.

Background and aims: Patients who discontinue nucleo (s)tide analogue (NUC) therapy are at risk of severe viral rebound and hepatitis flares, necessitating intensive off-treatment follow-up. We studied the association between HBsAg and HBV DNA levels at 6 months after therapy cessation (FU W24) with subsequent outcomes.
Method: Chronic hepatitis B patients who discontinued NUC therapy and who were still HBsAg positive and without clinical relapse or retreatment at FU W24 were identified in an existing multicenter database. The association between HBsAg and HBV DNA levels at off-treatment FU W24 with subsequent clinical relapse (defined as HBV DNA >2000 IU/ml + ALT >2× ULN or retreatment) and HBsAg loss was studied through univariable analyses using the Kaplan-Meier method, as well as multivariable Cox regression analysis adjusting for other potential predictors.
Results: We enrolled 641 patients, 86% Asian, 26% pretreatment HBeAg positive, and 59% treated with entecavir. At FU W24, we observed a weak correlation between HBV DNA and HBsAg levels (Pearson's $r = 0.254$, $p < 0.001$). Patients with higher HBV DNA levels at FU W24 had a higher risk of clinical relapse (hazard ratio [HR] 1.617, $p < 0.001$) and a lower chance of HBsAg loss (HR 0.496, $p < 0.001$). Similarly, patients with higher HBsAg levels at FU W24 had a higher risk of clinical relapse (HR 1.616, $p < 0.001$) and a lower chance of HBsAg loss (HR 0.247, $p < 0.001$). A combination of both HBsAg <100 IU/ml and HBV DNA <100 IU/ml at FU W24 identified patients with excellent outcomes (8.5% clinical relapse and 56% HBsAg loss at 192 weeks of subsequent follow-up). Conversely, patients with both HBV DNA >100 IU/ml and HBsAg >100 IU/ml had a very high risk of clinical relapse (68% at 192 weeks), and virtually no chance of HBsAg loss (<1% at 192 weeks). Findings were consistent in multivariable analysis.
Conclusion: Serum levels of HBV DNA and HBsAg at FU W24 can be used to predict subsequent clinical relapse and HBsAg clearance in patients who discontinued NUC therapy. A combination of HBsAg <100 IU/ml with HBV DNA <100 IU/ml identifies patients with very low risk of relapse and excellent chances of HBsAg loss, and could potentially be used as an early surrogate end point for studies aiming at finite therapy in HBV. Patients with both high HBsAg and HBV DNA levels have a very high risk of relapse and virtually no chance of HBsAg loss, and should be closely monitored and/or retreated.

NTCP genetic variants may influence early virological response to bulevirtide monotherapy in patients with HDV related cirrhosis

Pierluigi Toniutto[1], Edmondo Falleti[1], Sara Cmet[2], Annarosa Cussigh[2], Elisabetta Degasperi[3], Maria Paola Anolli[3], Dana Sambarino[3], Floriana Facchetti[3], Marta Borghi[3], Riccardo Perbellini[3], Sara Monico[3], Pietro Lampertico[3,4]. [1]*University of Udine, Hepatology and liver transplantation unit, Udine, Italy;* [2]*Azienda Sanitaria Universitaria Integrata, Clinical Pathology, Udine, Italy;* [3]*Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milano, Italy;* [4]*CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, Milano, Italy*
Email: pierluigi.toniutto@uniud.it

Background and aims: Bulevirtide (BLV) is an entry inhibitor conditionally approved by EMA for the treatment of patients with compensated Chronic Hepatitis Delta (CHD). Since it mimics the Na^+-taurocholate co-transporting polypeptide (NTCP) receptor binding domain, NTCP genetic mutants may potentially contribute to the susceptibility of HDV infection and response to treatment. This study aimed to assess whether NTCP genetic polymorphisms may influence virological and biochemical responses in BLV treated CHD.
Method: Fifty-two patients with CHD (age 49, 26 males, 46 with cirrhosis, pretreatment HDV RNA 5.2 log IU/ml) receiving 2 mg/daily of BLV up to 48 weeks (n = 37) were enrolled. Responses to BLV were categorized as: biochemical (BR), i.e. alanine aminotransferase (ALT) normalization; virological (VR), HDV RNA undetectable or ≥2 log IU/ml decline from baseline, and combined (CR), BR+VR. Virological non-response (VNR) was defined as <1 log IU/L decline in HDV RNA from baseline. HDV RNA was quantified by Robogene 2.0 (LOD 6 IU/ml). Six different NTCP single nucleotide polymorphisms (SNPs) (rs943277 C > T, rs943276 C > T, rs76385306 A > C, rs17556915 C > T, rs9323529 A > C, and rs4646296 C > G) were genotyped by Sanger sequencing.
Results: Among all the 6 SNPs investigated, only the carriage of rs17556915 CC (n = 27) *vs.* CT/TT (n = 25) genotypes was associated with higher HDV RNA levels, both at baseline (5.6 *vs.* 4.6 log IU/ml, p = 0.016) and at week 24 (3.3 *vs.* 2.0, p = 0.044), but not at week 48 (2.9 *vs.* 2.3, p = 0.26). In contrast, no significant correlations were found between these two genotypes and BR, VR, and CR, both at 24 (59.3% *vs.* 80.0%, p = 0.105; 63.0% *vs.* 64.0%, p = 0.938; 44.4% *vs.* 56.0%, p = 0.405) and at week 48 (68.2% *vs.* 73.3%, p = 0.736; 68.2% *vs.* 73.3%, p = 0.736; 63.6% *vs.* 60% p = 0.823). Interestingly, carriers of rs17556915 CC *vs.* CT/TT genotypes presented more frequently NVR at week 24 (25.9% *vs.* 4.0%, p = 0.029) but not at week 48 (22.7% *vs.* 13.3%, p = 0.474). HBsAg serum levels remained unchanged in VR at 48 weeks (3.56 *vs.* 3.61 Log IU/ml, p = 0.081) but significantly increased in VNR (3.69 *vs.* 3.83, p = 0.005), independently from the rs17556915 genotypes. Bile acids serum levels increased significantly from baseline to week 48 (21 *vs.* 42 mmol/L, p < 0.001) during BLV treatment. Carriers of rs17556915 CC genotype had similar bile acids levels compared to CT/TT both at baseline (21 *vs.* 30 mmol/L, p = 0.260), at week 24 (32 *vs.* 38 mmol/L, p = 0.203) and at week 48 (48 *vs.* 36 mmol/L, p = 0.608).
Conclusion: NTCP genetic variants may influence early virologic response of 2 mg BLV monotherapy in cirrhotic patients with CHD.

SAT-150

Stopping bulevirtide in long-term HDV-RNA suppressed patients seems safe and may enable long treatment-free intervals

Mathias Jachs[1], Marlene Panzer[2], Lukas Hartl[1], Michael Schwarz[1], Lorenz Balcar[1], Jeremy Camp[1], Petra Munda[1], Mattias Mandorfer[1], Michael Trauner[1], Stephan Aberle[1], Heinz Zoller[2], Thomas Reiberger[1], Peter Ferenci[1]. [1]*Medical University of Vienna, Austria;* [2]*Medical University of Innsbruck, Austria*
Email: peter.ferenci@meduniwien.ac.at

Background and aims: Bulevirtide (BLV) has been licensed for the treatment of chronic hepatitis D based on on-treatment data overlooking 24–48 weeks, without label recommendations on treatment duration or stopping rules.
Method: Patients included in the ongoing prospective Austrian BLV registry study were offered BLV treatment discontinuation upon the achievement of long-term HDV-RNA suppression to undetectable levels. Off-treatment safety and efficacy were closely monitored.
Results: Seven patients (aged 31–68 years, four with cirrhosis, BLV treatment duration: 46–141 weeks, negative HDV-RNA levels: 12–69 weeks) were included in the study and discontinued treatment. Five had undergone BLV monotherapy, while pegylated interferon-alpha2a (PEG-IFN) was used in combination with BLV in two patients. Until December 2022, patients were followed 10 to 98 weeks (≥24 weeks of BLV-free follow-up reached by n = 6). Only one patient showed significant ALT increases within 24 weeks of follow-up. Three patients showed a virological relapse, i.e., detectable HDV-RNA levels, within 24 weeks of BLV-free follow-up, while another relapse occurred after almost one year. So far, relapses occurred exclusively in patients who had undergone BLV monotherapy, while HDV-RNA remained undetectable in the two patients who had undergone combined treatment with PEG-IFN. Overall, treatment with BLV was reintroduced in three patients after 13 to 62 treatment-free weeks. All patients showed antiviral response during their second cycle of BLV treatment. Updated data will be presented at the meeting.
Conclusion: BLV discontinuation upon long-term HDV-RNA suppression appears to be safe, even in patients with cirrhosis, and enable long treatment-free intervals and off-treatment HDV-RNA suppression in some patients, particularly after combined treatment with BLV and PEG-IFN. In case of HDV-RNA relapse, BLV can be safely reintroduced.

Email: gudwns21@korea.ac.kr

Background and aims: In the previous 48-week phase 4 study, switching from TDF to BSV therapy contributed to the maintenance of antiviral effects and improved bone and renal safety in patients with virologically-suppressed CHB. We evaluated longer-term outcomes in CHB patients in the extended follow-up of the study.

Method: After 48 weeks of comparison of BSV with TDF, eligible patients who had agreed with participating in the extended study continued or switched to either of the drugs, and were followed-up to 96 weeks. We analyzed antiviral efficacy as well as bone and renal safety for the 4 groups.

Results: Among 130 patients who received randomized treatments, 101 patients were included for this observational study (BSV-BSV group, 5; BSV-TDF group, 46; TDF-BSV group, 4; TDF-TDF group, 46). At 96 weeks, 100.0% of patients in the BSV-BSV and TDF-BSV group, and 97.8% in the BSV-TDF and TDF-TDF group maintained virologic response (HBV DNA <20 IU/ml) (p = 1.00). Biochemical and serologic responses were comparable between the groups. Of note, bone turnover biomarkers were significantly improved in the BSV-BSV and TDF-BSV groups, and were worsened in the BSV-TDF and TDF-TDF group; accordingly, spine BMD increased in the BSV-BSV and TDF-BSV group, and decreased in the BSV-TDF and TDF-TDF group (% changes; 1.67 ± 1.68, 3.17 ± 4.31, −1.35 ± 3.98, −0.20 ± 3.91, respectively). The mean %changes of estimated glomerular filtration rates improved in the TDF-BSV group (2.29 ± 9.93%) while those decreased in the BSV-TDF group (−2.97 ± 10.40%). There were no adverse events in the BSV-BSV and TDF-BSV groups from 48 to 96 weeks while there were three in the TDF-TDF and BSV-TDF groups.

Conclusion: In this extensional study, antiviral efficacies were comparable between the groups at 96 weeks. Patients receiving BSV for up to 96 weeks showed improved bone and renal safety after the completion of 48 weeks of BSV or TDF therapy in virologically-suppressed CHB patients.

Email: olympiaevdoxia.anastasiou@uk-essen.de

Background and aims: Until recently pegylated interferon-alfa-2a (PEG-IFNa) therapy was the only treatment option for patients infected with the hepatitis D virus (HDV). Prolonged treatment of hepatitis D with PEG-IFNa with or without tenofovir disoproxil fumarate (TDF) for 96 weeks resulted in HDV RNA suppression in 44% of patients at the end of therapy but did not prevent short-term relapses within 24 weeks after therapy. The virological and clinical long-term effects after prolonged PEG-IFNa-based treatment of hepatitis D are unknown.
Method: The HIDIT-II study comprises of two parallel trials running in Germany, Romania and Greece as an investigator initiated trial and in Turkey as a Roche-sponsored study. Patients (including 41% with liver cirrhosis) received 180 µg PEG-IFNa weekly plus 300 mg TDF once daily (n = 59) or 180 µg PEG-IFNa weekly plus placebo (n = 61) for 96 weeks. Patients were followed until week 356 (5 years after the end of therapy).
Results: Until the end of follow-up 19 (16%) patients developed liver-related complications (n = 6, 32% receiving PEG-IFNa + TDF vs. n = 13, 68% in patients receiving PEG-IFNa plus Placebo, p = 0.113). Achieving HDV suppression at week 96 was associated with decreased long-term risk for the development of hepatocellular carcinoma (p = 0.022) and hepatic decompensation (p = 0.028). The number of patients developing serious complications was similar with (3/18) and without retreatment with PEG-IFNa (16/102, p < 0.999), but was associated with a higher chance of HDV-RNA suppression (p = 0.024, Odds Ratio 3.9 [1.3–12]).
Conclusion: Liver-related clinical events were infrequent and occurred less frequently in patients with virological response to PEG-IFNa treatment. PEG-IFNa treatment should be recommended to HDV-infected patients until alternative therapies become available. Retreatment with PEG-IFNa should be considered for patients with inadequate response to the first cycle of treatment.

Email: frida.abramov@gilead.com

Background and aims: In 2 similarly designed double-blind (DB), randomized (2:1), Phase 3 studies (Study 108 in HBeAg-negative [N = 425] and Study 110 in HBeAg-positive [N = 873] patients), tenofovir alafenamide (TAF) demonstrated noninferior efficacy with superior renal and bone safety compared to tenofovir disoproxil fumarate (TDF) at week 96. After completing DB treatment, all patients were eligible to receive open-label (OL) TAF through week 384 (year 8). Here we present the final safety results at year 8.

Method: In a pooled analysis, treatment-emergent adverse events (AEs), serious AEs (SAEs), discontinuations, and laboratory abnormalities were assessed in patients who received OL TAF. Changes from baseline in estimated GFR (by Cockcroft-Gault; $eGFR_{CG}$) and changes in hip and spine bone mineral density (BMD) by dual x-ray absorptiometry (DXA) scans were assessed.

Results: Of 1298 randomized and treated patients, 1157 (89%; 775 TAF; 382 TDF) entered the OL phase. Overall, 974 (75%) participants completed OL study treatment. The overall incidence of patients experiencing AEs was similar among groups (Table). Rates of Grade 3/4 AEs and AEs leading to discontinuation (D/C) were low and similar among groups. Few Grade 3/4 AEs or SAEs were related to the study drug. Overall, the most common Grade 3/4 lab abnormalities (>2%) were increased amylase (TAF 1.9%, TDF-TAF 2.7%), creatine kinase (TAF 1.4%, TDF-TAF 2.1%), fasting cholesterol (TAF 1.4%, TDF-TAF 2.9%), fasting LDL (TAF 5.9%, TDF-TAF 8.0%), and urine glucose (TAF 5.2%, TDF-TAF 2.7%). After experiencing declines in $eGFR_{CG}$ and hip/spine BMD with TDF treatment in the DB phase, renal and bone outcomes improved following the switch to OL TAF with minimal change through year 8. Overall, low rates of hepatocellular carcinoma (HCC) were observed over 8 years, with 11 cases occurring in the DB and 10 in the OL phases of the study.

Table. OL safety parameters[a]

n (%)	TAF n = 775	TDF→TAF total n = 382
Any AE	525 (68)	271 (71)
Grade 3/4 AE	60 (8)	27 (7)
Grade 3/4 AE related to study drug	2 (<1)[b]	0
SAE	97 (13)	49 (13)
SAE related to study drug	4 (1)[c]	0
AE leading to D/C	9 (1)	3 (1)
HCC (DB and OL), n	12	9
Median (Q1, Q3) change in $eGFR_{CG}$, ml/min	-5.4 (-15.1, 4.9)	-5.0 (-14.6, 6.5)
Mean (SD) %change in hip BMD	-1.64 (4.6180)	-2.05 (5.0434)
Mean (SD) %change in spine BMD	-0.64 (6.4448)	0.04 (6.6041)

[a] AEs are treatment-emergent during OL phase; renal/bone changes from original baseline; [b] renal neoplasma [G3] and cerebrovascular accident [G4]; [c] ALT increase [G2], renal neoplasm [G3], osteonecrosis [G2], cerebrovascular accident [G4]; No deaths were treatment-emergent, 6 total deaths (5 DB, 1 OL; TAF 3, TDF 3).

Figure:

Conclusion: Long-term TAF treatment was safe and well tolerated, with minimal changes in $eGFR_{CG}$ and BMD occurring over 8 years.

SAT-154

Association of post-treatment virologic relapse and biochemical flares with HBV serum biomarkers in long-term virologically suppressed HBeAg-negative patients stopping NA treatment: Exploratory analyses from the control arm of the REEF-2 study

Florian van Bömmel[1], Thierry Verbinnen[2], Kosh Agarwal[3], Thomas Vanwolleghem[4], Pietro Lampertico[5,6], Maria Buti[7], Ewa Janczewska[8], Marc Bourliere[9], John Jerzorwski[10], Thomas Kakuda[11], Sandra De Meyer[2], Adam Bakala[2], Oliver Lenz[2], Michael Biermer[2]. *[1]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany; [2]Janssen Pharmaceutica NV, Beerse, Belgium; [3]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [4]University of Antwerp, Faculty of Medicine and Health Sciences, Laboratory of Experimental Medicine and Pediatrics, Viral Hepatitis Research Group, Antwerp, Belgium; [5]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; [6]CRC "A. Email: florian.vanboemmel@medizin.uni-leipzig.de

Background and aims: REEF-2 (NCT04129554) assessed efficacy and safety of the combination of siRNA JNJ-73763989, CAM-E JNJ-56136379, and nucleos (t)ide analogues (NA) compared to NA only in virologically suppressed hepatitis B e-antigen (HBeAg)-negative patients with chronic hepatitis B (CHB). All treatments were discontinued in both treatment arms at week 48, followed by 48 weeks of follow-up. In the NA arm, a higher rate of post-treatment virologic relapse and alanine aminotransferase (ALT) flares was observed compared to the JNJ-73763989 arm. We have characterized post-treatment virologic relapses and biochemical flares in the NA arm of the REEF-2 study and assessed their association with end of treatment (EOT) hepatitis B virus (HBV) serum markers.

Method: The association of virologic relapses (confirmed increases in HBV DNA >2000 IU/ml) and biochemical flares (ALT increases ≥3 × upper limit of normal [ULN]) with serum HBV markers was assessed, including HBV RNA (Abbott; lower limit of quantification [LLOQ] = 22 and 11 copies/ml, depending on sample input volume), hepatitis B core related antigen (HBcrAg; Fujirebio; LLOQ/lower limit of detection [LOD] = 3.0/2.6 $\log_{10}$ U/ml), and quantitative anti-hepatitis B core (HBc) IgG (Fujirebio).

Results: 41 of 45 REEF-2 NA-control arm patients (mean NA treatment duration of 8 [range 2–17] years at study entry) who entered follow-up were included. At EOT, all patients had HBV DNA <LLOQ and a mean HBsAg level of 3.41 (range 1.8–4.7) $\log_{10}$ IU/ml. Following NA treatment discontinuation, 27 (66%) and 16 (39%) patients experienced virologic relapses and biochemical flares, respectively. Peak HBV DNA levels during virologic relapse were associated with the magnitude of ALT flares. Ten of 11 (91%) patients with peak HBV DNA >100,000 IU/ml had peak ALT levels ≥10× ULN versus none of 16 patients with virologic relapse and peak HBV DNA levels >2000-≤100,000 IU/ml. Virologic relapses were generally associated with parallel HBV RNA, HBcrAg, and anti-HBc kinetics, and in few patients with transient HBeAg seroreversion. Six (15%) and 20 (49%) patients had HBV RNA and HBcrAg levels target not

detectable (TND) at EOT, respectively. A similar proportion of patients with HBV RNA detectable and TND at EOT had virologic relapse or ALT flares (Figure). A higher frequency of virologic relapse (peak HBV DNA >100,000 IU/ml) and biochemical flares was observed in patients with detectable HBcrAg and HBsAg <1000 IU/ml at EOT compared to HBcrAg TND and HBsAg ≥1000 IU/ml, respectively (Figure). Patients with quantitative anti-HBc IgG titers <300 IU/ml at EOT had a significantly higher frequency of peak HBV DNA >100 000 IU/ml or biochemical flares than patients with EOT anti-HBc titers ≥300 IU/ml (Figure). None of 11 patients with anti-HBc titers ≥300 IU/ml at EOT had virologic relapse with peak HBV DNA >100,000 IU/ml or peak ALT ≥10× ULN.

Figure. REEF-2 NA-control arm patients with post treatment virologic relapse and ALT flare.

EOT Variables	N	Virological relapse (Confirmed HBV DNA >2000 IU/mL): Any virologic relapse n (%)	Virological relapse (Confirmed HBV DNA >2000 IU/mL): Peak HBV DNA (>100,000 IU/mL) n (%)	Biochemical flare (ALT ≥3× ULN): Any biochemical flare n (%)	Biochemical flare (ALT ≥3× ULN): Peak ALT (≥10× ULN) n (%)
Patients with EOT data who entered follow-up	41	27 (66%)	11 (27%)	16 (39%)	10 (24%)

p-value[c]		*1.000*	*0.0727*	*0.0035*	*0.0485*

[a]<LLOQ detectable or ≥LLOQ, [b]<LLOQ target not detected (TND), [c]excludes 1 patient with HBsAg <100 IU/mL.
[c]Two-sided p-value from Fisher's Exact test.
LLOQ HBV RNA assay = 22 and 11 copies/mL (depending on plasma sample input volume of 0.2 and 0.6 mL, respectively).
LLOQ HBcrAg assay = 3.0 log10 U/mL. Samples ≥2.6 <3.0 log10 U/mL are defined as <LLOQ detectable; samples <2.6 log10 U/mL are defined as <LLOQ TND.

Figure:

Conclusion: In patients discontinuing NA treatment, the level of HBV DNA increases during viral relapse correlated with the peak levels of biochemical flares. EOT anti-HBc IgG levels ≥300 IU/ml were strongly associated with the absence of high peak HBV DNA virologic relapse and high peak ALT flares ≥10× ULN, while this association was weaker for EOT HBcrAg and HBsAg levels and absent for HBV RNA.

SAT-155

Comparable risk of cardiovascular events in chronic hepatitis B patients treated with tenofovir disoproxil fumarate or tenofovir alafenamide

Hyeyeon Hong[1], Jonggi Choi[1], Won-Mook Choi[1], Danbi Lee[1], Ju Hyun Shim[1], Kang Mo Kim[1], Young-Suk Lim[1], Han Chu Lee[1]. *[1]Asan Medical Center, Department of Gastroenterology, Seoul, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and aims: Tenofovir alafenamide (TAF) has been widely used as the first-line antiviral treatment for chronic hepatitis B (CHB) due to its comparable efficacy to tenofovir disoproxil fumarate (TDF) but better safety profile. Previous studies showed that TDF is believed to have lipid-lowering effects, but TAF has exhibited less influence on lipid profiles. Consequently, there were concerns regarding the long-term cardiovascular risk might differ between the two treatments. Thus, we sought to examine the risk of cardiovascular events in a large cohort of patients treated with TAF or TDF.
Method: We retrospectively analyzed 3809 treatment-naïve patients with CHB treated with TDF (n = 2895) or TAF (n = 914) at Asan Medical Center, Seoul, Republic of Korea between 2012 and 2022. The primary outcome was a composite of major cardiovascular adverse events (MACE), which included myocardial infarction, ischemic stroke, and hospitalization for unstable angina or heart failure. Mean follow-up period was 3.8 years.
Results: The median age was 49.6 years, and 59.1% of the patients were male. At baseline, 365 (9.6%) and 560 (14.7%) of the 3,809 patients had diabetes and hypertension, respectively. Among 2,861 patients for whom smoking history was provided, 633 (22.1%), 514 (18.0%), and 1,714 (59.9%) were current, former, and never smokers, respectively. A total of 41 MACE was occurred with an annual incidence of 0.2%/100 person-years (PYs). At 1, 3, and 5 years, the cumulative risk of MACE was 0.5%, 0.9%, and 1.3% in patients with TDF, and 0.2%, 0.7%, and 0.7% in patients with TAF, respectively. No statistically significant difference in the risk of MACE between the TAF and TDF treatments p = 0.524). Older age, diabetes, hypertension, coronary artery disease history, and current smoking were associated with an increased risk of MACE in multivariable analysis.
Conclusion: In the present study, patients treated with TAF had a comparable risk of MACE as patients treated with TDF.

SAT-156

Improvements in ALT levels during Bulevirtide treatment for hepatitis D are seen regardless of virologic response

Email: dietz-fricke.christopher@mh-hannover.de

Background and aims: Hepatitis D is the most form of viral hepatitis leading to liver cirrhosis and hepatocellular carcinoma. The entry inhibitor bulevirtide was approved for the treatment of compensated liver disease in patients with chronic hepatitis D. The FDA and EMA suggest combined end points of virologic and biochemical response for clinical trials. Hence, the conditional approval was based on promising results regarding improvements in biochemical hepatitis activity and reduction of HDV-RNA. We aimed for the characterization of ALT improvements in a real-world setting.
Method: We retrospectively collected anonymized real-world data from 16 German centers treating patients with bulevirtide for chronic hepatitis D. A total of 114 baseline cases was collected. ALT levels were considered normal when <35 IU/l in female and <45 IU/l in male patients. Virologic response was assumed when HDV-RNA was either undetectable, below the lower limit of quantification or had decreased by ≥2 log.
Results: Elevated baseline ALT levels were measured in 99/114 patients (mean ALT level 115 IU/l). We covered 4289 patient weeks of bulevirtide treatment with a mean observation time of 38 weeks. Virologic response was observed in 87/114 cases. Mean ALT levels had declined by 68 (± 66) IU/l at the time point of viral response. Comparable to clinical trials we investigated datapoints at week 12 and week 24 in more detail. A subset of 33 patients had reached treatment week 24. In this group elevated baseline ALT levels were seen in 26/33 patients. At week 12 and 24, ALT had normalized in 9/26 (39%) and 11/26 (42%), respectively. Within the first 12 weeks of treatment a significant decline of ALT was observed (114 IU/l vs. 53 IU/l, $p < 0.001$). This decline was also seen in patients without virologic response (Figure 1). Updated data with additional follow-up weeks will be presented at the meeting.

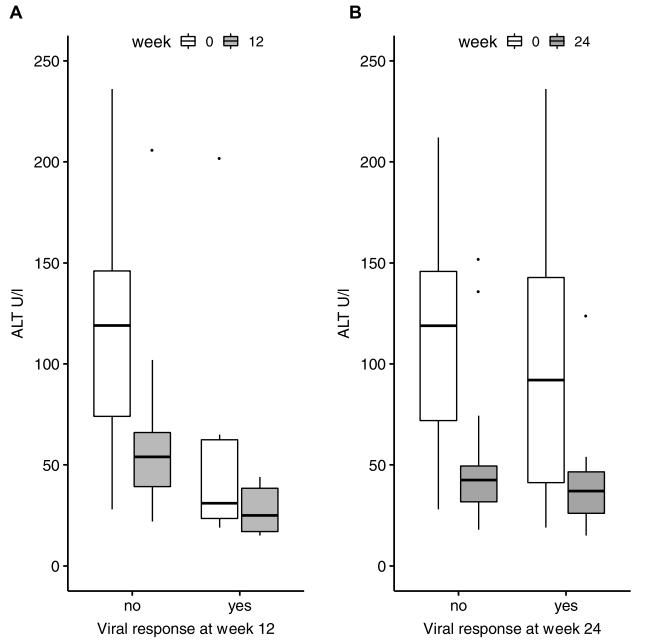

Figure 1: ALT levels at baseline and follow-up weeks grouped by viral response. Boxplots represent ALT levels at week 0 (white), week 12 (grey) and week 24 (dark grey). Outlying data points are visualized by dots. Wilcoxon signed-rank tests were used for comparison of ALT at week 0 and 12 or 24 showing a significant decline of ALT regardless of viral response.

Conclusion: In this real-world cohort ALT levels improved under bulevirtide treatment. This improvement was independent from the virologic response status when investigating distinctive follow-up time points. Different mechanistic explanations for this observation can be considered. The protection of hepatocytes from bile salts through bulevirtide mediated NTCP-blockade may have anti-inflammatory effects. At the same time, the rise in bile salts in the peripheral blood may affect immune cells. The observation of improved ALT values is of clinical relevance as such improvements should theoretically translate into better clinical outcomes.

SAT-157

Comparison of body weight and lipid profiles following tenofovir disoproxil fumarate or entecavir switchingto tenofovir alafenamide in chronic hepatitis B patients

Pin-Nan Cheng[1], Chun-Jen Liu[2], Jyh-Jou Chen[3], I-Cher Feng[4], Hsing-Tao Kuo[4], Pei-Lun Lee[3], Ming-Lung Yu[5], Yencheng Chiu[1], Chiu Hung-Chih[1], Shih-Chieh Chien[1], Pei-Jer Chen[2]. *[1]National Cheng Kung University Hospital, Department of Internal Medicine, Tainan, Taiwan; [2]National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan; [3]Chi-Mei Medical Center, Liouying, Department of Internal Medicine, Tainan, Taiwan; [4]Chi-Mei Medical Center, Department of Internal Medicine, Tainan, Taiwan; [5]Kaohsiung Medical University Hospital, Department of Internal Medicine, Kaohsiung, Taiwan*
Email: pncheng@mail.ncku.edu.tw

Background and aims: Body weight (BW) and lipid profiles changes have been reported in HIV infected patients treated with tenofovir alafenamide (TAF) containing regimens. Tenofovir disoproxil fumarate (TDF) treated chronic hepatitis B (CHB) patients exhibited lower lipid profiles in phase III study. The impact of TAF, as a new drug for CHB treatment, on BW and lipid profiles remains unclear and needs to investigate. The aim of this study was to compare the BW changes following switching to a 48-week TAF in prior tenofovir disproxil fumarate (TDF) or entecavir treated CHB patients.
Method: This was a prospective, multi-center, observational study. CHB patients from sevenhospitals in Taiwan treated with TDF or entecavir for at least 1 years and then switched to TAF were enrolled. Treatment indication based on reimbursement criteria. Demography and serial biochemical, hematology, lipid profiles and sugar profiles tests were measured at baseline and then at and an interval of 3 or 6 months after switching to TAF. Primary end point was the body weight changes following switching to TAF. Secondary end points included ASCVD score changes, changes of lipid and sugar profiles, and virologic responses following Switching to TAF.
Results: Between June 2020 and May 2021, 159 patients including 100 males and 59 females, were enrolled. The mean age was 56.1 years. Before switching to TAF, 97 patients received TDF and 62 patients received ETV. ETV-switch patients presented with significant older age, lighter BW, lower AST and ALT, higher total bilirubin, lower platelet counts, higher ASCVD risk score, and higher lipid profiles than TDF-switch patients. Significantly lower proportion of TDF-switch patients took lipid lower agents. BW increased shortly after 12 weeks (67.8 ± 12.7 kg, $p < 0.001$) of TAF in TDF-switch patients (Fig. 1). The increased BW maintained following 24 weeks (67.7 ± 12.7 kg, $p = 0.017$), 36 weeks (67.8 ± 12.5 kg, $p = 0.007$), and 48 weeks (67.9 ± 12.9 kg, $p = 0.037$) of TAF treatment. The BW of ETV-switch patients maintained during the first 36 weeks of TAF treatment, but significantly decreased at week 48 (62.6 ± 10.7 kg, $p = 0.033$). In TDF-switch patients, BW of males remained stationary during 48 weeks of TAF, while BW of females at 12 weeks (61.0 ± 8.4 kg, $p < 0.001$), 24 weeks (61.0 ± 9.0 kg, $p = 0.023$), and 36 weeks

Fig. 1 Fig. 2

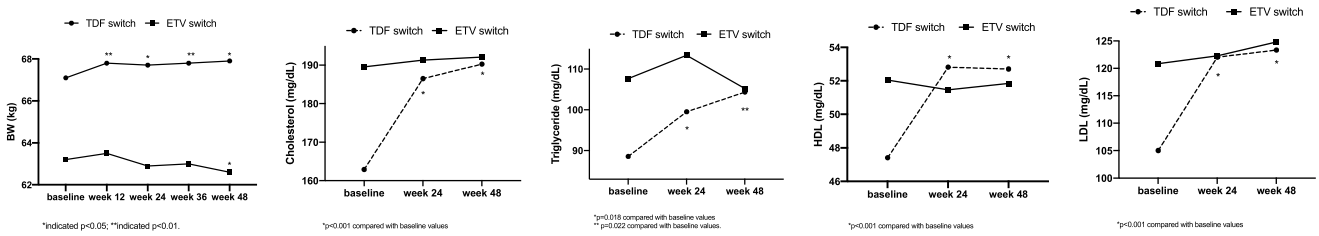

Figure 1: (abstract: SAT-157).

(61.2 ± 9.1 kg, p = 0.008) following TAF treatment increased significantly. In TDF-switch patients, cholesterol, triglyceride, HDL, and LDL significantly increased at week 24 and week 48 when compared with baseline (Fig. 2). After 48 weeks of TAF treatment, no significant change of the ASCVD risk score in TDF-switch patients (7.3 ± 9.9 at baseline vs. 7.9 ± 9.9 at week 48, p = 0.063) and ETV-switch patients (11.4 ± 13.7 at baseline vs. 12.0 ± 15.4 at week 48, p = 0.292).

Conclusion: After 48-week TAF treatment, BW gained significantly in TDF-switched rather than ETV- switched CHB patients. Lipid profiles increase only observed in TDF-switched to TAF CHB patients. ASCVD risk score remained similar following 48-week TAF treatment in either ETV or TDF.

switched patients.

Model-based meta-analysis of pegylated IFN-alpha induced HBsAg loss at end of treatment and 24 weeks post treatment in chronic hepatitis B virus infection

Nathan Hanan[1], Matthew L Zierhut[2], Ahmed Nader[1], Anadi Mahajan[3], Amandeep Kaur[3], Krishna Kumar[3], Susan Dixon[4], Joyeta Das[4], Mindy Magee[1], Dickens Theodore[5], Vera Gielen[4]. *[1]GSK, Collegeville, United States; [2]Certara, San Diego, United States; [3]Bridge Medical Consulting, London, United Kingdom; [4]GSK, Brentford, United Kingdom; [5]GSK, Durham, United States*

Email: vera.x.gielen@gsk.com

Background and aims: Pegylated interferon alpha (Peg-IFNa) is one of two current treatment options for chronic hepatitis B virus (HBV) infection. Peg-IFNa can induce immunological control of HBV with a finite duration treatment, however, response is highly variable. We performed a model-based meta-analysis (MBMA) to establish absolute effect models of hepatis B surface antigen (HBsAg) loss for peg-IFNa-based regimens at end of treatment (EOT) and 24 weeks post-treatment. This can be leveraged to perform clinical trial simulations that predict outcomes with respect to different populations.

Method: We conducted a systematic review of HBsAg loss rate with peg-IFNa monotherapy or in combination with a nucleos (t)ide analogue (NA) in participants with chronic HBV infection, searching major databases (Embase; MEDLINE; Cochrane) for literature published 2000 to July 2022. HBsAg loss was defined as HBsAg levels reported below the limit of detection (0.05 IU/ml). Models were developed to describe the proportion of participants achieving HBsAg loss at EOT and 24 weeks post treatment as a function of peg-IFNa and peg-IFNa + NA treatment effects. Baseline biological and demographic population characteristics were explored as covariates in both models.

Results: For the peg-IFNa EOT end point of HBsAg loss, a total of 83 study-strata-arms producing HBsAg loss results from 13 235 participants were included. 63 of the study-strata-arms were from randomised controlled trials, the rest are comprised from prospective and retrospective cohorts and single arm trials. For the 24 weeks post-peg-IFNa treatment end point, a total of 58 study-strata-arms producing HBsAg loss results from 4267 participants were included. 43 of the study-strata-arms are from RCTs, 8 from prospective cohorts, 3 retrospective cohorts and 3 single arm trials. In both EOT and post-treatment models, two covariates were identified that describe HBsAg loss in participants treated with peg-IFNa or peg-IFNa + NA: peg-IFNa treatment duration and baseline HBsAg levels. In the EOT model only, HBeAg status was an additional predictor of HBsAg loss. Age, gender, race, and continuation of NA after end of peg-IFNa treatment (24 weeks post-treatment only) were tested but not significant. Degree of missingness for HBV genotype, baseline HBV DNA and baseline alanine aminotransferase (ALT) did not support covariate assessments. The model was then used to simulate 100 000 trials of different populations and treatment arms. Example results of different populations are presented in the table.

Table: Simulated Peg-IFN HBsAg loss rate at EOT and 24 weeks post-treatment following 48 weeks of therapy in HBeAg negative patients (n = 100,000 trials)

Mean baseline HBsAg (log10 IU/mL)	Peg-IFNa Monotherapy Estimate (95% CI)	Peg-IFNa + NA Estimate (95% CI)
EOT*		
4.5	0.9 (0.2 – 4)	1.2 (0.3 – 5.5)

2.5	24 (6.6 — 58.9)	29.5 (8.4 — 66)
2.0	40.4 (12.8 — 75.9)	47.4 (16 — 81.1)
1.5	59.2 (23.1 — 87.6)	65.9 (28.1 — 90.6)
1.0	75.7 (37.9 — 94.1)	80.6 (44.2 — 95.6)
0.5	87 (55.1 — 97.4)	89.9 (61.5 — 98.1)

*Studies informing the EOT and 24 weeks analysis are partially overlapping only, therefore a comparison between these two analyses cannot be made.

Conclusion: The MBMA provides a quantitative description of between-trial variability in peg-IFNa-based regimens and has identified highly influential predictors of HBsAg loss that lend to

this variability. These findings provide an evidenced-based approach to predictions of HBsAg in different populations treated with peg-IFNa.
Funding: GSK (217324).

Kinetics of HBsAg forms in chronic hepatitis delta patients treated with bulevirtide for 48 weeks: correlation with virological response

Stefano D'Anna[1], Romina Salpini[1], Elisabetta Degasperi[2], Leonardo Duca[1], Maria Paola Anolli[2], Lorenzo Piermatteo[1,3], Dana Sambarino[2], Marta Borghi[2], Floriana Facchetti[2], Francesca Ceccherini Silberstein[1], Riccardo Perbellini[2], Valentina Svicher[1,3], Pietro Lampertico[2,4]. *[1]University of Rome "Tor Vergata", Department of Experimental Medicine, Italy; [2]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Italy; [3]University of Rome "Tor Vergata", Department of Biology, Italy; [4]CRC "A.M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, Italy*
Email: stefanodanna26@gmail.com

Background and aims: HDV exploits the HBV surface protein (HBsAg) for the release of its progeny and entry into hepatocytes. HBsAg consists of three different proteins: Large HBsAg (L-HBs), including preS-1, preS-2 and S regions; Middle HBsAg (M-HBs) including pre-2 and S regions and small HBsAg (S-HBs), containing only the S region. Among them, L-HBs is predominantly present in virions and is crucial for the binding to the NTCP receptor and thus for viral entry into the hepatocytes. Here, we investigate the still unknown kinetics of HBs forms in patients receiving the entry inhibitor bulevirtide (BLV).
Method: Consecutive patients with HDV-related compensated cirrhosis starting BLV monotherapy 2 mg/day were enrolled in this single-center retrospective/longitudinal study. All patients were under effective NUC treatment at entry. L-HBs, M-HBs and S-HBs (Beacle Inc.) were quantified by ad hoc ELISAs assays in baseline and week 48 samples. HDV-RNA was quantified by Robogene 2.0 (LOD: 6 IU/ml). Virological response (VR) was defined as HDVRNA undetectable (<6 IU/ml) or >2 Log decline compared to baseline, biochemical response as ALT normalization.
Results: Twenty patients with compensated cirrhosis were enrolled: at baseline, median (IQR) age was 50 (40–62) years, 65% males, liver stiffness measurement (LSM) 17.6 (13.1–28.4) kPa, median (IQR) ALT was 110 (83–147) U/L, platelets 72 (59–93) × 10^3/mm^3, serum HDV-RNA was 4.9 (4.4–5.7) IU/ml and HBsAg levels 3.7 (3.4–3.9) log IU/ml. Pre-treatment, median (IQR) levels of S-HBs, M-HBs and L-HBs were 3421 (1240–6209) ng/ml, 791 (260–1930) ng/ml and 7 (2–15) ng/ml, respectively. Following 48 weeks of BLV, serum HDV-RNA declined by 3.1 (1.8–3.6) log IU/ml and ALT normalized in 14 (70%) patients. VR was observed in 14 (70%) patients while HDV-RNA undetectability in 6 (30%) with 5 of them achieving ALT normalization. During BLV treatment, S-HBs, M-HBs and L-HBs decreased in 60%, 70% and 45% of patients with a median (IQR) decline of 1095 [839–2403] ng/ml, 145 [39–350] ng/ml, 10 [4–15] ng/ml), respectively. HDV-RNA undetectability as well as HDV-RNA undetectability plus ALT normalization at week 48 were significantly greater in patients with low pre-treatment L-HBs levels (54% with vs 11% without L-HBs <9 ng/ml, P = 0.042; 50% with vs 0% without L-HBs <9 ng/ml, P = 0.03). Notably, the combination of pre-treatment L-HBs levels <9 ng/ml + HDV-RNA levels <5 log IU/ml was the best predictor for achieving combined response (67% with versus 7% without this combination achieved this end point, P = 0.01).
Conclusion: Quantification of L-HBs along with serum HDV-RNA may reflect the burden of circulating infectious virions, possibly providing a new tool to identify patients more likely to respond to BLV monotherapy.

SAT-160

Comparison of kidney function decline between chronic hepatitis B patients with versus without antiviral therapy

Jae Seung Lee[1,2,3], Chan-Young Jung[1,4], Jung Il Lee[1,2,5], Sang Hoon Ahn[1,2,3], Beom Seok Kim[1,4], Seung Up Kim[1,2,3]. *[1]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Yonsei University College of Medicine, Institute of Gastroenterology, Seoul, Korea, Rep. of South; [3]Severance Hospital, Yonsei Liver Center, Seoul, Korea, Rep. of South; [4]Yonsei University College of Medicine, Institute of Nephrology, Seoul, Korea, Rep. of South; [5]Gangnam Severance Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: Kidney function can deteriorate in patients with chronic hepatitis B (CHB). Herein, we compared the risk of kidney function decline between untreated and treated CHB patients receiving antiviral therapy (AVT).
Method: This retrospective study included 1,061 untreated CHB patients, tenofovir alafenamide (TAF) or besifovir dipivoxil maleate (BSV) users (n = 556), and entecavir (ETV) users (n = 2,029). Primary outcome was kidney function decline, defined as an increase in chronic kidney disease (CKD) stage ≥1 for ≥3 consecutive months.
Results: The 1:1 propensity score matching yielded 588 pairs in each untreated and treated patient group. The risk of kidney function decline was significantly higher in the treated group (83 patients [2.7 per 1000 person-years (PYs)]) than in the untreated group (39 patients [1.3 per 1000 PYs]) (p <0.001), with an unadjusted hazard ratio of 2.09 (95% confidence interval, 1.43–3.05, P < 0.001), which remained the same after adjusting for potential confounders. However, when TAF or BSV users were matched, yielding 259 pairs, no significant difference in the kidney function decline risk was observed between the groups (12 patients in the untreated group [1.6 per 1000 PYs] and 21 in the treated group [2.9 per 1000 PYs], P = 0.107). However, when matched, ETV users showed a significantly higher risk of kidney function decline than untreated patients (100 patients [3.6 per 1000 PYs] vs. 31 patients [1.1 per 1000 PYs], P < 0.001).

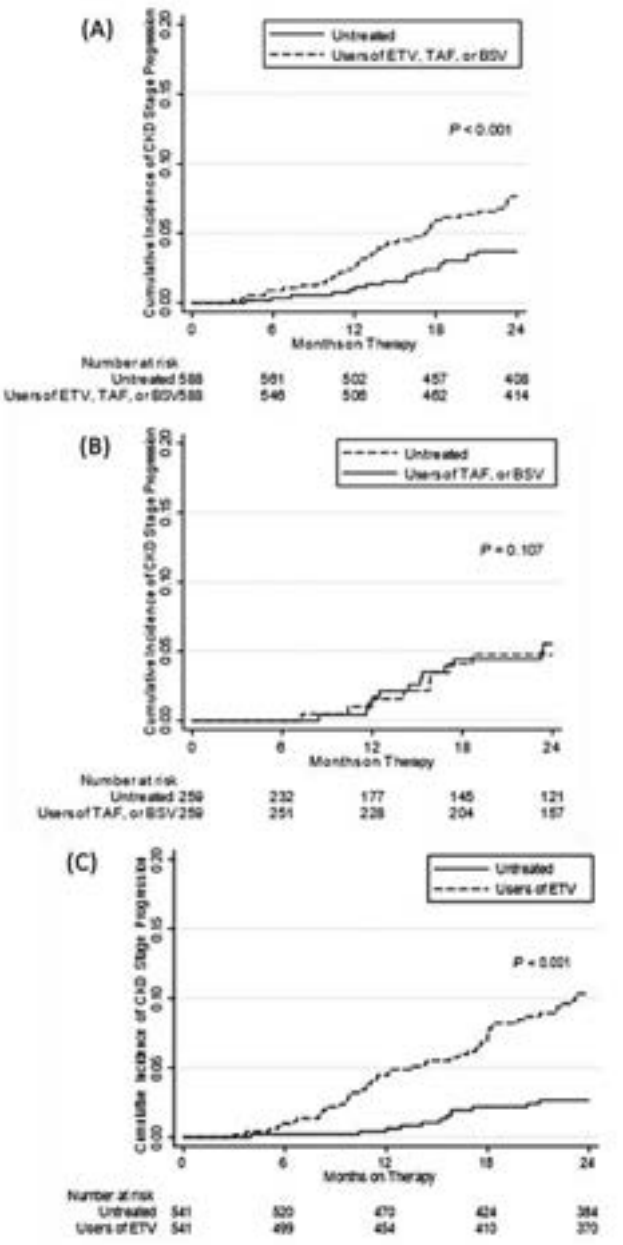

Figure: Cumulative incidence of progression in CKD stage ≥1 among (A) untreated patients vs. ETV, TAF, or BSV users, (B) untreated patients vs. TAF or BSV users, and (C) untreated patients vs. ETV users. Abbreviations: CKD, chronic kidney disease; ETV, entecavir; TAF, tenofovir alafenamide; BSV, besifovir disoproxil maleate.

Conclusion: Compared with untreated patients, TAF or BSV users showed a similar risk, whereas ETV users showed a higher risk of kidney function decline.

SAT-161

Effect of first-line nucleot (s)ide analogues on blood lipids in patients with chronic hepatitis B: a network meta-analysis

Kexin Tong[1], Mingjing Chen[1], Danni Wang[1], Jiayi Peng[1], Jia Zhang[1], Jiao Zhou[1], Yujiao Chang[1], Wenxiang Huang[1]. [1]*The First Affiliated Hospital of Chongqing Medical University, Chongqing, China*
Email: wenxiang_huang@163.com

Background and aims: It has been found that blood lipids levels in patients with chronic hepatitis B (CHB) might be changed during antiviral treatment. At present, most studies focused on the comparison of three first-line nucleot (s)ide analogues (NAs), entecavir (ETV), tenofovir disoproxil fumarate (TDF), and tenofovir alafenamide (TAF), but there lacks comprehensive evaluation of their effects on blood lipids under a unified standard. This study aims to evaluate the influence of first-line NAs on blood lipids in CHB patients by using the method of network meta-analysis.

Method: Seven Chinese and English databases were searched from the establishment of the database to November 1, 2022. Studies involving ETV, TDF and TAF on the effects of blood lipids in patients with CHB were included. The changes of serum total cholesterol (TC), triglyceride (TG), low-density lipoprotein cholesterol (LDL-C) and high-density lipoprotein cholesterol (HDL-C) before and after treatment were taken as outcome indicators. We used RevMan5.4 software for direct comparison, and Stata16.0 software for network meta-analysis based on the frequency framework.

Results: Eight articles were included in this study, including 2614 CHB patients in 10 trials, involving three different antiviral drugs, TAF, TDF and ETV, and the blank control group (inactive CHB patients without antiviral treatment). Direct comparison: Compared with TDF group, blood lipids in TAF group showed an increasing trend (ΔTC SMD = 15.18, 95%CI (11.44, 18.92); ΔTG SMD = 9.24, 95%CI (3.85, 14.63); ΔLDL-C SMD = 6.35, 95%CI (4.41, 8.28); ΔHDL-C SMD = 8.82, 95%CI (2.85, 14.80)); Compared with TDF group, blood lipids in ETV group also increased (ΔTC SMD = 20.39, 95%CI (12.85, 27.93); ΔTG SMD = 18.89, 95%CI (7.28, 30.51); ΔLDL-C SMD = 11.31, 95%CI (4.89, 17.74); ΔHDL-C SMD = 7.65, 95%CI (1.31, 14.00)). Network meta-analysis: TDF can reduce the levels of TC, TG, HDL-C and LDL-C (TDF vs blank control group: ΔTC SMD = −19.43, 95%CI (-27.90, − 10.97); ΔTG SMD = −24.11, 95%CI (−44.21, −4.00); ΔLDL-C SMD = −8.91, 95%CI (−16.37, −1.45); ΔHDL-C SMD = −8.6, 95%CI (−14.23, −2.96), while TAF and ETV have no significant difference compared with the blank control group (TAF vs blank control group: ΔTC SMD = 3.39, 95%CI (−4.31, 11.08); ΔTG SMD = 14.2, 95%CI (−5.24, 33.64); ΔLDL-C SMD = 2.37, 95%CI (−4.84, 9.58); ΔHDL-C SMD = −0.37, 95%CI (−4.73, 3.98). ETV vs blank control group: ΔTC SMD = 2.69, 95%CI (-7.04, 12.23); ΔTG SMD = 8.23, 95%CI (-13.07, 29.54); ΔLDL-C SMD = −0.36, 95%CI (−9.02, 8.30); ΔHDL-C SMD = 2.41, 95%CI (−3.81, 8.63)).

Conclusion: TDF had an effect on lowering the levels of TG, TC, HDL-C and LDL-C, and the effect is most obvious within first 24 weeks of treatment initiation. During follow-up for more than 48 weeks, the blood lipids of CHB patients would remain relatively stable. TAF and ETV had neutral effect on lipids change, and no significant difference in blood lipids changes among TAF, ETV and those without antiviral treatment. Switching from TDF to TAF or ETV made the blood lipids of CHB patients increase relatively, but such changes were still within an acceptable range.

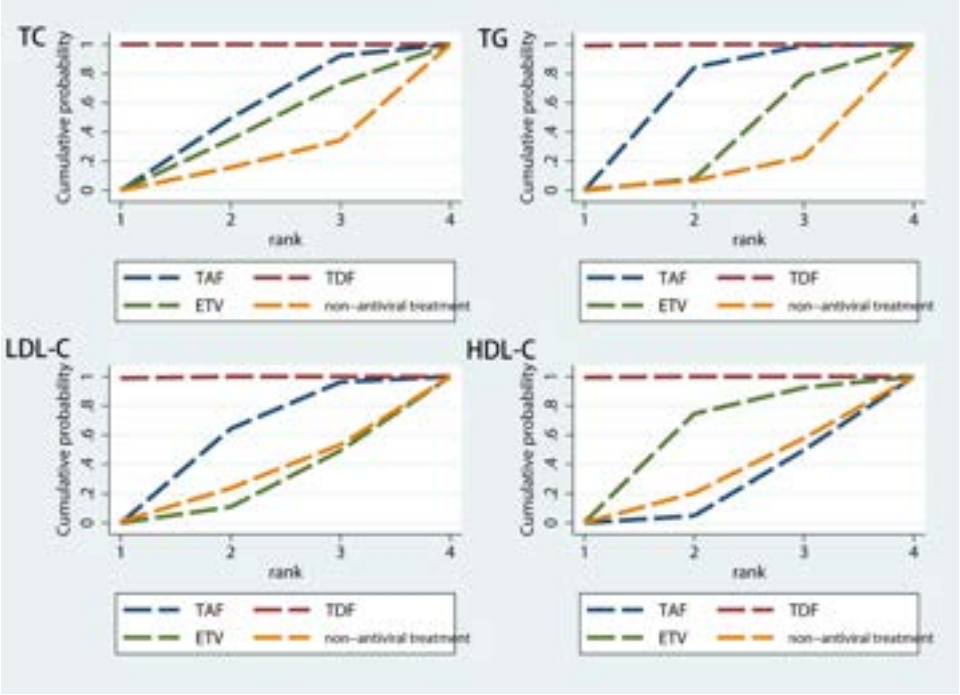

Figure: (abstract: SAT-161): The better the effect of lowering blood lipids, the larger the surface under the cumulative ranking curve (SUCRA).

SAT-162

The different immune response of B cells specific for hepatitis B virus core and envelope antigen in chronic hepatitis B patients with pegylated interferon-alpha treatment

Qi Zheng[1], Ruimin Lai[1], Jiawei Zhang[1]. [1]*the First Affiliated Hospital, Fujian Medical University, China*
Email: zhengqi0825@sina.com

Background and aims: T The humoral immune response against HBsAg and HBcAg have different functional capabilities during chronic hepatitis B virus (CHB) infection. The phenotype and functional impairment of HBsAg-specific B cells fail to produce detectable anti-HBs and promote the persistence of CHB infection. The seroconversion of the HBsAg provides a promising outcome for pegylated interferon-α (Peg-IFN-alpha) treated patients with CHB. But a detailed assessment of their impact on HBV-specific B-cell responses is lacking. The study aimed at functional cure including a thorough characterization of hepatitis B-specific B cell responses for Peg-IFN-alpha treatment.

Method: We included 13 nucleos (t)ide analogue-treated (NUCs) patients with chronic HBV for 48 weeks of Peg-IFN-alpha treatment. Peripheral blood mononuclear cells (PBMC) were collected before and at 24 weeks, 48 weeks with Peg-IFN-alpha treatment. Fluorescently labeled HBsAg and HBcAg reagents were synthesized and utilized to characterize ex vivo HBV-specific B cells. The frequency, phenotype and function of HBV-specific B cells and Tfh cells were examined by FACS.

Results: The frequency of HBcAg-specific B cells are similar to HBsAg-specific B cells in NUC-treated patients, and no significant change during Peg-IFN-alpha treatment. The phenotype and function of B cells specific for HBsAg and HBcAg were different in response to Peg-IFN-alpha treatment in CHB patients. The expression of CD38 on HBsAg-specific B cells was higher, with the subset of activated memory B cell (actMBC) and IgG+ class-switched memory B cells enriched (PactMBC = 0.0065; PIgG = 0.0006). And the subset of atypical memory B cells (atMBC) of HBcAg-specific B cells were increased along with IgG+ class-switched memory B cells reduced and IgM+ class-switched memory B cells increased during Peg-IFN-alpha treatment. HBsAg-specific B cells showed higher expression of liver-homing marker CXCR3, CD69 and IgG+ class-switched, and lower expression of CXCR5, IgM+ class-switched compared to HBcAg-specific B cells after 48 Weeks Peg-IFN-alpha treatment. Moreover, the expression of CD40 ligand in Tfh cells was increased (p = 0.0042) and showed a significant positive correlation with the expression of activation marker CXCR3、CD38 in HBsAg-specific B cells.

Conclusion: The humoral immune response against HBsAg and HBcAg was different in CHB patients with Peg-IFN-alpha treatment. The exhausted phenotype of HBsAg-specific B cells was recovered whereas HBcAg-specific B cells response was significantly reduced during Peg-IFN-alpha treatment. Moreover, the frequency of CD40L+ Tfh cells was increased and showed a positive correlation with the activation marker of HBsAg-specific B cells indicating the important role of CD40L+Tfh cells in functionally recovering HBsAg-specific B cells with Peg-IFN-alpha treatment.

SAT-163

Incomplete response with/without genotypic resistance to prior antivirals is not associated with a higher risk of hepatocellular carcinoma during tenofovir treatment for chronic hepatitis B

Ju Yeon Kim[1], Hyunjae Shin[1], Jeayeon Park[1], Moon Haeng Hur[1], Sungwon Chung[1], Min Kyung Park[1], Yun Bin Lee[1], Yoon Jun Kim[1], Jung-Hwan Yoon[1], Jeong-Hoon Lee[1]. [1]*Seoul National University College of Medicine, Korea, Rep. of South*
Email: pindra@empas.com

Background and aims: Resistance to antiviral agent is reportedly associated with a higher risk of hepatocellular carcinoma (HCC). However, tenofovir has enabled effective viral suppression even in chronic hepatitis B (CHB) patients who had incomplete response with/without genotypic resistance to previous antivirals. This study aimed to evaluate whether the incomplete response is a risk factor of HCC development in the tenofovir-available era.

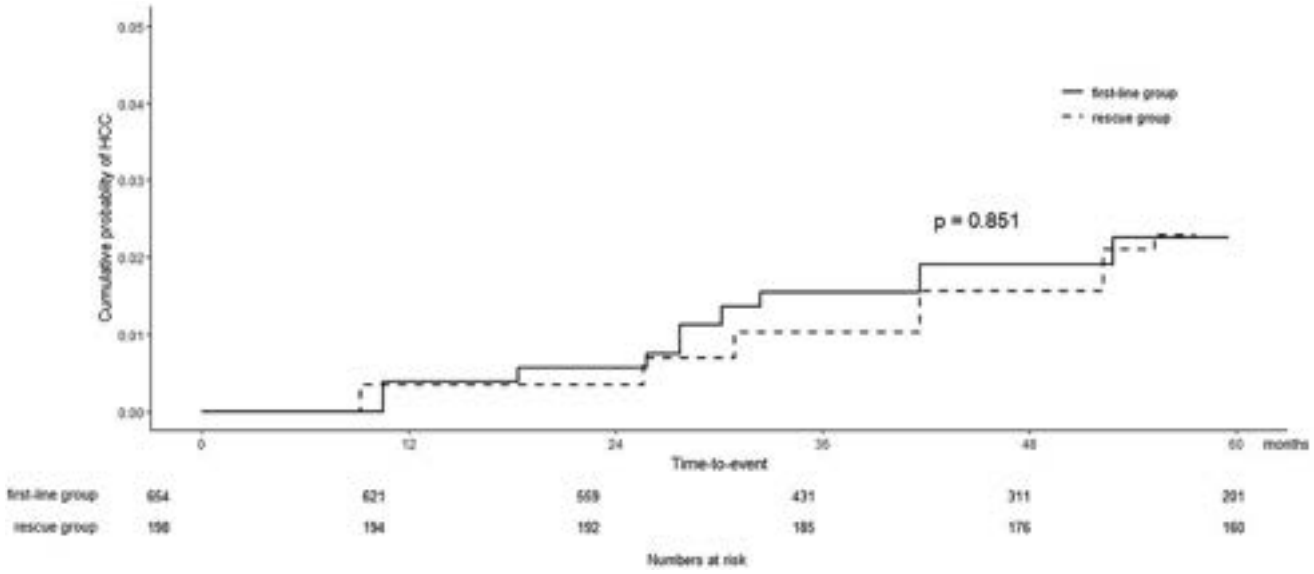

Figure: (abstract: SAT-163).

