Publication information: Journal of Hepatology (ISSN 0168-8278). For 2023, volumes 78 and 79 are scheduled for publication. Subscription prices are available upon request from the Publisher or from the Elsevier Customer Service Department nearest you or from this journal's website (http://www.elsevier.com/locate/jhep). Further information is available on this journal and other Elsevier products through Elsevier's website: (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Orders, claims, and journal enquiries: Please visit our Support Hub page https://service.elsevier.com for assistance.

Advertising information: Advertising orders and enquiries can be sent to: **USA, Canada and South America:** Elsevier Inc., 360 Park Avenue, Suite 800, New York, NY 10169-0901, USA; phone: (+1) (212) 989 5800. **Europe and ROW:** Robert Bayliss, Pharma Solutions, Elsevier Ltd., 125 London Wall, London EC2Y 5AS, UK; phone: (+44) 207 424 4454; e-mail: r.bayliss@elsevier.com.

Author enquiries: Visit the Elsevier Support Center (https://service.elsevier.com/app/home/supporthub/publishing) to find the answers you need. Here you will find everything from Frequently Asked Questions to ways to get in touch.
You can also check the status of your submitted article via https://service.elsevier.com/app/answers/detail/a_id/29155/ or find out when your accepted article will be published via https://service.elsevier.com/app/answers/detail/a_id/5981/.

Funding body agreements and policies: Elsevier has established agreements and developed policies to allow authors whose articles appear in journals published by Elsevier, to comply with potential manuscript archiving requirements as specified as conditions of their grant awards. To learn more about existing agreements and policies please visit http://www.elsevier.com/fundingbodies.

Special regulations for authors: Upon acceptance of an article by the journal, the author(s) will be asked to transfer copyright of the article to EASL. Transfer will ensure the widest possible dissemination of information.

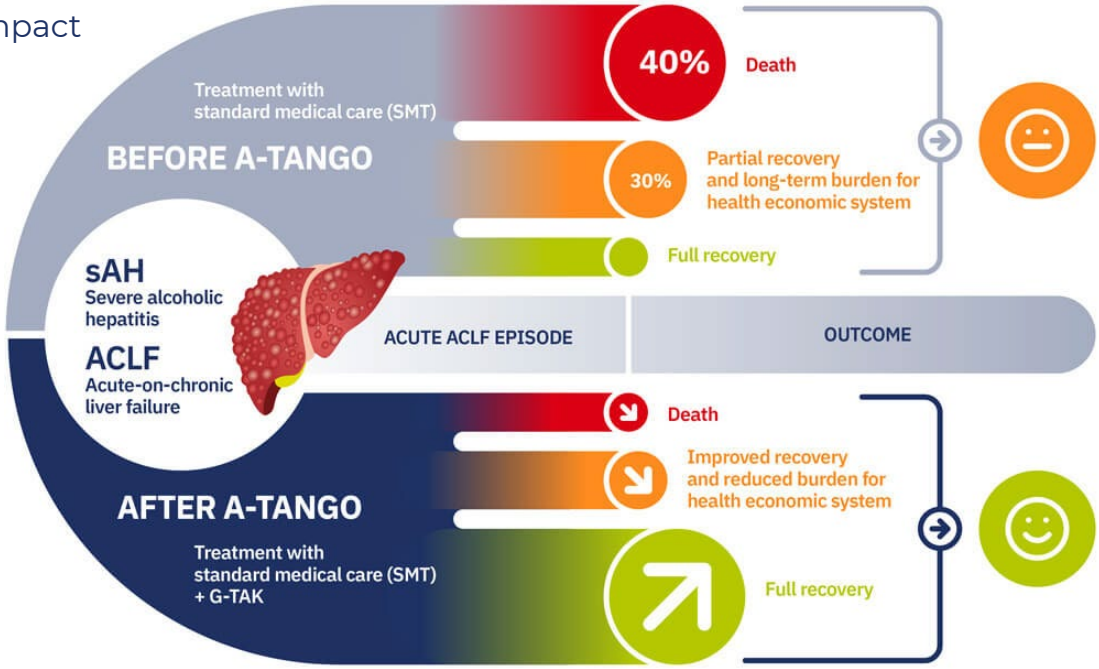
Registration of Clinical Trials
The *Journal of Hepatology* endorses the policy of the WHO and the International Committee of Medical Journal Editors (ICMJE) on the registration of clinical trials. Therefore, any trial that starts recruiting on or after July 1, 2005 should be registered in a publicly owned, publicly accessible registry and should satisfy a minimal standard dataset. Trials that started recruiting before that date will be considered for publication if registered before September 13, 2005.
More detailed information regarding clinical trials and registration can be found in New Engl J Med 2004; 351:1250–1251 and New Engl J Med 2005; 352:2437–2438.

A-TANGO

Featuring G-TAK, a novel combinatorial therapy for acute-on-chronic liver failure (ACLF)

Expected Impact



- More than **10 million people** suffer from **decompensated cirrhosis** worldwide.
- Effective treatment of ACLF is an urgent and unmet need.
- A-TANGO performs **Phase II clinical studies of G-TAK,** a novel and innovative therapeutic strategy that aims to **reduce inflammation** and **improve hepatocyte proliferation.**
- A-TANGO also strives to identify **reliable biomarkers** for better patient stratification and increased survival.

13 partners, one goal: Helping cirrhosis patients in Europe and beyond

kick-off
1st March 2021

project duration
5.0 years

grant amount
6.0 million €

www.a-tango.eu
info@atango.eu

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 945096.

DECISION

decision-for-liver.eu

DEcompensated CIrrhoSIs: identification of new cOmbiNatorial therapies based on systems approaches

Key facts

- **Project start**: 1st April 2020
- **Duration**: 5.5 years
- **Members**: 21 insititutions from 10 European countries
- **EC funding**: € 6 million

Follow us on social media:

AIM 1

Understanding at systems level

- Using **high-throughput technologies** to understand decompensated cirrhosis at systems level
- Re-analyzing standardized biobank samples from **2,200 patients** with decompensated cirrhosis by characterizing
  - epigenomics
  - transcriptomics
  - metabolomics
  - microRNA
  - extracellular vesicles
- Publication of results from all molecular characterizations forthcoming

AIM 2

New combinatorial therapy

- **COMBAT-Trial**: proof-of-concept, phase II randomized controlled clinical study
- **Goal**: Evaluate safety and efficacy of a novel combinatorial therapy (human albumin and enoxaparin) in patients with decompensated cirrhosis discharged from the hospital
- Comparison to standard medical treatment
- Study commencement planned for H1 2024

AIM 3

Preclinical models

- Existing rat models for acute decompensation of cirrhosis leading to ACLF lack full replication of human disease heterogeneity
- → We therefore aim to refine existing animal models
- Two papers will be published in soon:
  - Development and characterization of **novel rodent ACLF models**
  - Acceleration of an advanced **NASH model** by acute and toxic effects of Phenobarbital

AIM 4

Prognostic and response tests

- Novel and robust stratification method identifies three clusters of patients with acute decompensation of cirrhosis (AD)
- Method offers insights that could guide future clinical trial design
- Potential tool for healthcare providers to implement closer monitoring or preventative measures using existing data from electronic health records
- Results will be published soon.

The DECISION consortium

This project received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No. 847949.

GENIAL is a pioneering initiative targeting **alcohol-related liver cancer** (**ALD-HCC**). Our primary goal is to identify **genetic** and **environmental** factors contributing to ALD-HCC risk and unravel how their **interactions** drive alcohol-related liver carcinogenesis. By pinpointing individuals at risk, GENIAL will pave the way for innovative **prevention strategies** and potential **chemopreventive targets** to tackle this devastating disease. Moreover, GENIAL is dedicated to **educating** and empowering the entire EU community with vital knowledge for effective disease prevention and **early detection**.

A biomarker-based platform for early diagnosis of chronic liver disease to enable personalized therapy

Academia and industries are joining forces to undertake the largest project ever in the field of liver diseases

AIM:

To design and validate an AI-powered screening platform using biomarkers for the early diagnosis of liver diseases in the population, and to establish links to care through personalized interventions

This project is supported by the Innovative Health Initiative Joint Undertaking (IHI JU) under grant agreement No 101132901. The JU receives support from the European Union's Horizon Europe research and innovation programme and EFPIA, COCIR, MedTech Europe, Vaccines Europe and EuropaBio. Funded by the European Union, the private members, and those contributing partners of the IHI JU. Views and opinions expressed are however those of the author(s) only and do not necessarily reflect those of the aforementioned parties. Neither of the aforementioned parties can be held responsible for them.

Co-funded by the European Union

LIVER SCREEN

Funded by the European Union

Screening for liver fibrosis population-based study across European Countries

A project that will change the paradigm of diagnosis of chronic liver diseases

AIM:

To assess the prevalence of liver fibrosis in the general population using Transient Elastography, with the objective of establishing criteria for screening for liver fibrosis in the population.

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 847989

MICROBiome-based biomarkers to PREDICT decompensation of liver cirrhosis and treatment response

MICROB-PREDICT

Project duration

Grant amount
15 million €

10 Countries
22 Partners

www.microb-predict.eu

MICROB-PREDICT investigates

the human microbiome to identify predictors and mechanisms associated with the development of decompensation of cirrhosis and progression to acute-on-chronic liver failure (ACLF).

- → New microbiome-based tests for better stratification of cirrhosis patients
- → Personalized prediction and prevention of decompensation and ACLF
- → Clinical trial to predict response to treatment
- → Modern, effective nanobiosensors as clinical tools with improved specificity
- → More personalized treatment
- → Increased survival times
- → Decreased costs for the health systems

GENERAL SESSION I

GS-001

Thematic trial: phase 2 dose-ranging randomized clinical trial of capsular or enema fecal microbiota transplant to prevent hepatic encephalopathy in cirrhosis already on Rifaximin and Lactulose

Jasmohan Bajaj[1], Andrew Fagan[1], Edith Gavis[1], Richard Sterling[1], Hannah Lee[1], Brian Davis[1], Puneet Puri[1], Michael Fuchs[1], Amon Asgharpour[1], Travis Mousel[1], Joel Wedd[2], Scott Matherly[2], Vaishali Patel[2], Mohammad Siddiqui[2], Velimir Luketic[1], Mary Leslie Gallagher[1], Alexander Khoruts[3]. [1]*Virginia Commonwealth University and Richmond VA Medical Center, Richmond, United States;* [2]*Virginia Commonwealth University, Richmond, United States;* [3]*University of Minnesota, Minneapolis, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Patients with cirrhosis and hepatic encephalopathy (HE) already on lactulose and rifaximin have few options to prevent further HE. Fecal microbiota transplant (FMT) was helpful in small studies, but route/dosage remains unclear. Aim: to compare 2 FMT routes (oral capsule and enema) with dose-ranging in HE prevention.
Method: A double-blind, placebo controlled RCT with 2 modes of FMT administration in cirrhosis pts on lactulose and rifaximin was completed under FDA IND. 4 groups (*Gp1: both oral+enema active, Gp2:oral active+placebo enema, Gp3:oral placebo+active enema, Gp4: both oral+enema placebo*) received oral+enema FMT at baseline and a 3rd oral dose at day30. 2 donors were used for FMT products. Pts with recent infections, other antibiotics, MELD>22, transplant and immunosuppression were excluded. We needed 60 total (15/gp) for >90% power across gps at 6 mths on ITT analysis. The primary outcome was safety, especially HE recurrence defined as ≥Grade2 on West-Haven criteria. Secondary outcomes were other adverse events, changes in infections/cirrhosis severity/cognition (PHES/Stroop) and patient-reported outcomes (Sickness Impact Profile (SIP), total/physical/psych; high = worse). Regression for HE-recurrence was performed.
Results: 60 pts (15 per group) with similar MELD (13, 12, 12, 12, p = 0.5) and age (65, 63, 61, 63, p = 0.6) on lactulose+rifaximin were included. Last prior HE episode duration was similar (8–13 mths prior, p = 0.51). Baseline cognition, SIP, and cirrhosis severity were similar between gps. Course: All were followed till death or 6 mths in-person/remotely. 6 pts dropped out (2 Gp1 patients died after falls in rehab), 1 Gp2 died after a seizure), 1 Gp2 and 2 Gp 4 did not return for visits), but ITT analysis was performed. 2 pts in Gp 2 and 1 in Gp 1 did not receive the day30 active dose. 5 pts missed some visits due to COVID-19, but were seen remotely. 4 pts developed infections (SBP, cholecystitis and 2 cellulitis), all unrelated to FMT. Primary outcome: HE recurrence was highest in Gp 4 (both placebo: 40%) vs other (Gp 1:13%, Gp 2:13%, Gp3:0%, p = 0.03). Both Gp 1pts who died had HE prior to death. Secondary outcomes: liver-related hospitalizations tended higher in Gp 4 vs rest (47% vs Gps1–3: 7–20%, p = 0.12). MELD/PHES/Stroop did not change, but SIP total/physical and psych improved with FMT (p = 0.003) on RMANOVA. Regression in all pts: HE recurrence was related to dose number (OR 0.27, 95% CI 0.10–0.79, p = 0.02), male sex (OR 0.16, 0.03–0.89, p = 0.04) and Physical SIP (OR 1.05, 1.01–1.10, p = 0.05). Dose/route/donor: Within FMT recipients neither dose, route, nor FMT donor affected HE recurrence.
Conclusion: HE recurrence was significantly lower in FMT (enema or oral capsule) recipients versus placebo in a phase 2 placebo-controlled, double-blind, dose-ranging RCT in pts with cirrhosis and HE on lactulose and rifaximin. The FMT route, donor, and dose range did not affect HE recurrence.

GS-002

48-week off-therapy efficacy and safety of bulevirtide in combination with pegylated interferon alfa-2a in patients with chronic hepatitis delta: final results from the phase 2b, open-label, randomised, multicentre study MYR204

Background and aims: Bulevirtide (BLV) is a first-in-class entry inhibitor approved in the European Union for the treatment of chronic hepatitis delta (CHD). This Phase 2b study (MYR204; NCT03852433) evaluated the safety and efficacy of BLV (2 mg and 10 mg) with or without pegylated interferon alfa-2a (PegIFN) in patients with compensated CHD. Here we present the final results at 48 weeks (W) post-end of treatment (EOT).

ELSEVIER

Method: One hundred seventy-four patients with CHD were randomized (1:2:2:2) and stratified based on the absence or presence of compensated cirrhosis to receive: (A) PegIFN for 48W, (B) BLV 2 mg + PegIFN, (C) BLV 10 mg + PegIFN for 48W followed by 48W of monotherapy with BLV 2 mg or 10 mg, respectively; or (D) BLV 10 mg for 96W. All patients were followed for up to 48W after EOT (FU-48). The primary end point was the proportion who achieved undetectable HDV RNA (<lower limit of quantification (LLOQ), target not detected, LLOQ 50 IU/ml, limit of detection 6 IU/ml) at week 24 post-EOT (FU-24) with predefined comparison between arms C and D. The composite response was defined as undetectable HDV RNA and alanine aminotransferase (ALT) normalisation; other end points included ALT normalisation, change in liver stiffness (LS) by transient elastography and hepatitis B surface antigen (HBsAg) loss.
Results: Baseline characteristics were similar between arms and included: mean (SD) age of 41 (8.7) years, 71% male, and 87% White. Overall, 34% had compensated cirrhosis with mean (SD) LS of 13.1 (7.7) kPa, HDV RNA of 5.3 (1.2) $\log_{10}$ IU/ml, and ALT of 114 (94.8) U/L, 48% were on nucleos(t)ide analogue therapy and 48% were interferon experienced.
At FU-48, undetectable HDV RNA was achieved in 25% (6/24) of arm A, 26% (13/50) of arm B, 46% (23/50) of arm C, and 12% (6/50) of arm D (arm C vs D, p = 0.0003) compared with FU-24 where undetectable HDV RNA was achieved in 17% (4/24) of arm A, 32% (16/50) of arm B, 46% (23/50) of arm C, and 12% (6/50) of arm D (arm C vs D, p = 0.0003; arms C vs A, p = 0.0197; arms B vs D, p = 0.0283). At FU-48, ALT normalisation and composite end point were 42% and 25% in arm A; 38%, 22% in arm B; 46%, 40% in arm C; and 22%, 8% in arm D (arm C vs D, p <0.05), respectively. In BLV treated arms, at FU-48, LS (least-square mean) was improved compared with baseline (arm A −0.3, arm B −2.4, arm C −2.5, arm D −0.8). HBsAg loss at FU-48 was only observed in BLV treatment arms (arm A 0%, arm B 10% [5/50], arm C 4% [2/50], arm D 2% [1/50]). Overall, BLV was well-tolerated, one participant discontinued BLV due to an adverse event related to BLV and three participants experienced BLV related serious adverse events in the post-treatment period.
Conclusion: Combination therapy of BLV 10 mg with PegIFN resulted in the highest rates of undetectable HDV RNA at EOT and FU-24 which was sustained through FU-48, providing a viable finite treatment option for patients with compensated CHD.

GS-003-YI
The role of endothelial cells in the ductular reaction-driven regeneration

Rita Manco[1], Gauthier Neirynck[1], Camilla Moliterni[1,2], Isabelle Leclercq[1]. [1]*UCLouvain, Brussels, Belgium;* [2]*University of Rome La Sapienza, Rome, Italy*
Email: rita.manco@uclouvain.be

Background and aims: In chronic liver diseases (CLD), when native hepatocytes enter replicative senescence, new hepatocytes are produced via differentiation of reactive cholangiocytes, also known as ductular reaction-DR-cells. Our previous research demonstrated that during the development of chronic disease, there is a discrete but transient DR expansion and that the disappearance of those DR coincides with the appearance of new DR-derived hepatocytes. The newly formed DR-derived hepatocytes, clonally expand to contribute to the regeneration of the liver tissue. In the injured liver, the two populations of hepatocytes, native and DR-derived, experience similar stress and DNA damage. However, the new DR-derived hepatocytes are better equipped to handle these challenges and are less likely to transform into preneoplastic nodules or HCC. Despite such back-up mechanism exists, it is not enough to fully regenerate and to avoid liver transplantation in patients. Thus, there is a need to better understand the mechanism with the prospective of discovering new targets for the implementation of new therapies to enhance in vivo DR-driven regeneration. We propose that signals driving DR differentiation into hepatocytes might reside in the local niche, such as ECM composition (i.e. Laminin) and neighbor cells (i.e. Liver sinusoidal endothelial cells-LSEC).
Method: We used the Opn-iCreERT2; Rosa 26RYFP transgenic mouse model to be able to follow the fate of DR. For studying the origin of LSECs we worked with Cdh5-iCreERT2; Rosa 26RmT/mG transgenic mouse model. CLD was simulated by injecting CCl4 3x/week for 6 weeks. Liver tissues were analyzed using immunohistochemistry, flow cytometry and RT-qPCR techniques and RESOLVE molecular cartography for spatial transcriptomic. Finally, single-cell sequencing was used to characterize LSECs.
Results: We have identified two populations of DR cells in the liver parenchyma: surrounded or not by laminin. Using the Molecular Cartography RESOLVE, we found that DR with no laminin around have a lower expression of cholangiocytes genes and an increased expression of Hnf4α, suggesting a transition toward a hepatocyte-like state. Conversely, DR surrounded by laminin remain locked in biliary phenotype. Endothelial cells are located in close proximity to DR cells. However, the ones closer to DR with laminin around are characterized by the expression of CD34 and a higher expression of Pecam1 and Cdh5 genes, markers of capillarization. Also, during CLD, the $CD34^+$ cells have a more profibrogenic phenotype, with higher expression of the CXCR4 receptor and Timps genes. Finally, preventing LSEC capillarization impacts the DR differentiation.
Conclusion: Thus, $CD34^+$ capillarized endothelial cells contribute to the maintenance of the biliary phenotype in DR, by preventing the degradation of the laminin that surrounds DR and their differentiation into hepatocytes.

GS-004
Prognostic significance of a change in liver stiffness measurement by vibration-controlled transient elastography-a multicenter cohort study of 10, 920 patients with metabolic dysfunction-associated steatotic liver disease (MASLD)

Email: wongv@cuhk.edu.hk

Background and aims: To qualify as a surrogate end point for MASLD drug trials, a biomarker should demonstrate not only diagnostic accuracy to assess liver fibrosis but also the ability to predict prognosis, monitor disease progression and assess treatment response. Liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE) is a well-established tool to diagnose fibrosis and cirrhosis, but data on the prognostic implication of a change in LSM remain scarce.
Method: This study included data of patients with MASLD who had undergone serial VCTE examinations at 16 centres in Europe, the USA and Asia (prospective at 14 centres). The primary outcome was liver-related events (LREs), defined as hepatocellular carcinoma (HCC) or hepatic decompensation (ascites, variceal haemorrhage or hepatic encephalopathy).
Results: 10, 920 patients with MASLD had at least 2 VCTE examinations at a median (IQR) interval of 15 (11, 28) months (mean age 52.3, 57.6% male, body mass index 27.0 kg/m^2, 36.1% diabetes). Using the Baveno VII cutoffs of 10 and 15 kPa, 9, 009 (82.5%), 1, 120 (10.3%) and 791 (7.2%) patients were classified as low, intermediate and high risk at baseline, respectively. At the second examination, 9, 377 (85.9%) patients had stable risk category, 577 (5.3%) had progressed, and 966 (8.8%) had improved LSM. At a median follow-up of 34.0 months from the second examination, 124 (1.1%) patients developed LREs (55 HCC and 81 decompensation). In the low-risk group, the incidence rate of LREs was 0.9 per 1,000 person-years (PY) in patients who remained at low risk, compared with 4.1 and 8.5 per 1,000 PY in those who progressed to intermediate and high risk. In the high-risk group, the incidence rate of LREs was 38.7 per 1, 000 PY in patients who remained at high risk, compared with 7.8 and 19.4 per 1,000 PY in those who regressed to low and intermediate risk. The relative change in LSM correlated with the risk of LREs. In the high-risk group, the incidence of LREs was 16.1, 33.3, and 55.9 per 1,000 PY in patients with >30% relative decrease, stable, and >30% relative increase in LSM.
Conclusion: Changes in LSM over time are predictive of LREs. Serial LSM by VCTE can be used to monitor disease progression and regression in patients with MASLD. (This study is supported in part by the General Research Fund of the Hong Kong SAR Government [14106923].).

GS-005

mRECIST outcomes in EMERALD-1: a phase 3, randomized, placebo-controlled study of transarterial chemoembolization plus durvalumab with/without bevacizumab in participants with embolization-eligible hepatocellular carcinoma

Email: bsangro@unav.es

Background and aims: For over 20 years, transarterial chemoembolization (TACE) has been a standard of care for embolization-eligible unresectable hepatocellular carcinoma (uHCC); however, most people with uHCC treated with TACE progress within 1 year. The primary end point of EMERALD 1 (NCT03778957) was met, with a statistically significant improvement in progression-free survival (PFS) assessed by blinded independent central review (BICR) per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 with durvalumab (D) + bevacizumab (B) + TACE vs TACE (median [m]PFS (95% confidence interval [CI]), 15.0 (11.1–18.9) vs 8.2 (6.9–11.1) months [mo]; hazard ratio [HR], 0.77; 95% CI, 0.61–0.98; p = 0.032). Safety was consistent with the profiles of D, B, and TACE in uHCC. In addition to RECIST v1.1, efficacy of the regimens was assessed using modified RECIST (mRECIST).
Method: Participants (pts) with embolization-eligible uHCC, Child-Pugh A to B7 liver function, Eastern Cooperative Oncology Group performance status 0-1, and no evidence of extrahepatic disease were randomized 1:1:1 to the D+B+TACE, D+TACE, or TACE arms. TACE was cTACE or DEB-TACE (investigator choice). Pts received D (1500 mg) or placebo for D every 4 weeks (Q4W) plus TACE. After completion of last TACE, pts received D (1120 mg) plus placebo for B, D (1120 mg) plus B (15 mg/kg), or placebos for D and B (Q3W). PFS was assessed by BICR and the investigator per mRECIST as a secondary end point.
Results: Overall, 616 pts were randomised to D+B+TACE (N = 204), D+TACE (N = 207) or TACE (N = 205). PFS improved with D+B+TACE vs TACE as assessed by both BICR per mRECIST (mPFS (95% CI), 14.2 (11.1-17.4) vs 8.2 (6.9-9.5) mo; HR (95% CI), 0.75 (0.60-0.95)) and investigator per mRECIST (mPFS (95% CI), 13.2 (9.4-16.4) vs 7.5 (7.0-9.1) mo; HR (95% CI), 0.69 (0.55-0.86)). The estimation of effect was consistent with that of the primary end point, which showed a statistically significant improvement in mPFS with D+B+TACE vs TACE (p = 0.032, significance threshold 0.0435). D+TACE vs TACE showed similar PFS results as assessed by BICR per mRECIST (mPFS (95% CI), 9.0 (7.0–10.9) vs 8.2 (6.9–9.5) mo; HR (95% CI), 0.99 (0.79–1.25)), by investigator per mRECIST (mPFS (95% CI), 7.0 (6.7–9.0) vs 7.5 (7.0–9.1) mo; HR (95% CI), 1.03 (0.84–1.28)) and BICR RECIST v1.1 (mPFS (95% CI), 10.0 (9.0–12.7) vs 8.2 (6.9–11.1) mo; HR (95% CI), 0.94 (0.75–1.19), p = 0.638).
Conclusion: D+B+TACE is the first immune checkpoint inhibitor-based regimen in a global Phase 3 trial to show statistically significant improvement in PFS vs TACE in pts with embolization-eligible uHCC, as assessed by BICR per RECIST v1.1, with consistent PFS results, as assessed per mRECIST. These results further support the potential for D+B+TACE to set a new standard of care in uHCC.

GS-011

Denifanstat, a fatty acid synthase (FASN) inhibitor, shows significant fibrosis improvement and MASH resolution in FASCINATE-2, a Ph2b 52 week international, randomized, double blind, placebo-controlled trial in patients with F2 or F3 fibrosis

Rohit Loomba[1], Eduardo Martins[2], Katharine Grimmer[2], Wen-Wei Tsai[2], Marie O' Farrell[2], William McCulloch[2], George Kemble[2], Pierre Bedossa[3], Jose Cobiella[4], Eric Lawitz[5], Madhavi Rudraraju[6], Stephen A. Harrison[6]. *[1]MASLD Research Center, Division of Gastroenterology and Hepatology, Department of Medicine, University of California San Diego, La Jolla, United States; [2]Sagimet Biosciences Inc., San Mateo, United States; [3]Liverpat, Paris, France; [4]Global Research Associates, Homestead, Florida, United States; [5]American Research Corporation, Texas Liver Institute, San Antonio, United States; [6]Pinnacle Clinical Research, San Antonio, United States*
Email: roloomba@health.ucsd.edu

Background and aims: New therapies are needed for MASH in particular drugs that improve fibrosis, the main predictor of poor clinical outcomes. Denifanstat, an oral FASN inhibitor, directly blocks endogenous FASN in stellate cells, immune cells and hepatocytes, thereby directly inhibiting fibrosis, inflammation and steatosis. Denifanstat directly blocks collagen production in human primary stellate cells ex-vivo. Evidence of denifanstat's mechanism was demonstrated in previous studies including Ph2a FASCINATE-1 where denifanstat decreased de novo lipogenesis, liver fat and biomarkers of inflammation and fibrosis. A Ph2b study FASCINATE-2 was conducted to determine safety and efficacy of denifanstat on liver histology in F2/F3 MASH patients after 52 weeks of treatment.
Method: FASCINATE-2 was a phase 2b, multicenter, double-blind, randomized, placebo-controlled international trial. 168 patients (ITT) with biopsy-confirmed F2/F3 MASH were randomized 2:1 to once daily oral denifanstat 50 mg, or placebo. 126 had both pre- and post-treatment biopsies (mITT). Primary end points were liver histology improvement ≥2 points in NAS (≥1 point in ballooning or inflammation) and no worsening of fibrosis, or MASH resolution and ≥2 points improvement in NAS and no worsening of fibrosis, at week 52. Secondary end points included fibrosis improvement, MASH resolution, collagen/fibrosis by AI-assisted digital pathology and liver fat response by MRI-PDFF. Exploratory objectives included FibroScan-AST (FAST) score, biomarkers of liver injury, lipidomics and fibrosis.
Results: Denifanstat successfully met primary and secondary histology end points with statistical significance in both mITT and ITT populations, as follows for mITT: • ≥2-point improvement of NAS without worsening of fibrosis: 51.9% denifanstat vs 20.0% placebo ($p = 0.0003$). • MASH resolution and ≥2-point improvement of NAS with no worsening of fibrosis: 35.8% denifanstat vs 13.3% placebo ($p = 0.0044$).• Improvement of fibrosis by ≥1 stage without worsening of steatohepatitis: 40.7% denifanstat vs 17.8% placebo ($p = 0.01$). • Improvement of fibrosis by ≥2 stages without worsening of steatohepatitis: 19.8% denifanstat vs 2.2% placebo ($p = 0.0065$). Furthermore, both MASH resolution and fibrosis improvement were achieved in 23% denifanstat-treated patients compared to 7% placebo. Biomarkers of liver fat, inflammation and fibrosis also decreased. Denifanstat was generally well tolerated. Skin and subcutaneous adverse events, all of which were Grade 1 or 2, were more common in denifanstat-treated patients than placebo.
Conclusion: Denifanstat demonstrated a clinically meaningful and statistically significant improvement in both fibrosis regression and MASH resolution end points, consistent with mechanism. These results support progression of denifanstat to Phase 3 clinical trials in MASH.

Email: olivier.chazouilleres@aphp.fr

Background and aims: Predicting the risk and pace of progression of primary sclerosing cholangitis (PSC) by reliable and simple tools is an unmet need. Baseline liver stiffness (LS) and LS changes over time have been associated with adverse clinical outcome in retrospective studies (1). However, prospective validation is lacking.

Method: Clinical, biological and elastographic (LS measurement (LSM) by Fibroscan) data of adult patients with uncomplicated PSC from 13 institutions, members of the International PSC Study Group, were prospectively recorded at baseline and then annually for 5 years. The primary end point was transplant-free survival. Survival free of transplant and liver complications (ascites, variceal bleeding, encephalopathy, hepatocellular carcinoma, biliary cancer, serum bilirubin above 100 micromol/L for at least 3 months, listing for LT) was the main secondary end point. Cox proportional hazard models were used to estimate multivariable adjusted hazard ratios (aHRs). LS was assessed either continuously or according to pre-established fibrosis cut-offs (1). The time-dependent predictive performance of LS was assessed. We present here the final results at 5 years.

Results: 617 patients were included. Follow-up data (median: 60.8 months, Q1-Q3 (48.6–66.0)) were available in 538. Baseline characteristics were: 67% males, age: 43 ± 14 yrs, associated inflammatory bowel disease: 71%, small-duct PSC: 9%, AIH-PSC overlap: 7%, taking UDCA: 76%, bilirubin: 20 ± 24 micromol/L, ALP: 1.9 ± 1.6 ULN, LS: 11.9 ± 12.4 kPa. During follow-up, 19 patients died and 74 were transplanted. Baseline LS was strongly and independently (adjusted for age, gender, bilirubin, and ALP) linked to the risk of death or transplantation: aHR 1.05 (per kPa increase), 95%CI (1.04–1.06), P < 0.001. This association was independent of those observed with the Mayo and Amsterdam-Oxford prognostic scores. Observed transplant-free survival (Kaplan-Meier) at 5 yrs by LS strata was 93.8% CI95% (90.2–96.1), 79.0% CI95% (67.4–86.8) and 48.1 CI95% (36.7–58.5), respectively for [2.5–9.5]kPa group, [9.6–14.3]kPa group and ≥14.4 kPa group with corresponding aHR (vs 2.5–9.5) (95% CI) of 2.7 (1.4–5.4) for [9.6–14.3] kPa group and 7.8 (4.4–13.9) for ≥14.4 kPa group. The predictive performance assessed by the time-dependent area under the ROC curve was 0.85 CI95% (0.78–0.92). Results for the main secondary end point were consistent with those for the primary end point.

Conclusion: This large international prospective study validates the prognostic value of liver stiffness assessed by Fibroscan in PSC. These results support the major role of liver stiffness measurement in clinical trials as a risk stratifying tool and potential surrogate end point.

The combination of therapeutic vaccination with siRNA-mediated silencing of HBV and PD-L1 effectively breaks HBV-specific immunotolerance in high-titer HBV carrier mice

Anna D. Kosinska[1,2], Edanur Ates-Öz[1], Till Bunse[1], Merve Gültan[3], Swati Singh[1], Ulrike Protzer[1]. [1]*Institute of Virology, Technical University of Munich/Helmholtz Munich, Munich;* [2]*German Center for Infection Research (DZIF), Munich Partner Site, Munich;* [3]*Institute of Virology, Technical University of Munich/Helmholtz Munich, Munich, Germany*
Email: anna.kosinska@tum.de

Background and aims: High levels of hepatic HBV antigens prevent a successful therapeutic vaccination. Reducing HBV levels before vaccination by HBV-specific siRNAs (siHBV) enhanced the immunogenicity and antiviral efficacy of our clinical candidate protein-prime/MVA-boost therapeutic vaccine, TherVacB, in higher-titer HBV-carrier mice. Non-responsiveness to vaccination was associated with high PD-1 expression on vaccine-elicited hepatic CD8 T-cells. Consequently, silencing PD-1 ligand-1 by liver-targeted siRNA (siPD-L1) also improved the TherVacB-mediated therapeutic effects. We hypothesized that combining siHBV with siPD-L1 could further broaden the applicability of TherVacB in high-titer, persistent HBV infection settings.
Method: We established high-titer persistent HBV infection in C57BL/6J mice using AAV-HBV, resulting in over 80% of HBV-positive hepatocytes, HBsAg of 5500 IU/ml and HBeAg of 330 PEI U/ml We pretreated five mice per group for eight weeks with siHBV before TherVacB and applied siPD-L1 during the two protein priming immunizations. We followed up with the mice for 7.5 months after the MVA boost.
Results: Groups of mice receiving TherVacB and TherVacB+siPD-L1 demonstrated only a minor decrease in serum HBsAg and HBeAg levels shortly after treatment. Without vaccination, siHBV+siPD-L1 reduced HBsAg and HBeAg, as expected, but the antigen load eventually returned baseline values, and no induction of HBV-specific immunity was observed. Combining siHBV+TherVacB reduced HBsAg to undetectable levels for eight weeks, but a partial relapse finally resulted in only a 1-log10 decrease compared to the initial values. By contrast, mice receiving siHBV+TherVacB+siPD-L1 cleared HBsAg for 24 weeks. 3/5 mice remained negative for 7.5 months. Overall, the siHBV+TherVacB+siPD-L1 treatment resulted in a ≥3-log10 reduction in serum HBsAg, a 70% reduction in HBeAg, and, on average, a 90% reduction in intrahepatic HBV-DNA. A strong vaccine-elicited immunity accompanied this impressive antiviral effect.
Conclusion: Our data demonstrate that complementary siRNA-mediated silencing of HBV and the immune checkpoint PD-L1 helps to further enhance the efficacy of therapeutic vaccination in high-titer HBV carriers.

GS-009

Efficacy and safety of carvedilol in cirrhosis patients with uncomplicated ascites without high-risk esophageal varices-a randomized controlled trial [NCT05057572]

Rahul Khajuria[1], Ankur Jindal[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: dr.rahulkhajuria@gmail.com

Background and aims: Carvedilol is effective in preventing bleeding in patients with cirrhosis and high-risk varices. Although it reduces drivers of clinical decompensation (portal pressure, systemic inflammation and bacterial translocation), the data on carvedilol use for prevention of ascites related complications (SBP, HRS-AKI, refractory ascites or severe hyponatremia) are limited.
Method: Consecutive patients presenting with uncomplicated new-onset ascites and low risk esophageal varices were randomized to receive carvedilol (at the starting dose of 3.125 mg BD) (Group A) or placebo (Group B) in addition to ST (diuretics with or without albumin). The composite primary outcome was incidence of complicated ascites (any of refractory ascites, HRS AKI, SBP, severe hyponatremia) at 1 year. The secondary outcomes include need for paracentesis, change in HVPG, CTP and MELD score and mortality at 1 year.
Results: Of 302 consecutive patients screened, 104 patients were randomized into two groups. Baseline characteristics were comparable between two groups. In both groups, MAFLD was the most common etiology (overall 41.3%) followed by ethanol (21.2%) with comparable comorbidities. Patients in Group A had lower incidence of complicated ascites at 1 year (39.4% vs. 66.7% $p = 0.026$), mainly related to reduction of incident HRS AKI (33.3% vs 63.6% $p = 0.014$). Patients in Group A also had less frequent need for large volume paracentesis as compared to Group B at 1 year (27.3% vs 57.6% $p = 0.013$). Better resolution of ascites (66.6 vs 39.4% $p = 0.06$). Despite comparable at baseline, MELD (18.9 ± 1.3 vs. 15.34 ± 1.38; $p = 0.06$) and CTP score (9.36 ± 1.43 vs. 8.15 ± 1.7 vs $p = 0.003$) were higher in Group B as compared to Group A at the end of one year. Overall, the change in HVPG at one year among responders showed significant reduction from 14.89 to 11.86 mmHg ($p = 0.042$). Use of carvedilol was associated with lesser mortality at one year (9.1% vs 24.2% $p = 0.05$). None had treatment related severe adverse effects requiring discontinuation of therapy.
Conclusion: Carvedilol use in patients with cirrhosis with uncomplicated ascites and low risk varices is safe and prevented further complications, less frequent need for large volume paracentesis and improved survival.

Email: alexandre.louvet@chru-lille.fr

Background and aims: The QuickTrans study showed similar survival at 2 years in patients transplanted for alcohol-related hepatitis (AH) compared to alcohol-related cirrhosis but failed to demonstrate non-inferiority of alcohol relapse between the two groups. Long-term data are needed for early liver transplantation (LT) for AH.
Method: Patients were followed-up according to each center local practice after the 2-year end point of the QuickTrans study and our primary end point was alcohol relapse 5 years thereafter (i.e. at 84 months). Secondary end points were survival at 84 months and analysis of alcohol consumption pattern. End points were analyzed

according to 2 time frames: first 24 months and between M24 months and M84. A total of 240 patients were included in 3 groups: A: patients transplanted for AH (n = 68); B: patients transplanted for alcohol-related cirrhosis and 6 months of abstinence (n = 93); C: patients with AH, not transplanted (n = 47).
Results: The rate of any alcohol relapse, whatever the amount consumed, was not different between groups A and B, either during the first 24 months (HR 1.56, 95%CI: 0.87–2.76, p = 0.13) or between M24 and M84 (HR 1.23, 95%CI: 0.48–3.13, p = 0.66). The rate of heavy alcohol relapse (defined by ≥30 g/d in women and ≥40 g/d in men) was higher in group A than in group B at M24 (23.5 vs. 5.4%, HR 4.86, 95%CI: 1.78–13.2, p = 0.002) but was not different between M24 and M84 (34.3 vs. 16.7%, HR 1.17, 95%CI: 0.44–3.07, p = 0.76). There was a trend toward better survival at M84 in patients transplanted for AH (group A) vs. group B: 83.2 (A) vs. 70% (B), HR = 0, 34, 95%CI: 0.11–1.02, p = 0.054). Rejection rates after LT were not different between the two groups (2.9 vs. 3.2%, p = 0.9) but incidence of de novo alcohol-related cirrhosis was higher in group A (11.8 vs. 3.2%, p = 0.03) while incidence of cancers was more important in group B (22.6 vs. 8.8%, p = 0.02). Among all patients with AH, patients selected for LT (group A) had a better survival at 84 months than non-selected patients (group C): 64 vs. 13%, HR = 4, 2.5–6.67, p < 0.001).
Conclusion: Rates of alcohol relapse between M24 and M84 are similar between patients transplanted for AH and those with alcohol-related cirrhosis selected with the 6-month rule. Heavy alcohol relapse mostly occurs during the first 2 years in AH without significant differences between the two groups thereafter. Early alcohol management should be proposed after LT for AH. Patients transplanted for alcohol-related cirrhosis tend to have a lower long-term survival.

GS-012
Novel DGAT2 antisense inhibitor demonstrates significant MASH resolution in biopsy-proven F2/F3 MASH: results from a 51-week multicenter randomized double-blind placebo-controlled phase 2 trial

Rohit Loomba[1], Erin Morgan[2], Keyvan Yousefi[2], Dan Li[2], Richard Geary[2], Sanjay Bhanot[2]. *[1]UCSD, San Diego, United States; [2]Ionis Pharmaceuticals, Carlsbad, United States*
Email: roloomba@health.ucsd.edu

Background and aims: ION224 is an investigational ligand-conjugated antisense medicine designed to reduce the production of diacylglycerol acyltransferase 2 (DGAT2), an enzyme that catalyzes the final step in hepatic triglyceride synthesis. ION224-CS2 was an adaptive Phase 2 trial to study the safety and efficacy of monthly subcutaneous injections of ION224 in biopsy-proven MASH patients with MASLD activity score (NAS) ≥4 and baseline MRI-PDFF≥10%. The primary end point was improvement in steatohepatitis at Week 51 as measured by ≥2-point reduction in NAS with ≥1-point improvement in hepatocellular ballooning or lobular inflammation, and without worsening of fibrosis. An analysis of the primary end point along with key secondary end points was conducted.
Method: The study enrolled 160 patients to receive monthly doses of ION224 or placebo during a 49-week treatment period. In Part 1, 93 patients were randomized to three dose cohorts to receive either 60, 90, or 120 mg of ION224 or placebo (3:1). Based on a pre-specified interim analysis at 3 months, 2 of the 3 dose cohorts were selected by DSMB for expanded enrollment, based on safety and hepatic MRI-PDFF analysis. In Part 2, an additional 67 patients were randomized 1:1 into each of the two expanded dose cohorts (90 and 120 mg) and then in a 2:1 ratio to receive either ION224 or placebo within each cohort.
Results: Baseline characteristics included age 53 (12) (mean (SD)), BMI 37.8 (7.1), type 2 diabetes 50.6%, MRI-PDFF (%) 22.4 (7.4), baseline fibrosis stage: F2-49.6%, F3-39.1%. The primary end point of ≥2-point reduction in NAS was met in both expanded cohorts in 58.8% and 46.2% of patients treated with ION224 120 mg or 90 mg, respectively, compared to 18.8% for placebo (n = 34, p <0.001 and n = 39, p = 0.015, respectively, placebo n = 32). Subgroup analysis indicated that significant improvements in the primary end point were observed in patients with both F2 and F3 fibrosis. Additionally, 35.6% of patients treated with 120 mg or 90 mg achieved MASH resolution without worsening of fibrosis versus 15.6% for placebo (p = 0.039). Further, 32.4% of patients treated with 120 mg achieved ≥1 stage improvement in fibrosis without worsening steatohepatitis versus 12.5% for placebo. Forty-four (44) % of patients treated with 120 mg achieved ≥50% relative reduction in liver steatosis by MRI-PDFF vs 3% of placebo (p <0.001). ION224 was safe and well-tolerated. There were no treatment-related SAEs, no GI side effects or worsening of hepatic or renal function or plasma lipids (including no hypertriglyceridemia) after ION224 treatment.
Conclusion: This study provides the first clinical evidence that reduction of hepatic fat after DGAT2 inhibition leads to MASH resolution. ION224 was safe and well-tolerated in this study with once-monthly subcutaneous dosing. These data support the potential for ION224 treatment to provide benefit to patients with MASH and liver fibrosis.

Tirzepatide for the treatment of metabolic dysfunction-associated steatohepatitis with liver fibrosis: results of the SYNERGY-NASH phase 2 trial

Rohit Loomba[1], Mark Hartman[2], Eric Lawitz[3], Raj Vuppalanchi[4], Jerome Boursier[5], Elisabetta Bugianesi[6], Masato Yoneda[7], Cynthia Behling[8], Oscar Cummings[4], Yuanyuan Tang[2], Bram Brouwers[2], Deborah Robins[2], Amir Nikooie[2], Mathijs Bunck[2], Axel Haupt[2], Arun J. Sanyal[9]. *[1]MASLD Research Center, Division of Gastroenterology and Hepatology, University of California San Diego, San Diego, United States; [2]Eli Lilly and Company, Indianapolis, United States; [3]Texas Liver Institute, University of Texas Health, San Antonio, United States; [4]Indiana University School of Medicine, Indianapolis, United States; [5]Angers University Hospital, Angers, France; [6]University of Torino, Torino, Italy; [7]Yokohama City University, Yokohama, Japan; [8]Pacific Rim Pathology, San Diego, United States; [9]Virginia Commonwealth University School of Medicine, Richmond, United States*
Email: roloomba@health.ucsd.edu

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive liver disease associated with liver-related morbidity and mortality. This study evaluated the efficacy and safety of tirzepatide, a dual agonist of the glucose-dependent insulinotropic polypeptide and glucagon-like-peptide-1 receptors, in the treatment of non-cirrhotic MASH with significant liver fibrosis.
Method: SYNERGY-NASH (NCT04166773) was a multicenter, double-blind, randomized, placebo (PBO)-controlled Phase 2 dose-finding trial in patients with biopsy-confirmed MASH, stage 2 or 3 fibrosis and a non-alcoholic fatty liver disease activity score (NAS) ≥4. Participants (n = 190) were randomly assigned 1:1:1:1 to receive once-weekly s.c. tirzepatide (5 mg, 10 mg or 15 mg) or PBO for 52 weeks. The primary end point was MASH resolution without worsening of fibrosis at 52 weeks. Secondary end points included fibrosis improvement by ≥1 stage without worsening of MASH and a reduction in NAS by ≥2 points with ≥1 point reduction in at least 2 NAS components. Efficacy results were analyzed with the intent to treat population using multiple imputation for missing data.
Results: End-of-treatment liver biopsies were available for 157 participants. The proportion of participants who achieved MASH resolution without worsening of fibrosis was 9.8% for PBO, 43.6% for tirzepatide 5 mg, 55.5% for tirzepatide 10 mg and 62.4% for

tirzepatide 15 mg (differences vs. PBO 33.8–52.6%; p <0 .001 for all doses). Among 155 participants who completed the study on treatment with evaluable biopsies, the primary end point was achieved by 51.8%, 62.8%, and 73.3% for tirzepatide 5 mg, 10 mg and 15 mg, respectively, compared with 13.2% for PBO (p < 0.001 for all doses). The proportion who achieved ≥1-stage fibrosis improvement without worsening of MASH was 29.7% for PBO, 54.9% for tirzepatide 5 mg, 51.3% for tirzepatide 10 mg and 51.0% for tirzepatide 15 mg (differences vs. PBO 21.3–25.2%; p < 0.05 for all doses). A reduction in NAS by ≥2 points was achieved by 71.7% to 78.3% of participants across the three tirzepatide dose groups and by 36.7% with PBO (p < 0.001 for all doses). Body weight was reduced by up to 17.3% with tirzepatide. Liver enzymes and liver fat decreased, and serum as well as imaging biomarkers of liver inflammation and fibrosis significantly (p < 0.01) improved in the tirzepatide groups vs. PBO. Adverse events with tirzepatide were mostly gastrointestinal, and mild to moderate in severity.

Conclusion: In this Phase 2 study of patients with MASH and significant fibrosis, tirzepatide treatment for 52 weeks was more effective than placebo in achieving MASH resolution without worsening of fibrosis. Fibrosis also improved with tirzepatide treatment but without an apparent dose-response effect. Larger and longer trials are needed to further assess the efficacy and safety of tirzepatide for treatment of non-cirrhotic MASH.

LBO-002

Efruxifermin significantly reduced liver fibrosis in MASH patients with F2-F3 fibrosis, with sustained improvement in liver injury and resolution of steatohepatitis over 96 weeks (HARMONY phase 2b study)

Stephen A. Harrison[1], Juan P Frias[2], Guy Neff[3], Gary Abrams[4], Kathryn Jean Lucas[5], William Sanchez[6], Sudhanshu Gogia[7], Muhammad Y Sheikh[8], Cynthia Behling[9], Pierre Bedossa[10], Lan Shao[11], Doreen Chan[12], Erica Fong[12], Brittany de Temple[12], Matthew Minerva[12], Kimberly Barrett[13], Reshma Shringarpure[12], Erik Tillman[12], Tim Rolph[12], Andrew Cheng[12], Vlad Ratziu[14], Kitty Yale[12]. *[1]Department of Hepatology, University of Oxford, Oxford, United Kingdom; [2]Pinnacle Clinical Research, San Antonio, TX, United States; [3]Covenant Metabolic Specialists, Sarasota, FL; [4]Prisma Health, Greenville SC, United States; [5]Lucas Research, Morehead NC, United States; [6]Floridian Clinical Research, Miami Lakes, FL, United States; [7]Texas Digestive Disease Institute, Webster TX, United States; [8]Fresno Clinical Research Center, Fresno, CA, United States; [9]Department of Pathology, Sharp Memorial Hospital, San Diego, CA, United States; [10]Liverpat, Paris, France; [11]Fortrea Inc, Durham, NC, United States; [12]Akero Therapeutics Inc, South San Francisco, United States; [13]Akero Therapeutics Inc, San Francisco, United States; [14]Sorbonne University, Paris, France*
Email: reshma@akerotx.com

Background and aims: The HARMONY study met its primary end point of ≥1 stage improvement in fibrosis with no worsening of MASH in patients with stage 2 or 3 fibrosis (F2-F3) receiving once weekly (QW) efruxifermin (EFX) 50 mg (41%) or 28 mg (39%) vs placebo (20%; p < 0.05) after 24 weeks. The study continued to Week 96 to evaluate longer-term safety, tolerability, and durability of histologic improvements.

Method: 128 patients with MASH (F2-F3) were randomized to placebo or EFX (28 or 50 mg), QW for 96 weeks. Liver biopsies were collected at baseline, Week 24, and Week 96. End-of-study analyses included safety and tolerability, liver histopathology, and non-invasive markers of liver injury and fibrosis, including fibrogenesis.

Results: Among patients with baseline and Week 96 biopsies, 75% (p < 0.001) receiving EFX 50 mg and 46% (p = 0.07) receiving 28 mg had improvement in fibrosis without worsening of MASH, vs 24% for placebo. Furthermore, 36% (p < 0.001) of patients for EFX 50 mg and 31% (p < 0.01) for 28 mg had a 2-stage improvement in fibrosis without worsening of MASH, vs 3% for placebo. MASH resolved without fibrosis worsening in 57% (p < 0.01) of patients for EFX 50 mg and 62% (p < 0.01) for 28 mg vs 24% for placebo. MASH resolution AND fibrosis improvement of ≥1 stage were observed in 54% (p < 0.001) of the EFX 50 mg and 42% (p < 0.01) of the 28 mg group, vs 9% for placebo. Significant improvements in markers of liver injury and fibrosis were sustained through Week 96, corroborating EFX's durable effects. The most frequent drug-related adverse events over 96 weeks were diarrhea (16%, 40%, and 37%) and nausea (12%, 30%, and 33% for placebo, EFX 28 mg and 50 mg groups, respectively). Discontinuations due to study drug-related AEs by Week 24 were 0, 2, and 2 in the placebo, EFX 28 mg, and EFX 50 mg groups, respectively; another 0, 2, 1, patients discontinued by Week 96 due to drug-related AEs.

Conclusion: In a randomized trial with sequential liver biopsies, EFX demonstrated a significant and durable anti-fibrotic response in MASH patients with fibrosis (F2-F3). From Weeks 24 to 96, the response to EFX broadened (fibrosis improved by ≥1-stage in a more significant proportion of patients) and deepened (a greater proportion of patients experienced a 2-stage improvement in fibrosis). EFX has a promising therapeutic profile for treating MASH with moderate to advanced fibrosis.

Email: norman.sussman@icloud.com

Background and aims: Alcohol-associated hepatitis (AH) is a severe form of alcohol-associated liver disease with approximately 30% mortality at 90 days without approved therapy so far. Larsucosterol is an endogenous sulfated oxysterol that inhibits DNA methyltransferases and has been shown to reduce inflammation, lipotoxicity, oxidative stress, and cell death, and promote liver regeneration. In a phase 2a study in subjects with moderate or severe AH, larsucosterol improved liver function markers with 100% 28-day survival. Here we report findings in the Phase 2b AHFIRM trial of larsucosterol in hospitalized patients with severe AH.

Method: AHFIRM was a phase 2b randomized, double-blind, placebo-controlled, international, multicenter study that evaluated the safety and efficacy of larsucosterol in 307 subjects with severe AH (MDF ≥32 and MELD 21–30). Subjects were randomized 1:1:1 to

receive 1 or 2 intravenous infusions (72 hours apart) of larsucosterol 30 mg, larsucosterol 90 mg, or Placebo. All subjects received local standard of care at the investigators' discretion. If prescribed, subjects in the Placebo arm would receive 32 mg methylprednisolone daily while those in the larsucosterol arms received matching placebo capsules. The primary end point was death or liver transplant at 90 days measured by win-ratio. The key secondary end point was death at 90 days.

Results: The study did not meet the primary end point. There were more deaths but fewer liver transplants in the Placebo arm than in either larsucosterol arm with win probability differences of 0.078 (p = 0.196) in the 30 mg and 0.039 (p = 0.533) in the 90 mg larsucosterol arm against Placebo. Mortality at 90 days was reduced by 41% in the larsucosterol 30 mg arm (p = 0.068) and 35% in the larsucosterol 90 mg arm (p = 0.124). A significant regional difference was observed; US subjects (n = 232), which comprised 76% of the study population, showed a 57% and 58% reduction in 90-day mortality (p = 0.014 and p = 0.008, respectively) following larsucosterol treatment. Both doses of larsucosterol were well tolerated with fewer overall treatment emergent adverse events in the active arms than in the Placebo arm.

Conclusion: AHFIRM showed a compelling signal of mortality reduction with both doses of larsucosterol. A statistically significant reduction in 90-day mortality was observed in the US population. Significant regional differences in clinical practice, sample size, and randomization were seen—these should be addressed when designing future multinational AH trials. Larsucosterol was well-tolerated; both dose groups had numerically fewer adverse events than in Placebo arm.

LBO-004

Excess waitlist mortality and survival benefit of liver transplantation for patients with severe acute-on-chronic liver failure: Interim results of the CHANCE study

Email: thierry.gustot@erasme.ulb.ac.be

Background and aims: Mortality of patients with acute-on-chronic liver failure grades 2 and 3 (ACLF 2,3) exceeds 60% within 28-days. Therefore, liver transplantation (LT) is a potential therapeutic option. The current organ allocation systems based on MELD scores could underestimate mortality risk for ACLF 2,3 patients on the waiting list (WL). Moreover, the risk versus benefit of LT for ACLF 2,3 is still debated. The aim of the global CHANCE study was to assess, in the current allocation systems, the outcomes of ACLF 2,3 patients on the WL and for those who underwent LT.
Method: Data from 823 patients (~80% of the overall study cohort) is reported here: 376 patients with ACLF 2,3 (Group 1) and 313 patients with ACLF 0,1 and MELD>20 (Group 2), all listed for LT; and 134 patients with ACLF 2,3 referred but not listed (Group 3). Patients were recruited from 62 LT centers from Asia, Europe, Latin America and North America between July 2021 and October 2023. The rate of death/delisting is presented according to ACLF grade and MELD-Na score at study inclusion and by geographical distribution. Mortality within 3-months after LT is also described.
Results: Death/delisting on the WL occurred in 28% Group 1 patients compared with 16% Group 2 patients (p<0.001), while 85% Group 3 patients died. 68% and 79% for Groups 1 and 2 received LT (p<0.001). Significant differences in death/delisting on the WL were observed across continents (Asia: 13%; Europe: 18%; Latin America: 40%; North America: 20%; p<0.001). The higher rate of death/delisting for ACLF 2,3 patients was observed across all MELD-Na ranges [<25 (50%), 25-29 (35%), 30-34 (22%), >35 (29%)] compared to patients without ACLF 2,3 [MELD-Na <25 (12%), 25-29 (19%), 30-34 (15%), >35 (17%); p<0.001]. At the time of LT, 236 patients were ACLF 2,3 and 265 were ACLF 0,1. No differences in 3-month post-LT mortality were observed according to the number of organ failures (p=0.08) and ACLF grades (p=0.07). Significant differences were observed in 3-month post-LT mortality across continents (Asia: 12%, Europe: 7%, Latin America: 16%; North America: 3%; p=0.006).
Conclusion: The interim results of this first global prospective CHANCE study provide clear evidence of transplant benefits for patients with ACLF 2,3 and suggest that the current allocation systems are inadequate for patients with ACLF 2,3, leading to an excess of WL mortality, arguing strongly for a change in the organ allocation systems for these patients.

LBO-005

Intervention with oral LPCN 1148 improves sarcopenia and hepatic encephalopathy (HE) in patients with cirrhosis: a 52-week phase 2 randomized clinical trial

Benjamin Bruno[1], Josh Weavil[1], Jonathan Ogle[1], Nachaippan Chidambaram[1], Elizabeth Carey[2], Christopher Danford[3], Zachary Fricker[4], Joseph Galati[5], William M. Lee[6], Parvez Mantry[7], Kirti Shetty[8], Anthony DelConte[9], Mahesh Patel[1], Arun J. Sanyal[10], Jennifer Lai[11]. *[1]Lipocine Inc, Salt Lake City, United States; [2]Mayo Clinic Arizona, Divisions of Hepatology and Gastroenterology, Phoenix, United States; [3]Transplant Services, Intermountain Medical Center, Murray, United States; [4]Department of Gastroenterology, Hepatology, and Nutrition, Beth Israel Deaconess Medical Center, Boston, United States; [5]Liver Specialists of Texas, Houston, United States; [6]Division of Digestive and Liver Diseases, University of Texas Southwestern Medical Center, Dallas, United States; [7]Research and Hepatobiliary Tumor Program, The Liver Institute at Methodist Dallas Medical Center, Dallas, United States; [8]Division of Gastroenterology and Hepatology, University of Maryland School of Medicine, Baltimore, United States; [9]Department of Food, Pharma, and Healthcare, Saint Joseph's University, Philadelphia, United States; [10]Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, Virginia Commonwealth University, Richmond, United States; [11]Division of Gastroenterology and Hepatology, University of California San Francisco, San Francisco, United States*
Email: bjb@lipocine.com

Background and aims: Sarcopenia, a condition of progressive and generalized muscle loss, is prevalent in patients with cirrhosis and is associated with adverse clinical outcomes including HE. Androgens are multimodal hormones which can address these conditions, however their safety and efficacy in patients with cirrhosis have not been well studied.
Method: In this 8-center, phase 2 trial, men with cirrhosis and sarcopenia awaiting liver transplant were randomized 1:1 to receive either oral LPCN 1148, an oral prodrug of testosterone (T), or placebo for 24 weeks (NCT04874350). After week 24, all participants received LPCN 1148 during the study stage 2 open-label extension (OLE). Basal T level was not considered for study eligibility and participants were not asked to change diet, exercise, or background therapies including rifaximin or lactulose during the study. CT scans were performed at 12, 24, 36, and 52 weeks. The primary end point was the change in

skeletal muscle index (SMI) measured by computed tomography (CT) scan at 3rd lumbar spine level (L3-SMI) from baseline to 24 weeks. Secondary end points included overt HE (OHE), defined as HE events with CTCAE severity ≥2.
Results: 29 participants (mean age = 59 ± 8 years, BMI = 29 ± 7 kg/m2) were randomized and received ≥1 dose of LPCN 1148 (n = 15) or placebo (n = 14). Baseline characteristics were similar; mean MELD 17 and 76% of participants had a history of HE. At week 24, L3-SMI increased in patients taking LPCN 1148 vs. placebo (Δ 4.1 ± 0.9 vs Δ −0.6 ± 1.2 cm2/m2; p = 0.006), representing a placebo-adjusted 9.9% increase in L3-SMI with LPCN 1148. This increase from baseline was maintained with LPCN 1148 through Week 52 (Δ 4.1 ± 1.1 cm^2/m^2). All six participants in the placebo arm that converted to LPCN 1148 at Week 24 and had CT scans during stage 2 experienced an increase in SMI at Week 52 (Δ 8.1 ± 1.7 cm^2/m^2, +16.7%). During stage 1, OHE rates were lower in those on LPCN 1148 vs placebo (2 vs 6 events, p <0.05), and average time to first OHE recurrence was longer (114 vs 35 days). Two additional OHE events occurred during the OLE; one event from participants from each arm of the prior stage. LPCN-treated participants (vs. placebo) experienced improvements in anemia, patient-reported outcomes, muscle quality, 6-min walk test, and digital Stroop test. The number and severity of treatment-emergent adverse events were similar across both arms with no incident cases of drug-induced liver injury or thrombosis. There were two deaths in placebo-treated, and one in LPCN 1148-treated, participants.
Conclusion: LPCN 1148 is the first therapeutic intervention to both improve sarcopenia and reduce overt HE episodes in men with cirrhosis awaiting liver transplant. Furthermore, LPCN 1148 was well-tolerated with up to 52 weeks of therapy. These results provide support for further study of LPCN 1148 for the treatment of sarcopenia and prevention of HE recurrence in advanced cirrhosis.

LBO-006

A prospective, blinded, multicenter U.S. evaluation of a multi-analyte blood-based test for the detection of hepatocellular carcinoma (HCC) in patients with cirrhosis

David Taggart[1], Shivani Mahajan[1], Maxime Gallant[1], Itai Pinkoviezky[1], Jianfeng Xu[2], Allison Sorg[1], Curt Roberts[1], Dmitri Slinkov[1], Emmanuel Gorospe[3], Abdullah Mubarak[4], Bal Raj Bhandari[5], Bradley Freilich[6], Nadege Gunn[7], Ju Dong Yang[8], John Smith[9], Ziad H. Younes[10], Roniel Cabrera[11], Humberto Aguilar[12], Wei Li[13], Richard Van Etten[14], Mindie Nguyen[15]. *[1]Helio Genomics, Irvine, United States; [2]The Laboratory for Advanced Medicine, Beijing, China; [3]Texas Gastro Research, El Paso, United States; [4]Liver Center of Texas, Dallas, United States; [5]Delta Research Partners, Bastrop, United States; [6]Kansas City Research Institute, Kansas City, United States; [7]Velocity Clinical Research, Wako, United States; [8]Cedars-Sinai Medical Center, Los Angeles, United States; [9]Digestive and Liver Disease Specialists, Norfolk, United States; [10]Gastro One, Germantown, United States; [11]University of Florida, Gainesville, United States; [12]Louisiana Research Center, Shreveport, United States; [13]University of California, Irvine, Irvine, United States; [14]Chao Family Comprehensive Cancer Center, University of California, Irvine, Irvine, United States; [15]Stanford University Medical Center, Palo Alto, United States*
Email: davidt@heliogenomics.com

Background and aims: Hepatocellular carcinoma (HCC) surveillance with semi-annual abdominal ultrasound is recommended for patients with cirrhosis, but ultrasound suffers from low adherence and poor early stage sensitivity. To overcome these challenges, the HelioLiver Dx test has been developed to aid in the detection of HCC in cirrhotic patients. This multi-analyte blood test employs a proprietary algorithm utilizing a wide array of biomarkers from cell-free DNA (cfDNA) methylation and serum proteins to accurately detect HCC.
Method: In a prospective, blinded, multicenter study, we enrolled 1, 968 adult cirrhosis patients across the U.S. to compare the performance of the HelioLiver Dx test to ultrasound for HCC detection. Of these, 1, 556 participants made up the validation cohort. Multiphasic MRI was the gold standard for HCC diagnosis. The coprimary outcomes were for HelioLiver Dx to possess a superior sensitivity (>5%) and non-inferior specificity (>−10%) compared to ultrasound. The secondary outcome was superior sensitivity of HelioLiver Dx relative to ultrasound for HCC lesions less than or equal to 4 cm in diameter.
Results: 1, 268 patients in the validation cohort were evaluable and analyzed (49.4% male, 59.6 in mean age, 33.5% Hispanic, 85.1% white). A total of 46 participants (3.6%) had HCC, with most having HCC lesions of 4 cm or smaller (80%), or 2 cm or smaller (46%). HelioLiver Dx had a sensitivity of 47.8% (95%CI 32.9 to 63.1) for all HCC lesions and 37.8% (95%CI 22.5 to 55.2) for HCC lesions 4 cm or smaller. In contrast, ultrasound demonstrated lower sensitivities of 28.3% (95%CI 16.0 to 43.5) for all HCC lesions and 13.5% (95%CI 4.5 to 28.8) for HCC lesions 4 cm or smaller. Furthermore, HelioLiver Dx detected 28.6% (95%CI 11.3 to 52.2) of HCC lesions 2 cm or smaller, whereas ultrasound failed to detect any (0.0%; 95%CI 0.0 to 16.1). For T1 lesions by the TNM staging system (59%), HelioLiver Dx had a sensitivity of 44.4% (95%CI 25.5 to 64.7) compared to 11.1% (95%CI 2.4 to 29.2) for ultrasound. In subgroup analysis based upon participant sex, ethnicity, race and cirrhosis etiology, HelioLiver Dx consistently demonstrated sensitivities 12.5% to 33.3% higher and specificities 2.9% to 12.2% lower than ultrasound. The overall specificity of HelioLiver Dx and ultrasound were 87.6% (95%CI 85.6 to 89.4) and 94.1% (95%CI 92.6 to 95.4), respectively. The HelioLiver Dx test met both the coprimary and secondary study end points.
Conclusion: Compared to ultrasound, HelioLiver Dx detected more HCC lesions overall, as well as more small HCC lesions in a cohort of diverse patients with cirrhosis. HelioLiver Dx is an accurate and convenient blood-based test that has the potential to reduce HCC morbidity and mortality through improved early detection.

Nurses & AHPs

OS-001

The second stage of the mobile health application developed for patients with liver cirrhosis: results of the randomized controlled trial

Ferya Celik[1], Hicran Bektas[1]. *[1]Akdeniz University, Antalya, Turkey*
Email: feryacelik@gmail.com

Background and aims: We developed a web-based mobile health application (ReLiver-N App [Rehabilitation of Liver by Nurse Application]) for patients with liver cirrhosis. The aim of this study was to determine the effect of the ReLiver-N App on patient activation, self-efficacy, and quality of life.
Method: The study was carried out between October 2022 and May 2023 with 52 patients with liver cirrhosis by using the Patient Activation Measure, Self-efficacy for Managing Chronic Disease 6-item Scale, and Chronic Liver Disease Questionnaire. Patients in the intervention (ReLiver-N App) group received comprehensive health education and patient activation practices via the ReLiver-N App and were followed up by text messages once a week. Patients in the active control group received patient activation practices via the ReLiver-N App. All of patients reached routine care up in the hospital. Patients in the ReLiver-N App and active control groups completed the measurements for patient activation practice for 12 weeks. The data were evaluated using descriptive statistics, t-tests, Student's t-tests, variance, and regression analyses.

Results: A statistically significant difference was found between the post-test mean scores of the ReLiver-N App and active control groups in terms of patient activation, self-efficacy, and quality of life ($p < 0.01$). The ReLiver-N App group participated in patient activation practices at a rate of 70.8% and the active control group at a rate of 36.0%. At the end of this study 65.4% of the patients in the ReLiver-N App group and 15.4% of the patients in the active control group had an patient activity level of "3.".
Conclusion: Mobile educational content and patient activation practices aimed at increasing participation in self-care increased the level of activation, self-efficacy, and quality of life of patients with liver cirrhosis. It is recommended that the use of comprehensive educational content and patient activation practices in the care process of patients be generalized. Keywords**:** liver cirrhosis, nursing care, patient activation, self-efficacy, quality of life.

OS-002
Patients' experiences of liver cirrhosis health care
Maria Hjorth[1], Anncarin Svanberg[2], Daniel Sjöberg[3], Fredrik Rorsman[2], Elenor Kaminsky[4]. *[1]Department of Medical Sciences, Centre for Clinical Research in Dalarna, Uppsala, Sweden; [2]Department of Medical Sciences, Uppsala, Sweden; [3]Centre for Clinical Research in Dalarna, Falun, Sweden; [4]Department of Public Health and Care Science, Uppsala, Sweden*
Email: maria.hjorth@regiondalarna.se

Background and aims: When patients are diagnosed with liver cirrhosis, around 50% already present life-threatening symptoms. Perceived stigma and a hierarchy in the patient-healthcare professional relation may hinder patients' participation in their own care. Further, patients' knowledge regarding their disease, self-care, and medical treatment, may influence both treatment effects and patients' needs of inpatient care. Knowledge about patient experiences of liver cirrhosis health care is scarce. Hence, the aim of this study was to capture patients' descriptions of health care experiences in relation to cirrhosis illness.
Method: Qualitative data from semi-structured interviews ($n = 18$) and open-ended responses in patient surveys ($n = 86$), was collected at six Swedish hospitals, from 2016–2022. Data was analyzed with thematic analysis.
Results: Patients' experiences were reflected in two themes: In the first theme, 'struggle to be in a dialogue', patients expressed troubles in getting understandable information, being involved and being perceived as a person. In the second theme, 'being helped or harmed', most patients described to be satisfied with the received care. Despite this, they 'endured care', 'felt lost' in the healthcare organization and 'not taken care of'. Instead, they described as though they were falling through the cracks.
Conclusion: Patients need assistance to become certain regarding where to turn for cirrhosis health care. They should always be invited to tell their narrative and be provided with information based on their previous knowledge about their disease. Person-centered care where patients are being perceived as a unique person, is vital for patients' sense of a safe and trustful relationship. This may be realized by registered nurse involvement in the hepatology outpatient team, which may prevent patients from falling through the cracks.

OS-003
Longitudinal symptom burden in caregivers for patients with end-stage liver disease
Lissi Hansen[1], Shirin Hiatt[1], Susan Rosenkranz[1], Michael Chang[2], Nathan Dieckmann[1], Christopher Lee[3]. *[1]Oregon Health and Science University, Portland, United States; [2]VA Portland Health Care System, Portland, United States; [3]Boston College, Chestnut Hill, United States*
Email: hansenli@ohsu.edu

Background and aims: Globally, chronic liver disease (CLD) and cirrhosis is a serious public health problem and accounts for two million deaths annually. The care of patients with end-stage liver disease (ESLD), the final stage of CLD, is most often provided by the help from informal caregivers. Although, the burden of this care on caregivers has been found to be significant with experience of physical and psychological symptoms, longitudinal research on caregiver symptoms are few. Thus, the aim of this study was to identify trajectories of symptoms to broaden our understanding of caregiver symptom experiences to aid in design of interventions to improve outcomes for caregivers.
Method: Informal caregivers for patients with ESLD were recruited from liver clinics within two healthcare institutions in the Northwestern United States. Inclusion criteria: age ≥18 years and identified as the patient's primary caregiver. Exclusion criteria: major uncorrected hearing impairment and uncontrolled psychiatric illness. Survey data were collected at baseline and again at 3, 6, 9, and 12 months. Caregivers completed the Multidimensional Caregiver Strain Index, Patient Health Questionnaire, Uncertainty in Illness Scale for Family Members, Pittsburgh Sleep Quality Index, Short Form Health Survey, and Mutuality Scale (relationship quality with patient). Descriptive statistics and latent growth mixture modelling were used to analyse the data.
Results: The sample ($N = 186$, age 56.7 ± 13.2 years) was predominantly female (75.3%), white (89.2%), and cohabitating with patients (76.9%). Over time caregivers experienced statistically significant improvement in caregiver strain ($p = 0.001$) and uncertainty ($p = 0.001$) but not in sleep quality and depressive symptoms. Patient Charlson comorbidity index was associated with caregiver worsening mental quality of life over time ($p = 0.038$). In contrast to non-spousal caregivers, spousal caregivers had significantly worse mental quality of life at study enrolment ($p = 0.006$) but their mental quality of life improved over time. Relationship quality and female gender were significant predictors of change in caregiver physical quality of life, both were associated with worsening physical quality over time ($p = 0.011$ and $p = 0.012$, respectively).
Conclusion: It is essential for healthcare professionals to address caregiver burden and symptoms experiences by spouse and non-spouse caregivers to improve their overall health and ability to continue to provide care. Future researchers should include longitudinal and dyadic studies to examine how patients' disease progression may affect spouse and non-spouse caregivers differently with the goal of developing effective interventions.

OS-004
Testing for hepatitis C virus infection in prisons in England: room for improvement
Kathryn Jack[1], Brian Thomson[1], William Irving[2]. *[1]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [2]Nottingham University Hospitals NHS Trust, The University of Nottingham, Nottingham, United Kingdom*
Email: katejack2000@hotmail.com

Background and aims: Testing of all new entrants into prisons in England for hepatitis C virus (HCV) infection is a critical policy in the National Health Service England (NHSE) strategy to achieve the World Health Organisation (WHO) hepatitis C elimination goals. This study addresses the extent to which current testing targets are being met in remand prisons, possible reasons for failure, and ways in which testing rates might be improved.
Method: This mixed methods study comprised 4 distinct datasets: (I) HCV testing data was collected from 3 category B prisons (remand or short sentences) in the East Midlands for a period of one year (2022–23), together with location prior to prison arrival and length of stay. Failure to be tested was defined as no test recorded within 4 weeks of arrival. (ii) A questionnaire listing possible reasons for failure to be tested was administered to 166 people in prison (PIP) who were not tested. (iii) A survey, using the tool Expert Recommendations for Implementing Change (ERIC), and containing 76 implementation strategies in 8 clusters, was sent to heads of healthcare at 30 prison establishments in England, with a follow-up telephone call to encourage return. (iv) Face-to-face interviews were semi-structured

according to the five domains of the Consolidated Framework for Implementation Research (CFIR) containing 39 constructs, were held with 13 key healthcare professional staff at the study prisons. All 4 datasets were triangulated to facilitate the development of a novel model of sustainable blood-borne virus testing.
Results: Anti-HCV test uptake rates for the 52-week timeframe for Prisons 1, 2, and 3 were 17.2% (594/3456), 28.3% (590/2081), and 42.5% (558/1307). Testing was more likely if PIP were admitted from the community (39%) as opposed to via prison transfer (31%) and if length of stay was >21 days (39% versus 27%). Two-thirds of 166 PIP not tested gave the reason "I am not interested." Within the ERIC framework, staff education, stakeholder interrelationships, and prisoner engagement were the top three groups with the most interventions implemented, and the financial interventions group was the least implemented. Interviews with healthcare staff revealed 21 barriers and 9 facilitators to HCV testing within the 39 available CFIR constructs. Key barriers include a lack of time and space during the PIP arrival process, competing healthcare and prison regime priorities, and the interpretation that an opt-out approach involves a choice to accept or decline a test. Successful facilitators include incentivising PIP, external support, and adapting opportunities for healthcare delivery.
Conclusion: HCV testing rates within the 3 prisons in this study were far below the intended national target (75%). This study has identified a number of ways that testing rates might be improved, through removal of barriers and adoption of facilitators to testing.

THURSDAY 06 JUNE

Alcohol-related liver disease

OS-005-YI
Single-cell RNA sequencing analysis in alcohol-related liver disease identifies specific cell subpopulations characterized by an inflammatory profile in alcohol-associated hepatitis

Jordi Gratacós-Ginès[1], Alex Guillamon-Thiery[2], Aina Rill[3], Alicia Martínez[2], Silvia Ariño[2], Ana Belén Rubio[2], Martina Perez-Guasch[1], Celia Martinez-Sanchez[2], Emma Avitabile[2], Anna Soria[1], Adrià Juanola[1], Isabel Graupera[1], Mar Coll[2], Ramon Bataller[1], Elisabetta Mereu[3], Pere Ginès[1], Elisa Pose[1]. *[1]Liver Unit, Hospital Clínic de Barcelona-IDIBAPS, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Josep Carreras Leukaemia Research Institute (IJC), Badalona, Spain*
Email: jgrata@recerca.clinic.cat

Background and aims: Alcohol-related liver disease (ALD) alters the normal architecture of the liver impairing liver function and eventually leading to its severe form, alcohol-associated hepatitis (AH). The phenotypic alterations of the different cell types through ALD progression are largely unknown. The aim of this work was to dissect the transcriptomic identity of cellular populations across ALD stages by using single-cell RNA sequencing (SCRNAseq) of liver biopsies at different stages of the disease.
Method: Liver biopsies were obtained from patients with ALD with different disease stages (patients with compensated liver disease, n = 3 and patients with AH, n = 6) and from healthy donors (n = 3). Samples were processed by mechanical and chemical digestion and SCRNAseq was performed using the 10X Genomics platform. Data were analyzed with Seurat in R and Reactome, KEGG and Gene Ontology databases were used to describe biological function of cellular subtypes.
Results: A total of 30, 092 cells were clustered based on their expression pattern and 60 cell subpopulations with a unique transcriptomic identity were defined. Among these, 12 were found significantly enriched in AH and defined as the specific AH subpopulations. We analyzed the biological processes of every AH subpopulation: 1) 2 subpopulations of hepatocytes that expressed genes of cytokine signaling ($IL32^+$), neutrophil degranulation ($ORM1^+$) and cellular stress ($PRDX1^+$); 2) 2 subpopulations of cholangiocytes that expressed hepatic progenitor cell genes ($EPCAM^+$) and epithelial-to-mesenchymal cell transition genes ($FGFR1^+$); 3) 2 subpopulations of endothelial cells that expressed genes associated with cytokine production ($IRF1^+$) and extracellular matrix interaction ($ITGA6^+$); 4) 3 subpopulations of hepatic stellate cells with activated phenotype, expressing genes associated with inflammation and fibrogenesis ($COL1A1^+$); 5) 1 lymphocyte subpopulation that expressed genes related to cell stress and heat shock proteins ($HSPA1A^+$); and finally 6) 2 macrophages subpopulations characterized by an inflammatory profile expressing cytokines ($CCL4^+$) and complement related genes (VTN^+).
Conclusion: This study unveils for the first time the transcriptomic identity of the liver cell populations during in the progression of ALD at a single cell level. Moreover, the functional analysis of the specific subpopulations associated to AH reveals inflammation and matrix remodeling as common key biological features among cellular compartments.

OS-006
Incretin-based therapies reduce alcohol intake in lean and obese hamster models of chronic alcohol consumption

Francois Briand[1], Estelle Grasset[1], Natalia Breyner[1], Thierry Sulpice[1]. *[1]Physiogenex, Escalquens, France*
Email: f.briand@physiogenex.com

Background and aims: Rodent studies suggested that GLP-1 receptor agonists reduce alcohol intake in mouse and rat, but these species are not truly alcohol dependent. Golden Syrian hamsters spontaneously show a high preference for alcohol and may represent a better animal model. Here we setup two hamster models of chronic alcohol consumption to evaluate incretin-based therapies.
Method: In the first model, normal hamsters were fed a 4-week chow diet with free access to normal water or 15% alcohol-enriched water. Hamsters were then kept on the same diet and treated for 3 weeks with vehicle, semaglutide 0.04 mg/kg or tirzepatide 0.05 mg/kg subcutaneously every 3 days. The second model used hamsters with obesity and metabolic dysfunction-associated steatohepatitis (MASH), induced with a 20-week free choice diet which presents hamsters with a choice between control chow or high fat/cholesterol diet, and normal water or 10% fructose-enriched water. Hamsters were then maintained on the same diet with the 10% fructose water supplemented with 15% alcohol and treated with vehicle or semaglutide 0.06 mg/kg subcutaneously QD for 5 weeks.
Results: In the first model, hamsters reduced their normal water intake by >50% and gradually increased their 15% alcohol-enriched water intake by 275% during the 4-week induction period. Compared with vehicle, semaglutide and tirzepatide significantly prevented weight gain and reduced food intake only during the first week of treatment. Both drugs markedly increased normal water intake and significantly lowered 15% alcohol-enriched water intake during the 3-week treatment. This effect was associated with lower plasma free fatty acids levels and, for tirzepatide only, a significant reduction in hepatic triglycerides content. In the second model, obese hamsters treated with semaglutide showed a 17% body weight loss ($p < 0.01$ vs. vehicle) with a transient food intake lowering. While vehicle treated hamsters showed a progressive 52% increase in fructose/alcohol-enriched water intake, semaglutide strongly reduced it and significantly raised normal water intake. However, semaglutide did not alter MASH and liver fibrosis.

Conclusion: Incretin-based therapies reduce alcohol intake in lean and obese hamsters having free access to alcohol. These preclinical models will be helpful to evaluate the benefits of novel therapies on chronic alcohol consumption.

OS-007-YI

Intelligent liver function test 5 years on-the evolution of an intelligent platform

Damien Leith[1,2], Jennifer Nobes[1,2], Sava Handjiev[1,2], Iain Macpherson[1], Ellie Dow[2], John F Dillon[1,2]. [1]*University of Dundee, Dundee, United Kingdom;* [2]*Ninewells Hospital, Dundee, United Kingdom*
Email: damienleith86@gmail.com

Background and aims: Intelligent Liver Function Testing (iLFT) was introduced in NHS Tayside primary care in August 2018, in response to increasing mortality from chronic liver disease (CLD) and frequent liver function test (LFT) abnormalities without appropriate further investigation. Here we describe the utilisation and evolution of iLFT during the first five years of routine use in a primary care setting serving a population of approximately 400,000 people.
Method: This laboratory platform utilises an automated algorithm which combines clinician-entered clinical information with basic LFT results to reflex fibrosis scoring, relevant aetiological testing and recommended management outcomes. Earlier work demonstrated iLFT to be cost-effective and acceptable to primary care colleagues.
Results: Between August 2018 and August 2023 26,459 iLFT tests were performed. 16,112 (60.9%) cascaded to a full aetiology screen, 1, 967 (7.4%) to a partial aetiology screen and 8,380 (31.7%) required no further testing. Over the last 12 months demand has stabilised-averaging 860 requests per month, with 48% cascading further tests. Of the 20, 895 outcomes generated from cascaded iLFT, isolated abnormal ALT without fibrosis (n = 4, 962, 23.7% of all outcomes) was most frequent-the majority of which were likely metabolic dysfunction-associated steatotic liver disease (MASLD) on review. For iLFT with aetiology-specific outcomes, the majority were probable alcohol related liver disease (n = 3, 134; 15.0%) and MASLD (n = 2, 477; 11.9%). Additionally, iLFT identified 657 MetALD, 529 alpha-1 antitrypsin phenotypes associated with CLD, 470 possible haemochromatosis, 230 possible autoimmune conditions, 87 active hepatitis C infections and 19 active hepatitis B infections. Biochemical evidence of significant fibrosis was seen in 20.0% of all requests. 69.9% of outcomes recommended that patients could be safely managed in primary care. iLFT has proven rapidly adaptable to evolving clinical need. In response to increasing secondary care hepatology clinic waiting times, reflexive Enhanced Liver Fibrosis (ELF) testing for individuals with indeterminate FIB-4 or NAFLD Fibrosis Scores was introduced in July 2020, reducing referral by around one-third. In addition, new iLFT outcomes were developed in response to new evidence-such as highlighting risk of malignancy in patients with elevated alkaline phosphatase and thrombocytosis-and existing outcomes have adapted in line with new guidance e.g. incorporating new Steatotic Liver Disease nomenclature.
Conclusion: Five years on iLFT is an integral part of the investigation of liver disease in our region, with its high usage demonstrating wide acceptance by primary care. It has proven robust yet adaptable to the Covid pandemic, emerging evidence and nomenclature change. Ongoing work focuses on refining the algorithm and supporting national roll-out.

OS-008-YI

Cellular senescence is reduced following alcohol cessation in severe alcohol-associated hepatitis

Daniel Rodrigo-Torres[1], Alastair M Kilpatrick[1], Stephen R Atkinson[2], Sofia Ferreira-Gonzalez[1,3], Luke D Tyson[2], Nikhil Vergis[2], Mark R Thursz[2], Laura Martinez-Gili[2], Stuart J Forbes[1]. [1]*Centre for Regenerative Medicine, Institute for Regeneration and Repair, The University of Edinburgh, Edinburgh, United Kingdom;* [2]*Division of Digestive Diseases, Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom;* [3]*Centre for Inflammation Research, Institute for Regeneration and Repair, The University of Edinburgh, Edinburgh, United Kingdom*
Email: drodrigo@ed.ac.uk

Background and aims: Cellular senescence, a state of irreversible cell cycle arrest, has been associated with progression and poor outcomes in chronic liver diseases such as metabolic dysfunction-associated steatohepatitis (MASH). However, the role of senescence in alcohol-related liver disease and alcohol-associated hepatitis (AH) remains unclear. Here, we investigated temporal changes in the transcriptomic expression of senescence markers in a cohort of severe AH (sAH) patients following alcohol cessation.
Method: Liver tissue biopsies were obtained at day 0 (baseline) and day 28 (d28) from participants with sAH enrolled in the ISAIAH clinical trial of canakinumab (CAN), an anti-IL-1β antibody (n = 32; 27 paired samples). RNA was extracted, and bulk RNA sequencing performed. Gene level differential expression analysis was computed with respect to time as categorical variable, and with respect to CAN as an interaction with time, using a linear mixed effects model, adjusting for age and sex as fixed effects and with patient as random intercept. Gene set enrichment analysis (GSEA) was computed with fgsea; cell type specific markers were annotated using the Liver Cell Atlas. False discovery rate <0.05 was considered significant.
Results: CAN treatment revealed no significant transcriptomic differences at d28 compared to the placebo group. However, Model for End-Stage Liver Disease (MELD) score improved at d28 in 93% of patients with paired samples (CAN: 13/14; placebo: 12/13), with 2, 921 genes significantly dysregulated with respect to baseline. Expression of senescence markers including Cyclin Dependent Kinase Inhibitors 1A, 2A and 2B (CDKN1A; CDKN2A; CDKN2B) was significantly downregulated at d28. Genes linked to the senescence-associated secretory phenotype (SASP), including chemokine (C-X-C motif) ligand 1 (CXCL1) and transforming growth factor beta 2 (TGFB2) were also significantly downregulated. P53 pathway and apoptosis gene sets were significantly enriched, driven by widespread downregulation of gene set members. Markers of acute inflammation, including C-reactive protein (CRP), were significantly downregulated at d28. Genes associated with fatty acid and bile acid metabolism were upregulated at d28, suggestive of a restoration of liver metabolic function following alcohol cessation. Hepatocyte genes (e.g. albumin [ALB] and hepatocyte nuclear factor 4 alpha [HNF4A]) were also upregulated at d28, while markers of biliary cells (e.g. keratin 7 [KRT7], prominin-1 [PROM1]) and other cell types were downregulated.
Conclusion: Improvement in sAH patients following alcohol cessation is characterized transcriptomically by reduced expression of senescence, SASP and apoptosis-related factors. Concomitant downregulation of inflammatory factors and upregulation of hepatic and metabolic factors further suggest a partial restoration of hepatic gene expression.

OS-009-YI

Phosphatidylethanol complements urinary and scalp hair ethyl glucuronide for the detection of different levels of alcohol use in patients with alcohol-related cirrhosis: establishing a 3-days-3 weeks-3 months alcohol use profile

Benedict Vanlerberghe[1], Catalina Dumitrascu[2], Nele Van den Eede[1], Schalk van der Merwe[1], Frederik Nevens[1], Alexander van Nuijs[2], Jef Verbeek[1]. [1]*University Hospitals Leuven, Leuven, Belgium;* [2]*University of Antwerp, Antwerp, Belgium*
Email: b.vanlerberghe@maastrichtuniversity.nl

Background and aims: Phosphatidylethanol (PEth) is a mid-term biomarker (weeks) that could bridge the detection windows of urinary ethyl glucuronide (uEtG) (days) and scalp hair (h)EtG (months), but is barely validated in patients with alcohol-related liver disease (ALD). In addition, the reported detection windows per biomarker are highly variable (1 to 7 days for uEtG and 2 to 4 weeks

for PEth). While the assessment of *any* alcohol use is important in the follow-up of ALD patients, categorizing patients based on different levels of alcohol use could aid in assessing the contributive effect of alcohol in other liver diseases, such as metabolic dysfunction-associated steatotic liver disease. We assessed the diagnostic accuracy and optimal detection windows of PEth, uEtG, hEtG, and the novel biomarker fingernail (n)EtG, for different levels of alcohol use in patients with ALD cirrhosis.

Method: Alcohol use in the prior 3 months was questioned using the Alcohol Timeline Followback Method in patients with ALD cirrhosis. 1 to 7-day detection windows were assessed for uEtG and 1 to 5 weeks for PEth. hEtG (3 cm proximal hair strand) and nEtG were used to assess alcohol use in the prior 3 months. Increased alcohol use was defined as ≥2 U/d for females and ≥3 U/d for males, and excessive use as ≥5 U/d for females and ≥6 U for males. Possible confounding factors were assessed by uni- and multivariate linear regression.

Results: 110 patients (mean age 60.7 yrs (SD 10.7); male 74.5%, CP A 59.1%) were included. For any use, uEtG (n = 98) yielded the highest diagnostic accuracy over a 3-day detection window (sensitivity (SE) 100%, specificity (SP) 93.4%, positive predictive value (PPV) 81.5%, negative predictive value (NPV) 100%), and PEth (n = 105) over a 3-week window (SE 95.2%, SP 98.4%, PPV 97.6%, NPV 96.9). For any use in the prior 3 months, hEtG (n = 97) had a SE of 89.7%, SP of 86.2%, PPV of 81.4%, and NPV of 92.6%, and nEtG (n = 77) a SE of 78.9%, SP of 97.4%, PPV of 96.8%, and NPV of 82.6%.

PEth and hEtG had high NPV for increased (PEth: SE 76.9%, SP 89.9%, PPV 71.4%, NPV 92.2%; hEtG SE 89.3, SP 89.9%, PPV 78.1%, NPV 95.4%) and excessive use (PEth: SE 83.3%, SP 80.6%, PPV 35.7%, NPV 97.4; hEtG: SE 100%, SP 79.3%, PPV 46.9%, NPV 100%).

Absolute values of uEtG (B: 0.860 (SD 0.042); p < .001), PEth (B:1.594 (SD 0.191); p < .001), and hEtG (B: 0.931 (SD 0.097); p < .001) only correlated with alcohol use and not with renal dysfunction, CP score, or sex in multivariate analysis, nor diuretics use for uEtG and hemoglobin for PEth.

Conclusion: In patients with ALD cirrhosis, uEtG, PEth, and hEtG have excellent and complementary diagnostic accuracies to detect any alcohol use in the prior 3 days, 3 weeks, and 3 months, respectively. PEth and hEtG have high accuracies in excluding increased and excessive alcohol use. Nail EtG can provide an alternative when scalp hair is unavailable but needs further validation.

Cirrhosis and its complications: Experimental

OS-010

Endothelial-to-mesenchymal transition: a targetable mechanism involved in portal vein thrombosis in cirrhosis

Email: anton@recerca.clinic.cat

Background and aims: Portal vein thrombosis (PVT), a common thrombotic complication in cirrhosis (CH), lacks clear pathophysiology. Unlike thrombosis in other areas, in PVT anticoagulation rarely achieve complete recanalization and alternative treatments are scarce. Our study seeks to unravel the molecular-level pathophysiology of PVT in CH patients and to identify new therapeutic targets.

Method: 1) Histological analysis of portal vein segments from explanted livers of patients with cirrhosis with (CH-PVT, n = 15) and without (CH, n = 33) PVT, compared to a control group (CT, n = 28) without portal hypertension; 2) RNA sequencing of primary portal vein endothelial cells (PVECs) obtained during liver transplantation from CH-PVT (n = 5), CH (n = 12), and controls (n = 3); 3) Drug repurposing study using the DrugGene Interactions database; 4) In vitro treatment of previously isolated primary PVECs from CH (n = 7) and CH-PVT (n = 6) patients. Cells were treated with selected drugs for 24 h and analyzed using qPCR and Western blotting.

Results: Tunica Intima (TI) of PVs from CH was mildly increased vs. CT (TI thickness: 0.6 ± 0.5 vs. 0.4 ± 0.3 mm, p = 0.23). This increase was much more pronounced when PVT was present (TI thickness: CH-PVT 1.3 ± 0.7 mm; p = 0.05 vs CH). Increased thickness was primarily due to endothelial layer proliferation and notable changes in the subendothelial layer composition, which exhibited a secretory phenotype marked by heightened mucin and extracellular matrix (ECM) deposition and reorganization. Transcriptomic analysis of isolated PVECs revealed dysregulation of pathways related to cytoskeletal reorganization, ECM remodeling and TGFβ/SMAD signaling with endothelial-to-mesenchymal transition (EndMT) emerging as the predominant mechanism behind CH-PVT. Remarkably no markers of coagulation exhibited deregulation. In silico drug repurposing analysis identified statins as potential agents targeting these changes. In vitro simvastatin treatment of primary human PVECs ameliorated EndMT-related hallmarks, increasing endothelial markers (NOS3) and reducing mesenchymal markers (FSP1), adhesion molecules (VCAM), Snail1 transcription factor and pSMAD2/SMAD2 ratio levels, suggesting a preventive role in EndMT initiation/progression.

Conclusion: Portal vein undergoes significant changes at the endothelial level in cirrhosis, which are particularly pronounced in those patients developing PVT. EndMT has been identified as the underlying process driving these changes in portal endothelium, which appears to unfold gradually, commencing from CH and reaching its peak with the onset of PVT. Simvastatin's potential to modulate EndMT in PVEC makes it a promising option for PVT treatment and prevention.

The linoleic acid-derived leukotoxin 9, 10-DiHOME drives immunosuppression in patients with acute-on-chronic liver failure

Bryan J. Contreras[1,2], Cristina López-Vicario[1,2], Mireia Casulleras[1,2], Marta Duran-Güell[1,2], Berta Romero-Grimaldo[1,2], Jonel Trebicka[2,3], Vicente Arroyo[2], Joan Clària[1,2,4], on behalf of the MICROB-PREDICT study group[2]. [1]*Biochemistry and Molecular Genetics Service, Hospital Clínic-IDIBAPS, CIBERehd, Barcelona, Spain;* [2]*European Foundation for the Study of Chronic Liver Failure (EF CLIF), Barcelona, Spain;* [3]*Department of Internal Medicine B, University of Münster, Münster, Germany;* [4]*Department of Biomedical Sciences, University of Barcelona, Barcelona, Spain*
Email: bjcontreras@recerca.clinic.cat

Background and aims: Acute decompensation (AD) of liver cirrhosis is characterized by smoldering systemic inflammation that favors the development of organ failure, a condition known as acute-on-chronic liver failure (ACLF) associated with high short-term mortality. In this context, inflammation-related immunosuppression is a crucial factor contributing to secondary infections and multiple organ dysfunction. In this study we explored the profile of immunomodulatory lipid mediators in patients with AD cirrhosis with and without ACLF and investigated their effects on leukocyte function.
Method: The profile of 101 lipid mediators was determined by targeted lipidomics using liquid chromatography coupled to tandem mass spectrometry in plasma from 84 patients with AD cirrhosis without ACLF (stratified in stable decompensated cirrhosis (n = 53), unstable decompensated cirrhosis (n = 10) and patients with high-risk of developing ACLF (pre-ACLF) (n = 21)), and 9 patients with AD cirrhosis and ACLF. For comparison, 31 healthy donors were included. Bioassays determining degranulation, respiratory burst capacity and phagocytosis were performed to assess changes in polymorphonuclear leukocyte function. Cytokine secretion, autophagy responses and mitochondrial dynamics in mononuclear leukocytes were determined by high-throughput multiplex MILLIPLEX assays and Western blot analysis.
Results: The exploratory analysis of the baseline lipid mediator profile showed higher plasma levels of linoleic acid (LA)-derived lipid mediators in patients with AD cirrhosis as compared to healthy controls. Multiple testing identified the LA-derived 9, 10-dihydroxy-12-octadecenoic acid (9, 10-DiHOME) as the only lipid mediator with discriminating power between AD patients with established ACLF from those without. Plasma levels of 9, 10-DiHOME followed the severity course of the disease, were significantly higher at the time AD patients manifested an active infection and peaked at ACLF presentation. Moreover, expression of soluble epoxyde hydrolase (sEH), the enzyme responsible for the biosynthesis of 9, 10-DiHOME, was markedly upregulated in mononuclear leukocytes from AD patients. In the polymorphonuclear leukocyte bioassays, 9, 10-DiHOME impaired degranulation, phagocytosis, and respiratory burst capacity. In the mononuclear leukocyte bioassays, 9, 10-DiHOME significantly impaired cytokine secretion and altered autophagic responses and mitochondrial dynamics.
Conclusion: Leukotoxin 9, 10-DiHOME weakens immune-cell response and therefore the higher circulating levels of this lipid mediator in patients with AD cirrhosis might enhance susceptibility to bacterial infection and precipitate ACLF. These data also position sEH as potential candidate for drug treatment in this condition.

OS-012-YI

Investigating the role of specialized intestinal macrophages in preserving gut-vascular barrier integrity during experimental cirrhosis

Lena Smets[1], Maria Viola[2,3], Lukas Van Melkebeke[1], Niels Vandamme[4], Markus Boesch[1,5,6], Marie Wallays[1], Colinda Scheele[7], Frederik Nevens[8], Hannelie Korf[1], Guy Boeckxstaens[3], Schalk van der Merwe[1,8]. Email: lena.smets@kuleuven.be

Background and aims: Cirrhosis is characterised by a progressive decline in liver function coupled with a simultaneous breakdown of both the epithelial and gut-vascular barrier (GVB). This disrupted integrity allows for the translocation of pathogenic bacteria from the gut to the liver, intensifying systemic inflammation and exacerbating hepatic injury. In this study, we elucidate the critical role played by specialized intestinal macrophages in preserving vascular barrier integrity.
Method: Cirrhosis was induced in genetically modified mice by subcutaneous injection of CCl_4 for 20 weeks. We performed single-cell transcriptomics of the small intestinal lamina propria macrophage population from cirrhotic and control animals.
Results: The induction of cirrhosis in *Cx3cr1*^{CreERT2}*.Rosa26-LSL-YFP* mice, resulted in a decrease of YFP$^+$ cells lining the vasculature, as disease progresses. The loss of long-lived GVB-associated macrophages coincided with increased bacterial translocation to the liver. To investigate the transcriptional changes within lamina propria macrophages that may account for the elevated pathological bacterial translocation, we performed single-cell RNA sequencing on viable, CD45$^+$, CD11b$^+$ cells. We mapped the transcriptomes of the long-lived GVB-associated macrophages (YFP$^+$) along with all other lamina propria myeloid cells in experimentally induced cirrhosis versus control animals. Unbiased hierarchical clustering revealed distinct clusters of cells comprising distinct populations of myeloid cells, dendritic cells and lymphocytes. Further subclustering of myeloid cells revealed a monocyte cluster expressing *S100a4*, *Ly6c2* and *Ccr2* and four macrophage clusters expressing *Adgre1* (*F4/80*), *Cx3cr1* and *Csf1r*. Preliminary findings already suggest an increase in inflammatory monocytes in the experimental cirrhosis group (20% of the total myeloid population in control animals versus 33% in cirrhosis). Additionally, we identified one cluster upregulating core macrophage genes (*C1qa*, *Mrc1*, *Selenop*) (Resident Macs). Another cluster was marked by the upregulation of interferon response genes (*Ifit2*, *Isg15)* (IFN-responding Macs). We further identified an Adamdec1$^+$ Macs cluster co-expressing *Hes1* and *Acp5*. Of interest, in this cluster, *Hmox1* and *Vcam1* are downregulated in cirrhosis animals. Finally, we detected a Lyve1$^+$ Macs cluster that featured elevated expression of genes associated with phagocytosis (e.g. *Cd163)*. Currently, further in-depth analysis on disease differences between control and cirrhosis myeloid cells is ongoing.
Conclusion: Our data provide novel insights into the role of specialized intestinal lamina propria macrophages in GVB barrier failure and bacterial translocation in an experimental model of cirrhosis.

Targeting the histamine receptor 2 for HCC chemoprevention

Emilie Crouchet[1], Courtney Katz[2], Naoto Fujiwara[2], Frank Jühling[1], Marine Oudot[1], Sarah Durand[1], Antonio Saviano[3], Romain Martin[1], Fabio Giannone[3], Patrick Pessaux[3], Raymond Chung[4], Catherine Schuster[1], Laurent Mailly[1], Yujin Hoshida[2], Thomas Baumert[5]. [1]*University of Strasbourg, Inserm, Institute of Translational Medicine and Liver Disease (ITM), UMR_S1110, Strasbourg, France;* [2]*Liver Tumor Translational Research Program, Simmons Comprehensive Cancer Center, Division of Digestive and Liver Diseases, Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, United States;* [3]*University of Strasbourg, Inserm, Institute of Translational Medicine and Liver Disease (ITM), UMR_S1110, Institut Hospitalo-Universitaire, Pôle Hépato-digestif, Nouvel Hôpital Civil, Strasbourg, France;* [4]*Liver Center and GI Division Massachusetts General Hospital Harvard Medical, Boston, United States;* [5]*University of Strasbourg, Inserm, Institute of Translational Medicine and Liver Disease (ITM), UMR_S1110, Pôle Hépato-digestif, Strasbourg University Hospitals, Strasbourg, France*
Email: ecrouchet@unistra.fr

Background and aims: Advanced liver fibrosis is the key risk factor for hepatocellular carcinoma. Given the absent approved treatment options for treatment of fibrosis, there is a key unmet medical need for HCC chemoprevention to improve patient outcome. The liver tissue-based prognostic liver signature (PLS) and the blood-based prognostic liver secretome (PLSsec) have been shown to robustly predict progression of liver disease, HCC risk and survival in a large number of independent cohorts with chronic liver disease (Fujiwara et al. Sci Transl Med 2022). Using a cell-based assay modeling the clinical PLS, we previously identified the FDA approved histamine 2 receptor (HRH2) antagonist Nizatidine as a candidate compound for HCC chemoprevention (Crouchet et al. Nat Commun 2021). The aim of this study was to evaluate HRH2 as a target for chemoprevention to foster its clinical translation.
Method: HRH2 was evaluated as a driver for MASH-induced hepatocarcinogenesis in a loss-of-function study using a *Hrh2* KO mouse model subjected to CD-HFD. In parallel, HRH2 antagonist Nizatidine was investigated as candidate compound for chemoprevention in patient-derived human liver chimeric mice and patient-derived liver spheroids. Liver fibrosis, progression to HCC and the liquid biomarker PLSsec were used as clinical candidate readouts.
Results: The genetic loss-of-function study in a CD-HFD mouse model for MASH/HCC revealed a robust and significant effect of *Hrh2* KO on liver tumor burden, validating the functional role of HRH2 in hepatocarcinogenesis of MASH and therapeutic target. HRH2 blocker Nizatidine inhibited liver fibrosis progression in a human liver chimeric MASH mouse model without any detectable adverse effects as shown by Sirius red staining and a decreased expression of fibrosis markers. Moreover, macroscopic examination of humanized livers revealed reduced liver nodules in Nizatidine treated animals. Improvement of liver disease was associated with a PLSsec reversal associated with HCC risk in the serum of treated mice. The findings were validated in patient-derived liver spheroids showing a robust PLS reversal after Nizatidine treatment.
Conclusion: HRH2 is a driver of hepatocarcinogenesis in MASH. HRH2 antagonist Nizatidine is a candidate compound for HCC chemoprevention. The reversal of PLSsec offers a simple non-invasive biomarker as a readout. Our results using genetic validation, efficacy and safety studies in patient-derived models pave the way for clinical development of HRH2 inhibitors for HCC chemoprevention using the non-invasive biomarker PLSsec as a clinical readout.

OS-014-YI

Long-term albumin infusion reduces the mortality of cirrhosis and ACLF animal models by modulating the gut-liver axis and hepatic TLR4 signalling

Alexandra Phillips[1], Qianwen Zhao[1], Abeba Habtesion[1], Fausto Andreola[1], Nathan Davies[1], Lindsey Edwards[2,3], Jane Macnaughtan[1], Sabine Klein[4], Jonel Trebicka[4], Rajiv Jalan[1]. Email: alexandra.phillips5@nhs.net

Background and aims: Long-term albumin infusion has been shown to reduce mortality in cirrhosis, but the mechanism of its beneficial effect remains unknown. The aims of this study were to understand the role of albumin in modulating the gut-liver-axis by studying rat and mouse models of cirrhosis and ACLF, treated with long-term albumin injections.
Method: Models: Rats: 34 Analbuminaemic (NAR) and 36 wild-type (WT); 4-week bile duct ligation (BDL ± LPS (ACLF) (0.025 mg/kg ip) ± Human albumin 20% (1.5 g/kg ip; 2-week). Mice: 39 C57Bl mice 12-week carbon tetrachloride (CCL4) (orally ± 2 mg/kg LPS) (ACLF) ± albumin injections (1.5 g/kg ip; 2-week). Plasma biochemistry and hepatic TUNEL staining. Liver qPCR and RT^2 PCR profiler for TLR4 genes. Plasma cytokines analysed with Luminex, TLR4 reporter cells assay and plasma cell death ELISA. Gut permeability assessed with plasma D-lactate. Western blot and RT^2 PCR Profiler of tight junction proteins.
Results: Survival: Coma-free survival was reduced in both WT and NAR ACLF animals of both species, which was significantly increased in the ACLF treated with albumin ($p = 0.027$). Liver injury: Liver injury (assessed by plasma ALT and hepatic TUNEL staining) improved following albumin injection, with significant reduction seen in WT ACLF animals [$p = 0.01$; $p < 0.001$ respectively]. Gut permeability: In both cirrhosis and ACLF models, increased gut permeability (measured using plasma D-lactate) and reduced abundance of tight junction proteins, ZO-1, claudin-4 and occludin was observed, which were restored by albumin infusions (NAR ACLF $p = 0.011$). Cytokines, PAMPs and DAMPs: Albumin infusions decreased circulating cytokines (IL-1beta [WT ACLF 659.2->522.8 pg/ml, NAR ACLF 123.5->8.8 pg/ml], IL-10 [NAR ACLF 110.1->12 pg/ml], IL-6 [WT ACLF 13696.7->10310.0 pg/ml, NAR ACLF 4915.8->237.1 pg/ml] and TNFalpha [NAR ACLF 2519.4->97.7]), pathogen and damage associated molecular patterns (measured by plasma TLR4 activation and plasma markers of cell death respectively) in cirrhosis models and ACLF models significantly (TLR4 reporter NAR ACLF [$p < 0.001$], Cell death WT ACLF [$p < 0.001$], NAR ACLF [$p = 0.012$]). Gene expression: The absence of endogenous albumin was associated with greater hepatic TLR4 expression and related genes (TLR4, TNFalpha, and IL-1beta), with a significant reduction of expression in all disease groups with the addition of albumin injections ($p < 0.05$).
Conclusion: Long-term albumin infusions significantly reduce the mortality of ACLF animals by impacting on hepatic TLR4 related pathways that significantly reduce endotoxin sensitivity. This is manifested by significant reduction in the severity of inflammation, hepatocyte cell death and further endotoxemia. The data show for the first time that these beneficial effects are likely due to the effect of albumin on the integrity of the gut tight junctions and permeability.

Immune-mediated and cholestatic liver diseases – Clinical

Email: martine.pronk@ghz.nl

Background and aims: The primary goal of treatment in autoimmune hepatitis (AIH) is to achieve complete biochemical response (CBR) and prevent progression of disease, which may result in liver transplantation and death. Not achieving CBR within 6 or 12 months is associated with liver-related adverse outcomes. However, many patients reach CBR after 6–12 months. This may still be prognostically favorable compared to not achieving CBR at all. Also, some patients who achieve CBR may still have progression to cirrhosis or decompensation. This study aimed to investigate to what extent the time to CBR affects the risk of disease progression and adverse outcomes.

Method: This retrospective, observational, multicenter analysis included all patients from the updated international AIH group retrospective registry with data on CBR and follow-up data. Kaplan Meier and Cox regression were used to evaluate timing of CBR in relation to development of cirrhosis development and on liver transplant-free survival.

Results: This analysis included 1105 patients across 7 countries. CBR was achieved in 385 (35%), 115 (10%) and 210 (19%) patients at <6, 6–12 and >12 months respectively. 395 (36%) of the patients never achieved CBR. During a median follow-up of 6 (range 0–43) years, 113 deaths occurred, of which 55 were liver-related, and 43 patients underwent liver transplantation. Of the 814 patients without cirrhosis at diagnosis, 113 (14%) progressed to cirrhosis. Patients who never achieved CBR had a higher risk of progression to cirrhosis (HR 5.2 95% CI 3.4–7.7 p < 0.001) and liver-related death or liver transplantation (HR 9.8 95% CI 5.9–16.4 p < 0, 001) compared to patients who did achieve CBR. Progression to cirrhosis was lower if CBR <6 months (HR 0.3 95% CI 0.1–0.6 p < 0.001), but not when CBR 6–12 months (HR 0.6 95% CI 0.2–1.3 p = 0, 195), compared to CBR >12 months. Survival was not higher in patients with CBR at <6 months (HR 0.6 95% CI 0.2–1 p = 081) or 6–12 months (HR 0 95% CI 0–2 p = 0.676) compared to patients with CBR at >12 months.

Conclusion: Patients not achieving CBR face markedly higher risks of progression to cirrhosis and liver-related mortality or transplantation. While early CBR (<6 months) was associated with less progression to cirrhosis, there was no association between timing of CBR and liver transplant-free survival. Achieving CBR is crucial for prognosis, with delayed CBR still offering benefits compared to never reaching CBR at all.

OS-016

Elafibranor efficacy in primary biliary cholangitis according to biochemical response criteria in the phase III ELATIVE® trial

Mark Sonderup[1], C Wendy Spearman[1], Vincenza Calvaruso[2], Nuno Antunes[3], Jianfen Shu[3], Claudia O. Zein[3], Kris V. Kowdley[4]. *[1]Division of Hepatology, Department of Medicine, Faculty of Health Sciences, University of Cape Town and Groote Schuur Hospital, Cape Town, South Africa; [2]Gastroenterology and Hepatology Unit, Department of Health Promotion Sciences Maternal and Infantile Care, Internal Medicine and Medical Specialties, University of Palermo, Palermo, Italy; [3]Ipsen, Cambridge, MA, United States; [4]Liver Institute Northwest, Seattle, WA, United States*
Email: mark.sonderup@uct.ac.za

Background and aims: Elafibranor, a dual peroxisome proliferator-activated receptor-alpha/delta agonist, is being investigated in primary biliary cholangitis (PBC). In the phase III ELATIVE® trial (NCT04526665), elafibranor efficacy was assessed in patients with PBC with inadequate response or intolerance to ursodeoxycholic acid. PBC is characterised by elevated alkaline phosphatase (ALP) levels. As the disease progresses, total bilirubin (TB) levels increase. ALP and TB have prognostic value and form the basis of several clinical biochemical response criteria.

The primary end point (POISE trial end point criteria: ALp <1.67×upper limit of normal [ULN], ALP reduction ≥15% from baseline [BL] and TB at or below ULN) was met by a significantly greater proportion of patients receiving elafibranor vs placebo (treatment benefit: 47.2%) at Week 52. Results from other binary biochemical response criteria, secondary outcomes in ELATIVE®, are presented here.

Method: In the global, double-blind, placebo-controlled ELATIVE® trial, patients were randomised 2:1 to once-daily elafibranor 80 mg or placebo. Biochemical response rates at Week 52 were analysed using POISE and: Paris I (ALp <3 × ULN, aspartate aminotransferase [AST] <2 × ULN and TB ≤1 mg/dL); Paris II (ALP ≤1.5 × ULN, AST ≤1.5 × ULN and normal TB); Barcelona (ALP normalisation or reduction >40% from BL); Momah/Lindor (ALP ≤1.67 × ULN and TB ≤1 mg/dL); and complete biochemical response (normal ALP, TB, AST, alanine aminotransferase, albumin and international normalised ratio) criteria. Rotterdam criteria (normalisation of TB and/or albumin) were used but are not reported as few patients had abnormal BLTB or albumin (n = 6). Exact Cochran-Mantel-Haenszel tests stratified by the randomisation factors were performed to examine the treatment benefit of elafibranor vs placebo.

Results: 161 patients received elafibranor (n = 108) or placebo (n = 53). Mean age was 57 (standard deviation: 9) years, and 96% of patients were female. BL ALP and TB levels were similar in each group. Responder rates consistently favoured elafibranor over placebo across Paris I (treatment benefit: 22.0%; odds ratio [OR]: 2.85; 95% confidence interval [CI]: 1.34–7.18; p = 0.0061); Paris II (treatment benefit: 37.5%; OR: 16.65; 95% CI: 4.59–91.76; p < 0.0001); Barcelona (treatment benefit: 54.7%; OR: infinity; 95% CI: 20.22-infinity; p < 0.0001); and Momah/Lindor (treatment benefit: 42.8%; OR: 15.42; 95% CI: 4.60–50.00; p < 0.0001) criteria. A complete biochemical response was observed in 10 patients (9.3%) receiving elafibranor; none receiving placebo (OR: infinity; 95% CI: 1.51–infinity; p = 0.0305).
Conclusion: Elafibranor provided a consistent and significantly greater biochemical response in patients with PBC compared with placebo after one year of treatment using several prognostic scoring systems. Study sponsor: GENFIT; publication sponsor: Ipsen.

Email: alessio.gerussi@unimib.it

Background and aims: Differentiating Autoimmune Hepatitis (AIH) from Primary Biliary Cholangitis (PBC) histologically can be difficult. Florid PBC may show interface hepatitis in up to 25% of cases and errors may lead to overestimation of AIH and overtreatment with immunosuppressors. This study applies a deep learning (DL)-based pipeline for the diagnosis of AIH and PBC.
Method: We conducted a multicenter study across six European referral centers, and built a library of digitized liver biopsy slides dating from 1997 to 2023. A training set of 354 cases (266 AIH and 102 PBC) and an external validation set of 92 cases (62 AIH and 30 PBC) were available for analysis. A novel artificial intelligence (AI) model, the Autoimmune Liver Neural Estimator (ALNE), was trained on whole-slide images (WSIs) with haematoxylin and eosin staining. The ALNE model was evaluated against clinico-pathological diagnoses and tested for interobserver variability among general pathologists. Attention heatmaps and explainable machine learning (ML) were used for further characterization of the output.
Results: ALNE demonstrated high accuracy in differentiating AIH from PBC, achieving an AUROC of 0.81 in external validation. Attention heatmaps showed that ALNE tends to focus more on areas with increased inflammation, associating such patterns predominantly with AIH. Inconsistency among general pathologists was noticed when evaluating a random sample of the same cases. A multivariate explainable ML model including clinical variables revealed that misclassified PBC cases were more often characterized by abnormal AST levels. When applied to cases with overlapping features, ALNE was able to recognize the most prevalent disease.
Conclusion: The ALNE model is the first system generating a quantitative and accurate differential diagnosis among AIH, PBC and PBC-AIH cases, using digital pathology slides without preliminary expert annotation. The ALNE model has the potential to support differential diagnosis of autoimmune liver disease.

Email: lytvyak@ualberta.ca

Background and aims: Non-invasive techniques may have a promising potential in predicting disease outcomes and evaluating the effectiveness of therapies in people living with autoimmune hepatitis (AIH). In this study, we aimed to investigate the usefulness of liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE) in predicting clinical outcomes in a large cohort of people living with AIH across Canada.
Method: We conducted a nationwide, multicenter, retro- and prospective cohort study of people with AIH from the Canadian Network for Autoimmune Liver Diseases (CaNAL). Inclusion criteria were a simplified AIH score ≥6 and at least one reliable LSM by VCTE (LSM/IQR <0.30) performed before the occurrence of any adverse events. The primary composite end point was the occurrence of any adverse liver outcomes (development of decompensation, hepatocellular carcinoma (HCC), liver transplantation (LT) or death). Treatment response was defined as the normalization of ALT at 6 months after treatment initiation.
Results: We evaluated 853 people with AIH (73.8% females, 74.5% Caucasians, the median age at diagnosis of 45.9 y.o. [IQR 28.5–58.1]) with 8394 person-years follow-up. The first VCTE was performed at a median of 41.2 months [IQR 4.6–112.0] after the AIH diagnosis, and the median LSM value was 8.7 kPa [IQR 5.7–15.8]. The LSM was strongly associated with the development of adverse outcomes (HR 1.04; 95%CI 1.03–1.05; p <0.001). In a time-dependent multivariable Cox regression analysis, after adjustment for male sex, age at diagnosis, cirrhosis at diagnosis and lack of biochemical treatment response, LSM was independently associated with adverse outcomes (HR 1.03; 95%CI 1.01–1.05; p = 0.004). Based on the LSM value, people were stratified into low (<8.0 kPa), medium (8.0–13.9 kPa) and high-risk (≥14.0 kPa) groups. In comparison to the low-risk (reference) group, the medium-risk group had over four-fold (HR 4.64; 95% CI 2.03–10.59; p < 0.001) and high-risk-over ten-fold risk (HR 10.12; 95% CI 4.81–21.29; p < 0.001) of developing adverse outcomes. The median event-free survival times were comparable (43.6, 40.4 and 43.8 months for low-, medium- and high-risk groups, respectively; p = 0.477). After adjustment for the above-mentioned risk factors, only the high-risk group exhibited a significantly higher risk of adverse outcomes (HR 5.53; 95% CI 1.20–25.45; p = 0.028).
Conclusion: In people living with AIH, LSM by VCTE is a strong independent predictor for adverse liver outcomes when considering other risk factors and biochemical treatment response. LSM values by VCTE might help to establish risk stratification to identify people with AIH who may benefit from closer screening for liver decompensation, HCC, and timely LT referral. Future studies are warranted to explore the utility of LSM as a non-invasive surrogate end point in clinical trials.

Efficacy and safety of seladelpar in patients with primary biliary cholangitis and compensated liver cirrhosis in the open-label, long-term ASSURE safety study: interim results

Stuart C Gordon[1], Ira Jacobson[2], Ziad H. Younes[3], Marina Silveira[4], Joost P.H. Drenth[5], Ulrike Morgera[6], George Dalekos[7], Jeong Heo[8], Ke Yang[9], Carrie Heusner[9], Daria B. Crittenden[10], Charles A. McWherter[10]. *[1]Henry Ford Health, Detroit, United States; [2]NYU Langone Health, New York, United States; [3]Gastro One, Germantown, United States; [4]Yale School of Medicine, New Haven, United States; [5]Radboud Universiteit, Nijmegen, Netherlands; [6]Charité-Universitätsmedizin Berlin, Berlin, Germany; [7]Larissa General University Hospital, Larissa, Greece; [8]Pusan National University, Busan, Korea, Rep. of South; [9]CymaBay Therapeutics, Inc, Fremont, United States; [10]CymaBay Therapeutics, Fremont, United States*
Email: cmcwherter@cymabay.com

Background and aims: Seladelpar, a potent and selective PPAR-delta agonist (ie, a delpar), has anti-cholestatic and anti-pruritic activity in patients with primary biliary cholangitis (PBC). The ongoing, international, phase 3 ASSURE study (NCT03301506) is an open-label, long-term study of seladelpar in patients with PBC who participated in a prior seladelpar study. Here we report interim efficacy and safety results on a subset of patients with compensated liver cirrhosis.
Method: Patients with PBC and cirrhosis were eligible for ASSURE if they had an inadequate response or intolerance to ursodeoxycholic acid (UDCA), previously participated in a seladelpar study, and had no history of hepatic decompensation. All patients received open-label seladelpar 10 mg oral daily. As of the data cutoff (29 June 2023), 174 patients from previous seladelpar studies (CB8025–21629, NCT02955602; CB8025-31731, NCT03301506; ENHANCE, NCT03602560; CB8025-21838, NCT04950764) had enrolled, of whom 33 had compensated liver cirrhosis at study entry. Biochemical efficacy end points included the composite response of alkaline phosphatase (ALP) <1.67x upper limit of normal (ULN), ALP decrease ≥15%, and total bilirubin ≤ULN; ALP normalization; and change from baseline in ALP, total bilirubin, gamma-glutamyl transferase (GGT), alanine aminotransferase (ALT), and aspartate aminotransferase (AST) all at Month 12.
Results: Of the 33 patients with cirrhosis, most were female (91%) with a mean age of 60.4 years. Eight patients (24.2%) had portal hypertension, 93.9% were Child-Pugh (CP) class A, and 6.1% were CP-B. Mean baseline liver stiffness by FibroScan was 19.3 kPa. At baseline, mean ALP was 241.9 U/L, and total bilirubin was 0.92 mg/dL (27.3% >ULN). As of the data cutoff date, 23 patients with compensated cirrhosis had completed 12 months of treatment. Twelve out of 23 (52.2%) patients met the composite biochemical end point at Month 12. ALP normalization occurred in 39.1% (9/23 patients) at Month 12, and the mean percent change from baseline in ALP was −38.1% (absolute change: −99.5 U/L). Reductions were also observed in GGT and ALT (percent changes from baseline: −35.1% and −19.6%, respectively) at Month 12; no change was observed in AST or total bilirubin. There were no serious adverse events that were liver-related or related to study drug and no discontinuations due to adverse events.
Conclusion: In this interim analysis of the ongoing ASSURE study, PBC patients with compensated cirrhosis treated with seladelpar 10 mg for 12 months achieved clinically meaningful improvements in markers of cholestasis and liver injury. Seladelpar appeared overall safe and well tolerated. These findings suggest that seladelpar has the potential to offer a safe and effective therapy for PBC patients with compensated cirrhosis.

Liver transplantation and hepatobiliary surgery

Email: j.j.schaapman@lumc.nl

Background and aims: Liver function and histological assessment for fibrosis, inflammation and T-cell mediated rejection are essential elements of post-liver transplant monitoring. However, liver biopsy carries a risk of complications which are preferably avoided in low-risk patients. Multiparametric MRI (mpMRI) is a reliable non-invasive diagnostic method which quantifies liver disease activity (including fibroinflammation (cT1), liver fat content (PDFF) and liver iron) and has shown prognostic utility in chronic liver disease management. Our aim was to determine whether using mpMRI in combination with standard serum biochemistry (serum) tests could non-invasively identify low-risk post-liver transplant patients who are eligible to avoid invasive liver biopsies.

Method: RADIcAL2, a multicentre prospective study, included 131 adult and paediatric (children and adolescent) patients with previous liver transplant from the Netherlands, Portugal and UK. Biopsies were centrally read by two expert pathologists. T-cell mediated rejection (rejection) was assessed using BANFF global assessment (BANFF-GA). Diagnostic accuracy to discriminate no rejection vs. indeterminate or T-cell mediated liver transplant rejection was performed using area under the receiver operating characteristic curve (AUC).

Results: In the RADIcAL2 cohort, 38% of patients had no rejection, while 62% had either indeterminate (21%) or T-cell mediated rejection (41%). There was a wide range of inter-observer variability ($0 \leq$Cohen's Kappa <0.85) across all histology scores with moderate agreement between pathologists (Kappa <0.58) for BANFF-GA. A combination of mpMRI cT1 and liver fat with standard serum tests had AUC 0.7 (NPV: 0.8) to identify those without rejection (either indeterminate or T-cell mediated rejection). In the 18% of RADIcAL2 participants where therapy changed, cT1 (841 ms vs. 789 ms; $p = 0.006$), and GGT (284 vs. 125; $p = 0.013$) were significantly higher compared to those who did not get a change in therapy.

Conclusion: A combination of mpMRI cT1 and liver fat with standard serum tests accurately identified patients without indeterminate or T-cell mediated rejection who could avoid liver biopsy. mpMRI used alongside serum markers has utility to support non-invasive patient management in both adult and paediatric post-transplant populations.

Email: taubert.richard@mh-hannover.de

Background and aims: The relevance of chronic antibody mediated rejection (cABMR) after liver transplantation (LT) is controversial. Tissue gene expression has been used to better characterize T cell mediated rejection (TCMR) after LT, but a transcriptional signature of cABMR has not been reported. A transcriptional signature could improve the characterization of cABMR and help to establish molecular diagnostic tools in clinical practice. The aim of this retrospective single-center study was to identify a unique transcriptional signature of cABMR after LT.

Method: Graft tissue bulk RNAseq was performed in two independent cohorts of adult LT recipients with well-characterized histological phenotypes retrieved from our prospective institutional biobank including a surveillance biopsy program with more than 1400 liver biopsies. Diagnostic criteria were based on the 2016 Banff criteria. Differentially expressed genes (DEGs) were considered significant with a log2fold change >1, and an adjusted p value <0.05.

Results: The discovery cohort (2008–2016), included 71 patients with non-histologic rejection (NHR) (n = 18), cABMR (n = 11), clinical TCMR (clinTCMR) (n = 26), and subclinical TCMR (subTCMR) (n = 26) matched by age, sex, and time after LT. The validation cohort (2018–2022) included all patients (n = 58) within this period with cABMR (n = 6) and clinTCMR (n = 12), matched by age, sex, and time after LT, with patients with subTCMR (n = 20) and NHR (n = 20) as controls. cABMR had a prevalence of less than 2%, with normal or mild liver enzyme elevations in 81% of cases. Biologically, cABMR was associated with TNF signaling via NF-κB, fibrogenesis and complement activation compared to NHR. A unique transcriptional cABMR signature was identified in the discovery cohort, with 946 upregulated and 166 downregulated unique DEGs. Unique DEGs of cABMR were associated with biological fibrogenesis, cell adhesion and NF-κB signaling. Comparing cABMR and clinTCMR, DEGs relevant to basement membrane remodeling and collagen formation, both processes relevant to liver fibrogenesis, were overexpressed in cABMR. Common features of cABMR and clinTCMR related to chemokine signaling and cytokine responses. The transcriptome of subTCMR was barely distinguishable from biopsies with NHR. There was high concordance between cohorts, with 87% of cABMR DEGs and 93% of clinTCMR DEGs shared between them.

Conclusion: The cABMR transcriptional signature in LT is biologically similar to other solid organ transplants and simultaneously distinct from clinTCMR, strengthening cABMR as a distinct phenotype of graft rejection after LT with a unique transcriptional profile. We highlight a potential application of transcriptomics on liver biopsies to facilitate the diagnosis of cABMR after LT.

OS-022

Kinetics of immune dysfunction in liver transplanted patients and impact on clinical outcome

Email: fanny.lebosse@inserm.fr

Background and aims: Immune dysfunction is an important outcome determinant of end stage liver diseases. There is limited knowledge regarding the kinetic of this immune dysfunction following liver transplantation (LT) and its impact on LT outcomes. Our aim was to describe the post LT evolution of immune dysfunction and its association with clinical outcomes.
Method: Patients with cirrhosis or acute liver failure (ALF) were prospectively enrolled before LT in a monocentric study. The following immune response features were assessed both pre LT and twice a week for a duration of 1 month post LT: HLA-DR monoctytic expression (mHLA-DR), neutrophil-to-lymphocyte ratio (NTLR), T cell count and function (Interferon-gamma (IFNg) release assay). If an immune-related event occurred within 1 month post LT (infections or liver graft rejection), immunological data for the affected patients were censorerd at the time of the event.
Results: 99 patients were included: 20 exhibited compensated cirrhosis (CC), 44 presented with acute decompensation (AD), 30 with acute on chronic liver failure (ACLF) and 5 with ALF. Median MELD score was 20 [15–29]. Pre-LT mHLA-DR level decreased significantly with disease severity (median 26740 antibodies per cell (AB/C) [18740–33220] for AD/CC vs median 16740 AB/C [8250-25050] for ACLF/ALF patients ($p < 0.001$)) and the number of organ failure. T cell count and IFN-gamma release were significantly reduced in ACLF patients compared to CC whereas NTLR increased with disease severity ($p < 0.001$). Following LT, immune markers kinetic analysis suggested a marked immune dysfunction at day (D) 1 and 3. At D10 post LT, a more profound immune dysfunction was found in patients who died within 1 year post LT (n = 8) compared to survivors: respectively median mHLA-DR level 4900 AB/C [4200-8800] vs 15300 AB/C [10000–23000], $p = 0.002$; median NTLR 31.7 [11.7–45.6] vs 6.9 [4.9–11.5], $p = 0.005$, median T cell count 260 cells/µL [190–340] vs 530 cells/µL [350–690], no difference of IFNg release. Only post LT low mHLA-DR level (since D5, $p < 0.05$), and to a lesser extent high NTLR were significantly associated with the occurrence of post LT high-risk infection (intra-abdominal infections, pneumonia, bacteriemia). None of the immune markers were associated with liver graft rejection and no difference was found according to immune suppressive treatment.
Conclusion: This longitudinal study showed the early onset of a profound immune dysfunction post LT which is more severe for patients with poor outcomes. mHLA-DR level, NTLR and T cell count at D10 differed significantly between 1-year survivors and patients with fatal outcome. The clinical relevance of mHLA-DR to monitor the risk of early post LT high risk infection and to adjust immune suppressive treatment will be assessed in further studies.

OS-023-YI

Liver transplantation due to biliary tract dysplasia in primary sclerosing cholangitis

Sigurd Breder[1,2], Christina Villard[3,4], Emma Eide[1], Benny Wang[3], Lise Engesæter[1,2,5,6], Henrik Mikael Reims[7], Johannes R. Hov[1,2,5,6], Espen Melum[1,2,5,6,8], Lars Aabakken[1,9], Pål Dag Line[1,9], Kristine Wiencke[9], Annika Bergquist[4,10], Trine Folseraas[1,2,6]. *[1]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [2]Norwegian PSC Research Center, Department of Transplantation Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [3]Department of Transplantation Surgery, Karolinska University Hospital, Stockholm, Sweden; [4]Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden; [5]Research Institute of Internal Medicine, Oslo University Hospital, Oslo, Norway; [6]Section of Gastroenterology, Department of Transplantation Medicine, Oslo University Hospital, Oslo, Norway; [7]Department of Pathology, Oslo University Hospital, Rikshospitalet, Oslo, Norway; [8]Hybrid Technology Hub Centre of Excellence, Institute of Basic Medical Sciences, Faculty of Medicine, University of Oslo, Oslo, Norway; [9]Department of Transplantation Medicine, Division of Surgery, Inflammatory Medicine and Transplantation, Oslo University Hospital Rikshospitalet, Oslo, Norway; [10]Department of Upper Abdominal Diseases, Karolinska University Hospital, Stockholm, Sweden*
Email: sigurd.breder@medisin.uio.no

Background and aims: Primary sclerosing cholangitis (PSC) is a leading indication for liver transplantation (LTX) in the Nordic countries. Pre-emptive LTX in patients with biliary dysplasia to prevent development of cholangiocarcinoma (CCA) has been implemented but remains controversial. We aimed to perform a retrospective study of liver transplanted PSC patients in Oslo or Stockholm with a focus on the subgroup of patients with biliary dysplasia as main indication.
Method: PSC patients were identified using The Nordic Liver Transplant Registry (NLTR), the national PSC registries and data collected from medical records in Norway and Sweden. Patients who received their first LTX between January 1st 2000 and December 31st 2021 at an age ≥18 years at time of LTX were included. Clinical and biochemical status at time of listing, results of brush cytology and bile duct biopsies before listing and results of histopathological analyses of the explanted livers were registered. Brush cytology results were classified as reactive changes, low-grade dysplasia (LGD) or high-grade dysplasia (HGD).
Results: In total 512 PSC patients (76% male) were studied. Median age at PSC diagnosis was 33 years (IQR 25–44 years), and median age at first LTX was 45 years (IQR 36–65 years). Main indications for LTX were: LGD n = 29 (6%), HGD n = 58 (11%), suspicion of CCA n = 42 (8%), HCC n = 25 (5%), end-stage liver disease n = 271 (53%), recurrent

cholangitis/cholestasis symptoms n = 64 (13%) and combined indications n = 23 (4%). Before listing, n = 54 (11%) of the patients had at least one brush cytology sample with LGD and n = 74 (14%) with HGD. In patients with LGD as main transplant indication, biliary dysplasia was found in the explant in n = 15 (52%), out of which only 1 was HGD. Among those with HGD as main indication, dysplasia was found in the explant of n = 36 (62%), 19 of which classified as HGD. Cancer was found in n = 2 (7%) and n = 9 (16%) in the LGD and HGD groups, respectively. In 12 (41%) and 13 (22%) of the patients in the LGD and HGD groups, there were no signs of biliary neoplasia. CCA was found in 4 (2%) of the patients transplanted for end-stage PSC.
Conclusion: A large proportion (17%) of PSC patients were listed for LTX with biliary dysplasia as the main indication. Dysplasia or cancer were found in the majority of the liver explants with this indication. However, a substantial proportion of patients with LGD in brush cytology had no signs of neoplasia in the explanted liver, suggesting that the criteria for selecting candidates for LTX in the setting of dysplasia may be improved.

The gender-equity model for liver allocation built on artificial intelligence (GEMA-AI) improves outcome predictions among liver transplant candidates

Manuel Rodríguez-Perálvarez[1], Antonio M. Gómez-Orellana[2], David Guijo-Rubio[2,3], Pedro Gutierrez[2], Avik Majumdar[4], Geoff McCaughan[5], Rhiannon Taylor[6], César Hervás[2], Emmanuel Tsochatzis[7]. *[1]Hospital Universitario Reina Sofía, University of Córdoba, Córdoba, Spain; [2]Department of Computer Science and Numerical Analysis, University of Cordoba, Córdoba, Spain; [3]Department of Signal Processing and Communications, University of Alcalá de Henares, Madrid, Spain; [4]Victorian Liver Transplant Unit, Austin Health, Melbourne, Australia; [5]Royal Prince Alfred Hospital, Sydney, Australia; [6]NHS Blood and Transplant, Bristol, United Kingdom; [7]Sheila Sherlock Liver Unit and UCL Institute for Liver and Digestive Health, Royal Free Hospital, London, United Kingdom*
Email: ropeml@hotmail.com

Background and aims: Current prioritization models for liver transplantation (LT) are hampered by their linear nature, which does not fully capture the severity of patients with extreme analytical values. We aimed to develop and externally validate the Gender-Equity Model for Liver Allocation built on Artificial Intelligence (GEMA-AI) to predict waiting list outcomes in candidates for LT.
Method: Cohort study including adult patients who qualified for elective LT in the United Kingdom (2010–2020, model training and internal validation) and in two Australian institutions (1998–2020, external validation). The Gender-Equity Model for Liver Allocation corrected by serum sodium (GEMA-Na) was compared with GEMA-AI, which was built on a shallow artificial neural network optimized by neuroevolution and hybridization using the same input variables. The primary outcome was mortality or delisting for sickness within the first 90 days. Discrimination was assessed by Harrell's c-statistic (Hc). This study was funded by the Instituto de Salud Carlos III (Project no. PI22/00312) and co-funded by the European Union.
Results: The study population comprised 9, 320 patients: training cohort n = 5, 762, internal validation cohort n = 1, 920, and external validation cohort n = 1, 638. The prevalence of 90-days mortality or delisting for sickness ranged from 5.3% to 6% in the different cohorts. The transition from a linear to a non-linear score (from GEMA-Na to GEMA-AI) resulted in improved discrimination in the internal and external validation cohorts (Hc = 0.766 vs Hc = 0.781; p = 0.035 and Hc = 0.774 vs Hc = 0.793; p = 0.003, respectively), being these differences more pronounced in women (Hc = 0.802 vs Hc = 0.826; p = 0.048 and Hc = 0.796 vs Hc = 0.836; p = 0.014, respectively). Among 1, 403 patients (39.4% of the merged validation cohorts) who showed at least one extreme analytical value, GEMA-AI had Hc = 0.823 compared to Hc = 0.797 (p = 0.036). In this subpopulation, GEMA-AI showed a good calibration (chi-square = 5.04; p = 0.66) whereas GEMA-Na did not (chi-square = 18.94; p = 0.015). A meaningful change ≥2 score prioritization points occurred in 27.8% of patients (11.4% upgraded, 16.4% downgraded). Differential prioritization would occur in 6.4% of the available organs within the first 90 days and would save one in 59 deaths overall, and one in 13 deaths among women.
Conclusion: The use of non-linear explainable machine learning models may improve predictions of waiting list outcomes, particularly in the sickest patients showing extreme analytical values. Their use should be preferred over Cox's regression-based models.

Liver tumours: Experimental and Pathophysiology

Email: bertram.bengsch@uniklinik-freiburg.de

Background and aims: Hepatocellular carcinoma (HCC) is a heterogeneous entity with distinct subtypes treated with immune checkpoint inhibitor (ICI) therapy at an advanced stage. We hypothesized that the immune architecture in the tumor microenvironment (TME) determines response and survival of HCC patients under ICI therapy. We thus aimed to describe the immunotypes of the HCC TME on a spatially resolved, high-dimensional single-cell level to develop a classification that correlates with immunotherapy outcome.
Method: We applied highly multiplexed imaging mass cytometry (IMC) to a discovery cohort of tumors from n = 54 HCC patients. Tumor, interface and adjacent liver regions were analyzed in detail using an AI-aided bioinformatic pipeline for cell segmentation, high-dimensional single-cell clustering and neighborhood analysis with microanatomic region mapping to identify spatial immunotypes. The workflow was validated in an independent cohort of HCC patients that received ICI therapy (n = 42). Outcome analysis was performed based on spatial immunotype.
Results: Our approach identified several immune, stroma and tumor/hepatocyte clusters that reflect major cell types of the HCC and liver microenvironment. Unsupervised neighborhood detection based on spatial interaction of immune cells identified immune neighborhoods with distinct cellular networks: (1) CD8 T cell dominant, (2) myeloid cell dominant and (3) B/CD4 T cell dominant neighborhoods. The variation of the neighborhood architecture revealed three major spatial subtypes that could be classified based on T cell infiltration and tumor compartments. Their features conceptually resemble immune-deplete, immune-excluded and immune-rich TMEs. We identified the differential contribution of distinct immune subsets and immune checkpoints to spatial immune types. Analysis of the corresponding tumor interface regions showed clear differences between the intratumor stroma and the capsule and between spatial

immune types. These findings were validated in an independent cohort. Progression-free survival under ICI therapy differed significantly between the spatial immune types.
Conclusion: The spatial immunotypes identified describe the immune heterogeneity of the HCC tumor immune microenvironment on a spatially resolved level and represent potential pre-therapy biomarkers for ICI based therapies, with implications for the rational choice of treatment regimen.

Email: saffo@recerca.clinic.cat

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is the second most common primary liver tumor. With increasing incidence and poor survival, there is an urgent need to improve the treatment options for this deadly tumor. Cancer stem cell (CSC) markers are highly expressed in iCCA, however, the role of CSC and their crosstalk with the tumor microenvironment (TME) remain elusive. Here, we aim at investigating the functional role of $CD44^+$CSC in iCCA.
Method: GSE154170 was used for scRNA-seq analysis. CD44 floxed mice were injected with AAV8-TBG-Cre (n = 5) or control AAV8-TBG-Null (n = 5) to induce CD44 deletion in tumor cells after iCCA induction by HDTVI of pCaggs-$KRAS^{G12D}$, CRISPR/Cas9 sg-p19 and SB13 plasmids (KRAS/p19). Samples were submitted to bulk RNA sequencing, followed by Gene Set Enrichment Analysis. FibroNest™ platform was used for single fiber analysis. Statistical Analysis was performed using GraphPad Prism 10.
Results: scRNA-seq and CellphoneDB analysis revealed the presence of $CD44^+$CSC strongly interacting with the TME, in human and mouse iCCA. Quantifying $CK19^+CD44v6^+$ cells, we found that $CD44^+$CSC constitute the 30% (33.84 ± 8.007) of the tumor cells in human iCCA (n = 3) and the 40% (43.32 ± 2.459) in the KRAS/p19 model (n = 5). After deleting CD44 in tumor cells *in vivo*, we confirmed the depletion by qPCR ($p < 0.0001$) and by $CK19^+CD44v6^+$ double staining ($p = 0.0079$). Despite not observing changes in the overall $CK19^+$ tumor area ($p = 0.8$), we found a significant increase in tumor cells proliferation in the CD44-tumor cell deleted vs -non deleted mice, as assessed by double $CK19^+Ki67^+$ staining and quantification ($p = 0.0015$). In CD44-tumor cell deleted mice, we found increased stroma- ($p = 0.024$), myCAF- ($p = 0.001$) and epithelial-mesenchymal transition (EMT)- ($p = 0.002$) enrichment scores, when compared to the control group. We confirmed increased *Col1a1*- ($p = 0.0017$) gene expression and collagen deposition by PicroSirius Red ($p = 0.048$) in the tumors of CD44-tumor cell deleted mice. Moreover, using the AI-based platform FibroNest™, we found changes in fiber morphometric composite score ($p = 0.02$) and complexity architecture score ($p = 0.01$), accompanied by enriched matrisome- ($p = 0.001$) and core collagen matrisome- ($p = 0.024$) scores in the CD44-tumor cell deleted vs -non deleted mice. Finally, we found increased immune- ($p = 0.002$) and inflammatory stroma STIM class- ($p = 0.001$) enrichment scores, suggesting T cell exhaustion in the CD44-tumor cell deleted vs non deleted mice.
Conclusion: CD44+CSC are dispensable for iCCA initiation in the KRAS/p19 experimental model. Deletion of CD44+CSC increases tumor cell proliferation and induces drastic changes in the TME of iCCA. Our study defines a new functional role for CD44+CSC as regulator of tumor cell proliferation and as a mediator of collagens and EMT processes in iCCA, opening to new therapeutic opportunities.

OS-027-YI
Immune checkpoint profiles on circulating extracellular vesicles predict response to immunotherapy in heptaocellular carcinoma

Email: r.masood@uke.de

Background and aims: Atezolizumab and bevacizumab (AB) is the new standard of care for advanced hepatocellular carcinoma (HCC). However, with only 30% objective response, predictive biomarkers are urgently needed. Tissue expression of PD-L1 is associated with better response (Zhu Nat Med 2023), but with limited access to tissue specimens, blood-based biomarkers would be preferable. The aim was to correlate immune checkpoint (IC) expression of tumor-derived circulating extracellular vesicles (EV) with response to AB.
Method: This multicenter study included 4 independent cohorts with 158 HCC patients with 414 sequential blood samples and 50 tissue specimens (2 more cohorts collected: analysis of another 104 patients and 284 samples pending). Tissue specimens were stained for PD-L1 and PD-1 (CTLA-4 pending). EV were extracted from serum using differential ultracentrifugation and quality control of isolates was performed using nanoparticle tracking analysis and electron microscopy. IC were quantified using bead-based multiplex immunoassays, normalized to total protein input, and presented as pg/µl.
Results: Membrane-bound IC were enriched in EV isolates compared to whole serum or EV-depleted serum, e.g. PD-L1: 20.17 vs. 1.3 vs. 1.79, PD-1: 9.27 vs. 1.82 vs. 1.31, CTLA-4: 1.79 vs. 0.06 vs. 0.075, all $p < 0.01$, (Cohort 1: n = 40 HCC across all stages). Secondly, we found a strong correlation of IC levels between tumor tissue and paired serum EVs (PD-L1: r = 0.80, PD-1: r = 0.82, both $p < 0.001$; Cohort 2, N = 50 HCC). In HCC patients receiving AB (Cohort 3, N = 49 HCC with 254 sequential samples), baseline EV-IC levels were higher in non-responders (NR) vs. responders (R) (PD-L1 20.57 vs. 18.01, $p = 0.053$, PD-1 21.85 vs. 18.14, CTLA-4 18.87 vs. 13.35 (both $p < 0.01$), while clinical parameters, such as age, sex, etiology, or BCLC stage did not differ. Sequential testing at week 6 and 12 revealed significantly different EV-IC dynamics with increase in NR (PD-L1: 52.35 and 59.32, PD-1: 32.48 and 42.63, CTLA-4: 26.22 and 32.01, all $p < 0.001$) and decrease in R (PD-L1: 6.64 and 1.66, PD-1: 6.06 and 1.94, CTLA-4: 7.82 and 2.90, all $p < 0.001$). Of note, absolute EV concentrations were not significantly different between timepoints. These findings were validated in an independent cohort of patients treated with AB (Cohort 4, N = 19 HCC with 70 sequential samples). In fact, defining optimal cutoffs for PD-L1, PD-1, and CTLA-4 at baseline in the training cohort 3 was able to predict responders with 63.2%%, 89.5%, and 100% accuracy in the validation cohort 4.

Conclusion: Immune checkpoint levels on circulating extracellular vesicles from blood samples are able to predict response to atezolizumab and bevacizumab in two independent cohorts, both before initiation of therapy and based on early dynamics after initiation. Our results hold promise for the development of liquid biopsy-based biomarkers for treatment prediction in HCC.

OS-028

Tumour, immune and parenchymal cell neighbourhoods correlate with survival after cholangiocarcinoma resection

Johannes Eschrich[1,2], Zuzanna Kobus[1], Hilmar Berger[1], Yeni Ait Ahmed[1], Natalja Amiridze[1], Marlene Kohlhepp[1], Christian Müller[3], Maria Reich[3], Niklas Heucke[3], Verena Keitel-Anselmino[3], Frank Tacke[1], Adrien Guillot[1]. *[1]Charité University Medicine Berlin, Berlin, Germany; [2]Berlin Institute of Health at Charité-Universitätsmedizin Berlin, Berlin, Germany; [3]Otto-von-Guericke University Hospital Magdeburg, Magdeburg, Germany*
Email: johannes.eschrich@charite.de

Background and aims: Intrahepatic cholangiocellular carcinoma (iCCA) is a malignancy that originates from the bile ducts and accounts for 10–15% of primary liver cancers, with an overall 5-year survival of less than 20%. The poor survival is explained by a late diagnosis, limited treatment options and poor understanding of the disease-relevant pathological mechanisms involved. This project aims at better defining the cellular landscape in iCCA and identifying prognosis-related histological features that could help in patient stratification, improving patient management and identifying relevant therapeutic targets.
Method: We assembled a cohort of >130 patients from multiple centres who underwent iCCA resection. Formalin-fixed paraffin embedded (FFPE) tissues were subjected to a tailored, multiplex (>15 markers) immunostaining protocol. Machine-learning based algorithms were used for digital image (>15 mm^2 tissue) segmentation and clinical data integration. Spatial clustering was performed using imcRtools-based algorithms to define cellular neighbourhoods (CN).
Results: In-depth characterisation of the individual immune, parenchymal and tumour cells, e.g., distribution, cellular shape or phenotypic marker staining intensities, was performed. In this context, we observed a strong accumulation of immune cells at the tumour border with macrophages particularly densely located adjacent to the tumour in normal tissue. CD45+ leucocytes and in particular CD20+ B cells were almost absent in the tumour area and their numbers increased towards normal liver tissue. Despite these solid observations, a poor correlation was found between single cell-resolved analyses and clinical data. Combined analyses of multiple cell populations identified cellular neighbourhoods (CN). The CN-based image segmentation successfully distinguished between tumour, parenchymal, tumour border, and portal areas, thus supporting the relevance of a multicellular-based digital image analysis. We comprehensively characterised cells and cell interactions on many levels and found several significant correlations between given CN and clinical data. In particular, a CN that encompasses a scattered CK7+ cell distribution and altered lymphoid and myeloid cell accumulation within 300 micrometres from the tumour border was associated with a poor prognosis.
Conclusion: Multiplexed immunohistochemistry together with advanced bioinformatics profoundly expand our horizon for disease-driving mechanism investigations. Within resected iCCA, the cellular landscape varies considerably between tumour, border and non-tumour regions, with a remarkable heterogeneity between patients. The exact cellular composition is associated with prognosis, suggesting that multiplex immunostaining may be suitable to guide personalized treatment decisions after surgery.

Email: thomas.baumert@unistra.fr

Background and aims: Cholangiocarcinoma (CCA) is a hepatobiliary adenocarcinoma with dismal prognosis and unsatisfactory treatment options. Claudin-1 (CLDN1) is a transmembrane protein expressed in tight junctions, but also exposed at the cell surface on cancer epithelial cells. The functional role of CLDN1 in the pathogenesis of CCA is unknown. Here, we aimed to investigate the mechanisms by which CLDN1 drives cholangiocarcinogenesis and responds to treatment with target-specific monoclonal antibodies (mAbs).
Method: CLDN1 expression was studied in several cohorts of CCA patient tissues using scRNASeq and spatial transcriptomics. Gain-of-function studies in hydrodynamic tail vein injection (HTVi) mouse models were used to evaluate the role of CLDN1 as an oncogenic driver *in vivo*. Proof-of-concept (POC) studies using humanized CLDN1 mAbs in CDX and PDX mouse models as well as organoids were applied to understand the mechanism of action of antibody-mediated therapeutic intervention.
Results: Comprehensive analysis across several patient cohorts revealed robust CLDN1 upregulation at the transcriptional and protein level of CLDN1 exposed at the cancer cell surface. Spatial transcriptomics of patient CCA tissues revealed a robust association of CLDN1 expression with stemness, EMT and Wnt/beta-catenin, TNFalpha/NF-kB and YAP/Taz signaling. Gain-of-function studies in KRAS/p19 and AKT/YAP orthotopic HTVi models revealed a decrease in survival and enhanced tumor growth, unraveling a functional role of CLDN1 as an oncogenic driver. Mechanistic studies identified TNFalpha/NF-kB and Wnt/beta-catenin signaling as key signaling pathways mediating CLDN1 upregulation in intra- and extra-hepatic CCAs. Targeting exposed CLDN1 using CLDN1 mAbs in PDX and CDX models resulted in robust inhibition of proliferation, stemness and EMT by inhibiting Notch1, SRC-FAK, and Hippo-YAP signaling. Co-immunoprecipitation studies revealed an association of CLDN1 with drivers of cell plasticity and fate. Antibody-mediated inhibition of tumor growth was dependent on CLDN1 expression, observed also in CCA with low CLDN1 expression and a CCA model for lung metastasis. Treatment of patient-derived CCA organoids using mAbs decreased cellular viability and altered cancer cell plasticity and fate by similar pathways as in *in vivo* models.

Conclusion: Integrative spatial transcriptomic and mechanistic studies using CCA patient tissues and patient-derived models uncover CLDN1 as a previously undiscovered driver of cancer cell proliferation, plasticity, stemness and EMT. Robust target expression combined with completed in vivo proof-of-concept studies pave the way for the clinical development of CLDN1-specific mAbs for CCA treatment.

Viral hepatitis B/D: New treatments

OS-030

Efficacy and safety of xalnesiran with and without an immunomodulator in virologically suppressed participants with chronic hepatitis B: end of study results from the phase 2, randomized, controlled, adaptive, open-label platform study (PIRANGA)

Jinlin Hou[1], Qing Xie[2], Wenhong Zhang[3], Rui Hua[4], Hong Tang[5], Edward J. Gane[6], Luis Enrique Morano Amado[7], Sheng-Shun Yang[8], Cheng-Yuan Peng[9], Man-Fung Yuen[10], Xieer Liang[1], Cynthia Wat[11], Cong Cheng[12], Katerina Glavini[13], Sudip Das[14], Yan Huang[12], Farouk Chughlay[13], Nelson Guerreiro[13], Ethan Chen[15], Priyanka Kakrana[13], Avinash Patil[16], Ruchi Upmanyu[14], Maria Teresa Catanese[13], Rémi Kazma[13], Tarik Asselah[17]. *[1]Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Ruijin Hospital, Shanghai Jiaotong University School Of Medicine, Shanghai, China; [3]Huashan Hospital, Fudan University, Shanghai, China; [4]The First Hospital Of Jilin University, Jilin, China; [5]West China Hospital, Sichuan University, Chengdu, China; [6]Auckland Clinical Studies Limited, Auckland, New Zealand; [7]Alvaro Cunqueiro University Hospital, Health Research Institute South Galicia, Vigo, Spain; [8]Taichung Veterans General Hospital, Taichung, Taiwan; [9]China Medical University Hospital, Taichung, Taiwan; [10]Queen Mary Hospital, Hong Kong, China; [11]Former employee of Roche Products Ltd, Welwyn Garden City, United Kingdom; [12]China Innovation Center of Roche, Shanghai, China; [13]Roche Innovation Centre Basel, Basel, Switzerland; [14]Roche Products Ltd, Welwyn Garden City, United Kingdom; [15]Roche (China) Holding Ltd, Shanghai, China; [16]Parexel International (External Business Partner with Roche Innovation Centre Basel), Hyderabad, India; [17]Université de Paris-Cité, Hôpital Beaujon, INSERM UMR1149, Paris, France*
Email: tarik.asselah@aphp.fr

Background and aims: PIRANGA (NCT04225715) is a phase 2 platform study designed to evaluate the efficacy and safety of new finite duration therapies in virologically suppressed chronic hepatitis B (CHB) participants (pts) treated with nucleos (t)ide analogues (NUC) aimed at achieving higher functional cure rates than NUC therapy alone. Here, we report end of study results, including seroconversion and durability of HBsAg loss, of xalnesiran (RO7445482), an N-acetylgalactosamine (GalNAc)-conjugated small interfering ribonucleic acid (siRNA) targeting HBsAg transcripts with or without an immunomodulator: ruzotolimod (toll-like receptor 7 agonist, RO7020531) or pegylated interferon alfa-2a (Peg-IFN-α).
Method: Virologically suppressed CHB pts on established NUC therapy for at least 12 months were randomized into one of 5 arms comprising: 1) xalnesiran 100 mg, 2) xalnesiran 200 mg, 3) xalnesiran 200 mg with ruzotolimod, 4) xalnesiran 200 mg with Peg-IFN-α, or 5) NUC control. Xalnesiran was administered subcutaneously (SC) every 4 weeks (wks) for 48 wks. Ruzotolimod 150 mg was administered orally every other day during 2 cycles of 12 wks each (wks 13 to 24 and 37 to 48). Peg-IFN-α 180 mcg was administered SC weekly for 48 wks. The established daily oral administration of NUC therapy was continued in pts from all arms for at least 48 wks and until NUC stopping criteria were met during the 48 wks of post-treatment follow-up. Stratified randomization aimed at recruiting at least 12 pts per arm with screening HBsAg <1000 IU/ml. HBsAg loss (<0.05 IU/ml) and seroconversion (HBsAg loss and anti-HBsAb ≥10 IU/L) rates were measured throughout the study.
Results: A total of 160 pts were enrolled. The majority were male (83%) and Asian (94%), with a mean (range) age of 42 (24–65) years. At baseline, 70% were HBeAg negative, 98% had normal ALT levels with a mean (SD) serum HBsAg level of 2.8 (0.9) log10 IU/ml. At 48 wks post-EOT, HBsAg loss was observed in 3/30 (10.0%), 0/30 (0.0%), 4/34 (11.8%), 5/30 (16.7%), and 1/35 (2.9%) pts from arms 1 to 5, respectively. Of these 13 pts, 7 were off NUC therapy at 48 wks post-EOT and 9 had HBsAg seroconversion: 1, 0, 2, 5, and 1 pts from arms 1 to 5, respectively. The change in HBsAg loss between EOT and 48 wks post-EOT was +1 (+3.3%), −1 (−3.3%), −2 (−5.9%), −4 (−13.3%), and +1 (+2.9%) pts in arms 1 to 5, respectively. All pts who achieved HBsAg loss had a baseline HBsAg level <1000 IU/ml. No serious adverse events related to xalnesiran or ruzotolimod and no new safety findings were observed during the study.
Conclusion: The highest HBsAg loss and seroconversion rates were observed when xalnesiran was combined with an immunomodulator. The continued change in HBsAg loss rate between EOT and 48 wks post-EOT warrants adequate follow-up to confirm sustained functional cure. All treatments were generally safe and well tolerated.

OS-031

Imdusiran (AB-729) administered every 8 weeks for 24 weeks followed by the immunotherapeutic VTP-300 maintains lower HBV surface antigen levels in NA-suppressed CHB subjects than 24 weeks of imdusiran alone

Email: ksims@arbutusbio.com

Background and aims: Functional cure of CHB requires suppression of viral replication, reduction of HBsAg and stimulation of host HBV-specific immunity. Imdusiran (AB-729) is a GalNAc-conjugated single trigger siRNA that targets all HBV RNA transcripts and suppresses viral replication and all viral antigens. VTP-300 is an HBV-specific immunotherapeutic consisting of a chimpanzee adenoviral vector (ChAdOx1-HBV) dose and a Modified Vaccinia Ankara (MVA-HBV) dose both encoding the inactivated polymerase, core, and the entire S region from a consensus genotype C HBV virus. Study AB-729–202 is an ongoing, randomized, double-blinded Phase 2a study assessing the safety, pharmacodynamics and immunogenicity of repeat doses of imdusiran followed by VTP-300 ± low dose nivolumab or placebo in nucleos (t)ide analogue (NA) suppressed, non-cirrhotic CHB subjects.
Method: Sixty-two CHB subjects on stable NA therapy with HBsAg ≥100 but <5000 IU/ml were enrolled to receive imdusiran 60 mg every 8 weeks for 4 doses. The first 40 subjects were randomized 1:1 at Week (Wk) 24 to receive VTP-300 (Group A) or placebo (Group B) at

Wks 26 and 30. The remaining subjects (Group C) will receive VTP-300 plus 0.3 mg/kg nivolumab at Wk 30 only. Subjects were eligible for NA discontinuation (d/c) based on Wk 48/end of treatment (EOT) data (ALT <2× ULN, HBeAg negative, HBV DNA <lower limit of quantitation [LLOQ] and HBsAg <100 IU/ml). Safety data, HBV parameters and immunology samples were collected at multiple timepoints.

Results: Demographics and baseline characteristics were presented previously. To date 36/40 subjects have completed the VTP-300 or placebo regimen (Wk 30), and 25/40 have reached Wk 48/EOT. At EOT, 92% and 42% of Group A subjects (N = 13) have maintained HBsAg levels <100 IU/ml or <10 IU/ml respectively, vs 73% and 33% of Group B subjects (N = 12). At follow-up Wk 60 (N = 7/group), 100% and 57% of Group A subjects and 29% and 0% of Group B subjects have maintained these levels, respectively. Sixteen of 25 subjects met protocol eligibility criteria at Wk 48/EOT and stopped NA therapy: 11/13 (85%) in Group A vs 5/12 (42%) in Group B. One Group A subject has maintained HBV DNA <LLOQ for 6 months off NA therapy, 1 Group B subject restarted NA therapy after 3 months, the other 14 subjects remain off therapy at various durations of follow-up with no ALT flares. There have been no Serious Adverse Events (AEs), Grade 3 or 4 AEs or treatment d/c during the imdusiran/VTP-300 treatment periods.

Conclusion: Repeat dosing of imdusiran for 24 weeks followed by VTP-300 was well-tolerated and contributes to the maintenance of lower HBsAg levels compared to placebo in subjects who have reached EOT and follow-up Wk 60. More subjects who received VTP-300 have qualified to stop NA therapy at EOT and all remain off therapy. Additional on-treatment, follow-up and NA discontinuation data including HBV parameters and immunology data will be presented.

OS-032

Long-term hepatitis B surface antigen response after finite treatment with siRNAs ARC-520 or JNJ-3989

Lung Yi Loey Mak[1], Christine Wooddell[2], Oliver Lenz[3], Thomas Schluep[2], James Hamilton[2], Heather Davis[3], Xianhua Mao[1], Wai-Kay Seto[1], Michael Biermer[3], Man-Fung Yuen[1]. [1]*The University of Hong Kong, Hong Kong, Hong Kong;* [2]*Arrowhead Pharmaceuticals, Madison, United States;* [3]*Janssen Pharmaceutica NV, Beerse, Belgium*
Email: loeymak@gmail.com

Background and aims: RNA interference has been extensively explored in patients with chronic hepatitis B (CHB) infection. We aimed to characterize the long-term efficacy of small interfering RNA (siRNA) on hepatitis B surface antigen (HBsAg) suppression.

Method: We prospectively followed up subjects with CHB who received short term siRNA treatment, either ARC-520 (4 injections in study Heparc-2002 [NCT02604199] and Heparc-2003 [NCT02604212]) or JNJ-3989 (3 injections in study AROHBV1001 [NCT NCT03365947]), in combination with nucleoside analogue (NUC) in our centre. Subjects enrolled included 15 receiving ARC-520, 38 receiving JNJ-3989 and 5 receiving placebo in previous clinical trials. Serial blood sampling was performed according to the original protocols and upon completion every 24 weeks until last follow-up (LFU; mean duration 52.5 ± 14.4 months). An integer scoring system was used to construct the model score for achieving qHBsAg <100 IU/ml at LFU according to the results of multivariate regression analysis.

Results: Among the 53 NUC+siRNA-treated subjects (mean age 46.8, baseline HBsAg 3.08 log10 IU/ml, 5.7% <100 IU/ml, 83% previously on NUC, 34% HBeAg+), the proportion of patients achieving HBsAg seroclearance or <100 IU/ml at LFU was 1.9% and 31.2%, respectively, compared to 0% for both end points for placebo. The mean log10 reductions of HBsAg at LFU in siRNA treated and non-treated subjects were 0.85 and 0.52 respectively (p = 0.123). When the two siRNAs were analysed separately, qHBsAg levels were numerically lower at LFU compared to placebo without reaching statistical significance (ARC-520 vs placebo at 72 months: 2.15 vs 2.52 log IU/ml, p = 0.503; JNJ-3989 vs placebo at 60 months: 1.86 vs 2.63 log IU/ml, p = 0.368). Age was negatively correlated with log reduction of HBsAg at nadir (r = –0.406, p = 0.003) and LFU (r = –0.427, p = 0.001). Compared to placebo, siRNA led to faster annual decline rate of HBsAg (0.08 vs 0.21 log, respectively, p = 0.003). Baseline qHBsAg (OR 0.016, 95% CI 0.001–0.171) and log reduction in HBsAg at nadir (OR 16.979, 95% CI 3.131–92.083) were independently associated with HBsAg <100 IU/ml at LFU. Subjects with siRNA-100 score (derived from these two variables) of 0, 1, 2, 3 and ≥4 had 100%, 80%, 66.7%, 38.5%, and 0% probability of achieving HBsAg <100 IU/ml at LFU.

Conclusion: siRNA treatment suppressed HBsAg expression with a prolonged effect for up to 6 years. The siRNA-100 score consisting of baseline qHBsAg and log reduction at nadir may be indicative of HBsAg level <100 IU/ml at LFU.

OS-033

A phase 2 open-label study to evaluate safety, tolerability, efficacy, and pharmacodynamics of JNJ-73763989, nucleos (t)ide analogs, and a low-dose PD-1 inhibitor in patients with chronic hepatitis B-Interim results of the OCTOPUS-1 study

Email: tarik.asselah@aphp.fr

Background and aims: Treatment of chronic hepatitis B (CHB) with the small-interfering RNA (siRNA) JNJ-73763989 (JNJ-3989) and nucleos (t)ide analogs (NA) has shown reductions in hepatitis B viral markers. This study aims to assess the efficacy and safety of adding low-dose PD-1 inhibitor nivolumab to JNJ-3989 and NA once HBsAg levels are reduced.

Method: OCTOPUS-1 is a phase 2, randomized, open-label, parallel-group, multicenter study to evaluate safety, efficacy, and pharmacokinetics of JNJ-3989, nivolumab, and NA in hepatitis B e-antigen (HBeAg) negative, virologically suppressed (VS) CHB patients. Patients received daily NA, JNJ-3989 200 mg once a week for the first 4 weeks (loading dose), then once every 4 weeks until W24; nivolumab (0.3 mg/kg) was administered IV at W16 for Arm 1 (A1), and at W16, 20, and 24 for Arm 2 (A2) and follow-up with NA treatment is for 48 weeks. Primary end point is proportion of patients with HBsAg seroclearance (<0.05 IU/ml) at FU W24. Changes in viral markers (HBsAg, HBcrAg, and HBV DNA) and safety were assessed.

Results: At this W24 data snapshot, all patients have reached the end of treatment. Thirty-seven patients were enrolled, 18 in A1, 19 in A2, and received all doses of JNJ-3989. The protocol was amended and dosing of nivolumab was discontinued prior to the 3rd administration of the last two patients. The mean age (standard deviation: SD) was 44.38 years (7.38), 18.9% were female, 37.8% Asian. Mean (SD) baseline HBsAg levels were 3.25 (0.47) and 3.13 (0.54) in A1 and A2, respectively. Receptor occupancy 2 hrs post nivolumab administration at W16 was >90% in 29/35 (83%) of patients. At W24, mean HBsAg levels decreased by 2.0 (0.40) and 2.1 (0.58) $\log_{10}$ IU/ml from

BL in A1 and A2 with HBsAg reduction ≥2 $\log_{10}$ IU/ml in 58.8% and 55.6%, respectively. 88.2% and 35.3% in A1, 94.4% and 50.0% in A2 achieved HBsAg levels <100 and <10 IU/ml At W24 no patient achieved HBsAg seroclearance. No SAEs or grade 3 or 4 AEs were observed, and no patient discontinued the study prematurely. 48.6% of patients had TEAE, 13.3% were considered related to JNJ-3989 and 5.4% related to Nivolumab. JNJ-3989 loading dose led to mild increases of mean ALT from 23 U/L at BL to 35 U/L at W8 with no further increase until EOT, no patient met flare criteria. 2 cases of TSH suppression 8 weeks post nivolumab in A1 triggered the discontinuation of further nivolumab dosing, both cases resolved rapidly. No other immune-related events or cases of virologic breakthrough were observed.

Conclusion: After 24 weeks of treatment with JNJ-3989 + NA + nivolumab the mean decline of HBsAg from baseline was 2 $\log_{10}$ IU/ml in both arms. Cross-study analysis of JNJ-3989 with VS, HBeAg-patients in REEF-1 did not show an apparent benefit of JNJ-3989 loading dose or nivolumab. Treatment was generally safe and well tolerated but administration of low-dose nivolumab in the study was terminated due to observed TSH suppression.

Background and aims: REP 2139 blocks HDV replication and HBV SVP assembly. This study evaluated the real-life safety and efficacy of REP 2139 in HDV patients with advanced liver disease in a compassionate use program (NCT05683548).

Method: Of 33 patients (21–69 y.o.), 24 failed previous pegIFN, 20 failed previous bulevirtide ± pegIFN (11 with viral rebound during therapy) and 1 failed lonarfarnib. NUC therapy continued in all patients during REP 2139-Mg (250 mg qW SC) scheduled for 48 weeks. PegIFN 45–180ug qW SC was added in 17 patients. Safety and liver function were monitored weekly and antiviral response every 4 weeks with standard assays for quantitative HBsAg and anti-HBs, HBV DNA, HDV RNA and HIV RNA (in 2 HIV co-infected patients).

Results: Among 33 patients, 21 had compensated and 6 decompensated cirrhosis. Currently, 29 and 6 patients received ≥24 and ≥48 weeks of therapy, respectively. No REP 2139-related SAE and no REP 2139 discontinuations occurred. REP 2139 was well tolerated with transient grade 1 injection site reaction in the majority of patients. ALT elevations occurred in 20 patients: 14 with pegIFN (1 requiring pegIFN dose reduction, 1 pegIFN discontinuation) and 6 without pegIFN. Non-response to REP 2139 250 mg SC was rescued with 250 mg IV infusion or 500 mg (SC or IV) in 8/33 patients.

Biochemical response was achieved in 10/33 (30%). HDV RNA decline >2 log occurred in 24/33 (73%) with HDV RNA negativity in 20/33 (61%). HBsAg decline >2 log occurred in 17/33 (52%) with HBsAg loss in 7/33 (21%). Anti-HBs >10mIU/ml occurred in 9/33 (25%). Baseline HDV RNA ($p = 0.42$) and HBsAg ($p = 0.59$), and HDV RNA decline ($p = 0.82$) and HDV RNA loss ($p = 0.87$) during REP 2139-Mg were not different between +pegIFN and -pegIFN groups. A trend towards significantly higher HBsAg decline ($p = 0.06$) was present in the +pegIFN group (3.08 ± 2.19 log IU/ml) than in the -pegIFN group (1.68 ± 1.89 log IU/ml). Four patients completed ≥48 weeks of REP 2139-Mg with follow-up available. Two patients (compensated cirrhosis, +pegIFN) maintained HDV RNA + HBsAg loss with seroconversion and normal ALT 36 weeks during TDF monotherapy. One achieved HDV cure and functional cure of HBV 14 months after cessation of therapy. One patient (decompensated cirrhosis, -pegIFN) recompensated during therapy and maintained undetectable HDV RNA and HBsAg and anti-HBs seroconversion with normal ALT 24 weeks after cessation of REP 2139-Mg and no longer requires liver transplant. REP 2139-Mg + pegIFN extension therapy in 1 patient (advanced fibrosis) was mistakenly halted at 67 weeks (HDV RNA <LLOQ and HBsAg 4.07 IU/ml). After 12 weeks of TDF, HBsAg is 355 IU/ml, HDV RNA is 426 IU/ml with ALT 40 U/L.

Conclusion: REP 2139-Mg was safe and well tolerated in HDV patients with advanced liver disease and can lead to HDV cure and HBV functional cure. REP 2139-Mg treatment can lead to HDV cure independently of pegIFN, while HBV functional cure may be pegIFN dependent.

Cirrhosis and its complications: Clinical

OS-035-YI

Validating and expanding Baveno VII criteria of recompensation in patients with decompensated cirrhosis

Marta Tonon[1], Roberta Gagliardi[1], Gianluca Zilio[1], Simone Incicco[1], Valeria Calvino[1], Antonio Accetta[1], Nicola Zeni[1], Carmine Gambino[1], Anna Barone[1], Paolo Angeli[1], Salvatore Piano[1]. *[1]Unit of Internal Medicine and Hepatology, Department of Medicine, University of Padua, Padua, Italy*
Email: salvatore.piano@unipd.it

Background and aims: Baveno-VII consensus defines recompensation in cirrhotic patients achieving: 1) removal/suppression of cirrhosis's etiology; 2) resolution of ascites (off diuretics), hepatic encephalopathy (off lactulose/rifaximin) and bleeding for>12

months; c) stable improvement of liver function. This study aims to evaluate the incidence and prognostic impact of recompensation in patients with decompensated cirrhosis.
Method: Outpatients with cirrhosis and curable etiologies (alcohol, HCV, HBV) were consecutively included and followed up (median time = 35 months). Demographic, clinical, laboratory and endoscopic data were collected at enrolment and follow-up visits. Recompensation, defined by Baveno VII criteria, was assessed. Since the withdrawal of decompensation treatment is subjective, we evaluated expanded recompensation criteria for patients meeting all criteria, but still on decompensation treatment (low dose diuretics/lactulose/rifaximin). Recompensation was used as a time-varying covariate in survival analysis. In 160 patients (62 compensated, 60 decompensated, 38 recompensated), plasma samples were analyzed for inflammatory cytokines (IL-6, IL-10, IL1beta).
Results: 691 patients were enrolled (mean age = 57 ± 11 years, men = 72.5%; alcohol = 55%). Among decompensated patients (n = 525), 298 achieved an effective etiological treatment and 22 (4.2%) achieved recompensation (Baveno-VII criteria), while 115 patients achieved expanded recompensation criteria (22.3%). MELD score was the only independent predictor of recompensation (aHR = 0.90; p = 0.002). In multivariable analysis (adjusted for age, sex, MELD, albumin, varices and further decompensation), mortality risk was not significantly different between patients achieving recompensation and compensated patients (aHR = 2.53; p = 0.107), while decompensated patients had the highest risk (aHR = 4.74; p < 0.001). Mortality risk was not significantly different between patients meeting expanded recompensation criteria and Baveno-VII criteria (HR = 1.02; p = 0.961). IL-6 and IL-10 were significantly higher in decompensated patients than in compensated ones. Following recompensation, inflammatory cytokines significantly decreased and no difference was found vs compensated patients.
Conclusion: Baveno-VII recompensation criteria identify cirrhotic patients with a good prognosis, comparable to that of compensated patients, but less than 5% of decompensated patients achieve recompensation. Expanding the recompensation criteria to include patients on medical treatment for decompensation identifies patients with a similarly low risk of mortality.

OS-036-YI
Diagnostic potential of speech artificial intelligence analysis in minimal hepatic encephalopathy
Jakub Gazda[1], Peter Drotar[2], Mate Hires[2], Sylvia Drazilova[1], Martin Janicko[1], Peter Jarčuška[1]. *[1]Pavol Jozef Safarik University, L Pasteur University Hospital, Kosice, Slovakia; [2]Technical University in Kosice, Kosice, Slovakia*
Email: jkgazda@gmail.com

Background and aims: Hepatic encephalopathy (HE) is defined as cognitive impairment resulting from liver failure and can vary from clinically covert (minimal HE and West Haven I HE), through various degrees of clinically overt HE including hepatic coma. The treatment of HE involves removal of the precipitating factor, an osmotic laxative-lactulose-and a nonabsorbable antibiotic-rifaximin. The diagnosis of minimal HE requires the use of specific psychological tests, but these tests are time-consuming and are characterized by relatively low sensitivity and specificity, leading to underestimation of minimal HE in real world. The aim of this study was to identify the existence of any difference in the speech of patients with liver cirrhosis (with minimal HE and West Haven I HE) compared to a healthy control population, which could be used to diagnose minimal HE.
Method: Patients with known liver cirrhosis and varying degrees of HE (minimal HE diagnosed by STROOP test, West-Haven stage I HE) were included in this prospective study, with the main exclusion criteria being concomitant neurological disease, and an age- and sex-matched healthy control population. Patients' speech was then manually segmented, and concordant passages were compared using neural networks and tree classifiers, with 10-fold cross-validation.
Results: A total of 62 patients were included in the study, 31 patients with liver cirrhosis (50%) and 31 healthy controls (50%), 36 patients were male (58%) 26 patients were female (42%). The mean age at the time of examination was 56.13 years (± 11.47). Ten patients with liver cirrhosis were diagnosed as West-Haven stage I HE (32%) and the remaining 21 patients as minimal HE (68%). Of the tree classifiers, the XGBoost classifier achieved the best AUROC values, with AUROC ranging from 66.88% (95% CI 58.75–72.4) to 78.6% (95% CI 72.4–82.7), depending on the vowel and its intensity. Of the neural networks, EfficientNet achieved the best AUROC values, with AUROC ranging from 80.65% (95% CI 72.34–88.92) to 88.64% (95% CI 83.28–93.70) depending on the vowel and its intensity.
Conclusion: Artificial intelligence (machine learning in general, and deep learning specifically) detected a difference in the speech of patients with liver cirrhosis (minimal HE and West Haven I HE) compared to a healthy control population, and there is hope that we can use it in the future to diagnose minimal HE.

Email: claudiatorrasv@gmail.com

Background and aims: The prevalence of infections caused by multidrug resistant (MDR) bacteria in patients with cirrhosis is increasing and varies across different regions and hospitals. We aimed to assess and compare the epidemiology, prevalence of MDR infections, and outcomes of bacterial infections in patients with decompensated cirrhosis admitted at five university hospitals, two with liver transplant (LT centers) and three without it (non-LT centers).

Method: We conducted a multicenter retrospective study including all patients with decompensated cirrhosis and bacterial infection that were discharged from the Hepatology Department from January 2021 to 2022. Clinical, laboratory, and microbiological data were collected. Patients were followed for 3 months, until death, or liver transplantation.
Results: A total of 576 infections were reported in 352 patients. LT centers had more nosocomial and healthcare-associated infections, as well as septic shock compared to non-LT centers, while there were no significant differences in cirrhosis severity, ACLF, or comorbidities. Both LT and non-LT centers had similar frequencies of the most common isolated microorganisms, *Escherichia coli* (15% vs. 17%) and *Klebsiella pneumoniae* (10% vs. 7%), and similar rates of negative cultures (42% vs. 37%). However, LT centers had significantly higher rates of extended-spectrum betalactamases (ESBL) (12% vs. 6%), carbapenemases (3% vs. 0%), and resistance to piperacillin-tazobactam (14% vs. 7%) compared to non-LT centers ($p < 0.02$). The most common infections were urinary tract infections (20% vs. 27%) and spontaneous bacterial peritonitis (13% vs. 22%) in both LT centers vs. non-LT centers, respectively ($p < 0.01$). The proportion of MDR infections tend to be higher in LT centers compared to non-LT centers (22% vs. 16%; $p = 0.10$). The proportion of MDR varied among different centers (from 10% to 25%; $p < 0.05$), in addition to resistance mechanisms and types of infections. In-hospital mortality was higher in LT centers compared to non-LT centers (20% vs. 11%; $p = 0.03$). Independent predictors of in-hospital mortality were age (OR of 1.1 [1.01–1.1]; $p = 0.02$), leukocytes (OR 1.1 [1.04–1.2]; $p < 0.01$), healthcare-associated infections (OR 3.4 (1.1–12); $p = 0.04$), and ACLF (OR 5.8 [1.9–19]; $p = 0.01$).
Conclusion: Our study demonstrates significant differences in the epidemiology and prevalence of MDR infections among university hospitals, particularly between centers with and without liver transplant. Therefore, understanding the epidemiology of infections in each center is crucial for tailoring antibiotic treatment for these patients.

Email: salvatore.piano@unipd.it

Background and aims: Terlipressin is indicated for the treatment of hepatorenal syndrome (HRS)-acute kidney injury (AKI). However, real-world practice patterns on the use of terlipressin in AKI in general has not previously been reported, and outcomes in non HRS-AKI settings are largely unknown.
Method: International prospective study including patients admitted to the hospital for decompensated cirrhosis at 67 centres in 5 continents from July 2022 to May 2023. This was a subgroup analysis

of patients with AKI who received terlipressin for the treatment of AKI, excluding those who received it for portal hypertension-related bleeding. Primary outcome was absence of AKI resolution, defined as return of serum creatinine to a value within 0.3 mg/dl of the baseline value. Secondary outcomes were respiratory failure, as defined by CLIF-C ACLF, and 28-day mortality. The incidence of respiratory failure was compared with that of patients treated with norepinephrine.
Results: Of 1, 456 patients with cirrhosis and AKI, 243 (17%) received terlipressin for treatment of AKI. Most were from Europe (47%), Asia (27%) and Latin America (15%). Terlipressin was predominantly administered in continuous infusion form (75%), with a median maximum daily dose of 3 mg [IQR 2–4] and median duration of 5 days [IQR 3–8]. The AKI phenotype was HRS-AKI in 50%, acute tubular necrosis (ATN) in 17%, hypovolemia-induced in 25%, and others in 8%. Overall, complete AKI resolution occurred id 49% of patients. Lack of AKI resolution was highest in ATN (71%), followed by HRS-AKI (49%) and hypovolemia-induced (37%). On multivariable analysis (adjusted for age, sex, AKI stage, phenotype and acute on chronic liver failure grade [ACLF]), ATN was independently associated with a lack of AKI resolution (OR 2.77; p = 0.016), compared to HRS-AKI. AKI stage 3 and ACLF stages 2–3 were also associated to lack of AKI resolution. *De novo* respiratory failure occurred in 20% of patients of patients treated with terlipressin, a rate not higher than that observed in patients treated with norepinephrine (40%). There were no significant differences in amount of albumin or dose of terlipressin received in those who did and did not develop respiratory failure. On multivariable analysis, pneumonia (OR = 8.29; p < 0.001) or lack of volume loss/hypovolemia before AKI (OR = 2.70; p = 0.029) were independent predictors of respiratory failure. Mortality rate at 28-days was 36%. On multivariable analysis, age, ATN phenotype, ACLF grade and hospital-acquired AKI were independent predictors of 28-day mortality.
Conclusion: Terlipressin is often used for treatment of AKI outside its primary indication of HRS-AKI. AKI response is very poor in ATN. Therefore, terlipressin should be avoided in this setting as the risks associated with the treatment may outweigh its benefits. Respiratory failure is common, but does not seem to be driven by the amount of albumin received.

A placebo controlled, randomized, double blinded trial to evaluate the use of Tolvaptan for correction of hyponatremia in liver cirrhosis patients
Zubair Mohamed[1], Arun Valsan[2], George Malayil[3], Anna Paul[2], S Sudhindran[4], Nipun Verma[5], G Unnikrishnan[6], Anoop Koshy[1], Dinesh Balakrishnan[1], Lakshmi Kumar[1], SaiBala Madathil[7]. *[1]Amrita institue of Medical Sciences, kochi, Kochi, India; [2]Amrita Institute of Medical Sciences, Kochi, Kochi, India; [3]Rajagiri Hospital, Kochi, India; [4]Amrita Institute of Medical Sciences, kochi, Kochi, India; [5]Post graduate Institute of Medical Education and research, Chandigarh, Chandigarh, India; [6]Amrita Institute of Medical Sciences, kochi, kochi, India; [7]Amrita institue of Medical Sciences, kochi, Kochi*
Email: zubairumer@gmail.com

Background and aims: Patients with advanced cirrhosis develop dilutional hyponatremia (<130meq/dL) due to non-osmotic hypersecretion of arginine vasopressin (AVP). Hyponatremia is an independent risk factor for mortality. We undertook this study to ascertain the efficacy of tolvaptan in increasing serum sodium in cirrhosis with hyponatremia.
Method: In this single-centre placebo-controlled randomized double-blind study, all adult patients with established cirrhosis (imaging and/or biopsy) admitted to the hospital between August 2019 and June 2023 were screened. Exclusion criteria included age <18 years, pregnancy, serum creatinine >1.5 mg/dL 48 hours after admission, significant nervous system diseases. Consenting patients were enrolled into either Tolvaptan arm (15 mg orally once daily for 7 days) or the control arm (matched placebo) based on pre-prepared computer-generated randomization sequence. The medical management of cirrhosis was left to clinicians' discretion. At any point, if there was absolute increase of S Na+ ≥140 mEq/L or daily increment ≥8 mEq/L, the drug was withheld temporarily. All adverse events were evaluated using the common terminology criteria for adverse events (CTCAE) version 5.0. (3) Descriptive statistics, Chi-square and student t-test were used to summarize and analyse categorical and continuous clinical variables respectively. We recruited 50 patients per group based on previous studies. The study received institutional ethics committee approval (IEC-AIMS-2019-ANES-082) and was registered in CTRI (CTRI/2019/10/021479).
Results: Out of 2441 patients screened, 237 patients were eligible, of which 100 were recruited. No patient withdrew consent or was lost to follow-up. One patient in the tolvaptan group received only 1 dose of the medication and was removed from the final analysis. The results are presented in the following order: tolvaptan (T) and placebo (P). The mean age was (57.3 ± 8.5 (T) and 55.3 ± 7.7 (P), p < 0.05) with a male: female ratio was 43:6 and 48:2, p < 0.05 respectively. The S Na+ (mmol/L) at enrolment was 120.0 ± 4.2 (T) and 121.91 ± 2.4 (P), p < 0.05. The body weight, fluid intake, AST, bilirubin, total protein, urea, creatinine and MELD score were comparable between the groups at enrolment and at day 7. On day 7, S Na+ (mmol/L) was 130.77 ± 5.4 (T) and 125.9 ± 4.8 (P) (p = 0.004). S Na+ increased to at least 130meq/dL in 26/49 (T) (53%) versus 5/50 (P) (10%) patients. In the T group, the median time for S Na+ to increase to 130 mg/dL was 4 days (range 2–8 days). The mortality was similar in both groups (22%, p = 1) (22%) (p = 1). S Na+ increased ≥8 mmol/24 hours in 6/49 (12%) patients in the T group and 1/50 (2%) patient in the P group. None of the patients had serious adverse events.
Conclusion: Tolvaptan improved hyponatremia in 53% of cirrhotics and was safe. The optimal dose and duration of tolvaptan needs to be ascertained in larger randomized controlled trials.

Background and aims: A key challenge in the clinical course of cholangiopathies is biliary fibrosis with subsequent complications of decompensated liver disease and cancer. We have previously unraveled Claudin-1 (CLDN1) exposed at the basolateral membrane of liver hepatocytes as a mediator and therapeutic target for metabolic dysfunction-associated steatohepatitis (MASH) fibrosis

(Roehlen et al. Science Transl. Med. 2022). Here, we aimed to investigate the mechanistic role of CLDN1 as a mediator and therapeutic target for biliary fibrosis using primary sclerosing cholangitis (PSC) as a model disease.
Method: CLDN1 expression in liver tissues of patients with primary sclerosing cholangitis progressing to fibrosis was analyzed using bulk and single cell RNAseq, multicolor immunofluorescence and spatial transcriptomics. Proof-of-concept studies using humanized CLDN1 monoclonal antibodies (mAbs) in mouse models for cholangiopathies and biliary fibrosis, the HepaRG progenitor cell model and primary human cholangiocytes were performed to understand the mechanism of action of antibody-mediated therapeutic intervention.
Results: Analyses of CLDN1 expression in PSC patient tissues identified diseased cholangiocytes, ductular reactive cells, and cholestatic peri-portal hepatocytes as cell-types with the highest CLDN1 expression. Spatial transcriptomics revealed that CLDN1 expression in PSC co-localized with PSC disease drivers at the periphery of scar lesions, including senescence marker p21 and the NFkB pathway. In bile duct ligation, 3, 5-diethoxycarbonyl-1, 4-dihydrocollidine (DDC) and multidrug resistance protein 2-knockout ($Mdr2^{-/-}$) mouse models, human CLDN1-specific mAbs robustly improved liver function by potently reducing hepatobiliary fibrosis and cholestasis. Mechanistic studies in mouse and cell-based models revealed that mAb treatment resulted in inhibition of pro-inflammatory, pro-fibrotic and pro-carcinogenic signaling perturbed in liver tissues of PSC patients. Gene expression analyses in cell-based models unraveled antibody-mediated maturation of liver progenitor cells into hepatocyte-like cells.
Conclusion: Our results uncover a robust functional role of CLDN1 in the pathogenesis of PSC and biliary fibrosis. Completed in vivo proof-of-concept studies combined with expression analyses in PSC patients pave the way for the clinical development of CLDN1-specific mAb to treat PSC.

Email: schober@biochem.mpg.de

Background and aims: Alpha-1 antitrypsin deficiency (AATD) is a genetic disorder affecting the structure of the alpha-1 antitrypsin (AAT) protein. Misfolded AAT accumulates in liver cells, causing variable clinical outcomes, from no/mild liver fibrosis to cirrhosis requiring transplantation. The reasons for this heterogeneity are unclear, and understanding them could enhance risk-stratification and therapeutic interventions. Herein, we (1) identify proteomic signatures of hepatocytes accumulating AAT at various fibrosis stages, (2) map the spatial metabolic niches that drive hepatocyte stress response and (3) aim to define the toxicity of aggregates in relation to their morphology by neural network classifiers.
Method: We performed spatially resolved proteomics on formalin-fixed and paraffin-embedded (FFPE) liver tissues from Pi*ZZ individuals representing the full disease spectrum (F1–4; n = 33). Our Deep Visual Proteomics (DVP) method combined high-content imaging of three-micrometer-thick tissue sections, AI-based cell segmentation and classification, laser microdissection, and the latest generation of mass spectrometry using the Thermo Orbitrap Astral. We introduced a pseudo-time axis by separately measuring up to ten hepatocyte classes with neural network-defined AAT aggregate morphologies. In addition, we performed single-cell DVP in regions with aggregate-stressed and resilient hepatocytes in direct proximity.
Results: We quantified more than 5, 000 proteins per sample (n = 134), each of which contained the protein mass of 10 to 15 complete hepatocytes. Fibrosis was the main driver of data separation followed by AAT load. Of all quantifiable proteins, 955 (16.2%) were significantly changed across hepatocytes with high loads to no loads of AAT within the same patient (paired *t* test after multiple testing correction, FDR <5%). We observed most changes among proteins that were produced in the ER and targeted for secretion. This included the structurally similar SERPINs A3 to A7, coagulation factors and albumin, as well as known AATD biomarkers LMAN1 and P4HB. Importantly, our data highlights a robust and late-stage unfolded protein response (UPR) involving all canonical UPR pathways, as well as the calnexin/calreticulin glycosylation rescue pathway. These changes triggered a strong ROS defense response unique to aggregate-positive hepatocytes, followed by a reduction in mitochondrial complex I activity.
Conclusion: We present the first detailed spatially resolved proteomic profile of hepatocytes in Pi*Z-homozygous AATD patients, identifying new proteins linked to disease progression and confirming known markers. Our single-cell proteomics approach reveals unique UPR and ROS defense responses in affected cells. This data allows precise tracking of hepatocyte changes during AAT accumulation, suggesting new therapeutic targets in AATD.

OS-042-YI

Metabolic reprogramming induced by pravastatin prevents polycystic liver disease progression improving mitochondrial bioenergetics in cystic cholangiocytes

Enara Markaide[1], Laura Izquierdo-Sánchez[1,2,3], Mikel Ruiz de Gauna[4], Xabier Buque[4], Pedro M Rodrigues[1,2,5], Rui E. Castro[3], Matxus Perugorria[1,2,6], Luis Bujanda[1,2,6], Patricia Aspichueta[2,4,7], Jesus M Banales[1,2,5,8]. *[1]Department of Liver and Gastrointestinal Diseases, Biogipuzkoa Health Research Institute-Donostia University Hospital -, University of the Basque Country (UPV/EHU), San Sebastián, Spain; [2]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd, "Instituto de Salud Carlos III"), Madrid, Spain; [3]Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal; [4]Department of Physiology, Faculty of Medicine and Nursing, University of the Basque Country (UPV/EHU), Leioa, Spain; [5]IKERBASQUE, Basque Foundation for Science, Bilbao, Spain; [6]Department of Medicine, Faculty of Medicine and Nursing, University of the Basque Country UPV/EHU, San Sebastián, Spain; [7]Biobizkaia Health Research Institute, Barakaldo, Spain; [8]Department of Biochemistry and Genetics, School of Sciences, University of Navarra, Pamplona, Spain*
Email: enara.markaide@biodonostia.org

Background and aims: Polycystic liver diseases (PLDs) are hereditary genetic disorders marked by progressive development of intrahepatic

fluid-filled biliary cysts, representing a primary source of morbidity. The current pharmacological treatment for advanced disease involves the chronic administration of somatostatin analogs, aimed at reducing the elevated intracellular cAMP levels in cystic cholangiocytes. Nevertheless, this approach demonstrates limited effectiveness. Cystic cholangiocytes exhibit abnormal proteostasis and endoplasmic reticulum (ER) stress, promoting cystogenesis. Considering the interplay between ER and mitochondria, we investigated mitochondrial dynamics, bioenergetics, and metabolism within cystic cholangiocytes, further exploring their potential therapeutic regulatory value *in vitro* and *in vivo*.

Method: Human cystic cholangiocytes (ADPKD$^{GANAB-/-}$ or ADPLD$^{PRKCSH-/-}$) and normal human cholangiocytes (NHC) as controls were studied. Mitochondrial ultrastructure and its interaction with the ER were analyzed by transmission electron microscopy. Mitochondrial mass, dynamics, and functionality were evaluated using flow cytometry and qPCR. Mitochondrial bioenergetic activity was assessed by Seahorse Analyzer, and protein levels of electron transport chain (ETC) complexes through immunoblotting. Metabolic fluxes including *de novo* synthesis and oxidation of palmitate, glucose, and glutamine were analyzed in radioassays. The effect of pravastatin was investigated in male PCK rats (*Pkhd1*$^{-/-}$).

Results: Cystic cholangiocytes exhibited higher mitochondria-ER distance and increased mitochondrial mass. The expression of mitochondrial dynamics (*i.e.*, fusion, fission, and mitophagy) and biogenesis-related genes was found upregulated in cystic tissue and cells from PLD patients, compared to gallbladder tissue and NHCs, respectively. Cystic cells displayed higher mitochondrial membrane potential and abnormal bioenergetic capacities compared to NHCs. Consequently, ATP and mitochondrial reactive oxygen species levels were elevated in cystic cells, correlating with upregulation of ETC complexes. Both ADPKD and ADPLD cholangiocytes exhibited enhanced rates of glutamine and palmitate oxidation compared to NHCs, respectively, along with an increased capacity for the *de novo* synthesis of cholesterol. The chronic administration of pravastatin reduced liver volume and weight in PCK rats compared to controls. *In vitro*, pravastatin mitigated mitochondrial metabolic hyperactivity and decreased the proliferation of cystic cholangiocytes.

Conclusion: Cystic cholangiocytes exhibit altered mitochondrial dynamics, bioenergetics, and metabolism, with lipids playing a crucial role as energy substrate. Rewiring lipid metabolism with pravastatin halts hepatic cystogenesis, arising as a novel therapeutic opportunity.

OS-043

Site-specific maturation dynamics of type 2 conventional dendritic cells connect with gamma delta T17 effector differentiation in cholestatic liver disease

Stefan Thomann[1], Ankit Agrawal[1], Helene Hemmer[1], Sagar Sagar[2], Paul Kießling[3], Emilia Scheidereit[3], Tanja Poth[4], Marcell Tóth[5], Katja Breitkopf-Heinlein[6], Nuh Rahbari[7], Christoph Kuppe[3], Dominic Grün[1]. Email: stefan.thomann@uni-wuerzburg.de

Background and aims: Immunoepithelial crosstalk, immunologic surveillance and niche composition at the biliary niche in cholestatic liver disease involves a complex interplay of diverse immune cell populations residing within portal fields. In this project, dynamical changes of type 2 conventional dendritic cells (cDC2) are linked with the site-specific initiation of multicellular communication hubs that regulate the inflammatory response in liver cholestasis and in draining lymph nodes (LNs).

Method: Spatial transcriptomics and multicolour immunofluorescence (IF) were used to visualize the biliary niche in steady state. A liver and lymph-node 3, 5-diethoxycarbonyl-1, 4-dihydrocollidine (DDC) diet single-cell RNA-sequencing (scRNA-seq) atlas containing 5 disease timepoints was generated and data compared with publicly available scRNA-seq datasets of other disease modalities. Transcription factor regulon activity was predicted using SCENIC and genomic accessibility was investigated with combined snRNA-seq/snATAC-seq (10x Multiome). Different DC subtypes in hepatic LN were distinguished with the help of CITE-seq. Temporal cell type frequency dynamics were confirmed by FACS analysis and functional validation was performed using an inducible mouse model of cDC2 depletion as well as Tcrd and Il17a/f knockout mice.

Results: Visualization of the biliary niche revealed a spatial co-localization of biliary epithelial cells (BECs), cDC2 and T cells, which was conserved in mouse and human. Our DDC diet scRNA-seq atlas identified a disease-initiating Nfkb2-regulated, Sox9+ BEC cluster, which expressed a common gene expression programme that included Macrophage colony-stimulating factor 1 (Csf1), CC-chemokine ligand 2 (Ccl2) and Il23a. VarID2 predicted a cDC2 cell fate trajectory at disease onset connecting clusters of cDC2 maturation, homing and expression of Il17- inducing genes, while prolonged cholestasis resulted in a perturbed cDC2 differentiation and a cellular shift towards preDCs that were characterized by functional epigenetic restriction. Disease onset led to a gamma delta T cell (gdT cell) -specific Il17a-response, which was attenuated in an inducible model of cDC2-depletion. In draining LNs, gdT cell composition differed compared to the liver, yet T17 polarization could be equally observed.

Conclusion: Inflammatory onset in cholestatic liver disease initiates a multicellular crosstalk between BECs, cDC2, and gdT cells within the biliary niche. cDC2 rapidly mature and home to draining LNs thereby initiating site-specific T17 differentiation in tissue-specific gdT cell subsets.

OS-044-YI

Single-cell profiling of intrahepatic T cells uncovers expanded Th17/MAIT cells with overlapping gene expression in primary sclerosing cholangitis

Background and aims: Robust HLA associations and lymphocytic infiltration in the liver are consistently reported in both primary sclerosing cholangitis (PSC) and primary biliary cholangitis (PBC) indicating a role for T cells in the pathogenesis of both diseases. To determine if PSC and PBC livers harbour unique T cells, we used single-cell RNA sequencing (scRNA-seq) to compare relative abundances and differential gene expression (DEG) of intrahepatic T cells from PSC, PBC and alcohol-related liver disease (ALD) controls.
Method: Intrahepatic T cells were enriched from 12 PSC, 9 PBC and 3 ALD explants by negative bead selection, sorted for viability and analyzed by 5′ scRNA-seq (10X Genomics). Alignment and annotation of sequencing reads was performed using Cell Ranger. Cluster and DEG analysis were computed in Seurat 5 using DESeq2/Pseudobulk. Relative abundances of each cluster per disease were calculated from the median proportion of cells per cluster relative to total T cells per sample. Statistical significance for cluster abundances were determined using the Dunn's multiple comparison test; the Wald test corrected for multiple testing (Benjamini-Hochberg) was used for DEGs.
Results: ScRNA-seq of 42 575 intrahepatic T cells from PSC, PBC and ALD revealed 14 distinct clusters broadly defined by *CD4* (6 clusters), *CD8* (4 clusters) or lack of *CD4* and *CD8* (4 clusters). PSC livers showed a significant increase (PSC: 9.2%, PBC: 5.7%, ALD: 4.4%) in a unique cluster featuring high expression of T helper 17 (Th17) cell markers (*IL17A* and *RORC*) and mucosal-associated invariant T cell (MAIT) markers (*TRAV1-2* and *KLRB1*) compared to PBC ($p = 0.016$) and ALD ($p = 0.006$). By contrast, PBC livers did not show a significantly greater abundance of any T cell cluster in comparison to all diseases; *CD4+* effector memory T cells were significantly increased compared to PSC ($p = 0.029$) but similar in proportion to ALD (PBC: 12.2%, PSC: 8.7%, ALD: 9.6%). Increased numbers of *FOXP3+* regulatory T cells were also observed in PSC ($p = 0.038$) and PBC livers ($p = 0.057$) versus ALD (PSC: 4.6%, PBC: 4.1%, ALD: 1.0%,). As expected, DEG analysis showed that gene profiles of T cells in the same cluster were largely similar between diseases except for a 52-fold higher expression of *IL17A* in *CD4+TNF+* effector T cells and 3.2-fold higher levels of *RORC* in *CD4+* effector memory T cells in PSC livers compared to PBC ($p < 0.05$).
Conclusion: We found that gene profiles of intrahepatic Th17 cells more closely resemble liver MAIT cells than other T cell types and a combined Th17/MAIT cell cluster was significantly enriched in PSC livers compared to PBC and ALD controls. This suggests that Th17 and MAIT cells phenotypes may elicit similar molecular pathways in diseased liver.

