Results: The survey was completed by 804 NAFLD/NASH patients from SA: 63% between 25 and 44 years and 24% ≥45 years old, 75% male, 7% obese (BMI > 30), 79% living in urban regions, 76% with a college degree, 84% employed, 9% with type 2 diabetes and 87% with no comorbidities, 1.2% with cirrhosis. Of all patients, 17% ever disclosed having NAFLD/NASH to family/friends; the most used words when discussing the disease were "fatty liver" (96% used it at least sometimes, 79% frequently or always). At the same time, "NAFLD or NASH" and "liver steatosis" were never used by >94% patients, "liver disease" and "metabolic liver disease" never used by >75%. Interestingly, the term metabolic associated fatty liver or MAFLD was used by 50% at least sometimes, 20% frequently or always. There were 3.7% who reported experiencing stigma or discrimination (at least sometimes) due to obesity/overweight vs. only 2.7% due to NAFLD; female patients reported stigma more frequently than male: 5.9% vs. 3.0% due to obesity ($p = 0.06$), 5.4% vs. 1.8% due to NAFLD ($p = 0.01$). In addition, 43% of patients reported ever missing or avoiding a visit to a primary care provider due to NAFLD (48% male vs. 28% female, $p < 0.0001$). The greatest social-emotional burden among NAFLD patients was being identified as a person with liver disease (10% agree, 4% male vs. 26% female) and feeling like they cannot do anything about their liver disease (6.4% agree, 3% male vs. 16% female). As such, among 7 domains of the Liver Disease Burden instrument, the highest scores (the greatest burden) for both sexes were observed in the Self-Perception domain. Regarding how various diagnostic terms were perceived by patients, there were no

substantial differences between "fatty liver disease," "NAFLD," "NASH," or "MAFLD": the most popular response was being neither comfortable nor uncomfortable with either term (81%-97%) while only 0.2–1.5% were uncomfortable with any of those terms.
Conclusion: The disease burden, disease-related stigma, and perception of various diagnostic terms as stigmatizing are rarely observed in patients with NAFLD in SA. In comparison to male NAFLD patients from SA, female patients more commonly reported history of stigma and discrimination and a significantly greater disease burden.

FRI-293

Association between liver fibrosis, mental health, and lifestyle behaviors in patients with Metabolic Dysfunction-Associated Steatotic Liver Disease

Tayla Robertson[1,2], Nashla Hamdan[3], Chinmay Bera[2], Magdalena Kuczynski[2], Radin Pakseresht[2], Bo Chen[2], Keyur Patel[2]. *[1]Princess Alexandra Hospital, Brisbane, Australia; [2]University Health Network, Toronto, Canada; [3]University Health Network, Toronto, Canada*
Email: keyur.patel@uhn.ca

Background and aims: Understanding lifestyle behaviours and psychological factors are necessary to provide personalised interventions for individuals living with Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD). We hypothesised that advanced fibrosis (F3–4) is associated with poor diet quality, physical inactivity, and impaired mental wellbeing. Our aims were to prospectively examine the relationships between severity of fibrosis, diet quality/behaviour, physical inactivity, and measures of psychological distress.
Method: Patients with MASLD were prospectively recruited from a single tertiary centre between March and October 2023. Four questionnaires were administered to patients during their ambulatory clinic visit: Energy-Restricted Mediterranean Diet Adherence Screener (er-MEDAS), International Physical Activity Questionnaire Short Form (IPAQ-SF), Hospital Anxiety and Depression Scale (HADS), and Binge Eating Scale (BES). Patient demographics, clinical characteristics and laboratory data were collected from their electronic medical records. Fibrosis was assessed by Fibroscan (VCTE) or liver biopsy data, and statistical analysis performed using R (r-project.org).
Results: Our study cohort included 100 MASLD patients with higher proportion of male sex (n = 57), mean age 48.5 years, BMI 33 kg/m2, T2DM 31%, and F3–4 27%. Overall, 90% had poor (56%) to moderate adherence to Mediterranean diet, 74% reported low (33%) to moderate physical activity, 22% had anxiety, and moderate-severe binging reported in 21%. In multivariate logistic regression analysis, stage F3–4 was independently associated with weight (OR 1.01, 95% CI: 1.00–1.01; p = 0.04), diabetes mellitus (OR 1.38, 95%CI: 1.16–1.63; p = 0.0003), lower HADS-anxiety score (OR 0.98, 95%CI: 0.97–0.99; p = 0.04) and alcohol intake compliant with er-MEDAS (abstinence or ≤3 glasses red wine/day with meals for men/ ≤ 2 glasses red wine/day with meals for women, OR 1.17, 95%CI: 1.02–1.35; p = 0.03). In addition, abnormal binge eating (BES) was associated with lower risk of borderline or abnormal anxiety (HADS-A ≥ 8, OR 9.06, 95%CI 1.63–69.3; p = 0.02) and depression (HADS-D ≥ 8, OR 5.92, 95%CI 1.59–23.09; p = 0.008).
Conclusion: In our prospective MASLD cohort, most patients reported poor-moderate diet, reduced activity, and one-fifth reported anxiety and binge-eating behaviour. Advanced fibrosis was not independently associated with poor diet quality, physical inactivity, and impaired mental wellbeing. However, patients with more advanced disease may be modifying their lifestyle behavior in accordance with medical recommendations. Most patients in our cohort had non-advanced disease and further validation is ongoing.

FRI-294

Identification of key predictors of significant weight loss in metabolic dysfunction-associated steatotic liver disease (MASLD) patients: a multicentre study

Ivan Arcari[1], Nicola Pugliese[1], Simone Rocchetto[2], Rosa Lombardi[3], Grazia Pennisi[4], Michele Sagasta[5], Matteo Soleri[6], Federica Cerini[7], Annalisa Cespiati[8], Stella De Nicola[9], Francesca Colapietro[10], Chiara Masetti[9], Anna Fracanzani[11], Salvatore Petta[12], Mauro Viganò[13], Alessio Aghemo[1]. *[1]Humanitas University, Rozzano, MI, Italy; [2]Università degli Studi di Milano, Milan, Italy; [3]Unit of Internal Medicine and Metabolic Disease, Fondazione Ca' Granda IRCCS Ospedale Maggiore Policlinico, Milan, Italy; [4]Sezione di Gastroenterologia, Dipartimento Biomedico di Medicina Interna e Specialistica, Universita di Palermo, Palermo, Italy, Milan, Italy; [5]Maggiore Hospital and IRCCS Foundation, Milan, Italy; [6]Humanitas University, Milan, Italy; [7]Hospital, MultiMedica IRCCS, Università degli Studi di Milano, Milan, Italy; [8]Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico of Milan, Milan, Italy; [9]Humanitas Research Hospital IRCCS, Milan, Italy; [10]Humanitas Research Hospital IRCCS, Rozzano, MI, Italy; [11]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [12]University of Palermo, Palermo, Italy; [13]MultiMedica IRCCS, Università degli Studi di Milano, Milan, Italy*
Email: nicola.pugliese@humanitas.it

Background and aims: Significant weight loss is the only proven therapy for patients with metabolic dysfunction-associated steatotic liver disease (MASLD). This study aimed to identify factors that predict significant weight loss-exceeding 7% of the initial weight-in MASLD outpatients.
Method: We included all MASLD patients referred to four Italian tertiary liver centres between January 2019 and December 2021. They received advice on lifestyle changes according to current guidelines, with reassessment of anthropometric measures after 18 to 24 months.
Results: After evaluating 908 patients meeting the inclusion criteria, the majority were found to be male (518/908, 57%) with a mean age of 61.7 ± 13.31 years and a mean baseline body mass index (BMI) of 30.31 ± 4.49 kg/m2. Over a mean follow-up period of 21.88 ± 6 months, only 166 (18.3%) patients achieved significant weight loss. Unadjusted regression analysis revealed significant correlations between dyslipidaemia, baseline BMI ≥ 30 kg/m2, and the use of GLP-1 (glucagon-like peptide 1) agonists with significant weight loss ($p < 0.05$). Multivariate regression analysis identified only BMI ≥ 30 kg/m2 (OR = 1.96, 95% CI: 1.37–2.8) and dyslipidaemia (OR = 0.6, 95% CI: 0.44–0.88) as independent predictors of significant weight loss.
Conclusion: A baseline BMI ≥ 30 kg/m2 and the absence of dyslipidemia emerged as significant predictors of achieving substantial weight loss in MASLD patients. These findings highlight the need for personalized interventions to improve the effectiveness of weight management strategies in MASLD.

FRI-295

Risk factors for hepatocellular carcinoma in patients with metabolic dysfunction-associated steatotic liver disease

Ian Yang Liew[1], Hwee Pin Phua[2], Wei Yen Lim[3], Angela Chow[3], Xiu Ying Loo[1], Kevin Sim[1], Eng Sing Lee[4], Kuo Chao Yew[3]. *[1]Ministry of Health (MOH) Holdings Pte Ltd, Singapore, Singapore; [2]Tan Tock Seng hospital, Singapore, Singapore; [3]Tan Tock Seng Hospital, Singapore, Singapore; [4]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore*
Email: Liewianyang@gmail.com

Background and aims: Metabolic Associated Steatotic Liver Disease (MASLD) is associated with higher risk of Hepatocellular Carcinoma (HCC). For MASLD without advanced fibrosis, the incidence has been estimated to be 0.1 to 1.3 per 1, 000 patient-years. In this study, we aim to identify independent risk factors of HCC incidence among individuals with MASLD without advanced fibrosis.

Method: We conducted a retrospective cohort study using electronic medical records of MASLD patients with No Advanced Fibrosis (NAF) seen in a multidisciplinary hospital in Singapore. Patients with a diagnosis of MASLD with NAF made between 1st January 2007 and 31st October 2017 were identified using International Classification of Diseases (ICD-10) code, Fibrosis-4 (FIB-4) scoring, imaging, and histology, and followed up till 31st October 2017. The start date of follow-up was defined as the date of MASLD diagnosis. Multivariable Cox regression was performed to identify demographic, clinical, and/or laboratory variables with significant association with increased risk of HCC development. Proportional hazard assumption was tested using Schoenfeld residuals.
Results: Our cohort comprised 2170 patients with a median age of 51 [IQR 41–59] years. Patients were predominantly Chinese (77.1%) and slightly more than half (51.9%) were male. The median length of follow-up was 5.2 years and 19 (0.9%) patients developed HCC at the end of follow-up. There was no statistically significant difference in the proportion of HCC incident cases between patients with more or less than 3 years of follow-up (12/1597 (0.8%) versus 7/573 (1.2%) respectively), p = 0.300). Incidence rate of HCC was estimated at 1.6 per 1000 person-year. 431 (19.9%) patients developed advanced fibrosis during follow-up. Older age at diagnosis of MASLD (HR: 1.06, 95% CI: 1.02–1.10), male gender (HR: 5.61, 95% CI: 1.71–18.39), and development of advanced fibrosis over follow-up time (HR: 5.80, 95% CI: 2.14–15.69) were associated with increased risk of HCC incidence. Conversely, the presence of metabolic syndrome at baseline (HR:1.39, 95% CI: 0.49–3.94) and Charlson Comorbidity Index at baseline (HR: 1.01, 95% CI: 0.73–1.40) were not associated with increased HCC incidence. Due to the retrospective nature of the study, the proportion of patients with missing laboratory data was high. Laboratory variables explored were therefore not included in the analysis.
Conclusion: Our study demonstrated a difference in baseline HCC risk for MASLD. The risk factors could be delineated to identify at-risk subgroups for intensive management or surveillance programme enrolment.

FRI-296
Metabolic dysfunction-associated steatotic liver disease and low handgrip strength are independently associated with a higher risk for cardiovascular disease

Seung Up Kim[1], Jae Seung Lee[1], Hye Won Lee[1], Mi Na Kim[1], Beom Kyung Kim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1]. [1]*Yonsei University, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a term recently proposed to encompass the conventional concept of non-alcoholic fatty liver disease (NAFLD). This study investigated whether muscle function, as indicated by handgrip strength (HGS), is associated with the risk for cardiovascular disease (CVD) in individuals with MASLD.
Method: This study involved the data of 24, 682 individuals from the 2014–2019 Korea National Health and Nutrition Examination Survey. Steatotic liver disease was assessed using the Framingham steatosis index and simple NAFLD score, and advanced liver fibrosis was assessed using the Fibrosis-4 index. Low HGS was defined as <26 kg in men and <16 kg in women. The risk for CVD was evaluated using the 10-year atherosclerotic CVD (ASCVD) risk score. High probability ASCVD risk was defined as ASCVD >10%.
Results: The prevalence of MASLD and low HGS were 25.5% (n = 6, 282) and 6.3% (n = 1, 549), respectively. Individuals with both MASLD and low HGS were at greater risk for high probability ASCVD (odds ratio = 4.06, $p < 0.001$) than those without MASLD. The impact of low HGS on high probability ASCVD risk was higher when MASLD was accompanied by advanced liver fibrosis (odds ratio = 8.10, $p < 0.001$). CVD risk was lower in individuals who had low HGS but engaged in regular exercise than in individuals with neither low HGS nor regular exercise. Similar findings were observed when the simple NAFLD score was used to define steatotic liver disease.
Conclusion: Individuals with MASLD and low HGS had a significantly higher risk for CVD than those without MASLD. Concurrent advanced liver fibrosis further enhanced the risk for CVD among individuals with MASLD.

FRI-297
Clinical impact of pre-existing steatotic liver disease on clinical course in acute HEV infection

Kazunari Tanaka[1], Jong-Hon Kang[2], Takeshi Matsui[1], Hiroaki Okamoto[3]. [1]*Teine Keijinkai HospitaL, Sapporo, Japan;* [2]*Teinne Keijinkai Hospital, Sapporo, Japan;* [3]*Jichi Medical University School of Medicine, Shimotuke, Japan*
Email: kazunari0511@gmail.com

Background and aims: Steatotic liver disease (SLD) has been recognized as a prevalent underlying condition which could affect clinical course in newly occurred liver diseases including acute hepatitis (AH). Aim of this study was to elucidate the influence of pre-existing SLD on acute infection of hepatitis E virus (HEV).
Method: Among the patients with AHE treated between 2012 and 2017 in Japan, 503 cases collected from 155 medical facilities in Japan, 379 cases well-documented for BMI and alcohol consumption were included. SLD was defined as fatty liver detected by ultrasonography. The patients with chronic liver diseases other than SLD and liver cancer were excluded. They were divided into 2 groups: 27 cases with SLD as a target one and another 352 cases as a control. Acute liver failure (ALF) was defined as PT INR ≥ 1.5 and habitual drinking as ≥60 g/day. The impact of background SLD on the clinical course of AHE was retrospectively analyzed.
Results: Among 27 patients with underlying SLD, 23 (85%) were male and median age of years was of 58 (IQR, 50–62). In control patients, showed 292 (83%) were male and median age was of 56 (IQR 45–67). In the current study, SLD consisted of metabolic dysfunction associated steatotic liver disease (MASLD) in 11 patients, Met ALD [MASLD and alcohol-related fatty liver disease (ALD)] in 11, and cryptogenic in 5. In comparison with control, SLD group demonstrated higher BMI (24.8 vs. 23.0, p = 0.003), frequently complicated diabetes [n = 12 (44%) vs. n = 57 (16%), p = 0.001], and dyslipidemia [n = 12 (44%) vs. n = 67 (19%), p = 0.001], respectively. On admission, there was no differences in levels of AST, ALT, total bilirubin, and PT-INR between them. Identically, peak value of AST, ALT, total bilirubin, and PT-INR and nadir value of albumin did not differ between two groups. ALF was more frequent in SLD group than in control [n = 8 (30%) vs. n = 36 (10%), p = 0.006]. In univariate analysis, pre-existing SLD (HR 3.81, 95% CI 1.56–9.33), habitual drinking (HR 2.47, 95% CI 1.28–4.79), and diabetes (HR 2.16, 95% CI 1.07–4.39) were associated with progression to ALF, respectively, whereas BMI, ≥25 or ≥30, was not. In multivariate analysis, SLD (HR 2.94, 95% CI 1.13–7.62) and habitual drinking (HR 2.34, 95% CI 1.19–4.60) were remained as risk factors related with ALF. The frequency of ALF in MASLD, Met ALD and cryptogenic did not differ. There was no difference in requirement of corticosteroid therapy, hospitalization, or liver disease-related death in each group.
Conclusion: From these results, underlying SLD could affect to deteriorate liver reserve on clinical course of AHE. Clinicians should exercise caution and be cognizant of the potential for severity in the clinical course of AHE in cases with underlying SLD. Additional analyses are warranted to elucidate why SLD affected the course of acute hepatitis E.

FRI-298

Insulin resistance and sarcopenia as comorbid conditions in patients with MASLD

Kateryna Pivtorak[1], Oleksandr Ivanchuk[1], Natalya Pivtorak[1], Iryna Fedzhaga[2]. [1]*National Pirogov Memorial Medical University, Vinnytsia, Ukraine;* [2]*National Pirogov Memorial Medical University, Vinnytsia, Ukraine*
Email: ekaterina.pivtorak@yahoo.com.ua

Background and aims: Recent studies have shown that sarcopenia often accompanies MASLD. Sarcopenic obesity in combination with the progressive loss of skeletal muscle mass negatively affects the metabolic status of a person, which leads to a decrease in the quality of life and the development of cardiovascular diseases. The aim was to determine the relationship between inflammatory markers, insulin resistance and sarcopenia in patients with MASLD.
Method: The study included 202 normal, overweight, and obese MASLD patients and 106 non-MASLD patients. Anthropometric examination and MRI were performed, AST, ALT, GGT levels, degree of liver fibrosis using elastography (FibroScan), ECG were measured. Cardiovascular risk stratification was assessed using the SCORE version for high-risk countries. The level of inflammatory mediators (TNF-alfa, IL-1, IL-6), markers (CRP, fibrinogen), myostatin, endothelin-1, the thickness of the intima-media complex, the presence of atherosclerotic plaque and carotid artery stenosis, HOMA-IR insulin resistance index were determined for all patients.
Results: Thus, the body weight of men with MASLD was 1.3 times greater than in the group of healthy men. The body weight of women with MASLD was 1.5 times higher compared to the group of healthy women. There were no significant differences or trends in body length between healthy and MASLD males and MASLD females. The BMI of men with MASLD was 1.4 times higher than that of healthy men. The BMI of women with MASLD was also 1.4 times higher than that of healthy women. The muscle mass of men and women with MASLD was statistically significantly lower ($p < 0.05$) than that of sexually healthy men and women. Moreover, muscle mass in healthy men was statistically significantly higher ($p < 0.05$) than in the corresponding groups of women. Thus, healthy men's muscle mass increased by 20.5% compared to healthy women. Higher levels of inflammation, HOMA index, and decreased adiponectin levels were found in patients with MASLD, and sarcopenia compared to patients with preserved muscle mass. According to the results of the study, the component composition of body weight changes in MASLD. Compared with healthy men with MASLD, body fat mass was 35.2% higher, while muscle mass and bone mass in men were 29.1% and 32.0% lower, respectively. Compared to healthy women with MASLD., body fat mass was 30.2% higher, while muscle mass and bone mass in women were 17.4% and 22.7% lower, respectively. Strong inverse correlations ($r = 0.71$, $p < 0.001$) were found between muscle mass and hs CRP levels in men and women with MASLD.
Conclusion: The mechanisms of pathogenesis of sarcopenia and MASLD are common: insulin resistance, increased inflammation, secretion of myokines by skeletal muscles, myostatin, and decrease in adiponectin level.

FRI-299

Poor diet quality is associated with higher cardiovascular risk in a cohort of non-cirrhotic Italian MASLD (Metabolic dysfunction associated steatotic liver disease) outpatients

Rusi Chen[1], Chiara Abbati[1], Ernestina Santangeli[1], Roberta Capelli[1], Simona Leoni[2], Federico Ravaioli[1], Fabio Piscaglia[1], Silvia Ferri[2]. [1]*University of Bologna, Alma Mater Studiorum, Bologna, Italy;* [2]*IRCCS Azienda Ospedaliero Universitaria di Bologna, Bologna, Italy*
Email: silvia.ferri@aosp.bo.it

Background and aims: Poor diet quality accounts for 11 million deaths and approximately 50 % of cardiovascular (CV) disease-related deaths globally. Practical diet screening tools like REAP-S (Rapid Eating Assessment for Participants-Shortened Version) have been developed to quickly assess the diet quality in clinical settings. The aim of our study was to compare the physical, laboratory and ultrasound features and CV risk of the MASLD patients of our liver clinic, based on their REAP-S score.
Method: We enrolled, from February 2022 to January 2024, 92 consecutive non-cirrhotic subjects (47 % females, median age 61 years) followed in our MASLD outpatient clinic. All patients received a complete anamnestic, physical, laboratory and ultrasound evaluation. Their physical activity and dietary habits were assessed using validated questionnaires, respectively IPAQ (International Physical Activity Questionnaire) score and REAP-S score, the latter ranging from 13 to 39 points (with a higher score indicating a higher diet quality). Skeletal muscle function was evaluated using hand-grip strength. The CV risk was predicted using Italian National Institute of Health calculator "Progetto Cuore." According to a median REAP-S score of 30, we divided our cohort into 2 groups, namely "A" or poor diet quality (with score ≤ 30): 47 subjects and "B" or good diet quality (with score >30): 45 subjects.
Results: The two groups didn't show statistical differences in demographic and anthropometric data (age, sex, weight, height, BMI, waist circumference), nor in auto-reported physical activity or in hand-grip strength. Similar transaminases, lipid profile, renal function and total protein and albumin levels were found in the two groups. Compared to group A, in group B gamma-GT levels were lower (37 U/L vs. 52 U/L; $p = 0.03$). The two cohorts displayed similar values of non-invasive markers of fibrosis, within the range of normality (NAFLD fibrosis score, FIB-4 and liver stiffness evaluated with two-dimensional shear wave elastography). Regarding CV risks factors, similar prevalence of dyslipidemia and diabetes mellitus were found in the two groups. Compared to group B, more patients in group A were smokers (32% vs 9%, $p = 0.006$) and had been diagnosed and took medications for arterial hypertension (64% vs. 40 %; $p = 0.02$), though the overall probability to experience a major cardiovascular event in the following 10 years was similar in the two groups.
Conclusion: In our cohort of non-cirrhotic MASLD outpatients, a poor diet quality assessed by REAP-S was significantly associated to smoking habit and arterial hypertension. Bad lifestyle habits appear to affect more the cardiovascular system compared to the pathological features of progressive steatotic liver disease, such as liver fibrosis, at least in a context of non-advanced liver disease.

FRI-302

Non-obese non-alcoholic fatty liver disease and the risk of chronic kidney disease: a literature review and meta-analysis

Yixian You[1], Xiong Pei[1], Wei Jiang[1], Qingmin Zeng[1], Chang Hai Liu[1], Lang Bai[1], Dongbo Wu[1], Hong Tang[1]. [1]*Center of Infectious Diseases, West China Hospital of Sichuan University, Chengdu, China*
Email: htang6198@hotmail.com

Background and aims: Data on the risk of incident chronic kidney disease (CKD) in non-obese non-alcoholic fatty liver disease (NAFLD) patients compared to obese NAFLD patients are limited. The purpose of the current study was to examine the risk differences of incident CKD between non-obese and obese NAFLD patients.
Method: We searched PubMed, Embase, and Web of Science databases for studies which reported the incidence of CKD in non-obese and obese patients with NAFLD from inception to 16 July 2023. The primary and secondary outcomes were pooled using random-effects model. Subgroup analyses were used to examine the heterogeneity.
Results: A total of 15 studies were incorporated into the final analysis. The incidence of CKD in non-obese and obese NAFLD were 1450/38720 (3.74%) and 3067/84154 (3.64%), respectively. Patients with non-obese NAFLD had a comparable risk of incident CKD as obese NAFLD patients (random effects odds ratio [OR] 0.92, 95% CI 0.72–1.19, $I^2 = 88\%$). There were also no significant differences in estimated glomerular filtration rate (eGFR) and serum creatinine between non-obese and obese NAFLD. The mean differences (MD) and 95%

confidence interval (95%CI) were 0.01 (-0.02–0.04) and 0.50 (-0.90–1.90), respectively. In subgroup analyses, non-obese NAFLD patients were found to have higher eGFR compared to obese NAFLD when diagnosed with ultrasound (MD 1.45, 95%CI 0.11–2.79, I^2 = 21%). In non-Asia populations, non-obese NAFLD patients had higher levels of creatinine (MD 0.06, 95%CI 0.01–0.11, I^2 = 55%). When taking BMI greater than 30 as a criterion for obesity, non-obese NAFLD patients also showed higher levels of creatinine (MD 0.06, 95%CI 0.00–0.12, I^2 = 76%). Non-obese NAFLD patients were also categorized into overweight and normal-weight types, and the occurrence of CKD did not differ among normal-weight, overweight and obese NAFLD patients.
Conclusion: Non-obese NAFLD patients experienced a comparable risk of CKD compared to obese NAFLD patients.

FRI-303
Depression as a determinant of metabolic dysfunction-associated steatotic liver disease (MASLD) risk in the Paracelsus 10, 000 study
Florian Koutny[1,2], Elmar Aigner[3], Christian Datz[4], Sophie Gensluckner[3], Andreas Maieron[2], Andrea Mega[5], Bernhard Iglseder[6], Patrick Langthaler[7], Maria Flamm[8], Vanessa Frey[9], Bernhard Paulweber[10], Eugen Trinka[9], Bernhard Wernly[4].

Email: florian.koutny@stpoelten.lknoe.at

Background and aims: The increasing prevalence of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) comorbid depression is a significant health challenge. Despite the emerging recognition of this health burden, only few studies, particularly those incorporating the new MASLD nomenclature, have explored the interplay between depression and MASLD. Therefore, we aimed here to investigate the association between depression and the risk of MASLD while adjusting for potential confounders. The goal is to better understand how depression affects liver health, and how brain health may interact with metabolic dysfunction contributing new knowledge to this field.
Method: The study included 8, 315 participants from the Paracelsus 10, 000 study. The fatty liver index (FLI) score ≥60 served as a surrogate marker for MASLD. Depression was defined using the Beck Depression Inventory I-II (BDI) score. Initially, we examined the BDI score as a continuous variable. Subsequently, we categorized participants into two groups: those with a BDI score >8, indicating depression, and those with a BDI score ≤8, serving as the control group. Results were adjusted for covariates such as age, sex, and metabolic syndrome.
Results: The results from the linear regression model indicated that with each additional BDI point, the odds ratio (OR) for MASLD increased by 1% (OR: 1.01, p < 0.01, 95% CI: 1.01–1.02). Individuals with depression (BDI score >8) had a significantly higher OR for MASLD compared to those without depression (BDI score ≤8), (OR: 1.3, p < 0.01, 95% CI: 1.13–1.50). Depression was associated with a 17% increased risk for MASLD after adjusting for confounding factors (Adjusted Relative Risk = 1.17, p < 0.01, 95% CI: 1.07–1.28).
Conclusion: Our findings show a significant association between depression and an increased prevalence of MASLD. Early screening for MASLD in high-risk individuals is crucial to enhance health and the overall well-being of patients with depression. Further research is needed to explore the underlying mechanisms and potential interventions.

FRI-304
Assessment of ChatGPT-generated medical arabic responses for patients with metabolic dysfunction-associated steatotic liver disease
Saleh A. Alqahtani[1], Reem S. AlAhmed[1], Waleed S. AlOmaim[1], Saad Alghamdi[2], Waleed K. Al-Hamoudi[1], Khalid I. Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) has become increasingly prevalent in recent years due to the rise in obesity and unhealthy lifestyle choices. Artificial intelligence (AI)-powered chatbots, such as Chat Generative Pretrained Transformer (ChatGPT), have shown promising results in healthcare. These tools can provide guidance and support to individuals with MASLD by offering real-time responses to user queries, ensuring immediate access to relevant information. The present study aimed to explore the potential use of ChatGPT-generated medical Arabic responses for patients with MASLD.
Method: This cross-sectional study firstly involved the Arabic translation of a validated English patient questionnaire on MASLD. Second, the Arabic questions were entered in the ChatGPT 3.5 platform on November 12, 2023. Third, the responses were evaluated for accuracy, completeness, and comprehensiveness by 10 MASLD experts from Saudi Arabia who were native Arabic speakers. Different Likert scales were used to evaluate the three domains: 1) Accuracy: 6-point Likert scale (Correct, Nearly all correct, More correct than incorrect, Approximately equally correct and incorrect, More incorrect than correct, and Completely incorrect), 2) Completeness: 3-point Likert scale: (Incomplete, Adequate, and Comprehensive), and 3) Comprehensiveness: 3-point Likert scale: (Difficult, Partly difficult, and Easy to understand). An additional question was added to the Arabic questionnaire to capture any comments regarding the generated responses.
Results: The mean accuracy score was 4.9 on a 6-point Likert scale corresponding to "Nearly all correct." Kendall's coefficient of concordance (KCC) ranged from 0.649 to 0.025, with a mean of 0.28, indicating moderate agreement between all ten experts. The mean completeness score was 2.4 on a 3-point Likert scale corresponding to "Comprehensive" (KCC: 0.553–0.03; mean: 0.22). The average comprehensibility score was 2.74, which indicates that the ChatGPT generated responses were "Easy to understand" (KCC: 0.553–0.03; mean: 0.22).
Conclusion: Arabic-speaking experts in hepatology found that ChatGPT-generated medical Arabic responses for patients with MASLD were accurate, complete, and comprehensive. The results support the increasing trend of leveraging the power of AI chatbots to revolutionize the dissemination of information for patients with MASLD, ultimately improving overall health outcomes.

Lower aspartataminotranspherase activity is associated with dynapenia in middle-aged patients with metabolic dysfunction-associated steatotic liver disease

Anna Sheptulina[1,2], Elvira Mamutova[1], Ekaterina Lusina[1], Timur Tsoriev[1], Oxana Drapkina[1]. [1]*National Medical Research Center for Therapy and Preventive Medicine, Moscow, Russian Federation;* [2]*Department of Therapy and Preventive Medicine, A.I. Evdokimov Moscow State University of Medicine and Dentistry, Moscow, Russian Federation*
Email: sheptulina.anna@gmail.com

Background and aims: Increasing evidence suggest an important role of skeletal muscles in the pathogenesis of metabolic dysfunction-associated steatotic liver disease (MASLD). Both skeletal muscles and liver express aspartataminotranspherase (AST), and non-invasive indices based on the AST activity are wildly used for the assessment of liver fibrosis progression, which may depend at least in part on the quality and quantity of skeletal muscles. This study aimed to evaluate the association between the AST activity and grip strength (GS), in middle-aged patients with MASLD.
Method: 83 MASLD patients were included in the study. MASLD was diagnosed based on the ultrasonography findings, the absence of liver disease of other etiology (based on the laboratory data), and the presence of at least one cardiometabolic risk factor. Liver stiffness was measured using two-dimensional shear wave elastography (Affiniti 70, Philips, Amsterdam, Netherlands). Body composition was assessed via dual x-ray absorptiometry (Lunar iDXA, GE HealthCare, USA). Appendicular skeletal muscle mass index (ASMI) was calculated as the sum of the lean muscle mass of the upper and lower extremities adjusted with height. GS was measured using a mechanical hand dynamometer (ZAO "NTMIZ" Russia). Patients were asked to squeeze the dynamometer with as much force as possible three times with their dominant hand. 60 seconds of rest interval was allowed between each trial. The maximum value was registered.
Results: Median age was 59 years (interquartile range (IQR) = 47–65); 74.7 % were female. Median body mass index was 31.2 (28.9–34.8) kg/m2. All patients had arterial hypertension and dyslipidemia. Median liver stiffness value was 5.5 (4.1–6.5) kPa. Dynapenia, i.e. decreased GS, was present in 14 (16.9 %) patients. According to the results of correlation analysis, AST activity was associated with liver stiffness ($p < 0.001$), characteristic of liver disease progression, uric acid ($p = 0.05$) and triglyceride ($p = 0.049$) levels, both indicative of disturbed metabolic profile, and the quantity of skeletal muscles (ASMI, $p < 0.001$). Patients with dynapenia had substantially lower AST activity (17 [14–18.5] U/L vs. 20 [17–25] U/L, $p = 0.015$) compared to patients without dynapenia. Results of the logistic regression analysis using ASMI, muscle mass, and AST as covariates showed that AST activity was the only parameter significantly different between the MASLD patients with and without dynapenia ($p = 0.042$).
Conclusion: Our data demonstrate that AST activity which is often used as a marker of liver fibrosis progression (mainly as a component of non-invasive indices), is also associated with the presence of dynapenia in MASLD. Dynapenia is an early symptom of sarcopenia, which may negatively influence the ability of patients to perform physical activity, an established effective treatment strategy in MASLD, and affect disease outcome.

FRI-306

Insulin resistance in metabolic associated steatotic liver disease and its association with liver-related outcomes: a retrospective study and a nationwide, population-based study

Yeo Wool Kang[1], Yang-Hyun Baek[2], Sang Yi Moon[1], MinKook Son[1]. [1]*DongA University College of Medicine, Busan, Korea, Rep. of South;* [2]*DongA University College of Medicine, Busan, Korea, Rep. of South*
Email: p100100@dau.ac.kr

Background and aims: Insulin resistance (IR) is a well-known factor in the development and progression of in metabolic associated steatotic liver disease (MASLD). Many studies have investigated the development of fatty liver disease and the progression of liver fibrosis in individuals with high insulin resistance (IR); however, limited research exists on IR changes in patients advancing to cirrhosis and hepatocellular carcinoma (HCC). This study investigated the correlation between IR and liver-related outcomes in patients with MASLD.
Method: We retrospectively analyzed data from 361 patients diagnosed with MASLD who underwent liver biopsy at Dong-A University Hospital between January 2015 and November 2023. The study identified changes in insulin surrogate markers, including the triglyceride-glucose (TyG) index, triglyceride to high-density lipoprotein (TG/HDL) ratio, and metabolic score for IR (METS-IR), based on liver fibrosis grade. In a separate analysis, we retrospectively analyzed data from 362, 285 participants who underwent a health screening program in 2009 and 2010 using the Korean National Health Insurance Service (KNHIS) database. The participants were diagnosed and classified using the International Classification of Diseases, 10th Revision. Those with fatty liver were identified using the Fatty Liver Index with a threshold of 30. The study analyzed the relationship between liver-related outcomes such as decompensation or HCC and IR.
Results: 183 patients (50.7%) were in F0, 88 patients (24.4%) were in F1, 31 patients (8.6%) were in F2, and 59 patients (16.3%) were in F3 and F4. The three insulin surrogate markers showed an upward trend from F0 to F2, followed by a downward trend as they progressed to F3, F4. (mean TG/HDL in patients without advanced fibrosis vs with advanced fibrosis = 4.46 ± 2.63 vs 3.05 ± 1.69, $p < 0.001$). For the analysis of KNHIS data, 67, 908 participants met the MASLD criteria out of a total of 362, 285 participants and were followed for 9.4 years. Throughout this period, 2, 621 cases of decompensation and 2, 056 cases of HCC were documented. Insulin surrogate markers were divided into 4 categories according to their values (Q1, Q2, Q3, and Q4). Lower insulin surrogate markers during the follow-up period were observed to be associated with higher hazard ratios for liver-related outcomes. For example, the Q4 category (highest value) of TyG index had a lower HR for decompensation and HCC at 0.823 and 0.627 compared with Q1 (lowest value).
Conclusion: This study showed the change of IR according to fibrosis grade and revealed a decrease of IR was linked to a rise in fatal liver-related complications, indirectly suggesting nutritional imbalance and decreased liver mediator function during the progression of liver fibrosis. Changes in metabolic parameters in MASLD patients should be reassessed for its association with the liver-related diseases.

FRI-314

Plasminogen activator inhibitor-1 (PAI-1) is associated with hepatic steatosis improvement after lifestyle intervention in overweight/obese subjects with metabolic-dysfunction associated steatotic liver disease

Chiara Rosso[1], Marta Guariglia[1], Angelo Armandi[1,2], Gian Paolo Caviglia[1], Eleonora Dileo[1], Francesca Saba[1], Gabriele Castelnuovo[1], Marilu' Benedetta Scalici[1], Nuria Pérez Diaz del Campo[1], Kamela Gjini[1], Maria Lorena Abate[1], Antonella Olivero[1], Mirko Parasiliti-Caprino[1], Simona Bo[1], Elisabetta Bugianesi[1,3]. [1]*University of Turin, Department of Medical Science, Turin, Italy;* [2]*University Medical Center of the Johannes Gutenberg University, Department of Internal Medicine I, Mainz, Germany;* [3]*Città della Salute e della Scienza—Molinette Hospita, Gastroenterology Unit, I, Turin, Italy*
Email: chiara.rosso@unito.it

Background and aims: Obese/overweight patients with metabolic-dysfunction associated steatotic liver disease (MASLD) are at higher risk of developing cardiovascular (CVD) events over time. Plasminogen activator inhibitor (PAI-1) plays a key regulatory role in fibrinolysis and is predictive of CVD events. Here, we aimed to

analyze PAI-1 levels and cardiovascular (CVD) risk in overweight/obese subjects with MASLD, and to assess their association with hepatic steatosis improvement.
Method: We analyzed 73 subjects (mean age 51 ± 12 y; male, N = 50) with MASLD who underwent a restricted calories diet for 6 months. At baseline (t0) and after 6-months diet (t6) we collected blood samples, anthropometrical measurements and lifestyle changes through specific questionnaires. PAI-1 was measured by Luminex®. 10 years CVD risk was calculated by Framingham (FRM) score. For all the metabolic parameters, we calculated the variation from t6 to t0 (delta). Hepatic steatosis was determined by CAP (Fibroscan®). 20 % of CAP improvement was considered as clinical end point.
Results: At baseline, PAI-1 levels significantly correlated with fasting insulin ($r = 0.51$, $p < 0.001$), CAP ($r = 0.46$, $p < 0.001$), liver stiffness ($r = 0.29$, $p = 0.013$) and FRM score ($r = 0.24$, $p = 0.037$). The FRM score significantly correlated with waist circumference ($r = 0.27$, $p = 0.023$), fasting glucose ($r = 0.40$, $p < 0.001$), fasting total cholesterol ($r = 0.24$, $p = 0.040$), CAP ($r = 0.33$, $p = 0.005$) and liver stiffness ($r = 0.38$, $p < 0.001$). After 6 months diet, the FRM score decreased by 14 % ($p = 0.002$) independent by the established clinical end point. Conversely, PAI-1 levels improved by 20 % only in patients who ameliorated CAP by 20 % ($p = 0.008$) (Figure 1A-B). At multivariable logistic regression analysis adjusted for age, gender, delta energy intake and delta weight loss, 20 % of CAP decrease after diet was associated with a significant reduction of FRM and PAI-1 (OR = 6.9, 95 % CI = 1.2–39.4, $p = 0.029$ and OR = 3.9, 95 % CI = 1–15, $p = 0.05$).
Conclusion: The decrease in PAI-1 levels and FRM score obtained after a 20 % decrease in hepatic steatosis suggests that this threshold of steatosis improvement is necessary to significantly reduce the cardiovascular risk in MASLD patients. *The research was funded by the University of Turin, g.n. Metabolic dysfunction associated steatotic liver disease with development of decompensated cirrhosis as long-term complication after distal gastric bypass surgery

Pamela Meyer-Herbon[1], Irina Bergamin[2], Patrizia Kuenzler[1], Patrick Folie[3], Stefan Aczel[3], Sarah Sigrist[3], Roman Stillhard[1], Stephan Brand[4], David Semela[5]. *[1]Cantonal Hospital St. Gallen, St. Gallen, Switzerland; [2]Cantonal Hospital St. Gallen, St. Gallen, Switzerland; [3]Ostschweizer Adipositaszentrum, St. Gallen, Switzerland; [4]Cantonal Hospital St. Gallen, St. Gallen, Switzerland; [5]Cantonal Hospital St. Gallen, St. Gallen*
Email: pamela.meyer@web.de

Background and aims: Bariatric surgeries such as Roux-en-Y gastric bypass and sleeve gastrectomy generally improve metabolic dysfunction, including associated steatotic liver disease (MASLD/MASH). However, some types of bariatric surgeries leading to excessive weight loss and malabsorption can exacerbate these conditions. Notably, distal gastric bypass with a very short common channel can cause iatrogenic short-bowel syndrome with severe malnutrition, dysbiosis and excessive lipolysis potentially promoting progression of MASLD. Our aim was to analyze a series of 12 patients who developed decompensated cirrhosis after distal bypass surgery and recompensated after bypass proximalization.
Method: Retrospective study of patients who underwent distal very long Roux-en-Y gastric bypass (DVLRYGB) between 2005 and 2010 and subsequently progressed to liver cirrhosis with portal hypertension at our tertiary centre with approximately 200 bariatric operations per year
Results: Twelve patients were identified (initial BMI 39.1 to 56.1 kg/m2; 7 females, 5 males) who developed histologically confirmed cirrhosis due to steatohepatitis after DVLRYGB with clinically significant portal hypertension (hepatic venous pressure gradient (HVPG) 10 to 20 mmHg in 11/12 patients) and liver failure. Decompensation occurred on average 10 years (range 6–18) after bypass surgery at the age of 51 years (range 35–68). All except one patient presented with severe malnutrition, hypoalbuminemia and hepatic encephalopathy (West Haven grade 2–4) necessitating hospitalization. 10/12 (83%) patients presented with ascites, severely limited liver function (Child C, except 2 patients with B 9 points) and elevated MELD scores (mean 22, range 17–30). To date, 6/12 (50%) patients underwent successful proximalization of the gastric bypass. Surgical prolongation of the common channel (mean length 66 cm (range 30–80 cm) before to 274 cm (range 80–425 cm) after conversion) resolved symptoms (malnutrition, hepatic encephalopathy, ascites) and improved liver function (MELD score mean 22 (range 10–30) before to 11 (range 6–19) after conversion). A preoperative TIPS was placed in 4/6 patients with severe portal hypertension (mean HVPG 17 mmHg, range 14–20 mmHg) with a decrease to ≤10 mmHg in all patients after TIPS placement. Postoperative follow-up period (range 5–80 months) after conversion showed no new decompensation since proximalization (range 5–80 months). Two patients rejected proximalization surgery, 1 patient died before surgery and 3 patients are currently being prepared for proximalization.
Conclusion: Distal gastric bypass with very short common channel heightens the risk of steatohepatitis with development of long-term hepatic decompensation. Regular surveillance and early conversion to proximal gastric bypass are necessary for DVLRYGB patients to prevent MASLD progression and liver failure.

Influence of reproductive status, synthetic hormone use, and co-medication on serum homocysteine levels and disparities in its contribution to MASLD risk

Ayako Suzuki[1,2], Mizuki Suzuki[3], George Boon Bee Goh[4], Brijesh Kumar Singh[5], Madhulika Tripathi[5], Xiaoming Xu[6], Anna Mae Diehl[1], Paul Yen[5], Manal F. Abdelmalek[7]. *[1]Gastroenterology, Duke University, Durham, United States; [2]Gastroenterology, Durham VA Medical Center, Durham, United States; [3]Brody School of Medicine, East Carolina University, Greenville, United States; [4]Singapore General Hospital, Singapore, Singapore; [5]Duke-NUS Medical School, Singapore, Singapore; [6]Biostatistics, Duke University, Durham, United States; [7]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States*
Email: ayako.suzuki@duke.edu

Background and aims: Accumulation of hepatic homocysteine (Hcy) has been linked to inflammation and fibrosis, while vitamin B12 and B9 reduce Hcy in the liver and serum, offering protection against steatohepatitis in experimental metabolic dysfunction-associated steatotic liver disease (MASLD). Given the significant influence of sex hormone on Hcy metabolism and the sexual dimorphism in MASLD pathobiology, the contribution of Hcy to MASLD risk may vary based on age, sex, and menopausal status. We aim to assess the association of serum Hcy with the fatty liver index (FLI) and NAFLD fibrosis score (NFS), taking these factors into consideration.
Method: Data from the National Health and Nutrition Examination Survey (NHANES) 1999–2006 were utilized. Excess alcohol use was defined as ≥14 servings for males and ≥7 servings for females weekly. Pregnancy, synthetic sex hormone use (estrogen or progesterone), menopausal status, and comedication use were defined at evaluation. Fatty Liver Index (FLI) and NAFLD Fibrosis Score (NFS) were computed. After excluding pregnancy, viral hepatitis and excess alcohol use, the cohort was then classified based on FLI (MASLD by FLI of 30 or higher). Serum Hcy comparisons utilized appropriate statistical tests, with multiple linear regression adjusting for confounders.
Results: In 11, 249 subjects with available serum Hcy and FLI, serum Hcy was significantly higher in subjects of older age, male, postmenopausal women, and non-Hispanic White ($p < 0.0001$). Lower Hcy correlated with pregnancy and synthetic hormone use among post-menopausal women ($p < 0.0001$). Conversely, higher Hcy correlated with excess alcohol use, active HCV infection, co-

medication with proton pump inhibitors and/or metformin, and synthetic hormone use among premenopausal women ($p < 0.0001$). Following the exclusions, higher FLI was associated with higher Hcy levels (FLI < 30 vs. FLI ≥ 30, FLI ≥ 60, $p < 0.0001$), primarily driven by age, sex, menopause, and race/ethnicity. Notably, among postmenopausal women, those with MASLD vs. without tended to have higher Hcy, even after adjusting for age and race/ethnicity ($p = 0.05$). Among MASLD participants, those in a higher NFS group (by median) had elevated Hcy ($p < 0.05$). After adjusting for age and race/ethnicity, MASLD participants in the higher NFS group were associated with higher Hcy specifically among postmenopausal women ($p = 0.015$).
Conclusion: Serum Hcy is influenced by various patient factors, including age, sex, women's reproductive status, and comedications. While subjects with higher FLI exhibited higher Hcy levels, age, sex, menopause, and race/ethnicity were major contributors to this difference. The association between higher NFS and Hcy was notable among postmenopausal women even after age and race/ethnicity adjustment, suggesting a more prominent contribution of Hcy to MASLD risk in this subgroup.

FRI-317
Clinical outcomes of metabolic liver disease versus non-alcoholic fatty liver disease: a meta-analysis of observational studies
Grazia Pennisi[1], Giuseppe Infantino[1], Ciro Celsa[1], Gabriele Di Maria[1], Marco Enea[2], Marco Vaccaro[2], Roberto Cannella[3], Carlo Ciccioli[1], Claudia La Mantia[1], Alessandro Mantovani[4], Francesco Mercurio[1], Herbert Tilg[5], Giovanni Targher[4], Vito Di Marco[1], Calogero Camma[1], Salvatore Petta[1]. *[1]Section of Gastroenterology and Hepatology, Dipartimento Di Promozione Della Salute, Materno Infantile, Medicina Interna e Specialistica Di Eccellenza (PROMISE), University of Palermo, Italy, Palermo, Italy; [2]Dipartimento di Scienze Economiche, Aziendali e Statistiche, University of Palermo, Italy, Palermo, Italy; [3]Department of Biomedicine, Neuroscience and Advanced Diagnostics (BiND), University of Palermo, Italy, Palermo, Italy; [4]Department of Medicine, Section of Endocrinology, Diabetes, and Metabolism, University of Verona, Verona, Italy, Verona, Italy; [5]Department of Internal Medicine I, Gastroenterology, Hepatology, Endocrinology and Metabolism, Medical University Innsbruck, Austria, Innsbruck, Austria*
Email: graziapennisi901@gmail.com

Background and aims: The recent terminology change from non-alcoholic fatty liver disease (NAFLD) to metabolic dysfunction-associated fatty liver disease (MAFLD) and then metabolic dysfunction-associated steatotic liver disease (MASLD) highlights the link between hepatic steatosis and metabolic dysfunction, taking out the stigmata of alcohol. We examined the comparative effects of NAFLD and MAFLD definitions on the risk of overall and cardiovascular (CV) mortality, liver-related events (LRE), nonfatal CV events (CVE), chronic kidney disease (CKD) and extra-hepatic cancers (EHC).
Method: We systematically searched four large electronic databases for cohort studies (published through August 2023) that simultaneously used NAFLD and MAFLD definitions for examining the risk of mortality and adverse cardiovascular, renal, or oncological outcomes associated with both definitions. In total, 21 eligible cohort studies were identified.
Results: Compared with those with NAFLD, MAFLD individuals had significantly higher rates of overall mortality (random-effect OR 1.12, C.I. 1.04–1.21, $p = 0.004$) and cardiovascular mortality (OR 1.15, C.I. 1.04–1.26, $p = 0.004$), and a marginal trend towards higher rates of CKD (OR 1.06, C.I. 1.00–1.12, $p = 0.058$) and EHC events (OR 1.11, C.I. 1.00–1.23, $p = 0.052$). We found no significant differences in LRE and nonfatal CVE between MAFLD and NAFLD. Meta-regression analyses identified male sex and metabolic comorbidities as the strongest risk factors related to the risk of adverse clinical outcomes in MAFLD compared to NAFLD.
Conclusion: Individuals with MAFLD have higher rates of overall and cardiovascular mortality and higher rates of CKD and EHC events than those with NAFLD, possibly due to the less favorable metabolic risk profile of MAFLD.

MASLD – Diagnostics and non-invasive assessment

Email: katrine.tholstrup.bech@rsyd.dk

Background and aims: The rising prevalence of steatotic liver disease highlights the importance of timely detection of advanced fibrosis and continuous monitoring to detect those who progress. Liver stiffness measurements (LSM) by vibration-controlled transient elastography (VCTE) <8 kPa effectively rule out advanced fibrosis and therefore often serve as a threshold in fibrosis screening. However, the longitudinal trends in LSM in both general and at-risk

populations remain largely unexplored. We therefore aimed to assess the proportion of participants experiencing clinically significant changes in LSM in a longitudinal population-based screening cohort.
Method: This multicenter study, conducted across Spain (ES), The Netherlands (NL) and Denmark (DK), prospectively enrolled participants from the general population (ES and NL), as well as people with current or prior moderate-high alcohol consumption (DK). Participants initially underwent liver fibrosis screening using LSM by VCTE, and were invited to a follow-up investigation after a mean of 3.7 years. We defined a clinically significant LSM change as an alteration (increase or decrease) of ≥20%, with sub-analyses of examinations crossing the 8 kPa threshold.
Results: We included 5, 517 participants for baseline screening, with 3, 266 participants (2, 530 from the general population and 736 at risk of ALD) undergoing a follow-up investigation. Median ages for the ES, NL, and DK cohorts were 59, 71, and 59 years, respectively. Follow-up participation rate across the cohorts was 73–80% when excluding those lost to follow-up due to various reasons (not found, moved, ill, dead). Among participants with baseline LSM <8 kPa, 3.0% increased significantly and to a final LSM ≥8 kPa, a trend consistent across all cohorts. This group more often comprised male participants with metabolic dysfunction. Within this subset, 63% increased within the 8–9.9 kPa range. Overall, 1.1% participants increased from <8 kPa at baseline to ≥10 kPa at follow-up, most pronounced in the younger, general cohort (ES: 1.4%) and the ALD-risk cohort (DK: 1.2%) compared to the older, general cohort (NL: 0.5%). Of participants with baseline LSM ≥8 kPa, 8.8% increased significantly (ES: 6.2%, NL: 10.4%, DK: 10.0%). Conversely, 72% of participants either decreased significantly or decreased to LSM <8 kPa, with the biggest difference between the two general cohorts (ES: 80% vs. NL 61%).
Conclusion: An 8 kPa liver stiffness threshold provides relevant information for clinical decision making when monitoring steatotic liver disease in the population at intervals spanning 3–4 years. Our findings indicate, that about 1% of individuals screening below this threshold will progress to stages suggestive of advanced fibrosis, whereas up to nearly 10% of patients screening above the threshold will experience a clinically significant increase in liver stiffness.

Longitudinal changes of FIB-4 do not predict outcomes in patients with metabolic dysfunction-associated steatotic liver disease

Hannes Hegmar[1], Terry Therneau[2], Prowpanga Udompap[3], Rachel Canning[2], Jun Yin[2], Ross Dierkhising[2], Joanne Benson[2], Alina M Allen[3]. *[1]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, Minnesota, USA., Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden, Rochester, United States; [2]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, Minnesota, USA, Rochester, United States; [3]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, Minnesota, USA., Rochester, United States*
Email: hhegmar@gmail.com

Background and aims: Non-invasive biomarkers may predict the progression to liver-related outcomes in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). The predictive value of longitudinal changes, including the rate of change, is uncertain. We aimed to examine if changes in FIB-4 over time could predict progression to liver and cardiovascular-related outcomes in patients with MASLD.
Method: This is a population-based cohort study of all patients with MASLD from Olmsted County, Minnesota, diagnosed between 1996 and 2016 based on clinical, biochemical, and radiological criteria. Follow-up continued until first outcome, death, or end-of study (2019). Liver-related outcomes included compensated cirrhosis, a decompensation event, liver transplantation, and hepatocellular carcinoma (HCC). Cardiovascular outcomes included myocardial infarction, stroke, heart failure, angina, atrial fibrillation, and cardiac arrest. All outcomes were ascertained and validated through medical record review. All available FIB-4 scores during follow-up were calculated, and a Cox model treating FIB-4 as a time-dependent covariate was used.
Results: A total of 5, 123 patients with MASLD were included. The median age was 52 years (range 18–95 years), 53% were women. Over a median follow-up time of 6.4 (range 1–23 years), 137 patients experienced progression to a liver-related outcome. An elevated FIB-4 at any time point was associated with an increased rate of progression to liver-related outcomes, with a hazard ratio (HR) of 3.29 (95% confidence interval [CI] = 3.17–3.40) per unit increase in FIB-4 until a FIB-4 score of 5, beyond which the rate stabilized. Among the FIB-4 components, the natural logarithms of AST, (HR 9.17, 95% CI = 8.86–9.47), ALT (HR 0.63, 95% CI = 0.32–0.94), and the platelet level (HR 0.09, 95% CI = 0–0.38), respectively, were all individually associated with an increased rate of progression to liver-related outcomes. Additionally, 858 patients experienced a cardiovascular outcome, and an increased FIB-4 was associated with a higher rate of cardiovascular outcomes, HR 1.13 (95% CI = 1.07–1.19) per unit increase of FIB-4. However, longitudinal change in FIB-4 value was not significantly associated with an increased rate of progression to liver (p = 0.87) or cardiovascular-related (p = 0.86) outcomes.
Conclusion: An increased FIB-4 at any time point, but not the longitudinal trend over time, predicted a higher rate of progression to liver or cardiovascular outcomes in patients with MASLD. This indicates that repeated measurements can provide important prognostic information, but the optimal timing of a repeated measurement remains unknown.

TOP-253

Clinical, biological and imaging predictors of at-risk MASH: combined data from multiple therapeutic trials including more than 10, 000 patients

Stephen A. Harrison[1], Julie Dubourg[2], Naim Alkhouri[3], Mazen Noureddin[4], Jörn M Schattenberg[5], Sophie Jeannin[2], Vlad Ratziu[6], Michael Charlton[7]. *[1]Radcliffe Department of Medicine, University of Oxford, Pinnacle Clinical Research, Oxford, United Kingdom; [2]Summit Clinical Research, San Antonio, United States; [3]Arizona Liver Health, Phoenix, United States; [4]Houston Research Institute, Houston, United States; [5]Saarland University Medical Center, Homburg, Germany; [6]Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France; [7]University of Chicago, Chicago, United States*
Email: jdubourg@summitclinicalresearch.com

Background and aims: The identification of at-risk metabolic dysfunction-associated steatohepatitis (MASH) patients remains a main challenge in both clinical practice and clinical trial settings. Several non-invasive biomarkers have been developed to identify those at-risk MASH patients who would benefit from pharmacological therapy. We aimed to describe the main predictors of at-risk MASH across multiple therapeutic clinical trials.
Method: We combined screening data from 10 industry-funded MASH phase 2 trials. Predictors of at risk-MASH (MASH + NAS ≥4+ F2–3) were examined using logistic regression and excluding patients with cirrhosis.
Results: 3, 672 patients with centrally assessed liver biopsy and absence of cirrhosis were included in this analysis. Among them, 1, 395 (38%) met the histopathological criteria for at-risk MASH. The proportion of at risk-MASH patients was 12%, 25%, 41% and 59% in patients with AST <20, AST 20–30, AST 30–40, and AST ≥40 IU/L, respectively. This rised to 51% in patients with AST ≥30 versus 20% in patients with AST <30. In patients with FAST<0.35, FAST 0.35–0.67, and FAST ≥0.67, 38%, 57%, and 73% were "at-risk MASH," respectively. This rised to 68% for patients with FAST ≥0.5 versus 42% in patients with FAST <0.5. When focusing on Fib-4 categories (<1.3, 1.3–2.67, ≥2.67), the at-risk MASH population represented 27%, 53%, and 65% of the patients, respectively. The proportion of at-risk MASH patients

was 31% in patients with HbA1c <6.5% compared to 50% in patients with HbA1c ≥6.5%. In the population with AST ≥30, 64% of patients with HbA1c ≥6.5% were "at-risk MASH" compared to 43% with HbA1c <6.5%. Similarly, in the subgroup of patients with AST ≥40, 70% of patients with HbA1c ≥6.5% were "at-risk MASH" compared to 51% with HbA1c <6.5%. In the population with FAST ≥0.50, 74% of patients with HbA1c ≥6.5% were "at-risk MASH" compared to 63% with HbA1c <6.5%. Similarly, in the subgroup with FAST ≥0.67, patients with HbA1c ≥6.5% had a higher probability of at-risk MASH (79%) compared to those with HbA1c <6.5% (68%).
Conclusion: Simple non-invasive biomarkers can help stratify at-risk MASH patients. We recommend using the FAST-score or AST as simple tools to target at-risk MASH patients with cut-off points of 0.5 for FAST and/or 30 IU/L for AST in patients with HbA1c ≥6.5% and 0.67 for FAST and/or 40 IU/L for AST in patients with HbA1c <6.5%.

TOP-264

Paired assessment of enhanced liver fibrosis (ELF) and fibrosis-4 (FIB-4) scores is associated with an elevated risk of liver-related clinical events in participants with advanced fibrosis due to metabolic dysfunction-associated steatohepatitis (MASH)

Rohit Loomba[1], Naim Alkhouri[2], Mazen Noureddin[3], Jason H. Melehani[4], Xiaomin Lu[4], Xiangyu Liu[4], Lulu Wang[4], Catherine Jia[4], Jun Xu[4], Andrew N. Billin[4], Lisa Boyette[4], Timothy R. Watkins[4]. *[1]School of Medicine, University of California San Diego, La Jolla, United States; [2]Arizona Liver Health, Chandler, United States; [3]Houston Research Institute, Houston Methodist Hospital, Houston, United States; [4]Gilead Sciences, Inc., Foster City, United States*
Email: roloomba@health.ucsd.edu

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH, previously non-alcoholic steatohepatitis [NASH]) is a leading cause of cirrhosis and liver-related mortality. Non-invasive tests (NITs) are commonly used to stratify risk in individuals with MASH. Identifying individuals at risk of liver-related clinical events remains an important unmet need. Our objective was to determine whether a combination of commonly measured NITs was associated with risk of liver-related clinical events in people with advanced MASH.
Method: Data from participants with advanced fibrosis due to MASH enrolled in four placebo-controlled trials evaluating simtuzumab (NCT02466516, NCT01672879) and selonsertib (NCT03053050, NCT03053063) were analyzed. All participants had F3/F4 fibrosis at baseline (centrally read liver biopsy). Baseline Enhanced Liver Fibrosis (ELF™) and Fibrosis-4 (FIB-4) scores were assessed per trial protocol and categorized into concordant-low, concordant-high or discordant risk groups based on NIT thresholds established in previous studies (ELF ≥11.3 and FIB-4 ≥3.5). Event-free survival for these risk groups was estimated using the Kaplan-Meier method. Hazard ratios (HR) were estimated using a Cox regression model.
Results: Among 2153 participants (F3, n = 1020; F4, n = 1133), the baseline median (Q1, Q3) values of ELF and FIB-4 scores were 10.3 (9.7, 11.0) and 2.1 (1.4, 3.2), respectively. During a median follow-up of 16.5 months, 80 participants experienced liver-related clinical events. The 1-year event rates were 0.5%, 2.5% and 15.0% in the concordant-low, discordant and concordant-high risk groups, respectively. When evaluating ELF and FIB-4, the concordant-high risk group showed the strongest association with liver-related events versus those in the concordant-low risk group (HR 21.4; 95% confidence internal [CI] 11.5–39.5). Discordance between ELF and FIB-4 showed an intermediate association for liver-related events versus the concordant-low risk group (HR 6.5; 95% CI 3.4–12.7).
Conclusion: In this cohort of participants with advanced fibrosis due to MASH, paired evaluation of ELF and FIB-4 demonstrated a significant association with liver-related clinical events. Further research is required to validate this model, which could serve to identify and enrich trials designed to test drugs that could prevent or attenuate MASH disease progression.

TOP-265

Non-invasive predictive markers of resmetirom biopsy response

Rohit Loomba[1], Jörn M Schattenberg[2], Rebecca Taub[3], Dominic Labriola[3], Mazen Noureddin[4], Vlad Ratziu[5], Stephen A. Harrison[6]. *[1]University of California San Diego, LaJolla, United States; [2]Metabolic Liver Research Program, I. Department of Medicine, University Medical Center of Johannes Gutenburg University, Department of Internal Medicine II, Saarland University Medical Center, Mainz, Germany; [3]Madrigal Pharmaceuticals, West Conshohocken, United States; [4]Houston Methodist Hospital, Houston Research Institute, Houston, United States; [5]Sorbonne Université, ICAN Institute for Cardiometabolism and Nutrition, Assistance Publique Hôpitaux de Paris, Paris, France; [6]Pinnacle Clinical Research, San Antonio, United States*
Email: roloomba@health.ucsd.edu

Background and aims: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo-controlled Phase 3 trial evaluating the efficacy of resmetirom in patients with biopsy-confirmed non-alcoholic steatohepatitis (NASH) and fibrosis. 966 patients with biopsy-confirmed NASH were randomized 1:1:1 to resmetirom 80 mg, resmetirom 100 mg, or placebo administered once daily. Histologic end points were assessed after 52 weeks. Dual primary end points at Week 52 were achieved with both resmetirom 80 mg and 100 mg: NASH resolution with no worsening of fibrosis (NR) or ≥1-stage reduction in fibrosis with no worsening of NAS (FR).
Method: Adults with ≥3 metabolic risk factors, liver stiffness ≥8.5 kPa, hepatic fat ≥8%, biopsy-confirmed NASH with F1B-F3 fibrosis, and NAS ≥4 were eligible to participate in MAESTRO-NASH. In this analysis, the relationship of changes in (1) FibroScan CAP, (2) Fibroscan VCTE, and (3) alanine aminotransferase (ALT) to histological response (NR and/or FR) in the resmetirom 80 mg, resmetirom 100 mg, and placebo groups was assessed.
Results: Patients with biopsy-confirmed NASH with fibrosis had high metabolic risk including obesity (mean BMI = 36), type 2 diabetes (70%), hypertension (78%), and 10-year ASCVD risk score >14. Baseline mean (SD) FibroScan VCTE was 13.3 (6.8), 13.6 (7.1), and 12.9 (5.6) kPa for the resmetirom 80 mg, resmetirom 100 mg, and placebo groups. Baseline ELF across all fibrosis groups was 9.8 (0.87). FIB-4 across all dose groups was 1.3. CAP improved with resmetirom treatment. CAP improvement in individual resmetirom patients predicted both NR and FI responses; however, even no change in CAP predicted biopsy responses higher than the mean for placebo. A CAP improvement in placebo patients did not predict an FI on biopsy. VCTE was improved over time (1–3 years) years relative to placebo in resmetirom treated patients. Resmetirom treated patients, even those with no VCTE improvement, had higher NASH resolution and fibrosis improvement responses than the mean placebo response rates. VCTE improvement was poorly predictive of a placebo FI or NR response; worsening of VCTE in placebo patients predicted a lower-than-average NASH resolution and fibrosis improvement. Both doses of resmetirom significantly reduced ALT approximately 30% relative to placebo. In resmetirom treated patients, higher % reductions in ALT were associated with higher NR and FI on biopsy. For resmetirom treated patients without a reduction in ALT, the NASH resolution and fibrosis improvement responses were predicted to be higher than the mean placebo biopsy responses.
Conclusion: ALT was reduced and CAP and VCTE improved was by resmetirom relative to placebo. However, biopsy responses were not always associated with changes in these markers. Additional analyses, including artificial intelligence (AI)-based assessments of histological response, are ongoing.

Time-trends of fibrosis and steatosis in metabolic dysfunction-associated steatotic liver disease (MASLD): a retrospective cohort analysis

Umang Arora[1], Sagnik Biswas[1], Vignesh Dwarkanathan[2], Sabreena Sheikh[1], Ayush Agarwal[1], Arnav Aggarwal[1], Shubham Mehta[1], Shalimar Shalimar[1]. [1]*All India Institute of Medical Sciences, New Delhi, India,* [2]*E.S.I.C Medical College and Hospital, Chennai, India*
Email: umangarora@gmail.com

Background and aims: The progression of liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) on Transient Elastography (TE), well-accepted surrogates for fibrosis and steatosis, have not been well characterised in patients with metabolic dysfunction-associated fatty liver disease (MASLD). We aimed to identify the rate of progression of LSM and CAP scores and factors associated with this increase.
Method: We performed a retrospective analysis of a large cohort of patients with MASLD (n = 1016). We included all patients for whom at least 2 LSM were available, taken 6 months apart. We excluded LSM observations with baseline LSM >15 kPa (indicating cirrhosis), IQR/LSM value >30 (considered unreliable), and high liver enzymes (ALT >200 IU/ml). Repeated measurements of LSM and weight at each visit were obtained. The last observation (last observation carried forward method) replaced missing values for weight at each visit. The time duration between visits was rounded off to the nearest 6 months. Patient and their visits were assigned as panel data and random effects regression was performed to assess time-variable and time-invariant predictors of an increase in LSM or CAP using 'xtreg' in Stata v14 and coefficients reported with 95% confidence intervals (CI).
Results: A total of 1735 TE measurements were analysed from 421 patients, with a median (IQR) of 3 visits (2–5) and 2.5 years (1–4.5) of follow-up per patient. The mean (SD) age was 41.1 (10.4) years, 289 males (68.8%), 76 (18.1%) with diabetes, 86 (20.4%) with hypertension, and the mean (SD) BMI was 27.31 (3.76) kg/m^2. The median (IQR) LSM and CAP of the population was 6.1 kPa (4.9–7.9) and 320 dB/m (290–345). Throughout follow-up, the median (IQR) delta change in LSM between the baseline and last follow-up was 0 kPa (−1.20–1.70), and the delta change per year was 0 kPa/year (−0.70–0.57). Unadjusted regression coefficients for time duration (years) for LSM were 0.30 (95% CI 0.20–0.39) and CAP was −2.83 (95% CI −3.92–0.17). After multivariable regression, we found that a rise in LSM was influenced by age (0.03 (0.00–0.07), p = 0.05), presence of diabetes (1.23 (95% CI 0.30–2.16), p = 0.01), BMI (0.10 (0.02–0.18), p = 0.02), and time duration (0.29 (95% CI 0.20–0.39), p ≤0 .01), indicating a rise during follow-up. Assuming a linear rise in LSM, 1 year of follow-up would lead to an increase in LSM by 0.30 kPa, or a 1 kPa increase would require 3.3 years. The rise in LSM per year was higher among diabetics (0.56 (0.23–0.88) vs 0.24 (0.15–0.33), p < 0.001). On the contrary, only two factors affected change in CAP during follow-up including an increase in BMI (5.03 (4.25–5.81), p < 0.001) while CAP reduced with increased time duration of follow-up (-3.12 (95% CI −4.18–−2.07), p < 0.001).
Conclusion: LSM change on follow-up occurs at 0.3 kPa per year and is influenced by older age, higher BMI and presence of diabetes at baseline.

Liver fibrosis assessed via non-invasive tests is associated with incident heart failure in a general population cohort: a UK Biobank study

Theresa Hydes[1], Oliver Kennedy[2], Kate Glyn-Owen[2], Ryan M. Buchanan[1], Julie Parkes[2], Daniel Cuthbertson[1], Paul Roderick[2], Chris D. Byrne[2]. [1]*University of Liverpool, Liverpool, United Kingdom;* [2]*University of Southampton, Southampton, United Kingdom*
Email: therasa@doctors.org.uk

Background and aims: Liver fibrosis is associated with cardiovascular events. The association between liver fibrosis and heart failure in a general population cohort is unknown. The relationship between *PNPLA3* rs738409 and *TM6SF2* rs58542926 and heart failure is of interest, given the associations of these polymorphisms with increased risk of liver fibrosis and decreased risk of coronary artery disease. We aimed to determine whether liver fibrosis is associated with heart failure in a general population cohort, and if genetic polymorphisms (*PNPLA3* rs738409; *TM6SF2* rs58542926) linked to increased risk of liver fibrosis and decreased risk of coronary artery disease modify this association.
Method: Using UK Biobank data, we prospectively examined the relationship between non-invasive fibrosis markers (NAFLD fibrosis score (NFS), Fibrosis-4 (FIB-4) and AST to platelet ratio index (APRI)) and incident hospitalization/death from heart failure (n = 413, 860). Cox-regression estimated hazard ratios (HR) for incident heart failure. Effects of *PNPLA3* and *TM6SF2* on the association between liver fibrosis and heart failure were estimated by stratifying for genotype, and testing for an interaction between genotype and liver fibrosis using a likelihood ratio test.
Results: 12, 527 incident cases of heart failure occurred over a median of 10.7 years. Liver fibrosis was associated with an increased risk of hospitalization or death from heart failure (multivariable adjusted high risk NFS score HR 1.59 [1.47–1.76], p < 0.0001; FIB-4 HR 1.69 [1.55–1.84], p < 0.0001; APRI HR 1.85 [1.56–2.19], p < 0.0001; combined fibrosis scores HR 1.90 [1.44–2.49], p < 0.0001). These associations persisted for people with MASLD, Met-ALD or harmful alcohol consumption. *PNPLA3* rs738409 GG and *TM6SF2* rs58542926 TT did not attenuate the positive association between fibrosis markers and heart failure. For *PNPLA3* a statistically significant interaction was found between *PNPLA3* rs738409, FIB-4, APRI score and heart failure.
Conclusion: In the general population, serum markers of liver fibrosis are associated with increased hospitalization/death from heart failure. Genetic polymorphisms associated with liver fibrosis and decreased risk of coronary artery disease were not positively associated with elevated heart failure risk but did not attenuate this risk.

TOP-288

Serum GDF15 level, in combination with the FIB-4 index, is useful for refining the identification of high-risk patients for clinical event occurrence in MASLD patients

Hayato Hikita[1], Shunsuke Kumazaki[2], Yuki Tahata[1], Ji Hyun Sung[1], Kenji Fukumoto[1], Yuta Myojin[1], Sadatsugu Sakane[1], Kazuhiro Murai[1], Yoichi Sasaki[1], Kumiko Shirai[1], Takahiro Kodama[1], naruyasu kakita[3], Hirokazu Takahashi[4], Hidenori Toyoda[5], Goki Suda[6], Eiichi Morii[1], Takashi Kojima[1], Takeshi Ebihara[1], Kentaro Shimizu[1], Yutaka Sasaki[7], Tomohide Tatsumi[1], Tetsuo Takehara[1]. [1]*Osaka University, Graduate School of Medicine, Suita, Japan;* [2]*Osaka University, Graduate School of Medicine, Suita, Japan;* [3]*Kaizuka City Hospital, Kaizuka, Japan;* [4]*Saga University, Saga, Japan;* [5]*Ogaki Municipal Hospital, Ogaki, Japan;* [6]*Hokkaido University, Sapporo, Japan;* [7]*Osaka Central Hospital, Osaka, Japan*
Email: hikita@gh.med.osaka-u.ac.jp

Background and aims: Some MASLD patients develop liver cancer or decompensated liver event emphasizing the need for a biomarker identifying high-risk patients who should be followed up. GDF15 is a cell stress-responsive cytokine related to metabolic syndrome. The aim of the present study was to evaluate the utility of the serum GDF15 level as a novel predictive marker for liver-related events, including liver cancer, decompensated liver event and death, in patients with MASLD.
Method: GDF15 levels were measured in 518 MASLD patients with liver biopsy (biopsy-cohort), and 216 MASLD patients from another institution (validation cohort), and 361 individuals meeting MASLD criteria during health checkups.

Results: In biopsy-cohort, serum GDF15 level was an independent risk factor for liver cancer occurrence along with liver fibrosis stage or Fib-4 index. The AUROC of serum GDF15 level for 3-year and 5-year liver cancer incidence was 0.949 and 0.941, respectively. Using a GDF15 cutoff of 1.75, based on Youden index, GDF15-high patients (n = 153) had significantly higher liver cancer incidence rates with 4.8 and 7.7% at 3 and 5 years, respectively compared to GDF15-low patients (n = 365) with 0.0% within 5 years. Notably, GDF15-high patients exhibited significantly greater liver cancer incidence rates than GDF15-low patients, irrespective of fibrosis status or Fib-4 index levels. While no patients with a Fib-4 index <1.3 (n = 171) or GDF15-low patients with a Fib-4 index >1.3 (n = 209) developed liver cancer within 5 years, GDF15-high patients with a Fib-4 index >1.3 (n = 138) had high liver cancer incidence rates with 5.3% and 8.6% at 3 and 5 years, respectively. GDF15-high patients with a Fib-4 index >1.3 also developed liver decompensated events at higher rate and had poorer prognosis compared to the others. In validation cohort, GDF15-high patients (n = 72) had significantly higher liver cancer incidence rates with 7.2% and 16.8% at 3 and 5 years, respectively compared to GDF15-low patients (n = 144) with 0.8% within 5 years. While patients with a Fib-4 index <1.3 (n = 93) and GDF15-low patients with a Fib-4 index >1.3 (n = 60) rarely developed liver cancer with 1.5% and 1.8%, respectively, at 5 years, GDF15-high patients with a Fib-4 index >1.3 (n = 63) had high liver cancer incidence rates with 6.1% and 16.5% at 3 and 5 years, respectively, and also developed liver decompensated events at high rate and had poor prognosis. Among 364 health checkups with MASLD, 18 individuals (4.9%) had a GDF15 >1.75 ng/ml. Furthermore, 278 individuals (76.4%) had a Fib4 index <1.3, 76 individuals (20.9%) had a Fib4 index >1.3 and a GDF15 <1.75 ng/ml, and only 10 individuals (2.7%) had a Fib4 index >1.3 and a GDF15 >1.75 ng/ml.

Conclusion: Serum GDF15 level is a novel biomarker for liver cancer occurrence with high predictive capability and can be used in combination with the Fib-4 index to identify MASLD patients for close follow-up.

TOP-289

Artificial intelligence-based measurement of non-alcoholic steatohepatitis is an accurate tool for clinical trial enrollment and end point assessment

Hanna Pulaski[1], Hypatia Hou[1], Murray Resnick[1], Stephen A. Harrison[2], Arun J Sanyal[3], Vlad Ratziu[4], Alastair Burt[5], Pierre Bedossa[6], Michael Montalto[1], Katy Wack[1]. *[1]PathAI, Boston, United States; [2]Pinnacle Clinical Research, San Antonio, United States; [3]Virginia Commonwealth University, Richmomd, United States; [4]Sorbonne Université, Paris, France; [5]Newcastle University, Newcastle, United Kingdom; [6]LIVERPAT, Paris, France*
Email: hanna.pulaski@pathai.com

Background and aims: A major obstacle in the development of effective metabolic dysfunction-associated steatohepatitis (MASH) therapies is the lack of a reliable histologic scoring method. The current gold standard is histologic analysis of the liver biopsy, however, the scoring systems have suboptimal inter-reader agreement, even amongst expert pathologists. In this study, Artificial Intelligence-based Measurement of Non-alcoholic Steatohepatitis (AIM-NASH) was evaluated for overall percent agreement (OPA) and for positive and negative percent agreement (PPA and NPA) for main trial inclusion and end point criteria.

Method: In a clinical validation study (Harrison SA, EASL 2023), liver biopsies collected from multiple Phase II and Phase III MASH trials from cirrhotic and non-cirrhotic patients were analyzed. A panel of expert pathologists established GT MASH scores. Cases were also evaluated by at least 3 other experienced pathologists who independently provided MASH scores for the same samples (IMRs). After a minimum 2-week washout period, AI-assisted scores were collected. OPA, NPA and PPA were determined for main trial inclusion and end point criteria (NAS ≥4 with ≥1 in each score category, fibrosis 2 or 3, fibrosis 4 and MASH resolution) for AI-assisted vs GT and individual manual reader (IMR) vs GT.

Results: OPA and PPA for all trial inclusion and enrollment criteria were over 75% (AI-assisted vs GT for NAS ≥4 with ≥1 in each category OPA = 84%, PPA = 87.6%; fibrosis 2 or 3 OPA = 80.5%, PPA = 85.3%; fibrosis 4 OPA = 91.8%, PPA = 79.6% and MASH resolution OPA = 89.0%, PPA = 75.5%) and were higher for all of the categories compared to IMR vs GT, with NAS ≥4, MASH resolution and fibrosis 2 or 3 being superior (NAS ≥4 OPA difference 6.4%, p < 0.001, PPA difference 9.8%, p < 0.001; MASH resolution OPA difference 6.5% p < 0.001, PPA difference 18.3%, p < 0.001, fibrosis 2 or 3 OPA difference 3.3%, p = 0.01, PPA difference 9.3%, p < 0.001). For PPA, fibrosis 2 or 3 was also superior to IMR vs GT (PPA difference 9.3%, p < 0.001). Strikingly, MASH resolution PPA was 18.3% higher for AI-assisted than for unassisted compared to GT. For NPA, AI-assisted vs GT for NAS ≥4 with ≥1 in each NAS category was 76.0%, for fibrosis 2 or 3 71.2%, for fibrosis 4 95.1% and for MASH resolution 90.6%. AI-assisted was superior to IMR vs GT for MASH resolution (difference 4.8%, p < 0.001).

Conclusion: AIM-NASH is an accurate tool for assessment of MASH trial enrollment and end point criteria. AI-assisted pathologists displayed a superior OPA and PPA for trial enrollment criteria of NAS ≥4, MASH resolution and fibrosis 2 or 3, with the PPA of MASH resolution being 18.3% higher for AI-assisted vs IMRs. These data show that AIM-NASH may help to standardize histologic scoring by increasing accuracy for the most relevant clinical trial enrollment and end point criteria, allowing for a more reliable assessment of therapeutics under development.

TOP-300

Clinical, biological and imaging predictors of advanced fibrosis (F3-F4): combined data from multiple therapeutic trials including more than 10, 000 patients

Mazen Noureddin[1], Naim Alkhouri[2], Vlad Ratziu[3], Jörn M Schattenberg[4], Michael Charlton[5], Julie Dubourg[6], Stephen A. Harrison[7]. *[1]Houston Research Institute, Houston, United States; [2]Arizona Liver Health, Phoenix, United States; [3]Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France; [4]Saarland University Medical Center, Homburg, Germany; [5]University of Chicago, Chicago, United States; [6]Summit Clinical Research, San Antonio, United States; [7]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom*
Email: jdubourg@summitclinicalresearch.com

Background and aims: Advanced fibrosis, defined as fibrosis stages F3 or F4, is the strongest predictor of major liver-related outcomes in metabolic dysfunction-assocatied steatohepatitis (MASH). We aimed to describe the main predictors of advanced fibrosis across multiple therapeutic clinical trials.

Method: We combined screening data from 10 industry-funded MASH phase 2 trials. Predictors of advanced fibrosis (F3–4) were examined using logistic regression.

Results: 4, 119 patients with centrally assessed liver biopsy were included in this analysis. The prevalence of advanced fibrosis in this population was 37%. The proportion of patients with advanced fibrosis was 22%, 52% and 77% in patients with Fib-4 <1.3, Fib-4 1.3–2.67, and Fib-4 ≥2.67, respectively. The AST:ALT ratio was higher in patients with advanced fibrosis, independently of the baseline liver enzymes. The AST:ALT ratio was 0.90 (SD 0.28) and 0.92 (SD 0.31) in presence of advanced fibrosis versus 0.80 (SD 0.31) and 0.78 (SD 0.29) in absence of advanced fibrosis, in patients with normal liver enzymes, and elevated liver enzymes, respectively. The proportion of patients with advanced fibrosis was 38% and 71% in patients with ELF <9.8, and ELF ≥9.8, respectively. The proportion of patients with advanced fibrosis was 30% and 60% in patients with liver stiffness measurement (LSM) as assessed by FibroScan <9.7 kPa, and LSM ≥9.7, respectively. Glycemic control was a key independent predictor of

advanced fibrosis with 48% of the population having a HbA1c ≥6.5% compared to 30% in patients with HbA1c <6.5%. Glycemic control had the biggest impact on the ability of FIB-4 to classify patients with advanced fibrosis. In patients with Fib-4 <1.3, Fib-4 1.3–2.67, and Fib-4 ≥2.67, the proportion of patients with advanced fibrosis was 17%, 45% and 72%, respectively in patients with HbA1c <6.5% versus 31%, 62%, and 81 %, respectively, in patients with HbA1c ≥6.5%. ELF and LSM were the best predictors of advanced fibrosis in this population.
Conclusion: Patients with advanced fibrosis can be targeted by using simple non-invasive markers such as FibroScan LSM and ELF. FIB-4 appears to be too influenced by other parameters such as glycemic control and could lead to inadequate follow-up in patients with HbA1c ≥6.5%.

Diagnostic performance of non-invasive tests and comparison of AGA and EASL algorithm for the screening of MASLD-related advanced fibrosis in diabetes and nutrition clinics

Cyrielle Caussy[1], Bruno Vergès[2], Leleu Damien[2], Duvillard Laurence[2], Abichou-Klich Amna[3], Valerie Hervieu[4], Bérénice Ségrestin[5], Bin Sylvie[4], Rouland Alexia[6], Dominique Delaunay[5], Hadjadj Samy[7], Primot Claire[7], Jean-Michel Petit[2], Sybil Charrière[8], Philippe Moulin[5], Massimo Levrero[5], Bertrand Cariou[7], Emmanuel Disse[9]. *[1]Hospices Civils de Lyon, Pierre-Bénite, France; [2]Dijon University Hospital, Dijon, France; [3]Hospices Civils de Lyon, Villeurbanne, France; [4]Hospices Civils de Lyon, Lyon, France; [5]Hospices Civils de Lyon, Lyon, France; [6]Dijon University Hospital, Pierre-Bénite, France; [7]Nantes Université, CHU Nantes, CNRS, INSERM, l'institut du thorax, Nantes, France; [8]Hospices Civils de Lyon, Bron, France, [9]Hospices Civils de Lyon, Pierre-Bénite, France*
Email: cyrielle.caussy@gmail.com

Background and aims: The systematic screening for advanced fibrosis (AF) due to metabolic dysfunction-associated steatotic liver disease (MASLD) is recommended in patients with type 2 diabetes (T2D) and obesity. There are very few data of the use of non-invasive tests (NITs) for the detection of AF in this population. We aimed to compare the diagnostic performance of NITs and recommended AGA versus EASL algorithms for the referral in hepatology and the detection of patients with high risk of AF in diabetes and nutrition clinics.
Method: this is an interim analysis of prospective data from a multicenter study performed in 4 French diabetes/nutrition clinics between Oct. 2020 and Oct. 2023 (NCT04435054) enrolling participants with T2D and/or obesity and MASLD, age 40–80 years, BMI <40 kg/m2. All other causes of liver diseases were systematically excluded. All participants had a detailed liver assessment including: NFS, FIB-4, Fibrotest®, FibroMeter®, ELF™ and liver stiffness measurement (LSM) using FibroScan®. Low/high risk of AF was defined by a hierarchical composite criterion depending on availability: 1. liver biopsy </≥F3, 2. magnetic resonance elastography <2.6/≥3.62 kPa or overt imaging diagnosis of cirrhosis, or 3. LSM<8/≥12 kPa. Intermediate risk of AF was defined by no biopsy and 1. MRE 2.6–3.63 kPa or 2. TE 8–12 kPa.
Results: 652 patients were included with the following characteristics: T2D: 87%, female: 44%, hypertension: 68%, dyslipidemia 73%, mean 59.8 years and BMI: 32.6 kg/m^2. Overall, 17% had intermediate/high risk of AF and 9% were classified at high risk of AF, including 22 patients with fibrosis ≥F3, 15 with MRE values >3.6 kPa or overt imaging diagnosis of cirrhosis and 22 with LSM ≥12 kPa. The AUROCs of NITs for the detection of high-risk AF were: NFS: 0.72, FIB-4: 0.79, FibroMeter®: 0.74, Fibrotest®: 0.79, ELF™: 0.82. The AGA algorithm using FIB-4/LSM if FIB-4: 1.30–2.66, led to 16% hepatology referral including 47% (47/101) true positive (TP) for high-risk AF, 32% (32/101) with intermediate risk and 22% (22/101) false positive (FP) with low-risk AF. The EASL algorithm using FIB-4/LSM if FIB-4 ≥1.30, led to 14% hepatology referral, including 52% (47/90) TP with high-risk AF, 36% (32/90) with intermediate-risk AF and 12% (11/90) of FP with low-risk AF. Both AGA and EASL algorithm misclassified 4.6% of patients with high/intermediate-risk of AF. Replacement of LSM by ELF™ </≥9.8 in the EASL algorithm would increase the referral in hepatology to 18% including 32% TP with high-risk AF (37/114), 14% (16/114) with intermediate-risk AF and 54% FP with low-risk AF (61/114).
Conclusion: The use of AGA or EASL guidelines in patients with T2D or obesity leads to a referral in hepatology of 14 to 18% with good diagnostic performance. The EASL algorithm with LSM should be preferred as it led to lower number of referrals in hepatology, lower FP and higher detection of patients with high-risk of AF.

WED-195

NASH-PI: a randomized trial to compare cost-effectiveness across strategies for screening, referring and management of MASLD patients in clinical practice

Email: mromerogomez@us.es

Background and aims: Cost-effective strategies based on clinical pathways to detect and refer MASLD patients are urgently needed. The NASH-PI study aims to build a stepwise algorithm combining non-invasive freely available methods (FIB-4, NAFLD Fibrosis Score (NFS), Hepamet Fibrosis Score (HFS) alone or in combination) and vibration-controlled transient elastography (VCTE) in diabetic patients from both primary care and endocrinology units.
Method: From January 2021 to May 2023, 506 diabetic patients were prospectively recruited and randomized to one of these three arms: Arm A (n = 159) patients were referred following standard of care; Arm B (n = 168) patients referred due to altered combined fibrosis score (CFS) (FIB4 >1.3 or NFS >-1.456 or HFS >0.12); and Arm C (n = 179) patients referred due to HFS >0.12 or VCTE >8 kPa. Patients at risk of MASLD-fibrosis (VCTE >8kPa or clinical decision) underwent magnetic resonance elastography (MRE) protocols.
Results: Mean age was 58 years old, of them, 56.1% were male and 67.2% obese (BMI >30 Kg/m^2). Average time since diabetes diagnosis was 9.7 years. No significant differences in biochemical, anthropometrical or clinical features were observed among the three arms.

All patients from Arm A were referred, of them, 64/157 (40.7%) showed VCTE >8 kPa or were diagnosed at risk from the hepatologist, 38/64 (59.3%) underwent MRE, 9/38 (23.6%) with liver fibrosis (MRE >3.14 kPa; significant fibrosis). In Arm B, 102/136 (75%) patients were referred, 33/102 (32.3%) showed VCTE >8 kPa, 26/33 (78%) underwent MRE, 6/26 (23%) with significant fibrosis. In Arm C, 77/175 (44%) were referred, 35/77 (45.5%) showed VCTE >8 kPa or were diagnosed at risk from the hepatologist, 17/35 (48%) underwent MRE, 6/17 (35%) with significant fibrosis. The average cost for patient referral for strategy A, B and C was respectively €346, €289 and €275. Estimated cost for MASLD patient referral to the liver unit was approximately €5045, €4577 and €2708 for strategy A, B and C respectively. Strategy B and C dominates strategy A in terms of cost per significant fibrosis case detected. Globally, VCTE >8 kPa was found in 125/453 (27.6%); VCTE >10 kPa in 76/453 (16.6%) and VCTE >15 kPa in 37/453 (8.2%).
Conclusion: The NASH-PI stepwise algorithms for the management of type 2 diabetes patients with HFS and VCTE as well as with combined score between HFS, NFS and FIB-4 were both found to be cost-effective compared with the standard model of care, allowing to save respectively 46% and 9% for each case of significant fibrosis detected.

WED-196

Analyses of fibrosis biomarkers PRO-C3 and ELF in resmetirom treated patients from MAESTRO-NASH, a 52 Week NASH/MASH serial liver biopsy study

Quentin M. Anstee[1], Jörn M Schattenberg[2,3], Rebecca Taub[4], Dominic Labriola[5], Hang Zhang[4], Jim Hennan[4]. *[1]The Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle-upon-Tyne, United Kingdom; [2]Metabolic Liver Research Program, I. Department of Medicine, University Medical Center of Johannes Gutenburg University Mainz, Mainz, Germany; [3]Department of Internal Medicine II, Saarland University Medical Center, Homburg, Germany; [4]Madrigal Pharmaceuticals, Inc., West Conshohocken, PA, United States; [5]. Madrigal Pharmaceuticals, Inc., West Conshohocken, PA, United States*
Email: quentin.anstee@newcastle.ac.uk

Background and aims: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo-controlled Phase 3 trial evaluating the efficacy of resmetirom in patients with biopsy-confirmed non-alcoholic steatohepatitis (NASH/MASH) and fibrosis. 966 patients with biopsy-confirmed NASH were randomized 1:1:1 to resmetirom 80 mg, resmetirom 100 mg, or placebo administered once daily. Dual primary end points at Week 52 were achieved with both resmetirom 80 mg and 100 mg: NASH resolution with no worsening of fibrosis (NR) or ≥1-stage improvement in fibrosis with no worsening of NAS (FI). We evaluated the baseline and effect of resmetirom compared with placebo on fibrosis biomarkers PRO-C3 and P3NP/ELF.
Method: Pearson's correlation was used to examine the association between 2 PRO-C3 ELISA assay methods (ELISA GEN1 and ELISA GEN2, NORDIC BIOSCIENCE) using PRO-C3 baseline data (N = 919). The rest of the analyses used the ELISA GEN2 assay. Mean SD or SE and median [Q1, Q3] were calculated to summarize PRO-C3 data. ANCOVA was used for comparisons between resmetirom 80 or 100 mg vs. placebo in PRO-C3 change from baseline at week 52 (wk52CHG), while controlling for baseline PRO-C3 level. Mean difference with 95% CI and nominal p values were obtained from the ANCOVA. Scatterplots and Spearman's correlations with 95% CIs were used to assess the associations between P3NP/ELF and PRO-C3 both at baseline and wk52CHG.
Results: The two PRO-C3 assays ELISA GEN1 and ELISA GEN2 data were positively associated with a Pearson's correlation of 0.78 (P value <0.0001). At baseline, PRO-C3 was mean (SD) = 137 (71.7) ng/ml. At week 52, PRO-C3 wk52CHG for 100 mg resmetirom = −23.05 (4.76), 80 mg = −17.93 (4.61) and placebo = −0.19, 4.07 with mean difference (95% CI) in PRO-C3 wk52CHG between 80 mg and placebo = −16.9 (−27.0, −6.76; p = 0.0011); 100 mg and placebo = −22.1 (−32.3, − 11.84; p < 0.0001). Larger reductions in PRO-C3 mean (SD) on the resmetirom arms were observed in F3 patients: 80 mg = −22.42 (6.38) and 100 mg = −27.42 (6.72) compared with placebo = −0.50 (5.46). Baseline P3NP and ELF were correlated with PRO-C3 (0.563 and 0.458, respectively). The wk52CHG in P3NP was positively associated with wk52CHG in PRO-C3 (0.557, 0.548 and 0.524 for 100 mg, 80 mg and placebo; respectively). A weaker positive correlation between wk52CHG for ELF and PRO-C3 (0.483, 0.484 and 0.487 for 100 mg, 80 mg and placebo, respectively) were also observed.
Conclusion: Two Pro-C3 assays (ELISA GEN1 and ELISA GEN2, NORDIC BIOSCIENCE) were correlated at baseline, indicating ELISA GEN2 assay was reasonable for measuring PRO-C3 levels. For PRO-C3 ELISA GEN2, drug effects were statistically significant for both doses of resmetirom vs. placebo. The assay was more sensitive in detecting resmetirom effect in F3 patients. ELF and PRO-C3 was less strongly correlated than P3NP and PRO-C3.

WED-197

How many real world patients diagnosed with metabolic dysfunction-associated steatohepatitis meet clinical trial eligibility criteria? Findings from a large cohort study of more than 18, 000 patients from the United States

Jörn M Schattenberg[1], Claudio Sartini[2], Ronald Herrera[2], Mireia Raluy[3], Mark Yates[4], Ramy Younes[5]. *[1]Department of Medicine II, Saarland University Medical Center, Homburg, Germany; [2]Boehringer Ingelheim International GmbH, Global Epidemiology and Real-World Evidence, Ingelheim, Germany; [3]Evidera, Data Analytics, Borlänge, Sweden; [4]Evidera, Data Analytics, London, United Kingdom; [5]Boehringer Ingelheim International GmbH, Medicine, Cardio Metabolism and Respiratory, Ingelheim, Germany*
Email: joern.schattenberg@uks.eu

Background and aims: The distribution of key eligibility criteria typically used in Phase 2 and 3 metabolic dysfunction-associated steatohepatitis (MASH) trials in real-world data is unknown. Understanding how many real-world MASH patients meet certain criteria (e.g., presence of one metabolic risk factor) will help to refine eligibility requirements in future clinical trials (CTs) and improve representativeness of CT populations. This study estimated the proportion of patients with MASH diagnosed in the real world that could meet eligibility criteria typically used in MASH CTs and described basic socio-demographic patients characteristics, such as age, sex, Body Mass Index (BMI), and FIB-4 fibrosis score.
Method: Retrospective cohort study (2016–2021 years) using Optum Market Clarity (linked claims and electronic health records, EHRs) from the United States (US). MASH was defined by the first ICD10 diagnosis code (K75.81 Non-alcoholic steatohepatitis) recorded during the study period, presence of AST, ALT and platelets tests carried out 3 months prior/after diagnosis, and absence of diseases prior/at diagnosis, such as alcoholic/chronic liver diseases (minimum look-back period of 9 years). We estimated the size and characteristics (age, sex, BMI, and FIB-4) of a CT-like sample of non-cirrhotic patients after the following 6 standard criteria were applied: (1) BMI ≥25 (or weight ≥70 kg), (2) having ≥2 other metabolic risk factors (among obesity, diabetes, hypertension, hyperlipidemia, or hyperglycemia), (3) not having type 1 diabetes, (4) without elevated blood levels for bilirubin (≥1.3 mg/dL), INR (>1.3) ALT and/or AST (>5X ULN ~ 250 U/L), ALP (>2X UNL ~ 250–300 U/L) and MELD score (>12), (5) not using concomitant medications (e.g., vitamin E and pioglitazone among others), and (6) not being cirrhotic.
Results: 18, 710 patients met initial inclusion criteria for MASH. After the six selecting criteria were applied about 2 out of 10 patients with MASH met all criteria (4, 122 corresponding to 22% of the total). In this CT-like sample, the patients were on average 42 years old [standard deviation (SD) = 11], 48% female, and with average BMI of 34 (SD = 7). The mean FIB-4 score was 1.0 (SD = 0.8). In comparison to

previous CTs where patients with MASH and without cirrhosis were enrolled, the CT-like sample in Optum showed similar BMI and FIB-4 but younger age; the sex distribution was within the range previously observed (between 30% and 60%).
Conclusion: About 2 out of 10 patients with MASH diagnosed in the real-world setting met standard selecting criteria for enrollment in CTs for MASH without cirrhosis. As recruitment strategies in CTs can vary based on study design and objectives, the real-world evidence from this study brings new insights to inform decisions on inclusion and exclusion criteria.

WED-198
Novel deep learning models utilising domain adaptation outperform conventional statistical models for predicting the risk of liver-related complications in patients with metabolic dysfunction-associated steatotic liver disease
Terry Cheuk-Fung Yip[1,2,3], Jingwen Xu[4], Mandy Sze-Man Lai[1,2], Sherlot Juan Song[1,2], Yee-Kit Tse[1,2,3], Henry L.Y. Chan[2,5], Grace Lai-Hung Wong[1,2,3], Pong Chi Yuen[4], Vincent Wai-Sun Wong[1,2,3]. *[1]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong; [2]Medical Data Analytics Centre (MDAC), The Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Institute of Digestive Disease, The Chinese University of Hong Kong, Hong Kong, Hong Kong; [4]Department of Computer Science, Hong Kong Baptist University, Hong Kong, Hong Kong; [5]Department of Internal Medicine, Union Hospital, Hong Kong, Hong Kong, Hong Kong*
Email: tcfyip@cuhk.edu.hk

Background and aims: We aimed to build novel risk models to predict liver-related events including hepatic decompensation and hepatocellular carcinoma in patients with metabolic dysfunction-associated steatotic liver disease (MASLD).
Method: The training cohort included adult patients with MASLD identified from a territory-wide electronic database in Hong Kong from Jan 2000 to Jul 2021. Five modern domain adaptation (DA) methods were examined. Models were built based on fully connected neural network after different DA methods, assessed by area under the time-dependent receiver operating characteristic curves (AUCs) with death as the competing risk, and compared to FIB-4 index, NAFLD outcomes score (NOS), and a Fine-Gray model. The validation cohort comprised adult patients with type 2 diabetes (T2D) who likely had MASLD detected by NAFLD ridge score we previously developed. Patients with liver-related events before MASLD diagnosis or follow-up <6 months were excluded.
Results: Of 25,166 patients with MASLD in the training cohort (mean age 56.9 ± 13.2 years, 54.3% females, 0.7% cirrhosis), 272 (1.1%) developed liver-related events during 133,816 person-years (PYs) of follow-up. In the validation cohort of 411,395 patients (mean age 61.8 ± 12.4 years, 49.3% females, 0.4% cirrhosis), 5,984 (1.5%) developed liver-related events during 4,386,544 PYs of follow-up. Among the five DA methods, maximum classifier discrepancy (MCD) (AUC [95% CI] 0.822 [0.814–0.829]) and confidence regularised self-training (CRST) (0.825 [0.817–0.832]) performed best in validation cohort; their AUC in training cohort was 0.919 (0.904–0.934) and 0.831 (0.808–0.854) respectively. While the Fine-Gray model had an AUC of 0.804 (0.777–0.831) in the training cohort, the AUC dropped to 0.681 (0.672–0.691) in the validation cohort, showing the benefit of DA in preserving model accuracy in a less definite population at risk of MASLD. The AUC of NOS and FIB-4 was 0.649 (0.640–0.657) and 0.645 (0.635–0.655) in the validation cohort. Among the 19 factors including blood tests (liver and renal tests, lipids, fasting glucose), comorbidities, and demographics incorporated in MCD and CRST, the eight leading factors associated with liver-related events were cirrhosis, diabetes, platelets, aspartate aminotransferase, gamma-glutamyl transferase, international normalised ratio, dyslipidaemia, and albumin. MCD labelled 78.6% of patients with T2D who likely had MASLD as low risk, with a 99.2% negative predictive value for excluding liver-related events in 15 years.
Conclusion: We developed novel models including common clinical parameters which accurately identify patients who are at low risk for liver-related events among patients with MASLD and patients with T2D who likely had MASLD. This study was supported by Health and Medical Research Fund of Health Bureau of HKSAR Government (Reference number: 19202141).

WED-199
Optimizing MASLD trial recruitment: LiverPRO vs. FIB-4 in reducing false positives and unnecessary biopsies
Katrine Lindvig[1], Naim Alkhouri[2], Rida Nadeem[2], Aarya Patel[2], Manal Chughtai[2], Sahasraara Hemant[2], Yasmeen Fallouh[2], Himanshi Kapoor[2], Camilla Dalby Hansen[1], Katrine Thorhauge[1,3], Johanne Kragh Hansen[1,3], Stine Johansen[1,3], Helle Schnefeld[1], Peter Andersen[1], Ida Falk Villesen[1], Katrine Tholstrup Bech[1], Nikolaj Torp[1,3], Sönke Detlefsen[4], Mads Israelsen[1,3], Maja Thiele[1,3], Aleksander Krag[1,3]. *[1]Department of Gastroenterology and Hepatology, Centre for Liver Research, Odense University Hospital, Odense C, Denmark; [2]Arizona Liver Health, Chandler, Arizona, United States; [3]Institute of Clinical Research, University of Southern Denmark, Odense M, Denmark; [4]Department of Pathology, Odense University Hospital, Odense C, Denmark*
Email: katrine.prier.lindvig@rsyd.dk

Background and aims: Screen failures and high false positive rates present significant challenges in enrolling suitable candidates for clinical trials, yet in high prevalence populations false negatives is a challenge. This study compares the efficacy of two recruitment pathways, employing either Fibrosis-4 (FIB-4) Index or LiverPRO as initial screening tools for clinical trial entry, focusing on Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD). LiverPRO is a CE-marked diagnostic algorithm that utilises a machine learning model to predict the risk of liver fibrosis based on routine blood samples.
Method: We analysed data from a population-based low prevalence cohort study in Denmark (2017–2022), combined with participants from a high prevalence cohort referred for consideration in clinical trials to a tertiary hepatology clinic in the US (2019–2023). The clinical trials included participants with NAFLD activity score ≥4 and fibrosis stage ≥F2, defined as at-risk MASH. Participants underwent non-invasive tests including transient elastography (TE), and those with TE levels ≥8 kPa were referred for confirmatory liver biopsy.
Results: The study included 3,014 participants from Denmark and 705 from the US with risk factors of MASLD. The prevalence of elevated liver stiffness (TE ≥8 kPa) was 6.7% in the Danish cohort and 82% in the US cohort. The Danish and US cohorts were 58% vs. 71% female, with a median age of 57 vs. 58 years (IQR 52–62, IQR 49–65). The US participants exhibited more severe metabolic dysfunction than the Danish participants; BMI was 36 vs. 32 kg/m^2 (IQR 32–42 vs. IQR 29–35), and 46% vs. 16% had type 2 diabetes. The FIB-4 pathway referred 1,225 participants for TE measurements (cut-off ≥1.3). Of these, 366 of 1,225 (30%) underwent liver biopsy due to a TE ≥8 kPa. Conversely, the LiverPRO pathway referred 684 participants with a high risk LiverPRO score (cut-off >65%) for TE, with 467 of 684 (68%) proceeding to a biopsy. In the Danish cohort, only those with TE ≥8 kPa were referred for biopsy, whereas in the completely biopsied US cohort, at-risk MASH was confirmed in 170 (69%) and 485 (70%) of participants (42 vs. 94 had significant fibrosis, 26 vs. 165 had advanced fibrosis, and 7 vs. 226 had cirrhosis). These results indicate that adopting LiverPRO would result in a 75% reduction (n = 642) in unnecessary TE referrals compared to FIB-4. Finally, the FIB-4 pathway had a false-negative rate for predicting at-risk MASH in liver biopsies of 26% (173 of 673), whereas LiverPRO had a false-negative rate of 14% (99 of 710).
Conclusion: LiverPRO significantly improves MASH trial recruitment precision in both low and high-prevalence populations. In low-

prevalence cases, it reduces screen failures and unnecessary biopsies compared to FIB-4. In high-prevalence scenarios, LiverPRO lowers false negative rates, offering a more efficient participant selection method for clinical trials.

WED-200

Prevalence and tissue characteristics of steatotic liver disease subclassifications in the adult UK population using quantitative MRI clinical thresholds: a UK biobank study

Charlie Diamond[1], John McGonigle[1], Rajarshi Banerjee[1], Helena Thomaides Brears[1,2], Andrea Dennis[1], Naim Alkhouri[3].
[1]Perspectum Ltd., Oxford, United Kingdom; [2]Perspectum Ltd., Translational Science, Oxford, United Kingdom; [3]Fatty Liver Program, Arizona Liver Health, Chandler, Arizona, United States
Email: charlie.diamond@perspectum.com

Background and aims: Steatotic liver disease (SLD) represents a disease spectrum that results from fat accumulation in the liver. A new consensus nomenclature for the subclassification of SLD aetiologies was developed, including metabolic dysfunction-associated SLD (MASLD), alcohol associated liver disease (ALD), MetALD and cryptogenic SLD. Using data acquired as part of the UK Biobank (UKBB) imaging study, we sought to determine the prevalence of SLD subclassifications in the general UK population of older adults and describe their clinical characteristics using quantitative MRI markers of fat, iron and liver disease activity.
Method: Clinical and imaging data were acquired on 33, 607 volunteers from the UKBB between 2016 and 2020 (application 9914). Liver MRI scans were analysed using LiverMultiScan (for fat (MRI-PDFF), iron concentration (MRI-LIC) and disease activity (iron corrected T1 mapping, cT1). MASLD diagnosis was defined based on MRI criteria of liver fat ≥5% and presence of at least one cardiometabolic risk factor. In absence of data describing weekly grams of alcohol consumed, we used daily alcohol consumption as a proxy for ALD. Steatohepatitis (including metabolic-dysfunction associated, MASH) additionally required cT1 ≥800 ms. For groupwise statistical comparisons, Wilcoxon rank sum tests were applied for continuous variables and Fishers exact tests for categorical variables.
Results: In our population (mean age 64 (SD 8) years, 47% male, mean BMI 26 (SD 4) kg/m^2, 17% obese, 4.9% self-reported diabetic), 27% met the criteria for SLD, 20% for MASLD and 3.7% for MASH. ALD was rare (0.6%), whereas MetALD, with concurrent cardiometabolic risk factors, was more prevalent (4.7%). Cryptogenic SLD with no metabolic or alcohol associated risk factors occurred in 2% of the population. People with MASLD had a higher prevalence of abnormally elevated liver disease activity (cT1 ≥800 ms) compared to MetALD (19% vs 15%, $p < 0.001$), but similar liver fat distribution (both mean 11% (SD 6)). Advanced liver disease (cT1 ≥875 ms, equivalent to significant fibrosis) was also equally prevalent at 3%. Prevalence of clinically elevated iron content (≥1.8 mg Fe/g) was significantly higher in ALD (10%) and MetALD (6.4%) groups as compared to cryptogenic SLD (3%, $p < 0.001$) and MASLD (2.6%, $p < 0.001$), respectively.
Conclusion: These data provide the prevalence of SLD and various subgroups in the UK population using state of the art MRI technology. Of interest, the increased liver iron content in the ALD and MetALD groups requires investigation for association with liver outcomes, as seen for hyperferritinaemia.

WED-201

Performance of non-invasive tests to diagnose cirrhosis in MASH trials: combined data from multiple therapeutic trials

Naim Alkhouri[1], Mazen Noureddin[2], Jörn M Schattenberg[3], Vlad Ratziu[4], Michael Charlton[5], Julie Dubourg[6], Stephen A. Harrison[7].

Email: jdubourg@summitclinicalresearch.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) cirrhosis is a distinct group of patients with a high risk of major adverse liver outcomes . We aimed to assess non-invasive tests (NITs) including ELF, Fibrosis-4 score (FIB-4), vibration-controlled transient elastography (VCTE) and FibroScan-based score Agile 4 to distinguish this group of patients.
Method: We combined screening data from 10 industry-funded MASH phase 2 trials. Liver histology data were assessed centrally, and cirrhosis was defined as a fibrosis stage of 4 with or without MASH. Diabetes status required by the Agile 4 formula was defined using glycated hemoglobin (HbA1c). Areas under the receiver operating characteristic (AUROC) analysis for each NIT were calculated. We calculated the positive likelihood ratio, pre- and post-test probability of cirrhosis to express the clinical utility of each score.
Results: 1, 113 patients with histology results and NITs data were included, with a fibrosis prevalence of: 35 (3%) for F0, 167 (15%) for F1, 269 (24%) for F2, 461 (41%) for F3, and 181 (16%) for F4. AUROC for ELF, FIB-4, VCTE and Agile 4 in this population were 0.76 (95% CI: 0.72–0.79), 0.76 (95% CI: 0.72–0.79), 0.86 (95% CI: 0.83–0.89), and 0.88 (95% CI: 0.86–0.91), respectively. The LR+ of the published ELF rule-in cut-off (≥11.3) was 3.97. This reflects a post-test probability of cirrhosis of 43% compared to a pretest probability of 16%. Among the 1, 113 patients included in this analysis, 85 (8%) had ELF ≥11.3 with 48 of those having no cirrhosis. The LR+ of the published FIB-4 rule-in cut-off (≥3.48) was 7.55. This reflects a post-test probability of cirrhosis of 59% compared to a pretest probability of 16%. Among the 1, 104 patients included in this analysis, 37 (3%) had a FIB-4 ≥3.48, with 15 having no cirrhosis. The LR+ of the published VCTE rule-in cut-off (≥20) was 4.52. This reflects a post-test probability of cirrhosis of 46% compared to a pretest probability of 16%. Among the 1, 104 patients included in this analysis, 214 (19%) had a VCTE ≥20, with 114 of those having no cirrhosis but mainly F2 and F3. The LR+ of the published Agile 4 rule-in cut-off (≥0.57) was 10.64. This reflects a post-test probability of cirrhosis of 67% compared to a pretest probability of 16%. Among the 1, 113 patients included in this analysis, 138 (12%) had Agile 4 ≥0.57 with 45 of those having no cirrhosis.
Conclusion: The FibroScan-based score, Agile 4, has the best diagnostic accuracy for cirrhosis compared to VCTE alone, ELF and FIB-4 in this population.

WED-202

The 2023 AASLD practice guidance for MASLD does not adequately risk stratify MASLD patients in the context of therapeutic trials

Naim Alkhouri[1], Mazen Noureddin[2], Jörn M Schattenberg[3], Vlad Ratziu[4], Michael Charlton[5], Julie Dubourg[6], Stephen A. Harrison[7].
[1]Arizona Liver Health, Phoenix, United States; [2]Houston Research Institute, Houstom, United States; [3]Saarland University Medical Center, Homburg, United States; [4]Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France; [5]University of Chicago, Chicago, United States; [6]Summit Clinical Research, San Antonio, United States; [7]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom
Email: jdubourg@summitclinicalresearch.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a growing epidemic associated with significant morbidity and mortality. There is an unmet need to identify at-risk MASH patients (NASH + NAS ≥4 + F2-F3-F4) because they are the target population for therapeutic trials and future approved therapies. The latest AASLD guidance recommend the use of FIB4 in a first step followed by controlled transient elastography (VCTE) and/or ELF to risk-stratify patients. We aimed to assess the performance of the

2023 AASLD guidance in determining the at-risk population in the settings of randomized controlled trials.
Method: We combined screening data from 10 industry-funded MASH phase 2 trials and analyzed the proportion of at-risk MASH patients based on centrally read liver biopsy according to AASLD guidance using FIB-4 data, and VCTE and/or ELF data.
Results: 2, 273 patients with histology results and NITs data were included, with a fibrosis prevalence of: 137 (6%) for F0, 484 (21%) for F1, 524 (23%) for F2, 812 (36%) for F3, and 316 (14%) for F4. 1, 334 (59%) of patients were considered at-risk MASH. Following the AASLD guidance, FIB-4 classifies 1, 087 (48%), 1, 016 (45%), and 170 (7%) patients as low- (<1.3), intermediate, and high-risk (>2.67), respectively. Within the low-risk group, 51% were at-risk MASH patients based on liver histology. Within the high-risk group, 67% were at-risk MASH patients based on liver histology. Within the intermediate FIB-4 risk group, 67 (3%), 919 (40%), and 1, 287 (57%) of patients were classify in the low-, intermediate, and high-risk groups based on ELF and/or VCTE, respectively. Within these risk groups, 27%, 51%, and 66% of patients were at-risk MASH patients based on liver histology in the low-, intermediate, and high-risk population, respectively. By using the AASLD guidance, 43% of patients with at-risk MASH would have ben classified as low-risk.
Conclusion: The use of the current AASLD guidance to risk-stratify MASLD patients would miss a significant number of at-risk MASH patients. Further research, new biomarkers and refinement of guidances are warranted to more accurately risk-stratify patients with MASLD.

Email: hirooka.masashi.mb@ehime-u.ac.jp

Background and aims: Several preliminary reports have suggested the utility of ultrasound attenuation coefficient measurements based on B-mode ultrasound, such as iATT, for diagnosing steatotic liver disease. Nonetheless, evidence supporting such utility is lacking. This prospective study aimed to investigate whether iATT is highly concordant with magnetic resonance imaging (MRI)-based proton density fat fraction (MRI-PDFF) and could well discriminate between steatosis grades.
Method: A cohort of 846 individuals underwent both iATT and MRI-PDFF assessments. Steatosis grade was defined as grade 0 with MRI-PDFF <5.2%, grade 1 with 5.2% MRI-PDFF <11.3%, grade 2 with 11.3% MRI-PDFF <17.1%, and grade 3 with MRI-PDFF of 17.1%. The reproducibility of iATT and MRI-PDFF was evaluated using the Bland-Altman analysis and intraclass correlation coefficients, whereas the diagnostic performance of each steatosis grade was examined using receiver operating characteristic analysis.
Results: The Bland-Altman analysis indicated excellent reproducibility with minimal fixed bias between iATT and MRI-PDFF. The area under curve for distinguishing steatosis grades 1, 2, and 3 were 0.887, 0.882, and 0.867, respectively. A skin-to-capsula distance of ≥25 mm was identified as the only significant factor causing discrepancy. No interaction between MRI-logPDFF and MRE-LSM on iATT values was observed.
Conclusion: Compared to MRI-PDFF, iATT showed excellent diagnostic accuracy in grading steatosis. iATT could be used as a diagnostic tool instead of MRI in clinical practice and trials.

WED-206
Nash-FibroTest for the diagnosis of significant fibrosis, in severe obesity treated with bariatric surgery and external non-linear trajectories of test' components among obesity classes in a large US population
Thierry Poynard[1,2], Olivier Deckmyn[1], Raluca Pais[3], Judith Aron-Wisnewsky[2], Pierre Bedossa[4], Maharajah Ponnaiah[5], Jean Michel Oppert[2], Jean Michel Siksik[2], Laurent Genser[2], Frederic Charlotte[6], Dominique Thabut[2], Karine Clément[2], Vlad Ratziu[2], Valentina Peta[1]. *[1]BioPredictive, Paris, France; [2]Sorbonne University, Paris, France; [3]INSERM, Paris, France; [4]INSERM, Paris; [5]ICAN, Paris, France; [6]APHP, Paris, France*
Email: thierry@poynard.com

Background and aims: Biopsy (B) is recommended during (B1) and after (B2) bariatric surgery (BS) in severe obesity (sOb). The Nash-FibroTest (NFT), NASHFibroSure in USA, is widely used to predict significant fibrosis (sF = F2toF4), as well as GGT, ALT or AST combos. One study (Netanel 2021) showed that NFT can diagnose sF regression in sOb treated by sleeve gastrectomy (SG). Here, the first objective was to demonstrate, in patients treated with Roux-en-Y (RG) or SG, whether NFTd validated in T2 diabetes (T2D) (Poynard 2023), was similar to B for predicting Sf regression. Among BMI classes (BMIc = 27–30 kg/m^2 as controls, sOb = 30+, 35+, 40+, 45+), the trajectory (Tj) variability between NFT components may induce false positive/negative risks (Mehta 2023) but has never been compared in sOb according to age, sex, and T2D. Therefore, the second aim was to assess the Tj components prescribed consecutively to 60, 366 MASLD sF risk subjects in 2019, 53, 704 US sOb (n = 89%) and 6, 662 controls (11%), according to these factors for each BMIc.
Method: for the first aim, a posthoc analysis of the BARICAN study (Pais 2022) was performed in 55 sOb with 220 paired B and paired NFTd. The main end point was AUC for sF at B1 and B2, then adjusted kappa (K) and F-Test between spline curves for the second aim.
Results: sF prevalence in BS was 53% (29/55) at B1 and 42% (23/55) at B2 6 median years (yrs) later. For the first aim, AUCs were significant at B1 (0.75; 95%CI 0.58–0.86; p = 0.0002) and B2 (0.81; 0.66–0.90 p = 0.0001), with a significant K at B1 (0.75; p = 0.003) and B2 (0.65; p = 0.002). For the second aim in sOb (32, 866/53, 704 = 61% sF by NFT), 4 major differences in Tj were observed (all p < 0.0001): 1) In women (F) with T2D and a BMI of 30–35 (n = 7, 679), ALT and AST reached a plateau between the ages of 40 to 60, not present for other BMIc, nor in men (M), possibly due to menopausal transition. 2) haptoglobin in T2D F has a progressive increase with BMIc, with an age intraclass increase. In T2D M there was no change according to age nor sOb. These results suggest a sex-dependent inflammatory response to sOb and age. 3) A2M in M with BMI 30–45 started and increased with age 10 yrs earlier than in F, with or without T2D. 4) apoA1 levels at age 30 were higher in BMIc <30 regardless of sex and T2D.

Conclusion: NFTd predicts sF regression after BS. Tj of sF biomarkers are not linear. Sex, age, T2D and menstrual transition must be taken into account to prevent misinterpretations in sOb novel therapy.

WED-207

Non-invasive biomarkers of liver fibrosis may be used for diagnosing fibrosis and prognostication in patients with metabolic dysfunction-associated steatotic liver disease

Liv Eline Hetland[1], Mikkel Werge[1], Mira Thing[1], Elias Rashu[1], Puria Nabilou[1], Nina Kimer[1], Anders Junker[1], Diana Leeming[2], Morten Karsdal[2], Alejandro Mayorca Guiliani[2], Lise Lotte Gluud[1,3].
[1]Gastro Unit, Copenhagen University Hospital, Amager and Hvidovre Hospital, Hvidovre, Denmark; [2]Nordic Bioscience A/S, Herlev, Denmark; [3]Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen University, Copenhagen, Denmark
Email: livelinehetland@gmail.com

Background and aims: Identification of biomarkers that are both diagnostic and prognostic is essential in metabolic dysfunction-associated steatotic liver disease (MASLD). Fibrosis is the most important predictor of prognosis in MASLD, and we therefore evaluated non-invasive fibrosis biomarkers for diagnosing significant fibrosis (F2-F4) and prognostication in MASLD.
Method: Prospective cohort study including 644 patients MASLD (age 59 years; 47.0% female; 32.3% with type 2 diabetes) and two years of follow-up. The accuracy of biomarkers for diagnosing significant fibrosis and to predict liver-related events was assessed. The analyses included Fibrosis-4 index (FIB-4), FibroScan, Enhanced Liver Fibrosis test (ELF), PRO-C3, and the ADAPT score, which combines age, diabetes, platelet counts and PRO-C3. The area under the Roc-curve (AUROC) was calculated based on prediction values with adjustment for age, gender, and type 2 diabetes.
Results: Significant fibrosis was diagnosed in 148 of 273 who underwent a biopsy (54.2%). Patients with significant fibrosis had increased Fib-4, FibroScan, ELF, Pro-C3, and ADAPT ($p < 0.001$, for all analyses). The diagnostic accuracy of FibroScan was the highest with an adjusted AUROC of 0.88 (95% CI 0.85–0.92, sensitivity 0.89, specificity 0.83). Similar values were found for the remaining biomarkers. Sequential testing with FIB-4 followed by FibroScan increased diagnostic accuracy (adjusted AUROC 0.92 (0.86–0.95, sensitivity 0.91, specificity of 0.84). Sequential testing with FIB-4 followed by remaining biomarkers also accurately predicted significant fibrosis (adjusted AUROC ELF 0.86 (0.81–0.92), Pro-C3 0.83 (0.79–0.87), ADAPT 0.85 (0.80–0.89)). During the follow-up, twenty-three patients developed liver-related events (progression to cirrhosis, development of hepatic decompensation, esophageal varices, liver transplantation, hepatocellular carcinoma, or liver-related death). A FIB-4 cutoff of 1.3 was a significant predictor of liver-related events in unadjusted logistic regression analysis and after adjusting for age, sex, and type 2 diabetes (adjusted odds ratio [OR] 42.92 (95% CI 5.23–5618.90). Increasing the cut-off to 2.67 showed an adjusted OR of 12.87 (4.14–41.70). Remaining biomarkers also predicted liver related events (adjusted OR FibroScan 23.51, ELF 9.79, Pro-C3 4.26, ADAPT 12.10, $p < 0.001$ for all analyses).
Conclusion: Sequential testing with non-invasive fibrosis biomarkers, particularly Fib-4 and FibroScan, is useful for diagnosing significant fibrosis as well as prognostication in MASLD. The results support systematic testing in at-risk patients for identification of patients with an increased risk of liver-related events.

WED-208

Metabolomics-based model for predicting metabolic dysfunction-associated steatotic liver disease and stratifying risk

Takeshi Kimura[1], Masanori Nojima[2], Yutaka Aoki[3], Mai Higashi[4], Makoto Watanabe[4], Jyunya Ohtake[5], Takuya Koshizaka[6], Takahiro Yagi[5], Yasuhisa Kumakura[7], Katsunori Masuda[7], Taka-Aki Sato[4]. *[1]Center for Preventive Medicine, St. Luke's International Hospital, St. Luke's International University, Chuo-ku, Tokyo, Japan; [2]The University of Tokyo, The Institute of Medical Science, Minato-ku, Tokyo, Japan; [3]Life Science Research Center, Technology Research Laboratory, Shimadzu Corporation, Nakagyo-ku Kyoto city, Kyoto, Japan; [4]Life Science Research Center, Technology Research Laboratory, Shimadzu Corporation, Nakagyo-ku Kyoto city, Kyoto, Japan; [5]St. Luke's International University, Chuo-ku, Tokyo, Japan; [6]St. Luke's International University, Chuo-ku, Tokyo, Japan; [7]Center for Preventive Medicine, St. Luke's International Hospital, St. Luke's International University, Chuo-ku, Tokyo, Japan*
Email: takekimu@luke.ac.jp

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD; formerly non-alcoholic fatty liver disease [NAFLD]) is a global health concern due to its involvement in the development of a wide variety of non-communicable diseases. Presently, potent MASLD treatments have not been identified; therefore, prevention is essential; a tool able to predict MASLD and stratify disease risk would be practical due to the magnitude of the potentially affected population. We developed a metabolomics-based NAFLD prediction model that stratifies disease risk.
Method: This prospective case-cohort study involved 25, 748 participants who underwent annual health checks between 2015 and 2016, followed by three years of follow-up. During these health checks, clinical data, including a lifestyle questionnaire (e.g., alcohol consumption habits), anthropometric measurements, laboratory results, and abdominal ultrasounds, were routinely collected. Gas chromatography-mass spectrometry (GCMS-TQ8040. Shimadzu, Japan), measuring 40 metabolites, was utilized for the metabolomic analysis of residual serum samples collected during the health check-ups. The prediction model for NAFLD development was constructed by the least absolute shrinkage and selection operator (LASSO)-Cox regression algorithm using the "glmnet" package for R (Version 4.2.2). SAS 9.4 was used for time-dependent receiver operating characteristic (ROC) analyses, and incidence rate estimation was performed using the Poisson regression model.
Results: The number of eligible participants in the subcohort was 3141, and the total incident NAFLD cases were 829 (191 were included in the subcohort). A LASSO-based prediction model was developed to forecast NAFLD development, utilizing the measurements of 31 metabolites. This model was initially constructed using the training set and subsequently validated with the test set. Time-dependent ROC analysis in the test set yielded an area under the curve of 0.764 for new-onset NAFLD within three years. Participants were categorized based on hazard ratios (HRs) derived from the log-hazard divided by the median log-hazard in the training set. The yearly incidence rates were determined for different HR groups: 0.4% for HR ≤ 0.5, 1.1% for $0.5 < HR \leq 1$, 2.9% for $1 < HR \leq 2$, 7.6% for $2 < HR \leq 4$, and 10.0% for HR >4. In the highest risk group, the three-year risk of developing NAFLD was 27.1%.
Conclusion: This cutting-edge metabolomics-based model for predicting and stratifying the risk of NAFLD development may contribute to prevention of this disease, globally. Further analysis is needed to ensure that the prediction of MASLD is equally valid.

WED-209

Development of a novel non-invasive biomarker panel for hepatic fibrosis in MASLD

Lars Verschuren[1], Eveline Gart[1], Anne Linde Mak[2], Arianne van Koppen[3], Serdar Özsezen[1], Andre Boonstra[4], Joanne Verheij[5], Lise Lotte Gluud[6], Onno Holleboom[2], Maarten Tushuizen[7], Roeland Hanemaaijer[1]. *[1]TNO, Leiden, Netherlands; [2]Amsterdam UMC, Amsterdam, Netherlands; [3]TNO, leiden, Netherlands; [4]Erasmus Medical Center, Rotterdam, Netherlands; [5]Amsterdam University Medical Centers, Amsterdam, Netherlands; [6]Copenhagen University Hospital Hvidovre, University of Copenhagen, Copenhagen, Denmark; [7]Leiden University Medical Center, Leiden,*

Netherlands
Email: lars.verschuren@tno.nl

Background and aims: Considering the escalating prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD) and MASLD-related fibrosis, accurate non-invasive biomarkers for diagnosis and staging of fibrosis are urgently needed. This study applied a translational approach with the aim to develop a blood-based biomarker panel for fibrosis detection in MASLD.
Method: A first set of candidate biomarkers was identified using a translational diet-induced MASLD mouse model (LDLr-/-.Leiden), focused on the mechanism of collagen deposition using hepatic gene expression and new extracellular matrix deposition, as detected by dynamic D2O-labeling. To translate these findings to humans, gene expression profiles and biomarkers were analyzed in liver biopsies and serum samples from patients with histologically characterized MASLD and variable degrees of fibrosis and validated in two independent patient cohorts
Results: A panel of blood-based fibrosis biomarkers was identified consisting of IGFBP7, SSc5D and Sema4D. The accuracy of the biomarker panel was validated in a separate cohort of 128 patients with histologically characterized MASLD across different stages of fibrosis. Light Gradient Boosting Machine (LightGBM) modelling demonstrated that fibrosis stage can be predicted in MASLD (F0/F1: AUC = 0.82; F2: AUC = 0.89; F3/F4: AUC = 0.87). Additionally, by validation in an independent second patient cohort (n = 156), we successfully replicated the high-performance predictions for F0/F1 and F3/F4 fibrosis stages with an AUC of 0.84. Although the AUC for predicting F2 fibrosis was modest at 0.62 the overall accuracy of the model outperformed the FIB-4 and Fibroscan predictions.
Conclusion: Using a translational approach to identify novel biomarkers mechanistically related to the dynamics of collagen synthesis, we developed a blood-based biomarker panel with three biomarkers which is able to identify MASH patients with mild (F0/F1) or advanced (F3/F4) hepatic fibrosis with high accuracy.

WED-210
Plasma metabolite profile associates with liver fibrosis and incident liver-related death in men from finnish general population

Ville Männistö[1,2], Anniina Oravilahti[2], Fredrik Åberg[3], Markku Laakso[2]. [1]*Kuopio University Hospital, Kuopio, Finland;* [2]*University of Eastern Finland, Kuopio, Finland;* [3]*Helsinki University Hospital, Helsinki, Finland*
Email: ville.mannisto@kuh.fi

Background and aims: Chronic liver disease is a substantial health challenge and an increasing cause for morbidity and mortality. Metabolic dysfunction associated steatotic liver disease (MASLD) and alcohol-related liver disease (ALD) are the most common causes for the steatotic liver disease in Western countries. These diseases can progress to liver fibrosis and ultimately to cirrhosis. However, it is not completely understood why only some people develop fibrosis and what are the metabolic changes associated with liver fibrosis at population level.
Method: The association between plasma metabolites and liver fibrosis was evaluated using plasma sample metabolomics from Metabolon's Global Discovery Panel and the dynamic Aspartate-to-Alanine Aminotransferase Ratio (dAAR) score for fibrosis in a Finnish population-based METSIM cohort of 10124 male individuals (mean [± standard deviation] age 57.7 ± 7.1 years; body mass index 27.3 ± 4.3 kg/m^2). Furthermore, the association between the metabolites and incident liver-related death was evaluated.
Results: A total of 945 metabolites were available from at least 60% of the study individuals, and 498 of these were significantly ($p < 5.3 \times 10^{-5}$) associated with liver fibrosis in age and BMI adjusted linear regression analysis. The results were essentially similar with multiple different adjustment models, even when adjusted with fatty liver index and weekly alcohol use. A predictive XGBoost regression model for the dAAR score revealed that the 26 most significant metabolites [selected based on SHapley Additive exPlanations (SHAP) importance values] explained 32% of the variance in dAAR, and the most important metabolites were N-acetylmethionine, alpha-ketoglutarate, aconitate, and xanthine. Among the best predictors were several amino acids, cofactors, products of energy metabolism, lipids (including bile acids), nucleotides, and peptides. The AUROC values for these 26 metabolites, when validated as predictors for liver-related death, varied between 0.82–0.87 depending on the model used (XGBoost, logistic regression or support vector machine).
Conclusion: Liver fibrosis associates with vast amount of plasma metabolites from different metabolic traits in middle-aged men from the general population.

WED-211
Combination of Liverfast (LF) and Liver Stiffness Measurement (LSM) using fibroscan uutperforms FIB-4 and LSM, for the identification of MASLD advanced fibrosis (AF) in patients with type 2 diabetes (T2D)

Julie Dupuy[1], Adèle Delamarre[2], Paul Hermanbessiere[3], Ronald Quiambao[4], Parvez Mantry[5], Imtiaz Alam[6], Mona Munteanu[7], Victor de Lédinghen[8]. [1]*CHU Bordeaux, Bordeaux, France;* [2]*CHU Bordeaux, bordeaux, France;* [3]*CHU Bordeaux, Bordeaux, France;* [4]*Fibronostics, Florida, United States;* [5]*Methodist Dallas Medical Center, The Liver Institute, Dallas, United States;* [6]*Austin Hepatitis Center, Texas, United States,* [7]*Fibronostics, Medical Affairs, Florida, United States;* [8]*CHU Haut Leveque, Bordeaux University, Bordeaux, France*
Email: mona_munteanu@hotmail.com

Background and aims: Better identification of T2D patients (pts) with MASH-AF is mandatory as it requires further assessment, specific surveillance or targeted interventions. LF is an AI-based blood test for staging steatosis, activity and fibrosis (LF-Fib) and correlated to the long-term liver outcomes (*Alim Pharmacol Ther 2022*). We aimed to compare retrospectively two combinations for one-step assessment of AF: LF-FibandLSM versus FIB-4andLSM, for the identification of histological AF in T2D pts that undergone liver biopsy (LB).
Method: Data has been collected retrospectively from 583 MASLD pts (NCT01241227). Cut-offs used for AF were: 0.59 for LF-Fib and those recommended by AASLD guidance to rule in/out AF, respectively, 12k/8 kPa for LSM and, 1.3/2.67 for FIB-4, respectively.
Results: 583 MASLD pts had available LF-Fib, LSM, FIB-4 [males 56.4%, age 56 yrs, 51.6%T2DM, BMI 31.5 and LSM 9.6 KPa, 45.2%AF and 17%F4 on LB]. 235 pts had T2D and LB sample ≥2 cm and <6 months apart from biomarkers [males 50%, median age 61 yrs, HbA1c 6.9, LSM 10.4 KPa, 58.3% LB AF]. Among them, the combination LF-FibandLSM correctly identified AF (F3F4) as per LB in a higher number of T2D pts, than the combination FIB-4 and LSM [53/56 (94.6%), versus 32/36 (88.9%)]. Using lower LSM cut-off (8 kPa), LF-FibandLSM correctly identified AF in more pts than FIB-4andLSM [72/88 (81.8%) versus 37/41 (90%)].In the overall cohort with LB sample >2 cm (N = 399), LF-FibandLSM correctly identified AF in more cases than FIB-4 and LSM [70/74 (94.6%) versus 47/51 (92%)]. Using 8 kPa LSM cutoff LF-Fib and LSM correctly identified 25 pts more [94/117 (80.3%)] than FIB-4 and LSM combination.74% of AF pts LB had FIB-4 <2.67; LF-Fib and LSM correctly identified 41% of AF pts having FIB-4 in the indeterminate zone.
Conclusion: The combination LF-Fib and LSM outperformed FIB-4-LSM for the identification of MASLD-related AF in T2D pts; a lower LSM cutoff could improve AF identification.