Method: This retrospective study included 852 consecutive non-cirrhotic CHB patients who started tenofovir between May 2012 and December 2018 at a single tertiary center in Korea: 654 patients started tenofovir as a first-line antiviral treatment (first-line group) and 198 as a rescue therapy for incomplete response to prior antivirals (rescue group). The primary outcome was HCC development. Baseline characteristics were balanced using inverse probability of treatment weighting method.
Results: The rescue group had older age (median, 50 vs. 46 years), included less females (27.3% vs. 47.4%), and lower baseline HBV DNA level (median, 3.1 vs. 6.6 $\log_{10}$ IU/ml) (all $P < 0.05$) compared to the first-line group. 84.3% of the rescue group (167 of 198) had previously documented genotypic resistance. The incidence rates of HCC were comparable between the poor response group (0.63 per 100 person-years [PY]) and the initial therapy group (0.35 per 100 PY) by a univariable Cox proportional hazards model (hazard ratio [HR], 0.91; 95% CI, 0.32–2.54; $P = 0.851$). After adjustment for age, sex, and platelet count, the rescue therapy group was not an independent risk for HCC (adjusted HR, 0.90; 95% CI, 0.33–2.49; $P = 0.840$).
Conclusion: Incomplete response with/without genotypic resistance to prior antiviral therapy was not associated with HCC development in CHB patients with subsequent viral suppression through tenofovir therapy.

SAT-164

Hepatitis B surface antigen loss rate and safety and discontinuations with pegylated interferon alpha in chronic hepatitis B virus infection, a systematic review

Vera Gielen[1], Amandeep Kaur[2], Krishna Kumar[2], Saifuddin Kharawala[2], Joyeta Das[1], Jacob Vincent[1], Anadi Mahajan[2].
[1]*GSK, United Kingdom,* [2]*Bridge Medical Consulting, United Kingdom*
Email: vera.x.gielen@gsk.com

Background and aims: Pegylated interferon alpha (Peg-IFNa) is one of two treatment options for chronic hepatitis B virus (HBV) infection. Peg-IFNa can induce immunological control with a finite duration treatment, however, response is highly variable and its safety and tolerable profile impacts eligibility and willingness of patients to take this treatment. The aim was to conduct a systematic review of peg-IFNa treatment in participants with chronic HBV infection, for whom data on baseline HBsAg levels was available, to understand durability and rates of HBsAg related outcomes, safety and discontinuation.
Method: A systematic review of studies in participants with chronic HBV infection who received PegIFNa, for whom data on baseline hepatitis B surface antigen (HBsAg) was available, was conducted. Outcomes included HBsAg related outcomes for efficacy, safety and treatment discontinuations. Studies included were clinical trials and retrospective and prospective cohorts. Major databases (Embase; MEDLINE; Cochrane) were searched for literature published between 2000 to July 2022.
Results: 126 primary studies were included. 29 studies reported data on durability of HBsAg loss; 10 studies (12 study arms) reported HBsAg loss at end of treatment (EOT), 24 weeks post-treatment and further end points and 19 studies (31 study arms) reported data at EOT and further end points. Range of HBsAg loss in all studies was between 0.0%–84.2% at EOT and in studies assessing durability of response this was 0.0%-44.4%. The majority of studies showed that EOT HBsAg loss with peg-IFNa was durable, 84% or 36 out of 43 study arms showed either no change or increase in HBsAg loss rates over time. Only 7 arms showed a decrease in response rate over time with numerical differences in patients regaining HBsAg being minimal. Data on HBsAg loss at EOT and 24 weeks and factors associated with likelihood of HBsAg loss will be reported in a separate abstract.
Discontinuations were reported in 61 studies and ranged from 0.0% to 62.0%. Discontinuations due to AEs were reported in 52 studies and ranged from 0.0% to 26.8%. AEs were common. Fatigue was reported in 0.0–75.0% (34 studies), asthenia 5–44% (7 studies), headache 2.4–65.1% (30 studies), influenza like illness 8.5–92.9% (9 studies), myalgia 0.0–68.3% (28 studies), depression 0.0–21.5% (10 studies), other neuropsychiatric disorders 0–27% (19 studies, including anxiety, insomnia), and pyrexia 8.2–90% (34 studies).
Conclusion: These results show that some patients can achieve HBsAg loss with peg-IFNa and when achieved HBsAg loss is durable. However, this should be taken in the context of the safety and tolerability profile and therefore patients' willingness to take peg-IFNa with discontinuations ranging between 0 and 62% for a finite regimen.

SAT-165

The efficacy of peginterferon alpha in Chinese inactive hepatitis B carriers and nucleoside analogs-experienced patients: a real world research

Chaojing Wen[1,2], Xiaofeng Shi[1,2], Yu Lei[1,2]. [1]*The Second Affiliated Hospital, Chong Qing Medical University, Department of Infectious Diseases, Chong Qing, China;* [2]*Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, Chong Qing, China*
Email: sxf7776@163.com

Background and aims: Due to the different immune states in inactive hepatitis B carriers (IHCs) and nucleoside analogs-experienced patients, whether those two groups of patients show different effectivity to Peginterferon alpha is still unclear. Hence, this study aims to investigate the effectiveness and discrepancy of Peginterferon between inactive hepatitis B carriers and nucleoside analogs-experienced patients.

Method: In this real world, observational study, all subjects were enrolled from June 2019 to September 2021 at the Second Affiliated Hospital of Chong Qing Medical University. A total 58 inactive hepatitis B carriers assigned to receive PEG-IFNa2b alone for48 weeks (Peg-IFN group), 84 nucleoside analogs-experienced patients treated with PEG-IFNa2b plus nucleoside analogs (tenofovir disoproxil fumarate, entecavir or tenofovir alafenamide) for 48 weeks (Peg-IFN plus NAs group), 23 nucleoside analogs-experienced patients receive NAs alone for 48 weeks (NAs group). Patients were followed up 24 weeks after treatment discontinue. Twenty seven untreated IHCs were observed for 72 weeks (control group). The primary end point is the HBsAg clearance and seroconversion at 48 weeks and 72 weeks.

Results: Baseline characteristics are similar in every groups. At week 48, Intention-to-treat analysis showed that the rate of HBsAg clearance were 53.4% (31/58), 45.2% (38/84), 0% (0/27) and 0% (0/23) in Peg-IFN group, Peg-IFN plus NAs group, NAs group and control group respectively (ITT, P = 0.336, Peg-IFN VS Peg-IFN plus NAs; P < 0.001 Peg-IFN VS controls; P < 0.001, Peg-IFN plus NAs VS NAs). HBsAg seroconversion was achieved 36.2% (21/58) of Peg-IFN, 25.8% (23/89) of Peg-IFN plus NAs (ITT, P = 0.166). In Peg-IFN group, two patients (2/31, 6.5%) were observed HBsAg reappearance at 12 weeks and 48 weeks after HBsAg loss. Meanwhile, four subjects (4/38, 10.5%) experienced HBsAg relapse at 24 weeks, 32 weeks, 48 weeks and 56 weeks after HBsAg clearance in Peg-IFN plus NAs group (p = 0.867). Furthermore, we used the receiver operator curve to analyze HBsAg clearance. A baseline HBsAg level of <32 IU/ml provide good prediction for HBsAg clearance (sensitivity: 73.7%, specificity: 43.8%). All patients in treatment group exhibited virological response (HBV DNA<100 IU/ml). Generally, there are no serious adverse events during treatment, and the therapy was well tolerated.

Conclusion: Peg-IFN results in high rates of HBsAg loss and seroconversion in both IHCs and nucleoside analogs-experienced patients, especially, for those patients who HBsAg level below 32 IU/ml. Besides, HBsAg seroclearance achieved after Peg-IFN treatment was durable during 24 weeks' follow-up.

SAT-166

Similarly low risk of chronic kidney disease (CKD) progression in chronic hepatitis B patients with Stage 2 CKD on tenofovir alafenamide versus entecavir

Yan Liang[1], Vicki Wing-Ki Hui[1], Terry Cheuk-Fung Yip[1], Che To Lai[1], Shuk Man Lam[1], Yee-Kit Tse[1], Henry LY Chan[1], Vincent Wai-Sun Wong[1], Grace Lai-Hung Wong[1]. [1]*the Chinese University of Hong Kong, Hong Kong*
Email: wonglaihung@mect.cuhk.edu.hk

Background and aims: Tenofovir alafenamide (TAF) is a novel prodrug of tenofovir. There have been evolving data concerning its positive impact on renal safety as shown in registration trials. We aimed to compare the risk of chronic kidney disease (CKD) progression in chronic hepatitis B (CHB) patients on TAF versus entecavir (ETV).

Method: This is a retrospective cohort study. CKD Epidemiology Collaboration equation was used to determine the estimated

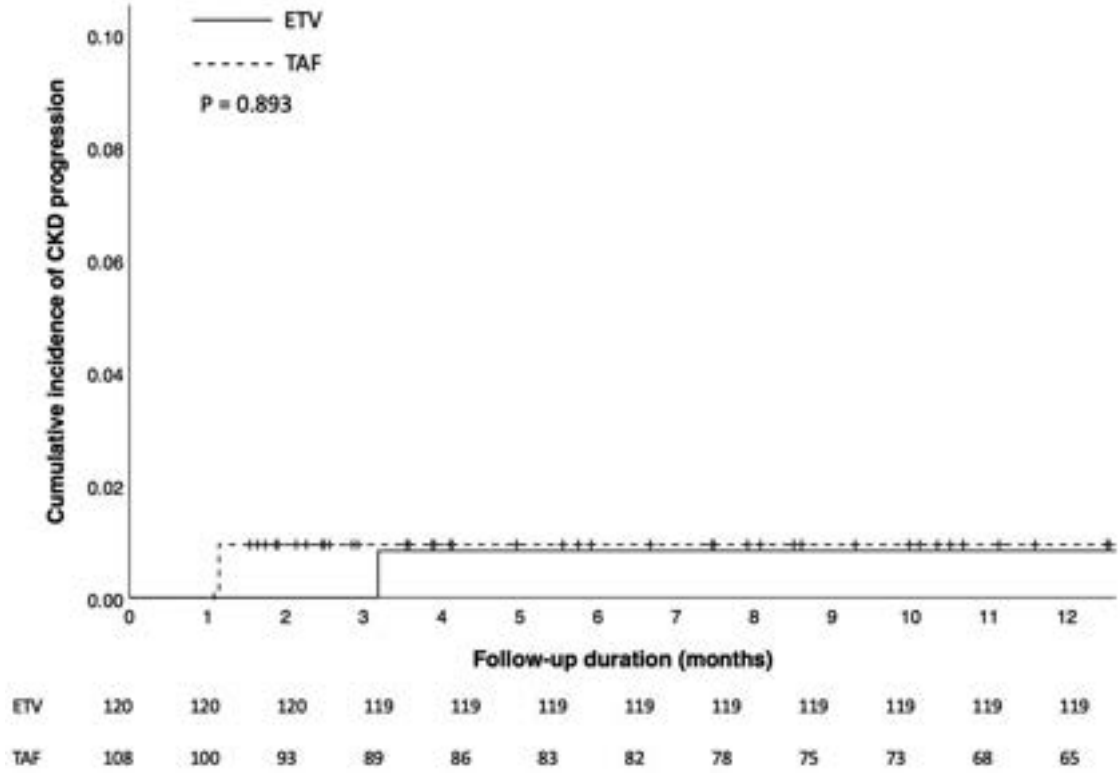

Figure: (abstract: SAT-166).

glomerular filtration rate (eGFR) and classified it into five CKD stages. Those TAF- and ETV-treated CHB patients who had Stage 2 CKD (i.e. eGFR 60–89 ml/min/1.73 m^2) and were previously treatment naïve were included. The baseline was defined as the start date of the antiviral treatment. The primary end point was the cumulative incidence of CKD progression at 12 months. Propensity score (PS) with the use of estimated average treatment effect was adopted in the analysis.

Results: 108 TAF-treated and 120 ETV-treated CHB patients were included in the analysis. 306 (58.2%) of them were males and their mean age was 60.0 ± 12.9 years old. Their mean baseline eGFR was 77.1 ± 8.3 and 79.3 ± 7.4 ml/min/1.73 m^2, respectively. During the first 12 months of follow-up, 1 (0.9%) TAF-treated and 1 (0.8%) ETV-treated patient with baseline Stage 2 CKD had CKD progression of at least one stage for at least three consecutive months, respectively. Kaplan-Meier curves showed that TAF-treated patients had a comparable risk of CKD progression compared with ETV-treated CHB patients (p = 0.893). (Figure).

Conclusion: TAF is associated with a similarly low risk of CKD progression compared with ETV in patients with Stage 2 CKD.

VIR-2218 and VIR-3434 therapy is efficacious in preclinical models of hepatitis delta virus infection

Jiayi Zhou[1], Hannah Kaiser[1], Tassilo Volz[2,3], Michael A. Schmid[4], Marc Luetgehmann[2,3], Maura Dandri[2,3], Davide Corti[4], Lisa A. Purcell[1], Andreas Puschnik[1], Florian Lempp[1]. *[1]Vir Biotechnology, United States; [2]University Medical Center Hamburg-Eppendorf, Dept. of Internal Medicine, Germany; [3]German Center for Infection Research, Hamburg-Luebeck-Borstel-Riems Site, Germany; [4]Humabs BioMed SA, a subsidiary of Vir Biotechnology, Switzerland*
Email: flempp@vir.bio

Background and aims: Chronic Hepatitis Delta Virus (HDV) infections represent the most severe form of viral hepatitis with limited treatment options. HDV is a satellite virus of Hepatitis B Virus (HBV) that depends on HBV-derived HBsAg for envelopment and viral dissemination in the liver. VIR-2218 is an investigational siRNA therapeutic that targets a highly conserved region within the HBx open reading frame and demonstrates potent knockdown of all HBV transcripts including of HBsAg. VIR-3434 is an investigational neutralizing monoclonal antibody targeting the antigenic loop of HBsAg thereby inhibiting viral entry and reducing circulating HBsAg in preclinical models. VIR-2218 and VIR-3434 are currently being evaluated in clinical trials as monotherapy and in combination. This study aims to determine the antiviral effect of VIR-2218 and VIR-3434 on HDV infection in preclinical models.

Method: *In vitro* antiviral efficacy of VIR-2218 was determined in an HBV/HDV co-infection model of primary human hepatocytes (PHH). After treatment with siRNA, secreted HBsAg was quantified by ELISA and secreted infectious HDV virions were quantified by re-infection of Huh7-NTCP cells. *In vitro* neutralization capacity of VIR-3434 was determined against HDV enveloped with HBsAg of eight different HBV genotypes. *In vivo*, humanized uPA/SCID/beige mice were intraperitoneally injected twice weekly for 4 weeks with VIR-3434 (1 mg/kg) after achieving stable HBV/HDV co-infection. Serological and intrahepatic viral markers were measured by ELISA and (RT-) qPCR.

Results: VIR-2218 reduced HBsAg and secreted infectious HDV with picomolar efficacy in a co-infection model of PHH. VIR-3434 neutralized HDV infection with >10 000-fold higher potency than Hepatitis B Immunoglobulins *in vitro*. Neutralization activity was pan-genotypic as tested with HDV enveloped with HBsAg of HBV genotypes A-H. *In vivo*, HBC34 (the parental molecule of VIR-3434) reduced HBsAg, HBV DNA and HDV RNA serum levels by >2 log10 copies/ml. As expected, intracellular levels of HBV and HDV RNAs were not affected by HBC34 treatment in the chronic infection model.

Conclusion: VIR-2218 and VIR-3434 have previously shown efficacy against HBV infection in multiple *in vitro* and *in vivo* models. Due to the shared usage of HBsAg by HBV and HDV, targeting HBsAg directly also influences concurrent HDV infection. By reducing HBsAg secretion, circulating HBsAg, and HDV virions, as well as blocking entry into hepatocytes, VIR-2218 and VIR-3434 exert antiviral efficacy against HDV through multiple modes of action. These data support the clinical development of VIR-2218 and VIR-3434 for treatment of patients with chronic HDV infection.

Email: florian.vanboemmel@medizin.uni-leipzig.de

Background and aims: In the prospective, multicenter, randomized STOP-NUC trial, discontinuation of long-term nucleos (t)ide analogues (NA) treatment resulted in Arm A 8/79 (10%) patients achieving HBsAg loss and 54/79 (68%) patients remaining free of treatment indication within 96 weeks, whereas there were no HBsAg losses in the control Arm B. In the second prospective observation period of the STOP-NUC trial we have assessed effects of NA discontinuation after week 96 up to a maximum follow-up time of 371 weeks (84 months), with a median follow-up time of 200 weeks (46 months).
Method: HBeAg-negative patients without cirrhosis who had achieved suppressed HBV DNA for ≥4 years during NA therapy were randomly assigned to either stop (Arm A) or continue (Arm B) treatment. The primary end point was sustained HBsAg loss at week 96. The objectives of the prolonged observation was to investigate the ratios of HBsAg losses, of HBsAg seroconversions, the duration of NUC treatment free follow-up and of response to re-treatment as well as the ratio of HBsAg loss in Arm B.
Results: A total of 99 of 158 originally included patients consented to take part in the prolonged follow-up (46 Arm A, 53 Arm B). At 72 months, the rate of HBsAg loss was 22.3% [95% CI: 7.9%–34.4%] in Arm A and 2.2% [95% CI: 0%–6.4%] in Arm B (Figure 1, p = 0.0013). Four further HBsAg losses had occurred after week 96 in Arm A. In Arm B, 13 patients had discontinued NUC treatment according to the discretion of the treating physician of which 1 had lost HBsAg during the follow-up period. Re-treatment with NA during follow-up was introduced at the discretion of the treating physician, and did not necessarily follow-up the stringent rules applied during the first 96 weeks. Re-treatment rate in Arm A was 20.7% [95% CI 9.8%–30.3%] at 72 months after NA stop. No patient in Arm A suffered any serious adverse events possibly related to lack of NA therapy during the prolonged observation period.
Conclusion: The follow-up period of the STOP-NUC trial demonstrates increasing HBsAg loss rates and stable retreatment rates after up to a maximum follow-up time of 84 months of discontinuation of long-term NA treatment in patients with HBeAg negative chronic hepatitis B (EudraCT-Nr.: 2013-004882-15).

Switching to peginterferon for chronic hepatitis B patients with hepatitis B e antigen seroconversion on entecavir-a long term follow-up study

Che To Lai[1], Vincent Wai-Sun Wong[1], Angel Mei-Ling Chim[1], Vicki Wing-Ki Hui[1], Yee-Kit Tse[1], Terry Cheuk-Fung Yip[1], Henry LY Chan[2], Grace Wong[1]. [1]*The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong;* [2]*Union Hospital, Department of Internal Medicine, Hong Kong*
Email: wonglaihung@gmail.com

Background and aims: Previous studies looking into switching from entecavir to peginterferon in chronic hepatitis B (CHB) patients showed a high rate of hepatitis B surface antigen (HBsAg) seroclearance; yet long term data are lacking. We aimed to study the long-term virological outcomes of CHB patients with nucleos (t)ide analogue (NA)-induced hepatitis B e antigen (HBeAg) seroconversion switching to peginterferon treatment.
Method: This was a long-term follow-up study of CHB patients recruited from 2013 to 2016 in a prospective, single-arm open-label study receiving 48 weeks of peginterferon alfa-2a monotherapy after achieving HBeAg seroconversion by entecavir. Baseline date was the end of the peginterferon treatment and the patients were followed until the date of latest virological blood tests. Patients were censored upon retreatment with NA. The virological response defined by sustained HBeAg seroconversion and serum hepatitis B virus (HBV) DNA <2000 IU/ml, as well as the cumulative incidence of HBsAg seroclearance were analysed.
Results: 41 patients from the original study were followed for a mean of 54 months. 30 (73%) were male with a mean age of 44 years. 37 (90%) patients completed the intended 48 weeks course of peginterferon alfa-2a. 11 (27%) patients achieved HBsAg seroclearance, with one patient achieving that at the end of peginterferon

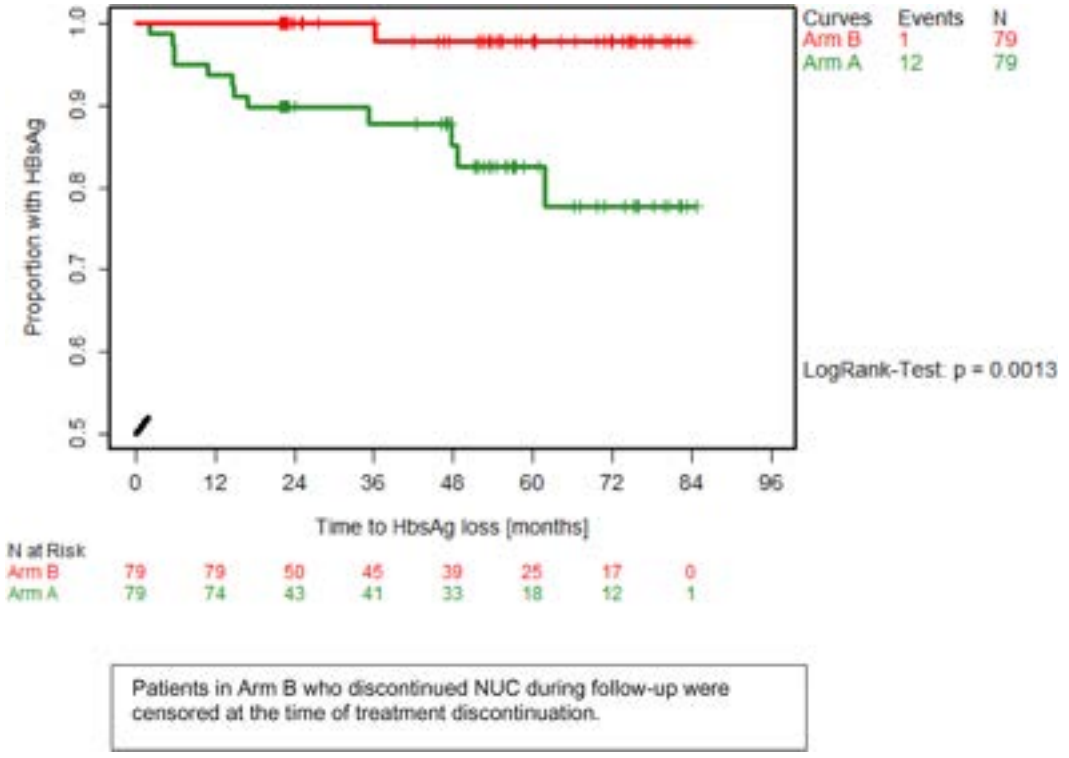

Figure: (abstract: TOP-110).

treatment. The cumulative incidences of HBsAg seroclearance were 16%, 19% and 31% at 12, 24 and 36 months respectively (Figure), and no HBsAg reversion was observed. 26 (63%) patients had sustained virological response with HBeAg seroconversion and serum HBV DNA <2 000 IU/ml throughout, of which 18 of them had undetectable HBV DNA. On the other hand, 15 (37%) patients had virological breakthrough requiring retreatment of NA at a median of 12 months after cessation of peginterferon treatment. End-of-peginterferon treatment HBsAg level <100 IU/ml (odds ratio 6.75, 95% confidence interval 1.24–36.85) was the best predictor for long term HBsAg seroclearance.

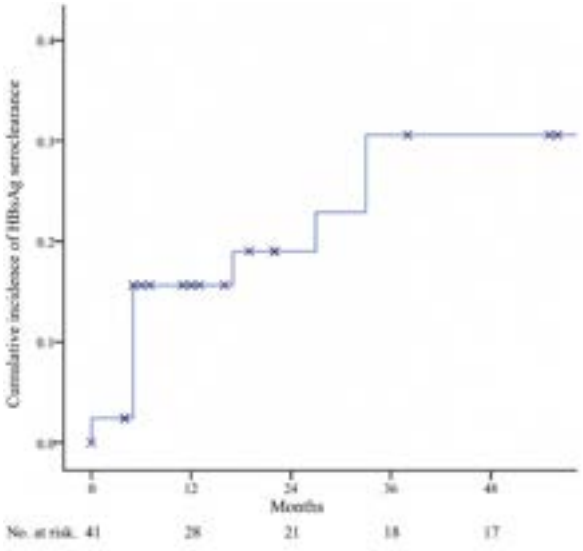

Figure. Cumulative incidence of HBsAg seroclearance in NA-treated CHB patients with HBeAg seroconversion switching to peginterferon alfa-2a

Figure:

Conclusion: In NA-treated patients with HBeAg seroconversion, switching from NA to peginterferon conferred to a high rate of durable HBsAg seroclearance, especially in those with low end-of-peginterferon HBsAg level.

SAT-168

Safety, pharmacokinetics, and antiviral activity of the next-generation hepatitis B core inhibitor ABI-H3733 in patients with hepatitis B e antigen negative chronic hepatitis B infection: preliminary results from a randomized, blinded, Phase 1b study

Edward J. Gane[1], Alina Jucov[2], Krum Katzarov[3], Oana Sandulescu[4], Ran Yan[5], Kathryn M. Kitrinos[5], Jieming Liu[5], Katie Zomorodi[5], Luisa M. Stamm[5], Steven J Knox[5], Michele Anderson[5], Grace Wang[5], Radoslava Tsrancheva[6], Anca Streinu-Cercel[4]. *[1]University of Auckland, Auckland, New Zealand; [2]ARENSIA Exploratory Medicine GmbH, Düsseldorf, Germany and Department of Gastroenterology, State University of Medicine and Pharmacy, Chisinau, Moldova; [3]Department of Gastroenterology, HPB and Transplant Surgery, Military Medical Academy, Sofia, Bulgaria; [4]Carol Davila University of Medicine and Pharmacy; National Institute for Infectious Diseases "Prof. Dr. Matei Bals", Bucharest, Romania; [5]Assembly Biosciences, South San Fransisco, United States; [6]Diagnostic Consultative Center Aleksandrovska, Sofia, Bulgaria*

Background and aims: ABI-H3733-102 (NCT05414981) is an ongoing, randomized, blinded, multiple-dose escalation study assessing the safety, pharmacokinetics (PK), and antiviral activity of the next-generation core inhibitor ABI-H3733 (3733), administered in patients (pts) with chronic hepatitis B virus infection. Here, we report preliminary safety, PK, and antiviral activity in hepatitis B e antigen (eAg) negative pts from completed cohorts.

Method: Each cohort randomized up to 10 pts (8:2 ratio) to 3733 or placebo (PBO) once-daily (QD) for 28 days. The first 2 cohorts evaluated 25 mg and 50 mg 3733. Eligible pts were male or female, aged 18–65 years, eAg positive (HBV DNA $\geq 2 \times 10^4$ IU/ml) or negative (HBV DNA $\geq 2 \times 10^3$ IU/ml), off antiviral therapy, non-cirrhotic with Fibroscan <9 kPa or Metavir F0-F2. Safety was assessed by adverse events (AEs), lab parameters, and electrocardiogram assessments. PK and viral biomarkers (including HBV DNA [Cobas TaqMan, lower limit of quantification = 20 IU/ml]) were assessed throughout.

Results: Baseline (BL) characteristics were similar between the 2 cohorts. As 18/20 pts enrolled were eAg negative, results are described for this subgroup. Most pts were male, White, aged ~40–50 years, with HBV DNA and hepatitis B surface antigen ranging from 3.3–4.5 $\log_{10}$ IU/ml and 3.2–3.9 $\log_{10}$ IU/ml, respectively. Treatment was well tolerated, with no serious AEs, deaths, or AEs leading to study drug discontinuation. AEs were reported in 4 pts and were all Grade 1. Graded lab abnormalities were observed in 53% (8/15) and 100% (3/3) of pts receiving 3733 and PBO, respectively, with most being Grade 1. No alanine aminotransferase (ALT) increases were observed. HBV DNA change from BL at Day 29 was –2.2 and –3.1 $\log_{10}$ IU/ml for 25 mg and 50 mg 3733, respectively. Mean Day 28 C_{max}, AUC_{0-24}, and $t_{1/2}$, respectively, were 959 ng/ml, 14,820 ng·h/ml, and 24.3 h for 25 mg 3733 and were 2,188 ng/ml, 31,510 ng·h/ml, and 23.9 h for 50 mg 3733.

Conclusion: 3733 was well tolerated at doses up to 50 mg QD for 28 days. All AEs and lab abnormalities were Grade 1 or 2, with no serious AEs, treatment discontinuations, or deaths. No ALT elevations were observed. Increased in vitro potency of 3733 relative to first-generation core inhibitors is reflected in rapid, multi-log declines in HBV DNA at low doses. PK properties of 3733 support daily dosing with C_{min}'s in multiple fold excess of protein-adjusted EC_{50}'s for HBV DNA and covalently closed circular DNA. These findings support further development of 3733.

Table. Summary results for eAg negative pts

Parameter	Cohort 1		Cohort 2	
	3733 50 mg (n = 8)	PBO (n = 1)	3733 25 mg (n = 7)	PBO (n = 2)

SAT-169

Rescue of cirrhotic HBV/HDV infection from bulevirtide failure by subcutaneous REP 2139-Mg

Marc Bourliere[1], Veronique Loustaud-Ratti[2], Christiane Stern[3], Souad Benali[1], Edouard Bardou-Jacquet[4], Laurent Alric[5], Michel Bazinet[6], Laurence Lecomte[1], Sandrine Francois[2], Cecilia De-Freitas[3], Anita Levacher[4], Segolene Brichler[7], Athenais Gerber[7], Emmanuel Gordien[7], Stéphane Chevaliez[8], Andrew Vaillant[6]. *[1]Hôpital Saint Joseph, Marseille, France; [2]CHU Limoges, Limoges, France; [3]Hôpital Beaujon AP-HP, Clichy, France; [4]CHU Rennes, Rennes, France; [5]CHU Rangueil, Université Toulouse 3, Toulouse, France; [6]Replicor Inc., Montreal, Canada; [7]Centre national de référence des hépatite B, C et Delta-Laboratoire associé, Hôpital Avicenne, Bobigny, France; [8]Hôpital Henri Mondor, Créteil, France*
Email: availlant@replicor.com

Background and aims: REP 2139 blocks HBV subviral particle assembly and hepatitis delta antigen function, driving HBsAg loss in HBV infection and HBsAg/HDV RNA loss in HBV/HDV co-infection. Compassionate access to REP 2139-Mg is being provided under the Replicor Compassionate Access Program (RCAP, NCT05683548). The safety and efficacy of SC injection of REP 2139-Mg in combination therapy is currently being assessed in cirrhotic patients with chronic HBV/HDV co-infection after failure on bulevirtide (BLV).
Method: Compassionate access to REP 2139-Mg has been approved by the ANSM in 11 patients with compensated cirrhosis having no response or viral escape in HDV RNA during 2 or 10 mg BLV. Existing TDF was supplemented with 48 weeks of QW SC 250 mg REP 2139-Mg and 90 µg pegIFN. Weekly safety evaluations were accompanied by virologic assessment every 4 weeks.
Results: As this abstract is submitted, seven patients have at least 4 weeks of REP 2139-Mg exposure. Four patients (#1, 2, 3 and 4) have greater than 24 weeks exposure with three (#1, 2 and 4) having no detectable HDV RNA and >3 log10 IU/ml decline in HBsAg and two (1 and 2) with HBsAg loss and anti-HBs seroconversion. One patient (#1) has completed 48 weeks of therapy and 8 months of TDF monotherapy and still maintains undetectable HDV RNA and HBsAg and anti-HBs seroconversion. TDF therapy has now been stopped in this patient. In patient 3, central obesity likely prevents optimal liver accumulation of REP 2139 with antiviral responses (declines in HDV RNA and HBsAg of 2.2 and 0.63 log10 IU/ml) proceeding with transition from SC injection to IV infusion and from 250 mg qW to 500 mg qW. Three patients (#6, 7 and 10) have completed 4–12 weeks exposure with mild declines in HDV RNA (0.5–1 log10 IU/ml) already present. The administration of SC 250 mg REP 2139-Mg with oral TDF and pegIFN has been well tolerated to date.
Conclusion: Subcutaneous REP 2139-Mg is safe, well tolerated, and effective against HBV and HDV infection in combination with TDF and low dose pegIFN in patients with compensated cirrhosis. REP 2139-Mg is also an effective salvage therapy in bulevirtide failure patients.

SAT-170

The Nuc-Stop study: an open-label, randomized trial of different re-start strategies after treatment withdrawal in HBeAg negative chronic hepatitis B patients

Asgeir Johannessen[1], Dag Henrik Reikvam[2], Soo Aleman[3], Nega Berhe[4,5], Nina Weis[6], Hailemichael Desalegn[7], Tore Stenstad[1], Lars Heggelund[8], Ellen Samuelsen[9], Karin Lindahl[3], Anni Winckelmann[6], Lars Normann Karlsen[10], Pascal Brugger-Synnes[11], Hans Erling Simonsen[12], Jan Svendsen[8], Marte Holmberg[1], Olav Dalgard[9]. *[1]Vestfold Hospital Trust, Tonsberg, Norway; [2]Oslo university hospital, Norway; [3]Karolinska institutet, Sweden; [4]Addis Ababa University, Ethiopia; [5]Oslo University Hospital-Ulleval, Regional Centre for Imported and Tropical Diseases, Oslo, Norway; [6]Hvidovre Hospital, Denmark; [7]St. Paul's Hospital Millennium Medical College, Ethiopia; [8]Vestre Viken Hospital, Norway; [9]Akershus University Hospital, Norway; [10]Stavanger University Hospital, Norway; [11]Ålesund hospital, Norway; [12]Nordland Hospital Trust, Norway*
Email: johannessen.asgeir@gmail.com

Background and aims: Stopping nucleos (t)ide analogue (NA) therapy in patients with chronic hepatitis B (CHB) may trigger a beneficial immune response leading to hepatitis B surface antigen (HBsAg) loss. However, treatment withdrawal may also induce a harmful hepatic necroinflammation that warrants re-start of therapy to prevent progressive liver injury. Whether it might be beneficial to allow patients to undergo a prolonged flare has not been studied in a prospective clinical trial. We therefore carried out the Nuc-Stop Study, an open-label, randomized, multicentre trial of two re-start strategies after stopping NA therapy in hepatitis B e-antigen (HBeAg) negative CHB.
Method: HBeAg negative CHB patients with at least 24 months of full viral suppression on NA therapy were eligible for inclusion. Patients with past or present evidence of cirrhosis were excluded. All study participants stopped antiviral therapy and were randomized to either low-threshold (alanine aminotransferase [ALT] >80 U/L and viral load >2000 IU/ml) or high-threshold (ALT >100 U/L for >4 months, or ALT >400 U/L for >2 month) for re-start of therapy. Patients in both groups re-started NA therapy in case of a severe flare, defined as ALT >800 U/L or any ALT flare with INR ≥1.4 or bilirubin >38 mmol/L. HBsAg loss was the primary end point. Differences between groups were analyzed with Chi-square tests or Fischer's exact tests, and associations with HBsAg loss were analyzed with logistic regression models.

Results: A total of 127 patients were included at 11 centres in Norway, Sweden, Denmark and Ethiopia; 121 patients completed 36 months of follow-up and were included in the final analysis. Median duration of antiviral treatment prior to inclusion was 46 months (interquartile range 32–78). Nine patients (7.4%) experienced a severe flare (maximum ALT 2600 U/L), all of whom quickly normalized after re-start of NA therapy; no other serious adverse events related to treatment withdrawal were observed. There was no statistically significant difference in HBsAg loss between the low-threshold and the high-threshold group (3 of 61; 4.9% vs. 7 of 60; 11.7%; $P = 0.205$). After 36 months of follow-up, 26 of 61 (42.6%) patients in the low-threshold group and 8 of 60 (13.3%) patients in the high-threshold group had met the pre-defined re-start criteria (Figure 1). Notably, none of the 34 patients who re-started therapy experienced HBsAg loss, compared to 10 of 87 (11.5%) of those who remained off therapy ($p = 0.060$). The only baseline factor independently associated with HBsAg loss was time on antiviral treatment prior to treatment withdrawal (per 1-year, adjusted odds ratio 1.30; 95% confidence interval 1.09–1.54, $P = 0.003$).

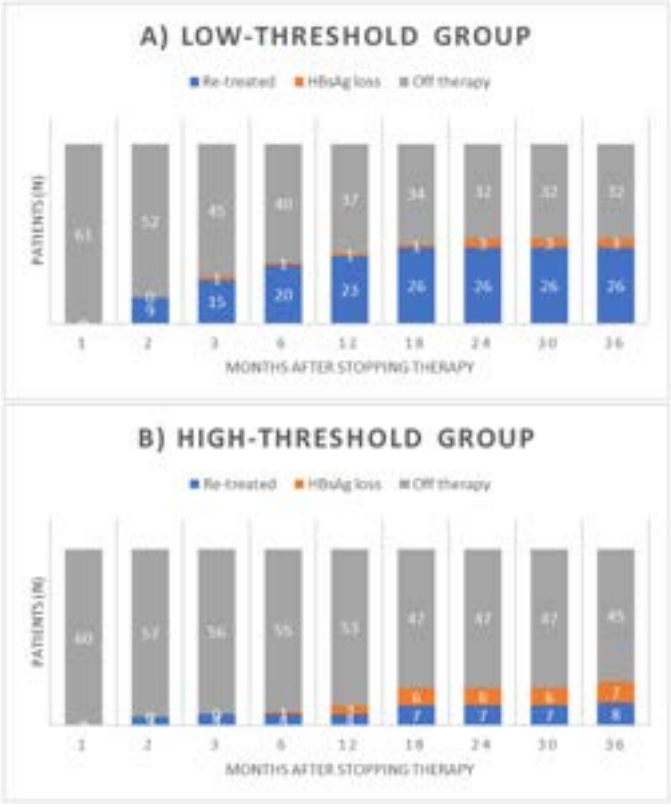

Figure: Outcome after treatment discontinuation in chronic hepatitis B patients randomized to: A) low-threshold for re-start of treatment, and B) high-threshold for re-start of treatment.

Conclusion: The re-start strategy did not significantly affect the chance of HBsAg loss among non-cirrhotic HBeAg negative CHB patients who stopped antiviral therapy.

SAT-171

Deep learning cluster analysis reveals subtypes in response to antisense oligonucleotide therapy in chronic hepatitis B

Caroline Weis[1], Maria Littmann[1], Aleksei Triastcyn[1], William Jordan[2], Dickens Theodore[3], Melanie Paff[2], Hannah Tipney[4], Jenn Singh[2], Patrick Schwab[1]. *[1]GSK, Artificial Intelligence and Machine Learning, Zug, Switzerland; [2]GSK, Collegeville, PA, United States; [3]GSK, Research Triangle Park, NC, United States; [4]GSK, Stevenage, United Kingdom*
Email: patrick.x.schwab@gsk.com

Background and aims: Chronic hepatitis B virus (CHB) infection is characterized by heterogeneity in disease trajectories and response to therapy. A comprehensive mapping of heterogeneity in CHB could potentially aid in supporting future research. In this study, we investigate the use of machine learning for characterizing heterogeneity in CHB from deep phenotypic patient profiles on and off bepirovirsen therapy.
Method: We used data from the B-Clear phase IIb study (NCT04449029) evaluating the efficacy of bepirovirsen in CHB patients ($N = 408$) to identify response groups. We employed machine learning methods to reduce the dimensionality of response data in a manner that conserves information related to patients' response trajectories. The condensed deep phenotypic patient profiles included virologic, immunologic, proteomics and transcriptomics measurements. We performed a cluster analysis on the compressed patient representations to identify subgroups of patients that respond differently in terms of biomarker trajectories following bepirovirsen therapy.
Results: Our results suggest that B-Clear study participants can be stratified into meaningful subpopulations indicative of heterogenous response to bepirovirsen therapy. The subpopulations recapitulate significant (Benjamini-Yekutieli corrected $p < 0.05$) differences in primary efficacy outcomes reflecting CHB virological markers, while identifying new response subtypes and giving a higher resolution on the temporal development of relevant biomarkers. Notably, we observe a high-primary response subtype that is correlated with a considerable decrease in median HBsAg to the lower limit of quantification ($p < 0.002$ to closest subtype from day 78 onwards) and a continuous decline of HBV-DNA levels ($p < 0.0001$ to the high HBV-DNA non-responder subtype throughout the study). Additionally, the high HBV-DNA non-responder subtype is correlated with higher GFER ($p < 0.04$ at baseline, 162, and 324 days) and lower ADGRG1 ($p < 0.03$ throughout the study) protein abundances compared to the mixed response subtype.
Conclusion: We present a machine learning-based method to identify meaningful response subgroups within a study cohort. We characterized five subpopulations with heterogenous clinical trajectories and differences in response to bepirovirsen therapy. The subtypes capture markers associated with patient response trajectories and may guide CHB research. Further validation of the identified markers in additional cohorts is needed.
Funding: GSK (205695).

Safety and antiviral activity of RBD1016, a RNAi therapeutic, in Chinese subjects with chronic hepatitis B virus (HBV) infection

Wai-Kay Seto[1,2], Zicai Liang[3], Li Ming Gan[3], Jing Fu[3], Man-Fung Yuen[2]. [1]*The university of Hong Kong-Shenzhen Hospital, Shenzhen, China, China;* [2]*Queen Mary Hospital, The University of Hong Kong, China;* [3]*Suzhou Ribo Life Science Co. Ltd., China*
Email: mfyuen@hku.hk

Background and aims: RBD1016, a small interfering RNA (siRNA) drug, is composed of siRNA and the N-acetylgalactosamine delivery system, targeting the conserved region of the X gene of chronic hepatitis B virus (HBV), and can concurrently inhibit 4 gene transcripts of HBV. Here, we report the preliminary data from an ongoing phase I clinical study evaluating the safety and antiviral activity of RBD1016 in subjects with chronic HBV infection.
Method: This randomized, double-blind, placebo-controlled, single and repeated dose escalation, phase I clinical study enrolled treatment naïve or previously treated subjects with chronic HBV infection without hepatic fibrosis or cirrhosis (NCT05017116). Subjects received RBD1016/placebo subcutaneously in combination with nucleos (t)ide analogues (NAs) during the study. In the single dose (SD) group, subjects were recruited in cohorts of six and were randomized 5:1 to receive RBD1016 or placebo. Upon cohort completion, RBD1016's dosage was escalated incrementally from 0.3 mg/kg to 1 mg/kg, 3 mg/kg and 6 mg/kg. For the multiple dose (MD) group, subjects were recruited in cohorts of eight and randomized 6:2 to receive RBD1016 (at 3 mg/kg, followed by 6 mg/kg) or placebo at Day 1 and D 29. Preliminary data for 0.3 mg/kg, 1 mg/kg, 3 mg/kg SD (follow-up to week 24) and 3 mg/kg MD (follow-up to week 16) are presented; dose escalation and follow-up are ongoing.
Results: As of December 28, 2022, twenty-seven subjects (mean age 43.2 years, 44.4% male) (SD = 20, MD = 7) were enrolled, of which 26 (96.3%) were on NAs therapy (entecavir: 17, tenofovir disoprovil fumarate: 6; tenofovir alafenamide: 3) for a median duration of 54.5 (range: 16–150) months. Maximum mean serum HBsAg reductions from baseline in subjects receiving RBD1016 of 0.3 mg/kg, 1 mg/kg, 3 mg/kg SD, 3 mg/kg MD and placebo were 0.48 (at week12), 0.75 (at week16), 0.97 (at week16), 1.34 (at week16) and 0.01 (at week16) $\log_{10}$ IU/ml, respectively. HBsAg reduction was durable till the end of study at week 24. Serum HBV DNA undetectability (<10 IU/ml) was achieved in three subjects with positive HBV DNA at baseline at weeks 1, 3 and 12, respectively. 9 subjects with RBD1016 therapy had positive serum HBV RNA (lower limit of quantification, 10 copies/ml) at baseline, median HBV RNA among positive subjects was 6240 (range: 11–518 000) copies/ml. By week 24, the median HBV RNA decline was 2450 (range: 1–50 980) copies/ml, with three subjects (one receiving 3 mg/kg SD and two receiving 3 mg/kg MD) achieving HBV RNA undetectability. For subjects with positive HBV RNA, an increased HBV RNA reduction was seen in patients with increased HBsAg decline. The 3 mg/kg MD cohort achieved 0.67 $\log_{10}$ kU/ml HBcrAg reduction at week 6 and 0.5 $\log_{10}$ cp/ml HBV RNA reduction at week 24. RBD1016 was safe, with no serious adverse events or drug-related adverse events reported. No subjects withdrew from the study or discontinued treatment.
Conclusion: A single dose of RBD1016 demonstrated a rapid and durable reduction in serum HBsAg in a dose-dependent manner. Multiple doses of RBD1016 showed increased reduction in HBsAg. Preliminary safety data suggested that RBD1016 was generally safe and well tolerated. The present data supports the further evaluation of RBD1016 for functional cure of patients with chronic HBV infection.

SAT-173

AHB-137, a novel hepatitis B virus antisense oligonucleotide with substantially enhanced in vitro and in vivo antiviral activity

Xiaoli Wu[1], Tingting Lu, Weiguo Zhang[1], Yang Bai[1], Liqun Zhang[1], Shaoyi Ma[1], Ying Chang[1], Jihai Lei[1], Chunxi Li[1], Yuying Liu[1], Zelei Pan[1], Wei Peng[1], Chang Shen[1], Yipeng Wang[1], Qingbo Xing[1], Lisha Zhang[1], Xue Zhou[1], Yang Tian[1,2], Chris Yang[1,2], Cheng Guofeng[1,2]. [1]*Ausper Biopharma, China;* [2]*AusperBio Therapeutics, United States*
Email: guofengcheng1@hotmail.com

Background and aims: Antisense oligonucleotide (ASO) bepirovirsen (BPV) monotherapy has demonstrated activity to achieve sustained HBsAg seroclearance in chronic hepatitis B (CHB) patients, with a promise to be a backbone for HBV cure treatment regimen. However, the current cure rate with BPV remains low, thus a more potent ASO with good safety profile could further improve the

efficacy. Here we report a novel HBV ASO AHB-137 with substantially enhanced in vitro and in vivo antiviral activity.

Method: AHB-137 and BPV were synthesized via solid phase synthesis. In vitro antiviral activity was evaluated in HBV stable cell lines HepG2.2.15 and HepAD38, and in primary human hepatocytes (PHH) infected with HBV. In vivo antiviral activity was evaluated in hydrodynamic injection (HDI) mouse model, AAV-HBV transduced mice, and HBV transgenic mice. Secreted HBsAg was quantified by a clinical HBsAg chemiluminescent immunoassay (AutoBio).

Results: AHB-137 is a novel ASO without conjugation that has a distinct structure from BPV and targets a highly conserved sequence close to the 3′ end of HBV mRNA at DR2 region. AHB-137 exhibited potent antiviral activity to inhibit HBsAg production in HepG2.2.15 cells with an EC_{50} value of 0.13 nM and a selectivity index (SI) >769-fold, compared to BPV with an EC_{50} of 1.50 nM and SI >67-fold. Similarly, AHB-137 demonstrated 10-fold and 6-fold more potent activity to reduce HBsAg than BPV in HepAD38 and HBV-infected PHH, respectively. More importantly, AHB-137 has shown potent and dose-dependent antiviral activity to reduce serum HBsAg, HBeAg, HBV DNA, and intrahepatic HBV RNA in AAV-HBV mice, HBV transgenic mice, and HDI HBV mice. A single subcutaneous dose of AHB-137 (60 mg/kg) could reduce serum HBsAg 1.3 to 3 log10 (IU/ml) and achieve at least 0.6 log10 additional reduction than BPV in every in vivo model. After 3 doses of AHB-137 (40 mg/kg) in HDI-HBV mice, the serum HBsAg was reduced by >3 log10 (IU/ml) to below LLOQ, compared to a 1.8 log10 (IU/ml) HBsAg reduction by BPV. The broad-spectrum antiviral activity of AHB-137 was also confirmed in HDI-HBV mice with higher potency than BPV across genotypes. As important, there was no significant body weight change and ALT increase in any of the animals treated with AHB-137. Finally, when combined with other classes of anti-HBV agents including Nuc and PEG-IFN in AAV-HBV mice, AHB-137 showed additive/synergistic activity and had no antagonistic activity.

Conclusion: The AHB-137 represents a novel class of HBV ASO that clearly demonstrated strong antiviral activity against HBV mRNA transcribed from both cccDNA and integrated genomes, and had more potent activity in reducing serum HBsAg than BPV across multiple in vitro and in vivo HBV models. Together with its favorable PK and safety profile, AHB-137 is advancing into clinical development.

Stamm[10], Steven J Knox[10], Michele Anderson[10], Kathryn M. Kitrinos[10], Grace Wang[10], Yu Chen[11], Junqi Niu[8]. *[1]Hepatology Unit and Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Guangzhou Eighth People's Hospital, Guangzhou, China; [3]Fudan University, Shanghai, China; [4]Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [5]Beijing Friendship Hospital, Capital Medical University, Beijing, China; [6]The First Affiliated Hospital, College of Medicine, Zhejiang University School of Medicine, Hangzhou, Zhejiang, China; [7]Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [8]The First Hospital of Jilin University, Jilin, China; [9]Former employee of Assembly Biosciences during the study; current affiliation Gilead Sciences, Foster City, United States; [10]Assembly Biosciences, South San Fransisco, United States; [11]Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: freeliang@163.com

Background and aims: Vebicorvir (VBR), a first-generation core inhibitor, in combination with entecavir (ETV) previously demonstrated deeper viral suppression compared to ETV alone in untreated patients (pts) with hepatitis B e antigen (eAg) positive chronic hepatitis B virus infection (cHBV). The addition of pegylated interferon alfa (IFN) may further increase the efficacy of VBR + ETV through complementary mechanisms of action. This open-label study (NCT04781647) assessed the relative safety and efficacy of VBR + ETV + IFN.

Method: Fifty-four eAg positive pts with cHBV with F0-F3 fibrosis who were off antiviral therapy were randomized to VBR + ETV (n = 20), VBR + ETV + IFN (n = 17), or IFN + ETV (n = 17) for 24 weeks (wks), after which all pts received VBR + ETV for 24 wks, then a 12-wk follow-up period with ETV alone. HBV DNA was measured by COBAS TaqMan (lower limit of quantification [LLOQ] = 20 IU/ml) and pregenomic (pg)RNA by Assembly Biosciences quantitative polymerase chain reaction assay (LLOQ = 165 U/ml). Quantitative hepatitis B surface antigen (sAg) was measured by Abbott Architect (LLOQ = 0.05 IU/ml). Safety was assessed by adverse events (AEs) and lab parameters.

Results: Baseline (BL) characteristics were similar across treatments; overall, mean (standard deviation [SD]) age was 32 (6.7) years, 39/54 (72%) pts were male, and all were Asian. Twenty-five of 54 (46%) and 29/54 (53%) pts were infected with HBV genotype B and C, respectively. Overall, mean (SD) BL HBV DNA, pgRNA, sAg, and alanine aminotransferase (ALT) were 8.0 (0.96) log_{10} IU/ml, 6.3 (1.30) log_{10} U/ml, 4.3 (0.58) log_{10} IU/ml, and 137 (84.3) U/L, respectively. After 24 wks of randomized treatment, there were no significant differences in change from BL between treatment arms for HBV DNA or HBsAg (Table). VBR + ETV + IFN resulted in a significantly greater reduction in pgRNA than ETV + IFN (p = 0.03). No pts developed anti-sAg antibodies or had evidence of functional cure. The safety profile was consistent with previous reports for VBR and IFN. The proportion of pts reporting treatment emergent AEs was higher in IFN containing arms; 13/20 (65%), 17/17 (100%), and 17/17 (100%) for VBR + ETV, VBR + ETV + IFN, and ETV + IFN, respectively. A single serious AE of Grade 4

[e]Wk 24: sAg LS Means (SE) difference: VBR + ETV + IFN vs VBR + ETV = −0.1 (0.19), p =0.6336. [f]VBR + ETV + IFN vs ETV + IFN = 0.1 (0.19), p = 0.7871.
BL, baseline; ETV, entecavir; HBV, hepatitis B virus; IFN, pegylated interferon alfa; LS, least squares; pgRNA, pregenomic RNA; sAg, hepatitis B surface antigen; SE, standard error; VBR, vebicorvir; Wk, week.

Figure: (abstract: SAT-174).

ALT elevation was reported in a VBR + IFN + ETV pt that led to study discontinuation. No deaths were reported.
Conclusion: Overall, the addition of IFN to VBR + ETV did not result in significantly greater declines in HBV parameters compared to the dual agent control arms and is unlikely to result in significant rates of functional cure following 24 wks of treatment.

SAT-175

Significant improvement of non-invasive fibrosis tests in HDV compensated cirrhotic patients with clinically significant portal hypertension treated with BLV monotherapy un to 96 weeks

Elisabetta Degasperi[1], Maria Paola Anolli[1], Sara Colonia Uceda Renteria[2], Dana Sambarino[1], Marta Borghi[1], Riccardo Perbellini[1], Floriana Facchetti[1], Roberta Soffredini[1], Sara Monico[1], Mirella Fraquelli[3], Andrea Costantino[3], Ferruccio Ceriotti[2], Pietro Lampertico[1,4]. *[1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Gastroenterology and Hepatology, Milan, Italy; [2]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, VirologyUnit, Milan, Italy; [3]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Endoscopy Digestive, Milan, Italy; [4]CRC "A.M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and transplantation, University of Milan, Milan, Italy*
Email: elisabetta.degasperi@policlinico.mi.it

Background and aims: Antiviral treatment of HBV- and HCV-related hepatitis has been shown to significantly improve non-invasive fibrosis tests (NITs), however their course in patients with chronic hepatitis Delta with a virological response during a long-term treatment with Bulevirtide (BLV) monotherapy is currently unknown.
Method: Consecutive HDV patients with compensated cirrhosis and clinically significant portal hypertension (CSPH) according to Baveno VII criteria with a virological response (≥2 Log HDV RNA decline vs. baseline) to BLV monotherapy 2 mg/day up to 96 weeks were enrolled in this single-center study. HDV RNA was quantified by Robogene 2.0 (LOD 6 IU/ml). Clinical variables, AST to Platelet Ratio Index (APRI) and Fibrosis-4 (FIB-4) Index were assessed at baseline and every 8 weeks. Liver (LSM), spleen (SSM) stiffness measurement assessed both by transient elastography (Fibroscan®) and point shear-wave elastography (ElastPQ) were performed every 24 weeks, as well as liver stiffness-spleen size-to-platelet ratio score (LSPS).
Results: 26 HDV cirrhotic patients were included: pre-treatment, median age was 49 (30–77) years, 54% males, ALT 102 (32–310) U/L, platelets 69 (17–217) × 10^3/mm^3, 73% with varices, spleen 16 (9–25) cm, CPT-A 100%, HDV RNA 5.1 (2.4–6.9) Log IU/ml. During BLV monotherapy, serological NIT significantly improved at all time-points, APRI decreasing from baseline 3.6 (1.2–16.5) to 1.1 (0.3–3.6) at week 96 (p < 0.001), and FIB-4 from 7.1 (1.3–28.1) to 4.1 (0.9–7.2) (p = 0.02). LSM decreased from baseline 17.3 (7.8–68.1) to 15.7 (5.0–51.9) kPa at week 24 (p = 0.03) and LSPS from baseline 5.9 (0.5–23.7) to 3.9 (0.3–9.7) at week 48 (p = 0.01), whereas no other significant changes were observed throughout weeks 48 and 72. Conversely, other NITs did not significantly modify during the whole course of BLV treatment: liver ElastPQ 14.3 (4.2–35.2) vs. 16.5 (6.6–25.9) kPa (p = 0.14); SSM 51.7 (20–100) vs. 54.7 (18.2–100) kPa (p = 0.66), Spleen ElastPQ 42.2 (13.1–102) vs. 43.7 (31.9–94.8) kPa (p = 0.68). Four patients underwent liver transplantation (HCC n = 2; liver decompensation n = 2) and one patient died of liver unrelated causes.
Conclusion: In HDV compensated cirrhotic patients with CSPH, long-term treatment with BLV monotherapy led to a statistically significant improvement of serological fibrosis NITs, liver stiffness and LSPS.

SAT-176

Analysis of HBV genotype association to bepirovirsen treatment response in patients with chronic HBV infection (Phase 2b B-Clear study)

Jerome Bouquet[1], Robert Elston[2], Phil Yates[2], Shihyun You[3], Amir Youssef[3], Ahmed Nader[3], Jennifer Cremer[4], Geoff Quinn[2], Fiona Campbell[2], Melanie Paff[3], Dickens Theodore[4]. *[1]GSK, South San Francisco, United States; [2]GSK, Stevenage, United Kingdom; [3]GSK, Collegeville, United States; [4]GSK, Durham, United States*
Email: jerome.x.bouquet@gsk.com

Background and aims: Bepirovirsen (BPV; GSK3228836) is an antisense oligonucleotide that targets a conserved 20 nucleotide sequence within HBV pregenomic RNA and mRNAs. B-Clear is a phase 2b trial (NCT04449029) assessing the efficacy and safety of 12 or 24 weeks (wks) of BPV treatment in patients (pts) with chronic hepatitis B (CHB) in which hepatitis B surface antigen (HBsAg) reductions and

Figure: (abstract: SAT-176).

HBsAg seroclearance have been observed. We present the HBsAg response for pts by viral genotype.