Liver immunology

The combination of TCR-redirected CD4+ and CD8+ T cells in T cell therapy of HBV infection enhances virus control in vivo by increasing IFN-γ and TNF-α secretion

Sophia Schreiber[1], Sven Schreiner[1], Eva Loffredo-Verde[1], Anna D. Kosinska[1,2], Ulrike Protzer[1,2]. [1]*Institute of Virology, Technical University of Munich/Helmholtz Munich, Munich, Germany;* [2]*German Center for Infection Research DZIF, Munich, Germany*
Email: sophia.schreiber@tum.de

Background and aims: T cell therapy represents a promising therapeutic approach to treating chronic HBV infection and HBV-associated hepatocellular carcinoma. To date, most T cell therapies have focused on $CD8^+$ cells as primary effector cells. Here, we investigate whether redirected HBV-specific $CD4^+$ T cells support $CD8^+$ T cells.
Method: We engrafted human and mouse $CD8^+$ and $CD4^+$ T cells with MHC I- or MHC II-restricted HBV-specific T cell receptors through retroviral transduction. Human $CD8^+$ and $CD4^+$ T cells were co-cultured with antigen-presenting cells and HBV-positive target cells *in vitro*. In a humanized mouse model of chronic HBV infection expressing human MHC class I and class II, we explored the therapeutic potential of MHC I-restricted HBV surface-specific $CD8^+$ T cells alone or in combination with MHC II-restricted HBV core-specific $CD4^+$ T cells.
Results: Human HBV-specific MHC II-restricted $CD4^+$ T cells enhanced $CD8^+$-mediated cytokine secretion, proliferation, and killing in co-culture with antigen-presenting cells and HBV-positive target cells. Murine $CD4^+$ T cells were successfully engrafted with HBV-specific MHC II-restricted TCRs and secreted IFN-γ and TNF-α upon encountering the target antigen. In a humanized mouse model that was chronically infected with AAV-HBV, both the transfer of $CD8^+$ T cells alone or in combination with $CD4^+$ T cells caused a significant decline of the virological markers HBeAg and HBsAg. In addition, in the combination group, virological markers declined more pronounced by 2 to 3 logs. Upon restimulation of $CD8^+$ T cells isolated from the liver and spleen, cells derived from the combination group secreted higher amounts of IFN-γ and TNF-α. Liver damage was limited, with ALT levels peaking between days 15 and 22 and normalizing again afterward.
Conclusion: We hypothesize a positive helper effect of HBV-specific $CD4^+$ T cells on HBV-specific $CD8^+$ cells for adoptive T cell therapy of chronic HBV infection. This translates into enhanced cytokine secretion, proliferation and killing *in vitro* as well as a stronger antiviral effect *in vivo*.

OS-046

Features of regulatory T cells in primary biliary cholangitis

Naomi Richardson[1], Grace Wootton[1], Ye Htun Oo[1]. [1]*University of Birmingham, Birmingham, United Kingdom*
Email: n.richardson@bham.ac.uk

Background and aims: Regulatory T cells (Treg) are critical components of a homeostatic immune system. In autoimmune diseases, these regulators are overpowered and are insufficient to maintain peripheral tolerance. In primary biliary cholangitis (PBC), inflammatory effector lymphocyte cells damage the intrahepatic bile ducts and cause ongoing biliary damage, eventually leading to liver fibrosis and cirrhosis. We set out to determine whether patients with PBC have defective regulatory T cells in blood and liver and whether Treg functionality has relevance to their disease progression.
Method: We used lymphocytes isolated from peripheral blood and explanted human liver tissue for flow cytometry, scRNAseq and spatial transcriptomic approaches and assessed localization of isolated cell subsets in the liver machine perfusion model system.
Results: We identified that patients with PBC disease have normal frequencies of regulatory T cells in the blood, and an elevated frequency of Treg in the diseased explant liver compared to non-autoimmune chronic liver disease controls (steatotic liver disease). PBC patient Treg also have normal expression of key functional markers CTLA-4, FoxP3 and CD39 which are key to their immunosuppressive capacity. PBC Treg can be readily expanded in vitro and used in suppression assays, displaying a similar suppressive capacity to Treg from healthy controls. Interestingly, we found 2 distinct subsets of patients-those with CD39high Treg and those with CD39low Treg. Liver Treg when infused into explant livers migrate and localize around biliary epithelium and our phenotyping data shows that these cells are enriched for biliary homing CCR6 and CXCR3. We identified that PBC liver is highly enriched for innate inflammatory cytokines IL-6 and IL-8 whilst also having low levels of IL-2 or IL-10. IL-6 promotes the generation of Th17 CD4+ T cells and Treg can be polarised to either Th1 or Th17 cells in vitro, indicating the propensity of patient cells to become inflammatory when faced with inflammatory milieu.
Conclusion: PBC patient Treg are not numerically deficient in peripheral blood or inflamed liver. PBC Treg also appear to be

functionally comparable to non-autoimmune liver disease patient and healthy controls in peripheral blood. This suggests that PBC Treg are not inherently defective. Their inability to control cholangitis is more likely due to a hostile microenvironment enriched with inflammatory mediators including IL-6. We believe there is a case for further investigation as to whether blocking IL-6 signalling could have therapeutic benefit in PBC.

OS-048

CD4+T cells license Kupffer cells to revert the CD8+T cell dysfunction induced by hepatocellular priming

Valentina Venzin[1], Cristian Beccaria[1], Valeria Fumagalli[1], Federica Moalli[1], Chiara Laura[1], Pietro Delfino[1], Leonardo Giustini[2], Elisa Bono[2], Chiara Perucchini[2], Marta Grillo[1], Keigo Kawashima[1], Pietro Di Lucia[2], Anna Celant[1], Sara De Palma[2], Giorgia De Simone[1], Elena Rodriguez Bovolenta[1], Luca Guidotti[1,2], Matteo Iannacone[1,2].
[1]Vita-Salute San Raffaele University, Milan, Italy; [2]San Raffaele Scientific Institute, Milan, Italy
Email: venzin.valentina@hsr.it

Background and aims: Efficient priming of $CD8^+$ T cell responses against non-cytolytic pathogens like HBV is believed to rely on $CD4^+$ T cell help within secondary lymphoid organs, as the immunological dogma would dictate. This hypothesis is supported by an observation in experimentally infected chimpanzees, where $CD4^+$ T cell depletion prior infection prevents $CD8^+$ T cell priming and leads to persistent infection. However, where when and how this issue occurs has never been described or mechanistically elucidated.
Method: We took advantage of unique HBV transgenic mouse models, in which we have demonstrated that adoptive transferred HBV-specific $CD8^+$ T cells that recognize hepatocellular viral antigens undergo activation and proliferation but fail to differentiate into antiviral effector cells. To understand the extent to which antigen-specific $CD4^+$ T cells help intrahepatic $CD8^+$ T cell differentiation, we generated HBV-specific $CD4^+$ TCR transgenic mice (Env126), where all $CD4^+$ T cells recognize an I-Ab-restricted T cell epitope of the HBV envelope protein.
Results: Here, we show that the adoptive transfer of Th1-like Env126 effector $CD4^+$ T cells in HBV-transgenic mice counteracts the $CD8^+$ T cell dysfunction induced by hepatocellular priming, boost their proliferation and stimulate their production of IFNγ, TNFα, and GranzymeB. This enhances $CD8^+$ T cell-mediated liver immunopathology and suppresses HBV replication. Surprisingly, we found that dendritic cells are dispensable for the observed effect while on the contrary, Kupffer cells' (KCs) cross-presenting capacity is enhanced after adoptive transfer of Env126 effector $CD4^+$ T cells. With multiphoton intravital microscopy we indeed revealed that HBV-specific $CD4^+$ and $CD8^+$ T cells simultaneously interact with individual KCs within the liver, and as such, the restorative process of Env126T effector $CD4^+$ T cells help is impeded upon KCs depletion. Preliminary data show that the CD40-CD40L signaling pathway engagement could be key for Env126T cells-mediated KCs licensing.
Conclusion: Our findings underscore the crucial role of antigen-specific $CD4^+$ T cells in mitigating the $CD8^+$ T cell dysfunction induced by intrahepatic priming through the extra-lymphoid licensing of KCs, revealing a hitherto unexplored dynamic. Deciphering the molecular mechanism behind this effect could lead to the development of innovative immunotherapeutic strategies to eradicate chronic hepatic infections and their life-threatening complications.

OS-049-YI

The anti-tumour effector function of mucosal-associated invariant T cells against hepatocellular carcinoma is impaired by fatty acids and aberrant lipid metabolism

Sebastian Deschler[1], Junika Pohl[1], Lukas Ramsauer[2], Philippa Meiser[2], Robin P. Schenk[1], H. Carlo Maurer[1], Juliane Kager[1], Sophia Erlacher[1], Joseph Zink[1], Karyna Pistrenko[1], Enric Redondo Monte[1], Julius Weber[1], Fabian Geisler[1], Douglas Thorburn[3], Gabriela M. Email: katrin.boettcher@mri.tum.de

Background and aims: Mucosal-associated invariant T (MAIT) cells, the most abundant innate-like T cell population in the liver, harbour anti-cancer potential. However, their effector function is impaired in hepatocellular carcinoma (HCC), a frequent cause of cancer-related deaths worldwide, for reasons that are incompletely understood. Here, we aim to decipher the mechanism by which MAIT cell effector function is impaired in the liver microenvironment. Therefore, we analysed how metabolic changes in metabolic dysfunction-associated steatotic liver disease (MASLD), a common precondition for HCC development, affect the phenotype and effector function of MAIT cells.
Method: MAIT cells from peripheral blood of MASLD patients or healthy controls were stimulated *ex vivo*, and MAIT cells from healthy controls were challenged with fatty acids during stimulation. MAIT cell phenotype and function was analysed by multi-colour flow cytometry, metabolism was investigated by metabolic flux analysis and gene expression by RNA sequencing.
Results: We show that MASLD MAIT cells express significantly higher levels of activation markers and effector cytokines *ex vivo*, suggesting MAIT cell activation in MASLD *in vivo*. However, upon *ex vivo* restimulation, these activated MAIT cells were dysfunctional and failed to produce effector cytokines, such as IFNγ, Granzyme B and TNFα. We further uncover a novel HCC tumour cell killing capacity of MAIT cells. Notably, culture with distinct fatty acid species characteristic of the MASLD microenvironment and accumulating in our MASLD patient cohort, impaired expression of effector cytokines by MAIT cells and abrogated their HCC cell killing capacity. Mechanistically, these effects were mediated by corrupted mitochondrial function, oxidative stress and aberrant lipid metabolism and could be rescued by treatment with redox regulators.
Conclusion: Taken together, we show that impairment of MAIT cell anti-tumour effector function against HCC is mediated by metabolic signals in the hepatic microenvironment in MASLD patients that induce oxidative stress and corrupt MAIT cell mitochondrial function. Our data provide novel mechanistic insight that could be harnessed to develop innovative strategies for MAIT cell-mediated anti-cancer immunity.

Therapeutic vaccine (BRII-179) induced immune response associated with HBsAg reduction in a subset of chronic hepatitis B participants

Yun Ji[1], Nina Le Bert[2], Ariel Lee[3], Chong Zhu[4], Ying Tan[4], Weihong Liu[4], Jianxiang Lv[4], Dong Li[4], Haiyan Ma[3], Xiaofei Chen[4], Antonio Bertoletti[2], Qing Zhu[1]. *[1]Brii Biosciences Inc., Durham, United States; [2]Programme in Emerging Infectious Diseases, Duke-NUS Medical School, Singapore, Singapore; [3]Hyris/TCD limited, Singapore, Singapore; [4]Brii Biosciences Co. Ltd., Beijing, China*
Email: qing.zhu@briibio.com

Background and aims: BRII-179, a therapeutic vaccine consisting of 3 HBV surface antigens (PreS1, PreS2, and S), is safe and immunogenic when administered alone or in combination with an HBV-targeted small interfering RNA, BRII-835 (VIR-2218). In the study BRII-179-835-001, chronic hepatitis B (CHB) participants on nucleoside reverse transcriptase inhibitor (NRTI) therapy received 9 monthly doses of BRII-835 either alone or in combination with 9 monthly doses of BRII-179 with or without IFNα co-adjuvant. While there was no notable difference of HBsAg reduction at group levels, a heterogeneity of immunological response was detected in CHB participants achieving different HBsAg reduction. In selected participants from the BRII-179-835-001 study we evaluated whether different virological outcomes were associated with specific profiles of treatment-induced anti-HBs and T cell immune responses.
Method: Peripheral blood mononuclear cells (PBMCs) were collected from 49 participants at 6 time points, with an additional 2 time points collected for one participant during NRTI discontinuation. HBV-specific T cell response was analyzed both directly *ex vivo* (cytokine assay upon HBV-specific peptides stimulation of whole blood) or after *in vitro* expansion of PBMCs (ELISpot assays, T cell epitope mapping, intracellular cytokine staining) in selected participants with different levels of HBsAg reduction.
Results: Both anti-HBs and the HBsAg-specific T cell responses were significantly enhanced in the BRII-179 and BRII-835 combination groups compared to the BRII-835 alone group. In addition, HBsAg-specific T cell epitopes were only mappable in participants receiving BRII-179. A unique epitope region adjacent to the NTCP binding site was identified in those participants with high HBsAg reduction (approximately greater than 2log). In contrast, discrete or non-identifiable epitope regions were mapped in those with lower HBsAg reduction relative to the mean HBsAg reduction induced by siRNA. A Th1 cytokine secretion profile upon HBV-specific peptides stimulation was also detected in participants with high HBsAg reduction. These features, as well as the long-term persistence of HBV-specific T cells, were pronounced in the participant who reached HBsAg loss and met NrtI discontinuation criteria.
Conclusion: Therapeutic vaccine BRII-179, in combination with siRNA BRII-835, induced substantial HBV-specific B and T responses in certain CHB participants. The unique immune response pattern observed in these participants receiving combination therapy, and their correlation with the reduction of HBsAg levels among these evaluable participants, suggests that T cells induced by BRII-179 may play a role in reducing HBsAg and controlling HBV. Assessing the neutralizing efficacy of anti-HBs in selected serum against different HBV genotype viruses is currently ongoing.

MASLD: Clinical aspects

OS-047-YI

Prediction of the risk of liver related events with non-invasive models is better than liver biopsy in MASLD cACLD patients

Laia Aceituno[1,2,3], Juan Bañares[1], Grazia Pennisi[4], Adele Tulo[4], Monica Pons[1,2,5], Juan Manuel Pericàs[1,2,5], Salvatore Petta[4], Juan G Abraldes[6], Joan Genesca[1,2,5]. *[1]Liver Unit, Digestive Diseases Division, Vall d'Hebron University Hospital, Barcelona, Spain; [2]Vall d'Hebron Institute of Research (VHIR), Vall d'Hebron Barcelona Hospital Campus, Universitat Autonoma de Barcelona, Barcelona, Spain; [3]Multi-Organ Transplant, Ajmera Transplant Centre, University Health Network, Toronto, Canada; [4]Section of Gastroenterology, PROMISE, University of Palermo, Palermo, Italy; [5]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain; [6]Liver Unit, Division of Gastroenterology, University of Alberta, Edmonton, Canada*
Email: laiaaceituno@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of chronic liver disease. Liver biopsy is considered the gold standard for risk stratification. Non-invasive models have been validated to predict clinically significant portal hypertension (CSPH), a major determinant of decompensation. The ANTICIPATE-NASH model uses liver stiffness measurement (LSM), BMI and platelet count to predict the presence of CSPH in MASLD. We recently showed that this model can be used for individualized risk prediction of liver-related events (LRE) in MASLD. This study aimed at evaluating if liver biopsy data improves the prediction of LREs compared to the ANTICIPATE-NASH model alone in MASLD patients with compensated advanced chronic liver disease (cACLD).
Method: European retrospective multicenter cohort study of patients with biopsy-proven F3-F4 MASLD with baseline data and follow-up incidence of LRE (composite event of decompensation, HCC, transplantation, or liver-related death). We estimated the CSPH/LRE risk distribution based on the ANTICIPATE-NASH model. We tested the added value of histology to the risk prediction provided by the ANTICIPATE-NASH model with Cox regression.
Results: 699 patients were included, 52% were male, median age was 60 years (54.3–65.6), and median BMI was 31 kg/m2 (27.8–34.5). 324 (46.4%) patients had F3 and 375 (53.6%) F4. Median follow-up was 42.8 months (18.9–66.6). During follow-up, 56 (8.0%) patients developed LRE. F4 patients had significantly higher median LSM (22.6 vs. 15.8 kPa), LRE rates (13.6% vs 1.5%), and CSPH probability estimated by the ANTICIPATE-NASH model (26.9% vs. 18.3%) than F3 patients (all p values <0.001). The ANTICIPATE-NASH model had a higher discrimination (c-statistic 0.93) for LRE compared to histology (0.67). Calibration was excellent. Adding histology to the model did not improve prediction accuracy. Using an ANTICIPATE-NASH model cutoff of 0.25 (which is associated with a pointwise 1.6% estimated 3-year risk of LREs), a substantial difference was observed in LRE rates: 0.98% in <0.25 vs. 18.5% in ≥0.25 ($p < 0.001$); 61% and 39% of the patients were below and above the 0.25 risk threshold of CSPH. This dichotomization provided better separation of the risk of LRE than the F3/F4 classification. Indeed, all LRE occurring in F3 patients (5/68) occurred in patients with an ANTICIPATE-NASH threshold ≥0.25. Similarly, 30% of F4 patients presented a CSPH risk <12% (median value for F3 patients) with no LREs.
Conclusion: The non-invasive ANTICIPATE-NASH model, based on LSM, BMI and platelet count, has better accuracy than histology for LRE prediction in MASLD. Histology does not refine the risk prediction provided by the model.

OS-051

Association between advanced fibrosis and NASH-CRN activity score (NAS) components: combined data from multiple therapeutic trials including more than 10, 000 patients

Stephen A. Harrison[1], Julie Dubourg[2], Mazen Noureddin[3], Naim Alkhouri[4], Jörn M Schattenberg[5], Sophie Jeannin[6], Vlad Ratziu[7], Michael Charlton[8]. Email: jdubourg@summitclinicalresearch.com

Background and aims: The association of advanced fibrosis and severity of metabolic dysfunction-associated steatohepatitis (MASH) have been previously described. We aimed to assess the association between NAS, NAS components and advanced fibrosis.
Method: We combined screening data from 10 industry-funded MASH phase 2 trials. We performed univariate and multivariate logistic regression analyses to assess the association between NAS, NAS components and advanced fibrosis, as defined as fibrosis stages 3 or 4. We developed a modified version of the NAS, namely "lean NAS" (=inflammation grade + ballooning grade, excluding steatosis) to predict the presence of advanced fibrosis.
Results: 4, 117 patients with centrally assessed liver biopsy were included. The prevalence of advanced fibrosis in this population was 36%. In univariate analysis, higher NAS, hepatocyte ballooning and lobular inflammation were associated with advanced fibrosis. Advanced fibrosis was observed in 27%, 19%, 19%, 25%, 34%, 47%, 55%, 66%, and 57% of patients with NAS 0 to 8, respectively. The odds of advanced fibrosis was significantly increased in patients with a NAS of 5 or more ($p < 0.0001$). Advanced fibrosis was observed in 15%, 29%, 51% and 71% in patients with inflammation grade 0 to 3, respectively. The odds of advanced fibrosis was 3.4 (95% CI: 2.8–4.0) in the presence of inflammation ($p < 0.0001$). Advanced fibrosis was observed in 15%, 37% and 66% in patients with ballooning grade 0 to 2, respectively. The odds of advanced fibrosis was 5.9 (95% CI: 5.0–6.9) in the presence of ballooning ($p < 0.0001$). Advanced fibrosis was observed in 39%, 39%, 36% and 32% in patients with steatosis grade 0 to 3, respectively. The odds of advanced fibrosis was lower in patients with steatosis grade 3 ($p = 0.048$). In a model including the "lean NAS" and steatosis grade, the presence of high degree of inflammation (grade 3) and ballooning (grade 2) was associated with a 32x greater odds (95% CI: 16.8–62.1) for the presence of advanced fibrosis. Inversely, the presence of steatosis grades 1, 2 or 3 were associated with lower probability of advanced fibrosis: odds ratio of 0.45 (95% CI: 0.31 – 0.66), 0.28 (95% CI: 0.19–0.40), and 0.20 (95% CI: 0.13–0.29), respectively.
Conclusion: Advanced fibrosis is strongly associated with the presence and severity of hepatocyte ballooning and to a lesser extent with the presence and severity of inflammation, independently of the NAS. A modified NAS, namely "lean NAS" can predict the presence of advanced fibrosis, and the severity of steatosis is inversely correlated with the severity of fibrosis.

Characteristics and risk of major adverse liver outcomes and major cardiovascular events among swedish patients with diagnosed and high risk of metabolic dysfunction-associated steatohepatitis-a REVEAL-MASH study

Emilie Toresson Grip[1,2], Nikolas Scheffer Apecechea[3], Ron Basuroy[3], Pierre Johansen[3], Kamal Kant Mangla[3], Helena Skröder[2], Hannes Hagström[4]. [1]*Karolinska Institutet, Stockholm, Sweden;* [2]*Quantify Research, Stockholm, Sweden;* [3]*Novo Nordisk A/S, Denmark, Copenhagen, Denmark;* [4]*Karolinska Insitutet, Stockholm, Sweden*
Email: emilie.toresson-grip@quantifyresearch.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is significantly under-diagnosed and requires liver biopsy. The Fibrotic NASH Index (FNI) is a validated risk score to classify patients at risk of MASH with fibrosis stage ≥2. We used the FNI to characterize patients at risk and to compare the incidence of major adverse liver outcomes (MALO) and major adverse cardiovascular events (MACE) between risk groups.
Method: This cohort study is based on Swedish registry data from 1998–2022, including lab data for patients with ≥1 liver-related test in routine clinical care in Stockholm 2001–2020. Patients were classified as high risk if they had FNI≥0.33 and a cardiometabolic risk factor (overweight/obesity, type 2 diabetes (T2D), hypertension or dyslipidemia), or low-risk (FNI<0.1 ± cardiometabolic risk factors). Diagnosed patients had a recorded ICD-10 code for MASH (K75.8) in specialist care. Patients with other liver diseases were excluded. All patients were followed from first diagnosis or FNI score.
Results: The FNI score was calculated for 154, 179 patients, of which 47, 154 were considered at high risk of MASH (31%) and 57, 609 at low risk of MASH (37%). Diagnosed patients (n = 485 in the register) were younger (median 63 years), included more females (52%) and less commonly had T2D (48%), than patients at high risk (median 66 years, 28% females and 59% with T2DM, p for all comparisons <0.001). Patients at low risk were about the same age as diagnosed (median 62 years, p >0.05) but included more females (65%) and less commonly had T2D (7%; p for all comparisons <0.01) than both diagnosed and high-risk patients. Diagnosed patients also more commonly had a history of MALO (42%) than patients at high (0.4%) and low risk (0.2%; p for all <0.001), but less commonly had a history of MACE (Diagnosed: 4.3%, High-risk: 9.5%, Low risk: 4.8%; p for all <0.01). Among patients with no history of MALO and MACE, respectively, the incidence rate (IR; per 1000 person-years (PY)) for MALO (mean follow-up: 6 years) was higher among diagnosed (IR = 19, 95% CI = 13–27) and high-risk patients (IR = 2.4, 95% CI = 2.2–2.6) vs low-risk patients (IR = 0.5, 95% CI = 0.4–0.6), and also for MACE (Diagnosed: IR = 19, 95% CI = 14–27; High-risk: IR = 31, 95% CI = 30–32; Low-risk: IR = 12, 95% CI = 11.6–12.3). In an adjusted Cox regression model (considering age, sex and T2D), the rate of MALO was higher in patients at high risk vs low risk (aHR = 3.8, 95% CI = 3.2–4.6), but lower for high risk vs diagnosed patients (aHR = 0.08, 95% CI = 0.05–0.12). The rate of MACE was also higher in patients at high vs low risk (MACE: aHR = 1.9, 95% CI = 1.8–2.0) but not significantly in high risk vs diagnosed patients (aHR = 1.3, 95% CI = 0.9–1.8).
Conclusion: The results indicate a large burden of undiagnosed fibrotic MASH in patients from the general population with risk factors for MASH and highlights FNI as a possible risk stratification tool.

OS-053

Screening candidates for therapeutic trials in MASH: choose the right non-invasive test for the diagnostic target considered

Jerome Boursier[1,2], Luisa Vonghia[3], Charlotte Costentin[4], Jeanne Fichez[2], Clemence Moreau[1], Marine Roux[1], Clémence M Canivet[1,2], Victor de Lédinghen[5], Sven Francque[3], Ming-Hua Zheng[6]. [1]*Angers University, Angers, France;* [2]*Angers University Hospital, Angers, France;* [3]*Antwerp University Hospital, Antwerp, Belgium;* [4]*Grenoble University Hospital, Grenoble, France;* [5]*Bordeaux University Hospital, Pessac, France;* [6]*Wenzhou university Hospital, Wenzhou, China*
Email: jeboursier@chu-angers.fr

Background and aims: The screen failure rate in therapeutic trials evaluating MASH treatments is very high, around 70–80%. One of the main reasons is the absence of fibrotic MASH on liver histology, underscoring the need for better selection of candidates for these studies. Our aim was to evaluate the performance of 8 non-invasive tests, specific or not, for the diagnosis of fibrotic MASH.

Method: 1, 005 patients with histologically proven MASLD were included in 5 centers across Europe and Asia. Fibrotic MASH was defined as the presence of MASH with a NAS score ≥4 and a fibrosis stage F≥2 according to the NASH CRN classification. Advanced fibrosis was defined as fibrosis stage F≥3. Three non-invasive tests specifically developed for fibrotic MASH were evaluated (the simple blood test Fibrotic NASH Index [FNI], the specialized blood test MACK-3, and the elastography-based test FAST), as well as 5 non-invasive tests developed for advanced fibrosis (the simple blood test FIB4, the specialized blood tests Fibrotest and ELF, and the elastography tests Fibroscan and Agile3+). The simple blood tests (FNI, FIB4) were available for all the 1005 patients included, the specialized blood tests (MACK-3, Fibrotest, ELF) for 545 patients, and the elastography tests (FAST, Fibroscan, Agile3+) for 817 patients.
Results: Median age was 56.7 years, 62.7% of the patients were male, and 49% had type 2 diabetes. The prevalence of fibrotic MASH and advanced fibrosis were, respectively, 41.8% and 31.9%. For the diagnosis of fibrotic MASH in the 1005 patients included, the simple blood test for fibrotic MASH FNI had a significantly higher AUROC than the simple blood test for advanced fibrosis FIB4 (0.709 [0.677–0.741] vs. 0.662 [0.628–0.695], p = 0.019). In the 545 patients with all specialized blood tests available, MACK-3 had a significantly higher AUROC for the diagnosis of fibrotic MASH (0.772 [0.734–0.811]) than Fibrotest (0.615 [0.568–0.663], p < 0.001) and ELF (0.700 [0.656–0.744], p = 0.003). In the 817 patients with all elastography tests available, FAST had a significantly higher AUROC for the diagnosis of fibrotic MASH (0.774 [0.743–0.806]) than Fibroscan (0.728 [0.694–0.763], p = 0.001) and Agile3+ (0.708 [0.672–0.744], p < 0.001). The dedicated specialized tests (MACK-3 and FAST) were significantly more accurate than the simple blood tests (FNI and FIB4) for the diagnosis of fibrotic MASH. The thresholds of tests for advanced fibrosis were recalculated for the diagnosis of fibrotic MASH. Despite these optimized thresholds, the specialized non-invasive tests specifically dedicated for fibrotic MASH remained more accurate than the specialized non-invasive tests for advanced fibrosis.
Conclusion: Specialized non-invasive tests specifically dedicated to fibrotic MASH should be preferred to non-invasive tests for advanced fibrosis to improve the screening of candidates for therapeutic trials in MASH.

Email: elballop@gmail.com

Background and aims: The Baveno VII 'rule of 5' based on vibration-controlled transient elastography (VCTE) determines the risk of hepatic decompensation and mortality. The aim of our study was to validate the 'rule of 5' in a real-life cohort of obese and non-obese patients with metabolic dysfunction-associated steatotic liver disease (MASLD).
Method: This is a retrospective study in which patients with MASLD undergoing baseline and repeated measurements of VCTE in 16 centers in USA, Europe and Asia were included. The ability of the 'rule of 5' to predict hepatic decompensation (HD) (ascites, variceal hemorrhage, hepatic encephalopathy or hepatorenal syndrome) and liver related death (LRD) was evaluated.
Results: From February 2004 to January 2023 data from 17949 subjects were collected, with 12664 finally included. Mean age was 51.9 years, 58% male, 28% were obese (BMI≥30). 166 (1.3%) had HD and 38 (0.3%) LRD after a median follow-up of 48.0 months (IQR 24.1–72.4 months). The competing risk analysis showed increased risk of

HD for each VCTE 'rule of 5' category in obese and non-obese patients (p < 0.001). The cumulative probability of HD at 1, 3 and 5 years of follow-up was: Obese: <10 kPa: 0.2%, 0.3%, 0.9%; 10–15 kPa: 0.2%, 0.9%, 2.9%; 15–20 kPa 1.0%, 3.3%, 6.1%; 20–25 kPa 0%, 4.0%, 8.7%; 25–30 kPa 1.5%, 4.9%, 11.5%, >30 kPa 1.6%, 14%, 23.6% p < 0.001; Non-obese: <10 kPa 0.1%, 0.4%, 0.9%; 10–15 kPa 0.9%, 1.6%, 3.0%; 15–20 kPa 1.7%, 5.8%, 12.5%; 20–25 kPa 2.1%, 4.5%, 4.5%; 25–30 kPa 2.8%, 5.8%, 20.5%; kPa; >30 kPa 4.2%, 11.6%, 19.5%; p < 0.001. This suggested that the predictive performance of VCTE is lower in patients with obesity. Time-dependent area under receiver operating characteristic (AUROC) curves for the 'rule of 5' to predict HD at 1 and 3 years were 0.71 and 0.86 as well as 0.87 and 0.82 in obese and non-obese, respectively, showing better performance of the 'rule of 5' in non-obese patients for HD. A model including 'the rule of 5' and obesity showed AUROC at 1 and 3 years 0.83 and 0.84 in the whole cohort. Competing risk analysis showed significantly lower risk of LRD for obese and non-obese patients in each category (p < 0.001). Incidence of LRD was higher as 'rule of 5' category increased for obese and non-obese patients (Obese: <10 kPa: 0%, 10–15 kPa 0.7%, 15–20 kPa 1.4%, 20–25 kPa 1.6%, 25–30 kPa 2.8%, >30 kPa 6.6% p < 0.001; non-obese: <10 kPa: 0.03%, 10–15 kPa 1%, 15–20 kPa 1%, 20–25 kPa 1%, 25–30 kPa 4.1%, >30 kPa 2.9% p < 0.001). Again, this suggested that the predictive performance of VCTE is lower in patients with obesity. AUROC for the 'rule of 5' to predict LRD at 3 and 5 years was: Obese: 0.9 and 0.88, non-obese: 0.9, 0.79. A model including 'the rule of 5' and obesity showed AUROC at 3 and 5 years 0.91 and 0.86 in the whole cohort.
Conclusion: The 'rule of 5' predicts HD and LRD in MASLD patients. However, obesity must be taken into account when using it given that the discriminative capacity of VCTE is lower in the presence of obesity.

Public Health

OS-055
Defining the thresholds for alcohol intake on the risk of liver-related mortality in people with metabolic risk factors

Hyunseok Kim[1], Polly Kirsch[1], Yee Hui Yeo[1], Walid S Ayoub[1], Alexander Kuo[1], Vijay Pandyarajan[1], Hirsch Trivedi[1], Aarshi Vipani[1], Yun Wang[1], Ekihiro Seki[1], Stephen Pandol[1], Debiao Li[1], Shelly C. Lu[1], Ju Dong Yang[1]. [1]*Cedars Sinai Medical Center, Los Angeles, United States*
Email: hyunseok.kim@cshs.org

Background and aims: The impacts of alcohol consumption in people with metabolic risk factors on the risk of liver-related outcomes are not fully studied. In this study, we investigated the effects of alcohol consumption amount on liver-related mortality in participants with metabolic risk factors in the United Kingdom Biobank study (UKB) study, a prospective cohort.
Method: We included participants without a prior diagnosis of cirrhosis at the time of enrollment. Metabolic traits (hypertension, type 2 diabetes mellitus, dyslipidemia, and obesity) were defined based on self-reported history, medication use, previous hospital diagnosis, or laboratory/anthropometric values. We obtained the alcohol consumption amount from a self-reported alcohol use questionnaire. We categorized the alcohol consumption into <10 g, 10–20 g, 20–30 g, 30–40 g, 40–50 g, 50–60 g, and >60 g per day to identify at which dose people start to have significantly higher risk for liver-related mortality. We performed Cox proportional hazards models to evaluate the effects of alcohol intake amount on time to liver-related mortality. In addition, we investigated whether the effect of alcohol intake can be altered by the *PNPLA3* genotype.
Results: In 263, 052 participants with at least one metabolic trait (mean age 57.39 years, male 51.7%),. 92, 481 (35%), 73, 758 (28%), 43, 606 (17%), 22, 499 (8.5%), 13, 358 (5.1%), 6, 832 (2.6%), 10, 518 (3.9%) participants consumed <10 g, 10–20, 20–30, 30–40, 40–50, 50–60, >60 g per day, respectively. During a median follow-up of 12 years, 654 participants developed liver-related mortality. We observed a statistically significantly higher risk of liver-related mortality from those who drank between 20 and 30 g per day (aHR 1.45 [95% CI: 1.10–1.92]) compared to those who drank <10 g per day, after adjusting for age, sex, race/ethnicity, BMI, diabetes, hypertension, hyperlipidemia, and household income. Furthermore, we observed synergistic interaction in those who drank >60 g per day and *PNPLA3* homozygote carriers (p-interaction <0.01, aHR 5.3 [95% CI: 3.7–7.6] in alcohol intake >60 g per day with normal *PNPLA3* trait, aHR1.6 [95% CI: 0.8–3.4] in *PNPLA3* homozygous carriers who drank <60 g per day, and aHR 25.6 [95% CI: 3.6–182] in both alcohol intake >60 g per day and *PNPLA3* homozygous carriers). While the absolute risks of liver-related mortality were lower in women, we could not find a significant interaction between sex and alcohol consumption.
Conclusion: In the UK Biobank, there was an incremental risk of liver-related mortality by the amount of alcohol consumption. The increased liver-related mortality was observed from those with >20 g/day of alcohol use. The *PNPLA3* genotype status also plays a synergistic interplay in those who drink excessively. We need to counsel the risk of alcohol consumption on the progression to liver-related outcomes in people with metabolic risk factors.

OS-056-YI
Poor referral of migrants with hepatitis B virus infection from primary care: a substantial missed opportunity for successful linkage to specialist care in Catalonia

Camila Picchio[1,2], Helena Martí Soler[1], Aina Nicolàs Olivé[1], Sabela Lens[3,4], Xavier Forns[3,4], Elisa Martró[5,6], Maria Buti[3,7], Jeffrey V Lazarus[1,8], Ana Requena[1]. Email: camila.picchio@isglobal.org

Background and aims: The impact of chronic hepatitis B virus (HBV) infection is particularly pronounced among vulnerable populations, such as migrants, who face unique challenges related to healthcare access, cultural differences, and social determinants in their host countries. Primary health care is one of the most frequent contact points with the health system migrants have, however, HBV infections in Spain are managed at the tertiary level and therefore referrals from primary care are needed to properly diagnose, manage, and treat chronic HBV infections. We aimed to categorize the referrals of HBV from all of the primary care centers in Catalonia in 2017 and 2018 to specialist care.
Method: We examined all first recorded patient visits in primary care across the autonomous community of Catalonia, Spain in 2017 and 2018 with data the central database primary health care database in Catalonia [Information System for Research in Primary Care (SIDIAP)]. The proportion of people born outside of Spain (classified as migrants) who were HBsAg+ and therefore eligible for a referral to specialist care (e.g. gastroenterology and hepatology or infectious diseases units) was categorized. Region of origin were classified as: North Africa, Central and Southern Africa, Northern Europe, Southern Europe, Central and Eastern Europe, Ibero-America and the

Caribbean, Anglo-Saxon America, Asia (Middle East), Eastern Asia, and Oceania. Basic standard descriptive statistics were used to analyze data using R software (R Core Team 2023).
Results: A total of 1, 688 and 1, 995 migrants had recorded first visits in primary care centers across Catalonia in 2017 and 2018, respectively. Most were female migrants (1553, 56%) and from Northern Africa (892, 24%). Overall, the prevalence of HBsAg+ was 6.5% (n = 239, 108 in 2017 and 131 in 2018). Migrants from Central and Southern Africa region accounted for 55% of all HBsAg+ cases (130/239). While all HBsAg+ patients were eligible for referrals, 73% (175/239) of these migrants did not receive an order for referral to specialist care. Although there is some heterogeneity between regions, no statistically significant differences were observed ($p > 0.05$). Overall, more than half of the HBsAg+ migrants were not referred from their primary care doctor to specialist care in 2017 and 2018, and 77% of migrants from Central and Southern Africa were not referred.
Conclusion: Almost three quarters of migrants who were eligible for and required a referral to specialist care across Catalonia were not provided one from primary care in 2017 and 2018. This presents a substantial missed opportunity to link migrants to indispensable liver care. Training of healthcare workers in primary care should be reinforced and additional strategies, such as community-based care, to diagnose and ensure linkage to specialist care for migrants are needed so that new HBV diagnoses are not missed or lost to follow-up.

OS-057-YI
CORE: a new risk score measuring GGT, AST, and ALT outperforms FIB-4 when predicting the risk of cirrhosis in a primary care setting
Rickard Strandberg[1], Mats Talbäck[2], Niklas Hammar[2], Hannes Hagström[1,3]. [1]*Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden;* [2]*Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden;* [3]*Karolinska University Hospital, Stockholm, Sweden*
Email: rickard.strandberg@ki.se

Background and aims: Metabolic associated steatotic liver disease (MASLD) has a high prevalence in the general population, and the incidence of MASLD-associated cirrhosis is increasing. The Fibrosis-4 score (FIB-4) is a diagnostic model used in patients with MASLD to estimate the present degree of fibrosis, but the FIB-4 score is inadequate for predicting future cases of severe liver disease. The aim of this study is to develop a risk score—the Cirrhosis Outcome Risk Estimator (CORE)—allowing physicians to identify individuals at a high risk of developing cirrhosis. Correct identification would allow for early intervention and preventive measures.
Method: We used a large Swedish population-based cohort, free of known liver diseases other than possibly MASLD, with available laboratory data—including biomarkers associated with liver disease—and national registry data. Using flexible parametric survival models, a 10-year risk model of cirrhosis or associated complications was created, with non-liver death as a competing event. The new comprehensive risk score initially included age, sex, body mass index (BMI), aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma-glutamyl transferase (GGT), cholesterol, platelet count, albumin, bilirubin, glucose, and triglycerides. From this, a simplified but clinically feasible model was extracted which includes only age, sex, GGT, AST, and ALT. The performance was assessed in terms of discrimination (time-dependent area-under-curve (AUC)), calibration (calibration curves), and clinical utility (decision curve analysis). The model was compared to the FIB-4 score.
Results: We used data of 504, 359 individuals that were followed over an average follow-up time of 25 years. During follow-up, 7604 liver-related outcomes were observed. The cumulative risk of liver cirrhosis at ten years was 0.22%. The new risk score CORE achieved a 10-year AUC of 81% (95%CI: 80–84) compared to the FIB-4 AUC of 73% (95%CI: 71–75). The calibration was considerably better in CORE than FIB, and according to the decision curve analysis CORE has a higher net benefit than FIB-4 for all risk thresholds.
Conclusion: The new risk score, the Cirrhosis Outcome Risk Estimator (CORE), based on a flexible modelling approach and using biomarkers easily accessible in primary care, outperforms FIB-4 when predicting liver-related outcomes in the general population. The model awaits external validation in the FINRISK cohort and the UK biobank.

OS-058
Disparities in hepatocellular carcinoma survival among people with hepatitis B or hepatitis C virus infection in Canada
Naveed Janjua[1,2], Stanley Wong[1], Dahn Jeong[2], Jean Damascene Makuza[2], Richard Morrow[2], Sofia Bartlett[1], Héctor Alexander Velásquez García[1], Prince Adu[1], Victor Lei[1], Amanda Yu[1], Maria Alvarez[1], Alnoor Ramji[3], Eric Yoshida[3], Mel Krajden[1]. Background and aims: Liver cancer has one of the fastest increasing incidence and mortality rates among all cancers in Canada. Liver cancer affects populations from diverse background. However, there are limited data on disparities in survival following hepatocellular carcinoma (HCC) diagnosis. We assessed disparities in survival following HCC diagnosis to identify gaps in care in British Columbia, Canada.
Method: We used data from the BC Hepatitis Testers Cohort. This cohort includes data on individuals tested for hepatitis C virus (HCV), hepatitis B virus (HBV), and HIV, integrated with data on cancers, mortality, and healthcare administrative data. The study included individuals diagnosed with HCC among people with HCV or HBV infection between January 2010 and March 2021. Individuals were followed from HCC diagnosis to death or the end of the study (December 31, 2021). We computed the crude mortality rates and constructed survival curves for overall population and by age, sex, ethnicity, and socioeconomic status. We used the Cox proportional hazards models to investigate factors associated with survival duration after HCC diagnosis.
Results: Among 117, 524 people with chronic HBV (n = 42, 259) or HCV (n = 69, 117) or HCV/HBV (n = 6, 148) infection, 2, 783 (HCV:1, 779, HBV:777, HCV/HBV:227) patients were diagnosed with HCC. The median age at HCC diagnosis was 61[57–66] years. Among patients with HCV related HCC, the crude mortality rate (overall: 35.6 per 1000-person years (PY), 95% CI: 33.7–37.5) showed a graded increase with material deprivation (most privileged: 31.2/1000 PY, 95% CI: 27.1–35.74; most deprived: 41.9/1000 PY, 95% CI: 38.0–46.0). Among those with HBV related HCC, the overall crude mortality rate was lower (rate: 13.4, 95%CI: 12.1–14.7) and, there was not a gradient across material deprivation.
In the multivariable model for HCV related HCC, people in the 4th [Adjusted Hazard Ratio (AHR): 1.31, 95% CI: 1.08 – 1.58] and 5th (AHR:1.29, 95% CI: 1.08–1.55) material deprivation quintiles compared with the most privileged (1st quintile), and people who inject drugs (PWID; AHR: 1.32, 95% CI: 1.16–1.51) had higher mortality rates after adjusting for age, sex, diagnosis stage, and ethnicity. In the multivariable model for HBV related HCC, people from "other" ethnicities (including White and other population groups with anglicized names) compared with people of East Asian ancestry (1.30, 95% CI: 1.04–1.61), and PWID (AHR: 1.89, 95% CI: 1.44–2.46) had higher mortality, although there was no gradient by material deprivation.
Conclusion: This study identified disparities in HCC-related survival by material deprivation and in PWID among those with HCV infection, and by ethnicity and in PWID among those with HBV

infection. As we strive toward hepatitis elimination goals, addressing disparities in HCC diagnosis and care needs to be part of the continuum to improve overall health and survival.

Background and aims: Steatotic Liver Disease (SLD) poses a major public health concern, requiring focused healthcare approaches. Socioeconomic factors affect disease outcomes, potentially accounting for the variations in progression to significant and advanced liver fibrosis across the SLD spectrum. We aimed to describe socioeconomic disparities across Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD), MASLD with concurrent moderate-high alcohol consumption (MetALD), and Alcohol-related Liver Disease (ALD). Finally, we sought to explore the impact of socioeconomic elements on liver fibrosis within these SLD subgroups.
Method: We screened individuals from the general population and individuals with SLD using controlled attenuation parameter (CAP) with a CAP-cut-off ≥248 dB/m and transient elastography (TE), with significant fibrosis indicated by TE ≥8 kPa and advanced fibrosis by TE >12 kPa. We classified participants according to the nomenclature with either metabolic factors or alcohol intake as predominant factors. We assessed socioeconomic status by self-reported income, education, employment, and marital status, and compared MASLD, MetALD, and ALD, using non-SLD as a comparator. We performed chi-square tests and logistic regression, to explore associations between socioeconomic factors and the distinct subgroups.
Results: We screened 6444 individuals with a median age of 57 (IQR 52–63), 52% female. The distribution of non-SLD/MASLD/MetALD/ALD was 2451 (38%)/2967 (46.0%)/663 (10.3%)/363 (5.6%). More than half of the ALD group earned below 40, 000 € (55%), which was significantly more than non-SLD (34%), MASLD (38%), and MetALD (34%), ($p < 0.005$). Within the ALD subgroup, 56% were unemployed, long-term ill, or retired due to disability or age, an overrepresentation compared to MASLD (35%), MetALD (44%), and the non-SLD group (32%) ($p < 0.005$). Nineteen percent of the MetALD group had a longer education, which was more than in the other groups ALD (14%) MASLD (10%) SLD (15%). A third (34%) of the ALD group lived alone, which was significantly more than in MASLD (22%), MetALD (21%), or 23% within the non-SLD group ($p < 0.005$). After adjusting for known risk factors for liver fibrosis, the likelihood of TE ≥ 8 was greater for men (OR 2.3; 95% CI 1.8–3.0), individuals with an income below 40, 000€ (OR 2.0; 95% CI 1.3–3.1), and those living alone (OR 1.3; 95% CI 1.1–1.8). These odds escalated for TE ≥ 12, signifying that being female, earning a higher income, and cohabiting independently decreased the risk of severe liver fibrosis.
Conclusion: Our study reveals that individuals with ALD are more likely to have a lower income, be unemployed, and live alone, while those with MetALD often possess higher educational levels. Being female, earning a high income, and living with a partner emerge as protective factors against liver fibrosis in these populations.

Background and aims: The risk of HCC development following HCV cure as a function of liver fibrosis regression is unknown. The aim of this study was to describe and analyze the dynamics of liver fibrosis assessed by both liver histology and non-invasive tests (NIT) at baseline and at the time of HCC occurrence several years after sustained virological response (SVR).
Method: Data were obtained in two prospective French multicenter cohorts of patients with HCV infection recruited since 2006 (ANRS CO22 Hepather and CO12 CirVir). Patients were regularly followed-up and when indicated included in HCC surveillance programs. The dynamics of NIT (Fib4, APRI and LSM) were evaluated in relation to HCC development and histological liver fibrosis in HCC patients was assessed.
Results: 8808 SVR patients (3500 with cirrhosis) were analyzed, among whom 298 (3.6%) HCC occurred during a 62-months follow-up. In the 3500 patients with cirrhosis, all baseline NIT tests (Fib4, APRI, LSM) were higher in patients who ultimately developed HCC. Except for Fib4 in patients who developed HCC, all NIT decreased significantly over time irrespective of subsequent HCC development with a maximum downward slope following antivirals implementation (all $p < 0.005$). This temporal dynamic was similar for all tests irrespective of HCC development ($p = 0.91$, $p = 0.29$ and $p = 0.37$, respectively). Joint modelling of association between the change in NIT and HCC showed that a unit decrease in APRI or Fib-4 scores at any time of follow-up were associated with a decreased HCC risk (HR = 0.62 [0.57–0.69] and HR = 0.91 [0.90–0.93], both $p < 0.0001$). Thirty-eight non-tumour liver biopsies specimen were analyzed at

time of HCC diagnosis, 37/38 (98%) patients having F3 or F4 fibrosis scores before SVR. At time of HCC diagnosis, this proportion was 33/38 (86%) The analysis of fibrosis evolution showed that 7/38 (18%) HCC patients were considered as having liver fibrosis regression (F0: 1 patient, F1: 2 patients, F2: 2 patients, F3: 2 patients). More precisely, 4 patients had a one-point regression and 3 had more than one point of fibrosis regression. Overall, values of NIT tests in these patients suggested the presence of advanced liver fibrosis at the time of HCC.
Conclusion: HCC occurs despite histological fibrosis regression following HCV cure. The dynamics of NIT may not accurately reflect histological fibrosis changes and may not be sufficient to refine HCC surveillance strategy.

OS-061

Chronic hepatitis C virus infection induces HCC risk by perturbing the human liver circadian transcriptome and epigenome through deregulation of the deacetylase SIRT1

Background and aims: Chronic liver disease (CLD) progressing to hepatocellular carcinoma (HCC) is a global health challenge. The role of the circadian clock (CC) as a regulator of liver physiology and disease is well established in rodents. However, in the human liver, the status of the CC-oscillator as well as the identity and the epigenetic landscape of circadian gene networks in CLD remain largely unknown. Despite a major research effort, the pathogenesis of hepatitis C virus (HCV)-induced liver disease and HCC is still only partially understood. Here, we aimed to investigate how HCV perturbs the liver CC to cause CLD and HCC.
Method: By performing circadian RNA- and ChIP-sequencing of livers from control and HCV-infected humanized liver chimeric mice (HM mice) combined with their analyses through *dryR* and JASPAR enabled us to identify genes in human liver displaying a circadian expression pattern and their epigenetic landscape under control condition and their perturbation upon HCV-infection. Through molecular analyses we validated key circadian genes and pathways which were perturbed by HCV in human hepatocytes and associated with risk to progress to HCC. Employing cellular models for HCV infection and perturbation studies, we identified the mechanism of HCV-induced CC perturbation. The clinical impact of these findings was validated with investigations in four independent cohorts of patients with chronic hepatitis C progressing to HCC.
Results: We identified numerous genes and biochemical pathways which are rhythmically expressed in the human hepatocytes under control conditions. Amongst rhythmic genes in human hepatocytes we identified master transcription factors, chromatin modifiers and key enzymes regulating different biochemical pathways. We show that HCV infection deregulates the human liver CC, circadian transcriptome, and epigenome, leading to an activation of key pathways mediating metabolic alterations, fibrosis, and cancer. Using cellular models for HCV infection, we identified the non-structural viral encoded proteins NS4 and NS5A to reduce the expression of deacetylase SIRT1. This reduction in SIRT1 levels leads to a decreased expression of key CC component BMAL1 and a concomitant virus-induced perturbation of the hepatocellular clock. HCV-disrupted circadian pathways remain deregulated in patients following HCV cure and advanced liver disease suggesting that the virus-induced perturbation of the liver CC plays a key role in HCC pathogenesis.
Conclusion: We have identified circadian genes and gene regulatory networks in human liver cells under control conditions and upon HCV infection, a major cause of CLD and HCC. We show that virus-induced alteration of the liver clock drives the perturbation of key genes and pathways implicated in HCC development. These results provide opportunities for HCC prevention and discovery of biomarkers to predict HCC risk.

OS-062

Long-term liver morbidity and mortality after HCV elimination by direct-acting antivirals in patients with chronic hepatitis C: results from a large-scale, multicenter cohort study

Email: e.ogawa.a65@m.kyushu-u.ac.jp

Background and aims: Treatment of hepatitis C with direct-acting antivirals (DAAs) results in permanent viral clearance (SVR) in the vast majority of patients with chronic hepatitis C (CHC). Many reports have shown that SVR is associated with a significant reduction of liver

morbidity and mortality for up to approximately five years. The aim of this study was to assess long-term liver-related outcomes and mortality after SVR by DAA treatment.
Method: This multicenter, retrospective cohort study consisted of 3, 128 consecutive adult CHC patients without decompensated cirrhosis who were treated with all-oral DAAs. After excluding patients who did not achieve SVR, 3, 024 were included in this study (2, 691 non-HCC experienced, 333 HCC experienced). The index date was the end of DAA treatment. Primary end points were the occurrence or recurrence of hepatocellular carcinoma (HCC), mortality, and the cause of death.
Results: The median follow-up durations were 6.6 (range 0.3–8.9) and 6.3 (range 0.3–8.9) years for the non-HCC and HCC experienced groups, respectively. Although the cumulative de novo HCC incidence rates were longitudinally increased (3-year, 4.0%: 5-year, 5.6%: 8-year, 7.0%), those of the recurrence rates reached a plateau in 3–5 years (3-year, 50.4%: 5-year, 59.1%: 8-year, 62.0%). None of the patients aged under 50 (n = 377) developed de novo HCC. In contrast, for patients with cirrhosis aged 50 and over (n = 536), the cumulative de novo HCC incidence rates were high (3-year, 11.2%: 5-year, 15.6%: 8-year, 18.9%). Even in patients without cirrhosis, the 8-year cumulative de novo HCC incidence increased with age (age 50–59, 1.8%: age≥60, 5.5%: age≥75, 8.7%) (log-rank test: P < 0.001). The 3-year, 5-year, and 8-year survival rates for patients with HCC were 85.2%, 74.6%, and 67.4%, respectively. 74% of the deaths were caused by liver-related complications, mainly HCC recurrence. For patients in the non-HCC group, 72% of the deaths were caused by non-liver-related complications (43% non-liver cancer, 20% cerebral/cardiovascular disease).
Conclusion: DAA treatment improves liver-related morbidity and survival irrespective of HCC experience. Non-cirrhotic patients aged over 60 should be considered for long-term HCC surveillance.

OS-063

What happens to HCV incidence after WHO elimination goal is met? Agent-based modeling predicts sustained availability of direct-acting antivirals among people who inject drugs is required to prevent returning to pre-elimination levels

Eric Tatara[1,2], Louis Shekhtman[3,4], Nicholson Collier[1,2], Marian Major[5], Jonathan Ozik[1,2], Basmattee Boodram[6], Harel Dahari[3].
[1]Consortium for Advanced Science and Engineering, University of Chicago, Chicago, IL, United States; [2]Decision and Infrastructure Sciences, Argonne National Laboratory, Argonne, IL, United States; [3]Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Loyola University Chicago, Maywood, IL, United States; [4]Department of Information Science, Bar-Ilan University, Ramat Gan, Israel; [5]Division of Viral Products, Center for Biologics Evaluation and Research, Food and Drug Administration, Silver Spring, MD, United States; [6]Division of Community Health Sciences, School of Public Health, University of Illinois at Chicago, Chicago, IL, United States
Email: harel.dahari@gmail.com

Background and aims: Persons who inject drugs (PWID) are at high risk for acquiring and transmitting hepatitis C virus (HCV). Direct-acting antiviral (DAA) therapy leads to high cure rates. However, high rates of reinfection after cure in PWID and the lack of protective immunity require access to multiple DAA treatments per person to reach the World Health Organization (WHO) goal of HCV elimination, defined as 90% HCV incidence reduction by 2030. A major public health concern is that treatment will be stopped or significantly reduced once the WHO elimination goal is met due to reduced funds or complacency. We use an agent-based model (ABM) to study the effects of varying levels of enrollment in DAA treatment among HCV infected PWID from Chicago, IL and surrounding suburbs and the effects of stopping access to DAAs after 2030.
Method: We extended our Hepatitis C Elimination in PWID (HepCEP) ABM [PMID: 32624641] to identify and optimize DAA therapy scale-up and treatment strategies. HepCEP uses a mathematical model to determine transmission probabilities relative to the HCV RNA titers of needle/syringe-sharing donors [PMID: 29997251]. Individual temporal viral load profiles are sampled from unique distributions for acute, chronic and reinfected individuals, and for individuals undergoing DAA treatment. DAA treatment enrollment is modelled as (unbiased) random sampling of chronically infected PWID and the annual target enrollment rate, defined as the total annual treatment enrollment as a fraction of the total PWID population, is a model parameter with a range of 2.5–10%. Access to DAAs is started in 2020 and provided through 2030, after which DAA treatment is stopped. We compared the rates of new chronic infections for different combinations of DAA enrollment and frequency of DAA treatment courses, from 2020–2030 when DAAs are available and after 2030 when DAA treatment is stopped.
Results: The model predicts that elimination can be achieved in the PWID population by 2030 for DAA enrollment rates ≥ 7.5% (75 per 1000 PWID). When DAA treatment is stopped in 2030, the rate of new chronic HCV infections rapidly increases and exceeds the WHO 2030 goal within 12 months, regardless of the enrollment rate prior to 2030.
Conclusion: Modeling results indicate that DAA scale-up of >7.5% is projected to achieve the WHO target of 90% HCV incidence reduction by 2030. HepCEP model simulations underscore the importance of DAA scale-up without any re-treatment prohibition to achieve significant reductions in HCV incidence when the rates of reinfection among PWID networks are high. Unrestricted re-treatment with enrollment rates of ≥ 7.5% should remain beyond 2030 to maintain the WHO elimination goal and prevent resurgence of HCV incidence to current levels. Our data also underscore the importance of other intervention strategies to maintain the elimination goal, such as syringe exchange programs and vaccines.

OS-064

Outcomes following liver transplantation from HCV-seropositive donors to HCV-seronegative recipients

Margaret C. Liu[1], Josiah McCain[2], Isabella Reitz[3], Alyssa K. McGary[4], Bashar Aqel[1], Surakit Pungpapong[2], Rolland Dickson[1]. *[1]Mayo Clinic Arizona, Phoenix, United States; [2]Mayo Clinic Florida, Jacksonville, United States; [3]Mayo Clinic Alix School of Medicine, Scottsdale, United States; [4]Mayo Clinic Arizona, Scottsdale, United States*
Email: liu.margaret@mayo.edu

Background and aims: The introduction of Direct-Acting Antiviral Agents (DAA) has provided an opportunity to transplant organs from hepatitis C virus (HCV) seropositive donors into HCV RNA negative recipients to help address the donor organ shortage. In 2020, our institution reported outcomes from 34 HCV-seronegative liver transplant (LT) recipients who received HCV-seropositive donors. Our current study expands this group with longer-term follow-up to further assess the outcomes of HCV-seropositive donors for LT.
Method: We conducted a retrospective observational study of HCV RNA negative recipients who received LT grafts from HCV-seropositive donors. Continuous variables were summarized using median and range, and categorical variables were summarized using the frequency and percentage. Comparisons between the groups were performed using Wilcoxon rank sum test for continuous variables and Fisher's exact test for categorical variables. The overall survival and graft survival between the groups were evaluated using Kaplan-Meier curves and compared using the log-rank test. All analysis was performed using R 4.0.3. All tests were 2-sided, and a p value <0.05 was considered statistically significant.
Results: There were 103 HCV RNA negative recipients who received HCV-seropositive grafts (51 HCV-viremic, 52 non-viremic). The median MELD at listing was 18 for both viremic and non-viremic groups. Primary etiologies of liver disease were metabolic dysfunction-associated liver disease (31%) and alcohol (28%). Other etiologies included HCV s/p DAA therapy with sustained virologic response (SVR) at the time of listing (5%) and previous allograft failure (3%).

Twenty-two recipients (21%) underwent simultaneous liver-kidney transplant. Fifty-one patients (50%) developed post LT HCV viremia, 1/51 (2%) from non-viremic donors and 50/51 (98%) from viremic donors. DAA treatment was started at a median of 18 days (range 5–103 days) after LT. Median pre-treatment viral load was 1980000 IU/ml (range 529–100000000). SVR was defined as undetectable HCV RNA 12 or more weeks post-DAA treatment completion and this was achieved in 48/48 with adequate data; three patients did not have an RNA checked after 12 weeks (1 death, 2 lost to follow-up). There was no statistically significant difference in graft ($p = 0.3$) or patient survival ($p = 0.6$) between the viremic and non-viremic groups. Overall graft and patient survival were 99% and 99% at 1 year, 99% and 95.9% at 2 years, and 99% and 95.9% at 3 years, respectively. No graft loss was related to recurrent HCV.

Conclusion: Our study demonstrates that liver transplantation with HCV-seropositive donors (both viremic and non-viremic) has excellent outcomes in both short and longer-term follow-up, including up to 3 years post-transplantation. Future studies should aim to evaluate a larger sample size and longer-term outcomes.

Acute liver failure and drug-induced liver injury

OS-065

Cerebral oedema at autopsy in acute liver failure: relationship to clinical features and changes over time

William Bernal[1], Mark J W McPhail[2], Pervez Ali Khan[1], Stacey Calvert[1], Robert Loveridge[1], Christopher Willars[1], Tasneem Pirani[1], Sameer Patel[1], Georg Auzinger[1], Julia Wendon[1]. *[1]Liver Intensive Therapy Unit, Kings College Hospital, London, United Kingdom; [2]Institute of Liver Studies, Kings College Hospital, London, United Kingdom*
Email: william.bernal@kcl.ac.uk

Background and aims: Cerebral Oedema (CO) in acute liver failure (ALF) may cause intracranial hypertension (ICH) and fatal cerebral herniation (CH). Reports assessing clinical signs of ICH suggest a falling prevalence over time. In a large series of ALF patients we assessed autopsy findings of CO and CH and their relation to clinical signs and changes over time.

Method: all autopsies of adult patients with ALF at a single specialist centre 2000–22 were studied. CO was classified with brain autopsy signs of external/cut surface swelling, flattened gyri, narrowed sulci or ventricles. Severe CO was present with additional signs of CH. Presentation of ALF was classified as Hyper-acute (HA), Acute (A) or sub-acute (SA) and clinical signs of ICH included pupillary and reflex abnormalities, and administered treatment.

Results: During the study period 1570 patients with ALF were admitted of whom 311 died at median 5 (1–15) days after admission. Mortality fell from 23% in 2000–09 to 18% in 2010–2022. 137 (44%) of those who died underwent autopsy examination. Median age was 44 (IQR 35–56) yrs, 57% female, 58% paracetamol overdose related. Peak hepatic encephalopathy (HE) grade was 3 (3–4) and 21% had clinical signs of ICH and died 1 (0–5) day later.

Overall, at autopsy 28% had findings of CO, in 7% with CH. CO was present in 33% with HA, 16% A and 8% SA presentations. CH was present only in HA cases. 51% of those with autopsy findings of CO did not have clinical signs of ICH, and 38% of those with apparent clinical signs did not have autopsy findings of CO-however 75% with autopsy findings of CH had pre-mortem clinical signs of ICH.

Evaluating only HA cases, autopsy CO closely related to patient age: present in 59% of age 16–30 yrs, 35% 30–50 yrs and 14% >50 yrs ($p < 0.01$), with CH in 29% 16–30 yrs, 7% 30–50 yrs and none >50 yrs ($p < 0.005$). Admission arterial ammonia was highest in those with CH: no CO 83 (43–117) vs. 144 (111–269) CH ($p < 0.01$). There was no difference in prevalence of CO comparing cases 2000–2009 with 2010–22, (28% in both eras) and no effect of era on adjusted multivariate analysis.

Conclusion: Autopsy findings confirm that CO occurs in only a minority of the most severely ill patients with ALF and severe HE and is associated with young age, HA presentations and high arterial ammonia concentration, features which identify those who may benefit from enhanced monitoring for ICH. CH is very rarely present. Clinical signs were unreliable predictors of CO except when severe. The prevalence of CO at autopsy has not changed significantly over time despite improvements in spontaneous survival in ALF.

OS-066-YI

Polyreactive immunoglobulin G is elevated in autoimmune hepatitis and drug-induced autoimmune-like hepatitis compared to self-limiting drug-induced liver injury

Theresa Kirchner[1], Alejandro Campos-Murguia[1], George Dalekos[2], Kalliopi Zachou[2], Mercedes Robles-Díaz[3], Raul J. Andrade[4], Marcial Sebode[5], Ansgar W. Lohse[6], Maciej Janik[7], Piotr Milkiewicz[8], Mirjam Kolev[9], Nasser Semmo[9], Tony Bruns[10], Tom J.G. Gevers[11], Benedetta Terziroli[12], Heiner Wedemeyer[13], Elmar Jaeckel[14], Richard Taubert[1], Bastian Engel[1]. *[1]Hannover Medical School, Hannover, Germany; [2]General University Hospital of Larissa, Larissa, Greece; [3]University Hospital Virgen de la Victoria, Malaga, Spain; [4]Serv Aparato Digestivo, Malaga, Spain; [5]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [6]University Medical Center Hamburg-Eppendorf, Hannover, Germany; [7]Medical University of Warsaw, Warsaw, Poland; [8]Pomeranian Medical University, Warsaw, Poland; [9]Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [10]Department of Medicine III, University Hospital RWTH Aachen, Aachen, Germany; [11]Department of Gastroenterology and Hepatology, Maastricht University Medical Centre, Maastricht, Netherlands; [12]Epatocentro Ticino, Lugano, Switzerland; [13]Medizinische Hochschule Hannover, Hannover, Germany; [14]University of Toronto, Toronto, Canada*
Email: Engel.Bastian@mh-hannover.de

Background and aims: Drug-induced liver injury (DILI), drug-induced autoimmune-like hepatitis (DI-ALH) and autoimmune hepatitis (AIH) are difficult to differentiate from each other as they often share various clinical characteristics. Recently, polyreactive immunoglobulin G (pIgG) was identified as a novel marker for the diagnosis of AIH in a multicenter study. However, the study included only few DILI cases. This retrospective multicenter study aims to evaluate the diagnostic capacity of pIgG to predict AIH in comparison to DI-ALH, DILI, vaccinia-induced liver injury (VILI) and non-AIH-non-DILI-liver disease (non-AIH-non-DILI-LD).

Method: Samples from 125 patients (AIH n = 82, DI-ALH n = 9, DILI n = 23, VILI n = 11) were recruited from existing biorepositories from 9 centers across Europe. Quantification of pIgG was done using an in-house ELISA with reactivity against human huntingtin-interacting protein 1-related protein in bovine serum albumin blocked ELISA (HIP1R/BSA) as published.

Results: There was no significant difference in median age ($p = .95$) and sex distribution ($p = .14$). Median ALT was highest in patients with DI-ALH (38.4 times upper limit of normal (xULN)) while it was lower in AIH (16.1 xULN) and DILI (8.7 xULN). Median alkaline phosphatase was lowest in AIH (1.11 xULN; DI-ALH: 1.9 xULN; DILI: 2.0 xULN; VILI: 1.9 xULN; $p = 0.001$). Positive serology (any positivity for ANA/SMA/SLA/LKM ≥1/40) was significantly more frequent in AIH (97%), DI-ALH (100%) and VILI (91%) compared to DILI (79%, $p = .002$). Median IgG elevation was significantly lower in the DILI-group (0.8 × ULN; AIH: 1.1 × ULN; DI-ALH: 0.9 × ULN; VILI 1.0 × ULN; $p = .001$). No patient in the DILI-group received immunosuppressive treatment (98% in AIH-, 100% in DI-ALH- and 82% in VILI-group; $p = .000$) while 99% in the AIH-group had immunosuppressive treatment six months after diagnosis (0% in DI-ALH-group, $p = .000$). Median pIgG levels

were significantly higher in the AIH- (1.9 nAU; p < 0.001) and DI-ALH-group (1.6 nAU; p = .04) compared to the DILI-group (1.1 nAU). No significant difference in pIgG levels was seen in AIH vs. DI-ALH and AIH vs. VILI. When comparing AIH to DILI, sensitivity and overall accuracy of pIgG (78%/74%), ANA (77%/70%) and SMA (76%/74%) were comparable. Specificity for LKM (100%) and SLA (91%) was higher compared to pIgG (61%), ANA (46%) and SMA (67%). In a second step the cohort was compared to a non-AIH-non-DILI-LD group (n = 596) that was published before. pIgG levels were significantly higher in the AIH- (p < 0.002), DI-ALH- (p = .003) and VILI-groups (p = .01) while they were comparable between DILI and non-AIH-non-DILI-LD.
Conclusion: Immune-mediated liver diseases (AIH, DI-ALH) were characterized by significantly higher pIgG levels compared to DILI. Therefore, pIgG determination might help to identify patients with self-limiting DILI avoiding unnecessary immunosuppressive treatment.

OS-067

Specific metabolomic and bile acid profiles and their relationship with gut microbiota composition in patients with drug-induced liver injury

Sara Román-Sagüillo[1], Raisa Quiñones Castro[2], Alba González-Robles[1], María Juárez-Fernández[1,3], Susana Martínez-Flórez[1], Javier González-Gállego[1,3], Francisco Jorquera[1,2,3], María-Victoria García-Mediavilla[1,3], Camilla Stephens[3,4], Mercedes Robles-Díaz[3,4], Esther Nistal[1,3], Ramiro Jover[3,5], Sonia Sánchez-Campos[1,3]. *[1]Instituto Universitario de Biomedicina (IBIOMED), Universidad de León, León, Spain; [2]Complejo Asistencial Universitario de León, Servicio de Aparato Digestivo, León., León, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain; [4]Unidad de Gestión Clínica de Aparato Digestivo y Servicio de Farmacología Clínica, Instituto de Investigación Biomédica de Málaga-IBIMA, Hospital Universitario Virgen de la Victoria, Facultad de Medicina, Universidad de Málaga, Málaga, Spain; [5]Hepatología Experimental, IIS Hospital La Fe and Dep. Bioquímica y Biología Molecular, Universidad de Valencia, Valencia, Spain*
Email: sroms@unileon.es

Background and aims: Drug-induced liver disease (iDILI) is a multifactorial hepatic disease considered as the fifth cause of liver-related death worldwide and one of the main causes of acute liver failure in the Western world. Bile acids (BAs) are signaling molecules closely related to iDILI progression and development. In this sense, gut microbiota plays a key role not only in the progression of several hepatic diseases but also in BA metabolism and homeostasis. Thus, our aim is to elucidate the existence of BA and metabolomic profiles associated to iDILI patients, as well as a particular gut microbiota composition pattern linked to this metabolic signature.
Method: 46 patients were divided in 3 groups: healthy controls (C), patients with non-acute hepatitis as a liver damage control group (H) and iDILI patients (iDILI). Blood and stool samples were obtained to perform biochemical analysis, determination of serum and fecal bile acids (BAs) as well as metagenomic and metabolomic examination. Moreover, correlation analyses were carried out.
Results: Significative differences were observed between C, H and iDILI. ALT, AST, ALP, GGT and total bilirubin levels were significantly increased in iDILI and H groups compared to C, whereas albumin concentration were markedly decreased, confirming the hepatic injury and dysfunction. Total and conjugated BAs in serum showed a significant increase in iDILI and H groups in comparison with C while unconjugated BAs were significantly reduced. Regarding fecal BAs, a significant reduction in the main secondary BAs was observed in iDILI compared to C. Moreover, a reduction in fecal metabolites such as n-acetylglutamic acid, dodecanedioic acid and pyridoxamine was observed in iDILI compared to the other groups. Concerning metagenomic analysis, a particular microbiota profile linked to iDILI was identified highlighting a reduction in Barnesiellaceae family and *Barnesiella*, *Clostridia UCG014* and *Eubacterium* genus as well as an increase in *Alloprevotella* genera in comparison with the other groups. Additionally, correlation analyses showed significative associations between concrete taxa, the BA profile and the fecal metabolome, highlighting the genus *Barnesiella* and *Eubacterium* and their positive correlation with fecal secondary BAs.
Conclusion: iDILI patients showed a particular BA profile and a defined metabolome which could be related to specific modifications in gut microbiota composition. However, more studies are needed.

Urinary amatoxin concentration as an early predictor for liver toxicity in patients with amanita spp poisoning

Ona Escoda[1], Valle Molina[2], Àngels Gispert[3], Cándido Díaz-Lagares[4], Xavier Ichart[5], Cristina Solé[6], Lídia Martínez[7], Emilio Salgado[1], Jordi To-Figueras[1], Santiago Nogué[8], Enric Reverter[1]. *[1]Hospital Clínic, Barcelona, Spain; [2]Clínica Universitaria de Navarra, Navarra, Spain; [3]Hospital Universitari Dr. Josep Trueta, Girona, Spain; [4]Hospital Vall d'Hebron, Barcelona, Spain; [5]Hospital Arnau de Vilanova, Lleida, Spain; [6]Hospital Universitari Parc Taulí, Sabadell, Spain; [7]Hospital Sant Joan de Déu, Esplugues de Llobregat, Spain; [8]Hospital Clinic, Barcelona, Spain*
Email: ereverte@clinic.cat

Background and aims: Mushroom poisoning with *Amanita phalloides* can lead to severe liver injury and associates a mortality around 15%. Early prognostic factors for liver injury development are lacking though a pilot study proposed urinary amatoxin concentration as a prognostic biomarker. In this multicenter study we aimed at validating and refining the prognostic role of urinary amatoxin quantification in patients with *Amanitin spp.* intoxication.
Method: 115 patients from 7 centres with a clinical diagnosis of *Amanita spp*. intoxication and in whom urinary amatoxins were determined (2002–22, ELISA technique) were retrospectively collected. We assessed the association of urinary amatoxin and other baseline variables with liver outcome variables: peak ALT, minimum prothrombin (%), severe hepatotoxicity (ALT>1000 U/L), severe acute liver injury (sALI, INR>1.5), acute liver failure (ALF, encephalopathy), transplantation and death.
Results: 115 patients (57% male, mean age 49.8 years) were included, 56 of whom had positive urinary amatoxins (mean concentration 32.9 ng/ml). Ninety-nine of 115 determinations were done within the first 48 hours after intake. Forty-three patients presented an increase in ALT/ALT levels and 25 had ALT>1000 U/L (20/56 among positive amatoxin patients and 5/59 among negative amatoxin patients). The five patients with negative urinay amatoxins developing hepatotoxicity had a late quantification (>48 h after intake). Among 25 patients with severe hepatotoxicity, 24 also developed sALI and 6 of them ALF (1 transplantation and 4 deaths). Urinary amatoxin concentration and prothrombin, along with other baseline variables, were the strongest predictors of all liver-related end points: peak ALT (with creatinine and haemoglobin), minimum INR and ALT>1000 U/L (with leucocyte and intake-quantification interval) and severe ALI (with intake-quantification interval). Predictions of ALT>1000 U/L and severe ALI were highly accurate with the resulting models with AUC/Nagelkerke R^2 of 0.918/0.624 and 0.908/0.549, respectively. Amatoxin concentrations >55 ng/ml were highly predictive of hepatotoxicity and severe ALI (10/11 patients) while a negative value within 48 h of intake ruled out the development of severe hepatotoxicity.
Sub-analysis in patients admitted within 48 h of intake (n = 99), in those with normal ALT at admission (n = 89) and only in positive amatoxin patients (n = 56), yelded similar results as in overall cohort.
Conclusion: In patients with *Amanitin spp.* poisoning, urinary amatoxin concentration and baseline prothrombin were the strongest predictors of hepatotoxicity and severe ALI. Urinary amatoxins >55 ng/ml identified patients at extremely high-risk, while negative

values within 48 h of intake ruled out the development of hepatotoxicity.

OS-069

3D bioengineered liver for the study of acute and chronic hepatic damage

Ainhoa Ferret Miñana[1], Estefania Alcaraz[2], Raquel Horrillo[2], Javier Ramon Azcon[1,3], Francesco De Chiara[1]. *[1]Institute for Bioengineering of Catalonia, Barcelona, Spain; [2]Grifols, Barcelona, Spain; [3]ICREA-Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain*
Email: aferret@ibecbarcelona.eu

Background and aims: The liver faces acute and chronic insults that disrupt its normal function. Acute damage, caused by toxins or infections, triggers inflammation and necrosis. Chronic insults, such as alcohol abuse or viral hepatitis, lead to fibrosis, cirrhosis, and hepatocellular carcinoma, posing significant clinical challenges. Fibrosis is a hallmark of liver damage driven by the activation of hepatic stellate cells (HSCs). Understanding the mechanisms underlying acute and chronic liver damage is crucial for developing effective treatments. Traditional liver models face several limitations. 2D cultures cannot maintain liver phenotype and functions for extended periods, making it difficult to model chronic exposure. Additionally, replicating fibrosis in 2D cultures is challenging due to HSC activation on plastic or glass surfaces. As a result, 3D models have emerged as a more physiologically relevant cellular microenvironment for investigating disease progression, identifying potential therapeutic targets, and developing new drugs.
Method: We developed a 3D liver using human hepatocytes, HSCs, and monocytes. The cells were encapsulated in a mixture of gelatin methacryloyl and carboxymethyl cellulose methacrylate, and LAP as a photo-initiator. The 3D livers were kept in culture for up to 30 days in serum-free medium. They were challenged with acetaminophen and LPS (APAP-LPS), known hepatotoxic compounds, to recreate the pathophysiological phenotype of liver damage in vitro. Dexamethasone was used as an anti-inflammatory drug to test the ability of 3D livers to predict drug efficacy.
Results: Extensive liver damage characterized by hepatic stellate cell (HSC) activation and proliferation was observed upon challenge with APAP-LPS. These cells exhibited the myofibroblast phenotype typical of activated HSCs. Additionally, impaired gene expression of hepatocyte functionality markers was observed. The transition from monocytes to proinflammatory cytokine-releasing macrophages measured the inflammation level. Dexamethasone demonstrated potent beneficial effects, reducing hepatocyte damage, inhibiting HSC activation, and decreasing collagen production. These results were observed in both acute and chronic models.
Conclusion: The 3D model presented here demonstrates its value as a versatile platform for drug screening in both acute and chronic liver damage scenarios. Its ability to reproduce critical features of liver pathophysiology, including hepatocyte functionality impairment, HSC activation, and inflammation, makes it a valuable tool for studying liver diseases and evaluating potential therapeutic interventions. Furthermore, the adaptability of this model for high-throughput screening provides an opportunity to accelerate the drug discovery process and improve patient outcomes in liver damage-related conditions.

Gut microbiota and liver disease

Patel[2,6,7], Julian R. Marchesi[4], Saeed Shoaie[1], Ivan Liachko[3], Simon Goldenberg[8], Debbie L. Shawcross[2,6]. *[1]Centre for Host Microbiome Interactions, King's College London, Faculty of Dentistry, Oral and Craniofacial Sciences, London, United Kingdom; [2]Institute of Liver Studies, King's College London, Department of Inflammation Biology, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, London, United Kingdom; [3]Phase Genomics Inc., Seattle, United States; [4]Imperial College London, Faculty of Medicine, Department of Metabolism, Digestion and Reproduction, London, United Kingdom; [5]Centre for Clinical Infection and Diagnostics Research, Department of Infectious Diseases, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [6]Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom; [7]The Roger Williams Institute of Hepatology, The Foundation for Liver Research, London, United Kingdom; [8]Centre for Clinical Infection and Diagnostics Research, Department of Infectious Diseases, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*
Email: lindsey.edwards@kcl.ac.uk

Background and aims: The World Health Organization States Antimicrobial Resistance (AMR) is "the biggest threat to global health." Patients with cirrhosis are at high risk for AMR because of frequent antimicrobials, regular invasive procedures such as large-volume paracentesis, and recurrent hospitalisations. Gastrointestinal tract (GIT) carriage of Antibiotic Resistance Genes (ARGs) increases with advancing cirrhosis and is associated with increased hospitalisation and mortality. Microbiota perturbations, intestinal inflammation, and barrier damage boost ARG carriage and susceptibility to infection. Translocation of bacteria and their products across the gut-epithelial-barrier induces cirrhosis-associated immune dysfunction. We hypothesised that faecal microbiota transplant (FMT) may reduce GIT ARG carriage and enhance intestinal barrier function and mucosal immunity.
Method: 32-patient prospective, randomised, single-blinded, placebo-controlled trial evaluating jejunely-transplanted FMT [50 g] against placebo [PROFIT Trial: NCT02862249] in patients with advanced stable cirrhosis (MELD 10–16). We assessed the impact of FMT/placebo 7, 30 and 90-days post-intervention on enteric pathogen and ARG carriage. Plasma and faecal cytokines, gut barrier integrity markers (electrochemiluminescence/ELISA), metabonomics (^{1}H-NMR), and faecal proteomics were performed. Phase-Genomics-ProxiMeta™-Metagenome-Deconvolution was undertaken to capture co-located-DNA enabling strain-level assignment of phages/ARGs within microbes, not previously possible.
Results: FMT reduced intestinal barrier damage and modified mucosal and systemic inflammation. 20% of participants were colonised with Multi-Drug-Resistant-Organisms including vancomycin-resistant *Enterococci*. FMT virtually eradicated carriage of *Enterococcus faecalis,* Enteropathogenic *Escherichia coli* (EPEC) and ARG [e.g., vanD contributing to vancomycin resistance in *E. faecalis*]. A healthy phagosome, *via* bacterial lysis, drives microbial diversity and stabilizes microbial populations. We observed bacteriophage network remodelling post-FMT such as the presence of beneficial phages from the family *Oscillospiraceae* which includes

Faecalibacterium prausnitzii. This contrasted with loss of phages from *E. faecalis*, EPEC and *Klebsiella*. Faecal proteomics quantified 301 proteins modified post-FMT, including enzymes involved in host/microbial immuno-metabolism alongside reduced proteins involved in bacterial virulence and AMR.

Conclusion: FMT increased gut microbial richness, reduced carriage of enteric pathogens, and reduced vancomycin-associated ARGs. This was associated with favourable phage network remodelling. FMT reduced intestinal barrier damage and systemic inflammation. Findings support continued evaluation of FMT as a treatment to reduce AMR in cirrhosis.

OS-071-YI

Variation of the human microbiome across multiple body sites and temporal dynamics in different stages of decompensated cirrhosis

Email: wenyi.gu@ukmuenster.de

Background and aims: Bacterial infections and/or translocation are major precipitants for acute decompensation (AD) in cirrhosis and for the development of acute-on-chronic liver failure (ACLF). This study explores high and low biomass microbiomes across different body compartments and their correlations with development of ACLF in cirrhosis.

Method: The study included 93 patients with decompensated cirrhosis from the PREDICT study, categorized into four groups based on their disease course: stable decompensated cirrhosis (SDC), unstable decompensated cirrhosis (UDC), pre-ACLF, and ACLF at admission.

We analyzed microbiome variations, using 16S metabarcoding optimized for low biomass and complex microbiomes. We longitudinally (up to 308 visits per compartment) analyzed microbiome variations across 11 anatomical locations, including buffy coat, saliva, upper gastrointestinal (GI) tract mucosa biopsies, lower GI tract mucosa biopsies, and feces. The analysis of microbiome correlations with clinical parameters and disease outcomes was conducted using workframes and tools like PLS-DA, ANCOM II, and SECOM.

Results: The analysis revealed that alpha and beta diversity of microbiome communities depends on the sample sites. Notably, microbiome load in buffy coat increased with cirrhosis severity in non-ACLF patients (SDC, UDC and pre-ACLF) ($p = 0.023$). Additionally, increased dissimilarity in longitudinal samples from different sites from patients who developed ACLF were observed, probably due to bacterial translocation.

Significant correlations were observed between different taxa across various GI tract compartments, suggesting potential bacterial migration from one compartment to another.

In saliva and upper GI, a positive correlation was found between relative abundance of *Lactobacillales* and ACLF severity. Increased *Pseudomonas* levels are significantly linked to the bacterial infections as precipitant of AD in the upper GI. In the lower GI, *Enterobacterales* abundance correlated with model of end-stage liver disease-sodium (MELD-Na) and CLIF-C AD score. *Enterobacterales* was highly increased in small bowel biopsies (duodenum) in ACLF compared to pre-ACLF patients. This association was still relevant after controlling for confounders (e.g. drugs).

Conclusion: This study reveals that dissimilarity of distinct microbiome profiles from different body compartments increased the progression towards ACLF. Further, different taxa are linked to relevant clinical events. Especially in small bowel and buffy coat, the microbiota and bacterial translocation seem to influence ACLF development.

OS-072-YI

Identifying patterns of steatotic liver disease severity: a multi-omic analysis of 834 distinct omics features from healthy to end-stage liver disease in 854 individuals

Email: johanne.kragh.hansen@rsyd.dk

Background and aims: Steatotic Liver Disease (SLD) ranges from simple steatosis to end-stage liver disease. Although specific aspects

of SLD development have been investigated in detail, we still lack a complete understanding of the mechanisms driving the disease. To uncover the potential drivers, we conducted a multi-omics analysis across seven cohorts including both metabolic and alcohol-related aetiologies, exploring the complexity of omics profiles across disease severity ranging from healthy to end-stage liver disease.

Method: Combining seven clinical cohorts, from Denmark and Germany, participants were categorized into six disease severity groups: A) healthy without metabolic or alcohol-related risk factors, B) F0-F1 with at least one risk factor, C) F2, D) F3-F4 incl. MELD-Na <10, E) MELD-Na 10–15, and F) MELD-Na >15. Using linear regression, we did multi-omics analyses of faecal metagenomics, targeted faecal metabolomics, targeted plasma inflammation markers, targeted and untargeted plasma metabolomics, and plasma lipidomics. We clustered omics data to reveal dynamic patterns across the spectrum of disease, identifying features with linear changes and those changing early while turning stable in advanced stages.

Results: We included 854 individuals stratified into disease severity groups: A/B/C/D/E/F 149/348/137/82/103/35. Of 834 omics features measured, 485 were significantly associated with higher levels of disease severity (false discovery rate <0.05). Of 92 circulating inflammation markers, 74 were associated with SLD severity mainly clustered into the linear increasing pattern. The strongest associations were hepatocyte growth factor (effect size = 4.5e-01, p = 1.2e-60) and interleukin 8 (effect size = 6.3e-01, p = 2e-57). Faecal metagenomics (438 microbial species) revealed 272 significant associations. The majority of features (n = 195) tended to decrease in abundance with SLD severity, while 47 features showed a significant increase. The strongest association was increaseing Ruminococcus gnavus (effect size = 2.8e-01, p = 2.3e-15). Targeted and untargeted metabolomics showed a similar trend with mainly significant increasing features. Plasma lipidomics (243 lipids) identified 117 features significantly associated with SLD severity, the majority of which showed a decrease. We could not identify a strong influence of genetic risk factors on the severity of SLD in our data sets.

Conclusion: Our extensive multi-omic analysis of SLD identified 485 key omic features significantly associated with disease severity, providing insights to the complex mechanisms of SLD development. These results highlight unique dynamics in inflammation markers, faecal metagenomics, and plasma metabolomics, set the stage for targeted strategies, and enhance our understanding of pathways from no disease to end-stage liver disease.

Background and aims: The human gut microbiome is recognized as a critical factor in human health. It can be clustered into enterotypes, which are distinct dominant ecological states of the human fecal microbiome that have also been associated with various health and disease states. In many diseases there are both specific alterations of the gut microbiome and a general state of microbial imbalance known as dysbiosis. Although the definition, causes and consequences of this dysbiosis are poorly understood, it is characterized by increased beta-diversity between patient, also in patients with liver disease. This study aims to integrate the concepts of enterotypes and dysbiosis to improve our understanding of the role of the microbiome in liver disease, particularly in patients with decompensated cirrhosis.

Method: The growth of publicly available metagenomic studies allows us to revisit the enterotype concept through an integrated meta-study of 16, 772 fecal metagenomes drawn from 129 studies, including healthy subjects and individuals with pathologies, covering 32 different diseases. We applied fuzzy k-means clustering to the genus-level taxonomic profiles of the samples to define enterotypes. By quantifying the classification strength of each sample for a given enterotype, we introduced an Enterotype Dysbiotic Score (EDS). A lower classification strength, reflecting inconsistency in enterotype assignment across multiple clustering iterations, indicates a higher level of dysbiosis.

Results: Samples from individuals with liver cirrhosis from the MICROB-PREDICT cohorts, as well as from individuals with other pathologies, had a higher EDS than to those from healthy individuals. Among patients with decompensated cirrhosis, those with acute-on-chronic liver failure and those who died within 90 days had more pronounced dysbiotic states compared to the other patients of the cohort. In addition, EDS is associated with the Model for End-Stage Liver Disease (MELD) score, which, when combined, improved prognostic accuracy for survival. To make enterotypes and EDS accessible, we have developed an online 'Enterotyper' tool (https://enterotype.embl.de) that requires no bioinformatic expertise to use. It predicts the enterotypes and the EDS for external cohorts using our reference dataset.

Conclusion: We established a dysbiosis marker that accounts for the underlying microbial ecological states, the enterotypes, and validate the dysbiosis measured by EDS as a key factor in liver disease severity. EDS is associated with disease states and health outcomes, suggesting a biomarker potential and its ability to guide clinical decisions in patients with liver diseases.

N-acetyl-phenylalanine, a new metabolite derived from the intestinal microbiota participating in hepatic steatosis by altering ER-mitochondria communication

Cyrielle Caussy[1], Rémy Lefebvre[2], Nadia Bendridi[2], Chanon Stéphanie[1], Humbert Alexandre[2], Arquier Delphine[3], Ayciriex Sophie[3], Bertocchini Nicolas[1], Margaux Nawrot[1], Vielle-Marchiset Aurélie[1], Pillot Bruno[1], Pinteur Claudie[2], Rohit Loomba[4], Jennifer Rieusset[2]. *[1]CarMeN Laboratory, UMR INSERM U1060/INRA U1393, Pierre-Bénite, France; [2]CarMeN Laboratory, UMR INSERM U1060/INRA U1393, Pierre-Bénite, France; [3]Institut des Sciences Analytiques, Univ Lyon, CNRS, Université Claude Bernard Lyon 1, Villeurbanne, France; [4]NAFLD Research Center, Division of Gastroenterology, La Jolla, United States*
Email: cyrielle.caussy@gmail.com

Background and aims: The gut-liver axis is a key component in the development of metabolic dysfunction-associated steatotic liver disease (MASLD), potentially mediated by microbial aromatic amino acids (AAA) derived from phenylalanine and tyrosine. However, the causal role of AAA in MASLD and their mechanisms of action are unknown. On the other hand, disrupted calcium coupling between the endoplasmic reticulum (ER) and mitochondria, at contact points called mitochondria-associated ER membranes (MAMs), contributes to the development of hepatic insulin resistance and steatosis. Therefore, some microbial AAAs could induce hepatic steatosis by disrupting MAMs and mitochondrial oxidative capacities.
Method: We analyzed the metabolomic profile of serum AAA in a derivation cohort of 156 subjects with and without MASLD assessed by magnetic resonance imaging proton density fat fraction (MRI-PDFF) and in a validation cohorts of 156 subjects with biopsy-proven MASLD, prospectively recruited at NAFLD Research Center, UCSD, USA. The per se pro-steatogenic role of MASLD-associated AAA were assessed using BODIPY, their actions on MAMs were assessed using *in situ* proximity ligation assay and mitochondria function was assessed by measuring oxygen consumption in the presence of palmitate, *in vitro*, in Huh7 cells and primary mouse hepatocytes (PMH, 500 µM, 16 h). Effect of AAA were confirmed *in vivo* in mice fed with candidate AAA (gavage of 20 mg/day) for 4 weeks.
Results: N-acetyl-phenylalanine (NAPA) had a strong correlation with MRI-PDFF hepatic fat content (r: 0.51 $p < 0.001$,) in the derivation cohort and was significantly correlated with the grade of steatosis ($r = 0.21$, $p < 0.01$) in the validation cohort. Serum level of NAPA was significantly correlated with bacterial species from human gut-microbiota using the GUTSY Atlas. *In vitro*, NAPA induces lipid accumulation in both Huh7 (+18.5%, $p < 0.0001$) and PMH (+11.4%, $p <$ 0, 001). It also alters the structure and function of MAMs including a reduction of MAMs in Huh7 (−37.1%, $p < 0.0001$) and PMH (−33.1%, $p <$ 0, 001). The reinforcement of MAMs using a linker prevented the effect of NAPA in HuH7. Likewise, diazoxide treatment, which inhibits membrane depolarization prevented the effect of NAPA. *In vivo*, chronic NAPA treatment in mice induced a significant increase in NAPA level in the portal vein and NAPA effects on MAMs alteration and hepatic steatosis development were confirmed.
Conclusion: NAPA is a metabolite potentially derived from the microbiota, strongly association with hepatic steatosis in human. NAPA has a causal effect in the development of hepatic steatosis during MASLD, by disrupting ER-mitochondria communication and mitochondrial oxidative capacities mediated by an electrogenic effect.

Liver tumours: Clinical aspects except therapy

OS-075-YI

GALAD score is effective for HCC surveillance among high-risk patients

Grishma Hirode[1,2,3], Hooman Farhang Zangneh[1], Orlando Cerocchi[1], Lima Awad El-Karim[4], Korosh Khalili[4], Harry L.A. Janssen[1,5], Bettina E. Hansen[1,6,7], Jordan J. Feld[1,2,3]. *[1]Toronto Centre for Liver Disease, Toronto General Hospital, University Health Network, Toronto, Canada; [2]The Viral Hepatitis Care Network Canada (VIRCAN), Toronto, Canada; [3]Institute of Medical Science, University of Toronto, Toronto, Canada; [4]Joint Department of Medical Imaging, University Health Network, Toronto, Canada; [5]Department of Gastroenterology and Hepatology, Erasmus MC University Medical Center, Rotterdam, Netherlands; [6]Department of Epidemiology and Biostatistics, Erasmus MC University Medical Center, Rotterdam, Netherlands; [7]Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, Canada*
Email: grishma.hirode@gmail.com

Background and aims: Although guidelines recommend regular, biannual hepatocellular carcinoma (HCC) surveillance among patients at higher risk, several patients continue to be diagnosed at an advanced stage. Improvements in early-stage HCC diagnoses require a better understanding of current methods, and the exploration of novel strategies. The GALAD score uses a combination of demographics and biomarkers (BMs) to assess HCC risk. We aim to analyze the utility of various surveillance methods for the detection of early-stage HCC.
Method: This is a secondary analysis of a prospective study of patients with cirrhosis or high-risk hepatitis B virus (HBV) infection (REACH-B score ≥9) randomized to HCC surveillance with ultrasound (US) alone (Group A) or US and BM (Group B) measuring alpha-fetoprotein (AFP), lectin-reactive fraction of AFP (AFP-L3), and des-gamma-carboxy prothrombin (DCP). For all analyses using Group B data, any BM levels above the specified thresholds (AFp >100 ng/ml, AFP-L3 >10%, DCp >2 ng/ml) or a positive US result triggered further imaging for HCC confirmation. We compared the effectiveness of the GALAD score to US alone, each BM alone, and all three BMs combined using the area under the receiver operating characteristic (AUROC) curve after logistic regression while accounting for patient-level variance.
Results: Among 1, 208 patients in this study (baseline age 58 ± 9.8 years, 72% male, 64% HBV, 64% cirrhosis), 35/603 (6%) patients were diagnosed with HCC (30 early-stage, 5 advanced) in Group A and 27/605 (5%) patients were diagnosed with HCC (22 early-stage, 5 advanced) in Group B. AUROCs for both groups were 0.81. In the absence of US in Group B, AUROC for any elevated BM was 0.71 which was higher than elevated AFP alone (0.55, $p = 0.01$), elevated AFP-L3 alone (0.64, $p = 0.11$), and elevated DCP alone (0.59, $p = 0.03$). The AUROC was 0.89 using a longitudinal GALAD score in Group B, which performed better than all three BMs combined at the prespecified thresholds ($p = 0.001$). The optimal cut-point for the GALAD score in Group B was – 1.8 which would yield a sensitivity of 0.89, specificity of 0.81, and an AUROC of 0.85. Using a GALAD score threshold of – 0.63 in this cohort, as suggested by previous studies, yielded a lower AUROC of 0.77 ($p = 0.17$).
Conclusion: In this large study, use of the GALAD score showed more promise compared to any of the BMs alone. There was no difference in the effectiveness of US alone compared to US plus any elevated BMs using the specified thresholds. However, each elevated BM alone was less effective compared to the use of US alone, US plus BMs, or the GALAD score. Establishing and validating optimal thresholds for the BMs and the GALAD score is crucial to improve surveillance methods for the detection of early-stage HCC.

OS-076-YI

Bile extracellular vesicles hold protein biomarkers for the early diagnosis of cholangiocarcinoma in individuals with primary sclerosing cholangitis

Ainhoa Lapitz[1,2], Marit Grimsrud[3,4,5], Pedro Miguel Rodrigues[1,2,6], Johannes R. Hov[4,5,7], Mette Vesterhus[7,8,9], Mikel Azkargorta[2,10], Krzysztof Grzyb[11], Henrik Mikael Reims[11], Felix Elortza[2,10], Laura Izquierdo-Sánchez[1,2], María Jesús Perugorria[1,2,12], Luis Bujanda[1,2,12], Lars Aabakken[4], Vemund Paulsen[4], Tom Hemming Karlsen[3,4,5], Jesus Maria Banales[1,2,6,13], Trine Folseraas[5,7,14]. *[1]Biogipuzkoa Health Research Institute, San Sebastian, Spain; [2]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd), ISCIII, Madrid, Spain; [3]Norwegian PSC Research Center, Oslo, Norway; [4]University of Oslo, Oslo, Norway; [5]Oslo University Hospital Rikshospitalet, Oslo, Norway; [6]Ikerbasque, Basque Foundation for Science, Bilbao, Spain; [7]Norwegian PSC Research Center, Oslo, Spain; [8]University of Bergen, Bergen, Norway; [9]University of Bergen, Bergen, Spain; [10]Proteomics Platform, CIC bioGUNE, Derio, Spain; [11]Oslo University Hospital, Oslo, Norway; [12]Faculty of Medicine and Nursing, University of the Basque Country, Leioa, Spain; [13]University of Navarra, Pamplona, Spain; [14]University of Oslo, Oslo, Spain*
Email: ainhoa.lapitz@biodonostia.org

Background and aims: Cholangiocarcinoma (CCA) presents a significant threat to individuals with primary sclerosing cholangitis (PSC), with a 20-year cumulative incidence of approximately 15%. Early diagnosis is challenging due to overlapping symptoms, and recommended MRI/MRCP surveillance every 6–12 months often proves suboptimal in detecting early-stage cancer. PSC-CCA patients face a grim prognosis, with a median overall survival of 5–12 months in unresectable cases, making CCA the primary cause of PSC-associated mortality. There is a critical need for more accurate early detection methods, allowing access to potentially curative options like tumor resection or liver transplantation. In this regard, investigating extracellular vesicles (EVs) in bile, which come into direct contact with CCA tumors, offers a promising avenue for identifying diagnostic CCA biomarkers in PSC, and these were evaluated in this study.

Method: Bile EVs were collected from patients with isolated PSC (PSC, n = 52), PSC with CCA (PSC-CCA, n = 14), or PSC at time of sampling but who later developed CCA (PSC to CCA, n = 8), at Oslo University Hospital Rikshospitalet (Norway). The EV-protein content was characterized using mass spectrometry. Diagnostic biomarkers for PSC-CCA, as well as early-diagnostic/predictive biomarkers for the PSC to CCA group were identified and combined using binary logistic regression multivariable models.

Results: High-throughput proteomics of bile EVs identified 21 diagnostic biomarkers for PSC-CCA, regardless of sex, age, the presence of inflammatory bowel disease, or cirrhosis at the time of sampling. Among these, 14 biomarkers were observed to be more abundant, and 7 exhibited lower levels in patients with PSC-CCA compared to patients with isolated PSC. Machine learning algorithms revealed COPA/ATP5H/VTNC/IQGA1/PRDX2 (AUC = 0.996) and COPA/ATP5H/VTNC/IQGA1/CALX/PRDX2 (AUC = 1.000) as highly effective in diagnosing PSC-CCA versus isolated PSC, surpassing the performance of serum CA19-9 alone (AUC = 0.846). Notably, the logistic model combining TM9S4/RS18/LPPRC/NHRF1 demonstrated predictive capacity for CCA development in PSC before any clinical evidence of malignancy with 100% sensitivity and specificity (AUC = 1.000), whereas serum CA19-9 exhibited no significant predictive capacity for CCA development (AUC = 0.596).

Conclusion: Bile EVs harbor valuable protein biomarkers for predicting the development of CCA and enabling early diagnosis in individuals with PSC. Given the ease of bile collection during stenting for dominant strictures in individuals with PSC, this innovative liquid biopsy tool may be of significant value for monitoring disease progression and aiding access of potentially curative treatment options.

Email: naultjc@gmail.com

Background and aims: The role of positron emission tomography (PET) with 18F-FDG and 18F-Fluorocholine in staging of hepatocellular carcinoma (HCC) and its impact on treatment decisions has never been prospectively assessed.

Method: We conducted a multicentric prospective study in nine centers in France, including patients with a first diagnosis of HCC classified as BCLC A to C (excluding extrahepatic metastasis) and without contraindications to contrast-enhanced CT and MRI (Clinical trial NCT04391348). Patients underwent 18F-FDG-PET-CT and 18F-fluorocholine-PET-CT, liver MRI, and chest and hepatic CT within 4 weeks. A first tumor staging and treatment decision were performed in the multidisciplinary tumor board using morphological imaging, blind to the results of the PET-CTs. The results of the PET-CTs were

then revealed, and a second tumor staging and treatment decision were recorded by the same team. New lesions detected by PET-CT were confirmed as HCC if they increase in size during follow-up or by histology. The primary end point was the proportion of patients whose treatment planned by the multidisciplinary meeting was modified (from curative intent to palliative or from locoregional palliative to systemic treatment) by the combined use of 18F-FDG and 18F-Fluorocholine PET-CTs. The minimal clinically significant difference in the proportion of patients who would have a change in their treatment plan due to the PET-CTs was set at 15% (CI95%: 10–20%), and we planned to include 230 patients.

Results: A total of 230 patients were included, with 215 analyzable for the primary end point. Among these 215 patients, the median age was 65.7, 89.8% were male, and 72% were cirrhotic. Using morphological imaging, HCC was classified as BCLC stage A (n = 140, 65.1%), -stage B (n = 49, 22.8%), and stage C (n = 26, 12.1%, mainly without metastasis). Overall, 202 patients (94%) underwent 18F-FDG and 18F-fluorocholine-PET-CTs; eight patients underwent 18F-fluorocholine only, and four 18F-FDG only. New lesions were identified in 20 patients (9.3%), by PET-CTs (16 new extrahepatic lesions and five new intrahepatic lesions, including eight identified by both tracers, six by 18F-FDG, and seven by 18F-fluorocholine). The PET-CTs modified the BCLC stage in 10 patients (4.7%): from BCLC A to B (n = 2), from BCLC A to C (n = 2), from BCLC B to C (n = 2), and from BCLC C without metastasis to BCLC C with metastasis (n = 4). The primary end point (modification of the initial treatment) was met in four patients (2.9%): SIRT + atezolizumab/bevacizumab to atezolizumab/bevacizumab only (n = 1), partial resection to atezolizumab/bevacizumab (n = 1) or to SIRT (n = 1), and TACE to atezolizumab/bevacizumab (n = 1).

Conclusion: 18F-FDG and 18F-Fluorocholine-PET-CTs should not be systematically performed for staging in patients with a first diagnosis of HCC, as they modified treatment decisions in a minority of patients.

Email: celsaciro@gmail.com

Background and aims: Unlike other malignancies, hepatic functional reserve competes with tumour progression in determining the risk of mortality from hepatocellular carcinoma (HCC), making overall survival (OS) a uniquely composite end point. Combination immunotherapy is the most effective modality to prolong OS through improved control of tumour progression in advanced HCC. However, the relative contribution of hepatic decompensation over tumour progression in influencing OS has not been assessed in immunotherapy recipients.

Method: From the AB-real observational study (n = 898), we accrued 346 patients with advanced/unresectable HCC, Child-Pugh A class treated with frontline atezolizumab plus bevacizumab. Hepatic decompensation and tumour progression during follow-up were studied in relationship to patients' OS using time-dependent Cox models. Baseline characteristics were evaluated as predictors of hepatic decompensation in competing risks analysis.

Results: During a median follow-up of 9.3 months (95%CI 8.0–10.3), 154 patients (44.5%) developed tumour progression without decompensation and 58 patients (16.8%) developed decompensation. Median OS was 14.9 months (95%CI 12.6–19.7) in patients with HCC progression in absence of hepatic decompensation and 7.1 months (95%CI 5.2–10.5) in patients with hepatic decompensation ($p < 0.001$). In multivariable time-dependent analysis, hepatic decompensation (hazard ratio[HR] 23.43, 95%CI 8.40–65.31), HCC progression (14.78, 95%CI 5.99–36.45), albumin-bilirubin (ALBI) grade 2/3 (HR 2.12, 95%CI 1.45–3.10) and successful aetiological

treatment for underlying chronic liver disease (HR 0.58, 95%CI 0.40–0.83) emerged as covariates independently associated with OS. Pre-treatment platelet count<140*10^9/L (HR 1.77, 95%CI 1.01–3.12) and ALBI grade 2/3 (HR 2.89, 95%CI 1.50–5.56) were independently associated with hepatic decompensation, whereas successful aetiological treatment was protective (HR 0.53, 95%CI 0.30–0.93). The probability of decompensation at 12 months was higher in patients with metabolic aetiology compared to others (31.4%vs17.5%, p = 0.030).

Conclusion: Hepatic decompensation identifies patients with the worst prognosis following atezolizumab plus bevacizumab and is more common in thrombocytopenic patients with baseline ALBI>1. Effective management of underlying liver disease may protect from decompensation, highlighting the prognostic disadvantage of patients with metabolic aetiology and the importance of multidisciplinary management to maximise OS.

OS-079-YI

Development and validation of the CABLE score to estimate individual prognosis of patients with hepatocellular carcinoma treated with 1L atezolizumab and bevacizumab

Background and aims: Immunotherapy with atezolizumab plus bevacizumab (a+b) has significantly prolonged survival of patients with unresectable hepatocellular carcinoma (uHCC). However, prognosis is not only dependent on tumor-associated characteristics, but on several other factors such as hepatic function or inflammation. The aim of this study was i) to develop and validate a prediction model allowing to estimate individual prognosis of patients treated with a+b and ii) to compare it with currently used models.

Method: In this retrospective, multinational study, patients with uHCC treated with first-line (1L) a+b from 24 centers across Europe and the US were included. TRIPOD guidelines were used for reporting and analysis. Overall survival (OS) was the primary objective.

Results: A total of 683 patients were analyzed (training set: n = 526, validation set: n = 157). In the training set, median age was 67 years (range 25–90), 81% were male and most had preserved liver function (Child A/B: 73%/27%). Median OS was 13.7 months (95% CI: 12.1, 15.8). In total, 235 outcome events occurred during follow-up in the training set. The objective response rate was 32%, the disease control rate 72%. After a stepwise model building procedure, C-reactive protein, albumin, bilirubin, lymphocytes, ECOG performance status, and extrahepatic spread (CABLE score) remained significantly associated with OS. In the training set, the CABLE score had a higher discriminatory performance compared to ALBI, EZ-ALBI, mALBI, CRAFITY, PNI, NLR, PLR, and GPS (time-dependent AUC 0.79, C-index 0.75 (95% CI 0.71–0.78) at 12 months). In the external validation set, the discriminatory accuracy of the CABLE score was comparable to ALBI, EZ-ALBI, and mALBI, but on average higher than PNI, CRAFITY, NLR, PLR, and GPS. To allow the estimation of individual prognosis, we built a web-based calculator for the CABLE score (http://shiny.imbei.uni-mainz.de:3838/CABLE_Score/).

Conclusion: The CABLE score yields good discriminatory accuracy and allows to estimate the individual prognosis of patients with uHCC undergoing 1L immunotherapy with a+b.

Background and aims: Spleen stiffness is associated with the severity of portal hypertension in patients with cirrhosis. Baveno VII consensus suggests that screening endoscopy can be safely spared in patients with compensated cirrhosis, when spleen stiffness measurement (SSM) by vibration-controlled transient elastography (VCTE) is ≤40kPa, as they have a low probability of high-risk varices (HRV). Conversely, in patients with extrahepatic portal vein obstruction in the absence of cirrhosis (EHPVO), endoscopic screening for varices is recommended in all patients, within 6 months of the acute episode. In the absence of varices, endoscopy should be repeated at 12 months, and 2 years later, for all patients in whom thrombosis have not been recanalized. Whether SSM could spare endoscopies in patients with EHPVO is currently unknown. This study aimed to evaluate the performance of SSM by VCTE to rule out HRV (i.e., large varices, small varices with red spot signs, or previous variceal band ligation for primary prophylaxis) in patients with chronic EHPVO.
Method: All the patients with chronic EHPVO, who underwent SSM by VCTE using FibroScan® performed at our center within 2 years before or after an upper endoscopy, were included. Non-inclusion criteria were a history of variceal bleeding, isolated thrombosis of the splenic or mesenteric vein or of one of the portal vein branch, prior TIPS, portal vein recanalization, or portosystemic surgical shunt, and tense ascites at the time of SSM-VCTE. Performance of SSM by VCTE was externally validated in a cohort of patients with chronic EHPVO from 13 VALDIG centers, according to the same inclusion and non-inclusion criteria.
Results: 141 patients were included in the derivation cohort: 63% men, median age 49; 84% with ≥1 risk factor for thrombosis. Median serum bilirubin was 0.76 mg/dL (IQR 0.52–1.12); median serum creatinine 74 µmol/L (IQR 63–86); and median SSM 45 kPa (IQR 27–74). HRV were present in 38% of the patients. In the validation cohort, including 178 patients with similar characteristics, HRV were present in 31% of them. By univariable analysis, serum bilirubin, spleen size, portosystemic collaterals, liver stiffness measurement and SSM by VCTE were associated with HRV status in both cohorts. By multivariable binary logistic regression analysis, only SSM by VCTE ($p < 0.0001$) remained associated with HRV in both cohorts. In the derivation cohort, SSM by VCTE ≤40 kPa had a sensitivity of 96% to rule out HRV, and could spare 43% of screening endoscopies, with 4% of HRV missed, and a negative predictive value (NPV) of 97%. In the validation cohort, SSM by VCTE ≤40 kPa could spare 46% of screening endoscopies, with 5% of HRV missed, and a NPV of 96%.
Conclusion: This study gathering a total of 319 patients with chronic EHPVO showed that SSM by VCTE ≤40 kPa identifies patients with probability of high-risk varices ≤5%, in whom screening endoscopy can be spared.

Email: pierre.deltenre01@gmail.com

Background and aims: In non-cirrhotic patients, portal vein recanalization (PVR) is a technique able to treat or prevent complications related to portal hypertension by addressing PVO itself. The aim was to dentify factors associated with PVR failure and evaluate long-term stent patency and outcome in a large series of patients with non-cirrhotic PVO.
Method: Retrospective study collecting health-related data of patients with chronic PVO in which placement of a stent has been attempted in 6 VALDIG centers. Extension of occlusion was assessed by portography before PVR. Central review of imaging was performed by a single radiologist expert. A TIPS was inserted at the discretion of each center when blood flow was judged non-sufficient after PVR.
Results: 85 patients were included (55 men [65%], median age 49 years [95% CI: 45–54]). Indications for PVR were gastrointestinal bleeding (n = 45, 53%), portal biliopathy (n = 11, 13%), the need for reducing portal pressure before surgery (n = 9, 11%), abdominal pain (n = 11, 13%) and other reasons (n = 9, 11%). A procoagulate state was identified in 34 patients (40%) and a local prothrombotic factor in 47 patients (55%). Occlusion involved the mesenteric vein in 55 patients (65%) and/or the splenic vein in 41 patients (50%). Regarding the intra-hepatic extension of PVO, patients were classified according to Marot classification: "type 1" with occlusion limited to the main portal vein (n = 38, 45%), "type 2" with involvement of portal bifurcation and extension to segmental branches (n = 29, 34%), and "type 3" with extension to distal branches (n = 18, 21%). Failure of PVR occurred in 18 patients: 1 in type 1 (3%), 9 in type 2 (31%) and 7 in type 3 PVO (39%) ($p < 0.001$). 18 patients underwent TIPS insertion in addition to PVR (21%), 4 in type 1, 7 in type 2 and 7 in type 3 PVO ($p = 0.048$). The median follow-up was 542 days (95% CI: 374–902). In an intention-to-treat analysis, 2-year PV patency was 58% (95% CI: 47–69): 76% (95% CI: 61–91) in type 1, 51% (95% CI: 33–70) in type 2 and 29% (95% CI: 5–54) in type 3 PVO ($p = 0.005$). In Cox regression analysis, 2-year PV non-patency was independently associated with PVO type 2 (RR: 4.0, 95% CI:1.5–10.9, $p = 0.006$) and type 3 (RR: 5.6, 95% CI:2.0–15.8, $p = 0.001$), and with abdominal pain (RR: 3.5, 95% CI:1.5–8.5, $p = 0.005$). In a per-protocol analysis, 2-year PV patency was 72% (95% CI: 60–83). 2-year cumulative incidence of recurrent symptoms of portal hypertension was 33% (95% CI: 23–46), 33% (95% CI: 20–55) in type 1, 27% (95% CI: 14–51) in type 2, 42% (95% CI: 23–77) in type 3 PVO ($p = 0.6$). 12 patients died (14%). 2-year probability of survival was 88% (95% CI:80–97).
Conclusion: PVR is feasible in most patients with PVO if there is no extension to distal branches. 2-year PV patency following PVR is 58% and 72% in intention-to-treat and per-protocol analyses. PVO types 2 and 3 and abdominal pain as an indication for PVR are independently associated with 2-year PV non-patency.

Sustained improvement of alanine aminotransferase levels in patients with lysosomal acid lipase deficiency treated with sebelipase alfa enzyme replacement therapy: longitudinal data from the international lysosomal acid lipase deficiency registry

William Balistreri[1], Jennifer Evans[2], Florian Abel[2], Lorenzo D'Antiga[3]. [1]*University of Cincinnati Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, United States;* [2]*Alexion, AstraZeneca Rare Disease, Boston, United States;* [3]*Pediatric Hepatology, Gastroenterology and Transplantation, Hospital Papa Giovanni XXIII, Bergamo, Italy*
Email: ldantiga@asst-pg23.it

Background and aims: Data from the International Lysosomal Acid Lipase Deficiency (LAL-D) Registry documented more severe liver disease in patients with LAL-D diagnosed at a younger age (Balwani, et al. Liver Int. 2023;43:1537–47). Alanine aminotransferase (ALT) values <1.5 times the upper limit of normal (x ULN) have been used to indicate less severe liver damage. This analysis evaluated ALT and aspartate aminotransferase (AST) elevations at baseline and changes reported during treatment with Kanuma® (sebelipase alfa enzyme replacement therapy [ERT]).
Method: This retrospective, observational study focused on children and adults treated with ERT ("treated patients"), excluding infants <6 months of age, identified from the International LAL-D Registry (NCT01633489). All had confirmed LAL-D with baseline results and >1 follow-up in 5 years through Oct 2, 2023. Baseline results were assessed prior to ERT in treated patients and at enrollment for non-treated patients. ALT and AST values for all patients were stratified from normal limits to >3 × ULN. A subset of treated patients with ALT values at baseline and 3 consecutive annual results was identified. The proportion of patients at each stratified ALT category was calculated. Linear regression analysis was performed to evaluate ALT trends among treated patients with elevated baseline ALT (>1.5 × ULN).
Results: Of 186 patients (92 [49%] males, median age at diagnosis 10.3 years), 162 (104 [64%] treated) had baseline results for ALT. Prevalence of baseline ALT readings <1.5 × ULN for ages 0 to <6 (n = 20), 6 to <12 (n = 54), 12 to <18 (n = 28), and >18 (n = 60) years were 35%, 22%, 25%, and 50%, respectively. Treated patients showed improvement from baseline at subsequent time points. A subset of 75 patients (53 [71%] treated) had 3 consecutive annual results. Baseline ALT values were >1.5 × ULN in 41 (77%) vs 11 (50%) of treated and non-treated patients. Of the 41 treated patients with baseline ALT >1.5 × ULN, 31 (76%) had ALT values <1.5 × ULN at 1 year of ERT. These trends were maintained throughout the 3-year study period and were similar for AST (to be presented). Results from linear regression indicated improvement in ALT levels (decrease) over time with a slope of – 0.40 (95% CI: – 0.57, – 0.24; P < 0.0001). No deaths occurred during follow-up. Adverse events (AEs) were mild to moderate in severity. There were 21 serious AEs, 1 of which (non-severe anaphylaxis in an adult male, resolved the same day) was deemed treatment-related.
Conclusion: Findings from this first longitudinal analysis of International LAL-D Registry data reflect a favorable treatment response to ERT. ALT values were elevated in most patients at baseline. Following ERT treatment, most patients experienced improvements in ALT levels. Sustained favorable trends, consistent with findings from clinical trials, were observed during ERT.

Background and aims: A rise in cases of acute hepatitis of unknown origin (AHUO) in children was observed in 2022 in several countries, some requiring liver transplantation. Evidence of a link to adeno-associated virus 2 (AAV2) infection and CD4 T cell mediated disease was reported in the UK cohort, but not in other countries and a possible contribution of SARS-CoV2 infection during the pandemic remains unclear.
Method: To understand the underlying pathophysiology in a central European patient cohort, we performed highly-multiplexed spatial and single-cell analysis of (n = 12) liver biopsies from children with AHUO manifestation during the pandemic and control patients.
Results: Clinical tests indicated no evidence of AAV2 infection but evidence of a history of SARS-CoV2 infection. We observed significant immune infiltration in patient livers with an enrichment of CD8 T cells. Patients with highest CD8 infiltration had the most severe courses of acute hepatitis and concomitant peripheral immune activation. CD8 T cell infiltration was connected to significant tissue pathology involving tissue necrosis and endothelial damage involving multiple immune cell subsets. Neighborhood analysis indicated disease-associated microanatomic interactions between endothelial cells, CD8 T cells and myeloid cell populations. Of note, we observed evidence for intrahepatic SARS-CoV2 antigens corresponding with ACE2 expression in endothelial cells and myeloid cells in the diseased areas in 11/12 samples using several detection methods. 11/12 patients were treated with corticosteroid therapy and no liver transplantation was required.
Conclusion: In children with AHUO, a possible manifestation of a post-acute sequel to Covid-19 associated with a characteristic immune infiltrate needs to be considered.

Background and aims: Porto-sinusoidal vascular disease (PSVD) is a rare cause of portal hypertension. Data on hepatopulmonary syndrome (HPS) in PSVD are limited. This study aimed to determine the prevalence, associated factors, and evolution of HPS in patients with PSVD.
Method: Retrospective multicenter observational study of patients with PSVD, according to VALDIG's criteria, with signs of portal hypertension who underwent contrast-enhanced transthoracic echocardiography.
Results: 196 patients were included in 17 centers of the French network for Vascular Liver Diseases. Contrast-enhanced transthoracic echocardiography was performed as part of the investigations carried out at inclusion in the phase III "APIS" clinical trial (NCT04007289) in 80 patients, as part of the initial work-up performed when patients were referred for PSVD in 95 patients and because of dyspnea in 21 patients. Out of the 196 patients included, 14 (7%) had a confirmed diagnosis of HPS. Hypoxemia (PaO_2 <80 mmHg) was found in 9 patients with HPS while 5 patients had elevated $AaPO_2$ without hypoxemia. Four (2%) additional patients had intrapulmonary shunts at contrast-enhanced echocardiography, but normal arterial oxygenation, precluding diagnosis of HPS. Patients with HPS had more frequently genetic disorder associated with PSVD (43% vs. 6%, p = 0.002). In particular, telomere biology disorders were found in 6 (43%) out of the 14 patients with HPS vs. 6 (3%) out of the 182 patients without HPS (p < 0.001). Liver function was less preserved in patients with HPS, since they had lower prothrombin time (63% vs. 86%, p = 0.04), higher serum total bilirubin (37 µmol/L vs. 14 µmol/L, p < 0.001), and lower serum albumin concentration (32 g/L vs. 38 g/L, p < 0.001). No significant difference was observed concerning signs of portal hypertension, liver and spleen stiffness, nor complications of PSVD. Out of the 14 patients with HPS, 5 underwent liver transplantation after a median follow-up of 34 months, because of HPS requiring long-term oxygen therapy for 4 and because of liver failure for one patient. HPS being an indication for LT in itself, we performed competing risk analyses considering LT for HPS as a competing risk. In this setting, overall cumulative incidence of death and of liver related events was similar between patients with and without HPS.
Conclusion: The prevalence of HPS in patients with PSVD was 7%. HPS in patients with PSVD is associated with genetic disorders, and especially telomere biology disorders. When applying liver transplantation MELD standard exception policy, overall survival of patients with HPS and PSVD is similar to that of patients with PSVD without HPS.

Sex and age disparities in MASH and the beneficial effects of estradiol for MASH in old female mice

Madhulika Tripathi[1], Suganya Sakthivel[2,3], Priyanka Gupta[4], Ayako Suzuki[5], Brijesh Kumar Singh[6], Paul Yen[6]. *[1]Duke-NUS Medical School, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore, Singapore; [3]Duke-NUS Medical School, Singapore, Singapore; [4]Duke_NUS Medical School, Singapore, Singapore; [5]Duke Durham, North Carolina, United States; [6]Duke-NUS Medical School, Singapore, Singapore*
Email: madhulika.tripathi@duke-nus.edu.sg

Background and aims: The prevalence of metabolic dysfunction-associated steatohepatitis (MASH) is higher in males than reproductive age females whereas the prevalence significantly rises in post-menopausal females and eventually equals those in males. The mechanism (s) for these observations is not known so we investigated sex and age differences and the therapeutic potential of estradiol in MASH *in vivo*.
Method: Young/reproductive age (12-week) and old/post-reproductive age (48∼50-week) male and female C57BL/6J mice were subjected to control chow, high-fat methionine/choline-deficient (HFMCD) diet for six weeks or WDF (Western diet +fructose) diet for 16–20 weeks to induce MASH. These mice received 17β-estradiol at physiological (200nM) dose for therapeutic groups. Serum and hepatic MASH parameters, ER stress, and lysosome-autophagy defects were analyzed.
Results: Young female mice fed HFMCD or WDF developed milder MASH and lower inflammation (Il-6, Il-β), inflammasome (Nlrp3, and Asc-1), and fibrosis (Tgf-b1, Col1a1 and a-SMA) gene expression, and decreased hepatic collagen content than age-matched males fed the same diet. Interestingly, Young females fed NASH-inducing diets had no significant changes in glucose sensitivity/insulin tolerance, and less impairment of hepatic autophagy and lysosomal activity than age-matched males fed the same diets. In contrast, post-reproductive age females significantly increased hepatic inflammation, fibrosis, and ER stress gene expression; glucose/insulin impairment; autophagic inhibition; and lysosomal defects to resemble age-matched males. Remarkably, physiological doses of estradiol reduced NASH by decreasing inflammation and fibrosis gene expression and improving lysosomal-autophagic defects in old females.
Conclusion: We found significant sex differences in MASH as males had more severe NASH than age-matched females that further progressed with age. However, old females had a sharp rise in NASH severity and progression and caught up with similar age males. Estradiol markedly decreased inflammation, fibrosis, and other features of NASH in old female mice. Our data suggest that estrogen supplementation may be warranted for post-menopausal patients with NASH who do not have cardiovascular and cancer risk factors.

OS-086-YI

Protein tyrosine phosphatase non-receptor type 2 controls hepatic function of cytotoxic T cells in metabolic dysfunction-associated steatohepatitis

Madita Determann[1], Luise Linzmeier[1], Marlene Schwarzfischer[1], Anna Niechcial[1], Marianne Rebecca Spalinger[1], Yasser Morsy[1], Doris Pöhlmann[1], Marijn Wilmink[1], Maria Walker[1], Federica Sella[2], Mitchell Levesque[2], Viktor Hendrik Koelzer[3], Anja Laura Frei[4], Stephan Buch[5], Jochen Hampe[5], Christian Datz[6], Clemens Schafmayer[7], Mathias Heikenwälder[8], Michael Scharl[1], Sena Blümel[1]. *[1]University of Zurich, University Hospital Zurich, Department of Gastroenterology and Hepatology, Zurich, Switzerland; [2]University of Zurich, University Hospital Zurich, Department of Dermatology, Zurich, Switzerland; [3]University of Basel, University Hospital Basel, Institute of Medical Genetics and Pathology, Basel, Switzerland; [4]University of Zurich, University Hospital Zurich, Department of Pathology and Molecular Pathology, Zurich, Switzerland; [5]University of Technology Dresden, University Hospital Dresden, Medical Department I, Dresden, Germany; [6]General Hospital Oberndorf, Teaching Hospital of the Paracelsus Medical University Salzburg, Department of Internal Medicine, Salzburg, Austria; [7]University Hospital Rostock, Department of General Surgery, Rostock, Germany; [8]German Cancer-Research Center, Department Chronic Inflammation and Cancer, Heidelberg, Germany*
Email: maditaelena.determann@usz.ch

Background and aims: Obesity and its complications, including metabolic dysfunction-associated steatohepatitis (MASH), cirrhosis, and hepatocellular carcinoma are a growing global epidemic. MASH development involves the hepatic recruitment of cytotoxic $CD8^+$ T cells causing liver damage and fibrosis. Protein tyrosine phosphatase non-receptor type 2 (PTPN2) attenuates $CD8^+$ T cell responses to self-antigens, tumors and inflammation. Thus, PTPN2 may have a crucial role in MASH pathogenesis by modulating $CD8^+$ T cell functionality. Here, we studied the impact of T cell-specific PTPN2 on MASH development and disease progression.

Method: The impact of human hepatic PTPN2 expression on MASH development was analyzed from (1) mRNA data from the sequence read archive (SRA) database (n = 106); (2) protein expression in liver biopsies using multicolor immunofluorescence staining (n = 8–12); (3) the presence of the single nucleotide polymorphism (SNP) rs2542151, which results in PTPN2 non-function, in an Austrian and German Metabolic Dysfunction-associated Steatotic Liver Disease (MASLD) cohort (n = 742–997).

To understand how T cell PTPN2 is connected to MASH development, mice with conditional PTPN2-knock-out in T cells (KO, $PTPN2^{fl/fl} \times CD4^{Cre}$) and their wild-type (WT, $PTPN2^{fl/fl}$) littermates (n = 4–19 mice per group) were fed 28 weeks with western-style fast food diet (FFD). The mice were investigated regarding their MASH characteristics.

Results: PTPN2 mRNA-expression was increased in livers from MASLD and MASH patients compared to healthy controls, and in MASH compared to MASLD ($p < 0.05$). PTPN2 expression in patients with non-alcoholic fatty liver disease (NAFLD) activity score (NAS) 5 and NAS 6 was higher compared to patients with NAS 0 ($p < 0.05$). Immunofluorescence analysis revealed increased numbers of $PTPN2^+$, $CD3^+$ $PTPN2^+$ and $CD8^+$ $PTPN2^+$ cells in MASH patients compared to controls ($p < 0.05$).

Of note, the frequency of severe liver fibrosis in MASH patients harboring the SNP rs2542151 was reduced (minor allele frequency (MAF) for F3/4 fibrosis and cirrhosis = 0.108–0.139 vs. fibrosis F0/1-MAF = 0.156).

The FFD-fed KO mice were lighter and their liver-body weight ratio was lower than their WT littermates ($p < 0.05$) with no differences in water or food consumption. In contrast to their WT littermates, the FFD-fed KO mice were protected from MASH and fibrosis (mean WT-NAS 6 vs. KO-NAS 4 and mean WT-fibrosis F2 vs. KO-fibrosis F0). In flow cytometry, livers of FFD-fed KO mice had higher amounts of exhausted and central memory $CD8^+$ T cells ($p < 0.05$), while all other immune cell groups were not different between genotypes.

Conclusion: While we observed increased PTPN2 mRNA and protein expression in human MASH livers, SNP analyzes and in vivo data suggested a protective effect of PTPN2 deficiency against MASH likely mediated by impacting on intrahepatic $CD8^+$ T cell functionality.

OS-087

Stain-free digital pathology imaging provides microarchitecturally-resolved insights into scar evolution allowing direct clinical outcome prediction in metabolic dysfunction-associated steatotic liver disease

Timothy Kendall[1], Stephen A. Harrison[2], Dean Tai[3], Elaine Chng[3], Yayun Ren[3], Jonathan Fallowfield[1]. *[1]University of Edinburgh, Edinburgh, United Kingdom; [2]Pinnacle Clinical Research, San Antonio, United States; [3]HistoIndex Pte. Ltd, Singapore, Singapore*
Email: tim.kendall@ed.ac.uk

Background and aims: Fibrosis stage in metabolic dysfunction-associated steatotic liver disease (MASLD) is associated with increased mortality and liver-related events. Direct prediction of outcomes from tissue has not been possible due to the lack of a suitable event-rich cohort. Using an unstained section from biopsies of the SteatoSITE cohort has allowed quantification of extracellular matrix features that are predictive of clinical outcome but unapparent to human observers.

Method: Sections from 452 SteatoSITE biopsies were randomized into train (300) or test (152) sets and imaged using second harmonic generation/two-photon excitation fluorescence microscopy (SHG/TPEF). Using sequential feature selection, 5 of 184 fibrosis parameters were chosen and linear regression used to construct individual indices for risk of all-cause mortality and hepatic decompensation. Using the test set, Kaplan-Meier analysis, with death a competing risk for decompensation, and Cox proportional hazards modelling was performed. The predictive power of the risk indices was compared with assigned NASH-CRN fibrosis stage (F0/1/2 v F3/4) and stain-free imaging derived qFibrosis stage (qF0/1/2 v qF3/4). Previous indices were established using a training set of 294 biopsies with leave-one-out cross-validation.

Results: Previously established all-cause mortality and hepatic decompensation indices had greater predictive power than either NASH-CRN or qFibrosis stage. New indices generated with these train and test sets from an extended MASLD cohort also outperformed existing predictive metrics. The new all-cause mortality index had greater predictive power (>0.14 vs. </= 0.14, hazard ratio (HR) 4.49, 95% confidence intervals (CI) 1.5–13.38) than qFibrosis-derived stage (HR 3.07, CI 1.3–7.26) or NASH-CRN fibrosis score (HR 3.41, CI 1.43–8.15). The new hepatic decompensation index had greater predictive power (>0.31 vs. </= 0.31, HR 5.96, CI 2.92–12.14) than qFibrosis-derived stage (HR 3.59, CI 1.79–7.2) or NASH-CRN fibrosis score (HR 3.65, CI 1.81–7.35). Parameters used in separate indices were related to extracellular matrix features in portal tract, periportal, and zone 2 regions.

Conclusion: We show that individual indices composed of micro-architectural features quantified by stain-free imaging have greater predictive value for all-cause mortality and liver-related events than ordinal fibrosis scores. These new indices may be used for more nuanced participant stratification or more meaningful end points in trials. To establish a definitive link between microarchitectural features at baseline, their modification following drug treatment, and associated clinical outcomes, it is essential to incorporate validation within a prospective study.

Email: ivolkert@ukaachen.de

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD), encompasses a range of liver diseases, spanning from steatosis to cirrhosis and hepatocellular carcinoma (HCC). Despite the global rise in MASLD prevalence, the precise mechanisms driving disease development remains elusive. The c-Jun N-terminal kinases (JNKs) play a pivotal role in liver physiology and disease pathogenesis. This study aims to investigate the mechanisms of liver damage following hepatocyte-specific deletion of Jnk1 and Jnk2 during the development of metabolic dysfunction-associated steatohepatitis (MASH).
Method: Mice with a hepatocyte-specific deletion of Jnk1 and Jnk2 (JNK1/2$^{\Delta hepa}$) and corresponding controls underwent an 8-week Western-Style Diet (WSD) to evaluate its impact on MASH progression. Subsequent to gene set pathway analysis, Caspase8/JNK1/2$^{\Delta hepa}$ animals were generated and subjected to a WSD. Following this, JNK1/2$^{\Delta hepa}$ and control animals were treated with a WSD for 8 weeks with weekly intravenous (*i.v.*) injections of hepatocyte-specific Caspase 8 (Casp 8) siRNA, initiated after four weeks of WSD.
Results: WSD led to significantly elevated transaminases, enhanced fibrogenesis and markedly increased inflammation in JNK1/2$^{\Delta hepa}$ mice compared to control mice. Gene set pathway analysis identified highly upregulated distinct pathways in JNK1/2$^{\Delta hepa}$ livers, including inflammatory signals and fibrogenesis. Notably, apoptotic pathways exhibited a substantial increase, confirmed by Cleaved Caspase 3 staining. Thus, Casp8/JNK1/2$^{\Delta hepa}$ mice were generated and subjected to WSD. Triple KO mice displayed a complete reversal of the severe phenotype, with liver transaminases, inflammation, fibrogenesis and cell death fully rescued and significantly reduced. Multiplex staining revealed a significant increase of infiltrating immune cells such as monocyte-derived macrophages in JNK1/2$^{\Delta hepa}$ mice, which were further reduced in Casp8/JNK1/2$^{\Delta hepa}$ mice. This was also confirmed by deconvolution of RNA bulk data, based on unpublished liver single-cell datasets. A therapeutic approach employing hepatocyte-specific liposomes containing Casp8 siRNA, administered four weeks after initiating WSD, resulted in significantly reduced liver transaminases, fibrogenesis, inflammatory signals and cell death.
Conclusion: Our results demonstrate that hepatocyte-specific Jnk1 and Jnk2 deletion induces a robust oxidative stress response, leading to increased MASH progression and heightened apoptotic cell death. This phenotype was fully rescued by genetic deletion of Casp8 in hepatocytes. Additionally, therapeutic treatment with Casp8 siRNA significantly mitigated MASH progression, suggesting that Casp8-directed therapy in hepatocytes might be a promising treatment for patients with an increased oxidative stress response and MASH.

Transgenerational maternal obesity induces mitochondrial dysfunction and aggravates MASLD, which can be reversed by metabolic drug candidates

Anneleen Heldens[1,2], Milton Antwi[1,2,3], Louis Onghena[1,2,4], Lindsey Devisscher[2,3], Xavier Verhelst[1,2], Sarah Raevens[1,2], Hans Van Vlierberghe[1,2], Ruth de Bruyne[5], Anja Geerts[1,2], Sander Lefere[1,2]. [1]*Department of Internal Medicine and Pediatrics, Hepatology Research Unit, Ghent University, Ghent, Belgium;* [2]*Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium;* [3]*Gut-Liver Immunopharmacology Unit, Department for Basic and Applied Medical Sciences, Ghent University, Ghent, Belgium;* [4]*Department for Human Structure and Repair, Department of Gastrointestinal Surgery, Ghent University Hospital, Ghent, Belgium;* [5]*Department of Internal Medicine and Pediatrics, Pediatric Gastroenterology, Hepatology and Nutrition, Ghent University Hospital, Ghent, Belgium*
Email: anneleen.heldens@ugent.be

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common pediatric chronic liver disease. Although maternal obesity is an independent risk factor, the pathogenesis remains unclear. We aimed to evaluate the effect and mechanisms of transgenerational maternal obesity on MASLD severity, and test drug candidates in a preclinical model.
Method: Maternal obesity was induced by feeding C57BL/6J mice a western diet (WD) from 8 weeks before breeding initiation, with a normal chow (NC)-fed male, throughout pregnancy and lactation. Female offspring were used to produce the next generation. Male offspring were weaned onto NC or WD and MASLD development was assessed at the age of 24 days and 16 weeks. MASLD severity and metabolic alterations were evaluated by histology, serum markers, bulk liver RNA sequencing, flow cytometric analysis of hepatic macrophages, and quantification of hepatic mitochondrial oxidative phosphorylation (OXPHOS) complex content. To evaluate the translational potential of our findings, the publicly available GSE220102 RNAseq dataset on maternal WD in non-human primates (NHP) was analyzed. Finally, we assessed the therapeutic efficacy of wildtype (WT) FGF-21, semaglutide, and an amylin analogue (provided by Novo Nordisk), from 8 to 16 weeks of age.
Results: 16-week-old male offspring exposed to maternal WD, especially multigenerational maternal WD, exhibited higher body, liver and gonadal adipose tissue weight, HOMA-IR, serum ALT levels, and infiltration of monocytes and monocyte-derived macrophages, whereas Kupffer cells were depleted. Maternal WD feeding aggravated steatosis and inflammation, and thus the NAFLD activity score. Fibrosis (F1-F3) was only observed in the offspring exposed to maternal WD. RNA sequencing analysis clustered samples based on maternal and postnatal diet, and presence of fibrosis. Among the top 10 GO-biological processes of significantly altered genes, 4 were related to oxidative phosphorylation. Furthermore, maternal WD exposure was associated with a lower hepatic OXPHOS complex content. Notably, transcriptomic analysis of WD-fed NHP offspring confirmed our findings, as 'oxidative phosphorylation' was one of only two KEGG pathways significantly affected by maternal WD feeding. To isolate the effect of maternal diet, offspring were evaluated at weaning age. Maternal diet alone was sufficient to induce liver steatosis and inflammation at this young age. In our model, treatment with WT FGF-21, semaglutide and the amylin analogue significantly improved steatohepatitis, with WT FGF-21 and the amylin analogue ameliorating fibrosis as well.
Conclusion: Transgenerational obesity aggravates MASLD in male offspring starting from weaning age. While mitochondrial dysfunction contributes to disease progression, WT FGF-21, semaglutide and the amylin analogue are effective treatments.

Viral Hepatitis: Experimental and pathophysiology

Novel epigenetic editing technology targets hepatitis B virus in vivo to deeply and durably repress viral markers

Yesseinia Anglero-Rodriguez[1], Sahar Abubucker[1], John Xiong[1], Jhon Medina[1], Caroline Mugambwa[1], Rayman Choo-wing[1], Carrietta Jacques[1], Glen Acosta[1], Scott Clarkson[1], Kendra Bayne[1], Mary Morrison[1], Ari Friedland[1], Narayan Wong[1], Zohan Hoque[1], Amber DiPiazza[1], Parthu Koppana[1], Kuo-Chan Hung[1], Sameer Abraham[1], Adam Zhai[1], Pietro Spinelli[1], Vic Myer[1], Aron Jaffe[1].
[1]Chroma Medicine, Boston, MA, United States
Email: yesse.anglero@chromamedicine.com

Background and aims: Current treatments for chronic hepatitis B virus (HBV) result in a low incidence of functional cure, which is thought to result from the persistence of covalently closed circular DNA (cccDNA) and the deregulation of the immune system resulting from HBsAg expression. Epigenetic editing is a powerful approach that leverages the endogenous cellular mechanism for gene regulation to durably silence or activate genes without introducing unintended genomic consequences associated with traditional gene editing. Our epigenetic editors (EE) consist of a DNA-targeting component fused to a transcriptional repressor domain and a DNA methyltransferase domain. Transient exposure of our HBV-EE results in binding to HBV cccDNA and integrated HBV DNA (intDNA) in a sequence-specific manner and localized DNA methylation of CpG dinucleotides in the viral genome, leading to a deep, durable reduction of multiple HBV viral markers including HBV DNA and HBsAg without cutting or nicking the DNA.
Method: A library of HBV-EEs were screened in vitro and hit confirmation was performed in HepG2.2.15 cells, an immortalized cell line that contains HBV intDNA, and in HBV infected primary human hepatocytes (PHH), which contains both intDNA and cccDNA. Multiple confirmed hits were tested for dose-dependent reduction of HBsAg levels in HepG2.2.15. Hybrid-capture methyl-seq was used to verify that our HBV-EE induced on-target methylation of HBV DNA. RNA-seq and whole genome methylation sequencing to analyze host gene expression and host genome methylation, respectively, were used to evaluate EE specificity in PHHs. In vivo activity was evaluated via IV administration of lipid nanoparticles (LNPs) delivering mRNA encoding our HBV-EE construct into two models: 1) AAV-HBV, a model of episomal DNA and 2) a transgenic (Tg)-HBV mouse, a model of intDNA.
Results: Our HBV-EEs durably and deeply reduced HBsAg and HBeAg in both cccDNA and intDNA in vitro models, demonstrating >80% silencing of each viral antigen. Targeted methylation of HBV DNA correlated with reduction of HBsAg and HBeAg, with no off-target changes seen in host gene expression or methylation in PHHs. In vivo, single administration of our EEs resulted in durable, dose-dependent reduction of HBsAg, achieving a 3.3 log reduction at 84 days in the AAV-HBV model, and 2.1 log reduction at 112 days in Tg-HBV mice.
Conclusion: Our results demonstrate in vivo proof-of-concept with deep, specific, and durable silencing of HBV using our HBV-EE. We believe our novel epigenetic editing approach represents a new therapeutic modality with the potential to achieve higher rates of functional cure in patients with chronic HBV.

OS-091

Precision-cut liver slices as a pre-clinical model for the evaluation of host-targeting agents against hepatitis B virus and hepatitis delta virus infection

Maud Michelet[1,2,3], Armando Andres Roca Suarez[1,2,3], Anaëlle Dubois[1,2,3], Sarah Heintz[1,2,3], Marie-Laure Plissonnier[1,2,3], Maria Saez-Palma[1,2,3], Simon Fletcher[4], Michel Rivoire[5], Sandra Phillips[6,7], Elena Palma[6,7], Shilpa Chokshi[6,7], Barbara Testoni[1,2,3], Fabien Zoulim[1,2,3]. *[1]INSERM U1052, CNRS UMR-5286, Cancer Research Center of Lyon (CRCL), Lyon, France; [2]University of Lyon, Université Claude-Bernard (UCBL), Lyon, France; [3]Hepatology Institute of Lyon, Lyon, France; [4]Gilead Sciences Inc., 324 Lakeside Dr., Foster City, CA, 94404, United States; [5]INSERM U1032, Centre Léon Bérard (CLB), Lyon, France; [6]The Roger Williams Institute of Hepatology, Foundation for Liver Research, 111, Coldharbour Lane, London SE5 9NT, United Kingdom; [7]Faculty of Life Sciences and Medicine, King's College London, London WC2R 2LS, United Kingdom*
Email: fabien.zoulim@inserm.fr

Background and aims: The development of new treatment strategies against hepatitis B virus (HBV) and hepatitis delta virus (HDV) is of high priority to achieve a cure of these infections. In this context, the pre-clinical evaluation of host-targeting agents (HTAs) with the currently available in vitro and in vivo study models remains challenging. The use of precision-cut liver slices (PCLS) represents a promising model that preserves the complex multi-cellular architecture and cellular communication of the hepatic environment, while offering the practical aspects of an in vitro system based on human cells. Therefore, we aimed to assess the potential application of PCLS as an HBV/HDV co-infection model for the evaluation of HTAs.
Method: We employed human PCLS derived from resected liver tissue samples from patients without history of chronic liver disease. Slices were mono- or co-infected ex vivo with HBV and HDV for a five-day period. Tissue architecture and viability were evaluated by immunohistochemistry, detection of ATP and total RNA content. Viral infection was assessed by the presence of HBV RNA, covalently closed circular (ccc)DNA and HDV RNA by RT-qPCR and hepatitis delta antigen (HDAg) by Western blot. The impact of HTAs targeting hepatocytes (i.e. Bulevirtide-1 µM), non-parenchymal immune cells (i.e. Selgantolimod-1 µM) or multiple populations (i.e. Lonafarnib-2 µM) was evaluated by the quantification of viral parameters and the production of inflammatory cytokines.
Results: Our ex vivo PCLS infection protocol allowed the detection of HBV RNA, cccDNA, HDV RNA and HDAg at the end of the five-day observation period. Treatment of PCLS with Bulevirtide prior to inoculation (24 h) led to a marked decrease in viral parameters for both HBV and HDV. Lonafarnib treatment post-infection (48 h) was associated with the intracellular accumulation of HDAg. In the same context, Selgantolimod induced a significant decrease of HBV RNA levels. The immunomodulatory action of Selgantolimod was confirmed by the production of inflammatory cytokines (e.g. IL-6) in the culture supernatant. PCLS architecture and viability were comparable between the different treatment conditions.
Conclusion: Our results represent the first characterization of PCLS as a relevant ex vivo study model of HBV/HDV co-infection. Moreover, the evaluation of HTAs directed against parenchymal and non-parenchymal hepatic cell populations highlights the potential relevance of this system for the pre-clinical study of novel molecules aimed to achieve HBV/HDV cure.

Email: mara.kloehn@rub.de

Background and aims: HEV is estimated to be responsible for 44,000 deaths annually, yet its therapy is still limited to the off-label use of Ribavirin and pegIFNalpha, despite unsatisfactory cure rates and severe side effects, emphasizing the need for new and improved therapy options. In the pursuit of effective antiviral therapies, targeting viral entry holds promise, as it disrupts the initial stage of viral replication and has been proven effective for other hepatropic viruses. Cellular proteases have emerged as a class of host factors required for viral surface protein activation and productive cell entry by many viruses. Hence, we aimed to investigate the functional requirement and therapeutic potentials of targeting cellular proteases during HEV infection to identify potential antiviral drugs specifically related to viral entry.
Method: We tested several protease and cathepsin inhibitors in our recently established HEV cell culture model for their ability to interfere with infections of HEV in human hepatoma cells, HepaRGs and primary human hepatocytes (PHHs) by immunofluorescence staining for the HEV capsid protein and microscopic analysis. The cytotoxicity of the compounds was evaluated using MTT and LDH release assay, while the potential impact on viral replication was assessed by employing HEV subgenomic replicon systems. To identify the specific stage of the HEV life cycle targeted by the compounds, we performed time-of-drug-addition experiments. Cathepsin L (CTSL) knockout cells and siRNA transcript knockdown was employed to evaluate CTSL as a potential host and drug target.
Results: We found that blocking lysosomal cathepsins with small molecule inhibitors, impedes HEV infection without affecting RNA replication. Remarkably, the cathepsin inhibitor K11777 exhibited potent suppression of HEV infections with an EC_{50} of approximately 0.01 nM and no significant toxicity until micromolar concentrations in hepatoma cells. Notably, the inhibitory effects of K11777 were consistently observed in HepaRGs and primary human hepatocytes. Furthermore, we confirmed that HEV entry is potently blocked by inhibition of cathepsins and that CTSL knockout and knockdown reduced permissiveness to HEV.
Conclusion: In summary, our study highlights the pivotal role of cathepsins, especially CTSL, in the HEV entry process. The profound anti-HEV efficacy of the pan-cathepsin inhibitor, K11777, especially with its notable safety profile in primary cells, further underscores its potential as a promising therapeutic candidate.

OS-093
Efficient and heritable elimination of HBV viral antigens in vivo by epigenome editing

Wenbo Peng[1], Junzheng Zhao[1], Dai-tze Wu[1], Shaoshuai Mao[1], Leilei Wu[1], Jing Sun[1], Ruimin Lv[1], Di Sun[1], Bob Zhang[1], YiDi Sun[1,2], Changyang Zhou[1,2]. *[1]Epigenic Therapeutics, Shanghai, China; [2]Institute of Neuroscience. Chinese Academy of Sciences Center for Excellence in Brain Science and intelligence Technology. Chinese Academy of Sciences, Shanghai, China*
Email: changyang.zhou@epigenictx.com

Background and aims: Chronic hepatitis B virus (HBV) infection is a major global health problem, causing significant morbidity and mortality. However, current therapies do not provide effective functional cure. We have developed EPIREG, a CRISPR-derived epigenetic modulation technology comprising inactivated Cas9 (dCas9) fused with DNA methyltransferase and histone modification effectors, which enables efficient, specific, and durable silencing of targeted genes. Here we evaluated the anti-HBV activity of EPI-003, discovered by the EPIREG technology, in eliminating HBV viral antigens by inhibiting the transcription of cccDNA and integrated DNA.
Method: The anti-HBV efficacy of EPI-003 was evaluated using HBV-infected primary human hepatocytes (PHHs). The *in vivo* efficacy of EPI-003 was assessed by administration of lipid nanoparticles (LNPs) encapsulating EPIREG and single guide RNA (sgRNA) targeting the promoter of the HBV genome in both transgenic (genotype A) and AAV-HBV (genotype D) mouse models. The sgRNA was designed and optimized to target 91–100% of HBV genotypes from A-H. HBV DNA and viral antigen levels were monitored weekly.
Results: In PHHs, EPI-003, following one time treatment at 2.5 µg/ml post HBV infection, potently suppressed over 90% of HBsAg, HBeAg and HBV DNA levels at 14 days post the treatment. In HBV transgenic mouse model, single dose of EPI-003 resulted in a dose-dependent reduction of serum HBsAg by up to 2.0 logs following 2 wks of administration; this reduction was well maintained thereafter in all the animals up to greater than 16 wks (the study is onging). Furthermore, among animals treated with safe and efficacious doses, 5 of out of 10 animals further lowered HBsAg from wk 8 by additional 1 to 2 logs, even to the levels close or under the LLOQ (1.5 IU/ml) in 3 animals by wk16. More strikingly, HBsAb was induced in these 2 animals following single dose administration of EPI-003 without need of additional immune stimulation. Mechanistically, methylation of HBV cccDNA was induced and correlated well with the elimination of viral antigens and HBV DNA. Similar anti-HBV results were obtained in AAV-HBV animal model even with the high titer of HBV infection (i.e. HBsAg levels were greater than 10, 000 IU/ml). Animals were tolerated well throughout the treatment with normal physical activity and body weight maintenance. No off-target effects were detected by EPI-003 *in vivo* in animal models by host transcriptional and whole genome methylation analyses.
Conclusion: EPI-003 demonstrated superior pharmacological efficacy in eliminating HBV viral antigens and inhibiting HBV DNA with HBsAb recovery and no viral rebound in preclinical studies as compared with other anti-HBV therapies in the same preclinical models. Epigenetic modifications of HBV cccDNA and integrated DNA may provide a potential therapeutic solution to achieve functional cure in chronic hepatitis B patients.

OS-094
Chronic HDV infection is sustained by an intense HBsAg production from integrated HBV-DNA in the setting of a limited or even absent HBV reservoir

Background and aims: HDV exploits HBV surface glycoproteins (HBsAg) for viral morphogenesis and infectivity. Here, we investigate HBV and HDV replicative activity and their interplay by analysing liver biopsies from patients with chronic HBV/HDV co-infection (CHD) and HBV monoinfection (CHB).
Method: Liver tissues are analysed from 57 HBeAg-negative patients (71% NUC treated): 32 with CHD and 25 with CHB (median [IQR] age: 49 [39–59] and 44 [38–61] years). Intrahepatic levels of covalently-closed circular DNA (cccDNA), pregenomic HBV-RNA (pgRNA) and HDV-RNA were assessed by droplet digital PCR (ddPCR). ddPCR assays were set-up to quantify total HBs transcripts and to distinguish those deriving from cccDNA and integrated HBV-DNA (Grudda, 2022).
Results: Patients with CHD have significantly higher ALT and HBsAg levels than those with CHB (median [IQR]: 68 [45–89] vs 27 [20–46] U/L, P < 0.001 and 12, 575 [6, 322–20, 222] vs 5, 079 [2, 035–9, 287] IU/ml, P = 0.01) and lower HBV-DNA (median [IQR]: 20 [12–50] vs 1, 094 [137–4, 170] IU/ml, P < 0.001). Median (IQR) serum HDV RNA is 6.0 (3.8–6.7) logIU/ml, positively correlated with intrahepatic HDV-RNA (Rho = 0.62, P = 0.006; 787 [18–2, 782] copies/1000cells). CHD is characterized by a more restricted HBV reservoir in term of cccDNA and pgRNA (median [IQR]: 1 (0.02–16) vs 10 (2–18) copies/1000cells, P = 0.02 and 10 [1–173] vs 72 [38–380] copies/1000cells, P = 0.08, respectively). Nevertheless, both CHD and CHB are characterized by an abundant production of HBs transcripts (median [IQR]: 6, 267 [345–31, 387] and 8, 081 [314–15, 189]), with 99% of them derived from integrated HBV-DNA in both groups. By stratifying CHD patients according to cccDNA reservoir, lower levels of HBV intrahepatic markers are observed in those with less cccDNA (median [IQR] pgRNA and cccDNA-derived transcripts: 1.4 [0.4–77.5] vs 108 [4.5–411], P = 0.01 and 0.3 [0.2–1.5] vs 48 [9.6–186] copies/1000cells, P = 0.002 in cccDNA<1 vs cccDNA>1 copy/1000cells). Conversely, no differences are observed for intrahepatic HDV-RNA levels (median [IQR]: 782 [0.7–5, 559] vs 844 [1–6, 371] copies/1000cells in cccDNA<1 vs >1 copy/1000cells, P = 0.6). Moreover, a relevant amount of intrahepatic and serum HDV-RNA is also detected in the 8 CHD patients with completely undetectable levels of cccDNA and serum HBV-DNA (median [IQR]: 5, 495 [976–15, 107] copies/1000cells and 6 [5.9–7.3] log IU/ml, respectively), consistent with HDV replication persisting independently of the HBV reservoir.
Conclusion: CHD is characterized by a restricted HBV reservoir and an intense HBsAg production from integrated HBV-DNA, that can sustain HDV persistence independently of the intrahepatic HBV reservoir. In light of this finding, the silencing/elimination of cccDNA may not necessarily imply the achievement of HDV cure and pharmacological strategies should also target HBsAg production from integrated HBV-DNA.

Cirrhosis and its complications: Portal hypertension

OS-095
A machine learning algorithm generated using routine parameters could avoid unnecessary taps to exclude SBP in a national VA cohort with internal and external validation

Scott Silvey[1], Mahum Nadeem[2], Asiya Tafader[2], Galvin Dhaliwal[2], Jinze Liu[2], Nilang Patel[2], Jasmohan Bajaj[1]. [1]Virginia Commonwealth University, Richmond VA Medical Center, Richmond, United States; [2]Virginia Commonwealth University, Richmond, United States
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Despite the poor prognosis of missed/delayed diagnosis of spontaneous bacterial peritonitis (SBP), there are logistical challenges in providing timely taps. These are related to expertise, training, and time needed in busy emergency settings. Therefore, measures to exclude SBP that obviate taps are needed. Aim: Use machine learning (ML) to create and validate models to exclude SBP without a tap using easily observed and collected parameters.
Method: Training cohort: Using the Veterans Affairs (VA) Corporate Data Warehouse (CDW), records of pts with cirrhosis and ascites who underwent first tap within a day of admission between 2009–2019 were included nationally. SBP was defined as PMN >250/ml, positive culture or validated SBP billing code. Demographics, admission laboratories, medications, vital signs and comorbidities were recorded. XGBoost analysis was performed using variables significant on regression that were collected before the tap to determine probability of excluding SBP based on variables that did not include ascites fluid details. The generated XGBoost model was then tested in 2 validation cohorts: (a) CDW: 2nd para during 2009–2019 and (2) Prospective NACSELD cohort from VCU/Richmond VA admitted non-electively. Negative predictive values (NPV) at 5, 10 and 15% probability were tested.
Results: Training cohort: 9, 643 patients (63.14 ± 8.69 years age, 95.5% men, 50.7% alcohol-related) got their first early tap, with 1, 448 (15.0%) having SBP after tap. We initially collected 147 predictor variables, which reduced to 20 variables with test set (crude comparisons p < 0.001). The variables were BMI, vitals (temp, systolic/diastolic BP) and labs (liver function tests (albumin, ALT/AST/alk phos, bilirubin, INR), basic panel (eGFR, BUN K, CO2) and, blood count (Hgb, WBC, Neutropils and eosinophils)] at/before the tap. Of these only eosinophils and BP were ↓ in SBP; rest were↑. NPV at 5–15% probability were (92–97%) for SBP. Validation cohort #1: 2844 pts (63.14 ± 8.37 years age, 97.4% men, 54.0% alcohol-related) had repeat tap; 10% had SBP. Using the 20-variable ML model, NPV to exclude SBP at 5–15% probability ranged from 95–99%. Validation cohort #2: 333 pts from NACSELD (57.08 ± 7.74years age, 65.1%men, 50.1% alcohol-related) were admitted non-electively of whom 9% had SBP. Using the 20-variable ML model, NPV to exclude SBP at 5–15% probability ranged from 97–100%.
Conclusion: A machine learning model to exclude SBP without needing a tap using 20 variables easily available on demographics, labs and vitals showed excellent NPV in a national Veterans cohort. The high NPV for SBP were validated in internal and external cohorts and could be utilized in emergency settings to reliably identify which patient with cirrhosis and ascites can avoid a tap to exclude SBP.

OS-096-YI

Spleen stiffness measurement by transient elastography at 100 Hz refines the non-invasive diagnosis of clinically significant portal hypertension in compensated advanced chronic liver disease-final results of a european multicenter study

Background and aims: The ANTICIPATE, and subsequently, the ANTICIPATE-NASH study demonstrated that in compensated advanced chronic liver disease (cACLD), the probability of clinically significant portal hypertension (CSPH) can be non-invasively estimated based on liver stiffness measurement (LSM), platelet count (PLT), and, in obese metabolic dysfunction-associated steatotic liver disease (MASLD), body mass index (BMI).
Spleen stiffness measurement (SSM) is an emerging non-invasive test (NIT) for CSPH which became broadly applicable owing to a recently introduced 100 Hz vibration-controlled transient elastography probe. This study aimed at investigating the diagnostic utility of SSM-100 Hz as a standalone NIT in contemporary cACLD aetiologies and at refining the non-invasive diagnosis of CSPH by adding SSM to the components of the ANTICIPATE models.
Method: This study included Child-Pugh stage A cACLD (LSM ≥10kPa and/or F3/4) patients from 16 specialized European centers who underwent paired assessment of the hepatic venous pressure gradient (HVPG), SSM-100 Hz, and LSM from 2020–2023. The cohort was split into a derivation (2020–2022) and a temporal validation (2023) dataset.
Results: 407 cACLD patients (derivation: n = 202, validation: n = 205) were included (MASLD: 40.3%, ALD: 32.7%, viral: 18.4%, other aetiologies: 8.6%). The median BMI was 28.1 (25th-75th percentile: 24.6–33.1) kg/m2, and 39.6% were obese (BMI ≥30). The median HVPG was 11 (7–14) mmHg and 59.2% had CSPH (≥10 mmHg); median LSM, SSM-100 Hz, and PLT were 21.4 (14.1–31.6) kPa, 45.0 (32.1–65.4) kPa, and 131 (90–181) G/L, respectively. Patients included in the validation cohort showed significantly lower BMI and PLT, while LSM, SSM-100 Hz and CSPH prevalence did not differ significantly. In the derivation cohort, SSM-100 Hz, LSM, PLT, and BMI were independently associated with CSPH in logistic regression analysis. SSM-100 Hz and LSM yielded comparable C-statistics for CSPH (SSM-100Hz: 0.779 vs. LSM: 0.781, DeLong-test: P = 0.973). Notably, a model comprising SSM-100 Hz, PLT, and BMI performed similarly to the ANTICIPATE ± NASH model (derivation: 0.849 vs. 0.849; P = 0.999, validation: 0.873 vs. 0.863; P = 0.750). Finally, the combined model (SSM-100 Hz, LSM, BMI, and PLT) was superior to the ANTICIPATE ± NASH model (derivation: 0.889 vs. 0.849, P = 0.022, validation: 0.906 vs. 0.863, P = 0.012). Importantly, the combined model showed excellent calibration in the validation cohort. A nomogram was developed to facilitate point-of-care risk stratification.
Conclusion: The addition of SSM-100 Hz to LSM, BMI, and PLT outperformed the ANTICIPATE ± NASH model in CSPH risk stratification in our European multicenter study comprising cACLD patients with predominantly steatotic liver disease. Consideration of SSM-100 Hz improves CSPH risk assessment, supporting its implementation into clinical practice.

OS-097

Effect of rifaximin in severe cirrhotic patients with ascites: a double-blind randomized placebo-controlled phase 3 trial

Background and aims: The strongest evidence supporting the long-term use of antibiotic prophylaxis in cirrhosis concerns patients who recover from a first spontaneous bacterial peritonitis (SBP) and acute gastrointestinal bleeding. Evidence for primary prophylaxis of SBP is weak and the selection of quinolone-resistant bacteria is a concern. Here we present preliminary results from the ProPILA-Rifax study, a phase 3 trial to evaluate whether rifaximin (RIF) has a beneficial effect on 12-month survival in severe cirrhotic patients with ascites (NCT03069131). Data were not fully consolidated at the time of analysis.

Method: In this randomized, double-blind, placebo-controlled trial conducted at 17 French centers, severe cirrhotic patients [**1**] with grade 2 or 3 ascites and protein level in ascites <15 g/L were randomized 1:1 to receive RIF 550 mg BID or placebo (PBO) for 12 months, as primary prophylaxis of SBP. The primary end point was the 12-month transplant-free survival (TFS). Secondary end points were hospital mortality, 3- and 6-month TFS, incidence of complications of cirrhosis, and safety of rifaximin.

Results: Between March 2018 and June 2022, 1798 cirrhotic patients with ascites were screened and 159 were randomized to the PBO (n = 84) or the RIF (n = 75) arms. Baseline characteristics of patients in RIF/PBO were well balanced: mean (SD) age 59.2 (9.9)/59.6 (9.8) years, male 69.3%/78.6%, alcohol 70.7%/72.6%, mean (SD) MELD score 16.8 (8.9)/13.5 (5). During the study period, 31/30 patients died, but deaths were not related to the study drug, and 7/7 were transplanted. The 12-month TFS rates were comparable between groups (RIF/PBO: 58/64.9%). The 3- and 6-month TFS rates in the RIF/PBO groups were 82.2%/74.7% and 75%/68.4%, respectively. Incidence of infections, hepatorenal syndrome, hepatic encephalopathy and variceal bleeding were not significantly different (all p = NS). The number of patients with adverse events (AEs) (RIF/PBO: 68 [90.7%]/79 [94.1%]) and serious AEs (RIF/PBO: 56 [74.7%]/67 [79.8%]) was similar between groups. The percentage of AEs leading to drug discontinuation, RIF *vs* PBO, was 44.6% *vs* 41.8%.

Conclusion: In this phase 3 trial, RIF was well tolerated but had no beneficial role on the 12-month TFS and incidence of complications of liver cirrhosis in severe cirrhotic patients with moderate to large ascites.

Addition of simvastatin to carvedilol improves survival in patients with decompensated cirrhosis after variceal bleed. A randomised controlled trial

Randeep Rana[1], Tabish Mohammad[1], Samagra Agarwal[1], Rajkumar Bayye[1], Syed Ahmed[1], Deepak Gunjan[1], Sanchit Sharma[1], Anoop Saraya[1]. [1]*All India Institute of Medical Sciences, New Delhi, India*
Email: sanchitsharma2188@gmail.com

Background and aims: While linked to improve portal hypertension and prevent complications, data on efficacy and safety of adding simvastatin to standard of care (SOC) in patients with decompensated cirrhosis is limited. We assessed whether addition of simvastatin to carvedilol could reduce mortality in patients with cirrhosis after variceal bleeding.

Method: In this single-centre open-label randomised controlled trial with superiority design, eligible patients with cirrhosis (Child-Turcot-Pugh[CTP] score 5–12) with recent (<5 days) variceal bleed without hepatocellular carcinoma (HCC) or portal-vein thrombosis were randomised to either simvastatin[20 mg once-daily] (n = 130) or no drug (n = 138) in addition to SOC (carvedilol with serial band ligation). Primary outcome was all-cause mortality over 24-month follow-up. Secondary outcomes included rates of individual decompensations with transplant/death before decompensation as competing event. Intention-to-treat analysis included all patients, while per-protocol analysis excluded 17 (12.3%) patients not compliant to simvastatin.

Results: Baseline characteristics (mean age: 45.0 ± 11.5 years, aetiology: alcohol related/NASH/HBV/HCV: 48.1%/15.3%/13.1%/6.7%), severity of liver disease[(CTP class- A/B/C:39%/44%/17% in simvastatin vs 30%/56%/14% in no drug arm;p = 0.14); MELD (median 14[IQR 11–19] vs 14[11–19];p = 0.57)] and follow-up (median 18[14–24] vs 18[12–22] months; p = 0.55) were comparable in both arms. On intention-to-treat analysis, patients on simvastatin had lower mortality (hazard-ratio:0.48[95%confidence-interval:0.29–0.81; Cox-proportional-hazards p = 0.006). Incidence of ascites was lower (sub distributional hazards-ratio (sHR):0.60[0.39–0.92]; competing risks regression, p = 0.02), All-cause decompensation (sHR:0.74 [0.521.05];p = 0.09), rebleeding (sHR:0.87[0.571.34];p = 0.53), hepaticencephalopathy (HE) (sHR:0.71[0.42–1.19;p = 0.19) and acute-on-chronic liver-failure (ACLF) (0.65[0.39–1.10];p = 0.11) were comparable. On per-protocol analysis (n = 251), rates of mortality (HR:0.48 [0.28–0.84];p = 0.01), all-cause decompensation (sHR:0.65[0.45–0.95];p = 0.025), ascites (sHR:0.54[0.340.86];p = 0.01), HE (sHR:0.51 [0.280.92];p = 0.027) and ACLF (sHR:0.54[0.31–0.95];p = 0.033) were lower in patients on simvastatin. On sub-group analysis, there was no heterogeneity of treatment-effect across CTP-class (p = 0.105) or etiology (p = 0.39). Adverse events on simvastatin included body-aches (n = 19; 14.6%) and transient creatinine-kinase elevation (n = 5; 2.9%) but no patients developed rhabdomyolysis.

Conclusion: Addition of Simvastatin to carvedilol improves transplant-free survival in patients with decompensated cirrhosis with recent acute variceal bleed by reducing the incidence of non-bleed related decompensation. [CTRI/2022/07/044263].

OS-099-YI

Assessment of sarcopenia improves the prediction of post-TIPS mortality in older adult patients with cirrhosis

Email: fschepis@unimore.it

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) has been demonstrated to be feasible in older adult patients (age ≥70 years), but the selection criteria are still suboptimal. Sarcopenia, highly prevalent in the elderly population, may be significantly associated with post-TIPS outcomes. This study aimed at evaluating the impact of baseline sarcopenia on post-TIPS survival in older adults with cirrhosis.
Method: A retrospective analysis of the prospective Italian TIPS Registry (RI-TIPS) was conducted to identify patients ≥70 years who received TIPS from June 2015 to March 2023. Availability of a baseline abdominal CT scan was a mandatory inclusion criterion. Skeletal muscle index (SMI) and muscle attenuation (MA) in Hounsfield units (HU) were evaluated at the L3-L4 intervertebral disc level. Sarcopenia was defined as SMI <50 cm^2/m^2 for men and <39 cm^2/m^2 for women; myosteatosis as MA <41 HU in patients with a BMI <25 and <33 HU in those with a BMI ≥25, respectively. Probability of liver-related death was evaluated by competing risks survival analysis. A prediction model for liver-related mortality was created.
Results: One-hundred and fifteen patients were included: median age 74.2 years (IQR 5.0), 61.7% male, median BMI 24.5 (IQR 5.3), 60% prevalence of sarcopenia [median SMI 42.5 (IQR 10.3)] and 80% prevalence of myosteatosis [median muscle attenuation 29.8 HU (IQR 12.2)]. The main etiologies were viral (41.7%), alcohol-associated cirrhosis (30.0%), and metabolic dysfunction-associated steatohepatitis (27.8%). Refractory ascites (54.7%) and secondary prophylaxis of variceal bleeding (33%) were the main indications for TIPS. During a median follow-up of 1-year (IQR 1.9), 40 (34.8%) patients died for liver-related causes and 16 (13.9%) for extrahepatic causes. All-cause mortality was higher in sarcopenic patients than in those without sarcopenia (6-months: 32.0% vs. 8.7%; 1-year: 47.0% vs. 11.0%, respectively; p value 0.005). The impact of sarcopenia was even more significant when considering liver-related mortality (6-months: 25.0% vs. 2.2%; 1-year: 43.0% vs. 4.8%, respectively; p value <0.001). Interestingly, no significant differences were found in all-cause and liver-related mortality between patients with and without myosteatosis (p values 0.6 and 0.8, respectively). A predictive model that includes INR, creatinine, and sarcopenia was developed to estimate liver-related mortality. The model achieved good predictive performances with AUCs of 0.826, 0.788, and 0.712 at 6-month, 1-year, and 2-years, respectively.
Conclusion: Due to its significant impact on survival, the evaluation of sarcopenia improves the selection of older adults with cirrhosis candidate to TIPS. The new predictive model for post-TIPS liver-related mortality deserves validation.

Elevated expressions of NTCP on NK cells from liver fibrosis of metabolic dysfunction-associated steatohepatitis patients are associated with increased bile acid uptake that impaired their function via STAT signaling pathway

Ahmad Salhab[1], Johnny Amer[1], Rifaat Safadi[1]. *[1]Liver Institute, Hadassah Hebrew University Hospital, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: Dysfunctional bile acid (BA) metabolism may influence immune cell activation, thereby exacerbating liver damage. However, the influence of BA on natural killer (NK) cells remains elusive. Our study aimed to assess the impact of the BA signaling pathway on NK cell functions and their immune and molecular features in humans with Metabolic dysfunction-associated steatohepatitis (MASH) and a mouse model of MASH.
Method: Human peripheral NK cells from patients (age ≥18 years) of histologically documented MASH with different Metavir scores of liver fibrosis were obtained. NK molecular aspects of BA signaling through NTCP expressions, STAT signaling pathway, RNA single seq, activatory markers [NKp46, NKp30, CD107a], and exhaustion markers [PD-1, TIGIT, LAG-3] were assessed. BA modulatory pathways and trNK phenotypic alterations were assessed in mice models of MASH and adoptive transfer models of immune alterations through NK cells transplantation following sorting cells according to NTCP expressions.
Results: Peripheral blood NK cells obtained from patients with MASH and severe liver fibrosis (METAVIR scores of F3/F4) exhibited 2.5-fold upregulation in sodium+/taurocholate cotransporting polypeptide (NTCP) expression compared with healthy donors, indicating that NTCP may be involved in liver fibrosis. Liver biopsy tissue-resident NK (trNK) cells were sorted based on NTCP expression and higher taurocholic acid (TCA) uptake, and increased exhaustion was observed in $trNK^{NTCP+}$ cells relative to $trNK^{NTCP-}$ cells from the same patients, patients with F1/2 scores, and healthy donors. Moreover, RNA single seq from 5200 genes detected, STAT3, PDCD1, LAG3, TGFβ, and TGFβ receptor mRNA expression was upregulated in $trNK^{NTCP+}$ cells in the F3/F4 scored patients as compared to their $trNK^{NTCP-}$ from the same patients. The $trNK^{NTCP+}$ cells also exhibited increased levels of STAT3 phosphorylation and decreased STAT1 and STAT5 phosphorylation. $trNK^{NTCP+}$ cells in which STAT3 was inhibited had significantly reduced NTCP expression, reduced NK cell exhaustion, and increased NK cell activity. In MASH mice with epigallocatechin gallate (EGCG)-mediated inhibition of NTCP expression, TCA uptake was reduced, and liver fibrosis was attenuated. Additionally, transplantation of $trNK^{NTCP-}$ cells into immunodeficient MASH model mice alleviated liver fibrosis, along with reducing the levels of proinflammatory and profibrotic cytokines and ameliorating lipid homeostasis.
Conclusion: Taken together, these results indicate that enhancing immune responses would be clinically beneficial though strengthening NK cells activity via treating with NTCP antagonists and therefore a potential strategy for preventing liver fibrosis in MASH patients.

Background and aims: Colorectal liver metastasis (CRLM) stands as the second leading cause of cancer-related mortality, as more than 50% of colorectal cancer (CRC) patients develop CRLM. Comorbidities such as dyslipidaemia are risk factors for the development of CRC. The hepatocyte, being the predominant liver cell, controls lipid and lipoprotein metabolism. However, it remains unclear whether the remodelling of cholesterol (CL) metabolism in hepatocytes is involved in the development of CRLM. Here, we aim to: 1) investigate the reprogramming of CL metabolism in CRLM; and 2) assess whether the modulation of CL metabolism in hepatocytes, achieved through PCSK9 overexpression, influences CRLM progression.
Method: The E-GEOD-14297 human transcriptome array, including healthy liver (HL), CRC and CRLM was analysed. The CRLM model involved intrasplenic injection of MC38 tumor cells in mice fed chow diet (CD), high fat diet (HFD) or Western diet. *In vivo Pcsk9* overexpression in hepatocytes was induced using adeno-associated virus 8. Metabolic fluxes, lipid content, protein and gene expression were analysed in control and metastatic surrounding (ST) and tumor (T) tissues. An *in vivo* extravasation assay was performed by intrasplenic injection of RFP-labelled MC38 cells. *In vitro* proliferation assays of MC38 cells were performed with conditioned media obtained from isolated hepatocytes.
Results: The analysis of the CRLM transcriptome revealed that one of the most altered pathways in CRLM was "lipid and lipoprotein metabolism". Mice fed HFD or CD exhibited similar tumor numbers, liver fibrosis and reprogramming of CL metabolism in CRLM. CL levels increased in the ST and T of CRLM, with no concurrent increases observed in metabolic fluxes regulating *de novo* synthesis or protein levels of the rate-limiting enzyme HMGCR. However, a decrease in serum CL and an increase in hepatic levels of LDLR in ST and T were observed compared to healthy livers. During CRLM, hepatocyte *Pcsk9* overexpression in mice prevented LDL uptake, as indicated by elevated serum CL levels, and induced a marked reduction in tumor number and associated fibrosis compared to their control counterparts. *Pcsk9* overexpression induced an increase in the *de novo* synthesis and accumulation of cholesteryl ester in the ST, predominantly in hepatocytes. While the extravasation of CRC cells during CRLM remained unchanged when *Pcsk9* was overexpressed in hepatocytes. Conditioned media from hepatocytes overexpressing *Pcsk9* decreased the proliferation of CRC cells. Treating hepatocytes with inhibitors of different enzymes of CL synthesis induced changes in the secretome as the proliferation of CRC cells showed.
Conclusion: Targeted remodelling of CL metabolism in hepatocytes reduces CRLM progression without affecting CRC cell extravasation. The results suggest the potential involvement of the hepatocyte secretome in this process.

A rule-based multiscale model of hepatic stellate cell plasticity: critical role of the inactivation loop in fibrosis progression

Matthieu Bougueon[1], Vincent Legagneux[2], Octave Hazard[3], Jérémy Bomo[2], Anne Siegel[4], Jérôme Féret[5], Nathalie Theret[2]. *[1]Centre national de la recherche scientifique, Paris, France; [2]Université de Rennes, Institut national de la santé et de la recherche médicale, Rennes, France; [3]École Normale Supérieure Lyon, Lyon, France; [4]Université de Rennes, Centre national de la recherche scientifique, Rennes, France; [5]Institut national de recherche en informatique et en automatique, Paris, France*
Email: mbougueon@di.ens.fr

Background and aims: Hepatic stellate cells (HSCs) are the source of extracellular matrix (ECM) whose accumulation leads to fibrosis, a condition that impair liver functions in chronic liver disease. Understanding the dynamics of HSCs will provide insight to develop new therapeutic approaches. Few computational models have been proposed for hepatic fibrosis and none include the heterogeneity of HCSs phenotypes recently highlighted by single-cell RNA sequencing analyses. The aim of the study is to develop a rule-based model to study HSCs dynamics during fibrosis and reversion.
Method: Kappa, a graph rewriting language, is used to build models that are calibrated with data from literature. Simulations are performed using the KaSim tool based on the Gillespie stochastic simulation algorithm. We generate biological data from a mouse model of CCl4-induced liver fibrosis to validate the final model and we use RNA sequencing data from patients with fibrosis to verify the predictions.
Results: We develop the first rule-based multi-scale model of HSCs integrating seven HSCs states and their interaction with TGFB1 molecules that regulate HSCs activation and secretion of type I collagen, the main component of the ECM. Simulation studies highlight the critical role of the HSCs inactivation process during fibrosis progression and reversion. While inactivation allows elimination of activated HSCs during reversion steps, reactivation loops of inactivated HSCs (iHSCs) is required to sustain fibrosis. We further have demonstrated the model's sensitivity to TGFB1 parameters, suggesting its adaptability to a variety of pathophysiological conditions in which TGFB1 release associated with the inflammatory response differs. Our model further predicts the accumulation of iHSCs during chronic liver disease and we confirmed this accumulation by using RNA sequencing data from patients with liver fibrosis.
Conclusion: Overall, our study provides the first model of HSCs dynamics during fibrosis and liver reversion that can be used to explore the regulatory role of HSCs in liver homeostasis. Thus, our model provides predictions showing the critical role of the inactivation loop in the development of hepatic fibrosis and identifying iHSCs as potential new markers of fibrosis progression.

Email: svenja.schuehle@gmail.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is the fastest-growing cause of primary liver cancer, specifically hepatocellular carcinoma (HCC). MASH-to-HCC progression is marked by necroinflammation, metabolic reprogramming and fibrosis. Due to the direct connection between the gut and the liver, the intestinal microbiota is suspected to be involved in inflammatory and metabolic processes during MASH development. Therefore, in this study we aimed to investigate the role of the gut microbiota and gastrointestinal B cells in a mouse model of MASH-to-HCC transition.
Method: C57Bl/6 mice were fed a choline-deficient high fat diet (CD-HFD) for 6 or 12 months to induce MASH and MASH-to-HCC progression. B cells were therapeutically depleted with anti-CD20 and the microbiota was depleted using broad-spectrum antibiotics (ABx) administered through the drinking water. Normal diet (ND) and CD-HFD mice without treatment served as control mice. Microbiota composition and liver pathogenesis were analyzed by shotgun metagenomic sequencing, serology, immunohistochemistry, RNA sequencing and metabolomics.
Results: We showed that B-cell depletion significantly reduced hepatic steatosis and fibrosis and that IgA from gastrointestinal B cells was sufficient to induce fibrosis. This axis was mediated by IgA-dependent activation of hepatic FCGR1^{+} cells which directly correlated with fibrosis development. Fibrosis still developed in AID^{G23S} mice with reduced somatic hypermutation indicating that antigen specificity of IgA was not required for fibrosis induction. Furthermore, we found that the role of B cells in MASH was independent of the gut microbiota since germ-free mice were not protected from MASH development. However, therapeutic microbiota depletion using ABx treatment in combination with CD-HFD significantly reduced fibrosis development during MASH progression despite similar obesity and steatosis development compared to non-treated CD-HFD mice. While MASH-associated T-cell infiltration was not affected by ABx treatment, activation of resident and infiltrating myeloid cells was reduced. ABx treatment also significantly decreased intestinal and systemic IgA and consequently the activation of hepatic FCGR1^{+} cells. Moreover, ABx treatment was associated with significant transcriptional and metabolic changes compared to non-treated CD-HFD mice.
Conclusion: Our results demonstrate that the intestinal microbiota promotes MASH progression through IgA-mediated fibrogenesis. Furthermore, our data suggest that certain immunological features of MASH occur independent of the microbiota while metabolic and transcriptional processes regulated by the microbiota might be involved in the pathogenesis.

Oxidative stress and metabolic reprogramming of hepatocytes forming liver cell rosettes in patients with primary sclerosing cholangitis

Carlotta Mayer[1], Silvia Radrezza[1], Ignacy Rzagalinski[1], Brian K. Chung[2], Tom Hemming Karlsen[3], Andrej Shevchenko[1], Marino Zerial[4]. *[1]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany; [2]Research Institute of Internal Medicine, NoPSC Center, Oslo, Norway; [3]Oslo University Hospital, Oslo, Norway; [4]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany*
Email: zerial@mpi-cbg.de

Background and aims: Patients with impaired bile flow frequently exhibit structural tissue changes described in histological sections as liver cell rosettes. Liver cell rosettes are clusters of >2 hepatocytes arranged around a dilated bile canalicular lumen, creating segments of epithelial tubes. The hepatocytes in liver cell rosettes have a single apico-basal axis, reflecting a change to the usual hepatocyte polarity. As a shift in polarity requires fundamental intracellular reorganization, we tested the hypothesis that hepatocytes forming liver cell rosettes may lose metabolic functionality, thus contributing to disease progression.
Method: We performed laser capture microdissection on liver tissue of patients with primary sclerosing cholangitis (PSC) (n = 7). We collected paired samples of parenchyma with normal hepatocytes and parenchyma of hepatocytes forming liver cell rosettes. From these samples we performed mass spectrometry and compared the proteome. We confirmed our findings using immunofluorescence microscopy and assays for liver metabolic functions.
Results: Principal component analysis revealed broad protein changes between usual parenchyma and liver cell rosette parenchyma. We identified 34 proteins enriched and 59 proteins reduced in liver cell rosette parenchyma (FDR = 0.05). Interestingly, the majority of proteins reduced in liver cell rosette parenchyma are enzymes of key metabolic pathways of hepatocytes e.g. glutathione detoxification pathway. Based on this, we quantified the glutathione (GSH) content in the PSC patients. While oxidized glutathione (GSSG) usually remains below 5% of total GSH, we detected an increase of ~45.7% in GSSG. The absolute levels of GSSG positively correlate with the patient's liver cell rosette affection (linear regression analysis, R^2 = 0.488) and the only known canalicular exporter of GSSG, MRP2, is specifically depleted in liver cell rosettes. Liver cell rosette parenchyma was enriched in lysosomal proteins and proteins involved in ATP production. In line with a decrease of glycolytic enzymes and the glucose transporter GLUT2 this suggests, a reduction of glucose-based energy production and mobilizing alternative energy sources from lysosomal breakdown processes.
Conclusion: Our analysis shows that in PSC patients hepatocytes forming liver cell rosettes are not only structurally (altered cell polarity) but also functionally different from normal hepatocytes. The rosette hepatocytes have a reprogrammed metabolism and accumulate oxidized glutathione, probably as a result of increased oxidative stress and decreased biliary excretion. In summary our results suggest that the changes in liver cell rosettes may have important consequences for hepatocytes to maintain their functionality and, thus, for disease progression.

Collagen-integrin signaling re-establishes bile duct morphogenesis and promotes adult ductular regeneration

Alexander Walker[1], Scott Waddell[1], Anabel Martinez Lyons[1], Paula Olaizola[1], Luke Boulter[2]. [1]*MRC Human Genetics Unit, University of Edinburgh, Edinburgh, United Kingdom;* [2]*MRC Human Genetics Unit, University of Einburgh, Edinburgh, United Kingdom*
Email: alex.walker@ed.ac.uk

Background and aims: Bile duct reaction (BDR) is a common feature of many cholangiopathies, characterized by the proliferation and migration of bile ducts between portal triads. How new ducts form with the correct anatomical location and dimensions during regeneration remains unresolved. Integrins are a key cell-surface receptor enabling cells to interact with the extra-cellular matrix (ECM) and move through their extracellular environment. Our group has recently shown that integrin signaling is necessary for morphogenic restructuring of the bile duct. We aimed to address whether ECM-integrin interactions are essential for the formation of complex elongating bile duct networks in adult BDR following damage.
Method: By combining human, pathological tissue and the 3, 5-diethoxycarbonyl-1, 4-dihydrocollidine (DDC) mouse model of biliary inflammation and fibrosis, dynamic changes in biliary integrin expression and peri-portal ECM composition were assessed by quantitative imaging and gene expression analysis. Flow cytometry was used to isolate integrin α2-high versus low populations which were analysed by bulk RNA sequencing. A transgenic *Krt19*:Cre/loxP mouse model allowed for the conditional knockout of *Itga2 and Itgb1* in cholangiocytes; this as well as *in vitro* assays were used to assess the role of integrin signaling in biliary regeneration and morphogenesis. Finally reverse phase protein arrays were used to interrogate the downstream mechanisms of integrin signaling in cholangiocytes.
Results: Collagen-binding integrins (particularly α2/β1) are elevated in bile ducts in mouse models of BDR and in human primary sclerosing cholangitis, mirroring an increase in structural collagens I and III in the peri-portal ECM during BDR. Integrin α2-high bile ducts are formed of predominantly immature cholangiocytes and localize to branching tips throughout the biliary network, partially overlapping with a proliferative cholangiocyte population. Bulk RNA-seq of integrin α2-high cholangiocytes shows the increased expression of genes involved in migration (*Inhba*, *Aif1l*), mitosis (*Smc2*) and mechano-transduction (*Piezo2*). In vitro inhibition of integrin α2 using both siRNA and chemical inhibition (TC-I 15) reduced the proliferation and migration in cholangiocytes, in part attributable to a reduced phosphorylation of FAK and Akt. In vivo studies showed that integrin knockout cholangiocytes have reduced regenerative capacity and fail to contribute to extensive regeneration of the biliary tree.
Conclusion: Collagen-binding Integrins are expressed at the leading tip of bile duct growth in biliary inflammation, mirroring increased expression in its cognate ligands between portal triads. Integrin α2 knockout reduces migration and morphogenesis in cholangiocytes, suggesting modulation of the ECM-Integrin axis is important in understanding how ductular systems regenerate.

OS-106-YI

TGR5 deficiency reduces angiocrine factor expression in liver sinusoidal endothelial cells and hepatocyte proliferation after partial hepatectomy

Impreet Kaur[1], Rajnish Tiwari[1], Pinky Juneja[2], Ashwini Vasudevan[3], Akash Kumar Mourya[4], Michael Trauner[5], Veronika Mlitz[6], Dinesh Mani Tripathi[7], Savneet Kaur[8]. [1]*Institute of liver and biliary sciences, Delhi, India;* [2]*Institute of liver and biliary sciences, Delhi;* [3]*Institute ofliver and biliary sciences, Delhi, India;* [4]*Institute of liver and biliary sciences, National Institute of Pharmaceutical Education and Research, Delhi, India;* [5]*Medical University of Vienna, Vienna, Austria;* [6]*Medical University of Vienna, Internal Medicine III, Vienna;* [7]*Institute of liver and biliary sciences, Delhi;* [8]*Institute of liver and biliary sciences, Delhi, India*
Email: savykaur@gmail.com

Background and aims: Bile acid (BA) receptors like FXR and TGR5 have been implicated in liver regeneration. Although FXR-mediated liver regeneration is well known, mechanisms underlying TGR5-mediated liver regeneration remain largely unknown. Here, we investigated role of TGR5 during liver regeneration in rat models of 70% partial hepatectomy (PHx).
Method: PHx rat models were developed and studied at day 2 and day 5 post-PHx. Primary hepatocytes, liver sinusoidal endothelial cells (LSECs) and hepatic stellate cells (HSCs) were isolated by collagenase perfusion. Gene expression of both FXR and TGR5 in liver tissues and liver cells was studied. *In vitro*, effects of silencing and enhancing TGR5 expression was studied in LSECs by RT-PCRs and ELISA. In vivo effects of TGR5 deficiency on LSECs was evaluated in TGR5 KO mice. Co-culture of LSECs and hepatocyte organoids were investigated. BA profiling of peripheral serum in PHx rat models and human liver donors (n = 5) undergoing hepatectomy for LDLT was performed using LC-MS.
Results: In liver tissues, TGR5 gene expression was increased by 4 fold ($p < 0.0001$) at day 2 post-PHx, compared to sham while its expression was similar to that of sham at day 5. Among liver cells, TGR5 expression was negligible in hepatocytes at day 2 and day 5 post-PHx, but significantly increased in both LSECs and HSCs compared to sham (3 fold and 2.5 fold at day 2; 5.7 fold and 6 fold at day 5, $p < 0.0001$, each). An inhibition of TGR5 receptor by siRNA in LSECs substantially reduced gene expression of Id1 (2 fold), HGF (2.5 fold), WNT2 (3 fold) ($p < 0.001$ each) and also reduced angiocrine factor release in cell soups (HGF: 2.5 fold, Wnt2: 3 fold, $p < 0.001$ each) compared to controls. This reduction of gene expression and angiocrine factor secretion by LSECs was partially restored by addition of TGR5 agonist, lithocholic acid, LCA in culture for 24 h. Also, compared to cell soups obtained from TGR5-siRNA treated LSECs, cell soups obtained from LCA treated LSECs significantly enhanced proliferation of hepatocyte organoids (3 fold; $p < 0.05$ each). In TGR5 KO, LSECs showed reduced gene expression of Id1 (2 fold), HGF (2.5 fold), Wnt2 (2 fold); $p < 0.001$ each compared to wild-type mice.
BA profiling clearly demonstrated that secondary BAs that activate TGR5, Lithocholic acid (LCA), Deoxycholic acid (DCA) were significantly increased in PHx compared to sham at day 2 post-PHx. Human donors undergoing hepatectomy with remnant liver volume to total liver volume between 35–40% showed increased ratio of serum secondary to primary BAs with specific increase of LCA and DCA levels at day 2 post-hepatectomy.
Conclusion: There is an increase in serum levels of secondary BAs and hepatic TGR5 expression at day 2 post-PHx. Deficiency of TGR5 in LSECs reduces angiocrine gene expression such as Id1, Wnt2 and HGF and hence hepatocyte proliferation during early phases of PHx.

OS-107-YI

Expression and regulation of HNF4α isoforms in liver development and disease

Paulina Zydowicz-Machtel[1], Lenka Belicova[1], Ting Huang[1], Joanna Sajkowska-Kozielewicz[2], David Kosek[1], Katja Petzold[1,2], Emma Andersson[1]. [1]*Karolinska Institutet, Solna, Sweden;* [2]*Uppsala University, Uppsala, Sweden*
Email: paulina.zydowiczmachtel@ki.se

Background and aims: Hepatocyte nuclear factor 4 alpha (HNF4α) is a crucial hepatocyte transcription factor controlling liver development and hepatocyte identity in mature livers. However, in mouse and human cells multiple HNF4α isoforms were found and can be further categorized into two classes: P1- and P2-HNF4α, based on the

transcription promoter usage. It is increasingly clear that the isoforms have different roles in the liver, while their expression depends on liver developmental stage, and is dysregulated in hepatocellular carcinoma (HCC). Their expression and function during embryonic development and cancer is not well understood, we therefore need detailed understanding of expression patterns and regulation of individual HNF4α isoforms, as well as comprehensive comparison between mouse and human models. Here, we aim to elucidate the role (s) of P1- and P2-HNF4α isoforms in hepatoblasts, cholangiocytes, and hepatocytes from healthy and diseased liver using mouse *in vivo* and *in vitro* liver models, human cell lines and gene silencing approaches.

Method: To determine the expression pattern of P1- and P2-HNF4a isoforms during liver development and maturation, we performed an immunohistochemistry (IHC) staining analysis on wild-type embryonic (embryonic day E17.5, E18.5) and postnatal (postnatal day P1, P7, P15, adult) mouse liver tissues, including livers of aged mice with spontaneous tumor development. For functional characterization of the isoforms, we used both mouse and human *in vitro* systems modeling liver development or liver disease e.g. mouse primary hepatoblasts and cell lines in which the expression of specific isoforms was manipulated using RNAi (RNA interference): *miRNA-34a* (*microRNA-34a*) and siRNAs (small interfering RNA). HNF4α isoform repression *in vitro* was verified by quantitative PCR (qPCR) and Western blot. Hepatoblasts development into hepatocytes or cholangiocytes after isoform downregulation was characterized by immunofluorescence staining.

Results: Interestingly, P2-HNF4α was found to be expressed in cholangiocytes at early stages of developing liver (P7 and P15) and in liver tumor tissue, while P1-HNF4α expression was almost exclusively restricted to hepatocytes. Preliminay experiments in cell lines indicate that *miRNA-34a*, a potential endogenous regulator of HNF4α, may repress both P1-HNF4α and P2-HNF4α. Repression of HNF4α isoforms in primary hepatoblasts affected the morphology and differentiation of hepatoblasts.

Conclusion: Our data suggests that P1-HNF4α and P2-HNF4α isoforms differentially control cell identity of liver epithelial cells in development and may become activated/disactivated in liver cancer. Further studies towards individual manipulation of HNF4α isoforms in the liver can be a promising tool for more controlled and precise treatment in liver disease.

OS-108-YI

Liver lymphatic endothelial cells regulate hepatic progenitor cells via lymphangiocrine factors in pathological liver regeneration

Aarti Sharma[1], Pinky Juneja[2], Ashwini Vasudevan[2], Deepika Jakhar[2], Jayesh Kumar Sevak[2], Impreet Kaur[2], Shiv Kumar Sarin[2], Dinesh Mani Tripathi[2], Savneet Kaur[2]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: savykaur@gmail.com

Background and aims: Liver sinusoidal endothelial cells (LSECs) are known to facilitate hepatocyte proliferation and liver regeneration. However, contribution of liver lymphatics and lymphatic endothelial cells (LyECs) to liver regeneration remains completely unexplored. Here, we comprehensively characterized LyECs vis a vis LSECs and studied their functions in physiological and pathophysiological liver regeneration.

Method: For physiological regeneration, 70% partial hepatectomy (PHx) rat models were used and for pathophysiological, we prepared impaired hepatocyte regeneration models, by 2-Acetyaminoflourene followed by 70% PHx (AAF-PHx). Sham-PHx and AAF-Sham were used as controls for PHx and AAF-PHx. Experiments were performed at day 2 post-PHx and day 8 in post AAF-PHx. Primary LSECs and LyECs were identified by imaging techniques and sorted with specific markers as LyVE1, CD31 and Podoplanin, CD31 respectively. Hepatic lymphatic drainage was assessed via FITC-dextran transport in portal lymph nodes. Proteomic analysis was performed on sorted LSECs and LyECs and some of secretory proteins were analyzed by ELISAs. Effect of LSEC and LyEC conditioned media (CM) on hepatocytes and OV6+ hepatic progenitor cell (HPC) organoids was studied in co-culture assays.

Results: Histologically, proliferating hepatocytes were seen day 2 post-PHx and in AAF-PHx 8day, we observed damaged hepatocytes, increased inflammation with fibrosis (grade I/II). OV6+ HPCs were increased in AAF-PHx compared to PHx (23 ± 0.5 vs $5.2 \pm 1\%$, $p = 0.003$) near peri-portal region, confirmed with IHC. Dual positive staining and imaging revealed that LyECs were mostly located adjacent to HPCs near portal areas in PHx and AAF-PHx. Increased percentage of LSECs ($17.66 \pm 2\%$) and LyECs ($1.68 \pm 1.2\%$) were observed in PHx verified with confocal imaging, IHC and FACS analysis. Compared to PHx, there was decreased LSECs ($10.4 \pm 0.01\%$; $p = 0.007$) and increased LyECs ($2.59 \pm 0.05\%$; $p = 0.04$) in AAF-PHx. Hepatic lymphatic drainage also increased by about 80% in AAF-PHx compared to PHx ($p = 0.001$). Proteome analysis in LSEC and LyECs identified more than 1000 proteins each and about 400 were differentially expressed among different study groups. Among differentially expressed secretory proteins, secretome of PHx-LSECs showed increased expression of Wnt-2 (4 fold, $p = 0.01$) and secretome of AAF-PHx LyECs showed increased expression of Wnt-2 (2 fold, $p = 0.01$) and R-spondin 3 (2.5 fold, $p = 0.05$) compared to sham. In co-cultures, there was a considerable increase in number of HPCs organoids in AAF-PHx LyECs-CM (9 ± 2 vs 16.6 ± 1.5, $p = 0.006$).

Conclusion: The number and drainage function of hepatic lymphatics increase significantly during pathological liver regeneration. Our study provides valuable insights into the novel role of specific lymphangiocrine factors secreted by LyECs in governing proliferation of HPCs during liver injury.

OS-109

Developmental gene regulatory networks driving human liver disease cell states identified by single cell multi-modal data integration

Nigel Hammond[1], Elliot Jokl[1], Syed Murtuza-Baker[1], Sokratia Georgaka[1], Varinder Athwal[1], Neil Hanley[1], Karen Piper Hanley[1]. [1]*University of Manchester, Manchester, United Kingdom*
Email: karen.piperhanley@manchester.ac.uk

Background and aims: Chronic liver disease is increasing and a major cause of death worldwide. Iterative injury prolongs an impaired wound-healing response, resulting in fibrosis. This unique microenvironment, involving complex interactions between multiple cell-types, drives progressive disease. We have previously shown similarities at the scar interface in cirrhosis with the ductal plate during liver development. However, it is clear this attempted regenerative response in on-going injury is impaired. To advance understanding of the heterogeneity underlying progressive liver disease we have integrated multi-modal single cell and spatially resolved datasets to uncover developmental gene regulatory networks (GRNs) driving cell state transitions in human liver disease.

Method: Single nuclei RNA and Assay for Transposase-Accessible Chromatin (ATAC) sequencing and spatial transcriptomics (ST) were generated from human cirrhotic tissue. Computational modelling integrated multiple-datasets to provide molecular spatial maps, directional trajectory and infer GRN associated with disease cell states. Molecular mechanisms were validated in vitro and in vivo.

Results: Data integration from RNA, ATAC and ST sequencing uncovered the cellular patho-architecture and spatial molecular signatures of diseased liver. Our results highlighted a spatial pattern of gene modules specifically localised at the scar interface. Unbiased computational analysis identified these subpopulations containing genes characteristic of both hepatocytes and cholangiocytes (HC1/CC1). Through pseudo temporal analysis of our single nuclei data, we uncovered a directional trajectory and transitional state from

hepatocytes to cholangiocytes. We showed transition of hepatocytes to a disease-associated state (HC1) correlated with the down-regulation of *HNF4A*, a master regulator of hepatocyte identity. Mechanistically, our gene expression and transcriptional motif analysis pointed toward signalling in cirrhosis involving crosstalk between the core developmental pathways Hippo, Notch and Wnt. Using our single cell RNA and ATAC data, we infered GRNs and identified SOX9/ONECUT1 co-regulation of transitional genes, consistent with their roles in ductal plate development. Through an integrative analysis, we identified a novel transitional axis, marked by *ESRP1* (involved in gene splicing) and *ARHGEF38* (involved in cell migration) expression, driven by ONECUT1 and SOX9 co-accessibility regulating transitional states in cirrhosis.
Conclusion: These data serve as a spatial atlas of gene regulation and altered cell state in human cirrhosis. They highlight developmental regulatory networks as molecular drivers of disease and provide a valuable resource to explore biomarkers and potential therapeutic targets in progressive liver disease.

Liver tumours: Therapy

Email: olivier.seror@aphp.fr

Background and aims: Multibipolar radiofrequency ablation (mbpRFA) based on "no touch" (NT) concept consists of inserting an arrangement of several electrodes just outside the tumour in order to ablate centripetally first a cancer-free margin then the nodule. The ARMCENVIN randomized trial was aimed to assess if sharing mbpRFA technology, NT concept outperforms IT approach for the treatment of early HCC.
Method: In 52 months, in 6 participating centers 216 naïve patients bearing up to 3 HCC up to 4 cm accepted to be submitted to stratified randomization according to number of nodules >1 and size >3 cm to receive either IT or NT mbpRFA. In the IT arm, conversely to the NT arm, arrangement of electrodes was deliberately inserted just inside the borders of the tumours. To comply with NT requirements for tumours ranging from 1 and 2 cm and from 3 to 4 cm, a supplemental electrode was used in the NT arm as compared to the IT arm. The 2-years recurrence free survival (2y-RFS) was the main end point of the study. Secondary end points were number of sessions to achieve complete response (up to 3), treatment failure rate, ablation ratio index (ARI) defined as the difference of maximum size of the nodule with the minimum size of ablation zone, the local (LRFS) and distant (DRFS), RFS, overall survival (OS) and complication rates.
Results: In the IT and NT arms 110 and 106 patients were randomized (mean age 65 y, 81% male, 89% Child-Pugh A, 29.15 ± 0.2 BMI, bearing 245 nodules, mean size 19.2 ± 7.7 mm, 84% single), respectively. The 2y-RFS were 56.6% and 50% (median 24.5 and 21.3 months; HR = 0.88 [0.59–1.39], p = 0.4), respectively. More than one procedure were performed in 11 (10.0%) and 12 (11.3%) and failure occurred in 1 (0.9%) and 5 (4.7%) (p = 0.06) patients, respectively. ARI were 10.35 ± 10.02 and 18.12 ± 9.93 in IT and NT arms, respectively (p <0.0001). The 2y LRFS, DRFS and OS were 88.0% and 84.8% (HR 0.71 [0.34–1.5], p = 0.37), 63.3% and 62.6% (HR 0.93 [0.6–1.46], p = 0.77) and 87.2% and 83.8% (HR 0.7 [0.34–1.42], p = 0.32), respectively. The rates of complications (Dindo Clavien >grade 1) were 43.1% and 24.5%, respectively (p = 0.0042). Subgroup analyses suggested a potential advantage of NT mbpRFA in case of tumours>3 cm and performance in an experienced centre (more than 30 mbpRFA/year).
Conclusion: Using mbpRF technology for the ablation of HCC up to 4 cm diameter, RFS is not improved by extratumourous insertion of electrodes conforming with strict applying of "no touch" concept. Peripheral positioning of applicators within the borders of the tumors provides safely comparable intrahepatic sustained cancer progression free survival and may provide a clinical benefit for ablation of tumours>3 cm by skilled operators.