WED-212

Pemvidutide treatment is associated with improvement in non-invasive tests indicating greater likelihood of histologic response in subjects with metabolic dysfunction-associated steatotic liver disease: a 24-week, randomized, double-blind, placebo-controlled trial

Naim Alkhouri[1], Shaheen Tomah[2], John Suschak[2], Jonathan Kasper[2], M. Scot Roberts[2], M. Scott Harris[2], Sarah Browne[2], Rohit Loomba[3].
[1]Arizona Liver Health, Tuscon, United States; [2]Altimmune, Inc, Gaithersburg, United States; [3]University of California, San Diego, United States
Email: naim.alkhouri@gmail.com

Background and aims: Pemvidutide is a long-acting, balanced GLP-1/glucagon dual receptor agonist under development for the treatment of metabolic dysfunction-associated steatohepatitis (MASH) and obesity. We previously reported that pemvidutide led to a greater than 75% reduction in liver fat content (LFC) by MRI-PDFF after 24 weeks of treatment, with up to 50% of subjects achieving normalization of LFC. Herein, we examined the effects of pemvidutide on the likelihood of histologic response.
Method: 64 subjects with metabolic dysfunction-associated steatotic liver disease (MASLD) defined as LFC ≥10% by MRI-PDFF, were randomized in a 1:1:1:1 ratio to receive 1.2 mg, 1.8 mg, 2.4 mg pemvidutide, or placebo weekly (QW) for 24 weeks. Subjects with baseline ALT >75 IU/L or evidence of advanced liver fibrosis, defined by liver stiffness measurement (LSM) by Fibroscan® ≥10 kPa, were excluded. Outcomes included the proportions of subjects who achieved a Fibroscan-AST (FAST) score <0.35 and the proportions of subjects with ALT ≥30 IU/L at baseline who achieved a simultaneous reduction in MRI-PDFF (≥30%) and ALT (≥17 IU/L) after 24 weeks of treatment.
Results: Median baseline BMI, LFC, ALT, and LSM, were 36.8 kg/m^2, 20.6%, 31.0 IU/L, and 6.5 kPa, respectively. Of the subjects, 53% were female and 27% had diabetes. 60%, 67%, and 75% of subjects with intermediate-to-high risk of MASH progression (FAST ≥0.35) at baseline achieved low-risk (FAST <0.35) at Week 24 at pemvidutide 1.2 mg, 1.8 mg, and 2.4 mg, respectively, vs 25% placebo. Simultaneously, 50%, 44%, and 60% of subjects with ALT ≥30 IU/L at baseline achieved a combined reduction of MRI-PDFF (≥30%) and ALT (≥17 IU/L) at Week 24 at pemvidutide 1.2 mg, 1.8 mg, and 2.4 mg, respectively, vs 0% placebo.
Conclusion: Pemvidutide administered QW for 24 weeks was associated with improvement in the FAST score and the combined ALT/MRI-PDFF response rates compared to placebo indicating greater likelihood of histologic response. These findings are expected to result in meaningful histopathological improvement with pemvidutide.

WED-213

Assessment of fibrosis change rates in placebo arm of metabolic dysfunction-associated steatohepatitis drug trials based on pathologist readouts and qFibrosis continuous values

Kutbuddin Akbary[1], Dean Tai[1], Galvin Gan[1], Julie Dubourg[2], Stephen A. Harrison[3]. *[1]HistoIndex Pte Ltd, Singapore, Singapore; [2]Summit Clinical Research, San Antonio, TX, United States; [3]Pinnacle Clinical Research, Radcliffe Department of Medicine, University of Oxford, Oxford, UK, San Antonio, TX, United States*
Email: akbary.kutbuddin@histoindex.com

Background and aims: Metabolic dysfunction-associated Steatohepatitis (MASH) drug trials face challenges in assessing treatment response due to substantial variability in the placebo group, observed both in pathologist readouts and qFibrosis continuous values (qFc). This significant variability hinders standardizing treatment effect and sample size calculations in MASH clinical trials and challenges the interpretation of the "true" treatment effect. The placebo cohort allows for describing the natural course of the disease. This study aims to describe the placebo response rates in NASH drug trials, focusing on pathologist readouts (NASH-CRN stage) versus qF continuous values.
Method: Anonymized placebo responses from 5 MASH Phase 2b drug trials are detailed, using NASH-CRN readouts and qFc values. Fibrosis regression, progression, and no-change results are presented. NASH-CRN-based regression/progression was defined as a 1-stage change in fibrosis at end-of-treatment (EOT) compared to baseline (BL). qFc, regression/progression was determined based on the change in qFibrosis continuous values at EOT compared to BL, using the standard error of mean (SEM). No-change in qFc is change of qFc values within SEM at EOT compared to BL, and no-change in NASH-CRN stage in EOT compared to BL, respectively.
Results: Based on qFc values, the average fibrosis regression rate from BL to EOT in the placebo group was 38% (range: 19%–49%), compared to an average regression rate of 21% (range: 7%–30%) based on NASH-CRN staging. Fibrosis progression rates based on NASH-CRN averaged 18% (range: 12%–29%), contrasting with qFc at 45% (range: 33%–76%). The percentage of patients with stable diseases was higher when assessed by the NASH-CRN staging approach (average 62%, range: 46%–81%), compared to qFc (average: 17%, range: 33%–76%).
Conclusion: This study contributes to our understanding of the variance on placebo responses based on both pathologists' staging and qF continuous values. The data underscores considerable variability in placebo response across different studies, reflected in pathologist staging and qFc values. The proportion of patients meeting the definition of progression or regression was higher when assessed by qFc values. As a result, qFc decreased the proportion of patients considering with no change in fibrosis. Both NASH-CRN staging and qFibrosis-based continuous values are essential considerations in understanding placebo responses in MASH drug trials.

WED-214-YI

Ferritin is a predictor of fibrosis, but not liver iron in metabolic hyperferritinaemia

Maria Rosina Troppmair[1], Benedikt Schaefer[1], Michaela Plaikner[2], Christian Kremser[2], Benjamin Henninger[2], Herbert Tilg[1], Heinz Zoller[1]. *[1]Department of Medicine I, Medical University of Innsbruck, Innsbruck, Austria; [2]Department of Radiology, Medical University of Innsbruck, Innsbruck, Austria*
Email: m.troppmair@i-med.ac.at

Background and aims: High serum ferritin is common in patients with metabolic dysfunction-associated steatotic liver disease and a marker of progressive disease. Metabolic hyperferritinaemia (MHF) was recently defined as hyperferritinaemia in patients with metabolic dysfunction. Stage 1-MHF is defined by a normal liver iron content, mild iron overload is MHF Stage 2 and severe iron overload MHF Stage 3. No validated consensus recommendations have been provided when patients should be referred for non-invasive iron quantification by MRI. The aim of the present study was to assess the association of high ferritin with liver iron concentration and fibrosis markers in patients with MHF to evaluate the biologic basis of the proposed staging system for MHF and develop evidence-based thresholds for MRI in MHF.
Method: A cohort of 882 patients with abdominal MRI between 2017 and 2023 was retrospectively evaluated for study inclusion. Of 494 patients with hyperferritinemia (Ferritin ≥200 µg/L in women, ≥300 µg/L in men) without anemia, inflammation or genetic iron overload, 167 patients with MHF could be included. This cohort was also compared with C282Y-homozygous patients (n = 71) and patients with MHF characteristics and a hemochromatosis phenotype (TSAT >50%, n = 31).
Results: Staging of MHF by serum ferritin concentration yielded in 44.3% of patients in MHF stage 1, 39.5% in stage 2 MHF and 16.2% of patients in stage 3 MHF. In contrast, disease staging based on liver iron concentration resulted in 70.7 % in MHF stage 1, in 27.4% in stage 2 and in 1.8% in stage 3. These results show that ferritin overestimates

the degree of iron overload in MHF. Higher levels of ferritin, but not of liver iron concentration were associated with significantly higher FIB-4 values as a surrogate of liver fibrosis. MHF-patients showed higher spleen iron concentrations when compared with C282Y homozygous hemochromatosis patients (45.2 s^{-1} (33.6; 64.4) vs. 32.3 s^{-1} (25.3; 40.6), p = <0.001). Further, hepcidin/log (ferritin) ratios in MHF patients were comparable to those in the MHF and TSAT >50% group (12.9 (8.3; 18.9) vs. 11.9 (5.9; 18.8), p = ns), but significantly higher than in hemochromatosis patients (3.4 (1.8; 7.5), p = <0.0001). When MHF patients were grouped by HFE genotype, significant differences were observed in liver iron concentrations (p = 0.02) but not in spleen iron concentrations (p = 0.43). Patients compound heterozygous for p.C282Y and p.H63D in HFE had higher liver iron concentrations than patients with a normal HFE phenotype (72.5 s^{-1} (66.5; 132.6) vs. 56.3 s^{-1} (47.7; 70.2), p = 0.002).

Conclusion: The present study shows that the prevalence of significant hepatic iron accumulation as assessed by MRI is low in patients with MHF. HFE genotype is a genetic determinant of liver iron concentration. The strong correlation between ferritin and hepatic fibrosis highlights the prognostic relevance of ferritin in MHF.

WED-215

HeparDx™ (by Metadeq, Inc.) is a reliable biomarker-based non-invasive test for MASH, capable of detecting the presence of inflammation and ballooning

Giulia Angelini[1], Sara Russo[1], Erminia Lembo[1], Ornella Verrastro[1], Caterina Guidone[2], Antonio Liguori[2], Stephen A. Harrison[3], Aldo Trylesinski[4], Luca Miele[2], Geltrude Mingrone[1,2,5]. *[1]Università Cattolica del Sacro Cuore, Rome, Italy; [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; [3]Radcliffe Department of Medicine, University of Oxford, UK, Oxford, United Kingdom; [4]Metadeq, London, United Kingdom; [5]King's college, London, United Kingdom*
Email: giulia.angelini@unicatt.it

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is the most common liver disease worldwide and the leading cause of liver-related morbidity and mortality. Currently high-risk MASH (NAS ≥4, F≥2) identification is a challenge, as it relies on liver biopsy that is invasive, expensive and fraught with scalability issues. Therefore, there is an urgent need to find non-invasive tests (NITs) for identification of at-risk MASH, to monitor disease progression and future treatment. PLIN2 is a ubiquitously expressed protein that plays an important role in the formation and stability of lipid droplets, contributing to the progression of MASH. Here we aim to evaluate the diagnostic performance of HeparDx™, a test based on the expression of PLIN2 in circulating monocytes, in a cohort of subjects with and without at-risk MASH.

Method: We analyzed data from two trials that included 198 subjects with histologically proven at-risk MASH (BRAVES cohort, n = 119) and no MASH (LIBRA cohort, n = 79). We used the Area Under the Receiver Operating Characteristic (AUROC) curve to assess the diagnostic performance of HeparDx™ in predicting at-risk MASH and determining the presence of lobular inflammation or ballooning. The Youden criterion was employed to determine the best threshold. To predict the presence/absence of at-risk MASH, inflammation, or ballooning, we used a binomial logistic regression model based on PLIN2 expression.

Results: PLIN2 expression was significantly increased in subjects with at-risk MASH compared with subjects without MASH (5.39 ± 0.31 vs. 2.32 ± 0.10 MFI; P < 0.0001). HeparDx™ analysis for the prediction of presence/absence of MASH yelded an AUROC of 91% with a sensitivity and specificity of 93.5% and 90.2% respectively. Positive and negative likelihood ratio were 26 and 0.12 respectively. HeparDx™ was able to detect lobular inflammation and ballooning with a high sensitivity (Lobular inflammation: 82.4%; Balloning: 71.7%) and specificity (Lobular inflammation: 95.6%; Balloning: 91.3%). Positive and negative likelihood ratio were 5.42 and 0.05 for lobular inflammation and 3.22 and 0.12 for ballooning. Based on a binomial logistic regression analysis, we estimated that HeparDx™ has the ability to accurately predict the presence of at-risk MASH, inflammation, and ballooning in 94.7%, 87.8%, and 88.1% of the cases, respectively.

Conclusion: NITs that use PLIN2 as a biomarker are reliable for the diagnosis of at-risk MASH subjects. HeparDx™ has the potential to replace invasive liver biopsy-based histology for diagnosis and can help in identifying patients eligible for MASH pharmacotherapy.

WED-218

Circulating mitochondrial bioenergetic profile reflects the hepatic one and represents a non-invasive biomarker of disease severity in MASLD genetically predisposed individuals

Erika Paolini[1], Miriam Longo[1], Marica Meroni[1], Paola Podini[2], Angelo Quattrini[2], Anna Ludovica Fracanzani[3], Paola Dongiovanni[1]. *[1]Medicine and Metabolic Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, Milano, Italy; [2]Experimental Neuropathology Unit, Institute of Experimental Neurology (INSPE), Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy, Milano, Italy; [3]Medicine and Metabolic Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, Department of Pathophysiology and Transplantation, Università Degli Studi di Milano, Milan, Italy, milano, Italy*
Email: paola.dongiovanni@policlinico.mi.it

Background and aims: Mitochondrial dysfunction is a key player in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) onset and progression. The co-presence of loss-of-function mutations in PNPLA3, TM6SF2 and MBOAT7 genes impacts on mitochondrial morphology and function in in vitro models. Conversely, the restore of MBOAT7 and/or TM6SF2 activity in knock-out HepG2 cells decreased the number of misshapen-dysfunctional mitochondria and improved OXPHOS capacity. Therefore, in order to translate our in vitro findings into a clinical perspective and discover novel non-invasive biomarkers, we assessed mitochondrial activity in 41 MASLD patients stratified according to GG-PNPLA3, TT-MBOAT7 and TT-TM6SF2 genotype, of whom frozen liver biopsies and peripheral blood mononuclear cells (PBMCs) were available.

Method: H2O2, ROS, mitochondrial complexes activities were measured by enzymatic assays, the oxygen consumption rate (OCR) by Seahorse.

Results: According to our in vitro results, liver biopsies and PBMCs of GG-PNPLA3, TT-MBOAT7 and TT-TM6SF2 carriers, alone and especially combined (number of risk variants, NRV = 3), showed higher H2O2 and ROS than MASLD patients with no variants. Consistently, the activity of mitochondrial complexes I, III, citrate and ATP synthase was lower in biopsies and PBMCs of GG-PNPLA3, TT-MBOAT7 and TT-TM6SF2 individuals, showing the sharpest effect in their co-presence (*p < 0.05, **p < 0.001, ***p < 0.0001 vs NRV = 0). Finally, biopsies and PBMCs of NRV = 3 subjects exhibited OCR depletion yielded by complex I/IV and II/IV activities compared to NRV = 0 at Seahorse (***p < 0.0001). At multivariate analysis adjusted for age, gender, BMI, diabetes and MASLD severity, NRV = 3 was associated with reduced OCR in hepatic biopsies (β = −21.24) and PBMCs (β = −20.08) (p < 0.0001). Finally, at nominal logistic analysis, adjusted for NRV = 3, OCR predicted MASH-fibrosis with AUC of 0.81 and 0.86 in biopsies and PBMCs, respectively.

Conclusion: PBMCs mitochondrial activity is impaired in NRV = 3 carriers and completely reflects the hepatic one. Therefore, PBMCs bioenergetic profile could represent a potential non-invasive biomarker of disease severity in MASLD genetically predisposed individuals.

WED-219

Pemvidutide, a glucagon-like peptide 1/glucagon dual receptor agonist, improves metabolic dysfunction-associated steatohepatitis activity and fibrosis in a clinical quantitative systems pharmacology model

Stephen A. Harrison[1], John Suschak[2], Matthew McDaniel[3], Zackary Kenz[3], Shaheen Tomah[2], Jonathan Kasper[2], M. Scot Roberts[2], Scott Siler[3], M. Scott Harris[2], Sarah Browne[2]. [1]*Pinnacle Clinical Research, San Antonio, United States;* [2]*Altimmune, Inc, Gaithersburg, United States;* [3]*Simulations Plus, Inc, Lancaster, United States*
Email: stephenharrison87@gmail.com

Background and aims: Elevated liver fat content (LFC) is recognized to be the primary pathophysiologic driver of metabolic dysfunction-associated steatohepatitis (MASH). In prior clinical trials, pemvidutide, a balanced (1:1) dual glucagon-like peptide 1 (GLP-1)/glucagon (GCG) receptor agonist, achieved significant reductions in LFC and improvements in two non-invasive markers of MASH inflammation: alanine aminotransferase (ALT) levels and corrected T1 magnetic resonance imaging. In the current study, NAFLDsym, a mechanistic quantitative systems pharmacology (QSP) model that includes interactive sub-models of steatosis, lipotoxicity, inflammation, and fibrosis, was used to predict the effects of pemvidutide and the relative contributions of GLP-1 receptor agonism and GCG receptor agonism on LFC, non-alcoholic fatty liver disease activity score (NAS), fibrosis, and weight loss in a simulated cohort of MASH subjects.
Method: The QSP modeling of pemvidutide, which included effects on weight loss and hepatocellular adenosine triphosphate (ATP) utilization, was linked to simulated pemvidutide pharmacokinetic profiles via a 1-compartment model. Data from a completed trial of pemvidutide in metabolic dysfunction-associated steatotic liver disease (MASLD) subjects were used to calibrate the quantitative effects of pemvidutide 1.8 mg once weekly dosing over 24 weeks. Simulations were conducted in a MASH cohort with median (Q1, Q3) NAS of 6.0 (4.0, 7.0), a median fibrosis stage of 2.0 (1.0, 3.0), and a median body weight of 106.2 (86.0, 123.8) kilograms.
Results: Excellent correlation was observed between clinically reported and QSP-predicted effects of pemvidutide on LFC at Week 12. The QSP model also predicted pemvidutide 1.8 mg to result in complete resolution of NAS and a 1-point median improvement in MASH fibrosis at 24 weeks of treatment. The addition of GCG receptor agonism to GLP-1 receptor agonism increased the relative reductions in LFC from 21% to 62% and resulted in a 4-point greater decrease in median NAS score. GLP-1 receptor agonism alone was predicted to have no effect on fibrosis within the 24-week timeframe.
Conclusion: The QSP model predicted the additive effects of adding GCG receptor agonism to GLP-1 receptor agonism on LFC, NAS, and fibrosis and suggested that success will be achieved with pemvidutide on these end points in an ongoing 24-week MASH clinical trial.

WED-220

BOS-580, a long-acting FGF-21 analogue, treatment shows beneficial changes in the circulating lipidome and improves MASEF score in patients with phenotypic metabolic dysfunction-associated steatohepatitis in a phase 2a randomized, placebo-controlled, 12-week study

Gerard Bain[1], Alicia Clawson[1], Juan Carlos Lopez-Talavera[1], Tatjana Odrljin[1]. [1]*Boston Pharmaceuticals, Cambridge, United States*
Email: gerard.bain@bostonpharmaceuticals.com

Background and aims: BOS-580, a highly engineered fusion of human FGF21 and IgG1 Fc, has a 21-day half-life that enables once-monthly dosing. BOS-580 has shown a statistically significant reduction in liver fat content and markers of liver injury/fibrosis and improved markers of metabolic health in a Phase 2a, double-blind, placebo-controlled, randomized study in phenotypic metabolic dysfunction-associated steatohepatitis (MASH) patients. MASH is driven by dysregulated energy metabolism with extensive changes in the liver and blood lipidome . Here we describe changes in the circulating lipidome of phenotypic MASH patients treated with BOS-580 and calculate metabolomics advanced steatohepatitis fibrosis (MASEF) scores, a novel composite biomarker to identify at-risk MASH patients (Noureddin M et al., 2024).
Method: Serum samples were collected for lipidomic profiling during a Phase 2a study of phenotypic MASH patients. Multiple dosing regimens were explored, with cohorts of 75 mg every 2 (Q2W) or 4 weeks (Q4W), 150 mg Q2W or Q4W, and 300 mg Q4W, or placebo. Metabolite extraction and analysis was performed according to published methods. Based on 12 lipids, body mass index (BMI), aspartate aminotransferase, and alanine aminotransferase, the MASEF score was calculated to determine at-risk MASH for each patient at baseline and at 12 weeks of BOS-580 treatment or placebo.
Results: A total of 480 lipid metabolic features were detected in the analyzed serum samples. Lipidomic profiles from patients with phenotypic MASH (n = 81) at baseline were enriched in triglycerides (especially those containing short acyl chains), diglycerides, bile acids and diacyl-phospholipids, while levels of non-esterified fatty acids (including mono- and poly-unsaturated and saturated fatty acids) and some lysophosphatidylcholines were reduced compared to a pre-existing obese control group (n = 30). BOS-580 treatment led to extensive changes in the circulating lipidome, including decreased levels of saturated fatty acids and triglycerides. Notably, these samples also had lower levels of lipotoxic molecules such as diglycerides and ceramides. MASEF scores identified 5 subjects in the placebo group with at-risk MASH at baseline, and all of them remained at-risk after 12 weeks, whereas 9 of 10 subjects in the treated group with at-risk MASH at baseline were no longer in the at-risk group after 12 weeks of treatment with BOS-580.
Conclusion: Treatment with once-monthly and bi-weekly BOS-580 improves the MASEF score at 12 weeks. Improvement of the MASEF score suggests reduction of at-risk MASH.

WED-221

A novel point-of-care prediction model for steatotic liver disease: based on bioimpedance analysis

Jeayeon Park[1], Goh Eun Chung[2], Yoosoo Chang[3], Seungho Ryu[3], Yunmi Ko[1], Youngsu Park[1], Hyunjae Shin[1], Moon Haeng Hur[1], Yun Bin Lee[1], Eun Ju Cho[1], Won Sohn[4], Jeong-Hoon Lee[1], Su Jong Yu[1], Jung-Hwan Yoon[1], Yoon Jun Kim[1]. [1]*Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Department of Internal Medicine, Seoul National University Hospital Healthcare System Gangnam Center, Seoul, Korea, Rep. of South;* [3]*Center for Cohort Studies, Total Healthcare Center, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South;* [4]*Division of Gastroenterology, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South*
Email: yoonjun@snu.ac.kr

Background and aims: Globally, the incidence of steatotic liver disease (SLD) is increasing across all age groups. The developed non-invasive biomarkers and prediction models for SLD often necessitate laboratory tests or imaging, leading to overlooked early diagnosis in under-screened groups, such as young adults and those with healthcare disparities. To address this challenge, we aimed to develop a machine learning-based point-of-care prediction model for SLD that is readily accessible to the broader population, facilitating early detection, timely intervention, and ultimately reducing the overall disease burden.
Method: We retrospectively analyzed 28, 506 adults who had routine health check-ups at seoul national university hospital healthcare center in South Korea from January 2022 to December 2022. For external validation, 159, 351 subjects were included who visited kangbuk samsung hospital healthcare center for routine health check-ups during the same period. All participants underwent abdominal ultrasound and bioimpedance analysis, in addition to

completing a questionnaire regarding their medical history and alcohol consumption. To analyze the data and make predictions, a logistic regression model was built using machine learning algorithms.
Results: A total of 20, 094 subjects were categorized into non-SLD and SLD groups based on the presence of fatty liver on abdominal ultrasound. SLD model 1 was based on age and body mass index (BMI), SLD model 2 was derived from age, BMI, and body fat mass per muscle mass, and SLD model 3 consisted of age, BMI, and visceral fat area per muscle mass. In the derivation cohort, the area under the receiver operating characteristic curve (AUROC) was 0.817 in the SLD model 1, 0.821 in the SLD model 2, and 0.820 in the SLD model 3. In the internal validation cohort, at the optimal upper and lower cutoff values, 86.8%, 86.9%, and 87.1% of subjects were correctly classified in SLD model 1, SLD model 2, and SLD model 3, respectively. In the external validation, all models showed an AUROC of 0.85, and demonstrated predictive values similar to the internal validation at each respective cutoff.
Conclusion: The three derived SLD prediction models, characterized by cost-effectiveness, non-invasiveness, and accessibility in settings outside of hospitals, could serve as novel and validated clinical tools for the mass screening of SLD.

WED-222
Impact of automated FIB-4 reporting on liver-related referral of patients with diabetes

Theodore Feldman[1,2], Sarah Altajar[3], Emilie Mitten[4], Nathanael Fillmore[4,5], Nhan Do[3,4,5], Mary Brophy[3,4,5], Gyorgy Baffy[3,4,6]. *[1]Boston Cooperative Studies Program Coordinating Center (CSPCC), VA Boston Healthcare System, Department of Biomedical Informatics, Harvard Medical School, Boston, MA, United States; [2]Department of Biomedical Informatics, Harvard Medical School, Boston, MA, United States; [3]Department of Medicine, Boston University Chobanian and Avedisian School of Medicine, Boston, MA, United States; [4]Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States; [5]Boston Cooperative Studies Program Coordinating Center (CSPCC), VA Boston Healthcare System, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States; [6]Department of Medicine, VA Boston Healthcare System, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States*
Email: Gbaffy@partners.org

Background and aims: Metabolic dysfunction-associated fatty liver disease (MASLD) is an underrecognized condition in patients with diabetes who are at an increased risk of advanced liver disease. FIB-4 is widely used for primary screening of liver fibrosis in MASLD. In 2020, we began reporting FIB-4 in the electronic health record (EHR) at our hospital and analyzed the impact of this measure on primary care referral practices. Preliminary findings of this work were presented earlier.
Method: Patients diagnosed with diabetes (HgbA1c >6.5% on at least one occasion) and seen in primary care clinics between 2011–2022 were identified. Subgroups of patients with low (<1.3), intermediate (1.3–2.67), and high (>2.67) FIB-4 values were defined based on EHR data. GI consults requested each year were analyzed by individual chart review and data were compared preceding (2011–2019) and following (2020–2022) the start of FIB-4 reporting with a focus on liver-related indications.
Results: A total of 14, 280 individual patients with diabetes seen in primary care at our hospital within the study period were identified. The average size of annualized cohorts was 4, 403 with the lowest number seen in 2020 (n = 3, 016), coinciding with the onset of COVID pandemic. Laboratory parameters allowed FIB-4 calculation in 64.8% of these cases, identifying 37.8%, 51.1%, and 11.1% with low, intermediate, and high FIB-4 scores, respectively, with no significant difference in the annual distribution. The number of outpatient GI consults placed each year ranged from 364 to 712 (10.1% to 15.7%, NS). Among these, the average rate of liver-related referrals was 11.8% with the highest rate of 14.6% found in 2020, indicating sustained referral rates despite an overall decreased number of GI referrals attributable to the pandemic. Further analysis of the rate of referrals related to abnormal liver tests indicated an average rate of 25.4% prior to FIB-4 index reporting, which increased to 43.4% immediately following its introduction ($p = 0.03$) and maintained an average of 39.3% (NS). MASLD as a referral indication showed a less robust change (13.1% vs. 19.2%, NS). During the same periods, rates of referrals related to hepatitis C virus infection dwindled from 29.2% to 3.6% (NS), consistent with the fact that most veterans at our center have received antiviral therapy prior to 2020. Finally, the average rate of liver-related referrals among patients with high FIB-4 increased from 4.6% to 8.1% (NS) after FIB-4 reporting.
Conclusion: Automated inclusion of pre-calculated FIB-4 in the EHR may change primary care referral practices and facilitate timely evaluation of patients with diabetes at increased risk of advanced liver disease. Additional steps are needed to bring robust increase in clinician awareness, improve screening rates, and facilitate risk assessment of patients with MASLD who are at increased risk for liver disease.

WED-223
Clinical and biological predictors of liver fat content ≥8% as assessed by MRI-PDFF: combined data from multiple therapeutic trials including more than 10, 000 patients

Mazen Noureddin[1], Sophie Jeannin[2], Naim Alkhouri[3], Vlad Ratziu[4], Jörn M. Schattenberg[5], Michael Charlton[6], Julie Dubourg[7], Stephen A. Harrison[8]. *[1]Houston Research Institute, Houston, United States; [2]Summit Clinical Research, San Antonio, United States; [3]Arizona Liver Health, Phoenix, United States; [4]Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France; [5]Saarland University Medical Center, Homburg, Germany; [6]University of Chicago, Chicago, United States; [7]Summit Clinical Research, San Antonio, United States; [8]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom*
Email: jdubourg@summitclinicalresearch.com

Background and aims: MRI-PDFF is a common inclusion criterion in metabolic dysfunction-associated steatotic liver disease (MASLD)/ metabolic dysfunction-associated steatohepatitis (MASH) and commonly a primary end point in early phase 2 trials, or secondary end points. We aimed to describe the main predictors of liver fat content content ≥8% across multiple therapeutic clinical trials.
Method: We combined screening data from 10 industry-funded MASH phase 2 trials. Predictors of liver fat content ≥8% were examined using linear regression.
Results: 2, 666 patients with MRI-PDFF data were included in this analysis. Among them, 2, 175 (82%) had a liver fat content ≥8%. In a multivariate model, liver fat content was associated with younger age ($p = 0.002$), and higher CAP-FibroScan ($p < 0.0001$), ALT ($p < 0.0001$), triglycerides (<0.0001), and platelet (<0.0001). Body max index, glycated hemoglobin (HbA1c) and AST were not associated with liver fat content. The proportion of patients with liver fat content ≥8% was 54%, 73%, 84% and 92% in patients with ALT <20, ALT 20–30, ALT 30–40, and ALT ≥40, respectively. This rised to 90% in patients with ALT ≥30 versus 66% in patients with ALT <30. In patients with triglycerides <150 mg/dL, 150–200 mg/dL, and ≥200 mg/dL, 79%, 87%, and 92% had liver fat content ≥8%, respectively. This rised to 90% in patients with triglycerides ≥150 mg/dL versus 79% in patients with triglycerides <150 mg/dL. The proportion of patients with liver fat content ≥8% was 83%, 83%, and 78% in patients with <40 years, 40–60 years, and ≥60 years, respectively.
Conclusion: Simple non-invasive biomarkers can help target patients with liver fat content ≥8%. We recommend using the ALT or triglycerides as simple tools with cutoff points of 30 for ALT and/or 150 for triglycerides.

WED-224

Screening for liver fibrosis in tertiary care using automatic calculation of FIB4 in patients at-risk of diabetes

Clémence M Canivet[1], Celine Rolland[1], Francoise Joubaud[1], Franck Genevieve[1], Stéphane Gervais[1], Frédéric Oberti[1], Delphine Prunier[1], Valérie Moal[1], Sophie Michalak[1], Isabelle Fouchard[1], Adrien Lannes[1], Jerome Boursier[1]. [1]*CHU of Angers, Angers, France*
Email: clemence.canivet@chu-angers.fr

Background and aims: Current recommendations from EASL and AASLD suggest targeted screening for liver fibrosis in patients at risk. For this reason, diabetic and metabolic patients are the first-line patients to be targeted. The aim of this study was to evaluate a targeted screening procedure for advanced liver fibrosis using automatic calculation of FIB-4 in a tertiary centre.
Method: Between March 2021 and February 2023 in a French university hospital, an automatic calculation of the simple FIB-4 blood test was carried out for all blood tests including AST, ALT, platelets and HbA1c to target metabolic or diabetic patients. If the FIB-4 was >2.67, the prescribing physician received an alert message inviting him to request a liver specialized evaluation (SLE) for the patient. If this was not done within 6 weeks, a hepatologist contacted the patient to propose the SLE. The SLE included an assessment of fibrosis using liver elastometry (Fibroscan®) and specialized blood tests (FibroMeter^{V2G} and FibroMeter^{VCTE}). Patients with hepatic elasticity ≥8 kPa werere ferred to a hepatology consultation. A liver biopsy was then proposed to confirm the diagnosis of advanced fibrosis. In patients without liver biopsy, the diagnosis of advanced hepatic fibrosis was made by an independent adjudication committee of 3 senior hepatologists (procedure in progress which will be available for presentation)
Results: Of the 8796 FIB-4 generated, 835 were >2.67 (9.5%) in 678 patients (7.7%). After excluding patients already followed in hepatology, 364 patients required SLE. 95 patients were deemed to be in too poor a state of health to warrant screening for liver fibrosis, and 62 patients refused or could not be contacted. A total of 207 patients were invited to undergo SLE, half of whom were invited by the prescribing physician (n = 101) and the other half by the hepatologist (n = 106). 185 patients underwent SLE: 52 patients (28.4%) had a liver elastometry ≥8 kPa. Nearly half of these patients came from the diabetology department (24/52), while the cardiology (4/52) and neurology (3/52) departments provided very few patients at risk of advanced fibrosis. Liver biopsy was offered to 34 patients, 5 of whom refused. A total of 29 patients was diagnosed with advanced fibrosis (12 by liver biopsy, 17 by non-invasive tests). The prevalence of advanced liver fibrosis was 7.9% in patients with a FIB-4 >2.67 with no previous liver follow-up and 15.7% in patients who underwent SLE. Patient compliance with the procedure was excellent (87% while compliance by prescribing physicians was 27.7%.
Conclusion: This study shows the value of a targeted automatic screening procedure for advanced liver fibrosis in tertiary centre. Raising awareness among hospital practitioners remains essential to improve compliance with the procedure.

WED-225

An intergenerational population-based cross-sectional study of MASLD in children and their parents

Oyekoya Ayonrinde[1,2,3], Shailender Mehta[1,2], Stephanie Dowden[4], Timothy Fairchild[5], Gina Ambrosini[6], Desiree Silva[3,7], Kemi Wright[8], Sheeraz Mohd[1], Leela King[1], Seyifunmi Afolabi[9], Janine Spencer[1]. [1]*Fiona Stanley Hospital, Murdoch, Australia;* [2]*Curtin University, Bentley, Australia;* [3]*The University of Western Australia, Perth, Australia;* [4]*NursePrac Australia, Success, Australia;* [5]*Murdoch University, Murdoch, Australia;* [6]*Department of Health, Government of Western Australia, Perth, Australia;* [7]*Joondalup Hospital, Joondalup, Australia;* [8]*The University of New South Wales, Sydney, Australia;* [9]*Oceania University of Medicine, Brisbane, Australia*
Email: oyekoya.ayonrinde@uwa.edu.au

Background and aims: Steatotic liver disease (SLD) is the most common chronic liver disorder globally. SLD in childhood reflects prevalent metabolic dysfunction in children and families and poses increased longer-term risk of early-onset cardiometabolic and liver-related complications. We examined the prevalence and significance of SLD in children and their parents.
Method: Population-based children, aged 5–15 years, and their parents participated in a cross-sectional observational study of SLD in Perth, Australia. Assessments included controlled attenuation parameter (CAP) with transient elastography, anthropometry, and blood tests. SLD was defined by CAP ≥249 dB/m in children and ≥275 in parents. Associations between SLD in children and their parents and associations with features of metabolic dysfunction were sought.
Results: One hundred and fifteen children (50% male), with mean [SD] age 9.6[2.7] years, 74 mothers aged 40.7[5.8] years and 24 fathers aged 44.2[5.8] years were examined. Among the children, 73 (64%) were aged 5–10 years. Comparing boys vs. girls, there were no significant differences in modified body mass index (BMI) z-score (-0.17 vs. −0.11), median (IQR) weight (45.6[29.3–59.2] kg vs. 39.5 [27.6–51.0) kg, p = 0.15), waist circumference (WC) (67.0 [53.0–81.0] cm vs. 65.0 [55.5–75.0] cm, p = 0.48), abdominal skinfold thickness (SFT) (23.0 [12.0–32.0] mm vs. 21.0 [11.0–31.0]) mm, and CAP (202 [185–244] dB/m vs. 210 [184–251] dB/m (p > 0.05 for all). Mean (SD) WC was 88.3 (13.4) cm in mothers and 91.8 (10.9) cm in fathers. Mean BMI was 27.7 (5.3) kg/m^2 in mothers and 27.3 (3.0) kg/m^2 in fathers. SLD was diagnosed in 20.2% children (15.8% male vs. 24.6% female, p = 0.24), 29.9% mothers and 37.5% fathers. SLD was seen in 55% of children with BMI ≥30 kg/m^2. Children with SLD had higher abdominal SFT, weight, WC, BMI, serum alanine aminotransferase (ALT), high-sensitivity C-reactive protein, and triglycerides, and lower levels of high-density lipoprotein cholesterol, compared with those without SLD (p < 0.05 for all). There was no significant correlation between SLD in children and their parents, however mothers of children with SLD had higher mean BMI than mothers of children without SLD (30.3[5.7] kg/m^2 vs. 27.1[5.1] kg/m^2, p = 0.04), and fathers had higher mean liver stiffness measurement (LSM), (7.6[4.6] kPa vs. 4.8[1.2] kPa, p = 0.02. Using multivariable logistic regression analysis, child ALT (OR 1.21, 95% CI 1.01–1.45) and abdominal SFT (OR 1.59, 95% CI 1.03–2.44) were associated with SLD in children, after adjusting for child WC (OR 0.94, 95% CI 0.87–1.04), and maternal BMI (OR 1.22, 95% CI 0.85–1.76).
Conclusion: SLD is common in children, and is associated with increased adiposity, raised ALT, features of metabolic dysfunction, maternal adiposity, and paternal liver stiffness. Our findings suggest possible intergenerational heritability of metabolic and hepatic risk.

WED-226

An algorithm based on serum phospholipid profiles to predict liver fibrosis degree in metabolic dysfunction-associated steatotic liver disease

Mayuko Shimizu[1], Yuko Miyakami[1], Minoru Matsumoto[2], Kentaro Yoshimura[3], Akemi Tsutsui[4], Yosuke Tsuchiyama[1], Koichi Takaguchi[4], Sén Takeda[5,6], Koichi Tsuneyama[1]. [1]*Tokushima University, Department of Pathology and Laboratory Medicine, Tokushima, Japan;* [2]*Tokushima University, Department of Molecular Pathology, Tokushima, Japan;* [3]*University of Yamanashi, Division of Molecular Biology, Yamanashi, Japan;* [4]*Kagawa Prefectural Central Hospital, Department of Hepatology, Takamatsu, Japan;* [5]*Teikyo University School of Medicine, Department of Anatomy, Tokyo, Japan;* [6]*University of Yamanashi, Department of Anatomy and Cell Biology, Yamanashi, Japan*
Email: ichimura.mayuko@tokushima-u.ac.jp

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) leads to liver cirrhosis and hepatocellular carcinoma. Although plasma/serum phospholipids are proposed non-invasive biomarkers of MASLD progression, they have not been put into clinical practice, in part because the mechanism underlying their efficacy remains unknown. The aim of this study was to evaluate serum phospholipid profiles in order to develop a novel biomarker for assessing the extent of liver fibrosis in MASLD patients and elucidate the underlying mechanisms.
Method: Liquid chromatography-tandem mass spectrometry was used to comprehensively analyse serum phospholipid profiles in 100 patients with clinically diagnosed MASLD. A total of 550 phospholipid species were analysed, including subclasses of phosphatidylethanolamine (PE), sphingomyelin (SM), phosphatidylcholine (PC), lysophosphatidylethanolamine, and lysophosphatidylcholine. Phospholipid profiles were associated with laboratory data and fibrosis stage in liver biopsy.
Results: MASLD patients with liver fibrosis exhibited distinct changes in serum phospholipids, characterised by reduced SM and PC levels and elevated PE levels. Based on these phospholipid changes, we developed a fibrosis prediction model and evaluated its performance using biopsy data, with samples divided based on classification (≥F2 versus <F2). Our phospholipid-based model exhibited both higher area under the curve values (AUC = 0.89) and greater specificity in comparison with other fibrosis biomarkers, including FIB-4 index, Mac-2 binding protein glycosylation isomer, and type IV collagen 7s (AUC = 0.81, 0.77, and 0.75, respectively). We also elucidated the underlying mechanism of these phospholipid changes in relation to serum lipoproteins of the patients and liver transcriptomics. Specifically, a significant correlation between serum SM and LDL-cholesterol levels was identified ($r = 0.64$, $p < 0.001$ for SM [36:3]; $r = 0.66$, $p < 0.001$ for SM [40:1–d18:1/22:0]). Reduced serum LDL-cholesterol levels could be attributed to fibrotic liver and down-regulated expression of *LIPC*, which encodes the hepatic lipase that catalyzes LDL-cholesterol synthesis.
Conclusion: Serum phospholipid profiles represent an effective biomarker of liver fibrosis and help enhance understanding of the pathology of MASLD.

WED-227

Transient elastography performance for the diagnosis of liver fibrosis in MASLD is independent of steatosis level as determined by MRI proton density fat fraction in a prospective multicentrer study

Oumnia Masrour[1], Florent Ehrhard[2], Maeva Guillaume[3], Jerome Boursier[4], Jérôme Gournay[5], Karim Aziz[6], Matthieu Schnee[7], Ronan Garlantezec[1], Victor de Lédinghen[8], Laine Fabrice[9], Turlin Bruno[1], Yves Gandon[1], Edouard Bardou-Jacquet[9]. *[1]CHU Rennes, Rennes, France; [2]CH Lorient, Rennes, France; [3]Clinique Pasteur Toulouse, Toulouse, France; [4]CHU Angers, Angers, France; [5]CHU Nantes, Nantes, France; [6]CH Saint Brieuc, Saint Brieuc, France; [7]CH La Roche sur Yon, La Roche sur Yon, France; [8]CHU Bordeaux, Bordeaux, France; [9]CHU Rennes, rennes, France*
Email: edouard.bardou-jacquet@chu-rennes.fr

Background and aims: Transient elastography using Fibroscan© (FS) is accurate to screen for severe liver fibrosis in MASLD. Some studies suggest that the severity of steatosis may influence elastography value. Treatment or management modifying liver steatosis might thus impact the relevance of FS in the management of patient. Hepatic steatosis quantification using MRI PDFF is easily accessible and has shown reliability and accuracy. The aim of our study is to evaluate the performance of FS combined with MRI PDFF for severe fibrosis diagnosis.
Method: In this prospective multicenter study, patients with MASLD and indication for biopsy underwent an MRI and FS within a month. Patients with weekly alcohol consumption exceeding 21 UI/14 UI (male/female) were excluded. Biopsies were centrally reviewed using the SAF score. Hepatic steatosis PDFF was centrally quantified using the MRQuantif software. Elastography quality criteria included an IQR <0.3 if FS >7.1 kPa, the M probe was used for patients with BMI <30, and the XL probe for BMI >30. ROC curves for the diagnosis of fibrosis ≥F2 and ≥F3 were determined for FS alone and for FS combined with PDFF as a continuous or categorical variable in a logistic regression. ROC curves were compared using the DeLong test.
Results: A total of 270 patients were included. 62 were excluded due to the absence of elastography or MRI, a delay >30 days, or uninterpretable elastography. The studied population comprised 208 patients. Median age was 57, 63.9% males, median was BMI 32, and 47.6% were diabetic. 56.3% of patients had fibrosis ≥F2, and 30.3% had fibrosis F3-F4 on biopsy. 35.7% of patients had MASH according to the SAF score. The mean elastography value was 8.2 kPa. The mean PDFF value was 14.8%. The mean intervals between MRI/biopsy and FS/biopsy were 6.5 and 0.8 days, respectively. The AUC of FS for fibrosis ≥F3 was 0.78 (0.72–0.85), with no significant difference compared to AUC considering PDFF as a continuous value = 0.78 (0.72–0.85) or in category = 0.77 (0.70–0.84). The AUC of FS for fibrosis ≥F2 was 0.67 (0.60–0.74), with no significant difference compared to AUC considering PDFF as a continuous value = 0.66 (0.59–0.73) or in category = 0.65 (0.58–0.73). Similarly, there was no significant difference in performance within the subgroup of diabetic patients or patients with BMI >30.
Conclusion: Quantifying hepatic steatosis using MRI PDFF, allows a comprehensive and accurate assessment of liver steatosis. Fibroscan performance for the diagnosis of liver fibrosis does not seem to be affected by the level of liver steatosis.

WED-230

Association of Quantitative Hepatic Collagen with Non-Invasive Tests (NITs) for Fibrosis in Patients with Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD)

Zobair Younossi[1,2], James M Estep[1,2], Sean Felix[2], Brian Lam[1,2], Daisong Tan[2], Aaron Koenig[2], Fanny Monge[2], Andrei Racila[1,2], Zachary Goodman[2], Maria Stepanova[1,2,3]. *[1]The Global NASH Council, Washington, DC, United States; [2]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, VA, United States; [3]Center for Outcomes Research in Liver Diseases, Washington, DC, United States*
Email: zobair.younossi@cldq.org

Background and aims: Hepatic collagen quantification determined as percent of hepatic collagen (PHC) can provide an accurate assessment of hepatic fibrosis. Although NITs for fibrosis have been shown to correlate with the semi-quantitative assessment of fibrosis by pathologic staging, the association of NITs with PHC in MASLD has not been established. Our aim was to associate PHC with common fibrosis NITs in patients with MASLD.
Method: Biopsy slides of patients with biopsy-proven MASLD and metabolic dysfunction-associated steatohepatitis (MASH) were stained with Sirius red, and PHC was estimated using computer-assisted morphometry (Aperio AT2, Leica Microsystems).The histologic stage of fibrosis was also evaluated using semi-quantitative F0-F4 scoring (NASH CRN system) by the study hepatopathologist (ZG). Serum samples collected at the time of biopsy were used to measure the fibrosis-4 (FIB-4) index and enhanced liver fibrosis (ELF) test, and DNA extracted from buffy coat was used to determine rs738409 (*PNPLA3)* genotype. Results are reported as % or mean and (SD).
Results: 331 MASLD patients were included [age 45 ± 11 years, 29% male, 97% obese (BMI>30), 36% type 2 diabetes, 53% hyperlipidemia, 59% hypertension, 44% MASH and 56% non-MASH, 46% with *PNPLA3* rs738409 CG or GG genotype, 63% histologic F1, 22% F2, 9% F3, 6% F4; FIB-4 score 1.10 (2.06) with 81% having FIB-4 <1.30 (low-risk); ELF score 8.97 (1.33) with 77% having ELF<9.8 (low-risk); PHC was 3.21 (2.79) %]. There was a strong association of PHC with histologic fibrosis stage: F1 patients had PHC 2.38 (1.99) %; F2: 3.45 (2.22) %; F3: 5.31 (3.39) %; F4: 8.19 (4.21) (trend $p < 0.0001$). Pooled together, patients with advanced fibrosis (F3-F4) had significantly higher PHC

than patients with mild or moderate fibrosis: 6.37 (3.93) % vs. 2.65 (2.10) % in F1-F2 ($p < 0.0001$). Among NITs, there were significant correlations of PHC with FIB-4 ($r = +0.23$) and ELF ($r = +0.21$) scores (all $p < 0.05$). Patients with elevated ELF (≥9.8) had higher PHC than those with low-risk ELF: 5.66 (4.55) % vs. 3.14 (2.53) %, $p = 0.0095$. Similarly, patients with elevated FIB-4 (≥1.30) had higher PHC than those with low-risk FIB-4: 4.83 (3.67) % vs. 2.86 (2.42) %, $p < 0.0001$. Finally, patients with high-risk *PNPLA3* rs738409 genotype (CG/GG) had higher PHC than those with the CC genotype: 3.45 (2.82) % vs. 2.67 (2.46) %, $p = 0.0112$.
Conclusion: In MASLD patients, common NITs are strongly associated with percent of hepatic collagen. These data provide additional validity of NITs as good surrogate of disease severity as determined by PHC and stage of fibrosis.

WED-231
Machine learning-based mortality prediction models for non-alcoholic fatty liver disease in the general United States population
Jiarui Zheng[1], Bo Feng[1]. [1]*Department of Hepatology, Peking University Hepatology Institute, Beijing, China*
Email: fengbo@pkuph.edu.cn

Background and aims: Nowadays, the global prevalence of non-alcoholic fatty liver disease (NAFLD) has reached about 25%, which is the most common chronic liver disease worldwide, and the mortality risk of NAFLD patients is higher. Our research created five machine learning (ML) models for predicting overall mortality in ultrasound-proven NAFLD patients and compared their performance with conventional non-invasive scoring systems, aiming to find a generalizable and valuable model for early mortality prediction in NAFLD patients.
Method: National Health and Nutrition Examination Survey (NHANES)-III from 1988 to 1994 and NHANES-III related mortality data from 2019 were used. 70% of subjects were separated into the training set (N = 2262) for development, while 30% were in the testing set (N = 971) for validation. The outcome was all-cause death at the end of follow-up. Twenty-nine related variables were trained as predictor features for five ML-based models: Logistic regression (LR), K-nearest neighbors (KNN), Gradient-boosted decision tree (XGBoost), Random forest (RF) and Decision tree. Five typical evaluation indexes including area under the curve (AUC), F1 score, accuracy, sensitivity and specificity were used to measure the prediction performance.
Results: 3233 patients with NAFLD in total were eligible for the inclusion criteria, with 1231 death during the average 25.3 years follow-up time. AUC of the LR model in predicting the mortality of NAFLD was 0.888 (95% confidence interval [CI] 0.867–0.909), the accuracy was 0.808, the sensitivity was 0.819, the specificity was 0.802, and the F1 score was 0.765, which showed the best performance compared with other models (AUC were: RF, 0.876 [95%CI 0.852–0.897]; XGBoost, 0.875 [95%CI 0.853–0.898]; Decision tree, 0.793 [95%CI 0.766–0.819] and KNN, 0.787 [95%CI 0.759–0.816]) and conventional clinical scores (AUC were: Fibrosis-4 Score (FIB-4), 0.793 [95%CI 0.777–0.809]; NAFLD fibrosis score (NFS), 0.770 [95%CI 0.753–0.787] and aspartate aminotransferase-to-platelet ratio index (APRI), 0.522 [95%CI 0.502–0.543]).
Conclusion: ML-based models, especially LR model, had better discrimination performance in predicting all-cause mortality in patients with NAFLD compared to the conventional non-invasive scores, and an interpretable model like Decision tree, which only used three predictors: age, systolic pressure and glycated hemoglobin, is simple to use in clinical practice.

WED-232-YI
Diagnostic accuracy of two-dimensional shear wave elastography (2D-SWE) for non-invasive assessment of liver fibrosis in biopsy-proven metabolic dysfunction-associated steatotic liver disease (MASLD). Systematic-review and multi-level random effects model meta-analysis
Madalina-Gabriela Taru[1,2,3,4], Dan-Corneliu Leucuta[3], Silvia Ferri[1], Ahmed Hashim[1,2], Olga Orasan[3], Bogdan Procopet[3,4], Monica Lupsor-Platon[3,4], Laura Turco[5], Horia Ștefănescu[4], Fabio Piscaglia[1,2], Federico Ravaioli[1,2]. [1]*Division of Internal Medicine, Hepatobiliary and Immunoallergic Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy;* [2]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy;* [3]*Faculty of Medicine, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania;* [4]*Regional Institute of Gastroenterology and Hepatology "Octavian Fodor", Cluj-Napoca, Romania;* [5]*Internal Medicine Unit for the Treatment of Severe Organ Failure, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy*
Email: madalinagabrielataru@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) represents a substantial healthcare concern. The early detection of advanced fibrosis (F3) and cirrhosis (F4) in MASLD is essential due to their association with unfavourable long-term outcomes. This systematic review and meta-analysis aimed to provide the best evidence for the diagnostic accuracy by a multiple thresholds model of two-dimensional shear wave elastography (2D-SWE) in detecting different stages of liver fibrosis in adult patients with biopsy-proven MASLD.
Method: We systematically searched PubMed/MEDLINE, EMBASE, Cochrane Library, Scopus, Web of Science, and LILACS electronic databases for full-text articles published in any language from inception to February 2023 and subsequently updated the search to December 2023. We included original studies that reported data on liver fibrosis assessment by 2D-SWE and employed histological diagnosis as the gold standard reference. A linear mixed-effects multiple thresholds model (CICS, Common random intercept and common slope) was endeavoured using the diagmeta R package, and summary estimates for sensitivity (Se), specificity (Sp), and the summary area under the curve (sAUC) were computed for all fibrosis stages. The study protocol was published online at https://doi.org/10.17605/OSF.IO/9WV8F.
Results: 23 observational studies (SuperSonic Imagine, GE Healthcare, Canon Medical Systems) were selected for the systematic-review, and 17 fulfilled the inclusion criteria for the subsequent meta-analysis, comprising a total of 1922 participants with biopsy-proven MASLD (mean age 51.4 [SE 2.53] years, mean BMI 28.2 [SE 0.87] kg/m^2, 51.3% females, prevalence of diabetes 40.3%. The prevalence of any stage of fibrosis (F1), significant fibrosis (F2), advanced fibrosis (F3) and cirrhosis (F4) was 29.2%, 19.6%, 18%, and 11.1%, respectively. The sAUCs [95% CI] in detecting ≥F1, ≥F2, ≥F3, and F4 for Se given Sp were 0.824 [0.129; 0.981], 0.822 [0.741; 0.884], 0.866 [0.756; 0.935], and 0.890 [0.772; 0.955], respectively. The optimal cut-off values were at 6.43 kPa (Se = 0.76, Sp = 0.76) for ≥F1, 8.17 kPa (Se = 0.76, Sp = 0.76) for ≥F2, 9.61 kPa (Se = 0.80, Sp = 0.80) for ≥F3, and 11.55 kPa (Se = 0.82, Sp = 0.82) for F4, respectively.
Conclusion: Our systematic review and meta-analysis suggest that 2D-SWE accurately diagnoses different stages of liver fibrosis in MASLD, underscoring the potential for standardising cut-off thresholds.

WED-233-YI

The single nucleotide polymorphism rs780094 C>T in the glucokinase regulator gene (GCKR) is associated with hepatic steatosis improvement after lifestyle intervention in overweight/obese subjects with metabolic dysfunction-associated steatotic liver disease

Eleonora Dileo[1], Chiara Rosso[1], Mariagrazia Tatoli[1], Gabriele Castelnuovo[1], Gian Paolo Caviglia[1], Angelo Armandi[1,2], Nuria Pérez Diaz del Campo[1], Marta Guariglia[1], Francesca Saba[1], Maria Lorena Abate[1], Antonella Olivero[1], Fabio Bioletto[1], Mirko Parasiliti-Caprino[1], Simona Bo[1], Elisabetta Bugianesi[1,3].

Email: eleonora.dileo@unito.it

Background and aims: The rs780094 C >T single nucleotide polymorphism (SNP) in the glucokinase regulator gene (*GCKR*), involved in the regulation of glucose metabolism, has been associated with obesity and hepatic steatosis in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). Our aim was to assess its impact on metabolic changes after lifestyle intervention in a group of overweight/obese MASLD patients.
Method: We analyzed 95 subjects (mean age 47 ± 52 y; male, N = 67) with MASLD who underwent a 6- month dietary intervention. At baseline (t0) and after 6-months diet (t6) we collected blood samples and anthropometrical measurements. The body composition was assessed by bioelectrical impedance analysis (BIA 101, Anker). *GCKR* rs780094 C >T genotyping was performed by allelic discrimination assay. Hepatic steatosis was determined by controlled attenuation parameter (CAP, Fibroscan®). A CAP improvement of 15 % was used as clinical end point. For all the metabolic parameters, we calculated the variation from t6 to t0 (delta).
Results: Overall, 57 (60%) patients were obese, 15 (15.8 %) had type 2 diabetes and 32 (33.7 %) had arterial hypertension. The prevalence of the *GCKR* rs780094 genotypes was 18.9 % (CC), 45.3 % (CT) and 35.8 % (TT). After 6 months of diet, all patients significantly improved body mass index (t0 = 30.8 kg/m^2 vs. t6 = 29.5 kg/m^2, p < 0.001), fat mass (FM) (27.9 kg vs. 26.0 kg, p = 0.007) and CAP (306 dB/m vs. 275 dB/m, p < 0.001). Specifically, a 15 % of CAP improvement was observed in 23 patients (24.2 %); among them, 12 carried the TT genotype (52 %), 2 (9 %) carried the CC wild type homozygosis and 9 subjects (39 %) carried the CT heterozygosis (p = 0.042). As expected, we showed that patients carrying the rs780094 TT genotype significantly improved glucose and insulin levels compared to those who carried the CC/CT variants (p = 0.004 and p = 0.001, respectively), while no differences were found concerning lipid profile. At multivariate logistic regression analysis adjusted for age, gender and diabetes, 15 % of CAP decrease after diet was associated with the rs 780094 TT risk homozygosis independent by delta FM (OR = 5.75, p = 0.05).
Conclusion: In overweight/obese subjects with MASLD, the *GCKR* rs780094 TT genotype predicts CAP improvement after diet. This finding may have implications in clinical practice for risk stratification and personalized medicine. *Funded by the University of Turin, g.n. ROSC_RILO_23_01.*

WED-234

Identifying the optimal cut off for relative reduction in liver fat content on MRI-PDFF to predict histologic response in MASH clinical trials

Michele Pansini[1,2], Cayden Beyer[3], Kitty Yale[4], Tim Rolph[4], Kenneth Cusi[5], Andrea Dennis[3], Naim Alkhouri[6]. *[1]Clinica Di Radiologia EOC, Istituto Di Imaging Della Svizzera Italiana (IIMSI), Lugano, Switzerland; [2]John Radcliffe Hospital, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [3]Perspectum Ltd, Oxford, United Kingdom; [4]Akero Therapeutics Inc, South San Francisco, United States; [5]Division of Endocrinology, Diabetes and Metabolism, University of Florida, Gainesville, United States; [6]Arizona Liver Health, Chandler, United States*
Email: andrea.dennis@perspectum.com

Background and aims: MRI-proton density fat-fraction (PDFF) is a reliable and accurate measure of liver fat content (LFC). Estimates from clinical trials data suggested a threshold of 30% relative reduction in PDFF is indicative of clinically meaningful improvement in liver histopathology, as this had been associated with a 2-point improvement in NAS and with MASH resolution. However, a significant proportion of non-responders on histology achieve a 30% or more relative reduction in PDFF. The aim of this study was to determine the optimal cut off for relative reduction in LFC by PDFF to predict histologic response in patients with MASH.
Method: A retrospective analysis of participants from two interventional clinical trials with histologically confirmed MASH who underwent LiverMultiScan and paired, contemporaneous biopsy at baseline and end of study. The IDEAL post-processing method was used to calculate PDFF as it is the most accurate. Histological responders were defined as (1) a decrease in NAFLD Activity score (NAS) ≥2 with no worsening in fibrosis, (2) a decrease in fibrosis ≥1 stage with no worsening in NAS, and (3) MASH resolution with no worsening in fibrosis. Optimal thresholds for PDFF were reported using Youden's index.
Results: 132 patients were included in the analysis (age: 57 [IQR: 17.0], BMI: 35 kg/m^2; 66% females, 37% diabetic, average baseline PDFF: 19.6%), 18 patients were recorded as in the placebo arms. Median change in PDFF for the 3 histological criteria ranged from 42–64% relative reduction, the median relative difference in PDFF from baseline in those on placebo was 21%. Using AUC, the optimal threshold for identifying histological responders ranged between 57%–63% relative change. For the histological category of MASH resolution, the optimal threshold for relative reduction in PDFF from baseline was –57%, this had an odds ratio of 16.8 (CI 4.7–67.3) and PPV of 65% to predict histological response. This compares to OR of 5.85 (CI 1.82–22.6) and PPV of 36% for a 30% relative reduction from baseline.
Conclusion: Whilst PDFF is a very useful end point in MASH trials, particularly for compounds expected to have a metabolic mechanism of action, the optimal threshold that would indicate a clinically meaningful improvement is much higher than the previous estimates of 30% relative change, which is only marginally more than the mean reduction observed for placebo. These data should be considered when designing clinical trials and setting thresholds for detecting meaningful change in MASH drug development.

WED-235

Prediction of metabolic dysfunction-associated steatohepatitis resolution

Rohit Loomba[1], Maral Amangurbanova[1], Ricki Bettencourt[1], Egbert Madamba[1], Harris Siddiqi[1], Lisa Richards[1], Mildred D. Gottwald[2], Shibao Feng[2], Maya Margalit[3], Daniel Huang[4]. *[1]MASLD Research Center, UC San Diego, La Jolla, United States; [2]89 Bio, San Francisco, United States; [3]89 Bio, Rehovot, Israel; [4]Division of Gastroenterology and Hepatology, Department of Medicine, National University Health System, Singapore, Singapore*
Email: roloomba@health.ucsd.edu

Background and aims: The resolution of metabolic dysfunction-associated steatohepatitis (MASH) is an accepted regulatory end point for subpart H approval of therapies developed for MASH but requires an invasive liver biopsy for its assessment. The MASH Resolution Index and FibroScan-aspartate aminotransferase (FAST) score have recently been reported to identify MASH resolution. We aimed to compare the diagnostic accuracy of the MASH Resolution Index and the FAST score to detect the histologic resolution of MASH.
Method: This prospective study included 163 participants (64% female) with biopsy-proven MASH and stage 2 or stage 3 fibrosis from

a randomized, multicenter, placebo-controlled trial of pegozafermin, a fibroblast growth factor 21 analog. Participants received either pegozafermin or placebo and underwent two sets of contemporaneous liver biopsies, magnetic resonance imaging-proton density fat fraction (MRI-PDFF), and FibroScan spaced 24 weeks apart. The *primary outcome* was diagnostic accuracy for MASH resolution. The Delong test was used to compare the area under the receiver operating curves (AUC).

Results: The median (IQR) age and body mass index of participants in the validation cohort were 56.0 (48.0–62.0) years and 36.5 (32.2–40.2) kg/m^2, respectively. At follow-up biopsy, 29 (21.6%) of participants (pooled placebo and pegozafermin) in the validation cohort had MASH resolution. The AUC of the MASH Resolution Index (0.83, 95% CI 0.76–0.91) for identifying MASH resolution was significantly higher than the FAST score (0.65, 95% CI 0.55–0.75), p = 0.001. When the rule-in criteria for the MASH Resolution Index were used, the positive predictive value for MASH resolution was 29%, compared to 23% for change in FAST. When the rule-out criteria for the MASH Resolution Index were used, the negative predictive value was 100% compared to 87% for change in FAST.

Conclusion: The MASH Resolution Index has superior diagnostic accuracy for MASH Resolution, compared to the FAST score.

WED-236-YI

Real world evaluation of a primary care pathway for the assessment of liver fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD)

Basil Ahmad[1], Oliver Mitchell[1], Sally Pannifex[1], Arjuna Singanayagam[1], Sarah Hughes[1], Sarah Clark[1], Metin Yalcin[1], Nicola Williams[2], Sarah Davie[3], Daniel Forton[1]. *[1]St George's University Hospitals NHS Foundation Trust, London, United Kingdom; [2]South West London Gastroenterology Clinical Network, London, United Kingdom; [3]South West London Pathology, London, United Kingdom*
Email: daniel.forton@nhs.net

Background and aims: Fibrosis stage is the strongest predictor for disease-specific mortality in MASLD. In 2021 we introduced an initiative in SW London to stratify fibrosis risk in patients in primary care (PC) with MASLD, using non-invasive biomarker (NIB) assessment. FIB-4 was offered as the first test, with nested enhanced liver fibrosis (ELF) for those with indeterminate FIB-4 scores (1.3 >FIB-4 <3.25 if <65 years, 2.0 >FIB-4 <2.67 if >65 years). ELF was only available to PC practitioners and testing was only performed if the FIB-4 was indeterminate. Referrals to Hepatology clinics are only accepted with a qualifying FIB-4 or ELF (>9.5). This two-step (or similar) pathway is recommended by most MASLD guidelines, yet it has not been fully evaluated in real world settings. We assessed utility, and limitations, of PC testing of ELF in patients with MASLD.

Method: Data were obtained for ELF tests performed in the regional laboratory between January 2021 and October 2023. We examined the management of patients who underwent ELF testing in PC and specialty assessment in hospital Hepatology clinics, to determine whether the pathway was effective in enriching the patients referred to hospital with significant fibrosis.

Results: 1371 ELF tests were requested and 1030 were performed for patients in PC with MASLD or MetALD. 588 (57%) patients had ELF >9.5 with a median age of 58 (male 340: female 248). At the time of analysis, 342/588 (58%) patients have been referred and 274 (47%) patients have had a hospital-based Hepatology assessment, including successful Fibroscan in 269. 139 (51%) were discharged to their PC practitioner for follow-up after clinical evaluation revealed a low risk of fibrosis (median liver stiffness measurement (LSM) 5.2 kPa, range 6.1). 126 patients remain under follow-up (median LSM 10.4 kPa, range 72). 106 (39%) patients had F2+ fibrosis (LSM >8.0 kPa), 75 (28%) had F3+ fibrosis (LSM >9.7 kPa). We then considered whether a higher ELF cut-off might improve the performance of the PC pathway. 52/88 patients (59%) with ELF>10.5 had F2+ fibrosis but using this cut-off missed 54 patients with LSM >8 kPa. 41 liver biopsies were performed in patients with LSM >8 kPa with the following grading of fibrosis: F0–1 (2%); F1–12 (29%, median ELF 10.45, median LSM 10.4 kPa); F2–10 (25%, median ELF 9.7, median LSM 10.9 kPa); F3–11 (27%, median ELF 10.3, median LSM 13.9 kPa); F4–7 (17%, median ELF 11.36, median LSM 18.2 kPa). There was a clear association between LSM and fibrosis stage, which was not seen for ELF.

Conclusion: The ELF cut-off >9.5 successfully enriches hospital referrals with fibrosis, as determined by clinical evaluation and LSM (39% likely F2+). However, >50% of referrals did not have significant fibrosis and there is poor concordance between ELF levels and LSM. For now, ELF has value in a community fibrosis pathway but novel NIBs with a higher positive predictive value are needed for this population.

WED-237

Novel circulating exosomal miRNA-mRNA network is linked to MASL-MASH and offers pathophysiologic insights with potential for biomarkers related to MASLD and hepatocellular carcinoma

Jing Zeng[1], Srinivas Koduru[2], Derrick Zhao[3], Arun J. Sanyal[4], Jiangao Fan[5], Huiping Zhou[3], Puneet Puri[3,6]. *[1]Virginia Commonwealth University, Richmond Veterans Affairs Medical Center, Richmond, United States; [2]Gene Arrays, Omelette Inc., Seaford, NY, United States; [3]Virginia Commonwealth University, Richmond Veterans Affairs Medical Center, Richmond, VA, United States; [4]Virginia Commonwealth University, Stravtiz-Sanyal Liver Institute, Richmond, VA, United States; [5]Shanghai Jiao Tong University School of Medicine, Shanghai, China; [6]Virginia Commonwealth University and Richmond VA Medical Center, Richmond, United States*
Email: puneet.puri@vcuhealth.org

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the leading cause of end-stage liver disease for liver transplantation. MASLD phenotypes include steatotic liver (MASL) and steatohepatitis (MASH) with MASH conferring a higher risk for disease progression including cirrhosis and hepatocellular cancer (HCC). Exosomes carry a variety of bioactive molecules including miRNAs, lipids, and proteins. The dysregulation of miRNAs is closely related to various pathological aspects of MASLD disease progression. We hypothesized that patients with MASL and MASH will have dysregulated circulating exosomal miRNAs (CE-miRNAs). To test this, we aimed to examine the expression profiles of CE-miRNAs in patients with biopsy proven MASL or MASH compared to healthy controls and identify CE-miRNAs linked with MASL and MASH with potential association with hepatocellular carcinoma.

Method: We extracted serum exosomes and isolated total RNA from exosomes. CE-miRNAs were analyzed using PartekFlow. Potential target genes were identified using TargetScan and mirnet v2.0. Protein-protein interaction (PPI) networks were constructed using STRING database, and Cytoscape software was used to visualize hub genes.

Results: In depth miRNA-seq data analysis of biopsy confirmed MASL (n = 10), MASH (n = 10), and healthy controls (n = 6) revealed 32 differentially expressed CE-miRNAs (DE-CE-miRNAs) in MASL patients compared to healthy controls. Of these, 6 miRNAs were upregulated and 26 were downregulated. In MASH patients, 43 DE-CE-miRNAs were identified, comprising 14 upregulated and 29 downregulated, compared to healthy controls. Interestingly, 5 upregulated DE-CE-miRNAs were common to both MASL and MASH patients, and 8 downregulated DE-CE-miRNAs in MASL were similarly reduced in MASH. Further, GO and KEGG analyses were performed to predict target genes for these 13 overlapping DE-CE-miRNAs. Additionally, a PPI network analysis identified the top 50 hub genes associated with these miRNAs. Specifically, hsa-miR-889-3p and hsa-mir-382 were significantly upregulated in both MASL and MASH. Also, MASL and MASH showed downregulation of hsa-mir-4651 and hsa-mir-940. Previous studies have shown that these miRNAs promote cell invasion, HCC cell growth and progression. Also, downregulated miRNAs which normally facilitate apoptosis via

targeting FOXP4 act as an oncogene by dysregulating Wnt/β-catenin signaling and promote unfavorable prognosis.
Conclusion: Our study has successfully identified DE-miRNAs in the circulating exosomes which may play a significant role in the progression from MASL to MASH and risk of HCC. These findings underscore the potential of exosomal miRNAs as diagnostic and prognostic markers as well as therapeutic targets for MASLD. The identified miRNAs merit further investigation to fully elucidate their clinical utility.

WED-238

High pancreatic fat and reduced volume stratify patients with F4 liver fibrosis

Edward Jackson[1], Alexandre Triay Bagur[2], Cayden Beyer[3], En Ying Tan[4], Nur Halisah Binte Jumat[5], Sophie Riddell[6], Elizabeth Shumbayawonda[2], Andrea Dennis[2], Helena Thomaides Brears[2], Rajarshi Banerjee[2], Mark Muthiah[7], Yock Young Dan[7]. *[1]Perspectum Ltd, Oxford, United Kingdom; [2]Perspectum Ltd., Oxford, United Kingdom; [3]Perspectum Inc, Texas, United States; [4]Division of Gastroenterology and Hepatology, Department of Medicine, National University Health System, Singapore, Singapore; [5]Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [6]Perpectum Asia Pte Ltd., Singapore, Singapore; [7]Division of Gastroenterology and Hepatology, Department of Medicine, National University Health System, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore*
Email: edward.jackson@perspectum.com

Background and aims: While there is an emerging body of evidence showing a relationship between the liver and pancreas due to altered metabolism and insulin resistance in diabetes, the relationship between the organs in the advanced stages of liver disease is unclear. Multi-parametric magnetic resonance imaging (mpMRI), with metrics iron-corrected T1 (cT1) and proton density fat-fraction (liver fat), is an established non-invasive alternative to liver biopsy for diagnosis and monitoring of metabolic dysfunction-associated steatotic liver disease (MASLD). Recent development of equivalent metrics in the pancreas, scanner-referenced T1 (srT1), fat and volume allows characteristics of the two organs to be evaluated simultaneously. The aim of this study was to investigate how different stages of liver fibrosis measured by histology relate to mpMRI biomarkers in the liver and pancreas.
Method: 126 individuals across the spectrum of biopsy-proven MASLD, underwent LiverMultiscan as part of the ongoing prospective EMULSION study in Singapore. A semi-assisted pipeline was used to derive additional measures of pancreatic volume, fat and srT1 from 59 mpMRI scans that met adequate quality criteria. Wilcoxon signed-rank test and receiver operating characteristic curve analyses were conducted to compare different liver fibrosis subgroups.
Results: In 59 South-east Asian individuals (19% Malaysian, 61% Chinese, 12% Indian, 46% male, median BMI 29 kg/m^2, median age 38 years) 44 (75%) showed histological fibrosis (>F0) and MRI confirmed liver steatosis in 47 of 59 (80%). Liver cT1 (median [IQR] 883 ms [114] vs 750 [139], $p < 0.005$), liver fat (15.2 % [12.2] vs 5.1 [5.1] $p < 0.001$) and pancreas fat (5.6 % [4.3] vs 3.0 [3.1] $p < 0.05$) were elevated in patients with >F0 fibrosis. Pancreatic srT1 (704 ms [78] vs 706 [31]) and volume (74 ml [24] vs 63 [21]) were similar with or without any liver fibrosis. Liver cT1 detected any fibrosis (F1–4) with an area under the curve (AUC) of 0.75. cT1 peaked with F2 fibrosis (888 ms [116]) and remained above reference ranges even at F4 (813 ms [107]). Liver fat was reduced at F4 fibrosis (10% [1]). In contrast, F4 liver fibrosis (n = 5) was associated with a combination of increased pancreatic fat (9.5 % [2.3] with F4 vs. 5.1% [4.2] all others, $p < 0.05$) and reduced pancreatic volume (59 ml [6.3] vs. 74 [24], $p < 0.05$). Pancreas fat showed very good discrimination of F4 liver fibrosis (AUC = 0.82).
Conclusion: In advanced steatotic liver disease, liver fat begins to decline yet pancreatic fat persists, and this multiorgan pattern of pathophysiology is highly suggestive of advancing disease. Specifically, increased steatosis and volume atrophy in the pancreas alongside increased liver cT1 is a distinct imaging phenotype to identify F4 fibrosis in the liver.

WED-239

Proteomics identifies a subpopulation of plasma extracellular vesicles able to improve non-invasive diagnosis of MASH in patients with type 2 diabetes: results of the RHU QUID-NASH study

Laure Elkrief[1], Marion Tanguy[2], Louise Biquard[3], Shantha Valainathan[2], Damarys Loew[4], Florent Dingli[4], Alix Cointet[5], Cedric Laouenan[6], Philippe Garteiser[3], Valérie Paradis[7], Agnes Lehuen[8], Laurent Castera[7], Thierry Poynard[9], Dominique Valla[7], Pierre-Emmanuel Rautou[10]. *[1]Université de Tours, Tours, France; [2]Inserm U1149, Université de Paris, Paris; [3]Inserm U1149, Université de Paris, Paris, France; [4]Institut Curie, Paris, France; [5]Inserm 1149, Université de Paris, Paris, France; [6]APHP, Hôpital Bichat, Paris, France; [7]APHP, Hôpital Beaujon, Clichy, France; [8]Institut Cochin, Paris, France; [9]Sorbonne Université, Paris, France; [10]APHP Hôpital Beaujon, Inserm UMR1149, Paris, France*
Email: laure_elkrief@yahoo.fr

Background and aims: Despite the high prevalence and serious clinical implications of metabolic associated steatohepatitis (MASH) in patients with type 2 diabetes (T2D), MASH is usually overlooked in clinical practice, due to the lack of accurate biomarkers. Aim: to evaluate the ability of plasma large extracellular vesicles (lEVs) to serve as non-invasive biomarkers for the diagnosis of MASH in patients with T2D and investigate the pathophysiological process they reflect
Method: Prior proteomic analysis of lEVs was performed on plasma samples from 23 patients with T2D (8 steatosis, 15 MASH) and 9 healthy individuals. Candidate lEV protein biomarkers were measured in the QUID-NASH patient population (NCT03634098) including consecutive patients with T2D and metabolic dysfunction-associated liver disease (MASLD), separated into a derivation (n = 278) and an independent validation cohort (n = 134). We then evaluated the relationship between candidate lEV protein biomarkers and the extensive phenotyping performed, including liver histology (centralized reading of liver biopsies), magnetic resonance imaging (MRI) and detailed phenotyping of circulating immune cells.
Results: Prior proteomic analysis identified Transferrin-receptor on lEVs (TFRC-lEVs) as associated with MASH. We thus measured TFRC-lEVs on plasma samples from patients included in the derivation cohort (63% men, median age 59 years, median BMI 32 kg/m², 55% MASH). The proportion of patients with TFRC-lEVs concentration >61 ng/ml (i.e. Youden index threshold) was significantly higher in patients with MASH than in those with steatosis (29% *vs.* 12%, $p < 0.001$). TFRC-lEVs >61 ng/ml remained associated with MASH after adjustment on either usual laboratory variables (AST, ALT, GGT and triglycerides) (odds ratio (95% CI) 4.15 (2.01–8.57), $p < 0.001$), or on the NASH-Test (odds ratio (95% CI) 4.03 (1.99–6.80), $p < 0.001$) or on the Fibroscan FAST-score (odds ratio (95% CI) 3.01 (1.53–5.92), $p < 0.001$). When combining TFRC-lEVs with available methods (NASH-test >0.50 or FAST score >0.67), the sensitivity for MASH diagnosis were 32% and 29%, versus 22% and 16% for NASH-test or FAST score alone ($p = 0.004$ and $p = 0.0004$, respectively), without decreasing specificity. Similar results were obtained in the validation cohort. TFRC-lEVs >61 ng/ml was associated with hepatocyte ballooning on liver biopsy (32% vs. 15%, $p < 0.001$), but not with liver inflammation nor fibrosis at histology. TFRC-lEVs concentration correlated with serum ferritin concentration ($p < 0.001$), although no association was observed with intra-hepatic iron concentration by MRI nor with circulating immune cells subpopulations.
Conclusion: TFRC-lEVs, an index of hepatocyte ballooning, is an independent biomarker for MASH, able to improve patients' screening to enlarge recruitment of patients with MASH in clinical trials.

WED-242

The use of ELF test, FIB-4 and sequential algorithms to screen the Type 2 Diabetes Mellitus (T2DM) population for advanced fibrosis in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD)

Yiying Pei[1], Wei Kwan Sng[2], Joanne Hui Min Quah[2], Jin Liu[3], Bee Yen Chong[2], Hwee Khim Lee[2], Xue Fei Wang[2], Ngiap Chuan Tan[2], Jason Pik Eu Chang[1], Hong Chang Tan[1], Yong Mong Bee[1], George Boon Bee Goh[1,3]. [1]*Singapore General Hospital, Singapore, Singapore;* [2]*SingHealth Polyclinics, Singapore, Singapore;* [3]*Duke-NUS Medical School, Singapore, Singapore*
Email: pei.yiying@singhealth.com.sg

Background and aims: Accurate screening programs for advanced fibrosis in the metabolic dysfunction-associated steatotic liver disease (MASLD) population for at risk subjects such as Type 2 diabetes mellitus (T2DM) are not well established. We compared the performance of serum biomarkers (enhanced liver fibrosis score (ELF) and the fibrosis-4 score (FIB4)) to screen for advanced fibrosis in a population of T2DM, using transient elastography (TE) as the reference standard.
Method: A cross-sectional study was carried out in a primary care and endocrinology clinic in Singapore. Subjects with T2DM were consecutively enrolled and those with chronic liver diseases of other aetiologies were excluded. All participants underwent TE and had their demographics, clinical parameters and biomarkers collected. Validated cut offs for advanced fibrosis (ELF: ≥9.8, FIB4: ≥1.3 and TE ≥8 kPa) were used.
Results: Analysis was performed on 425 subjects. Both ELF and FIB4 exhibited poor linear correlation with TE (Spearman's rho = 0.29, p < 0.01, R squared 0.12 and Spearman's rho = 0.11, p < 0.02, R squared 0.06 respectively). However ELF was able to diagnose elevated liver stiffness with moderate accuracy (AUROC 0.74, 95% CI 0.68–0.80) and outperformed FIB4 (AUROC 0.62, 95% CI 0.56–0.69). When using TE ≥12 as the reference, diagnostic accuracy improved dramatically, more so for ELF (AUROC of 0.91, 95% CI 0.85–0.97) rather than FIB4 (AUROC 0.70, 95% CI 0.59–0.82). Algorithms using first FIB4 followed by ELF in the cases of indeterminate FIB4 scores (1.3–2.67) resulted in a lower false positive rate of 9.6% (vs 21.2% with ELF and 26.8% with FIB4 alone). False negative rates however were higher than that of ELF alone at 12.5% vs 8%. Out of the 76 patients with TE ≥8, 53 (70%) would have been missed with this referral strategy, though the expense of the ELF test in 69 subjects would have been avoided. BMI and waist circumference impacted performance of FIB4, with mean BMI in the false negative group significantly higher than the true negative group (BMI 28.2 vs 26.4 (kg/m^2), p < 0.001, 95% CI −2.98 to −0.77). Waist circumference (WC) also was significantly different between the 2 groups for FIB4 (p < 0.001, 95% CI −9.71 to −3.53). Similarly, ELF performance was also affected (BMI 27.9 vs 25.7, p < 0.001, 95% CI −3.55 to −0.99, WC; p < 0.001, 95% CI −12.5 to −4.88). Neither groups showed significant difference in terms of age (FIB4; p = 0.588, ELF; p = 0.554).
Conclusion: ELF alone as a first line screening tool is more effective than FIB4 in identifying patients with significant fibrosis on transient elastography. The sequential method is also a viable alternative and reduces the false positive rates as compared to ELF test alone, with additional benefit of cost saving.

Department of Medicine, Mainz, Germany*
Email: gabriele.castelnuovo@unito.it

Background and aims: Insulin resistance plays a pivotal role in triggering metabolic dysfunction-associated steatotic liver disease (MASLD) and driving its progression. Irisin, a myokine activated by exercise, is involved in energy homeostasis and the modulation of glucose metabolism. This work aims to explore the conceivable association between irisin levels, anthropometric and biochemical variables in patients with MASLD after a 6-month lifestyle intervention.
Method: A total of 49 patients diagnosed with MASLD underwent a comprehensive lifestyle intervention based on nutritional and physical activity recommendations and were evaluated at baseline and after 6 months. Liver steatosis was assessed with the controlled attenuation parameter (CAP) (Fibroscan®530, Echosens), body composition was determined by bioelectrical impedance analysis (BIA 101, Anker), while leptin, adiponectin and irisin levels were measured by Bioplex (LuminexR).
Results: The median age of participants was 55 years (range 45; 63); 67.3 % of participants were male, 24.4 % had diabetes and the baseline median Body Mass Index (BMI) was 31.4 Kg/m^2. The lifestyle intervention led to significant reduction in BMI (p < 0.001), waist and neck circumference (p < 0.001 for both), fat mass (p < 0.001), systolic and diastolic blood pressure (p < 0.001 and p = 0.004, respectively), as well as improvement in biochemical parameters, including ALT (p = 0.002), AST (p = 0.005), GGT (p = 0.018), insulin levels (p = 0.049), HOMA-IR (p = 0.026) and leptin concentrations (p = 0.002). Additionally, handgrip score and adiponectin levels increased significantly (p < 0.001 and p = 0.006, respectively), while both CAP and liver stiffness values decreased significantly after 6 months (316 dB/m vs. 283 dB/m, p < 0.001 and 5.2 vs 4.9, p = 0.017, respectively). Notably, negative correlations were observed between the changes in irisin levels and CAP levels (r = –0.372, p = 0.008) and fat mass (r = –0.323, p = 0.025). Interestingly, at multiple regression analysis, the decrease in steatosis according to CAP levels was associated with an increase in irisin concentrations (beta = 2.3, 95% CI 0.1; 4.4, p = 0.035) and a decrease in HOMA-IR (beta = –9.2, 95% CI −15.7; −2.7, p = 0.007), independently from age, sex and the change in fat mass.
Conclusion: A 6-month lifestyle intervention in patients with MASLD is associated with a reduction in hepatic steatosis and HOMA-IR, with a potential restoration of energy and glycid homeostasis reflected by an increase in irisin levels. Along with efforts of non-invasive diagnostic approaches, irisin might be a potential biomarker for the diagnosis and prognosis of this disease. *This research has been supported by the University of Torino, grant number ROSC_RILO_21_01.*

Background and aims: The new nomenclature of metabolic dysfunction-associated steatotic liver disease (MASLD) has broaden its definition to encompass populations with viral hepatitis. However, the interplay between chronic hepatits B (CHB) and MASLD and its implications for non-invasive testings (NITs) accuracy remains under-explored. In this study, we determined the diagnostic accuracy of NITs for significant fibrosis leveraging a large cohort of MASLD patients with CHB.
Method: A total of 1079 adult CHB patients with liver biopsy from eleven medical centers were classfied into three groups, (A) with hepatic steatosis (HS) only, (B) with MASLD involving 1–3 cardio-metabolic risk factors (CMRFs), and (C) with MASLD involving 4–5 CMRFs. Significant fibrosis was defined as Scheuer's classification ≥2. The corresponding optimal cutoff values for three non-invasive tests (NITs), namely the fibrosis-4 index (FIB-4), aspartate aminotransferase-to-platelet ratio index (APRI), and non-alcoholic fatty liver disease fibrosis score (NFS), were determined to diagnose significant fibrosis (≥2) based on CHB combined with HS popultion (group A). The performance of these NITs was evaluated for area under the curve (AUC), accuracy, sensitivity, specificity, positive predictive value, and negative predictive value across three groups. The AUCs of these NITs in each group were compared using the DeLong test.
Results: The AUC for diagnosing significant fibrosis (≥2) was 0.73 in group A, using an optimal cutoff value of 1.26. However, the AUCs were significantly lower in group B (0.62) and group C (0.57). For APRI, the AUCs in the three groups were 0.75, 0.62, and 0.63, respectively, based on an optimal cutoff value of 0.56. The NFS exhibited more modest performance, with AUCs of 0.67, 0.55, and 0.54 in group A, B, and C, respectively. The diagnostic accuracy of the three NITs was all falling below 0.74, with the lowest accuracy observed for FIB-4 at 0.57 in group C. For APRI, the lowest accuracy was 0.63 in both group B and group C. NFS had the lowest accuracy of 0.52 in group B. The overall diagnostic accuracy showed a downward trend with the increased number of CMRFs.
Conclusion: A notable reduction was observed in diagnostic accuracy of the three NITs for significant fibrosis in patients with concomitant MASLD and CHB. Particularly pronounced in patients with an elevated count of CMRFs, this diagnostic gap underscores an urgent need for the development of more refined NIT methodologies. This is especially critical in regions where CHB prevalence is high, signaling a potential shift in clinical strategies for managing these complex patient profiles.

Background and aims: Patients with type 2 diabetes (T2D) with fibrotic metabolic dysfunction associated steatohepatitis (MASH) are at the highest risk of progression to complications of cirrhosis and those who should be treated with forthcoming pharmacologic treatments to be approved. Several non-invasive scores, including FAST (FibroScan-AST), MAST (magnetic resonance imaging [MRI]-aspartate aminotransferase [AST]), MEFIB (magnetic resonance elastography [MRE] plus FIB-4), and FNI (fibrotic NASH index) have been proposed to diagnose fibrotic MASH. However, data in patients with T2D are currently lacking and original published cut-offs may not be suited for this population. The aim of this multicenter prospective study was to compare the performances of these scores, using original and specific cutoffs for the diagnosis of fibrotic MASH in patients with T2D.
Method: 245 T2D outpatients with suspected metabolic dysfunction associated steatotic liver disease (MASDL) (ALT >20 IU/L in female and >30 IU/L in male) seen in secondary/tertiary diabetes clinics from the QUID-NASH study (NCT03634098). All had biopsy-proven MASLD, with FibroScan, MRI-PDFF and MRE data at the time of liver biopsy (LB). The main outcome was fibrotic MASH, defined as NAS ≥4 (with at least one point each) and fibrosis stage ≥2 (centrally reviewed by a single expert pathologist (PB)). The percentages of correctly classified patients (true positive and true negative) were compared using original rule-in and rule-out cutoffs as well as data driven cutoffs determined to have a sensitivity ≥0.90 and a specificity ≥0.90 with observed distributions for continuous scores (FAST, MAST, FNI) in our population.
Results: The characteristics of the 245 patients were: median age 59 years; male 65%; BMI 31 kg/m^2; HbA1c 7.5%; ALT 48 IU/L; fibrotic MASH 39%. FAST and MAST had similar accuracy (AUROCs 0.81 vs. 0.79, p = 0.41) but outperformed FNI (0.74; p = 0.01) and MEFIB (0.68; p < 0.0001). Using original published cutoffs, MAST (0.165/0.242) outperformed FAST (0.35/0.67), MEFIB and FNI (0.10/0.33) when comparing the percentage of correctly classified patients, in whom LB would be avoided (69% vs. 48%, 46%, 39%, respectively; p < 0.001). When using cutoffs specific to our T2D population, FAST (0.38/0.64) outperformed FNI (0.47/0.85) and MAST (0.038/0.199) (56% vs. 40%, and 38%, respectively; p < 0.001).
Conclusion: Our findings in this large cohort of well-characterized T2D patients suggest that FAST, MAST and FNI, using specific cutoffs, may be useful tools to identify T2D patients who should be prioritized for forthcoming pharmacologic treatments.

Background and aims: To propose a non-invasive index for detecting patients with type 2 diabetes mellitus (T2DM) at risk of significant liver fibrosis and cirrhosis in primary care and indicating these patients to further consult a hepatologist in secondary care.
Method: A total of 38, 160 adults with T2DM were included. Among them, 2, 154 patients (50.0% male), with a mean (standard deviation, SD) age of 52.5 (12.2) years, receiving transient elastography (TE) from the primary care between January 2021 and August 2023 were enrolled to develop and validate a non-invasive index. The accuracy of the proposed index followed by TE in diagnosing significant liver fibrosis was assessed in a liver biopsy-proven cohort of 241 patients (59.3%male), with a mean (SD) age of 46.0 (12.3) years, who were enrolled in the same period. In addition, 35, 765 patients (59.8% male), with a mean (SD) age of 59.8 (7.1) years, from the UK Biobank dataset between 2006 and 2010 were tested for the utility of the index in predicting the development of cirrhosis.
Results: Independent risk factors including Aspartate transaminase and boDy mass inDex were identified and fitted to develop a non-invasive index, termed the ADD index (available at: https://chess.nuist.edu.cn/consult/gzconsult/add_index). Using TE as the reference, the ADD index performed better than fibrosis-4 index (FIB-4) and non-alcoholic fatty liver disease fibrosis score (NFS) for significant liver fibrosis, with an area under the curve (AUC) of 0.75 (95% confidence interval [CI]: 0.69–0.80), 0.78 [95% CI: 0.70–0.86], and 0.78 [95% CI: 0.74–0.82], in the derivation and two validation cohorts. A cutoff of 0 of the ADD index was selected to stratify patients into low-risk and high-risk group that should receive TE. The AUC of the ADD index followed by TE was significantly higher than that of FIB-4 and NFS followed by TE in predicting significant liver fibrosis proven by liver biopsy, with the AUC of 0.75 [95% CI: 0.68–0.81] vs. 0.59 [95% CI: 0.52–0.65] and 0.59 [95% CI: 0.51–0.67] (all $p < 0.01$), respectively. Notably, using the ADD index combined with TE resulted in 11% cost savings compared to use TE alone to diagnose significant liver fibrosis. Compared with patients in low-risk group, those in high-risk group had a 2.90-fold (95% confidence interval: 1.44–5.82, $p < 0.01$) risk of developing cirrhosis.
Conclusion: The non-invasive ADD index can be applied to screen significant liver fibrosis and cirrhosis in patients with T2DM in primary care, and promoting those in high-risk group to further consult a hepatologist in secondary care.

WED-247

Unravelling metabolic dysfunction-associated steatotic liver disease with a Bayesian network approach in the UK biobank

Benjamin P.M. Laevens[1], Yazhou Chen[1], Jan Clusmann[1], Carolin V. Schneider[1]. [1]*Uniklinik RWTH Aachen, Aachen, Germany*
Email: blaevens@ukaachen.de

Background and aims: Data-driven Bayesian methods can be used to augment current understanding of disease development and progression, especially in the context of Metabolic dysfunction-associated steatotic liver disease (MASLD). Using a Bayesian network approach, we characterise (causal) relationships between 30 standard blood biomarkers and steatosis, using 35, 000 participants in the UK Biobank and contrast these with physician drawn networks.
Method: A Random Forest Classifier (RFC), enhanced by grid search hyperparameter tuning and validated through 5-fold cross validation, identifies the eight most important serum parameters that can differentiate between a binary target variable indicating healthy (<5% proton density fat fraction) or steatotic livers (>5%). These blood biomarkers are fed into a Hill Climb Search optimisation algorithm, which searches for the best fitting Bayesian network, scored according to the Akaike Information Criterion, a well known model selection measure. Thus, the favoured network, which best describes the data and the dependencies within them, is selected.
Results: The optimal RFC reveals SHBG, triglycerides, ALT, HDL cholesterol, C-reactive protein, GGT, apolipoprotein A and cystatin C as having the highest predictive value for MASLD (with an ROC AUC of 80% in the training set). The best network structure is characterised by 13 (causal) dependencies. Triglycerides, HDL cholesterol and SHBG point towards MASLD, whereas the remaining biomarkers, such as Cystatin C and ALT, point away from MASLD (i.e. a result of) or are connected more distantly to MASLD (Apolipoprotein A, C-reactive protein and GGT). The Bayesian network displays fewer connections between all the variables, when compared to unbiased physician drawn networks of MASLD, which display 18 strong dependencies. On a global level, the Bayesian and physician drawn networks look similar. Nevertheless, differences on a more detailed level reveal differences in prominence of some biomarkers (e.g. HDL cholesterol) and how they connect to MASLD and other parameters.
Conclusion: The strength of Bayesian Networks is their explainable and intuitive nature. By determining dependencies between serum parameters and disease, insights are obtained that can be used as an additional tool to complement physician-based views of MASLD.

Email: Jeffrey.Lazarus@isglobal.org

Background and aims: With high and increasing prevalence, but low diagnosis rates, identifying people living with MASH who require specialised care remains a significant challenge. Advances in the validation of non-invasive tests (NITs) promise to revolutionise diagnostic pathways. However, little focus has been given to operational considerations for implementing viable, scalable diagnostic pathways for MASH. We developed a model to estimate the testing requirements to double the diagnostic rates of ≥F2 MASH over a 5-year period in 4 countries.
Method: The baseline (2021) prevalence of ≥F2 MASH in the general population and the diagnostic rates, defined as the cumulative proportion of all MASH patients diagnosed with ≥F2 MASH at the end of a given year, were, respectively (%): France 2.9/14.0; Germany 2.6/11.0; UK 2.9/17.0; and USA 4.0/12.5. Using multiple data sources, we constructed diagnostic pathways covering identification (i.e. abnormal LFTs), screening (e.g. FIB-4, NAFLD-Fibrosis Score) and confirmatory diagnosis (e.g. Fibroscan, ELF, biopsy). A weighted average sensitivity and specificity was used for each stage in the pathway depending on the proportion of different NITs used. The model incorporated 5 healthcare settings (primary care, non-liver office (e.g. endocrinologist office), non-liver hospital (e.g. endocrinologist clinic), liver-office, and liver-hospital) and four patient pools (symptom-led presentation, obesity, type 2 diabetes, and cardiovascular disease). We accounted for annual growth in the general population and MASH prevalence. Bottlenecks in provider capacity across healthcare settings were estimated and future testing requirements adjusted accordingly.
Results: A doubling of the diagnostic rates of ≥F2 MASH across the four countries will result in the number of diagnosed patients increasing from 2.6 million (M) to 6.1M between 2022–2027, with the following breakdown by patient pool: 54% type 2 diabetes, 19% obesity, 18% CVD and 9% symptom-led presentations. This will require the number of screening tests to increase from 2.2M to 35.6M, and confirmatory diagnosis tests from 833, 000 to 11.6M between 2022 and 2027. To address capacity bottlenecks, the proportion of confirmatory diagnostic tests completed within liver specific settings must decrease from 95% in 2022 to 29% in 2027, with an increase from 1% to 27% in primary care setting and 4% to 34% in non-liver office and non-liver hospital settings over the same time.
Conclusion: Doubling the diagnosis rate of ≥F2 MASH by 2027 will require enormous expansion of diagnostic pathways. This necessitates a paradigm shift and greater collaboration across disciplines, with much of the testing burden moving from liver specialists to primary care and non-liver specialist settings. Identifying efficient approaches to reduce the operational burden and costs of this expansion will be key for success.

WED-249

Improved risk stratification by combination of FIB-4 with FGF21 serum levels in steatotic liver disease

Martin Franck[1], Katharina John[1], Sherin Al Aoua[1], Monika Rau[2], Andreas Geier[2], Jörn Schattenberg[3], Heiner Wedemeyer[1], Klaus Schulze-Osthoff[4], Heike Bantel[1]. [1]*Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany;* [2]*Division of Hepatology, Department of Internal Medicine II, University Hospital Würzburg, Würzburg, Germany;* [3]*Department of Internal Medicine I, University Medical Center Mainz, Mainz, Germany;* [4]*Interfaculty Institute of Biochemistry, University of Tübingen, Tübingen, Germany*
Email: bantel.heike@mh-hannover.de

Background and aims: Non-alcoholic steatohepatitis (NASH) with significant fibrosis (≥F2) represents a major prognostic factor in non-alcoholic fatty liver disease (NAFLD). Identification of patients at risk

for NASH with fibrosis ≥F2 is therefore important. Although the established fibrosis score FIB-4 is suitable to exclude advanced fibrosis, it does not allow the prediction of significant fibrosis in NAFLD patients. We therefore analysed whether fibroblast growth factor 21 (FGF21), a stress-inducible metabolic regulator, can be used as a non-invasive marker to identify at risk patients in NAFLD.
Method: We analysed FGF21 levels in sera from a retrospective multicenter cohort (n = 225) of biopsy-proven NAFLD patients with different disease activity and fibrosis stages by enzyme-linked immunosorbent assay. Most of these patients met also the criteria of the new nomenclature metabolic dysfunction-associated steatotic liver disease (MASLD). We evaluated whether the use of FGF21 in patients with low (<1.3) or intermediate (1.3–2.67) FIB-4 could improve risk stratification in NAFLD. In addition, we analyzed the diagnostic performance of FIB-4 in combination with FGF21 or transient elastography (TE) for the detection of NASH and fibrosis.
Results: FGF21 levels could significantly discriminate between NASH with fibrosis ≥F2 and NAFLD patients without significant fibrosis, even in patients with low or intermediate FIB-4. We calculated a cut-off value for FGF21 which allowed an improved risk stratification of NAFLD patients with low or intermediate FIB-4. NASH could be detected in patients with low FIB-4 and elevated FGF21 levels in 81% of cases, whereas patients with low FIB-4 and increased TE values (≥8 kPa) showed NASH in 75% of cases. Moreover, fibrotic NASH was detected in patients with low FIB-4 and elevated FGF21 levels or TE values in 49% and 54%, respectively, half of them had fibrosis stages ≥F2. NAFLD patients with intermediate FIB-4 and elevated FGF21 levels or TE values revealed NASH in almost all cases. Fibrotic NASH was detected in patients with intermediate FIB-4 and elevated FGF21 or TE (≥8 kPa) values in 71% versus 75% of cases, the majority of them revealed fibrosis stages ≥F2. Due to the higher sensitivity of FGF21 compared with TE, less patients were overlooked for fibrotic NASH when FIB-4 was combined with FGF21 instead of TE.
Conclusion: The combination of FIB-4 with serological FGF21 detection might be useful for the identification of patients at risk for progressed NAFLD, especially in primary care when TE is not available.

WED-250-YI
PNPLA3 I148M a useful diagnostic marker for significant fibrosis metabolic dysfunction-associated steatotic liver disease
Elias Rashu[1], Mikkel Werge[2], Mira Thing[2], Liv Hetland[2], Puria Nabilou[2], Nina Kimer[2], Anne-Sofie Houlberg Jensen[2], Anders Junker[2], Stefan Stender[3,4], Lise Lotte Gluud[2,4]. *[1]Gastro Unit, Copenhagen University Hospital Hvidovre, Denmark, Hvidovre, Denmark; [2]Gastro Unit, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark; [3]Department of Clinical Biochemistry, Rigshospitalet, Copenhagen, Denmark; [4]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*
Email: elias.badal.rashu@regionh.dk

Background and aims: Three common genetic variants are known to affect the onset and progression of metabolic dysfunction associated steatotic liver disease (MASLD): *PNPLA3* rs738409, *TM6SF2* rs58542926, and *HSD17B13* rs72613567. We tested if the use of these three variants, alone or combined into a genetic risk score (GRS), can be used in a clinical setting to identify significant fibrosis.
Method: Patients were included in a prospective observational cohort at the Gastro Unit, Hvidovre Hospital, Denmark. In total, 710 patients were evaluated clinically, biochemically, and with Fibroscan. MASLD was defined by the presence of steatosis on Fibroscan (CAP value >250 dB/m), without increased alcohol intake, at least one cardiometabolic risk factor, and exclusion of other liver diseases. A liver biopsy was performed if significant fibrosis was suspected (≥F2) based on the Fibroscan and/or Fibrosis-4 (Fib-4) index. The GRS was calculated as the total number of risk-increasing alleles in the *PNPLA3*, *TM6SF2*, and *HSD17B13* variants (range: from 0 to 6).
Results: Of the 710 patients (50.0 % women, mean age: 54.1 years, mean BMI: 31.2 kg/m^2). Significant fibrosis was diagnosed in 149 of 360 who underwent a liver biopsy. The risk of significant fibrosis increased with the number of *PNPLA3* G-alleles; compared to CC homozygotes, CG-heterozygotes had an odds ratio (OR) of 2.38 (95% CI 1.50–3.82, p = 0.0003) and GG-homozygotes had an OR of 2.51 (95% CI 1.29–4.95 p = 0.007). The *PNPLA3* G-allele was also associated with the Fib-4 (p = 0.006) and Fibroscan (p = 0.011). The variants in *TM6SF2* and *HSD17B13* were not individually associated with fibrosis. None of the individual SNPs predicted cirrhosis. The GRS was associated with an increased risk of significant fibrosis (OR 1.63 (95% CI 1.28–2.04, p = 0.00005) and cirrhosis (OR 1.42 (95% CI 1.05–1.96, p = 0.03).
Conclusion: This study found that the *PNPLA3* variant, as well as a 3-variant GRS, were associated with significant fibrosis in MASLD patients. Our findings suggest that these genetic risk factors may hold promise for prediction of significant fibrosis in MASLD patients in a clinical setting.

Background and aims: Subjects with metabolic dysfunction-associated steatohepatitis (MASH) frequently have dysregulated serum lipid profiles that can result in increased hepatic and systemic inflammation, exacerbating comorbidities such as cardiovascular disease. Pemvidutide is a long-acting, balanced glucagon-like peptide 1 (GLP-1)/glucagon dual receptor agonist under development for the treatment of MASH and obesity. The balanced 1:1 potency ratio combines the reduced caloric intake effects of GLP-1 receptor agonism with the increased energy expenditure and lipometabolic effects of glucagon receptor agonism. In a 12-week double-blind clinical trial in subjects with overweight/obesity, pemvidutide reduced body weight by up to 10.3% and significantly decreased multiple atherosclerotic lipid mediators such as total cholesterol (−28%), LDL-C (−26%), and triglycerides (−38%). Here we leveraged lipidomics to further investigate the effects of pemvidutide on lipid mediators associated with MASH.
Method: 34 subjects with overweight (BMI 27.0–29.9 kg/m^2) or obesity (BMI >30.0 kg/m^2) were randomized 1:1:1:1 to pemvidutide (1.2 mg, 1.8 mg, 2.4 mg) or placebo administered subcutaneously weekly for 12 weeks. Lipidomic profiling covering lipid species across classes of glycoproteins, bile acids, glycerophospholipids, and sphingolipids was performed by ultra-high performance liquid chromatography-mass spectrometry or nuclear magnetic resonance on plasma samples at baseline, Day 43, and Day 84.
Results: Pemvidutide treatment reduced several plasma biomarkers of MASH. Pemvidutide achieved significant reductions from baseline across multiple glycerophospholipid classes associated with MASH, including lysophosphatidylinositols (Lyso-PI) and lysophosphatidylethanolamines (Lyso-PE). Pemvidutide also improved bile acid dysregulation, yielding reductions in taurine and glycine conjugated bile acids. Finally, pemvidutide treatment reduced GlycA and GlycB, composite biomarkers of systemic inflammation correlated with cardiovascular disease.
Conclusion: Pemvidutide administered weekly for 12 weeks induced significant decreases in MASH associated lipid species. These findings support pemvidutide's potential benefit on MASH -associated co-morbidities, including atherosclerosis and metabolic syndrome.

WED-254

The true diagnostic performance of magnetic resonance elastography for the detection of advanced fibrosis in metabolic dysfunction-associated steatotic liver disease exceeds the diagnostic performance of liver biopsy

Ian Rowe[1,2], Mohsen Farzi[1], Clare McGenity[1], Alyn Cratchley[2], Alexander Wright[2], Richard Parker[2], Darren Treanor[1,2]. *[1]Department of Pathology and Data Analytics, Leeds Institute for Medical Research, University of Leeds, Leeds, United Kingdom; [2]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*
Email: i.a.c.rowe@leeds.ac.uk

Background and aims: Liver biopsy is recognised as an imperfect reference standard for the assessment of liver fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD). We aimed to describe the diagnostic accuracy of liver histology for the identification of advanced fibrosis and used this estimate to define the true diagnostic performance of non-invasive biomarkers of fibrosis.
Method: A diagnostic accuracy study of liver biopsy where the reference standard was a liver resection sample was done. Sections were stained with picrosirius red for fibrosis area estimation. Sections were divided into 2.5 mm × 1 mm tiles and virtual biopsies between 17.5 and 22.5 mm in length generated. The diagnostic performance of these virtual liver biopsies was then estimated from variation in fibrosis area between known fibrosis stages in silico using individuals drawn from a 100, 000 simulated patient cohort. The true performance of non-invasive biomarkers was calculated using apparent biomarker performance (drawn from a recent systematic review and diagnostic test meta-analysis) and the estimated diagnostic accuracy of liver biopsy. All diagnostic performance was assessed where the target condition was advanced fibrosis.
Results: 694 virtual biopsies were assessed. The area under the curve (AUC) for liver biopsy in the identification of advanced fibrosis was 0.93 (range 0.86–0.95), with a mean sensitivity of 0.82 and mean specificity of 0.94. Using this value to estimate true non-invasive test performance led to improvements in performance for imaging biomarkers. For all biomarkers, higher AUC and sensitivity and specificity values for the identification of advanced fibrosis were apparent once the imperfect reference standard was considered. For magnetic resonance elastography the calculated true performance for the detection of advanced fibrosis was as follows: mean AUC 0.97, mean sensitivity 0.97, mean specificity 0.95; all more than the values observed for the performance of liver biopsy. Vibration controlled transient elastography (VCTE, AUC 0.90) and P-shear wave elastography (P-SWE, AUC 0.92) had calculated true performance that was similar to liver biopsy.
Conclusion: Liver biopsy is an imperfect reference standard. Describing its diagnostic accuracy allows the calculation of true non-invasive biomarker performance. MRE has calculated diagnostic performance that is superior to that of liver biopsy while the performance of VCTE and P-SWE is similar to that of liver biopsy. This suggests that imaging biomarkers are sufficiently accurate to replace liver biopsy for the assessment of liver fibrosis in persons with MASLD.

WED-255-YI

Muscle composition as a predictor of advanced fibrosis in chronic liver disease

Wile Balkhed[1], Patrik Nasr[1], Mikael Forsgren[1,2], Anna Cederborg[1,3], Olof Dahlqvist Leinhard[2,4], Simone Ignatova[5], Peter Lundberg[6], Nils Dahlström[7], Christian Simonsson[8], Stergios Kechagias[1], Mattias Ekstedt[1]. *[1]Linkoping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden; [2]AMRA Medical AB, Linköping, Sweden; [3]Sahlgrenska Academy, University of Gothenburg, Department of Medicine, Sahlgrenska University Hospital, Göteborg, Sweden; [4]Linkoping University, Department of Health, Medicine and Caring Sciences, Center for Medical Image Science and Visualization, Linköping, Sweden; [5]Linkoping University, Linköping, Sweden; [6]Linkoping University, Radiation Physics and MR-Physics, Radiology and Center for Medical Imaging and Visualization, Linköping, Sweden; [7]Linkoping University, Department of Radiology in Linköping, Department of Health, Medicine and Caring Sciences, Center for Medical Image Science and Visualization, Linköping, Sweden; [8]Linkoping University, Department of Radiation Physics, Department of Health, Medicine and Caring Sciences, Center for Medical Image Science and Visualization, Department of Biomedical Engineering, Linköping, Sweden*
Email: balkhedwile@gmail.com

Background and aims: Sarcopenia and myosteatosis is common in patients with advanced liver disease but associations between muscle degeneration and early-stage liver disease have not been established. We aimed to investigate the relevance of these muscle-related factors at the investigational stage of chronic liver disease.
Method: Patients investigated for liver disease underwent a liver biopsy as well as a neck-to-knee MRI, including liver proton density fat fraction (PDFF) and muscle composition (MC) assessment (thigh muscle fat infiltration [MFI] and fat-free muscle volume z-score [MVZ]) using AMRA® Researcher. MC phenotypes were defined as high MFI (myosteatosis), low MVZ (low muscle volume), adverse MC ([AMC] *i.e.,* high MFI and low MVZ combined), or normal MC.
Results: Seventy-seven patients were studied. Thirty-one (40 %) were women and mean age and BMI were 58 ± 13 years and 30.9 ± 5.2 kg/m^2, respectively. Type 2 diabetes was present in 27 (35 %) and the most common etiology was metabolic dysfunction-associated steatotic liver disease (MASLD) in 47 cases (61 %) and MetALD in 8 cases (10 %). Median fibrosis stage was 2 (range, 0–4) and 28 (36 %) patients had advanced fibrosis (≥F3). Forty-seven (61 %) patients had normal MC, 16 (21 %) low MVZ and 24 (31 %) had high MFI. Thus 10 (13 %) had both low MVZ and high MFI (AMC). MVZ had a negative correlation to fibrosis stage ($r = -0.237$, $p = 0.038$) while MFI had a positive correlation ($r = 0.284$, $p = 0.012$). Patients with advanced fibrosis had lower MVZ (−0.26 ± 0.99 vs 0.68 ± 1.33, $p < 0.001$) and higher MFI (1.72 ± 3.43 vs −0.08 ± 2.12, $p = 0.012$) compared to patients without advanced fibrosis. Regression analysis of factors predicting advanced fibrosis found low MVZ, irrespective of MFI-status, to be predictive of advanced fibrosis. This was confirmed when adjusting for sex, T2D status and BMI (aOR 5.19, 95 %CI 1.39–19.36; $p = 0.014$). However, adding age to the adjusted model attenuated the predictability of the analysis (aOR 2.57, 95 %CI 0.63–10.52, $p = 0.190$). There were no significant differences in rates of advanced fibrosis comparing patients with or without high MFI or AMC.
Conclusion: Muscle health correlated to fibrosis stage in this cohort of patients under investigation for chronic liver disease. Low MVZ but not high MFI was predictive of advanced fibrosis. However, this relationship did not reach the threshold for significance when adjusting for age. Our findings suggest muscle degeneration could be used as a clinical marker for identifying advanced liver disease.

WED-256

The influence of rifaximin on bile acids composition

Iryna Biriuchenko[1], Olena Barabanchyk[2]. *[1]Bogomolest National Medical University, Kyiv, Ukraine; [2]Educational and Scientific Center "Institute of Biology and Medicine" of Taras Shevchenko National University of Kyiv, Kyiv, Ukraine*
Email: iryna.gastro@gmail.com

Background and aims: Due to some recent publications, intestinal bacteria play a crucial role in the pathogenesis and progression of Metabolic dysfunction-associated hepatitis (MASH) in patients with metabolic dysfunction-associated steatotic liver disease (MASLD), making gut microbiota a potential target for MASH treatment [1]. Rifaximin is a non-systemic selective antibiotic that has almost no absorption into the blood with less adverse reaction, although the full effect of rifaximin on gut flora remains limited. Our hypothesis was whether rifaximin modulation properties on gut flora may have impact on bile acids (BA) composition. Our aim was to assess the

spectrum of bile acids before and after modulation of intestinal flora using rifaximin.
Method: The diagnosis of MASH was established due to the following criteria on the basis of EASL (2016) NAFLD Guidelines. The eligible patients formed the main study group. To compare, we took the results of bile examination of healthy controls, performed during our previous study in 2022 [2]. The bile was obtained after intubation of the duodenum under the ultrasound control. The spectrum of BA was assessed using photocalorimetry. For the modulation of gut flora rifaximin was administered 400 mg 3 times per day for 10 days. The bile composition in the patients of the first group was assessed twice: before and 8 weeks after rifaximin treatment. The data were analysed using parametric and non-parametric methods through StatSoft Statistica program (USA).
Results: 12 adult patients were included into the study. The results of 15 healthy controls formed the second group. The groups were statistically comparable in age and sex. The levels of cholic acid (CA) and deoxycholic acid (DCA) were increased in patients with MASH comparing to healthy controls ($p < 0.05$). Both BA decreased after rifaximin use, especially DCA fast reaching the level of healthy controls ($p < 0.001$). The levels of taurodeoxycholic acid (TDCA) and glycocholic acid (GCA) were not changed significantly comparing to healthy controls either before or after interference with bacteria ($p > 0.05$).
Conclusion: Our study demonstrates the possibility of rifaximin to influence on bile acids composition shortly after application through decreasing the levels of metabolic byproduct DCA and increasing the concentration of CA. We suppose, that because the diet preferences of the patients were not changed/modified after the treatment, the levels of TDCA and GCA were not altered significantly 8 weeks after. This allows to assume that intestinal flora modulation may be a potential target for MASH treatment.

WED-257

FibroScan compared to liver biopsy for accurately detecting recurrent hepatic steatosis and fibrosis after liver transplantation for metabolic dysfunction-associated steatohepatitis

Laura Martínez-Arenas[1,2,3], Ângela Carvalho-Gomes[1,3], Carmen Vinaixa[1,3,4], Isabel Conde[1,4], Judith Pérez-Rojas[4], Eva Montalvá[1,3,4,5], Sara Lorente Perez[6,7,8], Fernando Diaz Fontela[9], Marta Guerrero-Misas[3,10,11], Jose Ignacio Herrero[3,12,13], Marina Berenguer[1,3,4,5]. *[1]IIS La Fe Health Research Institute, Valencia, Spain; [2]Universitat Politècnica de València, Valencia, Spain; [3]CIBEREHD, Madrid, Spain; [4]La Fe Hospital, Valencia, Spain; [5]University of Valencia, Valencia, Spain; [6]Lozano Blesa Hospital, Zaragoza, Spain; [7]IIS Aragón, Zaragoza, Spain; [8]University of Zaragoza, Zaragoza, Spain; [9]Gregorio Marañón Hospital, Madrid, Spain; [10]Reina Sofía Hospital, Córdoba, Spain; [11]Maimonides Institute of Biomedical Research of Cordoba, Córdoba, Spain; [12]University Clinic of Navarra, Pamplona, Spain; [13]Navarra Health Research Institute, Pamplona, Spain*
Email: laura_munera15@hotmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) recurrence after liver transplantation (LT) seems unavoidable and gradual in many patients. We aimed to compare the accurate detection of recurrent hepatic steatosis and fibrosis by vibration-controlled transient elastography (FibroScan) versus liver biopsy during the follow-up of patients transplanted for metabolic dysfunction-associated steatohepatitis (MASH).
Method: This prospective cohort study included adult patients transplanted for MASH between 2010–2022 in 2 LT centers in Spain who underwent both FibroScan and liver biopsy at least one year after LT. Hepatic steatosis and fibrosis were assessed by control attenuation parameter (CAP) and liver stiffness measurement (LSM), respectively. CAP values >275 dB/m were used to diagnose significant steatosis. LSM values <8 kPa and >12–15 kPa were used to rule out and rule in advanced fibrosis, respectively. Steatosis and fibrosis evaluation in the graft was performed according to the MASH Clinical Research Network criteria. MASH diagnosis was defined as a SAF (steatosis, activity and fibrosis) activity score ≥2 . Significant and advanced fibrosis were defined as a fibrosis stage ≥F2 and ≥F3, respectively.
Results: 38 patients transplanted for MASH (n = 18 [47.4%] categorized as having MASLD and alcohol-related fatty liver disease) with FibroScan and liver biopsy (89% performed as a protocol biopsy) after LT were included. The median time (interquartile range [IQR]) from LT to liver biopsy and FibroScan was 26 (16–51.5) and 26 (16–46.8) months, respectively. The median time (IQR) between liver biopsy and FibroScan was 2 (0–5) months, with 30 (78.9%) patients having a lag time lower than six months between both techniques. The median CAP and LSM values (IQR) were 273 (245.8–334.3) dB/m and 5.8 (4.4–7.8) kPa, respectively, with significant steatosis diagnosed in half of the patients (n = 19, 50%), yet advanced fibrosis in only 1 case (2.6%). On biopsy, about a third of biopsied patients (n = 11, 29%) had a MASH diagnosis, 2 (5.3%) with significant fibrosis and 1 (2.6%) with cirrhosis. All patients with LSM values <8 kPa (n = 30, 79%) had a fibrosis stage ≤F1, whereas of those with LSM values ≥8 kPa (n = 8, 21%), n = 2 (25%) had a fibrosis stage ≥F2 ($p = 0.040$).
Conclusion: Although liver biopsy remains the gold standard method for detecting fibrosis, our results suggest that LSM values <8 kPa after LT for MASH are strongly correlated with absence of significant/advanced fibrosis.

WED-258

Head fat correlates with the severity of non-alcoholic fatty liver disease: based on NHANES 2017–2018 data

Jiao Liu[1], Yunhao Xun[2], Yuecui Li[3], Weiyue Hu[1], Chenghang Li[1], Lili Zhang[1]. *[1]The First People's Hospital of Yongkang, Jinhua, China; [2]Xixi Hospital of Hangzhou, Hangzhou, China; [3]The First People's Hospital of Yongkang, Jinhua*
Email: xyhao1977@126.com

Background and aims: Body fat distribution takes an important part in the pathophysiology of non-alcoholic fatty liver disease (NAFLD), yet the role of head fat remains elusive. The purpose of this study was to explore whether head fat correlates with NAFLD and its severity or not, using the NHANES 2017–2018 dataset.
Method: Body composition values from dual energy X-ray absorptiometry as per the criteria of NHANES 2017–2018, together with medical records of the participants, were retrieved. NAFLD cases were identified on the basis of ultrasonographic steatosis or a controlled attenuation parameters value ≥302 dB/m, and without secondary causes of steatosis. Detailed statistical analysis were performed to explore the possible correlation.
Results: A total of 2051 subjects were included, with 22.38% (n = 459) of NAFLD. Patients with NAFLD indicated a higher head fat mass and the resulting percentage, and the following known metabolic factors: older, body mass index (BMI), larger waist circumference (WC), higher prevalence of hypertension and diabetes, higher levels of glucose, insulin, HOMA-IR, alanine aminotransferase, aspartate transferase, uric acid, triglyceride (TG), cholesterol and low density lipoprotein cholesterol, and lower level of high density lipoprotein cholesterol, as compared to non-NAFLD subjects. After propensity score matching analysis (1:1 matching, according to gender, age and ethnicity), head fat mass and its percentage in NAFLD patients remained higher than control subjects (1233 vs1138 [gram]; 24.4 vs 23.9 [%], respectively; $P < 0.05$ for both). Logistic regression analysis showed head fat percentage (OR = 2.162, 95%CI: 1.248~3.746), WC (OR = 1.054, 95%CI: 1.03~1.079), TG (OR = 1.005, 95%CI: 1.002~1.009), and HOMA-IR (OR = 1.151, 95%CI: 1.043~1.271) ($p < 0.05$ for all) were independently associated with NAFLD. In patients with NAFLD, head fat percentage, but not head fat mass and other reginal fat deposits, was positively correlated with the liver stiffness measurement, NAFLD fibrosis score and APRI ($r = 0.245, 0.171, 0.114$, respectively; $P < 0.05$ for all). The receiver operating curve by using head fat percentage alone showed an AUC of 0.771 (95%CI: 0.734~0.809) for the diagnosis of NAFLD, with a sensitivity of 55.2% and a specificity of

86.6% and an optimal cut-off of 24.35%. No significant correlation between head fat and metabolic syndrome was observed. Mediation effect tests showed that BMI and WC were the mediating variables between head fat percentage and NAFLD, with a mediating ratio of 36.58% and 46.52%, respectively. Head fat percentage was an independent risk factor for NAFLD in overweight people but not in normal weight or obese people.
Conclusion: Head fat is a newer valuable anthropometric parameter for predicting NAFLD and positively correlates with its hepatic severity. The interesting effect of this regional fat is even noteworthy in overweight people.

WED-259
Metabolic dysfunction-associated steatotic liver disease prevalence and predictors in patients with type 2 diabetes in primary care
Wile Balkhed[1], Patrik Nasr[1], Shan Cai[1], Christian Simonsson[2], Mikael Forsgren[1], Martin Bergram[3], Olof Dahlqvist Leinhard[1,4], Nils Dahlström[5], Carl-Johan Carlhäll[6], Peter Lundberg[7], Karin Rådholm[8], Fredrik Iredahl[1], Stergios Kechagias[1], Mattias Ekstedt[1]. *[1]Linkoping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden; [2]Linkoping University, Department of Radiation Physics, Department of Health, Medicine and Caring Sciences, Center for Medical Image Science and Visualization, Department of Biomedical Engineering, Linköping, Sweden; [3]Linkoping University, Division of Prevention, Rehabilitation and Community Medicine, Department of Health, Medicine and Caring Sciences, Linköping, Sweden; [4]AMRA Medical AB, Linköping, Sweden; [5]Linkoping University, Department of Radiology in Linköping, Department of Health, Medicine and Caring Sciences, Center for Medical Image Science and Visualization, Linköping, Sweden; [6]Linkoping University, Dept. of Clinical Physiology in Linköping, Dept. of Health, Medicine and Caring Sciences, Linköping, Sweden; [7]Linkoping University, Radiation Physics and MR-Physics, Radiology and Center for Medical Imaging and Visualization, Linköping, Sweden; [8]Linkoping University, Department of Health, Medicine and Caring Sciences, Division of Prevention, Rehabilitation and Community Medicine, Linköping, Sweden*
Email: balkhedwile@gmail.com

Background and aims: The number of people with metabolic dysfunction-associated steatotic liver disease (MASLD) has increased in parallel with the obesity epidemic. Type 2 diabetes (T2D) is associated with progressive MASLD. Therefore, many guidelines recommend screening for MASLD in T2D patients. Most MASLD studies have been conducted in specialist care, not necessarily representative for primary care. Therefore, we aimed to investigate the prevalence of MASLD and advanced fibrosis in primary care patients with T2D utilizing magnetic resonance imaging (MRI) and transient elastography (TE). In this study, we present results from the EPSONIP study (NCT03864510).
Method: Patients with T2D, without previous liver disease, were prospectively included from primary care. Study participants underwent laboratory investigation, TE with controlled attenuation parameter (CAP) and MRI including liver proton density fat fraction (PDFF).
Results: Two-hundred and seventy-nine participants were included. Out of these, 150 (54 %) had a PDFF ≥5% and were classified as MASLD. The mean PDFF in participants with MASLD was 12.9 ± 6.6 %. There was no difference in sex (37 % and 36 % were women in the MASLD and non-MASLD groups, respectively), age (63.5 ± 8.5 and 64.2 ± 7.8 years), nor in diabetes- or lipid lowering treatment between groups. However, participants with MASLD had a greater mean BMI (30.6 ± 4.3 vs. 27.3 ± 4.1 kg/m^2, p < 0.001), waist circumference (109 ± 10.4 vs. 99.8 ± 11.7 cm, p < 0.001), and HbA1c (52.5 ± 11.2 vs. 49.2 ± 9.2 mmol/mol, p = 0.018) compared to those without MASLD. Mean TE was higher in patients with MASLD (6.8 ± 5.3 vs 5.6 ± 4.8, p < 0.001). In the total cohort, 15 % and 4 % had a TE >8 kPa and >12 kPa, respectively. In patients with MASLD, 23 % had a TE >8 kPa and 4 % TE >12 kPa.
CAP was higher in participants with MASLD, with an AUROC of 0.853 for detecting PDFF ≥5%. Applying a sensitivity of >90% for the presence of PDFF ≥5%, a cut-off for CAP of 248 dB/m had a specificity of 64%. Regression analysis of factors to predict MASLD found BMI, elevated CAP (>248 dB/m), and elevation of ALT, HbA1c and GT predictive of MASLD, and this relationship was confirmed for all factors except HbA1c when adjusting for age, sex, and BMI. However, in analysis adjusting for all the factors together only elevated CAP was an independent predictor of MASLD (aOR 11.7, 95 %CI 5.1–27.2, p < 0.001).
Conclusion: In this cohort of highly phenotyped primary care patients with T2D, more than half had MASLD (54%), of whom 23% had suspected advanced fibrosis. Patients with MASLD had greater BMI, waist circumference and HbA1c, but the only independent predictor of MASLD was elevated CAP.

WED-260
Comparative analysis of Agile 3+, NFS, and BARD scores for diagnosing advanced fibrosis in MASLD and MetALD
Donghyeon Lee[1,2], Yun Kyu Lee[1], Heejoon Jang[1], Saekyung Joo[1], Won Kim[1], Young Ho So[3], Yong Jin Jung[4]. *[1]SMG-SNU Boramae Medical Center, Seoul, Korea, Rep. of South; [2]Seoul National University, College of Medicine, Seoul, Korea, Rep. of South; [3]Department of Radiology, SMG-SNU Boramae Medical Center, Seoul National University College of Medicine, Seoul, Korea, Rep. of South; [4]Boramae Medical Center, Seoul, Korea, Rep. of South*
Email: wonshiri@yahoo.com

Background and aims: Metabolic dysfuction-associated steatotic liver disease (MASLD) and MetALD (MASLD and increased alcohol intake) have emerged as significant public health concerns globally, driven by the rising prevalence of obesity and metabolic syndrome. This study evaluates the performance of commonly used indicators, including Agile 3+, Non-alcoholic Fatty Liver Disease Fibrosis Score (NFS), and BARD score, in diagnosing advanced fibrosis in both MASLD and MetALD.
Method: We conducted a retrospective analysis of 656 patients diagnosed with MASLD and MetALD. Patient data, including clinical, laboratory, and histopathological information, were collected. Agile 3+, NFS, and BARD scores were calculated for each patient. AUROC was employed to assess the discriminatory power of each scoring system, and the DeLong Test was used for pairwise comparisons.
Results: The results indicate no significant differences in the ability to diagnose advanced fibrosis among Agile 3+ (AUROC, 0.931 vs. 0.969; p, 0.333), NFS (AUROC, 0.856 vs. 0.792; p, 0.589), and BARD scores (AUROC, 0.710 vs. 0.513; p, 0.287) in both MASLD and MetALD, respectively. Agile 3+ and NFS demonstrated comparable accuracy and predictive capabilities in identifying advanced fibrosis in both conditions.
Conclusion: These findings suggest the interchangeability of these various scores in diagnosing advanced fibrosis in MASLD and MetALD, emphasizing the importance of selecting the optimal score based on individual patient characteristics and context. Thus, this study provides evidence that Agile 3+ and NFS can be effectively applied for diagnosing advanced fibrosis in MASLD and MetALD, demonstrating no substantial performance differences among these diverse scoring systems.

Prognostic significance of ELF test compared to liver biopsy in patients with metabolic dysfunction-associated steatotic liver disease (MASLD)

Antonio Liguori[1], Francesca D'Ambrosio[2], Nicholas Viceconti[3], Fabrizio Termite[3], Lucrezia Petrucci[3], Riccardo Beschi[3], Marco Orienti[2], Sara Cardinali[2], Simone Galletti[2], Laura Riccardi[3], Fabrizio Pizzolante[3], Nicoletta De Matthaeis[3], Maria Elena Ainora[3], Maria Assunta Zocco[3], Maria Cristina Giustiniani[4], Giuseppe Marrone[3], Marco Biolato[3], Fabio Maria Vecchio[4], Antonio Grieco[3], Andrea Urbani[2], Maurizio Sanguinetti[2], Antonio Gasbarrini[3], Luca Miele[3]. *[1]1Department of Traslational Medicine and Surgery, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [2]Department of Laboratory and Infectious Sciences, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; [3]Department of Traslational Medicine and Surgery, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [4]Department of Women, Children and Public Health Sciences, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy*
Email: lig.antonio91@gmail.com

Background and aims: Liver fibrosis stands out as the main prognostic risk factor in MASLD. The enhanced liver fibrosis (ELF) score is a composite of direct fibrosis biomarkers (tissue inhibitor of metalloproteinases 1, amino-terminal peptide of type 3 procollagen, and hyaluronic acid) that reflect extracellular matrix turnover. While the ELF test exhibits high diagnostic accuracy for advanced liver fibrosis in MASLD patients, its role as a prognostic biomarker remains uncertain. Our aim is to compare the prognostic effectiveness of ELF, FIB4, and liver histology in patients with MASLD.
Method: We retrospectively enrolled 289 patients with MASLD. The ELF score was automatically calculated in accordance with the manufacturer's instruction (Siemens Healthineers) using a serum sample collected at baseline. FIB4 computation and liver biopsy were performed at baseline. Liver fibrosis stage was assessed according to the METAVIR classification. The primary outcome was a composite end point including all-cause mortality, hepatocellular carcinoma, liver transplantation, or complications related to cirrhosis (ascites, variceal bleeding, hepatic encephalopathy, MELD ≥15). Subjects were stratified based on existing literature cut-offs for ELF (≤9.8, 9.8–11.3, ≥11.3), FIB-4 (<1.3, 1.3–2·67, 2.67), and histology (F ≤2, F3, F4) to assess the risk of occurrence of the primary outcome.
Results: We included data of 289 patients (88 [30.4%] were female, median age was 50 years [IQR 39–58], median BMI was 28.7 kg/m^2 [IQR 25.5–31.8] and 81 [28%] had type 2 diabetes). After a median follow-up of 41 months [IQR 21–68], the composite end point was observed in 34 (11.8%) patients. There was a stepwise increase in the frequency of developing primary outcome according with ELF <9.8 (0.5%), 9.8 to 11.2 (14.5%), and ≥11.3 (69.7%). Survival curves for pairwise comparisons between groups showed significant differences for all index tests according to pre-defined histological and NITs stratification (Log Rank test $p < 0.05$). At multivariate Cox regression analysis, ELF and liver histology were significant predictors of the primary outcome after adjusting for gender, type 2 diabetes, age and BMI. (ELF >11.2 vs <9.8 HR 135.4 [95%CI 15.9–1149.0 $p < 0.001$], 9.8–11.2 vs <9.8 HR 22.5 [95%CI 2.7–183.9 $p < 0.001$]) (Liver fibrosis 4 vs 0–2 HR 216.6 [95%CI 23.5–1999.2 $p < 0.001$], 3 vs 0–2 HR 5.44 [95%CI 1.0–30.9 $p = 0.05$]).
Conclusion: ELF, a simple non-invasive blood test, performed as well as histologically assessed fibrosis in predicting clinical outcomes and should be considered as alternative to liver biopsy for prognostic assessment in patients with MASLD.