Methods: Multicentre, randomised, partial-blind study in pts with CHB who were either receiving concomitant stable nucleos (t)ide analogue therapy (on-NA) or were not receiving NA (not-on-NA). Pts were randomised (3:3:3:1) to receive BPV 300 mg weekly either for 24 wks (Arm 1); for 12 wks then 150 mg for 12 wks (Arm 2); for 12 wks then placebo (PBO) for 12 wks (Arm 3); or PBO for 12 wks then BPV 300 mg for 12 wks (Arm 4). A loading dose of BPV (Arms 1–3) or PBO (Arm 4) was given on days 4 and 11. Pts were followed for 24 weeks (off-treatment [OT]-WK24) after end of treatment (EOT). B-Clear recruited patients in 22 countries encompassing Asia, Europe, the Americas and South Africa. Genotype was determined by HBV DNA or RNA sequencing and/or was investigator reported.

Results: Seven different genotypes were observed: A, B, C, D, E, F and H. Genotypes were in majority B and C in Asia, A and D in Europe, A, B, C and D in the Americas. Not-on-NA: Genotype (GT) C (31%, 70/229 pts) was most frequently observed, followed by GT-B (21%), GT-D (20%), GT-A (18%), other (6%) and undetermined (4%). Pts with GT-B virus had the lowest mean HBsAg level at baseline (3.155 log IU/ml) and GT-A the highest (3.982 log IU/ml). On-NA: GT-C (31%, 70/226 pts) was most frequently observed, followed by GT-B (9%), GT-D, GT-A (8% each) and others (3%). On-NA pts had low/undetectable RNA/DNA resulting in a high proportion of undetermined genotypes (41%). Pts with GT-B virus had the lowest mean HBsAg level at baseline (3.090 log IU/ml) and GT-A the highest (3.724 log IU/ml). Treatment Response: End of BPV treatment response and 24 wks off BPV treatment response by genotype is shown in Table 1 (treatment arms pooled).

Conclusion: In both not-on-NA and NA cohorts, GT-B had the lowest baseline HBsAg and demonstrated the greatest log reduction in HBsAg, consistent with lower baseline HBsAg predicting the ability to achieve HBsAg seroclearance. HBsAg seroclearance 24 wks off-BPV treatment was achieved in HBV genotypes A, B, C and D.

Funding: GSK (209668).

SAT-177

Single dose pharmacokinetics of VIR-3434, a novel neutralizing monoclonal antibody, in participants with chronic hepatitis B virus infection

Sneha V. Gupta[1], Sophia Elie[1], Andre Arizpe[1], George Hristopoulos[1], Pan Wu[1], Daniel Cloutier[1], Maribel Reyes[1]. [1]*VIR Biotechnology, San Francisco, United States*
Email: sgupta@vir.bio

Background and aims: VIR-3434 is an investigational Fc engineered human monoclonal antibody targeting the conserved antigenic loop of hepatitis B surface antigen (HBsAg) in development for the treatment of chronic hepatitis B virus (HBV) and hepatitis D virus (HDV) infection. Here, we report, the free VIR-3434 pharmacokinetics (PK) after single dose administration in participants with chronic HBV infection, including those with HBV viremia and high HBsAg levels.
Method: VIR-3434-1002 is a randomized, double-blind, placebo-controlled phase 1 single ascending dose study evaluating safety, tolerability, antiviral activity, and PK of VIR-3434. Part A enrolled healthy participants whose PK and safety has been previously reported. Parts B-D enrolled noncirrhotic adults with chronic HBV infection. Participants were randomized 6:2 to receive a single subcutaneous (SC) dose of VIR-3434 6 mg, 18 mg, 75 mg, or 300 mg, or placebo. In Parts B and C, participants received nucleos (t)ide reverse transcriptase inhibitor (NRTI) therapy for ≥2 months prior to study entry. Parts B and C participants had baseline HBsAg <3000 and ≥3000 IU/ml, respectively. Part D participants were not on NRTI therapy and had baseline HBV DNA ≥1000 IU/ml. Participants were followed for up to 40 weeks after study drug administration.
Results: 72 participants were enrolled in Parts B-D; 54 received VIR-3434. Among active participants, median T_{max} was 3–5 days. Larger and more durable HBsAg reductions and higher free VIR-3434 PK for 4 weeks postdose were observed at the 300 mg dose level. Participants with a wide range of baseline HBsAg across Parts B-D and with detectable free VIR-3434 PK received 75 or 300 mg and are described further. Free VIR-3434 PK exposures (AUC_{last} and C_{max}) negatively correlated with HBsAg levels at baseline (Figure 1). Following 300 mg VIR-3434 dose, mean (CV) AUC_{last} and C_{max} was higher in Part B at 967 (21%) ug/ml*day and 32.6 (18%) ug/ml than Part C with 365 (64%) ug/ml*day and 22.5 (39%) ug/ml, respectively. Similarly, VIR-3434 was cleared faster in participants with higher baseline HBsAg. At the 300 mg dose level, median CL/F was 600 ml/day in Part B vs 818 ml/day in Part C, suggestive of target-mediated drug disposition (TMDD).
Conclusion: Among participants who received a single dose of 6 mg, 18 mg, 75 mg, or 300 mg VIR-3434, the highest and most durable free VIR-3434 exposure was observed with the 300 mg dose irrespective of baseline HBsAg. Correlation plots with free PK demonstrate a moderate impact of baseline HBsAg in free VIR-3434 exposure, suggestive of TMDD. These PK data support continued evaluation of 300 mg SC VIR-3434 administered every 4 weeks as monotherapy or in combination for functional cure of participants with chronic HBV infection.

AHB-137, a novel and potent hepatitis B virus antisense oligonucleotide with a favorable preclinical pharmacokinetics and safety profile

Xiao Qiu[1], Tingting Lu[1], Hu Zhou[1], Haixia Cao[1], Weiguo Zhang[1], Guowei Chen[1], Bingxia Lu[1], Xiaoli Wu[1], Yilei Wen[1], Rumeng Cui[1], Qianxi Cui[1], Yuhua Pang[1], Liqun Zhang[1], Qingbo Xing[1], Yuying Liu[1], Lisha Zhang[1], Xue Zhou[1], Yang Tian[1,2], Chris Yang[1,2], Guofeng Cheng[1,2]. [1]*Ausper Biopharma, China;* [2]*AusperBio Therapeutics, United States*
Email: guofeng.cheng@ausperbio.com

Background and aims: Antisense oligonucleotide (ASO) bepirovirsen (BPV) monotherapy has demonstrated activity to achieve sustained HBsAg seroclearance in chronic hepatitis B (CHB) patients, with a promise to be a backbone for HBV cure treatment. AHB-137 is a novel HBV ASO with substantially enhanced antiviral activity over BPV both in vitro and in vivo. Here we report that AHB-137 has a favorable preclinical pharmacokinetics (PK) and safety profile.
Method: CD-1 mice, hydrodynamic injection (HDI) HBV mice, and cynomolgus monkeys were dosed subcutaneously (SC), or by intravenously in monkeys, to assess the PK properties of AHB-137 and BPV. For toxicokinetics and toxicity assessment, 4-week repeat ascending dose studies were conducted in CD-1 mice and cynomolgus monkeys, in which AHB-137 or dosing vehicle was given SC once a week with an additional dose on Day 4 in the first week. Serum and multiple organs were collected at various timepoints and analyzed for AHB-137 concentrations by LC-MS. Safety of AHB-137 was evaluated under GLP toxicology study guideline.
Results: AHB-137 and BPV showed comparable concentration-time profiles in serum in both mice and monkeys at the same dose levels. Despite comparable exposure, three doses of AHB-137 (each dose at 40 mg/kg) reduced the serum HBsAg by >3 log10 (IU/ml) to below LLOQ in HDI HBV mice while the same doses of BPV only reduced HBsAg by 1.8 log10 (IU/ml), confirming the higher potency of AHB-137 observed both in vitro and in vivo. Furthermore, AHB-137 demonstrated similar pharmacokinetic profile to BPV with a good bioavailability following SC injection (84% bioavailable) in monkeys. Like BPV, the half-life of AHB-137 in serum was approximately 3–4 h in the first 24 h post-dose but was much longer (>50 h) in latter phase in both mice and monkeys. The serum C_{max} and AUC of AHB-137 was dose-proportional and did not accumulate after 6 repeat doses over 29 days compared to the first dose in either mouse or monkey, as was observed for BPV. The liver and kidney were the main organs for AHB-137 distribution and the tissue concentration of AHB-137 were dose-proportional. AHB-137 is metabolically stable in liver S9 fraction, hepatocytes, and plasma across the mouse, rat, monkey, and human, with little or no drug-drug interaction. In acute tox studies in mice, AHB-137 showed a significantly better safety profile than BPV. In the 4-week repeat dosing GLP studies, AHB-137 was well-tolerated in mice and monkeys with no findings of adverse effect at 60 and 15 mg/kg/dose, respectively. AHB-137 also demonstrated low-risk profile in safety pharmacology studies.
Conclusion: In addition to potent antiviral activity, the novel HBV ASO AHB-137 has demonstrated a favorable preclinical pharmacokinetics and safety profile. AHB-137 is advancing into clinical development for the treatment of CHB patients.

Consolidation treatment with Tiaogan-Buxu-Jiedu granule (Traditional Chinese Medicine compound) plus entecavir reduces virological relapse following entecavir withdrawal in Chinese patients with chronic hepatitis B: a randomized, controlled trial

Xiaoke Li[1,2], Mei Qiu[3], Yi Huang[4], Huanming Xiao[5], Bingjiu Lu[6], Yuyong Jiang[7], Fuli Long[8], Hui Lin[9], Shuo Li[1], Jinyu He[10], Mingxiang Zhang[11], Qikai Wu[12], Li Wang[13], Xiaoning Zhu[14], Man Gong[15], Jianguang Sun[16], Xuehua Sun[17], Fengxia Sun[18], Wei Lu[19], Weihua Xu[20], Hongbo Du[1,2], Yong'an Ye[1,2]. *[1]Dongzhimen Hospital, Beijing University of Chinese Medicine, Hepatology, Beijing, China; [2]Beijing University of Chinese Medicine, Liver Diseases Academy of Traditional Chinese Medicine, Beijing, China; [3]Shenzhen Traditional Chinese Medicine Hospital, Hepatology, China; [4]Chongqing Traditional Chinese Medicine Hospital, Hepatology, China; [5]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Hepatology, China; [6]Liaoning Hospital of Traditional Chinese Medicine, Hepatology, China; [7]Beijing Ditan Hospital, China; [8]The First Affiliated Hospital of Guangxi University of Chinese Medicine, China; [9]Mengchao Hepatobiliary Hospital of Fujian Medical University, Hepatology, China; [10]Shaanxi Hospital of Traditional Chinese Medicine, Hepatology, China; [11]The Sixth People's Hospital of Shenyang, China; [12]The Third People's Hospital of Shenzhen, Hepatology, China; [13]The Public Health Clinical Center of Chengdu, Hepatology, China; [14]Affiliated traditional Chinese medicine hospital of Southwest Medical University, China; [15]The Fifth Medical Center of People's Liberation Army of China, Hepatology, China; [16]Shandong Hospital of Traditional Chinese Medicine, Hepatology, China; [17]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Hepatology, China; [18]Beijing Chinese Medicine Hospital, Beijing, China; [19]The Second People's Hospital of Tianjin, China; [20]The Second Hospital of Shandong University, China*
Email: yeyongan@vip.163.com

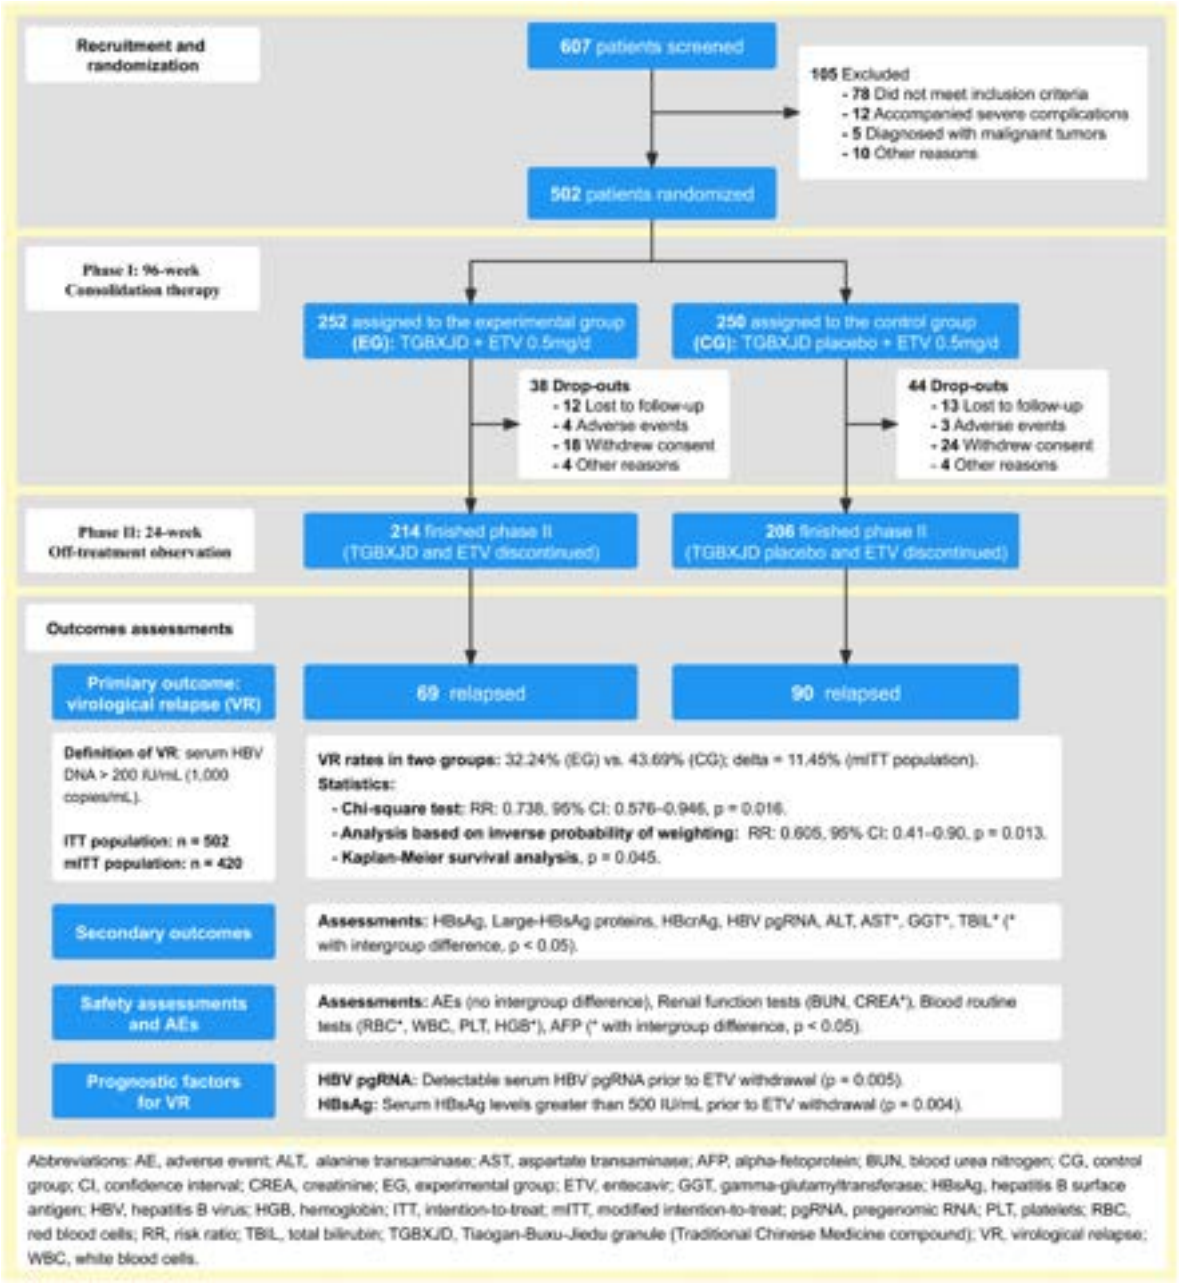

Figure: (abstract: SAT-179).

Background and aims: Several guidelines suggest that nucleoside analogues (NAs) may be discontinued in chronic hepatitis B (CHB) patients after hepatitis B e antigen (HBeAg) seroconversion, followed by a certain course of consolidation treatment. However, the withdrawal of NAs often results in virological relapse. In China, Traditional Chinese Medicine (TCM) is widely combined with NAs in treatment. The aim of this double-blind, placebo-controlled, randomized, multicentre trial was to assess whether enhanced consolidation therapy with entecavir (ETV) plus Tiaogan-Buxu-Jiedu granule (TGBXJD), an immune-modulatory TCM compound, can further reduce the risk of virological relapse following ETV withdrawal in CHB patients. The study was conducted as part of National Science and Technology Major Project of China, No.2018ZX10725505. Trial protocol was registered with the Chinese Clinical Trial Registry, ID: ChiCTR-TRC-12002784.
Method: 502 eligible NAs-treated CHB patients were randomly assigned to the experimental group (EG) or the control group (CG) in a 1:1 ratio as the intention-to-treat (ITT) population. During the initial 96-week consolidation phase, the EG received a combination therapy of ETV and TGBXJD, while the CG received ETV and a placebo for TGBXJD. Following the consolidation phase, an off-treatment observation phase of 24 weeks was implemented during which both groups discontinued ETV and TGBXJD (or placebo). The primary outcome measure of the study was the cumulative rate of virological relapse, defined as serum HBV DNA >200 IU/ml. The secondary outcome measures included levels of HBV serological markers, HBV DNA, liver enzymes, HBV pregenome RNA (pgRNA), and HBV large surface proteins.
Results: A total of 420 patients (modified intention-to-treat [mITT] population, 214 in the EG and 206 in the CG) completed consolidation therapy and finished the off-treatment observation. Upon completion of consolidation therapy, the levels of serum HBsAg were comparable between the two groups. During the off-treatment observation phase, 159 patients (69 in the EG and 90 in the CG) experienced virological relapse. In both the ITT population (27.38% vs. 36.00%, delta = 8.62%, relative risk [RR]: 0.761, 95% confidence interval [CI]: 0.586–0.987, p = 0.037) and the mITT population (32.24% vs. 43.69%, delta = 11.45%, RR: 0.738, 95% CI: 0.576–0.946, p = 0.016), the relapse rates were statistically lower in the EG than in the CG. According to the Kaplan-Meier survival analysis, the cumulative probability of virological relapse was reduced in the EG (p = 0.045). The decreased serum HBsAg levels (under 500 IU/ml, p = 0.004) and undetectable serum HBV pgRNA (p = 0.005) prior to ETV withdrawal may be related to a reduced risk of virological relapse.
Conclusion: A 96-week consolidation therapy combining the TGBXJD and ETV may improve off-treatment outcomes by reducing virological relapses. Serum HBV pgRNA and HBsAg levels could be evaluated as potential predictors of virological relapse prior to ETV withdrawal.

SAT-180

Positive impact of reflex testing in performing hepatitis delta serology in HBsAg+ patients

Régine Truchi[1], Anne De Monte[2], Albert Tran[1], Valérie Giordanengo[2], Laurence Ollier[2]. *[1]Archet 2 Hospital, Liver unit, NICE, France; [2]Archet 2 Hospital, Virology laboratory, NICE, France*
Email: truchi.r@chu-nice.fr

Background and aims: Several studies have shown that screening for the hepatitis Delta virus (HDV) was not optimal: between 30 and 50% of HBs antigen positive (HBsAg+) patients. The virology laboratory of University Hospital Center (CHU) from Nice has been carrying out HDV reflex testing (HDV RT) for several years in HBsAg+ patients.
Method: This work assesses the feasibility and effectiveness of HDV RT within the different departments of our establishment. HDV RT consists of systematically adding HDV serology to HBsAg+ patients if the latter was not requested by the prescriber. In the event of an insufficient quantity of sample, the virology laboratory contacts the clinical department to obtain a second sample in order to carry out HDV screening.
Results: From 01/01/2021 to 12/31/2021, 17 364 HBsAg screenings were carried out at the CHU. 182 HBsAg screenings were positive, corresponding to 138 patients (58 F and 80 M). 80 of these 138 patients (58%) were screened for the first time at the CHU and 58

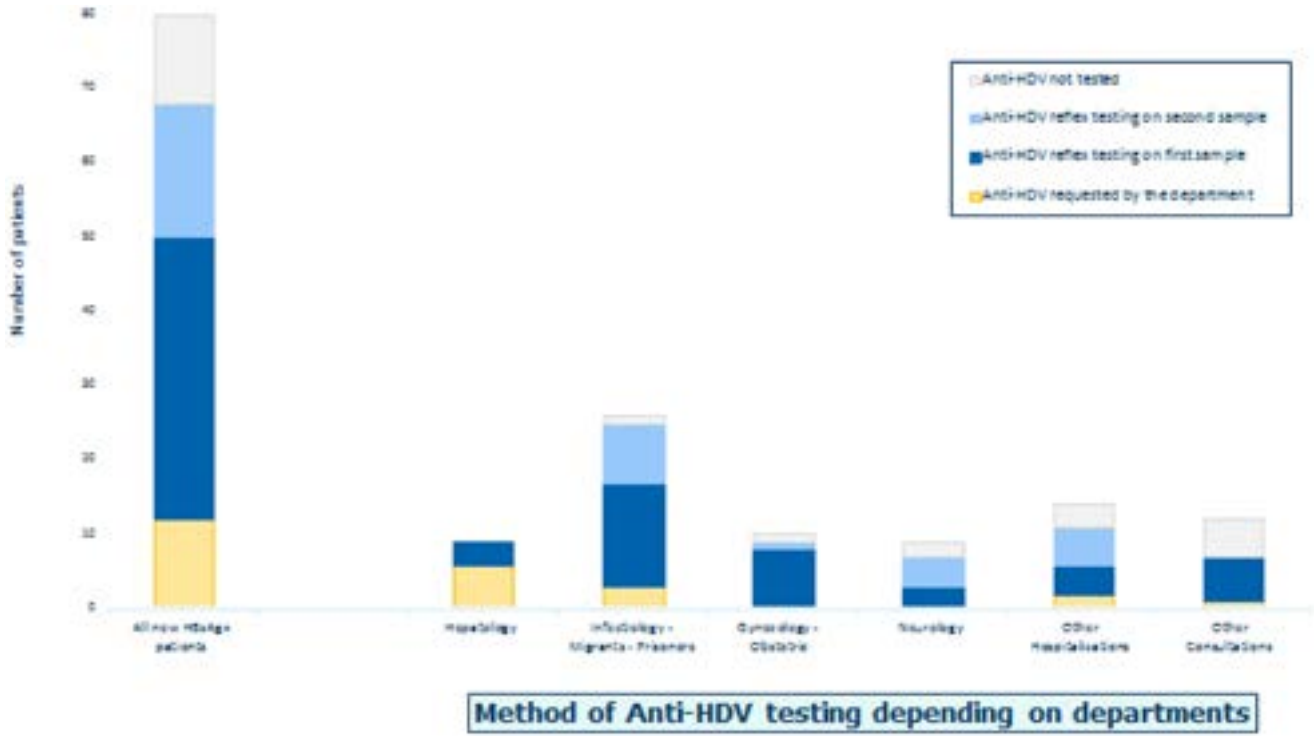

Figure: (abstract: SAT-180).

patients (42%) were already known to be positive for HBsAg. Among the 80 HBsAg+ patients screened for the first time in our center, HDV serology was immediately prescribed by the departments for 12 patients (15%). HDV serology could be added to the first sample for 38 patients (47%) and performed after obtaining a second sample for 18 patients (23%). Thus, 68 of the 80 HBsAg+ patients (85%) had an HDV serology result available, including 56 following reflex testing carried out by the virology laboratory. The operating procedure of the HDV serology is carried out by the different CHU departments is shown in the figure below. Among these 68 HBsAg+ screened for HDV, HDV serology was positive for 4 patients (6%), with HDV replication detected in 3 of them. Concerning the 58 patients already known to be HBsAg+ at the CHU, HDV serology was already available or prescribed from the outset for 49 patients (85%). The reflex testing made it possible to search for co-infection with HDV for 7 additional patients (12%), with a total of 97% of patients screened for HDV.
Conclusion: HDV reflex testing is feasible at the level of an university hospital virology lab and makes it possible to optimize HDV screening in HBV identified patients from different departments, including those not specialized in the management of viral hepatitis.

SAT-181

Pretreatment and on-therapy HDV RNA levels predict response to Bulevirtide monotherapy in HDV compensated cirrhotic patients treated up to 96 weeks

Elisabetta Degasperi[1], Maria Paola Anolli[1], Sara Colonia Uceda Renteria [2], Dana Sambarino[1], Marta Borghi[1], Riccardo Perbellini[1], Floriana Facchetti[1], Roberta Soffredini[1], Sara Monico[1], Ferruccio Ceriotti[2], Pietro Lampertico[1,3]. *[1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Gastroenterology and Hepatology, Mila, Italy; [2]Foundation IRCCA Ca' Granda Ospedale Maggiore Policlinco, Virology Unit, Milan, Italy; [3]CRC "A.M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: pietro.lampertico@policlinico.mi.it

Background and aims: Bulevirtide (BLV) has been approved for treatment compensated chronic hepatitis Delta (HDV), however baseline and on-therapy predictors of response are still unknown.
Method: Consecutive HDV patients with compensated cirrhosis treated with BLV monotherapy 2 mg/day up to 96 weeks were enrolled in this single-center study. HDV RNA was quantified by Robogene 2.0 (LOD 6 IU/ml). Clinical and virological variables were assessed at baseline and every 8 weeks.
Results: Overall, 49 HDV patients were enrolled: median age 52 (29–77) years, 59% males, platelets 78 (17–217) × 10^3/mm^3, liver stiffness measurement 17.3 (6.4–68.1) kPa, ALT 97 (30–1074) U/L, HBsAg 3.7 (0.8–4.4) LogIU/ml, HDV RNA 5.2 (2.4–6.9) LogIU/ml. At baseline, 6% and 24% patients had ALT<ULN (<40 U/L) and <1.5 ULN, respectively. None of the patients had baseline HDV RNA<100 IU/ml, while 8% had HDV RNA<1000 IU/ml, where HDV RNA<1000 IU/ml was associated with ALT<1.5 ULN (p = 0.02). Following BLV monotherapy, virological response rates (undetectable or HDV RNA ≥2 Log decline vs. baseline) resulted 71% at week 24, 84% at week 48, 75% at week 72 and 80% at week 96, respectively; the corresponding figures for biochemical response rates were 57%, 68%, 81% and 67%, while for combined response 46%, 63%, 63% and 66%, respectively. When considering main treatment timepoints (week 24; week 48; week 72; week 96), HDV RNA <1000 IU/ml at week 48 was associated with ALT <1.5 ULN at the same timepoint (p = 0.03). Conversely, no other significant associations were found between HDV RNA with different cut-offs (<6 IU/ml; <100 IU/ml; <1000 IU/ml) and concomitant ALT levels (<ULN; <1.5 ULN) in all remaining treatment timepoints. When analyzing baseline and on-treatment correlations between viremia, ALT and treatment end points, baseline HDV RNA <1000 IU/ml was associated with ALT<1.5 ULN at weeks 48 (p = 0.0002), 72 (p = 0.003) and 96 (p = 0.004) and predicted biochemical response at weeks 72 (p = 0.01) and 96 (p = 0.02). Baseline HDV RNA <1000 IU/ml was associated also with virological response at week 48 (p = 0.007), 72 (p = 0.04) and 96 (p = 0.04), while it did not predict combined response at any timepoint. In addition, HDV RNA<1000 IU/ml at week 24 predicted HDV RNA<100 at week 48 (p = 0.03), 72 (p = 0.04) and 96 (p = 0.03) and was also associated with ALT<1.5 ULN at weeks 72 (p = 0.01) and 96 (p = 0.03). Finally, HDV RNA <1000 IU/ml at week 24 predicted virological response (p = 0.03), combined response (p = 0.02) and ALT<1.5 ULN (p = 0.02) at week 96, but not biochemical response. Conversely, HDV RNA<100 IU/ml at week 24 was not associated with ALT values, virological response and combined response rates at weeks 48, 72 and 96.
Conclusion: In HDV compensated cirrhotic patients treated with BLV monotherapy up to 96 weeks, different baseline and on-treatment HDV RNA cut-offs may predict virological, biochemical and combined response rates.

SAT-182

Preliminary results of a Phase 1b, open-label, multicenter study of selgantolimod (GS-9688) in special populations of patients with chronic hepatitis B

Kosh Agarwal[1], Pin-Nan Cheng[2], Chun-Jen Liu[3,4], Ran Duan[5], Nikita Kolhatkar[5], Roberto Mateo[5], Ben Da[5], Christopher Richards[5], Leonard Sowah[5], Simon Fletcher[5], Patricia Mendez[5], Chi-Yi Chen[6], Wan-Long Chuang[7], Yao-Chun (Holden) Hsu[8,9]. *[1]King's College Hospital NHS Foundation Trust, Institute of Liver Studies, London, United Kingdom; [2]National Cheng Kung University, College of Medicine, National Cheng Kung University Hospital, Tainan, Taiwan; [3]National Taiwan University Hospital, Department of Internal Medicine, Division of Gastroenterology, Taipei, Taiwan; [4]National Taiwan University College of Medicine, Graduate Institute of Clinical Medicine, Taipei, Taiwan; [5]Gilead Sciences, Inc., Foster City, United States; [6]Ditmanson Medical Foundation Chiayi Christian Hospital, Division of Gastroenterology and Hepatology, Department of Medicine, Chiayi, Taiwan; [7]Kaohsiung Medical University Hospital, Kaohsiung Medical University, Department of Internal Medicine, Hepatobiliary Division, Kaohsiung, Taiwan; [8]E-Da Hospital, Kaohsiung, Taiwan; [9]I-Shou University, Kaohsiung, Taiwan*
Email: kosh.agarwal@nhs.net

Background and aims: Chronic hepatitis B (CHB) is a leading cause of chronic liver disease, cirrhosis, and hepatocellular carcinoma. Selgantolimod (GS-9688), a toll-like receptor 8 agonist (TLR8) in development for CHB treatment, was well tolerated in virally suppressed and viremic patients with CHB. This study evaluated the efficacy and safety of selgantolimod in 3 CHB populations.
Method: This open-label study enrolled 3 unique populations of adults with CHB. Cohort 1 included HBeAg-positive patients with high viral load (HBV DNA ≥1 × 107 IU/ml) and ALT ≤ULN (per AASLD criteria). Cohort 2 included HBeAg-negative patients with HBV DNA ≤2000 IU/ml, HBsAg ≤1000 IU/ml, and ALT ≤ULN. Cohort 3 included hepatitis D virus (HDV)-coinfected patients on a commercially available oral CHB antiviral. All patients received selgantolimod 3 mg weekly for 24 weeks (w) and were then followed for 24 more. Primary virologic end points at w24 included proportion of patients with ≥1 $\log_{10}$ IU/ml serum HBsAg decline from baseline (BL), proportion with HBV DNA <LLOQ in Cohorts 1 and 2, and proportion with ≥2 $\log_{10}$ IU/ml HDV RNA decline from BL in Cohort 3. Safety was evaluated by clinical laboratory tests and documentation of adverse events (AEs). Biomarker analysis for the TLR8 pathway-associated pharmacodynamic readouts was performed.
Results: Patients (N = 25) were recruited from sites in the UK and Taiwan; median age was 45 years, 56% were male, 72% were Asian. At w24, no patients in Cohorts 1 and 2 had HBV DNA <LLOQ, and no patients in Cohort 3 had ≥2 $\log_{10}$ IU/ml decline from BL in HDV RNA. No patients in any cohort had a ≥1 $\log_{10}$ IU/ml decline from BL in serum HBsAg at w24. In Cohort 3, there was a small decline in the median HDV RNA change from BL at w24 of −0.25 $\log_{10}$ IU/ml (IQR: −0.25, 0.47). All patients reported treatment-emergent AEs (TEAEs). In 43% of patients in Cohort 2 and 100% in Cohort 3, TEAEs were

judged related to study drug. In Cohort 3, 1 patient had severe nausea and vomiting. All other treatment-related AEs were Grade 2 or lower. No TEAEs led to study drug interruption or discontinuation. ALT elevation was observed in 1 patient in Cohort 1 and 2 patients each in Cohorts 2 and 3; all such increases were Grade 1 or 2. One patient (Cohort 2) met AASLD criteria for an ALT flare. Increases in serum IL-1RA and IL-12p40 levels were observed between 4 and 24 h after selgantolimod treatment in all cohorts.

Conclusion: In these unique populations of CHB, selgantolimod was safe with only 1 severe treatment-related AE. There was a small but consistent HBsAg decline in all cohorts with a trend in HDV RNA decline in the HDV/HBV Cohort. All ALT elevations were <Grade 3, and 1 met AASLD flare criteria.

SAT-183

Safety and efficacy of REP 2139-Mg in association with TDF in chronic hepatitis delta patients with decompensated cirrhosis

Christiane Stern[1], Cecilia De-Freitas[1], Michel Bazinet[2], Vincent Mackiewicz[3], Segolene Brichler[4], Emmanuel Gordien[4], Stéphane Chevaliez[5], Marc Bourliere[6], Andrew Vaillant[2]. *[1]Hôpital Beaujon AP-HP, Clichy, France; [2]Replicor Inc., Montreal, Canada; [3]Hôpital Bichat, Service de Virologie, Paris, France; [4]Centre national de référence des hépatite B, C et Delta-Laboratoire associé, Hôpital Avicenne, Bobigny, France; [5]Hôpital Henri Mondor, Créteil, France; [6]Hôpital Saint Joseph, Marseille, France*
Email: availlant@replicor.com

Background and aims: The only treatment option for chronic hepatitis delta (CHD) patients with decompensated cirrhosis is liver transplantation. REP 2139-Mg blocks the assembly and secretion of HBV subviral particles and hepatitis delta antigen function, providing multiple effects against both HBV and HDV infection. Compassionate access to REP 2139-Mg is being provided under the Replicor Compassionate Access Program (RCAP, NCT05683548). The objective of this study is to describe the safety and efficacy of REP 2139-Mg in CHD patients with decompensated cirrhosis.

Method: Compassionate use in the first three CHD patients with decompensated cirrhosis to receive REP 2139-Mg 250 mg QW SC and TDF 245 mg QD PO for 48 weeks was approved in France by the ANSM. Clinical, biological, virological and imaging data were collected at baseline and every week for the first month, then every month.

Results: Patient 1 is a Caucasian, 56-year-old female, HDV treatment-naïve, with decompensated cirrhosis (Child Pugh B8, portal hypertension and ascites) with HDV RNA 7.04 log10 IU/ml and HBsAg 1177 IU/ml at baseline. Reversal of ascites was confirmed by ultrasound at week 4 HBsAg loss occurred at week 10 with HBsAg seroconversion (27 mIU/ml) at week 14 increasing to 478.5 mIU/ml at week 30. HDV RNA has been undetectable since week 20. Patient 2 is an African, 56-year-old female with CHD and hepatocellular carcinoma (HCC) awaiting liver transplant. She had HDV relapse one year after discontinuing bulevirtide 2 mg and pegIFN 180 µg and progressed to decompensated cirrhosis (Child Pugh C11, portal hypertension, ascites and HCC) with accompanying edema and pronounced fatigue. Baseline HDV RNA was 3.64 log10 IU/ml and HBsAg 4270 IU/ml. A significant reduction of ascites was confirmed at week 4 with marked reduction of peripheral edema and fatigue. Successful liver transplant (due to HCC) was performed in this patient after 10 weeks of therapy. Prior to liver transplant, HDV RNA became undetectable at week 6, HBsAg was 1.75 IU/ml and anti-HBs was 8 mIU/ml. Patient 3 is an African, 47-year-old male, HDV treatment-naïve, with decompensated cirrhosis (Child Pugh C10, portal hypertension, ascites, and hepatic encephalopathy). As observed in the first 2 patients, antiviral response is not yet evident at week 4. A significant reversal of ascites is present at week 6. All three patients experienced no significant adverse events and have presented a good tolerance to subcutaneous injections of REP 2139-Mg to date.

Conclusion: REP 2139-Mg in association with TDF is safe and well tolerated in patients with CHD and decompensated cirrhosis. Liver function improvement with significant ascites reversal was rapid, occurring after only 4 weeks of treatment. HBV-HDV functional cure with HBsAg loss and HBs seroconversion appears achievable for the first time in this special population, which could prevent the need for a future liver transplant.

SAT-184

Is treatment with Bulevirtide 10 mg useful in poor responder patients to 2 mg? Results from the French multicenter early access program

Victor de Lédinghen[1], Anne Minello Franza[2], Nathalie Ganne-Carrié[3], Laurent Alric[4], Sophie Metivier[4], Martin Siguier[3], Bernard Prouvost-Keller[5], Bruno Roche[3], Frederic Heluwaert[6], Louis d'Alteroche[7], Leon Muti[8], Juliette Foucher[1], Fabien Zoulim[9], Marie-Noëlle Hilleret[10]. *[1]CHU, Bordeaux, France; [2]CHU, Dijon, France; [3]APHP, France; [4]CHU, Toulouse, France; [5]CHU, Nice, France; [66]CH, Annecy, France; [7]CHU, Tours, France; [8]CHU, Clermont-Ferrand, France; [9]INSERM, France; [10]CHU, Grenoble, France*
Email: victor.deledinghen@chu-bordeaux.fr

Background and aims: Significant HDV RNA decline was observed in HBV/HDV patients who received 48 weeks of Bulevirtide (BLV) in monotherapy or in combination with PEG-interferon α 2a (PEG-IFNα) in the French early access program and ANRS Buledelta cohort. However, no data are available of BLV 10 mg in poor responders to 2 mg. The aim of this analysis was to evaluate the efficacy and safety of BLV 10 mg daily with or without PEG-IFNα 2a for at least 6 months in HBV/HDV non-responder patients to BLV 2 mg.

Method: 15 patients (male 66.7%, mean age 43 years, cirrhosis 66.7%, median HDV-RNA at inclusion (BLV 2 mg) 6.52 $\log_{10}$ IU/ml) with chronic HBV/HDV infection, with compensated cirrhosis/severe fibrosis or moderate fibrosis with elevated ALT levels, were included in this study. Patients received BLV 2 mg qd sc alone or in combination with PEG-IFNα once weekly according to physician's choice. All patients received at least 3 months of BLV 2 mg. In case of poor responses according to the physician, BLV was switched from 2 mg to 10 mg. The duration of 10 mg (at least 3 months) was related to the availability of the drug since in January 2022, BLV 10 mg was no longer available.

Results: No specific side-effects were reported. At Day 0 of BLV 10 mg, median HDV RNA was 6.08 $\log_{10}$ IU/ml and median ALT level 63.5 IU/L (2/14 patients had ALT level <40 IU/L). 13 patients received BLV 10 mg monotherapy and 2 patients received BLV 10 mg plus PEG-IFNα. Main results (per protocol analysis) are indicated in Table. At M3, M6 and M9 or M12, median HDV-RNA was 5.29, 3.94, and 5.46 $\log_{10}$ IU/ml. Only one patient (no cirrhosis) had long-term undetectable HDV-RNA. His viral load was 5.15 $\log_{10}$ IU/ml when he started BLV 2 mg and 3.43 $\log_{10}$ IU/ml when he started BLV 10 mg. Two patients switched from 10 to 2 mg when 10 mg was no longer available. No variation of viral load was observed after this switch.

Table: Response to BLV 10 mg after 2 mg.

	Month 3 with BLV 10 mg	Month 6 with BLV 10 mg	Month 9 or 12 with BLV 10 mg
Normal ALT level (<40 IU/L)	30% (3/10)	37.5% (3/8)	33.3% (3/9)
2 log decrease from baseline or undetectable HDV-RNA (%)	18.2% (2/11)	25% (2/8)	9.1% (1/11)
Undetectable HDV-RNA (%)	9.1% (1/11)	25% (2/8)	0% (0/11)

Conclusion: In this first real-world cohort of HDV patients, daily administration of BLV 10 mg in poor responder patients to 2 mg was safe and well tolerated. Unfortunately, no significant virologic effect

was observed after at least 6 months of treatment, even in patients receiving PEG-IFN.

SAT-185

Treatment with Bulevirtide, with or without PEG-interferon, in HIV-HBV/HDV co-infected patients in a real-life setting

Victor de Lédinghen[1], Claire Fougerou-Leurent[2], Miroslava Subic-Levrero[3], Caroline Scholtes[3], Emmanuel Gordien[4], Stanislas Pol[4], Karine Lacombe[4], Dulce Alfaiate[3], Eric Billaud[5], Vlad Ratziu[4], Nathalie Ganne-Carrié[4], Georges-Philippe Pageaux[6], Vincent Leroy[4], Isabelle Rosa[7], Veronique Loustaud-Ratti[8], Philippe Mathurin[9], Christelle Tual[2], Estelle Le Pabic[2], Fatoumata Coulibaly[10], Dominique Roulot[4], Fabien Zoulim[11]. *[1]CHU, Bordeaux, France; [2]CHU, Rennes, France; [3]CHU, Lyon, France; [4]APHP, France; [5]CHU, Nantes, France; [6]CHU, Montpellier, France; [7]CHI, Créteil, France; [8]CHU, Limoges, France; [9]CHU, Lille, France; [10]ANRS, France; [11]INSERM, France*
Email: victor.deledinghen@chu-bordeaux.fr

Background and aims: Significant HDV RNA decline was observed in HBV/HDV patients who received 48 weeks of Bulevirtide (BLV) in monotherapy or in combination with PEG-interferon α 2a (PEG-IFNα) in the French early access program and ANRS HD EP01 BuleDelta cohort. However, no data are available in HIV co-infected patients. The aim of this analysis was to evaluate the efficacy and safety of BLV 2 mg daily with or without PEG-IFNα 2a for 12 months in HIV/HBV/HDV patients.

Method: 28 HIV patients (male 71.4%, mean age 48.8 years, cirrhosis 53.6%, median HDV-RNA 6.5 log (IU/ml), median HIV RNA 30 copies/ml, median CD4 620 cells/mm^3) with chronic HBV/HDV infection were included in the French early access program and ANRS Buledelta cohort. Patients received BLV 2 mg qd sc alone or in combination with PEG-IFNα once weekly according to physician's choice. HIV drugs regimen were TAF/FTC in 16 (57%) patients, Rilpivirine in 4, Bictegravir in 4, Elvitegravir in 3, Raltegravir in 1, Darunavir in 1, and Dolutegravir in 3.

Results: Twelve (50%) patients had detectable HIV-RNA at day 0 (all <100 cp/ml). At M12/EOT, median CD4 was 602/mm^3, and 3 patients had detectable HIV-RNA (all <100 cp/ml). Early discontinuation (before or at M12) was observed in 10 (35.7%) patients (1 (10%) adverse event, 3 (30%) lost to follow-up or patient decision, 6 (60%) other reason). HDV-RNA declined overtime as follow: D0 6.5 log (IU/ml), M3 2.4 log (IU/ml), M6 3.8 log (IU/ml), M9 3.5 log (IU/ml), M12/EOT 3.4 log (IU/ml). At M3, undetectable or HDV-RNA decline >2 log from baseline was observed in 3 (20%) or 8 patients (88.9%) treated with BLV or BLV + PEG-IFN, respectively. Main results at M12 or EOT are presented in Figure 1. Serious adverse events were observed in 7 (5,5%) patients. Mean biliary acid level was 54.9 µmol/L at M3 and 26.9 µmol/L at M12.

Conclusion: In this first real-world cohort of HIV/HDV patients, daily administration of BLV 2 mg for 12 months was safe and well tolerated. Strong HDV antiviral responses were observed in real-life whatever the schedule administrated.

	BLV alone (N = 18)	BLV + PEG-IFN (N = 10)
Normal ALT level (<40 IU/L)	10 (55.6 %)	4 (44.4%)
2 log decrease from baseline or undetectable HDV-RNA (%)	11 (61.1%)	6 (60.0%)
Undetectable HDV-RNA (%)	7 (38.9%)	5 (50.0%)

SAT-186

The safety and pharmacokinetics of ABI-4334, a novel next-generation HBV core inhibitor: interim results from a phase 1 study in healthy volunteers

Edward J. Gane[1], Christian Schwabe[2], Jieming Liu[3], Luisa M. Stamm[3], Kathryn M. Kitrinos[3], Steven J Knox[3], Michele Anderson[3], Grace Wang[3], Katie Zomorodi[3]. *[1]University of Auckland, Auckland, New Zealand; [2]New Zealand Clinical Research, Auckland, New Zealand; [3]Assembly Biosciences, South San Francisco, United States*
Email: edgane@adhb.govt.nz

Background and aims: ABI-4334 (4334) is a next-generation hepatitis B virus (HBV) core inhibitor in development for the treatment of chronic HBV infection. 4334 has demonstrated increased in vitro potency against HBV DNA and covalently closed circular (ccc) DNA formation compared with first-generation agents. Here, we report preliminary safety and pharmacokinetic data in healthy volunteers (HVs).

Method: ABI-4334-101 (NCT05569941) is an ongoing, single (SAD) and multiple ascending dose (MAD) study in HVs. During the SAD phase, 8 HVs (6 active, 2 placebo [PBO]) were enrolled in each of 5 dose cohorts, with 6 HVs receiving 4334 in both fasted and fed states to evaluate the effect of a high calorie meal. Following completion of SAD cohort (s), up to 8 HVs (6 active, 2 PBO) were enrolled in two MAD cohorts receiving assigned treatments for 8 days. Safety was assessed by physical exams, adverse events (AEs), and lab parameters. 4334 concentrations were measured by liquid chromatography mass spectrometry.

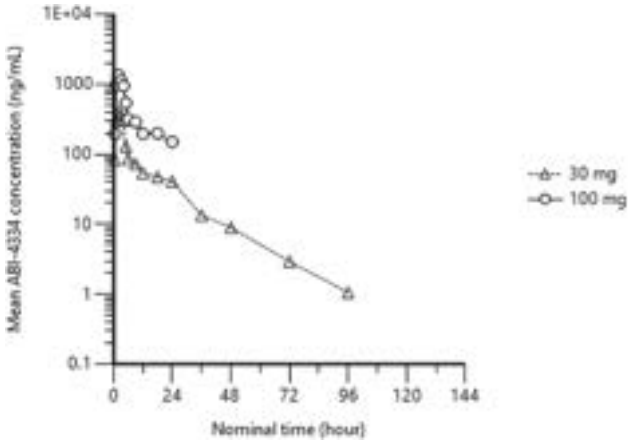

Figure: Mean ABI-4334 plasma concentrations versus time following single ascending doses of ABI-4334 in healthy volunteers (semi-log scale).

Results: At the time of the analysis, two SAD cohorts assessing 30 mg and 100 mg 4334 have been completed. Sixteen HVs enrolled and completed the study. Most were male 11 (69%) and White 11 (69%), with age and body mass index ranging from 20 to 61 years and 19–30 kg/m^2, respectively. Study drug was well tolerated, with no serious AEs or deaths. Half the HVs each at the 30 mg dose and 100 mg dose

(4334 or PBO recipients) reported an AE—7 Grade 1 and 1 Grade 2 (gastroenteritis). The most frequently reported AE was headache, with all cases being Grade 1. None of the AEs were considered related to the study drug. There were no Grade 3 or 4 lab abnormalities. 4334 was rapidly absorbed, with median t_{max} of 2 hrs, and exposure increased proportionally between the 30 mg and 100 mg single doses. Mean C_{max} and AUC_{0-24} values, respectively, were 446 ng/ml and 2503 h·ng/ml after the 30 mg dose, and 1376 ng/ml and 8772 h·ng/ml after the 100 mg dose (Figure). The projected C_{min} values for once daily administration at the 30 mg and 100 mg doses are in multiple-fold excess of protein-adjusted EC_{50}'s for HBV DNA and cccDNA formation.

Conclusion: 4334, a novel next-generation core inhibitor, was well tolerated in SAD cohorts when administered orally up to 100 mg. Plasma concentrations were higher than predicted by non-clinical models and exceeded in vitro EC_{50} values for the inhibition of cccDNA formation. Potent inhibition of HBV with daily dosing is projected.

SAT-187

Frequency of bepirovirsen binding site nucleotide polymorphisms at baseline and impact on end of treatment response to bepirovirsen (Phase 2b B-Clear study)

Jerome Bouquet[1], Robert Elston[2], Phil Yates[2], Shihyun You[3], Amir Youssef[3], Ahmed Nader[3], Jennifer Cremer[4], Geoff Quinn[2], Fiona Campbell[2], Melanie Paff[3], Dickens Theodore[4]. *[1]GSK, South San Francisco, United States; [2]GSK, Stevenage, United Kingdom; [3]GSK, Collegeville, United States; [4]GSK, Durham, United States*
Email: jerome.x.bouquet@gsk.com

Background and aims: Bepirovirsen (BPV; GSK3228836) is an antisense oligonucleotide that targets a conserved 20-nucleotide sequence within HBV pregenomic RNA and mRNAs. B-Clear is a Phase 2b study (NCT04449029) assessing the efficacy and safety of 12 or 24 weeks (wks) of BPV treatment (tmt) in patients (pts) with chronic hepatitis B (CHB). This analysis assessed the frequency of pre-existing BPV binding site single nucleotide polymorphism (SNP) at baseline and the impact on end of tmt (EOT) hepatitis B surface antigen (HBsAg) serum level reduction.

Method: Multicentre, randomised, partial-blind study in pts with CHB who were either receiving concomitant stable nucleos (t)ide analogue therapy (on-NA) or were not receiving NA (not-on-NA). Pts were randomised (3:3:3:1) to receive BPV 300 mg weekly either for 24 wks (Arm 1); for 12 wks then 150 mg for 12 wks (Arm 2); for 12 wks then placebo (PBO) for 12 wks (Arm 3); or PBO for 12 wks then BPV 300 mg for 12 wks (Arm 4). A loading dose of BPV (Arms 1–3) or PBO (Arm 4) was given on days 4 and 11. Next-generation sequencing was used to sequence HBV DNA or RNA at baseline. A SNP was reported if the frequency was ≥5% compared with wild type.

Results: Not-on-NA: Baseline sequence information was available for 219/229 pts. Thirteen pts (13/219, 5.9%) had SNPs detected at a frequency of ≥5%. The most common BPV binding site SNPs were C9A (n = 4/13, 31%) and T10G/C/A (n = 6/13, 46%). Pts w/or w/o baseline SNPs had similar mean baseline HBsAg levels (3.605 vs 3.714 log10 IU/ml). On-NA: Baseline sequence information was available for 90/226 pts. Nine pts (9/90, 10%) had a SNP detected at a frequency of ≥5%. The most common SNP detected was A13G (n = 2/9, 22%). Pts w/or w/o a baseline SNP had similar mean baseline HBsAg levels (3.370 vs 3.344 log IU/ml). EOT response: The mean log10 reductions in HBsAg levels were lower in pts with a BPV binding site SNP; however, reductions were observed regardless of SNP (Table; tmt arms pooled) and 4 pts with SNP achieved HBsAg <0.05 IU/ml. These 4 pts had SNPs detected at a frequency between 5.417% and 99.943% over wild-type.

Conclusion: SNPs within the BPV binding site were infrequent across tmt arms. Although the HBsAg reduction was lower in the presence of BPV binding site SNPs, reductions were observed, and some pts with SNPs achieved HBsAg <0.05 IU/ml at EOT. Larger studies are needed to confirm these findings.

Safety, pharmacokinetics, and antiviral activity of single ascending doses of ALG-125755, a GalNAc-conjugated small interfering RNA, in subjects with chronic hepatitis B

Alina Jucov[1,2], Edward J. Gane[3], Megan Fitzgerald[4], Kha Le[4], Stanley Wang[4], Lynne Ammar[4], Chris Burnett[4], Alexei Haceatrean[1], Kusum Gupta[4], Doug Clark[4], Meenakshi Venkatraman[4], Leonid Beigelman[4], Lawrence Blatt[4], Tse-I Lin[5], Sushmita Chanda[4], Matthew McClure[4], John Fry[4]. *[1]ARENSIA Exploratory Medicine, Republican Clinical Hospital, Chisinau, Moldova; [2]Nicolae Testemitanu State University of Medicine and Pharmacy, Moldova; [3]University of Auckland, New Zealand; [4]Aligos Therapeutics, Inc., South San Francisco, United States; [5]Aligos Belgium BV, Belgium*
Email: mfitzgerald@aligos.com

Background and aims: To evaluate the safety, pharmacokinetics (PK) and antiviral activity of ALG-125755, a small interfering RNA (siRNA) designed to reduce hepatitis B surface antigen (HBsAg) in subjects with chronic hepatitis B (CHB).

Method: Study ALG-125755-501 (NCT05561530) is a three-part, double-blind, randomized, placebo-controlled phase 1a/1b study. It

Table. Reduction in HBsAg at end of BPV treatment for patients with or without a BPV binding site SNP at Day 1 (pooled treatment arms)

Figure: (abstract: SAT-187).

is evaluating the safety, tolerability, PK and pharmacodynamics of single doses of ALG-125755 in healthy volunteers (HV; Part 1) and single (Part 2) and multiple (Part 3) doses of ALG-125755 in CHB patients. In Part 1, single subcutaneous (SC) doses of ALG-125755 up to 200 mg were well tolerated with linear PK in HVs (Gane et al, APASL 2023). In each cohort in Part 2, which is ongoing, 8 CHB subjects are being randomized 3:1 to receive single SC doses of ALG-125755 or placebo. Safety assessments (adverse events (AEs), vital signs, physical examination, ECG, and laboratories), viral markers (Parts 2 and 3), and plasma and urine PK samples are being collected throughout study conduct. Preliminary blinded results from the first cohort of Part 2 are reported here. Additional available data, including HBsAg, will be presented at the conference.

Results: 8 virologically suppressed hepatitis B e-antigen (HBeAg) negative CHB subjects received a single 50 mg SC dose of ALG-125755 or placebo in Cohort 1. Subjects were mainly female (62.5%), with a mean (SE) age of 58 (2.3) years, mean BMI (SE) of 30.4 (1.3) kg/m2, and baseline HBsAg of 2.11 to 4.14 log10 IU/ml. There have been no serious AEs or dose-limiting toxicities. All treatment emergent AEs (TEAEs) were mild (Grade 1) except for one Grade 2 back pain. Other than headache (N = 2), no TEAEs have been reported in more than one subject. No clinically concerning laboratory, physical examinations, vital sign, or ECG abnormalities have been reported. There was low inter-subject variability for ALG-125755 exposures, which were generally similar to those observed in healthy volunteers after dose and body weight adjustment.

Conclusion: Single SC doses of 50 mg ALG-125755 have been well tolerated to date in HBeAg negative CHB subjects with a safety and PK profile supporting further evaluation of higher dose levels.

SAT-189

Efficacy and safety of celecoxib add on nucleos(t)ide analogues on the hepatitis B surface antigen of virally suppressed patients with chronic hepatitis B-interim analysis

Feng Xue[1,2], Yingying Li[3], Jing Zhang[4], Qing Ye[5], Huiying Rao[6], Zhenhuan Cao[4], Jun Li[5], Xiaohe Li[6], Lai Wei[1,2]. *[1]Beijing Tsinghua Changgung Hospital, Tsinghua University, China; [2]School of Clinical Medicine, Tsinghua University, China; [3]HolyHaid Artificial Intelligence Drug Development Limited Company, China; [4]Beijing Youan Hospital, Capital Medical University, China; [5]Tianjin Third Central Hospital, China; [6]Peking University People's Hospital, China*
Email: weilai@mail.tsinghua.edu.cn

Background and aims: Hepatitis B surface antigen (HBsAg) loss is considered as function cure of chronic hepatitis B (CHB). We found that celecoxib treatment is likely associated with HBsAg loss via artificial intelligence drug screening and has been validated by cytology, in vitro tests and real-world retrospective study. This proof-of-concept study (NCT05256823) is aiming to investigate if celecoxib add on nucleos(t)ide analogues (NUCs) can induce HBsAg loss in virally suppressed patients with CHB.

Method: Virally suppressed patients were defined as patients with CHB taking NUCs for more than 1 year with HBV DNA below the lower limit of quantification. This multi-center, randomized, open-labelled trial was beginning in February, 2022. Patients who were treated with NUCs for more than 1 year with 100 IU/ml< HBsAg<1500 IU/ml and HBV DNA<20 IU/ml were recruited. Participants were randomly assigned (in a 3:1 ratio) to receive either celecoxib at a dose of 200 mg twice a day add on NUCs (experimental group) or NUCs continue (control group) for 48 weeks and then followed for another 24 weeks. The primary end points were the ratio of HBsAg loss and the reduction of HBsAg after treatment for 48 weeks and discontinuation for 24 weeks. The safety of celecoxib treatment was evaluated throughout the study. The interim analysis of data for patients by January 11, 2022. All statistical analyses were performed using SAS software (version 9.4), and $P < 0.05$ were considered significant.

Results: A total of 47 patients participated in this study. 35 participants in the experimental group and 12 participants in the control group. Baseline data were comparable for the two groups. To date, 2 patients withdrew from the study gave no reason. All 45 participants had completed 24 weeks of follow-up and 19 participants completed 36 weeks of follow-up. At week 24, the HBsAg was decreased in 51.5% (17/33) of the patients in the experimental group. The multivariate linear regression analysis suggested the subgroup of patients with HBsAg levels at 200–500 IU/ml was more likely to respond to celecoxib in HBsAg decline. The coefficient is −0.01 compared to reference group. One patient in the experimental group had HBsAg levels of 344.85 IU/ml at baseline, which decreased to 292.29 IU/ml at 12 weeks, to 147.05 IU/ml at 24 weeks and to 79.45 IU/ml at 36 weeks. The incidence of adverse events (AEs) in the experimental group and control group was 91.43% and 91.67%, respectively. The incidence of AEs related to celecoxib treatment was 60%. All AEs were mild or moderate, with no serious adverse events reported.

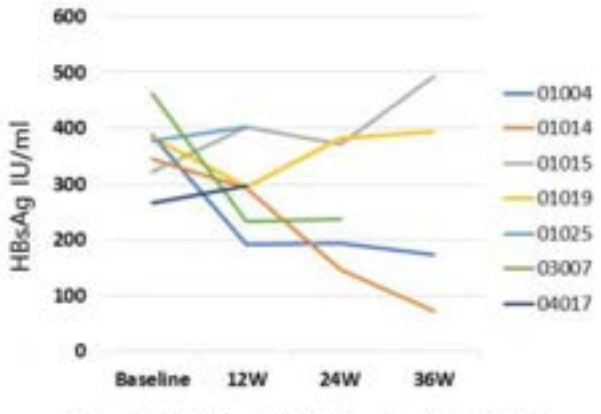
Figure 1. The change of HBsAg level in 200-500 IU subgroup

A

Factor	coefficient	95% CI	P value
HBsAg			
1000-1500 IU/ml	0.02	-0.14, 0.17	0.840
500-1000 IU/ml	0.05	-0.08, 0.18	0.446
200-500 IU/ml	-0.10	-0.26, 0.05	0.168
100-200 IU/ml	0(ref)		

Multivariate Linear Regression Analysis of HBsAg decline

B



Change in HBsAg level (IU/mL) from baseline to 36W

Figure: (abstract: SAT-189).