Predictive genomic biomarkers for Atezolizumab plus Bevacizumab combination immunotherapy response in liver cancer: insights from the IMbrave150 trial
Sun Young Yim[1], Seung-Woo Baek[2], Sung-Hwan Lee[3], BoHwa Sohn[4], Yun Seong Jeong[5], Sang-Hee Kang[6], Kena Park[7], Hyewon Park[4], Sunyoung Lee[4], Ahmed Kaseb[4], Ji Hoon Kim[6], In-Sun Chu[8], Ju-Seog Lee[4]. *[1]Anam Korea University Hospital, Seoul, Korea, Rep. of South; [2]Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Rep. of South; [3]CHA Bundang Medical Center, Seongnam, Korea, Rep. of South; [4]UT MD Anderson Cancer Center, Houston, United States; [5]UT MD Anderson Cancer Center, Houston, Korea, Rep. of South; [6]Korea University Guro Hospital, Seoul, Korea, Rep. of South; [7]Kyung Hee University Hospital at Gangdong, Seoul, Korea, Rep. of South; [8]Bioneer Corporation, Daejeon, United States*
Email: jlee@mdanderson.org

Background and aims: Combination immunotherapy, exemplified by atezolizumab plus bevacizumab, have become the established standard of care for individuals with inoperable hepatocellular carcinoma (HCC). Despite this advancement, the absence of clear predictive biomarkers and an understanding of the mechanisms governing response and resistance to these combined therapies pose challenges. Our aim is to evaluate whether previously defined immune signature scores (ISS) can identify HCC patients likely to derive enhanced benefit from the combination immunotherapy.
Method: We utilized the previously developed ISS predictor from analysis of TCGA pan-cancer data and applied it to gene expression data from the IMbrave150 trial. This phase 3 study compared atezolizumab plus bevacizumab versus sorafenib for treatment-naïve advanced HCC. Using an ISS cutoff of 0.5, patients were stratified into potential immunotherapy responders (high ISS) and non-responders (low ISS). The significance of this ISS-based stratification for predicting clinical outcomes was evaluated through Kaplan-Meier plots, log-rank tests, Chi-square tests, and Cox regression analyses. Multiple statistical approaches assessed the association between ISS groups and progression-free survival in both the immunotherapy combination arm as well as the sorafenib arm.
Results: In the IMBrave150 trial cohort, data on gene expression and outcomes were accessible for 247 patients who received

atezolizumab plus bevacizumab, and 48 patients who received sorafenib. The high ISS demonstrated a significant association with enhanced PFS in the atezolizumab plus bevacizumab group (p = 0.003), while no such association was observed in the sorafenib group (p = 0.6). Similarly, in the high ISS subgroup, the combination therapy exhibited superior OS (p.0.001) and PFS (p = 0.02) compared to sorafenib, but no discernible benefit was noted in the low ISS subgroup (both p > 0.7). The OS hazard ratio for the combination versus sorafenib was 0.26 (95% CI 0.14–0.51, p < 0.001) among high ISS patients, while it was not statistically significant in low ISS (HR 0.88, p = 0.68). Interaction testing confirmed a notable interaction between ISS subtype and treatment benefit, particularly for OS (p = 0.01). In the combination arm, the objective response rate was 45.6% in the high ISS group versus 22.8% in the low ISS group.
Conclusion: Our study suggests that ISS may serve as a promising predictive biomarker for enhanced therapeutic outcomes in patients undergoing combination immunotherapy for HCC. The identification of such markers is crucial for refining patient stratification and personalized treatment approaches, thereby advancing the effectiveness of current standard-of-care regimens. Further validation studies are warranted to solidify the clinical utility of ISS and its integration into the decision-making process for HCC immunotherapy.

Email: bernhard.scheiner@meduniwien.ac.at

Background and aims: The management and natural history of patients with hepatocellular carcinoma (HCC) who achieve complete response (CR) to immune checkpoint inhibitor (ICI)-based systemic therapies is not well described.
Method: We conducted a retrospective study of adult patients with HCC who had CR (according to mRECIST) to systemic ICI-based therapies from 18 centers in Europe and Asia. Patients who received immunotherapy as (neo-)adjuvant therapy before/after resection or ablation or in combination with loco-regional therapies were excluded.
Results: Of 2502 patients with HCC treated with ICI-based palliative systemic therapies, 123 patients (4.9%) achieved CR according to mRECIST (CR-mRECIST) and 72 patients (2.9%) had CR according to RECISTv1.1 (CR-RECISTv1.1) as well. The mean age of the total cohort (n = 123) was 65.2 ± 9.9 years, 103 were male (84%), and the majority had BCLC stage C (n = 87; 71%) and Child-Pugh class A (n = 112; 91%). Median follow-up was 32.1 (95%CI, 30.5–33.6) months. The majority (n = 106, 86%) received ICI-based combination therapies (atezolizumab/bevacizumab: n = 80, 65%). Time from immunotherapy initiation to first CR was 7.4 (95%CI, 5.3–9.5) months. Median alpha-fetoprotein declined from 19 (IQR, 4–1090) ng/ml at baseline to 2 (IQR, 1–3) ng/ml at nadir. Median duration of CR (mRECIST) was 35.5 (95%CI, not estimable) months. Overall, 41 patients (33%) experienced recurrence a median of 11.4 months (95%CI, 8.9–14.0) after mRECIST CR. Recurrence rate was similar in patients with CR-mRECIST only (26%) and CR-RECISTv1.1 (39%; p = 0.120), as were recurrence-free survival rates at one and two years (77% and 61% for CR-mRECIST only vs. 74% and 58% for CR-RECISTv1.1; log-rank p = 0.310). A total of 93 patients (75.6%) discontinued ICI during follow-up due to adverse events (n = 11, 11.8%), recurrence (n = 15, 16.1%), durable CR (n = 41, 44.1%), or other reasons (n = 26, 28.0%). Among those who discontinued treatment for reasons other than recurrence (n = 76), recurrence rate was 23.7% (n = 18); patients who received systemic treatment for >6 months after complete response had a numerically lower recurrence rate (15.8%, n = 6/38) compared to those who discontinued treatment earlier (31.6%, n = 12/38; p = 0.105). Eleven patients underwent curative conversion therapy after CR (ablation, n = 4; transplantation, n = 4; resection, n = 3); two of them (18%) experienced recurrence. One-/3-/5-year overall survival (OS) rates of the whole cohort were 98%/88%/77%.
Conclusion: Only a small proportion of patients with advanced HCC achieves CR to palliative immunotherapy, but these patients have an excellent overall survival. The recurrence rate was similar between CR-mRECIST only and CR-RECISTv1.1, affecting approximately one in three patients. When considering ICI discontinuation, treatment for >6 months beyond CR may be associated with a lower recurrence rate.

OS-113

Adoptive natural killer cell immunotherapy can increase the recurrence-free survival following transarterial-chemoembolization in patients with intermediate stage hepatocellular carcinoma

Jooho Lee[1], Sooyeon Oh[2], Min-Ji Ahn[3], Su-Kyung Chun[3], Seung-Min Lee[4], Kyumok Lee[5]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine, CHA Bundang Medical Center, CHA University, Seoul, Korea, Rep. of South; [2]1Chaum Life Center, CHA University School of Medicine, Seoul, Korea, Rep. of South; [3]Chaum*

Life Center, CHA University School of Medicine, Seoul, Korea, Rep. of South; [4]Center for Research and Development, CHA Advanced Research Institute, Seongnam, Korea, Rep. of South; [5]Department of Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Korea, Rep. of South
Email: piolee2000@naver.com

Background and aims: Transarterial-chemoembolization (TACE) represent a first-line therapy for intermediate stage hepatocellular carcinoma (HCC). Adoptive immunotherapy is one of the important cancer immunotherapies including cytotoxic T lymphocytes and natural killer (NK) cells. Some adoptive cellular immunotherapy treatment exhibited survival benefit in HCC patients. The current study reports the results of a prospective, open label trial investigating the safety and efficacy of the combination of autologous NK cells and TACE in patients with intermediate stage HCC. In this study, we assessed whether post-TACE adjuvant NK cell immunotherapy could lower the frequency of recurrence following conventional TACE.
Method: This prospective pilot study enrolled 10 consecutive patients with HCC of intermediate stage from CHA Bundang medical center in Korea from January 2023 to November 2023. Patients were assigned consecutively to receive adjuvant NK cell immunotherapy (immunotherapy group) or no adjuvant therapy (controls) after TACE. The patients who assigned to immunotherapy group underwent conventional TACE followed by activated autologous NK cell therapy ($2\sim6\times10^9$ cells/100 ml, intravenous infusion once a week, 1 weeks after TACE, up to 3 cycles). Tumor response was assessed according to the modified RECIST criteria. We also analyzed the progression-free survival (PFS) and objective tumor response rate (ORR), defined as the percentage of patients with either a complete response or a partial response, in terms of best response experienced.
Results: Mean age was 62 years, with male and hepatitis B predominance (90% and 60%, respectively). The 6-month ORR was significantly higher in the NK cell immunotherapy group compared with the controls (100% vs 60%, $p < 0.05$). Also, NK immunotherapy group showed significantly longer PFS (9.3 vs 3.2 months, $p < 0.05$) than the control group. A significantly higher proportion of patients in immunotherapy group had adverse events, but the proportion of patients with serious adverse events did not differ significantly between groups. The proportion of the patients with worsening liver function, whose ALBI scores increased 3 months after treatment, was not different between groups. However, the proportion of patients with improving liver stiffness (fibrosis), whose liver elastography scores decreased more than 1 kPa, 3 months after TACE, was higher in the immunotherapy group (80% vs 40%; $p = 0.18$).
Conclusion: In patients with intermediate stage HCC who underwent TACE, combination immunotherapy with activated NK cells increased the ORR and PFS. Adoptive immunotherapy with autologous NK cells is a safe, feasible treatment that can lower recurrence and improve recurrence-free outcomes after conventional TACE for HCC.

OS-114
Liver transplantation following hepatocellular carcinoma downstaging with atezolizumab/bevacizumab: preliminary results of the prospective ImmunoXXL study

Sherrie Bhoori[1], Marianna Maspero[1], Michele Droz Dit Busset[1], Marco Bongini[1], Matteo Virdis[1], Davide Citterio[1], Carlo Sposito[1], Valentina Bellia[1], Carlo Battiston[1], Jorgelina Coppa[1], Maria Flores[1], Vincenzo Mazzaferro[1]. *[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*
Email: sherrie.bhoori@istitutotumori.mi.it

Background and aims: Tumor downstaging (DS) is a viable strategy to increase the access to liver transplantation (LT) in patients with hepatocellular carcinoma (HCC) beyond conventional criteria. Given the exciting results of immune checkpoint inhibitor (ICI)-based combinations in intermediate/advanced stages of HCC, their use within DS protocols is now being investigated. We report the preliminary results of the ImmunoXXL study on LT after DS with atezolizumab/bevacizumab (A+B) in patients with unresectable intermediate-advanced HCC.
Method: ImmunoXXL (NCT 05879328) is an observational prospective single-arm study that includes patients with HCCs waitlisted for LT after achieving a sustained radiological partial or complete response with A+B. The primary outcome of the trial is recurrence free survival. Secondary outcomes are tumor response, complication rates, overall survival and immunomonitoring.
Results: Out of 66 patients treated with A+B at our center, 16 achieved sufficient response for transplant eligibility, 8 excluded because of non-oncological reasons. Up to now, 7 patients have been enrolled and transplanted (6/7 males, median age 62) into the ImmunoXXL study. Underlying liver disease was HBV (n.2), MetALD (n.2), MASLD (n.1), and HCV-ALD (n.1). All but one patients had received prior loco-regional treatments and all were treated with A+B because of beyond Up-to-7 tumor burden. Median AFP at treatment inception was 135 ng/ml, while at listing within normal limits for all but one (median AFP 2, 5 ng/ml). Mean duration of treatment was 120 days (median of 6 cycles) and the interval between the last A+B dose and LT was 58 days. All patients underwent LT from a cadaveric graft supported with hypothermic oxygenated machine perfusion. Explant pathology revealed 5 HCC within MC (3 complete responses). Post-LT immunosuppression was intensified with a triple regimen with one patient experiencing mild acute cellular rejection responding to steroid pulses. Median post-LT length of hospital stay was 16 days. Three patients (44%) experienced major complications (hepatic artery thrombosis requiring re-LT, biliary fistula requiring endoscopy and post-surgical Budd-Chiari requiring balloon dilation); 4 had high CMV viremia requiring treatment. After a median of 8 months, all patients are alive with no evidence of disease.
Conclusion: Our preliminary results demonstrate that sequential treatment with A+B followed by LT is safe; the higher than expected post-LT morbidity may be related to the intensified immunosuppressive regimen. A+B seems to be effective despite the short follow-up; at this time point, no HCC recurrence has occurred.

Background and aims: ZED1227 is an inhibitor of transglutaminase (TG) 2, which plays a critical role in the development of liver fibrosis. The CEC-11/NAS trial aimed to show efficacy and safety of ZED1227 in patients (pts) with phenotypic MASLD (Metabolic Dysfunction-Associated Steatotic Liver Disease) and significant fibrosis.
Method: This was a double-blind, randomized, multi-center, placebo-controlled, comparative, exploratory phase II dose-finding trial. Pts were treated orally for 12 weeks with 20, 50 or 100 mg/day ZED1227 or placebo (1:1:1:1). The trial enrolled pts with MASLD and significant fibrosis determined by non-invasive tests or liver biopsy. The primary efficacy end point was the relative change of serum levels of the fibrogenesis marker PRO-C3 (N-terminal propeptide of type III collagen).
Results: 334 pts were screened, 186 were randomized, and 174 received at least one dose of study drug or placebo and were included in the full analysis set (FAS). 168 pts completed the study. Baseline data were comparable between treatment groups (mean age 59.9 years, 55.2% males, mean BMI 33.8 kg/m^2, mean serum level of PRO-C3 44.12 ng/ml, T2DM 56.3%). Median treatment duration was 84 days and 97.7% of pts had a treatment compliance ≥80%. The primary efficacy analysis in FAS showed a numerical reduction of PRO-C3 in the low and high dose arms after 12 weeks of treatment (least squares (LS)-mean difference (SE) 20 mg vs placebo (%): – 6.5 (4.90) (95% CI [-16.12; 3.10]; p = 0.0921 [one-sided]) and 100 mg – 8.1 (4.84) (95% CI [-17.57; 1.43]; p = 0.0479 [one-sided]; that did not reach statistical significance (α = 0.025). No effect was seen in the 50 mg group. In a subgroup analysis in pts with PRO-C3 ≥median at baseline showed a dose-dependent reduction of PRO-C3 levels (LS mean difference (SE) vs placebo (%), 20 mg: −3.5 (6.71), 50 mg: −5.8 (6.78), 100 mg: −14.8 (6.59)). In this subgroup, a dose dependent decrease of PRO-C6, a marker of cardiovascular disease outcome was observed (median reduction after 12 weeks (ng/ml), 20mg: 0.0, 50 mg: −2.46, 100 mg: −6.77, Placebo: 2.69). In a responder analysis, pts responding to ZED1227 had higher baseline PRO-C3 values (mean 54.12 vs 40.55 ng/ml) and showed a trend to higher baseline AST and ALT levels compared to non-responder (AST mean 54.8 vs 41.4 U/L, ALT mean 74.4 vs 59.2 U/L). Treatment with ZED1227 was well tolerated and most of the adverse events (AEs) were of mild or moderate intensity. In three pts AEs led to a discontinuation of IP, two in the 20 mg and one in the placebo group. Nine serious AEs (SAEs) were reported. None of the SAEs were considered related to the study treatment.
Conclusion: ZED1227 was well tolerated and showed a positive trend for reducing profibrogenic PRO-C3 in phenotypic MASLD that however, did not reach statistical significance. In the subgroup of pts with higher PRO-C3 at baseline, the ZED1227 effect was more pronounced and dose dependent.

OS-116

Structured exercise plus mediterranean diet intervention in patients with metabolic-dysfunction associated steatotic liver disease (MASLD): a randomized controlled trial. The EHmet-DIA study

Background and aims: Exercise independent of weight loss is associated with improved liver steatosis and fibrosis in MASLD patients. Our objective was to study the effect of planned exercise and Mediterranean diet (MD) in patients with MASLD.
Method: Ninety-eight biopsy-proven MASLD patients [54/98 (55%) females, 46/98 T2DM (47%) and AHT (63/98 (64.3%)] were randomized to: Arm A) Hypocaloric MD and intensive structured physical exercise for 12 weeks. Arm B) Hypocaloric MD and standard recommendations for physical activity for 12 weeks. All patients were followed-up for another 12 weeks. Liver assessment included baseline VCTE (kPa and CAP), MR (PDFF (%), MRE (kPa)) and at end-of-treatment at 12 weeks and at the end-of-follow-up at week 24. Bioimpedance and liver biochemistry were also performed. Adherence to exercise was evaluated as adherents (Ad) if ≥5 sessions per week or non-adherents (NAd) if ≤4 sessions considering frequency, intensity, time, and type. Adherence to the MD and QoL were also evaluated baseline, 12 and 24 weeks.
Results: Patients in Arm A showed a significant improvement in MRE (Baseline MRE: 2.46 ± 0.67 kPa, MRE 12 weeks: 2.31 ± 0.65 kPa; p = 0.027) and PDFF-MRI (baseline: 12.4 ± 6.9%, PDFF 12 weeks: 9.5 ± 6.2%; p = 0.005), but not in arm B (Baseline MRE: 2.74 ± 0.95, MRE 12 weeks: 2.70 ± 0.98; p = 0.28) or steatosis (Baseline PDFF 14.27 ± 7.27%, PDFF 12 weeks: 12.67 ± 8.01%, PDF; p = 0.26). Weight loss at 12 weeks follow-up was significantly higher in Arm B (baseline 91.9 ± 19.6; 12 weeks 89.6 ± 20.5Kg; p = 0.001) vs Arm A (baseline 91.8 ± 20.4 Kg; 12 weeks 90.8 ± 22, 1 Kg; p = 0.5). There were also differences in muscle mass in Arm A vs Arm B: 7.6 ± 12% vs 2.1 ± 14% (p = 0.09). In Ad patients PDFF improved by −37.16+28.11%, while in NAd there was a worsening in 3.85 ± 41.8%;p < 0.01, Hedge's correction 0.15–1.86). Fibrosis improvement was 3.32 ± 19.1% in NAd patients vs −12.98 ± 9.8% in NAd patients; p < 0.007; Hedge's correction 0.04–1.84. During 12weeks follow-up no differences were seen between arms and between physical activity adherence groups.
Conclusion: A 12-week life-style intervention allowed stratifying patients in responders and non-responders. The implementation of a physical exercise program with 5 or more sessions per week with moderate/high intensity in patients receiving hypocaloric MD promoted fat removal and liver fibrosis improvement independently of weight loss rate.

Email: joern.schattenberg@uks.eu

Background and aims: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo-controlled Phase 3 trial evaluating the efficacy of resmetirom in patients with biopsy-confirmed non-alcoholic steatohepatitis (NASH) and fibrosis. 966 patients with biopsy-confirmed NASH were randomized 1:1:1 to resmetirom 80 mg, resmetirom 100 mg, or placebo administered once daily. Histologic end points were assessed after 52 weeks. Dual primary end points at Week 52 were achieved with both resmetirom 80 mg and 100 mg: NASH resolution with no worsening of fibrosis (NR) or ≥1-stage reduction in fibrosis with no worsening of NAS (FI). Body weight is the major factor influencing exposure to resmetirom in patients with NASH/MASH. This post-hoc analysis was performed to provide additional evidence of a relationship between resmetirom dose, baseline body weight and body mass index (BMI).
Method: To assess the impact of baseline body weight and BMI on resmetirom response, we stratified resmetirom efficacy data on the dual end points based on baseline patient body weight (≤100 and >100 kg) and BMI (≥35 and <35 kg/m^2).
Results: For patients treated with resmetirom 80 mg who weighed ≤100 kg, the 30% PDFF response was 66.9%; and in patients with a Week 52 biopsy, 35.4% showed fibrosis improvement (FI) compared with 32% who showed no worsening of fibrosis (NR). In patients >100 kg, the 30% PDFF response was 56.7%; FI = 22.5%; and NR = 27%. For patients who received resmetirom 100 mg who were ≤100 kg, the 30% PDFF response was 71.7%; FI was 33.6% and NR was 35.8%; for patients >100 kg, PDFF = 72.5%; FI = 32.5%; NR = 35.8%. Increases in FI were noted relative to placebo for patients who received resmetirom 80 mg (mITT population) who had BMI <35: 13.0% (5.2, 20.8); NR = 33.4% (14.2, 30.6); and in patients with BMI ≥35: FI = 7.0% (-0.7, 14.7); NR = 9.8% (3.1, 16.6). Increases were also noted relative to placebo for patients who received 100 mg of resmetirom (mITT population) who had a BMI <35: FI = 11.8% (4.2, 19.4) NR = 21.0% (13.4, 28.7); for patients with BMI ≥35: FI = 11.1% (3.4, 18.9); NR = 20.0% (12.3, 27.7).
Conclusion: As shown in these stratified data, resmetirom 100 mg was consistently more effective than 80 mg in achievement of the dual primary end points in the sample of patients who had higher baseline body weight and BMI. In patients with a lower BMI, there was no observed difference in efficacy between the 80 and 100 mg resmetirom doses.

Email: cindy.hartsfield@89bio.com

Background and aims: FGF21 analogs such as pegozafermin (PGZ) have demonstrated promising direct effects on liver fibrosis as well as additional hepatic and extrahepatic benefits in patients with MASH. The Phase 2b ENLIVEN trial evaluated the efficacy/safety of PGZ given weekly (QW) or every two-weeks (Q2W) versus placebo in MASH patients; the primary end point was assessed at Week 24. Both PGZ 30 mg QW and 44 mg Q2W led to significant improvements in fibrosis without worsening of MASH, MASH resolution without worsening of fibrosis, and markers for liver fibrosis and injury compared to placebo. After the main study, patients began a 24-week blinded extension phase for a total of 48 weeks of treatment.
Method: In the placebo-controlled, blinded, 24-week extension phase patients continued in their assigned treatment arm except for a subset of patients from the placebo arm who were re-randomized to receive PGZ 30 mg QW during the extension phase. The full analysis set includes patients who were F2-F3 and NAS ≥4 at baseline (n = 192 of which 163 continued into the extension phase). There were 14 patients, reclassified as F4 fibrosis at baseline per 3-panel read, of which 12 entered the extension study. Efficacy end points include non-invasive tests (NITs) to assess liver fat, markers of fibrosis, inflammation, and extrahepatic metabolic markers. Per protocol, patients did not undergo repeat liver biopsy at Week 48.
Results: PGZ benefit for the 30 mg QW and 44 mg Q2W doses was sustained from Week 24 to Week 48 across a wide range of end points including liver fat (MRI-PDFF), markers of liver fibrosis (VCTE, ELF, Pro-C3), inflammation and injury (ALT, AST), and metabolic markers. At the 30 mg QW dose in the total study population 90% of patients identified previously as ALT responders (defined as ≥17U/L reduction) and 84% of patients classified as MRI-PDFF super-responders (defining as ≥50% reduction of liver fat) at Week 24 retained that benefit at Week 48. At Week 48, pegozafermin also had continued benefit on metabolic end points such as lipids and HbA1c. The placebo cohort re-randomized to 30 mg QW recapitulated the robust and rapid treatment effects of PGZ that were observed in the main study, with significant improvements in NITs of liver fat, inflammation, and fibrosis over the extension period. Patients with F4 fibrosis at baseline also showed sustained benefit for markers of fibrosis and liver inflammation at Week 48. Safety and tolerability remained consistent with previously reported data. No new patients on PGZ during the main phase developed treatment-related nausea or diarrhea during the extension phase of the study.
Conclusion: These robust results substantiate the sustained efficacy of PGZ treatment up to 48 weeks on NITs and metabolic markers in MASH patients with advanced fibrosis. PGZ continues to demonstrate a favorable safety and tolerability profile. Confirmatory phase 3 studies are planned for 2024.

Email: pietro.lampertico@unimi.it

Background and aims: Bulevirtide (BLV) monotherapy yields high rates of virological and biochemical response in hepatitis Delta (HDV) cirrhotic patients, however clinical benefits on hard outcomes remain unknown.

Method: Patients with HDV-related cirrhosis treated with BLV monotherapy in a retrospective multicenter European study (SAVE-D) were compared with untreated HDV cirrhotic patients enrolled in a previous cohort study (Romeo, Gastroenterology 2009). Liver-related events (LRE: HCC, decompensation) and overall mortality were compared by inverse probability treatment weighting (IPTW) analysis.
Results: The BLV-treated cohort included 176 patients (median follow-up: 15 [2–46] months): at BLV start, median age was 50 (19–82) years, 59% men, ALT 77 (23–1, 074) U/L, albumin 3.9 (2.8–4.9) g/dL, 100% CPT score A, 55% with varices. The untreated cohort included 140 patients (median follow-up: 91 [3–359] months): at study entry, median age was 40 (18–66) years, 78% men, ALT 102 (11–3, 054) U/L, albumin 4.0 (2.0–5.2) g/dL, 94% CPT score A, 46% with varices. Overall, the 2-year cumulative probabilities of LRE were 6.9% (95% CI 3–11%) in the BLV-treated cohort vs. 15.7% (95% CI 9–22%) in untreated patients (p = 0.02): 4.9% vs. 6.7% for de-novo HCC (p = 0.45) and 2.0% vs. 9.1% for decompensation (p = 0.01), respectively. The 2-year probability of overall mortality was 1.2% (95% CI 0.3–3%) vs. 3% (95% CI 0.5–6%) in BLV-treated vs. untreated patients (p = 0.13). By IPTW analysis adjusted for confounding baseline factors and competing mortality risks, the BLV-treated cohort had a significantly decreased risk of all-type liver-related events (HR 0.38; 95% CI 0.24–0.60, p < 0.0001), decompensation (HR 0.15; 95% CI 0.06–0.36, p < 0.0001) and mortality (HR 0.27; 95% CI 0.08–0.93, p = 0.04) compared to untreated patients. Conversely, the HCC risk was similar (HR 0.76; 95% CI 0.42–1.40, p = 0.38).
Conclusion: Compared to an untreated matched control group, a 2-year course of BLV monotherapy significantly reduced the risk of decompensation and mortality but not of HCC in HDV patients with compensated cirrhosis.

OS-121

Multinational randomized trial to investigate the efficacy of tenofovir alafenamide in reducing adverse clinical events in chronic hepatitis B patients who are beyond treatment indications by current guidelines (ATTENTION trial): first interim analysis

Email: limys@amc.seoul.kr

Background and aims: There is lack of robust evidence regarding the efficacy of early antiviral therapy in reducing adverse clinical events among non-cirrhotic chronic hepatitis B (CHB) patients with significant viremia but without notable alanine aminotransferase (ALT) level elevation.
Method: The ATTENTION trial, an ongoing randomized, open-label, multicenter, phase 4 study (NCT03753074), is actively enrolling 780 participants across 22 sites in Korea and Taiwan. Key inclusion criteria are: age between 40 and 80 years, serum HBV DNA levels between 4–8 $\log_{10}$ IU/ml, serum ALT levels <70 U/L for males and <50 U/L for females, and absence of cirrhosis. Participants are randomly assigned at a 1:1 ratio to receive either 25 mg/day of tenofovir alafenamide (TAF) or no antiviral treatment (observation). The primary end point was a composite of hepatocellular carcinoma (HCC), death, liver transplantation, or hepatic decompensation, with the first interim analysis planned at year 4.
Results: From 2019 to 2023, 734 patients were randomized to either TAF group (n = 369) or observation group (n = 365). As of October 2023, the median follow-up duration was 1.5 years. Participants in the first interim analysis set had an average age of 53.4 years, with 46.5% male, and 82.7% HBeAg-negative. The median ALT level was 31 U/L. No significant differences were observed in baseline characteristics between the two groups. A total of 11 primary clinical events occurred: 2 in the TAF group (both HCC) and 9 in the observation group (7 HCC, 1 death, 1 hepatic decompensation), corresponding to incidence rates of 0.33 and 1.57 per 100 person-years, respectively. The hazard ratio for TAF was 0.21 (99.997% CI: 0.01–5.45). The log-rank test yielded Z = 2.22 (p = 0.027), which did not exceed the pre-defined upper stopping boundary (Z = 4.17; p = 0.00003) in this first interim analysis.
Conclusion: Preliminary findings from the ATTENTION trial suggest that early initiation of TAF treatment may significantly reduce the risk of liver-related adverse clinical events in non-cirrhotic CHB patients with significant viremia, but without elevated ALT levels. These results highlight the potential benefit of proactive antiviral therapy in these patients.

Background and aims: Bulevirtide (BLV) is a first-in-class entry inhibitor approved in the EU for the treatment of chronic hepatitis D (CHD). In a multicentre, open-label, randomized phase 2b study (MYR204; NCT03852433), safety and efficacy of BLV (2 and 10 mg/day) with or without pegylated interferon alfa-2a (PegIFNα) were evaluated in patients with CHD and compensated liver disease. This sub-study aimed to evaluate intrahepatic virologic changes 24 weeks after end of treatment (EOT) compared to baseline. To further understand the effect of treatment, the relationship between intrahepatic outcomes and peripheral parameters, including intrahepatic innate and inflammatory gene expression profiles, was evaluated.
Method: 174 CHD patients were randomized (1:2:2:2) to receive (A) PegIFNα for 48 weeks (48w); (B) BLV 2 mg + PegIFNα or (C) BLV 10 mg + PegIFNα for 48w, both followed by 48w of monotherapy with BLV 2 mg or 10 mg, respectively; or (D) BLV 10 mg for 96w. Paired liver biopsies were available at baseline and 24w after EOT in in a subset of patients (n = 42 for molecular and 44 for histological analysis). HDV

parameters and infection-related host genes were assessed by qPCR and HDAg immunohistochemistry.
Results: At follow-up (FU), 24w after EOT, median intrahepatic HDV RNA declines from baseline were 1.9Log10 in arm A (n = 5), 2.0Log10 in arm B (n = 14), 3.2Log10 in arm C (n = 11), and 0.8Log10 in arm D (n = 12). Intrahepatic HDV RNA levels strongly correlated with the number of HDAg positive cells ($r = 0.85$; $p < 0.0001$), which declined by 1.9Log10 in arm A (n = 6), 1.0Log10 in arm B (n = 14), 1.9Log10 in arm C (n = 11), and 0.8Log10 in arm D (n = 13). In the two combination arms B and C, 8/14 (57%) and 8/11 (73%) patients, respectively, were negative for HDV RNA at FU, while in monotherapy arms A and D, 3/5 (60%) and 1/12 (8%) patients had undetectable intrahepatic HDV RNA levels, respectively. Intrahepatic changes of HDV RNA mirrored HDV RNA changes determined in the serum ($r = 0.82$; $p < 0.0001$) while intrahepatic HBV parameters did not change significantly apart from a modest median reduction of total HBV RNA in both combination arms. Transcriptional levels of inflammatory chemokines and infection-related genes were decreased at FU in combination treatment arms. Notably, decreases from BL to FU in chemokines, such as CXCL10, strongly correlated with the reduction of intrahepatic HDV RNA ($r = 0.67$; $p < 0.0001$) and with changes of peripheral ALT levels ($r = 0.75$; $p < 0.0001$), suggesting an amelioration of liver inflammation.
Conclusion: Intrahepatic analysis in paired BL and post-treatment biopsies demonstrated a strong correlation between intrahepatic and serum HDV RNA reductions. Concomitant with the decrease of HDV parameters, expression levels of innate immune genes declined. The highest rate of the off-treatment virologic response in the liver was observed in the arm that received combination of BLV 10 mg + PegIFNα.

OS-123

Progression and risk factors after treatment with tenofovir or entecavir for chronic hepatitis B based on a multistate modeling approach

Wan-Jung Wu[1], Wen-Jie Liu[1], Chih-Lin Lin[2], Chun-Jen Liu[3], Yi-Wen Huang[4], Jui-Ting Hu[5], Ming-Whei Yu[1]. *[1]Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan; [2]Department of Gastroenterology, Ren-Ai Branch, Taipei City Hospital, Taipei, Taiwan; [3]Division of Gastroenterology, Department of Internal Medicine, National Taiwan University Hospital and Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine, Taipei, Taiwan; [4]Graduate Institute of Clinical Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [5]Liver Center, Cathay General Hospital Medical Center, School of Medicine, Fu-Jen Catholic University College of Medicine, Taipei, Taiwan*
Email: wendy1234599@gmail.com

Background and aims: Conflicting evidence exists on hepatocellular carcinoma (HCC) risk in patients with chronic hepatitis B (CHB) receiving tenofovir (TDF)- vs. entecavir (ETV)-based regimens, and data are lacking on whether there is a difference between the two agents in preventing hepatic decompensation. We aimed to compare clinical profile and long-term prognosis between the two drugs and examine the effects of age, sex, alcohol use, diabetes, and cirrhosis on transition rates using a multistate modeling approach.
Method: We conducted a retrospective nationwide cohort study using data from Taiwan's National Health Insurance Research Database, including 47478 treatment-naïve patients with CHB aged 30–75 years receiving TDF/TAF (n = 14353) or ETV (n = 33125) for at least 3 months between November 2009 and December 2019, and followed until December 2021. Multistate analysis modeled CHB progression by describing transitions between distinct disease states, including CHB with or without cirrhosis, hepatic decompensation, HCC, death (liver-related and unrelated death) and a switching treatment state. Propensity score matching (PSM) and inverse probability of treatment weighting (IPTW) methods were used for sensitivity analyses.
Results: During follow-up (median [interquartile range]: 4.7 [3.2–6.8] in TDF/TAF and 5.8 [3.8–8.7] in ETV group), 1228 patients developed hepatic decompensation and 2671 developed HCC. Comparing TDF/TAF-treated and ETV-treated patients, the risks of progression to hepatic decompensation (adjusted hazard ratio [aHR] 0.81, 95% CI 0.70–0.93) and HCC (aHR 0.76, 95% CI 0.68–0.84) were significantly lower in TDF/TAF-treated patients after adjusting for age, sex, excess alcohol use/alcohol-related disorder, diabetes, and cirrhosis. PSM (aHR 0.82 [p = 0.0080] and 0.75 [p < 0.0001] for decompensation and HCC, respectively) and IPTW (aHR 0.81 [p = 0.0032] and 0.75 [p < 0.0001] for decompensation and HCC, respectively) analyses yielded similar patterns of results. The 5-year absolute risks of HCC were 3.3% and 4.9% for TDF/TAF and ETV group, respectively; after hepatic decompensation, the 5-year risks of HCC were 12.2% and 27.3% for TDF/TAF and ETV group. Transition rates significantly increased with age, male sex, diabetes, excess alcohol use/alcohol-related disorder, and cirrhosis.
Conclusion: Using data from a large real-world cohort over a median follow-up time of 5 years, we provided detailed absolute risks and indicated a significantly reduced risk for both hepatic decompensation and HCC among TDF/TAF-treated patients compared with ETV treatment.

OS-127

Efficacy and safety of tobevibart (VIR-3434) alone or in combination with elebsiran (VIR-2218) in participants with chronic hepatitis delta virus infection: preliminary results from the phase 2 SOLSTICE trial in non-cirrhotic and compensated cirrhotic participants

Email: tarik.asselah@aphp.fr

Background and aims: Hepatitis D virus (HDV) infection is the most severe form of viral hepatitis with limited treatment options. The phase 2 SOLSTICE study is investigating the antiviral activity and safety of the monoclonal antibody tobevibart (VIR-3434) alone and in combination with the silencing RNA elebsiran (VIR-2218) in chronic HDV infection (NCT05461170).
Method: Participants with chronic HDV infection, with or without compensated cirrhosis (CPT-A) on NRTI therapy, were randomized 1:1 to receive either tobevibart 300 mg plus elebsiran 200 mg subcutaneously (SC) every 4 weeks (Combo Q4W) or tobevibart 300 mg SC every 2 weeks (tobevibart Q2W) for 96 weeks. The primary end point is a combined response (CR) defined as a virologic response plus normalization of ALT at week 24. A virologic response was defined as HDV RNA less than limit of detection (LOD, 14 IU/ml) or a decrease of ≥ 2 $\log_{10}$ IU from baseline. Lower limit of quantification (LLOQ) for HDV RNA was 63 IU/ml.
Results: Preliminary results from all participants completing 12 weeks of Combo Q4W (n = 18, 50% CPT-A) and tobevibart Q2W (n = 15, 27% CPT-A) are presented. Five participants who received tobevibart or elebsiran monotherapy for 12 weeks and failed to

achieve virologic response (n = 3) or normalize ALT (n = 2) transitioned to Combo Q4W. Week 40 results on combination treatment for these participants are reported. After 12 weeks of Combo Q4W treatment, 100% (18/18) of participants achieved a virologic response with 50% (9/18) <LOD, mean ALT decreased from 87 ± 53 IU/ml at baseline to 48 ± 30 U/L, 39% (7/18) achieved ALT normalization, 39% (7/18) achieved the CR and 28% (5/18) achieved HDV RNA <LLOQ + ALT normalization. Among tobevibart Q2W participants, 80% (12/15) achieved a virologic response with 13% (2/15) <LOD, mean ALT decreased from 56 ± 22 U/L at baseline to 36 ± 12 U/L, 60% (9/15) achieved ALT normalization, 40% (6/15) achieved the CR and 13% (2/18) achieved HDV RNA <LLOQ + ALT normalization after 12 weeks. ALT and HDV RNA declines, and CR were comparable among non-cirrhotic and compensated cirrhotic participants in both cohorts and no ALT flares were observed. All Combo roll-over Q4W participants (5/5) who have completed 40 weeks of combination therapy had HDV RNA <LOD. Both regimens were well tolerated with no reported serious adverse events, Grades 3 and 4 treatment-emergent adverse events (TEAEs) or TEAEs leading to discontinuations.

Conclusion: After 12 weeks of treatment, high rates of virologic response were observed in tobevibart and elebsiran combination therapy and tobevibart monotherapy cohorts. Reductions in ALT values occurred over time with no ALT flares. Similar results were observed in participants with non-cirrhotic and cirrhotic chronic HDV infection. Additional 12- and 24-week data will be presented. These results support continued development of tobevibart alone or in combination with elebsiran.

Identification and validation of pre-identified morphological baseline features for prediction of fibrosis progression in MAESTRO-NASH

Stephen A. Harrison[1], Rebecca Taub[2], Dominic Labriola[2], Hang Zhang[2], Elaine Chng[3], Yayun Ren[3], Dean Tai[3], Jörn M Schattenberg[4]. *[1]Pinnacle Research, San Antonio, Texas, United States; [2]Madrigal Pharmaceuticals, Pennsylvania, United States; [3]Histoindex Pte. Ltd., Singapore, Singapore [4]Saarland University Medical Center, Homburg, Germany*
Email: Dean.Tai@histoindex.com

Background and aims: Fibrosis staging remains the pinnacle predictor of clinical outcomes in metabolic-associated steatohepatitis (MASH) clinical trials, with liver biopsies as the gold standard. However, the ability to reflect dynamic fibrotic changes using ordinal scores in interventional trials remains contentious. Various non-invasive tests (NITs) have been developed but without success in replacing biopsies thus far. qFibrosis, an AI-driven fibrosis assessment methodology, has identified specific fibrotic features potentially more predictive of clinical outcomes than ordinal stages and the aim is to validate whether these pre-identified fibrotic features can distinguish fibrosis progressors in MAESTRO-NASH. MAESTRO-NASH is an ongoing 54-month phase 3 study which achieved NASH resolution and fibrosis reduction end points.

Method: Based on sample availability at baseline, 845 patients had qFibrosis assessment and corresponding selected NITs (VCTE, MRE, ProC3, AST, GGT and platelets), except for MRE where there were only 495 patients. 30 fibrosis features previously identified from SteatoSITE are used in this analysis and Spearman correlation against pathologist scores. Using univariate analyses and random forest model with baseline fibrosis stage as the outcome, 6 fibrosis features (5 from periportal region, 1 from zone 2) were chosen for exploration with clinical data and subsequent validation.

Results: Correlations of NITs with pathologist scores were modest, with MRE exhibiting the highest correlation (0.489), followed by VCTE (0.309). Against the NITs, these 6 fibrosis features showed varying degrees of correlation, albeit generally mediocre (0.05∼0.46). Notably, the feature from zone 2 (number of short strings) exhibited a negative correlation (−0.07∼−0.324), while the rest showed positive correlation. MRE and VCTE correlations with these 6 features aligned closely with pathologist scores, ranging from 0.393 to 0.464 with MRE and 0.233 to 0.342 with VCTE, suggesting nuanced fibrosis progression markers. Note that the correlation of zone 2 fibrosis feature to MRE and VCTE are −0.324 and −0.255, respectively.

Conclusion: Using pre-identified fibrosis features from SteatoSITE, which is an event-rich resource containing clinical and pathological data from MAFLD 940 cases, we validated them with MAESTRO-NASH for predicting fibrosis progression. The identification of negatively correlating features underscores the complexity of fibrosis progression markers. The findings argue against the sufficiency of NITs for predicting fibrosis progression based solely on fibrosis stages or specific fibrosis features. This highlights the necessity for a composite NIT approach, incorporating both positively and negatively correlating fibrosis features. Confirmation of clinical significance is necessary with month 54 biopsies and eventual clinical outcomes.

15-year liver outcomes after metabolic surgery in patients with compensated cirrhosis due to metabolic dysfunction-associated steatohepatitis (MASH)

Ali Aminian[1], Abdullah ALJabri[1], Sarah Wang[1], James Bena[1], Daniela Allende[1], Hana Rosen[1], Rickesha Wilson[1], Alex Milinovich[1], Rohit Loomba[2], Arun J Sanyal[3], Naim Alkhouri[4], Jamile Wakim-Fleming[1], Srinivasan Dasarathy[1], Arthur McCullough[1], Steven Nissen[1]. *[1]Cleveland Clinic, Cleveland, United States; [2]University of California San Diego, La Jolla, United States; [3]Virginia Commonwealth University, Richmond, United States; [4]Arizona Liver Health, Phoenix, United States*
Email: aminiaa@ccf.org

Background and aims: No therapy has been shown to reduce the risk of serious adverse outcomes in patients with compensated cirrhosis due to metabolic dysfunction-associated steatohepatitis (MASH).

Method: Among 36, 912 liver biopsies performed at the Cleveland Clinic Health System in the U.S. between 1995 and 2020, adult patients with obesity and compensated histologically-proven MASH-related cirrhosis (Child-Pugh class A with MELD-Na ≤10) were selected in the Surgical Procedures Eliminate Compensated Cirrhosis In Advancing Long-term (SPECCIAL) observational study. A doubly robust estimation combining the overlap weighting and multivariable-adjusted Cox regression analysis was utilized to compare time-to-incident major adverse liver outcomes (MALO), defined as first occurrence of ascites, variceal hemorrhage, hepatic encephalopathy, hepatocellular carcinoma, liver transplantation, or all-cause mortality, between patients who received metabolic bariatric surgery versus patients who received usual care. The secondary composite end point was the progression to decompensation, defined as the first occurrence of ascites, variceal hemorrhage, or hepatic encephalopathy. Follow-up ended in February 2024.

Results: The study analyzed 168 patients (69.6% female) including 62 metabolic surgery and 106 nonsurgical control patients with compensated MASH-related cirrhosis. Follow-up was over a 25-year period with a mean follow-up of 10.0±4.5 years. Distribution of key baseline characteristics was precisely balanced after overlap weighting including the mean age of 54.4 years, BMI of 42.7 kg/m^2, fibrosis-

4 score of 2.1, albumin of 4.1 g/dL, bilirubin of 0.6 g/dL, platelet count of 208.8 k/uL, and Elixhauser comorbidity index of 9.0 in both groups (standardized difference = 0 for all). In each group, 84.5% had type 2 diabetes and 79.1% had Ishak stage 6. The cumulative incidence of MALO at 15-years was 20.9% (95% CI, 2.5-35.9) in the surgical group and 46.4% (95% CI, 25.6-61.3) in the nonsurgical group, an adjusted absolute risk difference of 22.1% (95% CI, 4.6-37.2), with an adjusted HR of 0.28 (95% CI, 0.12-0.64), P = 0.003. The cumulative incidence of progression to decompensated stage at 15-years was 15.6% (95% CI, 0-31.3) in the surgical group and 30.7% (95% CI, 12.9-44.8) in the nonsurgical group, an adjusted absolute risk difference of 20.6% (95% CI, 3.7-35.2), with an adjusted HR of 0.20 (95% CI, 0.06-0.68), P = 0.01. The mean total weight loss at 15 years in the surgical and nonsurgical groups was 26.6% (95% CI, 24.5-28.7) and 9.8% (95% CI, 7.8-11.8), respectively (mean difference: 16.8% [95% CI, 13.9-19.7], P<0.001).Ten (16.1%) patients developed postoperative adverse events.

Conclusion: Metabolic surgery, compared with nonsurgical management, was associated with a significantly lower risk of incident MALO among patients with compensated MASH-related cirrhosis and obesity.

OS-126

Steatotic liver disease classification is highly dynamic impacting eligibility for clinical trials and subclass-specific interventions

Katrine Thorhauge[1,2], Mads Israelsen[1,2], Peter Andersen[1], Nikolaj Torp[1,2], Stine Johansen[1], Ellen Lyngbeck Jensen[1], Helle Schnefeld[1], Johanne Kragh Hansen[1,2], Katrine Tholstrup Bech[1], Ida Falk Villesen[1], Katrine Lindvig[1], Camilla Dalby Hansen[1], Maja Thiele[1,2], Aleksander Krag[1,2]. *[1]Odense University Hospital, Odense, Denmark; [2]University of Southern Denmark, Odense, Denmark*
Email: mads.egerod.israelsen@rsyd.dk

Background and aims: Steatotic liver disease (SLD) includes several subclasses including metabolic-dysfunction associated steatotic liver disease (MASLD), metabolic and alcohol-related liver disease MetALD and alcohol-related liver disease (ALD). The classification is based on the presences of hepatic steatosis, cardiometabolic risk factors (CMRF) and current alcohol use. However, these criteria may be sensitive to spontaneous changes in lifestyle making the SLD diagnoses dynamic. Our aim was to investigate the dynamics of SLD diagnoses over time.

Method: We performed a prospective cohort study among individuals from the general population and individuals at risk of SLD (obesity, type 2 diabetes or a history of excessive alcohol use). We defined presence of steatosis as CAp >275 dB/m and presence of advanced fibrosis as TE >12 kPa. Subclassification of SLD was based on the presence of at least one CMRF and self-reported current alcohol use (MASLD <20/30 (female/male) gram/day; MetALD 20-50/30-60 (female/male) gram/day; ALD >50/60 (female/male) gram/day). The SLD classification was assessed at baseline and after 2 years follow-up.

Results: We included 994 participants, mean age was 57 (±10) years, 633 were male (64%) and 361 (36%) female and 54 (5%) had advanced fibrosis. At baseline, 551 (55%) had SLD (CAp >275 dB/m and/or TE >12 kPa) while 443 (45%) did not have SLD. Among the patients with SLD, 337 (61%) met the criteria for MASLD, 133 (24%) for MetALD and 79 (14%) for ALD, and 2 (0.4%) were classified as cryptogenic SLD. Median time between baseline and follow-up visit was 25 months (IQR 25-31). At follow-up, 382 (38%) of the 994 participants were reclassified. Among the 443 participants that did not have SLD at baseline, 113 (26%) met the criteria for SLD at follow-up. Among the 551 participants classified as having SLD at baseline, 269 (49%) were reclassified of which 186 (69%) did not meet the criteria for SLD at follow-up and 83 (31%) changed SLD subclass. For the 382 participants reclassified, 299 (78%) were due to changes in steatosis, 83 (22%) due to changes in alcohol use, and 0 due to changes in presences of CMRFs.

Conclusion: SLD and the subclassification hereof is highly dynamic, especially driven by changes in alcohol use and steatosis. This affects eligibility for clinical trials and imply that patients with SLD should be reassessed regularly to ensure correct subclass diagnosis and management.

Rapid reductions of HDV RNA and ALT with the monoclonal antibody, BJT-778: results from a phase 2 study

Kosh Agarwal[1], Marta Dobryanska[2], Alina Jucov[3], Patrick Kennedy[4], Edward J. Gane[5], Man-Fung Yuen[6], Grace Lai-Hung Wong[7], Simone Strasser[8], Jacinta Holmes[9], Stuart Roberts[10], Hassan Javanbakht[11], Nancy Shulman[11]. *[1]Kings College Hospital, London, United Kingdom; [2]ARENSIA Exploratory Medicine, Kyiv, Ukraine; [3]ARENSIA Exlporatory Medicine, Chisinau; [4]Queen Mary University Hospital, London, United Kingdom; [5]New Zealand Clinical Research, University of Auckland, Auckland, New Zealand; [6]Queen Mary University Hospital, Hong Kong, Hong Kong; [7]Prince of Wales Hospital, Hong Kong, Hong Kong; [8]Royal Prince Alfred Hospital, Sydney, Australia; [9]St. Vincent's Hospital, Melbourne, Australia; [10]The Alfred Hospital, Melbourne; [11]Bluejay Therapeutics, Inc., San Mateo, United States*
Email: nshulman@bluejaytx.com

Background and aims: BJT-778 is a fully human anti-HBsAg monoclonal antibody that exhibits potent antiviral activity against HBV and HDV in vitro. BJT-778 is currently being evaluated in a Phase 1/2 study, BJT-778-001, for the treatment of chronic hepatitis B and chronic hepatitis D (CHD). We report the preliminary safety and efficacy results from the phase 2 portion of the study, where BJT-778 administered subcutaneously (SC) for a duration of up to 48 weeks in subjects with CHD.
Method: Approximately 10 subjects per arm were to be enrolled into: Arm 1: BJT-778 300 mg SC once weekly (QW); Arm 2: BJT-778 600 mg SC QW for 12 weeks followed by Q2W; and Arm 3: BJT-778 900 mg SC Q2W for 4 weeks followed by Q4W. Primary end points are safety and tolerability. Efficacy end points include absolute reductions and changes from baseline in HDV RNA and ALT levels, and the proportion of subjects achieving (i) virologic response defined as ≥2 $\log_{10}$ HDV RNA IU/ml reduction from baseline or below the limit of detection (BLD), (ii) ALT normalization (defined as ≤ULN in subjects with >ULN at baseline), and (iii) composite response (defined as virologic response and ALT normalization). Eligible patients have quantifiable HDV RNA, HBsAg levels of ≥10 IU/ml and HBV DNA <100 IU/ml on nucleos (t)ides. Arm 1 limited enrolment to non-cirrhotic patients, whereas Arms 2 and 3 included patients with compensated cirrhosis. Here, we provide results from Arm 1, with up-to-date results from all three arms to be presented.
Results: 10 subjects were enrolled into Arm 1 and 11 subjects into Arm 2. Recruitment for Arm 3 is ongoing. All subjects in Arm 1 have completed 16 weeks of treatment, with the data presented here. Baseline characteristics: Median (range) age of 41 years (31 to 47), ALT of 54 U/L (19 to 117), HDV RNA of 5.3 (2.9 to 7.1) $\log_{10}$ IU/ml, and HBsAg of 4.2 (3.8 to 4.9) $\log_{10}$ IU/ml. Six were men and all were Caucasian. In Arm 1, 90% of the subjects (9 out of10) achieved a virologic response, with 40% (4 out of 10) falling below the limit of quantification (BLQ) and 30% (3 out of 10) BLD. Additionally, 67% (6/9) achieved ALT level normalization and composite response. One subject had a normal ALT at baseline, which remains normal. The mean reduction in HDV RNA at Week 16 was 3.0 logs. Across all treatment arms, BJT-778 at doses up to 900 mg have been well tolerated, with no reported serious or Grade 3/4 adverse events, and no treatment discontinuations in any of the arms. Available data from all arms will be presented.
Conclusion: Monotherapy with BJT-778 was safe and well-tolerated and achieved rapid virologic responses with ALT normalization in most subjects with CHD. Comprehensive data from all study arms will be presented, offering further insights into the therapeutic potential of BJT-778.

GM-60106 (a peripheral 5HT2A antagonist) as a clinical candidate for metabolic dysfunction-associated steatohepatitis (MASH)

Jin Hee Ahn[1,2], Hail Kim[3], Sungmin Song[4], Peter Goughnour[4], Myung Ae Bae[5]. *[1]JD Bioscience INC, Gwangju, Korea, Rep. of South; [2]Gwangju Institute of Science and Tehcnology, Gwnagju, Korea, Rep. of South; [3]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Rep. of South; [4]JD Bioscience INC, #1414 B complex, Tera Tower, 167, Songpa-daero, Seoul, Korea, Rep. of South; [5]Korea research institute of chemical technology, Daejeon, Korea, Rep. of South*
Email: hailkim@kaist.edu

Background and aims: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) is a leading cause of chronic liver disease globally. Metabolic Dysfunction-Associated Steatohepatitis (MASH) represents an advanced stage of MASLD, capable of progressing to liver fibrosis, cirrhosis, and hepatocellular carcinoma. This study aimed to assess the safety profile and tolerability of GM-60106, a peripheral 5HT2A antagonist, in healthy adults and otherwise healthy adults with markers of metabolic dysfunction-associated fatty liver disease (MAFLD) in a Phase 1 trial (NCT05517564).
Method: The Phase 1 clinical trial is a randomized, double-blind, placebo-controlled study involving single and multiple ascending doses to evaluate the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of GM-60106 in healthy adult male and female participants, as well as otherwise healthy adults with elevated markers of MAFLD. The study was structured into three parts: Part A (Single Ascending Dose) included 64 healthy participants divided into 8 cohorts, assessing the safety, tolerability, PK, PD profiles, and food effects of GM-60106. Part B (Multiple Ascending Dose, 14 days once daily) involved 24 healthy participants divided into 3 cohorts, evaluating the safety, tolerability, PK, and PD profiles of GM-60106. Part C (Multiple Ascending Dose, 28 days once daily) included 8 otherwise healthy participants with elevated biomarkers for NAFLD, examining the safety, tolerability, PK, and PD profiles of GM-60106.
Results: The part A study has been completed, revealing that adverse events (AE) were mostly mild to moderate in severity following a single dose of GM-60106 and demonstrated minimal effect on a high-fat meal. Notably, at the maximum tolerated dose (160 mg), grade 2 AEs such as posture dizziness were documented. Pharmacokinetic (PK) data shows that the absorption of GM-60106 increased in a dose-proportional manner from 2.5 mg to 160 mg dosing.
Conclusion: In the first-in-human clinical trial, GM-60106, a novel HTR2A antagonist, has been determined to be safe and well-tolerated, displaying PK profiles optimal for oral administration. A multiple ascending dose study is currently ongoing to assess the

safety, PK, and PD of the compound, paving the way for further long-term toxicity assessments and human proof-of-concept studies to establish the potential of GM-60106 as a promising treatment for MASH.

LBP-003

Semaglutide achieves resolution of metabolic dysfunction-associated steatohepatitis via modulation of multiple pathogenic pathways: insights from human and animal studies

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) increases the risk of cardiovascular (CV) events and liver fibrosis. Semaglutide, a glucagon-like peptide-1 (GLP-1) receptor agonist, reduces CV risk associated with overweight and obesity in the absence of diabetes and has a profound effect on weight reduction and MASH resolution. Management of MASH may benefit from an understanding of the mechanistic basis of semaglutide-induced MASH resolution; thus, it is of interest to explore its effect on the hepatic microenvironment and fibrosis development.
Method: GLP-1 receptor expression was assessed using RNA *in situ* hybridization and immunohistochemistry in human liver tissue and immunohistochemistry in liver tissue from DIO-NASH and CDA-HFD mice. The effect of semaglutide treatment on liver fibrosis was assessed using liver transcriptome analysis in both mouse models of MASH. Proteomic analyses of 4979 proteins using the SomaScan Platform were conducted on serum samples from 293 patients with MASH who received semaglutide or placebo in a phase 2b study (NCT02970942), and an independent cohort of 141 patients with MASH and 89 healthy volunteers.
Results: GLP-1 receptor mRNA or protein expression were not detected in human or mouse liver tissue. However, semaglutide improved histological markers of fibrosis and expression of genes involved in collagen turnover in two distinct mouse models of MASH; one that phenocopies the metabolic-associated features of human disease and another that exhibits non-abdominal obesity-induced advanced steatohepatitis and rapid fibrosis. In semaglutide-treated patients with MASH, proteomics identified 72 proteins significantly associated with MASH resolution after 72 weeks of treatment. These 72 proteins were also identified as differentially expressed in patients with MASH who were not treated for MASH, relative to healthy individuals. In semaglutide-treated patients with MASH, the abundance of the 72 proteins was similarly altered; however, semaglutide reverted the altered disease profile to that seen in non-pharmacologically treated healthy individuals. In contrast, changes in the levels of the 72 proteins in patients who received placebo were negligible. Notably, changes in the abundance of 26 of the 72 proteins were significant even after correction for weight loss. Although most of these 26 proteins are associated with metabolic functions, several are implicated in fibrosis-related pathways and CV disease (e.g. ADAMTSL2 and ACY1), and hepatocellular carcinoma (e.g. SERPINC1).
Conclusion: Based on circulating proteomic profiling, semaglutide-induced MASH resolution is associated with changes in multiple pathogenic pathways even after correction for weight loss. Semaglutide appears to re-balance the expression levels of disease-associated proteins in MASH to levels found in healthy individuals.

LBP-005

Efficacy, safety, tolerability, and immunogenicity of JNJ-0535 following a reduction of viral antigen levels through administration of siRNA JNJ-3989 in patients with chronic HBeAg negative hepatitis B-interim data of the OSPREY study

Background and aims: JNJ-64300535 (JNJ-0535), a DNA vaccine with two plasmids encoding HBV core and polymerase (pol) proteins, delivered through electroporation-mediated intramuscular injection, has previously shown to induce strong to modest T-cell responses in healthy adults and weak responses in patients with chronic hepatitis B (CHB). The OSPREY study (NCT05123599) was designed to assess whether a reduction of viral antigens by siRNA JNJ-73763989 (JNJ-3989) prior to JNJ-0535 vaccination, can enhance HBV-specific T cell responses and improve HBsAg kinetics in CHB patients.
Method: OSPREY is a phase 1b, open-label, single-arm, multicenter study in virologically suppressed patients with HBeAg-negative CHB receiving daily doses of nucleos(t)ide analogs (NA) for 36 weeks (W), 7 JNJ-3989 injections (Q4W) until W24, and 4 doses of JNJ-0535 (Q4W) from W14 to W28. NA stopping criteria (HBsAg <10 IU/ml, DNA <LLOQ and ALT <ULN) are assessed based on W36 results and patients are followed up (FU) with or without NA treatment for 48W, accordingly. Changes in virologic markers are assessed in serum and peripheral blood mononuclear cells (PBMCs) are evaluated for T cell

responses against core, pol, and surface using ex vivo intracellular cytokine staining (ICS). Intrahepatic changes in immunology markers are assessed from fine needle aspirates (FNA) at baseline (BL) (n = 22), W14 (n = 19) and W28 (n = 14) by single-cell RNA-sequencing. We report interim data with all patients at FUW24.

Results: Of the 23 patients who completed dosing, 11 achieved the primary end point of ≥2 $\log_{10}$ IU/ml reduction in HBsAg from baseline (BL) at W36. NA treatment was stopped in 7 patients based on W36 results and was restarted in 2 following an HBV DNA flare. Mean change in HBsAg in $\log_{10}$ IU/ml (SE) from W28 to FUW24 was 0.41 (0.148; n = 22) with – 0.29 (0.248) in 7 patients who stopped NA (NA completers) versus 0.73 (0.113) in 15 NA non-completers. Among the 7 NA completers, polypositive CD4 T cells (PP CD4) to ³2 HBV antigens was enhanced at W28 in 4, detected at pre-vaccination and W28 in 1 and not in the 2 NA completers who re-started NA during FU. Among the 14 non-completers with available data, 3 had enhanced PP CD4 at W28 and 1 had PP CD4 at pre-vaccination and W28 with no further enhancement. NA completers had higher proportions of intrahepatic mucosal-associated invariant T cells (MAIT), at all timepoints with FNAs available. Except 1 grade 3 injection site reaction, no grade 3 or 4 adverse events (AE) or serious AEs were reported until FUW24.

Conclusion: Treatment with JNJ-3989, JNJ-0535 and NA, continued or stopped was generally safe and well tolerated. HBsAg lowering, followed by vaccination in OSPREY, showed more favourable HBsAg kinetics during FU in patients that were able to stop NA treatment versus patients who continued NA treatment. A potential role of HBV specific polypositive CD4 T cells needs further elucidation.

Email: clbowlus@ucdavis.edu

Background and aims: Primary biliary cholangitis (PBC) is a rare autoimmune cholestatic liver disease characterised by the destruction of interlobular bile ducts, resulting in cholestasis and liver fibrosis. Elafibranor, a dual peroxisome proliferator-activated receptor (PPAR)-alpha/delta agonist, significantly improved prognostic biomarkers of cholestasis at Week 52 in patients with PBC in the phase III ELATIVE® trial.[1] Here, efficacy data from ELATIVE® beyond Week 52 are reported.

Method: In ELATIVE® (NCT04526665), patients with PBC and an inadequate response or intolerance to ursodeoxycholic acid, with alkaline phosphatase (ALP) ≥1.67 × upper limit of normal (ULN) and total bilirubin (TB) ≤2 × ULN, were randomised 2:1 to elafibranor 80 mg or placebo once daily for at least 52 weeks. Patients continued their assigned regimen after Week 52 until all patients had completed the Week 52 visit or for a maximum of 104 weeks, whichever came first. We report efficacy outcomes beyond Week 52, in the variable double-blind period, with a focus on Week 78. Biochemical response, the primary end point at Week 52, was defined as ALp <1.67 × ULN, with ≥15% reduction from baseline, and TB ≤ULN. Week 78 data presented are descriptive; some patients had missing data at Week 78.

Results: Of 161 randomised patients, 96/108 (89%) receiving elafibranor and 47/53 (89%) receiving placebo completed treatment to Week 52; 30/108 (28%) patients receiving elafibranor and 13/53 (25%) receiving placebo attended a Week 78 visit. Efficacy data to Week 52 have been reported previously.[1] At Week 78, 19/27 (70%) patients receiving elafibranor achieved a biochemical response compared with 0/13 (0%) patients receiving placebo. ALP normalisation occurred in 5/27 (19%) patients receiving elafibranor compared with 0/13 (0%) patients receiving placebo. Mean change from baseline to Week 78 in ALP was – 135.3 U/L in patients receiving elafibranor (n = 26) versus 31.0 U/L in patients receiving placebo (n = 12). Mean change from baseline to Week 78 in TB was – 1.2 umol/L in patients receiving elafibranor (n = 25), while patients receiving placebo had a worsening of mean TB levels with an increase of 3.1 umol/L (n = 12). Mean change from baseline to Week 78 in gamma glutamyl transferase (GGT) was –56.3 U/L in patients receiving elafibranor (n = 26) versus –10.3 U/L in patients receiving placebo (n = 12).

Conclusion: Following previously reported efficacy outcomes to Week 52,[1] the results presented here indicate that treatment of patients with PBC with elafibranor results in improvements in prognostic biomarkers of cholestasis longer-term, through 78 weeks.

Beneficial effects of autologous macrophage therapy on clinical outcomes in patients with compensated cirrhosis: extended follow-up data from a randomized controlled phase 2 trial

Paul Brennan[1], Iain Macpherson[2], Debbie Troland[2], Alastair M. Kilpatrick[3], Thomas Manship[4], Neil McGowan[5], John Campbell[5], Alasdair Fraser[6], Chloe Pass[6], Francesca Moroni[7], David Morris[3], Alison Glover[5], Scott Semple[3], Mark MacMillan[3], Cat Graham[3], Marc Turner[5], John F. Dillon[1], Neil Lachlan[2], Jonathan Fallowfield[8], Stuart J. Forbes[3]. *[1]University of Dundee, University of Edinburgh, Dundee, United Kingdom; [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [3]University of Edinburgh, Edinburgh, United Kingdom; [4]Northumbria Healthcare NHS Foundation Trust, Newcastle-Upon-Tyne, United Kingdom; [5]Scottish National Blood Transfusion Service (SNBTS), Edinburgh, United Kingdom; [6]Scottish National Blood Transfusion Service (SNBTS), Edinburgh; [7]NHS Grampian, Aberdeen, United Kingdom; [8]University of Edinburgh, Institute of Regeneration and Repair, Edinburgh, United Kingdom*
Email: p.z.brennan@dundee.ac.uk

Background and aims: Preclinical models and early human studies using macrophage cell therapy for liver cirrhosis have produced promising results. We recently performed a multicentre, open-label, Phase 2, randomized controlled trial of autologous monocyte-derived macrophage therapy for cirrhosis (MATCH01; ISRCTN10368050). The long-term effects of advanced cellular therapies are vital to understanding the efficacy, duration of response, and adverse safety signals, but are poorly described. Here, we present an interim analysis of extended follow-up of participants from the MATCH01 study.
Method: In MATCH01, autologous monocyte-derived macrophage therapy was compared with standard medical care in adults (18 to 75 years inclusive) with compensated cirrhosis (minimum 3 months since decompensation episode) and MELD score ≥10 and ≤17. The trial was designed to administer three infusions in the treatment arm, but was later amended to a single infusion protocol. Treatment comprised leukapheresis, cell isolation and maturation with reinfusion of macrophages up to a maximum dose of 1×10^9 cells. In total participants were randomized to triple infusion (n = 3), single infusion (n = 23) or standard medical care (n = 24). Participants were followed-up for 12 months as part of the original trial which was reported (Brennan PN et al., Hepatology 2023;78 (S1):S168–169). Here, time-to-event analysis over 30 months post-randomization was estimated for each group using the Kaplan-Meier method and compared statistically using the log-rank test.
Results: After 18 months of additional follow-up (i.e., 30 months post-randomization)- there were 7 deaths, 2 liver transplants, 1 patient listed for transplant, and 3 malignancies (no HCC) in the control group; compared to 2 deaths, no liver transplants, no patients listed for transplant, and 1 malignancy (HCC) in the macrophage infusion group. The macrophage treated groups had significantly improved overall survival (Chi-square = 4.35; p = 0.037) and transplant-free survival (Chi-square = 7.07; p = 0.0078).
Conclusion: This study demonstrates proof-of-concept for the beneficial effect of macrophage therapy on clinical outcomes in patients with compensated cirrhosis and reinforces their longer-term safety profile. Further development of macrophage therapy for cirrhosis/end-stage liver disease is warranted.

LBP-008

AAV8 gene therapy for mitochondrial neurogastrointestinal encephalomyopathy

Teresa Brevini[1], Lisa Swift[2], Helen Reynolds[3], Richard Stopforth[4], Yogeshkumar Malam[3], John Ong[3], Harry Spiers[2], Emilija Jovanovic[3], Miki Scaravaglio[3], Vitushan Vakeeswarasarma[3], James Heslop[3], Sarah Hosgood[2], Claudia Fuchs[5], Michael Trauner[5], Adam Duckworth[2], Anna Paterson[2], Arthur Kaser[4], Jelle van Den Ameele[4], Vassillis Kosmoliaptsis[2], Gwilym Webb[2], Christopher Watson[2], Andrew Butler[2], Fotios Sampaziotis[2,3]. *[1]Jeffrey Cheah Biomedical Centre, Cambridge Biomedical Campus, Puddicombe Way, Cambridge, United Kingdom; [2]Cambridge University Hospital, Cambridge, United Kingdom; [3]Cambridge Stem Cell Institute, Cambridge, United Kingdom; [4]University of Cambridge, Cambridge, United Kingdom; [5]Medical University of Vienna, Vienna, Austria*
Email: fs347@cam.ac.uk

Background and aims: Mitochondrial neurogastrointestinal encephalomyopathy (MNGIE) is a rare genetic disorder caused by mutations in the thymidine phosphorylase (TYMP) gene. This results in nucleoside accumulation, mitochondrial damage, and progressive gastrointestinal and neurological dysfunction leading to cachexia and death before 40 years. There is no established treatment for MNGIE. Liver transplantation restores nucleoside levels, but it is not indicated in all patients (e.g. severely malnourished patients) and it is associated with complications. Adeno-associated-virus (AAV) gene therapy could provide an attractive therapeutic alternative, as it is already clinically approved for other genetic diseases and has been successful in MNGIE animal models. Nevertheless, it has not been tested in human and due to the rarity of MNGIE (<200 cases described) obtaining sufficient numbers for robust AAV trials is challenging. *Ex situ* machine perfusion (ESMP) of human organs has emerged as a new avenue to trial novel therapies in the liver and could address this limitation. Our aim was to test AAV gene therapy for MNGIE in the explanted liver of a patient transplanted for this disease, which was maintained on ESMP.
Method: A 34-year-old patient with MNGIE was listed for liver transplantation as enzyme replacement therapy. The explanted liver was divided into anatomical right and left lobe and perfused *ex situ* using 2 XVIVO Liver Assist devices for 9 days. Nucleoside levels in the perfusate were measured with mass spectrometry. An AAV type 8 encoding for the human TYMP gene was used at a dose of 10^11 viral genomes/kg of liver. Perfusion parameters (flow, pressure), biochemistry (ALT, pH, glucose) and histology were used to assess treatment toxicity.
Results: Within 24 hours of perfusion nucleosides accumulated in the perfusate recapitulating key features of MNGIE. Subsequently, one lobe received AAV8-TYMP, while the other received carrier injection. The viral vector was uptaken by hepatocytes and TYMP expression was restored in the treated lobe within 3 days. Importantly, AAV8-TYMP treatment resulted in clearance of nucleoside from the perfusate which recapitulated nucleoside clearance from the patient's blood following liver transplant. Furthermore, long-term ESMP of the 2 liver lobes revealed no evidence of hepatotoxicity following AAV8 gene therapy, including normal ALT.
Conclusion: Our report provides the first demonstration of the safety and efficacy of AAV gene therapy for MNGIE in a human liver, paving the road for clinical trials. Our results shift the paradigm of using ESMP exclusively for donor livers and establishes perfusion of patient explanted pathological livers as a novel platform for drug testing. Finally, our study provides proof-of-principle for the efficacy of AAV gene therapy for treating diseased livers on ESMP which could be applied to various other liver diseases.

LBP-009

Liver-infiltrating activated HBV-specific tissue-resident memory T cells and atypical memory B cells were correlated with acute-on-chronic liver failure

Yang Cheng[1], Nina Le Bert[2], Nicole Tan[2], Loghman Salimzadeh[2], Bavani Gunasegaran[3], Seng Gee Lim[4], Evan Newell[5], Antonio Bertoletti[2]. *[1]Institute of Biomedical Science, Academia Sinica, Taipei, Taiwan; [2]Duke-NUS Medical School, Singapore, Singapore; [3]Singapore Immunology Network, A*STAR, Singapore, Singapore; [4]National University Health System, Singapore, Singapore, Singapore; [5]Fred Hutchinson Cancer Center, Seattle, United States*
Email: ycheng@ibms.sinica.edu.tw

Background and aims: Chronic HBV infection can lead to liver fibrosis and cirrhosis, and in some cases, patients develop into

chronic liver failure (CLF), a progressive loss of liver function for more than 6 months. On the contrary, patients who characterized as acute-on-chronic liver failure (ACLF) have dramatic clinical conditions and high short-term mortality due to the sudden loss of substantial amount of hepatocytes, with 80% of the cases lead to death or liver transplantation. However, how the adaptive immunity targeting HBV in the liver contribute to the development of two clinically distinct liver diseases is largely unknown. Studies of adaptive immunity in human liver has been often limited to total T or B cell population without the understanding of antigen-specificity, which prevents the accurate interpretation of disease-specific immune responses and restrain the therapeutic implications of findings.

Method: Here, we combined the utility of highly multiplexed combinatorial peptide-MHC tetramer staining and mass cytometry to probe >100 HBV epitopes on intrahepatic $CD8^+$ T cells isolated from HBV-associated ACLF and CLF patients in conjunction with deep-profiling of T cell phenotype. In parallel, intrahepatic B cells were sorted and examined by HBcAg- and HBsAg-probe with a panel focusing on memory B cell responses.

Results: We identified a subset of HBV-specific tissue-resident memory T (T_{RM}) cells expressing tissue homing and activation molecules, including CXCR6 and CD38, were significantly enriched in the liver of ACLF patients compared with CLF patients. Importantly, this subset was not observed in paired blood isolated from the same patients. Similarly, we found that intrahepatic HBcAg-specific B cells, but not HBsAg-specific B cells, were substantially elevated in ACLF patients compared with CLF patients. Of note, these cells obtained an atypical memory B cell phenotype in the liver.

Conclusion: Thus, by comprehensively probing intrahepatic HBV-specific T and B cells, we provide novel insights of adaptive immune responses occurs during the development of HBV-associated liver failure in great details. Our data implies that these cells might have therapeutic potential such as tolerogenic vaccine.

LBP-010

Azemiglitazone in combination with GLP1 agonists increases benefit and could preserve lean body mass

Jerry Colca[1], Kelly Pyles[2], Kyle McCommis[2]. *[1]Cirius Therapeutics, Kalamazoo; [2]St. Louis University School of Medicine, St. Louis*
Email: jcolca@ciriustx.com

Background and aims: Azemiglitazone (0602K) is a second-generation insulin sensitizer designed based on the activity of metabolites of the first-generation insulin sensitizer pioglitazone to specifically bind to the recently identified target of the TZDs, the mitochondrial pyruvate carrier. Accumulating data suggests that this agent may preserve lean mass in the face of programs designed to cause weight loss.

Method: Here we provide data from a new post-hoc analysis of the Phase 2b EMMINENCE trial (Harrison et al, J Hepatol. 2020 Apr;72 (4):613–626) and examined the body composition in db/db mice treated with the combination of 0602K and liraglutide under conditions where there are synergistic improvements in liver histology including ballooning with the 0602K/lira combination (Kamm et al, J Biol Chem 2021: 296:100807).

Results: Analysis of the 23 subjects with NASH (MASH) and type 2 diabetes who had been enrolled in the trial while on a stable dose of a GLP1 receptor agonist (GLP1-RA; 11 liraglutide, 8 dulaglutide, and 4 exenatide) demonstrated that any dose of 0602K was able to further lower fasting glucose, insulin and liver enzymes. HbA1c decreased by more than 2% in some subjects (average 0.5%). No subjects on a GLP1-RA without 0602K had a reduction in fibrosis score, while 5 of the 19 subjects who had been on both 0602K and a GLP1-RA had a reduction in the liver fibrosis scores (52-week liver biopsies). Some subjects who had been on a GLP1-RA continued to lose weight while others did not, often with a reduction in waist circumference. Given the major effects of this pharmacology to improve insulin sensitivity in skeletal muscle, maintenance of lean mass could be a component of the overall pharmacology. To this end, we performed additional analysis of a preclinical study in db/db mice that examined the combination of 0602K and liraglutide. Here we report that the addition to 0602K to lira maintains lean body mass without significantly affecting overall adipose mass. Statistically significant increases in adipose mass occurred only in subcutaneous and brown adipose tissue.

Conclusion: Together these results suggest that clinical evaluation of azemiglitazone should include GLP1 incretins to take advantage of the combined efficacy of these mechanisms of action and to produce more favorable effects on body composition.

LBP-011

Streamlined serodiagnosis of hepatitis delta: a novel lateral flow assay kit for on-site rapid diagnostics

Arghun Dashdorj[1], Nomin Ariungerel[2], Sunguck Han[3], Gichan Choi[3], Su Ah Kim[3], Tae-Hoon Kim[3], Kyongman An[3], Minsup Chung[3], Odgerel Oidosambuu[2], Byambasuren Ochirsum[4], Purevjargal Bat-Ulzii[4], Enkhnomin Ochirbat[4], Sanjaasuren Enkhtaivan[4], Saruul Enkhjargal[2], Naranbaatar Dashdorj[1], Naranjargal Dashdorj[4], Nam Joon Choi[3]. *[1]Onom Foundation, The Liver Center, Ulaanbaatar, Mongolia; [2]Laboratory of Genetic Engineering, NUM, The Liver Center, Ulaanbaatar, Mongolia; [3]LUCA AICell, Inc., Anyang-si, Korea, Rep. of South; [4]The Liver Center, Onom Foundation, Ulaanbaatar, Mongolia*
Email: a.dashdorj@onomfoundation.org

Background and aims: Hepatitis Delta Virus (HDV), the most severe form of viral hepatitis in humans, exacerbates the liver disease caused by Hepatitis B Virus (HBV). Despite an estimated global prevalence of 15–20 million, HDV infections often go underdiagnosed due to insufficient training, testing, and funding. To address this challenge, we have developed and validated an anti-HDV Antibody Rapid Diagnostic Test (RDT), leveraging the lateral flow assay (LFA) technique to detect antibodies against Hepatitis Delta antigen (anti-HDV) in serum and plasma. The LFA, integral to our RDT, operates in a streamlined mechanism. When a sample, such as serum or plasma, is applied it migrates via capillary action, encountering reagents including antibodies labeled with colored particles. These particles bind to any present anti-HDV, producing a test line indicating a positive result. A control line further validates this procedure. Aim: Develop and validate LUCA AICell anti-HDV Antibody Rapid Diagnostic Test (RDT), leveraging the lateral flow assay (LFA) technique to detect antibodies against Hepatitis Delta antigen (anti-HDV) in serum and plasma.

Method: 10 μl of serum was collected using a micropipette. Held the micropipette at a 90° angle to the testing device and added the collected specimen into the specimen well. Held the buffer bottle at a 90° angle to the testing device without touching the specimen well to avoid buffer contamination. Added 3 drops of the buffer into the specimen well. Checked the results after 15 minutes. Then compared the results to conventional anti-HCV and HBsAg ELISA tests, as well as HDV-RNA quantification PCR kits.

Results: Our evaluation involved 200 samples, encompassing 122 HDV-RNA positive, 49 HDV-RNA negative but HBsAg and HBV-DNA positive, and 29 healthy individuals. The RDT showcased 100% sensitivity and specificity compared to conventional anti-HCV and HBsAg ELISA tests, as well as HDV-RNA quantification PCR kits.

Conclusion: The anti-HDV Antibody RDT emerges as an accessible, reliable tool for HDV diagnosis. Its simplicity, rapidity, and accuracy make it particularly valuable in both hospital and remote settings, paving the way for improved HDV screening and management worldwide.

LBP-012

Epidemiological trends and clinical impact of multidrug-resistant bacterial infections in patients with cirrhosis across Latin America: results from the ACLARA study

Background and aims: Decompensated cirrhosis represents a significant public health challenge in Latin America, with bacterial infections likely exacerbating morbidity and mortality. Multidrug-resistant (MDR) bacteria further complicate infection management and prognosis.We aimed to investigate the current epidemiology and prognostic impact of MDR bacterial infections in patients with cirrhosis across Latin America.

Method: Multicenter prospective study involving 1274 non-elective hospitalized patients with acutely decompensated cirrhosis across 44 centers in 7 Latin American countries (Brazil, Argentina, Chile, Mexico, Peru, Colombia, and Paraguay) from 2018 to 2020.

Results: Among the 1274 patients, 524 (41.1%) developed a total of 619 bacterial infections, of which 41.7% were culture-positive. Acute-on-Chronic Liver Failure (ACLF) developed in 47.1% of cases, while septic shock occurred in 26.9%, with higher rates observed in Mexico (ACLF: 62.5%, septic shock: 45.7%) and Peru (ACLF: 53.3%, septic shock: 37.8%), with p values of 0.042 and <0.001, respectively. Gram-negative bacteria (67.8%; *Escherichia coli:* 34.8%) were the most frequently isolated strains. MDR bacteria were isolated in 29.4% of the culture-positive infections, with higher rates observed in Mexico (41.7%), Argentina (35.1%), and Peru (33.3%). ESBL-producing *Escherichia coli* was the most prevalent MDR bacteria (27.6%). Relevant differences in the types of MDR bacteria were observed among countries. ESBL- and Amp-C producing *Enterobacteriaceae* were the most prevalent in Mexico (36.1%), followed by Colombia and Paraguay (25% each), Peru (22.2%), Chile (18.2%), Argentina (16.2%), and Brazil (12.1%). Methicillin-resistant *Staphylococcus aureus* (MRSA) and Vancomycin-resistant *enterococci* (VRE) were predominant in Argentina (5.4% and 2.7%, respectively). Carbapenem-resistant *Klebsiella pneumoniae* was prevalent in Argentina (5.4%) and Carbapenem-resistant *Pseudomonas* was prevalent in Brazil (2%). MDR infections were more frequently associated with septic shock (40%) and ACLF (57.4%). The 28-day mortality rate among infected patients was 29.4%, with a higher proportion in Mexico (47.1%, $p < 0.001$), whereas it increased to 47.8% in MDR-infected patients, with no difference between countries.

Conclusion: MDR bacterial infections are prevalent and associated with poor prognosis in patients with decompensated cirrhosis in Latin America. Predominant resistant strain varies markedly among countries.

LBP-013

Deciphering the role of mechanical forces in liver regeneration by a biomimetic liver regeneration chip

Xinyu Shu[1,2], Ning Li[1,2], Yu Du[1,2], Mian Long[1,2]. *[1]Institute of Mechanics, Chinese Academy of Sciences, Beijing, China; [2]University of Chinese Academy of Sciences, Beijing, China*
Email: duyu@imech.ac.cn

Background and aims: Mechanically regulated angiocrine signals induced by the increased blood flow have a key role in liver growth and regeneration. Although mechanical stretching has been proven to contribute to the regeneration in vivo, if shear stress which also changes in the blood perfusion contribute to the regeneration and how shear stress affect liver regeneration with mechanical stretch synergistically remains unclear. Part of the reason is the lack of in vitro models that allow manipulating mechanical stretch and shear stress independently and synergistically. To address this issue, we developed a biomimetic liver regeneration chip (LRC) consisting of a tubular blood vessel and neighbouring hepatocytes monolayer, which integrates stretch and shear stress to elucidate the underlying mechanisms that how two types of forces synergistically regulate liver regeneration.

Method: PDMS microfluidic devices were replicated from a high-resolution 3D printed resin mold. The LRC was fabricated by filling collagen gel into the PDMS microfluidic device with an inserted needle and two open ports nearby to create a tubular channel and two neighbouring defined hollow space for cell seeding. Primary murine liver sinusoidal endothelial cells (LSECs) and hepatocytes were isolated by collagenase perfusion and MACS sorting. LSECs were seeded through the tubular channel while hepatocytes were seeding into a plate form by side. Mechanical forces were applied by a pressure driven pump system. Various mode of applying mechanical forces to the vascular channel were achieved by restricting flow and adjusting the stiffness of surrounding matrix. By exerting shear stress and stretch separately and synergistically, we have then investigated how mechanical forces regulate the angiocrine signals and hepatocyte proliferation.

Results: In the LRC, LSECs were able to form a tubular monolayer with intact cell junctions and barrier function. Hepatocytes grew into a confluent monolayer with canaliculi formed between cells. The separated and synergistic mechanical loading of shear stress and stretch was validated by time lapse imaging and particle tracking visualization. Compared with static control, the LSECs in LRC under flow expressed higher genes of secretory factors such as HBEGF to promote hepatocytes proliferation. We are currently using the LRC as a model to study the role of shear stress and stretch in regulating the angiocrine signals and related mechanical sensing pathways to elucidate a mechanism for mechanical forces-initiated liver regeneration.
Conclusion: Overall, these results demonstrated that the LRC not only recapitulate liver sinusoid structurally and functionally, but also allow manipulation of shear stress and stretch separately and together. The LRC represents a novel tool for investigation of mechanical stimuli regulating the angiocrine signals to promote liver regeneration.

Email: winstondunnmd@gmail.com

Background and aims: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) affects approximately 30% of the global adult population and poses significant risks of disease progression, particularly in patients with moderate to advanced fibrosis (stages 2–3). Following the FDA's approval of Resmetirom for treating Metabolic Dysfunction-Associated Steatohepatitis (MASH) in these stages, there is a need for a surrogate marker to refine the selection of patients for liver biopsy. The ALADDIN study introduces a novel machine learning-based web calculator to estimate the probability of stage ≥2 fibrosis in MASLD using routine laboratory parameters, with and without Vibration Controlled Transient Elastography (VCTE).
Method: A total of 3708 patients with biopsy-confirmed MASLD from six centers worldwide were divided into Derivation and Internal Validation cohorts on a 1:1 basis, supplemented by 1289 patients from nine centers for External Validation. ALADDIN models, employing Random Forest, Gradient Boosting Machines, and XGBoost enhanced by Bayesian updates, were developed to evaluate moderate fibrosis (stage ≥F2).
Results: The VCTE model achieved an Area Under the Curve (AUC) of 0.800 (95% CI 0.773–0.827) in external validation, significantly outperforming the FAST (AUC: 0.707, 95% CI 0.674–0.739, $p < 0.0001$) and Agile-3 (AUC: 0.764, 95% CI 0.735–0.793, $p = 0.001$) models. The model using routine laboratory parameters without VCTE reached an AUC of 0.757 (95% CI 0.730–0.783), comparable to FAST and Agile-3. The VCTE model model also demonstrated superior decision curve analysis, calibration, and classification accuracy, using a dual cut-off approach, and outperformed existing models in predicting moderate fibrosis.
Conclusion: The ALADDIN study, via an international consortium, has successfully developed and externally validated machine learning models that predict moderate fibrosis with notable accuracy. Our VCTE model, available at https://aihepatology.shinyapps.io/ALADDIN1/, and our routine laboratory parameter model without VCTE, available at https://aihepatology.shinyapps.io/ALADDIN2/, demonstrate statistical superiority and comparable performance, respectively, against traditional models including Agile-3 and FAST. These algorithms will facilitate targeted liver biopsy in line with the new FDA approval for Resmetirom treatment.

LBP-015
The effect of precursors on extracellular nicotinamide adenine dinucleotide in plasma
Sue Easaw[1], Can Kamali[1], Al-Hussein Saqr[1], Naomi Chioma Okpala[1], Eriselda Keshi[1], Simon Moosburner[1], Karl Hillebrandt[1], Philipp Brunnbauer[1], Felix Krenzien[1]. *[1]Charité-Universitätsmedizin Berlin, Berlin, Germany*
Email: ellen-sue.easaw@charite.de

Background and aims: The presence of extracellular Nicotinamide adenine dinucleotide (eNAD+) and its effects have been investigated recently, it remains questionable whether it can be synthesized in the extracellular space. This study aims to investigate the effect of three different NAD^+ precursors on $eNAD^+$ content of plasma, to test the presence of enzymatic activity capable of converting these precursors into eNAD+.
Method: Initially, the individual impact of nicotinamide riboside (NR), L-Tryptophan (L-Tryp), and nicotinic acid (NA) on plasma $eNAD^+$ levels was evaluated. After incubating at 37°C for various time periods (0 min, 30 min, 60 min), the sample eNAD+ levels were measured using an enzymatic assay based on the principle of reactant cycling, employing alcohol dehydrogenase as the converting enzyme. Ultimately, a revised-simulated body fluid adjusted with albumin (r-SBFA) served as a NAD^+–free negative control. All plasma samples were obtained from healthy volunteers ($n = 2$).
Results: Plasma samples without any added precursors showed a noticeable decreasing trend in $eNAD^+$ concentration after both 30 and 60 minutes (−3.20% and −11.66%, respectively $p < 0.05$). Furthermore, the effect was more pronounced when plasma samples were spiked with NAD^+ (−90%, $p < 0.05$). In contrast, samples spiked with all precursors added (NR + L-Tryp + NA) and *NA-only-samples* presented a stable $eNAD^+$ within the first 30 min (with a percentage change in plasma with all precursors added: −0.02% and plasma with NA-only: +0.09%, respectively $p > 0.05$). The plasma samples with added L-Tryp were the only ones that demonstrated a slight increase in $eNAD^+$ after 30 minutes of incubation (3.82%, $p > 0.05$). However, after 60 minutes, the $eNAD^+$ levels dropped within all observed precursor conditions for NR, L-Tryp and NA (−3.51%, −13.3%, −8.49%, and −8.52%, respectively, $p < 0.05$). In contrast, there were no $eNAD^+$ changes observed in r-SBFA.
Conclusion: This study demonstrates the effects of NAD^+ precursors on plasma samples. The results indicate that the presence of NAD^+ precursors in blood plasma, such as NR, L-Tryp, and NA, can induce temporary $eNAD^+$ homeostasis as seen within the first 30 minutes of incubation post spiking. These findings suggest the presence of enzymatic activity within plasma, which might play a role in NAD^+ metabolism, whereby the addition of NAD^+ precursors seem to affect the synthesis of $eNAD^+$ or stabilize the extracellular consumption of NAD+.

LBP-016

Carvedilol versus propranolol in the prevention of decompensation and mortality in patients with compensated and decompensated cirrhosis

Jose Fortea[1], Edilmar Alvarado-Tapias[2], Benedikt Simbrunner[3], Iranzu Ezcurra[1], Virginia Hernández-Gea[4], Carlos Ferre Aracil[5], Elba Llop Herrera[6], Angela Puente[1], Cristina Roig[2], Thomas Reiberger[3], Juan Carlos García-Pagán[4], José Luis Calleja Panero[6], Mattias Mandorfer[3], Càndid Villanueva[2], Javier Crespo[1]. Email: jifortea@gmail.com

Background and aims: Data on the effectiveness of classic non-cardioselective beta-blockers (cNSBBs, i.e., propranolol and nadolol) versus carvedilol in patients with cirrhosis are scarce. We aimed to compare their potential to prevent decompensation and mortality in patients with compensated and decompensated cirrhosis.
Method: Multicenter retrospective study, including patients with cirrhosis and clinically significant portal hypertension undergoing measurement of hepatic venous pressure gradient (HVPG) to assess the acute hemodynamic response to intravenous propranolol prior to the initiation of primary prophylaxis for variceal bleeding. A competitive risk analysis was performed after adjusting for baseline covariates using Inverse Probability of Treatment Weighting (IPTW). The main objectives were (i) the prevention of decompensation in compensated patients and (ii) death or further decompensation in decompensated patients, considering death, liver transplantation, and viral clearance as competitive events.
Results: A total of 540 patients with cirrhosis were included, 256 compensated (cNSBBs n = 111; carvedilol n = 145) and 284 decompensated (cNSBBs n = 134; carvedilol n = 150). In patients with compensated cirrhosis, the median age was 61.5 years (IQR 53.4–69.4), viral disease was the predominant etiology (39.5%) and the median MELD score was 9 (IQR: 8–11). Decompensated patients were younger (59.0 years; IQR: 51.9–65.7), with alcohol-related liver disease as the primary etiology (66%) and a higher MELD score (12 points; IQR: 10–15). In both cohorts, cNSBB were more frequently used in earlier years (i.e., 2008–2014) and among acute hemodynamic responders. Median follow-up were 43.8 months (compensated) and 32.5 months (decompensated). After covariate balancing with IPTW, Carvedilol, compared to cNSBBs, significantly reduced the risk of first decompensation in compensated patients (SHR 0.57; 95% CI 0.36–0.90; p = 0.014) and the combined end point of further decompensation/death in decompensated patients (SHR 0.68, 95% CI 0.49–0.96; p = 0.026). A second HVPG was conducted in 176 (68.8%, compensated cohort) and 177 patients (62.3%, decompensated cohort). Among non-responders, both compensated (11.1% vs. 29.4%; p = 0.422) and decompensated patients (16.0% vs. 43.6%: p = 0.0247) showed a threefold increase in likelihood of response with Carvedilol. Discontinuation rates for cNSBB and Carvedilol were comparable in compensated patients (6.3% vs. 9.0%; p = 0.488), but cNSBB discontinuation was higher in decompensated patients (11.3% vs 4.7%; p = 0.046), predominantly due to non-safety-related factors.
Conclusion: Our data endorse the current recommendation favoring the use of carvedilol in the prevention of the first decompensation of cirrhosis and extend its preferential use in patients with decompensated cirrhosis without refractory ascites.

LBP-017

Liver-kidney crosstalk: the influence of hepatic oxalate release on kidney gluconeogenesis

Philipp Gabrys[1], Katharina Grgas[1], Jörg Reinders[1], Eduardo Salido[2], Jan G. Hengstler[1], Cristina Cadenas[1]. [1]*Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany;* [2]*Hospital Universitario de Canarias, Universidad La Laguna, San Cristobal de La Laguna (Canary Islands), Spain*
Email: philipp.gabrys21@gmail.com

Background and aims: Primary hyperoxaluria type 1 is a metabolic disease that affects the kidney by the formation of oxalate precipitates. The elevated oxalate levels originate in the liver due to a dysfunction of the enzyme, alanine-glyoxylate aminotransferase (Agxt). Our previous studies identified a downregulation and promoter hypermethylation of Agxt in steatotic liver disease. Evidence exists that Agxt is implicated in amino acid-driven gluconeogenesis, and oxalate is reported to inhibit key enzymes in gluconeogenesis, such as pyruvate carboxylase and phosphoenolpyruvate carboxykinase. Consequently, the oxalate effect on global glucose homeostasis and how organs driving gluconeogenesis are affected, is still elusive. Thus, the aim of the study is to understand the contribution of Agxt/oxalate to gluconeogenesis in gluconeogenic organs, such as the liver and the kidney, which together maintain glucose homeostasis under fasting.
Method: The effect of oxalate on gluconeogenesis driven by gluconeogenic substrates like pyruvate/lactate, alanine and glycerol was studied in vitro in primary mouse hepatocytes (PMHs) isolated from Agxt knockout (KO) and wild type mice using a hepatic glucose production assay. Hormonal and substrate-dependent regulation of Agxt was studied *in vivo* and *in vitro* with common biomolecular techniques. Additionally, abnormalities in glucose homeostasis were investigated in AgxtKO mice analyzing gene expression changes in the liver and kidney using qPCR and immunoblots and plasma biochemistry and metabolites after fasting.
Results: In primary mouse hepatocytes (PMHs), exposure to oxalate or precursors, e.g. hydroxyproline, significantly decreased the *de novo* production of glucose from pyruvate/lactate and amino acids, but not from glycerol. Although fasting glucose levels did not significantly differ between wt and AgxtKO mice (which represent oxalemia and hyperoxaluria), gene expression alterations in gluconeogenic genes in response to fasting were more pronounced in the kidney of AgxtKO mice, indicating a compensatory shift towards glycerol-driven gluconeogenesis. Moreover, *Agxt* was upregulated by glucagon administration *in vivo* and *in vitro*, and by the gluconeogenic substrates pyruvate/lactate, amino acids, but not by glycerol.
Conclusion: The results suggest a role for Agxt in glucose homeostasis *via* regulation of oxalate generation in hepatocytes. High hepatic oxalate release resulting from Agxt downregulation appears to influence gluconeogenesis in the kidney where oxalate levels massively increase. When oxalate rises to levels high enough to inhibit pyruvate carboxylase, gluconeogenesis from pyruvate/lactate is expected to be impaired, and compensatory gluconeogenesis from glycerol will be predominant. The consequences of the switch to global glucose homeostasis are currently under investigation.

LBP-018

Promising first-in-human, first-in-class, Phase 1B immunogenicity data of VRON-0200, a novel checkpoint modifier containing immunotherapy, for HBV functional cure

Edward J. Gane[1], Sue Currie[2], Andrew Luber[2], Hildegund Ertl[3], Marie Bonhomme[4], Grace Lai-Hung Wong[5]. *[1]New Zealand Liver Transplant Unit, Auckland City Hospital, University of Auckland, Auckland, New Zealand; [2]Virion Therapeutics, Philadelphia, United States; [3]The Wistar Institute, Philadelphia, United States; [4]PPD, Part of Thermo Fisher Scientific, Richmond, United States; [5]The Chinese University of Hong Kong, Hong Kong, Hong Kong*
Email: edgane@adhb.govt.nz

Background and aims: VRON-0200 is a therapeutic vaccine for functional cure of chronic hepatitis B virus (HBV) infection that expresses a genetically encoded checkpoint modifier (herpes simplex virus type 1 (HSV-1) glycoprotein D), fused with HBV core and polymerase antigens, designed to enhance, broaden, and prolong $CD8^+$ T cell responses. Here we report the first-ever immunogenicity data, and ongoing safety data, in VRON-0200 vaccinated patients.
Method: Chronic HBV-infected, virally suppressed adults, with HBsAg levels ≤500 IU/ml, are randomized to receive VRON-0200 1×10^{10}vp via one of 2 different chimpanzee adenoviral vectors intramuscularly. Cohort 1a receives a prime, followed by a heterologous boost, on day 91; Cohort 1b receives prime only. A higher dose Cohort 2 (5×10^{10}vp) may begin once 12 Cohort 1 patients reach Day 28. Study assessments include safety, virologic, and immunologic parameters. T cell frequencies are assessed pre-vaccination (two timepoints) and at multiple post-vaccination timepoints, via ELISpot (IFN-ɣ; LLOD <30 SFU/1e6) from PBMCs isolated from whole blood and incubated overnight using 3 separate peptide pools (core and pol representing the vaccine peptides, and peptides representing S antigen).
Results: As of March 15, 2024, 10 Cohort 1 pts received one dose of VRON-0200 (n = 5 each viral vector), and are included in the safety analysis; 6 pts have IFN-ɣ ELISpot results for 4 timepoints through Day 28 (2 pre-treatment (−28 to −7, Day 1) and Days 14 and 28). For the 10 pts, 100% are male, 80% Asian, mean age, 44.5 yrs (range 41–54), median baseline HBsAg, 244 IU/ml (range: 16–623). After 641 pt safety days, there were no SAEs reported, and no study discontinuations; 1 pt reported 2 discrete AEs (1 considered TEAE; both resolved without treatment). In the 6 pts with ELISpot results, all are male, 5 Asian, with mean age of 44 yrs (range:41–49); 5 are HBeAg-. As of Day 28, after VRON-0200 vaccination: 50% (3 of the 6 pts) showed increases in T cell frequencies to core; 2 of these 3 pts showed increases to both core and pol, despite having frequencies below LOD at baseline to both antigens. Three pts showed no consistent changes in T cell frequencies, after vaccination; one of those 3 had frequencies below LOD, at all timepoints evaluated. No sustained changes in frequencies to S antigen were observed in any pts through Day 28.
Conclusion: As of March 15, 2024, a single, intramuscular low dose of VRON-0200 was safe, well tolerated, and, in 50% of pts, increased or induced T cell responses, to one or both peptides, even in pts without immune responses at baseline, prior to vaccination. These data support VRON-0200's continued evaluation as a potential simple, easy-to administer, interferon-sparing immunotherapy for HBV functional cure. Further immunologic and safety analyses are ongoing and will be presented.

LBP-019

Safety and antiviral activity of AHB-137, a novel antisense oligonucleotide, in healthy volunteers and subjects with chronic hepatitis B

Edward J. Gane[1], Man-Fung Yuen[2], Wen Wang[3], Chi-Yi Chen[4], Yao-Chun (Holden) Hsu[5], Eric Lawitz[6], Joel Chua[7], Jinlin Hou[8], Hong Ren[9], Xian Yu[9], Chongyuan Xu[8], Paul Yien Kwo[10], Shyamasundaran Kottilil[7], Ira Jacobson[11], Wan-Long Chuang[12], Lung-Yi Mak[2], Wai-Kay Seto[2], Christian Schwabe[13], Mingyue Chen[14], Di Zhao[14], Chen Yang[14], Miao Wang[14], Cheng Yong Yang[14,15], Guofeng Cheng[14,15], Junqi Niu[16], Yanhua Ding[3]. *[1]University of Auckland, Auckland, New Zealand; [2]Queen Mary Hospital, The University of Hong Kong, Hong Kong, China; [3]Phase I Clinical Trial Center, The First Hospital of Jilin University, Changchun, China; [4]Division of Gastroenterology and Hepatology, Department of Medicine, Ditmanson Medical Foundation Chiayi Christian Hospital, Chiayi, Taiwan; [5]Center for Liver Diseases, E-DA Hospital, Kaohsiung, Taiwan; [6]Texas Liver Institute, University of Texas Health San Antonio, San Antonio, United States; [7]Division of Clinical Care and Research, Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States; [8]Nanfang Hospital, Southern Medical University, Guangzhou, China; [9]The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China; [10]Division of Gastroenterology and Hepatology, Stanford University School of Medicine, Stanford, United States; [11]NYU Grossman School of Medicine, New York, United States; [12]Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung, Taiwan; [13]New Zealand Clinical Research, Auckland, New Zealand; [14]Ausper Biopharma, Hangzhou, China; [15]AusperBio Therapeutics, San Mateo, United States; [16]The First Hospital of Jilin University, Changchun, China*
Email: edgane@adhb.govt.nz

Background and aims: AHB-137 is a novel naked antisense oligonucleotide (ASO) that targets a highly conserved sequence close to the 3′ end of hepatitis B virus (HBV) mRNA. AHB-137 has demonstrated a favorable pharmacokinetic (PK) and safety profile and potent antiviral activity in preclinical studies. Here, we report the safety and preliminary efficacy results from two phase I clinical studies of AHB-137 in healthy volunteers (HVs) and chronic hepatitis B (CHB) subjects.
Method: 40 HVs received either a single dose of AHB-137 up to 450 mg or multiple doses of 300 mg on Day 1, 4, 8, 15, and 22. A total of 52 hepatitis B e antigen (HBeAg) negative CHB subjects under stable nucleos (t)ide analogue (NA) treatment were enrolled and were dosed with up to 6 doses of 150 mg or 300 mg of AHB-137 within 4 weeks. All doses were administered subcutaneously. The baseline hepatitis B surface antigen (HBsAg) level was <1, 000 IU/ml in 35 CHB subjects and was between 1, 000 and 10, 000 IU/ml in 17 CHB subjects (HighS subjects).
Results: All HVs successfully completed the study. There were no grade 4 adverse events (AEs), no study drug discontinuations due to AEs and no study drug related serious AEs (SAE). Overall, 30 HVs (75%) experienced treatment-related adverse events (TRAEs). All TRAEs were Grade 1 or 2, except for one Grade 3 injection site erythema. The most common TRAEs (incidence >1 subject) were injection site reactions, headache, nausea, pyrexia, and myalgia. CHB subjects enrolled were aged 26–63, mostly male (81%) and Asian (92%). To date, a total of 37 CHB subjects completed at least Day 29 visit. Among them, AHB-137 was dosed at 150 mg and 300 mg in 8 and 18 CHB subjects with HBsAg <1, 000 IU/ml respectively and was dosed at 300 mg in 11 HighS subjects. HBsAg reduction >1 $\log_{10}$ IU/ml was achieved in 37.5% (3/8) subjects at 150 mg, in 55.6% (10/18) subjects at 300 mg, and in 45.4% (5/11) in HighS subjects at 300 mg. HBsAg reduction >2 $\log_{10}$ IU/ml was achieved in 12.5% (1/8) subjects at 150 mg, in 33.3% (6/18) subjects at 300 mg, and in 36.4% (4/11) in HighS subjects at 300 mg. To date, 5 subjects have achieved sustained HBsAg loss (HBsAg below lower limit of quantitation), including 2 with seroconversion (detectable hepatitis B surface antibody (HBsAb)) with a 4-week AHB-137 treatment. Maximum HBsAg reduction was reached between Day 29 and Day 50.
Conclusion: Single doses of AHB-137 up to 450 mg and multiple doses up to 300 mg for 4 weeks were safe and well tolerated in HVs and CHB subjects. Over 2 $\log_{10}$ IU/ml HBsAg reduction was achieved in >30% CHB subjects with baseline HBsAg <10, 000 IU/ml and could led to sustained HBsAg loss with a 4-week AHB-137 treatment at 300 mg. AHB-137 monotherapy with background NA treatment demonstrated promising potential for achieving a functional cure of CHB.

LBP-020

A phase 1, double-blinded, randomized, placebo-controlled, multicenter global study evaluating the safety, tolerability, and antiviral activity of DF-006 in chronic hepatitis B, virologically-suppressed patients

Edward J. Gane[1], Eshwari Kovoor[2], Alina Jucov[3], Igor Anastasiy[4], Marta Dobryanska[5], Susan Parker[2], Carl Cook[2], Cong Xu[6], Tian Xu[7], Henri Lichenstein[2], Jeysen Yogaratnam[2]. *[1]New Zealand Clinical Research, Auckland, New Zealand; [2]Drug Farm, Inc., Guilford, United States; [3]PMSI Republican Clinical Hospital "T. Mosneaga, " Arensia Exploratory Medicine Phase I Unit, Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova; [4]Medical Center of LLC "Arensia Exploratory Medicine" Department of Clinical Trials, Kyiv, Ukraine; [5]Municipal Non-Profit Enterprise "Kyiv City Clinical Hospital #12" Department of Emergency Medical Care, Kyiv, Ukraine; [6]Drug Farm, Inc., Zhejiang Yao Yuan Biotechnology Ltd, Jiashan, China; [7]Zhejiang Yao Yuan Biotechnology Ltd; Shanghai Yao Yuan Biotechnology Ltd, Shanghai, China*
Email: edgane@adhb.govt.nz

Background and aims: DF-006, an oral (PO), small molecule prodrug, activates alpha-protein kinase 1 and stimulates host immune response in the liver. The ongoing Phase 1 study DF-006–1001 evaluates safety, pharmacokinetics, and pharmacodynamics (PD) of DF-006 or placebo (PBO) in healthy volunteers and the safety, antiviral activity, and PD of DF-006 in virologically-suppressed (VS) hepatitis B e antigen (HBeAg)-negative chronic hepatitis B (CHB) patients. Preliminary blinded safety and antiviral results from 2 completed CHB cohorts are presented below.

Method: The study consists of 3 CHB cohorts. The first (0.4 mcg DF-006/PBO) and second (0.7 mcg DF-006/PBO) cohorts have completed the study; the last cohort (1 mcg DF-006/PBO) is ongoing. DF-006 or PBO (6:2) was administered PO once weekly (QW) for 4 weeks (Days 1, 8, 15, and 22) with a previously prescribed nucleotide reverse transcriptase inhibitor (NtRTI). After the last dose, subjects were followed up on Days 29, 36, 43, and 50. Of the 16 subjects randomized in the completed cohorts, 2 subjects from the 0.4 mcg DF-006/PBO cohort were excluded from efficacy analysis due to a protocol deviation pre-dosing.

Results: There were no serious adverse events, study discontinuations, adverse events of special interest, Grade 3–4 treatment emergent adverse events (TEAEs) or clinically significant vital signs, ECG, or urinalysis abnormalities. One subject (0.7 mcg DF-006/PBO) had mild alanine aminotransferase elevation 1 week after the last dose of the investigational product (IP); it was not related to the IP. There were 2 subjects with 3 TEAEs reported as possibly related to the IP (dysgeusia, asthenia, and fatigue); all were Grade 1 (mild) and resolved in 1–3 days without medical interventions. In subjects with baseline hepatitis B surface antigen (HBsAg) >2000 IU/ml (0.4 mcg DF-006, N = 3; 0.7 mcg DF-006, N = 4; PBO, N = 1), at Day 36, reduction in HBsAg was seen in 33% and 75% for doses of 0.4 mcg and 0.7 mcg DF-006, respectively. At Day 50, reduction in HBsAg was seen in 67% and 50% subjects dosed with 0.4 mcg and 0.7 mcg DF-006, respectively. The PBO subject missed sample collection on Days 36 and 50, though no HBsAg reductions were seen on Days 22 and 29. Days 36 and 50 HBsAg reductions in DF-006 subjects ranged from approximately 0.02 $\log_{10}$ IU/ml to 0.40 $\log_{10}$ IU/ml. Throughout the study, hepatitis B virus (HBV) DNA and HBV RNA remained below the lower limit of quantification for all subjects.

Conclusion: DF-006 is safe and well tolerated in VS HBeAg-negative CHB subjects after 4 weeks of PO QW dosing up to 1 mcg. Most VS CHB subjects with baseline HBsAg >2000 IU/ml achieved off-treatment HBsAg reductions. These data support further evaluation of DF-006 in a Phase 2 study.

LBP-021

BRII-179 induced functional immune response, demonstrating potential to improve chronic hepatitis B functional cure

Zhiliang Gao[1], Libo Yan[2], Jianping Li[3], Rong Hu[4], Peng Hu[5], Wei Yue[6], Fangfang Lv[7], Yiwen Liu[8], Chunming Li[9], Yue Wu[9], Weihong Liu[9], Xiaofei Chen[8], Qing Zhu[9]. *[1]The Third Affiliated Hospital Sun YAT SEN University, Guangzhou, China; [2]West China Hospital of Sichuan University, Chengdu, China; [3]Guangzhou Eighth People's Hospital, Guangzhou, China; [4]Public Health Clinical Center of Chengdu, Chengdu, China; [5]The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China; [6]The First People's Hospital of Yunnan Province, Kunming, China; [7]Sir Run Run Shaw Hospital, Hangzhou, China; [8]Brii Biosciences, Shanghai, China; [9]Brii Biosciences, Beijing, China*
Email: yiwen.Liu@briibio.com

Background and aims: BRII-179, a novel therapeutic vaccine comprised of PreS1, PreS2 and S hepatitis B virus (HBV) surface antigens that can induce functional HBV specific B-cell and T-cell immune responses is currently under evaluation in a randomized, double-blind, placebo-controlled phase 2a study in China. In the previous interim analyses, BRII-179 as an add-on therapy in patients with chronic hepatitis B (CHB) receiving Peginterferon alfa (PEG) and nucleos (t)ide reverse transcriptase inhibitors (NRTI) therapy improved HBsAg loss at end-of-treatment (EOT) (Primary end point, 26.3% vs. 19.3% in full analysis set [FAS]) and the numerical difference maintained through 24-week post EOT. Besides, HBsAb ≥10 IU/L was strongly associated with sustained HBsAg loss at 12 weeks and 24 weeks post EOT.

Method: 114 HBeAg and HBsAb negative virally suppressed CHB patients who have been treated with 24–28 doses of PEG and HBsAg levels reduced to ≥0.05 and <100 IU/ml were randomized 1:1 to BRII-179 or placebo every 3 weeks for 7 doses with PEG continued in both groups for another 24 weeks. Eligible patients with HBsAg <0.05 IU/ml for 2 consecutive visits at 12–24 weeks post EOT (Week 36 to 48) would be eligible to discontinue NRTI and be monitored for another 48 weeks. Safety and efficacy data as of the data cut-off date when all patients remain in study who discontinued NRTI and completed 24 weeks off-NRTI follow-up (36–48 weeks post EOT) were analysed and reported here.

Results: BRII-179 + PEG combination was generally safe and tolerated with adverse events (AEs) similar to those observed with PEG or BRII-179 as previously reported. The majority of AEs were Grade 1 or 2 in severity and the frequency of Grade 3 and above AEs were comparable between BRII-179 group and PEG alone group. BRII-179 + PEG group had higher percentage of patients discontinued NRTI by 24-week post EOT (FAS: 15/57, 26.3% vs. 9/57, 15.8%) and earlier NRTI discontinuation. No participant who discontinued NRTI required NRTI retreatment, 11 patients in BRII-179 + PEG group and 7 patients in placebo + PEG group remain HBsAg loss and were still in follow-up. Within the NRTI discontinuation group, a higher percentage of patients on BRII-179 had maximum post-baseline HBsAb ≥10 IU/L, ≥100 IU/L and ≥1000 IU/L. All but one patient experienced HBsAg rebound in the study had HBsAb <10 IU/L at EOT suggesting that strong treatment induced antibody responses are necessary to sustain the HBsAg loss.

Conclusion: The investigational BRII-179 and PEG combination treatment was generally safe and tolerated. The BRII-179 add-on induced functional immune responses, which improved HBsAg loss and NRTI discontinuation, demonstrating potential to improve CHB functional cure.

Email: emily.harrison@precisionbiosciences.com

Background and aims: ARCUS nucleases are single-component gene editors that can be engineered for optimal safety leveraging the unique 3′ DNA overhangs generated by ARCUS cuts. Systemically-administered ARCUS nucleases recently received approvals to initiate clinical trials for Ornithine Transcarbamylase (OTC) deficiency in neonatal patients. PBGENE-HBV is composed of an mRNA that encodes an ARCUS nuclease formulated in a clinically-utilized lipid nanoparticle (LNP) formulation. Preclinical efficacy models have shown that ARCUS nucleases have potential as a finite curative regimen for chronic hepatitis B due to their ability to eliminate covalently closed circular DNA and inactivate integrated HBV DNA resulting in durable reductions of HBV DNA and HBsAg. Given the potential for functional cure with this mechanism of action, preclinical safety of PBGENE-HBV was evaluated through a comprehensive specificity assessment and preclinical program to support advancement to clinical trials.
Method: The potential for PBGENE-HBV to create double strand breaks at unintended off-target sites in the human genome was assessed through a tiered approach. Potential off-target sites were identified orthogonally using genome-wide *in silico*, cellular, and biochemical assays and quantified using deep sequencing in HBV-infected primary human hepatocytes (PHH). Potential genomic rearrangements in untreated and ARCUS-treated PHH infected with HBV were evaluated using hybrid capture followed by long-read sequencing. The tolerability and pharmacokinetics of LNP-delivered ARCUS nucleases were tested at multiple dose-levels and after multiple administrations in non-human primates (NHPs).
Results: No off-target editing or editing-associated translocations were observed in HBV-infected PHH after treatment with PBGENE-HBV at therapeutically relevant doses. LNP-delivered ARCUS nucleases were well tolerated by NHPs and produced minor and transient elevations in liver transaminases typically associated with LNPs. Transaminase elevations normalized within 2 weeks after each dose administration and did not increase in magnitude after subsequent administrations. Components of the drug product, novel lipids and ARCUS mRNA, showed rapid clearance after administration without evidence of altered pharmacokinetics after multiple administrations.
Conclusion: ARCUS is a single-component gene editor that has been engineered to specifically cut HBV DNA leading to elimination of cccDNA and inactivation of integrated HBV DNA without impacting any sites in the human genome. LNP delivery of ARCUS mRNA was well tolerated in nonhuman primates over multiple administrations. Robust preclinical safety data supports the advancement of PBGENE-HBV to clinical trials as a potential curative, finite treatment for HBV.

LBP-023

Targeting RuvBL1 hampers NASH-HCC progression by tipping the scale from mTOR-driven lipogenesis to AMPK-induced lipolysis

Alice Guida[1], Irene Simeone[1], Dimitri Papini[1], Alice Giovannini[1], Simone Polvani[1], Gabriele Dragoni[1], Lucia Picariello[1], Andrea Galli[1], Tommaso Mello[1]. [1]*Department of Clinical and Experimental Biomedical Sciences "Mario Serio," University of Florence, Florence, Italy*
Email: tommaso.mello@unifi.it

Background and aims: RuvBL1 belongs to the highly conserved AAA + ATPases. It is deregulated in various human cancers and its expression correlates with a worse prognosis in HCC patients. We previously found that RuvBL1 haploinsufficiency impairs the PI3 K/Akt/mTOR pathway in liver.
Given the relevance of mTOR pathway hyperactivation in HCC, we hypothesized that RuvBL1 genetic targeting could reduce mTOR-driven hepatocarcinogenesis.
Method: Pten$^{hep-/-}$ and Ruvbl1$^{hep\pm}$ mice were crossed to generate Pten$^{hep-/-}$Ruvbl1$^{hep\pm}$ mice. NASH was assessed by histology at 12 weeks of age. Metabolic and inflammatory markers were evaluated by qPCR and IHC. mTOR pathway was analysed by WB of liver lysates. RuvBL1 interactome was evaluated by MS proteomics of RuvBL1-IP. HCC development was assessed by macroscopic tumour count and by histology. AML-12 PTEN KO cells were generated by CRISPR-Cas9 genome editing. TFEB nuclear translocation was evaluated by immunofluorescence. PPARalpha activity was evaluated by luciferase reporter assay. The publicly available dataset LIHC_TCGA was explored to investigate in *in vivo* and *in vitro* pre-clinical models for human HCC.
Results: Pten$^{hep-/-}$Ruvbl1$^{hep\pm}$ developed significantly less steatosis, fibrosis, and inflammation compared to Pten$^{hep-/-}$ mice at 12 weeks of age. Pten$^{hep-/-}$Ruvbl1$^{hep\pm}$mice aged to 15 months showed better survival than Pten$^{hep-/-}$ which developed significantly more HCC and of higher grade. The mTOR-driven lipogenic targets were similarly expressed in the two mice models. However, *Ppara* and its target CPT1 was increased in Pten$^{hep-/-}$Ruvbl1$^{hep\pm}$. The spontaneous and insulin-induced accumulation of lipid droplets in PTEN KO AML-12 cells was completely abrogated by RuvBL1 inhibition with CB-6644. Analysis of RuvBL1-IP in AML-12 revealed that RuvBL1 interacts with members of the lysosomal AMPK complex. Furthermore, p-AMPK and p-RAPTOR were increased in Pten$^{hep-/-}$Ruvbl1$^{hep\pm}$ compared to Pten$^{hep-/-}$mice. Inhibition of RuvBL1 activity by CB-6644 increased TFEB nuclear translocation and PPARalpha transcriptional activity in AML-12 WT and PTEN KO. TCGA pathway analysis highlights a significant correlation between RUVBL1 expression and hyperactivation of the PI3K-mTOR pathway, clearly portraited by the inverse correlation between RUVBL1 and PTEN. Accordingly, RUVBL1 positively correlates with PPARG and negatively correlates with PPARα, PGC1α, their direct targets CPT1A and several Acyl-CoA-dehydrogenases. Intriguingly, RUVBL1 shows either strong positive or negative correlation with different subunits of the AMPK complex.
Conclusion: RuvBL1 targeting reduces mTOR hyperactivation hampering NASH-HCC progression in Pten$^{hep-/-}$ mice, likely promoting the switch from mTOR-driven lipogenesis to AMPK-induced fatty acid catabolism.

LBP-024

Performance of AASLD, AGA, AACE guidelines to identify patients for resmetirom treatment: pooled dataset including more than 4, 000 patients with liver biopsy

Stephen A. Harrison[1], Julie Dubourg[2], Sophie Jeannin Megnien[2], Larissa Goli[3], Mazen Noureddin[4], Naim Alkhouri[5], Jörn M. Schattenberg[6], Vlad Ratziu[7]. [1]*Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom;* [2]*Summit Clinical Research, San Antonio, United States;* [3]*Summit Clinical Research, San Antontio, United States;* [4]*Houston Medical Research, Houston, United States;* [5]*Arizona Liver Health, Chandler, United States;* [6]*Saarland University Medical Center, Homburg, Germany;* [7]*CH Pitié-Salpêtrière, Paris, France*
Email: jdubourg@summitclinicalresearch.com

Background and aims: Resmetirom, a THR-β agonist, is the first and only treatment approved for metabolic dysfunction-associated steatohepatitis (MASH) as of March 2024. Resmetirom label indicates to treat patients with MASH and moderate to advanced fibrosis consistent with F2/F3. There is no requirement for liver biopsy. We aimed to describe the accuracy of AASLD, AGA and AACE guidelines and of non-invasive biomarkers to identify patients for resmetirom treatment.

Method: We combined screening data from 10 industry-funded MASH phase 2 trials. The target population for resmetirom treatment was defined as patients with MASH (at least 1 point in each component) and moderate (F2) to advanced (F3) fibrosis. We described the proportion of patients meeting those criteria according to existing guideline thresholds. We also explored additional biomarkers to further identify patients for resmetirom treatment.
Results: 4, 025 patients with centrally assessed liver biopsy were included in this analysis. Among them, 1, 490 (37%) met the criteria for resmetirom treatment, 441 (11%) had cirrhosis, 1, 787 (44%) had F0-F1, and 307 (8%) had F2-F3 without MASH. Among the patients considered as low risk who would not have an indication for resmetirom treatment according to existing guidelines, 31% met the criteria for resmetirom treatment, 4% had cirrhosis, 58% had F0-F1, and 7% had F2-F3 without MASH. Among the patients considered as intermediate or high risk who would have an indication for resmetirom treatment according to guidelines, 46% met the criteria for resmetirom treatment, 20% had cirrhosis, 27% had F0-F1, and 7% had F2-F3 without MASH. Among the group of patients with AST ≥40 (if HbA1c <6.5%) or AST ≥30 (if HbA1c ≥6.5%), 53% met the criteria for resmetirom treatment, 13% had cirrhosis, 28% had F0-F1, and 6% had F2-F3 without MASH. In the patients who do not meet these AST/HbA1c thresholds, 25% met the criteria for resmetirom treatment, 9% had cirrhosis, 58% had F0-F1, and 8% had F2-F3 without MASH. Among the group of patients with FAST ≥0.67 (if HbA1c <6.5%) or FAST ≥0.50 (if HbA1c ≥6.5%), 60% met the criteria for resmetirom treatment, 19% had cirrhosis, 17% had F0-F1, and 4% had F2-F3 without MASH.
Conclusion: The current guidelines support the appropriate selection of patients for resmetirom treatment. However, there is a significant proportion of patients requiring treatment that will not be identified and a non-negligeable proportion of patients who do not require treatment that will be treated. Alternative simple biomarkers increase accurate selection of patients. This highlights the need for a refined approach to identify patients for resmetirom treatment using combinations of NITs and their correlation to outcomes.

LBP-025

Shortened telomeres impact liver regeneration in mice

Michael Hu[1], Mark Tigue[1], Melissa Rowe[1], Yehuda Tzfati[2], Klaus Kaestner[1]. [1]*University of Pennsylvania, Philadelphia, United States;* [2]*The Hebrew University of Jerusalem, Jerusalem, Israel*
Email: kaestner@pennmedicine.upenn.edu

Background and aims: Telomeres, or the ends of linear chromosomes, consist of a short repeat sequence (TTAGGG in humans and mice) which is complexed with shelterin proteins that protect chromosome ends and are thus critical for maintaining genomic integrity. The *Mus musculus* strain C57BL/6 is the most widely used inbred strain of laboratory mouse to model human disease. The C57BL/6 mouse has telomeres about 5 times longer than those present in humans. We recently engineered the C57BL/6 "telomouse" with human-length telomeres by introducing into *Mus musculus* a single amino acid variation in the helicase 'Regulator of telomere elongation 1′ (*Rtel1*), enabling the study of human length telomeres in proliferation during short-term liver regeneration. In a partial hepatectomy (PHx) experiment, where two-thirds of the liver is surgically resected, strikingly, the remaining lobes of the liver grow to compensate for the excised liver mass within one-week post-surgery. Here, we employed our unique telomouse model to study the effects of shortened telomeres on short-term liver regeneration.
Method: 70% PHx surgical procedures were performed on telomice and age-matched wild-type C57BL/6 control mice. At 36 hours post-PHx, mice were intraperitoneally injected with 5-chloro-2′-deoxyuridine (CldU) with a dose of 100 mg/kg of weight. At 46 hours post-PHx, mice were intraperitoneally injected with 5-iodo-2′-deoxyuridine (IdU) with a dose of 100 mg/kg of weight. CldU and IdU are both thymidine analogs that incorporate into nuclear DNA during cells' S-phase. Staggering CldU and IdU injections allowed us to observe the different timings of proliferation for particular cell types. At the 48-hour end point the remaining liver was perfused and processed for histology. Immunofluorescence staining visualized CldU, IdU, and DAPI (nuclear stain). Other markers such as CK19 (cholangiocyte marker) and HNF4alpha (hepatocyte marker) were used to differentiate cholangiocytes and hepatocytes.
Results: By using CK19/CldU labeling, we found that *Rtel1* mutant mice display decreased cholangiocyte proliferation at the 36 hours time point compared to the wild type control. By using CK19/IdU labeling, we found that the cholangiocyte proliferation rate of *Rtel1* mutant mice further decreased at the 46 hours time point. In contrast, wild type control mice display increased proliferation at the 46 hours time point compared to the 36 hours time point. We did not observe significant hepatocyte proliferation in either *Rtel1* or control mice at the 36 hours time point. However, at the 46 hours time point, analysis of the HNF4alpha/IdU staining results showed that *Rtel1* mutant mice also exhibit reduced proliferative capacity compared to the wildtype control.
Conclusion: Our results suggest that human-length telomeres limit the proliferative capacity of cholangiocytes and hepatocytes in short-term liver regeneration in mice.

LBP-026

The global prospective observational study to evaluate the role of 'liver transplantation in patients with cirrhosis and severe acute-on-chronic liver failure (CHANCE)': study design, demographics and overall outcome

Email: rajiv.jalan@efclif.com

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by increasing risk of short-term mortality with number of organ failures. Liver transplantation (LT) improves the survival of these patients. However, the current worldwide organ allocation systems are principally based on the model for end-stage liver disease (MELD) scores or its variations, which underestimate death of ACLF patients. The aim of the global CHANCE study sponsored by EF CLIF and supported by ILTS and ELITA was to characterize, in the current allocation systems, the clinical outcomes of patients with ACLF 2,3 undergoing LT. This interim study describes the study design, demographics and overall outcomes.

Method: 66 LT centers from 21 countries recruited patients to this prospective observational study, (12 Asia [AS], 35 Europe [EU], 8 Latin America [LA], 11 North America [NA]). 549 investigators were involved and managed by 16 regional coordinators. Patients were recruited from July 2021 to October 2023. ACLF was defined by the EASL-CLIF-C criteria. The intention-to-treat survival of patients from the Group 1 (patients with ACLF 2,3 listed for LT), the Group 2 (patients with ACLF 0,1 listed for LT) and the Group 3 (patients with ACLF 2,3 referred to the waitlist evaluation but not listed) were assessed.

Results: Data from 823 patients (80% of the overall study cohort) is reported here: 92 patients were recruited from AS, 354 from EU, 188 from LA and 189 from NA; 376 patients were in Group 1, 313 in Group

2, and 134 in Group 3. LA patients were older than patients from other regions [57 (46, 64)] and higher proportion of male was observed in AS (83%). The main etiology of cirrhosis was related to alcohol in all continents but less frequently in LA (50-67% vs. 33%, p<0.001). Centers from NA included patients with higher MELD [34 (30-40)] compared to those from other regions. Centers from EU and NA recruited more ACLF 3 patients compared to those from AS and LA (33% and 39% vs. 16% and 26% respectively, p<0.001). In an intention-to-transplant analysis, less patients of the Group 1 were alive the 3-month post-LT time point compared to those of the Group 2 (66% vs. 78%, p<0.001). Only 15% of Group 3 patients survived.
Conclusion: The interim results of the CHANCE study reveal significant differences in the characteristics of ACLF patients listed for LT. In those that were not transplanted, mortality exceeded 85%. Patients with ACLF 2,3 have a lower probability of accessing LT and being alive at 3-months than patients with ACLF 0,1, providing the rationale for expedited LT for these patients.

LBP-027
Combined effect of obeticholic acid and bezafibrate in patients with primary biliary cholangitis and inadequate response or intolerance to ursodeoxycholic acid: 6-month results from a phase 2 trial

David E. Jones[1], Alexandre Louvet[2], Christophe Corpechot[3], Vaclav Hejda[4], Heng Zou[5], Antonio Civitarese[5], Alejandra Villamil[6], Frederik Nevens[7]. Email: david.jones@newcastle.ac.uk

Background and aims: Obeticholic acid (OCA) and bezafibrate (BZF) have each improved serum biomarkers of primary biliary cholangitis (PBC)-related liver damage. We assessed the effects of combination OCA + BZF vs placebo + BZF on serum biomarker levels and safety/tolerability. A range of doses and formulations was explored in patients (pts) with PBC who had inadequate response or intolerance to ursodeoxycholic acid.
Method: This randomized, double-blind (DB), active-controlled, phase 2 trial randomized pts 1:1:1:1 to once-daily oral BZF 200 mg (B200) immediate release (IR), BZF 400 mg (B400) sustained release (SR), OCA 5 mg titrated to 10 mg at week 4 + BZF 200 mg IR (OCA/B200 IR), or OCA 5 mg titrated to 10 mg at week 4 + BZF 400 mg SR (OCA/B400 SR) during a 12-week DB treatment period. After a DB follow-up period, pts then received once daily OCA/B400 SR in a 96-week open-label long-term safety extension (LTSE). Here, we present data from month 6 (12-week DB treatment period +12 weeks of LTSE). Percentage change from baseline and normalization rate of alkaline phosphatase (ALP; ≤upper limit of normal [ULN]) and total bilirubin (TB; ≤0.6 × ULN) were assessed. Biochemical remission was defined as normalization (≤ULN) or ≥40% reduction in ALP; gamma-glutamyl transferase, alanine aminotransferase, and aspartate aminotransferase ≤ULN; and TB ≤0.6 × ULN. GLOBE and UK-PBC scores estimated the risk of death and liver transplantation and were compared at baseline and month 6. Safety was assessed by treatment-emergent adverse events (TEAEs). Metabolic safety outcomes, including percentage change in total and low-density lipoprotein (LDL) cholesterol, were also assessed.
Results: The DB treatment period included 75 pts; 66 pts continued to the LTSE. At month 6, OCA/B400 SR demonstrated a 65.3% reduction in ALP and 27.6% reduction in TB; 61.1% of pts in this cohort achieved ALP ≤ULN and 83.3% achieved TB ≤0.6 × ULN. OCA/B400 SR induced biochemical remission in 66.7% of pts, and 77.8% of pts experienced ≥40% reduction in ALP from baseline. Compared with the other cohorts, OCA/B400 SR induced the greatest change in GLOBE (−0.7) and UK-PBC (−1.1) scores. TEAEs were generally balanced across cohorts. In the OCA/B400 SR cohort, 1 pt discontinued due to a serious TEAE of pruritus. The rate of new events of pruritus with OCA/B400 SR was low (11.1%) at month 6. OCA/B400 SR also demonstrated the greatest percentage reductions in total cholesterol (19.6%) and LDL cholesterol (18.7%).
Conclusion: These results suggest that OCA + BZF is generally well tolerated and has therapeutic potential to normalize multiple serum biomarkers associated with improved transplant-free and decompensation-free survival. Low rates of pruritus were observed with OCA/B400 SR, which were substantially lower than those with OCA in the phase 3 POISE study (56%–68%). The data support phase 3 development of the SR formulation of BZF with low doses of OCA.

Email: andreas.kremer@usz.ch

Background and aims: Primary biliary cholangitis (PBC) is a rare autoimmune cholestatic liver disease, in which pruritus is a commonly reported symptom that negatively impacts quality of life (QoL). In the phase III ELATIVE® trial, elafibranor, a dual peroxisome proliferator-activated receptor (PPAR)-alpha/delta agonist, significantly improved prognostic biomarkers of cholestasis in PBC. Here, the effect of elafibranor on the patient (pt)-reported pruritus measures 5-D Itch and PBC-40 Itch is reported.
Method: The 5-D Itch and PBC-40 questionnaires were recorded at each study visit in ELATIVE® (NCT04526665), in which pts with PBC were randomised to elafibranor 80 mg or placebo. 5-D Itch has 5 domains, with scores for each ranging from 1 to 5, for a total of 5 (no pruritus) to 25 (most severe). PBC-40 has 6 domains, including a PBC-40 Itch domain consisting of 3 questions for a maximum score of 15 (most severe). Change from baseline (BL) to Week (Wk) 52 in 5-D Itch and PBC-40 Itch in pts with moderate-to-severe pruritus (BL PBC Worst Itch Numeric Rating Scale [PBC WI-NRS] ≥4/10) is reported. Analyses of total scores used a mixed model for repeated measures with treatment, visits until Wk 52 and treatment by visit interaction as fixed factors, and adjusted for BL scores and stratification factors; p values are nominal. Shifts in responses from BL to Wk 52 to specific individual 5-D Itch domains/questions and PBC-40 Itch questions were analysed post hoc and are descriptively presented.
Results: Of 161 randomised pts, 66 (41%) had moderate-to-severe pruritus at BL (elafibranor: 44; placebo: 22). Pts receiving elafibranor had greater reductions at Wk 52 in 5-D Itch total score vs placebo (LS mean difference [95% CI]: −3.0 [−5.5, −0.5]; p = 0.0199). For the Duration domain, 14/24 (58%) pts receiving elafibranor had itching duration reduced from ≥6 hours/day to <6 hours/day from BL to Wk 52 vs 3/11 (27%) pts receiving placebo. In response to the sleep question of the Disability domain, 20/25 (80%) pts receiving elafibranor with at least frequently delayed sleep (score ≥3) improved to occasionally delayed sleep or no disturbance (score <3) from BL to Wk 52 vs 3/10 (30%) pts receiving placebo.

Pts receiving elafibranor had greater, clinically meaningful, [1, 2] reductions at Wk 52 in PBC-40 Itch total score vs placebo (LS mean difference [95% CI]: −2.3 [−4.0, −0.7]; p = 0.0070). Similar reductions to those observed in 5-D Itch domains from BL to Wk 52 were seen in mean scores for the individual PBC-40 Itch questions with elafibranor vs placebo.

Conclusion: In pts with PBC, elafibranor resulted in improvements in 5-D Itch and PBC-40 Itch, emphasising its potential to reduce both the severity of pruritus and impact on QoL, and address an important unmet need.

Email: pietro.lampertico@unimi.it

Background and aims: Bulevirtide (BLV) is a first-in-class entry inhibitor approved in Europe for chronic hepatitis delta (CHD). In a Phase 3 study over 96 weeks (wk), BLV 2 mg or 10 mg monotherapy was effective and safe. Here, we present week (W) 144 results.

Method: 150 patients (pts) with CHD were randomised: Arm A (delayed treatment): observed for 48 wk followed by BLV 10 mg/d for 96 wk (n = 51); Arm B: BLV 2 mg/d for 144 wk (n = 49); Arm C: BLV 10 mg/d for 144 wk (n = 50). All pts will be followed for 96 wk posttreatment. W144 efficacy end points included virologic response (VR; undetectable HDV RNA or ≥2 log decline from baseline [BL]), alanine aminotransferase (ALT) normalisation, combined response (CR; VR and ALT normalisation), and undetectable HDV RNA (target not detected). Univariate logistic regression was used to discern if any BL characteristics predicted undetectable HDV RNA at W144 for pts in Arms B/C who completed W144 and had BL HDV RNA ≥250 IU/ml. Predictors with p value <.05 were considered significant.

Results: BL characteristics were previously published. At W144, 96% (49/51), 91.8% (45/49), and 88% (44/50) in Arms A, B, and C remained in study. Arms B and C had similar rates of CR, VR, and ALT normalisation; rates increased through W96 and were maintained through W144. At W144, 57%, 73%, 59% (Arm B) and 54%, 76%, 60% (Arm C) of pts achieved CR, VR, and ALT normalization. Undetectable HDV RNA rates continually increased with BLV treatment and were 29% in Arm B and 50% in Arm C at W144. Time to first reaching undetectable HDV RNA (mean wk [SD]) was faster in Arm C (69.3 [41.2]) vs Arm B (77.3 [44.5]). BL predictors of W144 undetectable HDV RNA were lower HDV RNA $\log_{10}$ IU/ml (BLV 2 mg: OR 2.9, p = .0145; BLV 10 mg: OR 2.1, p = .0258) and lower hepatitis B surface antigen (HBsAg) $\log_{10}$ IU/ml (BLV 2 mg: OR 5.1, p = .0319; BLV 10 mg: OR 6.0, p = .0390). W144 HBsAg (mean change from BL $\log_{10}$ IU/ml [SD]) was −0.36 (0.596) and −0.19 (0.39) with BLV 2 mg and BLV 10 mg. At W144 in Arm A (96 wk of BLV), rates of CR, VR, ALT normalisation, and undetectable HDV RNA were 56%, 92%, 58%, and 52%. There was no progression to liver-related outcomes over 144 wk except for 1 case of mild ascites in Arm A (pt with BL cirrhosis). Platelet count and liver chemistries remained stable/improved including in pts with cirrhosis. Through 144 wks of BLV therapy, there were no drug discontinuations, serious adverse events, or deaths attributed to BLV; the safety profile was similar for BLV 2 mg and 10 mg doses. Dose-dependent increases in bile acids remained asymptomatic.

Conclusion: Long-term therapy with BLV therapy over W144 remains safe and effective. Improvements in biochemical, fibrosis and virologic markers including increased rates of undetectable HDV RNA, as well as low occurrence of liver-related events are supportive of the potential clinical benefits of long-term BLV therapy.

LBP-030

Use of tocilizumab for the treatment of steroid and mycophenolate-refractory hepatitis and cholangiohepatitis induced by immune checkpoint inhibitor immunotherapy

Sophia Ling[1], Bishma Jayathilaka[1], Chee Hui[1], Jonathan Segal[1], Andrew Trinh[1]. *[1]Peter MacCallum Cancer Centre, Parkville, Australia*
Email: liyiing@gmail.comEmail:

Background and aims: The use of immune checkpoint inhibitor (ICI) therapies to engage the immune system against a growing number of tumour types has seen a rise in unwanted immune-mediated hepatitis (IMH) and cholangiohepatitis (IMCH). The optimal strategy for complete resolution without need for ongoing immunosuppression is still being refined. Tocilizumab, an IL-6 receptor antagonist, is emerging as a safe and effective agent beyond steroids and mycophenolate. We aim to describe our experience with patients who received tocilizumab as third-line treatment for IMH/IMCH, and discuss its use in both acute and protracted episodes.

Method: Patients with IMH/IMCH who were given at least one dose of tocilizumab 8 mg/kg i.v. after an unsatisfactory response to steroids and mycophenolate were assessed. Clinical trajectory, imaging results, liver biopsies when available, outcomes and liver enzymes across each episode were analysed.

Results: Eight patients (6 IMH, 2 IMCH) received ICIs for advanced cancer (melanoma, mucosal melanoma, non-small cell lung, cervical adenoma and prostate). All patients reached at least grade 3 IMH/IMCH during their clinical course (ALT>. Four patients (including one with acute IMCH) had normalization of liver enzymes by mean 85.5 days of a single tocilizumab dose. Two patients improved after a single dose, but died before normalization of liver enzymes: one (who also had third line tacrolimus before tocilizumab) with progression of cervical adenomcarcinoma 76 days after tocilizumab; another of neutropaenic sepsis secondary to peptide receptor radionucleotide therapy for prostate cancer, 26 days after tocilizumab. The seventh patient with protracted IMCH proceeded to a

second dose of tocilizumab 8 mg/kg at 12 weeks after a liver biopsy confirmed persisting mild IMCH. The final patient with protracted IMH for 1088 days demonstrated only marginal improvement after four doses of tociliuzumab, which was ceased. There were no cases of tocilizumab toxicity.

Conclusion: Tocilizumab can be a safe and effective third-line agent in a group of patients in whom prompt resolution of adverse events improves quality of life and allows for ongoing cancer treatment. Current guidelines lack a clear alternative for IMH when steroids and mycophenolate are inadequate, nor treatment strategies upfront for IMCH, where response to steroids and mycophenolate is known to be poor. This study highlights an important need for high-quality data addressing the safety and efficacy of tocilizumab in such patients.

Email: javier.armisengarrido@astrazeneca.com

Background and aims: A common genetic variant (rs738409) encoding isoleucine (I) to methionine (M) at position 148 in the PNPLA3 protein is a key genetic determinant of hepatic steatosis, inflammation, fibrosis, cirrhosis and liver-related mortality. AZD2693 is a potent GalNAc-conjugated PNPLA3-targeted, antisense oligonucleotide (ASO) designed to specifically silence liver *PNPLA3* mRNA and subsequent protein expression. This phase 1 program evaluated the safety, tolerability, pharmacokinetic and pharmacodynamic effects of AZD2693.

Method: The single ascending dose (SAD) study was a single-blind, placebo-controlled study to evaluate 5–110 mg in obese but otherwise healthy volunteers. The multiple ascending doses (MAD) study was a double-blind, placebo-controlled study to evaluate three monthly doses of 25 mg, 50 mg, and 80 mg in participants with MRI-PDFF >8%. The MAD study included MRI-PDFF assessment of liver fat content (LFC) at baseline and after 8 and 12 weeks. The 80 mg MAD cohort included liver biopsy at baseline and one week after third dose for target engagement of *PNPLA3* mRNA knock-down.

Results: A total of 73 participants were randomized in the SAD study and 74 in the MAD study. There were no deaths or AEs leading to discontinuation in either study. AZD2693 displayed a typical ASO PK profile with rapid absorption and distribution followed by a slower terminal phase and a half-life ranging from 14 to 22 days across investigated doses. Baseline MRI-PDFF mean values were 16.5%, 15.5%, 18.6% for 25 mg (n = 15), 50 mg (n = 16), and placebo (n = 12) groups, respectively. Week 12 reduction in LFC of 11% and 15% (placebo-corrected LS means) was observed for the 25 mg and 50 mg MAD study cohorts, respectively. The mean knockdown of liver *PNPLA3* mRNA after 80 mg treatment was 87% (n = 4, $p < 0.0001$). There was a dose-dependent increase of polyunsaturated fatty acids (PUFA) in serum triglycerides (50 mg, $p < 0.01$), as well as a numerical reduction in hs-CRP levels.

Conclusion: AZD2693 treatment induced a potent reduction of liver *PNPLA3* mRNA with a safety, tolerability and PK profile consistent with that of other ASOs. Therapeutic knock-down of PNPLA3 is impacting proposed mechanistic drivers in homozygous PNPLA3 148MM risk allele patients. These data support the continued development of AZD2693 in the FORTUNA Ph2b study.

Email: sebastian.meyhoefer@uni-luebeck.de

Background and aims: Cardiovascular (CV) risk is increased in people living with metabolic dysfunction-associated steatohepatitis (MASH). Although liver biopsy remains the gold standard to diagnose MASH, it is not practical to implement on a large scale. However, non-invasive tests, such as the Fibrosis-4 score (FIB-4), are useful for staging patients with fibrotic MASH and predict overall, CV- and liver-related mortality. In the SELECT CV outcome trial, which included patients with a body mass index ≥27.0 kg/m^2 and established CV disease but without diabetes, those treated with the glucagon-like peptide-1 receptor agonist semaglutide had a 20% CV risk reduction compared with those receiving placebo. We examined the CV benefits of semaglutide in a subgroup of participants at high risk of MASH as defined by FIB-4.

Method: SELECT was a multicentre, randomised, double-blind, placebo-controlled, event-driven trial that enrolled 17, 604 patients aged ≥45 years. Patients were randomly assigned in a 1:1 ratio to receive once-weekly subcutaneous semaglutide 2.4 mg or placebo in

addition to standard of care recommendations for CV disease prevention. This subgroup analysis for the primary composite end point of 3-point major adverse cardiovascular event (MACE; non-fatal myocardial infarction, non-fatal stroke, CV death) was performed for patients with increased MASH risk as indicated by FIB-4 ≥1.3 for patients aged <65 years and FIB-4 ≥2.0 for patients aged ≥65 years, and for a second subgroup of patients of any age with FIB-4 >2.67, respectively. As identified by review of medical history and co-medication, patients with a cause of liver disease other than MASH were not included in this analysis.
Results: From the SELECT cohort, 3, 665 patients (20.8% of all) aged <65 years with FIB-4 ≥1.3 and aged ≥65 years with FIB-4 ≥2.0 were included in this analysis. The primary CV end point occurred in 140 of the 1, 834 patients (7.6%) in the semaglutide group and in 176 of the 1, 831 patients (9.6%) in the placebo group (hazard ratio [HR] 0.79; 95% confidence interval [CI] 0.63, 0.98; $p < 0.03$). In the subgroup of 475 patients with suspected MASH and advanced fibrosis (FIB-4 >2.67 irrespective of age), there were 22 CV events in 235 patients treated with semaglutide 2.4 mg compared with 35 events in 240 placebo-treated patients, yielding an HR of 0.64 (95% CI 0.37, 1.08; $p = 0.10$).
Conclusion: In line with the primary analysis of the SELECT trial, use of semaglutide 2.4 mg in a subgroup of patients at high risk of fibrotic MASH as defined by FIB-4 produced a 21% reduction in MACE outcomes.

LBP-033
Metabolic flux analysis using a 14C microtracer approach combined with accelerator mass spectrometry analysis-a proof of concept study on de novo lipogenesis

Martine C. Morrison[1], Lianne Stevens[1], Robert Kleemann[1], Elwin Verheij[1], Wouter Vaes[1]. [1]*The Netherlands Organisation for Applied Scientific Research (TNO), Department of Metabolic Health Research, Leiden, Netherlands*
Email: martine.morrison@tno.nl

Background and aims: Metabolic flux measurements play an important role in advancing our understanding of (patho)physiology, disease mechanisms and the development of new therapeutics. By incorporating stable or radioactive isotopes into specific molecules (tracers), the distribution and fate of the isotope can be followed-thereby providing insight into the movement and metabolic transformation of biomolecules. An isotope that is frequently used for such analyses is ^{13}C, which is analysed by isotope ratio mass spectrometry. The high natural abundance of ^{13}C (~1%) requires the use of large amounts of labelled substrates, especially in clinical studies. An alternative isotope is ^{14}C, which has an extremely low natural abundance (1 in 10^{12}). In combination with analysis by extremely sensitive accelerator mass spectrometry (AMS), this enables the detection of very small amounts of ^{14}C-labeled product/biomarker formed at very low (microtrace) amounts of labelled substrate administration. Here we provide proof of concept for this ^{14}C microtracer approach to assess activity of the de novo lipogenesis (DNL) pathway, an important metabolic pathway that is deregulated in various disease states, including metabolic dysfunction-associated steatotic liver disease (MASLD).
Method: De novo lipogenesis activity was assessed in Ldlr-/-.Leiden MASLD mice fed a standard chow or a MASH-inducing high-fat diet (HFD) with/without the DNL inhibitor firsocostat (ACCi), as well as in an ex vivo porcine liver perfusion model. Incorporation of ^{14}C from ^{14}C-acetate into total lipid extracts (from plasma and liver samples), bile, fatty acids and cholesterol was assessed by LC/MS and AMS.
Results: Using this method, we show that DNL activity is significantly higher in HFD-fed Ldlr-/-.Leiden MASH mice than in chow-fed controls. This is demonstrated by increased incorporation of ^{14}C into total lipid extracts, which we confirmed to be DNL by demonstrating incorporation into fatty acids profiled by LC/MS. Treatment with the DNL inhibitor firsocostat significantly reduced DNL activity as expected. In the ex vivo liver perfusion model we similarly demonstrate that ^{14}C from acetate is incorporated into total lipids and fatty acids. In addition, we show in this model that this method can also be used for assessment of de novo synthesised cholesterol using the same labelling protocol.
Conclusion: We show here that this ^{14}C microtracer approach combined with AMS analysis can be used for assessment of metabolic fluxes in various experimental models at much lower amounts of tracer used than in conventional tracer methodologies. This allows study of metabolic pathways without disrupting the pathway of interest by adding large quantities of precursor and opens up opportunities to study the activity of other (metabolic) pathways in which only very small amounts of product are produced.

LBP-034
Evaluation of the PIKfyve kinase inhibitor Apilimod against hepatitis E virus infections

Julian Ring[1], Sarah Schlienkamp[2], Jil Haase[2], Xin Zhang[3], Johan Neyts[3], Suzanne J.F. Kaptein[3], Mara Klöhn[2], Daniel Todt[2,4], Yannick Brüggemann[2], Eike Steinmann[2,5]. [1]*Department of Molecular and Medical Virology, Ruhr University Bochum, Bochum, Germany, Bochum, Germany;* [2]*Department of Molecular and Medical Virology, Ruhr University Bochum, Bochum, Germany;* [3]*KU Leuven Department of Microbiology, Immunology and Transplantation, Rega Institute for Medical Research, Laboratory of Virology and Chemotherapy, Leuven, Belgium;* [4]*European Virus Bioinformatics Center (EVBC), Jena, Germany;* [5]*German Center for Infection Research (DZIF), External Partner Site, Bochum, Germany*
Email: Julian.Ring@ruhr-uni-bochum.de

Background and aims: Hepatitis E Virus (HEV) is the most common cause of viral hepatitis with over 20 million cases and up to 70, 000 deaths annually. Despite its high risks especially among immuno-suppressed patients and pregnant women, the treatment of HEV is limited to the off-label use of nucleoside-analogue ribavirin (RBV) and PEGylated interferon-α. Since both cause significant side effects and are contraindicated in selected patients, there is an urgent need to develop novel antiviral strategies against HEV. The phosphoinositide kinase PIKfyve plays a crucial role during various endocytotic processes by modulating endosome morphology, function and biogenesis. Inhibition of PIKfyve kinase activity has been shown to prevent the entry of different viruses, including Ebola virus and SARS-CoV-2. However, the role of PIKfyve during HEV infections still remains unclear. Here we investigated the antiviral potential of different PIKfyve inhibitors against HEV infections *in vitro* and *in vivo*.
Method: Using a robust HEV cell culture model, we investigated the dose-dependent effect of three PIKfyve kinase inhibitors. To identify which step of HEV life cycle is affected by PIKfyve inhibition, we performed time-of-addition as well as subgenomic replicon assays. The requirement of PIKfyve during the HEV live cycle was further validated via siRNA-mediated knockdown. In addition, we evaluated the antiviral effect of the PIKfyve kinase inhibitors in primary human hepatocytes (PHH) and in a chronic rat HEV infection model.
Results: All three tested PIKfyve kinase inhibitors, Apilimod, YM201636 and APY0201 lowered HEV infectivity at nanomolar efficacy in hepatoma cells. Consistent with this, siRNA-mediated knockdown of PIKfyve lowered the infectivity of HEV. Time-of-addition experiments showed that the PIKfyve inhibitors exert its antiviral effect during virus entry, without affecting viral replication, as observed in the replicon assay. In PHH, Apilimod exhibited a potent effect in reducing the HEV infectivity. Moreover, treatment with Apilimod (75 mg/kg/day, once-daily for 12 consecutive days) resulted in decreased viral RNA replication kinetics in the feces as compared to vehicle-treated rats. In addition, rats treated with Apilimod showed strong reductions in viral loads in the liver, spleen and intestine.
Conclusion: Overall, our data suggests that PIKfyve plays a crucial role during the viral entry of HEV. Considering the proven safety profile of Apilimod in previous human clinical trials (unrelated to viral conditions), the pharmacological targeting of PIKfyve kinase activity might guide novel antiviral strategies against HEV infections.

LBP-035

Luji-1 reduces fibrosis by blocking Neuroligin-4 and β-neurexin and overexpressing thyroid hormone receptor-b, suggesting Rezdiffra sensitization and synergism in combination

Johnny Amer[1], Ahmad Salhab[1], Baker Saffouri[1], Ashraf Imam[1], Abed Khalaileh[1], Rifaat Safadi[1]. [1]*Liver Institute- Hadassah Medical Hospital, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: The anti-fibrotic effect of Natural Killer (NK) cells against active hepatic stellate cells (HSCs) is impaired in advanced fibrosis. Following uncover of a novel immune inhibitory checkpoint, Luji-1 designed as dual antagonist peptide to HSCs ligand β-neurexin (βNRXN) and NK Neuroligin-4 receptor (NLGN4). Rezdiffra, a thyroid hormone receptor-β (THR-β) agonist, added 11% fibrosis improve in metabolic dysfunction-associated steatohepatitis (MASH). Here-in, THR-β modulation by Luji-1 assessed on addition to its anti-fibrotic effects.
Method: Luji-1, scrambled-peptide (both 8 μg/ml), L-Thyroxin (T4, 10 nM) and combinations were *in vitro* incubated 6 hours with LX2 [HSCs cell line] monocultures in 1% FCS [quiescent] and 10% [activated]. Similar incubations assessed in peripheral-blood NK cells from F1/F2 and F3/F4 MASH donors monocultured in 10% FCS. Luji-1 *vs* scrambled-peptide treated NK cells were then cocultured 6 hours with LX2. For the *in vivo* study, biweekly i.p CCl_4 (0.5 μl/g body weight) fibrosis model induced in C57/Bl mice for 6 weeks; and biweekly Luji-1 (8μg/mice) treatment provided along last 2 weeks.
Results: Using flow cytometry, active LX2 monocultured cells significantly overexpressed αSmooth Muscle Actin (αSMA) and βNRXN (suggesting pro-fibrotic features), but reduced THR-β expressions by 8.3-folds compared to quiescent state. Treated LX2 cells with Luji-1, T4 and combination significantly reduced αSMA expressions (61%, 31% and 85%, respectively). As Luji-1 induced 3.2-folds THR-β overexpression, the achieved synergism by combination was significant. Monocultured F3/F4 NK cells with scrambled-peptide were impaired (low CD107a); associated with 3.2-folds NLGN4 overexpress and 2.4-folds THR-β down express as compared to active F1/2 counterparts and quiescent healthy donors ($p < 0.05$). Luji-1 or T4 promoted F3/F4 NK cytotoxicity against activate HSCs and enhanced THR-β expressions. Both Luji-1 and T4 achieved a significant synergistic increase of NK cytotoxic effect. In the *in vivo* CCl_4 model, Luji-1 significantly activated NK cells (increased CD107a and F-actin expressions) and improved all markers of liver inflammation and fibrosis (serum liver enzymes, histology HandE and serious red stains, liver extracts for αSMA and Collagen). Luji-1 downregulated NLGN4 and βNRXN expressions while increased THR-β expressions in liver extracts.
Conclusion: Luji-1 improved liver injury via: (1) direct βNRXN inhibition in myofibroblasts and decreased their activation, (2) NK cells stimulation against myofibroblasts directly via NLGN4 inhibition in NK cells and indirectly by blocking the myofibroblast βNRXN that serves as NK inhibitor and (3) THR-β over expressions that sensitizes Rezdiffra in combination.

Email: arun.sanyal@vcuhealth.org

Background and aims: Fibrosis is the strongest predictor of clinical outcomes in metabolic dysfunction-associated steatohepatitis (MASH). The phase 3 REGENERATE study of the farnesoid X receptor agonist obeticholic acid (OCA) evaluated progression to clinical outcomes over 48 months, with an interim analysis of histologic improvement at month 18 (M18). At M18, OCA demonstrated a statistically significant antifibrotic benefit. REGENERATE was discontinued in September 2023 for failure to achieve marketing approval after a consensus re-analysis of the M18 data. Final end-of-study results are presented.
Method: In this multicenter, randomized, double-blind, placebo (PBO)-controlled study, patients (pts) with biopsy-confirmed fibrosis (F2-F3) were randomized 1:1:1 to PBO, OCA 10 mg, or OCA 25 mg. The primary end point was time to first occurrence of prespecified clinical outcomes, including progression to cirrhosis. Secondary end points included measures of histologic improvement and biochemical markers of liver function. Efficacy was assessed in the intent-to-treat population (n = 2187); safety was assessed in 2477 pts with a median of >4 years of exposure. An independent expert committee adjudicated all outcomes.
Results: Baseline demographics and clinical characteristics were balanced across treatment groups. Clinical outcomes occurred in 18.8%, 15.8%, and 14.7% of pts treated with PBO, OCA 10 mg, and OCA 25 mg, respectively. Compared to PBO, the hazard ratio was 0.814 for OCA 10 mg and 0.772 for OCA 25 mg, driven by fewer pts receiving OCA progressing to cirrhosis. More pts receiving OCA had fibrosis improvement ≥1 stage with no worsening of MASH compared to PBO ($p < 0.001$ for both dose groups). Improvement in fibrosis by ≥1 stage was achieved in 27.0%, 37.1%, and 39.3% of pts treated with PBO, OCA 10 mg, and OCA 25 mg, respectively; worsening of fibrosis by ≥1 stage occurred in 23.5%, 19.3%, and 18.5%, respectively. OCA treatment produced dose-dependent reductions in mean serum alanine aminotransferase, aspartate aminotransferase, and gamma glutamyl transferase levels to a greater extent than PBO. Treatment-emergent adverse events (TEAEs), serious TEAEs, and deaths were similar across groups. Consistent with the M18 analysis, pruritus and gallbladder- and gallstone-related TEAEs occurred more frequently with OCA 25 mg than with PBO or OCA 10 mg.
Conclusion: Our end-of-study analysis demonstrated a trend for benefit in clinical outcomes, and histological progression to cirrhosis was reduced in patients receiving OCA 25 mg. Fibrosis improvement ≥1 stage and reductions in biochemical markers of liver injury and oxidative stress were observed for OCA 10 mg, which may be relevant in the treatment of primary biliary cholangitis. The safety results add to the largest safety database in MASH, with a median OCA exposure of 52 months and no new safety concerns with >2 years of additional exposure.

LBP-037

Role of early on-treatment serum hepatitis B virus RNA declines in the prediction of hepatocellular carcinoma risk in patients with chronic hepatitis B

Email: doctorsunjian@qq.com

Background and aims: Hepatocellular carcinoma (HCC) risk prediction models established in patients with chronic hepatitis B (CHB) under nucleoside analogue (NA) treatment rarely included viral factors because of mediocre predictability of traditional viral markers. Here, we investigate the role of serum hepatitis B virus (HBV) RNA, a novel biomarker, in predicting HCC risk in NA-treated patients.
Method: A total of 1374 patients treated with entecavir or tenofovir disoproxil fumarate were enrolled from two prospective CHB cohorts. Serum HBV RNA levels were detected at baseline and year 1, 2 and 3 of treatment by a commercial automated quantitative serum HBV RNA assay (Rendu Biotechnology, Shanghai, China), with lower limit of detection of 50 copies/ml. Restricted cubic spline analyses and Cox proportional hazard models were used to investigate the association of serum HBV RNA kinetics and HCC risk.
Results: After a median follow-up of 5.4 years, 76 patients developed HCC. Restricted cubic spline analyses showed significant non-linear parabolic associations of serum HBV RNA levels at baseline and year 1 with HCC risk (all p for non-linear trend <0.050). Similar trend was observed between serum HBV RNA levels at year 2 and HCC risk with marginal statistical significance (p for non-linear trend = 0.114). Interestingly, early on-treatment serum HBV RNA declines (at year 1 and 2) showed independent linear associations with HCC risk (all p for linear trend <0.05). Patients with lower HBV RNA decline at year 1 (=<0.4 $\log_{10}$ copies/ml) or 2 (=<0.6 $\log_{10}$ copies/ml) had 2.22- and 2.09-folds higher HCC risk, respectively, than those with higher declines. When incorporating these early on-treatment HBV RNA declines into existing HCC risk scores, including PAGE B, mPAGE B and aMAP score, they could enhance their predictive performance [i.e. C-index of models based on baseline parameters, 0.814 vs. 0.788, Model (PAGE B + HBV RNA decline at year 1) vs. PAGE B score; 0.825 vs. 0.804, Model (mPAGE B + HBV RNA decline at year 1) vs. mPAGE B score; 0.825 vs. 0.811, Model (aMAP + HBV RNA decline at year 1) vs. aMAP score], which were internally validated by repeated K-fold cross-validation.
Conclusion: Serum HBV RNA declines at year 1 and 2 were significantly associated with on-treatment HCC risk. Incorporating early on-treatment HBV RNA declines into HCC risk prediction models can be useful tools to guide appropriate surveillance strategies in NA-treated patients.

LBP-038

Expanding knowledge regarding real-world treatment of patients with primary biliary cholangitis with obeticholic acid from the Italian RECAPITULATE cohort

Background and aims: Obeticholic acid (OCA) is the only conditionally approved second-line treatment in PBC patients non-responder/intolerant to ursodeoxycholic acid. After OCA approval, a number of studies provided confirmations of the drug's effectiveness and safety in a real-world context. The aim of this study is to expand knowledge on long-term treatment with OCA in the largest real-world cohort described to date and with the longest follow-up.
Method: The RECAPITULATE cohort includes all PBC adult patients on OCA therapy from Italian centres belonging to "Italian PBC registry" and "CLEO/AIGO" groups. Efficacy was evaluated according to POISE (ALP < 1.67/upper limit of normal (ULN) with a reduction of 15% from baseline and a normal total bilirubin) or "normal range" (NR) criteria (normal ALP, ALT, bilirubin). Cumulative incidences of OCA response and discontinuation were evaluated through Aalen-Johansen (taking into account the competing risk of discontinuation) and Kaplan-Meier estimators, respectively. Risk factors analysis was carried out using Cox proportional hazard models.
Results: After excluding those with less than 6 months follow-up, 759 individuals (median age 58 years, women 87%, median time on OCA 24 months -IQR 12–42 months-) from 66 Italian centres were analyzed. The cohort includes 221 cirrhotic patients (29%), 104 with PBC/autoimmune hepatitis (AIH) overlap (14%) and 105 on concomitant off-label fibrate therapy (14%). Out of the total number of patients prescribed OCA, the relative percentage of cirrhotics has halved over time (~40% of those prescribed OCA in 2017–2020 Vs ~20% of those prescribed in 2021–2023). According to POISE criteria, response probabilities were 40.6%/49%/55.6%/54.7% at 12/24/36/48 months. Discontinuation probabilities were 10%/15%/20%/26% at 12/24/36/48 months. Pruritus (49 patients, 35%) and hepatic events (43 patients, 31%) were the main causes of OCA discontinuation. When compared with non-cirrhotics, cirrhotic patients showed significantly lower response ($p = 0.02$ for POISE, $p = 0.003$ for NR) and higher discontinuation ($p < 0.001$) probabilities, while no differences were observed between PBC/AIH overlap and "pure" PBC in terms both of response ($p = 0.8$) and discontinuation ($p = 0.07$) probabilities. Pre-treatment ALP (HR 0.72, IC 0.64–0.81), total bilirubin (HR 0.23, IC 0.16–0.33), pruritus (HR 0.70, IC 0.55–0.88), and AMA positivity (HR 1.53, IC 1.10–2.14) were independent predictors of POISE response in the multivariate analysis.
Conclusion: These results, derived from a large real-world dataset, confirm that the efficacy and safety profiles of OCA in treating PBC remain consistent in the long term. Although cirrhotics are a challenging population to treat, their proportion is reducing over time, aligning with earlier PBC diagnosis and the decline in more severe cases accumulated prior to the drug's availability.

LBP-039

Oral alpha-v/beta-6 and alpha-v/beta-1 integrin inhibitor bexotegrast in primary sclerosing cholangitis: updated 12-week interim safety and efficacy analysis of the INTEGRIS-PSC phase 2a trial

Email: michael.trauner@meduniwien.ac.at

Background and aims: Primary sclerosing cholangitis (PSC) is characterized by biliary inflammation and progressive fibrosis. Two integrins, alpha-v/beta-6 on cholangiocytes and alpha-v/beta-1 on myofibroblasts, are regulators of transforming growth factor (TGF)-beta signalling, which drives fibrosis. Bexotegrast (BEXO), an oral, once-daily, dual-selective inhibitor of these integrins, is in development for the treatment of PSC. We report 12-week safety and efficacy results, focusing on BEXO 320 mg vs placebo (PBO), from the double-blind, dose-ranging, randomized, Phase 2a INTEGRIS-PSC study (NCT04480840).
Method: Participants with PSC were randomized to once-daily BEXO 320, 160, 80 or 40 mg or PBO for 12 weeks. Analyses of 40-, 80- and 160-mg doses were presented previously, and results of the 320 mg dose vs PBO presented herein. Key entry criteria were large-duct PSC, stable inflammatory bowel disease (if present), ursodeoxycholic acid <25 mg/kg/day (if used), alkaline phosphatase (ALP) ≤10x upper limit of normal and suspected liver fibrosis (without cirrhosis) as evidenced by ≥1 of the following: enhanced liver fibrosis (ELF) score ≥7.7,

transient elastography ≥8 to ≤14.4 kPa, magnetic resonance [MR] elastography ≥2.4 to ≤4.9 kPa or historical biopsy indicating fibrosis. The primary end point was safety and tolerability at Week 12. Secondary and exploratory end points included changes in ELF score, PRO-C3 and gadoxetate contrast-enhanced MR imaging (MRI).

Results: Of 121 participants in the study, 27 were randomized to BEXO 320 mg and 30 to PBO (pooled group). A total of 20 (74.1%) and 20 (66.7%) BEXO 320 mg- and PBO-treated participants, respectively, reported treatment-emergent adverse events (TEAEs); no BEXO 320 mg-related TEAEs or serious TEAEs were reported. TEAEs of pruritus and cholangitis were less frequent with BEXO 320 mg (7.4% and 0%, respectively) than with PBO (20.0% and 13.3%, respectively). At Week 12, mean (SD) [n] change from baseline in ELF score (BEXO 320 mg vs PBO) was 0.2 (0.6) [25] vs 0.4 (0.7) [28], PRO-C3 mean percent change (SD) [n] from baseline was 3.3% (24.6) [25] vs 12.4% (25.5) [28] and mean (SD) [n] change from baseline in time to arrival of gadoxetate in the common bile duct was −22.2 (196.0) [10] vs 86.5 (217.6) [15] seconds. In the subgroup with elevated ALP, mean (SD) [n] change from baseline was 1.5 (50.3) [20] U/L with BEXO 320 mg vs 49.7 (150.4) [21] U/L with PBO.

Conclusion: In this study population with PSC enriched for liver fibrosis, BEXO 320 mg was well tolerated and associated with prevention of worsening of biomarkers of fibrosis and hepatobiliary excretory bile flow (as suggested by MRI) compared with PBO over 12 weeks, consistent with findings with lower doses. This analysis supports proof of mechanism for targeting integrin-mediated TGF-beta activation as a therapeutic approach for PSC.

LBP-040

Long-term efficacy and safety of open-label seladelpar treatment in patients with primary biliary cholangitis (PBC): interim results for 2 years from the ASSURE study

Palak J. Trivedi[1], Cynthia Levy[2], Kris V. Kowdley[3], Stuart C. Gordon[4], Christopher L. Bowlus[5], María Carlota Londoño[6], Gideon M. Background and aims: Seladelpar, a potent and selective PPAR-delta agonist, has been shown to reduce biochemical markers of cholestasis and pruritus in PBC patients. ASSURE (NCT03301506) is an ongoing, open label, long-term phase 3 trial of seladelpar in patients rolling over from the phase 3 registrational study RESPONSE (NCT04620733) or with prior participation in legacy studies: phase 3 ENHANCE (NCT03602560) study; CB8025–21629 (NCT02955602); CB8025-31731 (NCT03301506); and CB8025-21838 (NCT04950764). Here, we report interim 2-year efficacy and safety results for 337 enrolled patients.

Method: Patients with insufficient response or intolerance to first line PBC treatment ursodeoxycholic acid and prior participation in a seladelpar clinical trial could enroll in ASSURE. Key end points were the composite biochemical response (alkaline phosphatase (ALP) <1.67x upper limit of normal (ULN), ALP decrease ≥15%, and total bilirubin ≤ULN) and ALP normalization. Pruritus was reported using a numerical rating scale (NRS; 0–10). Baseline for participants who entered ASSURE from RESPONSE was entry to RESPONSE, analyzed as continuous seladelpar or crossover from placebo. Legacy patients were analyzed separately with baseline set as the entry to ASSURE.

Results: As of 31 January 2024, 158 patients from RESPONSE and 179 patients from legacy studies had received 10 mg seladelpar, daily, for up to 155 weeks in ASSURE. In RESPONSE, 61.7% (79/128) of seladelpar patients met the composite end point at Month 12 vs 20% (13/65) for placebo. With continued treatment in ASSURE, 61.8% (63/102) at 6 months in ASSURE and 72.4% (21/29) at 12 months in ASSURE met the composite end point. Among placebo patients crossing over to seladelpar, 75% (39/52) at 6 months and 93.8% (15/16) at 12 months met the composite end point. ALP normalized in 25% of seladelpar and 0 placebo patients at Month 12 in RESPONSE. With continued treatment, 33.3% (6 months) and 17.2% (12 months) had ALP normalization. For crossover patients, 26.9% and 50% had ALP normalization at these timepoints. The change in pruritus NRS with seladelpar in ASSURE was similar to RESPONSE: −3.8 and −3.7 change from baseline at 6 months in continuous and crossover patients, respectively, corresponding to the key secondary end point in RESPONSE. Among legacy patients, 73.2% (120/164) and 69.7% (69/99) met the composite end point at Month 12 and Month 24 in ASSURE. Normalization of ALP was achieved by 42.1% at 12 months and 42.4% at 24 months. Reduction in pruritus NRS in this group was −3.8 at Month 12 and −3.1 at Month 24. The safety profile was favorable with no treatment-related serious adverse events.

Conclusion: Continuous treatment with seladelpar for RESPONSE and legacy patients led to sustained effects on biochemical markers and pruritus. Seladelpar appeared safe and well tolerated with long-term use.

LBP-041

Screening and comparison of current clinical candidates in MASH using human 3D liver spheroids

Philip Vonschallen[1], Thomas Hofstetter[1], Radina Kostadinova[1], Jesus Glaus[1], Angelina Freitag[1], Francine Spalinger[1], Joel Zvick[1], Francisco Verdeguer[1]. *[1]InSphero AG, Schlieren, Switzerland*
Email: philip.vonschallen@insphero.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive severe disease characterized by hepatic lipid accumulation, inflammation, and fibrosis which lacks any approved drug therapy. Novel approaches to identify therapeutic candidates that predict clinical responses are needed. Human pre-clinical models, including organoids/spheroids, are powerful models for drug testing and discovery. Pre-clinical models combining fast, robust, high-throughput compatible and predictive outputs are still a limiting factor to identify novel clinical therapies. We aimed at performing a comparison of the safety and efficacy of existing clinical candidates for MASH in high-throughput manner using a human-derived 3D liver spheroid model and multiplex readouts.

Method: We used a previously developed a human-derived 3D liver spheroid model in 96-well plates, containing primary human hepatocytes, Kupffer cells, endothelial cells, and stellate cells from healthy donors. Incubation with a MASH-inducing cocktail of the 3D liver model during 10 days lead to the recapitulation of the main hallmarks of MASH including steatosis, inflammation, and fibrosis. We screened simultaneously the safety and efficacy of 20 current

clinical candidates in a concentration-dependent manner. We selected secreted lactate dehydrogenase (LDH), intracellular triglycerides (TGs) and secreted pro-collagen 1 (PC-1) as surrogate markers of cytoxicity, steatosis and fibrosis. LDH was measured at day 3, 5, 7 and 10, TGs at day 10 and PC-1 at day 7 and 10.
Results: The screen of 20 clinical candidates comprised different modalities including small molecules, antibodies, and antisense oligos (ASOs) targeting different mechanisms of action. The majority of compounds did not show signs of toxicity at lower doses but some lead to high LDH release at higher doses. We generated a matrix of anti-steatotic versus anti-fibrotic effect to plot the comparison of all tested clinical candidates. Examples of successful translational effect are the FASN inhibitor TVB2640 (Sagimet) showing a significant reduction of triglycerides and the alphav/beta1 integrin inhibitor (PLN-1474) demonstrating a strong reduction of PC-1 secreted levels.
Conclusion: We show for the first time a screening platform that combines safety and MASH efficacy readouts. We show the translational capacity of this human in-vitro 3D platform by recapitulating the clinical effects of several drug candidates.

LBP-042

First-in-human clinical result of a novel HBV-specific TCR T cell therapy (SCG101) in patients with HBV-related hepatocellular carcinoma (HCC)

Xueshuai Wan[1], Wei Wu[2], Yunpeng Liu[3], Shunda Du[1], Wei Li[4], Dongmei Quan[2], Ke Zhang[5], Karin Wisskirchen[6], Ulrike Protzer[7], Yuhong Zhou[4], Xiujuan Qu[3]. *[1]Peking Union Medical College Hospital, Beijing, China; [2]The Sixth People's Hospital of Shenyang, Shenyang, China; [3]The First Hospital of China Medical University, Shenyang, China; [4]Zhongshan Hospital, Fudan University, Shanghai, China; [5]SCG Cell Therapy, Shanghai, China; [6]SCG Cell Therapy, Munich, Germany; [7]Institute of Virology, Helmholtz Munich, Munich, Germany*
Email: qu_xiujuan@hotmail.com

Background and aims: SCG101, a first-in-class autologous HBV-specific TCR-T cell therapy that utilizes a natural, high-affinity TCR, has been evaluated for its antiviral and antitumor activities in patients with HBV-related HCC in an investigator-initiated phase I trial. Here, we present the summary of the clinical results of the trial.
Method: The trial enrolled 6 HLA-A*02:01 (+), serum HBsAg (+), and HBeAg (-) patients with advanced HBV-related HCC (BCLC B/C) who had received one to three prior systemic therapies. All patients received a single dose of SCG101 at 5×10^7 or 1×10^8 cells/kg intravenously 3 days after lymphodepletion. Safety, pharmacokinetics, pharmacodynamics, and efficacy of SCG101 were evaluated.
Results: After infusion, SCG101 showed dose-dependent proliferation. Serum HBsAg levels dropped in all six patients; four (66.7%) had a reduction >1 $\log_{10}$, with three of them maintaining <10 IU/ml for up to 21 months. Transient ALT elevation, correlating with serum HBsAg reduction, was observed in all patients, indicating on-target activity of SCG101. Tumor control was achieved in all four patients with HBsAg reduction >1 $\log_{10}$, with two exhibiting a partial response (PR) and two stable disease (SD) per mRECIST. The objective response rate (ORR) was 33.3%. Both patients with PR maintained remission for over 6 months. One patient achieved complete remission of the target lesion and remained progression-free for 27 months (data cut-off 9-Mar-2024). The other achieved durable remission with a tumor reduction of 74.6%. Patients with HBsAg reduction <1 $\log_{10}$ experienced disease progression. Median progression-free survival (mPFS) and overall survival (mOS) in patients with HBsAg reduction >1 $\log_{10}$ were longer than those without (mPFS: 5.9 vs 0.7 months, mOS: 19.0 vs 6.3 months as of the data cut-off). Overall, SCG101 treatment was well-tolerated, with no dose-limiting toxicity or neurotoxicity observed. The most common treatment-related adverse events were elevated liver enzymes, cytokine release syndrome, and cytopenia.
Conclusion: SCG101, as a monotherapy for patients with HBV-related HCC, demonstrated antiviral and antitumor activities alongside a survival benefit and manageable safety profile. The persistence of SCG101, reduction of serum HBsAg, and tumor response collectively underscore its on-target activity. A phase II trial to evaluate the safety and efficacy of SCG101 in HLA-A*02:01 (+) patients with HBV-related HCC will be initiated.

LBP-043

A phase 1, dose-escalation and dose-expansion study evaluating the safety, tolerability, pharmacokinetics and preliminary efficacy of AHB-137 in Chinese healthy volunteers and subjects with chronic hepatitis B

Wen Wang[1], Xieer Liang[2], Hong Ren[3], Xian Yu[3], Chongyuan Xu[2], Jiajia Mai[1], Jinlin Hou[2], Hong Zhang[1], Fu Kuang[3], Junting Wang[4], Tianwen Lan[4], Yilei Wen[4], Haixia Cao[4], Bingxia Lu[4], Xiaoli Wu[4], Tingting Lu[4], Xiao Qiu[4], Chen Yang[4], Lidan Wang[4], Di Zhao[4], Miao Wang[4], Cheng Yong Yang[4], Guofeng Cheng[4], Junqi Niu[5], Yanhua Ding[1]. *[1]Phase I Clinical Trial Center, The First Hospital of Jilin University, Changchun, China; [2]Nanfang Hospital, Southern Medical University, Guangzhou, China; [3]The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China; [4]Ausper Biopharma, Hangzhou, China; [5]The First Hospital of Jilin University, Changchun, China*
Email: dingyanhua2003@126.com

Background and aims: AHB-137, an antisense oligonucleotide (ASO) with a favorable preclinical safety profile and strong antiviral activity, is in early-stage clinical development. Here, we report the safety and pharmacokinetics (PK) data of AHB-137 from an ongoing phase I clinical study in China.
Method: 52 Chinese healthy volunteers (HVs) were enrolled into four placebo-controlled single ascending dose (SAD**,** 6:2) cohorts of 75 mg, 150 mg, 300 mg, and 450 mg and two multiple ascending dose (MAD**,** 8:2) cohorts of 150 mg and 300 mg. As of April 2nd, 2024, 20 hepatitis B e antigen (HBeAg) negative chronic hepatitis B (CHB) subjects under stable nucleos (t)ide analogue (NA) treatment with hepatitis B surface antigen (HBsAg) between 100 and 1, 000 IU/ml were sequentially enrolled into 150 mg or 300 mg placebo-controlled MAD cohorts (n = 10, 8:2, 6 doses within 4 weeks). 10 CHB subjects with baseline HBsAg up to 3, 000 IU/ml were enrolled into a 300 mg expansion cohort (open-label, 6 doses within 4 weeks). All doses were administered subcutaneously.
Results: The 52 HVs, with average age of 40.8 years and equal ratio of gender, had successfully completed the study. The 30 enrolled CHB subjects were mostly male (73.3%) with average age of 44.9 years. There were no serious adverse events (SAEs) and no treatment discontinuations due to adverse events (AEs) in HVs and CHB subjects. Most treatment-related adverse events (TRAEs) were mild or moderate. The most common TRAEs (incidence >1 subject) included injection site reactions, ALT increased, AST increased, and the following AEs that transiently occurred after the first dose: pyrexia, C-reactive protein increased, and lymphocyte count decreased, in both HVs and CHB subjects. Single dose of AHB-137 was well absorbed (T_{max} 3.5–5.0 hours), with rapid distribution to peripheral tissues, and slow elimination ($t_{1/2}$ approximately 85.8–90.5 hours). Plasma exposure increased with dose from 75 mg to 450 mg. No accumulation observed with repeated doses. Doses of 150 mg and 300 mg for 4 weeks resulted in a rapid dose-dependent reduction in HBsAg levels. Significant HBsAg reductions were observed in CHB subjects with HBsAg between 100 and 1, 000 IU/ml as well as between 1, 000 and 3, 000 IU/ml.
Conclusion: AHB-137 administrated subcutaneously as SAD up to 450 mg and MAD up to 300 mg was safe and well tolerated in both HVs and CHB subjects. Overall, AHB-137 was well tolerated, had favourable PK profile, and promising efficacy results, supporting the further development of AHB-137 as a candidate for functional cure of CHB.

LBP-044

Robust reduction of HBsAg and HDV RNA levels with low risk for ALT elevations in JNJ-73763989 treated patients with chronic hepatitis D (CHD) and baseline HBsAg levels below 10, 000 IU/ml: part 2 of the REEF-D study

Email: wedemeyer.heiner@mh-hannover.de

Background and aims: The siRNA JNJ-73763989 (JNJ-3989) profoundly reduced HBsAg in patients with chronic hepatitis B. In Part-1 of the REEF-D study, this reduction was associated with serum HDV RNA decline in patients with chronic hepatitis D (CHD). Treatment discontinuation due to relevant ALT elevations was primarily seen in patients with high HBsAg and HDV RNA levels at screening. Based on predefined virologic response criteria in Part-1, the confirmatory Part-2 was initiated with modified inclusion and stopping criteria for ALT elevations.

Method: In REEF-D, a phase 2, multicenter, randomized, double-blind, placebo-controlled study, adult participants with CHD were enrolled. After observing ALT elevations in Part-1, Part-2 excluded patients with liver cirrhosis and those with a combination of HBsAg >10, 000 IU/ml and HDV RNA >100, 000 IU/ml. Patients were randomized 4:1 to receive JNJ-3989 (100 mg sc. Q4W) + NA for 144 weeks (immediate active) or placebo + NA for 52 weeks followed by JNJ-3989 + NA for 96 weeks (deferred active). Changes in serum viral markers and safety were assessed. For Part-2, the primary composite end point reported here is the proportion of patients with HDV RNA decline from baseline (BL) of ≥2 $\log_{10}$ IU/ml (or undetectable) and normal ALT at treatment week (TW) 48.

Results: Of 30 patients enrolled in Part-2, 24 and 6 were randomized to the immediate and deferred treatment arms and 15 and 6 completed the double-blind phase up until TW48, respectively. The primary end point was met by 7/15 completers (47%) and 7/24 overall (29%) versus 0 in the deferred arm. Among 15 completers in the immediate active arm 10 (67%) reached an HDV RNA decline from BL of ≥2 $\log_{10}$ IU/ml and 7 (47%) had HDV RNA <LLOQ at TW48 and mean (SE) reductions of HBsAg and HDV RNA from BL were 2.44 (0.238)/ 2.09 (0.294) log10 IU/ml in the immediate arm versus 0.02 (0.026)/ 0.19 (0.199) log10 IU/ml in the deferred arm. Nine of 24 (37.5%) patients in the immediate arm had treatment-emergent ALT elevations (≥3× upper limit of normal and ≥2× nadir), which resulted in early discontinuation of JNJ-3989 in 7 patients. Six of those 7 patients had HBsAg levels at screening of >10, 000 IU/ml. In contrast, only one of 16 (6%) patients with HBsAg <10, 000 IU/ml at screening had an on-treatment ALT elevation leading to discontinuation. In general, ALT elevations returned to BL values after treatment discontinuation and no cases of liver decompensation occurred. Besides ALT elevations, no other safety issues were observed including four participants from Part-1 who continued treatment with JNJ-3989 for up to 144 weeks.

Conclusion: Patients with screening HBsAg <10, 000 IU/ml had a low risk for ALT flares and showed a profound and sustained on-treatment suppression of HBsAg and HDV RNA. ALT elevations seen in patients with HBsAg ≥10, 000 IU/ml were safely managed with strict stopping criteria for JNJ-3989.

Email: weelai@163.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) may progress to non-alcoholic steatohepatitis (NASH), which is associated with high liver-related or all-cause mortality. We

evaluated the efficacy and safety of the thyroid hormone receptor β agonist HSK31679 in Asian patients with NAFLD.
Method: This was a phase 2a, multicenter, randomized, double-blind, placebo-controlled study at 26 centres in China. Liver fat content (LFC) was assessed by magnetic resonance imaging-proton density fat fraction (MRI-PDFF) at screening and Week 12. Subjects with an LFC of ≥8% at screening and low-density lipoprotein cholesterol (LDL-C) ≥3.44 mmol/L were eligible. Subjects were stratified according to the LFC≥17.5% or <17.5% and were randomized 1:1:1:1:1 to oral HSK31679 doses of 40 mg QD, 80 mg QD, 160 mg QD, placebo, or ezetimibe 10 mg QD. The primary end point was a relative reduction from baseline in LFC (%) after 12 weeks of treatment.
Results: 784 participants were screened and 210 were randomly assigned to the five groups at 26 sites in China. At baseline, 10.0% had 2 diabetes mellitus, 27.8% had hypertension, mean BMI was 29.0 kg/m², mean LFC was 17.0% and mean LDL-C was 4.37 mmol/L. At week 12, the least squares mean relative reduction from baseline in LFC was −4.1% in the placebo group, −14.0% in the 40 mg group (mean difference versus placebo −9.9% [95% CI −21.5% to 1.6%], p = 0.092), −22.7% in the 80 mg group (−18.6% [−30.2% to −7.0%], p = 0.002), and −29.2% in the 160 mg group (−25.2% [−36.8% to −13.5%], p < 0.001). The proportions of participants with ≥30% relative reduction of LFC was 23.8% in the 40 mg HSK31679 group, 47.6% in the 80 mg HSK31679 group (difference versus placebo, p = 0.006), 50.0% in the 160 mg HSK31679 group (difference versus placebo, p = 0.002), 11.9% in the 10 mg ezetimibe group, and 17.1% in the placebo group. At least one treatment-emergent adverse event (TEAE) occurred in 24 (57.1%) of 42 patients in the 40 mg group, 31 (73.8%) of 42 patients in the 80 mg group, 31 (73.8%) of 42 patients in the 160 mg group, 24 (57.1%) of 42 patients in the ezetimibe group, and 17 (40.5%) of 42 patients in the 42 patients in the placebo group. The most common TEAE was diarrhoea (11 [26.2%] of patients in the 40 mg group, 13 [31.0%] in the 80 mg group, 16 [38.1%] in the 160 mg group, 4 [9.5%] in the ezetimibe group, and 2 [4.8%] in the placebo group). Non-drug-related serious adverse events or grade 3 events were reported.
Conclusion: In Asian patients with NAFLD, 12 weeks of HSK31679 treatment was safe and well tolerated, with 80 mg and 160 mg treatment significantly reducing LFC.

LBP-046
A phase IIa basket clinical trial of allogeneic CD362-enriched umbilical cord-derived mesenchymal stromal cells (ORBCEL-CTM) in patients with primary sclerosing cholangitis and autoimmune hepatitis

Email: julian.yeh@nhs.net

Background and aims: Mesenchymal stromal cells (MSC) are novel therapeutics for inflammatory diseases. MERLIN is a single-arm, adaptive, basket trial investigating safety and efficacy of a single MSC infusion in patients with primary sclerosing cholangitis (PSC) and autoimmune hepatitis (AIH).
Method: Allogeneic umbilical cord derived, antibody-purified allogeneic CD362^{+} MSC (ORBCEL-C^{TM}) were investigated at three potential doses; 1×10^6cells/kg (start dose A), 2.5×10^6cells/kg (dose B) and 0.5×10^6cells/kg (dose C), using 3 + 3 design with de-escalation if the dose-limiting toxicity (DLT) rate was >1 per 6 patients. The Highest Safe Dose (HSD) of MSC was determined by observing DLT defined as occurrence of adverse events graded 3–5 per the Common Terminology Criteria for Adverse Events within 14 days of infusion. Primary outcomes were safety/ascertainment of the HSD and a principal mechanistic outcome of change in circulating regulatory T cells (Treg) across both cohorts. Other outcomes included changes in serum ALP for PSC, serum ALT for AIH and circulating immune cell populations.
Results: For AIH (n = 6); mean age 48 (28–77) and 2 females. For PSC (n = 12); mean age 41 (27–73) and 3 females. 75% had concurrent PSC colitis. In the AIH cohort, 3 patients were recruited to dose levels A and B with no DLTs reported. In the PSC cohort there was one DLT at each dose level and thus 6 patients were treated at each dose. The HSD for both arms was 2.5×10^6 cells/kg. There were 7 reported serious adverse events across 5 patients. Related/possibly related events included fever, cholangitis, viral myocarditis, ALT and AST rises. The DLTs consisted of a rise in ALT/AST >10 times the upper normal limit at 1×10^6cells/kg dose, later identified as a flare of AIH in a PSC patient with immune overlap syndrome. The second DLT was an episode of viral myocarditis at the 2.5×10^6cells/kg dose, possibly related to COVID19. In repeated measures analysis of the primary mechanistic outcome there was an increase in total circulating CD25^{HI} Tregs following MSC infusion from 3.12% of CD4 population to 3.84% at day 14; p = 0.0085, with a rise in activated Tregs (FOXP3^{HI}CD45RA^{-}) peaking at day 3 from 1.23% to 1.39%; p = 0.0016. At the HSD for patients with AIH, there was a significant decrease in ALT by day 28 post MSC; – 41.54% (95% CI: – 70.7 – 12.4). ALP values in patients with PSC showed no change. Repeated measures analysis of M1:M2 polarisation in the PSC cohort (but not for AIH) demonstrated a reduction in mean M1:M2 ratio from 5.85 to 4.17 by day 14 post MSC p = 0.043).
Conclusion: In this population of 18 patients the HSD of MSC was identified as 2.5×10^6cells/kg. MSC were well tolerated in both AIH and PSC patients albeit with two DLT events in the PSC group. We observed expansion of Treg in response to the administration of MSC in both groups, a reduction in ALT in the AIH group, and a shift in macrophage polarisation toward a more immune-tolerant M2 state in PSC.

LBP-047
Development and validation of CLDQ-MASH: a disease specific health related quality of life instrument for patients with metabolic dysfunction-associated steatohepatitis (MASH)

Zobair Younossi[1], Maria Stepanova[1], Issah Younossi[1], Andrei Racila[1]. *[1]The Global NASH Council, Washington, United States*
Email: zobair.younossi@cldq.org

Background and aims: The new nomenclature for metabolic dysfunction associated steatohepatitis (MASH) requires presence of steatohepatitis in the context of at least one cardiometabolic risk (CMR). MASH is now considered the most common form of chronic liver disease with a global prevalence of 5–7%. MASH not only causes significant clinical burden (cirrhosis, hepatocellular carcinoma and liver mortality) but also leads to impairment of health-related quality

of life (HRQL) and other patient reported outcomes (PROs). Given the changes in the definition (requirement for CMR) with the new terminology, a HRQL instrument specifically for patients with MASH is important for clinical research and clinical trials.

Method: From our NASH/MASH Databases, we included patients with established diagnosis of MASH according to the new criteria. Patients had completed CLDQ, CLDQ-NAFLD, and other PRO instruments [Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F)] and had available clinico-laboratory data. The CLDQ-MASH was developed following a standard pipeline (Younossi Z et al. Gut 1999) to develop and validate disease-specific HRQL instruments; the instrument was validated in a non-overlapping set of subjects.

Results: There were 8003 metabolic dysfunction-associated steatotic liver Disease (MASLD) patients in our databases who also had PRO scores collected (age: 54 ± 12 years, male: 46%, body mass index (BMI): 33 ± 7, BMI >25: 94%, type 2 diabetes: 55%, biopsy-proven MASH: 53%, biopsy-proven advanced fibrosis (F3-F4): 36%. The MASH sample was split 1:2 into training set used for development of the instrument and testing set which was used for validation. After item reduction and exploratory factor analysis with the training set, the CLDQ-MASH was developed to contain 35 items and 7 domains. With the non-overlapping testing set, CLDQ-MASH demonstrated excellent face validity and internal consistency (Cronbach's alpha >0.85 for 6/7 domains) as well as known-groups validity (based on disease severity and the presence of non-hepatic comorbidities) and high correlations with relevant domains of other instruments ($p < 0.01$). Other psychometric assessments are current ongoing and will be available.

Conclusion: The CLDQ-MASH is a disease-specific HRQL instrument developed and validated using an established methodology and useful for clinical trials of MASH.

LBP-048

Preclinical proof of concept and discovery of siRNA therapeutics targeting CIDEB for metabolic dysfunction-associated steatohepatitis

Jianhua Zhang[1], Xujie Liu[2], Xudong Mao[1], Xueli Xu[1], Xing Zhang[1], Ke Shang[1], Xian Jin[1], Yuan Xu[1], Guofeng Meng[2], Ming Yue[2], Song Yang[2], Jinyu Huang[2], Jianwu Fang[2], Ling Pan[2], Lei Jiang[1], Stella Shi[2], Jianyong Shou[1]. *[1]Shanghai EnnovaBio Pharmaceuticals Co., Ltd., Shanghai, China; [2]Shanghai RONA Therapeutics Co., Ltd., Shanghai, China*

Email: jianyong.shou@ennovabio.com

Background and aims: CIDEB, a member of the CIDE (cell death-inducing DNA fragmentation factor alpha-like effector) family of proteins, is a lipid droplet (LD)-associated protein with high expression in the liver. It is involved in the regulation of very-low-density lipoprotein secretion, LD fusion and growth, and lipogenesis. Germline mutations in CIDEB have been found to confer protection against various liver diseases in humans, highlighting its significance as a potential therapeutic target for the treatment of metabolic dysfunction-associated steatohepatitis (MASH) as well as other related liver diseases. However, whether liver specific inhibition of CIDEB will bring potential clinical benefits remains to be determined. Our goals are to establish preclinical proof of concept by liver-targeting *Cideb* siRNAs for MASH and to develop siRNA drug candidates for clinical investigations in humans.

Method: Surrogate siRNAs targeting rodent *Cideb* were designed and tested via *in vitro* and *in vivo* assays for knock-down (KD) efficiency, duration, and cytotoxicity. *In vivo* administration of the surrogate siRNAs was conducted in two animal models: 1) diet-induced obesity (DIO) model and 2) choline-deficient L-amino acid defined high fat diet (CDAA-HFD) model. In each study, plasma and liver lipid levels were measured and liver histopathology features were analyzed. Additionally, RNA-seq analysis of liver tissues was also performed to gain a comprehensive systems biology understanding of *Cideb* target biology. Concurrently, humanized *Cideb* knock-in mice were generated to serve as a research tool for screening and validating human therapeutic siRNAs.

Results: The lead surrogate siRNA potently reduced *Cideb* mRNA level in primary mouse hepatocytes (IC_{50} 0.012 nM) without obvious cytotoxicity and off-target risks. Dose-dependent *Cideb* target KD effects were confirmed in both efficacy studies. Single administration of the surrogate siRNA (2, 10 mg/kg) resulted in more than 80% target KD up to two weeks. In the DIO model, *Cideb* KD led to significant reductions of plasma total cholesterol (TC) and triglyceride (TG) levels, a significant decrease in hepatic macro-steatosis and notable body weight loss. Furthermore, in the CDAA-HFD model, siRNA treatment resulted in significant reductions of liver weight as well as liver TC and TG levels. Consistently, remarkable reductions of both marco- and micro-steatosis and a significant NAS score reduction were observed. Importantly, histopathology analysis indicated a significant improvement of liver fibrosis. In parallel, candidate-like human *CIDEB* targeting molecules have been discovered through our proprietary siRNA drug discovery platform.

Conclusion: CIDEB exhibits significant potential as a therapeutic target for the treatment of MASH. Liver-targeting siRNA candidates are being developed to test the therapeutic hypothesis in humans.

Acute liver failure and drug induced liver injury – Basic

Plasma lipidomics and fungal peptide-based community analysis identifies signatures of severity and early mortality in acute liver failure

Neha Sharma[1,2], Jaswinder Maras[1], Sushmita Pandey[1], Gaurav Tripathi[1], Manisha Yadav[1], Nupur Sharma[1], Babu Mathew[1], Vasundhra Bindal[1], Sadam H Bhat[1], Rakhi Maiwall[1], Shvetank Sharma[1], Shiv Kumar Sarin[1]. *[1]Institute of Liver and Billiary Sciences, NEW DELHI, India; [2]Institute of Liver and Biliary Sciences, Molecular and cellular medicine, Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Acute liver failure (ALF) is a rapidly progressive disease with high mortality. Ongoing hepatocellular injury is likely to produce severe metabolic alterations that compromise the immune system and increase vulnerability to bacterial and fungal infections. We performed lipidome- (Lipid Species) landscape and fungal peptide-based community analysis- (mycobiome) to identify integrated metabolic signatures that segregate ALF non-survivors; (ALF-NS) and survivors; (ALF-S).
Method: Baseline plasma samples of 300 subjects (270-ALF, 30-healthy) were enrolled. Lipidomics and mycobiome analysis were performed in training cohort; [40 ALF, 5 controls]. Weighted lipid/Fungal correlation network analysis- (WL/FCNA) was correlated to disease severity and outcome. The probability of detection for mortality based on lipids and fungal-peptides was validated on test cohort [230 ALF; non-survivor-146, survivor-84] using High-resolution-mass-spectrometry- (HRMS) and machine learning- (ML).
Results: Untargeted lipidomics provided plasma lipid landscape in which total of 2, 013 lipid species and lipid-like metabolites associated with 8 lipid groups were identified from which 5 Lipid Species Phosphatidylcholine; PC (15:0/17:0), PC (20:1/14:1), PC (26:4/10:0), PC (32:0) and TG (4:0/10:0/23:6) significantly segregated ALF-NS (FC > 10, $p < 0.05$, FDR <0.01). Fungal peptide-based diversity was significantly higher (Alpha/Beta diversity) linked to 4 phyla and >20 species were found dysregulated in ALF-NS ($p < 0.05$). Functionally ALF-NS specific fungal peptide was linked with lipid-metabolism, fatty acid elongation in ER and others ($p < 0.05$). We observed striking correlation between Shannon-lipid and Shannon-fungal diversity profile in ALF-NS ($r^2 > 0.7$, $p < 0.05$). MMCN analysis showed striking associations between lipid and Fungal-peptides modules, functionality and Clinical paramaters specific to ALF-NS ($p < 0.05$). Increased Basidiomycota; *Trametes pubescens*, *Cryptococcus amylolentus CBS6039*, Ascomycota; *Penicillium oxalicum1142*, *Cladophialophora bantiana CBS173.52* and their functionality directly correlated with lipid classes such as Phosphatidylcholine, Triglycerides, others and severity in ALF-NS ($r^2 > 0.85$, $p < 0.05$). POD-lipid associated with hepatic encephalopathy whereas POD-fungus associated with infection, necrosis and multi-organ-failure (Beta >1.2, $p < 0.05$). POD-Lipid (AUC = 0.969) superseded POD-Mycobiome and severity with HR = 1.5 (1.021–1.844) for early mortality. Finally, POD-lipid>25% predicted early mortality and the lipid panel showed>95% accuracy/sensitivity/specificity (ML) for prediction of mortality.
Conclusion: In ALF plasma lipidome and mycobiome are dysregulated. Increased plasma levels of Phosphatidylcholine could stratify ALF predisposed to early mortality or require emergency liver transplantation.