AI-assisted, quantitative digital pathology-based continuous fibrosis scores perform better than conventional pathology in documenting fibrosis reduction

Vlad Ratziu[1], Louis Petitjean[2], Raluca Pais[3], Judith Aron-Wisnewsky[1], Li Chen[4], Leila Kara[5], Frederic Charlotte[1], Pierre Bedossa[6], Mathieu Petitjean[7]. *[1]Sorbonne Université, Paris, France; [2]Pharmanest, Inc, Princeton, United States; [3]ICAN, Paris; [4]PharmaNest, Princeton, United States; [5]ICAN, Paris, France; [6]LiverPat, Paris, France; [7]PharmaNest, Pricneton, France*
Email: vlad.ratziu@inserm.fr

Background and aims: Manual readings of liver biopsies using traditional histological fibrosis semi-quantitative classifications are subject to reader variability and poor sensitivity to change. We studied the performance of AI-assisted, quantitative digital pathology fibrosis scores in detecting fibrosis changes after bariatric surgery (BaS) a procedure with well-documented anti-fibrotic effects.
Method: Pts with morbid obesity who underwent BaS and had liver biopsy performed per operatively and at the last clinical follow-up were included. Liver biopsies were stained with Picrosirus red and staged using the NASH-CRN classification by an experienced hepatopathologist. The same slides were digitized (40X) and analyzed using a single-fiber, high-content image analysis platform to extract quantitative traits for collagen content, fiber morphometry and fibrosis architecture, allowing calculation of a continuous, quantitative fibrosis severity score (Ph-FCS, PharmaNest®). Changes in Ph-FCS before and after BaS were studied.
Results: 59 pts were included, 61% females, mean age 51.7 (sd 9.32) yrs. Prevalence of fibrosis stages was: stage 0: 1 (2%); stage 1: 14 (24%); stage 2: 10 (17%); stage 3: 25 (42%) and stage 4: 9 (15%). Gastric bypass (GB) was performed in 47 pts, sleeve gastrectomy (SG) in 11 pts and band ligation in 1 pt. The follow-up biopsy was performed a mean of 5.8 years (s.d. 2.6) post BaS. Overall, BMI was reduced by 11 (sd 3.9) kg/m^2. Baseline Ph-FCS was 7.07 (sd 1.65) and was reduced to 4.57 (sd 1.65) post-BaS. In the 19 pts with advanced fibrosis (stages 3 or 4) who no longer had advanced fibrosis at follow-up the Ph-FCS dropped by 2.75 (sd 1.89). There was an incremental decrease in Ph-FCs with reduction in histological NASH-CRN fibrosis stage: 1 stage reduction (N = 19): −2.62 (sd 2.26); 2 stage reduction (N = 10): −2.72 (sd 1.44); 3 stage reduction (N = 12): −3.02 (sd 3.13). Among the six patients with a one stage increase in fibrosis post BaS, 4 had an increase in the Ph-FCS (mean 2.34, sd 1.57) while two had a decrease. Importantly, in patients with no change in the NASH-CRN fibrosis stage (N = 12) the Ph-FCS decreased by a mean of 2.40 (sd 1.43). Pts who underwent GB had a stronger reduction in Ph-FCS than those who underwent SG: 2.64, sd 2.32 vs 1.35, sd 2.4, $p = 0.053$.
Conclusion: AI-assisted quantitative digital pathology provides fibrosis scores that are highly sensitive to liver fibrosis reduction and can uncover fibrosis changes not detectable by manual readings. These technologies have the potential to better identify drug or procedure-induced antifibrotic effects.

WED-263

A machine learning approach to identify patient features associated with metabolic dysfunction-associated steatohepatitis from the United Kingdom biobank

Jörn M Schattenberg[1], Amalia Gastaldelli[2], Harmeet Malhi[3], Alina M Allen[4], Mazen Noureddin[5], Umesh Karamchandani[6], Jonathon Romero[7], Peter Henstock[8], Birol Emir[9], Arun J Sanyal[10]. *[1]Saarland University Medical Center, Homburg, Germany; [2]National Research Council, Institute of Clinical Physiology, Pisa, Italy; [3]Mayo Clinic, Rochester MN, United States; [4]Mayo Clinic, Rochester, MN, United States; [5]Houston Methodist Hospital, Houston Research Institute, Houston TX, United States; [6]University of Illinois Urbana-Champaign, Champaign, IL, United States; [7]Syneos Health, Morrisville, NC, United States; [8]Pfizer Inc., Andover, MA, United States; [9]Pfizer Inc., New York, NY,*

Email: joern.schattenberg@uks.eu

Background and aims: Diagnosis of metabolic dysfunction-associated steatohepatitis (MASH) requires an invasive liver biopsy that is prone to sampling errors. Therefore, it is important to identify factors predictive of patients at risk. Using a machine learning (ML) approach applied on data from the UK Biobank, this study aimed to identify variables that have the highest predictive potential for MASH.
Method: This study included UK Biobank data of patients with MASH, defined as those having liver fat >5%. A combined set of features including biomarkers (e.g., alanine aminotransferase [ALT]), demographics and patient clinical characteristics were included. Time, date and features that had less than 10, 000 patients with non-null values (29%) were excluded. Missing data (21% of all values) were imputed by assigning a '0' value, using the k-nearest neighbour method, and ML algorithms that can handle missing values. All three approaches generated similar results and the 0 value was used for imputation. Predictive modelling was initially performed on the resulting full dataset (split 75/25 for cross-validation/testing) using classification models to predict the threshold output (5.5) and regression models to predict the continuous values. From comparisons of multiple ML models ranked in order of predictive value, random forest (RF) and CatBoost (CB) proved the best. Using feature importance, a subset of key features was selected for the final models. To identify additional features, a 'fat-free' model excluding fat-related features and a Boruta analysis were applied.
Results: The full dataset consisted of 5917 features from 34, 560 individuals. Consistent features were identified using RF and CB, despite these algorithms being fundamentally different. The fat-associated features were most predictive, particularly visceral adipose tissue and android fat tissue. The fat-free analysis identified sex hormone binding globulin, ALT, C-reactive protein and gamma-glutamyl transferase as the most predictive. Area under the curve values for RF and CB classification were 0.86 vs 0.88, respectively, for the top feature set, and 0.84 vs 0.85 for the fat-free feature set. Mean squared error values for RF and CB regression were 0.297 vs 0.286 for the top feature set, and 0.345 vs 0.318 for the fat-free feature set. The Boruta analysis also identified insulin-like growth factor 1, cystatin C and apolipoprotein B as features related to MASH.
Conclusion: CB and RF achieved accurate predictions and identified consistent features. These included measures of fat, its distribution and additional potential biomarkers predictive of MASH outcomes. ML could support the non-invasive identification of at-risk patients. New models will help the field and will need to be validated in non-population-based cohorts.

WED-266

Age impacts the diagnostic ability of the enhanced liver fibrosis test for advanced fibrosis in MASLD

Katrina Pekarska[1], Alexander Hinkson[1], Ian Rowe[1], Richard Parker[1].
[1]*Leeds Teaching Hospitals NHS Trust, St James's University Hospital, Leeds, United Kingdom*
Email: katrina.pekarska@gmail.com

Background and aims: Metabolic dysfunction associated liver disease (MASLD) has become one of the most frequent causes of chronic liver disease. Without appropriate management MASLD can progress to fibrosis and cirrhosis. Detection of liver fibrosis is an important diagnostic step, and several non-invasive fibrosis scores, including enhanced liver fibrosis test (ELF), have been introduced and are widely utilised to identify/exclude advanced fibrosis in patients with MASLD. It is noteworthy that ELF test has been validated in patients aged between 35 and 60 years where a reading ≥9.8 indicates a significant fibrosis. The aim of this study was to assess the effect of age on the performance of ELF test in MASLD.
Method: Patients who underwent a liver biopsy for diagnosis or staging of MASLD in routine practice at a single centre were included. The cohort was divided into four age-based groups: <40 (n = 52), 40–49 (n = 61), 50–59 (n = 111), and ≥60 years (n = 81). The performance of ELF test for advanced fibrosis stage (stage F3 and F4) for each age group was assessed using liver biopsy as the standard and using the area under the receiver operating characteristics (AUROC) curve. Statistical analysis was done in R.
Results: In total 305 patients had available data regarding age, ELF test and histopathology and were included in analysis. The median BMI was 35 kg/m^2 (IQR 31–40) and 60% of patients were male. Diabetes mellitus was present in 160 (52%) and hypercholesterolaemia in 133 (48%). The median age was 54 years (IQR 44–60). Advanced fibrosis was present in 120 patients. Overall, the ELF test in this cohort performed well to predict advanced fibrosis: AUROC 0.74. The performance of the ELF test was particularly good in patients aged >40: AUROC 0.93. However, the performance of the ELF test was worse in other age groups: 40–49 years, AUROC 0.70; 50–59 years, AUROC 0.68; and aged over ≥60 AUROC 0.72. The sensitivity (sens.) of the ELF test in all age groups was below 70% and dropped to 42% in those aged 40–49. Optimal cut offs for each age group were calculated: the optimal ELF test cut point increased from younger to older patients: 9.3 for patients aged <40 (sens. 100%), 9.34 for patients aged 40–49 (sens. 73%), 10 for patients aged 50–59 (sens. 69%) and 10.3 for the oldest patients aged over 60 (sens. 75%).
Conclusion: The ELF test has excellent performance to diagnose advanced fibrosis in those aged under 40 years, however the diagnostic performance falls with age. Clinicians should be mindful of this when treating patients of various age groups. New ELF test thresholds for advanced fibrosis are proposed in various age groups to improve ELF test sensitivity and therefore reduce the number of positive cases missed.

Background and aims: Metabolic dysfunction-associated steatotic disease (MASLD) drives chronic liver injury leading to fibrosis, which is the major correlate of adverse health outcomes. The non-invasive tests (NITs) for liver fibrosis must accurately discriminate fibrosis severity while minimising indeterminate results. Accurate NITs are especially needed for primary screening in general practise and diabetes and obesity clinics. Almost all current NITs are a multi-marker statistical model/algorithm based on markers of hepatocyte damage rather than products of the activated mesenchymal cells (stellate cells and fibroblasts) that create and regulate fibrosis. We previously showed that fibroblast activation protein (FAP) digests collagens and TGFbeta precursors and is strongly and specifically expressed by myofibroblasts and activated stellate cells in human cirrhosis. We investigated the utility of circulating FAP (cFAP) to detect fibrosis in MASLD.
Method: The FAP shed from cell surfaces as an active enzyme is stable in human serum and plasma. We applied our quantitative, specific, rapid, one-step FAP enzyme assay to sera from a bariatric cohort (training cohort P, n = 160, 36% diabetic; n = 182, 23% diabetic) and a bariatric/MASLD cross-validation cohort (n = 150).

Results: Both insulin resistance and fibrosis were associated with cFAP in the MASLD cohort ($p < 0.05$). We coin the term FAP Index for a multi-variate model that was developed combining cFAP with age, diabetes status and ALT to evaluate liver fibrosis risk, especially in individuals who had an indeterminate result of an NFS or FIB4 test. The training cohort AUROC was 0.875 with a negative prediction value of 92% and a positive prediction value of 95%, indicating high accuracy. The cross-validation cohort AUROC was 0.84, with 98.5% specificity and 55% sensitivity. By serial application of NFS or FIB4 then the FAP Index, the proportion of indeterminate results more than halved, to <15%. Therefore, applying cFAP measurement as a reflex test following an indeterminate FIB4 or NFS would likely have economies of time and expense, and lower the demand for obesity-specialised secondary testing.
Conclusion: We present a novel, inexpensive diagnostic tool for assessment and triage of individuals with diabetes, steatosis or obesity. We suggest that an advantage of including FAP Index in clinical fibrosis assessments is that FAP is strongly expressed by liver cell types that regulate the extracellular matrix.

Natural history and expected change over time for MRI derived cT1: Data from clinical trials and the UK Biobank

Charlie Diamond[1], Cayden Beyer[2], Elizabeth Shumbayawonda[1], John McGonigle[1], Tim Rolph[3], Kitty Yale[3], Rajarshi Banerjee[1], Helena Thomaides Brears[1], Andrea Dennis[1], Michele Pansini[4,5], Naim Alkhouri[6]. *[1]Perspectum Ltd., Oxford, United Kingdom; [2]Perspectum Inc., Dallas, United States; [3]Akero Therapeutics Inc., South San Francisco, United States; [4]Clinica Di Radiologia EOC, Istituto Di Imaging Della Svizzera Italiana (IIMSI), Lugano, Switzerland; [5]John Radcliffe Hospital, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [6]Fatty Liver Program, Arizona Liver Health, Chandler, AZ, United States*
Email: charlie.diamond@perspectum.com

Background and aims: Evaluation of the efficacy of new treatments in clinical trials in individuals with metabolic dysfunction-associated steatotic liver disease (MASLD) has been hampered by relatively high rates of histological changes in the placebo arms partly due to inconsistencies in pathologists' readings. Iron-corrected T1 (cT1) is an established, highly repeatable MRI biomarker of chronic liver disease activity, which strongly correlates with metabolic dysfunction-associated steatohepatitis (MASH) pathology and associates with liver and cardiovascular outcomes. A minimum detectable change in cT1 has previously been determined as >46 ms, while a change of >80 ms is associated with a 2-point change in NAFLD activity score (clinically meaningful). Using data acquired from volunteers in the UK Biobank (UKBB) imaging study and placebo controlled MASLD trials, we sought to measure change in liver disease activity based on cT1 over time in adults with and without MASLD.
Method: Paired clinical and imaging data from 2325 volunteers from the UKBB (application 9914) and 31 volunteers who served as placebo subjects in 3 interventional clinical MASLD trials, were analysed. All participants were scanned at baseline and follow-up; 115 weeks apart for UKBB and 18–52 weeks for the pooled clinical trial data. Liver MRI scans were analysed using LiverMultiScan (for fat (MRI-PDFF), iron concentration (MRI-LIC) and disease activity (iron corrected T1 mapping, cT1)). MRI criterion for definition of MASLD was of liver fat ≥5%, and criteria for MASH were liver fat ≥5% and cT1 ≥800 ms, both with cardiometabolic risk factors. Statistical comparisons across timepoints were performed using Wilcoxon rank sum tests for continuous variables and Fishers exact tests for categorical variables.
Results: In the UKBB (mean age 63 (SD 7) years, 48% male, mean BMI 26 (SD 4) kg/m^2, 15% obese, 4.1% self-reported diabetic, 18% MASLD and 2.5% MASH), the participants cT1 increased significantly by a mean of 5ms (SD 32; $p < 0.001$) over an average 115-week period. For the 410 individuals with MASLD at baseline, the change in cT1 over time was negligible (0ms (SD 40)). For the pooled clinical trial placebo cohort (mean age 56 (SD 8) years, 58% male, BMI 35 (SD 7) kg/m^2, 72% obese, 65% diabetic, 90% MASLD and 81% MASH), cT1 decreased by −7 ms (SD 84) over 18–52 weeks. In both cohorts the average change over time was considerably less than the reported minimal detectable change of 46ms, suggesting the observed changes are not clinically meaningful.
Conclusion: In both UKBB and placebo cohorts cT1 did not meaningfully change over time. These longitudinal datasets provide evidence of the stability of quantitative MRI liver biomarker cT1 in both healthy and MASLD populations. This information can be used to help power future studies and monitor disease over time in patients.

Simultaneous assessment of skeletal muscle mass and handgrip strength to identify patients with NAFLD at high risk of advanced liver fibrosis

David Kim[1], Jae Seung Lee[2], Mi Na Kim[2], Beom Kyung Kim[2], Jun Yong Park[2], Do Young Kim[2], Sang Hoon Ahn[2], Nikolaos T. Pyrsopoulos[1], Hye Won Lee[2], Seung Up Kim[2]. *[1]Rutgers New Jersey Medical School, Newark, United States; [2]Yonsei University College of Medicine, Seoul, Korea, Rep. of South*
Email: dsk143@njms.rutgers.edu

Background and aims: Sarcopenia diagnosis depends on various diagnostic criteria based on different diagnostic modalities. We aimed to identify the predictors of discordance between appendicular skeletal muscle mass (ASM) measured by bioimpedance analysis (BIA) and handgrip strength (HGS) in diagnosing sarcopenia and investigate whether their combined use can identify a subgroup of patients with non-alcoholic fatty liver disease (NAFLD) at high risk for advanced liver fibrosis.
Method: Between 2018 and 2023, NAFLD patients whose ASM was measured by BIA and HGS were recruited. Sarcopenia was diagnosed when ASM/body mass index (BMI) was <0.882 in men or <0.582 in women or when HGS was <28.9 kg in men or <16.8 kg in women. Advanced liver fibrosis was defined as a liver stiffness value by transient elastography of >9.6 kPa.
Results: Among 2, 044 patients, 794 (38.8%) and 200 (10.8%) patients had sarcopenia according to BIA and HGS, respectively. In multivariate analysis, male sex (odds ratio [OR] = 1.3) and BMI (OR = 1.2) were independent predictors of discordance between ASM- and HGS-diagnosed sarcopenia ($p < 0.05$). Patients with sarcopenia according to both BIA and HGS and those with sarcopenia according to BIA only demonstrated a significantly higher probability of advanced liver fibrosis than patients without sarcopenia according to both BIA and HGS (all $P < 0.001$).
Conclusion: In NAFLD patients, male sex and BMI were independently associated with discordance in diagnosing sarcopenia via ASM by BIA and HGS. Moreover, the combined use of the methods helped identify those at high risk of advanced liver fibrosis.

Background and aims: Chronic liver disease is a rising public health issue with significant contributions from steatotic liver diseases (SLD) such as MASH. Community screening, including blood testing, genetics and imaging such as elastography are important for patient identification for clinical trials. The FAST score is useful to identify those at-risk of progressive MASH with fibrosis. Herein, we investigated the clinical profile of patients screened within hepatology and general medicine clinical trial centres and utilized FAST to risk-stratify for MASH, including evaluating genetic profiles.
Method: The ALIGN screening study is an ongoing multicenter global prospective cohort study aimed at identifying individuals with a high likelihood of MASLD/MASH by collecting blood and genetic samples and using non-invasive imaging. The FAST score is a composite score derived from FibroScan® (Echosens, Paris, France) and AST composed to identify MASH with active disease (NAS ≥4), and fibrosis (F≥2). Patients were stratified into risk groups according to published cut-offs (low risk <0.35, intermediate between 0.35–0.67, high risk >0.67) and evaluated using their clinical and genetic profile. Continuous variables presented as mean with standard deviation [SD].
Results: Out of n = 1, 328 participants screened, 68.1%, 26%, 5.9% had low, intermediate and high risk FAST scores denoted by <0.35, >0.35–0.67; and >0.67, respectively. Individuals with high risk FAST score had a worse metabolic profile compared to those with low risk FAST, indicated by higher BMI (37.2 kg/m^2 [7.6] vs 32.6 kg/m^2 [6.1]), waist circumference (118 cm [16.7] vs 106.7 cm [12.2]), triglycerides (198.4 mg/dL [216.9] vs 149.7 mg/dL [111]) and a greater proportion living with type 2 diabetes (58.2% vs 29.6%). ALT was ~3-fold higher within the high risk FAST risk group compared to low risk FAST risk (93.2 IU/L [65] vs 31.9 IU/L [16.3]). Within the genotyped subgroup (n = 317) the proportion of PNPLA3 rs738409 risk alleles did not differentiate across FAST risk groups (GG prevalence was 21.3%, 33.6%, 22.9% for low, intermediate and high FAST).
Conclusion: FAST score is an important tool to screen for fibrotic MASH in individuals interested in participating in clinical trials. Within ALIGN, participants with a higher FAST had a worse metabolic profile and had elevated ALT compared to those with lower FAST. Within ALIGN, the FAST score had limited ability to stratify risk according to PNPLA3 genetic profile.

Background and aims: Non-invasive biomarker-driven algorithms are urgently needed for classifying Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) and monitoring its progression to Steatohepatitis (MASH) and Hepatocellular Carcinoma (HCC). In this study, we investigated microRNAs (miRs) present in serum extracellular vesicles (EVs) that may serve as diagnostic and prognostic biomarkers.
Method: EV-associated miRNAs from obese adults without Steatotic Liver Disease (SLD), lean or obese with simple steatosis, MASH with and without fibrosis (determined by liver biopsy), as well as in patients with MASLD-associated HCC were isolated following the exoRNeasy Midi kit (Qiagen). The small RNA transcriptome on EVs was sequenced following the QIAseq miRNA Library kit (Qiagen) workflow.
Results: A total of 71 individuals were clinically categorized into eight study groups (n = 9 individual per group): Obese without SLD, with simple steatosis, MASH-F0/F1 or MASH-F2-F3, lean with SLD, MASHF0/F1 or MASH-F2-F3, and MASLD-HCC. In total, 1, 461 EV-miRs were identified. Notably, the EV levels of 8 miRs were found to be dysregulated in MASH compared to simple steatosis, irrespective of the degree of liver fibrosis and BMI, with individual areas under the receiver operating curve (AUC) values over 0.8. Additionally, the EV levels of 6 miRs were associated with fibrosis scores (F0-F1 vs. F2-F3) regardless of BMI, with AUC values over 0.83. Finally, a total of 130 miRs were found to be dysregulated in serum EVs from patients with MASLD-HCC compared to MASLD, regardless of age, biological sex, and BMI, with some of them exhibiting maximal diagnostic AUC values (e.g., miR-629-5p, miR-488-5p, miR-4732-5p).
Conclusion: This study underscores the potential of EV-miRs as diagnostic tools for staging MASLD and its association with HCC. Ongoing work on logistic models that combine miRs will be valuable for future international validation efforts.

Background and aims: Hepatic steatosis may result in metabolic dysfunction-associated steatohepatitis (MASH), hepatocellular carcinoma (HCC), and mortality. We aimed to develop and validate a self-testing index to detect hepatic steatosis, and stratify risk of HCC and all-cause mortality in the general population.
Method: This prospective population-based study included 210, 679 participants from six cohorts. A prospective derivation (N = 7, 000), a prospective test (N = 2, 027), a prospective magnetic resonance imaging proton density fat fraction (N = 296), and an NHANES (N = 7, 436) cross-sectional cohorts were enrolled to develop and validate a new index for hepatic steatosis. The ability of prognostication stratified by the new index was evaluated in Chinese (N = 142, 505) and NHANES (N = 51, 415) follow-up cohorts.
Results: In the derivation cohort, three factors for hepatic steatosis were identified, including Age, body mass Index, and Diabetes mellitus, and fitted to develop the "AID" index (web calculator at https://chess.nuist.edu.cn/consult/gzconsult/aid_index). The AID index performed better ($p < 0.05$) capability in predicting hepatic steatosis than other methods in four cross-sectional cohorts. The hepatic steatosis risk was best stratified by the cut-off values at 0 and 2.11. The cumulative incidences of HCC at 15 years in the high-risk group were significantly higher (0.37% vs. 0.29%, P = 0.034) than that of the low-risk group in the Chinese follow-up cohort. Notably, the AID index also effectively identified individuals at risk of all-cause mortality in Chinese and NHANES follow-up cohorts.
Conclusion: The AID index that can be self-tested easily demonstrates strong capabilities in diagnosing hepatic steatosis, and stratifying risk of HCC and all-cause mortality in the general population.

Background and aims: The Enhanced Liver Fibrosis (ELF) test, a non-invasive test derived from serum biomarkers, is valuable for predicting liver fibrosis in chronic liver diseases. However, the impact of positive factors and the positive number in the cardiometabolic risk factors of metabolic dysfunction-associated steatotic liver disease (MASLD) on ELF tests is unknown. We aimed to evaluate the accuracy of the ELF test, according to the positive factors and the positive number in the cardiometabolic risk factors, comparing with the Fibrosis-4 (FIB-4) index and non-alcoholic fatty liver disease fibrosis score (NFS) in patients with MASLD.
Method: In this retrospective study, a total of 1038 patients with biopsy-proven SLD having at least one of five cardiometabolic risk factors were enrolled. The diagnostic performance of the ELF test, the FIB-4 index, and NFS for predicting advanced fibrosis (≥F3 and F4) by the positive factor or the positive number in the cardiometabolic risk factors were compared.
Results: The median value of the ELF test, the FIB-4 index, and NFS were 9.9, 1.84, and −0.654, respectively. The patient number of fibrosis stages (F) 0, 1, 2, 3, and 4 were 180, 350, 276, 196, and 36, respectively. The area under the curve (AUROC) of the ELF test for predicting advanced fibrosis was significantly higher than that of the FIB-4 index and NFS (ELF, 0.833; FIB-4, 0.753; NFS, 0.757). The diagnostic performances of the ELF test were significantly greater, regardless of the positive or negative for each cardiometabolic risk factor, although there was no difference in MASLD patients without type 2 diabetes. Furthermore, the AUROC of the ELF test was significantly higher than that of the FIB-4 index and NFS in MASLD patients with two or more positive cardiometabolic risk factors (ELF, FIB-4, and NFS; 0.832, 0.835, and 0.708 at 1 positive factor, 0.868,

0.789, and 0.792 at 2 positive factors, 0.832, 0.762, and 0.761 at 3 positive factors, 0.817, 0.725, and 0.732 at 4 positive factors, 0.818, 0.732, and 0.706 at 5 positive factors).
Conclusion: The ELF test showed high diagnostic performance for predicting advanced fibrosis compared with the FIB-4 index and NFS in patients with MASLD, regardless of the positive factor and the positive number in the cardiometabolic risk factors.

WED-274
Impact of sex, body mass index, elevated liver enzymes, and diabetes mellitus on risk-stratification of a large cohort of patients with MASLD
Abdel-Aziz Shaheen[1], Elizabeth Baguley[1], Wendy Schaufert[2], Alexandra Frolkis[1], Mark G. Swain[1], Juan G. Abraldes[3]. [1]*University of Calgary, Calgary, Canada;* [2]*Alberta Health Services, Calgary, Canada;* [3]*University of Alberta, Edmonton, Canada*
Email: az.shaheen@ucalgary.ca

Background and aims: The need to develop and implement clinical care pathways to risk-stratify patients with metabolic dysfunction-associated steatotic liver disease (MASLD) is growing. We aimed to assess risk-stratification of patients with MASLD in primary care and evaluate role of sex, body mass index (BMI), elevated alanine aminotransferase (ALT) and diabetes mellitus (DM) on risk-stratification.
Method: Patients with confirmed MASLD diagnosis from the Calgary MASLD pathway in primary care (n = 10, 844) and Calgary MASLD clinic (n = 806) were included in our study. We compared performance of fibrosis marker FIB-4 to shearwave elastography (SWE) among 7, 738 patients with available FIB-4. Among patients assessed in MASLD clinic, we compared performance of FIB-4, Transient Elastography (TE), SWE to liver biopsy (n = 359) to identify significant (≥F2) or advanced fibrosis (≥F3) according to our exposure variables of interest.
Results: In the MASLD primary care cohort (n = 7, 738), morbid obesity and DM were associated with higher probability of SWE ≥8 kPa while elevated ALT and sex had minimal impact on this association. Within the MASLD clinic, female patients with FIB-4≥1.30 had higher risk of advanced fibrosis compared to men (77.1% vs. 64%, $p = 0.044$). Patients with elevated ALT had two folds increase in advanced fibrosis (58.6% vs. 28.8%, $p < 0.001$). While morbid obesity did not affect risk stratification using FIB-4 as first step, patients with DM had double rates of advanced fibrosis (62.5% vs. 32.3%, $p < 0.001$). Independent predictors of significant fibrosis were age (adj OR 1.03, 95%CI: 1.00–1.06), female sex (adj OR: 2.42, 95%CI: 1.28–4.57), aspartate aminotransferase [AST] (adj OR: 1.03, 1.02–1.05) and DM (adj OR: 6.72, 3.64–12.39). Independent predictors of advanced fibrosis were age (adj OR 1.03, 95%CI: 1.01–1.06), female sex (adj OR: 2.60, 95%CI: 1.44–4.69), aspartate aminotransferase [AST] (adj OR: 1.02, 1.01–1.03) and DM (adj OR: 3.87, 2.04–7.35).
Conclusion: Future clinical care pathways should be designed to prioritize risk-stratification among women, patients with elevated liver enzymes or DM.

WED-275
Understanding barriers to adoption of clinical guidelines for metabolic dysfunction-associated steatotic liver disease among hepatologists in Europe

Background and aims: The global burden of metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic dysfunction-associated steatohepatitis (MASH) is high and rising. Clinical practice guidelines (CPGs) advise that patients with suspected MASLD and MASH be assessed for risk based on comorbidities, screened using non-invasive tests, referred to hepatologists when necessary, and offered appropriate interventions. This study aimed to understand attitudes and behaviours toward CPGs, as well as their use in diagnosing and managing MASLD/MASH among physicians in five European countries.
Method: A real-world, cross-sectional study was conducted in France, Germany, Italy, Spain, and the United Kingdom among hepatologists and gastroenterologists with a subspecialty in hepatology, grouped as "hepatologists" for the analysis. Data were collected from March to September 2023 using an online quantitative survey, which participants completed anonymously, and 45-minute qualitative interviews with physicians from each country. Descriptive statistics were used to analyse the data.
Results: 250 hepatologists in the study cared for an average of 116.3 patients per month diagnosed with MASLD/MASH, which they estimated represented 37.4% of their total patient population. Hepatologists reported that 32% of their patients with MASH were confirmed through liver biopsy. To profile patients suspected of MASH, hepatologists reported using vibration-controlled transient elastography (VCTE) (76%), ultrasound (76%), and liver biopsy (64%) most frequently. To confirm diagnosis, liver biopsy was used by 68% of hepatologists; however, 34% of hepatologists stated that liver biopsy was not necessary to confidently diagnose MASH. Hepatologists were most aware of EASL 2021 (55%), AASLD 2023 (44%) and AASLD 2018 (42%) clinical guidelines. A small proportion of hepatologists stated, even when prompted with a list, that they were not aware of any clinical guidelines for MASH (4%), did not follow any guidelines for the diagnosis of MASH (5%) and did not follow any guidelines for the treatment and management of MASH (7%). Among 25 hepatologists who participated in qualitative interviews, most (n = 15) had heard of the new MASLD/MASH nomenclature, and n = 15 also believe it will not change anything for their practice.
Conclusion: This study found that a number of barriers to adoption of CPGs exist, which may drive variation in hepatologists' approach to diagnosing and managing patients with MASH. The findings emphasise the need to continuously embed CPGs into routine care to address the implementation gap and to thereby optimise care for patients with MASH.

WED-278
MASLD assessment using a novel point of care device the Hepatoscope™ in diabetes and obesity clinics
Cyrielle Caussy[1], Bruno Vergès[2], Rouland Alexia[3], Bérénice Ségrestin[1], Dominique Delaunay[4], Sybil Charrière[5], Emmanuel Disse[1], Philippe Moulin[6], Jean-Michel Petit[7]. Email: cyrielle.caussy@gmail.com

Background and aims: The screening for metabolic dysfunction-associated steatotic liver disease (MASLD) and liver fibrosis is currently recommended in patients with type 2 diabetes (T2D) and

obesity. We aimed at evaluating the correlation of liver fibrosis and steatosis parameters between a FibroScan® and a new ultrasound imaging point-of-care device: Hepatoscope™.
Method: This is an interim analysis from a prospective multicenter study including participants with T2D and/or obesity and MASLD age 40–80 years, BMI <40 kg/m^2 enrolled in 3 diabetes clinics in France between Dec 2022 and Dec 2023 (ancillary study NCT04435054). All participants underwent the same day liver stiffness measurement using vibration controlled transient elastography (VCTE) by FibroScan®, 2D-measurements of shear wave speed (2DTE) by Hepatoscope™, hepatic fat content assessment using controlled attenuation parameter (CAP) by FibroScan® and ultrasound attenuation (ATT) and backscattering coefficient (BSC) by Hepatoscope™. An exploratory subgroup of 18 participants underwent also magnetic resonance imaging proton density fat fraction (MRI-PDFF). The spearman correlation coefficients and mean bias between VCTE and 2DTE were assessed in participants with both valid VCTE and 2DTE (interquartile range/median ratio ≤0.30). In addition, correlation between CAP or MRI-PDDF and CAP, ATT or BSC were also assessed.
Results: 148 participants were included in the analysis: 64.9% male, 87.8% with T2D, 70.3% with obesity and with mean age: 61.8 ± 9.4 years, BMI: 32.1 ± 3.8 kg/m^2 and median 2DTE of 6.1 kPa ± 4.3 kPa versus median VCTE: 6.4 ± 4.2 kPa, p = 0.947. VCTE and 2DTE were significantly correlated r_2: 0.46, p < 0, 001 with a mean bias of −0.2, (95%CI: −5.86–5.37). The median CAP was: 311 ± 52 dB/m versus ATT: 310 ± 42 dB/m, p = 0, 151 and the median BSC was −22.8 ± −5.4. Both ATT and BSC correlated significantly with CAP: r_2: 0.55, p < 0.001 and r_2: 0.59, p < 0.001, respectively.CAP, ATT and BSC were also significantly correlated with MRI-PDFF: r_2: 0.80, 0.78 and 0.88, respectively, all p < 0.001.
Conclusion: These preliminary data indicate that the Hepatoscope™ 2DTE is significantly correlated with VCTE. It provides the proof of concept that the Hepatoscope™ could be used for the assessment of liver fibrosis and steatosis in patients with MASLD. Further studies in larger cohort are needed to determine the cut-offs and diagnostic performance of the Hepatoscope™ in diabetes and obesity clinics.

WED-279
Landscape of the steatotic liver disease and its risk factors in the point-of-care liver screening program SIRIUS

Tomas Koller[1], Svetlana Adamcova Selcanova[2], Natalia Kubanek[2], Daniel Jan Havaj[2], Karolina Sulejova[2], Daniela Žilinčanová[2], Sylvia Dražilová[3], Martin Janičko[3], Marek Rac[4], Maria Szantova[5], Lubomir Skladany[2]. *[1]Comenius University Faculty of Medicine in Bratislava, University Hospital Bratislava, Bratislava, Slovakia; [2]FD Roosevelt Hospital, Banska Bystrica, Slovakia; [3]Louis Pasteur University Hospital, Kosice, Slovakia; [4]Faculty Hospital Nitra, Nitra, Slovakia; [5]Comenius University Faculty of Medicine in Bratislava, Bratislava, Slovakia*
Email: tomas.koller@fmed.uniba.sk

Background and aims: Metabolic syndrome and alcohol are the most common risk factors for liver disease worldwide. The recent global consensus on steatotic liver disease (SLD) detailed its definition into more etiology-specific categories. We aimed to map the landscape of both risk factors, liver steatosis, and their possible combinations among participants of the liver screening program.
Method: The point-of-care arm of the SIRIUS program has operated in Slovakia since 2022 and visited more than 25 sites. Free-of-charge screening for liver disease is offered to local community-dwelling adults. Inclusion criteria were age >18 y, cases with a history of chronic liver disease or incapacitating severe systemic disease were excluded. The screening procedure included questionnaires on medical history, AUDIT-C, quality of life, food habits, basic anthropometric measurements, blood drop analysis for aminotransferases and blood lipids, and liver stiffness and CAP (Fibroscan by Echosense). Steatosis was defined according to EASL by CAP >275 db/m. The metabolic syndrome (MS) was defined as at least one component according to the recent consensus and at-risk alcohol consumption (AUD) by AUDIT-C score ≥4 in women (F) or ≥5 in men (M).
Results: We included 1585 participants with a median (25–75 percentile) age of 53 y (44–64), M/F ratio 974/611, BMI 26, 9 (23, 9–30, 4), waist circumference M 101, F 91 cm, with 6, 3% having diabetes, 16, 7% of active smokers, 7, 8% having a history of unspecified liver disease. Steatosis was diagnosed in 31, 2% (M 39, 8, F 25, 9%). From the risk factors, we observed MS in 68, 8% (M72, 2, F66, 7%), and AUD in 15, 4% (M 21, 4, F 11, 4%). In males and females respectively, we observed no risk factors in 18, 3 and 26, 2%, elevated ALT in 33, 7 and 12, 2%, AUD alone in 4, 4 and 4, 6%, MS alone in 28, 3 and 39, 2%, AUD and MS in 9, 2 and 4, 1%, steatosis alone in 4, 3 and 2, 3%, steatosis and AUD (ALD) in 0, 8 and 0, 2%, steatosis and MS (MASLD) in 27, 7 and 20, 7% and steatosis, MS and alcohol (Met-ALD) in 7, 0 and 2, 7%.
Conclusion: Liver disease risk factors are frequently found in the screening program generating a substantial pool of patients eligible for preventive interventions. We observed a slight male predominance in the abnormal ALT, alcohol, and subgroups of steatotic liver disease.

WED-280
Spectroscopy of blood plasma has the potential to differentiate metabolic dysfunction-associated steatohepatitis from steatosis

Email: cizkova.barbora@gmail.com

Background and aims: Searching for disease-specific blood spectral patterns was suggested to be a promising advanced experimental diagnostic approach that may provide a characteristic “fingerprint” that can be used diagnostically in the field of hepatology. We aimed to test the potential of spectroscopic analysis of blood plasma for distinguishing different stages of metabolic dysfunction-associated steatotic liver disease (MASLD).
Method: We analyzed blood plasma samples using a combination of conventional and advanced spectroscopic methods (Fourier-transform infrared (FTIR) spectroscopy, Raman spectroscopy, and Electronic circular dichroism (ECD)) in an exploratory group of seven patients with biopsy confirmed metabolic dysfunction-associated steatohepatitis (MASH) and six patients with simple steatosis. Pilot results were validated on 29 patients with MASH and

24 patients with steatosis. Further, we tested these methods in the identification of MASH with moderate-to-advanced fibrosis (F2-3; *n* = 15) compared to MASH/steatosis with no/mild fibrosis (F0–1, *n* = 29). Finally, we wanted to differentiate patients with fibrosis (*n* = 39) from those with steatosis (*n* = 14), regardless of the presence of MASH. The presence or absence of MASH was biopsy-proven, as well as the fibrosis grade. The spectra were processed and compared between groups using PCA-LDA method with leave-one-out cross-validation in the exploratory group, and by PLS-DA algorithm with a repeated 10-fold cross-validation, complemented by permutation test in the validation cohort.

Results: The pilot study showed the potential of spectroscopic methods to identify MASH, as the classification accuracy reached up to 77% for the combination of the individual methods. The validation study showed that the combination of FTIR and Raman spectroscopy together with ECD discriminated MASH with a sensitivity of 90% and a specificity of 82% (AUROC 0.93), $p < 0.001$. Furthermore, the same combination of methods showed the ability to identify MASH with moderate-to-advanced fibrosis compared to MASH/steatosis with no/mild fibrosis F0–1 with a sensitivity of 83% and specificity of 82% (AUROC 0.90), $p < 0.001$. Apart from MASH, these methods also identified fibrosis (of any grade) from steatosis with a sensitivity of 80% and specificity of 90% (AUROC 0.91), $p < 0.001$.

Conclusion: Blood plasma spectroscopy seems to have the potential to differentiate patients with MASH or MASH with moderate-to-severe fibrosis, although external validation is necessary. Supported by: MH CZ-DRO-VFN00064165 and by AZV MHCZ NU23-01-00288.

WED-281-YI

A non-invasive score model for prediction of significant fibrosis and fibrotic metabolic dysfunction-associated steatohepatitis based on serum biomolecules

Nateneal Beyene[1], Wilhelmus J Kwanten[2], Lotte Schoenmakers[3], Jolien Derdeyn[3], Toon Steinhauser[3], Thomas Vanwolleghem[2], Ann Driessen[3], Sven Francque[2], Luisa Vonghia[2]. *[1]University of Antwerp, Antwerp University Hospital, Wilrijk, Belgium; [2]Antwerp University Hospital, University of Antwerp, Edegem, Belgium; [3]Antwerp University Hospital, Edegem, Belgium*
Email: natenealtamerat.beyene@uantwerpen.be

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) with significant fibrosis (*i.e.*, ≥F2 fibrosis) has a higher risk of developing advanced liver disease. The gold standard for identifying MASH and liver fibrosis remains a histological evaluation via liver biopsy, an invasive and costly procedure. Hence, blood biomarkers based prediction scores may provide an improved option. This study aims to generate serum based score model to predict significant fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD) patients.

Method: The study includes 120 subjects that underwent a liver biopsy for a suspicion of MASLD at the Antwerp University Hospital. The MASLD activity score system was used to determine the histological MASLD features. Besides standard serum biochemistry, concentrations of bio-molecules cytokeratin-18 (CK-18 M30), tissue inhibitors of metalloproteinases-1 (TIMP1), vascular cell adhesion molecule-1 (VCAM1), and fasting insulin (FI) were measured. Independent predictors of F≥2 identified by multivariate logistic regression, and the predicted probabilities used to generate prediction models with area under the receiver operating characteristic curves (AUROC). The AUROC of models compared using DeLong test in R via pROC package. $p < 0.05$ considered statistically significant.

Results: Histology revealed that 31 of the 120 subjects had no MASL, 31 had MASL, and 58 had MASH; 48 patients had fibrosis F ≥ 2, 34 of them had MASH. First, Model-B (combining TIMP1, VCAM1, CK18 and FI) predicted F ≥ 2 fibrosis with an AUROC of 0.95 (CI, 0.91–99, cut-off = 0.22) with 92% sensitivity and 85% specificity. Model-B predicted fibrotic MASH with an AUROC 0.91 (CI, 0.85–96, cut-off = 0.20) with 86% sensitivity and 83% specificity. Secondly, Model-E (comprising Gamma-glutamyl transpeptidase, aspartate aminotransferase, alanine transaminase and age) predicted F ≥ 2 with an AUROC of 0.88 (CI, 0.82–94, cut-off = 0.378) with 81% sensitivity and 79% specificity. Model-E predicted fibrotic MASH with an AUROC of 0.80 (CI, 0.72–88, cut-off = 0.205) with 82% sensitivity and 65% specificity. Thirdly, after computing FIB4 index, model-FIB4 predicted F ≥ 2 with an AUROC of 0.83 (CI, 0.76–91, cut-off = 0.911) with 81.3% sensitivity and 71.8% specificity. Model-FIB4 also predicted fibrotic MASH with an AUROC of 0.71 (CI, 0.61–81, cut-off = 1.00) with 71% sensitivity and 66% specificity. Model-B outperformed Model-FIB4 in F ≥ 2 prediction ($p = 0.006$), while there was no difference compared to Model-E ($p = 0.054$). Regarding fibrotic MASH prediction, Model-B was superior to Model-FIB4 and Model-E, $p = 0.001$ and, $p = 0.032$, respectively.

Conclusion: Serum biomolecule based composite score outperformed scores based on routinely available parameters to predict fibrotic MASH. This novel model might be a valuable diagnosis tool, after validation in an external cohort.

Email: benedix.sim@mohh.com.sg

Background and aims: The fibrosis-4 (FIB-4) index has been incorporated in major guidelines as a non-invasive method to risk stratify patients with metabolic dysfunction-associated steatotic liver disease (MASLD). Patients with FIB-4 <1.3 are considered to be at low risk of advanced fibrosis and are not recommended for follow-up with a hepatologist. However, previous studies have found limitations affecting the accuracy of FIB-4 including older age and diabetes. Hence, we aimed to evaluate the factors associated with falsely low FIB-4 in patients with MASLD-related hepatocellular carcinoma (HCC).

Method: We included adult patients diagnosed with MASLD-related HCC from January 2008 to August 2023 at six academic centers in India, Japan, South Korea, Singapore, and the United States. We compared patient and disease characteristics between patients with FIB-4 <1.3 versus ≥1.3. Predictors associated with FIB-4 <1.3 were also investigated with multivariate logistic regression models. p values <0.05 were considered statistically significant. All analyses were conducted in RStudio 2021.09.0.

Results: We included 538 patients with MASLD-related HCC, of which 38 patients (7.25%) had FIB-4 <1.3. In multivariate analysis adjusting for male sex, presence of cirrhosis, diabetes, obesity, and Barcelona Clinic Liver Cancer (BCLC) staging, diabetes (OR 0.44, 95%CI 0.21–0.90, p = 0.025) and cirrhosis (OR 0.23, 95%CI 0.10–0.51, p < 0.001) were associated with decreased odds of FIB-4 <1.3. Obesity was associated with increased odds of FIB-4 <1.3 (OR 2.11, 95%CI 1.00–4.41, p = 0.049) (Figure 1). Subgroup analysis of patients without cirrhosis was conducted due to the high reported prevalence of HCC in the absence of cirrhosis in patients with MASLD. In subgroup analysis of 229 patients with MASLD-related HCC without cirrhosis, 29 patients had FIB-4 <1.3 (12.66%). Multivariate analysis found that obesity continued to be associated with increased odds of FIB-4 <1.3 in patients without cirrhosis (OR 2.85, 95%CI 1.16–6.92, p = 0.021).
Conclusion: Obesity was associated with increased likelihood of FIB-4 <1.3 in patients with MASLD-related HCC, regardless of the presence of cirrhosis. Further studies are required to evaluate the effectiveness of FIB-4 as a risk stratification tool in the general population for patients with obesity.

WED-283

The distribution of fibrosis-4 index and vibration-controlled transient elastography-derived liver stiffness measurement for patients with metabolic dysfunction associated steatotic liver disease in the general population

Yuji Ogawa[1], Wataru Tomeno[2], Imamura Yasushi[3], Masaru Baba[4], Takato Ueno[5], Takashi Kobayashi[6], Michihiro Iwaki[6], Asako Nogami[6], Takaomi Kessoku[7], Yasushi Honda[6], Kento Imajo[8], Miwa Kawanaka[9], Mitsurou Hisatomi[10], Mamiko Takeuchi[11], Takashi Honda[12], Miwa Tatsuta[13], Asahiro Morishita[14], Shigeru Mikami[15], Ken Furuya[4], Noriaki Manabe[9], Tomoari Kamada[9], Takumi Kawaguchi[16], Masato Yoneda[6], Satoru Saito[17], Atsushi Nakajima[6]. *[1]NHO Yokohama Medical Center, Yokohama, Japan; [2]International University of Health and Welfare Atami Hospital, Atami, Japan; [3]Kagoshima Kouseiren Hospital, Kagoshima, Japan; [4]JCHO Hokkaido Hospital, Sapporo, Japan; [5]Kurume University, Kurume, Japan; [6]Yokohama City University Graduate School of Medicine, Yokohama, Japan; [7]International University of Health and Welfare Narita Hospital, Narita, Japan; [8]Shin-yurigaoka General Hospital, Kawasaki, Japan; [9]Kawasaki Medical School General Medical Center, Okayama, Japan; [10]Tsushima city hospital, Tsushima, Japan; [11]Anjo Kosei hospital, Anjo, Japan; [12]Nagoya University Graduate School of Medicine, Nagoya, Japan; [13]KKR Takamatsu Hospital, Takamatsu, Japan; [14]Kagawa University, Kita-gun, Japan; [15]Kikkoman General Hospital, Noda, Japan; [16]Kurume University School of Medicine, Kurume, Japan; [17]Sanno Hospital, Tokyo, Japan*
Email: yuji.ogawa01@gmail.com

Background and aims: The multisociety consensus nomenclature has introduced steatotic liver disease (SLD) with diverse sub-classifications which are metabolic dysfunction associated steatotic liver disease (MASLD), metabolic dysfunction and alcohol associated steatotic liver disease (MetALD), alcohol-associated liver disease (ALD), specific etiology, and cryptogenic. We investigated their prevalence, as per the new definition, in the general population. Additionally, we analyzed the distribution of fibrosis-4 (FIB-4) index and vibration-controlled transient elastography (VCTE)-derived liver stiffness measurement (LSM) for MASLD.
Method: In this cross-sectional study, 6, 530 subjects undergoing health check-ups were included. Conventional B-mode ultrasound was performed on all 6, 530 subjects, and those with MASLD were performed VCTE.
Results: The prevalence of SLD was 39.5%, comprising MASLD 28.7%, MetALD 8.6%, ALD 1.2%, specific etiology SLD 0.3%, cryptogenic SLD 0.7%. Subjects with VCTE-derived LSM ≥8 kPa constituted 2.1%. FIB-4 ≥1.3 showed that the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for diagnosing VCTE-derived LSM ≥8 kPa were 60.6%, 77.0%, 5.3%, and 98.9%, respectively. The referral rate to specialists was 23.8% using FIB-4 ≥1.30. "FIB-4 ≥1.3 in subjects <65 years and FIB-4 ≥2.0 in subjects ≥65 years" showed higher PPV (6.7%) and lower referral rate (17.1%) compared with FIB-4 ≥1.3, but the sensitivity (54.5%) of that was not adequate diagnostic capability as non-invasive test for diagnosing VCTE-derived LSM ≥8 kPa.
Conclusion: Acknowledging the selection bias in hepatology centers, we conducted this prospective general population-based study. While the FIB-4 index proves to be a convenient marker, it might not perform well as a primary screening for liver fibrosis in the general population. UMIN Clinical Trials Registry No. UMIN000035188.

WED-284-YI

The Fatty Liver Index (FLI) is more accurate than FIB-4 for detection of advanced liver fibrosis in patients with type-2 Diabetes Mellitus (T2DM) in Primary Care

Email: runadal@recerca.clinic.cat

Background and aims: The prevalence of advanced fibrosis (AF) in patients with T2DM may be as high as 20% due to the high prevalence of metabolic-associated steatotic liver disease (MASLD). Non-invasive tests, particularly FIB-4, have been proposed as the first step for early identification of AF in this population. This is mainly based on studies performed in cohorts from secondary care or specialized units. However, little information exists on prevalence of AF and usefulness of FIB-4 in the diagnosis of AF in patients with T2DM from Primary Care. The aim of this study was to assess the prevalence of AF in patients with T2DM from Primary Care as well as investigate the usefulness of FIB-4 in the diagnosis of AF.
Method: Cross-sectional study performed in a Primary Care practice in Barcelona. Patients were randomly identified from the center's database and invited to participate through telephone contact. Patients who accepted (54.7%) had a visit by a study nurse with collection of demographic and clinical data, anthropometric measurements, standard lab tests, and transient elastography to measure liver stiffness (LS). Patients with FIB-4 >1.3 (2.0 if age >65 years) or with LS ≥8 kPa were referred to the Hospital for a specialized visit.
Results: 430 patients were recruited, 64% men, with a mean age of 69 (SD ± 10) years. The most frequent comorbidity was arterial hypertension (72%), followed by dyslipidemia (69%), obesity (31%), and high-risk alcohol consumption (7%; >21 SU/w in men or >14 in women). The prevalence of AF, defined as LS >10 kPa, was of 4.7%. Mean LS in these patients was 12.2 kPa (SD ± 2.52). Etiologies of liver disease in these patients were MASLD and MetALD. Factors associated with an increased risk of AF were obesity [9% vs 3%, in patients with and without obesity, respectively; p = 0.004; OR = 3.35 (95%CI 1.39–8.04)] and high-risk alcohol consumption [15% vs 4%, respectively, p = 0.005; OR = 4.15 (95%CI 1.42–12.11)]. FIB-4 identified correctly only 32% of patients with LS >10 kPa. On the other hand, 104 patients

with elevated FIB-4 had LS ≤10 kPa (Se = 32%, Sp = 75%, PPV = 6%, NPV = 95%). By contrast, Fatty Liver Index (FLI), a score that estimates the degree of hepatic steatosis, identified correctly 86% of patients with AF (Se = 86%, Sp = 43%, PPV = 8%, NPV = 98%). The accuracy of FLI for the diagnosis of AF, as estimated by the ROC curve, was greater than that of FIB-4 [FLI = 0.77 (0.66–0.87) vs FIB-4 = 0.54 (0.39–0.70); p = 0.034].
Conclusion: The prevalence of AF in patients with T2DM in Primary Care was 4.7%, a value lower than that reported in cohorts from specialized care. Obesity and alcohol risk consumption were risk factors of AF. The accuracy of FIB-4 in identifying AF was only modest. FLI outperformed FIB-4 for identification of patients with AF. These results suggest that FLI but not FIB-4 should be used as the first step of assessment of liver fibrosis in patients with T2DM in Primary Care.

WED-285
Predicting significant hepatic steatosis from routine biochemistry in people with and without type 2 diabetes (T2D)
Magdalena Nowak[1], Andrea Dennis[1], Helena Thomaides Brears[1], Rajarshi Banerjee[1], Kenneth Cusi[2], Naim Alkhouri[3], Daniel Cuthbertson[4]. [1]*Perspectum Ltd., Oxford, United Kingdom;* [2]*University of Florida, Gainsville, FL, United States;* [3]*Arizona Liver Health, Chandler, Arizona, United States;* [4]*University of Liverpool, Liverpool, United Kingdom*
Email: magdalena.nowak@perspectum.com

Background and aims: Quantifying liver fat content (LFC) using MRI and assessing LFC change in response to therapy has been widely used as a primary end point in early-phase clinical trials of therapeutic agents for metabolic dysfunction-associated liver disease (MASLD). Identifying individuals with LFC of 8% or higher is typically used as an inclusion criterion and various blood-based biomarkers have been proposed, but their value has not been extensively studied in T2D. We aimed to identify the optimal combination of anthropometric and routinely available biochemical tests to better identify patients with high LFC.
Method: Data from participants with suspected MASLD were pooled from three clinical studies; with T2D (N = 173, 41% female, median age: 60y, mean: LFC = 11%, BMI 31 kg/m^2) and without T2D (N = 114, 46% female, median age: 55 y, mean: LFC = 12%, BMI 31 kg/m^2). Additional validation datasets were analysed: with T2D (N = 305, 43% female, median age: 58 y, mean: LFC = 16%, BMI 34 kg/m^2) and without (N = 452, 51% female, median age: 49 y, mean: LFC = 10%, BMI 30 kg/m^2). LFC was measured using either magnetic resonance imaging (proton-density fat fraction) or proton magnetic resonance spectroscopy. The diagnostic accuracy was evaluated using Area Under the Receiver Operating Characteristic curve (AUROC). Stepwise logistic regression was performed to select the optimal combination of continuous predictor variables. The Fatty Liver Index (FLI), Hepatic Steatosis Index (HSI) and controlled attenuation parameter (CAP) measured by Fibroscan were also assessed, where available.
Results: LFC (≥8%) was most effectively predicted by a simple combination of serum ALT and triglycerides. This model showed good diagnostic accuracy, in both training and validation datasets, in individuals with T2D (Training: AUC 0.78, CI: 0.68–0.88; PPV = 0.86; Validation: AUC: 0.83, CI: 0.78–0.88, PPV = 0.88) and without (Training: AUC: 0.83, CI: 0.73–0.93; PPV = 0.88; Validation: AUC: 0.86, CI: 0.82–0.90, PPV = 0.7). Addition of waist circumference did not significantly increase AUC (0.82–0.87; DeLong test p > 0.05). The accuracy of FLI and HSI was less consistent across both T2D and non-T2D groups (FLI, AUC range: 0.73–0.82, PPV range = 0.53–0.9; HSI, AUC range: 0.72–0.76, PPV range = 0.57–0.86). In T2D, the CAP score was less accurate (AUC: 0.71, CI: 0.58–0.83; PPV = 0.77).
Conclusion: This study demonstrates that the combination of ALT and triglycerides accurately identifies patients with LFC of 8% or higher. The integration of such models into the patient recruitment process in hepatology and endocrinology clinics could effectively reduce screen failure rates in clinical trials for MASLD.

WED-286
Identification of serum metabolome signatures associated with hepatocellular carcinoma in metabolic dysfunction-associated steatohepatitis
Atsumasa Komori[1], Kosuke Matsumoto[1], Yuki Kugiyama[1], Tomoyuki Suehiro[1], Yasuhide Motoyoshi[1], Akira Saeki[1], Shinya Nagaoka[1], Kazumi Yamasaki[1], Hiroshi Yatsuhashi[1]. [1]*NHO Nagasaki Medical Center, Omura, Japan*
Email: atsuriko1027@yahoo.co.jp

Background and aims: As the incidence of hepatocellular carcinoma (HCC) that arose in metabolic dysfunction-associated steatohepatitis (MASH) is increased worldwide, establishing an effective risk assessment and early diagnosis of HCC among MASH is much anticipated. On the other hand, not only genetic alterations, but also inflammatory humoral factors, that show causal relationship to hepatocarcinogenesis in MASH are still elusive. Serum metabolome is a promising candidate for the non-invasive monitoring of various disease status, reflecting host primary metabolites, gut microbiome, and dietary factors, all of which are likely associated with outcomes of disease. The aim of the study is to identify the serum metabolites in MASH that are associated with the occurrence of HCC.
Method: We profiled serum metabolites of patients with MASH with (n = 11) and without HCC (n = 21: Control) using a comprehensive non-targeted metabolomics approach with LC-MS/CE-MS. Differentially detected metabolites (DDMs) in those with HCC were defined statistically significant with p < 0.05 (t-test) and q < 0.1 (FDR). All HCC were diagnosed primary as a solitary lesion in pathology-proven MASH patients (Brunt stage 4; n = 5/3; n = 3/2; n = 2/1; n = 1, male n = 9/female n = 2, mean age 73.5), with 31mm of mean diameter (range: 20–37 mm). The demographics of Control patients were as follows: Brunt stage 4; n = 0/3; n = 3/2; n = 12/1; n = 6, male n = 8/female n = 13, mean age 64.5).
Results: 28 DDMs were demonstrated among 336 metabolites being identified by LC-MS/CE-MS. Top two significantly increased metabolites in HCC patients were 3-Methyladipic acid ($p = 5.2 \times 10^{-5}$) and 2-hydroxybutyric acid ($p = 5.1 \times 10^{-5}$), whereas top two in decrease were TG (58:9) and PE (40:4). Levels of 3-Methyladipic acid, a surrogate of omega-oxidation of free fatty acid (FFA), were not differed according to fibrosis stage and were significantly correlated with those of 2-hydroxybutyric acid (r = 0.7222, p < 0.0001), cortisol (r = 0.7306, <0.0001), and progesterone (r = 0.7861, <0.0001). PUFA-rich TG, *e.g.* TG (58:7), TG (58:9), and TG (58:10), were significantly decreased in HCC patients (p = 0.002, p = 0.00029, and p = 0.00098, respectively), whereas TG with saturated FFA, *e.g.* TG (46:0) and TG (48:0) were not (p = 0.41 and p = 0.41, respectively).
Conclusion: Our metabolome analysis exploratory identified the serum metabolite features of MASH patients with HCC, some of which may potentially be biomarkers for MASH-associated hepatocarcinogenesis.

WED-287
Sequential approach using combination of newly developed HOMA2-IR-ALT-TE-MASH (HALT-M) score and magnetic resonance elastography for non-invasive identifying at-risk metabolic dysfunction-associated steatohepatitis in obese subjects
Seung Kak Shin[1], Yoonseok Lee[1], Oh Sang Kwon[1], Yun Soo Kim[1], Ju Hyun Kim[1], Dae Ho Lee[2]. [1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, Gachon University College of Medicine, Gil Medical Center, Incheon, Korea, Rep. of South;* [2]*Division of Endocrinology, Department of Internal Medicine, Gachon University College of Medicine, Gil Medical Center, Incheon, Korea, Rep. of South*
Email: drhormone@naver.com

Background and aims: Presence of metabolic dysfunction-associated steatohepatitis (MASH) and significant fibrosis are associated with increased risk of disease progression and poor clinical outcomes in metabolic dysfunction-associated steatotic liver disease (MASLD) patients. Insulin resistance has been suggested to play a crucial role in

the pathogenesis of MASH. However, this has been given little consideration in most of the non-invasive markers for identifying at-risk MASH. This study aimed to develop the non-invasive sequential approach using combination of HOMA2-IR-ALT-TE-MASH (HALT-M) score and magnetic resonance elastography (MRE) for diagnosis of borderline/definite MASH [MASLD activity score (MAS) ≥4] and at-risk MASH (MAS ≥4 and fibrosis stage ≥2).

Method: Obese (BMI ≥25 kg/m^2) MASLD patients were prospectively enrolled at Gachon University Gil Medical Center between March 2018 and January 2023. All patients underwent histological confirmation. Newly developed HALT-M score consists of three risk factors: 1) presence of HOMA2-IR ≥2.35 or DM, 2) increased ALT (men ≥35 U/L, women ≥25 U/L), 3) transient elastography (TE) >8.0 kPa. The three factors were given a score of 1 point each, and a score of 0–3 was calculated and used for non-invasive diagnosis of borderline/definite MASH or at-risk MASH. And combination of HALT-M score and MRE (HALTME index) was used for non-invasive diagnosis of at-risk MASH. Diagnostic performance was evaluated based on the areas under the receiver operating characteristic curve (AUCs).

Results: A total 84 patients (mean age of 35 ± 11 years; 79.8% of female; mean BMI of 37.6 ± 6.1 kg/m^2; 35.7% of DM; 84.5% of bariatric surgery) were finally enrolled. At histological confirmation, 43 (51.2%) and 16 (19.0%) patients were diagnosed with borderline/definite MASH and at-risk MASH, respectively. The sensitivity, specificity, PPV, and NPV of HALT-M score ≥2 for diagnosis of borderline/definite MASH were 91%, 60%, 71%, 86%, respectively (AUC 0.753; 95% CI 0.645–0.862, p < 0.001). The sensitivity, specificity, PPV, and NPV of HALT-M score ≥2 for diagnosis of at-risk MASH were 100%, 41%, 29%, 100%, respectively (AUC 0.709; 95% CI 0.594–0.824, p < 0.001). The sensitivity, specificity, PPV, and NPV of HALTME index (HALT-M score ≥2 plus MRE ≥3.6 kPa) for diagnosis of at-risk MASH were 80%, 90%, 63%, 95%, respectively (AUC 0.849; 95% CI 0.723–0.974, p < 0.001).

Conclusion: Newly developed HALT-M score including HOMA2-IR, ALT and TE demonstrated high sensitivity in diagnosis of borderline/definite MASH and at-risk MASH. The sequential addition of MRE value increased the specificity for diagnosis of at-risk MASH, showing good diagnostic performance. A large-scale validation study is warranted.

WED-290

Assessment of transient elastography (FibroScan) in obesity patients with non-alcoholic fatty liver disease: a meta-analysis

Ziping Lin[1], Taoyuan Li[1], Jieying Li[1], Yi Liu[1], Xujing Liang[1]. [1]*The First Affiliated Hospital of Jinan University, Guangzhou, China*
Email: lxjlxj.lxj@163.com

Background and aims: Obesity is strongly associated with non-alcoholic fatty liver disease (NAFLD). Among the non-invasive tests, controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) have shown better diagnostic performance in NAFLD. However, the accuracy of Fibroscan in patients with obesity (body mass index (BMI) ≥30 kg/m^2) is not well-defined. This meta-analysis aimed to evaluate the performance of CAP and LSM for assessing steatosis and fibrosis in NAFLD patients with obesity.

Method: We searched the PubMed, Web of Science, Cochrane Library, and Embase databases for relevant articles published up to November 16th, 2023, and selected obese patients with NAFLD diagnosed by liver biopsy. Then we pooled sensitivity (SE), specificity (SP), and area under receiver operating characteristic (AUROC) curves.Quality of the included studies was assessed with the QUADAS-2 tool. Stata 17 and MetaDiSc1.4 were used to meta-analyze.

Results: A total of 19 articles were included which consisted of 2349 patients with NAFLD (BMI ≥30 kg/m^2). The AUROC of FibroScan in identifying the stage of steatosis for ≥S1 was 0.85 (sensitivity:80%; specificity:78%), that for ≥S2 was 0.80 (sensitivity:80%; specificity:66%) and that for S3 was 0.79 (sensitivity:87%; specificity:68%). The AUROC of FibroScan in identifying the stage of fibrosis for ≥F2 was 0.82 (sensitivity:80%;specificity:73%), that for ≥F3 was 0.77 (sensitivity: 75%; specificity:85%), and that for F4 was 0.97 (sensitivity: 97%; specificity:90%). The average values of the optimal cutoff values by fibroscan for S≥1, ≥2, and =3 are 295 dB/m, 314 dB/m, 331 dB/m, respectively. The average values of the optimal cutoff values by fibroscan for F≥2, ≥3, and =4 are 8.1 kPa, 9.9 kPa, and 13.1 kPa, respectively.

Conclusion: FibroScan still be reliable for quantifying and staging hepatic steatosis and fibrosis in patients with obesity (BMI ≥30 kg/m^2).The diagnostic performance of CAP decreased with the severity of liver steatosis. The average value of the optimal cutoff value for CAP was relatively high in obestiy patients.LSM has shown good accuracy in assessing significant liver fibrosis (AUC = 0.82), advanced liver fibrosis (AUC = 0.77), espeicially liver cirrhosis (AUC = 0.97) in obese patients. Further studies are needed to explore the result.

WED-291

New optimal cut-points for vibration controlled transient elastography and MR elastography for advanced fibrosis in hispanic versus non-hispanic adults with metabolic dysfunction-associated steatotic liver disease

Monica Tincopa[1], Ricki Bettencourt[1], Egbert Madamba[1], Harris Siddiqi[1], Lisa Richards[1], Rohit Loomba[1]. [1]*UCSD, San Diego, United States*
Email: mtincopa@health.ucsd.edu

Background and aims: Cut-points for non-invasive tests (NITs) in metabolic dysfunction-associated steatotic liver disease (MASLD) were derived from predominantly non-Hispanic populations. The aim of this study is to assess the performance characteristics of current NIT-based risk stratification cut-points to identify advanced fibrosis among Hispanic patients with biopsy-proven MASLD and to identify if alternative cut-points can improve NIT performance.

Method: This prospective cohort enrolled 244 well-characterized adults with biopsy-proven MASLD. Those with significant alcohol use, other causes of liver disease, and decompensated cirrhosis were excluded. Patients underwent a clinical research visit with vibration controlled transient elastography (VCTE), and MR elastography (MRE). Biopsies were read by one experienced hepatopathologist blinded to clinical data. We assessed the performance of currently recommended cut-points for VCTE and MRE to identify advanced (F≥3) fibrosis (VCTE 9.7, MRE 3.63) among Hispanic versus non-Hispanic individuals. We identified alternative cut-points that optimized VCTE and MRE performance for Hispanic individuals using Youden's J analysis.

Results: The mean age was 52.6 years, with 43% males, mean body-mass-index 31.6 kg/m^2 with 40% with diabetes and 31% (N = 75) Hispanic. Overall, 78 (32%) had significant fibrosis and 50 (20.4%) had advanced fibrosis on biopsy (40% and 28% among Hispanics, respectively). For advanced fibrosis, VCTE had an area under the receiving operator curve (AUROC) of 0.79 (0.66–0.92) vs 0.93 (0.89–0.98) (p = 0.04) and MRE had an AUROC of 0.90 (0.83–0.97) vs 0.96 (0.93–0.99) (p = 0.12) in Hispanic vs non-Hispanic adults, respectively. In Hispanic individuals, the cut-points for advanced fibrosis for 90% sensitivity for VCTE and MRE was >4.4 and >2.77 kPa, and for 90% specificity was >11.9 and >3.58 kPa, respectively. Using Younden's J analysis, the optimal cut-point for advanced fibrosis in Hispanic individuals for VCTE was 8.8 kPa and 2.73 kPa for MRE.

Conclusion: In a well-characterized cohort of adults with biopsy-proven MASLD, Hispanic individuals had higher prevalence of significant and advanced fibrosis. Currently recommended cut-points for VCTE and MRE for advanced fibrosis in MASLD had inferior performance among Hispanic compared to Non-Hispanic individuals. Given higher disease burden and more advanced disease, our analyses suggest that implementing lower cut-points for VCTE and MRE for advanced fibrosis may optimize screening and risk stratification for Hispanic individuals with MASLD.

WED-292

Non-invasive diagnosis of significant portal hypertension based on prealbumin proteomics model

Xiaoyan Wang[1], Chuan Liu[2], Jianhong Wang[1], Yunfang Liu[1], Dong Wang[1], Xiaoqing Guo[3], Ying Guo[4]. *[1]Deparment of Hepatology, The Third People's Hospital of Taiyuan, Taiyuan, China; [2]Center of Portal Hypertension, Department of Radiology, Zhongda Hospital, Medical School, Southeast University, Nanjing, China; [3]Department of Hepatology, The Third people's Hospital of Taiyuan, Taiyuan, China; [4]Department of Hepatology, The Third People's Hospital of Taiyuan, Taiyuan, China*
Email: taiyuanguoying001@163.com

Background and aims: The clinical significant portal hypertension (CSPH) is associated with the increased risk of decompensated cirrhosis in patients. However, the gold standard for its diagnosis, the measurement of hepatic venous pressure gradient (HVPG)is invasive, expensive, and requires a certain level of technical expertise from the operator. This study aims to explore the diagnostic value of a non-invasive model based on prealbumin (PA) proteomics for CSPH in patients with cirrhosis.
Method: This is a Retrospective study.A total of 176 patients with compensated cirrhosis who underwent HVPG measurement were included in this study. They were admitted to the Third People's Hospital of Taiyuan from January 2022 to December 2022. According to the results of HVPG, they were divided into CSPH group (n = 104) and Non-CSPH group (n = 72). CSPH was defined as the threshold of HVPG measurement above 10 mmHg.
Results: There were significant differences in PA, MELD score, and Child-Pugh Class between the two groups ($p < 0.05$); Serum PA levels were negatively correlated with HVPG in all patients ($r = -0.592$, $P < 0.05$); Ordered Logistic regression analysis showed that serum PA (OR = 0.99, 95%, CI: 0.98–1.00), PLT (OR = 0.99, 95%, CI: 0.98–1.00), and INR (OR = 184.01, 95%, CI: 4.19–8088.42) were independent risk factors for CSPH. In the diagnosis of CSPH, the AUC value of PA was 0.80 (0.73–0.87) ($p < 0.05$), and the optimal critical value was 141.00 mg/L. Its sensitivity was 69.2%, specificity was 81.9%, positive predictive value was 84.7%, and negative predictive value was 64.8%.
Conclusion: Based on the serum prealbumin, the established non-invasive assessment model is simple and feasible, and it has good predictive value for CSPH.

WED-293

Effectiveness of on different models of care based on Fibrosis-4 and/or liver stiffness measurement for the screening of patients with type 2 diabetes mellitus at risk of advanced liver disease

Email: elisabetta.bugianesi@unito.it

Background and aims: Patients with type 2 diabetes mellitus (T2DM) are at increased risk of advanced liver fibrosis and should be entered into risk stratification pathways for appropriate referral to hepatologists. An optimal model of care should allow the identification of the largest proportion of high-risk patients without overwhelming hepatology clinical services. In a cohort of patients with T2DM consecutively referred by diabetes Units, we aimed to investigate the efficacy of different models of care based on Fibrosis-4 (FIB-4) and/or vibration controlled transient elastography (VCTE) for the identification of patients needing referral to hepatology clinic.
Method: From April 2021 to October 2023, a total of 706 consecutive T2DM patients at their first referral to 6 different diabetology clinics were prospectively enrolled. All patients underwent liver stiffness measurement (LSM) by VCTE and liver steatosis assessment by controlled attenuation parameter (Fibroscan, Echosens, France). A LSM cut-off value of 8.0 kPa was used to rule out advanced liver fibrosis. Patients were stratified according to FIB-4 values <1.30, 1.30–2.67, and >2.67.
Results: Patients' median age was 59 (IQR 53–65) years and 411 (58.2%) of them were males; 370 (52.4%) patients were obese (BMI ≥30 kg/m^2) and 446 (64.3%) had arterial hypertension. Median LSM was 5.3 (IQR 4.3–6.5) kPa; 111 (14.6%) of patients had LSM ≥8.0 kPa. Median FIB-4 value was 1.05 (IQR 0.80–1.40); 490 (69.4%) patients had FIB-4 <1.30, 197 (27.9%) had FIB-4 between 1.30 and 2.67, while 19 (2.7%) patients showed FIB-4 values ≥2.67. In our cohort of T2DM patients, a 2-tier screening for advanced liver fibrosis by FIB-4 followed by VCTE would have led to 50 (7.1%) patients referred to the hepatologist, despite a false negative rate of 8.6% (n = 61). A single tier screening based on FIB-4 ≥1.3 would have resulted in an overflow of patients (n = 216; 30.6%) to hepatology clinic, while a FIB-4 >2.67 would have caused a disproportionate rate of false negative patients (n = 103; 14.6%). Finally, a first line screening based on VCTE would have resulted in a referral rate to hepatologists of 14.6% (n = 111) with a low probability of missing patients at risk of advanced liver fibrosis. However, first-line screening with VCTE could be unfeasible in resource-limited settings.
Conclusion: In diabetology clinics, the most appropriate screening approach for the identification of high-risk patients that require hepatologist's referral should be determined according to local health-care resources. *This research was supported by Gilead Sciences, Inc (study ID: IN-IT-989-5790).*

The use of the FibroScan-AST score and AST to pre-identify metabolic dysfunction-associated steatohepatitis patients with active fibrogenesis in a Phase 1b open-label clinical trial

Mazen Noureddin[1], Eric Lawitz[2], Naim Alkhouri[3], Zeid Kayali[4], Madhavi Rudraraju[5], Edward Mena[6], Rohit Loomba[7], Tarek Hassanein[8], Parvez Mantry[9], Mohammad Siddiqui[10], Kathryn Jean Lucas[11], Garry Reiss[12], Oni Aneiros[13], Dawn Farno[13], Shawna Differding[13], Debbie Marshall[13], Jaime Biracree[13], Bruno Devadas[14], Praveena Reddy[14], Chetna Patel[14], Jennifer Tsau[14], Michael Chen[14], Michelle Mendoza[14], Scott Butler[14], Holly Oakley[14], Wendi Lichtenberger[14], Shannon Hambridge[14], Paresh Thakker[14], Haakan Wennbo[14], Peter Nagy[14], Zoltan Derdak[14]. *[1]Houston Research Institute, Houston, TX, United States; [2]Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, United States; [3]Arizona Liver Health, Chandler, AZ, United States; [4]Jubilee Clinical Research, Rialto, CA, United States; [5]Pinnacle Clinical Research, San Antonio, TX, United States; [6]California Liver Research Institute, Pasadena, CA, United States; [7]University of California San Diego School of Medicine, La Jolla, CA, United States; [8]Southern California Research Center, Coronado, CA,*

Email: zoltan.derdak@takeda.com

Background and aims: Identifying patients with active fibrogenesis in proof-of-concept studies is an unmet need. We assessed screening data from an internal Phase 1b open-label clinical trial that is aimed to enroll patients with active fibrogenesis. Elevated Pro-C3 (≥12.6 ng/ml) and enhanced liver fibrosis (ELF) score ≥7.7 are active fibrogenesis markers and were used as key inclusion criteria in this study. We aimed to establish a pre-identification strategy that would make qualification on Pro-C3 and ELF more likely based on clinical parameters. We have assessed these clinical parameters and their cut-offs to help identifying patients with active fibrogenesis.
Method: Up to January 01, 2024, we have screened 114 patients with presumed fibrotic MASH. In 103 cases Pro-C3 and ELF values were available (both measured at Nordic Bioscience). All patients with qualifying Pro-C3 also qualified on ELF, therefore assessments focused on correlations between Pro-C3 and clinical parameters. Based on our findings, we performed Pearson's correlation tests between Pro-C3 and AST, liver stiffness measurement (LSM), Controlled Attenuation Parameter (CAP), and the overall FibroScan-AST (FAST) score. We stratified screened patients based on Pro-C3 qualification, determined the difference in AST, LSM, and FAST, and identified thresholds in AST and FAST that increased the likelihood of qualifying on Pro-C3.
Results: Pro-C3 statistically significantly ($p < 0.0001$) correlated with AST ($r = 0.4301$) and the FAST score ($r = 0.5071$). The correlation with CAP was low but reached statistical significance ($r = 0.1986$, $p = 0.0499$). The correlation with LSM was not significant ($r = 0.1034$, $p = 0.3109$). Those with qualifying Pro-C3 had statistically significantly higher mean AST (53.12 vs 33.13 U/L), FAST (0.6413 vs 0.3432) and CAP values (336.6 vs 314.5 kPa) but there was no statistically significant difference in LSM (12.12 vs 10.82 kPa, $p = 0.3144$). 77.27% of patients with AST<35 U/L and 86.67% of patients with FAST<0.35 failed on Pro-C3. Patients with qualifying Pro-C3 were more likely to have an AST ≥35 U/L (68.97%) and FAST ≥0.35 (67.68%). The Area Under the Receiver Operating Characteristic curve (AUROC) value describing the performance to distinguish patients with qualifying vs non-qualifying Pro-C3 was 0.7936 for AST and 0.8068 for FAST.
Conclusion: There have been limited stratification of MASH patients who have active fibrogenesis as evidenced by elevated Pro-C3/ELF levels. Commonly available clinical data can be used to increase the likelihood of qualification based on Pro-C3/ELF. This data may include AST and FAST that reflect the activity of steatohepatitis-a driver of fibrogenesis-and correlate with Pro-C3 levels. This finding highlights that fact that focusing on patients with FAST ≥0.35 and AST ≥35 U/L will increase the chance of providing direct biochemical evidence for active fibrogenesis.

WED-295-YI
Unmasking racial disparities of MASLD screening guidelines: underdiagnosis of MASLD among black patients with obesity

Gres Karim[1], Navim Mobin[1], Pratishtha Singh[1], Sara Hasan[2], Saamia Faruqui[1], Ilan Weisberg[1], Amreen Dinani[3]. *[1]New York Presbyterian Brooklyn Methodist Hospital, Brooklyn, United States; [2]New York Presbyterian Brooklyn Methodist Hospital, Brooklyn, United States; [3]New York Presbyterian Brooklyn Methodist Hospital, Brooklyn, United States*
Email: karimgres@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is rapidly increasing globally and is often underdiagnosed and undertreated. While considered to be less prevalent with a less aggressive course in the black population, evidence shows higher risk for all-cause mortality including HCC outcomes emphasizing the need for urgent awareness. The fibrosis 4 index (FIB-4) has been proposed as the initial non-invasive test (NIT) to screen for fibrosis, however its performance is varied, possibly leading to misrepresentation of disease burden in certain populations. We aimed to understand the disease burden in a cohort of black individuals with obesity (body mass index [BMI] >30 kg/m^2) and undiagnosed MASLD, while also investigating disparities in the early detection of MASLD through the diagnostic performance of the FIB-4 and NAFLD Fibrosis score (NFS).
Method: Patients with a diagnosis of obesity (BMI >30 kg/m^2) without documented chronic liver diseases (CLD) or MASLD were identified using electronic medical record (EMR) from a tertiary care gastroenterology clinic between 01/2019 to 01/2020. Demographic information, markers of liver inflammation and synthetic function, medical conditions, and imaging were recorded. FIB-4 and NFS were calculated to determine the stage of liver fibrosis. Outcomes including cirrhosis, development of hepatocellular carcinoma (HCC) and liver-related mortality were noted.
Results: 1082 patients with a BMI >30 kg/m^2 and no diagnosis of CLD or MASLD were identified. We identified 236 (22%) black patients, of which majority were female (78%), mean age was 57 years (SD 13), mean BMI was 36.3 kg/m^2 (SD 16.3), 73 were diabetic, 135 had hypertension, and 14 had coronary artery disease. Average AST and ALT were 22.7 and 22.8 U/L, respectively. 130 patients had class I obesity (BMI 30–34.9), 62 had class II obesity (BMI 35–39.9) and 44 had class III obesity (BMI >40). Mean FIB-4 was 1.20 and mean NFS was 0.69. While increased NFS was seen with increase in BMI (−0.082 in class I obesity; 1.26 in class III obesity), an inverse association was detected with increasing obesity class and FIB-4 (1.29 in class I obesity; 0.95 in class III obesity). In this cohort, 22 patients developed cirrhosis, 10 developed HCC and 4 died from liver-related causes. FIB-4 and NFS were higher in patients who developed cirrhosis.
Conclusion: In a cohort of black patients with obesity and undiagnosed MASLD, two NITs produced widely discordant results; mean FIB-4 was 1.20, suggesting F0-F1 fibrosis, while mean NFS was 0.69, indicative of advanced fibrosis. Based on current recommendations, relying on FIB-4 alone overlooked 45% of black patients who could benefit from secondary fibrosis assessment, delaying diagnosis in a vulnerable and often underdiagnosed group. Further studies are needed to ascertain if NFS performs better than FIB-4 in screening black patients for MASLD.

PLIN2 is a specific marker for liver related disease

Giulia Angelini[1], Sara Russo[1], Federico Biscetti[2], Andrea Flex[2], Jérôme Boursier[3], Sven Francque[4], Aldo Trylesinski[5], Stephen A. Harrison[6], Geltrude Mingrone[1]. *[1]Università Cattolica del Sacro Cuore, Rome, Italy; [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; [3]Angers University Hospital, Angers, France; [4]Antwerp University Hospital, Edegem, Belgium; [5]Metadeq, London, United Kingdom; [6]Radcliffe Department of Medicine, University of Oxford, UK, Oxford, United Kingdom*
Email: giulia.angelini@unicatt.it

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) represents the leading cause of chronic liver disease worldwide. Among those with MASH, cardiovascular disease (CVD) is the most common cause of mortality. MASH was also shown to be associated with the development of atherosclerosis and subclinical CVD. Monocytes can accumulate large amounts of lipids, transform into foam cells and drive atherogenesis. The same process of accumulation of lipid-loaded monocytes is also observed in MASH. PLIN2 is a major lipid droplets-associated protein in monocytes that has been linked to both atherosclerosis and MASH. Indeed, several studies report high levels of PLIN2 in MASH and atherosclerosis. This study aims to compare the levels of PLIN2 in subjects with MASH

with/without CVD as well as in subjects with CVD alone to assess whether PLIN2 is a specific biomarker for liver related disease.
Method: We analyzed 50 subjects with histologically proven MASH who underwent carotid intima-media thickness (CIMT), a marker of subclinical atherosclerosis to assess co-existing CVD. These patients were compared to 50 subjects with CVD assessed by coronary angiography from the cardiovascular unit who had normal liver tests as a proxy for the absence of liver disease.
PLIN2 was measured by ELISA (Abbexa, Cambridge Science Park, UK). To compare the expression of plasma PLIN2 between MASH and CVD subjects, we used Mann-Whitney U test. In the MASH population we performed a linear regression analysis to assess the correlation between PLIN2 and carotid intima-media thickness (CIMT), a marker of subclinical atherosclerosis.
Results: Fourteen % of individuals with MASH exhibited early atherosclerosis, as determined by CIMT. Within the MASH group, there was no differences in PLIN2 expression between those with and without early atherosclerosis (3.80 ± 0.38 vs. 4.25 ± 0.24; p = 0.37). Linear regression analysis of PLIN2 showed no correlation between PLIN2 and CIMT (left CIMT R = 0.04; P = 0.14; right CIMT R = 0.0001; P = 0.95). There was, however, a significantly higher PLIN2 expression in MASH patients compared to those with CVD (0.75 ± 0.09 vs. 3.61 ± 0.55 ng/ml; p < 0.0001).
Conclusion: Plasma PLIN2 is significantly higher in subjects with MASH compared to subjects without MASH but with confirmed CVD. In the MASH population PLIN2 was not able to discriminate subjects with early atherosclerosis, hence PLIN2 did not come out as a marker of CVD. Hepatic biomarkers such as PLIN2 may be used for non-invasive testing and as targets for MASH pharmacological treatment.

WED-297-YI
Characterization of the evolution of liver elasticity in a real-life population with metabolic dysfunction-associated steatotic liver disease: a prospective study
Joyce Scholtens[1], Stéphanie André-Dumont[1], Guillaume Henin[1,2], Géraldine Dahlqvist[1], Nicolas Lanthier[1,2]. *[1]Service d'Hépato-gastroentérologie, Cliniques universitaires Saint-Luc, UCLouvain, Brussels, Belgium; [2]Laboratory of Hepatogastroenterology, Institut de Recherche Expérimentale et Clinique, UCLouvain, Brussels, Belgium*
Email: nicolas.lanthier@saintluc.uclouvain.be

Background and aims: MASLD is very common and its course is variable, but there is little prospective data on the long-term follow-up of these patients. The aim of our study is to evaluate the evolution of liver disease using hepatic elastometry by identifying patients who will improve or progress over time.
Method: Transient elastography was conducted at baseline (Y0) and then reassessed at one year (Y1) and three years (Y3) in this prospective single-center study. Regression or progression of liver disease was determined by a decrease (improvers, *I*) or increase (progressors, *P*) in liver elasticity exceeding 1.5 kPa compared to the baseline value. Patients with elasticity changes ≤1.5 kPa were classified as stable (*S*).
Results: 229 patients were included (126 women and 103 men) with a mean age of 52 years, mean body mass index (BMI) of 33.9 kg/m² and mean waist circumference of 114 cm. 38% were treated for type 2 diabetes. The mean baseline elasticity was 10.5 kPa and the mean controlled attenuation parameter (CAP) was 331.1 dB/m. 44% were classified as F0-F1, 28% as F2, 19% as F3 and 10% as F4. Most patients received lifestyle advice by the hepatologist (69%), others underwent bariatric surgery (13%), were either included in an interventional clinical trial for MASLD/MASH (9%) or referred to the dietitian (8%). 146 patients (64%) and 110 patients (48%) underwent follow-up elastography at Y1 and Y3 respectively. Mean liver elasticity (Y0: 10.5, Y1: 7.8, Y3: 7.9 kPa; p = 0.0008) and CAP (Y0: 331.1, Y1: 307.1, Y3: 317.4 dB/m; p = 0.0007) decreased over time. At Y1 and Y3 respectively, a minority of patients were *P* (18–19%), 49–39% remained *S* and 34–42% were *I*. Compared with *P* or *S* patients, *I* at Y1 exhibit a more severe condition at Y0, characterized by higher BMI (*I*: 34.6, *S*: 31.7, *P*: 32.5 kg/m²; p = 0.05), waist circumference (*I*: 116, *S*: 108, *P*: 110 cm; p = 0.0048), fasting glucose, low HDL, high elasticity (*I*: 12.2, *S*: 6.6, *P*: 7.5 kPa; p < 0.0001) and CAP values. The same is also true for Y3 vs. Y0. At Y1, *I* are characterized by a significant BMI reduction (−3.7 kg/m²; −9%) compared with *S* patients (−1.1 kg/m², −2.6%) and *P* (−0.1 kg/m², −0.4%) (p = 0.0003), as well as a reduction in waist circumference, ALT (*I*: −36%, *S*: −15%, *P*: +5%; p = 0.0036) and GGT values (*I*: −31%, *S*: −12%, *P*: −9%; p = 0.0133). At Y3, *I* also experienced a notable decrease in BMI (-6%) compared to *S* patients (−1.7%) and *P* (+1.7%) (p = 0.0005). All the patients who underwent bariatric surgery demonstrated disease regression at either Y1 or Y3.
Conclusion: These are the first prospective data on the evolution of liver elasticity in MASLD patients. Hepatological management has a beneficial effect on liver stiffness and CAP, particularly among patients with initial severe MASLD. A reduction in BMI by 6 to 9% is correlated with a reduction in hepatic elasticity. A fifth of the population are patients who are progressing, characterised by the absence of weight loss.

WED-298-YI
Myosteatosis is associated with metabolic-associated steatotic liver disease (MASLD) but not liver fibrosis-Results from an Indian cohort
Dinesh Walia[1], Samagra Agarwal[2], Sumaira Qamar[3], Shila Patel[2], Rajni Yadav[2], Kumble S Madhusudhan[2], Deepak Gunjan[4], Anoop Saraya[5]. *[1]All India Institute of Medical Sciences, Gastroenterology and Human Nutrition Unit, New Delhi, India; [2]All India Institute of Medical Sciences, New Delhi, India; [3]All Institute of Medical Sciences, New Delhi, India; [4]All India Institute of Medical Sciences, New Delhi, India; [5]Institute of Liver and Biliary Sciences, New Delhi, India*
Email: dineshwalia.jul21@aiims.edu

Background and aims: Skeletal muscle alterations are seen in MASLD due to complex metabolic derangements in the liver-adipose-muscle axis. Data on the relationship between muscle alterations, specifically muscle fat infiltration (myosteatosis) and MASLD is scarce. Herein, we aimed to study the association of muscle fat infiltration with histological MASLD activity including fibrosis in obese Asian population, and test whether myosteatosis can be a non-invasive biomarker of MASLD.
Method: 124 cases of MASLD (mean age-40.7 ± 10.3 years, 73% males) and 30 healthy renal donors (mean age-45.8 ± 7.9 years, 23% males) as controls were recruited. All patients underwent biochemical tests, transient elastography (TE), bioelectrical impedance (BIA), computed tomography (CT) to measure the psoas muscle density, skeletal muscle fat index of psoas (SMFI Psoas), skeletal muscle index (SMI), visceral adipose tissue index (VATI), hand grip dynamometry for muscle strength assessment and 4-meter gait speed to assess muscle function. Liver biopsy was done for MASLD patients to assess histological activity (NAS-CRN score) and fibrosis stage. SMFI psoas was compared to other non-invasive tests (NITs) to detect 'at risk fibrosis' (F2-F4) among MASLD patients on ROC analysis.
Results: Compared to controls, patients with MASLD had higher muscle mass (CT-SMI 47.48 ± 8.37 vs 43.32 ± 8.72 cm^2/m^2, p-0.01) with similar muscle function and strength. However, patients with MASLD had a higher skeletal muscle fat content than healthy controls (CT- SMFI psoas 87.00 ± 33.41 vs 51.63 ± 21.84, p- 0.0001) and a higher visceral fat content per muscle mass (CT- VATI/SMI of 276.21 ± 105.91 vs 154.26 ± 102 cm^2/m^2, p-0.0001). SMFI psoas values were significantly higher among MAFL with no fibrosis (F0), MASH with mild fibrosis (F1), and MASH with 'at risk fibrosis' (F2-F4) when compared to healthy controls (75.06 ± 30.93, 89.74 ± 36.02, 91.07 ± 32.47 vs 51.63 ± 21.85, p < 0.001). However, when compared within MASLD, patients with MAFL-F0, MASH-F1, and MASH- F2 to F4 (at risk fibrosis) showed a statistically non-significant trend of increasing SMFI psoas values with progressive fibrosis *i.e.* 75.06 ± 30.93, 89.74 ± 36.02 and 91.07 ± 32.47, p-0.087, respectively. When compared to

NITs to detect 'at risk fibrosis' (F2-F4), SMFI psoas (AUROC-0.587) was inferior to liver stiffness-TE (AUROC- 0.844, p- 0.0001) but was comparable to FIB-4 (AUROC-0.686, p- 0.15), NAFLD Fibrosis score (AUROC-0.664, p- 0.29) and APRI (AUROC-0.646, p- 0.41). SMFI psoas had a diagnostic accuracy of 61.29% with a sensitivity and specificity of 64.62% and 57.63% respectively, at a cut-off of 79.54 to distinguish between 'at risk' from no to mild fibrosis in MASLD patients.
Conclusion: Myosteatosis is associated with MASLD independent of the degree of liver fibrosis.

WED-299
Utility of ultrasound attenuation imaging in the detection and grading of hepatic steatosis severity as compared to magnetic resonance imaging proton density fat fraction
Angus Patterson[1], Ross Apostolov[2], Darren Wong[2], Numan Kutaiba[2], Paul Gow[2], Mathis Grossmann[2], Marie Sinclair[2]. [1]*University of Melbourne, Heidelberg, Australia;* [2]*Austin Health, University of Melbourne, Heidelberg, Australia*
Email: ajpatterson@student.unimelb.edu.au

Background and aims: Ultrasound attenuation imaging (US-ATI) is a relatively new method of non-invasive quantification of hepatic steatosis. This study aimed to investigate the discriminatory capabilities of US-ATI to detect different grades of hepatic steatosis as quantified by magnetic resonance imaging proton density fat fraction (MRI-PDFF).
Method: We analysed 115 matched MRI-PDFF and US-ATI pairs in 82 male patients (mean age 51.9 years, standard deviation 12.3 years). All patients had non-alcoholic fatty liver disease (NAFLD) and were enrolled in the testosterone for NAFLD (TNT) randomised controlled trial (ACTRN 12619000701123). US-ATI imaging was performed by an experienced sonographer, using a Canon Aplio i800 ultrasound system. Hepatic steatosis was graded into grade 0 (<5.5% on MRI-PDFF), grade 1 steatosis (5.5% to <15.5%), grade 2 steatosis (15.5% to <20.5%), and grade 3 steatosis (≥20.5%). Pearson's r was used to examine the correlation between US-ATI values and MRI-PDFF percentage. A receiver operating characteristic (ROC) analysis was undertaken, with the area under the ROC curve (AUROC) used to assess the diagnostic performance of US-ATI for each grade of steatosis.
Results: 103 of 115 US-ATI and MRI-PDFF pairs were performed on the same day and all scans were performed within 4 weeks of each other. The median US-ATI values for grades 0, 1, 2 and 3 steatosis were 0.64 (interquartile range (IQR): 0.61–0.81), 0.83 (IQR: 0.75–0.9), 0.88 (IQR: 0.85–1.01), 0.92 (IQR: 0.82–1.05) dB/cm/MHz, respectively. The correlation coefficient between US-ATI and MRI-PDFF was of moderate strength with $r = 0.43$ (95% confidence interval (CI): 0.26–0.56, $p < 0.001$). The median US-ATI values of all steatosis grades showed statistically significant differences between each grade ($p \leq 0.02$), with the exception of grade 2 to 3 steatosis ($p = 0.8$). The AUROC of US-ATI for grades 0, 1, 2 and 3 steatosis was 0.77 (CI: 0.56–0.98), 0.62 (CI: 0.52–0.73), 0.62 (CI: 0.5–0.75) and 0.67 (CI: 0.56–0.78) respectively.
Conclusion: US-ATI had acceptable diagnostic utility for the exclusion of significant hepatic steatosis, which contrasted with poorer performance for the diagnosis of increasing grades of moderate and severe steatosis. Further studies with larger sample sizes are required to compare its diagnostic utility to other non-invasive techniques for measurement of hepatic steatosis such as controlled attenuation parameter measurement from transient elastography, as well as its ability to monitor changes in steatosis longitudinally.

WED-302-YI
A data-driven approach to determine minimum re-testing interval in persons with metabolic dysfunction associated steatotic liver disease
Richard Parker[1], Callum Wood[1], Ian Rowe[1,2]. [1]*Leeds Liver Unit, St James's University Hospital, Leeds, United Kingdom;* [2]*Leeds Institute for Medical Research, University of Leeds, Leeds, United Kingdom*
Email: callum.wood5@nhs.net

Background and aims: Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) is notable for its significant and increasing prevalence. There are no licensed drug therapies for MASLD; the mainstay of treatment is lifestyle modification. However, it is not clear that patients can make significant lifestyle changes or modify disease trajectory without targeted support. This study assesses MASLD disease progression in a tertiary hepatology service in the UK.
Methods: We extracted liver stiffness measurement data from outpatient and community FibroScan machines in a single tertiary centre, encompassing data from December 2017 to November 2023. Incomplete data was completed from electronic patient records. Data was analysed using R. Analysis included descriptive statistics and exploration of progression of fibroscan results.
Results: 21 925 scans were extracted, representing 13 635 individual patients.
The modal specific indication for fibroscan was MASLD (5 301 scans representing 3 434 patients). CAP was available for 2 323 scans. 937 persons with MASLD underwent follow-up scan after their index examination. The mean time between exams was 507 days (Interquartile range, IQR 364–815). Their mean age was 58.8 years (SD 13.8). The median result for LSM was 8.8 kPa (IQR 6.2–12.9) and (where available) 324 dB/m (IQR 283–360) for CAP. The change in CAP and LSM was calculated for each patient with MASLD and at least one follow-up exam. The median change in LSM was −0.1 kPa (IQR −2.7 to +1.8). The median change in CAP was 0 dB/m (IQR ± 27). The median rate of change in CAP was 0 dB/m/year and in LSM was – 0.06 kPa/year. Focusing on the 411 patients who had a baseline fibroscan suggestive of at least moderate fibrosis (LSM >10 kPA), 49 (11.9%) had an increase in LSM of at least 20%. Conversely, 113 patients (27.5%) had a decrease in LSM of at least 20%. The median follow-up interval was 489 days (IQR 344–794). 526 patients had a baseline exam showing LSM <10 kPa. Of these, 81 (15.4%) had a subsequent fibroscan showing LSM >10 kpa, suggestive of at least moderate fibrosis. The median follow-up period for these patients was 587 days. 70% of increases in LSM were identified at scans within 18 months of index scan.
Conclusion: In this dataset of 937 follow-up examinations, there was no overall change in liver stiffness. However, there was evidence of progression to clinically significant fibrosis in approximately 1 in 7 patients starting with LSM <10 kPa. This progression in fibrosis contrasts with a larger proportion of patients with elevated LSM at baseline apparently improving. Longitudinal changes in LSM can guide intervals for repeat testing but there is a need to define the magnitude of change that demands modifications to management.

WED-303
Assessment of the correlation and concordance between ELF and VCTE in the AASLD algorithm for MASLD severity assessment
Siham Abdelgani[1], Rida Nadeem[2], Yasmeen Fallouh[2], Phillip Leff[2], Aarya Patel[2], Manal Chughtai[2], Sahasraara Hemant[3], Shray Patel[2], Anushka Dharia[2], Gagana Ameneni[2], Helena Katchman[4], Naim Alkhouri[2]. [1]*Tel Aviv Medical center, Tel Aviv, Israel;* [2]*Arizona liver health, phoenix, United States;* [3]*Arizona Liver Health, Pheonix, United States;* [4]*Tel Aviv Medical Center, Tel Aviv, Israel*
Email: naim.alkhouri@gmail.com

Background and aims: Recently, the AASLD published an algorithm to assess the severity of MASLD and identify patients at risk for advanced disease. The algorithm recommends sequential testing starting with FIB4 followed by either enhanced liver fibrosis (ELF) or

vibration controlled transient elastography (VCTE). It was assumed that ELF and VCTE can be used interchangeably based on availability but the correlation and concordance between ELF and VCTE has not been evaluated.

Method: Consecutive patients with MASLD that were referred to a tertiary hepatology clinic and had laboratory tests to calculate FIB4 and ELF + VCTE done within a 3-month period were included. The AASLD algorithm was applied. Spearman's correlation coefficient was used to assess correlations.

Results: 263 patients were included with a mean age of 57 ± 14 years, 62% were female, mean BMI 34.73 ± 9.3. 48% had type 2 diabetes. 134 (51%) had FIB4 ≥1.3, the mean ELF was 9.91 ± 1.24 and the mean VCTE was 13.5 kPa ± 10.6 indicating a prevalence of advanced fibrosis consistent with specialty care. Overall, there was a significant but weak correlation between ELF and VCTE (Spearman correlation coefficient 0.38, p value <0.01, Kappa coefficient = 0.17). Importantly, in patients with FIB4 between 1.3–2.67 (n = 97) where the AASLD algorithm recommends sequential testing with a second test, ELF was >7.7 in 89 (91%) and VCTE >8 kPa in 66 (68%). ELF and VCTE showed concordant results in 65.5% and discordance in 34.5% with a spearman's correlation coefficient of 0.293 indicating poor association. In patients with FIB4 >2.67 (n = 37), ELF was >7.7 in 35 (94.5%) and VCTE >8 kPa in 24 (64.5%). ELF and VCTE showed concordant results in 68.5% and discordance in 31.5% with a significant spearman's correlation coefficient of 0.611 indicating high association.

Conclusion: Using ELF and VCTE interchangeably as part of the AASLD algorithm may lead to substantial misclassification of patients. Furthermore, in patients with FIB4 between 1.3 and 2.67, there is poor correlation between ELF and VCTE, emphasizing the need for a more refined approach in utilizing these tests for better risk stratification in this group.

WED-304

Accuracy of the recommended algorithm using Fib4 Score and fibroscan to identify MASLD patients with low risk for advanced liver fibrosis in "real world" practice

Inbal Zuckerman[1], Orly Azulay[2], Eli Zuckerman[2]. [1]*Carmel Medical Center, Haifa, Israel;* [2]*Carmel Medical Center, Haifa*
Email: elizuc56@gmail.com

Background and aims: Global guidelines summarise that Fib4 Score and fibroscan can be used for assessment of hepatic fibrosis. The negative predictive value is 0.9 with cut-off of 1.3 to rule out significant fibrosis in patients with Metabolic Associated Steatotic Fatty Liver Disease (MASLD).

The aim was to assess the accuracy of the practical algorithm using Fib4 as the initial step to distinguish NAFLD patients with low-risk from patients with moderate-high risk for liver fibrosis trying to identify clinical parameters indicating significant hepatic fibrosis despite low fib4 score.

Method: Included 828 patients with MASLD and Fib4 score less than 1.3 who were referred from primary care clinics from January 2021 to June 2023. All patients underwent fibroscan examination (Echosense). Statistical analysis: For multivariate analysis, a stepwise discriminant analysis model, successfully validated by the leave one out method was used. The true independent variables and their regression coefficients were used in order to build a discriminant score (DS) formula. ROC curves were separately built for the individual independent predictors as well as for their combination in the DS formula. Two tailed P values of 0.05 or less were considered to be statistically significant. Statistical analysis was performed using the IBS SPSS version 26. In parallel to the statistical model, an artificial intelligence (AI) based neural network (NNET) model was developed in order to test for higher predictive values of FIB4. This feedforward backpropagation algorithm was used to train the model. The AI based NNET model was developed using the Matlab 2015a version (MathWorks.

Results: Mean age of this group was 47.5 years old and 396 were males (47%). Mean Fib4 score was 0.84. In 97 patients (11%) fibroscan reading was not reliable. Fibroscan in 153 of 731 patients (21%) showed fibrosis score F2 or more [F2 130 (85%), F3–4 23 (15%)]. 120 of 153 patients underwent liver biopsy showing fibrosis score F3–4 in 21 patients, F2 in 15 and F0–1 in 84. Older age, higher ALT and higher ferritin level were significantly more prevalent in the group with high fibrosis score (despite low Fib4 score).

Conclusion: Fib4 score is highly accurate in distinguishing patients with low risk of fibrosis from those with moderate-high risk in real world clinical practice, missing approximately 5–7% of patients with significant liver fibrosis. Older age, high ALT level and high serum ferritin may indicate need for further investigation with fibroscan and/or liver biopsy in patients with low Fib4 score.

WED-305

Comparison of two non-invasive models for advanced fibrosis (AF) detection in patients with type 2 diabetes (T2D) and MASLD using LiverSTAT, FIB-4 and liver stiffness measurement (LSM) with transient elastography (TE)

Mona Ismail[1,2], Abdulrahman Alabdulgader[3,4], Abdulnaser Barmou[5], Mona Munteanu[6]. [1]*Division of Gastroenterology, Department of Internal Medicine, King Fahd Hospital of the University, Al-Khobar, Saudi Arabia;* [2]*College of Medicine, Imam Abdulrahman bin Faisal University, Dammam, Saudi Arabia;* [3]*Division of Gastroenterology, Department of Internal Medicine, King Fahd Hospital of the University, Al-Khobar, Al-Khobar, Saudi Arabia;* [4]*College of Medicine, Imam Abdulrahman bin Faisal University, Dammam, Saudi Arabia., Dammam, Saudi Arabia;* [5]*Department of Internal Medicine King Fahd Hospital of the University Al-Khobar, Al-Khobar, Saudi Arabia;* [6]*Fibronostics, Medical Affairs, Florida, United States*
Email: monai4@hotmail.com

Background and aims: Metabolic dysfunction-associated liver disease (MASLD) affects 24% of the population and can progress undetected from simple steatosis to advanced fibrosis (AF) and cirrhosis, especially in patients with type 2 diabetes (T2D). This underscores the importance of early detection and hepatology referrals, as patients with AF are identified late. Given the limitations of liver biopsy and the scarce availability of TE, there is a growing need for non-invasive, cost-effective blood-based tests for liver fibrosis assessment. Clinical care pathways integrating AI-based blood tests like LiverSTAT (LST) offer a promising approach to identifying AF in pts with T2D. These pathways can streamline the diagnostic process, facilitating early detection and intervention. This study evaluated the efficacy of using LST and LSM in identifying advanced fibrosis among patients with T2D and MASLD comparatively to FIB-4 and LSM.

Method: In this retrospective study, we reviewed pts diagnosed with T2D and MASLD with various demographic and clinical factors attending the diabetes clinics at a tertiary university hospital. Cut-offs for AF were those recommended by AASLD clinical practice guidelines: for LSM 12 kPa and for FIB-4 1.3 and 2.67 to rule out and rule in AF; LST used a cut-off of 0.59. We used logistic regression to identify predictors of advanced fibrosis.

Results: We identified 359 T2D pts, 349 pts were included with applicable LSM and complete biomarkers [46.7% males, median age 55 yrs, LSM 5.6 kPa, CAP 302 dB/m, ALT28 U/L, AST21 U/L, FIB-4 0.87, BMI 32.3 Kg/m^2]. 309 (88.5%) had LSM and LST that agreed: 23 (6.6%) had presumed AF and 286 (81.9%) had no presumed AF; 40 (11.5%) disagreed, with presumed AF in 16 and 24 as per LST and LSM, respectively. 254 (72.8%) had LSM and FIB-4 that agreed: 12 (3.4%) had presumed AF and 242 (69.3%) had no presumed AF; 25 (7.2%) disagreed, with presumed AF in 7 and 18 pts as per FIB-4 and LSM, respectively. 70 (20.1%) pts had indeterminate FIB-4 results (1.3–2.67), among them, 19 and 17 had presumed AF with LST and LSM, respectively, 11 (15.7%) agreed for AF and 45 (64.3%) agreed for non-AF. In a model including LST biomarkers, LSM, FIB-4, platelets, lipid panel, liver enzymes, glucose, age, and BMI, only age, LST and LSM

were independent predictors of AF. 273 (78%) and 316 (90.5%) had ALT and AST<50 U/l, respectively. ALT decreased significantly with age range while prevalence of AF and mean LST fibrosis scores increased with age range.
Conclusion: In pts with T2D, LST outperformed FIB-4 when combined with LSM for the detection of MASLD-related AF. Liver specific biomarkers should be used instead of liver enzymes as ALT that lack sensitivity for AF detection, especially in aged patients.

WED-306-YI
Prevalence of metabolic-dysfunction associated steatotic liver disease among diabetic and non-diabetic patients in a dutch cohort: evaluation of hepatic steatosis and fibrosis using Fibroscan™
Alina Saidi[1], Willy Theel[1], Vivian de Jong[2], Diederick Grobbee[3], Femme Dirksmeier-Harinck[4], Manuel Castro Cabezas[1]. *[1]Franciscus Gasthuis and Vlietland, Department of Internal Medicine, Rotterdam, Netherlands; [2]Julius Center for Health Science and Primary Care, Utrecht, Netherlands; [3]Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands; [4]Franciscus Gasthuis and Vlietland, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: a.saidi@franciscus.nl

Background and aims: Metabolic-dysfunction associated steatotic liver disease (MASLD) often coexists with metabolic disorders, such as type 2 diabetes mellitus (T2DM) and cardiovascular disease (CVD). We investigated the prevalence of MASLD among individuals visiting the cardiometabolic outpatient clinic in our hospital in a diabetic versus non-diabetic population.
Method: The study population consisted of 545 subjects attending the cardiometabolic outpatient clinic of Franciscus Hospital in Rotterdam (78 T1DM, 160 T2DM and 307 non-diabetics). Hepatic steatosis and fibrosis were assessed and graded using transient elastography (Fibroscan®). MASLD was defined as a Controlled Attenuation Parameter (CAP) ≥275 dB/m. Significant fibrosis was defined as a Transient Elastography (TE) value ≥8.1 kPa.
Results: 246 Women and 299 men were included (mean age 54 ± 14 years, mean BMI 29.7 ± 6.6 kg/m^2). 39.4% (n = 215) had MASLD and 29.0% (n = 158) had significant fibrosis. The prevalence of MASLD among individuals with T1DM, T2DM, and in those without diabetes was 19.2%, 56.3%, and 35.8%, respectively ($p < 0.001$). Significant fibrosis was observed in 9.0%, 33.8%, and 31.9% of the individuals, respectively ($p < 0.001$). Male subjects showed a significantly higher prevalence of significant fibrosis than females (35.0% vrs. 21.6%; $p < 0.001$).
In the overall population, a positive correlation was found between liver steatosis and liver fibrosis (Spearman's rho = 0.220; $p < 0.001$). This was also the case for each of the 3 subgroups (T1DM rho = 0.244, $p = 0.032$); T2DM rho = 0.307, $p < 0.001$; non-diabetics rho = 0.115, $p = 0.044$). However, in non-diabetics, when TE was above 8 kPa, the correlation between CAP and TE was lost.
Conclusion: The prevalence of MASLD and significant fibrosis in this Dutch cohort was higher among patients with T2DM compared to patients with T1DM and subjects without diabetes. Significant fibrosis was more prevalent in males. Interestingly, significant fibrosis was equally prevalent in T2DM and in non-diabetics attending the cardiovascular outpatient clinic. Why the association between CAP and TE was lost in these subjects with TE >8.1 kPa, is still unclear.

Head-to-head comparison of two different ultrasound systems to measure the liver attenuation parameter
Laura De Rosa[1,2], Simone Cappelli[3], Giovanni Petralli[4], Antonio Salvati[5], Gabriele Ricco[5], Filippo Oliveri[5], Barbara Coco[5], Piero Colombatto[5], Ferruccio Bonino[6], Maurizia Brunetto[3,5,6], Francesco Faita[1]. *[1]Institute of Clinical Physiology, National Research Council, Pisa, Pisa, Italy; [2]Department of Information Engineering and Computer Science, University of Trento, Trento, Italy; [3]Department of Clinical and Experimental Medicine, Pisa University, Pisa, Italy; [4]Department of Surgical Medical, Molecular and Critical Area Pathology, University of Pisa, Pisa, Italy; [5]Hepatology Unit, Pisa University Hospital, Pisa, Italy; [6]Institute of Biostructure and Bioimaging, National Research Council, Naples, Naples, Italy*
Email: laura.derosa.95@gmail.com

Background and aims: The liver ultrasound attenuation parameter is widely used for estimating the liver fat content (LFC) and its measurement is provided by commercial clinical scanners. In this study, we compared two different technologies currently used to assess LFC in a large cohort of patients (pts) with chronic liver disease (CLD) in order to study the agreement between two commercially available liver fat measurement devices.
Method: This single center study included 777 consecutive CLD pts enrolled at the Hepatology Unit of the University Hospital of Pisa from May 2022 to December 2023 whose LFC was assessed at with two different diagnostic systems: FibroScan® (Echosens, France) equipped with M or XL probe and FT9000 (Hisky Medical, China) equipped with a single convex probe. We compared the values of Controlled Attenuation Parameter (CAP, Fibroscan) and Ultrasound Attenuation Parameter (FT9000) obtained during the same single visit of each patient. Pearson correlation coefficients (R) and Bland-Altman analyses (BAA) were used to study the agreement between CAP and UAP overall and after stratification for BMI ≥25 kg/m^2. Correlations with biochemical variables (AST, ALT, AST/ALT, GGT) and platelets counts (PLTs) were evaluated also.
Results: Correlation coefficients of CAP and UAP were 0.48 overall, 0.30 in lean pts (BMI <25 kg/m^2), and 0.47 in overweight/obese pts ($p < 0.001$ for all). Overall, BAA showed a significant bias between CAP and UAP (−12 dB/m) and 95% limits of agreement (LoA) ranging from −130 to 100 dB/m; there was not any significant bias (−1.6 dB/m) in lean pts, whereas the bias was significant (−28 dB/m) in pts with BMI ≥25 kg/m^2. Both CAP and UAP did not correlate significantly with ALT, AST, GGT and PLTs overall and after stratifying with BMI. Both CAP and UAP correlated with the AST/ALT ratio significantly, but with poor coefficients both overall ($r = -0.22$ and $r = -0.15$, respectively) and in overweight/obese pts ($r = -0.22$ and $r = -0.20$, respectively); no significant correlation was found considering lean pts only.
Conclusion: Despite an overall acceptable and significant correlation between the attenuation parameter measurements provided by the two devices, a consistent bias and wide LoAs in BAA suggest that the two devices have a limited interchangeability, independently from body size, at least in this cohort of pts. Further comparative studies are needed using Magnetic Resonance as reference standard to explore the agreement between the two devices, as well as to define technology-specific cut-offs for fatty liver content quantification in clinical practice.

WED-315
Validation of Fibrosis-6, a novel machine learning non-invasive score to rule out advanced fibrosis and cirrhosis in patients with metabolic-associated fatty liver disease
Mona Ismail[1,2], Riham Soliman[3,4], Nabiel Mikhail[5], Gamal Shiha[3,6]. *[1]Division of Gastroenterology, Department of Internal Medicine, King Fahd Hospital of the University, Alkhoabr, Saudi Arabia; [2]College of Medicine, Imam Abdulrahman bin Faisal University., Dammam, Saudi Arabia; [3]Gastroenterology and Hepatology Department, Egyptian Liver Research Institute and Hospital (ELRIAH), Sherbin., El Mansoura, Egypt; [4]Tropical Medicine Department, Faculty of Medicine., Port Said University, Egypt; [5]Biostatistics and Cancer Epidemiology Department, South Egypt Cancer Institute, Assiut University., Assiut, Egypt; [6]Hepatology and Gastroenterology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University., El Mansoura, Egypt*
Email: monai4@hotmail.com

Background and aims: There is an urgent need for simple, blood-based, and non-invasive tests (NITs) to rule out advanced fibrosis/cirrhosis (F3 and F4) in metabolic-associated fatty liver disease. We

previously developed and validated the Fibrosis-6 (FIB-6) score, a novel non-invasive diagnostic score, through machine learning with a random forest algorithm. Originally validated for chronic hepatitis C, the FIB-6 score predicts liver fibrosis stages. This study evaluated the accuracy of the FIB-6 score in identifying advanced fibrosis/cirrhosis in patients with metabolic-associated fatty liver disease.

Method: In this retrospective cohort study, we included patients with metabolic-associated fatty liver disease following at the Hepatology clinics at a tertiary university hospital (KFHU) between April 1st, 2021, and April 30, 2022 (Before the new nomenclature). Patients with secondary causes of hepatic steatosis were excluded. Clinical and demographic data were collected. Transient elastography (FibroScan 502 touch, Echosens, Paris, France) was the reference standard for liver fibrosis. The diagnostic accuracy and performance of the FIB-6 score were compared against three established NITs: The fibrosis-4 index (FIB-4) and the aspartate aminotransferase-to-platelet ratio index (APRI), the aspartate aminotransferase (AST)/alanine aminotransferase (ALT) (AAR) ratio.

Results: The study included 406 patients, and the FIB-6 score was more effective in ruling out F3 and F4 stages of fibrosis compared to FIB-4, APRI, and AAR. The FIB-6 score showed a higher sensitivity (96.3%) and negative predictive value (NPV) (90.3%) in ruling out F3 and F4 stages of fibrosis in patients with metabolic-associated fatty liver disease (Table 1). In comparison, the sensitivity of FIB-4 was 43.9%, APRI was 23.2%, and AAR was 29.2%. Additionally, FIB-4, APRI, and AAR had lower NPVs of 86.2%, 83.3%, and 81.9%, respectively.

Conclusion: The FIB-6 score is an accurate and simple non-invasive test for ruling out advanced fibrosis and cirrhosis in patients with metabolic-associated fatty liver disease, surpassing the performance of existing NITs such as FIB-4, APRI, and AAR. This highlights its potential as a valuable diagnostic aid in clinical care pathways.

WED-316

Gadoxetic acid-enhanced MRI enables detection of fibrosis and inflammation in MASLD/MASH

Edvin Johansson[1], Salem Alsaqal[2], Paul Hockings[1], Håkan Ahlström[3], Johannes Hulthe[1], Lars Johansson[1], Charlotte Ebeling Barbier[4], Fredrik Rorsman[5], Johan Vessby[6]. *[1]Antaros Medical, Mölndal, Sweden; [2]Department of Surgical Sciences, Uppsala University, Uppsala, Sweden; [3]Department of Surgical Sciences, Uppsala University, Uppsala, Sweden; [4]Department of Surgical Sciences, Section of Radiology, Uppsala University, Uppsala, Sweden; [5]Uppsala University Hospital, Uppsala University, Uppsala, Sweden; [6]Dept of Gastroenterology and Hepatology, Uppsala University Hospital, Uppsala, Sweden*
Email: paul.hockings@antarosmedical.com

Background and aims: There is a need for non-invasive biomarkers to measure fibrosis and inflammation in subjects with metabolic dysfunction associated steatotic liver disease (MASLD) or steatohepatitis (MASH). Gadoxetic acid-enhanced Magnetic Resonance Imaging (GA-MRI) can quantify hepatocellular function and potentially identify dysfunction. The purpose of this study was to evaluate the ability of various parameters obtained using GA-MRI to measure fibrosis and inflammation and to assess repeatability.

Method: The study population consisted of 68 participants with biopsy-proven MASLD or MASH (40 male, 28 female) with a mean age of 54.5 years and a mean body mass index of 31 kg/m^2. Histopathology found 39 participants had fibrosis stage F0–1, and 29 had F2–4, while 15 participants had activity score 0–1 and 53 had activity scores of 2–4. Participants fasted for 6 hours before MRI with a 3.0 T Signa scanner (GEHC). Dynamic contrast-enhanced MRI (DCE-MRI) was performed for a total of 22 minutes (90 timeframes). After 2 minutes of baseline imaging, a bolus of 0.025 ml/kg (25% of the standard dose) of gadoxetate (Primovist, Bayer) was injected intravenously. 30 participants were invited back for a rescan 2–4 weeks after their initial scan to estimate repeatability of the imaging parameters. A tracer-kinetic model was used to estimate flow (F), extracellular volume fraction (V_e) and hepatocyte uptake rate of gadoxetate (k_{he}) from the DCE-MRI. Liver relative enhancement (RE), the percent change in liver signal from baseline to the hepatobiliary phase (20 min), is also reported.

Results: Fibrosis stage: F0–1 could be distinguished from F2–4 by the flow parameter (AUROC 0.67, p 0.015). Flow also correlated with the histopathological fibrosis stage (Rs –0.30, p 0.01). Similarly, RE could separate F0–1 from F2–4 (AUROC 0.66, p 0.02) and had Rs –0.29, p 0.02. Activity grade: k_{he} correlated with activity grade (Rs –0.29, p 0.02) but failed to separate grade 0–1 from 2–4 (AUROC 0.63, p 0.11). For the same tests, RE performed better (Rs –0.34 p 0.006 and AUROC 0.73 p 0.007). Repeatability: The ICC for repeatability of flow was 0.63, k_{he} was 0.74, and RE was 0.88.

Conclusion: This relatively small study of MASLD/MASH subjects showed that the flow and k_{he} tracer-kinetic parameters derived from gadoxetate MRI correlated with fibrosis and inflammation, respectively. RE at 20 min also correlated with fibrosis and inflammation and importantly has excellent repeatability, however it lacks specificity to distinguish fibrosis from inflammation. Together these parameters provide information about MASLD/MASH disease state, fibrosis, and inflammation without invasive biopsy. This could also have utility in longitudinal monitoring of MASLD/MASH subjects.

WED-317

Guided Vibration-Controlled Transient Elastography, a new vibration-guided FibroScan examination

Jean-Pierre Bronowicki[1], Christiane Stern[2], Stéphane Audière[3], Julie Foucquier[3], Cécile Bastard[3], Anne Llorca[3], Céline Fournier-Poizat[3], Véronique Miette[3], Laurent Sandrin[3], Cyrielle Caussy[4]. *[1]Nancy University Hospital, Nancy, France; [2]Hôpital Beaujon, Clichy, France; [3]Echosens, Paris, France; [4]Hospices Civils de Lyon-CHU de Lyon, Lyon, France*
Email: cyrielle.caussy@chu-lyon.fr

Background and aims: FibroScan (FS) medical device allow assessment of liver stiffness measurement using Vibration-Controlled Transient Elastography (LSM by VCTE™). A new technology named "Guided VCTE" was developed to help operators localize an optimal region of interest for LSM in a simple and reliable way. The aims of this study were to compare the examination time of LSM by Standard versus Guided VCTE and to demonstrate the equivalence of LSM values between both methods.

Method: This is a prospective study including patients with all causes of chronic liver diseases recruited in 3 expert Hepatology Centers in France between November 2022 and March 2023. For each patient, LSM was performed by expert operators using Standard and Guided VCTE consecutively, with alternating the examination order from a patient to another. Time needed to obtain the first and 10th valid LSM after the operator places the probe on the patient were compared with log-rank tests. LSM equivalence between Standard and Guided VCTE was evaluated in patients with at least 10 valid LSM and Interquartile Range (IQR)/Median ≤30% with both methods. LSM values by Standard and Guided VCTE were compared using a Wilcoxon signed-rank test. The agreement between both methods was assessed using mean bias, Spearman correlation coefficient (rho) and intraclass correlation coefficient (ICC). Estimates are presented with their 95% confidence intervals (CI) and two-sided $p < 0.05$ are considered statistically significant.

Results: Sixty-six participants (38% female, mean BMI: 33.9 ± 10.0 kg/m², mean age: 55.8 ± 15.4 years) were included in the analysis of the LSM examination time. Time needed to obtain the first valid LSM was significantly lower using Guided VCTE (median survival times 7.3 s [6.0;11.7]) compared to Standard VCTE (22.4 s [10.1;44.8]) with $p < 0.0001$. Moreover, time needed to reach the 10th valid LSM measurement was also significantly lower with Guided VCTE (33.6 s [28.1–38.8]) compared to Standard VCTE (50.2 s [45.3–70.3]) with $p = 0.00012$. Fifty-seven participants (42% female, mean BMI: 33.0 ± 9.1 kg/m², mean age: 54.9 ± 15.2 years) were included in the equivalence analysis. There was no significant difference between

the LSM obtained by both methods (p = 0.778). The mean bias between LSM by both methods was −0.6 kPa [−2.3;1.1] therefore not significantly different from 0. Rho and ICC were 0.92 [0.87;0.95] and 0.88 [0.80;0.93], respectively, highlighting a strong correlation and a good agreement.
Conclusion: Guided VCTE significantly reduces the time needed to obtain the first and 10th valid LSM compared to Standard VCTE. Furthermore, LSM obtained by Standard and Guided VCTE were strongly correlated and in agreement, reflecting an equivalence of LSM between both methods. Therefore, LSM cut-off values derived in the literature using Standard VCTE are applicable using Guided VCTE. Further studies are needed to confirm these results.

WED-318-YI
Steatotic liver disease in diabetic patients: more serious diabetes mellitus, more serious liver disease
Zülal İstemihan[1], Fatih Bektaş[2], Ali Emre Bardak[3], Cansu Kızıltaş[3], Gamze Kemeç[3], Kanan Nuriyev[1], Aynure Rüstemzade[1], Sezen Genç Uluçeçen[1], Hülya Hacışahinoğulları[2], Kubilay Karşıdağ[2], Bilger Çavuş[1], Asli Çifcibasi Örmeci[1], Filiz Akyuz[1], Kadir Demir[1], Fatih Beşışık[1], Sabahattin Kaymakoğlu[1]. *[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Gastroenterohepatology, Istanbul, Turkey; [2]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism Diseases, Istanbul, Turkey; [3]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*
Email: kaymakoglus@hotmail.com

Background and aims: It was aimed to investigate the frequency of metabolic dysfunction-associated steatotic liver disease (MASLD) in patients with type 1 diabetes mellitus (T1DM) and type 2 diabetes mellitus (T2DM) and to reveal the relationship between complications of diabetes and steatotic liver and fibrosis.
Method: In a single-center study conducted at a tertiary university hospital, MASLD was prospectively evaluated with non-invasive scoring based on biochemical tests and FibroScan® in adult patients with T1DM and T2DM and without other causes of liver disease. In FibroScan® measurements, a CAP score of ≥275 dB/m was considered as steatosis and ≥8.0 kPa was considered as clinically significant fibrosis (F2). Demographic information, waist circumference, weight and height, biochemistry, non-invasive scoring, and FibroScan® measurements of the patients were recorded.
Results: 504 (83%) of a total of 605 diabetic patients had T2DM. 267 (44%) of the patients were male, the mean age was 56.22 ± 14.68 years, and the mean body mass index was 29.02 ± 6.02 kg/m^2. The frequency of steatotic liver and clinically significant fibrosis was higher in T2DM patients than in T1DM patients (p <0.05). Clinically significant fibrosis was more common in patients with hypertension (HT) and microalbuminuria (p = 0.01). As the severity of liver steatosis increased, the rate of clinically significant fibrosis increased (p = 0.01). The grade of liver steatosis was higher in diabetic patients with microvascular complications (p <0.05). Considering the lipid profiles, the degree of significant fibrosis and steatosis was higher in patients with low HDL levels (p = 0.003, p = 0.001, respectively).
30% (n = 153) of T2DM had clinically significant fibrosis, and only 23.5% of them (n = 36) had ALT >45 U/L. 5% (n = 5) of T1DM had clinically significant fibrosis, and only 1 patient had ALT >45 U/L. FIB-4 score was ≥1.3 in 60 (23.8%) of 252 patients with T2DM and SLD, and the rest had FIB-4 <1.3. Liver stiffness was found ≥8 kPa in 32.8% of those with FIB-4 score <1.3.
In all patients, 'FIB-4' had the strongest correlation with liver stiffness measurement, and 'fatty liver index' had the strongest correlation with CAP score.
Conclusion: Steatotic liver and fibrotic liver are more common in patients with T2DM than in T1DM. As the severity of liver steatosis increases, fibrosis progresses. Concomitant hypertension, microalbuminuria, microvascular complications, and dyslipidemia in diabetic patients are associated with significant fibrosis and increased steatosis in the liver. The non-invasive tests that correlate best with FibroScan® measurements are FIB-4 and 'fatty liver index'. According to the results of our study, 40% of patients with T2DM and SLD need to be referred to gastroenterologists because they have clinically significant fibrosis.

WED-319
AI digital pathology unmasked the "No Change" in conventional pathological assessment of MASLD patients with one year lifestyle intervention in a prospective cohort study
Xiaoxue Zhu[1], Aruhan Yang[1], Wen Wang[1], Hong Zhang[1], Guoyue Lv[1], Yanhua Ding[1], Qiang Yang[2], Xiao Teng[3]. *[1]The First Hospital of Jilin University, Changchun, China; [2]Hangzhou Choutu Technology Co.Ltd., Hangzhou, China; [3]HistoIndex Pte Ltd, Singapore, Singapore*
Email: zhuxiaoxue@jlu.edu.cn

Background and aims: At present, there is no medication approved for the treatment of metabolic dysfunction-associated steatotic liver disease (MASLD). Lifestyle interventions that result in weight loss are considered to offer some improvement in MASLD. Pathology serves as the benchmark for evaluating their effectiveness. This study aimed to assess the efficacy of lifestyle interventions in patients with MASLD with the help of AI digital pathology.
Method: This prospective cohort study involved 31 patients who were diagnosed with MASLD based on histological and clinical criteria, then they received monthly lifestyle intervention guidance for one year. The conventional pathology was assessed using the NASH-CRN Histologic Scoring System, while finer evaluation of hepatic steatosis and fibrosis was used AI digital pathology based on SHG/TPEF technology. Clinical markers and pathology changes were analyzed by Pearson Correlation. A p value of <0.05 was considered statistically significant.
Results: Regarding steatosis, the conventional discrete readings indicated that the numbers of patients with progression, no change, and regression were 3 (9.7%), 17 (54.8%), and 11 (35.5%), respectively. While the continuous measurement from the AI digital pathology changed the numbers to 15 (48.4%), 1 (3.2%) and 15 (48.4%), respectively. Regarding fibrosis, the conventional readings indicated that 6 (19.4%) patients experienced progression, 19 (61.3%) showed no change, and 6 (19.4%) showed regression. While AI digital pathology revealed the numbers were 21 (67.7%) with progression, 3 (9.7%) with no change and 7 (22.6%) with regression. For steatosis assessment, the same trends in MRI-PDFF changes were observed in 14 (45.2%) and 18 (58.1%) individuals with conventional pathology and AI digital pathology, respectively. The numbers of individuals with CAP changes that were consistent with the two pathology methods were 14 (45.2%) and 17 (54.8%), respectively. Stronger statistically significant correlations were found between clinical markers (MRI-PDFF, CAP and weight changes) and AI pathology vs conventional pathology (r = 0.468 vs 0.308, 0.428 vs 0.363, 0.578 vs 0.530). For fibrosis assessment, the same trends in LSM changes were observed in 10 (32.2%) and 12 (38.7%) individuals with conventional pathology and AI digital pathology, respectively. No statistically significant correlation could be found between NITs (LSM, FIB-4, and FAST) and either conventional or AI pathology.
Conclusion: Continuous measurement from AI digital pathology unmasked the "No Change" in pathological assessment. Changes in other clinical indicators were more consistent with the changes revealed by AI digital pathology, which may provide a more sensitive assessment of lifestyle intervention effectiveness and potentially even therapeutic efficacy in MASLD patients.

WED-320

Optimizing non-alcoholic fatty liver disease care using mac-2 binding protein glycosylation isomer and correlations with advanced diagnostics

Thu Thuy Pham Thi[1], Dat Ho Tan[2], Chanh Pham Cong[3], Boi Hoan Phan Huu[4], Thai Bieu Phu Dung[3], Toan Nguyen Bao[3], Khue Nguyen Minh[3]. [1]*Medic Medical Center Ho Chi Minh City, Ho Chi Minh, Viet Nam;* [2]*Medic Medical Center Ho Chi Minh, Ho Chi Minh, Viet Nam;* [3]*Medic Medical Center Ho Chi Minh City, Ho Chi Minh, Viet Nam;* [4]*Medic Medical Center, Ho Chi Minh, Viet Nam*
Email: drthuthuypham@gmail.com

Background and aims: The escalating prevalence of non-alcoholic fatty liver disease (NAFLD) in Vietnam necessitates early detection. This study aims to establish precise mac-2 binding protein glycosylation isomer (M2BPGi) cut-offs for NAFLD fibrosis stages, evaluating correlations with existing diagnostic methods. Secondary objectives explore variations in M2BPGi levels based on age, gender, and diabetes, providing insights into NAFLD across diverse demographics.
Method: In our Hepatology department, 301 individuals meeting strict inclusion criteria, aged 18 and above, were enrolled with confirmed fatty liver diagnosis via Ultrasound or Fibroscan. Participants, treatment-naïve or having ceased treatment for over 6 months, were included based on MRE suitability. Stratification by fibrosis stage (F0/1, F2, F3, F4) was conducted, excluding co-infection with Hepatitis B or C, pregnancy, underlying cancers, excessive alcohol intake, and end-stage renal disease. Standardized routine tests and imaging, including MRE, were performed. The primary analysis aimed to establish M2BPGi cut-offs for each fibrosis stage, assessing correlations with MRE, Fibroscan, and FIB-4. Sub-population analysis considered age groups, diabetes, and gender for nuanced insights into NAFLD across diverse demographics.
Results: The accuracy of M2BPGi was ascertained through stratified fibrosis cases analyzed using Magnetic Resonance Elastography (MRE). In early NAFLD cases (F0–1), the mean cutoff for M2BPGi was 0.69 with a standard error of the mean (SEM) of 0.039. Similarly, for F2–3 cases, the mean cutoff was 0.77 with SEM 0.031, while F4 cirrhotic cases exhibited a mean cutoff of 1.0 with SEM 0.121. The observed results demonstrated statistical significance between early liver disease and cirrhotic study groups. Notably, significant gender-based differences were observed across all fibrosis stages, with males exhibiting lower M2BPGi levels than females. In terms of age groups, patients aged >65 years demonstrated the highest detected M2BPGi levels. Furthermore, within the cirrhotic group, those with diabetes exhibited significantly higher M2BPGi levels, whereas the differences observed in other groups were statistically non-significant.
Conclusion: This study in Vietnam aims to define precise M2BPGi cut-offs for NAFLD fibrosis stages, improving early detection. Results show significant M2BPGi differences between early NAFLD and cirrhotic groups, with notable gender and age variations. These findings emphasize M2BPGi's potential for nuanced NAFLD characterization and early detection in diverse demographics.