Conclusion: Celecoxib is safe and well tolerated in virally suppressed patients with CHB within first 24 weeks. Subgroup analysis showed that participants with baseline HBsAg levels between 200IU/ml and 500IU/ml had a significant decrease trend in HBsAg. Longer follow-up is needed to assess the long-term efficacy of celecoxib add on NUCs treatment.

SAT-190

Quantification of serum HDV RNA in untreated and Bulevirtide-treated patients with CHD: a comparison between Robogene 2.0 and Eurobioplex

Maria Paola Anolli[1], Sara Colonia Uceda Renteria[2], Elisabetta Degasperi[1], Dana Sambarino[1], Marta Borghi[1], Floriana Facchetti[1], Riccardo Perbellini[1], Roberta Soffredini[1], Sara Monico[1], Ferruccio Ceriotti[2], Pietro Lampertico[1,3]. *[1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Gastroenterology and Hepatology, Milan, Italy; [2]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Virology unit, Milan, Italy; [3]CRC "A.M: and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: maria.anolli@unimi.it

Background and aim: Diagnosis and management of chronic hepatitis Delta (CHD) largely relies on HDV RNA quantification but a significant variability between different assays does exist. Aim of the study was to compare two different methods to quantify serum HDV RNA in untreated and Bulevirtide (BLV)-treated CHD patients.
Method: Frozen plasma from consecutive untreated and BLV treated-CHD patients were tested in a single-center retrospective study for HDV RNA levels by using two different quantification methods: Robogene 2.0 (Roboscreen GmbH, Leipzig, Germany; LOD 6 IU/ml) and EurobioPlex (HDV qRT-PCR, Eurobio, France, LLOQ 100 IU/ml). RNA extraction was performed manually for both assays according to manufacturer indications: INSTANT Virus RNA/DNA kit (Analytik Jena AG, Jena, Germany) for Robogene and NucleoSpin® Dx Virus Kit (Macherey-Nagel, Düren, Germany) for Eurobioplex.
Results: A total of 165 plasma samples collected from 123 CHD (88 untreated and 35 BLV-treated) patients were analyzed: median age was 53 (21–78) years, 57% males, 89% of European origin, 61% with cirrhosis, 78% under NUC treatment, 97% HDV genotype 1, ALT were 68 (6–743) U/L, HBsAg 3.8 (0.3–4.6) Log IU/ml, 91% HBeAg negative, 73% HBV DNA undetectable. Overall, median HDV RNA levels were 2.96 (0.30–7.36) vs. 3.03 (1.52–8.19) Log IU/ml by Robogene vs. EurobioPlex ($p < 0.0001$). Compared to the Robogene test, EurobioPlex reported similar HDV RNA levels ($\Delta \pm 0.5$ Log) in 56 (34%) patients, higher in 102 (62%) [Δ between +0.5 and +1 Log in 41; Δ between +1 and +2 Log in 55; Δ>2 in 6] and lower in 7 (4%) [Δ between – 0.5 and – 1 Log in all 7 cases]. Of the 45 (27%) samples that were target not detected (TND) with Robogene, 73% tested TND with EurobioPlex, 13% <LLOQ, while 13% tested positive (>100 IU/ml). Of the 10 (6%) samples <LOD with Robogene, 80% were TND with Eurobioplex, 10% were <LLOQ and 10% positive. Overall, 55 (33%) of samples tested TND or <LOD with Robogene and 64 (39%) with EurobioPlex ($p < 0.0001$). When setting Robogene as the reference standard, EurobioPlex had a Sensitivity of 86% and a Specificity of 87% in detecting HDV viral load. In BLV treated patients, virological response rates differed according to the assay: the proportion of patients achieving HDV RNA <LOD/LLOQ was 20% with Robogene and 42% with EurobioPlex. 13% of Robogene negative patients tested positive with EurobioPlex while 59% of those negative with EurobioPlex tested positive with Robogene.
Conclusion: Quantification of HDV RNA is significantly influenced by the quantification method, and this could influence clinical management of patients with CHD, being viral load a surrogate treatment end point in CHD

SAT-191

A monoclonal antibody 4G2 exhibits anti-viral activity in mouse models of chronic hepatitis B

Aileen Rubio[1,2], Aditi Deshpande[3], Renae Walsh[4], Hans Netter[4], Chee Leng Lee[4], Rachel Hammond[5], Marcela Toro[4], Stephen Locarnini[4]. *[1]ClearB Therapeutics, Inc, Concord, United States; [2]ClearB Therapeutics, Inc, United States; [3]ClearB Therapeutics, Inc., United States; [4]2Victorian Infectious Diseases Reference Laboratory, Melbourne Health, Australia; [5]VIDRL, Australia*
Email: arubio@clearbtherapeutics.com

Background and aims: We have previously reported that chronic hepatitis B (CHB) patients who achieve functional cure have an antibody clearance profile (CP) associated with the occupation of key loop 1 and 2 epitopes within the Hepatitis B surface antigen (HBsAg) [Walsh, R et al 2019. Liver Int 39 (11) pp2066]. To identify a therapeutic monoclonal antibody (mAb) specifically targeting these epitopes, we immunized a single BALB/c mouse with modified HBsAg to over-represent CP epitopes. The hybridoma pools were screened to select clones producing antibodies with specificity to CP epitopes. The mAb clone 4G2 was selected based on specific recognition to HBsAg loop 1 CP and backbone epitopes. 4G2 mAb was evaluated for anti-viral activity in two murine models of CHB.
Method: Hydrodynamic tail vein injection (HDI) of HBV genotype A2adw2 plasmid into CBA/CaJ mice was performed to establish persistent infection of ~3 log IU/ml HBsAg [Chou H-H et al 2015. PNAS 112 (7) pp2175]. CHB mice were administered 200 or 400 µg 4G2 by intravenous (IV) injection. 4G2 at 400 µg was also assessed in an AAV (serotype 8)/HBV (genotype D ayw) CHB model established in C57BL/6 mice with a stable infection of ~4 log IU/ml HBsAg [Yang D, et al 2014 Cell Mol Immunol 11 (1) pp71–8]. Mice were monitored over time for serological markers of HBsAg, HBV DNA, anti-HBs antibody, as well as liver HBsAg and HBcAg immunohistochemistry at end of study.
Results: Treatment of CHB mice in the HDI model displayed a dose-dependent efficacy with 4G2 at 200 and 400 µg resulting in an average reduction of 2.1 and 2.5 log IU/ml HBsAg respectively, 4 days post-dose antibody administration. A rebound in HBsAg level was observed one week post dose in a subset of animals, but multiple weekly injections of 4G2 at 400 µg maintained the serological HBsAg control. Seroclearance of HBsAg resulted in seroconversion to anti-HBs and clearance of HBsAg and HBcAg positive cells in the liver. 400 µg of 4G2 also displayed efficacy in the AAV/HBV model resulting in an average reduction of 1.5 log IU/ml HBsAg. In both models, placebo and isotype control treatment resulted in no significant change in virological serum markers or seroconversion.
Conclusion: 4G2 mAb therapy was highly efficacious in two CHB murine models with rapid serum HBsAg decline and clearance, anti-HBs seroconversion, and clearance of infected hepatocytes. These findings further support the development of humanized 4G2 mAb for the treatment of CHB.

SAT-192

Treatment for up to 24 weeks with the capsid assembly modulator ALG-000184 results in dose related reductions in HBsAg in subjects with HBeAg positive chronic hepatitis B

Figure: (abstract: SAT-192).

Background and aims: To evaluate the safety, pharmacokinetics (PK), and antiviral activity of ALG-000184, an oral prodrug of ALG-001075, a novel, pan-genotypic capsid assembly modulator-empty (CAM-E) with picomolar potency.
Method: ALG-000184-201 is a multi-part, multi-center, double-blind, randomized, placebo-controlled study (NCT04536337). Part 4 is evaluating the safety, PK, and antiviral activity of daily doses of ALG-000184 for up to 48 weeks in currently not treated subjects with chronic hepatitis B (CHB). Subjects in Cohorts 1 and 2 were randomized in a 4:1 ratio to ALG-000184 plus entecavir (ETV) or placebo plus ETV for 12 weeks followed by 36 weeks of ALG-000184 plus ETV. Cohorts 1 and 2 evaluated 100 mg and 300 mg of ALG-000184, respectively. A third cohort evaluating open label monotherapy of 300 mg ALG-000184 is also being evaluated. Available data from all three cohorts will be presented at the conference.
Results: To date, 25 subjects have enrolled in Cohorts 1 (100 mg, N = 11) and 2 (300 mg, N = 14) and have dosed for up to 24 and 16 weeks, respectively. All subjects are Asian, most female (52%), mean age 33.2 years, BMI 22.3 kg/m^2 and HBV genotype B or C. At baseline (BL), most subjects had an ALT less than 1.2 × ULN. Study drug was well tolerated; there were no serious adverse events (AEs) and no discontinuations due to an AE. All treatment emergent AEs were Grade 1 or 2, except for one Grade 4 AE of ALT elevation, which improved despite continuing dosing, and was assessed by the ALT Flare Committee as not due to drug toxicity. No clinically concerning laboratory, ECG, or vital sign findings were reported. The Day 1 PK profile is consistent with earlier findings in healthy volunteers. Mean BL and change from BL in HBV DNA and HBsAg are shown in the table. HBsAg levels were unchanged with ETV, but declined to a maximum of 0.7 log_{10} IU/ml with 100 mg ALG-000184 plus ETV for at least 22 weeks, and to a maximum of 1.0 log_{10} IU/ml with 300 mg ALG-000184 plus ETV for at least 14 weeks.
Conclusion: Dosing with ALG-000184 plus ETV for up to 24 weeks was well tolerated, exhibited predictable PK and resulted in substantial reductions in HBV DNA and HBsAg compared to ETV alone. Importantly, dosing with ALG-000184 plus ETV resulted in dose-dependent, clinically relevant declines in HBsAg, suggesting a potential role of ALG-000184 in combination regimens for functional cure.

SAT-193

Efficacy and prediction analysis of pegylated interferon alpha-2b in treatment-naive HBeAg negative chronic hepatitis B patients with normal ALT: a multicenter real-world study (Ice-breakting Project in China)-Interim analysis

Chong Zhang[1,1], Da-Wu Zeng[2], Da-Chuan Cai[3], Xiu-Lan Xue[4], Ling-Yi Zhang[5], Bao-Jun Song[6], Yu-Feng Gao[7], Yan Huang[8], Jia Shang[9], Xiao-Feng Wu[10], Ying Zhang[11], Hua Jin[12], Hui Chen[13], Hong Tang[14], Xiaobo Lu[15], Yujuan Guan[16], Feng Min[17], Liang Xu[18], Gang Li[19], Zhen-Guang Wang[20], Xiaoguang Dou[1]. *[1]Shengjing Hospital of China Medical University, China; [2]The First Affiliated Hospital of Fujian Medical University; [3]The Second Affiliated Hospital of Chongqing Medical University, China; [4]The First Affiliated Hospital of Xiamen University, China; [5]Lanzhou University Second Hospital, China; [6]The Sixth People's Hospital of Fushun, China; [7]The First Affiliated Hospital of Anhui Medical University, China; [8]Xiangya Hospital Central South University, China; [9]Henan Provincial People's Hospital, China; [10]The Sixth People's Hospital of Shenyang, China; [11]Dalian Public Health Medical Center, China; [12]The Sixth People's Hospital of Benxi, China; [13]Hepatobiliary Hospital of Jilin, China; [14]West China Hospital of Sichuan University, China; [15]The First Affiliated Hospital of Xinjiang Medical University, China; [16]Guangzhou Eighth People's Hospital Guangzhou Medical University, China; [17]Army Seventy-three Army Hospital, China; [18]Tianjin Second People's Hospital, China; [19]Liaohe Oilfield General Hospital, China; [20]Anshan City Hospital For Infectious Disease, China*
Email: douxg@sj-hospital.org

Background and aims: In China, the proportion of HBeAg negative chronic hepatitis B (CHB) patients is gradually increasing, which is related to the pre-C region mutation of long-term HBV infection. The disease progression of Hepatitis B e antigen (HBeAg) negative CHB patients is fast, a large proportion of them have moderate or advanced liver inflammation or fibrosis, even if alanine aminotransferase (ALT) is normal, which requires timely antiviral treatment. The purpose of this study was to analyze the efficacy of pegylated interferon alpha-2b (PegIFN alpha-2b) in HBeAg negative CHB patients with normal ALT, and to explore the predictive factors of virological and serological responses.
Method: This is a multi-center, prospective, non-interventive, real-world clinical study conducted in China, involving 20 hospitals in 12 provinces or municipalities, which enrolled CHB patients with age of 18–60 years, Hepatitis B surface antigen (HBsAg) positive for more than 6 months, HBeAg negative, HBV DNA >20 IU/ml and normal ALT, without antivirus treatment history. PegIFN alpha-2b 180 ug/week was applied on a voluntary basis. The treatment strategy is adjusted according to the virological and serological response every 24 weeks, the total treatment course is not exceed 96 weeks.
Results: A total of 200 patients were planned to be enrolled in the project, which have been completed. Up to now, 75 (37.5%), 95 (47.5%) and 30 (15.0%) patients has completed 48, 72 and 96 weeks of treatment. 53 patients with complete data collection have been summarized for 24 weeks of treatment, and the remaining data are being collected. 35 (66.0%) were male, with an average age of 38.04 ± 8.15 years. The median baseline HBV DNA was 1.01×10^3 IU/ml (1.46×10^3~1.94×10^6), of which 56.6% was ≤2000 IU/ml (Figure 1a), the median baseline HBsAg was 657.22 IU/ml (0.92~32828.22), of which 43.4% had HBsAg ≤500 IU/ml (Figure 1b). After 24 weeks of PegIFN alpha-2b treatment, the median HBV DNA was 0 IU/ml, and the rate of HBV DNA negative was 62.3% (Figure 1c), the median HBsAg was decreased to 106.45 IU/ml, and the HBsAg loss rate was 11.3% (Figure 1d). The patients with HBV DNA undetectable at treatment week 24 had much lower baseline HBsAg level than those HBV DNA detectable. ($p = 0.032$). The rate of HBV DNA negative at 24 weeks was 71.1% in patients with baseline HBsAg ≤1500 IU/ml, significantly higher than those with baseline HBsAg >1500 IU/ml ($p = 0.036$). There were no adverse events affecting the continued treatment.

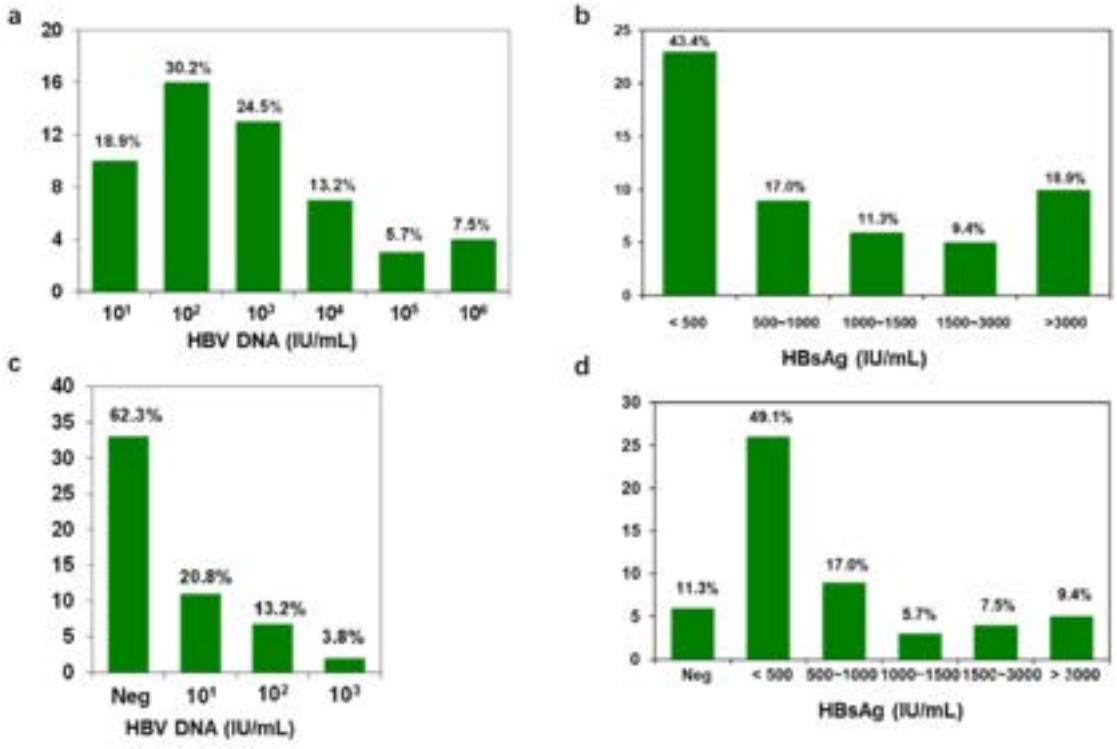

Figure: (abstract: SAT-193): a. Baseline HBV DNA viral load distribution; b. Baseline HBsAg level distribution; c. HBV DNA viral load after 24 weeks of PegIFN alpha-2b treatment; d. HBsAg level after 24 weeks of PegIFN alpha-2b treatment.

Conclusion: For HBeAg negative CHB patients with normal ALT, PegIFN alpha-2b treatment for 24 weeks can achieve a high rate of HBV DNA negative and significant HBsAg decrease, even HBsAg loss. The baseline HBsAg level is related to HBV DNA negative at 24 weeks, and the rate of HBV DNA negative was higher in patients with HBsAg ≤1500 IU/ml.

SAT-194

The safety and efficacy of hepalatide (L47) treatment combined with pegylated interferon-alpha 2a in patients with chronic hepatitis B: the preliminary data from a double-blind, RCT phase II trial

Junliang Fu[1], Qing Mao[2], Qinglong Jin[3], Hui Cheng[4], Yongqian Cheng[1], Xiaolu Tang[5], Hongli Liu[5], Fu-Sheng Wang[1]. *[1]Senior Department of Infectious Diseases, The Fifth Medical Center of Chinese PLA General Hospital, National Clinical Research Center for Infectious Diseases, Beijing, China; [2]Department of Infectious Diseases, Southwest Hospital, Army Medical University, Chongqing, China; [3]Department of Hepatology, The First Hospital of Jilin University, Jilin University, Changchun, China; [4]Depatment of hepatitis, Hepatobiliary hospital of Jilin, Changchun, China; [5]Shanghai HEP Pharma Co. Ltd., Shanghai, China*
Email: fswang302@163.com

Background and aims: Hepalatide (L47), a 47aa synthetic peptide derived from Hepatitis B virus (HBV) Pre-S1, can blocks HBV entry into hepatocytes by competitively binding to HBV entry receptor sodium taurocholate co-transporting polypeptide (NTCP) on the surface of hepatocytes. The aims of this study were to explore the safety and efficacy of hepalatide in the treatment-naïve patients with chronic hepatitis B (CHB).

Method: This randomized, placebo-controlled, double-blind phase 2 clinical trial (NCT 04426968) was planned to enroll 96 treatment-naïve CHB patients with HBV DNA ≥20000 IU/ml, 2 × ULN ≤A LT ≤1 0 × ULN from 12 hospitals in China. The CHB patients were randomly assigned to three groups with different open-label L47 doses (group A 2.10 mg, group B 4.20 mg, and group C 6.30 mg). In each group, patients were double-blindly randomized to receive L47 or placebo treatment in a 3:1 ratio. All patients received subcutaneous injections of L47 or placebo once-daily, combined with subcutaneous injections of pegylated interferon-alpha 2a (PegIFN) (180μg/Week) for 24 weeks, then followed up for 24 weeks with PegIFN treatment alone. The primary end point is HBV DNA loss (cut-off value 20 IU/m at the end of 24 weeks).

Results: As of December 26, 2022, 22 enrolled patients (including 19 patients with HBeAg positive and 3 patients with HBeAg negative) have completed 24-week combination treatment (group A, n = 7; group B n = 8; group C, n = 7). The uncovered preliminary data showed that, in all groups, the adverse events (AEs) were generally grade 1 or 2, and most were identified to be related to PegIFN, such as fever, headache, fatigue, leukocytosis, neutropenia. No treatment-related serious AEs were reported. The baseline HBV DNA levels in the three groups were 8.29 ± 0.61 log IU/ml, 7.34 ± 1.42 log IU/ml and 7.69 ± 0.58 log IU/ml, respectively. At 12 weeks of treatment, the HBV DNA levels were declined by 2.39 ± 1.28 log IU/ml in group A, 2.21 ± 1.53 log IU/ml in group B and 4.23 ± 1.8 log IU/ml in group C, respectively. At the end of 24-week treatment, the HBV DNA levels were further declined by 3.70 ± 2.02 log IU/ml, 2.82 ± 1.71 log IU/ml, 4.54 ± 1.62 log IU/ml in the three groups, respectively. One patient in group A and one patient in group B reached primary end point. The levels of quantitative hepatitis B surface antigen (qHBsAg) were declined from baseline by 1.36 ± 0.99 log IU/ml, 0.89 ± 0.79 log IU/ml, 0.70 ± 0.76 log IU/ml IU/ml in the three groups at the end of 24-week treatment, respectively. And one patient achieved HBsAg loss (below 0.05 IU/ml) with presence of hepatitis B surface antibody, one patient achieved HBeAg seroconversion. The ALT normalization rate was 28.6%, 37.5% and 57.1% in the three groups at the end of 24-week treatment, respectively.

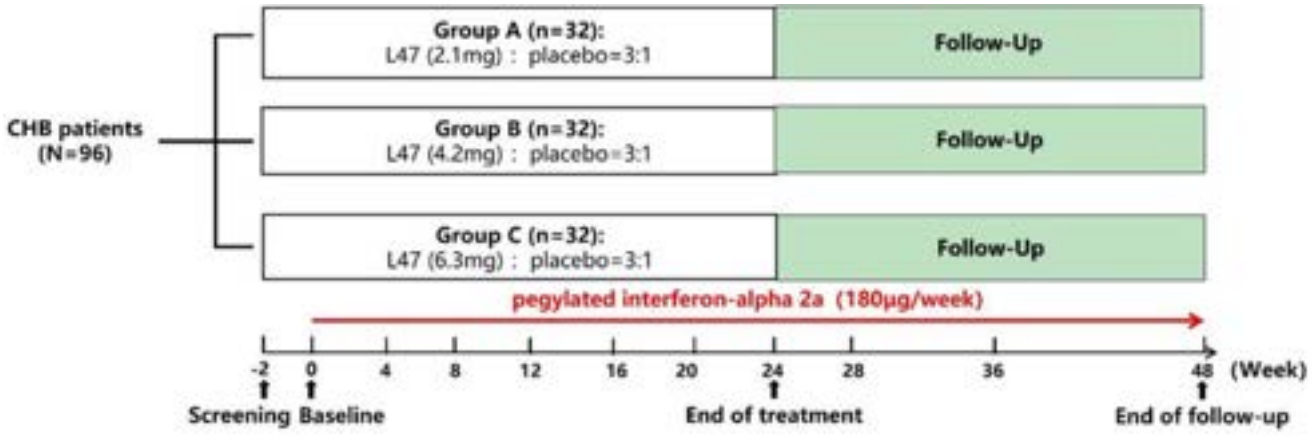

Figure: (abstract: SAT-194): Protocol of clinical trial.

Conclusion: Though the study is not complete, the preliminary data show a good safety and well tolerance of L47 treatment in combination with Peg-IFN. Importantly, the HBV DNA levels were declined rapidly in a L47 dose-dependent manner, highlighting its therapeutic potential in anti-HBV treatment.

SAT-195

A novel class of orally-available small molecules potently inhibiting hepatitis B and D virus entry

Nuruddin Unchwaniwala[1], Heidi Contreras[1], Jinghu Carl Li[1], Dinara Azimova[1], Joseph Tan[1], Lida Guo[1], Francielle Tramontini Gomes de Sousa[1], Kirsten Stray[1], Michael Shen[1], Jiaxin Yu[1], Marc P. Windisch[1], Michel Perron[1], Michael A. Walker[1], William E. Delaney[1], Min Zhong[1]. [1]*Assembly Biosciences, South San Fransisco, United States*
Email: mwindisch@assemblybio.com

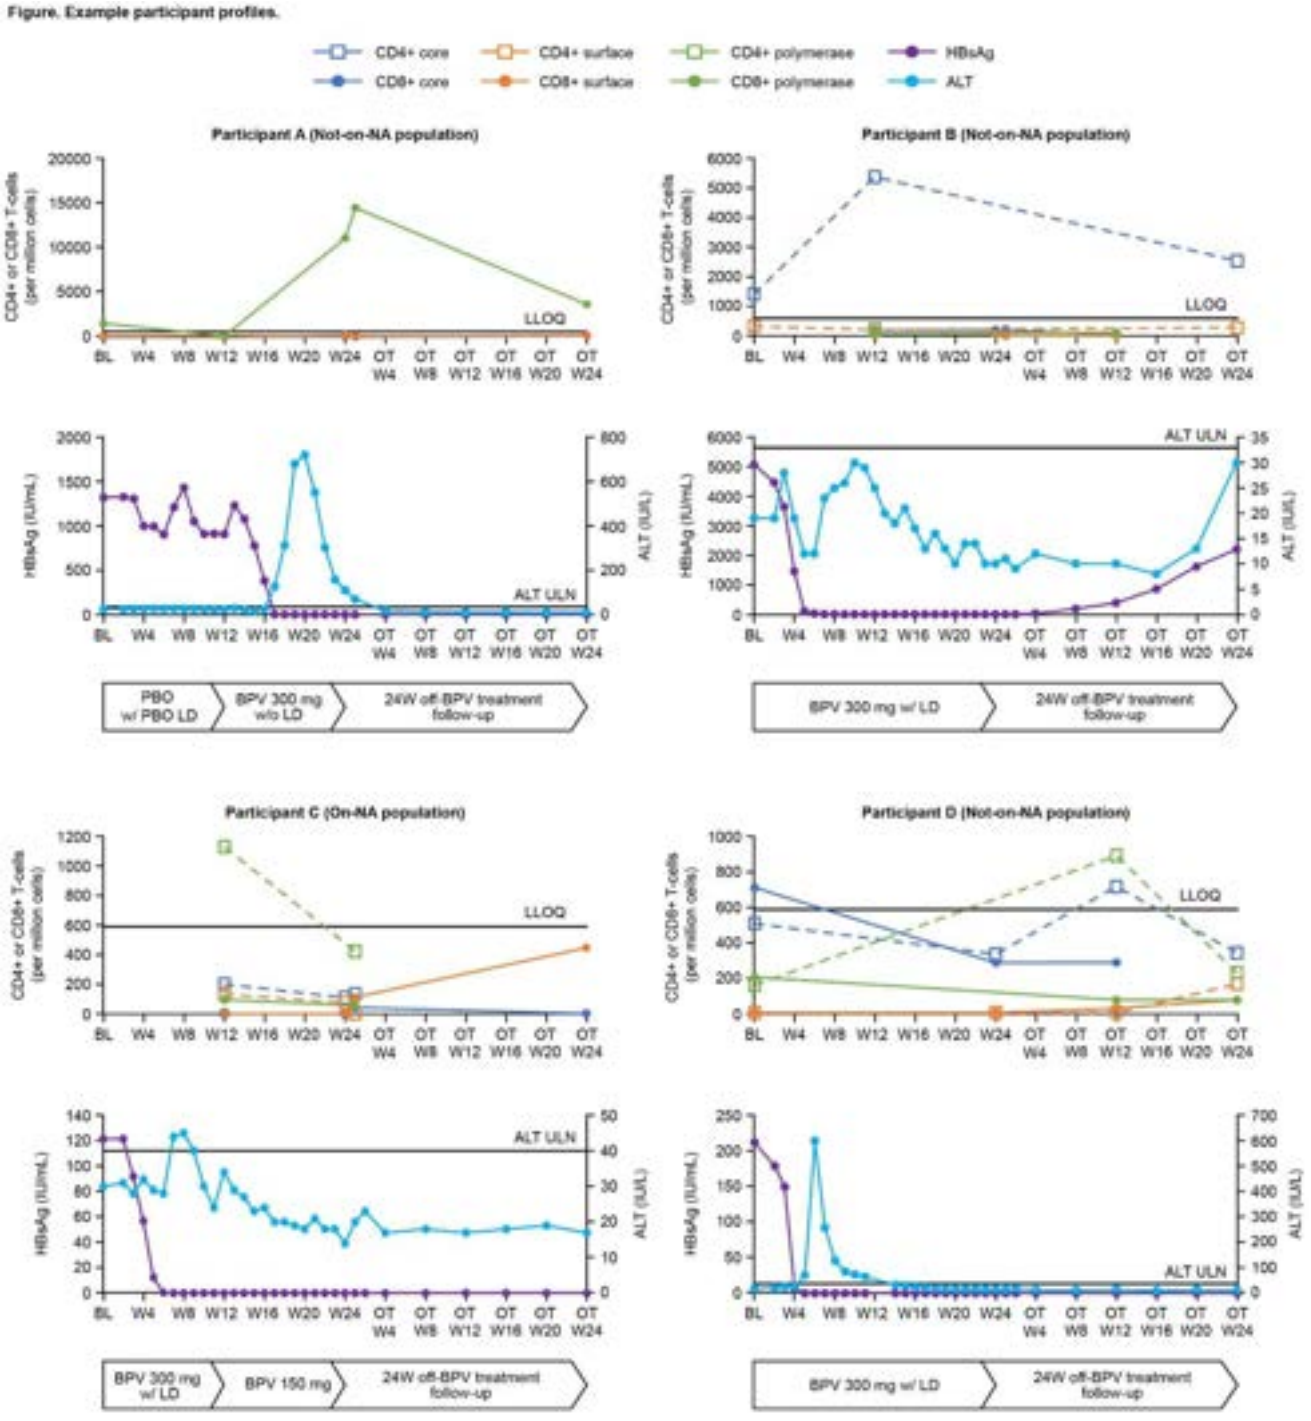
Background and aims: Approximately 296 and 12 million patients worldwide are chronically infected with hepatitis B virus (HBV) and hepatitis D virus (HDV), respectively. HDV is a small RNA satellite virus that requires HBV envelope proteins to form its own virions. HDV/HBV co-infection is considered the most severe form of chronic viral hepatitis due to faster liver disease progression. Bulevirtide (BLV), a peptide binding to sodium taurocholate co-transporting polypeptide (NTCP), the entry receptor for HBV and HDV, was conditionally approved in Europe for the treatment of chronic HDV. Although clinical trials demonstrated safety and efficacy, BLV requires inconvenient daily injections. Here we describe the preclinical profiling of a novel class of orally-available small molecules that potently inhibit HBV and HDV entry.
Method: EC_{50}s for extracellular hepatitis B e antigen were measured in infected HepG2-NTCP cells and primary human hepatocytes (PHHs) by ELISA. Protein-adjusted HBV EC_{50}s were determined in infected HepG2-NTCP cells cultured with physiologic concentrations of human serum albumin and alpha acidic glycoprotein. EC_{50}s for intracellular hepatitis D antigen were determined by in-cell ELISA in infected HepG2-NTCP cells. The impact on NTCP-dependent bile acid uptake and HBV preS-binding competition were determined in HEK293 cells by measuring fluorescence-labeled bile acid uptake and fluorescence-conjugated preS-binding, respectively. Metabolic stability was evaluated in human, non-human primate (NHP), dog, and rodent liver microsomes (LMs). Pharmacokinetic studies were performed in rodents, dogs, and NHPs.
Results: Three structurally-related compounds potently inhibited HBV in HepG2-NTCP cells (EC_{50} 4–12 nM) and in PHHs (EC_{50} 124–233 nM), as well as HDV (EC_{50} 21–28 nM). A reduction of anti-HBV potency (27- to 36-fold) was observed in a functional serum shift assay. The compounds inhibited preS-binding (IC_{50} 22–50 nM) and NTCP-dependent bile acid uptake (NTCP IC_{50} 8–13 nM). The tested small molecules showed high metabolic stability in rodent LMs (mouse LM CL_{pred} 5–9 ml/min/kg and rat LM CL_{pred} 2–11 ml/min/kg), non-rodent LMs (dog LM 6–8 ml/min/kg and NHP LM 0.6–6 ml/min/kg), and human LMs (CL_{pred} 0.4–1.8 ml/min/kg). Good oral bioavailability was observed in all preclinical species (F = 100% in mice, rats, and NHPs and 76%-100% in dogs) with terminal half-lives of 3.2–3.4 hours in mice, 3.4–5.7 hours in rats, 5–13 hours in dogs, and 7.6–11 hours in NHPs.
Conclusion: We have identified a novel class of highly-potent, orally-bioavailable HBV and HDV entry inhibitors with good drug-like properties, potentially compatible with once-daily dosing in human. Lead optimization of this series of compounds is in progress, with a focus on nominating an investigational clinical development candidate for HDV and HBV therapy in 2023.

SAT-196

Cell-mediated immunity analysis to assess the characteristics of immune response to bepirovirsen: Examples from the B-Clear study

Jenn Singh[1], Bruno Salaun[2], Shihyun You[1], Stephen Corson[3], Melanie Paff[1], Dickens Theodore[4]. [1]*GSK, Collegeville, United States;* [2]*GSK, Rixensart, Belgium;* [3]*Phastar, United Kingdom;* [4]*GSK, Research Triangle Park, United States*
Email: jennifer.m.singh@gsk.com

Background and aims: B-Clear assessed the efficacy and safety of bepirovirsen (BPV), an antisense oligonucleotide, in participants (pts) with chronic hepatitis B virus (HBV) infection. BPV 300 mg for 24 weeks (wks) resulted in 9–10% of pts achieving the primary end point of HBV DNA and hepatitis B surface antigen (HBsAg) loss maintained for 24 wks post BPV discontinuation. This analysis used T-cell functional characterisation of a subset of pts in B-Clear to understand the immunological response of pts treated with BPV.
Method: B-Clear was a Phase 2b randomised trial in 457 pts either on stable nucleos (t)ide analogue (NA) therapy or not on NA therapy. Methods and results have been published.[1] Briefly, pts were randomized (3:3:3:1) to receive up to 300 mg BPV for 12 or 24 wks with/without loading doses. The primary outcome was the proportion of pts achieving HBsAg <lower limit of detection (LLOD) and HBV DNA <lower limit of quantification (LLOQ) maintained for 24 wks without additional newly initiated antiviral medication after end of BPV treatment. In this analysis, peripheral blood mononuclear cells (collected at baseline, Wk 12 and 24, and off-treatment Wk 1, 12 and 24) from B-Clear study pts were stimulated overnight with overlapping peptide pools to HBV core, surface or polymerase



Doses were administered once weekly as two subcutaneous injections (two syringes total; one syringe contained either BPV at a dose of 150 mg or PBO). The LD of BPV (300 mg) or PBO was administered on Days 4 and 11. LLOQ of CD4+ and CD8+ is 590 per million cells. ALT ULN is 40 IU/L for males and 33 IU/L for females. Pt A CD4+ data were missing.

ALT, alanine aminotransferase; BL, baseline; BPV, bepirovirsen; HBsAg, hepatitis B surface antigen; LD, loading dose; LLOQ, lower limit of quantification; NA, nucleos(t)ide analogue; OT, off treatment; PBO, placebo; ULN, upper limit of normal; W, week

Figure: (abstract: SAT-196).

antigens. Expression of activation markers was analyzed by flow cytometry and used to quantify frequencies of polypositive CD4 and CD8 HBV-specific T-cells (expressing ≥2 markers including ≥1 cytokine among CD40L, 4-1BB, IFN-γ, TNF-α, IL-2, IL-13 and IL-17).

Results: Here we show individual pt-level example datasets from pts who developed or exhibited core- or polymerase-specific CD4+ or CD8+ T-cells. None of these example pts exhibited surface-specific CD4+ or CD8+ T-cells. Overall, 159 and 224 pts had CD4+ or CD8+ T-cell data available at any timepoint; 42 pts had at least one CD4+ or CD8+ T-cell value above LLOQ (590 polypositive per million cells) at any timepoint; however, the lack of longitudinal data across the whole dataset due to poor sample quality limited comprehensive

analysis. The pts shown here had variable efficacy responses to BPV. HBsAg level dropped in all 4 pts in this subset (Figure) and at Wk 24 was <LLOD in pts A, C and D and 0.35 IU/ml in pt B. Pt treatment, HBsAg, alanine aminotransferase (ALT), CD4+ and CD8+ T-cell profiles are presented in Figure. Notably, pt A developed polymerase-specific CD8+ T-cells in a similar timeframe as ALT increased; however, the relationship between polymerase-specific CD8+ T-cells and ALT is still unclear.

Conclusion: Some pts have complex and varying HBV-specific T-cell responses during BPV treatment. Available datasets are currently being expanded to clarify the relationships between the multiple factors at play in response to BPV.

SAT-197

Therapeutic vaccine candidate CLB-3000 (CLB-405 and CLB-505 adjuvanted with Alhydrogel): a Good Laboratory Practice (GLP)-compliant 15-week intramuscular toxicity study in rabbits with a 4-week recovery

Aileen Rubio[1], Bharat Dixit[2], Laurie Iciek[3]. *[1]ClearB Therapeutics, Inc, Executive, Concord, United States; [2]ClearB Therapeutics, Inc, Concord, United States; [3]ClearB Therapeutics, Inc, Concord, United States*
Email: arubio@clearbtherapeutics.com

Background and aims: ClearB Therapeutics is developing a therapeutic vaccine candidate, CLB-3000, designed to drive functional cure (FC) in patients with chronic Hepatitis B (CHB). CLB-3000 consists of 2 modified Hepatitis B surface antigens (HBsAg), CLB-405 and CLB-505, expressed in *Pichia pastoris*, purified and adjuvanted with Alhydrogel. CLB-405 and CLB-505 were designed to display clearance profile associated epitopes on HBsAg and were identified from anti-HBs responses of FC patients. The toxicity and immunogenicity of CLB-3000 was evaluated following repeated, intramuscular (IM) injection in New Zealand White (NZW) rabbits for 15 weeks and following a 4-week recovery period.

Method: NZW rabbits (8/sex/group) received 0.9% saline, Alhydrogel only (1000 µg) or CLB-405 and CLB-505 (40 100 and 250 µg each antigen; 80 200, or 500 µg total) with Alhydrogel (1000 µg) via IM injection, Q3W for 15 weeks. Evaluated parameters included: viability, clinical observations, local tolerance, ophthalmology, body weights, food consumption, body temperature, hematology, clinical chemistry, coagulation, organ weights, macroscopic and microscopic pathology, and immunogenicity.

Results: All animals survived to the scheduled necropsy. CLB-3000-related clinical and microscopic pathology findings were limited to effects at the injection sites; no adverse systemic effects were noted. CLB-3000-related clinical pathology changes at ≥80 µg included increases in fibrinogen, CRP, and/or creatine kinase, suggestive of an inflammatory response and muscle damage due to injection site reactions. Microscopic changes including granulomas, macrophage infiltrates, and/or mixed cell inflammation at the injection sites generally occurred at a higher incidence and/or severity in animals administered ≥80 µg CLB-3000. These findings are consistent with expected findings in a vaccine study formulated with adjuvant, did not result in clinical impairment, exhibited some degree of reversibility, and are not considered adverse. CLB-3000 was immunogenic, confirming pharmacologic activity in NZW rabbits.

Conclusion: Repeated IM injection of CLB-3000 was well tolerated at doses up to 500 µg antigen (250 µg CLB-405 and 250 µg CLB-505) with 1000 µg Alhydrogel/animal, the highest dose tested. Findings in this study, which were limited to effects at the injection sites, were consistent with expected findings in a vaccine study formulated with adjuvant and were not considered adverse. The safety profile of CLB-3000 in NZW rabbits supports further investigation for the treatment of CHB patients.

SAT-198

Phase 1b/2a study of heterologous ChAdOx1-HBV/MVA-HBV immunotherapy (VTP-300) combined with low-dose nivolumab (LDN) in virally suppressed patients with CHB on nucleos (t)ide analogues

Tom Evans[1], Eleanor Barnes[2], Reena Mehta[1], Louise Bussey[2], Katie Anderson[1], Antonella Vardeu[2], Anthony Brown[1], Young-Suk Lim[3], Wan-Long Chuang[4], Chiyi Chen[4], Won Young Tak[3], Gin-Ho Lo[4]. *[1]Vaccitech Ltd, United Kingdom; [2]Oxford University, United Kingdom; [3]Asan Medical Center, Korea, Rep. of South; [4]Kaohsiung Medical University Chung-Ho Memorial Hospital, Taiwan*
Email: tom.evans@vaccitech.co.uk

Background and aims: Induction of a functional CD8+ T cell response to HBV is likely a required mechanism to achieve a functional cure of chronic hepatitis B (CHB). The use of a heterologous immunotherapeutic regimen combined with low dose checkpoint inhibition is a promising approach.

Method: Vaccitech's HBV immunotherapeutic (VTP-300) combines an adenoviral vector (ChAdOx1-HBV) and a heterologous Modified Vaccine Ankara boost (MVA-HBV) encoding polymerase, core, and S antigen from a consensus genotype C HBV. A Phase 1b/2a trial to evaluate four different regimens enrolled (n = 55) patients with CHB on prolonged antivirals (VL undetectable and HBsAg <4000 IU/ml) in 4 groups. Group 1 (n = 10), MVA-HBV d0 and d28; Group 2 (n = 18), ChAdOx1-HBV d0 and MVA-HBV d28; Group 3 (n = 18), Group 2 regimen with low dose Nivolumab (LDN) (0.3 mg/kg IV) at d28; Group 4 (n = 9) Group 2 regimen with LDN at d0 and d28.

Results: All 55 patients were enrolled and treated, and there was no concerning safety signal or immunotherapy-related SAE reported. Mild transaminase flares occurred in two patients. Groups 1 and 4 had no appreciable change in mean HBsAg. In Group 3, the mean log10 reduction was −0.76, −0.77 and −0.93 at 3, 6, and 9 months. Two patients in group 3 (genotypes B and C) had non-detectable HBsAg, which persisted until the end of follow-up. In Group 2, three patients with HBsAg <50 IU/ml at screening had HBsAg reductions of −0.94, −0.96 and −1.44 log10 at month 9; reductions >0.5 log10 persisted in most patients for 8 months until study end. Responses were seen in diverse genotypes and were associated in some cases with reductions of pgRNA. HBV T cell responses were assessed in all patients, and responses to all included antigens were observed. Final study results and the relationship between immune response and HBsAg reduction will be presented at the next EASL conference.

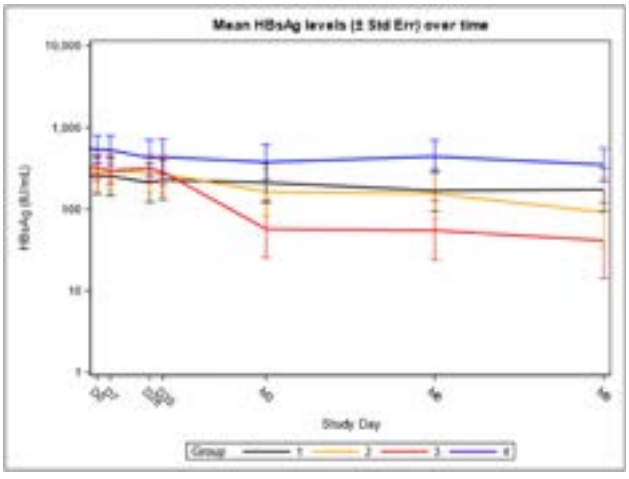

Figure:

Conclusion: VTP-300 immunotherapy, as monotherapy and when combined with low dose nivolumab at the boosting time point, was shown during the Phase 1b/2a trial to be immunogenic and associated with sustained reductions in HBsAg levels in well-

controlled CHB patients, and was administered with no concerning treatment-related SAEs or safety signal observed.

Email: elisabetta.degasperi@policlinico.mi.it

Background and aims: Serum Hepatitis B Core Related Antigen (HBcrAg) has been proposed as a useful biomarker in naïve and treated HBV patients, however its role and kinetics in HDV patients receiving Bulevirtide (BLV) treatment is still unknown.
Method: Consecutive HDV cirrhotic patients treated with BLV 2 mg/day monotherapy for 72 weeks were enrolled in a single-centre study. Clinical/virological characteristics were collected at baseline and every 8 weeks. HDV RNA was quantified by Robogene 2.0 (LOD 6 IU/ml), HBcrAg levels were measured using LUMIPULSE® G HBcrAg assay (Fujirebio Europe, LLOQ 3 log10 U/ml).
Results: Overall, 49 HDV patients were enrolled: median age 52 (29–77) years, 59% males, platelets 78 (17–217) × 10^3/mm^3, liver stiffness measurement 17.3 (6.4–68.1) kPa, ALT 97 (30–1074) U/L, HBsAg 3.7 (0.8–4.4) LogIU/ml, HDV RNA 5.2 (2.4–6.9) LogIU/ml, HBcrAg 4.1 (3.0–5.2) U/ml. At baseline, HBcrAg was detectable (≥3 U/ml) in 86% of patients and showed a direct correlation with HBsAg levels ($r = 0.33$, $p = 0.03$), while no association with HDV RNA or ALT levels was observed. Following 72 weeks of BLV monotherapy, HDV RNA declined by 2.8 (0.2–5.3) LogIU/ml ($p < 0.001$ vs. baseline), becoming undetectable in 33% of patients. Virological response (undetectable or at least 2 Log HDV RNA decline vs. baseline) was achieved by 78% of patients, a biochemical response (ALT<40 U/L) was observed in 72% and a combined response (biochemical + virological) in 56%. During BLV treatment, patients testing HBcrAg positive declined from 86% to 70%, however the difference was not significant ($p = 0.21$). In HBcrAg positive patients, HBcrAg levels significantly declined from 4.1 (3.0–5.2) U/ml at baseline to 3.9 (3.1–4.7) U/ml at week 72 ($p = 0.03$), while no change in HBsAg levels was observed: from 3.7 (0.8–4.4) to 3.6 (2.5–4.3) LogIU/ml ($p = 0.77$). In HBcrAg positive patients, HBcrAg levels at week 72 were associated with biochemical response (OR 5.2, $p = 0.03$), while week 24 (OR 3.9, $p = 0.04$) and week 48 HBcrAg levels (OR 5.4, $p = 0.01$) were associated with combined response. Conversely, neither baseline nor on-treatment HBcrAg levels correlated with HDV RNA levels or virological response rates.
Conclusion: In cirrhotic HDV patients treated with BLV monotherapy for 72 weeks, HBcrAg tested positive in most of the patients, being associated with baseline HBsAg levels. During BLV treatment, HBcrAg levels significantly declined and were associated with biochemical and combined response rates.

SAT-200

Modeling-based response-guided therapy with bulevirtide monotherapy for chronic hepatitis D to identify patients for finite treatment duration

Sarah Duehren[1], Louis Shekhtman[1,2], Scott Cotler[1], Stephan Aberle[3], Thomas Reiberger[4,5], Peter Ferenci[5], Harel Dahari[1]. *[1]Loyola University Chicago, Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, United States; [2]Northeastern University, Network Science Institute, United States; [3]Medical University Vienna, Center of Virology, Austria; [4]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Austria; [5]Medical University Vienna, Rare Liver Disease (RALID) Center of the European Reference Network for Rare Hepatological Diseases (ERN RARE-LIVER), Austria*
Email: harel.dahari@gmail.com

Background and aims: Bulevirtide (BLV) is a novel antiviral drug against hepatitis D virus (HDV) that was conditionally approved in Europe in 2020. While it recently was suggested that BLV treatment discontinuation may be considered for patients who achieve long-term HDV RNA suppression (PMID:35514008), a computational approach may help to define the required duration of BLV therapy. Here we analyze HDV RNA kinetics in 7 patients undergoing BLV therapy and examine whether mathematical modeling could potentially be used to predict a finite duration of BLV therapy.
Method: Seven chronic HDV-infected patients receiving BLV monotherapy at two clinics in Vienna were included. HDV RNA was quantified by a sensitive PCR assay throughout treatment. ALT and HBsAg data were frequently collected in 7/7 and 3/7 patients, respectively. A recently developed mathematical model (AASLD 2022: late breaking abstract 5031) accounting for HDV RNA, HBsAg and ALT dynamics during BLV treatment was used to predict the time to reach <1 virus copy in the entire extracellular body fluid (BF).
Results: Median pre-treatment HDV RNA, ALT, and HBsAg were 5.0 log IU/ml [interquartile range, IQR 1.7], 44 U/L [IQR 69.5], and 3.1 log IU/ml [IQR 1.0], respectively. Two patients had normal ALT levels at pre-treatment. A delay in HDV RNA decline was seen in 4/7 patients at the beginning of therapy, lasting between 2 and 7 weeks. All 7 patients experienced a rapid phase of HDV decline (median of 0.11 log/week [IQR 0.09]) with a median duration of 14.7 weeks [IQR 13.3] and median magnitude of decline of 2.2 log cp/ml [IQR 0.8]. Thereafter, 2 patients experienced a 2nd slower phase of HDV decline (termed biphasic) of whom only one patient reached HDV undetectable (Fig. 1a). In the remaining 5 patients HDV RNA levels dropped to a subsequent lower viral plateau (termed flat partial response) throughout therapy (Fig. 1b). The two biphasic patients were both young (29 and 30 years old) without cirrhosis, while all flat-partial patients had a median age of 51 [IQR 14] and had cirrhosis. ALT normalized (Female<35 U/L; Male<50 U/L) in all but one (biphasic) patient during therapy. Five patients had normal ALT levels by week 24, and one patient by week 36. In 5/6 of these patients, HDV viral load declined ≥2 log from pre-treatment levels before ALT normalization. HBsAg remained at pre-treatment levels. In the mathematical model, the predicted values fit well the measured values (Fig. 1). In the biphasic patient who achieved undetectable HDV RNA levels, the model accurately predicted that a duration of ~100 weeks is required to achieve <1 virus copy in the BF (Fig. 1a).

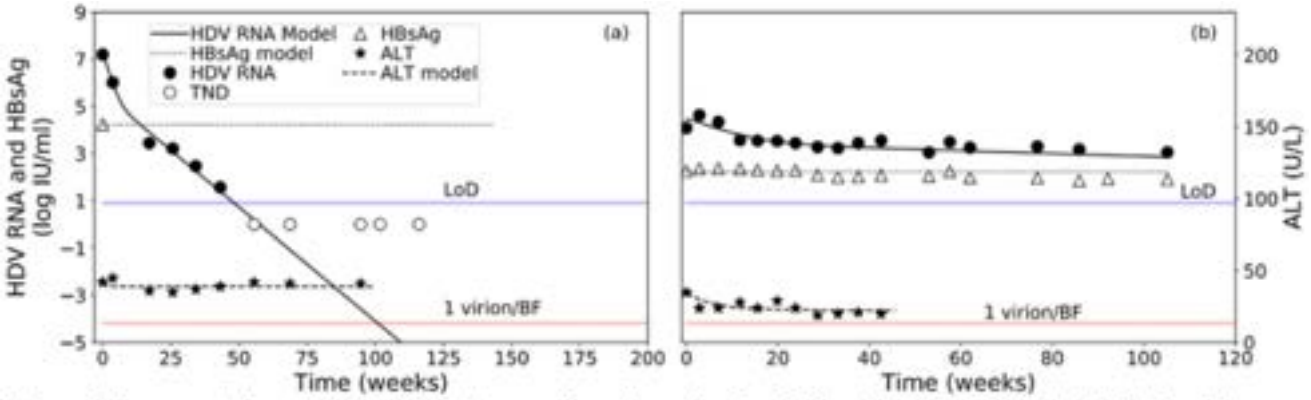

Figure 1. Representative viral kinetic patterns and mathematical modeling: **(a)** Biphasic (n=2); **(b)** Flat Partial Response (n=5). LoD, HDV RNA limit of detection (8 IU/ml).

Figure: (abstract: SAT-200).

Conclusion: The developed viral kinetic model provides an initial step toward to guide individualized BLV therapy allowing finite treatment durations in patients with HDV.

SAT-201

A phase 2 study of ASC42, a novel farnesoid X receptor (FXR) agonist, in combination with PEGylated interferon (PEG-IFN) and entecavir(ETV) in chronic hepatitis B patients with 12-week treatment

Jinlin Hou[1], Qianguo Mao[2], Jing Yuan[3], Guoxin Hu[4], Yao Xie[5], Handan He[6], Jinzi Wu[6]. *[1]Nanfang Hospital of Southern Medical University, China; [2]Xiamen Hospital of Traditional Chinese Medicine, China; [3]The third People's Hospital of Shenzhen, China; [4]Peking university Shenzhen hospital, China; [5]Beijing Ditan Hospital Capital Medical University, China; [6]Ascletis BioScience Co., Ltd., China*
Email: jlhousmu@163.com

Background and aims: ASC42 is a novel non-steroidal, selective, potent farnesoid X receptor (FXR) agonist. Preclinical studies showed that ASC42 might be a novel anti-viral candidate for hepatitis B virus (HBV) functional cure through inhibiting transcription of HBV covalently closed circular DNA (cccDNA) into HBV RNA and reducing the HBV cccDNA stability. PEGylated interferon (PEG-IFN) and nucleos(t)ide analogs, such as entecavir (ETV), are the major antiviral drugs for chronic hepatitis B (CHB). As ASC42, PEG-IFN and ETV have different mechanisms of action (MoA), a combination of these 3 drugs might enhance the function cure rates in CHB patients. This study aimed to evaluate the safety and efficacy of combined treatment and pharmacokinetic (PK) of ASC42 in CHB patients treated with ASC42 combined with PEGylated interferon-α-2a (PEG-IFN-α-2a) and ETV.
Method: This Phase 2 trial (NCT05107778) was a multi-center, randomized, single-blind, placebo-controlled study conducted in China. Forty-three subjects with CHB were enrolled and randomized into 3 cohorts of 10 mg ASC42 (n = 15), 15 mg ASC42 (n = 14) or matching placebo (n = 14) orally once daily (QD) in combination with ETV (0.5 mg, orally QD) and PEG-IFN-α-2a (180 μg, subcutaneous injection once a week). Subjects were treated for 12 weeks, and followed for 24 weeks (still on ETV). Serum hepatitis B surface antigen (HBsAg) and hepatitis B virus (HBV) pregenomic RNA (pgRNA) changes from baseline were measured during the 12-week intervention period and 24-week follow-up period.
Results: Two subjects in 15 mg ASC42 cohort withdrew from the study due to grade 2 adverse events (AEs) of dermatitis allergic and pruritus, respectively, while the other subjects completed the study. All subjects in ASC42 and PBO cohorts experienced at least one AE. In total, 153 146, and 127 AEs were reported in 10 mg, 15 mg ASC42 and PBO cohorts, respectively, and most AEs (94.4%) were mild (grade 1) or moderate (grade 2) in severity. One subject in 15 mg ASC42 cohort experienced a grade 3 serious AE (SAE) of liver function injury with a final outcome of recovered. AEs of pruritus were reported in 2 (2/15, 13.3%), 9 (9/14, 64.3%) and 0 (0%) subjects in 10 mg, 15 mg ASC42 and PBO cohorts, respectively. ASC42 exposure measures (C_{max} and AUC_{0-24}) in 10 mg cohort is 4 times lower than those in 15 mg cohort (C_{max}: 106 versus 441 [ng/ml]; AUC_{0-2}: 733 versus 2920 [h*ng/ml]). There was no accumulation following multiple doses. No significant changes of HBV specific biomarkers from baseline at end of intervention or follow-up were observed among these 3 cohorts.
Conclusion: As a novel FXR agonist, 10 mg ASC42 in combination of PEG-IFN-α-2a and ETV, was safe and well-tolerated and showed minimum and mild pruritus (13.3%) in Chinese CHB patients with a 4-fold safety margin and better efficacy biomarker 7α-hydroxy-4-cholesten-3-one (C4) inhibition (67%) than obeticholic acid (OCA) at 10–50 mg (40.1–47.3%).

SAT-202

Hepatitis B virus core protein variant profiles observed in chronic hepatitis B patients treated with capsid inhibitor AB-836

Christine L. Espiritu[1], Nagraj Mani[2], Timothy Eley[3], Andrzej Ardzinski[2], Kim Stever[2], Joanne Brown[4], Tilly Varughese[5], Karen Sims[5], Gaston Picchio[6], Angela M Lam[2], Michael J. Sofia[6], Emily P. Thi[1]. *[1]Arbutus Biopharma, Immunology and Biomarkers Research, Warminster, United States; [2]Arbutus Biopharma, Biology, United States; [3]Arbutus Biopharma, Clinical Pharmacology, United States; [4]Arbutus Biopharma, Clinical Operations, United States; [5]Arbutus Biopharma, Clinical Development, United States; [6]Arbutus Biopharma, United States*
Email: ethi@arbutusbio.com

Background and aims: Current treatments for chronic Hepatitis B virus (HBV) infection are limited to nucleos(t)ide analogs (NA) or pegIFNalpha which have low cure rates and often necessitate life-long treatment. AB-836 is an oral, pan-genotypic, CAM-E (empty) capsid inhibitor that inhibits HBV pre-genomic RNA (pgRNA) encapsidation by binding to HBV core protein and accelerating capsid assembly. In previously described results from the first-in-human clinical study AB-836-001, AB-836 resulted in robust HBV DNA log_{10} declines of −2.66 (50 mg), −3.04 (100 mg), and −3.55 (200 mg), respectively. Herein we report the prevalence and impact of HBV core protein variants on virologic response to AB-836 treatment. AB-836 is no longer in development.
Method: HBV DNA was extracted from plasma collected from 48 subjects enrolled in AB-836-001 (randomized 10:2 per cohort

AB-836:placebo) who were administered AB-836 at either 50 mg, 100 mg, or 200 mg QD for 28 days. Extracted DNA samples underwent HBV-specific PCR amplification followed by Illumina MiSeq next generation sequencing. HBV core protein variant viral fitness and sensitivity to HBV inhibitors was determined using a cell-based *in vitro* system where single point mutations were introduced by site-directed-mutagenesis into an HBV replicating plasmid and then transfected into HepG2 cells.