Email: imcaliz@uma.es

Background and aims: Idiosyncratic drug-induced liver injury (DILI) is a complex pathology involving drug, host and environmental factors. In a previous analysis of our group, an overall tendency towards DNA hypomethylation was observed in the DILI group when compared to healthy subjects. This study aimed to identify the most affected cellular processes during a DILI episode and if DNA methylation in CpG sites is a good DILI biomarker when compared with healthy controls.
Method: Peripheral blood DNA was extracted from 32 DILI patients enrolled in the Spanish DILI Registry and 32 healthy controls. DNA methylation analysis was carried out by microarray assays using Infinium MethylationEPIC BeadChip Kit (Illumina). Whole-genome amplification and hybridization were performed with BeadChip microarray (Illumina). Cytosine methylation state was assessed by single-base extension and analysis with the HiScan SQ module (Illumina). Analysis of differentially methylated CpG sites, gene ontology (GO), and KEGG enrichment and kNN classification were done with R.
Results: The kNN classification analysis for the 347 most significative differentially methylated CpG sites (FDR ≤ 0.05 | Δ beta-value | ≥ 0.125) between groups has shown an AUC = 0.965. The kNN analysis using the minimum p value approach for the top 6 most significative differentially methylated CpG sites between groups resulted in an AUC = 0.932. The GO cellular component enrichment analysis has shown the top cellular functions associated with the most significative differentially methylated genes in DILI were related to cell junction processes and early endocytosis. The GO biological process enrichment analysis revealed the most significative differentially methylated genes in DILI were related to adaptative immune system activation, especially the ones involved in T-cell activation. Regarding the KEGG pathway enrichment analysis, the most relevant were those

implicated in endocytosis, platelet activation, MAPK and T-cell receptor signalling pathways.
Conclusion: This preliminary study has shown that differential CpG site methylation during a DILI episode is a potential DILI biomarker when compared with healthy controls. Moreover, during DILI episodes differential CpG site methylation was especially associated with genes involved in diverse processes on the cell membrane (early endocytosis, cell-cell junction and signalling pathways) and adaptive immune system activation. A therapeutic strategy to target CD47 using SIRP alpha expressed extracellular vesicles derived from engineered mesenchymal stem cells to promote liver regeneration following severe injury

Seohyun Kim[1], Yoonjeong Choi[1], Gi-Hoon Nam[1,2], In-San Kim[3,4,5].
[1]SHIFTBIO INC., Seoul, Korea, Rep. of South; [2]Korea University College of Medicine, Seoul, Korea, Rep. of South; [3]SHIFTBIO INC, Seoul, Korea, Rep. of South; [4]KU-KIST Graduate School of Converging Science and Technology Korea University, Seoul, Korea, Rep. of South; [5]Korea Institute of Science and Technology, Seoul, Korea, Rep. of South
Email: kkksh03@shiftbio.net

Background and aims: CD47 is known to transmit a 'don't eat me' signal to immune cells and is overexpressed in pathological cells, including inflammatory dying cells. Consequently, uncleared dead cells in liver injury significantly contribute to a high pro-inflammatory process, exacerbating the condition. In this study, we aim to develop and validate the therapeutic efficacy of SIRP alpha overexpressed mesenchymal stem cell-derived extracellular vesicles (SIRP-EVs). SIRP-EVs can effectively block CD47 on dying hepatocytes, thereby facilitating their clearance through macrophages, mediating anti-inflammatory and pro-resolutive effects in acute liver injury.
Method: To explore CD47 as a promising therapeutic target in acute liver injury, we established various severe injury models using acetaminophen (APAP), thioacetamide (TAA), or carbon tetrachloride (CCl4) and evaluated through histological analysis and spatial transcriptomics. SIRP-EV we developed strongly binds and blocks CD47, the 'don't eat me signal.' Using the IVIS Spectrum in vivo imaging system, we validated the biodistribution of SIRP-EV in normal and liver-injured mice. The therapeutic potential of SIRP-EV was evaluated in diverse mouse models by treating them with SIRP-EV and subsequently assessing liver enzyme levels, histological changes, survival rates, and inflammatory cytokine profiles.
Results: In this study, we observed CD47 overexpression in severely injured liver, predominantly on necroptotic hepatocytes. We found that SIRP-EV preferentially accumulated in the injured liver in a CD47-dependent manner; however, this accumulation was noticeably reduced when CD47 was pre-blocked using an anti-CD47 antibody. Treatment with SIRP-EV in acute liver-injured mice led to a notable improvement in liver histology and reductions in serum ALT and AST levels. Furthermore, SIRP-EV significantly increased survival rates, and the immune profile was transmitted from pro-inflammatory to pro-resolutive. We also demonstrated the therapeutic superiority of SIRP-EV over naïve MSC derived EVs and CD47 antibodies.
Conclusion: CD47 is a potent therapeutic target for acute liver injury. Importantly, SIRP-EV, which targets CD47, offers a promising strategy for treating acute liver injury by mitigating the inflammatory responses and inducing pro-resolutive immune responses.

Serum proteomics can help identify new prognostic biomarkers in adults with acute liver failure

Katharina Remih[1], Franziska Hufnagel[1], Anna Karl[1], Valerie Durkalski-Mauldin[2], William M. Lee[3], Zemin Su[2], Jody Rule[3], Petra Tomanova[4], Laura Krieg[5], Isabel Karkossa[5], Kristin Schubert[5], Martin von Bergen[5], Sonja Luckhardt[6,6], Nicole Ziegler[6], Aimo Kannt[6], Robert Fontana[7], Pavel Strnad[1]. *[1]University Hospital RWTH Aachen, Clinic for Gastroenterology, Metabolic Disorders, and Internal Intensive Medicine, Aachen, Germany; [2]Medical University of South Carolina, Department of Public Health Sciences, Charleston, SC, United States; [3]UT Southwestern Medical Center, Department of Internal Medicine, Division of Digestive and Liver Diseases, Dallas, TX, United States; [4]Quantitative Consulting, Prague, Czech Republic; [5]Helmholtz Centre for Environmental Research, Department of Molecular Systems Biology, Leipzig, Germany; [6]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Frankfurt am Main, Germany; [7]University of Michigan, Department of Internal Medicine, Division of Gastroenterology, Ann Arbor, MI, United States*
Email: kremih@ukaachen.de

Background and aims: Acute liver failure (ALF) is defined as rapid onset coagulopathy and encephalopathy in patients without prior history of liver disease. Liver transplantation (LT) represents the only curative treatment, but the decision for/against LT remains challenging. We used untargeted and targeted proteomics to explore novel diagnostic and prognostic proteomic/cytokine profiles in adult ALF patients.
Method: Serum proteomic and cytokine patterns were compared in 200 and 119 (discovery/validation cohort) adult ALF patients, ~50% were acetaminophen (APAP)-related and there were 30 healthy controls without liver disease. The former were randomly selected from admission samples (<48 h) of the multi-center US ALF study group database. Non-survivors had died or required LT within 21 days. Biomarkers were mapped to their presumed cell of origin from single cell RNAseq data and Ingenuity pathway analysis (Qiagen) was used to obtain mechanistic insights. Novel prognostic scores were calculated and compared to MELD and ALFSG Prognostic index scores.
Results: In the discovery cohort, 188 proteins were detected. 82% of these differed between ALF cases and healthy controls. The key altered pathways involved IL-6 signaling, acute phase response and prothrombin activation. 167 proteins differed between 95 APAP and 105 non-APAP cases of which 47% were hepatocyte derived. Among those hepatocyte derived proteins, 3 proteins (ALDOB, CAT and PIGR) were robust discriminators of ALF etiology (AUROCs ~ 0.9 in both cohorts). 37 proteins significantly differed between 21-day survivors and non-survivors (discovery cohort). The majority were secreted hepatocellular proteins that were nearly uniformly decreased in non-survivors. Activated immune and acute-phase responses were the most significantly enriched pathways and the latter associated with a better outcome. Cytokine profiling revealed most cytokines to be elevated in non-survivors, with interleukin 6 being most prominently affected. Alpha1-antitrypsin and leucine-rich alpha-2 glycoprotein constituted the best discriminators of 21-day survival (AUROCs >0.7 in both cohorts. Two mathematically derived 5-feature models including SERPINA1 outperformed MELD and ALFSG PI and were reproduced in the validation cohort (AUROCs of 0.83 and 0.85). Finally, combining SERPINA1 with the ALFSG PI numerically improved patient prognostication (from AUROC of 0.75 to 0.77).
Conclusion: Unbiased proteomics and cytokine profiling identified several new biomarkers associated with APAP vs non-APAP etiology and 21-day transplant free survival. Use of these biomarkers may improve prognostication and guide medical decision making in ALF patients and lead to improved understanding of the etiopathogenesis of ALF.

FRI-318-YI
NGFR inhibition by TAT-Pep5 protects mice from acetaminophen-induced liver injury

Laura Kitto[1], John Wilson-Kanamori[1], Neil Henderson[1]. [1]*Institute for Regeneration and Repair, Edinburgh, United Kingdom*
Email: Laura.kitto@ed.ac.uk

Background and aims: Acetaminophen (APAP) poisoning is the commonest cause of acute liver failure (ALF) in the Western world. Therapeutic options for the treatment of APAP-induced liver injury (AILI) are limited. In severe AILI, transplantation remains the only curative option, but donor organ demand outstrips supply. Hepatic stellate cells (HSCs) play a central role during liver injury and regeneration. Traditionally HSCs were considered a functionally homogeneous population. However, single cell RNA sequencing (scRNA-seq) studies have revealed heterogeneity. Identification of an NGFR-expressing HSC subpopulation following AILI prompted us to specifically inhibit NGFR using TAT-Pep5 (TP5), which inhibits activation of Rho signalling through NGFR.
Method: 6–12-week-old male mice were fasted for 12 hours prior to intraperitoneal (IP) injection of APAP (300 mg/kg). eGFP$^+$ (PDGFRβ$^+$) mesenchymal cells were FACS-sorted from PDGFRβ-bac-eGFP mouse livers for scRNA-seq (10X Chromium). TP5 (1.7 mg/kg, dissolved in 10% DMSO/PBS) or N-acetylcysteine (NAC, 150 mg/kg) were administered by IP injection, 2 hours following APAP. Alanine aminotransferase (ALT) and glutathione (GSH) levels were assessed, along with percentage necrotic area in liver tissue. Flow cytometry and immunofluorescence staining was used to quantify hepatic immune cells.
Results: (1) scRNA-seq analysis of mesenchymal cells from healthy and APAP-injured mouse livers demonstrated an NGFR-expressing peri-portal subpopulation of HSCs, in both human and murine liver. Significant upregulation of NGFR was seen following both human (mean %area NGFR positive using IF, 12.96% uninjured vs. 38.70% AILI, $p = 0.0022$) and murine (2.03% vs. 12.01%, $p = 0.029$) AILI. (2) TP5 inhibition of NGFR *in vivo* reduced hepatic injury post-APAP, with a significant reduction in necrosis apparent from 12 hours post-injury (control mean necrosis 62.1% vs. TP5 39.2%, $p = 0.0087$). (3) TP5 did not interfere with APAP metabolism, with comparable GSH levels in both groups (control mean GSH 2.47 μmol/g liver vs. TP5 2.35 μmol/g, $p = 0.93$). (4) TP5 was as effective as NAC in reducing liver injury at 24 hours following AILI (ALT: NAC 1448 u/L, TP5 728 u/L, $p = 0.11$, necrosis: 8.24% vs. 9.86%, $p = 0.39$)). (5) Delayed administration of NAC and TP5 led to loss of benefit (mean necrosis, 24 hours: control 26.6%, TP5 26.6%, NAC 22.8%, $p = 0.642$). (6) TP5 treatment was associated with an early increase in infiltrating immune cells located specifically around the portal vein.
Conclusion: TP5 administration resulted in a significant reduction in hepatic injury following murine AILI. We have performed single nuclei RNA-seq of hepatic tissue from TP5 and control treated mice to help understand the mechanisms by which NGFR inhibition protects against AILI. Modulation of HSC NGFR signalling could represent a novel therapeutic strategy for patients with AILI.

FRI-319
SEMA6B triggers macrophage mediated systemic inflammation in acute-on-chronic liver failure

Hui Yang[1], Qun Cai[2], Jiaxian Chen[1], Xi Liang[3], Jiaojiao Xin[1], Dongyan Shi[1], Jing Jiang[1], Jun Li[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China;* [2]*Department of Infectious Diseases and Liver Diseases, Ningbo Medical Center Lihuili Hospital, Affiliated Lihuili Hospital of Ningbo University, Ningbo, China;* [3]*Precision Medicine Center, Taizhou Central Hospital (Taizhou University Hospital), Taizhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) is a complex syndrome characterized by high short-term mortality. Semaphorin-6B (SEMA6B) crucial role in its pathogenesis is unclear. This study aims to clarify mechanisms of SEMA6B in ACLF.
Method: Fifty ACLF patients underwent mRNA sequencing with peripheral blood mononuclear cells (PBMCs). The mechanisms were validated in vivo with SEMA6B knockout mice, and in vitro with macrophage and hepatocytes.
Results: Transcriptome analysis of PBMCs showed that the expression of 5 genes (SEMA6B/PPARG/MERTK/ADAMTS2/FAM20A) were significantly higher in patients with ACLF than with liver cirrhosis, chronic hepatitis B and healthy subjects (all, $p < 0.05$). Area-under-ROC analysis demonstrated that SEMA6B was the most robust diagnostic performance for ACLF development and prognostic performance for 28-day mortality (AUROCs = 0.9788/0.7692). Significant high-expression of SEMA6B was observed in ACLF-2/3, INR (≥2.5) and coagulation failure groups, and was significantly correlated with clinical indicators (INR, ALT) and pathways involved in 28-day ACLF non survivors (inflammatory-related pathways, apoptosis and oxidative phosphorylation). SEMA6B high-expression was observed in macrophage/hepatocytes in liver tissue of ACLF patients. Overexpression of SEMA6B in macrophages activated the immune-response and inflammatory-cytokines secretion (IL-6/IL-1β/IL-10/CCL2; all, $p < 0.05$). The knockout of SEMA6B in liver failure mice improved the liver functions (ALT/AST/TBil/TBA; all, $p < 0.05$) and downregulated the inflammatory cytokines expression (TNF-α/IL-6/IL-1β/IL-10; all, $p < 0.05$), and significantly rescued liver failure mice ($p < 0.05$). The downregulation of inflammation related biological processes (T cell proliferation and activation, interleukin-1 beta type II interferon and production, chemokine-/integrin-mediated pathways) and immuno-inflammation related IL-17 signaling pathway, and the low expression of IL-17 pathway receptor (Il17a/Il17f) were observed in the knockout of SEMA6B mice with liver failure.
Conclusion: SEMA6B, as is a potential diagnostic and diagnostic biomarker in the progression of ACLF, aggravates liver failure by macrophage medicated systemic inflammation, providing a novel clinical target for treating ACLF.

FRI-321
Clinical and molecular features of immune-mediated and drug-induced liver injury

Thais Leonel[1], Anna Pocurull[1], Ignasi Olivas[1], Ester García-Pras[1], Sofía Pérez-del-Pulgar[1], María Carlota Londoño[1], Xavier Forns[1]. [1]*Liver Unit, Hospital Clínic, IDIBAPS, University of Barcelona, CIBEREHD, Barcelona, Spain*
Email: leonel@recerca.clinic.cat

Background and aims: Differential diagnosis of drug-induced liver injury (DILI) from autoimmune hepatitis (AIH) can be difficult due to the common presence of serum autoantibodies and similar histological findings. Likewise, "autoimmune-like hepatitis" (DI-ALH) is a particular phenotype linked to drugs (Andrade R et al., J Hepatol 2023) with laboratory and histological characteristics that closely resemble those of AIH. However, our understanding of DI-ALH pathogenesis is limited due to the lack of well-defined biological markers. Hence, the aim of our study was to evaluate liver transcriptome profiles in patients diagnosed with DILI, HAI and DI-ALH.

Method: We included 44 patients (with liver biopsy) that were classified into 3 groups: DILI (n = 16), DI-ALH (n = 13) and AIH (n = 15). FFPE liver samples from healthy controls (n = 7) were provided by the IDIBAPS Biobank. DILI and AIH were diagnosed according to EASL guidelines. DILI-ALH was defined as liver injury with analytical (positive ANA or SMA plus IgG elevation) and histological features of autoimmunity within 3 months of drug exposure. Gene expression analysis was performed by using the nCounter Host Response Panel (770 genes), Nanostring.
Results: Median age of patients diagnosed with AIH was 63 years (IQR 56–72), 46 (IQR 34–57) for DILI and 43 (IQR 43–62) for DI-ALH (p = 0.01). Most patients were women, 93% AIH, 56% DILI and 92% DI-ALH. ALT levels were significantly higher in DILI than AIH patients (2350 IU/L [IQR 632–3451] vs 853 IU/L [IQR 592–1211], p = 0.049). ANA were detected in 100% of patients with AIH, 77% with DI-ALH and 63% with DILI patients (p = 0.03), whereas SMA were detected in 87% AIH, 77% DI-ALH and 56% DILI (p = ns). Both AIH and DI-ALH patients were positive for either ANA or SMA. Median IgG levels were significantly higher in patients with AIH (28.4 g/L) as compared to the other groups (12.5 g/L in DILI and 13.6 g/L in DI-ALH; p = 0.01). Principal component analysis (PCA) showed that healthy controls clustered separately but there was not a clear delineation between DI-ALH, DILI, and AIH patients. Differential expression (DE) analysis showed that 292, 250 and 231 genes were upregulated in DI-ALH, DILI and AIH patients, respectively, compared to healthy controls (Log2 fold-change>1, p-adj<0.05. Proinflammatory (IL-17 and chemokine signaling) and immune activation (BCR and TCR signaling) pathways were enriched in the DI-ALH group. In addition, pathways related to liver damage such as apoptosis or oxidative stress were upregulated in DI-ALH patients compared to AIH.
Conclusion: Despite observing slight differences in liver damage and inflammation pathways among AIH, DI-ALH and DILI, our data show significant overlap at the transcriptomic level. This indicates potential common pathophysiological mechanisms, as well as the lack of accuracy of current clinical criteria to distinguish the three groups.

FRI-322

Up-regulation of hyaluronan synthase 2 in hepatocytes contributes to oxaliplatin-induced portal hypertension

Ling Wu[1,2], Xiaoquan Huang[1], Feng Li[1,3], Siyu Jiang[1], Detlef Schuppan[2,4], Shiyao Chen[1,3]. [1]*Zhongshan Hospital, Fudan University, Shanghai, China;* [2]*Institute of Translational Immunology and Research Center for Immunotherapy, University Medical Center, Johannes Gutenberg University, Mainz, Germany;* [3]*Minhang Hospital, Fudan University, Shanghai, China;* [4]*Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
Email: wuling01@uni-mainz.de

Background and aims: Oxaliplatin is a first-line drug in chemotherapy regimens, while the incidence of portal hypertension (PH)-related symptoms during follow-up of oxaliplatin (Op)-treated patients without prior liver disease is increasing. However, oxaliplatin-related PH studies are mainly clinical reports, and the specific mechanism is still unclear. We aimed to explore the potential pathological mechanism, discover key molecules, and provide clinical clues for the prevention and treatment of Op-related PH.
Method: Gene expression profiles related to Op treatment were obtained from the GEO database. Key molecules and pathways were identified by screening differentially expressed genes (DEG) between Op-treated and untreated patients. Transcriptome analysis was performed on liver samples from rats with Op-induced PH. Focus was on Op related pathways common to patients and rats. Key molecular pathways were validated in liver samples from rats and oxaliplatin-treated patients. Since main RNA-seq detected signatures in liver are due to abundant hepatocytes, the direct effect of oxaliplatin was studied in human LO2-hepatocytes, and subsequently in co-cultures of human hepatocytes with primary human liver sinusoidal endothelial cells (HHSEC).
Results: Based on the DEG between 19 oxaliplatin-treated patients and 5 untreated patients, hyaluronan synthase 2 (HAS2) and the ERK pathway showed the highest regulation by Op. PH was induced by a 6-week Op treatment in rats, showing a comparable regulation of the ERK pathway. Liver samples from Op-treated patients showed hepatic sinusoidal dilatation, combined with central vein dilatation and fibrosis. Op-treated rats lacked overt sinusoidal obstruction, but showed prominent perivenous monocyte-macrophage infiltration. Moreover, as in humans Op treatment of rats upregulated HAS2, and induced (sinusoidal) endothelial cell activation in vivo. Op could directly upregulated HAS2 in hepatocyte culture and activate the ERK pathway in both LO2 human hepatocytes and HHSEC. The co-culture of HHSEC and Op-treated LO2-hepatocytes showed that mediators released from LO2 cells induced HHSEC damage and activation with increased expression of tissue plasminogen activator, von Willebrand factor and tissue factor, as well as increased cell migration. The migration of HHSEC was also increased after hyaluronic acid treatment, which in co-culture was mainly secreted from hepatocytes after the upregulation of HAS2 with Op treatment.
Conclusion: The MAPK/ERK pathway activation is a key signaling pathway underlying oxaliplatin-induced portal hypertension. It induces the upregulation of HAS2 in hepatocytes, which releases hyaluronic acid, resulting in the activation of hepatic sinusoidal endothelial cells, likely promoting sinusoidal endothelialitis.

The TAK1-β-catenin signaling is essential for inducing chaperone-mediated autophagy and M2 macrophage polarization in acetaminophen-induced liver injury

Xiao Wang[1], Tao Yang[1], Xiaoye Qu[1], Dongwei Xu[1], Xiyun Bian[2], Christopher King[2], Jun Li[3], Longfeng Jiang[3], Bibo Ke[2]. [1]*The Dumont-UCLA Transplant Center, Department of Surgery, David Geffen Scholl of Medicine at UCLA, Los Angeles, United States;* [2]*The Dumont-UCLA Transplant Center, Department of Surgery, David Geffen School of Medicine at UCLA, Los Angeles, United States;* [3]*Department of Infectious Diseases, the First Affiliated Hospital, Nanjing Medical University, Nanjing, China*
Email: xiawang@mednet.ucla.edu

Background and aims: TAK1 plays a central role in triggering an inflammatory signaling cascade. β-catenin is essential for immune regulation during inflammatory response. However, it is unknown how macrophage TAK1-β-catenin signaling may regulate macrophage autophagy and cell differentiation in acetaminophen (APAP)-induced liver inflammatory injury. This study was designed to dissect the regulatory mechanism of the macrophage TAK1-β-catenin axis on inflammatory and immune responses during APAP-induced liver damage.
Method: A mouse model of APAP-induced liver injury was used in the myeloid-specific TAK1 knockout ($TAK1^{M\text{-}KO}$) and floxed TAK1 ($TAK1^{flox/flox}$) mice (n = 10/group). Mice were intraperitoneally injected with APAP (400 ug/g) or PBS. The animals were sacrificed at the indicated time. For the *in vitro* study, bone marrow-derived macrophages (BMMs) from these conditional knockout mice were transfected with CRISPR/Cas9-mediated β-catenin knockout (KO), Hebp1 KO or control vector followed by LPS (100 ng/ml) stimulation.
Results: $TAK1^{M\text{-}KO}$ reduced APAP-induced liver damage with decreased serum ALT/AST levels and proinflammatory mediators and increased animal survival compared to the $TAK1^{FL/FL}$ controls. $TAK1^{FL/FL}$ mice treated with APAP increased JNK and β-catenin phosphorylation, leading to increased β-catenin degradation. However, $TAK1^{M\text{-}KO}$ reduced JNK and β-catenin phosphorylation, increasing β-catenin nuclear translocation. Interestingly, $TAK1^{M\text{-}KO}$ increased autophagic gene ATG5, ATG7, and LC3B but reduced SQSTM1/p62 expression compared to the $TAK1^{FL/FL}$ controls. Moreover, $TAK1^{M\text{-}KO}$ increased macrophage Argnase1 and reduced iNOs expression after the APAP challenge. Chromatin immunoprecipitation (ChIP) coupled with massively parallel sequencing (ChIP-

Seq) revealed that macrophage β-catenin activated its target gene *Hebp1*. Activating macrophage Hebp1 increased cFLIP and Rab10 expression and the cFLIP-Rab10 interaction, which augmented p-ULK1, Hsc70, and LC3B but diminished NLRP3, cleaved caspase-1, and IL-1β expression. However, disruption of macrophage Hebp1 or cFLIP with CRISPR/Cas9 KO inhibited p-ULK1, Hsc70, LC3B, NLRP3, Argnase1, and augmented iNOs with reduced IL-10 and TGF-β expression. Furthermore, adoptive transfer of Hebp1-expressing macrophages in $TAK1^{M\text{-}KO}$ mice ameliorated APAP-induced liver damage.
Conclusion: Macrophage TAK1 deficiency promotes β-catenin activity in APAP-challenged livers. Activating β-catenin targets Hebp1 and activates cFLIP. The cFLIP-Rab10 interaction is crucial for the modulation of chaperone-mediated autophagy and M2 macrophage polarization in APAP-challenged livers. Our findings underscore a novel role of the macrophage TAK1-β-catenin axis in APAP-induced liver injury, implying the potential therapeutic targets in liver immune and inflammatory diseases.

FRI-324
Advancing in drug-induced liver injury models development: high content screening in cell-based models derived from skin tissues

Email: anseza9@gmail.com

Background and aims: Idiosyncratic Drug-Induced Liver Injury (DILI) encompasses unexpected liver damage from both prescribed and over-the-counter medications and herbal and dietary supplements (HDS). Developing human-relevant *in vitro* models is vital for studying DILI and mitigating drug development risks. Recently, keratinocytes, skin-derived cell cultures, showed gene overexpression liked to DILI when exposed to DILI-inducing drugs, providing new alternatives to traditional models. Our study aims to harness this discovery for early-stage DILI prediction, emphasizing the importance of High Content Screening (HCS) methods for speed and automation to enhance these models' accuracy and relevance.
Method: The human immortalized keratinocyte cell line HaCaT was used to perform all the experiments. Cells were seeded onto a 96-well. After 24 hours they were exposed to the drugs of study at eight different concentrations for 24 hours. Cells were stained with different fluorescent markers (membrane, nucleus, mitochondria, and ROS markers) and fixated with formalin. Six different drugs (3 DILI positive and 3 DILI negative) were studied. The HCS imaging was performed using the Operetta CLS system. The image analysis was implemented and automated using the Harmony 4.9 software measuring nine different morphological and functional end points.
Results: 14 different parameters were examined for each of the concentrations, to investigate which could best predict hepatotoxicity. Among all the concentrations studied, the one at which the greatest number of parameters could distinguish between hepatotoxic and non-hepatotoxic drugs was 30 times the base study concentration. Under these conditions, using five distinct parameters (nuclei count, cell area, nucleus area, nuclear marker intensity, and nuclear marker intensity per squared micrometer), all non-hepatotoxic and two out of three hepatotoxic drugs were correctly classified. This yielded an accuracy value of 83%, sensitivity of 66%, specificity of 100%, a positive predictive value of 1, and a negative predictive value of 0.75.
Conclusion: Although the drug panel need to be expanded, the HaCaT cell line exhibits substantial potential as a predictive model for DILI. This bears considerable preclinical significance, as the need for valid models to study DILI is pressing. Furthermore, it holds crucial clinical value, given that keratinocytes are more accessible than hepatocytes, opening up new avenues for clinical investigations.

FRI-325
DDX3X regulates the functional transition of endoplasmic reticulum stress in the pathogenesis of liver failure
Ling Xu[1], Zihao Fan[1], Yao Gao[1], Yaling Cao[1], Yuan Tian[1], Xiangying Zhang[1], Feng Ren[1]. [1]*Capital Medical University Beijing Youan Hospital, Beijing, China*
Email: renfeng7512@ccmu.edu.cn

Background and aims: The functional transition of endoplasmic reticulum stress (ERS) plays a critical role in the pathogenesis of liver failure (LF), but the underlying molecular mechanisms remain unclear. Here, we explored the role of DDX3X under ERS to regulate cell fate in the progression of LF.
Method: Primary hepatocytes were isolated from C57BL/6J mice and induced ERS with tunicamycin (TM). C57BL/6J mice were induced ERS with TM and liver injury with concanavalin A (ConA), respectively. The expression level of DDX3X in liver tissue and serum were analyzed in healthy, chronic hepatitis B (CHB) patients and HBV-associated LF patients. Quantitative real-time PCR (qRT-PCR) and western blotting (WB) methods were used to detect the expression of related genes and proteins; cell viability, cell death rate and cell apoptosis rate was detected by cell counting kit-8 (CCK-8), lactate dehydrogenase (LDH) assays and flow cytometry, respectively; serum alanine transaminase (ALT) and aspartate aminotransferase (AST) levels and hematoxylin-eosin (HandE) staining of liver sections were used to evaluate liver injury in this study.
Results: We demonstrated that DDX3X increased and translocated into nucleus with prolonged ERS; secondly, DDX3X plays dual roles under different periods of ERS mediated cell fate; in addition, phosphorylation modification of DDX3X is the key mechanism to regulate its subcellular localization. Under short-term ERS, DDX3X was mainly expressed in cytoplasm and interacted with peroxisome proliferators-activated receptor alpha (PPARα), which translationally up-regulated transcription factor EB (TFEB) to promote the adaptive cell response. Under prolonged ERS, phosphorylated DDX3X increased nuclear translocation to promote cell apoptosis by CCAAT enhance-binding protein homologous protein (CHOP) activation. In addition, we demonstrated that DDX3X was increased in ConA-induced liver injury in mice and its nuclear translocation was increased; secondly, DDX3X plays dual roles during ConA-induced liver injury, which exerts a protective effect in early phase (6 h) and a pro-injury effect in the late phase (24 h). Furthermore, we found that DDX3X levels were significantly increased in serum and liver tissues of HBV-related LF patients; secondly, the fluctuation of DDX3X serum level is correlated with the prognosis of HBV-LF patients, which consistent decline was correlated with the good prognosis.
Conclusion: Our novel findings document the key regulatory function of DDX3X signaling under ERS in the pathophysiology of liver failure, and provide a rationale to target DDX3X as a refined therapeutic strategy to ameliorate liver injury.

FRI-326-YI
Multi-omics uncovers spatial remodelling of the hepatic lipidome in acute liver injury
Aleksandra Gruevska[1], Kylie Matchett[2], Evangelos Triantafyllou[1], Neil Henderson[2], Zoe Hall[1]. [1]*Department of Metabolism, Digestion and*

Reproduction, Imperial College London, London, United Kingdom;
[2]Centre for Inflammation Research, Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom
Email: zoe.hall@imperial.ac.uk

Background and aims: Drug-induced liver injury (DILI), including acetaminophen (APAP) poisoning, is a major cause of acute liver failure (ALF) with limited therapeutic choices. Dysregulated lipid metabolism has been implicated in DILI, however, lipids and lipid metabolism remain underexplored targets for improving drug safety. Further investigation is also needed to understand the complex interplay between the immune system and local metabolic remodelling during the resolution of injury. The aim of this study is to map the spatial hepatic lipid signature following APAP-induced injury and subsequent resolution.
Method: A multimodal approach including mass spectrometry imaging (MSI) for spatial lipidomics, spatial transcriptomics (ST) and single nuclei RNA sequencing (snRNA-seq) was applied to analyse human APAP-ALF liver explant tissue samples and control background liver tissue (n = 3). The same multimodal approach was used to analyse APAP-induced acute liver injury in wild-type mice (male C57BL/6J, i.p. dosage: 300 mg/kg) across multiple timepoints.
Results: Haematoxylin and eosin staining was used to identify necrotic or remnant viable regions (RVR) in APAP-ALF samples and periportal/pericentral zones in control samples. Spatial lipidomics performed on adjacent tissue sections revealed that metabolic lipid zonation was disrupted in APAP-ALF. The necrotic regions of the APAP-ALF liver tissue exhibited a strikingly different lipid profile to the RVR, with increased sphingolipids, ether lipids, saturated and monosaturated fatty acid-containing phospholipids. Further analysis of the MSI data revealed that cardiolipins (CLs; key mitochondrial lipids) and their precursors phosphatidylglycerols (PGs), had characteristic perinecrotic (PNR) spatial distribution. In line with the MSI data, ST analysis of an adjacent cryosection, demonstrated that genes implicated in PG and CL metabolism (*PGS1, CDS2, TAZ*, *PLSCR3*) had increased expression in necrotic and PNR regions of human APAP-ALF liver tissue, compared to RVR. In APAP-treated mice, PG and CL lipid abundance and *Pgs1* gene expression were increased in the PNR regions, during the resolution of injury phase. Of note, CL is involved in mitochondrial biogenesis and dynamics, mitophagy, as well as in the apoptotic process. We found that genes implicated in mitophagy (*ULK1*, *BECN1*, *BNIP3L*) had increased expression in the same histological regions as increased abundance of CL lipids. Interestingly, analysis of human snRNA-seq data showed that genes involved in CL metabolism and mitophagy were upregulated specifically in endothelial and myeloid cells.
Conclusion: Overall, we have shown that mitochondrial lipids have increased abundance in PNR regions of APAP-induced ALF. Altered PG and CL metabolism in endothelial and myeloid cells may be involved in mitigating APAP poisoning-related injury and promoting liver regeneration.

FRI-327-YI

Plasma multi-omic reveals dysregulated gut arbitrated increase in bacterial peptides and metabolites predictive of poor outcomes in acute liver failure

Sushmita Pandey[1], Neha Sharma[1], Nupur Sharma[1], Gaurav Tripathi[1], Babu Mathew[1], Manisha Yadav[1], Vasundhra Bindal[1], Sadam H Bhat[1], Rakhi Maiwall[1], Shvetank Sharma[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. *[1]Institute of Liver and Biliary Sciences, NEW DELHI, India*
Email: jassi2param@gmail.com

Background and aims: Acute liver failure (ALF) has high mortality and identification of microbial/metabolic signatures in plasma could stratify ALF patients predisposed to early mortality.
Method: Plasma multi-omics was performed on 40 ALF patients and 5 controls (training-cohort). Multi-omics signatures differentiating ALF Non-survivor (ALF-NS) from ALF Survivor (ALF-S) were validated in 270 ALF patients (TC-1; plasma and paired one drop blood (n = 160); TC-2; external validation (n = 70)) and Diseases control (TC-3 (n = 70)), using High Resolution Mass Spectrometry (HRMS), Machine-Learning (ML) and correlated with clinical parameters and outcome.
Results: Multi-omics signature were distinct for ALF, more so for ALF-NS. Non-survivors showed increased metabolites; bile-acids, tryptophan, tyrosine linked to inflammation, cell death, stress and proteins linked to hyper-inflammation ($p < 0.01$, FDR<0.01, FC>1.5). Bacterial-peptide based alpha/beta diversity was higher in ALF-NS corresponding to Proteobacteria, Firmicutes, Actinobacteria functionally associated to energy, amino-acid and xenobiotic metabolism ($p < 0.05$). ALF-NS specific metaproteomic modules/functionality directly correlated with metabolic modules/functions and clinical parameters ($R^2>0.7$, $p < 0.05$). Metabolomic signature directly correlated with clinical parameters and bacterial-peptides e.g., (chenodeoxycholic acid-Firmicutes: alkaliphilus oremlandii and Proteobacteria: phyllobacteriaceae; ($R^2>0.75$)). Probability of detection (POD) of Non-survival built on top five metabolites, namely, chenodeoxycholic acid, 4- (2-Amino phenyl)-2, 4-dioxobutanoate, L-Tyrosine, carnosine and alanyl-tyrosine showed diagnostic accuracy of 98% (AUC = 0.98 (0.92–1.0)) and distinguish ALF predisposed to early mortality (log-rank<0.05). Validation using HRMS on TC-1, TC-2 and TC-3 and 5 ML-algorithm on (ALF = 270) the metabolome panel showed>98% accuracy/sensitivity and specificity for prediction of mortality.
Conclusion: Plasma multi-omics outlines hyper-inflammation and hydrophobic bile acid accumulation as characteristic features for ALF-NS. Baseline plasma metabolite signatures could segregate ALF predisposed to early mortality.

FRI-330

MiRNA/mRNA network topology in acute-on-chronic liver failure identified miR-503-5p as a regulatory hub of lymphocytes activation through antigen-presentation suppression

Heng Yao[1], Xi Liang[2], Jing Jiang[1], Jiaojiao Xin[1], Dongyan Shi[1], Xin Chen[3,4], Jun Li[1]. *[1]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [2]Precision Medicine Center, Taizhou Central Hospital (Taizhou University Hospital), Taizhou, China; [3]Institute of Pharmaceutical Biotechnology and the First Affiliated Hospital Department of Radiation Oncology, Zhejiang University School of Medicine, Hangzhou, China; [4]Joint Institute for Genetics and Genome Medicine between Zhejiang University and University of Toronto, Zhejiang University, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: The pathology of acute-on-chronic liver failure (ACLF) remains uncharted. This study aimed to uncover the disease mechanisms by identification of regulatory hubs in the disease-related miRNA/mRNA network using topological analysis.
Method: Ninety peripheral blood mononuclear cell samples (ACLF, n = 30, liver cirrhosis (LC), n = 25; chronic hepatitis B (CHB), n = 25; normal controls (NC), n = 15) were collected from a prospective cohort for paired miRNA/mRNA sequencing. Differentially expressed (DE) transcripts were used to construct miRNA/mRNA networks enabling topological analysis and capturing the regulatory hubs through the disease progression of ACLF.
Results: Two miRNA/mRNA networks were constructed based on the DE-miRNA/mRNA of NC/ACLF and Chronic disease group (LC and CHB)/ACLF containing 83 and 100 miRNA/mRNA pairs. MiRNA/mRNA sequence matching and tissue miRNA level screening were performed to confirm these miRNA/mRNA were potentially matched in targeting region and expressed in liver tissue. Topological analysis identified miR-503-5p as the most influencing miRNA nodes shared by two networks, whose co-expressed gene set were closely related to acute inflammatory response, humoral immune response, heterotypic cell-cell adhesion, and lymphocyte mediated immunity in

enrichment analysis, which indicates miR-503-5p's participation in the complex immune disorder through the disease progression. The potential target genes of miR-503-5p were down-regulated through ALCF disease progression and involved in the decrease of lymphocytes activation, which were confirmed in the validation group independently.
Conclusion: Topological analysis of the miRNA/mRNA network in ACLF reveals its regulatory complexity through the disease progression and identified miR-503-5p as a hub involved in the lymphocytes activation by suppressing its potential targets to hamper antigen presentation, which may help to discover novel early-warning markers or therapeutic targets of ACLF.

IL-1B exacerbates acute-on-chronic liver failure by promoting neutrophil extracellular traps formation via IL1R1/MyD88/TBK1 axis

Jia Chen[1], Qiongchi Zhang[2], Zhipeng Li[1], Qiumin Luo[1], Wenxiong Xu[1], Liang Peng[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China;* [2]*Xi'an Jiaotong University Health Science Center, Xi'an, China*
Email: pliang@mail.sysu.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by hepatic damage and systemic inflammation, particularly notable for significant neutrophil accumulation within the liver. Our research focuses on understanding the role of neutrophils in ACLF to gain insights into disease mechanisms.
Method: In this study, four ACLF-related datasets retrieved from the Gene Expression Omnibus (GEO) database were conducted comprehensive bioinformatics analyses. Furthermore, We established an ACLF mouse model and utilized IL-1R1 knockout mice to confirm IL1R1's role in vivo. In vitro, we stimulated neutrophils with IL-1B, co-cultured them with hepatocytes, and employed co-immunoprecipitation (CO-IP). Finally, we recruited peripheral blood samples from ACLF patients for experiments and tracked the patients' 28-day prognosis.
Results: Bioinformatics analysis indicated elevated IL-1-related pathways in the peripheral blood of ACLF patients, which were validated by Bulk-RNA sequencing. Simultaneously, ACLF mice exhibited significant GSDME/Caspase3-mediated hepatocyte pyroptosis and notable neutrophil infiltration which were alleviated in IL-1R1 knockout mice. In vitro, IL1R1 deficiency in neutrophils exposed to IL-1B had reduced ROS levels, neutrophil extracellular traps (NETs) formation, and chemotactic factor release. CO-IP results suggested that MyD88, the downstream molecule of IL-1B/IL-1R1, interacts with TBK1 to mediate NETs formation and promote the transcriptional expression of interferon-beta (IFNB). IFNB, upon acting on neutrophils, induces mitochondrial oxidative stress damage. Additionally, a novel MyD88 inhibitor (ST2825) significantly reduced hepatic damage and neutrophil aggregation in ACLF mice. Serum levels of IL-1, soluble IL-1R1, IL-18, CXCL-1, and CXCL-2 significantly increased in ACLF patients, along with increased neutrophil IL-1R1, MyD88, MPO, and CD177 expression. Furthermore, soluble IL-1R1 was identified as a risk factor for 28-day mortality in patients.
Conclusion: In ACLF, hepatocyte pyroptosis-induced IL-1B release triggers NETs formation via the IL1R1/MyD88/TBK1 pathway, worsening hepatic damage and increasing hepatic neutrophil infiltration. IL-1R1 and MyD88 are potential therapeutic targets in ACLF.

FRI-332
Mechanical stress of acute portal hypertension aggravates PA-HSOS by damaging gut-vascular barrier targeting NR4A3/PV1

Han Zhang[1], Si Zhao[1], Rui Fang[1], Xue Wang[1], Suzhen Yang[1], Bing Xu[1], Ming Zhang[1], Yuzheng Zhuge[1], Jiangqiang Xiao[1]. [1]*Department of Gastroenterology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, nanjing, China*
Email: jiangqiang86@drumtowerhep.group

Background and aims: Portal hypertension is considered to play an important role in the progression of many liver disease which is associated with impaired intestinal barrier and increasing gut vascular permeability. However, the specific mechanism is yet to be defined. This study focused on the relationship between portal hypertension, gut vascular permeability and liver injury progression based on pyrrolizidine alkaloids-induced hepatic sinusoidal obstruction syndrome (PA-HSOS), a kind of drug-induced vascular liver disease characterized by acute portal hypertension.
Method: Plasma, hepatic and intestinal tissue from PA-HSOS patients were collected and PA-HSOS mice model was established by MCT intragastric administration. In addition, we also performed partially ligation of the posterior hepatic segment of inferior vena cava (pIVCL) in mice to simulate the portal hypertension of PA-HSOS. Gut vascular permeability was measured in these mice by intravenous injection of FITC -dextrans. Propranolol was used to reduce portal pressure to observe the effects of pressure on intestinal vascular barrier and liver damage. The effect of MCT on endothelial cell proliferation and permeability was explored in vitro. HUVECs under mechanical stress with a stretch device were used to perform RNA-sequencing analyses to identify gene expression patterns associated with stretch.
Results: We found increased intestinal permeability in patients with PA-HSOS and gut-vascular barrier (GVB) is disrupted in mice gavaged MCT which is marked by up-regulation of PV1 and impaired structure of endothelial cells. We confirmed that activated MCT damaged endothelial cells in vitro, meanwhile, confocal laser endomicroscopy revealed hyperpermeability of GVB in the both PA-HSOS mice and post-hepatic portal hypertension (pIVCL) mice, a model to simulate the portal hypertension in PA-HSOS. Reducing portal pressure by pharmacological intervention ameliorated the GVB and liver function. RNA-sequencing of HUVECs identified genes that were altered in response to mechanical stretch, including NR4A subfamily. Mechanical stretch of HUVECs increased expression of NR4A3 and NR4A3 repressed wnt singling pathway to mediate stretch-induced PV1 expression.
Conclusion: We have identified the important role of portal hypertension in PA-HSOS progression. Treatment aimed at reducing portal pressure have protected against intestinal barrier damage and PA-HSOS development. Mechanical stress of portal hypertension is an important component of GVB destruction through the NR4A3/PV1 pathway, which enriches the liver injury mechanism of PA-HSOS and provides new targets for therapeutic strategies.

Email: melanie.simoeseugenio@seabelife.com

Background and aims: Acetaminophen, also known as APAP (N-acetyl-para-aminophenol) or paracetamol is one of the most commonly used analgesics. Overconsumption of more than 4 g/day

of APAP could lead to liver injury. Thus, APAP-induced liver injury (AILI) is the second cause of liver transplantation worldwide and is involved in more than 50% of acute liver failure. For patients diagnosed within 8 hours after APAP ingestion, N-acetyl-cysteine (NAC) is the only approved antidote treatment capable to resolved AILI. For late diagnosis, the mortality is higher since NAC is not effective and liver transplantation remains the only solution. With the aim of discovering a new therapy, SeaBeLife Biotech has developed a new compound, named Sibiriline (SBL01), able to rescue liver after AILI.

Method: After overnight fasting, AILI was induced by intraperitoneal injection of APAP (400 or 450 mg/kg) in C57Bl6J male mice. One hour later, mice were treated with intravenous injection using either vehicle, NAC (200 mg/kg), SBL01 (10 mg/kg) or a combination of NAC and SBL01. Mice survival was followed during 72 hours. Blood and liver tissue samples were collected 8 hours after AILI for further analyses.

Results: 24 hours after APAP intoxication, survival rates increased from 40% to 70% if the vehicle contains SBL01 or NAC. No deaths occurred in mice injected with APAP and treated with a combination of SBL01 and NAC. AILI in mice only treated with the vehicle was associated with an increase of hepatic transaminase levels in plasma (AST and ALT) and the presence of centrilobular necrosis in liver tissue stained with HandE. When AILI mice were treated with SBL01, a decrease of hepatic transaminases and a reduction of hepatic necrosis area were observed showing a protective effect of SBL01. Similar results were also observed in AILI mice treated with NAC. The combination of NAC and SBL01 provided complete and synergistic protection to AILI mice against liver injury. Thus, plasma levels of hepatic transaminases were comparable to those measured in healthy mice and HandE staining of liver sections did not show any centrilobular necrosis. In order to understand the mechanism of SBL01 protection, further analyses were performed. NAPQI-adducts quantification and JNK signalling pathway analyses showed that SBL01 exerted a protective action different from that obtained with NAC.

Conclusion: When AILI mice were treated with SBL01 and NAC, a super-additive effect of SBL01 improve NAC treatment of AILI. SBL01 is a news promising molecule in APAP-induced liver injury.

Adipose-derived mesenchymal stem cells ameliorate APAP-induced liver injury via REDD1-ULK1-FUNDC1 axis-mediated mitophagy

Yelei Cen[1], Guohua Lou[1], Caixia Xia[1], Min Zheng[1], Yanning Liu[1]. [1]*The State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, College of Medicine, Zhejiang University, National Clinical Research Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hang Zhou, China*
Email: liuyanning@zju.edu.cn

Background and aims: Acetaminophen (APAP) overdose is the leading cause of drug-induced acute liver failure in the United States and Europe. Mitochondrial dysfunction is a major contributor to APAP-induced liver injury (AILI). Mesenchymal stem cell (MSC) therapy is a potential method to reduce AILI. We found that adipose-derived mesenchymal stem cells (AMSCs) can promote mitochondrial function and significantly upregulate REDD1, a classical inhibitor of mTOR signaling and serves an important role in autophagy. This study aims to explore the role and mechanism of REDD1 in regulating mitochondrial function in AILI by AMSC therapy.

Method: AMSCs were injected into mice with APAP-induced liver injury to assess changes in serology, liver pathology and the function of mitochondria. RNA sequencing was used to identify differentially expressed genes between APAP-intoxicated and AMSC-treated mice. The results were verified in APAP-injured AML12 cells co-cultured with AMSCs using a transwell model. To further reveal the molecular mechanism, AML12 cells were transfected with a plasmid over-expressing REDD1 and exposed to excess APAP. And hepatocyte-specific REDD1 knockout mice were used to evaluate the role and mechanism of AMSCs-induced REDD1 expression in AILI.

Results: Treated mice with AMSCs showed significant reductions in liver injury and improvements in mitochondrial function compared to APAP-intoxicated mice. RNA sequencing showed a significant increase in REDD1 expression in mouse liver tissue after AMSCs infusion and was verified by western blot and immunohistochemistry. In *in vitro* experiments, we also found that co-culture of AMSCs and AML12 cells could upregulate REDD1 expression and alleviate the mitochondrial dysfunction in the hepatocytes with APAP exposure, whereas the effect of AMSCs on restoring mitochondrial function in APAP-injured hepatocytes was impaired by interfering REDD1 expression in AML12 cells. Furthermore, we found that overexpression of REDD1 in AML12 cells can promote phosphorylation of FUNDC1 by activating ULK1, a kinase substrate in the mTOR pathway, and thereby promote mitophagy. This effect can be inhibited by the ULK1 inhibitor SBI-0206965. In addition, we detected a decrease in the expression of ULK1 and p-FUNDC1 and more severe liver necrosis in hepatocyte-specific REDD1 knockout mice after APAP overdosing. Moreover, AMSCs infusion could increase ULK1 and p-FUNDC1 expression and promote mitophagy in the liver of APAP-intoxicated mice.

Conclusion: These results showed AMSCs therapy mitigating mitochondrial damage in AILI by upregulating REDD1-ULK1-FUNDC1 axis-mediated mitophagy.

An exploration of plasma neurofilament protein as a marker of neuronal damage in acute liver failure

Marilena Stamouli[1,2], Christos Konstantinou[1,2], Francesca M Trovato[2,3], Ane Zamalloa[3], Mark J W McPhail[2,3], Anna Hadjihambi[1,2], Vishal C Patel[1,2,3]. [1]*The Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom;* [2]*Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom;* [3]*Institute of Liver Studies and Transplantation, King's College Hospital, London, United Kingdom*
Email: m.stamouli@researchinliver.org.uk

Background and aims: Acute liver failure (ALF) is a life-threatening condition marked by an abrupt liver dysfunction, disordered coagulation and high-grade hepatic encephalopathy (HE), in individuals without pre-existing liver disease. HE in ALF has several manifestations with a reduction in consciousness driven by disruptions in neurotransmission. Neurofilaments (NfL), structural proteins indicative of neuronal damage, are potential markers for various neurological conditions. This study aims to elucidate the associations of plasma NfL in ALF as a circulating marker of neuronal damage.

Method: A cohort of 22 ALF patients underwent baseline sampling, compared to 19 healthy controls (HC) and 25 acute-on-chronic liver failure (ACLF) patients with HE, serving as positive chronic liver disease controls. ALF and ACLF patients were longitudinally sampled on days 3, 7, and 10, where feasible and prior to liver transplantation. HE severity was clinically assessed using the West Haven criteria (scale 1–4). Plasma levels of NfL and IL-6 were quantified utilising electrochemiluminescent-based assays (MSD). Clinical outcomes and ammonia data were extracted from the patients' clinical records.

Results: Median plasma NfL levels were significantly elevated in ALF patients compared to HC (66 vs 13 pg/ml, $p < 0.0001$), but did not reach the levels observed in ACLF patients (66 vs 158 pg/ml, not significant). However, there was a greater fold change between baseline and follow-up NfL in ALF patients compared to ACLF patients (6.4 vs 1.3, $p = 0.002$). Longitudinal NfL levels remained elevated in both ALF (61 vs 346 pg/ml, $p < 0.0001$) and ACLF patients (158 vs 390 pg/ml, $p < 0.0001$) compared to baseline levels irrespective of outcomes, such as transplant-free survival and HE resolution. Baseline NfL levels were unable to distinguish ALF spontaneous

survivors from non-survivors (deceased and transplanted patients). Additionally, baseline NfL in both ALF showed no correlation with IL-6 nor ammonia levels.
Conclusion: This study demonstrates that plasma NfL levels are elevated in ALF, indicative of neuronal damage that is associated with HE. Elevated NfL levels persist in the systemic circulation of ALF patients up to 10 days, even after the improvement in HE and liver injury, at significantly higher levels than ACLF. However, baseline NfL did not predict transplant-free survival in ALF. The lack of correlation with conventional systemic inflammation cytokines or ammonia levels emphasises that there may be other contributory mechanisms in the pathophysiology of HE in ALF.

FRI-338
Obeticholic acid promotes the hepatic ductular reaction via hepatocyte-mediated HMGB1 by disrupting autophagosome-lysosome fusion in cholestasis
Jie Wang[1], Qianhui Tang[1], Weishuang Shen[1], Qingyu Chen[1], Qinwei Yu[1], Luyong Zhang[1,2], Zhenzhou Jiang[1,3]. *[1]China Pharmaceutical University, New drug screening center, Nanjing, China; [2]Guangdong Pharmaceutical University, Center for drug research and development, Guangdong, China; [3]China Pharmaceutical University, Jiangsu center for pharmacodynamics research and evaluation, Nanjing, China*
Email: jiangcpu@163.com

Background and aims: Obeticholic acid (OCA) is the established second line therapy for primary biliary cholangitis (PBC) patients. However, OCA-induced liver injury in PBC patients puts them at risk for liver failure and increases mortality. OCA exacerbated biliary injury when used during biliary obstruction. The safety studies of OCA will help to guide the clinical medication. High-mobility group box 1 (HMGB1), a extracellular damage/danger associated molecular pattern (DAMP) molecule, is closely involved in various liver diseases. And HMGB1 is a critical regulator of autophagy, which the deficiency also leads to inflammation, ductular reaction (DR) and fibrosis. However, it is not clear how these events are mechanistically linked to OCA-induced liver injury.
Method: Bile duct ligation (BDL) was performed as the complete biliary obstruction model. Ethyl pyruvate (EP) was chosen to pharmacological inhibition of HMGB1 release. The primary mouse hepatocytes were used to investigate the mechanism of HMGB1 and autophagy. ELISA, immunohistochemistry, immunofluorescence, Western blot, Kits and Flow analysis were performed for in vitro and vivo experiments.
Results: The serum concentration of HMGB1 was obviously increased in OCA-treated BDL mice. The images revealed that the positive staining area of HMGB1 in cytoplasm was significantly increased in BDL OCA group. OCA induced the enhancement of cytoplasmic HMGB1 level analyzed by flow in BDL mice. Pharmacological inhibition of HMGB by EP alleviated ductular reaction, necrosis and fibrosis caused by OCA in BDL mice. In vitro, OCA 100 μM treatment induced the increased release of lactate dehydrogenase (LDH) (about 30–40%) and HMGB1 (about 100 pg/ml) from the supernatant of primary hepatocytes. And the release of LDH was significantly reduced in OCA combination with EP group. As reported, secretory autophagy and multivesicular body formation mediate HMGB1 secretion. So, the expression of markers of autophagy were detected. Significantly augmented expression of LC3-II and p62 proteins were observed in OCA dose-dependent manner. Immunofluorescence analysis revealed increased numbers of LC3- and p62-positive puncta in OCA-treated hepatocytes. Furtherly, the release of LDH was upregulated by OCA in the presence of chloroquine (CQ), indicating the compromised process of autophagosome-lysosome fusion. Consistent with this, OCA-treated hepatocytes showed a reduction in acridine orange (AO)-stained acidic organelles, an enhanced release of the lysosomal enzyme CTSB (cathepsin B) into the cytosol, increased expression of lysosome-associated membrane protein (LAMP-1) and the reduction of acidification of lysosomes.
Conclusion: OCA triggered cell death of hepatocytes via lysosomal membrane permeabilization and subsequent HMGB1 release, and the increased release of HMGB1 accelerated the process of liver injury in cholestasis.

FRI-339
Obeticholic acid promotes the hepatic ductular reaction via macrophage-mediated Relb-TNFSF14 signaling in cholestasis
Jie Wang[1], Zihang Yuan[1], Haoran Zhang[1], Qianhui Tang[1], Qingyu Chen[1], Weishuang Shen[1], Qinwei Yu[1], Luyong Zhang[1,2], Zhenzhou Jiang[1,3]. *[1]China Pharmaceutical University, New drug screening center, Nanjing, China; [2]Guangdong Pharmaceutical University, Center for drug research and development, Guangdong, China; [3]China Pharmaceutical University, Jiangsu Center for Pharmacodynamics Research and Evaluation, Nanjing, China*
Email: jiangcpu@163.com

Background and aims: Obeticholic acid (OCA) is approved as a second-line treatment in Primary Biliary Cholangitis (PBC). However, several side effects were reported in clinical studies. And long-term feeding of 30 mg/kg OCA even slightly induced proliferation of cholangiocytes in normal mice. Recent studies have reported that the non-classical NF-kappaB pathway plays an essential role in the process of ductular reaction (DR). But, the effect of OCA on the non-classical NF-kappaB pathway and the mechanism involved have not been clarified.
Method: The bile duct ligation (BDL) model was chosen for in vivo experiments. And the primary mouse bone marrow derived macrophages (BMDMs), Kupffer cells, THP-1 and human intrahepatic bile epithelium cells (HiBECs) were used for in vitro experiments.
Results: The dose of 40 mg/kg of OCA significantly increased the level of serum alkaline phosphatase (ALP) in BDL mice. The mRNA level of *F4/80*, *Il-1beta* and *Tnf-alpha* were elevated by OCA compared with BDL mice. The protein of CK19 in liver was obviously increased in OCA-treated BDL group. And the serum level of TNFSF14, one of the non-classical NF-kappaB pathway ligands, was significantly induced by OCA in BDL mice. In liver non-parenchymal cells, OCA induced the upregulation of LTbetaR mediated Relb signaling, such as the increased mRNA expression of Ltbr, Relb and Tnfsf14 (one of the ligands combined with LTbetaR), while Ltb (another ligand combined with LTbetaR) unchanged. To further identify the Relb-positive cells in liver, immunohistochemistry was performed. The images showed that the expression pattern of Relb was located not only in cholangiocytes but also in non-parenchymal cells around the portal area and OCA led to an apparently increased area in BDL mice. So, we isolated the liver primary Kupffer cells. And OCA could induce the increased fluorescence intensity of Relb compared with BDL group, indicating the participation of macrophages. In addition, OCA 20μM upregulated the Relb and Tnfsf14 expression in mouse BMDMs and THP-1 cells. The content of TNFSF14 in OCA-treated conditional medium of THP-1 cells was significantly increased. And OCA-treated conditional medium could promote the proliferation of HiBECs. Clodronate liposomes were used to deplete macrophages. The depletion of macrophages alleviated the liver injury caused by OCA in BDL mice. After macrophage depletion, the protein expression of Relb in liver was downregulated compared with BDL OCA group. And the protein of CK19, SOX9, alpha-SMA and Fibronectin 1 were also significantly reduced in BDL OCA group with depletion of macrophages.
Conclusion: The OCA-treated BDL mice displayed aggravated inflammatory infiltration and ductular reaction. OCA induced the upregulation of LTbetaR-Relb signaling in macrophages and subsequent TNFSF14 production to further enhance TNFSF14-mediated proliferation of cholangiocytes.

Hepatocyte TAF15 promotes APAP-induced acute liver injury via activating NF-κB to induce PANoptosis

Si Zhao[1], Bing Xu[1], Jiangqiang Xiao[1], Yuzheng Zhuge[1]. [1]*Department of Gastroenterology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China, nanjing, China*
Email: 2469981887@qq.com

Background and aims: Drug-induced liver injury (DILI) has become the leading reason of acute liver failure (ALF), posing a serious threat to human health worldwide. Acetoaminophen (APAP), commonly used as an analgesic and antipyretic drug, is the principal cause of drug-induced ALF after APAP overdose. TATA-binding protein-associated factor 15 (TAF15) is a FET membrane protein participating in the regulation of gene transcription and inflammation signalling pathways in multiple diseases although its role in DILI remains elusive. Here, we examined whether PANoptosis, a novel type of programmed cell death closely associated with inflammation damage, was involved in APAP-induced liver injury, and TAF15-mediated regulation of hepatocyte PANoptosis, if any.
Method: Human DILI liver tissues and control liver samples were collected for detecting TAF15 expression. The APAP models of DILI (350 mg/kg) were established and compared between hepatocyte-specific TAF15 knockout ($TAF15^{\Delta hep}$) and wild-type control ($TAF15^{fl/fl}$) mice. HE, western blotting, PCR, Co-immunoprecipitation (IP), immunofluorescence (IF), primary hepatocyte cells extraction, and immunohistochemistry (IHC) staining were performed to further clarify the mechanism by which TAF15 regulates the occurrence and development of DILI.
Results: epatic expression of TAF15 and PANoptosis was significantly increased in the pathogenesis of DILI compared with controls in human and mice. TAF15 deficiency alleviated APAP-induced liver dysfunction, inflammatory responses, and hepatocyte PANoptosis. Further examination revealed that TAF15 promoted inflammatory responses and the activation of PANoptosome through interaction with NF-κB factor p65, a key factor in the transcript expression and regulation of programmed cell death. Moreover, NF-κB activation inhibitor JSH-23 markedly blocked APAP-induced PANoptosis in primary hepatocytes.
Conclusion: Our findings shed light toward a deleterious role of TAF15 in hepatocyte PANoptosis, thus offering therapeutic promises in APAP-induced acute liver injury.

FRI-341

Clusterin deficiency exacerbates cholestatic liver disease through ER stress and NLRP3 inflammasome activation

Hye-Young Seo[1], So-Hee Lee[1], Ji Yeon Park[1], Jae-Seok Hwang[1], Mi-Kyung Kim[2], Byoung Kuk Jang[1]. [1]*Keimyung University School of Medicine, Daegu, Korea, Rep. of South;* [2]*Keimyung University School of Medicine, Daegu, Korea, Rep. of South*
Email: jangha106@dsmc.or.kr

Background and aims: Cholestatic liver disease, characterized by impaired bile flow leading to the accumulation of harmful metabolites and toxins, results in liver damage. Inflammatory cytokines play a crucial role in the progression of this condition. This study investigates the potential anti-inflammatory effects of clusterin, a glycoprotein known for its roles in cell death, lipid transport, and cellular protection, on liver injury induced by a DDC diet.
Method: The study examined the impact of clusterin on liver injury using C57BL/6 mice and Clusterin knockout mice fed a DDC diet for 10 to 20 days. Both primary kupffer cells (KC) and hepatocytes (HC) from these mice were analyzed. Assessments included Sirius red staining, immunohistochemistry, real-time RT-PCR, ELISA, and western blot analysis to determine the effects of clusterin.
Results: In Clusterin knockout mice, elevated levels of ALT, AST, collagen, and aSMA were observed post DDC diet-induced liver injury. These mice also showed increased ER stress markers (CHOP, ATF6, p-eIF2alpha) and inflammasome markers (NLRP3, ASC, caspase1, IL1beta protein expression, and IL1beta and IL18 secretion). Thapsigargin, an ER stress inducer, escalated the NLRP3 inflammasome response in primary KC and HC, which was reduced by overexpressing clusterin.
Conclusion: This study demonstrates that the absence of clusterin exacerbates ER stress and NLRP3 inflammasome activation in mice fed a DDC diet. Conversely, overexpression of clusterin suppresses ER stress and NLRP3 activation. Therefore, clusterin deficiency is linked to an increased inflammatory response in the liver, which is associated with the upregulation of ER stress.

FRI-342

Visualisation of intrahepatic activation of coagulation and its contribution to disease progression in mice with acetaminophen-induced acute liver injury

Fien von Meijenfeldt[1], Agostina Carestia[2], Laura Godin[2], James Luyendyk[3], Ton Lisman[1], Craig Jenne[2]. [1]*University Medical Center Groningen, Groningen, Netherlands;* [2]*University of Calgary, Calgary, Canada;* [3]*Michigan State University, East Lansing, United States*
Email: f.a.von.meijenfeldt@umcg.nl

Background and aims: Acute liver failure (ALF) is a life-threatening disease that is most often caused by acetaminophen overdose. ALF is characterized by profound hemostatic changes, and experimental evidence suggests that activation of coagulation contributes to disease progression. Here, we aimed to study and visualize intrahepatic activation of coagulation in a mouse model of acetaminophen-induced acute liver injury.
Method: Acute liver injury was induced by intraperitoneal injection of acetaminophen in mice. To study the contribution of activation of coagulation to progression of disease we treated mice with argatroban, DNase, or saline (n = 6 per group). We imaged formation of thrombin, and influx of platelets and neutrophils in mice livers using intravital microscopy. Liver injury was studied by plasma alanine transferase levels and histology (HandE staining).
Results: Acetaminophen overdose resulted in extensive liver injury, intrahepatic platelet aggregation and neutrophil influx in the injured liver at 6 and 24 hours after overdose. Interestingly, we observed formation of bursts of thrombin in extravascular spaces in the liver, presumably the space of Disse. Mice treated with argatroban prior to acetaminophen overdose showed a remarkable reduction in liver injury and platelet aggregation with levels similar to controls. In these mice we did not observe intrahepatic thrombin formation. DNAse treatment had no effect on liver injury or intrahepatic thrombin formation.
Conclusion: Acetaminophen-induced acute liver injury in mice results in formation of thrombin, formation of platelet aggregates, and influx of neutrophils in the injured liver. Intrahepatic thrombin formation likely contributes to liver injury as livers of mice that were pre-treated with argatroban showed minimal injury. We did not find a role for neutrophil extracellular traps or extracellular DNA in acetaminophen-induced liver injury in mice.

FRI-343-YI

APAP induced liver damage is prevented by activation of PPAR-gamma and PPAR-alpha

Email: patricia.aspichueta@ehu.eus

Background and aims: Acetaminophen (APAP), a common pain reliever, is the leading cause of hepatotoxicity. Thus, effective antidotes are required. The APAP induced toxicity involves the dysregulation of pathways involved in liver metabolism, immunity and regeneration, processes in which E2F1 and E2F2 might also be involved. The aims were: 1) to investigate if E2F1 and/or E2F2 are involved in APAP-induced liver injury; 2) to identify the mechanism and investigate whether the activation of beneficial processes improve the survival.
Method: *E2f1*$^{-/-}$, *E2f2*$^{-/-}$ and wild-type (WT) mice were used. CD45.1 WT mice underwent bone marrow (BM) transplant. Hepatotoxicity was induced by IP injection of 750 mg/kg or 360 mg/kg APAP. Mice were sacrificed 6, 24 and 48 h post treatment. Survival and metabolic studies, anatomopathological evaluation of necrosis and immune infiltrate, immunohistochemistry, and protein and lipid levels analysis were performed. Additionally, both a PPAR-gamma protein agonist (Rosiglitazone) and inhibitor (GW9662), a PPAR-alpha/PPAR-gamma agonist (Saroglitazar), and a Pan-PPAR agonist (Lanifibranor) were administered.
Results: E2F1 deficiency exacerbated APAP-induced liver injury, whereas E2F2 deficiency conferred protection. Accordingly, the increased inflammatory component, with neutrophils as the main recruited cells, was found in *E2f1*$^{-/-}$ mice, while was decreased in *E2f2*$^{-/-}$ mice when compared to WT mice. This was reinforced with the determination of CD45^{+}, CD11b^{+} and F4/80^{+} cells in the whole liver. BM transplantation showed that the protection of *E2f2*$^{-/-}$ mice or the susceptibility of *E2f1*$^{-/-}$ mice was related to the effect of its deficiency in the liver rather than to changes in myeloid cell activity. The higher survival and protection in *E2f2*$^{-/-}$ mice were linked to increased levels of ATGL, lipase involved in hydrolysis of lipid droplets, and LC3-II levels while decreased p62 levels. This pro-lipophagy profile was associated with higher β-oxidation rate (FAO) and mitochondrial mass. Simultaneously, increased levels of the autophagy and FAO regulators, PPAR-alpha and PPAR-gamma were observed in *E2f2*$^{-/-}$ mice livers. Pharmacological inactivation of PPAR-gamma exacerbated APAP induced hepatotoxicity in *E2f2*$^{-/-}$ mice, while rosiglitazone, saroglitazar or lanifibranor administration protected against APAP-induced hepatotoxicity in *E2f1*$^{-/-}$ mice and WT mice, prolonging survival and reversing transaminases levels. Notably, anatomopathological evaluation revealed no necrotic foci in the livers of agonist-treated mice.
Conclusion: PPAR-gamma activation is involved in the protection of *E2f2*$^{-/-}$ mice against APAP-induced hepatotoxicity. The activation of both PPARs confers protection against APAP-induced liver injury and might be consider as a potential treatment in the future.

FRI-347
HYX1-derived exosomal let-7c-5p protects against acute liver failure by inhibiting SLC11A2-mediated ferroptosis

Huixin Tang[1], Li Bai[1], Yu Chen[1]. *[1]Capital Medical University, Beijing, China*
Email: tender78@126.com

Background and aims: Acute liver failure (ALF) is characterized by rapid progression, high short-term mortality, and poor prognosis. Unfortunately, there is no effective therapy for ALF currently except for liver transplantation, which is limited by critical shortage of donor liver. Therefore, it is imperative to seek for novel therapeutic means for ALF. We previously have documented that the transfer of hepatic stem cell HYX1 confers the hepatoprotection against ALF. In the present work, we aimed to demonstrate the hepatoprotection conferred by HYX1-derived exosomes (Exos) against D-GalN/LPS-induced ALF and to dissect the underlying molecular mechanism.
Method: Normal mice were pre-treated with HYX1-Exos or negative control, followed by D-GalN/LPS insult. HYX1-Exos were subjected to miRNA sequencing and KEGG enrichment analysis. The pivotal role of ferroptosis in ALF was confirmed. The ferroptosis levels were evaluated after HYX1-Exos treatment. The special miRNAs related to ferroptosis were screened out and identified. Let-7c-5p agomir or negative control was injected into normal mice followed by acute insult. And the expression of ferroptosis-related markers was detected. The targeted relationship between let-7c-5p and SLC11A2 was analyzed. The molecular basics underlying the hepatoprotection conferred by let-7c-5p was dissected using stable AML cells with SLC11A2 overexpression (OE) or knockdown.
Results: HYX1-Exos alleviates ALF, as shown by improved hepatic architecture and reduced pathology scores. miRNA sequencing analysis displayed that miRNAs derived from HYX1-Exos could be enriched in ferroptosis signaling pathway. The administration of fer-1 led to significant mitigation in hepatic damage. HYX1-Exos treatment resulted in remarkable decrease in the levels of ferroptosis signaling molecules. Let-7c-5p was screened out as the potential miRNA responsible for the hepatoprotection conferred by HYX1-Exos. The administration of let-7c-5p agomir brought about obvious alleviation in hepatic damage and marked inhibition in ferroptosis signaling. Let-7c-5p targetedly inhibited SLC11A2. The cell viability was decreased but the ferroptosis levels were enhanced in SLC11A2-OE cells compared with control (CT) cells. Especially, the hepatoprotection conferred by HYX1-Exos or let-7c-5p agomir was obviously weakened in SLC11A2-OE cells compared with CT cells. On the other hand, the cell viability was increased but the ferroptosis levels were reduced in SLC11A2-knockdown cells compared with CT cells.
Conclusion: Let-7c-5p carried by HYX1-Exos protects from ALF by inhibiting SLC11A2-mediated ferroptosis. Our finding will shed novel insights into the pathogenesis and treatment of ALF.

FRI-348
Endogenous Annexin A1 has a protective effect on the liver in a diabetic mouse model

Diego Dias dos Santos[1], Rafael André da Silva[2], Luiz Philipe de Souza Ferreira[1], Cristiane Damas Gil[1]. *[1]Federal University of São Paulo, Department of Morphology and Genetics, São Paulo, SP, Brazil; [2]Institute of Biosciences, Letters and Exact Sciences, Department of Biology, São José do Rio Preto, SP, Brazil*
Email: dias.diego@unifesp.br

Background and aims: Diabetes mellitus (DM) is a global public health problem, which leads to systemic dysregulations affecting several tissues, including severe liver complications. Patients with DM2 have increased plasma levels of annexin A1 (AnxA1) and, in an experimental murine model of DM2, the AnxA1 protein plays a fundamental role in attenuating the effects caused by insulin resistance, such as hepatosteatosis. Despite these important findings, its role has been little explored in hepatocytes in DM1. Thus, this study aims to evaluate the role of AnxA1 in hepatocyte biology in a streptozotocin (STZ)-induced DM1 mouse model.
Method: Male C57BL/6 mice (AnxA1+/+ and AnxA1−/−) were randomly distributed into two experimental groups (n = 6 animals/

group): control (CTR) and DM. DM was induced in mice with intraperitoneal injection of STZ (65 mg/kg × 5 days) or citrate vehicle. After 12 weeks, livers were collected for different analysis. GSE39752 study, which presents murine liver transcriptome from control (n = 7) and STZ-induced DM (n = 6) groups, was selected from the Gene Expression Omnibus repository (http://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE39752). The datasets were analyzed using the GEO2R tool to detect expressions of AnxA1, Fpr1, Fpr2/3 (formyl peptide receptors) and S100A11 (S100 calcium-binding protein A11). The procedures were approved by the UNIFESP Animal Experimentation Ethics Committee (n° 5520161123).
Results: Morphological evaluation of the AnxA1+/+ CTR livers showed a normal appearance of hepatocytes and sinusoids, contrasting with the AnxA1−/− CTR group where 70% of mice showed hepatocytes with cytoplasmic vacuolation. In the AnxA1+/+ DM group, ~50% presented hepatocytes with vacuolated and damaged cytoplasm and nucleus, exacerbated in AnxA1−/− DM mice (~75%). Both AnxA1+/+ and AnxA1−/− DM livers exhibited a significant reduction in glycogen, fibroblast growth factor 2 and vascular endothelial growth factor A levels compared to the respective CTR groups. AnxA1+/+ DM livers showed higher levels of reactive oxygen species, IL-10 and TNF-α compared to the CTR ones. The lack of AnxA1 in DM livers was associated with raised monocyte chemoattractant protein-1 levels and no alterations were detected in ROS levels. Transcriptome analysis revealed an increase in the transcriptional levels of Fpr1, Fpr2/3 (AnxA1 receptors), and S100A11 (marker of hepatic steatosis and AnxA1 adaptor protein) in the DM livers compared to the controls, with no changes in AnxA1 transcripts.
Conclusion: Our study showed that AnxA1 deficiency exacerbates the pathological aspect of the liver, suggesting its important hepatoprotective role in the context of DM1.

Acute liver failure and drug induced liver injury – Clinical

Personalized prediction of spontaneous recovery in acute liver failure listed for liver transplantation

Xun Zhao[1], Yingji Sun[2], Hannah Wozniak[2], Mamatha Bhat[3].
[1]*University of Toronto, Toronto, Canada;* [2]*Toronto General Hospital, Toronto, Canada;* [3]*University Health Network, Toronto, Canada*
Email: xun.zhao@mail.mcgill.ca

Background and aims: Acute liver failure (ALF) is a rare clinical presentation characterized by rapid deterioration of hepatic function in people without pre-existing liver disease. Transplant-free survival is low at 50%, and early referral to liver transplantation is crucial. In the United States, ALF can be considered for urgent organ allocation and listed as status 1A if life expectancy is anticipated to be less than 7 days. However, spontaneous recovery is still possible in certain patients, even when listed under status 1A. Currently there is no clinical tool that predicts spontaneous recovery. We have built and validated a machine learning algorithm that accurately predicts spontaneous recovery in patients listed with the highest urgency for liver transplantation.
Method: We used the Scientific Registry of Transplant Recipients to train, test, and validate our model. We identified all patients listed as status 1A for ALF. Patients who died or spontaneously recovered on the waitlist were included. Patient demographic data, comorbidities, and intensive care unit specific variables were collected (37 variables in total). Clinical findings and serum variables up to 72 hours from the time of listing were collected. We built two machine learning models, a logistic regression model, and a random forest model to predict spontaneous recovery or death on the waitlist. Training and testing of the data was split 70% and 15%, with 15% of data held out for validation.
Results: 2, 347 patients were included in our study, with 1, 335 dying on the waitlist (mean age 41, MELD 35) and 1, 012 recovering spontaneously (mean age 34, MELD 32). 33.2% of the recovery group had ALF to acetaminophen overdose, compared to 17.6% in the deceased group. Mean change in MELD from initial MELD and most recent MELD within 72 h was −0.1 in those who died and −2.6 in those who recovered. Logistic regression had an accuracy of 0.77 ± 0.01, and an AUC of 0.76 ± 0.01. Our random forest model had an accuracy of 0.92 ± 0.01, a F1 score of 0.91 ± 0.01, and AUC of 0.92 ± 0.01. This corresponded to a sensitivity of 89.2% and specificity of 94.3%. SHAPLEY analysis showed that bilirubin, mechanical ventilation, MELD score, encephalopathy grade, and age were top features contributing to our model.
Conclusion: We have built a score that accurately predicts spontaneous recovery in listed ALF patients based on variables at time of listing and is personalized to individual patients.

Clinical and HLA associations of fluoroquinolone induced liver injury: results from the drug induced liver injury network (DILIN)

Jawad Ahmad[1], Andrew Dellinger[2], Paola Nicoletti[3], Huiman Barnhart[4], Marwan Ghabril[5], Robert Fontana[6], Victor Navarro[7], Gina Choi[8], Paul Hayashi[9]. [1]*Recanati-Miller Transplantation Institute, Icahn School of Medicine at Mount Sinai, New York, United States;* [2]*Duke University School of Medicine, Durham, NC, United States;* [3]*Icahn School of Medicine at Mount Sinai, New York, United States;* [4]*Duke University School of Medicine, Durham, United States;* [5]*Indiana University, Indianapolis, United States;* [6]*University of Michigan, Ann Arbor, United States;* [7]*Einstein University, Philadelphia, United States;* [8]*UCLA, Los Angeles, United States;* [9]*FDA, Silver Spring, United States*
Email: jawad.ahmad@mountsinai.org

Background and aims: Fluoroquinolones are widely prescribed antimicrobials with a favorable safety profile but a well-described risk of drug-induced liver injury (DILI). The aim of this study was to identify clinical features and HLA genetic variants associated with fluoroquinolone-induced DILI in a large national registry.
Method: Analysis was limited to cases of fluoroquinolone-induced liver injury enrolled in DILIN between 2004 and 2022, adjudicated as definite, highly likely or probable (high confidence). HLA class I and II alleles were sequenced by Illumina MiSeq platform and compared to population controls from publicly available datasets inferred by HIBAG software.
Results: 61 high-confidence cases (13% definite, 49% highly likely, and 38% probable) were included: 32 from ciprofloxacin, 22 from levofloxacin, and 7 from moxifloxacin. Clinical features of liver injury for the 3 drugs were similar. Indication for use were genitourinary (41%), gastrointestinal (13%), respiratory (20%), orthopedic/cutaneous (10%), and other/unknown (16%) infections. The median duration of therapy was 7 (range 2–54) days; median age 53 (range 22–80) years; 67% female; 72% non-Hispanic-white, 10% non-Hispanic-black, 5% Asian, and 13% other. Median latency to onset was 10 (range 1–83) days; 28% had rash, 26% had fever, 64% were hospitalized, 61% were jaundiced; 44% had hepatocellular, 30% mixed, 26% cholestatic pattern of liver injury as determined by the R-value; 31% were ANA and 18% SMA positive; median time to recovery was 65 days, but 13% developed evidence of chronic injury, 15% died (11% due to liver failure). HLA association results were available on 60 cases. Two HLA alleles were associated with an increased risk of liver injury compared to controls: HLA-DQA1*03:01 (carriage frequency (CF) 0.38 in cases vs 0.19 in controls) and HLA B*57:01 (0.15 vs 0.06). There was a significant difference between the combined CF of the two alleles of 0.48 in cases vs 0.24 controls, OR: 2.8 (1.7–4.8), p = 0.0001. For each individual drug the associations were: ciprofloxacin HLA-DQA1*03:01 (CF 0.28 in cases vs 0.19 in controls) and HLA B*57:01

(0.16 vs 0.06), combined 0.40 vs 0.24, OR: 2.0 (1.0–4.1), p = 0.06; levofloxacin HLA-DQA1*03:01 (CF 0.53 in cases vs 0.19 in controls) and HLA B*57:01 (0.10 vs 0.06), combined 0.53 vs 0.24, OR: 3.2 (1.2–8.9), p = 0.01; moxifloxacin HLA-DQA1*03:01 (CF 0.43 in cases vs 0.19 in controls) and HLA B*57:01 (0.29 vs 0.06), combined 0.71 vs 0.24, OR: 9.3 (1.5–97.4), p = 0.006. No clinical characteristics or outcomes were associated with carriers compared to non-carriers.
Conclusion: Fluoroquinolone-induced liver injury typically presents with a short latency, variable pattern of liver injury, and carries a significant risk of chronicity and mortality. There is a significant association with HLA-DQA1*03:01 and HLA B*57:01.

TOP-346-YI

Therapeutic plasma exchange in Amatoxin associated acute liver failure-results from an interim analysis of the Amanita-PEX study

Email: stahl.klaus@mh-hannover.de

Background and aims: Amatoxin related acute liver failure (AT-ALF) is associated with high mortality if no urgent liver transplantation (LTX) is performed. Therapeutic plasma exchange (PEX) has been demonstrated to improve LTX-free survival in patients with ALF of other etiologies. It is however unclear, if PEX may also improve LTX-free survival in AT-ALF and clinical practice in utilizing PEX in AT-ALF varies substantially between different centers. Of note, due to the scarcity of this ALF entity, realization of a randomized controlled trial investigating use of PEX in AT-ALF does not appear to be feasible in the future.
Method: This is an interim analysis of a multicenter, international, retrospective cohort study (Amanita-PEX study, NCT06187220) investigating the effect of additive PEX compared to standard medical therapy (SMT) alone in AT-ALF. So far, 57 patients diagnosed with AT-ALF over the past 10 years have been successfully recruited into the study from fifteen liver transplant referral centers across seven countries. LTX-free and overall survival within the first 28 days following fulfillment of ALF criteria (encephalopathy and INR >1.5) were recorded and compared between patients receiving PEX and SMT, respectively.
Results: In this interim analysis, 49 adults with AT-ALF were included (of anticipated total n = 60 patients), of which 18 received PEX in six centers and 31 SMT only (all but one center). Median (Interquartile Range (IQR) patient age, BMI, INR, bilirubin, MELD- and SOFA-Scores in the adult cohort were: 57 (41–65) years, 25.8 (22.7–28) kg/m^2, 4.0 (2.4–6.4), 75 (44–124) umol/l, 31 (26–38) and 6 (4–10) points, respectively (without significant differences between groups). 96% and 90% of patients received intravenous silibinine and n-acetylcysteine. LTX-free survival up to day 28 was 61.1% (11/18) and 41.9% (13/31) in patients receiving PEX and SMT, respectively (HR 0.544 (95%-Confidence Interval (CI): 0.246–1.205), p = 0.125 for 28 day survival (Kaplan-Meier test); p = 0.064 for early survival (Gehan-Breslow test)). In patients with higher grade (>I°) encephalopathy, LTX-free survival was 41.7% (5/12) and 20% (4/20) in the PEX and SMT group, respectively (HR 0.526 (95%-CI: 0.231–1.194, p = 0.094 for 28 day survival (Kaplan-Meier test); p = 0.049 for early survival (Gehan-Breslow test)).
Conclusion: In this interim analysis of a multicenter retrospective study, adjunctive PEX was associated with a trend towards improved LTX-free survival in patients with AT-ALF. Data retrieval is ongoing in 10 further centers. The study is still open for new study centers.

Time to use the right classification to predict the severity of checkpoint inhibitor-induced liver injury

Lina Hountondji[1], Stéphanie Faure[1], Pascale Palassin[1], Philine Witkowski Durand Viel[2], Marie Dupuy[1], Dominique Larrey[1,3], Anouck Lamoureux[1], Dimitri Pureur[1], Cyril Coustal[1], Candice Lesage[1], Eric Assenat[1], Benjamin Riviere[1], Jean-Luc Faillie[1], Xavier Quantin[2], Alexandre Maria[1], Georges-Philippe Pageaux[1], Lucy Meunier[1,4]. *[1]Montpellier University Hospital, Montpellier, France; [2]Montpellier Cancer Institute, Montpellier, France; [3]REFEPS, Montpellier, France; [4]REFEPS, Montpellier*
Email: lina.hountondji@outlook.fr

Background and aims: Immune checkpoint inhibitors (ICIs) targeting CTLA-4 and PD (L)1 have revolutionized the prognosis of many cancers. ICIs may induce several immune-related adverse events, including checkpoint inhibitor-induced liver injury (CHILI). The CTCAE classification grades all multi-system toxicities and considers the elevation of liver enzymes in CHILI. Thus, CTCAE does not include liver function, whereas European guidelines call for liver function assessment to evaluate the severity of drug-induced liver injury. The aim of this study is to evaluate and compare the severity of CHILI according to the CTCAE, DILI-N and DILI IEWG classifications.
Method: CHILI-S is an observational multicenter study of CHILI patients grade CTCAE ≥2 presented to the ToxImmun meeting in Montpellier. Clinico-biological data were collected at diagnosis, S2, S4, and then once a month for 6 months. CHILI was classified according to CTCAE, DILI-N and DILI IEWG: non-severe (grade 1–2) and severe (grade 3–4–5). The primary end point was the occurrence of severe liver dysfunction (ALI), defined by hyperbilirubinemia and INR ≥1.5. Secondary end points were critical liver dysfunction (ALF), 3-month survival, overall survival, hospitalization, optimization of steroids, and use of a second-line immunosuppressant. Easymedstat software was used for statistical testing. Survival curves were calculated using the Kaplan Meyer method and compared with the

log-rank test. The prognostic performances of the 3 classifications were compared with ROC curves.
Results: 114 patients were included in the study between December 2018 and September 2023, mostly men (n = 67, 58.8%), with a median age of 65.5 years (23–88). The most common cancers were lung adenocarcinoma (n = 38, 33.3%) and melanoma (n = 37, 32.5%). Anti-PD1 was the most prescribed ICI (n = 103, 90.3%), either alone (n = 72, 63.2%) or in combination with anti-CTLA4 (n = 31, 27.2%). Hepatitis severity according to classifications was predominantly grade 3–4 CTCAE (n = 102, 89.5%), and grade 1–2 DILI-N (n = 99, 86.8%) and DILI IEWG (107, 93.9%). Hyperbilirubinemia was present in 27 patients (23.7%), and 16 patients were hospitalized (14%). Liver biopsy was significantly more performed for severe CHILI according to CTCAE, DILI-N and DILI IEWG (37.3%, 66.7% and 71.4%). ALI was not significantly associated with any histological lesion, but lobular necrosis with bridge necrosis tended to be more frequent in patients with ALI. The DILI-N and DILI IEWG classifications performed better in predicting liver dysfunction (AUC 0.988 and 0.994), compared with CTCAE (AUC 0.795).
Conclusion: The CTCAE classification, which is recommended in clinical practice to assess the severity of CHILI, does not accurately predict liver dysfunction, in contrast to the DILI-N and DILI IEWG classifications. These results support the need to revise current CHILI management recommendations.

SAT-314

Impact of hepatic steatosis on risk of acute liver injury among people with chronic hepatitis B and SARS-CoV-2 infection

Matthew Shing Hin Chung[1,2], Carlos King Ho Wong[2,3,4], Xue Li[1,2,3], Francisco Tsz Tsun Lai[2,3], Eric Yuk Fai Wan[2,3,4], Celine Sze Ling Chui[3,5,6], Franco Wing Tak Cheng[2], Esther Wai Yin Chan[2,3], Ching Lung Cheung[2,3], Xi Xiong[2], Lanlan Li[1,2], Wai-Kay Seto[1,7], Man-Fung Yuen[1,7], Lung Yi Loey Mak[1,7], Ian Chi Kei Wong[2,3,8,9]. *[1]Department of Medicine, School of Clinical Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [2]Centre for Safe Medication Practice and Research, Department of Pharmacology and Pharmacy, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [3]Laboratory of Data Discovery for Health (D24H), Hong Kong, Hong Kong; [4]Department of Family Medicine and Primary Care, School of Clinical Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [5]School of Nursing, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [6]School of Public Health, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [7]State Key Laboratory of Liver Research, The University of Hong Kong, Hong Kong, Hong Kong; [8]Research Department of Practice and Policy, UCL School of Pharmacy, University College London, London, United Kingdom; [9]Aston School of Pharmacy, Aston University, Birmingham, United Kingdom*
Email: loeymak@gmail.com

Background and aims: SARS-CoV-2 infection was known to be associated with higher risk of liver impairment in people with chronic hepatitis B infection (CHB). However, evidence regarding the impact of concomitant hepatic steatosis (HS) on the risk of liver disease among people with CHB and SARS-CoV-2 infection is lacking. We investigated the impact of concomitant HS on people with CHB suffering from SARS-CoV-2 infection.
Method: This retrospective cohort study was performed using an electronic health database for people in Hong Kong with CHB and confirmed SARS-CoV-2 infection between 1st January 2020 and 31st January 2023. People with HS diagnosis (HS+CHB+COVID-19) were identified and matched 1:1 by propensity-score with those without (CHB + COVID-19). Each person was followed up until death, outcome event, or 31st January 2023. Study outcome was incidence of acute liver injury (ALI) within first 28 days since COVID-19 diagnosis. Severity of ALI and comparison of ALI risk stratified by the presence of CHB infection and HS were also analyzed. Incidence rate ratios (IRRs) were estimated by Poisson regression models.
Results: Of 52, 259 COVID-19 patients with CHB infection in the cohort, 15, 391 people with HS + CHB + COVID-19 and 15, 391 people with CHB + COVID-19 were included after matching. HS + CHB + COVID-19 was associated with increased risk of ALI (IRR: 1.41, 95% CI:1.05–1.90, p = 0.023), compared to CHB + COVID-19. Over 99% ALI cases were mild to moderate severity and there were no differences in the severity of ALI between HS + CHB + COVID-19 and CHB + COVID-19 (p = 0.127).
Conclusion: Concomitant HS was associated with increased risk of ALI among people with CHB infection suffering from SARS-CoV-2 infection.

SAT-315

High volume plasma exchange may improve transplant-free survival in patients with severe paracetamol-induced acute liver failure: a case control study

Sébastien L'Hermite[1], Valentin Coirier[1], Pauline Houssel-Debry[1], Baptiste Giguet[1], Florent Artru[1], Claire Francoz[2], Sophie Pellegrin[2], Emmanuel Weiss[2], Federica Dondero[2], Kieran Pinceaux[1], Francois Durand[2], Christophe Camus[1], Olivier Roux[2]. *[1]Centre Hospitalo-Universitaire de Rennes, Rennes, France; [2]Hopital Beaujon-APHP, Clichy, France*
Email: sebastienlhermite7@gmail.com

Background and aims: Paracetamol-induced Acute Liver Failure (P-ALF) is a severe condition that may justify emergency liver transplantation (LT). It has been suggested that High Volume Plasma Exchange (HVPE) may improve survival of ALF patients who are not candidate for LT. Yet indication for and timing of HVPE in candidates for LT remain to be defined. The aim of this study was to compare 28-day transplant-free and overall survival in patients admitted for P-ALF, depending on HVPE.
Method: We included all consecutive patients admitted in two high-volume liver transplant centers between 2016 and 2023 with P-ALF. All patients met King's College Hospital (KCH) transplant criteria. Clinical and biological data were collected retrospectively. In one center, HVPE was the first-line option whereas in the second center, LT without HVPE was the first-line option.
Results: Seventy-three patients were included: 31 (42.5%) in HVPE-group and 42 (57.5%) in non-HVPE group. There were 74% of female, with a median age of 41 years. Admission severity scores were similar in the 2 groups (SOFA score: 7 in both groups, IGS-2: 42.5 in HVPE group and 45 in non-HVPE group, ns). The proportion of patients requiring mechanical ventilation, or vasopressors, were similar (51.6% and 45, 2% in the HVPE group and 40.5% and 42, 9% in the non-HVPE group, respectively, p = ns). Patients in the HVPE group received a median of two sessions. Thirty-two (76.2%) patients out of 42 in the non-HVPE group had renal replacement therapy. At admission ALAT, INR, bilirubin, were similar in the 2 groups (4825 UI/L, 6.69, 3.7 mg/L in the HVPE group vs 4507 UI/L, 5.81, 3.8 mg/L in the non-HVPE group respectively, p = ns), as well as creatinine and lactate levels (1.01 mg/L and 5.4 mmol/L vs 1.51 mg/L and 7.85 mmol/L, p = ns). Arterial ammonia was significantly lower in the HVPE group (95.5 vs.190 μmol/L, p < 0.0001). One (3.2%) of 31 patients was transplanted in the HVPE group, compared with 17 (40.5%) of 42 patients in the non-HVPE group. Five (16.1%) patients died at day 28 in the HVPE group, versus 18 (42.9%) patients in the non-HVPE group (p = 0.012). In the HVPE group, none of the 5 deceased patients received LT, in the non-HVPE group 15 patients died prior to LT and 3 after (at day 1 or 2 post LT). 28-day transplant-free survival was significantly higher in the HVPE group (80, 7% vs 23.8%, p < 0.0001), as well as overall survival (83.9% vs 57.1%, p = 0.002). Lactate level at admission and the use of HVPE were significantly associated with both transplant-free and overall survival in a multivariate analysis.
Conclusion: This study suggests that in patients with P-ALF meeting the KCH criteria, the use of HVPE may improve transplant-free and

overall survival. Whether HVPE is an alternative to LT or serves as a bridge to LT remains to be evaluated in larger populations.

SAT-316

β-adrenergic drive impairs small intestinal gut-vascular barrier (GVB): mechanism involved in gut-vascular-barrier dysfunction in acute-on-chronic liver failure (ACLF)

Marco Felber[1,2], Tim Wolfisberg[1,2], Lorena Wyss[1,2], Sheida Moghadamrad[3], Oriol Juanola[3], Andrea De Gottardi[3], Reiner Wiest[1]. *[1]Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [2]Department for BioMedical Research, Visceral Surgery and Medicine, University of Bern, Bern, Switzerland; [3]Laboratories for Translational Research, Ente Ospedaliero Cantonale and Faculty of Biomedical Science, Università della Svizzera italiana, Lugano, Switzerland*
Email: marco.felber@unibe.ch

Background and aims: Acute on chronic liver failure (ACLF) is often characterized by precipitating events of which pathological bacterial translocation (BT) from the gut and/or bacterial infections have been proposed to be of particular pathophysiological relevance. In ACLF i) excessive adrenergic drive has been shown by markedly increased serum levels of norepinephrine (Jalan et al. (2015) *Liver international*) and ii) non-selective beta-blocker therapy appears to improve short-term mortality (Mookerjee et al. (2016) *Journal of Hepatology*). The gut-vascular-barrier (GVB) is fundamental for limiting access of pathological BT to the gut-liver-axis but has not been addressed as for changes induced by adrenergic drive and/or ACLF.Thus, we aimed to characterize the small intestinal GVB in terms of function, structure and integrity in dependency on beta-adrenergic stimulation, blockade (by propranolol) and/or presence of liver cirrhosis and ACLF.
Method: ACLF was induced in C57Bl/6 cirrhotic mice (bile-duct-ligation) via LPS i.p. and beta-adrenergic hyperactivity was induced by chronic intraperitoneal delivery of isoproterenol (by osmotic mini pump) for 7 days. Duodenal GVB-function was determined in-vivo by confocal laser endomicroscopy assessing extravasation of FITC-albumin. Endothelial intercellular junctions (VE-cadherin, claudin-5) were evaluated in duodenal tissues by immunofluorescence. To evaluate the direct effects of beta-adrenergic hyperstimulation on murine vascular endothelial cells (MIVECs), we performed transwell-permeability-assays for FITC-albumin.
Results: Chronic beta-adrenergic hyperstimulation caused pathological increases in FITC-albumin extravasation into the duodenal lamina propria being even more pronounced in cirrhotic and ACLF mice. Moreover, propranolol-treatment ameliorated FITC-albumin-extravasation in ACLF mice. Changes in GVB-function induced by beta-adrenergic stimulation were associated with significant reductions in VE-cadherin and claudin-5 in duodenal capillaries and disrupted murine vascular endothelial cell monolayer in in-vitro.
Conclusion: Beta-adrenergic hyperstimulation modulates intercellular junctions impairing vascular barrier integrity and function of small intestinal GVB. This GVB-dysfunction may be a leading cause of pathological loss of albumin as well as pathological BT fueling the gut-liver-axis in ACLF.

SAT-317

Assessment of liver fibrosis in patients taking Methotrexate: long-term outcomes and changes in measurements over time

Lucy O'Reilly[1], Robert Greig[1], Stephen Barclay[1], Ewan H. Forrest[2]. *[1]Glasgow Royal Infirmary, Glasgow, United Kingdom; [2]Glasgow Royal Infirmary, University of Glasgow, Glasgow, United Kingdom*
Email: loreilly24@gmail.com

Background and aims: Methotrexate is used to treat a variety of inflammatory diseases, particularly inflammatory arthritis and psoriasis. Despite its effectiveness, there have been concerns about the risk of liver fibrosis, although the relationship has been poorly understood. Recently there has been greater acknowledgement of the importance of metabolic dysfunction risk factors. In this context we have reviewed our use of FibroScan for Liver Stiffness Measurement (LSM) in patients prescribed Methotrexate over 12 years.
Method: This was a retrospective, single-centre study. Patients on Methotrexate referred to our Liver Service with suspicion of liver injury were identified from FibroScan studies. Data was collated between October 2008 and December 2020. LSM was categorised as <8 kPa, 8–12 kPa and >12 kPa with regards to risk of subsequent liver related events. From the laboratory data, the AST-to-ALT ratio, APRI and FIB-4 index were calculated and P3NP value, if available, recorded. A reliable FibroScan was defined as an IQR percentage of median LSM ≤30%, or >30% if LSM <7.1 kPa as previously described.
Results: 369 LSMs were obtained, of which 325 (88.1%) were reliable. The most common indication for Methotrexate was psoriasis (68.9%). The Medium probe was used in 180 scans (61.8%). Overall, abnormal LSM (>8 kPa) were seen in 25.8% with just 10.8% having high risk scores >12 kPa. On logistic regression analysis diagnosis of diabetes ($p < 0.0001$ (6.21; 2.58, 14.96)), use of the XL probe ($p = 0.006$ (3.76; 1.46, 9.6)) and FIB-4 index $p = 0.0004$ (2.52; 1.51, 4.21)) were related to a LSM >12 kPa. In total there were 44 deaths (15.9%) after a median follow-up of 2767 (2536, 3011) days from their index assessment. Two of these deaths were liver-related (following decompensation with ascites) and both of these patients had a LSM >12 kPa. The 33 patients with a LSM >12 kPa had a median follow-up of 3509 (2672, 3954) days. Of these patients there were just 3 (9.1%) who experienced liver related events: the 2 deaths as above and 1 patient with bleeding from portal hypertensive gastropathy. Forty eight patients had more than 1 LSM: median time interval between scans was 726 (623, 817) days. The median change in LSM −0.3 (−0.7, 0.3) and change in FIB-4 +0.04 (−0.08, 0.08). Sixteen patients changed LSM category: 7 to a lower and 9 to a higher category. 1 patient progressed to LSM >12 kPa.
Conclusion: Liver-related events are rare in patients taking Methotrexate and occurred only in those with a baseline LSM >12 kPa. FIB-4 index and markers of metabolic dysfunction (diabetes and XL probe use) were related to high LSM values. Clinically significant change in LSM on interval scanning after a median of 2 years was rare.

SAT-318

Evaluating the life-saving potential of liver transplantation for acute-on-chronic liver failure with circulatory failure: an observational cohort study

Jinjin Luo[1], Peng Li[1,2], Meiqian Hu[1], Xi Liang[3], Jiaojiao Xin[1], Jing Jiang[1], Dongyan Shi[1], Huazhong Chen[4], Jinjun Chen[5], Yu Chen[6], Jun Li[1]. *[1]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [2]Department of Gastroenterology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [3]Precision Medicine Center, Taizhou Central Hospital (Taizhou University Hospital), Taizhou, China; [4]Department of Infection Diseases, Taizhou Hospital of Zhejiang Province Affiliated to Wenzhou Medical University, Linhai, China; [5]Hepatology Unit, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China; [6]Beijing Municipal Key Laboratory of Liver Failure and Artificial Liver Treatment Research, Fourth Department of Liver Disease, Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: lijun2009@zju.edu.cn

Background and aims: Circulatory failure (CF) is a severe type of extrahepatic organ failure in acute-on-chronic liver failure (ACLF), but its clinical characteristics and outcomes were undefined. This study aimed to clarify the clinical characteristics and survival benefit of liver transplantation (LT) in hepatitis B virus-related ACLF (HBV-ACLF) patients with CF.

Method: Data from 2247 hospitalized HBV-ACLF patients, with and without CF, were enrolled from the Chinese Group on the Study of Severe Hepatitis B open cohort to assess the survival benefit of LT by propensity score matching (PSM) analysis and stratification analysis.
Results: Among all patients, 222 individuals were diagnosed with CF, while 2025 did not exhibit CF. Patients with CF were older, had worse laboratory indicators, and had higher higher proportions of cirrhosis and complications, more frequent multiorgan failures and mortality (28/90/360-day: 93.6%/95.2%/95.7% vs. 26.9%/37.7%/43.1%, $p < 0.001$) than those without CF. Age, white blood cell counts, and international normalized ratio (INR) were identified as independent risk factors for the onset of CF during hospitalization. HBV-ACLF patients with CF who underwent LT exhibited significantly improved survival rates compared to those without transplantation (28-/90-/360-day: 62.9%/54.3%/54.3% vs. 6.4%/4.8%/4.8%, $p < 0.001$), supported by PSM analysis (28-/90-/360-day: 62.9%/54.3%/54.3% vs. 7.1%/7.1%/7.1%, $p < 0.001$). Furthermore, stratification analysis showed that CF patients with an INR <3.5 had a higher 360-day post-LT survival rate.
Conclusion: HBV-ACLF patients with CF exhibited a poor prognosis, and LT significantly improved their survival. Patients with INR <3.5 had a higher survival benefit from LT. These findings could provide evidence for the appropriateness and limitations of LT in ACLF patients with CF and help refine candidate selection for LT in clinical practice.

Email: a-tanaka@med.teikyo-u.ac.jp

Background and aims: The diagnosis of drug-induced liver injury (DILI) is very challenging, because there is no highly sensitive and specific biomarker or pathological findings for the diagnosis. In Japan, a scoring system based on RUCAM was developed in 2004, but it has not been revised since then. In 2022, a revised electronic version of RUCAM (RECAM) was reported based on the American and Spanish DILI databases. In this study, we validated the RECAM using Japanese DILI database and aimed to develop a Japanese version of the RECAM.
Method: Clinical information on Japanese patients with DILI were retrospectively collected from 5 centers. The diagnosis of DILI was made by expert's causality decision in each center. We collected the clinical information required for validation of RECAM, included suspected drug, time from taking or discontinuing suspected drug to onset of liver injury, liver function test values at onset (AST, ALT, ALP, GGT), dechallenge or washout, and information to exclude alternative diagnosis for liver injury, such as hepatitis virus markers, autoantibodies, imaging results, and alcohol intake. The obtained clinical information was then used to score each case using RECAM to examine the likelihood of DILI for each case. Finally, we investigated the factors contributing to instances where scores were low, leading to a determination of "possible" or "unlikely" with RECAM.
Results: We collected 533 patients with DILI in Japan, and the scoring using RECAM revealed that the median score was 2 [range −16–13] and the categorization into highly probable (≥8), probable (4–7), possible (−3–3), and unlikely (≤−4) yielded 53 (10%), 146 (27%), 254 (48%), and 80 (15%) cases, respectively. The combined percentage of highly probable + probable was only 37%, indicating a low concordance rate with the experts' diagnosis. Upon investigating the reasons for low scores, it was observed that the primary cause of low scores was due to the deduction with missing hepatitis virus markers, such as anti-HBc IgM, which was not measured in cases with negative HBs antigen, or anti-HEV IgM; anti-HEV IgA is used in Japan instead. Deductions related to other domains were minimal. Since it is unlikely that deductions related to missing hepatitis virus markers will be issues in prospective applications of RECAM, we decided to re-score without deductions related to hepatitis virus markers. At this time, the median score increased to 7 [range −13–15]. The categorization into highly probable, probable, possible, and unlikely resulted in 197 (37%), 216 (41%), 106 (20%), and 14 (3%) cases, respectively, with a combined percentage of highly probable + probable reaching 78%.
Conclusion: By modifying the scoring related to viral hepatitis markers, RECAM has demonstrated improved alignment with the DILI diagnosis by Japanese experts. We hereby announce the modified Japanese version as RECAM-J 2023.

SAT-320

Early diagnosis and treatment with Terlipressin for adults with hepatorenal syndrome improves clinical outcomes and reduces healthcare resource utilization

Juan F. Gallegos-Orozco[1], Jacqueline G. O'Leary[2], Gautham Reddy[3], Khurram Jamil[4], Jas Bindra[5], Ishveen Chopra[6], John Niewoehner[4], Xingyue Huang[4]. *[1]University of Utah, Salt Lake City, Utah, United States; [2]Dallas Veteran Affairs Medical Center, Dallas, Texas, United States; [3]University of Chicago Medicine, Chicago, Illinois, United States; [4]Mallinckrodt Pharmaceuticals, Bridgewater, New Jersey, United States; [5]Falcon Research Group, North Potomac, Maryland, United States; [6]Manticore Consultancy, Bethesda, Maryland, United States*
Email: juan.gallegos@hsc.utah.edu

Background and aims: Hepatorenal syndrome (HRS) is a potentially reversible form of acute kidney injury. A recent analysis of 3 North American clinical trials showed that patients with lower serum creatinine (SCr) levels at diagnosis derived greater benefit from terlipressin (TERLIVAZ®), emphasizing the importance of early identification and treatment of HRS. Terlipressin is currently the only Food and Drug Administration-approved medication to treat HRS in adults. This study evaluated the potential impact of a national strategy for earlier HRS diagnosis and terlipressin treatment in the United States (US).
Method: A decision-analytic model was developed to compare various scenarios, assessing the distribution of patients across 3 different SCr groups at the time of HRS diagnosis (Curry et al, 2023). Under the current clinical practice scenario, patients were grouped by SCr level based on the CONFIRM trial data (<3 mg/dL: 45%; ≥3 to <5 mg/dL: 55%). Under the early diagnosis and treatment scenario,

the distribution of patients was assumed (<3 mg/dL: 85%; ≥3 to <5 mg/dL: 15%) based on the results of an HRS medical chart review study from the United Kingdom. The model only assessed terlipressin on-label treatment, hence patients with SCr ≥5 mg/dL or grade 3 acute-on-chronic liver failure (ACLF) were excluded. Terlipressin HRS reversal rate for the on-label population (SCr <5 mg/dL and ACLF grade 0 to 2), 52.2% and 33.3% for SCr <3 mg/dL and ≥3 to <5 mg/dL, respectively were generated from the CONFIRM trial. The annual HRS incidence of 50, 000 was used to assess the impact of the early diagnosis and treatment strategy. The incremental benefit was calculated based on the difference between the scenarios multiplied by the 40, 000 patients (based on the label).

Results: Earlier HRS diagnosis and treatment with terlipressin yields 3, 040 greater HRS reversals compared with the current clinical practice. Consequently, this early treatment strategy results in 1200 more patients with 90-day survival without transplant and 960 fewer patients with renal replacement therapy rate during hospitalization compared with the current clinical practice. This strategy also leads to fewer intensive care unit (ICU) days and a shorter overall length of hospitalization. Further, a reduction in hospitalization, including ICU stay, results in $11, 504 savings/cost offset per person and total annual national savings of $460.2 million in the US (2023 US dollars).

Conclusion: Earlier HRS diagnosis and treatment with terlipressin shows improved clinical outcomes including transplant-free survival and reduced healthcare resource utilization compared to the current clinical practice.

SAT-321

A nationwide, multi-center, prospective study of drug-induced liver injury in mainland China

Yan Wang[1], Mengmeng Zhang[1], Yao Meng[1], Tiantian Guo[1], Zikun Ma[1], Yun Zhu[2], Zhengsheng Zou[2], Fangcheng Zhao[3], Juan Li[4], Xiaoju Liu[5], Liuyi Chang[6], Rongkuan Li[7], Xinyan Zhao[1]. *[1]Liver Research Center, Beijing Friendship Hospital, Key Laboratory on Translational Medicine on Cirrhosis, National Clinical Research Center for Digestive Disease, Capital Medical University, Beijing, China; [2]The Fifth Medical Center of PLA General Hospital, Beijing, China; [3]The Second Affiliated Hospital of Dalian Medical University, Beijing, China; [4]Qinghai Provincial People's Hospital, Qinghai, China; [5]The First People's Hospital of Qinzhou, Qinzhou, China; [6]Shanxi Yuncheng Central Hospital, Shanxi, China; [7]The Second Affiliated Hospital of Dalian Medical University, Dalian, China*
Email: zhao_xinyan@ccmu.edu.cn

Background and aims: A majority of studies have reported the clinical characteristics and outcomes of drug-induced liver injury (DILI), which originated from retrospective DILI cohorts in China. No nationwide prospective study of DILI has been reported yet. Since June 2022, we commenced a nationwide, multi-center, prospective study (NCT05060289) to better understand the nature of DILI in China.

Method: DILI patients hospitalized in the eight clinical centers, located in the north, south, east, and west of mainland China were enrolled. Eligible patients were those meeting the diagnostic criteria of DILI with a RUCAM higher than three points with an acute clinical course (<three months since onset). Competing etiologies of liver injury were all excluded.They were followed up to either normalization of liver biochemical tests or appearance of outcome events (chronicity, acute liver failure, and death/liver transplantation). Demographic, labratory, disease severity, liver pathology (if any), and prognostic data were collected.

Results: A total of 130 patients were enrolled with 88 (67.7%) females and the median age was 53 (42, 63) years old. 54.6% were attributed to herbal and dietary supplements (HDS) and 22.3% were associated with conventional agents and 22.3% with combination of HDS and conventional agents. The median latency was 20 (7, 40) days. Most of the cases were hepatocellular injury type 103 (79.2%), the mixed type was 12 (9.2%) and the cholestatic type was 15 (11.5%).The alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were significantly stepwised decrease along with hepatocellular, mixed, and cholestatic group (ALT: 1037.0 (694.0, 1483.6), 345.0 (185.0, 429.0), 111.0 (89.3, 160.7), $p < 0.001$; AST: 709.0 (363.0, 975.4), 204.0 (145.0, 306.0), 93.5 (56.8, 202.0), $p < 0.001$). Mild, moderate and sever liver injury occurred in 49 (37.6%), 77 (59.2%) and 4 patients (3.1%), respectively. Liver biopsy was completed in 25 patients (19.2%) and cholestatic hepatitis [11/25 (44%)] and acute hepatitis [9/25 (36%)] were the top two common pathological patterns. Significantly more patients with hepatocellular injury type had liver chemistries normalization [85/103 (75%) vs. 9/12 (75%) vs. 8/15 (53.3%), $p = 0.171$]. Two patients with hepatocelluar injury type died of liver fairlure.

Conclusion: This is the first nationwide, multi-center, prospective DILI study in mainland China. HDS were the leading cause of DILI, accounting for about half of the cases. Patients with hepatocellular injury type have more proportion of liver normalization.

SAT-322

Longitudinal single-cell transcriptomics analyses reveal distinct peripheral immune characteristics linked to ACLF progression

Xi Liang[1,2], Qian Zhou[1], Jinjin Luo[1], Jiaqi Li[1], Jun Li[1]. *[1]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [2]Precision Medicine Center, Taizhou Central Hospital (Taizhou University Hospital), Taizhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) is a life-threatening syndrome involving dysfunction in multiple immune cells. This study aims to comprehensively depict the dynamic immune responses along the progression of ACLF.

Method: We conducted single-cell RNA-sequencing (scRNA-seq) of 45 samples from 32 subjects using peripheral blood mononuclear cells (PBMCs). Among the subjects, 17 hospitalized hepatitis B virus-related ACLF and early stage non-ACLF patients were included to exhibit a progressive, stable or recovering course of ACLF. Bulk RNA-Seq, flow cytometry and histological assays were employed for external validation.

Results: The scRNA-seq identified forty-one immune cell clusters, including 4 low-density neutrophil clusters, revealing cell-type-specific changes in ACLF progression. FCGR4B+-neutrophil with hyper-inflammatory phenotype and CD163+-macrophage emerged as pivotal in progressive ACLF, especially in the end stage. Enhanced CD39 and IL10 signaling have been identified, showing an anti-inflammation effect in the end stage of ACLF. A significant reduction in highly activated cytotoxic T cells, including GZMK+CD4+- and GZMK+-COTL1+-CD8+- T cells, was correlated with disease severity. Cellular interferon response and antigen presentation process gradually decreased with the progression of ACLF. The patients were stratified into six subtypes with specific features, significantly associated with ACLF outcome. External validation confirmed the specificity of cell cluster signatures in ACLF progression.

Conclusion: Our comprehensive immune profiling reveals dynamic changes in the innate and adaptive immune responses in progressive ACLF, highlights anti-inflammatory role of macrophage and provides diverse immune subtypes for ACLF stratified medicine.

SAT-323

Establishing a predictive nomogram for 21-day transplant-free survival in drug-induced liver failure

Mengyu Tao[1], Xiaoping Wu[1], Zhilong Wen[2], Jiwei Fu[1], Wentao Zhu[1]. [1]*The First Affiliated Hospital of Nanchang University, National Medical Center for Infectious Diseases, Nanchang, China;* [2]*The First Affiliated Hospital of Gannan Medical University, Ganzhou, China*
Email: wuxiaoping2823@aliyun.com

Background and aims: The high prevalence of drug-induced liver failure (DILF) have drawn great attention from clinicians.
Method: 202 DILF patients were enrolled between January 2016–December 2022, and were followed up from DILF diagnosis to death, liver transplantation, or 91 days afterward, whichever came first. The primary end point, though, was 21-day TFS. Clinical data was collected from all patients, and independent risk factors associated with death/liver transplantation was identified using both uni- and multi-variate Cox regression analyses.
Results: Independent risk factors incorporated into the predictive nomogram are neutrophils (HR = 1.148, 95% CI = 1.048–1.257), prothrombin time (HR = 1.048, 95% CI = 1.017–1.080), albumin (HR = 0.880, 95% CI = 0.823–0.941), acute kidney injury (HR = 2.487, 95% CI = 1.134–5.452), and hepatic encephalopathy (HR = 3.378, 95% CI = 1.744–6.543). The resulting nomogram was highly predictive, with an area under the curve of 0.947 for 21-day TFS.
Conclusion: Compared to existing models, such as the Model for End-Stage Liver Disease score, the predictive nomogram is more accurate, only requires easily-measurable clinical and laboratory metrics, as well as being able to directly calculate TFS at various time points.

SAT-324

Efficacy of magnesium isoglycyrrhizinate in patients with immune checkpoint inhibitor-related hepatotoxicity

Yang Zhi[1], Yinuo Dong[1], Yimin Mao[1]. [1]*Division of Gastroenterology and Hepatology, Renji Hospital, Shanghai Jiaotong University School of Medicine, NHC Key Laboratory of Digestive Diseases, Shanghai, China*
Email: maoym11968@163.com

Background and aims: Liver injury significantly impacts the continuity of antineoplastic therapy, and even leads to drug discontinuation in patients receiving immune checkpoint inhibitors (ICIs). Currently available management for ICI-related hepatotoxicity (IRH) is limited including glucocorticoids (GC) and certain immunosuppressants. In this study, we explore the efficacy of magnesium isoglycyrrhizinate (MgIG), a therapeutic agent previously proven to be safe and effective in acute drug-induced liver injury (DILI), in patients with IRH.
Method: We conducted a 3-year, retrospective, multicenter, electronic medical record-based real-world study to evaluate the efficacy of MgIG compared to GC in patients with IRH. Patients above 18 years old who received only MgIG or GC after IRH episode with liver biochemistry fulfilling the International DILI Expert Working Group criteria for DILI were included. Liver injury due to other competitive etiologies were excluded based on differential diagnosis by investigators. Propensity score matching (PSM) was used to match age, sex, and baseline alanine aminotransferase (ALT) between groups. The primary end point is the change of ALT from baseline 10 days after treatment. Secondary end points include change of aspartate aminotransferase (AST), alkaline phosphatase (ALP), and total bilirubin (Tbil) from baseline at day 10; change of liver biochemistry before discharge; normalization rate and the proportion of patients with >50% reduction of liver biochemistry 10 days after treatment and before discharge.
Results: From December 2019 to December 2022, a total of 504 cases were included, among which 358 received only MgIG and 146 received only GC. After PSM in a 2:1 ratio, these cases were divided into MgIG group (n = 260) and GC group (n = 130). In MgIG group, the change of ALT (−142.56 vs. −131.95 p = 0.047) was more remarkable compared to GC group 10 days after treatment, as well as AST (−255.86 vs. −178.64, p = 0.013). The proportion of patients with >50% reduction in ALT (60% vs. 46.92%, p = 0.014) and AST (55.38% vs. 50%, p = 0.046) were higher compared to GC group 10 days after treatment. Before discharge, a higher proportion of patients with >50% reduction in ALT (65.77% vs. 50.77%, p = 0.004), AST (61.15% vs. 53.08%, p = 0.008), and Tbil (32.69% vs. 20.77%, p = 0.014) were observed in the MgIG group. Moreover, MgIG achieved a greater change in AST (−264.51 vs. −166.91, p = 0.008) and higher normalization rate in ALP (30% vs. 15.38%, p = 0.025) before discharge.
Conclusion: The study provided preliminary evidence that MgIG improves recovery of liver injury in IRH with possibly better efficacy than GC. Further rigorous studies are warranted to support the use of MgIG in IRH.

Email: pocurull@recerca.clinic.cat

Background and aims: Drug-induced liver injury (DILI) represents a diagnostic challenge for both general practitioners (GPs) and hepatologists. Its estimated incidence ranges between 5 and 20 cases per 100, 000 persons/year. Since prospective studies assessing DILI in the primary care setting are scarce, our study aimed to assess its incidence, causes and outcomes among patients attending three primary healthcare centers in Barcelona.
Method: This prospective study involved three primary care centres attending a population of 100, 600 residents. An automated system was designed to trigger an alert whenever a patient undergoing a blood test (including liver function assessment), met one of diagnostic DILI criteria: 1) ALT >5 ULN (upper limit of normal), 2) ALp >2 ULN, or 3) ALT >3 ULN and total bilirubin (TB) >2 ULN. We excluded other potential causes of abnormal liver function. The study started in August 2022 and is scheduled to conclude in July 2024.
Results: During the initial 18 months, a total of 88 patients met the specified analytical criteria: 37 (42%) ALT >5 ULN, 47 (53%) ALp >2 ULN, and 4 (5%) ALT >3 ULN and TB >2 ULN. Among these patients, half (52%) were male, with a median age of 61 years (IQR 39–82). DILI was confirmed in 10 cases, with an estimated incidence of 7 cases per 100, 000 habitants/year (95%CI 1.5–11.8). Implicated drugs included metamizole (2), atorvastatin (2), diclofenac (1), ibuprofen (1), oral contraceptives (1), and metamizole plus diclofenac (1). Energetic protein supplements were implicated in the remaining 2 cases. All patients were managed by their GPs and subsequent analyses returned to normal after discontinuation of the respective drug or supplement.Among the 37 patients with ALT >5 ULN, the most prevalent diagnoses were DILI (8; 22%) and infectious mononucleosis (7; 19%). Among patients with ALp >2 ULN the most common diagnoses were cancer involving the liver (12; 26%), heart failure (7; 15%), and primary biliary cholangitis (4; 47%). Notably, only 1 patient (2%) received a diagnosis of DILI in this group. Among those with ALT >3 ULN and TB >2 ULN, one individual (25%) had DILI. Thus, the positive predictive value for diagnosis of DILI was acceptable for patients with hepatocellular or mixed patterns (22% and 25%, respectively) and very low for cholestatic pattern (2%).
Conclusion: The incidence of DILI in primary care is low, but GPs should consider this diagnosis if ALT are significantly elevated (>5 ULN). Pain killers, statins and dietary supplements are among

the most common causes. Outcomes are good and liver test normalization is the rule after drug interruption.

SAT-326

Immune-mediated liver injury induced by PD-1/PD-L1 checkpoint inhibitors is different from idiosyncratic drug-induced liver injury

Yan Wang[1], Yao Meng[1], Mengmeng Zhang[1], Tiantian Guo[1], Wei Chen[1], Liwei Liu[2], Xinyan Zhao[1]. [1]*Liver Research Center, Beijing Friendship Hospital, Key Laboratory on Translational Medicine on Cirrhosis, National Clinical Research Center for Digestive Disease, Capital Medical University, Beijing, China;* [2]*Fourth Department of Liver Disease (Difficult and Complicated Liver Diseases and Artificial Liver Center), Beijing You'an Hospital, Capital Medical University, Beijing, China*
Email: zhao_xinyan@ccmu.edu.cn

Background and aims: Immune-mediated liver injury induced by immune checkpoint inhibitors (ILICI) has been reported in recent years. However, ILICI differs from idiosyncratic drug-induced liver injury (iDILI) in various aspects. In this study, we aimed to study the differences of clinical characteristics between ILICI induced by PD-1/PD-L1 inhibitors and iDILI.
Method: Data of ILICI and iDILI patients from January 2016 to December 2022 at Beijing Friendship Hospital were retrospectively collected. The clinical and laboratory data were collected and compared between the two groups. Patterns of injury were defined according to the R value.
Results: A total of 66 cases of ILICI and 316 cases of iDILI were included in this study. The ILICI group exhibited a significantly higher age compared to the iDILI group [65 (57, 70) vs. 56 (46, 64) years old, $p < 0.001$] and a lower proportion of females [17 (25.8%) vs. 254 (80.4%), $p < 0.001$]. Among the ILICI group, 18 (27.3%) cases had no available ALP at the time of onset, resulting in the absence of the R value. Among the remaining 48 cases, a higher proportion of patients were classified as cholestatic and mixed [39 (59.1%) vs. 93 (29.4%), $p < 0.001$], while a lower proportion were categorized as hepatocellular [9 (13.6%) vs. 223 (70.6%), $p < 0.001$] than that in the iDILI group. The alanine aminotransferase (ALT) and aspartate aminotransferase (AST) in the ILICI group were significantly lower compared to iDILI group at peak levels [ALT: 125.0 (75.8, 231.0) vs. 635.0 (340.8, 1087.0) U/L, $p < 0.001$; AST: 132.9 (85.1, 296.3) vs. 476.0 (221.5, 820.5) U/L, $p < 0.001$]. The serum immunoglobulin G levels were similar between the ILICI and iDILI group [1220.0 (972.5, 1435.0) vs. 1350.0 (1100.0, 1612.5) mg/dL, $p = 0.078$].
Conclusion: The ILICI demonstrates distinct clinical characteristics that differ from iDILI, with a higher prevalence of older individuals and males in the ILICI group. Additionally, ILICI tends to present as cholestatic and mixed liver injury, in contrast to iDILI. Notably, there was no difference in the levels of serum immunoglobulin G between the two groups.

SAT-327

The combination of s-ademethionine with Bifidobacterium infantis 35624 inhibits oxidative stress as a risk factor for cytostatic-induced liver injury

Igor Skrypnyk[1], Ganna Maslova[1], Roman Skrypnyk[1]. [1]*Poltava State Medical University, Poltava, Ukraine*
Email: inskrypnyk@gmail.com

Background and aims: The conduction of chemotherapy (CT) in patients with chronic lymphoproliferative disorders (CLPD) is associated with oxidative stress which is considered a key pathogenic mechanism of cytostatic-induced liver injury.
The aim is to investigate the effect of s-ademetionine (s-AMe) in combination with Bifidobacterium infantis 35624 on oxidative stress, as a method of prevention of liver injury in patients with CLPD during CT.
Method: 38 patients with CLPD were examined. 20 (53%)-B-cell Chronic lymphocytic leukemia, 18 (47%)-B-cell Non-Hodgkin lymphoma, 8 (21%) females and 30 (79%) males, age 30–76. Patients received CT according to current guidelines. Patients were divided into groups: I-A (n = 13)-patients with CLPD, who underwent only CT; I-B (n = 12)-patients with CLPD who during CT received s-Ame 1000 mg/day for 30 days, I-C (n = 13)-patients with CLPD who during CT received S-AMe 1000 mg/day and Bifidobacterium infantis 35624 1 capsule/day for 30 days and group II (n = 20) -the control group of practically healthy individuals. Several biochemical markers were determined: the activity of alanine aminotransferase (ALT) and aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma glutamyl transferase (GGT), level of plasma bilirubin and concentration of substances that form a trimethine complex with 2-thiobarbituric acid (TBA).
Results: Preexisted liver function test abnormalities were determined in 38.5% (5/13) patients in group I-A, in 25% (3/12) patients in group I-B and in 38.5% (5/13) patients in group I-C. At the same time in patients of groups I-A and I-B, the concentration of TBA in plasma was in 1.38 (p = 0.0479) and 1.3 times (p = 0.0122) accordingly higher compared to controls. After the 3d course of CT liver function test abnormalities were present more frequently in patients of group I-A compared to group I-B X^2 (1, N = 25) = 9.07 (p = 0.002) and group I-C X^2 (1, N = 26) = 9.90 (p = 0.001). At the same time after the conduction of CT the level of several biochemical markers in group I-A were higher compared to I-B and I-C groups: ALT was higher in 2.1 (p = 0.012) and 2.5 times (p = 0.046) accordingly, AST in 1.74 (p = 0.009) and 2.0 times (p = 0.0037) accordingly, GGT in 2.13 times (p = 0.0195) and in 2.4 times (p = 0, 002), ALP in 1.5 times (p = 0.012) and in 1.3 times (p = 0.0149) accordingly, without reliable changes in the level of bilirubin. Important that in groups I-B and I-C after the conduction of CT the level of TBA was in 1.39 (p = 0.0005) and 1.46 times (p = 0.0002) accordingly lower compared to group I-A.
Conclusion: The infusion of s-AMe and the combination of s-AMe with Bifidobacterium infantis 35624 during CT in patients with CLPD provides inhibition of oxidative stress that can prevent abnormalities in liver function.

SAT-330

Depressed TFAM promotes acetaminophen-induced hepatotoxicity regulated by DDX3X- PGC1α-NRF2 signaling pathway

Sisi Chen[1], Qin Ouyang[1], Mei Liu[2], Feng Ren[2], Jian Huang[1]. [1]*Beijing Friendship Hospital, Capital Medical University, Beijing, China;* [2]*Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: thoughtfmu@163.com

Background and aims: Acetaminophen-induced acute liver injury (AILI) is the most prevalent cause of acute liver failure in developed countries and mitochondrial dysfunction plays a dominant role in the pathogenesis of AILI. Mitochondrial transcription factor A (TFAM) is an important marker for maintaining mitochondrial functional homeostasis and also helps to maintain the integrity of mitochondrial DNA (mtDNA), while its possible functions in AILI are unclear. This study aimed to investigate the function of TFAM and its regulatory molecular mechanism in the progression of AILI.
Method: TFAM was detected in the liver of AILI patients and mouse models. The role of TFAM and DEAD (Asp-Glu-Ala-Asp) box polypeptide 3 X-linked (DDX3X) in AILI was determined in mouse and cellular models with TFAM overexpression or DDX3X knockdown, respectively.
Results: TFAM expression is suppressed in the liver of AILI patients and mtDNA levels are increased in serum. Overexpression of TFAM alleviates the liver necrosis, activated inflammatory and apoptotic responses, and mitochondrial dysfunction caused by APAP overdose. Treatment of the AILI mouse model with N-acetylcysteine (NAC), a drug used to treat APAP overdose, resulted in significant activation of TFAM. In vivo experiments confirmed that TFAM expression was negatively regulated by DDX3X. Knockdown of TFAM superseded the protective effect of DDX3X knockdown on APAP overdose induced

liver injury. Mechanistic studies showed that nuclear respiratory factor 2 (NRF-2), a key regulator of TFAM, was selectively activated after DDX3X knockdown via activated peroxisome proliferator-activated receptor γ coactivator 1 (PGC-1α), both in vivo and in vitro experiments.
Conclusion: This study demonstrates that depressed hepatic TFAM plays a key role in the pathogenesis of AILI, which is regulated by DDX3X- PGC1α-NRF2 signaling pathway.

SAT-331
Anticancer drugs are the first cause of drug-induced liver injury in the REFHEPS network
Lucy Meunier[1], Eleonora De Martin[2], Bénédicte Delire[3], Fanny Lebosse[4], Amel Zahhaf[1], Dominique Larrey[5], Yves Horsmans[6]. *[1]CHU Montpellier, Montpellier, France; [2]Centre Hepato Biliaire, Villejuif, France; [3]Saint Luc Hospital, Bruxelles, Belgium; [4]Hopital Croix Rousse, Lyon, France; [5]CHU Montpellier, Montpellier; [6]Hopital Saint Luc, Bruxelles, Belgium*
Email: lucy-meunier@chu-montpellier.fr

Background and aims: Drug hepatotoxicity is the main cause of drug withdrawals from the market and halted development of new molecules. International hepatotoxicity networks are essential for the emergence of hepatotoxicity data. At the end of 2021, REFHEPS was created to collect hepatotoxicity cases in France and Belgium and provide specialist advice on request. We report data from the first 2 years of the network's existence.
Method: All cases submitted to REFHEPS were analyzed retrospectively by a panel of hepatotoxicity experts. The profile of liver damage (cytolytic, cholestatic or mixed), its severity and the imputability of suspected drugs or other health products were assessed according to recently defined international criteria (RUCAM score and American DILIN method (1–3)).
Results: In 2022 and 2023, 213 cases were submitted to REFHEPS. Four cases were excluded for differential diagnosis, and 36 are currently being adjudicated. A total of 173 cases were analyzed, 116 (67%) with a single implicated drug, 46 (26.6%) with 2 and 11 (6.4%) with 3 or more drugs. The mean age of patients was 55.8 years (95% CI: 53.0–58.5), and the majority were women (n = 106; 63.6%). Drugs causing DILI were antineoplastic (65%), antibiotics (5%), analgesics (7%), herbal and dietary supplement (2%), biotherapy and immunosuppressive drugs (4%), non-steroidal anti-inflammatory drugs (3%) and recreational drugs (1%). In 13% of cases, the drug involved is more unusual. The main category of drugs incriminated were antineoplastic. In this category, the therapeutic classes most frequently found were: immune checkpoint inhibitors (n = 66, 38.2%) and CDK4/6 inhibitors (n = 24, 13.9%).
Conclusion: After 2 years of REFHEPS existence, over 200 cases have been submitted. The majority of cases are related to anticancer drugs. In two-thirds of cases, several drugs are potentially responsible for toxicity. Antineoplastic drugs have become the first cause of DILI in our network, mainly represented by immune checkpoint inhibitors. Some cases are currently being analyzed, and more complete data may be presented at the EASL congress.

Frequency and clinical features of tamoxifen-induced liver injury
Masayuki Ueno[1,2], Takahisa Kayahara[1], Hiroyuki Takabatake[1], Youichi Morimoto[1], Motowo Mizuno[1], Hirokazu Mouri[1]. *[1]Department of Gastroenterology and Hepatology, Kurashiki Central Hospital, Kurashiki, Japan; [2]Department of Gastroenterology and Hepatology, Graduate School of Medicine, Kyoto University, Kyoto, Japan*
Email: masayuki.u.0819@outlook.jp

Background and aims: Tamoxifen (TAM) is the most widely used hormonal treatment for breast cancer, and it is well-known for causing drug-induced steatotic liver disease. However, the clinical manifestation and optimal management of TAM-induced liver injury remain insufficiently understood. Therefore, we aimed to explore the frequency and clinical characteristics of drug-induced liver injury in breast cancer patients receiving TAM treatment.
Method: We retrospectively analyzed 192 breast cancer patients who initiated TAM treatment between January 2008 and December 2017 at our institution. Patients who underwent blood tests and abdominal ultrasonography after receiving TAM for at least one year were included. In this study, liver injury was defined as alanine transaminase (ALT) exceeding twice the upper limit of normal and/or alkaline phosphatase (ALP) exceeding the upper limit.
Results: Among the 192 patients, 191 (99.5%) were female, with a median age of 47 years. The median duration of TAM treatment at the time of the last abdominal ultrasonography was 3.4 years. Pretreatment abdominal ultrasonography was performed in 155 patients, revealing liver steatosis in 83 patients. After TAM treatment, 140 patients (72.9%) exhibited liver steatosis, with ALT elevation in 6 cases, ALP elevation in 3 cases, and both in 3 cases. Two patients (1.0%) showed morphological changes in the liver and splenomegaly, which suggested progression to cirrhosis. Thirteen patients (6.8%) discontinued TAM treatment due to liver injury or severe steatosis. Several years were required to recover from liver steatosis after TAM discontinuation. Among the 72 patients without pre-existing liver steatosis, 32 patients (44.4%) developed liver steatosis after TAM treatment, but no patients showed elevated ALT or ALP.
Conclusion: In patients without pre-existing steatotic liver disease, approximately 40% developed liver steatosis after TAM treatment, but no patients showed significant elevation of ALT or ALP. On the other hand, some patients with pre-existing liver steatosis developed significant liver injury, with two cases progressing to cirrhosis. During TAM treatment, careful monitoring of liver function is needed, especially in patients with pre-existing steatotic liver disease.

SAT-333
Efficacy of magnesium isoglycyrrhizinate as add-on therapy to glucocorticoids in immune checkpoint inhibitor-related hepatotoxicity
Yinuo Dong[1], Yang Zhi[1], Yimin Mao[1]. *[1]Division of Gastroenterology and Hepatology, Renji Hospital, Shanghai Jiaotong University School of Medicine, NHC Key Laboratory of Digestive Diseases, Shanghai, China*
Email: maoym11968@163.com

Background and aims: Immune checkpoint inhibitor (ICI)-related hepatotoxicity (IRH) impedes antineoplastic therapy and often requires glucocorticoids (GC) as treatment. In this study, we explore the efficacy of magnesium isoglycyrrhizinate (MgIG), a therapeutic agent previously proven to be safe and effective in acute drug-induced liver injury (DILI), as add-on therapy to GC in IRH.
Method: We conducted a 3-year, retrospective, multicenter, electronic medical record-based real-world study to evaluate the efficacy of MgIG as add-on therapy to GC compared to GC monotherapy in patients with IRH. Patients above 18 years old who received GC in combination with MgIG or GC monotherapy after IRH episode with liver biochemistry fulfilling the International DILI Expert Working Group criteria for DILI were included. Liver injury due to other competitive etiologies were excluded based on differential diagnosis by investigators. Propensity score matching (PSM) was used to match age, sex, and baseline alanine aminotransferase (ALT) between groups. The primary end point is the change of ALT from baseline

10 days after treatment. Secondary end points include change of aspartate aminotransferase (AST), alkaline phosphatase (ALP), and total bilirubin (Tbil) from baseline at day 10; change of liver biochemistry before discharge; and normalization rate of liver biochemistry 10 days after treatment and before discharge.
Results: From December 2019 to December 2022, a total of 318 cases were identified, among which 172 received GC in combination with MgIG and 146 received only GC. After PSM in a 1:1 ratio, these cases were divided into MgIG + GC group (n = 134) and GC group (n = 134). In MgIG + GC group, the change of ALT (−187.19 vs. −134.27, p = 0.004) was more remarkable compared to GC group 10 days after treatment, as well as AST (−232.94 vs. −180.16, p = 0.028), and Tbil (−16.56 vs. −9.49, p < 0.001). Before discharge, MgIG + GC achieved a higher normalization rate in AST (49.25% vs. 28.36%, p < 0.001), Tbil (49.25% vs. 35.82%, p = 0.026), and ALP (26.12% vs. 16.42%, p = 0.029) compared to GC group. The change in ALT (−196.1 vs −136.86, p = 0.006) and Tbil (−21.68 vs. −9.39, p < 0.001) were also more significant in MgIG + GC group before discharge. There was no statistical difference in the dose of GC or course of treatment after the occurrence of liver injury between two group.
Conclusion: The study provided preliminary evidence that MgIG may aid to improve recovery as add-on therapy to GC in patients with IRH. Further rigorous studies are warranted to explore whether MgIG can partially substitute GC in IRH.

Email: pedica.federica@hsr.it

Background and aims: Patients affected by multiple sclerosis (MS) undergoing disease-modifying therapies (DMTs) may develop liver injury, due to their hepatotoxic potential. Even today, the differential diagnosis between drug-induced liver injury and autoimmune hepatitis remains a challenge. In this study, we report a case series of 8 patients, 3 exposed to methylprednisolone (MTP), 2 undergoing fingolimod therapy and 2 treated with natalizumab. One more patient underwent MTP administration during fingolimod long-standing treatment. We document the pattern of liver disease, diagnosis and consequences on therapy.
Method: From 2015 and 2023, 8 patients with MS (pwMS) underwent liver biopsy because of elevation of liver enzymes during or after DMTs administration. Indices of hepatocellular damage, autoimmune antibodies, viral serology were evaluated and liver biopsies were investigated for all patients.
Results: Six patients were females (75%) and 2 males (25%). Mean age at presentation of liver enzyme elevation was 41 years and mean MS duration was 7.10 years. All patients displayed a relapsing remitting phenotype and median Expanded Disability Status Scale at liver enzyme elevation was 1.5 (interquartile range 1.0–2.0). In 5 of the 8 (62, 5%) patients anti-nucleus autoantibodies (ANA, equal or superior to 1:160) and in 1 of them anti-smooth muscle autoantibodies (ASMA, equal to 1:40) were found and possible autoimmune hepatitis was suspected. No hypergammaglobulinemia was detected. No patients had viral infection. There was no evidence of metabolic and storage liver disease. On liver biopsies, none of the patients had histology consistent with autoimmune hepatitis. PwMS treated with MTP and natalizumab developed severe acute hepatitis, with confluent necrosis. Portal tracts were only mildly affected. Patients on treatment with fingolimod exhibited vascular alterations, resembling porto-sinusoidal vascular disease, with minimal lobular inflammation. The patient undergoing MTP during fingolimod treatment had overlapping features with those administered with MTP.
Conclusion: In all cases, the hepatocellular damage indices returned to the normal range when the aforementioned drugs were discontinued. The results emerged from liver biopsies turned out to be decisive, allowing patients to benefit from the switch to new therapies for MS. This highlights liver biopsy contributes, with clinical and laboratory data, to the management of pwMS with liver injury, avoiding an overdiagnosis of autoimmune hepatitis, which can impact negatively on the follow-up and therapy.

SAT-335

Pathological dynamics and clinical implications of hepatitis in cancer patients undergoing immune checkpoint inhibitor

Ryo Izai[1], Sadahisa Ogasawara[1], Teppei Akatsuka[1], Chihiro Miwa[1], Takuya Yonemoto[1], Sae Yumita[1], Miyuki Nakagawa[1,2], Ryuta Kojima[1], Hiroaki Kanzaki[1], Keisuke Koroki[1], Masanori Inoue[1], Kazufumi Kobayashi[1], Soichiro Kiyono[1], Masato Nakamura[1], Naoya Kanogawa[1], Takayuki Kondo[1], Shingo Nakamoto[1], Mina Komuta[3], Naoya Kato[1]. *[1]Department of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba, Japan; [2]Department of Gastroenterology, Asahi General Hospital, Asahi, Japan; [3]Department of pathology, International University of Health and Welfare, Narita Hospital, Narita, Japan*
Email: izai.ryo@chiba-u.jp

Background and aims: With the widespread use of immune checkpoint inhibitors (ICIs) in cancer therapy, cases of suspected hepatitis as an immune-related adverse event have increased. However, detailed investigations of the clinical course and liver biopsy findings at the onset of hepatitis are limited, especially in patients with coexisting chronic liver diseases such as hepatocellular carcinoma (HCC). Our study investigates the clinical course and pathologic liver biopsy findings during ICI-related hepatitis in our institution, focusing on the changes from ICI initiation to hepatitis onset in HCC patients.
Method: We analyzed the clinicopathologic features of patients treated with ICIs who underwent liver biopsy for suspected ICI-related hepatitis.
Results: The study included 23 patients: 13 with HCC, 4 with renal cell carcinoma, 2 with lung cancer, and one each with malignant melanoma, paranasal sinus cancer, esophageal cancer, and breast cancer. The median time from the start of ICI to the development of hepatitis was 52 days. Eighteen patients had grade 3 or higher hepatitis as indicated by elevated aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), or total bilirubin (T-BIL), with 14 requiring steroid treatment. Pathologic

examination revealed 19 cases (82.6 percent) of hepatitis type, 2 of bile duct type, and 2 of mixed type. In hepatitis type, the inflammation was limited to the lobule in 5 cases, to the pericentral vein in 5 cases, and to both in 9 cases. Among 14 patients with periportal inflammation, 12 had elevated AST/ALT of grade 3 or higher. In HCC patients, comparison of liver biopsies taken before ICI and at the onset of hepatitis provided detailed insights into the progression of inflammation.
Conclusion: ICI-related hepatitis predominantly presents as hepatitis type with lobular or central venous perivascular inflammation. Specifically, 11 patients with central venous perivascular inflammation showed significant AST/ALT elevation requiring steroid therapy. Comparison of liver biopsies before and after ICI treatment in HCC patients was critical for accurate diagnosis and treatment planning.

SAT-336
Monocytes/macrophages imbalance in chronic drug-induced liver injury: potential candidates for disease pathogenesis
Xing-Ran Zhai[1], Zhe-Rui Liu[1], Ya-Wen Lu[2], Shao-Ting Chen[3], Yun Zhu[3], Ying Sun[3], Ang Huang[4], Jia-Bo Wang[2], Zhengsheng Zou[3]. *[1]Peking University 302 Clinical Medical School, Beijing, China; [2]Capital Medical University, Beijing, China; [3]The Fifth Medical Center of PLA General Hospital, Beijing, China; [4]The Fifth Medical Center of PLA General Hospital, The First Medical Center of PLA General Hospital, Beijing, China*
Email: zszou302@163.com

Background and aims: Monocytes/macrophages are core immune cells involved in the initiation, development, progression, and/or resolution of drug-induced liver injury (DILI). However, it is unclear whether monocytes/macrophages are involved in the chronicity of DILI. In this study, we aimed to characterize monocytes/macrophages in chronic DILI and provide a basis for understanding the pathogenesis of DILI chronicity.
Method: This study was conducted according to the ethical guidelines of the 1975 Declaration of Helsinki (6th revision, 2008), and approved by the Ethics Committees of Fifth Medical Center of Chinese PLA General Hospital (No. R2015139DC020). Participating patients provided written consent for both liver biopsy and blood collection during the period of hospitalization. Plasma cytokines related to monocytes/macrophages [interleukin (IL)-12p70, IL-6, and IL-10], immunophenotype of peripheral monocytes and hepatic macrophages were evaluated by flow cytometry and immunofluorescence staining in patients with chronic DILI, acute DILI, and healthy volunteers.
Results: In patients with chronic DILI, plasma levels of IL-12p70 and IL-6 (M1-related cytokines) were significantly increased ($p < 0.01$, $p < 0.05$, respectively), whereas the plasma level of IL-10 (M2-related cytokine) was significantly decreased ($p < 0.01$). The secretion of IL-12 (M1-like marker) was increased ($p < 0.05$), while the secretion of IL-10 (M2-like marker) was decreased ($p < 0.05$) by lipopolysaccharide-stimulated peripheral monocytes in patients with chronic DILI. The expression of CD206 (M2-like marker) on peripheral monocytes was significantly decreased ($p < 0.05$). An increase in CD68 + CD80+ macrophages (M1-like macrophages) and a decrease in CD68 + CD206+ macrophages (M2-like macrophages) was also observed in the liver tissue of chronic DILI.
Conclusion: M2-like monocytes/macrophages are significantly decreased and M1-like monocytes/macrophages are significantly increased in chronic DILI, potentially contributing to the disease pathogenesis. These findings would inspire monocyte/macrophage-based targeted therapies for this challenging disease.

Alcohol-related liver disease and MetALD – Basic

Functional characterization of intrahepatic CD8+ T lymphocytes in patients with severe alcohol-associated hepatitis
Luca Maccioni[1,2], Yukun Guan[1], Yang Wang[1], Dechun Feng[1], George Kunos[3], Bin Gao[1]. *[1]Laboratory of Liver Diseases, National Institute on Alcohol Abuse and Alcoholism (NIAAA), Bethesda, United States; [2]Laboratory of Physiologic Studies, National Institute on Alcohol Abuse and Alcoholism (NIAAA), Bethesda, United States; [3]Laboratory of Physiologic Studies, National Institute on Alcohol Abuse and Alcoholism (NIAAA), Bethesda, United States*
Email: luca.maccioni@nih.gov

Background and aims: Intrahepatic neutrophil and T lymphocyte infiltrations have been associated with severe alcohol-associated hepatitis (SAH). Our previous study identified two SAH phenotypes despite a similar clinical presentation, one with high intrahepatic neutrophils but low numbers of $CD8^+$ T cells ($Neu^{hi}CD8^{lo}$), and one with low neutrophils but high CD8+ T cells ($Neu^{lo}CD8^{hi}$) and explored the neutrophil function in SAH. Interestingly we have previously found that patients with alcohol use disorder have markedly reduced T cells in small intestines. However, the functions of T cells in SAH and the effects of intestinal T cells on SAH remain largely unknown. This translational study aims to characterize the role of T cell infiltration in SAH pathogenesis.
Method: Multiplex immunofluorescence, bulk RNA-Seq and single-cell RNA sequencing were performed in livers from SAH patients. Mechanisms were evaluated using the chronic-plus-binge model.
Results: Multiplex immunofluorescence and transcriptomic analyses confirmed two SAH phenotypes. Strikingly, CD8+ T cells in $Neu^{lo}CD8^{hi}$ positively correlated with degree of cirrhosis and fibrotic gene signatures. Furthermore, single-cell RNA sequencing revealed different specific subpopulations of T cells in patients with SAH. To study specifically the mechanisms of CD8+ T cell infiltration and the role CD8 in the pathogenesis of SAH, wild-type control mice and several strains of genetically modified mice were subjected to the chronic plus-binge alcohol model, and we found that intrahepatic CD8 T cells control neutrophil infiltration and ethanol-induced liver cell apoptosis. We also found that intestinal T cells, but not intrahepatic T cells were markedly reduced in mice with chronic-plus-binge ethanol feeding.
Conclusion: High number of CD8+ T cells infiltrate the liver in SAH patients with underlying cirrhosis. CD8+ T cells control intrahepatic neutrophil infiltration and liver cell death during SAH. Future studies will investigate how the reduced intestinal T cells affects SAH.

Farnesoid X receptor agonist INT-787 protects human liver organoids from alcohol-induced injury
Francesca De Franco[1], Daniela Passeri[1], Sanjay Kansra[2], Luciano Adorini[2], Mary Erickson[2], Roberto Pellicciari[1]. *[1]TES Pharma S. r.l., Perugia, Italy; [2]Intercept Pharmaceuticals, Inc., Morristown, United States*
Email: fdefranco@tespharma.com

Background and aims: Alcohol-associated liver disease (ALD) represents a spectrum of liver injury ranging from steatosis to cirrhosis, and potentially to hepatocellular carcinoma. Activation of the farnesoid X receptor (FXR) has been shown to decrease liver steatosis, inflammation, and fibrosis in multiple animal models and in patients with primary biliary cholangitis or metabolic dysfunction-associated steatohepatitis. We assessed the therapeutic potential of a semisynthetic bile acid analog and potent FXR agonist, INT-787, to

determine its effect on alcohol-induced liver injury using an in vitro human liver organoid model.
Method: Human liver organoids (3D InSight™) were obtained from InSphero and were produced from primary human hepatocytes in co-culture with non-parenchymal cells, including primary human Kupffer cells and primary liver endothelial cells. Organoids were cultured in human liver lean maintenance medium (InSphero). To determine alcohol-induced liver injury and any mitigating effects by INT-787, liver organoids were exposed to 0.5% ethanol (EtOH) or 0.5% EtOH in presence of 0.3 micromolar INT-787 for 96 hours. Steatosis was evaluated using Nile red staining; bead-based multiplex enzyme-linked immunosorbent assay and adenosine triphosphate (ATP) bioluminescence were used to quantify pro-inflammatory cytokines (interleukin-6 [IL-6], tumor necrosis factor [TNF]-alpha) and cell viability, respectively. Expression of genes implicated in inflammation (*COX2*), fibrosis (*TGFB1*), oxidative stress (*CYP2E1*), disruption of bile canaliculi (*MRP2*), and apoptosis (*BAX*) were measured by real-time quantitative reverse transcription polymerase chain reaction. Eight organoids per treatment group were pooled for each assay. Statistical significance was determined using 1-way analysis of variance with Dunnett's multiple comparison test.
Results: EtOH-induced steatosis was significantly reduced in the presence of INT-787 ($p < 0.001$). Treatment with INT-787 also led to decreases in EtOH-dependent IL-6 ($p < 0.001$) and TNF-alpha production ($p < 0.01$). EtOH-induced *COX2*, *TGFB1*, and *CYP2E1* expression was reduced in the presence of INT-787 ($p < 0.001$). Decreased *MRP2* expression with EtOH was inhibited by INT-787 ($p < 0.001$). Treatment with INT-787 significantly mitigated the nearly 50% reduction in cell viability observed with EtOH ($p < 0.01$) and suppressed the EtOH-induced expression of *BAX* ($p < 0.001$).
Conclusion: Human liver organoids exposed to 0.5% EtOH demonstrated alcohol-induced liver injury, providing a reliable in vitro model to study ALD. INT-787 significantly reduced the effects of alcohol-induced liver injury via multiple protective mechanisms, including inhibition of steatosis, inflammation, fibrosis, oxidative stress, and apoptosis. Thus, INT-787 represents a promising molecule for clinical evaluation of ALD treatment.

TOP-328-YI

Single-nucleus RNA sequencing of the liver identifies predictive markers to corticosteroid treatment in patients with severe alcohol-related hepatitis

Lukas Van Melkebeke[1,2], Markus Boesch[1,3,4], Hannelie Korf[1], Tessa Ostyn[5], Dóra Bihary[6,7], Marie Wallays[1], Rita Feio-Azevedo[1], Bram Boeckx[6,7], Lena Smets[1], Ann Reekmans[8], Isabelle Colle[8], Hannah Van Malenstein[2], Halit Topal[9], Joris Jaekers[9], Eveline Claus[10], Lawrence Bonne[10], Geert Maleux[10], Tania Roskams[5], Frederik Nevens[1,2], Diether Lambrechts[6,7], Olivier Govaere[5], Schalk van der Merwe[1,2], Jef Verbeek[1,2]. *[1]Laboratory of Hepatology, CHROMETA Department, KU Leuven, Leuven, Belgium; [2]Department of Gastroenterology and Hepatology, University Hospitals Leuven, Leuven, Belgium; [3]KULeuven institute of single cell omics (LISCO), KULeuven, Leuven, Belgium; [4]Department of Human Genetics, KULeuven, Leuven, Belgium; [5]Department of Imaging and Pathology, Translational Cell and Tissue Research, KULeuven, Leuven, Belgium; [6]Laboratory for Translational Genetics, Department of Human Genetics, KU Leuven, Leuven, Belgium; [7]VIB Center for Cancer Biology, Leuven, Belgium; [8]Department of Gastroenterology and Hepatology, ASZ Aalst, Aalst, Belgium; [9]Department of Abdominal Surgery, University Hospitals Leuven, Leuven, Belgium; [10]Department of Interventional Radiology, University Hospitals Leuven, Leuven, Belgium*
Email: lukas.vanmelkebeke@kuleuven.be

Background and aims: Severe alcohol-related hepatitis (sAH) has a high 28-day mortality and corticosteroids are the only proven therapy. However, 45% of patients do not respond, resulting in a dismal prognosis and a 70% mortality rate. In this study, we elucidate the intricacies of therapy response in the liver through an integrated transcriptomics analysis.
Method: We performed single-nucleus RNA sequencing (snRNA-seq, 10X) on liver biopsies from sAH patients ($n = 8$) before initiation of corticosteroids, acutely decompensated alcohol-related liver disease patients (AD) ($n = 5$) and healthy controls ($n = 4$). A definite diagnosis of sAH was established excluding patients with infection or acute-on-chronic liver failure (ACLF) grade 0 or 1. We followed patients for one year or until death. Mean Maddrey score was 18.8 ± 3.4 for the AD group, and 59.1 ± 13.8 for the sAH group. Protein validation of selected targets was done using immunohistochemistry (IHC) in an independent cohort and associated with outcome.
Results: We retrieved 152.283 good quality nuclei after analysis. Comparing sAH to healthy, we observed changes in cell proportions in immune and parenchymal cells. In hepatocytes at the RNA level, 1701 genes were differentially expressed (DEGs, logFc >0.25), including a decrease in SULT2A1 (logFc = 0.78, p_{adj}-value <0.0001), an enzyme that plays an essential role in bile acid and steroid metabolism. No significant differences were observed in cell proportions in sAH vs. AD. However, multiple differences were found at the RNA level. 478 DEGs were observed in hepatocytes, including a decrease in SULT2A1 (logFc = 0.54, p_{adj}-value <0.0001). When stratifying sAH based on therapy response at day 7, a higher proportion of monocytes in responders (R, $n = 4$) vs non-responders (NR, $n = 4$) (0.67 ± 0.28% vs 0.28 ± 0.19, p_{adj}-value = 0.02) was observed. At the RNA level (372 DEGs), SULT2A1 expression was significantly increased in R (logFc = 0.71, p_{adj}-value <0.0001) which was confirmed at the protein level using IHC in an independent sAH cohort ($p = 0.02$) including patients with infection and ACLF grade 2–3. In addition, S100A9, as a monocyte marker, was significantly more expressed in R vs NR on IHC ($p = 0.04$).
Conclusion: We have constructed a snRNA-seq liver atlas for sAH, providing a comprehensive resource to unravel its pathophysiology and to identify novel therapeutic targets within the molecular landscape of the liver during sAH. Additionally, we have developed innovative models based on protein markers, enhancing our ability to predict the response to corticosteroid therapy before its initiation. This advancement holds promise for a more precise and personalized approach in determining the most effective treatment strategies for individual patients with sAH.

TOP-329-YI

Integrated plasma multi-omics analysis classifies key mycobiome, microbiome and metabolome changes linked to development of poor outcome in severe alcoholic hepatitis

Gaurav Tripathi[1], Vasundhra Bindal[2], Sushmita Pandey[3], Neha Sharma[4], Manisha Yadav[5], Nupur Sharma[1], Babu Mathew[5], Rimsha Saif[5], Sadam H. Bhat[5], Rakhi Maiwall[5], Shiv Kumar Sarin[5], Jaswinder Maras[6]. *[1]Institute of Liver and Biliary Sciences, Delhi, India; [2]Institute of Liver and Billiary Sciences, Delhi; [3]Institute of Liver and Billiary Sciences, Delhi, India; [4]Insitute of Liver and Biliary Sciences, Delhi, India; [5]Institute of Liver and Biliary Sciences, Delhi, India; [6]Institute of Liver and Biliary Sciences, Delhi*
Email: jassi2param@gmail.com

Background and aims: Severe Alcoholic Hepatitis (SAH) often encompasses complication such sepsis, shock, fungal growth and has high mortality rates. Plasma indicators linked to predisposition to shock and early mortality, and mycobiome and its association in SAH is elusive.
Method: Plasma multi-omics (Metabolomics, Metaproteomics and fungal peptide based mycobiome) analysis was performed in derivative cohort (50 healthy (HC), 50 alcoholic cirrhosis (AC) and 100 SAH patients (50 with sepsis and 50 with septic shock) using High Resolution Mass Spectrometry (HRMS).The results were validated using HRMS and Machine Learning (ML) in 300 SAH patients, cross correlated and benchmarked with clinical parameters and severity indices.

Results: SAH patients median age (46) and MDF score>32 were enrolled in the study. A total of 482 metabolite were upregulated and 356 metabolite were down regulated in the plasma of SAH as compared to AC or HC (FC>1.5, $p < 0.05$). Alpha and beta diversity of microbiome and mycobiome was significantly higher in SAH as compared to AC or HC ($p < 0.05$). Patients with Septic shock and those attaining early mortality (SAH-NS) were enriched for B-oxidation, TCA Cycle, Fatty acid, and Tryptophan metabolism. Plasma level of Stearaldehyde (FC > 4), L-Dihydroorotic acid (FC > 6), 2-Hydroxyglutaric acid (FC > 4.34), and others significantly stratified patients with Septic shock or those predisposed to early mortality in SAH patients ($p < 0.05$). The microbiome and mycobiome diversity were distinct in SAH patients with sepsis, septic-shock, Vasoplegic shock or those attaining early mortality. Plasma microbiome/metabolome-based Probability for Diagnosis (POD) for sepsis was >90% and of Septic-shock was 89% in SAH patients. Microbiome modules/functionality directly correlated with metabolite modules, clinical parameters, and severity indices in SAH-NS ($R2 > 0.5$, $p < 0.05$). Increased bacterial and fungal taxa Clostridia species (FC > 2.3), Actinomycetes (FC > 3.75), Chlorobiia (FC > 5.4), Bacteroidia (FC > 81), Gammaproteobacteria (FC > 3.2), and Erysipelotrichia (FC > 2.7) and functionality showed a direct correlation with bile acids, tryptophan metabolites, others, and development of Shock ($r2 > 0.85$). ML Validation of SAH-NS metabolite panel on 300 SAH patients showed accuracy (>90%) and sensitivity/specificity (>95%) for mortality prediction.
Conclusion: SAH septic patients showed iincrease in bacterial/fungal taxa which reduces as patients become sicker due to prolonged antibiotic administration. Further, we identified novel clinical indicators and mycobiome for sepsis, shock and early mortality which outperforms the diagnostic capabilities of current markers like SIRS, SOFA and identify outlier patients, which do not fall under current diagnostic criteria's but have similar clinical presentation thus covering a broader range of SAH patients.

HSD17B13 loss-of-function splice variant delays onset of incident steatotic liver disease and suggests slower progression in established liver disease

Audrey Chu[1], Jonathan Davitte[2], Damien Croteau-Chonka[1], Jessica Chao[2], Diogo Ferrinho[3], Nikhil Vergis[3], Cathy O'Hare[4]. *[1]GSK, Cambridge, MA, United States; [2]GSK, Collegeville, PA, United States; [3]GSK, Brentford, United Kingdom; [4]GSK, South San Francisco, CA, United States*
Email: audrey.y.chu@gsk.com

Background and aims: The genetic variant rs72613567 in hydroxysteroid 17-beta dehydrogenase 13 (*HSD17B13*) leads to enzymatic loss of function (LOF) reducing the risk of developing steatotic liver diseases (SLD) including metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic dysfunction-associated steatohepatitis and alcohol-related liver disease. Most research uses simple case-control comparisons to measure the relationship between LOF and SLD susceptibility, yet linkage of electronic health records and whole-genome sequencing (WGS) in the UK Biobank (UKB) in nearly 500, 000 participants enables exploration beyond SLD susceptibility. We leveraged UKB's longitudinal follow-up to measure *HSD17B13* LOF impact on age of SLD onset, progression from MASLD to cirrhosis, and risk for liver-related or all-cause mortality.
Method: We captured *HSD17B13* rs72613567 LOF genotype from WGS data in 416, 000 unrelated UKB participants of non-Finnish ancestry and modelled genotype additively. We used primary care, hospital episodes and mortality registry data to identify clinical diagnoses for MASLD and cirrhosis, and Cox-proportional hazards regressions (CPH) to measure hazard ratios (HR) and 95% confidence intervals (CI) for the association between *HSD17B13* and age-of-onset for MASLD and cirrhosis. CPH were adjusted for standard covariates to evaluate *HSD17B13* impact on progression risk from MASLD to cirrhosis over 10 years post-MASLD diagnosis in 5600 cases, *HSD17B13* impact on 10 year liver-related mortality, and all-cause mortality within each of 374, 000 participants without SLD, 7000 MASLD and 2500 cirrhosis cases. We used Kaplan-Meier survival curves (KM) to inspect survival rates between *HSD17B13* LOF allele carriers and non-carriers.
Results: Each *HSD17B13* LOF allele significantly reduced MASLD (HR [95% CI], 0.94 [0.90–0.97]; $p = 0.00046$) and cirrhosis (0.87 [0.83–0.93]; $p = 0.0000039$) risk; KM showed delayed age-of-onset for LOF carriers. For MASLD cases, KM showed separation by *HSD17B13* allele with slower progression from MASLD to cirrhosis for LOF carriers; CPH results were not significant (0.85 [0.69–1.05]; $p = 0.14$). From CPH, the LOF allele was not significantly associated with liver-related or all-cause mortality in the non-SLD ($p > 0.58$), MASLD ($p > 0.57$) or cirrhosis cohorts ($p > 0.20$), with no clear separation by *HSD17B13* LOF allele carriers in the KM. While not statistically different, deaths in *HSD17B13* LOF allele carriers in the cirrhosis cohort were lower than non-carriers (8.8% [96/1092] vs 9.4% [136/1446], respectively).
Conclusion: *HSD17B13* LOF variant rs72613567 was associated with delayed age-of-onset for SLD and trends to delayed progression from MASLD to cirrhosis. There was no significant effect of *HSD17B13* LOF on liver-related or all-cause mortality in this analysis; however, the small number of deaths observed limits inference.

THU-316

Farnesoid X receptor agonist INT-787 exhibits high intestinal localization

Jennifer Burkey[1], Sanjay Kansra[1], Antonio Macchiarulo[2], Kenneth Brouwer[3], Luciano Adorini[1], Mary Erickson[1], Roberto Pellicciari[4]. *[1]Intercept Pharmaceuticals, Inc., Morristown, United States; [2]Department of Pharmaceutical Sciences, University of Perugia, Perugia, United States; [3]ADME-TOX Division, BioIVT, Chapel Hill, United States; [4]TES Pharma S.r.l., Perugia, Italy*
Email: jennifer.burkey@interceptpharma.com

Background and aims: Disruption of the intestinal barrier and dysbiosis-driven inflammation are key factors in the pathogenesis of alcohol-associated liver disease. Farnesoid X receptor (FXR) activation within the intestine reduces inflammation and preserves the integrity of the intestinal epithelial and endothelial barriers. INT-787 is a hydrophilic, semisynthetic bile acid-derived FXR agonist with significant intestinal activity in animal models, protecting intestinal barrier integrity and promoting gut microbial reshaping. Here, we report unique distribution properties of INT-787 that support its potential for treatment of severe alcohol-associated hepatitis (sAH).
Method: In a phase 1, single-center, open-label study, 8 healthy male subjects were administered a single oral dose of 50 mg [^{14}C]-INT-787. Mass balance recovery of total radioactivity and concentrations of INT-787 and its conjugates (glyco-INT-787 and tauro-INT-787) were measured in urine, fecal, and plasma samples. Additionally, intestinal permeability of parent and conjugated INT-787 were evaluated in a Caco-2 human intestinal epithelial cell model (American Type Culture Collection). Binding affinity for the ileal bile acid-binding protein (IBABP), a regulator of bile acid transport and activity in the small intestine, was assessed by MicroScale Thermophoresis (MST).
Results: Overall mean recovery of [^{14}C]-INT-787 from feces and urine over the 504-hour study was 94.1%; the primary route of elimination was through the feces, with an arithmetic mean fecal recovery of 86.3%. INT-787 underwent moderate metabolism via glycine and taurine conjugation and oxidation to yield a total of 17 metabolites. The major compounds recovered from feces and urine were INT-787 (72.3%) and glyco-INT-787 (4.85%), respectively. Major plasma components were glyco-INT-787 (40.3%), INT-787 (32.8%), and tauro-INT-787 (8.89%). In vitro intestinal absorption of INT-787 in Caco-2 cells was low compared to FXR agonist obeticholic acid (OCA;

$P_{app\ (A\text{-}to\text{-}B)}$: 6.4×10^{-6} cm/s vs 38.3×10^{-6} cm/s, respectively) and even lower for tauro-INT-787 and glyco-INT-787 ($P_{app\ (A\text{-}to\text{-}B)}$: 0.7×10^{-6} cm/s and 0.3×10^{-6} cm/s, respectively). INT-787 and its metabolites demonstrated markedly weaker binding affinity to IBABP compared to OCA and its metabolites (MST dissociation constant [K_D] >1000 microM for INT-787, glyco-INT-787, and tauro-INT-787 vs 135 ± 22 microM, 33 ± 6 microM, 43 ± 8 microM for OCA, glyco-OCA, and tauro-OCA, respectively).

Conclusion: Oral INT-787 is a unique FXR agonist with low intestinal absorption resulting in high gut localization, likely due to the inability of INT-787 and its metabolites to bind to IBABP. These findings further support clinical studies evaluating the therapeutic use of INT-787 in alcohol-associated liver disease, including sAH, in which the integrity of the intestinal barrier is critical.

Email: luke.tyson@nhs.net

Background and aims: Alcohol-related hepatitis (AH) is characterised by acute cholestasis and liver dysfunction in patients misusing alcohol. We aimed to characterise the bile acid (BA) profile of AH and explore its aetiology.

Method: BA concentrations were measured using UHPLC-MS in serum and stool samples from patients with severe AH, healthy controls, and controls with acute decompensation of alcohol-related cirrhosis; classified as moderately decompensated (MDC, MELD <21) or severely decompensated (SDC, MELD >21). Fibroblast growth factor 19 (FGF19) concentrations were measured by ELISA in fasted, early morning serum. RNA was extracted from liver biopsies (AH patients only). Pairwise comparisons were made by Mann-Whitney U test; correlation assessed by Spearman's Rank.

Results: Serum conjugated primary BAs were notably elevated in AH, even compared to SDC (n = 69 vs 36; glycochenodeoxycholic acid median 82.0 microM vs 48.0, taurochenodeoxycholic acid [TCDCA] 59.8 vs 25.0, glycocholic acid 36.3 vs 9.1, taurocholic acid [TCA] 16.0 vs 3.8; all $p < 0.001$). However, the serum concentrations of the unconjugated primary BAs were highest in MDC (n = 135; chenodeoxycholic acid [CDCA] median 0.861 microM; cholic acid [CA] 0.176). In AH, the serum unconjugated primary BA concentrations were comparable to HC (n = 69 vs n = 63; CDCA median 0.201 microM vs 0.179; CA 0.071 vs 0.066; all $p > 0.05$). Faecal unconjugated primary BA were higher in AH compared to HC (n = 39 vs 51; CDCA median 74.9 microgram/gram dry stool vs 16.6, CA 47.7 vs 13.3; all $p < 0.003$), yet secondary BA were significantly lower (deoxycholic acid median 9.8 microgram/gram dry stool vs 970.7, ursodeoxycholic acid 4.1 vs 24.5, lithocholic acid 3.8 vs 734.0; all $p < 0.001$). The faecal concentration of conjugated primary BA in AH was negligible, with many samples below the lower limit of quantification of the assay. FGF19 was markedly elevated in AH compared to SDC and MDC (n = 10 vs 10 vs 8; median 5.84 ng/ml vs 0.61 vs 0.34; all $p < 0.005$). Hepatocyte BA transporter gene expression, particularly NTCP, inversely correlated with MELD score and serum conjugated BAs such as TCDCA and TCA (n = 25; NTCP vs MELD rho = –0.562; vs TCDCA rho = –0.549; vs TCA rho = –0.581; all $p < 0.004$).

Conclusion: In AH, conjugated primary BAs accumulate in the serum, even compared to SDC. Unconjugated primary BA do not. FGF19 is elevated implying reduced BA synthesis. Unlike the passive, non-ionic diffusion of unconjugated BA, conjugated BA require transporters to cross hepatocyte cell membranes for excretion into bile. Downregulation of hepatocyte BA transporters appears to explain the accumulation of conjugated BA in serum which distinguishes AH from acute decompensation. BA transporter expression inversely correlates with MELD score.

THU-318

Deep lipidomic analysis of plasma classifies lipid species capable of segregating septic-shock and predictive of early mortality in severe alcoholic hepatitis (SAH)

Gaurav Tripathi[1], Vasundhra Bindal[1], Sushmita Pandey[1], Neha Sharma[1], Manisha Yadav[1], Nupur Sharma[1], Babu Mathew[1], Rosmy Babu[1], Sadam H. Bhat[1], Rimsha Saif[1], Rakhi Maiwall[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. *[1]Institute of Liver and Billiary Sciences, Delhi, India*
Email: jassi2param@gmail.com

Background and aims: SAH encompasses high mortality, primarily due to complications like sepsis and septic shock. Lipids play crucial role in cell signaling, energy metabolism. There is limited understanding of role of lipids in sepsis initiation, shock induction, and early mortality in SAH patients.

Method: Plasma lipidomics was used to explore the roles and diagnostic efficacy of lipids in derivative cohort of (50 healthy (HC), 50 alcoholic cirrhosis (AC) and 100 SAH patients (50 with sepsis; 50 with septic shock) using high resolution mass spectrometry (HRMS). Lipid species and based Probability of detection (PODs) for sepsis, shock, and early mortality were validated by HRMS and Machine Learning (ML) in 300 SAH patients and were cross-correlated and benchmarked with clinical parameters/severity indices (MELD, SOFA, and others).

Results: Lipidomics identified 3388 lipid species (8 major classes; 94 classes; 570 subclasses). Progressive decrease of total lipid pool was seen, with increasing severity in SAH patients. SAH patients showed (>1300 differentially expressed lipid species (DEL)'s vs AC or HC) with significant downregulation of sphingolipids (31%), ceramides (15%), and upregulation of Eicosanoids (15%), Bile acid derivatives (18%), Fatty esters (11%) and others. Lipid Alpha diversity was significantly lower in SAH and POD-SAH showed AUC>0.959 ($p < 0.05$). Patients with sepsis, septic shock, and Vasoplegic shock showed distinct lipidomic signatures (>1.5 FC, $p < 0.05$). Lipid species-based diagnostic accuracy of sepsis (POD-Sepsis = 98%) and shock (POD-Shock = 97%) were found in SAH patients. Lipid Species; 2, 5-didehydro-D-gluconic acid (157 FC), 2, 5-Diaminopentanoic acid (14 FC), and others significantly segregated non-survivors. POD-Mortality showed >94% accuracy ($p < 0.05$). All PODs directly correlated with clinical

parameters (lactate, NORAD, FIO2, MELD, AARC and others R2>0.5, p < 0.05). POD-shock/mortality showed highest beta-coefficient with AKI/HE grades (p < 0.05). POD-mortality had highest AUC>0.99 and hazard ratio (HR = 10, p < 0.05) when benchmarked against severity parameters. Finally, POD-mortality>45% predicted early mortality and the mortality lipid panel showed>95% accuracy/sensitivity and specificity in ML for mortality prediction.
Conclusion: SAH patients have hypolipidemia which worsens as the patients become sicker. Restoring lipid pool in patients can reverse the outcome. Also, clearance of classes like Fatty esters, eicosanoids, bile acid- derivatives, and others could change patient's outcome. Further, we identified novel clinical indicators for sepsis, shock and early mortality which outperforms the diagnostic capabilities of current markers like SIRS, SOFA and identify outlier patients, which do not fall under current diagnostic criteria's but have similar clinical presentation thus covering a broader range of SAH patients.

THU-319

Hepatocyte response to metabolic stress in alcoholic fatty liver leads to sublethal cell toxicity through the perturbation of protein translation-elongation machinery

Email: saitotak@usc.edu

Background and aims: Alcoholic fatty liver (AFL) and metabolic dysfunction-associated fatty liver (MAFL), representing the initial stages of steatotic liver disease, serve as prerequisites for disease progression to advanced stages. ALF and MAFL are distinguished solely by clinical context as these conditions share histological and radiographic features, as well as genetic risk factors. Hence, it remains elusive whether they represent distinctive or shared pathophysiology. This study aims to characterize the hepatocytic response to the metabolic stress of AFL by contrasting it with that of MAFL, with the goal of advancing our understanding of how AFL primes the development of advanced stages of alcoholic liver disease (ALD).
Method: Human hepatocytes (HH), either primary or derived from humanized liver chimeric mice (HLCM), were seeded onto collagen-coated plates and cultured with DMSO-containing medium for 7 days, promoting the reinstatement of genuine characteristics. Subsequently, HH were cultured with either ethanol (EtOH) or a free fatty acid-sugar cocktail for an additional 7 days, during which time DMSO was replaced with DMSO2 due to its potent inhibitory effect on a multitude of hepatic metabolic enzymes. were characterized via mRNA-seq, ribosome profiling, and quantitative proteomics to decipher the impact of metabolic stresses on the transcriptome, translatome, and proteome. The results obtained from in vitro studies were validated through in vivo experiments with HLCM.
Results: In vitro cultured HH exhibits the efficient EtOH metabolism to acetate, the final metabolite, at a rate comparable that of the human liver. In parallel, HH treated with EtOH developed macrovesicular steatosis at a comparable level to AFL liver tissue. HH treated with the free fatty acid-sugar cocktail also developed macrovesicular steatosis to an extent indistinguishable from AFL-HH. Despite the identical appearance, mRNA-seq analysis revealed substantial differences in the number and type of differentially expressed genes, with only a small proportion exhibiting overlap. Furthermore, polysome profiling of AFL-HH but not MAFL-HH revealed substantial dissociation of mRNAs from ribosomes, indicating that metabolic stress in AFL results in potent suppression of translatome. Subsequent in vitro and in vivo biochemical and protein studies indicate that the translatome perturbation in AFL-HH is largely attributed to an impairment of elongation processes rather than initiation machineries. We also found that the translatome deficiency results in the sublethal activation of cell death pathways in AFL-HH but not in MAFL-HH upon exposure to inflammatory cytokines.
Conclusion: Our work revealed a marked translatome perturbation at the elongation stage and consequential cell toxicity in HH of AFL, uncovering a previously unrecognized pathophysiology of ALD.

THU-320-YI

The pan-cyclophilin inhibitor rencofilstat exhibits therapeutic anti-fibrotic effects in human relevant models of alcohol-related liver disease via extracellular matrix remodelling

Email: u.rastovic@researchinliver.org.uk

Background and aims: Alcohol-induced liver disease (ALD) represents a substantial challenge to global health as the foremost cause of cirrhosis. The severity of hepatic fibrosis is a crucial prognostic factor contributing to liver-related morbidity and mortality. Improved diagnostic methods have enabled the early detection of fibrosis in ALD patients, consequently driving a significant demand for pharmaceutical interventions aimed at halting the progression to end-stage liver disease. Inhibition of cyclophilins, peptidyl-prolyl isomerases that facilitate protein folding and are overexpressed in fibrosis, has been proven beneficial in several diseases, but the impact on ALD and the mechanism of action is still unclear. Here, we investigate the efficacy of a pan-cyclophilin inhibitor (rencofilstat) currently in Phase 2 clinical evaluation for metabolic dysfunction-associated steatohepatitis, on patient-derived models of ALD and liver fibrosis.
Method: Rencofilstat was tested in human Precision Cut Liver Slices (PCLS) exposed to ethanol and other stimuli to mimic key characteristics of ALD, and in primary human hepatic stellate cells (HSCs) activated by TGFbeta to model fibrogenesis. Fibrosis and cell activation were assessed by gene (RNAseq, Quantigene) and protein analysis (proteomics, immunofluorescence, ELISA). A comprehensive characterisation of changes in the extracellular matrix (ECM), biochemical composition and fibre patterns/orientation, was performed in PCLS and HSC-derived matrix using immunofluorescence, confocal imaging, proteomics and TWOMBLI pipeline. Stiffness of PCLS upon treatment was assessed by atomic force microscopy.
Results: The expression and secretion of pro-fibrogenic markers was decreased in PCLS by the cyclophilin inhibitor. This was accompanied

by a reduced amount of cell-derived matrix deposited by HSCs treated with the drug in presence of TGFbeta. RNAseq and proteomic analysis highlighted a consistent effect of rencofilstat on pathways involved in ECM and collagen fibril organisation in PCLS and HSC-derived matrix *in vitro*. These results were supported by significant changes in fibre alignment, matrix density, and bundle arrangement, suggesting ECM remodelling towards a potentially softer 3D matrix structure, which was confirmed by a reduced stiffness of PCLS exposed to rencofilstat.
Conclusion: Despite promising results in animal models, a substantial "translational gap" persists and there are no approved therapies to target alcohol-related fibrosis. This study demonstrates the therapeutic effects of rencofilstat in relevant patient-derived 3D models of ALD and fibrosis and proves the significant impact of cyclophilin inhibition on ECM remodelling, with direct consequences on tissue stiffness.

THU-321
Protein source differentially alters the outcome of fecal microbiota transplant in mouse model of alcohol-related liver disease
Shvetank Sharma[1], Ashi Mittal[2], Nishu Choudhary[1], Kavita Yadav[1], Anupama Kumari[1], Jaswinder Maras[1], Shiv Kumar Sarin[3]. *[1]Molecular and Cellular Medicine, Institute of Liver and Biliary Sciences, Delhi, India; [2]Molecular and Cellular Medicine, Institute of Liver and Biliary Sciences, D1 Vasant Kunj, Delhi, India; [3]Hepatology, Institute of Liver and Biliary Sciences, Delhi, India*
Email: shvetanks@gmail.com

Background and aims: Fecal microbiota transplantation (FMT) is an effective therapeutic option in alcohol-related liver disease (ALD). Selection of donor and its microbiota composition defines the FMT success. We evaluated the efficacy of pre-educating the donor microbiota with variable protein sources (plant or animal based) prior to FMT in remission of ALD.
Method: ALD mice were developed in 8wks by using Lieber-DeCarli diets with incremental ethanol (5–25%) and twice a week thioacetamide (150 mg/kg, i.p.). Donors (n = 6) for FMT were fed egg or soya protein isocaloric diet (1000 kcal/L) for 2 weeks. Gut microbiota changes were assessed by 16 s rRNA sequencing post day7 of FMT. PICRUSt analysis was performed to capture the functional pathways. Histopathology, serum biomarkers of liver injury, and gene expression (RT-PCR) of inflammation were assessed.
Results: Egg-FMT (eFMT) reduced the liver injury significantly compared to abstinence [AST (1.5-fold, p = 0.002), ALT (1.4-fold, p = 0.002), bilirubin (1.4-fold, p = 0.02), steatosis (6-fold, p = 0.001), fibrosis (2.8-fold, p = 0.001)], or soya-FMT (sFMT) [AST (1.2-fold, p = 0.002), ALT (1.06-fold, p = 0.1), bilirubin (1.2-fold, p = 0.03), steatosis (1.7-fold, p = 0.01)]. Both the FMTs reduced fibrosis similarly (1.1-fold, p = 0.14). eFMT also reduced the gene expression of hepatic pro-inflammatory markers [TNFa (1.5-fold, p = 0.02), IL6 (1.6-fold, p = 0.02). sFMT or eFMT lead to significant variation (79.54%, p = 0.001) in gut microbiota composition when compared to abstinence. eFMT increased the Shannon diversity more than sFMT (1.08-fold, p = 0.06). eFMT significantly increased the abundance of beneficial taxa Dubosiella (13.7-fold, p = 3.23E-14) and commensals Bacillus (7.8-fold, p = 2.77E-10) and Vagococcus (5.7-fold, p = 3.05E-05) compared to sFMT. eFMT reduced opportunistic pathogens Muribaculum (10.9-fold, p = 3.23E-14) and Enterococcus (3.7-fold, p = 0.0003). Bacterial pathways involved in amino acid, lipid, and carbohydrate metabolism were significantly modulated by eFMT (2-fold increase in hexitol degradation, p = 0.005 and phenylpropanoate degradation, p = 0.013; 1.5-fold increase in toluene degradation, p = 0.04 and glycerol degradation, p = 0.004) in comparison to sFMT.
Conclusion: Protein source in FMT donors is an important controller of post-FMT outcome in ALD. FMT from egg protein donor improves ALD injury better compared to FMT from soya donor. Along wit increases in abundance beneficial species there is a concomitant increase in carbohydrate and amino acid metabolism accompanied by significant reduction in hepatic inflammation and steatosis.

THU-322-YI
Plasma cell-free mtDNA is released in alcohol-associated liver disease and correlates with liver injury
Maram Alenzi[1], Gao Wen[1], Heansika Matta[1], Pinzhu Huang[1], Disha Badlani[1], David Guardamino Ojeda[2], Gloria Horta[1], Michelle Lai[1], Z. Gordon Jiang[1], Yury Popov[1]. *[1]Division of Gastroenterology and Hepatology, Beth Israel Deaconess Center, Harvard University, Boston, United States; [2]Beth Israel Deaconess Medical Center-Harvard Medical School, Division of Gastroenterology and Hepatology, Boston, United States*
Email: malenzi@bidmc.harvard.edu

Background and aims: Mitochondrial DNA (mtDNA) is a pro-inflammatory and pro-fibrogenic damage-associated molecular pattern (DAMP) with a pathogenic role in several inflammatory diseases. Due to common evolutionary origins, mtDNA shares many similarities with immunogenic bacterial DNA. We performed a pilot study to evaluate the potential significance of circulating mtDNA as a functional disease driver and biomarker in patients with alcohol-associated liver disease (ALD).
Methods: We collected EDTA-plasma and serum from 71 ALD patients (40 alcohol-associated hepatitis [AH] and 31 alcohol-associated cirrhosis [AC]) and 27 healthy controls in our tertiary hospital Liver Center (BIDMC) and measured absolute copy number of circulating mtDNA using our novel in-house high sensitivity duplex digital droplet polymerase chain reaction (ddPCR) mtDNA assay. The relationship between multiple clinically relevant AH parameters and mtDNA levels was assessed using linear regression analysis.
Results: Plasma mtDNA levels were significantly increased in both AH (2219 ± 5445 copies/ul of plasma, $P = 0.01$) and AC (1233 ± 1716 copies/ul of plasma, $P = 0.008$) compared with healthy controls (387.6 ± 426.5 CI copies/ul of plasma). In active AH, mtDNA levels were significantly higher compared to AC ($p = 0.01$). Plasma mtDNA level in alcohol-associated hepatitis, but not alcohol-associated cirrhosis, significantly correlated with parameters of liver injury-alanine aminotransferase (ALT, $P < 0.001$) >alkaline phosphatase (ALK-P, $P < 0.001$) >white cell count (WBC, $P = 0.02$), and markers of abnormal lipid metabolism-triglycerides (TG, $P = 0.005$) >lipoprotein X (LPX, $P = 0.01$) >lipoprotein Z (LPZ, $P = 0.03$) but not with aspartate aminotransferase (AST, $P = 0.06$), and total bilirubin (TBILI, $P = 0.38$). mtDNA levels in AH serum were about two-fold lower compared to those detected in plasma, and demonstrated similar pattern of significant, but weaker associations with above clinical parameters.
Conclusion: Using our novel ddPCR assay for circulating mtDNA we show for the first time that pro-inflammatory and pro-fibrogenic mtDNA is released during active AH and correlates with parameters of alcohol-related liver injury and dyslipidemia. These results support multi-center disease biomarker validation studies. The potential pathogenic role of mtDNA in AH should also be interrogated in follow-up mechanistic studies.

Differential apoptotic and non-apoptotic cell death profiles in alcohol associated liver disease and their prognostic impact on acute-on-chronic liver failure
Pratibha Garg[1], Nipun Verma[1], Parminder Kaur[1], Samonee Ralmilay[1], Aishani Wadhawan[1], Rohit Nadda[1], Jiya Prajapati[1], Sahaj Rathi[1], Arka De[1], Madhumita Premkumar[1], Sunil Taneja[1], Ajay Kumar Duseja[1]. *[1]Postgraduate Institute of Medical Education and Research, Chandigarh, India*
Email: nipun29j@gmail.com

Background and aims: Cell death as a driver of disease progression in alcohol-associated liver disease (ALD) remain underexplored. This study aims to compare apoptotic and non-apoptotic forms of cell

death across distinct ALD stages and assess their prognostic impact using plasma-based biomarkers.
Method: 301 patients across stages of ALD were enrolled; 125 with acute-on-chronic liver failure (ACLF), 50 with acute decompensation (AD), 95 with non-acute decompensation (non-AD), 17 with compensated cirrhosis (CC), and 14 with alcohol use disorder-fatty liver (AUD-FL). Baseline plasma samples were collected and analysed for various forms of cell death using immunoassays. Expression profiles of these markers were evaluated across ALD spectrum, between ACLF grades, and their potential associations with short-term outcomes within ACLF were investigated. ROC analysis and AUC comparison through DeLong's test were performed.
Results: The cohort comprised mostly males (98%) with mean age of 45.2 years, with relatively older patients in non-AD and CC subgroup. MELD score increased significantly from AUD-FL to ACLF [8.2 (IQR: 6.5–11.5) to 29.3 (IQR: 24.9–35.8), $p < 0.001$). A progressive, step-wise elevation in the concentrations of apoptotic (M30), total cell death (M65), pyroptosis (Gasdermin D), and necroptosis (RIPK3, MLKL) was seen across the ALD spectrum ($p < 0.001$ each). Overall, non-apoptotic forms of cell death became more prominent with increasing ALD severity, and specifically, MLKL exhibited significantly higher expression in ACLF than AD, serving as an indicator for the progression to ACLF (AUC: 0.761, $p < 0.001$). A consistently increasing trend was noted in all cell death markers between the ACLF grades ($p < 0.001$ each), except for M65 ($p = 0.056$).
All cell death markers; except M65 ($p = 0.061$) were associated with short-term mortality in ACLF patients ($p < 0.05$, each). Notably, Gasdermin D (HR: 2.970) and RIPK3 (HR: 2.213) remained significantly elevated in non-survivors even after adjusting for severity scores (MELD) ($p < 0.05$ each). Gasdermin D emerged as a pivotal prognostic marker in ACLF; strongly associated with mortality [HR: 2.970; adjusted for MELD with AUC of 0.732, $p < 0.001$) which was better than the MELD score (HR: 1.071; AUC: 0.644, $p = 0.008$). Adding Gasdermin D with MELD significantly enhanced the predictive performance of the MELD for 30-day mortality (AUC: 0.741), representing substantial improvement of 10%, (DeLong's test, $p = 0.017$).
Conclusion: Pyroptosis and necroptosis are predominant forms of cell death driving the progression of ALD. Non-apoptotic cell death exhibited a progressive increase with greater ACLF severity and mortality, offering valuable prognostic insights. Dynamic assessments of cell death and their targeted manipulation are promising avenues for disease modification in ALD.

THU-326
Improvement in alcohol-associated hepatitis is characterized by reduction of RNA modification processes

Alastair M. Kilpatrick[1,2], Daniel Rodrigo Torres[1], Stephen Atkinson[2], Luke D. Tyson[2], Nikhil Vergis[2], Mark R. Thursz[2], Laura Martinez-Gili[2], Stuart J. Forbes[1]. *[1]Centre for Regenerative Medicine, The University of Edinburgh, Edinburgh, United Kingdom; [2]Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom*
Email: alastair.kilpatrick@ed.ac.uk

Background and aims: Alcohol-associated hepatitis (AH) has a high mortality rate; however, disease mechanisms are still poorly understood. Here, we investigated the hepatic transcriptomic expression of a cohort of severe AH (sAH) patients to determine potential molecular mechanisms associated with disease prognosis.
Method: Paired baseline and day 28 (d28) liver tissue biopsies were obtained from participants with sAH enrolled in the ISAIAH randomised controlled clinical trial of canakinumab (CAN), an IL-1β blocking antibody ($n = 32$; 27 paired samples). RNA was extracted and sequenced and gene level differential expression (DE) analysis was computed with respect to Model of End-Stage Liver Disease (MELD) score using a linear mixed effects model, adjusting for age, sex and timepoint as fixed effects and with patient as random intercept. Gene set enrichment analysis (GSEA) was computed with fgsea. A false discovery rate <0.05 was considered significant.
Results: MELD score improved at d28 similarly in both treated and untreated patients with paired samples (CAN: 13/14; placebo: 12/13). We identified 3, 557 genes significantly differentially expressed with respect to MELD. Posttranscriptional regulation of gene expression was significantly enriched. Core enrichment genes included several eukaryotic initiation factors (eIFs) significantly upregulated with decreasing MELD. RNA modification, methylation and splicing processes were also enriched. Common to all these processes were methyltransferases 14 and 16 (METTL14; METTL16), significantly upregulated with decreasing MELD and known factors in m6A modification of RNA. Non-coding RNA (ncRNA) processing is also enriched with MELD; enrichment drivers include terminal uridylyl transferases 1 and 7 (TUT1; TUT7), upregulated with decreasing MELD and responsible for 3′ RNA uridylation, a process important in epitranscriptomics. A substantial proportion of genes significantly downregulated with decreasing MELD are small nuclear and small nucleolar RNAs (snRNAs; snoRNAs) (12.6%), while almost all upregulated are protein coding. TUT1 has a known role in modification of snRNAs and may mediate gene expression and cell proliferation. Integrator complex subunits (INTSs) 2, 6, 7 and 12 also contribute to the enrichment of ncRNA-related gene sets; the integrator complex is a multiprotein complex involved in the 3′ end processing of snRNAs.
Conclusion: Diverse posttranscriptional RNA modification processes and expression of snRNAs and snoRNAs are depleted with decreasing AH severity following alcohol cessation. Epitranscriptome and epigenome modulation may therefore be promising therapeutic targets in alcohol-related liver disease.

THU-327
Exploring the AhR molecular pathways to improve gut microbiota and liver injury in alcohol-associated liver disease

Wanchao Hu[1], Geraldine Schlecht-Iouf[1], Nicolas Trainel[1], Francoise Mercier-nome[1], Aurore Desmons[2], Sophie Viel[3], Gabriel Perlemuter[4], Dragos Ciocan[4], Anne-Marie Cassard[5]. *[1]Université Paris-Saclay, INSERM, Inflammation, Microbiome and Immunosurveillance, 91400 Orsay, France; [2]Clinical metabolomic department, Sorbonne Université, INSERM, CRSA, Saint Antoine Hospital, AP-HP, Paris, France; [3]INSERM, CNRS, Institut Paris-Saclay d'Innovation Thérapeutique, 91400 Orsay, France; [4]Université Paris-Saclay, INSERM, Inflammation, Microbiome and Immunosurveillance, AP-HP, Hepato-Gastroenterology and Nutrition, Antoine-Béclère Hospital, 92140 Clamart, France; [5]Université Paris-Saclay, INSERM, Inflammation, Microbiome and Immunosurveillance, Paris Center for Microbiome Medicine (PaCeMM) FHU, 91400 Orsay, France*
Email: wanchao.hu@universite-paris-saclay.fr

Background and aims: Alcohol-associated liver disease (ALD) is the leading cause of cirrhosis worldwide, with few therapeutic options other than alcohol withdrawal. Intestinal microbiota (IM) plays a causal role in the severity of the disease both in mice and humans. Among metabolites produced by IM, bile acids and tryptophan metabolites are mainly modified in ALD. We previously demonstrated that pectin, a soluble fiber, improves liver and gut injuries in ALD through bile acid metabolism and indoles production acting through the aryl hydrocarbon receptor (AhR) signaling. However, the potential of tryptophan metabolites to improve ALD through the AhR and which cells are involved in mechanisms remain unknown. In this study, we aimed to decipher the involvement of AhR, specifically in the liver and the gut.
Method: We established conditional knockout mice models for AhR in hepatocytes, enterocytes, or dendritic cells (DCs) and CD11c expressing macrophages, followed by implementing preventative treatments with tryptophan or pectin in the context of ALD. Based on metagenomic and metabolomic analyses, we focused on changes in IM and microbiota tryptophan metabolites, which are ligands of AhR.

Results: We found that a tryptophan-enriched diet partially reproduced the effect of pectin without major changes in IM but with significant modification in the relative abundance of some bacteria. The tryptophan diet also modifies tryptophan metabolism and AhR ligands. These changes are closely related to IM but differ from the effect of the pectin diet. Serum tryptophan levels increased in the tryptophan group but not in the pectin group, while the serum tryptamine levels exhibited the opposite trend. Through conditional AhR knockout mice, we observed that AhR deficiency in hepatocytes or enterocyte-expressing cells worsened the ALD. However, the protective effect of pectin and tryptophan is not abrogated by AhR deficiency. In these AhR deficient mice, pectin and tryptophan treatments improve the alcohol-induced liver injury, conversely, the improvement of the gut barrier was abrogated.
Conclusion: Our data showed that tryptophan reproduces a part of the effect of pectin on the improvement of liver and gut injuries, which is independent of the AhR expression in hepatocytes and enterocytes. Conversely, the improvement of the gut injury depends at least on part of the AhR expression in the gut but not in the liver, suggesting that gut improvement is not a prerequisite to improve the liver injury.

Complement protein signatures in patients with alcohol-associated hepatitis

Laura Nagy[1], Moyinoluwa Taiwo[2], Emily Huang[3], Vai Pathak[3], Esperance Schaefer[4], Jay Luther[4], Le Day[5], Jon Jacobs[5], Russell Goodman[4], Daniel Rotroff[6,7], Gyongyi Szabo[8]. *[1]Cleveland Clinic, Cleveland; [2]Cleveland, Cleveland, United States; [3]Cleveland Clinic, Lerner Research Institute, Cleveland, United States; [4]Massachusetts General Hospital, Alcohol Liver Center, Boston, United States; [5]Pacific Northwest National Laboratory, Richland, United States; [6]Cleveland Clinic, Endocrine and Metabolism Institute, Cleveland, United States; [7]Cleveland Clinic, Center for Quantitative Metabolic Research, Cleveland, United States; [8]Beth Israel, Boston, United States*
Email: len2@po.cwru.edu

Background and aims: Diagnostic challenges continue to impede development of effective therapies for successful management of alcohol-associated hepatitis (AH), thus creating an unmet need to identify and develop non-invasive biomarkers for AH. In murine models of ethanol-induced liver injury, complement activation contributes to hepatic inflammation and injury. Therefore, we hypothesized that complement proteins could be rational diagnostic/prognostic biomarkers in AH.
Method: We performed a comparative analysis of data derived from the human hepatic and serum proteome to identify and characterize complement protein signatures in severe AH (sAH). The hepatic proteomics data were generated by liquid chromatography-mass spectrometry analysis of de-identified liver samples acquired by University of Louisville and Johns Hopkins University Clinical Resource Center for Alcohol Hepatitis Investigations (R24AA025017). Samples used included healthy controls ($n = 12$; UL-7 and JHU-5) and patients with severe AH ($n = 6$ JHU) with an average Model for End-Stage Liver Disease (MELD) score of 37.2 ± 1.8. The dataset was generated from the MS resources at PNNL (accession number MSV000089168; https://massive.ucsd.edu/ProteoSAFe/static/massive.jsp). The circulating proteomic data were acquired using the aptamer-based, proteomic SomaScan platform by Luther et al. (10.1172/jci.insight.159775). Serum samples from healthy controls (HC) (n = 6), patients with alcohol use disorder (AUD) (n = 20) and patients with mild (n = 21) (MELD <10), moderate (n = 15) (MELD 11–20), or severe (n = 18) (MELD >20) AH, and patients with alcohol-associated cirrhosis (AC) (n = 13) were included in the cohort.
Results: The quantity of multiple complement proteins was perturbed in liver and serum proteome of patients with sAH. Multiple complement proteins differentiated patients with sAH from those with AC, AUD and HCs. Notably, serum collectin 11 and C1q binding protein were strongly associated with sAH and exhibited good discriminatory performance amongst patients with sAH, AC, AUD, and HCs. Furthermore, lower serum mannose-binding lectin associated serine protease 1 and coagulation factor II were associated with and independently predicted 90-day mortality.
Conclusion: In summary, meta-analysis of proteomic profiles from liver and circulation revealed complement protein signatures of AH, highlighting a complex perturbation of complement and identifying potential diagnostic and prognostic biomarkers for patients with sAH.

Email: putignano.anto@gmail.com

Background and aims: severe forms of alcohol-related liver disease (ALD) are burdened by high short-term mortality. Translocation of microbiota components might trigger immunoglobulins production (M-Ig) and M-Ig might contribute to ALD progression and prognosis. Systems serology (SS) profiles biophysical and functional features of antigen-specific antibodies and their relationship with clinical outcomes. The aims of this study were to characterize M-Ig using a SS approach and to investigate their role in ALD severity stratification and outcomes prediction.
Method: Single-center retrospective study enrolling ALD patients with steato-fibrosis (n = 48), compensated cirrhosis (n = 54), decompensated cirrhosis (CP B/C, n = 59) and severe alcoholic hepatitis (sAH, n = 46). M-Ig specific for 11 classes of microbiota antigens were considered. M-Ig titers, subclasses, Fc receptors (FcR) binding and antibody-dependent complement deposition were determined by Multiplex Immunoassay; antibody-dependent NK cells activation and antibody-dependent neutrophil and monocytes phagocytosis were assessed with *in vitro* cellular models. Unsupervised computational analysis (PCA) was used to determine M-Ig humoral signature of ALD severity groups, dBscan to identify clusters of patients, Chi Square or Fisher Test and Kruskal-Wallis test to compare variables or outcomes, Cox Regression to model predictors of 90-day mortality ($p < 0.05$).
Results: M-Ig titers, subclasses, and FcR binding increased according to ALD severity, however this was not associated to a parallel increment in the respective M-Ig function. PC1, PC2 and PC3 discriminated between ALD severity groups ($p = 0.0009$, <0.0001 and =0.031 respectively). VIP ranking showed that ALD humoral variability defined by PC1 was related to M-Ig specific for *E. Coli* and to FcR binding, whilst PC2 depended on *S. Aureus* specificities and IgA/IgG titers and PC3 on *C. Albicans* and IgG titer and subclasses. The DBscan analysis performed on CP B/C and sAH identified two clusters of patients ("nested" and "dispersed" cluster), clinically comparable, however septic shock occurrence and 90-day mortality were higher for patients belonging to the "dispersed" cluster (28.1% vs 10.8%, $p = 0.03$ and 36.4% vs 16.7%, $p = 0.029$ respectively). At the multivariate

analysis, to belong to the "dispersed" cluster resulted to increase the 90-day mortality risk (HR 4.2, CI 1.7–10.2, p = 0.002) independently from the MELD score (HR 1.2, CI 1.1–1.3, p < 0.0001).
Conclusion: Despite increased titers in severe ALD groups, M-Ig do not show higher functional potential, suggesting that other Fc biophysical factors might affect M-Ig final function and a reduced M-Ig potential to clear infection. M-Ig humoral signature defined by PCA discriminates between ALD severity groups and identifies a cluster of patients at higher 90-day mortality, independently from the stage and severity of the disease.