WED-321

Association between psoriasis severity and steatosis measured by artificial Intelligence-based algorithm (LIVERFASt)

Sabrina Ab Wahab[1], Rafiz Abdul Rani[1], Liyana Dhamirah Aminuddin[1], Tarita Taib[1]. [1]*Universiti Teknologi MARA, Sungai Buloh, Malaysia*
Email: sabrinaabwahab@gmail.com

Background and aims: Psoriasis is a chronic, inflammatory skin disease often associated with steatotic liver disease. Non-invasive diagnostic tests may assist in detecting liver disease without a liver biopsy, especially in psoriasis patients who require systemic treatment. LIVERFASt (Fibronostics) is an artificial intelligence (AI) technology that uses surrogate blood-serum biomarkers to assess steatosis, fibrosis and activity scores. This study aims to explore the association between psoriasis severity and steatosis by utilising LIVERFASt.
Method: A cross-sectional study was conducted on patients ≥18 years old with chronic plaque psoriasis in the Dermatology Clinic, Universiti Teknologi MARA (UiTM) Medical Specialist Centre, Sungai Buloh, Malaysia. We assessed psoriasis severity measured by psoriasis area and severity index (PASI) scores <10 (mild) and ≥10 (moderate-to-severe) after excluding other liver diseases. We evaluated the relationship with steatosis by comparing PASI scores with steatosis, fibrosis, and activity scores measured by LIVERFASt. Serum biomarkers performed, including alpha-2 macroglobulin, haptoglobin, apolipoprotein A1, total bilirubin, gamma-glutamyl transferase, fasting glucose, total cholesterol, triglycerides, alanine aminotransferase, and aspartate aminotransferase, as well as age, sex, height, and weight were entered into LIVERFASt algorithms to analyse the scores.
Results: A total of 50 patients with chronic plaque psoriasis had a mean PASI of 8.7 ± 6.3, and body surface area (BSA) was 7.0 [interquartile range (IQR) 9)]% with disease duration of 5.5 years (IQR 11.38). Based on the PASI score, the proportions of mild and moderate-to-severe subjects were 28 (56.0%) and 22 (44.0%), respectively. The proportions of steatosis in the overall cohort were 36%, which was higher in the moderate-to-severe group (40.9%), with no significant difference compared to the mild group (32.1%), $p = 0.565$. Steatosis scores were higher among patients with moderate-to-severe group vs mild group [0.30 (IQR 0.48) vs (0.23 (IQR 0.42)], $p = 0.145$. Mild and moderate-to-severe psoriasis patients differed significantly in the duration of disease ($p = 0.033$) and age ($p = 0.040$). Fibrosis was detected in 16.7% of patients with steatosis detected by LIVERFASt. Psoriatic patients with steatosis were older, with a median of 47.0 (IQR 25) years and had a longer disease duration, with a median of 9 years (IQR 20.25). Waist circumferences were significantly correlated with the PASI score ($r = 0.285$, $p = 0.045$).
Conclusion: Both steatosis scores and proportion were higher in the moderate-to-severe psoriasis group. LIVERFASt, an AI-based blood algorithm, is convenient for screening steatosis, particularly in psoriasis patients. Early detection of fibrosis is also recommended.

WED-322

Sequential diagnostic approach utilizing FIB-4 and ELF for predicting advanced fibrosis in metabolic-associated steatotic liver disease

Yeo Wool Kang[1], Yang-Hyun Baek[1], Sang Yi Moon[1]. [1]*Department of Internal Medicine, Dong-A University College of Medicine, 32 Daeshingongwonro, Seo-gu, Busan, Korea, Rep. of South*
Email: p100100@dau.ac.kr

Background and aims: Hepatic fibrosis is a critical predictor of liver-related mortality in patients with liver diseases. Various screening non-invasive tests (NITs) are available, and the American Association for the Study of Liver Diseases (AASLD) proposed a two-step approach, focusing on diagnostic accuracy, cost, and accessibility. This study aims to evaluate the diagnostic accuracy of fibrosis in metabolic-associated steatotic liver disease (MASLD) patients by utilizing the previously proposed two-step approach, starting with the serum-based fibrosis-4 index (FIB-4) and subsequently employing the Enhanced Liver Fibrosis (ELF) test.
Method: This clinical data and liver biopsies were used for MASLD patients between 2018 and 2023. Various NITs were utilized. The degree of fibrosis was determined based on the results of the liver biopsy. The diagnostic performance of these NITs was assessed using the Area Under the Receiver Operating Characteristic curve (AUROC). Moreover, the diagnostic performance of each test, both when used independently and within the two-step strategy using FIB-4 following ELF, was further analyzed using sensitivity, specificity, accuracy, positive predictive value (PPV), and negative predictive value (NPV).
Results: A total of 150 MASLD patients were included, with a mean age of 46.6 years (median 48 years), 53.3% being male, and 27.3% having type 2 diabetes. The performance of the NITs in identifying advanced fibrosis was as follows: The AUROC of the

aminotransferase-to-platelet ratio index, FIB-4, Non-Alcoholic Fatty Liver Disease (NAFLD) fibrosis score, and ELF for advanced fibrosis (≥F3) were 0.799 (95% CI, 0.726–0.860), 0.732 (95% CI, 0.656–0.803), 0.662 (95% CI, 0.528–0.796), and 0.812 (95% CI, 0.740–0.871), respectively. The combination of FIB-4 ≥1.30 and ELF score ≥7.7 showed a sensitivity of 76.0%, specificity of 72.0%, PPV of 53.77%, NPV of 87.5%, and accuracy of 73.2% in predicting the diagnosis of advanced fibrosis. Additionally, the combination of FIB-4 ≥1.30 and ELF score ≥9.8 demonstrated a sensitivity of 56.0%, specificity of 89.6%, PPV of 69.8%, NPV of 82.6%, and accuracy of 79.5% in predicting the diagnosis of advanced fibrosis. This approach allowed the exclusion of 28 individuals (71.8%) from unnecessary liver biopsies.
Conclusion: Our study demonstrated that applying NITs previously used in NAFLD to MASLD patients for predicting fibrosis levels did not show inferiority. Therefore, it revealed that implementing a two-step strategy for MASLD patients at primary healthcare facilities, following the AASLD clinical guidelines, can early predict advanced fibrosis. Consequently, this suggests that adopting the diagnostic approach previously utilized for NAFLD patients in MASLD cases can lead to a reduction in unnecessary referrals or biopsies.

WED-323
Diagnostic performances of FIB-4 and NFS in metabolic dysfunction-associated steatotic liver disease in primary care clinic of Asia

Eileen Yoon[1], Jihyun An[2], Ha IL Kim[3], Joo Hyun Sohn[3], Bo-Kyeong Kang[4], Eun Chul Jang[5], Huiyul Park[6], Hye-Lin Kim[7], Sang Bong Ahn[8], Joo Hyun Oh[8], Hyo Young Lee[9], Dae Won Jun[2].

Email: noshin@hanyang.ac.kr

Background and aims: We aimed to explore extent to which individuals previously diagnosed with non-alcoholic fatty liver disease (NAFLD) meet the criteria fulfilled with the new nomenclature, metabolic dysfunction-associated steatotic liver disease (MASLD), within an Asian primary care cohort. Additionally, we assessed the reliability of the diagnostic performance of FIB-4 and NFS for MASLD within the primary care clinic cohort.
Method: This retrospective cross-sectional study included participants who underwent 6, 740 magnetic resonance elastography (MRE) and abdominal ultrasonography during their health checkups at nationwide health promotion centers.
Results: The prevalence rates of NAFLD and MASLD diagnosed based on ultrasonography results were 36.7% and 38.0%, respectively. Notably, 96.8% of patients in the NAFLD cohort fulfilled the new criteria for MASLD. A small proportion of patients with NAFLD (n = 80, 3.2%) did not meet the MASLD criteria. Additionally, 168 patients (6.6%) were newly added to the MASLD group. The areas under the receiver operating characteristic curves for diagnosing advanced hepatic fibrosis for FIB-4 (0.824 in NAFLD vs. 0.818 in MASLD, p = 0.891) and NFS (0.803 in NAFLD vs. 0.781 in MASLD, p = 0.618) were comparable between the MASLD and NAFLD. Furthermore, the sensitivity, specificity, positive and negative predictive value of FIB-4 and NFS for advanced fibrosis in MASLD were also comparable to those in NAFLD.
Conclusion: Almost patients (96.8%) previously diagnosed with NAFLD fulfilled the new criteria for MASLD in an Asian primary clinic cohort. Diagnostic performance of FIB-4 in the primary care MASLD cohort demonstrated satisfactory results.

WED-324
Use of FIB4 as a screening test in the bariatric population instead of the NAFLD fibrosis score reduces referral rate to hepatology without reducing identification of significant fibrosis: a retrospective audit

Michael Carbonell[1], Craig Lennie[1], Nuala Davison[1], Naim Fakih Gomez[1], Veronica Greener[1], R. Daniel Abeles[1,2].
[1]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom; [2]Division of Digestive Diseases, Imperial College London, London, United Kingdom
Email: michael.carbonell2@nhs.net

Background and aims: Identification of significant metabolic dysfunction-associated liver disease (MASLD) is important for risk stratification prior to bariatric surgery. In our institution prior to 2020, a NAFLD Fibrosis score (NFS) >0.676 triggered referral to Hepatology from the Bariatric service. From 2021 a FIB4 >1.3 was used. This study aims to compare the use of NFS with FIB4 for identifying bariatric patients with significant fibrosis.
Method: Consecutive new patients referred to the bariatric service with calculable NFS and FIB4 at time of referral from Jan-Dec 2017 (n = 296, cohort A) and from Jan 2021-Dec 2022 (n = 406, cohort B) were included. Data including demographics, enhanced liver fibrosis (ELF) test and transient elastography (Fibroscan) at Hepatology appointment were recorded. A median liver stiffness measurement (LSM) >8 kPa identified significant fibrosis. Microsoft Excel 2016 was used for data collection and statistical analysis. Categorical variables were compared using chi-squared test, continuous variables using Mann-Whitney U-test.
Results: Cohort A had a significantly higher body mass index (BMI) (45.4 vs 44, p = 0.028), higher rate of hypertension (HTN) (40.9% vs 26.9%, p < 0.01), type 2 diabetes (T2DM) (29.5% vs 23.4%, p < 0.01), and higher median NFS (−0.35 vs −0.86, p < 0.01), and FIB4 (0.81 vs 0.68, p < 0.01) than cohort B. A significantly higher proportion of patients in Cohort A were referred to Hepatology compared to Cohort B (14.9% vs 6.9%, p < 0.01). However, a lower (but not significant) proportion of referred patients in Cohort A had significant fibrosis (20.5% vs 28.6%, p = 0.43). Compared to Cohort B, patients in cohort A referred to Hepatology had a significantly higher BMI (44.2 vs 50.5, p = 0.02), but there was no significant difference in the presence of HTN (42.9% vs 50%, p >0.5) or T2DM (39.3% vs 50%, p > 0.5). There was a higher failure rate of Fibroscan in cohort A (38% vs 5%, p = 0.01). Of the 44 patients who underwent a Fibroscan, a FIB4 cut-off of 1.3 had a Sensitivity of 0.65 and Specificity of 0.375, whilst a NFS of 0.676 had a Sensitivity of 0.75 and Specificity of 0.33 for detecting significant fibrosis. In patients with a qualifying NFS or FIB4, an ELF cut-off of 10.51 had a Sensitivity of 0.27 and Specificity of 0.94 for significant fibrosis, with an AUROC of 0.49.
Conclusion: Use of a FIB4 of >1.3 compared to a NFS of >0.676 in the bariatric population reduces the number of referrals to Hepatology but does not reduce identification of patients with significant fibrosis. This may be due to the inclusion of BMI in the NFS over-predicting fibrosis in this population. In this population standard biomarkers, including ELF, did not perform particularly well in identifying significant fibrosis, and even Fibroscan may not function as a gold-standard. Therefore, further studies are warranted to optimize the identification of significant fibrosis in this at risk population.

WED-325-YI

Non-invasive assessment of hepatic steatosis by ultrasound-derived fat fraction (UDFF) in individuals at high-risk for metabolic dysfunction-associated steatotic liver disease

Email: fede.tavaglione@gmail.com

Background and aims: Given the increasing number of individuals developing metabolic dysfunction-associated steatotic liver disease (MASLD) and the low rate of those with progressive liver disease, there is a pressing need to conceive simple and affordable biomarkers to assess MASLD in general population settings. Herein, we aimed to investigate the performance of the recently developed ultrasound-derived fat fraction (UDFF) for hepatic steatosis in high-risk individuals.
Method: A total of 302 individuals with obesity, type 2 diabetes, or clinical history of hepatic steatosis were included in the analyses. Clinical, laboratory, and imaging data were collected using standardized procedures during a single screening visit in Rome, Italy. Hepatic steatosis was defined either by controlled attenuation parameter (CAP) ≥263 dB/m or ultrasound-based Hamaguchi's score ≥2. UDFF performance for hepatic steatosis was estimated by the area under the receiver operating characteristic curve (AUC).
Results: Overall, median (IQR) UDFF was 12% (7–20). UDFF was positively correlated with CAP ($\rho = 0.73$, $p < 0.0001$) and Hamaguchi's score ($\rho = 0.79$, $p < 0.0001$). Independent predictors of UDFF were circulating triglycerides, alanine aminotransferase (ALT), and ultrasound-measured visceral adipose tissue (VAT). UDFF AUC was 0.89 (0.85–0.93) and 0.92 (0.88–0.95) for CAP- and ultrasound-diagnosed hepatic steatosis, respectively. UDFF AUC for hepatic steatosis was higher than those of fatty liver index (FLI), hepatic steatosis index (HSI), and ALT ($p < 0.0001$). Lower age, ALT, and VAT were associated with discordance between UDFF and ultrasound.
Conclusion: UDFF may be a simple and accurate tool to detect hepatic steatosis and to monitor changes in hepatic fat content over time or in response to therapeutic interventions beyond clinical trial settings.

WED-326

Effects of weight loss on overweight or obese MASLD patients after six months of dieting

Pietro Torre[1], Luigi Schiavo[1], Benedetta Maria Motta[1], Marco Aquino[1], Federica Belladonna[1], Mario Masarone[1], Marcello Persico[1].
[1]Department of Medicine, Surgery and Dentistry, "Scuola Medica Salernitana", University of Salerno, Baronissi (SA), Italy, Baronissi, Italy
Email: pietrotorre90@gmail.com

Background and aims: MASLD is a multifactorial disease for which there are no approved pharmacological therapies and for which lifestyle changes still represent the most effective remedy. Nutritional studies could be essential to increase knowledge and assess causality in the field of MASLD. Our aim is to monitor patients diagnosed with MASLD who attend a weight-loss program at our Hepatology Unit, through repeated measurements of clinical parameters, transient elastography (TE), controlled attenuation parameter (CAP), and blood tests. The interaction between genetics and TE/CAP is also considered.
Method: Overweight or obese MASLD patients, aged ≥18, without decompensated cirrhosis or active cancer, were proposed to start a low-glycemic index, nutritionist-guided diet. Weight, BMI, TE/CAP, and blood tests recorded at baseline were compared with the same measurements obtained after 6 months. Weight loss was categorized into classes of weight change compared to baseline (<5%, 5%–10%, >10%). A genetic risk score (GRS) was calculated for each patient and related to changes in TE/CAP results.
Results: Among the 131 patients who underwent the first nutritional visit, 50 attended the 6-months control visit to date. At this time-point, as we previously observed in earlier follow-up visits, a significant difference compared to baseline was found in weight, BMI, and CAP (respectively −7.47 kg [−8.10%], −2.67 Kg/m^2, and −45.88 dB/m; all $p < 0.0001$). The latter improved proportionally to the extent of weight loss; mean liver stiffness, on the contrary, remained almost unchanged, but it decreased in the >10% weight reduction class. Patients with high GRS experienced a greater decrease in TE/CAP values after 6 months of diet. Liver biochemistry also improved.
Conclusion: Diet-induced weight loss has beneficial effects on MASLD, and liver disease improves proportionally to its extent. Genetics appear to modulate change in liver disease severity in patients on diet. Weight loss data represent the backbone of our ongoing studies on changes in metabolomics and gut microbiota for these patients, aimed at further investigate the pathophysiology of the disease.

WED-327

Utility of transient elastography in inflammatory bowel disease

Arun Vaidya[1], Vaibhav Padole[1], Chetan Saner[2], Jitendra Yadav[2], Shubham Gupta[1], Ankita Singh[2], Sidharth Harindranath[2], Biswa Ranjan Patra[1], Leela Shinde[2], Apurva Kubal[2], Mayur Satai[2], Love Garg[2], Michael Kuruthukulangara[2], Nitish Patwardhan[2], Akash Shukla[2]. *[1]KEM Hospital, Mumbai, Mumbai, India; [2]KEM hospital, Mumbai, Mumbai, India*
Email: arunvaidyagastro@gmail.com

Background and aims: Inflammatory bowel disease (IBD) is associated with various extraintestinal manifestations including hepatic involvement. Hepatic fibrosis and steatotic liver disease (SLD) is an emerging cause of concern in this population. The reported prevalence of SLD in IBD varies from 1.5% to 55%. Transient elastography (TE) is a non-invasive diagnostic tool to measure liver stiffness, splenic stiffness and controlled attenuation parameter (CAP) and has been validated in a variety of clinical populations. We performed this study to explore the utility of TE in patients with IBD.
Method: This was a prospective cohort study including patients with IBD above 18 years of age. Patients with pre-existing liver disease, chronic kidney disease, alcohol abuse and pregnancy were excluded. Consecutive patients underwent Fibroscan (ECHOSENS 630 Xpert)

after written informed consent and CAP value, liver stiffness measurement (LSM), splenic stiffness measurement (SSM) was performed. F1/F2, F3 and F4 fibrosis was defined as LSM values 6–8 kPa, 8.1–12.5 kPa and >12.5 kPa respectively. Advanced fibrosis was considered when LSM value was >8 kPa. Steatosis severity; S1 (mild), S2 (moderate) and S3 (severe) was defined as CAP values 238–260 dB/m, 261–290 dB/m and ≥291 dB/m respectively.
Results: A total of 80 IBD cases [Ulcerative colitis (UC): 62, Crohn`s disease (CD): 18)] were included, of which 37 (46.3%) were females. Mean age of cohort was 39.3 ± 10.8 years. Among patients with IBD, F1/F2, F3 and F4 fibrosis was seen in 13 (16.3%), 6 (7.5%) and 5 (6.3%) respectively. In UC, F1/F2, F3 and F4 fibrosis was seen in 12 (19.4%), 4 (6.5%) and 4 (6.5%) cases respectively and in CD, F1/F2, F3 and F4 fibrosis was seen in 1 (5.6%), 2 (11.1%) and 1 (5.6%) cases respectively. Among IBD cases, S1, S2 and S3 steatosis was seen in 12 (19.4%), 8 (10%) and 5 (6.3%) respectively. In UC, S1, S2 and S3 steatosis was seen in 7 (11.3%), 7 (11.3%) and 2 (3.2%) patients respectively and in CD, S1, S2 and S3 steatosis was seen in 5 (27.8%), 1 (5.6%) and 3 (16.7%) respectively. Steatosis was significantly more common in CD as compared to UC [9/18 (50%) vs 16/62 (25.8%), p = 0.05). Three patients with IBD had concomitant metabolic syndrome and among them, only one had steatosis and advanced fibrosis. SSM was elevated (>40 kPa) in 7 cases, of which only one patient had advanced fibrosis and rest had normal LSM values. Of those 7 cases with increased SSM, 3 patients were subsequently diagnosed with portal hypertension on cross sectional imaging and/or endoscopy. Two patients diagnosed with portal hypertension were on azathioprine for more than 3 years.
Conclusion: Based on TE findings, there is an increased risk of advanced hepatic fibrosis and steatosis in IBD, even in the absence of metabolic syndrome. SLD occurs more commonly in CD than UC.

WED-330
Description of a cohort of patients with metabolic dysfunction-associated steatotic liver disease followed at an urban liver centre (Toronto liver centre), high prevalence of extrahepatic conditions
Elizaveta Shpilevaia[1], Jason Xu[1], Josh Rais[1], Eva Pavic[1], Eva Fragoso[1], Farah Imdad Ali[1], Mehrdad Modarresi[1], Aleena Ghafoor[1], Anish Jammu[1], Marzena Magnes[1], Magdy Elkhashab[1]. *[1]Toronto Liver Centre, Toronto, Canada*
Email: eshpilevaia@tlccure.com

Background and aims: Non-alcoholic fatty liver disease which is now named as metabolic dysfunction associated steatotic liver disease (MASLD) is considered a systemic disorder encompassing a spectrum of hepatic and extrahepatic conditions. The most common cause for morbidity and mortality among patients with MASLD is cardiac events and extrahepatic malignancies. This study aims to characterize a cohort of patients with MASLD evaluated at an Urban Liver Centre shading light on demographic, MASLD-associated comorbidities and extrahepatic manifestations.
Method: A comprehensive analysis was conducted on cohort of 406 patients diagnosed with metabolic dysfunction associated steatotic liver disease (MASLD) utilizing a complete data set. Demographic information, MASLD-associated comorbidities, FibroScan parameters (fibrosis and steatosis) and extrahepatic conditions were recorded.
Results: The cohort demonstrated a diverse age distribution with the majority falling within 50–69 age range (58.1%). Gender distribution were almost equal with female patients constituting 52% of the cohort. Associated common metabolic comorbidities included obesity (38.2%), hypertension (30.5%), dyslipidemia (26.6%) and type 2 diabetes (28.6%). Severe steatosis, as measured by CAP (Controlled Attenuation Parameter), was reported in 52.7%. Moderate fibrosis (F2), as measured by transient elastography, was reported in 19.5%, F3 was reported in 14% and F4 (cirrhosis) in 17.5%. Common extrahepatic conditions included depression (6.2%), coronary artery disease (1.7%), obstructive sleep apnea (2.5%), gastro-esophageal reflux disease (10.3%), irritable bowel syndrome (4.9%) and hypothyroidism (8.1%). The most common extrahepatic malignancy was breast cancer in 1.7% of female patients.
Conclusion: Non-alcoholic fatty liver disease, now named as MASLD, is a systemic disorder associated with a broad range of extrahepatic conditions. Patients with MASLD should be evaluated and followed by a multidisciplinary team approach to optimally manage disease-associated metabolic comorbidities and extrahepatic conditions. This comprehensive approach to patient care can be a crucial step in preventing major morbidities and reducing high risk of mortality.

Subclinical myocardial fibrosis is related to disease severity in patients with metabolic dysfunction-associated steatotic liver disease (MASLD)
Puria Nabilou[1], Signe Wiese[1], Liv Hetland[1], Mikkel Werge[1], Mira Thing[1], Elias Rashu[1], Anders Junker[1], Mads Barløse[2,3], Hartwig Siebner[2,3], Søren Møller[2,3], Flemming Bendtsen[1,3], Lise Lotte Gluud[1,3], Jens Hove[3,4]. *[1]Gastro Unit, Medical Division, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark; [2]Dept. Clinical Physiology and Nuclear Medicine, Centre of Functional and Diagnostic Imaging and Research, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark; [3]Dept. of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen University, Copenhagen, Denmark; [4]Dept. of Cardiology, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark*
Email: purianabilou@hotmail.com

Background and aims: Myocardial extracellular volume (ECV), derived from advanced cardiac magnetic resonance imaging (CMR), reflects connective tissue in the myocardium. Quantification of myocardial ECV is based on T1 mapping technique with comparison between the pre- and post-contrast T1 relaxation times. An increase in ECV may signify increased fibrosis in the myocardium. We assessed myocardial ECV in metabolic dysfunction associated steatotic liver disease (MASLD) which is increasingly being recognised as a systemic fibroinflammatory disease and which is associated with increased cardiovascular morbidity.
Method: We included 39 patients with histologically verified MASLD without a history of cardiac disease and 11 healthy controls. All participants underwent contrast enhanced CMR with T1 mapping and quantification of myocardial ECV. The patients were extensively characterized including non-invasive biomarkers of liver fibrosis: FibroScan, Fibrosis-4 index (FIB-4), Enhanced Liver Fibrosis Test (ELF), and Pro-C3.
Results: The FibroScan showed that 16 patients had advanced fibrosis with a median value of ≥12.5 kPa and that these patients had an increased myocardial ECV suggesting myocardial fibrosis (28% vs. 27% p = 0.031. Similar results were found for patients (n = 12) with increased ELF score (29% vs. 26%, p = 0.036) and Pro-C3 (n = 11, 29% vs. 27%, p = 0.015). Patients with abnormal myocardial ECV, defined as ECV >27% had significant alterations in structural cardiac parameters including native T1 and T2 relaxation times (1216 vs. 1179, p = 0.032 and 41 vs. 39 ms, p = 0.006) and functional parameters including increased end-diastolic volume (p = 0.034), and cardiac index (p = 0.010).
Conclusion: Myocardial ECV values as well as other structural and functional parameters may have prognostic implications that could be used for risk stratification in MASLD, and our findings suggest that CMR could be considered in the monitoring of patients and possibly in the assessment of pharmacological treatments.

WED-332
FAST and Agile-the MASLD Drift: validation of Agile 3+, Agile 4 and FAST scores in 246 biopsy-proven MASLD patients of prevalent caucasian origin
Madalina-Gabriela Taru[1,2,3,4], Cristian Tefas[3,4], Lidia Neamti[3,4], Iulia Minciuna[3,4], Vlad Taru[3,4,5], Anca Maniu[4], Ioana Rusu[4], Bobe Petrushev[4], Lucia Maria Procopciuc[3], Dan-Corneliu Leucuta[3], Bogdan Procopet[3,4], Silvia Ferri[1], Horia Ștefănescu[4],

Email: madalinagabrielataru@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a prevalent chronic liver condition with substantial clinical implications. This study aimed to assess the effectiveness of three new, elastography-based, scoring systems for advanced fibrosis ≥F3 (Agile 3+), cirrhosis F4 (Agile 4), and fibrotic MASH: MASH + NAS ≥4+ F ≥2 (FAST score), in a cohort of biopsy-proven MASLD patients of prevalent Caucasian origin. Our secondary aim was to compare their diagnostic performances with those of other fibrosis prediction tools, such as liver stiffness measurement by vibration-controlled transient elastography (LSM-VCTE) alone, Fibrosis-4 Index (FIB-4), AST to Platelet Ratio Index (APRI).
Method: We conducted a single-center, retrospective study, in our tertiary medical center from Cluj-Napoca, Romania, on consecutive patients with baseline laboratory tests, liver biopsy, and reliable LSM-VCTE measurements performed within a maximum timeframe of 3 weeks. The discrimination between tests was evaluated by analyzing the AUROCs. Dual cut-off approaches were applied to rule-out and rule-in ≥F3, F4 and fibrotic MASH, respectively. We tested previously reported cut-off values and provided our best thresholds to achieve Se ≥85%, Se ≥90%, and Sp ≥90%, Sp ≥95%. The DeLong test was used for comparison of diagnostic performance between Agile scores, LSM only, FIB-4, and APRI. The statistical significance was considered for p values <0.05 for all tests.
Results: Among 246 patients, 113 (45.9%) were women, and 75 (30.5%) presented diabetes. The median age at baseline was 52 years (IQR, 20) and median BMI was 29.0 kg/m^2 (IQR, 5.1). Agile 3+ and Agile 4 demonstrated excellent performance in identifying ≥F3 and F4, achieving AUROCs of 0.909 [0.866–0.942] and 0.968 [0.937–0.986], while the FAST score yielded acceptable results in distinguishing fibrotic MASH, with an AUROC of 0.679 [0.594–0.757]. By using Agile 3+ standard cut-off values for ≥F3, 0.451 and 0.679, and LSM-VCTE standard cut-off values for ≥F3, 8 kPa and 12 kPa, the proportion of patients that were left unclassified were 12.6% and 21.9%, respectively (McNemar's exact test p = 0.003). By using Agile 4 standard-cut-off values for F4, namely 0.251 and 0.565, and the LSM-VCTE cut-offs of 8 kPa and 20 kPa, then 10 kPa and 20 kPa, the proportion of patients that were left unclassified were 11.4%, 39.4% and 26.8%, respectively (McNemar's exact test p < 0.0001 for both scenarios).
Conclusion: This study validates Agile 3+ and Agile 4 as reliable, non-invasive tests for identifying advanced fibrosis or cirrhosis in MASLD patients, while FAST score demonstrated only moderate performance in identifying fibrotic MASH. Importantly, we showed that Agile scores show better classification of patients with advanced fibrosis or cirrhosis compared to LSM-VCTE, as they significantly reduce the number of patients left in the "grey zone."

WED-333
Association of clinical and biochemical parameters and polygenic risk score in a metabolic steatosis population of southern Italy

Benedetta Maria Motta[1], Mario Masarone[1], Pietro Torre[1], Marco Aquino[1], Federica Belladonna[1], Marcello Persico[1]. [1]*Internal Medicine and Hepatology Division, Department of Medicine, Surgery and Dentistry, "Scuola Medica Salernitana", University of Salerno, Baronissi (Salerno), Italy*
Email: bmotta@unisa.it

Background and aims: Metabolic Associated Steatotic Liver Disease (MASLD) is the leading cause of liver diseases, ranging from simple steatosis to steatohepatitis. Environmental and genetic factors have been demonstrated to influence the susceptibility to MASLD development. The gold standard for diagnosis and staging of MASLD is liver biopsy, however, it is an invasive procedure, subject to sampling errors and inter-observer variability. Several non-invasive methods aim at diagnosing hepatic steatosis and predicting significant/advanced fibrosis. GWAS studies identified genetic risk factors, which have been analyzed to develop genetic risk scores (GRS) for liver disease risk stratification. MASLD susceptibility is highly associated with four genetic variants: *PNPLA3* rs738409, *TM6SF2* rs58542926, rs641738 close to *MBOAT7* locus, *GCKR* rs1260326. Our aim was to evaluate how a polygenic risk score based on these variants correlate with liver steatosis and biochemical phenotypes in our dysmetabolic population of Southern Italy.
Method: We enrolled 103 patients attending our Hepatology Unit department, which were genotyped for rs738409, rs58542926, rs641738, rs1260326 by TaqMan 5′-nuclease assays. We used a weighted polygenic risk score (PRS), calculated by multiplying the effect size (beta-coefficient) on steatosis by respective risk alleles and summing the products. Anthropometric data and blood test results were collected.
Results: The effect of the 4 variants on the risk of developing more severe liver disease was evaluated in our population by a weighted PRS, which increased from simple steatosis to MASH/MASH-cirrhosis subjects (p = 0.03).
The effect of the 4 variants together was evaluated by PRS also in biochemical parameters. ALT (p = 0.01), AST (p = 0.003), total cholesterol, and triglycerides levels increase proportionally with PRS, while LDL levels decrease (p = N.S).
Subjects with high PRS (≥0.532) show a significant higher level of ALT (p = 0.04) and an increased AST level (p = N.S.)
Conclusion: This study shows that in our population, the polygenic risk score correlates with biochemical and clinical parameters, identifying the most dysmetabolic subjects.

WED-334
Comparison of Hepatoscope® and FibroScan® for non-invasive assessment of hepatic steatosis and fibrosis among mexican immigrant adults along the southern Arizona United States/ Mexico border

Edgar Villavicencio[1], Adriana Maldonado[1], Estefania Ochoa Mora[2], Ana Gonzalez[1], Naim Alkhouri[3], David Garcia[1]. [1]*University of Arizona, Mel and Enid Zuckerman College of Public Health, Health Promotion Sciences, Tucson, Arizona, United States;* [2]*University of Arizona, Clinical Translational Sciences, University of Arizona Health Sciences, Tucson, Arizona, United States;* [3]*Arizona Liver Health, Chandler, Arizona, United States*
Email: evillavicencio@arizona.edu

Background and aims: Mexican-origin adults have one of the highest rates of metabolic dysfunction-associated steatotic liver disease (MASLD) in the United States (U.S). Given the costs and invasiveness of liver biopsy as the gold standard assessment, transient elastography (TE) by FibroScan® (Echosens, France) has emerged as the non-invasive reference tool for hepatic steatosis and fibrosis within clinical care. However, as other point-of-care non-invasive tests (NITs) for TE are introduced to the commercial market, it is important to assess the comparisons of such methods. Therefore, this study compares a new commercially available TE (Hepatoscope®) and FibroScan® for the non-invasive assessment of hepatic steatosis and fibrosis among Mexican immigrant adults along the Southern Arizona U.S./Mexico border.
Method: Paired sample t-tests were conducted to analyze data from an ongoing prospective cross-sectional community-based sample of 138 Mexican-origin adults (women = 101; men = 37). Hepatic steatosis is assessed via FibroScan® and Hepatoscope® using continuous

attenuation parameter (CAP) values measured in decibels per meter (dB/m). MASLD was identified as having a CAP score ≥288 dB/m. Liver stiffness measurements (LSM) in kilopascals (kPa) indicate fibrosis values.

Results: Based on FibroScan® results, 51 participants (37%) were identified with MASLD, including 23% of women and 14% of men. Whereas Hepatoscope® results indicated that 28 participants (20%) had MASLD, including 50% of women and 50% of men. FibroScan® and Hepatoscope® steatosis (r = 0.51, p <0.001) and fibrosis levels (r = 0.42, p < 0.001) were positively correlated. CAP scores were higher for FibroScan® (mean = 269.3 dB/m ± 49 dB/m) compared to Hepatoscope® (mean = 250.9 dB/m ± 43 dB/m). More specifically, an 18.4-point difference (*SD* = ±45.8dB/m) between FibroScan® and Hepatoscope® was observed (95% CI = 10.7, 40.9, $p < 0.001$) for CAP scores. While fibrosis levels were slightly higher for Hepatoscope® (mean = 5.6 kPa ± 2.5 kPa) than for FibroScan® (mean = 5.2 kPa ± 2.7 kPa), there were no statistically significant differences between screening methods (95% CI = –0.8, 0.1, $p = 0.1$).

Conclusion: Our results indicate hepatic steatosis levels are underestimated via Hepatoscope® in comparison to FibroScan®; however, liver fibrosis levels are comparable between screening methods. This study expands on the critical need for the continued availability of reliable and cost-effective NITs for the assessment of liver disease, particularly among high-risk underrepresented populations.

Email: carmenlararomero@gmail.com

Background and aims: Metabolic-Associated Steatotic Liver Disease (MASLD) is an overwhelming burden for the health care system. Accurate algorithms are need to select patients at risk of progression better.

Method: We included patients with MASLD at risk of fibrosis referred from primary care. One-hundred and nineteen patients (65 males and 54 females; 68% with T2DM) showing at least one NIT altered: FIB4>1.3; Hepamet Fibrosis Score (HFS)>0.12 or NAFLD Fibrosis Score (NFS)>-1.455 were included in a two steps algorithm comparing TE (Fibroscan®) and ELF® (Siemens) as reflex test. Fibrosis stage was confirmed by MRE. Significant fibrosis was defined by MRE ≥3.14 kPa and when not available: TE>10 kPa + ELF>11.3 + combined score = 3. Combined score was calculated adding 1 point if FIB-4 >1.3; NFS>-1.455; HFS >0.12 or zero when under the cut-off scoring from 0 to 3. Age: 63 ± 10; BMI: 30.4 ± 6 kg/m^2; HbA1c: 6.4 ± 1.2%; FIB4: 1.90 ± 1.64; HFS: 0.19 ± 0.17; NFS: –0.25 ± 2.9 and combined score: 1p: 69 (50%); 2p: 33p (28%); 3p: 26p (22%). VCTE: 9.19 ± 11.41 kPa; CAP: 276 ± 55; ELF: 10.24 ± 1.01.

Results: NITs alteration was found: FIB4: 78/118 (66%); HFS: 63/118 (53%); NFS: 99 (84%); VCTE>8 kPa: 35/118 (30%) and ELF: 78/118 (66%). Significant fibrosis in 20.7% (24/116). ELF>9.8 was found in 49 patients with VCTE<8 kPa and VCTE >8 kPa was found in 6 patients with ELF<9.8; p < 0.018. Just 1 patient with VCTE<8 kPa showed significant fibrosis at MRE and just one too with ELF>9.8 but VCTE<8 kPa showed fibrosis. Sensitivity (S), specificity (Sp) and diagnostic accuracy (DA) were calculated: FIB-4 (S:0.88, Sp:0.39; DA:0.49); HFS (S:0.67; Sp:0.51; DA:0.54), NFS (S:0.88, Sp: 0.16, DA 0.31), TE (S: 0.96; Sp: 0.87, DA 0.88), ELF (S: 0.72, Sp 0.41, DA 0.52), combining ELF>9.8 + VCTE>8 kPa (S:0.88, Sp:0.91, DA: 0.9). A Sankey diagram showed in clear difference between both algorithms.

Conclusion: Referral rate using just freely available NITs seems suboptimal. Combining NITs + VCTE or ELF significantly reduced referral rate, but the combination of both altered VCTE and ELF could better select patients at risk of advanced fibrosis and save unnecessary referral. These results confirmed available data on AGA and AASLD Clinical Practice Guidelines recommending VCTE or ELF respectively after FIB-4.

Background and aims: The epidemic of metabolic-dysfunction associated steatotic liver disease (MASLD) and its related hepatic and extrahepatic complications, mostly observed in patients with advanced liver fibrosis, raise concerns about the lack of standardized approaches for case finding and linkage to care. The overall goal is the building of a regional network -RESIST-NASH- using standardized models for identification and referral of MASLD patients at risk for liver fibrosis.
Method: Networking Sicilian specialists in gastroenterology, internal medicine and diabetology. Building a web-based platform for the standardized recording of data about patients with MASLD and/or metabolic risk factors. Automatical elaboration of the FIB-4 score, and according to Italian AISF/SID/SIO guidelines, only patients with a FIB-4 >1.3 are further evaluated by performing FibroScan and by recording further data. The platform allows a direct booking of FibroScan test and of hepatological evaluation across centers. Follow-up visits recording clinical events are also allowed.
Results: From 1th April 2023 to 31th October 2023 thirty-eight centers were activated across the Sicily, and twenty-one actively recruited patients with MASLD and/or metabolic risk factors. Nine FibroScan devices were available across the Sicily and shared among centers. Data on 1, 424 patients were recorded. Mean age was 58.9 years, 55.2% were male, 47.6% obese, 45.9% were affected by diabetes. Fifty-six percent of patients had a FIB-4 <1.3 and were not worthy of further assessment, while 31.7% were at intermediate risk (FIB-4 1.3–2.67) and 12.3% at high risk (FIB-4 >2.67) of advanced liver fibrosis. Elaboration of data of liver stiffness measurement in patients with at risk FIB-4 and characteristics of this population are ongoing.
Conclusion: RESIST-NASH network can allow a systematic approach to patients with NAFLD and/or with metabolic comorbidities, leading to the correct identification and early referral of patients with liver disease worthy of a specialistic follow-up and management.

WED-337

The non-invasive assessment of liver fibrosis in metabolic dysfunction associated steatotic liver disease (MASLD) in the chinese population: a scoping review

Lai Wei[1,2], Di Cao[3], Xuan Qi[3], Ying Wang[3], Yuemin Nan[4].
[1]*Hepatopancreatobiliary Center, Beijing Tsinghua Changgung Hospital, Beijing, China;* [2]*School of Clinical Medicine, Tsinghua University, Beijing, China;* [3]*Novo Nordisk (China) Pharmaceuticals Co., Ltd, Beijing, China;* [4]*Department of Traditional and Western Medical Hepatology, Hebei Medical University Third Hospital, Shijiazhuang, China*
Email: weelai@163.com

Background and aims: Non-invasive tests (NITs)-based risk stratification pathways have been recommended in growing numbers of MASLD guidelines. However, the current guidelines in China do not include the aforementioned pathways, and the awareness, acceptance and clinical practice of NITs among Chinese physicians are relatively low. Therefore, we carried out a scoping review to evaluate the sufficiency of NITs related evidence in China, scrutinize their performance and identify potential data gap.
Method: We followed the Arksey and O'Malley framework for scoping reviews. A search was conducted in 3 English and 4 Chinese databases from Jan 2012 to Mar 2023. Eligible studies must target liver fibrosis assessment in Chinese patients with MASLD (previously known and studied as NAFLD or MAFLD), use liver biopsy as the gold standard, and report at least AUROC for diagnostic performance.
Results: Out of 12, 714 retrieved articles, 81 studies were included, involving 35, 260 subjects. The majority of the studies (66) focused on the general MASLD population, one on children, and the remaining 14 investigated MASLD patients with comorbidities such as chronic hepatitis B, diabetes/prediabetes, or obesity. Furthermore, several confounders of the diagnostic performance have been tested, including BMI, age, the degree of hepatic steatosis, HBV infection, AST level, genetic polymorphism of PNPLA3 and the diabetes status. Advanced fibrosis (≥F3) is generally recommended to be screened as the high-risk stage. 35 studies reported diagnostic performance in identifying advanced fibrosis in general MASLD population. 15 studies reported imaging diagnostic methods, 9 of which included evidence of transient elastography (TE), AUROC ranging 0.71–0.94. In 3 with more substantial sample sizes in China (>200), AUROCs was reported to be 0.78–0.94. MRE had the best AUROC of 0.937–0.95, but only 2 studies were identified with relatively small sample sizes (72 and 77 respectively). 25 studies reported evidence for serological biomarkers, scoring tools or algorithms in identifying advanced fibrosis in general MASLD population, among which FIB-4, NFS, and APRI (≥15 studies for each) had the most abundant evidence, but a highly scattered distribution of AUROC. However, when using the recommended cut-off value, FIB-4 had high negative predictive value (range: 89.6%-91.5%, cut-off value 1.3) in ruling out advanced fibrosis, as well as NFS (NPV range: 88%-94.8%, cut-off value −1.455). Similar analysis has been conducted for significant fibrosis (≥F2) and cirrhosis (F4).
Conclusion: FIB-4, NFS and TE have been extensively studied in the Chinese population. The performance of FIB-4 and NFS as ruling out tools and TE as a diagnostic tool was similar to that reported in the Western population. The risk stratification pathway recommended by western guidelines might also be applicable to the Chinese population.

Transcriptomic analysis reveals novel biomarkers and PI3K-AKT signaling pathway findings of at-risk metabolic dysfunction-associated steatohepatitis

Wen Wang[1], Xiaoxue Zhu[1], Aruhan Yang[1], Yanhua Ding[2], Guoyue Lv[3].
[1]*Department of Phase I Clinical Trial Center, The First Hospital of Jilin University, Changchun, Jilin, China, changchun, China;* [2]*Department of Phase I Clinical Trial Center, The First Hospital of Jilin University, Changchun, Jilin, China, Department of Phase I Clinical Trial Center, The First Hospital of Jilin University, Changchun, Jilin, China, China;* [3]*The First Hospital of Jilin University, Changchun, Jilin, China, changchun, China*
Email: dingyanhua2003@126.com

Background and aims: At-risk metabolic dysfunction-associated steatohepatitis (NASH), which NAFLD activity score ≥4 and significant fibrosis ≥2, lacks systematic research on the genes and potential novel biomarker.24 patients liver biopsy RNA-seq distinguishes differential gene expression between Healthy, MASL and at-risk MASH, clarifies the relationship between these differences and changes in clinical indicators in order to screen out at-risk NASH and reveal the genetic susceptibility mechanism of at-risk MASH.
Method: 24 liver biopsy samples were classified into Healthy (N = 8), MASL (N = 8), and at-risk MASH (N = 8) according to the NAFLD Activity Score (NAS)The multiple groups comparisons were based on Generalized Linear Model (GLM, adjusted p value <0.05 corrected by BH). The Gene set enrichment analysis (GSEA) was based on the Kyoto Encyclopedia of Genes and Genomes (KEGG) database. The transcriptomic and clinical data integrated network analysis were performed by Weighted correlation network analysis (WGCNA) method. The correlation between gene expression module and clinical phenotypes were calculated by Pearson's correlation. Subsequently, the functional enrichment analysis for each co-expressed gene module were based on over-representation analysis, the co-expression network analysis were based on string database.
Results: 786 potential biomarkers were identified among Healthy (10), MASL (49), and at-risk MASH (727) which were highly expressed based on transcriptomic analysis. The gene set enrichment analysis (GSEA) revealed the MASLD pathway were activated whereas the PI3K-AKT signaling pathway was inhibited in at-risk MASH ($p.adj < 0.001$). The biosynthesis of co-factors and protein processing pathway related genes were down regulated at Healthy and MASL.

The WGCNA analysis indicated 3 gene modules related to at-risk NASH is not only highly correlated with Metabolic syndrome (TG, $r^2$0.56, *p.adj* < 0.05; HbA1C, $r^2$0.50, *p.adj* < 0.01; UA, $r^2$0.65, *p.adj* < 0.001) but also MRI-PDFF ($r^2$0.83, *p.adj* < 0.001), LSM (r^2 = 0.62, *p.adj* = 0.001). Spontaneously, ALT ($r^2$0.88, *p.adj* < 0.001), AST ($r^2$0.75, *p.adj* < 0.001) and ferritin ($r^2$0.58, *p.adj = 0.003*) are highly related to. Those genes mainly related to fatty acid biosynthesis as well as PARP signaling pathway (*p.adj = 0.03*). Additionally, fabp4 and ccl22 genes were located in this cluster, which could be considered as biomarker of MASH.
Conclusion: This study systematically described novel biomarkers at-risk MASH, which provide potential drug target and suggest the genetic susceptibility mechanism of at-risk MASH.

WED-339
MASLD patients with liver cirrhosis have an increased early cardiovascular risk measured by epicardial adipose tissue
Marta Hernández Conde[1], Elba Llop Herrera[2], Christie Perelló[3], Susana Mingo[4], Marta López-Gómez[2], Javier Abad Guerra[2], José Luis Martínez Porras[2], Natalia Fernández Puga[2], Jesús Rivera[2], José Luis Calleja Panero[2]. [1]*Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain;* [2]*Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain;* [3]*Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain;* [4]*Hospital Puerta de Hierro Majadahonda, Madrid, Spain*
Email: marta.hernandez.conde@gmail.com

Background and aims: Epicardial adipose tissue (EAT) has been related to a higher risk of cardiovascular events. Its presence is related to excess visceral fat. The relationship between MASLD and the presence of EAT is unknown. We aimed to evaluate the association of liver fibrosis in MASLD patients with TAE.
Method: Cross-sectional observational study of 65 patients with MASLD diagnosed by liver biopsy at the Puerta de Hierro University Hospital between 2016 and 2023 and without a history of previous cardiovascular events.
Results: Regarding baseline characteristics: Most patients (70.8%) have metabolic syndrome. According to liver fibrosis: 30.6% of patients have liver cirrhosis and 37.5% have advance fibrosis. Mean BMI is 32.8 kg/m^2. Elevated EAT (>9.5 mm men; >7.5 mm women) is presented in 15% of patients. The EAT has good correlation with excess body fat (VAT: r = 0.36, p = 0.003; BMI: r = 0.35, p = 0.005; CAP through Fibroscan®: r = 0.30, p = 0.018). Furthermore, patients with Metabolic syndrome have more EAT (7.6 vs. 6.1; p = 0.009), although it is not associated with the number of metabolic risk factors (p = 0.169). In our study, a direct association between liver fibrosis and EAT is evident (Kwallis; p = 0.049; Image). Patients with liver cirrhosis have more EAT (8 vs 6.8; p = 0.06). Furthermore, elevated EAT is more common among patients with cirrhosis (31.5% vs. 10.2%; p = 0.043).
Conclusion: Liver fibrosis in patients with MASLD is associated with higher EAT. Therefore, MASLD staging could help identify patients at cardiovascular risk.

Agreement between two-dimensional shear wave elastography and transient elastography in metabolic dysfunction-associated steatotic liver disease: implications for primary care screening
Shelley Keating[1], Kanishk Chaudhary[2], Nicolette Gale[3], Thomas Lloyd[4], Graeme Macdonald[2]. [1]*The University of Queensland, School of Human Movement and Nutrition Sciences, Brisbane, Australia;* [2]*Princess Alexandra Hospital, Department of Gastroenterology and Hepatology, Woolloongabba, Australia;* [3]*Princess Alexandra Hospital, The Medical Imaging Department, Woolloongabba, Australia;* [4]*Princess Alexandra Hospital, Department of Radiology, Woolloongabba, Australia*
Email: s.keating@uq.edu.au

Background and aims: Current practice guidance (AASLD 2023) recommend screening patients with metabolic dysfunction-associated steatotic liver disease (MASLD) for advanced liver disease for specialist referral. Algorithms currently rely on vibration-controlled transient elastography (VCTE) and blood-based tests. In Australia and elsewhere, access to VCTE in the community is limited. However, other elastography modalities such as two-dimensional shear wave elastography (SWE) are being incorporated into ultrasound services available to primary care. The utility of SWE in evaluating MASLD is not known. We examined the agreement between SWE and VCTE in patients referred from primary care to a specialist service.
Method: Participants were patients referred from primary care to a MASLD clinic. All participants had VCTE and SWE. Agreement between these were evaluated by Bland-Altman plots and/or Passing-Bablok regression analysis. Systematic bias (via one-sample t-test and examination of y = 0) and proportional bias (via linear regression) were determined. Variables impacting agreement between the methods were examined via multiple regression. The McNemur test determined differences in the proportions of participants correctly identified by SWE with VCTE result of >8 kPa.
Results: 72 patients (54 ± 14 years, 43 % male, BMI 34.0 ± 7.1 kg/m^2) were recruited, but in 12 the VCTE and/or the SWE study were of poor quality and their data not further analysed. The remaining 60 patients had a median VCTE of 5.5 [3.4 to 7.7 kPa], with a IQR centile of 6.0 [2.3 to 9.8 %]. The mean difference between VCTE and SWE was 0.93 kPa (95 % CI, 0.06 to 1.80 kPa; Lower to Upper Limit of Agreement 5.69 to 7.55 kPa), with systematic and proportional bias present. Increasing VCTE interquartile range (IQR) centile (adjusted for age, controlled attenuation parameter and alanine aminotransferase) was the only factor identified that correlated with the discrepancy between methods (beta = 0.9, p < 0.001). Every one-centile increase in VCTE IQR was associated with an increase in the difference between VCTE and SWE of 0.9 kPa. The predictive performance of SWE to identify patients with a VCTE of >8 kPa was evaluated at SWE of 7 kPa (based on the observation that SWE underreporting VCTE by ~1 kPa), with specificity 25 %, sensitivity 94 %, and positive and negative predictive powers of 50 % and 83 % respectively. A SWE cut-off of 6 kPa improved sensitivity to 42 % with specificity at 80 %.
Conclusion: On average, SWE underestimated liver stiffness compared with VCTE by 0.93 kPa. The discrepancy between VCTE and SWE increases as VCTE and VCTE IQR increase. SWE has the potential to be used in the evaluation of patients with MASLD where VCTE is not readily available in the community.

WED-341
EUS-guided assessment of steatotic liver disease in bariatric surgery patients
Paula Fernandez Alvarez[1], Rafael Romero Castro[1], Maria Tous Romero[1], Alvaro Gutierrez Dominguez[1], Félix Conde Martín[1], Juan José Ríos Martín[1], Victoria Alejandra Jiménez García[1], Eduardo Dominguez Adame[1], Patricia Cordero Ruiz[1], Francisco Luis Bellido Muñoz[1], Manuel Rodríguez Téllez[1], Angel Caunedo Alvarez[1], Isabel Carmona Soria[1]. [1]*Virgen Macarena University Hospital, Seville, Spain*
Email: paulafer7@gmail.com

Background and aims: Bariatric surgery patients have a higher prevalence of metabolic dysfunction-associated liver disease (MASLD). Percutaneos liver biopsy has technical difficulties and non-invasive markers are not very accurate in this population. The aim was to evaluate the efficacy and safety of EUS-guided bilobar liver biopsy plus EUS-guided portal pressure gradient measurement in diagnosing MASLD and its correlation with non-invasive test patients undergoing bariatric surgery.
Method: An observational, prospective and single-center study was carried out. Patients with suspected of MASLD by liver ultrasound or fatty liver index (FLI) score >60 were included. Demographic, anthropometrics, blood test, non-invasive serological markers (FLI, NAFLD, HEPAMET, APRI, FIB-4) and transient elastography (TE) with XL probe variables were evaluated.

Results: A total of 48 patients were evaluated between august 2022 and June 2023. Finally, 33 patients were included (10 refused to participate, 4 were excluded, 1 due totechnical difficulties). The prevalence of MASLD was 68.8%, of metabolic dysfunction-asociated steatohepatitis (MASH) was 54.5%, and of fibrosis (F1-F2) was 12.6%. EUS-guided portal pressure gradient median was 4.25 mmHg. Remarkably, 9/33 (27.7%) patients had a portal pressure gradient >6 mmHg. MASLD patients showed higher levels of fibrosis determined by transient elastography (TE), steatosis evaluated by coefficient attenuated parameter (CAP) and portal vein pressure, although they were not statistically significant. No differences were detected in FIB-4, NAFLD and HEPAMET scores according to MASLD patients. The quality of liver biopsies was deemed adecuated with a median of 7 portal spaces. Adverse events were observed in 2 patients after procedure. One patient suffered mild abdominal pain and the other was diagnosed of atrial fibrillation with rapid ventricular that was successfully reversed with medical therapy.
Conclusion: The prevalence of MASLD and MASH was high in morbid obesity patients. EUS-guided portal pressure gradient and EUS-guided liver biopsies in one-step seem safe and accurately in evaluating the presence of portal hypertension and the underlying steatotic liver disease.

WED-342
Can we define MASLD in liver outpatient clinics? Keeping up with the changing nomenclature

Mercy Karoney[1], Riham Soliman[2], Mzamo Mbelle[3], Ashley Barnabas[4].
[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Institute of Liver Studies, King's College Hospital, london, United Kingdom; [3]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [4]Institute of Liver Studies, King's College Hospital, London, Kenya
Email: karoneymercy@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) remains the most common chronic liver disease which affects one third of the adult global population. A multi-society Delphi consensus introduced the new nomenclature MASLD which was previously termed Non-Alcoholic Fatty liver disease (NAFLD) in July 2023. This new nomenclature is considered less stigmatizing, more affirmative, and adequately reflects the role of metabolic dysfunction in the disease spectrum. While NAFLD was based on the exclusion of any other liver disease, MASLD is defined by evidence of hepatic steatosis and at least 1 out of 5 cardiometabolic risk factors. Additionally, the updated nomenclature added MetALD which a distinct subtype that considers weekly alcohol consumption more than 140 grams or 210grams for women and men respectively. This change in terminology calls for reclassification of patients previously labelled NAFLD and some discrepancy is expected. The aim of this project was to describe how a cohort of already defined NAFLD patients fit into the newly defined criteria for MASLD and the subtype MetALD.
Method: This was an audit project on NAFLD patients attending the outpatient liver service of King's College Hospital, London. We collected data from records of patients previously diagnosed as NAFLD by the presence of fatty liver on ultrasound, controlled attenuation parameter of FibroScan (Echosens, Paris), or liver biopsy. The collected data was evaluated against the 2023 MASLD criteria.
Results: A total of 201 patients were included in the final analysis, the mean age was 57.4 years, range of 19.7 to 87.6 years, majority of the patients were male 112/201 (55%). Most of the patients, 156/201 (77.6%) had at least one cardiometabolic risk factors out of the five required in the definition for MASLD. The most common cardiometabolic risk factor present was Diabetes 47.8%, followed by Dyslipidaemia in 40.3%. Alcohol use was recorded in 25% (95%CI 8.21 to 17.8%), out of those who reported alcohol consumption, 46% had excess weekly consumption of alcohol. Other liver comorbidities were present in 22% of the patients including Hepatitis B, Hepatitis C, alcohol related liver disease, autoimmune liver disease, Haemochromatosis and Alpha one antitrypsin deficiency. Out of the total 201 patients, those who met the criteria for MASLD were 89%, Met-ALD was 9% while only 3% did not fit the MASLD criteria.
Conclusion: The new nomenclature, though simple with easily measurable parameters might have some discrepancy with previously defined terminologies as demonstrated here. The use of this nomenclature should be adopted in clinical practice as it eliminates the heterogeneity observed with the previous definition. It is important to check for all the cardiometabolic risk factors as they may indicate a higher risk of fibrosis.

WED-343
Transducer reproducibility in liver ultrasound-derived fat fraction measurements

Reinhard Kubale[1], Guenther schneider[1], Paul Lessenich[1], Arno Bücker[1], Sebastian Wassenberg[2], Gabriela Torres[3], Arati Gurung[3], Timothy Hall[4], Yassin Labyed[3]. *[1]Universität des Saarlandes, Homburg, Germany; [2]punkt05, Düsseldorf, Germany; [3]Siemens Healthineers, Issaquah, United States; [4]University of Wisconsin Madison, Madison, United States*
Email: kubale@mac.com

Background and aims: Ultrasound-Derived Fat Fraction (UDFF) is an emerging, multiparametric imaging tool used for non-invasive quantification of liver fat content. This technique shows promise in the evaluation of Metabolic Associated Steatotic Liver Disease (MASLD). The reproducibility of UDFF measurements remains a key determinant of its wider clinical application and potential. Our study aims to assess the reproducibility of liver UDFF measurements across different transducers.
Method: This study included adult subjects with clinical indication for ultrasound examination. 25 participants were scanned using the Siemens SEQUOIA Ultrasound System (software revision, VA30), with three different transducers: DAX (Deep Abdominal Transducer), 5C1, and 9C2. The DAX transducer, designed for high BMI subjects, was used alongside the more broadly used 5C1 and the 9C2, which is typically used for lower BMI individuals and children. For each subject, five UDFF measurements were obtained using each transducer. These measurements were acquired intercostally, targeting approximately the same liver region, about 1.5 cm below the liver capsule. Transducer reproducibility was evaluated using the Intraclass Correlation Coefficient (ICC). The agreement in UDFF measurement among the three transducers was assessed through Bland-Altman Analysis, and the linearity with the Pearson Correlation Coefficient (r).
Results: The study demonstrated good agreement between UDFF measurements using the DAX and 5C1 transducers, with a mean difference of 0.94% (95% CI −0.7–2.6) and 95% limits of agreement ranging from −7.5% (95% CI −9.8–−5.2) to 9.6% (95% CI 7.9–11.3). The Pearson correlation coefficient and ICC for agreement between DAX and 5C1 were r = 0.81 (95% CI: 0.39–0.87) and 0.81 (95% CI: 0.62–0.91) respectively. Likewise, the mean difference between DAX and 9C2 transducers was −1.14% (95% CI −2.5–2.2), with 95% limits of agreement from −7.9% (95% CI −9.3–−6.6) to 5.6% (95% CI 4.3–7.0); the Pearson correlation coefficient r = 0.88 (95% CI: 0.49–0.93) and ICC was 0.87 (95% CI: 0.73–0.94). When comparing the 5C1 and 9C2 transducers, the mean difference was −2.0% (95% CI −3.5–0.7), with 95% limits of agreement from −9.1% (95% CI −10.5–−7.7) to 4.9% (95% CI 3.5–6.3). The Pearson correlation coefficient and ICC for agreement between 5C1 and 9C2 were r = 0.87 (95% CI: 0.55–0.88) and 0.84 (95% CI: 0.60–0.93).
Conclusion: This study demonstrates good reproducibility of UDFF measurements with various transducers on the Siemens SEQUOIA Ultrasound System. The findings suggest the potential benefit of a correction factor to minimize differences between transducers. Future research is needed to understand and mitigate confounding

factors to further optimize UDFF clinical protocols and expand its clinical relevance.

WED-347

Diagnosis of advanced liver fibrosis: the synergy of open data, synthetic data generation, CatBoost, and feature engineering

Athanasios Angelakis[1,2,3]. [1]*Amsterdam University Medical Centers, Amsterdam, Netherlands;* [2]*Amsterdam Public Health Research Institute, Amsterdam, Netherlands;* [3]*University of Amsterdam-Data Science Center, Amsterdam, Netherlands*
Email: a.angelakis@amsterdamumc.nl

Background and aims: In the landscape of liver disease management, accurately predicting advanced liver fibrosis is crucial yet challenging. This study illuminates the transformative role of synthetic data generation, advanced machine learning algorithms like CatBoost, and sophisticated feature engineering in enhancing the prediction of advanced fibrosis using the FIB-4 score.
Method: Leveraging open MASLD datasets from China (540 patients), Malaysia (147 patients), and India (97 patients), our study introduces a novel approach combining CatBoost—a potent gradient boosting algorithm—with intricate feature engineering on the components of the FIB-4 score. A distinguishing aspect of our methodology is the use of CTGAN for synthetic data generation, a cutting-edge technique that synthesizes realistic and diverse tabular data, addressing issues of data scarcity and imbalance. The training dataset, comprising data from China and India (637 patients), was enriched with a synthetic dataset of 802 instances (originally 1000, with negative values removed) generated via CTGAN. This resulted in a robust and augmented training set of 1517 instances, providing a more comprehensive representation of the patient spectrum.
Results: The inclusion of synthetic data proved pivotal. The ROC-AUC on the test set (Malaysia) for the standard FIB-4 score was 0.7514. Our ML model, which intricately utilizes the FIB-4 score parameters (ML-FIB4), achieved a ROC-AUC of 0.7857. Remarkably, the model enriched with synthetic data augmentation (DA_ML_FIB4) further elevated the ROC-AUC to 0.7944. These results underscore the significant impact of synthetic data generation in enhancing the model's predictive capability and generalizability to diverse patient populations.
Conclusion: The integration of CTGAN-generated synthetic data, coupled with the predictive power of the CatBoost algorithm and innovative feature engineering, marks a substantial advancement in the field of liver fibrosis prediction. This study not only demonstrates improved diagnostic accuracy but also paves the way for leveraging synthetic data in medical research, particularly in scenarios of limited or unbalanced datasets.

WED-348

High prevalence of liver fibrosis and cirrhosis among cohort of patients referred to an urban liver centre for evaluation of metabolic dysfunction-associated steatotic liver disease (utility of transient elastography)

Anish Jammu[1], Jason Xu[1], Josh Rais[1], Elizaveta Shpilevaia[1], Aleena Ghafoor[1], Farah Imdad Ali[1], Eva Pavic[1], Eva Fragoso[1], Mehrdad Modarresi[1], Marzena Magnes[1], Magdy Elkhashab[1]. [1]*Toronto Liver Centre, Toronto, Canada*
Email: anishjammu@live.ca

Background and aims: Metabolic dysfunction associated steatotic liver disease (MASLD) is a prevalent liver disorder worldwide. It encompasses a spectrum of conditions ranging from simple steatosis to advanced fibrosis and cirrhosis. Metabolic dysfunction associated steatohepatitis (MASH) is a potentially progressive form of MASLD that can lead to liver fibrosis and cirrhosis. To date, MASH diagnosis is only done through liver biopsy which is an invasive procedure. Transient elastography is a non-invasive tool that can stratify fibrosis stage in order to identify a subgroup of patients who may benefit from having a liver biopsy.
Method: A total of 406 patients were evaluated with a full liver profile to rule out other associated liver diseases. Only patients with pure MASLD were included and stratified with transient elastography to assess the degree of liver fibrosis and steatosis. Patients who had moderately elevated liver stiffness of 8.5 kPa and above were considered for liver biopsy to diagnose MASH. Biopsy results were available in 93.3% of the eligible patients.
Results: The cohort demonstrated a diverse age distribution, with the majority falling within the 50–69 age range (58.1%). The female-to-male ratio was almost equal, with females constituting 52% of the cohort. Common associated comorbidities included obesity (38.2%), hypertension (30.5%), dyslipidemia (26.6%), and type 2 diabetes (28.6%). Transient elastography results demonstrated stage 2 fibrosis (F2 in 19.5%), stage 3 fibrosis (F3 in 14% of the patients), and cirrhosis (F4 in 17.5% of patients). Among patients eligible for liver biopsy, MASH was reported in only 30.5% of cases by the liver pathologist.
Conclusion: Transient elastography is a valuable non-invasive technology for stratifying the severity of liver fibrosis among patients with MASLD referred for liver evaluation. While liver biopsy is still considered to be the gold standard for diagnosing MASH, it has demonstrated significant limitations even when interpreted by a qualified liver pathologist. There is a pressing need for new non-invasive serological markers/technologies to identify patients with MASH who are at greatest risk of developing liver fibrosis and cirrhosis.

MASLD – Experimental and pathophysiology

CD36-mediated hepatocyte-macrophage coordination drives hepatic fibrosis in MASLD

Zhe Dai[1], Yijin Wang[2]. [1]*Southern University of Science and Technology, Shenzhen, China;* [2]*Southern University of Science and Technology, Shenzhen, China*
Email: wangyj3@sustech.edu.cn

Background and aims: In the context of metabolic dysfunction-associated liver disease (MASLD), a progressive replacement of resident Kupffer cells (ResKCs) by a distinct population of macrophages known as lipid-associated macrophages (LAMs), characterized by CD36 upregulation occurs. However, the precise roles and underlying mechanisms of the CD36-expressing LAMs involved in MASLD pathogenesis remains to be elucidated.
Method: We first investigated the characteristics of LAMs through single-cell RNA sequencing (scRNA-seq) data. Oleic acid (OA)-pretreated THLE-2 cells were co-cultured with macrophages to mimic LAMs to further investigate their functional properties *in vitro*. We explored the molecular regulatory mechanism for SPP1 (encoding osteopontin, OPN) upregulation using chromatin immunoprecipitation sequencing (ChIP-seq) datasets. Lastly, to identify the potential role of CD36 inhibitor in metabolic dysfunction-associated steatohepatitis (MASH) treatment, we employed high-fat diet (HFD)- and high-fat methionine-restriction choline-deficient diet (HFMRCD)-induced mouse models.
Results: The findings from scRNA-seq analysis demonstrated an enhanced CD36 expression in LAMs, which correlates with a distinct immunosuppressive phenotype. By utilizing the co-culture system, we were able to confirm that the increased expression of CD36 in LAMs facilitated a more efficient uptake of lipids from hepatocytes with steatosis, subsequently triggering the release of SPP1 through the peroxisome proliferator-activated receptor gamma (PPAR-gamma) signaling pathway. ChIP-seq data revealed a PPAR-gamma binding site in the SPP1 transcript region, which was further confirmed by chromatin immunoprecipitation-quantitative real-

time PCR (ChIP-qPCR) experiments, indicating the direct regulatory interaction between PPAR-gamma and SPP1. Furthermore, the stimulation of hepatic stellate cells (HSCs) by SPP1 was demonstrated by the upregulation of alpha-smooth muscle actin (alpha-SMA) and collagen type I alpha 1 (COL1A1) in LX-2 cells, ultimately contributing to the progression of liver fibrosis. The knockdown or inhibition of CD36 in LAMs effectively impedes lipid uptake and SPP1 release, leading to alleviation of fibrosis. These promising effects have been observed in both in vitro cell models and in mice. Notably, the combination of a CD36 inhibitor and pioglitazone exhibits a synergistic effect in effectively inhibiting the progression of liver fibrosis in MASH murine models.
Conclusion: CD36 serves as a facilitator for the transfer of lipids from hepatic cells to LAMs, thereby initiating the activation of hepatic stellate cells and promoting the progression of liver fibrosis. The identification of CD36 as a potential therapeutic target offers promising prospects for the treatment of advanced liver fibrosis associated with MASLD.

The E2F2 target glycerophosphodiester phosphodiesterase domain containing 3 is involved in MASLD progression to HCC and related dyslipidemias

Maider Apodaka-Biguri[1], Nerea Muñoz-Llanes[1], Francisco Gonzalez-Romero[1], Igor Aurrekoetxea[1], Beatriz Gómez Santos[1], Igotz Delgado[1], Xabier Buque[1,2], Ane Nieva-Zuluaga[1], Mikel Ruiz de Gauna[1], Idoia Fernández-Puertas[1], Paul Gomez-Jauregui[1], Natalia Sainz-Ramírez[1], Kendall Alfaro-Jiménez[1], Estibaliz Castillero[1], Daniela Mestre Congregado[1], Ashwin Woodhoo[3,4], Marta Varela-Rey[5], Amaia Lujambio[6], Ana Zubiaga[7], Patricia Aspichueta[1,2,8]. *[1]Department of Physiology University of the Basque Country UPV/EHU, Faculty of Medicine and Nursing, Leioa, Spain; [2]Biocruces Bizkaia Health Research Institute, Cruces University Hospital, Barakaldo, Spain; [3]Center for Cooperative Research in Bioscience (CIC bioGUNE), Santiago de Compostela, Spain; [4]Ikerbasque, Basque Foundation for Science, Bilbao, Spain; [5]Liver Disease Laboratory, Center for Cooperative Research in Biosciences (CIC bioGUNE), Derio, Spain; [6]Icahn School of Medicine at Mount Sinai, New York, United States; [7]Department of Genetic, Physical Anthropology and Animal Physiology, Faculty of Science and Technology, University of Basque Country UPV/EHU, Leioa; [8]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd, Carlos III Health Institute), Madrid, Spain*
Email: patricia.aspichueta@ehu.eus

Background and aims: Hepatocellular carcinoma (HCC) is the most common primary liver cancer, which is the fourth leading cause of cancer-related mortality worldwide. Metabolic dysfunction-associated steatotic liver disease (MASLD), and related dyslipidemias are risk factors for HCC development. The role of Glycerophosphodiester phosphodiesterase domain containing 3 (GDPD3) promoting hepatoesteatosis has been described; however there is no information about a specific role in promoting dyslipidemias or progression to HCC. Thus, the aims were 1) to identify the role of GDPD3 in the metabolic dysregulation of progressive-MASLD. 2) to investigate the mechanism involved in modulation of GDPD3 expression in progressive MASLD and HCC.
Method: To induce MASLD-related HCC, diethylnitrosamine (DEN) was administrated to 14-day-old mice (WT), and fed a high-fat diet (HFD) until sacrificed at 3 and 9 months. HCC was also induced by the sleeping beauty technique (*Myc;sg-Pten* plasmids) combined with feeding a high-fat-diet (HFD). *Gdpd3* was specifically overexpressed in liver with adeno-associated viruses-serotype 8 (AAV8). *E2f2*$^{-/-}$ mice were also used. Hepatic and serum lipidomic and apolipoprotein (Apo) profile was assessed, serum lipoproteins were separated using an ACTA-FPLC. ChIP and gene expression assays were also performed. TCGA-LIHC cohort data were used.
Results: *Gdpd3* overexpression in mice induced hepatoesteatosis and a remodeling in serum lipidome reflected in several species of fatty acids, triglycerides (TG) and cholesterol esters, which were increased when compared with the corresponding controls. Accordingly, an increased number of circulating VLDL particles and decreased number of HDL were found, as levels in ApoB and apoE showed. The dyslipidemia was more pronounced in a lipid-rich environment induced by feeding a HFD, where the FPLC analysis showed that *Gdpd3* overexpression in liver increased levels of TG in VLDL particles and cholesterol levels in VLDL and LDL particles. Overexpression of *Gdpd3* in the *Myc;sg-Pten* mice model promoted MASLD-related HCC increasing the number of tumors. Our data showed that *GDPD3* was upregulated in human HCC livers within the TCGA-LIHC cohort and that correlated positively with *E2F2*. Hepatic *Gdpd3* and *E2f2* were also increased in preclinical models of MASLD-related HCC where E2F2 bound directly to the *Gdpd3* promoter at two different sites. In *E2f2*$^{-/-}$ DEN-HFD mice, protected from MASLD-related HCC, *Gdpd3* levels were decreased and its overexpression by AAV8 resulted on partial loss of this protection.
Conclusion: *Gdpd3* is a target of E2F2 in MASLD-related HCC and promotes dyslipidemia and disease progression. Thus, GDPD3 arises as a novel target for treatment.

Email: panu.luukkonen@helsinki.fi

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease which can progress to cirrhosis and eventually death. Recent studies have shown that histological severity of MASLD associates with hepatic mitochondrial reductive stress as determined by plasma beta-hydroxybutyrate-to-acetoacetate ratio (bOHB/AcAc). However, it is unclear whether hepatic mitochondrial reductive stress associates with clinically relevant end points. Here, we aimed to investigate whether bOHB/AcAc predicts liver-related mortality in a large prospective cohort. Furthermore, we aimed to identify genetic factors that regulate bOHB/AcAc and whether genetically determined bOHB/AcAc predicts liver-related mortality.
Method: In the prospective UK Biobank data, we excluded participants with liver diagnosis before or at baseline or chronic viral disease at any time. Cases were defined using registry-based causes of death. We assigned participants without liver diagnoses at any time as controls. We matched the cases to controls for age, sex, waist-to-hip ratio, BMI, type 2 diabetes, smoking, and alcohol use in a 1:4 ratio. Plasma bOHB and AcAc concentrations were determined using the Nightingale NMR metabolomics platform. We used Cox regression to evaluate the association between baseline bOHB/AcAc and liver-related mortality. We performed a genome-wide association analysis (GWAS) using REGENIE in the UK Biobank (n = 94, 092), FINRISK and Health 2000 (n = 17, 229), and METSIM cohorts (n = 9, 607). The GWAS results were meta-analysed using the fixed-effects model with

PLINK v1.9. We constructed a genome-wide polygenic risk score (PRS) from high-quality variants using PRSice2 for the unrelated UKB participants (n = 250, 357), whom we did not consider in the initial GWAS. We used Cox regression to evaluate the association between the PRS and liver-related mortality.
Results: Baseline bOHB/AcAc predicted liver-related mortality (HR = 1.16 per 1-SD, p = 0.022) during a median follow-up time of 13.1 years (IQR 11.9–14.2). Amongst distinct causes of liver-related death, baseline bOHB/AcAc predicted particularly cirrhosis-related mortality (HR = 1.27 per 1-SD, p = 0.019). In the GWAS, we identified 18 significant loci associated with bOHB/AcAc (p ≤5E-8). Most of these loci annotated to genes that encode for mitochondria-specific proteins (e.g. MPC1 and DHODH) or genes known to modify the risk of MASLD (e.g. GCKR, APOE, and PPP1R3B). Similar to the observed bOHB/AcAc, the PRS predicted cirrhosis-related mortality (HR = 1.19 per 1-SD, p = 0.010).
Conclusion: Both the observed and genetically determined bOHB/AcAc predict liver mortality, particularly cirrhosis-related mortality, independent of common risk factors. These data suggest mitochondrial reductive stress as a possible causal factor in the pathogenesis of liver disease.

THU-194
Semaglutide links with improved survival and liver outcomes in MASLD patients, a large multicenter retrospective real-world cohort study

Mohammed Suki[1], Yael Milgrom[1], Mohamad Masarowah[1], Wadiaa Hazo[1], Yariv Tiram[2], Ofer Perzon[3], Esther Forkosh[1], Joseph Sackran[1], Johnny Amer[1], Achraf Imam[1], Abed Khakayla[4], Rifaat Safadi[5]. *[1]Liver institute, Hadassah Hebrew University Hospital, Jerusalem, Israel; [2]Liver institute, Hadassah Hebrew University, Jerusalem, Israel; [3]Livei institute, Hadassah Hebrew University Hospital, Jerusalem, Israel; [4]Liver institute, Hadassah Hebrew University Hospital, Jerusalem, Israel; [5]Liver Insititute, Hadassah Hebrew University Hospital, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: Semaglutide (SEMA) has potential benefits in Metabolic dysfunction-associated steatotic liver disease (MASLD). In this large real-world study, SEMA effect on MASLD patients evaluated.
Method: TriNetX is a global research platform de-identified database that spanning 135 million patients across 112 healthcare organizations worldwide. We analyzed electronic medical records of MASLD patients according ICD9 Diagnosis. Following propensity score matching based on 34 variables (demographics, comorbidities, laboratory tests and medication history), SEMA treated (n = 18, 473) correlated with non-SEMA (n = 18, 473) cases. Exclusion criteria: ALT and ALP levels >4 UNL, advanced liver disease (ALD), liver transplant and cancer, past anticoagulation and non-MASLD etiologies. Assessed outcomes were survival, biochemical, hematologic, AFP, metabolic and cardiovascular (CV), ALD, abnormal synthetic function and poor metabolic markers. ALD defined according to ICD9 diagnosis (Portal hypertension, Chronic passive congestion of liver, Ascites, Esophageal/Gastric varices, Hepatic encephalopathy, Hepatorenal/Hepatopulmonary syndromes, Spontaneous bacterial peritonitis, Hepatic failure, Other and unspecified cirrhosis), blood tests (Ammonia >50 umol/L, Platelets <100 k/uL, Bilirubin >2 mg/dL, Albumin <2.80 g/dL) and specific treatments (Neomycin, Rifaximin, Propranolol, Carvedilol, spironolactone >100 mg). Abnormal synthetic function defined by either albumin <2.8, bilirubin >2 or INR>1.7. Poor metabolic markers defined either LDL>130, HDL<40, TG>200 or HBA1c>8%.
Results: Following matching, both cohorts were well-balanced, except of higher BMI in SEMA group; 36.7 ± 6.3 *vs.* 34.9 ± 7.1 kg/m^2. Otherwise, rest parameters were well matched, including mean age 51.1 ± 12.8 *vs.* 51.4 ± 13.5 years, females in 59.9 *vs.* 60%, white background in 68.5 *vs.* 67.5%, diabetes in 61.2 *vs.* 62.2%, respectively. After one year, the SEMA group demonstrated ~1 BMI point reduction, but kept with significantly higher BMI increase 35.6 ± 6.4 *vs.* 34 ± 6.9 (p < 0.0001). LDL, triglycerides, and HbA1c levels significantly improved by SEMA, that also reflected by decrease in rates of poor metabolic markers (31.2% *vs.* 34. 4%, p < 0.0001). The SEMA group showed higher survival rates (99.3% *vs.* 98.1%, p < 0.0001), fewer cardiovascular events (4 *vs.* 5.4%, p < 0.0001), and reduced progression rates to advanced liver disease (4.098 *vs.* 9.133%, p < 0.0001), reduced rates of abnormalities in liver enzymes (33.411 *vs.* 39.419%, p < 0.0001) and liver synthetic function markers (1.4 *vs.* 6%, p < 0.0001).
Conclusion: In this large real-world cohort, SEMA use in MASLD patients was associated with significantly improved 1-year survival, cardiovascular and liver-related outcomes. Though BMI changes were small in magnitude, potential mechanisms for SEMA's benefits warrant further study.

THU-195
Synergistic effects of thyroid hormone treatment and mitochondrial thyroid receptor p43 overexpression on regression of metabolic dysfunction-associated steatotic liver disease in mice by improving key mitochondrial quality markers

Raghu Ramanathan[1,2], Sarah Johnson[1,2], Jamal Ibdah[1,2,3]. *[1]Division of Gastroenterology and Hepatology, University of Missouri, Columbia, Missouri 65212, USA, Columbia, United States; [2]Harry S. Truman Memorial Veterans Medical Center, Columbia, Missouri 65212, USA, Columbia, United States; [3]Department of Medical Pharmacology and Physiology, University of Missouri, Columbia, Missouri 65212, USA, Columbia, United States*
Email: raghu.ramanathan@health.missouri.edu

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a major public health problem affecting 30% of the world's population. Mitochondrial dysfunction plays an important role in development and progression of MASLD. Thyroid hormone (TH), notably triiodothyronine (T_3), plays a vital role in regulating mitochondrial metabolic activity. T_3 binds to nuclear thyroid receptor (TR) isoforms and within mitochondria, a truncated TR_{alpha} isoform known as p43 serves as a mitochondrial TR (mTR). The function of mTR is not fully understood and its potential role in MASLD is not known. This study aims to: 1) explore whether mTR overexpression has beneficial effects on MASLD regression in mice; and 2) characterize mTR overexpression effects on key mitochondrial quality markers.
Method: 3-month-old male mice with C57BL/6 background (n = 32) were fed western diet (Research Diets Inc, D12451, 45% kcal fat, 1% cholesterol) for a period of 16-weeks to develop MASLD. Adenoviruses, either Ad-mTRp43 or Ad-beta-gal, at a concentration of 1×10^{10} viral particles per mouse, diluted in saline, were administered through the tail vein to induce expression in the liver. Three days post-injection, the mice underwent a 7-day intraperitoneal injection treatment with 25 µg of T_3 per 100 g body weight, or a vehicle control (saline). The mice (n = 8 for each treatment group) were then sacrificed for histological and gene expression studies.
Results: : Mice overexpressing beta-gal treated with T_3 and mice overexpressing mTR treated with saline demonstrated significant reduction in hepatic steatosis compared to mice overexpressing beta-gal treated with saline, however mice overexpressing mTR treated with T_3 demonstrated a maximal effect on MASLD regression compared to other groups with histological resolution of hepatic steatosis. Mice overexpressing mTR treated with T_3 had 2-fold upregulation of Opa1 (p < 0.001) and Mfn1 (p < 0.05) gene expression and 2-fold reduction in Drp1 gene expression (p < 0.001) compared to other groups. Further, mice overexpressing mTR treated with T_3 demonstrated marked increases in gene expression of AMPK-alpha

($p < 0.001$), Nrf1 ($p < 0.05$), and PPAR-alpha ($p < 0.05$) compared to other groups. These results indicate that combination of mTR overexpression and T_3 treatment enhances markers of both mitochondrial dynamics and mitochondrial biogenesis. Similarly, mice overexpressing mTR treated with T_3 demonstrated significant increases in gene expression of the mitophagy markers Pink ($p < 0.01$) and Bnip-3 ($p < 0.05$) compared to other groups.
Conclusion: Overexpression of mitochondrial thyroid receptor (mTR-p43) in mice synergises thyroid hormone effects on regression of MASLD likely by improving mitochondrial quality markers. Further studies are needed to fully understand the underlying mechanisms for this synergy. (Supported by VA Merit 1BX 004710).

THU-196
Targeting lysyl-tRNA synthetase alleviates metabolic dysfunction-associated steatohepatitis through inhibition of monocyte-derived macrophages in preclinical models

Junghyun Kim[1], Hyeree Kim[1], Kang Soo Lee[1], Hyuk-Sang Kwon[2], Nam Hoon Kim[2], Sunghoon Kim[2,3,4,5], Yeup Yoon[1,6], Wonseok Kang[1,7].

Email: wonseok1202.kang@samsung.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is characterized by steatosis and hepatic inflammation, where macrophages play a pivotal role in the pathogenesis. Although Lysyl-tRNA synthetase (KRS) is known as an enzyme that catalyzes the attachment of lysine to the cognate tRNA during protein synthesis, recent reports have drawn attention toward its non-canonical role for the control of macrophage migration. The goal of the study was to address whether inhibition of monocyte-derived macrophages (MoMFs) by targeting KRS could ameliorate steatohepatitis in preclinical models of MASH. In addition, the single-cell transcriptome analysis was performed on the leukocyte population in early inflammation stage to analyze the dynamic changes in MoMFs.
Method: A specific inhibitor of KRS was administered in various animal models of MASH, including methionine-choline-deficient (MCD) diet model, western diet model combined with carbon tetrachloride administration (WD/CCl4), and choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) model. Hepatic steatosis, fibrosis and inflammation were assessed by immunohistochemistry, triglyceride (TG) assay, and flow cytometry. For a high-dimensional characterization of MoMFs, scRNA-seq was performed for intrahepatic $CD45^+$ cells isolated from the non-diseased (chow fed) and MASH (MCD-diet) mice treated with or without KRS-specific inhibitor. The cells were identified based on the differentially expressed genes (DEGs) and their expression of a set of standard cell identity genes.
Results: Administration of KRS-specific inhibitor significantly reduced hepatic inflammation and fibrosis in MCD diet-induced model as well as in CDAHFD and WD/CCl4-induced MASH models, as demonstrated by the reduction of serum alanine and aspartate transaminases, hepatic TG content, and NAFLD activity score. Flow cytometry showed an enrichment of intrahepatic $Ly6C^{hi}$ monocytes in vivo, where it was significantly diminished upon administration of KRS-specific inhibitor. Unsupervised clustering of scRNA-seq revealed 38 distinct cell clusters, including 12 distinct clusters of myeloid cell populations. Among the myeloid cell populations, four clusters representing the MoMFs were significantly diminished in the KRS-specific inhibitor-treated group, whereas the KC clusters were modestly affected. DEGs and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis demonstrated that the suppression of MoMFs was related to downregulation of NF-kB and TNF signaling pathways.
Conclusion: Specific inhibition of KRS is associated with reduced steatohepatitis and fibrosis in preclinical models of MASH through inhibition of MoMF recruitment, suggesting KRS as a potential target for therapeutic intervention.

THU-197
Restoration of natural killer cell antifibrotic activity via a novel immune target; the Neuroligin-4/β-Neurexin pathway

Johnny Amer[1], Ahmad Salhab[1], Rifaat Safadi[1]. *[1]Liver institute, Hadassah Hebrew University Hospital, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: Several studies demonstrated a cross talk between hepatic stellate cells (HSCs, the source of fibrotic tissue) and Natural Killer (NK) cells. Deterioration in NK cells functionality was described in advanced liver injury of liver fibrosis and metabolic dysfunction-associated liver disease (MASLD). In this study, we aimed to investigate for a novel immune checkpoint that contributes to NK cell impairment and HSCs activations in MASLD with advanced liver fibrosis by assessing neuroligin-4 (NLGN4X) and β-neurexin (β-Nrxn; NLGN4X ligand)) expressions, respectively.
Results: Human peripheral and liver tissue-resident NK (trNK) cells as well as primary HSCs from liver biopsies from adult patients (age ≥18 years) of histologically documented MASLD with different Metavir scores were obtained. Our data showed 1.8-fold elevated trNK cells expressions of NLGN4X ($NK^{NLGN4X+}$) in Metavir scores of F3/F4 as compared to their F1/F2 counterparts. $NK^{NLGN4X+}$ subpopulations were associated with impaired function associated with reduced activity of activity related pathway of survival and proliferation as well as inhibited of cytoskeleton protein of F-actin. Moreover, these subpopulations showed an increase in exhaustion markers indicating reduced cytotoxic activity. On the other hand, activated HSCs exhibited elevated β-Nrxn expression, and induced an increase in NLGN4X expression in NK cells, which inhibited their cytotoxic effects. Disruption of the NLGN4X/β-Nrxn immune axis via NLGN4X knockdown or anti-NLGN4X neutralizing antibodies, promoted reductions in the $NK^{NLGN4X+}$ population to levels similar to those in healthy donors and restored trNK cell survival marker expression and the cytotoxic effects of NK cells against activated HSCs. $NLGN4X^{-/-}$ mice displayed protection against CCl_4-induced liver fibrosis and kept a restored trNK cell activity. Moreover, NLGN4X neutralizing antibody administered to naive mice model with CCl_4 induction reduced NLGN4X expressions on sorted $trNK^{NLGN4X+}$ cells accompanied with elevated AKT, ERK and P70S6 K phosphorylation while inhibited liver fibrosis outcome. Moreover, adoptive transfer of $trNK^{NLGN4X-}$ cells into immunodeficient recipient mice with liver fibrosis resulted in delayed disease progression compared to mice receiving $trNK^{NLGN4X+}$ cells.
Conclusion: These findings describe a novel NLGN4X/β-Nrxn axis with dual immunotherapeutic potential target approach of NK cells and HSCs in delaying liver fibrosis and attenuating disease progressions.

In vitro and in vivo pharmacological characterization of human PNPLA3-targeting short interfering RNA molecules for the treatment of metabolic dysfunction-associated steatohepatitis

Jieun Song[1], Jerome Deval[1], Lillian Adame[1], Ruchika Jaisinghani[1], Emily Tso[2], Daniel Lin[2], Aneerban Bhattacharya[1], Antitsa Stoycheva[1], Jacquelyn Sousa[1], Craig Parish[2], Saul Martinez Montero[1], Vivek Rajwanshi[1], Shane Daguison[1], Vikrant Gohil[1], Qingling Zhang[1], Toni Williamson[2], Sushmita Chanda[1], Saswata Talukdar[2], David Smith[1], Leonid Beigelman[1], Julian Symons[1], Yingjiang Zhou[2],

Xuan Luong[1]. [1]*Aligos Therapeutics, Inc., South San Francisco, United States;* [2]*Merck and Co., Inc., Rahway, United States*
Email: xluong@aligos.com

Background and aims: Patatin-like phospholipase domain-containing protein 3 (PNPLA3), specifically the single nucleotide polymorphism rs738409[G] (I148M) variant, is a strong genetic risk factor for the development and progression of metabolic dysfunction-associated steatotic liver disease (MASLD) into the more severe metabolic dysfunction-associated steatohepatitis (MASH). While there is still no approved treatment for MASLD/MASH, the field of oligonucleotide-based therapeutics has been rapidly advancing in recent years, with several drugs achieving market approval and many more in clinical trials for metabolic indications. The aim of our studies was to characterize short interfering RNA (siRNA) molecules that effectively silence the expression of *PNPLA3* and could be used as potential therapies for MASLD/MASH.
Method: A luciferase reporter assay in COS-7 cells and RT-qPCR assay in Huh-7 cells were used to initially screen proprietary human *PNPLA3*-targeting siRNAs in vitro for effective silencing of *PNPLA3* gene expression. Select compounds were then tested in vivo in PK/PD studies using human *PNPLA3* knock-in mice and a subset of molecules was then characterized in MASH efficacy studies using GAN diet-induced obese (DIO), human *PNPLA3* knock-in mice. End points included target quantification via RT-qPCR and Western blot analysis, blood liver enzyme levels, and liver histology.
Results: In the luciferase reporter assay, compounds of interest showed target inhibition greater than 50% inhibition at concentrations of 5 to 50 nM. In the RT-qPCR assay, compounds inhibited the endogenous expression of *PNPLA3* with half maximal effective concentrations (EC_{50}) ranging between 1 and 60 pM. Select siRNAs demonstrated robust, dose-dependent knockdown of the human RNA target in PK/PD studies using human *PNPLA3* knock-in mice. These effects were observed after a single dose at concentrations as low as 0.1 mg/kg and gene expression silencing could be sustained for up to 28 days post-dose. Furthermore, repeat dosing of compounds in DIO mice led to robust target RNA and protein knockdown; one select compound was shown to also decrease in liver enzyme levels, improve MAFLD Activity Score (NAS) score, and reduce liver fibrosis and necrosis/apoptosis in this model.
Conclusion: We discovered several siRNA molecules that effectively silence human *PNPLA3* gene expression in vitro and in vivo and repeat dosing of a select compound in a DIO mouse model ultimately led to the improvement of MASH end points. The data generated in these studies allowed for the selection of a lead compound for progression into late-stage preclinical studies.

THU-199
Role and therapeutic potential of miR-22 in MAFLD and obesity: from mouse model to human relevance

Riccardo Panella[1,2], Simone Tomasini[1], Anna Altieri[3], Francesco Margiotta[4], Philip Vonschallen[5], Ulrik Scheele[3], Lei Cai[6], Ryan Temel[7], Sakari Kauppinen[3]. [1]*Aalborg University, Center for RNA Medicine, Copenhagen SV;* [2]*Resalis Therapeutics, Torino, Italy;* [3]*Aalborg University, Center for RNA Medicine, Copenhagen SV, Denmark;* [4]*Dipartimento di Neuroscienze, Psicologia, Area del Farmaco e Salute del Bambino (NEUROFARBA), University of Florence, Florence, Italy;* [5]*InSphero, Schlieren, Switzerland;* [6]*University of Kentucky, Saha Cardiovascular Research Center, Lexington, United States;* [7]*University of Kentucky, Saha Cardiovascular Research Center., Lexington, United States*
Email: riccardop@dcm.aau.dk

Background and aims: Non-coding RNAs (ncRNAs) role in MAFLD and their potential for being therapeutic targets is very little explored but it could have a very high impact on patient outcomes. We identified miR-22 as a crucial regulator of hepatic lipid homeostasis using multiple genetic models, and we confirmed its involvement in metabolism and MASH progression. In human subject we found a positive correlation between miR-22 level and disease progression. Moreover, we developed an antisense oligonucleotide (ASO) based on LNA to inhibit miR-22 pharmacologically. We tested our therapeutic approach in different mouse models, non-human primate (NHP) and primary human samples to demonstrate that miR-22 inhibition has a great protective effect toward hepatic lipid accumulation, inflammation, fibrosis and weight lost.
Method: Genetic engineered mouse (GEM) models, overexpressing mir-22 or knock-out for miR-22 were used to demonstrate the role of miR-22 in metabolism. A dataset from 127 patients with different stages of NASH was used to confirm the role of miR-22 in humans. To prove the therapeutic effect of miR-22 inhibition we used diet induced obesity (DIO) mouse models, the biopsy-confirmed Gubra Amylin (GAN) model, NHP fed with a fast-food diet and human derived liver organoids.
Results: We found that over-expression of miR-22 leads to an obese phenotype and a strong liver steatosis around 10 months of age, in mice fed with normal chow. miR-22 null mice fed with High Fat Diet (HFD) were unable to increase their body weight and their liver were protected from steatosis and inflammation. We designed and tested an anti-sense oligonucleotide (ASO) based on LNA chemistry able to target mir-22 and inhibit its function and we tested it in DIO and GAN mice, as well as in in a 24 weeks long experiment with non-human primates and in a 3D model of human liver organoids. We detected a strong and consistent effect of our anti-miR-22 therapy on triglyceride levels, body weight and hepatic collagen deposition, demonstrating the efficacy of miR-22 inhibition in MALFD and obesity.
Conclusion: We demonstrate the central role of miR-22 in liver metabolism and obesity. miRNA-22 influences the expression of genes involved in lipid biogenesis, energy expenditure, hepatic inflammation and fibrosis. By modulating its levels with an ASO that we designed and tested, we have been able to simultaneously impact different pathways that all contributes to the insight and the progression of systemic diseases like obesity and MASH. We tested our therapy in multiple mouse models, as well as in NHP and primary human organoids, providing extensive evidence that miR-22 role is conserved and that its pharmacological inhibition is an effective therapy to address MASH. Our data are paving the way for a new pharmacological approach to one of the most serious diseases of our time, with an innovative approach based on targeting a non-coding RNA.

Email: surwang@nus.edu.sg

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a severe form of fatty liver disease, characterized by hepatic steatosis, inflammation, and fibrosis. Recent reports have shown positive correlation between accumulation of senescent cells in the liver of MASH patients and poor prognosis. These cells are resistant to apoptosis, exhibit a pro-inflammatory secretome, have dysfunctional mitochondria, limit tissue regeneration, and further

induce senescence in neighbouring cells. Hence in this study we aim to clear the senescent cells in the liver to alleviate MASH progression.
Method: A senolytic agent was encapsulated within polymer-based nanoparticles (nano-senolytic) and characterized using dynamic light scattering and transmission electron microscopy. These particles were administered intravenously to C57BL/6J mice fed with methionine choline deficient diet or western diet with weekly injection of low dose carbon tetrachloride. One week after the last dose, the liver was harvested, and senescent cells in the liver were analyzed using flow cytometry. Liver steatosis was assessed by Oil red O (ORO) staining and hepatic triglyceride levels. Hepatic inflammation was determined by measurement of inflammatory cytokines and immunofluorescence staining of CD68. Oxidative stress was measured using dichlorodihydrofluorescein diacetate staining and the mitochondria function was tested using the seahorse assay.
Results: The nanoparticles synthesized were around 100 nm in size with a neutral surface charge. Nano-senolytic showed better efficacy in reducing senescent cells in the liver ($p < 0.05$) as compared to the free drug after 4 weeks of treatment. Clearance of senescent cells by nano-senolytic resulted in a significant reduction in steatosis ($p < 0.001$). Moreover, compared to the control group, nano-senolytic treatment reduced macrophages (CD68 staining positive area) by 25%. Biochemical analysis showed a marked reduction in expression of inflammatory cytokines in the liver, including IL-1a ($p < 0.001$), IL-1b ($p < 0.001$), IL-6 ($p < 0.001$), IFN-g ($p < 0.01$), MCP-1 ($p < 0.001$) and TNF-a ($p < 0.001$). In contrast, the anti-inflammatory cytokines IL-10 ($p < 0.05$) and IL-13 ($p < 0.001$) were upregulated, indicating a reparative microenvironment in the liver after clearing of senescent cells. Furthermore, we observed a reduction in oxidative stress and restoration of mitochondria function, which contribute to the reduction in steatosis.
Conclusion: Our findings suggest that senescent cell clearance restores liver tissue function by reducing hepatic steatosis and inflammation. Encapsulation of the senolytic drug into nanoparticles achieves higher drug concentration at the diseased organ and thereby improving therapeutic efficacy.

Artificial intelligence-assisted multiomics depicting the immunometabolism landscape of steatotic livers undergoing bariatric surgery

Shuai Chen[1], Qinghe Zeng[2,3], Jiaming Xue[1], Xiurong Cai[4,5], Peng Song[1], Liming Tang[1], Christophe Klein[3], Frank Tacke[6], Adrien Guillot[6], Hanyang Liu[1,6]. *[1]Nanjing Medical University, Changzhou Medical Center, Changzhou, China; [2]Université Paris Cité, Laboratoire d'Informatique Paris Descartes (LIPADE), Paris, France; [3]Université Paris Cité, Centre d'Histologie, d'Imagerie et de Cytométrie (CHIC), Centre de Recherche des Cordeliers, INSERM, Sorbonne Université, Paris, France; [4]Charité-Universitätsmedizin Berlin, Department of Hematology, Oncology and Tumor Immunology, Berlin, Germany; [5]The Jackson Laboratory, Bar Harbor, United States; [6]Charité-Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, CCM/CVK, Berlin, Germany*
Email: hanyang.liu@charite.de

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a highly prevalent chronic liver disease worldwide. MASLD encompasses a spectrum of steatosis, inflammation, and fibrosis. Evidence suggests that weight loss can lead to remission of hepatic steatosis alone or steatosis and inflammation, respectively. Therefore, weight loss approaches such as dietary intervention (DI) and bariatric surgery (BS) represent therapeutic options for MASLD. It is currently unclear how these interventions affect the hepatic immune mechanisms in MASLD. This study aims to elucidate the intricate immunometabolism landscape of steatotic livers following DI and BS.
Method: This study employed the sleeve gastrectomy (a typical BS procedure) and comparable food intake after sham surgery on a rat model of MASLD induced by high-fat diet (HFD) feeding for 12 weeks. Circulating markers and in situ pathological alterations were assessed respectively on serum and liver tissue. Simultaneously, single-cell (sc) and single-nuclei (sn) transcriptome analysis were performed on freshly acquired liver cells, and spatial metabolomics analysis was conducted on cryo-sectioned liver. Furthermore, artificial intelligence (AI)-based image analysis was employed to identify the relevant cell type contributions on HandE-stained liver tissue sections. In a translational human study, 18 patients with obesity and liver steatosis were evaluated within 6 months after BS.
Results: In experimental MASLD in rats, both DI and BS attenuated serum triglyceride levels, as well as liver steatosis and fibrosis. The expression of Ppara, Cyp2e1 and Cyp7a1 were increased on hepatocytes upon DI and BS, while BS broadly upregulated lipid metabolism on cholangiocytes, monocytes, macrophages and neutrophils. In contrast, cholangiocytes appear more interactive with other cells upon BS. Additionally, two distinct types of hepatocytes were identified and associated with hepatic zonation characteristics, indicating an explicit loss of periportal features upon DI. In addition, metabolomics analysis suggested enhanced metabolite enrichments on fatty acid and cholesterol metabolism upon BS. AI-based image analysis illustrated the differential infiltration levels of myeloid cells in the liver, leading to metabolic differences among regions. Lastly, serum data from patients as well as in the rat model elucidated a significant increase of FGF-19 levels upon BS.
Conclusion: BS facilitates PPARα-related metabolic enhancement on hepatocytes and intrahepatic myeloid cells. In addition, the gut-derived signal (FGF-19) may be a key metabolic regulator induced by BS. This study provides the first insight into the immunometabolic dynamics of steatotic livers undergoing BS, thereby shedding light on the pathogenic consequences of this procedure.

Prophylactic and therapeutic hepatoprotective effects of the dual FXR/TGR5 agonist INT-767 in the GAN diet-induced ob/ob mouse model of advanced MASH with progressive fibrosis

Jacob Nøhr-Meldgaard[1], Susanne Pors[2], Rebecca Wendelbo Olsen[3], Henrik B. Hansen[3], Michael Feigh[4]. *[1]Gubra A/S, Hørsholm; [2]Gubra A/S, Hørsholm, Denmark; [3]Gubra A/S, Hørsholm, Denmark; [4]Gubra AS/, Hørsholm, Denmark*
Email: jnm@gubra.dk

Background and aims: The farnesoid X receptor (FXR) and G protein-coupled receptor (GPCR) TGR5 have been implicated in the pathogenesis of metabolic dysfunction-associated steatohepatitis (MASH). Here, we evaluated the efficacy of the dual FXR/TGR5 agonist INT-767 on metabolic, biochemical and histological outcomes in a genetically obese mouse model of accelerated GAN diet-induced MASH with progressive fibrosis.
Method: Male leptin-deficient male B6.V-Lepob/JRj (ob/ob) mice were fed GAN diet high in fat, fructose, and cholesterol for total of 12-weeks or 24-weeks. GAN ob/ob-MASH mice received treatment from the first day of GAN diet feeding (prophylactic treatment) or after 12-weeks of GAN diet feeding (therapeutic treatment). Animals were randomized into treatment groups according to body weight prior to study start. Animals received daily oral dosing with INT-767 (10 mg/kg, n = 14–16) or vehicle (n = 14) for 12-weeks. Terminal end points included plasma biomarkers, liver biochemistry, NAFLD Activity Score (NAS), fibrosis stage and quantitative liver histology.
Results: Prophylactic and therapeutic INT-767 intervention had no effect on body weight while both improving hepatomegaly. Both interventions reduced plasma ALT/AST, and plasma/liver triglyceride and total cholesterol concentrations, as well as liver hydroxyproline levels. Furthermore, both interventions promoted a significant reduction in NAS, supported by reduced quantitative histological markers of steatosis (liver lipid, number of hepatocytes with lipid droplets) and inflammation (number of inflammatory foci, galectin 3). Prophylactic, but not therapeutic, INT-767 treatment improved

fibrosis stage. In contrast, both interventions significantly reduced histological markers of fibrosis (PSR, Col1a1) and stellate cell activation/fibrogenesis (α-SMA).
Conclusion: The dual FXR/TGR5 agonist INT-767 improves hallmarks of MASH in the GAN ob/ob-MASH mouse model in settings of both prophylactic and therapeutic treatment, respectively. Greater anti-fibrotic effects of INT-767 were attained by prophylactic treatment. These findings suggest the potential utility of dual FXR/TGR5 activation as disease intervention strategy in MASH. Furthermore, it highlights the GAN ob/ob-MASH mouse as an accelerated obese mouse model of advanced MASH with progressive fibrosis, thus having significant utility in preclinical drug discovery for MASH.

Email: stephen.8.atkinson@gsk.com

Background and aims: Steatotic liver disease (SLD) is a common cause of chronic liver disease characterised by steatosis, inflammation and fibrosis on biopsy. Biological heterogeneity of SLD is unable to be fully captured by classical histopathological evaluation. Traditional transcriptomic approaches require tissue homogenization or dissociation and thus lack the ability to map spatial gene expression specifically to localized pathological features. We integrated machine learning (ML) based measurement of SLD histological features with high-resolution spatial transcriptomics (ST) to overcome these limitations, demonstrating that transcriptomic features can be mapped to specific SLD histopathology at scale.
Method: Human liver tissues preserved by formalin fixation and paraffin embedding (FFPE) were obtained from subjects with healthy livers (n = 8) or SLD (n = 8). ST was performed using 10X Genomics Visium for FFPE which has 55 µm capture spots. AIM-NASH (PathAI, Boston, MA) was deployed on high-resolution scans of hematoxylin and eosin stained samples on Visium Capture slides and adapted to facilitate per-spot analysis. Transcriptomic and image data were analysed in R and python using pipelines to i) train ML classifiers to predict inflammation or steatosis from gene expression data, and ii) define unsupervised gene expression based clusters.
Results: AIM-NASH-derived features associated with steatosis and inflammation were extracted for each spot. Gene expression could predict the presence of inflammation or severe steatosis. Predictive gene sets contained previously proposed biomarkers and therapeutic targets for inflammation (*HLA-DRA*, *CD74*, *CD63* and *IL32)* and steatosis (*APOC1*, *APOA1*, *APOE*, *ATF5* and *FGF21*). Clustering of transcriptomic data identified nine distinct cellular niches variously enriched for gene markers of hepatocytes, pericentral zonation, hepatic stellate cells and plasma cells. Two niches were associated with significant steatosis identified by AIM-NASH yet expressed distinct gene sets (lipid uptake and metabolism *vs.* inflammation and immune response). Ingenuity Pathway Analysis inferred lipopolysaccharide, TGFβ1 and IFNɣ and inhibition of PPARɣ as potential drivers of these disparate profiles. These results suggest multiple distinct local responses to steatosis occur in SLD.
Conclusion: This study demonstrates the feasibility and power of applying two cutting-edge techniques (spatial transcriptomics and ML-based histological feature prediction) to the same single FFPE tissue section. Integrated data analysis of spatially resolved transcriptomic and high-resolution ML based histopathology data directly links transcriptomic patterns to the local steatosis burden in SLD, revealing dynamic and complementary responses to disease.

Deep learning-based predictive modeling of patatin-like phospholipase domain-containing protein 3 variant carriers using magnetic resonance imaging data
Yazhou Chen[1], Benjamin P.M. Laevens[1], Carola Dlugosch[1], Jan Clusmann[1], Teresa Lemainque[2], Gustav Anton Müller-Franzes[2], Daniel Truhn[*,2], Carolin V. Schneider[1]. *[1]Uniklinik RWTH Aachen Medizinische Klinik III, Aachen, Germany; [2]Uniklinik RWTH Aachen Clinik for Diagnostic and Interventional Radiology, Aachen, Germany*
Email: yachen@ukaachen.de

Background and aims: Steatotic liver disease (SLD) affects 30% of western population due to environmental, lifstyle but also to genetic factors especially the patatin-like phospholipase domain-containing protein 3 (PNPLA3) gene, with its most prominent variant rs738409_G. Identification of variant carriers, based on genome analysis, is expensive. Therefore, we propose a novel deep learning-based approach to discern rs738409_G carriers utilizing magnetic resonance imaging (MRI) data of the liver.
Method: Our study cohort was constructed by selecting patient samples from the UK Biobank for which both data on PNPLA3 rs738409_G status and MRI data were present. To extract the liver fat content, we reconstructed fat fraction maps via r2*-corrected water and fat images based on the IDEAL post-processing water fat separation technique. We extracted liver regions from MRI magnitude images using liver-specific masks, which provide pixel-level segmentation delineating the liver region. Liver masks were segmented by a UNet segmentation model, which was trained with 600 ground truths manually segmented by a medical professional. These segmented liver areas and corresponding variant labels were subsequently utilized as input for the Vision Transformer classification model. The dataset was split into an 8:2 ratio for training and validation purposes respectively.
Results: Firstly, we divided the study cohort into individuals with SLD and without SLD. Within each of these groups, we re-balanced the samples such that a 50:50 ratio was obtained for homozygous and non-carriers. This was achieved by undersampling the majority class (the non-carriers). The SLD group (N_homozygotes = 1018, N_non_carriers = 1018) achieved an AUROC of 0.63 on the validation set. In comparison, the healthy group (N_homozygotes = 803, N_non_cariers = 803) achieved a lower AUROC of 0.55 on the validation set. These results provide first evidence that features on MRI could be present that allow for a better differentiation between homozygous carriers and non-carriers in the SLD group.
Conclusion: In this study, we demonstrated a novel deep learning-based approach to identify PNPLA3 rs738409_G carriers utilizing MRI image data from a well-characterized large cohort. Our method presents an innovative and streamlined technique for identifying genetic variant carriers, offering significant potential for advancing diagnostics in SLD and contributing to the evolution of personalized healthcare.

THU-207-YI
Brain dysfunction is prevented by alpha 2A adrenergic receptor antagonism in a rodent model of diet-induced metabolic dysfunction-associated steatotic liver disease
Anne Catrine Daugaard Mikkelsen[1], Kristoffer Kjærgaard[1], Cecilie Bay-Richter[2], Abeba Habtesion[3], Alexandra Phillips[3], Olivia Greenham[3], Stephen Hamilton-Dutoit[4], Anna Hadjihambi[5], Karen Louise Thomsen[1,3], Rajeshwar Prosad Mookerjee[1,3].

Email: ancami@clin.au.dk

Background and aims: Cognitive dysfunction is a common and recognised complication of metabolic dysfunction-associated steatotic liver disease (MASLD) but there are still no approved treatments. We have previously shown that antagonising the alpha 2A adrenergic receptor (ADRA2A) modulates inflammation and MASLD progression. This study aims to investigate the potential of ADRA2A as a novel target also for treating brain dysfunction in MASLD.
Method: Male Sprague Dawley rats received a high-fat, high-cholesterol diet (HFHC-an established MASLD model) or standard diet (controls) for 16 weeks. Half of the HFHC rats received treatment with the ADRA2A antagonist Yohimbine in the drinking water, for the final 10 weeks. Memory was studied with the novel object recognition (NOR) test and depression-like behaviour with the Porsolt's Swim test (PST). Mean arterial pressure was measured in the carotid artery, and partial pressure of oxygen (PtO2) was assessed in the somatosensory cortex of the brain to quantify tissue oxygen availability. At termination, blood was obtained to examine ammonia concentrations and biochemistry. The liver was collected for histological scoring.
Results: ADRA2A antagonism significantly ameliorated inflammation in the liver, reduced NAS score, and prevented high plasma cholesterol levels induced by the HFHC diet. The HFHC animals exhibited impaired memory in the NOR test (NOR ratio 46 ± 15% versus 79 ± 10%, $p < 0.0001$) and depression-like behaviour in the PST (floating 72 ± 25 versus 39 ± 18 seconds, $p < 0.05$), which was prevented by ADRA2A antagonism (NOR ratio 66+11%, floating 55 ± 20 seconds). Mean arterial pressure was similar between groups, whilst the cortical PtO2 was reduced by HFHC diet (26 ± 2 versus 21 ± 2 mmHg, $p < 0.0001$) and restored to control levels by ADRA2A antagonism (27 ± 2 mmHg). PtO2 positively correlated with the performance in the NOR test ($r = 0.6$, $p = 0.002$). The HFHC diet elevated blood ammonia levels compared to control animals (29 ± 6 versus 51 ± 15 µmol/L, $p = 0.001$), and remained unchanged after ADRA2A antagonism (55 ± 7 µmol/L).
Conclusion: Ten weeks of ADRA2A antagonism in a rodent model of MASLD reduced liver inflammation, prevented impaired memory and depression-like behaviour, and maintained oxygen availability in the brain cortex, without impacting on hyperammonaemia. This paves the way for further mechanistic studies and consideration of future clinical translation in MASLD patients at risk of cognitive dysfunction.

THU-208
Clinical translatability of the GAN diet-induced obese and biopsy-confirmed mouse model of MASH

Michael Feigh[1], Maja Andersen[1], Nicolas Eskesen[2], Denise Oró[2], Henrik B. Hansen[2]. *[1]Gubra, Hørsholm; [2]Gubra, Hørsholm, Denmark*
Email: mfe@gubra.dk

Background and aims: The Gubra-Amylin NASH (GAN) diet-induced obese (DIO) mouse is an industry-standard model of metabolic dysfunction-associated steatohepatitis (MASH) with progressive fibrosis. The present study aimed to assess liver histopathological effects of 6 late-stage clinically drugs in the GAN DIO-MASH mouse with reference to primary end points in corresponding clinical trials in NASH patients with liver fibrosis.
Method: Male C57BL/6J mice were fed the GAN diet (40 kcal-% fat, 22% fructose, 10% sucrose, 2% cholesterol) for ≥34 weeks. Only mice with biopsy-confirmed NAFLD Activity Score (NAS≥5) and fibrosis (≥stage F1) were included. GAN DIO-MASH mice ($n = 14–18$ per group) were administered resmetirom (THR-β agonist, 3 mg/kg, QD, PO), semaglutide (GLP-1 receptor agonist, 30 nmol/kg, SC, QD), obeticholic acid (FXR agonist, 30 mg/kg, PO, QD), lanifibranor (pan-PPAR agonist, 30 mg/kg, PO, QD), elafibranor (PPAR-α/δ agonist, 30 mg/kg, PO, QD), (PPAR-δ agonist, 10 mg/kg, PO, QD), firsocostat (ACC inhibitor, 5 mg/kg, PO, QD), or vehicle for 12 weeks. Histopathological pre-to-post individual assessment of NAS and fibrosis stage was performed and evaluated against FDA/EMA-accepted co-primary/secondary histological end points (resolution of NASH with no worsening of liver fibrosis; ≥1-stage fibrosis improvement without worsening of NASH).
Results: Histological outcomes in GAN DIO-MASH mice were comparable to corresponding clinical trials for resmetirom (MAESTRO-NASH), semaglutide (Newsome *et al.* NJEM 2020), and lanifibranor (NATIVE). Obeticholic acid reversed NASH but not fibrosis in GAN DIO-MASH mice, being line with the FLINT trial, whereas the opposite effect has been reported the pivotal REGENERATE trial. Elafibranor only resolved NASH, being consistent with the GOLDEN-505 trial but contrasting no histological benefits in the pivotal RESOLVE-IT trial. Firsocostat improved both NASH and fibrosis, although these end points were not met in the ATLAS trial.
Conclusion: GAN DIO-MASH mice faithfully reproduce histological outcomes of several compounds profiled in clinical trials for MASH, highlighting clinical translatability and utility of the model in preclinical drug development.

Email: pvaldecantos@iib.uam.es

Background and aims: Oval cells (OCs) are hepatic progenitor cells with differentiation capacity towards hepatocytes or cholangiocytes under damage. However, the impact of the lipoinflammatory environment of non-alcoholic steatohepatitis (NASH) in the OC niche has not been characterized in depth. Inhibition of protein tyrosine phosphatase 1B (PTP1B) is a pharmacological strategy against metabolic liver damage. The aim of this study was to analyze the role of *Ptpn1* in the plasticity of OCs in mice with NASH and to characterize the interactome between immune and OCs.
Method: Ptpn1+/+ mice were fed a choline-deficient L-amino acid defined high fat (CDAA-HF) diet for 3 weeks, time at which Ptpn1+/+ or Ptpn1-/- OCs were transplanted. Mice continued under CDAA-HFD diet for 5 weeks. A lipoinflammatoty conditioned medium (CM) generated from macrophages treated with palmitate/LPS (PA/LPS) was used to stimulate OCs. Mitochondrial respiration, transcriptomic and lipidomic profiles were also analyzed.
Results: $Ptpn1^{+/+}$ mice fed a CDAA diet presented NASH features with expansion of OCs surrounded by inflammatory cells. $Ptpn1^{+/+}$ mice transplanted with $Ptpn1^{-/-}$ OCs showed higher *Krt19* expression pointing to OC expansion during NASH. Transcriptomic analysis revealed upregulation of hepatocyte, cholangiocyte and

proliferation-related genes in Ptpn1-/- OCs. Treatment with PA/LPS-CM for 24 h induced apoptosis in Ocs but it was attenuated in the absence of *Ptpn1* concurrently with a higher proliferation rate. Interestingly, PA/LPS-CM collected from Ptpn1-/- OCs after 16 h contained less proinflammatory mediators suggesting their utilization to activate proinflammatory cascades that have been shown to prime hepatocyte proliferation in liver regeneration. In fact, stimulation of OCs with PA/LPS-CM rapidly phosphorylated STAT3, p65-NFκB, AKT and ERK together with IκBα degradation and p65-NFκB nuclear translocation, responses exacerbated in *Ptpn1*$^{-/-}$ OCs. Under NASH-like conditions, basal/maximal respiration, ATP production and proton link were higher in Ptpn1-/- OCs concurrently with an upregulation of antioxidant defences.
Conclusion: OC expansion concurs with inflammatory features in NASH. The in vitro studies revealed that *Ptpn1* deletion in oval cells favors survival/proliferation under a lipoinflammatory millieu concurrently with higher mitochondrial function and antioxidant capacity, opening therapeutic perspectives to preserve OC plasticity under damage associated to NASH.

THU-210

Dysfunctional activation of the DNA damage response is associated with MASLD progression through an E2F2-dependent mechanism

Beatriz Gómez Santos[1], Idoia Fernández-Puertas[1], Paul Gomez-Jauregui[1], Natalia Sainz-Ramírez[1], Kendall Alfaro-Jiménez[1], Estibaliz Castillero[1], Ane Nieva-Zuluaga[1], Maider Apodaka-Biguri[1], Igor Aurrekoetxea[1,2], Igotz Delgado[1], Aritz Lopategi[1], Ainhoa Iglesias[3], Lorena Mosteiro González[2], Gaizka Errazti Olartekoetxea[2], Sonia Gaztambide[4], Luis A. Email: patricia.aspichueta@ehu.eus

Background and aims: The DNA damage generated as a response to lipotoxicity is a feature often observed in the progression of Metabolic dysfunction-associated steatotic liver disease (MASLD), where E2F transcription factors are overexpressed. However, if the activation of DNA damage response (DDR) could be beneficial in preventing MASLD-related metabolic dysregulation remains unclear. Aims: 1) Identify the relationship between DNA damage, DDR activation and E2F2 overexpression in MASH; 2) Investigate if the activation of DDR is impaired when E2F2 is overexpressed, contributing to metabolic dysregulation.
Methods: In a cohort of patients with obesity, individuals were classified as MASH or no-MASH based on liver biopsy. Hepatic levels of pH2AX (DNA damage marker), Ser15-p-p53 (a DDR activation marker) and E2F2 were analyzed. Hepatic and serum parameters and the activity of liver mitochondrial complexes were evaluated. *E2f2*$^{-/-}$ and their control mice injected with DEN and fed a high-fat diet were used to induce progressive DNA damage-related MASLD. Primary hepatocytes were exposed to UV or palmitic acid (PA) to induce DNA damage, *E2f2* was overexpressed with adenovirus, and AZD6738 was used to inhibit DDR.
Results: MASH patients that exhibited higher liver DNA damage displayed increased liver triglyceride and diglyceride levels, coupled with an inefficient fatty acid oxidation (FAO). These findings were corroborated in mouse models, indicating that DNA damage contributes to metabolic rewiring impeding FAO. Levels of E2F2, a FAO regulator, correlated positively with pH2AX in MASH. *E2f2*$^{-/-}$ mice were protected from DNA damage induced by DEN and lipotoxic diets. Concordantly, overexpressing *E2f2* in hepatocytes led to increased DNA damage when exposed to PA or UV, leading to elevated lipid accumulation and an unresponsive FAO. Moreover, MASH patients with higher damage but incomplete DDR activation (reduced Ser15 p-p53) exhibited a more adverse inflammation than those with complete DDR. In *E2f2*-overexpressing hepatocytes, blocking DDR with AZD6738 upon damage resulted in an ineffective increase in FAO that did not reduce the lipid levels, indicating that a dysfunctional DDR further disrupts metabolism when *E2f2* is overexpressed. Specifically, MASH patients with high E2F2 and dysfunctional DDR showed elevated liver damage levels. The results suggest that higher E2F2 levels in MASH increase the extent to which a deficient DDR leads to metabolic disruption and vulnerability to progression. Notably, in MASH, elevated levels of both E2F2 and pH2AX were associated with faster disease progression.
Conclusion: In MASH patients with higher DNA damage, overexpression of E2F2 and deficient DDR activation are linked to altered FAO and increased liver damage. Thus, DDR activation might be beneficial to prevent the MASLD-related metabolic dysregulation, especially in patients with high E2F2 levels.

THU-211

Hepatoprotective effects of a HSD17b13 inhibitor in the CDAA-HFD mouse model of advanced MASH with progressive fibrosis

Joo Hyun Park[1], Denise Oró[1], Henrik B. Hansen[1], Rick Dewey[2], Katie Gammon[2], Michael Feigh[1]. *[1]Gubra, Hørsholm, Denmark; [2]Foresite Labs, San Francisco, United States*
Email: mfe@gubra.dk

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) has emerged as a major challenge for public health because of high global prevalence and lack of evidence-based drug therapies. The newly identified liver-enriched, hepatocyte-specific and lipid droplet-associated protein 17-beta-hydroxysteroid dehydrogenase 13 (17beta-HSD13, encoded by *HSD17B13*) is strongly associated with the development and progression of MASH and liver fibrosis. The present study aimed to evaluate treatment effects of HSD17B13 inhibitor (M5475) in the non-obese, choline-deficient, L-amino-acid defined, high-fat diet (CDAA-HFD) mouse model of advanced MASH with progressive fibrosis.
Method: C57BL/6JRj mice were fed chow or CDAA-HFD (45 kcal% fat, 0.1% methionine, 1% cholesterol, 28 kcal% fructose) for 3 weeks prior to treatment start (before onset of liver fibrosis) and throughout the treatment period. Animals were randomized into treatment groups based on body weight. A CDAA-HFD baseline group (n = 12) was terminated prior to treatment start. CDAA-HFD fed mice (n = 10–12 per group) were orally administered vehicle or M5475 (30 or 100 mg/kg) for a total of 9 weeks. Chow-fed mice (n = 8) served as normal controls. Terminal end points included plasma/liver biochemistry, AI-assisted histopathological scoring (NAFLD Activity Score (NAS), fibrosis stage), quantitative liver histology and RNA sequencing.
Results: M5475 (100 mg/kg) reduced body weight and liver weight in CDAA-HFD mice compared to vehicle controls. While M5475 dose-dependently reduced hepatic cholesterol levels, other biomarkers (plasma transaminases/PIIINP/TIMP-1, liver triglycerides) were unaffected by treatment. M5475 (100 mg/kg) significantly improved

fibrosis stage, but not NAS. In contrast, M5475 dose-dependently reduced quantitative markers of liver inflammation (number of inflammatory foci, %-area of galectin-3), but not steatosis. The antifibrotic efficacy of M5475 was supported by dose-dependent reductions in quantitative fibrosis markers (hydroxyproline, %-area of PSR, collagen-1a1, α-smooth muscle actin). M5475 treatment increased several gene expression markers of hepatic lipid and carbohydrate handling in combination with suppression markers of the immune system and extracellular matrix organization. M5475 significantly downregulated hepatic *HSD17B13* expression, indicative of target engagement.
Conclusion: M5475 improves biochemical and histological markers of inflammation and fibrosis in the non-obese CDAA-HFD mouse model of advanced MASH with progressive fibrosis, suggesting therapeutic potential of targeting HSD17B13 in MASH.

THU-213
Exploring the role of FXR activation in mitigating ceramides-driven lipotoxicity and endoplasmic reticulum stress in metabolic dysfunction associated steatohepatitis
Basma Abdelrahman[1], Rasha Tawfiq[1], Olfat Hammam[2], Yasmeen Attia[1]. [1]*Department of Pharmacology, Faculty of Pharmacy, The British University in Egypt, Cairo, Egypt;* [2]*Pathology Department, Theodor Bilharz Research Institute, Giza, Egypt*
Email: Basma.alaa@bue.edu.eg

Background and aims: The disruption in ceramides (CER)/sphingolipids balance precipitating lipotoxicity can induce endoplasmic reticulum (ER) stress, thereby contributing to the incidence and progression of metabolic dysfunction associated steatohepatitis (MASH). The impact of the hepatic nuclear farnesoid x receptor (FXR) activation on CER synthesis and the associated ER stress remains to be elucidated. Given the favourable metabolic regulatory impact of FXR in MASH, targeting the FXR/CER axis can be sought as a possible avenue for the alleviation of CER-induced lipotoxicity and inflammatory events in the liver. This has led us to investigate the potential influence of the FXR agonist, obeticholic acid (OCA), in modulating CER synthesis and the associated ER stress in experimental MASH.
Method: Dietary high-fat diet (HFD) model was adopted in the present study to induce MASH. Male C57BL/6 mice were allocated into 3 groups as follows: (I) Normal group that was kept on normal chow, (II) Control group (HFD) that was kept on HFD and received drug vehicle, and (III) OCA-treated group that was kept on HFD and received OCA at a dose of 5 mg/kg/day, p.o. Treatment started after 8 weeks of induction for 4 weeks. Livers were harvested for histopathological evaluation and subsequent analyses. Gene expression of sterol regulatory element binding protein-1c (SREBP1c) and small heterodimer partner-1 (SHP-1) was measured using qRT-PCR. Protein levels of bile acid synthesis rate-limiting enzyme CYP7A1 were also measured by ELISA. Catabolic and salvage CER synthesis pathways were investigated by assessing hepatic levels of sphingosine-1 phosphate (S1P) and acid sphingomyelinase (ASMase), respectively, using ELISA. Hepatic ER stress key regulators, 78-kDa glucose-regulated protein (GRP78) and protein kinase RNA-like endoplasmic reticulum kinase (PERK), as well as the apoptotic marker, C/EBP homologous protein (CHOP), were also measured using ELISA.
Results: Upon histopathological examination, OCA alleviated MASH hallmarks observed in the HFD-fed mice that included macro steatosis and lymphocyte aggregates. OCA treatment resulted in SHP-1 upregulation and SREBP1c downregulation implying the likely reduction of lipogenesis by FXR activation. To further attest to FXR activation, it was observed that CYP7A1 was 79% lower with OCA compared to HFD. Moreover, S1P and ASMase levels were reduced by 63.5% and 49.1% in OCA-treated mice compared to their untreated counterparts, respectively. In line with CER synthesis repression, ER stress markers, GRP78 and PERK, were curtailed by 55.3% and 76.1% in the OCA-treated group when compared to the HFD group, respectively. Analogously, OCA curbed CHOP protein levels by 60.5%.
Conclusion: These findings might imply that FXR activation by OCA can mitigate CER-induced lipotoxicity and the ensuing ER stress in MASH.

Spatiotemporal non-invasive characterization of the hepatic microenvironment during metabolic dysfunction-associated liver disease progression
Rallia Velliou[1], Aigli-Ioanna Legaki[1], Aikaterini Avdi[1], Polyxeni Nikolakopoulou[1], Antonios Chatzigeorgiou[1]. [1]*Department of Physiology, Medical School, National and Kapodistrian University of Athens, Athens, Greece*
Email: rvelliou@med.uoa.gr

Background and aims: Metabolic dysfunction-associated liver disease (MASLD) is a growing health concern, with an estimated prevalence of 25% and is strongly linked to metabolic syndrome components. Among MASLD patients, 30% will advance to the more severe stage of metabolic dysfunction-associated steatohepatitis (MASH); a multiparametric disease characterized by hepatic steatosis, inflammation and fibrosis. Despite its prevalence and severity, there is no MASLD-specific therapy available and existing treatments only tackle MASLD-associated pathologies. A limiting factor affecting prompt diagnosis and monitoring of MASLD, is insufficiency in characterizing the hepatic microenvironment and disease scoring in a spatiotemporal non-invasive manner. Thus, this study aimed towards a longitudinal analysis of MASLD progression at three distinct disease stages by performing a multi-stage phenotypic characterization.
Method: A diet-induced MASLD mouse model was utilized to investigate using in vivo micro-CT (μCT) imaging techniques as a non-invasive method for assessing MASLD progression. Spatiotemporal changes in liver morphology, ECM structure, and inflammation were analyzed, focusing on the hepatic vascular endothelium and hepatic vascular network, since they are implicated in MASLD-related hepatic dysregulation. Liver steatosis, functional tissue uptake/lipid (chylomicron) transfer, portal vein diameter and vascular network density were assessed via μCT at three distinct stages. Steatosis, fibrosis, inflammation and angiogenesis were evaluated via histology and qPCR at the equivalent timepoints.
Results: Findings show that a longitudinal analysis of important disease markers can be performed to assess MASLD progression. μCT analysis revealed that liver steatosis and functional tissue uptake/lipid (chylomicron) transfer were higher for pathological compared to control mice and progressively elevated along with disease advancement. Similarly, pathological mice had an increasingly larger portal vein diameter at all timepoints, a structural alteration linked to portal hypertension. Total hepatic vascular network volume was elevated in pathological mice and progressively increased following MASLD progression. Results were validated using basic laboratory approaches. Liver steatosis, inflammation, fibrosis and angiogenesis were assessed via qPCR and histology, confirming disease progression at three stages.
Conclusion: Our work provides valuable insights into spatiotemporal dynamics of MASLD/MASH advancement and highlights the potential of μCT imaging to support MASLD preclinical research with a cutting-edge, non-invasive method to monitor disease progression, which can pave the way towards more efficient and reproducible approaches to MASLD research and contribute to the development of novel therapies targeting disease progression.