Results: None of the subjects undergoing AB-836 dosing experienced on-treatment viral rebound. HBV core variants with frequencies of >1% at 31 amino acid sites located in and proximal to the AB-836 binding site were analyzed. No enrichment of core variants was observed between baseline and Day 28 (end of treatment). Higher frequency variants were identified at amino acid sites Y38, I105, T109, T114, I116, and Y118; however, there was no difference in HBV DNA reduction in subjects where core variants were detected at baseline. In cell culture, HBV core variants L30F, T33N, T33Q, L37Q, and I105T resulted in AB-836 EC_{50} fold changes of 4.7, 64.8, 42.4, 20.8, and 8.3, respectively. Testing of an expanded panel of core variants, including Y38F/H, I105V, T109M/I/S, T114I, Y118F, Y132F, and the Y38F+T109S double variant, showed no effect on AB-836 activity.

Conclusion: No viral breakthrough or enrichment of HBV core protein resistant variants was observed in subjects receiving AB-836 for 28 days. Multiple core protein variants at amino acid positions Y38, I105, T109, T114, and I116 were observed to occur at higher frequencies, suggesting viral plasticity at these sites.

Viral Hepatitis C Clinical aspects including follow up after SVR

THU-162

External validation of models to predict hepatocellular carcinoma (HCC) in HCV SVR F3-F4 patients

Iván Sahuco[1], Ângela Carvalho-Gomes[1,2], Tsveta Valcheva[1,3], Enrique Vidal[1], Laura Martínez-Arenas[1,2,4], Carmen Vinaixa[1,2,5], Victoria Aguilera Sancho[1,2,5], Marina Berenguer[1,2,3,5]. *[1]La Fe Health Research Institute, Spain; [2]CIBEREHD, ISCIII, Spain; [3]University of Valencia, Spain; [4]Polytechnic University of Valencia, Spain; [5]La Fe Polytechnic and University Hospital, Spain*
Email: marina.berenguer@uv.es

Background and aims: Several HCC risk-models have been developed to individualize patient surveillance following sustained viral response (SVR) in HCV patients. Validation of these models in different cohorts is an important step to incorporate a more personalized risk assessment in clinical practice. We aimed at applying these models to stratify the risk in our patient population.

Method: Patients with baseline F3-4 fibrosis treated between 2015 and 2018 with interferon-free oral antivirals (DAA) and SVR regularly followed as part of HCC surveillance strategy. The end point of interest was the development of HCC after at least 1 year of FU since end-of-therapy. Five models were applied to our sample population: Pons (http://doi.org/10.1016/j.jhep.2019.10.005), aMAP (https://doi.org/10.1016/j.jhep.2020.07.025), Ioannou HCC risk (https://doi.org/10.1016/j.jhep.2018.07.024), Alonso (https://doi.org/DOI%2010.1002/hep.31588) and Semmler (https://doi.org/10.1016/j.jhep.2021.11.025). Validation of the models was performed by repeated cross-validation 100 times, choosing randomly in each iteration 75% of the samples to train the model and the remaining 25% to validate it.

Results: Twenty-five (7%) of 357 F3-4 SVR patients regularly followed developed HCC. The number of patients analyzed by each model varied between 82 (Semmler) and 353 (Ioannou) depending on the number of variables available. The sensitivity of the different models varied between 0.17 (Semmler) and 1 (Alonso, aMAP). In our cohort, the model that would allow the most reliable reduction in HCC follow-up visits would be Ioannou HCC risk (see table) with a sensitivity of 96% and a proportion of patients labeled as high risk of 72%. In second place is Semmler model with a sensitivity of 71% and a proportion of patients labeled as high risk of 23%.

Model	N	N high risk	N with HCC	N high risk with HCC	Proportion classified as high risk	Sensitivity
Alonso	133	84	7	7	0.63	1
aMAP	350	313	24	24	0.89	1
Ioannou	352	253	24	23	0.72	0.96
Semmler7	144	33	7	5	0.23	0.71
Semmler7_no OH	144	23	7	4	0.16	0.57
Semmler6	82	10	6	2	0.12	0.33
Semmler6_no OH	82	4	6	1	0.05	0.17
HCCrisk	353	175	24	17	0.5	0.71
Pons	146	31	7	3	0.21	0.43

Figure:

Conclusion: Incorporating the HCC risk model in our center would safely allow for one third reduction in HCC surveillance in HCV SVR F3-4 patients.

THU-163

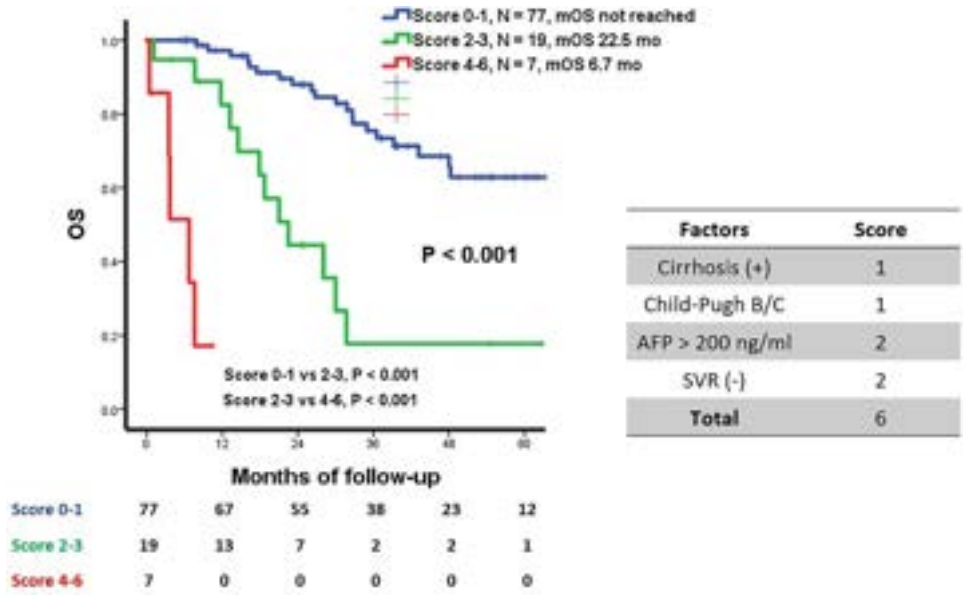
Impact of direct-acting antiviral therapy on tumor progression and survival in intermediate to advanced hepatocellular carcinoma patient with HCV infection

Chen-Ta Chi[1], I-Cheng Lee[1], Keng-Hsin Lan[1], Chi-Jen Chu[1], Chien-Wei Su[1], Ming-Chih Hou[1], Yi-Hsiang Huang[1]. *[1]Taipei veterans general hospital, Taiwan*
Email: ctchi2@vghtpe.gov.tw

Background and aims: Direct-acting antiviral agents (DAAs) are effective to reduce incidence of hepatocellular carcinoma (HCC) and mortality among hepatitis C virus (HCV) patients. The beneficial impact of DAAs on outcomes in patients with intermediate to advanced HCC remains uncertain. This study aimed to assess the survival of patients with Barcelona Clinic Liver Cancer (BCLC) stage B/C HCC following DAAs treatment.

Method: From April 2015 to May 2022, consecutive 103 HCV-related HCC patients with BCLC stage B or C who had received DAAs therapy were retrospectively reviewed from Taipei Veterans General Hospital. Time to progression (TTP) and overall survival (OS) were assessed and factors associated with TTP and OS were analyzed.

Results: Of the 103 BCLC B/C HCC patients received DAAs, 86 patients were BCLC B and 17 patients were BCLC C. The mean age was 71 years old, and 66% had underlying cirrhosis. Most patients were within Child-Pugh class A (87.4%) and Albumin-bilirubin (ALBI) grade 1/2 (95.1%). Forty-two (40.8%) patients with active HCC during DAAs therapy. Of them, 76 (73.8%) patients received genotype-specific DAAs, and 27 (26.2%) patients received pan-genotypic DAAs. The sustained virological response (SVR) rate was 95.3% (82/86) in BCLC B, and 70.6% (12/17) in BCLC C, respectively. Seral AFP level >200 ng/ml (HR, 2.474; p = 0.010) was the independent predictor of TTP. Presence of cirrhosis, Child-Pugh B/C, seral AFp >200 ng/ml, and fail to achieve SVR were independent risk factors associated with OS. A novel scoring system to predict OS into 3 groups was created based on the multivariate analysis. For the 86 BCLC B HCV-HCC patients, ALBI grade 2/3 (HR, 2.435; p = 0.026) was the only factor associated with unTACEable-progression (TTUP) in multivariate analysis.



Factors	Score
Cirrhosis (+)	1
Child-Pugh B/C	1
AFP > 200 ng/ml	2
SVR (-)	2
Total	6

Figure: (abstract: THU-163).

Conclusion: DAAs could achieve a high SVR rate in BCLC B HCC patients even with active HCC. The novel model can be applied to predict survivals after DAAs therapy.

THU-164

The PNPLA3 genotype is the main driver of weight gain after the hepatitis C cure

Veronika Pitova[1], Sona Frankova[1], Mikolas Holinka[1], Magdalena Neroldova[1], Milan Jirsa[1], Jan Sperl[1]. [1]*Institute for Clinical and Experimental Medicine, Czech Republic*
Email: sona.frankova@ikem.cz

Background and aims: The cure of chronic hepatitis C (HCV) is associated with decreased risk of liver-related complications. Body weight gain is currently discussed as a negative consequence of the HCV cure. The aim of the study was to evaluate body weight gain and changes in serum lipid levels, the presence of diabetes mellitus, hypertension and the genotype of *PNPLA3, HSD17B13* and *IL28B* gene in patients treated with direct-acting antiviral (DAA).

Method: We retrospectively evaluated data of 230 patients treated for HCV infection with DAAs who achieved sustained virologic response (127 males, 103 females), with an average age of 52 years. One hundred and seventy-nine (77.8%) were infected with HCV genotype 1, 45 (19.6%) with genotype 3 and 6 with other genotypes (2.6%). Sixty-eight patients (29.6%) had compensated liver cirrhosis. We recorded the body weight, clinical and laboratory data and assessed liver stiffness (LSM) and liver steatosis expressed as the Controlled Attenuation Parameter (CAP) by Fibroscan® before treatment and three years after the cure. *PNPLA3*, *HSD17B13* and *IL28B* genotypes were assessed by the TaqMan predesigned SNP genotyping assays using the Applied Biosystems ABI 7300 Real-Time PCR instrument (Thermo Fischer Scientific).

Results: The mean patients' weight before treatment was 79.9 kg (46-130 kg). Three years after treatment, the mean body weight gain was 3 kg ($p < 0.0001$). Thirty-five patients (15.2%) gained more than 10% of their initial body weight. The weight gain did not differ between males and females and patients infected with HCV genotypes 1 and 3. The liver stiffness significantly decreased after the treatment, with a mean of 12.1 kPa (range 3.3–73.5 kPa) vs 8.1 kPa (range 1.9–75 kPa), $p < 0.0001$, but the CAP value did not change significantly (256 dB/m vs 261 dB/m, $p = 0.74$). There was also an increased proportion of patients with hypertension (68 vs 93, $p < 0.03$) and hypercholesterolemia (21 vs 48, $p < 0.0006$), but not with diabetes (24 vs 31, $p = 0.39$). The patients with newly diagnosed hypertension or hypercholesterolemia did not have a more pronounced weight gain than patients without the aforementioned ($p = 0.14$ and 0.14, respectively). The frequency of the genotypes was as follows: *PNPLA3* CC 136 (59.1%), CG 85 (37.0%) and GG 9 (3.9%) patients, *HSD17B13* TT 136 (59.1%), TTA 75 (32.6%) and TATA 19 (8.3%) patients, and *IL28B* CC 54 (23.5%), CT 132 (57.4%) and TT 44 (19.1%) patients. The weight gain was associated with the *PNPLA3* G allele in the allelic model (CC vs CG+GG, + 3 kg vs + 0 kg, respectively, $p = 0.0035$). Dose-dependent effect of the *PNPLA3* G allele on weight gain was apparent between different genotypes (CC + 0 kg, CG + 3 kg, GG + 7 kg). There was no association between *HSD17B13* and *IL28B* genotypes and weight gain.

Conclusion: A significant weight gain is common in patients who achieve DAAs-induced HCV cure. *PNPLA3* G allele carriage is a risk factor for weight gain after successful HCV therapy.

THU-165

MAFLD (metabolic associated fatty liver disease) outperforms ultrasonographic steatosis to stratify hepatocellular carcinoma risk in patients with advanced hepatitis C cured with direct antiviral agents

Serena Pelusi[1], Cristiana Bianco[1], Massimo Colombo[2], Giuliana Cologni[3], Paolo Del Poggio[4], Tiziana Re[5], Nicola Pugliese[6], Daniele Prati[1], Marie Graciella Pigozzi[7], Pietro Lampertico[1], Roberta D'Ambrosio[1], Stefano Fagiuoli[8], Luca Valenti[1]. [1]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy;* [2]*San Raffaele Hospital, Milan, Italy;* [3]*Papa Giovanni Hospital, Bergamo, Italy;* [4]*Papa Giovanni Hospital, Zingonia, Italy;* [5]*Legnano Hospital-ASST Milano Ovest, Milan, Italy;* [6]*Humanitas Research Hospital, Milan, Italy;* [7]*Spedali Civili Hospital, Brescia, Italy;* [8]*Azienda Socio Sanitaria Territoriale Papa Giovanni XXIII, Bergamo, Italy*
Email: serenapelusi@libero.it

Background and aims: Metabolic dysfunction associated fatty liver disease (MAFLD) has been proposed to identify individuals at risk of liver events irrespectively of the contemporary presence of other liver disease drivers. Aim of this study was to examine the impact of MAFLD in patients cured of chronic hepatis C (CHC).

Method: We analyzed data from a real-life cohort of 2611 Italian patients cured of CHC with direct antiviral agents and advanced liver fibrosis, without HBV/HIV, transplantation and negative for hepatocellular carcinoma (HCC) history (age 61.4 ± 11.8 years, 63.9% males, median follow-up 34, i.q.r. 24–40 months). Information about ultrasonographic fatty liver disease (FLD) after sustained virological response was available in 1978.
Results: MAFLD affected 58% of patients, diagnosed due to the presence of diabetes (19%), overweight (37%), or multiple metabolic abnormalities (2%). MAFLD was more frequent than and not coincident with FLD (32% MAFLD-only, 23% MAFLD-FLD, 13% FLD-only). MAFLD was associated with higher liver stiffness ($p < 0.05$), particularly in patients with MAFLD-diabetes and MAFLD-only subgroups, comprising older individuals with more advanced metabolic and liver disease ($p < 0.05$). At Cox proportional hazard multivariable analysis, MAFLD was associated with increased risk of HCC (HR 1.97, 95% c.i. 1.27–3.04; $p = 0.0023$). Further classification according to diagnostic criteria improved risk stratification ($p < 0.0001$), with the highest risk in patients with MAFLD-diabetes. When considering MAFLD together with FLD, patients with MAFLD-only appeared at highest risk since the sustained virological response achievement ($p = 0.008$), with a later catch-up of those with combined MAFLD-FLD, whereas FLD-only was not associated with HCC (figure 1).

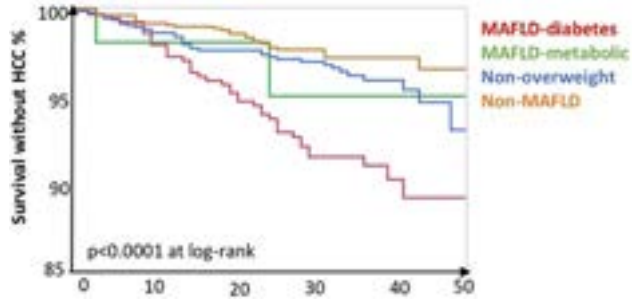


Figure 1:

Conclusion: MAFLD is more prevalent than FLD in patients cured of CHC with advanced fibrosis and identifies more accurately individuals at risk of developing HCC.

THU-166

Most vulnerable HCV patient groups treated with direct acting antivirals achieve high response rates and gain quality of life-data from the German hepatitis C-registry (DHC-R)

Stefan Christensen[1,2], Albrecht Stoehr[3], Gerlinde Teuber[4], Jörg Petersen[3], Ralph Link[5], Uwe Naumann[6], Christine John[7], Yvonne Serfert[8], Karl-Georg Simon[9], Stefan Zeuzem[10], Heiner Wedemeyer[8,11]. *[1]Center for Interdisciplinary Medicine, Muenster, Germany; [2]University Hospital Muenster, Department of Gastroenterology and Hepatology, Muenster, Germany; [3]ifi-Institute for Interdisciplinary Medicine, Hamburg, Germany; [4]Practice PD Dr. med. Email: christensen@cim-ms.de

Background and aims: DAA therapy cures most HCV-patients. To reach micro-elimination, the focus has to be on most vulnerable patient groups. With the aim to improve patient care we characterize treatment outcomes and quality of life (QoL) of these patients in a large prospective real world cohort.
Method: The DHC-R is a national multicenter real-world registry including about 18,200 patients. The present analysis is based on 6849 patients with available data as of July 15, 2022 and comprises the following subgroups: active drug use (yes N = 478; no N = 6371), alcohol abuse (yes N = 650; no N = 6199), former/current homelessness (yes N = 81, no N = 6768) and prison experience (yes N = 140; no N = 6709). Data on homelessness and prison experience have been obtained since October 2020. One patient can belong to several subgroups. Baseline characteristics, sustained virological response (SVR) rates, QoL (36-Item Short Form Survey, SF-36) at baseline and 12 to 24 weeks after end of treatment (EOT) as well as safety data were analyzed.
Results: The majority of the patients with active drug use, alcohol abuse, former/current homelessness or prison experience were male (79–84%). Patients from these vulnerable subgroups were significantly younger than patients not belonging to these subgroups ($p < 0.05$). With 22 and 23%, respectively, significantly more patients with active drug abuse and alcohol abuse suffered from psychiatric disorders than those without drug or alcohol abuse (12 and 11.8%, respectively; $p < 0.05$). Lost-to-follow-up (LTFU) rates ranged between 31 and 46% in the vulnerable subgroups and where higher after EOT than before EOT. In vulnerable subgroups, Intention-to-treat SVR rates ranged between 61% (active drug abuse) and 67% (alcohol abuse) and was mainly affected by high LTFU rates. In Per-Protocol-Analysis, the SVR rates ranged between 93% (active drug abuse) and 97% (alcohol abuse). According to all SF-36 scales, all vulnerable subgroups benefited significantly from DAA therapy ($p < 0.05$; Figure 1). Of note, the QoL of patients with former/current homelessness improved the most. Adverse events were documented for 19% (prison experience) to 32% (active drug abuse) of the patients. Serious adverse events occurred in a maximum of 5% in each patient group.
Conclusion: Active drug users, people with alcohol abuse, prison experience and former/current homelessness as most vulnerable patient groups respond well to DAA therapy but still need special attention shown by higher rates of LTFU. Although often living in precarious circumstances all these patients gain quality of life from baseline up to 24 weeks after EOT which is a good argument to make efforts to grant access to DAA therapy for the most vulnerable patient groups.

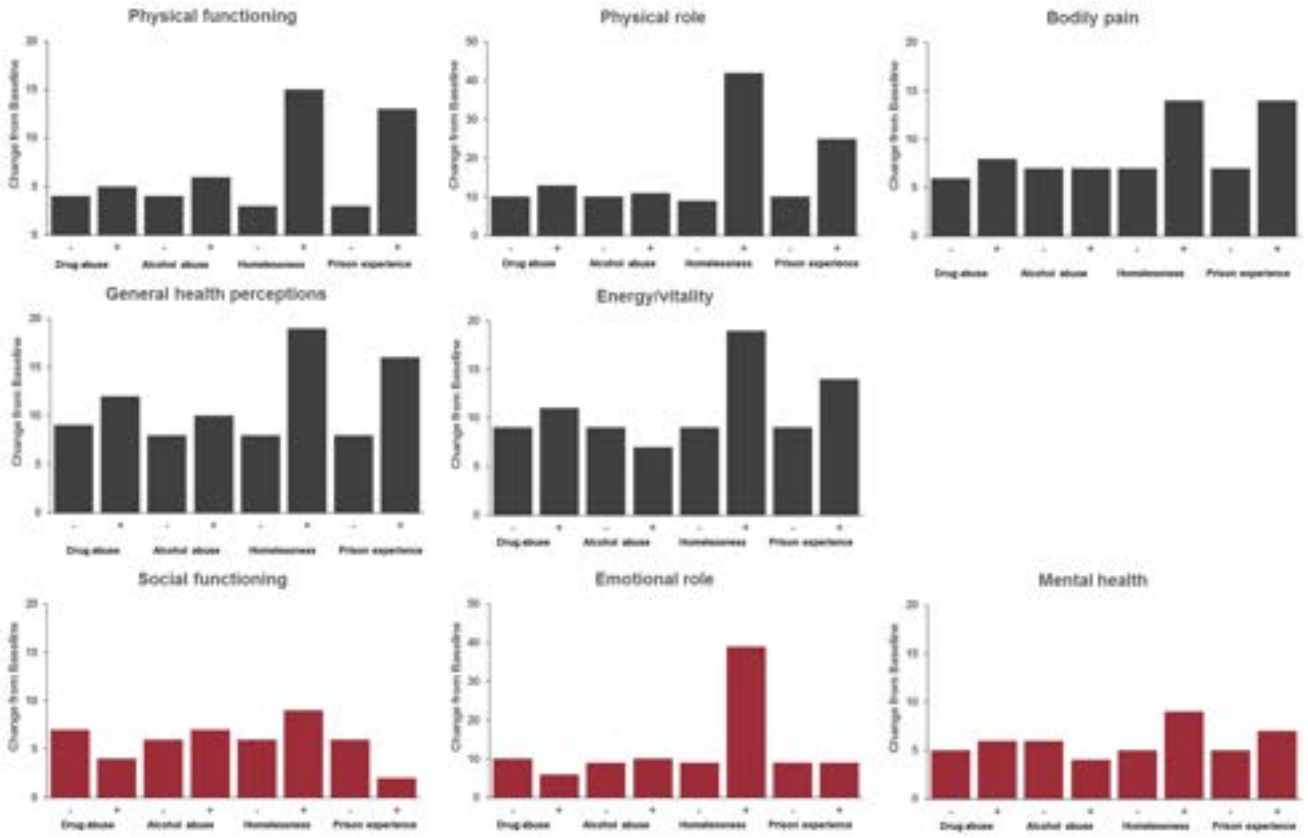

Figure: (abstract: THU-166): Change in SF-36 scales from baseline (BL) to week 12/24 after end of treatment (EOT) according to each subgroup (+yes, –no; changes between BL and week 12/24 after EOT were significant within each subgroup, $p < 0.05$).

THU-167

The impact of 5 years of testing for hepatitis C in prisons in the north east of England

Amy Johnson[1], Jessica Shearer[1], Craig Thompson[2], Yusri Taha[1,3], Stuart Mcpherson[1,4]. *[1]Newcastle upon Tyne Hospitals NHS Foundation Trust, Viral Hepatitis Service, Newcastle upon Tyne, United Kingdom; [2]Spectrum Community Health-CIC, Durham, United Kingdom; [3]Newcastle upon Tyne Hospitals NHS Foundation Trust, Department of Infection and Tropical Medicine, Newcastle upon Tyne, United Kingdom; [4]Newcastle upon Tyne, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom*
Email: amy.johnson12@nhs.net

Background and aims: The prevalence of hepatitis C virus (HCV) in the prison population is high, and diagnosis and treatment of this group is vital to achieving elimination. Universal offering of blood borne virus (BBV) testing was established in all North-East of England (NEE) prisons in March 2016, and data is collected by the prison service. The aim of the study was to review the frequency of HCV among people incarcerated in prison.

Method: Data was collected from three NEE prisons (two male [1 remand, 1 medium sentence], one female). BBV testing offer and screening rates were reviewed for all new inmates between July 2017 and June 2022. HCV antibody (HCV-Ab) and HCV-RNA positivity rates were assessed per quarter. HCV-Ab tests taken within six months of another test were excluded.

Results: There were 39,652 new receptions into prison during the data collection period. 35,906 new receptions (90.6%) were offered BBV testing and 17,068 (47.5%) accepted testing at reception. BBV offer and testing rates over 5 years are shown in Fig. A. Testing rates fell during the COVID-19 pandemic. Despite this reception testing rate, in June 2022, 77.0% of inmates had had BBV testing in 12 months. 3014 tests (17.7%) were HCV-Ab positive and 1249 (7.3%) were HCV-RNA positive (median 238/year). Over time, there was an increase in HCV-Ab frequency from 14% to 17% (Fig. B). There was also an increase in the number of HCV-Ab positive results during the pandemic, suggesting that BBV testing may have been more targeted in the period. Overall, the HCV-RNA positivity rate as a proportion of the total number screened reduced from 7% to 6% during the study period (Fig. C). HCV-RNA prevalence was higher in the female prison than the male prisons (14% vs. 6%). The HCV-RNA positivity rate in HCV-Ab positive individuals fell from 50% to 34% during the study period (Fig. D).

Conclusion: Overall, prevalence of HCV-Ab positivity has increased in NEE prisons over 5 years, but rates of HCV-RNA positivity are falling suggesting that robust testing and treatment programmes are having a meaningful impact. However, the number of individuals with active hepatitis C in prison remains worryingly high. Further work is needed to increase uptake of testing and treatment in this high-prevalence population.

Email: johannes.wiegand@medizin.uni-leipzig.de

Background and aims: The World Health Organization proposed a strategy to eliminate chronic hepatitis C virus (HCV) infection by the year 2030, which was adapted with the BIS2030 program in Germany. One part of this program is adequate screening for hepatitis B virus (HBV) und HCV infection. Therefore, the Federal Joint Committee decided to include a hepatitis B and C screening in the preventive medical examination named "Check-Up 35+," which is performed in patients of at least 35 years at the primary care level. We investigated the results one year after implementation of the structured screening program.

Method: Analysis of the database of the LADR laboratory group which covers 11 ambulatory health care centers. HBsAg and anti-HCV screenings were identified by the billing categories GOP 01865. The codes GOP 01866 and 01867 were used for HBV-DNA and HCV-RNA (PCR) results in case of positive HBsAg and anti-HCV screening tests.
Results: Between 01 October 2021 and 30 September 2022, 286,192 laboratory requisitions were analyzed (56% females, median (SD) age 61.2 (14.0) years). HBsAg and anti-HCV prevalence were 0.54% and 0.78%, respectively. 73% of HBsAg positive patients were HBV-DNA positive (prevalence of HBV-DNA: 0.39% (total), 0.48% (male), 0.33% (female)), 16% of anti-HCV positive cases were HCV-RNA positive (HCV-RNA prevalence 0.13% (total), 0.15% (male), 0.11% (female)).
Age and sex specific prevalences of HBsAg, HBV-DNA, anti-HCV, and HCV-RNA are provided in the figure. The highest HCV-RNA prevalence was observed in young men and was 2.4–3 times higher than in young women.
Conclusion: A structured hepatitis screening program at the primary care level could be successfully established and leads to a large number of tests within the first year of implementation.

Age category (years)	HBsAg		HBV DNA		Anti-HCV		HCV-RNA	
	Male (%)	Female (%)	Male (%)	Female (%)	Male (%)	Female (%)	Male (%)	Female (%)
35-44	1.00	0.66	0.86	0.52	1.11	0.58	0.24	0.08

Microbiology and virology-AOU Città della Salute e della Scienza, Turin, Italy*

Email: marco.tizzani91@gmail.com

Background and aims: Extrahepatic manifestations have always been a difficult-to-manage problem, complicating clinical outcome of Hepatitis C virus (HCV)-infected patients. Direct acting antivirals (DAAs) have significantly changed the history of HCV infection, inducing high rates of sustained virologic response (SVR). The aim of this study is to evaluate the outcomes of patients affected by mixed cryoglobulinemia (MC) and/or B-cell Non-Hodgkin Lymphomas (B-NHL) and HCV after eradication with DAAs.

Method: Virological and haematological end points have been analyzed in 151 patients (62 Male/89 Female, mean age 70.4 (± 13.1)) with MC and/or B-NHL treated with DAAs between February 2015 and March 2022 at 3 months (T1), 6 months (T2) and at their most recent hepatologic/haematologic examination (T3) after SVR12. HCV genotype 1a has been found in 8.2% of patients, 1b in 51.4%, 2 in 27.4%, 3 in 9.6%, 4 in 2.7%, 5 in 0.7%. Ninety-five patients were naive, 34 non-responder and 22 relapser to INF-based therapy. Fifty patients were cirrhotic (33.8%). Symptomatic MC (neuropathy, nephropathy, vasculitis) was present in 57 out of 88 (64.7%) patients and in 13 of them MC was associated with a B-NHL, while asymptomatic MC was present in 31 patients (35.2%). Seventy-three patients had B-NHL: diffuse large B-cell (21), marginal zone (13), follicular (9), mantle (1), others were indolent B cell-NHL not otherwise specified.

Results: SVR12 has been obtained in all 151 patients (100%). Preliminary data showed that, among patients with symptomatic MC, 17 (29.8%) at T1, 16 (28%) at T2 and 26 (45%) at T3 had improvement and/or remission from clinical symptoms, with higher rate among vasculitis symptoms. Cryoglobulines resulted undetectable in 10 (11%), 14 (16%) and 38 (43%) patients at T1, T2 and T3 respectively. Five patients (8.7%), instead, had worsening of symptoms at T3. Among patients with B-NHL, 5 patients had disease progression and 2 of them died during follow-up because of haematological complications, 39 (54.9%) had or stayed in complete remission at T2, while the others had partial haematological regression or disease stability.

Conclusion: HCV eradication with DAAs is safe in patients with MCs and/or B-NHL, and it is associated with clinical improvement and haematological response or stability. Data collection is still ongoing in order to evaluate longer term outcomes.

THU-170

Analysis of mortality rate in the patients after hepatitis C virus elimination using direct acting antivirals and comparison with the general population

Satoshi Miuma[1], Hisamitsu Miyaaki[1], Naota Taura[1], Yasuhiko Nakao[1], Masanori Fukushima[1], Ryu Sasaki[1], Tatsuki Ichikawa[2], Kazuhiko Nakao[1]. *[1]Nagasaki university hospital, Department of Gastroenterology and Hepatology, Japan; [2]Nagasaki Harbor Medical Center, Department of Gastroenterology, Japan*

Email: miuma1002@gmail.com

Background and aims: Direct acting antivirals (DAAs) therapy has enabled the achievement of sustained virologic response (SVR) in many patients with chronic hepatitis C and cirrhosis (post-SVR patients). There have been many studies on the outcomes of post-SVR patients treated with interferon (IFN)-based therapy. However, the outcomes of post-SVR patients treated with DAAs therapy may be different, because patients may be intolerant and refractory to IFN-based therapy, such as older patients and those with liver cirrhosis. In this study, we analyzed the mortality rate and cause of death in post-

Figure 1. Evolution of lymphoma after HCV eradication during the follow up.

Figure: (abstract: THU-169).

SVR patients treated with DAAs therapy. Additionally, the mortality rates were compared with those of the general population.
Method: This was a multicenter retrospective cohort study. A total of 1,682 patients were introduced to DAAs therapy at 15 institutions between September 2014 and December 2020. After excluding those with non-SVR, decompensated liver cirrhosis, previous hepatocellular carcinoma (HCC) treatment history, liver transplantation, and loss to follow-up, 1,298 post-SVR patients were enrolled in this study. The mortality rate after SVR was examined, and the factors contributing to unfavorable outcomes were analyzed using the Cox proportional hazard model. The mortality rates between post-SVR patients and the general population were compared by calculating the standardized mortality ratio (SMR) adjusted for age and sex (referring to the Population Survey Report vital statistics in 2020, reported by the Minister of Health, Labour and Welfare in Japan).
Results: The median age of study participants at DAAs induction was 68 years (555 males and 743 females), and the proportion of patients with cirrhosis was 17.8%. The mortality rate was 12.8 per 1,000 person-years (3-year survival rate, 96.4%; 5-year survival rate, 93.5%). Forty-nine post-SVR patients died during the observation period. Among these, non-liver-related deaths were the most predominant, accounting for 71.4% (35/49), of which malignant neoplasms accounted for the highest proportion of deaths (57.1%, 20/35). The Cox proportional hazards analysis showed that old age was the only factor at DAAs induction contributing to unfavorable outcomes in post-SVR patients (risk ratio = 1.095, p <0.001). Compared with the general population adjusted for sex and age, the SMR for overall mortality in post-SVR patients was 92.8. Additionally, the SMR for malignant neoplasm mortality in post-SVR patients was 118.6; however, the SMR for malignant neoplasm mortality other than HCC was 103.6. These results suggest that the overall mortality rate is lower in post-SVR patients than in the general population and that the malignant neoplasm mortality rate is almost the same between them.
Conclusion: In this study, we found that outcomes of post-SVR patients were favorable, affected only by old age, and were better than those of the general population. Although malignant neoplasms resulted in the highest proportion of non-liver-related deaths, the comparison of mortality rates adjusted for sex and age showed that the malignant neoplasm mortality in post-SVR patients was almost equal to that of the general population.

Email: alvarohr90@gmail.com

Background and aims: Direct-acting antivirals (DAAs) have changed the natural history of disease in patients with compensated HCV cirrhosis. However, we do not know the long-term impact on liver function and survival in patients with decompensated cirrhosis. Our aim was to evaluate the long-term benefits of DAAs in patients with cirrhosis and ascites.
Method: Observational, multicentre and retrospective study including patients with HCV cirrhosis and ascites, prior or concurrent to treatment with DAAs, who started therapy between 2014-November 2018. We assessed liver function parameters, survival and need for transplantation at 5 years of follow-up. STATA software was used for the analysis, with Cox regression for categorical variables and survival analysis using Kaplan-Meier and log-rank test.
Results: 289 patients were included, 274 (94.8%) with a history of ascites and 132 (45.7%) with ascites at baseline. Mean age was 56 years (50–66), 64% male. Liver function: 144 (49%) Child A and 128 (44%) Child B, mean MELD 11.8 (9–14). Overall survival at 5 years was 77.8%, with negative predictive factors being hypoalbuminaemia (p: 0.048) and advanced age (p: 0.001). Overall, 43 patients (15%) received a liver transplant. The 5-year transplant-free survival was 84.9%, with hyperbilirubinaemia (p: 0.000), MELD (p: 0.006) and Child-Pugh classification (p: 0.000) being negative predictors. There was a long-term reduction of 2 points in Child (p < 0.001), with improvement in bilirubin (p < 0.001) and albumin (p < 0.001).

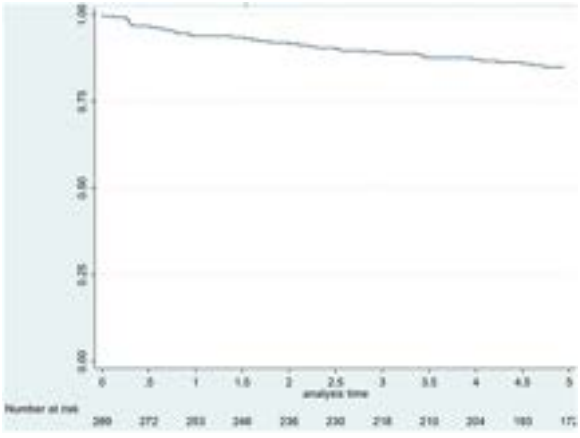

Figure: Transplant-free survival.

Conclusion: Treatment with DAA improves long-term liver function parameters even in patients with ascites, making survival at 5-year follow-up of these patients high compared to that expected based on the natural history of hepatitis C without treatment.

THU-172

HCV elimination: reengagement of previously diagnosed but unlinked patients with chronic hepatitis C to initiate treatment

Maria Guerra Veloz[1], Kate Childs[2], Teresa Bowyer[1], Kathryn Oakes[1], Esra Derin[1], Claire Mannion[1], Mary D Cannon[1], Geoffrey Dusheiko[1], Kosh Agarwal[1]. [1]*King's College Hospital, Institute of Liver Studies, London, United Kingdom;* [2]*King's College Hospital, Sexual Health and HIV, United Kingdom*
Email: maria.guerraveloz@nhs.net

Background and aims: Hepatitis C elimination requires multiple complex approaches in groups with high-risk factors. Identifying patients with known chronic hepatitis C virus (HCV) infection who have not engaged with the health care system and not been successfully cured has proved to be an effective strategy in many different countries. *The aim of this project was to identify viraemic HCV-infected patients who have been lost in the HCV test and treat care cascade in South-East London, and link them to care.*

Method: All laboratory-positive HCV RNA tests from 2010 to 2020, (but with undocumented SVR status in either the National Hepatitis C registry or the local Kings College Hospital viral hepatitis laboratory data) were included. *In the first phase, each HCV RNA test result was linked with national primary care medical records or with the relevant local London hospital record in order to identify whether or not the HCV care cascade was completed.* In the second phase, subjects who remained without known SVR status were contacted by telephone a maximum of 5 times on different days/months (with voicemails being left) before being sent an appointment reminder by post when contact by telephone was unsuccessful. Subjects were referred to a one-stop clinic at King's, their local viral hepatitis team, or their local outreach service, according to the subject's preference and address. After treatment, an SVR was confirmed 12 weeks after the end of the treatment.

Results: 1,254 HCV RNA-positive tests (from viremic patients) with unknown SVR status were included. After reviewing their medical records, 446 subject had not completed the HCV care cascade, and so were eligible for recall. 192/446 individuals were located and 86% (166/192) accepted relevant information and were linked with medical care. 108/166 (65%) initiated direct acting antiviral treatment; 96/108 (89%) completed treatment and 40/96 (42%) attended a post treatment appointment to confirm a SVR. At the end of the project SVR was achieved in 26/40, i.e. 65% of those who attended the SVR appointment or 24% (26/108) of those who initiated treatment (Figure 1).

Conclusion: This simple administrative exercise identified 1,254 HCV viraemic patients and used staff resources already present within the team. Large-scale testing projects are logistically challenging but seldom identify more than a small number of viraemic patients whereas our project proved to be more effective as it identified over 30% of viraemic patients who were previously tested but not linked with treatment. Initiation and treatment completion were high in this project however, there is still a high proportion of non-attendance to confirm HCV cure. This could mean that the treatment initiation rate could be a sensible goal in populations who it is difficult to engage with the system.

Acknowledgements: the authors want to thank the multidisciplinary team involved in this project especially the administrative team, data manager and viral clinical nurse specialists at Kings College Hospital for all of their assistance and efforts to enable the project to be concluded in an efficient manner.

Email: roshni.singh@bmc.org

Background and aims: In 2020, the US Preventative Services Task Force (USPSTF) and the US Centers for Disease Control and Prevention (CDC) recommended screening all asymptomatic adults, including pregnant persons, for hepatitis C virus (HCV) at least once in their lifetime (by CDC guidelines, only if local HCV prevalence is ≥0.1% and also during each pregnancy). Yet few studies describe changes in HCV screening since these recommendations, which occurred at the onset of the COVID-19 pandemic. This study aims to compare HCV screening occurring in women with and without a recent pregnancy, before and after the 2020 CDC/USPSTF guidelines.

Method: Using TriNetX, a national electronic medical records database, we calculated HCV screening rates from 2014 to 2022 in 6-month intervals for females of reproductive age (15–44 years old) with and without an encounter for a delivery (ICD10 codes O80-O82) over the study. We counted one HCV antibody test per women, and censored follow-up at the time of the first HCV screening. We compared the change in HCV screening rates between the two groups before and after the universal screening guidelines using a difference-in-differences model with a 6-month washout period (January-June 2020) to account for the onset of the COVID-19 pandemic and publication and dissemination of the revised guidelines. We used year fixed effects and robust standard errors.

Results: Of 17,799,141 females 15–44 years old with a visit at a TriNetX US Collaborative Network health care organization between 2014 and 2022, 704,929 had an encounter for a delivery during that period. The HCV screening rate increased for all women over the study period, but more steeply for those with a recent delivery: from 7.3 screens/1000 person years (PY) in 2014 to 126 screens/1000 PY in 2022 for women without a delivery and from 22.7 to 237 screens/1000 PY for women with a delivery. After the 2020 guidelines, women with a delivery had a 59% increase in HCV screening rate compared to those without a delivery (95% CI 31–88%, $p < 0.001$; Figure).

Conclusion: Despite interruptions of the COVID-19 pandemic, HCV testing has increased among reproductive age women since the 2020 CDC/USPSTF universal screening recommendations, with a significantly higher increase among women experiencing a recent delivery. These data highlight that pregnancy is a valuable time to capture individuals for healthcare interventions and suggest that perinatal care could be a key venue to test and treat to achieve national HCV elimination goals

THU-174

The impact of HCV cure on glycemic indices in patients using glecaprevir/pibrentasvir from nationwide Taiwan HCV registry

Background and aims: Hepatitis C virus (HCV) infection impairs insulin signalling and increases the risk of type 2 diabetes mellitus (T2DM). Several studies have shown that the benefits of HCV cure using direct-acting antivirals (DAAs) might improve glycemic indices in chronic hepatitis C (CHC) patients. To further validate the data in the real-world setting, this study aimed to measure the effect of HCV cure by glecaprevir/pibrentasvir (G/P) on glucose parameters in diabetes and non-diabetes patients between baseline and at the time of assessment of sustained virological response at 12 weeks (SVR12) after end of treatment in TASL HCV Registry (TACR).

Method: The TACR is an ongoing nationwide registry program organized and supervised by Taiwan Association for the Study of the Liver (TASL), which aims to setup a database and biobank of patients with CHC in Taiwan. Data was analyzed as of 30 September 2022 for CHC patients treated with G/P. The definition of diabetes are patients documented with diabetes and treated with oral hypoglycemic agents and/or insulin or fulfilled the criteria of fasting plasma glucose (FPG) ≥126 (mg/dl) or glycosylated hemoglobin A1C (HbA1c) >6.5%. In this analysis, the laboratory changes for diabetes and non-diabetes patients, including glycemic and liver-related parameters, which were measured in diabetes and non-diabetes patients between baseline and at SVR12 are presented.

Results: Of the 7,520 patients achieving SVR with G/P, 1,171 were diabetes patients and 6,349 were non-diabetes patients. Overall, the HbA1c (N = 1,473, 6.0 ± 1.3 vs 5.9 ± 1.0, p <0.001) demonstrated a significant decrease at SVR12 compared to their baseline level. However, the FPG (N = 1,375, 112.0 ± 39.6 vs 112.2 ± 40.3, p = 0.461) did not show the significance. For diabetes patients, the HbA1c (N = 582, 7.4 ± 1.7% vs 7.0 ± 1.3%, p <0.001) and FPG (N = 513, 148.7 ± 66.7 mg/dL vs 141.0 ± 59.0 mg/dL, p = 0.017) at SVR12 decreased significantly compared to their baseline level. For non-diabetes patients, the HbA1c (N = 1,806, 5.6 ± 0.7% vs 5.5 ± 0.5%, p = 0.005) at SVR12 showed a significant improvement compared to their baseline level. However, the FPG did not change significantly (N = 1,713, 100.1

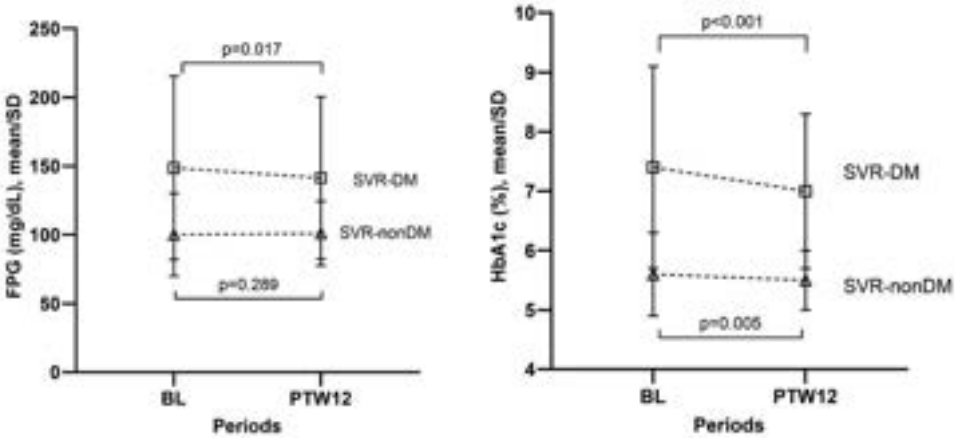

Figure: (abstract: THU-174): Changes in glycemic parameters FPG, HbA1c at baseline (BL) and post-treatment follow-up at week 12 (PTW12) in all SVR, SVR-DM and SVR-nonDM patients using G/P.

± 30.1 mg/dL vs 101.0 ± 23.4 mg/dL, p = 0.289). The other laboratory data, including AST, ALT, Albumin, Platelet counts, FIB-4, GGT, and creatinine, showed a significant improvement after HCV cure compared to baseline for diabetes and non-diabetes patients.
Conclusion: In this real-world cohort, HCV cure by G/P therapy significantly improved short-term glycemic control in Taiwanese CHC patients.

THU-175
Predicting vertical transmission of hepatitis C in pregnant women using a composite score: a multicenter study
Paul Wasuwanich[1], Joshua So[1], Brett Presnell[2], Robert Egerman[3], Tony Wen[3], Wikrom Karnsakul[4]. [1]*University of Florida College of Medicine, Gainesville, United States;* [2]*University of Florida, Department of Statistics, Gainesville, United States;* [3]*University of Florida College of Medicine, Division of Maternal-Fetal Medicine, Department of Obstetrics and Gynecology, Gainesville, United States;* [4]*The Johns Hopkins University School of Medicine, Division of Pediatric Gastroenterology, Hepatology, and Nutrition, Department of Pediatrics, Baltimore, United States*
Email: p.wasuwanich@ufl.edu

Background and aims: Prevention of vertical transmission of hepatitis C virus (HCV) presents an obstetric challenge. We aimed to create a composite score to accurately isolate a population of pregnant women with HCV who will have a high rate of vertical transmission.
Method: In a retrospective, multicenter, cohort study, we identified pregnant women with hepatitis C with linked data to their infants who have had HCV RNA or HCV antibody testing. Demographic data including age and race/ethnicity as well as clinical and laboratory data including tobacco/alcohol history, infection history, liver function tests, HCV RNA titer, HCV antibody, HCV genotype, absolute lymphocyte count, and platelet count were collected. Data were analyzed by logistic regression and receiver operating characteristic (ROC).
Results: We identified 157 pregnant women and 163 corresponding infants. The median maternal delivery age was 29 (IQR: 25–33) years, and the majority (141, or 89.8%) were White. Higher HCV RNA titer (OR = 5.18; 95 CI = 1.95–17.00; p < 0.001), higher absolute lymphocyte count (OR = 3.74; 95% CI = 1.24–12.70; p = 0.020), and higher platelet count (OR = 2.42; 95% CI = 1.07–5.70; p = 0.034) were associated with vertical transmission. Alcohol or tobacco use during pregnancy, diabetes, high BMI, vaginal bleeding, placental previa, history of abnormal pap smear, history of chlamydia/gonorrhea infection, previous cesarean section, ABO blood type, Rh type, white blood cell count, absolute monocyte count, albumin, alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, total bilirubin, direct bilirubin, HCV genotype, hepatitis B virus infection, HIV infection, and herpes simplex infection were not associated with HCV vertical transmission (p > 0.05). A composite score combining the three significant risk factors had an AUROC of 0.902 (95% CI = 0.840–0.964), superior to any of the three risk factors individually. The sensitivity, specificity, and positive predictive value, and negative predictive value were 100.0%, 85.24%, and 40.9%, and 100.0% respectively.
Conclusion: A composite score combining risk factors HCV vertical transmission can isolate a population of pregnant women where the rate of vertical transmission is high, allowing for potential interventions during antepartum or intrapartum care. The risk-benefit analysis of using antiviral treatment during pregnancy could be determined in selective group of pregnant women with higher probabilities of transmitting HCV to the fetus. Further investigation with larger cohort will be needed to refine the composite score and validate its components.

THU-176
Achieving hepatitis C micro-eliminating in 4 female prisons through a nurse led test and treat approach of pathway optimisation and whole prison testing
Nichola Royal[1], Arran Ludlow-Rhodes[1], Julie Henderson[1], Rob Cheetham[1], Julia Sheehan[2], Andrew Milner[3], Louise Missen[3], Andrew Jones[3]. [1]*Practice Plus Group, Health In Justice, Reading, United Kingdom;* [2]*Hepatitis C Trust, London, United Kingdom;* [3]*Gilead Sciences Ltd, Medical, London, United Kingdom*
Email: andy.jones@gilead.com

Background and aims: Drug dependence among incarcerated women has been found to be higher than men which correlates to the higher HCV prevalence observed in female prisons. Women only represent approximately 5% of the prison population in England and Wales but research shows they typically enter prison with more acute mental health and substance misuse profiles requiring services to be adapted to their needs. Prisons are an important setting for National Health Service England's plans to eliminate Hepatitis C (HCV) in England by 2025, both in terms of diagnosis and treatment and in understanding prevalence.
Method: In May 2019, a partnership between Gilead Sciences, Practice Plus Group (PPG) and the Hepatitis C Trust (HCT) was formed with the aim of eliminating HCV by 2024 in PPG prisons. This partnership included 4 female prisons where the healthcare was provided by PPG. Regional BBV Lead Nurses, Gilead Medical Scientists and HCT peers worked with prison and HCV stakeholders to optimise test and treat pathways for new prison admissions. HCT peers engaged with staff and residents with the aim of raising awareness and reducing stigma. In the first quarter of 2020, whole prison HCV Intensive Test and Treat events (HITTs) were run in in all 4 prisons to ensure testing of residents who were incarcerated before these optimisations were implemented.
Results: In January 2019, 24% of women were screened for HCV within the first 7 days of admission compared to 91% in December 2022, a 279% increase. HITTs were run in February and March of 2020 where 1,096 (98.3%) of the total 1,115 population were tested, with 37 residents being diagnosed as HCV RNA+ and 34 being initiated on DAA therapy. In the final 3 months of 2022, the network of prisons achieved the micro-elimination target of ≥95% of residents having been tested in the previous 12 months and ≥90%of diagnosed patients having been initiated on treatment with results being 95% and 97% respectively.
RNA prevalence observed in new prison admissions has reduced from 9.1% in quarter 1 of 2019 to 3.5% in quarter 2 of 2022 (figure 1), a 62% reduction despite antibody rates increasing from 12.6% to 14.6 from 2019 to 2022.
Conclusion: Test and treatment optimisation in combination with whole prisons testing has demonstrated that it is feasible to effectively micro-eliminate HCV in this high-risk population. The

Table: (abstract: THU-175): (abstract: THU-175): AUROC with sensitivity and specificity of significant risk factors for hepatitis C vertical transmission and the resulting composite score.

Scoring System	AUROC Curve (95% CI)	Standard Error	Optimized Cutoff	Sensitivity	Specificity
HCV Titer (Log IU/ml)	0.815 (0.730–0.899)	0.043	≥6.05	100.0%	59.1%
Lymphocyte Absolute (10^3/ml)	0.688 (0.530–0.845)	0.080	≥1.86	88.9%	46.6%
Platelet (10^3/ml)	0.709 (0.570–0.849)	0.071	≥235	91.7%	49.0%
Composite Score	0.902 (0.840–0.964)	0.032	≥12.91	100.0%	85.2%

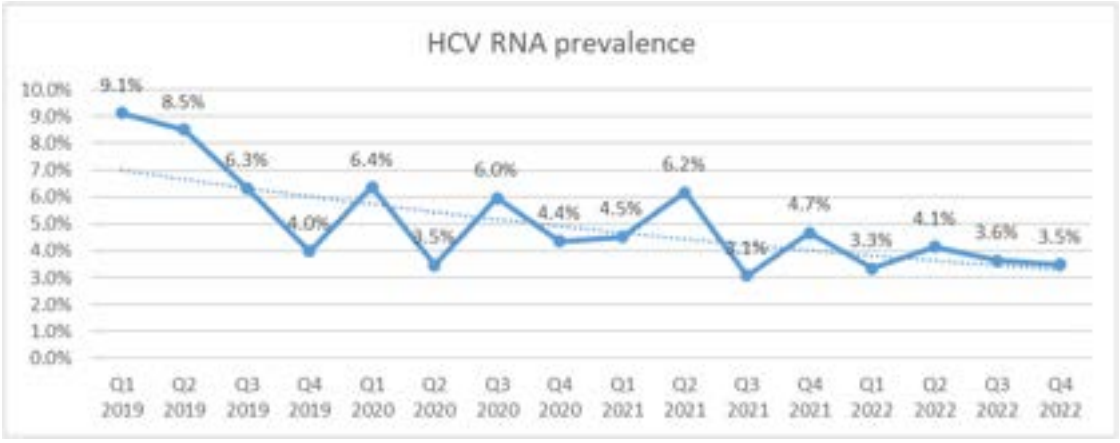

Figure: (abstract: THU-176).

62% reduction in HCV RNA prevalence also demonstrates the effectiveness of England's elimination strategy of optimising HCV services such as those in drug treatment services and prisons.

THU-177

Post-treatment liver function, but not baseline liver function, predicts survival in hepatitis C virus patients with decompensated cirrhosis after direct-acting antiviral treatment

Yuki Tahata[1], Hayato Hikita[1], Satoshi Mochida[2], Nobuyuki Enomoto[3], Akio Ido[4], Hidekatsu Kuroda[5], Daiki Miki[6], Masayuki Kurosaki[7], Yoichi Hiasa[8], Ryotaro Sakamori[1], Norifumi Kawada[9], Taro Yamashita[10], Goki Suda[11], Hiroshi Yatsuhashi[12], Hitoshi Yoshiji[13], Naoya Kato[14], Taro Takami[15], Kazuhiko Nakao[16], Kentaro Matsuura[17], Yasuhiro Asahina[18], Yoshito Itoh[19], Ryosuke Tateishi[20], Yasunari Nakamoto[21], Eiji Kakazu[22], Shuji Terai[23], Masahito Shimizu[24], Yoshiyuki Ueno[25], Norio Akuta[26], Takahiro Kodama[1], Tomohide Tatsumi[1], Tomomi Yamada[27], Tetsuo Takehara[1]. *[1]Osaka University Graduate School of Medicine, Japan; [2]Saitama Medical University, Japan; [3]University of Yamanashi, Japan; [4]Kagoshima University Graduate School, Japan; [5]Iwate Medical University, Japan; [6]Hiroshima University, Japan; [7]Musashino Red Cross Hospital, Japan; [8]Ehime University Graduate School of Medicine, Japan; [9]Osaka Metropolitan University, Japan; [10]Kanazawa University, Japan; [11]Hokkaido University, Japan; [12]National Hospital Organization Nagasaki Medical Center, Japan; [13]Nara Medical University, Japan; [14]Chiba University Graduate School of Medicine, Japan; [15]Yamaguchi University Graduate School of Medicine, Japan; [16]Nagasaki University Hospital, Japan; [17]Nagoya City University Graduate School of Medical Sciences, Japan; [18]Tokyo Medical and Dental University, Japan; [19]Kyoto Prefectural University of Medicine, Japan; [20]The University of Tokyo, Japan; [21]University of Fukui, Japan; [22]National Center for Global Health and Medicine, Japan; [23]Niigata University, Japan; [24]Gifu University Graduate School of Medicine, Japan; [25]Yamagata University Faculty of Medicine, Japan; [26]Toranomon Hospital, Japan; [27]Osaka University Hospital, Japan*
Email: yuki.tahata@gh.med.osaka-u.ac.jp

Background and aims: Direct-acting antiviral (DAA) treatment has enabled SVR rates of around 90% in patients with hepatitis C virus (HCV)-related decompensated cirrhosis. However, the factors associated with survival after DAA treatment in patients with decompensated cirrhosis are unclear.

Method: A total of 206 patients with HCV-related decompensated cirrhosis who started DAA treatment between February 2019 and December 2021 at 31 Japanese hospitals was enrolled. Decompensated cirrhosis was defined as Child-Pugh (CP) class B or C or CP class A with previous decompensating events. SVR was defined as undetectable serum HCV-RNA at 12 or 24 weeks after the end of treatment (EOT). We examined the factors associated with liver transplantation (LT)-free survival after DAA treatment in patients with decompensated cirrhosis.

Results: The median age was 68, and 52% of patients were male. The distribution of patients with CP class A, B and C was 10% (20/206), 76% (156/206) and 15% (30/206), respectively. In ITT analysis, the SVR rate was 91.3% (188/206). Six patients had a virological relapse, one had non-response, five died and six were missing. During the median observation period of 28.1 months, 26 patients died (the most common cause of death was liver failure), and two patients underwent LT. LT-free survival rates at 2 and 3 years were 90.0% and 83.2%. Next, we examined the factors associated with LT-free survival by Cox proportional hazard analyses excluding five patients who died by 12 weeks after the EOT to evaluate the impact of post-treatment liver function on LT-free survival. In these analyses, we used 2 models, including either CP class (Model 1) or MELD score (Model 2). In multivariate analysis, serum alanine aminotransferase level ($p = 0.046$), serum creatinine level ($p = 0.003$) and CP class at 12 weeks after the EOT ($p = 0.001$) in Model 1, the presence of hepatic encephalopathy ($p = 0.014$) and MELD score at 12 weeks after the EOT ($p = 0.007$) in Model 2 were identified as significant factors. In these analyses, baseline CP class and MELD score were not significant factors. LT-free survival rates at 3 years were 91.0%, 86.4% and 51.8% in patients with CP class A ($n = 76$), CP class B ($n = 97$) and CP class C ($n = 18$) at 12 weeks after the EOT, respectively. The LT-free survival rates of patients with CP class C at 12 weeks after the EOT were significantly lower than the other two groups. On the other hand, the LT-free survival rate of patients with CP class C at baseline was not significantly lower than the other two groups, whether analyzed with or without the patients who died before 12 weeks after the EOT.