THU-332-YI
Growth differentiation factor 15 and adrenergic receptor beta 2 modulate free fatty acid release by inducing foamy macrophage in adipose tissue under chronic alcohol consumption
Min Jeong Kim[1], Kyurae Kim[1], Sung Eun Choi[1], Won-il Jeong[1,2]. *[1]Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Rep. of South; [2]Center for the Hepatic Glutamate and Its Function, KAIST, Daejeon, Korea, Rep. of South*
Email: wijeong@kaist.ac.kr

Background and aims: Alcohol-related liver disease (ALD) is a leading cause of liver-related illness and death worldwide. Especially, among various organs influencing ALD, adipose tissue (AT) contributes the acceleration of alcohol-related hepatic steatosis by releasing free fatty acids (FFAs). Particularly, foamy macrophages in AT contribute to lipid metabolism and modulate inflammatory responses by accumulating cytosolic lipid droplets, subsequently participating in the systemic regulation of fat metabolism. Previous studies have reported that hepatic growth differentiation factor 15 (GDF15) increased the expression of adrenergic receptor beta-2 (ADRB2) in Kupffer cells (KCs) and the resultant activation of ADRB2 induced apoptosis of inflammatory KCs in ALD. However, GDF15 production and ADRB2 expression in AT macrophages have not been investigated clearly in ALD. Here we explored the GDF15/ADRB2 axis in AT macrophages and its effect on hepatic steatosis in ALD.
Method: To investigate the roles of GDF15 and ADRB2 on AT macrophage in ALD, wild-type mice were fed Lieber-DeCarli liquid EtOH diet (4.5%) for 8 weeks. Liver, blood, and AT samples were analyzed for biochemical parameters, histopathology, and bulk RNA-sequencing. In vitro experiments, Raw 264.7 cell were treated with recombinant GDF15 and ADRB2 agonist for BODIPY staining, flow cytometry, western blot, and qRT-PCR analyses.
Results: Chronic alcohol consumption induced hepatic steatosis and increased blood levels of catecholamine and FFA. AT decreased in weights and increased the numbers of crown-like structures, followed by elevated expression of GDF15 in adipocytes and ADRB2 in AT macrophages. Interestingly, flow cytometry revealed an increase of foamy macrophages in AT. In vitro, EtOH exposure increased GDF15 expression in adipocytes. Moreover, ADRB2 expression was induced in Raw 264.7 cells by GDF15 treatment. Furthermore, co-treatments of GDF15 and ADRB2 agonist enhanced not only lipid metabolism-related gene expression but also anti-inflammatory gene expression, thereby promoting foamy appearance in Raw 264.7 cells. These findings suggest a peculiar role of GDF15 and ADRB2 in regulating fat storage in AT macrophages.
Conclusion: Our study revealed that alcohol intake produced GDF15 in adipocytes, and increased ADRB2 expression in neighboring AT macrophages, increasing uptake of FFAs and promoting fat storage through triglyceride synthesis. Thus, targeting the GDF15/ADRB2 axis may provide novel therapeutic strategy for ALD by alleviating the blood levels of FFAs and inducing foamy macrophages.

Novel mechanism of golgiphagy in hepatocytes and the protective impact of hydroxychloroquine on alcohol-induced liver damage and steatosis
Armen Petrosyan[1], Carol Casey[2], Amanda Macke[2], Taylor Divita[2].
[1]University of Nebraska Medical Center, Omaha, United States; [2]University of Nebraska Medical Center, Omaha, United States
Email: ccasey@unmc.edu

Background and aims: The progression of alcohol-associated Liver Disease (ALD) involves the disruption of the Golgi apparatus and the accelerated formation of phagophores. Although Golgi membranes may play a role in phagophore development, the connection between ethanol (EtOH)-mediated Golgi alterations and autophagy remains unclear. The research from our laboratory identified the impact of Rab3D GTPase downregulation in the development of EtOH-mediated intracellular alterations, including impaired trafficking of one of the critical hepatic proteins, the asialoglycoprotein receptor (ASGP-R). Herein, we studied the pivotal role of the dimeric Golgi matrix protein, p230, the regulator of trans-Golgi protein transport, in phagophore formation.
Method: VA-13 cells (mouse ADH1-transfected HepG2 cells) and WIF-B cells underwent exposure to 35–50 mM EtOH for a duration of 72–96 hours. In our in vivo studies, primary hepatocytes and liver homogenates from rats and mice were analyzed after being fed a control diet or the EtOH-containing Lieber-DeCarli diet for 5–7 weeks, along with the NIAAA chronic/binge mice model. We used various methodologies, including high-resolution, electron, and atomic force microscopies.
Results: We revealed that the morphology of the trans-Golgi is regulated by the cooperative actions of Rab3D, p230, and the motor protein non-muscle Myosin IIB (NMIIB). In the context of EtOH-induced Golgi scattering, Rab3D undergoes redistribution from trans-Golgi compartments to cis-medial, disrupting its complex with p230 and NMIIB. This redistribution induces conformational changes in the p230 molecule, specifically a shift from its bent configuration to an extended form, leading to the formation of p230-positive phagophores and their incorporation into autolysosomes. Deficiency in Rab3D within the trans-Golgi also results in the segregation of NMIIB from Golgi membranes, while its isoform NMIIA becomes tethered to the Golgi, giving rise to NMIIA-positive phagophores. Inhibition of NMIIA, both in vitro and in vivo, effectively prevents EtOH-induced Golgi dispersal. Additionally, in both chronic and chronic/binge models, we observed that Hydroxychloroquine (HCQ)-mediated autophagy inhibition prevents Golgi disorganization. This rescue of Golgi architecture re-establishes ASGP-R distribution. Significantly, HCQ blocks collagen deposition and steatosis and reduces the expression of upregulated hepatic cytochrome P450 2E1 (CYP2E1), suggesting the protective impact of HCQ on alcohol metabolism in hepatocytes.
Conclusion: Rab3D deficiency at the trans-Golgi and p230 conformational changes emerge as crucial events in NMIIA-driven, EtOH-mediated Golgiphagy. The promising results of HCQ treatment indicate its potential as a novel therapeutic approach for ALD.

Supplementation of the amino acid L-arginine attenuates the onset of alcohol-related liver diseases
Anja Baumann[1], Franziska Kromm[1], Victor Sánchez[1], Katja Csarmann[1], Raphaela Staltner[1], Annette Brandt[1], Ina Bergheim[1].
[1]University of Vienna, Vienna, Austria
Email: ina.bergheim@univie.ac.at

Background and aims: Alcohol-related liver diseases (ALD) are still one of the major chronic liver diseases world-wide. Ethanol intake has been shown to alter intestinal barrier function, leading to an increased translocation of bacterial toxins and activation of toll-like receptor-dependent signaling cascades thereby promoting hepatic inflammation and progression of ALD. Studies suggest that changes of

intestinal nitric oxide (NO) metabolism are critical in the development of intestinal barrier dysfunction and that amino acids like L-citrulline and L-arginine may attenuate these alterations. Here, we assessed the effect of an oral L-arginine supplementation on the development of ALD in mice.

Method: Female C57BL/6J mice (n = 8/group) were pair-fed a control or an ethanol-enriched Lieber deCarli diet (EtOH, 5% ethanol) ±2.49 g L-arginine/kg bw/d for 28 days. Parameters of liver damage and intestinal permeability as well as markers of NO homeostasis in small intestine were determined. Moreover, everted small intestinal tissue sacs were challenged with EtOH in the presence of 0–4 nM L-arginine.

Results: The concomitant treatment of EtOH-fed mice with L-arginine significantly attenuated the development of ALD with markers of hepatic steatosis and inflammation such as the number of neutrophils, hepatic interleukin 6 concentration, 4-hydroxynonenal protein adducts and NO levels, all being significantly lower compared to mice fed only EtOH. The protective effect of L-arginine on the development of alcohol-related liver damage was associated with a protection from the significant increase in intestinal permeability in EtOH-fed mice. Moreover, the beneficial effects of supplementing L-arginine in EtOH-fed mice on changes in intestinal barrier function were associated with an alleviation of the significant increase of NO in small intestine. Additionally, in everted gut sacs ex vivo, EtOH-induced intestinal barrier dysfunction was almost abolished by L-arginine being associated with a normalisation of NO levels.

Conclusion: Our data suggest that L-arginine may attenuate the development of ALD in mice and that this is associated with a protection against the development of intestinal barrier dysfunction and alterations in intestinal NO homeostasis.

The new nomenclature of steatosic liver disease identifies different risk trajectories for liver-related complications

Bocquillon Adrien[1], Jackie Bitton[1], Lauren-Ange Djia Meyapyali[1], Delphine Degré[1], Antonia Lepida[1], Laura Weichselbaum[1], Nathalie Boon[1], Thierry Gustot[1], Eric Trépo[1], Guillaume Lassailly[2], Lukas Otero Sanchez[1], Christophe Moreno[1]. *[1]HUB Erasme, Brussels, Belgium; [2]CHU Lille, Lille, France*
Email: adrien.bocquillon@ulb.be

Background and aims: A new nomenclature for Steatosic Liver Disease (SLD) was endorsed by EASL and AASLD. It encompasses Metabolic dysfunction Associated Steatosic Liver Disease (MASLD), Metabolic dysfunction and alcohol-related Steatosic Liver Disease (MetALD) and Alcohol-related Liver Disease (ALD). Data regarding liver-related complications according to this new nomenclature in compensated SLD are lacking. The aim of this study was to assess risk factors associated with liver-related events (LRE) in compensated patients with SLD, aiming to identify at-risk individuals regarding the new nomenclature.

Method: In this single-center study we included all patients with compensated biopsy-proven SLD performed at Erasme hospital (Brussels, Belgium) between January 2009 and December 2021. The main inclusion criteria were: ≥18 years old, biopsy-proven SLD (steatosis >5%); exclusion criteria were: other causes of chronic liver diseases, decompensated liver disease at the time of the biopsy or previous liver decompensation. We defined LRE as the occurrence of at least one of the following complications: ascites, encephalopathy, variceal hemorrhage, or hepatocellular carcinoma (HCC). To assess factors predicting outcomes of interest, univariate and multivariable regression analyses were performed using the Fine and Gray competing risks regression model, with non-liver-related death considered as competitive risk event.

Results: 316 patients were included and were followed for a median of 3.4 years. 233 patients were categorized as MASLD, 36 as MetALD and 47 as ALD. 47% of MASLD patients had advanced fibrosis stage (F3-F4), compared to 58% and 81% for MetALD and ALD respectively. During follow-up, 8.2% of MASLD patients presented a LRE, compared to 22.3% for MetALD patients and 27.4% for ALD patients. The cumulative incidences of LRE at 2, 4 and 8 years were 4.61% (95% CI ± 0.032), 6.06% (95% CI ± 0.037) and 10.58% (95% CI ± 0.056) for patients with MASLD, compared to 3.13% (95% CI ± 0.061), 14.04% (95% CI ± 0.121) and 18.65% (95% CI ± 0.153) for patients with MetALD and to 9.67% (95% CI ± 0.091), 18.83% (95% CI ± 0.130) and 32.23% (95% CI ± 0.182) for patients with ALD. In the multi-state model, fibrosis stage (HR = 1.62, 95% CI [1.04–2.51], p = 0.031), units of alcohol per day (HR = 1.08, 95% CI [1.01–1.15], p = 0.027), diabetes (HR = 4.36, 95% CI [1.56–12.01], p = 0.005) and bilirubin serum level (HR = 1.64, 95% CI [1.28–2.11], p < 0.001) were associated with LRE.

Conclusion: The new SLD classification identifies distinct at-risk groups for liver-related complications, highlighting liver fibrosis, daily alcohol consumption, and diabetes mellitus as key drivers. These findings underscore the critical necessity of screening for liver fibrosis in more at-risk SLD population for liver-related complicated, including individuals with diabetes and those with significant daily alcohol consumption.

Portal neutrophils exhibit an activated phenotype in alcohol-related liver disease

Sara Reinartz Groba[1], Mathis Richter[2], Raphael Chevre[2], Jonel Trebicka[1], Michael Praktiknjo[1], Oliver Soehnlein[2]. *[1]Medicine B (Gastroenterology, Hepatology, Endocrinology, Infectious Diseases), University Hospital Münster, Münster, Germany; [2]Institute of Experimental Pathology, University of Münster, Münster, Germany*
Email: sara.reinartz@uni-muenster.de

Background and aims: Neutrophils are drivers of hepatic injury in alcohol-related liver disease (ALD). However, the neutrophil population is heterogeneous and disease-driving neutrophil subsets were identified in many pathological conditions, also in ALD. The portal venous compartment in ALD-related cirrhosis is distinct from those in other etiologies likely due to changes in gut microbiome and bacterial translocation. Immune cells passing through the splanchnic vascular bed are exposed to high levels of bacterial metabolites. This study aimed to examine the effects of the portal venous milieu on the neutrophil phenotype in ALD and non-ALD related cirrhosis.

Method: During transjugular intrahepatic portosystemic shunt (TIPS) placement blood was collected from the jugular, hepatic and portal vein prior to the establishment of the TIPS stent. Leukocytes were isolated from whole blood by red blood cell lysis, stained with a multicolor antibody panel and subsequently analyzed by spectral flow cytometry. For statistical analysis geometric mean of fluorescent intensities within the neutrophil populations were compared using Wilcoxon matched-pairs signed rank test. Further, inducibility of the portal phenotype was assessed by exposure to portal plasma. Neutrophils isolated from the jugular vein were treated with autologous portal plasma and characterized by spectral flow cytometry as described above.

Results: A total of 22 cirrhotic patients were included in this study (ALD = 12, non-ALD = 10). ALD and non-ALD groups had similar severity of liver disease (MELD, Child-Pugh-Score, portosystemic pressure gradient). Portal neutrophils of patients with ALD showed an increased expression of CD11b, CD10, CD45, and CD177 (all p <0.01) compared to neutrophils from the jugular vein. Uniform Manifold Approximation and Projection for Dimension Reduction revealed that portal neutrophils clustered apart from neutrophils derived from the hepatic and jugular vein. Upon incubation with portal plasma, neutrophils from the jugular vein adopted the portal phenotype with increased expressions of CD11b, CD10 and CD45 (all p < 0.01) compared to controls. Those differences in phenotype could not be observed in patients with etiologies of cirrhosis not related to ALD.

Conclusion: Neutrophils derived from the portal vein of ALD patients exhibit a highly activated phenotype compared to those isolated from the jugular vein. This phenotype is probably induced by plasma factors from the portal vein.

THU-339

Abstinence induces site-specific metabolomic alterations in resolution from alcohol-related liver disease

Nupur Sharma[1], Sadam H. Bhat[1], Babu Mathew[1], Manisha Yadav[1], Sushmita Pandey[1], Gaurav Tripathi[1], Vasundhra Bindal[1], Neha Sharma[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: nupush1995@gmail.com

Background and aims: Alcohol increases gut permeability, allowing endotoxins to enter the blood, activating inflammation, and inducing not only liver injury but also affecting other organs. Continued alcohol drinking and abstinence from alcohol are likely to produce different metabolites, which are likely to be site specific and may influence gut permeability and disease pathophysiology. We investigated site-specific metabolomic changes upon alcohol or abstinence and correlated them to disease pathophysiology to identify potential therapeutic targets.
Method: Male and female LE rats (6–8 weeks old) were randomly assigned to Control (Lieber Di Carli control diet, n = 6), or alcohol-related liver disease (ALD, LDC ethanol diet for 24 weeks, n = 6), and Abstinence groups (24 weeks ALD rats abstained from alcohol for 7 days, n = 6). Liver, plasma, and intestine samples were subjected to metabolomic analysis.
Results: In ALD model, histology showed increased steatosis (28%, $p < 0.05$) and fibrosis (15%, $p < 0.05$) while in abstinence group, it resolved by 19% ($p < 0.05$) and 12%, respectively. The AST, ALT, bilirubin, triglycerides, and cholesterol, were significantly elevated in plasma of ALD rats but decreased in abstinence group ($p < 0.05$). Metabolomics analysis in liver of abstinence rats showed induction of steroid biosynthesis, terpenoid pathways, and reduction of amino acid metabolism (pathway intensity: >2fold, $p < 0.05$) associated with ameliorating inflammation. Plasma of rats under 7 days of alcoholic abstinence showed metabolites with phenylalanine metabolism surged while fatty acid metabolism reduced compared to ALD rats (>2fold, $p < 0.05$).
Intestine of alcoholic abstinence rats exhibited increased malate aspartate shuttle and glutamate metabolism whereas methionine metabolism was decreased (>4fold, $p < 0.05$). Metabolite integration analysis showed that abstinence resolved metabolites linked to pyrimidine (Deoxyuridine, 5-Thymidylic acid, Deoxycytidine, Thymidine, Uridine) and galactose metabolism (Melibiitol, D-Gal alpha 1->6D-Gal alpha 1->6D-Glucose, Stachyose, Galactosylglycerol) in liver, plasma and intestine thereby producing a systemic increase in energy metabolism which corroborates with improvement in the liver injury. In-depth analysis revealed metabolic shift from pyrimidine to arginine synthesis resulting in increased urea formation. Interestingly, urea showed inverse correlation ($r2 > 0.6$) with clinical parameters in abstinence from alcohol.
Conclusion: Our results demonstrate that alcohol abstinence for 7 days induces site specific alterations and a metabolic shift towards arginine synthesis. This promotes functioning of urea cycle, reducing ammonia, and facilitating the recuperation from ALD. Consequently, targeting arginine biosynthesis and urea cycle could be a beneficial approach in ALD treatment.

Multiomics landscape of alcohol detoxification and the role of PNPLA3 genotype

Anna Karl[1], Katharina Remih[1], Franziska Hufnagel[1], Francesca Barletta[2], Mohamed Ali Jarboui[3], Johannes Müller[4], Sebastian Mueller[4], Zbyněk Zdráhal[5], David Potěšil[5], Pavel Hruška[5], Olivia Pleßow[6], Ulrike Rolle-Kampczyk[6], Martin von Bergen[6], Pavel Strnad[1]. [1]*University Hospital RWTH Aachen, Aachen, Germany;* [2]*University of Tübingen, Tübingen, Germany;* [3]*University of Tübingen, Tübingen, Germany;* [4]*University of Heidelberg, Heidelberg, Germany;* [5]*Masaryk University, Brno, Czech Republic;* [6]*Helmholtz Centre for Environmental Research, Leipzig, Germany*
Email: akarl@ukaachen.de

Background and aims: Alcohol-related liver disease (ALD) is the most predominant type of chronic liver disease and accounts for 50% of all cases of liver-related death. Despite that, the underlying mechanism remains incompletely understood. To change that, we systematically analyzed the proteomic and metabolomic changes in subjects undergoing inpatient alcohol detoxification and studied the relevance of PNPLA3 variant as the major genetic ALD modifier.
Method: Sera from 95 ALD subjects (44 $PNPLA3^{WT/WT}$, 20 $PNPLA3^{I148M/I148M}$) were collected prior to and after inpatient detoxification (median duration: 6 days) and were compared to sera of 32 liver-healthy controls. Liver fibrosis was assessed through liver stiffness measurement via transient elastography. All samples were subjected to untargeted mass spectrometry-based proteomic analysis and a subset was studied by depleted proteomics (14 most abundant proteins were removed). For targeted metabolomics, samples were extracted with the AbsoluteIDQ p180 kit and analyzed via high-throughput QTRAP mass spectrometry.
Results: The nondepleted dataset of ALD subjects strongly differed from healthy controls and changes were more pronounced in subjects with advanced vs. low fibrosis. Several inflammation-related proteins (CD14, immunoglobulin chains, PIGR etc.) were increased in alcoholic while protease inhibitors were often diminished (ITIHs, SERPINF2). The changes in immunoglobulin chains and protease inhibitors were even more pronounced at advanced liver disease stages. Detoxification was associated with a decrease in controlled attenuation parameter (CAP) values as surrogate of steatosis as well as diminished levels of several apolipoproteins (APOA1, APOA2, APOC3). Compared to $PNPLA3^{WT/WT}$, $PNPLA3^{I148M/I148M}$ subjects harbored more pronounced changes in apolipoproteins suggestive of stronger lipidomic alterations. Depleted proteomics provided a better coverage of hepatocellular injury markers that typically decreased after alcohol withdrawal. Metabolomics revealed that detoxification led to a decrease in several acylcarnitines and an elevation in various glycerophospholipids.
Conclusion: Our multiomic-approach provides novel insights into changes occurring in ALD subjects during inpatient alcohol detoxification treatment.

THU-341

Mouse models of MetALD and metabolic dysfunction-associated steatohepatitis elicit similar patterns of liver injury

Naomi Lange[1,2], Amani Lee[3], George Marek[4], Luke Doskey[4], P. Vineeth Daniel[4], Amy Mauer[4], Vijay Shah[4], Harmeet Malhi[4]. [1]*Graduate School for Health Sciences, University of Bern, Bern, Switzerland;* [2]*Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland;* [3]*University of Minnesota, Minneapolis, Minnesota, United States;* [4]*Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, Minnesota, United States*
Email: malhi.harmeet@mayo.edu

Background and aims: Both MetALD and metabolic dysfunction-associated steatohepatitis (MASH) are characterized by severe progressive liver injury. To gain further insight into shared and unique patterns of liver injury, we compared mouse models of advanced MetALD and MASH against several control groups.
Method: Liver injury was evaluated in 40 male C57Bl/6 (Jackson) mice at 16 and 24 weeks (n = 4 per group per timepoint). In the control groups (n = 8 per group), mice were fed chow diet with water (CW), sugar water containing glucose and fructose (CS), or 10% ethanol in sugar water (CE). In the condition groups (n = 8 per group), MetALD mice were fed a high-fat, -fructose, and -cholesterol (FFC)

diet with 10% ethanol sugar water (FE), and MASH mice were fed FFC with sugar water (FS). Liver tissue specimen were evaluated using NAFLD activity score (NAS), Sirius Red histological staining for fibrosis, immunohistochemistry for myofibroblasts (aSMA) and BODIPY staining for lipid droplet morphology. Liver injury and inflammation were measured by alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels, differential gene expression by multiplex nucleic acid hybridization (NanoString nCounter), and quantitative PCR (qPCR). Statistical analysis was performed in R, NanoString nSolver and GraphPad Prism.

Results: At 16 and 24 weeks, absolute body weight and liver mass to body mass index were significantly increased in both MetALD and MASH compared to controls. At 16 weeks, both MetALD and MASH exhibited increased ALT levels whereas AST levels did not differ from controls. Analysis of lipid droplet morphology in BODIPY staining demonstrated higher steatotic area and lipid droplet size in both conditions compared to controls. The number of lipid droplets per nucleus was lower in MetALD compared to MASH. Relative fibrotic area under polarized light (Sirius Red) was increased in MetALD compared to MASH at 16 weeks. Analysis of fibrotic gene expression revealed comparable patterns in both conditions, distinctly differing from controls. At 24 weeks, both NAS histological scoring and Sirius Red polarized light fibrosis assessment showed increased steatosis, inflammation and fibrosis in both conditions compared to controls, but indicated no differences between conditions. Accordingly, qPCR assessment revealed an increased expression of inflammatory (IL1beta and Mac2) and fibrotic (aSMA and Col1a) genes in both conditions. Multiplex hybridization of an immune gene panel revealed comparable patterns of differential gene expression in both MetALD and MASH.

Conclusion: In male C57Bl/6 mice, both MetALD and MASH demonstrate similar patterns of liver injury at 16 and 24 weeks. However, our data suggest a potentially distinct pattern of lipid droplet morphology as well as distinct dynamic of fibrosis progression, characterized by more pronounced early fibrosis in MetALD compared to MASH.

THU-342

Establishment of a mouse model of severe alcoholic hepatitis and study on the material basis of traditional chinese medicine rhubarb in the treatment of severe alcoholic hepatitis

Min Liu[1], Xue-Jin Zhu[2], Jia-Bo Wang[1]. *[1]Capital Medical University, Beijing, China; [2]Fujian University of Traditional Chinese Medicine, Fuzhou, China*
Email: jiabo_wang@ccmu.edu.cn

Background and aims: Severe alcoholic hepatitis is a fatal liver disease with limited therapeutic options, and the lack of accurate animal models impedes research progress. Traditional Chinese medicine has demonstrated potential in the treatment of severe alcoholic hepatitis, and the development of efficient animal models is crucial for drug advancement.

Method: To establish a murine model of severe alcoholic hepatitis (SAH) in C57BL/6 mice using an enhanced NIAAA model, it is necessary to incorporate the final high-dose alcohol administration and bacterial endotoxin stimulation to mimic acute severe hepatitis induced by excessive alcohol consumption and gut toxins. Subsequently, the effects of rhein and sennoside A should be investigated in vivo.

Results: Observe the presence of abundant lipid vacuoles and neutrophil infiltration in liver tissue of SAH group using HandE staining and immunohistochemical staining.Compared with the control group, the serum ALT and AST in the NIAAA group and the SAH group increased, and there was a significant difference, especially in the SAH group ($p < 0.001$). The survival rate of mice in the SAH group was 66.7%, the survival rate of the positive drug hydrocortisone group was 83.3%, and the survival rate of the control group, the rhein dose group and the sennoside A dose group was 100%. Mitigate hepatic meutrophil infiltration and suppress hepatitis in SAH mice through the administration of varying dose of rhein and sennoside A.The administration of a low dose of rhein (30 mg/kg) and a moderate dose of sennoside A (30 mg/kg) significantly ameliorate hepatic function indicators in mice, including reducing the levels of alanine transaminase (ALT), aspartate transaminase (AST), direct bilirubin (DBIL), lactate dehydrogenase (LDH), and total bile acids (TBA), while increasing the levels of albumin (ALB) and cholinesterase (CHE).The research findings indicate that different doses of sennoside A (low, medium, and high) significantly impact LDH, TBA, ALB, and CHE indicators when compared to the model group. Moreover, varying concentrations of emodin A and rhein also demonstrate regulatory effects on factors such as TNF-alpha, IL-6, IL-1beta, and CCL2.

Conclusion: We established an animal model of SAH.The hepatic inflammation in mice, primarily characterized by neutrophil infiltration, was aberrant. Concurrently, there was significant impairment in liver function, mimicking the pathogenesis of clinical SAH. Rhein and sennoside A exhibited pronounced therapeutic effects on severe alcoholic hepatitis by significantly reducing levels of neutrophil infiltration and inflammatory factors in the liver. Among them, a low dose of rhubarb extract (30 mg/kg) and a moderate dose of sennoside A (30 mg/kg) demonstrated superior therapeutic efficacy compared to hormone drugs as they not only reduced mortality in SAH mice but also preserved their body weight.

THU-343

Dissecting metabolic dysfunction-associated steatotic liver disease with increased alcohol intake (MetALD): clinical and molecular insights and classification

Jun Liu[1], Sile Hu[2], Sihao Xiao[1], Rui Huang[1], Lingyan Chen[2], Jeremy Tomlinson[3,4], Jeremy Cobbold[4,5], Joanna Howson[2], Cornelia van Duijn[1]. *[1]Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom; [2]Genetics Centre-of-Excellence, Novo Nordisk Research Centre Oxford, Oxford, United Kingdom; [3]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Churchill Hospital, Oxford, United Kingdom; [4]NIHR Oxford Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust and the University of Oxford, Oxford, United Kingdom; [5]Translational Gastroenterology Unit, University of Oxford, Oxford, United Kingdom*
Email: jun.liu@ndph.ox.ac.uk

Background and aims: Metabolic dysfunction-associated SLD (MASLD) with increased alcohol intake (MetALD) is a condition that straddles MASLD and alcohol-related liver disease (ALD). This study aims to elucidate the distinct clinical and molecular characteristics of MetALD and to refine its subtypes using metabolomics and proteomics data.

Method: We analyzed 475, 204 European participants from UK Biobank with 33, 877 MetALD patients detected. We compared clinical, metabolomic, and proteomic profiles of MetALD with pure MASLD and ALD. Logistic or Cox regression were used to analyse features and assess risk of serious outcomes over 15 years. Classification models were developed using Elastic Net Regression.

Results: MetALD patients exhibited generally intermediate features between pure MASLD and ALD. Despite a significant overlap in metabolite and protein profiles among the three SLDs, MetALD still shared 10% metabolites and 4% proteins exclusively with either ALD or pure MASLD. The proteome model achieved an Area Under Curve (AUC) of 0.97 to differentiate pure MASLD from ALD in a separate dataset, while the metabolome combined with traditional markers reached an AUC of 0.91. The metabolome model identified a significantly higher risk for hepatocellular carcinoma (247%), cirrhosis (198%), mortality (50%), and heart failure (39%) in patients with ALD-predominated MetALD than MASLD-predominated MetALD. The proteome model identified a higher risk for cirrhosis (222%) and mortality (127%). In contrast, the alcohol model either did not

identify significant differences or identified much smaller differences (38% for cirrhosis and 22% for mortality).
Conclusion: This study provides a robust classification framework for MetALD and highlighting the prognostic significance of differentiating between MASLD-predominated and ALD-predominated MetALD. This could help healthcare providers tailor interventions more effectively, potentially improving prognosis and reducing complications.

Minibioreactor arrays (MBRAs) to model microbiome response to tryptophan and alcohol in the context of alcohol-associated liver disease (ALD)
Wanchao Hu[1], Nicolas Trainel[1], Vanessa Liévin-Le Moal[1], Gabriel Perlemuter[2], Benoit Chassaing[3], Sabrine Naimi[3], Dragos Ciocan[2], Anne-Marie Cassard[4]. *[1]Université Paris-Saclay, INSERM, Inflammation, Microbiome and Immunosurveillance, 91400 Orsay, France; [2]Université Paris-Saclay, INSERM, Inflammation, Microbiome and Immunosurveillance, AP-HP, Hepato-Gastroenterology and Nutrition, Antoine-Béclère Hospital, 92140 Clamart, France; [3]INSERM U1016, CNRS UMR8104, Institut Cochin, Université Paris Cité, Paris, France; [4]Université Paris-Saclay, INSERM, Inflammation, Microbiome and Immunosurveillance, Paris Center for Microbiome Medicine (PaCeMM) FHU, 91400 Orsay, France*
Email: wanchao.hu@universite-paris-saclay.fr

Background and aims: Intestinal microbiota (IM) plays a causal role in the severity of alcohol-associated liver disease (ALD). Using IM transplantation in mice, we proved that the dysbiosis of alcohol use disorder (AUD) patients with severe alcohol-associated hepatitis (sAH) could be modified, leading to an improvement in alcohol-induced liver injury by increasing tryptophan metabolites to activate aryl hydrocarbon receptor (AhR) signaling pathway. However, the effect of tryptophan on IM in AUD patients, as well as its interactions with alcohol, remain to be elucidated. For this purpose, we used an in vitro approach with Minibioreactor arrays (MBRAs) that allows for the study of IM in a continuous-flow culture with well-controlled factors.
Method: Fecal samples from AUD patients with sAH (n = 2) or with noAH (n = 2) were transferred to MBRAs chambers. After 24 hours of adaptation in the initial medium, treatments with different tryptophan concentrations (low: 8 mg/L, normal: 24 mg/L and high: 72 mg/L) were initiated for 48 hours. Subsequently, alcohol was introduced in the system for 5 days (50 mM ethanol/Day). Finally, alcohol was removed and the cultures were maintained for an additional 5 days. IM analysis was conducted by 16 s sequencing. AhR activity of tryptophan derivatives in supernatants was determined using two reporter lines: intestinal epithelial cells (HT-29) and hepatocytes (HepG2) labelled with Lucia-AhR.
Results: After 24 h of stabilization, MBRA effectively maintains each fecal community. Tryptophan had no effect on the alpha and beta diversity of the IM from sAH and noAH patients. However, normal tryptophan level decreased the relative abundances of *Escherichia-Shigella* and increased *Bacteroides* in noAH IM, decreased *Proteobacteria* and increased *Bacillus* in sAH IM. In the absence of alcohol, tryptophan changed more number of bacteria in noAH IM (43 species) than in sAH IM (8 species). However, with alcohol conditions, tryptophan had minimal effect on the noAH IM. Compared to low tryptophan, normal and high tryptophan levels increased the AhR activity.
Conclusion: Our results suggest that maintaining a normal tryptophan level in patients with noAH could be essential to prevent dysbiosis and high concentrations of tryptophan may have a beneficial effect on the IM of sAH patients. Tryptophan holds potential as a novel therapeutic agent for ALD treatment but these results must be confirmed in vivo.

THU-348
Identification of alcoholic associated hepatitis-related genes and mesenchymal stem cell treatment target genes by meta analysis
Seul Ki Han[1], Taesic Lee[2], Sang Gyune Kim[3], Yeon Seok Seo[4], Soon Koo Baik[1], Young Uh[5], Moon Young Kim[1]. *[1]Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Rep. of South; [2]Department of Family Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Rep. of South; [3]Department of Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon, Korea, Bucheon, Korea, Rep. of South; [4]Department of Internal Medicine, Korea University College of Medicine, Seoul, Korea, Rep. of South; [5]Department of Laboratory Medicine, Yonsei University Wonju College of Medicine, Wŏnju, Korea, Rep. of South*
Email: drkimmy@yonsei.ac.kr

Background and aims: Alcoholic associated hepatitis (AH) is a life-threatening condition and widespread chronic liver condition that places patients at risk of short-term mortality if it is not properly managed. This study aimed to identify transcriptomic biomarkers and cell therapy targets for AH.
Method: We conduct a systematic meta-analysis of published human gene expression studies on liver biopsies and blood derived gene data. First, three liver AH transcriptome datasets and a blood AH dataset were combined to discover a common phenotype. Second, two AH prognosis datasets were compiled, which are including gene phenotype reflecting prognosis. Using inverse weighted variance-based method mounted in METAL software, the candidate genes related to AH in liver and blood tissues and annotated them as the liver-blood AH meta genes. Third, three MSC datasets were curated for gene identification in stem cell response. Meta-analysis was implemented on the individual cohort-specific summary statistics obtained from differential expression methods to identify the AH-related biomarkers. To narrow down the candidate hub genes among stem cell treated data, TF database, protein-protein interaction network, disease-gene association database, and disease- and expression-related SNP database were used to analysis.
Results: With previously identified alcoholic gene-related databases, external verification was performed and 47 upstream AH-related genes were presented. The analysis contains some genes that have not been previously characterized in the context of alcoholic liver disease.
Conclusion: We present key genes involved in the progression of AH and provide a meta-analysis of results in a objective, statistically-based format. And at the same time, we suggest this biomarkers that can predict the prognosis of AH and treatment response. By using these genes, we can confirm the genetic changes caused by stem cell treatment and this can be used to lay the foundation for targeted cell therapy or function-enhanced genetic therapy.

Alcohol-related liver disease and MetALD – Clinical

TOP-311-YI
Subtypes of steatotic liver disease have differing clinical outcomes
Katrina Pekarska[1], Alexander Hinkson[1], Ian Rowe[1], Richard Parker[1]. *[1]Leeds Teaching Hospitals NHS Trust, St James's University Hospital, Leeds, United Kingdom*
Email: katrina.pekarska@gmail.com

Background and aims: Steatotic liver disease (SLD) is a major health problems because of their potential to evolve into cirrhosis. SLD is an umbrella term for diseases typified by accumulation of fat in the liver. SLD includes a spectrum of diseases caused by cardiometabolic risk factors (CMRF) and alcohol including metabolic dysfunction

associated steatotic liver disease (MASLD), metabolic alcohol associated liver disease (MetALD) and alcohol related liver disease (ALD). This spectrum has made it possible to recognize patients having CMRF with increased alcohol consumption. Little data is available on all-cause mortality of the newly suggested SLD subtypes. We aimed to investigate the risk of all cause and liver-related outcomes in MASLD, MetALD and ALD.

Method: Patients who underwent liver biopsy for diagnosis or staging of NAFLD (non-alcoholic fatty liver disease) or ALD in routine practice at a single centre were included. Patient electronic records were reviewed for variable extraction. These two patient cohorts were then reclassified according to the new SLD nomenclature into three cohorts. Cox proportional hazards regression analysis was performed to understand the outcomes in MASLD, MetALD and ALD patients. Statistical analysis was done in R.

Results: In total 712 patients were included with a mean age of 51 (SD = 12.7) years. In old classification terms, 528 (74%) had a diagnosis of NAFLD, and 184 (26%) had ALD. After reclassification 477 (67%) had MASLD, 100 (14%) metALD and 135 (19%) patients had ALD. Patients with MASLD had significantly higher BMI ($p < 0.001$), cholesterol levels ($p < 0.001$), higher prevalence of diabetes mellitus ($p < 0.001$). Patients were followed up after biopsy for a median of 55.5 months (IQR 26–81), during which time 75 (11%) of patients died, including 30 liver-related deaths (40% of all deaths). Mortality was commonest in ALD (49 deaths, 36% of cohort), compared to metALD (13 deaths, 13%) and MASLD (13 deaths, 2.7%). Death due to decompensated liver disease was more frequent in ALD patients ($p = 0.044$), accounting for 16 deaths (66.7% of all deaths in ALD cohort). Multivariate Cox proportional hazards regression adjusting for baseline fibrosis stage showed a hazard ratio for death of patients with ALD of 5.59 (95% confidence interval, 2.74–11.4, $p < 0.001$) compared to MASLD.

Conclusion: ALD carries the highest risk of all-cause and liver-related mortality. To reduce the burden of liver disease alcohol should be a priority for policy makers. It is more important now than never to alert physicians to advise against any amount of alcohol intake as well as to have a good public education regarding alcohol intake and its effect on liver health. We should work with public health campaigns to tackle the ever-growing burden of the disease that leads to cirrhosis and decompensation.

SAT-249

Reduced Pannexin-1 and IL-33 in liver tissue are associated with lesser neutrophilic satellitosis and a higher rate of infections in severe alcoholic hepatitis patients

Shraddha Singh[1], S. Muralikrishna Shasthry[1], Archana Rastogi[1], Shiv Kumar Sarin[1], Chhagan Bihari[1]. [1]*Institute of Liver and Biliary Sciences, Delhi, India*
Email: drcbsharma@gmail.com

Background and aims: Pannexin-1 releases nucleotide "find me" signals from apoptotic cells for the recruitment of inflammatory cells in tissue via IL-33 and promotes tissue innate immunity. Genetic predisposition to low Pannexin 1 (PANX1) expression can reduce hepatic recruitment of macrophages and neutrophils with higher chances of infections. In severe alcohol related hepatitis (SAH) patients, lower neutrophilic satellitosis is a poor prognostic indicator. We aimed to assess the status of PANX-1 and IL-33 in SAH patients' liver biopsies and their association with neutrophilic satellitosis and sepsis/infections within four weeks.

Method: We analyzed the patients who underwent trans-jugular liver biopsies, performed per the standard protocol before treatment administration. Patients who had active infections, sepsis, recent bleeding, renal insufficiency, active tuberculosis, associated viral hepatitis, drug-induced liver injury, and inadequate liver biopsy were excluded. Standard treatment was administered per the institutional protocol. We followed up patients for 28 days; the development of infection/sepsis was registered as an outcome measure. Liver biopsies were assessed for Pannexin-1 and IL-33 by immunohistochemistry (IHC) and calculated by Image-J software using an IHC analyzer, and the score was calculated as intensity x % cell positivity. We performed a quantitative real-time reverse transcriptase-polymerase chain reaction (RT-PCR) for PANX1, NLRP3, IL-33, and IL1beta.

Results: A total of 287 patients were screened and after applying exclusion criteria, 120 patients [median age 38 (IQR 32–46.2), 95% males, MELD Na 28.8 (25.6–34.5)] were included. Amount of alcohol days was 360 (200–375), median jaundice and ascites days were 30 (15–42.5) and 9 (6–21). Thirty six out of 120 (30%) patients developed infections within 4 weeks. The baseline IHC PANX1 score was significantly lower in those who developed infections {25 (0–50) vs. 150 (100–200), $p < 0.001$}. Likewise, IL-33 was more deficient in these patients {20 (0–50) vs. 120 (100–225), $p < 0.001$}. 80% of patients who developed infection had lower neutrophilic satellitosis of ≤ grade 1 vs 13% of those who did not have the infection. PANX1 and IL-33 intensity correlated with the neutrophilic satellitosis grades ($p < 0.001$ and $p = 0.004$, respectively). RT-PCR of liver tissues also showed downregulated PANX1 (-1.8 folds) and IL33 (-3.4 folds) in those who eventually had infection compared to those who did not.

Conclusion: Downregulated PANX1 and IL-33 in liver biopsies were associated with lesser neutrophilic satellitosis and higher chances of infection in SAH patients.

SAT-250

Substituting FIB-4 with LiverPRO as an initial test for detecting advanced fibrosis leads to a 6-fold reduction in false positive results

Katrine Lindvig[1], Katrine Thorhauge[1,2], Helle Schnefeld[1], Johanne Kragh Hansen[1,2], Camilla Dalby Hansen[1], Stine Johansen[1,2], Peter Andersen[1], Ida Falk Villesen[1], Katrine Tholstrup Bech[1], Nikolaj Torp[1,2], Mads Israelsen[1,2], Aleksander Krag[1,2], Maja Thiele[1,2]. [1]*Department of Gastroenterology and Hepatology, Center for Liver Research, Odense University Hospital, Odense C, Denmark;* [2]*Institute of Clinical Research, University of Southern Denmark, Odense M, Denmark*
Email: katrine.prier.lindvig@rsyd.dk

Background and aims: EASL recommends starting with the Fibrosis-4 Index (FIB-4) in a fibrosis screening sequence for individuals at risk of Steatotic Liver Disease (SLD), followed by confirmatory Transient Elastography (TE), and the Enhanced Liver Fibrosis (ELF) test if available. Our study evaluates this pathway and compares it to an alternative approach where FIB-4 is replaced by LiverPRO, a CE-marked diagnostic tool, that utilizes a machine learning model to assess the likelihood of liver fibrosis based on routine blood samples.

Method: We retrospectively applied the EASL pathway to a Danish screening cohort of at-risk individuals, recruited based on either metabolic or alcohol-related risk factors. We evaluated the accuracy of patient classification by FIB-4 and LiverPRO using TE as a reference. We used LiverPRO as the first-tier test in the alternative pathway, LiverPRO is considered positive, when the risk is >65%. SLD groups were defined according to the new nomenclature and based on the past three months alcohol intake. The outcomes of both pathways were validated against liver biopsy data in the subgroup of patients who received a liver biopsy due to elevated TE (≥8 kPa).

Results: We included 4, 869 patients with risk factors for SLD. Average age was 57 (IQR 52–63), with males comprising 52%. We found that 31% had Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD), 7% had MASLD and associated alcohol intake (MetALD), 3% had Alcohol-related Liver Disease (ALD), and 59% had no SLD according to the new nomenclature. Using the FIB-4 initiated pathway, 35% (n = 1, 724) had a FIB-4 score ≥1.3, necessitating a subsequent TE measurement. Of these, 218 (13%) had TE ≥8 kPa, meaning FIB-4 showed 1501 false positives (87%). If LiverPRO replaced FIB-4, 388 patients (8%) would have been referred for further testing, and of these, 35% were identified as high-risk by TE.

LiverPRO had 252 false positives (65%). The effectiveness in patient classification was therefore higher with LiverPRO, with 90% of patients correctly classified (true negatives + true positives), compared to 66% in the FIB-4 pathway. Looking in a biopsied subgroup (n = 238), FIB-4 had an AUC of 0.70 (0.62–0.77), and LiverPRO an AUC of 0.79 (0.73–0.84) for predicting advanced fibrosis (≥F3).
Additionally, when analyzing ELF as a third-tier assessment, 62% (88 out of 143) of those with positive FIB-4 and high TE score had a positive ELF (>9.8), compared to 63% (63 out of 100) in the high-risk LiverPRO and high TE group. In cases where TE and ELF disagreed a liver biopsy showed mild to significant liver fibrosis (F1-F2).
Conclusion: Substituting FIB-4 with LiverPRO as the initial test for individuals at risk of SLD, significantly improves the accuracy of participant classification, notably decreasing the incidence of false positives 6-fold.

SAT-251

Semaglutide can reduce alcohol use in patients with metabolic dysfunction-associated steatotic liver disease

Vladislav Fomin[1], Adam Buckholz[1], Yihan Liu[1], Himel Mallick[1], Sonal Kumar[1,2]. *[1]Weill Cornell Medicine, New York, United States; [2]New York Presbyterian Hospital-Weill Cornell Medicine, New York, United States*
Email: sok9028@med.cornell.edu

Background and aims: In patients with metabolic dysfunction-associated steatosis liver disease (MASLD) moderate alcohol use is associated with less steatosis reduction and less steatohepatitis resolution; heavy use is associated with accelerated liver injury and fibrosis progression. As a result, patients with MASLD are recommended to avoid alcohol. Glucagon-like peptide-1 (GLP-1) receptor agonists such as semaglutide are approved for diabetes and obesity, and associated with steatohepatitis resolution in clinical trials. GLP-1 receptors in brain areas are associated with reward and addiction and in primate studies GLP-1 s reduce alcohol intake. We hypothesize semaglutide use decreases self-reported alcohol use through neurohormonal mechanisms.
Method: This single-center retrospective cohort study evaluated semaglutide use on weekly alcohol intake in patients with MASLD. The intervention group was started on semaglutide for obesity or overweight with complications in the setting of MASLD. The control group was patients with MASLD not started on semaglutide due to a variety of recorded factors. Both groups received standard counselling to discontinue alcohol. The primary end point was change in self-reported drinks per week (d/w) at 6, 12, and 24 months. Groups were stratified by BMI. A linear mixed effects model was used to compare changes both across and within cohorts. Age, sex, race, diabetes, HLD, metformin use, and use of other weight loss medications were controlled as covariates in the models of each cohort.
Results: 175 patients were included, 60 in the control and 115 in the semaglutide group. Age, liver enzymes, and liver stiffness per transient elastography were similar between groups. The semaglutide group had more women, diabetes, a lower mean BMI (31 vs 35), metformin use, and use of other weight loss medications. Mean initial alcohol use per week was similar (5.2 d/w with semaglutide, 6.6 d/w in control, p = 0.36). The semaglutide group decreased alcohol use during the first 6 months of treatment −4.2 d/w (95%CI −7.3, −1.4 p = 0.0108). The change in alcohol use was −4.5 d/w (95%CI −9.0, −1.1, p = 0.0407) at 12 months and −7.1 d/w (95%CI −26.4, 12, 2, p = 0.0407) at 24 months. The control group decreased −1.8 d/w (95% CI −6.4, 0.2, p = 0.4791). Compared to the control the semaglutide group decreased alcohol use −2.8 d/w (95%CI −5.2, −0.4, p = 0.027). When stratified for obesity at the combined time points with a BMI >30, patients trended towards decreased use −3.0 d/w (95%CI −6, 0 p = 0.067).
Conclusion: In patients with MASLD semaglutide was associated with decreased alcohol use when combined with counselling. Semaglutide is increasingly used in patients with MASLD to treat comorbid conditions like obesity and diabetes and may be a powerful tool to decrease alcohol use. Further studies in prospective randomized controlled trials can further evaluate the utility of GLP-1 s in these patients.

SAT-254

Diet modifies the association between alcohol intake and alcohol-related liver disease: a prospective study of individual patient data from the UK Biobank

Fanny Petermann[1], Ziyi Zhou[2], John Mathers[3], Carlos Celis-Morales[2], David Raubenheimer[4], Naveed Sattar[2], Jill Pell[2], Ewan H. Forrest[5], Frederick Ho[2]. *[1]Universidad Diego Portales, Santiago, Chile, Santiago, Chile; [2]University of Glasgow, Glasgow, United Kingdom; [3]Institute of Population Health Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [4]University of Sydney, Sydney, United Kingdom; [5]Glasgow Royal Infirmary, University of Glasgow, Glasgow, United Kingdom*
Email: fanny.petermann@udp.cl

Background and aims: Whilst alcohol-related liver disease (ALD) incidence is proportional to the amount of alcohol consumed, only 10 to 20% of individuals with chronic heavy alcohol use develop advanced ALD. Other factors must influence the effect of alcohol intake and the evolution of ALD. Associations between diet and the development of ALD have previously been seen only in animal models or in ecological studies. This study aimed to investigate if the incidence of ALD is influenced by an individual's diet.
Method: This was a prospective study of UK Biobank participants. At baseline, participants completed a questionnaire to collect the frequency of consumption of 20 food items over the previous year. Alcohol intake in units (u) was estimated using self-reported consumption of alcoholic beverages. ALD was defined as ICD-10 K70. The food items were included in Cox regression models with a 'Least Absolute Shrinkage and Selection Operator' algorithm. A 10-fold cross-validation for Cox Models was used to predict food items to be included in the diet score and determine dietary risk (DR). Joint association of diet and alcohol with ALD were investigated using Cox proportional hazard models. Results are reported as hazard ratios (HR) and their 95% confidence intervals (95%CIs). Analyses were adjusted for sociodemographic factors, components of the metabolic syndrome, and lifestyle factors.
Results: Of the 303, 269 participants included in the main analyses, 539 (0.2%) were diagnosed with incident ALD over a median follow-up of 10.7 years (IQR 10.0–11.4). Four food items achieved the minimum error and were used in the score: processed meat, beef, cereal, and salt intake (coefficients 0.0098, 0.0061, −0.098 and 0.202 respectively). Those at highest risk (higher DR and ≥14u alcohol/week) were younger, more likely to be men, to smoke previously and to drink alcohol daily: hyperglycaemia, high triglycerides, central obesity and hypertension were also more prevalent. There was a non-linear association between the score and ALD incidence. The highest ALD incidence risk was in those with higher DR and ≥14u alcohol/week (HR: 6.08 [95% CI: 4.30 to 8.59]), followed by those with lower DR and ≥14u alcohol/week (HR: 3.01 [95%CI: 2.04 to 4.44]), and those with higher DR and <14u alcohol/week (1.52 [95% CI: 1.02 to 2.26]) compared with those who were in the healthiest classification. A higher dietary score accounted for 40.5% (95% CI: 39.1% to 41.9%) of incident cases of ALD, while alcohol accounted for 50.9% (95% CI: 48.6% to 53.4%) assuming causality.
Conclusion: Using the UK Biobank study with individual patient data, we identified that diet amplified the association between alcohol consumption and ALD. Poor diet appears to exacerbate disease progression beyond alcohol intake and metabolic dysfunction. If these findings are corroborated, relevant guidelines should consider diet change to address ALD incidence.

SAT-255

Assessing LSM thresholds to identify clinically relevant SLD in individuals with excessive alcohol intake and absence of steatosis

Mette Lehmann Andersen[1,2], Nikolaj Torp[1,3], Stine Johansen[1,3], Camilla Dalby Hansen[1], Emil Deleuran Hansen[1,3], Ellen Lyngbeck Jensen[1,3], Katrine Thorhauge[1,3], Johanne Kragh Hansen[1,3], Ida Falk Villesen[1], Katrine Tholstrup Bech[1,3], Charlotte Wernberg[1,4], Peter Andersen[1], Katrine Lindvig[1], Maja Thiele[1,3], Aleksander Krag[1,3], Mads Israelsen[1,3]. *[1]Liver Research Centre, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense C, Denmark; [2]Department of Gastroenterology and Hepatology, Herlev Hospital, Herlev, Denmark; [3]Institute of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense C, Denmark; [4]Institue for Regional Health Science, Liver Research Group, Department of Gastroenterology and Hepatology, University, Hospital of South Denmark, Esbjerg, Denmark*
Email: mette_98@hotmail.com

Background and aims: According to the new nomenclature for steatotic liver disease (SLD), a diagnosis of alcohol-related liver disease (ALD) or metabolic dysfunction and alcohol-associated steatotic liver disease (MetALD) requires the presence of hepatic steatosis or advanced fibrosis indicated by liver stiffness measurement (LSM) >14 kPa. However, alcohol-induced steatosis typically resolves with abstinence, why many patients with a history of excessive alcohol use do not meet the SLD criteria. We aimed to identify the threshold of LSM that associate with increased risk of decompensation in patients with a history of excessive alcohol use but without steatosis.

Method: This prospective cohort recruited individuals aged 18–75 with a current or previous alcohol overuse (>24 g/day for women, >36 g/day for men) for over a year and no history of decompensation. Participants were categorized based on the absence of steatosis, confirmed through histological assessment per NASH-CRN standards and controlled attenuation parameter (CAP) score <290 dB/m. A valid LSM was also required. Follow-up was done through manual reading of electronic medical records with decompensation events categorized according to the Baveno VII criteria.

Results: Of 441 patients with a history of excessive alcohol intake, 178 (40%) had absence of steatosis according to the histological assessment and CAP. For patients without steatosis 116 (65%) were male, mean age 54 years (SD 11), mean BMI 26 kg/m² (SD 4), and 110 (62%) were reported at least one week of abstinent at baseline. LSM was <8 kPa in 133 patients (75%), 8–14 kPa in 18 patients (10%), and >14 kPa in the remaining 27 patients (15%). Over a mean follow-up of 68 months (IQR 40), 21 (12%) patients developed decompensation (11 ascites, 5 hepatic encephalopathy and 5 variceal bleeding). In the subgroup with LSM<8 kPa, 2 of 133 patients (2%) had a decompensating event. For LSM 8–14 kPa, the rate increased to 17% (3 of 18 patients), whereas in the LSM >14 kPa group, 16 events occurred among 27 patients (59%). The risk of decompensation increased stepwise from LSM <8 kPa to LSM 8–14 kPa (HR = 7.8 95%; CI 1.1–55.8) and LSM >14 kPa (HR = 63.3, 95%; CI 13.1–307.2) independent of age, gender, and current alcohol intake.

Conclusion: In patients with a history of excessive alcohol use, 40% show no signs of hepatic steatosis. Due to the significant risk of developing hepatic decompensation in these patients with LSM >8kPa, it is necessary to incorporate distinct thresholds for MetALD and ALD when classifying these patients according to the nomenclature for SLD.

SAT-256

Liver-related complications are the fastest growing cause of mortality from alcohol consumption: results from the global burden of disease 2019 study

Benedix Sim[1], Pojsakorn Danpanichkul[2], Darren Jun Hao Tan[3], Cheng Han Ng[1], Wen Hui Lim[3], Benjamin Nah[1], Benjamin Koh[3], Christen Ong[3], Nicholas Syn[3], Jia Hong Koh[1], Daniel Tung[1], Karn Wijarnpreecha[4], Mark Muthiah[1], Margaret Teng[1], Daniel Huang[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine, National University Hospital, Singapore, Singapore, Singapore, Singapore; [2]Immunology Unit, Department of Microbiology, Faculty of Medicine, Chiang Mai University, Thailand, Chiang Mai, Thailand; [3]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, Singapore; [4]Division of Gastroenterology and Hepatology, Department of Medicine, University of Arizona College of Medicine, Phoenix, Arizona, USA, Phoenix, United States*
Email: benedix.sim@mohh.com.sg

Background and aims: Alcohol consumption plays a major role in global disability and mortality. Excessive alcohol consumption leads to liver-related complications, alcohol use disorder (AUD), and cardiovascular complications. Furthermore, alcohol significantly contributes to disparities in health outcomes across different socioeconomic groups. We aimed to investigate the global burden of disease attributable to alcohol consumption, in terms of AUD, liver and cardiac-related complications.

Method: Utilizing data from the 2019 Global Burden of Disease (GBD 2019) study, our study focused on assessing the annual age-standardized rates (ASRs) of prevalence, deaths and disability-adjusted life years (DALYs) attributable to AUD, liver-related complications, and cardiovascular complications from alcohol. We also conducted stratified analysis by sex and sociodemographic index (SDI).

Results: In 2019, the greatest contributor of DALYs ASRs was AUD (207.31 per 100, 000; 95%CI 163.71 to 261.66 per 100, 000), followed by alcohol-associated cirrhosis (133.31 per 100, 000; 95%CI 112.68 to 156.17 per 100, 000). Prevalence ASRs decreased in AUD (APC [annual percentage change] −0.38%), and alcohol-induced cardiomyopathy (APC −1.85%), but increased in alcohol-associated cirrhosis (APC +0.44%) and liver cancer (APC +0.53%). Death ASRs from alcohol generally decreased, but there was an increase in death ASRs from alcohol-associated liver cancer (APC +0.51%). Between 2010 and 2019, there was a rise in the contribution of alcohol-related complications to the overall burden in countries with low and low-to-middle SDI, relative to the global scale. The contribution of DALYs from these complications among young adults was more pronounced in countries with lower SDI.

Conclusion: There was a significant rise in the global impact of cardiovascular and liver complications due to alcohol over the past decade, particularly in alcohol-associated liver disease. Countries with lower income levels are contributing more to this global burden from alcohol. There is a pressing need for effective strategies in response to the escalating burden.

Background and aims: Acute kidney injury (AKI) is common and is associated to high morbimortality in patients with alcohol-associated hepatitis (AH). Hepatorenal syndrome (HRS) is a severe form of AKI arising in patients with advanced cirrhosis. Information regarding prevalence and prognostic implications of HRS-AKI in patients with AH is scarce.
Method: Retrospective analysis of patients with AH admitted to 28 Spanish hospitals from 2014 to 2022. AH was defined based on the NIAAA criteria of "probable" or "definite" AH. Patients were classified into 3 groups based on AKI occurrence and phenotype: AH with HRS-AKI, HA with non-HRS-AKI (including prerenal AKI, acute tubular necrosis and unable to classify), and AH without AKI. We analyzed the prevalence of the different AKI phenotypes, and assessed survival at 28 and 90 days with Kaplan-Meier curves and log-rank test. Patients with AH and HRS-AKI were compared to a prospective cohort of patients with cirrhosis and HRS-AKI (n = 63) from Hospital Clínic of Barcelona.
Results: Out of 1, 746 patients with AH, 408 (23%) developed AKI; 77 (19%) were HRS and 331 (81%) were non-HRS-AKI (187 [46%] prerenal AKI, 36 [9%] acute tubular necrosis y 108 [26%] unable to classify). Patients with HRS-AKI had the lowest survival out of the three AH groups, followed by non-HRS-AKI and no-AKI (44%, 77%, 96% at 28 days; 24%, 65%, 91% at 90 days; both $p < 0.01$). Compared to patients with cirrhosis and HRS-AKI, patients with AH and HRS-AKI were younger, had higher median MELD, greater proportion of ACLF and lower survival (44% vs 75% at 28 days; 24% vs 54% at 90 days; both $p < 0.01$). Terlipressin was used in 46/77 (60%) patients with AH and HRS-AKI, with a 50% response rate. HRS-AKI recurrence rate among responders was 57%. Six (13%) patients developed severe adverse events related to terlipressin (acute respiratory failure [n = 2]; gastrointestinal hemorrhage [n = 2]; acral ischemia [n = 2]); 5 of them required treatment discontinuation. Predictive factors of response were AKI stage at diagnosis (HR 3.1[1.1–9.2]) and absence of ACLF (HR 3.3[1.3–10.0]). Terlipressin responders had higher 28-day survival (71% vs 24% in non-responders; $p < 0.01$).
Conclusion: HRS has the worst prognosis out of all AKI phenotypes in patients with AH. Terlipressin may be useful in patients with AH and HRS-AKI as a bridge to liver transplant or to recovery.

Metadoxine improves alcohol abstinence and is related to a lower risk of decompensation in cirrhosis at a median five-year follow-up: propensity score matching analysis

Fatima Higuera-de-la-Tijera[1], Alfredo Servin-Caamaño[2], Juan Miguel Abdo-Francis[3], Elia Hernández-Labra[4], Adriana Tovar-Aguilar[5], José Luis Pérez-Hernández[6]. *[1]Head of Gastroenterology and Hepatology Department, Hospital General de México "Dr. Eduardo Liceaga," Facultad de Medicina, Universidad Nacional Autónoma de México (UNAM), Mexico City, Mexico; [2]Internal Medicine Department, Hospital General de México "Dr. Eduardo Liceaga," Facultad Mexicana de Medicina, Universidad La Salle, Mexico City, Mexico; [3]Gastroenterology Department, Hospital Angeles Acoxpa, Mexico City, Mexico; [4]Psychology and Psychiatry Department, Hospital General de México "Dr. Eduardo Liceaga," Mexico City, Mexico; [5]Social work assistant from Gastroenterology and Hepatology Department, Hospital General de México "Dr. Eduardo Liceaga," Mexico City, Mexico; [6]Liver Clinic, Hospital General de México "Dr. Eduardo Liceaga," Facultad de Medicina, Universidad Nacional Autónoma de México (UNAM), Mexico City, Mexico*
Email: fatimahiguera@hotmail.com

Background and aims: Abstinence is the key in alcohol-related cirrhosis (AC). Some studies suggest metadoxine (MTD) reduces alcohol craving (OHc), but its long-term impact on AC has not been evaluated. Aim was to compare long-term MTD vs. non-pharmacological therapy on alcohol abstinence in compensated AC.
Method: Patients with compensated AC were included in a retrospective cohort. Data were collected on attendance at Alcoholics Anonymous (AA) meetings, adherence to psychiatric therapy provided by addiction-trained personnel (PTA), family support (FS), self-reported commitment to stop drinking (CSD), decompensations, and relapse in alcohol intake (RAI) during follow-up. Patients were divided in 2 groups: A) MTD, B) without specific pharmacological therapy. To compare between groups, a propensity score matching (PSM) was conducted. The risk of RAI was assessed using Kaplan-Meier analysis with a log-rank test in the PSM cohort. A p value<0.05 was significant.
Results: In the pre-matched cohort were 1042 pts, 79.1% men, mean age 52 ± 11 y/o, media follow-up 5.2 ± 1.3 years, 31.9% received long-term MTD to reduce OHc (median dose 1000 [500–2000] mg/d). Despite 67.7% reporting CSD and 68.9% having FS; adherence to AA meetings attendance and PTA was low: 31.2 and 27.3%. RAI occurred in 53.4%, median time to relapse was 22 (4–58) months, median number of relapses was 3 (1–10) times. Four covariables were associated with lower RAI: Age >40 y/o (456/877 [51.9%] vs. 100/165 [60.6%]; $p = 0.04$), MTD (122/332 [36.7%] vs. 434/710 [61.1%]; $p < 0.0001$), assistance to AA meetings (156/325 [48%] vs. 400/717 [55.8%]; $p < 0.02$), PTA (129/284 [45.4%] vs. 427/758 [56.3%]; $p = 0.002$). FS, CSD and sex were not significant. We conducted PSM to estimate the effect of MTD by pairing cases based on sex, age, AA attendance, PTA, FS and CSD. In the PSM cohort, 662 pts were obtained. MTD remained effective for reducing RAI (122/332 [36.7%] vs. 194/330 [58.7%]; OR: 0.41, 95%CI: 0.30–0.56; $p < 0.0001$). Even in those who experienced RAI, MTD prolonged the median time to the first RAI event (32 [8–84] vs. 17 [4.72] months; $p < 0.0001$). The total number of RAI events was lower in those receiving MTD (2 [1–6] vs. 3 [1–10]; $p < 0.0001$). Long-term MTD was also associated with fewer complications: variceal bleeding (28.3% vs. 37.9%; OR: 0.65, 95%CI: 0.47–0.89; $p = 0.009$), ascites (27.4% vs. 37.6%; OR: 0.63, 95%CI: 0.45–0.87; $p = 0.005$), encephalopathy (8.7% vs. 19.4%; OR: 0.39, 95%CI: 0.25–0.64; $p < 0.0001$), acute kidney injury (0% vs. 8%; OR: 0.97, 95% CI: 0.96–0.99; $p = 0.004$). MTD did not have an impact on development of spontaneous bacterial peritonitis, progression to Child-Pugh B/C, development of hepatocellular carcinoma, or mortality.
Conclusion: MTD is effective to improve alcohol abstinence. It is not clear whether the reduction of complications in patients with AC is directly driven by MTD or is indirectly related to abstinence itself.

Preliminary results of a phase I study of SZN-043, a novel R-Spondin mimetic, in healthy volunteers and subjects with liver cirrhosis

Edward J. Gane[1], Michael Lauw[2], Jay Tibbitts[2], Josh Koons[2], Jianyong Huang[2], Trudy Vanhove[3], Mark Yen[4], Chris Stevens[2], Christian Schwabe[5], Craig Parker[2]. *[1]Faculty of Medicine, University of Auckland, Auckland, New Zealand; [2]Surrozen Inc., South San Francisco, United States; [3]Longitude Capital, Menlo Park, United States; [4]Prometheus BioSciences, Los Angeles, United States; [5]New Zealand Clinical Research Limited, Auckland, New Zealand*
Email: jtibbitts@surrozen.com

Background and aims: Severe alcohol-associated hepatitis (SAH) is a huge unmet medical need, associated with high mortality. Corticosteroids have not been associated with improved long-term survival benefit and there has been no improvement in survival in SAH with medical management during the last 60 years. SAH is associated with impaired hepatocyte proliferation. Elevated Wnt signaling and increased hepatocyte proliferation have been linked to greater survival, suggesting that therapies that can enhance hepatocyte proliferation can benefit patients. R-spondins (RSPOs) are known enhancers of Wnt signaling. SZN-043 is a bispecific fusion protein and hepatocyte-specific RSPO mimetic shown to induce hepatocyte-targeted Wnt signaling and hepatocyte proliferation in preclinical studies. SZN-043 was evaluated for safety, pharmacokinetics, and pharmacodynamics in a single center, first-in-human, Phase 1, randomized, double-blind, placebo-controlled, single ascending dose (SAD) and multiple ascending dose (MAD) study in healthy volunteers (HV) and subjects with liver cirrhosis (LC).
Method: Thirty-five (35) subjects were recruited across SAD and MAD cohorts. In Part 1, 12 HVs (6 active/2 placebo per cohort) received a single IV dose of SZN-043 at 1 or 3 mg/kg. In Part 2, 8 LCs (3 active/1 placebo per cohort) received a single IV dose at 0.5 or 1 mg/kg. In Part 3, 18 HVs (6 active/2 placebo per cohort) received 0.5, 1, or 1.5 mg/kg of SZN-043 on Days 0 and 4.
Results: SZN-043 was well tolerated across all populations and dosing regimens. No serious adverse reactions nor infusion reactions were observed. Asymptomatic serum transaminase elevations were observed in 4 HVs in Part 1 and 2 HVs in Part 3. No transaminitis was observed in any LC subject. Severity appeared to be dose dependent, with 5 subjects experiencing no more than a mild (Grade 1) transaminase elevation and a Grade 2 alanine aminotransaminase elevation observed in 1 subject at 3 mg/kg. All resolved without intervention. No clinical sequalae or other related significant indicators of liver dysfunction were observed. In all other subjects, only mild to moderate adverse events judged to be at least possibly related were observed in 4 (other) subjects. Serum SZN-043 exposure was consistent with an IgG-based fusion protein. Pharmacologic activity in the liver was observed, as measured by increased metabolism of methacetin by cytochrome P450 1A2, a Wnt-target gene.
Conclusion: Administration of SZN-043 to HVs and LCs was well tolerated at doses where evidence of pharmacology was observed. Combined with the promise of the underlying biological mechanisms, the results from this study warrant further clinical investigation of SZN-043. A Phase Ib study in subjects with severe alcohol-associated hepatitis is under way.

SAT-262

Assessing efficacy and safety of baclofen in the management of alcohol dependence among patients with alcoholic liver disease

Email: bertalopezsaez@gmail.com

Background and aims: Alcohol use disorder (AUD) is the main cause of cirrhosis. Abstinence enhances survival, with clinical guidelines favoring baclofen as the first choice for preventing/reducing consumption in alcohol-related liver disease (ALD). Limited evidence exists regarding its real-world use. Our study assesses baclofen's efficacy (abstinence/reduction) and safety in ALD patients.
Method: A retrospective, single-center observational study was conducted, involving patients with ALD and alcohol-related cirrhosis (AC) who initiated baclofen between December 2022 and October 2023. Demographic, clinical and laboratory data were collected at baclofen onset (baseline) and 3 and 6 months thereafter.
Results: A total of 46 patients were included. The mean age was 53.8 (SD ± 9.3) years, 84.7% were men, and 84.7% had AC (Child A: 38.5%, Child B/C: 61.5%). The median Child-Pugh score and MELD score in patients with AC was 7 [IQR: 5–11] and 11 [IQR: 6–22], respectively. At 3 months, 54.3% were abstinent and 24% had reduced consumption, while 54.3% continued with baclofen, 15.2% reduced the dose and 30.4% discontinued it. Abstainers presented a decline of 1.06 (SD 0.6) points in MELD score, while that of consumers increased by 2.25 (SD 2.9) points compared to baseline ($p = 0.001$). Among patients followed up at 6 months ($n = 33$), 54.5% were abstinent and 15.2% had reduced consumption. Of these, 44% continued with baclofen, 23.5% had reduced the dose and 30.3% had discontinued it. The MELD of abstainers decreased by 1.47 (SD 1.3) points, whereas that of consumers increased by 2.87 (SD 2.1), $p < 0.001$.Concerning safety, there were no instances of renal or hepatic impairment attributable to baclofen. However, 32.6% experienced drowsiness without signs of hepatic encephalopathy. Abstinent patients were compared to those non-abstinent. The univariate analysis showed that the use of psychotropic drugs (68% vs 31%, $p = 0.04$), Child-Pugh score (7 [5–11) vs 5 [5–11], $p = 0.01$), MELD score (12 [6–22] vs. 9 [6–22], $p = 0.02$); baclofen treatment (80% vs 24%, $p < 0.01$), and baclofen onset during hospital admission (60% vs 14%, $p = 0.02$) were associated with abstinence at 3 months. Only treatment with baclofen was independently associated with abstinence (OR 13.4, CI 2.4–24.9, $p = 0.002$). The univariate analysis showed that the baclofen onset during hospital admission (66.7% vs 26.7%, $p = 0.03$) and baclofen treatment (66.7% vs 26.7%, $p = 0.02$) were associated with abstinence at 6 months. Only treatment with baclofen was independently associated with abstinence (OR 4.5, CI 1.3–6.8, $p = 0.03$).
Conclusion: Baclofen demonstrates efficacy in achieving alcohol abstinence in ALD and AC, with rates of 78% and 70% at 3 and 6 months. Drowsiness, the most common side effect, led to dose adjustments or withdrawal in one-third of patients. Baclofen treatment emerged as an independent predictor of abstinence, supporting its use in ALD.

SAT-263

Resmetirom treatment of a subgroup of patients with possible MetALD enrolled in MAESTRO-NASH, a phase 3 NASH/MASH serial liver biopsy study

Stephen A. Harrison[1], Jörn M. Schattenberg[2,3], Rebecca Taub[4], Dominic Labriola[4], Brandon Hill[4], Vlad Ratziu[5]. *[1]Pinnacle Clinical Research, San Antonio, TX, United States; [2]Metabolic Liver Research Program, I. Department of Medicine, University Medical Center of Johannes Gutenburg University Mainz, Mainz, Germany; [3]The*

Department of Internal Medicine II, Saarland University Medical Center, Homburg, Germany; [4]Madrigal Pharmaceuticals, Inc., West Conshohocken, PA, United States; [5]Pinnacle Clinical Research, San Antonio, TX, United States
Email: vlad.ratziu@gmail.com

Background and aims: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo-controlled Phase 3 trial evaluating efficacy of resmetirom in patients with biopsy-confirmed non-alcoholic steatohepatitis (NASH/MASH) and fibrosis. 966 patients with biopsy-confirmed NASH were randomized 1:1:1 to resmetirom 80 mg, resmetirom 100 mg, or placebo once daily. Dual primary end points at Week 52 were achieved with both resmetirom 80 mg and 100 mg: NASH resolution with no worsening of fibrosis (NR) or ≥1-stage improvement in fibrosis with no worsening of NAS (FI). The benefit of resmetirom in patients with and without indicators of increased alcohol consumption above protocol-allowed limits for NASH/MASH was assessed on biopsy end points and MRI-PDFF (liver fat reduction).
Method: Carbohydrate Deficient Transferrin (CDT) was collected longitudinally in all patients over 52 weeks. Post-randomization, a PEth test was performed in patients suspected of increased alcohol consumption. Patients with baseline or post-baseline CDT >2.5% (ULN 2.47) and/or a PEth >20 ng/ml (ULN 20 ng/ml) were assigned to a possible "MetALD" subgroup. Analyses were performed on 782 patients who had both a baseline and Week 52 biopsy.
Results: Of the 782 patients, 75 patients (9.6%) were included in the MetALD subgroup and 707 were not. Baseline characteristics, mean (SD), for the MetALD and non-alcohol subgroups included Age = 57.7 (10.5), 60.1 (10.7); percent male = 59%, 42%; Presence of diabetes = 50.7%, 67.9%; CDT% = 2.2 (1.0), 1.6 (0.3); BMI 33.0 (5.5), 35.8 (6.6); MRI-PDFF = 21.7% (7.4), 17.4 (6.5), Fibroscan VCTE = 13.4 (6.7), 13.2 (6.6); Fibroscan CAP = 348.5 (38.5), 347.0 (38.7); FIB-4 = 1.67 (0.69), 1.37 (0.66); AST = 45.6 (21.8), 40.3 (22.9); ALT = 55.2 (24.8), 55.5 (32.2); GGT = 117.9 (170.8), 75.3 (85.6); Bilirubin = 0.69 (0.31), 0.65 (0.29); MCV = 92.3 (5.8), 90.3 (5.6); Platelets = 200, 229; NAS (median) = 5 (5, 6), 5 (5, 6); and %F3 = 66.7, 62.5. For the group of patients with low or no alcoholic consumption:.
Patients treated with 80 mg and 100 mg resmetirom doses (n = 224 and 228, respectively): 29.9% and 36% had NR, 29% and 33.3% had FI, 59.2% and 71.2% showed a ≥30% reduction from baseline in MRI-PDFF. For patients treated with placebo (n = 255), the corresponding results were 10.3%, 13.7%, and 24.5%. For the possible MetALD group: Patients treated with 80 mg and 100 mg resmetirom doses (n = 34 and 20, respectively): 29% and 35% had NR, 35% and 30% had FI, and 88% and 81% showed a ≥30% reduction from baseline in MRI-PDFF. For patients treated with placebo (n = 21), the corresponding results were 10%, 19%, and 14%.
Conclusion: A total of 75 (9.6%) of patients had possible MetALD during the first 52 weeks of MAESTRO-NASH. Baseline characteristics showed a higher mean GGT and FIB-4 in the MetALD versus low alcohol group. Response rates to resmetirom in patients with suspected MetALD were similar to those without MetALD.

SAT-266

Fibrosis stage progression in alcohol-related liver disease evaluated by repeated biopsies

Ellen Lyngbeck Jensen[1,2], Nikolaj Torp[1,2], Stine Johansen[1,2], Katrine Thorhauge[1,2], Camilla Dalby Hansen[1], Johanne Kragh Hansen[1,2], Peter Andersen[2], Emil Deleuran Hansen[1,2], Ida Falk Villesen[1,2], Katrine Tholstrup Bech[1,2], Charlotte Wernberg[1], Katrine Lindvig[1], Sönke Detlefsen[2,3], Aleksander Krag[1,2], Maja Thiele[1,2], Mads Israelsen[1,2]. *[1]Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark; [2]Department of Clinical Research, University of Southern Denmark, Odense, Denmark; [3]Department of Pathology, Odense University Hospital, Odense, Denmark*
Email: ellen.lyngbeck.jensen@rsyd.dk

Background and aims: Alcohol-related liver disease (ALD) is recognised as the most severe form of steatotic liver disease, yet precise progression rates are not well established. Understanding the annual rate of fibrosis progression in ALD patients, along with the impact of current alcohol intake and cardiometabolic risk factors, is crucial for optimizing management and informing clinical trial design. We therefore assessed annual fibrosis progression from patients with ALD in a repeated biopsy design.
Method: We included patients with ALD who had undergone liver biopsies twice in randomised trials and prospective cohorts at Centre for Liver Research in Odense. Biopsies were assessed by a single expert pathologist who was masked to all clinical data. Liver fibrosis was evaluated according to the Kleiner scoring system for fibrosis: F0, F1, F2, F3, and F4. We excluded patients who could not have progression of fibrosis stage (F4 at baseline). We calculated annual fibrosis stage progression rates along with 95% confidence intervals (CI). In multivariable models, we calculated the impact of self-reported current alcohol use and cardiometabolic risk factors (type 2 diabetes, BMI) on fibrosis stage progression, adjusted for age and sex.
Results: We included 80 patients from four studies from 2013 to 2022. The median age at baseline was 60 (IQR: 11) years, 69 (86%) were male and 35 (44%) reported abstinence for at least one week. The median BMI was 29 (IQR: 8) and 18 (23%) had type 2 diabetes at baseline. At baseline, fibrosis stages 0, 1, 2, and 3 were detected in 4 (5%), 23 (29%), 32 (40%), and 21 (26%) of the patients. Over a median follow-up of 2.2 (IQR: 1.5) years, 36 (45%) experienced fibrosis stage progression, 30 (38%) had stable disease, and 14 (18%) regressed. The number of patients who experienced fibrosis stage progression was higher compared to patients with improvement and stable disease (p = 0.027). We calculated the mean change in fibrosis stage based on the difference between fibrosis stage in the paired biopsies and found a fibrosis progression rate of 0.22 stages/year (95% CI: 0.053–0.382, p = 0.010). This is equivalent to fibrosis progression of one stage over 4.5 years. After adjusting for sex and age in a multivariate analysis, the fibrosis progression rate was 0.24 stages/year (95% CI: 0.084–0.401, p = 0.003) and no significant associations were observed with BMI and type 2 diabetes. In the same analysis, current alcohol use at baseline exhibited an impact correlating with a 0.66-stages increase (95% CI: 0.224–1.105, p = 0.004) compared to patients reporting abstinence.
Conclusion: In this study we show the disease dynamic of ALD and found that patients with ALD progress one stage per 4.5 years and is accelerated in patients with current alcohol intake. These data should be used for guiding clinical management of patients with ALD and informing clinical trial design.

Email: jgrata@recerca.clinic.cat

Background and aims: Metabolic risk factors (MRF) and harmful alcohol consumption often coexist in the same patient. The synergistic effect of both risk factors on the risk of liver disease has been previously described; however, information regarding prevalence and prognostic implications of MRF in patients with alcohol-associated (AH) is scarce.
Method: Retrospective analysis of patients admitted to 28 Spanish hospitals for an episode of AH meeting the NIAAA criteria between 2014 and 2022. We assessed the prevalence of both individual MRF and metabolic syndrome (MS), and their impact on mid-term (90 days) and long-term (1 year) survival. MS was defined based on the *National Cholesterol Education Program, Adult Treatment Panel III (NCEPT-III)* criteria. As an exploratory analysis, we also assessed the prevalence of steatotic liver disease associated with MRF and moderate alcohol consumption (MetALD) in this population as defined by a recent consensus (Rinella ME et al, *J Hepatol* 2023). We used Chi-square and Mann-Whitney tests for the descriptive analyses, the Kaplan-Meier curves and log-rank test for the survival analyses and the Cox regression analysis to identify risk factors of mortality. All statistical analyses were performed with SPSS version 27.0.1.0.
Results: Out of 1, 746 patients included, 403 (23%) had arterial hypertension, 324 (19%) had obesity (BMI ≥30) and 208 (12%) had diabetes. One hundred eighty-seven (11%) patients met criteria for MS. Patients with MS were older (median age of 53 [48–60] vs 51 [45–57] years, $p < 0.01$), less frequently women (14% vs 29%, $p < 0.01$) and had slightly higher baseline serum creatinine (median of 0.8 [0.6–0.9] vs 0.7 [0.6–0.9] mg/dL, $p < 0.01$). Patients with and without MS had both similar alcohol intake (10 [7–14] vs 10 [7–14] units/day, $p = 0.992$) and duration of alcohol consumption prior to AH (24 [14–35] vs 20 [15–30] years, $p = 0.384$). MS was not associated with mortality in the total cohort; however, it was an independent risk factor of mortality (HR 1.7 [1.1–2.9]) in the subgroup of patients who survived an episode of AH and resumed alcohol intake during follow-up. In this latter subgroup, 1-year survival was lower in patients with MS (65.2% vs 82.8, $p < 0.01$). Only 249 (14%) patients met the MetALD consensus criteria; the most frequent reason for failing to meet the criteria was an alcohol consumption >50 g/day in women and >60 g/day in men (80%). Survival in patients with and without MetALD was similar (84.2% vs 83.6% at 90 days, $p = 0.873$; 76.2% vs 73.8% at 1 year, $p = 0.352$).
Conclusion: MRF are common in patients with AH. After surviving an episode of AH, the combination of active alcohol consumption and the presence of metabolic risk factors defines a population at high risk of death.

SAT-268

Bariatric surgery is a major independent factor of disease progression in cirrhotic patients with alcohol-related liver disease

Louis Onghena[1,2,3], Lindsey Devisscher[4], Hans Van Vlierberghe[5], Sarah Raevens[5], Xavier Verhelst[5], Yves Van Nieuwenhove[6], Sander Lefere[5], Anja Geerts[5]. [1]Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium; [2]Department for Human Repair and Structure, Department of Gastrointestinal Surgery, Ghent University Hospital, Ghent, Belgium; [3]Department of Internal Medicine and Paediatrics, Hepatology Research Unit, Ghent University, Ghent, Belgium; [4]Gut-Liver Immunopharmacology Unit, Ghent, Belgium; [5]Hepatology Research Unit, Ghent, Belgium; [6]Department of Gastrointestinal Surgery, Ghent, Belgium
Email: Louis.onghena@ugent.be

Background and aims: Patients with a history of bariatric surgery (BS) are susceptible to developing alcohol use disorder, potentially resulting in end-stage liver disease. There is paucity of data on the evolution of cirrhotic disease. Our aim was to describe the demographics and mortality in hospitalizations over time in patients diagnosed with alcohol-related liver disease, in relation to BS.
Method: We included patients hospitalized at our hospital between 1/1/2010 and 30/09/2023 with ARLD. Data were retrieved retrospectively from the most recent hospitalization. Statistical analysis was performed using Mann-Whitney U and Chi^2 tests.
Results: 46/275 (16.7%) of cirrhotic patients admitted with ARLD had a history of bariatric surgery. Patients with a history of BS were predominantly female (76.1%), in contrast to the non-BS population (29.7%) ($p < 0.0001$) and were significantly younger at the time of diagnosis (46 vs 58 years, $p < 0.0001$), as well as the first hospitalization (48 vs 61, $p < 0.0001$). Liver disease evolved at a faster pace in BS group with a shorter time to first hospitalization (5 vs 13 months, $p = 0.036$), and a shorter time between first and second (45 vs 114 months, $p = 0.011$) and second and third (31 vs 86, $p = 0.006$) hospitalizations. The population with primary hospitalization due to ACLF was significantly larger in the BS group (60.9% vs 27.6%, $p < 0.0001$) and throughout the following hospitalizations remained more prominent in the BS group; with significantly more patients hospitalized with pre-ACLF as well (8.7% vs 2.6%, $p = 0.045$). Conversely, stable decompensated cirrhosis occupied a substantial share in the group without BS during the first four ($p = 0.004$, $p < 0.0001$, $p < 00.1$, $p = 0.034$) hospitalizations. Modeled transplant-free survival, through Cox proportional regression analysis with age at diagnosis, was lower in the BS group ($p = 0.004$), with the main cause of death was ACLF in 81.3% vs 25.0% in the control group. Within the ACLF hospitalizations, alcoholic steatohepatitis (25.0% vs 12.9%, $p = 0.0014$) and bacterial infection (57.1% vs 43.5%, $p < 0.0001$) were predominant triggers for the BS group, whereas gastro-intestinal bleeding (3.6% vs 21.0%, $p = 0.037$) occurred significantly more often in the non-BS group. The weekly amount of alcohol consumed during drinking periods (41.0 (22.5, 64.5) vs 55.0 (35.0, 80.0) units/week, $p = 0.002$) and duration of use (8.0 (5.0, 15.0) vs 23.0 (15.0, 30.0) years, $p < 0.001$) were significantly lower in the BS group.
Conclusion: Cirrhotic BS patients hospitalized with ARLD develop acute decompensations at a faster pace, with more overall ACLF hospitalizations, with an equally evolving cumulative mortality, despite being 12 years younger on average. There is a need for prospective research to substantiate stricter pre-BS patient selection guidelines, especially regarding alcohol use.

SAT-269

Portal hypertension in alcohol-related hepatitis: natural history and prognostic value

Karim Gebara[1], Lionel Moulis[1], Benjamin Riviere[1], Stéphanie Faure[1], Georges-Philippe Pageaux[1], José Ursic Bedoya[2]. [1]Montpellier University Hospital, Montpellier, France; [2]Montpellier University Hospital, Université de Montpellier, Montpellier, France
Email: jose.ursicbedoya@chu-montpellier.fr

Background and aims: Portal hypertension (PH) is a prominent feature in the setting of alcohol-related hepatitis (AH). It is however unclear whether the severity of PH has a prognostic impact in this context. Moreover, the natural history of PH after an episode of AH is not thoroughly understood. The aim of our study was to evaluate the impact of severe PH on 6-months transplant-free survival (TFS) in patients admitted for histologically proven symptomatic AH and describe natural history of PH in this context.
Method: We retrospectively included all patients with a histologically proven AH diagnosis admitted to our tertiary care center, between January 2013 and December 2021. We excluded transplanted patients and patients with uncontrolled infection/gastrointestinal bleeding or multi-organ failure at admission. Severe PH was defined by endoscopic PH and ascites or portal pressure gradient >22 mmHg. We defined persistence of PH at 6 months: by the persistence of ascites and/or an episode of GI bleeding linked to PH and/or the need for a TIPS placement and/or the persistence of at least grade II oesophageal varices. Primary outcomes were 6-month TFS and the impact of severe PH on 6-month TFS. We also aimed to describe the evolution of PH and investigate if there were factors associated with severe PH at admission and its persistence at 6 months.
Results: 127 patients were included; median follow-up was 20 months. Mean age was 52 (±9.45) and 83% were male patients. Mean discriminant function (DF) was 59.54 (±23.40) and mean MELD score was 25.17 (±6.59). PH was severe in 71.6%. During the follow-up 25% died and 25% underwent liver transplantation, median TFS was 16.8 months (95% CI [7.75; 24.31]). Severe PH was not significantly associated with 6-month TFS ($p = 0.96$). On multivariate analysis, independent factors associated with 6-month TFS were MELD score (OR 1.22 95% CI [1.07; 1.38]) and non-response to corticosteroids (OR 6.39 95% CI [1.63; 25.10]). On multivariate analysis, independent factors associated with severe PH at admission were male gender (OR 3.84 95% CI [1.28; 11.55]), Child-Pugh score (OR 1.35 95% CI [1.00; 1.82]) and CLIF-C ACLF score (OR 1.08 95% [1.02; 1.13]. At 6 months 39 patients (30.7%) had persistent PH, among whom 25 (59.5%) were considered abstinent. In the multivariate model among patients with initial PH only the baseline CLIF-C ACLF score (which includes leukocytes count) was identified as a risk factor for the persistence of PH at 6 months (OR = 1.07 95% CI [1.00; 1.15], $p = 0.05$).
Conclusion: Severe PH was not significantly associated with 6-month TFS. Our results underscore a central role of systemic inflammation in the development and persistence of PH over time after an episode of AH, irrespective of alcohol withdrawal. These results are consistent with recent reports highlighting the role of extracellular vesicles persistent over time.

SAT-272

Updated definition of healthy alanine aminotransferase levels in a metabolically and histologically normal population

Jonggi Choi[1], Ji Won Yang[1], Hyeyeon Hong[1], Sung Won Chung[1], Chaeyeon Lim[1], Jina Park[1]. [1]*Asan Medical Center, Seoul, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and aims: This study re-evaluates the upper limit of normal (ULN) for alanine aminotransferase (ALT), traditionally set at 40 U/L, using histological and metabolic parameters in Asian living liver donors.
Method: We conducted a retrospective analysis of 5, 455 potential living liver donors from 2005 to 2019. Patients were screened for hepatitis B, C, HIV, and alcohol use. Histologically and metabolically healthy participants was assessed using the modified Prati criteria (body mass index <23 kg/m^2, triglyceride ≤200 mg/dL, fasting glucose ≤105 mg/dL, total cholesterol ≤220 mg/dL). The new healthy ULN of ALT was determined at the 95th percentile among participants without hepatic steatosis or metabolic dysfunction.
Results: The median age of the cohort was 30 years, with a predominance of males (66.2%). While 3, 162 (58.0%) did not have hepatic steatosis, 1, 553 (49.1%) met the modified Prati criteria, being metabolically healthy. The new healthy ULN of these participants was 34 U/L for males and 22 U/L for females, significantly lower than the conventional 40 U/L. A 'borderline' ALT category (34–40 U/L for males, 22–40 U/L for females) was also introduced to participants at risk of hepatic steatosis or metabolic dysfunction.
Conclusion: Our study suggests that the traditional ALT ULN is higher than healthy levels for a metabolically and histologically verified Asian population. The proposed ULN values are 34 U/L for males and 22 U/L for females. The introduction of a 'borderline' category aids in better disease risk stratification, highlighting the need for updated ULN of ALT.

Is it worth staining for hepatic glucocorticoid receptors in alcohol related hepatitis?

Mina Ignat[1,2,3], Ioana Rusu[1,2], Adelina Horhat[2], Bumbu Andreea Livia[1,2,3], Andreea Fodor[1,2,3], Petra Fischer[1,2,3], Oana Nicoara-Farcau[1,2,3], Bogdan Procopet[1,2,3], Horia Ștefănescu[1,2,3]. [1]*Regional Institute of Gastroenterology and Hepatology "Prof. Dr. O. Fodor," Cluj-Napoca, Romania," Cluj-Napoca, Romania;* [2]*University of Medicine and Pharmacy "Iuliu Hatieganu," Cluj Napoca, Romania, 3rd Medical Clinic, Cluj-Napoca, Romania;* [3]*Liver Research Club, Cluj-Napoca, Romania*
Email: ignat.mina@gmail.com

Background and aims: The precise mechanism of action of corticotherapy for treating severe alcohol related hepatitis (AH) is still unknown. The function of glucocorticosteroids (CS) are mediated by intracellular glucocorticoid receptors (GR). The most known GR isoform is GR alpha, which is the most widely expressed, being responsible for the classic functions of glucocorticoids. Other isoform, such as GR beta, acts as a dominant negative inhibitor of GR alpha. Our aim is to evaluate the role of hepatic GR as a prognostic tool in AH.
Method: All consecutive patients with a history of alcoholism, suggestive liver chemistry data, biopsy proven AH, were included between November 2015–December 2020. Immunohistochemistry (IHC) staining was performed using a fully automated slide preparation system (Leica automatic Bond-Max system). IHC staining was performed with Anti-Glucocorticoid Receptor alpha antibody (Abcam3580) and Beta antibody (ab233165). The staining was scored according to intensity (0-no staining, 1-weak, 2-moderate and 3-strong), in hepatocyte nuclei, citoplasma and biliary epithelium.
Results: We included 110 patients with severe alcohol related hepatitis, 75.5 were male and the median age was 52. 90.9% were decompensated, 36.5% patients had an infection at admission and 25.5% developed a nosocomial infection. Median Child-Pugh at diagnostic was 11 (6; 14), Meld 23 (6; 51), Maddrey 72.2 (32; 203). Median follow-up was 23 months (0–78) with 1 month survival of 80%. Out of all patients, 85 (83.8%) were treated with corticotherapy and 82.9% responded to the corticotherapy treatment, evaluated with Lille score at day 7. 28.9% had none-low alpha GR, 71.7% had moderate-strong alpha GR. Otherwise, 65.6% had none-low beta GR and 34.4% had moderate-strong GR. In the biliary epithelium, alpha GR 34.1% had no receptors, 45.9% had weak receptors and 20% had moderate receptors. In the group of patients treated with corticotherapy, the patients with low intensity of alpha biliary GR receptors had a worst survival at 1 month ($p = 0.01$). Patients with lower expression of the biliary GR receptors had higher bilirubin level ($p = 0.04$), Maddrey score (0.03) and Meld score ($p = 0.04$). Alpha biliary GR were not associated with infections.Overall expression of alpha GR receptors (hepatocyte nuclei, citoplasma and biliary epithelium) was associated with higher risk of mortality on short term ($p = 0.06$) and medium term, $p = 0.01$.

Conclusion: Alpha glucocorticoid receptors subclasses show distinct prognoses. Biliary epithelium GR expression could be a marker for short term survival, possibly by mediating the effects of glucocorticoids. The glucocorticoid receptors in the liver may not be the only ones implicated in GS response, others sites such as intestinal epithelium could have an important role.

SAT-274

Serum proteomic analyses reveal elevated HGF and IL-8 in patients with alcohol-related hepatitis compared to decompensated alcohol-related cirrhosis and can differentiate patients with AH at risk of infection from those at risk of acute kidney injury

Luke D. Tyson[1,2,3], Stephen R. Atkinson[1,2,4], Vishal C. Patel[5,6,7], Michael Allison[8], Andrew Austin[9], James W. Dear[10], Ewan H. Forrest[11,12], Robert W. Email: luke.tyson@nhs.net

Background and aims: Alcohol-related hepatitis (AH) is the most severe alcohol-related liver disease (ALD). Infection and acute kidney injury (AKI) are associated with mortality. Multiple serum cytokines and growth factors have been associated with AH in comparison to compensated ALD or healthy controls. Our aim was to compare AH to controls with decompensated ALD cirrhosis to identify analytes associated with severe AH and to characterize endophenotypes of severe AH at risk of incident infection and AKI.

Method: Using MSD U-PLEX assays, the serum concentrations of IL-1alpha, IL-1beta, IL-6, IL-8, IL-10, IL-18, IL-22, IL-1 receptor antagonist, TGF-beta1, TGF-beta2, TGF-beta3, TNF-alpha, IFN-gamma, epidermal growth factor, hepatocyte growth factor (HGF), insulin-like growth factor, platelet-derived growth factor subunit A, vascular endothelial growth factor, cluster of differentiation 163, lipopolysaccharide binding protein, programmed cell death protein 1, programmed death-ligand 1, TWEAK, cystatin C, neutrophil gelatinase-associated lipocalin, and beta-2 microglobulin (B2M) were quantified in baseline (day-0) serum from patients recruited to several RCTs and cohort studies with similar inclusion criteria. AH was defined by Steroids or Pentoxifylline for Alcoholic Hepatitis (STOPAH) criteria; controls had decompensated ALD cirrhosis without AH. Incident infection was defined as infection at day-7 without infection at day-0; incident AKI as AKI at day-7 without AKI at D0, AKI defined by an adapted International Club of Ascites definition. Significance was tested by Mann-Whitney U, adjusted for multiple comparisons by Bonferroni correction.

Results: HGF and IL-8 were notably elevated in AH vs decompensated ALD cirrhosis (n = 856 vs n = 187; 7.90 ng/ml vs 2.61 ng/ml, p < 2.60E-16; 0.39 vs 0.07, p < 2.60E-16, respectively), other analytes less so. Within the AH cohort, IL-6, IL-22, and B2M were elevated at day-0 in those who died at day-90, compared to those alive at day-90 (n = 170 vs n = 556; 0.027 ng/ml vs 0.018 ng/ml, p = 1.95E-8; 0.004 vs 0.002, p = 2.05E-4; 169 vs 96, p = 1.05E-3, respectively). Day-0 IL-6 was elevated in those who developed incident infection compared to those who did not (n = 76 vs n = 656; 0.029 ng/ml vs 0.019 ng/ml, p = 3.09E-3). Day-0 HGF and IL-8 were elevated in those who developed incident AKI compared to those without AKI at day-0 or day-7 (n = 75 vs n = 300; 12.66 ng/ml vs 7.49 ng/ml, p = 1.70E-3; 0.73 vs 0.39, p = 7.25E-3).

Conclusion: In severe AH, HGF and IL-8 are markedly elevated compared to decompensated ALD cirrhosis without AH. Different AH endotypes may suffer different complications, implying differing pathophysiology with implications for putative treatments. Further work exploring the role of IL-6 in patients with AH who develop infection, and IL-8 and HGF in those who develop AKI, may help in the early identification and treatment of these deadly complications.

SAT-275

Role of neutrophil lymphocyte ratio in transition of alcoholic cirrhosis with acute decompensation to unstable decompensated cirrhosis

Feixiang Xiong[1], Tingting Jiang[2], Lihua Yu[3], Yandan Jiang[2], Qin Zhang[2], Zhiyun Yang[2], Xian-bo Wang[2], Yuyong Jiang[2]. *[1]Beijing Ditan Hospital, Capital Medical University, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China; [2]Beijing Ditan Hospital, Capital Medical University, Beijing, China; [3]Beijing Ditan Hospital, Capital Medical University, Beijing, China*
Email: xiangakb@163.com

Background and aims: According to PREDICT research conducted by EASL, the 90-day mortality rate of unstable decompensated cirrhosis (UDC) can be up to 21%, with the recurrence of infection being the main cause for the worsening of patients with acute decompensation (AD). As a key indicator of inflammation and immunity, neutrophil lymphocyte ratio (NLR) is regarded as an important predictor of liver diseases and inflammatory diseases, such as acute-on-chronic liver failure (ACLF) and sepsis. The aim of this study is to investigate the predictive value of NLR in the progress from AD of alcoholic cirrhosis (AC) to UDC within 90 days.

Method: We enrolled 679 patients of AC with AD in Beijing Ditan Hospital of Capital Medical University and collected all previous data of the patients within 48 hours of admission. With the previous data and the clinical and laboratory data collected within 90 days, we predicted the possibility of UDC. The end point was hospitalization due to liver-related complications (bacterial infection, variceal bleeding, hepatic encephalopathy, or grade 2 or worsening ascites). Multivariable COX regression analysis was conducted to predict the risk factors for UDC and to test NLR's value of prediction in liver-related complications. Kaplan-Meier survival curve, restricted cubic spline, and subgroup analysis were performed to analyze the predictive value of NLR.

Results: 185 (27.2%) cases of AD progressed to UDC in 90 days. In multivariable analysis, NLR was an independent predictor of UDC (HR 1.51; 95% CI 1.06–2.15; p = 0.024).COX regression showed that NLR was an independent risk factor for UDC in 3 patients groups separately with ascites (HR: 1.58, 95%CI:1.07–2.32, p = 0.021), infection (HR:1.6 4, 95%CI:1.03–2.6, p = 0.036) and variceal bleeding (HR:2. 12, 95%CI:1.21–3.71, p = 0.009). Maximally selected rank statistics were utilized to find 2.45 as the optimal cut-off to divide patients into high-risk group and low-risk group and statistical differences existed in the two groups when it came to predict the

progress from AD to UDC and the mortality within 90 days ($p < 0.001$ and $p = 0.012$ respectively). Restricted cubic splines showed that the risk of UDC was associated with increasing NLR in both groups regardless of high or low CLIF-C AD scores. NLR remained the key predictor for UDC across all Age, TB, Creatinine, INR subgroups and was correlated with Sodium ≤135 mmol/L, Leukocyte ≤10 subgroups.
Conclusion: NLR was a novel indicator predicting the transition of AC with AD to UDC, which can help identify patients with UDC early and prevent deterioration of clinical end points.

FIB-4 score as a predictor of mortality outcomes in individuals with metabolic dysfunction-associated steatotic liver disease with moderate alcohol consumption: a nationwide cohort study

Majd Aboona[1], Pojsakorn Danpanichkul[2], Vincent Chen[3], Pooja Rangan[1], Donghee Kim[4], Naim Alkhouri[5], Mazen Noureddin[6], Juan Pablo Arab[7,8], Karn Wijarnpreecha[1,9,10]. *[1]University of Arizona College of Medicine-Phoenix, Phoenix, United States; [2]Chiang Mai University, Thailand, Thailand; [3]University of Michigan Health System, Ann Arbor, United States; [4]Stanford University School of Medicine, Stanford, United States; [5]Arizona Liver Health, Chandler, United States; [6]Houston Research Institute and Houston Methodist Hospital, Houston, United States; [7]Pontificia Universidad Catolica de Chile, Santiago, Chile; [8]Western University and London Health Sciences Centre, London, Canada; [9]Banner University Medical Center, Phoenix, United States; [10]BIO5 Institute, University of Arizona College of Medicine-Phoenix, Phoenix, United States*
Email: aboona@arizona.edu

Background and aims: Steatotic liver disease, more specifically Metabolic dysfunction-associated steatotic liver disease (MASLD) has become a leading cause of chronic liver disease worldwide. MASLD is defined as patients with steatosis meeting 1 of 5 cardiometabolic criteria. The global prevalence of MASLD is thought to be 30% and its prevalence is increasing yearly by 0.7%. A new subcategory termed MetALD has also been described and defined as individuals with MASLD with increased alcohol intake. In males, increased alcohol consumption is defined as 3–6 drinks (210–420 g) per week. In females, increased alcohol consumption is defined 2–5 drinks (140–350 g) per week. We conducted a population-based study with the aim to compare the longitudinal outcomes of individuals with MetALD stratified by FIB-4 scores.
Method: This study was performed within the National Health and Nutrition Examination Survey (NHANES) data from 2017 to 2018. Vibration controlled transient elastography (VCTE, FibroScan) was used to evaluate the presence of steatosis. Steatosis was defined as a Controlled Attenuation Parameter ≥288 dB/m. We excluded patients with other causes of liver disease, underweight, baseline decompensated cirrhosis, baseline cancer diagnosis, prior bariatric surgery, or missing data on race, body mass index (BMI), aspartate and alanine aminotransferase, and platelet. Patients who met 1/5 cardiometabolic criteria including BMI >25 (BMI >23 in Asians), hypertension, DM, dyslipidemia, hypertriglyceridemia were included in the study. We used Cox proportional hazard model to assess mortality risk among patients stratified by FIB-4 scores.
Results: The cohort consisted of 2, 557 individuals with MetALD. The median age of the cohort was 45 (33–56). Race was classified as 36.72% Non-Hispanic White, 33.32% Hispanic, 22.29% Black, 3.71% Asian. In Multivariable cox analysis adjusted for age, sex, race, smoking status, hypertension, dyslipidemia, insulin resistance, when compared to patients with FIB-4 ≤2.67, patients with FIB-4 >2.67 were at increased risk of all-cause mortality (Hazard Ratio (HR) 2.95; 95% Confidence Interval (CI), 1.46–6.00; p value, <0.01), cardiovascular mortality (HR 2.68; 95% CI, 1.18–6.07; p value, 0.02), and cancer related mortality (HR 5.08; 95% CI, 1.08–23.96; p value, 0.04).
Conclusion: In this cohort of patients with MetALD, individuals with high FIB-4 scores were at higher risk for all-cause mortality, cardiovascular mortality, and cancer-related mortality. It is known that hepatic fibrosis is considered a prognostic factor in advanced liver disease. This suggests that FIB-4 scores can also be used in metALD, as they have been used in MASLD as a non-invasive score which can help determine advanced fibrosis or higher risk of death.

SAT-279

Transplantation for alcoholic liver disease: impact of on-site substance use disorder treatment on outcome

Shehzad Niazi[1], Aaron Spaulding[2], Emily Brennan[2], Terry Schneekloth[3], Sheila Jowsey-Gregoire[2], Adriana Vasquez[2], Burcin Taner[2]. *[1]Mayo Clinic, Jackosnville, United States; [2]Mayo Clinic, Jacksonville, United States; [3]Mayo Clinic, Rochester, United States*
Email: niazi.shehzad@mayo.edu

Background and aims: About 63% of the US transplant centers lack Substance Use Disorder (SUD) treatment programs[1]. We compared the outcomes of those who received liver transplant (LT) due to alcoholic liver disease at centers that offered SUD services with those that did not.
Method: Using CMS identification codes, we merged the United Network for Organ Sharing and the American Hospital Association (AHA) 2011–2018 Annual Survey data. Study included subjects aged 18–60 with alcoholic cirrhosis who received LT between 2011 and 2018. The primary end points were graft failure and patient survival. We identified centers offering SUD services from the AHA dataset. Patient-related variables from UNOS, included age and functional status, body mass index (BMI), race/ethnicity, sex, diabetes status, encephalotomy, MELD score, and the center's transplant volume. Patients receiving a transplant from a center offering SUD services vs. those who did not were matched (1:1). Patient age was matched within ten years, the MELD closest to transplant was matched within 5 points, and all other were matched exactly. We used Chi-square and Kruskal-Wallis tests to evaluate differences among unmatched and matched LT recipients. Cox proportional hazard models were used to compare the time till graft failure and death.
Results: Of 5, 383 LT recipients, 2, 850 (53%) received a LT from a center with SUD services. Recipients from non-SUD service centers had a higher MELD (28.37 vs. 27.07, $p < 0.0001$), likely to be Hispanic (17.8% vs 11.6%, $p < 0.0001$), higher representation in the highest volume centers (37.5% vs 31.9%, $p < 0.0001$), and among the highest BMI category (37.6% vs. 34.5%, $p = 0.009$). LT recipients from centers providing SUD services were more likely to be White (80.8% vs. 75.0%, $p < 0.0001$) and receive care at the lowest volume centers (34.0% vs. 32.6%, $p < 0.0001$). There were no differences in the proportion of deaths or graft failures in unmatched outcomes. After matching, we evaluated 1, 624 recipients who received LT at centers providing SUD services vs those that did not. The hazard of graft failure was 0.97 (95% CI: 0.71–1.32) for SUD service facilities, and the hazard of death was 0.96 (95% CI: 0.78–1.18).
Conclusion: We found no differences in LT outcomes between centers offring SUD services and those that did not. While only about 37% of the US transplant centers provide SUD services, a substantial 87% offer mental health services, which may have adequately addressed the SUD evaluation and treatment. However, the increasing number of patients receiving LT due to acute alcoholic hepatitis[2] may change future trends.

Emergence of co-morbidities in alcohol-related hepatitis over time: insights from the WALDO cohort

Douglas Corrigall[1], Keval Naik[2], Guruprasad Aithal[3], Mayur Brahmania[4], Ewan H. Forrest[5], Hannes Hagström[6], Anne McCune[7], Steven Masson[8], Neil Rajoriya[9], Juan Pablo Arab[10], Richard Parker[11], Michael Allison[12]. *[1]North Middlesex Hospital, London, United Kingdom; [2]Mid and South Essex NHS Foundation Trust, Chelmsford, United Kingdom; [3]Nottingham Digestive Diseases Centre, School of Medicine, University of Nottingham, UK, Nottingham, United Kingdom; [4]University of Toronto, Toronto, Canada; [5]Glasgow Royal Infirmary, Castle Street, Glasgow, United Kingdom; [6]Karolinska Institutet, Stockholm, Sweden; [7]University of Bristol, Bristol, United Kingdom; [8]Liver Unit, Freeman Hospital, The Newcastle Upon Tyne Hospital Trust, Newcastle, United Kingdom; [9]Liver Unit, University Hospital Birmingham NHS Foundation Trust, Birmingham, Birmingham, United Kingdom; [10]Pontificia Universidad Católica de Chile, Santiago de Chile, Chile; [11]Leeds Teaching Hospitals NHS Trust, St. James's University Hospital, Leeds, United Kingdom; [12]Cambridge Liver Unit, Cambridge, United Kingdom*
Email: michael.allison6@nhs.net

Background and aims: Alcohol-related Liver disease (ALD) is a major cause of liver disease. Alcohol-related Hepatitis (AH) is the most florid manifestation of ALD conferring significant morbidity and mortality[1]. We aim to examine the natural history of AH.

Method: WALDO is an international multi-centre cohort of 723 patients with biopsy-proven ArLD and associated outcome data. Baseline clinical data and events occurring after index biopsy were collected retrospectively. Patients with a diagnosis[2] of AH were examined (n = 185). The primary outcome was overall survival (OS) and the effects on this of liver-associated clinical events and major adverse medical events both at the time of biopsy and subsequently were examined. Median follow-up was 900 days. Survival analysis was performed using Kaplan-Meier/Log rank analysis. Time-dependent variables and their effect on mortality were assessed using Cox-proportional hazards.

Results: 69% (128/185) had severe AH at baseline (SAH) defined by a discriminant function of >32. 67% (124/185) died in the follow-up period. The presence of SAH significantly decreased survival (HR 1.891, 95% CI 1.332–2.687, $p < 0.05$). Ongoing alcohol use was recorded in 59% (110/185). In those who survived past 5 years, abstinence significantly associated with survival (HR 2.339, 95% CI 1.220–4.485, $p < 0.05$). Subsequent liver-related adverse clinical events occurred in 29% (53/185). 3 developed a new HCC. 21 developed ascites, 25 varices, 18 had a variceal bleed, 27 developed hepatic encephalopathy (HE) and 6 Hepatorenal Syndrome (HRS). Additional mortality risk was conferred by development of HE (HR 2.78 95% CI 1.58–4.88, $p < 0.001$) and new episodes of AH (HR 2.80 95% CI 1.37–5.72, $p = 0.005$). Baseline medical comorbidities were present in 21% (38/185) of patients and their presence did not significantly affect OS. Subsequent major medical comorbidities developed in 16% (30/185). 14 developed a new cancer. 15 developed cardiovascular disease, and 7 developed diabetes. Time dependent analysis reveals that development of diabetes conferred a significantly higher risk of death (HR 3.29 95% CI 1.21–8.92, $p = 0.020$).

Conclusion: Cardiovascular disease and diabetes were the most common medical co-morbidities that developed in this cohort. This may have consequences for long term management and decisions about transplant in these patients.

Email: daniel.tung@mohh.com.sg

Background and aims: The disease burden of alcohol-related hepatocellular carcinoma (HCC) is increasing globally with rising per-capita alcohol consumption. Data regarding clinical characteristics and outcomes of alcohol-related HCC versus other etiologies are limited by geographical location or by etiology of liver disease. We aimed to assess the clinical characteristics, treatment allocation, and survival outcomes of alcohol-related HCC via a systematic review and meta-analytic approach.

Method: Medline and Embase were searched from inception to January 2023 for articles in English that compared clinical features, and outcomes of alcohol-related HCC versus HCC from other causes. Primary outcomes included (1) the proportion of HCC related to alcohol, (2) a comparison of clinical characteristics, and (3) survival outcomes between alcohol-related HCC and HCC from other causes. Proportional data was analysed using a generalized linear mixed model. A pairwise meta-analysis was conducted to obtain the odds ratio (OR) or mean difference comparing alcohol-related HCC and non-alcohol-related HCC. Survival outcomes were evaluated using hazard ratio pooled analysis. p values <0.05 were considered statistically significant. All analyses were conducted in RStudio 2021.09.0.

Results: 37 articles comprising 67, 045 patients with HCC were included in the overall analysis (25, 779 with alcohol-related HCC and 41, 266 patients with HCC of other etiologies). Overall, 27.48% (CI: 18.93% to 38.09%) of HCC were alcohol-related, with the highest proportion in Europe and the lowest in the Americas. Patients with alcohol-related HCC were more likely to be male, and there was no significant difference in age or comorbidities between alcohol-related HCC and HCC from other causes. Patients with alcohol-related HCC were more likely to have cirrhosis (OR: 1.87, CI: 1.46 to 2.38; $p < 0.001$) and BCLC stage C/D cancers (OR: 1.30, CI: 1.05 to 1.61;

p = 0.021) compared to HCC from other causes. A lower proportion of alcohol-related HCC patients underwent surveillance (17.04%, CI: 7.58% to 33.95% versus 20.08%, CI: 6.99% to 45.65%) and were less likely to receive curative therapy (OR 0.72, CI: 0.53 to 0.97; p = 0.037) compared to HCC from other causes. In terms of overall survival, alcohol-related HCC was associated with increased mortality (HR: 1.27, CI: 1.13 to 1.42, p = <0.001) compared to non-alcohol-related HCC.

Conclusion: We found that alcohol-related HCC was associated with a lower likelihood of receiving surveillance, more advanced BCLC stage, and higher mortality compared to HCC from other etiologies of liver disease. Further research and collective efforts are required to address these disparities in care.

SAT-284

Diagnostic performance of non-invasive tests in patients with metabolic dysfunction-associated steatotic liver disease (MASLD) with increased alcohol intake (MetALD) in a primary care setting

Eileen Yoon[1], Jihyun An[2], Ha Il Kim[2], Joo Hyun Sohn[2], Huiyul Park[3], Sang Bong Ahn[4], Joo Hyun Oh[5], Hyunwoo Oh[6], Hyo Young Lee[7], Dae Won Jun[1]. *[1]Department of Internal Medicine, Hanyang University College of Medicine, Seoul, Korea, Rep. of South; [2]Department of Internal Medicine, Hanyang University College of Medicine, Guri, Korea, Rep. of South; [3]Department of Family Medicine, Myoungji Hospital, Hanyang University College of Medicine, Goyang, Korea, Rep. of South; [4]Department of Internal Medicine, Nowon Eulji Medical Center, Eulji University, College of Medicine, Seoul; [5]Department of Internal Medicine, Nowon Eulji Medical Center, Eulji University, College of Medicine, Seoul, Korea, Rep. of South; [6]Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South; [7]Department of Internal Medicine, Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Korea, Seoul, Korea, Rep. of South*
Email: noshin@hanyang.ac.kr

Background and aims: Non-invasive tests (NITs) for liver fibrosis have been recognized for its clinical utility in metabolic dysfunction-associated steatotic liver disease (MASLD); however, its diagnostic efficacy is notably diminished in alcohol-related liver disease. It is essential to ascertain the reliability of NITs in MASLD with increased alcohol intake (MetALD) patients.

Methods: In this cross-sectional study, we reviewed data from 7, 918 health checkup participants who underwent both magnetic resonance elastography (MRE) and ultrasound with hepatic steatosis diagnosed by ultrasound. Participants were categorized into MASLD and MetALD, and the performance of fibrosis-4 (FIB-4) and NAFLD fibrosis score (NFS) were assessed. Advanced hepatic fibrosis (F3) was defined as MRE ≥3.6 kPa.

Results: In this health check-up cohort, the prevalence of MetALD was 5.8%, and 1.5% of these cases exhibited advanced hepatic fibrosis. Both MetALD and MASLD displayed similar metabolic profile and hepatic fibrosis burdens but the alcohol consumption levels were significantly higher in MetALD group (0.85 vs 0.80 in FIB-4). The diagnostic performance of FIB-4 and NFS for significant fibrosis revealed no noticeable differences in the area under the receiver operating characteristic values between the two groups. Moreover, the sensitivity (71.4%), specificity (77.3%), and both positive (4.6%) and negative (99.4%) predictive values of NITs for MetALD closely mirrored those observed in MASLD.

Conclusion: The newly defined MetALD showed high performance of FIB-4 with reasonable sensitivity and negative predictive value for the first screening tier for advanced hepatic fibrosis in MetALD.

Email: mohsan.subhani@nottingham.ac.uk

Background and aims: Cholestasis has been associated with various liver disorders, but its role in predicting outcomes in alcohol-related liver disease (ARLD) remains unclear. This study aims to investigate the role of cholestasis on liver biopsy and serum alkaline phosphatase (ALP) in predicting survival in patients with ARLD.

Method: This cohort study with historical data included adult patients (≥18 years), with biopsy proven ARLD from nine international centres in UK, Sweden, and Canada. Data from the UK centres were used as a training cohort and from non-UK centres as validation cohort. The primary outcome was transplant-free survival (TFS) measured as survival without transplantation from the time of liver biopsy to the end of the study. Concordance of the area under the receiver operating characteristic curve (AUC) was used to quantify the prognostic performance of scoring models and Model for End-stage Liver Disease (MELD) scores. ROC curves were used to compare the predictive ability of cholestasis alone, ALP alone, MELD scores plus cholestasis, and MELD score plus ALP. A reclassification approach was used to compare the added values of selected variables in the MELD score. We used the incidence of the event (p = 0.45) values as the cutoff, i.e., 0, p/2 = 0.23, p = 0.45, and 1 for risk categories used in the reclassification model.

Results: A total of 485 patients were included (training n = 345, validation n = 140), the mean age was 53 years (IQR 44–61), and 60% (n = 289) were male. The median alcohol use at the peak was 63 grams/day (IQR 20, 129), the drinking duration was 10 years (IQR 5, 21), and 27% (n = 132) had cholestasis on liver histology. On multivariable Cox analysis, the histological findings of cholestasis, cirrhosis, Mallory-Denk bodies, and steatohepatitis were significantly associated with reduced TFS. Among the laboratory investigations, increased ALP, Bilirubin, Urea, and decreased Albumin were significantly associated with reduced TFS. MELD plus ALP presents a higher AUC value (0.78) than the MELD score alone (0.74), while MELD plus cholestasis (0.74) also showed a comparable AUC value. Of 232 subjects who experienced TFS events, classification improved in 53 subjects using the model with cholestasis, but for 7 subjects it became worse, with an overall net gain in reclassification proportion of 0.198. On the other hand, the net gain in reclassification proportion for subjects who did not experience a TFS event (n = 178) was 0.112; 25 individuals were reclassified down and 5 were reclassified up. The

NRI for MELD plus cholestasis was estimated at 0.086 and was statistically significant (p value = 0.04). Similarly, the NRI for MELD plus ALP was estimated at 0.13 (p < 0.001).
Conclusion: The study shows that adding ALP and cholestasis to standard scoring systems (MELD) for ARLD could improve the predictive outcomes in patients with biopsy proven ARLD.

SAT-286-YI
Long-term risk of alcohol-related liver disease after community-based treatment for alcohol use disorder: a nationwide register based cohort study from Denmark
Line Molzen[1,2], Matilde Winther-Jensen[2], Lone Madsen[3], Merete Osler[2], Peter Jepsen[4], Gro Askgaard[1,2]. [1]*Section of Gastroenterology and Hepatology, Medical Department, Zealand University Hospital, Køge, Denmark;* [2]*Center for Clinical Research and Prevention, Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark;* [3]*Section of Gastroenterology and Hepatology, Medical Department, Zealand University Hospital, Køge, Denmark;* [4]*Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark*
Email: limol@regionsjaelland.dk

Background and aims: Screening for ALD (Alcohol-related Liver Disease) is suggested in individuals with a high alcohol consumption such as individuals in community-based treatment for Alcohol Use Disorder (AUD). Our primary aim was to examine the risk of developing ALD in individuals attending community-based treatment for AUD according to sex-, age-, and diabetes. Our secondary aim was to estimate their absolute risk of mortality due to alcohol-related causes.
Method: We used nationwide health registries to identify individuals 18 years or older with no prior ALD diagnosis who attended community-based treatment for AUD in Denmark from 2006 to 2019. Individuals were followed for an ICD-10 diagnosis of ALD (K70) until 2021. We estimated the cumulative risk of ALD in a competing risk setting according to age group (18–34, 35–44, 45–54, 55–64 and >64 years), sex (men/women) and diabetes at treatment start. In a secondary analysis, we estimated the 10-year risk of death due to any cause, ALD; other alcohol-specific cause and due to external causes, based on the underlying cause of death. Finally, we estimated the 10-year risk of death due to cancer and cardio- and cerebrovascular disease.
Results: There were 58, 408 individuals attending community-based treatment for AUD, their median age was 47 years and men constituted 69.5%. The average number of years with excessive drinking (>15 units/week) was 25.8 at treatment start. During 423, 056 person-years of follow-up, 3, 933 was diagnosed ALD and 11, 590 died. Overall, the 10-year risk of ALD was 5.7% (95%CI 5.5–5.9) and according to age the highest risk was found for 45–54 years (7.3%), the lowest for 18–34 years (2.0%) and no difference was found according to sex. The 10-year cumulative risk was higher in individuals with diabetes. For example at age 45–64 years, it was 11.8% (95%CI 9.0–14.6) for individuals with diabetes vs 6.9% (95%CI 6.5–7.3) for individuals without diabetes. The 10-year risk of death from any cause was 14.3% (95CI 14.0–14.6), and it was 1.6% (95CI 1.5–1.7) for ALD, 2.5% (95CI 2.3–2.6) for other alcohol-specific causes, and 0.6% (95CI 0.5–0.7) for external causes. The 10-year risk of death from cancer was 2.7 (95%CI 2.6–2.9) and for cardio- and cerebrovascular death it was 1.8 (95% CI 1.7–1.9).
Conclusion: About 6% of individuals attending community-based AUD treatment was diagnosed with ALD within 10 years, although the risk was nearly doubled in those with diabetes. Only a small fraction of deaths during follow-up could be attributed ALD. These findings imply that the potential number of lives saved by screening for ALD in this population is likely limited.

SAT-287
Association between serum homocysteine levels and advanced hepatic fibrosis in alcohol-related liver disease: a cross-sectional study
Hui Yang[1,2], Cheng Ma[2], Xiaoqian Zhang[1,2], Wenxin Zhang[2], Jianzhou Duan[2], Lubing Gu[2], Wenhong Zhang[3]. [1]*Department of Infectious Diseases, the First Hospital of Shanxi Medical University, Taiyuan, China;* [2]*First Clinical Medical College, Shanxi Medical University, Taiyuan, China;* [3]*Department of Infectious Diseases, National Medical Centre for Infectious Diseases, Huashan Hospital, Shanghai Medical College, Fudan University, Shanghai, China*
Email: sydyyyh@163.com

Background and aims: In Western and industrialized countries, Alcohol-related liver disease (ALD) has replaced viral hepatitis as the main cause of advanced hepatic fibrosis and cirrhosis. The liver is the primary site of methionine metabolism and transsulfuration pathways, and alcohol-induced hepatic parenchymal cell injury will cause impaired homocysteine (HCY) metabolism. This study aimed to investigate the relationship between serum HCY and advanced hepatic fibrosis in ALD patients.
Method: We included 10, 033 participants from the 1999–2006 National Health and Nutrition Examination Survey (NHANES). 496 individuals with excessive alcohol consumption, elevated liver enzymes, and no other chronic liver disease were identified as ALD. Fibrosis-4 index (FIB-4), aspartate aminotransferase to platelet ratio index (APRI), and Frons index were used as non-invasive indicators for assessing the extent of liver fibrosis. Weighted multivariate logistic regression was used to analyze the correlation between serum HCY and advanced hepatic fibrosis in ALD participants.
Results: Compared to non-ALD, ALD participants had higher serum HCY levels. In weighted multivariable-adjusted logistic regression models, we observed a positive correlation between serum HCY levels and the risk of advanced hepatic fibrosis in ALD (OR = 1.07, 95% CI, 1.01–1.12), and the highest tertile of HCY was significantly associated with an increased risk of advanced hepatic fibrosis (OR = 3.36, 95% CI, 1.34–8.43). In subgroup analyses, this association remained significant in men (OR = 1.07, 95%CI, 1.01–1.13), vigorously physically active (OR = 1.46, 95%CI, 1.06–2.01), and obese participants (OR = 1.36, 95%CI, 1.10–1.67). In ALD participants, the area under the working characteristic curve (AUROC) of HCY for advanced hepatic fibrosis was 0.686 (95% CI, 0.639–0.733).
Conclusion: Serum HCY levels were independently associated with an increased risk of advanced hepatic fibrosis in ALD. This study supports the predictive value of HCY for advanced hepatic fibrosis and suggests that HCY may become a therapeutic entry point for ALD.

Background and aims: Severe alcoholic hepatitis (SAH) pose a significant threat, often accompanied by complications such as the development of oesophageal varices. Variceal bleeding in patients with severe alcohol-associated hepatitis (SAH) is associated with poor outcomes. Beta blockers are most commonly recommended medications to decrease portal pressures and prevent bleeding from varices. However, there are no studies evaluating the role of beta blockers on the course of variceal/portal hypertensive gastropathy (PHG) progression in patients with SAH, which we aimed to assess.

Method: We conducted a prospective analysis of data collected over five years from patients with SAH, focusing on endoscopy reports. The objectives were to assess the variceal and PHG stage at baseline, and the course of variceal/PHG progression, and the impact of non-selective beta blockers (NSBB) and alcohol relapse on variceal progression and PHG.
Results: A total of 133 patients with SAH were identified and 103 with baseline endoscopy reports were included in the study. Of the 103 patients, 29.1% did not have any varices at baseline, 57.2% had small low-risk varices and 13.6% had large high-risk varices. 11 patients underwent prophylactic variceal ligation. Of the 30 patients with no varices at baseline, 13 underwent follow-up endoscopy, 4 developed small low-risk varices, 1 developed fundal varix and 8 had no varices. Of the 59 patients with small low-risk varices, only 13 underwent follow-up endoscopy with 1 having no varices, 7 still having small low-risk varices and 5 developing large high-risk varices, including 1 with fundal varices. A total of 38.4% (10/26) had progression of varices. 6 of the 14 patients with high-risk varices underwent endoscopy and all had large high-risk varices. Of the 24 patients who received NSBB, 12.5% (3/24) had progression of varices compared to 6.42% (7/109) in those who did not receive BB ($p = 0.3$). Of the patients who were evaluated endoscopically, only 25% (3/12) had stage migration in the BB group compared to 35% (7/20) in the non-BB group ($p = 0.56$). One patient in the non-BB group developed variceal bleeding and required EVL, while none in the BB group developed variceal bleeding. 15% (3/20) in the abstainer group compared to 50% (6/12) in the relapse group had progression of varices ($p = 0.03$). Of the total cohort, sixty-nine patients had no evidence of PHG, while 30 patients had mild PHG, and two had both severe PHG and gastric antral vascular ectasia (GAVE). 5% (1/20) in the non-beta-blocker and 25% (3/12) in the beta-blocker group had progression of PHG by one grade ($p = 0.1$).
Conclusion: 70% of patients with SAH had varices and an additional 38.4% developed varices during the five-year study period. Alcohol relapse was identified as a significant factor increasing the risk of variceal progression in this population.

SAT-291
Screening for alcohol related liver disease in acute hospital admissions

Jessica Lovatt[1], Kerry Badger[1], Claire Cussons[1], Richard Parker[1]. [1]*Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*
Email: jessicalovatt@nhs.net

Background and aims: Heavy alcohol consumption has a major impact on both morbidity and mortality but also on healthcare systems: in the UK alcohol is linked to 5.7% of all hospital admissions. Of those, 74220 admissions were linked to alcohol related liver disease (NHS data). Despite heavy drinkers often having multiple contacts with healthcare, these patients frequently remain undiagnosed and present at a later stage of the disease. To address this NHS England recently offered an incentive to hospitals to screen hazardous drinkers for liver disease. This is a service evaluation of this initiative in a single centre.
Method: A prospective project as part of NHS England 'CQUIN' service development initiative between July 2022 and July 2023; acute admissions to hospital who had evidence of alcohol misuse-defined as AUDIT-C >12 and/or requiring treatment for alcohol withdrawal were offered testing for liver fibrosis. The enhanced liver fibrosis (ELF) test was used, taken at the same time as other routine blood sampling. A cut off of 9.5 was used to differentiate between low risk and high risk requiring further investigation in the form of a transient elastography.
Results: At baseline (pre-screening period) only 7% (10 of 138) of hazardous drinkers were offered a test for liver fibrosis, during the assessment period this rose to 47% of hazardous drinkers being offered testing. During the service evaluation, a total of 1015 patients were identified as suitable for testing, of whom 669 (66%) had an ELF test done. Of these tests, 164 (24%) were considered low risk (<9.5) and 505 (76%) were high risk (>9.5) requiring further investigation. Of the high-risk tests, 82 patients (16%) had a previous diagnosis of liver disease and a further 34 (7%) patients presented with decompensated disease at the time of ELF testing. This left 389 high risk patients (65% of all tests, 84% of high-risk tests) with no previous history of liver disease. After ELF testing, 59 patients died before further tests could be done (58 cases from non-liver causes, 98%), 145 underwent transient elastography, and 84 patients were discharged from follow-up after review. To date, 49 new cases of compensated advanced chronic liver disease (cACLD) have been confirmed and are in clinical follow-up (5% of total population tested, 7% of patients who had a test). At the time of analysis 114 patients are pending further investigation.
Conclusion: ELF testing can be used to screen acute hospital admissions with high-risk alcohol use for underlying cACLD. The results of the ELF test can allow for non-invasive transient elastography to be used more efficiently in high-risk populations. By identifying cACLD earlier, patients can receive specialist hepatology input, ongoing alcohol cessation support and commence surveillance for hepatocellular carcinoma.

SAT-292
Coinfection with viral hepatitis increases the short-term but not the long-term risks of hepatocellular carcinoma and hepatic events in adults with alcohol-related cirrhosis

Vicki Wing-Ki Hui[1], Terry Cheuk-Fung Yip[1], Zeyuan Yang[2], Ramsey C. Cheung[2,3], Robert Wong[2,3], Vincent Wai-Sun Wong[4], Grace Lai-Hung Wong[5]. [1]*Department of Medicine and Therapeutics, Medical Data Analytics Centre (MDAC), and Institute of Digestive Disease, The Chinese University of Hong Kong, Hong Kong, Hong Kong;* [2]*Gastroenterology and Hepatology Section, Veterans Affairs Palo Alto Healthcare System, Palo Alto, CA, Palo Alto, United States;* [3]*Division of Gastroenterology and Hepatology, Stanford University School of Medicine, Palo Alto, CA, Palo Alto, United States;* [4]*Department of Medicine and Therapeutics, Medical Data Analytics Centre (MDAC), and Institute of Digestive Disease, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Hong Kong;* [5]*Department of Medicine and Therapeutics, Medical Data Analytics Centre (MDAC), and Institute of Digestive Disease, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Hong Kong*
Email: 1155063467@link.cuhk.edu.hk

Background and aims: Rapid urbanization and economic growth in Hong Kong have led to increased alcohol consumption, resulting in a rise in alcohol-related cirrhosis (AC). Chronic hepatitis B virus (HBV) and hepatitis C virus (HCV) infections are prevalent, with rates of 6.2% for HBV and 0.3% for HCV in the general population. This research focuses on examining the interaction between AC and chronic viral hepatitis in Hong Kong.
Method: Patients with AC from 2000 to 2023 were identified from a territory-wide database in Hong Kong. Exclusions were made for those with other chronic liver diseases namely autoimmune hepatitis, hemochromatosis, only non-alcoholic fatty liver disease (NAFLD)-specific codes, and primary biliary cholangitis. AC was identified using a combination of ICD-9/10 codes, based on previously validated algorithms. Chronic HBV and HCV infections were identified through diagnosis codes and laboratory tests. Liver complications, including hepatocellular carcinoma (HCC) and hepatic events, were identified using diagnosis codes. Baseline events were defined as those occurred with 30 days from baseline, incident events were defined as those happened beyond 30 days.
Results: We identified 10, 670 AC patients, with 3, 155 (30%) having concurrent chronic HBV (2, 612 [83%]) and/or HCV (685 [22%]) infection. The cohort predominantly consisted of males (91%, 9, 752

patients), with an average age of 60.8 ± 12.5 years and a body mass index of 22.9 [20.6, 25.6]. Over 44% were unhealthy drinkers, consuming more than 50 ml/day of alcohol. Patients with HBV/HCV displayed worse liver conditions, showing higher median AST (73 vs. 65) U/L, ALT (40 vs. 33) U/L, total bilirubin levels (30.5 vs. 27.6) μmol/L. The follow-up duration for the 5, 526 patients (4, 068 without hepatitis, 1, 458 with hepatitis) with at least 30 days of follow-up was 31.9 [11.1, 75.0] months. Baseline HCC were identified in 84 (3.0%) patients without hepatitis and 47 (3.7%) patients with hepatitis. Baseline hepatic events were observed in 920 (32.7%) patients without hepatitis and 412 (32.5%) patients with hepatitis. A significant number of patients with (517, 40.8%) and without (998, 35.4%) hepatitis died within 30 days. Beyond 30 days, HCC cases were 14 (0.3%) without hepatitis and 9 (0.6%) with hepatitis. Hepatic events were recorded in 903 (22.2%) without hepatitis and 319 (21.9%) with hepatitis, with deaths in 2, 636 (64.8%) without hepatitis and 823 (56.4%) with hepatitis.

Conclusion: Coinfection with HBV or HCV worsens liver conditions in AC patients at the time of diagnosis, whereas the clinical courses of AC patients with or without chronic viral hepatitis are similar afterwards. Our findings emphasis the importance of prompt recognition and interventions for the unhealthy alcohol use as well as chronic viral hepatitis to slow disease progression and reduce the burden of liver-related morbidity and mortality.

SAT-293-YI

Dietary habits and ultra-processed food consumption in steatotic liver diseases: differences among etiologies and impact on liver histology

Salomé Declerck[1], Guillaume Henin[1,2], Stéphanie André-Dumont[2], Alexis Goffaux[1], Pamela Baldin[3], Paulina Henry[4], Audrey Loumaye[5], Peter Stärkel[1,2], Nicolas Lanthier[1,2]. *[1]Laboratory of Hepatogastroenterology, Institut de Recherche Expérimentale et Clinique, UCLouvain, Brussels, Belgium; [2]Service d'Hépato-gastroentérologie, Cliniques universitaires Saint-Luc, UCLouvain, Brussels, Belgium; [3]Service d'Anatomie pathologique, Cliniques universitaires Saint-Luc, UCLouvain, Brussels, Belgium; [4]Institut de Pathologie et de Génétique, Gosselies, Belgium; [5]Service d'Endocrinologie, diabétologie et nutrition, Cliniques universitaires Saint-Luc, UCLouvain, Brussels, Belgium*
Email: nicolas.lanthier@saintluc.uclouvain.be

Background and aims: The consumption of ultra-processed foods (UPF) has increased in recent years and has been associated with a higher risk of metabolic dysfunction-associated steatotic liver disease (MASLD), obesity, and diabetes. However, the relationship between UPF consumption and liver histology is unknown, as well as its evaluation in alcohol-related liver disease (ALD) patients. Our aim is to assess the nutritional intake and UPF consumption in individuals with histologically evaluated steatotic liver disease (SLD).

Method: Patients with histologically confirmed SLD (MASLD or ALD) are prospectively recruited. Anthropometric and biological data are collected. Dietary intake is assessed through a 24-hour recall, and UPF consumption in grams is quantified using the NOVA classification. Fermented alcoholic beverages fall under the category of processed foods, while both fermented and distilled alcoholic beverages are classified as UPF. Histological evaluation of hepatic phenotype severity is conducted using the Beaujon score (SAF).

Results: We analyze 62 patients with SLD, including 46 with MASLD and 16 with ALD. The average age and body mass index (BMI) for MASLD and ALD patients are 54 and 52 years (ns), and 35 and 22 kg/m² ($p = 0.0001$), respectively. Three patients are classified as F0 (4.9%), 12 as F1 (19.7%), 28 as F2 (45.9%), 17 as F3 (27.9%), and 1 as F4 (1.6%). One patient could not be evaluated due to the small size of the biopsy. In terms of nutritional intake, compared to patients with ALD, MASLD patients consume more lipids (73 vs. 53 g/day; $p = 0.050$), saturated fatty acids (29 vs. 22 g/day; $p = 0.0201$) and fibers (17 vs. 8 g/day; $p = 0.0003$) but fewer calories (1806 vs. 2716 kcal/day; $p = 0.0003$). Nevertheless, there are no significant differences in the average consumption of proteins or carbohydrates between patients with MASLD and those with ALD. Patients with ALD consume more processed foods than MASLD patients (2628 vs. 196 g/day; $p = 0.0001$). The average consumption of UPF among individuals with moderate or severe steatosis, low or high activity, or absence or presence of fibrosis in MASLD or ALD patients does not demonstrate any difference (ns).

Conclusion: ALD patients exhibit higher caloric consumption compared to MASLD patients, despite their lower BMI. The disparity in energy intake between the two groups is primarily attributed to the caloric contribution from alcohol consumption, which is also associated with a greater consumption of processed foods. In MASLD and ALD patients, UPF consumption evaluated through a 24-hour recall does not impact the severity of the hepatic phenotype.

SAT-294

The prognostic value of the hepatic venous pressure gradient in severe alcohol-related hepatitis

Andreea Livia Bumbu[1], Adelina Horhat[2], Mina Ignat[3], Bogdan Procopet[4], Horia Ștefănescu[5]. *[1]Iuliu Hatieganu University of Medicine and Pharmacy, Cluj Napoca, Romania; [2]Iuliu Hatieganu University of Medicine and Pharmacy Cluj-Napoca, Cluj Napoca, Romania; [3]Octavian Fodor Institute of Gastroenterology and Hepatology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj Napoca, Romania; [4]Octavian Fodor Regional Institute of Gastroenterology and Hepatology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj Napoca, Romania; [5]Octavian Fodor Regional Institute of Gastroenterology and Hepatology, Cluj Napoca, Romania*
Email: andreea_bumbu@yahoo.com

Background and aims: Severe alcohol-related hepatitis (SAH) has a high mortality rate. In this study we aimed to evaluate the prognostic role of the hepatic venous pressure gradient (HVPG) in alcohol-related hepatitis and to determine which of the cut-off values proposed by previous studies (22 mmHg in the study conducted by Rincon et al in 2007 or 20 mmHg in the one by Dominguez et al in 2009) best correlates with mortality.

Method: We enrolled 246 consecutive patients with a clinical suspicion of SAH (MaddreyDF >32). 233 patients underwent HVPG measurement before the transjugular liver biopsy (TJLB) procedure. Mortality at 1, 3 and 9 months was recorded.

Results: The age of the patients ranged from 23 to 78 (median 51.5), 178 (72.4%) were male and 68 (27.6%) female. Regarding the complications, 85% of patients had ascites, 37.8% had hepatic encephalopathy, out of which 36.6% was covert, 18.7% had variceal bleeding, 33.3% of patients were infected at admission time and 11% developed hepatorenal syndrome. A total of 172 patients (69.9%) were administered 40 mg/day of Prednisone, out of which 66.9% were responders according to the day 7 Lille score. The mean and median survival were 31.8 months (S.E. 2.26; 27.4–36.3; 95%CI) and 22 months (11.3–32.6; 95%CI), respectively. Mortality at 1 month was 23.9%, at 3 months was 29.6% and at 9 months 43.4%. The median HVPG in our cohort was 19 mmHg (range 7–40). HVPG correlated with the overall mortality ($p < 0.01$, HR 1.083; 1.029–1.141; 95%CI) in the binary logistics regression. Both the 22 mmHg and the 20 mmHg threshold correlated with the disease severity scores (MELD, Child-Pugh, MaddreyDF), while only the 20 mmHg cut-off correlated with the hepatic rigidity in kPa, and only the 22 mmHg cut-off correlated with the platelets number ($p < 0.01$) in the Man Whitney U test.

The Cox regression model showed that the higher the HVPG, the higher the probability of death (HR 1.050; 1.015–1.086 95%CI; $p < 0.01$). Both values associated very strongly with the overall mortality: Chi-square test for HVPG <20 mmHg ($p < 0.05$) with a Phi coefficient of 0.487, and Chi-square test for HVPG <22 mmHg ($p < 0.05$) with a Phi coefficient of 0.549.

Conclusion: HVPG is a good predictor of short and medium term mortality in SAH, but needs to be validated in bigger cohorts of

patients. It is not far-fetched to assume that it could be included in the MELD score. Both the 20 mmHg and the 22 mmHg values correlate with mortality.

SAT-295

Sarcopenia, frailty and growth hormone-insulin like growth factor axis among decompensated and alcohol-associated hepatitis patients

Aishani Wadhawan[1,2], Nipun Verma[1], Parminder Kaur[1], Pratibha Garg[1], Samonee Ralmilay[1], Rohit Nadda[1], Naveen Kalra[1], Sahaj Rathi[1], Arka De[1], Madhumita Premkumar[1], Sunil Taneja[1], Ajay Kumar Duseja[1], Virendra Singh[1]. *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [2]Postgraduate Institute of Medical Education and Research, Chandigarh, India*
Email: nipun29j@gmail.com

Background and aims: Sarcopenia, frailty and growth hormone insulin like growth factor axis impairment in alcohol-associated hepatitis (AH) and decompensated cirrhosis (ALD-DC) remain elusive. This study investigates sarcopenia, frailty and GH IGF 1 axis between ALD-DC and AH patients.
Method: We enrolled patients with ALD-DC and ALD-AH at single cross-section at a tertiary care institute between 2023–24. Sarcopenia and frailty assessments were done through DEXA or CT-SMI and liver frailty index, respectively and GH IGF 1 levels through immunoassays.
Results: A total of 100 patients were recruited (99% males, median age of 44 years) exhibiting ascites (grade-I: 24%, grade-II: 32%, grade-III: 40%), HE (grade-I: 5%, grade-II: 6%) and CTP of 9 (8–11) [CTP A-7%, CTP B-51%, CTP C-42%]. Median MELD score, MELDNa score, GH and IGF 1 levels were 17.4 (IQR: 13.9–23.3), 19.9 (IQR: 15.5–25.6), 4.23 ng/ml (IQR: 2.1–7.2) and 39.8 ng/ml (IQR: 31.6–52.4). Sarcopenia and frailty were noted in 59.6% and 25.6% patients. Patients with AH had worse CTP, MELD and MELD-Na scores than ALD-DC patients. Although GH levels were similar, patients with AH had lower IGF 1 levels 36.2 (20.1–43.1) than DC patients 43.9 (38.8–54.1). AH patients exhibited more frailty and malnutrition ($p = 0.001$) than ALD-DC (41.3% vs 9%, $p = 0.001$). Sarcopenia through either DEXA or CT-SMI and osteodystrophy was not statistically different between AH and DC patients ($p > 0.05$, each). Patients with sarcopenia had lower IGF1 levels [39.3 (IQR: 34.4–45.8)] compared to patients without sarcopenia [48.8 (IQR: 35.3–59.5)] with a trend significance ($p = 0.056$). Within the subset of frail and pre-frail patients, frail individuals exhibited significantly diminished IGF-1 levels [37.5 (IQR: 32–40)] compared to their pre-frail counterparts [42.4 (IQR: 35.8–55)] ($p = 0.006$). We observed a stepwise decline in IGF 1 levels with worsening CTP classes [CTP A [54.6 ng/ml (IQR: 48.8–60.3)] to CTP B [41 ng/ml (IQR: 36.7–50.2)] and CTP C [36.5 ng/ml (IQR: 29–53.7)] ($p = 0.012$). Linear regression analysis revealed, log IGF1 was negatively associated with MELD (beta = –11, $p < 0.001$), MELDNa (beta = –12.7, $p < 0.001$) and CTP score (beta = –3, $p < 0.001$).
Conclusion: AH patients are sicker and frailer than DC patients, possibly mediated by lower IGF 1 levels. Reduced IGF 1 levels are associated with sarcopenia, frailty and disease severity in alcohol associated cirrhosis patients with DC or AH. Modulation of GH IGF 1 axis is a potentially disease modifying target in cirrhosis.

SAT-296

Prevalence and characteristics of MASLD with greater alcohol consumption (MetALD) in the general population

Eileen Yoon[1], Jihyun An[1], Ha Il Kim[2], Joo Hyun Sohn[1], Bo-Kyeong Kang[3], Eun Chul Jang[4], Huiyul Park[5], Hye-Lin Kim[6], Sang Bong Ahn[7], Joo Hyun Oh[8], Hyunwoo Oh[9], Hyo Young Lee[10], Dae Won Jun[1]. *[1]Department of Internal Medicine, Hanyang University College of Medicine, Seoul, Korea, Rep. of South; [2]Department of Internal Medicine, Hanyang University College of Medicine, Guri, Korea, Rep. of South; [3]Department of Radiology, Hanyang University College of Medicine, Seoul, Korea, Rep. of South; [4]Department of Occupational and Environmental Medicine, Soonchunhyang University College of Medicine, Chun An, Korea, Rep. of South; [5]Department of Family Medicine, Myoungji Hospital, Hanyang University College of Medicine, Goyang si, Korea, Rep. of South; [6]College of Pharmacy, Sahmyook University, Seoul, Korea, Rep. of South; [7]Department of Internal Medicine, Nowon Eulji Medical Center, Eulji University, College of Medicine, Seoul; [8]Department of Internal Medicine, Nowon Eulji Medical Center, Eulji University, College of Medicine, Seoul, Korea, Rep. of South; [9]Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South; [10]Department of Internal Medicine, Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Korea, Seoul, Korea, Rep. of South*
Email: noshin@hanyang.ac.kr

Background and aims: The term MetALD has been introduced to describe individuals who have metabolic dysfunction-associated steatotic liver disease (MASLD) with greater alcohol consumption, according to the new nomenclature for steatotic liver disease (SLD). This study aims to evaluate the prevalence and clinical characteristics of MetALD in the general population.
Method: This study is a retrospective, cross-sectional analysis that utilizes the population-based data from the Fifth Korea National Health and Nutrition Examination Survey (KNHANES) conducted between 2019 and 2021. A total of 16, 521 participants aged over 18 years were included in the analysis. The presence of hepatic steatosis was determined based on a hepatic steatosis index of 36 or higher.
Results: The prevalence of MetALD was 2.8% (95% CI, 2.5–3.2). Individuals with MetALD were predominantly men (85.4%) and tended to be younger compared to those with MASLD. They exhibited a higher prevalence of hypertension and had significantly higher levels of aspartate aminotransferase, fasting glucose, triglycerides, HDL cholesterol, and creatinine compared to individuals with MASLD. The average daily total energy intake, with and without energy from alcohol, was higher in the MetALD group (2496 and 4250 kcal) compared to the MASLD group (1821 and 1963 kcal). The amount of fat and sodium intake levels were also higher in the MetALD group than in the MASLD group. In addition, the MetALD group had a higher proportion of clerical support workers and technicians, machine operators, and assemblers with higher income compared to the MASLD group.
Conclusion: MetALD exhibited distinct characteristics from MASLD, which was similar to those of ALD. Therefore, MetALD would be on the spectrum of ALD than MASLD.

SAT-297

Recidivism and post-transplant outcomes in patients with alcohol-associated liver disease

Nilofar Najafian[1], Suaka Kagbo-Kue[2], Rachana Punukollu[1], Margaret C. Liu[1], Laura Budvytyte[3], Xingjie Li[1], Alyssa K. McGary[1], David M. H. Chascsa[1], Caroline Jadlowiec[1], Channa Jayasekera[4], Michele S. Barnhill[5], Rolland Dickson[1]. *[1]Mayo Clinic Arizona, Phoenix, United States; [2]Intermountain Medical Center, Salt Lake City, United States; [3]Mayo Clinic Alix School of Medicine, Scottsdale, United States; [4]Mayo Clinic Arizona, Phoenix, United States; [5]Mayo Clinic Arizona, Phoenix, United States*
Email: najafian.nilofar@mayo.edu

Background and aims: Alcohol-associated liver disease (ALD) is the most common indication for liver transplant (LT) in the USA. Alcohol recidivism, a complication of ALD, is associated with decreased graft and patient survival. Identifying risk factors prior to LT, post-LT recidivism, and strategies to improve survival are not well defined. We aim to describe post-LT outcomes and identify predictive risk factors for relapse among patients transplanted for ALD.
Method: Patients with LT for ALD at Mayo Clinic Arizona from 2019 to 2022 were reviewed retrospectively. Patients had at least one screening test for alcohol. We examined medical comorbidities, clinical and psychosocial characteristics, relapse, and 1-year patient and graft survival. Subgroup analysis compared patients with and

without relapse and by alcohol transplant pathways: traditional (6 months of sobriety pre-LT), expedited (cirrhotic patients with less than 6 months sobriety), and alcohol-associated hepatitis (AH).
Results: 157 patients were transplanted for ALD, 17 were excluded given lack of alcohol screening. Most were Caucasian (76%) and male (76%), with mean age of 55.9 years. Ninety-one percent were transplanted through the traditional pathway, 6% expedited, and 3% for AH. Twenty-three patients (16%) resumed alcohol use post-LT. Of the relapsed, 43% had sustained alcohol use and 22% had relapse prevention therapy post-transplant. Relapse was detected by alcohol testing alone in 15/23, by self-report alone in 2/23, and by combination of self-report and alcohol testing in 6/23 patients. Relapsed patients were more likely to have psychiatric disease (p = 0.004) or depression (p = 0.04) than those without relapse. There was no difference in relapse by transplant pathway, medical comorbidities, substance use history, length of pre-transplant sobriety, prior rehabilitation attempts, alcohol related legal issues, or SIPAT (Stanford Integrated Psychosocial Assessment for Transplantation). Overall survival at 1-year was 99.1% in those without relapse vs 100% in those with relapse (p = 0.17). Graft survival at 1-year was 96.5% in those without relapse vs 91.3% in those with relapse (p = 0.16). No significant difference was noted in fibrosis or steatosis at 1-year post-LT regardless of transplant pathway or alcohol recidivism.
Conclusion: Traditional, expedited and AH pathways resulted in similar outcomes, arguing against a defined period of sobriety. Early identification with routine alcohol testing and intervention is essential for patients transplanted for ALD given inaccuracy of self-reporting, high rate of relapse (16%), and trend toward worsened graft outcomes in those with relapse.

SAT-298

Annual decompensation and death in patients with intermediate severity of alcohol-related liver fibrosis

Sara Hauskov[1], Mads Israelsen[2], Katrine Lindvig[3], Katrine Thorhauge[3], Johanne Kragh Hansen[3], Camilla Dalby Hansen[3], Stine Johansen[3], Ida Ziegler Spedtsberg[3], Helle Lindholm Schnefeld[3], Peter Andersen[1], Ida Falk Villesen[3], Katrine Tholstrup Bech[1], Nikolaj Torp[3], Aleksander Krag[3], Maja Thiele[3]. *[1]Centre for Liver Research, Fibrosis, Fatty Liver and Steatohepatitis Research Center Odense (FLASH), Odense C, Denmark; [2]Centre of Liver Research, Fibrosis, Fatty Liver and Steatohepatitis Research Center Odense (FLASH), Odense C, Denmark; [3]Centre of Liver Research, Fibrosis, Fatty Liver and Steatohepatitis Research Center Odense (FLASH), Odense C, Denmark*
Email: sara.tonder.hauskov@rsyd.dk

Background and aims: Patients with alcohol-related liver disease (ALD) of intermediate severity of liver fibrosis experience a far higher rate of progression to decompensation than other liver disease aetiologies. We therefore aimed to identify variables contributing to five year decompensation or death in ALD patients with intermediate disease severity.
Method: We defined intermediate severity as either moderate fibrosis (F2), transient elastography (TE) 10–15 kPa, or ELF test 9.8–10.5. We selected patients from a prospective, biopsy-controlled cohort of patients with a history of harmful drinking and followed them for 4–9 years. We used Cox regression analyses to investigate baseline predictors of decompensation-free survival: histological features (fibrosis, lobular inflammation, ballooning and steatosis), metabolic risk factors, alcohol intake, Transient Elastography (TE) and Enhanced Liver fibrosis (ELF) test.
Results: We included 157 patients, 78% male, with a median age of 58 ± 13 years, a TE of 9.5 ± 5.7 kPa, and an ELF score of 9.8 ± 1.2. Concordant ELF and TE results were seen in 62% (n = 96): 48 with ELF<9.8 and TE <10 kPa, and another 48 with both elevated. Over a median of 6.3 years (IQR 4.6–7.9), 22 patients decompensated and 39 died, with 38% of deaths following decompensation. Decompensation and death rates were 2.2% and 4.1% per year. Univariable analyses identified higher fibrosis stage, severe steatosis, ballooning and lobular inflammation, ELF and TE as predictors of death or decompensation. Alcohol abstinence and insulin resistance measured by HOMA-IR ≥2.5 were protective. Multivariable analysis showed severe steatosis (hazard ratio 5.94, 1.68–21.00), significant fibrosis (HR 4.33, 1.33–14.15), insulin resistance (HR 0.33, 0.14–0.79), ELF ≥9.8 (HR 2.27, 1.03–4.99), and TE ≥10 kPa (HR 5.36, 2.28–12.62) as independent predictors of decompensation-free survival. While 23% (11/48) with concordance between low ELF <9.8 and TE <10 kPa met the end point, only 3 were decompensations. Conversely, 32% (35/109) with high ELF and/or high TE met the end point, with 19 decompensations.
Conclusion: In patients with ALD and intermediate fibrosis most fatalities occur without prior decompensation. However, not to neglect liver-related morbidity as it exceeds 2% annually. Patients with high ELF or TE require management in secondary care due to an increased decompensation risk. Notably, insulin resistance may be associated with improved prognosis, while severe steatosis suggests poorer outcomes.

SAT-299

There is a need to improve retention of people with alcohol-related liver disease in clinical trials: a systematic review and meta-analysis of retention rates in interventional trials

Paula Boeira[1], Kris Bennett[2], Tamar Avades[2], Ashwin Dhanda[2], Jaiveer Arora[3], Matthew Cramp[2]. *[1]University of Plymouth, Plymouth, United Kingdom; [2]University Hospitals Plymouth NHS, Plymouth, United Kingdom; [3]University of Bath, Bath, United Kingdom*
Email: paula.boeira@plymouth.ac.uk

Background and aims: Alcohol-related liver disease (ARLD) is the leading cause of cirrhosis and liver-related mortality in Europe but few interventional clinical trials have been completed in this patient group. Such patients can experience challenges accessing and engaging with their treatment. High levels of retention in clinical trials enable more efficient trial design and ensure that the outcomes can be fully assessed as intended. However, it is not known how well patients with ARLD and recent or ongoing alcohol use engage with clinical trials. This study aimed to quantify retention rates of ARLD patients recruited to interventional clinical trials at 1, 3, 6 and 12 months after recruitment.
Method: According to our published review protocol (https://osf.io/5kuge/), we conducted systematic searches of Medline, Embase, Web of Science, and Scopus. We included interventional clinical trials, published 2008 onwards in people with ARLD (including alcohol-related hepatitis [AH]). We excluded studies where patients had been abstinent from alcohol for more than 6 months. Data were extracted on study design, population and retention rates and a risk of bias assessment was made. Two-step meta-analysis was conducted to generate a random effects model.
Results: 3072 studies were identified, of which 55 were eligible for inclusion, 37 in AH and 18 in alcohol-related cirrhosis. Studies were heterogeneous in design, intervention and outcome. Median study duration was 90 days. The primary outcome was mortality in 25 and 3 of the AH and cirrhosis trials, respectively. Overall retention rates at 1, 3 and 6 months were: 89% (95% CI 85–92%), 67% (61–72%) and 56% (47–66%), respectively. Only 6 trials reported retention at 12 months at 59% (38–79%; I^2 = 97%). In cirrhosis trials (n = 5), retention (excluding mortality) at 3 months was 92% (67–100%; I^2 = 94%) versus 97% (94–99%; I^2 = 91%) in AH trials (n = 24).
Conclusion: Most ARLD trials have been conducted in AH, with an outcome of mortality with relatively good short-term retention. In contrast, few interventional trials have been reported in people with alcohol-related cirrhosis. ARLD cirrhosis trials have lower short-term retention that may undermine interpretation of outcome data. Estimated retention in cirrhosis trials was 92% at 3 months, substantially lower than in comparable interventional trials in other chronic diseases e.g. tirzepatide for diabetes; retention excluding mortality: 96% at 72 weeks. Methods to improve

participant engagement in ARLD cirrhosis trials needs to be tested and applied to improve the quality of future studies.

SAT-302

Long-term trends in the prevalence of alcohol-related cirrhosis among national U.S. veterans affairs data and territory wide Hong Kong data-an east-west perspective

Robert Wong[1], Terry Cheuk-Fung Yip[2], Zeyuan Yang[3], Vicki Wing-Ki Hui[2], Jimmy Che-To Lai[2], Vincent Wai-Sun Wong[2], Ramsey C. Cheung[1], Grace Lai-Hung Wong[2]. *[1]Veterans Affairs Palo Alto Health Care System, Stanford University School of Medicine, Palo Alto, United States; [2]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Veterans Affairs Palo Alto Health Care System, Palo Alto, United States*
Email: rwong123@stanford.edu

Background and aims: The increasing prevalence of alcohol-related cirrhosis (AC) has been exacerbated by the COVID-19 pandemic and is rapidly becoming a major cause of end-stage liver disease. However, it is not clear if the prevalence and trends in AC are similar in Asia-Pacific regions (where viral hepatitis is endemic) vs. U.S. populations. We aim to evaluate long-term trends in the prevalence of AC across two large population-based cohorts in the U.S. and Hong Kong (HK).
Method: Trends in the prevalence of AC were analyzed using two separate cohorts representing distinct populations in the U.S. and HK from 2010 to 2023: 1) U.S. National Veterans Affairs data and 2) HK territory-wide data of adults. AC was identified using a combination of ICD-9/10 codes based on previously validated algorithms. Annual prevalence of AC (per 100, 000 person-years (py)) were stratified by sex and age groups, and compared between groups using the z-statistic. Patients were censored during follow-up if they died, received a liver transplant, or were lost to follow-up (defined as no healthcare encounters within a 12-month period).
Results: Among 3.0 million U.S. Veterans, 45, 670 were identified with AC (96.5% men, mean age 59.6 ± 11.8 years). The prevalence of AC was significantly higher in men vs. women throughout the study period, and in 2023, AC prevalence was 787 per 100, 000-py in men vs. 315 per 100, 000-py in women, $p < 0.01$. When stratified by age, the highest AC prevalence was observed among Veterans age 50–59 years. However, following onset of the COVID-19 pandemic, the prevalence of AC among young Veterans age 18–29 years rose rapidly, and in 2023, the prevalence was similar to that of Veterans age 50–59 years (1382 vs. 1392 per 100, 000-py, $p = 0.87$). Among 6.15 million HK adults, 5, 591 patients with AC were identified (93.4% men, mean age 60.7 ± 12.6 years). While AC prevalence was significantly lower than the U.S. cohort, similar gender-specific differences were observed. In 2023, AC prevalence was more than 10 times higher in men vs. women (55.7 vs. 4.3 per 100, 000-py, $p < 0.01$). In the HK cohort, AC prevalence rose steadily from 2010 to 2023, and similar to the U.S. cohort, the highest prevalence was observed among adults age 50–59 years.
Conclusion: Among U.S. Veterans, the prevalence of AC was highest among adults age 50–59 years. While the prevalence of AC among most age groups plateaued or declined following the pandemic, there was a rapid rise among young Veterans age 18–29 years, highlighting the need for greater awareness about the dangers of high-risk alcohol use in this group. Among HK adults, while the prevalence of AC was overall lower than the U.S. cohort, prevalence of AC has continued to rise among all age groups, particularly after the pandemic. Similar to the U.S. cohort, adults age 50–59 years had the highest prevalence of AC.

SAT-303

Vitamin D deficiency is associated with advanced liver fibrosis and Type 2 diabetes mellitus in alcohol use disorder

Paola Zuluaga[1,2], Julia Casado-Carbajo[1], Daniel Fuster[1], Anna Hernandez-Rubio[1], Marvin Bueno-Vélez[1], Carmen Garcia-Martin[3], Xoel Pena[3], Robert Muga[1]. *[1]Universitat Autònoma de Barcelona, Barcelona, Spain; [2]University Hospital Germans Trias i Pujol, Badalona; [3]University Hospital Germans Trias i Pujol, Badalona, Spain*
Email: ypzuluaga.germanstrias@gencat.cat

Background and aims: Vitamin D deficiency is a risk factor for liver disease including cirrhosis and HCC. Individuals with Alcohol Use Disorder (AUD) are comorbid, with a heavy burden of liver disease and metabolic complications including Type 2 Diabetes Mellitus (T2DM). We aimed to analyze the prevalence and associations of Vitamin D deficiency in AUD patients enrolled in a detoxification program.
Method: Cross-sectional study in patients consecutively admitted for the treatment of AUD between January 2017 and October 2023. Socio-demographic, substance use characteristics and blood parameters were available at admission. Vitamin D status was assessed through the level of 25-Hydroxyvitamin D (25 (OH)D) using a direct competitive chemiluminescent Immunoassay method. Vitamin D deficiency was defined as serum 25 (OH)D concentration <20 ng/ml, Impaired Fasting Glycaemia (IFG) was defined by fasting blood glucose >100 mg/dl and advanced liver fibrosis by a FIB-4 index >3.25.
Results: 243 patients (75% M) with mean age of 49 ± 10 years, mean BMI of 26.4 ± 7, 3 kg/m^2, mean alcohol consumption of 163 ± 81 gr/day and mean duration of AUD of 18.1 ± 11.2 years, were included. Mean of 25 (OH)D, fasting blood glucose, AST, ALT and platelets were 14.4 ± 10.2 ng/ml, 103.4 ± 40.9 mg/dl, 55.1 ± 75.8 U/L, 44.8 ± 76.6 U/L, and 206.3 ± 84.8 × 10^9/L, respectively. Overall prevalence of Vitamin D deficiency was 80.6% (41.1% of them having serum levels of 25 (OH)D < 10 ng/ml). In addition, 32.3% of patients had IFG and 20.5% a FIB-4 index suggestive of advanced liver fibrosis. Vitamin D deficiency was associated with older age ($p < 0.05$), IFG ($p < 0.05$) and FIB-4 >3.25 ($p < 0.05$). In multivariate analysis adjusted for renal function, IFG (OR, 2.33; 95% CI 1.00–5.49, $p < 0.05$) and FIB-4 >3.25 (OR, 4.1; 95% CI 1.18–14.5, $p < 0.05$) were the only factors associated with Vitamin D deficiency.
Conclusion: Type 2 Diabetes Mellitus and Vitamin D deficiency may have a synergistic effect in AUD patients at risk of adverse liver-related outcomes.

Email: meritxell.ventura@vallhebron.cat

Background and aims: The asymptomatic forms of alcohol-related liver disease (ArLD) have been ignored worldwide leading to the late diagnosis of the disease. The main factor linked to progression and mortality among ArLD patients is the lack of abstinence. We aim to compare an intervention (i.e hepatology visit, psychology visit including brief intervention and assessment of the underlying liver disease with non-invasive test) with a historical control group to establish a better strategy to promote abstinence.
Method: Prospective interventional study (currently recruiting) including subjects ≥30 years old with a diagnosis of alcohol use disorder or excessive alcohol consumption as well as ALT and AST <5 times UNL, bilirubin <3 mg/dL, AST/ALT ratio >1.5 and GGT >100 mg/dL gathered from primary care and the emergency department (ER). Patients with known liver disease were excluded. Patients from the historical cohort were gathered from the ER (discharge with the recommendation to cease drinking and control for either primary care and/or addiction center). Patients were followed for 1 year with an initial assessment of the underlying liver disease with Fibroscan® and thereafter visited every three months by the psychologist. Control patients (n = 19) were followed for 1 year.
Results: Up to date 23 patients had been included in the intervention group and 21 completed 3 month follow-up. In summary, most patients were men (81.82% intervention vs 78.95% control, p = 0.8) with a mean age of 50.58 vs 49.07 years (p = 0.6). There were no differences in the prevalence of diabetes, hypertension, and dyslipidemia. There was a higher use of cannabis in the intervention group 54.55% vs 21.05% p = 0.02, with no differences between other drugs. The average of standard drink units was 81.64 [IQR = 33.6–129.6] for the intervention group vs 128.3 [IQR = 67.7–189] in the control (p = 0.2). Both groups presented similar Fib-4 score 4.4 vs 3.4, p = 0.5, without relevant differences in the analytical parameters. At 3 months follow-up, 8 patients from the intervention group stopped drinking while only 5 of the control did (p = 0.3). Of note, 14 patients in the intervention vs 6 in the control cohort achieved a ≥50% reduction of baseline consumption (p = 0.02). A reduction in total number of standard drink units/week among the intervention group was also observed 17.2 vs 69.5; p = 0.02. While up to 6 patients from the control group required a second ER admission, none of the study group did (p = 0.009). Finally, up to 9 patients from the study group presented advanced liver disease assessed by Fibroscan (10.8 kPa).
Conclusion: Asymptomatic forms of advanced ArLD are common and frequently underdiagnosed. A holistic approach including hepatology, psychology and assessment of the underlying liver disease decreases alcohol consumption and promotes abstinence in patients with a suspected underlying ArLD as compared with a historical cohort.

SAT-305

Impact of corticosteroid treatment and clinical risk factors in patients with alcohol-associated hepatitis and clinically significant portal hypertension

Petra Dinjar Kujundžić[1], Marko Milosevic[1], Mislav Barišić-Jaman[1], David Dohoczky[1], Viktoria Skurla[1], Marta Defar[2], Sara Cepic[2], Frane Pastrovic[3], Ivica Grgurević[3]. *[1]University Hospital Dubrava, Zagreb, Croatia; [2]School of Medicine, University of Zagreb, Zagreb, Croatia; [3]University Hospital Dubrava, School of Medicine, University of Zagreb, Zagreb, Croatia*
Email: petra.dinjar@gmail.com

Background and aims: There is limited knowledge about the clinical features and prognostic factors of hospitalized patients diagnosed with alcohol-associated hepatitis (AH) and clinically significant portal hypertension (CSPH) who undergo corticosteroid (CS) treatment. This study aims to analyse impacts of CS treatment and identify mortality-associated risk factors within this specific subgroup of patients with AH.
Method: A retrospective analysis was conducted of patients hospitalized for AH at University Hospital Dubrava from January 2012 to December 2023. The primary outcome assessed was 90-day mortality. AH was defined based on the criteria established by the NIAAA AH Consortia, and CSPH was defined clinically based on either endoscopic evidence of esophageal varices, or platelet count<150 × 10^9/L plus splenomegaly (>12 cm).
Results: Our cohort comprised 168 AH patients, with 81% males and a with median age of 54. Half of patients (n = 84) received CS treatment and 58.9% (n = 99) had CSPH. At admission patients with CSPH were more likely to have ascites, experienced more decompensation events and were treated more often with CS (p < 0.05 for all, using Chi-squared test). The 90-day mortality rate was slightly higher in CSPH patients (42.4%) than in non-CSPH patients (33.3%), but without statistical significance (p = 0.23). Moreover, there wasn't statistically significant difference in CSPH group depending on the use of CS (39.7% vs 47.2%, p = 0.47). The same outcome was observed in non-CSPH group depending on CS therapy (31.2% vs 38.1% p = 0.13). Higher leukocytes and neutrophil counts, lower lymphocytes and higher AST/ALT ratios and lipid levels at admission were observed in CSPH group (p < 0.05 for all, using Kruskal-Wallis test). Although GAHS and MELD scores showed no differences at day 0, variations emerged on the 7th day where CSPH patients had higher scores. Encephalopathy (HR = 2.506, 95% CI: 2.506–2.506, p < 0.001) and number of decompensated events at admission (HR = 1.641, 95% CI: 1.641–1.641, p < 0.001) were independently associated with 90-day mortality in CSPH group. CS treatment did not significantly impact 90-day survival in the CSPH group (HR = 1.365, 95% CI: 0.838–2.223, p = 0.21). However, in the non-CSPH group, CS treatment independently associated with lower 90-day mortality (HR = 0.383, 95% CI: 0.161–0.911, p = 0.04).
Conclusion: CSPH had no significant impact on 90-day survival in AH patients. CS treatment didn't significantly affect 90-day survival in CSPH patients but was linked to lower mortality in non-CSPH. A larger cohort should be considered for further evaluation.

Cirrhosis and its complications – ACLF and Critical illness

TOP-097-YI

Dynamics of systemic inflammation after TIPS implantation and their impact on acute-on-chronic liver failure and liver-related death

Andrea Kornfehl[1], Lukas Hartl[1], Theresa Müllner-Bucsics[1], Michael Schwarz[1], Benedikt Hofer[2], Nina Dominik[3], Benedikt Simbrunner[3], Mathias Jachs[3], Lukas Reider[4], Maria Schoder[4], Michael Trauner[3], Mattias Mandorfer[5], Thomas Reiberger[3]. *[1]Division of Gastroenterology and Hepatology, Departement of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Division of Gastroenterology and Hepatology, Departement of Medicine III, Medical University of Vienna, benedikt.s.hofer@meduniwien.ac.at, Austria; [3]Division of Gastroenterology and Hepatology, Departement of Medicine III, Medical University of Vienna, Vienna, Austria; [4]Division of Interventional Radiology, Department of Radiology, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [5]Medical University of Vienna, Vienna, Austria*
Email: andrea.kornfehl@meduniwien.ac.at

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) placement is an option for treatment of portal hypertension (PH)-related complications. Systemic inflammation is associated with acute-on-chronic liver failure and death in patients with cirrhosis.

Method: Patients undergoing covered TIPS implantation at two Viennese centers with available data on longitudinal levels of C-reactive protein (CRP) were included from a prospective cohort (AUTIPS study, NCT03409263: 01/2017 to 11/2022; n = 64) and a retrospective cohort (09/2000 to 09/2019, n = 191). Inflammation parameters CRP (available in n = 84), interleukin 6 (IL-6; n = 80), procalcitonin (PCT; n = 84) and lipopolysaccharide-binding protein (LBP; n = 75) were measured before (BL) and 3 (M3), 6 (M6), 9 (M9) and 12 (M12) months after TIPS implantation. Competing risk regression (CRR) was performed considering liver transplantation and death as competing events. For the analysis of the association of the difference in CRP and IL-6 with clinical outcomes, only events that occurred at least 3 months after TIPS implantation were considered for CRR.

Results: A total of 255 patients (71% male, median age 57 years) were included and followed for a median of 22 (IQR 47) months. Main indications for TIPS were PH bleeding (n = 81, 32%) and refractory ascites (n = 174, 68%). At BL, median levels were 0.91 (IQR 1.51) mg/dL for CRP, 25.15 (IQR 27.89) pg/ml for IL-6, 0.13 (IQR 0.15) ng/ml for PCT and 8.37 (IQR 4.69) µg/ml for LBP. Among patients with available CRP at each time point (n = 84; BL: 0.96; 1.12 mg/dL), CRP increased 3 months after TIPS implantation (1.29; IQR 1.80 mg/dL) before decreasing significantly at M6 (0.47; IQR 0.94 mg/dL), 9M (0.37; IQR 1.15 mg/dL) and M12 (0.45; IQR 0.98 mg/dL; p < 0.001). IL-6 decreased from BL to M3 in 53% (ΔIL-6 median −1.61; IQR 13.94 pg/ml), PCT in 37% (ΔPCT median 0.01; IQR 0.16 ng/ml) and LBP in 84% (ΔLBP median −2.21; IQR 4.13 µg/ml) of patients. In multivariable CRR adjusted for age, albumin and MELD at BL, IL-6 at BL was independently associated with post-TIPS ACLF (asHR: 1.007; 95%CI: 1.004–1.010; p < 0.001) and liver-related death (asHR: 1.020; 95%CI: 1.008–1.020; p < 0.001). Moreover, multivariable CRR adjusted for age, albumin and MELD at 3M revealed that ΔIL-6 after three months was independently associated with subsequent ACLF asHR: 1.014; 95%CI: 1.006–1.020; p = 0.001) and liver-related death; asHR: 0.018; 95%CI: 1.010–1.030; p < 0.001). ΔCRP was not independently associated with ACLF und liver-related death.

Conclusion: In patients with decompensated cirrhosis, several biomarkers of inflammation show a consistent decrease after TIPS implantation. The decrease in LBP early (M3) after TIPS also suggests an improvement of bacterial translocation. Importantly, a favourable dynamic of IL-6 3 months after TIPS implantation is independently associated with a lower risk of ACLF and liver-related death.

Evaluation of the scoring systems dedicated to liver transplantation in acute-on-chronic liver failure (ACLF) in an international multicenter cohort

Sébastien L'Hermite[1], José Ursic Bedoya[2], Sébastien Halter[3], Philippe Ichai[4], Line Carolle Ntandja Wandji[5], Audrey Coilly[4], Christophe Camus[1], Samir Jaber[2], Rhiannon Taylor[6], Sébastien Dharancy[5], Douglas Thorburn[7], Filomena Conti[3], Georges-Philippe Pageaux[2], Faouzi Saliba[4], Constantine Karvellas[8], Antoine Monsel[3], Alexandre Louvet[5], William Bernal[9], Florent Artru[1]. *[1]Rennes University Hospital, Rennes, France; [2]Regional University Hospital Center of Montpellier, Montpellier, France; [3]Pitié-Salpétrière University Hospital-APHP, Paris, France; [4]Centre Hépato-Biliaire, Paul Brousse Hospital, Villejuif, France; [5]Lille University Hospital, Lille, France; [6]Statistics and Clinical Research, NHS Blood and Transplant, Bristol, United Kingdom; [7]The Sheila Sherlock Liver Centre, London, France; [8]University of Alberta Hospital, Edmonton, France; [9]Institute of Liver Studies, Kings College Hospital, London, United Kingdom*
Email: sebastienlhermite7@gmail.com

Background and aims: Liver transplantation (LT) in patients with acute-on-chronic liver failure (ACLF) require a thorough selection process to optimise post-procedural survival. The Transplantation for ACLF-3 model (TAM) and Sundaram ACLF LT models (SALT) have been proposed to aid in the selection process. To date the performance of these models has not been assessed in a large independent cohort.

Method: All patients transplanted in the context of ACLF grade 3 from 6 retrospective cohort (involving 5 French and 1 Canadian centres) and 1 prospective cohort (a multicentric cohort from the United Kingdom) covering the period 2008–2023 were included in this study. The primary end point was 1-year patient survival. All variables included in both scores and their cut-offs were included in logistic regression analyses.

Results: Two hundred thirty-two patients, median age of 55 years (IQR:46–61), were included. Alcohol consumption was the main cause of cirrhosis (51%). Median BMI was 26.4 kg/m² (22.9–30.3), 23% had diabetes. At LT, CLIF-C-ACLF score was 67 (61–73), MELD 40 (34–40), PaO2/FiO2 ratio 280 (206–502), leukocytes count 10 G/L (6–15), 67% patients needed vasopressors; TAM and SALT were 1 (1–2) and 14 (10–18). Median follow-up was 858 days (218–2429) with a 1-year survival of 77% (95%CI:71–82) without difference in overall comparison. At 1-year, 53 deaths (23%) occurred in a median timeframe of 77 days (16–156). PaO2/FiO2 ratio as continuous (OR 0.98, 95%CI:0.99–0.98, p = 0.04) or according to the threshold of TAM and SALT (200 mmHg-OR 3.39, 1.68–6.86, p < 0.0006) and lactate level according to TAM threshold (4 mmol/l -OR 2.26, 1.02–5.07, p = 0.04) were independently associated with 1-year post transplant mortality. All other components of the TAM and SALT including age, diabetes, BMI, leukocytes counts or vasopressors were not associated with 1-year mortality after transplantation. Discriminant abilities of TAM (AUC 0.63, 0.54–0.70) and SALT (AUC 0.63, 0.53–0.71) were moderate and not different (p = 0.86) in the overall cohort. However, AUCs varied widely between groups (from 0.38 to 0.79 and 0.48 to 0.74 respectively) and were best in the three cohorts with the lowest survival rate (1-year survival 70–72%, accounting for 120 patients) with an AUC of 0.69 (0.56–0.76) for TAM and 0.70 (0.56–0.81) for SALT. Both scores showed good performance in calibration testing with a median difference in observed vs. expected 1-year survival after LT of 6% and 5% respectively.

Conclusion: Both TAM and SALT have acceptable discriminative abilities supported by good calibration of 1-year post-LT survival in patients with ALCF-3. These scores could aid the decision-making process to optimise outcome after LT. Thresholds of 200 for PaO2/FiO2

ratio and 4 mmol/l for arterial lactate are confirmed to be independently associated with 1-year mortality in this population.

THURSDAY 06 JUNE

THU-049

Supplemental low-dose hydrocortisone in cirrhotic patients with septic shock: a double-blind, randomised, placebo-controlled, multicentre trial; the SCotCH study

Philippe Meersseman[1], María Hernández-Tejero[2], Juan Manuel Diaz[3], Joost Wauters[1], Greet Hermans[1], Fatima Aziz[4], Helga Ceunen[1], Veronica Enith Prado Gonzalez[5], Mireya Arteaga[4], Juan Acevedo Haro[6], Miriam Valdivieso[4], Cristina Sanchez[3], Vicente Arroyo[3], Alexander Wilmer[1], Javier Fernández[7]. *[1]University Hospital Leuven, Leuven, Belgium; [2]Mayo Clinic, Rochester, Rochester, United States; [3]EF-Clif, Barcelona, Spain; [4]Hospital Clinic Barcelona, Barcelona, Spain; [5]C.H. Luxembourg, Luxembourg, Luxembourg; [6]University Hospitals Plymouth NHS Trust, Plymouth, United Kingdom; [7]Hospital Clinic Barcelona, EF-Clif, Barcelona, Spain*
Email: jfdez@clinic.cat

Background and aims: Steroid treatment in septic shock remains controversial, partially due to a heterogenous study population. Ample evidence suggests that cirrhotic patients frequently develop relative adrenal insufficiency in case of sepsis. Therefore, we hypothesized that early administration of low-dose hydrocortisone (HCS) in cirrhotic patients with septic shock, a specific population, might reduce mortality and facilitate shock reversal and organ recovery.
Method: Double-blind, randomised, placebo-controlled multicentre trial, enrolling adult cirrhotic patients with septic shock. Patients were assigned to receive an i.v. bolus of 100 mg HCS prior to a continuous infusion of 200 mg/24hr or placebo, for at least 3 days, followed by a tapering period of 3 to 7 days, depending on the time of hemodynamic recovery. Primary end point was 28-day all-cause mortality.
Results: After enrolment of 83 patients, the trial was stopped early due to slow inclusions. There was no difference in 28-day (14/40 (35%) in HCS and 16/43 (37.2%) in placebo group, p = 1) and 90-day mortality (23/40 (57.5%) versus 20/43 (46.5%), p = 0.43). Moreover, no difference was seen in shock resolution (34/40 (85%) versus 31/43 (72.1%), p = 0.25) or in days to shock resolution (3 days (2.2–4, IQR) versus 4 (2–7.5, IQR), p = 0.34). More patients died of refractory shock in the placebo group (2/23 (8.7%) vs 9/20 (45%), p = 0.01), whereas ACLF was the main cause of death in the HCS group (15/23 (65.2%)). No difference was seen in new shock episodes or new bacterial, CMV or fungal infections during hospital stay between groups. Severity of ACLF (HR = 3.25, 95% CI: 1.94–5.46) and inadequacy of empirical antibiotic therapy (HR = 6.25, 95% CI: 3.03–12.5) were the only independent predictors of 28-d mortality.
Conclusion: Supplemental hydrocortisone did not improve survival in cirrhotic patients with septic shock. Its role in refractory shock deserves further evaluation.

Background and aims: Hepatorenal syndrome (HRS-AKI) is the most severe type of acute kidney injury in patients with cirrhosis. Less than 50% of patients with HRS-AKI show renal function recovery with albumin and vasoconstrictors. The lack of renal recovery is still poorly understood and there is a lack of biomarkers able to predict it. We aimed to identify biomarkers of renal recovery and 90-day mortality in patients with HRS-AKI.
Method: We identified patients with a clinical diagnosis of HRS-AKI and serum creatinine >1.5 mg/dl among those enrolled in the PREDICT and ACLARA studies. Demographics, clinical and laboratory characteristics were collected. Urinary biomarkers of tubular damage (neutrophil gelatinase-associated lipocalin [NGAL], Cystatin C, Albumin, Epidermal growth factor, Osteopontin) and cell cycle arrest (insulin growth factor binding protein 7 [IGFBP-7]) were measured by multiplex ELISA. Urinary metabolites of de novo NAD+ biosynthetic pathway were measured by HPLC-MS. Serum inflammatory cytokines (IL-1beta, IL-1ra, IL-6, IL-8, TNF-alpha, MCP-1, VEGF-A) were measured by a multiplexed immunoassay. Primary outcome was renal recovery (defined as serum creatinine <1.5 mg/dl) and all the analysis were adjusted for false discovery rate. Predictors of 90-day mortality were explored using renal recovery as a time-varying covariate.
Results: Overall, 171 patients with HRS-AKI were identified. Most frequent etiology was alcohol-related cirrhosis (61%) and 138 patients (81%) had acute on chronic liver failure (ACLF). Renal function recovery was achieved in 69 patients (40%). Patients with renal recovery were younger (57 vs 62 years; p = 0.021), had lower serum creatinine (2.1 vs 2.7 mg/dl; p < 0.001) and lower prevalence of ACLF (69 vs 88%; p = 0.033). Patients with renal recovery had lower levels of urinary NGAL (184 vs 533 ng/ml; p = 0.007), urinary albumin (4.3 vs 8.2 mg/dl; p = 0.025) and serum MCP-1 (235 vs 329 pg/ml; p = 0.033) than those without. Metabolites of de novo NAD+ biosynthetic pathway were not significantly different between the two groups. During 90-day follow-up 88 patients died. In multivariable analysis, white blood cell count (subdistribution hazard ratio [sHR] = 1.05; p = 0.001], bilirubin (sHR = 1.04; p < 0.001) and IGFBP-7 (sHR = 1.27; p = 0.002) were identified as independent predictors of 90-day mortality, while renal recovery was associated with a lower risk of 90-day mortality (sHR = 0.31; p < 0.001).
Conclusion: Urinary biomarkers of tubular (NGAL) and glomerular damage (albumin) are strong predictors of renal recovery in patients with HRS-AKI. Urinary IGFBP-7, a biomarker of cell cycle arrest, predicts survival independently from renal recovery in patients with HRS-AKI.

Extended validation of proteomics and machine learning guided biomarker discovery and pathway perturbations in infection-related acute-on-chronic liver failure

Nipun Verma[1], Pratibha Garg[2,3], Arun Valsan[4], Vivek Sarohi[5], Trayambak Basak[6], Parminder Kaur[2], Shreya Singh[7], Arka De[2], Madhumita Premkumar[2], Sunil Taneja[2], Ajay Kumar Duseja[2], Virendra Singh[8]. *[1]Department of Hepatology, Postgraduate Institute of Medical Education and Research, Chandigarh, India; [2]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [3]Postgraduate Institute of Medical Education and Research, Hepatology, Chandigarh, India; [4]Amrita Institute of Medical Sciences, Kerala, India; [5]Indian Institute of Technology, Mandi, India; [6]Indian Institute of Technology, Mandi, Himachal Pradesh, India; [7]Post graduate Institute of Medical Education and Research, Ambedkar Institute of Medical Sciences, Chandigarh, India; [8]Post Graduate Institute of Medical Education and Research, Punjab Institute of Liver and Biliary Sciences, Chandigarh, India*
Email: nipun29j@gmail.com

Background and aims: Evaluating infections in acute-on-chronic liver failure (ACLF) presents a formidable challenge. This study deciphers protein signatures and pathway perturbations associated with bacterial or fungal infections in ACLF.
Method: We prospectively enrolled 391 patients with ACLF (92% males, median age: 41 years, 63% alcohol-associated hepatitis), with and without bacterial or fungal infections. High-resolution-untargeted proteomics was performed on plasma samples from 84 patients for biomarker discovery utilizing differential expression, discriminant analysis, and machine learning. Selected biomarkers were validated through immunoassays in two cohorts (N = 147 and 160) with predictive modelling for identifying infections. Perturbed pathways between groups were analyzed.
Results: Patients with infection exhibited higher leucocytosis, procalcitonin, organ failures, severity scores, and 30-day mortality ($p < 0.001$; each). Of 516 identified proteins, 27 were upregulated and 38 were downregulated in infected-cases (adjusted $p < 0.05$). A four-protein panel (LGALS3BP, PLTP, CFP, GPX3) yielded an AUC of 0.854 (0.787–0.922) in validation cohort-I, retaining significance after adjusting for severity (MELD or CLIF-C OF) and systemic inflammatory response criteria. We developed a PACIFY model (LGALS3BP + procalcitonin + CLIF-C OF + lactate) with excellent discrimination (AUC: 0.965; 0.933–0.997), sensitivity: 92%, and specificity: 91.7% for diagnosing infections. Its utility for identifying infections was further established in validation cohort-II with an optimal AUC: 0.906; 0.860–0.952, sensitivity: 80.6%, and specificity: 86.5%. PACIFY model's discriminatory ability outperformed procalcitonin, SIRS, WBC, NLR, neutrophil%, and composite models ($p < 0.001$). Pathway analysis unveiled diverse perturbations including impaired pathogen-response, reduced-phagocytosis, neutrophilic extracellular traps, complement functions, hypocoagulation and hypofibrinolysis, dysregulated carbohydrate metabolism, autophagy, heightened cell death and proteolysis.
Conclusion: A PACIFY model emerges as a robust tool for identifying infections in ACLF, surpassing existing markers. Pathway disruptions provide novel therapeutic targets for managing infections in ACLF.

Background and aims: Therapeutic plasma-exchange (TPE) could ameliorate systemic inflammation and reduces liver-failure related deaths in patients with acute on chronic liver failure (ACLF). We aimed to study the outcomes of TPE in patients admitted to the intensive care unit with organ failures from the multicentric-multinational AARC database.
Method: Prospectively collected data from AARC was analysed. Our primary outcome was to evaluate TPE compared to standard medical treatment (SMT) in improving 15-day transplant-free survival and secondary outcomes included 28-day survival and predictors of mortality in patients treated with TPE. The decision of TPE was taken by the treating physician at each center. In a subset of 50 patients pre and post TPE, an analysis of cytokines (interleukin-6, C-reactive protein), endotoxin, and nitric oxide was performed.
Results: Patients with ACLF (n = 1053) who underwent TPE (n = 117) were significantly older (46.7 ± 11.8 vs. 44.2 ± 11.6; p = 0.03), majority being males (78% vs.89%), predominantly alcoholics (89% vs. 92%), and, sicker with higher AARC score (9.9 ± 2.4 vs.8.3 ± 1.9; p < 0.001) and number of extrahepatic organ failures (EH-OFs) [4 (21% vs. 6%) and 3 (20% vs.10%) vs. 1 (39% vs. 75%) and 2 (20% vs. 9%); p < 0.001] respectively. Majority of patients, 90% underwent low-volume TPE with mean of 2 ± 0.6 sessions per patient. At day 28, 536 (51%) died and 171 (16%) underwent liver transplant. TPE (HR 0.73, 0.56–0.95) independently improved 15-day transplant free survival. Higher AARC (HR 1.21, 1.06–1.38) and SOFA scores (HR 1.05, 1.02–1.08) (Model-1) while number of EH-OFs (HR 1.16, 1.11–1.22) (Model-20 predicted higher 15-day mortality. TPE however, could not improve 30-day survival. On competing-risk survival analysis, considering liver transplant as the competing event, the survival benefit with TPE was not observed. In the subgroup of patients who underwent TPE, higher SOFA (HR 1.11, 1.02–1.22), age (HR 1.04, 1.01–1.06) and AARC score (HR 1.21, 1.06–1.38) (Model-1) and higher arterial lactate (≥3 mmol/L) (2.61, 1.49–4.57) and MELD (HR 1.03, 1.01–1.06) (Model-2) predicted 15-day mortality. Survivors (n = 22) post-TPE had significant improvement in markers of systemic inflammation, nitric oxide, endotoxin, oxidative stress and arterial lactate compared to non-survivors (n = 28).
Conclusion: TPE could only improve short-term 15-day transplant-free survival without improving long-term outcomes in patients with ACLF admitted to the intensive care unit with organ failures. Severity of liver failure and number of extrahepatic organ failures determine mortality in these patients. Patients with higher age, AARC score and arterial lactate have higher mortality with TPE.

THU-053
Longitudinal salivary metagenomics in acute-on-chronic liver failure patients

Manolo Laiola[1], Maria Papp[2], Wenyi Gu[3], Nathalie Galleron[1], Benoit Quinquis[1], Mamadou-Gabou Thiam[1], Emmanuelle Le Chatelier[1], Hervé Blottière[1], S. Dusko Ehrlich[4], Mathieu Almeida[1], Jonel Trebicka[3,5]. *[1]INRAE MetaGenoPolis, Jouy-en-Josas, France; [2]University of Debrecen, Debrecen, Hungary; [3]University of Münster, Münster, Germany; [4]UCL, London, United Kingdom; [5]EF CLIF, Barcelona, Spain*
Email: laiola.manolo@gmail.com

Background and aims: The main clinical events precipitating acutely decompensated cirrhosis (AD) patients are bacterial infections and alcoholic hepatitis, while in 30–40% of the cases no clinical event is identifiable [1]. When not identified, bacterial translocation is thought to be causal for the AD. Recent studies showed evidence for the presence of oral microbes in stool [2], and salivary microbiome could reflect changes in the cirrhotic patients' gut microbiome [3]. Hence, elucidating the role of the salivary microbiome might pave the way for the development of new diagnostic and therapeutic strategies in the etiology of AD cirrhosis and progression to ACLF [4]. The aim of the study is to longitudinally assess the clinical and oral microbial evolution of 91 patients of the MICROB-PREDICT project.
Method: Shotgun metagenomic analysis was performed on saliva samples collected from 91 patients, collected over more than 75 days after baseline. The samples were DNA extracted then sequenced using Ion Proton technology. A human oral microbial gene catalog was used as a reference database [5]. The sequenced DNA was mapped to the reference using Meteor software [6] to generate the microbial taxonomical abundance profile and identify biomarkers of ACLF progression.
Results: At the inclusion, ACLF patients showed significantly lower levels of oral dominant species in saliva compared to AD subjects. Over time, a loss of oral-related taxa was observed for some AD patients independently of rifaximin treatment, along with an accumulation of non-oral species, after adjustment from known confounders. A microbial drift towards a unique compositional state was significantly associated to the accumulation of non-oral taxa like *Enterococcus faecalis* only for pre-ACLF subjects (53.7% mortality rate in 3 months), whereas this pattern was not evident for stable AD individuals (9% of mortality per year).
Conclusion: Our analysis shows the potential of saliva as reservoir of microbiome-based biomarkers for acute decompensated cirrhosis and progression to ACLF. The monitoring of opportunistic pathogens in the salivary microbial composition might support the management of precipitating events, delivering guidance in a personalized medicine approach.
Funding: The MICROB-PREDICT project has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement No 825694. This reflects only the author`s view, and the European Commission is not responsible for any use that may be made of the information it contains.

Background and aims: Patients with chronic liver disease (CLD) receive frequently proton pump inhibitors (PPIs), statins, and non-selective beta-blockers (NSBB). The role of these drugs on the overall survival of CLD patients at different disease stages are still debated.
Method: This study includes a comprehensive univariable analysis of 2029 patients from six multicentric studies (PREDICT, CANONIC, FCRB, NEPTUNE, VA-US and GALA-ALD), assessing the effects on short- and long-term survival associated with PPIs, statins, and NSBB usage during hospital admission across different stages of liver disease, including CLD without cirrhosis, stable decompensated cirrhosis (SDC), unstable decompensated cirrhosis (UDC), pre-acute-on-chronic liver failure (pre-ACLF), and ACLF.
Results: Notably, PPI was associated with increased long-term mortality, especially in less severe disease (SDC [90-day: 5.8% vs. 2.1%, p = 0.043] and CLD without cirrhosis [overall: 16.2% vs. 4.4%, p < 0.001]). Patients with statin therapy had improved survival across all patient groups, with a significant effect on 1-year survival (mortality: 21.4% vs. 24.2%, p = 0.040). However, in SDC patients, statins were associated with lower long-term survival (overall mortality: 10.2% vs. 20.0%, p = 0.037). Finally, NSBB use demonstrated the most consistent benefit on short-term mortality (28-day and 90-day) in all patient categories. Of note, patients with ACLF (28-day mortality: 14.0% vs. 33.5%, p = 0.009; 90-day: 21.9% vs. 45.9%, p < 0.001) and with pre-ACLF (90-day mortality: 43% vs. 61.6%, p = 0.024; 1-year: 58.1% vs. 74.4%, p = 0.013) seem to benefit as well from NSBB therapy.
Conclusion: Our comprehensive study of 2029 CLD patients indicates that PPI and statins may not be beneficial in stable decompensated cirrhosis. In contrast, statins were associated with better survival when all disease stages were analyzed. Notably, patients with NSBBs consistently linked to improved survival outcomes, even in advanced stages like pre-ACLF and ACLF. These findings highlight the necessity for personalized treatment approaches to maximize patient outcomes in chronic liver disease.

Background and aims: Acute-on-chronic liver failure (ACLF) is the most severe complication in patients with decompensated cirrhosis (DC). In recent years, studies have demonstrated the activation of inflammatory pathways as liver cirrhosis progresses. Notably, increased expression of the PD-L1 pathway has been associated with the risk of bacterial infection due to impaired phagocytic capacity of macrophages in patients with DC. Additionally, its soluble form (sPD-L1) has been linked to the risk of bacterial infections. However, the potential relationship between sPD-L1 levels and ACLF has not been evaluated. This study aims to evaluate the role of sPD-L1 as biomarker in the prediction of ACLF.
Method: This is a sub-analysis of the LiverHope Efficacy trial. Serum samples from patients recruited in the study were collected at baseline. Data on ACLF development in patients enrolled in the study was evaluated. PD-L1 pathway activity was estimated by measuring serum levels of PDL1 (ELISA), which estimates the soluble isoform of PDL1 (sPDL1) expressed in monocytes. Factors associated with ACLF development were identified in a bivariate analysis. Competing risk analysis was performed, being transplant and mortality considered as competing events for ACLF development. A second prospective cohort, previously reported (EASL-ILC 2022), was used to validate the findings.
Results: Baseline samples from the Liverhope cohort were available for analysis in 214 patients (out of 254 patients included in the trial, 84%). The most common etiology was alcohol-related in 82% of cases, followed by MASLD in 7%. At inclusion, the median MELD Na score was 14 (11–17), and the median levels of soluble PD-L1 (sPD-L1) were

97 (74–121) pg/ml. Over the course of a 1-year follow-up, 25 patients (12%) experienced at least one episode of ACLF. Baseline levels of sPD-L1 were higher in patients who developed ACLF versus those of patients who did not develop ACLF: 116 (97–151) vs 93 (74–118) pg/ml, p value = 0.019. A multivariate competing risk analysis revealed that MELD Na, a history of hepatic encephalopathy (HE), and levels of sPD-L1 were independently associated with ACLF development during 1 year of follow-up. To validate these findings, an independent prospective cohort consisting of 305 hospitalized patients with decompensated cirrhosis (DC) was analyzed. In this new cohort, levels of sPD-L1 and MELD-Na were the only two independent factors predicting ACLF at the 3-months of follow-up.
Conclusion: Levels of sPD-L1 are associated with the risk of ACLF in patients with DC. These may reflect the degree of immune dysfunction reported in patients with DC. Soluble PD-L1 is a promising biomarker, providing the potential to predict the risk of ACLF in the context of DC.

Background and aims: Severe alcohol-related hepatitis (sAH) and infection are the most common precipitating factors for the development of acute-on-chronic liver failure (ACLF). The pathophysiological basis and prognostic impact of sAH progressing to ACLF (sAH-ACLF) is still poorly understood. Here, we aimed to characterize the clinical profile and disease course of patients with sAH-ACLF as compared to those with infection-induced ACLF (inf-ACLF).
Method: We studied cirrhotic patients admitted with sAH-induced acute decompensation (sAH-AD, n = 546), sAH-ACLF (n = 239) and inf-ACLF (n = 234), that were included in three prospective observational cohort studies (CANONIC, PREDICT and ACLARA). Organ failures and the presence of ACLF were defined according to the CLIF-consortium organ failure (CLIF-C OF) score. Clinical and laboratory baseline data were compared between the three groups. A competing-risk regression analysis was performed to evaluate the impact of clinical and laboratory factors on 28-day mortality and ACLF development.
Results: Patients with sAH-ACLF had more often liver or coagulation failure as compared to those with inf-ACLF ($p < 0.001$ and $p = 0.001$, respectively), whereas kidney, circulatory and respiratory failure were more frequently present in inf-ACLF ($p < 0.001$, $p = 0.002$ and $p < 0.001$, respectively). Plasma C-reactive protein (CRP) was higher in inf-ACLF as compared to sAH-ACLF ($p < 0.001$), whereas white blood cell count (WBCC) was higher in sAH-ACLF ($p = 0.001$). Despite their different phenotype, cumulative incidence of 28-day mortality was comparable between sAH-ACLF and inf-ACLF (42.2 vs. 39.3%). When dividing the sAH-ACLF group into patients with and without an infection at admission, patients with an infection showed higher CRP and creatinine levels ($p = 0.01$ and $p < 0.001$, respectively), higher CLIF-C OF scores ($p = 0.036$) and higher mortality rates (53.6 vs. 32.6%) as compared to those without. Multivariate analysis for 28-day mortality revealed INR as the only independent predictor in sAH-ACLF, whereas age, creatinine, CRP, WBCC, INR and bilirubin independently predicted mortality in inf-ACLF. In the sAH-AD group, creatinine and sodium levels were independent predictors of mortality and ACLF development at 28 days.
Conclusion: sAH-ACLF is distinct from inf-ACLF and is characterized by 'liver-centered' OFs, whereas inf-ACLF is characterized by extra-hepatic OFs. Despite the different phenotypes, short-term mortality rates are the same. As opposed to inf-ACLF, markers of systemic inflammation do not predict outcome in sAH-ACLF, nor disease progression in sAH-AD which speaks against the notion that inflammation is a hallmark in alcohol-related severe liver disease. These findings underline the need for a better understanding of the pathophysiological basis of sAH progressing to ACLF and for more accurate risk stratification in these patients.

THU-058

Portal vein thrombosis increases short-term mortality independent of liver disease severity score among hospitalized patients of decompensated cirrhosis-result from CLEARED consortium

Email: doctor.ashokchoudhury@gmail.com

Background and aims: Portal Vein Thrombosis (PVT) in cirrhosis is multifactorial and is associated with poor outcome in the natural history. However, etiology, presentation and implications of PVT in decompensated cirrhosis as well as its distribution across different regions is unclear.

Method: The multi-national CLEARED consortium enrolled prospectively non-electively admitted patients with cirrhosis with 30-days follow-up post-discharge. PVT was diagnosed on USG and/or CT scan and was analysed in relation to demographic, aetiology, clinical presentation, mode of decompensation, complications, course in hospital and survival at 30-days post discharge across all 6 continents.

Results: Total of 4305 patients from 107 centres in 27 countries were included. The predominant aetiology was alcohol (1723, 40%) followed by NASH/Cryptogenic (1104, 25.6%), HBV (903, 17.7%), Autoimmune (495, 11.5%), HCV (420, 9.8%). PVT was seen in 420 (9.8%) patients and is more among NASH/Cryptogenic (32.6%) and lesser with ethanol (27.9%) than other aetiologies. PVT prevalence increased in proportion to WHO income group i.e. with lower, middle- or high-income region as 17.1%, 39.8% and 43.1% respectively, more among diabetics (39% vs 28.5%). More hospital visit (13.6% vs 9.1%) and infection (23%19%) was observed in the preceding 6 months than those without PVT. At admission the CTP and MELD Na score were comparable. Those with PVT get admitted more with infections (25.5% vs 20.2%, $p = 0.03$) or GI bleed (27.6% vs 21.4%, $p = 0.01$), and during hospital course higher ICU transfers (21. % vs 17.2%), AKI (37.4% vs 32.2%, $p = 0.02$) and brain failure (15.5% vs 11.4%, $p < 0.004$) was observed. The in-hospital mortality (14.8% vs 10.8%, $p = 0.02$), 30-day mortality (23% vs 12.4%, $p = 0.004$) were more with PVT. In multivariate (MV) analysis, the in-patient mortality [OR 1.69 (1.23, 2.34), $p < 0.001$], 30-day mortality [OR 1.71 (1.27, 2.31), $p < 0.001$] were increased significantly with presence of PVT.