Artificial intelligence-derived granular histological markers of fibrosis from hematoxylin and eosin-stained whole slide images associate with non-invasive tests of fibrosis and prognosis to cirrhosis in patients with metabolic dysfunction-associated steatohepatitis

Neel Patel[1], Lara Murray[1], Adam Stanford-Moore[1], Victoria Mountain[1], Jun Xu[2], Lisa Boyette[2], Benjamin Glass[1], Timothy R. Watkins[2], Andrew N. Billin[2], Ylaine Gerardin[1], Robert Egger[1]. [1]*PathAI, Inc., Boston, United States;* [2]*Gilead Sciences, Inc., Foster City, United States*
Email: neel.patel@pathai.com

Background and aims: Certain non-invasive tests (NITs) are predictive of progression to liver related events (LRE) in MASLD/MASH; however, there is an incomplete understanding of the relationship between NITs and liver histopathology across the spectrum of MASH disease states. NASH Explore™ is a suite of machine learning models that identifies liver cell, tissue, histological landmarks, and fibrosis subtypes in HandE-stained whole slide images (WSIs). Over a thousand human interpretable features (HIFs) are extracted from these model predictions, which quantitatively describe the spatial organization of these substances in relation to one another on a granular level. Here we have deployed NASH Explore to better understand which specific MASH histologies: (i) have the strongest correlations with common NITs and (ii) are associated with progression to cirrhosis and LRE.
Method: We deployed NASH Explore on 4454 HandE WSIs from 3 clinical datasets (STELLAR 3 and STELLAR 4, trials of selonsertib on MASH patients with F3 or F4 fibrosis, respectively, and ATLAS, a trial testing combinations of selonsertib, cilofexor, and firsocosat in F4 MASH patients). We performed correlation analysis of NASH Explore HIFs with fibrosis related NITs (ELF, FIB-4, NFS and FibroScan). Strength of association was measured using Pearson's rho and the effect HIFs on progression to cirrhosis and LRE in STELLAR 3 patients was estimated using Cox proportional hazards regression.
Results: Across time points in all three trials (baseline [BL] and end of study), the fraction of pathological fibrosis area over all tissue positively correlated with fibrosis related NITs (Pearson's rho-ELF: 0.43–0.48; FIB-4: 0.32–0.41; FibroScan: 0.45–0.48; NFS: 0.35–0.36). Nodular fibrosis related HIFs demonstrated the highest positive correlation; additionally, a positive correlation existed between the fraction of nodular fibrosis area over pathological fibrosis and all examined NITs (Pearson's rho-ELF: 0.40–0.49; FIB-4: 0.31–0.37; FibroScan: 0.32–0.37; NFS: 0.38–0.43). The value of these features at BL was prognostic for progression to cirrhosis or LRE (fraction of pathological fibrosis area over tissue HR: 1.59 [1.01–2.47], fraction of nodular fibrosis area over all pathological fibrosis HR: 1.71 [1.19–2.60]). Prognostic value was higher compared to all fibrosis NITs apart from ELF (ELF HR: 2.34 [1.60–3.42], FIB-4 HR: 1.23 [0.99–1.52], FibroScan HR: 1.38 [1.18–1.66], NFS HR: 1.51 [1.0–2.19]).
Conclusion: Using NASH Explore HIFs, we showed that relative areas of pathological and nodular fibrosis positively associate with non-invasive measurement of fibrosis severity and prognosis. Further research is required to validate the association between NITs and granular histological features, which may support the assessment of MASH disease progression or regression through non-invasive surrogates of liver histopathology.

THU-218

A novel role for the epigenetic regulator SUV420H1 in MASLD and its complications

Alessia Pagani[1], Letizia Bavuso Volpe[1], Mariateresa Pettinato[1], Francesco Malvestiti[2], Valeria Furiosi[3], Rossana Carleo[1], Antonella Nai[3], Luca Valenti[4], Laura Silvestri[1]. [1]*IRCCS San Raffaele Scientific Institute, Milan, Italy;* [2]*Università degli Studi di Milano, Milan, Italy;* [3]*IRCCS San Raffaele Scientific Institute, Milan;* [4]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*
Email: silvestri.laura@hsr.it

Background and aims: Several factors contribute to MASLD development and worsening, including deregulated iron metabolism, but the molecular mechanisms involved are still unknown. Notably, a genomic region encompassing the histone methyltransferase Suv420 h has been associated with iron-dependent hepatic steatosis in mice, suggesting that epigenetic remodelling may play a role in linking lipid and iron metabolism.
Method: To determine whether Suv420 h might play a role in MASLD, we compared the differentially expressed pathways in the liver of bariatric patients stratified for Suv420h1 expression (High = 42 vs Low = 44) accounting for age, gender and the carriage of the PNPLA3 I148M at-risk variant. Then, we generated mice lacking Suv420h1 in hepatocytes (h1-LCKO) and characterized them after 16 weeks of a NASH-inducing diet (FPC).
Results: In bariatric patients, Suv420h1 positively correlated with inflammatory response, NF-κB-mediated TNFα and IL-6/JAK/STAT3 signalling, IFNγ response, and EMT, independently of other confounders. Additionally, overrepresentation analysis indicated enrichment in genes involved in extracellular matrix and collagen fibril organization, leukocyte migration, proliferation and migration, in patients expressing higher levels of Suv420h1. h1-LCKO mice were born in the expected Mendelian ratios and developed without problems. Body weight was comparable to that of control mice at a young age, while adult mice had a lower body weight compared to controls. The FPC diet resulted in mild overweight and hepatomegaly in ctrl mice, while h1-LCKO mice were protected. Hepatic inactivation of h1 counteracted hepatomegaly and reduced white adipose tissue hypertrophy. This was associated with a reduced number and size of lipid droplets in the hepatocytes, decreased monocyte recruitment and collagen deposition. Consistently, triglycerides and transaminases in the liver were also reduced. Compared to FPC-treated ctrl mice, FPC-treated h1-LCKO mice showed improved glucose tolerance and increased insulin sensitivity. MASLD is often associated with impaired iron metabolism, which may contribute to disease progression. Mice fed the FPC diet showed increased serum iron and decreased expression of hepcidin, the key hormone regulating iron metabolism. Interestingly, deletion of h1 in hepatocytes also improved iron metabolism by decreasing serum iron and increasing hepcidin on FPC diet. Pharmacologic targeting of h1 in the liver, when hepatostatosis is already established, is ongoing.
Conclusion: Inactivation of Suv420h1 in the liver counteracts MASLD development and progression and improves iron metabolism. Thus, Suv420h1 can be considered a promising therapeutic target for MASLD and its complications, including deregulated iron metabolism. Further studies are underway to decipher the signalling pathway modulated by Suv420h1 in hepatocytes.

THU-219

Inhibition of HSD17B13 by INI-822 phenocopies the hepatic lipidomic profile of humans with the protective allele

Cindy McReynolds[1], Michael Carleton[1], Chuhan Chung[1], Heather Hsu[1]. [1]*Inipharm, Bellevue, WA, United States*
Email: hhsu@inipharm.com

Background and aims: HSD17B13 is an oxidoreductase associated with lipid droplets in hepatocytes. HSD17B13 polymorphisms that result in inactive enzyme protect against MASH, cirrhosis, and liver cancer. Analysis of human liver tissue from subjects with metabolic syndrome demonstrated increased hepatic phosphatidylcholines (PC) in individuals with inactive HSD17B13 (Luukkonen 2020 JCI Insight). In this work, we hypothesized that INI-822, a selective HSD17B13 small molecule inhibitor, could replicate lipidomic changes found in humans carrying the inactive HSD17B13 gene.
Method: INI-822 was dosed orally once daily in obese Zucker rats on a normal chow (NC), high fat, high cholesterol atherogenic diet (HFHCD) and choline deficient, amino acid defined high fat diet (CDAA-HFD), n = 4/group. Changes in liver transaminase levels, circulating and hepatic lipids (GC/MS, LC/MS) were measured.

Statistical significance was evaluated by ANOVA followed by a Bonferroni multiple comparison test for liver transaminases, mean ± SD. The lipidomics were evaluated by multiple unpaired t-tests with adjustment for a false discovery rate of <1%, significance reported for $p < 0.01$.

Results: INI-822 treatment of Zucker obese rats led to a decrease in ALT in animals on the challenge diets compared to vehicle control with the largest change in rats on the CDAA-HFD with a 49 ± 10% decrease with treatment ($p < 0.05$ for all diets). INI-822 treatment did not result in hepatic lipidomic changes in Zucker rats consuming normal chow. Hepatic PCs were elevated in a dose-dependent-manner with INI-822 treatment in rats on the CDAA-HFD with 12 PCs elevated vs. controls more than two-fold. PCs were also enriched in rats on HFHCD with 4 PCs elevated >1.7-fold. These included PC 36:2e and PC 34:3 which have been shown to be elevated in liver biopsies from patients with inactive HSD17B13 alleles. In INI-822-treated animals on the CDAA-HFD, circulating lipids demonstrated a decrease in overall PCs; however levels of specific long chain, polyunsaturated PCs including >10-fold increases in PC 38:4e, PC 40:5 and 42:3e increased in the HFHCD animals. Plasma levels of esterified hydroxy-lipid HSD17B13 substrates increased while free fatty acids of these same substrates decreased.

Conclusion: HSD17B13 inhibition with INI-822 decreased liver transaminases and led to increased hepatic PC content in Zucker rats on metabolic diets. HSD17B13 inhibition led to lipidomic changes consistent with those found in patients with the loss-of-function protective allele.

ATM, guardian of genome integrity, is a new player in NAFLD pathogenesis by modulating mitochondrial metabolism

Pierre Cordier[1], Christelle Kabore[1], Irene Portoles-Plaza[1], Marie Lagouge[1], Alice Verdier[1], Ivan Nemazanyy[2], Romain Donne[3], Jean-Pierre Couty[1], Fatima Mechta-Grigoriou[4], Géraldine Gentric[5], Severine Morizur[1], Chantal Desdouets[1]. *[1]Centre de Recherche des Cordeliers, INSERM U1138, Paris, France; [2]Inserm US 24-CNRS UMS 3633, Platform for Metabolic Analyses, Structure Fédérative de Recherche Necker, Paris, France; [3]Icahn school of medicine at Mount Sinai, New York, United States; [4]Institut Curie, Stress and Cancer Laboratory, Inserm U830, Paris, France; [5]Institut Curie, Stress and Cancer Laboratory, Inserm, U830, Paris, France*
Email: chantal.desdouets@inserm.fr

Background and aims: The incidence of non-alcoholic fatty liver disease (NAFLD) and its progressive form non-alcoholic steatohepatitis (NASH) have become the most prevalent chronic liver disease and a terrifyingly health problem. Key molecular mechanisms behind this sequence have to be still clarified. Based on observations reported by us and others, we propose that Replication Stress (RS) conjointly to an underperforming DNA Damage Response (DDR) might be involved in the progression of NAFLD development.

Method: We analyzed publicly available RNA-seq datasets from patients with NAFLD. We also used mice with targeted hepatocyte ablation of ATM expression and fed them with Choline Deficient High Fat Diet mimicking to induce NASH. Non targeted RNA seq, lipidomic, metabolomic and targeted energy metabolomic analyses as well as cellular and molecular approaches were performed.

Results: First, we exploited a publicly available liver RNA-seq dataset from a cohort of biopsy-proven NAFLD patients to analyze the expression of RS and other DDR genes covering all major DNA repair pathways. Strikingly, we identified RS as the most prominently upregulated DDR pathways, appearing as early as the NAFL state and maintained in NASH-F3 stage. Furthermore, we demonstrated that escalating genotoxicity accompanies progression to fibrosing NASH with cell cycle checkpoint activation, mediated by the ATM-p53 axis, and exemplified by the upregulation of various DNA double-strand break (DSB) responsive genes. We investigated whether inhibition of ATM in a preclinical mouse model of NAFLD could favour disease progression. We demonstrated that ATM deficiency in NAFLD livers enhances liver tissue damage and liver fibrosis independently of its potential role in regulating compensatory proliferation. In fact, ATM deletion exacerbates toxic lipids accumulation and induces reprogramming of central carbon metabolism as well as nucleotide pool imbalance with underlying liver energy deficit. Mechanistically, we observed that ATM regulates mitochondria function in steatotic hepatocytes by acting on Tricarboxylic acid (TCA) cycle and purine/pyrimidine biosynthesis.

Conclusion: Altogether, our findings shed new light on the mechanism by which an under-performing DDR promotes NAFLD disease progression.

THU-221

Association of non-invasive tests (NITs) with genetic polymorphism in patients with metabolic dysfunction-associated steatotic liver disease (MASLD)

Zobair Younossi[1,2], James M. Estep[1,3], Zohal Zekrya[1], Sean Felix[1], Brian Lam[1,3], Zaid Younossi[1,4], Andrei Racila[1,3], Maria Stepanova[1,3,4]. *[1]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, VA, United States; [2]The Global NASH Council, 2411 I Street, Washington, DC, United States; [3]The Global NASH Council, Washington, DC, United States; [4]Center for Outcomes Research in Liver Diseases, Washington, DC, United States*
Email: zobair.younossi@cldq.org

Background and aims: Genetic risk factors have been linked to advanced histologic stage of fibrosis among patients with MASLD. The association of the genetic factors with non-invasive biomarker-based tests (NITs) or liver stiffness measurement (LSM) by transient elastography (TE) has not been well established.

Method: Clinical, laboratory (Enhanced Liver Fibrosis, FIB-4), liver biopsy and TE data were collected from consented patients with MASLD. Genomic DNA was extracted from the whole blood [QIAamp DNA Blood Mini Kit (Qiagen)] and used for determination of minor allele frequency for genomic loci rs641738 (*MBOAT7*), rs58542926 (*TM6SF2*), rs738409 (*PNPLA3*), rs62305723 (*HSD1713B*) using CFX96 (BioRad). Individual alleles were evaluated for association with high ELF (≥11.3), high FIB-4 (≥3.25), high LSM (≥10 kPa), and histologic fibrosis (stage 3 or 4 vs. stages 0–2).

Results: We included 1915 MASLD patients [52 ± 14 years, 47% male, BMI 36.9 ± 10.4, 28% type 2 diabetes (T2D)]. Of these patients, 1.9% had high ELF, 3.4% had high FIB-4; of those with TE (n = 638), 15% had high LSM, and of those with a biopsy (n = 580), 15% had advanced histologic fibrosis (F3 or F4). Of 4 studied SNPs, only *PNPLA3*-rs738409 (51% CC, 39% CG, 10% GG) was significantly associated with higher NIT scores: high ELF 0.9% in CC vs. 2.9% in CG/GG, high FIB-4 2.3% in CC vs. 4.7% in CG/GG, high LSM 10% vs. 19%, respectively, and advanced histologic fibrosis 10% in CC vs. 19% in CG/GG (all $p < 0.01$). Similar associations of *PNPLA3*-rs738409 with NITs were observed in a subgroup of MASLD patients with T2D (n = 536): high ELF 2.5% in CC vs. 5.5% in CG/GG, high FIB-4 4.1% in CC vs. 9.1% in CG/GG, high LSM 20% in CC vs. 39% in CG/GG, advanced histologic fibrosis 21% in CC vs. 42% in CG/GG (all $p < 0.05$). In multivariate analysis adjusted for age, sex, BMI and T2D, having *PNPLA3*-rs738409 CG/GG genotype was independently associated with having high ELF and FIB-4 scores, high LSM, and advanced histologic fibrosis: odds ratio (OR) = 3.53 (1.39–8.99) for high ELF; OR = 2.24 (1.26–4.00) for high FIB-4, OR = 2.56 (1.53–4.27) for high LSM, and OR = 1.99 (1.18–3.37) for advanced histologic fibrosis (all $p < 0.01$).

Conclusion: In patients with MASLD, the polymorphism rs738409 in the *PNPLA3* gene is not only associated with advanced histologic

fibrosis but also independently associated with commonly used NITs such as liver stiffness by transient elastography, ELF and FIB-4 scores.

Email: s.a.gad@leeds.ac.uk

Background and aims: Obesity is a common pathology arising from energy disbalance which increases the risk of metabolic and cardiovascular disease. Exercise is an effective intervention, decreasing obesity and associated cardiometabolic risks. Beta-aminoisobutyric acid (BAIBA), a skeletal muscle metabokine regulated by exercise and the transcriptional coregulator Pgc1α mediates muscle-liver-adipose crosstalk. BAIBA enhances hepatic fatty acid beta oxidation (FaβO) and browning of fat. The effects and signals of BAIBA on hepatic tissue are poorly elucidated. We hypothesize that BAIBA regulates and can improve hepatic metabolism to treat dietary obesity induced fatty liver.
Method: 8-week-old male C57BL/6J mice were either fed chow diet {CD} ± BAIBA (100 mg/kg/day water-added) for 6 weeks (A), 14 weeks (B) or high fat diet {HFD} ± BAIBA for 14 weeks (C) (n = 10/group). We investigated hepatic 1) Metabolism: mitochondrial density (citrate synthase {CS} assay) and function (carnitine palmitoyl transferase {CPT} activity and high resolution mitochondrial respirometry analysis); 2) Molecular phenotype: gene (RT-qPCR) and protein (immunoblotting) expression for FaβO, mitochondrial, lipid and carbohydrate metabolic markers; 3) Histomorphological analysis. Nominal Significance, $p < 0.05$ using GraphPad Prism software.
Results: Hepatic tissue from CD 6-week BAIBA treated mice (A) was characterised by significantly: 1) lower acetyl CoA carboxylase alpha (Acaca) gene and protein expression. 2) greater expression of Cpt1a gene and protein as well as peroxisome proliferator activated receptor alpha (Ppara) gene and protein. 3) increased mitochondrial density, total CPT activity and CPT1 activity (identifying increased fatty acid oxidation). 4) enhanced mitochondrial FaβO. 5) higher gene expression of fatty acid transporter 2, hepatic and monoacylglycerol lipases and fasting induced adipose factor with lower triglycerides. Analysis of hepatic tissue from 14-week BAIBA treated mice under CD (B) and HFD (C) revealed significantly: 1) raised total CPT functional activity. 2) enhanced Acaca protein expression driven by HFD which was reduced with BAIBA treatment. 3) higher expression of Cpt1a, Ppara and gluconeogenic genes with BAIBA treatment under chow conditions. 4) reduced the expression of HFD-induced denovo lipogenesis (DNL) genes including Acaca, diacylglycerol acyltransferase2, stearoyl CoA desaturase1 and elongas6 lipogenic genes. 5) decreased plasma cholesterol in both CD and HFD fed mice. 6) decreased hepatic fat accumulation and decreased fibrosis (collagen I) (n = 5) in BAIBA-treated mice.
Conclusion: BAIBA has beneficial metabolic effects in the livers of lean and obese mice, enhancing hepatic FaβO, mitochondrial energetics and decreasing DNL leading to reduced hepatic fat accumulation and fibrosis.

THU-223

A novel circular RNA therapy expressing a long-acting FGF21 analog protein reversed obesity, insulin resistance, and steatosis in mouse models

Rui Cao[1], Haitao Wan[1], Jing Zeng[1], Lu Gao[2]. *[1]Therorna Shanghai Co., Ltd., Shanghai, China; [2]Therorna Inc., Beijing, China*
Email: lu.gao@therorna.com

Background and aims: Fibroblast growth factor 21 (FGF21) is a promising therapeutic target for the treatment of metabolic dysfunction-associated steatotic liver disease (MASLD). However, the clinical development of FGF21 analogs were challenging, due to their short half-life *in vivo*. Here we report a novel circular RNA circRNA-0222 expressing long-acting FGF21-fusion protein *in vivo* and investigated its therapeutic effect on glycaemic control, weight loss and steatosis in MASLD mouse models.
Method: Murine 3T3-L1 preadipocytes was stimulated with cultured medium from circRNA-0222 lipid nanoparticle (LNP) transduced cells. Cell lysates were subjected to immunoblot analysis for extracellular signal-regulated kinase 1/2 (ERK) activation. To evaluate the activity of FGF21 analog, luciferase reporter assays were performed in 293 T cells stably transfected with human Beta-Klotho. Expression pharmacokinetics were measured by ELISA post intravenous injection in C57BL/6 mice and cynomolgus monkeys. Oral glucose tolerance test (OGTT) was conducted in male BKS wild-type mice. In the chow diet fed BKS-db/db obese model, body weight, body composition and insulin resistance were measured upon weekly circRNA-0222 administration (n = 6) for 4 weeks. Biomarkers of liver function, blood sugar and steatosis were analyzed in the western-diet induced BKS-db/db mice.
Results: cicrRNA-0222 rapidly induced phosphorylation of ERK upon stimulation in 3T3-L1 cells. Particularly, cicrRNA-0222-expressed FGF21 analog (EC50 = 45.3 ng/ml) showed significantly better potency than that of the recombinant FGF21 analog (EC50 = 470 ng/ml). Upon intravenous injection of circRNA-0222 LNP, FGF21 analog became detectable in mouse sera at 2 h post dosing and decayed slowly over 3 weeks. The FGF-21 analog expressed from circRNA-0222 exhibited longer half-life (54–80 h) compared with that of reported recombinant proteins (11–18 h) in mice. In the OGTT study, administration of circRNA-0222 significantly reduced the blood glucose level in a dose-dependent manner. In the BKS-db/db mice, weekly administration of 0.1, 0.25, 0.5 mg/kg circRNA-0222 for 4 weeks resulted in the bodyweight reduction of 9.7%, 14%, 18%, respectively. Surprisingly, the weight reduction was mainly from the loss of fat mass, but not the lean mass. cicrRNA-0222 led to improvement of insulin secretion at 0.25 mg/kg ($p < 0.001$). Moreover, circRNA-0222 significantly attenuated circulating ALT, LDL-C, total cholesterol, triglycerides and HbA1c in the western diet-fed BKS-db/db mice. Confirmed with histopathological evaluation, circRNA-0222 significantly improved hepatic steatosis ($p < 0.05$).
Conclusion: Administration of circRNA-0222 LNP prevented the development of obesity and improved liver disease hallmarks in mouse disease models. Such finding supports further clinical investigation of circRNA-0222 for the treatment of MASLD.

CRISPR/Cas9-mediated somatic gene editing in adult mice reveals hepatic KLB as a regulator of bile acid synthesis and hepatic lipid metabolism

Alexandra Aaldijk[1], Dicky Struik[1], Cristy Verzijl[1], Rick Havinga[1], Milaine Hovingh[1], Nicolette Huijkman[1], Marieke Smit[1], Bart van de Sluis[1], Johan Jonker[1]. *[1]Department of Pediatrics, University Medical Center Groningen (UMCG), Groningen, Netherlands*
Email: alexandraaaldijk@outlook.com

Background and aims: Fibroblast growth factor (FGF) 19 and 21-based drugs have emerged as powerful new biologicals for treating metabolic dysfunction-associated steatotic liver disease (MASLD) due

to their ability to lower liver fat in preclinical models and humans. Rodent studies have revealed that the activity of these drugs is strictly dependent on the expression of the transmembrane protein beta-klotho (KLB) in the adipose tissue and the brain, while its role in the liver remains unclear. To date, only germline mouse models have been used to study the function of KLB, demonstrating an effect on body weight, bile acid metabolism, and cholesterol metabolism. However, these models are confounded by various developmental abnormalities. Therefore, we aim to explore hepatic KLB function in adult mice by applying liver-specific Cas9-mediated somatic gene editing.

Method: Liver-specific Cas9-transgenic mice on a C57BL/6J background were injected intravenously with 0.5 × 1011 adeno-associated virus particles containing three single guide RNAs (sgRNAs) targeting exon 1 of the mouse Klb gene to induce a liver-specific knock-down of Klb or a matched viral dose containing scaffold sgRNA as a control. Mice were maintained on a chow diet for 4 weeks after virus injection, followed by extensive phenotypic characterization.

Results: Liver-specific somatic knock-down of Klb led to a 2.6-fold increase in hepatic Cyp7a1 mRNA expression ($p = 0.008$), suggesting increased bile acid synthesis. In line with this, we identified a 3-fold increased fecal bile acid concentration and excretion ($p = 0.008$) despite an unaltered bile flow. Hepatic Klb deficiency also altered bile acid composition as reflected by the increased percentage of unconjugated bile acids in the bile and feces ($p = 0.008$). Finally, hepatic Klb deficiency resulted in a 41% decrease in plasma triglyceride levels ($p = 0.008$) and a 37% increase in hepatic triglyceride levels ($p = 0.016$).

Conclusion: Through applying liver-specific Cas9-mediated somatic gene editing in mice, we provide new insights into the function of KLB during adulthood, independent of developmental effects, and reveal a direct role for hepatic KLB in the regulation of bile acid synthesis and hepatic lipid metabolism. In addition, our findings identify hepatic KLB as a potential target in FGF19- and FGF21-based treatment of MASLD.

GDF15 activates AMPK and inhibits gluconeogenesis and fibrosis by attenuating SMAD3 phosphorylation

Javier Jurado-Aguilar[1,2,3], Emma Barroso[1,2,4], Maribel Bernard Montuenga[1,2,3], Meijian Zhang[1], Mona Peyman[1], Patricia Rada[2,5], Angela Martinez Valverde[2,5], Walter Wahli[6,7,8], Xavier Palomer[1,2,3], Manuel Vázquez-Carrera[1,2,3]. *[1]Department of Pharmacology, Toxicology and Therapeutic Chemistry, Faculty of Pharmacy and Food Sciences and Institute of Biomedicine of the University of Barcelona (IBUB), University of Barcelona, Barcelona, Spain; [2]Spanish Biomedical Research Center in Diabetes and Associated Metabolic Diseases (CIBERDEM)-Instituto de Salud Carlos III, Madrid, Spain; [3]Pediatric Research Institute-Hospital Sant Joan de Déu, Esplugues de Llobregat, Spain; [4]Pediatric Research Institute-Hospital Sant Joan de Déu, Esplugues de Llobregat, Spain; [5]Instituto de Investigaciones Biomédicas Alberto Sols (CSIC/UAM), Madrid, Spain; [6]Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland; [7]Lee Kong Chian School of Medicine, Nanyang Technological University Singapore, Singapore, Singapore; [8]ToxAlim (Research Center in Food Toxicology), Tolouse, France*
Email: javierjuradoaguilar@ub.edu

Background and aims: The metabolic sensor AMP-activated protein kinase (AMPK) has been reported to be reduced via unknown mechanisms in the liver of mice deficient in growth differentiation factor 15 (GDF15). This is a stress response cytokine that regulates energy metabolism mainly by reducing food intake through its central receptor GFRAL.

Method: Wild-type and *Gdf15*$^{-/-}$ mice, the human hepatic cell line Huh-7, and primary mouse hepatocytes, we examined how GDF15 regulates AMPK.

Results: *Gdf15*$^{-/-}$ mice exhibited glucose intolerance and reduced hepatic phosphorylated AMPK levels that were accompanied by an increase in the phosphorylated levels of the mediator of the fibrotic response mothers against decapentaplegic homolog 3 (SMAD3), together with increased gluconeogenesis and fibrosis. Recombinant (r)GDF15 increased AMPK activation and reduced phosphorylated SMAD3 and the levels of markers of gluconeogenesis and fibrosis in mouse primary culture of hepatocytes, indicating that these effects were independent of GFRAL, and in the liver of mice. Pharmacological inhibition of SMAD3 phosphorylation in *Gdf15*$^{-/-}$ mice prevented glucose intolerance, the deactivation of AMPK and the increase in the levels of proteins involved in gluconeogenesis and fibrosis.

Conclusion: The overactivation of the SMAD3 pathway is responsible for the metabolic alterations in *Gdf15*$^{-/-}$. Overall, these findings indicate that GDF15 activates AMPK and inhibits gluconeogenesis and fibrosis by attenuating the SMAD3 pathway.

THU-226

CAMSAP1 aggravates liver fibrosis in metabolic dysfunction-associated steatohepatitis by promoting microtubule acetylation

Zhiping Wan[1], Xiaoan Yang[1], Xiaoquan Liu[1], Xiaoman Chen[1], Hong Deng[2]. *[1]The Third Affiliated Hospital of Sun Yat-sen University, Guangdong Key laboratory of Liver Disease Research, Guangzhou, China; [2]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: wanzhp@mail2.sysu.edu.cn

Background and aims: Liver fibrosis is a worrisome feature of metabolic dysfunction-associated steatohepatitis (MASH), and its central event is the activation of hepatic stellate cells (HSCs). Calmodulin-regulated spectrin-associated protein 1 (CAMSAP1) -mediated microtubule acetylation is related to HSCs activation, but the specific mechanism remains unclear. We aimed to explore the role and mechanism of CAMSAP1 in HSCs activation and MASH liver fibrosis.

Method: The CAMSAP1 expression was analyzed in MASH patient livers, MASH rat livers, and activated HSCs. SD rats were fed a high-fat and high-cholesterol diet (HFHCD) for 16 weeks to construct a MASH rat model. A plasmid overexpressing CAMSAP1 was constructed and transfected into HSCs to upregulate the expression of CAMSAP1. RNA sequencing was used to analyze gene expression profiles after upregulation of CAMSAP1.

Results: We found that the expression of CAMSAP1 was not only increased in the livers of MASH patients and MASH rats, but also in activated HSCs. Besides, the level of CAMSAP1 was positively correlated with the degree of liver fibrosis. Upregulation of CAMSAP1 in HSCs increased expression of alpha smooth muscle actin (αSMA), collagen type I alpha 1 (COL1A1), collagen type III alpha 1 (COL3A1) and acetylated α-tubulin (Ac-α-Tub). Moreover, alpha tubulin acetyltransferase (ATAT1) was confirmed to be regulated by CAMSAP1, and CAMSAP1 promoted its expression. Importantly, upregulation of ATAT1 in HSCs also promoted microtubule acetylation and activation of HSCs.

Conclusion: CAMSAP1 is increased in MASH progression. CAMSAP1 upregulates the expression of ATAT1 to promote microtubule acetylation, thereby activating HSCs and aggravating liver fibrosis in MASH.

Macrophage phenotype is affected by longitudinal treatment with Zalfermin in a model of metabolic dysfunction-associated steatohepatitis

Benedicte Kapel[1], Dora Hancz[1], Cesar Medina[2], Maria Dermit[2], Lise Flyger Walther Jensen[1], Sanne Skovgård Veidal[3], Jenny Egecioglu Norlin[4], Anouk Oldenburger[3], Birgitte Andersen[1],

Dominik Pfister[1]. [1]*Liver Biology Novo Nordisk A/S, Måløv, Denmark;* [2]*Novo Nordisk Research Centre Oxford, Oxford, United Kingdom;* [3]*Obesity and Liver Pharmacology Novo Nordisk A/S, Måløv, Denmark;* [4]*Translational Medicine Novo Nordisk A/S, Måløv, Denmark*
Email: DRPF@novonordisk.com

Background and aims: Obesity and diabetes are on a steady global rise and together with genetic predisposition, this increases the risk of Metabolic Dysfunction-Associated Steatohepatitis (MASH). Hallmarks of MASH are chronic necro-inflammation and hepatic fibrosis potentially resulting in liver failure or cancer. There is currently no approved pharmaceutical treatment for MASH thus there is a large unmet medical need to develop effective and safe medication. To increase our understanding of disease progression as well as mode of action (MoA) of pharmacological intervention we aimed to generate longitudinal liver treatment data using a murine model of diet-induced MASH treated with long acting GLP1 or FGF21 analogues.
Method: Disease induction was performed in male C57BL/6J mice fed the Gubra Amylin NASH (GAN) diet, high in fat, fructose, and cholesterol, for 34 weeks. In addition, a chow-fed group was included as a control. Upon disease induction, the mice were randomized into four treatment regimens: 1. vehicle (control), 2. Semaglutide, a long-acting GLP-1 (SC q.d.; 30 nmol/kg) 3. Zalfermin, a long-acting FGF21 agonist (SC q.d.; 0, 24 mg/kg) or 4. diet intervention by reversal to chow feeding for two, eight, and sixteen weeks. Besides histological and serological assessment, flow cytometry and single-cell RNA sequencing (scRNA-seq) of hepatic tissue were performed.
Results: MASH phenotype (steatosis, inflammation, and fibrosis) was induced, and all treatments (chow reversal, Semaglutide and Zalfermin) lowered body weight, plasma ALT, liver total cholesterol, and liver triglycerides. Zalfermin lowered liver lipids more than Semaglutide in this model. Histological analyses indicate in the treatment groups a stop of fibrosis progression (PSR, Col1a1), a decrease in fibrosis activity (a-SMA), and reduction of myeloid staining (CD11b). To investigate disease progression and treatment MoA at a single-cell transcriptomic level, we generated a scRNA-seq dataset of more than 393200 hepatic cells. The dataset included data from more than 166800 myeloid cells and 74500 hepatocytes among other cell types. The data confirmed changes in myeloid cells upon MASH induction, as previously reported in literature. Furthermore, the data revealed that all treatments affected myeloid cell abundance and transcriptome. Noteworthy, longitudinal treatment with Zalfermin increased abundance of macrophages to a larger degree compared to Semaglutide.
Conclusion: The data support changes in myeloid cells upon MASH disease development and suggest a role for myeloid cells in treatment MoA. The scRNA-seq data will in the future be expanded with single-nucleus RNA sequencing (snRNA-seq) of the same liver samples to support and validate our findings. Furthermore, future analysis will explore the translative value to human sc- and snRNA-seq datasets of MASH patients including clinical perturbations.

Human embryonic stem cell-derived mesenchymal stem cells improve mitochondrial oxidative dysfunction in metabolic dysfunction-associated liver disease via the AMPK pathway

Min Kyung Park[1], Yun Bin Lee[2], Se-Mi Jung[2], Yoo-Wook Kwon[3], Jung-Hwan Yoon[2]. [1]*Seoul National University Bundang Hospital, Department of Medicine, Seongnam-si, Gyeonggi-do, Korea, Rep. of South;* [2]*Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South;* [3]*Seoul National University Hospital, Biomedical Research Institute, Seoul, Korea, Rep. of South*
Email: alsrud627@snu.ac.kr

Background and aims: Metabolic dysfunction-associated liver disease (MASLD) is one of the most common chronic liver diseases and is associated with a high disease burden. Nonetheless, there is no approved pharmacological treatment option for it. This study aimed to investigate the therapeutic potential of embryonic stem cell-derived mesenchymal stem cells (ESC-MSCs) for mitochondrial dysfunction and hepatic steatosis using cellular and mouse models of MASLD.
Method: HepG2 cells were treated with palmitic acid (PA) and then co-cultured with ESC-MSCs. C57BL/6 mice were chronically fed a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) or normal diet for 24 weeks. At 20 weeks, ESC-MSCs or phosphate-buffered saline was injected into mice via the tail vein. Lipid accumulation was measured through oil red O staining in both cellular and animal models. Mitochondrial mass, reactive oxygen species (ROS), and the activity of antioxidant enzymes were measured to assess mitochondrial oxidative functions.
Results: In the cellular model, PA-induced intracellular lipid accumulation was attenuated by co-culture with ESC-MSCs. Functional mitochondrial mass was reduced by PA treatment and then recovered after co-culture with ESC-MSCs. Increased cellular ROS production mediated by PA treatment was attenuated after co-culture with ESC-MSCs. The activity of superoxide dismutase (SOD) and the ratio of reduced/oxidized glutathione were decreased after PA treatment and restored via co-culture with ESC-MSCs. The expression levels of phosphorylated AMP-activated protein kinase (AMPK) and peroxisome proliferator-activated receptor gamma coactivator-1 (PGC1α) were significantly increased following co-culture with ESC-MSCs. Severe hepatic steatosis was observed in the liver tissues of CDAHFD-fed mice, which ameliorated following the transplantation of ESC-MSCs. Decreased mitochondrial DNA content in the liver tissues of CDAHFD-fed mice was reinstated to near-control levels after the transplantation of ESC-MSCs. Augmented hepatic ROS accumulation caused by CDAHFD was attenuated after the transplantation of ESC-MSCs, with dynamic changes in the activity of SOD and the ratio of glutathione. Furthermore, the transplantation of ESC-MSCs into CDAHFD-fed mice significantly augmented the expression levels of phosphorylated AMPK and PGC1α in the liver tissues.
Conclusion: ESC-MSCs could ameliorate hepatic steatosis in cellular and animal models of MASLD by reducing ROS and restoring mitochondrial oxidative functions through activating the AMPK pathway. This study suggests the therapeutic potential of ESC-MSCs for MASLD.

THU-231

Combination of fatty acid synthase (FASN) inhibitor and thyroid hormone receptor beta (THRb) agonist, resmetirom, improved markers of NASH and cardiovascular health in LDL receptor knockout NASH mice

Wen-Wei Tsai[1], Eveline Gart[2], Martine C. Morrison[2], Geurt Stokman[2], Eduardo Martins[1], George Kemble[1], Marie O'Farrell[1]. [1]*Sagimet Biosciences, San Mateo, United States;* [2]*TNO Metabolic Health Research, Leiden, Netherlands*
Email: wen-wei.tsai@sagimet.com

Background and aims: Increased *de novo* lipogenesis (DNL) drives the development of NASH and FASN is the key enzyme in the DNL pathway. FASN inhibition not only reduces liver fat but also acts directly on immune and hepatic stellate cells (HSCs) reducing inflammation and fibrosis. Denifanstat (TVB-2640), an oral FASN inhibitor, has demonstrated improvements in liver fat and biomarkers associated with inflammation and fibrosis in NASH trials. THRb agonists increase lipid oxidation which decreases liver fat and resmetirom recently demonstrated significant NASH resolution and fibrosis improvement in the phase 3 trial. We hypothesized that the

combination of FASN inhibitor and resmetirom may increase efficacy for NASH treatment based on complementary mechanisms of liver fat reduction and the direct anti-fibrotic effect of FASN inhibitor. This study was designed to evaluate FASN inhibitor alone and in combination with resmetirom on plasma biomarkers and liver histology in LDL receptor knockout (Ldlr-/-) NASH mice. Denifanstat and resmetirom were also evaluated *in vitro* in HSCs for direct anti-fibrotic effects.

Method: Male Ldlr-/- mice were fed with fast-food diet (FFD) for 18 weeks to induce NASH features and treated with either TVB-3664 (a surrogate FASN inhibitor for denifanstat, 5 mg/kg, PO, QD) or THRb agonist resmetirom (MGL-3196, 3 mg/kg, PO, QD) alone or in combination for 10 weeks. End points included liver enzymes, lipids and liver histology (pending). Primary human HSCs were stimulated by TGF-b1 and treated with denifanstat or resmetirom at various concentrations.

Results: FFD feeding significantly increased plasma ALT/AST, total cholesterols and triglycerides in Ldlr-/- mice. TVB-3664 or resmetirom alone rapidly reduced plasma ALT/AST, total cholesterols and triglycerides with 4 weeks treatment and these reductions were sustained until end of the study (10 weeks); importantly, combination of TVB-3664/resmetirom showed further additive improvements compared to either agent alone. Lipoprotein analysis showed that LDL-C and VLDL-C were highly induced by FFD and both were strongly reduced by TVB-3664 or resmetirom alone and further reduced by the combination. In primary human HSCs, TGF-b1-stimulated collagen production and plasminogen activator inhibitor 1 secretion were decreased by denifanstat, but not resmetirom, in a dose-dependent manner.

Conclusion: Combination of FASN inhibitor and THRb agonist resmetirom showed further ALT/AST improvement and lipid lowering compared to either agent alone in a mouse model of dyslipidaemia and NASH. *In vitro*, denifanstat, but not resmetirom, directly reduced collagen production. These results suggest that complementary MOAs of denifanstat (DNL inhibition and direct anti-fibrotic effect) and resmetirom (lipid burning) combined could provide added benefit and support future clinical evaluation of this combination for NASH.

THU-232

Additive hepatoprotective effects of DA-1241, a novel GPR119 agonist, in combination with semaglutide in the GAN diet-induced obese and biopsy-confirmed mouse model of MASH

Monika Lewinska[1], Malte H. Nielsen[2], Susanne Pors[3], Henrik B. Hansen[3], Il Hoon Jung[4], Hyung Heon Kim[5], Michael Feigh[3], Mi-Kyung Kim[6]. *[1]Gubra A/S, Hørsholm; [2]Gubra A/S, Hørsholm, Denmark; [3]Gubra, Hørsholm, Denmark; [4]Dong-A, Yongin-Si, Korea, Rep. of South; [5]NeuroBo Pharmaceuticals Inc, Cambridge, United States; [6]Dong-A ST Co., Ltd., Yongin-Si, Korea, Rep. of South*
Email: mle@gubra.dk

Background and aims: The G protein-coupled receptor 119 (GPR119) and glucagon-like peptide-1 receptor (GLP1R) is promising therapeutic targets for metabolic dysfunction-associated steatohepatitis (MASH). The aim of this study was to evaluate the effects of DA-1241 (GPR119 agonist) and semaglutide (GLP-1R agonist) combination therapy in the GAN diet-induced obese and biopsy-confirmed mouse model of MASH with moderate-severe liver fibrosis.

Method: Male C57BL/6JRj mice were fed the GAN diet for 36 weeks before treatment initiation. Only biopsy-confirmed GAN DIO-MASH mice (steatosis score = 3, lobular inflammation score ≥2, fibrosis stage F2-F3) were stratified to treatment (n = 14–15 per group). GAN DIO-MASH mice received once daily treatment with vehicle, DA-1241 (100 mg/kg, PO) or semaglutide (30 nmol/kg, SC) alone or in combination for 8 weeks. Within-subject comparisons (pre vs. post treatment) were performed for liver biopsy histopathological NAFLD Activity Score (NAS) and Fibrosis Stage. Terminal quantitative end points included plasma/liver biochemistry, liver histomorphometry and RNA sequencing.

Results: DA-1241 was weight-neutral and did not influence liver weight. In contrast, semaglutide robustly reduced body weight by approx. 25% and improved hepatomegaly in GAN DIO-MASH mice with or without combination treatment. There was no additional weight loss in the combination group compared to semaglutide alone. Each monotherapy ameliorated plasma transaminases and liver cholesterol levels, with combination therapy providing further improvement compared to monotherapies. DA-1241 and semaglutide monotherapy each improved NAS (≥2-point) in 21% of mice, whereas combination treatment led to marked improvements (≥2-point in 80% of mice and ≥1-point in all mice), driven by reduction in steatosis and lobular inflammation scores. Correspondingly, combination therapy synergistically promoted quantitative histology for steatosis (%-area of liver lipids, % lipid-laden hepatocytes) compared to monotherapies. While treatments did not significantly influence quantitative markers of fibrosis (PSR, Col1a1), DA-1241 and semaglutide monotherapy lowered α-SMA levels with further improvement in combination treatment, suggesting additive inhibitory effects on fibrogenesis.

Liver transcriptome analysis demonstrated a significant increase in the number of differential expressed genes (DEGs) with prominent signature changes in lipid metabolism, chemokine signaling, and fiber proteins following combination therapy compared to monotherapies.

Conclusion: DA-1241 and semaglutide demonstrate more than additive effects on metabolic, biochemical, and histological end points in GAN DIO-MASH mice, highlighting the therapeutic potential of dual targeting GPR119 and GLP1R function in MASH with liver fibrosis.

THU-233

External validation of machine learning model (MASML) adjusted for prevalence for determining the histologic severity of MASLD in a large cohort of patients with biopsy-proven disease

Naim Alkhouri[1], Joseph Rubinsztain[2], Karen Taub[2], Stephen A. Harrison[3], Devon Y. Chang[4], Mazen Noureddin[5]. *[1]Arizona Liver Health, Chandler, AZ, United States; [2]Pulsar Diagnostics, LLC, Sunrise, FL, United States; [3]Pinnacle Clinical Research, Oxford University, San Antonio, TX, United States; [4]Stanford University, Palo Alto, CA; [5]Houston Research Institute, Houston, Thanks, United States*
Email: nalkhouri@azliver.com

Background and aims: Recently, a machine learning model to predict the severity of MASLD was developed using a balanced cohort from 3 tertiary hepatology centers in the U.S. The aim of this study was to 1) externally validate this model in an independent cohort of patients with biopsy-proven MASLD and high-prevalence of advanced disease, 2) compare its performance to FIB-4 and VCTE, and 3) determine the impact of disease prevalence in the model's performance.

Method: Consecutive patients who presented to tertiary hepatology clinics in the US between 2019–2023 were included. Participants were referred by their primary care doctor or gastroenterologist for consideration for clinical trials. VCTE was performed by experienced operators and the NASH CRN scoring system was used to assess histologic severity on liver biopsy. MASML was applied to a cohort of patients with 62.16% prevalence of significant fibrosis stages F2 through F4 (high prevalence cohort). The high-prevalence MASML was then applied to a patient population with the following fibrosis

prevalence: F0-F1: 58.72%, F2: 13.63%, F3: 14.4%, F4: 13.25% (balanced cohort). Descriptive statistics and diagnostic accuracy measures, such as false positive or negative rates, were used.
Results: 1068 patients with biopsy-proven MASLD and VCTE/laboratory tests within a 3-months period were included in this analysis. The median age was 54 years (IQR 17), median BMI was 37.6 kg/m^2 (IQR 8.09), 62.93% were female, 37.41% were diabetics. The median platelet count was 234 (IQR 75.06), median ALT 49 (IQR 34.49), median AST 42 (IQR 21.96) and median LSM on VCTE was 11.8 kPa (IQR 8). The high-prevalence MASML model had good accuracy for predicting significant fibrosis, advanced fibrosis, and cirrhosis with AUROC for the high-prevalence MASML versus FibroScan and FIB-4 for ≥F2, ≥F3, and F4 being (0.77 vs. 0.59, 0.61), (0.87 vs. 0.67, 0.61), and (0.82 vs. 0.76, 0.56), respectively (p value <0.01 for all). In external validation, the balanced-prevalence MASML model had good intrinsic performance for detecting significant fibrosis with AUROC of 0.88, sensitivity 0.78, specificity 0.82, PPV 0.76 and NPV 0.84.
Conclusion: The MASML model performed better than FIB-4 and VCTE in the high-prevalence patient cohorts. This model has the potential to be used in clinical trials to decrease the screen failure rate due to histology. The MASML model trained with a high-prevalence cohort performed well in the external validation balanced cohort. Additional testing should be performed to improve model performance for primary care, tertiary care and research patient cohorts.

THU-234
Development of a new mouse model combining rapid and robust MASH, liver fibrosis and atherosclerosis: time- and sex-dependent effects

Fanny Lalloyer[1], Eric Baugé[1], Doriane Henry[1], Bart Staels[1]. [1]*Univ. Lille, INSERM, CHU Lille, Institut Pasteur de Lille, U1011-EGID, Lille, France*
Email: fanny.lalloyer@univ-lille.fr

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) prevalence is the leading cause of chronic liver disease, affecting 2 out of 5 persons worldwide. MASLD patients are at increased risk for cardiovascular diseases. In MASLD patients, the expression of the nuclear receptor peroxisome proliferator-activated receptor-alpha (PPARalpha) is decreased in the liver, suggesting an important role of PPARalpha de-activation in MASLD development. In the current study, we developed a new genetic and diet-induced mouse model combining MASLD and atherosclerosis, and investigated the diet- and genetic-induced responses in addition to sex-dependent effects on both pathologies.
Method: Male and female low-density lipoprotein receptor knockout (LDLRKO) mice, deficient (LDLRKO PPARalphaKO) or not (LDLRKO PPARalphaWT) for PPARalpha, were fed a chow or a high-fat (HF) diet during 12 and 18 weeks. Plasma biochemical markers of liver damage (alanine transaminase (ALT) and aspartate transaminase (AST)) were measured. Histological analysis of metabolic dysfunction-associated steatohepatitis (MASH) and fibrosis development was performed in the liver. Atherosclerosis development was quantified in the aortic sinus.
Results: Plasma ALT and AST levels significantly increased in all LDLRKO mice at 12 and 18 weeks of HF diet, with higher levels in both male and female PPARalphaKO compared to PPARalphaWT mice. At the histological level, LDLRKO mice develop all the characteristics of human MALSD, ie liver steatosis, inflammation and ballooning, as well as liver fibrosis. Interestingly, compared to PPARalphaWT mice, PPARalpha deficiency aggravated MASLD progression overtime with higher MASH development and liver fibrosis in both male and female PPARalphaKO mice. Interestingly, whereas male LDLRKO PPARalphaKO mice developed more rapidly MASH (at 12 weeks of HF diet, presence of MASH in 100% of male LDLRKO PPARalphaKO), female LDLRKO PPARalphaKO mice exhibited the more liver fibrosis at 12 and 18 weeks of HF diet, and developed more pronounced atherosclerosis at 18 weeks, compared to male mice or PPARalphaWT mice.
Conclusion: Our new mouse model highlights the importance of PPARalpha down-regulation as a key factor in MASH development, liver fibrosis and atherosclerosis, with sex-specific differences in pathological phenotypes. Given the development of robust and progressive MASLD with all histological characteristics of the human disease in a relatively short period of time (12 to 18 weeks), this model will enable to test new drugs for the treatment of MASH and liver fibrosis and their impact on cardiovascular function.

THU-235
Bridging hepatic pathologies: protein expression dynamics in metabolic dysfunction-associated liver disease (MASLD), benign liver tumours and hepatocellular carcinoma

Saima Ajaz[1], Kosh Agarwal[1]. [1]*King's College Hospital, London, United Kingdom*
Email: saima.ajaz@nhs.net

Background and aims: Liver diseases, ranging from benign tumors and metabolic dysfunction-associated steatotic liver disease (MASLD) to hepatocellular carcinoma (HCC), present diverse molecular complexities. This study aims to thoroughly investigate the proteome of liver tissues and blood samples from patients with MASLD, benign liver tumors, and HCC, focusing on mitochondrial, metabolic, and liver disease proteins. Understanding these molecular details is vital for enhancing liver disease diagnosis and treatment, especially given the global variations in severity and etiology.
Method: This cross-sectional study included subjects divided into four groups: Group 1 (Healthy controls, n = 20), Group 2 (Patients with mild liver fibrosis, n = 40), Group 3 (Patients with moderate to advanced liver fibrosis, n = 40), and Group 4 (Patients with diagnosed HCC, n = 30). Liver tissue was collected from subjects with MASLD, HCC, and benign liver tumors. Proteins were extracted for liquid chromatography-mass spectrometry (LC-MS) analysis from a subset of these groups. Additionally, mitochondrial function was assessed using the Seahorse XFp analyzer.
Results: A total of 3417 proteins were analyzed in the HCC samples and corresponding normal tissue samples. 125 proteins showed significant variation (p < 0.001) with the 10 most significant proteins related to mitochondria. Key findings include the lower expression of Fat Acid Synthase (FASN) in HCC samples compared to controls, indicating a limitation in HCC-induced lipid synthesis pathways. Guanine Nucleotide-Binding Protein Subunit Beta-4 (GNB4) was highly expressed in HCC tissues. Albumin, a marker of liver function, was consistent in controls but decreased in HCC samples. Glutamate Dehydrogenase 1 (GDH1) and Carbamoyl Phosphate Synthetase I (CPS1) also showed notable expression patterns, indicating changes in energy metabolism pathways. Mitochondrial functional studies showed significantly reduced maximal respiration in HCC (275 pmol/min) versus HC (327 pmol/min). Substrate reliance test showed decrease in maximal respiration (500 pmol/min versus 380 pmol/min) on blocking glucose in HCC samples highlighting dependence on glucose utilsation in these samples.
Conclusion: This study highlights the intricate protein expression profiles associated with liver diseases, particularly in mitochondrial and metabolic functions. The predominance of carbohydrate-metabolizing proteins in HCC is notable. Cancer is characterized by increased glycolysis, known as the Warburg effect. These proteins imply HCC cells may use glucose differently. By speeding up energy production and biosynthesis, glycolysis can help cancer cells thrive. Understanding HCC's metabolic adaptations, especially glucose metabolism regulation, is essential for creating targeted therapeutics that exploit these vulnerabilities.

THU-236-YI

Oxysterol treatment causes indirect stellate cell activation: a potential mechanism linking steroid metabolising enzyme dysregulation with fibrosis

Hamish Miller[1,2], Patricia Garrido[1], Wenhao Li[3], Raju Kumar[1], Iris Gines[4], Nikolaos Nikolaou[5], Tom Potter[2,6], Maíra Bailey[2,6], Fredrik Karpe[2], Matthew Neville[2], Márta Korbonits[7], William Griffiths[8], Yuqin Wang[8], William Alazawi[1], Jeremy Tomlinson[2]. *[1]Barts Liver Centre, Blizard Institute, Queen Mary University of London, London, United Kingdom; [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, United Kingdom; [3]Blizard Institute, Queen Mary University of London, Immunobiology, London, United Kingdom; [4]Department of Biochemistry and Biotechnology, Universitat Rovira, Tarragona, Spain; [5]Definigen Ltd, Babraham Research Campus, Cambridge, United Kingdom; [6]Department of Biological and Medical Sciences, Oxford Brookes University, Oxford, United Kingdom; [7]Centre for Endocrinology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom; [8]Swansea University Medical School, Swansea, United Kingdom*
Email: hamish.miller@nhs.net

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the hepatic manifestation of the metabolic syndrome and affects 30% of the population worldwide. Steroid metabolising enzymes activity and expression become dysregulated as MASLD progresses and advanced liver fibrosis has a specific urinary steroid metabolite signature. As a specific example, aldo-keto reductase family 1 member D1 (AKR1D1) is downregulated as liver fibrosis progresses, leading to the accumulation of an oxysterol substrate, 7-alpha-hydroxy-3-oxo-4-cholestenoic acid (7-HOCA). Here we hypothesise that 7-HOCA itself contributes to fibrosis through stellate cell activation in vitro, as measured by expression of collagen type 1 alpha 1 (COL1A1).
Method: Hepatocyte-like cells (HepG2) were treated with fatty acids (oleic acid 1000 micromolar and palmitic acid 500 micromolar, 24 hours) and steroid metabolising enzyme mRNA expression was quantified using qPCR. HepG2 cells were treated with 7-HOCA (25 micromolar, 24 hours) and RNA-Seq analysis performed. Stellate-like cells (LX-2) were treated with 7-HOCA directly or with conditioned media from 7-HOCA-treated HepG2 cells and activation was measured using qPCR for COL1A1. 7-HOCA levels were measured using mass-spectrometry based platforms in serum samples from patients with MASLD cirrhosis (and matched controls) (n = 20) and in a large cohort of patients (n = 2251) who had undergone detailed metabolic phenotyping including body composition analysis with dual energy x-ray absorptiometry.
Results: Using in vitro models, fatty acid treatment downregulated AKR1D1 by 40% (p = 0.005). We have previously shown that AKR1D1 genetic knock down leads to 7-HOCA accumulation. Analysis of RNA-Seq data from 7-HOCA-treated HepG2 cells compared to untreated control cells showed that TGF-beta regulation of extracellular matrix was the most upregulated pathway ($p = 3 \times 10^{-6}$). We therefore investigated the effect of 7-HOCA on stellate cell activation. 7-HOCA did not cause direct activation of LX-2 cells. However, when the media from 7-HOCA-treated HepG2 cells was added to LX-2 cells, we observed a 25% upregulation of COL1A1 when compared to control treated cells, consistent with stellate cell activation. Consistent with these observations, 7-HOCA levels were elevated in patients with cirrhosis (p = 0.0024) and correlated positively with BMI (r = 0.1584, p < 0.0001) and with central adiposity (r = 0.2179, p < 0.0001).
Conclusion: Fatty acid treatment leads to down regulation of AKR1D1 with the consequent potential for 7-HOCA accumulation. 7-HOCA is elevated in patients with metabolic disease, and indirectly (via its action on hepatocytes) activates stellate cells to drive a pro-fibrotic phenotype in the liver. These data underscore the novel finding of a significant association between dysregulation of AKR1D1 and the progression of fibrosis in MASLD.

Peripheral natural cytotoxic cells are associated with development of non-alcoholic liver fatty disease (NAFLD) in children

Małgorzata Wiese[1], Aldona Wierzbicka[2], Lidia Gackowska[1], Wojciech Janczyk[2], Zbigniew Kułaga[2], Jacek Michalkiewicz[2], Piotr Socha[2]. *[1]Nicolaus Copernicus University Collegium Medicum, Bydgoszcz, Poland; [2]The Children's Memorial Health Institute, Warszawa, Poland*
Email: mwiese@cm.umk.pl

Background and aims: NAFLD is characterized by chronic, low grade systemic inflammation and changes in distribution of different peripheral immune cell subsets play a role in the development of NAFLD in experimental models and in adults. The aim of the study was to establish which types of lymphocytes are associated with early stages on NAFLD development (as observed in children).
Method: We recruited 45 obese children with NAFLD (diagnosis based on Fibroscan CAP value >250 suggestive of liver steatosis in general pediatric population- Ferraioli G, BioMed Central 2017) aged 15 ± 1.45 years and 30 aged matched controls. Using multicolor flow cytometry the frequency of the whole blood lymphocyte subsets were assessed including, CD4+, Th1 (CCR6-/CCR4-/CXC3+), Th2 (CCR6-/CCR4+/CXC3-), TH17 (CCR6+/CCR4+/CXCR3-), Th17.1 (CCR6-/CCR4-/CXCR3+), CD8+ and CD8+ with granzyme B, perforin or CD161 expression, mucosal associated invariant CD8+ T cells (MAIT) and NK, iNKT, NKT (with or without granzyme B and perforin expression).
Results: NAFLD children compared to controls presented with a) increase in frequency of memory CD45RO bearing CD4+ T cells (45 ± 14% vs 36 ± 6%, p = 0.03), b) elevation of granzym B or perforin expressing NK cells (68 ± 21% vs 49 ± 26%, p = 0.02, and 75 ± 23% vs 57 ± 30%, p = 0.02, respectively), c) increase in proportion of CD8 +/CD161int + T cells (9 ± 3% vs 7 ± 3%, p = 0.02), d) decrease of frequency of CD8+/CD161 (–) T cells (82 ± 8% vs 87 ± 5%, p = 0.02). The following correlations with clinical parameters were obtained: 1) CAP vs % perforin expressing CD8+ T cells (r = 0, 287, p = 0, 021) and CAP vs granzyme B (r = 0, 291, p = 0.019,) and perforin (r = 0.294, p = 0.018) expressing NK cells, 2) ALT vs granzyme B (r = 0.392, p = 0.013) and perforin (r = 0.308, p = 0.014,) expressing NK cells, 3) GGTP vs perforin bearing iNKT cells (r = 0.278, p = 0.034), 4) TG vs granzyme B expressing NK cells (r = 0.326, p = 0.008), 5) glucose levels vs NKT (r = 0.857, p = 0.013) and vs granzyme (r = 0.787, p = 0.03,) or perforin (p = 0.787, p = 0.03,) bearing NKT cells, 6) HDL-C levels vs granzyme B bearing NK cells (r = 0.342, p = 0.006), 7) insulin levels vs TH1/TH2 cells (r = 0.557, p = 0.010), 8) RWT vs TH1/TH2 (r = 0.262, p = 0.039) and iNKT (p = 0.293, 0.029), 8) IMTR vs iNKT (r = 0.239, p = 0.007), 9) c IMT vs % of iNKT (p = 0.01, r = 0.314).
Conclusion: Proportions of peripheral, natural cytotoxic cells including NK and iNKT expressing granzyme B or perforin may be predictors of NAFLD progress and metabolic disturbances of obesity in early stages of this condition in the pediatric patients. At this stage of NAFLD development innate immunity seems to play a major role.

THU-239-YI

Metabolic dysfunction-associated steatotic liver disease (MASLD) modeling with hepatocyte-like cells derived from adult liver stem cells via air-liquid interface

Soe Einsi Lynn[1,2], Jian Hui Low[1], Yee Siang Lim[1], Chwee Tat Koe[1], Tiffany Woo[1], Junyu Zhao[1], Ganakirthan Kalpenath Rajah[1], Wee Jug Teow[1], Royston Kwok[1], Cheng Peow Bobby Tan[1], Lai Ping Yaw[1], Torsten Wuestefeld[1], Mei Chin Lee[1], Huck Hui Ng[2,3]. *[1]Genome Institute of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore; [3]Agency for Science, Technology and Research, Genome Institute of Singapore, Singapore, Singapore*
Email: e0744034@u.nus.edu

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common liver disease worldwide estimated to affect about 38% of the world's population and is the leading cause of liver-related mortality. Therefore, the development of non-invasive diagnosis methods and novel treatments is of priority to manage the disease. To create a robust MASLD target identification and validation system, our laboratory aims to develop an in vitro hepatocyte-like cell model that can faithfully recapitulate the disease.
Method: Our laboratory has developed a reproducible method to isolate self-renewable adult liver stem cells (LSC) from donor tissues. Isolated LSC can be differentiated into hepatocyte-like cells (HLC) when cultured via the air-liquid interface (ALI) under defined media culture conditions. The HLC were treated with free fatty acid (FFA) to induce steatosis condition and metabolic dysfunction-associated steatohepatitis (MASH) -inducing compounds to induce MASH-like phenotype. Subsequently, these treated cells were exposed to drugs such as diacylglycerol acyltransferase (DGAT) and acetyl-CoA carboxylase (ACC) inhibitors for observation of drug response.
Results: Differentiated HLCs were validated to express hepatocyte markers and displayed hepatic functionality *in vitro*. Transcriptomic profiling of HLC reveals hepatocyte-specific gene signatures similar to primary human hepatocytes (PHH). FFA-treated HLCs are found to be responsive to drug treatments with DGAT and ACC inhibitors treatment.
Conclusion: Isolated LSC are renewable sources of cells that can generate HLC upon differentiation via ALI under defined media culture conditions. Differentiated HLCs are functionally and transcriptionally similar to primary human hepatocytes, indicating their likeness to hepatic cells. The drug-treated HLC successfully demonstrated the reversal of steatosis, suggesting these cells as reliable cell resources for MASLD modeling.

THU-242

Comparison of machine learning model (MASML), VCTE, and FIB-4 scores for predicting the presence of MASLD in a large cohort of patients in the U.S. using the NHANES database

Mazen Noureddin[1], Joseph Rubinsztain[2], Karen Taub[3], Devon Y. Chang[4], Stephen A. Harrison[5], Naim Alkhouri[6]. *[1]Houston Research Institute, Houston, TX, United States; [2]ChronWell, Inc., Pulsar Diagnostics, LLC, Sunrise, United States; [3]Pulsar Diagnostics, LLC, Sunrise, United States; [4]Stanford University, Palo Alto, CA, United States; [5]Pinnacle Clinical Research, Oxford University, San Antonio, TX, United States; [6]Arizona Liver Health, Chandler, AZ, United States*
Email: mnh86@hotmail.com

Background and aims: Recently, a machine learning model to predict the severity of MASLD was developed using a cohort from 3 tertiary hepatology centers in the U.S. with a balanced learning set for fibrosis stages F0 through F4. The aim of this study was to compare the performance of this model to FIB-4, and VCTE in a large cohort of patients in the NHANES database from 2018–2020.
Method: Patients stored in the NHANES US database between 2018–2020 that included age, gender and BMI and laboratory values for platelets, AST, ALT and HgA1C + VCTE were included. Those with excessive alcohol consumption or viral hepatitis were excluded. FAST and Agile 3+ scores were applied as the gold standard (given the lack of liver biopsy data) to determine indeterminate and high probability of at-risk MASH and fibrosis stage 3 or higher, respectively. Descriptive statistics and diagnostic accuracy measures, such as false positive or negative rates, were used.
Results: 5, 130 patients with sufficient values were included in this analysis. The median age was 52 (IQR 31), median BMI was 27.8 (IQR: 7.95) kg/m^2, 51.91% were female, 12.01% were diabetics. The median platelet count was 236 (IQR: 79.75), median ALT 18 (IQR: 12), median AST 19 (IQR: 8) and CAP on VCTE was 158 db/M (IQR: 96), median LSM was 4.8 kPa (IQR: 2.3).
7.39% of patients were predicted to have at-risk MASH (MASH with F2-F4) using FAST and 9.02% of patients were predicted to have fibrosis stage 3 or higher using the Agile 3+ score. The MASML model had good accuracy for predicting at-risk MASH based on the FAST score (AUROC of 0.72) and advanced fibrosis based on AGILE3+ (AUROC of 0.76). Surprisingly, both VCTE and FIB-4 demonstrated low AUROC for advanced fibrosis (0.55 and 0.63 respectively) using AGILE3+ as the gold standard. All models demonstrated a high NPV for advanced fibrosis (>90%), but only FIB-4 demonstrated a moderate PPV (0.69).
Conclusion: MASML outperformed VCTE and FIB4 in predicting at-risk MASH and advanced fibrosis in a representative U.S. cohort with low prevalence of advanced MASLD. MASML relies on readily available clinical and laboratory characteristics avoiding the need for expensive VCTE machines which may facilitate large scale screening at the general population level.

Macrophage driven fibrosis resolution assessed by a cross-linked and MMP degraded type III collagen fragment (CTX-III) declines with age and is prognostic for survival in chronic liver disease

Alejandro Mayorca Guiliani[1], Peder Frederiksen[2], Emilie Skovgaard[2], Ida Lønsmann[2], Morten Karsdal[3], Flemming Bendtsen[4], Julie Steen Pedersen[5], Jonel Trebicka[6], Diana Leeming[2]. *[1]Nordic Bioscience, Herlev, Denmark; [2]Nordic Bioscience A/S, Herlev, Denmark; [3]Nordic Bioscience A/S, Herlev; [4]University Hospital, Hvidovre, Hvidovre, Denmark; [5]Copenhagen University Hospital Hvidovre, Hvidovre, Denmark; [6]Universitätsklinikum Münster (UKM), Muenster, Germany*
Email: amg@nordicbio.com

Background and aims: A wave of unsuccessful antifibrotic drugs for chronic liver disease has created an urgent need for biomarkers to understand the pharmacodynamic effects on fibrogenesis and fibrolysis. Here, we describe how CTX-III, a crosslinked and matrix metalloproteinase-degraded fragment of collagen type III, works as a systemic biomarker of ECM degradation and fibrosis resolution.
Method: An automated platform (IDS-i10, UK) quantifies CTX-III using a sandwich ELISA. First, we detected CTX-III in healthy (n = 1) and fibrotic (F2–3; n = 5) human livers. We then modeled CTX-III production *in vitro*, culturing hepatic stellate cells to generate an ECM and then culturing macrophages (MAC) on this matrix, measuring CTX-III in conditioned medium before and after 8 days of MAC culturing. Furthermore, we established the CTX-III healthy reference in persons of different age groups: 19–29 yrs (n = 23), 30–39 yrs (n = 22), 40–49 yrs (n = 12) and 50–59 yrs (n = 10), as well as in a cohort of MAFLD patients undergoing bariatric surgery (n = 70), and in cirrhotic patients with transjugular intrahepatic portosystemic shunts (TIPS) (n = 86) along with the N-terminal pro-peptide of collagen type III (PRO-C3, a biomarker of fibrogenesis).
Results: CTX-III could be extracted from human fibrotic livers. Non polarized MAC 0 (M0) produced MMPs and generated CTX-III, thus degrading the HSC-produced matrix. CTX-III in serum of healthy adults (median 14.49 ng/ml) CTX-II decreased with age (18.64 ng/ml in 19–29 y.o, 13.6, 10.48 and 8.215 ng/ml in subsequent decades- non sig.) In cirrhotic patients, CTX-III further decreased to a median of 2.5 ng/ml. In bariatric surgery CTX-III begins at a median of 4.91 ng/ml prior to surgery, 4.934 ng/ml after 3 months, 4.730 ng/ml after 6 months and 5.21 after 12 months. CTX-III and PRO-C3 in TIPS patients revealed that patients with high CTX-III and low PRO-C3 survive a significantly longer time than vice versa (p = 0.0348).
Conclusion: CTX-III was detected in human fibrosis tissue. *In vitro* experiments suggest that CTX-III may be the result of immune-mediated degradation and released by macrophages. In healthy humans, CTX-III decreases with age, and decreases even further during diseases such as MAFLD and cirrhosis. This potentially suggests that the ability to degrade crosslinked collagen type III is characteristic of homeostasis and youth. Progressing (MAFLD) and terminal (cirrhosis) fibrosis depress CTX-III production, pointing to impaired ECM degradation as a factor in fibrosis progression along with ECM deposition. This imbalance may be associated with a

defective immune response. A combination of CTX-III and PRO-C3 could become a biomarker of healthy ECM balance, fibrosis resolution and prognosis in liver fibrosis.

Synergistic hepatoprotective effects of semaglutide and resmetirom combination therapy in the GAN diet-induced obese and biopsy-confirmed mouse model of MASH

Kristoffer Voldum-Clausen[1], Jenny Egecioglu Norlin[2], Sanne Skovgård Veidal[2], Denise Oró[1], Line Nilsson[1], Henrik B. Hansen[3], Michael Feigh[4]. [1]*Gubra A/S, Hørsholm, Denmark;* [2]*Novo Nordisk, Måløv, Denmark;* [3]*Gubra A/S, Hørsholm, Denmark;* [4]*Gubra A/S, hørsholm, Denmark*
Email: kvc@gubra.dk

Background and aims: Semaglutide (glucagon-like receptor-1 (GLP-1R) agonist) and resmetirom (THR-β receptor agonist) are both in late-stage clinical development for treatment of metabolic dysfunction-associated steatohepatitis (MASH). The present study aimed to compare metabolic, biochemical, and histological effects of semaglutide and resmetirom as mono- and combination treatment in a translational GAN diet-induced obese and biopsy-confirmed mouse model of MASH with liver fibrosis.
Method: C57BL/6JRj mice were fed the GAN diet high in saturated fat, fructose, and cholesterol for 38 weeks before treatment start. Only animals with biopsy-confirmed MASH (NAFLD Activity Score, NAS≥5) and moderate fibrosis (stage ≥F2) were included and stratified into treatment groups. GAN DIO-MASH mice (n = 17–18 per group) received vehicle (SC), semaglutide (30 nmol/kg, SC), resmetirom (3 mg/kg, PO) or resmetirom (3 mg/kg, PO) + semaglutide (30 nmol/kg, SC) once daily for 12 weeks. Vehicle-dosed (SC) chow-fed controls (n = 10) served as healthy controls. Within-subject comparisons (pre- vs. post-treatment) were performed for NAS and fibrosis stage. Terminal quantitative end points included plasma/liver biochemistry and quantitative liver histology.
Results: While resmetirom was weight-neutral, semaglutide significantly reduced body weight (28%) and combination treatment led to further weight loss (37%) in GAN DIO-MASH mice. Both monotherapies and combination treatment reduced plasma transaminases and plasma/liver markers of inflammation (MCP-1) and fibrogenesis (TIMP-1). Combination treatment improved hepatomegaly and liver lipid levels greater than individual monotherapies. NAS (pre-post) was significantly improved by semaglutide (≥2-point, 28% of mice) and resmetirom (≥2-point, 17% of mice) and combination treatment led to synergistic reductions in NAS (≥2-point, 71% of mice) largely driven by improved steatosis scores, being further supported by quantitative histology. Only semaglutide significantly reduced quantitative histological markers of inflammation (galectin-3) and fibrogenesis (α-SMA). Treatments did not improve fibrosis stage and quantitative histological markers of fibrosis (PSR, Col1a1).
Conclusion: Both semaglutide and resmetirom improve biochemical and histological hallmarks of MASH in GAN DIO-MASH mice. Further therapeutic benefits are achieved by combination treatment, demonstrating the feasibility of combined stimulation of GLP-1R and THR-β receptor function to improve outcomes in MASH.

Email: drrehaakpinar@gmail.com

Background and aims: Data on ChatGPT's ability to evaluate liver fibrosis histopathology is limited. This study aims to assess ChatGPT-4's diagnostic accuracy in evaluating liver fibrosis in metabolic dysfunction-associated steatohepatitis (MASH) by comparing its performance to that of pathologists.
Method: A total of 59 consecutive MASH tissue specimens using Sirius red-stained slides were digitized and evaluated by ChatGPT-4 and four pathologists using the NASH CNR system. The process included converting whole slide images (WSIs) to a compatible format for ChatGPT-4, employing various magnifications, and extracting random fields of view. The diagnostic accuracy of ChatGPT-4 was compared with pathologists' evaluations, complemented by a collagen proportionate area (CPA) quantification for additional insight.
Results: On selected by pathologist images, ChatGPT-4 demonstrated an overall diagnostic accuracy of 81%. Its accuracy dropped to 63% when using randomly cropped images. ChatGPT-4 performed comparably to a liver pathologist on F1, F2 and F3 stages. However, ChatGPT's diagnostic accuracy for F4 (40%) was lower than that of every pathologist. The study also found a moderate to strong correlation between ChatGPT's fibrosis staging and a quantitative evaluation of collagen in the liver biopsy.
Conclusion: ChatGPT can be used to stage liver fibrosis in MASH, if diagnostic areas are selected by expert pathologists. However, even with selected images, F4 stage accuracy is low: a finding suggesting the impossibility of prefiguring the presence of nodules if they are not clearly present in the biopsy. On the other hand, ChatGPT seems to recognize different nuances of fibrosis progression.

Email: c.hateley@ic.ac.uk

Background and aims: Obesity drives maladaptive changes in the white adipose tissue (WAT) which can progressively cause insulin resistance, type 2 diabetes mellitus (T2DM) and metabolic dysfunction associated liver disease (MASLD). Obesity-mediated loss of WAT homeostasis can trigger liver steatosis through dysregulated lipid pathways such as those related to polyunsaturated fatty acid (PUFA)-derived oxylipins. However, the exact relationship between oxylipins and liver steatosis remain elusive and cross-tissue dynamics of oxylipins remains ill-defined.
Method: We quantified PUFA-related oxylipin species in the omental WAT, liver biopsies and plasma of 88 patients undergoing bariatric surgery and 9 patients undergoing upper gastrointestinal surgery, using UPLC-MS/MS. We integrated oxylipin abundance with WAT phenotypes (adipogenesis, adipocyte hypertrophy, macrophage

infiltration, type I and VI collagen remodelling) and the severity of MASLD (steatosis, ballooning, inflammation, fibrosis) quantified in each biopsy. The integrative analysis was subjected to (i) adjustment for known risk factors and, (ii) control for potential drug-effects through UPLC-MS/MS analysis of metformin-treated fat explants *ex vivo*.
Results: We reveal a generalized down-regulation of cytochrome P450 (CYP)-derived diols during obesity conserved between the WAT and plasma. Notably, epoxide:diol ratio, indicative of soluble epoxide hydrolyse (sEH) activity, increases with WAT inflammation/fibrosis, hepatic steatosis and T2DM. Increased 12, 13-EpOME:DiHOME in WAT and liver is a marker of worsening metabolic syndrome in patients with obesity.
Conclusion: These findings suggest a dampened sEH activity and a possible role of fatty acid diols during hepatic steatosis and T2DM. They also have implications in view of the clinical trials based on sEH inhibition for metabolic syndrome.

Unraveling the interplay of FGF21 and GLP1 analogue in metabolic dysfunction-associated steatohepatitis in vivo
Anouk Oldenburger[1], Birgitte Björkenberg[1], Henning Hvid[2], Matthew Gillum[1], Dominik Pfister[3], Sanne Skovgård Veidal[1], Birgitte Andersen[3]. *[1]Obesity and Liver Pharmacology, Novo Nordisk A/S, Måløv, Denmark; [2]Pathology and Imaging, Novo Nordisk A/S, Måløv, Denmark; [3]Liver Biology, Novo Nordisk A/S, Måløv, Denmark*
Email: auog@novonordisk.com

Background and aims: FGF21 and GLP-1 are under clinical investigation for the treatment of metabolic dysfunction-associated steatohepatitis (MASH). Both FGF21 and GLP-1 analogues have been shown to resolve MASH and prevent fibrosis. Mice lacking FGF21 (FGF21 knockout mice) has been shown to accelerate metabolic induced liver injury in mice and the use of FGF21 KO mouse model presents an opportunity to investigate whether the beneficial effects of a GLP1 analogue on body weight (BW) and MASH parameters are dependent on FGF21 signaling.
Method: Male wildtype (WT) and FGF21 KO were fed chow (Altromin 1324) or choline deficient high fat diet (CDHFD) (Research Diets, A16092003) for 6 weeks. After 6 weeks on CDHFD, the mice were treated with vehicle or a long acting GLP1 analogue (NNC'2220, s.c., q. d., 5 nmol/kg) for an additional 6 weeks (n = 15). Body weight (BW) was recorded during the study and terminal plasma (TG and FFA) and liver were collected. MASH-related (HE, CD45, CD11b, αSMA and PSR staining) parameters were accessed by histology.
Results: The CDHFD did not affect BW in wild type mice nor the FGF21 KO mice but induced a MASH phenotype in both WT and FGF21 KO mice. No difference in inflammation was seen between genotypes while the FGF21 KO mice have significantly more stellate cell activation measured by αSMA staining. Oppositely, liver fibrosis was comparable between WT and FGF21 KO mice. The long acting GLP1 analogue NNC'2220 induced a 18% body weight loss in wild type CDHFD fed mice while the body weight loss was significantly blunted in the FGF21 KO CDHFD fed mice. GLP-1 treatment did not reduce hepatic steatosis in the CDHFD fed mice, while an increase in steatosis was observed in GLP-1 treated FGF21 KO mice. The GLP1 analogue showed a reduction in liver CD45 levels in both WT and FGF21 KO mice. Hence, FGF21 is not required for the inhibitory effect of GLP1 on the abundance of CD45. Furthermore, GLP1 showed a trend towards reduced CD11b, a marker for monocyte recruitment in WT but not in FGF21 KO mice. In terms of fibrotic markers, no significant effect of GLP-1 was observed of PSR staining in neither WT nor FGF21 KO mice and no reduction in αSMA was observed in response to GLP-1 treatment WT nor FGF21 KO mice.
Conclusion: In this study no major difference in MASH parameters induced by CDAHF diet were observed between WT and FGF21 KO mice. However, a significant increase in αSMA in the FGF21 KO mice was observed.In this model the GLP-1-induced BW loss and the GLP-1 induced decrease in CD11b recruitment were blunted in the FGF21 KO mice. In conclusion, the use of FGF21 KO mouse model showed that markers like BW and potentially CD11b are affected by GLP-1 via FGF21.

Email: cedric.peleman@uantwerpen.be

Background and aims: Evidence is accumulating for a recently discovered type of cell death in metabolic dysfunction-associated steatohepatitis (MASH), i.e. ferroptosis. This cell death occurs when uncontrolled peroxidation of polyunsaturated fatty acids overrides physiologic ferroptosis defenses. One prominent ferroptosis brake is glutathione peroxidase 4 (GPX4) which uses reduced glutathione (GSH) as cofactor. In the present study we examined the role of GPX4 in a preclinical MASH model using transgenic mice with whole body GPX4 overexpression or conditional hepatocyte-specific GPX4 knockout.
Method: Male C57BL/6J mice were sacrificed after 1, 2, 3, 4, or 6 weeks on the choline-deficient L-amino acid-defined high-fat diet (CDAHFD) or standard diet (SD) and levels of ferroptosis marker malondialdehyde (MDA) and GPX4 were measured. Whole body GPX4 overexpressing male animals (Gpx4Tg/+) and wild-type littermates were fed CDAHFD or SD for 4 weeks. Likewise, male mice with tamoxifen-inducible hepatocyte-specific GPX4 knockout (Gpx4fl/fl AlbCreERT2Tg/+) and wild-type littermates were fed the CDAHFD or SD for a maximum of eight weeks. After 4 weeks on their respective diets, tamoxifen was administered to induce hepatocyte-specific knockout. Hepatic ferroptosis defenses, vitamin E and ferroptosis-suppressor protein 1 (FSP1) levels, were measured with mass spectrometry and real-time quantitative PCR (RT-qPCR), respectively.
Results: Livers from CDAHFD fed animals displayed MASH already after 1 week and a significant increase in hepatic MDA after 4 weeks ($p < 0.01$), compared to SD. Immunohistochemistry showed a panlobular increase in GPX4 after 4 weeks CDAHFD, while this epitope was limited to the pericentral region in SD. No increase was noted in GPX4 levels on western blot and RT-qPCR at the same timepoint. Overexpression of GPX4 had no effect on histological lesions of MASH induced by CDAHFD, failed to lower hepatic MDA and did not alter hepatic GSH levels. Gpx4fl/fl AlbCreERT2Tg/+ animals fed SD suffered from acute liver failure and mortality by day 12 after tamoxifen. Unexpectedly, CDAHFD protected Gpx4fl/fl AlbCreERT2Tg/+ animals from mortality (log-rank test: $p < 0.01$). GPX4 loss after tamoxifen was confirmed on a protein level. Serum vitamin E and FSP1 mRNA expression were significantly higher in Gpx4fl/fl AlbCreERT2Tg/+ on CDAHFD, compared to those on SD ($p < 0.001$ and $p < 0.01$, respectively).
Conclusion: CDAHFD induces hepatic cell death with ferroptosis breakdown products and panlobular GPX4 expression. GPX4 over-expression has no effect on liver lesions in CDAHFD. In normal livers, hepatocyte-specific GPX4 knockout is incompatible with life and

associated with a drop of other ferroptosis defenses. MASH induced by CDAHFD protects against hepatocyte-specific loss of GPX4, compensated by other ferroptosis defenses that render GPX4 dispensable.

THU-250-YI

Untargeted lipidomics unveils distinct signature of metabolic dysfunction-associated steatohepatitis in the context of obesity

Alina-Iuliana Onoiu[1], Vicente Cambra-Cortes[2], Andrea Jiménez-Franco[1], Cristina Placed-Gallego[3], Juan Manuel Jiménez-Aguilar[1], Cristian Martínez-Navidad[4], Helena Castañé[5], Jordi Camps[6], Jorge Joven[7]. *[1]Universitat Rovira i Virgili, Unitat de recerca biomèdica, Reus, Spain; [2]Universitat Rovira i Virgili, Centre de recerca biomèdica, Reus, Spain; [3]Universitat Rovira i Virgili, Unitat de recerca biomèdica, Reus, Spain; [4]Fundació Institut d'Investigació Sanitària Pere Virgili, Unitat de recerca biomèdica, Reus, Spain; [5]Institut d'Investigació Sanitària Pere Virgili, Unitat de recerca biomèdica, Reus, Spain; [6]Hospital Universitari Sant Joan de Reus, Unitat de recerca biomèdica, Reus, Spain; [7]Hospital Universitari Sant Joan de Reus, Unitat de recerca biomèdica, Reus, Spain*
Email: alinaonoiu@hotmail.com

Background and aims: Obesity and metabolic dysfunction-associated liver disease (MASLD) are two closely related diseases characterized by an excessive accumulation of fat and an alarming and increasing prevalence. Type 2 diabetes mellitus, cardiovascular problems, dyslipidemia, and cancer are commonly associated with obesity. On the other hand, MASLD can progress negatively to metabolic dysfunction-associated steatohepatitis (MASH), characterized by a dangerous proinflammatory and fibrotic state that can lead to liver dysfunction. Lipid metabolism is altered in these pathologies; however, it is still unknown which role the different lipid species play.
Method: A non-directed lipidomic analysis by UHPLC-ESIQTOF-MS was performed to assess the concentration of lipid species through liver biopsies from the participants. Group comparisons were made between the 110 obese patients (BMI ≥35 kg/m²) classified into nonMASH (n = 50), MASH (n = 50) and uncertain MASH (n = 10) groups.
Results: Obese patients with MASH had a higher lipid concentration of all species except Phosphatidylcholines (PCs), with cholesteryl ester (ChoEs) being the most different compared to non-MASH. From significantly different lipids, ChoE 18:2, ChoE 22:6 and diglyceride (DG) 40:4 were highlighted by multivariate analysis. Histological parameters (NAS, steatosis, ballooning, lobular inflammation, and fibrosis) were analyzed together with the lipid classes, but they did not show a clearly specific behavior in any parameter. Contrarily, ChoE 18:2 and ChoE 22:6 showed a positive tendency as steatosis, lobular inflammation and ballooning increased, while DG 40:4 behaved contrarily.
Conclusion: MASH caused a specific lipid signature in the liver, causing increased ChoEs and diminished PCs. ChoE 18:2, ChoE 22:6 and DG 40:4 were highlighted by the multivariate analysis. Lipid classes were not associated with any histological parameter, although ChoE 18:2 and 22:6 correlated positively with steatosis, inflammation, and ballooning, while DG 40:4 correlated negatively with these same parameters.

Liver sinusoidal endothelial cells induce senescence in activated hepatic stellate cells via extracellular vesicles

Junyu Wang[1], Jia Li[1], Manon Buist-Homan[1], Martin Harmsen[1], Han Moshage[1]. *[1]University Medical Center Groningen, University of Groningen, Groningen, Netherlands*
Email: j.wang03@umcg.nl

Background and aims: Liver sinusoidal endothelial cells (LSECs) are considered as key gatekeepers in maintaining hepatic stellate cells (HSCs) homeostasis. The intricate intercellular crosstalk between HSCs and LSECs plays a fundamental role in modulating HSC quiescence and activation. Previous studies have identified LSEC-derived extracellular vesicles (EVs) as primary mediators in this regulatory process. However, the mechanisms through which LSECs and their EVs modulate the activated phenotype of HSCs (aHSCs) remain unclear. This study aims to investigate the molecular mechanisms of LSECs-mediated modulation of HSC phenotype.
Method: Primary rat LSECs and HSCs were isolated from male Wistar rats. EVs were isolated from the conditioned medium (CM) through differential centrifugation and characterized by nanoparticle tracking analysis, transmission electron microscopy, and marker determination. EVs were added to target cells for 24–72 hours. A primary cell co-culture system was also established to dissect the intercellular signaling mechanisms. Gene expression was determined by qPCR and protein expression by Western blot and immunofluorescence and proliferation of cells by Xcelligence and BrdU assay.
Results: LSEC-derived EVs induced increased expression of inflammation and senescence markers in aHSCs, including IL-1 and senescence-associated β-galactosidase activity and decreased aHSC proliferation. Furthermore, LSEC-derived EVs activated the TLR4/NF-κB and AKT signaling pathways in aHSCs. The observations with LSEC-derived EVs were replicated in the LSCE-aHSC transwell co-culture system.
Conclusion: LSECs induce aHSC senescence by secreting EVs, which depends on the activation of the TLR4/NF-κB and AKT pathways. Our results show the importance of LSECs in determining the HSC phenotype.

Email: lina.jegodzinski@uksh.de

Background and aims: Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) is characterized by heterogeneous clinical traits. The presence of metabolic disturbances, predominantly obesity, plays an important pathophysiological role. Herein, regional predominance of fat accumulation in different adipose tissues are characterized by distinct phenotypic and molecular properties tightly associated with MASLD severity. Importantly, the underlying mechanisms and differential impact of signals from visceral and subcutaneous adipose tissue in this process, as well as the molecular hallmarks, remain to be fully elucidated.
Method: Serum metabolomic and tissue transcriptomic profiles of liver tissue, subcutaneous (SC) and visceral (VF) adipose tissue from patients undergoing bariatric surgery as well as controls were obtained (n = 40) and subdivided according to histological presence of steatotic liver diseases. All tissue samples were subjected to RNA sequencing and corresponding serum samples were analyzed by NMR spectroscopy.

Results: Significant differences in gene expression were observed between all four groups (control, healthy obese, simple steatosis and steatohepatitis (MASH)) and reflected in all analyzed tissues (liver, subcutaneous and visceral adipose tissue), respectively. Interestingly, overlap in gene expression profiles in steatotic liver tissue and MASH showed higher concordance than livers from healthy obese patients. In contrast expression profiles of both VF and SC were highly distinct between all three groups. Interestingly, phenotypic differences across the groups were associated with a significant increase in serum VLDL and IDL particles from healthy obese to MASH patients.
Conclusion: Differences in transcriptomic and metabolomic profiles of heavily obese patients with healthy liver, steatotic liver or steatohepatitis can be recapitulated in expression profiles of adipose tissues from VF and SC, confirming an important role in the development and progression of MASLD. Surprisingly, profiles of adipose tissue display a clear separation of the three groups, suggesting a pathophysiological role in MASLD progression which could be of diagnostic value in the future. Further work is needed to elucidate the exact mechanisms and the relationship to the observed differences in serum lipoprotein metabolism.

Background and aims: The roaring global prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD) in tandem with the lack of approved therapeutic modalities addressing this ailment raises an alarming unmet health need. Failure of the gut barrier integrity is a critical pathological event driving the progression of MASLD towards its more aggressive form, metabolic dysfunction-associated steatohepatitis (MASH). Prior research alludes to an intricate interplay between AMPK/SIRT1 signaling and autophagy in preserving intestinal homeostasis against a plethora of pathological settings. We and others have reported the gut-protective effects of calcitriol (CAL) and its cognate intracellular vitamin D receptor (VDR). However, whether and if CAL-mediated activation of VDR could potentially modulate the crosstalk between AMPK/SIRT1 signaling axis and autophagy alleviating barrier dysfunction triggered by metabolic insults in MASH remains to be explored.
Method: In this study, we utilized a diet-induced MASH model in male C57BL/6 mice randomly allocated into four experimental groups: (I) a normal standard chow diet group, (II) a group fed with a high-fat diet (HFD), (III) a group treated with CAL at 5 ng/gm/day i.p. twice a week, and (IV) a group that received both CAL and hydroxychloroquine (HQ; an autophagy inhibitor), at a dosage of 60 mg/kg/day, p.o. Interventions were initiated after 12 weeks of MASH induction and mice were sacrificed at the end of week 16. VDR and p62 genes expression were assessed using qRT-PCR. Ileal IL-10, AMPK, and SIRT1 were estimated using ELISA.
Results: HandE-stained liver sections of HFD-fed mice showed hepatocyte ballooning and inflammatory cell infiltration, effects that were ameliorated in HFD+CAL mice. HandE-stained ileal sections displayed mucosal atrophy and distorted villous-crypt ratios. Meanwhile, ileal sections from CAL-treated mice showed amelioration of intestinal inflammation that was abolished upon HQ treatment. Expression of VDR was reduced in HFD-fed mice ileums that paralleled augmented expression of p62, the latter suggesting impaired autophagy. In contrast, VDR ileal levels surged upon treatment with CAL while significantly lowering p62. Additionally, levels of the anti-inflammatory cytokine IL-10 significantly decreased in HFD-fed mice alongside an 84% and 64% decline in AMPK and SIRT1 ileal levels, respectively. Treatment with CAL, however, led to a significant 6-fold surge in IL-10 levels and augmented the expression of both ileal AMPK and SIRT1 compared to the HFD group which was negated upon treatment with the autophagy inhibitor HQ.
Conclusion: The present study findings suggest the capacity of CAL to improve barrier function and curb intestinal inflammation in MASH partly through augmenting AMPK/SIRT1 signaling in an autophagy dependent manner.

THU-256
Without effect on weight loss, semaglutide does not improve MASLD in a dietary mice model for MASLD

Katharina Luise Hupa-Breier[1], Janine Dywicki[1], Björn Hartleben[2], Michael P. Manns[3], Heiner Wedemeyer[1], Fatih Noyan[1], Matthias Hardtke-Wolenski[1], Elmar Jaeckel[4]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology, Infectious Disease and Endocrinology, Hannover, Germany; [2]Hannover Medical School, Institute of Pathology, Hannover, Germany; [3]Hannover Medical School, Department of Gastroenterology, Hepatology, Infectious Disease and Endocrinology, Hannover, Germany; [4]University of Toronto, Toronto, Canada*
Email: hupa.katharina@mh-hannover.de

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is currently one of the most common causes of chronic liver disease with the metabolic syndrome with the central pathogenic factor. As weight loss is a central treatment aspect, GLP1-agonists- as recently established anti-obesity treatments- are also promising treatments of MASLD. The aim of this study was to investigate the effect of GLP1-agonist semaglutide in a new dietary mice model for MASLD with a polygenetic background for the metabolic syndrome and obesity.
Method: TALLYHO/JngJ (TH) mice received 16 weeks of high-fat/high-carbohydrate (HF-HC) diet with a surplus of cholesterol. After 12 weeks of HF-HC, mice were treated with semaglutide.
Results: After 16 weeks of HF-HC treatment, TH mice developed obesity, hyperglycemia and histological proven MASLD (median NAS = 5). Treatment with semaglutide led to a significant improvement of hyperglycemia and dyslipidemia. However, it has interestingly no effect neither on body weight nor on body fat composition in this mice model, which is known to develop obesity by increased food intakedue to changes in the central hypothalamus. Furthermore, no significant clinical or histological improvement of MASLD were detectable. Significant reduction of CD36, Srebf1, TNF and Col1a1 reveals mild anti-inflammatory, anti-fibrotic and anti-lipogenic effects on gene level. Nevertheless, intrahepatic CD4+ (p = 0, 018) and Tregs (p = 0, 047) as well as pro-inflammatory macrophages (p = 0, 023) were significantly reduced after semaglutide treatment.
Conclusion: By testing semaglutide in a new polygenetic mouse model of obesity and MASLD, we could demonstrate that semaglutide reduces intrahepatic cellular inflammation. Nevertheless, semaglutide has no significant clinical effects on MASLD, if significant weight loss could not be achieved. Therefore, this data supports the central role of significant weight loss in the therapeutic strategy of MASLD.

Email: crisplaced@hotmail.com

Background and aims: Obesity is a complex disease whose prevalence has been observed to be growing exponentially in recent years. Obesity is associated with other diseases such as type 2 diabetes mellitus, respiratory diseases, and cardiovascular diseases, including Metabolic Dysfunction-Associated Steatohepatitis (MASH), which is a severe form of liver disease that poses a global health threat due to its potential to progress to advanced fibrosis, leading to cirrhosis and liver cancer. These diseases are related to adipose tissue, which is primarily responsible for storing triglycerides in adipocytes. Depending on morphology and location, different types of adipose tissue are found, including subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT).
Method: The study has been conducted with samples from morbidly obese patients who have undergone bariatric surgery. Firstly, a lipidomic study of visceral and subcutaneous adipose tissues was conducted in patients with Metabolic Dysfunction-Associated Steatohepatitis (MASH) (n = 49) and without MASH (n = 51). Subsequently, a proteomic study of visceral and subcutaneous adipose tissues was conducted in patients with MASH (n = 49) and without MASH (n = 51). For both studies, both univariate and multivariate statistical analyses were performed.
Results: In visceral adipose tissue, a higher presence of proteins related to the extracellular matrix has been observed, indicating potential changes in the tissue microenvironment. On the other hand, lipidomics reveals a decrease in the quantity of phospholipids, which could have implications for the integrity of cell membranes and intracellular signaling. It is interesting to note that, despite the observed changes in VAT, no significant alterations have been recorded in SAT. This suggests heterogeneity in metabolic responses between tissues, which could have important implications in terms of MASH treatment and management. In an additional analysis, DNA methylation was performed, revealing no significant changes in either VAT or SAT, although the sample size was small.
Conclusion: All those findings highlight the need to address metabolomics to gain a more comprehensive understanding of metabolic changes in MASH. Currently, metabolomics is underway, and it is expected to provide valuable information about the underlying biochemical processes. The DNA methylation finding suggests epigenetic stability amidst the observed metabolic alterations, raising intriguing questions about the interplay between genetics and the environment in the pathogenesis of MASH.

THU-258-YI
Altered liver vascular biology occurring in early stages of metabolic dysfunction-associated steatotic liver disease is significantly improved by the pan-peroxisome proliferator-activated receptor agonist lanifibranor, associating with improved liver histology

Shivani Chotkoe[1,2], Guillaume Wettstein[3], Luisa Vonghia[1,2], Denise van der Graaff[2], Joris De Man[1], Benedicte De Winter[1,2], Pierre Broqua[3], Jean-Louis Junien[3], Wilhelmus Kwanten[1,2], Sven Francque[1,2]. *[1]University of Antwerp, Laboratory of Experimental Medicine and Paediatrics, Wilrijk, Belgium; [2]University Hospital Antwerp, Gastroenterology and Hepatology, Edegem, Belgium; [3]Inventiva Pharma, Daix, France*
Email: shivani.chotkoe@uantwerpen.be

Background and aims: The pan-peroxisome proliferator-activated receptor agonist lanifibranor normalized the intrahepatic vascular resistance (IHVR), the related endothelial dysfunction and liver histology in a methionine-choline-deficient diet rat model of early metabolic dysfunction-associated steatotic liver disease (MASLD) (EASL 2023; S776). We studied the effects of lanifibranor in the Zucker fatty rat (ZFR) to exclude model specificity, to test a model considered a more clinically relevant representation of MASLD and to examine the effects at the stage of steatohepatitis rather than isolated steatosis.
Method: Male ZFR (8 weeks old, n = 6–8/group) were fed a high-fat high-fructose diet (HFHFD) and compared to Zucker lean rats (ZLR, 8 weeks old, n = 6–8/group) fed a control diet for 8 weeks. ZFR and ZLR were treated orally with either lanifibranor (100 mg/kg/d) or placebo preventively during the complete 8 weeks of HFHFD. *In vivo* liver and systemic haemodynamics were measured, followed by *in situ ex vivo* liver perfusion in the same animal to assess baseline transhepatic pressure gradient (THPG) at different perfusion flows (10–50 ml/min). Dose-response curves were generated with vasoconstrictor methoxamine (Mx) and vasodilator acetylcholine (ACh) after Mx pre-constriction. Haematoxylin-eosin and Sirius red staining were performed on liver tissue for histology.
Results: In vehicle-treated groups, the livers of ZFRs showed prominent ballooning, mild steatosis and some lobular inflammation compatible with a diagnosis of metabolic dysfunction-associated steatohepatitis. Fibrosis was absent. In ZFRs the mean arterial blood pressure (MABP) was significantly elevated (159.1 ± 2.49 vs. 132.8 ± 2.7 mmHg, $p < 0.0001$), portal pressure *in vivo* (7.07 ± 0.24 vs. 4.86 ± 0.29 mmHg, $p < 0.0001$) was significantly higher as well as THPG *ex vivo* with $p < 0.001$. The ZFRs were not hyperreactive to Mx, but there was hyporeactivity to ACh in comparison with ZLRs. In ZLR, lanifibranor induced no changes in *in vivo* and *ex vivo* haemodynamics. In ZFRs, however, it normalized the MABP (from 159.1 ± 2.49 to 132.6 ± 3.03 mmHg, $p < 0.0001$), strongly decreased the portal pressure *in vivo* (from 7.07 ± 0.24 to 5.2 ± 0.23 mmHg, $p < 0.001$) and normalized THPG *ex vivo* at all flows ($p < 0.001$). Lanifibranor further decreased reactivity to Mx and normalized hyporeactivity to ACh in ZFRs. This was associated with a decrease in ballooning and steatosis on histology.
Conclusion: This study, performed in a dietary model more reflective of human MASLD, confirms that lanifibranor significantly improves portal pressure and associated functional intrahepatic vascular changes, alongside histological improvement. These findings support the role of intrahepatic vascular alterations in the development of MASLD-related portal hypertension, the progression to MASH, and the potential of lanifibranor as an efficacious treatment for MASH.

THU-259
Non-invasive staging of liver disease in C57BL/6NTac mice preconditioned on the modified-Amylin NASH diet using automated shear wave elastography

Laura Griffin[1], Steven Yeung[2], Sridhar Radhakrishnan[2], Christopher Moore[3], Juan Rojas[3], Brian Velasco[4], Paul Dayton[4], Tomek Czernuszewicz[3]. *[1]Taconic Biosciences, Rensselaer, United States; [2]Research Diets, Inc, New Brunswick, United States; [3]Revvity, Inc, Durham, United States; [4]University of North Carolina Chapel Hill, Chapel Hill, United States*
Email: laura.griffin@taconic.com

Background and aims: C57BL/6 mice on a modified Amylin NASH (GAN) diet demonstrates SLD and more closely recapitulate human MASLD compared to other preclinical models. While translatable, this model is characterized by variation which can be addressed through liver biopsies to assess disease stage. However, biopsies are invasive and labor intensive. While non-invasive techniques like liver elastography for humans exist, there is a need for translatable, non-invasive, and high-throughput alternatives for preclinical models. The study goal was to determine whether a non-invasive, automated shear wave elastography (SWE) imaging instrument could accurately determine the progression of SLD in GAN-diet fed C57BL/6NTac (NASH B6) mice.

Method: Commercially available (NASH B6 mice conditioned for 12, 23, 31, or 34 weeks on diet (D09100310, Research Diets, *n* = 8/group) and age-matched C57BL/6NTac controls (*n* = 4/group) were shipped by Taconic Biosciences to the University of North Carolina Chapel Hill (UNC) and acclimated for 3 weeks. Liver stiffness, volume, and echogenicity was assessed in each animal via 3D B-mode and SWE imaging (Vega, Revvity, Inc.). Livers were manually segmented from 3D image datasets and median stiffness and echogenicity were quantified by mouse. A separate cohort of NASH B6 mice (*n* = 8; 12 weeks on diet) and age-matched C57BL6/NTac mice were shipped to UNC and acclimated for 1 week. Liver stiffness was assessed longitudinally every 3 weeks up to 24 weeks on diet. Non-invasive ultrasound measurements from all cohorts were compared to histological data to assess correlation with fibrosis scores.
Results: Liver volume (1.4 ± 0.2 cm^3 vs. 1.9 ± 0.4 cm^3, p = 0.028) and liver echogenicity (27.2 ± 6.7 a.u vs. 62.4 ± 21.6 a.u., p = 0.048) were significantly increased in NASH B6 mice, suggesting hepatomegaly and the presence of moderate to advanced steatosis. Liver stiffness was not statistically different between groups (4.0 ± 0.5 kPa vs. 3.9 ± 0.5 kPa, p = 0.570), suggesting no onset of MASH and/or fibrosis after 12 weeks on diet in the longitudinal cohort. These results are in close agreement with histopathological data which demonstrated substantial liver weight increase at 12 weeks, but no fibrosis onset until 26 weeks or later. Additionally, imaging detected two mice that could be classified as "slow responders" to GAN feeding due to low echogenicity, indicating a lack of steatosis (26 a.u. and 31 a.u., respectively). Further longitudinal and cross-sectional imaging will determine if these mice are indeed outliers or if phenotype will normalize across the cohort.
Conclusion: Our data present the potential of ultrasound to assess SLD progression in a clinically translatable preclinical model in a non-invasive and high-throughput manner. This allows for an improved study design targeting specific SLD stages and reduced model variability in the pursuit of SLD drug discovery.

Serum thrombospondin-2 and insulin -like growth factor binding protein 7 predict liver fibrosis and fibrosis regression in patients with MASLD post bariatric surgery

Rambabu Surabattula[1], Pierre Bel Lassen[2,3], Sudha Rani Myneni[1], Aron-Wisnewsky Judith[2,3], Laurent Genser[3], Jean-Daniel Zucker[4], Karine Clément[2,3], Detlef Schuppan[1,5]. *[1]Institute of Translational Immunology, University Medical Center Mainz, Mainz, Germany; [2]INSERM, Nutrition and Obesities: Systemic Approaches Research Group (NutriOmics), Sorbonne Université, Paris, France; [3]APHP, Nutrition and surgery departments, Pitié-Salpêtrière hospital, Paris, France; [4]UMMISCO, Unité de Modélisation Mathématique et Informatique des Systèmes Complexes, IRD, Sorbonne Université, Bondy, France; [5]Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA, United States*
Email: rasuraba@uni-mainz.de

Background and aims: The prevalence of MASLD in patients eligible for bariatric surgery (BS) can reach 75%-100%. BS usually leads to significant weight loss and often to metabolic normalization. This is accompanied by liver histological improvement in some but not all patients. We established and assessed novel serum markers of fibrogenesis in follow-up of a well-defined cohort of patients with obesity and MASLD undergoing bariatric surgery.
Method: We established sandwich ELISAs measuring the matricellular fibrosis marker thrombospondin-2 (TSP2) and the metabolism/fibrosis-related marker insulin-like growth factor binding protein-7 (IGFBP7) using combinations of recombinant proteins, commercial and self-produced monoclonal and polyclonal antibodies. Sensitivity and specificity were optimized, with intra- and Inter assay variations for serum or plasma below 10% and 15%, resp. 132 severely obese patients with matched liver biopsies were included. 74 patients showed fibrosis stage F0–1 and 54 patients intermediate to advanced fibrosis stage F2–4. Apart from baseline determinations, the evolution of the serum fibrosis markers post-bariatric surgery was analyzed from a subset of 51 subjects with follow-up at 3 and 12 months BS.
Results: Patients with F2–4 fibrosis displayed significantly higher baseline levels of the two markers vs patients with fibrosis F0–1 at baseline for TSP2 (88.6 vs 53.9) and IGFBP7 (208.8 vs 128 ng/ml). TSP2 and IGFBP7 were significantly higher in patients with severe fibrosis F3–4 (mean values 114.4 and 234.5 ng/ml, resp.) indicating more rapid fibrosis progression compared to fibrosis F0–2 (means 62 and 152.3 ng/ml, resp.). The AUROC values to distinguish fibrosis F2–4 or F3–4 from F0–1 or F0–2 were 0.74 and 0.84 for TSP2, and; 0.84 and 0.78 for IGFBP7. The AUROC value to distinguish fibrosis F2–4 from F0–1 was significantly increased for the combination of TSP2 and IGFBP7 (0.86), reaching the range of a perfect test in view of biopsy sampling error. Serum levels of both markers could further differentiate between the presence vs absence of type 2 diabetes. There was a significant correlation of 2 markers with liver enzymes and insulin resistance, while these parameters had a low predictive value. Levels of TSP2 decreased significantly 3 months and remained at a low level at 12 months after BS in patients with baseline F2–4 fibrosis, but not in patients with F0–1 fibrosis supporting its prominent role in liver fibrogenesis, while IGFBP7 was related to fibrogenic inflammation.
Conclusion: The matricellular serum markers TSP2 and IGFBP7 reflect liver fibrogenesis and fibrogenesis combined with metabolic inflammation in a unique cohort of patients undergoing BS. TSP2 alone showed the currently highest predictive value for fibrosis F2–4 and the combination of both markers uniquely predicted response to BS.

THU-261

Artificial intelligence models deployed at scale on hematoxylin and eosin-stained whole slide images reveal stage-dependent collagen composition in metabolic dysfunction-associated steatohepatitis

Ylaine Gerardin[1], Neel Patel[1], Lara Murray[1], Adam Stanford-Moore[1], Jacqueline Brosnan-Cashman[1], Jun Xu[2], Lisa Boyette[2], Benjamin Glass[1], Timothy R. Watkins[2], Andrew N. Billin[2], Robert Egger[1]. *[1]PathAI, Inc., Boston, United States; [2]Gilead Sciences, Foster City, United States*
Email: ylaine.gerardin@pathai.com

Background and aims: Diagnosis and staging of metabolic dysfunction-associated steatohepatitis (MASH; formerly NASH) requires manual pathologist identification of fibrotic structures on collagen-stained slides. The qualitative assessment of these structures makes MASH staging prone to inter-rater variability. Granular, quantitative histopathologic assessment could inform the understanding of fibrosis progression and regression in MASH. We developed AI models to detect and quantify fibrotic features from scanned hematoxylin and eosin-stained (HandE) whole slide images (WSI) at scale and used the results to characterize fibrosis composition in MASH biopsies.
Method: NASH Explore models were deployed on HandE-stained liver biopsies from the STELLAR-3 and STELLAR-4 trials of selonsertib, which enrolled MASH patients with bridging fibrosis or compensated cirrhosis, respectively. Quality filtering was performed to remove WSI with low amounts of analyzable liver tissue (final n = 3198). Quantitative features were extracted from each WSI, describing the proportionate areas of 5 pathological fibrosis types (periportal, perisinusoidal, incomplete septal, complete septal, and nodular) and 4 non-pathological collagen types (structural, portal, and non-specific collagen; perivenular fibrosis). These HandE-based features were compared to pathologist-assessed CRN fibrosis stages and sub-ordinal fibrosis scores derived from previously reported AIM-NASH algorithm deployed on paired trichrome-stained slides.

Results: AI-based fibrosis quantification revealed increased total collagen, pathological fibrosis, and advanced fibrosis with CRN fibrosis stage. Collagen at lower stages was mainly composed of structural collagen and non-pathogenic fibrosis types, incomplete septal fibrosis peaked at intermediate stages (F2–F3), and the F4 stage was dominated by nodular fibrosis. Dimensionality reduction revealed nodular fibrosis driving the first component of greatest variation across the samples, separating out F4 at the highest extreme and F3 samples at intermediate values. Manually-staged F0, F1, and F2 subpopulations were highly overlapping in the first two principal components, which accounted for 67% of total sample variation.
Conclusion: Characterization of pathological fibrosis and non-pathological collagen features via AI digital pathology yields an understanding of MASH fibrosis progression beyond the resolution provided by CRN scoring. The presence of expected associations, such as nodular fibrosis in F4, provides biological support for empirically-validated AI fibrosis staging. Quantifying fibrosis directly from scanned HandE images with NASH Explore requires no custom microscopy and is scalable for applications in drug development, enhancing understanding of therapeutic mechanisms for anti-fibrotic drugs, and potentially use in clinical care.

THU-262

Targeting macrophage BTK, a potential therapeutic strategy for metabolic dysfunction-associated steatohepatitis

Shiwei Chen[1], Cheng Zhou[2], Yanbo Wang[2], Guohua Lou[2], Min Zheng[2]. [1]*The First A!liated Hospital, College of Medicine, Zhejiang University, Hang Zhou, China;* [2]*The First A!liated Hospital, College of Medicine, Zhejiang University, Hang Zhou, China*
Email: minzheng@zju.edu.cn

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a severe inflammatory liver disease without available pharmacological treatment currently. Bruton's tyrosine kinase (BTK) is a crucial mediator in immune response which plays an important role in various inflammatory diseases. However, the effect of BTK on MASH still remains unknown. This study aimed to investigate the role and mechanism of BTK in methionine and choline deficient (MCD) diet-induced mice MASH.
Method: In our study, mice MASH was induced by MCD diet feeding. The BTK phosphorylation and expression levels were detected in the livers of MASH mice. BTK inhibitor, BTK knockout and myeloid-conditional BTK knockout were applied to explore the effect of BTK in mouse MASH. Further, the molecular mechanism of BTK in MASH was investigated with gain or loss of function approaches in vitro and vivo experiments. Flow cytometry, western blot, ELISA, immunohistochemistry, qPCR, RNA-seq were used in our research.
Results: Our study found that BTK was markedly activated and upregulated in MASH mice fed by MCD diet. Both BTK inhibitor and BTK knockout were able to alleviate mice MASH, and BTK from macrophages and granulocytes were proved to play the key role through BTK phosphorylation detection in multiple immune cell subtypes. Moreover, our results indicated that BTK knockout in myeloid cells could also attenuated mice MASH progression. In terms of mechanism, we found that BTK inhibitor could downregulate phosphatidylinositol-3-kinase (PI3 K)/Akt/forkhead Box Protein O1 (FoxO1) signaling pathway, further suppressed macrophage polarization towards the M1 phenotype, as well as reduced macrophage infiltration in the liver.
Conclusion: Our results proved that BTK inhibition could protect against MASH progression, partially by suppressing PI3 K/Akt/FoxO1 signaling pathway in macrophages. Therefore, macrophage BTK might be a potential therapeutic target for the treatment of MASH.

Significance of adipose tissue fibrosis and adipocyte in the progression of metabolic dysfunction-associated steatohepatitis in severe obesity patients

Andrea Jiménez-Franco[1], Marina Ramirez-Baños[2], Cristina Placed-Gallego[1], Juan Manuel Jiménez-Aguilar[1], Cristian Martínez-Navidad[3], Helena Castañé[4], Alina-Iuliana Onoiu[1], Vicente Cambra-Cortes[1], Jordi Camps[5], Jorge Joven[6]. [1]*Universitat Rovira i Virgili, Unitat de Recerca Biomèdica, Reus, Spain;* [2]*Universitat Rovira i Virgili, Universitat Rovira i Virgili, Reus, Spain;* [3]*Fundació IISPV, Unitat de Recerca Biomèdica, Reus, Spain;* [4]*Institut d'Investigació Sanitària Pere Virgili, Unitat de Recerca Biomèdica, Reus, Spain;* [5]*Hospital Universitari Sant Joan, Unitat de Recerca Biomèdia, Reus, Spain;* [6]*Hospital Universitari Sant Joan de Reus, Unitat de Recerca Biomèdica, Reus, Spain*
Email: andreajfranco99@gmail.com

Background and aims: Obesity stands as the primary risk factor for the development of metabolic dysfunction-associated steatotic liver disease (MASLD), with an increasing prevalence of both conditions. Adipose tissue dysfunction is considered a critical factor in the development of obesity-related comorbidities, closely tied to tissue morphology. When the capacity to store lipids in adipose tissue is surpassed, it can lead to hypertrophy, hyperplasia, hypoxia, apoptosis, and inflammation. This cascade may result in ectopic lipid deposition, altered adipokine secretion, and the progression of MASLD into metabolic dysfunction-associated steatohepatitis (MASH). However, not all severely obese patients develop MASH, emphasizing the need to study adipose tissue morphology and function for a comprehensive understanding of MASLD development.
Method: A total of 163 patients with severe obesity undergoing bariatric surgery provided liver, subcutaneous adipose tissue (SAT), and visceral adipose tissue (VAT) biopsies, along with blood samples. Of these, 71 were diagnosed with MASH, and 92 were non-MASH. Plasma concentrations of adiponectin, leptin, and FGF21 were assessed using enzyme-linked immunosorbent assay. Histological analysis of SAT and VAT included FAT score evaluation and adipocyte area measurement using ImageJ. Preliminary Western blot analysis of TIMP-4 and MMP-12 expression in VAT and SAT was conducted.
Results: Fatty tissue fibrosis and SAT adipocyte area did not differ between MASH and non-MASH patients. Both groups exhibited larger SAT adipocyte areas compared to VAT adipocyte areas. MASH patients displayed a greater VAT adipocyte area, unrelated to VAT fibrosis, while the opposite was observed in non-MASH patients. Lower adiponectin and higher FGF21 concentrations were found in MASH patients. Adipose tissue histological features were associated with blood concentrations of adiponectin and leptin.
Conclusion: Differences in VAT, but not SAT, histology were observed between MASH and non-MASH patients with severe obesity. Varied blood concentrations of adipokines were noted between these groups, with associations identified between adipokine concentrations and adipose tissue histological features. Our findings suggest a potential influence of adipose tissue on the liver's health status in MASH and non-MASH patients.

THU-266

S100A11 is a pro-inflammatory lipotoxic damage associated molecular pattern in metabolic dysfunction-associated steatohepatitis

Gopanandan Parthasarathy[1], Amy Mauer[1], Harmeet Malhi[1]. [1]*Mayo Clinic, Rochester, United States*
Email: malhi.harmeet@mayo.edu

Background and aims: The endogenous damage associated molecular pattern S100A11 is upregulated on lipotoxic hepatocytes in vitro and is enriched on extracellular vesicles (EVs) in metabolic dysfunction associated steatohepatitis (MASH). Its cognate receptor-receptor for advanced glycation endproducts (RAGE) is upregulated on proinflammatory macrophages in MASH and RAGE

inhibition is associated with amelioration of MASH in a diet induced mouse model. We hypothesized that hepatocyte derived S100A11 enriched EVs promote proinflammatory signalling in macrophages via RAGE activation. To test this hypothesis, we performed in silico and in vitro analyses to confirm hepatocyte specific upregulation of *S100A11* and its secretion in EVs in murine and human MASH.
Method: In vitro, EVs released from human and mouse hepatocyte cell lines were analysed for upregulation of S100A11 by unbiased proteomics and confirmed by western blotting and immunogold electron microscopy. To corroborate this, we analysed publicly available whole liver bulk RNA sequencing and single cell RNA sequencing datasets to confirm hepatocyte upregulation of *S100A11* in MASH. Interaction between S100A11 and RAGE was assessed by immunofluorescence microscopy and western blotting.
Results: S100A11 was enriched on lipotoxic EVs from human Huh7, mouse AML-12 and primary mouse hepatocytes. S100A11 lacks a transmembrane domain and was found to be bound to annexin A2 by co-immunoprecipitation, and furthermore, both annexin A2 and S100A11 were enriched on lipotoxic hepatocyte-derived EVs. In scRNA sequencing of whole mouse livers, *S100a11* and *Anxa2* were respectively 11.5-and 9.9 fold upregulated in MASH compared to chow mice. Specifically on hepatocytes, expression of *S100a11* and *Anxa2* were increased by 36- and 95 fold after 34 weeks of a high fat-high fructose diet. In humans, expression of *S100A11* and *ANXA2* were significantly increased in bulk RNA sequencing of whole livers from patients with NASH compared to healthy controls. We confirmed in vitro that S100A11 enriched EVs led to RAGE oligomerization and activation of bone marrow derived macrophages and macrophage cell lines.
Conclusion: We have demonstrated that hepatocyte derived S100A11 is a lipotoxic DAMP and along with Annexin A2 is significantly upregulated and enriched on lipotoxic EVs. These S100A11 enriched EVs activate RAGE signalling suggesting that in vivo hepatocyte derived EVs could mediate an intercellular signalling axis via RAGE activation on recruited macrophages.

Email: sgato-ibis@us.es

Background and aims: Extracellular vesicles (EVs) released under activation and apoptosis conditions contain genetic and protein material from the originating cell. They act as vectors for intercellular communication, contributing to the initiation, pathogenesis, and progression of numerous liver diseases. Both platelets and platelet-derived EVs interact with liver cells, contributing to hepatic damage.
Objectives: (i) To determine the use of platelet-derived EVs as biomarkers for the severity of MASLD, (ii) to determine the differential miRNA profile contained in platelet-derived EVs in patients with different severity degrees.
Method: A total of 97 biopsy-proven MASLD patients were recruited. They were classified into steatosis (n = 23) or steatohepatitis (n = 70) based on the SAF score. EVs quantification was performed by flow cytometry (LRS Fortessa) using Annexin V-PE and CD41-FITC antibodies. Isolation of EVs was carried out on the Facs Aria Fusion cell sorter (Becton Dickinson) in plasma from 8 patients with steatohepatitis and 4 patients with steatosis. Total RNA enriched in miRNAs was extracted using the miRNeasy Mini Kit (Qiagen), and the differential expression profile of microRNAs was determined by microarray (GeneChip miRNA 4.0 Assay Affymetrix, ThermoFisher CA, USA).
Results: CD41+ EVs levels were significantly elevated in patients with steatohepatitis compared to those with steatosis (1511 ± 268 vs. 28882 ± 542.5; p = 0.04). The results of the differential analysis showed that 9 microRNAs were upregulated in platelet-derived EVs from patients with steatohepatitis (fold change >2, p value <0.05): miR-16, miR-4486, miR-5035p, miR-6727, miR-4498, miR-4708, miR-7855, and miR-6790; and one downregulated: miR-6085.
Conclusion: Platelet-derived EVs are elevated in patients with steatohepatitis, suggesting they could be use as biomarkers for the severity of the pathology. Furthermore, these preliminary data indicate a differential miRNA profile within platelet-derived EVs. However, further studies are needed to elucidate their potential contribution to hepatic damage.

Effects of semaglutide, Peptide YY3-36 and empagliflozin on metabolic dysfunctions-associated fatty steatotic liver disease in diet-induced obese rats with chronic nitric oxide synthase-inhibition

Niklas Geiger[1], Simon Kloock[1], Jana Gerner[2], Aisha-Nike Landthaler[2], Alexander Georg Nickel[2], Michael Kohlhaas[2], Andreas Geier[3], Martin Fassnacht[1], Ulrich Dischinger[1,2]. *[1]University Hospital Wuerzburg, Department of Internal Medicine, Division of Endocrinology and Diabetes, Wuerzburg, Germany; [2]University Hospital Wuerzburg, Comprehensive Heart Failure Center, Wuerzburg, Germany; [3]University Hospital Wuerzburg, Hepatology, Wuerzburg, Germany*
Email: Geiger_N1@ukw.de

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a common comorbidity of obesity. In this study, we sought to determine hepatic metabolic and mitochondrial effects of the Glucagon-like Peptide-1-agonist semaglutide, the sodium-glucose linked transporter 2-inhibitor empagliflozin and Peptide YY_{3-36} in diet-induced obese rats with additional chronic inhibition of nitric oxide synthase via N^{ω}-nitro-L-arginine methyl ester (L-NAME), to induce accelerated liver injury.
Method: Following an eight-week feeding period with a high-fat/ fructose-diet (HFD) and L-NAME, male wistar rats were randomized into the following treatment groups: semaglutide, empagliflozin, PYY_{3-36}, semaglutide in combination with empagliflozin or PYY_{3-36}, a food restricted body weight matched group (BWM) and saline control. After an additional 8 weeks, qRT-PCR was performed to quantify hepatic mRNA expression of metabolic and inflammatory marker genes. Serum was analysed for insulin, glucose, adiponectin and leptin levels. Moreover, in isolated mitochondria, mitochondrial respiration in different states using Oroboros O2K-FluoRespirometer was examined.
Results: In the liver, the de-novo lipogenesis regulating genes MLXIPL and SREBF-1 were downregulated in the BWM, semaglutide and PYY_{3-36} -mono groups and significantly lower in the semaglutide +PYY_{3-36} group ($p < 0.05$) compared to saline treated controls. HOMA-index was significantly lower in PYY-mono treated animals ($p < 0.05$) and in the semaglutide+empagliflozin- group ($p < 0.05$), adiponectin-leptin-ratio was significantly higher in semaglutide +PYY_{3-36} ($p < 0.01$) and BWM treated animals in comparison to saline ($p < 0.01$). Moreover, there was a significant downregulation of IL-1b mRNA in the semaglutide-mono treated group ($p < 0.05$). In the semaglutide+empagliflozin treated group, TNF-alpha-levels were lower compared to saline. Regarding mitochondrial respiration, fatty acid-dependent state 3 respiration, empagliflozin ($p < 0.001$)

as well as semaglutide+empagliflozin ($p < 0.05$) decreased O_2-consumption significantly in comparison to controls. In the uncoupled state, empagliflozin and PYY_{3-36} mono-treatment decreased the O_2-rate significantly ($p < 0.05$) compared to saline control. Moreover, semaglutide in combination with PYY_{3-36} or empagliflozin lowered O_2-consumption.
Conclusion: In summary, the presented data indicate a strong improvement of insulin sensitivity shown by presented metabolic parameters and associated genes. O_2-consumption of the respiratory chain in mitochondria is decreased in semaglutide, PYY_{3-36}, and empagliflozin treated rats, supposing reduced metabolic stress in these groups. The strongest effect was detected in semaglutide+PYY_{3-36} treated animals, which points towards PYY_{3-36} as a promising additive substance in the treatment of MASLD.

THU-271-YI
Brain inflammation and cognitive impairment is not mitigated by a low-fat dietary intervention in ageing mice with MASLD
Matthew Siddle[1,2], Deepika Goel[2], Christos Konstantinou[1,2], Rajiv Jalan[3], Nathan Davies[3], Lindsey Edwards[4,5], Debbie L. Shawcross[1], Anna Hadjihambi[1,2]. *[1]King's College London, London, United Kingdom; [2]The Roger Williams Institute of Hepatology, London, United Kingdom; [3]University College London, London, United Kingdom; [4]Institute of Liver Studies, King's College London, Department of Inflammation Biology, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, London, United Kingdom; [5]Centre for Host Microbiome Interactions, King's College London, Faculty of Dentistry, Oral and Craniofacial Sciences, London, United Kingdom*
Email: matthew.siddle@kcl.ac.uk

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is linked to cognitive decline, brain hypoxia and inflammation, accelerated ageing, and neurodegeneration. Here, we assessed a low-fat diet (LFD) as a potential neuroprotective intervention in ageing mice.
Method: 6-week-old male C57BL/6NTac mice were fed either a control diet (CD) or a high-fat high-cholesterol diet (HFHC) for 26 weeks to induce MASLD. Half the mice in each group were then placed on the LFD and aged to 18-months. Steatosis was confirmed by histology. All mice were subjected to a battery of behavioural tests. Cortical partial pressure of oxygen (PO2) and tissue saturation (SO2) at baseline and in response to systemic hypercapnia (10% CO2) were monitored under anaesthesia by optical fluorescence and optoacoustic tomography, respectively. CD31 staining was used to assess cortical vasculature. Brain inflammation was evaluated in the cortex and hippocampus using microglial immunofluorescence (Iba-1), with 3D reconstruction and morphological assessment.
Results: Both HFHC and HFHC-LFD mice exhibited anxiety-like behaviour; whilst only aged CD-LFD and HFHC-LFD mice exhibited memory impairment. HFHC, HFHC-LFD, and CD-LFD mice exhibited lower baseline PO2 and SO2 but preserved cerebrovascular reactivity. No changes were observed in cortical vascular morphology. HFHC and HFHC-LFD mice showed increased cortical microglia density, coverage, and volume, indicating reactive microglia. Only HFHC-LFD mice exhibited microglial alterations in the hippocampus.
Conclusion: LFD was not sufficient to counteract MASLD progression and its associated brain alterations in ageing mice. Both reduced brain oxygenation and increased inflammation may be contributing to the increased risk of neurodegeneration.

MASH-associated endothelial dysfunction in mice: is there no effect?
Justine Lallement[1], Sebastian Bott[2], Hrag Esfahani[3], Dessy Chantal[4], Isabelle Leclercq[5]. *[1]Institute of Experimental and Clinical Research (Laboratory for Hepato-gastroenterology and Pole of Pharmacology and Therapeutics), Université Catholique de Louvain, Brussels, Belgium; [2]Institute of Experimental and Clinical Research (Laboratory of Hepato-Gastroenterology and Pole of Pharmacoly and Therapeutics), Université Catholique de Louvain, Brussels, Belgium; [3]Institute of Experimental and Clinical Research (Integrated physiology platform), Université Catholique de Louvain, Brussels, Belgium; [4]Institute of Experimental and Clinical Research (Pole of Pharmacology and Therapeutics), Université Catholique de Louvain, Brussels, Belgium; [5]Institute of Experimental and Clinical Research (Laboratory of Hepato-Gastroenterology), Université Catholique de Louvain, Brussels, Belgium*
Email: justine.lallement@uclouvain.be

Background and Aims: Metabolic dysfunction-associated steatohepatitis (MASH) confers a superimposed risk to develop cardiovascular disease (CVD). Although numerous clinical studies have demonstrated a robust association between MASH and CVD, independent of cardiometabolic risk factors, the pathogenic mechanisms supporting a liver-to-CVD axis remain unknown. Endothelial dysfunction is characterized by an imbalanced endothelium-production of protective (among which nitric oxide (NO) is the most prominent) vs deleterious factors that promote a pro-constrictive phenotype. It is the earliest feature of atherosclerosis and hypertension contributing to the development of major CV events. This study aims to characterize the vascular system with a special focus on endothelial function in a murine model of MASH disease.
Method: Male *Foz* mice fed with high fat diet (HFD) for 24 weeks were used as a model of MASH. HFD-fed littermates are used as dysmetabolic controls (no MASH). Blood pressure was monitored over 24 h using telemetry and the presence of aortic atherosclerotic plaques was investigated through red oil staining. Endothelial function was evaluated in the first-order mesenteric arteries by wire myograph measurements. Blood nitrosylated hemoglobin (HbNO) was quantified by electron paramagnetic resonance. Asymmetric dimethylarginine (ADMA), an endogenous inhibitor of NO production, was measured using ELISA. Western blot analysis and qPCR were conducted to investigate the NO pathway.
Results: Despite the absence of atherosclerotic plaques and hypertension, HFD-fed Foz mice (FH) exhibit endothelium-dependent impaired relaxation compared to the dysmetabolic controls. We demonstrated reduced NO-dependent vasodilatation in response to carbachol in FH compared to controls. Consistent with these findings, our results indicate reduced expression and activation of endothelial NO synthase (eNOS), as measured by Ser^{1177} phosphorylation level, in the aorta of FH. This is associated with higher plasma ADMA. However, there is no difference in blood HbNO level between the two groups. The hepatic expression of inducible NO synthase (iNOS), induced by inflammation as seen in MASH liver, is significantly increased in FH (fold change 15).
Conclusion : Our results demonstrate that mice with MASH but not the dysmetabolic controls present endothelial dysfunction characterized by impaired NO-dependent vasodilation. This dysfunction may be attributed to lower expression and activation of eNOS and elevated plasma ADMA level. Our data further suggest that the inflamed liver could contribute to the disruption of NO balance by the upregulation of iNOS expression, thereby disturbing systemic NO production. These findings underscore the importance of unraveling the liver-vessel-heart crosstalk to better understand the pathophysiological substratum for MASH-driven increase in CV risk.

THU-273
Distinct gut microbiome and intestinal permeability biomarker in patients with lean MASLD without type 2 diabetes
Natthaya Chuaypen[1], Thananya Jinato[1], Pisit Tangkijvanich[1]. *[1]Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*
Email: pisittkvn@yahoo.com

Background and aims: An altered gut microbiome has been linked to the development of metabolic dysfunction-associated liver disease (MASLD). However, data regarding gut dysbiosis and the mechanistic

insight in Asian patients with lean MASLD (BMI<23 kg/m^2), particularly among non-diabetic individuals, are not well defined.
Method: This study included 16 Thai healthy individuals and 100 patients with MASLD without type 2 diabetes (8 lean and 92 non-lean patients). Hepatic steatosis was identified by transient elastography (controlled attenuation parameter >248 dB/m). The 16S rRNA sequencing in fecal samples and bioinformatics analysis were performed for gut microbiome composition. The differential abundance of bacterial composition between groups was analyzed by the DESeq2 method. Plasma intestinal fatty acid-binding protein (I-FABP) and lipopolysaccharide-binding protein (LBP) were analyzed to determine intestinal permeability and bacterial translocation, respectively.
Results: The alpha and beta diversities of the gut microbiome were significantly different between patients with MASLD and healthy subjects. However, the diversities did not differ between the lean and non-lean MASLD (p = 0.077 for Shannon index, and PERMANOVA = 0.217 for beta-diversity). Compared to non-lean individuals, patients with lean MASLD revealed significant enrichment of pro-inflammatory bacteria including *Escherichia-Shigella*. Moreover, significant reduction of short-chain fatty acids (SCFAs)-producing bacteria such as *Lachnospira* and *Subdoligranulum* were observed in the lean patients. Combined analysis of these bacterial genera based on a logistic regression model was able to differentiate between lean and non-lean MASLD with a high diagnostic performance (AUC of 0.82). There was a marginally significant increase in I-FABP levels in lean patients when compared to the non-lean individuals [median (95% CI); 544.2 (152.8–1, 330) versus. 261.8 (269.2–377.1) pg/ml, *P* = 0.054). However, there was no difference in LBP levels between these subgroups of patients [10, 972 (6, 535–16, 525) versus. 12, 437 (11, 429–13, 721) ng/ml, *P* = 0.541].
Conclusion: Non-diabetic patients with lean MASLD exhibited distinct bacterial composition and a trend toward higher circulating intestinal permeability levels than their non-lean counterparts. These findings suggest the role of gut dysbiosis, particularly the decrease of SCFAs-producing bacteria, and increased intestinal barrier disruption that might contribute to the pathogenesis and disease severity of lean MASLD.

THU-274

Targeting mitochondrial complex I modulates lipid metabolism, inflammation and hepatic fibrosis in a MCD-diet model of benign steatosis

Francesca Protopapa[1], Laura Giuseppina Di Pasqua[1], Michelangelo Trucchi[1], Erica Scotti[1], Peng Sun[2], Stefan Günther Kauschke[3], Mariapia Vairetti[1], Anna Cleta Croce[4], Andrea Ferrigno[1]. *[1]Department of Internal Medicine and Therapeutics, University of Pavia, Pavia, Italy; [2]Boehringer Ingelheim Pharma GmbH and Co. KG, Biberach an der Riss, Germany; [3]Boehringer Ingelheim Pharma GmbH and Co. KG, Biberach an der Riss, Germany; [4]Institute of molecular genetics, Italian National Research Council (CNR), Pavia, Italy*
Email: francesca.protopapa@unipv.it

Background and aims: MASLD affects 25% of the global population, rising up to 75% in obese or diabetic people. The transition from simple steatosis to MASH is driven by oxidative stress and mitochondrial dysfunction. ROS promote pro-inflammatory cytokine release and chronic inflammatory response, along with HSC activation and hepatic fibrosis development. Mitochondrial complex I is the main ROS producer in MASLD progression, so this study aims to investigate whether the selective inhibition of complex I could contribute to reducing lipid accumulation, regulating specific lipid-related pathways, and mitigating hepatic fibrosis.
Method: male Wistar rats fed a Methionine and Choline deficient (MCD) diet or a Control diet for 6 weeks were orally administered (3 weeks) with complex I modulator (CIM, Boehringer Ingelheim) 10 mg/Kg/day or vehicle, starting from the 4th week. Lipid peroxidation and ROS production were evaluated using TBARS and DCHF-DA methods. Nitrate/Nitrite concentration was established. Total lipid content was measured using Nile Red dye. The area of lipid droplets and the rate of inflammatory cell infiltration were calculated on HandE stained liver sections. Changes in the expression of factors involved in lipid metabolism (PPAR-α, SREBP1c and mTOR) were analyzed by Western Blot. Collagen deposition was calculated on Sirius Red stained liver sections.
Results: TBARS increased in MCD rats versus Control rats, without changes after CIM administration. ROS increased in MCD groups, but a significant reduction in CIM-treated Controls was detected, compared with untreated ones. Nitrate/Nitrite were reduced in CIM-treated MCD rats compared with untreated ones. Hepatic total lipid content was significantly decreased in CIM-treated MCD rats compared with untreated ones. A significant decrease in lipid droplet areas was observed in CIM-treated MCD rats, compared with untreated ones. Inflammatory cell infiltration was reduced in MCD rats treated with CIM, together with a significant reduction in collagen deposition in Control rats treated with CIM and in CIM-treated MCD rats, compared with untreated groups. Nuclear expression of PPAR-α significantly increased in MCD rats treated with CIM, compared with untreated ones. Nuclear SREBP1c expression was reduced in CIM-treated control and MCD rats, although not significantly. The same trend, significant for Controls, was observed for the ratio P-mTOR/mTOR. Lastly, AST and ALT were decreased in CIM-treated Controls, compared to untreated ones.
Conclusion: this study demonstrates for the first time that administration of complex I modulator could be a feasible strategy to counteract lipid accumulation, inflammation and collagen deposition in a MCD model of steatosis. Although further investigations are needed, these data suggest a promising role of CIM in the modulation of lipid metabolism in a model of benign steatosis.