Conclusion: In patients with decompensated cirrhosis treated with DAA, post-treatment liver function but not baseline liver function were predictors for survival.

THU-178

Network transmission of hepatitis C genotype 2c and 4d in men who have sex with men in Cape Town, South Africa

Mark Sonderup[1], Ziyaad Valley-Omar[2], Heidi Smuts[2], Stephen Korsman[2], Diana Hardie[2], Wendy Spearman[1]. [1]*University of Cape Town Faculty of Health Sciences, Division of Hepatology, Cape Town, South Africa;* [2]*University of Cape Town Faculty of Health Sciences and NHLS, Division of Medical Virology, Cape Town, South Africa*
Email: msonderup@samedical.co.za

Background and aims: Men who have sex with men (MSM) are at risk for sexual transmission of hepatitis C virus (HCV). Concomitant HIV infection enhances this risk. Network HCV transmission has been reported in Europe, Canada and more recently, Mexico. South Africa is an HCV pan-genotypic region, with genotype (GT) 1 and 5 dominant, followed by GT, 3, 4 and 2, though GT 2c and 4d are infrequent subtypes. We observed a pattern of mostly MSM with HCV 2c or 4d subtype infection presenting for HCV care and investigated for possible HCV network transmission.
Method: All clinical and demographic data of those with the 2 HCV subtypes, and self-identified as MSM, were captured. HCV genotype was determined by sequencing the NS5B gene. Nested NS5B amplification was performed using pan-genotypic primers and sequenced directly with the BigDye terminator cycle. Genotype assignment used the *geno2pheno* algorithm and aligned with reference sequences from the GenBank database using BioEdit version 7.2.5. Phylogenetic trees were constructed in MEGA 6.06 using the maximum-likelihood algorithm with 1000 bootstrap re-samplings to evaluate phylogenetic relatedness within HCV 2c and HCV 4d clusters.
Results: 30 patients, n = 16 GT 2c and n = 14 GT 4d, were evaluated. Median overall age was 50 years [IQR 41–54], with no significant difference in age between GT 2c (52 years) and 4d (47 years) patients, p = 0.08. 73% (n = 22) were HIV infected, with 3% (n = 3) previously or currently having used injecting drugs. All noted casual sex partners and 43% (n = 13) confirmed recreational, non-injecting drug use during sex. Overall, median baseline HCV viral load was 6.2 [IQR 5.4–6.6] $\log_{10}$ IU/ml; baseline ALT was 71 U/L [IQR 60–153]. 50% had F1, 44% F2 and 6% F3 fibrosis. All HIV positive patients were virally suppressed and 90% (n = 27) have completed HCV treatment: 38% (n = 10 with SOF/Daclatasvir), 33% (n = 5 with SOF/Ribavirin); 19% (n = 9 with SOF/Ledipasvir) and 10% (n = 3 with SOF/Velpatasvir), with a 100% SVR rate. Maximum-likelihood trees (fig. 1) support the phylogenetic relatedness within the GT 2c and 4d clusters.
Conclusion: Demonstrated for the first time in South Africa, phylogenetic analysis strongly suggests a network transmission of 2 HCV GT subtypes in MSM in Cape Town. This data emphasizes the need for an important policy focus in the local viral hepatitis strategy for a micro-elimination, targeted education, prevention, and treatment program within this key population. Treatment outcomes to date are excellent.

THU-179

Direct-acting antivirals reduce disease burden in patients with chronic hepatitis C: a Korean nationwide, multicentre, retrospective cohort study

Won Sohn[1], Sang Hoon Ahn[2], Young Seok Kim[3], Seung Up Kim[2]. [1]*Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Korea, Rep. of South;* [2]*Severance Hospital, Yonsei University College of Medicine, Korea, Rep. of South;* [3]*Soonchunhyang University, Bucheon Hospital, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: Direct-acting antivirals (DAAs) improve the prognosis of patients with chronic hepatitis C (CHC). This study investigated whether DAA treatment improves the disease burden by ameliorating the fibrotic burden in CHC patients.
Method: A nationwide, multicentre, retrospective cohort study was conducted that included patients with CHC recruited from 29 tertiary academic institutes in South Korea. The primary outcome was disease burden, assessed using the measure disability-adjusted life years (DALYs), with age weighting and discounting in untreated and DAA-

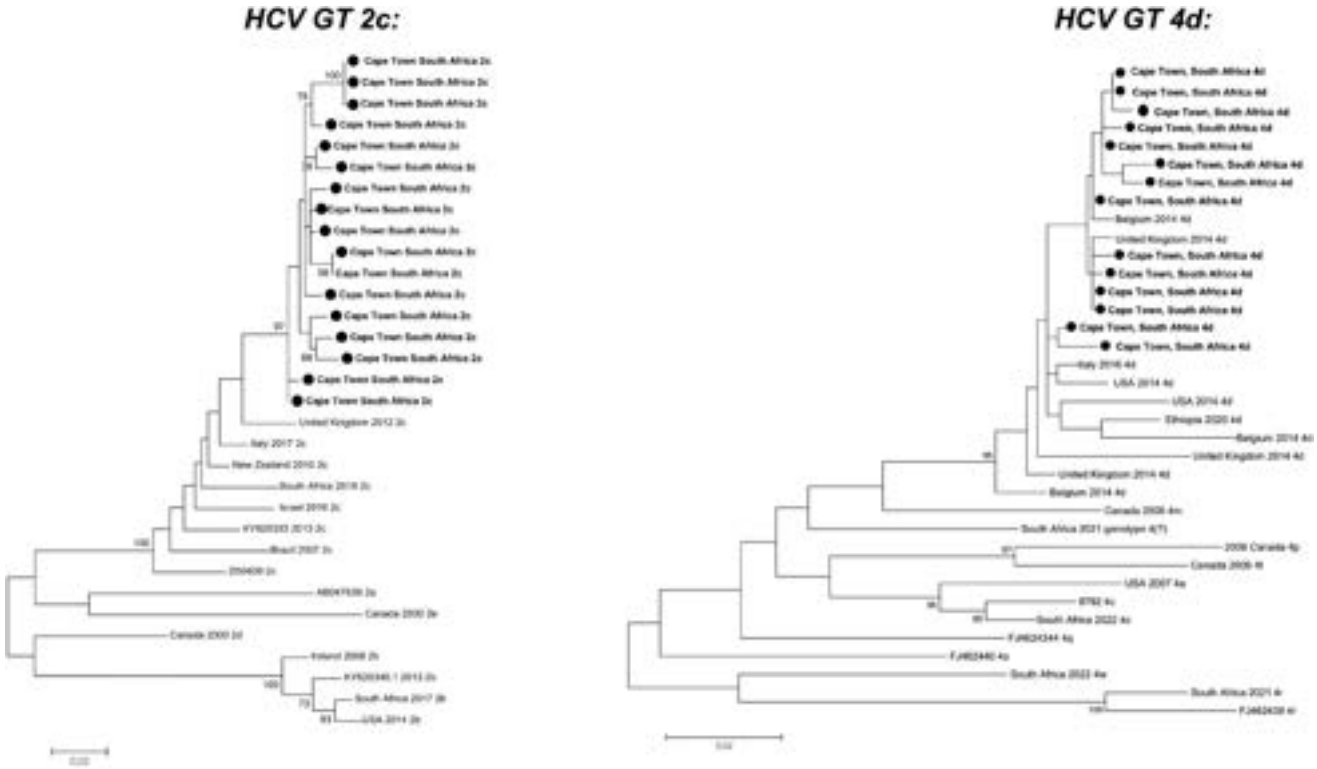

Figure 1: (abstract: THU-178).

treated groups. Improvement of fibrotic burden after DAA treatment was assessed using the APRI score and FIB-4 index. The clinical outcomes were hepatocellular carcinoma, liver transplantation, decompensation, or death.

Results: Between January 2007 and December 2022, data from 11,726 patients with CHC, including 8,464 (72%) treated with DAAs, were analysed. During the follow-up period (median 27.5 months), 469 patients died (353 [10.8%] in the untreated group, 116 [1.4%] in the DAA-treated group), 586 developed hepatocellular carcinoma (343 [10.5%] in the untreated group, 243 [2.9%] in the DAA-treated group), 580 developed decompensation (372 [11.4%] in the untreated group, 208 [2.5%] in the DAA-treated group), and 18 underwent liver transplantation (8 [0.2%] in the untreated group, 10 [0.1%] in the DAA-treated group). The multivariable analyses showed that DAA-treated group significantly reduced mortality, HCC risk, and decompensation development compared to the untreated group (hazard ratio [HR] = 0.22, 95% confidence interval [CI] 0.17–0.27; HR = 0.47, 95% CI 0.39–0.58; and HR = 0.31, 95% CI 0.26–0.37, respectively) (all $p < 0.001$). The APRI-based DALY estimate was significantly lower in the DAA-treated group than in the untreated group (mean 5.0 ± 2.9 vs. 5.9 ± 3.8 years, $p < 0.001$), as was the FIB-4-based DAL estimate (mean 5.7 ± 2.7 vs. 6.3 ± 3.5 years, $p < 0.001$). The difference between the two groups with respect to either the APRI- or FIB-4-based DALYs was highest in patients 40–60 years of age.

Conclusion: DAA treatment significantly improved the clinical outcomes of CHC patients and reduced the disease burden, by improving the fibrotic burden after DAA treatment.

THU-180

Hepatitis C micro-elimination program in Zhuhai: a concerted citywide effort to eliminate hepatitis C by 2030

Jinyu Xia[1], Zhongsi Hong[1], Xinchun Zheng[1], Xiaoyan Ye[1], Mengdang Ou[1], Ying Li[1]. [1]*The Fifth Affiliated Hospital of Sun Yat-Sen University, China*
Email: xiajinyu@mail.sysu.edu.cn

Background and aims: To support the World Health Organization's goal of eliminating hepatitis C by 2030, we established a collaborative model called "Lucky Star Program" (LSP) in Zhuhai, Guangdong Province in China and evaluated its effectiveness in screening, treatment and follow-up for HCV infection.

Method: Under the leadership of the Zhuhai Infectious Disease Medical Quality Control Center (ZMQCC), We provide an import platform in bridging the gap between the government, different-level hospitals and communities, a homogeneous mode of Hepatitis C micro-elimination–LSP. ZMQCC is responsible for training and patient network management. Designated hospitals and community hospitals are responsible for HCV antibody (HCV-Ab) screening and activate cascade referral system when necessary. Patients with HCV-Ab positive are referred to a designated hospital for HCV RNA testing, where the positive patients receive standard treatment. We have dedicated staff to supervise and use unique referral QR codes citywide to make the process uniform and minimize patient attrition. Meanwhile, KPI evaluation will be conducted for hepatitis C management in designated hospitals to facilitate the implementation of the program.

Results: LSP kicked off in May 2021. 96,035 in-patients before LSP (from December 2019 to May 2021) and 39,502 in-patients after LSP with dedicated staff (from May 2022 to December 2022) were screened in the Fifth Affiliated Hospital of Sun Yat-Sen University. The seropositive rate of HCV-Ab was 0.43% (410/96,035) before LSP and 0.70% (275/39,502) after LSP, the HCV RNA positive rate were 50% (122/244) before LSP and 86.3% (226/262) after LSP in hospital population. The treatment rate of patients with HCV RNA positive increased from 32.0% (39/122) to 88.1% (199/226) since set up dedicated staff to supervise the whole process. During 2022, 1,175 patients with HIV infection, 36 patients from methadone clinic and 1,571 people from community were screened, the seropositive rate of HCV-Ab were 2.64% (31/1,175), 94.4% (34/36) and 1.02% (16/1,571), the HCV RNA positive rate were 100% (31/31), 52.9% (18/34) and 62.5% (10/16), the DAA treatment rate were 93.5% (29/31), 55.6% (10/18), 80% (8/10) in the HIV-infected, methadone clinic and community population, respectively. SVR12 was greater than 97.0% in all patients with SOF/VEL.

Conclusion: Zhuhai's LSP has already achieved its initial objectives. The successful experience of the pilot hospital should be extended to other designated hospitals citywide. It could improve treatment rates for CHC through focusing on key populations and enhancing follow-up both in the hospitals and in the community.

Email: cornberg.markus@mh-hannover.de

Background and aims: Globally, 58 million people are infected with hepatitis C virus (HCV) many of whom have comorbidities such as injection drug use. Some HCV-infected patients may be motivated by benefits beyond virologic cure; insights into patient-reported outcomes associated with treatment may help efforts to improve linkage to care. This study used data from the German Hepatitis C registry (DHC-R) to evaluate the real-world effect of glecaprevir/pibrentasvir (G/P) on quality of life (QoL) 1-year posttreatment.

Method: The DHC-R is an ongoing, prospective, observational cohort study of patients being treated for chronic HCV infection. Patients were recruited from 159 sites between August 2, 2017, and February 10, 2021, the data cut off for this analysis was November 17, 2021. Patients had HCV genotype (GT) 1–6 and were treated with on-label G/P. Mean short-form 36 health survey questionnaire (SF-36) scores at baseline (BL), posttreatment Week 12 (PTW12) and 1-year posttreatment were reported. Patients achieving sustained virologic response at PTW12 (SVR12), safety and tolerability were also assessed.

Results: The analysis included 2727 patients. Most were treatment-naïve (91.2%) and noncirrhotic (85.4%). Reported BL comorbidities included opioid substitution therapy (OST; 27.0%), active drug use (6.3%), psychiatric disorders (13.1%), alcohol abuse (8.5%) and HIV coinfection (6.0%). In patients with valid BL, PTW12 and 1-year posttreatment data (n = 119), mean SF-36 physical component score (PCS) and mental component scores (MCS) were improved and maintained in the overall population. Similar improvements were observed for all patient populations, excluding those with alcohol abuse (PCS and MCS scores) and HIV coinfection (MCS score), which showed no improvement. The biggest improvement in MCS scores were seen in patients receiving OST at BL and the biggest different in PCS scores were seen in patients with psychiatric disorders and those receiving OST at BL (Figure 1). The intention to treat (ITT) SVR12 rate was 96.2% (2083/2166) and the modified ITT (mITT) rate was 99.0% (2083/2103). There were no new or unexpected safety signals.

Conclusion: On-label treatment with G/P was highly effective and well-tolerated in routine clinical practice. Improvements in patient QoL were consistent and pronounced across all comorbidities studied, particularly when related to mental components, further supporting the use of G/P in real-world patient populations.

Acknowledgments: Glecaprevir was identified by AbbVie and Enanta. Medical writing support was provided by Laura Whiteley, PhD, and Tom Owen, PhD, of Fishawack Health, funded by AbbVie.

Disclosures: AbbVie sponsored the study; contributed to its design; and participated in the collection, analysis, and interpretation of the data and in the writing, reviewing, and approval of the abstract. All authors had access to relevant data, and participated in the writing, review, and approval of the final abstract.

THU-182

What is the impact of a Hepatitis C 'test and trace' pilot using peer workers?

Caroline Allsop[1], Kate Mcque[1], Mark Roberts[2], Suzanne Murphy[2], Carrie Richardson[2], Yusri Taha[3], Stuart Mcpherson[1,4]. *[1]The Newcastle upon Tyne Hospitals NHS Foundation Trust, Liver unit, United Kingdom; [2]Hepatitis C Trust, United Kingdom; [3]The Newcastle upon Tyne Hospitals NHS Foundation Trust, Virology, United Kingdom; [4]Newcastle University, Translational and Clinical Research Institute, United Kingdom*
Email: stuart.mcpherson2@nhs.net

Background and aims: Chronic Hepatitis C virus (HCV) infection is a major cause of morbidity and deaths worldwide. HCV treating teams in England have made steady progress towards the goal of eliminating HCV by 2025. However, HCV reinfection rates are high, particularly in North-East England, suggesting a significant reservoir of untreated infections. Contact tracing, a tool successfully used to identify and treat cases in other infectious diseases, is not routine practice in HCV. Here we present the outcomes of an "HCV Test and Trace" pilot scheme.

Method: Individuals with recently acquired HCV infection or reinfection were invited to participate when they presented to our service for treatment. For those who agreed to participate, a Hepatitis C Trust peer worker approached them to invite potential contacts for HCV test using "dry blood spot." To encourage participation, incentives (vouchers for a food outlet) were given to index individuals and contacts upon HCV testing. We collected data on uptake, HCV test results, treatment rates and reasons for declining.

Results: Between April 2022 and Jan 2023 (9 months), 241 individuals were invited to participate, of whom 118 (49%) agreed. The overall interim outcomes of the pilot are summarised in Fig. 1. To date, 24 (10% of all, 20% of those agreeing) have brought forward contacts for testing. A total of 88 contacts were identified and tested, averaging 3 or more contacts per participant. Of these, 33 (38%) were HCV RNA positive indicating active HCV. Of these, 16 were new infections and 17 were known cases (7 never seen by HCV services, 10 had treatment prescribed previously, including 5 reinfections). To date, 10 have started antiviral treatment and 14 are awaiting assessment or treatment initiation. The most common reason for individuals declining participation was that they were no longer in contact with at risk individuals (65%).

Conclusion: Overall, about half of individuals with recent HCV infection or reinfection agreed to participate in a test and trace pilot scheme, but to date only 20% actually brought contacts forward. However, the frequency of active HCV among the contacts appears to be high at 38%. Work is ongoing to refine the pathway to increase uptake, and testing and treatment rate.

THU-183

Evaluation of the follow-up in patients with advanced fibrosis after achieve sustained viral response with direct-acting antivirals. Screening and risk of hepatocellular carcinoma

Belén Julian[1], Diego Casas-Deza[1,2], Silvia Espina[1,2], Luis Javier Lamuela[3], Olivia Sierra[1], Carmen Yagüe[1], Sara Lorente Perez[4,5], Trinidad Serrano[4,5], Jose M Arbones Mainar[2,6,7], Vanesa Bernal Monterde[1,2]. *[1]Miguel Servet University Hospital, Zaragoza, Spain; [2]IIS Aragon. Unidad de Investigación Clínica HUMS, Zaragoza, Spain; [3]Hospital General San Jorge, Huesca, Spain; [4]Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain; [5]IIS Aragon, Spain; [6]Instituto Aragonés de Ciencias de la Salud, Zaragoza, Spain; [7]Carlos III Health Institute, Madrid, Spain*
Email: vbernalm@gmail.com

Background and aims: The risk of developing hepatocellular carcinoma (HCC) persists in patients with hepatitis C virus (HCV) and cirrhosis who achieve sustained viral response (SVR) with direct-

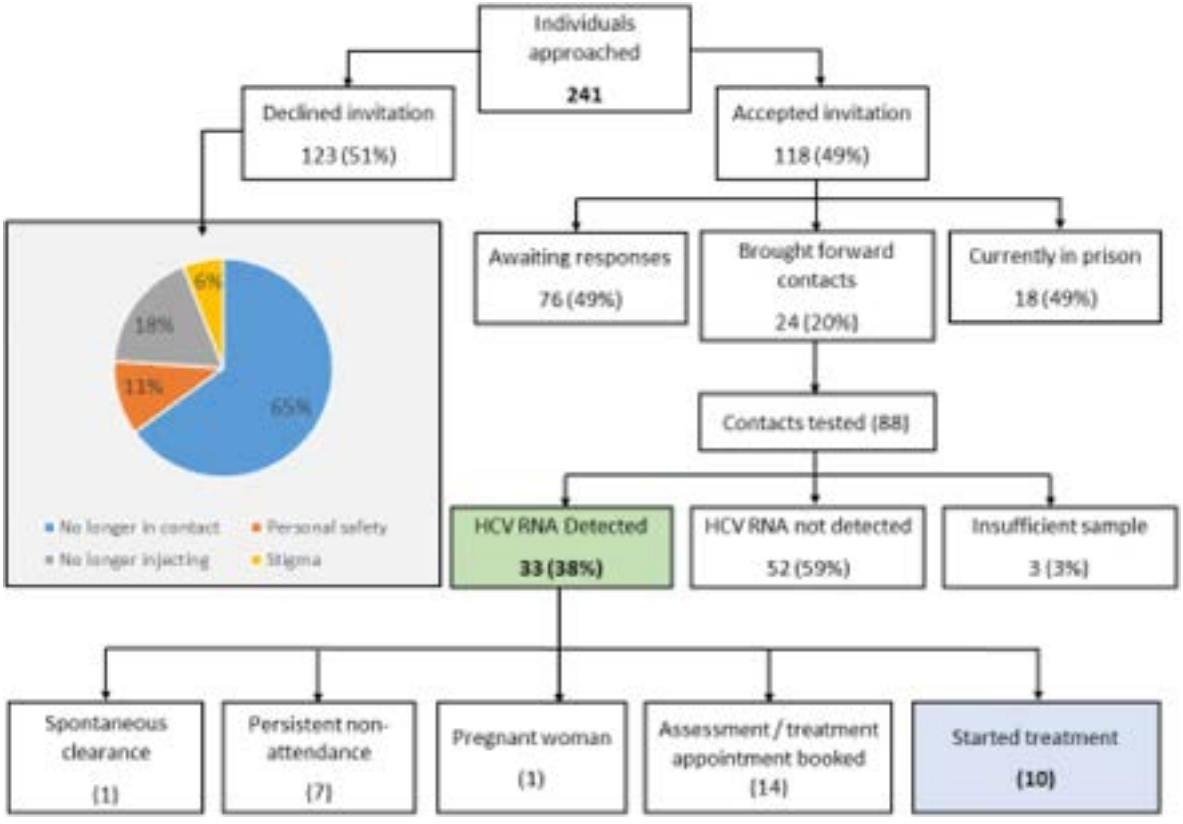

Figure: (abstract: THU-182).

acting antiviral agents (DAA). In patients with advanced fibrosis (F3) without cirrhosis the risk is not well established and the different clinical guidelines differ in their recommendations. Our objective was to describe the management and post-SVR evolution of patients with F3 in our community, as well as assessing the incidence of HCC.
Method: Retrospective multicenter study including all patients HCV monoinfected patients with advanced fibrosis without cirrhosis (Fibroscan® [TE] >9, 5 and <14, 5Kpa) who achieved SVR with AAD between November 2015 and April 2021 in the 8 Hospitals of Aragon, an autonomous community of Spain. Follow-up was carried-out until the development of HCC, death, last visit registered or January 2022. A statistical analysis was performed with the R software.
Results: A total of 258 patients (age 58 (11.6) years; 163 (63%) male) were included. Mean [TE] = 10.9 (1.26) Kpa. 39 (15%) were diabetic, 60 (23.3%) hypertensive and 20 (7.8%) affected by harmful use of alcohol. In the pre-SVR ultrasound scan, 42 (17%) presented steatosis and 32 (13.2%) non-specific alterations of the hepatic echostructure. 193 patients (74.8%) have continued HCC screening and 107 (55%) of these underwent a posterior Fibroscan® (F0-1: 27.1%, F2: 5.8%, F3: 7%, F4: 1.6%). Among the factors associated with performing HCC screening after SVR, a higher degree of fibrosis was observed by pre-SVR [TE] (10.6 vs 11.1Kpa; $p = 0.021$), the presence of steatosis (1.5% vs 21.7%, $p < 0.001$) and/or non-specific abnormalities on ultrasound (3.1% vs 38.6%; $p < 0.001$) and the prescribing service (68% Hepatology, 24% General Gastroenterology and 8% Infectious Diseases; $p < 0.001$). During the follow-up (median 53.4 months), 5 of 193 (2.59%) patients developed HCC. Only a post-SVR FIB-4 >3.25 was independently related to its appearance.
Conclusion: HCC screening of patients with F3 and HCV who achieve SVR is heterogeneous in our community, and is determined by the results of pre-SVR [TE] values, pre-SVR ultrasound scan and the prescribing service. HCC incidence is low in these patients. Evaluation of post-SVR fibrosis with the FIB-4 index can help to select for screening the patients with the highest risk.

Hepatitis C virus (HCV) infection and neurocognitive impairment in subjects with mild liver disease: the role of neuropsychological and cognitive provoked P300 tests

Marcia Maria Amendola Pires[1], Rafael Espindula[2], Jefferson Abrantes[2], Carlos Brandão-Mello[1]. [1]*Gastrointestinal and Liver Unit, Gaffrée e Güinle University Hospital, Internal Medicine, Rio de Janeiro, Brazil;* [2]*Postgraduate Program in Neurology, Department of Neurology, Neurology, Rio de Janeiro, Brazil*
Email: cedubrandao@gmail.com

Background and aims: Hepatitis C virus (HCV) infection is one of the leading causes of liver cirrhosis, hepatocellular carcinoma, and liver-related deaths. It is estimated that 40%-74% of HCV subjects will experience at least one extra-hepatic manifestation within their lifetime, including neurocognitive deficits. Cognitive changes are well documented in patients with chronic liver disease, most often as a result of decompensated liver encephalopathy. However, evidence has shown that cognitive changes can occur before the development of liver cirrhosis. Neuropsychiatric symptoms such as: "brain fog", fatigue and weakness occur in approximately 50% of patients with HCV, regardless of the severity of liver impairment. The long latency auditory evoked potential or cognitive evoked potential (P300) is an endogenous potential dependent on cognitive abilities and it can reflect the individual's functional use of the stimulus, not directly depending on his physical characteristics. The P300 component is evaluated by analysing its amplitude (microvolts (μV) and latency in milliseconds (ms). The aim of the study was to evaluate the presence of cognitive changes in HCV subjects with the P300 and neuropsychological tests with an emphasis on attention and working memory.
Method: Observational study conducted at the Liver Unit of Gaffrée e Güinle University Hospital (HUGG), from November 2019 through March 2020. All HCV-infected subjects (anti-HCV and HCV-RNA detectable) over 18 years old were considered eligible for investigation. Only HCV subjects with compensated liver disease were included. Liver fibrosis assessment by liver stiffness as well genotyping (sequencing) and HCV-RNA viral load (RT-PCR) were performed. Patients were tested in a single day with cognitive evoked potential and neuropsychological tests (random letter test, form A and B trail test, direct, reverse order digit test and code test). We excluded coinfection with HIV, HBV and syphilis; hypothyroidism or psychiatric illness; neurological diseases that affect the cognition, mainly neurodegenerative diseases; decompensated liver cirrhosis; alcoholism or use of illicit drugs; formal education less than 4 years; complete deafness and subjects over 80 years old. The mean normal value of P300 latency and amplitude was 348.2 milliseconds and 8.9 microvolts, respectively, as described by Torres, Abrantes and Brandão-Mello, 2020
Results: A total of 124 patients were analysed and 91 excluded according to exclusion criteria. Thus 33 HCV subjects (51.5% male) were enrolled. Mild liver fibrosis (F0-F2) was identified in 72.8%. Genotype was predominately 1 (72%). The neuropsychological and P300 results are displayed in table 1. Of the 33 patients with HCV, 57.6% had changes in P300 latency and 60.6% in amplitude, that is, more than 50% globally detectable changes in this complementary method. There was not significant correlation between P300 latency and amplitude and demographic and virological characteristics of HCV subjects, such as gender, education level, age, viral load and liver fibrosis.

RESULTS	HCV SUBJECTS		
	n	%	95% Confidence interval
Latency P300 (milissegundos)			
< 348,2 (normal)	14	42,4	
≥ 348,2	19	57,6	40,4% - 73,4%
Amplitude P300 (microvolts)			
> 8,9 (normal)	13	39,4	
≤ 8,9	20	60,6	43,4% - 76,0%
Random Letter (number of errors)			
0	21	63,6	
At least 1 mistake	12	36,4	21,4% - 53,6%
Trail Test A (seconds)			
≤ 46,3 (normal)	20	60,6	
> 46,3	13	39,4	23,9% - 56,6%
Trail Test B (seconds)			
≤ 135,7 (normal)	20	60,6	
> 135,7	13	39,4	23,9% - 56,6%
B/A ratio (Executive function)			
≤ 2,91 (normal)	20	60,6	
> 2,91	13	39,4	23,9% - 56,6%
Direct Order Range Scores (DOR)			
> 4 (normal)	32	97,0	
≤ 3	1	3,0	0,15% - 14,1%
Indirect Order Range Scores (IOR)			
> 4 (normal)	15	45,5	
≤ 3	18	54,5	37,5% - 70,8%
Difference in score (DOR- IOR)			
≤ 3 (normal)	13	39,4	
>4	20	60,6	43,4% - 76,0%
Code testing (points)			
≤ 23 (normal)	31	93,9	
> 22	2	6,1	1,0% - 18,6%

Table 1: HCV Subjects according to P300 and neuropsychological results (n=33)

Figure:

Conclusion: In conclusion, HCV subjects with mild or no fibrosis, presented cognitive deficits in more than 50% in the tests applied to assess working memory and attention. Thus, we suggest that triage for HCV-infection must be included in the list of screening tests in patients who exhibit cognitive decline.

THU-185

A prospective, pragmatic post-authorisation safety study of early recurrence of hepatocellular carcinoma in hepatitis C virus-infected patients after direct-acting antiviral (DAA) therapy: DAA-PASS

Amit Singal[1], Michael Fried[2], Massimo Colombo[3], Roniel Cabrera[4], Katie Kelley[5], Neil Mehta[5], Bruno Sangro[6]. [1]*UT Southwestern, United States;* [2]*Target RWE, United States;* [3]*Humanitas Hospital, Italy;* [4]*University of Florida, United States;* [5]*University of California San Francisco, United States;* [6]*Clinica Universidad de Navarra, Spain*
Email: bsangro@unav.es

Background and aims: Early reports of DAA therapy for chronic hepatitis C (HCV) after successful treatment of hepatocellular carcinoma (HCC) raised concerns about an increased risk of early and aggressive HCC recurrence. The European Commission recommended that DAA marketing authorisation holders should perform a prospective observational study to assess risk of early recurrence of previously treated HCC after DAA therapy.
Method: A prospective, pragmatic, multinational observational study was designed to estimate the risk of HCC recurrence, after successful treatment of early-stage HCC, associated with DAA therapy exposure during routine clinical care. Patients were eligible if they had HCV mono-infection, no prior DAA therapy, and had radiologically confirmed successful treatment for Barcelona Clinic Liver Cancer (BCLC) stage A HCC. Treatment modalities for HCC and choice/timing of DAA therapy for HCV were at the discretion of investigators. Patients were followed at regular intervals for evidence of HCC recurrence on imaging, beginning from first cross-sectional imaging study (index date) demonstrating complete response to HCC treatment for up to 24 months.
Results: The planned prospective sample size of 600 patients (n = 122 expected HCC recurrences) was not achieved due to the evolving global landscape of DAA therapy resulting in slower than expected enrollment. Of 222 patients screened, 142 were screen failures and 32 did not meet the enrollment criteria. Of the 42 patients enrolled (33 U.S., 9 Italy), median age at HCC diagnosis was 62 (IQR: 8.0) yrs with 79% male and 74% White. Nearly all (95%) had cirrhosis, with 45% with evidence of hepatic decompensation. Treatment for HCC included locoregional therapy (74%) and surgical resection (17%). Eighteen patients never received DAA therapy during follow-up. Twenty-four patients were treated with DAA therapy after index imaging showing complete response (median time from index imaging to DAA initiation = 3.1 months). Median duration of DAA exposure was 2.8 months and median follow-up from DAA initiation was 18.9 months. Ten HCC recurrence events were observed during the study, with 5 each in DAA-treated and DAA-untreated patients (cumulative incidences of 23% and 37%, respectively). The overall crude HCC recurrence rate at 24 months was 17.7 per 100 person-years (PY) with a crude hazard ratio (HR) for HCC recurrence associated with DAA therapy of 0.6 (95% CI, 0.2–2.2). The age-adjusted HR was 0.7 (95% CI, 0.2–2.3). All HCC recurrences occurred intra-hepatic and most (60%) were detected within Milan Criteria, with no differences between the two groups.
Conclusion: Although limited by small sample size, this prospective pragmatic study suggests DAA therapy is not associated with increased HCC recurrence risk among patients with a previous successfully treated HCC.

THU-186

Clinical outcomes after hepatitis C treatment in patients with advanced chronic liver disease

Fabio Correia[1], Gonçalo Alexandrino[1], Mariana Cardoso[1], Joana Branco[1], Mariana Costa[1], Rita Carvalho[1], Alexandra Martins[1]. [1]*Hospital Professor Doutor Fernando Fonseca, Portugal*
Email: fabioprcorreia@gmail.com

Background and aims: Patients with advanced chronic liver disease (ACLD) and chronic hepatitis C are at high risk of developing clinically significant portal hypertension (CSPH) and its complications. Direct-acting antivirals have radically changed the outcomes of hepatitis C treatment. However, data on the impact of cured hepatitis C on the medium-term clinical evolution of patients with ACLD has only recently emerged. We aimed to evaluate the outcomes related to hepatic decompensation, hepatocellular carcinoma (HCC) and mortality in a cohort of patients with ACLD and cured hepatitis C with sustained virological response (SVR).
Method: Prospective, single-centre study, in patients with ACLD and chronic hepatitis C with SVR, treated since February 2015 and with a minimum follow-up (FU) of 2 years. The definition of ACLD was based on liver biopsy or Baveno VII's concepts: liver stiffness measurement (LSM) >10 kPa and/or clinical/imaging elements of CSPH. During FU, hepatic decompensation (ascites, variceal bleeding, and hepatic encephalopathy) unrelated to HCC, development of HCC and mortality were recorded. In decompensated ACLD, the recompensation rate was also evaluated.
Results: We included 147 patients (78.2% male, mean age of 59 years-old). At baseline, 84% (123/147) had compensated ACLD (cACLD), 16% (24/147) had decompensated ACLD (dACLD) and none had suspicious liver nodules. Among patients with cACLD with baseline LSM evaluation (97/123), 65% (63/97) had a LSM >15 kPa. The median follow-up was 52 months. During follow-up, 13% (16/123) of cACLD patients developed complications: first decompensation in 5% (6/123) and HCC in 8% (10/123). All these 16 patients had LSM >15 kPa or clinical/imaging elements of CSPH, and the majority (14/16) had platelet count $<150 \times 10^9$. The mortality rate was 3% (4/123). In dACLD patients, we observed clinical recompensation in 21% (5/24), HCC in 17% (4/24), with a global mortality irate of 8% (2/24).
Conclusion: In this cohort of patients with ACLD and cured hepatitis C, the medium-term clinical evolution was globally favorable, with emphasis on clinical recompensation in about 25% of dACLD patients. However, HCC remains a major concern, especially in decompensated ACLD, but also in compensated patients. Adverse events occurred only in patients with pre-treatment LSM >15 kPa, the majority with platelets count $<150 \times 10^9$). These cut-offs, with an established role in ACLD stratification, could perhaps redefine follow-up surveillance in compensated patients. The impact of other cofactors, such as alcohol and obesity, in the development of complications, needs to be further evaluated.

THU-187

Mortality risk following HCV cure among people with HIV coinfection

Naveed Janjua[1,2], Stanley Wong[1], Hector Velasquez[1], Dahn Jeong[1,2], Sofia Bartlett[1,2], Mawuena Binka[1], Jean Damascene Makuza[2], Prince Adu[1,2], Maria Alvarez[1], Jason Wong, Dr.[1,2], Mel Krajden[1,3]. [1]*BC Centre for Disease Control, Vancouver, Canada;* [2]*University of British Columbia, School of Population and Public Health, Vancouver, Canada;* [3]*University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada*
Email: naveed.janjua@bccdc.ca

Background and aims: Hepatitis C (HCV)/human immuno-deficiency virus (HIV) co-infection is associated with higher morbidity and mortality compared to HCV mono-infection. Sustained virologic response (SVR) following HCV treatment is associated with reduced morbidity and mortality. We assessed all-cause, liver-, drug- and non-liver, non-drug- related mortality following SVR among people with HCV/HIV co-infection (PWHI) compared to people with HCV mono-infection (PWHC) in a large population-based cohort in British Columbia (BC), Canada.
Method: We used data from the BC Hepatitis Testers Cohort, which includes ~1.3 million people tested for HCV since 1990, linked with data on medical visits, hospitalizations, prescription drugs and mortality. We followed PWHC and PWHI who achieved SVR following DAA treatment to death or October 31, 2021. We computed mortality rates by HIV co-infection status and performed multivariable

proportional hazard modeling to assess the effect of HIV co-infection on all-cause, liver-, drug-, and non-liver, non-drug- related mortality.
Results: There were 12,150 people who achieved SVR following direct-acting antiviral treatment. PWHI: n = 970, person-years (PY) = 3,188.5, deaths = 171; PWHC: n = 11,180, PY = 36,905.3, deaths = 1,146. Median follow-up time was 3.2 years (interquartile range 1.9–4.5; maximum = 7.4). All-cause, liver-, drug- and non-liver, non-drug-related mortality rate among PWHI and PWHC was 53.6 vs. 31.1/1,000PY, 6.0 vs. 8.2/1,000PY, 24.4 vs. 6.5/1,000PY, 23.2 vs. 16.3/1,000PY, respectively. In the multivariable model, HCV/HIV co-infection was associated with higher all-cause (adjusted hazards ratio (AHR): 1.43, 95%CI: 1.20–1.78), drug-related (AHR: 1.57, 95%CI: 1.17–2.10) and non-liver, non-drug related mortality (AHR: 1.39, 95% CI: 1.07–1.80), while risk of liver-related mortality (AHR: 0.90, 95%CI: 0.54–1.51) was not significantly different compared to HCV mono-infection.
Conclusion: After successful HCV treatment, people with HCV/HIV co-infection have similar liver-related mortality as people with HCV mono-infection, but have higher all-cause, drug- and non-liver, non-drug- related mortality. Higher drug-related and non-liver, non-drug-related mortality indicate tailoring services based on syndemic conditions co-occurring with HIV and HCV infections, such as substance use and mental health support and care for chronic non-communicable conditions.

THU-188
Cholestatic HCV-related cryoglobulinemia, a new clinical and pathological entity: a case-control study

Sara Romeo[1], Andrea Dalbeni[1], Serena Amendola[2], Filippo Cattazzo[1], Anna Tomezzoli[2], David Sacerdoti[3]. *[1]University and Azienda Ospedaliera Universitaria Integrata of Verona, Division of General Medicine C, Department of Medicine, Verona, Italy; [2]University and Azienda Ospedaliera Universitaria Integrata of Verona, Department of Diagnostics and Public Health, Section of Pathology, Verona, Italy; [3]University and Azienda Ospedaliera Universitaria Integrata of Verona, Liver Unit, Department of Medicine, Verona, Italy*
Email: sara.romeo26@yahoo.it

Background and aims: Mixed cryoglobulinemia (MC), the most common extrahepatic manifestation in chronic hepatitis C virus (CHC), persisting even after virus eradication with direct-acting antiviral agents, can manifest clinically as a systemic vasculitis with manifestations ranging from purpura, arthralgia, and weakness to more severe neurological and kidney involvement and cirrhosis development. Up today, the relationship between MC and liver intrahepatic cholestasis is unknown. Our study aims to investigate a possible correlation between MC and intrahepatic cholestasis in CHC patients.
Method: 31 hepatitis C virus (HCV) + MC + patients were enrolled, matched for age, sex and genotype with 31 HCV + MC –. Patients with known autoimmune diseases were excluded. For each participant, cholestatic parameters (direct bilirubin, alkaline phosphatase and gamma-glutamyl transferase), HCV-RNA, genotype, plasma MC were measured; liver histology and plasma cells (aggregation and distribution), observed blinded by two different operators, were analyzed. Results were evaluated by the Mann-Whitney U test, Fisher's exact test and by stepwise multivariate analysis ($p \leq 0.05$).
Results: 62 participants (mean age 57.3 ± 11.1 years; males = 50%) with CHC were enrolled. Serum cholestasis (2 or more increased cholestatic parameters) was significantly higher in MC + group (p = 0.02) and correlated in univariate analysis with cryoglobulinemia (OR 6.9; p = 0.02). Plasma cells on liver histology were found in a significantly higher number in MC + group (p = 0.01) and tended to form aggregates more than in the control group (p = 0.05). In stepwise multivariate analysis with genotype, HCV-RNA, steatosis, gender and age, cholestasis was only related to MC + (OR 13.57; p = 0.01).
Conclusion: Our study identified for the first time a correlation between MC, cholestasis and intrahepatic plasma cells in patients with chronic CHC. Future studies are needed to understand how MC causes cholestasis.

THU-189
Hospitalisation-missing an opportunity to link to hepatitis C care: a retrospective study at a regional Australian health service

Christine Roder[1,2,3], Carl Cosgrave[4], Kathryn Mackie[1,5], Bridgette McNamara[1], Joseph Doyle[3,6], Amanda Wade[1,2,3]. *[1]Barwon Health, Barwon South West Public Health Unit, Geelong, Australia; [2]Deakin University, Centre for Innovation in Infectious Disease and Immunology Research (CIIDIR), Geelong, Australia; [3]Burnet Institute, Disease Elimination Program, Melbourne, Australia; [4]Barwon Health, University Hospital Geelong, Geelong, Australia; [5]Alfred Health, Pharmacy Department, Melbourne, Australia; [6]Alfred Health and Monash University, Department of Infectious Disease, Melbourne, Australia*
Email: christine.roder@gmail.com

Background and aims: Western Victoria has the highest rate of hepatitis C treatment uptake in Australia. Key to achieving micro-elimination in Western Victoria is developing targeted, data driven strategies to increase testing and linkage to care. This study aimed to assess the proportion of inpatients and emergency department (ED) patients identified at risk of hepatitis C or living with hepatitis C who were tested and linked to care and treatment at University Hospital Geelong (UHG), a regional health service in Victoria, Australia.
Method: A retrospective study was performed of adults admitted as hospital or ED inpatients from November 2018 to November 2021. Data were collected from the following databases: hospital admissions (International Classification of Disease, Tenth revision (ICD-10) coded separations), Australian Clinical Labs (pathology), the hospital pharmacy (direct acting antiviral (DAA) scripts), and Liver Clinic (UHG) outpatient service. Separations were selected if they had a code that indicated intravenous drug use (IDU) or hepatitis C.

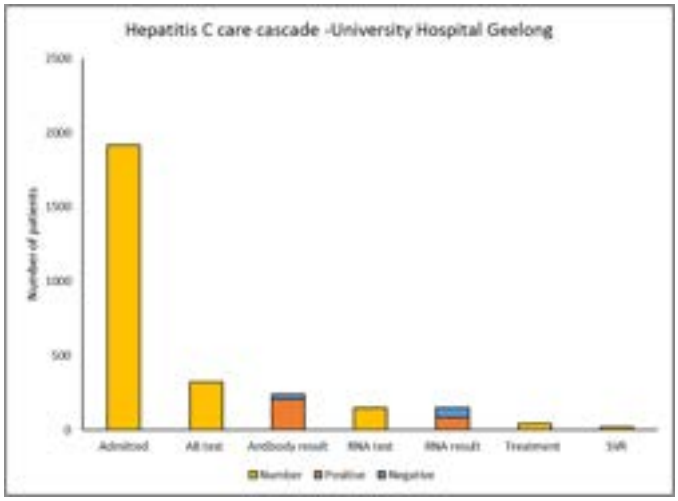

Figure:

Results: There were 1370 patients with IDU coded separations and 628 patients with hepatitis C coded separations (total n = 1917 patients). 16.8% (323/1917) had a documented antibody test and 7.7% (148/1917) had a documented RNA test, 2.2% (43/1917) had a DAA script either dispensed by the hospital pharmacy or prescribed through the Liver Clinic, and 1% (20/1917) had documented cure.
Antibody positivity was 65% (210/323) and of those who had an RNA test, RNA was detected in 57.4% (85/148). Of the patients with detectable RNA, 50.6% (43/85) received DAA therapy and 23.5% (20/85) achieved a sustained virologic response (SVR). For hepatitis C coded separations, antibody testing rates were highest in general

medical units (57.1%), and lowest in ED (29.6%). Follow-up RNA testing rates for antibody positivity was similar for all hospital units (67%–73%). For IDU coded separations, antibody testing rates were lower than hepatitis C coded separations, with the highest being hepatitis specialist units (37.5%), and the lowest ED (6.9%). Follow-up RNA testing rates for antibody positivity varied across units (61.5% to 100%).

Conclusion: A targeted intervention that increases hepatitis C antibody testing of people with a history of IDU whilst hospital inpatients is likely to improve linkage to hepatitis C care at our health service, and contribute to micro-elimination.

THU-190

Hepatitis C virus infection follow-up of people who use drugs in the Balearic Islands, Spain

Andrea Herranz[1], Camila Picchio[1], Lucia Bonet[2], Marita Trelles[3], Alicia R Rubí[4], Leticia Martín[4], Andreu Sansó[5], Maria Victoria Moreno[6], Ana María Sánchez[6], Jerònima Serra[7], María Soledad Velasco[7], Rosa Joy[8], Marina Lloves[9], Nora Soria[9], Maria Buti[10,11], Àngels Vilella[12], Jeffrey Lazarus[1,13]. *[1]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain, Spain; [2]Department of Gastroenterology, Hospital Universitari Son Espases, Palma, Mallorca, Spain; [3]Department of Gastroenterology, Hospital Comarcal d'Inca, Inca, Mallorca, Spain; [4]Department of Gastroenterology, Hospital Can Misses, Eivissa, Spain; [5]Department of Gastroenterology, Hospital de Manacor, Manacor, Mallorca, Spain; [6]Unitat de Conductes Addictives Bons Aires (IBSalut), Palma, Mallorca, Spain; [7]Unitat de Conductes Addictives Ponent (IBSalut), Palma, Mallorca, Spain; [8]Centre Inclusió Social (IMAS), Palma, Mallorca, Spain; [9]Unitat de Conductes Addictives Eivissa, Consell d'Eivissa, Eivissa, Spain; [10]Liver Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [11]CIBER Hepatic and Digestive Diseases (CIBERehd), Instituto Carlos III, Madrid, Spain; [12]Department of Gastroenterology, Hospital Universitari Son Llàtzer, Palma, Mallorca, Spain; [13]Faculty of Medicine and Health Sciences, University of Barcelona, Barcelona, Spain*
Email: Jeffrey.Lazarus@isglobal.org

Background and aims: The hepatitis C virus (HCV) infection affects an estimated 56.8 million people and one of the most affected groups are people who use drugs (PWUD). Moreover, PWUD suffer from stigma and discrimination that make it difficult to access healthcare and eliminate HCV infection in this population. In Spain, the *Hepatitis C Free Balears* project was launched to simplify the existing hepatitis C virus (HCV) model of care for people who use drugs (PWUD) in addiction service centres in the Balearic Islands. This new model of care aims to facilitate treatment completion and monitors for reinfection in this population that, despite being treated, often has difficulties in continued follow-up and has a higher probability of reinfection. The objective of this study is to understand if using simplified and decentralized methods for diagnosis, treatment and follow-up of HCV among PWUD is effective.

Method: This new model of care is being implemented in 21 addiction service centres in the Balearic Islands and includes four phases: 1) recruitment and HCV screening onsite via a point-of-care anti-HCV antibody (Oraquick®) and dried blood spot (DBS) testing or blood analysis to confirm viremia (HCV-RNA); 2) linkage to care; 3) treatment prescription via telemedicine; and 4) monitoring onsite of sustained virological response (SVR) at 12 weeks after treatment and monitoring for reinfection after a year, using DBS testing or standard phlebotomy.

Results: Since April 2021, 1251 participants have been recruited of which 409 (33%) were anti-HCV+ and 148 (12%) were HCV-RNA+. Of those, 82 (55%) reported active drug and alcohol use and 25 (17%) had an HIV co-infection.

Of those with active HCV infection, 128 (86%) initiated treatment and 107 (84%) have completed it. SVR12 monitoring was performed in 83 (72%) of those patients who completed treatment, of which 67 (81%) were done by DBS testing. The others (n = 24) did not undergo SVR12 monitoring because the date has not yet arrived (5, 21%) or because they did not show up for the appointment (19, 79%). Of those who were monitored for SVR12, 79 (95%) showed undetectable HCV-RNA. Of the participants screened a year ago or more (612), 70 (11%) have been screened again, using DBS testing in 97% of the cases. Three reinfections were detected in previously treated patients, and no new infections were detected in patients never infected with HCV.

Conclusion: DBS testing is an effective strategy to offer post-treatment and reinfection monitoring in decentralized settings, increasing testing for PWUD participants. With adapted and simplified care models, HCV care can be accessible to those at higher risk of suffering from the infection and facilitates HCV elimination.

Serum myostatin decreased after direct acting antivirals for cirrhotic patients

Tomoyuki Suehiro[1], Kosuke Matsumoto[1], Yuki Kugiyama[1], Yasuhide Motoyoshi[1], Akira Saeki[1], Shinya Nagaoka[1], Kazumi Yamasaki[1], Atsumasa Komori[1], Hiroshi Yatsuhashi[1]. [1]*Nagasaki Medical Center, Clinical Reseach Center, Japan*
Email: chuntomo0902@gmail.com

Background and aims: Direct-acting antivirals (DAAs) can eradicate HCV even in patients with liver cirrhosis in older age. As cirrhosis itself is also a cause for secondly sarcopenia, optimal and appropriate management of sarcopenia after sustained virological response (SVR) among older patients is of great importance. The purpose of this study is to clarify whether extermination of HCV contributes to the improvement of sarcopenia in patients with type C cirrhosis (LCC), with special attention to chronological changes in sarcopenia-associated molecules including myostatin, which negatively regulate the number and the function of skeletal muscle cells, after secreting from skeletal muscle.
Method: Ninety-nine patients with LCC were treated with DAAs. The median age was 73 (36–92) years. There were 69 patients with Child Pugh (CP)- grade A, and 30 patients with CP-grade B+C. We measured serum myostain, decorin, follistatin, insulin like growth factor-1 (IGF-1), and skeletal muscle mass index (SMI) at baseline and at SVR 48.
Results: At baseline, patients with CP- B+C group showed significantly higher serum myostatin level than those with CP-A group (CP-B+C, 11409 (3445–26949) pg/dl vs CP-A, 5863 (2292–21795) pg/dl, $p < 0.001$). Multivariate analysis revealed that total bilirubin, prothrombin time, SMI, and M2BPGi were independent factors associated with serum myostatin. Serum myostatin levels were significantly decreased after DAA treatment (baseline 8257 pg/ml vs SVR 48 6394 pg/ml, $p < 0.001$). Though decorin showed similar decrease (baseline 12604 pg/ml vs SVR 48 7953 pg/ml), follistatin and IGF-1 increased significantly (follistatin: baseline 853 pg/ml vs SVR 48 1058 pg/ml, $p < 0.001$; IGF-1: baseline 16.1 ng/ml vs SVR 48 18.2 mg/ml, $p = 0.005$). SMI was restored significantly after DAA treatment (baseline 4.197 vs SVR 48 4.380, $p = 0.009$).
Conclusion: DAA treatment could contribute to improve sarcopenia for LCC patients, possibly by the modulation of sarcopenia-associated molecules.

THU-192

HCV micro-elimination strategy in a tertiary hospital: identification of lost cases and linkage to care

Maria Torner[1], Laura Muñoz Castillo[1], Xavi Grau[2], Ariadna Clos Parals[1], Aroa Muñoz[3], Alba Ardevol Ribalta[1], Gema Fernández-Rivas[3], Helena Masnou[1], Águeda Hernández[3], Rosa López[2], Pere Joan Cardona[3], Lidia Carabias[4], Elisa Martró[3], Rosa M Morillas[1]. [1]*Germans Trias i Pujol Universitary Hospital, Hepatology, Badalona, Spain;* [2]*Catalan Institute of Health, North Metropolitan Territorial Management Department, Barcelona province, Spain, Spain;* [3]*Germans Trias i Pujol Universitary Hospital, Badalona, Microbiology Department, Spain;* [4]*Germans Trias i Pujol University Hospital, Pharmacy Department, Spain*
Email: mariatrnrsm@gmail.com

Background and aims: Hepatitis C virus (HCV) elimination by 2030 is one of the main goals of the World Health Organization (WHO). The implementation of micro-elimination strategies in each area can help to achieve this goal. Among them, the identification of lost patients (meaning those with active HCV infection not visited and/or treated by a specialist) has been proved to be useful, advisable and cost-effective[1,2].
Our aim was to identify patients with active HCV infection lost during the 2010–2022 period in the Northern Metropolitan area of Barcelona, from the Northern Metropolitan Clinical Laboratory (LCMN) registries, describing their characteristics and the success of their linkage to the health system.
Method: As part of an "HCV elimination program" in our area, we designed a strategy based on a computer search of positive HCV-RNA cases with no prior treatment or not cured and retrieval of test results and associated clinical information from clinical records of patients tested at the Microbiology Service of the LCMN, in coordination with the Hospital Information System. The second phase of the intervention focused on the comprehensive review of all clinical records by the Hepatology Unit and selection of candidates for contact, appointment and treatment.
Results: Among the 1461 viremic patients identified, 696 (47.6%) belonged to the area of influence of our tertiary care hospital. Among the latter, 121 (17.4%) were already dead (41.3% due to an hepatic cause). 29 patients (4.2%) had severe comorbidity/frailty and 499 (71.7%) were already under follow-up by an specialist or had already

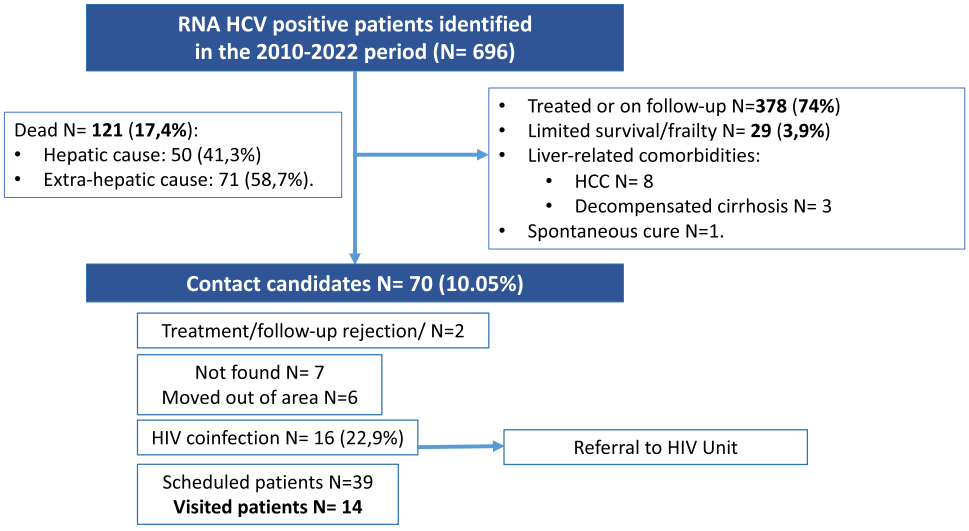

Figure 1. Flowchart of identified patients, selection of candidates for contact and linkage to care. HCC: hepatocellular carcinoma. HIV: human immunodeficiency virus.

Figure: (abstract: THU-192).

been treated. 70 (10.1%) candidates to be contacted were identified, of which 16 (22.9%) had HIV co-infection. Among those not co-infected, 39 patients were referred to the Hepatology Unit and, currently, 10 patients have already started treatment with DAA (3 patients were cured and the rest have a pending evaluation of SVR). Among those patients visited, 3 patients (33%) already had advanced fibrosis/cirrhosis and 1 had an hepatocellular carcinoma.
Conclusion: In our Hospital, up to 10% of RNA-positive patients identified as "lost in the system" were candidates to be contacted. This identification is a demanding task but it has allowed us to identify patients who can benefit from treatment. 33% of patients identified already had advanced liver disease. This strategy can contribute to the elimination of HCV both in our Hospital and others in the Barcelona North Metropolitan region covered by the LCMN.

THU-193
The influence of direct acting antiviral treatment in chronic hepatitis C virus infection on arterial stiffness
Mircea Istrate[1], Letitia Toma[1], Elena Laura Iliescu[1], Razvan Rababoc[1].
[1]*Fundeni Clinical Institute, Department of Internal Medicine, Bucharest, Romania*
Email: mircea.istrate@rez.umfcd.ro

Background and aims: Chronic hepatitis C virus infection represents an important factor of atherosclerosis, related to systemic inflammation and the presence of metabolic syndrome. The aim of this study was to determine the influence of direct acting antiviral treatment in chronic hepatitis C virus infection on arterial stiffness and subsequently on the risk of developing potential cardiovascular pathologies.
Method: We performed a prospective observational study including patients with chronic hepatitis C (all genotypes), without cirrhosis, previously naïve to antiviral therapies. The study was performed during January 2022-January 2023 and included 108 patients receiving Sofosbuvir (400 mg)/Velpatasvir (100 mg), for 12 weeks. Sustained virologic response was defined as undetectable viremia at 12 weeks after the end of therapy. Arterial stiffness was determined both before the initiation of antiviral therapy, as well as after achieving sustained virologic response using oscillometric technique, such as pulse wave velocity (PWV) and pulse wave analysis (PWA) of arterial wave forms. All patients were treated according to current national guidelines and signed informed consent forms regarding the use of their personal data for medical and scientific purposes under the condition of anonymization. Patients with HBV or HIV co-infection were excluded, as well as patients with cirrhosis, solid or hematologic malignancies.
Data analysed were age, sex, Aortic Pulse Wave Velocity (PWVao), Central Systolic Blood Pressure (SBPao) and Aortic Augmentation Index (AIXao). Statistical analysis was performed using IBM SPSS Statistics for Windows, version 26.0 (IBM Corp., Armonk, NY, USA).
Results: The study group included 69 women (69.68%) and 33 men (33.32%), with a mean age and standard deviation of 57.13 ± 8.8 years. Before initiation of antiviral therapy most of the patients had a mean Central Systolic Blood Pressure of 113,13 mmHg (± 10,51 mmHg), a mean Aortic Augmentation Index of 0,29% (± 0,09%) and a mean Aortic Pulse Wave Velocity of 5,27 m/s (± 0,42 m/s). After the 12 weeks of treatment all patients achieved Sustained virologic response and the mean values determined by oscillometric methods varied as follow: the medial Central Systolic Blood Pressure was 108,93 mmHg (± 8,8 mmHg), a mean Aortic Augmentation Index of 0,25% (±0,1%) and a mean Aortic Pulse Wave Velocity of 5,03 m/s (± 0,35 m/s). While results are not statistically significant, we note a descending trend in arterial stiffness in patients with SVR after DAA.
Conclusion: Obtaining Sustained virologic response in patients with chronic infection with the hepatitis C virus, leads to a decrease in the mean values of Aortic Pulse Wave Velocity, Central Systolic Blood Pressure and Aortic Augmentation Index. The reduction of arterial stiffness merits further longitudinal study in larger cohorts in order to demonstrate the impact of SVR on the cardiovascular risk of HCV infected patients.