Conclusion: In a prospective global cohort of hospitalized decompensated cirrhosis, PVT was seen in 10% cases, more often among those with diabetics, or NASH related cirrhosis and is associated a higher in-hospital complications and greater mortality even when the CTP or MELD Na score were comparable. All decompensated cirrhosis needs to be evaluated for the presence of PVT and deserve special focus and monitoring during and after discharge from the hospital worldwide.

THU-059

Therapeutic plasma exchange improves organ function and potentially increases short-term survival in ACLF-3 patients who do not respond to standard medical treatment: a single centre propensity score-matched retrospective study

Jonas Schumacher[1], Rhea Veelken[1], Adam Herber[1], Lorenz Weidhase[2], Raymund Buhmann[3], Reinhard Henschler[3], Sirak Petros[2], Thomas Berg[1]. *[1]Leipzig University medical center, Division of Hepatology, Leipzig, Germany; [2]Leipzig University Medical Center, Medical ICU, Leipzig, Germany; [3]Leipzig University Medical Center, Institute of Transfusion Medicine, 04103 Leipzig, Germany*
Email: thomas.berg@medizin.uni-leipzig.de

Background and aims: Acute on chronic liver failure (ACLF) is a severe syndrome, with Grade 3 having a 28-day mortality approaching 80%. The prognosis becomes crucial within 3–7 days of full organ support. Beyond transplantation, there is no causative therapy. ACLF is marked by an inflammatory response syndrome, and therapeutic plasma exchange (TPE) holds promise in eliminating circulating pro-inflammatory mediators. Thus, TPE emerges as a potential therapeutic intervention for ACLF patients showing resistance to standard medical treatment (SMT).

Method: This retrospective study focused on ACLF patients receiving SMT with TPE from January 1, 2017, to March 11, 2023, at a tertiary care medical centre in Germany. Patients were monitored for at least 90 days post-ACLF diagnosis. The primary end point measured transplant-free survival at 28, 60, and 90 days. Secondary end points included changes in organ dysfunction, CLIF-C scoring systems, and global inflammatory markers. Data were collected by chart review. A cohort of 23 patients treated with SMT + TPE and 25 patients undergoing SMT alone was identified. Propensity scores, accounting for age, sex, ACLF grade, CLIF-C-ACLF Score, CLIF-C-OF Score, and

white blood cell count, facilitated 1:1 patient matching. 40 patients (N = 20 SMT + TPE; N = 20 SMT) underwent final analysis. Statistical analysis utilized non-parametric methods. Each patient underwent a median of 3 TPE sessions (SD 2.3), initiated a median of 14 days after the ACLF diagnosis (SD 15.27).

Results: The 28-day transplant-free survival rates were 65% (SMT + TPE) compared to 45% (SMT alone). Four patients died on the day of TPE or the following day, all attributed to uncontrolled septic shock. No TPE-related adverse events were observed. At day 60, the survival rates were 30% (SMT + TPE) versus 25% (SMT alone), and at 90 days, the rates were 25% versus 20%, respectively. Evaluation of ACLF grade, and CLIF-C scoring systems 24–48 hours after the last TPE application revealed improvements in ACLF grade (Median grade 3, SD 0.686 vs. grade 1.5, SD 1.125, p = 0.046), CLIF-C-ACLF Score (Median 59.5, SD 11.08 vs. 50, SD 23.14, p = 0.049), CLIF-C-OF Score (Median 13, SD 2, 53 vs. 10, SD 2.579, p = 0.079), Bilirubin levels (Median 282.45 µmol/l, SD 196.12 µmol/l vs. Median 184.9 µmol/l, SD 170.82 µmol/l, p = 0.07), and PT levels (Median 32%, SD 16.89% vs. Median 38%, SD 17.72%, p = 0.009). Patients who did not show improvement in ACLF with SMT and were subsequently treated with TPE demonstrated a significantly improved 28-day transplant-free survival compared to patients in the SMT alone cohort (50% vs. 21%, p = 0.012). This improvement was consistent specifically in patients with ACLF-3 (36.4% vs. 11.1%, p = 0.026).

Conclusion: TPE demonstrates efficacy in improving organ dysfunction in ACLF patients. In the subset of severe ACLF patients unresponsive to standard medical treatment, TPE may enhance short-term survival.

THU-060

Lower inpatient mortality and second infections in inpatients with cirrhosis managed between 2021–22 than between 2011–13 in prospective North American cohorts

Jasmohan Bajaj[1], Puneeta Tandon[2], Paul J. Thuluvath[3], Florence Wong[4], Patrick S. Kamath[5], Hugo Vargas[6], Sumeet Asrani[7], Jacqueline O'Leary[8], Leroy Thacker[9], K. Rajender Reddy[10]. *[1]Virginia Commonwealth University and Richmond VA Medical Center, Richmond, United States; [2]University of Alberta, Edmonton, Canada; [3]Mercy Medical Center and University of Maryland School of Medicine, Baltimore, United States; [4]University of Toronto, Toronto, Canada; [5]Mayo Clinic, Rochester, United States; [6]Mayo Clinic, Phoenix, United States; [7]Baylor Scott and White, Dallas, United States; [8]Dallas VA Medical Center, Dallas, United States; [9]Virginia Commonwealth University, Richmond, United States; [10]University of Pennsylvania, Philadelphia, United States*

Email: jasmohan.bajaj@vcuhealth.org

Background and aims: With changing demographics, etiology and treatments for cirrhosis, a temporal analysis of inpatient outcomes is needed. Aim: Determine inpatient mortality, organ failures and ICU in cirrhosis patients admitted non-electively at the same centers 10 years apart.

Method: The CLEARED Consortium (max 50/site from 2021 to 22) and NACSELD2 (from 2011 to 13) prospectively enrolled pts with cirrhosis admitted non-electively across 9 North American centers using identical eligibility criteria. Both consortia required non-electively admitted cirrhosis patients without HIV, organ transplant, or inability to consent. CLEARED pts were COVID negative. Patients were followed for inpatient course. We matched CLEARED to NACSELD2 pts using age, gender and admission MELD-Na using 1:2 propensity matching. Outcomes included inpatient ICU use, second infections, death andliver transplant.

Results: 450 pts were enrolled from 9 centers in CLEARED while 2067 were enrolled from the same centers in NACSELD2. Cohort details: 441 CLEARED pts were matched 1:2 with 882 NACSELD2 patients on age (57.2 vs 57.3, p = 0.92), Male sex (57 vs 58%, p = 0.67) and MELD-Na (median 22 each). More pts in CLEARED had alcohol etiology (48 vs 30%, p < 0.001), MASH (33 vs 22%, p < 0.001) but lower HCV (5 vs 17%, p < 0.001) and HCV ± alcohol (9 vs 14%, p = 0.004). More CLEARED pts were admitted for liver-related conditions (81 vs 73%, p = 0.002), especially HE (25 vs 15%), AKI (27 vs 8%) and fluid overload (19 vs 8%, all p < 0.001). Admission due to infections (24 vs 27%, p = 0.2) or liver-unrelated reasons (13 vs 14%, p = 0.2) were similar. Admission WBC (8.7 vs 8.0, p = 0.08) and serum albumin (2.9 vs 2.8, p = 0.06) trended higher in CLEARED. Admission beta-blocker use was lower in CLEARED (27 vs 38%, p = 0.001) and PPI were higher (60 vs 53%, p = 0.02). Lactulose, rifaximin and SBP prophylaxis use was similar. Outcomes: A lower % of CLEARED pts (6% vs 9%, p = 0.04) died or had second infection (1 vs 8%, p < 0.0001) while transplant (5 vs 4%, p = 0.4), and ICU transfer (21 vs 20%, p = 0.8) were similar. On multivariable analysis, being in CLEARED vs NACSELD2 (OR 0.4, 95% CI 0.24–0.67, p = 0.006), age (1.04, 1.02–1.07, p < 0.001), admission AKI (2.66, 1.59–4.43, p = 0.002), admission albumin (0.64, 0.47–0.88, p = 0.006) and MELD-Na (1.12, 1.09–1.16, p < 0.0001) were linked with death. Etiology, admission reasons and medications were not contributory.

Conclusion: In two inpatient cirrhosis cohorts using similar eligibility criteria enrolled in the same North American centers 10 years apart and propensity score matched on age, sex and admission MELD-Na, the more recent cohort had a lower risk of inpatient death and second infections (likely related to COVID restrictions). This persisted on multi-variable analysis despite higher alcohol and MASH etiology vs hepatitis C and greater liver-related causes of admission in the later versus the earlier cohort.

THU-067

Predictors of clinical response to empirical antibiotic therapy in patients with cirrhosis and bacterial infections: results from a resource-constrained setting

Chitta Ranjan Khatua[1], Prajna Anirvan[2], Manas Kumar Panigrahi[3], Shivaram Prasad Singh[2]. *[1]MKCG Medical College And Hospital, Brahmapur, Brahmapur, India; [2]Kalinga Gastroenterology Foundation, Cuttack, India; [3]All India Institute Of Medical Sciences, Bhubaneswar, India*

Email: gudduchhotu3@gmail.com

Background and aims: Multidrug-resistant (MDR) bacterial infections pose a significant challenge in cirrhosis, hampering the efficacy of empirical antibiotic treatments and thus, adversely affecting patient outcomes. The International Club of Ascites Global Study Group had determined the predictors of lack of response to empirical antibiotic therapy in patients with cirrhosis. In this study, we sought to validate the predictors of clinical response to empirical antibiotic treatment in a South Asian cohort of cirrhosis patients with infections.

Method: From October 2016 to September 2023, all cirrhosis patients with bacterial infections were included and on hospitalization, all parameters were recorded. The outcomes were compared between patients with and without MDR bacterial infections, with a three-month follow-up to discern the short and long-term impacts of MDR infections.

Results: Out of 1203 patients, 44.2% had infections, with MDR infections prevalent in 21.8% (n = 116). Urinary tract infection (UTI) was the most common at 73.3%, followed by pneumonia at 30.2%, spontaneous bacterial peritonitis (SBP) at 26.7%, skin and soft tissue infection at 11.2%. Patients with MDR infections had higher Model for End-Stage Liver Disease (MELD) scores, MELD-Na scores, Child-Turcotte-Pugh (CTP) scores, and a higher incidence of acute-on-chronic liver failure (ACLF). MDR infection was also associated with decreased serum albumin levels. Furthermore, patients with MDR infection demonstrated increased multiple site infections (36.2% vs. 8.2%; p < 0.001), increased use of vasopressors, prolonged hospital stay, elevated in-hospital mortality (57.8% vs. 8.9%), decreased survival at 28 days (25% vs. 75.2%), and 90 days (11.2% vs. 52.9%). The presence of respiratory infections (OR = 3.813; 95%CI = 1.062–13.690; p = 0.40), UTIs (OR = 4.973; 95%CI = 1.125–21.977; p = 0.34),

and SBP (OR = 0.109; 95%CI = 0.017–0.718; p = 0.021) were identified as factors associated with increased in-hospital mortality and lack of clinical response to antibiotic treatment.
Conclusion: Bacterial infections were observed in approximately half of cirrhosis patients, with one-fifth having MDR infection. MDR infection was associated with multiple site infections, hypotension, an increased prevalence of ACLF, and prolonged hospitalization. MDR infection, respiratory infections, UTIs, and SBP were associated with a lack of clinical response to antibiotic treatment and increased short-term mortality.

THU-068
Predicting with the "POAD" score the course of acute kidney injury in acute-on-chronic liver failure: a metabolomics approach
Rakhi Maiwall[1], Neha Chauhan[2], Ashini Hidam[1], Gaurav Tripathi[1], Jaswinder Maras[1], Shiv Kumar Sarin[3]. *[1]Institute of Liver and Biliary Sciences, Delhi, India; [2]Institute of Liver and Biliary Sciences, Delhi, India; [3]Institute Liver and Biliary Sciences, Delhi, India*
Email: rakhi_2011@yahoo.co.in

Background and aims: Acute kidney injury is an ominous complication in patients with acute on chronic liver failure. The rapidity of AKI progression in ACLF patients is anongoing clinical challenge. The serum metabolites and pathways associated with AKI progression could be useful for timely identification and institution of therapeutic interventions.
Method: ACLF patients with AKI at enrolment were enrolled and carefully followed. Plasma metabolomic studies using LC-MS/MS were conducted. We utilized area under the receiver operating curve (AUC), random forest analysis, for identification of biomarkers and pathways associated with AKI progression.
Results: A total 242 ACLF patients with AKI, 91% males, aged 43.2 ± 9.8 years, 73% with alcohol as etiology were enrolled. At day 4, AKI progression was seen in 42.6% and 26% required dialysis. AKI progression was an independent predictor of 28-day mortality (HR 1.98, 1.25–3.16). Plasma metabolomic analysis identified 54, 372 LC-MS/MS peaks, leading to the annotation of 778 metabolites. PLSDA and hierarchical clustering analysis demonstrated a distinct separation between AKI progressors and non-progressors with a total of 445 differentially expressed metabolites (241 upregulated, 231 downregulated; FC>1.5; p < 0.05). The top 5 biomarkers predicting AKI progression were arachidonic acid (FC > 35, p value <0.05, AUC > 0.95), alpha-linolenic acid (FC > 5, p < 0.05, AUC > 0.90), oleamide (FC > 3, p < 0.05, AUC > 0.91), cysteic acid (FC > 2.5, p < 0.05, AUC > 0.87), and 10-Nitrolinoleate (FC > 4, p < 0.05, AUC > 0.88). This panel of five biomarkers- together *POAD score* (*P*robability *O*f *A*KI *D*etection *score*) reliably predicted AKI progression (AUC >0.91, p < 0.05). The score positively correlated with the serum creatinine, and urine NGAL and also surpassed the prediction accuracy of these known biomarkers for AKI progression. The progressors further exhibited upregulated pathways such as arginine and proline metabolism, primary bile acid biosynthesis, taurine and hypotaurine metabolism, alpha-linolenic acid metabolism, among others. Conversely, downregulated pathways included glutathione metabolism, alanine metabolism and sphingolipid metabolism.
Conclusion: We identified and developed the "*POAD score*" (comprising top 5 metabolites-arachidonic acid, alpha-linolenic acid, oleamide, cysteic acid, and 10-Nitrolinoleate) implicated in cellular toxicity from differentially expressed metabolites for prediction of AKI progression in ACLF patients. AKI progressors exhibited altered metabolic pathways, providing insights into potential mechanisms for developing novel therapeutic interventions for improving AKI outcomes of ACLF patients.

THU-069
Serum bile acids determine AKI progression and terlipressin non-response in patients with acute-on-chronic liver failure with acute kidney injury
Rakhi Maiwall[1], Neha Chauhan[1], Ashini Hidam[1], Gaurav Tripathi[2], Sherin Sarah Thomas[2], Jaswinder Maras[2], Shiv Kumar Sarin[2].
[1]Institute of Liver and Biliary Sciences, Delhi, India; [2]Institute of Liver and Biliary Sciences, Delhi
Email: rakhi_2011@yahoo.co.in

Background and aims: Acute-on-chronic liver failure (ACLF) patients frequently have hyperbilirubinemia and limited response to vasoconstrictors. Cholemic nephropathy (CN) is distinctly noted in patients with ACLF, however, the association of the number and type of bile acids with AKI progression, and non-response to terlipressin, has not been studied.
Method: In a prospective cohort of ACLF patients (n = 242) with AKI, quantitative serum bile acids, urine neutrophil-gelatinase associated lipocalin (NGAL), and LC-MS/MS-based conventional serum bile acid profiling for 16 bile acids was performed for all patients at enrolment.
Results: ACLF patients, aged 43.2 ± 9.8 years, 91.2% males, 73% with alcohol etiology, 87% with sepsis, AKI stages (1:2:3) (40%:31%:29%), 61% with HRS-AKI were enrolled. The mean total serum bile acids were 154.2 ± 45.8 µmol/L, and NGAL was 1881 ± 1714 ng/ml. AKI progression at day 4 was observed in 42.6%, 26% required dialysis, and 48% died at 28 days. The bile acids showed a significant direct but weak correlation with total bilirubin (p = 0.001, r = 0.21 and with NGAL (p = 0.04, r = 0.13). On multivariable analysis, serum bile acids (OR 1.008, 1.001–1.016), higher AARC score (OR 1.72, 1.37–2.15), NGAL (OR 1.56, 1.01–2.46) and number of organ failures (OR 1.89, 1.27–2.83) predicted AKI-Prog. AKI progression was an independent predictor of 28-day mortality (HR 1.98, 1.25–3.16). Bile acids >175 µmol/L predicted non-response in HRS-AKI (3.25, 1.38–7.67) and AKI-Prog (OR 2.52, 1.42–4.45). The bile acid profiling showed a significant increase in the glycochenodeoxycholic (FC>10; p < 0.05) acid while taurolithocholic acid (FC>−12 folds, p < 0.05)) and glycodeoxycholic acid (FC>−3 folds, p < 0.05) were downregulated in the AKI-Prog compared to non-progressors. In the subset of patients with HRS-AKI, 6 bile acids were differentially expressed. Levels of deoxycholic acids (FC > 9, p < 0.05), taurodeoxycholic acids (FC > 5, p < 0.05), tauroursodeoxycholic acid (FC > 3.1, p < 0.05) were found upregulated while glycodeoxycholic acid, chenodeoxycholic acid, glycoursodeoxycholic acid were found downregulated in terlipressin non-responders (FC> −10folds, p < 0.05).
Conclusion: Severity of liver failure, number of organ failures, presence of tubular injury, and total serum bile acids independently predict AKI progression and non-response in HRS-AKI in ACLF patients. High levels of glycochenodeoxycholic acid in AKI progressors and deoxycholic acid in terlipressin non-response (PMID: 23685124, 26351365) could be used as markers of mitochondrial destruction by these cell-toxic bile acids which in-turn drive worse outcomes of AKI in ACLF patients.

THU-070
Dynamic assessment of lactate and AARC-Laclear score could determine survival in acute-on-chronic liver failure with septic shock admitted to the intensive care unit: a prospective cohort study [NCT06116305]
Rakhi Maiwall[1], Vishnu Girish[1], Shiv Kumar Sarin[1], Manoj Kumar[1], Ashok Kumar Choudhury[1], Chitranshu Vashitshtha[1], Harshvardhan Tevethia[1], S. Muralikrishna Shasthry[1], Vinod Arora[1], Vijayraghavan Rajan[1], Ankur Jindal[1], Satender Pal Singh[1], Dr Babu Lal Meena[1]. *[1]Institute of Liver and Biliary Sciences, Department of Hepatology, Delhi, India*
Email: rakhi_2011@yahoo.co.in

Background and aims: Data on acute-on-chronic liver failure (ACLF) and septic shock is few. We aimed to study impact of lactate kinetics

on outcome in ACLF with septic shock and effect of therapeutic interventions on lactate kinetics.
Method: Prospective cohort study; ACLF with septic shock and lactate >3.0 mmol/L were checked for arterial lactate every 6 h until 72 h and outcomes of survivors and non-survivors compared. Primary outcome was impact of lactate kinetics at 6 h on 7- d survival. Delta lactate, defined as difference in lactate at inclusion and at specific time and lactate clearance, percentage decrease in lactate from time of inclusion, were noted.
Results: One hundred five ACLF patients with septic shock, age 43.4 ± 10.4 years, 92.3% males, 49% alcohol-related, model for end stage liver disease (MELD) 33.8 ± 6.2, sequential organ failure assessment (SOFA) 12.26 ± 2.6, and Asia Pacific ACLF research consortium (AARC) score 11.35 ± 1.6, were enrolled. Mean arterial pressure (MAP)- 54 mmHg (Interquartile Range [IQR] 46, 62), norepinephrine equivalent (NEE) was 0.12 ± 0.06 mcg/kg/min and mean lactate was 3.8 ± 1.3 mmol/l at inclusion, at day 7, 66% patients were alive. Of these, 42 received continuous renal replacement therapy (CRRT). Predominant focus was pneumonia (74.8%). Admission lactate (3.53 ± 1.72 vs. 4.46 ± 1.96, p = 0.045), Lactate at 6 h (2.13 ± 0.81 vs. 4.70 ± 1.57; p < 0.001), delta lactate at 6 h (1.39 ± 0.78 mmol/L vs. −0.326 ± 0.71, p < 0.001), lactate clearance at 6 h (33.38 ± 3.3% vs. −15.75 ± 4.23%, p < 0.001)all significantly correlated with 7d survival, Lactate clearance at 6 hours had highest predictive accuracy for determining 7d survival (AUROC of 0.826 (cutoff = 15%, sensitivity = 75%, specificity = 71%). High lactate at 12, 24, 48, and 72 h were significantly associated with high mortality (HRs: 1.513, 1.413, 1.492, 1.493, 1.477) while higher lactate clearance at 12 h (HR 0.993, p = 0.033) predicted better survival, but not at 24 and 48 h. Fluid resuscitation correlated positively (r = 0.21, p = 0.031) and NEE negatively with 6 h lactate clearance (r = –0.20, p = 0.040). CRRT was associated with lactate clearance after 24 h of start (r = 0.20, p = 0.043). Multivariable analysis derived two models; Model-1 (based on delta lactate)- need of mechanical ventilation, [HR 6.219, 95% CI 1.467–26.360, p = 0.013], higher AARC [HR 1.258, 95% CI 1.03–1.54, p = 0.026] and delta lactate at 6 hours [HR 0.637, 95% CI 0.514–0.791, p < 0.001]; Model-2- (lactate clearance at 6 hours) [HR 1.236, 95% CI 1.013–1.509, p = 0.037], mechanical ventilation [HR 6.205, 95% CI 1.467–26.39, p = 0.013], and AARC [HR 1.236, 95% CI 1.013–1.509, p = 0.037]) predicted 7-d survival.
Conclusion: Predictive models incorporating lactate kinetics and AARC score (AARC-Laclear) are predictors of short-term survival in ACLF with septic shock. Need of mechanical ventilation, high AARC and failure to clear lactate at 6 h predict early death.

Impact of underlying portal hypertension and systemic inflammation on acute-on-chronic liver failure (ACLF) severity and outcome

Vlad Taru[1,2,3], Georg Kramer[1,2], Lorenz Balcar[1], Benedikt Hofer[1,2], Michael Schwarz[1], Nina Dominik[1], Lukas Hartl[1], Mathias Jachs[1], Mathias Schneeweiss-Gleixner[1], Bogdan Procopet[3], Michael Trauner[1], Bernhard Scheiner[1], Philipp Schwabl[1,2], Mattias Mandorfer[1], Thomas Reiberger[1,2,4], Benedikt Simbrunner[1,2]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Christian-Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria; [3]Regional Institute of Gastroenterology and Hepatology "Octavian Fodor, "Hepatology Department and "Iuliu Hatieganu" University of Medicine and Pharmacy, 3rd Medical Clinic, Cluj-Napoca, Romania; [4]Center for Molecular Medicine (CeMM) of the Austrian Academy of Science, Vienna, Austria*
Email: vlad.taru@meduniwien.ac.at

Background and aims: In patients with cirrhosis, acute-on-chronic liver failure (ACLF) may develop on top of acute decompensation (AD) and is characterized by profound systemic inflammation (SI) and extra-hepatic organ failure (s). The impact of portal hypertension (PH) in the context of AD/ACLF remains poorly investigated. We have analyzed the impact of PH on the incidence, the severity and the course/outcome of ACLF.
Method: We have retrospectively identified patients developing ACLF (EASL-CLIF criteria) at the Vienna General Hospital between 11/2003 and 11/2022. Data at several timepoints was collected: Pre-ACLF (30–180 days prior to ACLF), ACLF diagnosis (D0) and 7 days after ACLF (D7). Post-ACLF mortality was recorded at D90, D180 and 1 year (Y1). Pre-ACLF results on hepatic venous pressure gradient (HVPG), liver stiffness measurement (LSM), platelet count (PLT), presence/size of varices Von Willebrand factor levels (VWF) served as surrogates of PH severity. Severity of SI was evaluated by WBC, CRP, and IL-6.
Results: The study included 192 patients with ACLF (Grade G1: 91 [47.4%], G2: 62[32.3%], G3: 39[20.3%]). When comparing pre-ACLF surrogates of PH (PLT p = 0.908, LSM p = 0.692, VWF p = 0.340, presence of varices p = 0.078) and of systemic inflammation (WBC p = 0.575, CRP p = 0.814, IL-6 p = 0.565), there was no difference across different ACLF grades. Accordingly, HVPG (available in n = 95) was non significantly different across ACLF grades (G1: 20.9 ± 6.1 vs. G2: 20.3 ± 6.1 vs. G3: 17.3 ± 5.8 mmHg; p = 0.148). Pre-ACLF MELD-Na scores were similar in patients with different grades of ACLF (G1: 18.4 ± 5.9 vs. G2: 19.9 ± 4.6 vs. G3: 19.5 ± 5.3; p = 0.133). At D0 systemic inflammation increased significantly in parallel to ACLF severity (WBC p = 0.020, CRP p = 0.132, IL6 p = 0.032); while PLT tended to decrease with higher ACLF grades (G1: 91 (93) vs. G2: 81 (93) vs. G3: 72 (86) G/L; p = 0.094), and were significantly lower in higher ACLF grades at D7 (G1: 89 (84) vs. G2: 64 (47) vs. G3: 39 (80) G/L; p < 0.001). D90 mortality increased with ACLF severity (G1: 41.8%, G2: 58.1%, G3: 79.5%, log-rank p < 0.001). The CLIF-C ACLF score at D0 was predictive of D90, D180 and Y1 mortality in univariate Cox regression analyses (all p < 0.001). The addition of PLT at D0 to the CLIF-C-ACLF score components improved the model fit (C-indexes, likelihood ratio tests) of D90 (0.72 vs. 0.70, p = 0.005), D180 (0.71 vs. 0.69, p = 0.004) and Y1 (0.71 vs. 0.69, p = 0.004) mortality prediction.
Conclusion: While PH represents an established risk factor for AD, pre-ACLF PH severity does not impact on the severity of subsequent ACLF. Interestingly, pre-ACLF SI levels were not associated with subsequent ACLF grade, however, were linked to ACLF severity at ACLF onset. Our results indicate that PH is not a major driver of ACLF severity, but ACLF severity impacts on PLT and the addition of PLT to the CLIF-C-ACLF scores improves prediction of mortality.

THU-074
Effect of terlipressin on patients with hepatorenal syndrome, alcohol-associated hepatitis, and acute-on-chronic liver failure grade 0–2

Kevin Moore[1], Priya Grewal[2], Marco Olivera[3], Khurram Bari[4], Khurram Jamil[5]. *[1]University College London, London, United Kingdom; [2]Mount Sinai Medical Center, New York, NY, United States; [3]University of Nebraska Medical Center, Omaha, NE, United States; [4]University of Cincinnati, Cincinnati, OH, United States; [5]Mallinckrodt Pharmaceuticals, Bridgewater, NJ, United States*
Email: kevin.moore@ucl.ac.uk

Background and aims: Patients with severe alcohol-associated hepatitis (AAH) frequently have underlying liver cirrhosis, which leads to the development of acute kidney injury (AKI) in 10–40% of these patients. Hepatorenal syndrome (HRS) is a potentially reversible form of AKI. Terlipressin is the first and only treatment for adult patients with HRS-AKI approved by the United States Food and Drug Administration and is more likely to clinically benefit those with acute-on-chronic liver failure (ACLF) grade 0–2. In this study, we determined the effect of terlipressin on renal function among patients with AAH and HRS-AKI who had ACLF grades 0–2.
Method: Data from a subpopulation (pooled from the Phase III studies: OT-0401, CONFIRM, and REVERSE) of patients with AAH, HRS-AKI, and ACLF grades 0–2 who received terlipressin or placebo were examined. Change in renal function—measured as least squares

(LS) mean changes in serum creatinine (SCr) with and without interaction between treatment and day—from baseline through the end of treatment (EOT) was evaluated within and between treatment arms. Incidence of death and renal replacement therapy (RRT) on Days 30, 60, and 90 were reported.
Results: For the 141 patients evaluated, the LS mean decrease in SCr from baseline to EOT with and without interaction between treatment and day were −0.98 mg/dL and −1.02 mg/dL for terlipressin, and −0.35 mg/dL and −0.26 mg/dL for placebo, respectively. The decrease in SCr from baseline to EOT was significantly larger in the terlipressin vs placebo arms; the difference in LS mean change in SCr between terlipressin and placebo was −0.64 mg/dL without interaction, and −0.76 mg/dL with interaction between treatment and day (both $p < 0.001$). In the terlipressin (n = 84) and placebo (n = 60) arms, the incidence of HRS reversal (defined as at least 1 SCr value of ≤1.5 mg/dL while on treatment by Day 14 or discharge) was 44.0% vs 11.7% ($p < 0.001$ respectively; incidence of death on Days 30, 60, and 90 were 33% vs 48% ($p = 0.070$), 41% vs 58% ($p = 0.034$), and 44% vs 60% ($p = 0.059$), respectively. Incidence of RRT on Days 30, 60, and 90 were similar between the terlipressin and placebo arms: 24% vs 25%, 26% vs 27%, and 26% vs 27% ($p > 0.800$ for all), respectively.
Conclusion: Compared with placebo, terlipressin significantly improved renal function and increased HRS reversal among patients with AAH and HRS-AKI who had ACLF grades 0–2 and was associated with fewer deaths on Day 60. However, the need for RRT was similar between treatment arms in this population.

THU-075-YI
Incidence and prognostic value of zinc and selenium deficiency in cirrhosis
Nina Dominik[1], Lorenz Balcar[1], Georg Semmler[1], Benedikt Simbrunner[1], Michael Schwarz[1], Benedikt Hofer[1], Lukas Hartl[1], Mathias Jachs[1], Bernhard Scheiner[1], Matthias Pinter[1], Michael Trauner[1], Mattias Mandorfer[1], Alexander Pilger[2], Thomas Reiberger[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria*
Email: nina.dominik@meduniwien.ac.at

Background and aims: Zinc and selenium are essential trace elements involved in important (patho)physiological processes. The incidence and prognostic implications of zinc and selenium deficiency in patients with cirrhosis remain unknown.
Method: We determined serum zinc and selenium concentrations in 309 patients with cirrhosis undergoing hepatic venous pressure gradient (HVPG) measurement between 2017–2022. We evaluated the prevalence of zinc/selenium deficiency and assessed its association with cirrhosis severity and liver-related events (i.e. hepatic decompensation/liver-related death).
Results: Among 309 cirrhotic patients [median: age: 57 (IQR 50–64) years, MELD: 11 (IQR 9–16) points, HVPG: 17 (IQR 11–20) mmHg], 73% (n = 227) and 63% (n = 195) were deficient in zinc and selenium, respectively. Decompensated (dACLD) patients showed significantly lower serum zinc [median: 48 (IQR 38–59) vs. compensated, cACLD: 65 (IQR 54–78) µg/dL, $p < 0.001$] and selenium levels [median: 4.9 (IQR 4.0–6.2) vs. cACLD: 6.1 (IQR 5.1–7.3) µg/dL, $p < 0.001$]. Significant correlations of zinc and selenium levels were found with MELD (zinc: Spearman's Rho = −0.498, $p < 0.001$; selenium: Spearman's Rho = −0.295, $p < 0.001$), HVPG (zinc: Spearman's Rho = −0.400, $p < 0.001$; selenium: Spearman's Rho = −0.157, $p = 0.006$), and liver disease-driving mechanisms (IL6, bile-acid homeostasis). Zinc and selenium consistently decreased with progression of liver disease as evaluated by disease severity scores (CTP score: $p < 0.001$ for zinc, $p = 0.001$ for selenium; MELD score: $p < 0.001$ for zinc and selenium) as well as with the severity of portal hypertension ($p < 0.001$ for zinc, $p = 0.003$ for selenium) and across clinical stages of cirrhosis ($p < 0.001$ for zinc and selenium). On multivariable analysis adjusting for clinically important co-factors, only low zinc levels [adjusted HR, aHR: 0.98 (95% CI: 0.96–0.99), $p = 0.014$] and the MELD score [aHR: 1.06 (95% CI: 1.00–1.11), $p = 0.044$] remained independently associated with liver-related events. Selenium was also found to be a prognostic parameter in univariable analysis [HR: 0.78 (95% CI: 0.64–0.95), $p = 0.016$], but did not independently predict liver-related events after multivariable adjustment. We evaluated a data-driven cut-off for zinc at 44.6 µg/dL to stratify patients at distinct risk.
Conclusion: Zinc and selenium deficiencies are highly prevalent in patients with cirrhosis and are associated with key disease-driving mechanisms, most importantly with disease progression/hepatic dysfunction (i.e., MELD) and portal hypertension severity (i.e., HVPG). Patients with low serum zinc levels had a significantly increased risk of hepatic decompensation and liver-related death. Further studies should evaluate the impact of zinc and selenium supplementation on liver-related outcomes in patients with cirrhosis.

THU-076-YI
Machine learning algorithms predict survival in patients with cirrhosis hospitalized due to infections based on routine features obtained within 24 hours of addmision
Shoham Dabbah[1,2], Yana Davidov[1,2], Ehud Zigmond[1,2]. *[1]Tel-Aviv University Faculty of Medicine, Tel-Aviv, Israel; [2]Sheba Medical Center, Ramat Gan, Israel*
Email: shohamdbh@gmail.com

Background and aims: Infections in cirrhotic patients increase the risk for death by a factor of 4 with mortality rates estimated as 30%, 44% and 63% at 1-, 3-, and 12-month, respectively. Hence, infection is considered a prognostic landmark in cirrhosis. Management entails decisions regarding the spectrum of therapeutic intervention, referral for critical care evaluation and liver transplantation, all rely heavily on the determination of prognosis. We aimed to train machine learning algorithms (MLAs) to predict survival in cirrhotic patients hospitalized due to infections and to provide explanations for the predictions.
Method: In this cross-sectional study 14 readily available features documented within 24 hours of hospitalization due to a diagnosis of an infection were used to train three MLAs. Hyperparameters were tuned to maximize time dependent ROC (tdROC) at 1-, 3-, and 12-month across 3-folds cross-validation of the training sample (n = 472). In order to stratify patients into three risk categories, two thresholds were tuned to maximize Youden index at 3- and 12-month for each MLA. The tdROC of MLAs were compared to model of end-stage liver disease (MELD) 3.0 and log-rank test was utilized to compare between survival curves of different risk categories from the validation sample (n = 118). Feature importance via permutation and partial dependence for survival probability were used to explain the best-performing MLA.
Results: In the validation sample mortality rates were 25%, 36% and 47% at 1-, 3-, and 12-month, respectively. Mean tdROC for random forest (RF), gradient boosting machine (GBM), penalized cox proportional hazard (COXPH) and MELD 3.0 were 0.8, 0.82, 0.76 and 0.71 respectively. RF and GBM, but not COXPH, outperformed MELD 3 at all time points ($p < 0.05$). The thresholds derived for GBM achieved sensitivity of 93% and 100% with specificity of 45% and 25% for mortality at 3- and 12-month, respectively. Patients from the validation sample were stratified into high, intermediate and low risk categories based on these thresholds. Survival curves differed significantly between these categories ($p < 0.05$). In contrast to COXPH, GBM identified time-dependent feature importance; while serum lactate had stronger influence on the survival probability at 3- compared to 12-month, the opposite was true for serum creatinine. Overall, the most important features considered by GBM were albumin, urea, age, creatinine and alkaline phosphatase.

Conclusion: An explainable GBM algorithm outperformed MELD 3.0 in determining prognosis among cirrhotic patients hospitalized due to infections using easily obtainable features measured within 24 hours of hospital admission. This risk stratification algorithm enables clinicians to understand the relationship of features with the survival probability and to tailor management at an early stage, hopefully translating into improvement in prognosis.

THU-077

Prognostic value of nutritional index in patients with decompensated cirrhosis: a single-center cohort study

Heechul Nam[1], Hee Yeon Kim[1], Chang Wook Kim[1]. [1]*The Catholic University of Korea, Seoul, Korea, Rep. of South*
Email: hcnam128@catholic.ac.kr

Background and aims: Nutritional assessment is critical in patients with decompensated liver cirrhosis to maintain quality of life and improve survival. Nevertheless, the predictive value of nutritional index for the outcome of decompensated cirrhosis remains uncertain. This study aims to determine the potential prognostic value of nutritional index in predicting the liver transplantation (LT)-free survival of decompensated cirrhosis.
Method: This is a single-center, retrospective study that included consecutive patients presenting with first-onset decompensated complications to Uijeongbu St. Mary's Hospital from January 2013 to December 2022. Nutritional assessment in this study utilized the nutritional risk index (NRI), which was calculated based on serum albumin levels, body weight, and height. The primary end point was LT-free survival.
Results: The study included 1273 patients, with a median age of 57 years, of whom 69.5% were male. Alcoholic-related liver disease was the most common cause of liver disease in this cohort (65.2%), followed by chronic hepatitis B (15.9%), non-alcoholic steatohepatitis (11.6%), chronic hepatitis C (3.7%), and autoimmune hepatitis or primary biliary cholangitis (3.5%). The median MELD score of the patients was 16 (IQR, 12–22), and 19.8% of them met the criteria for APASL ACLF. At the time of the first admission, the most common complications observed were ascites (71.2%), followed by variceal bleeding (52.2%), hepatic encephalopathy (26.6%), spontaneous bacterial peritonitis (5.4%), and hepatorenal syndrome (11.8%). The median LT-free survival was 22.2 months (95% CI; 18.7–25.6 months). We conducted analysis based on ACLF; ACLF group (n = 1021) and non-ACLF (n = 252). The median LT-free survival was 29.5 months (95% CI, 26.4–33.1) in the non-ACLF group and 2.6 months (95% CI, 2.1–3.8) in the ACLF group ($p < 0.001$), respectively. In the non-ACLF group, Age ≥55 (HR, 1.53; 95% CI, 1.30–1.80, $p < 0.001$), MELD ≥20 (HR, 1.63; 95% CI, 1.33–2.04, $p < 0.001$), Child-Pugh class C (HR, 1.94; 95% CI, 1.42–2.65, $p < 0.001$), and NRI ≤83.5 (HR, 1.61; 95% CI, 1.23–2.10, $p < 0.001$) were identified as independent predictors of LT-free survival. In the ACLF group, NRI ≤83.5 (HR, 1.47; 95% CI, 1.10–1.96, $p = 0.010$) was only independently associated with LT-free survival.
Conclusion: In conclusion, nutritional index is independent predictor of LT-free survival in patients with decompensated cirrhosis irrespective of ACLF. Integrating nutritional index with established prognostic factors may improve prognostic accuracy and guide treatment decisions.

Email: doctor.ashokchoudhury@gmail.com

Background and aims: ACLF syndrome is liver failure with or without extra-hepatic organ failure (OF) like- renal, circulatory and cardiac. Therapy, liver transplant and survival are confounded by the organ failures often with or without sepsis. We studied the impact of the type, time frame, evolution and impact on therapy as well as survival of the extra-hepatic OF (EHOF) among hospitalized patients of ACLF.
Method: We analysed prospectively collected data of ACLF patients (APASL criteria) from AARC registry. History, clinical course and OF development, sepsis laboratory parameters, treatment received and survival were compared among those with ACLF with or without EHOF. Liver failure is defined as jaundice, coagulopathy or HE whereas extra-hepatic OF is defined as per CLIF-SOFA.
Results: Total of 8, 683 ACLF patients [mean age 44.5 ± 8.9 years, 86.8% male], predominant aetiologies being alcohol (57.1%) and HBV reactivation (12.4%). At presentation majority (6258, 72.1%) of ACLF patients had an additional EHOF i.e. renal (42.1%), circulatory (8.6%) and respiratory (2.2%). Those with EHOF were younger, male, with high WBC, MELD, AARC score, low platelet, low albumin ($p < 0.01$) and often sepsis (39.6% vs. 30.1%, $p < 0.001$). They had greater new onset sepsis (6.9% vs 2.2%), need of RRT (27.4% vs 0.5%) or ventilator (3.6% vs 0.5%) and higher mortality (26.1% vs 18.4%) in first week. In absence of EHOF at baseline and at day 4, a lower 90-day mortality (21.9%) noted, while single EHOF at baseline or day 4 increases it to 50.8% and 85.5% respectively. With organ support and improved EHOF at end of first week-mortality showed a decline. Two or three EHOF were uniformly associated with high mortality (>80%). The 90-day mortality increased proportionately with 1 [HR 1.23 95 CI (1.22–1.29)], 2 [HR 1.49 95CI (1.46–1.53)] and 3 [HR 2.38 95CI (2.35–2.41) EHOF respectively. These patients could be offered LT in limited cases (2.9% vs. 10.7%, $p < 0.001$). Presence of EHOF associated with high 90-days mortality (55.3% vs. 37.1%, $p < 0.01$) and is an independent predictor HR [1.23 95 CI (1.22–1.29), $p < 0.001$] at 90 days.
Conclusion: ACLF is serious condition with only half surviving at the 90 days and two third patients have associated EHOF at presentation to tertiary centres, most common being renal. Presence of EHOF is an independent and dynamic predictor of survival, also precludes liver transplant, whereas optimisation of the organs is associated with improved survival.

Background and aims: The outcome after liver transplantation (LT) for acute-on-chronic liver failure (ACLF) is acceptable with a 1-year survival exceeding 80%. However, access to LT lies on a narrow timeframe as death commonly occurs early after admission. Hence, the period dedicated to the pre-transplant work-up is shortened. Notably, cardiovascular (CV) events emerge as a prominent cause of post-LT mortality in ACLF cases questioning the adequacy of the screening. There is a current lack of consensus regarding the components of the pre-transplant work-up for these patients. We aimed to investigate the status of pre-transplantation work-up practices in patients with ACLF.
Method: A questionnaire was devised with hepatologists and addictologists' involvement and distributed to 39 French centers. It was divided into 3 sections: work-up for ambulatory patients (AP group), work-up for hospitalized patients with decompensated cirrhosis but without ACLF (DC), and work-up for patients with ACLF in intensive care units (ACLF). Each section was divided into 4 parts including CV and respiratory comorbidities, oncological, nutritional and addictology assessment.
Results: 31 (80%) centres answered to the survey. 15 (48%) were LT centres with 67% of them transplanting ≥6 patients with ACLF/year. Of the 16 non-LT centres, 67% estimated to transfer ≥6 patients with ACLF/year to LT centre. Electrocardiogram and transthoracic echocardiography were the only CV work-up performed in 97% of centres in patients with ACLF whilst 58% and 68% centres performed a least another CV exploration in DC and AC respectively ($p < 0.0001$). While chest CT-scan was performed in all groups and centres, respiratory function testing was performed in 19% of the centers in ACLF vs. 68% vs. 87% in DC and AP respectively ($p < 0.0001$). Regarding addictology assessment, there was a non-significant increase of centres considering transplantability without a minimal period of abstinence in patients with ACLF 68% vs. 45% in DC and vs. 42% in AP, $p = 0.08$. Relative requesting to investigate the addictology profile was more frequent in ACLF patients 81% vs. 68% in DC, vs. 52% in AP, $p = 0.05$. An esophagograstroduodenoscopy combined with a thoraco-abdominopelvic CT-scan and PSA concentration in males was considered sufficient to screen for cancer in most cases of ACLF 55% but not in DC (0%) or AP (0%), $p < 0.0001$. The estimated timeframe to placement on waiting list was 7 days in ACLF vs. 21 days in DC vs. 45 days in AP, $p < 0.0001$. 97% of centres agreed that the pre-LT work-up had to be shortened to optimise access to LT but 26% thought that it increased the risk of not identifying LT contraindication.
Conclusion: The survey results emphasize the distinctive nature of the pre-LT assessment in ACLF patients compared other groups. The definitive impact of the shortened work-up on outcome after LT remain to be prospectively investigated.

THU-080-YI

The predictive role of immunoglobulins indicative of gut barrier dysfunction in a prospective patient cohort with cirrhosis and acute decompensation

David Tornai[1], Boglarka Balogh[1], Aniko Csillag[1], Istvan Tornai[1], Zsuzsanna Vitalis[1], Patricia Kovats[1], Péter Antal-Szalmás[2], Florian Rosenberger[3], Matthias Mann[3,4], Wim Laleman[5], Minneke J. Email: tornai.david@med.unideb.hu

Background and aims: Cirrhosis is associated with impaired gut mucosal immunity, thereby facilitating bacterial translocation, which activates the proinflammatory cascade, further exacerbating tissue damage and progression of liver disease. However, little is known about the role of antibody-mediated adaptive immunity in this process. Therefore, we measured serum levels of immunoglobulin (Ig) indicators of gut barrier function in a prospective patient cohort with cirrhosis and acute decompensation (AD) to determine their ability to predict outcomes.

Method: Serum samples of 128 patients recruited in the frame of MICROB-PREDICT have been assayed at inclusion and acute-on-chronic liver failure (ACLF) development to determine levels of IgA and IgG antibodies against various targets (F-actin; *Saccharomyces cerevisiae* [ASCA]; glycoprotein 2 [GP2]; gliadin; endotoxin core [EndoCab]), secretory (s)IgA, total IgA, IgG, IgM and free Ig kappa and lambda light chains. Disease severity was assessed by CLIF-C AD, MELD and Child-Pugh scores and presence of ACLF. ACLF development and liver-related death were assessed in a 3-month follow-up period.

Results: The presence of target specific IgA type antibodies increased in parallel to diseases severity as defined by Child-Pugh stages. Higher total IgA level was associated with increased detection of IgA type antibodies and elevated levels of individual antibodies in patients. At inclusion, high CLIF-C AD score (≥50) was associated with decreased total IgG levels (median [IQR]: 16 [11.15–19.89] vs. 18.8 [13.45–24.05] mg/ml; $p = 0.042$), while the presence of ACLF was associated with elevated free Ig kappa light chain (29.6 [20.18–40.65] vs. 20.5 [14.23–31.93] µg/ml; $p = 0.043$) and decreased total IgG levels (12.4 [8.23–19.3] vs. 17.3 [11.6–22.5] mg/ml; $p = 0.046$). ACLF development during follow-up was associated with increased free Ig kappa light chain level ($p = 0.018$).

Ninety-day mortality in all patients with ACLF (at inclusion and during follow-up) was associated with increased sIgA levels (AUROC: 0.819; at the cut-off of >20.9 µg/ml: 15% vs 79% mortality $p < 0.001$).

Conclusion: Mucosal immune activation as indicated by increased total IgA level occurs along the increasing severity of Cirrhosis. The presence of target specific IgA antibodies suggest a link to enhanced BT. Increased sIgA level is a promising marker of 90-day mortality in ACLF patients.

THU-082

A clinical decision support tool to identify predictors of decompensation, acute-on-chronic liver failure and mortality in liver cirrhosis from the multi-center SingHealth chronic liver disease registry (SoLiDaRity-DAM)

Jason Pik Eu Chang[1], Wei-Quan Teo[2], Amber Chung[2], Rahul Kumar[3], Marianne DeRoza[4], Hiang Keat Tan[1], Prema Raj[2]. [1]*Singapore General Hospital, Singapore, Singapore;* [2]*SingHealth Duke-NUS Transplant Center, Singapore, Singapore;* [3]*Changi General Hospital, Singapore, Singapore;* [4]*Sengkang General Hospital, Singapore, Singapore*
Email: jason.chang@singhealth.com.sg

Background and aims: Chronic liver disease, particularly cirrhosis, poses a significant health burden resulting in substantial mortality rates. Timely identification of decompensation and acute-on-chronic liver failure (ACLF) in cirrhosis patients is crucial to reduce mortality and improve outcomes. In this study, we address the pressing need for predictive tools by leveraging electronic health records (EHR) and advanced machine learning techniques to develop an automated clinical decision support system using data from the multi-center SingHealth Chronic Liver Disease Registry (SoLiDaRity-DAM). This system aims to predict decompensation events, facilitate timely referral for liver transplantation, and enhance patient care in cirrhosis management.

Method: SoLiDaRity-DAM encompasses a comprehensive approach to convert longitudinal structured and unstructured patient data from diverse EHR sources into predictive algorithms and machine learning models. The development process places a strong emphasis on merging clinical expertise with statistical methods. In this proof-of-concept (POC) study, we generated a Random Forest Classifier model using clinically annotated data from our registry. The model's primary objective was to predict the likelihood of cirrhosis patients developing decompensation based on collected clinical indicators. Furthermore, we applied linear regression to estimate the time to decompensation events in the cirrhotic cohort.

Results: The Random Forest Classifier achieved an impressive accuracy score of ~89%, highlighting its potential for identifying patients at risk of decompensation. Feature selection identified the top 10 ranking variables, with biomarkers like Alpha Fetoprotein (AFP) and the presence of ascites and varices highlighted as critical factors in distinguishing patients with decompensated cirrhosis. Among the five regression models we used for the prediction of the time to decompensation, Random Forest is identified as the best model with the lowest loss function value.

Conclusion: SoLiDaRity-DAM demonstrates the feasibility of utilizing AI and machine learning techniques to predict decompensation events in cirrhosis patients with high accuracy. By integrating clinical expertise and EHR data, this AI-powered clinical decision support system holds promise in improving patient outcomes by enabling timely interventions, including the referral for liver transplantation. The development of SoLiDaRity-DAM represents a crucial step towards personalized, data-driven cirrhosis management, with the potential to significantly reduce mortality and healthcare costs in Singapore's population.

THU-083

Acute kidney injury (AKI) severity in critically-ill patients with decompensated liver cirrhosis and acute-on-chronic liver failure (ACLF)

Martin Schulz[1], Lena Wolters[1], Helen Jurr[1], Wenyi Gu[1], Maximilian Joseph Brol[1], Frank Erhard Uschner[1], Michael Tischendorf[1], Konrad Buscher[1], Alexander Zarbock[1], Robert Schierwagen[1], Sabine Klein[1], Stefan Zeuzem[2], Kai-Henrik Peiffer[1], Jonel Trebicka[1,3]. [1]*University Hospital Münster, Münster, Germany;* [2]*Goethe University, Frankfurt, Germany;* [3]*European Foundation for Study of Chronic Liver Failure, Barcelona, Spain*
Email: martinsebastian.schulz@ukmuenster.de

Background and aims: Acute kidney injury (AKI) is a frequent complication in patients with acutely decompensated liver cirrhosis (AD) and acute-on-chronic liver failure (ACLF). Although it has been acknowledged that underlying pathomechanisms and clinical courses may differ between AKI in AD and ACLF, differences in clinical trajectories between AKI in AD and ACLF are not well characterized to date.
Method: In this retrospective analysis 498 patients with cirrhosis and IMC/ICU admission were included. To assess differences of AKI severity in the spectrum of AD/ACLF, patients were enrolled into the following subgroups: AD-AKI, ACLF-AKI, ACLF-renal failure (ACLF-AKI-RF) or ACLF-AKI requiring renal replacement therapy at admission (ACLF-AKI-RRT). AKI was defined according to ICA criteria. ACLF was defined according to EASL-CLIF criteria. All patients with history of chronic kidney disease (CKD) were excluded. Clinical data, laboratory and urinary results were retrospectively collected. Urine analysis was performed in spot-urine.
Results: Median age was 60 years, 71.5% were male. At admission, 173/498 (34.7%) of patients presented defined ACLF. While only 19% of ACLF patients (33/173) presented AKI, 43.9% (76/173) presented ACLF-AKI-RF and an additional 12.7% (22/173) required RRT at admission due to AKI. 28-day mortality was strongly associated with AKI and ACLF severity (AD-AKI: 14.3%, ACLF-AKI: 51.1%%, ACLF-AKI-RF: 53.6%, ACLF-AKI-RRT: 77.8% $p < 0.001$). Surrogates of SI increased among AD/ACLF progression (leucocytes: AD-AKI: 8.6/nl vs. ACLF-AKI: 9.3/nl vs ACLF-AKI-RF: 11.6./nl, ACLF-AKI-RRT: 15.0/nl, $p < 0.001$; neutrophil-to-monocyte-ratio 7.9 vs 10.1 vs 13.2 vs 14.23, $p = 0.01$). Upon disease progression among the subgroups, and colinear to SI severity, patients showed increasing proteinuria (AD-AKI: 17 mg/dl, ACLF-AKI: 24 mg/dl, ACLF-AKI-RF: 38 mg/dl, ACLF-AKI-RRT: 87 mg/dl, $p < 0.001$). This was also reflected in protein-to-creatinine ratio, showing a significant association within ACLF severity grades ($p < 0.05$). BUN-to-creatinine-ratio >20, a hallmark of prerenal AKI, decreased upon AKI progression (AD-AKI: 50.9%, ACLF-AKI: 51.7%, ACLF-RF: 30%, ACLF-RRF: 21.1% $p < 0.05$).
Conclusion: AKI in AD and ACLF is closely linked to patient outcomes. Interestingly, our data show that increasing severity of SI is paralleled by increased proteinuria upon ACLF progression and urinary surrogates of intrarenal kidney injury. While AD-AKI patients present urinary profiles predominantly associated with prerenal injury, our data suggests that the aggravation of AKI upon ACLF progression could be increasingly driven by intrarenal injury mechanisms.

THU-086

Proton pump inhibitors does not impact on the severity and mortality of the acute-on-chronic liver failure: andalusian multicentric prospective study

María Carmen García-Gavilán[1], Marta Guerrero-Misas[2], Alberto García-García[3], Marta Casado-Martin[4], Laura Castillo-Molina[5], Yolanda María Sanchez-Torrijos[6], Carmen Sendra[7,8], Jose Miguel Rosales-Zábal[1]. Email: marigarciagavilan@hotmail.es

Background and aims: The proton pump inhibitors (PPI) are widely consumed worldwide and there is no prospective study that evaluates their influence on acute-on-chronic liver failure (ACLF). The main objective was to assess the possible influence of the chronic PPI consumption and the severity of the ACLF. The secondary objectives were to assess its possible relation with the mortality and different types of decompensation of the ACLF.
Method: Prospective cohort study (7 participants hospitals from Spain) between august 2020 to 2023. We recruited all patient with diagnosis of ACLF and classified them as exposed or not exposed, according to the chronic PPI intake. All patients with hepatocellular carcinoma, immunosuppression, digestive surgery or PPI intake under 3 months were excluded. On admission, chronic PPI intake, norfloxacin, rifaximin, lactulose, statins, antiaggregation and anticoagulation were recorded. The CLIF-C-OF was determined at admission, the CLIF-C-ACLF at admission, 3 and 7 days, the Child-pugh score, MELD-Na score and the type of decompensation were registered too. Analytical variables of liver, kidney and hematological function were collected as well as critical care unit admissions, new hospitalizations for ACLF and the mortality at 28 days, 3 and 6 months were recorded.
Results: 60 patients were enrolled with a median age of 59 years: 26 chronic IBP users (76.9% Omeprazole) and 33 non-users. Among consumers, 69% do not have an established indication for PPI consumption. They regularly take lactulose in the 27.1% of the cases, rifaximin in 10.2%, norfloxacin in 16.9%, simvastatin in 6.8%, chronic antiaggregation in 7.3% and chronic anticoagulation in 10.9%. At admission they had a median CLIF-C-OF of 9, CLIF-C-ACLF of 52, CHILD of 10 and MELD-Na of 29. The most frequent type of decompensation was the hepatic encephalopathy, followed by the hydropic decompensation and infections (66.7%, 56.7% y 48.3% respectively). The urine infection was the most frequent one (20%), followed by spontaneous bacterial peritonitis and respiratory infections (18.3%). 15.8% were admitted to the critical care unit and 45.8% died during the hospitalization. When analyzing, no relation was found between the chronic PPI consumption and the severity of the ACLF ($p = 0.44$ for the CLIF-C-OF score and $p = 0.87$ for the CLIF-C-ACLF score), with the mortality during the admission ($p = 0.63$), at 28 days ($p = 0.70$) and 3 months ($p = 0.98$). Nor was a significant relationship found with each type of decompensation within the ACLF.
Conclusion: This is the first prospective study assessing the influence of the PPI and the ACLF. With our results we can conclude that no relationship is observed between chronic PPI consumption and the severity of the ACLF, the mortality of the ACLF and the different types of acute decompensation within the ACLF.

THU-087

Herpesvirus viremia-cause or consequence of ACLF? Higher prevalence of cytomegalovirus, Epstein-Barr virus and herpes simplex virus viremia in patients with acute-on-chronic liver failure

Jannik Sonnenberg[1], Keerthihan Thiyagarajah[2], Esra Görgülü[3], Mirco Glitscher[2], Nico Kraus[3], Toska Wiedemann[3], Marcus Maximilian Muecke[3], Michael Praktiknjo[1], Hans-Peter Erasmus[3], Frank Erhard Uschner[1], Wenyi Gu[1], Maximilian Joseph Brol[1], Martin Schulz[1], Michael Tischendorf[1], Robert Schierwagen[1], Sabine Klein[1], Jessica Vasseur[3], Stefan Zeuzem[3], Holger Storf[3], Christoph Welsch[3], Jonel Trebicka[1], Sandra Ciesek[4], Eberhard Hildt[2], Kai-Henrik Peiffer[1]. Email: jannik.sonnenberg@ukmuenster.de

Background and aims: Acute-on-chronic liver failure (ACLF) is a life-threatening clinical syndrome characterized by the rapid deterioration of liver and other organ function in individuals with pre-existing chronic liver disease. In 40–60% of patients, the precipitants contributing to ACLF remain unknown. Herpesviruses, including Cytomegalovirus (CMV), Epstein-Barr virus (EBV) and Herpes simplex virus (HSV) are highly prevalent viruses, which may cause isolated self-limiting hepatitis in immune competent patients, but severe infections leading to fulminant hepatic failure in immunocompromised patients, such as liver cirrhosis.

Method: We analysed blood samples from 212 patients (42 ACLF vs. 170 liver cirrhosis patients) registered in the ACLF-I-study for viremia of the herpesviruses CMV, EBV and HSV. Viral nucleic acids were extracted from 200 µl serum and multiplex-qPCR was performed. Absolute copy numbers were calculated based on standard curves and were correlated with clinical data.
Results: Higher prevalence of overall viremia (47, 6% vs. 26, 4%, p < 0, 001), CMV (28, 6% vs. 16, 0%, p = 0, 016), EBV (16, 7% vs. 9, 0%, p = 0, 039) and HSV1 (7, 1% vs. 2, 4%, p = 0, 025) were observed in ACLF patients in comparison to non-ACLF patients. Viremia remained clinically undetected and there was no suspicion for viral infections documented. In a third of ACLF patients with experimentally detected viremia the precipitant of ACLF was unknown. Viremia was associated with overall higher bilirubin levels, CLIF score and ACLF grade. CMV and HSV1 were significantly associated with liver failure while EBV correlated with failure of the respiratory system.
Conclusion: The presence of viral infections may tip the balance towards ACLF and impair hepatocellular function in individuals with chronic liver disease. However, the observed high prevalence of herpesviruses in our study may be a cause or a consequence of acute-on-chronic liver failure.

THU-088
Blood and peritoneal metabolomics suggest VS-01 actively captures metabolites associated with acute-on-chronic liver failure

Olaf Tyc[1], Frank Erhard Uschner[1,2], Berenice Alard[3], Meriam Kabbaj[4], Jeremy Magnanensi[3], Désirée Füglistaller[4], Marie Bobowski-Gerard[3], Dean Hum[3], Bart Staels[5], Katharina Staufer[4], Jonel Trebicka[1,2].

Lille, INSERM, CHU Lille, Institut Pasteur de Lille, Lille, France
Email: berenice.alard@genfit.com

Background and aims: Acute-on-Chronic Liver Failure (ACLF) is characterized by systemic inflammation, organ failure, and high short-term mortality. ACLF is associated with an accumulation of metabolites in blood, altering major metabolic pathways which may contribute to disease progression. VS-01 is a novel investigational intraperitoneal (*i.p.*), pH-gradient, liposomal suspension that enhances the clearance of ammonia and potentially of other metabolites as suggested by prior metabolomic analysis in blood. Using both peritoneal and blood data from the Phase 1 clinical trial evaluating VS-01 safety in patients with decompensated cirrhosis, ascites and covert hepatic encephalopathy, we aimed to confirm the captures of metabolites previously proposed and to explore further metabolites in the context of ACLF.
Method: Metabolomic analyses were performed in blood and peritoneal fluid samples of 9 patients in whom a single dose of VS-01 (15, 30 or 45 ml/kg body weight, 3 patients each) was administered *i.p.* and left to dwell for 2 h following paracentesis. Blood samples were collected concomitantly with ascites at baseline (T0), and with peritoneal fluid samples at the end of the dwell time (T2) and 24 h after VS-01 infusion start (T24). Metabolomic analyses were first performed on all samples using an untargeted LC/MS approach. Among identified metabolites, we focused on 24 compounds which were already described in the literature as being potentially related to organ failures and ACLF and aimed to analyze the potential capture of these metabolites by VS-01. Statistical analyses, using MetaboAnalyst package in R, were performed on the peak lists containing mass features of identified compounds, computing fold changes and t-tests.
Results: At the end of the 2 h dwell time (T2), we observed a significant capture of 10 metabolites out of the 24 in ascites when compared to T0 ($p < 0.05$). Among the 10 metabolites, 5 were concomitantly associated with a numerical decrease in blood at T2 vs T0, suggesting a potential specific capture of these metabolites by VS-01. Moreover, comparing fold changes, 4 of these metabolites were associated with an increase at T2 vs T0 compared to T24 vs T0 in the peritoneal fluid, whereas a decrease was observed in blood, respectively, confirming a potential removal of those metabolites by VS-01. The identified compounds which appeared to be captured by VS-01 are Trimethylamine N-Oxide (TMAO), Carnitine, N-Acetyl-Alanine and 4-Acetamidobutanoic acid.
Conclusion: VS-01 seems to specifically capture metabolites that may be associated with organ failures and inflammation, which are hallmarks of ACLF. TMAO, reported to be toxic for the kidney and associated with the progression of multiple diseases, could represent an interesting metabolite to clear out in the context of ACLF. Further analyses should be performed to confirm our findings.

THU-089
Bilirubin monoglucuronides play an important role in the pathophysiology of acute-on-chronic liver failure

Stephany Castillo-Castañeda[1], Jacqueline Cordova-Gallardo[2], Liliana Rivera-Espinosa[3], Juan Chavez-Pacheco[3], Mariana Ramírez-Mejía[1], Nahum Méndez-Sánchez[1]. *[1]Medica Sur Clinic and Foundation, National Autonomous University of Mexico, Mexico City, Mexico; [2]General Hospital Dr. Manuel Gea González, National Autonomous University of Mexico, Mexico City, Mexico; [3]National Pediatric Institute, Mexico City, Mexico*
Email: nmendez@medicasur.org.mx

Background and aims: Acute-on-chronic liver failure (ACLF) is a syndrome characterized by acute decompensation of chronic liver disease associated with organ failures and high short-term mortality. ACLF frequently occurs in a closed temporal relationship to a precipitating event, involving systemic inflammation due to infections and acute liver damage. The development of organ failures may be a result of a combination of tissue hypoperfusion, direct immune-mediated damage and mitochondrial dysfunction. The aim of the present study was to evaluate the molecular species of bilirubin in patients with compensated liver cirrhosis (LC) and those with ACLF.
Method: We included patients diagnosed with LC and ACLF, and healthy subjects (HS) as controls. The ACLF patients were diagnosed using the EASL-CLIF definition and ACLF grades. We collected all clinical and biochemical data. Bilirubin molecular species: BMG, BDG and UCB were measured in serum by LC-MS, monitoring their m/z. Results are expressed as median, IQR, frequency and percentages. Statistical analyses were performed by the Mann-Whitney and Kruskal-Wallis tests, with p values <0.05 as significant.
Results: A total of 58 consecutive patients were included, 29 with ACLF diagnosis, 11 with LC, and 18 HS. The median age of the ACLF patients was 54 years, compared with 46 years for LC and 63 years for HS. The most common etiology was alcohol-associated liver disease, 63.3% in ACLF and 28.6% in LC. Bilirubin molecular species levels (BMG, BDG and UCB) in ACLF patients were 28.57, 1.32 µmol/L and 19.69 µmol/L. In the LC, the median concentrations were 1.49, 0.055 and 11.29 µmol/L, respectively. In the HS, levels were 0.52, 0.028 and 6.42 µmol/L. With a p value of 0.000.
According to ACLF grade, BMG, BDG and UCB were 11.36, 0.62 and 36.08 µmol/L for NO ACLF, 15.87, 1.19 and 21.16 µmol/L for ACLF 1, 28.07, 1.21 and 18.76 µmol/L for ACLF 2 and 239.07, 7.37 and 23.04 µmol/L for ACLF 3. The p values were 0.007 and 0.009 for BMG and BDG.
Conclusion: We found that bilirubin molecular species levels are significantly higher in cirrhosis, especially in those who develop ACLF. We believed that at high concentrations, bilirubin lost its protective antioxidant and anti-inflammatory effects, contributing to the distinctive feature of ACLF development including systemic inflammation. As more bilirubin is released into the system, more toxicity occurs, causing membrane and mitochondrial dysfunction, oxidative stress, apoptosis, inflammation, and even epigenetic modifications in susceptible organs. All these bilirubin-induced toxic mechanisms can

exacerbate multiple organ dysfunction. In addition, BMG was the most elevated molecular species in the serum of ACLF patients, suggesting that the conjugation process is not well completed by UGT1A1 enzyme and therefore the normal excretion of diglucuronide into the bile is impaired making it difficult to get into the serum.

Safety and efficacy of liver hemodialysis in managing hepatic dysfunction: a systematic review and meta-analysis

Eyad Gadour[1,2], Moahmmed Kaballo[3], Khalid Shrwani[4], Zeinab Hassan[5], Ahmed Kotb[6], Ahmed Aljuraysan[7], Bogdan Miuțescu[8,9], Nouf Sherwani[10], Alaa Sherwani[11], Waleed Mahallawi[12], Mohammed Raza[13]. *[1]King Abdulaziz National Guard Hospital, Department of Gastroenterology and Hepatology, Alahsa, Saudi Arabia; [2]Zamzam University College, School of Medicine, Khartoum, Sudan; [3]King Abdulaziz National Guard Hospital, Department of Nephrology, Al-Ahsa, Saudi Arabia; [4]Saudi Center for Disease Prevention and Control, Public Health Authority, Jazan, Saudi Arabia; [5]Stockport Hospital NHS Foundation Trust, Internal Medicine, Manchester, United Kingdom; [6]Glan Clwyd Hospital, Department of Vascular Surgery, Rhyl, United Kingdom; [7]King Abdulaziz National Guard Hospital, Department of Gastroenterology and Hepatology, Al-Ahsa, Saudi Arabia; [8]"Victor Babes" University of Medicine and Pharmacy Timisoara, Department of Gastroenterology and Hepatology, Timisoara, Romania; [9]"Victor Babes" University of Medicine and Pharmacy, Advanced Regional Research Center in Gastroenterology and Hepatology, Timisoara, Romania; [10]Mohammed bin Nasser Hospital, Department of Surgery, Jazan, Saudi Arabia; [11]Abu-Arish General Hospital, Department of Pediatrics, Jazan, Saudi Arabia; [12]Taibah University, College of Applied Medical Sciences, Madinah, Saudi Arabia; [13]Al-Fatima University College, Karachi, Pakistan*
Email: eyadgadour@doctors.org.uk

Background and aims: Since not all liver dysfunction patients are suitable for transplantations and there is a shortage of grafts, liver support therapies have gained interest. In this regard, extracorporeal albumin dialysis devices such as Single-Pass Albumin dialysis (SPAD), Prometheus, and Molecular Adsorbent Recycling System (MARS) have been valuable in supplementing standard medical therapy (SMT). However, the efficacy and safety of these devices is often questioned. Therefore, we performed a systematic review to summarize the efficacy and safety of MARS, SPAD, and Prometheus as supportive treatments for liver dysfunction.
Method: PubMed, Medline, Cochrane Library, Web of Science, and Google Scholar electronic databases were extensively searched for all randomized trials published in English. In addition, meta-analytic analyses were performed with the Review Manager software, and Cochrane's risk of bias tool embedded in this software was used for bias assessment.
Results: 12 trials with 653 patients were eligible for inclusion. Subgroup analyses of data from these trials revealed that MARS and Prometheus were associated with significant removal of bilirubin (MD: −5.14 mg/dL; 95% CI: −7.26–3.02; p < 0.00001 and MD: −8.11 mg/dL; 95% CI: −12.40–3.82; p = 0.0002, respectively) but not bile acids and ammonia when compared to SMT. Furthermore, MARS was as effective as Prometheus and SPAD in the reduction of bilirubin (MD: 2.98 mg/dL; 95% CI: −4.26–10.22; p = 0.42 and MD: 0.67 mg/dL; 95% CI: −2.22–3.56; p = 0.65), bile acids (MD: −17.06 µmol/L; 95% CI: −64.33–30.20; p = 0.48) and MD: 16.21 µmol/L; 95% CI: −17.26–49.68; p = 0.34), and ammonia (MD: 26 µmol/L; 95% CI: −12.44–64.44; p = 0.18). In addition, MARS had a considerable effect in improving hepatic encephalopathy (HE) (RR: 1.54; 95% CI: 1.15–2.05; p = 0.004). However, neither MARS nor Prometheus had a mortality benefit compared to SMTRR: 0.86; 95% CI: 0.71–1.03; p = 0.11 and RR: 0.87; 95% CI: 0.66–1.14; p = 0.31, respectively).
Conclusion: MARS, SPAD, and Prometheus as liver support therapies are equally effective in reducing albumin-bound and water-soluble substances. Moreover, MARS is associated with HE improvement. However, none of the therapies was associated with a significant reduction in mortality or adverse events.

THU-091

Predictors of acute-on-chronic liver failure (ACLF) and mortality in ambulatory cirrhotic patients

Maamoun Basheer[1], Prof Nimer Assy[2]. *[1]Internal Medicine Department, Galilee Medical Center, Nahariya, Israel, Nahariya, Israel, Israel; [2]Internal Medicine Department, Galilee Medical Center, Nahariya, Israel, Nahariya, Israel, Israel*
Email: maamon.basheer@mail.huji.ac.il

Background and aims: Acute-on-chronic liver failure (ACLF) is the most life-threatening complication of cirrhosis. ACLF's prevalence and outcomes have been described in hospitalized patients with cirrhosis. However, no data is available on the prevalence and predictors of ACLF in ambulatory cirrhotic patients. Aims: Assessment of the incidence and predictors of ACLF in cirrhotic ambulatory patients.
Method: A retrospective study of 204 ambulatory patients with cirrhosis consecutively evaluated in a tertiary hospital at the Galilee Medical Center from Feb. 2015 to Dec. 2022 and followed for eight years. Data on developing hepatic and extrahepatic organ failures were collected. ACLF was defined and graded according to the European Association for the Study of Liver-Chronic Liver Failure (EASL-CLIF) Consortium definition.
Results: Outpatients with cirrhosis developed ACLF in 40% of cases (82 patients). The mortality rate was significantly high in the ACLF group as compared to the non-ACLF group (38% VS 8.5%, respectively P < 0.001). Patients with ACLF were older, had increased CRP, NLR and WBC, increased LFTS and kidney function, and increased MELD, Child-Pugh, CLIF-C and PADUA scores than the non-ACLF group. Univariate regression analysis determined that the MELD score was the most powerful predictor of organ failure. Multivariate analysis showed that MELD and CLIF-C scores were associated with organ failure and developing ACLF (OR 4.5, P < 0.001, OR 3.2, P < 0.001, respectively). Discriminant analysis showed that BUN, MELD, CLIF-C and PADUA scores predicted mortality in ambulatory outpatients with cirrhosis with 87% accuracy. Inflammatory markers CRP and NLR were not selected as independent predictors of ACLF or of mortality.
Conclusion: Outpatients with cirrhosis developed ACLF in 40% of cases. MELD and CLIF-C scores are the best ACLF development predictors. PADUA, CLIF-C and MELD scores are the best predictors of mortality. Therefore, we should use MELD, PADUA and CLIF-C scores to evaluate and follow-up cirrhotic outpatients in liver units.

THU-092

Enrolling patients in ACLF trials-the need to increase ACLF awareness (DHELIVER trial)

Email: dominique.thabut@aphp.fr

Background and aims: Inclusion of ACLF patients in clinical trials requires awareness of existing clinical trials, prompt recognition of the disease characteristics and thorough pre-screening for inclusion/exclusion criteria. In addition to major investigational hospitals, the HEP102 DHELIVER ACLF phase IIB study enrolled patients referred from other hospitals through local information sessions to support patient recruitment in the study. We reviewed the data of all screened patients to better understand the reasons for delayed diagnosis and screening.
Method: Retrospective analyses of dates of hospitalization (at investigational sites or other hospitals) and ACLF diagnosis were performed in relation to the causes of admission.
Results: Of the 185 patients screened in the DHELIVER study (up to mid-December), 107 were randomized. Complete hospitalization data have been available for 99 patients so far. These patients were hospitalized either in investigational sites (63%) or other hospitals (37%) before being randomized. The average number of days between initial healthcare encounter and ACLF diagnosis was 2.7 days when hospitalized in investigational sites and 7.5 days when hospitalized in other hospitals. Causes of admission to the hospital varied widely. Of the 99 randomized patients for whom hospitalization data are available, only 10% were admitted for diagnosed or suspected ACLF, while 61% were admitted for signs of acute decompensation (AD) including jaundice, ascites, hepatic encephalopathy, gastrointestinal bleeding, and 17% for acute alcoholic hepatitis (AAH). When the causes of admission were not specifically ACLF, the average time to ACLF diagnosis was 3.0 days in investigational sites, vs 7.7 days in other hospitals. Forty-four percent of patients were admitted to intensive care units (ICU) before being randomized. Overall, the average time from initial healthcare encounter to ACLF diagnosis was the same between ICU vs non-ICU patients (4.5 days). However, the average time to ACLF diagnosis in other hospitals compared to investigational sites was 3.3 times longer for non-ICU patients (8.0 vs 2.5 days), and 2.3 times longer for ICU-patients (6.8 vs 3.0 days).
Conclusion: The DHELIVER study has demonstrated those hospitals that are not participating in the study have high potential in recruiting patients in ACLF trials (37%). The DHELIVER data have also highlighted the challenges facing the recruitment of ACLF patients due to late diagnosis of ACLF in hospitalized patients, as only 10% of patients displaying ACLF symptoms are admitted for ACLF itself. Early and regular assessment of ACLF criteria in patients with signs of AD and AAH in ICU and non-ICU wards and better awareness campaign on ACLF diagnosis would allow timely identification of ACLF. This would allow earlier transfer of patients to tertiary hospitals with better access to clinical trials.

Cirrhosis and its complications – Experimental and pathophysiology

Red blood cell distribution width-to-platelet ratio estimates the 3-year risk of decompensation in patients with metabolic dysfunction-associated steatotic liver disease-related cirrhosis

Mario Romeo[1], Marcello Dallio[1], Marina Cipullo[1], Paolo Vaia[1], Simone Mammone[1], Salvatore Auletta[1], Silvio Naviglio[2], Luigi Sapio[2], Angela Ragone[2], Marco Niosi[1], Alessandro Federico[1].
[1]Hepatogastroenterology Division, Department of Precision Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy; [2]Clinical Biochemistry Division, Department of Precision Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy
Email: mariomeo@virgilio.it

Background and aims: For compensated advanced chronic liver disease (cACLD) patients, the first decompensation represents a dramatically worsening prognostic event. Based on the first decompensation event (DE), the transition to decompensated advanced chronic liver disease (dACLD) can occur through two modalities referred to as acute decompensation (AD) and non-acute decompensation (NAD), respectively. Clinically Significant Portal Hypertension (CSPH) is considered the strongest predictor of decompensation in these patients. However, CSPH is seldom evaluated in clinical practice due to its invasiveness and costs. Therefore, recognizing non-invasively predicting tools still has more appeal across healthcare systems. The red blood cell distribution width-to-platelet ratio (RPR) has been reported to indicate hepatic fibrosis in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD). However, its predictive role in decompensation has never been explored. In this observational study, we investigated the clinical usage of RPR in predicting DEs in MASLD-related cACLD patients.
Method: 40 controls and 150 MASLD-cACLD patients were consecutively enrolled and followed up (FUP) semiannually for 3 years. At baseline, biochemical, clinical, and Liver Stiffness Measurement (LSM), Child-Pugh (CP), Model for End-stage Liver Disease (MELD), AST to Platelet Ratio (APRI), Fibrosis-4 (FIB-4), Albumin-Bilirubin (ALBI), ALBI-FIB4, and RPR were collected. During FUP, DEs (timing and modalities) were recorded. CSPH was assessed through methods proposed by the Clinical Practice Guidelines.
Results: Of 150 MASLD-cACLD patients, 43 (28.6%) progressed to dACLD at a median of 28.9 months (29 NAD; 14 AD). Baseline RPR values were significantly higher in cACLD compared to controls, as well as MELD, CP, APRI, FIB-4, ALBI, ALBI-FIB-4, and LSM in dACLD-progressing compared to cACLD individuals [all $p < 0.0001$, except for FIB-4 (p:0.007) and ALBI (p:0.011)]. ROC analysis revealed RPR $\geq$0.472 and $\geq$0.894 as the best cut-offs [AUC: 0.95; AUC: 0.94] in the prediction respectively of 3-year first DE and relative modality (AD), as well as its superiority for both the outcomes compared to APRI [AUC: 0.88; AUC: 0.88], FIB-4 [AUC: 0.72; AUC: 0.75], ALBI [AUC: 0.90; AUC: 0.77], ALBI-FIB-4 [AUC: 0.93; AUC: 0.79], MELD [AUC: 0.81;

AUC: 0.73], CP [AUC: 0.79; AUC: 0.82], and LSM [AUC: 0.88; AUC: 0.85] (all p <0.0001). The RPR [adjusted Hazard Ratio (aHR): 1.91; 95% C.I:1.72–1.98; p:0.02] and the presence of baseline-CPSH [aHR: 1.84 95% C.I.: 1.72–1.91; p:0.04] were significantly associated with the DE. Patients presenting baseline-CSPH and RPR ≥0.472 showed a higher risk [HR: 3.10; p:0.0023] of decompensation.
Conclusion: RPR is a valid and potentially applicable non-invasive tool in predicting the timing and modalities of decompensation in MASLD-related cACLD patients.

Background and aim: Patients with acutely decompensated (AD) cirrhosis present a systemic hyperinflammatory response causally linked to the development of acute-on-chronic liver failure (ACLF), characterized by multi-organ failure and short-term mortality. In this study, we analyzed the systemic circulation secretome through a combination of omics to identify biomarkers associated with infection, 28-day ACLF development and 90-day mortality in patients with AD cirrhosis.
Method: The study included patients with AD cirrhosis from PREDICT (discovery cohort, n = 766) and ACLARA (validation cohort, n = 580). Plasma cytokines/chemokines were evaluated using multiplex bead-based immunoassays. Bioactive lipids and low-molecular weight metabolites were assessed by targeted lipidomics and untargeted metabolomics in plasma and serum, respectively. A multifactorial regression network was built to identify significant associations between high-dimensional multi-omics data and infection and outcome of AD cirrhosis.
Results: Among the 292 features included in the integrated network analysis, we identified a strong connection between arachidic acid (a hydrogenated product of arachidonic acid) and glucuronic acid (a marker of extramitochondrial glucose oxidation) and a high negative association with the anti-inflammatory marker 15-HETE in patients with active infections. Considering ACLF development as outcome, we identified a network that strongly correlated with the arachidonic acid-derivative 20-HETE and the hydroxylated fatty acid hydroxydodecanoic acid with acylcarnitines (established markers of mitochondrial dysfunction). In addition, arachidic acid together with interleukin-8 interconnected with glucuronic acid. Importantly, levels of sphingosine-1-phosphate, a signaling molecule that controls immune cell trafficking, were strongly and negatively associated with this outcome. When we interrogated mortality as outcome, we identified a network of lipids that converged into acylcarnitines, hydroxy-3-methoxyphenylglycol sulfate (MPHG, a major metabolite of norepinephrine) and glucuronic acid. Most features appearing in the above described immunometabolic networks were primarily associated with the ramping neutrophilia existing in these patients, except sphingosine-1-phosphate which was linked to thrombocytopenia. Furthermore, glucuronic acid, interleukin-6 and hydroxydodecanoic acid were the best predictors of ACLF development (AUC>0.66) whereas MPHG sulfate (AUC>0.72) was the best prognostic marker of imminent death, findings that were validated in the ACLARA cohort.
Conclusion: A network-based multi-omics analysis allowed us to uncover new pathophysiological events associated with ACLF development and death and to identify new biomarkers to fuel prognostic tests to improve prediction of outcome in patients with AD cirrhosis.

Galectin 9 predicts clinical outcome and regulates immune dysfunction in acute-on-chronic liver failure

Antonio Riva[1,2], Douglas Corrigall[1,2,3], Hio Lam Phoebe Tsou[1,2], Nicola Harris[1,2], Dhruti Devshi[1,2], Sarah Fairclough[3], Gavin Wright[3], Jonel Trebicka[4,5], Carlo Alessandria[6], Paolo Angeli[7], Rajiv Jalan[8], Joan Clària[9], Richard Moreau[10], Vicente Arroyo[5], Shilpa Chokshi[1,2]. *[1]Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [2]King's College London, Faculty of Life Sciences and Medicine, London, United Kingdom; [3]Basildon and Thurrock University Hospitals NHS Foundation Trust, Basildon, United Kingdom; [4]Medical Department I, Goethe University Clinic, Frankfurt, Germany; [5]European Association for the Study of the Liver-Chronic Liver Failure (EASL-CLIF) Consortium and European Foundation for the study of Chronic Liver Failure (EF-CLIF), Barcelona, Spain; [6]Division of Gastroenterology and Hepatology, San Giovanni Battista Hospital, Torino, Italy; [7]Unit of Internal Medicine and Hepatology, Dept. of Medicine, DIMED, University of Padova, Padova, Italy; [8]Institute for Liver Disease Health, University College London, Royal Free Hospital, London, United Kingdom; [9]Hospital Clínic, IDIBAPS, Barcelona, Spain; [10]Inserm, U1149, Centre de Recherche sur l'Inflammation (CRI), Paris, France*
Email: a.riva@researchinliver.org.uk

Background and aims: Acute-on-Chronic Liver Failure (ACLF) is an immunological paradox characterised by a highly activated hyperinflammatory immune system that is simultaneously profoundly suppressed in its antibacterial functionality. We have previously revealed the importance of immune checkpoints (membrane-bound and soluble) in modulating antipathogen and inflammatory responses in alcohol-related liver disease, but their role in the immunopathogenesis and progression of ACLF are unknown.
Method: We quantified 17 soluble (s) immune checkpoints and D-Lactate (DL) as a marker of bacterial translocation by Luminex and ELISA in the serum of 511 patients with decompensated cirrhosis from the CANONIC Cohort (at inclusion: 334 acute decompensation, AD, ACLF 0; 177 ACLF 1/2/3). Predictive multivariable regression models were used to quantitatively weigh contributions to ACLF grade, development, resolution, and day (d)28/90 transplant free survival (TFS). Kaplan-Meier analyses were used to find TFS cutoffs. Peripheral blood mononuclear cells (PBMC) from AD and ACLF patients (n = 10) were assessed for antibacterial immune functionality (IFNg, IL-17, TNFa, IL-10, CD107a, Granzyme B, Perforin on CD4 and CD8 T cells by flow cytometry) upon bacterial challenge with/without Galectin (Gal)9 blockade.
Results: Gal9, Gal1 ($p < 0.002$), sCD40, sBTLA, sCD137, sCD27 ($p < 0.008$), and DL ($p = 0.002$) were all significantly associated with ACLF and ACLF grade. In predictive models, Gal9 and Gal1 were found to be significant positive predictors of ACLF severity ($p < 0.005$; standardised Gal9 odds ratios (OR) >1.3; 95% CI 1.1–1.6) and transplant/death

(day 28 and day 90) (p < 0.015; st. Gal9 hazard ratios >1.2; 95% CI 1.1–1.6). Gal9 was also significantly unfavourable to ACLF resolution (p < 0.003; st. Gal9 OR <0.7; 95% CI 0.5–0.8). Immune scoring based on Gal9 was able to discriminate ACLF from AD (p < 0.001; AUROC 0.71, 95% CI 0.67–0.76, Sens/Spec >65%) and addition of Gal9 marginally enhanced the CLIF ACLF score, increasing discriminating accuracy for both AD vs ACLF (78 to 80%) and between ACLF grades (59 to 63%). Significant TFS cutoffs were also found for Gal9 (d28 TFS, p = 5.6E-9, <22611 pg/ml; d90 TFS, p = 1.8E-10, <22402 pg/ml). Post-hoc analyses by sex (as assigned at birth) showed that Gal9 associations with ACLF and ACLF grade were similar in male and female patients, unlike other receptors. In vitro blockade of Gal9 in PBMCs restored antipathogen responses boosting antibacterial cytokines and also anti-inflammatory IL-10 in both AD and ACLF.
Conclusion: Gal9 is a promising biomarker of AD and ACLF progression and represents a promising novel therapeutic target for restoration of anti-pathogen immunity in these patients.

Email: paolo.gallo@policlinicocampus.it

Background and aims: Severe thrombocytopenia (platelet count <50.000/μL) presents management challenges in patients with chronic liver disease (CLD). Recently, thrombopoietin receptor agonists, such as lusutrombopag, have been developed as alternatives to platelet transfusions. However, existing real-world data are limited to sporadic reports or administrative databases. We aimed to assess the first post-marketing real-world European cohort of cirrhotic patients treated with lusotrombopag to verify the efficacy and safety of the drug.
Method: In the REAl-world Lusutrombopag treatment in ITalY (REALITY) study, we collected data from consecutive cirrhotic patients who underwent lusotrombopag treatment before invasive procedures between March 2021 and March 2023. The data were collected from 19 Italian hepatologic centers, mostly affiliated with the "Club Epatologi Ospedalieri" (CLEO). Efficacy, defined as the ability of lusutrombopag to raise platelet count to ≥50.000/μL and avoid transfusions, as well as treatment-related adverse events, were recorded and analyzed.
Results: A total of 73 patients were enrolled in the study (median age 66 years, female 32%, Child-Pugh A/B/C 63/28/9%). Twelve patients (15%) had a previous medical history of portal vein thrombosis. Chronic viral hepatitis emerged as the leading cause of chronic liver disease (55%), with endoscopic band ligation being the most frequently performed procedure (38% of cases). Lusutrombopag induced a significant increase in platelet count [from 37.000 (33.000–44.000/μL) to 58.000 (49.000–82.000), p <0.001]. The overall efficacy of lusutrombopag was determined to be 74%. Multivariate logistic regression analysis identified baseline platelet value as the only independent factor associated with the response (OR 1.13, CI95% 1.04–1.26, p 0.01) and with an adequate discriminative ability (AUROC of 0.78). Notably, a baseline platelet count of ≤29.000/μL was identified as the threshold for identifying patients unlikely to respond to the drug, exhibiting a sensitivity of 91%. Finally, de novo portal vein thrombosis was observed in 4 patients (5%), while no other safety events were recorded.
Conclusion: In this first real-world European series of CLD, lusutrombopag demonstrated efficacy and safety consistent with findings from registrative trials. Finally, according to our results, patients with baseline platelets ≤29.000/μL are unlikely to respond to the drug.

Glucagon-like peptide-1 receptor agonist, semaglutide attenuates liver cirrhosis-related skeletal muscle atrophy in diabetic mice

Kosuke Kaji[1], Shohei Asada[1], Shinya Sato[1], Tadashi Namisaki[1], Hitoshi Yoshiji[1]. *[1]Department of Gastroenterology, Nara Medical University, Kashihara, Japan*
Email: kajik@naramed-u.ac.jp

Background and aims: Recent studies have demonstrated the molecular role of the glucagon-like peptide-1 receptor agonist (GLP-1RA) in skeletal muscle homeostasis; however, the therapeutic efficacy of semaglutide, a GLP-1RA, on skeletal muscle atrophy in liver cirrhosis. The aim of the present study was to investigate the effect of semaglutide on skeletal muscle wasting and dysfunction in liver cirrhosis-related skeletal muscle atrophy under diabetic conditions.
Method: To induce liver cirrhosis under diabetic condition, male diabetic KK-Ay mice were fed with diethoxycarbonyl-1, 4-dihydrocollidine (DDC) diet for 6 weeks. Semaglutide (3 nmol/kg) was subcutaneously injected every 3 days. We assessed the effect of semaglutide on psoas muscle mass index by using CT image and grip strength as well as hepatic and muscular phenotypes. Moreover, in vitro assay was performed to evaluate direct effect of semaglutide on C2C12 myocytes.
Results: Semaglutide inhibited psoas muscle atrophy and suppressed declines in grip strength in mice. Moreover, semaglutide inhibited ubiquitin-proteosome-mediated skeletal muscle proteolysis and promoted myogenesis in C2C12 myocytes. Mechanistically, this effect of semaglutide on skeletal muscle atrophy was mediated by multiple functional pathways. First, semaglutide protected against hepatic injury in mice accompanied by increased production of insulin-like growth factor 1 and reduced accumulation of reactive oxygen species (ROS). These effects were associated with decreased proinflammatory cytokines and ROS accumulation, leading to suppression of ubiquitin-proteosome degradation in the skeletal muscle tissue. Moreover, semaglutide inhibited the amino acid starvation-related stress signaling which was activated under chronic liver injury, resulting in the recovery of mammallian target of rapamycin activity in the skeletal muscle of mice. Second, semaglutide improved skeletal muscle atrophy by directly stimulating GLP-1R in myocytes. Treatment with semaglutide induced cAMP-mediated activation of PKA and AKT, enhanced mitochondrial biogenesis, and reduced ROS accumulation, thereby resulting in inhibition of NF-κB/myostatin-mediated ubiquitin-proteosome

degradation and the augmentation of heat-shock factor-1-mediated myogenesis.
Conclusion: Semaglutide may have potential as a new therapeutic strategy for liver cirrhosis-related skeletal muscle wasting.

Email: juanola@clinic.cat

Background and aims: The progression of cirrhosis is associated with an activation of immune cells in response to liver injury and bacterial translocation. However, immune tolerance mechanisms that follow proinflammatory state, are also increased at latter stages, mainly in the monocyte subsets. Furthermore, metabolic alterations have been also described to play a role in the progression of the disease. The LiverHope Efficacy study has evaluated the treatment combination of simvastatin and rifaximin against placebo in patients with decompensated cirrhosis to prevent the development of acute-on-chronic liver failure. This study aims to describe the effect that this treatment induces on peripheral blood mononuclear cells (PBMCs).
Method: This is a sub-study of the LiverHope Efficacy trial (NCT03780673). Single-cell RNA-Seq analysis was performed in PBMCs collected in 6 patients with decompensated cirrhosis: 4 from the treatment group and 2 from the placebo group. For each individual, paired samples of PBMCs were obtained before the start of treatment and at month 6 of treatment. Baseline/follow-up differences between the placebo and treatment groups were evaluated.
Results: A total of 17 cell populations were identified from the 44, 709 cells analyzed. Compositional analysis showed no changes in the proportion of cell subpopulations according to the treatment group. Differential gene expression analysis revealed classical monocytes as the population with higher transcriptional changes, detecting a total of 1, 253 differentially expressed genes (p value <0.05 and fold-change >1.5) in the classical monocyte population treated with simvastatin/rifaximin when compared with patients treated with placebo (944 genes up-regulated and 309 genes down-regulated). Functional enrichment analysis using the gene set enrichment analysis (GSEA) showed a decrease in the expression of molecular pathways involved in the immune response, as well as an increase in the expression of pathways related to mitochondrial metabolism in monocytes from patients treated with the drug combination.
Conclusion: Treatment with simvastatin/rifaximin decreases the expression of proinflammatory genes and promotes changes in mitochondrial metabolism in monocytes of patients with decompensated cirrhosis. These findings reveal beneficial effects at the cellular level of treatment with simvastatin and rifaximin.

WED-056

Activated cytotoxic T-cells in mesenteric lymph nodes limit systemic bacterial dissemination, inflammation, and disease progression in chronic liver injury

Pinky Juneja[1], Aarti Sharma[2], Deepika Jakhar[2], Impreet Kaur[2], Ashwini Vasudevan[2], Dinesh Mani Tripathi[2], Savneet Kaur[2]. *[1]Institute of Liver and Biliary Science, Delhi, India; [2]Institute of Liver and Biliary Sciences, Delhi, India*
Email: savykaur@gmail.com

Background and aims: Mesenteric lymph nodes (MLNs) are immune inductive sites that limit pathogens in gut, preventing their systemic spread. We studied the role of MLNs in bacterial spread, systemic inflammation, and progression of fibrosis using MLN resection models (MLNx).
Method: MLNs were resected from healthy rats (C-MLNx) and allowed to reconstitute lymphatic connections for next 3wk, and were compared with healthy rats (control). CCl_4-MLNx model was prepared by administering CCl_4 to 3wk post MLNx rats for next 8wk and compared with 8wk CCl_4 fibrotic model. LPS, 1 mg/Kg, I.P., was administered in all groups. Tissues and blood were collected 24 h post-LPS. Immune cells were quantified in liver, spleen, and blood. Endogenous bacterial load was quantified in these organs along with lung and MLNs. Cytokines and endotoxin levels were examined in plasma and MLNs. Gut permeability was studied by Claudin-1 expression.
Results: In C-MLNx vs. control, inflammatory CD43 monocytes (2.6 fold, $p < 0.01$), IL-6 (0.8 fold, $p < 0.05$), and TNF-alpha (0.6 fold, $p < 0.05$) were increased in blood 24 h post-LPS. Endogenous bacterial load was observed in lungs (540 CFU/g) of C-MLNx, while no bacteria were present in control. Plasma endotoxin levels were increased in C-MLNx compared to control (5.1 vs. 4.4 EU/ml, $p > 0.05$). No mortality, fibrosis, or cell infiltration was observed in C-MLNx. Endogenous bacterial load in MLNs (2000 CFU/g) and other organs in CCl_4 were higher in comparison to control, where bacteria were contained in MLNs (564 CFU/g) only. Bacterial load was further increased in liver (785 CFU/g), spleen (352 CFU/g), and lung (1084 CFU/g) in CCl_4-MLNx vs. CCl_4. Chronic lung inflammation and splenomegaly were observed in CCl_4-MLNx vs CCl_4 with no change in gut permeability. TNF-alpha

(3.2 fold) and IFN-gamma (2.1 fold) were increased in MLNs of CCl_4 vs control ($p < 0.03$). IL-6 (2.4 fold) and TNF-alpha (2.3 fold), along with endotoxin levels (2.8 fold), were increased in plasma of CCl_4 vs control ($p < 0.03$ each). This was aggravated in CCl_4-MLNx vs CCl_4 (IL-6: 1.4 fold, TNF-alpha: 1.5 fold, endotoxins: 1.4-fold, $p < 0.04$ each). Compared to control, activated CD134+ Tc cells are higher in MLNs (1.28 vs. 10.96%) and blood (1.03 vs. 3.23%) of CCl_4 ($p < 0.04$ each). However, in CCl_4-MLNx vs. CCl_4, activated CD134+Tc cell count was reduced (2.03 vs. 3.23%, $p < 0.05$), and Treg cells were increased (8.7 vs. 3.5%, $p < 0.001$) in blood. In CCl_4-MLNx, we observed increased liver fibrosis (30% F3, 70% F4 grade fibrosis) with 30%mortality rate compared to CCl_4 (90% F3, 10% F4) 24 h post LPS.

Conclusion: In the absence of MLNs, fibrosis progression and mortality are enhanced owing to increased systemic dissemination of bacterial endotoxins, causing systemic inflammation, gut immunosuppression, and endotoxemia. Hence, the preservation of MLNs functionality is crucial for limiting the spread of bacterial infections and disease progression.

WED-057

Exercise alters immune cell senescence and inflammation in cirrhosis patients with sarcopenia

Preeti Negi[1], Nidhi Nautiyal[1], Swati Thangariyal[1], Ashmit Mittal[1], Rakesh Kumar[1], Akhil Deshmukh[2], Vinod Arora[2], Shiv Kumar Sarin[1], Sukriti Baweja[3]. *[1]Institute of Liver and Biliary Sciences, Delhi, India; [2]Institute of liver and biliary sciences, Delhi, India; [3]Institue of Liver and biliary Sciences, Delhi, India*
Email: sukritibiochem@gmail.com

Background and aims: Sarcopenia is a gradual and widespread reduction of skeletal muscle mass, commonly associated with physical impairment. In cirrhosis, sarcopenia is linked to immune cells aging and inflammation. The aim of the study was to investigate the association of exercise with immune cells rejuvenation, inflammation and muscle strength in cirrhosis patients.

Method: Cirrhosis patients (n = 70) [78.1% male, age 54 ± 12 yr; MELD 14.5 (IQR 9.7–20.2] sarcopenic (SP, n = 44) or non-sarcopenic (NSP) as assessed by Appendicular skeletal muscle index [ASMI (<5.5 kg/m2 for women, <7.0 kg/m2 for men)], dual-energy X-ray absorptiometry (DXA), gait speed, liver frailty index were included. Samples were collected before and immediately post-exercise (exercise by pedaling a half bicycle, sitting on a chair for 20 minutes with maximal effort). High-dimensional immune profiling was done using flow cytometry, plasma cytokines and myokines (TNFα, IL-6, Myostatin and Follistatin by ELISA and senescence associated secretory proteins [SASP; (IL-6, IL-1b, CXCL10, MAPK3, TNFα, p21, p53IL-10, IL-22, IL-17A) mRNA was assessed.

Results: In SP patients gait speed, liver frailty index were significantly low than NSP ($p < 0.001$). At baseline we observed, high absolute counts of neutrophils (77.2 ± 12.9 vs 64.7 ± 13.6; $p = 0.03$), low lymphocytes ($p < 0.001$; 17.5 ± 5.6 vs 26.3 ± 9.4) and neutrophil/lymphocyte ratio (NLR) (4.23 ± 1.1 vs 2.9 ± 0.8; $p = 0.03$) in SP patients. In plasma, inflammatory markers, IL-6 and TNF-α levels were high in SP than NSP ($p < 0.05$), myostatin (MYST) and follistatin levels were comparable between the groups. Interestingly, the number of neutrophils and IL-6 levels were significantly low ($p = 0.05$; $p = 0.015$) post- exercise in SP than NSP patients, but without differences in MYST and Follistatin levels. NLR and IL-6 were found to be independent predictors of sarcopenia (AUROC-0.75, $p = 0.004$ and 0.72, $p = 0.014$) and the levels of MSYT were inversely proportional to MELD-Na ($r = -0.289$; $p = 0.002$). The mRNA levels IL-6 ($p = 0.031$) and p21 ($p = 0.008$) were decreased significantly in SP, but no differences in CXCL10 and MAPK3 in both the groups post-exercise. IL-10 ($p = 0.05$; $p < 0.0001$) and IL-22 ($p = 0.04$; $p = 0.02$) were increased significantly in both SP and NSP post-exercise.

Conclusion: Our results clearly document the positive immunological and molecular alterations associated with exercise in sarcopenic cirrhosis patients. Single supervised exercise program, improve immune senescence, and reduce inflammation and can be of great help in patients with advanced cirrhosis and high MELD.

WED-058-YI

High shear stress induced PIEZO1 activation promotes cytoskeleton remodelling and a nuclear deformation develops pro-thrombotic microenvironment and contributes to portal hypertension

Rajni Yadav[1], Parul Singh[2], Vaibhav Tiwari[1], Aishwarya Bhatnagar[1], Ashwini Vasudevan[1], Himanshi Himanshi[1], Prem Prakash[2], Shiv Kumar Sarin[1], Savneet Kaur[1], Dinesh Mani Tripathi[1]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India; [2]Jamia Hamdard University, New Delhi, India*
Email: dineshmanitripathi@gmail.com

Background and aims: LSECs sense and respond to both shear stress and hydrostatic pressure via mechanocrine signalling and regulates endothelial homeostasis. Aberrant shear mediates endothelial dysfunction and promote portal hypertension through varied mechanisms is still unexplored. We investigated high shear-induced mechanosensors and involved signalling in the development of portal hypertension.

Method: Experimental high shear rat model was developed by resection of 70% liver (PHx). Intrahepatic shear flow was evaluated by transonic flow system and intra-vital imaging with Rhodamine-6G-fluorophore-stained platelet. Hepatic hemodynamic was monitored at 24 and 48 hrs post PHx. Sham animals were used as controls. Further in liver tissues proteomics, gene expression and histological analysis and electron microscopy was performed.

Results: Hemodynamic studies revealed significant increase in portal blood flow index by +222% and +200% at 24 hrs and 48 hrs respectively post 70% PHx and PP was raised (17.19 ± 3.28 +83.33% and 17.66 ± 2.51 +150%) at 24 h and 48 h respectively in comparison to controls. Intra-vital imaging revealed Intrahepatic shear flow was raised 2-fold at 48 h post PHx. Mechanistically, at mRNA level PIEZO1 pathway was upregulated including NOTCH-1, TRPV4 in PHx at 24 h and 48 h. Hepatic proteome analysis confirmed significant upregulation (L2FC = –1 to +1) of α, β-integrin, cadherins, ICAM1 while FAK and cytoskeleton proteins such as f-actin, ROCK, myosin, Kinesin, dynein, vimentin were downregulated in high shear. Interestingly, downregulated nucleoskeleton proteins- Lamin A/C, Lamin B1, and nuclear matrix protein matrin-3 were evident and promotes nuclear deformation further confirmed with Electron Microscopy. Elevated calcium binding proteins calmodulin, calpain, and SERCA complex, and calcium-calmodulin kinase II confirms elevated intracellular calcium influx in high shear, which is re-validated increase expression of PIEZO1 and TRPV4. Additionally, increased expression of coagulation factors XII, IX and neutrophil elastase and MPO was observed suggest NETosis and pro thrombotic milieu. Mechanosensors like VEGFR2, VEGFR3, VE-cadherin, CD-31 were also upregulated, as well as in the expression of α-SMA, vWF, ET-1 genes by RT-PCR in high shear further established disturb vascular homeostasis.

Conclusion: High shear stress activates coagulation cascade and mechanosensitive PIEZO1 dependent cytoskeleton rearrangement promotes nuclear deformation. Which leads hepatic trans-endothelial migration and vascular adhesion.

WED-059

Effects of albumin treatment on cell death markers in patients with decompensated cirrhosis and in acute-on-chronic liver failure

Estefania Alcaraz[1], Anna Mestre[1], Raquel Horrillo[1], Jordi Vidal[1], Mireia Torres[1], Joan Clària[2,3,4], Javier Fernández[2,4], Vicente Arroyo[4], Isabel Bravo[1], Montserrat Costa[1]. *[1]Scientific Innovation Office, Grifols, Barcelona, Spain; [2]Hospital Clínic, IDIBAPS and CIBERehd, Barcelona, Spain; [3]Department of Biomedical Sciences, University of Barcelona*

Medical School, Barcelona, Spain; [4]EF CLIF, EASL-CLIF Consortium and Grifols Chair, Barcelona, Spain
Email: estefania.alcaraz@grifols.com

Background and aims: Cytokeratin 18 (K-18) and caspase-cleaved keratin 18 (cK-18) are cell death markers which reflect overall cell death and apoptosis, respectively. They are released into the plasma and increased in patients with decompensated cirrhosis and in acute on chronic liver failure (ACLF). For these liver pathologies, albumin-based therapies are under clinical investigation where the potential beneficial effects of albumin administration may be related to its non-oncotic properties (i.e. antioxidant, transport, immunomodulation). This study evaluated whether albumin-based treatments decrease cell death markers in patients with different stages of cirrhosis.
Method: Plasma samples from patients included in Pilot-PRECIOSA and Pilot-APACHE trials were assessed at baseline and during their follow-up. The Pilot-PRECIOSA trial (NCT00968695) analyzed the long-term albumin 20% administration (high dose, 1.5 g/kg weekly or low dose, 1 g/kg every 2 weeks, for 12 weeks, n = 5–6 patients each dose) to treat patients with decompensated cirrhosis and ascites. The Pilot-APACHE trial (NCT01201720) evaluated the effects of plasma exchange with human serum albumin 5% (PE-A5%) in 6 patients with ACLF for 10 days (6 sessions). Additionally, samples from age-matched healthy controls (HC, n = 7) were included. K-18 and cK-18 levels were detected by M65 and M30 ELISA kits, respectively.
Results: At baseline, both cell death markers were elevated in patients with decompensated cirrhosis and ACLF compared with HC. This increase was related to clinical disease severity, being higher in patients with ACLF. In patients with decompensated cirrhosis, necrotic cell death was decreased only in patients receiving high albumin dose (change from baseline, K-18 = −188 IU/L) vs low albumin dose (−20 IU/L). Similarly, high dose albumin treatment, but not low dose, reduced apoptotic cell death (p = 0.0343, between arms after 10 weeks).High dose albumin resulted in a cK-18 change from baseline of −257 IU/L while low albumin dose was 4 IU/L. In patients with ACLF, just after each PE-A5% session a reduction of both cell death markers was observed. After the last (sixth) PE-A5%, K-18 was reduced in 1300 IU/L and cK-18 in 118 IU/L. The effect on necrosis cell death was statistically significant for K-18 (ANOVA, p = 0.0003), and maintained longer (24–48 h after session), while the effect on apoptotic cell death marker was more transient.
Conclusion: Both apoptotic and necrotic cell death markers were increased in patients with decompensated cirrhosis and ACLF, being this increase associated with disease severity. Two different albumin-based treatments proposed for different stages of liver disease decreased circulating cell death markers. Further investigation is warranted to elucidate the beneficial effects of albumin, and its mechanism of action as a therapeutic agent in cirrhosis.

WED-060-YI
Type-I interferon shapes peritoneal immunity in cirrhosis and drives caspase-5-mediated progranulin release during spontaneous bacterial peritonitis

Michael Rooney[1], Shivalee Duduskar[2], Mohamed Ghait[2], Johanna Reißing[3], Sven Stengel[1], Philipp Reuken[1], Alexander Zipprich[1], Michael Bauer[4], Ashley Russo[5], Vijay Rathinam[5], Andreas Stallmach[1], Ignacio Rubio[4], Tony Bruns[3]. *[1]Department of internal medicine IV, Jena university hospital, Friedrich schiller university, Jena, Germany; [2]Integrated research and treatment center, center for sepsis control and care, Jena university hospital, Jena, Germany; [3]Department of internal medicine III, University hospital RWTH aachen, Aachen, Germany., Aachen, Germany; [4]Integrated research and treatment center, Center for sepsis control and care, Jena university hospital, Department of anesthesiology and intensive care medicine, Jena university hospital, Friedrich schiller university, Jena, Germany; [5]Department of immunology, University of connecticut health school of medicine, Farmington, United States*
Email: michael.rooneyd@gmail.com

Background and aims: Gut-derived translocation of bacteria and their components contributes to alterations in immune responses and development of infections such as spontaneous bacterial peritonitis (SBP) in cirrhosis. Many bacterial products including bacterial DNA and lipopolysaccharide (LPS) are capable of producing type-I interferon (IFN) thereby influencing numerous important immune responses. We hypothesized peritoneal macrophage (PMs) exposure to bactieral-derived DNA or type-I IFN shapes their subsequent responses, activation of the inflammasome and release of certain damage-associated molecular patterns (DAMPs).
Method: PMs were isolated from the ascitic fluid of patients with decompensated cirrhosis and treated with *E. coli* single-stranded DNA (ssDNA), LPS, and type-I or II IFN or infected with *E. coli*, *S. aureus,* and Group B streptococcus. Inflammasome activation, changes in gene expression and release of cytokines and progranulin utilizing primary PMs, monocytes, and IFN pathway/caspase-deficient THP-1 cells were measured by qPCR, ELISA, western blot, and IFN-alpha/beta reporter cells. The concentration of serum progranulin was analyzed for correlation with transplant-free survival in 77 patients who developed SBP.
Results: *E. coli* ssDNA was a strong activator of type-I IFN in PMs and monocytes from patients and subsequently primed these cells for tumor necrosis factor production in response to LPS stimulation. During live-bacterial infection, PMs released type-I IFN and upregulated the expression of IFN-inducible genes, IFN-regulatory factors (IRF)1/IRF2, guanylate binding proteins (GBP)2/GBP5 and inflammasome components such as caspase-4/5. Exposure of PMs to bacterial ssDNA or type-I IFN also upregulated important inflammasome-associated proteins. PMs release significant amounts of interleukin-1beta and progranulin upon *S. aureus* or *E. coli* infection and utilizing THP-1 macrophages progranulin release through gasdermin-D pores occurs via a type-I IFN and caspase-5 dependent manner. A serum progranulin concentration greater than 93 ng/ml was found to be a marker for poor 90-day transplant-free mortality following SBP.
Conclusion: Type-I IFN influences the immune response in the peritoneal cavity and regulates caspase-5-mediated progranulin release during SBP. Progranulin may be a novel and useful biomarker for disease severity and caspase-5 mediated non-canonical inflammasome activation during SBP.

WED-068-YI
Cell-free DNA dynamics in advanced cirrhosis: unravelling the role of nuclear and mitochondrial DNA in inflammation, coagulation dysfunction and short-term mortality

Marilena Stamouli[1,2], Jelle Adelmeijer[3], Dana Huskens[4], Elena Palma[1,2], Neil Youngson[1,2], Ane Zamalloa[5], Shilpa Chokshi[1,2], William Bernal[2,5], Mark Roest[4], Ton Lisman[3], Vishal C Patel[1,2,5]. *[1]The Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [2]Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom; [3]Surgical Research Laboratory and Section of Hepatobiliary Surgery and Liver Transplantation, Department of Surgery, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [4]Synapse Research Institute, Cardiovascular Research Institute Maastricht, Maastricht University Medical Center, Maastricht, Netherlands; [5]Institute of Liver Studies, King's College Hospital, London, United Kingdom*
Email: m.stamouli@researchinliver.org.uk

Background and aims: Cirrhosis is characterised by increased cell death, leading to the release of cell-free DNA (cfDNA) into the systemic circulation, previously identified as a predictor of mortality. cfDNA primarily composed of nuclear (nDNA) and mitochondrial (mtDNA), each with distinct genomes, is thought to contribute to systemic inflammation and coagulation dysfunction. However, the patterns of cfDNA abnormalities at varying stages and severities of cirrhosis are poorly understood.
Method: Patients with varying cirrhosis severities [stable cirrhosis (SC, n = 30), decompensated cirrhosis (DC, n = 60) and acute-on-

chronic liver failure (ACLF, n = 40)] were included and compared to healthy controls (HC, n = 40) and to patients with sepsis without cirrhosis (non-liver sepsis/NLS, n = 25) as 'positive disease' control group. Plasma-derived total cfDNA (tDNA), nDNA, and mtDNA were quantified using Nanodrop, quantitative and digital droplet PCR. nDNA and mtDNA levels were related to cirrhosis severity and 30-day mortality. Markers of systemic inflammation and haemostasis including platelet activation proteins, coagulation and fibrinolysis factors were measured using a combination of ELISA, multiplex electrochemiluminescence assays, and on optimised in-house developed assays.

Results: Elevated tDNA and nDNA levels were detected in cirrhosis compared to HC but not as profoundly as in NLS, with a step-wise increase with worsening cirrhosis severity. However, mtDNA levels decreased progressively in cirrhosis compared to both HC and NLS. Notably, nDNA outperformed mtDNA in discriminating between patients with SC and DC (AUROC 0.79 vs 0.62) whereas both were equally effective in differentiating DC and ACLF (AUROC 0.73 vs 0.72). Higher nDNA levels were associated with a 10-fold higher risk of death or transplantation within 30 days. However, higher mtDNA levels were linked to a 6-fold increase of transplant-free survival. nDNA exhibited more robust correlations with inflammatory cytokines (IL-6, r = 0.70), and haemostatic markers (vwf, r = 0.73 and D-dimer, r = 0.71) compared to the overall weaker associations observed in mtDNA.

Conclusion: These findings reveal new insights into cirrhosis-specific cfDNA dynamics, compared to health and sepsis. To the best of our knowledge, we are the first to describe that circulating nDNA levels increase while mtDNA decrease proportionally to the severity of cirrhosis, suggesting differential release mechanisms for the two cfDNA subtypes. Both nDNA and mtDNA levels may serve as valuable biomarkers for predicting short-term mortality in cirrhosis patients, as well as offering insights into differential roles in disease processes. These data are in line with the established role of nDNA release with aberrant immunoregulatory processes, and support a plausible role of nDNA in endothelial dysfunction and haemostasis that requires further study.

WED-069

Bone morphogenic protein 9 (BMP9): a novel therapeutic agent for the prevention of extrahepatic organ failure in acute-on-chronic liver failure (ACLF)

Alexandra Phillips[1], Abeba Habtesion[1], Fausto Andreola[1], Nathan Davies[1], Paul Upton[2], Nick Morrell[2], Rajiv Jalan[1]. *[1]Institute of Liver and Digestive Health, University College London, London, United Kingdom; [2]Heart and Lung Research Institute, University of Cambridge, Cambridge, United Kingdom*
Email: alexandra.phillips5@nhs.net

Background and aims: Endothelial dysfunction in ACLF is associated with severity of inflammation and extrahepatic organ dysfunction resulting in reduced organ perfusion and lactatemia. Bone morphogenic protein 9 (BMP9), a member of the transforming growth factor beta (TGFβ) superfamily, is involved in the regulation of endothelial cell function. BMP9 is reduced in cirrhosis and this correlates with increased liver and renal injury. We hypothesise that BMP9, by virtue of its known effect on the endothelium may be a novel therapeutic agent for prevention and treatment of extrahepatic organ dysfunction in models of cirrhosis and ACLF, reducing organ injury and improving survival.

Method: Rat cirrhosis model induced by 4-week bile duct ligation (BDL) ± 0.025 mg/kg intraperitoneal (ip) Lipopolysaccharide (LPS) to induce acute-on-chronic liver failure (ACLF) ± 90 µg/kg/day BMP9 ip. Mouse fibrosis induced by 12-week oral gavage of 0.5 ml/kg carbon tetrachloride (CCL4) ± 2 mg/kg LPS (ACLF) ± 90 µg/kg/day BMP9 ip in C57Bl mice. Mean arterial pressure assessed by arterial catheterisation under gaseous anaesthesia. Plasma biochemistry analysed by COBAS and Fujifilm DriChem slides. Histological staining with TUNEL assay, Sirius red and Haematoxylin and Eosin. Survival assessed by absence of coma. Statistical analysis performed using SPSS.

Results: BMP9 administration led to a significant increase in coma-free survival at 3-hours post LPS injection in the rat ACLF models [75% vs 22%, p = 0.03]. An increase in body weight change was observed in BDL and BDL+LPS animals treated with BMP9 [1.9% to 4.2% p = 0.076, 5.8% to 9.4% p = 0.037], and a reduction in liver weight compared to vehicle control was observed in BMP9-treated animals [20.9 g to 17.4 g in BDL animals, 21.2 g to 17.8 g in BDL+LPS animals]. BMP9 increased the mean arterial pressure (MAP) at termination in all models, with a significant increase in the ACLF model [82.1 to 108.5 mmHg, p = 0.01]. BMP9 administration modulated renal injury in the ACLF model with a reduction in plasma creatinine [82.3 to 65.4 µmol/L, p = 0.056], in addition to a reduction in plasma lactate [10.4 to 6.6 mmol/L, p = 0.019]. No significant changes were observed in the severity of liver injury, portal pressure, portal vein flow, markers of cell death and systemic inflammation. The effects seen in BDL animals were validated in the CCL4 mouse model.

Conclusion: This study provides novel insights that directly targeting the endothelium can prevent circulatory and renal failure improving effective organ perfusion resulting in significant survival benefit in ACLF animal models. BMP9 is therefore, an attractive therapeutic strategy that should be explored in clinical trials.

Isolation and immortalization of human endothelial cells from the portal vein

Aina Anton[1,2,3], Genís Campreciós[1,2,3], Sarah Shalaby[1,3,4], Annabel Blasi[1,2,5], Yilliam Fundora[6], Rosa Montañés[1,3], Héctor García-Calderó[1,2,3], Juan Carlos García-Pagán[1,2,3,7], Virginia Hernández-Gea[1,2,3,7]. *[1]Fundació de recerca clínic Barcelona-Institut d'investigacions biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), Barcelona, Spain; [2]Centro de investigación biomédica red de enfermedades hepáticas y digestivas (CIBEREHD), Madrid, Spain; [3]Liver unit, Hospital Clínic, Health care provider of the european reference network on rare liver disorders (ERN-Liver), Barcelona, Spain; [4]Department of surgery, oncology, and gastroenterology, Padua University hospital, Health care provider of the european reference network on rare liver disorders (ERN-Liver), Padua, Italy; [5]Anesthesiology department, Hospital Clínic, Barcelona, Spain; [6]Department of surgery, division of hepatobiliary and general surgery, Institut de malalties digestives i metabòliques (IMDiM), Hospital Clínic, Barcelona, Spain; [7]Medicine department, Faculty of medicine, Universitat de Barcelona, Barcelona, Spain*
Email: anton@recerca.clinic.cat

Background and aims: Cirrhosis (CH) profoundly affects the portal venous system that frequently develops thrombosis (PVT). The exact mechanisms responsible for PVT development are not well understood and the contribution of endothelial cells (EC) to thrombosis, although well established in other vascular territories, remains unexplored in the portal vein, mainly due to its remote access. To the best of our knowledge portal vein EC (PVEC) have never been isolated and EC from other areas may not fully represent the splanchnic characteristics during CH. Moreover, for the study of PVT we lack suitable preclinical models (i.e., rodents do not develop PVT) challenging splanchnic vascular bed research in CH. The aim of our study is to generate a unique tool that can facilitate a more in-depth exploration of splanchnic vasculature diseases by isolating and immortalizing PVECs.

Method: 1) PVECs were isolated from human portal vein (PV) tissue obtained during hepatic transplantation. PV samples were trypsinized, scratched and cells detached from the inner wall were cultured until confluence. FACS sorting, based on CD31 and CD144 positive markers, was performed to select pure EC. Cells were expanded, characterized through functional assays (tub formation assay) and phenotypically analyzed using flow cytometry and immunofluorescence staining (CD31, CD144, eNOS and Von Willebrand markers). 2)

PVECs were immortalized (IM cells) with lentiviral particles expressing the SV40 large T-antigen containing the GFP-puromycin marker, selected and characterized as previously described.
Results: Human primary PVECs were successfully obtained from PV tissues, exhibiting a uniform morphology, forming monolayers that proliferate normally as plaques of small, tightly clustered cells. PVECs showed endothelial features, including positive staining for eNOS and vWF and demonstrated endothelial behavior by forming tubes in a matrigel matrix. PVECs were able to grow and expand until passage 6–9, when they started to gain a senescent phenotype -enlarged and multinucleated- and ceased growth. Compared to primary PVECs, IM cells exhibited a normal growth rate but could grow until passage 25–40. IM cells maintained a normal phenotype, expression of EC markers, and tube-forming capacity across all passages. Importantly, they did not exhibit a tumorigenic phenotype, as evidenced by the absence of colony formation in a soft agar assay.
Conclusion: For the first time, we successfully isolated PVEC utilizing an innovative strategy. Moreover, we have generated IM cell lines for physiopathological investigations and drug screening. This advance may deep our understanding of conditions like PVT, with treatment limited to anticoagulation-often falling to achieve complete recanalization-but also enhance our comprehension of vascular complications in liver diseases, paving the way for precise translational research.

WED-071
The association of hepatocyte large extracellular vesicles with plasma biomarkers levels improve prediction of mortality in patients with cirrhosis

Email: audrey.payance@gmail.com

Background and aims: Biomarkers and scores used to predict mortality in patients with decompensated cirrhosis are still imperfect tools. We identified 8 biomarkers reflecting tissues and processes altered in patients with decompensated cirrhosis. The aims of this study were to 1) evaluate features associated with circulating concentrations of these 8 biomarkers, 2) define a prognostic signature including some of these biomarkers and test its accuracy to predict mortality in patients with stable decompensated cirrhosis.
Method: All patients with cirrhosis undergoing liver catheterization at two centers were prospectively included (derivation cohort, n = 239; validation cohort n = 103). Circulating concentrations of hepatocyte large extravesicles (lEVs) and of 7 biomarkers derived from the kidneys (podocalyxin), gut (Villin), platelets (P-selectin), reflecting systemic inflammation (leukosialin, C-reactive protein and complement C6) and mitochondrial function (GPD2) were measured. Univariate and multivariate analyses were conducted using the Fine and Gray model with liver transplantation considered as a competing event.
Results: In the derivation cohort, 162 (68%) Child-Pugh score B or C cirrhosis. During the 6 months follow-up, 45 (19%) patients underwent liver transplantation and 16 (7%) patients died. Among the 8 biomarkers, circulating concentrations of hepatocyte lEVs, C-reactive protein, and Villin were significantly associated with features reflecting liver disease severity, i.e. Child-Pugh score, MELD and HVPG. We then focused on the 162 patients with Child-Pugh B or C cirrhosis to assess the predictive ability of the identified plasma biomarkers. We observed that plasma concentrations of hepatocyte lEVs, of CRP, and of Villin were associated with 6-month mortality by univariate analysis. Cut-off values of plasma biomarkers were identified using the Youden Index for CRP and Villin and a previously identified value for hepatocytes lEVs. Values above those cut-offs are thereafter referred to as "high-risk plasma biomarkers." Patients with one or more high-risk plasma biomarkers had a 6-month cumulative incidence of death higher than that of patients with no high-risk plasma biomarkers (19% vs. 2.8%, p = 0.007). This association with survival was independent from Child-Pugh score and MELD. When separating patients according to a threshold of MELD of 15, we observed that patients with one or more high-risk plasma biomarkers and MELD >15 were at higher risk for 6-month mortality than the other patients (27% vs. 4.5%; p = 0.004). Similar results were obtained in the validation cohort.
Conclusion: A signature including circulating concentrations of hepatocyte lEVs, C-reactive protein, and Villin combined with MELD, is able to identify a population of patients with cirrhosis at particularly high risk of 6-month mortality.

WED-074
The role of endothelial FoxO1 pathway in decompensated liver cirrhosis and acute-on-chronic liver failure

Fabian Schachteli[1], Yang Zhang[2,3], Sabine Klein[1,4], Maximilian Joseph Brol[1,4], Robert Schierwagen[1,4], Pia Lembeck[1], Sara Noemi Reinartz Groba[1], Wenyi Gu[1,4], Stefan Zeuzem[4], Jonel Trebicka[1,4,5], Michael Potente[2,3], Frank Erhard Uschner[1,4]. *[1]University Hospital Münster, Münster, Germany; [2]Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany; [3]Max Plank Institut for Heart and Lung Research, Bad Nauheim, Germany; [4]Hospital of the Goethe University Frankfurt, Frankfurt am Main, Germany; [5]European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain*
Email: frankerhard.uschner@ukmuenster.de

Background and aims: Endothelial dysfunction, in response to severe systemic inflammation, is majorly involved in the development of acute decompensation (AD) and Acute-on-Chronic Liver Failure (ACLF). The transcription factor Forkhead Box O1 (FoxO1) regulates the activity and growth of healthy endothelium as well as its stress response. The aim of this study was to investigate the role of FoxO1 signaling in human endothelial cells *in vitro* as well as in experimental and human liver cirrhosis and ACLF *in vivo*.
Method: Liver cirrhosis was induced in rats using bile duct ligation (BDL), CCl4 injections with Western diet (WD rats) or CCl4 injections with ethanol in drinking water (EtOH rats), and compared to healthy and sham operated animals respectively. Acute alcohol binge, lipopolysaccharide (LPS) i.p. injections, transnasal stool inoculation or cecal pole ligation and puncture were used for ACLF induction. FoxO1 signaling was analyzed in rat liver tissue and patient samples using cRNA microarray, Western Blot and qPCR. Human umbilical

vein endothelial cells (HUVECs) were treated with FoxO1 inhibitor AS1842856 or plasma of healthy patients, patients with AD or with ACLF to reproduce disease conditions *in vitro*. FoxO1 pathway expression and endothelial cell functional assays (apoptosis, senescence, quiescence, proliferation and angiogenesis) were performed after FoxO1 inhibitor or plasma incubation.
Results: Gene expression levels of FoxO1 pathway components, nuclear and cytoplasmic protein expression, as well as mRNA levels of FoxO1 and its downstream target MYC, were markedly reduced after ACLF induction in BDL, WD and EtOH rats. Similarly, FoxO1 signaling was downregulated in liver explants from patients undergoing liver transplantation with alcohol-related liver disease and ACLF. Thus, FoxO1 correlates with severity of experimental and human liver cirrhosis and ACLF *in vivo*. Incubation of HUVECs with AD plasma, mimicking systemic inflammation *in vitro*, decreased FoxO1 and MYC expression. Interestingly, FoxO1 downregulation was even more pronounced after incubation with ACLF plasma, thus reflecting the changes observed *in vivo*. Incubation with ACLF plasma and FoxO1 inhibitor AS1842856, however, not with plasma from AD patients, inhibited angiogenesis and proliferation without inducing apoptosis or autophagy in HUVECs.
Conclusion: Loss of FoxO1 expression and function is associated with experimental and human liver cirrhosis and ACLF. Furthermore, incubation with plasma of ACLF patients or pharmacological inhibition decreased FoxO1 expression *in vitro* and induced endothelial dysfunction. Therefore, the FoxO1 pathway seems to be crucial for the development of endothelial dysfunction in ACLF.

WED-075-YI
Exploring the immunomodulatory potential of TLR7/8 agonism in decompensated cirrhosis
Dimitrios Patseas[1], Roosey Sheth[2], Wing Yu Lee[1], Georgina Hagger[1], Eoin Mitchell[1], Francesca M Trovato[2], Cathrin L C Gudd[1], Lucia A Possamai[1], Mark R Thursz[1], Mark J W McPhail[2], Evangelos Triantafyllou[1]. [1]*Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom;* [2]*Department of Inflammation Biology, King's College London, London, United Kingdom*
Email: d.patseas@imperial.ac.uk

Background and aims: Immune dysfunction and bacterial infections are common in patients with acute decompensation (AD) of cirrhosis, contributing to high morbidity and mortality. This is more profound in those with accompanying organ-failure (acute-on-chronic liver failure; ACLF). Toll-like receptors (TLRs) recognize microbial-related factors such as LPS (via TLR4) or single-stranded RNA (via TLR7 and TLR8). TLR7 and 8 are expressed within the myeloid compartment and some of their ligands are currently considered in clinical trials as potential therapeutics. We utilized an ex-vivo whole blood culture setting to study the functional effects of TLR7, TLR8 or dual TLR7/8 agonism on AD/ACLF patient-derived monocytes and T cells.
Method: AD/ACLF patient (n = 13) and healthy control (HC; n = 13) derived whole blood was cultured overnight in the presence (5 ug/ml) of TLR7-L (R837), TLR8-L (ssRNA40/LyoVec), or TLR7/8-L (R848) in comparison to PBS. The effects of TLR agonism on immune function were evaluated by flow cytometry assays; apoptosis (Annexin-V/7-AAD stain) and intracellular cytokine production by monocytes and T cells following 4-hour whole blood stimulation with LPS (100 ng/ml) or PMA/ionomycin were measured. Monocyte phagocytosis of E. coli GFP+ bacteria was also evaluated.
Results: TLR7/8 (R848) dual agonism improved the E. coli uptake of monocytes in AD/ACLF patients (PBS:44.7% vs TLR7/8:65.3%, p = 0.001). Notably, individual TLR7 or TLR8 agonism did not exert a similar effect, whilst HC monocyte phagocytosis was not impacted by TLR treatment. PBS-treated patient monocytes produced less pro-inflammatory cytokines such as TNFa (HC:59.8% vs AD/ACLF:11.6%, p < 0.0001), IL-1β, IL-6, and more of IL-10 and OPN, in comparison to HC. We found that TLR7/8 dual agonism reduced OPN production by AD/ACLF monocytes (PBS:71.6% vs TLR7/8-L:46.8%, p = 0.0017) while an increased, non-significant, TNFa and IL-1β production by monocytes was observed. In addition, PBS-treated CD4+ T cells from patients produced less IL-4 (HC:69.4% vs AD/ACLF:8.85%, p = 0.0317) and more IL-2, in comparison to HC samples, and CD8+ T cells showed higher production of IL-4 (HC:60.85% vs AD/ACLF:84.6%, p = 0.0635) and TNFa (HC:45.3% vs AD/ACLF:59.2%, p = 0.0635). Overall, TLR7, 8 or 7/8 agonism did not alter T cell cytokine production, in both HC and AD/ACLF samples, nor impacted apoptosis of monocytes or T cells.
Conclusion: We demonstrate that TLR7/8 agonism improves the bacterial phagocytosis of AD/ACLF monocytes, while showing promise in augmenting their pro-inflammatory cytokines. Our findings suggest TLR7/8 agonism (using R848) as an immunomodulatory approach for improving monocytic function that could prove beneficial for AD/ACLF patients. Future ex vivo and in vivo studies will further evaluate this TLR-directed approach for improving antimicrobial responses in cirrhosis.

WED-076
Increased gut urease activity contributes to hyperammonemia and is a potential biomarker of disease severity in cirrhosis
Deepika Jakhar[1], Pinky Juneja[2], Aarti Sharma[2], Nishu Choudhary[2], Ashi Mittal[3], Shiv Kumar Sarin[2], Dinesh Mani Tripathi[3], Shvetank Sharma[2], Savneet Kaur[4]. Email: savykaur@gmail.com

Background and aims: Hyperammonemia is an important prognostic factor for liver related complications. Gut is one of the main source of endogenous ammonia and it is generated from urea by urease expressing bacteria. In view of the fact that gut microbiota undergoes profound changes, we hypothesised that higher gut urease bacteria is associated with increased gut ammonia production and hence hyperammonemia in cirrhosis.
Method: For experimental cirrhosis, 10 wk CCl4 rat model was prepared. Ammonia was measured in plasma and stool. Gut ammonia metabolism was studied. 16S rRNA gene sequencing analysis was done in stool samples to see gut microbiota. To ascertain role of gut urease bacteria in ammonia production, we gavaged representative live and attenuated urease producing bacteria, *Klebsiella pneumonia (Kp)* in bowel cleansed controls and cirrhotic rats for 7 days, and then studied ammonia metabolism and its levels in gut, stool and plasma. In clinical study, stool and plasma of healthy controls (n = 15) and cirrhotic patients (n = 32) were obtained and their normalized plasma ammonia and stool urease activity was studied.
Results: In cirrhotic rats, plasma ammonia (3.6 fold change (fc) p = 0.02), stool ammonia (1.5 fc p = 0.1) and stool urease (2 fc p = 0.05) activity were significantly increased as compared to controls. 16S rRNA analysis of stool samples showed reduced species diversity (p = 0.01) and evenness (p = 0.01) in cirrhotic rats as compared to controls. Taxonomic analysis revealed that abundance of *Lactobacillus acidophilus* (probiotic) was relatively reduced while that of *Kp* and *Prevotella* (pathogenic) was increased in cirrhotic animals as compared to controls. In gut microbiota replenishing studies, in controls, after bowel cleansing, rats given live *Kp* showed higher colon (4.3 fc p = 0.05), stool urease activity (3.8 fc p = 0.05) and increase stool ammonia (6000 ± 50 vs 4500 ± 50 ug/dl p = 0.08) than rats given attenuated bacteria. While, there was no change in plasma ammonia between two groups. In cirrhotic rats, given live urease bacteria, both colon, stool urease activity (4 fc and 4.5 fc p = 0.05 each) and plasma ammonia (2 fc p = 0.02) were increased as compared to those given attenuated *Kp*. In clinical study, normalized plasma ammonia (3 ± 0.5 vs 1 ± 0.2 p = 0.01) and stool urease activity (2.5 fc p = 0.009) was significantly higher in cirrhosis patients than healthy subjects. Both stool urease activity (2 fc p = 0.05) and normalized plasma ammonia levels (3.4 ± 0.5 vs 1.1 ± 0.1 p = 0.04) of CTP class C

was significantly higher than class A patients. There was however no significant direct correlation between stool urease activity with plasma ammonia in our patients.
Conclusion: Our experimental findings elucidate the role of gut microbial urease activity as a significant contributor of stool and plasma ammonia. Stool urease activity increases with severity of cirrhosis and indicates higher gut ammonia production.

WED-077
APASL-ACLF without previous decompensation is rare but immunological distinct from ACLF with previous decompensation in a european cohort
Mona-May Langer[1], Sabrina Guckenbiehl[2], Alina Bauschen[1], Gerald Denk[1], Christian M. Lange[1]. *[1]Department of Medicine II, University Hospital, LMU Munich, Munich, Germany; [2]Department for gastroenterology and hepatology, University hospital Essen, Essen, Germany*
Email: monamay.langer@med.uni-muenchen.de

Background and aims: Definitions of acute-on-chronic liver failure (ACLF) are heterogeneous. EASL-CLIF-definition focusses on extra-hepatic organ failures, whereas in APASL-definition the liver is the most important organ failure. More importantly, APASL-ACLF definition excludes patients with previous decompensation. In the present study, we provide an updated analysis of associations between the presence and absence of ACLF without/with previous decompensation and correlate these with inflammatory molecules, immune cell phenotyping, clinical parameters and outcome.
Method: 207 hospitalized patients with liver cirrhosis without or with ACLF were recruited from a prospective cohort study. 76 inflammatory molecules were quantified by proximity extension analysis assay (Olink, Uppsala, Sweden). Associations between inflammatory profiles and types of ACLF were determined. Moreover, surface expression profiles of immune cells were analyzed by flow cytometry.
Results: Of 207 patients, 126 had no ACLF at all, while 81 had any ACLF. Of patients with ACLF, 30 had ACLF exclusively based on the EASL-CLIF-definition. 17 patients had ACLF based on the APASL-definition without/with previous decompensation events. Of these patients, 9 have been decompensated before, while 8 have never been decompensated. Overall, patients who met the EASL-definition of ACLF showed signatures of substantial systemic inflammation. Discrimination of APASL-ACLF regarding previous decompensation event shows striking differences in inflammatory profiles of these patients compared to patients with AD or EASL-CLIF-ACLF. Patients with APASL-ACLF without previous decompensation show, among others, significant lover levels of NT-3, FGF-5 and IL-17. Patients with EASL- or APASL-ACLF-definition show significant decreased frequencies of $CD8^+$ T cells in peripheral blood (APASL-ACLF 7%, CLIF-ACLF 16%) compared to healthy donors (36%) and AD (26%). Moreover, the frequency of specific surface markers on T cells are significantly decreased in APASL-ACLF (46%) compared to healthy donors (90%, $p = 0.4$) or AD (92%, $p = 0.2$), leading to presumption of senescent T cell subpopulations in the blood of these patients.
Conclusion: Not only do patients with APASL- versus EASL-CLIF-ACLF show distinct inflammatory profiles, but moreover inflammatory profiles of patients fulfilling APASL-ACLF without vs. with previous decompensation differ significantly. The changes in surface expression of T cells may point towards distinct pathophysiological mechanisms in different types of ACLF.

WED-078
Systemic albumin administration improves the gut microbiome and intestinal permeability in animal models of cirrhosis and ACLF
Alexandra Phillips[1], Yi Jin[2], Florian Rosenberger[3], Qianwen Zhao[1], Abeba Habtesion[1], Fausto Andreola[1], Nathan Davies[1], Frederick Clasen[4], Lindsey Edwards[5,6], Jane Macnaughtan[1], Sabine Klein[7], Jonel Trebicka[7], Saeed Shoaie[8], Matthias Mann[3], Rajiv Jalan[1]. *[1]Institute of Liver and Digestive Health, University College London, London, United Kingdom; [2]Centre for Host-Microbiome Interactions, King's College London, London, United Kingdom; [3]Department of Proteomics and Signal Transduction, Max Planck Institute of Biochemistry, Munich, Germany; [4]Cancer Metabolism Laboratory, The Francis Crick Institute, London, United Kingdom; [5]Centre for Host Microbiome Interactions, King's College London, Faculty of Dentistry, Oral and Craniofacial Sciences, London, United Kingdom; [6]Institute of Liver Studies, King's College London, Department of Inflammation Biology, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, London, United Kingdom; [7]Department of Internal Medicine, University of Munster, Munster, Germany; [8]Centre for Host Microbiome Interactions, Kings College London, London, United Kingdom*
Email: alexandra.phillips5@nhs.net

Background and aims: Gut dysbiosis impacts negatively on gut permeability, bacterial translocation and endotoxemia, which is a target of therapy in patients with decompensated cirrhosis. Long term albumin administration in cirrhosis patients reduces endotoxemia, modulates inflammatory response and improves survival. This study was designed to test the hypothesis that albumin modulates the composition of the gut microbiome and permeability. We also tested whether the administered albumin could cross into the gut lumen.
Method: Cirrhosis induced in 70 rats by 4-week bile duct ligation (BDL) and acute-on-chronic liver failure (ACLF) model induced by lipopolysaccharide (LPS) 0.025 mg/kg intraperitoneal injection (ip) to BDL model. Human albumin 20% administered (1.5 g/kg ip; 2-week) to cirrhosis and ACLF models in analbuminaemic (NAR) and wild-type (WT) rats. Caecal stool 16 s PCR analysis of microbiome and mass spectrometry analysis for gut proteome of ileal, caecal and left colon stool. Plasma biochemistry and cytokines were measured. Plasma D-lactate was used as a measure of gut permeability.
Results: The absence of endogenous albumin in NAR rats was associated with significant differences of 3 operational taxonomic unit (OTUs) in healthy rats. Albumin infusion in NAR rats restored these OTUs to that observed in wild-type (WT) rats. In both WT and NAR cirrhotic rats, 20 and 25 OTUs were different compared with their sham controls. Treatment of both WT and NAR rats with albumin ameliorated the differential abundance seen in cirrhosis. Proteomic analysis of stool detected *human albumin* in the gut of albumin-treated animals, with the highest levels in the left colon. Otherwise, albumin treatment did not change the proteome. The highest number of significant changes in proteins following albumin treatment was seen in ACLF models of WT rats, where proteomic differences were associated with pathways of precursor metabolites, energy generation, and protein digestion and absorption. These microbiome changes in human albumin-replete rats were associated with preserved gut permeability, reduced systemic inflammation, severity of liver injury and survival in the ACLF animals.
Conclusion: The results of this study show for the first time the importance of albumin in maintaining the health of the gut microbiome. The detection of administered human albumin in the rat colonic lumen suggests that this effect of albumin may at least partially be mediated by the action of administered albumin directly in the colonic lumen. These novel data allow development of potential new therapeutic uses of albumin.

WED-080
Hepatic inflammation-senescence-regeneration gene expression during recovery from ACLF and the effect of granulocyte-colony stimulating factor (GCSF), toll-like receptor-4 (TAK-242) inhibition and their combination (G-TAK)
MohammadMahdi Saeidinejad[1], Daniel Shaw[2], Cornelius Engelmann[3,4], Abeba Habtesion[4], Fausto Andreola[4], Rajiv Jalan[4,5]. *[1]Liver failure Group, Institute for Liver and Digestive*

Health, Division of Medicine, London, United Kingdom; [2]Institute for Liver and Digestive Health, Division of Medicine, London, United Kingdom; [3]Medical Department, Division of Hepatology and Gastroenterology, Berlin, Germany; [4]Liver failure Group, Institute for Liver and Digestive Health, Division of Medicine, London, United Kingdom; [5]European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain
Email: mohammad.saeidinejad@nhs.net

Background and aims: Failure of hepatic regeneration in acute-on-chronic liver failure (ACLF) is pathophysiologically related to inflammation and hepatocyte senescence but how these evolve during recovery from ACLF is unknown. Toll-like receptor-4 antagonist (TAK242) with or without GCSF (G-TAK), improves survival of animal models. The aims of this study were to explore the inflammation-senescence-regeneration gene expression in animals that survived an episode of ACLF with or without treatment.
Method: Six groups of animals were studied: Control (vehicle), carbon tetrachloride (CCL4 0.5 mg/ml, 0.5 ml/kg twice weekly for 6 weeks) (cirrhosis), CCL4+ Lipoploysaccharide (LPS, 6.25 µg/µl, 4 mg/kg i.p) (ACLF), CCL4+LPS+GCSF, CCL4+LPS+TAK242, and CCL4+LPS+G-TAK. Of the 86 mice in the study, 24 mice (4/group), surviving 5-days were studied. Liver samples were then assessed at the NanoString nCounter laboratory for expression of genes in the metabolic pathways panel and analysed using NanoString Software.
Results: 5-day survival was 100% except for the mice treated with G-CSF (mortality-66%). Within 24 hours, LPS injection led to significant liver and renal injury (mean ALT >1500 U/L, creatinine >30 µmol/L in CCL4+LPS mice), which was prevented by TAK242 and G-TAK. By day-5, ALT and creatinine normalised and were similar in all groups. TLR signalling: In animals recovering spontaneously, hepatic TLR signalling pathway remained upregulated; in those treated with GCSF alone this was further accentuated but in those treated with TAK-242 or GCSF+TAK-242, this was normalised. Chemokine and cytokine signalling pathways (Ccl5 and 9) were similar. Senescence: G-CSF increased p53 gene expression. Treatment with TAK242, or G-TAK, downregulated p53 pathway compared to ACLF mice recovering spontaneously. Regeneration: Spontaneous recovery and TAK-242, in terms of pro- and anti-regeneration genes was not different to control. G-TAK significantly augmented proliferation and cell survival genes as evidenced by the increase in expression of Cyclin A2, Cyclin D1, Ki67, and STAT3.
Conclusion: The results of this study show for the first-time that despite spontaneous recovery from liver and renal injury in ACLF, pathways involved in inflammation through TLR signalling and senescence remain elevated leaving animals prone to future episodes of decompensation and ACLF. Treatment with TAK242 with or without G-CSF downregulates senescence pathways but only G-TAK improved regeneration. These data indicate that G-TAK may reduce the risk of future decompensation and ACLF.

WED-081

Carvedilol decreases hepatic vascular resistance in cirrhosis by deactivating hepatic stellate cells (HSC) and improving liver sinusoidal endothelial cells (LSEC) dysfunction, resulting in decreased liver fibrosis and improved nitric oxide release

Yeldos Nulan[1,2,3], Eric Felli[2,3], Cong Wang[2,3], Sonia Emilia Selicean[2,3], Annalisa Berzigotti[2,3], Jordi Gracia-Sancho[2,3,4], Jaime Bosch[2,3].

Email: jaime.bosch@unibe.ch

Background and aims: Portal hypertension (PH) in cirrhosis results primarily from increased hepatic vascular resistance, promoted by structural changes (architectural remodeling, parenchymal extinction, fibrosis and nodular regeneration) and increased hepatic vascular tone (endothelial dysfunction with decreased availability of nitric oxide-NO, and increased production and sensitivity to vasoconstrictors). Later on, PH is aggravated by extrahepatic circulatory abnormalities. Non-selective-beta-blockers (NSBBs) are the mainstream of medical therapy, reduce PH by decreasing the cardiac output and splanchnic blood flow. Carvedilol, a new generation NSBB with anti-alpha1-adrenergic activity, causes a greater fall in portal pressure than traditional NSBBs and is better tolerated. Carvedilol is thought to decrease the hepatic vascular tone, but its effects on the determinants of hepatic vascular resistance in cirrhosis have not been well characterized. In this study we analyze the effects of carvedilol on the HSCs and endothelial cells function in vitro, as well as on liver fibrosis and hepatic hemodynamics after in vivo administration to cirrhotic rats.
Method: *In vitro*: LSECs and HSCs were isolated from cirrhotic rats (ip thioacetamide for 12 weeks) and then cultured with 10 µM Carvedilol/vehicle for 24 hours. Endothelial function was assayed by immunocytochemistry (DAF-FM NO assay) in human umbilical vein endothelial cells (HUVECs) and cirrhotic LSECs. Cell contraction assays were performed in human hepatic stellate cell line (LX2) and cirrhotic HSCs. (n = 3–5 per condition).
In vivo: hepatic hemodynamic studies were performed in thioacetamide cirrhotic rats treated with carvedilol (10 mg/kg/day, p.o.) or vehicle for 2 weeks (n = 14 per group). Hepatic remodeling was assessed in collagen-stained sections by calculating the collagen proportionate area (CPA), and HSC activation by immunofluorescence of alpha-smooth muscle actin (αSMA) in liver sections.
Results: NO release was significantly increased in carvedilol vs vehicle in HUVECs and in cirrhotic LSECs, by 2 and 2.2 fold-change respectively. Carvedilol significantly reduced cell contraction in LX2 and HSCs, by 32% and 48% respectively vs vehicle. Oral administration of carvedilol in cirrhotic rats significantly reduced portal pressure by 27.1% and decreased CPA and αSMA positive area in liver tissue slides, by −29.8% and −32.1% respectively vs vehicle (all $p < 0.01$).
Conclusion: These results suggest that carvedilol improves portal hypertension in liver cirrhosis not only by its systemic hemodynamic effects, but also by its intrahepatic effects ameliorating HSCs function with ensuing reduction of liver fibrosis, and by counteracting LSECs dysfunction, leading to increased hepatic NO delivery and decreased hepatic vascular tone.

WED-082

Multifactorial modulation of the endothelial transcription factor ERG in chronic liver disease

Sonia Selicean[1,2,3], Eric Felli[2,3], Cong Wang[1,2,3], Yeldos Nulan[1,2,3], Horia Ștefănescu[4], Jaime Bosch[2,3], Annalisa Berzigotti[2,3], Jordi Gracia-Sancho[2,3,5].

Email: jgracia@recerca.clinic.cat

Background and aims: Chronic liver disease (CLD) is characterized by profound dysfunction of liver sinusoidal endothelial cells (LSECs). The escalation of matrix stiffness during fibrosis progression predisposes LSECs to adopt a proinflammatory phenotype. Despite recent significant advances in the mechanobiology of CLD, the impact of stiffness and inflammation on the regulation of transcription factors remains unclear. The ETS-related gene (ERG) is a well-known endothelial-specific transcription factor involved in maintaining endothelial cell quiescence and homeostasis in the post-developmental phase of adult vasculature. Recent findings have implicated ERG in lung and liver disease, demonstrating its role in preventing

endothelial-to-mesenchymal transition. However, the effects of stiffness and inflammation on ERG expression in LSECs during CLD is not well understood. This study aims to elucidate the potential role ERG as mechanosensitive transcription factor in the context of CLD.
Method: ERG knockdown RNA sequencing data were retrieved from the Gene Expression Omnibus database. Functional enrichment was conducted using GSEA and Panther. ERG expression was assessed in human liver tissue slides obtained from two cohorts of patients (n = 11 healthy vs 41 CLD). Cirrhotic rat models were developed in male rats through chronic carbon tetrachloride (CCl4) inhalation (10 weeks) or i.p. thioacetamide (TAA) (12 weeks). Freshly isolated LSECs from healthy or cirrhotic rats, as well as human umbilical vein endothelial cells (HUVEC), were cultured on polyacrylamide substrates with low (0.5 kPa) and high stiffness (30 kPa). Interleukin 1β (IL1β) was employed as an in vitro inflammatory stimulus (n = 3–5 independent experiment per condition).
Results: Gene set enrichment analysis revealed that loss of ERG has a major influence on the upregulation of inflammatory pathways and in integrin signaling. ERG expression was significantly downregulated in liver samples from patients with cirrhosis compared to healthy (−53%, $p < 0.01$), irrespective of disease stage or aetiology. Endothelial ERG expression, sensitive to substrate stiffness (−69% at 30 kPa vs 0.5 kPa; $p < 0.001$), faced additional downregulation by inflammation at physiological stiffness (−36% control vs IL1β at 0.5 kPa; $p = 0.03$). Interestingly, no synergistic effect between stiffness and inflammation was noted. In cirrhotic rat liver, ERG displayed a −20% downregulation vs healthy ($p = 0.02$), followed by recovery in the regression phase.
Conclusion: ERG downregulation by stiffness and inflammation, without a synergistic effect, implies their complementary and sequential role in suppressing ERG, aligning with CLD's pathophysiology. Our findings emphasize ERG as a responsive transcription factor to inflammation and mechanical cues, confirming its downregulation in the dysfunctional LSEC phenotype in CLD.

WED-083
Multi-compartment metabolomics for stratifying cirrhotic patients with acute decompensation

Email: christophe.junot@cea.fr

Background and aims: Acute decompensation (AD) of cirrhosis and its progression to acute-on-chronic liver failure (ACLF) are associated with intense systemic inflammation, multiple organ dysfunctions, and a major risk of short-term mortality. There is a need to develop tools to stratify patients in order to improve their management and reduce the mortality observed in decompensated patients and ACLF. Metabolomics has already been proved to its relevance to the field with the identification of a 38-metabolite blood fingerprint specific for ACLF whose intensity correlates with systemic inflammation and which revealed mitochondrial dysfunction in peripheral organs (Moreau R et al., J. Hepatol., 2020). Here, the aims are to evaluate (i) the added value of investigating urine and feces compartments for improving the description of the metabolite landscape in cirrhotic patients with decompensations, (ii) the ability of multi-matrix metabolomics to improve the stratification of patients with decompensated cirrhosis.
Method: We performed untargeted metabolomics using liquid chromatography coupled to high-resolution mass spectrometry from serum, urine and stool samples of the MUCOSA-PREDICT cohort, which deals with the longitudinal follow-up of 93 cirrhotic patients with acute decompensation (300 samples for each biological matrix).
Results: A total of 402 metabolites were detected and identified in the three biological matrices. A greater number of metabolites were detected in urine (326 metabolites) and fecal (314 metabolites) samples compared to serum (222 metabolites) samples, whereas 162 metabolites are shared within the 3 biological matrices. Our results show that metabolomic signatures of ACLF can be drawn from serum, fecal and urinary samples of the MUCOSA-PREDICT cohort. Twenty-five metabolites out of the 38-metabolite blood fingerprint specific for ACLF previously established (Moreau R. et al., J Hepatol, 2020) were detected and had similar concentration trends (i.e., 65% of the fingerprint). The greatest number of metabolites whose concentrations are impacted by ACLF is observed in serum samples. Interestingly, some urinary and fecal metabolites not detected in serum also have their concentrations impacted by ACLF. However, ROC curve analyses performed for the metabolomics signatures in individual or combined matrices indicated that the best performance in terms of discrimination between AD and ACLF is obtained with the serum signature.
Conclusion: Blood, but also urine and fecal metabolomic signatures can discriminate between AD patients having or not ACLF. Although the three compartments provide complementary metabolic information, data obtained from the blood compartment enabled the best stratification performances.

WED-086
Nicotinamide riboside supplementation improves bacterial clearance and mitigates fibrosis in animal model of cirrhosis

Nidhi Nautiyal[1,2], Deepanshu Maheshwari[3], Sandeep Kumar[1], Manisha Bhardwaj[4], Sunidhi Diwakar[1], Shivi Chauhan[5], Jaswinder Maras[1], Anupama Kumari[1], Subhrajit Biswas[6], Chhagan Bihari[1], Shiv Kumar Sarin[1], Anupam Kumar[1]. *[1]Institute of Liver and Biliary Sciences, Delhi, India; [2]Amity Institute of Molecular Medicine and Stem Cell Research, Amity University, NOIDA, Uttar Pradesh, India; [3]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [4]Institute of Liver and Biliary Scineces, Delhi, India; [5]Institute of Liver and Biliary SCiences, Delhi,*

India; [6]Amity Institute of Molecular Medicine and Stem Cell Research, Amity University, NOIDA, India
Email: nidhinautiyal113@gmail.com

Background and aims: Poor liver clearance of invading intestinal/systemic bacteria are one of the major hallmarks of cirrhosis. The underlying cause of bacterial translocation in cirrhosis is not well established. In this study, we examined the kinetic changes in protein landscape and investigated whether Nicotinamide Riboside (NR) supplementation can improve the bacterial clearance in animal models of cirrhosis, explored the underlying mechanism.
Method: C57BL/6 (J) mice were used to develop chronic liver injury through intraperitoneal injections of carbon tetrachloride (0.1–0.5 ml/kg) for 15 weeks (W) and studied at specific time points for quantitative liver proteome using LC-MS. NR supplemented in animals (3 mg/ml) and mice bone marrow derived macrophages (BMDM, 2 mM) for 7 days and studied.
Results: Histopathology of liver showed progressive increase in chronic liver injury (steatosis (W3), fibrosis (W6), compensated cirrhosis (W10) and decompensated cirrhosis (W15)). Proteome analysis of liver tissue showed defect in NAD metabolism and cellular bioenergetics in transition from healthy to W3, followed by increase in bacterial response, inflammation and ECM accumulation from W3 to W10 with further increase in apoptosis and cell-cycle arrest from W10-W15. Further analysis of liver tissue showed significant reduction in NAD level in both cirrhosis animal ($p = 0.0065$) and human ($p = 0.0084$) liver tissue. Prolonged LPS treatment reduced NAD level ($p = 0.0063$), mitochondrial respiration ($p < 0.0001$) and phagocytic function of BMDM ($p = 0079$). This was mitigated with NR supplementation with improved mitochondrial respiration ($p = 0.0003$) and phagocytic activity ($p = 0.0079$). In-vivo supplementation of NR showed improved OXPHOS and Glycolysis in BMDM. It also increases the phagocytic function of BMDM ($p = 0.0084$) as well as Liver macrophages ($p < 0.0001$). In comparison to cirrhosis, NR showed improved in-vivo bacterial clearance. Further analysis of liver tissue showed reduction in fibrosis (Massons trichrome, $p = 0.0004$). Both in-vivo and in-vitro data suggested that NR improves the health of BMDM by improving their energy metabolism and effective clearance of bacteria by increasing their phagocytic activity.
Conclusion: Early dysfunction of NAD metabolism and cellar bioenergetics in liver cells may contribute to loss of liver macrophages mediated bacterial clearance during chronic liver injury. NR supplementation augments energy metabolism and bacterial clearance of resident macrophages.

WED-087
Exploring the potential of human serum albumin to reprogram B cell function

Berta Romero-Grimaldo[1,2,3], Mireia Casulleras[1,2,3], Marta Duran-Güell[1,2,3], Bryan J. Contreras[1,2,3], Javier Fernández[3,4], Vicente Arroyo[3], Richard Moreau[3], Cristina López-Vicario[1,2,3], Joan Clària[1,2,3,5]. *[1]Biochemistry and Molecular Genetics Service-Hospital Clínic, Barcelona, Spain; [2]Hospital Clínic-IDIBAPS and CIBERehd, Barcelona, Spain; [3]European Foundation for the Study of Chronic Liver Failure (EF CLIF) and Grifols Chair, Barcelona, Spain; [4]Liver Unit-Hospital Clínic, Barcelona, Spain; [5]Department of Biomedical Sciences of University of Barcelona, Barcelona, Spain*
Email: romerog@recerca.clinic.cat

Background and aims: Recent randomized clinical trials have demonstrated that immunocompromised patients with acutely decompensated (AD) cirrhosis receiving albumin infusions have lower incidence of infections than patients receiving standard medical therapy. In the current study, we explored the potential actions of albumin on the production of immunoglobulins by B cells, an essential host defense response to microorganisms.
Method: B cell immunophenotyping was performed by flow cytometry in peripheral blood from patients with AD cirrhosis and healthy subjects. In vitro studies were performed in peripheral blood mononuclear cells (PBMCs) isolated by ficoll and B cells isolated by magnetic-activated cell sorting incubated with human serum albumin (15 mg/ml) or vehicle for increasing periods of time (from 24 to 72 hours). In some experiments, cells were stimulated with T-dependent or T-independent stimuli. Immunoglobulin levels in plasma and cell supernatants were assessed by nephelometry and enzyme-linked immunosorbent assay (ELISA), respectively. mRNA expression was determined by FLUIDIGIM technology and conventional real-time PCR.
Results: The systemic adaptive immune cell landscape of patients with AD cirrhosis was characterized by a profound suppression of the B cell compartment. These patients also showed a notable dysregulation in the circulating levels of IgM, IgG, and IgA, an alteration that was more evident in female patients. PBMCs isolated from patients with AD cirrhosis showed lower capacity to produce immunoglobulins under both unstimulated conditions and following T-dependent and T-independent stimulation than PBMCs from healthy subjects. Incubation of PBMCs with albumin significantly increased IgG production and the IgG/IgM ratio, an observation that was confirmed in isolated B cells and was independent of the gender of the blood donor. The increase in IgG levels was the result of the gain of the IgG2 subtype, which responds to bacterial capsular polysaccharide antigens. Consistent with these findings, albumin induced a significant upregulation of immunoglobulin-related genes. Notably, albumin upregulated the expression of activation-induced cytidine deaminase (AID), a key enzyme for class switch recombination and somatic hypermutation, which are crucial processes for the humoral responses of adaptive immunity.
Conclusion: These data provide direct evidence of the ability of albumin to reprogram B cell function and to boost the production of immunoglobulins by these adaptive immune cells. This observation might contribute to explain why long-term albumin infusions are associated with lower incidence of infections.

WED-088-YI
Enhancing infection diagnostics and antimicrobial resistance detection in cirrhosis: a clinical metagenomics approach for blood culture assessment

Merianne Mohamad[1,2], Veena Ramachandran[3], Dhaarica Jeyanesan[3], Marilena Stamouli[1,2], Jack Wright[3], Themoula Charalampous[4], Kyle Leung[1,2], Ane Zamalloa[3], Tasneem Pirani[2,3,5], Vishal C Patel[1,2,3]. *[1]The Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [2]School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom; [3]Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom; [4]Centre for Clinical Infection and Diagnostics Research, Department of Infectious Diseases, School of Immunology and Microbial Sciences, King's College London, London, United Kingdom; [5]Liver Intensive Therapy Unit, King's College Hospital NHS Foundation Trust, London, United Kingdom*
Email: m.mohamad@researchinliver.org.uk

Background and aims: The adverse consequences of increasing rates of antimicrobial resistance (AMR) in cirrhosis patients, coupled with suboptimal and delayed infection detection, persistently impact outcomes and mortality (Fernandez et al., 2019). Harnessing antibiotic efficacy depends on promptly and precisely identifying the causative bacterial and fungal pathogens and their AMR profiles (Patel and Williams, 2020). This study seeks to assess the utility of clinical metagenomics (CMg) for rapidly identifying pathogens and profiling AMR genes in positive blood culture (+BC) samples from

hospitalised cirrhosis patients, in comparison to standard microbiological testing (SMT).
Method: +BC samples identified as positive through SMT were obtained from acutely decompensated cirrhosis patients with a strong clinical suspicion of infection. Oxford Nanopore MinION platform and optimised protocols were employed for CMg sequencing. The accuracy and speed of pathogen identification and AMR profiling were evaluated by comparing CMg data with SMT results. The results were not shared with clinicians for decision-making purposes.
Results: 19 +BC samples obtained from 16 cirrhosis patients were subjected to CMg sequencing and SMT. The time required for reporting AMR profiling through CMg ranged from 10–16 hours from BC positivity, contrasting with an average of 72 hours for SMT. In all 19 samples, CMg results demonstrated concordance with both the bacterial and fungal species identified by SMT. Moreover, CMg detected an additional pathogen in two of the samples. CMg AMR profiling matched resistance phenotypes reported by SMT in 52.6% (10/19) of cases, while in the remaining 9 samples, CMg results diverged from SMT. In 6 samples, CMg identified AMR determinants that conferred resistance to clinically prescribed antibiotics, contradicting SMT, which classified these pathogens as fully sensitive. In 3 samples, CMg failed to detect AMR genes or mutations associated with resistance phenotypes reported by SMT, suggesting a distinct phenotypic resistance profile. In 1 case, CMg revealed genes conferring resistance to aminoglycosides, macrolides, and tetracyclines, which were not reported by SMT.
Conclusion: These initial findings indicate that CMg pathogen detection align with SMT and could offer more precise and rapid identification. Implementing CMg as an adjunct to SMT may improve the ability to more rapidly diagnose bloodstream infections in cirrhosis. Nevertheless, additional research is required to explore the disparities in AMR profiles between the approaches given their inherent differences (genotype versus phenotype), evaluate cost implications and feasibility within healthcare settings, and assess the impact on clinical outcomes.

Email: vlad.taru@meduniwien.ac.at

Background and aims: Acute-on-chronic liver failure (ACLF) is defined as hepatic and extrahepatic organ failure (s) and often triggered by infections. A systemic proinflammatory state and high short-term mortality are important hallmarks of ACLF. We aimed to develop and characterize a representative rat model of ACLF.
Method: Cirrhosis was induced in 18 male Sprague-Dawley rats (10 weeks old) by repeated i.p. of carbon tetrachloride (CCL4, 0.3 ml/kg)- or olive-oil (Healthy control, HC) 3x/week for 12 weeks. ACLF was induced by a single i.p. injections of lipopolysaccharide (LPS, E. coli O111:B4, 1 mg/kg) 3 hours prior to hemodynamic characterization (portal pressure, PP; mean arterial pressure, MAP) and organ/blood harvesting. The following groups were examined: HC (n = 3), HC+LPS (n = 3), CCL4 (n = 6), and CCL4+LPS (n = 6). Collagen proportionate area (CPA) was quantified on picro-sirius red (PSR)-stained full liver lobe scans. Gene expression and plasma protein expression were quantified by RT-qPCR of bulk liver tissue (expressed as log10-fold change) and ELISA. Results are expressed as mean ± SD and significance level was set at $p < 0.05$.
Results: Body weight was similar across the different animal groups after 12 weeks ($p = 0.25$). The CCL4 animals showed a trend towards higher PP (9.4 ± 1.7 vs. 7.4 ± 0.3 mmHg, $p = 0.184$ and higher liver fibrosis (CPA: 3.3 ± 1.2 vs. 1.7 ± 0.8%, $p = 0.059$) compared to HC. The CCL4+LPS animals had lower MAP (52.9 ± 18.1 vs. 78.4 ± 8.9 mmHg, $p = 0.019$) and higher HR (410 ± 51.2 vs. 376 ± 18.6 bpm, $p = 0.188$) compared to the CCL4 group, while PP was not significantly different (10.9 ± 3.9 vs. 9.4 ± 1.7 mmHg, $p = 0.462$). Blood lactate levels were significantly elevated in CCl4+LPS animals (7.8 ± 2.8 vs. 2.8 ± 1.3 mmol/L, $p = 0.005$) indicating circulatory failure. Hepatic gene expression analysis revealed significantly increased IL-1beta (1.86 ± 0.27), IL-6 (3.5 ± 0.27), TNF-alpha (2.1 ± 0.30), MCP1 (2.46 ± 0.28) and IL-10 (0.89 ± 0.21) mRNA levels in CCl4+LPS (all $p < 0.001$ vs. CCl4). The plasma levels of IL-1beta (4093 ± 2111 vs. 33 ± 7 pg/ml; $p = 0.031$), IL-6 (12142 ± 6206 vs. 77 ± 67 pg/ml; $p = 0.030$), TNF-alpha (2935 ± 2001 vs. 42 ± 67 pg/ml; $p = 0.028$), MCP1 (219.2 ± 29.2 vs. 2.5 ± 1.1 ng/ml; $p < 0.001$) and IL-10 (2391 ± 756 vs. 74 ± 29 pg/ml; $p = 0.009$) were significantly elevated in the CCl4+LPS as compared to the CCl4 group. Blood biochemistries suggested renal dysfunction (creatinine: 1.41 ± 0.25 vs. 0.92 ± 0.12 mg/dL; $p = 0.008$) and hepatic injury/liver dysfunction (AST: 1341 ± 491 vs. 635 ± 355 UI/L, $p = 0.031$; ALT: 894 ± 394 vs. 515 ± 513 UI/L, $p = 0.228$; glucose: 59 ± 56 vs. 176 ± 21 mg/dL, $p = 0.003$) in CCl4+LPS vs. CCl4, respectively.
Conclusion: Our rat model induced by CCl4+LPS resembled key features of the ACLF syndrome with high-grade hepatic and systemic inflammation, circulatory, kidney, and liver dysfunction and failure. These features qualify this rat ACLF model for preclinical drug research.

Developing a discovery platform for engineered macrophage cell therapies for end stage liver disease
Niya Aleksieva[1], Kayleigh Thirlwell[1], Philip Starkey Lewis[1], Mark Cant[1], Moony Su[1], Hollie Bartley[1], Alejandro Armesilla Diaz[1], Amol Ketkar[1], Benjamin J Dwyer[2], John Campbell[1], Stuart J Forbes[1,3], Lara Campana[1]. *[1]Resolution Therapeutics, Edinburgh, United Kingdom; [2]Curtis University, Perth, Australia; [3]University of Edinburgh, Edinburgh, United Kingdom*
Email: lara.campana@resolution-tx.com

Background and aims: Patients with end-stage liver disease (ESLD) have extensive fibrosis and inflammation, which result in loss of organ function leading to decompensation events, and limited life expectancy. Incidence and prevalence of ESLD is projected to increase in western countries, and currently there are no licensed therapies to treat ESLD. Macrophages play a pivotal role in fibrosis remodeling, dampening the inflammatory response, and in coordinating liver regeneration. Autologous non-engineered macrophages have been tested in patients with cirrhosis in the MATCH clinical studies ("MATCH cells"), displaying an excellent safety profile and significant efficacy with a significant reduction of all-cause mortality one-year post-treatment in a population of patients with liver cirrhosis and baseline MELD score 10–16.
Method: Further enhancement of the pro-regenerative profile of the native macrophage therapy is needed to provide a long-term solution for a more severe patient population with ESLD. To achieve this, a

novel, genetically engineered autologous macrophage is under development. To support the development of such a product, three key technological advancements are necessary, namely: (i) an improved differentiation protocol to maximise yields without compromising phenotype (no significant changes in surface expression levels of 25F9, CD206, CD163, CD169 *vs* MATCH); (ii) a robust engineering method to allow for overexpression of candidate therapeutic genes; (iii) a cryopreservation method which allows administration of multiple doses from a single leukapheresis collection.

Results: Herein, we show results from the optimisation of a culture protocol that delivers increased yields (average increase 10% over previous method); we also report the definition of an engineering method based on transfection delivering high transfection efficiency (>80%) without affecting cell viability (>70%). Finally, we defined a cryopreservation method based on progressive temperature lowering as best to ensure macrophage viability and function post-thawing (viability ≥70% and maintenance of ability to phagocytose beads coated with bacterial particles).

Conclusion: Resolution Therapeutics has established a reliable discovery platform to differentiate, engineer and cryopreserve macrophages for therapeutic use in patients with ESLD. Further studies will determine what genes are best suited to enhance macrophage efficacy in this clinical setting.

Hyperuricemia leads to early cognitive dysfunction and neuronal cell injury in bile-duct ligated rats

Sydnée L'écuyer[1,2], Maximilian Steger[3], Farzaneh Tamnanloo[4], Mariana M. Oliveira[4], Mélanie Tremblay[4], Emmanuel Charbonney[5,6], Christopher F. Rose[4,6]. *[1]Hepato-Neuro Lab, CRCHUM, Montreal, Canada; [2]Department of Pharmacology and Physiology, Université de Montréal, Montréal, Canada; [3]University of Applied Sciences Weihenstephan-Triesdorf, Munich, Germany; [4]Hepato-Neuro Lab, CRCHUM, Montréal, Canada; [5]Intensive Care Unit, CHUM, Montréal, Canada; [6]Department of Medicine, Université de Montréal, Montréal, Canada*
Email: christopher.rose@umontreal.ca

Background and aims: Hyperammonemia plays a major role in the pathogenesis of hepatic encephalopathy (HE). However, other factors may be involved in cognitive dysfunction in patients with chronic liver disease (CLD). Hyperuricemia, an increase in plasmatic uric acid (UA), arises with excessive alcohol and fructose consumption, both factors known to contribute to the onset of CLD. Hyperuricemia has been demonstrated to be associated the progression of liver steatosis and fibrosis as well as negatively impacting cognitive function. We investigated the impact of hyperuricemia on neurological dysfunction and brain integrity in a rat model of CLD with HE.

Method: In Sprague-Dawley rats, CLD was induced following bile-duct ligation (BDL) for 5 weeks, with SHAM-operated rats as controls. To induce hyperuricemia, rats were fed a diet containing 3% UA (HUAD) compared to regular diet (RD). Fifty-six male rats were randomly assigned to 1 of 4 experimental groups: (1) SHAM+RD, (2) SHAM+HUAD, (3) BDL+RD et (4) BDL+HUAD. Behavioural assessment for anxiety (Open-Field and Elevated Plus-Maze) and memory (New-Object Recognition) was performed at day 14 to evaluate for early cognitive impairments. At day 33, animals were sacrificed, to measure plasma UA and liver injury markers. Liver was collected for histological analysis (HandE and Sirius Red staining). The frontal cortex, amygdala and hippocampus were isolated to measure apoptosis (caspase-8, 9 and 3) and neuronal loss (NeuN and SMI311) by Western Blot and immunohistochemistry. All statistical analysis used a one-way ANOVA with Tukey's or Games-Howell post-hoc.

Results: The HUAD diet leads to a significant increase in plasma UA in BDL+HUAD animals at day 33 compared to BDL+RD animals. No significant increase in liver injury evaluated by plasmatic markers and histology was observed in either HUAD-fed groups. For behavioural assessment, we detected an impairment of short-term memory for both SHAM+HUAD and BDL+HUAD animals compared to their RD counterparts. We also observed an increase of anxiety and long-term memory impairments for BDL+HUAD rats compared to all three other groups. Regarding neuronal cell loss in the frontal cortex, both apoptosis pathways (caspase-8, 9 and 3) are increased and neuronal markers are decreased for both HUAD groups compared to their RD counterparts. In the amygdala and hippocampus, the intrinsic pathway of apoptosis (caspase-9 and 3) is activated in BDL-HUAD rats compared to all three other groups which was associated with a decrease in neuronal markers.

Conclusion: In a BDL rat model, the administration of a high UA diet leads to the early-onset of anxiety-like behaviour and memory impairments. The behavioural alterations are associated with increased apoptosis and neuronal cell loss in the frontal cortex, amygdala and hippocampus. These results suggest a potential role for UA in irreversible brain damage in the context of CLD.

WED-094

Food antigen-specific antibodies contribute to hypergammaglobulinemia in patients with decompensated liver cirrhosis

Lara Kelsch[1], Jill Werner[1], Giuseppe Rusignuolo[1], Dominik Bettinger[1], Michael Schultheiß[1], Maike Hofmann[1], Robert Thimme[1], Tobias Böttler[1]. *[1]Department of Medicine II, Medical Center-University of Freiburg, Freiburg, Germany*
Email: lara.kelsch@uniklinik-freiburg.de

Background and aims: Portal hypertension is the major driver in disease progression from the compensated to the decompensated stage of liver cirrhosis. Hypergammaglobulinemia (HGG), characterized by elevated immunoglobulin G (IgG) levels, is a common feature of decompensated liver cirrhosis (dCirr). The mechanisms underlying HGG and the antigen specificity of these IgG antibodies remain incompletely understood. As the healthy liver mediates local and systemic tolerance to self and foreign antigens, including antigens from ingested food, we hypothesize that food antigens can bypass the liver in the presence of portal hypertension, thereby failing to undergo tolerization and subsequently eliciting immune responses contributing to increased IgG levels.

Method: Food-specific IgGs against 90 different food antigens were analyzed in a cohort of 11 healthy controls (HCs), 26 individuals with dCirr and 8 with a transjugular intrahepatic portosystemic shunt (TIPS) via an ELISA assay. As the generation of IgGs is a T cell-dependent process, T cell markers indicative of tolerance induction were analyzed by flow cytometry in bulk peripheral blood mononuclear cell (PBMCs). Additionally, food antigen-specific T cell responses were measured using overlapping peptides (OLPs) targeting previously described immunodominant regions of four different food antigens and evaluated by intracellular cytokine staining.

Results: Individuals with dCirr showed significantly increased food-specific antibodies (mean values: 9.1 µg/ml in dCirr patients, 16.6 µg/ml with TIPS and 1.9 µg/ml in HCs) with percentages of food-specific IgGs relative to the total IgGs of 1.6% in HCs, 3.8% in dCirr and 5.8% in patients with TIPS. While there was no difference in markers indicative of tolerance induction in bulk analysis, food-specific CD4 T-cells responses were enriched in dCirr compared to HCs (mean values: 7.9 responses in dCirr and 5.6 responses in HCs).

Conclusion: Our data demonstrate that food-specific immune responses contribute to HGG in dCirr patients with portal hypertension that might result from portosystemic shunting of gut-derived antigens, circumventing tolerance induction in the liver parenchyma.

WED-095-YI

Pharmacological inhibition of high mobility group box 1 ameliorate sepsis induced hepatic micro vascular dysfunction and portal hypertension in non-cirrhotic and cirrhotic animals

Vaibhav Tiwari[1], Rajni Yadav[2], Akash Kumar Mourya[1], Aishwarya Bhatnagar[1], Himanshi Himanshi[2], Parul Singh[2], Kanchi Sharma[2], Savneet Kaur[1], Dinesh Mani Tripathi[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: dineshmanitripathi@gmail.com

Background and aims: Septic shock is shattering multiple cellular injury progress to organ failure, leading to short-term mortality. Sepsis is key event that promotes early hepatic decompansation, disturb vascular homeostasis, hepatic microvascular complications and aggravates portal pressure. High mobility group box1 (HMGB1) initiates immune reponses that triggers hepatic injury in response to pathogens. We investigated the role of HMGB1 in sepsis induced hepatic microvascular-dysfunction and portal-hypertension in cirrhosis.
Method: Experimentally, sepsis was induced by intraperitonial administration of LPS 4 mg/kg in non-cirrhotic and CCl_4-cirrhotic animals. Controls (Ct1). Non cirrhotic Ct+LPS (Ct2), Ct+LPS +Glycyrrhizin (Ct3) were compared with CCl_4 cirrhotic rats (Gr1), CCl_4+LPS (Gr2), CCl_4+LPS+Glycyrrhizin (Gr3).HMGB1 pharmacological inhibition was achieved by glycyrrhizin (GLZ).Hepatic hemodynamic was monitored followed by *in-situ-ex-vivo* Hepatic microvascular functionality analysis. To investigate the changes in HMGB1 in-vitro, vascular endothelial cells were stimulated with LPS after giving pretreatment of Glycyrrhyzin. Cellular, Molecular and histological analysis was performed in hepatic tissues.
Results: Studies shows a noticeable increased PP (9.2 ± 1; + 27.7% (CT2), vs 7.2 ± 1 in CT1) a marked reduction in CT3 (8.1 ± 0.5; −15.2%) vs CT2 ($p = 0.01$) was observed.CT2 animals also had increased SMABF ($p = 0.001$) and PBF ($p = 0.05$) in comparison to CT1 and CT3. However, in cirrhotic animals we observed significantly raised PP (12.6 ± 1;+26% (Gr2), vs 10 ± 1; in Gr1) a marked reduction in Gr3 (10.8 ± 0.2;−14%) vs Gr2 ($p = 0.01$) was observed. Gr2 animals had increased SMABF ($p = 0.001$) ($p = 0.001$) and PBF ($p = 0.05$) ($p = 0.001$) in comparison to Gr1 and Gr3. Endothelial dysfunction assay under perfused ex-vivo condition showed improvement in endothelial activity showed by percentage change in Portal perfusion pressure ($p = 0.005$) in Gr3andCt3 vs Gr2andCt2. Periportal inflammation and inflammatory cells infiltration was evidently reduced in both Ct3 and Gr3 rats vs Ct2andGr2 respectively. Gene expression of TNF-alpha, IL-6, HMGB1, TLR4 were significantly upregulated in Gr2 andCt2 ($p < 0.05$) vs Gr3 and Ct3. Moreover, Endothelial dysfunction genes ICAM1, VCAM1, fold was downregulated ($p < 0.05$)in Gr3andCt3 vs Gr2andCt2. Gene expression analysis of endothelial cells showed that upregulation of VCAM-1 ($p = 0.001$) and ICAM-1 ($p = 0.001$) as well as HMGB1 ($p < 0.05$) was effectively abolished by Glycyrrhizin without affecting cell viability.
Conclusion: This study demonstrated that pharmacological inhibition of HMGB1 ameliorates PP and protects vascular function during sepsis in liver cirrhosis.

WED-098-YI

Low-density lipoprotein can predict hospital readmissions and outcomes following acute decompensation of cirrhosis

Email: k.gananandan1@nhs.net

Background and aims: In liver cirrhosis, serum lipid and lipoprotein levels are altered due to pathological changes in synthesis, secretion and catabolism. Whilst most research has focussed on the role of high-density lipoprotein (HDL), relatively little attention has been given to the predictive capacity of low-density lipoprotein (LDL). We aim to explore the role of serial LDL measurements in predicting liver-related events following acute decompensation (AD).
Method: 232 patients from the PREDICT cohort were included in this study. This was a European, multicentre, prospective, observational study recruiting patients admitted non-electively with an episode of AD of cirrhosis. Blood tests including lipids were performed at baseline and day 7. Patients were followed up for 3 months to obtain clinical outcome data.
Results: There was no difference in baseline LDL and HDL levels when comparing patients treated with statins versus those who were not. During the 3-month follow-up period, 32 (14%) patients developed acute-on-chronic liver failure (ACLF), 62 patients (27%) had re-admissions and 13 patients (6%) died. HDL measurements and LDL/HDL ratios were not associated with outcomes. In contrast, when comparing patients who were subsequently re-admitted versus those who were not, day 7 LDL results were significantly lower (55.0 vs 78.6 mg/dL, $p = 0.003$). Indeed, day 7 LDL remained an independent predictor of subsequent readmissions in both univariable and multivariable analyses (OR 0.984 [95% CI 0.972–0.995], $p = 0.01$). With regards to ACLF development, a marked difference was noted in the delta change between baseline and day 7 LDL in those who developed ACLF versus those who did not (−7.7 vs 3.8 mg/dL, $p = 0.05$). Finally, with respect to 90-day transplant-free mortality, when comparing those who died versus those who survived, there was a trend towards lower day 7 LDL levels (42.5 vs 75.8 mg/dL, $p = 0.06$) as well as decreased LDL between baseline and day 7 (−12.3 vs 3.9 mg/dL, $p = 0.08$).
Conclusion: This study demonstrates novel findings that decreased LDL, independent of statin treatment, can predict readmissions and provide a potential signal for other liver-related events, including mortality, though this needs further validation. Given its biological relevance, ease of measurement, and low cost, LDL may be an ideal biomarker for predicting outcomes in patients with decompensated cirrhosis.

WED-099-YI

Hyperammonemia-induced mitochondrial dysfunction is abrogated by targeting toll-like receptor 4

Supachaya Sriphoosanaphan[1,2], Annarein Kerbert[3], Abeba Habtesion[3], Fausto Andreola[3], Gautam Mehta[3], Jan-Willem Taanman[4], Rajiv Jalan[3]. [1]*Institute for Liver and Digestive Health, University College London, London, United Kingdom;* [2]*Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand;* [3]*Institute for Liver and Digestive Health, University College London, London, United Kingdom;*

[4]*Department of Clinical and Movement Neurosciences, Queen Square Institute of Neurology, University College London, London, United Kingdom*
Email: r.jalan@ucl.ac.uk

Background and aims: Inhibition of the toll-like receptor 4 (TLR4) protects against hyperammonemia but the underlying mechanism is unknown. We hypothesized that TLR4 inhibition protects against hyperammonemia-induced mitochondrial dysfunction, thereby preserving the urea cycle enzyme (UCE) function. The aims of this study were to investigate the impact of hyperammonemia and TLR4 inhibition on oxidative phosphorylation (OXPHOS), a key mitochondrial function.
Method: Hyperammonemia was induced in wild type (WT) and TLR4 knock-out (TLR4KO) mice by an amino acid (AA) diet for 14 days. WT mice fed with the AA diet (WT-AA) were treated with a vehicle, the TLR4 antagonist TAK-242 (10 mg/kg i.p.), or the ammonia scavenger Ornithine Phenylacetate (OP, 300 mg/kg i.p.) during days 10–14. Plasma ammonia and protein expression of UCEs were studied, while isolated mitochondria from the liver were assessed for concentration and activity of OXPHOS complexes I-V by immunoblot and in-gel activity assay, respectively.
Results: A significant increase in ammonia levels was observed in WT-AA compared to controls (333.4 ± 54.5 vs. 47.0 ± 11.9 μmol/L, $p < 0.0001$). Treatment with both TAK-242 and OP significantly reduced ammonia levels (121.1 ± 51.5 and 131.6 ± 79.8 μmol/L; both $p < 0.0001$). Hepatic protein expression of key mitochondrial UCEs, carbamoyl phosphate synthase and ornithine transcarbamylase, was significantly reduced in WT-AA as compared to controls and restored with both TAK-242 and OP. Although the concentration of the OXPHOS complexes were similar, the activity of all of the OXPHOS complexes were increased in hyperammonemic mice compared to controls. TAK-242 treatment significantly reduced enzyme activities of all OXPHOS complexes compared to WT-AA (all $p < 0.05$). OP only led to a significantly reduced activity of complex I. TLR4KO mice fed with the AA diet had significantly lower blood ammonia levels compared to WT-AA (149.9 ± 104.6 μmol/L, $p < 0.0001$). No changes were observed in complex I–V concentration and activity between TLR4KO mice with or without the AA diet.
Conclusion: Hyperammonemia increases the activity of OXPHOS complexes, which is associated with the downregulation of mitochondrial UCEs. In contrast to treatment with OP, TLR4 inhibition prevented an increase in OXPHOS complex activity. This points towards TLR4 as a mediator of hyperammonemia-induced oxidative stress and mitochondrial dysfunction, providing an explanation why TLR4 inhibition preserves the expression of mitochondrial UCEs and ammonia levels.

Email: lorena.paule@uah.es

Background and aims: Cirrhosis-associated immune dysfunction involves various abnormalities, such as altered activation and reduced effector functions of the innate and adaptive immune systems. The impact of B lymphocyte compartment dysregulation on immune dysfunction in cirrhosis has been minimally explored. Our aims consist of investigate in patients at different cirrhosis stages: i) the differentiation/activation stage of circulating B lymphocytes, ii) the degree of apoptosis within this compartment, and iii) the role of cirrhosis-related metabolic abnormalities in apoptosis.
Method: Analysis by flow cytometry of circulating B lymphocytes' differentiation (CD27/IgD), thymus-dependent/independent (CD5) subpopulations in patients with cirrhosis or with ACLF. Groups: compensated cirrhosis (CC, n = 10), decompensated cirrhosis (DC, n = 12), ACLF (n = 9), healthy controls (HC, n = 10). B-lymphocyte apoptosis was studied using Annexin-V and Caspases-3-8-9 at baseline and after 48 h culture of B lymphocytes from HC with serum from HC or patients.
Results: The percentage and absolute values of B lymphocytes in patients were lower ($p < 0.01$) than in HC, with a more pronounced difference observed in DC and ACLF groups (HC: 5.2%, 102200 cells/ml; CC: 4.0%, 59200 cells/ml; DC: 3.2%, 28800 cells/ml; ACLF: 3.0%, 31900 cells/ml). Lymphopenia affected all B lymphocyte subpopulations. In patients with CC and DC, there was a decrease in naive and an increase in memory populations, while ACLF showed a decrease in naive and an increase in effector populations. At baseline all groups of patients exhibit a significant increase in the frequency of apoptosis markers (Annexin-V and Caspases-3, –8, and –9) in B-lymphocytes compared to HC. Notably, apoptosis significantly escalated when B lymphocytes from HC were cultured with serum from patient CC or DC or ACLF, showed increased expression of apoptosis markers: Annexin-V (7.2, 13.7, 16.7%) and Caspases-3 (8.3, 8.7, 14.9%), –8 (7.7, 9.4, 13.0%), and –9 (7.6, 10.1, 11.0%).
Conclusion: Cirrhosis leads to severe abnormalities in the circulating B lymphocyte compartment, correlating with disease severity. Despite the redistribution causing an increase in effector cells, it is inadequate to compensate for the compartmental retraction in decompensated cirrhosis and ACLF. This inadequacy is partly due to increased apoptosis, activated through the caspase pathway by cirrhosis-induced metabolic alterations.

WED-101-YI
Modulation of portal and hepatic venous flow leads to fibrotic liver changes and can be prevented through anticoagulation
Beat Moeckli[1,2], Graziano Oldani[3], Andrea Peloso[4], Florence Slits[5], Quentin Gex[6], Neil Theise[7], Stéphanie Lacotte[1], Christian Toso[1,2].

Email: beat.moeckli@gmail.com

Background and aims: Cirrhosis is a progressive, irreversible liver disease with a myriad of diverse etiologies. We hypothesize that different etiologies share a common vascular injury pattern that occurs early in the disease course. Hence, two simultaneous insults to the liver vasculature are responsible for the initiation and progression of the fibrotic disease process.
Method: Adult male C57Bl6 mice were subjected to the following procedures: 1) Partial ligation of the inferior vena cava (IVC) to generate an outflow obstruction 2) Injection of microspheres in the portal vein to obstruct distal venules. Animals were sacrificed at 6, 12, and 18 weeks after the interventions (n = 6–8/group). Controls received either a sham surgery, partial IVC ligation, or portal embolization. As a preventive intervention, an additional group received a vitamin K antagonist (warfarin) for anticoagulation.
Results: At 12 weeks, two-thirds of animals subjected to combined partial ligation of the IVC and portal embolization developed macronodular liver disease resembling cirrhosis, compared to none in the control groups (62.5 vs. 0%, p = 0.002). Combining both procedures resulted in elevated serum bilirubin levels (5.9 vs. 0.3 µmol/L, p = 0.001), increased portal pressure (12.5 vs. 5.0 mmHg, p = 0.008), and an increased collagen staining in the liver (2.84 vs. 0.13%, p < 0.001) compared to controls. Moreover, animals with combined interventions exhibited an overexpression of fibrotic markers such as *Col1a1*, *aSMA*, *TGFb* and *Timp1*. Continuous anticoagulation improved the rate of macronodular liver disease (37.5 vs 62.5%) and portal pressure (6 vs. 12.5 mmHg, p = 0.002). Furthermore, it decreased aspartate transaminase serum levels (95 vs 202 IU/L, p = 0.002) and expression of fibrotic markers. Additionally, anticoagulation led to a marked compensatory proliferation characterized by increased Ki67 staining (0.03 vs 0.08% +cells, p < 0.001).
Conclusion: The results of our study highlight the importance of vascular mechanisms in the development of cirrhosis. The combination of portal and hepatic venous intervention potentiates the effect on liver fibrosis. Anticoagulation potentially slows the progression of liver disease and, therefore, represents a therapeutic target common to all etiologies of cirrhosis.

WED-102
Transplanted acellular liver scaffold is not affected by the cirrhotic liver remaining a healthy template for cell growth

Marlon Dias[1], Ines Wajsenzon[1], Raysa de Sousa[1], Bruno Paranhos[1], Victoria Monteiro[2], Cherley de Andrade[3], Debora Mello[4], Regina Goldenberg[1]. *[1]Precision Medicine Research Center, Carlos Chagas Filho Biophysics Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [2]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [3]Department of Histology and Embryology, Rio de Janeiro State University, Rio de Janeiro, Brazil; [4]National Center for Structural Biology and Bioimaging, CENABIO, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*
Email: marlonlemos@biof.ufrj.br

Background and aims: Acellular Liver Scaffolds (ALS) are a promising tool in tissue engineering that can help overcome the organ shortage problem. While the potential of using ALS has been demonstrated, it remains unclear whether the transplanted scaffold can be affected by the cirrhotic liver that received it, either by becoming cirrhotic or by remaining a healthy template for healthy cell growth. This study aimed to evaluate the influence of the cirrhotic liver on the recellularization of transplanted liver scaffolds in cirrhotic rats.
Method: To address this issue, donor Wistar rats (n = 5) underwent a surgical procedure to promote liver procurement, which was approved by the Animal Care Committee CEUA/CCS-UFRJ 097/20. The livers were decellularized by being perfused through the portal vein using an infusion pump at 3 ml/min with water for 2 hours, followed by 1% Triton X-100 for 2 hours and SDS 1% for 18 hours. Subsequently, the livers were washed with distilled water for 8 hours and then subjected to DNA quantification and histological analysis (HandE). Cirrhotic recipient rats (n = 5), which had previously received 5% ethanol in drinking water and intraperitoneal injections of carbon tetrachloride (1 ml/Kg) every other day for 8 weeks, underwent median lobe hepatectomy (10%) and partial ALS orthotopic transplantation. Various histological analyses (HandE, Sirius red, Gomori's trichrome, Periodic Acid- Schiff), Ki67, CK19 and CK7 immunohistochemistry and non-invasive ultrasound analysis were performed to evaluate the transplanted ALS at different time points post-transplantation.
Results: The decellularization process effectively removed the cells and preserved the 3D vascular structure and extracellular matrix (ECM) components of the ALS, as evidenced by whole liver macroscopy, HandE staining, and DNA quantification. Serum biochemical analysis showed that the transplanted ALS normalized the ALB and ALT serum biochemical parameters after transplantation in cirrhotic rats. Histological findings revealed that liver resident cells migrated to the ALS, promoting full recellularization 30 days post-transplantation. Various cell types were detected including hepatocytes, cholangiocytes, endothelial, and immune cells. Furthermore, the ALS underwent ECM remodeling after transplantation and no signal of fibrotic ECM deposition was observed.
Conclusion: The study concluded that the transplanted ALS was not affected by the cirrhotic livers and remained a template for healthy cell growth. In a translational context, this study demonstrates that ALSs derived from decellularization can be transplanted into patients with liver disease undergoing hepatectomy procedures in the future.

WED-104
Loss of heterogeneity and CD4+ T-cell differentiation in patients with alcohol-related cirrhosis

Paola Zuluaga[1,2], Coral Zurera[1], Daniel Fuster[1], Anna Hernandez-Rubio[1], Eva Martínez-Cáceres[3], Robert Muga[1]. *[1]Universitat Autònoma de Barcelona, Barcelona, Spain; [2]University Hospital Germans Trias i Pujol, Badalona; [3]Universitat Autònoma de Barcelona, Barcelona, Spain*
Email: ypzuluaga.germanstrias@gencat.cat

Background and aims: $CD4^+$ T-cells have a central role on the immune response through different subsets. Lymphopenia is common in patients with alcohol-related cirrhosis (AC); however, changes in $CD4^+$ T-cell subsets are not sufficiently studied. The present pilot study analyzes the changes over time in the $CD4^+$ T-cell subsets and the interactions between them in patients with AC.
Method: Patients with Alcohol Used Disorder (AUD) admitted at least twice for treatment and evaluated for alcohol-related liver disease, were included in the study. The presence of AC was evaluated according to clinical and ultrasound criteria. Patients without clinical evidence of alcohol-related liver disease were the control group. The following $CD4^+$ T-cell subsets were analyzed through flow cytometry; naïve ($CCR7^+/CD45RA^+$), central memory ($CCR7^+/CD45RA^-$), effector memory ($CCR7^-/CD45RA^-$), terminally differentiated effector memory (TEMRA) ($CCR7^-/CD45RA^+$), Th1 ($CXCR3^+/CCR6^-$), Th2 ($CXCR3^-/CCR6^-$), Th17 (CXCR3-/CCR6+), early activated cells ($CD38^-/HLA\text{-}DR^+$) and late activated cells ($CD38^+/HLA\text{-}DR^-$).
Results: 27 patients (46 ± 8 years, 81% male, IMC 25 ± 5.7 kg/m^2) with a mean alcohol consumption of 186.5 ± 112 gr/day and a mean AUD duration of 17.4 ± 9.5 years were included. During the follow-up, TEMRA $CD4^+$ T-cells were increased (1.24 ± 1.16 vs. 2.14 ± 1.14, p = 0.03) in patients with AC (n = 5) and Th17 cells were decreased (14.16

± 4.31 vs. 12.35 ± 6.40, p = 0.03) in the control group (n = 22). Early activated cells were associated with an increase of memory cells in the control group (r = 0.51, p = 0.01), and late activated cells were associated with a decrease of memory cells in both groups. This association was stronger in patients with AC than in control group (r = –0.90, p = 0.04; r = – 0.44, p = 0.05, respectively). The proportion of memory cells was associated with an increased proportion of Th1, Th2 and Th17 cells in the control group (r = 0.70, r = 0.68, r = 0.63; p < 0.01, respectively), while in patients with AC the proportion of memory cells was associated with a decrease in the Th17 cells (r = –0.90, p = 0.03).

Conclusion: Patients with alcohol-related cirrhosis experience an increase in the proportion of $CD4^+$ TEMRA cells, lymphocyte populations associated with the presence of inflammation and immunosenescence. The loss in heterogeneity and the decreased lymphocyte differentiation in patients with alcohol-related cirrhosis are findings that suggest an inappropriate immune response.

WED-105

Nitazoxanide directly protects from stress-induced cell death to alleviate liver damage in preclinical models of acute-on-chronic liver failure

Marie Bobowski-Gerard[1], Simon Debaecker[1], Nicolas Stankovic Valentin[1], Alexia Tessier[2], Hana Elkhatib[1], Philippe Delataille[1], Remy Hanf[3], Sakina Sayah Jeanne[1], Dean Hum[1], Vanessa Legry[1], Bart Staels[2,4]. [1]*Genfit S.A., Loos, France;* [2]*Univ. Lille, INSERM U1011, Lille, France;* [3]*Pradial-consulting, Lille, France;* [4]*CHU Lille, Institut Pasteur de Lille, Lille, France*
Email: marie.gerard@genfit.com

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by an acute decompensation of liver function in patients with cirrhosis; associated with multiple organ failures and high short-term mortality rates. We previously showed that the anti-parasitic drug nitazoxanide (NTZ) counteracts LPS-induced inflammatory responses and organ failures in disease models of ACLF (*J Hepatol.* 2022 vol. 77, THU-528 and *J Hepatol.* 2023 vol. 78, THU-342). The aim of this study was to investigate the effect of NTZ on liver damage and cell death, using animal and cellular models of ACLF.

Method: ACLF was triggered through lipopolysaccharide (LPS) injection in rats displaying cirrhosis induced by bile duct ligation (BDL). A single dose of NTZ (100 mg/kg) or vehicle was orally administered concomitant to LPS injection. Liver samples were collected 3 h post-LPS for RNA sequencing and transcriptomic analysis. To assess NTZ's effect on cell death, immortalized human hepatocytes were stimulated with two pathogenic factors contributing to ACLF pathophysiology: H_2O_2 (0.5 mM) and ethanol (0.6 mM). In parallel, necroptotic cell death was induced in HT-29 cells using a combination of the pan-caspase inhibitor zVAD (10 µM), the Smac mimetic BV6 (2 µM) and TNF-alpha (20 ng/ml). Cells were treated with Tizoxanide (TZ), NTZ's circulating active metabolite, at the same time or after the stress inducer. Cell death was evaluated through measurement of caspase 3 activation and cleavage, and LDH release.

Results: ACLF induction with LPS injection significantly remodeled the transcriptome of cirrhotic rat liver. Enrichment analysis showed that NTZ reversed the hepatic ACLF-related gene signature, modifying cell death-related pathways such as apoptosis and necroptosis, two modes of cell death reported in patients with ACLF (Adebayo *et al., Liver Int.*, 2015; Kondo *et al., CDD,* 2022). Cellular models were therefore used to investigate direct effect of NTZ on stress-induced cell death. In human hepatocytes, TZ blunted apoptosis induced by H_2O_2 or ethanol treatment in a dose dependent manner as shown by a reduction of caspase 3/7 activity and caspase 3 cleavage (IC50 = 2 to 2.8 µM). When stressed with necroptotic stimuli, HT-29 cells displayed an activation of the necroptosis effectors MLKL and RIPK3, accompanied by plasma membrane leakage, as measured by lactate dehydrogenase (LDH) release. Interestingly, TZ inhibited LDH release in this model with a maximum efficacy of 57% at 7.5 µM. These results highlight a direct protective effect of TZ on stress-induced cell death.

Conclusion: The direct protective effects of TZ on apoptosis and necroptosis suggest that NTZ treatment is a promising approach to protect the liver of patients with ACLF from cell death. Combined with its antibacterial and anti-inflammatory activities, this further supports NTZ development for the potential treatment of ACLF.

WED-106

Liver cirrhosis and epithelial damage-The gut-liver axis in spontaneous bacterial peritonitis and its modulation by p53

Martha Ernst[1], Celina Macek[2], Carina Steindl[1], Marika Haderer[1], Christoph Brochhausen[3], Arne Kandulski[1], Kunst Claudia[1], Karsten Guelow[1], Martina Müller-Schilling[1]. [1]*University Hospital Regensburg, Regensburg, Germany;* [2]*University Hospital Regensburg, Regenburg, Germany;* [3]*Medical Faculty Mannheim, Mannheim, Germany*
Email: martina.mueller-schilling@ukr.de

Background and aims: The gut-liver axis is pivotal in preserving overall health and modulating essential (patho)physiological processes. Patients with liver cirrhosis show reduced mucus thickness, facilitating direct contact of bacteria with epithelial cells and the breakdown of cell junctions (Haderer et al., Gut 2022). The translocation of gut bacteria into mesenteric lymph nodes constitutes a pivotal event in spontaneous bacterial peritonitis (SBP). Cellular stress triggered by direct contact with bacteria involves the p53 family of transcription factors, serving as crucial regulators of the cell cycle, repair mechanisms, and cell death. We investigate the effects of ascites-derived bacteria on the expression of p53 isoforms concerning cell death induction in epithelial cells using a novel reporter system.

Method: Three exon-specific intein-luciferases (EXSISERS) were cloned into exons 2, 4, and 7 of the TP53 gene. Split inteins allow for the cleavage of luciferase from the p53 polypeptide, preserving the structural integrity of p53 isoforms (Truong et al., Nat Cell Biol 2021). This method precisely quantifies p53 protein isoform ratios at the cellular level. HCT116-EXISERS cells were co-cultured with patient-derived Escherichia coli, and the three main groups of p53 isoforms—cell cycle-arrest-inducing full-length p53, cell death-inducing Δ40p53, pro-proliferative Δ133p53/Δ160p53—were measured. Concurrently, bacterial-induced cell death was quantified in HCT116 p53 wild-type and p53 knockout cells. Electron microscopy was used for determination of the type of cell death.