THU-275

Interleukin 10 reduces fat accumulation and promotes fatty acid degradation and intracellular glucose maintenance in a high-fat-diet mouse model of metabolic dysfunction-associated steatotic liver disease

Akira Kado[1,2], Kazuya Okushin[1], Takeya Tsutsumi[1], Kazuhiko Ikeuchi[1], Kyoji Moriya[3], Hiroshi Yotsuyanagi[4], Kazuhiko Koike[1,5], Mitsuhiro Fujishiro[1]. *[1]The University of Tokyo, Tokyo, Japan; [2]Health Service Promotion, The University of Tokyo, Tokyo, Japan; [3]Tokyo Health Care University, Tokyo, Japan; [4]Medical Science, The University of Tokyo, Tokyo, Japan; [5]Kanto Central Hospital, Tokyo, Japan*
Email: monteruterubest@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) has been increasing globally, and causes fatty acid and glucose metabolism dysregulation; several MASLD cases are difficult to treat. Interleukin (IL) 10 is immunologically an anti-inflammatory cytokine, whereas it was previously shown to affect intracellular homeostasis, especially autophagy; its cytoprotective effect may be also expected. IL10 is more expressed in peripheral immune cells and liver tissues of patients with advanced MASLD than with relatively mild MASLD. Although the detailed effects of IL10 have not been elucidated, its cytoprotective effect may improve MASLD progression. In this study, we used a high-fat diet (HFD) mice to assess changes in hepatic fat accumulation, and fatty acid and glucose metabolism induced by IL10; these changes were also assessed in vitro.
Method: Six-week-old male C57BL/6J mice were fed with either normal diet (ND) or HFD for 6 weeks. Mice fed with both the ND and HFD were treated with or without IL10 (50 μg/kg) once every two days for a week before sacrifice. Body weight (BW), liver weight (LW)/BW ratio, blood biochemistry, and liver histology were evaluated. Changes in fatty acid and glucose metabolism were also evaluated in mRNA and protein levels using real-time PCR and western blotting. Furthermore, these changes were evaluated in vitro in normal human

hepatocytes using palmitic acid (PA) and various concentrations of IL10.
Results: In the HFD group, LW/BW ratio and serum ALT level were significantly decreased in the IL10-treatment group. Histological analysis revealed that IL10 treatment led to a significant reduction of hepatic steatosis and lobular inflammation; no histological findings of ballooning and fibrosis were observed. The IL10-treatment group showed a significant decrease in fatty acid synthase (FAS) and a significant increase in fatty acid degrading enzyme [carnitine palmitoyltransferase (CPT) 1/2] and glucose metabolism-related enzymes [glucose transporter (GLUT) 2, glycogen synthase (GS), phosphoenolpyruvate carboxykinase (PCK) 1)] compared to the non-treatment. In the ND group, few significant changes were observed between these two groups. Focused on the IL10 non-treatment groups, the HFD mice showed a significant increase in FAS, CPT 1/2, GLUT2, and GS, and a significant decrease in PCK1 compared to the ND. These results suggested that fatty acid synthesis upregulated by HFD was reduced by IL10, and fatty acid degradation and intracellular glucose maintenance were promoted. Furthermore, in the presence of PA, similar results were observed in normal hepatocytes by IL10 treatment in vitro.
Conclusion: These results indicate that IL10 can reduce hepatic fat accumulation and promote intracellular glucose uptake and energy maintenance; IL10 offers the potential as a novel therapy for MASLD.

Digital pathology with artificial intelligence analysis provides insight to the efficacy of anti-fibrotic compounds in human 3D MASH model

Radina Kostadinova[1], Simon Ströbel[1], Li Chen[2], Katia Fiaschetti-Egli[1], Jana Gadient[1], Agnieszka Pawlowska Pawlowska[1], Louis Petitjean[2], Manuela Bieri[1], Eva Thoma[1], Mathieu Petitjean[2,3]. [1]*InSphero AG, Schlieren, Switzerland;* [2]*PharmaNest, Princeton, United States;* [3]*PharmaNest, Inc, Princeton, United States*
Email: radina.kostadinova@insphero.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a severe liver disease characterized by lipid accumulation, inflammation and fibrosis. The development of MASH therapies has been hindered by the lack of human translational models and limitations of analysis techniques for fibrosis. Here we aimed to establish an algorithm for automated phenotypic quantification of fibrosis of Sirius Red stained histology sections of MASH hLiMTs model using a digital pathology quantitative single-fiber artificial Intelligence FibroNest image analysis platform.
Method: The MASH hLiMT model consists of primary human hepatocytes, Kupffer cells, liver endothelial cells and hepatic stellate cells. Upon exposure to defined lipotoxic and inflammatory stimuli such as free fatty acids and LPS in media containing high levels of sugar and insulin the 3D MASH model displayed key disease pathophysiological features within 10 days of treatment. Quantifiable markers were established for drug efficacy testing such as secretion of pro-collagen type I/III and TIMPs/MMPs as well as quantification of fibrosis using FibroNest platform based on the Sirius Red staining of histology slides. Next generation sequencing was used for the assessment of the gene expression changes.
Results: The FibroNest algorithm for MASH hLiMTs was validated using anti-fibrotic reference compounds with different therapeutic modalities-ALK5i and anti-TGF-beta antibody. The phenotypic quantification of fibrosis demonstrated that both reference compounds decreased the deposition of fibrillated collagen in alignment with effects on the secretion of pro-collagen type I/III, tissue inhibitor of metalloproteinases-1 and matrix metalloproteinase-3 and pro-fibrotic gene expression. In contrast, clinical compounds, Firsocostat and Selonsertib, alone and in combination showed strong anti-fibrotic effects on the deposition of collagen fibers, however less pronounced on the secretion of pro-fibrotic biomarkers.
Conclusion: In summary, the phenotypic quantification of fibrosis of MASH hLiMTs combined with secretion of pro-fibrotic biomarkers and transcriptomics represents a promising drug discovery tool for assessing anti-fibrotic compounds.

THU-279
Time-restricted feeding alleviates metabolic associated fatty liver disease via PPAR-related lipid metabolism signaling pathway

Jiang Deng[1], Yikai Wang[1], Xiongtao Liu[1], Xiaoli Jia[2], Shuangsuo Dang[1], Juanjuan Shi[1]. [1]*the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China;* [2]*the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*
Email: juanjuan_shi@xjtu.edu.cn

Background and aims: Specific drugs for treating metabolic associated fatty liver disease (MAFLD) are lacking. In this study, we analyzed the efficacy and mechanism of time-restricted feeding (TRF) and caloric restriction (CR) to provide a theoretical basis for the treatment and prevention of MAFLD.
Method: Fifty Sprague-Dawley (SD) rats were randomly divided into the normal group (10 kcal% fat, n = 12) and the MAFLD group (60 kcal % fat, n = 38) for 10 weeks. The MAFLD group was randomly divided into the TRF group (4 h TRF = feeding at 18:00–22:00), the caloric intake (CR) group (60% CR = the food intake per unit body weight of normal control rats was multiplied by 60%), the TRF+CR group (feeding at 18:00–22:00 and 60% CR) and the model group (free eating), which were fed normal diet (10 kcal% fat) for 14 weeks. Body weight, daily food intake, liver lipid content and biochemical indices were measured, differentially abundant metabolites were screened using liquid chromatography tandem mass spectrometry (LC–MS/MS), and the related molecular mechanism was analyzed using Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis and RT-PCR.
Results: After the high-fat diet was discontinued, the lipid content of the liver of MAFLD rats was significantly reduced, but the weight was not significantly changed. The body weight in the model group were heavier than those in the other four groups ($p < 0.01$). Triglyceride (TG) levels were higher in the TRF+CR group than in the model group ($p < 0.01$); however, there were no significant differences among the other groups. The average daily food intake of the individuals in the normal group, the TRF group, the CR group, the TRF+CR group and the model group were significant differences compared with those in the normal group ($p < 0.001$), and 4 h TRF restricted approximately 29% of the daily food intake. KEGG pathway enrichment indicated that the mechanism of liver lipid clearance involved the PPAR signaling pathway, AMPK signaling pathway, metabolic pathway, etc. Importantly, we observed differences in SIRT1 mRNA levels among the five groups ($p = 0.003$). Compared with those in the normal group, the SIRT1 mRNA levels in the other four groups were significantly increased only in the CR group and the model group ($p < 0.05$). The mRNA expression levels of PPARα and SIRT1 in the TRF +CR group were lower than those in the TRF, CR and model groups.
Conclusion: We observed that 4 h TRF, 60% CR and 4 h TRF+60% CR significantly reduced body weight and liver lipid content in MAFLD rats, 4 h TRF+60% CR significantly increased serum TG levels, and 4 h TRF improved MAFLD without restricting food intake. These findings may be related to PPAR-related lipid metabolism signaling pathway.

DC-SIGN+ macrophages alleviates non-alcoholic steatohepatitis by modulating inflammatory cytokine secretion

Jinxia Liu[1], Haifeng Wu[2], Xiaojun Zhang[2], Qin Jin[2], Huoyan Ji[2], Lishuai Qu[2], Rajiv Jalan[3], Chunhua Wan[4]. [1]*Affiliated Hospital of Nantong University, Nantong, China;* [2]*Affiliated Hospital of Nantong University, Nantong, China;* [3]*UCL Institute for Liver and Digestive Health, London, United Kingdom;* [4]*Nantong University, Nantong, China*
Email: chwan@ntu.edu.cn

Background and aims: The modulation of immune responses by innate immune receptors plays a crucial role in the progression of

non-alcoholic steatohepatitis (NASH). In this study, we aim to comprehensively investigate the involvement and mechanisms by which the C-type lectin receptor DC-SIGN modulates macrophage inflammatory responses and NASH progression.
Method: Histological analyses were utilized to investigate DC-SIGN expression profile in patients with NASH and healthy subjects. Additionally, immunofluorescence was employed to examine specific cell types expressing DC-SIGN. Adeno-associated viruses (AAV) carrying human DC-SIGN or control viruses were administered via tail vein injection to mice fed with either a high-fat and high-cholesterol (HFHC) diet or a normal chow diet (NCD). Moreover, THP1-differentiated macrophages were employed as an in vitro macrophage model to investigate the molecular mechanism by which DC-SIGN participates in inflammatory regulation.
Results: The expression of DC-SIGN was decreased in the liver tissues from NASH patients and HFHC-fed mice, as well as macrophages stimulated with LPS or PA. Remarkably, the transduction of human DC-SIGN into the livers of HFHC-fed mice notably ameliorated liver lipotoxicity, hepatic steatosis, inflammation, and fibrosis. Additionally, DC-SIGN facilitates macrophage TLR4 endocytosis via direct TLR4 binding, leading to the attenuation of pro-inflammatory environments during NASH progression.
Conclusion: Overall, our findings highlight an active crosstalk between DC-SIGN and TLR4 within hepatic macrophages, demonstrating a protective effect of DC-SIGN in NASH progression. Collectively, this study highlights a promising potential of manipulating macrophage DC-SIGN expression as a novel therapeutic strategy for NASH.

THU-281
Gut dysbiosis is associated with the severity of liver fibrosis assessed by magnetic resonance elastography in patients with MAFLD

Thananya Jinato[1], Nantawat Satthawiwat[1], Natthaya Chuaypen[1], Pisit Tangkijvanich[1]. [1]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*
Email: pisittkvn@yahoo.com

Background and aims: The gut microbiome might affect the severity of metabolic dysfunction-associated steatotic liver disease (MASLD), however, data regarding their association in Asian populations are limited. We analyzed the differences in gut microbial composition in Thai patients with MASLD according to the severity of liver fibrosis assessed by magnetic resonance (MR) imaging.
Method: This cross-sectional study included 157 patients with MASLD (51% male, mean age 56 ± 10 years). Liver steatosis grades ≥1 were identified by MR-proton density fat fraction (PDFF) ≥5.2%. Based on MR-elastography (MRE) at the cut-off of 2.97 kPa, there were 131 and 26 patients with mild fibrosis (F01) and significant fibrosis (F234), respectively. Fecal specimens were sequenced targeting the V4 region of the 16S rRNA gene and analyzed using the nf-core ampliseq bioinformatics pipeline. Differential analysis of individual taxa between two groups was conducted through linear discriminant analysis effect size (LEFSe), employing a cut-off of LDA Effect Size >2 and a significance level of $p < 0.05$.
Results: There was no significant difference in alpha-diversities (Chao1, Shannon, and Simpson indices) between patients with F01 and F234. However, the beta diversity significantly differed between the two groups ($p = 0.012$). A high abundance of *Fusobacterium*, a pathogenic bacteria contributing to the inflammatory process and carcinogenesis, was significantly detected in fecal samples of patients with F234 compared with the F01 group (OR = 3.31, 1.30–8.42, $p = 0.012$). Additionally, enriched *Fusobacterium* significantly correlated with MRE (kPa) ($r = 0.235$, $p = 0.003$). In contrast, the abundance of *Lachnospira,* a short-chain fatty acid-producing bacterium, was significantly lower in patients with F234 compared with the F01 group (OR = 0.38, 0.15–0.93, $p = 0.033$). The enrichment of *Lachnospira* was also negatively correlated with MRE ($r = -0.206$, $p = 0.010$).
Conclusion: In an analysis of the gut microbiome of Thai patients with MASLD, we found that gut dysbiosis was correlated with the severity of liver disease. Specifically, the greater abundance of bacterial genera involving inflammatory processes and lower enrichment of beneficial bacteria was significantly associated with fibrosis severity in patients with MASLD. Thus, an altered gut microbiome might contribute to the pathogenesis of MASLD and could be used as biomarkers of disease severity.

THU-282
Evaluation of performance of a cellular profiling technique for quantification of inflammation and steatosis in liver biopsies of patients with MASH

Adi Lightstone[1,1], Li Chen[1], Dmitri Fedorov[2], Mathieu Petitjean[1]. [1]*PharmaNest, Princeton, United States;* [2]*ViQi, Santa Barbra, United States*
Email: adi.lightstone@pharmanest.com

Background and aims: The gold standard for assessment of liver inflammation and steatosis is through pathologist analysis of MASH biopsies. Using a new AI cellular detection, classification, and quantification method trained on pathologist annotations of individual cells and validating the results on pathologist classification of the overall tissue we can generate a quantitative continuous score based on single cell analysis. This is an asset to RandD, diagnosis, as well as addressing limitations of current histological nomenclatures and methods (doi:10.1002/hep.32475).
Method: This retrospective study included 87 NASH liver biopsies diagnosed by a pathologist for histologic assessment resulting in lobular inflammation grades of 0 (N = 7), 1 (68), and 2 (12), and steatosis grades of 0 (N = 2), 1 (40), 2 (30) and 3 (14). Quantitative image analysis of these biopsies stained with HandE detects cell nuclei (~20 k per biopsy) and quantify their morphometric and local surroundings in 86 parameters. A subset of 18 images (~260 K nuclei) was used to develop a machine learning (ML) model using 34.8 K annotations (respectively 7.3 K, 12 K, 7.8 K, 5.4 K, 2.3 K) for steatotic hepatocytes, normal hepatocytes, inflammatory cells (all kinds), liver specialized cells (all kinds), and "debris" (degraded cellular bits). Once the cells were classified, the density (count/mm^2) and relative cell count (%) for each cell type were calculated. Macro-steatosis Area Ratio was calculated through vacuole detection as a secondary method (the first being comparison of the cell detection to pathologist definition). Clusters of inflammatory cells were segmented into "small," "medium," and "Large" foci.
Results: The cell classification accuracy (error) of the ML model ranged from 65.2% (28%) for specialized cells to 91.1% (11.7%) for inflammatory cells. The steatotic hepatocytes count ratio (detected from ML from pathologists' annotations) correlates well with Steatosis Area Ratio ($R^2 = 0.5989$). The Inflammatory cell ratio (percent of cells that are inflammatory) corresponds well with the Inflammation grades ($p\ 0v1 = 0.12$, $p\ 0v2 = 0.015$), count of small inflammation foci clusters ($p\ 0v1 = 0.053$, $p\ 0v2 = 0.015$) moderately corresponds to the histological grades, which is attributed to the histological definition of inflammatory clusters and their assessment.
Conclusion: Quantitative digital pathology can automatically generate tissues panels from HandE stained biopsies. While the scores extracted from these tissue panels correspond to NASH-CRN histological stages, they present the benefit of being quantitative and translational, and not sensitive to liver tissue variation due to swelling, fat invasion, or other various artifacts. The marked improvement from previous work by PharmaNest also demonstrates that the field is improving, and more work can be done to further advance AI digital pathology methods.

Email: isabel.fuster-martinez@uv.es

Background and aims: Pan-cyclophilin inhibitors have been proposed as a strategy for the treatment of metabolic dysfunction-associated steatotic liver disease (MASLD). Although some members of this enzyme family are described to participate in MASLD pathogenesis, little is known about peptidylprolyl isomerase C (PPIC), whose expression was found to be increased in the liver of patients with chronic liver disease (CLD). Our aim was to characterise its role in this pathology.
Method: Gene expression of *PPIC* was analysed in different experimental models of liver injury*: in vivo*, in a meta-analysis from published transcriptomic studies of liver samples of murine models of high fat diet (HFD), with and without anti-steatotic treatments, and in murine models of CCl_4 and Bile Duct Ligation (BDL); and *in vitro*, in fatty acid (FA)-overloaded human hepatoma cells (Hep3B) and TGFβ1-stimulated human hepatic stellate cells (HSCs) (LX-2 cell line). Plasmatic PPIC levels in MASLD patients and healthy controls were measured by ELISA. Furthermore, we examined the effect of silencing *PPIC* in Hep3B and LX-2 cells, analysing cell viability (MTT and phosphatase activity assays), RNA and protein expression (qPCR and Western blotting, respectively), and reactive oxygen species (ROS) levels (CM-H_2DCFDA assay).
Results: Hepatic expression of *Ppic* was significantly increased in all the mouse models of liver injury studied (HFD, CCl_4 and BDL) and reversed by the anti-steatotic treatments investigated in the meta-analysis. It was also upregulated in FA-overloaded Hep3B cells and TGFβ1-stimulated HSCs. In addition, plasma levels of PPIC were significantly increased in MASLD patients (n = 12) compared to healthy donors (n = 11). When *PPIC* was silenced in Hep3B cells, cell viability was not changed, but there was an induction of the IRE1α-XBP1 pathway (involved in the ER stress response) and a reduction in NF-κB phosphorylation and the expression of the chemokines *CXCL9* and *CXCL10*. In LX-2 cells, *PPIC* silencing did not alter cell viability, but showed a tendency to increase ROS levels. Moreover, it triggered pathways associated with the ER stress response (IRE1α-XBP1 and PERK/eIF2α) and promoted the pro-fibrotic state of these cells, since it increased mRNA and protein levels of collagens and α-SMA. It also downregulated the gene expression of the NLRP3-inflammasome components in these cells.
Conclusion: PPIC may be a marker of CLD since it was elevated in the liver of several experimental models and in the plasma of patients with MASLD. However, its role in CLD may be pleiotropic, as silencing of PPIC downregulated some pro-inflammatory mediators in a hepatoma cell line and induced a cellular stress response together with a pro-fibrotic effect in a HSCs cell line.

THU-284

Prediction of MASH features from liver biopsy images using a pre-trained self-supervised learning model

Yang Wang[1], Saurabh Vyawahare[1], Carson McNeil[1], Jessica Loo[1], Marc Robbins[1], Roman Goldenberg[1]. [1]*Verily Life Sciences, South San Francisco, United States*
Email: wayang@verily.com

Background and aims: Using neural networks to identify medically relevant features from histology slide images has greatly increased recently. However, as adoption of the technique becomes available for more diseases, the demand for and expense of training data rises as well. Digital pathology images are gigapixel (s) in size, and a single slide can contain many features. These features are both very time consuming for human annotations due to size alone, and need trained experts, making annotations extremely expensive. To address this problem, self-supervised pathology foundation models trained on existing corpuses of unlabeled training data, such as The Cancer Genome Atlas (TCGA) can be used. These foundation models can serve as a module in the network architecture, reducing the labeled data requirement.
Method: We take an SSL model based on vision transformers (*arXiv preprint arXiv:2310.13259* 2023), which is trained on hematoxylin and eosin (HandE) slides. The SSL model takes as input a 224 × 224 × 3 image patch and outputs an embedding vector. We apply this model to predict features relevant to metabolic dysfunction-associated steatohepatitis (MASH), including inflammation, steatosis, and ballooning. The MASH-labeled data is from the CENTAUR study (*Hepatology, 72* (3), pp.892–905) which we previously analyzed (in *Modern Pathology* 37.2 (2024): 100377) using fully supervised models. Note that the original SSL model was not trained on the images from this dataset. To apply the SSL model, we perform a two-stage process. First, we use the SSL model as a component in an architecture trained on the smaller set of labeled images to produce a patch classification. Second, the patch classifications are aggregated over a slide to make a slide-level prediction.
Results: While use of the SSL model produced patch-level results similar to previous work on this dataset (*Modern Pathology 37.2* (2024): 100377), superior results were obtained for grading of ballooning and lobular inflammation slide level scores. Our model had an AUC improved from 0.77 to 0.88 for ballooning, and 0.76 to 0.85 for lobular inflammation. Steatosis performance remained high and consistent. We believe this reflects better generalizability of the model, and increased resilience to messy patch-level labels. We also show that the amount of data needed to segment features of MASH on liver biopsy images is reduced, and in addition, training is made simpler and faster.
Conclusion: Self-supervised foundation models can improve machine learning performance in digital pathology, including for liver diseases. These models can lead to better downstream generalization, and allow training using smaller labeled datasets.

Low nonpsychedelic dosed of psilocybin for the therapy of MASLD

Martina Colognesi[1], Daniela Gabbia[1], Andrea Rinaldi[2], Luciano Cascione[2], Ilaria Zanotto[1], Stefano Comai[3], Katia Sayaf[4], Andrea Mattarei[1], Marco Banzato[1], Gianfranco Pasut[3], Franco Folli[5], Lucia Centofanti[5], Sergio Traversa[6], Marco Pappagallo[6], Paolo Manfredi[6], Sara De Martin[1]. [1]*Department of Pharmaceutical and Pharmacological Sciences, University of Padova, Padova, Italy;* [2]*Genomic Facility, IOR Institute of Oncology Research, Università della Svizzera Italiana, Bellinzona, Switzerland;* [3]*Department of Pharmaceutical and Pharmacological Sciences, University of Padova, Padova;* [4]*Department of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy;* [5]*Department of Health Science, Università degli Studi di Milano, Milano, Italy;* [6]*Relmada Therapeutics Inc., Miami, United States*
Email: sara.demartin@unipd.it

Background and aims: Psilocybin, an alkaloid of *Psilocybe* mushrooms known for its psychedelic activity after its dephosphorylation to the active compound psilocin, is an agonist of the serotonin receptor 2A isoform (5-HT2AR) and has been shown to reduce weight gain in animal models, although the relevance and mechanism of this effect is controversial. No data are available on the effect of psilocybin in MASLD, which is often associated to obesity. The aim of this study is to assess the activity, toxicity, and mechanism of psilocybin in mice with MASLD induced by a diet rich of fat and fructose (HFHFD).
Method: The effect of psilocybin was tested on 20 C57BL/6 male mice fed with HFHFD for 17 weeks. The treatment group (n = 10) received daily 0.05 mg/Kg*bw psilocybin orally, while the control group (n = 10) received vehicle. Standard diet-fed mice (n = 10) were used as healthy controls. Body weight and food intake were assessed twice weekly. The oral glucose tolerance test (OGTT) and a selection of behavioral studies were performed before sacrifice. MASLD was histologically evaluated by HandE and ORO staining. Blood immunophenotyping was performed by FACS. Alterations in the global hepatic transcriptome were evaluated by RNA sequencing. The expression of proteins involved in insulin signaling was assessed by western blot and immunohistochemistry. Mechanistic studies were performed in HepG2 cells treated with palmitic and oleic acid (1:2, 0.1 mM).
Results: In MASLD mice, psilocybin did not cause central detrimental effects, but a reduction of anxiety-like behavior, $p < 0.05$. Body weight gain, hepatic fat deposition, fasting glucose and plasma triglycerides ($p < 0.05$) were significantly reduced by the treatment. Gene ontology analysis (GO-Biological Processes, GOBP) on mRNA-seq data revealed that psilocybin restored the basal hepatic expression of the gene sets involved in the localization and organization of lipid droplets, and the catabolic processes of lipids, which are dysregulated in MASLD mice. The improvement of insulin sensitivity observed in the OGTT ($p < 0.05$) was confirmed by the normalization of the hepatic insulin signaling, since the protein expression of insulin receptor and IRS-1 was increased vs untreated mice ($p < 0.05$). Immune function was also affected, since psilocybin reverted the increase of PD-1-expressing exhausted NK cells, which was present in MASLD mice ($p < 0.01$). The pivotal role of hepatic 5HT2AR in the metabolic effects of psilocin was confirmed since the pharmacological inhibition of ketanserin abrogated the psilocin-induced reduction of lipid accumulation in HepG2 cells.
Conclusion: Low, nonpsychedelic doses of psilocybin significantly ameliorate MASLD features in experimental models, by a 5-HT2A mediated pleiotropic action. Psilocybin may be considered as a candidate drug for MASLD and associated metabolic disorders.

THU-286
PNPLA3 p.I148M variant affects lipid droplets number and size in patient-derived liver organoids

Elia Casirati[1], Alessandro Cherubini[1], Laura Cerami[1], Fabrizia Carli[2], Amalia Gastaldelli[2], Daniele Prati[1], Daniele Dondossola[3], Luca Valenti[4]. *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; Transfusion Medicine and Hematology, Milano, Italy; [2]National Research Council (CNR), Institute of Clinical Physiology (IFC), Pisa, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Hbp Surgery and Liver Transplantation Unit, Milano, Italy; [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; Transfusion Medicine and Hematology, Università Degli Studi di Milano; Department of Pathophysiology and Transplantation, Milano, Italy*
Email: e.casirati@gmail.com

Background and aims: PNPLA3 rs738409 C > G p.I148M variant is the main genetic determinant of metabolic dysfunction-associated steatotic liver disease (MASLD). To this day, this association still lacks a molecular characterization, due to the lack of comprehensive human models. To overcome this gap in knowledge, we generated patient-derived human liver organoids (HLOs) and studied lipid accumulation across different PNPLA3 genotypes.
Method: We generated HLOs from 49 surgical specimens (14 I/I, 24 I/M and 11 M/M for PNPLA3 p.I148M). HLOs were differentiated toward a hepatocyte-like phenotype (Hep-HLO) and exposed to 300 µM Palmitic and Oleic fatty acids (FAs) for 72 h. Lipid droplets (LDs) average size and number (normalized for nuclei) were quantified by NileRed staining and compared between PNPLA3 Hep-HLOs (n = 3 for each genotype). Finally, lipidomics were conducted on 3 wild-type and 3 homozygous Hep-HLO lines, treated or not with 300 µM Palmitic and Oleic Acid for 3 days.
Results: As a propaedeutic step, we ascertained that Hep-HLO retain PNPLA3 expression before evaluating its genotype impact on LDs. Untreated organoids displayed LDs average sizes of $0.51 \pm 0.26\ \mu m^2$ (I/I), $0.51 \pm 0.23\ \mu m^2$ (I/M) and $1.31 \pm 1.41\ \mu m^2$ (M/M). While FAs did not impact on average LD size, M/M Hep-HLOs displayed larger LDs ($p = 0.002$ of I/I vs M/M, $p = 0.0002$ for I/M vs MM). Conversely, LDs number were 7.28 ± 5.16, 21.17 ± 12.40 and 53.14 ± 60.2 in I/I, I/M, M/M respectively, and increased to 18.61 ± 9.31, 47.68 ± 30.16 and 81.46 ± 54.59 upon exposure to FAs. After ANOVA testing, 23.9% of variability in LDs number can be attributed to genotype and 6.9% to FAs ($p < 0.0001$ for both). Lipidomic analyses highlighted an enrichment of sphyngomyelins, lysophosphatidylcholines and ceramides in PNPLA3 M/M Hep-HLO, which was exacerbated by FAs administration. These lipid species are associated with cellular damage, inflammation, Insulin resistance, oxidative stress and MASH development. The opposite trend was observed for phosphatidylcholines, which are essential for LDL loading and triacylglycerols export from the liver and whose levels drop during MASLD development.
Conclusion: Regardless of FA treatment, M/M Hep-HLOs show increased LDs size when compared to I/M and I/I. Conversely, LDs number showed direct correlation with the number of mutated alleles, suggesting that the p.I148M substitution promotes the formation of new LDs, which was exacerbated by exposure to FAs. Preliminary lipidomic analyses highlight an unbalance towards lipid species that are proinflammatory and pro-apoptotic in Hep-HLO homozygous for PNPLA3 rs738409. Overall, these data corroborate the robustness of Hep-HLO as a preclinical in vitro model for genetic predisposition for MASLD. We are now developing siRNAs specific for silencing PNPLA3 rs738409 transcripts to examine the impact on LD phenotypes.

THU-287
Dysregulation of ureagenesis and glutaminolysis in DIAMONDTM mice played a major role in MASLD progression

Hospital*

Universitario Virgen Del Rocío, Sevilla, Spain
Email: mromerogomez@us.es

Background and aims: The main aim of our study was to evaluate the implication of ammonia metabolism on MASLD progression in a DIAMOND™ preclinical model under different dietary interventions.
Method: DIAMOND mice (Sanyal Biotechnology, n = 28) were randomized to three dietary regimens with different lengths: high-fat diet supplemented with fructose/glucose in drinking water (HF-HFD), choline-deficient high-fat diet model supplemented with 0.1% methionine (CDA-HFD) or standard diet, which was used as a control. HF-HFD and control animals were sacrificed after 21 or 30 weeks of diet intake and CDA-HFD animals were sacrificed after 12 weeks. Oral glutamine challenge (OGC) was performed by gavage administrating glutamine (0.5 g/kg) in n = 14 animals, and ammonia levels were evaluated at 0, 30, 60, 90, 120, 180 and 240 minutes. AUROC was calculated in microg/dl/h. Liver damage characterization included markers for fibrosis (collagen deposition and COL3A1, COL1A1, and α-SMA expression levels) and inflammation (TNF-α and IL-6 expression). An anatomopathologist blinded to provenance of samples calculated liver fibrosis and NAS Score. UCEs and glutaminase-1 (GLS-1) expression levels were evaluated by qRT-PCR.
Results: Both dietary interventions promoted a general upregulation of fibrotic and inflammatory markers, especially marked in CDA-HFD animals when compared to controls: COL3A1 (17.6 fold [CI95% 12.8–22.4] *vs.* 1 fold [CI95% 0.67–1.3]; p = 0.001) and TNF-α (21.5 fold [CI95% 12.8–30.2] *vs.* 1 fold [CI95% 0.3–1.9]; p = 0.002. CDA-HFD animals showed higher NAS Score rates than both 30w controls (6.8 ± 0.4 *vs.* 0.33 ± 0.52; p < 0.001) and HF-HFD (6.2 ± 1.5; p = ns). Transcriptomic evaluation of UCEs revealed a significant mRNA downregulation in carbamoyl phosphate synthetase-1 (CPS1) and ornithine transcarbamylase (OTC1) in both CDA-HFD and HF-HFD animals *versus* controls, together with an increase in GLS1 expression in all groups of animals. Further, GLS1 was correlated with hepatic α-actin (r = 0.792; n = 28; p < 0.001) and TNF-α (r = 0.876; n = 28; p < 0.001). CDA-HFD animals showed increased ammonia levels when compared to controls (54.3 ± 19.23 mcg/dl/h) *vs.* controls (29.5 ± 2.2 mcg/dl/h; p < 0.05), and HF-HFD animals showed an increased trend that did not reach statistical significance (51.87 ± 29.95 mcg/dl/h; p = ns). OGC was found altered in 4/5 CDA-HFD and all HF-HFD mice; $\chi^2 = 10, 73$; p < 0.005. A positive correlation was found between ammonia and weight gain (r = 0.543; n = 14; p < 0.045). Multiple linear regression revealed that both GLS-1 and weight gain were independent predictors for liver fibrosis progression.
Conclusion: Ammonia metabolism was found impaired in both production and detoxification in DIAMOND mice. OGC dysregulation were correlated with weight gain and a higher expression of GLS-1. These alterations could play a key role in the development and progression of MASLD.

Email: juanmaaguilar106@gmail.com

Background and aims: Genome-wide Association Studies (GWAS) have revolutionized genetic exploration, providing crucial insights into complex disease mechanisms. This newfound genetic understanding holds immense promise for enhancing diagnostics and treatment strategies. This progress has proven especially invaluable in Metabolic-Associated Fatty Liver Disease (MAFLD). GWAS approaches have revealed a multitude of Single Nucleotide Polymorphisms (SNPs) associated with MAFLD. However, the escalating prevalence of MAFLD driven by obesity underlines a pressing healthcare challenge. MAFLD's progression to severe stages like Metabolic-Associated Steatohepatitis (MASH) and advanced liver diseases emphasizes the urgent need for non-invasive diagnostic tools, early detection methods, and treatment strategies. The objective of this study was to determine if genetic variants identified through GWAS can serve as predictive indicators of MAFLD development in patients with obesity types II and III.
Method: The Open Array platform was utilized to genotype 25 specific SNPs from plasma samples. The study cohort comprised 1719 individuals, meticulously divided into the control group (n = 415) and the severe obesity group (n = 1313). The latter encompassed three subgroups: MAFL (n = 137), MASH (n = 532), and individuals without MAFLD (n = 405). We subsequently conducted an extensive analysis to evaluate the correlation, significance, and strength of the identified SNPs across the various groups while assessing their predictive power for disease progression.
Results: Four significant SNPs (rs58542926, rs1800629, rs8107974, and rs5982) were discovered to be correlated with disease progression within the subset of severely obese patients. Among these, rs5982 (F13A1) exhibited dual significance in both MAFLD and obesity, with a stronger association observed for the disease. Notably, rs58542926 (TM6SF2) significantly affected steatosis scores, while rs1800629 (TNFA) correlated with inflammation scores. All identified SNPs presented weak associations and held little predictive power for disease progression.
Conclusion: The identified SNPs showed significant correlations with MAFLD progression in severely obese patients with obesity types II and III. However, these associations do not translate into robust predictive power for MAFLD progression assessment.

THU-291-YI
Cellular senescence is a common hallmark in diverse models of steatotic liver diseases

Charalampos Pavlidis[1], Mohsin Hassan[1], Marlene Kohlhepp[1], Juan Wang[1], Frank Tacke[1], Tobias Puengel[1], Pavitra Kumar[1], Cornelius Engelmann[1]. [1]*Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany*
Email: charalampos.pavlidis@charite.de

Background and aims: Senescence involves irreversible cell cycle arrest, triggering specific alterations while sustaining cellular viability. Cellular stress, injury, or disease conditions such as steatotic liver disease (SLD) are associated with an accumulation of senescent hepatocytes. This study seeks to elucidate the evolving role of cellular senescence in the progression of metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic alcohol-related liver disease (metALD), aiming to identify potential therapeutic targets for disease-modifying interventions.
Method: MASLD was induced in wild-type C57BL6/J mice using a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) and a Western Diet (WD). We analyzed the effects of dietary interventions at different time points: CDAHFD: 8 and 12 weeks; WD 4, 7 and 16 weeks. Experimental metALD was induced by a combination of WD and 10% ethanol in drinking water for 4 weeks, followed by an ethanol binge (6 g/kg), and then sacrificed after 24 hours. To dissect the role of senescence in our independent models, we employed Western blot (WB), multiplex immunofluorescence (mIF), and senescence-associated beta-galactosidase (SA-beta-gal) focusing on senescence-associated markers (p53, p21, Lamin B1, ph-RB, Ki67, gamma-H2A.X).
Results: CDAHFD models showed steatosis and inflammation but no fibrosis, while in WD less steatosis and mild inflammation with no fibrosis were observed. Senescence-associated markers p53 (p < 0.02), p21 (p < 0.02), and gamma-H2A.X were markedly elevated in

CDAHFD models at 8 weeks, intensifying at 12 weeks (p53: $p < 0.03$; p21: $p < 0.008$). Lamin B1 ($p < 0.001$), ph-RB ($p < 0.02$), and Ki67 exhibited reduced expression at 8 weeks for CDAHFD, further decreasing at 12 weeks (Lamin B1: $p < 0.02$; ph-RB: $p < 0.02$). WD models displayed similar senescence trends at 4, 7, and 16 weeks for p53, p21, gamma-H2A.X, Lamin B1, ph-RB, and Ki67, confirmed by mIF as well as by heightened SA-beta-gal levels. Histologically, metALD models showed moderate to high amounts of overall cell death (TUNEL), but mild fibrosis with accumulated adipocytes. In addition, metALD models showed heightened p21 ($p < 0.03$) and p53 but reduced Lamin B1 ($p < 0.006$) and ph-RB in WB. These findings were corroborated by elevated SA-beta-gal levels and by mIF, which showed elevated levels of gamma-H2A.X and reduced levels of Ki67. CDAHFD group showed higher senescence after 12 weeks of WD than at 16 weeks. MetALD models had lower p21 expression and a smaller decrease in ph-RB than MASLD models.
Conclusion: MASLD and metALD induced senescence in hepatocytes, while overall increased senescent cell accumulation correlated with disease severity. CDAHFD accelerates the onset of senescence compared to the WD, highlighting the importance of dietary factors, when determining optimal timing for therapeutic interventions, including senolytics.

THU-292
Genome-wide association study identifies PTPRD associated with metabolic dysfunction-associated steatotic liver disease in South Korea

Dong Yun Kim[1], Heon Yung Gee[2], Jung Il Lee[3], Jun Yong Park[1].

Email: jlkyy@yuhs.ac

Background and aims: Numerous single nucleotide polymorphisms (SNPs) related to metabolic dysfunction-associated steatotic liver disease (MASLD) have been identified individually by Genome-Wide Association Studies (GWASs) in Western countries. However, there remains a persistent unmet need to conduct GWAS research exploring the genetic background of MASLD in non-Western populations. Our study aimed to identify genetic variants in patients with MASLD in South Korea.
Method: We performed a GWAS in a discovery group of 414 biopsy proven MASLD patients, alongside a control group of 1, 064 healthy control. A replication analysis was conducted in a cohort of 1, 246 participants. Additionally, we investigated the associations of SNPs related to MASLD, previously identified in a GWAS on Western populations, within our own cohort.
Results: Nine SNPs in *PTPRD* on chromosome 9p23 and one SNP in *RUNX3* on chromosome 1p36.11 showed a significant association with MASLD at genome-wide significance ($p = 5.0 \times 10^{8}$). The nine variants in *PTPRD* were all successfully replicated in the replication cohort ($p < 0.0001$). In our cohort, we also observed significant associations with previously reported GWAS signals, such as *PNPLA3* at 22q13 and *SAMM50* at 22q13.31.
Conclusion: Our study discovered novel associations between PTPRD at 9p23 and MASLD in Korean patients. These findings enhance our understanding of the genetic pathophysiology of MASLD in non-European populations.

THU-293
Non-invasive assessment of liver inflammation in metabolic dysfunction-associated steatohepatitis (MASH) using MRI cytometry

Xiaoyu Jiang[1], Manhal Izzy[1], Kay Washington[1], John Gore[1], Junzhong Xu[1]. *[1]Vanderbilt University Medical Center, Nashville, United States*
Email: xiaoyu.jiang@vumc.org

Background and aims: The current diagnostic gold standard for Metabolic dysfunction-associated steatohepatitis (MASH) involves invasive biopsy to assess steatosis, lobular inflammation, and ballooning. A non-invasive imaging method that can distinguish MASH from simple hepatic steatosis would reduce risks to patients and allow improved resource allocation. While MRI-based Proton Density Fat Fraction (PDFF) and elastography reliably quantify steatosis and fibrosis, respectively, there is a notable lack of non-invasive methods for assessing inflammation in MASH. As liver inflammation involves smaller-sized inflammatory cells (<10 μm) distinct from hepatocytes (15–25 μm), we aim to demonstrate the capability of MRI cytometry to non-invasively quantify changes in non-fat cell volume and density associated with inflammation.
Method: MRI cytometry integrates water diffusion rate measurements over various timescales, corresponding to probing cellular properties at different distances. The size range of most relevance in the liver is 5 μm to 25 μm, which corresponds to diffusion times of about 5–70 ms. A combination of OGSE (oscillating gradient spin echo) and PGSE (pulsed gradient spin echo) measurements sample this range of diffusion times. Non-fat cell volumes and densities are extracted by fitting diffusion signals to a three-compartment model (blood, intra and extracellular water). Histology-based simulation: MRI cytometry analysis was conducted on simulated PGSE and OGSE signals using segmented histological images of normal human liver tissue, steatosis, and stroma, at three signal-to-noise (SNR) levels (10, 20, and 50). In vivo imaging: MRI cytometry was conducted in three healthy subjects and a MASH patient using a Philips Ingenia CX 3 T scanner. The fat fraction was measured by a clinical standard mDixon sequence.
Results: Simulation: MRI-derived average cell sizes, and densities in stroma significantly exceed those in steatosis and normal liver tissues at all SNR levels, with variations increasing at lower SNRs. In vivo: The fitted average cell size and density for healthy subjects were about 19 μm, and $15 \times 104/mm^3$, respectively, consistent with existing literature. The MASH liver displayed uniformly high fat content, inhomogeneous high cell densities, and small cell sizes. Two cell populations in the MASH liver were identified: one with cell sizes of 12 ± 2.4 μm and low cell density ($<106/mm^3$) and another with cell sizes of 7 ± 1.9 μm and high cell density ($>106/mm^3$), likely associated with fatty hepatocytes and inflammatory cells, respectively.
Conclusion: We demonstrate that MRI cytometry can quantify changes in cell size and density associated with inflammation using clinical 3 T scanners in under 12 minutes. These findings establish a solid foundation for future studies into the role of non-invasive assessment of liver cellular characteristics in diagnosing MASH.

THU-294
Resmetirom protects against diet-induced MASLD and reduces atherogenic risk factors in obese Ldlr-/-.Leiden mice

Eveline Gart[1], Geurt Stokman[1], Robert Kleemann[2], Martine C. Morrison[1]. *[1]TNO, Leiden, Netherlands; [2]TNO, leiden, Netherlands*
Email: eveline.gart@tno.nl

Background and aims: The thyroid hormone receptor-β agonist MGL-3196 (Resmetirom) is expected to become the first approved drug for metabolic dysfunction-associated steatotic liver disease (MASLD). Since resmetirom was found to lower plasma LDL cholesterol levels in clinical trials, it may also affect obesity-associated cardiovascular disease (CVD), which is the primary cause

of mortality in MASLD patients. The Ldlr-/-.Leiden mice have previously been compared with biopsy-confirmed MASLD patients, which demonstrated that patients with a high risk of developing CVD are particularly well reflected by the Ldlr-/-.Leiden mouse model. In the present study we studied the effect of resmetirom on progression of atherosclerotic CVD, in addition to its effects on MASLD-associated liver fibrosis.

Method: Ldlr-/-.Leiden mice underwent an initial 18-week period of fast-food diet (FFD) feeding to establish early stages of MASLD and atherosclerosis. After this run-in period, one group of mice was terminated as a start-of-treatment reference. The remaining mice were maintained on FFD and received vehicle (FFD + vehicle controls) or 3 mg/kg resmetirom (FFD + Res) by oral gavage for an additional 10 weeks after which they were terminated at t = 28 weeks. Chow-fed mice were included as a healthy reference group. Plasma parameters, liver, adipose and heart tissues, were analyzed in the study.

Results: FFD fed mice developed obesity, dyslipidemia as confirmed by elevated plasma cholesterol and triglycerides levels, and MASLD associated liver fibrosis as compared to chow-fed controls. Therapeutic treatment with resmetirom significantly reduced plasma cholesterol and triglycerides compared to FFD +vehicle-treated controls. Plasma lipoprotein profiles demonstrated that the FFD-induced increase in plasma TGs can mainly be ascribed to an increase in VLDL lipoprotein particles and the increase in plasma cholesterol to an increase in (V)LDL-sized particles. Resmetirom lowered atherogenic risk factors, i.e. TG in VLDL and cholesterol in (V) LDL-sized particles. Subsequent effects on atherosclerosis will be presented (analysis ongoing). Notably, all effects were observed independent of changes in body weight, adiposity, and food intake, as resmetirom did not impact these factors. Furthermore, FFD-induced circulating liver injury markers ALT and AST were significantly reduced upon resmetirom treatment, and reduced to that in the chow-fed group. Consistent with this data, MASLD-associated liver fibrosis was attenuated with resmetirom relative to the FFD control group, as hepatic collagen content corrected for total liver weight was significantly reduced with resmetirom.

Conclusion: Our findings demonstrate that in Ldlr-/-.Leiden mice, treatment with resmetirom has additional protective effects on CVD risk factors and possibly on the extent of atherosclerosis, on top of its effects on MASLD.

MiR-4449-merlin-TAZ axis modulates fibrosis progression in MASH

Young-Sun Lee[1], Yoonseok Lee[2], Seong Hee Kang[1], Young Kul Jung[1], Ji Hoon Kim[1], Yeon Seok Seo[1], Hyung Joon Yim[1], Jong Eun Yeon[1].
[1]Korea University, Seoul, Korea, Rep. of South; [2]Gachon University Gil Medical Center, Incheon, Korea, Rep. of South
Email: lys810@korea.ac.kr

Background and aims: While the majority of metabolic dysfunction-associated steatotic liver disease (MASLD) patients experience benign clinical courses, those with metabolic dysfunction-associated steatohepatitis (MASH) accompanied by fibrosis show poorer prognoses in comparison to patients with simple steatosis or MASH without fibrosis. This study aims to examine the involvement of miR-4449 in the progression of MASH-related fibrosis.

Method: Liver tissue and sera were obtained from MAFLD patients who underwent liver biopsies at Korea University Guro Hospital. MicroRNA sequencing was conducted on sera, while mRNA sequencing was performed on liver tissue from patients with biopsy-confirmed MAFLD. In vitro lipotoxicity was induced in hepatocyte cell lines (HepG2 and Huh7 cells) by treating them with palmitic acids (PA). To investigate the impact of miR-4449 during lipotoxicity, hepatocytes were transfected with either miR-4449 mimic or inhibitor.

Results: A total of 24 MAFLD patients were enrolled, with 15 patients exhibiting simple steatosis or MASH without fibrosis, while nine patients had MASH with fibrosis. In the miRNA sequencing analysis, 31 miRNA sequences displayed significant differences in expression levels between the two groups. Notably, miR-4449 exhibited the highest expression among the miRNAs showing increased levels in the MASH-fibrosis group compared to the simple steatosis or MASH without fibrosis group. Palmitic acid (PA) treatment elevated the expression of miR-4449 in both the supernatant and hepatocytes. Conversely, the expression of merlin, a potential target of miR-4449, decreased in PA-treated hepatocytes compared to vehicle-treated hepatocytes. Furthermore, merlin expression significantly decreased in MASH patients with fibrosis compared to simple steatosis and MASH patients without fibrosis. Hepatocytes transfected with the miR-4449 mimic displayed decreased merlin expression but increased phosphorylated TAZ expression. In contrast, hepatocytes transfected with the miR-4449 inhibitor exhibited increased merlin expression but decreased phosphorylated TAZ expression.

Conclusion: Patients with MASH-fibrosis exhibited elevated expression of miR-4449. miR-4449 regulates merlin expression and TAZ phosphorylation in hepatocytes during lipotoxicity. Thus, miR-4449 may serve as a promising therapeutic target in the treatment of MASH-fibrosis.

Hospital Universitario Virgen Del Rocío, Sevilla, Spain*
Email: mromerogomez@us.es

Background and aims: First-line Non-Invasive Tests (NITs), such as FIB-4, are valuable for detecting, particularly excluding, advanced liver disease. However, their modest sensitivity and specificity result in many undiagnosed cases and unnecessary hospital referrals due to the absence of powerful confirmatory tests like TE in key screening locations, such as primary and endocrine units. Identifying new biomarkers easily assessable in them is essential to enhance patient selection for Hepatology Unit referrals.

Method: Two-step meta-analysis identified candidates based on gene expression in MASLD patient liver biopsies, using significant

fibrosis as readout. Four Fibrosis Inducible Circulating Elements (FICEs) were selected from cohorts analyzed by Microarray (139 F0-F1 vs. 47 F2-F4) and RNA-seq (234 F0-F1 vs. 197 F2-F4). Circulating levels were measured in a Spanish cohort of biopsy-proven MASLD patients (N = 201).
Results: FICE 2-4 levels (a) increase in the liver (1st 2nd panel) and the bloodstream (3rd panel) of patients with significant fibrosis (F2+), advanced fibrosis (F3+) and at-risk MASH. Logistic regression favoured a score combining FICE2 and FICE4 circulating levels (FICE24; $AUC_{95\%CI}$ F2+: 0.78 [0.70–0.85]; F3+: 0.80 [0.73–0.87]; at-risk: 0.80 [0.72–0.88]). Incorporating age with standard analytes (named hereafter as FICE-24C) significantly improved its diagnostic accuracy (FICE24C; $AUC_{95\%CI}$ F2+: 0.88 [0.83–0.93]; F3+: 0.86 [0.80–0.92]; at-risk: 0.82 [0.75–0.90]) (b). Diagnostic performance analysis suggests a slight (FICE24) or clear (FICE24-C) superiority of both when compared against primary NITs (FIB4, NFS, HFS, APRI) (c) or confirmatory tests (TE, ELF or FAST) (d). Comparative analyses with common derivation pathways based on FIB-4 and TE indicate that FICE24-C can be used as a confirmatory test and improve the identification of true positive cases (e).
Conclusion: FICE24 and FICE24C, which can be easily assessed by ELISA, show a higher diagnostic accuracy than most primary risk assessment tools and a similar (FICE24) or higher (FICE24C) accuracy than well-established secondary risk assessment tools like TE and ELF. Validation in a separate independent cohort is on its way.

THU-297
Treatment with the CCR2/CCR5 antagonist Cenicriviroc does not affect MASH and fibrosis development in Ldlr-/-.Leiden mice, translational to clinical phase 3 trial results

Martine C. Morrison[1], Eveline Gart[1], Wim van Duyvenvoorde[1], Jessica Snabel[1], Aswin L. Menke[1], Anita M. van den Hoek[1], Robert Kleemann[1]. [1]*The Netherlands Organisation for Applied Scientific Research (TNO), Department of Metabolic Health Research, Leiden, Netherlands*
Email: martine.morrison@tno.nl

Background and aims: Cenicriviroc (CVC) is a dual CCR2/CCR5 antagonist that was developed for the treatment of metabolic dysfunction-associated steatohepatitis (MASH) and associated fibrosis. While it showed antifibrotic potential in the phase 2B CENTAUR trial, the phase 3 AURORA trial was terminated at the 1-year interim analysis due to lack of efficacy on improvement of fibrosis. In contrast with these results in humans, many preclinical studies have shown anti-inflammatory and anti-fibrotic efficacy of CVC-which brings into question the translational value of these models for human MASH. Here we studied the effects of CVC treatment in the Ldlr-/-.Leiden mouse model for obesity-associated MASH and liver fibrosis, to investigate if this model can more accurately predict treatment effects in MASH patients.
Method: Male Ldlr-/-.Leiden mice were fed a MASH and fibrosis-inducing high-fat diet (HFD) for 20 weeks, after which the 14-week treatment with CVC (20 mg/kg BW, provided as dietary admix) was started in one group of mice (HFD+CVC) and another group of mice was kept on HFD as an untreated control. A chow-fed group was included as an aging reference. All mice were terminated at t = 34 weeks for histological and biochemical analysis of MASH and fibrosis development as well as analysis of MASH and fibrosis-related biomarkers.
Results: Twenty weeks of HFD feeding induced obesity, hyperinsulinemia and atherogenic hyperlipidemia with increased plasma LDL cholesterol and triglyceride levels relative to chow. Treatment with CVC did not affect body weight or food intake. CVC significantly lowered fasting blood glucose with a concomitant increase in plasma insulin towards the end of the study. Fasting plasma cholesterol was not affected by CVC treatment while fasting plasma triglycerides were significantly increased. Histologically, CVC treatment did not affect macrovesicular or microvesicular steatosis in the liver. In addition, CVC had no effect on hepatic inflammation or fibrosis as measured histologically. This lack of anti-fibrotic effect was further corroborated by biochemical analysis of hepatic collagen content and the plasma markers PIIINP, TIMP-1 and CK18-M30, none of which were reduced by CVC treatment.
Conclusion: While many preclinical models have shown efficacy of CVC that contrasts clinical observations, CVC treatment (at a translational dose that did show efficacy in other preclinical models) in the HFD-fed Ldlr-/-.Leiden mouse did not reduce hepatic fibrosis-in line with the outcome of the phase 3 AURORA trial. These findings underline the importance for validation of preclinical MASH models not only with treatments that have been found to have clinical efficacy, but also with treatments that have failed clinically.

THU-298
Evaluation of performance of AI digital pathology on the reproducibility and repeatability of fibrosis phenotyping in MASH liver biopsies

Li Chen[1], Nathan Aist[1], Louis Petitjean[2], Mathieu Petitjean[2]. [1]*PharmaNest, Princeton, United States;* [2]*Pharmanest, Princeton, United States*
Email: li.chen@pharmanest.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a chronic liver disease characterized by inflammation, steatosis, and fibrosis. The inter-observer and intra-observer variability in diagnosing MASH, especially liver fibrosis staging, by pathologist has long been a concern. This concern is transcended to AI based quantitative image analysis and the generation of fibrosis continuous scores. In this study, we demonstrate the precision of the phenotypic analysis of fibrosis using the FibroNest™ digital pathology platform (PharmaNest Inc, USA).
Method: Three liver biopsies with MASH conditions, each visually determined to have a low, mid, or high fibrosis and steatosis, were stained with Masson's Trichrome for collagen and imaged at 40X with Aperio Microscopy. Three operators (image analysts) independently performed the precision study using FibroNest™, an AI-based digital pathology quantitative image analysis tool that generates a Phenotypic Fibrosis Composite Scores (Ph-FCS) as a biomarker for fibrosis disease progression. Each operator applied their own perceived full tissue selection and a color normalization step to "extract" collagen stains and remove staining artifacts. Analysis of the three liver biopsies by three different operators is conducted once daily for 5 consecutive days. Coefficient of variation (CoV), calculated using standard deviation divided by the average, is used to determine the inter-observer and intra-observer variability.
Results: For the repeatability performance, the CoV% of the intra-observer variability for the Ph-FCS fibrosis severity is 0.47%, 0.21%, and 0.29% for the low, mid, and high fibrosis samples, respectively. For the reproducibility performance, the CoV% of the intra-observer variability for the Ph-FCS fibrosis severity is 11.53%, 4.95%, and 3.33% for low, mid, and high fibrosis samples, respectively.
Conclusion: As the result for the CoV% are very low, the reproducibility and repeatability performance by the FibroNest™ digital pathology platform to provide fibrosis severity scores is acceptable. This is important as it indicates the precision and consistency of the analysis tool. FibroNest™ is a reliable tool to investigate potential ant-fibrotic drug efficacy for treatment of MASH.

THU-299
A 4-week mouse model allows the rapid evaluation of resmetirom and tirzepatide benefits on metabolic dysfunction-associated steatohepatitis

Francois Briand[1], Natalia Breyner[1], Estelle Grasset[1], Thierry Sulpice[1]. [1]*Physiogenex, Escalquens, France*
Email: f.briand@physiogenex.com

Background and aims: There is currently no marketed drug for the treatment of metabolic dysfunction-associated steatohepatitis

(MASH). To expedite preclinical drug development, we have developed a mouse model fed a high fat/cholesterol/cholic acid diet with cyclodextrin in drinking water (HFCC+CDX diet) to promote hepatocyte cholesterol loading, liver inflammation and MASH within 4 weeks. For future head-to-head comparison or drug combinations studies with incretin-based therapies, we evaluated the efficacy of resmetirom, a thyroid hormone receptor-β agonist, and tirzepatide, a dual gastric inhibitory polypeptide receptor and glucagon-like peptide-1 receptor agonist.

Method: Male, 8-week-old, C57BL6/J mice were fed the HFCC+CDX diet for 4 weeks. After 2 weeks of diet, animals were randomized based on their plasma transaminases levels and body weight. Mice were kept on the same diet and were treated once daily with vehicle, resmetirom 3 mg/kg p.o. or tirzepatide 3 µg/kg s.c. for 2 weeks. At the end of the treatment period, blood and liver samples were collected for biochemistry and histology analysis.

Results: Resmetirom did not alter plasma transaminases levels but significantly reduces plasma total cholesterol and LDL-cholesterol levels (−27% and −37% respectively, both $p < 0.001$ vs. vehicle). This LDL-lowering effect was associated with higher LDL-receptor (+39%) and lower apolipoprotein B (−17%) hepatic gene expression (both $p < 0.01$). Resmetirom reduced hepatic triglycerides content (−25%, $p < 0.01$) and significantly reduced NAFLD activity score through lower inflammation score ($p < 0.01$), as well as lower IL-6 and IL-1b hepatic gene expression (both $p < 0.05$). Resmetirom also showed anti-fibrotic effects as shown by a significantly lower % Sirius Red labelling. As expected, tirzepatide induced body weight loss, leading to a 13% lower body weight after 2 weeks of treatment, as compared to vehicle ($p < 0.001$). Although it did not alter plasma transaminases levels significantly, tirzepatide significantly lowered the hepatic gene expression of IL-1b and IL-6 (both $p < 0.05$ vs. vehicle). It also reduced liver triglycerides content by 18% and hepatic inflammation score ($p < 0.05$ vs. vehicle).

Conclusion: Resmetirom and tirzepatide both improve MASH in our 4-week diet-induced mouse model. This preclinical model will be useful to expedite preclinical drug development for the treatment of MASH.

THU-302

Suitability of non-invasive tests in the evaluation of liver fibrosis in patients with metabolic dysfunction-associated steatotic liver disease

Álvaro Yagüe Parada[1], Andrés Felipe Castañeda Agredo[1], Rocio Calvo Hernandez[1], Agustina Gonzalez Guirado[1], Andres Varela Silva[1], Marta Morán Ortiz de Solorzano[1], Michelle Casanova Cabral[1], Benjamin Polo Lorduy[1]. [1]*Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain*
Email: alvaro.yague@quironsalud.es.

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the main cause of liver disease in our environment and its incidence is raising due to the outbreak of metabolic syndrome and obesity. The spectrum ranges from simple steatosis to steatohepatitis, cirrhosis and hepatocellular carcinoma. It is essential to stratify patients with MASLD according to the degree of liver fibrosis, since its presence and progression determines the prognosis of the disease. Liver biopsy is the gold standard for the diagnosis of cirrhosis and staging of fibrosis. However, it is an invasive procedure with many drawbacks. Non-invasive markers have been developed for the evaluation of liver fibrosis. The aim of this study is to analyze the usefulness of FibroScan, NFS, APRI and FIB-4 indexes in evaluating presence and severity of liver fibrosis in MASLD, using liver biopsy as the reference standard.

Method: The case records of 210 patients who underwent liver biopsy from March 2019 until January 2023 were retrospectively reviewed, selecting for the study those who had undergone FibroScan measurements and blood samples simultaneously or with a maximum difference of three months from liver biopsy. Patients without histological confirmation of hepatic steatosis (defined as a liver fat content ≥5% on biopsy) were later excluded. Non-alcoholic fatty liver disease fibrosis score (NFS), fibrosis-4 index (FIB-4) and AST to platelet ratio index (APRI) were calculated. In all markers, indeterminate results were discarded. Liver fibrosis stage was determined using the METAVIR system.

Results: 194 patients were initially examined, detecting the presence of hepatic steatosis on biopsy in 44.3% of them, who were selected for the study. These patients had a mean age of 54.5 ± 10.6 years, being women the majority of them (76.7%). FibroScan liver stiffness results ranged from 2.6 to 45 kPa (mean: 8.6 kPa). Serological marker values ranged from −5.2 to 1.3 (mean: −2.1) for NFS, from 0.2 to 9.3 (mean: 1.8) for FIB-4 and from 0.1 to 6.1 (mean: 0.9) for APRI. In liver biopsy, 73.3% of the patients presented F0–1, while mild fibrosis (F≥2) was found in the remaining 26.8%. For the detection of advanced fibrosis (F3-F4), FibroScan showed a sensitivity of 64.3% and a specificity of 87.3% with a positive predictive value of 50% and a negative predictive value of 92.5%. Its degree of concordance with the biopsy was moderate (kappa index: 0.46). NFS showed low sensitivity (25%) and high specificity (98.2%), with a kappa index of 0.3. Regarding FIB-4 and APRI, both showed high sensitivity (85.7% for FIB-4 and 75% for APRI) and specificity (86.1% for FIB-4 and 81.2% for APRI), with a kappa index of 0.55 and 0.36, respectively.

Conclusion: FibroScan and FIB-4 are comparable to liver biopsy with a moderate degree of agreement, being useful tools for the non-invasive detection of advanced fibrosis among patients with MASLD.

THU-303

Elevated SIRT1 levels in arterial hypertension patients with a heightened risk of non-alcoholic fatty liver disease

Anastasiia Radchenko[1], Olena Kolesnikova[1]. [1]*L.T. Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine*
Email: kolesnikova1973@gmail.com

Background and aims: Sirtuin 1 (SIRT1) is associated with the aging process and has been found to have protective effects on the liver due to its ability to regulate lipid metabolism and reduce inflammation. However, some studies suggest that SIRT1 levels may increase in the context of non-alcoholic fatty liver disease (NAFLD) and with older age as a result of compensatory processes. Arterial hypertension (AH) is closely associated with metabolic alterations and is believed to be strongly linked to NAFLD. Nonetheless, the relationship between SIRT1 levels and the risk of NAFLD in patients with AH remains unclear.

Method: Our study involved 86 AH patients with a mean age of 49.1 [40.3;54.6] years (63% women), divided into groups based on the Fatty Liver Index (FLI): group 1-<30 (n = 38), group 2–30–60 (n = 30), group 3->60 (n = 18), matched for age and gender. Each group was further divided by age: <45 years (n = 12, n = 15, n = 3 respectively) and 45–59 years (n = 26, n = 15, n = 15). Body mass index, waist and hip circumferences, carbohydrate and lipid profiles, liver and kidney blood tests, C-reactive protein (CRP), and SIRT1 were evaluated in all patients.

Results: The levels of SIRT1 were significantly lower in group 1 compared to group 2 ($p = 0.004$) and group 3 ($p = 0.010$). Among patients of younger age (<45 years), no significant difference was found between groups 1 and 2, and group 3 was not compared due to an insufficient number of cases. In the middle-aged patient group, SIRT1 levels were also the lowest in group 1 compared to group 2 ($p = 0.004$) and group 3 ($p = 0.039$). Correlation analysis indicated that in the middle-aged group, SIRT1 was associated with alanine aminotransferase (ALT) ($r = 0.419$, $p = 0.001$), HOMA-IR ($r = 0.412$, $p = 0.002$), low-density lipoprotein cholesterol (LDL-C) ($r = -0.355$, $p = 0.009$), high-density lipoprotein cholesterol (HDL-C) ($r = -0.398$, $p = 0.003$), uric acid (UA) ($r = 0.538$, $p = 0.0001$), glomerular filtration rate (GFR) ($r = 0.620$, $p = 0.0001$), and C-reactive protein (CRP) ($r = 0.377$, $p = 0.039$).

Conclusion: Among middle-aged patients with AH, but not among the younger ones, moderate and high risk of NAFLD according to FLI values were associated with higher levels of SIRT1 compared to patients at low NAFLD risk. This could be a result of complex compensatory mechanisms. Probable factors contributing to these changes include increased insulin resistance, levels of liver enzymes, pro-inflammatory processes, and the development of dyslipidemias, supported by the correlation between SIRT1 and HOMA-IR, ALT, CRP, HDL-C levels. However, middle-aged patients with AH may still benefit from the positive impact of SIRT1 on LDL-C, GFR-both recognized as risk factors for AH and NAFLD-and on UA, often associated with an extended lifespan.

THU-304

Performance of non-invasive indexes in the assessment of metabolic dysfunction-associated steatotic liver disease

Álvaro Yagüe Parada[1], Andrés Felipe Castañeda Agredo[2], Rocio Calvo Hernandez[2], Agustina Gonzalez Guirado[1], Andres Varela Silva[1], Marta Morán Ortiz de Solorzano[1], Michelle Casanova Cabral[1], Benjamin Polo Lorduy[2]. [1]*Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain;* [2]*Hospital Universitario Fundación Jiménez Diaz, Madrid, Spain*
Email: alvaro.yague@quironsalud.es

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) includes a spectrum of liver diseases ranging from steatosis to steatohepatitis, fibrosis and cirrhosis. Its prevalence increases with age and obesity, and it is associated with metabolic syndrome and an increased risk of cardiovascular and malignant diseases. Liver biopsy is the gold standard for the diagnosis of MASLD. However, it is and invasive and inaccurate technique with many drawbacks. In order to overcome the limitations of liver biopsy, a number of non-invasive markers have been developed for the evaluation of hepatic steatosis. The aim of this study is to evaluate the ability of CAP, HSI and TyG indexes to predict hepatic steatosis using liver biopsy as the reference standard.
Method: The case records of 210 patients who underwent liver biopsy from March 2019 until January 2023 were retrospectively reviewed. Those patients who had undergone CAP measurements and blood samples simultaneously or with a maximum difference of three months from liver biopsy were included in the study, with a final number of 194 patients. Hepatic Steatosis Index (HSI: sex, body mass index [BMI], alanine aminotransferase [ALT], aspartate aminotransferase [AST], diabetes) and TyG (triglycerides, glucose) were calculated. In all markers, indeterminate results were discarded. Biopsies were performed percutaneously using Tru-cut 16/18G needles. Hepatic steatosis was diagnosed if liver fat content was 5% or greater on biopsy.
Results: 194 patients with a mean age of 51.9 ± 13.5 years were examined, being women the majority of them (73.2%). CAP results ranged from 100 to 400 dB/m (mean: 242.9 dB/m), while serological marker values ranged from 22.8 to 57.2 (mean: 38.7) for HSI and from 7.1 to 11.9 (mean: 8.6) for TyG. In liver biopsy, 44.3% of the patients presented hepatic steatosis, being 59 of them S1 (68.6%), 19 S2 (22.1%) and 8 S3 (9.3%). For the detection of hepatic steatosis, CAP showed a sensitivity of 74.4% and a specificity of 75.3% with a positive predictive value of 71.8% and a negative predictive value of 77.7%. Its degree of concordance with the biopsy was moderate (kappa index: 0.495). Regarding HSI and TyG, both showed high sensitivity (98.5% for HSI and 91.8% for TyG) and low specificity (4% for HSI and 59.3% for TyG), with a kappa index of 0.029 and 0.49, respectively.
Conclusion: Although liver biopsy is the reference standard for the diagnosis of hepatic steatosis, CAP and TyG are accurate and comparable to liver biopsy with a moderate degree of agreement. As CAP needs a specific device and a trained health practitioner that might not be available in some cases, TyG could represent the first step in the diagnosis of MASLD.

THU-305

Evaluation of the performance of AI digital pathology method (FibroNest) on subsections of biopsies to assess performance variability due to region selection

Adi Lightstone[1], Li Chen[1], Mathieu Petitjean[1]. [1]*PharmaNest, Princeton, United States*
Email: adi.lightstone@pharmanest.com

Background and aims: The gold standard for assessment of liver fibrosis and steatosis is using MASH biopsies, though there has often been concern that the disease may present differently in different liver lobes (particularly in early stages). This concern is magnified when using quantitative or AI based digital pathology techniques, as depending on the algorithm, small changes in structure (e.g. the presence of veins) can have large impacts on results. Additionally, when using a digital pathology analysis technique, the computational costs and time are magnified greatly with increased biopsy size. The goal of this study is to analyze the phenotypic fibrosis scores generated by our FibroNest™ Digital Pathology platform on subsections of wedge-shaped biopsies (large biopsies from liver transplants) and see how the results may vary within the wedge.
Method: This study included 17 wedge shaped biopsies from the LITMUS MASH cohort (a large set of biopsies funded by the Innovative Medicines Initiative for the purpose of finding novel biomarkers) stained with Mason's Trichrome and imaged at 20x. Each wedge was sectioned into between 4 and 7 smaller portions; in cases where the staining was inconsistent the subsections were placed such that the stain had a similar pattern throughout. The biopsies were then processed and analyzed using FibroNest™ which calculated and extracted a total of 335 Quantitative Fibrosis traits. The most biologically relevant of these traits were then used to generate a Phenotypic Fibrosis Composite Score (Ph-FCS) which indicates the progression of fibrotic diseases. The scores from each biopsy were then used to generate an overall Coefficient of Variation (CoV) by taking the standard deviation from each section within a wedge biopsy and dividing it by the mean. Allowing us to understand how different sectioning methods may impact the calculated fibrosis score.
Results: Of the 17 wedge biopsies, only 4 of the Ph-FCS scores had a Coefficient of Variation above 15%, of those only 3 were greater than 20% and none were above 26%. 7 had a variation of 10% or below, and the 6 remaining were between 10 and 15%. The biopsy with the greatest variations in the subsections (one with a Ph-FCS of 2.3, another with that of 5.4) was bisected with a large break and included a vein in only one of the subsections.
Conclusion: Barring a few outliers, the low variation in the overall result from a digital pathology measurement of fibrosis in biopsy subsections indicates that the technique works well. With an acceptable CoV below 15%, the intra observer variability results from the FibroNest™ platform show completely acceptable levels for the purposes of scoring and analysis. It also shows that larger biopsies can be cropped down when doing digital pathology, provided a representative portion is selected, to allow for large savings in both time and cost.

Study of alternative splicing changes during metabolic dysfunction-associated liver disease development and progression

Eirini Giannousi[1,2], Zoi Erpapazoglou[2], Antonios Chatzigeorgiou[1], Panagiota Kafasla[2]. [1]*Department of Physiology, Medical School, National and Kapodistrian University of Athens, Athens, Greece;* [2]*Institute for Fundamental Biomedical Research, B.S.R.C. "Alexander Fleming", Vari, Athens, Greece*
Email: eirinigiannousi@hotmail.com

Background and aims: Alternative splicing (AS) is a fundamental molecular mechanism during which exons are joined into different combinations resulting in different mRNA transcripts and producing

proteins with distinct structures and functions. An association between AS and liver diseases has been reported, but the exact mechanism is yet to be elucidated. Metabolic dysfunction-associated liver disease (MASLD) is a burgeoning health problem, affecting 25% of the global population, and is strongly associated with the dramatic increase of metabolic syndrome. It ranges from simple steatosis to metabolic dysfunction-associated steatohepatitis (MASH), which is a more severe form, and can lead to fibrosis, cirrhosis, and, ultimately, hepatocellular carcinoma (HCC). Studies have reported a significant correlation between the dysregulated expression of several spliceosome components and splicing factors with the development of MASLD and transition to MASH and HCC. The main goal of this study was to conduct an initial investigation on the alternative splicing changes during MASLD development and progression by focusing on a key player in splice site recognition and AS regulation, the hnRNPM protein. Firstly, hnRNPM expression was examined in various murine and cellular MASH models and then hnRNPM-dependent alternative splicing changes were evaluated across different disease stages.
Method: Murine models mimicking MASLD and MASH development were utilized, namely mice on high-fat diet (HFD) and HFD-high fructose corn syrup 55 (HFCS), mice on TACONIC diet and mice on a combined western diet (WD) and carbon tetrachloride (CCL4) injections. Moreover, HepG2 cells were either treated with palmitate acid to induce steatosis or were silenced for hnRNPM. In the forementioned models, the gene and protein levels of hnRNPM were evaluated by qPCR and immunohistochemistry respectively. Furthermore, examination of the alternative isoform expression of selected, based on a literature search, AS events regulated by hnRNPM was performed with PCR followed by acrylamide gel electrophoresis.
Results: The hnRNPM mRNA and protein levels in the *in vivo* models and the HepG2 steatosis cellular model revealed their progressive decrease during MASLD development. The evaluation of the alternative isoform expression of the chosen hnRNPM-dependent AS events both in the *in vivo* and *in vitro* MASH models did not reveal any major alterations.
Conclusion: This study suggests that hnRNPM expression is significantly altered in three well established murine models that resemble MASLD and MASH progression at different stages. A more comprehensive analysis of hnRNPM-dependent AS-derived isoform is required to address the role of hnRNPM deregulation during disease development.

THU-314
Evaluation of suitable in vitro and in vivo models for metabolic dysfunction-associated steatotic liver disease
Anja Geisler[1], Lisa Börmel[1], Yvonne Hupfer[1], Lara Zoe Preisner[1], Stefan Lorkowski[1], Maria Wallert[1]. [1]*Friedrich Schiller University, Jena, Germany*
Email: anja.geisler@uni-jena.de

Background and aims: To understand development and progression of metabolic dysfunction-associated steatotic liver disease (MASLD), elucidating the molecular mechanisms is of utmost importance. Due to the high metabolic activity of the liver, the selection of appropriate cell models is a challenge. Primary human hepatocytes are the gold standard. However, primary cells are limited due to a lack of availability, ethical concerns, as well as complex and time-limited culture. Therefore, immortalized cell lines from different sources are often used. Because *in vitro* studies are not sufficient to cover the complex conditions of a living organism, mice are widely used as a model organism. In mice, MASLD can be induced chemically or by diet. Due to the high heterogeneity of the study designs, obtained data are difficult to compare. It is of note that the expression of liver-specific enzymes can differ depending on species (murine vs. human) and model (*in vitro* vs. *in vivo*).
Method: For comparing different *in vitro* models, HepG2, HepaRG, and AML-12 cells as well as primary murine hepatocytes (PMH) were used. Basal gene expression of liver-specific and metabolism involved genes (albumin (alb), pregnane X receptor (PXR), glutathione S-transferase (GST) α, cytochrome P450 (CYP) 2E1, CYP3A4, CYP4F2) were analyzed by RT-qPCR. To characterize the different stages of MASLD *in vivo* C57BL/6 mice are fed with a high-fat and high-fructose diet (HFFD). In addition to body weight, organ weight and histology, phenotypic markers (e.g. liver inflammation markers) and lipid mediators in blood and liver are determined.
Results: Initial *in vitro* studies revealed that the human hepatic cell line HepG2 and the murine liver cell line AML-12 are of limited use due to the low expression of metabolic key enzymes. Comparative studies of HepG2, HepaRG and AML-12 cells as well as PMH revealed the following differences: mRNA expression of alb, GSTα, CYP2E1 and CYP3A4 is significantly higher in PMH than in AML-12. HepaRG cells show higher CYP2E1 and GSTα expression levels than HepG2. The studied liver cell models differ significantly in their metabolic activity. HepaRG cells are metabolically more active cells than HepG2 and AML-12 but are not comparable to PMH in the expression of several liver- and inflammation-specific genes.
Conclusion: These results demonstrate the importance of a comprehensive characterization and application-oriented selection of existing hepatic and MASLD model systems.

THU-336
Combination of fatty acid synthase (FASN) inhibitor and thyroid hormone receptor beta (THRb) agonist resmetirom shows synergistic improvement of NAFLD activity score (NAS) within 6-weeks in diet-induced obese mice with biopsy-confirmed MASH
Wen-Wei Tsai[1], Malte H. Nielsen[2], Michael Feigh[2], Eduardo Martins[1], George Kemble[1], Marie O' Farrell[1]. [1]*Sagimet Biosciences, San Mateo, United States;* [2]*Gubra ApS, Horsholm, Denmark*
Email: wen-wei.tsai@sagimet.com

Background and aims: Increased *de novo* lipogenesis (DNL) drives the development of MASH, and FASN is the rate-limiting enzyme in the DNL pathway. In preclinical studies, denifanstat (TVB-2640) directly blocks endogenous FASN in stellate cells, immune cells and hepatocytes, thereby directly inhibiting fibrosis, inflammation and steatosis. Denifanstat, an oral FASN inhibitor, has demonstrated significant improvements in MASH resolution and fibrosis improvement in the Ph2b MASH study, FASCINATE-2, as well as decreased liver fat and biomarkers of inflammation and fibrosis. THRb agonists increase lipid oxidation which decreases liver fat; resmetirom (RES) recently demonstrated significant MASH resolution or fibrosis improvement in Phase 3 and is FDA approved for the treatment of MASH with moderate to advanced liver fibrosis. We hypothesized that the combination of a FASN inhibitor and RES may increase efficacy for MASH treatment based on complementary mechanisms of liver fat reduction and the FASN inhibitor's direct anti-fibrotic effect. This study was designed to evaluate a FASN inhibitor alone and in combination with RES on liver histology in biopsy-confirmed MASH mice.
Method: Male C57BL/6J GAN-diet-induced obese mice with histologically confirmed NAS ≥5 and fibrosis stage F1-F3 were randomized and treated with either vehicle, TVB-3664 (a surrogate FASN inhibitor for denifanstat, 5 mg/kg, PO, QD) or RES (3 mg/kg, PO, QD) individually or in combination for 6 weeks (n = 10-12 for each group).
Results: After a 6-week treatment, the response rate (RR) for reduction of NAS by 2 or more points was 33% for TVB-3664, 25% for RES, 0% for vehicle and 80% for the combination. Notably, 100% of combination-treated mice showed at least 1-point reduction in NAS, and 30% had 3 or more points of NAS reduction. For steatosis, the RR for 1-point reduction was 17% for TVB-3664, 50% for RES and 100% for the combination, with a 2-point reduction in 80% of combination-treated animals. This was consistent with significant reduction of % hepatocytes with lipid droplets and % area of liver lipids in drug-treated groups. For lobular inflammation, the 1-point RR was 42% for TVB-3664, 8% for RES, and 10% for the combination although these

10% combination-treated animals all had a 2-point reduction. Some ballooning hepatocytes (ballooning score 1) were present before initiation of treatment and all treatments decreased the ballooning score to 0.
Conclusion: Combination of FASN inhibitor and THRb agonist RES had a synergistic effect on histological improvement of NAS compared to single agents within 6-weeks in a mouse model of MASH. These results suggest that the complementary mechanisms of action of denifanstat (directly decrease lipid synthesis, inflammation and fibrosis) and RES (increase lipid oxidation) combined could provide added benefit and support future clinical evaluation of this combination for MASH.

MASLD – Therapy

Consumption of a mediterranean diet with high-polyphenol content extra-virgin olive oil (EVOO) in patients with MASLD: effects on clinical parameters and gene expression on peripheral blood mononuclear cells (PBMCs)

Aurelio Seidita[1], Alessandra Cusimano[2], Roberto Citarrella[1], Antonina Azzolina[3], Roberta Chianetta[4], Ida Muratori[1], Rosalia Caldarella[5], Antonino Terranova[1], Anna Licata[6,7,7], Antonio Carroccio[1], Juan Iovanna[8], Melchiorre Cervello[3], Maurizio Soresi[1], Lydia Giannitrapani[1]. *[1]Department of Health Promotion Sciences, Maternal and Infant Care, Internal Medicine and Medical Special-ties (PROMISE), University of Palermo, Palermo, Italy; [2]Department of Biological, Chemical and Pharmaceutical Science and Technology (STEBICEF), University of Palermo, Palermo, Italy; [3]Institute for Biomedical Research and Innovation (IRIB), CNR, Palermo, Italy; [4]Department of Health Promotion Sciences, Maternal and Infant Care, Internal Medicine and Medical Special-ties (PROMISE), University of Palermo, Palermo; [5]UOC Laboratory Medicine-CORELAB, University Hospital, Palermo, Italy; [6]Department of Health Promotion Sciences, Maternal and Infant Care, Internal Medicine and Medical Special-ties (PROMISE), University of Palermo, Dipartimento di Promozione della Salute, Materno-Infantile, di Medicina Interna e Specialistica "G. D'Alessandro", PROMISE, University of Palermo, Palermo; [7]Medicina Interna ed Epatologia, Dipartimento di Promozione della Salute, Materno-Infantile, di Medicina Interna e Specialistica "G. D'Alessandro", PROMISE, University of Palermo, Palermo; [8]INSERM U624, Marseilles, France*
Email: lydiagiannitp@gmail.com

Background and aims: The term metabolic dysfunction-associated steatotic liver disease (MASLD) has been introduced to indicate the involvement of liver in Metabolic Syndrome (MetS). Extra Virgin Olive Oil (EVOO), could be the added value of Mediterranean Diet (MD) in the dietary intervention for this condition. We evaluated the efficacy of a high-polyphenol content EVOO (HPPE) on clinical and laboratory parameters of liver function and on expression levels of genes related to endoplasmic reticulum (ER) stress and lipid metabolism, in two groups of MetS/MASLD patients.
Method: Sixty consecutive MetS/MASLD patients were enrolled at Internal Medicine Unit of University Hospital of Palermo and randomized, in a single-center double-blind prospective study, to add HPPE or standard EVOO (SE) (40 ml/daily for 6 months) to the MD. Anthropometric measures, liver function, metabolic status, flow mediated dilatation (FMD), liver ultrasound and abdominal fat features, were analyzed at baseline (T0) and after 6 months (T6). We analyzed the gene expression pattern of some metabolic pathways involved in ER and oxidative stress, lipidic metabolism and development of steatosis, by extraction and subsequent amplification of the RNA from PBMCs
Results: The dietary intervention was well accepted by patients who showed high compliance. From T0 to T6, waist circumference (WC), glycated hemoglobinemia (HbA1C), subcutaneous and visceral fat thickness significantly improved in both HPPE ($p < 0.0001$, $p < 0.03$, $p < 0.0001$, $p < 0.04$ respectively) and SE ($p < 0.0001$, $p < 0.04$, $p < 0.0001$, $p < 0.03$ respectively) group. Insulinemia, HOMA-IR, AST and FMD improved only in HPPE group ($p < 0.03$, $p < 0.03$, $p < 0.01$, $p < 0.001$ respectively). At US evaluation, we observed a trend in reduction in both groups, especially in moderate to severe stages. A significant reduction in the expression of TRB3 (gene involved in ER stress), FASN, SREBP1, PPARα, PPARγ and CPT1a (involved in lipid metabolism) was observed from T0 to T6 in the HPPE group, while a significant increase in the expression of TRB3 and FASN was observed in the SE group. We analyzed PNPLA3 (rs738409), TM6SF2 (rs58542926), PCSK9 (LOF) (rs1159114), PCSK9 (GOF) (rs505151) and GCKR (rs1260326) polymorphisms, proving that the minor allele frequency (MAF) in both HPPE and SE group are equivalent to general population.
Conclusion: MD plus EVOO intake for 6 months can improve metabolic and cardiovascular parameters in MetS/MASLD subjects, reducing both anthropometric and insulin resistance indexes, and improving endothelial disfunction. A trend in reduction has been observed for liver steatosis, consistent to the reduction of FASN and SREBP1 expression. This suggest that MD plus EVOO intake might influence the pathways involved in liver steatosis development and that a longer duration of this dietary intervention might reduce the degree of liver steatosis in a more significant way.

TOP-204

Inhibition of sodium-glucose cotransporter-2 and liver-related complications in diabetic patients

Sung Won Chung[1,2], Hyunjae Shin[1], Jeayeon Park[1], Moon Haeng Hur[1], Min Kyung Park[1], Yun Bin Lee[1], Su Jong Yu[1], Jung-Hwan Yoon[1], Jeong-Hoon Lee[1], Yoon Jun Kim[1]. *[1]Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, Korea, Rep. of South; [2]Division of Gastroenterology, Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Rep. of South*
Email: pindra@empal.com

Background and aims: No medication has been found to reduce the liver-related events. We evaluated the effect of sodium-glucose cotransporter-2 inhibitor (SGLT2i) on liver-related outcomes.
Method: Single nucleotide polymorphisms (SNPs) associated with SGLT2 inhibition were identified, and a genetic risk score (GRS) was computed using the UK Biobank (UKB) data (n = 337, 138). Two-sample Mendelian randomization (MR) was conducted using the FinnGen (n = 218, 792) database and UKB data. In parallel, a nationwide population-based study using the Korean National Health Insurance Service (NHIS) database was conducted. The development of liver-related complications (i.e., hepatic decompensation, hepatocellular carcinoma, liver transplantation, and death) was compared between individuals with type 2 diabetes mellitus and steatotic liver diseases treated with SGLT2i (n = 13, 208) and propensity score-matched patients treated with dipeptidyl peptidase-4 inhibitor (DPP4i) (n = 70, 342).
Results: After computing GRS with six SNPs (rs4488457, rs80577326, rs11865835, rs9930811, rs34497199, and rs35445454), GRS-based MR showed that SGLT2 inhibition (per 1 SD increase of GRS, 0.1% lowering of HbA1c) was negatively associated with cirrhosis development (adjusted odds ratio = 0.83, 95% confidence interval [CI] = 0.70-0.98, P = 0.03). When the individuals of UKB population were divided based on GRS and compared the risk of liver-related complications between the upper 5% and the lower 95% of individuals, the top 5% of individuals had substantially fewer liver-related complications than the bottom 95% of individuals (adjusted hazard ratio [aHR] = 0.60, 95% CI = 0.37-0.97, P = 0.038). This was consistent in two-sample MR (odds ratio = 0.73, 95% CI = 0.60-0.90, P = 0.003). In the Korean NHIS database, the risk of liver-related

complications was significantly lower in the SGLT2i group than in the DPP4i group (adjusted hazard ratio [aHR] = 0.88, 95% CI = 0.79–0.97, P = 0.01), and this difference remained significant (aHR = 0.75–0.88, all P < 0.05) across various sensitivity analyses.
Conclusion: Both Mendelian randomizations using two European cohorts and a Korean nationwide population-based cohort study suggest that SGLT2 inhibition is associated with a lower risk of liver-related events.

TOP-205
Effect of a physical exercise program on the cerebral hemodynamics of patients with metabolic dysfunction-associated steatotic liver disease
Berenice M. Román-Calleja[1], Fernando Martinez Cabrera[1], Regina Romo[1], Carlos Cantu Brito[2], Carlos Aguilar Salinas[3], Ricardo Macias-Rodriguez[1], Astrid Ruiz Margáin[1]. *[1]Department of Gastroenterology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [2]Department of Neurology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [3]Direction of Investigation, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*
Email: astrid.ruizm@incmnsz.mx

Background and aims: In patients with obesity and metabolic conditions, microvascular changes can be found, leading to early cognitive impairment. Impairment in the normal cerebral blood flow and cognition have been described in patients with liver steatosis. Physical exercise is beneficial for patients with metabolic dysfunction-associated steatotic liver disease (MASLD) and can potentially help with cognitive function and cerebral hemodynamics, however this has not been explored. Therefore, we aimed to evaluate the effects of a physical exercise program on cerebral hemodynamics in patients with MASLD.
Methods: This was a 16-week randomized open clinical trial. Control group (n = 20) received diet with caloric restriction of 20% of energy needs by indirect calorimetry and the Intervention group (n = 20) received diet (same as control) + exercise; exercise intervention consisted of walking and gradually increasing 5000 steps, monitored by an activity tracker combined with resistance exercise. All patients received printed book as a cognitive exercise. Body composition, controlled attenuation parameter, liver stiffness, neurocognitive tests, and transcranial doppler ultrasound were obtained at baseline and final evaluations. Patients received weekly text messages to assess compliance and had monthly in-person visits.
Results: 57% of patients were female with a mean age of 46 ± 7 years and BMI of 35.9 ± 5.0 kg/m^2. Adherence to the intervention was >85%. In the exercise group, the number of steps increased from 6177 (4881–9187) to 11190 (10533–15767) (p < 0.01) vs 6339 (4982–8166) to 7341 (6104–9111) (p = 0.180) in controls. In both groups, patients had significant reduction in waist circumference and BMI (3.4% and 4.2% intervention p < 0.05 vs 2.8% and 3.1% in controls p < 0.05). Exercise group showed improvement in: cerebral hemodynamics [Resistance index 0.76 (0.51–0.98) to 0.56 (0.43–0.73), p = 0.033, pulsatility index in 0.99 (0.98–1.01) to 0.74 (0.68–0.90), p = 0.012] and Breath Holding Index 0.65 (0.54–0.72) to 0.71 (0.63–0.89), p = 0.096, cognitive function [Addenbrooke 84 (82–87) to 96 (92–98), p = 0.002], steatosis (CAP 362 ± 31 to 304 ± 35 dB/m, p = 0.031). Fat mass was reduced in the intervention group (4.6 ± 1.2%, p = 0.018) while muscle mass increased (1.9 ± 0.7%, p = 0.033). The proportion of patients having >7% reduction in body weight loss were also significantly higher in the intervention (55%) compared to control group (30%), p = 0.023.
Conclusion: Exercise improves cerebral hemodynamics and cognitive function, as well as body composition in patients with MASLD.

TOP-216
The three strain probiotics for metabolic dysfunction-associated steatotic liver disease improvement: a parallel, double-blind, randomized, placebo-controlled trial
Sung-Min Won[1,1], Sang Jun Yoon[1], Jin-Ju Jeong[1], SatyaPriya Sharma[1], Ki Kwang Oh[1], Dong Hoon Yang[1], Hyun Joon Park[1], Sang Gyune Kim[2], Moon Young Kim[3], Ki Tae Suk[4]. *[1]Institute for Liver and Digestive Diseases, Hallym University, Chuncheon, Korea, Rep. of South; [2]Soonchunhyang University Hospital, Bucheon, Korea, Rep. of South; [3]Department of Internal Medicine, Division of Gastroenterology and Hepatology, Yonsei University Wonju College of Medicine, Wonju, Korea, Rep. of South; [4]Hallym University College of Medicine, Chuncheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: metabolic dysfunction-associated steatotic liver disease (MASLD) is associated with an dysbiosis in the gut microbiota. We evaluated whether probiotic treatment affected liver function parameters and stool microbiome in patients with MASLD.
Method: We performed a double-blind parallel trial of 110 patients with MASLD. Participants (mean age, 47.0 ± 13.6 years; 61% men) were randomly assigned to groups given the probiotics (*Lactobacillus lactis* CKDB001, LL001; *Lactobacillus helveticus* CKDB001, LH001; *Pediococcus pentosaceus* KID7, PPKID7; 1 capsule: 9.0 × 109 CFU, 3 capsule per day; n = 85) or placebo (n = 25) for 8 weeks. Stool and blood samples were collected at the start and end point of the study. The stool microbiome was analyzed by 16S ribosomal DNA sequencing.
Results: After 8 weeks, in the probiotic group, LL001 treatment improved ALT (87.3 ± 8.2 to 71.1 ± 6.0, p = 0.01) and AST levels (64.9 ± 4.9 to 50.0 ± 3.5 U/L, p = 0.001), LH001 treatment improved body weight (78.4 ± 3.0 to 77.2 ± 2.8 kg, p = 0.01), and PPKID7 treatment improved total cholesterol levels (186.1 ± 7.0 to 178.0 ± 7.9 mmol/L, p = 0.03). Additionally, LH001 treatment significantly decreased PT and INR. In the 16S sequencing analysis, probiotic treatment decreased the abundance of Proteobacteria, and in particular, an increase in the abundance of family Ruminococcaceae and Lachnospiraceae was observed in the LL001 group after 8 weeks. In the pre- and post-comparison of probiotic treatment at the level of the top 20 genera, a tendency was observed to decrease genera Haemohlius and Ruminococcus_g2, while increasing genus Bifidobacterium.
Conclusion: In a randomized clinical trial of patients with MASLD, 8 weeks of treatments of three probiotics were associated with changes in the stool microbiome and improvements in blood biochemical parameters of MASLD (ClinicalTrials.gov, Number: NCT04555434).

A randomized, placebo-controlled phase Ib/IIa trial to evaluate the safety, tolerability, and efficacy of BGT-002, an adenosine triphosphate citrate lyase inhibitor in patients with NAFLD: interim analysis
Yue Hu[1], Hong Zhang[1], Guoyue Lv[1], Fajun Nan[2], Jingya Li[2], Yangming Zhang[2], Dandan Wu[1], Yanhua Ding[3], Junqi Niu[1]. *[1]The First Hospital of Jilin University, Changchun, China; [2]Burgeon Therapeutics Co., Ltd., Shanghai, China; [3]The First Hospital of Jilin University, Chanchun, China*
Email: dingyanhua2003@126.com

Background and aims: The prevalence and incidence rate of NAFLD are increasing, which has become a serious public health burden, but the treatment options are limited worldwide. The primary aim of this clinical trial is to evaluate the safety, pharmacokinetics, and efficacy of BGT-002 that is an adenosine triphosphate citrate lyase inhibitor in NAFLD patients.
Method: This is a double-blind and randomized phase Ib/IIa study in 48 NASH patients (aged 18–65 years), the study is consisted of four multiple ascending dose cohorts (50 mg, 75 mg, 100 mg and 150 mg) in which twelve participants were enrolled for every cohorts of which nine received BGT-002 and three received placebo orally once daily

for 28 days. The patients who met the following major criterias: ALT >1 × ULN within 3 months without other reasons; BMI ≥25 kg/m^2; MRI-PDFF ≥10% during screening and baseline and body weight gain or loss ≤5% within 4–8 weeks prior to administration were enrolled.
Results: A total of 42 NAFLD patients were enrolled, 36 patients completed the study and 12 patients are undergoing treatment.
36 NAFLD patients were evaluated for safety up to now. 18 of 36 (50%) patients experienced at least one adverse drug reaction (ADR). Most ADRs were grade 1–2. No drop-outs, no SAE. BGT-002 was safe and well-tolerated in this study. After the consecutive administration of BGT-002 50 mg QD, 75 mg QD and 100 mg for 28 days, the plasma concentration reached steady state on the third day, with a T_{max} of 1.056 to 1.537 h, respectively. The mean C_{max} and AUC_{tau} were 22577.78–48955.56 ng/ml and 423943.6–913589.4 ng·h/ml respectively. The mean half-life of BGT-002 was 30 h. The accumulation ratio of drug plasma exposure was 4.876–5.690. LFC was measured by MRI-PDFF at baseline and day 29. LFC have been significantly decreased after a 28-day therapy. The patients receiving BGT-002 or placebo 50 mg, 75 mg or 100 mg once daily had a mean relative reduction from baseline in LFC of −26.6% (n = 12), −27.0% (n = 12) and −28.5% (n = 12). The mean absolute reduction of the LFC in three cohorts were −5.1%, −4.0% and −6.4% from baseline at the end of the treatment. ≥30% LFC reduction relative to baseline was measured in 4 (33.3%), 5 (41.7%) and 6 (50.0%) in the 50 mg QD, 75 mg QD and 100 mg QD cohort, respectively. There were 10 (10/36) patients whose LFC level less than 10% on day 29. The biomarker of lipids such as TC, LDL-C and TG declines of varying degrees were observed, especially the decrease in LDL-C was more significant. The level of liver enzyme were evaluated throughout the study. And the improvement of ALT, AST and GGT was observed, especially the GGT level showed a significantly decrease during treatment.
Conclusion: The findings from interim analysis of this study, it was observed that a significant reduction in LFC, lipids and GGT level of NAFLD patients enrolled after 28-days treatment. BGT-002 is safe and well-tolerated. And it might be a promising for NAFLD.

Effect of statin therapy in patients with obesity and cirrhosis secondary to metabolic dysfunction-associated steatotic liver disease (MASLD) on pre-liver transplant mortality

Ami Patel[1], Katherine Cooper[2], Alessandro Coletta[2], Deepika Devuni[2].
[1]UMass Chan Medical School, Worcester, United States; [2]UMass Chan Medical School, Worcester, United States
Email: ami.patel@umassmemorial.org

Background and aims: There is increasing data to suggest that statin medications have beneficial effects in patients with liver disease. In our previous work, we demonstrated that statins reduced pre-liver transplant (LT) mortality in patients with metabolic dysfunction associated liver disease/steatohepatitis (MASLD). In this study we analyzed the impact of statins on pre-LT mortality in patients based on disease etiology and BMI.
Method: We performed a single-center retrospective review of patients evaluated for LT between January 1, 2018–June 30, 2021. Demographic and clinical data were collected through review of electronic medical records. Patients were categorized by statin prescription (statin vs. no statin), liver disease etiology (Metabolic dysfunction-associated steatohepatitis (MASH) vs. non-MASH), and body mass index (BMI >40 vs. BMI <40). The primary outcome was pre-LT death. Variables were assessed for association using chi-squared and t-tests.
Results: A total of 623 patients were included, of which 115 were on a statin medication. Patients on a statin were significantly more likely to have cirrhosis secondary to MASH (53% vs. 15%, p < 0.001), have a BMI >40 (15% vs. 8%, p = 0.020) and have a prior cardiac diagnosis (39% vs. 17%, p < 0.001). Patients with BMI >40 experienced higher pre-LT mortality compared to patients with a BMI <40 (36.4% vs. 17.3%, p < 0.001). In patients prescribed a statin medication, there was no significant relationship between BMI and pre-LT mortality (16.7% vs. 17.2%, p = 0.958) or MASH and pre-LT mortality (13.1% vs. 21.4%, p = 0.180). In patients not on a statin, BMI >40 was associated with higher pre-LT mortality (44.7% vs. 17.2%, p < 0.001) and MASH was also associated with pre-LT mortality in this subgroup (28.6% vs. 17.9%, p = 0.023). Interestingly, statins had the largest impact on pre-transplant mortality in patients with combined diagnoses of MASH and a BMI >40 (8.3% vs. 60%, p = 0.004). Cardiac history was associated with death in the non-statin group (p = 0.014) but not in the statin group (p = 0.349).
Conclusion: In this analysis, we found that patients with MASH cirrhosis and patients with a BMI >40 who were taking a statin medication at the time of their LT evaluation were less likely to die on the waitlist compared to patients with MASH or BMI >40 who were not prescribed a statin medication. Our results may suggest that statins confer protective benefits to patients with MASH cirrhosis and patients with BMI >40, especially when in combination. These findings may be related to optimization of cardiac health in LT candidates.

SAT-195

Effects of icosabutate, a dual free fatty acid receptor-1 and -4 agonist, on elevated non-invasive markers of liver injury, fibrosis and glycemic control in type 2 diabetic MASH patients and F1-F3 fibrosis

Naim Alkhouri[1], David A. Fraser[2], Hilde Steineger[3], Mazen Noureddin[4], Quentin M. Anstee[5], Stephen A. Harrison[6,7].
[1]Arizona Liver Health, Chandler, United States; [2]Northsea Therapeutics, Amste, Netherlands; [3]Northsea Therapeutics, Amsterdam, Netherlands; [4]Houston Research Institute and Houston Methodist Hospital, Houston, United States; [5]Newcastle University, Translational and Clinical Research Institute, Faculty of Medical Science, Newcastle, United Kingdom; [6]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom; [7]Pinnacle Clinical Research, San Antonio, United States
Email: david.fraser@northseatherapeutics.com

Background and aims: Icosabutate (ICO) is a novel, oral, once-daily, liver-targeted, dual free fatty acid receptor (FFAR) -1 and -4 agonist. In the 52 wk phase 2B ICONA study comparing 300 mg or 600 mg ICO therapy with placebo in subjects with MASH and F1–F3 fibrosis, a significant histological response was identified in patients with type 2 diabetes (T2D) treated with 600 mg ICO for both MASH resolution with no worsening of fibrosis and ≥2-point decrease in NAS (effect size 31%, p = 0.007) and for ≥1-stage improvement in fibrosis with no worsening of MASH (effect size 19%, p = 0.02). These findings were seen in conjunction with a placebo-corrected decrease in HbA1c of ~1% (p < 0.05) in subjects with poor glycemic control (baseline HbA1c ≥6.5%). The aim of this study was to assess the effects of ICO therapy on cases with elevated baseline non-invasive markers of liver injury and fibrosis (NITs), along with concordance between fibrosis response and decreases in ALT and enhanced liver fibrosis score (ELF).
Method: Liver chemistries (ALT, AST) and markers of fibrosis (neoepitope-specific, N-terminal pro-peptide of collagen Type III collagen [PRO-C3], ELF score and amino terminal of type III procollagen peptide (P3NP) and fasting plasma glucose (FPG) were assessed in T2D MASH with baseline and week 52 biopsies receiving 300 mg ICO (n = 39), 600 mg ICO (n = 40) or placebo (n = 35). Treatment effect versus baseline was established using ANCOVA in subjects with elevated baseline levels (ALT >40 U/L; AST >34 U/L; PRO-C3 ≥12.6 ng/ml; ELF ≥9.8; P3NP ≥10 ng/ml; FPG ≥126 mg/dl).
Results: Sixty-eight percent of all T2D subjects were identified with elevated baseline ALT, with corresponding values of 57% (AST), 76% (PRO-C3), 55% (ELF) and 64% for both P3NP and FPG. Treatment with 600 mg ICO induced pronounced and significant (all p < 0.0001 vs baseline) reductions in mean ALT (-40 U/L [-50%]), AST (−30 U/L

[−50%]) and P3NP (−6.5 ng/ml [−40%]). Significant reductions were also observed in mean PRO-C3 (−6.1 ng/ml [−30%], p = 0.0002) and ELF score (−0.63 units, p = 0.008). A similar, but more attenuated, effect was observed in the 300 mg ICO treatment arm for all biomarkers (range −19 to −28% versus baseline), whereas the placebo arm showed no significant change in any variable (range −7 to +3% versus baseline). In alignment with the observed decrease in HbA1c, ICO treatment reduced mean FPG by 21% (p = 0.01) and 20% (p = 0.007) versus baseline for 300 mg and 600 mg respectively (placebo unchanged). Irrespective of T2D status, 82% (9/11) of fibrosis in the 600 mg treatment arm had a combined decrease in ALT of >17 U/L and ELF score >0.5 units versus 13% in non-responders.
Conclusion: Once-daily, oral therapy with 600 mg ICO induces pronounced reductions in multiple elevated markers of liver injury and fibrosis in T2D MASH patients. Furthermore, a simultaneous decrease in ALT and ELF score may help identify histological responders to ICO therapy.

SAT-196

A significant decrease in steatosis using non-invasive measurements during monitoring for life style changes in patients with MASLD: interim 6 m results of a monocentric study

Wouter Robaeys[1,2,3], Leen Heyens[4,5,6,7], Struyve Mathieu[8,9], Gert Stockmans[10], Kirsten Cardone[11], Joop Arends[4,12], Ger Koek[13,14], Geert Robaeys[9], Joris Penders[8,9], Sven Francque[15,16,17]. *[1]Hasselt University, Faculty of Medicine and Life Sciences, Diepenbeek, Belgium; [2]Ziekenhuis Oost Limburg, Department of Gastroenterology and Hepatology, Genk, Belgium; [3]Ziekenhuis Oost Limburg, Department of Limburg Clinical Research Center, Genk, Belgium; [4]Maastricht University, Maastricht, Netherlands; [5]Hasselt University, Hasselt, Belgium; [6]Ziekenhuis Oost Limburg, department of Gastroenterology and Hepatology, Genk, Belgium; [7]Ziekenhuis Oost Limburg, department of Limburg Clinical Research Center, Genk, Belgium; [8]Ziekenhuis Oost Limburg, Genk, Belgium; [9]Hasselt University, Diepenbeek, Belgium; [10]Ziekenhuis Oost Limburg (Maas en Kempen), Maaseik, Belgium; [11]Ziekenhuis Oost Limburg, Department of Limburg Clinical Research Center, Genk, Belgium; [12]Maastricht University Medical Center, Maastricht, Netherlands; [13]Maastricht University, Faculty of Health, Medicine and Life Sciences, Maastricht, Belgium; [14]Maastricht University Medical Center, Department of Internal Medicine division Gastroenterology and Hepatology, Maastricht, Netherlands; [15]University of Antwerp, Antwerp, Belgium; [16]Translational Sciences in Inflammation and Immunology, Laboratory of Experimental Medicine and Paediatrics, Faculty of Medicine and Health Sciences, Antwerp, Belgium; [17]Antwerp University Hospital, Department of Gastroenterology and Hepatology, Edegem, Belgium*
Email: wouter.robaeys@uhasselt.be

Background and aims: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) is an important cause of chronic liver disease. Currently, the cornerstone of therapy is lifestyle modification (diet and exercise). Using paired liver biopsy studies, a weight reduction of more than 5% of body weight (BW) might be sufficient to reduce steatosis (at least one stage). This study investigates the outcome of a reduction of more than 5% of body weight (BW) on steatosis in patients with MASLD using non-invasive methods.
Method: In this ongoing, monocentric (Ziekenhuis Oost Limburg, Genk, Belgium), prospective study patients with MASLD (Controlled Attenuation Parameter CAP^{TM} ≥215 dB/m) are consecutively included since October 2022 to receive lifestyle intervention during 1 year. After 6 months (M6) and 1 year they are re-evaluated (clinical and biochemical evaluation, as well as liver stiffness measurement (LSM) by transient elastography (FibroScan®) and CAP^{TM}).
Results: From October 2022 until December 2023, 297 patients were included. Their mean age was 52 ± 12 years, 47 % were female, 9 % had type 2 diabetes, 40 % metabolic syndrome, 53 % were living with obesity, 20 % were known with arterial hypertension. As of the 31st of December 2023, 111 patients presented at the M6 control visit: 41 (37 %) of the patients lost of more than 3 % of BW, 23 (21 %) more than 5 % of BW, 13 (12 %) more than 7 % of BW, and 3 (3 %) more than 10 % of BW. Eight percent (n = 9) of the patients demonstrated a complete resolution of steatosis using the CAP^{TM} criterion. In 66 % of them this occurred only after a weight reduction of more than 7 % of BW. In patients with a weight loss of more than 5 % of BW a significant reduction in Hepatic Steatosis Index (HSI), Fatty Liver Index (FLI) and CAP^{TM} (M-probe) was observed (p < 0.001, p = 0.001, p = 0.02, resp.), but not in FIB-4 and LSM. The change in Body Mass Index (BMI) explained 65% of the variation in HSI change but only 15% in FLI change. After addition of other variables in the HSI and FLI formula to the regression model only ALAT explained extra 12% of the variation in HSI. Biochemically, there was a significant decrease in alanine transferase (ALAT) (p = 0.04), HbA1c (p < 0.001) and triglycerides (TG) (p = 0.02), but not in aspartate transferase (ASAT), total serum cholesterol, HDL- cholesterol, LDL-cholesterol, Homeostatic model for insulin resistance (HOMA-IR) value and glycaemia.
Conclusion: A significant reduction in steatosis and liver biochemistry, as well as HbA1c and TG was seen already after 6 months using non-invasive blood-based measurements (HSI and FLI) and CAP^{TM} in patients decreasing more than 5% of BW. The change in BMI only partly explained the variation in HSI and to a lesser extent FLI change, suggesting they can be used as markers of steatosis improvement. To achieve a resolution of MASLD a significant weight loss of more than 7% of BW is needed in most of the patients.

SAT-197-YI

Higher serum vitamin D levels is associated with lower MASLD prevalence and incidence: the Rotterdam study

Ibrahim Ayada[1], Yasir J. Abozaid[2,3], Jesse Pustjens[1], Laurens van Kleef[1], Robert J. de Knegt[1], Willem Pieter Brouwer[1], Mohsen Ghanbari[2]. *[1]Department of Gastroenterology and Hepatology, Erasmus MC, University Medical Center, Rotterdam, The Netherlands, Rotterdam, Netherlands; [2]Department of Epidemiology, Erasmus MC, University Medical Center, Rotterdam, The Netherlands, Rotterdam, Netherlands; [3]Department of Microbiology and Pathology, College of Veterinary Medicine, University of Duhok, Iraq, Duhok, Iraq*
Email: i.ayada@erasmusmc.nl

Background and aims: Metabolic dysfunction associated steatotic liver disease (MASLD) affects around 30% of adults worldwide and there is no approved therapy yet. Therefore, it remains pivotal to identify risk factors impacting this global healthcare burden. Emerging evidence indicates a potential link between vitamin D deficiency and the development of MASLD and progression towards fibrosis. However, the evidence is conflicting, longitudinal assessments are lacking and data on MASLD severity is scarce. Therefore we investigated the associations between vitamin D and MASLD and its severity in a longitudinal cohort study.
Method: We included participants from the prospective population-based Rotterdam study with data on serum concentration of 25-hydroxyvitamin D and FLI. MASLD was assessed by fatty liver index (FLI) at baseline. Associations between vitamin D and MASLD were investigated by logistic regression models that were adjusted for demographics, indicators for metabolic dysfunction, season and kidney function. Longitudinal analysis included associations between vitamin D and incident MASLD based on FLI and on ultrasound obtained 5 to 10 years after baseline. Sensitivity analysis included incident MASLD with ALT>35 or high liver stiffness defined as LSM ≥8 kPa.
Results: We included 7921 participants (age 62.8 (7.9), 57% female) and MASLD was prevalent in 34.1% at baseline. Vitamin D was significantly associated with MASLD at baseline (aOR 0.83, 95%CI 0.75-0.91, per 1 increase of log Vitamin D). Of the 5217 participants that did not have MASLD at baseline, 3102 (age 59.2 (6.06), 65% female) were included for longitudinal analysis and 13.7% developed incident MASLD based on FLI). Additionally, 3204 participants had follow-up data on ultrasound (age 59.3 (6.1), 65% female) and 21.8%

developed incident MASLD). In line with the cross-sectional analysis, vitamin D was significantly associated with incident MASLD, for both MASLD based on FLI (aHR 0, 84, 95% CI 0, 72–0, 98, per 1 increase of log Vitamin D) and ultrasound (aHR 0, 88 95% CI 0, 78–0, 99, per 1 increase of log Vitamin D). Results were consistent across both sexes. Similar directions of effect were obtained when focusing on incident MASLD with elevated ALT (aHR 0, 74 95% CI 0, 53–1, 03, per 1 increase of log Vitamin D) and incident MASLD with high liver stiffness (aHR 0, 87, 95% CI 0, 64–1, 17, per 1 increase of log Vitamin D), though not reaching statistical significance.

Conclusion: In this study, higher serum vitamin D concentration demonstrated significant association with lower prevalence and incidence of MASLD, and potentialy linked with reduced MASLD severity. While the exact mechanisms are unknown, maintaining adequate vitamin D levels may have an impact on the development and progression of MASLD, particularly in individuals at risk of or diagnosed with MASLD.

SAT-198

ASC41, a selective THRβ agonist significantly reduces liver fat and ALT in biopsy-confirmed MASH patients after 12-week treatment: an interim analysis of a 52-week serial liver biopsy study

Email: corresponding@ascletis.com

Background and aims: ASC41 is a liver-targeting small molecule agonist. Oral, once-daily ASC41 tablet was developed using proprietary formulation technology. ASC41-A, an active metabolite from ASC41, is highly potent and selective against THRβ. Three phase I or Ib studies were completed in healthy or obese subjects with elevated LDL-C >110 mg/dL. A U.S. Phase I study demonstrated no clinically significant drug-drug interactions between ASC41/ASC41-A and most frequently used antidepressants and statins as well as no significant difference in drug exposure between Americans and Chinese at the same dose. We reported here a pre-specified interim analysis.

Method: ASC41-202 (NCT05462353) is a randomized, double-blind, placebo-controlled and multi-center Phase II clinical study, which enrolls approx. 180 liver biopsy-confirmed MASH patients (≥7.5% liver fat, NAS ≥4, F1 (<15%), F2, F3) in 3 cohorts of ASC41 tablet (2 mg or 4 mg), once-daily and placebo (1:1:1) for 52-week treatment. Primary end point is a histological reduction in NAS ≥2 points that results from reduction of necro-inflammation without worsening fibrosis. Pre-specified interim analysis was conducted when 42 patients completed 12-week treatment.

Results: Mean baseline liver fat content was 18.2%, 17.8% and 18.9% for placebo (n = 14), 2 mg (n = 13) and 4 mg ASC41 (n = 15), respectively. At week 12, mean relative changes from baseline (CFBs) in liver fat were −13.1%, −55.0% (p = 0.0001 vs placebo) and −68.2% (p < 0.0001 vs placebo) for placebo, 2 mg and 4 mg ASC41, respectively. Percentages of patients achieving ≥30% and ≥50% relative reduction in liver fat from baseline were 21.4% and 21.4%, 92.3% (p = 0.0002) and 46.2% (p = 0.24), 93.3% (p < 0.0001) and 86.7% (p = 0.0004) for placebo, 2 mg and 4 mg ASC41. Percentages of patients achieving normalized liver fat (≤5% absolute liver fat) were 0.0%, 30.8% (p = 0.16) and 66.7% (p = 0.0017) for placebo, 2 mg and 4 mg ASC41. Mean baseline ALT was 77.6, 65.9 and 84.8 U/L for placebo, 2 mg and 4 mg ASC41. At week 12, mean relative CFBs in ALT were 5.2%, −8.5% (p = 0.61) and −32.6% (p = 0.0051) for placebo, 2 mg and 4 mg ASC41. Percentages of patients achieving mean ALT decrease >17 U/L were 21.4%, 30.8% (p = 0.68) and 73.3% (p = 0.0052) for placebo, 2 mg and 4 mg ASC41. Statistically significant reduction in AST was also observed for 4 mg ASC41. Statistically significant mean relative CFBs in LDL-C, TC and TG were observed for both 2 and 4 mg ASC41 vs placebo. AEs were grade 1 in majority across all cohorts. Among patients receiving ASC41 treatment, only two patients (2/28, 7.1%) reported drug-related grade 2 TEAEs. No drug-related grade 3 or higher TEAEs or SAEs were observed in patients receiving ASC41 treatment. ASC41 demonstrated excellent GI tolerability.

Conclusion: Significant reductions in Liver fat, ALT, AST and lipids at week 12 warrant further clinical studies for ASC41 tablet.

SAT-199

Long term outcomes of Saroglitazar in metabolic-dysfunction associated steatotic liver disease related cirrhosis-a prospective cohort study

Rakhi Maiwall[1], Neha Chauhan[1], Priyanka Sharma[1]. *[1]Institute of Liver and Biliary Sciences, Delhi, India*
Email: rakhi_2011@yahoo.co.in

Background and aims: Saroglitazar (SARO), a peroxisome proliferator-activated receptor agonists (PPAR) agonist has shown efficacy in metabolic-dysfunction associated steatotic liver disease (MASLD), however, the data is limited in patients with cirrhosis. We aimed to investigate the efficacy of SARO in improving outcomes in patients with MASLD-related cirrhosis.

Method: Prospective cohort study wherein patients treated with SARO were compared to controls managed with standard of care (SOC). Liver (LSM) and spleen stiffness measurements (SSM)were performed for all patients using transient elastography (reported in KPa) at enrolment, at the time of drug initiation and last follow-up. Response was defined as reduction in LSM by 20% or a decrease in SSM by 10% from the baseline

Results: A total of 182 patients with MASLD-cirrhosis, 44% biopsy-proven, mean age 50.3 ± 10.2 years, 77% males, 79% morbidly obese, 30% with diabetes were enrolled. The mean controlled attenuation parameter (CAP) was 252 ± 49.4, LSM 34.5 ± 18.7, SSM 51.6 ± 24.3, HOMA-IR 2.95 ± 2.62, hepatic venous pressure gradient (HVPG), n = 80) 13.3 ± 4.6 mm of Hg, and CTP score was 6.3 ± 1.6 and all these patients were followed for median 399 days. Of the total patients, 6% had a family history, 51% with patatin-like phospholipase domain-containing 3 (*PNPLA3* rs738409) GG-genotype, and 73 (40%) received SARO. A significant correlation of HVPG was seen with LSM (p < 0.001, r-0.45) and SSM (p < 0.001, r-0.41). Patients treated with SARO were significantly more morbidly obese, worse lipid profile, and LSM and C-reactive protein (CRP) levels compared to SOC group (p < 0.05). The LSM and SSM response on the SARO was observed in 25 (34%) and 43 (60%) while 15 (20.5%) had response in both parameters at median of 8 (IQR 9–13) months. A significant reduction was observed in the LSM [(29.5 ± 16.1)vs (26.9 ± 14.9);p = 0.032], CAP[(255.2 ± 48.2)vs. (237.4 ± 45.6);p = 0.008], HOMA-IR [(2.76 ± 2.43 vs. (2.08 ± 1.02); p = 0.01], LDL-cholesterol [(96.4 ± 1.6)vs. (83.9 ± 36.6);p = 0.07], HBA1C [(6.1 ± 1.60vs. (5.7 ± 1.10); p = 0.04) and SSM [(50.1 ± 23.3) vs. 42.9 ± 22.28); p < 0.001] pre and post SARO respectively. On the contrary, only a significant reduction in SSM [(52.7 ± 25.1 to 47.6 ± 21.9); p < 0.001] and HBA1C [(6.01 ± 1.90 to (5.5 ± 1.4); p = 0.002) was observed in the SOC group. Adverse events were mild and reversed with drug discontinuation in 8%.

Conclusion: Almost one in five patients of MASLD-related cirrhosis showed response in both LSM and SSM after saroglitazar. Reduction in SSM was seen in 60% and 30% had LSM response. Improvement in surrogate parameters of fibrosis, portal hypertension and insulin resistance could be achieved after long-term treatment with saroglitazar in patients with MASLD-related cirrhosis without any major adverse events.

Statin use is associated with liver fibrosis regression in the general population: a longitudinal analysis of The Rotterdam Study

Jesse Pustjens[1], Laurens van Kleef[1], Ibrahim Ayada[1], Harry L.A. Janssen[1,2], Maryam Kavousi[3], Layal Chaker[3,4], Arfan Ikram[3], Robert J. de Knegt[1], Bruno Stricker[3], Bettina E. Hansen[1,2,3,5], Willem Pieter Brouwer[1]. *[1]Department of Gastroenterology and Hepatology, Erasmus MC, University Medical Centre, Rotterdam, Netherlands; [2]Toronto Centre for Liver Disease, Toronto General Hospital, University Health Network, Toronto, Canada; [3]Department of Epidemiology, Erasmus MC University Medical Centre, Rotterdam, Netherlands; [4]Department of Internal Medicine, Erasmus MC University Medical Centre, Rotterdam, Netherlands; [5]IHPME, University of Toronto, Toronto, Canada*
Email: j.pustjens@erasmusmc.nl

Background and aims: Liver fibrosis is a growing public health concern, especially due to the increasing prevalence of steatotic liver disease. There are no approved therapeutic options that target fibrosis progression. Recently, statins have demonstrated possible protective effects in cross-sectional studies. Here we assess the effects of incident statin use on liver stiffness changes through longitudinal analyses.

Method: We analyzed participants from the Rotterdam Study, a large prospective population-based cohort study, who underwent serial liver stiffness measurements (LSM) by FibroScan. Participants with an unreliable Fibroscan, viral hepatitis, excessive alcohol use (>60 g/day in males, or >50 g/day in females), or those already on statin treatment, were excluded. To diminish confounding and assess the potential therapeutic effect of statin use, inverse probability of treatment weighting (IPTW) was used in combination with linear and logistic regression analyses. Covariates included in the propensity score model were age, sex, baseline LSMlg10, body mass index, waist circumference, serum lipid-profile, (pre-)diabetes, steatotic liver disease, smoking status and alcohol intake, and weights were truncated at the 99th percentile. Only those without statin use at baseline were included in the analyses to avoid adjusting for mediators in the causal pathway. Primary end points were difference in LSM compared to baseline (delta LSM) and significant LSM increase (≥20% from baseline). Additional sensitivity analyses were performed in at-risk groups with group-specific weights.

Results: In total, 595 statin-naive participants with two separate valid LSM were included with a median follow-up of 4 years [4.0; 4.0], median age 70 [68; 72], 42% male, 29.2% MASLD, 6.4% diabetes mellitus type 2. At follow-up there were 157 (26%) incident statin users. At baseline, median LSM was 4.8 [4.0; 8.9] kPa and 5.1 [4.3; 6.1] kPa at follow-up. The median delta LSM was 0.2 [−0.7;1.3], 33.1% had a clinically significant LSM increase, and 17.1% had a significant decrease. By IPTW analysis, there was a significant protective effect of statin use (delta LSM ß = −0.39 95% CI: −0.69; −0.88, p = 0.012). In sensitivity analysis the strength of the association proofed stronger the (pre-)diabetic (delta LSM ß = −0.64 95% CI −1.12; −0.17, p = 0.008) and overweight (delta LSM ß = −0.54 95% −0.93; −0.15, p = 0.007) population. Moreover, within a median follow-up of 4 years, statin use may reduce the risk of significant LSM progression in the (pre-) diabetic population (aOR 0.56 95% CI 0.30; 1.03, p = 0.06).

Conclusion: Statin use is associated with a protective effect on LSM progression in the general population, which was especially prominent within the (pre-)diabetic population. Our findings support the use and study of statins among those patients deemed at risk of clinically significant liver fibrosis.

SAT-201

Phase 3 randomised, placebo-controlled ESSENCE trial of semaglutide 2.4 mg in participants with non-cirrhotic non-alcoholic steatohepatitis: baseline characteristics, impact of new metabolic dysfunction-associated steatotic liver disease criteria and non-invasive tests

Philip N. Newsome[1], Elisabetta Bugianesi[2], Vlad Ratziu[3], Mary E. Rinella[4], Michael Roden[5,6,7], Kristiane A. Engebretsen[8], Iris Kliers[8], Laura Østergaard[8], Denise Vanni[8], Jeppe Zacho[8], Arun J. Sanyal[9]. *[1]National Institute for Health Research, Birmingham Biomedical Research Centre at University Hospitals Birmingham NHS Foundation Trust, Centre for Liver and Gastrointestinal Research, Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom; [2]Department of Medical Sciences, University of Turin, Turin, Italy; [3]Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France; [4]Department of Medicine, University of Chicago, Chicago, IL, United States; [5]Department of Endocrinology and Diabetology, Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Düsseldorf, Düsseldorf, Germany; [6]German Center for Diabetes Research, Partner Düsseldorf, München-Neuherberg, Germany; [7]Institute for Clinical Diabetology, German Diabetes Center, Leibniz Center for Diabetes Research at Heinrich Heine University Düsseldorf, Düsseldorf, Germany; [8]Novo Nordisk A/S, Copenhagen, Denmark; [9]Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, VCU School of Medicine, Richmond, VA, United States*
Email: p.n.newsome@bham.ac.uk

Background and aims: We report the baseline characteristics of participants randomised in the Phase 3 ESSENCE trial of the glucagon-like peptide-1 analogue, semaglutide 2.4 mg subcutaneous once weekly (OW) for non-cirrhotic metabolic dysfunction-associated steatohepatitis (MASH).

Method: ESSENCE (NCT04822181) is an ongoing 247-week Phase 3, randomised trial. Following a 14-week screening phase, 800 participants (part 1) of 1200 planned (part 2) with MASH and fibrosis stages 2/3 (F2/F3) were randomised 2:1 to receive semaglutide 2.4 mg subcutaneous OW or placebo OW added to standard of care. In part 1, the two primary end points at 72 weeks are resolution of steatohepatitis and no worsening of liver fibrosis, and improvement in liver fibrosis and no worsening of steatohepatitis. Based on a

central pathologist evaluation, inclusion criteria were histological presence of steatohepatitis stages F2/F3 per the Non-alcoholic Steatohepatitis Clinical Research Network classification, and a non-alcoholic fatty liver disease activity score (NAS) of ≥4, with a score of ≥1 in steatosis, lobular inflammation and hepatocyte ballooning.
Results: 800 participants (250 F2; 550 F3) were randomised. Mean (SD) age was 56 (11.6) years; 57.1% were female; ≥99% had ≥1 cardiometabolic risk factor (s) in accordance with the metabolic dysfunction-associated steatotic liver disease (MASLD) definition. Mean (SD) NAS was 5.05 (0.95), and higher in F3 versus F2 (5.11 [0.95] vs 4.92 [0.93], respectively). Notably, participants with a higher NAS had more cardiometabolic risk factors for MASLD (52.9% with NAS ≥5 vs 45.3% with NAS 4). Similarly, a greater proportion of participants with F3 had all five cardiometabolic risk factors versus F2 (52.9% vs 44.8%, respectively). Although cardiometabolic comorbidities were highly prevalent, 44.5% of participants did not have type 2 diabetes (T2D), and 27.3% did not have obesity. Normal liver transaminases were observed in 26.3% of participants (28% F2; 26% F3). Mean (SD) FibroScan liver stiffness was 12.8 (6.9) kPa, and values of <8 kPa were observed in 15.3% of participants. Mean (SD) controlled attenuation parameter value was 329 (46) dB/m; mean (SD) enhanced liver fibrosis (ELF) score was 10.0 (1.0), and 43.5% of participants had an ELF score of <9.8. Overall, 8.8% and 9.0% of participants with/without T2D did not meet any of the following non-invasive criteria: Fibrosis-4 index ≥1.3, vibration-controlled transient elastography ≥8.1, or ELF ≥9.8, and more participants with F2 (14.7–16.4%) did not meet these criteria versus F3 (4.5–6.7%).
Conclusions: The ESSENCE baseline population includes participants with significant fibrosis (F2 and F3) and approximately 91% of the trial population had ≥1 positive diagnostic non-invasive test. Cardiometabolic risk factors were found in ≥99% of participants, and in increased numbers in those with higher NAS and fibrosis stages.

SAT-202

TERN-501, a highly selective thyroid hormone receptor β agonist, significantly improved MRI-PDFF, cT1, and liver volume in clinically relevant patient populations with presumed MASH: subgroup analyses from a 12-week phase 2a trial

Stephen A. Harrison[1], Naim Alkhouri[2], Mazen Noureddin[3], Eric Lawitz[4], Kris V. Kowdley[5], Rohit Loomba[6], Lois Lee[7], Christopher Jones[7], Erin Quirk[7]. [1]*Pinnacle Clinical Research, San Antonio, United States;* [2]*Arizona Liver Health, Tucson, United States;* [3]*Houston Methodist Hospital, Houston Research Institute, Houston, United States;* [4]*Texas Liver Institute, University of Texas Health, San Antonio, United States;* [5]*Liver Institute Northwest, Elson S. Floyd College of Medicine, Washington State University, Seattle, United States;* [6]*NAFLD Research Center, University of California at San Diego, La Jolla, United States;* [7]*Terns Pharmaceuticals, Foster City, United States*
Email: sharrison@pinnacleresearch.com

Background and aims: In a dose ranging Ph2a MASH study, TERN-501, a highly selective thyroid hormone receptor β (THR-β) agonist, demonstrated significant, dose-dependent reductions in magnetic resonance imaging proton density fat fraction (MRI-PDFF) and corrected T1 (cT1), meeting all primary and secondary end points. TERN-501 showed a favorable safety profile with similar incidences of adverse events across all doses and placebo with no gastrointestinal or cardiovascular safety signals and no evidence of central thyroid axis effects, demonstrating its high selectivity for THR-β. Here we evaluated efficacy of TERN-501 6 mg, the highest dose tested in the study, using clinically relevant MR based assessments in key patient (pt) subgroups relevant to MASH.
Method: This was a 12 wk, randomized, double-blind, placebo-controlled study in pts with presumed MASH. Changes in liver fat by PDFF, fibro-inflammation by cT1, and liver volume (LV) were assessed at 12 wks using MRI in the following subgroups: pts with 1) cT1>875 msec at baseline; 2) obesity; 3) hypertension; 4) dyslipidemia; 5) type 2 diabetes mellitus (T2DM); and 6) Hispanic ethnicity.
Results: Of the 162 pts equally randomized to 7 arms in the study, 22 and 21 pts were randomized to TERN-501 6 mg and placebo, respectively. After 12 wk once daily dosing of TERN-501 6 mg, −45% mean PDFF, −72 msec mean cT1, and −20% mean LV changes were observed vs. −4%, 4 msec, and 1% in placebo, respectively (all $p < 0.001$). In pts with cT1>875 msec at baseline, indicating at-risk MASH pts, −47% mean PDFF ($p < 0.001$), −82 msec mean cT1 ($p < 0.01$), and −22% mean LV ($p < 0.001$) changes were observed vs. −9%, −15 msec, and 0% in placebo, respectively. For pts with obesity, hypertension, dyslipidemia, or Hispanic ethnicity, a statistically significant improvement in mean PDFF, cT1, and LV was observed in all TERN-501 6 mg subgroups vs. placebo (all $p < 0.01$). The small sample size of diabetic pts limited the analysis results despite considerable reduction in all three assessments observed in TERN-501 6 mg vs. placebo ($n = 6$ in TERN-501 6 mg). Notably, the placebo subgroups with obesity, hypertension, dyslipidemia, or T2DM, all of which are metabolic risk factors associated with MASH, showed worse cT1 outcomes than the overall placebo group whereas TERN-501 6 mg in these subgroups showed comparable cT1 improvement vs. the overall TERN-501 6 mg group. Overall, TERN-501 6 mg given once daily for 12 wks consistently demonstrated improvement in PDFF, cT1, and LV in all the key pt subgroups vs. placebo.
Conclusion: 12 wk treatment of TERN-501 6 mg, the highest dose tested in this Ph2a study significantly improved liver fat, cT1, and LV in at-risk MASH pts including those with comorbid conditions or risk factors associated with MASH. With the favorable safety profile of TERN-501 observed in the study, these analyses results support further investigation of TERN-501 in MASH pts.