THU-194
One year of HCV/HBV/HIV screening in a psychiatric population consulting in the emergency room (Beaujon Hol/REVHEPAT)
Nathalie Boyer[1], Jamal Abdelkader[2], Matthieu Gay[2], Raphael Allali[2], Prabakar Vaittinada[2], Cecilia De-Freitas[2], Murielle Brisson[2], Béatrice Monnier[2], Tarik Asselah[2]. [1]*Hôpital Beaujon, Service d'hépatologie, France;* [2]*Hôpital Beaujon, France*
Email: tarik.asselah@aphp.fr

Background and aims: Hepatitis C virus (HCV) chronic infection is thought to affect 5% of patients with psychiatric pathology. HCV screening in this population is part of the French elimination plan by 2025. In a "patient reach out" approach, seeking medical attention in the emergency room represents an opportunity for contact with care for this precarious population. The treatment of HCV can represent part of the treatment of psychiatric pathology (anxiety, depression). HBV vaccination is also recommended (risk factors, promiscuity). The objective of this pilot work is to evaluate HCV/HBV/HIV screening in the psychiatric population consulting in the emergency room.
Method: Emergency screening (SAU) at Beaujon Hospital (Clichy), of any patient admitted for a psychiatric and/or addiction reason, for whom a Psychiatric expertise is requested. After proposal by the psychiatrist and acceptance by the patient, a screening for the 3 viruses (HCV/HBV/HIV serologies) is carried out at the SAU. The results are collected by the Hepatology department, which makes the diagnosis announcement and ensures, with the REVHEPAT city hospital network, the management of patients tested positive. This collaboration demonstrates the essential role of the hepatologist in a psychiatric setting.
Results: Over 12 months (April 2021–March 2022) (Table) in 665 patients, mean age: 43 years (16–97 years), 64% <50 years, with a F/M ratio of 47%/53%. On the available data, there are consumptions: of alcohol in 32% (189/588) of patients (severe in 54% and moderate in 46%); opiates in 8% (48/565); benzodiazepines = 18% (105/569); cannabis = 23% (131/582); psychostimulants = 10% (56/558). Psychiatric hospitalization was necessary in 50% of cases. Previous viral status was unknown for 90% (357/396) of patients. HCV 3.3% (19/569); HBV 1.6% (9/556); HIV 2.2% (12/558) patients. Among the 19 HCV Antibody positive patients: 10 patients contacted directly: 6 HCV RNA negative patients, 1 refusal of care, 3 appointments not honored; 9 could not be recontacted: 3 psy hospitalizations, 1 remand center, 5 letters to the attending physician. Two patients are co-infected with HIV and 42% patients are to be vaccinated with HBV. All had an unknown prior viral status. Among the 9 HBSAg positive patients: 5 patients have positive HBV DNA (4 F1 patients now followed; 1 PDV), 1 patient already followed by attending physician, 3 letters to the attending physician. Among the 547 HBSAg negative patients: 52% to be HBV vaccinated, 12% immunized and 36% already vaccinated.

Emergency screening	Total : n, (%)	Positive	Positive	Positive
N	**665**	**19***	**9**	**12***
n/total available		**3, 3%**	**1, 6%**	**2, 2%**
Gender F/H	315/350	5/14	1/8	5/7
Average age (years)	43	52	52	50
Alcohol	32%	60%	38%	20%
Opiates	8%	31%	13%	25%
Benzodiazépines	18%	53%	29%	40%
Cannabis	23%	50%	5%	30%
Psychostimulants	10%	21%	0%	30%

*2 HCV-HIV coinfected patients; **11 patients already followed with known HIV serology, 1 discovery in a homeless man treated
Figure:

Conclusion: HCV/HBV screening, by going to populations with psychiatric pathology, in particular during emergency contact with care, confirms the high prevalence of viral infection in these

populations (HCV ten times higher than in the general population), the opportunity to be able to take care of them, protect them from complications, vaccinate them with HBV and also potentially cure them (HCV) and improve their psychiatric state.

THU-195

Long term normalization of systemic inflammation and endothelial activation after hepatitis C virus (HCV) eradication in HIV/HCV coinfected, HCV monoinfected patients and HCV-infected liver transplant recipients

Laura Benitez Gutierrez[1], Ana Arias[2], Ana Duca[2], Valentin Cuervas-Mons Martínez[3], María Jesus Citores[4]. [1]*Research Institute and University Puerta de Hierro Majadahonda Hospital, Liver Transplant Unit, Majadahonda, Spain;* [2]*University Puerta de Hierro Majadahonda Hospital, Liver Transplant Unit, Majadahonda, Spain;* [3]*Universidad Autónoma de madrid, Medicine, Madrid, Spain;* [4]*Research Institute Puerta de Hierro- Segovia de Arana, Liver Transplant Unit, Internal Medicine Laboratory, Majadahonda, Spain*
Email: lauramariabenitez@gmail.com

Background and aims: Hepatitis C Virus (HCV) infection is associated with a state of chronic inflammation. Patients infected with HCV present increased levels of soluble markers of endothelial dysfunction. We have evaluated the effect of HCV on several soluble markers of systemic inflammation and endothelial activation which favors the development inflammation and result in sustained liver damage in patients infected with HCV, as well as their evolution after long term HCV eradication with DAAs therapy.
Method: A total of 53 patients with chronic HCV infection treated with DAAs were subgroupes as: HCV monoinfected (n = 14, group 1), HCV-infected liver transplant recipients (n = 17, group 2) and HIV/HCV coinfected patients (n = 22, group 3). Blood samples were collected from all subjects at baseline (pre-DAAs treatment), 12 weeks after the end of treatment when sustained virological response (SVR) was evaluated and 4.19 (± 0.55) years after the SVR. Liver stiffness (LS) assessed using a FibroScanâ, and the results were expressed in kilopascals (KPa). The next cut-off LS were used: LS<7.1KPa F0-F1; 7.1–9.4 KPa F2,; 9.5–12.4 KPa F3; and >12.5 KPa F4., biochemical parameters of liver damage (bilirrubin, albumin, ALT, AST, GGT, AP) and ICAM-1 and CXCL10 quantified by Cytometric Bead array (CBA) were recorded at each time point.
Results: Baseline LS was F4 in 45%, F2-F3 in 26% and F1 in 28% patients. F4 stage of LS was present in 80% patients of group 1, while only in 25% and 38% of patients of group 2 and 3 respectively. Levels of ICAM-1, CXCL10, LS (Kpa), bilirrubin, ALT, AST, GGT and AP significantly decreased (all $p < 0.001$) and albumin levels increased ($p < 0.01$) in SVR and long term post-SVR compared to baseline in all the three study groups. ICAM-1 baseline levels were positively correlated with bilirrubin, AST and AP while negatively correlated with albumin levels (all $p < 0.05$). There was a positive correlation between CXCL10 and ALT/AST basal levels (all $p < 0.01$) Considering fibrosis stage according the LS ICAM-1 baseline levels were higher in patients with LS ≥ F2 ($p = 0.008$)
Conclusion: The state of chronic inflammation decreases after HCV clearance and it is maintained long term post-SVR in HCV mono-infected patients, HCV-infected liver transplant recipients and HIV/VHC coinfected patients.

THU-196

Differences in baseline characteristics of direct acting antiviral (DAA)- treated Greek HCV patients according to source of infection

Spyridon (Spyros) Siakavellas[1], Hariklia Kranidioti[1], Anastasia Kourikou[1], Charalampos Karageorgos[1], Anestis Goulas[1], Sofia Vasileiadi[1], Georgios Kontos[1], Nikolaos Papadopoulos[1], Melanie Deutsch[1], Spilios Manolakopoulos[1]. [1]*Geniko Nosokomeio Athinon "Ippokrateio", Hepatogastroenterology Unit, 2nd Academic Department of Internal Medicine, Greece*
Email: s.siakavellas@gmail.com

Background and aims: With the introduction of direct-antiviral medication (DAAs), eradication of HCV infection is considered now an achievable goal. While people with history of drug use (PWHD) form the most common population at risk for the infection, in Greece historically there has been a significant proportion of patients arising from the general population with no prior drug use. These two different subgroups exhibit different characteristics, that may be pertinent in the management of HCV infection and long-term follow-up. The aim of this study was to identify potential differences in the makeup of these two HCV patient subgroups.
Method: The HERACLIS cohort, is the largest national HCV registry of patients treated with DAAs in tertiary liver centers from 2015 until 2022. Clinical data and characteristics were obtained from medical records, while transient elastography (TE) measurements and APRI and FIB-4 score calculations were conducted at baseline. Patients were followed up initially for the duration of their treatment.
Results: 680 patients were included in the study, 70.9% (n = 482) of them were men with median age 50.8 years old and 13.6% of these had decompensated liver disease at DAA initiation. 62% (n = 422) of this cohort were PWHD, while the rest had been infected in another manner (non-PWHD). When comparing these two populations, PWHD were younger in age (47.3 ± 9.8 vs 56.3 ± 12.8 years, $p < 0.001$) and with lower BMI (24.3 ± 4.2 vs 26.1 ± 4.6 kg/m2, $p < 0.001$). Non-PWHD cases had more often diabetes (4.9% vs 1.3%, $p < 0.001$), hypertension (10.7% vs 8.8%, $p < 0.001$) as well as decompensated liver disease (8.0% vs 5.6%, $p < 0.001$). This was also reflected by TE measurements (14.6 ± 11.1 vs 11.3 ± 7.9 kPa, $p = 0.001$) and FIB-4 score calculations (2.8 ± 2.6 vs 2.2 ± 4.0 vs, $p < 0.001$) but not by the APRI score. Moreover, PWHD patients tended to have been more often infected with genotype 3 (36.8% vs 8.8%, $p < 0.001$) while for other genotypes no such stark differences were observed. There was no significant variance observed regarding DAA regimen use but non-PWHD patients tended to suffer more often from adverse events secondary to DAA treatment (1.6% vs 0.3%, $p = 0.001$).
Conclusion: The Greek PWHD and non-PWHD populations of HCV patients seem to exhibit different baseline characteristics which may be relevant to treatment selection and long-term follow-up regimens. The main differences observed imply the concomitant presence of an element of metabolic syndrome in the non-PWHD cohort with a subsequent potential effect on the degree of underlying liver fibrosis.

THU-197

Incidence and associations of HCV reinfection in the era of direct acting antivirals

Sofia Vasileiadi[1], Kanellos Koustenis[1], Maria Manolakopoulou[1], Charalampos Karageorgos[1], Anestis Goulas[1], Hariklia Kranidioti[1], Spyridon (Spyros) Siakavellas[1], Melanie Deutsch[1], Olga Anagnostou[1], Spilios Manolakopoulos[1]. [1]*Geniko Nosokomeio Athinon "Ippokrateio", Hepatogastroenterology Unit, 2nd Academic Department of Internal Medicine, Athens, Greece*
Email: s.siakavellas@gmail.com

Background and aims: The introduction of highly effective direct acting antivirals (DAAs) has dramatically changed our practice against HCV infection with high therapy uptake and high response rates; one may argue for higher reinfection rates. The reinfection rates especially in high-risk populations could become a significant barrier in the strategy of HCV elimination. Our aim is to explore the HCV reinfection rate after successful HCV therapy with DAAs in a cohort of people who use drugs (PWUD) and define factors associated with reinfection.
Method: We included patients with chronic compensated hepatitis C who had history of past or current illicit drug use. All had been treated successfully with DAAs in our tertiary center between 2014 and 2021. HCV cure was defined with serum HCV RNA no detectability 3–12

months after the end of treatment (SVR). All patients were contacted at least one year after the end of the treatment via phone call and were invited to a follow-up visit where HCV RNA levels, liver function tests and transient elastography (TE) were performed. Parameters regarding their social-economic status and drug use habits, were also recorded. Serum HCV RNA detectable after SVR was defined as reinfection. This is a preliminary analysis of 174 patients who were called twice; 78 of them did not respond.

Results: 96 patients (82.3% men) were included in the study, with median age 53 (range 34–68) years. 24% (n = 23) had evidence of cirrhosis. 62.5% (n = 60) were unemployed, 66.7% (n = 64) were single and 22.8% (n = 21) had been incarcerated at some point in the past. Almost 60% (n = 57) attended a substitution or therapeutic community program for drug use, with 34.4% (n = 33) reporting drug use in the last 12 months, of which 36.4% (n = 12) shared syringes/other paraphernalia, while 39.4% (n = 13) reported intravenous drug use and 39.4% (n = 13) used drugs via the nasal route. We identified 7 HCV reinfections during 189 PY of follow-up, yielding a reinfection rate of 3.7/100 PY. We found that the reinfection group included younger (44 ± 5 vs 53 ± 8 years, p = 0.005) patients, the majority (n = 6, 85.7%) of them under the age of 50, and with a concomitant history of having been imprisoned (85.7% vs 20.2%, p < 0.001). Moreover, people in the reinfection group reported longer total history of intravenous drug use (24 ± 8 vs 15 ± 8 years, p = 0.012), more often active drug use in the past 12 months (100% vs 29.2%, p < 0.001), intravenous drug use (71.4% vs 9%, p < 0.001) and shared syringes/paraphernalia (85.7% vs 21.3%, p < 0.001). Reinfection was also significantly associated with HIV co-infection (42.9% vs 0%, p < 0.001) and cannabis consumption (85.7% vs 37.1%, p = 0.017). HCV genotypes in reinfected patients were different compared to baseline pretherapy ones.

Conclusion: HCV reinfection rates after SVR were higher among younger patients who continued high risk behaviors. These data underlined the importance of follow-up assessment for PWUD and the necessity of sustained linkage to health care services.

THU-198

Evaluation of patients treated with direct-acting anti-viral therapy for chronic hepatitis C and their risk of hepatocellular carcinoma in Hong Kong

Victor Yung Sin Chow[1], Veronica Wing I Cheung[1]. [1]*Our Lady of Maryknoll Hospital, Hong Kong*
Email: victor.chow06@gmail.com

Background and aims: To evaluate the risk of early hepatocellular carcinoma (HCC) and its risk factors in chronic hepatitis C patients treated with direct-acting antivirals (DAAs) in Hong Kong.

Method: 333 consecutive chronic hepatitis C patients treated with DAAs from two hospitals over the past 6 years were identified. Kaplan-Meier method was used to calculate cumulative HCC incidence. Cox regression was used to identify factors associated with HCC development. Receiver operating characteristic curve analysis was performed to determine the optimal cut-off levels of AFP for predicting HCC development.

Results: During a median follow-up of 23.4 months after DAA started, 15 (5.4%, 95% Confidence Interval 3.3%-8.7%) out of 279 total included patients developed HCC. The overall sustained virological response (SVR) rate was 98.9%. The 1-year cumulative incidence for de-novo HCC and HCC recurrence were 0.8% and 30.9%, respectively (log-rank test p <0.001). The 1-year cumulative HCC incidence for patients without and with cirrhosis were 0.7% and 5.1%, respectively (log-rank test p = 0.036). Univariate analysis showed that significant factors associated with HCC after DAA were: history of previous HCC with curative treatment with subsequent complete radiologic response (Hazard Ratio, HR, 28.88, 95% CI 9.32–89.49, p < 0.001), cirrhosis (HR 3.57, 95% CI 1.00–12.77, p = 0.0499), evidence of portal hypertension (HR 4.27, 95% CI 1.51–12.07, p = 0.006), higher AFP at the start (HR 1.02, 95% CI 1.01–1.03, p < 0.001) or end (HR 1.09, 95% CI 1.05–1.14, p < 0.001) of DAA therapy, higher bilirubin (HR 1.09, 95% CI 1.04–1.14, p < 0.001), lower platelets (HR 0.99, 95% CI 0.98–0.999), lower albumin (HR 0.89, 95% CI 0.81–0.97, p = 0.007), and older age (HR 1.07, 95% CI 1.02–1.12, p = 0.007). The optimal cut-off level of AFP at the start of DAA therapy for predicting HCC was 10.5 ng/ml (sensitivity 80%, specificity 84.2%, AUROC 0.868). The cumulative incidence of HCC development for the group with AFP level <10.5 ng/ml at the start of DAA therapy was significantly lower than that for the group with AFP level ≥10.5 ng/ml (log-rank test p <0.001). The 1-year cumulative incidence of HCC were 0.5% (95% CI 0%–1.6%) and 12.6% (95% CI 3.1%–22.1%) for the groups with AFP level <10.5 ng/ml and ≥10.5 ng/ml at the start of DAA therapy, respectively. On the other hand, the optimal cut-off level of AFP at the end of DAA therapy for predicting HCC was 5.6 ng/ml (sensitivity 78.6%, specificity 80.5%, AUROC 0.864). The cumulative incidence of HCC development for the group with AFP level <5.6 ng/ml at the end of DAA therapy was significantly lower than that for the group with AFP level ≥5.6 ng/ml (log-rank test p <0.001). The 1-year cumulative incidence of HCC were 0.6% (95% CI 0%–1.7%) and 11.8% (95% CI 2.8%–20.8%) for the groups with AFP level <5.6 ng/ml and ≥5.6 ng/ml at the end of DAA therapy, respectively.

Figure:

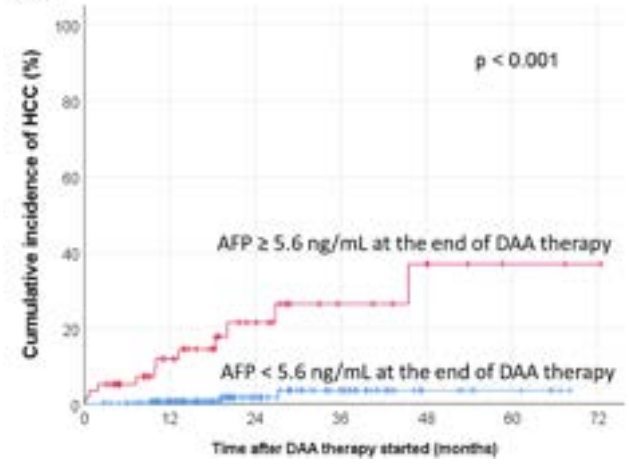

Figure:

Conclusion: Following DAA therapy and achieving SVR in the vast majority of chronic hepatitis C patients, the risk of early de-novo HCC development is low, but the risk of early HCC recurrence remains very high. Higher AFP levels, with cut-off at 10.5 ng/ml and 5.6 ng/ml, at the start and end of DAA therapy respectively, can be useful in stratifying the risk of HCC development.

THU-199

The prevelance of hepatitis C virus infection in high-risk patients with high normal alanine aminotransferase (ALT) in Israel: a bio bank analysis

Amir Shlomai[1], Daniella Beller[2], Sapir Hadadi[3], Galit Rimler[4], Licita Schreiber[4], Gabriel Chodik[5], Asaf Peretz[2]. [1]*Rabin Medical Center, Medicine D, Israel;* [2]*KSM, Maccabi's research and innovation institute, Israel;* [3]*AbbVie Inc, Hod-Hasharon, Israel;* [4]*Maccabi MEGA lab, Maccabi Healthcare Services, Israel;* [5]*SM, Maccabi's research and innovation institute, Israel*
Email: shlomaiamir@gmail.com

Background and aims: Chronic hepatitis C virus (HCV) infection is a major worldwide problem. Direct antiviral agents (DAAs) are highly effective against HCV and result in nearly 100% cure rate. In Israel, the current prevalence of HCV is estimated at 2% among high-risk adult population, such as former union of soviet socialist republics (USSR) residents. However, the majority of HCV carriers in Israel remain unaware of their disease and are therefore untreated, despite the wide availability of DAAs that are included in the Israeli health-basket. In recent years, it became clear that "healthy" alanine

aminotransferase (ALT) values are even lower than previously thought and that a substantial fraction of people with "high normal" ALT might still have an underlying liver disease, including chronic HCV infection. The aim of this study is to determine the prevalence of chronic HCV infection in high-risk population with high-normal ALT.

Method: Adults that opt-in to the Maccabi Healthcare Services biobank and were never tested for HCV before were included. We assessed the prevalence of anti-HCV antibodies in patients who were tested for serum ALT in 2020. Based on inclusion criteria and based on ALT levels, fresh samples from biobank participants were tested for HCV antibodies by CMIA. In case of borderline results, immunoblotting was performed. RT-PCR for HCV RNA was performed on samples with positive HCV antibodies.

Results: The study was conducted in two stages: First, a total of 350 individuals with serum ALT >25 IU/L for women and >33 IU/L for men (mean age = 55 [19, 100]; 36% males; 21% (73/350) former USSR residents, mean ALT = 49.5 [26, 787]) were included in the analysis. Among them, five were positive for HCV antibodies, and only one female patient (0.29%; 95%CI: 0.01% to 1.58%), a former USSR resident with ALT = 30 IU/L, was confirmed positive by PCR. We next focused on former USSR residents with high-normal ALT. Of 202 samples (mean age 57, 39% males) who had high-normal ALT (>25 IU/L <50 IU/L for women, >33 IU/L <50 IU/L for men, mean level 34.3 [25, 50]) tested for anti-HCV antibodies, only 1 patient (0.5%) was found positive by RT-PCR.

Conclusion: The prevalence of HCV positivity in a large Israeli biobank setting is lower than expected. Focusing on high-risk adults with high normal ALT does not improve the yield of screening for HCV carriers in this setting.

THU-200

HCV screening: shortening read time of point-of-care rapid diagnostic test does not effect detection rates of antibodies against hepatitis C virus

Muhammad Nabeel Shafqat[1], Auj Chaudhry[2], Najam-us-sehar Saeed[1], Asad Choudhry[2], Muhammad Sohail Khan[3], Ghania Shafqat[2], Fatima Akram[1]. *[1]District Headquarter Hospital-Gujranwala Medical College, Department of Gastroenterology, Gujranwala, Pakistan; [2]PARSA Trust Liver Clinic, Al-Raee Hospital, Gujranwala, Pakistan; [3]Univeristy of the Punjab, Institute of Business and Information Technology, Lahore, Pakistan*

Email: nabeelshafqat89@gmail.com

Background and aims: Hepatitis C virus (HCV) infection is a public health threat worldwide and Pakistan has one of the highest HCV prevalence in the world. The WHO has proposed the goal of eliminating viral hepatitis as a public health threat by 2030. This requires a massive scale-up in screening efforts. Simplification of point-of-care (POC) rapid diagnostic test (RDT) which detects anti-HCV antibodies would enhance overall linkage to care, particularly for mass screening and difficult-to-reach populations. Currently, the recommended read time of POC rapid diagnostic detection test to identify antibody positive samples is 20 min. A positive POC RDT result is then followed by a reflex HCV RNA testing to confirm active viremia. This study was conducted to determine whether a shorter read time of 5 minutes could be used to identify all anti-HCV antibody positive samples, and decrease the need for reflex testing by conducting HCV RNA test on the same sample to identify active viremia.

Method: The SD Bioline HCV POC RDT was used for the qualitative detection of antibodies specific to HCV. Any detectable band on RDT was counted as positive, regardless of band intensity. Samples were collected at two sites: a tertiary care hospital and through community screening. HCV screening was done on the mentioned kit at District Headquarter Hospital-Gujranwala Medical College and PARSA Trust Liver Clinic at Gujranwala, Pakistan. Blood samples were tested immediately after collection of whole blood, via finger prick. Two blinded observers, at both collection centres, separately recorded the time-to-positivity by continuous observation during the first 5 minutes, then each minute after, up to 10 minutes and then again at 15 and 20 minutes. The time-to-positivity on RDT was measured by using a stopwatch to note the exact duration of time from the point when sample was placed on RDT kit till the point a positive result appeared. A sample of HCV RNA by PCR was collected in all those who tested positive for anti-HCV antibodies.

Results: Of 1266 patients with a positive test result on anti-HCV antibody POC RDT test, there were 766 (61%) cases with active viremia. In participants with active viremia, 52.7% (404/766) females and 47.3% (362/766) males, the mean age (± SD) was 46.37 years (± 15.53). In viremic patients, the median time-to-positivity was 1.8

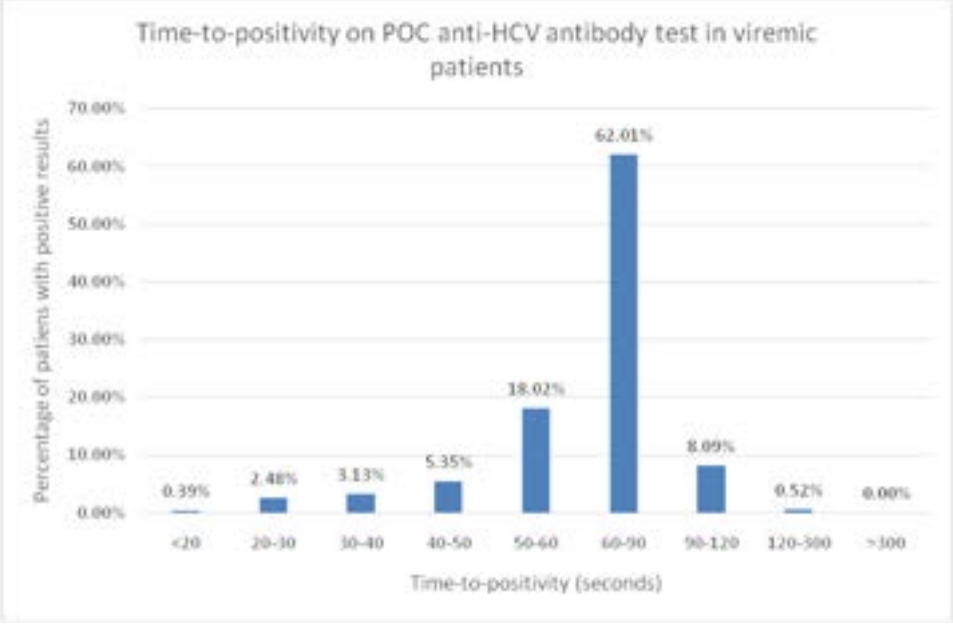

Figure: (abstract: THU-200).

minutes (range, 0.2–2.2 min). Out of all viremic cases, 62.01% of participants had a positive test result in between 60 and 90 seconds whereas 18.02% produced a positive result within 50–60 seconds. Less than 1% of patients with active viremia had a positive screening test within 120–300 seconds. All the patients with active viremia produced a positive result in the antibody RDT test within 5 minutes read time.

Conclusion: Reducing read time of SD bioline rapid antibody POC test from 20 minutes to 5 minutes causes no loss of antibody detection in patients with active viremia. Shortening read time could improve screening efficiency, decrease loss to follow-up rates and can potentially reduce the need for reflex HCV RNA testing. Further studies evaluating POC RDT should be undertaken to explore its utility in replacing HCV RNA by PCR test to detect active viremia in resource poor settings.

THU-201

Digital pathology quantification of cirrhosis severity continuum in human HCV liver biopsies and its correspondence with Laennec and Beijing stages

Louis Petitjean[1], Xiaofei Zhang[2], Thomas Schiano[3], Mathieu Petitjean[1], Maria Isabel Fiel[4]. *[1]PharmaNest, Inc, Princeton, United States; [2]NYU Long Island School of Medicine, Department of Pathology, Mineola, United States; [3]Icahn School of Medicine at Mount Sinai, Intestinal Transplantation, Liver Transplantation, Gastroenterology, New York, United States; [4]Icahn School of Medicine at Mount Sinai, Department of Pathology, Molecular and Cell-Based Medicine, New York, United States*
Email: mathieu.petitjean@pharmanest.com

Background and aims: Cirrhosis severity is defined histologically as a continuous process in which the normal anatomical lobules are replaced by architecturally abnormal nodules separated by fibrous tissue of different morphological phenotypes. The Laennec system, and, more recently the Beijing classification, have been used to sub-classify various histological degrees of cirrhosis severity and activity. These methods lack intra-operator reproducibility and have poor detection thresholds. Here, we report on the development of an automated quantitative Digital Pathology and AI method (FibroNest) to quantify cirrhosis severity and activity and assess its correspondence with Laennec and Beijing scores.

Method: 20 consecutive hepatitis C (HCV) patients undergoing liver transplantation consented to participate in an IRB-approved protocol. 5 core biopsies were taken from five segments of the liver immediately after explantation. Formalin-fixed, paraffin embedded sections of the biopsies were stained with Masson trichrome and scanned at 20X for Digital Pathology. The Laennec system (4A-4C indicating increasing degrees of cirrhosis) and Beijing classification (P-progressive, I-indeterminate, R-regressive,) were assessed by an expert pathologist (MIF). This HCV cohort (n = 100) demonstrated a large variety of severity stages (doi 10.1038/s41379–021-00881-z). Quantitative image analysis was performed to extract single fiber quantitative traits (qFTs, N = 335) to describe the collagen, the fiber morphometric and fibrosis architectural phenotypic dimensions. Principal components of the qFT dataset were automatically identified to account for variability along the Laennec, and the Beijing stages, and then assembled into a normalized Cirrhosis Severity composite Score (CFS) and a Cirrhosis Activity composite Score (CAS).

Results: The AI-enabled CFS and CAS scores classify extreme stages (4A vs 4C, P vs R) with strong statistical significance (p = 0.0011 and p = 0.0004 respectively) in contrast to earlier studies where the Collagen Proportional Area did not correlate with Laennec and Beijing histological scores (doi 10.1038/s41379-021-00881-z.)The intermediate stages (4A vs 4B; 4B vs 4C; P vs I; I vs R) are classified with moderate performance (p values = 0.016; 0.082; 0.004; 0.042 respectively) but it is not clear if the uncertainty is driven by the computational method of the pathologist's interpretation. All the three sub-phenotypic layers (for which specific sub-scores are also created) play complementary roles. For instance, the Architecture-CFS classifies 4A vs 4B groups with a p value of 0.001.

Conclusion: The automated quantification of multiple histological phenotypic traits resolves the complexity of the histological assessment of severity and the activity in the cirrhosis continuum with a performance that benchmarks pathologist assessments.

Prognostic factors of post-sustained virological response outcome in patients with chronic hepatitis C treated with direct-acting antivirals

Won Sohn[1], Sang Hoon Ahn[2], Young Seok Kim[3], Seung Up Kim[4]. *[1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Korea, Rep. of South; [2]Severance Hospital, Yonsei University College of Medicine, Korea, Rep. of South; [3]Soonchunhyang University, Bucheon Hospital, Korea, Rep. of South; [4]Severance Hospital, Yonsei University College of Medicine, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: Direct acting antivirals (DAAs) is the mainstay of antiviral therapy for patients with chronic hepatitis C (CHC). We investigated prognostic factors for the post-sustained virological response (SVR) outcomes in patients with CHC treated DAAs.

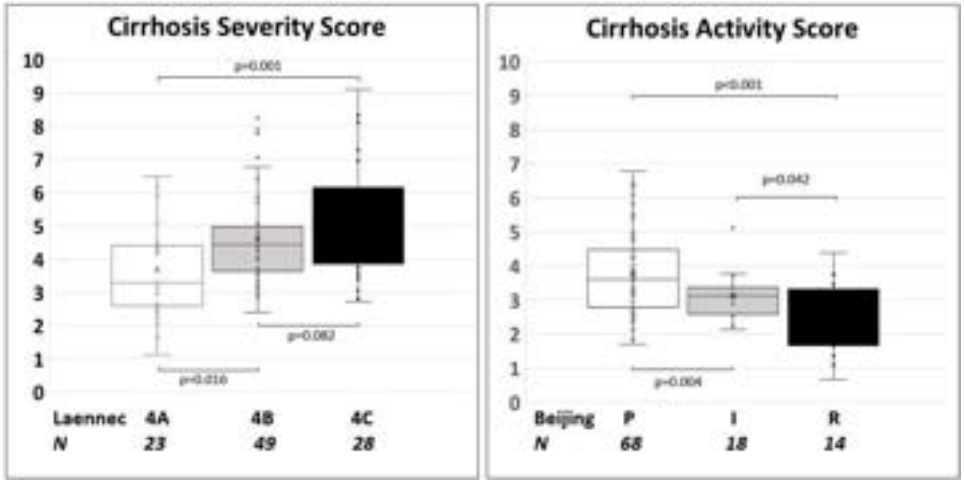

Figure: (abstract: THU-201).

Method: This multicentre, retrospective, nationwide cohort study consisted of 1,248 patients with CHC who were seen at 29 expert hepatology centres in Korea from January 2015 to December 2022 and who achieved SVR after DAA therapy. The primary outcome was the development of liver-related events (LREs) after SVR, including all-cause death, hepatocellular carcinoma (HCC), decompensation, or liver transplantation. The fibrotic burden at baseline and at SVR was assessed using transient elastography (TE) and the FIB-4 index.
Results: The mean age of the patients was 59.8 years and 58% (n = 722) were male. The prevalence of genotypes 1 and 2 was 52% and 46%, respectively. The mean liver stiffness value was 11.6 ± 9.8 kPa at baseline and 8.8 ± 7.5 kPa at SVR. LREs developed in 77 (6.2%) patients and consisted of death in 13, HCC in 34, decompensation in 44 and liver transplantation in 2 patients. The multivariable analysis showed that TE-defined cirrhosis at baseline (liver stiffness ≥14.4 kPa; hazard ratio [HR] = 2.56; 95% confidence interval [CI] 1.30–5.07) and FIB-4-defined advanced fibrosis stage at SVR (>3.25) (HR = 3.24; 95% CI 1.45–7.22) were independently associated with an increased risk of developing LREs (all p <0.05), together with male sex (HR = 1.99; 95% CI 1.26–3.14) and lower serum albumin level at SVR (<4.0 g/dL) (HR = 1.87; 95% CI 1.12–3.13) (all p < 0.05).
Conclusion: The fibrotic burden decreased in patients with CHC after DAA treatment. However, the risk of developing LREs remained even after SVR. Our study showed that an assessment of fibrotic burden before and after DAA treatment is required for predicting outcomes in patients with DAA-treated CHC who achieve SVR.

Utilising peer support workers in hepatitis C screening in emergency departments: a pilot study

Alex Caulder[1,2], Jane Gitahi[1], Ann Archer[1,3], Abigail Sellick[1,2], Julie Marshall[1], Kushala Abeysekera[1,3], Fiona Gordon[1]. [1]*University Hospitals Bristol and Weston NHS Foundation Trust, Liver Medicine, Bristol, United Kingdom;* [2]*Hepatitis C Trust, London, United Kingdom;* [3]*University of Bristol, Population Health Sciences, Bristol, United Kingdom*
Email: alex.caulder@uhbw.nhs.uk

Background and aims: As widespread availability of directly acting antivirals (DAAs) for hepatitis C (HCV) has improved, engaging with hard-to-reach groups with higher HCV prevalence has become a major focus of public health strategy. People who inject drugs (PWIDs) and the homeless often have difficulty engaging with screening measures and subsequent treatment. Outcomes for patients with liver disease have been repeatedly demonstrated to be worse in those with greater social deprivation. Baseline HCV testing of PWIDs attending our ED was low (6.3%) with a local HCV RNA positive prevalence of 10% in patients who were current injectors (2022 unpublished NHS England data). Peer support workers (PSW) have been shown to have high acceptability amongst patients with HCV to facilitate community-based screening and treatment. We sought to embed a PSW in the emergency department (ED) to see if this impacted detection of HCV and treatment initiation amongst PWIDs and homeless patients.
Method: 9-month pilot conducted between Feb-Nov 2022. PWIDs and homeless patients attending Bristol Royal Infirmary ED who identified through ED triage nurses and electronic alert systems. Highlighted patients were screened with OraQuick™ antibody and/or capillary blood-borne virus (BBV) testing. HCV positive patients were reviewed by a PSW, supported with Homeless Health team and Drugs and Alcohol nurse specialist. All HCV RNA positive patients were referred for treatment unless declined.
Results: 135 patients (81 males; 60%) were offered HCV testing at 159,126 patient ED episodes during the study period, which was accepted by 113 patients (26 OraQuick™ antibody; 88 BBV testing). In total, 24% of patients offered screening were HCV RNA positive (n = 33/135). 18 of these patients were known HCV RNA positive but had not been treated (54%), whilst 8/53 (15%) HCV RNA negative patients had previously missed their SVR check post-treatment. 5 of the 33 HCV RNA positive patients (15%) had become re-infected post prior successful treatment. 25/33 HCV RNA positive patients were aided by PSW to start treatment, giving a treatment conversion rate of 76% (positive test to treatment initiation). SVR data will be presented.
Conclusion: PSWs embedded within ED encourage high levels of engagement from PWIDs and homeless patients with HCV screening and treatment. This targeted strategy in a hard-to-reach population with high HCV prevalence offers an alternative approach to opt-out BBV testing of ED blood samples.

A large-scale, centralized viral hepatitis screening model in Hainan province of China during the COVID-19 pandemic

Tao Wu[1], Biao Wu[1], Feng Lin[1], Jiao Wang[1], Jianzhi Zhao[2], Lan Chen[3], Jinjie Li[4]. [1]*Hainan General Hospital, Haikou, China;* [2]*Dongfang Municipal Health Commission, Dongfang, China;* [3]*Dongfang People's Hospital, Dongfang, China;* [4]*Dongfang Center for Disease Control and Prevention, Dongfang, China*
Email: wutao1_ren@163.com

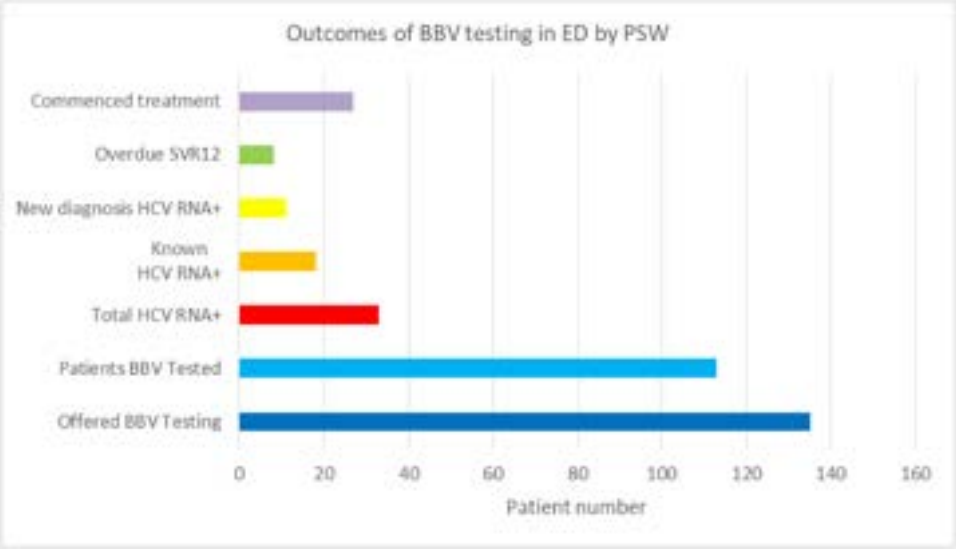

Figure: (abstract: THU-203).

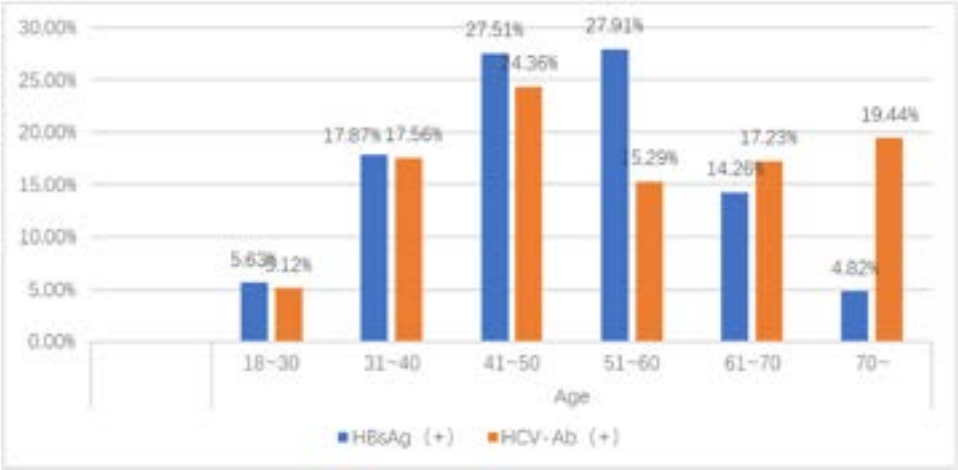

Figure: (abstract: THU-204): The baseline characteristics.

Background and aims: Hainan Province of China is on target to meet the 2030 WHO goal of viral hepatitis elimination by 2025. An increase in screening rates is required to meet this target. The Viral Hepatitis Elimination project kicked off in Jan. 2022. Dongfang city of Hainan Province is listed as a pilot. HBV/HCV screening should be considered a priority in this regard. And over the past year, we have also carried out regular screening for SARS-COVID-2, which means that all people can participate in the screening.
Method: Under the leadership of the Hainan government, the specialists from 3A hospitals in Hainan province worked with the primary doctors in Dongfang city on the training to increase the awareness of viral hepatitis. We have also worked with the staffs of community, who are trained to handle outbreak prevention and control, to conduct screening campaigns. We completed screening for HBV/HCV at one time in pilot areas in Dongfang.
Results: We conducted a daily public screening campaign in the pilot areas from Nov.11th, 2022 to Dec.8th, 2022. Totally, 22,137 people (>18y) were screened in the pilot area, and 38,774 of them were screened HCV at one time, 2.3% of them are HCV-Ab (+), 183,593 of them were screen HBV, 7.3% of them are HBsAg (+). The incidence rate of HBsAg (+) people is higher when they are >30 <70 years old, especially when they are 40–60 years old. There are more cases of HCV-Ab (+) in people over 30 years old, especially in people aged 41–50.
Conclusion: This is a model of government-led and multi-party collaboration to increase awareness about viral hepatitis and successfully conduct screening campaigns. When the resources are limited, it is more beneficial to improve the efficiency of screening by focusing on the screening of HBsAg and HCV-Ab for people over 30 years old. It would be a good model for contributing to viral hepatitis elimination.

THU-205

Usefulness of serum CCL20 as a post sustained viral response biomarker for HCV-associated liver fibrosis

Atsumasa Komori[1], Kosuke Matsumoto[2], Yuki Kugiyama[2], Tomoyuki Suehiro[2], Yasuhide Motoyoshi[1], Akira Saeki[2], Shinya Nagaoka[2], Hiroshi Yatsuhashi[2]. *[1]National Hospital Organization Nagasaki Medical Center, Clinical Research Center, Omura, Japan; [2]National Hospital Organization Nagasaki Medical Center, Hepatology, Omura, Japan*
Email: atsuriko1027@yahoo.co.jp

Background and aims: CCL20 is one of the advanced fibrosis-associated genes, that were commonly up-regulated among livers in advanced HCV, HBV, and NASH patients (Komori et al. Hepatology; 68: 909A, 2018). We analysed the chronological changes of serum CCL20 after the treatment with direct acting agents (DAAs) among patients with HCV-associated advanced fibrosis, in order to evaluate its potential as a post sustained viral response (SVR) serum biomarker for liver fibrosis.
Method: A) Serum CCL20 were compared between healthy volunteers (HV, n = 8) and HCV-eradicated patients whose FIB-4 index at SVR24 were larger than 3.25 after DAA treatment (cohort 1, n = 15). B) Serum CCL20 among HCV infected patients whose pre-treatment (Pre) liver stiffness (LS) were larger than 12.5 kPa by transient elastography (FibroScan) (median: 18.1 kPa, range: 13.1–47.2, cohort 2, n = 52) were analysed chronologically at Pre, SVR24, and SVR72. Correlation between serum CCL20 and either LS or serum fibrosis-associated glycosylated marker M2BPGi (Yamasaki et al. Hapatology, 2014) was evaluated (Spearman). Measurement of serum CCL20 was performed with ELISA kit (Quantikine, RandD systems, U.S.A.)
Results: A) Even after SVR, serum CCL20 were higher in cohort 1 than in HV (mean; 33.6 vs. 9.88 pg/ml, p = 0.015) B) Before treatment in cohort 2, serum CCL20 was correlated with serum M2BPGi (r_s = 0.5806, p = 0.0002), but not with LS (r_s = 0.2220, p = 0.1140). Decrease value from Pre to SVR24 in serum CCL20 (ΔCCL20) was correlated with ΔM2BPGi (r_s = 0.5129, p = 0.019), but not with ΔLS (r_s = 0.2520, p = 0.1646). Serum CCL20 was significantly decreased from Pre to SVR24, but not from SVR24 to SVR72 (Wilcoxon, p < 0.00001 vs p = 0.12749). Cumulative incidence of hepatocellular carcinoma until the end of observation among patients whose CCL20 were increased from SVR24 to SVR72 (Rebounding, n = 19) was not different to those in decrease (n = 33) (p = 0.12749). 6 out of 19 Rebounding experienced non-HCC liver-related events (de novo AIH, alcohol liver disease, fatty liver: n = 2, ascites, and esophageal varix).
Conclusion: Serum CCL20 may be an alternative biomarker for liver fibrosis that is useful even after SVR, as is M2BPGi. Such integrated character may partly be explained by the literature in which CCL20 was identified as fibrosis and steatosis marker for non-alcoholic steatohepatitis (Govaere et al. Sci Trans Med 2020).

THU-206

Hepatitis C and monoclonal gammopathy of undetermined significance: clinical and hematological outcome after eradication with direct acting antivirals

Rosa Claudia Stasio[1], Elisabetta Bretto[1], Marco Tizzani[1], Roberta Lasco[1], Yulia Troshina[1,2], Giacomo Scaioli[3], Fabrizia Pittaluga[4], Giorgio Maria Saracco[1,2], Alessia Ciancio[1,2]. *[1]S.C. Gastroenterology U, AOU città della salute e della scienza, Turin, Italy; [2]Departement of medical sciences, University of Turin, Italy; [3]Departement of public health sciences and pediatrics, AOU città della salute e della scienza, Turin, Italy; [4]S.C. Microbiology and virology, AOU città della salute e della scienza, Turin, Italy*
Email: stasio.rosa.claudia@gmail.com

Background and aims: Monoclonal gammopathy of undetermined significance (MGUS) has previously been reported among extra-hepatic manifestations of HCV. Currently, limited data are available about the impact of HCV eradication on MGUS progression. Hence, the aim of our study is to investigatethe outcome of patients with MGUS and HCV after eradication with Direct acting antivirals (DAAs).
Method: Between February 2015 and March 2022, 2914 patients with HCV were treated with DAAs in our hospital. Among them, 62 patients (29 Male/33 Female, mean age 71.3 (± 10.9)) presented MGUS before DAAs therapy. HCV genotype 1a has been found in 9 patients, 1b in 32, 2 in 14, 3 in 4, 4 in 2, 5 in 1 patient. Forty patients were naive, 16 non-responder and 6 relapser to INF-based therapy. Twenty patients were cirrhotic (32.8%). Virological and haematological end points have been retrospectively assessed at 3 months (T1), 6 months (T2) and at the most recent hepatologic/haematologic examination (T3) after sustained viral response (SVR12). MGUS progression was defined as development of symptomatic disease (CRAB criteria) and/or as an increase of monoclonal component (MC) ≥10%. Disease improvement was defined as reduction of MC ≥10%.
Results: Prevalence of MGUS in the selected cohort was 2.1%, similar to MGUS prevalence in the general population. SVR12 was obtained in all 62 patients (100%). MGUS improvement was reported in 20.3% of patients at T1, in 21% at T2 and in 19.6% at T3. Six patients (11.7%) showed MC regression at blood testing. Disease progression was reported in 1 patient (1.7%) at T1, in 2 (3.5%) at T2 and in 5 (9.8%) at T3. Only one of them progressed to Multiple myeloma (MM) at T3. All the others remained stable.
Conclusion: HCV eradication with DAAs is efficient and safe in patients with MGUS, and it is associated with very low rates of disease progression. Further studies are required to accurately reinforce their correlation.

THU-207

Ethnic disparity in mortality related to extrahepatic manifestations among people with chronic HCV infection: a large, linked administrative population-based study in British Columbia, Canada

Dahn Jeong[1], Stanley Wong[2], Mohammad Ehsanul Karim[1,3], Amee Manges[1,2], Jean Damascene Makuza[1], Hector Velasquez[2], Prince Adu[2], Sofia Bartlett[2], Eric Yoshida[4], Maria Alvarez[2], Amanda Yu[2], Mawuena Binka[2], Alnoor Ramji[4], Mel Krajden[5], Naveed Janjua[1,2,3]. *[1]The University of British Columbia, School of Population and Public Health, Canada; [2]BC Centre for Disease Control, Canada; [3]St. Paul's Hospital, Centre for Health Evaluation and Outcome Sciences, Canada; [4]The University of British Columbia, Division of Gastroenterology, Canada; [5]The University of British Columbia, Department of Pathology and Laboratory Medicine, Canada*
Email: dahn.jeong@bccdc.ca

Background and aims: Previous studies showed ethnic disparities in HCV-related clinical outcomes. Asian Americans living with HCV had higher cirrhosis and hepatocellular carcinoma. As for extrahepatic manifestations (EHM), Asians in US and Canada had a greater risk of diabetes than people of other ethnicities. Currently, there is little research on ethnic disparities in other EHMs. This analysis assessed the ethnic disparity in EHM-related mortality in a large, population-based cohort.

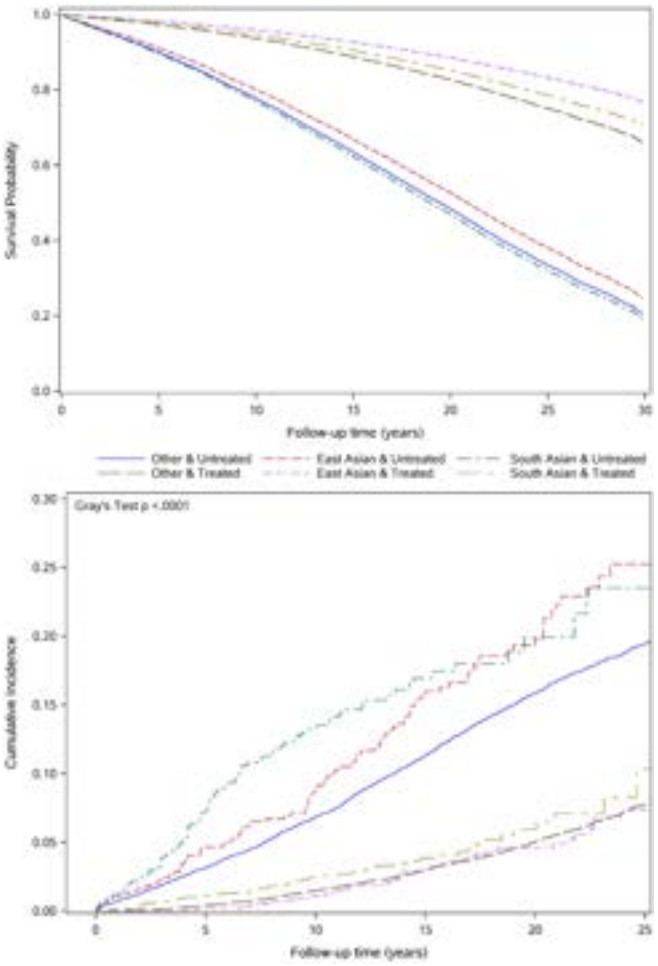

Figure 1: Upper: Overall survival curves for people diagnosed with HCV in BC-HTC, by ethnicity and treatment status. Lower: EHM-related mortality rates for people diagnosed with HCV in BC-HTC, by ethnicity and treatment status.

Method: We used the British Columbia Hepatitis Testers Cohort (BC-HTC) to identify all individuals diagnosed with HCV from 1990 to 2015, linked with administrative health datasets. We defined EHM-related deaths with causes of death from cardiovascular and cerebrovascular diseases, chronic kidney disease (CKD), and diabetes mellitus. Individuals were followed from their first HCV diagnosis until the earliest of: 1) death due to EHM, 2) other death, or 3) end of study (2021/12/31). EHM mortality rates were generated for each ethnic group (East Asian, South Asian, and Other) by HCV treatment (treated, untreated). We used multivariable subdistribution hazards models to account for competing risk and confounders, stratified by HCV treatment.
Results: Study population included 1,399 East Asian, 1,522 South Asian and 37,890 Other people diagnosed with chronic HCV in the BC-HTC. East Asian and South Asian were older compared to Other (45.4% vs 43.0% vs 25.9% ≥50 years of age, respectively), had a greater prevalence of diabetes (7.4% vs 12.8% vs 4.3%), end-stage renal disease (1.1% vs 2.4% vs 0.6%), and hypertension (15.7% vs 17.5% vs 8.4%), with greater material deprivation (28.6% vs 44.2% vs 23.6%), respectively. However, East and South Asian, compared to Other, had a lower prevalence of alcohol use disorder (2.6% vs 8.3% vs 17.8%) and injection drug use (5.5% vs 7.1% vs 20.9%). The overall EHM-related mortality rate was the highest among untreated South Asian (14.26 per 1,000 PYs) followed by untreated East Asian (13.25 per 1,000 PYs)

and untreated Other (10.44 per 1,000 PYs). The mortality rates were considerably lower for all individuals who were treated (2.52, 3.06, 2.87 per 1,000 PYs, for East Asian, South Asian and Other, respectively). Among untreated people, East Asian had a lower risk of overall EHM-related death (adjusted subdistribution hazard ratio [asHR] 0.79 95%CI 0.63–0.98) compared to Other; South Asian had a higher risk of CKD-related mortality compared to Other (asHR 1.61 95%CI 1.15–2.25). Among those who were treated, the risk of EHM-related death did not statistically differ for East and South Asians compared to Other.

Conclusion: EHM-related mortality was high among East and South Asians diagnosed with HCV, particularly among those who didn't receive treatment. HCV treatment decreased the risk of EHM-related death across all ethnicities and reduced disparities in EHM-related mortality. Continued provider and patient engagement efforts for HCV treatment could reduce HCV-related disease burden.

THU-208

Hepatitis C virus (HCV) infection and neurocognitive impairment in subjects with mild liver disease

Carlos Brandão-Mello[1], Marcia Maria Amendola Pires[1], Max Fakoury[1], Helen Rose Maia Salazar[2], Silvia Bastos de Oliveira[2], Sergio Schmidt[2].
[1]Gastrointestinal and Liver Unit, Gaffrée e Güinle University Hospital, Internal Medicine, Rio de Janeiro, Brazil; [2]Postgraduate Program in Neurology, Department of Neurology, Neurology, Rio de Janeiro, Brazil
Email: cedubrandao@gmail.com

Background and aims: Hepatitis C virus (HCV) infection is one of the leading causes of liver cirrhosis, hepatocellular carcinoma, and liver-related deaths. It is estimated that 40%-74% of HCV subjects will experience at least one extra hepatic manifestation within their lifetime, including neurocognitive deficits. The finding of HCV-RNA sequences in post[1]mortem brain tissue raised the possibility that HCV infection may affect the central nervous system and be the source of subtle neuropsychological symptoms, even in non-cirrhotic patients. Our investigation aimed to evaluate whether untreated, asymptomatic, mild HCV-infected subjects showed cognitive disfunctions.

Method: In this case-control observational study conducted at the Liver Unit of Gaffrée e Güinle University Hospital (HUGG), from May 2019 through March 2020. All HCV-infected subjects (anti-HCV and HCV-RNA detectable) over 18 years old were considered eligible for investigation. Only HCV subjects with compensated liver disease were included in the patient group. The comparison group consisted of subjects HCV negative and who were over 18 years old and paired by age and Human Development Index (HDI). HCV[1]subjects and healthy controls were tested at the same moment using three neuropsychological instruments in a random sequence: Symbol Digit Modality Test (SDMT), COWAT and the Continuous Visual Attention test (CVAT). We performed depression screening by DSM-V, liver fibrosis assessment by liver stiffness and blood tests, as well genotyping (sequencing) and HCV-RNA viral load (RT-PCR). A MANCOVA was performed to examine group differences (HCV vs. Healthy) in the six variables: OE (omission-errors), CE (commission-errors), reaction time (RT), variability of RT (VRT), SDMT, COWAT, using age, HDI and sex as covariates. Univariate ANCOVAs assess the effect of HCV on each one of the six neuropsychological variables. A discriminant analysis was performed to identify which variables effectively discriminate HCV-infected subjects and healthy controls.

Results: A sample of 48 subjects was initially evaluated. After applying the exclusion and inclusion criteria, 20 patients were excluded due to the following reasons: a) previous use of α-interferon: n = 8; b) cirrhosis: n = 3 c) type 2 mellitus diabetes: n = 3; d) depression: n = 2; e) patients without assessment of renal function: n = 2; f) hypothyroidism: n = 1 and g) bridging fibrosis (F3 fibrosis) subject with three abnormal liver enzymes: n = 1. Age and HDI did not differ among all groups. Mild fibrosis (F0-F2) was identified in 82.14%. Genotype was predominately 1 (82.14%). There were no differences in COWAT, (p = 0, 614) and SDMT (p = 0.608) between the groups. Performance of HCV group was poorer than the controls based on the CVAT. The univariate analysis indicated specific significant differences in RT (p = 0.047) and VRT (p = 0.046). We found RT to have significant discriminant ability (71.7%).

Table 3: Raw Scores of CVAT, SDMT, Fluency Tests (Animal & Letters) HCV subjects versus Healthy controls

Neuropsychological battery (mean; SD)		HCV - initial sample (n=48)	Mild Hepatitis HCV (n=28)	Control Group (n=18)
CVAT	OE	2.87 ± 6.37	1.54 ± 4.04	0.67 ± 1.28
	CE	6.14 ± 6.19	6.96 ± 7.23	5.50 ± 2.52
	RT (ms)	453.83 ± 67.01	448.18 ± 58.94	408.33 ± 29.02
	VRT (ms)	93.0 ± 38.43	86.71 ± 18.25	78.94 ± 14.41
COWAT	FL Animal	17.97 ± 5.10	18.67 ± 5.17	18.33 ± 4.21
	FL Fruit	14.20 ± 3.59	13.71 ± 3.82	15.61 ± 2.32
	FL F	11.5 ± 5.22	11.42 ± 5.35	12.78 ± 4.95

HCV: Hepatitis C virus; CVAT: Continuous Visual attention test; OE: omission error; CE: commission error; RT: reaction time; VRT: variability of reaction time; COWAT: controlled oral word association test; FL: Fluency; SDMT: Symbol digit modality test

Figure:

Conclusion: HCV subjects with mild disease showed deficits in RT and intraindividual VRT as compared to healthy controls in CVAT. The higher VRT and RT exhibited by the HCV group might be explained by lapses in attention which affected the stability of response times and caused an increase in VRT. Our finding suggests that patients with mild HCV exhibit sustained attention problems and it may reflect deficits in the intrinsic alertness subdomain.