Results: Co-culturing patient-derived bacteria with HCT116-EXISERS cells initially enhanced the production of the cell death-inducing p53 isoform Δ40p53 within 15 minutes. This was followed by a decrease in the pro-proliferative p53 isoforms Δ133p53/Δ160p53. Concurrently, the induction of cell death was detected in response to bacterial contact, exhibiting morphological characteristics of paraptosis, including mitochondrial swelling, and cytoplasmic vacuolization. In parallel with the observed morphological changes, damage to the mitochondria and plasma membrane was confirmed through flow cytometry. The known paraptosis inhibitor Acinomycin D efficiently blocked bacteria-induced cell death. In accordance with the measured induction of the Δ40p53 isoform, the induction of cell death was significantly delayed through a CRISPR/Cas9-mediated p53 knockout.

Conclusion: Bacterial translocation occurs due to an impaired epithelial integrity in patients with liver cirrhosis. Cellular responses to bacterial-induced stress are regulated by specific p53 isoforms. Thus, the p53 status exerts a crucial influence on paraptosis

susceptibility. Targeted induction or stabilization of particular p53 isoforms could thus represent a therapeutic option for the management of SBP.

WED-107

Administration of xyloglucan alone or in combination with norfloxacin improves intestinal barrier homeostasis in cirrhotic rats with ascites

Ramon Bartoli[1,2], Ignacio Iborra[1,3], Helena Masnou[1,2,3], Alba Ardevol[3], Maria Torner[3], Maria Bermudez[3], Ana Bargallo[4], Rosa M Morillas[1,2,3].
[1]Germans Trias i Pujol Research Institute (IGTP), Badalona, Spain; [2]CIBER de Enfermedades Hepáticas y Digestivas, Instituto de Salud Carlos III, Madrid, Spain; [3]Hepatology Unit, Gastroenterology Department. Germans Trias i Pujol University Hospital, Badalona, Spain; [4]EndosMedicina. Gastroenterology Department, HM Nou Delfos Hospital, Barcelona, Spain
Email: rbartoli@igtp.cat

Background and aims: Cirrhosis leads to a multifactorial alteration of the intestinal barrier, resulting in increased intestinal permeability that promotes bacterial translocation (BT) and is associated with infections in these patients. Currently, selective intestinal decontamination with norfloxacin is the only effective strategy to reduce BT. Xyloglucan, a hemicellulose obtained from land plants, has been shown to be effective in improving the integrity of the intestinal mucosa in various pathologies due to its mucoprotective and mucin-like properties. However, there is a lack of data on its role in the intestinal barrier in cirrhosis with ascites. The aim was to evaluate the effect of xyloglucan alone or in combination with norfloxacin on the mucosal and vascular intestinal barrier in cirrhotic rats with ascites.
Method: Cirrhosis and ascites decompensation was induced in 32 rats using carbon tetrachloride. Subsequently, they were orally administered xyloglucan (group 1), norfloxacin (group 2), xyloglucan + norfloxacin (group 3), or water (group 4, control), for one week. The following parameters were determined in colonic mucosa: IFN-gamma and IL-23 as markers of inflammatory activity, occludin (a tight junction protein) as a marker of mucosal barrier integrity, PV1/CD34 ratio as a marker of vascular permeability, in addition to endotoxemia and the incidence of BT.
Results: All treatment groups (groups 1, 2 and 3) significantly showed an increase of the parameters of mucosal barrier integrity (occludin) and a significantly decrease in vascular permeability (PV1/CD34 ratio) compared to controls (group 4). Regarding inflammatory activity, there were no differences in IL-23 levels but all treatment groups showed a decrease in IFN-gamma, significantly in groups 2 and 3. Similarly, BT was lower in all treatment groups compared to controls but differences were only significant in groups 2 and 3. Furthermore, all treatment groups showed a significant decrease of endotoxemia compared to controls, which values significantly correlated with BT incidence, occludin expression, IFN-gamma levels, IL-23 levels, and PV1/CD34 ratio.
Conclusion: Xyloglucan reduces inflammation of the intestinal mucosa and improves both mucosal integrity and vascular permeability, thereby reducing endotoxemia and the incidence of BT; two factors implicated in the pathogenesis of infections in cirrhosis. This would justify evaluating the use of xyloglucan as a new therapeutic strategy to prevent infections associated with cirrhosis.

WED-109

Evaluation of statins as a new therapy to alleviate hepatic encephalopathy in cirrhotic mice

Subas Aroob[1], Qamar Niaz[1], Muhammad Ovais Omer[1], Syed Muhammad Muneeb Anjum[2], Ghulam Mustafa[3], Sania Mehreen[4], Muhammad Bilal Khan[5], Muhammad Adil Rasheed[1].

Email: qamar.niaz@uvas.edu.pk

Background and aims: Hepatic encephalopathy (HE) is a neurological disorder of liver cirrhosis characterized by elevated plasma ammonia levels, oxidative stress, and neuronal inflammation and death. Current therapies for HE target the ammonia levels to decrease. Statins, antilipidemic drugs, reduce the portal pressure (PP), fibrosis, inflammation, and oxidative stress in liver cirrhosis. Therefore, we evaluated the atorvastatin (Ato) effect on HE in cirrhotic mice.
Method: Total 64 male albino mice were randomly selected and divided into two groups of sham (control) i.e., Sham/Saline, Sham/Ato-15 mg/kg, Sham/Ato-30 mg/kg, and Sham/Lac-1.43 g/kg sub-groups and bile duct ligated (cirrhotic) i.e., BDL/Saline, BDL/Ato-15 mg/kg, BDL/Ato-30 mg/kg, and BDL/Lac-1.43 g/kg sub-groups. BDL surgery was performed to induce liver cirrhosis for 28 days, while sham surgery was used for control groups. Each group was gauged orally the respective drug once daily for 14 days. Following the treatment, the plasma ALT, AST, bilirubin, cholesterol, and ammonia levels were evaluated along with histopathology for the liver (inflammation and fibrosis) and brain (inflammation and vacuolar degeneration). Finally, the anxiety and cognitive functions were assessed through the elevated plus maze test and open field test and Y-maze test, respectively.
Results: The findings revealed that the spleen weight was decreased in the BDL/Ato-30 group in comparison to the BDL/Saline group. The liver inflammation and fibrosis and brain inflammation and vacuolar degeneration were noted as moderate and mild in the BDL/Ato-15 and BDL/Ato-30 groups, respectively than the BDL/Saline group. The plasma ALT, cholesterol, and ammonia levels were decreased equally in the BDL/Ato-15 and BDL/Ato-30 groups, while the plasma AST level was decreased in the BDL/Ato-30 group than BDL/Saline group. The plasma bilirubin level was reduced more in the BDL/Ato-30 group than the BDL/Ato-15 group as compared to the BDL/Saline group. The anxiety (the distance traveled in the open field) was high in the BDL/Saline group and was raised further in the BDL/Ato-15 group than in the BDL/Ato-30 group. The anxiety (time spent in the center of the open field) was high in the BDL/Saline group and was not treated in the BDL/Ato-15 and BDL/Ato-30 groups. The anxiety (number of entries and time spent in closed arms in the elevated plus maze) was absent in the BDL/Saline group and was reduced in the BDL/Ato-30 group. No change in cognitive function (percent spontaneous alteration in Y-maze) in the BDL/Saline group was observed and the BDL/Ato-30 group decreased the cognitive functions.
Conclusion: The atorvastatin at 30 mg/kg body weight alleviates the HE in cirrhotic mice by decreasing the plasma ammonia level and treating the liver inflammation and fibrosis and brain inflammation and vacuolar degeneration without affecting anxiety and cognitive functions.

College Hospital, London, United Kingdom
Email: m.stamouli@researchinliver.org.uk

Background and aims: Hepatic encephalopathy (HE) is a challenging neuropsychiatric complication that contributes to cognitive and motor symptoms frequently observed in cirrhosis. Central to the pathophysiology of HE are neuronal injury and astrocyte swelling. Neurofilament light chain (NfL), a neuronal cytoplasmic protein reflecting neuroaxonal damage, and glial fibrillary acidic protein (GFAP), the principal intermediate filament found in astrocytes serving as a marker of astrocytic activation, are potential diagnostic tools for HE in cirrhosis. This study aims to investigate the diagnostic potential of these circulating proteins and explore their roles in the complex underlying mechanisms that cause HE.
Method: Cirrhosis patients were stratified based on disease severity into three groups: stable cirrhosis (SC, n = 14), decompensated cirrhosis (DC, n = 13), and acute-on-chronic liver failure (ACLF, n = 20), and compared to healthy controls (HC, n = 8) and non-liver sepsis patients (NLS, n = 14). HE was assessed at the time of blood sampling using the West Haven criteria, ranging from patients with no detectable symptoms (grade 0, n = 32) to mild behavioral and cognitive alterations (grades 1/2, n = 9) and severe symptoms including coma (grades 3/4, n = 6). Plasma levels of NfL and GFAP were quantified using electrochemiluminescent-based assays (MSD R-PLEX™).
Results: Plasma NfL concentration progressively increased with cirrhosis severity, while GFAP showed an upward trend without reaching statistical significance. NfL effectively discriminated cirrhosis patients with HE from those without (median: 183 vs 51 pg/ml, $p = 0.007$). Receiver-operating curve analysis discriminated HE grades 1/2 compared to grade 0 based on NfL levels ($r = 0.87$, $p = 0.0009$). Circulating NfL and GFAP levels directly related to each other in all cirrhosis patients, regardless of severity of liver disease ($r = 0.59$, $p < 0.0001$), with stronger associations observed in patients with ACLF ($r = 0.67$, $p = 0.01$) or HE ($r = 0.75$, $p = 0.002$). Both markers exhibited an inverse correlation with estimated glomerular filtration rate (eGFR), a marker of renal function (NfL: $r = -0.61$, $p < 0.0001$; GFAP: $r = -0.30$, $p = 0.04$). Notably, NfL, but not GFAP, positively correlated with IL-6 ($r = 0.63$, $p < 0.0001$), while neither of them showed a correlation with ammonia.
Conclusion: Plasma NfL and GFAP exhibit potential as diagnostic tools for HE in cirrhosis, especially at the challenging to diagnose more covert stage. NfL, particularly, demonstrated superior discriminatory capabilities between HE grades and stronger associations with cirrhosis severity. Their correlations with renal function and inflammatory markers further underscore their clinical and mechanistic relevance, respectively. The neuronal and glial-derived proteins may offer valuable insights into the complex pathophysiology of HE that warrant further evaluation.

Email: schober@biochem.mpg.de

Background and aims: Acute-on-Chronic Liver Failure (ACLF) is a life-threatening condition that includes failure of one or more organs after acute decompensation of cirrhosis. The clinical mode of action depends on accurate predictions of near-future events. Herein, we aim to identify prognostic biomarkers of ACLF events in patient plasma.
Method: We deployed mass spectrometry-based proteomics to quantify the in-depth plasma proteome profile of 93 patients in four disease groups (stable and unstable decompensated cirrhosis, pre-ACLF, at ACLF onset and after ACLF recovery) across multiple timepoints (n = 346). These discovery samples were part of the MICROB-PREDICT study cohort MUCOSA-PREDICT. We used an automated processing protocol for patient plasma and the highly reproducible Evosep system for liquid chromatography, coupled to a Thermo Scientific Orbitrap Exploris 480 mass spectrometer. Validation of the data on additional 550 plasma samples of VALIDATION-PREDICT measured on the latest Thermo Orbitrap Astral mass spectrometer is currently ongoing.
Results: On average, we detected 410 proteins across all discovery samples, and around 1, 500 proteins in the validation cohort. The data complied with quality control standards, including low coefficient of variation across 80% of all proteins, and low levels of typical erythrocyte, platelet and coagulation contamination markers. A set of nine differentially abundant proteins ($p < 0.05$ after multiple testing adjustment) was identified in a paired longitudinal analysis of pre-ACLF patients (n = 15). The levels of all nine potential biomarkers increased drastically upon ACLF onset compared to the admission timepoint, and dropped in the recovery period. This signature correlate strongly with creatinine levels and kidney failure.
Conclusion: We identified nine potential plasma biomarkers for ACLF that are significantly elevated upon disease onset compared to the baseline inclusion timepoint within the same patients. In combination with already established clinical read-outs, these proteins can contribute to predicting ACLF onset and to specifying the clinical mode of action.

WED-112

Plasma extracellular vesicles improve prediction of 90 day mortality in patients with acute decompensation of cirrhosis

Background and aims: Accurate prediction of survival in patients with acute decompensation of cirrhosis (AD) is key to orientate

patients with a poor predicted outcome to liver transplantation or to novel therapeutic approaches. The Clif-Consortium Acute Decompensation (Clif-C AD) score, dedicated to predict mortality in patients with AD, has been a step forward in that respect, but its predictive ability needs further improvements. Extracellular vesicles are released by cells undergoing a stress and are attractive biomarkers. The aim of the study was to identify plasma large extracellular vesicles (lEVs) able to improve prediction of death at 90 days in patients with AD.

Method: A pilot proteomic analysis was performed on plasma lEVs from two cohorts: 25 patients with AD, including 7 who died at 90 days, and 14 patients with stable decompensated cirrhosis, including 6 who died at 180 days. The identified lEV proteins were measured in plasma samples from patients with AD without ACLF at inclusion included in two prospective multicenter cohorts: PREDICT (serving as derivation cohort, n = 763) and ACLARA (serving as validation cohort, n = 579). Fine-Gray models were used to assess the risk of death at 90-days, liver transplantation being considered as a competing event.

Results: Proteomic analysis identified tenascin-C, IgG-Fc binding protein (FCGBP) and olfactomedin-4 on lEVs to be associated with mortality in patients with AD. We thus measured the three lEV proteins in plasma samples from patients of the PREDICT cohort (68% men, median age 59, median MELD 15, 90-day mortality rate 14%). Using multivariate analysis, concentrations of all three lEV were independently associated with 90-day mortality after adjustment on Clif-C AD and MELD scores. Mortality at 90 day gradually increased with the number of lEV above cut-off values identified using Youden index, from 3% to 30% for 0 and 3 high lEV, respectively. When combined with Clif-C AD score, plasma concentration of the 3 lEV improved prediction offered by Clif-C AD, reaching a 93% specificity for 90-day mortality vs. 40% for Clif-C AD score alone. We then measured these 3 lEVs on plasma samples from patients of the ACLARA validation cohort (65% men, median age 59, median MELD 15, 90-day mortality rate at 20%) and confirmed our Results: 90 day mortality increased with the number of high lEVs from 15% to 31% for 0 and 3 high lEV, respectively; the 3 lEV improved prediction offered by Clif-C AD, reaching a 95% specificity for 90-day mortality vs. 50% for Clif-C AD score alone.

Conclusion: We identified a lEV signature, including tenascin-C, FCGBP and olfactomedin-4 on lEVs able to identify a group of AD patients at high risk of short-term mortality. This added prognostic value might be explained by the fact that these lEV are released by organs and tissues (fibroblasts, gut and neutrophils) strongly implicated in the pathophysiology of AD.

WED-113

Histological, molecular, and neuromotor alterations of the liver-brain axis in an aged model of experimental cirrhosis

Oriol Juanola[1], Sebastian Martinez[1,2], Marina Serrano-Maciá[1], Enrique Angel[1,2], Isabel Gómez-Hurtado[2,3], Paula Boix[1], Francisco Navarrete Rueda[4], Maria Salud García Gutierrez[4], Esther Caparrós[1,2], Rubén Francés[1,2,3]. *[1]Grupo de Inmunobiología Hepática e Intestinal, Dpto. Medicina Clínica e Instituto IDIBE, Universidad Miguel Hernández, San Juan de Alicante, Spain; [2]IIS ISABIAL, Hospital General Universitario de Alicante, Alicante, Spain; [3]CIBERehd, Instituto de Salud Carlos III, Madrid, Spain; [4]Grupo de Neuropsicofarmacología Traslacional, Instituto de Neurociencias CSIC-UMH, San Juan de Alicante, Spain*
Email: rfrances@umh.es

Background and aims: During chronic liver disease (CLD), dysregulation of hepatic immunosurveillance and intestinal dysbiosis promote systemic inflammation and metabolic alterations, affecting neurocognitive function through the liver-brain axis. As aging may worsen neurological damage and CLD and its complications are more prevalent in the aging population, our aim was to assess differences in hepatic and neurocognitive damage based on age during experimental CLD.

Method: CLD was induced by oral administration of carbon tetrachloride (CCl_4) for 12 weeks (w) in young mice (6 w old) and aged mice (40 w old). Liver damage was assessed through histology and molecular biology. Levels of ammonia in different tissues were examined, and a panel of behavioural assays was conducted to assess neurological impairment.

Results: Hepatic damage was more severe following the induction of CLD in aged mice compared to young ones, exhibiting significantly elevated levels of ALT and AST, as well as, higher levels of red Sirius staining and lymphocyte recruitment (CD3), compared to the latter. Ammonia concentrations were higher in cirrhotic aged mice than in young ones in both serum (2.47 ± 0.74 vs 5.18 ± 2.36 nmol/uL, $p = 0.015$) and the brain (4.65 ± 0.41 vs 5.27 ± 0.86 nmol/uL, $p = 0.114$). Cirrhotic animals showed motor impairment and a tendency towards anxiety compared to healthy controls. Aged cirrhotic animals exhibited a significantly higher severity index in motor function than the young ones ($p = 0.023$). Interestingly, only ammonia levels in the brain correlated with results in the open field test ($r: -0.544$, $p = 0.003$) and motor evaluation test ($r: 0.444$, $p = 0.018$), suggesting a direct relationship between brain ammonia and neurological impairment. The increased anxiety shown by aged cirrhotic animals did not reach significant differences compared to the young ones.

Conclusion: Aged animals exhibit more severe liver damage during the experimental cirrhosis model, with higher levels of ammonia in the brain, and worse neurological function. Neurocognitive damage in young cirrhotic animals is similar to the impairment observed in healthy aged animals, suggesting a contribution of liver damage to neurological impairment during experimental cirrhosis.

WED-114

In vivo experiments and network pharmacology to explore the effect and mechanism of JiGuCao capsule in treating liver cirrhosis

Shihao Zheng[1], Wenying Qi[2], Size Li[2], Xu Cao[2], Xiaoke Li[2], Xiaobin Zao[2]. *[1]Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing 100700, China, Institute of Liver Diseases, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing 100700, China; [2]Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing 100700, China*
Email: A3417@bucm.edu.cn

Background and aims: Liver cirrhosis (LC) has been a serious threat to the health of people all over the world which has no effective treatment for now. Traditional Chinese medicine (TCM) has shown a good therapeutic effect for LC. The JiGuCao capsule (JGC) is a commonly used TCM that is already on the market for the treatment of acute and chronic hepatitis. However, the effect and mechanism of JGC in treading LC is not clear.

Method: The LC mice model was established by intraperitoneal injection of 10% CCl4 of olive oil mixture for 12 weeks. From the seventh week, the treatment group was given JGC granule aqueous solution by gavage. After treatment, the mice's body weight was recorded, and the mice's serum was used to detect biochemical indicators including alanine aminotransferase (ALT) and aspartate aminotransferase (AST). The rats' liver tissues were used to perform pathological examinations including HE staining, Masson staining, and Sirius red staining. The key compounds of JGC were detected by UHPLC-MS/MS analysis, and target genes of JGC in treating LC were obtained from the public databases. Then constructed the protein-protein interaction network and performed further enrichment analyses including the Gene Ontology (GO) and the Kyoto Encyclopedia of Genes and Genomes (KEGG) of the target genes.

Results: Compared to the control group, after modeling, the weight of the model mice was significantly decreased. Compared to the model group, significantly lower levels of serum ALT and AST in the JGC group than in the model were observed. The HE staining, Sirius red staining, and Masson staining showed less inflammatory damage and collagen production after JGC treatment compared to the model.

After UHPLC-MS/MS analysis and database mining, we obtained 337 overlapping genes (OGEs) between JGC targets and LC targets. The GO analysis of OGEs was mainly enriched in protein phosphorylation, cytosol, and enzyme binding. KEGG pathway enrichment analysis of OGEs showed that the key targets were significantly associated with the HIF-1 signaling pathway and PI3K-Akt signaling pathway.
Conclusion: JGC exerted a reversion effect on the progress of earlier LC in mice. Its molecular mechanism may be related to the regulation of the HIF-1 signaling pathway and PI3K-Akt signaling pathway.

Primary biliary cholangitis increases the risk of hepatocellular carcinoma: results from Mendelian randomization analysis and bioinformatics analysis

Yikai Wang[1], Muqi Wang[1], Xiaqing Zhou[1], Chenrui Liu[1], Meng Zhang[1], Miao Hao[1], Wenjun Wang[1], Yaping Li[1], Juanjuan Shi[1], Shuangsuo Dang[1]. [1]*The Second Affiliated Hospital of Xi'an Jiaotong University, xi'an, China*
Email: dang212@126.com

Background and aims: Primary biliary cholangitis (PBC) is an inflammatory factor closely associated with hepatocellular carcinoma (HCC); however, the relationship between these two liver diseases has not been well studied.
Method: GWAS data was obtained from the IEU Open GWAS database. Gene expression profiles were retrieved from the GEO and ICGC databases, respectively. A prediction model was constructed using COX regression with TCGA data, and its performance was assessed using ROC curves. Additionally, differentially expressed genes (DEGs) analysis at various stages was conducted using UALCAN, and their prognostic significance was evaluated using Kaplan-Meier (KM) curves. The correlation between DEGs and immune infiltration was assessed using TIMER. Finally, Cytoscape was employed to identify hub genes and perform enrichment analysis.
Results: MR analysis revealed a significant causal relationship between PBC and an elevated risk of HCC (OR >1, $p < 0.05$). Following prognostic analysis, LGALS3 and PRKCD exhibited associations with patient prognosis. These genes exhibited upregulation in HCC and were correlated with tumor grade and lymphatic metastasis. KM analysis further confirmed their close relationship with HCC prognosis. The prognostic model exhibited lower prognostic outcomes in the high-risk group. Both two genes exhibited positive correlations with tumor immune cell infiltration. Subsequent hub gene identification and enrichment analysis underscored their pivotal role in immune cell recruitment and migration in HCC.
Conclusion: This study establishes that PBC may contribute to an elevated risk of developing HCC, and the overexpression of LGALS3 and PRKCD may facilitate the progression of HCC.

WED-117

Targeted breath biopsy® profiling of induced biomarkers unveils a metabolic adaptation in cirrhosis toward alcohol production

Giuseppe Ferrandino[1], Federico Ricciardi[1], Antonio Murgia[1], Menisha Manhota[1], Daniela Fonseca[1], Louise Nicholson-Scott[1], Chloe Fitzpatrick[1], Olga Gandelman[1], Max Allsworth[1], Billy Boyle[1], Agnieszka Smolinska[1,2], Alexandra Ginesta Frings[3,4], Jorge Contreras[3], Victor Gabrielli[3], Claudia Asenjo-Lobos[5], Francisca Bascur[5], Viviana Barrientos[4], Nataly Clavo[4], Melissa Jerez[6], Luis Mendez[3,4]. [1]*Owlstone Medical, Cambridge, United Kingdom;* [2]*2Department of Pharmacology and Toxicology, School for Nutrition and Translational Research in Metabolism (NUTRIM), Maastricht University Medical Center, Maastricht, Netherlands;* [3]*Unidad de Gastroenterología y Endoscopía, Clínica Alemana, Facultad de Medicina Clínica Alemana, Universidad de Desarrollo, Santiago, Chile;* [4]*Unidad de Endoscopia, Hospital Padre Hurtado, Santiago, Chile;* [5]*Centro de Estudios Clínicos, Instituto de Ciencias e Innovación en Medicina (ICIM), Facultad de Medicina Clínica Alemana, Universidad del Desarrollo, Santiago, Chile;* [6]*Nursing School, Universidad de Las Américas, Santiago, Chile*
Email: giuseppe.ferrandino@owlstone.co.uk

Background and aims: Subjects with chronic liver disease have shown higher circulating ethanol levels after fasting or carbohydrates ingestion. However, clinical functional data about the capability of the injured liver to cope with alcohols remain limited. In this study we used exhaled breath analysis to explore the conversion of an alcohol to the corresponding ketone, and a ketone to the corresponding alcohol, to establish the suitability of potential metabolic alterations and identify subjects with cirrhosis using a non-invasive breath test.
Method: 2-butanol, and 2-pentanone (the substrates) were selected as an alcohol and a ketone based on their safe profile for human consumption, their reported hepatic metabolism, and their presence in breath. Hepatic metabolism was confirmed by simultaneous treatment of human suspension hepatocytes with 10 ng/µl of 2-butanol, and 2-pentanone to measure their conversion to respectively 2-butanone, and 2-pentanol (the bioproducts) by using headspace analysis coupled with gas-chromatography mass-spectrometry (GC-MS). Clinical metabolism of these compounds was evaluated by measurement of the breath profile in 14 subjects with cirrhosis and 14 healthy controls before and at different timepoints (10–120 minutes) after simultaneous ingestion of 2-butanol (100 mg) and 2-pentanone (100 mg) using Breath Biopsy® OMNI.
Results: The bioproducts were present in the head space of primary hepatocytes treated with the substrates and absent in control conditions omitting primary hepatocytes or substrates. After an overnight fasting all the participants showed breath levels of investigated compounds with no differences between healthy and cirrhosis groups ($p > 0.05$). After ingestion of the substrates, all the subjects showed a >100-fold increase of investigated compounds within 10 minutes. Subjects with cirrhosis showed higher levels of 2-butanol and 2-pentanol ($p < 0.05$) compared to healthy controls between 20- and 90-minutes post-administration. An exploratory classification model built on these breath-induced biomarkers at 20 minutes showed an area under the ROC curve of 0.92.
Conclusion: 2-butanol and 2-pentanone are metabolized to the corresponding ketone and alcohol in primary hepatocytes, supporting previous findings reporting hepatic metabolism. Subjects with cirrhosis showed higher breath levels of secondary alcohols independently from administration of the alcohol or the corresponding ketone, suggesting that the hepatic function is more balanced toward the alcohol production compared to healthy controls. This metabolic adaptation may contribute to higher circulating ethanol levels observed in subjects with chronic liver disease and be exploited in a breath test for cirrhosis detection.

WED-118

Mitoquinol intervention ameliorates cirrhosis associated hematopoietic imbalance and improves innate immune function

Deepanshu Maheshwari[1], Nidhi Nautiyal[1,2], Sandeep Kumar[1], Manisha Bhardwaj[3], Sunidhi Diwakar[1], Shivi Chauhan[1], Anupama Kumari[1], Archana Rastogi[1], Chhagan Bihari[1], Shiv Kumar Sarin[1], Anupam Kumar[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Amity Institute of Molecular Medicine and Stem Cell Research, Amity University, Noida, India;* [3]*Institue of Liver and Biliary Sciences, New Delhi, India*
Email: deepanshu.maheshwari@gmail.com

Background and aims: Myeloid-biased hematopoiesis play a key role in promotion and resolution of injuries and infections. In cirrhosis, this process becomes dysregulated, leading to poor resolution of infections and impaired healing. In this study, we aim to elucidate mechanism behind this and evaluate the potential of Mitoquinol (MQ) in improving innate immune function during cirrhosis.
Method: Cirrhosis was induced in C57Bl6 (n = 35) mice using CCl_4. Mice were culled for studying bone marrow (BM) hematopoietic stem cells (HSC), myeloid progenitors (MyP), multipotent progenitors

(MPP), and long-term HSCs (LT-HSC). Myeloid cell populations and functions were studied. In vitro, bone marrow-derived macrophages (BMDM) were treated with MQ (50 nM). In vivo, cirrhotic mice received MQ treatment (50 uM), controls were treated with PBS.
Results: We show progressive increase in myeloid-biased differentiation of HSC during chronic liver injury. During the transition from healthy to steatosis, there was an increase in monocytes and neutrophils in BM, along with elevation in MyP and MPP, without any loss of LT-HSC. From steatosis to fibrosis and cirrhosis, there was increase in MyP and MPP at the expense of LT-HSC. During this transition, while neutrophils increased, there was decline in monocytes and their phagocytosis and efferocytosis. Liver showed increased influx of neutrophils ($p < 0.01$), loss of the monocytes ($p < 0.01$), and impaired function ($p < 0.05$). Both BM-HSCs and monocytes showed progressive increase in cellular and mitochondrial (mt) ROS with loss of mt biomass and potential during cirrhosis. In vitro treatment of BMDM with MQ demonstrated elevated production of naïve macrophages with improved phagocytosis ($p < 0.05$) and efferocytosis ($p < 0.01$). MQ-BMDM showed increased mt potential. In vivo treatment with MQ resulted in reduced neutrophil infiltration and decreased Kupffer cell loss. HSCs from MQ-treated mice showed increased glucose uptake and mt biomass compared to controls. MQ-HSCs displayed lower TLR2 expression compared to controls. MQ mice did not show changes in MyP but showed increased production of functional monocytes ($p < 0.01$) with reduced neutrophils ($p < 0.01$). BMDM from MQ mice showed increased mt respiration and ATP-linked oxygen consumption. MQ mice showed reduced liver injury and fibrosis compared to controls.
Conclusion: Our study shows an increase in myeloid-biased differentiation of HSC during chronic liver injury. Shift from steatosis to fibrosis and cirrhosis show increased myelopoiesis, impacting LT-HSC, along with altered monocyte and neutrophil dynamics. Overall, suggesting potential role of dysregulated hematopoiesis in the loss of liver monocyte/macrophages and their function. In vivo and in vitro MQ treatments demonstrated therapeutic potential by mitigating neutrophil infiltration, enhancing macrophage function, and reducing liver injury.

WED-120
Albumin infusion in decompensated cirrhotic patients with ascites induced decreasing serum active form of vitamin D, 1, 25 dihydroxy vitamin D, an opposite effect on promoting systemic inflammatory cytokines reduction

Thitaporn Roongrawee[1], Sirinporn Suksawatamnuay[2], Nunthiya Srisoonthorn[3], Nipaporn Siripon[4], Panarat Thaimai[5], Prooksa Ananchuensook[6], Supachaya Sriphoosanaphan[7], Kessarin Thanapirom[8], Piyawat Komolmit[9]. *[1]King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [2]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand; [3]Center of Excellence in Liver Diseases, King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [4]Center of Excellence in Liver Diseases, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [5]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand, King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [6]Division of Gastroenterology, Department of Medicine, Chulalongkorn University, Bangkok, Thailand; [7]Institute for Liver and Digestive Health, University College London, London, United Kingdom; [8]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Bangkok, Thailand; [9]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand*
Email: thitagiftr@gmail.com

Background and aims: Decompensated cirrhosis, characterized by excessive inflammation, contributes to multiorgan dysfunction. Current comprehension of albumin extends beyond its oncotic properties to encompass anti-inflammatory effects. A prior study, in a small number of cases, exhibited a notable decrease in inflammatory cytokine levels following high-dose albumin infusion in cirrhotic patients, suggesting a potential link between albumin replacement therapy and its anti-inflammatory mechanisms. This study aims to explore the intricate role of albumin infusion by focusing on its immunomodulatory properties. The hypothesis posits that the anti-inflammatory attributes of albumin replacement therapy in cirrhotic patients might be partially linked to alterations in 1, 25 $(OH)_2$ vitamin D levels, thereby influencing immune regulation.
Method: This prospective open-label study was conducted at the Liver Clinic of King Chulalongkorn Memorial Hospital, and targeted patients diagnosed with decompensated cirrhosis with ascites. Participants meeting inclusion criteria underwent high-dose albumin infusion therapy (80 grams of albumin). Primary objectives centered on evaluating changes in 1, 25 $(OH)_2$ vitamin D levels, and 25 (OH) vitamin D levels before and after albumin infusion over one week. Secondary outcomes involved assessing alterations in ten inflammatory cytokine levels pre- and post-albumin infusion.
Results: Interim analysis encompassed seventeen cases of decompensated cirrhosis with ascites. Alcohol-associated cirrhosis was the most prevalent cause (N = 5), followed by NASH (N = 4), chronic hepatitis B infection (N = 3), cryptogenic (N = 2), and other causes. Ten patients had Child Pugh scores B, while seven had Child-Pugh scores C, averaging a Child-Pugh score of 9 points. The average MELD-Na score was 15.7 ± 5.11. Post-albumin infusion, 1, 25 $(OH)_2$ vitamin D levels significantly decreased over a week ($p = 0.011$), while 25 (OH) vitamin D levels slightly decreased ($p = 0.101$). Importantly, IL-1 beta, IL-6, TNF-alpha, and IFN-gamma levels significantly decreased post-intervention ($p = 0.043$, 0.037, 0.005, and 0.02, respectively). However, no correlation was observed between changes in vitamin D levels and cytokine levels.
Conclusion: This study evidenced a significant reduction in 1, 25 $(OH)_2$ vitamin D and inflammatory cytokine levels following high-dose albumin infusion in decompensated cirrhosis patients. While the direct relationship remains unclear at this stage, these findings hint at a potential mechanism influencing the complex interplay between albumin therapy, vitamin D alterations, and immune modulation. Further comprehensive investigations are warranted to elucidate this intricate relationship.

WED-121-YI
Increased procoagulant activity of tissue factor-expressing microvesicles in patients with liver cirrhosis

Adonis Protopapas[1], Anna Takardaki[2], Nefeli Protopapa[1], Ioanna Papagiouvanni[3], Andreas Protopapas[1], Lemonia Skoura[2,2], Christos Savopoulos[1], Ioannis Goulis[3]. *[1]First Propaedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [2]Department of Microbiology, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [3]Fourth Internal Medicine Department, Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece*
Email: adoprot@hotmail.com

Background and aims: Cirrhosis is characterized by significant perturbations of the coagulation mechanism. Tissue factor (TF) is the main activator molecule of the coagulation cascade. The main mode of TF activation is through its expression by microvesicles, establishing them as an important research focus in multiple prothrombotic syndromes. Therefore, their study may provide valuable insights into the hypercoagulability of cirrhosis and possible mechanisms by which it contributes to disease progression. Our study aimed to assess TF levels and activity of TF-expressing microvesicles in the plasma of cirrhotic patients and correlate them with disease severity.
Method: Sixty-one cirrhotic patients [including 11 with hepatocellular carcinoma (HCC)] and 21 controls were prospectively enrolled in

the study. Exclusion criteria were history of cancer (except HCC), haematological diseases, thrombophilia, history of thrombosis, recent hospitalization, anticoagulant, antiplatelet or contraceptive drugs, ongoing infection or alcohol use and chronic kidney disease. In addition to workup for disease staging and exclusion criteria testing, plasma TF antigen concentration (Quantikine®ELISA) and TF-expressing plasma microvesicle activity (ZYMUPHEN MP-TF) were measured.

Results: 50% of the patients had decompensated cirrhosis (DeCi). The patients' Child-Pugh (CP) stage was A in 56%, B in 26% and C in 18% of cases, respectively. TF antigen concentration (TFa) was 71.2 [56.8–81.9], 59.7 [47.1–66.6] and 43.9 [29.4–47.9] pg/ml in the cirrhosis with HCC (group 1), cirrhosis without HCC (group 2) and control (group 3) groups, respectively. There was a statistically significant difference between groups 1 and 3 ($p < 0.001$) and groups 2 and 3 ($p < 0.001$), while group 1 had higher values than group 2 without statistical significance ($p = 0.133$). The activity of TF-expressing microvesicles (MV-TF) showed values of 4.03 [3.35–4.92], 3.22 [2.44–4.09] and 2.17 [1.49–3.05] pg/ml in groups 1, 2 and 3 respectively. There was a statistically significant difference between groups 1 and 3 ($p < 0.001$) and groups 2 and 3 ($p = 0.003$), while group 1 had higher values than group 2 without statistical significance ($p = 0.088$). There was a significant correlation of MV-TF but not TFa with DeCi ($p = 0.005$ and $p = 0.404$), with DeCi patients having higher MV-TF values. There was also a significant correlation with CP stage ($p = 0.011$ for MV-TF and $p = 0.037$ for TFa), with higher values reported in patients of higher CP stage.

Conclusion: Increased TFa and MV-TF values in cirrhotic patients highlight the prothrombotic dynamics of the disease, which increase with disease severity. The fact that all patients had stable disease indicates that these dynamics are intrinsic to cirrhosis and independent of acute complications. The next step is to investigate the association of these with disease progression and thrombotic complications.

WED-122-YI

The soluble guanylate cyclase pathway is dysregulated in rodent models of cirrhosis and portal hypertension

Thomas Sorz-Nechay[1,2,3], Ksenia Brusilovskaya[1,3], Philipp Königshofer[1,3], Benedikt Hofer[1,3], Oleksandr Petrenko[1,2,3], Benedikt Simbrunner[1,2,3], Vlad Taru[1,3], Kerstin Zinober[1,3], Katharina Regnat[1,3], Katharina Bonitz[1,2,3], Henriette Horstmeier[1], Ines Truebenbach[4], Peng Sun[4], Stefan Günther Kauschke[4], Larissa Pfisterer[4], Michael Trauner[1], Philipp Schwabl[1,2,3], Thomas Reiberger[1,2,3]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria; [3]Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria; [4]Department of CardioMetabolic Diseases Research, Boehringer Ingelheim Pharma GmbH and Co.KG, Biberach an der Riss, Germany*
Email: thomas.sorz-nechay@meduniwien.ac.at

Background and aims: Stimulation of the nitric oxide (NO)-soluble guanylate cyclase (sGC) pathway represents a promising approach for the treatment of liver disease. We investigated key molecular nodes of the NO-sGC pathway in different rodent models of liver fibrosis and portal hypertension (PH).

Method: 44 Sprague Dawley rats were used in four models of liver disease: 4 weeks (W) bile duct ligation (BDL, n = 4), W12 choline deficient high fat diet (CDHFD, n = 6), W12 carbon tetrachloride induced (CCl4, n = 6) and W12 thioacetamide induced (TAA, n = 6). Controls were: sham-operated (SHAM, n = 4), chow fed (CHOW, n = 6), olive oil (OO, n = 6) and natrium-chloride (NaCl, n = 6). Portal pressure (PP) measurement and livers were collected at the end of each timeline. Fibrosis was evaluated by collagen proportionate area (CPA). Gene expression and protein levels were assessed via RT-qPCR and Western-blot.

Results: All models developed liver fibrosis (CPA: BDL: 9.01 ± 3.09%; CDHFD: 8.97 ± 4.27%; CCl4: 4.86 ± 1.54%; TAA: 8.67 ± 1.84%) and PH (PP: BDL: 13.57 ± 2.85 mmHg; CDHFD: 11.30 ± 2.91 mmHg; CCl4: 9.03 ± 0.63 mmHg; TAA: 12.68 ± 2.94 mmHg). The BDL model showed potent upregulation of inducible nitric oxide synthetase (iNOS, 28.10 ± 11.95-fold; $p = 0.029$) and downregulation of sGC beta2 (0.19 ± 0.07-fold; $p = 0.029$). In the CDHFD model, the sGC alpha1 (1.75 ± 0.57-fold, $p = 0.004$) and beta1 (2.04 ± 0.72-fold, $p = 0.004$) subunits were upregulated; sGC beta1 was also upregulated in the CCl4 model (1.40 ± 0.17-fold, $p = 0.030$). The TAA model also showed upregulation of sGC beta1 (1.64 ± 0.27-fold, $p = 0.004$) and a downregulation of sGC alpha2 (0.66 ± 0.09-fold; $p = 0.026$) subunits. Proteinkinase G1 (PKG1) was upregulated only in CDHFD (1.90 ± 0.62-fold, $p = 0.002$) and TAA (1.90 ± 0.34-fold, $p = 0.002$) models. In all models, we observed significant upregulation of phosphodiesterase (PDE) 5 (BDL: 5.72 ± 0.75-fold; $p < 0.029$; CDHFD: 5.70 ± 2.22-fold, $p = 0.004$; CCl4: 1.97 ± 0.33-fold, $p = 0.002$; TAA: 5.56 ± 0.74-fold, $p < 0.002$). Protein content of all three sGC subunits, PKG1 and PDE5 on Western-blot was concordant to the respective changes on the RNA level.

Conclusion: The NO-sGC pathway was dysregulated, albeit at different molecular nodes in all rat models of PH induced by distinct types of liver injury. These results underline the potential of sGC activators for the treatment of cirrhotic portal hypertension.

WED-123

Female mice with cirrhosis are more prone to acute and chronic effects of psilocybin exposure without tolerance compared to male mice

Jessica Maltman[1], Derrick Zhao[1], Alaina Jaster[1], Yunling Tai[1], Jing Zeng[1], Javier Maeso-Gonzalez[1], Huiping Zhou[1], Jasmohan Bajaj[1]. *[1]Virginia Commonwealth University, Richmond, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Use of psychedelics such as psilocybin for treating psychiatric disorders including PTSD and recalcitrant depression is rising. Preclinical findings indicate sex differences in response to psychedelics. Cirrhosis often coexists in subjects using psychoactive substances, but the safety profile is unclear. Aim: Define the impact of sex and of concomitant cirrhosis on response to psilocybin in a mouse model.

Method: MDR2KO and wild type (WT) mice (both male and female, 8–10 mths old) were included; we ensured the MDR2KO mice had developed cirrhosis. The head-twitch response (HTR) is a rapid side-to-side rotational head movement used as a behavioral proxy of human psychedelic potential in rodents. Psilocybin or vehicle was administered i.p. dose of 1 mg/kg (5 µl/g) at days 1, 12 and 21. HTR was tested 60 min post injection at days 1 and 21. 3-way ANOVA (drug x genotype-sex) analyses for genotype, sex, and drug effects were performed along with separate sex-collapsed and genotype-collapsed analyses.

Results: We included 3–4 mice/subgroup (MDR2KO vs WT, males vs females). Day 1: After a single psilocybin dose, the acute HTR showed significant interactions between treatment, sex and genotype (MDR2KO vs WT); while psilocybin increased HTR across all groups, only MDR2KO females showed a significant HTR increase vs all vehicle/psilocybin-Rx groups. 3-way ANOVA revealed a significant effect of psilocybin ($p < 0.0001$), genotype ($p = 0.0237$), sex ($p = 0.0044$). Significant interactions were observed between all variables (psilocybin × Genotype $p = 0.03$, psilocybin × Sex $p = 0.015$, Genotype × Sex $p = 0.0414$, and psilocybin × Genotype × Sex $p = 0.02$) Day 21: After 3 psilocybin doses (days 1, 12 and 21), the HTR showed a significant effect of treatment, and only MDR2KO females displayed a significant effect of psilocybin vs all vehicle groups. On multiple comparisons, a significant difference between psilocybin-treated KO females vs vehicle groups (WT males $p = 0.016$, WT females $p = 0.019$, KO males $p = 0.021$, KO females $p = 0.022$) was seen. Combined day 1 +21 data: HTR showed several significant interactions, again showing

that psilocybin's impact is greater in MDR2KO females vs both vehicle- and psilocybin-treated groups. 3-way ANOVA showed significant effect of psilocybin ($p < 0.0001$), genotype ($p = 0.037$), sex ($p = 0.007$), and an interaction between psilocybin x genotype ($p = 0.008$) and psilocybin x genotype x sex ($p = 0.034$).
Conclusion: MDR2KO female mice with cirrhosis have an increased acute response to psilocybin in the head twitch assay, and do not develop a potential tolerance effect developed by other groups with repeated exposure to psilocybin. This suggests that females with cirrhosis may display differences in the establishment of tolerance to psilocybin and increased subjective effects from this psychedelic and should inform upcoming investigations into safe use of this drug in patients.

WED-124
Assessment of plasma VCAM-1 levels in pediatric portal hypertension and its relationship with disease severity
Tengfei Si[1], Huihong Yu[2], Bethany Tucker[3], Fabiola Di Dato[1], Xiaohong Huang[1], Qing Shao[1], Bowen Gao[1], Xuan Luo[1], Eirini Kyrana[3], Yun Ma[1], Tassos Grammatikopoulos[4]. *[1]Institute of Liver Studies, King's College London, London, United Kingdom; [2]Institute Of Liver Studies, King's College London, London, United Kingdom; [3]King's College Hospital, King's College London, London, United Kingdom; [4]King's College Hospital, Paediatric Liver Department, London, United Kingdom*
Email: tengfei.si@kcl.ac.uk

Background and aims: Portal hypertension (PHT), often a consequence of chronic liver disease (CLD) or portal vein thrombosis (PVT), lacks specific inflammatory biomarkers for early detection and monitoring. This study explores the potential of plasma VCAM-1 as a biomarker in children with PHT.
Method: We analysed plasma samples from 55 children (33 males) with PHT and oesophageal varices, alongside 15 healthy, age-matched controls. The study involved investigation of various immune markers and collection of clinical data for correlation studies.
Results: In the PHT group, levels of soluble CD163 (sCD163) and vascular cell adhesion molecule-1 (VCAM-1) were significantly higher (633.5 ng/ml vs. 414.8 ng/ml, $p = 0.0028$; 861 ng/ml vs. 397.7 ng/ml, $p < 0.0001$, respectively) compared to controls. A positive correlation was noted between VCAM-1 and both sCD163 ($r = 0.5267$, $p = 0.0002$) and matrix metalloproteinase 7 (MMP7) ($r = 0.3374$, $p = 0.014$). VCAM-1 exhibited a high diagnostic accuracy for PHT (ROC curve area: 0.957), with an optimal cut-off of 549.1 ng/ml yielding a sensitivity of 93.3% and specificity of 91.1%. VCAM-1 levels were stable across different PHT subgroups but were lower in patients with a history of bleeding (816 ng/ml vs. 964 ng/ml, $p = 0.04$). A positive correlation was found between VCAM-1 levels and liver stiffness. Notably, treatment with non-selective beta blockers significantly reduced VCAM-1 levels (869.7 ng/ml to 651.9 ng/ml, $p < 0.0001$).
Conclusion: Plasma VCAM-1 levels are closely linked to the development and progression of PHT in children, offering high diagnostic accuracy. This suggests its potential as a reliable biomarker for the condition.

Differential regulation of soluble guanylate cyclase signaling during liver fibrosis regression
Thomas Sorz-Nechay[1,2,3], Ksenia Brusilovskaya[1,3], Philipp Königshofer[1,3], Benedikt Hofer[1,3], Oleksandr Petrenko[1,2,3], Benedikt Simbrunner[1,2,3], Vlad Taru[1,3], Kerstin Zinober[1,3], Katharina Regnat[1,3], Katharina Bonitz[1,2,3], Henriette Horstmeier[1], Ines Truebenbach[4], Peng Sun[4], Stefan Günther Kauschke[4], Larissa Pfisterer[4], Michael Trauner[1], Philipp Schwabl[1,2,3], Thomas Reiberger[1,2,3]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria; [3]Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria; [4]Department of CardioMetabolic Diseases Research, Boehringer Ingelheim Pharma GmbH and Co.KG, Biberach an der Riss, Germany*
Email: thomas.sorz-nechay@meduniwien.ac.at

Background and aims: Pharmacologic agonists of the nitric oxide (NO)-soluble guanylate cyclase (sGC) pathway exert antifibrotic effects when administered during ongoing liver disease. We aimed to investigate key molecular nodes of the hepatic NO-sGC pathway in mouse models of ongoing fibrogenesis and fibrosis regression.
Method: Male C57BL/6 mice were used for two models of liver fibrosis: carbon tetrachloride induced (CCl4, oral gavage 3x/week for 12 weeks, $n = 8$) and thioacetamide induced (TAA, intraperitoneal injection 3x/week for 12 weeks, $n = 8$). The respective controls received olive oil (OO, $n = 5$) or natrium chloride (NaCl, $n = 8$). Both models included additional groups with 1 or 2 week (s) of regression ($n = 7$ for CCl4-R1 and R2, $n = 8$ for TAA-R1 and R2), when no toxic agent was administered. Portal pressure (PP) measurement and sample collection occurred at the end of each timeline. Collagen-proportionate area (CPA) was measured via histomorphometry of digitized picrosirius-red stained liver sections. Gene expression was assessed via RT-qPCR and expressed as fold-change to healthy controls. Liver cGMP content was determined by LC/MS.
Results: Both models developed fibrosis and increased PP which decreased during regression: CCl4: CPA: 16.91 ± 3.64% vs R1 10.93 ± 2.83% vs R2 5.43 ± 1.33%, $p < 0.001$; PP: 9.98 ± 1.09 mmHg vs R1 8.35 ± 0.73 mmHg vs R2 7.89 ± 1.07 mmHg, $p < 0.001$; TAA: CPA: 3.87 ± 0.34% vs R1 3.49 ± 0.59% vs R2 2.90 ± 0.28%, $p < 0.001$; PP: 7.71 ± 0.53 mmHg vs R1 7.28 ± 0.44 mmHg vs R2 6.04 ± 0.48 mmHg, $p < 0.001$. In the CCl4 model, we found transcriptional changes mostly at R2 with increased expression of inducible nitric oxide synthase (4.80 ± 2.28-fold vs CCl4 2.23 ± 1.89-fold, $p = 0.108$), sGC alpha1 (3.15 ± 0.74-fold vs CCl4 1.80 ± 1.13-fold, $p = 0.054$), sGC alpha2 (1.98 ± 0.18-fold vs CCl4 0.64 ± 0.44-fold, $p = 0.001$), phosphodiesterase (PDE) 5 (2.50 ± 0.72-fold vs CCl4 1.23 ± 0.78-fold; $p = 0.020$) and PDE9 (0.82 ± 0.15-fold vs CCl4 0.14 ± 0.08-fold; $p = 0.001$). In the TAA model transcriptional changes occurred already at R1 with increases in sGC alpha2 (1.30 ± 0.13-fold vs TAA 0.65 ± 0.07-fold, $p < 0.001$), sGC beta1 (2.04 ± 0.35-fold vs TAA 1.36 ± 0.12-fold, $p = 0.018$), and PDE9 (0.72 ± 0.15-fold vs TAA 0.11 ± 0.02-fold, $p = 0.007$). Hepatic cGMP levels were decreased in diseased livers vs healthy controls (CCL4: 3.86 ± 0.63 nM vs. OO 4.13 ± 0.37 nM, $p = 0.985$; TAA 2.96 ± 0.73 vs NaCl 5.23 ± 0.90 nM, $p = 0.001$) and recovered with liver disease regression: CCL4-R1 (6.28 ± 1.46 nM; $p = 0.030$) and R2 (5.49 ± 2.41 nM; $p = 0.162$); TAA-R1 (5.22 ± 1.26 nM, $p = 0.001$) and R2 (6.68 ± 1.04 nM, $p < 0.001$).
Conclusion: The NO-sGC-cGMP pathway is dysfunctional in CCl4/TAA mouse models with dysregulated sGC subunits and decreased hepatic cGMP bioavailability. With liver disease regression, hepatic cGMP levels recover spontaneously. Future studies should evaluate if pharmacological sGC activation can promote fibrosis regression.

WED-126
Biglycan as a biomarker in acute-on-chronic liver failure (ACLF)
Martin Schulz[1,2,3], Esther Roth[3], Jinyang Zeng-Brouwers[3], Konrad Buscher[1], Robert Schierwagen[1], Maximilian Joseph Brol[1], Frank Erhard Uschner[1], Sabine Klein[1], Stefan Zeuzem[2], Kai-Henrik Peiffer[1], Jonel Trebicka[1,4], Liliana Schaefer[3]. *[1]University Hospital Münster, Münster, Germany; [2]University Hospital Frankfurt, Frankfurt am Main, Germany; [3]Institute of Pharmacology and Toxicology, Frankfurt, Germany; [4]European Foundation for Study of Chronic Liver Failure, Barcelona, Spain*
Email: martinsebastian.schulz@ukmuenster.de

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by systemic inflammation (SI), development of organ failures and a high short-term mortality in patients with liver cirrhosis. Recently, danger-associated molecular pattern (DAMPs) have received an increased focus as endogenous triggers of SI. Biglycan is a proteoglycan of the extracellular matrix (ECM), which is

released into the blood as a response to tissue injury. Soluble biglycan can trigger distinct pro-inflammatory pathways by direct toll-like receptor 2 (TLR2) and TLR4 interaction. However, its role in ACLF remains uncharted.

Method: In this observational study we collected plasma samples from patients with compensated cirrhosis (CC, n = 10), acute decompensation (AD, n = 10) and ACLF (n = 10). ACLF was defined according to EASL-CLIF definition. Samples were centrifuged (2, 000 rpm, 10 min), biglycan was extracted, semipurified and analysed by western blot. Pro-Inflammatory cytokines were measured by a human-specific ELISA assays.

Results: Median age of CC patients was 66 years (IQR 58–70), while AD and ACLF patients were younger (57 years, n.s.) and predominantly male (70%). Median MELD was 6 (IQR 6–15) in CC patients, 17 (IQR 11–19) in AD and 36 (IQR 30–40) in ACLF. 28-day mortality was 0% in CC patients, 12.5% in AD and 30% in ACLF ($p < 0.001$). In AD patients, plasma levels of soluble biglycan were 2.6-fold higher compared to CC, while ACLF patients showed an even steeper increase by 7.5-fold ($p < 0.001$). Compared to AD, ACLF biglycan levels were also significantly elevated (2.9-fold, $p < 0.01$). Moreover, soluble biglycan was strongly correlated with severity of liver disease (MELD, $r = 0.88$, $p < 0.0001$) and ACLF grade ($r = 0.86$, $p < 0.001$). It also showed significant correlations with markers of systemic inflammation, such as IL-8 ($r = 0.663$, $p < 0.001$) and IL-6 ($r = 0.587$, $p < 0.001$). In ACLF patients, soluble biglycan was the strongest predictor for short-term mortality (AUC 0.91), higher than IL-6 (AUC 0.81) or MELD score (AUC 0.67).

Conclusion: Our data show that soluble biglycan could constitute a novel biomarker in ACLF. As a biomarker, biglycan could synthesize distinctive characteristics of hepatic fibrosis and the inflammatory liver microenviroment, since it can be released from the cirrhotic liver upon tissue injury. Moreover, in its role as a canonical ECM-derived DAMP, increased levels of soluble biglycan could then possibly trigger and perpetuate SI upon ACLF progression. However, further studies are necessary to elucidate the mechanistical role of biglcan in ACLF and its utility as a biomarker.

Cirrhosis and its complications – Other clinical complications except ACLF and critical illness

Background and aims: Acute kidney injury (AKI) is a serious complication of cirrhosis. Little is known about the epidemiology of AKI in different regions in the world. We performed a multicenter prospective intercontinental study to assess the global differences in the characteristics, management and outcomes of AKI in hospitalized patients with cirrhosis.
Method: Patients admitted to the hospital for decompensated cirrhosis were enrolled from July 2022 to May 2023 at 67 centers in 5 continents (Africa, Asia, Europe, North America and South America). We captured demographics, AKI precipitants, stage and phenotypes [hypovolemic, hepatorenal syndrome (HRS-AKI), acute tubular necrosis (ATN), and others] and details on AKI management and clinical course. Data on AKI resolution and 28-day mortality were collected. AKI characteristics, management and outcomes were compared among the five regions, utilizing multivariable models to assess the independent association between regions and outcomes.
Results: Among 3, 792 enrolled patients, 1, 456 (36%) developed AKI, of which the majority were community-acquired (71%). The most common precipitant for AKI was volume loss (47%), followed by infections (42%). Peak AKI stage was highest in North America and lowest in Europe ($p < 0.001$). Significant differences in the management of AKI (use of albumin, crystalloids, diuretics and vasoconstrictors) were found between regions. Overall, hypovolemic AKI was the most common phenotype (58%). The prevalence of HRS-AKI was similar among regions (ranging from 14% to 20%; $p = 0.275$), while ATN was more frequent in Asia and North America (25% and 17%, respectively; $p < 0.001$ vs other regions). AKI outcomes also differed significantly between regions. Non-resolution rates were highest in North America and lowest in Europe (51% vs 32%; $p < 0.001$). On multivariable analysis (adjusted for age, sex, etiology of cirrhosis, ascites, hepatic encephalopathy, MAP, ACLF grade, AKI stage and phenotype), patients admitted in North America and Asia had higher risk of AKI non-resolution [odds ratio 2.42 ($p < 0.001$) and 2.14 ($p < 0.001$), respectively]. Overall, 23% of patients died at 28 days. On multivariable analysis, patients admitted in Asia and North America had an increased risk for 28-day mortality [subdistribution-hazard ratio 1.85 ($p = 0.002$) and 1.73 ($p < 0.001$), respectively].
Conclusion: This global study found important regional differences in AKI severity, phenotype, management and outcomes. In particular, the differences identified in AKI resolution and mortality rates across regions should be further explored and drive the implementation of strategies to improve kidney- and patient-related outcomes.

The efficacy of Glucagon-like Peptide-1 receptor agonists in patients with compensated cirrhosis and obesity

Wee Han Ng[1], Yee Hui Yeo[2], Amit Singal[3], Neehar D. Parikh[4], Alexander Kuo[2], Hyunseok Kim[2], Yun Wang[2], Hirsch Trivedi[2], Nicole Rich[5], Jamil Samaan[2], Walid S Ayoub[6], Kevin Ma[7], Ju Dong Yang[2]. *[1]Bristol Medical School, Bristol, United Kingdom; [2]Karsh Division of Gastroenterology and Hepatology, Cedars-Sinai Medical Center, Los Angeles, United States; [3]UT Southwestern Medical Center, Dallas, Texas, United States; [4]University of Michigan Medical School, Ann Arbor, United States; [5]UT Southwestern Medical Center, Dallas, United States; [6]Karsh Division of Gastroenterology and Hepatology, Cedars-Sinai Medical Center, Bristol, United States; [7]Department of Epidemiology, Harvard T. H. Chan School of Public Health, Boston, United States*
Email: qx21999@bristol.ac.uk

Background and aims: Glucagon-like Peptide-1 receptor agonists (GLP-1RAs) are effective treatment for type 2 diabetes mellitus (T2DM) and obesity. Herein, we aimed to investigate the association between the use of GLP-1RAs and overall survival, hepatocellular carcinoma (HCC), and hepatic decompensation in patients with compensated cirrhosis and obesity.
Method: We conducted a retrospective cohort study using a multicenter nationwide database (TriNetX). We compared patients with obesity (body mass index (BMI) $\geq 35\ kg/m^2$) and compensated cirrhosis who started GLP-1RA after the diagnosis of cirrhosis vs. never received any GLP-1RA between 28 April 2005 (date of FDA approval of exenatide) and 31 October 2022 using propensity score matching (based on age, sex, race, diabetes status, BMI, cardiovascular risk factors, chronic kidney disease, AST, ALT, INR, albumin, bilirubin, creatinine, cirrhosis etiology, diabetic, hypertensive, antiviral drugs for hepatitis B and C infections, lipid-lowering agents including statins, and aspirin). The primary end point was overall survival, and secondary end points were HCC and hepatic decompensation events.
Results: Of 27497 obese patients with compensated cirrhosis, 1699 were GLP-1RA users and 25797 non-users. After propensity score matching, 1498 users and 1496 non-users were included. The two arms were well-balanced in all examined demographic and clinical characteristics. GLP-1 RA user non-user groups had a mean (SD) age of 56.1 (12.1) vs 56.2 (13.2); 68.7% vs. 70.7% were White, and 42.0% vs. 40.6% were males, respectively. At 10-year follow-up, GLP-1 RA use was associated with significantly lower all- cause mortality (Hazard ratio (HR) 0.56, 95%CI 0.45–0.68). Compared to short duration GLP-1 RA use (1–3 refills), both medium (3–6 refills) and long (>7 refills) durations were associated with lower all-cause mortality (medium: HR 0.58, 05% CI 0.37–0.93) (long: HR 0.43, 95% CI: 0.25–0.73). GLP-1 RA use was associated with significantly lower risk of decompensated cirrhosis (HR 0.52, 95%CI 0.38–0.72), including a lower risk of hepatic encephalopathy (HR 0.50, 95%CI 0.35–0.72) and ascites (HR 0.57, 95% CI 0.33–0.99). GLP-1 RA use was also associated with a lower risk of developing HCC (HR 0.41, 95%CI 0.19–0.88). As a negative control, GLP-1 RA use was not associated with lower risk of overall cancer (HR 0.71, 95%CI 0.49–1.03) or lung cancer (HR 0.86, 95%CI 0.31–2.4).
Conclusion: GLP-1RA use is associated with a lower risk of overall mortality, HCC development, and hepatic decompensation in patients with obesity and compensated cirrhosis. Future trials investigating the safety and efficacy of GLP-1RA in patients with compensated cirrhosis and obesity are needed.

Email: salvatore.piano@unipd.it

Background and aims: Acute kidney injury (AKI) is a common complication in patients with decompensated cirrhosis. Bacterial infection (BI) is a frequent precipitating factor for AKI. However, it is unknown whether BI-related AKI has different characteristics and outcomes than AKI not precipitated by BI.
Method: We performed a multicenter, prospective, intercontinental study to investigate global differences in the characteristics, management and outcomes of AKI in patients with cirrhosis. Patients admitted to the hospital for decompensated cirrhosis were included at 67 hospitals in 5 continents, between July 2022 and May 2023. Demographical data, AKI precipitants, phenotypes and treatment were collected. Patients were followed until 90 days, death, or liver transplantation. AKI characteristics and outcomes were compared between patients with BI-related AKI and those in whom AKI precipitant was other than BI. In this analysis, competing-risk multivariable models were used to determine the independent association of BI-related AKI with 28-day mortality.
Results: Among 3, 792 enrolled patients, 1, 456 patients (36%) had AKI and BI was the second most common AKI precipitant after volume loss/hypovolemia. BI was identified as the precipitant of AKI in 598 patients (41%), with urinary tract infection, spontaneous bacterial peritonitis (SBP), and pneumonia as the most common types of infection (28%, 26% and 25%, respectively). Patients with BI-related AKI had worse kidney and liver function at the time of AKI diagnosis, as shown by higher AKI stage (peak AKI stage 2/3 70% vs 55%; $p < 0.001$), higher MELD score (25 vs 22; $p < 0.001$) and higher prevalence of acute-on-chronic liver failure (ACLF, 64 vs 56%; $p = 0.003$). In addition, those with BI-related AKI had increased signs of systemic inflammation, with higher C-reactive protein (6.0 vs 2.4, $p < 0.001$) and white blood cell (WBC) count (10.7 vs 7.5, $p < 0.001$). The prevalence of acute tubular necrosis (ATN) was significantly higher in patients with BI-related AKI than in those with AKI not triggered by BI (22% vs 10%, $p < 0.001$) while no difference was found in the prevalence of hepatorenal syndrome-AKI. Complete AKI resolution was significantly lower in BI-related AKI (55% vs 62%; $p = 0.004$) Mortality rates at 28 days were higher in patients with BI-related AKI than in those with non BI-related AKI (31% vs 17%, $p < 0.001$). In multivariable analysis (adjusted for age, sex, etiology of cirrhosis, ascites, hepatic encephalopathy, MAP, WBC, ACLF grade, and AKI stage) BI-related-AKI was associated with higher risk of 28-day mortality (sHR 1.35; $p = 0.013$). Among infections, pneumonia and SBP were associated with the highest risk of mortality.
Conclusion: Bacterial infection-related AKI is common and associated with worse kidney function, ATN, ACLF and worse survival. Preventive strategies to avoid BI may be helpful in improving AKI outcomes.

Outcomes of thromboelastography guided versus routine empirical or on-demand platelet transfusion in patients with liver cirrhosis and severe thrombocytopenia undergoing high-risk invasive percutaneous and vascular procedures: an open-label, randomized controlled trial

Sagnik Biswas[1], Shekhar Swaroop[1], Arnav Aggarwal[1], Tushar Sehgal[2], Manas Vaishnav[1], Ayush Agarwal[1], Abhinav Anand[1], Piyush Pathak[1], Shubham Mehta[1], Anshuman Elhence[1], Soumya Jagannath Mahapatra[1], Deepak Gunjan[1], Shivanand Gamangatti[1], Shalimar Shalimar[1]. *[1]All India Institute of Medical Sciences, New Delhi, New Delhi, India; [2]All India Institute of Medical Sciences, New Delhi, India*
Email: sagnik_biswas@yahoo.co.in

Background and aims: There is a lack of consensus regarding periprocedural platelet transfusions in patients with liver cirrhosis and severe thrombocytopenia (platelet counts less than 50, 000/mm^3) undergoing high risk invasive procedures. We aimed to compare the utility of thromboelastography (TEG) guided platelet transfusion to routine empirical or on-demand transfusions in this patient group in avoiding unnecessary platelet transfusions and for outcomes in terms of post-procedural bleeding.
Method: Patients with liver cirrhosis and severe thrombocytopenia undergoing high-risk invasive procedures were randomized into three groups- Group 1: Transfusion based on deranged TEG parameters, group 2: routine empirical platelet transfusion, group 3: on-demand transfusions (platelets or packed red cells) based on

the procedural complications. All patients underwent thromboelastography pre-procedurally. In group 1, patients with maximum amplitude <32 mm were transfused 3 units of random donor platelets (RDP) pre-procedure, while in group 2, all patients received 3 units of RDP routinely pre-procedure. In group 3, patients did not receive any pre-procedure transfusions and were transfused blood products if they developed post-procedure bleeding. No correction was done for deranged INR. Primary outcome was assessment of periprocedural platelets transfused in each randomized arm.
Results: Eighty-seven patients were randomized (29 in each group). There were no differences in baseline demographics, hemostatic profile, and types of procedures between the three groups. The median platelet count was 33 (26–43) $x10^3/mm^3$. The most commonly performed procedure was percutaneous liver biopsy (46) followed by transjugular intrahepatic portosystemic shunt (13). Median MELD scores in groups 1, 2 and 3 were 13 (9.5–16), 13 (10.5–16) and 12 (10.5–14.5) respectively. Significantly lower numbers of patients in the TEG guided transfusions group received platelets (4 cases, 13.8%; 95% CI: 3.9–31.7) as compared to those receiving routine transfusions (100%; 95% CI: 88.1–100) ($p < 0.001$). Four cases in the on-demand group received RDPs (13.8%; 95% CI: 3.9–31.7). Minor (CTCAE grade 1) post-procedure related bleeding was seen in 3 (10%; 95% CI: 2.2–27.4) patients in the TEG guided transfusion group as compared to 1 (3.4%; 95% CI: 0.1–17.8) each in groups 2 and 3 respectively ($p = 0.43$). The bleeding episodes in the TEG group were from the local site and did not require packed red cell transfusions. There were no bleeding related mortality in any of the 3 groups at the 28-day follow-up period.
Conclusion: Thromboelastography guided transfusion reduces unnecessary platelet transfusions in patients with liver cirrhosis and severe thrombocytopenia undergoing high risk invasive procedures without a significant increase in major bleeding events as compared to those receiving empiric transfusions.

Development and validation of a prognostic model (AMMON-AD) to define risk of overt hepatic encephalopathy in cirrhosis patients with acute decompensation
María Pilar Ballester[1], Juan Antonio Carbonell-Asins[2], Shalimar Shalimar[3], Rajiv Jalan[4]. [1]*Clinic University Hospital of Valencia, INCLIVA Biomedical Research Institute, Valencia, Spain;* [2]*INCLIVA Biomedical Research Institute, Valencia, Valencia, Spain;* [3]*All India Institute of Medical Sciences, New Delhi, New Delhi, India;* [4]*University College London, London, United Kingdom*
Email: mapibafe@gmail.com

Background and aims: Overt hepatic encephalopathy (OHE) is the most common cause of hospitalization in patients with cirrhosis, but which patients with an acute decompensation (AD) will develop OHE is unknown. In addition, the real impact of OHE occurrence during admission on the patient's prognosis is not clear, and therefore, prophylactic therapies are not routinely used. The aims of the study were to determine the impact of OHE development on the risk of death and to develop and validate a prognostic model (AMMON-AD) that defines the group of patients at risk of OHE during hospitalization. Secondary aims were to evaluate the impact of OHE recovery on survival and to assess the utility of the new prognostic model on the probability of recovery from OHE.
Method: This observational, prospective study included 310 consecutive patients with cirrhosis hospitalized for an AD (non-ACLF). Patients were followed up to 90-days. Ammonia was normalized to upper limit of normal (AMM-ULN) of the laboratory. Fast unified random forest was performed to predict future OHE and recovery and Kaplan-Meier curves were used to compare risk of death according to development of OHE during hospitalization. An independent cohort of 50 patients was included for validation.
Results: 76% were male with a mean age of 42 (SD 12) years and an AD-CLIF score of 56 (SD 11). Out of 243/310 patients without OHE at admission, 102 (42%) developed OHE within 90-days. Development of OHE was associated with an increased risk of death (HR = 4.3; 95%CI = 3.03–5.97; $p < 0.001$), with significant differences in time to death between patients with and without OHE occurrence during hospitalization (Log Rank $p < 0.001$). The best model (AMMON-AD) to predict development of OHE included sodium, albumin, AMM-ULN, white cell count, INR and bilirubin, with an integrated Brier score (IBS) of 0.180 (Child-Pugh 0.187, MELD-Na 0.191, AD-CLIF score 0.194). Out of 67 patients with OHE at admission, 39 (58%) resolved the episode, with a significant impact in time to death compared with patients who did not recover from OHE (Log Rank $p < 0.001$). AMMON-AD also predicted OHE recovery with an IBS of 0.181. Out of 17/50 patients that did not present OHE at admission in the validation cohort, 8 (47%) developed OHE, with an accuracy of the model of 71%.
Conclusion: This study revealed that development of OHE during hospitalization is associated with a high risk of death, highlighting the importance of prophylactic therapies. In addition, we developed and validated the AMMON-AD model to select patients that may benefit from prophylaxis. This new model can also be used to evaluate the probability of recovery from OHE and risk of death.

Silver-coating of tunneled peritoneal drainage system is associated with a lower incidence of spontaneous bacterial peritonitis and device explanation
Sarah Lisa Schütte[1], Heiner Wedemeyer[1,2,3], Benjamin Maasoumy[1,2], Tammo Lambert Tergast[1]. [1]*Hannover Medical School, Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover, Germany;* [2]*German Center for Infection Research (DZIF), Hannover-Braunschweig, Germany;* [3]*Excellence Cluster Resist, Hannover Medical School, Hannover, Germany*
Email: schuette.sarah@mh-hannover.de

Background and aims: Patients with refractory ascites (RA) have limited treatment options, if contraindications for the implantation of transjugular intrahepatic portosystemic shunt (TIPS) are present or liver transplantation (LTx) is not available. Novel therapeutic devices such as tunneled peritoneal catheter systems (PeCa) have emerged to enable home-based care of RA. However, device infections are a common reason for device explantation or rehospitalization. Recently, silver-coated PeCa (scPeCa) have been introduced. The silver coating has been associated with a lower bacterial burden in in-vitro studies and presumably leads to a lower rate of device infections. However, clinical data to support this are lacking. This study compared conventional PeCa with scPeCa regarding the incidence of device explantations and the incidence of spontaneous bacterial peritonitis (SBP).
Method: All patients that received a PeCa at Hannover Medical School between 2012 and 2023 were considered for this study. Exclusion criteria included presence of malignant diseases, except for HCC within the MILAN criteria or absence of cirrhosis. Overall, 177 patients were included in this study of whom 27 received scPeCa (15%). To adjust for potential group differences, propensity score matching (PPSM) was applied. Matching factors included MELD and history of SBP. After PPSM, we compared 81 patients with PeCa and 27 patients with scPeCa. Competing risk analysis was conducted to analyse longitudinal end points. Analysed end points included SBP incidence, device explantation within one year and LTx-free survival.
Results: At the time of device implantation, history of SBP was less frequent and MELD score was numerically lower in patients with scPeCa (33% vs. 61%, P = 0.008; 16 vs. 18, P = 0.15). After PPSM, baseline factors like age, MELD score, history of SBP or intake of Norfloxacin after device implantation were comparable between patients with and without scPeCa (Age: 64 ± 13.5 vs 61 ± 10.6, p =

0.29, MELD: 16 ± 5 vs 16 ± 5, p = 0.91; History of SBP: 33% vs 33%, p = 1.00; Intake of Norfloxacin: 70% vs 59%, p = 0.40, respectively). One year LTx-free survival was comparable between both groups (57% vs 63%, HR 1.66, 95% CI 0.65–4.22, p = 0.29). However, presence of scPeCa was associated with a significantly lower SBP incidence within one year after device implantation (69% vs 74%, HR 0.38, 95% CI 0.17–0.86, p = 0.02). Moreover, device explantation within one years was significantly less frequent in those with scPeCa (61% vs 87%, HR 0.39, 95%CI 0.016–0.95, p = 0.038, median time to explantation: 344 days vs 83 days). Device infections were the most frequent reason for explantation in both groups (scPeCa: 3 (60%) vs. PeCa: 19 (66%)).
Conclusion: Compared to conventional uncovered PeCa, scPeCa were associated with a lower SBP incidence and less device explantations within one year.

FRI-039
Terlipressin therapy is associated with increased risk of colonization with multidrug-resistant bacteria in patients with decompensated cirrhosis

Marcus Mücke[1], Maria Hernandez-Tejero[2], Wenyi Gu[3], Michael Kuhn[4], Malte Janz[1], Marisa Isabell Keller[4], Anthony Fullam[4], Laura Altepeter[1], Victoria Mücke[1], Fabian Finkelmeier[1], Katharina Maria Schwarzkopf[1], Cremonese Carla[1], Peter Hunyady[1], Myriam Heilani[1], Frank Erhard Uschner[1,3], Robert Schierwagen[1,3], Maximilian Joseph Brol[1,3], Sabine Klein[1,3], Kai-Henrik Peiffer[1,3], Michael Hogardt[5], Saeed Shoaie[6], Minneke Coenraad[7], Jörg Bojunga[1], Vicente Arroyo[8], Stefan Zeuzem[1], Volkhard A. J. Kempf[5], Christoph Welsch[1], Wim Laleman[9], Peer Bork[4], Javier Fernandez[2], Jonel Trebicka[1,3]. *[1]Medical Clinic 1, University Hospital, Goethe-University Frankfurt, Frankfurt a.M., Germany; [2]Liver ICU, Liver Unit, Hospital Clinic, University of Barcelona, IDIBAPS and CIBERehd, Barcelona, Spain; [3]Department of Internal Medicine B, University of Münster, Münster, Germany; [4]Structural and Computational Biology Unit, European Molecular Biology Laboratory, Heidelberg, Germany; [5]Institute of Medical Microbiology and Infection Control, Goethe University Frankfurt, Frankfurt a.M., Germany; [6]Science for Life Laboratory, KTH-Royal Institute of Technology, Stockholm, Sweden; [7]Department of Gastroenterology and Hepatology, Leiden University Medical Center, Leiden, Netherlands; [8]European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain; [9]Department of Gastroenterology and Hepatology, Section of Liver and Biliopancreatic Disorders, University Hospitals Leuven, Leuven, Germany*
Email: marcus.m.muecke@gmail.com

Background and aims: Patients with liver cirrhosis are susceptible to develop bacterial infections, the most frequent trigger for acute decompensation (AD) and progression to acute-on-chronic liver failure (ACLF). The CANONIC and the PREDICT study demonstrated that infection with multidrug-resistant organisms (MDROs) are associated with deleterious outcome. MDRO infections are frequent following MDRO colonization. The influence of non-antibiotic medication contributing to MDRO colonization and selection remains unclear.
Method: 324 patients with AD and ACLF admitted to the ICU wit MDRO screening and details concerning past medication intake were eligible for inclusion. Regression mode. Were performed to identify drugs associated with MDRO colonization. A second series (n = 129 patients with AD and ACLF from Barcelona, Spain) was included to validate results. A third multi-center validation cohort (n = 203 decompensated cirrhosis patients) with metagenomic sequencing data was included to detect antibiotic resistance genes.
Results: Upon admission, 97 patients (30%) were defined to have MDRO colonization and 35 of them (11%) developed MDRO infection. Patients with MDRO colonization had a significantly higher risk of MDRO infection than those without (p = 0.0098). Apart from antibiotic therapy (OR 2.91, 95%-CI 1.72–4.93, p < 0.0001), previous terlipressin therapy over 14 days was the only independent covariate associated with MDRO colonization in both, the overall (OR 12.6, 95%-CI 4.04–39.0, p < 0.0001) and the propensity score matched cohort (OR 6.79, 95%-CI 1.55–29.79, p = 0.011). In the second series, prior terlipressin therapy appeared as a risk factor for MDRO colonization (OR 2.49, 05%-CI 0.911–6.823, p = 0.075) and was associated with an increased risk of MDRO infection during follow-up (p = 0.017). The external validation cohort confirmed these results and demonstrated that antibiotic inactive genes were significantly associated with terlipressin administration (p = 0.001).
Conclusion: Our study reports an increased risk of MDRO colonization in patients with AD or ACLF, who recently received terlipressin therapy, while other commonly prescribed non-antibiotic comedication had negligible influence. Further studies are needed to confirm our results and to identify the underlying mechanisms.

FRI-040
Male sex is associated with worse outcomes in primary biliary cholangitis

Nirbaanjot Walia[1], Julian Pohl[1], Matthias Reinhardt[1], Frank Tacke[1], Cornelius Engelmann[1]. *[1]Gastroenterology and Hepatology, Charité-Universitätsmedizin Berlin, Berlin, Germany*
Email: nirbaanwalia@gmail.com

Background and aims: Although Primary Biliary Cholangitis (PBC) predominantly effects women, limited evidence suggests men experience worse outcomes. The aims of this study were to assess sex related differences in outcomes in PBC, and to determine whether these differences are more specific to PBC compared to other causes of cirrhosis.
Method: This was a retrospective study conducted at The Charité-Universitätsmedizin Berlin. Inpatient admissions with a documented diagnosis of PBC based off the International Statistical Classification of Diseases and Related Health Problems (ICD-10) codes were extracted from 2011–2022. Further information such as patient age, sex, comorbidities, inpatient complications, procedures, blood test results and in-hospital mortality were obtained. The primary outcome was a composite of in-hospital mortality or liver transplant. Secondary outcomes included in-hospital mortality, liver transplant, decompensated cirrhosis, and length of hospital admission. Univariable and multivariable logistic and linear regression was used to assess the impact of sex on outcomes in PBC. A control group of patients with alternate cirrhosis aetiologies, matched on age and comorbidities on a 1:1 ratio, was compared against, and an interaction term for sex and PBC was included in the modelling.
Results: 940 patient admissions with a diagnosis of PBC were obtained, with 82% being female. Men with PBC had higher rates of most acute and chronic complications of liver disease, and significantly higher ALT, AST, GGT, ALP, Bilirubin and INR levels. Women had a reduced odds of the primary outcome on univariable analysis (OR = 0.23, 95% CI:[0.14, 0.40], p < 0.001) and following adjustment for age and comorbidities (OR = 0.27, 95% CI:[0.15, 0.49], p < 0.001). This was in contrast to the control group, where female sex was associated with an increased odds of death or transplant on univariable (OR = 1.54, 95% CI:[1.02, 2.30], p = 0.036) and multivariable (OR = 1.58, 95% CI:[1.04, 2.39], p = 0.030) logistic regression. The interaction analysis across the combined cohort revealed a modification effect of PBC on the risk of the primary outcome by sex (OR for interaction = 0.15, 95% CI:[0.08, 0.30], p < 0.001). Similar findings were noted in the assessment of secondary outcomes.
Conclusion: Men with PBC experience worse outcomes across a spectrum of measures. This difference appears to be more specific to PBC compared to other causes of cirrhosis, suggesting the pathological progression of PBC in males may be more severe than in females. Further research is required to consolidate these findings.

FRI-041

Evaluating the influence of human albumin infusions on the MELD and MELD-Na scores in patients hospitalized with an acute decompensation of cirrhosis: an ATTIRE trial analysis

Nikolaj Torp[1,2], Nicholas Freemantle[3], Aleksander Krag[1,2], Alastair O'Brien[3,4]. [1]*Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark;* [2]*Department of Clinical Research, University of Southern Denmark, Odense, Denmark;* [3]*Comprehensive Clinical Trial Unit, University College London, London, United Kingdom;* [4]*Royal Free Hospital, London, United Kingdom*
Email: nikolaj.christian.torp@rsyd.dk

Background and aims: The model for end-stage liver disease (MELD) score is widely used in hospitalized patients with cirrhosis and changes in MELD has been proposed as a surrogate end point for phase II trials. Albumin can affect the levels of creatinine, bilirubin and sodium, but if human albumin infusions represent a confounder for changes in MELD score is unknown. Therefore, we studied the effect of 20% human albumin infusions on the MELD and MELD sodium (MELD-Na) scores in patients hospitalized with cirrhosis.
Method: We used data from ATTIRE trial, which consisted of 777 patients randomized to daily 20% human albumin infusions or standard of care, during a hospitalization due to an acute decompensation of cirrhosis. Dosing of human albumin was based on a target serum albumin >30 g/L and human albumin infusions were allowed in the standard of care group as per clinical practice guidelines. We only included patients discharged during the trial period (within 15 days) in the analysis. We compared changes in MELD models from baseline to discharge according to the human albumin use. We looked at three- and six-month mortality to investigate the prognostic utility of MELD and MELD-Na after albumin infusions.
Results: We included 499 discharged patients during the trial period. Majority were men (71%) with mean age 53 years (SD: +11 years). Median baseline MELD was 18 (IQR: 15–22) and MELD-Na 22 (IQR: 18–26). Of included patients, 335 (68%) received 20% human albumin during their hospitalization, where the median amount of albumin given was 140 grams (IQR: 80–220). On average, one vial of 20% human albumin (20 gram) was associated with a −0.82 μmol/L decrease in creatinine (95% CI: −1.63; −0.01, p = 0.046), a −1.13 μmol/L decrease in bilirubin (95% CI: −2.04; −0.22, p = 0.015) and a +0.24 mEq/L increase in sodium (95% CI: +0.16; +0.32, p < 0.001). Discharge MELD (median 17, IQR: 14–21) and MELD-Na (median 20, IQR: 16–24, p < 0.001) were both lower compared to baseline MELD (p < 0.001) and MELD-Na (p < 0.001). Number of deaths were 69 (14%) and 113 (23%) after three- and six months, respectively. MELD at discharge, predicted death at three months (HR = 1.11, 95% CI: 1.08–1.15, p < 0.001) and six months (HR = 1.09, 95% CI: 1.06–1.12, p < 0.001). Similarly, discharge MELD-Na predicted death after three months (HR = 1.13, 95% CI: 1.09–1.17, p < 0.001) and six months follow-up (HR = 1.10, 95% CI: 1.07–1.13, p < 0.001). Divided into MELD and MELD-Na severity groups, a stepwise increase in mortality was observed for both models.
Conclusion: Human albumin infusions were associated with statistically significant but not clinically significant changes in components of the MELD and MELD-Na scores. A MELD and MELD-Na calculated at discharge in patients hospitalized with an acute decompensation of cirrhosis, may therefore serve as a surrogate for survival and prognostication, irrespective of human albumin use.

FRI-042

Comparison of clinical outcomes among patients with refractory ascites and implantation of either Alfapump®, tunneled peritoneal drainage system or transjugular intrahepatic portosystemic shunt

Sarah Lisa Schütte[1], Anja Tiede[1,2], Jim Benjamin Mauz[1], Hannah Schneider[1], Nicolas Richter[3], Heiner Wedemeyer[1,4,5], Benjamin Maasoumy[1,2], Tammo Lambert Tergast[1]. [1]*Hannover Medical School, Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover, Germany;* [2]*German Center for Infection Research (DZIF), Hannover-Braunschweig, Germany;* [3]*Hannover Medical School, Department of Abdominal and Transplant surgery, Hannover, Germany;* [4]*German Center for Infection Research (DZIF), Hannover, Germany;* [5]*Excellence Cluster Resist, Hannover Medical School, Hannover, Germany*
Email: schuette.sarah@mh-hannover.de

Background and aims: Onset of refractory ascites (RA) is a severe complication in patients with liver cirrhosis. If liver transplantation (LTx) is not available, implantation of a transjugular intrahepatic portosystemic shunt (TIPS) is the current standard of care. If TIPS implantation is not possible due to contraindications, alternative treatment options with devices such as Alfapump® or tunneled peritoneal catheters (PeCa) have been introduced to enable home-based treatment. Currently, data comparing TIPS, Alfapump® and PeCa are limited. This study investigated clinical outcomes between patients that received TIPS, Alfapump® or PeCa due to RA.
Method: All patients with liver cirrhosis and RA who received treatment at Hannover Medical School between 2009 and 2023 were considered. Patients with malignancies were excluded from this study. Study end points comprised one-year incidences of mortality, acute kidney injury (AKI), hyponatremia (<130 mmol/l) and spontaneous bacterial peritonitis (SBP). Competing risk regression analysis was conducted, treating death and/or LTx as competing events. Due to expected differences in baseline characteristics, propensity score matching (PPSM) was performed. Patients with PeCa (Analysis 1) or TIPS (Analysis 2) were matched in a 2:1 manner with individuals from the Alfapump® group, respectively. Afterwards, patients with PeCa underwent 1:1 matching with TIPS patients (Analysis 3).
Results: Overall, 35 patients with Alfapump®, 126 with PeCa and 138 patients with TIPS were included in this study.
Analysis 1: After PPSM, 60 patients who underwent PeCa implantation were compared with 30 patients with Alfapump®. Mortality (HR 0.74, p = 0.53), incidence of AKI (HR 1.46, p = 0.13) and hyponatremia (HR 0.92, p = 0.77) did not differ. Yet, incidence of SBP (32% vs 81%, HR 0.32, p = 0.006) and explantation of the device (41% vs. 86%, HR 0.25, p = 0.005) were significantly less frequent in patients with Alfapump®.
Analysis 2: Overall, 70 patients with TIPS were matched with 35 patients with Alfapump®. Mortality and SBP incidence were comparable (HR 0.84, p = 0.69 and HR 1.47, p = 0.44, respectively). However, incidences of AKI and hyponatremia were significantly higher in patients with Alfapump® (AKI: 84% vs 46%, HR 3.84, p < 0.001 and hyponatremia: 78% vs. 27%, HR 4.46, p < 0.001).
Analysis 3: Finally, 118 patients with PeCa were matched against 118 patients with TIPS. Mortality did not differ (HR 1.15, p = 0.58), while incidences of AKI (81% vs 30%, HR 6.05, p < 0.001), hyponatremia (75% vs 37%, HR 3.72, p < 0.001) and SBP (81% vs. 35%, HR 2.50, p < 0.001) were significantly higher in patients with PeCa.
Conclusion: Overall, TIPS implantation is associated with lower incidences of clinical complications when compared to devices like Alfapump® or PeCa. Furthermore, Alfapump® was linked with a lower SBP incidence and a lower rate of device explantations compared to PeCa.

FRI-043

A multi-center randomized controlled study of primary prevention of esophageal variceal bleeding in cirrhotic patients treated with HVPG-guided therapy or standard heart rate-guided therapy: an interim analysis of the PORTHOS trial

Annelotte Broekhoven[1], Jelte Schaapman[1], Annarein Kerbert[1], Hein W Verspaget[1], Bart van Hoek[1], Suzanne Cannegieter[2], Arian van Erkel[3], Wilbert van den Hout[4], Bart Mertens[5], Roeland Veenendaal[1], Ulrich Beuers[6], R. Bart Takkenberg[6],

Email: a.g.c.broekhoven@lumc.nl

Background and aims: Nonselective beta-blockers (NSBB) are the standard of care for primary prevention of esophageal variceal bleeding in patients with liver cirrhosis. However, about 50% of these patients do not reach target hemodynamic response. These non-responders have significantly higher rate of first variceal hemorrhage as compared to NSBB responders. In clinical practice, NSBB therapy is evaluated according to heart rate. However, the reduction in heart rate due to NSBB does not correlate with the reduction in portal venous pressure. We aimed to compare the effectiveness of hepatic venous pressure gradient (HVPG)-guided NSBB therapy to standard heart rate-guided NSBB therapy.
Method: Randomized controlled multi-center trial comparing NSBB therapy guided HVPG-measurements before and after start of NSBB therapy, to standard heart rate-guided NSBB therapy in patients with liver cirrhosis and large (≥5 mm) esophageal varices without a history of variceal hemorrhage. Follow-up period was 2 years. In patients randomized to the HVPG group, a HVPG-measurement was performed before and 4 weeks after the start of propranolol to determine the hemodynamic response. In hemodynamic responders, NSBB's were continued. In hemodynamic non-responders, NSBB's were continued and additional repeated endoscopic band ligation was performed until complete obliteration of large varices. In the control group propranolol was started, and NSBB's were continued throughout the whole study period, no routine gastroscopy was required. This study constitutes the planned interim analysis according to the protocol.
Results: In total 64 patients were included in this interim analysis: 33 were randomized to the HVPG group, 31 to the control group. The median follow-up time was 9.6 months (IQR 3.38–23.95). Within the HVPG group 20 (60.6%) patients were non-responders to propranolol. Within the HVPG group, 5 (15.2%) patients experienced a variceal hemorrhage versus 5 (16.1%) within the control group (NS). The observed risk reduction was 0.9% (95% CI −0.25–0.26). The cumulative incidence of having a variceal bleeding within 2 years was 19% in the HVPG group and 17.8% in the control group (NS).
Conclusion: In this randomized controlled trial, no clinical benefit from HVPG guided NSBB therapy could be demonstrated. Although around 60% of the patients were hemodynamic non-responders to NSBB treatment and were subsequently treated with endoscopic band ligation on top of NSBB therapy as primary prophylaxis of variceal bleeding, no risk reduction in variceal hemorrhage could be demonstrated.

FRI-044-YI

Impact of underlying etiology of liver cirrhosis on tests for diagnosing minimal hepatic encephalopathy

Julius Egge[1], Alena Friederike Ehrenbauer[1], Maria Magdalena Gabriel[1], Jana Al-Ayoubi[1], Lea Wagner[1], Jennifer Witt[1], Jim Benjamin Mauz[1], Anja Tiede[1], Heiner Wedemeyer[1], Anika Grosshennig[1], Gerrit M. Grosse[1], Benjamin Maasoumy[1], Karin Weissenborn[1]. [1]*Hannover Medical School, Hannover, Germany*
Email: Egge.Julius@mh-hannover.de

Background and aims: Diagnosing minimal hepatic encephalopathy (mHE) is a challenge. Many determinants may affect mHE test results. One major issue discussed is the impact of liver cirrhosis etiology. It remains unclear whether different tests for mHE are differentially affected by etiology. This study aims to investigate the effect of cirrhosis etiology on mHE test results.
Method: A total of 215 patients with liver cirrhosis underwent six mHE tests: Portosystemic-Encephalopathy-Syndrome Test (PSE), Continuous Reaction Time Test (CRT), Animal-Naming-Test, Stroop Encephal_App (Stroop), Inhibitory Control Test, and Critical Flicker Frequency. The effect of cirrhosis etiology on test results was analyzed using multivariable linear and binary logistic regression models. A directed acyclic graph model identified the factors sex, age, native language, and diabetes mellitus as minimal sufficient adjustment set for multivariable analyses.
Results: The cause of liver cirrhosis was alcohol-related (AC) in 73, metabolic dysfunction-associated steatohepatitis (MASH) in 32, metabolic dysfunction and alcohol associated steatotic liver disease (MetALD) in 24, autoimmune hepatitis, cholangitis or Hepatitis C in 44 (infectious or autoimmune liver disease (IALD)), and cryptogenic or of other etiology in 42 patients. MetALD patients exhibited the lowest results in PSE (mean −4.25), while the IALD group performed best (mean −2.02). Abnormal PSE was most prevalent in AC patients (39.7%) and least in IALD (20.7%). Stroop test results were comparable. In line with this, in multivariable linear regression analyses IALD was associated with higher PSE score values (adjusted regression coefficient beta = 1.59, 95% confidence interval (CI) 0.24–2.95) in comparison to patients with AC. In multivariable binary logistic regression analyses, the adjusted odds ratio (aOR) for an abnormal PSE result was 0.42 (95% CI 0.17–1.034) in IALD patients compared to AC patients. For other etiologies, similar effects to AC patients were observed. Regarding CRT, patients with cryptogenic or other etiology showed an aOR of 3.02 (95% CI 1.28–7.12) for an abnormal result compared to AC patients. For the other mHE tests, no effect of cirrhosis etiology on test results was observed.
Conclusion: The etiology of cirrhosis appears to impact mHE test results. Patients with cirrhosis due to metabolic syndrome and/or alcohol exhibit similar results, while those with autoimmune hepatitis, cholangitis or Hepatitis C fare better compared to the aforementioned etiologies. This discrepancy is especially notable in the surrogate gold standard for diagnosing mHE, the PSE-Test. As shown in the past, alcoholism per se has no observable effect upon PSE test results. Thus, these data suggest an amplification of the liver cirrhosis associated harm on brain function in patients with nutritive/toxic etiology of cirrhosis compared to IALD.

FRI-045

Superior prognostic accuracy of the LiverPRO score versus FIB-4 in predicting liver-related events in a cohort of 457, 152 individuals

Katrine Lindvig[1], Sören Möller[2,3], Katrine Thorhauge[1,3], Johanne Kragh Hansen[1,3], Camilla Dalby Hansen[1], Stine Johansen[1,3], Helle Schnefeld[1], Mads Israelsen[1,3], Peter Andersen[1], Ida Falk Villesen[1], Katrine Tholstrup Bech[1], Nikolaj Torp[1,3], Aleksander Krag[1,3], Maja Thiele[1,3]. Email: katrine.prier.lindvig@rsyd.dk

Background and aims: Steatotic liver disease (SLD) poses a growing healthcare burden, often undetected until advanced stages. Improved prognostic tools are urgently needed. LiverPRO is a CE-marked decision tool that utilizes a machine learning model to assess the percentage likelihood of having liver fibrosis based on routine blood samples and has shown strong diagnostic capabilities, surpassing current solutions. However, its prognostic potential remains unexplored. In this study, we compared the prognostic accuracy of LiverPRO to Fibrosis-4 Index (FIB-4) for prediction of liver-related events in the UK Biobank.
Method: We conducted a retrospective study on data from UK Biobank collected between 2006 and 2010 and followed until 2020. Information on ICD-10 codes and mortality is included in the database. The outcome was the risk of liver-related events, analysed using Cox regression and cumulative incidence curves, and the overall prognostic accuracy was presented with Harrell's C statistic and hazard ratios (HR).
We have used the following ICD-10 codes for defining a liver related event: ascites (R18.9), Esophageal and gastric varices, not bleeding (I85.9, I98.2, I864), Esophageal and gastric varices, bleeding (I85.0, I98.3, I864A), Spontaneous bacterial peritonitis (K658I), Liver failure (K72.1, K72.0, K72.9), Liver cirrhosis (K74.6), Portal hypertension (K76.6), Hepatorenal syndrome (K76.7), Hepatocellular carcinoma (C22.0).
Results: The analysis encompassed 457,152 participants with a mean age of 58 years (interquartile range, IQR: 51–64), 56% male. In the cohort a total of 1, 174 liver related events was observed. LiverPRO predicted liver-related events with a Harrell's C of 0.86 (95% confidence interval, CI: 0.85–0.87), compared to 0.78 (95%CI: 0.76–0.79) for FIB-4. Furthermore, a HR of 64.21 (95%CI: 53.18, 77.54) with p <0.001 was observed for LiverPRO in the high-risk category (>65%) versus the low-risk category (<25%). Similarly, an elevated HR of 41.07 (95%CI: 35.03, 48.16) with p <0.001 was estimated for FIB-4 >2.67 compared to FIB-4 <1.3. These findings means that patients with elevated FIB-4 (≥2.67) have an 311% increased risk compared to patients with a low FIB-4, for developing a liver related event. Similarly, patients with a high risk LiverPRO (>65%) have a 542% increased risk of developing a liver related event.
Conclusion: This extensive study demonstrates the superior prognostic accuracy of LiverPRO over FIB-4 in predicting liver-related events, underscoring its potential as a vital tool in early detection and management of liver disease. The marked difference in hazard ratios highlights the need for integrating advanced non-invasive diagnostic methods like LiverPRO in routine clinical practice, significantly enhancing risk stratification and patient care in SLD.

FRI-046

Alfapump implantation significantly improved quality of life and showed similar safety outcomes compared to a contemporaneously enrolled refractory ascites cohort

Jasmohan Bajaj[1], Patrick S. Kamath[2], K. Rajender Reddy[3], Puneeta Tandon[4], Jennifer Lai[5], Jacqueline O'Leary[6], Gijs Klarenbeek[7], Jeroen Capel[8], Scott Biggins[9], Hugo Vargas[10], Guadalupe Garcia-Tsao[11], Leroy Thacker[12], Florence Wong[13]. *[1]Virginia Commonwealth University, Richmond, United Arab Emirates; [2]Mayo Clinic, Rochester, United States; [3]University of Pennsylvania, Philadelphia, United States; [4]University Of Alberta, Edmonton, Canada; [5]University of California San Francisco, San Francisco, United States; [6]Dallas VA Medical Center, Dallas, United States; [7]Sequana Medical, Ghent, Belgium; [8]Sequana Medical, Zurich, Switzerland; [9]University of Pittsburgh Medical Center, Pittsburgh, United States; [10]Mayo Clinic in Arizona, Phoenix, United States; [11]VA-CT Healthcare System, West Haven, United States; [12]Virginia Commonwealth University, Richmond, United States; [13]Toronto General Hospital, Toronto, Canada*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: The POSEIDON study evaluated alfapump to relieve refractory ascites (RA) in a multi-center North American cohort but a contemporaneous cohort of RA to compare outcomes is needed. NACSELD3 (North American Consortium for Study of End-Stage Liver Disease), is a prospective outpatient cirrhosis cohort that includes RA patients which is enrolled contemporaneously to POSEIDON and could serve as comparators. Aim: Determine changes in quality of life (QOL), and safety outcomes (death, hospitalization, liver transplant) over 6 months vs baseline in POSEIDON compared to age, gender, Ascites-Q and MELD-Na matched NACSELD3 patients.
Method: NACSELD3 included outpatients with cirrhosis enrolled from 10 North American centers who were followed at 6 monthly intervals. 157 NACSELD3 patients with RA were matched to the 40 POSEIDON patients with propensity score matching calculated using age, sex, MELD-Na, and Ascites-Q score. Patients were matched 1:1, minimizing the difference between logits of the calculated propensity scores for cases and controls with a caliper of 0.2 using greedy nearest neighbor match. Ultimately 37 of 40 POSEIDON patients were matched 1:1 with the NACSELD3 RA subgroup. Ascites-Q and SF-36 are QOL questionnaires validated for ascites and overall health respectively. Outcomes were QOL [Ascites-Q, low = good and SF-36 physical component summary (PCS), high = good), any serious adverse event (SAE) resulting in death or hospitalization, and liver transplant (LT) through 6 months.
Results: Baseline parameters were comparable between POSEIDON and NACSELD3 (mean age 62.5 vs 61.0 years, 65% vs 62% men, MELD-Na 15.5 vs 16.6, Ascites-Q 50.1 vs 52.1). QOL: Ascites-Q improved over 6 months in POSEIDON (Delta −17 ± 16, p < 0.001) but not in NACSELD3 (Delta – 4 ± 20, p = 0.37). Similarly, SF-36 PCS improved at 6 months over baseline in POSEIDON (Delta 6 ± -8, p = 0.002) but not NACSELD3 (Delta 0.2 ± -8, p = 0.92). Safety outcomes: Mortality was equal (10.8% each). Hospitalization rate was statistically similar (35.1% vs 46.9%, p = 0.48) but trended higher in POSEIDON due to implant-related events for the alfapump. LT occurred in 8.1% of NACSELD3 and 5.4% of POSEIDON patients, which was similar statistically (p = 1.0).
Conclusion: The POSEIDON open-label trial of alfapump demonstrated significant improvement in quality of life focused on ascites symptoms and physical function compared to baseline, which is not seen in refractory ascites patients enrolled contemporaneously in the prospective NACSELD3 cohort despite matching for Ascites-Q, age, sex, and enrollment MELD-Na. No statistically significant difference in mortality, hospitalizations, or transplant were observed. Within the limitations of not being a RCT, this matched comparison provides evidence that the alfapump significantly improves QOL over standard paracentesis without significant impact on 6-month safety outcomes.

FRI-047-YI

Predictors of ascites resolution in patients with cirrhosis receiving long-term albumin treatment. Results from a real-world study in Italy (Real-ANSWER)

Email: paolo.caraceni@unibo.it

Background and aims: Long-term albumin (LTA) treatment in patients with cirrhosis and ascites has become widespread in Italy, but several issues still deserve clarification. The present study focuses on predictors of ascites resolution in patients receiving LTA in a real-world setting.
Method: We performed a multicenter, retrospective, observational study enrolling patients with cirrhosis and ascites who received LTA for at least one month between January 2016 and February 2022. Ascites resolution was defined as improvement to grade 0–1.
Results: 312 patients were included in the present analysis. The most common etiology was alcohol (60%) followed by MASLD (30%). Median Child-Pugh was 8, MELD 15 and MELD-Na 18. Ascites was grade 2 in 55% of patients, grade 3 in 36% and refractory in 28%, while 47% received paracentesis in the prior 6 months. Median dose of albumin was 40 grams/week (IQR 40–40). Albumin dose was decreased in 24% of patients before discontinuation for ascites resolution or increased in 12% due to the lack of response. At the time of the last observation (at treatment interruption due to any cause or at the end of follow-up in patients still on treatment [February 2023]), ascites was grade 0/1 in 56% of patients, with a median length of treatment of 11 (6–19) months. Notably, of the 123 patients who received a paracentesis prior LTA, 53% had no additional paracentesis between 3 and 6 months of treatment. At multivariable logistic regression analysis, independent predictors of response were age ($p = 0.007$), baseline grade of ascites ($p = 0.007$), no paracentesis in the previous 6 months ($p = 0.001$), etiological treatment in the past 12 months or during LTA ($p = 0.005$), weekly albumin dose ($p = 0.014$) and a serum albumin concentration of 40 g/L after one month of treatment ($p = 0.017$). Ascites resolution often occurred within few months after the start of LTA. Indeed, ascites improved to grade 0/1 in 34% of patients within the first 3 months, in 37% within 6 months and in 46% within 12 months. Factors independently associated with ascites resolution within 3 months were: baseline grade of ascites ($p = 0.038$) and no paracentesis in the previous 6 months ($p = 0.004$), baseline INR ($p = 0.003$), weekly dose of albumin ($p = 0.025$) and a serum albumin level of 40 g/L at one month of treatment ($p = 0.003$).
Conclusion: These data indicate that: 1) LTA on top of diuretic therapy greatly facilitates the management of ascites, leading to a significant reduction in the need for paracentesis and ascites resolution in almost 60% of cases, including in some with a previous diagnosis of refractory ascites; 2) one-third of patients achieved grade 0/1 ascites within 3 months, and 3) clinical and treatment-related factors could help in predicting response to LTA, providing useful information for tailoring treatment at the individual level.

Development of a screening tool for covert hepatic encephalopathy through automated speech signal analysis in patients with chronic liver diseases and/or portosystemic shunts

Apolline Leproux[1,2,3], Lyès Kheloufi[1,2], Kishanthan Kingston[4], Philippe Sultanik[1,2,3], Sarah Mouri[1,2,3], Charlotte Bouzbib[1,2,3], Marika Rudler[1,2,3], Jean-Luc Zarader[4], Mohamed Chetouani[4], Nicolas Weiss[1,2,5], Dominique Thabut[1,2,3]. *[1]AP-HP, Brain-Liver Pitié-Salpêtrière Study group (BLIPS), Paris, France; [2]INSERM UMR_S 938, Centre de recherche Saint-Antoine, Maladies métaboliques, biliaires et fibro-inflammatoire du foie, Institute of Cardiometabolism and Nutrition (ICAN), Paris, France; [3]AP-HP, Sorbonne Université, Liver Intensive Care Unit, Hepatogastroenterology Department, Pitié-Salpêtrière Hospital, Paris, France; [4]Sorbonne Université, Institut des Systèmes Intelligents et de Robotique (ISIR), Paris, France; [5]AP-HP, Sorbonne Université, Neurology Intensive Care Unit, Neurology Department, Pitié-Salpêtrière Hospital, Paris, France*
Email: apolline.leproux@aphp.fr

Background and aims: Covert hepatic encephalopathy (CHE) encompasses a range of neurological and neuropsychological symptoms associated with chronic liver diseases (CLD) and/or portosystemic shunts. The current diagnostic approach relies on clinical and paraclinical work-up, which are often not available in routine practice. This lack of sensitive and specific tools leads to underdiagnosis of CHE, despite its impact on patient prognosis and quality of life, and the availability of effective therapies. The aim of this study was to develop a screening tool for CHE through automated speech signal analysis, by developing a machine-learning algorithm dedicated to our CLD patients.
Method: Cross sectional analysis of a cohort of patients with CLD evaluated by the BLIPS (Brain Liver Pitié-Salpêtrière) study group (outpatient's clinics with complete neuropsychological assessment, clinical evaluation by hepatologist and neurologist, blood sample with ammonia, MRI with spectroscopy, electroencephalogram) between March and June 2023. The diagnosis of CHE and the presence of factors of brain injury (FBI : vascular leucopathy, sequelae of alcohol abuse, epilepsy, stroke) was set based on an adjudication committee. This organization led to two classifications : presence or absence of CHE (two-class model) and presence or absence of CHE and/or FBI (four-class model). Patients were recorded during two verbal tasks: a short text reading and the animal naming test in 2 minutes, enabling to extract 63 rhythm, prosody and acoustic features. Three machine learning algorithms were developed (SVM : Support Vector Machine, RF : Random Forest, GB : Gradient Boosting).
Results: The study included 39 patients: 69% were males, median of age was 61 (55–66), 64% had cirrhosis, with a median MELD score of 14 (11–16). The two-class model led to 51% of patients with CHE. The four-class model led to 15% of patients with only CHE, 36% with CHE and FBI, 28% with only FBI and 21% without CHE nor FBI. SVM demonstrated significantly greater results than GB and RF, its prediction based solely on rhythmic features yielded an accuracy of 67.6% and a precision of 65.0% (two-class model). For the four-class model, it yielded an accuracy of 55.9% and a precision of 86.1%. However, by combining the 20 best rhythm, prosody, and acoustic features, it achieved an accuracy and precision of 100% in the two-class model, and an accuracy of 97.1% with a precision of 98.1% for the four-class model.
Conclusion: This automated speech signal analysis could represent a cost-effective and reliable screening tool for CHE and differential diagnosis of neurocognitive impairment in patients with CLD. The best results combined rhythm, prosody, and acoustic features analysis, and yielded to an excellent accuracy and precision. Our results could translate into a rapid CHE screening tool in hospital and at home, if larger validation studies confirm these findings.

Email: lidia.canillas.alaves@gmail.com

Background and aims: In patients with advanced chronic liver disease (ACLD), emergent surgery has been related to higher mortality (up to 4–10 times) in contrast to elective surgery. Studies that reevaluate these results in recent populations are required. Our main aim was to evaluate the predictive capacity of the VOCAL-Penn in urgent surgery compared to elective surgery. As secondary objectives, we wanted to describe the baseline differences and complications of patients with ACLD undergoing urgent and elective surgery.
Method: Retrospective and unicentric study in patients with ACLD operated on major surgeries between 2010–2019. Patients undergoing emergent and elective surgery were compared (test de Fisher, X^2 o U-Mann Whitney), as well as the discriminant capacity of the VOCAL-Penn to predict mortality (ROC curves and agreement statistics) at 30 and 90 days.
Results: We included 512 patients, and 206 (40%) required an emergent surgery. Patients who underwent emergent surgery had more frequently ACLD due to alcohol consumption (56% vs. 47%; p = 0.04), higher comorbidity (ASA-IV 39% vs. 14%; p < 0.01), worse liver function (Child B/C 46% vs. 19%; p < 0.01 and MELD-Na 14 vs. 10; p < 0.01) and ascites (27% vs. 8%; p < 0.01). Abdominal (cholecystectomy, colectomy, etc.) and abdominal wall (hernia repair) surgeries were performed more frequently urgently (49% and 25%) than electively (39% and 20%) (p < 0.01). Fifteen percent of urgent surgeries (30/206) were related to previous known diseases, and 63% of these (19/30) were already on the waiting list for elective surgery. After surgery, the urgently operated patients developed more frequently ascites (29% vs. 11%; p < 0.01), AKI (54% vs 38%; p < 0.01), and infection (59% vs 26%; p < 0.01). The mortality observed at 30 and 90 days after emergent surgery was 10% (21/206) and 16% (32/206) and after elective surgery 4% (12/306) and 6% (18/306) (p < 0.01). The cause of mortality after urgent surgery was hepatic (38%) or infection (33%); and after elective surgery it was hepatic (50%) or cardiovascular (17%) (p = ns). The median (IQR) 30- and 90-day mortality estimated by VOCAL-Penn in emergent surgeries was 3.4% (1.4–10.5%) and 6.7% (2.7–16.3%) and in elective surgeries 0.5% (0.2–1.8%) and 1.3% (0.5–4.2%) (p < 0.01). VOCAL-Penn's c-statistic at 30- and 90-days for urgent surgery (0.83 and 0.82) was lower than for elective surgery (0.87 and 0.90), without reaching statistical significance.
Conclusion: The VOCAL-Penn has a good discriminant capacity in patients with advanced chronic liver disease undergoing emergent surgery. However, the mortality of emergent surgeries was 2–3 times higher than elective surgery. Patients undergoing emergent surgeries had more comorbidity, worse liver function, and more postoperative complications. Thus, improving the waiting list and perioperative management should be enhanced in patients with advanced chronic liver disease.

FRI-052

Anthropometric muscle mass indicators are effective in diagnosing muscle mass loss but are unable to diagnose myosteatosis, thus failing to identify all patients with sarcopenia in liver cirrhosis

Eleni Geladari[1], Theodoros Alexopoulos[2], Larisa Vasilieva[3], Meropi Kontogianni[4], Roxani Tenta[4], Vasilios Sevastianos[1], Iliana Mani[5], Alexandra Alexopoulou[5]. *[1]3rd Department of Internal Medicine and Liver Outpatient Clinic, Evangelismos General Hospital, Athens, Greece; [2]Gastroenterology Department, National and Kapodistrian University of Athens, Medical School, Laiko General Hospital, Athens, Greece; [3]Gastroenterology Department, Alexandra Hospital, Athens, Greece; [4]Department of Nutrition and Dietetics, School of Health Sciences and Education, Harokopio University, Athens, Greece; [5]2nd Department of Internal Medicine and Research Laboratory, Medical School, National and Kapodistrian University of Athens, Hippokration Hospital, Athens, Greece*
Email: elgeladari@gmail.com

Background and aims: In patients with liver cirrhosis (LC), sarcopenia is correlated with more frequent complications such as hepatic encephalopathy and increased mortality. To date, the use of computed tomography (CT) at the level of the third lumbar vertebra (L3) is considered one of the most sensitive approaches to evaluate muscle quantity and quality. However, radiation exposure and the need for experienced staff and expensive software render CT scans a challenging tool in daily clinical practice. In this study we aimed to explore the effectiveness of anthropometric measurements in assessing muscle mass compared to CT.
Method: Muscle mass was assessed by measuring the muscle mass area at L3 by CT scan, using appropriate software (SliceOmatic V4.3, Tomovision, Montreal, PQ). The area was then adjusted to height to calculate the skeletal mass index (SMI) $(cm)^2/height^2$ (in m^2). Myosteatosis (low muscle quality) was defined as muscle radiodensity at L3 <41 HU for patients with dry BMI <24.9 kg/m^2 and <33 HU for those with ≥25 kg/m^2. Handgrip (HG) strength was measured using a calibrated hydraulic hand dynamometer. Sarcopenia diagnosis, according to the latest European Working Group on Sarcopenia in Older People-2 (EWGSOP-2) criteria, consisted of low muscle strength in combination with low muscle quantity and/or quality. Low (below the 5th percentile) mid-arm circumference (MAC), mid-arm muscle circumference (MAMC), and mid-arm muscle area (MAMA) were also assessed.
Results: One hundred ninety-seven consecutive patients with LC [65.7% male, median age 61 years (IQR 52–68.5), MELD 10.5 (7.7–16), 60.9% with decompensated LC] were included. Low MAC, MAMC, MAMA, and low SMI were determined in 20.8%, 53.3%, 52.3%, and 43.4%, respectively. Sarcopenia was diagnosed in 45.2% and was the Method of Reference. HG strength in combination with low SMI (without myosteatosis) showed a sensitivity of 61.8%, specificity 100%, positive predictive value (PPV) 100%, and negative predictive value (NPV) 76%. If SMI is replaced by MAC, then the combination of low MAC with low HG offered a sensitivity of 69.7%, specificity 99%, PPV 98.4%, and NPV 79.8% in diagnosing sarcopenia. If low SMI is replaced by the presence of any one of the following: low MAC or MAMC or MAMA in combination with low HG, then sarcopenia is diagnosed with sensitivity of 61.8%, specificity 89.1%, PPV 83.3%, and NPV 74.5%. If MAC was replaced by low MAMC or low MAMA, the combination with low HG was inferior compared to MAC in diagnosing sarcopenia.
Conclusion: Among anthropometric indices, MAC is as effective as the skeletal mass index in identifying sarcopenia in LC. However, no anthropometric marker assessing muscle mass can diagnose myosteatosis, and therefore about one third of sarcopenic cases could be misdiagnosed as non-sarcopenic, if myosteatosis is not determined by imaging studies.

Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Proton pump inhibitors (PPI) are linked with infections and cirrhosis complications. A worldwide assessment of patterns, indications and effect on outcomes is unclear. Aim: Determine impact of PPI on outcomes in a multi-national cohort of cirrhosis inpatients.

Method: CLEARED Consortium, consisting of >110 centres across 6 continents enrolled patients with cirrhosis admitted prospectively. Patients are followed through their hospitalization to track deaths, ICU and organ dysfunction, or hospice transfer. Cirrhosis details, admission reasons and medications are recorded. Centres are classified based on World Bank into High/upper or lower middle income (HIC/UMIC/LMICs). PPI type, indications (appropriate/not assessed by site PIs based on guidelines), regional variations and impact on outcomes (AKI, infections, death, ICU) were analysed.

Results: 4305 pts (56yrs, 64% men, 40% alcohol, MELD 21) for 26 countries (37% HIC, 45% UMI and 18% LMICs) were enrolled. 21% were admitted with infections. 33% developed AKI, 18% ICU transfer, 2% got transplanted and 13% died during the admission. PPI use: 1831 (42%) were on PPI; only 58% had adequate indications. Most were pantoprazole (52%) then omeprazoe (30) and esomeprazole (9%). A higher percent of HIC pts was on PPI on admission vs UMIC/LMICS (48 vs 31 vs 21%, $p < 0.0001$). Lowest PPI use (~30%) was in China, rest of Asia and Africa, while >48% of pts in rest of the world were on PPI. Rates of adequate PPI indications were lowest in Indian sites (40%) and highest in North American (67%) sites. Infections and PPI: PPI use was higher in pts with spontaneous bacteraemia (9 vs 5%, $p = 0.02$) and lower in respiratory infections (14 vs 20%, $p = 0.004$) on admission. Remaining infections were similar. PPI use was not associated with higher nosocomial infections (12% both). Inpatient course and outcomes: PPI users on admission had similar MELD (21 both, $p = 0.2$) but higher use of NSBB, lactulose, diuretics, rifaximin, statins and HBV antivirals (all $p < 0.001$). PPI users had higher respiratory failure (10 vs 8%, $p = 0.03$), renal failure (5 vs 3%, $p = 0.001$), AKI (35 vs 30%, $p = 0.003$) and transplant (3 vs 1%, $p < 0.001$). Circulatory (11% both) and brain failure (12% both), and mortality (13 vs 12, $p = 0.7$) were similar regardless of PPI use. Multivariable analysis: PPI use was not significantly associated with ICU transfer, AKI, in-hospital mortality or in-hospital transplant. Variables predictive of these outcomes were age, MELD-Na, infections on admission and not being in an HIC.

Conclusion: In a multi-national inpatient prospective cirrhosis cohort across 6 continents, PPI use was seen in 42% of patients, which was highest in Indian sites and lowest across Chinese and African sites. Only 58% of PPI use was for approved indications. Although PPI use was associated with certain infections, transplant, AKI, and ICU on crude analysis none of these associations remained significant on multivariable analysis.

FRI-055

Outcomes of minimal ascites in patients with etiologically controlled liver cirrhosis

Haiyu Wang[1]. [1]*Nanfang Hospital, Southern Medical University, Guangzhou, China*
Email: 375612668@qq.com

Background and aims: Insufficient data are available regarding whether a minimal amount of ascites only detected in imaging procedures can be considered as decompensation. Little is known about the effects of minimal ascites on patient outcome. We aimed to evaluate prognostic significance of minimal ascites in aetiology controlled cirrhosis.
Method: We performed a post-hoc analysis of data from 1674 patients with cirrhosis with etiology controlled (1440 compensated, 234 patients with minimal ascites, 297 with decompensated) who participated a prospective cohort study from April 2019 to October 2022. and we also included homogenous patients who screened in the ultrosound room and difined as minimal ascites in our clinical unit (N = 403). Patients were evaluated at least every 6 months. Liver related events including decompensation events (development of clinically significant ascites, bleeding due to portal hypertensive sources, or overt hepatic encephalopathy), HCC development and death were documented.
Results: Among the 1674 patients, the etiologies included HBV (85.7%), HCV (3.6%), and alcoholic liver disease (6.4%), all of which were removal/suppression. Liver stiffness and spleen stiffness measurements were higher in patients with minimal ascites than in those with decompensation ($p < 0.0001$). Additionally, the prevalence of high-risk varices was higher in patients with minimal ascites compared to those with decompensation (16.7% vs. 52.5%, $p < 0.0001$). Over a median follow-up of 29 months (IQR 20–42), 24 patients developed decompensated episodes, and 46 patients developed HCC among the 1440 compensated cirrhosis cases. In the subgroup of 234 patients with minimal ascites, 34 patients experienced decompensated episodes, and 18 patients developed HCC during follow-up. The risk of developing decompensation in the minimal ascites group was significantly higher compared with compensated cirrhosis (HR = 8.505, 95% CI 5.51–13.12, $p < 0.0001$). Furthermore, compared with the compensated group, the minimal ascites group had a significantly increased risk for the development of HCC (HR = 1.75, 95% CI 1.09–2.80, $p < 0.05$). We also validated a higher incidence of decompensation and HCC in the clinical cohort of 406 cirrhosis cases with minimal ascites.
Conclusion: In an analysis of data from a large cohort of cirrhosis with controlled etiology, we discovered that minimal ascites is associated with more complications, a higher incidence of HCC and increased mortality compared with compensated patients. Patients with cirrhosis with minimal ascites should be monitored closely as they show an increased risk of mortality and complications.

FRI-056-YI

Clinical impact of acute kidney disease in patients with decompensated cirrhosis: insights from a prospective observational study on renal dysfunction

Alberto Calleri[1], Marco Tizzani[1], Francesco Frigo[1], Elisa Bertoldi[1], Daniela Campion[1], Gian Paolo Caviglia[1], Antonio Ottobrelli[1], Alfredo Marzano[1], Giorgio Maria Saracco[1], Carlo Alessandria[1].
[1]*Division of Gastroenterology and Hepatology, A.O.U. Città della Salute e della Scienza di Torino, University of Turin, Turin, Italy*
Email: alberto.calleri.md@gmail.com

Background and aims: Renal dysfunction is very common among patients hospitalized for decompensated cirrhosis. In this setting, acute kidney disease (AKD) has been suggested to impact significantly on prognosis, but data are scant. We aimed to assess prevalence and clinical outcomes of AKD compared to patients with no kidney disease (NKD) and acute kidney injury (AKI).
Method: All patients hospitalized in a 18-month period for decompensated cirrhosis were prospectively evaluated. Patients were classified according to their renal function as per International Club of Ascites definitions and then followed-up until death or liver transplant (LT). Patients with eGFR persistently <60 ml/min for a follow-up period of at least three months were considered to have new-onset chronic kidney disease (CKD).
Results: 295 patients were screened, 204 enrolled. The most frequent etiology of cirrhosis and cause of hospitalization were alcohol (55%) and ascites (64%), respectively. Renal function was categorized as follows: 17% NKD, 35% AKD, 27% AKI, 10% CKD, 11% acute-on-chronic kidney disease (ACKD). Median serum creatinine was: 0.83, 0.98, 1.70, 1.77, 3.13 mg/dL, respectively. Age was not significantly different between the three groups. Similarly, the proportion of patients with worst liver function (Child C) was not significantly different between patients with AKD (47%) and both NKD (29%, $p = 0.1$) and AKI (57%, $p = 0.2$). Median follow-up was 3.9 months (IQR 1.6–9.2). Overall, 53 patients (26%) were transplanted and 46 (23%) died. Out of 79 patients with follow-up ≥3 months, 8 (10%) developed new-onset CKD. The incidence was 0/25 for NKD, 5/33 (15%) for AKD and 3/21 (14%) for AKI (AKD vs NKD, $p = 0.06$; AKD vs AKI, $p = 0.9$; NKD vs AKI, $p = 0.09$). Among the patients discharged after the index hospitalization, the rate of hospital readmission was comparable between the three groups (Log-rank $p = 0.9$). The 1 and 6-month LT-free survival was respectively 100% and 96% in NKD, 96% and 89% in AKD, 77% and 65% in AKI. Survival of AKD patients was then similar to those with NKD (Log-rank $p = 0.22$ and $p = 0.19$, respectively) and significantly better if compared with AKI (Log-rank $p = 0.003$ and $p = 0.002$, respectively).
Conclusion: AKD is very common among patients hospitalized for decompensated cirrhosis. Our preliminary results suggest that AKD, unlike the few data currently available in the literature, is not clinically meaningful, being associated with a short- and medium-term LT-free survival similar to that of NKD and significantly better if compared with AKI.

FRI-057

End of life care in advanced chronic liver disease: results from a national audit of practice in the United Kingdom

Daniel Maggs[1], Emma Saunsbury[2]. [1]*University Hospitals of Bristol and Weston NHS Trust, Bristol, United Kingdom;* [2]*Somerset NHS Foundation Trust, Taunton, United Kingdom*
Email: danrmaggs@gmail.com

Background and aims: The last year of life (LYOL) in advanced chronic liver disease (ACLD) is associated with a high symptom burden and healthcare utilisation. End of life care (EOLC, i.e. palliative care given to patients in their LYOL) is historically poorer in ACLD compared to other life-limiting conditions and barriers to high-quality EOLC in ACLD are recognised. Advance care planning (ACP) and palliative interventions improve EOLC, yet opportunities for ACP are frequently missed and utilisation of specialist palliative care services (SPCS) is variable. EVOLVE (End of life care in adVanced chrOnic LiVEr disease) is the first national audit of EOLC provision in ACLD in the United Kingdom (UK). We aimed to evaluate patient and service level factors associated with quality EOLC and measure the impact of deprivation on EOLC provision.
Method: A retrospective, multi-centre audit was undertaken of adults who died of ACLD between 1st January-30th June 2022 and had at least one non-terminal admission in their LYOL. Site recruitment was undertaken via trainee research networks, social media and promotion via endorsing organisations. Patients were identified by ICD-10 (International Classification of Diseases Tenth Revision) coding and review of electronic records. Patient and service level variables were analysed against markers of quality EOLC (assessed via the surrogate outcomes of documented discussions regarding prognosis, ACP and SPCS referral).

Results: Eighty-three sites contributed data for 803 patients. In the LYOL, 49.9% had a documented discussion about prognosis and 36.9% received ACP. Documentation of prognostic scores (39.6%) and transplant suitability (56.2%) was inconsistent. Only 26.2% of patients were discussed at an ACLD multidisciplinary team (MDT) meeting. 46.9% were referred to inpatient SPCS, though 79.1% of these referrals were only during a terminal admission. Documentation of transplant suitability was significantly associated with prognosis being discussed ($p < 0.001$), prognostic discussion at an earlier stage ($p = 0.04$), ACP ($p < 0.001$) and SPCS referral ($p < 0.001$). Discussions about prognosis were more likely ($p < 0.001$) when a prognostic score was documented. ACP was more likely following ACLD MDT ($p = 0.046$) and in patients having outpatient paracentesis ($p < 0.001$). 11% of patients were in the lowest two Index of Multiple Deprivation centiles, but there was no significant variation in any outcomes.
Conclusion: EVOLVE has revealed inadequacies in EOLC for patient with ACLD in the UK. Utilisation of SPCS prior to a terminal admission was poor. Factors associated with improved EOLC have been demonstrated, highlighting a focus for service improvement. Recent guidance statements from North America highlight standards for EOLC in cirrhosis and similar guidance from professional bodies in the UK and Europe could aid in changing practice.

FRI-058

Smoking cessation correlates with rapid decrease of inflammatory markers in patients with decompensated cirrhosis

Letitia Toma[1], Mihai Daniel Dodot[1], Teodora Isac[1], Simona Ioanitescu[1], Laurentiu Micu[1], Adriana Rusie[2], Laura Iliescu[1]. *[1]Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*
Email: letitia_toma@yahoo.com

Background and aims: Smoking is a well-known cardiovascular risk factor as well as an important risk factor for metabolic syndrome-associated steatotic liver disease (MASLD), by promoting systemic inflammation. Recent studies have found significant differences in white blood cell count (WBC) and serum c-reactive protein (CRP) in patients with compensated and decompensated liver disease, in relationship with smoker status. We aim to evaluate the impact on smoking cessation in patients with decompensated cirrhosis.
Method: We performed a prospective observational study in active smoker patients with decompensated cirrhosis (Child B and C) admitted to our clinic between January 2023 and June 2023. Patients were classified as light smokers (less than 1 pack/day) or heavy smokers (more than 1 pack/day). Patients were entered into smoking quitting programs and reevaluated at 6 months after smoking cessation. We determined WBC count and serum levels of CRP, ferritin and B12 vitamin.
Results: Out of 132 patients included, only 74 completed the smoking cessation programs (48 Child B and 26 Child C patients, mean age 51.94 ± 28.17 years, 69% female). Etiology of cirrhosis was: 31% alcohol-related, 28.4% viral, 40.6% MASLD. Initial evaluation revealed 58.1% light smokers and 41.9% heavy smokers. We noted a significant decrease in inflammatory markers after smoking cessation, in light smokers as well as heavy smokers. In light smokers, WBC decreased from 6.82 G/L to 6.23 G/L, $p = 0.04$, CRP decreased from 4.47 mg/L to 3.11 mg/L, $p = 0.02$, ferritin decreased from 213 ng/ml to 176 ng/ml, $p = 0.03$, and B12 vitamin decreased from 987 pg/ml to 881 pg/ml, $p = 0.01$. In heavy smokers, WBC decreased from 7.33 G/L to 5.71 G/L, $p = 0.01$, CRP decreased from 7.22 mg/L to 3.98 mg/L, $p = 0.01$, ferritin decreased from 289 ng/ml to 138 ng/ml, $p = 0.02$, and B12 vitamin decreased from 1387 pg/ml to 935 pg/ml, $p < 0.001$. We also found that inflammation was significantly more diminished in Child B versus Child C patients: WBC 1.52 G/L versus 0.6 G/L, $p = 0.01$, CRP 3.31 mg/L versus 2.04, $p < 0.001$, ferritin 114 ng/ml versus 65 ng/ml, $p = 0.02$, B12 vitamin 421 pg/ml versus 132 pg/ml, $p < 0.001$.
Conclusion: Smoking cessation decreases systemic inflammation in Child B and C cirrhosis at 6 months follow-up. As systemic inflammation is a key point in progression of liver disease, smoking cessation is an important contributor to its management, regardless of the severity of liver disease.

FRI-059

Proton pump inhibitors are not associated with an increased risk of hepatic encephalopathy

Simon Johannes Gairing[1], Chiara Mangini[2], Lisa Zarantonello[2], Elise Jonasson Nielsen[3], Henrike Dobbermann[4], Philippe Sultanik[5], Peter R. Galle[1], Joachim Labenz[6], Dominique Thabut[7], Jens U. Marquardt[4], Patricia Bloom[8], Mette Lauridsen[3], Sara Montagnese[2,9], Christian Labenz[1]. *[1]University Medical Center of the Johannes Gutenberg-University, Mainz, Germany; [2]University of Padova, Padova, Italy; [3]Hospital of South West Jutland, Esbjerg, Denmark; [4]University Hospital Schleswig-Holstein, Lübeck, Germany; [5]Sorbonne Université, Paris, France; [6]Diakonie Hospital Jung-Stilling, Siegen, Germany; [7]Sorbonne Université, Paris, Germany; [8]University of Michigan, Ann Arbor, United States; [9]University of Surrey, Guildford, United Kingdom*
Email: sgairing@uni-mainz.de

Background and aims: Several studies suggest an association between proton pump inhibitor (PPI) use and hepatic encephalopathy (HE). However, multicenter studies including a large number of patients are scarce. This study aimed to analyze the association between PPI use, minimal HE (MHE) and overt HE (OHE) in a large multicenter setting.
Method: This retrospective study included patients with cirrhosis from seven centers (Germany, France, Italy, Denmark, Michigan, US). MHE was defined by the Psychometric Hepatic Encephalopathy Score (PHES) at baseline. Scoring was done according to validated country-specific norms. Patients were followed for the development of OHE, liver transplantation or death. In multivariable competing risk regression analysis, transplantation and death were considered as competing events.
Results: Data from 1160 patients were analyzed. Median age was 60 years (range 23–87), and most patients were male (65%). Median MELD was 11, Child-Pugh stages were A 49%, B 39%, C 11%. MHE was diagnosed in 385 patients (33.2%). On the day of study inclusion, 58% of patients used PPIs of whom only 30% had a hard indication for PPI treatment. During follow-up (median 18.1 months), 20% of patients developed an episode of OHE, and 19% died or underwent liver transplantation. In multivariable logistic regression analysis, PPI use was not associated with MHE at study inclusion (odds ratio 1.07, 95% CI 0.80–1.43, $p = 0.7$). In addition, PPI use was not associated with an increased risk of developing OHE in competing risk regression analysis (subdistribution hazard ratio 1.13, 95% CI 0.81–1.59, $p = 0.5$). These findings were confirmed in subgroup analysis including only patients without a history of OHE ($n = 803$) or only patients with Child-Pugh A or B. In addition, PPI use was neither associated with an increased OHE risk in patients with an indication for PPI treatment nor without an indication.
Conclusion: PPI use does not appear to be associated with an increased HE risk in patients with cirrhosis.

FRI-067

Impact of Farnesoid X receptor polymorphisms on prognosis in hepatocellular carcinoma

Talha Ozudogru[1], Elvan Isik[2], Fulya Günsar[2], Ilker Turan[2], Zeki Karasu[2], Ulus Akarca[2]. *[1]Ege University, Faculty of Medicine, Department of Internal Medicine, Izmir, Turkey; [2]Ege University, Faculty of Medicine, Department of Gastroenterology, Izmir, Turkey*
Email: ulusakarca@gmail.com

Background and aims: Refining staging and treatment for Hepatocellular Carcinoma (HCC) is crucial, particularly considering the biological behavior and genetic characteristics. The Farnesoid X

receptor (FXR) has been implicated as a tumor suppressor in HCC, warranting further investigation.
Objective: This study explores the distribution of genotypes for four FXR-linked single nucleotide polymorphisms (SNPs) in cirrhotic patients with and without HCC, and examines the correlation of these genotypes with prognostic parameters and survival.
Method: A cohort of 101 consecutive newly diagnosed HCC patients developed on cirrhosis (2020–2021) was compared with 101 age, sex, and etiology-matched cirrhotic controls without HCC. Genotyping of SNPs rs56163822, rs35724, rs11110385, and rs11110390 in peripheral blood mononuclear cells was conducted. Statistical analysis assessed allelic distributions between groups and the impact of genotypes on clinical severity, alpha-fetoprotein levels, liver function, and patient survival.
Results: Genotypic distributions of the SNPs did not significantly differ between HCC and cirrhosis patients. However, the rs35724 GG genotype in HCC patients was linked to notably lower survival rates in those with poor prognostic features compared to GC/CC (non-GG) genotypes. This trend was consistent across various patient subgroups, with statistical significance in survival differences for those with vascular invasion, higher ALBI grades, elevated Child-Pugh scores, and increased alpha-fetoprotein levels. In vascular invasion, ALBI grades 2–3, ALBI grade 3, Child-Pugh >5, and AFp >400 ng/ml subgroups, median survivals for GG vs non-GG were 3 vs 12 ($p = 0.0332$), 8 vs 24 ($p = 0.0176$), 6 vs 20 ($p = 0.0103$), 7 vs 24 ($p = 0.0100$), and 3 vs 24 months ($p = 0.0551$), respectively.
Conclusion: FXR polymorphisms, particularly the rs35724 GG genotype, do not increase HCC risk in cirrhotic patients but are associated with reduced survival in HCC patients with adverse prognostic factors. This genotype could be a vital consideration in tailoring therapeutic strategies for HCC, as non-GG variants of rs35724 appear to indicate a more favorable prognosis. Our findings underscore the importance of genetic profiling in HCC management, offering potential for personalized treatment approaches.

FRI-068
Predictors of clinical trajectories in patients surviving an acute decompensation of cirrhosis
Carmine Gambino[1], Antonio Accetta[1], Simone Incicco[2], Roberta Gagliardi[3], Nicola Zeni[3], Marta Tonon[3], Valeria Calvino[3], Anna Barone[3], Paolo Angeli[4], Salvatore Piano[3]. *[1]Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine, University of Padova, Padova, Italy; [2]Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine, University of Padova, Padova, Italy; [3]Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine, University of Padova, Padova, Italy; [4]Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine, University of Padova, Padova, Italy*
Email: salvatorepiano@gmail.com

Background and aims: three different clinical trajectories have been described in patients surviving an acute decompensation (AD) of cirrhosis, namely stable decompensated cirrhosis (SDC), unstable decompensated cirrhosis (UDC) and pre-ACLF (Acute-on-chronic Liver Failure). The identification of these patients could be crucial in their clinical management, however, predicting the clinical course at time of discharge is challenging. The aim of the study was to investigate predictors of clinical course after discharge for AD and 180-day mortality.
Method: clinical, laboratory and pharmacological data at admission, during hospitalization and at discharge were collected from patients surviving an AD of cirrhosis in our Unit. Patients were followed up until transplant, death, or 180 days.
Results: We included 360 patients (age 62 ± 12; male 66%; alcoholic aetiology 55%; MELD 16 [12–22]). At 90-day after discharge, 195 (54%) patients were identified as SDC, 115 (32%) as UDC and 50 (14%) as pre-ACLF. Sixteen (22%) patients underwent LT. At discharge, pre-ACLF patients showed, if compared to SDC and UDC patients, higher serum creatinine (1.29 vs 0.83 vs 0.85 mg/dl; $p < 0.001$), INR (1.59 vs 1.39 vs 1.38; $p = 0.027$), neutrophils (3.82 vs 2.92 vs 2.97 × 10^9/l; $p = 0.033$), MELD (19 vs 14 vs 14; $p < 0.001$). We couldn't find any difference between SDC and UDC patients at discharge. At 180-days after discharge, mortality rate was higher in pre-ACLF respect to UDC and SDC (38% vs 16% vs 2%; $p < 0.0001$), and 30 (8.3%) patients underwent LT. In a multivariable model (adjusted for age, gender, aetiology, presence of varices, AKI or HE during hospitalization, serum creatinine, INR, bilirubin, CRP at discharge, and clinical trajectory) higher levels of CRP (HR 1.02; CI 1.00–1.05; $p = 0.021$), UDC (HR 9, 98; CI 1.76–56; $p = 0.009$) and pre-ACLF (HR 31.4; CI 4.71–209; $p < 0.001$) were independent predictors of 180-day mortality.
Conclusion: Our study is one of the first external confirmation of the clinical trajectories after AD of cirrhosis showed in PREDICT cohort. Pre-ACLF patients showed worse liver and kidney function, and higher systemic inflammation at discharge. We were unable to distinguish SDC from UDC at discharge. Future trials and more raffinate biomarkers could be help in answering this question.

FRI-069
Rifaximin monotherapy has significantly reduced the risk of overt hepatic encephalopathy recurrence versus lactulose monotherapy in patients with cirrhosis and a history of previous episode (s): a post hoc analysis of randomized trials
Jasmohan Bajaj[1], Robert Rahimi[2], Christopher Allen[3], Zeev Heimanson[3], Robert Israel[3], Kris V. Kowdley[4]. *[1]Virginia Commonwealth University, Richmond VA Medical Center, Richmond, United States; [2]Baylor University Medical Center, Dallas, United States; [3]Salix Pharmaceuticals, Bridgewater, United States; [4]Liver Institute Northwest, Elson Floyd College of Medicine, Spokane, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Lactulose monotherapy is recommended as secondary prophylaxis after an initial episode of overt hepatic encephalopathy (OHE), with rifaximin as add-on therapy when additional episodes occur. However, lack of patient adherence and/or adverse effects of lactulose may require alternative management strategies. The aim of this analysis was to compare the efficacy and safety of rifaximin monotherapy with lactulose monotherapy for reducing the risk of OHE recurrence in patients with cirrhosis and a history of OHE.
Method: Two randomized trials (1 phase 3 double-blind and 1 phase 4 open-label) of adults who had cirrhosis and a history of OHE occurrence during the previous 6 months and were currently in OHE remission (Conn score ≤1) were included in this post hoc analysis. Only data from patients who received rifaximin 550 mg twice daily (ie, no concomitant lactulose [phase 3 or 4]) or lactulose (titrated to 2–3 soft stools/d) plus placebo (ie, lactulose monotherapy [phase 3]) for up to 6 months were analyzed. The primary efficacy end point in both trials was time to first breakthrough OHE episode (Conn score ≥2).
Results: A total of 270 patients were treated with rifaximin monotherapy ($n = 125$) or lactulose monotherapy ($n = 145$). The mean (SD) age in the rifaximin and lactulose groups was 58.2 (9.5) vs 56.6 (9.3) y, respectively; 60.0% vs 68.3% were male, 51.2% vs 46.2% were Child-Pugh class B, and the median Model for End-Stage Liver Disease score was 12 for both groups. The majority of patients had a baseline Conn score of 0 (rifaximin, 68.8%; lactulose, 67.6%). Significantly fewer patients treated with rifaximin monotherapy experienced an OHE episode vs lactulose monotherapy (23.2% vs 49.0%, respectively; $p < 0.0001$), with a 60% reduction in the risk of a breakthrough OHE event during 6 months of monotherapy treatment with rifaximin compared with lactulose (hazard ratio, 0.40; 95% CI, 0.26–0.62). Fewer patients treated with rifaximin monotherapy had an HE-related hospitalization compared with lactulose monotherapy, although the difference was not statistically significant (19.2% vs 23.4%, respectively, $p = 0.18$). The most commonly reported AEs (excluding HE) in rifaximin vs lactulose groups were nausea (13.6% vs

14.5%), fatigue (12.8% vs 12.4%), peripheral edema (16.0% vs 9.0%), constipation (14.4% vs 6.9%), diarrhea (4.8% vs 14.5%), headache (7.2% vs 11.7%), insomnia (11.2% vs 7.6%), and ascites (7.2% vs 10.3%). Discontinuation from study participation was higher in the lactulose monotherapy group (62.1%) vs the rifaximin monotherapy group (36.0%), most commonly due to OHE occurrence.
Conclusion: Rifaximin monotherapy was well tolerated and was associated with significantly fewer episodes of OHE recurrence than lactulose monotherapy in patients with cirrhosis and a history of OHE.

FRI-070-YI
Prevalence of dysgeusia in patients with advanced chronic liver disease, relationship with the liver-disease progression status, and impact on malnutrition-sarcopenia-frailty
Marcello Dallio[1], Mario Romeo[1], Marina Cipullo[1], Annachiara Coppola[1], Simone Mammone[1], Giuseppe Zagaria[1], Giorgia Iadanza[1], Carmine Napolitano[1], Simone Olivieri[1], Luigi Maria Vitale[1], Alessandro Federico[1]. *[1]Hepatogastroenterology Division, Department of Precision Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy*
Email: marioromeo@virgilio.it

Background and aims: Dysgeusia is a disorder defined by a distortion of the sense of taste whose prevalence, relationship with the progression of the disease, and direct contribution to malnutrition (and consequently, sarcopenia-frailty) in advanced chronic liver disease (ACLD) have never been systematically explored.
Method: In this observational study, 40 controls, 50 chronic-liver disease-affected individuals staging initial-mild fibrosis (<F3), and 150 ACLD patients of various etiologies were enrolled. Anthropometrical, biochemical, clinical, and nutritional data were collected. The opportunely-modified CITAS (Chemotherapy-induced Taste Alteration Scale) questionnaire was used to assess the dysgeusia. Child-Pugh (CP) and Liver Frailty Index (LFI) calculations, Liver Stiffness Measurement (LSM), and Bioelectrical Impedance Analysis (BIA) were performed. Skeletal Muscle Mass (SMM) index (SMMI) (SMM/height^2) <7 kg/m^2 (male) and <5.7 kg/m^2 (female) defined sarcopenia. ACLD patients were 2 years followed up semiannually and Liver-related events (LREs) (ascites, hepatic encephalopathy, bleeding, jaundice, and bacterial infection) were collected.
Results: The prevalence of dysgeusia was significantly higher in ACLD (68%) in comparison to <F3 (8%) individuals and controls (5%) and in decompensated ACLD (dACLD) than compensated (cACLD) (54% vs 6%) patients (all $p < 0.0001$). In line, CITAS-dysgeusia severity positively correlated with CP (R:0.81), as well as with the levels of appetite impairment (R:0.93) (both $p < 0.0001$).
Logistic regression analysis, appropriately weighted for factors notoriously impacting food intake in ACLD patients (low-sodium diet, drugs/supplements taken, physical activity frequency, occurrence of encephalopathy and ascites episodes in the previous 2 weeks), revealed the level of impairment of the appetite as a factor significantly associated with dysgeusia [HR: 2.12; p:0.02].
Compared to no-dysgeusia-affected dACLD (p:0.03), dysgeusia-affected dACLD patients (dys-dACLD) showed a decreased daily protein intake, reduced Free Fat Mass % ($p < 0.0001$), and SMMI ($p < 0.0001$: p:0.04), in contrast with increased LFI ($p < 0.0001$).
Consistently, dys-dACLD patients showed a higher prevalence (59% vs 39%) of sarcopenia (p:0.0002). The Kaplan-Meier Log-Rank Test analysis on LREs'occurrence showed HR:3.53 for dys-dACLD individuals.
Conclusion: The prevalence of dysgeusia, increasing in parallel to the worsening of liver disease, promoted sarcopenia-frailty pictures, negatively influencing ACLD patients' outcomes.

FRI-071
Complications following percutaneous liver biopsy: results of a nationwide database
Markus Graf[1], Christiana Graf[2], Sebastian Ziegelmayer[1], Joshua Gawlitzka[1], Markus Makowski[1], Philipp Paprottka[3], Nele Willemsen[3], Jonathan Nadjiri[3]. *[1]Klinikum rechts der Isar, Technical University Munich; Department of Diagnostic Radiology, Munich, Germany; [2]LMU University Hospital Munich, Munich, Germany; [3]Klinikum rechts der Isar, Technical University Munich; Department of Interventional Radiology, Munich, Germany*
Email: markus.m.graf@tum.de

Background and aims: Liver biopsy is the gold standard for evaluating liver diseases, the diagnosis of liver fibrosis and cirrhosis and malignancy. However, it is susceptible to complications, and safety data on liver biopsies remain scarce. The following study examined the complication rates following percutaneous liver biopsies.
Method: We performed a study using data collected by the German interventional radiology society (DeGIR) from 2018 to 2021 of elective percutaneous liver biopsies. Clinical and biochemical parameters, technical features and adverse events were retrospectively examined.
Results: From 2018 to 2021 a total of 12228, liver biopsies were performed in 194 participating centers in Germany. The median age of the study cohort was 66.16 years (range: 18–104 years) and 6120 were male (50.05%). 8127 punctures were performed CT-guided (66.4%), whereas 4101 interventions (33.5%) were performed with ultrasound. Complications occurred in 224 biopsies (1.83%), of which 183 (1.5%) were major adverse events. Minor complications in form of procedural hypotension and pain occurred in 7 and 34 cases (0.06% and 0.28%, respectively). Major complications such as bleeding, organ injury and pneumothorax were observed in 155, 4 and 24 cases (1.27%, 0.03%, 0.20%). Six subjects (0.05%) died as a result of massive intraperitoneal bleeding. Major complications were significantly more frequently observed in patients with thrombocytopenia ($p = 0.01$) as well as in patients undergoing ultrasound-guided procedure compared to a computed tomography (CT-) guided one ($p < 0.001$). In contrast, the type of needle size used ($p = 0.323$), internationalized ratio (INR) ($p = 0.09$), aPTT ($p = 0.98$), gender ($p = 0.83$), age ($p = 0.08$) and the liver segment punctured ($p = 0.97$) did not influence the frequency of major adverse events. By multivariate logistic regression analysis, platelet count and ultrasound-guided modality were identified as the only independent risk factors of post-biopsy bleeding ($p = 0.001$ and $p < 0.001$, respectively).
Conclusion: Percutaneous liver biopsies are safe with rare procedural morbidity. Our data confirm previous data by showing that post-procedural bleeding was not associated with INR and aPTT in patients undergoing invasive procedures. However, measurement of platelet count is indicated especially in patients with liver cirrhosis to identify patients with increased procedural bleeding risk. Moreover, patients with liver cirrhosis as well as patients with complex findings and difficult localizations should undergo CT-guided puncture.

FRI-074-YI
Rifaximin reduces healthcare utilization but not overall costs in patients with cirrhosis and recurrent episodes of hepatic encephalopathy: a retrospective efficacy study
Diederick van Doorn[1], Kirsi van Eekhout[1], Koos de Wit[1], L.C. Baak[2], Michael Klemt-Kropp[3], Bart Verwer[4], Philip W. Friederich[5], Gijs J. de Bruin[6], Xander Vos[7], R. Bart Takkenberg[1]. *[1]Amsterdam UMC, Amsterdam, Netherlands; [2]OLVG, Amsterdam, Netherlands; [3]Noordwest Ziekenhuisgroep, Alkmaar, Netherlands; [4]Spaarne Gasthuis, Hoofddorp, Netherlands; [5]Meander Medisch Centrum, Amersfoort, Netherlands; [6]Tergooi MC, Hilversum, Netherlands; [7]Dijklander Hospital, Hoorn, Netherlands*
Email: d.j.vandoorn@amsterdamumc.nl

Background and aims: Hepatic encephalopathy (HE) is a frequent complication of cirrhosis. Rifaximin has been approved and included in guidelines for secondary prevention of HE, but there are few real-world data on its efficacy and impact on healthcare utilization. In this study, we aimed to assess the efficacy of rifaximin as secondary prophylaxis for HE in Dutch patients.
Method: We conducted a real-life cohort analysis from March 2010 to May 2023 in patients from 7 hospitals in the province of North Holland and Utrecht (The Netherlands), reflecting approximately 10% of the Dutch population, who received rifaximin as secondary prophylaxis for HE. Data were collected and compared six months before and six months after the prescription of rifaximin. The primary end point was transplant free survival (TFS). Secondary end points were the effect of rifaximin on healthcare utilization, defined as the quantification of each patient contact with the hospital, such as the number and length of admissions and emergency department visits, and the effect of rifaximin on healthcare costs.
Results: We included 126 patients [65% male; median age 68 (IQR: 61.0–75.3)] with a median Model for End-stage Liver Disease (MELD) score of 15 (IQR: 12–20). Most common etiology was alcohol related liver disease (55%). At end of follow-up, 63% of patients were deceased with a median TFS of 23 months (95%CI: 14.6–31.4). The mean number of HE episodes after starting rifaximin was 0.9 (± 1.1), which was lower than before starting rifaximin (2.2; ± 1.3; 95%CI: 1.0–1.6; $p < 0.001$). In addition, mean healthcare utilization decreased from 6.1 (± 3.3) contacts in the six months before rifaximin to 3.3 (± 2.6) contacts in the six months after rifaximin (95%CI: 2.1–3.5; $p < 0.001$). The mean number of hospital admissions decreased from 1.7 (± 1.6) admissions per patient before to 1.0 (± 1.3) admissions after starting rifaximin (95%CI: 0.4–1.1; $p < 0.001$). Mean length of admission did not differ. The mean number of outpatient visits decreased from 2.4 (± 1.8) visits per patient before starting rifaximin to 1.7 (± 1.4) visits after starting rifaximin (95%CI: 0.3–1.0; $p = 0.001$). The mean number of visits to the emergency department decreased from 0.33 (± 0.6) per patient to 0.15 (± 0.5; 95%CI: 0.0–0.3; $p = 0.024$). An estimate of the annual costs was made based on publicly available data in the Netherlands. The annual costs of rifaximin are € 4.555 per patient. The estimated annual costs of healthcare utilization per patient before starting rifaximin were € 13.320. This was similar to the costs after rifaximin was prescribed (€ 13.120).
Conclusion: In this Dutch real-life cohort, rifaximin significantly reduced the number of episodes of HE, the number of hospital admissions and the number of outpatient and emergency department visits, hereby contributing to a reduction in healthcare utilization. Unfortunately, rifaximin did not lead to reduced overall costs.

FRI-075

The lower, the worse? Impact of PHES results on the risk of overt hepatic encephalopathy in patients with minimal hepatic encephalopathy

Simon Johannes Gairing[1], Chiara Mangini[2], Lisa Zarantonello[2], Elise Jonasson Nielsen[3], Sven Danneberg[4], Philippe Sultanik[5], Peter R. Galle[1], Stefania Gioia[6], Joachim Labenz[7], Anna Lok[8], Jens U. Marquardt[4], Mette Lauridsen[3], Patricia Bloom[8], Dominique Thabut[9], Silvia Nardelli[6], Sara Montagnese[2], Christian Labenz[1]. *[1]University Medical Center Mainz, Mainz, Germany; [2]University of Padova, Padova, Italy; [3]Hospital of South West Jutland, Esbjerg, Denmark; [4]University Hospital Schleswig-Holstein, Lübeck, Germany; [5]Sorbonne Université, Hôpital Pitié-Salpêtrière Assistance Publique Hôpitaux de Paris, Paris, France; [6]Sapienza University of Rome, Rome, Italy; [7]Diakonie Hospital Jung-Stilling, Siegen, Germany; [8]University of Michigan, Ann Arbor, United States; [9]Sorbonne Université, Hôpital Pitié-Salpêtrière Assistance Publique Hôpitaux de Paris, Paris, Germany*
Email: christian.labenz@unimedizin-mainz.de

Background and aims: Minimal Hepatic Encephalopathy (MHE), defined by the psychometric hepatic encephalopathy score (PHES), is associated with a higher risk of subsequent OHE. However, it remains unclear if there is a stepwise increase in OHE risk with worse PHES results in patients with MHE.
Method: This multicenter study analyzed data of 1462 patients from eight centers (Italy, France, Denmark, USA, Germany), who underwent testing with the PHES and had available follow-up data. For this analysis, we only included patients with PHES-MHE, no history of OHE, and no prescription for lactulose or rifaximin (excluded: 959 without PHES-MHE, 212 with PHES-MHE but with a history of OHE, 84 with a prescription for lactulose or rifaximin). For subsequent analyses and to make results between centers more comparable, we calculated a scoring system adjusted PHES score (adjusted PHES) by dividing the PHES score by the number of subtests (e.g. for German patients: if a patient had a PHES score of −12, this score was divided by the number of subscores of PHES (in Germany 6 subscores) resulting in an adjusted PHES of −2). All patients were followed for the occurrence of OHE and liver transplantation (LTx)-free survival.
Results: In total, 207 patients with PHES-MHE were included. Median adjusted PHES was −1.20 (range −2.67; −0.80), median MELD score 11 (range 6; 33), and median follow-up time was 18.5 months (95% CI 13.9–20.6). In total, 59 (29%) patients developed an OHE episode during follow-up. There was no stepwise increase in OHE risk with worse PHES results. In multivariable competing risk regression analyses, adjusted PHES as a continuous variable (sHR 1.05, 95% CI 0.55–2.01, $p = 0.9$) or categorized into quartiles (each $p \geq 0.2$) were not associated with the development of OHE. In addition, no association was observed in multivariable models only including patients with Child-Pugh A or B/C.
Conclusion: MHE defined by PHES is associated with a higher OHE risk. However, we found no stepwise increase in OHE risk with worse PHES results among patients with PHES below the MHE-defining cutoff. Our findings stress that MHE with PHES just below the cutoff of −4 should be treated with the same rigor as patients with PHES of −18.

FRI-076

Physical frailty diagnosed by short physical performance battery test is an independent poor prognostic factor of 360-day mortality in patients with liver cirrhosis

Eleni Geladari[1], Theodoros Alexopoulos[2], Larisa Vasilieva[3], Meropi Kontogianni[4], Roxani Tenta[4], Vasilios Sevastianos[1], Iliana Mani[5], Alexandra Alexopoulou[5]. *[1]3rd Department of Internal Medicine and Liver Outpatient Clinic, Evangelismos General Hospital, Athens, Greece; [2]Gastroenterology Department, National and Kapodistrian University of Athens, Medical School, Laiko General Hospital, Athens, Greece; [3]Gastroenterology Department, Alexandra Hospital, Athens, Greece; [4]Department of Nutrition and Dietetics, School of Health Sciences and Education, Harokopio University of Athens, Athens, Greece; [5]2nd Department of Internal Medicine and Research Laboratory, Medical School, National and Kapodistrian University of Athens, Hippokration Hospital, Athens, Greece*
Email: elgeladari@gmail.com

Background and aims: Physical frailty (PF) is defined as a syndrome of decreased physical function and reserves, preventing patients from coping with stressful factors. The Liver Frailty Index (LFI) and Short Physical Performance Battery (SPPB) in patients with liver cirrhosis (LC) can help evaluate the risk of death and complications before or after liver transplantation. The study aimed to explore the characteristics of frail patients by either method and compare the performance of LFI and SPPB as prognostic markers of mortality in LC.
Method: The Liver Frailty Index (LFI) was calculated using the equation (−0.330 × gender-adjusted grip strength) + (−2.529 × number of chair stands per second) + (−0.040 × balance time) + 6. SPPB, including gait speed, chair stand, and balance tests, was also performed. Patients with LFI ≥4.5 or SPPB ≤8 were considered frail.

All included patients were prospectively followed up for 360 days, and their mortality was recorded.
Results: A total of 197 consecutive patients with LC without acute events were included [65.7% male, median age 60 years, (IQR 52–68), MELD 10.5 (7.7–16), 60.9% with decompensated LC (DC)]. Causes of LC were 43.1% alcohol-related, 23.3% viral, and 33.5% miscellaneous. PF, as assessed by LFI, was present in 40.8% of DC versus 9.1% of compensated cirrhosis (CC) patients ($p < 0.001$), and by SPPB, in 39.2% versus 9.1% ($p < 0.001$), respectively. Forty-three patients were frail by both tests, 13 by LFI only, and 11 by SPPB only. Overall, frail patients (diagnosed by either LFI or SPPB) were older ($p < 0.001$ for both), underweight ($p = 0.018$ and $p = 0.004$, respectively), had anemia ($p < 0.001$ for both), had more severe liver disease [higher MELD and Child-Pugh scores ($p < 0.001$ for both)], lower serum sodium ($p < 0.001$ for both), and more frequently hepatic encephalopathy ($p < 0.001$ for both). The Kaplan-Meier survival curve at 360 days showed higher mortality in frail compared to non-frail ones (log rank $p < 0.001$ for cases diagnosed by either method). PF defined by both LFI and SPPB was associated with a high mortality rate in univariate binary logistic regression analysis [HR 5.442 (95%CI 2.879–10.286), $p < 0.001$ and HR 0.151 (95%CI 0.079–0.288), $p < 0.001$]. In the multivariate binary logistic regression model, PF defined by SPPB (but not by LFI) and adjusted for age, gender, and MELD score (as a continuous variable) emerged as an independent prognostic factor of 360-day mortality [HR 0.358 (95%CI 0.170–0.753), $p = 0.007$].
Conclusion: PF, defined using either LFI or SPPB, was related to older age, underweight, and advanced liver disease in this cohort of patients with LC. Patients characterized as frail by LFI or SPPB were not identical. PF defined by SPPB (but not by LFI) was proven to be an independent poor prognostic factor for long-term mortality after adjustment for covariates. The assessment of PF is crucial in patients with cirrhosis as it may predict mortality.

FRI-077-YI
Cirrhotic liver transplant candidates with portosystemic shunts benefit from low dietary soluble fiber consumption
Simona Parisse[1], Sara Carnevale[2], Elio Damato[3], Flaminia Ferri[4], Monica Mischitelli[5], Mario Corona[6], Pierleone Lucatelli[3], Alfredo Cantafora[7], Domenico Alvaro[5], Maurizio Muscaritoli[5], Stefano Ginanni Corradini[5]. *[1]Department of Translational and Precision Medicine, Sapienza University of Rome, Rome, Italy; [2]Belcolle Hospital, Viterbo, Italy; [3]Department of Radiological, Oncological and Anatomopathological Sciences, Sapienza University of Rome, Rome, Italy; [4]Deparment of Translational and Precision Medicine, Sapienza Univeristy of Rome, Rome, Italy; [5]Department of Translational and Precision Medicine, Sapienza University of Rome, Rome, Italy; [6]Department of Radiological, Oncological and Anatomopathological Sciences, Sapienza University of Rome, Rome, Italy; [7]Department of Translational and Precision Medicine, Sapienza Univesity of Rome, Rome, Italy*
Email: simona.parisse@gmail.com

Background and aims: In cirrhotic patients, spontaneous portosystemic shunts (PS) are associated with liver damage and more severe prognosis. Cholestatic liver damage and fibrosis occur in some patients with congenital PS and, always, in C57BL/6 mice with congenital PS on a diet rich in soluble fiber. Therefore, we aimed to investigate whether there is an association between dietary fiber consumption, cholestasis, and changes in MELD score over time in cirrhotic patients according to the presence of PS.
Method: We enrolled 80 consecutive cirrhotic outpatients under evaluation for liver transplantation who had been abstinent from alcohol and non-viremic for at least 6 months. At baseline we extrapolated the dietary intake of soluble and insoluble fiber, using the FiberTAG repertoire of Neyrinck et al to analyze 3-day food records, we measured serum alkaline phosphatase (ALP), calculated the MELD score and verified the presence of any PS, analyzing the portal venous phase of the abdominal CT. After six months the MELD score was measured again. Separate multivariable binary logistic regression models were constructed using as dependent variables: a) normal vs abnormal ALP values at enrollment; b) improvement after six months of the MELD score vs its stability or worsening.
Results: PS were found in 48 (60%) patients. At enrollment patients with PS compared to those without had higher MELD score [13.1 (IQR 11.5–15.4) vs. 11.3 (IQR 8.3–14.2); $p < 0.05$] and ALP values [167.5 (IQR 110.8–262.0) vs. 131.0 (IQR 90.5–151.8) IU/L, $p < 0.05$], while fiber intake did not differ. At the end of follow-up there was an improvement in the MELD score compared to enrollment in 19/48 (39.6%) in the group with PS and in 10/32 (31.3%) in the group without PS ($p = 0.448$). Total fiber intake, expressed in mg per kg of body weight per day, was independently and negatively associated with improvement in MELD score after 6 months, both in cirrhotic patients with PS [O.R. 0.985, 95% CI: 0.974–0.997, $p = 0.014$] and in those without [O.R. 0.983, 95% CI: 0.968–0.999, $p = 0.043$]. In cirrhotic patients with PS we found the following independent associations of soluble fiber intake: a) negative with the improvement of the MELD score after 6 months [O.R. 0.946, 95% CI: 0.912–0.982, $p = 0.004$]; b) positive with abnormal ALP values [O.R. 1.032, 95% CI: 1.001–1.064, $p = 0.046$].
Conclusion: In cirrhotic patients with PS, consumption of soluble dietary fiber is associated with cholestatic liver damage and failure to improve prognosis over time. The detrimental effect of soluble fiber is likely due to chronic spillover of cholestatic metabolites stimulated by a dysbiotic microbiota.

Background and aims: Type 2 diabetes mellitus (DM) is a frequent comorbidity in patients with liver cirrhosis and an independent risk factor for bacterial infections, occurrence of cirrhosis-related complications, and mortality. Apart from DM control, treatment strategies protecting patients from these risks remain an unmet need. The present study aims to determine whether long-term human albumin (HA) administration improves survival and reduces the incidence of complications in outpatients with decompensated cirrhosis and DM.
Method: The ANSWER trial enrolled 431 patients with cirrhosis and uncomplicated ascites to receive either the standard medical treatment (SMT) or SMT plus HA (40 g twice weekly for 2 weeks, and then 40 g weekly) up to 18 months. We performed a post-hoc analysis of the trial database extrapolating the subgroup of patients with insulin-treated DM. Overall survival rates during a follow-up of 18 months were determined. To assess the incidence of complications, we calculated and compared their incidence rates (IRs) in the two arms of the trial by calculating incidence rate ratios (IRRs). The SMT group served as the reference category.
Results: Eighty-five (19.7%) patients presented insulin-treated DM at baseline (50 in the SMT and 35 in the SMT+HA arm, respectively). At baseline, diabetic patients who received long-term HA did not significantly differ from those randomized to SMT, as regards age, etiology of cirrhosis, body mass index, Child-Pugh class, and MELD score. During the follow-up, 39 patients ended the study prematurely (17 of them for medically uncontrolled ascites requiring at least 3 paracenteses per month, 14 in the SMT and 3 in the SMT+HA arm). Sixteen patients died (12 in the SMT and 4 in the SMT+HA arm), 13 of them from liver-related causes (10 [83%] in the SMT and 3 [75%] in SMT+HA arm). Eighteen month overall survival was significantly higher in patients enrolled in the SMT+HA arm compared to SMT (86% [95%CI: 66–95] vs 57% [95%CI: 35–74], $p = 0.016$). Patients treated with SMT+HA also presented a lower IR of paracenteses (0.89 vs 4.31, IRR 0.21, $p < 0.001$), overt hepatic encephalopathy (0.39 vs 1.32, IRR 0.30, $p < 0.001$), bacterial infections (0.50 vs 0.95, IRR 0.53, $p = 0.023$), acute kidney injury (0.42 vs 1.32, IRR 0.32, $p < 0.001$), electrolyte disorders (0.60 vs 1.26, IRR 0.47, $p = 0.003$). No significant differences were seen in hospital admissions (IR 1.35 vs 1.52, IRR 0.89, $p = 0.53$), but the number of days spent in the hospital was lower in the SMT+HA group (IR 10.95 vs 19.23, IRR 0.57, $p < 0.001$).
Conclusion: Long-term HA administration appears a beneficial therapeutic intervention improving survival and reducing the incidence of cirrhosis-related complications in insulin-treated diabetic outpatients with decompensated cirrhosis and ascites.

FRI-080
Hypodynamic cardiocirculatory status measured at echocardiography is associated with one-month mortality in patients admitted for acute decompensation of liver cirrhosis

Alexandru Victor Dragan[1], Ancuta Vijan[1], Caterina Delcea[1], Mihaela Birligea[1], Paul Balanescu[2], Andreea Bengus[1], Theodor Voiosu[3], Ioana Daha[3], Bogdan Mateescu[3], Cristian Baicus[3], Andrei Voiosu[3]. *[1]Colentina Clinical Hospital, Bucharest, Romania; [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania; [3]Colentina Clinical Hospital, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania*
Email: victoradragan@gmail.com

Background and aims: Systemic inflammation is a crucial component in the cardiocirculatory dysfunction observed in liver cirrhosis. The aim of our study is to assess the mortality and hospital readmission at 1 and 3 months in patients with acute decompensation of liver cirrhosis based on their cardiocirculatory status and to explore their inflammatory profile.
Method: This is a prospective, observational study conducted at a tertiary center, involving the follow-up of patients admitted for acute decompensation of liver cirrhosis without known cardiac comorbidities. We monitored them clinically, electrocardiographically, biologically, and echocardiographically at admission, 5–7 days later, and one month later. A follow-up phone call was conducted at three months. The patients cardiocirculatory status was stratified based on the cardiac index measured by echocardiography into hypodynamic (<3.2 L/min/m^2), normodynamic (3.2–4.2 L/min/m^2), and hyperdynamic (>4.2 L/min/m^2).
Results: We included 66 patients with liver cirrhosis (mean age 59 ± 10 years, 69.6% women), primarily due to alcohol-related liver disease (79%). Mean Child Pugh score was 9 (IQR 8–11) and MELD-Na 19 (IQR 15–23). 86.3% were admitted for acute decompensation, while 13.6% fulfilled the criteria for acute-on-chronic liver failure. The cardiocirculatory status of the patients was hypodynamic in 48.5%, normodynamic in 30.3%, and hyperdynamic in 13.6%. 40.9% of the patients were treated with chronic beta-blockers. Mortality was higher in patients with hypodynamic status compared to those with normo and hyperdynamic status at one-month (24% vs 0% vs 0%, $p = 0.049$), but not at 3 months (28% vs 26.6% vs 28.5%, $p = 0.9$). The hospital readmission rate did not differ at either one month (33.3% vs 21.0% vs 22.2%, $p = 0.5$) or three months (57.6% vs 42.1% vs 66.6%, $p = 0.4$). No patients with ACLF on admission had hyperdynamic circulation according to the cardiac index. There was no difference between groups in the serum concentrations of inflammatory markers (C-reactive protein, IL-6, TNF-alpha, GAS6).
Conclusion: Patients with acute decompensation of liver cirrhosis and hypodynamic cardiac status have a higher mortality rate in the first month following admission.

FRI-081
Lisinopril is associated with reduced hepatocellular carcinoma and mortality risk in patients with MASLD-related compensated cirrhosis: a multicenter, nationwide propensity score matching analysis

Yee Hui Yeo[1], Wee Han Ng[2], Manal F. Abdelmalek[3], Seema Khan[4], Cynthia Moylan[5], Luz Rodriguez[6], Augusto Villanueva[7], Kevin Ma[8], Ju Dong Yang[1]. *[1]Karsh Division of Gastroenterology and Hepatology, Cedars-Sinai Medical Center, Los Angeles, United States; [2]Bristol Medical School, Bristol, United States; [3]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States; [4]Department of Surgery, Northwestern University Feinberg School of Medicine, Chicago, United States; [5]Division of Gastroenterology, Duke University, Durham, United States; [6]National Cancer Institute, Division of Cancer Prevention, Rockville, United States; [7]Liver Cancer Program, Divisions of Liver Disease, Tisch Cancer Institute, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, United States; [8]Department of Epidemiology, Harvard T. H. Chan School of Public Health, Boston, United States*
Email: yeehui.yeo@cshs.org

Background and aims: Lisinopril, an angiotensin-converting enzyme inhibitor (ACEi), appears to have a role in preventing fibrosis progression in a preclinical model of steatotic liver disease. Little is known about the antifibrotic effect of lisinopril in patients with MASLD and cirrhosis. Hepatic fibrosis and cirrhosis are associated with an increased risk for hepatocellular carcinoma (HCC). Our objective was to assess the impact of lisinopril use on the occurrence of HCC in comparison to other antihypertensive medications in patients with MASLD-related compensated cirrhosis.
Method: We conducted a retrospective cohort study utilizing TriNetX, a multicenter, nationwide database with detailed clinical information. We included all patients with MASLD-related compensated cirrhosis from 1/12011 to 12/31/2023 defined as having one of the five cardiometabolic risk factors in individuals with steatotic liver disease. Laboratory data, medications for metabolic diseases, physical measurements, and ICD codes were used to define the diagnosis.

Lisinopril users (having three or more prescriptions) were matched with users of non-ACEi, non-angiotensin receptor blocker antihypertensives using propensity score matching (PSM) method based on demographic characteristics, BMI, blood pressure, comorbidities, medications, and laboratory data such as platelet count, INR, liver biochemistry, HbA1c, lipid profile, and renal function test. The index date was defined as the start date of lisinopril or other antihypertensives. Cox regression was used to determine the risk of mortality and HCC. Colorectal cancer, which shares similar sources of bias with the targeted outcome but is unrelated to the treatment of interest, was selected as a negative control.

Results: Of the 16897 eligible patients, 5265 were lisinopril users and 11632 were users of other antihypertensive medications. After PSM, 4769 pairs of users and non-users were well-balanced. For both groups, the mean age was 60.3 years, with 43% males and 75.3% whites. Lisinopril was associated with a significantly decreased mortality risk, with a hazard ratio (HR) of 0.72 (95% confidence interval [CI]: 0.66–0.79). Moreover, lisinopril was associated with a significantly reduced risk of developing HCC, with an HR of 0.70 (95% CI: 0.55–0.89). The effect of lisinopril was duration-dependent, with the HR of mortality in patients who had three to five prescriptions of lisinopril as 0.65 (95% CI: 0.46–0.91) while it was 0.58 (95% CI: 0.39–0.86) in those with six to eight prescriptions. When using colorectal cancer as a negative control, the HR for lisinopril use was non-significant (HR 0.80, 95% CI: 0.57–1.13).

Conclusion: In our cohort lisinopril use in patients with MASLD-related compensated cirrhosis was associated with a reduced risk of mortality and HCC development compared to other antihypertensive medications.

FRI-082

Unveiling the role of GH-IGF1 axis in decompensated cirrhosis: implications for sarcopenia, frailty, decompensations, and mortality

Parminder Kaur[1], Nipun Verma[2], Aishani Wadhawan[3], Pratibha Garg[4], Samonee Ralmilay[4], Naveen Kalra[4], Gaurav Sharma[4], Sahaj Rathi[4], Arka De[4], Madhumita Premkumar[4], Sunil Taneja[4], Ajay Kumar Duseja[4], Pinaki Dutta[4], Virendra Singh[5]. *[1]Postgraduate Institute of Medical Education and Research, Chandigarh, India; [2]Postgraduate Institute of Medical Education and research, Chandigarh, India; [3]Postgraduate Institute of Medical education and Research, Chandigarh, India; [4]Postgraduate Institute of Medical education and Research, Chandigarh, India; [5]Punjab Institute of Liver and Biliary sciences, Mohali, India*
Email: nipun29j@gmail.com

Background and aims: The impact of the Growth Hormone-Insulin-like Growth Factor (GH-IGF1) axis on sarcopenia, frailty, bone health, and overall prognosis remains underexplored in cirrhosis. This study investigates their interplay in patients with decompensated cirrhosis, unveiling potential therapeutic targets.

Method: We associated plasma GH (ng/ml) and IGF1 levels (ng/ml) with sarcopenia (CT-SMI), frailty (LFI), decompensations, and outcomes up to 180 days among adult decompensated cirrhosis outpatients at a tertiary care institute between 2021 and 2023.

Results: We recruited 172 patients, 95% males with a median age of 46.5 years, MELD-Na of 16.3 (IQR: 12.8–21.6), Child-Pugh status-A (12.8%), -B (62.2%), or-C (25%), and 180-day mortality of 17.4%. GH and IGF1 levels were 3.6 ng/ml (IQR: 2.02–6.45) and 39.3 ng/ml (IQR: 28.7–50) among patients. Sarcopenia, frailty, and osteodystrophy were observed in 59.5%, 24.3%, and 42% of patients, respectively. Patients were categorized by observed range of IGF1 levels: low IGF1 (first quartile: IGF1 <28.7), intermediate IGF1 (second and third quartile: IGF1–28.7–50), and high IGF1 (fourth quartile: IGF1 >50). $_{log}$IGF1 levels were significant predictors of sarcopenia (OR: 0.094, 0.013–0.676; p = 0.019), and osteodystrophy (OR: 0.101, 0.014–0.724; p = 0.022). $_{log}$IGF1 levels were negatively associated with frailty (beta = –0.419), MELD-Na (beta = –4.55), and CTP scores (beta = –1.48) (p <0.05, each). Cumulative incidence of overall complications at 90-day were highest among patients with low IGF1 (39.5%) than intermediate (25%), and high IGF1 levels (17.1%); with a corresponding incidence at 180-days of 48.8%, 39.8%, and 22.0%, p = 0.001, respectively. Ascites and hepatic encephalopathy were the main drivers of complications among patients with low IGF1 levels. 90-day and 180-day survival were significantly lower in patients with low IGF1 levels than those with intermediate or high IGF1 levels (90-day: 76.7% vs 93.2% vs 95.1% (p = 0.023); 180-day: 69.8% vs 85.2% vs 90.2%; p = 0.001). Both logIGF1 (AUC: 0.709 and 0.648) and MELD (AUC: 0.710 and 0.659) could predict 90 and 180-day mortality (p <0.05, each). Adding $_{log}$IGF1 with MELD could further improve the discriminative-accuracy of MELD for mortality at 90-day (0.756) and 180-day (0.685), p < 0.05. Patients with sarcopenia and osteodystrophy showed lower GH levels than counterparts (sarcopenia: 4.32 vs 3.88; osteodystrophy: 3.88 vs 3.99). A trend towards lower GH levels was observed among 90-day non-survivors compared to survivors [3.11 vs. 4.08, p = 0.070].

Conclusion: Reduced IGF1 levels reflect sarcopenia, frailty, and osteodystrophy in cirrhosis. Low IGF1 contributes to complications and mortality in cirrhosis outpatients. Our findings suggest that modulating this axis could be a novel approach for improving patient outcomes in decompensated cirrhosis.

FRI-083

The impact of acute kidney injury in cirrhosis: a meta-analysis of 5, 202, 232 patients

Vasileios Lekakis[1], Ioannis Vlachogiannakos[1], George Papatheodoridis[1], Evangelos Cholongitas[2]. *[1]Academic Department of Gastroenterology, General Hospital of Athens "Laiko", Athens, Greece; [2]1st Department of Internal Medicine, General Hospital of Athens "Laiko", Athens, Greece*
Email: lekakis.vas@gmail.com

Background and aims: Acute kidney injury (AKI) is a commonly seen condition in the natural course of cirrhosis. The aim of this study was to evaluate the pooled incidence and mortality of AKI in different clinical settings and to identify high-risk factors for both the incidence and mortality of AKI.

Method: A systematic search of several databases was performed up to May 2023. Meta-analysis was performed using a generalized linear mixed model, while a random effects model was utilized for all calculations. All analyses followed a pre-specified protocol (PROSPERO: CRD42023487736).

Results: In total, 73 studies with 5, 202, 232 patients fulfilled eligibility criteria and were finally enrolled in the meta-analysis. The overall pooled incidence of AKI was 33% (95% confidence interval (CI): 29–38%), and prerenal was the most common AKI type [59% (95% CI: 50–67%)]. On admission, patients with infection had the highest AKI rate [47% (95% CI: 40–55%)]. Pooled AKI rates were also high in inpatients with hepatic encephalopathy [41% (95% CI: 32–50%)] and significantly lower in those with gastrointestinal bleeding [31% (95% CI: 24–38%)]. Furthermore, the severity of liver disease proved to be a substantial driver for AKI development, as the pooled incidence of AKI was significant greater in patients at Child-Turcotte-Pugh (CTP) C than B than A class [48% vs 29% vs 16%, p <0.01]. Noteworthy, patients at intensive care unit (ICU) had the greatest AKI incidence [61% (95% CI: 53–69%)], whereas the AKI rate was higher in patients with than without acute on chronic liver failure (ACLF) [43% (95% CI: 32–55%) vs 29% (95% CI: 25–33%), p = 0.02]. The overall short-term pooled mortality rate was significantly higher among cirrhotic patients with than without AKI [34% (95% CI: 28–41%) vs 9% (95% CI: 6–13%), p < 0.01]. Interestingly, AKI patients in the ICU had the greatest mortality rate [76% (95% CI: 73–79%)], while AKI patients with ACLF experienced higher mortality rates than those without [54% (95% CI: 33–73%) vs 28% (95% CI: 23–34%), p < 0.01]. Moreover, the 30-day pooled mortality rate was significant higher in patients with hospital-acquired compared to community-acquired AKI [39% (95% CI: 34–

45%) vs 28% (95% CI: 22–36%), p = 0.03]. The mortality rates were also significantly correlated with AKI stage being significantly higher in cases with stage 3 than stage 2 than stage 1 (62% vs 50% vs 29%, p < 0.01).
Conclusion: Approximately one third of cirrhotic patients experience AKI during follow-up. Patients at ICU and those with severe liver disease, infection, sepsis, hepatic encephalopathy or ACLF upon admission are at higher risk for AKI. AKI patients experience significantly higher mortality rates than non-AKI cases, especially those admitted at ICU or diagnosed with ACLF. Significant risk factors for AKI-associated short-term mortality include both hospital-acquired AKI and high AKI stage.

FRI-086
Untargeted serum metabolomic profiles remain stable over time in large multi-center cohort of >700 outpatients with cirrhosis
Jasmohan Bajaj[1], Puneeta Tandon[2], Jennifer Lai[3], Jacqueline O'Leary[4], Guadalupe Garcia-Tsao[5], Hugo Vargas[6], Scott Biggins[7], Florence Wong[8], Patrick S. Kamath[9], Nicolas Lugon[5], Ana Limon-Miro[2], Jawaid Shaw[1], Brian Bush[1], K. Rajender Reddy[10].

Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Untargeted metabolomics could be biomarkers for disease progression in cirrhosis but stability over time is unclear. Aim: define differences in serum metabolomics at baseline and changes over time in multi-center outpatient cirrhosis cohort.
Method: NACSELD-3 (North American Consortium for Study of End-Stage Liver Disease) is a multi-center outpatient cirrhosis cohort of compensated (comp) and decompensated (decomp) pts seen at 6M intervals. Clinical and demographic data and serum for metabolomics (done with LC/MS) are collected at each visit. Metabolomic profile at baseline and 6M were compared between/within comp vs decomp groups using paired and unpaired t-tests as appropriate.
Results: We enrolled 744 subjects (285 comp, 459 decomp) from 10 centers of whom 165 comp and 150 decomp were seen again at 6M. All pts' comp/decomp status was stable over time. Between group comparisons: 892 metabolites were different between comp/decomp, of which 500 were higher and 392 were lower in decomp pts. At 6M, 676 metabolites were different, of which 350 were higher and 326 were lower in decomp pts. These comparisons were consistent at both timepoints apart from 8 metabolites. *8 metabolites changed direction from baseline to 6M between comp/decomp pts*: 2-ketocaprylate (0.81 to 1.36-fold), indole propionate (0.98 to 1.05), 2-aminooctanoate (0.9 to 1.47), N-methylhydroxyproline (0.85 to 1.24) and glycodeoxycholate (0.91 to 1.31) were lower in decomp vs comp at baseline but flipped i.e., increased at 6M post. The reverse (higher at baseline and lower at 6M in decomp) was seen with glycoursodeoxycholate (1.2 to 0.71), 5-hydroxyindole sulfate (1.23 to 0.69) and tauroursodeoxycholate sulfate (1.09 to 0.3). Within group analysis: *Compensated*: 130 metabolites differed of which 95 ↑ and 35↓ at 6M vs baseline. Those that reduced at 6M were biliverdin, vitamin C/E metabolites, long-chain fatty acids, phosphocholines, sex steroids, and tauro/glycoursodeoxycholate sulfate. Those that ↑ were amino acid derivatives related to urea cycle (arginosuccinate) and protein breakdown, bioenergetics (aconitate, malate, citrate) and hormones (cortisol). *Decompensated*: 66 metabolites changed (37↑/29↓) at 6M vs baseline. Those that ↓were biliverdin, long chain FAs, carnitine derivatives, and serotonin. Metabolites that ↑ were again amino acid derivatives and urea cycle intermediates (citrulline, ornithine), GABA derivatives (imidazole acetate), short/medium fatty acids (butyrate, valerate) and N-acetylated amino acids that are linked with renal disease.
Conclusion: Serum metabolomics are largely stable over time in outpatients with cirrhosis in a multi-center study across North America, which encourages their use as biomarkers. Few metabolites that changed differentially were microbially modified metabolites (bile acids, indoles, short chain fatty acids), long-chain fatty acids, and urea cycle intermediates.

FRI-087
Cerebral diffusion tensor imaging in patients with liver diseases admitted for evaluation of neurological symptoms
Nicolas Weiss[1], Lyès Kheloufi[1], Philippe Sultanik[1], Sarah Mouri[1], Charlotte Bouzbib[2], Marika Rudler[2], Vincent Perlbarg[3], Louis Puybasset[2], Dominique Thabut[2]. *[1]Sorbonne Université, Paris, France; [2]Sorbonne Université, PARIS, France; [3]BrainTale, PARIS, France*
Email: nicolas.weiss@aphp.fr

Background and aims: Hepatic encephalopathy (HE), especially overt HE (OHE), is a common complication of liver diseases. Its occurrence is associated with decreased survival, increased risk of further boots of OHE, altered quality of life. Recent animal data suggested that several boots of OHE could be associated with cerebral neurodegeneration. Diffusion tensor imaging (DTI) is a MRI sequence that enables to study cerebral damage and try to dismantle between axonal and myelin damage. Data are scarce in HE with conflicting results. In this study, we take advantage of DTI in a cohort of patients with chronic liver diseases that were referred for neurocognitive symptoms, and underwent a standardized multimodal work-up.
Method: Patients with chronic liver diseases admitted for a one-day exploration of neurocognitive symptoms were included if they had a cerebral MRI with DTI sequences. They were evaluated with a standardized multimodal work-up and underwent a complete neuropsychological testing by a neuropsychologist encompassing PHES (French and Spanish version, critical flicker frequency (CFF) test and animal naming test (ANT). DTI sequences were analyzed by using the BrainQuant software (BrainTale, Paris) providing automatically global fractional anisotropy (FA) and mean diffusivity (MD). P < 0.05 were considered significant and analysis were performed using JMP Pro 17 (SAS Institute).
Results: Among 164 patients that were evaluated, 156 (95%) underwent a cerebral MRI and among them 118 (72%) had DTI sequences acquisition. 94 (80%) had cirrhosis and 24 (20%) had vascular liver disease. Patients with cirrhosis were 61 [55–68] years-old, 68 (72%) were men, Child-Pugh of 8 [7–9] and MELD of 13 [10–15]. In cirrhotic patients FA values were lower (p = 0.0128) in patients having a history of previous HE, whereas MD was not different (p = 0.1436). MD differed between patients with a history of neurological disease compared to those without (p = 0.0113), whereas FA did not (p = 0.0549). There was no difference in FA (p = 0.4309) nor in MD (p = 0.5669) between patients with cHE or not. On neuropsychological testing, FA and MD were correlated with MoCA (Montreal Cognitive Assesment) (p = 0.0136 and p = 0.0112), and ANT (p = 0.0081 and p = 0.0077). At long-term, FA decrease and MD increase were correlated to the number of boots of OHE (p = 0.0057 and p = 0.0046).
Conclusion: FA and MD are altered in patients with liver diseases and neurological symptoms. Cirrhotic patients had lower FA and higher MD values. FA was decreased in cirrhotic patients with previous boots of HE and not in patients with previous neurological diseases. FA and MD correlated to neuropsychological testing especially the ANT. At long-term, a decrease in FA and an increase in MD were positively correlated with number of further boots of OHE.

Email: wkseto@hku.hk

Background and aims: Postacute out-of-hospital care in cirrhosis is associated with major quality-of-life, resource implications and return to a productive life. But patterns and predictors of post-discharge outcomes are unclear. We aimed to describe global determinants of discharge location other than home for patients with cirrhosis after acute hospitalization.

Method: We prospectively recruited pts with cirrhosis hospitalized non-electively via the CLEARED Consortium, involving >110 centers worldwide across 6 continents, and categorized centers based on World Bank income groups: Low/Lower Middle Income (LIC/LMIC), Upper Middle Income (UMIC) and High Income (HIC). Patients with inpatient death and transplantation were excluded. We recorded demographics and inpatient details, medications, laboratory values and outcomes, and analyzed differences in patients discharged to home vs. non-home locations.

Results: 3, 678 patients (63.9% male, mean age 56.3 ± 13.3 years) were recruited from 26 countries (LIC/LMIC 15.9%, UMIC 46.6%, HIC 37.5%). Alcohol was the most common etiology (39.2%), then hepatitis B (22.4%), MASH (17.5%) and hepatitis C (9.9%). 233 patients (6.8%) were discharged to a non-home location [specialized nursing facilities (49.4%) or non-acute hospitals (50.6%)]. Non-home discharges, vs. home discharges, were more likely to occur in HIC centers (69.5% vs. 35.3%, $p < 0.001$), but with a significantly lower proportion of UMIC centers (14.2% vs. 48.8%, $p < 0.001$) while the proportion of LIC/LMIC centers were similar (16.3% vs. 15.8%). Non-home discharges also had a higher admission median MELD-Na score (23 vs. 19, $p < 0.001$) and a greater mean length of hospital stay (17.6 vs 11.4 days, $p < 0.001$). These patients had higher rates of hepatic encephalopathy (28.3% vs. 22.3% $p = 0.032$); similar associations were observed for nosocomial infection (18.0% vs. 8.1%), acute kidney injury (43.8% vs. 24.3%) and need of intensive care (20.6% vs. 10.2%) (all $p < 0.001$). Concerning inpatient medications, non-home discharges had increased use of spontaneous bacterial peritonitis (SBP) prophylaxis (24.5% vs. 11.4%), and increased use of lactulose, rifaximin and proton-pump inhibitors (all $p < 0.001$). Multivariate analysis found increased age (OR 1.01, 95%CI 1.00–1.03), income group (HIC vs. LIC/LMIC: OR 1.61, 95%CI 1.09–2.44) and SBP prophylaxis (OR 2.51, 95%CI 1.77–3.54) to be independently associated with non-home discharge.

Conclusion: Among patients who survived hospitalization without transplant in a worldwide cohort of inpatients with cirrhosis, 7% are discharged to locations other than home. These were more likely to occur in HIC centers in older patients with more advanced cirrhosis. Our study results show variations in non-home discharges that

encourage cirrhosis-specific measures of risk stratification, useful for health system metrics and advance care planning.

FRI-089

Infections and outcomes in patients hospitalized with an acute decompensation of cirrhosis: insights from the ATTIRE trial

Nikolaj Torp[1,2], Nicholas Freemantle[3], Alastair O'Brien[3,4]. [1]*Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark;* [2]*Department of Clinical Research, University of Southern Denmark, Odense, Denmark;* [3]*Comprehensive Clinical Trial Unit, University College London, London, United Kingdom;* [4]*Royal Free Hospital, London, United Kingdom*
Email: nikolaj.christian.torp@rsyd.dk

Background and aims: Infections in patients hospitalized with cirrhosis are common. We studied the natural history of hospitalized patients with cirrhosis and infection from a large randomized clinical trial, to determine whether outcomes were associated with use of prophylactic antibiotics, proton pump inhibitors (PPIs), statins, non-selective beta-blockers (NSBBs), spironolactone or prednisolone at baseline.
Method: We included patients from the ATTIRE trial, which was a neutral trial of daily in-hospital 20% human albumin infusions to patients admitted with an acute decompensation of cirrhosis. We identified infections upon enrollment, as reported by the attending clinicians. Baseline medication use was captured through the concomitant medication log. Daily biochemistry with white blood cell count (WBC) and C-reactive protein (CRP) was available during hospitalization and until discharge or death. Patients were followed at site for up to 180 days post randomization, by manual review of medical records.
Results: Of 777 patients, 211 (27%) were diagnosed with an infection, upon inclusion into the trial. Patients with baseline infections were older ($p = 0.034$), had higher WBC ($p < 0.001$) and CRP ($p < 0.001$), but a similar baseline MELD score as patients without an infection at baseline (median 19 IQR: 16–23 vs. 20 IQR: 15–23, $p = 0.740$). During 180 day follow-up, 84 (40%) of the patients with a baseline infection died. An infection at baseline was associated with increased risk of death (aHR = 1.51, 95% CI: 1.16–1.97, $p = 0.002$) during follow-up, independent of baseline MELD (aHR = 1.07, 95% CI: 1.05–1.09, $p < 0.001$). For patients with a baseline infection, rifaximin use upon enrollment was associated with an increased risk of death (aHR = 1.90, 95% CI: 1.11–3.25, $p = 0.019$), while a similar trend was observed for antibiotic prophylaxis in general (aHR = 3.09, 95% CI: 0.97–9.90, $p = 0.057$) after controlling for disease severity. No clear associations were observed between 180-day mortality and the use of PPIs ($p = 0.569$), statins ($p = 0.391$), NSBBs ($p = 0.367$), spironolactone ($p = 0.167$) nor prednisolone ($p = 0.790$). During the trial treatment period of 14 days, the overall WBC remained unchanged ($p = 0.425$) while CRP decreased ($p < 0.001$) in patients with a baseline infection. When controlling for disease severity, only increasing WBC was associated with the risk of death during the treatment period (aOR = 1.12, 95% CI: 1.05–1.19, $p < 0.001$), while CRP was not (aOR = 1.01, 95% CI: 1.00–1.02, $p = 0.285$).
Conclusion: Up to one in four patients hospitalized with an acute decompensation of cirrhosis had an infection at baseline. The use of antibiotic prophylaxis upon hospitalization was associated with an increased risk of death, independent of disease severity: However, the association may be due to residual confounding, despite controlling for baseline MELD score.

FRI-090

New concept of cirrhosis recompensation in clinical practice: it's key time

Inês Rodrigues[1], Francisco Capinha[1], Sofia Carvalhana[1], Luís Correia[2], Helena Cortez-Pinto[2]. [1]*Serviço de Gastrenterologia e Hepatologia, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal;* [2]*Serviço de Gastrenterologia e Hepatologia, Centro Hospitalar Universitário Lisboa Norte, Clínica Universitária de Gastrenterologia, Faculdade de Medicina de Lisboa, Universidade de Lisboa, Lisbon, Portugal*
Email: mines.bcrodrigues@gmail.com

Background and aims: The concept of liver recompensation challenges the classic unidirectional trajectory in cirrhosis. Suppression of underling aetiology of liver disease is a necessary factor; however other contributors are still undercover. We aim to evaluate the natural history of hepatic disease, focusing recompensation events and factors that predict the potential of recompensation.
Method: Retrospective study including all consecutive patients admitted with their first decompensation of cirrhosis, in a tertiary center (2016–2022) and followed >1 year. Recompensation was defined according to Baveno VII consensus: removal of etiological factor; resolution of encephalopathy and ascites without diuretics, and absence of variceal bleeding in the last year; sustained improvement of biochemical liver function. Statistical analysis was performed using SPSSv23 and considered pvalue <0.05.
Results: We included 175 cirrhotic patients, 76% (n = 133) males, with a median of 60 years-old at time of first decompensation. Regarding etiology, 69% (n = 120) had alcohol-related liver disease (10% with concomitant viral etiologies), 22 (13%) viral hepatitis alone, 12 (7%) metabolic dysfunction-associated steatotic liver disease (MASLD) and 23 (11%) other causes. The mean follow-up was 3.8 years (± 2.7 years). Etiological factor was suppressed in 66% (n = 116) of patients, within 55% (n = 58) before or at the first decompensation. Due to lack of etiological control definition in MASLD, these patients were considered as non-recompensated, although 42%fulfilled all other recompensation criteria. Recompensation was achieved in 20% (n = 35) of patients and 30% of those who controlled etiological factor, positively correlating with etiological factor control before or at the time of first decompensation ($p = 0.02$). Median time from diagnosis to decompensation was 0.5 months, with 86 patients (49%) decompensated at diagnosis. Patients' age at first decompensation ($p = 0.05$) also correlated with recompensation outcome. On logistic regression, for each additional year age, recompensation's probability dropped 3.7%. Gender, different etiological factors and manifestation of decompensation did not correlate with recompensation outcome. Nine (5%) patients without recompensation underwent a liver transplant. There was no correlation between an oncologic disease diagnosis during follow-up, and hepatocellular carcinoma in particular, and recompensation events. Death at the end of follow-up (n = 83, 48%) strongly correlated with absence of recompensation ($p < 0.01$).
Conclusion: Patient's age and etiological factor control at first decompensation seems a key element for achieving recompensation. In conclusion, since timely diagnosis and identification of etiological factor is so important, there is a pivotal role for early identification and reference to hepatology differentiated care.

FRI-091

Development of global leadership initiative on malnutrition-dictated nomograms to predict long-term mortality among hospitalized cirrhosis with external validation cohort

Chao Sun[1], Qing Liu[1]. [1]*Department of Gastroenterology and Hepatology, Tianjin Medical University General Hospital, Tianjin, China*
Email: liuqing317@tmu.edu.cn

Background and aims: Global Leadership initiative on Malnutrition (GLIM) gradually accounts for the mainstay evaluating nutritional status. Herein we sought to establish GLIM-dictated nomograms with other factors influencing long-term mortality and further validated

their predictive performance in an independent external cohort among inpatients experiencing decompensated cirrhosis.
Method: The derivation cohort comprised 301 patients hospitalized due to acute insults and the validation cohort recruited 101 cirrhotic subjects from another medical center. Two nomograms were established to predict 1-year all-cause mortality based on the GLIM criteria. Study populations were divided into low-, moderate- and high-risk nutritional groups according to the established nomogram.
Results: By incorporating Child-Pugh class (Nomo#1) and Model for End-stage Liver disease-Sodium (Nomo#2), respectively, GLIM criteria was independently associated with 1-year mortality in multivariate Cox regression models (HR for Nomo#1 = 2.934, CI: 1.529–5.629, p = 0.001; HR for Nomo#2 = 3.428, CI: 1.744–6.739, p < 0.001). The C index and time-ROC concerning Nomo#1 and Nomo#2 performed significantly better than those of GLIM criteria alone. The survival rate of low-risk nutritional group was significantly higher when compared with moderate- and high-risk groups (Nomo#1: high risk (18/27 = 66.67%) >moderate risk (27/79 = 34.18%) >low risk (8/160 = 5%); Nomo#2: high risk (21/28 = 75%) >moderate risk (22/62 = 35.48%) >low risk (10/176 = 5.68%)). Furthermore, the proposed nomograms still exhibited modest predictive accuracy (C index = 0.719) and were capable of identifying malnourished patients with cirrhosis and high mortality risk (log-rank test: p = 0.013) in another cohort for external validation.
Conclusion: GLIM criteria-defined malnutrition independently impact long-term mortality in the context of decompensated cirrhosis. Our established nomograms can predict survival status with sufficient accuracy on account of sizable samples and solid analyzing modalities.

FRI-092

Thyroid and adrenal dysfunction is associated with negative mid-term prognosis in decompensated cirrhosis

Laura Iliescu[1], Mircea Istrate[2], Razvan Rababoc[2], Simu Razvan-Ioan[2], Ioana Tanasie[2], Alexandra Alina Mihaela Mihaila[2], Letitia Toma[2].
[1]Department of Internal Medicine, Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania
Email: laura_ate@yahoo.com

Background and aims: Chronic liver diseases are associated with a variety of endocrine abnormalities, including pituitary, thyroid and adrenal dysfunction, in correlation to the severity of liver disease. Low levels of thyroid-stimulating hormone (TSH), free triiodothyronine (fT3) and serum cortisol have been described in patients with advanced chronic liver disease. We aim to determine the prognostic value of thyroid and adrenal dysfunction in patients with decompensated cirrhosis.
Method: We performed a prospective observational trial in patients with decompensated cirrhosis (Child B, Child C) admitted to our clinic between June 2013 and June 2023. We excluded patients with hepatocellular carcinoma or other malignancies, vascular liver diseases, infections, liver transplantation or intake of thyroid hormones or cortisone therapy. We measured a jeune serum levels of TSH, fT3 and cortisol. Patients were monitored at 6 months.
Results: We included 635 patients (mean age 65.3 ± 34.1 years, 55.6% male) with cirrhosis Child B (217 patients) and C (418 patients). Main etiologies were: 17.0% alcohol related, 67.4% viral, 15.6% MAFLD related cirrhosis. Patients with Child B cirrhosis has significantly higher levels of TSH, fT3 and cortisol compared to Child C patients (TSH 3.14 uUI/ml versus 2.54 uUI/ml, p = 0.03; fT3 3.67pg/ml versus 2.95 pg/ml, p = 0.04; cortisol 465 mmol/L versus 218 mmol/L, p = 0.02). At 6 months follow-up, 23 patients (10.6%) progressed from Child B to Child C and 32 Child C patients (7.6%) patients presented with cirrhosis complications, with a mortality rate of 0.7%. Progression of liver disease was associated with decreased TSH, fT3 and cortisol levels in patients with Child B (2.87 uUI/ml versus 3.23 uUI/ml, p = 0.04, 3.23 pg/ml versus 3.84 pg/ml, p-0.01, 408 mmol/L versus 482 mmol/L, p = 0.01 respectively) and Child C cirrhosis (2.18 uUI/ml versus 2.72 uUI/ml, p = 0.02, 2.34 pg/ml versus 3.02 pg/ml, p = 0.01, 141 mmol/L versus 235 mmol/L p < 0.001).
Conclusion: Decreases in thyroid and adrenal hormones are associated with a poor mid-term prognosis in patients with decompensated cirrhosis. In this scenario, the serum levels of TSH, fT3 and cortisol may be used to predict rapid deterioration in Child B and C cirrhotic patients. Hormonal supplementation may be an option for these patients and needs to be further investigated.