Pegozafermin added to background GLP-1 therapy in patients with metabolic dysfunction-associated steatohepatitis with F2/F3 fibrosis: ENLIVEN 48-week extension data

Arun J. Sanyal[1], Manal F. Abdelmalek[2], Kris V. Kowdley[3], Naim Alkhouri[4], Stephen A. Harrison[5], Jörn M. Schattenberg[6], Mildred D. Gottwald[7], Shibao Feng[8], Germaine D. Agollah[9], Cynthia L. Hartsfield[10], Hank Mansbach[10], Maya Margalit[11], Rohit Loomba[12]. [1]*Virginia Commonwealth University, Richmond, United States;* [2]*Mayo Clinic, Rochester, United States;* [3]*Liver Institute Northwest, Seattle, United States;* [4]*Arizona Liver Health, Chandler, United States;* [5]*Pinnacle Clinical Research, San Antonio;* [6]*Saarland University Medical Center, Homburg, Germany;* [7]*89bio, San Francisco, United States;* [8]*89bio, San Francisco;* [9]*89bio, San Francisco;* [10]*89bio, San Francisco, United States;* [11]*89bio, Rehovot, Israel;* [12]*University of California San Diego School of Medicine, La Jolla, United States*
Email: cindy.hartsfield@89bio.com

Background and aims: Pegozafermin (PGZ), a long-acting fibroblast growth factor 21 (FGF21) analog, was evaluated for efficacy and safety in the Phase 2b ENLIVEN trial in metabolic dysfunction-associated steatohepatitis (MASH) patients with biopsy-proven F2/F3 fibrosis. PGZ 30 mg QW and 44 mg Q2W demonstrated statistically significant improvements in histology (primary end points) and improvement in markers of hepatic and extrahepatic metabolic health. Co-morbidities such as obesity and T2DM are common in patients with MASH and may be treated with glucagon-like peptide-1 receptor agonists (GLP-1 therapy). We previously showed that for patients on stable background GLP-1 therapy, PGZ provided additional improvement in non-invasive tests (NITs) of liver steatosis, fibrosis, inflammation, and metabolic markers compared to GLP-1 therapy alone in a post-hoc analysis at week 24. Following the main study, these patients entered a 24-week extension phase allowing analyses of 48-week data.
Method: In this placebo-controlled, blinded, 24-week extension phase of the Phase 2b ENLIVEN study, patients continued with their assigned treatment arm. The GLP-1 therapy population included 36 patients who received a GLP-1 during the study with the majority

having baseline utilization of ≥6 months. Most received semaglutide (53%) or dulaglutide (36%) along with additional T2DM medications. Twenty-six patients received PGZ (30 mg QW or 44 mg Q2W) and 10 patients received placebo. Changes at 48 weeks were assessed for NITs of liver steatosis, fibrosis and inflammation, metabolic effects, safety, and tolerability.

Results: In the GLP-1 therapy subgroup, patients had comparable baseline characteristics between placebo and treatment arms. Relative to the full study population, patients on background GLP-1 therapy were more likely to be female (72%) and have T2DM (94%). At week 48, patients on PGZ and GLP-1 combination therapy maintained greater benefits in markers of liver steatosis (MRI-PDFF), fibrosis (ELF and ProC3), and inflammation (ALT) compared to those on background GLP-1 alone. There was also an additional reduction in the FAST score for those receiving PGZ. Metabolic benefits seen at week 48 include a sustained reduction in triglycerides in conjunction with greater reduction of LDL-C compared to GLP-1 therapy alone. Combination of GLP-1 and pegozafermin therapy retained acceptable safety and tolerability with no treatment-related AE discontinuations.

Conclusion: In MASH patients with F2/F3 fibrosis who were receiving background GLP-1 therapy, addition of PGZ demonstrated additional and sustained improvement in markers of liver and metabolic health compared to GLP-1 therapy alone. Confirmatory phase 3 studies are planned to begin in 2024 and will include patients on background incretin therapies per local standard of care.

SAT-206

Improvements in MACK-3, a diagnostic test for active metabolic dysfunction-associated steatohepatitis, parallel response to lanifibranor therapy

Michael Cooreman[1], Sven Francque[2], Philippe Huot-Marchand[3], Lucile Dzen[4], Martine Baudin[3], Jean-Louis Junien[3], Pierre Broqua[3], Manal F. Abdelmalek[5], Jerome Boursier[6]. *[1]Inventiva, New York, United States; [2]University Hospital Antwerp, Edegem; [3]Inventiva, Daix, France; [4]Inventiva, Daix; [5]Mayo Clinic, Rochester, United States; [6]CHU Angers, Angers, France*
Email: michaelpcooreman@msn.com

Background and aims: The pan-PPAR agonist lanifibranor has shown efficacy on histological 'MASH resolution and fibrosis improvement' and on non-invasive markers of cardiometabolic health (CMH), MASH activity and fibrosis-including MACK-3, adiponectin and Pro-C3-in the NATIVE phase 2b study. MACK-3 has been validated against histology as a diagnostic marker for active MASH with fibrosis. Its components (AST, HOMA-IR, and CK-18) reflect the spectrum of MASH biology. We therefore evaluated the correlation of MACK-3 response with improvement of liver histology and CMH markers with treatment.

Method: NATIVE evaluated lanifibranor 800 and 1200 mg/d versus placebo in 247 patients with non-cirrhotic MASH for 24 weeks of treatment. MACK-3, liver histology, adiponectin (ADP), and Pro-C3 (as a marker of fibrogenesis) were evaluated at baseline (BL) and at end of treatment (EOT). Correlations between MACK-3 and ADP, Pro-C3 and histological components according to NASH-CRN and SAF activity (SAF-A) scoring were assessed using Spearman's rank (Rs) among all randomized patients at BL and at EOT. Change in MACK-3 between histological responders and non-responders in the pooled lanifibranor arms were compared using Wilcoxon test.

Results: At BL, MACK-3 correlated with histological fibrosis stage (Spearman Rs = 0.25, p < 0.001), disease activity (CRN-NAS: Rs = 0.22, p < 0.001; SAF-A: Rs = 0.16, p = 0.015) and circulating biomarkers (ADP: Rs = –0.18, p = 0.006; Pro-C3: Rs = 0.50, p < 0.001). At EOT, MACK-3 still correlated with histological fibrosis stage (Rs = 0.23, p = 0.01), disease activity (CRN-NAS: Rs = 0.54, p < 0.001; SAF-A: Rs = 0.50, p < 0.001) and circulating markers (ADP: Rs = –0.44, p < 0.001; Pro-C3: Rs = 0.29, p < 0.001). Decrease in MACK-3 value at EOT from BL was significantly higher among lanifibranor-treated histological responders vs non-responders for 'MASH resolution and fibrosis improvement' (–62% vs –51%, p = 0.006), for 'Fibrosis improvement without worsening of MASH' (–60% vs –50%, p = 0.05), and for 'MASH resolution without fibrosis worsening' (–63% vs –46%, p < 0.001). Similar results were observed for improvement of CRN-NAS of at least 2 points (–61% vs –39%, p = 0.001), SAF-A (–59% vs –30%, p = 0.007), and individual liver lesions: steatosis (–62% vs –40%, p < 0.001), CRN-lobular inflammation (–61% vs –46%, p = 0.004), and CRN-ballooning (–60% vs –28%, p = 0.002). With lanifibranor, decrease in MACK-3 score at EOT from BL was also correlated with ADP increase (Rs = –0.48, p < 0.001) and Pro-C3 decrease (Rs = 0.23, p = 0.01).

Conclusion: MACK-3 is a practical diagnostic algorithm for fibrotic MASH that also shows good correlation with improvement of histological disease activity and fibrosis, as well as with improvement of non-invasive biomarkers following therapy with lanifibranor, and thus warrants further study as a potential marker for evaluation of treatment response.

SAT-207

Safety and efficacy outcomes of endoscopic sleeve gastroplasty and lifestyle intervention in post-orthotopic liver transplant patients: A single-center, prospective pilot study

Jaclyn Tuck[1], David M. H. Chascsa[1], Blanca Lizaola-Mayo[1], Justin Potter[1], Alexis Baughman[1], Brian Arizmendi[1], Jaxon Quillen[1], Katie Kunze[1], Abraham Neena[1], Rahul Pannala[1]. *[1]Mayo Clinic, Phoenix, United States*
Email: tuck.jaclyn@mayo.edu

Background and aims: Patients that are post-orthotopic liver transplantation (p-OLT) for metabolic dysfunction-associated steatotic liver disease (MASLD) are at risk for developing recurrent steatosis, fibrosis and complications from chronic liver disease. Obesity management can be challenging in this population as some patients may have contraindications to bariatric surgery. We hypothesized that endobariatric therapy (EBT), particularly endoscopic sleeve gastroplasty (ESG), and lifestyle intervention, in the framework of a protocol-based, multidisciplinary care pathway can be an effective, less invasive treatment option for obesity in these patients. In a single-center, prospective, pilot study, we evaluated the safety and efficacy outcomes of a tailored EBT approach in p-OLT for MASLD and recurrent steatosis.

Method: P-OLT patients with recurrent steatosis and obesity were considered for EBT. ESG (Overstitch, Apollo Endosurgery) was the preferred intervention. A multidisciplinary evaluation and follow-up protocol were established a priori and patient selection was based on performance status, preoperative cardiopulmonary assessment, BMI, and patient readiness for lifestyle change. Demographic and clinical data were collected prospectively. Data were analyzed using R (V 4.2.2) to examine descriptive statistics and graphical representations.

Results: Five patients (male, n = 4) underwent ESG. Mean BMI at enrollment was 35.5 kg/m^2. BMI range was 32–41.3 kg/m^2. Two patients (40%) had either class 2 or class 3 obesity. The median percent total body weight loss (%TBWL) was 15.14 (range 4–19.6; 1–6 months). A pre- and post-ESG fibroscan and liver biopsy was collected on one patient which showed reduction in liver fibrosis F3-4 to F2-3. There was also substantial histologic improvement with steatohepatitis, NAFLD activity score 6/8 to 4/8, macrosteatosis 35% to 5%, and a rejection activity index 3/9 to no rejection noted. Four patients had initial improvement in their HbA1c, however, 3 eventually had a post-ESG HbA1c that either returned to or was higher than pre-ESG. One patient was able to stop insulin. None of the patients were on GLP-1 agonists at the time of ESG. Blood pressure (BP) was stable for 4 patients. Three patients had improvement in triglycerides. Four patients had improvement in HDL. One patient did not have post-ESG HbA1c, BP or lipid data. 3/5 patients (60%) had improvement in their transaminases. There were no procedural adverse events.

Conclusion: ESG combined with lifestyle intervention and multidisciplinary care, may be an effective and safe obesity treatment option in complex p-OLT patients with recurrent steatosis. We found that patients had significant %TBWL with improvement in triglycerides and HDL following ESG. Future studies should evaluate predictors of efficacy and safety and optimal care frameworks specifically for this patient population.

SAT-208

Sex hormone binding globulin as an effective predictor of treatment response to TERN-501, a potent, highly selective thyroid hormone receptor β agonist: post-hoc analyses from a 12-week phase 2a trial

Naim Alkhouri[1], Stephen A. Harrison[2], Eric Lawitz[3], Kris V. Kowdley[4], Rohit Loomba[5], Lois Lee[6], Christopher Jones[6], Erin Quirk[6], Mazen Noureddin[7]. *[1]Arizona Liver Health, Tucson, United States; [2]Pinnacle Clinical Research, San Antonio, United States; [3]Texas Liver Institute, University of Texas Health, San Antonio, United States; [4]Liver Institute Northwest, Elson S. Floyd College of Medicine, Washington State University, Seattle, United States; [5]NAFLD Research Center, University of California at San Diego, La Jolla, United States; [6]Terns Pharmaceuticals, Foster City, United States; [7]Houston Methodist Hospital, Houston Research Institute, Houston, United States*
Email: nalkhouri@azliver.com

Background and aims: In a 12-week, randomized, double-blind, placebo-controlled phase 2a study in patients with presumed MASH, TERN-501, a highly selective thyroid hormone receptor β (THR-β) agonist, showed significant, dose-dependent decreases in MRI-PDFF (PDFF) and cT1 with a favorable safety profile. Sex hormone binding globulin (SHBG), a protein produced in the liver in response to THR-β agonism, also significantly increased in a dose-dependent manner, demonstrating robust target engagement. Here we evaluated the potential clinical utility of SHBG, a simple blood-based marker, in predicting TERN-501 efficacy measured by PDFF.
Method: PDFF and SHBG were measured at baseline, Week 6 and Week 12 of the study. Receiver operating characteristic (ROC) curve was built to identify an optimal SHBG increase threshold associated with ≥30% PDFF reduction, a response criterion that has been linked to histologic improvement in MASH, using pooled data from the TERN-501 3 mg and 6 mg groups at Week12. The proportion of patients with ≥30% PDFF reduction at Week 12 was then assessed using the optimal SHBG increase threshold identified from the ROC curve. The proportion of responders with ≥30% PDFF reduction at Week 12 was also assessed using a previously reported SHBG increase threshold of ≥120%. Finally, the performance of SHBG measured at Week 6 was evaluated as a predictor of PDFF response at Week 12.
Results: At Week 12, 39% ($p < 0.01$) and 64% ($p < 0.001$) of patients in the TERN-501 3 mg and 6 mg groups, respectively, achieved ≥30% PDFF reduction vs. 4% of the patients in placebo. SHBG increase ≥70% was identified as an optimal threshold associated with ≥30% PDFF reduction at Week 12 (sensitivity = 80.7%; specificity = 85.7%; AUROC = 0.84). Majority (86%) of the patients with ≥70% SHBG increase at Week 12 achieved ≥30% PDFF reduction at Week 12 compared to only 17% of patients with <70% SHBG increase. At a higher SHBG increase threshold of ≥120%, while all patients with ≥120% SHBG increase at Week 12 achieved ≥30% PDFF reduction at Week 12, 44% of patients with <120% SHBG increase still achieved ≥30% PDFF reduction at Week 12. Of the patients with ≥70% SHBG increase at Week 6, 74% achieved ≥30% PDFF reduction at Week12. Impressively, 93% of the patients with ≥120% SHBG increase at Week 6 achieved ≥30% PDFF reduction at Week 12 compared to 30% of patients with <120% SHBG increase.
Conclusion: Treatment response to TERN-501 in MASH may be effectively predicted or monitored with SHBG, potentially as early as Week 6. Patients achieving a high SHBG increase with TERN-501 treatment may not require MR-based demonstration of liver fat reduction.

SAT-209-YI

A Markov model unveiling the impact of Resmetirom on the natural history of MASLD patients with baseline significant or severe liver fibrosis

Grazia Pennisi[1], Gabriele Di Maria[2], Marco Enea[2], Marco Vaccaro[3], Carlo Ciccioli[1], Ciro Celsa[1], Giuseppe Infantino[1], Adele Tulone[1], Vito Di Marco[1], Calogero Camma[1], Salvatore Petta[1]. *[1]Section of Gastroenterology and Hepatology, Dipartimento Di Promozione Della Salute, Materno Infantile, Medicina Interna e Specialistica Di Eccellenza (PROMISE), University of Palermo, Italy, Palermo, Italy; [2]Dipartimento Di Promozione Della Salute, Materno Infantile, Medicina Interna e Specialistica Di Eccellenza (PROMISE), University of Palermo, Italy, Palermo, Italy; [3]Dipartimento di Scienze Economiche, Aziendali e Statistiche, University of Palermo, 90133 Palermo, Italy, Palermo, Italy*
Email: graziapennisi901@gmail.com

Background and aims: The MAESTRO-NASH phase 3 trial reported that 52-week treatment of Resmetirom is effective in improving fibrosis and MASH in patients with metabolic-dysfunction associated steatotic liver disease (MASLD) with F2 or F3 fibrosis, while data on the impact on 5-year and long-term clinical outcomes are still lacking. Moreover, data about the full spectrum of the natural history of MASLD patients with F2 or F3 fibrosis are scarce and fragmentary. We simulated the transition probabilities of disease progression in MASLD patients with F2 or F3 fibrosis, and the effect of Resmetirom treatment on clinical outcomes.
Method: Data from 12 studies and individual sources on MASLD subjects formed transition matrices for fibrosis stages and complications, defined as compensated (CC) and decompensated cirrhosis (DC), hepatocellular carcinoma (HCC) and mortality-liver-related mortality (LR-M), cardiovascular mortality (CV-M) and extra-hepatic cancer mortality (EHC-M). Markov model was developed to depict the F2 and F3 fibrosis stage progression towards the complications and to evaluate the effect of Resmetirom treatment on the natural history of MASLD.
Results: We estimated the five-year probability of Resmetirom-treated and untreated MASLD patients with baseline F2 fibrosis of developing CC (5.16 vs 6.82, respectively), DC (0.25 vs 0.3, respectively), HCC (0.25 vs 0.32, respectively) and mortality (0.15 vs 0.16 for LR-M; 1.02 vs 1.1 for CV-M; 1.07 vs 1.2 for EHC-M, respectively). Similarly, we estimated the five-year probability of Resmetirom-treated and untreated MASLD patients with baseline F3 fibrosis of developing CC (17.12 vs 21.34, respectively), DC (1.1 vs 1.47, respectively), HCC (1.21 vs 1.73, respectively) and mortality (0.59 vs 0.91 for LR-M, 1.92 vs 2.14 for CV-M and 1.04 vs 1.14 for EHC-M, respectively). Comparable results were obtained extending these probabilities to a lifetime horizon for both F2 and F3 MASLD patients. Sensitivity analyses considering changes in transition probabilities, treatment efficacy and treatment duration are ongoing.
Conclusion: Resmetirom decreases the 5-year and lifetime Markov-model estimated risk of CC, DC, HCC, and liver-related and extra-hepatic mortality in patients with MASLD and F2 or F3 fibrosis.

SAT-210

Role of Saroglitazar in the treatment of metabolic dysfunction-associated steatohepatitis (MASH) in nondiabetic patients: a prospective observational study

Jata Shankar Kumar[1], Priyanshu Bhardwaz[2], Premashis Kar[3]. *[1]Max Superspeciality Hospital, Ghaziabad, India; [2]Max Hospital, Vaishali, Ghaziabad, India; [3]Max Superspeciality Hospital, Ghaziabad, India*
Email: jatashankar.dr@gmail.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a metabolic disorder characterized by the accumulation of fat and significant inflammation in the liver. MASLD encompasses patients who have hepatic steatosis and have at least one of five cardiometabolic risk factors. MASH is diagnosed when examination of the liver tissue with a microscope shows fat accumulation in hepatocytes along with inflammation and damage to

liver cells. Saroglitazar is a dual PPAR (proliferator peroxisome activated receptor) agonist. Aim of this study is to discuss the role of Saroglitazar in the medical management of MASH in nondiabetic patients.

Method: It was a prospective observational study in a tertiary care center in north India. The study followed the principles of declaration of Helsinki and good clinical Practice as laid down by Indian council of medical research. Total 51 nondiabetic MASH patients (Males or females, 18–75 year of age, body mass index >23 kg/m^2, nondiabetics) were included in this study. Diagnosis of MASH was done on the basis of liver fibroscan (CAP score >238, LSM value >7 kPa) along with raised liver enzymes (SGOT, SGPT >upper value of normal limits). All of these 51 patients received 4 milligram once daily dose of Saroglitazar for the treatment of MASH. In our study standard treatment protocol were used. ANOVA test and Multiple regression analysis was used to assess the percentage changes in Aspartate transaminase (AST), Alanine transaminase (ALT), Alkaline phosphatase (ALP), Triglyceride (TG), Low density lipoprotein (LDL) and Liver stiffness measurement (LSM) with Controlled attenuation Parameter (CAP).

Results: All of 51 patients who were treated with 4 mg daily dose of Saroglitazar for 24 weeks. 72.5% of these patients were male and 27.5% were female (male: female ratio of 2.6). The mean age of patients was 51 ± 13.13 years. Pretreatment and post treatment values of different parameters were compared. Pretreatment Mean values of ALT and AST were 93.83 ± 6.16 U/L and 76.13 ± 4.1 U/L respectively while their post treatment mean values were 32.97 ± 2.15 U/L and 34.57 ± 1.65 respectively (p value for AST and ALT were <0.001). Pretreatment mean values of fibroscan in terms of LSM and CAP were 16.2 ± 1.57 kPa (kilopascal) and 297.80 ± 37.38 dB/m (decibel/meter) and post treatment Mean values were 7.67 ± 0.23 kPa and 264.80 ± 6.81 dB/m respectively (p values for LSM and CAP were <0.001 and 0.049 respectively). Pretreatment and post treatment value of LDL were 122.1 ± 4.84 and 93.51 ± 4.12 respectively (p < 0.001).

Conclusion: Saroglitazar; a PPAR agonist, was found to be effective in medical management of metabolic dysfunction-associated steatohepatitis (MASH). It reduces the liver stiffness and decreases the elevated liver enzymes (SGOT/SGPT) as well as serum LDL level over duration of 6 months.

SAT-212

Real-world use of Glucagon-like peptide 1 receptor agonists in patients with MASLD: a cross-sectional analysis from TARGET-NASH

A. Sidney Barritt, IV [1], Andrea Mospan[2], Heather Morris[2], Anthony Perez[2], Rohit Loomba[3], Michael Fried[2], Arun J. Sanyal[4], Philip N. Newsome[5]. [1]*UNC Liver Center, University of North Carolina, Chapel Hill, United States;* [2]*Target RWE, Durham, United States;* [3]*3Division of Gastroenterology, Department of Medicine, University of California at San Diego, San Diego, United States;* [4]*Virginia Commonwealth University, Richmond, United States;* [5]*University of Birmingham, Birmingham, United Kingdom*
Email: sid_barritt@med.unc.edu

Background and aims: Glucagon-like peptide 1 receptor agonists (GLP-1 RA) are approved in the United States for diabetes and obesity. There is considerable interest in using this class of medications in patents with metabolic dysfunction associated steatotic liver disease (MASLD). Clinical trials have shown these drugs are well tolerated, but real-world data from larger cohorts are lacking. This study aims to describe characteristics of patients with MASLD who are prescribed GLP-1 RA including duration of use and tolerance.

Method: TARGET-NASH is a real-world patient cohort designed to follow patients with MASLD in routine clinical settings. In part, the study aims to gain insights into use of off-label drugs in usual clinical care. Patients are enrolled in TARGET-NASH based on a treating physician's diagnosis of MASLD.

Results: In a cohort of 5, 361 TARGET-NASH US adult participants, 603 (11%) were on one or more GLP-1 RA including with MASL (n = 109), MASH (n = 269), and cirrhosis (n = 225). Median age among users was 59 years, 99% type 2 diabetes, 76% obese (BMI >30 kg/m^2). Insurance coverage was similar across users vs nonusers. Age differed significantly with GLP-1 RA users disproportionately centered in the 40-64 age group compared to non-GLP-1RA. Relative to Non-Hispanic Whites, Asians (OR = 0.16, p < 0.001) and those with other race/ethnicity (OR = 0.46, p < 0.01) had significantly lower odds of GLP-1 RA use. Across the spectrum of disease severity, patients were more likely to receive a GLP-1 RA when being treated at an academic vs. community site, female, and with obesity class II/III (all p < 0.0001). Comorbidities were more common among GLP-1 RA users including type 2 diabetes, cardiovascular disease, hyperlipidemia, hypertension, autoimmune/rheumatological conditions, anxiety/depression, and arthritis. Duration of GLP-1 treatment was similar across disease severity with a median duration of 2.4 years. Treatment discontinuation, temporary disruptions, or treatment modifications among the 770 patient exposures occurred in 256 (42%) cases overall, 36 (33%) MASL cases, 130 (48%) MASH cases, and 90 (40%) MASH cirrhosis cases. The majority of treatment disruptions (215/256 or 83%) were for non-medical reasons including cost/insurance constraints, temporary pauses, dosage modifications, supply shortages, and various patient/provider decisions. Only 41 (8%) patient-exposures actually *stopped* following medical events such as GI intolerance.

Conclusion: In TARGET-NASH, 11% of participants were prescribed a GLP-1 RA. Most users were Caucasian women from age 40–64; despite drug access concerns, insurance type did not differ between users and non-users. This real-world population had significant comorbid conditions, including cardiovascular disease and cirrhosis. Despite this, GLP-1 RA were well tolerated with the majority of discontinuations due to non-medical reasons.

SAT-213

Postbiotic supplementation for metabolic dysfunction-associated steatotic liver disease

Maryana Savytska[1], Olena Baka[2], Elina Manzhalii[3], Dmytro Kyriienko[4], Tetyana Falalyeyeva[5], Maksym Zhayvoronok[6], Oleksandr Kovalchuk[7], Nataliya Deresh[8], Fedir Grygoriev[9], Nazarii Kobyliak[10]. [1]*Danylo Halytsky Lviv National Medical University, Lviv, Ukraine;* [2]*Center for Innovative Medical Technologies of the National Academy of Sciences of Ukraine, Kyiv, Ukraine;* [3]*Bogomolets National Medical University, "Verum-expert" Clinic, Kyiv, Ukraine;* [4]*Kyiv City Clinical Endocrinology Center, Kyiv, Ukraine;* [5]*Taras Shevchenko National University of Kyiv, Medical Laboratory CSD, Kyiv, Ukraine;* [6]*Shupyk National Healthcare University of Ukraine, Medical Scientific and Practical Association "MedBud", Kyiv, Ukraine;* [7]*Taras Shevchenko National University of Kyiv, Kyiv, Ukraine;* [8]*Lifescan Clinic, Kyiv, Ukraine;* [9]*MirImmunoPharm LLC, Kyiv, Ukraine;* [10]*Bogomolets National Medical University, Kyiv, Ukraine*
Email: nazariikobyliak@gmail.com

Background and aims: The current study aim was to conduct placebo-controlled randomize clinical trial (RCT) to assess the short-term efficacy and safety of postbiotics on hepatic fat content as measured by magnetic resonance imaging (MRI)-estimated proton density fat fraction (PDFF) and ultrasonography in patients with metabolic dysfunction-associated steatotic liver disease (MASLD).

Method: A total of 39 patients met the criteria for inclusion. The study includes 2 periods. Screening period of up to 1 week to assess the eligibility to inclusion/exclusion criteria. Treatment period for 3 months where the participants receive a twice daily oral dose of postbiotics (cell lysate and DNA fragments of the probiotic strain *L. rhamnosus DV*-NRRLB-68023) at the assigned dose of 100 mg or placebo in capsules. The primary main outcomes were the change of MRI-PDFF in % and ultrasound-based attenuation coefficient measurement (ACM) and hepatorenal index (HRI). Secondary outcomes

were the changes in serum lipid content, anthropomorphic variables, and liver stiffness (LS) measured by Shear Wave Elastography (SWE). ANCOVA was used to assess the difference between groups. Trial registration: NCT05804422

Results: We observed significant decrease in hepatic fat content using both modalities only in postbiotic group: MRI-PDFF (15.02 ± 2.33 to 10.84 ± 2.63 %; p = 0.045), ACM (2.63 ± 0.07 to 2.54 ± 0.06 dB/cm; p = 0.043) and HRI (1.33 ± 0.05 to 1.24 ± 0.04; p = 0.011) respectively. In placebo group slight insignificant reduction of MRI-PDFF (10.84 ± 2.13 to 7.88 ± 2.34 %; p = 0.283) and ACM (2.60 ± 0.08 to 2.54 ± 0.08 dB/cm; p = 0.250) was found. In parallel intervention with placebo was associated with increase of HRI (1.22 ± 0.05 to 1.24 ± 0.04; p = 0.429) and LS measured by SWE (4.76 ± 0.21 to 4.87 ± 0.21; p = 0.046). As compared to placebo group LS decreased insignificant in postbiotic group (5.51 ± 0.38 to 5.39 ± 0.36; p = 0.222). In secondary outcomes analysis significant changes were found only in postbiotic group.

Conclusion: To our knowledge its first RCT which demonstrate that postbiotic supplementation can reduce hepatic fat content in MASLD patients. Modulation of the gut microbiota represents a new treatment for MASLD and should be tested in larger studies.

SAT-214

Using machine learning models to predict baseline fibrosis stage in patients from phase 3 resmetirom trials (MAESTRO-NAFLD and MAESTRO-NASH)

Jörn M. Schattenberg[1,2], Quentin M. Anstee[3], Stephen A. Harrison[4], Mazen Noureddin[5], Rebecca Taub[6], Dominic Labriola[6], Jan Priel[7], Krishna Padmanabhan[8]. *[1]Metabolic Liver Research Program, I. Department of Medicine, University Medical Center of Johannes Gutenburg University Mainz, Mainz, Germany; [2]The Department of Internal Medicine II, Saarland University Medical Center, Homburg, Germany; [3]The Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle-upon-Tyne, United Kingdom; [4]Pinnacle Clinical Research, San Antonio, TX, United States; [5]Houston Methodist Hospital, Houston Research Institute, Houston, TX, United States; [6]Madrigal Pharmaceuticals, Inc., West Conshohocken, PA, United States; [7]Cytel, Inc., Berlin, Germany; [8]Cytel, Inc., Waltham, MA, United States*
Email: joern.schattenberg@uks.eu

Background and aims: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo-controlled Phase 3 trial evaluating the efficacy of resmetirom in patients with biopsy-confirmed NASH/MASH and fibrosis (F1B-F3 and exploratory F1). MAESTRO-NAFLD-1 (NCT04197479) is a completed, randomized, placebo-controlled trial Phase 3 trial evaluating resmetirom safety and its effects on biomarkers in patients with NASH without a biopsy confirmation. 180 patients with well-compensated NASH cirrhosis were enrolled in an open label arm of MAESTRO-NAFLD-1. 1813 patients had baseline or historic biopsy spanning stage F0–F4 with multiple non-invasive biomarker and imaging measures of NASH with fibrosis.

Method: Adults with ≥3 metabolic risk factors were screened. Pts with FibroScan VCTE, liver stiffness ≥8.5 kPa, MRI-PDFF ≥8%, biopsy-confirmed F1B-F3 NASH, NAS ≥4, were eligible for MAESTRO-NASH. MAESTRO-NAFLD-1 included pts with non-invasive measures of NASH (MRI-PDFF ≥8%, Fibroscan VCTE ≥5.5) or well-compensated NASH cirrhosis. Machine learning models evaluated the relative importance of patients' intrinsic characteristics and screening/baseline biomarkers. The Random Forrest (RF) model was selected due to its predictive performance. The Full model (FM) included 36 possible explanatory variables, and the lean model (LM) had 21 predictors more likely to be used in clinical practice. LM was based on 1765 patients with non-missing data compared to 607 pts in FM. Among the potential predictors assessed were demographic characteristics, T2DM, liver tests, MRI-PDFF, MRE, Fibroscan CAP and VCTE, FAST, MAST, FIB-4, Pro-C3, ELF, M30, thyroid hormones, SHBG, and liver and spleen volumeS.

Results: Baseline characteristics excluding the population with liver biopsies included: 207 = F0, 271 = F1a or c, 156 = F1b (designated F2-equivalent), 395 = F2, 605 = F3, 131 = F4 (Cirrhotic). The RF model was used to classify patients: F0/F1a/F1C (Early) vs. F1B/F2/F3 (At-risk) vs. F4, a 3-class model. AUC and classification error rates were assessed in repeated cross-validation. The variables that most impacted classification (FM) included: MRE, Fibroscan VCTE, MRI-PDFF, MAST, SHBG and Platelet count; for LM: Fibroscan VCTE, FIB-4, Pro-C3, FAST, GGT, Platelets, AST and Fibroscan CAP. In the FM, mean (SD) AUROC for F0/1A/1C vs Rest = 0.804 (0.055); F1B/F2/F3 = 0.776 (0.047); F4 vs Rest = 0.930 (0.031). In the LM AUROC for F0/1A/1C vs Rest = 0.854 (0.017); F1B/F2/F3 = 0.815 (0.018); F4 vs Rest = 0.89 (0.028)

Conclusion: In a population selected for high baseline metabolic risk factors, liver stiffness and liver fat, both FM and LM were able to accurately identify early NASH pts versus those with more significant fibrosis. FM and LM accurately discriminated F4 (cirrhosis) from all others. LM, based on commonly collected biomarkers and lab tests, performed as well as FM.

SAT-215

Healthcare cost and resource utilization among patients with non-alcoholic steatohepatitis (NASH), stratified by glucagon-like peptide 1 receptor agonist (GLP-1) use in real world data

Yestle Kim[1], Jesse Fishman[1], Elliot Tapper[2], Dave Lewandowski[3], Taylor Marlin[3], Alina Bogdanov[3], Machaon Bonafede[3]. *[1]Madrigal Pharmaceuticals, Inc., West Conshohocken, United States; [2]University of Michigan, Ann Arbor, United States; [3]Veradigm, Chicago, United States*
Email: ykim@madrigalpharma.com

Background and aims: Non-alcoholic steatohepatitis (NASH, also known as metabolic-dysfunction associated steatohepatitis [MASH]), is a progressive condition associated with cirrhosis, liver failure, and hepatocellular carcinoma. GLP-1 s are currently approved for type 2 diabetes (T2D) and obesity. This study aims to characterize GLP-1 use among patients with NASH and summarize healthcare costs and resource utilization.

Method: Adults ≥18 years at index with a NASH diagnosis code were identified in electronic health records or claims between 7/1/2018 and 8/31/2022 in the Veradigm Integrated Dataset. Patients with viral hepatitis, alcohol-use disorder or alcoholic liver disease, opioid disorders, cirrhosis, type 1 diabetes, gestational diabetes, or bariatric surgery were excluded. Patients were required to have ≥12 months of continuous claims enrollment pre- (baseline) and post- index (follow-up), and not have any GLP-1 claims in the baseline period. Patients were stratified into 3 cohorts based on GLP-1 use (≥1 prescription) in the follow-up period: no GLP-1, high-dose GLP-1, and low-dose GLP-1. Duration of GLP-1 use was not analyzed for this abstract. High and low doses of GLP-1 s were determined based on the drug prescribing information; T2D-indicated GLP-1 doses were used as the thresholds for high/low categories. We summarized baseline patient characteristics and costs during the 12-month follow-up period.

Results: We identified 56, 756 patients with NASH, 50, 094 of whom had no GLP-1 at follow-up, 348 had a high-dose GLP-1, and 2, 315 had low-dose GLP-1. Mean (SD) age was 53.8 (14.4), 48.1 (12.0), and 53.1 (11.9) years for no GLP-1, high-dose GLP-1, and low-dose GLP-1 cohorts, respectively. Among those with BMI reported in the baseline period, 16.9% of the no GLP-1 cohort had BMI of 40+, compared to 38.9% in the high-dose GLP-1 cohort and 33.5% in the low-dose GLP-1 cohort. Of the patients with HbA1c measurement during the baseline period, the mean (SD) HbA1c values were 6.4% (1.3%), 6.8% (1.3%), and 7.5% (1.7%) for the no GLP-1, high-dose GLP-1, and low-dose GLP-1 cohorts, respectively. During the follow-up period, 11.0% of no GLP-1 cohort had an inpatient admission, with mean inpatient costs of $4,

516, compared with 6.6% of the high-dose GLP-1 cohort ($9, 472) and 11.4% of the low-dose GLP-1 cohort ($3, 877). Mean emergency department costs were $1, 073 for the no GLP-1 cohort, $1, 222 for the high-dose GLP-1 cohort, and $1, 373 for the low-dose GLP-1 cohort. After excluding costs in the top 1%, mean unadjusted total follow-up costs were $12, 265 for the no GLP-1 cohort, $17, 140 for the high-dose GLP-1 cohort, and $18, 860 for the low-dose GLP-1 cohort.
Conclusion: Compared with patients with no GLP-1 utilization, patient costs with both high- and low-dose GLP-1 utilization were higher; this trend was not explained by expected costs from more medication use.

SAT-218

Liver fibrosis and obesity associated with stroke in an elderly population: protected effect by pravastatin

Willy Theel[1,2,3], Vivian de Jong[4,5], Diederick Grobbee[5,6], J. Wouter Jukema[7], Stella Trompet[7], Manuel Castro Cabezas[5,8,9].
[1]Franciscus Gasthuis and Vlietland, Rotterdam, Netherlands; [2]Centrum Gezond Gewicht, Rotterdam, Netherlands; [3]Erasmus University Medical Center, Rotterdam, Netherlands; [4]Julius Global Health, University Medical Center Utrecht, Utrecht, Netherlands; [5]Julius Clinical, Zeist, Netherlands; [6]Julius Global Health, University Medical Center Utrecht, Utrecht, Netherlands; [7]Leiden University Medical Center, Leiden, Netherlands; [8]Franciscus Gasthuis and Vlietland, Rotterdam, Netherlands; [9]Erasmus Medical Center, Rotterdam, Netherlands
Email: w.theel@franciscus.nl

Background and aims: Liver fibrosis, as part of the Metabolic dysfunction Associated Steatotic Liver Disease (MASLD) in subjects with obesity may increase cardiovascular risk. A recent meta-analysis demonstrated that statins could be beneficial in the MASLD population. Nevertheless, the effect of statins on cardiovascular disease in elderly subjects with obesity and liver fibrosis remains understudied.
Method: The PROspective Study of Pravastatin in the Elderly at Risk (PROSPER) database was used for this analysis. PROSPER evaluated the effect of pravastatin on major adverse cardiovascular events in an elderly population (>70 years). We divided the study group into three subgroups based on their body mass index (BMI): healthy (<25 kg/m^2), overweight (25–29, 9 kg/m^2) and obese (≥30 kg/m^2). In each group we calculated for all participants the FIB4 score which reflects liver fibrosis using age-adjusted cutoffs: low risk of advanced fibrosis (FIB-4 <2.0), intermediate risk (2.0 ≤FIB-4 ≤2.66) and high risk (FIB-4 ≥2.67). Time-to-event data were analyzed using the Cox proportional hazards model for the placebo and pravastatin groups separately and adjusted for sex.
Results: In total 5244 subjects were included. Compared to the reference group with low FIB4 and healthy BMI, the hazard ratio for a (non) fatal stroke was significantly higher (HR 2.58–95%CI 1.14–5.84) in the highest risk group (high FIB4 score and obesity) on placebo. In the pravastatin groups, the differences disappeared, suggesting that pravastatin protects against (non) fatal stroke in elderly subjects with obesity and liver fibrosis. Pravastatin did not influence other cardiovascular end points in this elderly population when analyzed based on different BMI levels and different grades of liver fibrosis.
Conclusion: Elderly people with obesity and liver fibrosis have an increased risk of (non) fatal stroke when compared to a reference population and treatment with pravastatin has a protective effect.

SAT-219

Discovering 1-piperidine propionic acid inhibiting effect on protease activated receptor 2 and serpinb3 as a new therapeutic strategy for metabolic dysfunction-associated steatohepatitis

Monica Chinellato[1], Gianmarco Villano[1], Erica Novo[2], Cristian Turato[3], Santina Quarta[1], Mariagrazia Ruvoletto[1], Alessandra Biasiolo[1], Andrea Martini[1], Stefania Cannito[2], Camilla Mazzucco[1], Matteo Gasparotto[1], Francesco Filippini[1], Luca Spiezia[1], Laura Cendron[1], Maria Guido[1], Roberto Vettor[1], Maurizio Parola[2], Patrizia Pontisso[1]. *[1]University of Padova, Padova, Italy; [2]University of Torino, Torino, Italy; [3]University of Pavia, Pavia, Italy*
Email: monica.chinellato@phd.unipd.it

Background and aims: The serine protease inhibitor SerpinB3 has a pivotal role in liver fibrosis and its involvement in MASH development and insulin resistance has been described recently. Conversely, Protease Activated Receptor 2 (PAR2) is a well well-established regulator of inflammatory cascade and it has been proposed as novel target for metabolic liver disease. Recently a small molecule, 1-Piperidine Propionic Acid (1-PPA), has been reported to inhibit inflammatory processes involving SerpinB3. In this work we aim to investigate the pathway involving both proteins to find new therapeutic strategy for MASH treatment.
Method: The effect of 1-PPA has been evaluated with a wide approach, including: a) Biophysical studies to determine the interaction with PAR2; b) Cellular models using cell lines with different extent of expression of SerpinB3, to explore the downstream effects on SerpinB3 and other inflammation and fibrosis genes transcriptional levels; c) mice transgenic or KO for in experimental MASH models.
Results: 1-PPA stabilization effects observed by cellular thermal shift assay and in-silico investigations revealed a putative site of interaction within PAR2 molecule, determining its inactivation. Functional studies showed indeed its antagonist effect on MAPKs signalling. A parallel reduction of the synthesis of SerpinB3 was also observed both in vitro and in vivo in presence of 1-PPA and this effect was associated with the inhibition of lipids accumulation, inflammation and fibrosis in experimental MASH.
Conclusion: 1-PPA has been identified as a novel PAR2 regulator, that was able to inhibit the PAR2-SerpinB3 axis in inflammatory condition. Its effects can protect from MASH development and progression, supporting the potential use of a similar approach for a targeted therapy of this pathological condition.

SAT-220-YI

Efruxifermin treatment improved collagen biomarkers consistent with remodelling of the extracellular matrix in patients with F2-F3 fibrosis due to MASH

Erik Tillman[1], Doreen Chan[1], Reshma Shringarpure[1], Diana Leeming[2], Morten Karsdal[2], Stephen A. Harrison[3], Andrew Cheng[1], Kitty Yale[1], Tim Rolph[1]. *[1]Akero Therapeutics, South San Francisco, United States; [2]Nordic Bioscience, Herlev, Denmark; [3]Pinnacle Clinical Research, San Antonio, United States*
Email: erik@akerotx.com

Background and aims: Efruxifermin (EFX) is a long-acting, bivalent Fc-FGF21 analogue in phase 3 clinical trials for the treatment of liver fibrosis due to metabolic dysfunction-associated steatohepatitis (MASH). Across multiple phase 2 studies in patients with moderate-to-severe (F2–F3) fibrosis or compensated cirrhosis (F4) due to MASH, EFX significantly improved markers of liver injury, fibrosis, and fibrogenesis. In the phase 2b HARMONY study in F2–F3 MASH fibrosis, 28 mg and 50 mg EFX improved fibrosis without MASH worsening in significantly more patients than pbo, while also leading to substantially higher rates of MASH resolution without worsening fibrosis after 24 weeks. Here, we aimed to assess the effects of EFX on markers of various components of the extracellular matrix (ECM) to understand EFX pharmacology and the relationship between hepatic ECM remodelling and fibrosis improvement.
Method: We undertook a *post hoc* analysis of biomarkers of fibrogenesis and fibrolysis of collagens associated with pathological fibrosis (types III, VI, and VIII) and components of the basement membrane (type IV collagen). Pro-C3, Pro-C4, Pro-C6, and Pro-C8 are markers of collagen synthesis, while CTX-III and C4M are markers of collagen degradation, Pro-C3/CTX-III or Pro-C4/C4M ratios indicate the balance between fibrogenesis and fibrolysis. Pro-C6, also known as endotrophin, has both *in vitro* and *in vivo* pro-fibrotic activity, and is associated with adipose tissue dysfunction and risk of clinical

outcomes in patients with heart failure with preserved ejection fraction.
Results: After 24 weeks, we identified significant EFX-related shifts towards a potentially beneficial ECM remodelling endotype, with decreased type-III collagen fibrogenesis relative to fibrolysis (suggesting resorption of type-III collagen), with mean reductions in Pro-C3/CTX-III ratio of 16%* and 13%* for 28 mg and 50 mg EFX, respectively, compared to a 7% increase for pbo. EFX also significantly reduced Pro-C8, with mean reductions of 2% and 9%* for 28 mg and 50 mg EFX, compared to a 5% increase for pbo. We observed a trend toward increased type-IV collagen fibrogenesis relative to fibrolysis (suggesting regeneration of type-IV collagen), with mean increases in Pro-C4/C4M ratio of 6% and 11% for 28 mg and 50 mg EFX, respectively, compared to a 2% increase for pbo. EFX significantly reduced Pro-C6, with mean reductions of 11%*** and 12%*** for 28 mg and 50 mg EFX, compared to a 9% increase for pbo. We observed associations between ECM remodelling and improvements in liver pathology, including both fibrosis improvement and MASH resolution [* $p < 0.05$, *** $p < 0.001$ vs pbo].
Conclusion: Together, these results suggest overall beneficial remodelling of the ECM and modulation of markers of pathological fibrosis consistent with improvements in metabolic health, liver health, and suppression of fibrogenesis following EFX treatment.

SAT-221

Effectiveness of Polyene phosphatidylcholine in metabolic-associated fatty liver disease treatment : a real-world study in China

Yi Pan[1], Feng Xue[1], Shanshan Wang[2], Shuangqing Gao[2], Lai Wei[1].
[1]Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China; [2]Beijing North Medical and Health Economic Research Center, Beijing, China
Email: weelai@163.com

Background and aims: Metabolic-associated fatty liver disease (MAFLD) has increasingly become the primary cause of liver transplantation and cirrhosis globally. To date, there is no approved pharmacotherapy for MAFLD in the world. Previous studies showed that polyenyl phosphatidylcholine (Essentiale capsule, Ess) could be used for MAFLD due to its action of accelerating liver cell membrane regeneration. We conducted a retrospective observational study based on multicenter real-world data to evaluate the effectiveness of Ess in Chinese MAFLD patients.
Method: MAFLD patients (aged ≥18) were identified from the tertiary public hospital between January 1st 2020 and December 31st 2022 following APASL 2020 guideline. Propensity score matching (PSM) was used to match Ess monotherapy group and control (non-hepatoprotective-treated) group. The primary end point was the changes of fibrosis-4 index (FIB-4) from baseline to 24 weeks between the two groups. Changes of liver biochemistry from baseline also were compared between the two groups at 4 weeks, 12 weeks, and 24 weeks of the treatment. In MAFLD patients with hyperlipidemia, between-group differences in changes of blood lipids parameters were compared.
Results: A total of 82, 908 MAFLD patients were identified from 11 hospitals. The median age was 53 (43–63) years old and 64.3 % were male. 7, 093 of MAFLD patients were treated with Ess and those whose test parameters could be available during the follow-up were included in the analysis. After PSM analysis matching for age, sex, type 2 diabetes (T2DM), hypertension, hyperlipidemia, and cardiovascular disease (CVD), there was a statistical difference in the reduction of FIB-4 at 24 weeks between the two groups (−0.12 ± 0.62 for Ess vs. 0.11 ± 0.50 for control, p = 0.034). There was a significant difference in the changes of aspartate transaminase from baseline to 12 weeks between the two groups (−6.25 ± 15.18 for Ess vs. −2.41 ± 15.40 for control, p = 0.0392). The significant difference between Ess and control group was also observed in the changes of alkaline phosphatase from baseline to 4 weeks (−6.46 ± 60.62 for Ess vs. 2.45 ± 28.12 for control, p = 0.0269). Between-group differences in changes of total bilirubin from baseline to 4, 12, 24 weeks were significant (4 weeks: −2.80 ± 5.59 for Ess vs. −0.10 ± 7.92 for control, p = 0.0063; 12 weeks: −1.97 ± 5.93 for Ess vs. 0.23 ± 6.12 for control, p = 0.0122; 24 weeks: −3.39 ± 5.65 for Ess vs. 1.24 ± 3.94 for control, p = 0.0010). In the subgroup of MAFLD patients with hyperlipidemia, low-density lipoprotein cholesterol was significantly decreased in Ess-treated group than control group after 12 weeks of treatment (−0.23 ± 0.71 for Ess vs. 0.13 ± 0.67 for control, p = 0.0442).
Conclusion: This study found that, in MAFLD patients, Ess treatment could improve liver function and might have beneficial effects on reducing the risk of fibrosis and improving lipid disorders.
Funding: Sanofi.

SAT-224

Pharmacokinetics of the selective glucocorticoid receptor modulator miricorilant in healthy volunteers and patients with presumed metabolic dysfunction-associated steatohepatitis (MASH)

Joseph M. Custodio[1], Kirsteen Donaldson[2], Jeevan Kunta[1], Kavita Juneja[1], Naim Alkhouri[3], Hazel J. Hunt[1]. *[1]Corcept Therapeutics Incorporated, Menlo Park, CA, United States; [2]Jade Consultants (Cambridge) Limited, Cambridge, United Kingdom; [3]Arizona Liver Health, Tucson, AZ, United States*
Email: jcustodio@corcept.com

Background and aims: Miricorilant (MIRI) is an oral, nonsteroidal selective glucocorticoid receptor (GR) modulator (SGRM) that acts as a mixed agonist/antagonist of the GR and a modest antagonist of the mineralocorticoid receptor. MIRI is in development for the treatment of metabolic dysfunction-associated steatohepatitis (MASH). Over 450 patients (pts) and healthy volunteers (HVs) have received MIRI in clinical trials to date. Here, we describe the pharmacokinetics (PK) and metabolism of MIRI in several non-clinical and phase 1 clinical development trials.
Method: Tissue distribution of oral [^{14}C]-MIRI 50 mg/kg was assessed in albino mice. Study 850 (NCT03315338) was a first-in-human, double-blind, randomized, placebo-controlled study testing multiple ascending doses (150–900 mg) of oral MIRI for 14 days in fasted HVs; PK was assessed. Study 851 (NCT03878264) evaluated the absorption, distribution, metabolism, and excretion (ADME) and mass balance of a single oral dose of [^{14}C]-MIRI 150 mg in fed HVs. Study 854 (NCT05553470) was an open-label, adaptive design study of single-dose MIRI 600 mg given under fed conditions in pts with moderate hepatic impairment compared to HVs with normal hepatic function; PK was assessed. Study 861 (NCT05117489) was a phase 1b, open-label trial of adult pts with presumed MASH that included 11 cohorts of pts who received MIRI doses ranging from 30–200 mg intermittently or daily for 12 or 24 weeks; efficacy and PK were assessed. Safety was assessed in all trials.
Results: High levels of radioactivity were present in the liver 1 and 4 hours following oral administration of [^{14}C]-MIRI in mice. In study 850, systemic concentrations increased with repeated dosing with MIRI 150 mg daily for 14 days in HVs (n = 9). Steady state plasma exposures were achieved by Day 7, resulting in an overall accumulation ratio from Days 1 to 14 of 1.68 for C_{max} and 2.17 for $AUC_{(0\text{-}tau)}$, with an elimination half-life of 21.6 hours. MIRI was generally well tolerated in HVs. In study 851, following administration of a single oral dose of [^{14}C]-MIRI 150 mg to HVs (n = 6), 89.1% of the total radioactivity was recovered in the feces, with minimal recovery in the urine (<5%), suggesting that the predominant route of elimination is hepatic. MIRI accounted for >50% of the total radioactivity in plasma based on $AUC_{(0\text{-}inf)}$, indicating that parent MIRI was the main circulating species in plasma. In study 854, there was no apparent difference in plasma exposures in pts with moderate hepatic impairment (n = 10) compared to HVs (n = 10) with normal hepatic function. In study 861, MIRI plasma PK behaved in an approximately

dose proportional manner across the range of MIRI doses and dosing regimens evaluated in pts with MASH (n = 71).
Conclusion: The presented studies characterize the PK/ADME of MIRI in HVs and pts with MASH. A phase 2b study (MONARCH, NCT06108219) of MIRI 100 mg twice weekly in MASH is underway.

SAT-225
Berberine Ursodeoxycholate (HTD1801) provides a unique therapeutic approach for patients with metabolic diseases and severe insulin resistance
Leigh MacConell[1], Alexander Liberman[1], Abigail Flyer[2], Kui Liu[3].
[1]*HighTide Therapeutics, Rockville, United States;* [2]*Pacific Northwest Statistical Consulting, Woodinville, United States;* [3]*HighTide Therapeutics, Shenzhen, China*
Email: lmacconell@hightidetx.com

Background and aims: Hyperinsulinemia is a significant risk factor for several metabolic diseases. HTD1801 is a gut-liver anti-inflammatory metabolic modulator with a unique molecular structure which has been shown to significantly reduce liver fat content (LFC; via MRI-PDFF) and important cardiometabolic end points in an 18-Week, placebo (PBO)-controlled Phase 2 study in patients with MASH and T2DM. HTD1801 is hypothesized to activate AMPK, increasing cellular utilization of glucose and fat, thereby alleviating the effects induced by high insulin. Based on this hypothesis, HTD1801 evaluated post hoc based on baseline insulin levels.
Method: 100 patients were randomized and treated with HTD1801 1000 mg BID, HTD1801 500 mg BID, or PBO for 18 weeks. Patients were then analyzed by subgroups defined by baseline fasting insulin (FIN) levels: ≤40 μIU/ml (HTD1801 1000 mg BID: n = 19, HTD1801 500 mg BID: n = 22, PBO: n = 20) vs >40 μIU/ml (HTD1801 1000 mg BID: n = 8, HTD1801 500 mg BID: n = 7, PBO: n = 12).
Results: 27/100 patients had severe insulin resistance (baseline FIN >40 μIU/ml). Baseline characteristics were generally similar across insulin subgroups. Across the primary end point (LFC) and key cardiometabolic parameters, dose dependent improvements were observed irrespective of baseline insulin levels with HTD1801 compared to PBO after 18 weeks.
LFC (%)
FIN ≤40 μIU/ml; HTD1801 1000 mg BID: −4.0, HTD1801 500 mg BID: −2.8, PBO: −2.6
FIN >40 μIU/ml; HTD1801 1000 mg BID: −6.9, HTD1801 500 mg BID: −3.7, PBO: −0.6
HbA1c (%)
FIN ≤40 μIU/ml; HTD1801 1000 mg BID: −0.4, HTD1801 500 mg BID: −0.4, PBO: 0.03
FIN >40 μIU/ml; HTD1801 1000 mg BID: −0.9, HTD1801 500 mg BID: −0.3, PBO: 0.2
Weight (kg)
FIN ≤40 μIU/ml; HTD1801 1000 mg BID: −1.6, HTD1801 500 mg BID: −1.2, PBO: −1.1
FIN >40 μIU/ml; HTD1801 1000 mg BID: −8.0, HTD1801 500 mg BID: −2.7, PBO: −1.0
However, in the HTD1801 1000 mg BID group, substantially greater improvements were observed across parameters in patients with elevated baseline insulin compared to patients with lower baseline insulin
Conclusion: These data, while limited to a small number of subjects, suggest that HTD1801 can alleviate the metabolic inhibitory effects caused by hyperinsulinemia, leading to greater metabolic benefits and therefore may offer a unique therapeutic approach for individuals with metabolic diseases and elevated insulin levels. HTD1801 continues to be evaluated in the ongoing Phase 2b study in patients with MASH and T2DM.

SAT-226
Statin prescriptions and progression to a high-risk for advanced fibrosis in primary care patients with metabolic dysfunction-associated steatotic liver disease (MASLD)
Andrew Schreiner[1], Jingwen Zhang[1], Mulugeta Gebregziabher[1].
[1]*Medical University of South Carolina, Charleston, United States*
Email: schrein@musc.edu

Background and aims: Statin medications reduce the risk of cardiovascular events, an important consideration in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). Statins may also reduce the risk of fibrosis progression in MASLD and other chronic liver diseases. We aimed to determine the association of statin prescriptions, and the intensity of statin prescriptions, with progression to a high-risk for advanced fibrosis in primary care patients with low-risk MASLD.
Method: This retrospective cohort study of primary care electronic health record data from 2012 to 2021 included patients with MASLD and an initial low- or indeterminate-risk for advanced fibrosis, determined by Fibrosis-4 Index score (FIB-4 <2.67). Patients were followed from the index FIB-4 score until the primary outcome of a FIB-4 at high-risk for advanced fibrosis (FIB-4 ≥2.67). Prescription for a statin during follow-up, treated as a fixed and time-varying covariate, was the primary exposure of interest. We developed Cox regression models for the time to a high-risk FIB-4 score with statin therapy as the primary covariate and adjusting for advanced fibrosis risk at baseline, demographic, and comorbidity variables during follow-up.
Results: The cohort included 1, 238 patients with MASLD and a mean age of 54 years and a mean body mass index of 33 kg/m^2. Of included patients, 64% and 36% had low- and indeterminate-risk FIB-4 scores at baseline. During follow-up of a mean 3.3 (±2.5) years, 47% (586) of patients received a prescription for a statin, and 18% (220) of patients progressed to a FIB-4 at high-risk for advanced fibrosis. In the fully adjusted Cox regression model with statin prescription as a time-fixed covariate, statins were associated with a lower risk (HR 0.60; 95%CI 0.45–0.80) of progressing to a FIB-4 ≥2.67. In the fully adjusted Cox model with statin prescription as a time-varying covariate, statins were not associated with time to high-risk for advanced fibrosis (HR 0.89; 95%CI 0.67–1.18).
Conclusion: Though evidence from the analysis of statin prescription as a time-fixed covariate demonstrates a protective association with progression to advanced fibrosis, the Cox model with statin prescriptions as a time-varying covariate showed no association between statin prescription and progression of advanced fibrosis risk.

SAT-227
Evaluation of efficacy of Berberine Ursodeoxycholate (HTD1801) compared to ongoing use of GLP-1 receptor agonists in patients with MASH and T2DM
Stephen A. Harrison[1], Guy Neff[2], Nadege Gunn[3], Abigail Flyer[4], Leigh MacConell[5]. [1]*Pinnacle Clinical Research, San Antonio, United States;* [2]*Covenant Metabolic Specialists, Sarasota, United States;* [3]*Impact Research Institute, Waco, United States;* [4]*Pacific Northwest Statistical Consulting, Woodinville, United States;* [5]*HighTide Therapeutics, Rockville, United States*
Email: lmacconell@hightidetx.com

Background and aims: HTD1801 is a gut-liver anti-inflammatory metabolic modulator with a unique molecular structure which has been shown to significantly reduce liver fat content (LFC) as determined by MRI-PDFF and important cardiometabolic end points in an 18-Week, placebo (PBO)-controlled Phase 2 study in patients with MASH and T2DM (NCT03656744). GLP-1 receptor agonists (RA) are widely used for the treatment of T2DM and obesity and are under investigation for treatment of MASH. The purpose of this post-hoc analysis was to evaluate ongoing GLP-1RA use compared to newly initiated HTD1801 treatment alone.

Method: 100 patients were randomized and treated with HTD1801 1000 mg BID (n = 34), HTD1801 500 mg BID (n = 33), or PBO (n = 33) for 18 weeks. The primary end point was change in LFC. This analysis included patients who were randomized to HTD1801 and were not treated concomitantly with GLP-1RA (HTD1801 1000 mg BID: n = 28; HTD1801 500 mg BID: n = 27) or PBO randomized patients who were receiving ongoing GLP-1RA (n = 13).
Results: At baseline, 39% of PBO patients were utilizing GLP-1RA compared with 18% of patients randomized to HTD1801. Baseline characteristics were balanced across groups with the exception of ALT (HTD1801 1000 mg BID: 62.7 U/L: HTD1801 500 mg BID: 46.2 U/L; GLP-1RA: 43.1 U/L). Dose-dependent improvements were observed at Week 18 with HTD1801 treatment in LFC (HTD1801 1000 mg BID: −4.5%; HTD1801 500 mg BID: −3.2%; GLP-1RA: −2.9%), ALT (HTD1801 1000 mg BID: −16.7 U/L; HTD1801 500 mg BID: −4.6 U/L; GLP-1RA: −4.5 U/L), HbA1c (HTD1801 1000 mg BID: −0.4%; HTD1801 500 mg BID: −0.4%; GLP-1RA: 0%), and weight (HTD1801 1000 mg BID: −3.7 kg: HTD1801 500 mg BID: −1.4 kg; GLP-1RA: −1.9 kg). Furthermore, reductions in each of these parameters were greater with HTD1801 1000 mg BID vs ongoing GLP-1RA.
Conclusion: This data suggests newly initiated HTD1801 provides greater benefit than ongoing GLP-1RA use. Utilization of GLP-1RA continues to grow and may be confounding in studies of MASH. This has resulted in their exclusion from some new studies of MASH which is unlikely to be reflective of real-world use. In order to address this concern, GLP-1RA utilization is a stratification factor in the ongoing Phase 2b study of HTD1801.

SAT-230

Effect of omega 3 fatty acid supplementation on hepatic steatosis and liver stiffness in patients with non-alcohol-related fatty liver disease

Muhammad Abedur Rahman Bhuyan[1], Eshita Ashab[2], Shahinul Alam[3], Mamun Al-Mahtab[4]. *[1]Shaheed Syed Nazrul Islam Medical College Hospital, Kishorganj, Bangladesh; [2]Shaheed Syed Nazrul Islam Medical College Hospital, Kishorganj, Bangladesh; [3]Department of Hepatology, Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh; [4]Department of Interventional Hepatology, Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh*
Email: drabedurrahmanzimi@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) describes a spectrum of clinicopathological changes in liver extending from simple steatosis through non-alcoholic steatohepatitis (NASH) to fibrosis. NAFLD is an increasingly prevalent disease, there is a lack of approved therapies for it. Omega-3 fatty acids (OMG-3 FA) are beneficial in the treatment of hypertriglyceridaemia. OMG-3 FA treatment might be beneficial to decrease liver triglyceride. OMG-3 FA have a beneficial effect: a) on bioactive metabolites involved in inflammatory pathways, b) on alteration of nuclear transcription factor activities such as peroxisome proliferator-activated receptors, sterol regulatory element-binding protein 1c and carbohydrate-responsive element-binding protein, involved in inflammatory pathways and liver lipid metabolism. OMG-3 FA treatment in patients with NAFLD would be beneficial in treating hepatic steatosis and possibly also in ameliorating inflammation. To evaluate the efficacy of supplementation of OMG-3 FA on hepatic steatosis and liver stiffness in NAFLD patients.
Method: This was a six months randomized open level clinical trial. Study was done in Department of Hepatology Bangabandhu Sheikh Mujib Medical University. 100 patients with sonographic evidence of Fatty liver, who fitted the inclusion and exclusion criteria were enrolled. All the included patients were randomized into OMG-3 FA group (case group) and control group in 1:1 ratio. Transient Elastography (TE) was done in all patients. After six months of follow-up patients underwent biochemical and TE follow-up. All data was presented as mean ± SD and analyzed by SPSS (version 23). Qualitative data was analyzed by Chi-square test and quantitative data was analyzed by student's t-test. A statistically significant result was considered when P value was less than 0.05.
Results: Hepatic steatosis improvement was significant in the case group. Controlled attenuation parameter (CAP) in case group (baseline 305.9 ± 38.8 dB/m, after treatment 284.4 ± 47.1 dB/m, p = 0.005) and in control group (baseline 279.3 ± 52.9 dB/m, after treatment 288.4 ± 49.8, p = 0.144). Fibrosis improvement was insignificant in both groups, Liver stiffness measurement (LSM) in case group was (6.06 ± 2.5 vs 6.07 ± 2.6 kPa p = 0.977) and LSM in control group was (7.1 ± 8.6 vs 7.2 ± 8.3 kPa, p = 0.826). In Comparative analysis of anthropometric, biochemical and TE changes between baseline and after intervention in OMG-3 FA group ALT improvement was significant (64.2 ± 57.8 vs 37.4 ± 21.9 U/L, p = 0.003).
Conclusion: NAFLD and NASH are well recognized causes of progressive chronic liver disease leading to cirrhosis and hepatocellular carcinoma. To date, no therapy provided evidence of significant efficacy. This study has demonstrated that OMG-3 FA supplementation may improve steatosis and ALT but not stiffness.

SAT-231

GL0034 (Utreglutide), a long acting, glucagon-like peptide-1 receptor agonist, improves body weight loss, lipid and liver injury markers in individuals with obesity: A phase 1 multiple ascending dose study

Rajamannar Thennati[1], Vinod Burade[1], Muthukumaran Natarajan[1], Pradeep Shahi[1], Ravishankara Nagaraja[1], Sudeep Agrawal[1], Bernard Jandrain[2], Thierry Duvauchelle[3], Richard E. Pratley[4], Bernard Thorens[5], Tina Vilsbøll[6], Rohit Loomba[7]. *[1]High Impact Innovations-Sustainable Health Solutions (HISHS), Sun Pharmaceutical Industries Limited, Vadodara, India; [2]Former MD, Clinical Pharmacology Unit, ATC Co, and Division of Diabetes, Nutrition and Metabolic Disorders, Academic Hospital of Liège, Liège, Belgium; [3]Phaster1, Paris, France; [4]AdventHealth Translational Research Institute, Orlando, United States; [5]Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland; [6]Clinical Research, Steno Diabetes Center Copenhagen, Herley, University of Copenhagen, Copenhagen, Denmark; [7]University of California San Diego School of Medicine, La Jolla, CA, United States*
Email: rajamannarthennati@yahoo.com

Background and aims: GL0034 (Utreglutide) is a potent glucagon-like peptide-1 receptor agonist (GLP-1 RA) under development for the treatment of metabolic disorders and metabolic dysfunction-associated steatotic liver disease (MASLD). GL0034 (GL) has demonstrated significant reductions in body weight (BW) up to Day 22 in a single ascending dose study in individuals with obesity. Here, we present safety and MASLD-relevant pharmacodynamic (PD) results of a multiple ascending dose (MAD) phase 1 study in individuals with obesity.
Method: A randomized, double-blind, placebo (PBO)-controlled study was conducted to evaluate the safety, tolerability and PD of MAD study. Individuals with BMI ≥28 kg/m^2 (n = 12) were randomized (9:3) to subcutaneous GL increasing doses (680, 900, 1520, 2000 µg) or placebo, once weekly for four weeks. Biomarker measurements included, body weight, lipid profile (triglycerides (TG), total cholesterol (TC) and low-density lipoprotein (LDL)) and liver enzymes (alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyl transferase (GGT)), free fatty acids (FFA), homeostatic model assessment-insulin resistance (HOMA-IR), and leptin.
Results: Most common adverse events (AE) were gastrointestinal (GI) with dose-dependent nausea, decreased appetite and vomiting. One individual with a GI related serious AE rapidly recovered upon treatment with intravenous rehydration. BMI (kg/m^2) at baseline was 32.4 ± 4.6 for GL treatment group and 27.9 ± 1.3 for PBO. Reduction in body weight (kg) from baseline (BL) was significant on day 29 [GL: −4.6 ± 1.5 (p < 0.001); PBO: 0.0 ± 0.9]. Similarly, on day 23 significant reduction in TG (mg/dL) [GL: −47.1 ± 54.2 (p < 0.05); PBO −16.7 ±

28.7] was noted from BL. TC (mg/dL) [GL: −20.0 ± 26.8; PBO 8.7 ± 26.9] and LDL (mg/dL) [GL: −5.7 ± 23.9; PBO 11.3 ± 19. 6] also reduced from BL. A trend towards lower ALT, AST and GGT from BL was observed [ALT (U/L)-GL: −9.1 ± 13.9; PBO: 6.3 ± 43 and AST (U/L)-GL: −2.7 ± 4.2; PBO: 1.7 ± 18.7]. The reduction in GGT (U/L) from BL was significant on day 23 [GL: −4.2 ± 2.4 ($p < 0.001$); PBO 4.3 ± 15.3]. There was no change in the free fatty acid levels from BL in GL and PBO. In the treatment group an improved HOMA-IR was observed on day 23 and day 50 [BL value of 2.3 ± 1.2 to 1.7 ± 1.0, 1.7 ± 0.4 vs. PBO BL 3.2 ± 0.5 to 2.1 ± 0.1 and 2.6 ± 0.9, respectively]. A decrease was observed in leptin, on day 23 and day 50 for GL group [Day 23 GL: −5.7 ± 5.9; PBO: −3.7 ± 5.3, Day 50 GL: −4.5 ± 10.2; PBO: 5.1 ± 16.4].
Conclusion: GL0034, a potent, long-acting GLP-1RA, was safe, well tolerated and with significant body weight reduction as well as improvements in lipids, liver injury and metabolic biomarkers in individuals with obesity. The observed PD effects suggest potential therapeutic benefits in MASLD patients.

SAT-233
Clinical pharmacokinetics of INI-822, a small molecule inhibitor of HSD17B13
Chuhan Chung[1], Kelly Regal[1], Greg Coulter[1], Paul Pearson[1], Heather Hsu[2]. *[1]Inipharm, Bellevue, WA, United States; [2]Inipharm, Bellevue, United States*
Email: cchung@inipharm.com

Background and aims: Human genetic validation studies identify inactive variants of HSD17B13 as protective against the development of MASH, MASH and alcohol-related cirrhosis, and hepatocellular carcinoma. INI-822, a selective small molecule inhibitor of HSD17B13, was developed to be a once daily oral inhibitor of HSD17B13 for the treatment of chronic liver disease. Nonclinical pharmacokinetic/pharmacodynamic studies measuring plasma levels of bioactive lipid substrates and products demonstrated target engagement with an ED_{50} of 5.4 ± 2.2 mg/kg in rats and an EC_{50} for C_{trough} of 56 ng/ml (abstract McReynolds 2023 J Hepatology). The objective of these studies was to evaluate the pharmacokinetics (PK) of INI-822 in nonclinical and clinical settings.
Method: INI-822 was orally administered to mice (10 mg/kg, n = 3/group, sparse sampling), rats (30 mg/kg, n = 3) and dogs (10 mg (~1 mg/kg), n = 6). Blood was collected, processed to plasma at timed intervals and INI-822 plasma concentrations were determined by LC/MS-MS. In a first-in-human study, PK was determined in a Phase 1, placebo-controlled study of INI-822 in healthy volunteers (n = 6/cohort) following a single oral dose of INI-822. Noncompartmental PK parameters were calculated. Data was presented as mean ± SD.
Results: INI-822 exposure (AUC_{0-24}) was 17, 500 ng*h/ml for 10 mg/kg in mice, 22, 200 ± 5480 ng*h/ml for 30 mg/kg in rats and 10, 600 ± 3390 ng*h/ml for 10 mg in dogs. The resulting oral bioavailability (F%) was 44%, 36% and 97% in mice, rats and dogs, respectively. In humans, exposure increased in an approximately dose-proportional manner. The mean C_{max} increased from 289 ± 80, 569 ± 92 and 1040 ± 337 ng/ml for 25, 50 and 100 mg, respectively. The mean AUC_{0-inf} increased from 3590 ± 1060, 6930 ± 1920 and 10400 ± 4210 ng*h/ml for 25, 50 and 100 mg, respectively. The mean half-life in these clinical cohorts were amenable to once daily dosing with means ranging from 18.9 to 27.2 h. The estimated steady state AUC and C_{trough} values for the 25 mg dose level exceeded those for the ED_{50} for the rat pharmacokinetic/pharmacodynamic assessment of bioactive lipid substrates and products.
Conclusion: The small molecule HSD17B13 inhibitor, INI-822, achieved clinical plasma exposures that exceeded concentrations projected to inhibit HSD17B13 based on preclinical models. Single ascending dose PK in healthy subjects appeared to achieve dose-proportional maximal plasma concentrations and exposure (AUC). The half-life of INI-822 is suitable for once daily dosing in future clinical trials of MASH subjects. A Phase 1 study, to include evaluation of multiple doses of INI-822 in healthy volunteers and patients with liver disease, is ongoing.

SAT-236
Efficacy and safety of incretin-based therapies in patients with metabolic dysfunction-associated steatotic liver disease complicated by type 2 diabetes mellitus
Tadamichi Kawano[1], Taeang Arai[1], Masanori Atsukawa[1], Toshifumi Tada[2], Tsunekazu Oikawa[3], Akihito Tsubota[3], Kentaro Matsuura[4], Toru Ishikawa[5], Hiroshi Abe[6], Keizo Kato[6], Asahiro Morishita[7], Joji Tani[7], Tomomi Okubo[8], Katsuhiko Iwakiri[1]. *[1]Nippon Medical School, Tokyo, Japan; [2]Japanese Red Cross Society Himeji Hospital, Himeji, Japan; [3]The Jikei University School of Medicine, Tokyo, Japan; [4]Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; [5]Saiseikai Niigata Hospital, Niigata, Japan; [6]Shinmatsudo Central General Hospital, Chiba, Japan; [7]Kagawa University, Kagawa, Japan; [8]Nippon Medical School Chiba Hokusoh Hospital, Chiba, Japan*
Email: taeangpark@yahoo.co.jp

Background and aims: The aim of this study was to evaluate the efficacy and safety of oral semaglutide (Sema), a GLP-1 receptor agonist, and tirzepatide (TZP), a dual GIP/GLP-1 receptor agonist, in patients with metabolic dysfunction-associated steatotic liver disease (MASLD) complicated by type 2 diabetes mellitus (T2DM).
Method: Verification 1; multi-institutional prospective study. Eighty-three patients with MASLD who received Sema for T2DM were included. Sema was initiated at a dose of 3 mg once daily, and the dose was gradually increased, while being monitored for any adverse events. Verification 2; single-center prospective pilot study. Thirteen patients with MASLD who received TZP for T2DM were included. TZP was initiated at a dose of 2.5 mg once weekly and was increased to a maintenance dose of 5.0 mg once weekly at week 4.
Results: Verification 1; Sema treatment resulted in significant improvements in glycemic control, liver transaminases, and lipid profiles with weight loss at week 12. These significant improvements were maintained at week 24: glycemic control (plasma glucose 132 mg/dL to 107 mg/dL, HbA1c 7.0% to 6.0%), liver transaminases (ALT 61 U/L to 37 U/L, γ-GTP 63 U/L to 43 U/L), and lipid profiles (LDL-cho 116 mg/dL to 110 mg/dL, TG 133 mg/dL to 116 mg/dL). In 43 patients after 48 weeks of treatment, controlled attenuation parameter (315 dB/m to 296 dB/m) and each non-invasive test for liver fibrosis decreased significantly from baseline (Wisteria floribunda agglutinin-positive Mac-2-binding protein 0.82 to 0.64, type IV collagen 7 s 4.0 ng/ml to 3.4 ng/ml, fibrosis-4 index 1.29 to 0.93, liver stiffness measurement 7.0 kPa to 6.5 kPa). A number of gastrointestinal disorders, including grade 1–2 nausea, were observed during the observation period. Verification 2; TZP treatment resulted in a decrease in body weight (−4.6 kg) at week 12, together with improvements in glycemic control (plasma glucose 134 mg/dL to 100 mg/dL, HbA1c 6.7% to 5.6%), liver transaminases (ALT 61 U/L to 32 U/L, γ-GTP 100 U/L to 41 U/L), and TG (165 mg/dL to 130 mg/dL). Gastrointestinal disorders such as grade 1–2 nausea and constipation were frequently observed in the early phase of treatment. The subsequent course of treatment is being followed.
Conclusion: Both Sema and TZP treatments offered a favorable effect on MASLD as well as improving diabetic status and reducing body weight.

SAT-237
Efficacy and safety of FGF21 analogues in the treatment of metabolic dysfunction-associated steatohepatitis: an updated systematic review and meta-analysis
Fabiana Dolovitsch de Oliveira[1], Emmily Daiane Buarque de Santana Sato[2], Samira Mohamad Khalil[3], Matheus Souza[4], Gilmara Coelho Meine[5]. *[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil; [2]Pontifícia Universidade Católica de Campinas, Campinas, Brazil; [3]Universidad de*

Buenos Aires, Buenos Aires, Argentina; [4]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [5]Universidade Feevale, Novo Hamburgo, Brazil
Email: gilmara@feevale.br

Background and aims: Fibroblast growth factor 21 (FGF21) regulates energy homeostasis, as well as lipid and glucose metabolism. The FGF21 analogues are believed to benefit patients with metabolic dysfunction-associated steatohepatitis (MASH), but their efficacy and safety are not yet established. Therefore, we aimed to perform a systematic review and meta-analysis to assess the efficacy and safety of FGF21 analogues in the treatment of MASH.
Method: We searched PubMed, Embase, and Cochrane Library databases for randomized controlled trials (RCTs) comparing FGF21 analogues to placebo for the treatment of patients with biopsy-confirmed MASH, reporting at least one of the outcomes of interest. Primary outcomes: fibrosis improvement ≥1 stage without worsening of MASH and MASH resolution without worsening of fibrosis. Secondary outcomes: relative reduction ≥30% of the hepatic fat fraction (HFF) measured by magnetic resonance imaging derived proton density fat fraction (MRI-PDFF) and adverse events (AEs). We compared binary outcomes using risk ratio (RR), with 95% confidence interval (CI). Heterogeneity was assessed using Cochran's Q test and I^2 statistics. We performed subgroup analyses by the grade of fibrosis (F1–F3 vs. F4) for all outcomes, provided there were at least two studies in each subgroup.
Results: 7 RCTs were included, encompassing 886 obese patients. Among them, 3 studies used Efruxifermin (238 patients), 3 used Pegbelfermin (426 patients) and 1 used Pegozafermin (222 patients). The overall analysis showed significantly higher probability of fibrosis improvement ≥1 stage without worsening of MASH (RR 1.74; CI 95% 1.22, 2.46; p = 0.002; I^2 = 0%), MASH resolution without worsening of fibrosis (RR 2.29; CI 95% 1.06, 4.94; p = 0.04; I^2 = 49%), and reduction ≥30% in the HFF by MRI-PDFF (RR 3.03; CI 95% 2.12, 4.33; p < 0.00001, I^2 = 0%) with FGF21 analogues in comparison to placebo. Moreover, FGF21 showed no significant difference in the risk of overall AEs (RR 1.04; CI 95% 0.95, 1.14, p = 0.37; I^2 = 44%) and serious AEs (RR 0.8; CI 95% 0.50, 1.28; p = 0.035; I^2 = 0%) compared to placebo. Regarding the subgroup analysis by the stage of fibrosis: (1) patients with fibrosis stages F1-F3 presented higher fibrosis improvement ≥1 stage without worsening of MASH, MASH resolution without worsening of fibrosis, reduction of ≥30% in the HFF by MRI-PDFF, and overall AEs with FGF21 analogues compared to placebo, but the risk of serious AEs was similar between both; (2) patients with fibrosis stage F4 showed a non-significant difference in the probability of fibrosis improvement ≥1 stage without worsening of MASH, overall AEs, and serious AEs between FGF21 analogues and placebo.
Conclusion: FGF21 analogues seem effective and safe in obese patients with biopsy-confirmed MASH, but the clinical benefit may be restricted to non-cirrhotic patients. New RCTs are necessary establish FGF21 analogues as a therapy for MASH.

SAT-238

Statins are not associated with an increased risk of decompensated cirrhosis in patients with type 2 diabetes mellitus

Jonathan Tjerkaski[1], Emilie Toresson Grip[2], Anthony Matthews[1], Hannes Hagström[1]. *[1]Karolinska Institutet, Stockholm, Sweden; [2]Karolinska Institutet, Quantify research, Stockholm, Sweden*
Email: jonathan.tjerkaski@ki.se

Background and aims: The prevalence of type 2 diabetes mellitus (T2DM) is increasing. T2DM is a major risk factor for atherosclerotic cardiovascular disease (ASCVD). Furthermore, T2DM is also associated with Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD), a major contributor to liver-related morbidity and mortality worldwide. Statins are frequently used to prevent ASCVD in T2DM patients by treating hypercholesterolemia, an important risk factor for ASCVD. Although some studies suggest that statins may protect against liver disease, statins have also been associated with hepatotoxicity. Statin-induced hepatotoxicity might be particularly harmful in T2DM patients, due to their elevated risk of liver disease. Therefore, the aim of this study was to examine the association between statin therapy and liver disease in T2DM patients.
Method: The participants of this observational cohort study were T2DM patients who did not have any known liver disease or history of alcohol use disorder at the time of inclusion. Data on baseline characteristics and patient outcomes was obtained from electronic health records and nationwide quality registers. We carried out sequential emulated target trials with three-month intervals between 2007 and 2020 to examine the effect of statin therapy on the outcome of decompensated liver cirrhosis, a composite of bleeding esophageal varices, hepatorenal syndrome, ascites, portal hypertension, hepatic encephalopathy and liver transplantation. Marginal structural models were used to compute the effect estimates.
Results: This study included 7837 T2DM patients who were treated with statins and 19359 controls. The adjusted 10-year cumulative risk of developing decompensated liver cirrhosis was 2.7% in the statin group and 2.0% among the controls (risk difference 0.6 [95% confidence interval −2.2–3.3]; risk ratio 1.3 [95% confidence interval 0.44–3.23]).
Conclusion: We found that statin therapy was not associated with a significantly increased risk of developing decompensated liver cirrhosis in this cohort of T2DM patients.

SAT-239

A phase 4, multicenter, open-label, single-arm study to evaluate the safety and efficacy of saroglitazar 4 mg in patients with non-alcoholic fatty liver disease with obesity, type 2 diabetes mellitus, dyslipidemia, or metabolic syndrome

Deven Parmar[1], Arun J. Sanyal[2], Kevin Kansagra[3], Rahul Shrivastava[3]. *[1]Zydus Therapeutics, Pennington, United States; [2]Virginia Commonwealth University, Richmond, VA, United States; [3]Zydus Research Center Zydus Lifesciences Ltd, Ahmedabad, India*
Email: dparmar@zydustherapeutics.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a common disease, with a prevalence of 13–32% globally and 5–28% in Asian countries, including India.[1,2] NAFLD is a hepatic component of the metabolic syndrome, which is a clinical syndrome characterized by obesity, dyslipidemia, type 2 diabetes mellitus (T2DM), and hypertension. Saroglitazar is a dual peroxisome proliferator-activated receptor (PPAR) alpha/gamma agonist and is approved in India for the treatment of NAFLD and non-cirrhotic non-alcoholic steatohepatitis (NASH). In EVIDENCES I and III clinical studies, Saroglitazar Mg demonstrated improvement in liver enzymes and liver fat content in patients with NAFLD. However, the impact of saroglitazar in real-world setting in Asian population with NAFLD and comorbidities remains unclear. Here, we describe the design and plan of a study that aims to evaluate the safety and efficacy of saroglitazar 4 mg in patients with NAFLD with comorbidities (obesity, dyslipidemia, T2DM, and metabolic syndrome) in India in real-world settings.
Method: This Phase 4, non-randomized, multicenter, open-label, single-arm study will be conducted at multiple centers in India with approximately 1500 patients. The study consists of a screening period of up to 4 weeks, a treatment period of 52 weeks, and end of the study assesssment on completion of 364 days/52 weeks of the treatment. The primary safety and efficacy end points include frequency and severity of treatment-emergent adverse events/serious adverse events and change in liver stiffness measurement (LSM) performed by transient elastography from baseline to week 52, respectively.
Results: At present, more than 200 patients have been enrolled at various centers across India in this study. The mean (±SD) age, BMI, and waist circumference of first 50 enrolled patients were 47 ± 11 years, 29 ± 3.7 kg/m^2, and 91 ± 25, respectively, and the men to women ratio was 37:13. Further, enrolled patients had LSM ≥8 kPa and/or serum ALT ≥45 U/L. The enrolled patients with NAFLD also had obesity, T2DM, dyslipidemia, and/or metabolic syndrome. In addition to efficacy, the safety data of large-scale population will

further establish the safety of saroglitazar Mg 4 mg dose in patients with NAFLD.
Conclusion: This ongoing study is currently recruiting patients actively. The study will prove the efficacy and safety of saroglitazar Mg 4 mg in patients with NAFLD with different comorbidities.

SAT-242
Efficacy and safety of FGF-analogs for the treatment of MASH: a systematic review and meta-analysis
Maria Viana[1], Arthur Braga[1], Dermeval Neto[1], Junior Samuel Menezes[2], Luis Felipe Silva[3], Antônio Ricardo Cardia Ferraz de Andrade[2]. [1]*Bahiana School of Medicine and Public Health, Salvador, Brazil;* [2]*Federal University of Bahia, Salvador, Brazil;* [3]*Federal Fluminense University, Niterói, Brazil*
Email: mariaviana21.1@bahiana.edu.br

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH), an intermediary stage of metabolic dysfunction-associated fatty liver disease (MAFLD), denotes a serious liver condition marked by hepatic steatosis, inflammation, and injury that can lead to cirrhosis. Currently, there is no specific treatment for MASH, with FGF-19 analogs being a possible contender to combat this ailment. We aimed to perform a meta-analysis comparing a novel FGF-19 analog, Aldafermin, to placebo, in patients with MASH.
Method: PubMed, Cochrane Library and EMBASE were systematically searched for RCT comparing FGF-19 analogs to placebo in patients with MAFLD. Statistical analysis was performed using RevMan 5.4 and the PRISMA framework was followed. Outcomes of interest were ELF score, C4 concentration, liver fat content, fibrosis improvement with no worsening of MASH, MASH resolution with no worsening of fibrosis, PRO C3. Safety measures were pooled regarding drug-related side effects (PROSPERO register: CRD42023482818).
Results: From an initial pool of 931 studies, 4 were included comprising 413 patients, of whom 137 received Aldafermin 1 mg, 125 Aldafermin 3 mg, and 151 received placebo; 63% were females and 260 patients were diagnosed with type II diabetes. The mean follow-up period was 5.5 weeks. In the pooled analysis, both Aldafermin 1 mg and 3 mg had significant reduction of ELF score (MD 0.1; 95% CI 0.07–0.13; $p < 0.01$), (MD 0.6; 95% 0.01–0.51; $p = 0.04$) respectively, liver fat content and C4. In addition, Aldafermin 1 mg achieved statistical significance in regards to MASH resolution without worsening of fibrosis (OR 0.3; 95% CI 0.11–0.82; $p = 0.02$). In regards to safety measures, Aldafermin 1 mg and 3 mg did not demonstrate significant abdominal pain, nausea, and no serious adverse events, but 3 mg significantly increased the incidence of diarrhea when compared to placebo (OR 0.4; 95% CI 0.22–0.72; $p < 0.01$), with the 1 mg dosage not displaying any significant side effects.
Conclusion: The results of our meta-analysis suggest that in patients with MASH, Aldafermin is associated with a decrease of ELF score, liver fat content, and C4. Notably, only Aldafermin 1 mg displayed an increase in MASH resolution with no worsening of fibrosis and no significant side effects compared to placebo. Further studies with larger sample size and extended follow-up are essential for comprehensively assessing the sustained efficacy and safety of the drug.

SAT-243
Time course of onset, incidence and prevalence of gastrointestinal adverse events with HTD1801 (Berberine Ursodeoxycholate) in patients with MASH and T2DM
Guy Neff[1], Stephen A. Harrison[2], Nadege Gunn[3], Abigail Flyer[4], Kui Liu[5], Alexander Liberman[6]. [1]*Covenant Metabolic Specialists, Sarasota, United States;* [2]*Pinnacle Clinical Research, San Antonio, United States;* [3]*Impact Research Institute, Waco, United States;* [4]*Pacific Northwest Statistical Consulting, Woodinville, United States;* [5]*HighTide Therapeutics, Shenzhen, China;* [6]*HighTide Therapeutics, Rockville, United States*
Email: aliberman@hightidetx.com

Background and aims: HTD1801 is a gut-liver anti-inflammatory metabolic modulator consisting of an ionic salt combination including berberine and ursodeoxycholic acid. The unique molecular structure has been shown to significantly reduce liver fat content (LFC) as determined by MRI-PDFF. Clinically, HTD1801 has improved multiple cardiometabolic end points in an 18-Week, placebo-controlled Phase 2 study in patients with metabolic dysfunction-associated steatohepatitis (MASH) and type 2 diabetes (T2DM) (NCT03656744). The most commonly occurring adverse events (AEs) in studies of HTD1801 across several indications have been mild to moderate gastrointestinal (GI) AEs, primarily diarrhea and nausea. The purpose of this post-hoc analysis is to present time course and severity of GI AEs in patients with MASH and T2DM treated with HTD1801 for 18 weeks.
Method: One hundred patients were randomized and treated with HTD1801 1000 mg BID (n = 34), HTD1801 500 mg BID (n = 33), or placebo (n = 33) for 18 weeks. Onset was defined as the first occurrence of an event for each subject; incidence was defined as any new event within a visit window; and prevalence was defined as any new or ongoing event within a visit window. As AEs can occur at any time, they are assigned to scheduled visits using the following windows based on the study day: Day 0: Day 0; Week 2: Day 1–28; Week 6: Day 29–56; Week 10: Day 57–84; Week 14: Day 85–112; Week 18: Day 113 onward.
Results: Treatment with HTD1801 resulted in significant reductions in LFC, HbA1c, weight, and liver biochemistry compared to placebo. GI AEs were experienced by 10%, 42%, and 56% of patients randomized to placebo, HTD1801 500 mg BID and HTD1801 1000 mg BID, respectively; all of which were mild or moderate in severity. Four subjects in the HTD1801 1000 mg BID group and 1 subject in the HTD1801 500 mg BID group discontinued study drug due to a GI AE. The incidence or GI AEs peaks within the first 4 weeks of treatment (Week 2: HTD1801 1000 mg BID: 29%; HTD1801 500 mg BID: 21%; PBO: 15%) and then rapidly declines with ongoing treatment with HTD1801 (Week 6: HTD1801 1000 mg BID: 9%; HTD1801 500 mg BID: 9%; PBO: 6%). Furthermore, the prevalence of GI AEs also declines with ongoing treatment (HTD1801 1000 mg BID: Week 2: 41%; Week 18: 28%). Diarrhea and nausea were the most commonly occurring GI AEs and follow a consistent trend with all GI AEs; they are early onset, mild or moderate in severity, with a decreasing incidence and prevalence over the course of treatment.
Conclusion: HTD1801 was found to be generally safe and well tolerated in this study. Although most commonly occurring AEs in studies involving HTD1801 are GI related, these events are typically mild to moderate in severity with decreasing incidence over time. Furthermore, these data indicate that tolerability to HTD1801 improves over the course of treatment.

SAT-244
FGF-19 analogues for the treatment of metabolic dysfunction-associated steatohepatitis: a systematic review and meta-analysis
Samira Mohamad Khalil[1], Matheus Souza[2], Fabiana Dolovitsch de Oliveira[3], Emmily Daiane Buarque de Santana Sato[4], Gilmara Coelho Meine[5]. [1]*Universidad de Buenos Aires, Buenos Aires, Argentina;* [2]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil;* [3]*Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil;* [4]*Pontifícia Universidade Católica de Campinas, Campinas, Brazil;* [5]*Universidade Feevale, Novo Hamburgo, Brazil*
Email: gilmara@feevale.br

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is characterized by steatosis, inflammation, and cellular injury, with or without fibrosis. Preclinical models with fibroblast growth factor 19 (FGF19) analogues demonstrated anti-steatotic, anti-inflammatory, and anti-fibrotic activities. Therefore, we aimed to perform a systematic review and meta-analysis to assess

the efficacy and safety of FGF19 analogues for treating patients with MASH.
Method: We searched Embase, PubMed, and Cochrane databases for randomized controlled trials (RCTs) comparing FGF19 analogues to placebo for the treatment of patients with biopsy-confirmed MASH, reporting at least one of the outcomes of interest. Primary outcomes: (1) fibrosis improvement by at least one stage with no worsening of MASH, and (2) MASH resolution with no worsening of fibrosis. Secondary outcomes: (1) change in hepatic fat fraction (HFF) by magnetic resonance imaging derived proton density fat fraction (MRI-PDFF) >30%; (2) change in hepatic enzymes alanine aminotransferase (ALT) and aspartate aminotransferase (AST); (3) changes in fibrogenesis markers (neoepitope-specific N-terminal propeptide of type III collagen [Pro-C3] and Enhanced Liver Fibrosis [ELF] score); and (4) rate of adverse events. We used random-effects model to calculate the pooled risk ratio (RR) for dichotomous variables and mean difference (MD) for continuous variables, with corresponding 95% confidence interval (CI). Heterogeneity was assessed using Cochran's Q test and I2 statistics.
Results: We included 4 RCTs (491 patients). All patients were obese adults and received Aldafermin (also known as NGM282), with daily dosages of 0.3 mg, 1 mg, 3 mg, or 6 mg. Mean follow-up ranged from 12 to 48 weeks. The probability of MASH resolution with no worsening of fibrosis (RR 2.74; 95% CI 1.06–7.04; p = 0.04; I^2 = 0%) and reduction in HFF by MRI-PDFF >30% (RR 2.69; 95% CI 1.63–4.43; p < 0.0001; I^2 = 29%) were higher with FGF-19 analogues compared to placebo. Additionally, FGF19 analogues showed higher reduction in ELF score (MD −0.19; 95% CI −0.33, −0.06; p = 0.006; I^2 = 0%), ALT (MD −17.70; 95% CI −23.33–12.06; p < 0.0001; I^2 = 32%), AST (MD −11.18; 95% CI −15.18, −7.18; p < 0.00001; I^2 = 0%) and Pro-C3 (MD −4.56; 95% CI −7.22, −1.90; p = 0.0008; I^2 = 21%). There was no significant difference between the groups in terms of fibrosis improvement by at least one stage with no worsening of MASH (RR 1.50; 95% CI 0.94–2.38; p = 0.09; I^2 = 0%), overall adverse events (RR 1.02; 95% CI 0.94, 1.12; p = 0.58; I^2 = 0%) and serious adverse events (RR 0.96; 95% CI 0.43, 2.15; p = 0.92; I^2 = 0%).
Conclusion: FGF19 analogues might be a safe and effective treatment option for patients with biopsy-confirmed MASH. However, new large RCTs with long-term follow-up are needed to confirm these findings.

SAT-245
Semaglutide for type 2 diabetes control in metabolic dysfunction-associated steatotic liver disease (MASLD): a two-way effect?

Giovanni Petralli[1], Antonio Salvati[2], Simone Cappelli[3], Gabriele Ricco[2], Lidia Surace[2], Ranka Vukotic[2], Piero Colombatto[2], Francesco Raggi[1], Anna Solini[1], Maurizia Brunetto[2,3]. [1]*Department of Surgical, Medical, Molecular and Critical Area Pathology, Pisa, Italy;* [2]*Hepatology Unit, Pisa University Hospital, Pisa, Italy;* [3]*Department of Clinical and Experimental Medicine, Pisa, Italy*
Email: g.petralli94@gmail.com

Background and aims: Therapeutic options for MASLD burden in T2D patients are scanty. GLP1-receptor agonists (GLP1-ra) are clearly indicated for T2D treatment and Semaglutide was shown to induce the steatohepatitis resolution at high daily dosage. In consecutive MASLD-GLP1-ra naïve diabetic patients we studied the impact on liver disease of Semaglutide introduction for glycemic control indication using non-invasive surrogate markers of liver steatosis and fibro-inflammation.
Method: In 62 consecutive overweight/obese T2D pts with MASLD (age 61.4 ± 11.3 yrs, females 32%, BMI 31.4 ± 5.0 kg/m^2), anthropometric, bio-humoral and transient elastography (TE) data were collected before (t0) and after 6.4 (6.1–6.6) months (t1) from the 1st injective/oral Semaglutide prescription. GIP, GLP1, Glucagon, Insulin, fasting glucose, glycated hemoglobin, AST, ALT and GGT were measured in t0-t1 serum samples. FibroScan CAP and liver stiffness (LS) were used as non-invasive markers of liver steatosis and fibro-inflammation involvement, respectively.
Results: BMI (−1.4 ± 0.2 kg/m^2), Waist Circumference (−3 ± 1 cm), AST (−10 ± 3 UI/L), ALT (−18 ± 5 UI/L), GGT (−33 ± 15 UI/L), glycol-metabolic parameters [fasting glucose (−40 ± 6 mg/dl) and glycated hemoglobin (−12 ± 1 mmol/mol)], CAP (−25 ± 8 dB/m), and LS (−0.8 ± 0.4 kPa) t0–t1 reductions were significant (p < 0.006), while GLP1 (+95.9 pM, p < 0.0001) increased. Variations of serum ALT and GGT levels associated with glycated hemoglobin reduction (r = 0.340, p = 0.0196 and r = 0.368, p = 0.0210, respectively), but not with change in serum concentration of incretin hormones. CAP declined in association with BMI reduction (r = 0.391, p = 0.0035) and GLP1 increase (r = −0.415, p = 0.0251). In a multivariate model adjusted for all above mentioned variations, only the GLP1 increase was associated with CAP reduction (p = 0.0468).
Conclusion: Semaglutide treatment for T2D in MASLD pts associates with a significant decline of non-invasive surrogate markers of liver steatosis and fibro-inflammation. While glycemic optimization correlated with a reduction of transaminases, an independent effect of GLP1 increase was associated with a reduction of the steatosis.

SAT-248
Liver stiffness improvement with pioglitazone in brazilian patients with metabolic dysfunction-associated steatohepatitis: a multicentric pilot study

Oliveira[1]. [1]*Laboratório de Gastroenterologia Clínica e Experimental LIM-07, Division of Clinical Gastroenterology and Hepatology, Hospital das Clínicas HCFMUSP, Department of Gastroenterology, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil, São Paulo-SP, Brazil;* [2]*Federal University of Minas Gerais, Belo Horizonte-MG, Brazil;* [3]*School of Medicine, Clementino Fraga Filho University Hospital, Federal University of Rio de Janeiro, Rio de Janeiro-RJ, Brazil;* [4]*School of Medicine, Clementino Fraga Filho University Hospital, Federal University of Rio de Janeiro, Rio de Janeiro-RJ, Brazil*
Email: mgpessoa@usp.br

Background and aims: Pioglitazone, an agonist of peroxisome proliferator-activated receptor gamma, demonstrated efficacy in ameliorating indirect markers of liver steatosis, inflammation and fibrosis as well as addressing systemic and adipose tissue insulin resistance in patients with type 2 diabetes and metabolic dysfunction-associated steatotic liver disease. This study aims to evaluate whether sustained pioglitazone consumption over a period of 12-24 months can improve liver stiffness in individuals diagnosed with metabolic dysfunction-associated steatohepatitis (MASH).
Method: Retrospective data from thirty-six (36) biopsy-proven MASH patients, receiving pioglitazone treatment for 12–24 months were gathered from three public hospitals in Brazil. Vibration-controlled transient elastography parameters pre- and post-pioglitazone treatment were evaluated, as a non-invasive method to monitor the disease progression. Additionally, a thorough analysis of both laboratory and clinical data was undertaken.
Results: The study population was equally divided into male and female subjects (50%, n = 18), with a mean age of 65.7 (±11.37) and a mean BMI of 31.4 (±6.05). At baseline, participants mostly had hypertension (75%, n = 27), type II diabetes (75%, n = 27), and dyslipidemia 75% (n = 27). During the second evaluation, the number of subjects with comorbidities increased to 83.3% (n = 30) for hypertension, 77.8% (n = 28) for diabetes, and 83.3% (n = 30) for dyslipidemia. Furthermore, 58.8% (n = 20) of patients were using antihypertensive drugs, and 69.4% (n = 25) were using lipid-lowering drugs. At baseline, the liver stiffness measurement (LSM) median was 8.10 (IQR = 5.42) and 9.50 (IQR = 8.38) at the second evaluation.

Prolonged pioglitazone treatment demonstrated LSM attenuation in 47.2% of cases (n = 17), resulting in an absolute reduction ranging from 0.1 to 15.4 kPa and a relative reduction ranging from 1.67% to 62.9% (p = 0, 0002), with no difference in the CAP parameter. In the reduction group, we also observed a decrease in ALT (56.06 ± 48.9/ 38.4 ± 8.5, p = 0.01) and AST (39.5 ± 6.2/31.44 ± 5.4, p = 0.05), with no changes in weight, BMI, FA, GGT, platelets, LDL, HDL, cholesterol, serum glucose, and glycated hemoglobin.
Conclusion: The administration of pioglitazone led to an improvement in liver stiffness among MASH patients although there was no difference in metabolic conditions, indicating its potential advantages in managing both diabetes and MASH.

Non-invasive assesment of liver disease except MASLD

Development and validation of a home-based score to detect advanced liver fibrosis and long-term liver-related outcomes in the general population: a multicohort study

Shanghao Liu[1], Jie Shen[2], Victor W. Zhong[3], Qing-Lei Zeng[4], Heng Wan[2], Yuping Chen[5], Xuanwei Jiang[6], Jiawei Zhang[5], Chuan Liu[7], Gao-Jun Teng[8], Xiaolong Qi[9]. *[1]Center of Portal Hypertension, Department of Radiology, Zhongda Hospital, School of Medicine, Southeast University, Nanjing, China, Basic Medicine Research and Innovation Center of Ministry of Education, Zhongda Hospital, Southeast University, Nanjing, China; [2]Department of Endocrinology and Metabolism, Shunde Hospital, Southern Medical University (The First People's Hospital of Shunde), Foshan, China; [3]Department of Epidemiology and Biostatistics, School of Public Health, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [4]Department of Infectious Diseases and Hepatology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [5]Center of Portal Hypertension, Department of Radiology, Zhongda Hospital, Medical School, Southeast University, Basic Medicine Research and Innovation Center of Ministry of Education, Zhongda Hospital, Southeast University, Nanjing, China; [6]Department of Epidemiology and Biostatistics, School of Public Health, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [7]Center of Portal Hypertension, Department of Radiology, Zhongda Hospital, Medical School, Southeast University, Basic Medicine Research and Innovation Center of Ministry of Education, Zhongda Hospital, Southeast University, Nanjing, China; [8]Basic Medicine Research and Innovation Center of Ministry of Education, Zhongda Hospital, Southeast University, Center of Interventional Radiology and Vascular Surgery, Department of Radiology, Zhongda Hospital, Medical School, Southeast University, Nanjing, China; [9]Center of Portal Hypertension, Department of Radiology, Zhongda Hospital, School of Medicine, Southeast University, Basic Medicine Research and Innovation Center of Ministry of Education, Zhongda Hospital, Southeast University, Nanjing, China*
Email: qixiaolong@vip.163.com

Background and aims: Liver fibrosis and its subsequent cirrhosis are major global health burden, and early screening and identification is critical; although several tools are available to stratify individuals at risk of liver fibrosis, they are all hospital- or clinic-based. We aimed to develop a simply free home-based score to identify general population at risk of advanced liver fibrosis and liver-related outcomes.
Method: The LiverHome score was derived from a prospective Chinese cohort including the general population who underwent liver fibrosis evaluation by transient elastography. The score's discriminatory accuracy was validated in two prospective cohorts containing Chinese and American general population. Moreover, we determined the prognostic value of the score in the prediction of all-cause and liver-related outcomes in the NHANES and UK Biobank follow-up cohorts. Advanced fibrosis was defined as liver stiffness measurement ≥10 kPa.
Results: We enrolled 410,428 participants: 6,174 in the derivation cohort, 2,646 in the Chinese validation cohort, 7,394 in the American validation cohort, 16,010 in the NHANES prognosis cohort (median follow-up of 2.0 years), and 378,204 in the UK Biobank prognosis cohort (median follow-up of 14.7 years). The new LiverHome score (free online calculator: https://sourl.cn/ED9GSD) included waist circumference, diabetes, and viral hepatitis history, and low-risk (LiverHome score <0) and high-risk (LiverHome score ≥0) groups were created. The LiverHome score was superior to fibrosis-4 index in identifying advanced fibrosis as measured by area under the receiver-operating characteristics curve (AUC), i.e., 0.77 (0.72–0.82) vs. 0.61 (0.56–0.67), 0.77 (0.70–0.84) vs. 0.68 (0.61–0.76), and 0.83 (0.81–0.85) vs. 0.65 (0.62–0.68), in the derivation, Chinese and American validation cohorts, respectively. In the subgroup analysis from American validation cohort (n = 3, 647), the LiverHome score is superior to the LiverRisk score for detecting advanced fibrosis (0.83 [0.80–0.87] vs. 0.77 [0.74–0.81], p = 0.016). Furthermore, compared to the low-risk group, the high-risk group had a higher risk of all-cause mortality (hazard ratio [HR] = 1.87 [1.60–2.19], p < 0.001) in the NHANES prognosis cohort. Similarly, in the high-risk group, the HR for all-cause mortality was 2.47 (2.40–2.54), and the subdistribution HRs for incident cirrhosis, incident liver cancer, and liver-related mortality were 5.55 (5.02–6.14), 7.07 (5.49–9.12), 5.64 (4.96–6.41) compared with the low-risk group in the UK Biobank prognosis cohort.
Conclusion: The home-based free LiverHome score can accurately predict advanced liver fibrosis and development of all-cause and liver-related outcomes in the general population, and might be used for the most primary screening of risk individuals before the blood- or machine-based stratifications.

TOP-012
Validation of transient elastography and the enhanced liver fibrosis test as prognostic biomarkers across the spectrum of steatotic liver disease

Nikolaj Torp[1,2], Mads Israelsen[1,2], Stine Johansen[1,2], Camilla Dalby Hansen[1], Emil Deleuran Hansen[1,2], Ellen Lyngbeck Jensen[1,2], Katrine Thorhauge[1,2], Johanne Kragh Hansen[1,2], Ida Falk Villesen[1], Katrine Tholstrup Bech[1], Charlotte Wernberg[1,3], Peter Andersen[1], Katrine Lindvig[1], Maja Thiele[1,2], Aleksander Krag[1,2]. *[1]Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark; [2]Department of Clinical Research, University of Southern Denmark, Odense, Denmark; [3]Institute for Regional Health Science, Liver Research Group, Department of Gastroenterology and Hepatology, Hospital of South Denmark, Esbjerg, Denmark*
Email: nikolaj.christian.torp@rsyd.dk

Background and aims: Steatotic liver disease (SLD) provides a consensus-driven approach to clinically phenotype patients with hepatic steatosis. As this was not data-driven, the prognostic value of existing non-invasive test cut-offs across the new subgroups needs validation. Therefore, we aimed to validate the prognostic performance of transient elastography (TE) and the enhanced liver fibrosis (ELF) test in patients with SLD.
Method: We included patients from an observational cohort (n = 446) with information on hepatic steatosis, cardiometabolic risk factors and self-reported alcohol intake. All patients had a historic alcohol intake of ≥36 g/day for men and ≥24 g/day for women for ≥1 year, with no prior hepatic decompensation. We classified patients with SLD if they had: 1) ultrasonic or histological signs of steatosis, 2) CAp >290 dB/m or 3) ≥F2 fibrosis on biopsy attributable to SLD. We used the alcohol intake from the preceding three months to

subclassify into metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic and alcohol-related liver disease (MetALD) and alcohol-related liver disease (ALD). We stratified patients according to the TE ≥15 kPa and ELF ≥9.8 cut-offs. By review of medical records, we identified hepatic decompensation (Baveno VII) and deaths occurring during follow-up.
Results: In total, 308 patients with TE and ELF measurements, fulfilled the SLD criteria and were subclassified as MASLD (n = 143), MetALD (n = 75) and ALD (n = 90). Average alcohol intake the previous three months were MASLD = 0 g/day (IQR: 0–0), MetALD = 48 g/day (IQR: 36–51) and ALD = 96 g/day (IQR: 69–252). Median TE was 9.3/7.9/8.7 kPa and ELF 9.7/9.5/9.2 (MASLD/MetALD/ALD). During a median follow-up of 61 months (IQR: 50–88), 28 MASLD, 13 MetALD and 15 ALD patients experienced hepatic decompensation. Adjusting for age and sex, the TE ≥15 cut-off predicted decompensation in MASLD (HR = 23.1; 95% CI: 6.8–78.1), MetALD (HR = 34.2; 95% CI: 7.3–161.1) and ALD (HR = 9.8; 95% CI: 3.1–31.1). ELF ≥9.8 exhibited comparable prognostic performance across all three subgroups. Majority (79%) of decompensations developed in patients with concordant TE ≥15 kPa and ELF ≥9.8 results. Death occurred in 80 patients, with hepatic decompensation preceding the event in 39 (49%) cases. A TE ≥15 kPa was an independent predictor of all-cause mortality in all subgroups (MASLD HR = 4.9; 95% CI: 2.4–10.0, MetALD HR = 7.0; 95% CI: 2.7–18.2 and ALD HR = 4.1; 95% CI: 1.8–9.3). Stratifying by the ≥9.8 cut-off, ELF predicted mortality in MASLD (HR = 3.6; 95% CI: 1.7–7.6) and ALD (HR = 6.8; 95% CI: 2.7–17.1) but not MetALD (HR = 1.6; 95% CI: 0.6–4.2).
Conclusion: Our study validates the TE ≥15 kPa and ELF ≥9.8 cut-offs in patients across the SLD spectrum, demonstrating their effectiveness in predicting hepatic decompensation and all-cause mortality. These findings affirm the utility of TE and ELF test thresholds in clinical practice.

FRI-008
Association of elevated liver biochemistries and clinical outcomes within strata of alkaline phosphatase levels in patients with primary biliary cholangitis

David W. Victor, III[1], Joanna P. MacEwan[2], Jennifer Hernandez[2], Radhika Nair[3], Mustafa Kamal[3], Darren Wheeler[3], Jing Li[3], Leona Bessonova[3], Christopher Gasink[3], Kris V. Kowdley[4,5]. [1]*Houston Methodist Hospital, Houston, United States;* [2]*Genesis Research Group, Hoboken, United States;* [3]*Intercept Pharmaceuticals, Inc., Morristown, United States;* [4]*Washington State University Elon S. Floyd College of Medicine, Spokane, United States;* [5]*Liver Institute Northwest, Seattle, United States*
Email: dwvictor@houstonmethodist.org

Background and aims: In patients (pts) with primary biliary cholangitis (PBC), elevated liver biochemical tests and the duration of elevation are correlated with increased risk of negative clinical outcomes. We assessed the relationship between the degree of elevation of liver biochemical tests (aspartate aminotransferase [AST] and alanine aminotransferase [ALT]) and 2 fibrosis scores (fibrosis-4 [FIB-4] and AST/platelet ratio index [APRI]) within different strata of alkaline phosphatase (ALP).
Method: Pts ≥18 years old with ≥1 inpatient or ≥2 outpatient PBC diagnosis claims separated by ≥30 days between July 2014 and February 2022 were identified from the US Komodo Healthcare Map™ merged with national lab data; the date of the first claim was the index date. Included pts had ≥1 biochemistry measurement of ALP, total bilirubin, ALT, and AST during the pre-index period (6 months before and including index date) and ≥1 post-index measurement. Pts with a history of hepatic decompensation, liver transplant, significant comorbidities, or prescribed obeticholic acid or fibrates pre-index were excluded. Pts were stratified into 3 groups based on baseline ALP levels: ALP ≤upper limit of normal (ULN), ALp >ULN to ≤1.67 × ULN, and ALp >1.67 × ULN. Within each ALP strata, a multivariable Cox proportional hazards model with time-varying covariate was used to assess the association between ALT, AST, FIB-4, and APRI with the composite end point (hospitalization for hepatic decompensation, liver transplant, or death). Within each ALP strata, a separate model was run for each biomarker and fibrosis score. Pts were censored at initiation of second-line therapy, end of insurance enrollment, or end of follow-up.
Results: A total of 3974 pts were stratified into 3 groups: ALP ≤ULN (n = 1443), ALp >ULN to ≤1.67 × ULN (n = 1279), and ALp >1.67 × ULN (n = 1252). Regardless of ALP strata, pts with FIB-4 ≥3.25 and APRI >0.5 had consistently increased risk of negative hepatic outcomes compared to pts with FIB-4 <1.3 and APRI ≤0.5, respectively (hazard ratio (HR) range: 5.0 [95% CI, 2.3–11.1] to 7.0 [95% CI, 3.4–14.3] and 1.6 [95% CI, 1.0–2.6] to 17.4 [95% CI, 9.1–33.4]). Compared to pts with AST <ULN, those with AST ≥1.5 × ULN generally had increased risk of negative hepatic outcomes regardless of ALP strata (HR range: 2.6 [95% CI, 1.6–4.3] to 5.6 [95% CI, 3.2–9.8]). Among pts with baseline ALP ≤1.67 × ULN, pts with ALT ≥2 × ULN had higher risk of negative hepatic outcomes compared to pts with ALT<ULN (HR range: 2.9 [95% CI, 1.0–8.2] to 3.2 [95% CI, 1.2–8.2]).
Conclusion: Across ALP strata, even when ALP is <ULN, elevated liver biochemical tests and fibrosis scores were associated with increased risk of hospitalization for hepatic decompensation, liver transplant, or death, highlighting the importance of comprehensive and timely monitoring and treatment of pts with PBC.

FRI-009-YI
Diagnostic and prognostic performance of the LiverRisk score in tertiary care

Georg Semmler[1], Lorenz Balcar[1], Benedikt Simbrunner[1], Lukas Hartl[1], Mathias Jachs[1], Michael Schwarz[1], Benedikt Hofer[1], Laurenz Fritz[1], Anna Schedlbauer[1], Katharina Stopfer[1], Daniela Neumayer[1], Jurij Maurer[1], Sophie Gensluckner[2], Bernhard Scheiner[1], Elmar Aigner[2], Michael Trauner[1], Thomas Reiberger[1], Mattias Mandorfer[1]. [1]*Medical University of Vienna, Department of Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria;* [2]*Paracelsus Medical University Salzburg, First Department of Medicine, Salzburg, Austria*
Email: georg.semmler@meduniwien.ac.at

Background and aims: The LiverRisk score has been developed as blood-based tool to estimate liver stiffness measurement (LSM) in the general population (i.e., in subjects without known chronic liver disease (CLD), and thus, detect compensated advanced chronic liver disease (cACLD; LSM ≥10kPa) and stratify their risk of liver-related events. Notably, its utility in other settings is unclear as a one-size-fits-all blood-based test. We aimed to evaluate its diagnostic/prognostic performance in patients referred to specialized hepatology outpatient clinics (i.e., tertiary care).
Method: Subjects with known/suspected CLD at first LSM (cohort-I, n = 5897) or first referral and LSM (cohort-II, n = 1558) were retrospectively included. Calibration/agreement of the LiverRisk score with LSM was assessed as well as its diagnostic accuracy for LSM-defined cACLD compared to FIB-4/APRI. Finally, its predictive performance for hepatic decompensation was evaluated.
Results: In cohort-I/II, mean age was 48.3/51.8 years, 44.2%/44.7% were female, predominant etiologies were viral hepatitis (51.8%)/MASLD (63.7%), median LSM was 6.9 [5.1–10.9]/5.8 [4.5–8.8]kPa, and 1690 (28.7%)/322 (20.7%) had cACLD. Despite a moderate correlation (Pearson's r: 0.325/0.422), the LiverRisk score systematically underestimated LSM (mean difference according to the Bland-Altman-Method: – 2.9/-1.8 points≙kPa). Variation of observed differences was considerable (95%CI of agreement: 39.4 and 35.2 points≙kPa), and showed a clear pattern towards larger disagreement at higher values with lower LiverRisk score values than corresponding LSM.

The diagnostic accuracy of the LiverRisk for cACLD (AUROC: 0.757 [95%CI: 0.744–0.770]/0.790 [95%CI: 0.762–0.819]) was comparable to FIB-4 (0.769/0.813) and APRI (0.747/0.765). The cut-off of 10points≙kPa yielded an overall accuracy of 74.2%/81.2%, high specificity (91.9/93.4%), but low negative predictive value (76.6/84.5%) with false-negative results in 20.0%/13.5% in cohort-I/II, respectively. In cohort-I, 208 (3.5%) patients developed hepatic decompensation (median follow-up: 4.7 years). The LiverRisk score showed a reasonable accuracy for predicting hepatic decompensation within 2 years (AUROC: 0.817); however, it was inferior to LSM (0.891, $p < 0.001$) and FIB-4 (0.912, $p < 0.001$). The strata of LiverRisk score (and of LSM/FIB-4) discriminated patient groups of distinct risks for hepatic decompensation.

Conclusion: While being a major step forward for screening subjects without known liver disease in primary care, the LiverRisk score was not superior (vs. FIB-4) for diagnosis of cACLD or (vs. FIB-4/LSM) for prediction of hepatic decompensation in a tertiary care setting, i.e., in cohorts with a higher pre-test probability of cACLD.

FRI-010

A non-invasive predictive model based on CT radiomics for hepatic venous pressure gradient in liver cirrhosis

Xu Guo[1], Wuque Cai[2], Huan Tong[1], Tingrui Han[1], Jiayi He[2], Hongze Sun[2], Guiying Zhang[2], Xin Quan[1], Shuaijie Qian[1], Ying Li[1], Bo Wei[1], Yang Tai[1], Daqing Guo[2], Hao Wu[1]. *[1]Department of Gastroenterology and Hepatology, West China Hospital, Sichuan University, Chengdu, China; [2]School of Life Science and Technology, University of Electronic Science and Technology, Chengdu, China*
Email: hxxhwh@163.com

Background and aims: Hepatic venous pressure gradient (HVPG) is used to quantitatively reflect the level of portal vein pressure and HVPG in the different interval could predict the occurrence of end point events in cirrhotic portal hypertension, thus making accurate prognosis judgments and treatment decisions for patients with liver cirrhosis. However, the measurement of HVPG is an invasive, costly, and requires specialized personnel and equipment, resulting in limitation in routine clinical practice. Thus, the study aimed to develop a predictive model based on CT imaging data combined with artificial intelligence (AI) algorithms as a non-invasive, accurate and convenient method to assess HVPG.

Method: A total of 359 patients with cirrhosis, who had both HVPG measurement and contrast-enhanced CT within 14 days prior to the catheterization were collected in the study from July 2016 to June 2022. We selected 4 major levels of CT image for each patient including the first hepatic hilum, second hepatic hilum, intersection of splenic vein and portal vein, and the largest cross-sectional area of the spleen. Then the region of interest (ROI) in each level was performed by manual delineation and sampled into training and testing cohort to develop the predictive model. The predictive performance was evaluated by the area under receiver operating characteristic curves (AUC).

Results: The overall prediction accuracy of the model for HVPG was over 85%. In the training cohort, the AUC value for HVPG >5 mmHg, ≥10 mmHg, ≥12 mmHg, ≥16 mmHg, ≥20 mmHg, were 0.990 (95%CI, 0.986–0.994), 0.993 (95%CI, 0.989–0.996), 0.991 (95%CI, 0.987–0.995), 0.981 (95%CI, 0.976–0.986), 0.978 (95%CI, 0.972–0.984) respectively. In the testing cohort, the AUC value for HVPG >5 mmHg, ≥10 mmHg, ≥12 mmHg, ≥16 mmHg, ≥20 mmHg, were 0.894 (95%CI, 0.868–0.919), 0.852 (95%CI, 0.828–0.876), 0.872 (95%CI, 0.852–0.893), 0.790 (95%CI, 0.765–0.815), 0.797 (95%CI, 0.772–0.823) respectively.

Conclusion: The predictive model showed relatively accurate results of HVPG classification and performed well in the prediction of clinically significant portal hypertension (CSPH, HVPG ≥10 mmHg) and esophagogastric variceal bleeding (EGVB, HVPG ≥12 mmHg), which provided a non-invasive and rapid method for predicting complications of decompensated liver cirrhosis when HVPG measurement is not available. Besides, multi-center and large sample tests should be carried out in the future to improve the model.

FRI-014

Comparison of two ultrasound diagnostic systems for measuring liver stiffness in clinical practice

Simone Cappelli[1], Giovanni Petralli[2], Laura De Rosa[3,4], Antonio Salvati[5], Filippo Oliveri[5], Barbara Coco[5], Gabriele Ricco[5], Piero Colombatto[5], Ferruccio Bonino[6], Francesco Faita[3], Maurizia Brunetto[1,5,6]. *[1]Department of Clinical and Experimental Medicine, Pisa University, Pisa, Italy; [2]Department of Surgical, Medical, Molecular and Critical Area Pathology, Pisa, Italy; [3]Institute of Clinical Physiology, National Research Council, Pisa, Italy; [4]Department of Information Engineering and Computer Science, University of Trento, Trento, Italy; [5]Hepatology Unit, Pisa University Hospital, Pisa, Italy; [6]Institute of Biostructure and Bioimaging, National Research Council, Naples, Italy*
Email: cappellisimone14@gmail.com

Background and aims: The values of liver stiffness by transient elastography using different ultrasound systems could differ and jeopardize the patients' clinical management. Our aim was to compare the results of two different technologies for liver stiffness measurement in a large cohort of chronic liver disease (CLD) patients (pts).

Method: In 777 consecutive CLD pts admitted at Hepatology Unit of University Hospital of Pisa from May 2022 to December 2023 liver stiffness was at the same time with two different diagnostic systems: FibroScan® (Echosens, France) equipped with M or XL probe and FT9000 (Hisky Medical, China) equipped with a single probe liver stiffness measurement ($LSM_{Fibroscan}$/LSM_{FT9000}). Pearson correlation coefficients and Bland-Altman analyses (BAA) were conducted to study the agreement between $LSM_{Fibroscan}$/LSM_{FT9000}. Delta FT9000-FibroScan® LSM (D) associations with CLD clinical parameters was observed too. AST/GGT and platelets counts/portal veins caliper/spleen long axis were used as proxies of necro-inflammatory activity and portal hypertension-vascular congestion.

Results: Overall $LSM_{Fibroscan}$ was strongly correlated with LSM_{FT9000} ($r = 0.77$, $p < 0.001$). LSM correlation varied among BMI classes (normal weight $r = 0.84$, overweight $r = 0.75$, obese $r = 0.65$, $p < 0.001$). LSMs obtained with the two devices showed a bias of 0.52 kPa ($p = 0.01$) with-11/12 kPa 95% LoA, with a clear trend for higher values measured by LSM_{FT9000} for LSM <10 kpa and vice versa for LSM >10 kPa. In fact, D was equal to zero for $LSM_{Fibroscan}$ 9.6 kPa. In $LSM_{Fibroscan}$ >10 kPa cohort D significantly correlated with AST, GGT, portal vein caliper, spleen long axis, and platelets ($r = –0.22$, $r = –0.17$, $r = –0.189$, $r = –0.287$, and $r = 0.031$, respectively). In a bivariate analysis D correlated with $LSM_{Fibroscan}$ and AST (beta = 0.002, $p = 0.001$) with a p of interaction equal to 0.018 and D was also associated with spleen long axis (beta = 0.033, $p = 0.027$) and platelets count (beta = –0.008, $p = 0.018$, respectively), with a significant interaction of both with $LSM_{Fibroscan}$ ($p < 0.001$).

Conclusion: $LSM_{Fibroscan}$ and LSM_{FT9000} measures showed a limited agreement across different dynamic ranges with a good agreement only around 10 kPa. The discrepancies associated with anthropometry and necro-inflammatory activity and vascular congestion proxies. LSM_{FT9000} provides higher values than $LSM_{Fibroscan}$ below 10 KPa whereas $LSM_{Fibroscan}$ higher values, with wider dynamic range, over 20 KPa. Comparative studies using as gold standard reference liver histology and porto-systemic gradient will help to better understand the reasons for the discrepancies. Whether these results will be confirmed, method specific cut-offs in clinical practice will be required.

FRI-015

Stabilization of enhanced liver fibrosis and liver stiffness measures in the open-label extension of the phase 3 POISE trial of obeticholic acid for the treatment of primary biliary cholangitis

Robert G. Gish[1], Darren Wheeler[2], Jing Li[2], Christopher Gasink[2], Alan Bonder[3]. [1]*Robert G. Gish Consultants, LLC, San Diego, United States;* [2]*Intercept Pharmaceuticals, Inc., Morristown, United States;* [3]*Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
Email: rgish@robertgish.com

Background and aims: Transient elastography (TE) is a non-invasive alternative to biopsy to determine liver stiffness and indirectly assess fibrosis, which can be predictive of adverse outcomes in patients (pts) with primary biliary cholangitis (PBC). Enhanced liver fibrosis (ELF) is a blood test that consists of an algorithm of 3 fibrosis markers and is a well-validated measure of fibrosis. Obeticholic acid (OCA) was approved for the treatment of PBC based on biomarker improvement in POISE, a 12-month randomized, double-blind (DB), placebo-controlled phase 3 study. Here, we report the results from a post hoc analysis of the impact of OCA on ELF and TE in pts from POISE.
Method: Pts with PBC who could not tolerate or had an inadequate response to first-line ursodeoxycholic acid were randomized to receive placebo, OCA 5–10 mg (OCA titration), or OCA 10 mg daily in the DB phase. During the 5-year open-label extension (OLE), all pts were initially treated with OCA 5 mg daily for 3 months, after which the dose could be titrated based on response and tolerability. ELF was assessed at baseline (BL) and each year after OCA initiation, using an algorithm based on hyaluronic acid, type III procollagen peptide, and tissue inhibitor of metalloproteinase I levels. Liver stiffness was measured by TE at BL and each year after OCA initiation at sites where FibroScan was the available form of TE. For pts who received placebo in the DB phase, BL measures were the last assessment before the first OLE OCA dose. If pts received OCA in the DB phase, their BL measures were from the DB BL period. Data points after pts titrated to >10 mg OCA in the OLE were excluded from the analysis.
Results: OCA stabilized ELF over 24 months in pts with evidence of moderate (ELF score ≥7.7 and <9.8) or severe (≥9.8 and <11.3) fibrosis or cirrhosis (≥11.3) at BL. The mean ELF scores were 9 at BL (n = 98), 9.19 at month 12 (n = 86), and 9.31 at month 24 (n = 51) in pts with moderate fibrosis. In pts with severe fibrosis, mean ELF scores were 10.35 at BL (n = 62), 10.36 at month 12 (n = 50), and 10.56 at month 24 (n = 31), and in pts with cirrhosis, mean ELF scores were 11.92 at BL (n = 26), 11.54 at month 12 (n = 16), and 11.35 at month 24 (n = 11). In pts with lower liver stiffness (TE <10 kPa) at BL, the mean TE measures were 6.09 (n = 47) at BL, 6.37 at month 12 (n = 41), and 5.86 at month 24 (n = 31). The mean TE measures in pts with higher liver stiffness (TE ≥10 kPa) were 19.27 at BL (n = 32), 18.39 at month 12 (n = 23), and 17.37 at month 24 (n = 19). ELF and TE values after month 24 were similar to those observed from BL to month 24, although the number of pts with TE and ELF measurements decreased over time through month 72.
Conclusion: These results suggest that OCA stabilized fibrosis over time regardless of severity at BL, although interpretability of the data is limited after 24 months because of decreasing sample size over time. Pts with PBC may benefit from OCA treatment early before PBC progresses and fibrosis worsens.

FRI-016

PT-LIFE model for the diagnosis of pediatric liver fibrosis after pediatric liver transplantation

Hao Feng[1], Zicheng Lv[1], Qiang Xia[1]. [1]*Shanghai Jiaotong Uni aff. Renji Hospital, shanghai, China*
Email: lyuzicheng@163.com

Background and aims: Pediatric liver transplantation is now considered a curative treatment for children with chronic end-stage liver diseases and specific metabolic defects, and has become very successful with high survival rate. Prevalence of fibrosis as high as 65% at 5 years and 69% at 10 years after pediatric liver transplantation has been reported. The gold standard to assess the stage of liver fibrosis is liver biopsy. However, liver biopsies are invasive and can occasionally cause severe morbidity and even mortality. Thus, we aimed to develop and validate a blood-based diagnostic multivariate index test that is specifically designed to rule in and rule out allograft fibrosis in the pediatric liver transplantation recipients.
Method: The discovery cohort included 150 pediatric patients underwent liver graft biopsy in our tertiary liver transplantation department from Aug 2022 to Feb 2023 were prospectively recruited. a logistic bootstrap-based stepwise regression process was done in the discovery cohort to identify a biomarker-based model.
Results: From Aug 2022 to Aug 2023, 262 liver biopsy specimens were prospectively collected in our tertiary liver transplantation department, and 250 of them were eligible and enrolled. The PT-LIFE model showed higher discriminatory accuracy to identify pediatric liver transplantation recipients with moderate to severe fibrosis (LAFSc 3–6) compared with individual components of the score. The AUROC for PT-LIFE in the discovery set was 0·92 (95% CI 0·88–0·97). To enable real-world clinical use, a lower cutoff was established at less than 0·12 to provide a rule-out decision with 90.7% sensitivity, and 94.7% NPV. In addition, an upper cutoff was established at 0·29 or higher to enable a rule-in decision with 76.7% specificity, 90.6% sensitivity, and 76.7% PPV. The so-called grey or indeterminate zone comprised 32 (21.3%) of 150 patients in the discovery cohort, indicating the PT-LIFE test yielded actionable clinical results in 118 (78.7%) patients.
Conclusion: PT-LIFE significantly outperformed other non-invasive fibrosis diagnostics, including APRI, GPR, FIB-4, Forns index, AGILE3+ and AGILE 4 score for the identification of allograft fibrosis in the pediatric liver transplantation recipients. In addition, although PT-LIFE was not developed to specifically identify the subpopulation of recipients with LAFSc ≥5, performance was also significantly better than other non-invasive fibrosis diagnostics (all $p < 0.05$).

FRI-017

Fibrosis activity versus disease stage: systemic markers of fibrosis activity have better prognostic performance than the liver biopsy in patients with alcohol-related liver disease

Stine Johansen[1,2], Mads Israelsen[1,2], Katrine Lindvig[1], Katrine Thorhauge[1,2], Johanne Kragh Hansen[1,2], Camilla Dalby Hansen[1], Ida Ziegler Spedtsberg[1,2], Helle Schnefeld[1], Peter Andersen[1], Ida Falk Villesen[1], Katrine Tholstrup Bech[1,2], Nikolaj Torp[1,2], Diana Leeming[3], Torben Hansen[4], Morten Karsdal[3,5], Maja Thiele[1,2], Aleksander Krag[1,2]. [1]*Centre for Liver Research, Odense University Hospital, Odense, Denmark;* [2]*Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark;* [3]*Nordic Bioscience A/S, Herlev, Denmark;* [4]*Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark;* [5]*Department of Molecular Medicine, Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark*
Email: stine.johansen@rsyd.dk

Background and aims: Excessive alcohol consumption is the most significant risk factor for fibrosis progression in patients with steatotic liver disease. As liver fibrosis screening becomes more widespread, patients are identified at varying fibrosis stages, necessitating stage-specific clinical outcome predictions. Consequently, there is a need for prognostic, non-invasive tests that are effective at all fibrosis levels. We aimed to evaluate if the active fibrogenesis marker PRO-C3 can predict clinical outcomes in alcohol-related liver disease (ALD) patients, independent of their baseline liver fibrosis stage, and compare its prognostic accuracy to the established blood-based fibrosis markers Enhanced Liver Fibrosis test (ELF) and Fibrosis-4 Index (FIB-4).
Method: We conducted a prospective cohort study of patients with a prior or current excessive alcohol intake (men: ≥36 g/day, women:

≥24 g/day for more than 1 year), and no previous decompensation. At baseline, we performed liver biopsies and assessed non-invasive fibrosis tests, along with clinical investigations. During follow-up, we manually reviewed patients' electronic healthcare records for decompensations, all-cause mortality, and reports of alcohol intake. We defined decompensation according to the Baveno VII recommendations.

Results: We followed 458 patients with ALD for median 5.9 years (IQR 4.5–7.8). Mean age was 57 ± 10 years, 76% were males, with fibrosis stages F0-1/F2/F3-4 = 261/107/91 at baseline. During follow-up, 67 patients decompensated, and 100 patients died. In all Kleiner fibrosis stages, PRO-C3 added prognostic value on top of fibrosis stage as a predictor of later decompensation, both for patients with no to moderate fibrosis, F0-2 (hazard ratio, HR_{PRO-C3} 1.05; 95% CI 1.03–1.07, p < 0.001), and for patients with advanced fibrosis, F3-4 (HR_{PRO-C3} 1.01; 95% CI 1.00–1.02, p = 0.027). In a head-to-head comparison between PRO-C3 (<15.6 ng/ml vs ≥15.6) and Kleiner fibrosis stage (F0-2 vs F3-4) both baseline markers independently predicted later decompensation, though PRO-C3 was a better predictor of the outcome (HR_{PRO-C3} 7.09; 95% CI 3.21–15.68, p < 0.001 and $HR_{Kleiner}$ 5.16; 95% CI 2.98–8.94, p < 0.001). In a multivariable regression including Kleiner fibrosis stage (F0-2 vs F3-4), PRO-C3 (<15.6 ng/ml vs ≥15.6), ELF (<9.8 vs ≥9.8) and FIB-4 (<1.3 vs ≥1.3) only Kleiner fibrosis stage and PRO-C3 were independent predictors of decompensation.