THU-209

Chronic hepatitis C and aging: search for cognitive changes

Carlos Brandão-Mello[1], Max Fakoury[1], Marcia Maria Amendola Pires[1], Sergio Schmidt[2]. *[1]Gastrointestinal and Liver Unit, Gaffrée e Güinle University Hospital, Internal Medicine, Rio de Janeiro, Brazil; [2]Postgraduate Program in Neurology, Department of Neurology, Neurology, Rio de Janeiro, Brazil*
Email: cedubrandao@gmail.com

Background and aims: Hepatitis-C virus (HCV) exhibits neurotropism, including brain areas associated with cognitive impairment (CI). Therefore, HCV infection is a risk factor for CI, even without hepatic manifestations. Most infected elderlies acquired HCV when they were young by parenteral route, and the disease remains asymptomatic. However, elderlies chronically infected might be at a greater risk of CI. AIM: To investigate cognitive performance of asymptomatic elderlies with HCV controlling for risk factors commonly associated with cognitive decline.

Method: Cross sectional observational study conducted between May 2018 to February 2020 at the Gastroenterology and Liver outpatient clinic of the Gaffrée e Güinle University Hospital (HUGG). The patients underwent a global health assessment, which provided information on the epidemiological and comorbidity profile, functionality and general well-being, in addition to data on liver function tests, grade of fibrosis (evaluated by liver stiffness), genotype (sequencing) and viral load (RT-PCR). Then, the study participants were subjected to a battery of neurocognitive tests, namely, the Minicog, Mini-Mental State Examination (MMSE), verbal fluency test (VFT) semantic category (animals), and clock drawing test (CDT). Elderlies uninfected (n = 41) and chronically HCV-infected (n = 41) were paired by age, sex, comorbidities, depression, lifestyle, and level of education. HCV-infection was confirmed by anti-HCV reactive and detectable HCV-RNA for more than six months. Participants coinfected with hepatitis B (HBV) or HIV were excluded. A MANCOVA tested whether HCV infection affected cognitive

performance. The possible effect of each covariate and its respective interactions were analysed.
Results: There were not any significant differences between the two groups regarding age, sex, and educational level. However, schooling affected both groups. We found a highly significant main effect of education in relation to cognitive tests ($F = 4.42$, 293 df = 4/73, $P = 0.003$, $\eta 2 = 0.20$) and a main effect with no difference between groups, that is, nonsignificant effect of Group ($F = 1.31$, df = 4/73, $P = 0.27$, $\eta 2 = 0.07$). Based on the results of the MANCOVAs, in which education was the only one that had statistical significance in the analyses, we performed the ANCOVAs, where the univariate tests showed that education affected the performance of the MMSE scores ($F = 12.3$, 299 df = 1/76, $P = 0.001$, $\eta 2 = 0.14$) and VFT ($F = 11.1$, df = 1/76, $P = 0.001$, $\eta 2 = 0.13$). The difference in education level approached the significance level in the CDT ($F = 3.63$, df = 1/76, $p = 0.06$, $\eta 2 = 0.05$). In contrast, MINICOG did not differ between the two groups regarding years of formal education (Low and High). All other univariate measures did not reach significant results.
Conclusion: HCV infection did not influence performance of the cognitive screening tests in elderly subjects. Formal years of education (cognitive reserve) may have protected elderlies with HCV-infection. Future studies should be performed using specific tests associated with the brain regions affected by HCV.

THU-210
Coadministration of hepatitis C direct-acting antivirals and enzyme-inducing antiepileptic drugs: real-world experience from a multi-centre case series

Alison Boyle[1,2], Fiona Marra[1,2], Helen Boothman[3], Sonal Patel[4], Yun Jung Kim[5], Rachael Kamiri-Ngugi[6], Aimee Francisco[7], Rebecca Turley[8]. *[1]NHS Greater Glasgow and Clyde, Pharmacy, United Kingdom; [2]University of Liverpool, Pharmacology and Therapeutics, United Kingdom; [3]St George's University Hospitals NHS Foundation Trust, Pharmacy, United Kingdom; [4]Guy's and St Thomas' NHS Foundation Trust, Pharmacy, United Kingdom; [5]University Hospital Southampton NHS Foundation Trust, Pharmacy, United Kingdom; [6]Royal Surrey NHS foundation trust, Pharmacy, United Kingdom; [7]King's College Hospital NHS Foundation Trust, Pharmacy, United Kingdom; [8]Barking, Havering and Redbridge University Hospitals NHS Trust, Pharmacy, United Kingdom*
Email: alison.boyle@ggc.scot.nhs.uk

Background and aims: Coadministration of enzyme-inducing anti-epileptic drugs (eiAEDs) and hepatitis C (HCV) direct-acting antivirals (DAAs) is not currently recommended due to potential drug-drug interaction (DDI) resulting in significantly reduced DAA levels and risk of treatment failure. This presents a significant barrier to HCV treatment for patients who are unable to stop or switch to alternative antiepileptic agents. There have been a small number of case reports published describing successful outcomes in patients receiving HCV DAA treatment while remaining on eiAEDs[1, 2]. This has led to updated recommendations in the University of Liverpool DDI resource, www.hep-druginteractions.org, to allow consideration of HCV DAA treatment where coadministration is unavoidable. However, the lack of widespread clinical experience may still lead to hesitancy in prescribing in this patient cohort.
Method: A retrospective case series evaluating treatment outcomes of patients prescribed HCV DAAs in combination with eiAEDs in 6 centres across the UK.
Results: A total of 11 patients with chronic, treatment-naïve HCV were treated with HCV DAAs in combination with eiAEDs. Median age was 56 years (range 38–64 years), 8 (73%) patients were non-cirrhotic, 9 (82%) were male and 7 (64%) had GT1A HCV. HCV DAAs were prescribed at standard doses (12 weeks sofosbuvir/velpatasvir (n = 6), 8 weeks ledipasvir/sofosbuvir (n = 3), 8 weeks glecaprevir/pibrentasvir (n = 2)). Coadministered eiAEDs included carbamazepine (n = 6), phenytoin (n = 3), oxcarbazepine (n = 1), phenobarbitone (n = 1). High treatment adherence was reported for 10/11 individuals with 1 patient completing 50% of prescribed treatment course. On-treatment HCV PCR data was available for 7 (64%) patients; of those, 6 had an undetectable HCV PCR and 1 had HCV PCR 156 IU/ml within the first 4–6 weeks of treatment. End of treatment HCV PCR was available for 6 (55%) patients with all achieving undetectable levels. SVR 12 results are available for 3 patients so far with all achieving SVR 12. The remaining 8 patients are awaiting SVR 12 results. Full SVR data will be presented.
Conclusion: This is the largest single case series of coadministered eiAEDs and DAAs. Preliminary data of treatment outcomes are very encouraging and support previously published real-world case reports. These results will help inform HCV treatment decisions in this cohort who continue to face challenges in accessing treatment.

Impact of hepatitis C treatment on biochemical and metabolic parameters in HIV/HCV coinfected patient

Lourdes Pedroza[1], Misael Osmar Garcia Martin[2], Victor Ahumada Topete[2], Karina Sevilla[2], Manuel Castillejos Lopez[2], Gustavo Reyes Teran[3], Andrea Carenas Ortega[4], Akio Murakami Ogasawara[4], Santiago Ávila Ríos[4], Arturo Rodea Monroy[2]. *[1]Instituto Nacional de Enfermedades Respiratorias, Gastroenterology and Endoscopy, Ciudad de México, Mexico; [2]Instituto Nacional de Enfermedades Respiratorias, Hospital Epidemiology and Infectious Disease Unit, Ciudad de México, Mexico; [3]CCINSHAE, principal of the coordinating commission of national health institutes and highly specialized hospitals, Ciudad de México, Mexico; [4]Instituto Nacional de Enfermedades Respiratorias, infectious disease research center, Ciudad de México, Mexico*
Email: drapedroza.lourdes@gmail.com

Background and aims: Efficacy and effectiveness of direct-acting antivirals (DAAs) in HIV/HCV coinfected patients such as mono-infected patients; however, few studies analyze post-treatment improvement in this population. This study aimed to evaluate the changes in renal and hepatic function and fibrosis in coinfected patients treated with direct-acting antivirals.
Method: In this observational and prospective study, from April 2017 to April 2022, HIV/HCV coinfected this patient from a specialized care clinic in Mexico; the duration of treatment with DAÁs was 12 weeks. Quantitative variables were described using the mean and standard deviation or median and interquartile range. Using the Wilcoxon rank test, the continuous quantitative variables were compared with the 24-week results (sustained viral response).
Results: 86 patients were included, mean age of 40.36 (SD 9.08); 79 (91.9%) men and 7 (8.1%) women, all on ART with virological suppression. The following results were obtained when comparing the baseline data vs. sustained viral response: glomerular filtration 102.0 ml/min/1.73 m^2 (88.5–114.0) vs. 96. (79.5–109.5) with $p = 0.000555$, albumin 4.20 gr/dl (4.01–4.40) vs. 4.32 gr/dl (4.17–4.54) with $p = 0.000234$, total bilirubin 0.74 mg/dl (0.50–1.10) vs. 0.65 mg/dl (0.44–0.89) with $p = 0.029954$, direct bilirubin 0.16 mg/dl (0.11–0.24) vs. 0.12 mg/dl (0.08–0.15) with $p = 0.000714$, GOT 48.50 IU/l (37.0–69.5) vs. 22.0 IU/l (20.0–28.0) with $p = 4.3255E-11$, GPT 60.0 IU/l (42.0–86.250) vs. 21.1 IU/l (15.25–26.92) with $p = 1.0582E-12$, ALP 105.0 IU/l (79.0–129.85) vs. 92.0 IU/l (74.0–120.0) with $p = 0.001719$, GGT 82.35 IU/l (45.5–183.25) vs. 22.0 IU/l (17.0–34.1) with $p = 0.000229$, Total cholesterol 149.75 mg/dl (134.55–182.75) vs. 167.95 mg/dl (143.25–187.87) with $p = 0.035503$, LDL Cholesterol

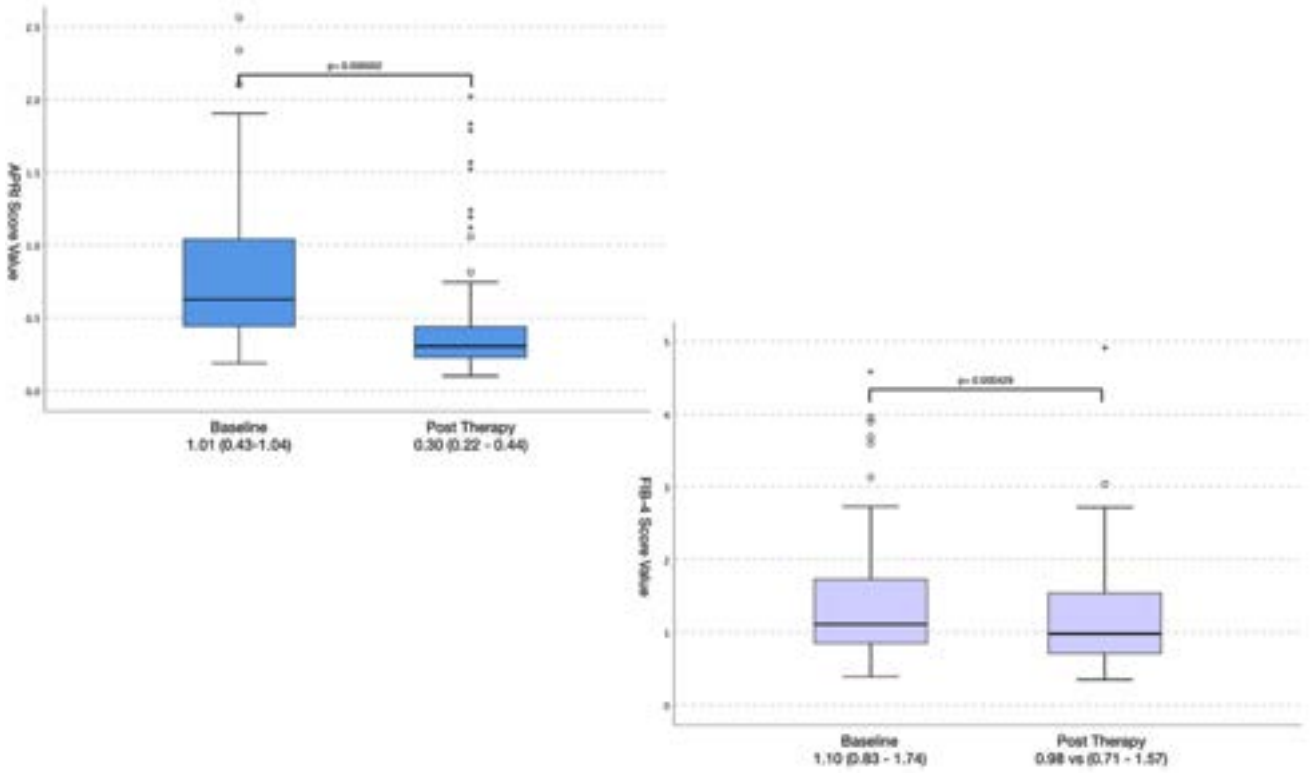

Figure: (abstract: THU-211): Represents the box-and-whisker plots of the Score for hepatic fibrosis.

85.0 mg/dl (63.22–104.05) vs. 102.2 mg/dl (85.65–120.85) with p = 0.002335.
Conclusion: HIV/HCV coinfected patients in virological suppression showed medium-term improvement in most biochemical and metabolic parameters. Simultaneously, a decrease in fibrosis scores was observed after presenting a sustained viral response.

THU-212
Sustained virologic response outcomes in patient with hemodialysis-hepatitis C receiving treatment with direct-acting antivirals agents
Fardhah Akil[1,2,2], Rini Bachtiar[1,2], Muhammad Luthfi Parewangi[1,2], Nu'man AS Daud[1,2], Susanto Kusuma[1,2], Amelia Rifai[1,2], Hasyim Kasim[3], Haerani Rasyid[3]. *[1]Centre of Gastroenterology-Hepatology HAM Akil/DR. Wahidin Sudirohusodo General Hospital, Indonesia; [2]Hasanuddin University, Division of Gastroenterology-Hepatology, Department of Internal Medicine, Indonesia; [3]Hasanuddin University, Division of Nephrology, Department of Internal Medicine, Indonesia*
Email: dndakil@gmail.com

Background and aims: Direct-acting antiviral agents (DAAs) have become first-line treatment for hepatitis C virus (HCV) infection and was associated with a survival benefit among persons on hemodialysis. Study of efficacy treatment of DAAs by sustained virologic response (SVR) in dialysis patients are still limited especially in Indonesian population.

Method: This retrospective cohort study was conducted in tertiary care hospital in Makassar, Indonesia between 2017 and 2020. From 90 patients naïve HCV on hemodialysis, 75 of them had received DAAs with regimen Sofosbuvir/Simeprevir, Sofosbuvir/Daclastavir, Sofosbuvir/Ribavirin, and Elbastavir/Grazoprevir. The outcome were sustained virological responses by 12 weeks (SVR12), improvement or deterioration of kidney function by estimated Glomerular Filtration Rate (eGFR)/creatinine, hepatic fibrosis assessed by aspartate aminotransferase-to-platelet ratio index (APRI)/Fibrosis-4 index (FIB-4) scores and the associated factors.
Results: Overall the SVR12 rate was 93.3% and by regimen SOF/SIM, SOF/DAC, SOF/RIB, and ELB/GRV were 95.7%, 90%, 100%, and 80%, while Child-Pugh (CP) class A/B/C had 95.6%/90%/100% respectively. In patients with cirrhosis/no cirrhosis, the SVR rate were similar 93.5%/93.2%. The mean eGFR for SOF/SIM associated with SVR12 were deteriote from 36.1 to 17.15, while SOF/DAC were improve from 14.54 to 18.79; but no statistically significant for overall eGFR. Both overall mean score APRI and FIB-4 improvement was associated with SVR12 0.16 (95% CI 0.03–0.30) and 0.42 (95% CI 0.13–0.71) respectively; similar to APRI/FIB-4 pre and post treatment regardless of the DAAs regimens ($p < 0.05$).
Conclusion: DAA-mediated SVR12 in HCV dialysis patients resulted in high rate SVR12 >90% and similar rate in all CP class, cirrhosis status with improvement of hepatic fibrosis and kidney function especially on sofosbufir/daclastavir regimen.

Viral hepatitis C Therapy and resistance

THU-213

Sofosbuvir/Velpatasvir/Voxilaprevir for re-treatment in direct-acting antiviral experienced hepatitis C virus patients: a systematic review and meta-analysis

Devan Pooja[1], Tiong Kai Le Ashley[1], Neo Jean Ee[1], Yu Jun Wong[2,3].
[1]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore;* [2]*Changi General Hospital, Singapore;* [3]*Duke-NUS Medical School, Singapore*
Email: wongyujun1985@gmail.com

Background and aims: About 5% of chronic hepatitis virus (HCV) patients treated with direct-acting antiviral did not achieve sustained virological response (SVR12). Data on treatment outcome and predictor of treatment failure on DAA-experienced HCV patients receiving sofosbuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX) is limited. We performed a systematic review and meta-analysis to evaluate the efficacy and safety of SOF/VEL/VOX as salvage treatment in DAA-experienced HCV patients.

Method: A comprehensive search of 5 electronic databases were performed from inception to 1st January 2023. All English literature, irrespective of study design, publication dates were extracted. Pooled estimates were reported in odds ratio (OR) with 95% confidence interval (CI) using random-effect model. Our study outcome was the SVR12, based on modified intention-to-treat; secondary outcome was treatment discontinuation due to treatment-related adverse effect. Subgroup analysis performed based on genotype, status of cirrhosis, HCC, prior SOF/VEL exposure and region.

Results: Over 517 citations identified from 5 databases (PubMed, EMBASE, MEDLINE, Clinical-trial.gov and Web of Science). Data from 24 studies (Asia pacific = 5, Africa = 3, America = 7, Europe = 9) involving 2,822 DAA-experienced HCV patients were included. All studies had low to moderate risk of bias. The mean age was 53 years old, 81% were male, 42% had liver cirrhosis. Genotype distributions were diverse (GT1: 74.4%, GT2: 9.9%, GT3: 26.1%, GT4: 8.5%, GT6: 1.4%, indeterminate: 0.9%). 17.2% receive SOF/VEL prior to SOV/VEL/VOX; 25% received ribavirin with SOF/VEL/VOX. 42% had pre-treatment RAS testing performed, where mutation was present in 51%,.

Overall pooled SVR12 was 95.0% (95%CI: 94.0–95.8%), with lower SVR12 in Europe compared to region (Europe 84.3% vs Asia Pacific: 96.2%; America 93.0% or Africa 98.9%. $p < 0.0001$ for all). Predictors for treatment failure for retreatment by SOF/VEL/VOX were genotype 3 (OR 0.39, 95%CI: 0.23–0.64, I^2:7%), active HCC (OR 0.22, 95%CI: 0.08–0.57, I^2:0%) and baseline cirrhosis (OR 0.25, 95%CI: 0.11–0.60, I^2:0%), decompensated cirrhosis (OR 0.09, 95%CI: 0.03–0.23, I^2:3%) and prior SOF/VEL (OR 0.35, 95%CI: 0.13–0.94, I^2:54%). Baseline RAS mutation and addition of ribavirin to SOF/VEL/VOX was not associated with higher SVR12. Treatment discontinuation due to drug-related was uncommon (10 studies, 0.2%).

Conclusion: SOF/VEL/VOX is efficacious and safe for retreatment in HCV patients with prior DAA failure. even with RAS mutation. Our findings support SOF/VEL/VOX as 1st-line rescue treatment for DAA-experienced HCV patients.

Email: tt@aidscenter.ge

Background and aims: The country of Georgia launched the world's first national hepatitis C elimination program in April 2015. Key strategies include nationwide screening, active case finding, linkage to care, decentralized care, and provision of treatment for all persons with hepatitis C virus (HCV) infection, along with effective prevention interventions. The elimination program aims to achieve the following targets: a) diagnose 90% of HCV-infected persons, b) treat

95% of those diagnosed, and c) cure 95% of those treated. We report progress toward elimination targets of the elimination program.
Method: The estimated number of persons with HCV infection was based on a 2015 population-based national seroprevalence survey, which showed that 5.4% of the general adult population had current HCV infection (approximately 150,000 persons). We analyzed data in the national HCV screening and treatment databases during April 2015–December 2022.
Results: As of December 31, 2022, 154,428 adults screened positive for HCV antibodies. Of those, 128,093 (82.9%) received HCV RNA or core antigen testing. A total of 100,576 (78.5%) persons tested had detectable HCV infection, and 80,828 (80.4%) initiated treatment. Of 57,031 adults who were evaluated for sustained virologic response (SVR), 56,447 (99.0%) had no detectable HCV RNA. Based on the 90–95-95 program goals, Georgia has diagnosed 67.1% of the estimated 150,000 adults with current HCV infection, treated 63.0% of the target 128,250 (95% of 150,000), and cured 46.3% of the target 121,837 (95% of 128,250). Treatment effectiveness was comparable among persons with advanced fibrosis (FIB-4 score F3 or F4) with 98.3% achieving SVR, and among patients with mild or no liver fibrosis (FIB-4 score≤F2), SVR = 99.2%, p < .0001.
Conclusion: Georgia has made substantial progress towards eliminating hepatitis C. Over 65% of persons with current HCV infection have been diagnosed, and most have initiated treatment and experienced high cure rates regardless of fibrosis status. Challenges remain in identifying and linking to care persons with current HCV infection in Georgia. The Nationwide integrated, decentralized model of HCV treatment, which is already implemented in many locations, will be critical to improve linkage to care and close gaps in the HCV cascade of care.

THU-215

The most difficult to cure with pangenotypic regimens HCV infected population

Robert Flisiak[1], Hanna Berak[2], Anna Parfieniuk-Kowerda[1], Dorota Dybowska[3], Krzysztof Tomasiewicz[4], Marek Sitko[5], Dorota Zarębska-Michaluk[6], Włodzimierz Mazur[7], Ewa Janczewska[8], Jakub Klapaczynski[9], Jerzy Jaroszewicz[10]. *[1]Medical University of Białystok, Białystok, Poland; [2]Hospital for Infectious Diseases in Warsaw, Warsaw, Poland; [3]Ludwik Rydygier Collegium Medicum in Bydgoszcz Faculty of Medicine Nicolaus Copernicus University in Toruń, Bydgoszcz, Poland; [4]Medical University of Lublin, Lublin, Poland; [5]Jagiellonian University, Kraków, Kraków, Poland; [6]Jan Kochanowski University Kielce, Kielce, Poland; [7]Medical University of Silesia, Chorzów, Chorzów, Poland; [8]ID Clinic, Mysłowice, Poland; [9]Central Clinical Hospital of the Ministry of Internal Affairs and Administration, Warsaw, Poland; [10]Medical University of Silesia, Katowice, Bytom, Poland*
Email: robert.flisiak1@gmail.com

Background and aims: Pangenotypic therapies for HCV infections, although universal and highly effective, leave the risk of treatment failure. The aim of the analysis was to find out the most difficult to cure with pangenotypic regimens population of HCV infected patients.
Method: The analysis included patients selected from the EpiTer-2 database, a large retrospective, multicentre, national real-world study evaluating DAA treatment during period of 2015–2022 in 17, 166 consecutive subjects with hepatitis C virus (HCV) infection. The effectiveness of treatment was assessed in populations known as a worse response to treatment, and then in a population with a combination of all these characteristics.
Results: A total of 5,549 patients were treated with pangenotypic regimens, of which 5,217 achieved SVR, that after excluding 194 lost to follow-up resulted in a response rate of 97.4%. In the group of 1,338 patients infected with genotype 3, the SVR rate was 94.9%, among 1,142 patients with cirrhosis-94.2%, in the population of 2,852 men-96.5%, and among 941 people with BMI>30 it reached 96.8%. The analysis carried out in a group of 82 men with cirrhosis and obesity, infected with genotype 3 showed the effectiveness of pangenotypic therapy at the level of only 85.4%, with 89.3% in treatment naive patients and 76.9% in patients with previous therapy failure.
Conclusion: Studying a large population of pangenotypically treated HCV-infected patients, we showed relatively low effectiveness in men with cirrhosis and obesity, infected with genotype 3. Triple therapy should be considered initiating the treatment of HCV infections in this group, which, however, needs to be confirmed in further studies. Previous studies (Polaris-3) were conducted in a less demanding population of patients with cirrhosis infected with genotype 3, so they did not take into account gender and BMI, which significantly worsen the effectiveness.

THU-216

Real-life effectiveness of voxilaprevir/sofosbuvir/velpatasvir in hepatitis C patients previously treated with sofosbuvir/velpatasvir or glecaprevir/pibrentasvir

Background and aims: Voxilaprevir/sofosbuvir/velpatasvir (VOX/SOF/VEL) is the recommended therapy for patients with chronic hepatitis C who failed to direct-acting antivirals (DAAs). This is based on studies that mainly included failures to DAAs that are not currently recommended. There is still limited data on retreatment after failure to current first line therapies, sofosbuvir/velpatasvir (SOF/VEL) and glecaprevir/pibrentasvir (GLE/PIB). The aim of the study was to analyze the effectiveness and safety of VOX/SOF/VEL in a real- world setting among only failures to SOF/VEL or GLE/PIB.
Method: Patients with HCV retreated with VOX/SOF/VEL after SOF/VEL or GLE/PIB failure were enrolled in 26 centers in Spain between December of 2017 and December of 2022. All patients received VOX/SOF/VEL ± ribavirin (RBV) for 12 weeks. Sustained virological response (SVR) was defined as undetectable HCV-RNA 12 (SVR12) weeks after the end-of-treatment. Patients with HCV reinfection were excluded.
Results: A total of 135 patients were included, 98 (72.6%) had failed to SOF/VEL and 37 (27.4%) to GLE/PIB. Baseline characteristic were median age 54.1 (IQR 9) years, 84.4% male, 96% Caucasian, 11.9% coinfected by HIV, 50.9% had history of injected drug use and 44.2% were cirrhotic. GT3 was the predominant in 50.4% of patients followed by GT1 in 36.8%. Median HCV-RNA was 2.9×10^6 (2.4×10^5–3.2×10^6). Up to now, 97 (86.6%) of 111 patients who reached follow-up 12 weeks after treatment have achieved SVR. There was a trend to higher rate of SVR in patients previously treated with GLE/PIB than SOF/VEL (88.9% vs 85.5%) (p = 0.43). There were no significant differences in SVR between patients with or without cirrhosis (84% vs 90%) (p = 0.24), or based on HCV genotype, being 83% for GT3 vs. 89% in other genotypes (p = 0.29). Among the 14 patients without SVR to VOX/SOF/VEL despite completing treatment, 9 were GT3, 7 had cirrhosis and 4 (29%) were both GT3, cirrhotic and previously treated with SOF/VEL. RBV was added to VOX/SOF/VEL in 8 (6%) patients and all of them achieved SVR including 5 (63%) GT3 with cirrhosis and prior failure to SOF/VEL. There were no adverse relevant events related to the medication.
Conclusion: VOX/SOF/VEL in the real world is an effective rescue therapy for failures to SOF/VEL or GLE/PIB. There is a trend towards higher SVR in patients previously treated with GLE/PIB. The addition of RBV to VOX/SOF/VEL could rise the rates of SVR and might be considered in patients with GT3, cirrhosis and prior failure to SOF/VEL.

Background and aims: Although pan-genotypic direct-acting antivirals (DAA) sofosbuvir/velpatasvir (SOF/VEL) and glecaprevir/pibrentasvir (GLE/PIB) have simplified hepatitis C virus (HCV) treatment, treatment access remains limited due to constraints of specialist resource (e.g., gastroenterologist). Task-sharing by directing non-complicated cases to non-specialists is therefore crucial for upscaling treatment delivery. This study aimed to develop an algorithm to identify patients who can be safely managed by non-specialists.

Method: In this observational study, 10,641 HCV-infected patients registered in the Taiwan HCV Registry (TACR, a nationwide database of HCV-infected patients treated with DAA) between August 2019 and August 2021 were screened, and were included if they received ≥1 dose of SOF/VEL or GLE/PIB and fulfilled the eligibility criteria for simplified treatment by either the European Association for the Study of the Liver (EASL) or the American Association for the Study of Liver Diseases (AASLD) guidelines. Multivariate analysis was conducted to identify patient risk factors associated with Grades 2–4 laboratory abnormalities in liver function parameters (including alanine aminotransferase, aspartate aminotransferase, and total bilirubin) during treatment and the three-month post-treatment follow-up period. An algorithm for simplified treatment with non-specialists (the TACR algorithm) was then developed based on 1) the EASL and AASLD criteria, 2) the risk factors identified, and 3) previous studies regarding additional management needs for special populations.

Results: A total of 7,677 patients were included in this analysis. Multivariate analyses identified the following patient characteristics associated with higher risks of Grades 2–4 abnormalities: age >70 years old, presence of hepatocellular carcinoma, total bilirubin >1.2 mg/dL, estimated glomerular filtration rate (by the Modification of Diet in Renal Disease equation) <60 ml/min/1.73 m2 , and Fibrosis-4 >3.25. Incorporating these factors into the algorithm can help better differentiate patient populations with less and more safety management needs. The TACR algorithm for simplified HCV treatment with non-specialists (Figure) was then formulated. Briefly, patients with any ineligibility factors (such as history of hepatic compensation) should seek specialist care due to more complex management needs. Patients with any conditional ineligibility factors (such as age >70 years old) can be managed by specialist care, or by non-specialist care after consultation with a specialist. Patients without any ineligibility factor can be safely managed by non-specialists.

Conclusion: The TACR algorithm can provide important guidance in the effort to promote task sharing to non-specialists, which would be an important step towards HCV elimination.

THU-218

Evaluating utilization and management of comedications with potential for drug-drug interactions among patients with chronic hepatitis C initiating treatment with sofosbuvir/velpatasvir or glecaprevir/pibrentasvir

Stuart C Gordon[1], Andrea Steffens[2], Laura Weber[2], Kimberly McNiff[2], Alon Yehoshua[3]. [1]*Henry Ford Hospital, United States;* [2]*Optum, United States;* [3]*Gilead Sciences, Inc., United States*
Email: andrea.steffens@optum.com

Background and aims: Direct-acting antiviral (DAA) agents for treatment of chronic hepatitis C (HCV) include glecaprevir/pibrentasvir (GLE/PIB), a protease inhibitor with known drug-drug interaction (DDI) effects, and sofosbuvir/velpatasvir (SOF/VEL), a protease inhibitor-free regimen with a more favorable DDI profile. This analysis compared rates and management of comedications with DDI risk (DDI comedications) among patients initiating DAA treatment with SOF/VEL or GLE/PIB.

Method: Adults initiating SOF/VEL or GLE/PIB from July 2016–April 2020 were identified from US administrative claims data in the Optum Research Database. The index date was the first claim for SOF/VEL or GLE/PIB. Continuous enrollment 12 months before (baseline) and 6 months after the index date was required. Patients with baseline liver disease, HCV treatment, or HIV were excluded. Demographics and DDI comedication use were measured. All DDI comedications associated with GLE/PIB and SOF/VEL and DDI comedication severity, defined from more to less severe as red, amber, or yellow, were from the Liverpool HEP Drug Interactions Database. DDI comedication discontinuation, dose decrease, and change to medication with no DDI risk during DAA treatment were measured in the subset of patients with prevalent DDI comedications 90 days prior to index.

Results: Among 4,528 patients meeting study criteria, 66.6% of GLE/PIB initiators and 43.7% of SOF/VEL initiators had any baseline DDI comedication use ($p < 0.01$). Compared with SOF/VEL initiators, GLE/PIB initiators had higher baseline rates of red (21.4% vs 2.3%), amber (51.9% vs 41.6%), and yellow (31.4% vs 2.8%, all $p < 0.01$) DDI comedications. DDI comedication use decreased during DAA treatment but remained higher in GLE/PIB initiators vs SOF/VEL initiators (41.5% vs 28.9%, $p < 0.01$). Overall, 979 GLE/PIB and 658 SOF/VEL initiators used prevalent DDI comedications in the 90 days pre-index. Of these, GLE/PIB vs SOF/VEL initiators had similar mean age (61.6 vs 61.8 years), proportions of female (42.2% vs 38.8%) and commercially insured (32.0% vs 29.5%) patients; baseline compensated cirrhosis was lower among GLE/PIB vs SOF/VEL initiators (5.8% vs 9.6%, $p < 0.01$). A higher proportion of GLE/PIB vs SOF/VEL initiators discontinued at least 1 DDI comedication before initiating DAA treatment (52.2% vs 38.0%, $p < 0.01$). During DAA treatment, GLE/PIB vs SOF/VEL initiators had higher rates of dose decrease (10.8% vs 6.8%, $p = 0.026$) and change to medication with no DDI risk (3.5% vs 1.1%, $p = 0.014$).

Conclusion: Use of DDI comedications was identified among a substantial proportion of patients, with higher rates of DDI comedication use and actions taken to manage DDI comedication use in GLE/PIB vs SOF/VEL initiators. Additional research is needed to assess real-world consequences of potential DDIs.

THU-219

Concomitant use of proton pump inhibitors and Sofosbuvir/Velpatasvir: evidence from randomized clinical trials and real-world data

Rafael Esteban[1], Steve Flamm[2], Maria Buti[1], Juan Turnes[3], Liyun Ni[4], Candido Hernández[5], Alessandra Mangia[6]. *[1]Hospital Vall Hebron, Barcelona, Spain; [2]NorthwesternUniversity Feinberg School of Medicine, Chicago, United States; [3]Complejo Hospitalario Universitario de Pontevedra, Gastroenterology and Hepatology Department, Pontevedra, Spain; [4]Gilead Sciences, Biostatistics Virology, Foster City, United States; [5]Gilead Sciences, Global Medical Affairs, Madrid, Spain; [6]IRCCS Casa Sollievo della Sofferenza, UOSD Epatologia, San Giovanni Rotondo, Italy*
Email: candido.hernandez@gilead.com

Background and aims: Literature and product labels suggest velpatasvir bioavailability may be reduced when administered concomitantly with a proton pump inhibitor (PPI), based mainly on pharmacokinetic studies. We aimed to determine the clinical relationship between PPI use and sustained virologic response rates (SVR) in patients treated with sofosbuvir/velpatasvir (SOF/VEL) for chronic hepatitis C virus (HCV) infection in available data coming from Phase 2/3 clinical trials (RCT) and Real-Word Data (RWD).
Method: Retrospective and descriptive analysis of data from patients treated with SOF/VEL for 12 weeks with and without concomitant use of PPIs and participating in Phase 2/3 RCTs and RWD studies. In RCT, PPI use was captured as part of standard concomitant medication reporting, with specific details regarding PPI dosing not collected. Main variables collected for this analysis consisted of SVR12 and relapse rate.
Results: Overall, 546 patients with PPI use were identified, 87 coming from RCT and 459 from RWD. The overall control group of patients without PPI use was 5,201; 2,517 in RCTs and 2,684 in RWD.
In RCT, patients receiving PPI and SOF/VEL were mainly male (79%), with a mean age of 57 years (26–78), GT3 in 56% and cirrhotic in 35%. Most patients participating in RCT (66%, 57/87) continuously used PPI during the 12-week course of treatment with SOF/VEL, omeprazole being the most used PPI (68%). Overall SVR12 in PPI users was 97% (84/87), comparable to the reported by non-PPI users (97%). SVR12 in GT3 patients was 96% (47/49), in F4 was 94% (30/32). In GT3 plus F4 patients, SVR12 was 96% (23/24). Of the 3 patients who did not achieve SVR12 in PPI-users, 2 patients relapsed (relapse rate 2%) and one patient with a history of diabetes discontinued SOF/VEL after 7 days of dosing due to hyperglycemia. In RWD, patients receiving PPI and SOF/VEL were male (54%), with a mean age of 61 years, GT3 in 25% and cirrhotic in 29%. Overall SVR12 in PPI users was 99% (454/459), comparable to the reported by non-PPI users (99%).
Conclusion: In RCTs and RWD, the single-tablet regimen of SOF/VEL for 12 weeks was effective in patients with concomitant PPI use. These data support the use of SOF/VEL according to labeled recommendations with respect to co-administration of PPIs and other acid reducing agents.

THU-220

Sofosbuvir/Velpatasvir plus Ribavirin for chronic hepatitis C virus genotype 3 infected cirrhotic patients with or without HIV or HBV coinfection: real-world experience from southwest China

Ti Wu[1], Ti Wu[1], Kang Huang[1], Xiaofei Li[1], Nihong Lu[1], Zhirong Zhao[1], Lei Wu[1], Jingsong Bai[1], Junyi Li[1], Haiwen Li[1], Yingrong Du[1]. *[1]The 3rd People's Hospital of Kunming, Yunnan Province, China*
Email: 2894502062@qq.com

Background and aims: Evidence of direct-acting antiviral (DAA) treatment for refractory chronic hepatitis C (CHC) patients was limited. We aimed to evaluate the effectiveness and safety of Sofosbuvir/Velpatasvir (SOF/VEL) plus Ribavirin (RBV) in cirrhotic patients with hepatitis C virus genotype 3 (GT3) with or without HIV or HBV coinfection.
Method: From June 2018 to December 2021, CHC GT3 patients who received SOF/VEL plus RBV (dosage of RBV depended on weight) for 12 weeks were enrolled. Liver cirrhosis was diagnosed by clinical presentation and radiology examination. The primary end point was

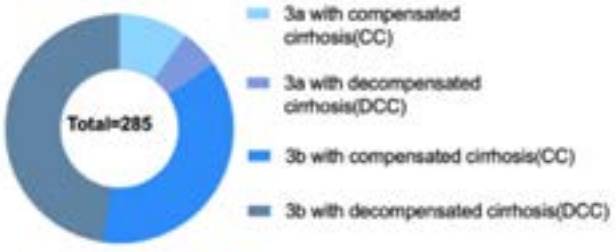

Figure 1. Distribution of HCV GT 3 infected patients with CC or DCC

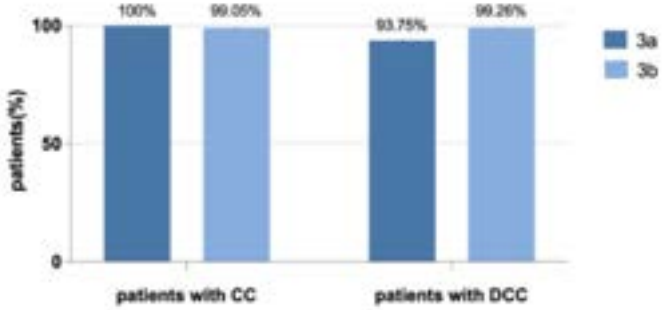

Figure 2. SVR 12 in patients with CC or DCC

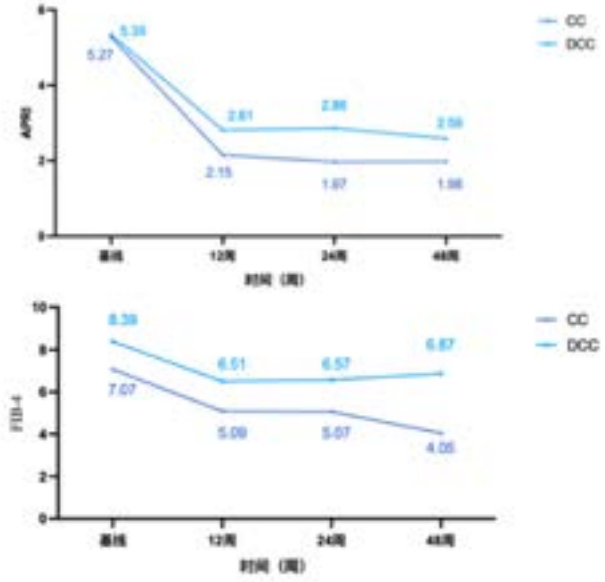

Figure 3. APRI and FIB-4 change in patients with CC or DCC

Figure: (abstract: THU-220).

sustained virologic response at 12 weeks off-therapy (SVR12). Adverse events (AE)were assessed during treatment.
Results: In total, 285 treatment-naive patients were recruited at the Third People's Hospital of Kunming. Mean age was 48.18 ± 8.27 years-old and 74.04% (211/285) were male. All patients had GT3 HCV infection including 44 patients with GT3a and 241 patients with GT3b. All patients had liver cirrhosis, 47% (133/285) had compensated cirrhosis (CC), 53% (152/285) had decompensated cirrhosis (DCC). 98.95% (282/285) patients achieved SVR12 with SOF/VEL plus RBV treatment for 12 weeks, including 97.72% (43/44) in GT3a and 99.17% (239/241)in GT3b. According to coinfection condition, SVR12 rate in CC group were:99.25% (132/133) in mono-HCV infected patients, and 100% (22/22) in HCV/HIV. In DCC group, 98.68% (150/152) in mono-HCV infected patients, 94.12% (16/17) in HCV/HIV and 100% (7/7)in HBV/HCV coinfected and 100% (1/1)in HBV/HCV/HIV coinfected patients achieved SVR12. At the end of treatment, the APRI score and FIB-4 score in CC group and DCC group were improved, and the improvement in the compensated cirrhosis group was better than that in decompensated cirrhosis group (PAPRI = 0.001, PFIB-4 = 0.001). Mean ALT (from 74 ± 27.23U/L to 39.31 ± 12.22U/L, $p < 0.05$) and AST (from 73.98 ± 25.54U/L to 44.17 ± 15.56U/L, $p < 0.05$) also significantly declined after treatment.1 patient had serious AE of hemolysis but recovered after 2–3 days of interruption of RBV. Most AEs were consistent with clinical sequelae of advanced liver disease or known toxicities of RBV.
Conclusion: SOF/VEL combined with RBV for cirrhotic GT3 hepatitis C patients all obtained high SVR12 (>95%) and improved liver function during treatment, and SOF/VEL combined with RBV regimen is recommended for cirrhotic GT3 hepatitis C patients.

THU-221

Efficacy of direct-acting antivirals in patients with hepatitis C virus-associated cryoglobulinemia and monoclonal gammopathy

Sofiia Gavrisheva[1], Dzhamal Abdurakhmanov[2], Nikolay Bulanov[2], Tatiana Krasnova[1,2], Elena Tanashchuk[2], Teona Rozina[1,2], Elena Nikulkina[2], Svetlana Milovanova[2], Anna Filatova[1,2], Sergey Moiseev[1,2]. *[1]Lomonosov Moscow State University, Moscow, Russian Federation; [2]Sechenov First Moscow State Medical University, Moscow, Russian Federation*
Email: gavrisheva.sofiia@gmail.com

Background and aims: Monoclonal gammopathy (MG) is caused by a clonal expansion of plasma cells producing a unique immunoglobulin. MG is common in patients with B-cell lymphoproliferative disorders such as hepatitis C virus (HCV)-associated mixed cryoglobulinemia, and the long-term outcomes of direct-acting antiviral (DAA) therapy in these patients are not fully understood.
Method: We conducted a case series investigation of 10 HCV-positive patients with cryoglobulinemia and MG (diagnosed by serum and urine protein electrophoresis with immunofixation), who received DAA therapy (Table 1). Nine patients met the criteria for HCV-associated cryoglobulinemic vasculitis (HCV-CV) and one patient had asymptomatic cryoglobulinemia (AC). Patients were evaluated at baseline (before starting DAAs) and every 6 months after the end of HCV treatment (EoT). The activity of HCV-CV was assessed by using Birmingham Vasculitis Activity Score version 3 (BVAS.v3).
Results: All patients achieved sustained virological response. Skin purpura was improved in 9/9 (100%) patients, joint involvement — in all 5/5 (100%), sicca syndrome — in 2/2 (100%), and peripheral polyneuropathy — in 2/6 (33.3%) patients. Signs of kidney involvement persisted in 3/5 (60%) patients, including declined glomerular filtration rate in two cases and persistent proteinuria in one patient. In the latter patient a kidney biopsy showed membranoproliferative glomerulonephritis with large subendothelial deposits, there were no typical signs of kidney involvement associated with multiple myeloma. Patient with AC developed Waldenstrom macroglobulinemia 2 years after the EoT and received rituximab-containing chemotherapy. The monoclonal proteins disappeared in 8/10 (80%) patients with a median time of 13.5 months after EoT, in 2 of them — only after rituximab therapy (including the patient with Waldenstrom macroglobulinemia); 3 other patients received glucocorticosteroids during follow-up (for 3, 6 and 30 months). Immunologic response (defined as absence of circulating cryoglobulins, rheumatoid factor and normal C4 level) was achieved only in 4 (40%) patients, whereas elimination of cryoglobulins occurred in 9 (90%) patients. Complete (defined by a BVAS.v3 score of 0) and partial (defined as BVAS.v3 score <50% of the baseline score) clinical response were achieved by 4 (44.4%) and 5 (55.6%) patients with HCV-CV, respectively. No patient died during follow-up.

Cirrhosis, n (%)	6 (60)
Clinical manifestations in 9 patients with HCV-CV, n (%)	
Skin purpura	9 (100)
Arthralgia/arthritis	5 (55.6)
Peripheral polyneuropathy	6 (66.7)
Kidney involvement	5 (55.6)
Sicca syndrome	2 (22.2)
Monoclonal immunoglobulin type, n (%)	
IgM kappa	5 (50)
IgA kappa	1 (10)
IgG kappa	1 (10)
IgG lambda and IgM kappa	1 (10)
Not determined	2 (20)
Follow-up period after EoT, months	62.0 (46.5-76.6)

Note: Continuous data are expressed as median (interquartile range)

Conclusion: DAA therapy in patients with HCV-associated cryoglobulinemia and MG was associated with high rates of monoclonal immunoglobulin elimination and clinical improvement, however in some cases additional immunosuppressive therapy is required.

THU-222

Resistance-associated substitutions described after failure of anti-NS5A direct-acting antiviral treatment in 58 hepatitis C virus (HCV) infected patients in Cameroon

Serge Tchamgoue[1,2,3], Maurelle Magatsing[1], Tatiana Nganso[1], Marthe Ntep Eboko[1], Mathurin Kowo[4], Christian Tzeuton[5]. *[1]Polyclinique Bordeaux Douala, Infectious Disease, Douala, Cameroon; [2]National Network for the fight against viral Hepatitis, deputy chairman, Douala, Cameroon; [3]Centre Hospitalier de Libourne, Infectious disease, Libourne, France; [4]yaounde hospital university, yaounde, Cameroon; [5]university of douala, douala, Cameroon*
Email: stchamgoue@gmail.com

Background and aims: The World Health Organization (WHO) set the goal to eliminate Hepatitis C as a major public health threat by 2030. This goal is challenging in sub- Saharan African countries, where HCV seroprevalence remains too high (i.e. around 3% in Cameroun), due to insufficient funding, lack of screening policies, poor-linkage-to-care strategies, expensive HCV treatments, and more recently, failure of HCV DAA combinations pan-genotypic drugs. Recent European data report suboptimal rates of sustained virological response (SVR) in patients of African origin who were infected with HCV genotype subtypes unusually found in Western Europe (i.e. Genotype (G)1e, G1g, G1l as well as G4c, G4e, G4f, G4r). We aim to describe clinical and virological characteristics of patients escaping from first line HCV treatment including DAA combination in a

national survey data collected in the two biggest Camerounian city: Douala and Yaounde.
Method: Retrospective descriptive study. Data collected from Jan 1st 2020 to Dec 31th 2021. Inclusion criteria: patients escaping from HCV first line treatment including a DAA combination; coming to polyclinic Bordeaux douala's hospital, having a blood test for NS5a genotype virologic test which was sent to Grenoble University hospital (France); giving their consent agreement. This study was agreed by the regional ethical committee.
Results: 58 patients were included; aged 31 to 91 (median 69.5). Women (n = 35; 60%). Weight (BMI>25): (n = 49, 67.2%). HCV was diagnosed since a median of 7.4 years before. All patients received their first line regiment. Fibrosis stage 4 (METAVIR F4) or cirrhosis: (n = 18; 31%). Proven relapsed treatment (n = 32; 55%). HIV co-infected patients (n = 2; 3.4%). Died by dec 31th 2021 (n = 10; 17.2%). Failure associated factors: Antiacid or Proto-pump inhibitor IPP (n = 8; 13%). Traditional medicine (n = 5; 8.6%); Poor compliance (n = 3; 5.1%). Treatment regimen on failure: SOFOSBUVIR/LEDIPASVIR (n = 25; 43%); SOFO/LEDI/RIBAVIRIN (n = 9; 15.5%); SOFOSBUVIR/DACLATASVIR (n = 9; 15.5%); SOFO/DACLA/RIBA (n = 2; 3.4%), SOFOSBUVIR/VELPATASVIR (n = 11; 18.9%); SOFO/VELPA/RIBA (n = 2; 3.4%). Genotypes distibution : G1 (n = 36; 62%); G4 (n = 15; 25.8%); G2 (n = 4; 6.9%); Non ampli (n = 3; 5.7%). Subtypes Distribution :G1l (n = 19; 32%); G4f (n = 13; 22.4%); G1e (n = 7; 12%); G1 not a not b (n = 3; 5%), Non ampli (n = 3; 5%); G1a (n = 2; 3.4%); G1b (n = 2; 3.4%); one patient for :G1c; G1g; G1h; G2e; G2i; G2k or q; G4t; G4 not a not b. Resistance-associated distribution: L31/M/V (n = 18; 31%); Q30H/KQ/S/R/W (n = 16; 27%); Y93/C/H/M (n = 13; 22%); L31M+Q30R (n = 4; 6%); L28M+Q30R (n = 2; 3%); M28V/M/T (n = 2; 3%); R30/Q (n = 2; 3%); Others (n = 22; 37%)
Conclusion: We described a high proportion of unusual subtypes (G1l, G4f, G1e) in HCV patients escaping from their first line treatment including DAA combination, underlining the high interest on accessing to affordable genotypic resistance tests in this context

THU-223

Retreatment of patients experiencing failure with Hepatitis C direct-acting antivirals

Nessa Quinn[1], Colm Bergin[2], Ciaran Bannan[2], Susan McKiernan[3], Suzanne Norris[3], Gillian Farrell[2], Ciara Houlihan[2], Catherine Murray[2], Lewel Alvarado[3], Noelle Cullen[3], Linda Finnerty[3], Suzanne Hunt[3], Bernard Carr[1], Gail Melanophy[1], Miriam Coghlan[1]. *[1]St. James's Hospital, Pharmacy, Ireland; [2]St. James's Hospital, Genito Urinary Medicine and Infectious Diseases (GUIDE), Ireland; [3]St. James's Hospital, Hepatology, Ireland*
Email: nequinn@stjames.ie

Background and aims: The sustained virological response (SVR) rate for first line direct-acting antiviral (DAA) therapy for hepatitis C virus (HCV) infection in Ireland surpasses 95%. Factors associated with the limited number of treatment failures include incomplete adherence, advanced cirrhosis (Child Pugh class B and C) and the presence of resistance associated substitutions (RASs). The aim of this study was to determine the frequency of treatment failure in patients treated in St James Hospital (SJH), Dublin and to review retreatment regimens and outcomes.
Method: Data was extracted from hospital HCV treatment records and the National Hepatitis C Treatment Registry to identify patients

First line treatment	Genotype	RAS conferring reduced susceptibility	Cirrhosis	Re-treatment	Outcome

DAC = daclatasvir; G/p = glecaprevir/pibrentasvir; PrOD = paritaprevir/ritonavir/ombitasvir/dasabuvir; RBV = ribavirin; SOF = sofosbuvir; SVR = sustained virological response; VEL = velpatasvir; VOX = voxilaprevir

Figure: (abstract: THU-223).

who received all-oral DAA treatment for HCV from 2014 to 2021 in SJH.

Results: A total of 2,015 patients received at least one course of all-oral DAA treatment for HCV. A total of 1,589 patients achieved SVR (97.9%) (per protocol analysis). Twenty-five patients failed to achieve SVR, twenty of whom had RASs detected. The most common RASs conferring reduced susceptibility to treatment included NS5A RASs at positions Q30 and Y93 and NS3 RASs at position Q80. Eight patients had >1 NS5A mutation and/or dual class resistance. Of 23 patients who were retreated, 18 achieved SVR (14 of whom received triple therapy with sofosbuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX) or sofosbuvir/glecaprevir/pibrentasvir (SOF/G/P) and 9 of whom received concurrent ribavirin). Five patients failed to achieve SVR with retreatment, two of whom were successfully treated with a third course of DAAs. The remaining three patients are awaiting third line treatment.

Conclusion: Three class DAA regimens are a highly effective retreatment for HCV even in the presence of multiple NS5A and NS3 mutations.

THU-224

Efficacy and safety of Sofosbuvir Plus Daclatasvir bilayer tablet with or without Ribavirin in patients with chronic hepatitis C genotype 4 Infection

Mohamed Hassany[1], Sameh Ramadan[2], Ehab Moustafa[3], Basem Eysa[1], Ahmed Zidan[1], Amany Hassan[1], Heba Abdulaziz[1], Shimaa Afify[1], Mohamed Saeed[1], Hanaa Shalabi[1], Asmaa Gomaa[4], Naglaa Allam[4], Eman Abdelsameea[4], Reda Badr[4], Aliaa Sabry[4], Alzhraa Alkhatib[4], Heba Sameh[4], Mostafa Elhelbawy[4], Ahmed Radwan[3], Sahar Hassany[3], Enas Attia[2], Mai Abdel Razek[2], Fatema Elamrawy[5], Waseem Medhat[5], Omar Hamed[5], Dalia Safwat[5], Doris Ezzat[6], Khaled Prince[5], Imam Waked[4]. *[1]National Hepatology and Tropical Medicine Research Institute, Egypt; [2]Fayoum General Hospital, Egypt; [3]Assuit University, Egypt; [4]National Liver Institute, Menofia University, Egypt; [5]ClinMax, Egypt; [6]Minapharm Pharmaceuticals, Egypt*
Email: mohamadhassany@yahoo.com

Background and aims: The evolution of the hepatitis C virus (HCV) therapies, and its very high efficacy, led to a remarkable improvement of the treatment outcome. The combination of sofosbuvir 400 mg and daclatasvir 200 mg is considered one of the best pan-genotypic regimens which was endorsed by many regional and global guidelines, especially after the robust availability of the generic versions of both drugs, which promoted the access to care. Several countries have adopted the concept of developing the bilayer tablets as an innovative drug formula for enhancing the drug delivery and treatment adherence especially in the long-term therapies and multi-medicated diseases. The aim of this study is to evaluate the safety and efficacy of a single bilayer tablet that contains 400 mg of Sofosbuvir (SOF) and 60 mg of Daclatasvir (DAC) administered once daily with or without Ribavirin (RBV) in patients with genotype 4 HCV.

Method: The study is a Phase IV, prospective, open-label, multicenter study. The patients were classifies into 2 groups (easy or difficult to treat), patients with no liver cirrhosis, FIB-4 ≤3.25, albumin >3.5 g/dl, total bilirubin ≤1.2 mg/dl, INR ≤1.2, platelet count >150,000 mm3 and treatment-naïve are considered as the easy to treat group, and the patients with any opposite parameter were considered as the difficult to treat group. All patients received a single Bilayer tablet that contains 400 mg of SOF and 60 mg of DAC once daily. The difficult-to-treat patients also received RBV divided into two daily doses to reach a total dose of 1200 mg/day if the patient's weight was ≥75 kg or 1000 mg/day when the weight was <75 kg. The treatment duration was 12 weeks, and the patients were followed up for an additional 12 weeks after the end of treatment. The safety data and the relation of each of the adverse events to study medications were reported.

Results: A total of 198 patients were screened throughout the study, out of which 142 were enrolled in the study (easy to treat = 120; difficult to treat = 22). The study drug has proven to be effective and safe to be used for patients with HCV disease. The viral load reached the level of low detection and was sustained after 12 weeks of stopping the drug in 88.7% (126/142) of the patients according to the ITT analysis and 100% (99/99) in the per protocol analysis. Only 2 patients (1.4%) showed related AE that were mild or moderate and were resolved by week 24 of the study, additional non-related one death and other adverse events were reported.

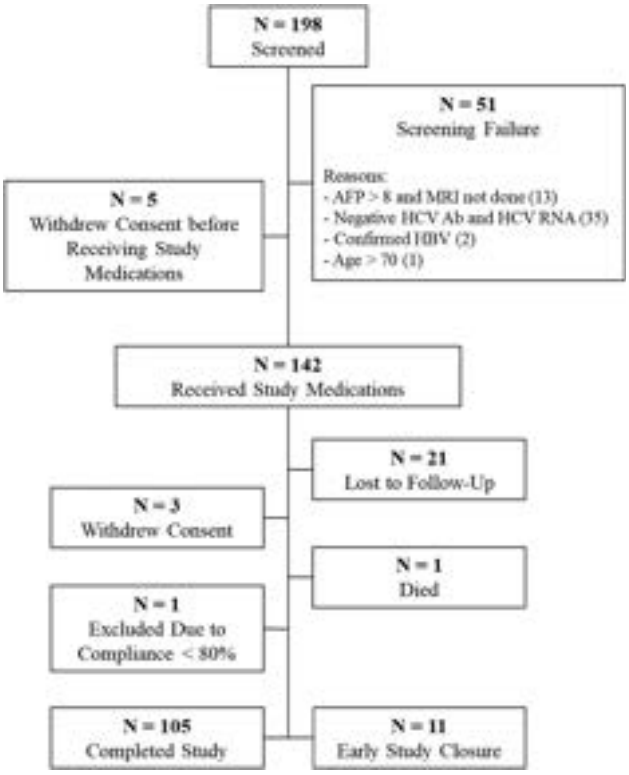

Figure 1: Patient Disposition.

Conclusion: the combination of SOF and DAC in a single bilayer tablet ± ribavirin is an effective and tolerable treatment regimen for HCV genotype 4 patients.