Email: kessarin.t@chula.ac.th

Background and aims: Clot wave analysis (CWA) provides a global assessment of hemostasis and may be useful for patients with cirrhosis with complex hemostatic abnormalities. This study aims to assess the association between CWA values of prothrombin time (PT) and activated partial thromboplastin time (aPTT) clotting assays and the severity of cirrhosis. In addition, we prospectively evaluate the role of CWA in predicting acute decompensation in compensated cirrhotic patients.
Method: Adult cirrhotic patients were prospectively enrolled at Chulalongkorn University Hospital from June 2021 to October 2023. At the enrollment, patients with active bleeding, bleeding disorders, antiplatelet or anticoagulant use, hemodialysis, and active malignancy were excluded. Acute decompensation (AD) is defined as the acute development of ascites, variceal bleeding, overt hepatic encephalopathy, bacterial infection, jaundice, or any combination of these complications. CWA values were performed on the CS-2500 (Sysmex Corporation).
Results: A total of 466 cirrhotic patients were enrolled, with 144 (30.9%) having decompensated cirrhosis. Of these, 123 (26.4%) and 40 (8.6%) had Child-Pugh B and C, respectively. Maximum velocity (min1), maximum acceleration (min2), and maximum deceleration (max2) of CWA based on PT and aPTT assays were significantly lower (p ≤0 .05) in decompensated patients than in those with compensated cirrhosis. Advanced stage of cirrhosis was associated with more hypocoagulable CWA parameters. In addition, patients with Model For End-Stage Liver Disease (MELD) score of ≥18 had lower CWA values than those with MELD score of <18. The min1, min2, and max2 of PT CWA assays were significantly negatively correlated with Child-Pugh (r = −0.37 to −0.46, p ≤0 .001), MELD score (r = −0.35 to −0.41, p ≤0 .001), and transient elastography evaluated by Fibroscan (r = −0.16 to −0.26, p ≤0 .05). There was no significant difference in CWA values between patients with and without portal vein thrombosis. Among patients with compensated cirrhosis at baseline, 11.8% (38/322) developed acute decompensation within one year of follow-up. Baseline PT-based CWA values were significantly lower in patients

who developed decompensating events compared to those without progression.
Conclusion: Hypocoagulable CWA measurements are associated with advanced cirrhotic stage and the progression to decompensated complications. CWA may be a useful objective marker of the severity of cirrhosis.

Differential diagnosis of covert hepatic encephalopathy in a cohort of outpatients with chronic liver disease
Lyès Kheloufi[1,2], Philippe Sultanik[1,2], Apolline Leproux[1,2], Charlotte Bouzbib[1,2,3], Sarah Mouri[1,2,3], Antoine Santiago[1], Marika Rudler[1,2,3], Nicolas Weiss[1,2,4], Dominique Thabut[1,2,3]. *[1]AP-HP, Brain-Liver Pitié-Salpêtrière Study group (BLIPS), Paris, France; [2]INSERM UMR_S 938, Centre de recherche Saint-Antoine, Maladies métaboliques, biliaires et fibro-inflammatoire du foie, Institute of Cardiometabolism and Nutrition (ICAN), Paris, France; [3]AP-HP, Sorbonne Université, Liver Intensive Care Unit, Hepatogastroenterology Department, Pitié-Salpêtrière Hospital, Paris, France; [4]AP-HP, Sorbonne Université, Neurology Intensive Care Unit, Neurology Department, Pitié-Salpêtrière Hospital, Paris, France*
Email: lyes.kheloufi@aphp.fr

Background and aims: Covert hepatic encephalopathy (CHE) is a complex and multifactorial complication of chronic liver diseases (CLD). Other etiologies may cause neurocognitive impairment (NI) independently form the liver condition, making the differential diagnosis difficult using cognitive tests. The aim of this study was to search for cognitive tools enabling to identify patients with CHE, taking into account the presence of other sources of NI.
Method: Retrospective analysis of a prospective cohort of patients with CLD (March 2018-November 2022) referred to our outpatient clinics for suspicion of CHE. Multimodal work-up was performed in our multidisciplinary team: hepatologists, neurologist, neuropsychologist, biomarkers, electroencephalogram (EEG) and brain MRI (MRI) with spectroscopy (MRS). An adjudication committee involving the aforementioned physicians set the diagnosis of CHE and the presence of factors of brain injury (FBI: alcohol abuse sequelae, vascular leukopathy, stroke, epilepsy) based on medical history, clinical examination, complete neuropsychological evaluation (general cognitive efficiency, attention, executive functions, memory, instrumental functions, including tests validated for HE diagnosis : PHES, *Psychometric Hepatic Encephalopathy Score,* ANT, *Animal Naming Test*), EEG and MRI-MRS. Descriptive analyses were conducted with Chi squared test for qualitative data proportions association, and Mann-Whitney U test or Kruskall-Wallis test for quantitative data associations.
Results: 164 pts were included: a majority of males (64%), median age was 60 (50–66) years, 77% cirrhosis (alcohol/MASH/virus in 62/54/16%), 23% portosinusoïdal vascular liver disease. Overall, 63% patients were diagnosed with CHE. FBI were found in 36% of patients and 25% with mix causes of NI (CHE and FBI). Only 37% of patients had CHE without FBI. Age, prevalence of cirrhosis, and presence of FBI were similar between CHE and non-CHE groups. MoCA ($p = 0.049$), PHES ($p = 0.003$), ANT ($p = 0.001$), executive and attention evaluating tests were significantly worse in CHE patients. When comparing patients with or without FBI, MMSE ($p = 0.008$), MoCA ($p = 0.027$), and tests evaluating attention, executive functions, and episodic memory were significantly worse in patients with FBI. When separating in four groups taking into account the presence of CHE and FBI, the evaluation of episodic memory (FCSRT, recall of Rey's Figure) enabled to separate patients with FBI from patients without, independently from HE diagnosis.
Conclusion: The diagnosis of HE based only on the presence of NI is complicated. Validated tests (PHES, ANT) can be sensitive for HE but for other sources of NI as well, such as the presence of FBI. The evaluation of episodic memory seems to be a promising tool for differential diagnosis between HE and FBI.

FRI-095
Privative verbal fluency test (PVFT): a quick-to-use cognitive tool for the screening of covert hepatic encephalopathy
Lyès Kheloufi[1,2], Aliyya Ahamada[1], Apolline Leproux[1,2], Philippe Sultanik[1,2], Sarah Mouri[1,2,3], Charlotte Bouzbib[1,2,3], Marika Rudler[1,2,3], Nicolas Weiss[1,2,4], Dominique Thabut[1,2,3]. *[1]AP-HP, Brain-Liver Pitié-Salpêtrière Study group (BLIPS), Paris, France; [2]INSERM UMR_S 938, Centre de recherche Saint-Antoine, Maladies métaboliques, biliaires et fibro-inflammatoire du foie, Institute of Cardiometabolism and Nutrition (ICAN), Paris, France; [3]AP-HP, Sorbonne Université, Liver Intensive Care Unit, Hepatogastroenterology Department, Pitié-Salpêtrière Hospital, Paris, France; [4]AP-HP, Sorbonne Université, Neurology Intensive Care Unit, Neurology Department, Pitié-Salpêtrière Hospital, Paris, France*
Email: lyes.kheloufi@aphp.fr

Background and aims: Hepatic encephalopathy (HE) is a severe complication of chronic liver diseases (CLD). It is associated to a lower survival rate and an alteration of quality of life. Therefore, it is crucial to detect HE as soon as possible, at the stage of covert HE (CHE), in order to start effective therapies. Cognitive tests validated for HE (PHES, *Psychometric Hepatic Encephalopathy Score*, ANT, *Animal Naming Test* or Stroop test) are focused on psychomotor speed, attention and executive functions. PHES is currently the gold-standard for CHE diagnosis but is time-consuming and not available in routine clinical practice. The aim of this study was to evaluate the sensibility of a quick cognitive test, the privative verbal fluency test (PVFT) for the diagnosis of HE and comorbidities.
Method: Cross sectional analysis of a prospective cohort (February 2022-October 2023) of patients with CLD referred to our outpatient clinics for suspicion of HE. An adjudication committee involving hepatologists, a neurologist and a neuropsychologist set the diagnosis of HE encompassing the results of brain MRI with spectroscopy, blood sample with ammonia, electroencephalogram and cognitive tests including PHES, ANT, CFF, verbal fluency and cognitive inhibition. The PVFT task consists on giving as many words not containing the letter "a," in one minute, evaluating verbal fluency and cognitive inhibition. Chi squared test was used for qualitative data and Mann-Whitney U test, Kruskall-Wallis test and Spearman's Rho correlation for quantitative data associations.
Results: Sixty-one patients referred to our outpatient clinics went through all the cognitive tests and clinical evaluation. Among them, 71% were men and the median age was 60 (53–65), 69% had liver cirrhosis with a median MELD score of 13 (10–15). Thirty patients (49%) were diagnosed with CHE. Patients with CHE displayed lower scores in the PVFT ($p = 0.013$), PHES ($p < 0.001$) and ANT ($p = 0.049$). Correlation between PVFT and ANT ($r = 0.76$) and PHES ($r = 0.61$) were significantly high ($p < 0.001$). ROC analysis for PVFT, ANT and PHES yielded to areas under the ROC curve of respectively 0.69, 0.64 and 0.79. The best compromise between sensitivity and specificity for the PVFT was the cut-off of 10 production in one minute (Youden index = 0.32; sensitivity = 0.87; specificity = 0.45), whereas, 20 animals in one minute for the ANT yielded a Youden index of 0.19 (sensitivity = 0.82; specificity = 0.38). The PHES, with a cut-off score of −4 yielded a Youden index of 0.29 (sensitivity = 0.37; specificity = 0.92).
Conclusion: PVFT is a quick (1 min) cognitive sensitive test for the screening of CHE in CLD patients. Correlation analysis have shown a significant association between PVFT, ANT and PHES. PVFT displayed greater sensitivity than ANT and PHES. PVFT can represent a very promising and accessible tool for HE screening.

FRI-098

Feasibility of bedside ultrasonography of rectus femoris muscle for sarcopenia diagnosis in liver cirrhosis

Sara De Monte[1], Philipp Altmann[1], Hans Benno Leicht[1], Roswitha Brandl[1], Florian P Reiter[1], Mathias Plauth[2], Andreas Geier[1], Monika Rau[1]. [1]*University hospital Würzburg, Würzburg, Germany;* [2]*Dessau community general hospital, Dessau-Rosslau, Germany*
Email: sra.demonte@gmail.com

Background and aims: Malnutrition and sarcopenia are highly prevalent in patients with advanced liver cirrhosis (LC), both serving as independent risk factors for increased morbidity and mortality. The diagnostic algorithm for sarcopenia involves measuring muscle mass and/or muscle function. This prospective study aims at assessing the feasibility of bedside ultrasonography of the Rectus femoris muscle (RFM) as an indicator for muscle mass for diagnosing sarcopenia in patients with LC.
Method: 79 patients with LC hospitalized at a tertiary center from 05/22 to 12/23 were prospectively included. Assessment of sarcopenia was performed 24–48 h after admission, using hand grip strength, chair rising test, ultrasound measurement of RFM and bioelectrical impedance analysis (BIA). Physical performance was tested by Timed Up and Go (TUG) and gait speed test. Statistical analysis was performed by SPSS.
Results: 48/79 (61%) patients were male, and 20 had compensated LC (CHILD A), while 59 had decompensated LC (40 = CHILD B, 19 = CHILD C). RFM thickness (MT) and cross-sectional area (CSA) were significantly lower in CHILD C patients compared to CHILD A (MT 7.3 ± 2.8 vs. 9.0 ± 2.5 mm; $p < 0.05$; CSA 172.1 ± 100.9 vs. 213.6 ± 72.2mm²; $p < 0.05$) with an even more pronounced difference when adjusting for height (m²) or body surface area (BSA). No significant difference in appendicular skeletal mass (ASM) or fat-free mass (FFM) as determined by BIA was observed in decompensated vs. compensated LC, even when analyzing only patients without ascites and/or edema. However, CHILD C patients had a significantly lower BIA-derived phase angle (PA) compared to CHILD A patients (3.7 ± 0.9° vs. 4.7 ± 0.5°; $p < 0.01$). Patients with low muscle function, assessed by hand grip strength had significantly lower MT and CSA of RFM, as well as lower PA, ASM, and FFM by BIA. MT of RFM and PA were significantly negatively correlated to the chair rising test, but no correlation was found to TUG or gait speed test. ROC curve analysis demonstrated the highest accuracy for MT/m² and CSA/m² of RFM in predicting low PA (<4.9°) (MT/m² 0.68; CSA/m² 0.74)).
Conclusion: In patients with cirrhosis, ultrasound of RFM is a feasible and easily applicable bedside method for detecting those at risk for sarcopenia. Both, low RFM thickness and cross-sectional area are associated with lower muscle strength. These findings underscore the potential of ultrasonography as a practical bedside tool for diagnosing sarcopenia in patients with cirrhosis.

FRI-099

Risk of serious infection in patients with chronic liver disease: a nationwide population-based cohort study

Won Sohn[1], Ju-Yeon Cho[2], Jung Hee Kim[3], Jae Yoon Jeong[4], Yong Kyun Cho[1], Byung Ik Kim[1]. [1]*Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South;* [2]*Chosun University Hospital, Gwang-Ju, Korea, Rep. of South;* [3]*Hallym University Dongtan Sacred Heart Hospital, Dongtan, Korea, Rep. of South;* [4]*National Medical Center, Seoul, Korea, Rep. of South*
Email: hand0827@naver.com

Background and aims: This study aimed to investigate the risk of serious infection in patients with chronic liver disease.
Method: This cohort study from the Korean National Health Insurance Service included a population-based data collected from 1, 699, 159 patients with chronic liver disease between 2009 and 2021. The definition of serious infection was hospital admissions with ICD-10 codes for acute meningitis, acute osteomyelitis, bacteremia, pneumonia, pyelonephritis, serious gastrointestinal infection, skin and soft tissue infections, spontaneous bacterial peritonitis, and COVID-19 infection. We compared the development of serious infection, the admission of intensive care unit (ICU), and mortality between chronic liver disease/compensated cirrhosis and decompensated cirrhosis.
Results: The mean age of the patients was 57.4 years, with 55.6% of them being men. The most common cause of chronic liver disease was chronic hepatitis B (59.5%). The study population consisted of 1, 614, 085 patients (95%) with chronic liver disease/compensated cirrhosis and 85, 074 patients (5%) with decompensated cirrhosis. During the follow-up period, 12.5% of patients with chronic liver disease/compensated cirrhosis, and 23.9% of patients with decompensated cirrhosis experienced serious infections ($p < 0.01$). The most common infections were pneumonia, followed by serious gastrointestinal infection, pyelonephritis, bacteremia, skin and soft tissue infections, spontaneous bacterial peritonitis, acute osteomyelitis, acute meningitis, and COVID-19 infection. The risk of serious infections is higher in decompensated cirrhosis than in chronic liver disease/compensated cirrhosis (adjusted hazard ratio [HR] 2.43 with confidence interval [CI]: 2.38–2.47). Patients with decompensated cirrhosis had higher admission rate on ICU for serious infections compared to chronic liver disease/compensated cirrhosis: 16.9% vs. 1.8%, $p < 0.01$). The mortality rates were 4.2, 40.0, and 107.7 per 1, 000 person years in patients with no, 1, and ≥2 serious infections. The adjusted HRs for all-cause mortality in patients with 1 and ≥2 serious infections, compared to no serious infection were 5.48 (95% CI: 5.41–5.56), and 11.20 (95% CI: 11.00–11.40).
Conclusion: The risk of serious infection is higher in patients with decompensated cirrhosis. The mortality in patients with chronic liver disease is growing as the risk of serious infection increases.

FRI-100

Bleeding risk after endoscopic polypectomy in patients with cirrhosis

Guenseli Bloch[1], Haedge Frederic[2], Gabriel Allo[3], Philipp Kasper[3], Benedikt Hild[1], Tony Bruns[2], Jassin Rashidi-Alavijeh[1], Hartmut Schmidt[1], Christoph Schramm[1]. [1]*University Hospital Essen, Essen, Germany;* [2]*University Hospital RWTH Aachen, Aachen, Germany;* [3]*University Hospital Cologne, Cologne, Germany*
Email: christoph.schramm@uk-essen.de

Background and aims: Endoscopic polypectomy of colorectal polyps is recognised as a safe procedure and a cornerstone in the prevention of colorectal cancer. In patients with cirrhosis, an increased bleeding risk is often assumed since alterations in global coagulation tests and platelet count are frequently present. However, both are of limited value for predicting bleeding complications in several procedures. We aimed to investigate risk factors for post-polypectomy bleeding complications in patients with cirrhosis.
Method: We performed a retrospective multicenter study of patients with cirrhosis who underwent colonoscopy with polypectomy at three academic medical centers in Germany from 01/01/2013 and 31/12/2022. Clinical significant portal hypertension (CSPH) was diagnosed in the case of liver stiffness >25 kPa, present or history of ascites, or esophageal, gastric or etopic varices. Severe bleeding was defined as death, drop in hemoglobin ≥2 g/dl and/or transfusion of ≥2 red blood cell concentrate.
Results: We included 337 patients with a median age of 61 years (interquartile range (IQR) 54–67), of which 69% were male and 31% female. Alcohol-associated liver disease (40%), chronic hepatitis C (17%), and steatotic liver disease (13%) were the most common etiology of chronic liver disease. 48%, 38%, and 14% of patients were Child Pugh class A, B, and C, respectively, the median MELD score was 11 (IQR 7–16). CSPH was present in 84%, of which 44% received treatment with non-selective betablocker and/or transjugular intrahepatic portosystemic shunt. Platelets <50.000/µl and/or INR >1.5 was present in 23%, platelets <30.000/µl and/or INR >2.5 in 11%. A total of 664 polyps with a median size of 7 mm (IQR 5–10) were

removed by endoscopic polypectomy. 40% of patients had polyps ≥10 mm and 9% of patients had polyps ≥20 mm in size. Intraprocedural bleeding occurred in 11.6% of patients. Sixteen patients (4.7%) experienced post-polypectomy bleeding, of which 7 (2.1%) were severe. Intraprocedural bleeding was significantly increased in polyps ≥20 mm in size (26.7% vs. 10.1%, p = 0.007). INR >1.5 (12.1% vs. 3.3%, p = 0.004) and >2.5 (11.8% vs. 4%, p = 0.045), and Child-Pugh class (A: 1.9% vs. B: 6.3% vs. C: 10.2%, p = 0.034), but not thrombocytopenia or CSPH were significantly associated with post-polypectomy bleeding.
Conclusion: Post-polypectomy bleeding is infrequent in patients with cirrhosis. Elevated INR and higher Child-Pugh class, i.e. parameters for more advanced chronic liver disease, but not platelet count or CSPH including treatment, were significantly associated with the occurrence of bleeding complications. The benefit of correcting altered coagulation parameters prior to polypectomy needs to be demonstrated.

FRI-101-YI
Rectus femoris cross sectional area predicts 90-day readmission in patients hospitalized for an acute decompensation of cirrhosis
Roberta Gagliardi[1], Paola Campadello[1], Silvia Brocco[1], Simone Incicco[1], Valeria Calvino[1], Beaudelaire Sikadi[1], Marta Tonon[1], Alessandra Brocca[1], Carmine Gambino[1], Nicola Zeni[1], Giorgio De Conti[2], Chiara Giraudo[2], Paolo Angeli[3], Salvatore Piano[3]. *[1]Unit of Internal Medicine and Hepatology, Department of Medicine, University and Hospital of Padova, Padova, Italy; [2]Radiology Unit, Department of Medicine, University and Hospital of Padova, Padova, Italy; [3]Unit of Internal Medicine and Hepatology, Department of Medicine, University and Hospital of Padova, Padova, Italy*
Email: salvatore.piano@unipd.it

Background and aims: Sarcopenia is frequent in patients with cirrhosis and is associated with poor clinical outcomes. Ultrasound measurement of rectus femoris cross sectional area (RF-CSA) is an easy bedside tool for assessing sarcopenia in patients with cirrhosis. The aim of this study was to evaluate the ability of RF-CSA in predicting 90-day readmission in patients hospitalized for an acute decompensation (AD) of cirrhosis.
Method: We prospectively enrolled cirrhotic patients surviving a hospitalization for AD between 2019 and 2023. At discharge, clinical, demographic and laboratory data were collected and RF-CSA was measured at two-thirds of the distance from the anterior superior iliac spine to the superior patellar border. Patients were classified in two groups according to the median values of RF-CSA for males (3.38 cm^2) and females (2.60 cm^2): "high" if the RF-CSA value was above or equal to the median, and "low" if it was below the median. Follow-up continued until death, liver transplant, or 90 days, during which readmissions were documented.
Results: We enrolled 161 patients (mean age 64 ± 11 years, mean MELD 16 ± 5), the majority had alcohol-related cirrhosis (57%) and ascites (75%). During the 90-day follow-up 69 patients were readmitted (43%). Patients readmitted were older (67 vs 62 years; p = 0.012), had higher rate of hepatic encephalopathy during the index admission (44 vs 27%; p = 0.023) and lower RF-CSA (3.4 vs 2.8 cm^2; p < 0.001). Patients with "low" RF-CSA had a higher probability of 90-day readmission than those with "high" RF-CSA (67 vs 46%; p = 0.005). In multivariable analysis (adjusted for age, sex, MELD and hepatic encephalopathy during index admission) a "low" RF-CSA was an independent predictor of 90-day readmission (aHR = 1.79; p = 0.026), along with the development of HE during index admission (aHR = 5.55; p < 0.001).
Conclusion: Low muscle mass assessed by RF-CSA independently predicts 90 day-readmission in patients with cirrhosis surviving a hospitalization for AD. These findings suggest that preventing muscle loss and/or promoting increases in muscle mass could be potential targets for strategies aimed at preventing readmissions.

FRI-103-YI
Screening and assessing Sarcopenia in liver cirrhosis: feasibility and implications for clinical outcomes
Philipp Altmann[1], Sara De Monte[1], Roswitha Brandl[1], Florian P Reiter[1], Hans Benno Leicht[1], Andreas Geier[1], Monika Rau[1]. *[1]Division of Hepatology, Department of Internal Medicine II, University hospital Wuerzburg, Wuerzburg, Germany*
Email: altmann_p@ukw.de

Background and aims: The prevalence of sarcopenia, a nutrition-related condition, is high among patients with advanced liver disease, posing an independent risk for increased morbidity and mortality. This prospective study aims to analyze the feasibility of sarcopenia assessment outlined in the European Working Group on Sarcopenia in Older People (EWGSOP 2) criteria in patients with liver cirrhosis.
Method: A total of 81 cirrhotic patients were included in this prospective study from 05/22–12/23. Sarcopenia assessment was performed between 24–48 h after hospital admission at a tertiary university hospital. The assessment encompassed screening with SARC-F, muscle strength measurements, physical performance tests, and bioelectrical impedance analysis (BIA). Nutritional status was evaluated using Subjective Global Assessment (SGA) and Royal Free Nutrition Prioritizing Tool (RFH-NPT) questionnaires.
Results: Baseline characteristics indicated a mean age of 59 years, with 61.7% males and 38.3% females. Of the patients, 22 (27.2%) had compensated cirrhosis CHILD A, while 59 (72.8%) had decompensated cirrhosis (CHILD B or C). The mean MELD score was 15.6 ± 6.6. Only 17 (21%) patients had a positive screening with SARC-F (≥4), which was significantly associated with higher MELD score (SARC-F pos. 19.6 ± 1.7 vs. SARC-F neg. 14.6 ± 0.8, p < 0.05), but not with age. Reduced muscle strength by low HG strength was observed in 33% of cirrhotic patients and in 60.5% with an impaired chair rise test (>15 s). There was no significant association between low muscle strength tests and CHILD stage or MELD, but a significant association between both muscle strength tests and malnutrition by SGA in this study cohort. A substantial proportion of patients (75.3%) had a low phase angle (<4.9°) by BIA, significantly associated with a higher CHILD stage, MELD score, and malnutrition assessed by SGA. In terms of physical performance, 18.5% of patients had a low Timed Up and Go (TUG) test (≥14 s) and 22.2% had a low gait speed (≤0.8 s). Both physical performance tests were significantly associated with impaired muscle strength tests (HG and chair rise test). ROC analysis indicated that grip strength, phase angle and gait speed had the highest accuracy in predicting mortality or transplantation among our participants (0.573 vs 0.726 vs 0.729) in the 12-month follow-up, available at the time point of the abstract for only 28.5% of our study cohort.
Conclusion: The current EWGSOP2 algorithm for diagnosing sarcopenia has limited applicability in patients, as screening by SARC-F identifies only a minority of patients with high risk for sarcopenia characterized by reduced muscle strength and/or low phase angle by BIA-both associated with malnutrition and adverse outcome in this patient group. A valid screening instrument for sarcopenia in patients with liver cirrhosis is needed and should be addressed in further studies.

FRI-104
The respiratory assessment of cirrhotic patients: six-minute walk test is an independent predictor of mortality in cirrhosis
Burcu Gurbuz[1], Aytekin Idikut[2], Ugur Karakulak[3], Ebru Damadoglu[4], Baris Kaya[3], Taylan Kav[5], Erkan Parlak[5], Onur Keskin[5]. *[1]Hacettepe University School of Medicine Department of Internal Medicine, Ankara, Turkey; [2]Hacettepe University School of Medicine Department of Pulmonology, Ankara, Turkey; [3]Hacettepe University School Of Medicine Department of Cardiology, Ankara, Turkey; [4]Hacettepe University School*

Of Medicine Department of Pulmonology, Ankara, Turkey; [5]Hacettepe University School Of Medicine Department of Gastroenterology, Ankara, Turkey
Email: drburcuusta@gmail.com

Background and aims: Respiratory status of cirrhosis patients has not been adequately studied in the literature. The effectiveness of tests showing cardiopulmonary dysfunction in predicting survival in patients with cirrhosis has not been elucidated. This study aimed to investigate the type and frequency of respiratory symptoms in cirrhotic patients, to perform spirometric evaluation, and to investigate the effects of the 6-minute walk test on mortality prediction.
Method: Between September 2022 and June 2023, 75 patients followed up with cirrhosis were included in the study. Patients under 18 years of age and those with known moderate to severe cardiac or pulmonary disease were not included. Patients who came for routine gastroenterological examination were directed to the pulmonology department, whether they had complaints or not, all patients were questioned in detail about respiratory symptoms, spirometric measurements were made and a 6-minute walk test was performed. Walking test results were standardized according to gender, age, height and weight, and percentage values were calculated by proportioning the distances walked by the patients to the expected distances. Hospitalizations, decompensation and exitus status of the patients were recorded during the study period.
Results: Fifty-one patients (68%) reported dyspnea on exertion, 70 patients (93.3%) reported dyspnea on exertion at any time, and 22 patients (29.3%) had orthopnea. In the presence of decompensation, dyspnea ($p < 0.001$), exertional dyspnea (p:0.001), orthopnea symptoms ($p < 0.001$) were more common and modified Medical Research Council (mMRC) score was significantly higher (p:<0.001). In spirometric examination, FEV1% (p:0.003), FVC % ($p < 0.001$) were significantly lower and 6-minute walk distance was 14% shorter than expected in decompensated patients (p:0.001). Patients with FVC <70% on spirometry were considered restrictive, and the 6-minute walking distance of patients with restrictive results was found to be 173 meters lower on average ($p < 0.001$). Multivariate analysis showed that the failure to complete the 6- minute walk test was an independent predictor of mortality (OR: 16.00 [95% CI; (2.40–106)], p:0.004).
Conclusion: In conclusion, most cirrhotic patients have respiratory symptoms and signs and failure to complete the 6-minute walk test is an independent predictor of mortality in cirrhosis.

FRI-105

Tissue factor pathway inhibitor and serum amyloid A-4 protein are promising to predict occurrence of overt hepatic encephalopathy after transjugular intrahepatic portosystemic shunt

Huan Tong[1], Rui Yang[1], Xin Quan[1], Bo Wei[1], Hao Wu[1]. *[1]West China Hospital, Sichuan University, Chengdu, China*
Email: doctortonghuan@163.com

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) is increasingly applied to treat portal hypertension subsequent to liver cirrhosis. However, hepatic encephalopathy (HE) is a complication of concern for TIPS creation. There is still in lack of biomarkers to predict post-TIPS overt HE (OHE) currently. Therefore, this study was conducted to seek for feasible biomarkers to predict post-TIPS OHE.
Method: Serum of liver cirrhosis patients in this study came from another study (register No. ChiCTR2000039674), and those blood samples were collected before TIPS creation. Samples were divided into two groups (OHE group and non-OHE group) depending on the occurrence of OHE within 2 years after TIPS creation. Serum of 5 OHE and 5 non-OHE patients were firstly tested by non-labeled quantitative proteomics to screen for differentially expressed proteins. Proteins with p <0.03 and fold change >1.3 were eligible for further validation. The chosen biomarkers were thereafter quantified in 40 OHE and 40 non-OHE patients using enzyme-linked immunosorbent assay (ELISA). Logistic regression were used to determine the significance of biomarkers in predicting post-TIPS OHE and receiver operating characteristic curve was also used to display the diagnostic efficacy.
Results: Non-labeled quantitative proteomics identified 15 differentially expressed proteins between OHE and non-OHE patients. These secretory proteins mainly reside in the extracellular space to negatively regulate peptidase/endonuclease activity and protein hydrolysis to function. ELISA confirmed the up-regulation of tissue factor pathway inhibitor (TFPI), keratin type I cytoskeletal 10 (KRT10), metalloproteinase inhibitor 2 (TIMP2), serum amyloid A-4 protein (SAA4), and coagulation factor IX (F9), and down-regulation of fetuin-B (FETUB) in OHE group (OHE vs. non-OHE: TFPI 72.1 ± 21.9 vs. 52.2 ± 22.3 ng/ml, $p < 0.001$; KRT10 188.1 ± 159.2 vs. 126.4 ± 100.4 ng/ml, $p = 0.042$; TIMP2 417.5 ± 222.0 vs. 325.0 ± 104.2 ng/ml, $p = 0.020$; SAA4 4423.1 ± 2699.9 vs. 3207.1 ± 2592.4 ng/ml, $p = 0.021$; F9 1.4 ± 1.6 vs. 0.7 ± 0.5 ug/ml, $p = 0.014$; FETUB 11.1 ± 2.3 vs. 12.3 ± 3.0 ug/ml, $p = 0.036$). Logistic regression suggested that both serum TFPI and SAA4 were the risk factors to develop post-TIPS OHE in model 0 (6 aforementioned proteins), model 1 (age, gender, HE history, and model 0) and model 2 [alcoholic cirrhosis, portal pressure gradient decrement, blood ammonia, model for end-stage liver disease (MELD) score, hydrothorax, and model 1]. ROC curves showed that TFPI bore a better area under curve (AUC), comparing with SAA4 and MELD score (AUC: TFPI 0.716, $p < 0.001$; SAA4 0.654, $p = 0.018$; MELD score 0.509, $p = 0.889$).
Conclusion: Serum levels of TFPI, KRT10, TIMP2, SAA4, F9 and FETUB before TIPS differ between post-TIPS OHE and non-post-TIPS OHE patients, and serum TFPI and SAA4 are promising to predict the occurrence of post-TIPS OHE.

FRI-106-YI

Change in frailty status with nutritional therapy in patients with cirrhosis-a randomized controlled trial

Sudhir Maharshi[1], Saksham Seth[1], Shyam Sunder Sharma[1]. *[1]SMS Medical College and Hospitals, Jaipur, India*
Email: sudhir.maharshi@gmail.com

Background and aims: Frailty is characterized by low physiologic reserve and decreased functional status and is associated with poor prognosis in patients with cirrhosis. There is limited data on nutritional intervention on frailty status in cirrhosis. Aim was to assess the effects of nutritional therapy on changes in frailty status in cirrhotic patients.
Method: A randomized controlled trial conducted in a tertiary care centre on patients with cirrhosis, who were randomized to assigned to nutritional therapy (group A 30–35 kcal/kg/day, 1.0–1.5 g protein/kg/day) and no nutritional therapy (group B: patients continued on their same diet) for 6 months. Frailty status was assessed by liver frailty index (LFI) and gait velocity (GV). Primary end points were improvement or worsening in frailty status. Secondary end points were improvement of other nutritional parameters and liver functions.
Results: Till date 34 patients were randomized to group -A (n = 18, age 43.4 SD 9.8 yr, 14 men) and group-B (n = 16, age 42.7 SD 10.1 yr, 12 men). Alcohol was most common (64%) ethology. Baseline characteristics including age, body mass index (BMI), haemoglobin, MELD score, mid arm circumference (MAC), hand grip (HG), GV and LFI were comparable in both the groups. Improvement in GV (delta GV 0.99 SD 0.32 vs-0.82 SD 0.28, $p = 0.001$), LFI (delta LFI-0.62 SD 0.24 vs 0.3 SD 0.32, $p = 0.001$) HG strength (delta HG 4.2 SD 1.3 vs – 2.9 SD 1.2, $p = 0.001$), MAC (delta MAC 2.69 SD 0.28 vs-2.15 SD 0.26, $p = 0.01$) was observed in group A compared to group B at the end of study. Liver functions assessed by Child Turcotte Pugh and Model for end stage liver disease also significantly improved in group A compared to group B, p less than 0.001.

Conclusion: Nutritional therapy is effective in the improving the frailty status, nutritional parameters and liver functions in cirrhotic patients.

FRI-107-YI

Folic acid prescription is associated with a lower mortality and hospital readmission in patients with decompensated alcohol-related liver cirrhosis

Email: Buttler.Laura@mh-hannover.de

Background and aims: Patients with alcohol-related liver cirrhosis (aLC) frequently develop a state of malnutrition and micronutrient deficiencies, that are linked to a poor prognosis and disease progression. Particularly, an inadequacy of thiamine and folate supply is often observed in this group of patients. Consequently, guidelines recommend broad vitamin B prescription, but the impact on the clinical outcome remains questionable. Therefore, we aimed to evaluate the real-world use of thiamine and folic acid and its effect on liver-related complications and transplant-free survival in patients with decompensated aLC.
Method: The investigated cohort included 289 consecutive patients with aLC and ascites who were treated at our center between 2011 and 2023. Discharge medication was screened for thiamine- or folic acid containing supplements. Patients were followed up for hepatic encephalopathy (HE), infections, spontaneous bacterial peritonitis (SBP) and liver transplantation (LTx) free survival up to one year after hospital discharge.
Results: Thiamine containing supplements were prescribed to 139 (48.1%) patients. Most frequent was intake of a fixed vitamin B combination including vitamin B1 (n = 73; 52.5%) and single thiamine (n = 66; 47.5%). Only 12 patients (8.6%) took multivitamin supplements. Folic acid was prescribed to a minor proportion of 52 (18.0%) patients. Regarding clinical outcome, 22 (7.6%) patients underwent LTx, 69 (23.9%) died, 168 (58.1%) were readmitted due to a complication of cirrhosis and 100 (34.6%) patients were affected by HE within one year. Moreover, SBP occurred in 85 (29.4%) patients and any infection was acquired by half of the cohort (n = 145; 50.2%). Of note, after adjusting for MELD, age, sex and hemoglobin in the multivariable model, competing risk analyses indicated a superior 1-year LTx-free survival in the folic acid group (HR = 0.48; p = 0.04). Furthermore, folic acid prescription was associated with a significant decreased risk of hospital readmission within one year. This remained statistically significant even after adjusting for the potential confounders MELD, age and hemoglobin (HR = 0.55; p = 0.01). In contrast, no impact was detected on HE or infections. Similarly, thiamine prescription was not associated with an improved LTx-free survival (HR = 0.84; p = 0.45) and did not ameliorate the risk of hospital readmission (HR = 0.93; p = 0.65) or other liver-related complications regarding 365 days follow-up. Additionally, neither folic acid nor thiamine were linked to an improved clinical outcome when considering a shorter 90 days observation period.
Conclusion: Folic acid prescription is associated with an improved outcome in patients with decompensated aLC. However, possible risks of broad vitamin application, especially the potential aggravation of polypharmacy, have to be investigated.

FRI-109

Differences in the clinical phenotype of decompensated liver cirrhosis between MASLD, MetALD and ALD patients

Laura Buttler[1], Anja Tiede[1,2], Marie Griemsmann[1], Hannah Schneider[1], Jim Benjamin Mauz[1], Heiner Wedemeyer[1,2,3,4], Markus Cornberg[1,2,4,5], Tammo Lambert Tergast[1], Benjamin Maasoumy[1,2], Katharina Luise Hupa-Breier[1]. *[1]Department of Gastroenterology, Hepatology, Infectious Disease and Endocrinology, Hannover Medical School, Hannover, Germany; [2]German Centre for Infection Research (DZIF), partner-site Hannover-Braunschweig, Hannover, Germany; [3]RESIST Cluster of Excellence, Hannover Medical School, Hannover, Germany; [4]Centre for Individualised Infection Medicine (CiiM), A Joint Venture Between the Helmholtz Centre for Infection Research (HZI) and Hannover Medical School (MHH), Hannover, Germany; [5]TWINCORE, A Joint Venture Between the Helmholtz-Centre for Infection Research (HZI) and the Hannover Medical School (MHH), Hannover, Germany*
Email: Buttler.Laura@mh-hannover.de

Background and aims: Recently, a new nomenclature of steatotic liver disease (SLD) has been implemented, which does not only differentiate MASLD (Metabolic Dysfunction-Associated Steatotic LD) from alcohol-related LD (ALD), but also introduces metabolic and alcohol-related liver disease (MetALD) as a new etiology. The impact of the newly defined etiologies on the clinical management among those with advanced liver disease still needs to be determined. We aimed to analyze whether MASLD, ALD and MetALD patients with decompensated liver cirrhosis (dLC) differ in the clinical phenotypes with regard to the most relevant cirrhosis-associated complications.
Method: A number of 416 consecutive patients with dLC and undergoing at least one paracentesis between 2011 and 2023 were investigated. All patients were diagnosed with NASH- or alcohol-related LC and reclassified into the SLD groups. Liver transplantation (LTx) free survival, development of infections, spontaneous bacterial peritonitis (SBP), hepatic encephalopathy (HE), portal hypertensive bleeding and hospital readmission due to any further decompensation were examined up to one year of follow-up.
Results: 52 patients were formerly diagnosed with NASH- and 338 with alcohol-related cirrhosis, whereas predominance of metabolic or alcohol-related liver damage was undetermined in 26 cases. When using the new definitions, 55 (13.2%) patients fulfilled the criteria for MASLD, MetALD was present in 67 (16.1%) and ALD in 294 (70.7%) patients. The proportion of male patients was 64% in MASLD, 70% in MetALD and 74% in patients with ALD etiology (p = 0.29). Median age was 59 years both in patients with MASLD and MetALD and 56 years in the ALD group (p <0.001). Moreover, median baseline MELD was 18 in MASLD and 17 in MetALD and ALD, respectively (p = 0.92). There was no difference between MASLD, MetALD and ALD with regard to the incidence of HE, portal hypertensive bleeding and LTx-free survival. In contrast, ALD was found to be associated with a lower risk for infections within 90 days (HR = 0.60; p = 0.004) and one year (HR = 0.55; p = <0.001) compared to MASLD etiology. This remained statistically significant after adjusting for MELD, serum-cholinesterase and diabetes in the multivariable model (90 days: HR = 0.61; p = 0.04; 1 year: HR = 0.59; p = 0.02). Of note, incidence of infections in the new MetALD group was lower than in MASLD but numerically higher than in patients with ALD. In all three groups, most common infections were SBP and urinary tract infection.
Conclusion: The risk for infections seems to be elevated among SLD patients with underlying metabolic-dysfunction associated liver

damage. Further studies are necessary to address, whether this could lead to etiology-specific prophylactic measures.

FRI-110

Safety and effectiveness of anticoagulation in patients with cirrhosis listed for liver transplantation: a single center observational study

Riccardo Caccia[1], Giulia Tosetti[1], Massimo Primignani[1], Martina Lucà[1], Sonia Stella[1], Pietro Lampertico[1,2]. *[1]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: pietro.lampertico@unimi.it

Background and aims: Anticoagulation (AC) in patients with cirrhosis is safe, decreases decompensation and increases survival. However, no data on safety and effectiveness of AC in patients listed for liver transplantation (LT) is available. We evaluated decompensation rate, delisting (either for improvement or progression) and liver-related mortality in patients listed for LT treated with anticoagulants mostly because of portal vein thrombosis (PVT), compared with patients not anticoagulated. Secondary aim was PVT outcome.
Method: Retrospective data of consecutive patients followed at our Center (2017–2021), from listing until LT, delisting or death were collected. Univariate and multivariate logistic regression analyses (adjusted for age, Child-Pugh (CP) class and time in list) were performed to evaluate the effect of AC on bleeding, de-novo decompensation in CP A patients, further decompensation in CP BC patients, delisting for improvement or worsening, OLT and death.
Results: 251 patients listed for OLT, 165 CP class B/C, 34 AC (13.5%), mainly for Portal Vein Thrombosis (PVT) (85%). AC patients were more likely CP class B/C (85% vs 63%, p = 0.002). AC included LMWH (67%), fondaparinux (18%), VKA (12%) and DOAC (3%). The bleeding rate was similar in AC and non-AC patients, either for total (23.5% vs. 20.7%; p = 0.711), severe (8.8% vs. 9.7%; p = 0.823) or portal hypertensive bleedings (2.9% vs. 1.8%; p = 0.686). Overall, there was no difference in the rate of de-novo decompensation (14.7% vs 9.7%; p = 0.398); in CP class B/C patients there was no difference on further decompensation rate (48.3% vs 41.9%; p = 0.617). CP B/C AC patients had more delisting for improvement (10.3% vs 2.2%. p = 0.034) and less deaths in list (0.0% vs 13.2%; p = 0.038). In CP A patients delisting for worsening (85% due to HCC progression) occurred in 20% AC vs 7% non-AC, while delisting for worsening in CP B/C occurred in 2 patients (1 AC and 1 non-AC). Eight patients were delisted for non-liver related events (n = 3) or poor compliance (n = 5). Twenty-eight (82%) AC patients and 178 (82.4%) non-AC patients were transplanted (p = 0.963). PVT regressed in 13 (45%, 10 total and 3 partial regression), was stable in 12 (14%) and worsened in 4 (14%). None was delisted for PVT worsening.
Conclusion: In cirrhotic patients listed for LT requiring AC for PVT, AC was safe and associated with higher delisting for improvement and improved survival in list.

FRI-111

Risk factors for hepatocellular carcinoma in cirrhosis: a comprehensive analysis from a decade-long study

Daqiong Zhou[1], Lili Liu[1], Jiangyu Liu[1], Jing Zhang[1], Zhenhuan Cao[1]. *[1]The Third Unit, Department of Hepatology, Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: caozhenhuanyu@mail.ccmu.edu.cn

Background and aims: Cirrhosis represents a significant risk factor for the development of hepatocellular carcinoma (HCC). The variability in HCC risk among cirrhotic patients is notable, particularly when considering the diverse etiologies of cirrhosis. This study aimed to identify specific risk factors contributing to the development of HCC in patients with cirrhosis.
Method: This retrospective study analyzed data from patients with cirrhosis admitted to Beijing Youan Hospital, Capital Medical University, from January 1, 2012, to September 30, 2022, with a minimum follow-up duration of six months. Patient demographics, medical history, liver disease etiology, and clinical characteristics at initial admission were examined. Cox regression was employed to analyze correlations with hepatocarcinogenesis, and competing risk regression was utilized to account for death as a competing event, estimating adjusted hazard ratios (aHR) for identified risk factors.
Results: The study included 5, 417 patients, with a median age of 54 years; 65.8% were male, and 76.6% presented with decompensated cirrhosis. During the follow-up, 25% (n = 1352) developed HCC. The highest incidence of HCC was observed in patients with hepatitis B virus (HBV) (29.5%), followed by hepatitis C virus (HCV) (26.3%), Alcohol-associated cirrhosis (AC) (20.5%), metabolic dysfunction-associated liver disease (MASLD) (17.6%), primary biliary cirrhosis (15.3%), drug-induced cirrhosis (18.2%), and cryptogenic cirrhosis (26.5%). Competing risk analysis revealed significant associations between increased HCC risk and factors such as male gender (aHR: 1.422, 95% CI: 1.259–1.608), advanced age (aHR: 1.025, 95% CI: 1.021–1.030), HBV (aHR: 1.900, 95% CI: 1.690–2.136), HCV (aHR: 1.523, 95% CI:1.267–1.832), HBV/HCV co-infection (aHR: 2.171, 95% CI:1.082–4.356), elevated blood ammonia (aHR: 1.002, 95% CI:1.001–1.003), and reduced albumin (aHR: 0.984, 95%CI:0.974–0.994) and platelet levels (aHR: 0.999, 95%CI:0.998–1.000) were associated. Cumulative incidence function (CIF) curves estimated the HCC risk in cirrhotic patients at 3.24% (1 year), 19.2% (3 years), and 35.2% (5 years).
Conclusion: The study underscores that cirrhosis due to HBV has the highest correlation with HCC incidence. Additionally, male gender, older age, viral hepatitis-related cirrhosis, elevated blood ammonia, and lower albumin and platelet levels significantly elevate HCC risk in cirrhotic patients.

FRI-112

Rapid infection diagnostics in liver disease- evaluation of a multiplex PCR platform to improve infection and antimicrobial resistance detection

Patel[1,5,6]. *[1]Institute of Liver Studies, King's College Hospital NHS Foundation Trust, Denmark Hill, London, SE5 9RS, UK, London, United Kingdom; [2]The Roger Williams Institute of Hepatology, Foundation for Liver Research, 111 Coldharbour Lane, London, SE5 9NT, UK, London, United Kingdom; [3]Liver Intensive Therapy Unit, King's College Hospital NHS Foundation Trust, Denmark Hill, London, United Kingdom; [4]School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, 125 Coldharbour Lane, London, London, United Kingdom; [5]The Roger Williams Institute of Hepatology, Foundation for Liver Research, 111 Coldharbour Lane, London, SE5 9NT, UK, London, United Kingdom; [6]Centre for Clinical Infection and Diagnostics Research, Department of Infectious Diseases, School of Immunology and Microbial Sciences, King's College London, Strand WC2R 2LS, London, London, United Kingdom*
Email: v.ramachandran@nhs.net

Background and aims: Chronic liver disease is the second leading cause of work years lost in Europe, driving a significant burden in premature mortality [1]. Cirrhosis is associated with an increased susceptibility to infection [2]. Antimicrobial resistance (AMR) presents a significant risk in cirrhosis, further compounding morbidity and mortality [3]. Early pathogen detection, alongside prompt initiation and de-escalation of antibiotics according to AMR profiles, are therefore critical to improving outcomes [4]. The Curetis Unyvero™ platform (CUp) utilises multiplex polymerase chain reactions (PCR) for rapid pathogen and AMR identification, utilising a range of biofluids based on where infection is suspected. The aim of this study was to compare the CUp against SMT (standard microbial testing) in infection diagnostics and AMR detection in.

Method: Ascitic fluid, blood cultures (BC) and broncheoalveolar lavage (BAL) samples were obtained from hospitalised liver disease patients, in whom infection was clinically suspected. Ascites and BAL samples were analysed on CUp prior to culture. Blood cultures-once flagged positive via SMT-based incubation-were in parallel run on CUp for comparison. Following a run time of 4.5hrs, CUp provided pathogen identification data and AMR profiles. Treating clinicians remained blinded to results.
Results: 69 samples from 51 patients were tested: ascites (42), BAL (7), BC (20). Time to positive result was reduced with CUp (4.75hrs) compared with SMT in BAL (mean 73.71hrs; SD = 25.99) and ascites (mean 58.57hrs; SD = 16.38). For all ascites and BAL samples, CUp demonstrated 100% sensitivity and 100% negative predictive value (NPV) in pathogen detection. In positive BCs, CUp showed 94.74% sensitivity for pathogen detection *vs* SMT. In 1 BC sample, CUp detected E.coli *spp* with corresponding AMR profiles (ctx-M, aacA4) that was SMT negative, retrospective analysis identified a BC sample 24hrs prior that also detected *via* SMT *E.coli* and a similar AMR profile. In 6 ascites samples, CUp identified pathogens where SMT was negative. On retrospective analysis, 4/6 ascitic samples also showed that prior SMT of earlier samples within 5 days of collection had detected pathogens detected by CUp. CUp identified AMR profiles in 50% (4/8) of BAL and ascites samples, and in 42.85% (3/7) of BC samples, vs SMT, respectively.
Conclusion: These preliminary data demonstrate good concordance in pathogen detection accuracy of CUp vs SMT in all body fluids, with a significant reduction in time to result with CUp. AMR detection with CUp was less optimal, potentially due to PCR limitations in AMR targets. CUp may have a role in rapid infection diagnosis and early de-escalation of antimicrobial therapy in liver disease. Future work will focus on evaluating the cost-effectiveness of CUp vs other sequencing-based approaches.

FRI-113
Diagnostic scoring system for diagnosis of covert hepatic encephalopathy in child-pugh class a cirrhosis patients
Masanori Fukushima[1], Yasuhiko Nakao[1], Ryu Sasaki[1], Masafumi Haraguchi[1], Satoshi Miuma[1], Hisamitsu Miyaaki[1], Kazuhiko Nakao[1]. [1]*Department of Gastroenterology and Hepatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*
Email: ma-fukushima@nagasaki-u.ac.jp

Background and aims: Covert hepatic encephalopathy (CHE) is a cirrhosis-related complication that warrants diagnosis and treatment. In Japan, a neuropsychiatric test (NPT) performed on a touch-screen tablet has been the diagnostic method. This includes the number connection tests (NCT)-A and B, and the Stroop test. However, the test is time-consuming. Therefore, a simple CHE screening model based on biomedical parameters is desirable. It has been previously reported that hypoalbuminemia and hyperammonemia are useful in diagnosis, but most of these cases were in patients with Child-Pugh class B. For earlier diagnosis, detection of Child-Pugh class A is necessary. This study aimed to establish a simple diagnostic method of CHE in patients with Child-Pugh class A.
Method: Sixty-five patients with Child-Pugh class A cirrhosis who underwent NPT at our hospital were included. They were divided into two groups according to the presence or absence of CHE using the NCT-B. Clinical data, including liver function, fibrosis markers, presence of esophageal varices, and liver volume, were compared. Liver volume was measured with computed tomography using SYNAPSE VINCENT software (Fujifilm) and corrected by liver volume/body surface area.
Results: Of the 65 patients, 23 (35%) were diagnosed with CHE by NCT-B. The Child-Pugh score was 5 in 14 patients (61%) from the CHE group, and in 28 patients (67%) from the non-CHE group. The difference in platelet count between the two groups was 96, 000/microliter in the CHE group and 129, 000/microliter in the non-CHE group ($p = 0.02$). Hyaluronic acid was 213 ng/ml in the CHE group and 177 ng/ml ($p = 0.02$) in the non-CHE group. Liver volume to body surface area ratio was 550 ml/m^2 in the CHE group and 726 ml/m^2 in the non-CHE group ($p = 0.001$). The cut-off values for each of these items in the ROC curve analysis showed that the complication rate of CHE was 55% in patients with a liver volume to body surface area ratio of 618 ml/m^2 or less, which was 2.8 times higher than that in patients with larger liver volume. Referring to the cut-off values for each item, a score from zero to three was created, with platelet count of 120, 000/microliter or less, hyaluronic acid of 200 ng/ml or more, and liver volume/body surface area ratio of 620 ml/m^2 or less each counting as 1 point, respectively. Ninety-two percent of cases with 0 points had non-CHE, and 80% of cases with 3 points had CHE.
Conclusion: In a group of patients with Child-Pugh class A liver cirrhosis, platelet count, hyaluronic acid, and liver volume/body surface area ratio were associated with CHE. The score created using these three items made it possible to diagnose or exclude CHE in 80% and 92% of cases, respectively. Since CHE complications can be highly-detected based on clinical test values, these parameters are considered useful as a CHE diagnostic scoring system as an alternative to NPT in patients with Child-Pugh class A liver cirrhosis.

FRI-114
Entecavir can significantly improve the prognosis of patients with first decompensated hepatitis B cirrhosis
Rui Ding[1], Wen Xie[2], Jidong Jia[3], Qi Wang[2]. [1]*Beijing Ditan Hospital, Capital Medical University, Beijing Friendship Hospital, Beijing, China;* [2]*Center of Liver Diseases, Beijing, China;* [3]*Liver Research Center, Beijing, China*
Email: ddingrui1989@126.com

Background and aims: Untreated patients with HBV infection are at high risk of progression to cirrhosis, clinical decompensation, HCC and liver-related death. Even in patients with HBV-related decompensated cirrhosis, the long-term effect of antiviral therapy significantly modifies the natural history of decompensated cirrhosis, resorting to liver function, and increasing survival. However, data compare the clinical outcomes of them with similar patients who were not subject to antiviral treatment are still limited. Here, we assessed the clinical efficacy of entecavir (ETV) antiviral therapy in patients with decompensated hepatitis B cirrhosis by comparing with the similar patients who do not receive any antiviral therapy, and evaluated the effect of treatment on hepatocarcinogenesis and mortality.
Method: This is a multicenter, ambi-directional cohort study. More than 5 thousand of patients with decompensated hepatitis B cirrhosis between February 2001 and December 2018 were screened for study eligibility. The observation started from the time of first episode of decompensation present with ascites. Propensity score matching (PSM) analysis was used to reduce the potential confounding variables at baseline. Factors associated with all-cause mortality or LT were analysed using the Cox proportional hazards model. Inverse probability of treatment weighting (IPTW) analysis was also carried out using the same variables to confirm the results of the PSM analysis on the cumulative risk of HCC and all-cause mortality or LT.
Results: A total of 480 patients with hepatitis B virus-related first-time decompensated cirrhosis were analysed in this study, of whom 301 were treated with ETV therapy (ETV group) and 179 of whom treatment-naïve (non-antiviral group). PSM analysis was used to reduce the potential confounding variables at baseline and generated 172 pairs of cases. At weeks 48, the changes in ALT, total bilirubin, albumin, platelet count and international normalized ratio over the ETV treatment period were improved dramatically (all $p < 0.005$). However, liver function did not show significant changes in non-antiviral group at 48 weeks. It is interesting to note that ETV antiviral therapy cannot effectively rescue the platelet counts when compared to non-antiviral group ($p > 0.005$). Non-antiviral group (HR = 3.08, $p < 0.001$) and high iMELD score (HR = 1.09, $p = 0.01$) were independently associated with mortality. non-antiviral group (HR = 3.75, p =

0.002), low PLT counts (HR = 0.98, p = 0.036) and high ALP level (HR = 1.01, p = 0.047) were independently associated with HCC occurrence.
Conclusion: ETV treatment can significantly improve the overall prognosis in patients with first-time decompensated hepatitis B cirrhosis. Further studies are needed to validate our results.

FRI-115
Validation of an easy-to-use malnutrition screening in cirrhosis to predict outcome
Stefan Fürst[1], Julia Traub[1], Jakob Schwarzl[1], Lukas Gulden[1], Johannes Woltsche[1], Angela Horvath[1], Vanessa Stadlbauer[1]. [1]*Medical University of Graz, Graz, Austria*
Email: stefan.fuerst@medunigraz.at

Background and aims: Malnutrition in liver cirrhosis is widespread and often underdiagnosed. The RFH-NPT (Royal Free Hospital Nutritional Prioritizing Tool) as gold standard does not correlate well with other, easier available screening tools, such as GMS (Graz Malnutrition Screening), NRS-2002 (Nutritional Risk Screening), and MNA-SF (Mini Nutritional Assessment-Short Form). (1) It is unclear which of these scores can predict outcome. We tested the predictive merit of these scores either as a standalone score or in combination with easily accessible parameters and comorbidities.
Method: Hospitalized patients aged 18 years or above with cirrhosis were included. Exclusion criteria encompassed hepatic encephalopathy ≥2, other cognitive disorders impeding informed consent, or hepatocellular carcinoma at stage BCLC C or D. Univariate Cox-regression and a stepwise multivariate Cox-regression were utilized for analysis.
Results: One hundred eighteen patients were included (median age 63 years (IQR 13); 88 (74.6%) men; etiology alcohol (57.6%), NASH (18.6%), HCV (16.1%), others (7.6%)). During the median follow-up period of 39 month, 60 patients (50.1%) died.The following parameters were predictive for mortality in a univariate Cox-regression: age, body mass index, severe sarcopenia, gait speed, GMS, Charlson Comorbidity Index, the use of statins and opioids, history of gastrointestinal bleeding due to liver cirrhosis, history of acute kidney injury, presence of hepatocellular carcinoma and blood levels of neutrophils, basophils, eosinophiles, C-reactive protein (CRP), gamma-glutamyl transferase (GGT), glomerular filtration rate (GFR) and mean platelet volume (MPV). In contrast to GMS, other malnutrition scores were not predictive. In the multivariate model, accounting for age and CRP, GMS was an independent predictor for mortality. (HR 1.24, p = 0.046, 95%CI 1.00–1.53). Using the GMS malnutrition cut-off values, 8.8% of patients in the survivor group and 68.8% in the non-survivor group were classified as malnourished. The percentages for malnutrition according to RFH-NPT, NRS-2022, and MNA-SF were 19.3% vs. 20.0%, 5.2% vs. 6.7%, and 6.9% vs. 5.0% for survivors vs. non-survivors, respectively.
Conclusion: GMS independently predicts mortality in patients with liver cirrhosis. Neither other malnutrition scores such as RFH, NRS and MNA, nor markers of sarcopenia were predictive in the multivariate prediction model for mortality in this patient cohort. GMS can be implemented easily into an electronic patient record system and therefore can provide an added value for cirrhotic patient care to identify patients with malnutrition and high risk of death, who may benefit from intensive nutritional therapy.

Prognostic significance of HDL-associated apolipoproteins in patients with decompensated cirrhosis and spontaneous bacterial peritonitis
Mohamad Murad[1], Johanna Reißing[1], Majda El Hassani[1], Mick Frissen[1], Oluwatomi Ibidapo-Obe[1], Karsten Große[1], Theresa Hildegard Wirtz[1], Christian Trautwein[1], Philipp Reuken[2], Tony Bruns[1]. [1]*University Hospital RWTH Aachen, Aachen, Germany;* [2]*University Hospital Jena, Jena, Germany*
Email: muradmohamad@outlook.com

Background and aims: Apolipoproteins (Apo) A-I and A-II are the two major components of high-density lipoproteins (HDL) and possess immune-modulating functions, affecting lipopolysaccharide signaling. Recent studies have identified a correlation between low serum apoA-I levels and complications of cirrhosis associated with poor prognosis. This study investigates whether serum and ascitic fluid (AF) concentrations of apoA-II are differentially regulated during spontaneous bacterial peritonitis (SBP) and can be used to predict outcomes.
Method: We performed a case-control study including 118 patients with decompensated cirrhosis and ascites, comprising 59 patients with SBP and 59 without. AF concentrations of apoA-II, apoA-I, and IL-6 were determined using enzyme-linked immunosorbent assay (ELISA). Cumulative 90-day transplant-free survival after SBP was compared using Kaplan-Meier analysis and multivariable Cox regression analysis.
Results: In patients without SBP, lower AF levels of HDL-related biomarkers apoA-I and apoA-II correlated with lower AF protein and albumin levels, higher serum bilirubin, and lower platelet counts, indicating depletion with progression of liver disease. During SBP, apoA-II significantly increased in serum and AF, leading to an increased ratio of apoA-II to apoA-I in AF compared to patients without SBP. Lower levels of serum and/or AF apoA-II correlated with more severe inflammation (white blood cells, AF neutrophils) and organ failure (bilirubin, Model for End-Stage Liver Disease [MELD]). Higher AF levels of apoA-II correlated with higher levels of IL-6, suggesting augmented peritoneal macrophage responses. An AF apoA-II level of 45 µg/ml or higher during an SBP episode indicated an increased risk of death or transplantation within 90 days (p = 0.01 in log-rank test). High AF apoA-II levels during SBP remained a predictor of transplant or death after adjustment for age and MELD score (HR 2.59; 95% CI: 1.08–5.91; p = 0.032).
Conclusion: The composition of HDL-associated apolipoproteins is altered during SBP, which carries prognostic implications.

FRI-117
Acute kidney injury and infections as the main determinants of outcome in hospitalised patients with liver cirrhosis: a retrospective cohort from a tertiary hospital
Adonis Protopapas[1], Alexandra Tsankof[2], Vaia Kyritsi[1], Christiana Gogou[2], Maria Kyziroglou[2], Erofili Papathanasiou[2], Charikleia Chatzikosma[2], Christos Savopoulos[2], Andreas Protopapas[1]. Email: adoprot@hotmail.com

Background and aims: Complications of portal hypertension, renal dysfunction and infections are the leading causes of hospitalisation of cirrhotic patients, with a significant impact on outcome. Our study aimed to record the specific characteristics of complications and infections in hospitalised cirrhotic patients.
Method: Patients with cirrhosis admitted to our department from 2019 to 2022 were retrospectively analysed. Patients admitted for scheduled investigation or intervention were omitted.

Results: A total of 302 hospitalisations from 184 different patients were recorded. Patients had a mean age of 65.4 ± 11.9 years and were predominantly male (74.5%) and with decompensated liver cirrhosis (84.2%). Alcohol-associated liver disease (46.2%) and metabolic dysfunction-associated steatohepatitis (27.7%) were the main causes of cirrhosis. 15.3% of hospitalisations had a fatal outcome (46 patients). Most patients were classified as Child-Pugh stage B (53.3%), followed by patients in stage C (33.8%) and stage A (11.7%), while 36.4% and 15.1% of patients presented with acute kidney injury (AKI) and variceal bleeding, respectively. AKI at presentation had a statistically significant association with prior diuretic use ($p < 0.001$), whereas patients presenting with a combination of AKI and moderate or severe ascites (47 patients, 15.9%) were in a large majority on diuretic treatment (87.2%). 149 (49.3%) patients developed an infection, with almost half being hospital-acquired (48.3%). The leading causes of infection were urinary tract infection (27.9%), spontaneous bacterial peritonitis (21.7%) and respiratory tract infection (19.4%). The majority of the bacterial species were Gram-negative (57.4%) and multi-drug resistant (MDR) (54%). Development of infection was significantly correlated with increased Child-Pugh score, MELD and MELD-Na values ($p < 0.001$). There was no association between PPI use and the presence of infection or the degree of hepatic encephalopathy. In multivariate analysis, patient survival was significantly associated with cirrhosis severity indices (Child-Pugh, MELD, MELD-Na, $p < 0.001$), age ($p = 0.03$), infection ($p < 0.001$) and AKI at presentation ($p = 0.005$). Furthermore, the presence of MDR bacteria was independently associated with survival in patients who developed an infection and the pathogen was successfully isolated ($p = 0.003$).
Conclusion: Inpatients with cirrhosis have significant mortality, which is associated with disease severity and the occurrence of complications such as AKI and infections. In addition, they are often burdened by infections from MDR pathogens, which are an unfavourable outcome indicator. In these patients, proper diuretic management, timely treatment of AKI, safety measures to avoid infections (especially from MDR bacteria) and appropriate antimicrobial therapy are of utmost importance.

FRI-118

Independent association of loss of skeletal muscle mass with long-term liver-related mortality in cirrhotic patients

Jiarui Zheng[1], Shuo Yang[2], Wenhui Ren[3], Bo Feng[4], Rui Huang[1]. *[1]Peking University Hepatology Institute, Beijing, China; [2]Department of Radiology, Beijing, China; [3]Peking University People's Hospital, Beijing, China; [4]Peking University Hepatology Institute, Beijing, China*
Email: strangehead@163.com

Background and aims: Sarcopenia has a detrimental impact on the prognosis of individuals with liver cirrhosis, however, the clinical significance of alterations in muscle mass remains uncertain. This study aimed to investigate the influence of loss of skeletal muscle mass (LSMM) on the prognostic outcomes among patients diagnosed with cirrhosis.
Method: In this retrospective analysis, a total of 158 individuals with cirrhosis who visited our hospital during the period from January 2018 to August 2023 were included. Computed tomography was utilized to measure the cross-sectional area of the skeletal muscles at the level of the third lumbar vertebra, which could enable the determination of the skeletal muscle index for the purpose of diagnosing sarcopenia and all patients underwent a follow-up CT scan performed at least 6 months after the initial scan. The annual relative change in skeletal muscle area (ΔSMA/y) was calculated for each patient, and LSMM was defined as ΔSMA/y <0. To assess the risk factors associated with liver-related mortality, a competing risk model was applied.
Results: Of the 158 cirrhotic patients, 95 (60.1%) patients were identified as LSMM. The median of ΔSMA/y% was −0.9 (interquartile range [IQR], −3.8, 1.6) in all patients. Chronic kidney disease (CKD) was confirmed as a risk factor of LSMM. During a median follow-up period of 68.1 (IQR, 43.5, 105.0) months, 57 patients (36.1%) died due to the liver-related diseases. The competing risk model found that LSMM was significantly associated with liver-related mortality in cirrhotic patients (hazard ratio [HR], 1.86; 95% CI, 1.01–3.44, $p = 0.047$). Cumulative survival was significantly higher in patients without LSMM than in those with LSMM ($p = 0.004$). Survival rates at 1-, 3-, and 5-years were 96.8%, 81.0%, and 65.1%, respectively, in patients without LSMM, and 97.9%, 80.0%, and 56.8%, respectively, in patients with LSMM.
Conclusion: The utilization of LSMM can be valuable in the prediction of liver-related mortality among individuals diagnosed with liver cirrhosis. Paying attention to the management of skeletal muscle might play a role in enhancing the prognosis of patients with cirrhosis.

FRI-119

Role of HLA DR+ CD4+ T cell %T cell in mediating the effect of Lactobacillus delbrueckii on liver cirrhosis

Xuanchen Liu[1], Ningning Zhang[1], Wei Lu[2], Yiyan Zhang[1], Kaipeng Liu[2], Huiru Liu[1]. *[1]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [2]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*
Email: 15931873318@163.com

Background and aims: We investigated the causal relationships between the gut microbiota (GM), liver cirrhosis, and potential immunophenotype mediators using Mendelian randomization (MR).
Method: The data on GM, immunophenotype, and liver cirrhosis all come from the GWAS Catalog website (http://www.ebi.ac.uk/gwas/). The data of GM were under the study accession numbers GCST90027446-GCST90027857. Immunophenotype from GCST0001391-GCST0002121, and Lactobacillus delbrueckii from GCST90027782. We performed bidirectional MR analyses to explore the causal relationships between the GM and liver cirrhosis, and two mediation analyses, two-step MR to discover potential mediating immunophenotype.
Results: There is a causal relationship between 14 gut microbial taxa and liver cirrhosis, with Lactobacillus delbrueckii showing the most significant association (ivw:p = 0.0019, OR:1.2073 (1.0722–1.3595)), and there is no evidence of reverse causation. Performing a bulk MR analysis with Lactobacillus delbrueckii and 731 immunophenotypes revealed causal relationships with 5 immunophenotypes. Subsequently, conducting a bulk MR analysis with these 17 immunophenotypes and liver cirrhosis showed a causal relationship only between the immunophenotype HLA DR+ CD4+ T cell %T cell and liver cirrhosis (ivw:p = 0.0388, OR:1.1529 (1.0073–1.3194)).
Conclusion: Through Mendelian randomization, it was revealed that Lactobacillus delbrueckii acts on liver cirrhosis through HLA DR+ CD4 + T cell %T cell as intermediate factors.

FRI-120

Impact of diabetes mellitus on results in the animal naming test in patients with and without liver cirrhosis

Eva Maria Schleicher[1,2], Matthias Weber[1], Julia Tuchscher[1], Peter R. Galle[1,2], Marcus-Alexander Wörns[3], Simon J. Gairing[1,2], Christian Labenz[1,2]. *[1]University Medical Center of the Johannes Gutenberg-University, Mainz, Germany; [2]Cirrhosis Center Mainz (CCM), Mainz, Germany; [3]Department of Gastroenterology, Hematology, Oncology and Endocrinology, Klinikum Dortmund, Dortmund, Germany*
Email: eva.schleicher@unimedizin-mainz.de

Background and aims: Diabetes mellitus (DM) is a common comorbidity in patients with cirrhosis and is associated with the development of hepatic encephalopathy (HE) and cognitive dysfunction. The simplified Animal Naming Test (S-ANT1) has been established for detecting minimal HE (MHE). It is currently unknown whether S-ANT1 results are affected by DM in patients with and without cirrhosis.

Method: This study analyzed data from 268 patients with cirrhosis who showed no signs of HE ≥1 according to the West-Haven-Criteria. MHE was defined using the psychometric hepatic encephalopathy score (PHES). All patients were also tested with S-ANT1. As controls, 14 patients with severe DM and diabetic foot syndrome but no cirrhosis (DFS), as well as 37 healthy controls, were also tested with S-ANT1.
Results: Diabetes mellitus was present in 79 (29.5%) patients with cirrhosis and MHE according to PHES was detected in 81 (30.2%) patients. Median S-ANT1 in the total cohort was 20 (IQR 16; 24) animals. In the total cohort, results in S-ANT1 did not differ between patients with and without diabetes mellitus (19 vs. 20 animals, p = 0.108). Subgroup analyses, stratified by MHE status, showed no difference in S-ANT1 results when comparing patients with and without diabetes mellitus. In multivariable logistic regression analysis, the only variables independently associated with performance in S-ANT1 were PHES-MHE, school education, sodium, and age, while DM was not. Given that patients with DFS were significantly older than patients with cirrhosis and healthy controls, we selected patients with an age >60 years for the following analyses to make the groups comparable. Patients with DFS performed poorer in S-ANT1 compared to healthy controls, while patients with cirrhosis and MHE performed poorer in S-ANT1 compared to patients with diabetic foot syndrome. Performance in S-ANT1 was comparable between patients with cirrhosis without MHE and patients with DFS. Of note, 8 out of 14 patients with diabetic foot syndrome had an S-ANT1 <20 animals (cut-off for MHE according to German norms).
Conclusion: Results in S-ANT1 seem to be affected in patients with severe forms of DM and apparent complications. The S-ANT1 appears to be applicable in patients with liver cirrhosis and compensated DM.

FRI-121

Safety and tolerability of long-term albumin treatment in patients with decompensated cirrhosis

Javier Fernández[1,2], Laura Núñez[3], Montserrat Costa[3], Mireia Torres[3], Raquel Horrillo[3], Natalia Afonso[3], Anna Mestre[3], Luis Ruiz Del Árbol[4], Càndid Villanueva[5], Antonio Paez[3], Vicente Arroyo[1]. *[1]EF Clif, EASL-CLIF Consortium and Grifols Chair, Barcelona, Spain; [2]Hospital Clínic, IDIBAPS and CIBERehd, Barcelona, Spain; [3]Scientific Innovation Office, Grifols, Barcelona, Spain; [4]Department of Gastroenterology, Hospital Ramón y Cajal and CIBERehd, Madrid, Spain; [5]Department of Gastroenterology, Hospital de Sant Pau and CIBERehd, Barcelona, Spain*
Email: jfdez@clinic.cat

Background and aims: Long-term albumin treatment reduces systemic inflammation and cardiocirculatory dysfunction in patients with decompensated cirrhosis and ascites, but safety data are limited. This study was aimed at evaluating the safety and tolerability of long-term human albumin administration in patients with decompensated cirrhosis and ascites.
Method: This was a prospective, open-label clinical trial (Pilot-PRECIOSA study NCT00968695, EudraCT Number: 2008-003920-40), which enrolled decompensated cirrhotic patients with ascites and were treated with a 20% human albumin solution at low doses (1 g/kg every two weeks, LAlbD group) or high doses (1.5 g/kg every week, HAlbD group) for 12 weeks. Adverse events (AEs), serious adverse events (SAEs), biochemistry and hematology laboratory parameters were assessed during the treatment period in both groups. The effect of long-term albumin therapy on ascites, edema, and hepatic encephalopathy grade was also evaluated. Safety analyses were conducted on intention-to-treat population.
Results: Thirty-one out of 33 screened patients were analyzed (n = 15, LAlbD; n = 16, HAlbD). Overall, 140 AEs were reported in 26 patients (83.9%) during the study period and most of them were mild (28.6%) or moderate (25.7%) in severity. There were no differences in the overall incidence of AEs between groups. None of the albumin-treated patients experienced AEs related to pulmonary edema or respiratory failure at any treatment dose. Two AEs (1.4%), gastrointestinal hemorrhage and pruritus, were related to albumin treatment. Eighty-seven (62.1%) were considered SAEs, being the most frequent: hepatic encephalopathy (n = 12, 13.8%), ascites (n = 6, 6.9%), gastrointestinal hemorrhage (n = 6, 6.9%; including esophageal varices hemorrhage, n = 3, 3.4%), anemia (n = 5, 5.7%), and dyspnea (n = 3, 3.4%). No differences in the main biochemistry and hematology parameters over time and between groups were observed. In the HAlbD group, the percentage of patients without ascites at the end of the study period was higher (42.9%) compared with baseline (12.5%).
Conclusion: Long-term albumin treatment in the patients with decompensated cirrhosis was safe and well-tolerated.

FRI-122

Decompensated cirrhosis is associated with disruption of nuclear positioning in skeletal muscle and selective atrophy of type II myofibers

Aldo J Montano-Loza[1], Maryam Motamedrad[2], Maryam Ebadi[1], Norberto Sanchez-Fernandez[3], Alessandro Parente[3], Abha Dunichand-Hoedl[2], Elora Rider[1], Norman Kneteman[3], James Shapiro[3], David Bigam[3], Khaled Dajani[3], Blaire Anderson[3], Vickie Baracos[4], Vera C. Mazurak[2]. *[1]Division of Gastroenterology and Liver Unit, University of Alberta Hospital, Edmonton, Canada; [2]Division of Human Nutrition, University of Alberta, Edmonton, Canada; [3]Division of Transplantation, Department of Surgery, University of Alberta Hospital, Edmonton, Canada; [4]Department of Oncology, Cross Cancer Institute, Edmonton, Canada*
Email: montanol@ualberta.ca

Background and aims: Low skeletal muscle mass is a common complication in cirrhosis and is associated with morbidity and mortality. However, specific muscle pathophysiology in cirrhosis and its decompensated stages is unknown. Muscle fibers type I are oxidative with slow contraction speed adapted for aerobic work, while type II are glycolytic, have fast contraction speed and confer strength. Muscle fibers nuclei are normally situated near the cell membrane. Size and proportions of muscle fiber types and nuclei position may be affected in different pathological conditions. In this study, we aimed to compare muscle morphological features in patients with cirrhosis receiving liver transplantation (LT) and appraise the differences in compensated and decompensated stages.
Method: Biopsies of *rectus abdominis* muscle were collected from the surgical incision at LT from 57 patients. Fiber type and size was determined immunohistochemically with primary and secondary antibodies for membrane (Laminin and Dystrophin) and myosin heavy chain (MyHC) isoforms [BAD5 (MyHCI) and SC71 (MyHCIIA)]. 4′, 6-diamidino-2-phenylindole was used for nuclei staining. Stages of cirrhosis were defined based on the D'Amico classification: 1) no varices, 2) development of varices, 3) variceal bleeding without other decompensation events, 4) first nonbleeding decompensation event, and 5) any second decompensation event. Patients in stages 1 and 2 were classified as compensated cirrhosis, and those in stages 3–5 were classified as decompensated cirrhosis.
Results: Thirty-seven (65%) patients were male, with a mean age of 52 ± 11 years, and BMI of 26.8 ± 4.8 kg/m^2 at the time of LT. Indication for LT was alcohol-associated cirrhosis in 21 (37%) patients, autoimmune liver diseases in 14 (25%), viral hepatitis in 12 (21%), MASH in 4 (7%), and 6 others (11%). Sixteen patients (28%) had concomitant hepatocellular carcinoma. Thirty-six patients (63%) were in decompensated and 21 (37%) were in compensated stage at the time of LT. Median overall muscle fiber area was smaller in decompensated patients (4407 ± 1882 *vs.* 3187 ± 1512 μm^2, p = 0.01). Median fiber type I area was similar between compensated and decompensated patients (3727 ± 1670 *vs.* 3086 ± 1312 μm^2, p = 0.068). However, median size of fiber type IIA was smaller in decompensated patients (5105 ± 2525 *vs.* 3358 ± 1915 μm^2, p = 0.005). Furthermore, the percentage of centralized nuclei was higher in decompensated patients (5.1 ± 2.8% vs. 12.3 ± 7.4%).

Conclusion: Patients with decompensated cirrhosis have overall smaller muscle fibers and are more susceptible to fiber type II atrophy and disruption of nuclear positioning. These changes would be likely associated with functional deficits, especially of muscle strength. Further work is warranted to evaluate regimens of muscle rehabilitation for this patient population pre- and post-LT.

FRI-123

Measuring the burden and impact of comorbidity in cirrhosis: insights from clinical database analysis

Dina Ali[1], Jessica Shearer[2], Lynsey Corless[3]. [1]*Zagazig University, Zagazig, Egypt;* [2]*St James University Teaching Hospital, Leeds, United Kingdom;* [3]*Hull University Teaching Hospitals, Hull, United Kingdom*
Email: lynsey.corless@nhs.net

Background and aims: Cirrhosis is a serious long-term condition, with high rates of morbidity and mortality. Effectively managing this long-term condition requires consideration of interlinked factors such as comorbidity, which can influence treatment decisions, the appropriateness of cancer surveillance, and decision making during acute illness. This study was undertaken to determine the burden of comorbidity within our cirrhosis population.
Method: The cirrhosis database in our centre, comprising over 800 individuals, was searched for comorbidities using the widely recognised Charlson comorbidity index (CCI). CCI was calculated from hospital discharge records using an ICD-10 coding algorithm. To mitigate the risk of missing comorbidities not documented at discharge, the CCI was corroborated through a secondary search of Primary Care (PC) records. Only those with both ICD-10 and complete PC data were included.
Results: 331 patients with cirrhosis were included (female 42%; n = 138) with **a** median age of 61 years (range 30–91). Aetiology was predominantly alcohol-related (ArLD) (42.6%; n = 141) and metabolic dysfunction associated steatotic liver disease (MASLD) (18.1%; n = 60), among other causes. These characteristics were representative of the entire database. Median CCI score was significantly higher by PC record (5) than ICD-10 (2) (difference 2.8; 95% CI 2.56–2.97; $p < .05$), indicating that ICD-10 under-represents the degree of comorbidity. Consequently, PC records were used for further analysis. The most prevalent comorbidity was diabetes mellitus (n = 119; 36%), followed by COPD (n = 44; 13.3%). MASLD and diabetes were closely linked, with substantial overlap; 39.8% of individuals with diabetes had MASLD, and 78.3% of those with MASLD had diabetes. Almost two thirds of the cohort had five or more comorbidities (CCI ≥5; 57.7%), and those with MASLD had the greatest proportion of severe comorbidity (79.3%). 37 patients in the cohort died during follow-up. Whilst there was no significant association between liver aetiology and death ($p = 0.124$), CCI grade was significantly associated with mortality ($p = 0.048$).
Conclusion: We found high levels of comorbidity, particularly diabetes, in our cirrhosis population. The greatest burden was observed in those with MASLD. CCI grade was associated with increased mortality, and recording this will inform both individual management plans and development of care pathways. Relying solely on ICD-10 codes underestimates the true burden of comorbidity, and linked databases are recommended for future analysis to provide a more comprehensive understanding of the association between cirrhosis and comorbid disease.

FRI-124

Upper extremity skeletal muscle index to assess sarcopenia in patients with cirrhosis

Anna Ostrovskaya[1], Marina Maevskaya[1]. [1]*Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russian Federation*
Email: mertanen@mail.ru

Background and aims: Sarcopenia is a complication of liver cirrhosis that affects the patient's prognosis. Methods of its objective assessment (including DEXA) are often distorted in lower extremity edema. The norm for calculating the skeletal muscle index (SMI) of the upper extremities with regard to gender, age has not been clearly developed. Purpose: To develop norm criteria of SMI for patients with decompensated cirrhosis and sarcopenia taking into account sex, age and lower extremity edema.
Method: A prospective cohort study was performed. The main group included patients with.
cirrhosis with lower extremity edema, Child-Pugh class B and C, of various etiologies. There.
was also a group of healthy volunteers to determine the norm criteria for SMI of the upper extremities. All patients were evaluated for muscle mass with DEXA, shoulder volume with a centimeter tape, caliperometry, muscle strength measurement-dynamometry, muscle function-test with lifting from a chair, tests to determine balance.
Results: Fifty-six patients were studied: 39 (main group) with cirrhosis and 17 (control group) healthy volunteers. There were 16 men (41%) and 23 women (59%) with mean age 52.1 ± 11.9 years in main group, and 6 men (35.3%) and 11 women (64.7%) with mean age 60.3 ± 6.7 years in the control group. SMI was evaluated by DEXA method in patients with cirrhosis and had the median of 6.77 (interquartile range: 5.55–7.43), in patients of control group-6.8 (IQR: 6.2–7.3) ($p = 0.164$). SMI for upper extremity had the median 1.38 (IQR: 1.27–1.68) in patients with liver cirrhosis, and 1.62 (IQR:1.48–1.98) for the control group ($p = 0.007$). It indicates statistically significant differences for the upper extremity SMI compared to the standard SMI in the main and control groups. The cutoff value assessed with ROC analysis for SMI for upper extremity was <1.398 (sensitivity 82.35%, specificity 59.0%) compared to the standard SMI cutoff <6.215 (sensitivity 70.59% and specificity 43.6%). Upper extremity SMI is a more accurate marker of sarcopenia than the standard SMI.
Conclusion: Normative values for the upper extremity SMI for patients with decompensated liver cirrhosis and sarcopenia have been developed. It makes it possible to correctly evaluate the index in dynamics against the background of patients' treatment.

FRI-125

Recompensation after TIPS reduces the risk of hepatocellular carcinoma and death in patients with decompensated cirrhosis

Jose Sanchez-Serrano[1], María Pilar Ballester[1], Sheila González-Padilla[1], Paloma Poyatos-García[1], Desamparados Escudero-García[2], Cristina Montón-Rodríguez[1], Jose Ballester[1], Juan Antonio Carbonell-Asins[3], Elisabetta Casula[1], Jorge Guijarro[1], Paloma Lluch-García[2]. [1]*Clinic University Hospital of Valencia, Valencia, Spain;* [2]*Clinic University Hospital of Valencia, University of Valencia, Valencia, Spain;* [3]*INCLIVA Biomedical Research Institute, Valencia, Valencia, Spain*
Email: josase6195@gmail.com

Background and aims: It has been recently described that some patients with decompensated cirrhosis can recompensate, which results in an improved prognosis. However, recompensation after transjugular intrahepatic portosystemic shunt (TIPS) and its impact on the risk of hepatocellular carcinoma (HCC) and death have not been studied. In addition, whether prognosis of patients who recompensate is similar to those with compensated cirrhosis is not known. The main aim of our study was to evaluate the impact of recompensation at 6 months and 1 year after TIPS placement on the risk of HCC and death.
Method: An observational, single-centre study of consecutive patients with decompensated cirrhosis who underwent TIPS between 2005–2022 was performed. Main outcomes were recompensation after TIPS, development of HCC and death. Recompensation was defined as removal/suppression/cure of the primary aetiology of cirrhosis, resolution of ascites, hepatic encephalopathy (HE) (with or without diuretics/HE prophylaxis) and absence of recurrent variceal haemorrhage and stable improvement

of liver function tests. A prospective cohort of consecutive outpatients with compensated cirrhosis was used for comparison.
Results: 208 patients with cirrhosis were included, 92 compensated and 116 decompensated who underwent TIPS, of whom 28 (24%) were compensated 1 year after TIPS placement.
Liver function at the time of TIPS placement was the only factor associated with recompensation at 1 year, with lower MELD (12 ± 5 vs 15 ± 6; p value = 0.049) and Child-Pugh (8; interquartile range [IQR] 7–9 vs 9; IQR 8–10, p value = 0.078) scores in recompensated patients. Median follow-up was 37 months (IQR 12–59). Cumulative incidence of HCC at 1, 3 and 5 years was 4%, 9% and 14% in recompensated patients, 2%, 6% and 16% in the compensated group and 19%, 32% and 38% in non-recompensated patients, respectively. Significant differences were found between non-recompensated patients and the other two groups (log-rank p value <0.001), but not between recompensated and compensated patients (log-rank p value 0.84). Survival was 100%, 88% and 76% at 1, 3 and 5 years follow-up in recompensated, 99%, 95% and 83% in compensated (log-rank p value 0.41 vs recompensated) and 44%, 35% and 24% in decompensated patients, respectively (log-rank p value <0.001 compared with the other groups). Similarly, recompensation at 6 months was associated with a lower incidence of HCC (log-rank p value = 0.004) and longer survival (log-rank p value <0.001).
Conclusion: recompensation at 6 months and 1 year after TIPS has a clear impact on patients with decompensated cirrhosis by reducing incidence of HCC and increasing survival, with a similar prognosis than patients with compensated cirrhosis. Liver function is the only factor associated with recompensation, suggesting the importance of considering early TIPS placement in patients with indication.

FRI-126

Impact of micronutrient deficiencies on the mortality of patients with cirrhosis admitted for acute decompensation

Ariadna Altadill[1], Gemma Llibre-Nieto[2], Cristina Solé[3], José Alberto Ferrusquía[3], Mireia Miquel[3,4], Meritxell Casas[1], Valentí Puig-Diví[1], Alba Lira[1], Berta López-Sáez[1], Claudia Torras[1], Isabel Laucirica[1], Andrea Peña[1], Carla de Sárraga[1], Judith Cortada[1], Mar Salas[1], Laia Grau[5], Mercedes Vergara[3], Jordi Sánchez[3].

Background and aims: Deficiencies in micronutrients, including vitamins and trace elements, are prevalent among patients with decompensated cirrhosis. However, the correlation between these deficiencies and mortality remains unclear. Therefore, we aimed to assess the impact of micronutrient deficiencies on mortality at one, three, six, and twelve months in patients with cirrhosis admitted for acute decompensation.
Method: This is an observational, retrospective, and single centre study that included all cirrhotic patients admitted for acute decompensation from October 2017 to February 2020. During admission, levels of trace elements (iron, ferritin, calcium, phosphorus, magnesium, zinc and copper) and vitamins (A, B1, B6, B9, B12, C, D, E and K) were measured. Different demographic and clinical data, including mortality at one, three, six, and twelve months from admission, were collected. Univariate analysis was used to assess the correlation between micronutrients deficiencies and mortality.
Results: 125 patients were included: 77% male with a mean age of 62 ± 6.3 years. The most common aetiology was alcohol-related cirrhosis (79.2%) and 57.4% had active alcohol consumption. 90% of the patients were Child-Pugh class B or C with a mean MELD score of 16 ± 6 points. At admission, ascites, bacterial infection, hepatic encephalopathy and alcohol-associated hepatitis were present in 80%, 38%, 25% and 14% of the cases. Deficiencies of vitamin D, vitamin A, zinc and vitamin B6 were detected in 95%, 94%, 86% and 61% of the patients, respectively. Mortality at 1, 3, 6, and 12 months was 4.8%, 13.6%, 18.4% and 31.2%, respectively. The univariant analysis showed no association between micronutrient deficiencies or excesses and mortality at any of the assessed time periods. Higher MELD score was associated with lower levels of vitamin A (p < 0.001), vitamin E (p < 0.001), magnesium (p = 0.01) and zinc (p = 0.001) and higher levels of ferritin (p = 0.002) and vitamin B12 (p < 0.001). Factors related to mortality at one, three, six and twelve months were older age and worse liver function measured by Child and MELD points. Admission for alcohol-associated hepatitis was related to mortality in the first month (50% (n = 3) vs 12.6% (n = 15), p = 0.03) and third month (29.4% (n = 5) vs 12% (n = 13), p = 0.05).
Conclusion: In patients with cirrhosis admitted for acute decompensation, neither micronutrient deficiencies nor excesses were associated with mortality at 1, 3, 6, and 12 months. However, diminished levels of zinc, vitamin E and vitamin A, and elevated levels of vitamin B12 and ferritin were associated with a more advanced liver disease according to MELD classification. Further studies are needed to assess the potential influence of correcting micronutrient deficiencies on the severity of liver disease in patients presenting an acute decompensation of cirrhosis.

FRI-127

The relationship between abnormal body composition by computed tomography imaging and long-term mortality in patients with cirrhosis

Jiarui Zheng[1], Wenhui Ren[2], Shuo Yang[3], Rui Huang[1]. *[1]Peking University Hepatology Institute, Beijing, China; [2]Department of Clinical Epidemiology, Beijing, China; [3]Department of Radiology, Peking University People' s Hospital, Beijing, China*
Email: strangehead@163.com

Background and aims: Emerging evidence on cirrhosis suggests a close correlation between abnormality in body composition characteristics and poor prognosis. This study aimed to evaluate the impact of dynamic changes in body composition on the prognostic outcomes in patients with cirrhosis.
Method: This retrospective analysis included patients diagnosed as cirrhosis in our hospital, from January 2018 to August 2023. Skeletal muscle mass index (SMI), visceral adipose tissue index (VATI), subcutaneous adipose tissue index (SATI) and visceral adipose to subcutaneous adipose area ratio (VSR) were evaluated using computed tomography (CT) imaging at the third lumbar vertebra level and all patients underwent a follow-up CT scan performed at least 6 months after the initial scan. Competing risk model was performed in four different body composition status (i.e., normal, only sarcopenia, only myosteatosis, and combined status) for liver-related mortality. We also explored the relationship between the dynamic change in body composition and long-term prognosis by applying Gray's test.
Results: Of the 158 cirrhotic patients (mean [SD] age, 57.1 [12.6] years), sarcopenia was present in 85 (60.1%) patients, while 22 (13.9%) patients had sarcopenic obesity and 68 (43.0%) had myosteatosis. Patients solely diagnosed with sarcopenia exhibited a higher mortality rate compared to those with normal body composition (Gray's test, $P = 0.006$), while patients solely diagnosed with myosteatosis or with a combination of sarcopenia and myosteatosis did not reach statistical significance (Gray's test, $P = 0.076$; $P = 0.140$). Multivariable analysis also revealed that VSR (HR = 1.10 [1.01～1.20]; $P = 0.028$), sarcopenia (HR = 2.73 [1.20～6.22], $P = 0.017$) and

myosteatosis (HR = 2.39 [1.10～5.18], *P* = 0.028) were independent predictors of liver-related deaths. Otherwise, patients exhibiting aggravating body composition during follow-up period were associated with a significantly higher mortality risk compared to those with normal or remission body composition status (HR = 7.63 [1.12～51.14]; *P* = 0.036).

Conclusion: Progressive alterations in body composition status appears to be associated with liver-related mortality in individuals with liver cirrhosis. Focusing on the management of skeletal muscle, along with visceral and subcutaneous adiposity, may contribute to improving the prognosis of cirrhotic patients.

FRI-128

Usefulness of liver volume assessment for simple screening of covert hepatic encephalopathy

Masanori Fukushima[1], Yasuhiko Nakao[1], Ryu Sasaki[1], Masafumi Haraguchi[1], Satoshi Miuma[1], Hisamitsu Miyaaki[1], Kazuhiko Nakao[1]. [1]*Department of Gastroenterology and Hepatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*
Email: ma-fukushima@nagasaki-u.ac.jp

Background and aims: Covert hepatic encephalopathy (CHE) signifies a precursor to overt hepatic encephalopathy (OHE) and is associated with decreased quality of life. Therefore, it is a clinically significant complication of liver cirrhosis (LC). In Japan, a neuropsychiatric test (NPT) performed on a tablet is used in CHE diagnosis; however, interpretation is challenging because of variations influenced by education levels, cultural backgrounds, cognitive decline in elderly, and physical impairments. Therefore, this study aimed to explore a facile screening method by investigating the characteristics and associated factors of CHE development in patients with LC using various clinical data.

Method: One hundred patients with liver cirrhosis without a history of OHE admitted to our institution from January 2019 to October 2022 were enrolled. CHE diagnosis was conducted using the number connection test B in NPT. Clinical data, including liver function, fibrosis markers, presence of esophageal varices and portal-systemic shunts, and liver volume, were included. Liver volume was measured by CT using SYNAPSE VINCENT software (Fujifilm Medical Co., Tokyo, Japan) and corrected by liver volume/body surface area.

Results: Median age was 68 years, and there were 62 men and 38 women. The causes of LC were alcohol-related in 29 cases, MASLD in 24 cases, HCV in 16 cases, HBV in 15 cases, and others in 16 cases. The distribution of Child-Pugh scores was A (55 cases), B (38 cases), and C (seven cases). Among all cases, 47 (47%) were diagnosed with CHE. The CHE-positive rates in Child-Pugh classes A, B, and C were 30.9% (17/55), 63.2% (24/38), and 85.7% (6/7), respectively. Significant differences between the CHE and non-CHE groups were observed in liver function markers (PT, Alb, T.Bil), fibrosis markers (hyaluronic acid, type 4 collagen 7S, M2BPGi), and liver volume/body surface area ratio. CHE cases (530 vs 691 p = 0.002) had significantly lower liver volume/body surface area ratio. ROC curve analysis revealed an AUC of 0.64, with a cutoff value set at 586. In the low liver volume group, 60% had CHE, representing a 1.76-fold increase compared to the high-volume group.

Conclusion: In patients with LC, CHE occurrence is associated with impaired liver reserve function, fibrosis markers, and liver volume. While higher prevalence of CHE in cases with poor liver function is consistent with previous reports, its association with liver volume is a novel finding. The measurement of liver volume can be easily determined within one minute using CT scans. Liver volume calculation may be a simple screening tool independent of blood test to identify high-risk groups for CHE.

FRI-129

Construction and validation of a nomogram prediction model for predicting cirrhosis-related deaths based on severe sarcopenia and clinical serological indicators

Hong Yu[1], Jinhua Jing[2], Guzainuer Yiliyaer[3], Wei Sun[1], Yuyu Li[4], Feng Guo[5]. [1]*The Fourth Clinical Medical College of Xinjiang Medical University., Urumqi, China;* [2]*No.4 Department of Internal Medicine of Traditional Chinese Medicine Hospital of Xinjiang Changji Prefecture, Urumqi, China;* [3]*College of Nursing of Xinjiang Medical University, Urumqi, China;* [4]*Fourth Clinical Medical College of Xinjiang Medical University, Urumqi, China;* [5]*Department of Hepatology of Tradtional Chinese Medicine Affiliated to Xinjiang Medical University, Urumqi, China*
Email: gf_sj@163.com

Background and aims: Predicting the risk of liver disease-related death in cirrhotic patients based on severe myasthenia gravis and clinical serological indicators, constructing a nomogram prediction model and validating its predictive power.

Method: We retrospectively analyzed 239 patients with liver cirrhosis in the Department of Hepatology of Traditional Chinese Medicine of Xinjiang Medical University, from January 2019 to December 2020; based on the third lumbar vertebral level Skeletal Muscle Index according to the Malnutrition, Frailty, and Sarcopenia in Patients With Cirrhosis: 2021 Practice Guidance by the American Association for the Study of Liver Diseases, use (L3-SMI)<50 cm^2/m^2 (male) or <39 cm^2/m^2 (female) for the diagnosis of sarcopenia, and a combined 6 m step speed <1.0 m/s for the diagnosis of severe sarcopenia.Using random sampling method, the included patients were randomly assigned to the training cohort (167 cases) and the validation cohort (72 cases) in a ratio of 7:3;using multivariate COX regression and nomogram predicting death at 6, 12, and 24 months in patients with with cirrhosis;Internal validation was performed on the resulting nomogram through consistency indices (C-index) to check their predictive accuracy, calibration curves to assess their consistency, and clinical decision analyses to assess their clinical benefits;the risk of death in cirrhotic patients was assessed by the Kaplan-Meier curve.

Results: The prevalence of severe sarcopenia in this study was as high as 31.3% (75/239), with a higher prevalence in females than in males (56.0% vs 44.0%), and 81.3% (61/75) of patients with Child-Pugh class B/C. The results of multivariate COX regression analysis based on the training cohort showed that BMI, MELD score, and comorbid severe sarcopenia were risk factors predicting death related to liver disease; severe sarcopenia was independently associated with death in cirrhotic patients, with a multi-factorial-corrected HR of 3.42 (*95% CI*: 1.19～9.83). These factors were included and evaluated in the construction of a nomogram model, then predicted the risk of liver disease-related deaths at 6, 12, and 24 months with receiver operating characteristic curve, the area under the curve is 0.709 (*95% CI*:0.323 ～ 1.096), 0.813 (*95% CI*:0.626～1.000), 0.778 (*95% CI*:0.558～0.999), and the C-index obtained from internal validation was 0.725 (*95%CI*:0.513～0.937) indicating a high predictive value and fair consistency of the validation of the calibration curves for liver disease-related deaths in cirrhotic patients.

Conclusion: Severe sarcopenia increases the risk of death in cirrhotic patients by more than 3-fold and significantly affect the survival prognosis of patients. The nomogram prediction model based on BMI, MELD score, and severe sarcopenia has great clinical predictive value for liver disease-related deaths in cirrhotic patients.

FRI-130

Pre- and post-test diagnostic concordance rates of TJLB for suspected liver and blood diseases

Asako Nogami[1], Naohiro Wada[2], Tomohiro Otani[1], Michihiro Iwaki[1], Takashi Kobayashi[2], Satoru Saito[1], Masato Yoneda[1], Atsushi Nakajima[1]. [1]*Yokohama City University Graduate School of Medicine, Yokohama, Japan;* [2]*Yokohama City University Graduate School of Medicine, Yokohama*
Email: nogamia@yokohama-cu.ac.jp

Background and aims: Percutaneous liver biopsy (PLB) is the main method for histological diagnosis of liver disease. However, PLB may be difficult or impossible to perform in cases with signs of liver failure such as ascites effusion or decreased coagulability, or liver damage due to blood disorders. TJLB (transjugular liver biopsy) is an alternative test for PLB. Although there are many reports on the safety of TJLB, there are few reports on the concordance rate between pre- and post-test diagnoses. We investigated the rate of concordance between pre- and post-test diagnoses using TJLB.
Method: We retrospectively examined the concordance rate between pre- and post-test diagnoses in 107 patients who underwent TJLB at our hospital from May 2009 to December 2023.
Results: The median age of patients was 53 years (17–82), 47 males and 60 females. Fifty-seven patients (53.3%) had ascites effusion as a sign of liver failure, 14 patients (14.9%) had platelet counts <50, 000/μl, and 37 patients (29.8%) had coagulation abnormalities (PT-INR>1.5). HVPG was measured at the time of TJLB in 86 patients. TJLB was successfully performed in 95 patients (88.8%). Seventy-two (75.8%) of the cases in which tissue samples were successfully obtained were for the search for the cause of chronic liver damage, and 23 (24.2%) were for the search for liver damage due to haematological disease. Of the 72 cases in which TJLB was performed to search for the cause of chronic liver disease, the diagnosis before and after the test was consistent in 32 cases (71.6%), the diagnosis of blood disease was reached in 1 case (1.4%), and the diagnosis was not reached in 18 cases (25%). In 4 cases (5.6%), the diagnosis was changed before or after the examination, and symptoms improved with the decision of treatment. Of the 23 patients who underwent TJLB because of suspected hematologic disease, the diagnosis was consistent before and after the examination in 9 cases (39.1%), liver disease was diagnosed in 5 cases (21.7%) based on histological diagnosis, and the diagnosis was not reached in 4 cases (17.4%).
Conclusion: In this retrospective study, the agreement rate of diagnosis before and after TJLB examination was 70% for suspected liver disease and about 40% for suspected haematological disease, suggesting that there is a great possibility that the diagnosis may change after TJLB is performed. On the other hand, the patients who underwent TJLB for suspected liver disease tended to be more difficult to diagnose than those who underwent TJLB for suspected haematological disease. In cases in which PLB is difficult to be performed due to signs of liver failure or hematologic disease, TJLB is a useful method of tissue diagnosis that may influence diagnosis and treatment.

FRI-131

Effect of adipose-related parameters on survival in patients with cirrhosis: a systematic review and meta-analysis

Zhang Wen[1,2], Qiu Ju Ran[1,2], Shuyue Tuo[1,2], Jia Yuan[1,2], Yong Li[1,2], Chan Li[1,2], Shejiao Dai[1,2], Jinhai Wang[1,2], Xinxing Tantai[1,2]. [1]*Department of Gastroenterology, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China;* [2]*Clinical Research Center for Gastrointestinal diseases of Shaanxi Province, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*
Email: xinxingtantai@foxmail.com

Background and aims: Some adipose-related parameters exhibited distinct prognostic value in patients with cirrhosis. However, the association, magnitude, and direction of the association between individual adipose parameter and mortality in patients with cirrhosis remain to be determined. This study aimed to evaluate the association between individual adipose parameter and mortality in patients with cirrhosis using the meta-analysis method.
Method: PubMed, Embase, Web of Science, and some Chinese databases were searched from inception to November 19, 2023 to identify the eligible studies. The prevalence of dichotomous adipose parameters and their corresponding 95% confidence interval (CI) were pooled using the random-effects model. The impact of each adipose parameter on mortality was assessed by the pooled unadjusted or adjusted hazard ratio (HR) with 95% CIs using the random-effects modeling.
Results: A total of 27 studies involving 7, 906 patients were included in our analysis. Initially, 15 adipose parameters were identified and underwent screening, ultimately resulting in the inclusion of 10 parameters: visceral fat area (VFA), visceral adipose tissue index (VATI), subcutaneous fat area (SFA), subcutaneous adipose tissue index (SATI), the visceral to subcutaneous ratio (VSR), myosteatosis, sarcopenic obesity (SO), muscle radiodensity (MR), visceral adipose radiodensity (VAR), and subcutaneous adipose radiodensity (SAR). The pooled prevalence of SO and myosteatosis in patients with cirrhosis was 15.5% and 34.4%, respectively. In unadjusted analyses, associations with mortality were observed for SATI (unadjusted HR 0.99, 95% CI 0.99–0.99), VSR (unadjusted HR 2.46, 95% CI 1.84–3.28), myosteatosis (unadjusted HR 2.52, 95% CI 1.90–3.33), SO (unadjusted HR 2.27, 95% CI 1.63–3.16), MR (unadjusted HR 0.96, 95% CI 0.94–0.98), and SAR (unadjusted HR 1.02, 95% CI 1.01–1.02), while no such associations were found for VFA (unadjusted HR 1.00, 95% CI 0.99–0.1.01), VATI (unadjusted HR 1.00, 95% CI 1.00–1.00), SFA (unadjusted HR 1.00, 95% CI 0.99–1.00), and VAR (unadjusted HR 1.02, 95% CI 1.00–1.03) in patients with cirrhosis. In adjusted analysis, each unit increase in SATI (adjusted HR 0.99, 95% CI 0.98–1.00) or MR (adjusted HR 0.94, 95% CI 0.90–0.98), and each unit decrease in VSR (adjusted HR 1.92, 95% CI 1.45–2.54), showed an independent association with a decreased risk of mortality. However, concurrent myosteatosis (adjusted HR 1.88, 95% CI 1.48–2.40) or SO (adjusted HR 2.77, 95% CI 1.95–3.93) significantly increased the risk of mortality in patients with cirrhosis.
Conclusion: Different adipose parameters exhibited varying prognostic value: decreased SATI or MR, increased VSR, and concurrent myosteatosis or SO were independently associated with a higher risk of mortality in patients with cirrhosis.

FRI-132

Spontaneous bacterial empyema is a rare yet life-threatening complication in patients with hepatic hydrothorax

Grace Lai-Hung Wong[1], Mandy Sze-Man Lai[1], Jimmy Che-To Lai[1], Terry Cheuk-Fung Yip[1], Lilian Liang[1], Yichong Jiang[1], Vincent Wai-Sun Wong[1]. [1]*The Chinese University of Hong Kong, Medical Data Analytics Centre (MDAC), Department of Medicine and Therapeutics, Hong Kong, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: Hydrothorax is one of the most debilitating complications in patients with cirrhosis. We aimed to evaluate the detailed pleural fluid analysis and the outcome of spontaneous bacterial empyema in patients with hepatic hydrothorax in a territory-wide cohort over the last two decades in Hong Kong.
Method: This was a territory-wide cohort study of consecutive patients with cirrhosis and hepatic hydrothorax from 2000–2022. We reviewed pleural fluid analysis of patients who underwent diagnostic and/or therapeutic thoracentesis. Spontaneous bacterial empyema was defined as a polymorphonuclear leukocytes (PMN) >500 cells/mm3 with negative pleural fluid culture, or PMN >250 cells/mm^3 with positive pleural fluid culture.
Results: Among the 31, 542 patients with cirrhosis, 3, 251 (10.3%) patients suffered from hydrothorax; their mean age was 58 ± 14 years; 65.4% were male; cirrhosis was mostly caused by chronic hepatitis B (72.5%). 687/3, 251 (21.1%) patients underwent

thoracentesis with pleural fluid sent for analysis. Spontaneous bacterial empyema occurred in 43/3, 251 (1.3%) all patients with hydrothorax, and 43/687 (6.3%) of those underwent thoracentesis. Compared with uninfected individuals, patients with spontaneous bacterial empyema had lower median (interquartile range) pleural fluid pH 7.33 (7.21–7.39) vs. 7.46 (7.36–7.51), higher total protein 23.2 (16.7–31.5) vs. 19.5 (12.3–29.2) g/L, higher lactate dehydrogenase (LDH) 107 (79–177) vs. 88 (63–158) IU/L, higher pleural fluid/serum protein ratio 0.52 (0.42–0.83) vs. 0.35 (0.21–0.65). The 30-day and 6-month mortality of patients with spontaneous bacterial empyema was as high as 21.3% and 65.4% respectively, compared to 3.4% and 17.5% respectively in uninfected patients.
Conclusion: Spontaneous bacterial empyema is a rare yet deadly complication in patients with liver cirrhosis and hepatic hydrothorax. A high index of suspicion, timely diagnosis and treatment may improve the clinical outcome.

FRI-133
Decreasing incidence of cirrhosis due to hepatitis C following the treatment as prevention for hepatitis C nationwide elimination campaign
Einar S. Björnsson[1], Halldor A. Haraldsson[2], Magnús Gottfredsson[3], Sigurdur Olafsson[3]. [1]*Landspitali University Hoospital, Reykjavik, Iceland;* [2]*University of iceland, Reykjavik, Iceland;* [3]*Landspitali University Hospital, Reykjavik, Iceland*
Email: einarsb@landspitali.is

Background and aims: In the late 20th century the incidence of liver cirrhosis was low in Iceland at 3 cases per 100.000 inhabitants but subsequently increased in the past two decades due to increased alcohol consumption, obesity and hepatitis C virus (HCV) infections to around 10 cases per 100,000 per year in 2015. In 2016 a nationwide elimination program for HCV was initiated, entitled Treatment as Prevention for Hepatitis C (TraP HepC), providing unrestricted access to antiviral treatment. The aims were to describe the changes in risk factors and epidemiology of cirrhosis and to assess the trends in HCV-related cirrhosis following TraPHepC.
Method: The study included all patients newly diagnosed with cirrhosis in Iceland from 2016 to 2022. Diagnosis was based on liver elastography, histology, and/or 2 of 4 criteria: cirrhosis on imaging, ascites, varices, and/or elevated international normalized ratio (INR).
Results: Over the study period, 342 new cirrhosis patients were identified, 223 (65%) males, median age 62 years, MELD 9 (8–14). The crude overall incidence was 13.8 cases per 100,000 inhabitants annually. The most common etiologies were alcohol (40%), metabolic dysfunction associated steatotic liver disease (MASLD) (28%), and HCV with/without alcohol overconsumption (15%). The proportion of cirrhotics with either alcoholic related liver disease or MASLD etiology increased from 53% in a previous prospective study of 2010–2015 to 68% of all cirrhosis etiologies. The number of HCV cirrhosis cases was higher in 2016 (n = 23) due to intensified case-finding in the TraP HepC project but dropped by more than 90% in 2021 and 2022. The overall 5-year survival was 55% (95% CI 48.9–62.3%). The most common causes of death were hepatocellular carcinoma (26%) and liver failure (25%).
Conclusion: During the past two decades the incidence of cirrhosis has increased in Iceland associated with increased alcohol consumption, obesity, and HCV. Alcohol overconsumption *per se* and MASLD now collectively make up two thirds of incident cases in Iceland. Following a nationwide elimination campaign, HCV cirrhosis has dropped by >90% in Iceland.

FRI-134
Six years long-lasting clinical benefits of previous short-term resistance training in cirrhosis-follow-up after a clinical randomized trial
Luise Aamann[1,2], Gitte Dam[1], Mette Borre[1], Peter Jepsen[1], Hendrik Vilstrup[1], Niels Kristian Aagaard[1]. [1]*Aarhus University Hospital, Aarhus, Denmark;* [2]*Copenhagen University Hospital Hvidovre, Copenhagen, Denmark*
Email: luise.aamann@gmail.com

Background and aims: In many chronic diseases, training promotes general health and may improve survival. In patients with cirrhosis, our previous randomized clinical trial on supervised resistance training showed reduced risk for the first acute hospital admission and decreased all-cause mortality. The effects were maintained up to three years after randomization. We now extended the follow-up in order to evaluate possible long-lasting effects of resistance training.
Method: 12 weeks of supervised intensive resistance training was the intervention. 39 participants with cirrhosis Child-Pugh stage A/B were randomly assigned to resistance training or continued sedentary living. There was no after-study intervention. After randomization all-cause first acute hospital admissions and deaths were recorded during a 6-year follow-up.
Data were analyzed according to intention-to-treat. We used Fine and Gray regression to analyze time to first admission with death before hospitalization as a competing risk and Cox regression for survival analysis. We adjusted for Child-Pugh, age, gender, and comorbidity (CirCom) at randomization.
Results: Baseline characteristics were similar in both groups. During the 6 years, a total of 15 participants who trained, and 18 who did not were acutely hospitalized. There was a significantly decreased admission risk in the training group (adjusted subdistribution hazard ratio 0.46 (95% CI: 0.24–0.9) p = 0.02).
In total, 17 participants died during the 6 years (7 who trained and 10 who did not) but the reduction was not statistically significant (adjusted hazard ratio 0.37 (95% CI: 0.12–1.09) p = 0.07).
Conclusion: 6 years after an intensive 12-week resistance training program of cirrhosis patients there was still a beneficial effect on their risk of the first acute hospital admission. Also, mortality was lower although not maintaining statistical significance. The mechanisms of this long-lasting positive effect of short-term training are unresolved but are likely related to a reduction in sarcopenia maintained by life-style changes.
The results suggest lasting clinically meaningful benefits of resistance training in cirrhosis and motivate further trials.

FRI-135
Von Willebrand factor is associated with portal vein thrombosis in patients with liver cirrhosis
Wenting Lu[1], Ming Zhang[1], Lei Wang[1], Yuzheng Zhuge[1], Feng Zhang[1]. [1]*Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China*
Email: fzdndx@126.com

Background and aims: von Willebrand factor (vWF) plays a key role in hemostasis and is reported to be related with the outcome of advanced chronic liver disease. The aim of the present study is to investigate the relationship between vWF and portal vein thrombosis (PVT) in patients with cirrhosis.
Method: Consecutive cirrhotic patients with gastroesophageal varices admitted to our hospital between January 2020 and April 2022 were prospectively recruited and divided into PVT and non-PVT groups. We collected clinical, routine blood tests, biochemical tests, coagulation tests, and hemostatic protein profiles data to explore the risk factors of PVT.
Results: A total of 154 patients were enrolled including 83 patients with PVT and 71 patients without PVT. Plasma levels of vWF (OR = 1.013, 95%CI: 1.005~1.021, P = 0.002), D-dimer (OR = 2.263, 95%CI: 1.504~3.877, P = 0.001), and decreased portal blood flow velocity (OR

= 0.827, 95%CI: 0.749~0.897, P < 0.001) were the variables independently associated with the existence of PVT. Areas under the curve of ROC (AUROC) analyses for vWF, D-dimer and portal blood flow velocity were 0.773, 0.847, and 0.839, respectively. A nomogram model was established involving the three parameters, and the AUROC was 0.930. In the internal validation using bootstrap, the AUROC was 0.930 (95%CI: 0.887–0.966).
Conclusion: Higher vWF levels were related with PVT in patients with decompensated cirrhosis, indicating that vWF might serve as a risk factor for PVT, and a nomogram containing vWF, D-dimer and portal blood flow velocity could be an important tool of PVT risk prediction in cirrhotic patients. Further external validation is warranted.

FRI-136
Aspirin reduces risk of ascites and encephalopathy in cirrhotic patients without increasing the risk of gastrointestinal bleeding
Roie Tzadok[1], Nir Bar[2], Ayelet Grupper[3], Eugene Feigin[4], Helena Katchman[5]. *[1]Division of Gastroenterology and Hepatology, Tel Aviv Sourasky Medical Cneter, Faculty of Medicine, Tel Aviv University, Tel Aviv; [2]Division of Gastroenterology and Hepatology, Tel Aviv Sourasky Medical Center, Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Department of Nephrology, Tel Aviv Sourasky Medical Center, Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [4]Department of Endocrinology, Tel Aviv Sourasky Medical Center, Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [5]Division of Gastroenterology and Hepatology, Tel Aviv Sourasky Medical Center, Faculty of Medicine. Tel Aviv University, Tel Aviv, Israel*
Email: ROIET@TLVMC.GOV.IL

Background and aims: There is accumulating data regarding the beneficial effects of aspirin on the advancement of liver fibrosis, both in animal models and on laboratory indices of fibrosis. Aspirin was also shown to be associated with reduced HCC risk in cirrhotic patients. This study was aimed to evaluate clinical outcomes in cirrhotic patients treated with aspirin in comparison to non-treated cirrhotic patients.
Method: In a retrospective study at Tel Aviv Sourasky Medical Center, we compared aspirin treated cirrhotic patients for various indications to non-treated patients. Patients were followed-up for composite clinical outcomes, including decompensations, thrombotic and vascular complications (portal vein thrombosis, DVT, TIA, CVA, acute coronary syndrome and myocardial infarction) and HCC. Cox regression multivariate models were used to compare clinical sequalae between the groups.
Results: From 2009–2018, 2413 patients with cirrhosis were treated at our center. One thousand and sixty-nine patients were followed up for a minimum of three months (median 13 months, IQR 33.1–57.67 months). One hundred and thirty-six patients (12.7%) were treated with aspirin for various indications. Baseline clinical and laboratory characteristics of both groups were comparable. Aspirin use was associated with risk reduction for decompensations, including a composite risk of ascites and hepatic encephalopathy, in a multivariate Cox regression analysis (p = 0.035). Aspirin use showed a tendency toward encephalopathy risk reduction as a single variable (p = 0.055), but not for the development of ascites. Aspirin was not associated with an increased risk of gastrointestinal bleeding in both univariate (p = 0.281) and multivariate analyses models adjusted for gender, age, platelet count, MELD score, statin, beta blocker and PPI use (p = 0.446).
Conclusion: Aspirin use may confer a protective effect against a composite outcome of hepatic encephalopathy and ascites, and is not associated with increased risk of gastrointestinal bleeding in patients with cirrhosis. Further prospective studies on larger cohorts are necessary to elucidate its mode of action and confirm our findings.

Cirrhosis and its complications – Portal Hypertension

Whole blood thrombin generation improves the understanding of cirrhotic coagulopathy and predicts clinical outcomes in patients with cirrhosis: a prospective cohort study
Alberto Zanetto[1], Elena Campello[2], Cristiana Bulato[2], Ruth Willems[3], Joke Konings[3], Mark Roest[3], Sabrina Gavasso[2], Giorgia Nuozzi[2], Serena Toffanin[2], Paola Zanaga[1], Patrizia Burra[1], Francesco Paolo Russo[1], Bas de Laat[3], Paolo Simioni[2], Marco Senzolo[1]. *[1]Gastroenterology and Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padova University Hospital, Padova, Italy; [2]General Internal Medicine Unit, Thrombotic and Hemorrhagic Disease Unit and Hemophilia Center, Department of Medicine, Padova University Hospital, Padova, Italy; [3]Department of Functional Coagulation, Synapse Research Institute, Maastricht, Netherlands*
Email: alberto.zanetto@yahoo.it

Background and aims: Patients with cirrhosis have an increased thrombin generation (TG) in platelet-poor plasma (PPP). By reflecting the contribution of circulating blood cells, whole blood (WB) TG may allow a more physiological assessment of coagulation, thus improving our understanding of cirrhotic coagulopathy and its clinical implications. We conducted a prospective study to 1) compare WB-TG vs. PPP-TG in cirrhosis; 2) assess whether WB-TG could predict hepatic decompensation, further decompensation/ACLF, bleeding unrelated to portal hypertension and thrombosis.
Method: Assessment of coagulation included routine tests, factor VIII, natural anticoagulants, PPP-TG and WB-TG (with and without thrombomodulin [TM]). Twenty-five healthy subjects were included as controls. All patients were prospectively followed for development of hepatic decompensation and bleeding/thrombosis.
Results: We included 203 patients (Child-Pugh A/B/C 81/55/67). In compensated cirrhosis, both PPP-TG and WB-TG indicated an increased TG capacity, as reflected by an endogenous thrombin potential (ETP) significantly higher than controls; in decompensated cirrhosis, PPP-TG indicated a hyper-coagulable state with increased ETP and higher peak height, whereas WB-TG revealed a progressive impairment of TG kinetics and total capacity, resulting in a profound hypo-coagulable state in Child-Pugh C. Median duration of follow-up was 13 months in compensated and 10 months in decompensated patients. In compensated cirrhosis, patients who experienced 1st decompensation had a significantly higher WB-TG than those who did not, whereas in decompensated cirrhosis WB-TG was comparable in patients with vs. without further decompensation/ACLF during follow-up. In decompensated patients, WB-TG was more severely compromised in patients who experienced bleeding complications, whereas no association was found with thrombosis.
Conclusion: In compensated cirrhosis, a more pronounced hypercoagulable state, as assessed by WB-TG, indicated a higher risk of decompensation, suggesting that hyper-coagulability may be responsible for cirrhosis progression. In decompensated cirrhosis, contrary to PPP-TG that indicates hypercoagulability, WB-TG reveals a significant hypo-coagulable state, which was associated with bleeding complications.

Accuracy of spleen stiffness measurement for the diagnosis of high-risk esophageal varices in patients with advanced chronic liver disease: a systematic review and individual patient data meta-analysis

Elton Dajti[1], Federico Ravaioli[1], Xiaolong Qi[2], Jinjun Chen[3], Horia Ștefănescu[4], Young Seo Cho[5], Cristophe Cassinotto[6], Rui Gaspar[7], Saveria Lory Croce'[8], Maha Elsabaawy[9], Mirella Fraquelli[10], Ivica Grgurevic[11], Carmen Fierbinteanu Braticevici[12], Grace Wong[13], Renata Bende[14], Maciej Janik[15], Flavia Fernandes[16], Laure Elkrief[17], Pierre-Emmanuel Rautou[18], Atsushi Nakajima[19], Romanas Zykus[20], Matthias Buechter[21], Giovanni Galati[22], Thomas Reiberger[23], Ekaterina Lusina[24], Julia Arribas Anta[25], Jose Ignacio Fortea[26], Jason Pik Eu Chang[27], Natalie Lucchina[28], Hirooka Masashi[29], Giorgio Soardo[30], Luigi Colecchia[1], Davide Roccarina[31], Fabio Piscaglia[32], Francesco Azzaroli[33], Giovanni Marasco[34], Agostino Colli[35], Davide Festi[1], Annalisa Berzigotti[36], Antonio Colecchia[37]. *[1]University of Bologna, Bologna, Italy; [2]Center of Portal Hypertension, Department of Radiology, Zhongda Hospital, School of Medicine, Southeast University, Nanjing, China; [3]Southern Hospital of Southern Medical University, Guangzhou, China; [4]Regional Institute of Gastroenterology and Hepatology Octavian Fodor, Cluj-Napoca, Romania; [5]Hanyang University College of Medicine, Hanyang University Guri Hospital, Guri, Korea, Rep. of South; [6]University Hospital of Montpellier, Montpellier, France; [7]Centro Hospitalar São João, Porto, Portugal; [8]Università degli Studi di Trieste, Trieste, Italy; [9]Menoufia University, Shebeen El-Kom, Egypt; [10]Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Milan, Italy; [11]Dubrava University Hospital, Zagreb, Italy; [12]Carol Davila"University of Medicine and Pharmacy, University Hospital Bucharest, Romania, Bucharest, Romania; [13]The Chinese University of Hong Kong, Hong Kong, China; [14]Victor Babes University of Medicine, Timisoara, Romania; [15]Department of Hepatology, Transplantology and Department of Hepatology, Transplantology and Internal Medicine, Warsaw, Poland; [16]Bonsucesso Federal Hospital, Rio de Janeiro, Brazil; [17]Tours University Hospitals, Tours, France; [18]Hôpital Beaujon-Assistance Publique-Hôpitaux de Paris, Paris, France; [19]Yokohama City University Graduate School of Medicine, Yokohama, Japan; [20]Department of Gastroenterology, Lithuanian University of Health Sciences, Kaunas, Kaunas, Lithuania; [21]University of Duisburg-Essen, Essen, Germany; [22]University Campus Bio Medico of Rome, Rome, Italy; [23]Medical University of Vienna, Vienna, Austria; [24]M. Background and aims: Diagnosis and management of esophageal varices (EV) is of critical importance in compensated advanced chronic liver disease. We performed an individual patient data (IPD) meta-analysis to investigate the performance of spleen stiffness measurement (SSM)-based algorithms using different elastography techniques to rule-out high-risk varices (HRV) as compared to the existing standard of care (Baveno-VI criteria).
Method: We systematically researched databases (PubMed, Embase, Scopus, Cochrane) until November 1st, 2023. Studies reporting data on endoscopy and SSM in adult patients were eligible. The main outcome was an acceptable rate (<5%) of missed HRV, defined by a summary sensitivity and negative predictive value (NPV) ≥95%. The evaluated algorithms for transient elastography (TE) were: i) Baveno-VI Criteria, ruling-out HRV if liver stiffness measurement (LSM) <20 kPa and platelet count (PLT >150 G/L); ii) SSM ≤40 kPa; iii) combined Baveno VII-SSM criteria, followed by SSM cut-off ≤40 kPa in patients outside Baveno VI criteria. This study is registered with PROSPERO, CRD42019127164.
Results: We assessed 1436 articles for eligibility, of which 37 studies including 4353 patients from 19 countries were included in the analysis. In the TE cohort (18 studies, 1996 patients), the Baveno VI algorithm showed a sensitivity of 100% (95%-CI: 98–100%) and a NPV of 100% (95%-CI:98–100%); the rate of spared endoscopies was 16% (95%-CI: 12–21%). SSM ≤40 kPa alone was accurate to rule-out HRV: sensitivity 98% (95%-CI: 94–99%), NPV 99% (95%-CI: 97–100%), rate of spared endoscopies 30% (95%-CI: 25–35%). The combined Baveno VII-SSM criteria were the best performing for ruling-out HRV: sensitivity 97% (95%-CI: 95–99%), NPV 99% (95%-CI: 97–100%] and rate of spared endoscopies 36% (95%-CI: 30–41%). These results were robust in all sensitivity analyses, including a large subgroup of patients (n = 569) with non-viral etiology. SSM evaluated by other techniques was also accurate to diagnose HRV: the AUROC was 0.69 for two-dimensional shear wave (2D-SWE) (n = 851 patients), 0.74 for VTQ-SWE (n = 1215 patients), and 0.65 for ElastPQ-SWE (n = 291 patients). However, the cut-offs proposed by Baveno VI-VII did not have an acceptable rate of missed HRV in the p-SWE and 2D-SWE cohorts.
Conclusion: This large, multicenter, international study validated SSM-TE as an accurate test for the diagnosis of esophageal varices. The combined Baveno VII-SSM criteria were the best performing algorithm to rule-out HRV.

SAT-069

Effects of zibotentan and dapagliflozin on patients with compensated cirrhosis: a randomized double-blind placebo controlled exploratory pilot study

Juan Carlos García-Pagán[1], Lise Lotte Gluud[2], Mattias Mandorfer[3], Jörn M. Schattenberg[4], Andrea De Gottardi[5], Annalisa Berzigotti[6], Jose Ignacio Fortea[7], Agustín Albillos[8], Edilmar Alvarado-Tapias[9], Marco Berning[10], Pawel Petryszyn[11], Min Lin[12], Philip Ambery[13], Jaime Bosch[14], Jan Oscarsson[13], Don Rockey[15]. *[1]Hospital Clínic de Barcelona, Barcelona, Spain; [2]Copenhagen University Hospital Hvidovre, Hvidovre, Denmark; [3]Medical University of Vienna, Vienna, Austria; [4]Saarland University Medical Center, Homburg, Germany; [5]Università della Svizzera Italiana, Lugano, Switzerland; [6]Bern University Hospital, University of Bern, Bern, Switzerland; [7]Department Hospital Universitario Marqués de Valdecilla, Santander, Spain; [8]Hospital Universitario Ramon y Cajal, Madrid, Spain; [9]Autonomus University of Barcelona, Barcelona, Spain; [10]University Hospital Dresden, Dresden, Germany; [11]AstraZeneca, Warsaw, Poland; [12]AstraZeneca, Gaitersburg, United States; [13]AstraZeneca, Gothenburg, Sweden; [14]Bern University Hospital, Bern, Switzerland; [15]Medical University of South Carolina, Charleston, United States*
Email: rockey@musc.edu

Background and aims: Endothelin-1 is a potent vasoconstrictor that contributes to intrahepatic vasoconstriction and portal hypertension (PH) in patients with cirrhosis. Endothelin receptor antagonists (ERA) may significantly reduce elevated portal pressure gradient but are associated with fluid retention. Sodium-glucose co-transporter 2 inhibitors (SGLT2i) induce osmotic diuresis. In this exploratory pilot study, the effects of the combination of zibotentan, an ER_A selective antagonist, and dapagliflozin, a selective SGLT2i, on hepatic venous pressure gradient (HVPG), safety and tolerability, were investigated.

Method: Eligible participants with compensated cirrhosis (MELD <15 and Child-Pugh A) of any etiology, except chronic cholestatic liver diseases, were randomized to placebo (n = 14) or combined 2.5 mg zibotentan/10 mg dapagliflozin (zibo/dapa, n = 14) in a 6 week parallel, double-blind study. The primary objectives were to evaluate change in HVPG, safety and tolerability of the treatment. Secondary objectives included changes in body weight, total body water, extracellular water volume (ECV) and blood pressure (BP). The absolute change in HVPG from baseline to week 6 (primary end point) was analysed in the full analysis set using an ANCOVA model.
Results: Patients had a mean (SD) age of 64.5 (10) years, 71% were males, 36% had type 2 diabetes, and cirrhosis was most commonly caused by ALD (39%) or MASLD (46%). The mean MELD score was 7.4 (range: 6–11); 46% were treated with non-selective beta-blockers. Baseline HVPG ranged from 6.5 to 19 mmHg (median: 10.0), and 16/28 had clinically significant PH (CSPH = HVPG ≥10 mmHg). One participant in each group did not complete the study. There was no difference in the absolute change in HVPG at week 6 (1.0 mmHg (90% CI: −0.31, 2.35)). In participants with more severe PH treated with zibo/dapa, there was a trend towards a decrease in HVPG (which was not seen in placebo treated participants). Systolic (−20 mmHg (90% CI: −31.8, −8.7)) and diastolic BP (−9.5 mmHg (90% CI: −13.4, −5.7)) decreased significantly with zibo/dapa vs placebo. The estimated difference in body weight and ECV change was −0.8 kg (90% CI: −1.86, 0.34) and −0.9 L (90% CI: −2.1, 0.3), respectively. Adverse events (AEs) were mild or moderate and similar in both groups. Two mild AEs of fluid retention in the zibo/dapa group and one in the placebo group were reported. One AE of orthostatic hypotension and one early withdrawal due to AE (headache) occurred in the placebo group. No serious AEs or DILI were observed.
Conclusion: Six weeks of treatment with zibo/dapa was safe and well tolerated in compensated cirrhosis. Fluid retention events were fewer than described in previous ERA trials. A reduction in HVPG was not observed, possibly reflecting a low number of patients with severe PH. An ongoing phase 2b study investigating patients with CSPH is powered to identify an effect on HVPG.

SAT-070

Argon plasma coagulation or endoscopic band ligation for gastric antral vascular ectasia: a randomized comparative analysis

Ashok Jhajharia[1,2,3], Shashank Singh[3], Prachis Ashdhir[3], Rupesh Pokharna[4]. [1]*Sawai Man Singh Medical College and Hospital, Jaipur, India;* [2]*Sawai Man Singh Medical College, Gastroenterology, Jaipur, India;* [3]*Sawai Man Singh Medical College, Jaipur, India;* [4]*Sawai Man Singh Medical College, Jaipur, India*
Email: drashokjhajharia@gmail.com

Background and aims: Gastric antral vascular ectasia (GAVE) causes iron-deficiency anemia and gastrointestinal bleeding, albeit uncommonly. Some patients need frequent transfusions. While APC effectively treats lesions, new methods like endoscopic band ligation (EBL) in periodic manner are being explored. The study assessed APC versus EBL for GAVE treatment, focusing on lesion obliteration and session frequency.
Method: The Department of Gastroenterology, SMS Medical College and Associated Hospital, Jaipur, conducted a single-centre, prospective, open-label, randomized controlled study. 60 participants with UGI bleeding from GAVE, confirmed by esophagogastroduodenoscopy (EGD), were chosen. Participants without prior GAVE endotherapy were divided into two groups: APC (30) and EBL (30). Sessions were held every 3–4 weeks until GAVE lesions cleared. Afterward, patients followed monthly for 6 months. The study is registered as CTRI Reg. No. CTRI/2023/10/058739.
Results: Outcome analysis compared 27 participants in the EBL group to 29 in the APC group. Both groups had similar baseline parameters. EBL required fewer treatment sessions (2.9 ± 0.6) than APC (3.2 ± 0.7). EBL achieved endoscopic obliteration earlier than APC ($p < 0.01$). At 6 months, both groups showed comparable bleeding control and lesion obliteration. Initially, both groups had similar hemoglobin levels, prior hospitalizations, and transfusion needs. After 6 months, the EBL group had better hemoglobin levels, fewer transfusions (non-significant), and fewer hospital visits ($p = 0.001$) as compared to APC group. While analysing both groups separately, the pre and post intervention values differ significantly in terms of haemoglobin values, hospitalisation and need for transfusion, with a p value <0.01.
Conclusion: Both EBL and APC are effective in treating GAVE lesions and relieving associated symptoms. Although outcomes were mostly comparable, EBL exhibited benefits in treatment duration, hospital stays and hemoglobin changes. Nonetheless, more comprehensive, long-term data is needed.

SAT-071

Pre-emptive TIPS should not be contra indicated in high-risk patients with acute variceal bleeding and alcohol hepatitis

Marika Rudler[1], Sarah Mouri[1], Charles Roux[1], Maxime Mallet[1], Manon Allaire[1], Frederic Charlotte[1], Philippe Sultanik[1], Charlotte Bouzbib[1], Dominique Thabut[1]. [1]*APHP Sorbonne Université Hôpital Pitié-Salpêtrière, Paris, France*
Email: marika.rudler@aphp.fr

Background and aims: Patients (pts) with severe alcoholic hepatitis (AH) may have a very bad prognosis, depending on liver function, response to corticosteroids and alcohol withdrawal. pTIPS is improving liver-transplant-free survival in high-risk cirrhotic patients with acute variceal bleeding (AVB). No data have been reported in pts with severe AH requiring a pre-emptive TIPS (pTIPS) placement (i.e. pts with Child-Pugh B and active bleeding or Child-Pugh C10–13 cirrhosis). Clinicians may intuitively think that pTIPS may not be as beneficial in high-risk cirrhotic patients with AVB and severe AH. This study aimed to evaluate the prevalence of severe AH in patients with AVB requiring pTIPS and to compare the clinical outcomes of pts with severe AH and pts with alcohol-related cirrhosis without severe AH.
Method: Monocentric prospective observational study including all consecutive pts with AVB who were treated with pTIPS between January 2018 and December 2022. The pTIPS policy was applied our center since 2011, and all patients with a suspected AH and a Maddrey's discriminant function ≥32 had a transjugular liver biopsy. Severe AH was systematically treated with corticosteroids. The primary end point was one-year transplant free survival (TFS) in patients with or without AH. Secondary end points were survival and rebleeding at one year.
Results: 248 pts with variceal bleeding were hospitalized in our ICU during the study period, and 67 were treated with pTIPS in a median delay of 37 hours after admission (male gender 86%, age 53, cause of cirrhosis alcohol in 73%, MetOH in 23%, other in 4%, Child-Pugh score 11, MELD score 21, hemoglobin 8.3 g/dL, HVPG before/after TIPS 15.5/7 mmHg). Overall, 21/67 pts (31.1%) had histologically proven AH. AH pts were significantly younger (49 vs 53 years, $p = 0.04$), had a higher MELD score (21 vs 19, $p = 0.03$) and a higher bilirubin level (130 vs 70 μmol/L, $p = 0.03$). Infection rate was similar between the 2 groups (38.1% vs 43.5%, $p = 0.88$). The one-year TFS was similar in AH and in non-AH pts (81% vs 72%, $p = 0.37$), as well as the one-year global survival (81% vs 81%, $p = 0.16$). Rebleeding rate was also similar in the 2 groups. The only factor independently associated with survival was MELD score at admission (OR = 0.92, 95% CI [0.82–0.99], $p = 0.04$).
Conclusion: Severe AH pts with AVB treated by pTIPS presented similar prognosis when compared to pts without severe AH. When suspected, severe AH should be histologically proven and pTIPS should be not be contra-indicated in those pts.

SAT-074

Hemodynamic profile of terlipressin and octreotide in patients with cirrhosis and portal hypertension. A randomized, double-blind clinical trial

Valeria Perez-Campuzano[1,2,3,4,5], Pol Olivas[1,2,3,4,5], Anna Baiges[1,2,3,4,5], Lara Orts[1,2,3,4,5], Sarah Shalaby[1,2,3,4,5], Asunción Ojeda[1,2,3,4,5], Fanny Turon[1,2,3,4,5], Virginia Hernández-Gea[1,2,3,4,5], Andres Cardenas[1,2,3,4,5], Juan Carlos García-Pagán[1,2,3,4,5]. [1]*Hospital Clínic Barcelona, Barcelona, Spain;* [2]*Institut de Investigacions Biomèdiques August Pi I Sunyer (IDIBAPS), Barcelona, Spain;* [3]*Departament de Medicina I Ciències de la Salut-University of Barcelona, Barcelona, Spain;* [4]*CIBEREHD (Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas), Barcelona, Spain;* [5]*Health Care Provider of the European Reference Network on Rare Liver Disorders (ERN-Liver), Barcelona, Spain*
Email: jcgarcia@clinic.cat

Background and aims: In patients with acute variceal bleeding terlipressin is administered by bolus injection every 4–6 hour. Continuous terlipressin infusion administration may achieve a more persistent reduction in portal pressure (PP) with fewer side effects. However, the potential time and profile reduction in PP after continuous terlipressin infusion have yet to be adequately assessed. This study aimed to compare the hepatic and cardiopulmonary hemodynamic effects and safety of terlipressin as a bolus vs. its continuous infusion or octreotide bolus followed by continuous infusion.

Method: This is a single-center, double-blinded, double-dummy, parallel-group, clinical trial in which 38 patients with cirrhosis and portal hypertension (HVPG ≥12 mmHg) were randomized to receive (during 2 hours): 1) bolus of octreotide (250 mcg) + continuous infusion (50 mcg/h) (n = 12; group OCTR), 2) bolus of terlipressin (1 mg) followed by continuous infusion of placebo (n = 12; group TERLBOL) or 3) bolus of placebo followed by a continuous infusion of terlipressin (initially 2 mg/day) (n = 14; group TERLINF). Hepatic venous pressure gradient, cardiopulmonary pressures and cardiac output were measured at baseline, and after 30, 60 and 120 minutes. If less than 10% HVPG reduction was observed at 30 min of the infusion, an independent observer, manipulated the infusion rate only doubling the rate of infusion (to 4 mg/day) in the TERLINF group.

Results: 68% of patients were male, with median age 59 years; there were no relevant differences in age, sex, etiology of liver disease, Child-Pugh score, or baseline HVPG in the 3 groups. In OCTR group, there was a non-significant reduction in HVPG (from 20.2 to 19.2 mmHg at 120 min (–4.9%; p:0.08)). PCP significantly decreased at 120 min (from 12.4 to 10.3 mmHg, p:0.0045). No significant changes in other cardiopulmonary parameters were observed. In TERLBOL group, there was a non-significant reduction in HVPG (from 18.4 to 17.5 mmHg at 120 min, –4.9%; p:0.14). However, PAP, PCP RAP, and mean arterial pressure significantly increased, and cardiac output and heart rate decreased within the 60–120 min of the observation. In TERLINF group, there were no significant changes in cardiopulmonary hemodynamics or HVPG despite doubling the dose after 30 min infusion in all patients. All treatments were well tolerated, and no adverse events were observed.

Conclusion: Octreotide produced a mild reduction in HVPG with no or mild systemic hemodynamic effects. A bolus administration of terlipressin also slightly reduced HVPG but with substantial changes in systemic hemodynamics. However a 2-hour continuous infusion of terlipressin did not induce significant changes in cardiopulmonary or hepatic hemodynamics. Further studies with different doses may help elucidate the optimal dosing of continuous terlipressin infusion in patients with cirrhosis and portal hypertension.

SAT-075-YI

Hemodynamic alterations and survival outcomes in cirrhotic patients with cirrhotic cardiomyopathy undergoing transjugular intrahepatic portosystemic shunt

Yaozu Liu[1], Fangmin Meng[2], Jingqin Ma[1], Wen Zhang[1], Zhiping Yan[1], Cuizhen Pan[2], Jianjun Luo[1]. [1]*Department of Interventional Radiology, Zhongshan Hospital, Fudan University, Shanghai, China, Shanghai, China;* [2]*Department of Echocardiography, Zhongshan Hospital, Fudan University, Shanghai, China, Shanghai, China*
Email: luo.jianjun@zs-hospital.sh.cn

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) is a commonly used method for managing portal hypertension, effectively reducing the portal pressure gradient (PPG). However, TIPS placement results in a sudden increase in central circulating blood volume, which requires precise regulation of the cardiovascular system. The presence of cirrhotic cardiomyopathy (CCM) indicates myocardial dysfunction which may lead to adverse outcomes in patients treated TIPS. However, evidence is scarce concerning cirrhotic patients with primarily viral etiologies and those undergoing treatment with 8 mm stents. The aim of our study was to explore whether patients with CCM can adapt to acute volume expansion induced by TIPS placement and whether CCM affects patient survival after TIPS in the short term.

Method: A consecutive case series of patients with cirrhosis aged 18–65 years who underwent TIPS were prospectively studied from June 2020 and January 2022. All participants underwent comprehensive transthoracic echocardiography (TTE) prior to (within 24 hours) TIPS and 48 hours postoperatively. Right atrial pressure (RAP), inferior vena cava pressure (IVCP), and portal venous pressure gradient (PPG) were measured before TIPS stent implantation, immediately after implantation, and 48 hours postoperatively. The primary end point of the study was mortality.

Results: From June 2020 to January 2022, 107 patients were included. According to the Cirrhotic Cardiomyopathy Consortium, 38 (35.5%) patients are considered CCM. The results indicate that right atrium pressure (RAP) increased post-TIPS and returned to baseline after 48 hours in CCM patients, while patients without CCM exhibited lower RAP than baseline after 48 hours. The echocardiographic results after 48 hours postoperatively indicated elevated left ventricular filling pressures, and a notable increase in the absolute value of LV-GLS was evident within the CCM cohort. The 1-year probability of all-cause mortality for CCM and no-CCM groups were 13.2% and 4.3% (log-rank test, $p = 0.093$). E/e' (p = 0.014, HR 1.42, 95%CI [1.073–1.886]), MELD score (p = 0.014, HR = 2.00, 95%CI [1.148–3.497]) and preoperative RAP ($p = 0.003$, HR = 1.63, 95%CI [1.178–2.266]) were significantly associated with the mortality.

Conclusion: In conclusion, cirrhotic patients with CCM also exhibit an effective regulatory capacity in response to hemodynamic alterations elicited by TIPS, without adversely impacting one-year survival outcomes.

SAT-076

Patients with hepatorenal syndrome and lower baseline mean arterial pressure derive significant survival benefit from treatment with terlipressin

Paul Yien Kwo[1], Nikolaos T. Pyrsopoulos[2], Paul J. Thuluvath[3], Sujit Janardhan[4], Khurram Jamil[5]. [1]*Stanford Health Care, Redwood City, CA, United States;* [2]*Rutgers New Jersey School of Medicine, Newark, NJ, United States;* [3]*Mercy Medical Center, Lutherville, MD, United States;* [4]*RUSH University, Chicago, IL, United States;* [5]*Mallinckrodt Pharmaceuticals, Bridgewater, NJ, United States*
Email: pkwo@stanford.edu

Background and aims: Patients with decompensated liver disease may develop hepatorenal syndrome (HRS), a rapidly progressive form of acute kidney injury. The underlying liver disease can also lead to a hypotensive state. Thus, patients with HRS may present with a mean arterial pressure (MAP) below the optimal target MAP of 65 mm Hg,

used in the management of septic shock. Terlipressin, a vasopressin analogue, is used to treat patients with HRS to improve renal perfusion and kidney function. This post hoc analysis of the largest database of patients treated with terlipressin in prospective Phase III studies aimed to examine the cohort of patients with a MAp <65 mm Hg for their clinical response to terlipressin.

Method: Patient data were collated from 3 Phase III placebo-controlled studies of terlipressin in patients with HRS and rapidly deteriorating kidney function (defined as a serum creatinine ≥2.5 mg/dL [OT-0401, REVERSE] or ≥2.25 mg/dL [CONFIRM]). Baseline MAP (ie, the pre-study value) <65 mm Hg was assessed for its association with HRS reversal (defined as SCr ≤1.5 mg/dL on treatment, up to 24 hours after the last dose of study drug). A multivariate logistic regression analysis was used to determine the association of baseline MAP with overall survival (OS). Patients with low baseline MAP (<65 mm Hg) were assessed for HRS reversal and OS at Day 90. The proportion of patients requiring renal replacement therapy (RRT) at Days 30, 60, and 90, were also assessed.

Results: In the pooled intent-to-treat patient dataset (N = 608), patients with a baseline MAp <65 mm Hg who received terlipressin had a higher likelihood of achieving HRS reversal versus placebo (odds ratio: 4.632, 95% confidence interval [CI]: 0.956–22.448). Further, among patients with a low MAP of <65 mm Hg at baseline (terlipressin, n = 49; placebo, n = 34), significantly more patients achieved HRS reversal with terlipressin than placebo (22.4% [11/49] vs 5.9% [2/34], p = 0.041). Baseline MAP was associated with OS in the terlipressin group (odds ratio: 0.966, 95% CI: 0.947–0.986, p < 0.001). Notably, patients with low MAP (<65 mm Hg) had significant improvements in OS estimates up to 90 days in the terlipressin group (p = 0.002), with 59.2% of patients alive at Day 90 (vs 26.5% in the placebo group). The proportion of patients with low baseline MAP who received RRT was numerically higher in the placebo group, at Days 30, 60, and 90 (terlipressin vs placebo: Day 30, 28.6% [14/49] vs 47.1 [16/34], p = 0.085; Day 60, 30.6% [15/49] vs 47.1% [16/34], p = 0.128; Day 90, 34.7% [17/49] vs 47.1% [16/34], p = 0.258).

Conclusion: Patients with HRS who presented with low MAP (<65 mm Hg) at baseline derived significant benefits from terlipressin treatment, including improved renal function (eg, HRS reversal) and improvements in OS, with over half of these patients surviving at Day 90.

Prevention of hepatic encephalopathy after transjugular intrahepatic portosystemic shunt by live combined Bifidobacterium and Lactobacillus tablets: a randomized controlled trial

Ying Li[1], Xin Quan[1], Xiuling Ye[1], Bo Wei[1], Huan Tong[1], Zhidong Wang[1], Yang Tai[1], Linhao Zhang[1], Can Gan[1], Shuaijie Qian[1], Xu Guo[1], Hao Wu[1]. [1]*Department of Gastroenterology and Hepatology, West China Hospital, Sichuan University, Chengdu, China*
Email: hxxhwh@163.com

Background and aims: Hepatic encephalopathy (HE) is a major complication in cirrhosis after transjugular intrahepatic portosystemic shunt (TIPS) and is closely related to gut microbiota. Efficacy of probiotics in the improvement of minimal HE (MHE) is well studied, but its effectiveness in preventing the first episode of overt HE (OHE) in patients after TIPS has not been established. We aimed to determine whether Live Combined Bifidobacterium and Lactobacillus Tablets, a commonly used probiotic preparation in China, reduce the risk of post-TIPS HE.

Method: We conducted a randomized controlled trial of 142 patients with cirrhosis receiving TIPS (ChiCTR2200062996). Patients were randomly assigned to receive probiotics (2 g three times daily) or not, lasting for 12 weeks after TIPS. The primary outcome was incidence of OHE within 24 weeks after TIPS. The secondary outcomes were the improvement of MHE [defined by number connection test-A (NCT-A) and digit symbol test (DST)] and incidence of other cirrhosis-related complications at 24 weeks.

Results: The incidence of post-TIPS OHE was 50% in the control group (n = 70), which was significantly reduced in the probiotics group (n = 72, 34%, p = 0.044). DST was significantly worsen at 24 week compared with baseline in the control group (30.95 ± 8.55 vs 29.34 ± 9.31, p = 0.017). By contrast, both DST (30.46 ± 9.95 vs 32.34 ± 11.16, p < 0.001) and NCT-A (66.28 ± 33.48 vs 60.63 ± 30.89, p = 0.001) were significantly improved at 24 week in the probiotics group. There was no significant difference in other cirrhosis-related complications and survival between the two groups.

Conclusion: Live Combined Bifidobacterium and Lactobacillus Tablets reduced the risk for OHE and improved cognitive function in cirrhosis patients receiving TIPS, with good tolerance. Multicenter study should be performed to provide further evidence.

SAT-078-YI

Prospective 5-year follow-up study of spleen stiffness measurement with a spleen-dedicated module (SSM@100 Hz) for predicting hepatic decompensation in cACLD: competitive risk analysis

Luigi Colecchia[1], Federico Ravaioli[1], Elton Dajti[1], Amanda Vestito[1], Arianna Gobbato[1], Francesca Lami[2], Matteo Renzulli[1], Matteo Serenari[1], Francesco Azzaroli[1], Davide Festi[1], Antonio Colecchia[2], Giovanni Marasco[1]. [1]*Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy;* [2]*Gastroenterology Unit, Department of Specialistic Medicines, University of Modena and Reggio Emilia, University Hospital of Modena and Reggio Emilia, Modena, Italy*
Email: luigi.colecchia@studio.unibo.it

Background and aims: Liver and spleen stiffness measurements using FibroScan® (SSM@50 Hz) have been endorsed by the Baveno VII consensus to assess clinically significant portal hypertension (CSPH), which is the main driver of hepatic decompensation (HD) in patients with compensated advanced chronic liver disease (cACLD). A new, dedicated 100 Hz module for spleen stiffness measurement (SSM@100 hz) seems to increase the clinical applicability of this technique, but there is currently no data available about its diagnostic performance for CSPH and its complications. The aim of our 5-years prospective study was to evaluate the role of the SSM@100 hz module compared to HVPG in predicting HD in a group of patients with cACLD.

Method: In this prospective study, we included patients with cACLD who underwent paired laboratory tests, liver stiffness measurement (LSM), hepatic venous pressure gradient measurement (HVPG), and SSM@100 Hz. We used univariate and multivariate competing-risks regression analyses to evaluate the outcome, taking liver transplantation or death into account as competitive events.

Results: In this study, 69 patients were enrolled and followed until either HD or a competitive event occurred. During a median follow-up of 69 [31–105] months, 34 patients developed HD. Among the HD events, 17/69 (24.6%), 13/69 (18.8%), and 28/69 (40.6%) patients developed variceal bleeding, hepatic encephalopathy, and ascites, respectively. The results of univariate analysis revealed that SSM median value (SSM@100 hz), male sex, metabolic etiology, presence of esophageal varices, bilirubin levels, and combined Baveno VII single cut-off rule-in criteria (by SSM@100 hz) were independent predictors of HD. Further multivariate analysis was conducted, and two models were developed. The first model revealed that age (Hazard Ratio (HR): 0.955, 95% confidence interval: (0.918–0.994), BMI (HR: 0.794 (0.663–0.951)), a higher SSM@100 hz value (HR: 1.05 (1.029–1.073)), higher bilirubin values (HR: 1.233 (1.108–1.371), and MASLD (HR: 18.997 (4.486–80.449)) were independent predictive factors of HD. The second model revealed that age (HR: 0.954 (0.918–0.991)), lower BMI (HR: 0.75 (0.604–0.931)), male sex (HR: 7.178 (1.359–37.91)), MASLD (HR: 20.911 (5.639–77.547)), and a higher HVPG value (HR: 1.14 (1.018–1.288)) were predictors of HD. The two

models showed comparable accuracy (AUROC 0.869 and 0.868) and competitive risk regression analysis demonstrated that both models could effectively predict the risk of HD over time (p < 0.001 for both models).
Conclusion: The SSM@100 Hz dedicated module is an accurate predictor of hepatic decompensation and can be useful to rule out the risk of complications at 5 years in patients with compensated cirrhosis.

SAT-080-YI
Residual minimal ascites 3 months after TIPS implantation indicates risk of further decompensation and death
Lukas Hartl[1,2], Jim Benjamin Mauz[3], Andrea Kornfehl[1], Sarah Lisa Schütte[3], Paul Hemetsberger[1], Theresa Müllner-Bucsics[1,2], Mathias Jachs[1,2], Anja Tiede[3,4], Hannah Schneider[3], Michael Schwarz[1,2], Bernhard Meyer[5], Lukas Reider[6], Maria Schoder[6], Michael Trauner[1], Mattias Mandorfer[1], Benjamin Maasoumy[3,4], Tammo Lambert Tergast[3], Thomas Reiberger[1,2,7]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [3]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany; [4]German Center for Infection Research (DZIF), Hannover/Braunschweig, Germany; [5]Department of Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany; [6]Division of Interventional Radiology, Department of Radiology, Medical University of Vienna, Vienna, Austria; [7]Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria*
Email: lukas.a.hartl@meduniwien.ac.at

Background and aims: Placement of a transjugular intrahepatic portosystemic shunt (TIPS) improves control of recurrent/refractory ascites and increases survival. However, ascites may not fully resolve in all patients after the procedure and especially the impact of residual minimal ascites remains unknown. We investigated the impact of different grades of residual ascites at 3 months after TIPS placement on further clinical outcome of patients.
Method: We included patients with cirrhosis undergoing implantation of covered TIPS due to recurrent/refractory ascites in Vienna (between 2000–2022) and in Hannover (between 2013–2021). Exclusion criteria were hepatocellular carcinoma, vascular liver disease, and previous liver transplantation. Only patients with available abdominal imaging 3 months (M3) after TIPS were included and followed-up for further decompensation (paracentesis or other ascites-related complication, hepatic encephalopathy or variceal bleeding) and death starting at this time point (M3). Competing risk regression was performed considering liver transplantation and death as competing events.
Results: In total, 297 patients (71.7% male, median age 57.5 years, median MELD at M3 14) were included. Alcohol-related liver disease (71.7%) was the main etiology of cirrhosis. With TIPS implantation the median portal pressure gradient (PPG) was reduced from 18 to 7 mmHg. At M3 after TIPS implantation, n = 106 (35.7%) patients did not show any ascites on imaging, while n = 84 (28.3%) had minimal and n = 107 (36.0%) had moderate/severe ascites. PPG after TIPS implantation was similar in all 3 groups (median 6–7 mmHg; p = 0.284). Comparing the outcomes of patients with no vs. minimal ascites 3 months after TIPS, competing risk regression adjusted for age, MELD, sodium and albumin at M3 showed that minimal ascites was an independent predictor of further decompensation (adjusted subdistribution hazard ratio [aSHR]: 1.66; 95% confidence interval [95%CI]: 1.03–2.67; p = 0.038) and death (aSHR: 1.60; 95%CI: 1.01–2.55; p = 0.047). Of note, among patients with moderate/severe ascites, the 1-year-cumulative incidence of further decompensation after M3 tended to be higher than in the no or minimal ascites cohort (34.9% vs. 27.0%; p = 0.101) and more patients with moderate/severe ascites at M3 underwent liver transplantation (9.4% vs. 2.7%; p = 0.013). Importantly, patients with moderate/severe ascites at M3 after TIPS had a significantly higher 1-year-cumulative incidence of death (26.0% vs. 9.4%; p < 0.001).
Conclusion: Patients with cirrhosis who still exhibit ascites 3 months after TIPS implantation have a worse clinical outcome. While moderate/severe ascites is particularly detrimental without liver transplantation, even minimal residual ascites at M3 represents an independent risk factor for further decompensation and death.

SAT-081
Association between alleviation of portal vein thrombosis and mortality rate in cirrhotic patients: a prospective cohort study
Xiaoquan Huang[1], Yingjie Ai[1], Ling Wu[1], Shiyao Chen[1]. *[1]Zhongshan Hospital, Fudan University, Shanghai, China*
Email: huang.xiaoquan@zs-hospital.sh.cn

Background and aims: Portal vein thrombosis (PVT) is common in patients with cirrhotic patients with a history of variceal bleeding. In the present study, we aimed to investigate the influence of PVT on the endoscopic treatment for prevention of variceal re-bleeding.
Method: This study includes 625 consecutive cirrhotic patients with a history of gastroesophageal variceal bleeding and received endoscopic treatment. They were divided into the PVT group (n = 166) and the non-PVT (n = 459) group according to computer tomography angiography. Patients were follow-up to 3 years or death, and re-bleeding and mortality rates were compared between the groups.
Results: PVT group had a significantly increased 3-year all-cause mortality rate (18.8% vs. 7.6%, p = 0.0001) 3-year rebleeding rate (36.5% vs. 29.3%, RR 1.4, 95% CI 1.0–1.9, p = 0.0468) when compared to the non-PVT group. After adjusting covariates including age, Child-Pugh score, type of gastroesophageal varices, the usages of NSBBs, the increased mortality (aHR 2.5, 95% CI 1.5–4.2; p = 0.001) and re-bleeding rate (aHR 1.4, 95%CI 1.0–1.9; p = 0.046) in the PVT group persists. In patients with PVT, the alleviation of PVT was associated with a significantly lower mortality rate in 3 years (aHR 0.2, 95% CI 0.05–0.095, p = 0.043). And anticoagulation treatment did not increase the rebleeding rate.
Conclusion: Cirrhotic patients with PVT had a worse prognosis after endoscopic management for secondary variceal bleeding prophylaxis than patients without PVT. Anticoagulation therapy exhibited predisposition to ameliorate the prognosis without increasing the re-bleeding rate.

SAT-082
A phase 2 study of OCE-205, a novel, selective vasopressin receptor mixed agonist-antagonist: positive proof-of-concept established in subjects with cirrhosis and hepatorenal syndromeacute kidney injury (HRS-AKI)

Email: aallegretti@mgh.harvard.edu

Background and aims: OCE-205 is a mixed agonist-antagonist selective for the vasopressin 1a (V1a) receptor with no vasopressin 2 (V2) receptor activity across a wide therapeutic range. It is being developed for treatment of HRS-AKI, a serious renal complication in subjects with cirrhosis, portal hypertension and ascites. The safety, pharmacokinetics (PK) and efficacy of OCE-205 were evaluated in subjects with HRS-AKI.
Method: A randomized, double-blind, placebo-controlled, dose-ranging study (ClinicalTrials.gov: NCT05309200) was conducted at 23 North American centers in subjects aged 18–75 years diagnosed with decompensated cirrhosis, ascites and HRS-AKI. Subjects received a continuous IV infusion of OCE-205 8, 15, 30 or 50 mcg/h or placebo. The primary end point was time to confirmed clinical improvement for 2 consecutive days defined as serum creatinine (SCr) <1.5 mg/dL; or if SCr was 1.5 to 1.8 mg/dL at screening, a reduction of 0.3 mg/dL.
Results: Subjects were randomized to OCE-205 (n = 37) or placebo (n = 10). Baseline characteristics were balanced across OCE-205 and placebo cohorts; mean SCr 2.6 vs 2.3 mg/dL, mean MELD score 27.9 vs 25.8, and mean total bilirubin 6.09 vs 4.35 mg/dL. The etiology of cirrhosis for OCE-205 vs placebo cohorts was MASH (29.7% vs 30.0%), alcohol (51.4% vs 60.0%), and other (18.9% vs 10.0%). PK of OCE-205 were dose proportional: clearance, half-life, and volume of distribution were 12.6 L/h, 2.6 h and 30 L, respectively. The primary end point was met in 48.6% of subjects with OCE-205 and 30.0% with placebo (p = NS). Complete response was observed in 54.5%, 54.5%, 28.6% and 50% in 8, 15, 30 and 50 mcg/h cohorts vs 30% in placebo, respectively. Partial response (≥30% reduction in SCr) was observed in 18.2%, 18.2%, 14.3% and 0% at OCE-205 doses of 8, 15, 30 and 50 ug/h respectively vs 10% with placebo. Mean change in MELD score was −2.3 with OCE-205 and −3.4 with placebo. In OCE-205 responders, mean arterial pressure increased (≥5 mm Hg) at 2 and 4 h post infusion, then decreased after stopping the infusion. Drug-related AEs occurred in 7 (18.9%) subjects with OCE-205. Drug-related bradycardia (HR <60 bpm) occurred in 6 (16.2%) subjects with OCE-205; most events were asymptomatic, requiring no intervention. No new/unexpected safety findings, no events of ischemia, and no related events of pulmonary edema, fluid overload or cardiac failure occurred.
Conclusion: OCE-205 was well tolerated, with no evidence of excessive vasoconstriction and no ischemic AEs, and no related events of pulmonary edema or serious infections, at any dose level. OCE-205 had a predictable, capped maximal efficacy that was effective in reversing HRS-AKI in more patients than placebo. OCE-205 carries great promise to become a novel HRS therapy with a favorable risk/benefit profile.

SAT-083-YI

Changes in mean arterial pressure are inadequate to guide treatment with terlipressin and albumin in patients with hepatorenal syndrome-acute kidney injury

Valeria Calvino[1], Anna Barone[1], Marta Tonon[1], Carmine Gambino[1], Simone Incicco[1], Roberta Gagliardi[1], Nicola Zeni[1], Paolo Angeli[1], Salvatore Piano[1]. [1]Unit of Internal Medicine and Hepatology, Department of Medicine, University and Hospital of Padova, Padova, Italy
Email: salvatore.piano@unipd.it

Background and aims: Terlipressin and albumin are the first-line treatment of hepatorenal syndrome (HRS-AKI). Terlipressin is titrated according to changes in serum creatinine (SCr) on Day-3. An increase in mean arterial pressure (MAP) was associated with resolution of HRS-AKI, leading some experts to suggest titration of terlipressin according to MAP changes. However, the optimal MAP targets remain unclear. The aim of this study was to evaluate the association between MAP changes on Day-3 and response to treatment with terlipressin and albumin in patients with HRS-AKI.
Method: Patients with cirrhosis and HRS-AKI treated with terlipressin and albumin as continuous infusion were identified. Clinical and biochemical data, including MAP, were collected on Day-0 and Day-3. Patients were followed up until death, liver transplantation or up to 90 days. The primary end point was response to treatment (i.e. SCr <1.5 mg/dl). Death and transplant were considered competing risks for response to treatment. Secondary end points were early response (i.e. reduction of SCr > 25% vs Day-0 on Day-3) and 90-day mortality.
Results: We enrolled 108 patients (mean age = 59 ± 9 years; male = 70%; MELD = 29 ± 7; alcohol related cirrhosis = 58%). On Day-3 most of patients had an increase in MAP (delta MAP = 5.6 ± 11.5 mmHg; p < 0.001). Response to treatment was found in 56 patients (52%). Delta MAP on Day-3 was not significantly different between responders and non-responders (7.8 vs 4.4 mmHg; p = 0.218). Delta MAP on day-3 was not significantly different between early responders and non-responders (5.3 vs 6.0 mmHg; p = 0.751). Responders had lower baseline SCr (2.91 vs 2.51 mgl/dl; p = 0.016) and higher rate of precipitating factors of HRS-AKI (61 vs 38%; p = 0.007). In multivariable analysis (adjusted for age, precipitating factors, baseline SCr and ACLF grade) delta MAP on Day-3 was not significantly associated with response to treatment (sHR = 1.00; p = 0.870). Lower baseline SCr (sHR = 0.75; p = 0.012) and precipitating factors of HRS-AKI (sHR = 1.89; p = 0.014) were independent predictors of response. Delta MAP on Day-3 was not associated with 90-day mortality (sHR = 0.99; p = 0.530). The risk of 90-day mortality was significantly lower in responders than in non-responders (sHR = 0.45; p = 0.004).
Conclusion: Delta MAP on Day-3 was not associated with response to treatment with terlipressin and albumin. These findings do not support the use of MAP changes on Day 3 for titrating the dose of terlipressin in patients with HRS-AKI.

SAT-086-YI

Assessment of portal hypertension risk by liver and spleen stiffness using real-time 2D-shear wave elastography-the prospective AiXplore study

David Bauer[1,2,3], Mathias Jachs[1,2,4], Lukas Hartl[1,2,4], Michael Schwarz[1,2], Lorenz Balcar[1,2,4], Benedikt Hofer[1,2,4,5], Nina Dominik[1,2,4], Bernhard Scheiner[1,2,4], Albert Friedrich Stättermayer[1,2], Benedikt Simbrunner[1,2,4,5], Rafael Paternostro[1,2], Till Schöchtner[1], Friedrich Haimberger[1], Nicolas Balutsch[1], Michael Trauner[1], Mattias Mandorfer[1,2,4], Thomas Reiberger[1,2,4,5]. Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [3]IV. Department of Internal Medicine for Gastroenterology and Hepatology, Klinik Ottakring, Vienna, Austria; [4]LBG clinical research group MOTION, Medical University of Vienna, Vienna, Austria; [5]Christian-Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria
Email: david.bauer@meduniwien.ac.at

Background and aims: Liver (LSM) and spleen (SSM) stiffness measurement using real-time 2D-shear wave elastography (2D-SWE) present as promising non-invasive tests (NITs) for estimating the risk of clinically significant portal hypertension (CSPH), defined as a hepatic venous pressure gradient (HVPG) of ≥10 mmHg.
Method: In the prospective AiXplore study, patients with chronic liver disease underwent concurrent measurements of HVPG and real-time 2D-shear wave elastography (2D-SWE) on the Aixplorer Ultimate device. We applied reliability criteria of IQR/Med ≤0.30 for 2D-SWE-LSM and median SD of single measurements <15 kPa for 2D-SWE-SSM. The Pearson correlation of LSM and SSM with HVPG was calculated, and their diagnostic accuracies for CSPH were assessed using receiver operator characteristics analysis (AUC).
Results: Of 366 patients with combined LSM, SSM, and HVPG measurements (66.4% men, median age: 56.5 [IQR: 48.0–64.0] years, median HVPG: 15.0 [10.0–19.0] mmHg) 77.9% and 46.4%, respectively, showed CSPH or HVPG ≥16 mmHg. Median 2D-SWE LSM was 38.5 [19.9–60.9] kPa and 269 patients (68.0%) had LSM ≥25 kPa. Median SSM was 55.3 [38.3–72.3] kPa and 212 (57.9%) had SSM ≥50 kPa. 278 LSM (77.0%) and 256 (69.9%) SSM met the reliability criteria. The Pearson R for HVPG and LSM was 0.53 overall, increasing to 0.59 for reliable LSM; for HVPG, and SSM, it was 0.43, rising to 0.52 in reliable SSM (all p < 0.001). The AUC for CSPH was 0.83 (CI95%: 0.77–0.89) for LSM and 0.77 (0.71–0.83) for SSM, increasing to 0.88 (0.82–0.94) and 0.82 (0.75–0.89) for reliable LSM and SSM, respectively. The 90%-specific rule-in and 90%-sensitive rule-out cutoffs for CSPH were ≥27.0 kPa and <18.0 kPa for LSM, and ≥52.0 kPa and <30.0 kPa for SSM, respectively. In patients with both LSM ≥25 kPa and SSM ≥50 kPa the observed prevalence of CSPH was 98.1% (101/103), while in patients with both LSM <18 kPa and SSM <30 kPa, the observed CSPH prevalence was 11.5% (3/26). This algorithm left a grey zone of 37.4% (77/206) of patients.
Conclusion: For 2D-SWE-SSM median SD < 15 kPa seems useful as a reliability criterion. 90% -specific/sensitive 2D-SWE LSM/SSM cut-offs for CSPH assessment were calculated. A clinical algorithm based on 2D-SWE LSM > 25andSSM > 50 kPa can rule-in and 2D-SWE LSM < 18.0 and SSM < 30.0 kPa can rule-out CSPH.

SAT-087-YI

The presence of NOD2 risk variants is associated to a higher incidence of first decompensation in patients with cirrhosis and varices

Henrik Karbannek[1], Matthias Reichert[2], Robin Greinert[3], Alexander Zipprich[1], Frank Lammert[4], Cristina Ripoll[1]. *[1]Department of Internal Medicine IV, Jena University Hospital, Jena, Germany; [2]Department of Internal Medicine II Saarland University Hospital, Homburg, Germany; [3]Department of Internal Medicine I, Martin Luther University Halle-Wittenberg, Halle, Germany; [4]Hannover Medical School (MHH), Hannover, Germany*
Email: henrik.karbannek@icloud.com

Background and aims: *NOD2* mutations are associated with an impaired gut mucosal barrier function. Prevalence of *NOD2* risk variants is higher in patients with cirrhosis than in the general population. According to the systemic inflammation hypothesis, bacterial translocation plays a major role in the development of decompensation. Previous studies indicated that the presence of *NOD2* variants modulates the development of infection in compensated rather than decompensated cirrhosis (PMID 30702490). The aim was to evaluate whether the presence of *NOD2* variants is associated with the development of first decompensation in compensated cirrhosis.
Method: Secondary analysis of a prospectively collected database (n = 1000) of consecutive patients with cirrhosis, who were screened for the randomized controlled INCA trial (EudraCT 2013-001626-26) at two academic medical centers between 2014 and 2019. Only patients with previously compensated disease were included in this analysis. Patients were followed up until the first decompensation, as defined by the development of ascites, variceal bleeding, or hepatic encephalopathy. Patients with and without *NOD2* variants were compared. Stratified analysis according to the presence or absence of varices was performed. Univariate and multivariate Cox regression analysis was performed.
Results: Overall, 360 patients [239 (66%) men, median age 61 (53–69) years, 70 (19%) with *NOD2* variants, 90 (25%) with varices] were followed for a median of 9 (4–16) months. No differences were observed in baseline characteristics between groups according to *NOD2* status, except for the use of beta-blockers (45% vs. 32% among *NOD2* variant carriers and non-carriers, respectively). During follow-up, 34 patients (12%) developed their first decompensation. There were no differences in the incidence of first decompensation during follow-up according to *NOD2* status [HR 1.75 (95%CI 0.84–3.67)]. On multivariate analysis with beta-blockers, MELD, *NOD2* variants and varices, only MELD remained an independent predictor. Stratified analysis was performed given the association between varices and decompensation. Among the 90 patients with varices, 18 (24.4%) carried a *NOD2* variant. These patients had greater incidence of first decompensation [HR 3.00 (95%CI 1.08–8.32)], determined mainly by a higher incidence of ascites [HR 3.32 (1.07–10.32)] during follow-up as compared to patients with varices without a *NOD2* variant. On multivariate analysis in the subgroup with varices, MELD [1.18 (95%CI 1.06–1.32)] and *NOD2* variants [2.91 (95%CI 0.95–8.89)] variants were independent predictors of decompensation.
Conclusion: The presence of *NOD2* risk variants leads to a greater incidence of first decompensation in compensated patients with varices. This observation could guide individualized strategies for the prevention of complications in cirrhosis.

SAT-088

Safety and Efficacy of the Natriuretic Peptide Ularitide in Refractory Cirrhotic Ascites: Interim Analysis of a Randomized Controlled Trial

Rasmus Gantzel[1,2,3], Emilie Møller[1], Niels Kristian Aagaard[1], Hugh Watson[4], Peter Jepsen[1,2], Henning Grønbæk[2,5]. *[1]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus N, Denmark; [2]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [3]Department of Medicine, Regional Hospital Gødstrup, Herning, Denmark; [4]Evotec ID, Medical Development and Translational Sciences, Lyon, France; [5]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus N, Denmark*
Email: ragant@rm.dk

Background and aims: Refractory ascites denotes the most severe ascites status in patients with cirrhosis and portal hypertension. The condition develops as dietary and medical treatments are ineffective or induce intolerable side effects. Therefore, new treatments are warranted for refractory ascites, and we here investigate the efficacy and safety of the natriuretic peptide ularitide in patients with refractory cirrhotic ascites.
Method: We conducted a randomized, placebo-controlled clinical trial using a continuous intravenous infusion of ularitide to manage refractory ascites. We randomized 17 participants in a 2:1 ratio between ularitide (n = 11) and placebo (n = 6). While hospitalized and closely monitored, the participants received the treatment for up to 48 hours as an add-on to any habitual diuretic treatment. The dose regimen allowed individualization of the therapy according to renal

responsiveness and safety. The primary efficacy end point was change in renal water excretion and the main secondary end points were changes in renal sodium excretion rate and body weight. Initially, all participants started with a 30 ng/kg/min dose. However, the starting dose was reduced to 20 ng/kg/min halfway through the trial period because of safety concerns.
Results: The background characteristics were similar for participants randomized to ularitide and placebo. The urine volume decreased after 24 hours of ularitide treatment compared with the baseline level ($p = 0.04$) and decreased more in patients randomized to ularitide than placebo ($p = 0.06$). There was no effect of ularitide on renal sodium excretion rate or body weight change compared with placebo ($p = 0.20$ and $p = 0.65$). The participants treated with ularitide developed significant reductions in systolic blood pressure and the incidence rate ratio of adverse reactions in ularitide vs. placebo was 8.5 (95% CI: 2.0–35, $p = 0.003$).
Conclusion: Ularitide in doses of 30 and 20 ng/kg/min did not show clinically meaningful effects on urine volume and renal sodium excretion rate after 24 hours of continuous intravenous infusion. The participants randomized to ularitide developed significant reductions in blood pressure and had more adverse reactions compared with placebo. Further studies are needed to clarify the optimal dose and treatment regimen of ularitide in patients with refractory ascites.

SAT-089
Evaluating the correlation between portal pressure, collagen proportional area, and α-smooth muscle actin in patients with portal hypertension due to MASH cirrhosis
Pol Boudes[1,1], Michael Inkmann[1], Seth Zuckerman[1]. [1]*Galectin Therapeutics, Norcross, United States*
Email: pfbcmo@gmail.com

Background and aims: In liver cirrhosis, the evaluation of the amount of collagen on histology is of interest as it is related to the pathophysiology of the disease. The Kleiner/Brunt and Ishak staging of fibrosis are frequently used in liver diseases but in cirrhotic patients they lack granularity to evaluate disease prognosis or response to treatment. The collagen proportional area (CPA), the amount of tissue that is occupied by collagen could address this shortfall. Similarly, α-smooth muscle actin (α-SMA), an indicator of stellate cells activation, and its proportional area could provide further pathophysiologic information. We studied patients with compensated cirrhosis due to Metabolic-dysfunction Associated SteatoHepatitis (MASH) and portal hypertension (PH) to evaluate the correlation between CPA, α-SMA, and portal pressure estimated by the hepatic venous pressure gradient (HVPG).
Method: The population consisted of patients with MASH cirrhosis (NCT02462967). Cirrhosis was confirmed by liver histology (Ishak 5 or 6, Brunt F4). Patients had no current or recent history of alcohol consumption and no cirrhotic decompensation (varix bleeding, ascites, encephalopathy). Data were collected at time of eligibility. PH was evaluated hemodynamically and HVPG was required to be >6 mm Hg. The collagen proportional area was evaluated with trichrome staining and represented the surface of biopsy tissue occupied by collagen divided by the total amount of tissue, expressed as a %. α-SMA was evaluated with a specific immuno-staining and expressed the same way. Descriptive statistics, mean, standard deviation (SD), and ranges are provided as well as correlation between CPA, α-SMA, and HVPG.
Results: The population consisted of 162 patients The mean age was 58.2 (8.4), 70% were females. All patients were Brunt F4, and most (70.4%) Ishak 6. The mean (SD) CPA was 10.6 (6.1), range 1 to 29%. The mean (SD) α-SMA was 14.2 (10.8), range 1 to 58%. The mean (SD) HVPG was 12.2 (4.2), range 6 to 27.5 mm Hg. CPA was moderately correlated with α-SMA (R^2 0.427). Neither CPA nor α-SMA were correlated with HVPG, R^2 0.023 and 0.020, respectively.
Conclusion: In this well-defined cohort of patients with PH and compensated MASH cirrhosis while the collagen proportional area and the α-smooth muscle actin were somewhat correlated, neither of these parameters were correlated with portal pressure (HVPG), a major indicator of disease prognosis.

SAT-090-YI
Improvement of liver frailty, hand grip strength and mid-upper arm circumference in cirrhotic patients after TIPS insertion
Martin Kabelitz[1], Anja Tiede[1,2], Hannah Schneider[1], Jim Benjamin Mauz[1], Alena Friederike Ehrenbauer[1], Liv Grete Ahl[1], Lea Wagner[1], Heiner Wedemeyer[1,2,3], Benjamin Maasoumy[1,2], Lisa Sandmann[1,3]. [1]*Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany;* [2]*German Center for Infection Research (DZIF), Hannover/Braunschweig, Germany;* [3]*Excellence Cluster RESIST, Excellence Initiative Hannover Medical School, Hannover, Germany*
Email: Kabelitz.Martin@mh-hannover.de

Background and aims: Frailty and sarcopenia are highly prevalent in patients with liver cirrhosis and clinically significant portal hypertension. Moreover, they are associated with an increased risk of hepatic decompensation and reduced quality of life. So far, data on frailty following transjugular intrahepatic portosystemic shunt (TIPS) placement is lacking. Our study aims to investigate the effects of TIPS insertion on frailty and sarcopenia.
Method: From 2019 to 2023, we prospectively enrolled 190 patients who underwent TIPS insertion at Hannover Medical School. A structured follow-up (FU) with outpatient visits at one, three, six, and 12 months after TIPS insertion was conducted. Frailty was assessed using the "Liver Frailty Index" (LFI) categorizing patients into "frail," "pre-frail," and "robust" groups. Hand grip strength (HGS) and mid-upper arm circumference (MUAC) were measured using anthropometric instruments. FU time points were combined into early follow-up (EFU, combining FUs at one and three months) and late follow-up (LFU, combining FUs at six and 12 months). Statistical analyses were performed using paired t-tests and McNemar's test, with p values adjusted using the Bonferroni-Holm method.
Results: A total of 130 patients qualified for the final analysis after excluding cases with Budd-Chiari syndrome, absence of cirrhosis, HCC outside the Milan criteria, or insufficient baseline data on HGS, MUAC or LFI. Patients were predominantly male (65%) with a median MELD score of 11 (IQR 9–14). The main indication for TIPS placement was refractory ascites (70%). At baseline (BL), mean HGS and MUAC were 24.3 ± 9.7 kg and 25.8 ± 5 cm, with 43% and 70% of patients showing abnormal parameters, respectively. After TIPS insertion, HGS improved significantly from BL to LFU (25.4 ± 10.4 kg vs. 28.4 ± 11 kg, $p = 0.005$). Similarly, MUAC increased significantly from BL to EFU (25.7 ± 4.8 cm vs. 26.5 ± 4.4 cm, $p = 0.002$) and from BL to LFU (26.1 ± 4.4 cm vs. 28.7 ± 4.9 cm, $p < 0.001$). At BL, 44%, 50% and 6% of patients were classified as "frail," "pre-frail," and "robust" by LFI, respectively. After TIPS insertion, overall mean numeric LFI did not change from BL to EFU or LFU. However, numerical LFI of "frail" patients improved from BL to EFU (5.31 ± 0.69 vs. 4.79 ± 0.85, $p = 0.005$) and from BL to LFU (5.08 ± 0.55 vs. 4.38 ± 0.65, $p = 0.03$). Overall, the proportion of "frail" patients significantly decreased from BL to EFU (47% to 36%, $p = 0.04$) and LFU (48% to 19%, $p = 0.03$). No significant differences were found between "frail" patients at BL who did or did not show improvement of frailty during follow-up, while frailty at BL was the only identified risk factor for frailty at EFU.
Conclusion: TIPS insertion has the potential to improve frailty, HGS and MUAC. Furthermore, our results suggest that individuals with a high degree of frailty benefit most. This should be considered for patient selection.

SAT-092-YI

The Toulouse algorithm identifies patients with an increased risk of cardiac decompensation only in patients with TIPS for refractory ascites

Emma Vanderschueren[1,2], Youri Bekhuis[3], Jan Clerick[1], Philippe Meersseman[4], Alexander Wilmer[4], Eveline Claus[5], Lawrence Bonne[5], Guido Claessen[6], Chris Verslype[1], Geert Maleux[5], Wim Laleman[1,2]. *[1]Department of Gastroenterology and Hepatology, University Hospital Leuven, Leuven, Belgium; [2]Department of Chronic Diseases, Metabolism and Aging (CHROMETA), Catholic University of Leuven, Leuven, Belgium; [3]Department of Cardiology, University Hospital Leuven, Leuven, Belgium; [4]Department of General Internal Medicine, Medical Intensive Care Unit, University Hospital Leuven, Leuven, Belgium; [5]Department of Radiology, Interventional Radiology, University Hospital Leuven, Leuven, Belgium; [6]Department of Cardiology, Jessa Hospital Campus Virga Jesse, Hasselt, Belgium*
Email: emma.vanderschueren@student.kuleuven.be

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) placement is an effective, possibly life-saving, treatment for complications of portal hypertension. The pressure shift induced by the stent can lead to the development of cardiac decompensation (CD) in some cases. We investigated the incidence of CD, possible variables associated with CD and the validity of the Toulouse algorithm for risk prediction of CD post-TIPS.
Method: All patients receiving TIPS for variceal bleeding (VB) or refractory ascites (RA) between 2011 and 2021 were retrospectively reviewed. A total of 106 patients (41.5% VB, 58.5% RA) had echocardiography and NT-proBNP results available and were included. Development of CD between time of TIPS placement and occurrence of liver transplantation, death or loss-to-follow-up was recorded. Competing risk regression analysis was performed to assess which baseline variables predicted occurrence of CD post-TIPS.
Results: A total of 12 patients (11.3%) developed CD after a median of 11.5 days (IQR 4 to 56.5) post-TIPS. Patients who developed CD were significantly older than patients who did not (66.8 vs 59.8 years old, p = 0.045). Other baseline parameters were not significantly different, specifically active alcohol abuse, MELD score, Child-Pugh score, pressure gradients before and after TIPS, NT-proBNP and echocardiographic parameters were similar. Multivariate regression showed age (HR 1.06, CI 1.01–1.11, p = 0.019), albumin (HR 1.10, CI 1.03–1.18, p = 0.009) and NT-proBNP (for every 100 ng/L increase HR 1.04, CI 1.00–1.07, p = 0.023) predicted CD in the RA group. No clear predictors were found in those receiving TIPS for VB. Correspondingly, the Toulouse algorithm successfully identified patients at risk for CD, however only in the RA population (zero risk 0% vs. low risk 12.5% vs. high risk 35.3% with CD; p = 0.003). CD post-TIPS was well managed with diuretics in most cases and did not lead to increased mortality in our series (1-year mortality 44.7% without CD vs. 33.3% with CD, p = 0.455).
Conclusion: CD is not an infrequent complication post-TIPS occurring in 1/10 patients and mostly in the first month post-TIPS. The Toulouse algorithm can identify patients at risk of CD, though only in patients receiving TIPS for RA. Allocation to the high-risk category warrants close monitoring but should not preclude TIPS placement.

SAT-093-YI

Sustainable endoscopy in hepatology: quantifying the effect of applying BAVENO VII guidelines on the endoscopic carbon footprint; a multi-centred regional assessment

Dylan Angel[1], Sanjayan Anandanadarajah[2], Mohannad Alqedrh[3], Saad Butt[2], Ayman Elkholi[3], Noam Pinchas Gessler Roth[4], Emily Kooner[5]. *[1]East and North Hertfordshire Trust, Stevenage, United Kingdom; [2]Queen Elizabeth Hospital Kings Lynn, Kings Lynn, United Kingdom; [3]Norfolk and Norwich University Hospital, Norwich, United Kingdom; [4]Mid and South Essex NHS Foundation Trust, London, United Kingdom; [5]East and North Hertfordshire NHS Trust, Stevenage, United Kingdom*
Email: dylan.angel@nhs.net

Background and aims: With the global move towards net zero, the UK NHS has committed to reduce its carbon footprint by 80% between 2028–2033 and achieve net zero by 2040 [1]. Endoscopy is the third greatest contributing department per daily bed occupied [2], therefore re-evaluation of endoscopic indications is an important factor in achieving net zero. The Baveno VII guidelines recommend that patients with compensated cirrhosis and Fibroscan scores of less than 20 kPa and platelet counts greater than 150×10^9/L are unlikely to have clinically significant varices [3], thereby negating the need for endoscopic surveillance. By applying these guidelines in conjunction with estimated energy costs from previously published data [4], we aimed to retrospectively calculate the regional endoscopic carbon footprint generated by potentially avoidable gastroscopies across four NHS trusts with access to Fibroscan.
Method: In this retrospective study, data was analysed from four hospitals in the East of England. Patients undergoing primary variceal surveillance between January 2021 and October 2023 were identified and their pre-endoscopy Fibroscan results and platelet counts were assessed against the criteria listed in Baveno VII. Exclusion criteria comprised features of decompensation, previous variceal haemorrhage or portal- or splenic vein thrombosis. We defined Baveno VII non-compliance as having both Fibroscan and platelet data available but not meeting the required cut offs, or only having a platelet count available above 150×10^9/L. Patients with no Fibroscan data and a platelet count less than 150×10^9/L were deemed indeterminate. Use of water, mass and energy costs per procedure were estimated using previously published data.
Results: 730 patient records meeting eligibility criteria were analysed. 45% (n = 330) of procedures were Baveno non-compliant. Of these 330 patients, 38% (n = 126) had pre endoscopy Fibroscan and platelet data available but did not fulfil Baveno criteria whilst 62% (n = 204) patients underwent endoscopy without Fibroscan and with platelet count above 150×10^9/L. During the study dates, these 330 procedures generated approximately 37620 L of water and 78 kg of plastic waste. This totalled a carbon cost of 1657 KgCO2e.
Conclusion: The exact carbon cost of a single gastroscopy has yet to be determined, however, our data which is likely to represent a significant underestimate, demonstrates that if used correctly and extrapolated on a larger scale, Baveno VII could rationalise and reduce the significant burden generated by endoscopy.

SAT-094-YI

Mild overt hepatic encephalopathy (HE)-more than meets the eye

Davide Erminelli[1], Chiara Mangini[1], Lisa Zarantonello[2], Paolo Angeli[1], Sara Montagnese[1,3]. *[1]Department of Medicine, University of Padova, Padova, Italy; [2]Department of Medicine, University of Padova, Padova, Italy, Padova, Italy; [3]Chronobiology Section, Faculty of Health and Medical Sciences-University of Surrey, Guildford, United Kingdom*
Email: sara.montagnese@unipd.it

Background and aims: The diagnosis of covert/mild overt HE remains a matter of debate. While practices are becoming more homogeneous, the semi-quantitative assessment of overt HE is not necessarily performed, and the interpretation of results when different neuropsychiatric tests are utilized remains poorly defined. The aim of the present study was to assess the impact of a qualitative approach to clinical HE diagnosis, and to describe the features of patients being diagnosed with covert HE on abnormalities in either the Psychometric Hepatic Encephalopathy Score (PHES) or the electroencephalogram (EEG).
Method: 411 patients evaluated in our dedicated HE clinic between April 2009 and June 2023 [292 males (71%), 60 ± 10 years, MELD = 14.4 ± 5.9, MELD-Na 18.6 ± 16.1] were included. Patients were qualified as: 1) unimpaired, when they were clinically normal and both the PHES and the EEG were normal; 2) having covert HE when they were clinically normal but the PHES and/or the EEG were abnormal, or 3) having overt HE based on the semi-quantitative modification of Conn's criteria (Vilstrup et al., J Hep 2014). Patients

were also classified as having/not having overt HE based on a qualitative impression of the clinician, prior to any formal assessment.
Results: 137 (33%) patients were unimpaired, 174 (42%) had covert HE and 100 (25%) overt HE; 122 (30%) were qualified as having overt HE on qualitative assessment. Of the 100 patients with overt HE, 30% were missed on qualitative assessment. In addition, 17% unimpaired/covert HE patients were erroneously qualified as having overt HE on qualitative assessment. Across the HE spectrum, patients with an abnormal EEG were older (61.5 ± 9.1 vs 58.1 ± 10.3, $p < 0.001$), had higher MELD (15.8 ± 6.1 vs 12.8 ± 5.2, $p < 0.001$), higher MELD-Na (21.2 ± 18.9 vs 16.1 ± 13.7, $p < 0.01$) and higher ammonia levels (76.2 ± 43.6 vs 54.9 ± 41.6 µmol/l, $p < 0.001$) compared with their counterparts with normal EEG. Patients with an abnormal PHES were older (60.8 ± 9.3 vs 58.9 ± 10.0, $p < 0.05$), had lower educational attainment (9.0 ± 3.3 vs 10.6 ± 4.1 years, $p < 0.0001$), higher MELD (15.7 ± 6.4 vs 13.4 ± 5.3, $p < 0.001$), higher MELD-Na (22.0 ± 20.0 vs 16.3 ± 12.5, $p < 0.01$) and higher ammonia levels (70.9 ± 48.1 vs 59.7 ± 38.9 µmol/l, $p < 0.05$) compared with their counterparts with normal PHES. Amongst patients with covert HE diagnosed on one abnormal test only, those with abnormal PHES had lower educational attainment compared to those with abnormal EEG (8.2 ± 3.1 vs 10.2 ± 4.1 years, $p < 0.002$).
Conclusion: Qualitative clinical evaluation of mild HE is unreliable, with significant proportions of false negatives and, unexpectedly, also false positives. The EEG and PHES work well in this context, with both being affected by age, and PHES also by educational attainment, despite adjustment based on local norms.

SAT-095
Trial of the establishment of shear wave elastography measurement methods for improvement of versatility
Hidemi Unozawa[1], Takayuki Kondo[1], Kentaro Fujimoto[1], Sae Yumita[1], Kisako Fujiwara[1], Keisuke Koroki[1], Masanori Inoue[1], Kazufumi Kobayashi[1], Soichiro Kiyono[1], Naoya Kanogawa[1], Masato Nakamura[1], Sadahisa Ogasawara[1], Shingo Nakamoto[1], Naoya Kato[1]. *[1]Graduate School of Medicine, Chiba University, Chiba, Japan*
Email: unozawa.hidemi@chiba-u.jp

Background and aims: Liver stiffness measurement using ultrasound is widely used to understand the pathophysiology of liver diseases due to its low invasiveness and simplicity. Although various devices have been used to measure liver stiffness, and the results of shear wave elastography (SWE) may depend on how the region of interests (ROIs) at placed, and there are no clear standards on how to place ROIs. In this study, we investigated the correlation between FibroScan and clinical and the intraclass correlation coefficient (ICC) between FibroScan and SWE to establish a measurement method of SWE.
Method: This retrospective study included 215 patients from our institutual database, who underwent abdominal ultrasonography for liver disease and had FibroScan and SWE at the same site on the same day. Correlation between liver reserve function and FibroScan was analyzed. In addition, the correlation between the waveform of the right hepatic vein. The ICC between FibroScan and SWE was analyzed in patients with or without cirrhosis, ascites, and fatty liver. The definition of fatty liver was based on the Controlled Attenuation Parameter value, and fatty liver was defined as 240 dB/m. To determine the optimal area of treatment in SWE, ROIs of 1 cm^2 were placed at 1 cm, 2 cm, and 3 cm from the liver surface, and the units of measurement were nified as kPa.
Results: Correlation between FibroScan and clinical findings. The FibroScan reading increased significantly with decreased hepatic function ($r = 0.555$, $p < 0.001$). The correlation coefficient between the right hepatic vein and FibroScan was – 0.267 ($p < 0.001$). As the values of Fibroscan increased, the waveform of the right hepatic vein changed from 3-phase wave to 2-phase wave to 1-phase wave. Conformity between FibroScan and SWE. The ICCs between FibroScan and SWE were –0.050 ($p = 0.638$), 0.845 ($p < 0.001$), and 0.762 ($p < 0.001$) for 1 cm, 2 cm, and 3 cm, and especially the values of shear wave at 2 cm was significantly consistent with FibroScan. Stratifying into various groups the ICCs were –0.231 ($p = 0.892$)/–0.382 ($p = 0.932$] for 1 cm, 0.808 ($p < 0.001$)/0.897 ($p < 0.001$) for 2 cm, and 0.709 ($p < 0.001$)/0.835 ($p < 0.001$) for 3 cm in patients with cirrhosis/without, (0.216 [$p = 0.190$]/–0.249 [$p = 0.919$] for 1 cm, 0.847 [$p < 0.001$]/0.816 [$p < 0.001$] for 2 cm, 0.718 [$p < 0.001$]/0.741 [$p < 0.001$] for 3 cm in patients with ascites/without), 0.146 [$p = 0.252$]/–0.274 [$p = 0.913$] for 1 cm, 0.872 [$p < 0.001$]/0.831 [$p < 0.001$] for 2 cm, 0.813 [$p < 0.001$]/0.718 [$p < 0.001$] for 3 cm in patients with fatty liver/without), with the measurement at 2 cm from liver surface showing the most consistency.
Conclusion: SWE at 2 cm from the liver surface showed the highest conformity with FibroScan, which may help in the establishment of future measurement methods in SWE.

SAT-098
Prognostic factor which can predict esophageal varices aggravation after plug-assisted retrograde transvenous obliteration (PARTO)
Chan Jin Yang[1], Jeong-Ju Yoo[1], Sang Gyune Kim[1], Young Seok Kim[1], Hong Soo Kim[2], Gab Jin Cheon[3], Jong Joon Shim[4], Jae Myeong Lee[4]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon, Korea, Bucheon, Korea, Rep. of South; [2]Soonchunhyang University College of Medicine Cheonan Hospital, Cheonan, Korea, Rep. of South; [3]Department of Internal Medicine, Gangneung Asan Hospital, University of Ulsan College of Medicine, Gangneung, Korea, Gangneung, Korea, Rep. of South; [4]Department of Radiology, Soonchunhyang University Bucheon Hospital, Bucheon, Korea, Bucheon, Korea, Rep. of South*
Email: liverkys@schmc.ac.kr

Background and aims: Plug-assisted retrograde transvenous obliteration (PARTO) is known to be an effective treatment for gastric varices. However, it is also known that it worsens esophageal varices after PARTO. The aim of this study is to identify prognostic factors which can predict the worsening of esophageal varices after PARTO in patients with gastric varices.
Method: Ninety-nine patients who underwent PARTO between Jun 2015 and Jan 2023 were enrolled in this study. Esophageal varices and their exacerbation were evaluated by esophagogastroduodenoscopy (EGD).
Results: Of the 99 patients, 74 patients who could confirm the change in esophageal varix with EGD performed after PARTO were analyzed. The mean age of patients were 57.9 ± 9.9 years and 64.9% were male. Most common etiology of liver cirrhosis was alcoholic liver disease (40.5%) followed by hepatitis B virus (28.4%). The cumulative worsening rate of esophageal varices at 1, 2, and 3 years were 32.4%, 48.6% and 50.0%. In the univariate logistic regression analysis, total bilirubin, aspartate aminotransferase, albumin, prothrombin time international normalized ratio, previous hepatic vein pressure gradient (HVPG) which meausre before PARTO, post HVPG which measure after PARTO, MELD score, Child-Pugh class were associated with worsening of esophageal varices after PARTO. Additionally, from the perspective of vascular anatomy, left gastric vein (LGV) dilatation which LGV diameter more than 3.55 mm and type 2 gastric varix according to the Saad-Caldwell classification were also associated with worsening of esophageal varices after PARTO. In multivariate logistic regression analysis, previous HVPG (OR 1.172; 95% CI 1.011–1.358; $p = 0.035$) was independent risk factor of worsening of esophageal varices.
Conclusion: HVPG is associated with esophageal varices aggravation after PARTO. The left gastric vein diameter tended to predict EV exacerbation after PARTO.

SAT-099-YI

Splenic stiffness using spleen-dedicated 100 Hz transient elastography compared with the Baveno criteria to predict high risk esophageal varices in cirrhosis

Harsh Jain[1], Prajna Anirvan[2], Mohd. Imran Chouhan[3], Biswajit Sahoo[1], Hemanta Nayak[1], Subash Samal[1], Manas Kumar Panigrahi[4]. *[1]All India Institute of Medical Sciences, Bhubaneswar, India; [2]Kalinga Gastroenterology Foundation, Cuttack, India; [3]Government Medical College, Rajouri, Jammu and Kashmir, Jammu, India; [4]All India Institue of Medical Sciences, Bhubaneswar, India*
Email: imharshjain@gmail.com

Background and aims: Spleen-dedicated Transient Elastography (TE) utilizes 100 Hz shear waves to estimate Splenic Stiffness Measurement (SSM). Recent Baveno consensus suggests the use of SSM to rule out High Risk Esophageal Varices (HREV) in patients not fulfilling the Baveno VI criteria. The evidence supporting the role of SSM is limited. This study was designed to establish the diagnostic accuracy of SSM in predicting HREV using spleen-dedicated 100 Hz TE, and compare it with the existing Baveno criteria.
Method: Single centre cross-sectional study including patients with cirrhosis. Endoscopy was done to grade esophageal varices, LSM was estimated using standard 50 Hz TE and SSM was estimated using spleen-dedicated 100 Hz TE. Area under Receiver Operating Characteristic (AUROC) curves were obtained for LSM, SSM individually as well as for the combination of parameters used in the Baveno VI and VII criteria. SSM cut-off value was derived from the study cohort. The diagnostic performance of SSM was compared with the existing cut-offs proposed by the Baveno VI and VII criteria by determining the endoscopy spare rate and HREV miss rate.
Results: Out of 156 patients with cirrhosis included in the study, 34% (n = 53) had HREV. SSM could not be obtained in 3 patients (1.9%). The AUROC of SSM alone, LSM alone, combined LSM and platelet count (PC), and, combined LSM, PC and SSM was 0.805, 0.643, 0.735 and 0.801, respectively. An SSM cut-off value of 35 kPa was selected, having a corresponding sensitivity of 96.2%. At this cut-off, SSM alone spared more endoscopies as compared to the Baveno VI criteria (37.2% vs 16.6%) and had a lower HREV miss rate as compared to the Baveno VII criteria (3.8% vs 11.3%). All the non-invasive parameters performed better in the compensated cirrhosis subgroup (n = 97) as compared to those having prior history of decompensating event (n = 59). SSM alone had an AUROC of 0.705 in the decompensated cirrhosis subgroup, possibly avoiding 23.7% endoscopies in this subgroup.
Conclusion: SSM can accurately rule out HREV in cirrhosis and save a significant number of endoscopies in these patients. The SSM cut-off to rule out HREV may vary in different populations and may depend on the etiology of cirrhosis. The combination of LSM, platelet count and SSM was not superior to SSM alone in predicting HREV. SSM may have a role in stratifying the risk of HREV in patients with decompensated cirrhosis.

SAT-100

Heart failure outcomes following transjugular intrahepatic portosystemic shunts

Jemima Finkel[1], Silke Francois[2], Amine Benmassaoud[3], Louise China[4], David Patch[5], Emmanouil Tsochatzis[6]. *[1]Insititute of Liver and Digestive Health, London, United Kingdom; [2]Royal Free Hospital, London, United Kingdom; [3]McGill University, Montreal, Canada; [4]Institute of Liver and Digestive health, Royal Free Hospital, London, United Kingdom; [5]Institute of Liver and Digestive Health, London, United Kingdom; [6]Institute for Liver and Digestive Health, Royal Free London, London, United Kingdom*
Email: jfinkel@doctors.org.uk

Background and aims: Transjugular intrahepatic portosystemic shunts (TIPSS) are increasingly used for the management of variceal bleeding and diuretic refractory ascites. Complications include cardiac failure in up to 20%. TIPSS outcomes over a 12-year period were reviewed for predictors of the occurrence of heart failure.
Method: Data was collated retrospectively for TIPSS performed at a tertiary referral centre between 2010 and 2022. The primary outcome was the occurrence of heart failure. Referring hospitals were contacted and information requested for data missing up to 12 month follow-up. Statistical analysis included Mann-Whitney and *t*-tests for comparison of continuous variables between groups and binary logistic regression to determine predictive factors for the occurrence of heart failure.
Results: 472 patients underwent TIPSS, including 279 for ascites (A) and 193 patients for variceal bleeding (B). Overall, 65% of patients were male and the mean age was 55 years. The most common aetiology was alcohol at 64%, 13% were due to metabolic dysfunction-associated steatotic liver disease and 8% were secondary to hepatitis C infection. In 57.5% (46/80) heart failure was detected in the outpatient setting, most commonly due to new onset peripheral oedema, and was successfully managed with outpatient diuretic therapy. 10% (8/80) required re-admission to hospital for fluid overload (3% of the overall cohort). Five patients had multi-system involvement driving their symptoms as opposed to solely the TIPSS. Two patients required haemodialysis for fluid removal before subsequently undergoing TIPSS reductions as definitive management. Heart failure was documented in 80/472 (16.9%). Similar proportions of patients developed heart failure between the two cohorts, 40/279 (14.3%) in ascites and 32/193 (16.5%) in bleeding. Univariate analysis showed that age and cryptogenic cirrhosis were predictive factors for heart failure, with both remaining significant at multivariate analysis (Age: aOR 1.024, 95% C.I 1.001–1.049, cryptogenic cirrhosis: aOR 2.979, 95% C.I 1.118–7.937).
93 patients had a pro-BNP within 6 months of the TIPSS, with no significant baseline increase in those who developed heart failure.
Conclusion: The majority of heart failure following TIPSS procedures is manageable in an outpatient setting and does not require re-admission to hospital or intervention beyond diuretic therapy. Cardiovascular risk factors did not predict the risk of heart failure in this cohort.

SAT-101

Morphological changes in esophageal varices in patients with HCV related cirrhosis who achieved sustained virological response by direct-acting antivirals