Conclusion: In alcohol-related liver disease, patients' prognoses are predicted by both baseline markers of disease stage and fibrosis activity. PRO-C3, a marker of fibrosis activity, was a better prognostic marker than Kleiner fibrosis stage, and predicted decompensation in all stages of fibrosis.

FRI-018

Procalcitonin as a predictive marker of incident liver disease

Amanda Finnberg-Kim[1], Mats Pihlsgård[2], Kristina Önnerhag[3], Sofia Enhörning[2]. *[1]Department of Clinical Sciences in Malmö, Lund University, Malmö, Sweden; [2]Perinatal and Cardiovascular Epidemiology, Lund University Diabetes Centre, Department of Clinical Sciences in Malmö, Malmö, Sweden; [3]Dept of Gastroenterology and Hepatology Skåne University Hospital Malmö, Malmö, Sweden*
Email: amanda.finnberg-kim@med.lu.se

Background and aims: Previous studies have shown that procalcitonin (PCT) concentration can be elevated in patients with liver disease without evidence of ongoing bacterial infection. The relationship between elevated PCT and liver damage is not completely understood. We aimed to investigate the association between elevated PCT and future risk of liver disease.

Method: PCT was measured in individuals without prevalent liver disease in the Malmö Diet and Cancer Cardiovascular Cohort (MDC-CC) and in a sample of the Malmö Preventive Project cohort (MPP). Complete data was available in 3897 individuals in MDC-CC and 3854 individuals in MPP. According to Swedish National Patient Registers which cover almost all hospital-based care in Sweden, 70 subjects in MDC-CC and 49 subjects in MPP developed non-viral liver disease during a median follow-up of 27.1 and 14.8 years respectively. Cox proportional hazards models were used to analyse risk of incident liver disease by PCT levels. We performed our analyses in a pooled sample of both the MPP and MDC-CC cohorts as well as separate analyses for each cohort.

Results: PCT was strongly and independently associated with incident non-viral liver disease of any type during follow-up. In multivariate adjusted models (age, gender, body mass index, hazardous alcohol consumption, total cholesterol, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, triglycerides, lipid lowering treatment, prevalent diabetes, creatinine, prevalent hypertension and smoking) in the pooled sample, individuals with high PCT (>0, 05 ng/ml) had a significantly increased risk of developing liver disease compared to subjects with PCT concentrations below the cutoff (hazard ratio (HR) 3.4, 95% confidence interval (CI) 2.06–5.61, p < 0.001). The HR per standard deviation increase of log-transformed PCT was 1.56 (95% CI 1.32–1.85, p < 0.001) in multivariate adjusted models. Separate cohort-specific sensitivity analyses, out of which the cohort-specific analysis of MDC-CC was additionally adjusted for C-reactive protein, showed similar effect estimates as the pooled analyses.

Conclusion: PCT is an independent predictive marker of future diagnosis-verified non-viral liver disease. In selected patients, these findings could have implications for risk assessment leading to earlier detection of liver disease and in turn earlier treatment of the underlying cause of liver injury. Our results also highlight the possibility of PCT as a direct cause of hepatocyte damage.

Email: kalswat@ksu.edu.sa

Background and aims: We recently developed a simple novel index called fibrosis 6 (FIB-6) using machine learning data analysis. We aimed to evaluate its performance in diagnosis liver fibrosis and cirrhosis in CHB.

Method: Retrospective observational analysis of data obtained from seven sites (Egypt, KSA, Turkey, Greece, Oman, Qatar, and Jordan) of CHB patients. The inclusion criteria include receiving an adequate liver biopsy and a complete biochemical and hematological data. Diagnostic performance analysis of the FIB-6 index was conducted and compared with other non-invasive scores.

Results: 603 patients were included for analysis; the AUROC for FIB-6 for the discrimination of patients with cirrhosis (F4), cACLD (F3 and F4), and significant fibrosis (F2-F4), were 0.854, 0.812, and 0.745, respectively. Analysis using the optimal cut-offs of FIB-6 showed sensitivity of 70.9%, specificity of 84.1%. PPV = 40.3% and NPV = 95.0% for diagnosis of cirrhosis. For diagnosis of cACLD, the results were 71.5%. 69.3%. 40.8% and 89.2% respectively, while for diagnosis of significant fibrosis, the results were 68.3%, 67.5%, 59.9% and 75.0%). When compared with those of FIB-4, APRI, and AAR, the AUROC for the performance of FIB-6 was higher than those of FIB-4, APRI, and AAR in all fibrosis stages. FIB-6 gave the highest sensitivity and NPV (89.1% and 92.4%) in ruling out compensated advance liver disease (cACLD) and cirrhosis, as compared to FIB-4 (63.8% and 83.0%), APRI (53.9% and 86.6%), and AAR (47.5% and 82.3%) respectively.

Conclusion: The FIB-6 index could be used in ruling out cACLD, fibrosis, and cirrhosis with good reliability.

FRI-021

An integrative machine learning method enhances postoperative liver failure risk assessment with preoperative indicators

Zongkun Zhang[1], Haoyu Wu[1], Hongxuan Li[2,3], Bin Shu[2,3], Xiaojuan Wang[2,3], Yongfeng Huang[1], Shizhong Yang[2,3]. [1]*Department of electronic engineering, Tsinghua University, Beijing, China;* [2]*Hepatopancreatobiliary Center, Beijing Tsinghua Changgung Hospital, Key Laboratory of Digital Intelligence Hepatology (Ministry of Education), School of Clinical Medicine, Tsinghua University, Beijing, China;* [3]*Research Unit of Precision Hepatobiliary Surgery Paradigm, Chinese Academy of Medical Sciences, Beijing, China*
Email: ysza02008@btch.edu.cn

Background and aims: Post-hepatectomy liver failure (PHLF) is a severe complication and leading cause of death during the peri-operative period. Presently, the hepatectomy decision-making is mainly based on preoperative ICG-R15 tests and the liver remnant volume assessment. Nevertheless, it is still difficult to completely avoid PHLF. This study aims to develop a comprehensive method that utilizes preoperative indicators to optimize the PHLF risk evaluation using machine learning techniques.
Method: A two-step framework was employed to analyze clinical data. At first, unsupervised learning clustering algorithms were used to identify potential risk levels, forming the basis. Then, supervised models were used to verify the replicability and usefulness of the risk levels. Based on this, the T-test was employed to compare the magnitude of differences between risk levels, and interpretative analysis of the logistic regression classifier was utilized to summarize a practical risk-scoring formula.
Results: The study incorporated the clinical data of 197 patients who underwent hepatectomy, comprising a development cohort (n = 118) and a validation cohort (n = 79). Within the development cohort, two critical risk levels were identified using the k-means cluster Method: a high-risk group (n = 15, PHLF rate = 20.0%) and a low-risk group (n = 103, PHLF rate = 1.9%). The incidence of PHLF showed significant differences between these groups (p = 0.001). Several key preoperative indicators, such as Child score (p = 5.12e-25), DBIL (p = 1.55e-13), TBIL (p = 5.62e-8), and ICG-R15 (p = 2.00e-4), exhibited significant disparities between the two risk groups. Furthermore, a supervised classifier, trained in the development cohort using risk levels as labels, was applied to stratify risk in the validation cohort. In the validation cohort, the high-risk group (n = 9, PHLF rate = 22.2%) and the low-risk group (n = 70, PHLF rate = 4.2%) demonstrated a significant difference in the incidence of PHLF (p = 0.037). The indicators such as Child score (p = 1.55e-10), DBIL (p = 2.03e-09), TBIL (p = 1.34e-07), and ICG-R15 (p = 0.012) still showed substantial differences, thereby confirming the robustness of the risk levels. Moreover, through interpretative analysis of the supervised classifier, we identified the importance of each clinical indicator in risk assessment and developed a risk-scoring formula. Compared to ICG-R15 (AUC = 0.67), the risk-scoring formula (AUC = 0.82) demonstrated superior predictive capability for PHLF.
Conclusion: This study utilizes the superiority of machine learning algorithms to accurately detect possible clinical risk factors and their connections from the data structure itself, providing insight into the impact of preoperative clinical indicators on the risk of PHLF. Moreover, a risk assessment formula is proposed to be used as a reference to optimize surgical decision-making.

FRI-022

N-terminal type III collagen propeptide, golgi protein 73 and their combination accurately assess siginificant and advanced fibrosis in chronic hepatitis B patients

Qianqian Chen[1], Yee Hui Yeo[2], Xinyu Hu[3], Li Zhu[4], Fajuan Rui[1], Shengxia Yin[5], Chuanwu Zhu[4], CHao Wu[6], Mindie Nguyen[7], Jie Li[6]. Email: lijier@nju.edu.cn

Background and aims: There is an urgent need for non-invasive biomarkers to detect the progression of liver fibrosis in patients with chronic hepatitis B (CHB). PRO-C3, N-terminal type III collagen propeptide, has shown potential as a serum biomarker for diagnosing significant fibrosis in patients with non-alcoholic fatty liver disease. Similarly, GP73, Golgi protein 73, has been suggested as a marker for liver fibrosis progression in CHB patients. However, the diagnostic efficacy of PRO-C3, GP73, and their combination in CHB-related liver fibrosis remains uncertain. Therefore, we aims to assess the performance of these three biomarkers in diagnosing significant and advanced fibrosis in CHB patients.
Method: This study included treatment-naive CHB patients who underwent simultaneous liver biopsy and blood testing at two tertiary centers. Liver fibrosis was assessed using the Scheuer scoring system (S0-S4). The cohort was divided into groups based on fibrosis stages: S0-1 versus S2-4, and S0-2 versus S3-4. Serum levels of PRO-C3 and GP73 were measured using ELISA. The diagnostic accuracy of PRO-C3, GP73, PRO-C3 combined with GP73, FIB-4, and APRI in identifying fibrosis related to CHB was evaluated using receiver operating characteristic (ROC) curves. The significance of the area under the curves (AUCs) was determined using the Delong test.
Results: A total of 324 individuals with matched liver biopsies were enrolled in this study, with 167 of them undergoing transient elastography (TE). Significant elevation of PRO-C3 and GP73 levels was observed in patients with fibrosis stages S2-4 and S3-4 compared to those with stages S0-1 and S0-2 (p <0.001). After adjusting for sex, age, body mass index, liver enzymes, and HBV DNA level, PRO-C3 was identified as an independent predictor for significant (OR 1.04, 95% CI: 1.03–1.06) and advanced fibrosis (OR 1.04, 95% CI: 1.03–1.05). In the overall cohort, PRO-C3 combined with GP73 (AUC = 0.84 [0.77–0.89]) outperformed LSM (AUC = 0.74 [0.67–0.81], p = 0.049), FIB-4 (AUC = 0.64 [0.56–0.71], p <0.001), and APRI (AUC = 0.72 [0.64–0.78], p = 0.007) in detecting significant fibrosis. When used individually, PRO-C3 and GP73 demonstrated comparable diagnostic performance to LSM and outperformed or showed similar performance to APRI and FIB-4 in both diagnoses.
Conclusion: Our findings indicate that PRO-C3, GP73, and their combination are the most effective blood tests for identifying significant and advanced fibrosis in CHB patients, with diagnostic accuracy comparable to TE. This suggests a novel, cost-effective, and accurate option for monitoring fibrosis progression in CHB and guiding clinical decision-making.

FRI-023

Effect of obeticholic acid on reduction and normalization of alanine aminotransferase and aspartate aminotransferase in the phase 3 POISE trial in primary biliary cholangitis

Robert G. Gish[1], Darren Wheeler[2], Jing Li[2], Christopher Gasink[2], David W. Victor, III [3]. [1]*Robert G. Gish Consultants, LLC, San Diego, United States;* [2]*Intercept Pharmaceuticals, Inc., Morristown, United States;* [3]*Houston Methodist Hospital, Houston, United States*
Email: rgish@robertgish.com

Background and aims: Obeticholic acid (OCA) is a potent farnesoid X receptor agonist with accelerated approval for primary biliary cholangitis (PBC) based on improvement in alkaline phosphatase (ALP) and total bilirubin (TB) levels in the randomized, double-blind, placebo-controlled phase 3 POISE study. In addition to ALP and TB, elevated alanine aminotransferase (ALT) and aspartate aminotransferase (AST) are associated with an increased risk of negative clinical outcomes in patients with PBC. Herein, we evaluate the effect of OCA on ALT and AST, including the proportion of patients attaining normal

levels (defined as ALT ≤41 U/L and AST ≤34 U/L) among patients with abnormal levels at baseline (BL).
Method: In the POISE study, PBC patients with inadequate response or intolerance to ursodeoxycholic acid were randomized 1:1:1 to receive placebo (PBO), OCA titration (OCA 5 mg daily with option to titrate to 10 mg after 6 months), or OCA 10 mg daily for 12 months. Serum ALT and AST levels were assessed at all visits. The Cochran-Mantel-Haenszel method was used to assess the association between OCA treatment and normalization of ALT or AST among patients with elevated levels at BL.
Results: Among the intention-to-treat (ITT) population, mean BL values for ALT were 56.0 U/L for PBO, 61.6 U/L for OCA titration, and 56.3 U/L for OCA 10 mg. Baseline AST levels were 48.8, 52.3, and 50.5 U/L for PBO, OCA titration, and OCA 10 mg, respectively. Among the 61% of patients with ALT >41 U/L at BL, 16% (7/45) receiving PBO normalized at Month 6 vs 55% (26/47) on OCA 5 mg and 53% (21/40) on OCA 10 mg (p ≤0 .001 for both). As early as Week 2, 3 to 4 times more patients had normalized ALT in both OCA groups (both p < 0.01 vs PBO). Among the 71% of patients with AST >34 U/L at BL, normalization rates at Month 6 were 12% (6/51) in the PBO arm, 30% (16/53) in the OCA 5-mg arm, and 31% (15/49) in the OCA 10-mg arm (p < 0.05 for both). The proportions of patients normalizing ALT and AST on OCA were similar at Month 12. Overall reductions in ALT and AST in the ITT population were significant for both OCA groups vs PBO at all visits (all p < 0.001) as early as Week 2, with least-squares mean changes from BL for ALT of −6.6 U/L for PBO, −18.9 U/L for OCA 5 mg, and −22.0 U/L for OCA 10 mg, and −3.8 U/L, −10.6 U/L, and −12.2 U/L for AST, respectively.
Conclusion: OCA significantly reduced ALT and AST as early as Week 2 in both OCA treatment groups, and by Month 6, normalized ALT in >50% and AST in almost 33% of patients with elevated levels at BL. These data suggest that in addition to reductions in ALP, OCA meaningfully reduces ALT and AST below thresholds that are prognostic for improved clinical outcomes. Additional research is required to understand how measuring ALT and AST levels contributes to a more complete assessment of PBC treatment response in order to minimize the risk of disease progression.

FRI-026
Longitudinal association of magnetic resonance elastography with liver-related events and cardiovascular events in chronic hepatitis

Nobuharu Tamaki[1], Mayu Higuchi[1], Yutaka Yasui[1], Kaoru Tsuchiya[1], Hiroyuki Nakanishi[1], Namiki Izumi[1], Masayuki Kurosaki[1]. *[1]Musashino Red Cross Hospital, Tokyo, Japan*
Email: nobuharu.tamaki@gmail.com

Background and aims: Magnetic resonance elastography (MRE) is a non-invasive modality for liver fibrosis and has a high diagnostic accuracy, but the association between MRE and the risk of complications including liver-related events and cardiovascular events (CVD) remains unclear. In this study, we investigated the longitudinal association between MRE and the risk of complications.
Method: This retrospective study included 2373 consecutive patients with chronic liver disease. The primary outcome was the risk of liver-related events and CVD for MRE. In the subgroup of chronic hepatitis B, the association between MRE and hepatocellular carcinoma (HCC) was also investigated.
Results: In the whole cohort, the adjusted hazard ratios (aHR) (95% confidence interval [CI]) of each 1-kPa increase in liver stiffness for HCC, decompensation, and CVD were 1.28 (1.2–1.4), 1.34 (1.3–1.4), and 0.96 (0.9–1.1), respectively. Similarly, the aHR (95% CI) for HCC, decompensation, and CVD were 4.20 (2.2–8.2), 67.5 (9.2–492), and 0.83 (0.4–1.7), respectively, in patients with cirrhosis (>4.7 kPa) compared to those with minimal fibrosis (<3 kPa). In the subgroup of 504 chronic hepatitis B, the 1-, 3-, and 5-year cumulative incidence of HCC in patients with liver stiffness ≥3.6 kPa and those with liver stiffness <3.6 kPa were 3.8%, 7.0%, and 22.9%, and 0%, 0.9%, and 1.5%, respectively (p < 0.001). In the multivariable analysis, MRE-based liver stiffness (per 1 kPa) or liver stiffness ≥3.6 kPa was an independent factor for HCC development with an aHR (95% CI) of 1.61 (1.3–2.0) or aHR of 8.22 (2.1–31).
Conclusion: Increased MRE-associated liver stiffness was associated with increased risk for HCC, and decompensation in a dose-dependent fashion and may be used for the early prediction of liver-related events and determination of indications for treatment.

FRI-027
Fibroblast activity kills-circulating endotrophin (PRO-C6) is prognostic for liver-related events in patients with cirrhosis from chronic hepatitis C

Thomas Møller[1,2], Emilie Skovgaard[3], Diana Leeming[1], Morten Karsdal[1], Keyur Patel[4]. *[1]Nordic Bioscience A/S, Herlev, Denmark; [2]University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark; [3]Nordic Bioscience A/S, University of Copenhagen, Herlev, Denmark; [4]University Health Network, Toronto, Canada*
Email: twm@nordicbio.com

Background and aims: Prognostic markers for patients with compensated cirrhosis at increased risk of developing liver-related events are required. Endotrophin, a potential driver of fibroblast activation and mediator of fibroinflammatory disease, may be assessed non-invasively using PRO-C6. Blood-based collagen extracellular matrix remodeling markers may provide novel prognostic information to identify patients with cirrhosis at higher risk of developing a liver-related event. Here we aimed to investigate the ability of PRO-C6 to predict liver-related events in The Hepatitis C Antiviral Long-Term Treatment Against Cirrhosis Trial (HALT-C) (ClinicalTrials.gov #NCT00006164).
Method: A subgroup of 151 patients with cirrhosis and serum samples from the HALT-C cohort, were included in this study. NordicPRO-C6™ was assessed in serum using a fully validated competitive enzyme-linked immunosorbent assay. Between groups comparison of biomarker levels was performed using Mann-Whitney U test. Patients were stratified above and below a 15.0 ng/ml cut-off of baseline PRO-C6. Cox proportional hazards regression was used to analyze the prognostic value of serum PRO-C6 to identify patients at risk of developing liver-related events. Data provided by NIDDK CR, a program of the National Institute of Diabetes and Digestive and Kidney Diseases.
Results: 69% of the included 151 patients were male. The median (Q1, Q3) age and BMI were 50 (47, 55) years and 29.3 (26.7, 32.6) kg/m^2, respectively. 47 (31%) of the patients had a liver related outcome over median follow-up (Q1, Q3) of 755 days (371, 1098). PRO-C6 was significantly elevated at baseline in patients who had a liver-related event (p = <0.001). When stratifying the patients above and below the cut-off of 15 ng/ml (high versus low level), the hazard ratio for having a liver related outcome was 3.56 times higher (SD = 0.30, 95% CI = [1.48, 5.52], p = <0.001) in the group with high serum PRO-C6 at baseline, compared to low serum PRO-C6.
Conclusion: PRO-C6, a biomarker of circulating endotrophin was associated with an increased risk of developing a liver-related event, in cirrhotic patients with chronic hepatitis C (CHC). PRO-C6 may be a potential monitoring blood-based marker that may provide prognostic information on cirrhosis patients at higher risk of developing a liver-related event. Comparison with other collagen neo-epitopes and clinical outcome predictor models is ongoing, but validation of PRO-C6 as prognostic marker following sustained virologic response in CHC, and for other compensated advanced chronic liver disease is still required.

FRI-028

Spleen stiffness measurement improves non-invasive prediction of clinically significant portal hypertension in patients with compensated advanced chronic liver disease of mixed etiology

Giulia Francesca Manfredi[1,2], Angelo Strada[1], Mattia Lotto[1], Valentina Romano[1], Vincenzo Bonafede[3], Michela Burlone[4], Rosalba Minisini[3], Mario Pirisi[1], Cristina Rigamonti[1]. [1]*Department of Translational Medicine, Università del Piemonte Orientale and Division of Internal Medicine, AOU Maggiore della Carità, Novara, Italy;* [2]*Department Department of Surgery and Cancer, Imperial College London, Hammersmith Hospital, Du Cane Road, London, United Kingdom;* [3]*Department of Translational Medicine, Università del Piemonte Orientale, Novara, Italy;* [4]*Division of Internal Medicine, AOU Maggiore della Carità, Novara, Italy*
Email: cristina.rigamonti@uniupo.it

Background and aims: Recently, non-invasive assessment of clinically significant PH (CSPH) in compensated advanced chronic liver disease (cACLD) has been refined by adding spleen stiffness measurement (SSM) to liver stiffness measurement (LSM). We aimed at evaluating the role of SSM in patients with cACLD of mixed etiology in identifying CPSH.
Method: Monocentric prospective study of 149 patients with cACLD (defined as LSM ≥10 kPa) out of 309 who consecutively underwent both liver stiffness measurement (LSM) and SSM by vibration-controlled transient elastography (FibroScan® 630, Echosens, Paris) at University Hospital in Novara between December 2023 and November 2023. Esophagogastroduodenoscopy (EGDS) was performed according to Baveno VI guidelines and in all patients with SSM >40 kPa. The Baveno VII criteria (BVII) for assessing CSPH using LSM alone [LSM ≤15 kPa + platelets (PLTs) ≥150000/mmc to rule out CSPH; LSM >25 kPa to rule in CSPH) were compared with the BVII for CSPH incorporating both LSM and SSM (at least 2 out of 3 between LS ≤15 kPa, PLTs ≥150000/mmc, SSM ≤40 kPa to rule out CSPH; at least 2 out of 3 between LS >25 kPa, PLT <150000/mmc, SSM >40 kPa to rule in CSPH) to evaluate their ability to identify patients with CSPH.
Results: Among the 149 patients, etiology of liver disease was viral hepatitis (16%), alcohol (31%), metabolic associated steatotic liver disease (15%) or cholestatic/autoimmune disease (21%) or mixed (17%). Eighty-nine were male (60%), median age was 66 years (IQR 22–86), median LSM 19.5 kPa (IQR 13.7.8–31.7), median SSM 43.6 kPa (IQR 29.5–54.8), median platelet count 128000/mmc (IQR 90000–173000/mmc), median albumin 4.1 g/dl (IQR 3.8–4.4), median total bilirubin 1.1 mg/dl (IQR 0.8–1.8). Sixty-four (43%) patients had any size varices, 18 (12%) had high-risk varices. Considering the BVII assessing only LSM, 21 patients (14%) belonged to rule out zone for CSPH, 51 (34%) belonged to rule in zone, 77 (52%) were in the grey zone. According to the BVII incorporating both LSM and SSM, 45 patients (30%) belonged to rule out zone for CSPH, 53 patients to rule in (35%), while 51 patients (34%) belonged to the grey zone. Diagnostic performance of BVII with LSM alone was: sensitivity 94% (LR- 0.31) for ruling out CSPH and specificity 70% (LR 1.38) for ruling in CSPH. Diagnostic performance of BVII for CSPH incorporating both LSM and SSM was sensitivity 87% (LR- 0.29) for ruling out CSPH and specificity 71% (LR 1.49) for ruling in CSPH. SSM ≤40 kPa alone identified patients without any size varices with 80% sensitivity (LR-0.38) and those without high-risk varices with 89% sensitivity (LR-0.26).
Conclusion: The combined use of SSM with LSM helped in reducing the proportion of patients in the grey zone for ruling in and ruling out CSPH. Moreover, SSM ≤40 kPa alone confirmed its potential role in excluding CSPH in cACLD patients.

FRI-029

Shear wave elastography predicts risk categories in patients with cirrhosis, PANDORA study

Jorge Poo[1], José Raúl Izaguirre[2], Frida Gasca-Díaz[1], Juan Ramón Aguilar[1], Carlos Ramírez-Castillo[1], Javier Lizardi[1], Juan Francisco Rivera-Ramos[1], Juan Alfredo Tamayo[1], Carina Zapata[2], Carolina Treviño-Garcia[2], Miroslava Hernández[2], Ilsa López[2], Graciela Tapia[3], Paula Cordero-Pérez[2], Linda Elsa Muñoz-Espinosa[2]. [1]*Grupo Mexicano para el Estudio de las Enfermedades Hepáticas, Ciudad de México, Mexico;* [2]*Hospital Universitario "Dr. José E. González," UANL, Monterrey, Nuevo León, Mexico;* [3]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Nacional Autónoma de México, Ciudad de México, Mexico*
Email: consultorio.jpoo@gmail.com

Background and aims: Several non-invasive studies have demonstrated a good correlation between hepatic and/or splenic elastography values and risk categories, including the size of esophageal varices (EV). However, few Latin American studies have described their experience with this non-invasive methodology. The objective was to evaluate the predictive value of shear wave elastography (SWE) to identify patients with cirrhosis and different risk categories related to esophageal varices, Child-Pugh liver function class and/or type of hepatic decompensation.
Method: 3016 patients were evaluated (site 1 = 1606, site 2 = 1410); 137 participants with IQR/median values >30% were excluded (4.5%); the remaining 2879 subjects had a mean age of 57 ± 14 years; 57% were women; 307 were F0 as a control group (10.7%), 1224 with chronic liver disease F1-F3 (42.5%) and 1348 with cirrhosis (46.8%); the etiology was metabolic in 45.9%, HCV 19.0%, AILD 19.6%, alcohol related 11.4%, HBV 2.1%, DILI 1.0% and idiopathic 0.9%. 2D SWE was evaluated with an Aixplorer ultrasound (Supersonic Imagine) with an SXC 6–1 convex transducer using shear wave (SW) technology. Median and IQR measurements were obtained and the degree of liver stiffness was estimated according to a semiquantitative system. The reliability criterion of SWE was IQR/median less than 30%. In patients with cirrhosis, Child-Pugh and MELD were calculated and endoscopy was performed and EV was classified according to Baveno 7 criteria. Non-parametric Kruskall-Wallis and Mann-Whitney U tests and linear regression were used.
Results: Stiffness scores (median ± SE (kPa)) were lower in the control group (4.3 ± 0.03) and in patients with chronic liver disease (7.6 ± 0.05) than in patients with cirrhosis (34.8 ± 0.53, $p < 0.001$) and the following differences were found using Child-Pugh Category: A (22.3 ± 0.7), B (37.2 ± 1.2), C (49.5 ± 2.6) ($p < 0.001$). Cirrhotic patients with and without the following categories of decompensation were significantly different: variceal hemorrhage (39.8 ± 1.8 vs. 29.1 ± 0.9, $p < 0.05$); ascites (41.7 ± 1.3 vs. 23.1 ± 0.7, $p < 0.001$); encephalopathy (40.8 ± 2.0 vs. 25.7 ± 0.7, $p < 0.001$), liver cancer (49.5 ± 4.6 vs 27.3 ± 0.6, $p < 0.05$), respectively. Liver stiffness was also different according to endoscopic findings: without EV 16.5 ± 0.4, small EV 24.0 ± 1.3, and large EV 32.1 ± 1.6 kPa ($p < 0.001$), and significantly correlated with Child-Pugh score, ascites, and BMI ($r = 0.45$, $p < 0.001$).
Conclusion: The shear wave elastography methodology clearly identifies patients with different risk categories, whether related to liver function, type of liver decompensation or size of esophageal varices, which could be an excellent diagnostic support tool in outpatient clinics dedicated to liver care.

FRI-030

Evaluation of aspartate aminotransferase to platelet ratio index and fibrosis-4 index stabilization in the phase 3 POISE trial of obeticholic acid for the treatment of primary biliary cholangitis

Alan Bonder[1], Darren Wheeler[2], Jing Li[2], Christopher Gasink[2], Robert G. Gish[3]. [1]*Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States;* [2]*Intercept Pharmaceuticals, Inc., Morristown, United States;* [3]*Robert G. Gish Consultants, LLC, San Diego, United States*
Email: abonder@bidmc.harvard.edu

Background and aims: Recent studies suggest that APRI and FIB-4 index predict fibrosis progression in liver disease, but these measures have not been validated in patients (pts) with primary biliary cholangitis (PBC). Obeticholic acid (OCA) was approved for the

treatment of PBC based on biomarker improvement in POISE, a 12-month randomized, double-blind (DB), placebo (PBO)-controlled phase 3 study. Here, we report the results from a post-hoc analysis of the impact of OCA on APRI and FIB-4 index in pts from the POISE study.

Method: In the DB phase of POISE, pts with PBC who were intolerant of or had an inadequate response to first-line ursodeoxycholic acid were randomized to receive PBO, OCA 5–10 mg (OCA titration), or OCA 10 mg daily. During the 5-year open-label extension (OLE), all pts were initially treated with OCA 5 mg daily for 3 months, after which the dose could be titrated based on response and tolerability. APRI and FIB-4 were calculated at baseline (BL) and each year during the DB phase and OLE, including based on low vs high BL APRI (<0.5 vs ≥1.5) or FIB-4 (<1.45 vs ≥2.67). Summary statistics for APRI and FIB-4 for all pts who received OCA (≤10 mg), either in the DB phase or OLE, were generated starting from OCA initiation.

Results: In the DB phase, mean APRI scores increased in the PBO group for pts with low or high APRI at BL (0.37 at BL [n = 15] vs 0.38 [n = 15] at month 12 and 2.76 at BL [n = 12] vs 3.37 at month 12 [n = 11], respectively) but decreased in the OCA 5–10 mg group for pts with low or high APRI at BL (0.37 at BL [n = 10] vs 0.32 [n = 10] at month 12 and 2.50 at BL [n = 14] vs 2.16 at month 12 [n = 14], respectively). Mean FIB-4 increased in the PBO group for pts with low or high FIB-4 at BL (1.04 at BL [n = 32] vs 1.22 [n = 31] at month 12 and 4.62 at BL [n = 16] vs 5.43 at month 12 [n = 15], respectively). FIB-4 values in the OCA 5–10 mg group were lower than those in the PBO group at the end of the DB phase for pts with low or high FIB-4 at BL (1.08 at BL [n = 30] vs 1.04 [n = 26] at month 12 and 4.20 at BL [n = 15] vs 4.60 at month 12 [n = 14], respectively). Among OCA-treated pts with low BL APRI, mean APRI scores were 0.39 at BL (n = 45) and 0.36 at month 60 (n = 23). In OCA-treated pts with high APRI at BL, mean APRI scores were 2.74 at BL (n = 35) and 2.48 at month 60 (n = 15). In OCA-treated pts with low FIB-4 at BL, mean FIB-4 values were 1.06 at BL (n = 91) and 1.20 at month 60 (n = 41). In OCA-treated pts with high FIB-4 at BL, mean FIB-4 values were 4.45 at BL (n = 45) and 5.65 at month 60 (n = 20). The sample size for APRI and FIB-4 substantially decreased at month 72, limiting interpretability of the data at this time point.

Conclusion: The data suggest that OCA prevents fibrosis or mitigates worsening of fibrosis in pts with no or low risk at BL through the surrogates APRI and FIB-4, and OCA stabilized fibrosis during the OLE in pts with moderate-to-severe fibrosis at BL. The findings imply that it may be beneficial to treat pts with OCA early before PBC progresses and risk of fibrosis increases.

FRI-033

Enhancing MRCP precision: a comprehensive analysis of intramuscular glucagon administration impact on biliary visualization

Fadi Abu Baker[1], Oren Shibolet[2], Mohamad Garra[1], Randa Taher[1], Amani Beshara[1], Saif Abu Mouch[1], Michael Oster[1], Abdel-Rauf Zeina[1].
[1]Hillel Yaffe medical center, Hadera, Israel; [2]Tel Aviv medical center, Tel Aviv, Israel
Email: Fa_fd@hotmail.com

Background and aims: Magnetic resonance cholangiopancreatography (MRCP) has continuously evolved to enhance visualization capabilities, yet the diagnosis of primary sclerosing cholangitis (PSC) remains challenging, especially in its early stages. This study explores the impact of intramuscular glucagon (IMG) administration on final image quality and biliary ductal system diameter in MRCP.

Method: Forty patients (57.5% female; average age 34.45 ± 8.2) with suspected inflammatory bowel disease (IBD) referred for Magnetic Resonance Enterography (MRE) underwent MRCP before and 8–12 minutes after IMG administration. Coronal T2-weighted fast spin-echo high-resolution 3D MRCP images were analyzed quantitatively and qualitatively by two independent MRI specialists. Quantitative assessments included measurements of predefined biliary ductal segments (distal, mid, and proximal common bile duct (CBD), right hepatic duct (RHD), left hepatic duct (LHD), and gallbladder volume). Qualitative evaluation used a five-point Likert-type scale (1 = perfect visualization; 5 = not visible). Interobserver variation was assessed using Intraclass Correlation Coefficient (ICC) and R-Pearson correlation.

Results: IMG administration led to significant increases in mean bile duct diameters compared to pre-injection. Combined pre- and post-IMG mean diameters were: distal CBD (3.079 ± 1.16 vs. 3.621 ± 1.05), Mid CBD (3.596 ± 1.46 vs. 4.207 ± 1.41), proximal CBD (3.736 ± 2.23 vs. 4.283 ± 1.90), RHD (2.227 ± 1.25 vs. 2.953 ± 0.91), and LHD (2.672 ± 1.30 vs. 3.392 ± 0.81). The differences were statistically significant (p <0.01) for all measurements. Interobserver agreement was strong (ICC 0.798 to 0.931, R 0.731 to 0.939).

IMG administration improved visualization scores significantly (2.65 ± 0.80 vs. 1.67 ± 0.68; P < 0.01), with a moderate-strong interobserver agreement (ICC 0.655 to 0.829). Additionally, IMG increased gallbladder volume (20.45 ml pre-IMG vs. 38.81 ml post-IMG; P < 0.01). Two PSC-associated biliary duct changes showed significant improvement post-IMG.

Conclusion: IMG administration enhances MRCP imaging parameters, increasing ductal diameters, improving biliary tree visualization, and aiding in the detection of associated pathologies, emphasizing its potential utility in early and improved PSC detection.

FRI-034

Radiomics based on MRI for predicting microvascular invasion at edge of hepatic alveolar echinococcosis

Wenya Liu[1]. *[1]The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China*
Email: 13999202977@163.com

Background and aims: To observe the value of radiomics model based on MR T2WI for predicting microvascular invasion at the edge of hepatic alveolar echinococcosis (HAE).

Method: Preoperative MRI data of 89 patients with HAE confirmed by pathology after surgical resection were retrospectively analyzed, including 32 cases with and 57 without microvascular invasion at the lesions edges. Then radiomics features of lesions were extracted based on T2WI, and both variance selection method and univariate selection method were used for screening the optimal features. Three classifiers, including random forest (RF), extreme gradient enhancement tree (XGBoost) and Logistic regression (LR) were used to construct machine learning (ML) models for predicting microvascular invasion at the edge of HAE lesions. Then 89 patients were divided into training set (n = 70) and test set (n = 19) at the ratio of 8:2, The corresponding receiver operating characteristic (ROC) curves were drawn, and the areas under the curves (AUC) were calculated, and the predictive performance of each ML model was observed.

Results: A total of 1409 radiomic features were extracted, and 7 optimal radiomic features were screened out by feature dimension reduction to construct machine learning models, ROC curve showed that XGBoost model performed well in both training set and testing set, with AUC of 0.96 and 0.89, respectively.

Conclusion: Radiomics XGBoost ML model based on MR T2WI could effectively predict microvascular invasion at the edge of HAE lesions.

Development of a non-invasive machine learning-based model for predicting hepatic steatosis in patients with chronic hepatitis B

Zhiyi Zhang[1], Li Zhu[2], Yiguang Li[3], Jian Wang[4,5], Shaoqiu Zhang[4], Fei Cao[1], Juan Xia[4], Renling Yao[4], Xingxiang Liu[6], Jie Li[1,4,5], Chuanwu Zhu[2], Yuanwang Qiu[3], Rui Huang[1,4,5], CHao Wu[1,4,5].
[1]Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, China; [2]Department of Infectious Diseases, The Affiliated Infectious Diseases Hospital of Soochow University, Suzhou, China; [3]Department of

Infectious Diseases, The Fifth People's Hospital of Wuxi, Wuxi, China; [4]Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China; [5]Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, China; [6]Department of Clinical Laboratory, Huai'an No. 4 People's Hospital, Huai'an, China
Email: dr.wu@nju.edu.cn

Background and aims: The incidence of chronic hepatitis B (CHB) combined with hepatic steatosis (HS) is increasing. However, the screening of individuals using liver biopsy and expensive imaging modalities does not appear to be cost-effective for most primary hospitals. This study aimed to develop a non-invasive machine learning-based model for predicting HS in treatment-naïve CHB patients.
Method: Eight hundred and fifty consecutive CHB patients who underwent liver biopsy from four medical centers were retrospectively included. HS was assessed by Brunt classification. The patients were randomly divided into a training set and a test set with a ratio of 7:3. Nine machine learning (ML) models were built, including logistic regression, support vector machine, k-nearest neighbors, random forest (RF), extreme gradient boosting, gradient boosting, adaboost, decision tree, and naive bayes. The best model was selected based on the highest area under the receiver operating characteristic curves (AUC). The performance of the selected model was compared with the hepatic steatosis index (HSI). SHapley Additive exPlanation (SHAP) analysis was used for model explanation.
Results: The median age was 40.0 years and male gender accounted for 63.3%. Among the nine models, RF exhibited a superior predictive performance with an AUC of 0.810 (95% confidence interval: 0.739–0.881) in the test set, significantly higher than HSI (AUC: 0.659, p = 0.003). The decision curve analysis showed that the net benefit of the RF model surpassed HS under a wide range of threshold probabilities. SHAP analysis lists the feature importance ranking, and serum uric acid was the most important predictive variable of HS.
Conclusion: This study developed a novel cost-effective, non-invasive RF model to evaluate the presence of HS, which can be used as a promising tool to identify HS in patients with CHB, especially in primary hospitals.

Does the use of liver frailty index in liver transplant assessment aid clinical decision making and correlate with patient outcomes?

Thomas Crame[1], Rachel Edwards[1], Rachel Howarth[1], Rachel Thomson[1], Emily Bonner[1], Preya Patel[2]. *[1]Liver Unit, Freeman Hospital, The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom; [2]Liver Unit, Freeman Hospital, The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*
Email: thomas.crame1@nhs.net

Background and aims: Frailty is associated with adverse outcomes in cirrhosis and liver transplantation (LT) and has an independent association with mortality. EASL guidelines recommend measurements of frailty, in addition to sarcopenia, when assessing patients with chronic liver disease. The Liver Frailty Index (LFI) is widely used in patients being assessed for LT. We aimed to review the use of LFI in liver transplant assessments at our institution, its role in clinical decision making and correlation with patient outcomes.
Method: A retrospective review of a prospectively maintained database of liver transplant assessments performed at a single liver unit (Freeman Hospital, Newcastle Upon Tyne, UK) was undertaken. Combined organ and super urgent transplants were excluded from analysis. Dietetic assessment of patients included anthropometry, SARC-F (Strength, Assistance in walking, Rise from a chair, Climb stairs, and Falls) and LFI which incorporates 3 measurements: balance, hand grip strength and five timed chair stands.
Results: 268 individuals were assessed by a specialist dietitian between 19/9/2019 to 30/11/23. The median age was 59 years (range 19–73) and 66.8% were male. The predominant aetiologies were alcohol-related liver disease (40%) and metabolic dysfunction-associated steatotic liver disease (MASLD) (24%). On the LFI, 10.9% were classified as robust, 76.4% were pre-frail, and 12.7% were frail. There was a significant, moderately negative correlation between LFI and anaerobic threshold (Spearnan's Rho −0.351 $p < 0.001$), and a moderately positive correlation between SARC-F and LFI (Spearnan's Rho 0.465 $p < 0.001$). 121 patients were listed for liver transplant with 90 undergoing transplant in the follow-up period. According to LFI, frail patients were significantly less likely to be listed for transplant (5%) compared to robust patients (14.9% $p < 0.001$). Post liver transplant, those classed as pre-frail had a longer time to discharge (mean 18.43 days ± 11.6 days) than those who were robust (mean 14.5 ± 5.1 days), however this was not statistically significant ($p = 0.231$).
Conclusion: LFI has added depth to liver transplant assessment at our institution. LFI correlates well with other commonly used pre transplant assessments of sarcopenia and anaerobic threshold testing. Our data corroborates published data supporting LFI as an effective tool to predict liver transplant outcomes, including likelihood of being listed for transplant and duration of post transplant inpatient stay. Further work is needed to assess whether targeted interventions to optimise patients pre transplant LFI could improve post transplant outcomes.

THU-009

Implementation of food insecurity screening within outpatient hepatology services: a clinical audit

Rachel Howarth[1], Thomas Crame[1], Stuart McPherson[1,2], Quentin M. Anstee[1,2], Laura Haigh[1,2]. *[1]Newcastle NIHR Biomedical Research Centre, Newcastle upon Tyne Hospitals, NHS Trust, Newcastle upon Tyne, United Kingdom; [2]Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom*
Email: racheljean.howarth@nhs.net

Background and aims: Liver disorders disproportionately affect the most economically disadvantaged, exacerbating health inequalities. Across Europe, the prevalence of food insecurity (FI) has increased by 130% since 2019, affecting 8.2% of the general population. Evidence indicates a paradox wherein FI contributes to both obesity and compromised nutritional status. FI may also influence the adoption of recommended diet lifestyle advice. We aimed to assess the extent of FI and its associated factors among patients with liver disease in a northern European population.
Method: A prospective audit was undertaken assessing consecutive patients attending hepatology outpatient services between October to December 2023. Food security status was assessed using validated tools (Hunger Vital Signs Two-Item Screener and United States Department of Agriculture, Food and Nutrition Service Six-Item Food Security Survey). Brief advice/signposting was offered to individuals identified as food insecure. Descriptive statistics were conducted, and Chi-square or Fisher's exact tests were performed, as appropriate.
Results: 227 patients (mean age 59 years [range 25–85]; 56% male and 80% white British) completed FI screening. Metabolic dysfunction-associated steatotic liver disease (MASLD) (46%) predominated, followed by alcohol-related liver disease (16%), viral hepatitis (16%) and other diagnoses (17%). 50 patients (22%) were identified as food

insecure. Comparing food insecure and secure groups, FI was more prevalent in those with MASLD (52% vs 45%, p = 0.036), type 2 diabetes (56% vs 41%, p = 0.002), hypertension (58% vs 53%, p = 0.04), depression (22% vs 11%, p = 0.012), mixed anxiety and depression (20% vs 12%, p = 0.04) and psoriasis (18% vs 10%, p = 0.037). No significant differences were observed between groups in relation to age, gender, ethnicity, smoking status, presence of cirrhosis, HbA1c, alcohol intake or body mass index.
Conclusion: FI was higher amongst patients with liver disease attending hepatology outpatient services than in the background population, and our results suggest that FI was associated with MASLD and metabolic syndrome features. FI presents an important barrier to implementation of diet lifestyle advice. Healthcare professionals should consider FI within holistic patient assessment to optimise outcomes and attenuate inequalities.

THU-010
Screening for liver disease in alcohol use disorder-is it worthwhile?
Marie Archibald[1], Lynsey Corless[1], Thomas Phillips[2]. *[1]Hull University Teaching Hospitals, Hull, United Kingdom; [2]University of Hull, Hull, United Kingdom*
Email: lynsey.corless@nhs.net

Background and aims: Alcohol Use Disorder (AUD) is a major risk factor for alcohol-related liver disease (ArLD). Screening for ArLD in AUD may offer an opportunity for earlier detection or intervention. We sought to determine the burden of liver disease in a cohort of patients with suspected AUD referred for assessment to our hospital Alcohol Care Team (ACT).
Method: Universal screening for AUD is performed for all admissions to our hospital using electronic entry of FAST (modified AUDIT) score alongside initial observations. ACT referrals are generated automatically on a virtual dashboard for FAST 5+ (i.e. possible alcohol dependence), or if a person is already known to ACT. Referrals can also be made where staff suspect AUD regardless of FAST. Following review, Enhanced Liver Fibrosis (ELF) test is advised for those with suspected AUD followed by Transient Elastography (TE) for those with non-reassuring result. We performed a case note review to identify the proportion of those with AUD who ultimately required 2-stage fibrosis testing, severity of ArLD identified, and reason for admission.
Results: All unique admissions referred to ACT from 1/11/22 to 30/6/23 were reviewed (n = 857). 112 (13.1%) required 2-stage fibrosis assessment and were further analysed. The cohort was 63.4% male, mean age 56 (23–82)-representative of our AUD population. Mean FAST score was 9.4 (SD 5.1), indicating high levels of alcohol dependence. There was no direct correlation between FAST score and ArLD stage by ELF/TE, suggesting alcohol severity does not reliably predict ArLD severity. Mean ELF was 10.1 (7.7–17.2), and was >9.8 in 51.8% (n = 58), demonstrating a high level of suspected advanced ArLD in the cohort. Mean TE was 11.3 (2.2–75 kPa). 38.4% (n = 43) had abnormal TE (>7 kPa), with 24 (21.4%) suggestive of advanced fibrosis (>11 kPa). 62% of the group had normal TE, emphasising the opportunity ACT can offer for ArLD prevention, even in severe AUD. The 20.1% (n = 23) admitted primarily due to alcohol were younger (mean age 52.8 vs 56) with higher FAST (11 vs 9.4), but there was no significant difference in ArLD severity versus rest of cohort. 53.6% (n = 60) were admitted for non-alcohol/gastroenterology reasons and were identified at risk of ArLD only as a result of universal screening. Most frequent reasons for admission were falls (n = 17; 15.8%) and abdominal pain (n = 13; 11.6%) but we identified 19 admission triggers overall, including elective surgery.
Conclusion: We identified high rates of advanced ArLD in our AUD cohort, showing the potential value of screening in this group to give opportunities to modify ArLD trajectory via specialist AUD/ArLD management. As AUD severity did not directly correlate with ArLD extent, screening should be considered for all presenting with AUD. Universal screening identified many people who would not otherwise have had ArLD screening or AUD support, and broader adoption should be encouraged.

THU-015-YI
Feasibility of a digital lifestyle intervention (VITALISE) to support self-management in patients with metabolic dysfunction-associated steatotic liver disease
Hollie Smith[1], Leah Avery[1,2], Stuart McPherson[2,3,4], Rebecca Livingston[5], Kate Hallsworth[2,3,4]. *[1]Centre for Rehabilitation, School of Health and Life Sciences, Teesside University, Middlesborough, United Kingdom; [2]Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [3]NIHR Newcastle Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [4]Liver Unit, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [5]School of Social Sciences, Humanities and Law, Teesside University, Middlesborough, United Kingdom*
Email: h.a.smith@tees.ac.uk

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is defined as the presence of hepatic steatosis in conjunction with one cardiometabolic risk factor and no other discernible cause. MASLD is directly linked to overweight and obesity, often caused by dietary excess and inactivity/sedentary behaviour. Weight loss, achieved through lifestyle behaviour change, is the recommended management approach. However, many patients find this challenging. Using intervention mapping we developed a MASLD-specific digital intervention (VITALISE) with tele-coaching support to target changes in dietary and physical activity behaviours. This study aimed to assess the feasibility and acceptability of delivering VITALISE in routine secondary care.
Method: VITALISE is a single-centre, one-arm feasibility study for patients aged ≥18 with MASLD. Primary outcomes relate to feasibility (recruitment rate, intervention uptake, engagement/adherence, follow-up rate) and acceptability (patient views via semi-structured interview). Secondary outcomes include clinical measures (body weight, blood pressure, liver stiffness, lipid profile, liver enzymes, glycaemic control), non-invasive measures (QRISK3, FIB-4, NFS), physical activity levels (accelerometry) and patient empowerment (Patient Activation Measure (PAM)).
Results: From November 2022 to May 2023, 35/59 patients eligible to participate were recruited (recruitment rate 59%; mean age 54 ± 13 years; 69% male; 43% with Type 2 Diabetes). 29/35 activated their VITALISE account (intervention uptake 83%) and, of those, 22/29 provided data at 6-month follow-up (follow-up rate 76%; 3/29 patients awaiting follow-up). Interviews are underway, with early data (n = 12) indicating acceptability of the intervention. There were significant improvements in body weight (−4.3 kg, p < 0.001), liver stiffness (−3.7 kPa, p = 0.046), liver enzymes (ALT −29.7 IU/L, p = 0.016; AST −13.9 IU/L, p = 0.044; GGT −21.1 IU/L, p = 0.040) and HbA1c (−2.3 mmol/mol, p = 0.023) from pre- to post-intervention. Blood pressure, lipid profile, and non-invasive measures did not significantly differ from pre- to post-intervention. Sedentary time significantly decreased (−332 mins/week, p < 0.001), time spent in light exercise significantly increased (+183 mins/week, p = 0.002) and time spent in moderate exercise showed no change (−5 mins/week, p = 0.443) from pre- to post-intervention. Early indications of patient empowerment (n = 15) show no change in PAM score or level from pre- to post-intervention.
Conclusion: Delivery of a digital lifestyle intervention for patients with MASLD in routine secondary care is feasible and acceptable. Significant reductions in body weight and improvements in liver health were achievable. These findings will be used to inform optimisation and larger-scale evaluation of VITALISE.

THU-016

A meta-ethnographic review of experiences and perceptions of physical activity and exercise in people with metabolic dysfunction-associated steatotic liver disease

Shelley Keating[1], Carla Dreyer[1], Kate Hallsworth[2,3,4], Jonathan Stine[5,6,7,8], Ingrid Hickman[9]. [1]*The University of Queensland, School of Human Movement and Nutrition Sciences, Brisbane, Australia;* [2]*Newcastle Upon Tyne Hospitals NHS Foundation Trust, NIHR Newcastle Biomedical Research Centre, Newcastle Upon Tyne, United Kingdom;* [3]*Newcastle Upon Tyne Hospitals NHS Foundation Trust, Liver Unit, Newcastle Upon Tyne, United Kingdom;* [4]*Newcastle University, Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle Upon Tyne, United Kingdom;* [5]*The Pennsylvania State University-, Milton S. Hershey Medical Center, Division of Gastroenterology and Hepatology, Department of Medicine, Hershey, United States;* [6]*The Pennsylvania State University-, College of Medicine, Department of Public Health Sciences, Hershey, United States;* [7]*The Pennsylvania State University-, Milton S. Hershey Medical Center, Liver Center, Hershey, United States;* [8]*The Pennsylvania State University-, Milton S. Hershey Medical Center, Cancer Institute, Hershey, United States;* [9]*The University of Queensland, The University of Queensland ULTRA Team, Clinical Trials Capability, Centre for Clinical Research, Herston, Australia*
Email: s.keating@uq.edu.au

Background and aims: International guidelines have recently been published for physical activity (PA)/exercise in people with metabolic dysfunction-associated steatotic liver disease (MASLD), which have highlighted broad benefits for MASLD management. However, <20% of people with MASLD meet recommended PA targets. We aimed to review published data on the lived experiences and perceptions of PA and exercise in people with MASLD to inform strategies for increasing the uptake and adherence to exercise in clinical practice.
Method: A meta-ethnographic synthesis was utilised to systematically review articles published in English relating to the experiences and perceptions of PA/exercise in people with MASLD. Databases (PubMed, Embase, Web of Science) were searched from inception to November 2023. Two researchers (CD, SK) independently screened titles and extracted data. Data (study-level themes and subthemes) were coded, translated into third-order concepts, and themed using the validated Noblit and Hare model. Study quality was assessed using the Critical Appraisal Skills Programme checklist.
Results: A total of 1538 articles were screened, with seven studies included (n = 161 participants across six countries; mainly recruited via purposive sampling; overall study quality rated 'high'). Data collection was predominantly via semi-structured interviews and focus groups. Key findings encompassed barriers to PA/exercise uptake and maintenance including: lack of awareness of MASLD and its health impact, which lowered risk perception; lack of information provision regarding the role and importance of PA/exercise for MASLD management; lack of resources, tailored exercise plans or referrals to exercise professionals; multiple comorbidities and symptoms including obesity, musculoskeletal conditions, pain and fatigue; ambivalence of perceived exercise capabilities and low exercise-related self-efficacy; lack of time and competing priorities. Reported enablers of PA/exercise included: accountability to themselves (e.g., habit forming) and to the healthcare professional overseeing their care; social support from family, friends, and healthcare providers; the experience of symptom relief and holistic benefits.
Conclusion: This study translated firsthand experiences and perceptions of PA and exercise for people with MASLD. To improve uptake and maintenance of regular PA/exercise, interventions should focus on increasing awareness of MASLD and its impact on cardiometabolic and liver health and the role of exercise in its management. Appropriate referral to exercise professionals and logistical and behavioural support for personalised exercise care is critical for long-term adherence and sustainability of health benefit.

THU-017-YI

Development of a nurse-led out-patient service to support earlier diagnosis and management of liver disease

Amy Thatcher[1], Vernujaa Nagandiram[1], Vijay Grover[1]. [1]*The Hillingdon Hospital, London, United Kingdom*
Email: amy.thatcher@nhs.net

Background and aims: Hillingdon Hospital is a district general hospital serving a population of 350, 000, with one consultant Hepatologist, two Clinical Nurse Specialists (CNS) and a junior Hepatology Assistant Practitioner (HAP). We streamlined processes for diagnosis and management of liver disease, with limited healthcare resources by using a blended workforce, seeking to minimise the number of formal consultant reviews.
Method: HAP employed in June 2023 with independent Fibroscan® clinics from August 2023. Data collected on suspected aetiology of liver disease, Fib4 score, Fibroscan result, Diabetic status and BMI for 523 patients attending a first out-patient appointment in the CNS/HAP clinic where a Fibroscan® was performed (March 2022–October 2023). Retrospective analysis of waiting times, compared three months prior and post-employment of a HAP. Outcomes analysed for patients who were independently reviewed by the HAP (with virtual oversight from Consultant/CNS).
Results: 85% of 523 referrals were received from General Practitioners (GP) and all non-invasive liver screens were reviewed by the Hepatologist or CNS prior to acceptance. 265 patients had Metabolic Associated Steatotic Liver Disease (MASLD). Fib4 scores triaged against local guidelines ('low' cut off <1.3). Advice is that patients with a Fib4 >1.3 are referred for a Fibroscan® for liver fibrosis assessment. However, some 'lows' were referred and accepted due to abnormal liver imaging- ultrasound suggesting coarse echotexture/nodular outline. Of these 265 patients, 67% were non-fibrotic (Fibroscan® <8.1 kPa), 19% fibrotic, 14% cirrhotic (>12 kPa). Of the 62 patients with MASLD and a low fib4 who were accepted for a Fibroscan®, 22% had at least advanced liver fibrosis (Fibroscan® >8.1 kPa). Between August–October 2023, HAP reviewed 47 new patients independently, all patients received brief intervention. 49% patients with normal Fibroscans® were reassured and safely discharged back to GP at initial review, 47% required CNS follow-up and 2% required an interval Fibroscan® with HAP. Waiting times decreased from an average of 121 days in July 2023 prior to employment of HAP, compared to 48 days in November.
Conclusion: Implementation of an innovative service delivery model for Hepatology outpatients has led to faster diagnosis and access to specialty care, whilst reducing the need for formal consultant review. This model supports patients and clinicians to address and manage health issues at an earlier stage, ensuring appropriate and timely interventions to reduce complications. An interesting observation was that a cohort of MASLD patients with a low Fib4, had advanced liver fibrosis.

THU-020-YI

Evolution of health-related quality of life in liver transplantation patients in relation to acceptance and metabolic liver disease

Janne Suykens[1,2], Louis Onghena[2,3,4,5], Frederik Berrevoet[5], Hans Van Vlierberghe[2,3], Xavier Verhelst[2,3], Sarah Raevens[2,3], Eric Hoste[6], Sander Lefere[2,3], Anja Geerts[2,3], Carine Poppe[2,6]. [1]*Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium;* [2]*Department of Internal Medicine and Paediatrics, Hepatology Research Unit, Ghent University, Ghent, Belgium;* [3]*Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium;* [4]*Department for Human Repair and Structure, Department of Gastrointestinal Surgery, Ghent University Hospital, Ghent, Belgium;* [5]*Department of General and HPB Surgery and Liver Transplantation, Ghent University Hospital, Ghent, Belgium;* [6]*Department of Transplantation, Ghent University Hospital, Ghent, Belgium*
Email: janne.suykens@ugent.be

Background and aims: The parallel between obesity and metabolic dysfunction-associated steatotic liver disease (MASLD) is remarkable, with potentially harmful effects post-liver transplantation (LT). Illness cognitions regarding helplessness and acceptance are known to play a role in health-related quality of life (HRQoL) of LT patients. We aimed at investigating the evolution of these constructs in relation to specific indications for LT.
Method: A cohort of liver transplantation patients received follow-up from the moment of listing to two years post-LT. We used self-report questionnaires to measure HRQoL, illness cognitions (acceptance, helplessness, disease benefits), depression, anxiety, and stress respectively at different time frames: pre-LT, 1- and 2-years post-LT.
Results: The study included 56 patients with consecutive evaluations, 76.8% were male with a mean age of 51 ± 12.1 at time of diagnosis. Mental HRQoL (MQoL), acceptance and disease benefits increased significantly over time compared to pre-LT with significant attenuation of helplessness, depression, and stress. Alcohol-related liver disease (ALD) listed patients exhibited higher HRQoL, perceived disease benefits and acceptance pre-LT as well as attenuated levels of depression, anxiety, and stress post-LT_{1and2y}. Patients listed for MASLD exhibited significantly lower acceptance when compared to ALD and metabolic and ALD (metALD) listed patients ($p = 0.05$). Acceptance ($p = 0.015$) and MQoL ($p = 0.032$) were higher post-LT_{2y} when patients were transplanted due to ALD, contrary to MASLD transplanted patients.
Conclusion: Acceptance of health status in liver transplantation is dynamic and seems to be an important parameter for HRQoL and follow-up. Considering the hedonistic reflex involved in obesity, MASLD should not be underestimated as an indicative pathology of LT where acceptance of the disease and HRQoL is and remains low after LT, requiring broad preventive societal education and interventions focusing on coping strategies and illness cognitions.

THU-021
Outcomes from a nurse-led home-based care program for patients with liver cirrhosis

Catherine Yu[1], Kendall Fitzpatrick[1], Vanessa Lowen[1], Kristen Peake[1], Mayur Garg[1], Diana Lewis[1], Siddharth Sood[1]. [1]*Northern Health, Epping, Australia*
Email: yucatherineyu@gmail.com

Background and aims: Hospitalised patients with cirrhosis have high readmission rates. Home-based nursing programs for conditions such as heart failure have shown reduced readmission rates, yet similar programs rarely exist for cirrhosis. Liver at Home (LAH) is a new, state-funded 3-month program providing at-home, liver specialist nurse-led care for cirrhotic patients following a hospital admission. Reviews occur in-person or via telehealth. We aim to demonstrate reduced readmission rates in enrolled patients for the duration of the program.
Method: Cirrhotic patients admitted under Gastroenterology were referred to LAH between 1/03/2023–31/09/2023. Patients with at least 90 days of follow-up were included. An admission within 7 days of discharge from the index admission was considered a failed discharge; admission between 8–90 days was considered a readmission. LAH patients were compared to referred, but non-enrolled patients (non-LAH) as an intention to treat analysis. Cox proportional hazard ratios were calculated for all-cause and liver-related first readmission.
Results: There were 27 LAH patients and 16 non-LAH patients (n = 6 declined, n = 6 resided outside hospital catchment areas, n = 4 other reasons). LAH and non-LAH patients were similar in age (59 v 62 years old, p = 0.50), gender (66.7% v 62.5% male, p = 0.88), cirrhosis aetiology (77.8% v 62.5% alcohol-related [p = 0.29]) and severity (median Child-Pugh score: 8 v 8). LAH patients had a similar risk of all-cause readmission compared to non-LAH (40.7% [11/27] v 56.3% [9/16] respectively; HR 0.68, 95% CI = 0.28–1.6 [p = 0.38]). LAH patients appeared less likely to have liver-related admissions in the first 90 days compared to non-LAH patients (25.9% [7/27]) v 50% [8/16] respectively, HR 0.47 95% CI = 0.17–1.30 [p = 0.14]). There were a total 10 liver-related admissions for LAH patients and 13 liver-related admissions for non-LAH patients. Infection and hepatic encephalopathy were the main reason for LAH patient admissions, though this was not significantly different to non-LAH patients (Infection: 50% [5/10] in LAH v 7.7% [1/13] in non-LAH, p = 0.05; Hepatic encephalopathy: 30% [3/10] v 15.4% [2/13], p = 0.6). There were no admissions for ascites in the LAH group (0/10 v 38.5% [5/13], p = 0.04). Other causes of readmission in non-LAH group were too low to accurately perform statistical analysis.
Conclusion: Cirrhotic patients enrolled in a 3-month liver specialist nurse-led, at-home care program had a trend towards being less likely to be readmitted for a liver-related reason. No LAH patients were readmitted for ascites, suggesting a primary benefit of the program in managing fluid balance. More data will be required to evaluate program success rates in preventing readmissions.

THU-022
Impact of a joint clinical nurse specialist and dietitian clinic on health related quality of life outcomes for patients with decompensated liver disease

Leah Cox[1], Katie Ballesteros[1], Vikram Sharma[1]. [1]*Royal London Hospital, Barts Health NHS Trust, London, United Kingdom*
Email: leah.cox3@nhs.net

Background and aims: It is well documented that chronic liver disease, particularly decompensated liver disease is associated with poor health related quality of life (HrQoL). A joint Clinical Nurse Specialist (CNS) and Dietitian outpatient clinic was established to provide holistic advice for patients with decompensated liver disease. The interventions provided included disease education, diuretic management, medication review and nutritional assessment. Patients requiring support with alcohol abstinence were referred to the Alcohol Care Team. We aimed to review the clinical outcomes and patient reported HrQoL for patients who attended a newly established joint CNS and Dietitian outpatient clinic.
Method: HrQoL was assessed using the Eq5D-5L questionnaire. All patient's HrQoL was assessed on initial assessment, and repeated at a time frame between 4–6 months. Clinical outcomes were assessed at the same time frame. All patients included in this review attended at least 3 appointments over a 4–6 month period.
Results: The aetiology of liver disease was 82% alcohol related, 9% metabolic dysfunction-associated steatohepatitis, 9% cryptogenic. 55% were males. 27% were Asian and 50% Caucasian. 23% were from other ethnic backgrounds. The median age was 60. Ascites was the main cause of decompensation for 82%. 86% were managed with diuretics. 27% required enteral feeding for nutritional optimisation. 75% had a Child Pugh score of B. The mean MELD score was 12.5. The average number of appointments attended was 3.8. Due to improved nutritional status, 27% re-compensated and did not require a TIPSS procedure as previously planned. 9% are now optimised for consideration for liver transplantation. 13% are now palliative and for conservative management. A comparison of baseline HrQoL scores compared to review at 4–6 months demonstrated an improvement for the majority of patients. 42% had improved mobility, 63% had improved ability to wash and dress themselves, 57% had improved ability to carry out usual activities, such as working and shopping, 68% reported improvement in pain and discomfort and 57% reported improvement in anxiety and depression. Average overall HrQoL scores improved from an average of 48% to 68% over a 4–6 month period. 32% of patients reported an overall improvement in HrQoL of between 30–55%.
Conclusion: A combined nursing and dietetic outpatient review has demonstrated the ability to improve clinical outcomes for patients with decompensated liver disease, in particular inducing recompensation with diuretic management, nutritional optimisation and abstinence support. Close monitoring, and a combined, holistic

assessment has also proven beneficial for patients in relation to HrQoL scores. Analysis should be undertaken to evaluate the cost-effectiveness of this specialist multi-disciplinary clinic as part of a hepatology outpatient service.

THU-027-YI

A pilot pharmacist led carvedilol titration service leads to sustained doses of high dose carvedilol in patients with clinically significant portal hypertension

Yun Jung Kim[1], Din He Tan[2,3,3], Kathryn L Nash[4], Salim I Khakoo[5], Mark Wright[4], Ryan M Buchanan[6]. [1]*University Hospital Southampton NHS Foundation Trust, Pharmacy, Southampton, United Kingdom;* [2]*University of Southampton, Southampton, United Kingdom;* [3]*University of Southampton Highfield Campus, Medical Student BM5, Southampton, United Kingdom;* [4]*University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom;* [5]*University of Southampton, School of Clinical and Experimental Sciences, Faculty of Medicine, Southampton, United Kingdom;* [6]*University of Southampton, School of Primary Care, Population Sciences, and Medical Education, Faculty of Medicine, Southampton, United Kingdom*
Email: yun.kim@uhs.nhs.uk

Background and aims: Non-selective beta blockers (NSBBs) reduce the risk of hepatic decompensation in patients with cirrhosis and clinically significant portal hypertension (CSPH). However, prescribed doses in real-world practice are frequently below those used in clinical studies and sub-therapeutic doses risk beneficial effects not manifesting as improved clinical outcomes for patients. To address this implementation challenge, we set up a pharmacist led supervision service to initiate and carefully titrate carvedilol to therapeutic doses.
Method: Eligible patients included those meeting the Baveno VII criteria for CSPH without contraindications to NSBB who were on a dose of carvedilol of <25 mg per day. Patients who needed NSBB as secondary prophylaxis for variceal haemorrhage or with decompensated liver disease (defined as Child-Pugh (CP) >B7 or C) were not eligible and remained in the consultant led service. Patients were seen at a single face to face appointment where eligibility was confirmed or reassessed. Blood pressure (BP) and pulse were measured. Patients were followed up with 1–2 weekly telephone calls to assess adverse events and review ambulatory BP and pulse monitoring results. Statistical analysis was performed using Wilcoxon signed-rank test and paired t-test.
Results: In 12 weeks (September to December 2023) 29 patients were reviewed face to face at a community hepatology clinic in Southampton (UK). Mean Age was 59 (standard deviation 11), 69% were male, and MASLD was the most common underlying aetiology (58%). All patients met criteria for CSPH with the following biochemical values (mean ± SD); platelet count (157.2 ± 75.3 × 109/L), liver stiffness (37.7 ± 22.8 kPa), ELF (11.4 ± 1.1). 4 (14%) were CPB7 the remainder were CPA. 22 (76%) completed dose optimisation. Median time to maximum tolerated dose was 2 weeks (range 1–6). Median dose at the first appointment was 6.25 mg (range, 0–25 mg) with 10 (38%) not taking any carvedilol as baseline. Only 1 (3%) was not started on carvedilol due to a persistently low pulse <55 beats per minute. Post follow-up dose (median = 25 mg, range 6.25–25 mg), was significantly higher than pre-intervention dose (median = 6.25 mg, range 0–25 mg) (Wilcoxon, $p < 0.001$). No significant change was observed for mean arterial pressure ($p = 0.13$) or pulse rate ($p = 0.162$) before and after dose optimisation. 4 experienced fatigue, but no significant adverse events requiring treatment cessation occurred.
Conclusion: Our pharmacist led carvedilol optimisation service was well attended by patients. The clinic achieved rapid, sustained, and safe titration of carvedilol dosing. Although NSBBs are not universally recommended, wherever the practice is implemented we must ensure doses match trials as closely as possible. An intensive pharmacist led service is a feasible approach to achieve this.

THU-028

Usefulness of an educational activity through an informatic tool in participants with chronic hepatitis B infection

Judit Romero-Vico[1,2], Anna Feliu-Prius[1,3], Ester Sánchez-Gavilán[4], Marc Ribó[4], Adriana Palom[5,6], Juan Carlos Ruiz-Cobo[1,3,7], Elena Vargas-Accarino[1], Núria Fabrellas[8], Mar Riveiro[1,3,7,9], Maria Buti[1,3]. [1]*Research group of liver diseases, Vall Hebron Research Institute., Barcelona, Spain;* [2]*Department of Nursing and Health, University of Barcelona., Barcelona, Spain;* [3]*Department of Medicine, Universitat Autònoma of Barcelona., Barcelona, Spain;* [4]*Neurology Department, Vall d'Hebron University Hospital., Barcelona, Spain;* [5]*Research group of liver diseases, Vall Hebron Research Institute, Barcelona, Spain;* [6]*Biomedical Research Networking Centre for Hepatic and Digestive Diseases., Madrid;* [7]*Department of Hepatology, Vall d'Hebron University Hospital., Barcelona, Spain;* [8]*Department of Nursing and Health, University of Barcelona, Barcelona., Barelona, Spain;* [9]*Biomedical Research Networking Centre for Hepatic and Digestive Diseases., Madrid, Spain*
Email: judviro1630@gmail.com

Background and aims: Low linkage to care rate is a major issue in the management of people living with hepatitis B virus (HBV). This can be attributed to several factors, such as the asymptomatic nature of the infection until advanced stages and the lack of awareness of the potential consequences of the infection. The aim of this study was to assess the knowledge on HBV among patients with chronic HBV infection and to evaluate the performance of an educational activity.
Method: Prospective study including people living with HBV from the outpatient clinics. Through a phone application, the subjects answered a self-response questionnaire designed to assess HBV knowledge. This included aspects related to disease transmission, prevention, treatment, and complications of hepatitis B. The questionnaire comprised 16 dichotomous questions, requiring "yes" or "no" responses. A scoring system from 0 (lowest) to 10 (highest) was used to evaluate the participants' level of knowledge. After completing the questionnaire, an app alert notifies the patients to view an educational video, followed by an invitation to repeat the initial questionnaire.
Results: A total of 92 participants responded to the first questionnaire. Baseline characteristics were: 72% male, mean age 50.2 years (± 12.6), 67% Caucasian, and 40% undergoing treatment for HBV. Regarding their education levels, 7.6% had no basic education, 33.7% basic education, 50% superior education, and 8.7% declined to answer. The questionnaires revealed that the lowest scores were observed for questions related to treatment, while the highest scores were related to transmission pathways. The mean score from the first survey was 8.1 (± 1.6). Following the educational video, 40 (43%) participants completed the second questionnaire. Among them, the initial score was 8.4 (± 1.0) and after the educational activity the score rose to 9.0 (± 1.0), resulting in a significant increase ($p = 0.05$). No other differences were observed in sociodemographic characteristics or educational levels between the patients who responded only to the first or both tests.
Conclusion: These results demonstrate that an educational activity through an application is a useful tool for enhancing participants' knowledge of chronic HBV infection. Therefore, a phone application is a supportive tool in educating patients with this infection.

THU-029

Nurse-led hepatocellular cancer surveillance in district general hospital

Kate Pingoy[1], Areeb Zar[1], Karen Street[1], Karen Railton[1], Abhishek Ray[1], Prayman Sattianayagam[1], Kunchana Thebuwana[1], Gayatri Chakrabarty[1]. [1]*Surrey and Sussex NHS Trust, Redhill, United Kingdom*
Email: kate.pingoy@nhs.net

Background and aims: Hepatocellular carcinoma (HCC) surveillance is recommended by the National Institute for Health and Care

Excellence (NICE) for at-risk patients with 6-monthly liver ultrasound scans (USS). A nurse-led surveillance pathway was introduced at Surrey and Sussex Healthcare NHS Trust (SaSH) in April 2021 to manage patients eligible for surveillance. This study aims to identify the scale of the demand on this service, and scope for improvement.
Method: Patients eligible for surveillance were identified from the existing database. A search of electronic patient records via Discern Reporting Portal in Cerner identified patients who had USS requested from April 2021 to November 2023 under Gastroenterology and Hepatology. Keywords used for search were 'HCC, liver lesions, liver cancer, Hepatoma'. Suspected or confirmed cases of HCC were obtained from regional multidisciplinary meeting (MDM) records. Liver surveillance nurse had access to a dedicated mobile phone which allowed easy access to patient and arranged patients' appointments. A random selection of 30 patients who failed to attend their last ultrasound or clinic appointments were contacted via phone to understand reasons for non-attendance.
Results: In total 344, 381, and 441 patients on the database were for eligible for HCC screening in 2021, 2022 and 2023 respectively. In 2021, 376 USS were requested of which 296 (78.7%) were completed. In 2022, 464 requested and 361 completed (77.8%). In 2023, 690 were requested, and 428 completed so far. From 2021 to 2023, scan requests increased by 83.5%. In 2021 there was 1 case of suspected HCC, 10 in 2022 and 21 in 2023. There were 4 confirmed cases of HCC in 2022 and 9 (7 are Barcelona Clinic Liver Cancer stage 0/A, and 2 stage D) in 2023. 30 selected patients who were contacted via phone for non-attendance had underlying Alcohol-related liver disease (ArLD) or Hepatitis C. 22 of 30 patients attended their appointments after the phone contact. It was highlighted that single hospital visit allowing for same day scan, clinic review with blood tests may improve patient compliance. We recognise some limitations in the nurse-led surveillance pathway. The service requires a high level of data management and patient contact. A dedicated staff to manage patient booking and patients having easy access to liver team via phone has shown better patient engagement.
Conclusion: Since introduction of nurse-led surveillance, there has been an annual increase in the number of scan requests, completed scans, and detection of liver cancer. Patients with ArLD and hepatitis C are more likely to not attend for USS, and requires higher engagement with the team to maintain compliance. There is an increased demand on the service which requires adequate staffing.

THU-032
"Ama il tuo Fegato" program: screening for hepatic fibrosis using liver stiffness measurement (LSM)

Paolo Scivetti[1], Martina Costanzo[2], Daniela Ferrari[3], Anna Lisa Gandolfi[4], Stefano Pisu[4], Pietro Raco[4], Lorena Zanchetta[5].
[1]hepatology clinic, Department of Internal Medicine, ASLBI, Biella, Italy, Ponderano, Italy; [2]Liver Team, ASLBI, Biella, Italy, POnderano, Italy; [3]Liver Team, ASLBI, Biella, Italy, Ponderano; [4]Liver Team, ASLBI, Biella, Italy, Ponderano, Italy; [5]Liver Team, ASLBI, Biella, Biella, Italy
Email: paolo.scivetti@aslbi.piemonte.it

Background and aims: The "AMA IL TUO FEGATO" program at ASLBI explores the potential of Liver Stiffness Measurement (LSM) as a screening tool for hepatic fibrosis in the general population. While LSM is well-established for chronic liver disease assessment, its application in seemingly healthy individuals remains underexplored. The aim is to understand whether LSM can be effectively used to identify early-stage liver fibrosis in individuals without apparent symptoms of liver disease. The program seeks to contribute to the prevention and timely treatment of liver fibrosis through a broader assessment of the population, thereby expanding the possibilities for early intervention and improving overall liver health management within the community.
Method: In the year 2023, a comprehensive initiative was undertaken, involving 981 participants aged over 40 who responded to an open invitation to participate in the "AMA IL TUO FEGATO" program at ASLBI. The program was meticulously executed by professional nurses who conducted Liver Stiffness Measurement (LSM) adhering to rigorous international standards. This standardized approach ensures the reliability and accuracy of the gathered data, laying the foundation for a robust analysis of liver health in the studied population.
Results: Results revealed that 81.8% exhibited normal LSM values (<6 kPa), 16.9% exceeded 6 kPa, and 1.6% had stiffness surpassing 14 kPa. Analysis indicated correlations between LSM values and diabetes, BMI, and alcohol intake. Among those with normal LSM, 4.26% were diabetics, 31.85% had a BMI over 26, and 23.33% reported alcohol intake exceeding 2 units/day. For LSM values over 6 kPa, 20.22% were diabetics, 45.95% had a BMI over 26, and 37.84% reported alcohol intake exceeding 2 units/day. In cases exceeding 14 kPa, 20.72% were diabetics, 40% had a BMI over 26, and 20% reported alcohol intake exceeding 2 units/day. Subjects with LSM >6 kPa were referred to their GP for further investigation, and those exceeding 14 kPa were scheduled for Hepatology clinic visits.
Conclusion: The "AMA IL TUO FEGATO" program not only underscores the significance of Liver Stiffness Measurement (LSM) as an efficient tool for the early detection of hepatic fibrosis in seemingly healthy individuals but also accentuates the critical role it plays in preventing the progression of liver diseases. Early identification through LSM is paramount, as it facilitates timely surveillance for potential complications, including hepatocellular carcinoma. Furthermore, the program serves as a noteworthy example, demonstrating the practicality and effectiveness of involving nursing staff in the implementation of LSM.

THU-033
Early evaluation of a pharmacist-led clinic for the management of patients with chronic hepatitis B on antiviral treatment

Aya Al-Hasani[1], David Sherman[1], Uchu Meade[1], Jayshri Shah[1]. *[1]London North West University Healthcare NHS Trust, London, United Kingdom*
Email: jayshri.shah@nhs.net

Background and aims: Between 2020 and 2022, the COVID-19 pandemic resulted in unprecedented service pressures affecting hepatology outpatient clinics in our institution due to various staff and patient factors. Chronic hepatitis B (CHB) patients experienced appointment delays and rescheduling, partly due to prioritisation of new or more urgent referrals. In 2023, we found that 35% of patients requiring monitoring of antiviral therapy for CHB had breached service targets. In addition, due to the high prevalence of CHB in our catchment area in inner North West London, implementation in April 2022 of the National Health Service (NHS) initiative for testing blood borne viruses within emergency departments (ED) resulted in an additional 30 new referrals per month. To support increases in service pressures, a pharmacist-led clinic for the management of patients with CHB was introduced. We aimed to evaluate the achievements of this clinic in its first year.
Method: A protocol for the pharmacist-led clinic was written outlining inclusion criteria: those with a confirmed diagnosis of CHB, who were already stabilised on oral antiviral treatment. Exclusion criteria: new patients referred with diagnosis of CHB, those not on antiviral treatment, patients with decompensated cirrhosis, patients co-infected with hepatitis C, hepatitis D or HIV, patients diagnosed with hepatocellular carcinoma (HCC) and patients who have received liver transplant. In this retrospective study we analysed patient attendance rates, medication adherence and pharmacist interventions between December 2022 to December 2023. Interventions offered included lifestyle advice, referral for HCC screening as per EASL guidelines, checking for co-infection with HIV, hepatitis C and hepatitis D where this had not been previously checked in initial assessment, medication adherence support, and drug-drug interactions (DDIs).
Results: 108 patients were offered appointments in the pharmacist-led clinic. 81% (n = 88) attended their appointment. Lifestyle advice

was given to 64% (n = 57) of patients with concomitant risk factors for chronic liver disease. 24% (n = 21) met the criteria for HCC screening, with some patients with no ultrasound imaging for up to seven years. 24% (n = 21) were screened for co-infection with HIV, hepatitis C or hepatitis D. 17% (n = 15) were non-adherent with antiviral medication. 41 patients were on concomitant medications, 90% (n = 37) were screened for DDIs.
Conclusion: Specialist pharmacists are well positioned to support hepatologists in the management of patients with CHB. With increasing demand and capacity issues, the introduction of a pharmacist-led clinic helps free up consultant time. The service can be delivered safely and effectively as demonstrated. Further studies will need to be carried out with larger patient numbers, including qualitative data on the patient's experience.

THU-034-YI
Dietary composition in individuals with primary sclerosing cholangitis-high prevalence of inadequate fat-soluble vitamin intake
Catarina Lindqvist[1], Michael Ingre[2], Annika Bergquist[3]. [1]*Unit of Gastroenterology and Rheumatology, Department of Medicine Huddinge, Karolinska Institutet, Medical Unit Clinical Nutrition, Karolinska University Hospital, Stockholm, Sweden;* [2]*Unit of Gastroenterology and Rheumatology, Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden;* [3]*Unit of Gastroenterology and Rheumatology, Department of Medicine Huddinge, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden*
Email: catarina.lindqvist.1@ki.se

Background and aims: Individuals with primary sclerosing cholangitis (PSC) express a demand for more information about lifestyle and its potential impact on their disease. Despite this, limited research has explored the dietary habits of individuals with PSC. The aim of this study is to compare the dietary intake of individuals with PSC in Sweden to the Estimated Average Requirement according to the Nordic Nutrition Recommendations 2023.
Method: A cross-sectional assessment of dietary intake was performed using a food-frequency questionnaire among 120 individuals with PSC enrolled in PiSCATIN (Effect of Simvastatin on the Prognosis of Primary Sclerosing Cholangitis), an ongoing, randomized placebo controlled multicenter study. Macro- and micronutrient intake was compared to The Nordic Nutrition Recommendations 2023. A dietary quality index developed by the National Food Agency in Sweden was used to determine dietary quality. The index considers factors such as fiber, fat, and discretionary foods, as well as adherence to dietary recommendations concerning the consumption of fruits, vegetables, fish, and whole grain bread.
Results: The median age was 47 (IQR 18) and body mass index 25.2 (IQR 5.9) kg/m^2. Eight persons (10%) had a BMI <20 and 16 (13%) a BMI >30. The median daily energy intake was 1762 (IQR 1132) kilocalories (95% CI 1759–2067). The percentages of energy from different nutrients were as follows: fat 36%, saturated fat 15%, polyunsaturated fat 4.6%, protein 17%, and carbohydrate 43%. On average, participants consumed 18 grams (IQR 18) of fibre. Consumption of low amounts of carbohydrates, fiber, and polyunsaturated fats, along with a high intake of saturated fats, signifies an imbalanced diet. More than 50% of the subjects had suboptimal intake of zinc, selenium and vitamins C, D, and K. In addition, >30% had suboptimal intakes of other micronutrients such as vitamins A, B6, E, niacin, folate, potassium, magnesium, and iron. A substantial proportion of participants (41%) were classified as having a poor dietary quality.
Conclusion: Individuals with PSC, despite the majority having a normal BMI, do not meet the recommended levels of intake for polyunsaturated fat and many of the micronutrients. The high prevalence of low intake of fat-soluble vitamins warrants further exploration in this population where malabsorption is frequent.

THU-039-YI
Educational intervention in cirrhotic outpatients with hepatic encephalopathy secondary to constipation
Martina Perez-Guasch[1,2], Alba Martinez[1], Gloria De Prada[1], Ana Alonso[1], Carmen Cierco[1], Eva Lopez-Benages[1]. [1]*Liver Unit, Hospital Clínic of Barcelona, Barcelona, Spain;* [2]*Fundació de Recerca Clínic Barcelona-Institut d'Investigacions Biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), Barcelona, Spain*
Email: maperezgu@clinic.cat

Background and aims: Hepatic encephalopathy (HE) represents one of the most limiting complications in end stage liver diseases (ESLD). Its presence makes patients incapable of self-care, reducing their quality of life and survival. HE precipitating factors include constipation and being a transjugular portosystemic shunt (TIPS) carrier. Part of the treatment of HE is non-absorbable disaccharides rectal administration form. Currently, there is a lack of patients and caregiver's educational program focused on HE management at home, as well as there's an absence of specific devices for efficient and autonomous rectal enema administration. Consequently, most HE episodes are treated either in emergencies or through hospital admissions. The aims of this study are to evaluate the educational program impact, in the need of hospital admissions, emergency visits and in the quality of life.
Method: Pilot interventional study, spanning 6 months of follow-up, conducted at the Hepatology Service of Hospital Clinic of Barcelona between 2017 and 2019. Patients with ESLD, having at least one prior hospital admission for HE either spontaneous or related to TIPS, participated in an educational program. The educational intervention involved an initial visit providing information on HE (diet, treatment, early symptom detection) and training on enema device usage. Six follow-up visits reinforced HE management monthly. All visits were individual and had an approximate duration of 60 minutes. To assess treatment adherence and quality of life, Morisky-Green and SF-12 questionnaires have been used at the beginning and at the end of the study. The remaining data has been retrospectively extracted from the patient's medical history.
Results: 17 subjects were included, mostly male (88%), mean age 63 years. Most subjects were married (77%), lived with the primary caregiver (100%), mainly their partner (82%). The most common cause of ESLD was alcohol consume and Non-Alcoholic Steatohepatitis (24%), followed by Hepatitis C Virus (24%). The average MELD-Na Score was 14 and 10 patients were TIPS carriers. After the intervention, hospital admissions/emergency visits related to constipation-induced HE significantly decreased from a median (interquartile range) of 1 (0.5–3) admissions pre-study to 0 (0–2) during the study. Although the trend is clear, this reduction does not reach statistical significance ($p < 0.060$). Quality of life assessment did not show statistically significant results in any questions.
Conclusion: The implementations of educational program focus on patients with recurrent HE episodes show a clear tendency to reduce hospital admissions and emergency visits. The nursing care aims to empower patients with knowledge necessary for effective disease management, could positively influencing various aspects of their health and well-being.

THU-040-YI
Establishment of the irish hepatology nurses association: an association for nurses working in liver disease in Ireland
Michèle Bourke[1], Anne Brennan[2], Shauna Davitt[1], Edel Dolan[2], Aileen Murphy[2], Joanne Murphy[2]. [1]*St. Vincent's University Hospital, Dublin 4;* [2]*St. Vincent's University Hospital, Dublin 4, Ireland*
Email: mbourke02@gmail.com

Background and aims: In the early 2000's a group of liver nurses with a special interest in hepatitis C, began meeting biannually to discuss their practice. In recent years, this group has expanded. The attendees share a common goal-to improve the care of patients with liver disease in Ireland. The growth in personnel attending the

meetings coupled with the diversification of sub-specialties within liver nursing, gave way to a natural progression to formalise the group's structures and develop its scope.
Method: The organising committee developed a survey to assess the opinions of attendees on current practices and expectations for the future. The survey was circulated via email. It comprised questions relating to respondent demographics, perceived objectives of the group in its current state, thoughts on future aims, opinions on formalising a national association with a committee structure, and the payment of an annual membership fee. Responses were returned via email within a 2 month period. The results were collated and presented at the next scheduled meeting. A vote was then conducted to adopt the findings, or not.
Results: 51 eligible participants were identified and contacted via email. A 37% response rate was achieved (n = 19). 1 (5%) Advanced Nurse Practitioner, 17 (90%) Clinical Nurse Specialists (or equivalent level), 1 (5%) Staff Nurses. 13 (68%) worked in a tertiary hospital and 6 (32%) were community based. 6 (32%) worked in general hepatology, 9 (47%) specialised in viral hepatitis, 3 (16%) in hepatocellular carcinoma and 1 (5%) in liver transplant. 2 (10%) of the group were founding members, the remaining 17 (90%) joined in subsequent years. 10 (53%) have been members for 0–5 years, 3 (16%) 6–10 years and 6 (31%) >11 years. Themes identified for current objectives; (i) education, (ii) peer support. Themes identified for future aims; (i) education, (ii) research opportunities, (iii) career development pathways, (iv) promotion of liver nursing (v) networking. 10 (52%) in favour of formalising an association and electing a board to achieve these objectives. 10 (52%) willing to be a board member. 19 (100%) willing to pay a membership fee.
Conclusion: The survey results were presented to the group. In June 2023, the Irish Hepatology Nurses Association (IHNA) was established. A board was elected comprising a Chairperson, Secretary, Treasurer, plus 4 board members. Terms of reference were devised, agreed and adopted by the association. There are 36 paid memberships. The 1st official IHNA meeting organized by the elected board was held in December 2023. A social media presence has been generated to advertise the IHNA to all nurses working within the hepatology field in Ireland and abroad. Works are underway to identify a timeline and processes for achieving the identified future aims.

THU-044
Global subjective assessment and global leadership initiative on malnutrition as predictors of mortality in patients with cirrhosis

Valesca Dall'Alba[1], Nairane Boaventura[1], Larissa Maffini[1], Camila Saueressig[2], Vittoria Zambon Azevedo[3]. [1]*Universidade Federal do Rio Grande do Sul, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil;* [2]*Universidade Federeal do Rio Grande do Sul, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil;* [3]*Universidade Federal do Rio Grande do Sul (UFRGS), Porto Alegre, Brazil*
Email: camilasaueressig@gmail.com

Background and aims: The prevalence of malnutrition in patients with cirrhosis varies widely, ranging from 10 to 100%. The pathogenesis of malnutrition in chronic liver disease is multifactorial and there is not a gold standard nutritional assessment. Taking this into account the objective of this study was to evaluate the prevalence of malnutrition in hospitalized patients with cirrhosis using Subjective Global Assessment (SGA) and Global Leadership Initiative on Malnutrition (GLIM) and their ability to predict mortality in one year.
Method: A cross-sectional study was conducted with adult hospitalized patients with cirrhosis at the Hospital de Clínicas in Porto Alegre, Brazil. BMI, mid-arm muscle circumference (MAMC), weight loss, physical examination, dietary intake, functional capacity metabolic demand, and CRP were used to assess nutritional status by SGA and GLIM. Cox regression model was performad, adjusted for sex and age to evaluate the mortality risk in one year. This study was approved by the Research Ethics Committee (CAAE: 39507820130015352 7).
Results: A total of 100 patients were evaluated (60.1 ± 10.4 years, 63% men, 80% white, 61% Child_Pugh B and 30% Child_Pugh C). Regarding the etiology of cirrhosis, HCV and alcohol were the most prevalent (32% and 23%), 33% had diabetes mellitus and 35% hypertension. The prevalence of malnutrition according to the GLIM criteria was 59.8% and according to the SGA (B or C) was 69%. The presence of malnutrition (SGA and GLIM) was an independent risk factor for one-year mortality (HR: 3; 95% CI 1.5–6; p = 0.02, HR: 2.2; 95% CI 1. 1–4.1; p = 0.01, respectively).
Conclusion: Both tools (SGA and GLIM) identified a high prevalence of malnutrition and proved to be predictors of mortality. Carrying out early nutritional assessment is important to implement the most assertive dietary therapy approach.

THU-045
Medicines optimisation in patients admitted with hepatic encephalopathy in UK centres

Connor Thompson[1,2,3], Arron Jones[1,4], Alison Boyle[1,5], Niamh Forde[1,6], Fiona Rees[1,2], Alban Clareburt[5]. [1]*British Hepatology Pharmacy Group (BHPG), London, United Kingdom;* [2]*University Hospitals Sussex NHS Foundation Trust, Brighton, United Kingdom;* [3]*Medicines Use Research Group (MURG), University of Brighton, Brighton, United Kingdom;* [4]*Barts Health NHS Trust, London, United Kingdom;* [5]*NHS Greater Glasgow and Clyde, Glasgow, United Kingdom;* [6]*The Royal Liverpool Hospital, Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom*
Email: C.Thompson3@brighton.ac.uk

Background and aims: Hepatic encephalopathy (HE) occurs in up to 40% of people with advanced chronic liver disease and has been estimated to affect 200, 000 people in Europe. Medication management for these patients is critical in reducing events and hospital admissions, as well as some medicines being implicated in worsening HE. Optimising medications is an important intervention in improving care of these patients. EASL recommends optimised lactulose dosing as first line followed by rifaximin in recurrence within 6 months of first presentation. We aimed to assess medication use in patients admitted to hospital against medication prescribed at discharge to understand whether there are opportunities for optimisation.
Method: A retrospective service evaluation of inpatients admitted with documented HE was conducted by hepatology specialist pharmacists between April to July 2022 in 4 UK centres. Patient records were used to review prescribed medications at admission and discharge, with focus on medicines frequently prescribed in decompensated cirrhosis, as well as antibiotics and proton pump inhibitors (PPIs). Decompensation history was also recorded. Those with same-day discharge, condensed or missing discharge summaries, who remained an inpatient during the data collection period, or who died during their stay were excluded from data collection.
Results: A total of 31 patients met the inclusion criteria with an average hospital stay of 19 days. With 61% (n = 19) male and a mean age of 61 years. Nine patients had their first presentation with HE. The most common underlying aetiology was alcohol-related liver disease (ArLD) (n = 20). For those with the first presentation of HE, all (n = 9) patients were discharged on lactulose and 44% (n = 4) were discharged on rifaximin. For those with a history of HE, 86% (n = 19/22) were prescribed lactulose on admission. Of the 3 who were not, 1 patient was subsequently started during admission, 1 was prescribed alternative laxatives and the other had no laxatives prescribed on discharge. 36% (n = 8/22) of patients with a history of HE were prescribed rifaximin on admission. This increased to 73% (n = 16/22) at discharge. Overall, there was an increase in lactulose dose from 49 ml/day (n = 23) on admission to 62 ml/day (n = 27) on discharge. There was a 25% (n = 5) reduction in the number of patients on PPIs on discharge.

Conclusion: We found that the majority of patients were prescribed lactulose therapy and this was up-titrated as required. There was an increase in rifaximin prescriptions at discharge compared with admission, although there is potential for further optimisation. There is scope to review other medicines which may contribute to worsening HE, including PPIs. Further work is planned to increase data collection to more centres in the UK and gain evidence of pharmacists' role within these interventions, especially in centres with hepatology specialist pharmacists.

THU-046

Exploring the feasibility of ultrasound liver imaging reporting and data system (US LI-RADS) and visualisation score in clinical application

Dorothy Seng[1], Albert Low[2], Azizah Afif[1], Denise Lau[1], Teo Simin[1], Pei-Yuan Chang[1]. [1]*Radiography department, Singapore general hospital, Singapore;* [2]*Division of radiological sciences, Singapore general hospital, Singapore*
Email: usdoro@gmail.com

Background and aims: Routine surveillance is highly recommended for patients at risk of developing hepatocellular carcinoma (HCC). The American College of Radiology (ACR) developed an Ultrasound Liver Imaging Reporting and Data System (US LI-RADS) to standardise the imaging technique, interpretation, reporting and data collection for surveillance of ultrasound exams for this group of patients. The US LI-RADS comprises of two components: Ultrasound (US) Category and Visualisation Score (VS). The US Category comprises of 3 scores: US-1 Negative, US-2 Subthreshold, and US-3 Positive. The US VS has 3 ratings: A-No or minimal limitations, B-Moderate limitations, and C-Severe limitations. This study aims to determine the clinical applicability of US LI-RADS during clinical observations and if VS is affected by age, gender body-mass index (BMI) and type of liver diseases.
Method: This is a retrospective, single-centre clinical audit review study. All patients who underwent US Abdomen or Hepatobiliary system for HCC surveillance between May to July 2023 were identified through an anonymised data depository of US clinical audit cases. All US examinations using 3 US machines: Philips Epiq, Canon Aplio, and GE Logiq, using standard institution scanning protocol, were included. Demographic and clinical data, including US category, VS, age, gender, BMI and type of liver diseases were retrieved from the existing data depository. Patients with previously diagnosed or treated HCC were excluded. Data was analysed by IBM SPSS Version 26. Descriptive statistics and Fisher exact tests were performed to test the association between VS and the patient demographics.
Results: A total of 160 patient records were retrieved from the data repository. The mean age of these patients was 62.2 ± 13.3 years. Among them, 69 (43.1%) were male, while 91 (56.9%) were female and the patients' mean BMI was 24.2 ± 4.3. Majority of patients, 137 (85.6%) were classified as US-1, 14 (8.8%) as US-2, and 9 (5.6%) as US-3. Among the US-3 cases, 3 were subjected to further imaging, leading to 2 cases identified as HCC. The HCC outcomes were associated with the US category observations ($p = 0.033$). VS revealed that 112 (70.0%) cases were assigned VS-A, 43 (26.9%) cases were VS-B, and 5 (3.1%) cases were VS-C. A weak positive correlation existed between age and VS, $R2 = 0.210$ ($p = 0.008$). However, VS exhibited no significant correlation with BMI, gender, or the specific type of comorbidities. Among the factors affecting VS, poor beam penetration emerged as the primary factor contributing to insufficient visualisation of the liver (17/42, 10.6%).
Conclusion: Our study concluded that US LI-RADS is useful for screening patients at risk. Apart from age, VS has no association between patient demographics and type of liver diseases. It may be feasible to implement US LI-RADS at our institution for more consistent recommendations and standardised reporting.

Associations of food insecurity and healthcare access with the prevalence and mortality of metabolic dysfunction-associated steatotic liver disease (MASLD): a global study of the United Nation and the global burden of disease data

Zobair Younossi[1,2], Shira Zelber-Sagi[1,3], Carina Kugelmas[1,4], Jeffrey V. Lazarus[1,5], Annette Paik[1,6], Leyla Deavila[1,6,7], Lynn Gerber[1,6], James M. Paik[1,6]. [1]*The Global NASH Council, Washington DC, United States;* [2]*Beatty Liver and Obesity Liver Research Program, Falls Church, VA, United States;* [3]*School of Public Health, University of Haifa, Haifa, Israel;* [4]*Denver Health Medical Center, Denver, United States;* [5]*Barcelona Institute for Global Health (ISGlobal), Hospital Clinic, University of Barcelona, Barcelona, Spain;* [6]*Beatty Liver and Obesity Research Program, Falls Church, United States;* [7]*The Center for Outcomes Research in Liver Disease, Washington DC, United States Minor Outlying Islands*
Email: zobair.younossi@cldq.org

Background and aims: Food insecurity and lack of healthcare access are important social determinants of health contributing to global MASLD burden. We assessed the impact of food insecurity and healthcare access on the prevalence and mortality of MASLD, globally.
Method: This ecological study linked surrogates of food security and nutrition data from the Food and Agriculture Organization (FAO) of the United Nations (2016–2019) with MASLD prevalence, MASLD mortality, Socio-Demographic Index (SDI), and Healthcare Access and Quality (HAQ) index data from the Global Burden of Disease Study-2019. High vs low MASLD prevalence (≥22% vs <22%) and SDI (≥0.67 vs <0.67) were determined according to the median of country-level rates. FAO defines a healthy diet as providing both adequate calories and adequate levels of all essential nutrients/food groups needed for active and healthy life. Amount of calories insufficient to cover energy requirement for an active and healthy life indicated undernourishment (hunger).
Results: In 204 countries, the mean prevalence of MASLD, MASLD-related liver death rate, HAQ and SDI scores were 24.08%, 0.39 per 100, 000, 54.7 and 0.64. MASLD prevalence was similar between high and low SDI countries (24.56% vs. 23.60%, $p = 0.668$). In both high and low SDI countries, T2D and obesity were associated with higher prevalence of MASLD ($p < 0.001$). Among high SDI countries, those with high MASLD prevalence experienced higher prevalence of severe food insecurity (6.46% vs. 1.86%), higher cost of a healthy diet ($3.43 vs $3.08 per person per day), higher percentage of inability to afford a healthy diet (19.24% vs. 3.99%) and higher rates of MASLD-related liver deaths (0.38 vs. 0.27 per 100, 000) as compared to high SDI countries with low MASLD prevalence ($p < 0.02$). In contrast, high SDI countries with low MASLD prevalence had higher HAQ index (78.25 vs. 61.09, $p < 0.001$). Among high SDI countries, generalized linear regression (GLM) models showed that increased MASLD prevalence was associated with severe food insecurity [2.43% increase (95% CI: 0.73–4.17%)] and inability to afford a healthy diet [0.76% increase (0.20–1.31%)], while a higher HAQ index was associated with decreased MASLD prevalence [1.48% reduction, (−1.97 to −1.02%)]. A higher HAQ index was the only parameter inversely associated with MASLD-related deaths [0.91% risk reduction, (−1.49 to −0.32%)]. In similar analyses among the low SDI countries, the opposite patterns were observed where higher food insecurity, undernourishment/hunger and HAQ index were associated with lower MASLD prevalence ($p < 0.03$).
Conclusion: Surrogates of food insecurity are major drivers of MASLD prevalence in high SDI countries while higher access to healthcare is protective against both MASLD prevalence and death. A different pattern was observed in low SDI countries suggesting different factors (poverty, hunger) playing an important role.

SATURDAY 08 JUNE

SAT-424

The impact of air pollution on the occurrence of steatotic liver disease in Korea

Jae Moon Yun[1], Su Hwan Cho[2], Jin-ho Park[1]. [1]*Seoul National University Hospital, Seoul, Korea, Rep. of South;* [2]*Seoul National University Hospital, Family Medicine, Korea, Rep. of South*
Email: iwsby@naver.com

Background and aims: Previous studies investigating the impact of air pollution (AP) on the occurrence of steatotic liver disease (SLD) faced significant challenges in general applicability, primarily due to issues related to the reliability of measuring concentrations of air pollutants and the variability in air pollutant levels between the country of study and most other nations. To address these limitations, we evaluated the association between the prevalence of SLD and long-term AP exposure in a Korean population, using a more accurate method for calculating AP exposure.
Method: We conducted a cross-sectional study of 20, 553 participants who had undergone of a health screening program carried out at the Seoul National University Hospital Health Promotion Center between January 2015 and December 2019. SLD was diagnosed through ultrasound in cases exhibiting hepatic steatosis, specifically defined to include only those satisfying at least one cardio-metabolic criteria, obesity, elevated blood glucose, elevated blood pressure, or dyslipidemia. 250 administrative districts-specific levels of air pollutants, including particulate matter (PM) 2.5, PM 10, nitrogen dioxide (NO2), sulfur dioxide (SO2), and carbon monoxide (CO), were estimated by validated Community Multiscale Air Quality (CMAQ) modeling system. The odds ratios of SLD according to AP exposure was evaluated using a multiple logistic regression analysis, after adjustments for age, sex, body mass index, presence of abdominal obesity, lifestyle, and comorbidities. SLD was classified as metabolic dysfunction-associated steatotic liver disease (MASLD), MASLD and increased alcohol intake (MetALD), and Alcohol-related liver disease (ALD) based on alcohol consumption. To investigate the influence of AP on SLD in relation to these alcohol-related classifications, stratified analyses were conducted.
Results: Increased the 5-year average exposure levels of PM 2.5, PM10, NO2, CO were significantly associated with an increased odds of SLD, with odds ratios (ORs) of 1.04 (95% CI 1.01–1.07), 1.06 (1.01–1.11), 1.10 (1.04–1.16), and 1.07 (1.02–1.12) for each 1 interquartile range (IQR) increase in PM 2.5, PM 10, NO2, and CO, respectively. For SO2, there was no significant association observed between the increase in average AP exposure concentration and SLD. In stratified analysis targeting subgroups based on alcohol consumption, for each 1 IQR increase in PM2.5, there was a significant increase in the odds of MetALD (OR 1.12, 1.01–1.24), while no significant association was observed in the case of MASLD and ALD.
Conclusion: This study suggests that long-term exposure to ambient PM2.5, PM10, NO2 and CO may increase the odds of SLD. These effects suggest that the impact of air pollution on the occurrence of fatty liver due to metabolic abnormalities may vary depending on the level of alcohol consumption.

SAT-425

Food swamps and easy access to unhealthy food increases the risk of metabolic dysfunction-associated steatotic liver disease (MASLD) mortality in the United States (U.S.)

Annette Paik[1,2], Linda Henry[1,2], Leyla Deavila[1,2], Saleh Alqahtani[1,3,4], Fatema Nader[1,2,5], James M. Paik[1,2,6], Zobair Younossi[1,7]. [1]*The Global NASH Council, Washington DC, United States;* [2]*Beatty Liver and Obesity Research Program, Falls Church, United States;* [3]*Liver Transplant Center, King Faisal Specialist Hospital, Research Center, Riyadh, Saudi Arabia, Division of Gastroenterology and Hepatology, Riyadh, Saudi Arabia;* [4]*Division of Gastroenterology and Hepatology, Johns Hopkins University, Baltimore, United States;* [5]*The Center for Outcomes Research in Liver Disease, Washington DC, United States;* [6]*Center for Outcomes Research in Liver Disease, Washington DC, United States;* [7]*Beatty Liver and Obesity Research Program, Falls Church, United States*
Email: zobair.younossi@cldq.org

Background and aims: Environmental factors such as living in neighborhoods with easy access to poor quality food may increase the risk of MASLD. We assessed the association of food deserts and food swamps with MASLD-related mortality in US.
Method: In this population-based study, MASLD-related deaths were obtained from the National Vital Statistics System (NVSS) (2010–2020). These data were merged with food environment factor from US Department of Agriculture (USDA) Food Environment Atlas (FEA) data (2012, 2014, 2015, 2017, and 2020) by Federal Information Processing System code. Food desert is a proportion of county's total population having both low income and low grocery store access. Retail food environment index (REFI), indicative of food swamps, is a county's ratio of the number of fast-food restaurants and convenience stores to the number of retail healthy food outlets. High mortality was based on ≥75 percentiles of US country-level score vs low (<75 percentiles).
Results: Of the eligible 2, 400 counties in US (2010–2020), the median (range) of age-adjusted MASLD-related mortality was 19.50 (5.60–122.30) per 100, 000 population. Compared to counties with low age-adjusted MASLD-related mortality rate, counties with high age-adjusted MASLD-related mortality rate had higher percentage of elderly residents (≥65 years, 16.54% vs. 14.64%), adult type 2 diabetes (T2D) (13.0% vs. 11.10%), and adult obesity (33.00% vs. 32.10%). These counties experienced higher poverty rates (20.25% vs. 15.10%), higher food desert rates (7.90% vs. 5.93%) and higher REFI (ratio, 4.83 vs. 4.38) with lower median household income ($38, 758 vs. $48, 063) and lower Supplemental Nutrition Assistance Program (SNAP) participation among eligible population (78.18% vs. 86.27%), (all p values <0.01). Multivariable logistic regression model showed people living in counties with higher REFI score (4th quartile) had higher odds of MASLD-related mortality (Odds Ratio [OR] = 2.27, 95% CI, 1.36–3.80) compared to those living in counties with lower REFI score (1st quartile). The strongest risk factors for higher MASLD-related mortality were T2D (OR = 1.30, 1.21–1.46), obesity (OR = 1.07, 1.01–1.13), poverty (OR = 1.20, 1.16–1.24) and percentage of Hispanic residents (OR = 1.05, 1.03–1.07), while SNAP participation among eligible population (OR = 0.95, 0.93–0.97), number of available fitness center (per 100, 000) (OR = 0.91, 0.87–0.95), and increase change in the number of community supported agriculture farm (OR = 0.997, 0.996–0.999) were protective against MASLD-related deaths. In contrast, there were no associations of food desert with MASLD-related deaths.
Conclusion: Having more access to fast-food restaurants and convenience stores in relation to retail healthy food outlets is associated with increased MASLD related mortality. Efforts must continue to evolve to provide easily accessed healthy food options.

SAT-426-YI

Prevalence and association between chronic kidney disease and steatotic liver disease in a nationally representative sample in the United States

Mason Lai[1], Jennifer Lai[1], Andrew S. Allegretti[2], Kavish Patidar[3], Giuseppe Cullaro[1]. [1]*University of California, San Francisco, San Francisco, United States;* [2]*Massachusetts General Hospital, Boston, United States;* [3]*Baylor College of Medicine and Michael E. DeBakey Veterans Affairs Medical Center, Houston, United States*
Email: mason.lai@ucsf.edu

Background and aims: Steatotic liver disease (SLD) and chronic kidney disease (CKD) are common conditions that are strongly associated. Yet, there is a paucity of data regarding the prevalence of this overlap and the factors that may drive its occurrence.
Method: Using the National Health and Nutrition Examination survey, we examined trends among adult participants from 2005–

2020 that defined SLD with the Fatty Liver Index in the United States. Next, we completed correlative analyses that defined SLD using fibrosis based on the liver stiffness measure among participants from 2017–2020 who underwent FibroScan. We utilized multivariable survey-weighted binomial generalized linear models to determine the factors that were associated with CKD, defined as eGFR <60 or urine albumin-creatinine-ratio >30.

Results: Among the 76, 496 participants included in the trend analyses, the estimated prevalence of CKD was 15.7% (95CI 15.2–16.2%) and SLD was 42.3% (95CI 41.4–43.2%). As compared to those without SLD, those with SLD had a significantly higher estimated prevalence of CKD (SLD: 15.7%, 95CI 14.9–16.5% v. No SLD 11.2%, 95CI 10.7–11.7%). As compared to those without SLD (estimated prevalence 11.2%, 95% CI 10.7–11.8%), we found that those with SLD and no to minimal fibrosis had similar levels of CKD (estimated prevalence 10.1%, 95% CI 9.4–10.8%) and those with SLD and advanced fibrosis (estimated prevalence 31.3%, 95% CI 29.6–33.1%) had higher estimates of CKD. In multivariate analyses of 3 824 participants who underwent FibroScan and had SLD by Fatty Liver Index, adjusting for control and presence of DM, HTN, and HLD, compared to those with normal liver stiffness, those with moderate scarring (F2) had similar odds of CKD (1.42, 95CI 0.91–2.20), those with severe scarring (F3) had higher odds of CKD (1.95, 95CI 1.09–3.49), and those with cirrhosis had higher odds of CKD (1.90, 95CI 1.04–3.47).

Conclusion: Our findings highlight that CKD is common among patients with SLD and that higher degrees of hepatic fibrosis are independently associated with CKD, independent of other co-morbidities of the metabolic syndrome.

SAT-427-YI

Hepatocellular carcinoma surveillance in the United Kingdom: a multi-centre study assessing uptake and inequalities

Maria Qurashi[1], Varsha Chaitanya-Bhide[1], Shahid Khan[2], Kate Hyams[3], Pamela Rice[4], Nina Stafford[3], Jayshri Shah[3], Zinu Philipose[4], Hooshang Izadi[5], Rohini Sharma[1]. *[1]Imperial College London, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, London, United Kingdom; [3]London North West University Hospitals NHS Trust, London, United Kingdom; [4]Croydon University Hospitals NHS Trust, London, United Kingdom; [5]Oxford Brookes University, Oxford, United Kingdom*
Email: maria.qurashi09@imperial.ac.uk

Background and aims: Biannual ultrasound surveillance for hepatocellular carcinoma (HCC) in patients with cirrhosis is recommended by international professional bodies. Previous studies in American and Asian cohorts suggest fewer than 25% of patients receive surveillance at recommended intervals; however, there is a paucity of research on HCC surveillance uptake in the United Kingdom (UK). We aimed to quantify HCC surveillance uptake across a multi-centre cohort in the UK and examine socio-demographic factors affecting surveillance attendance.

Method: A multi-centre retrospective review of 869 patients eligible for HCC surveillance at five hospitals in the UK from March 2021–March 2023 was conducted. Attendance at surveillance was categorised as regular (biannual, in line with European Association of Study of the Liver (EASL) guidance), infrequent (received some surveillance, not at recommended intervals) or non-attendance (no surveillance received). We collected data on socio-demographic factors (age, gender, aetiology of liver disease, socio-economic status, hospital site, distance from hospital). Multivariate logistic regression analysis was undertaken to examine if factors were associated with reduced attendance at surveillance.

Results: 16.5% of patients received regular surveillance; 73.1% of patients were in receipt of infrequent surveillance and 10.4% received no surveillance over the two year study period. On multivariate analysis, low socio-economic status (OR 2.8, CI 1.3–6.2, p = 0.01) and being under the care of a non-specialist hospital (OR 5.3, CI 2.9–9.5, p < 0.001) were both associated with reduced attendance. Ages 45–75 were a protective factor (OR 0.3, CI 0.1–0.7, p = 0.004) for non-attendance at surveillance. There was no association between aetiology of liver disease or gender and attendance at surveillance.

Conclusion: This is the first multi-centre study assessing HCC surveillance and its determinants in the UK. HCC surveillance uptake is universally low, with patients of low socio-economic status and those under the care of non-specialist centres most at risk of reduced attendance at surveillance. Our findings highlight the urgent need to address low HCC surveillance uptake in the UK.

SAT-428

Identifying treatment naïve and undiagnosed primary biliary cholangitis patients using a novel case finding database and treatment pathway

Timothy Jobson[1], Christina Owen[1], Almuthana Mohamed[1], Sarah Gormley[1]. *[1]Somerset NHS Foundation Trust, Musgrove Park Hospital, Taunton, United Kingdom*
Email: timothy.jobson@somersetft.nhs.uk

Background and aims: Primary Biliary Cholangitis (PBC) is a chronic, yet under-diagnosed condition with treatment available that can avoid progression to end stage disease or transplantation. In the Somerset Liver Improvement Project (SLIP) we developed a unique case-finding tool (covering >0.5 M patients) enabling rapid longitudinal analysis of blood test results by clinicians to identify cohorts at risk of developing liver disease. We aimed to a) identify patients who had blood markers suggestive of PBC, b) develop a recall treatment pathway co-designed with our public and patient reference group without overloading primary and secondary care and c) offer a clinical review and treatment where appropriate.

Method: Blood test results from 2005 to 2020 were analysed to a) identify the overall number of patients who had ever had a positive mitochondrial antibody (AMA) test b) find those that had AMA reversal on last testing from positive to negative AMA (reverted) and c) identify patients aged 18–70 years with persistent positive AMA and Alkaline Phosphatase (ALP) above 130 U/L to call to clinic. Patients unknown to our service were sent postal letters inviting them to attend a liver clinic. All communication materials were developed with patient and public involvement aiming to maximise response rates. Patients who attended clinic had a clinical assessment performed and confirmatory blood tests taken.

Results: Our database showed 267 males with positive AMA at some point with 31 having reverted AMA on their last test. 951 females had a positive AMA at some point with 107 having reverted AMA on their last test. Overall, 40 patients (9 M, 31 F) met the criteria for clinic invitation. 20 (50%) responded to the invitation and were seen face to face in clinic with 18 having repeat blood tests (2 patients had already been started on treatment in another clinical encounter or setting). 4 of those attending were patients who had been lost to follow-up or previously discharged. Of the 18 patients to have repeat bloods, 10 had a positive AMA on repeat testing and 8 had reverted. 1 patient had reverted twice over time with the last result being negative. 10 patients were considered treatment naive and started on Ursodeoxycholic acid.

Conclusion: Our novel case finding database can be used to identify treatment naïve and undiagnosed PBC patients. Using our co-designed recall pathway we achieved a 50% response rate leading to clinical review of patients with PBC who were commenced on treatment where appropriate. Variability in AMA status and liver enzyme levels emphasises the importance of longitudinal analysis of past blood results. The AMA reversion rate seen here has not been previously reported in the scientific literature to our knowledge. We demonstrated a powerful methodology for identifying and engaging treatment naïve patients with clear benefits for prognosis, and potentially for clinical trial recruitment.

SAT-429

Impact of body mass index on non-invasive test accuracy for the diagnosis of at-risk metabolic dysfunction-associated steatohepatitis

Paula Iruzubieta[1], Rebeca Mayo[2], Itziar Mincholé Canals[2], Ibon Martínez-Arranz[2], Maria Teresa Arias Loste[3], Luis Ibañez-Samaniego[4], Cristina Alonso[2], José Luis Calleja Panero[5], Manuel Romero-Gómez[6], Rocío Aller[7], Mazen Noureddin[8], Javier Crespo[1]. *[1]Gastroenterology and Hepatology Department, Marqués de Valdecilla University Hospital, Clinical and Translational Research in Digestive Diseases, Valdecilla Research Institute (IDIVAL), Santander, Spain; [2]OWL Metabolomics, Derio, Spain; [3]Gastroenterology and Hepatology Department, Marqués de Valdecilla University Hospital, Clinical and Translational Research in Digestive Diseases, Valdecilla Research Institute (IDIVAL), Santader, Spain; [4]Department of Gastroenterology and Hepatology, Gregorio Marañón General University Hospital, Madrid, Spain; [5]Gastroenterology Department, Hepatology Unit, Puerta de Hierro University Hospital, IDIPHISA, Madrid, Spain; [6]Department of Digestive Diseases, Virgen del Rocío University Hospital, Clinical and Translational Research Group in Liver and Digestive Diseases, Biomedicine Institute of Sevilla, Sevilla, Spain; [7]Gastroenterology Department, Centro de Investigación de Endocrinología y Nutrición, Centro de Investigación Biomédoca en Red de Enfermedades Infecciosas (CIBERINF), Facultad de Medicina, University of Valladolid, Hospital Clínico de Valladolid, Valladolid, Spain; [8]Houston Research Institute, Houston, TX, USA, Houston, United States*
Email: p.iruzubieta@gmail.com

Background and aims: The prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD) worldwide in obese population is around 75% and the prevalence of metabolic dysfunction-associated steatohepatitis (MASH) about 33%. This study aimed to determine the accuracy of metabolomics-advanced steatohepatitis fibrosis score (MASEF), liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE), and FibroScan-AST (FAST) for the evaluation of at-risk MASH (MASH with NAFLD Activity Score (NAS) ≥4 and significant fibrosis) according to the body mass index (BMI).

Method: The study included 265 biopsy-proven MASLD patients from tertiary care centers. MASEF score, FAST and LSM by VCTE (Fibroscan) performances were compared to biopsy for the assessment of at-risk MASH. Performances were evaluated by means of area under de curve (AUC) in the different BMI groups.

Results: Patients included in the study had a mean age of 56.9 (±9.5) years, 46.8% females and 68.7% with type 2 diabetes. 151 patients had a BMI <35 kg/m^2, 75 patients (28.3%) had a BMI between 35 and 40 kg/m^2, and 39 patients (14.7%) had a BMI ≥40 kg/m^2. Prevalence of at-risk MASH was 47.0% (BMI <35 kg/m^2), 42.7% (BMI 35–40 kg/m^2) and 33.3% (BMI ≥40 kg/m^2). MASEF score, FAST and VCTE performances were, respectively: BMI <35 kg/m^2, AUC = 0.78/0.75/0.78; BMI between 35 and 40 kg/m^2, AUC = 0.77/0.74/0.75; BMI ≥40 kg/m^2, AUC = 0.79/0.75/0.65. Not statistical differences were found among the three methods, except for LSM that showed statistically lower AUC in the BMI ≥40 kg/m^2 group, (MASEF vs. FAST: p = 0.17, FAST vs. LSM: p < 0.01, MASEF vs. LSM: p < 0.01).

Conclusion: Our study suggests that MASEF and FAST scores show acceptable accuracy for the detection of at-risk MASH in patients with grade 2 and 3 obesity. MASEF and FAST outperformed VCTE accuracy in morbid obese patients.

SAT-430

Vaccir study: evaluation of vaccination coverage against diphtheria-tetanus-poliomyelitis, pneumococcus, hepatitis A and B, influenza and SARS-COV2 in cirrhotic patients in 17 french general hospitals

Aurore Baron[1], Jean-François Cadranel[2,3], Mourad Medmoun[4], Jacques Arnaud Seyrig[5], François Xavier Laborne[6], Florence Skinazi[7], Xavier Causse[8], Lemaitre Caroline[9], Serge Bellon[10], Juliette Verlynde[11], Isabelle Rosa[12], Florent Ehrhard[13], Gilles Macaigne[14], Arnaud Boruchowicz[15], Guillaume Allard[16], Paul Strock[17], Stéphanie De Montigny-Lenhardt[18], Mathilde Petiet Dumont[19], Frederick Moryoussef[20], Bénédicte Lambare[21]. *[1]Centre Hospitalier Sud Francilien, Corbeil Essonnes, France; [2]CH Creil, Creil, France; [3]GHPSO, Liver and Digestive Diseases Department, Creil, France; [4]CH Creil, Creil, France; [5]Hôpital de Pontivy, Pontivy, France; [6]CHSF, Corbeil Essonnes, France; [7]CH SAINT DENIS, Saint Denis, France; [8]CHR La Source, Orléans, France; [9]CH le havre, Le Havre, France; [10]Avignon Hospital, Avignon, France; [11]CH Dunkerque, Dunkerque, France; [12]CHI Creteil, Créteil, France; [13]CH Lorient, Lorient, France; [14]CHI Montfermeil, Montfermeil, France; [15]CH Valenciennes, Valenciennes, France; [16]Centre Hospitalier du Pays d'Aix, Aix en provence, France; [17]Centre Hospitalier de Carcassonne, Carcassonne, France; [18]Centre Hospitalier Edmond Garcin, Aubagne, France; [19]Grand Hôpital de l'Est Fracilien-, Site de Meaux, Meaux, France; [20]Centre Hospitalier Intercommunal Poissy Saint-Germain-en-Laye, Poissy, France; [21]Centre Hospitalier Sud francilien, Corbeil Essonnes, France*
Email: aurore.baron@chsf.fr

Background and aims: Cirrhosis exposes patients to an increased risk of serious infections, leading to decompensation of liver disease and death. Vaccination is a simple and effective preventive measure. In France, vaccination against pneumococcus, seasonal influenza, SARS COV2, hepatitis A and B is recommended for all patients with liver disease. Few recent data on vaccination coverage in cirrhotic patients in the world are availabled but they suggest that it is low. The aim of this study was to estimate, the vaccination coverage of cirrhotic patients, against DTpolio, Pneumococcus, HAV, HBV, influenza, and SARS COV2 in France.

Method: It is a French, prospective, multicentric study, conducted between 09/27/2021 and 12/27/2022. The vaccination coverage of cirrhotic patients, followed for more than six months, in 17 general hospital was estimated via a questionnaire. Patients with vaccination contra-indication or additional immunosuppressive therapy unrelated to their liver disease were excluded. Subgroups were compared according to cirrhosis severity, psychosocial or precariousness risks. Factors associated with incomplete vaccination status were analyzed using a uni- and multivariate logistic regression model. Cases of infection were collated according to vaccination status in order to estimate efficacy.

Results: 728 cases were analyzed comporting 70% men (n = 511), with 58.2 years median age. Cirrhosis was more often caused by alcohol (63% n = 461), mostly non-severe child A (79% n = 549). At the time of diagnosis, rates of vaccination against DTP, HAV, HBV, Influenza and Pneumococcus were 51%, 3%, 12%, 22% and 4% respectively. The rates of de novo vaccinations more than six months after diagnosis were low for DTP 38% (n = 274), HAV 6% (n = 30/481), HBV 10% (on the population eligible for the vaccine) (n = 45/468) with only 50% of complete vaccinations, Pneumococcus 19% (n = 141) with 79% complete vaccination; vaccination rates were better for Influenza 69% (n = 503), and SARS COV2 94% (n = 686). Serological controls were exceptional for HAV or HBV. The main reason for non-vaccination against HAV, HBV and Pneumococcus was non-prescription. Among the non-vaccinated, infections were not rare with 4 HAV, 3 HBV, 16 influenza, 27 COVID cases. In uni and multivariate analyses, vaccination coverage did not differ according to severity of cirrhosis. Precariousness was associated with poorer access to DTP and SarsCOV2 vaccines, and better access to pneumococcal vaccines.

Conclusion: Vaccination coverage of cirrhotic patients against pneumococcus, HAV and HBV is highly inadequate in France, causing frequent and sometimes severe infections, whereas coverage against SARS COV2 and influenza is satisfactory because of strong vaccine incentive from the health authorities. The hepatologist must be aware of the importance of vaccination and become the major conductor of an effective vaccination policy.

SAT-431-YI

Exploring liver vitamin A status and histopathological associations in a Guatemalan cohort: insights into prolonged consumption of vitamin A fortified sugar

Giorgio Cazzaniga[1,2], Eric Boy[3], Anthony Oxley[4], Francisco Chew[5], Keyla Castellanos[6], Roberto Orozco[7], Zarina Guzmàn[8], Augusto Rodas[8], Elmar Gonzalèz[8], Georg Lietz[9], Dina Tiniakos[2,10]. *[1]Department of Medicine and Surgery, Pathology, Fondazione IRCCS San Gerardo dei Tintori, University of Milano-Bicocca, Monza, Italy; [2]Dept of Pathology, Aretaieion Hospital, National and Kapodistrian University of Athens, Athens, Greece; [3]HarvestPlus/IFPRI, Washington D.C., United States; [4]Fera Science Ltd, Sand Hutton, United Kingdom; [5]Ministry of Health Guatemala/INCAP, Guatemala City, Guatemala; [6]Universidad del Valle de Guatemala, Guatemala City, Guatemala; [7]Departamento Patología Hospital General San Juan de Dios, Guatemala City, Guatemala; [8]Instituto Nacional de Ciencias Forenses de Guatemala, Guatemala City, Guatemala; [9]Newcastle University, Newcastle upon Tyne, United Kingdom; [10]Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, United Kingdom*
Email: giorgio9cazzaniga@gmail.com

Background and aims: Guatemala's successful elimination of vitamin A (VA) deficiency is credited to a four-decade-long mandatory sugar fortification initiative. Despite proven effectiveness, concerns have risen regarding the risk of chronic hypervitaminosis A, a recognized cause of liver toxicity. We aimed to evaluate VA status in a cohort of Guatemala City residents, exposed to VA-fortified sugar throughout their lives, and to investigate the associated liver histopathological changes.

Method: This cross-sectional study involved examination of 95 anonymised autopsy liver tissue samples from 95 adolescents and adults without cardiometabolic disease or alcohol toxicity. Informed consent was provided by the family representative. Liver samples were collected within 24 hours of demise due to fatal injuries. Liver VA concentration was measured in all cases. Histology sections were stained with haematoxylin eosin, Masson trichrome and reticulin histochemical stains and were evaluated by two pathologists in consensus. Histological features related to architectural abnormalities, steatosis, inflammation, and vascular changes were semi-quantified. Fibrosis was staged according to Kleiner et al, 2005 and hypertrophic hepatic stellate cells (HSC) were counted per 10 high power fields (HPF, x40) in each acinar zone.

Results: The study cohort included 85 (89%) males (median age 26, range 10–76 years). Thirtyfour (37%) were overweight or obese and 13 (14%) underweight. The mean liver VA concentration was 1.5 μmol/g; 61% samples had liver VA >1 μmol/g and 11% >3 μmol/g. Liver VA values were lower in the 20–39 year age group (mean ± SEM 1.09 μmol/g ± 0.11 μmol/g). One case did not undergo histological scoring due to marked autolysis. Histological changes included: nodular regenerative hyperplasia 16 (17%), steatosis 36 (38%), more than minimal inflammation 4 (4%), more than mild sinusoidal congestion/dilatation 22 (23%), peliosis 4 (4%), and fibrosis stage 1 39 (41%), 2 12 (13%), 3 2 (2%) and 4 1 (1%). In 72 (78%) cases, HSC were <8/10 HPF, while in the remaining 22 (24%) were increased (mean 5, range 0–36/10 HPF). VA concentration was significantly correlated with HSC count (Pearson correlation coefficient $r = 0.24$, $p = 0.02$) and hepatocyte nuclear glycogenation ($r = 0.23$, $p = 0.03$) and was inversely correlated with the extent of steatosis ($r = -0.30$, $p < 0.01$). in samples with increased VA, HSC hyperplasia showed a tendency for zone 2–3 predilection (zone 1 $r = 0.18$ vs zone 2–3 $r = 0.26$) and panzonal steatosis ($r = 0.13$, $p = 0.23$).

Conclusion: The mean liver VA concentration in a Guatemala City cohort surpasses the threshold for hypervitaminosis A. One quarter of affected individuals shows HSC hyperplasia, a histological hallmark of VA liver toxicity. Increased VA appears to affect HSC zonal distribution and hepatic steatosis topography indicating a possible retinol-related pathogenetic mechanism.

SAT-432

A multi-channel educational communication campaign to improve liver disease screening and awareness for clinical care in Southern Arizona along the United States/Mexico border

David Garcia[1], Adriana Maldonado[1], Edgar Villavicencio[1], Naim Alkhouri[2], Joy Mockbee[3], Doug Spegman[3]. *[1]University of Arizona, Mel and Enid Zuckerman College of Public Health, Tucson, United States; [2]Arizona Liver Health, Chandler, United States; [3]El Rio Health, Tucson, United States*
Email: davidogarcia@arizona.edu

Background and aims: An estimated 25% (~84 million) of adults in the United States (U.S.) have metabolic dysfunction-associated steatotic liver disease (MASLD), an emerging risk factor for liver cancer. In Southern Arizona, liver disease and liver cancer are among the leading causes of death. Thus, there is a critical need to improve liver disease health literacy and promote screenings to increase awareness for clinical care to reduce the disparities experienced among this population. This study aims to implement a multi-channel educational communication campaign along the U.S./Mexico border.

Method: The study team worked with a media firm to create content that is specific to increasing awareness of MASLD risk factors (e.g., obesity, type 2 diabetes) and non-invasive testing (FibroScan®) in both English and Spanish. The 6-month multi-channel educational communication campaign began October 2023 and includes display advertisements in local convenience stores, social media (Facebook and Tik Tok), radio/television (including streaming ads), animated story boards, and testimonial commercials. All advertisements direct individuals interested in a FibroScan® to a website developed by a federally qualified health center (FQHC), in partnership with an academic program developed to foster community-engaged research collaborations, service, and education to advance health equity. All interested individuals can receive a FibroScan® and one-on-one educational sessions about liver disease. High risk individuals identified by FibroScan® are referred to a hepatology clinic.

Results: From October 2023–December 2023 (3 months), over 4.29 million impressions (count of total number of times digital advertisements) have been shown throughout the Southern Arizona region. Paid social media resulted in 2.46 million impressions. Notably, 505, 710 impressions came from TikTok in English and 349, 780 in Spanish. In addition, there were approximately 1.0 million impressions from display advertisements in English and 916, 230 in Spanish. In total, 252, 000 impressions were from English television streaming ads. Overall, 5, 930 individuals went to the study website to learn more about MASLD and 556 completed a request to complete a FibroScan® with over 350 scans completed to date with 25% of the study sample referred to a hepatology clinic for follow-up care.

Conclusion: The on-going multi-channel educational communication campaign has resulted in increased MASLD screenings and awareness of liver disease in Southern Arizona. Future efforts will focus on the process evaluation to gather ongoing feedback about the execution and evolution of the educational campaign to inform the development of a clinical care pathway model.

SAT-433

Transient elastography identifies previously undiagnosed advanced liver disease among those presenting with alcohol dependence

Rachel Edwards[1], Lorraine Hussain[1], Stuart McPherson[1,2], Steven Masson[1,2]. *[1]Liver Unit, Freeman Hospital, The Newcastle Upon Tyne Hospital Trust, Newcastle Upon Tyne, United Kingdom; [2]Translational and Clinical Research Institute, Newcastle University, Newcastle Upon Tyne, United Kingdom*
Email: rachelmedwards72@gmail.com

Background and aims: Alcohol-related liver disease (ARLD) is the major cause of liver-related morbidity in Europe. EASL recommends screening for the presence of fibrotic liver disease in people drinking

alcohol at higher-risk levels. We aimed to assess the uptake of fibrosis testing with Transient Elastography (TE) liver stiffness measurement (LSM), and determine the prevalence of clinically significant fibrosis, among people with alcohol dependence admitted to our institution. This was part of an NHS quality improvement initiative, with a target of inviting ≥35% of those admitted with alcohol dependence for fibrosis testing.

Method: All admissions to the Newcastle upon Tyne Hospitals Trust between April 2022 and March 2023 were reviewed prospectively to identify adults admitted for ≥1 night with a primary or secondary diagnosis of alcohol dependence. Exclusion criteria were known cirrhosis, already attending liver services, LSM within previous 12 months, life-limiting comorbidity, or lived out of area. Those eligible were invited for TE with Fibroscan®. TE was considered reliable if at least 10 measurements were performed, and the IQR/median ratio was ≤30%. LSM <8 kPa excluded clinically significant fibrosis. LSM >15 kPa indicated probable advanced fibrosis/cirrhosis. Those with a LSM ≥11.5 kPa were offered liver clinic review and those with LSM 8–11.4 kPa were offered 2 year follow-up TE. Data on self-reported alcohol intake was collected.

Results: There were 981 admissions amongst 696 people with alcohol dependence, 100 of whom were known to have cirrhosis. 324 (54% of eligible) individuals were invited for TE, of which 159 (49%) attended. The median age of attendees was 50 years [IQR 38–58], 64% were male and the median weekly alcohol consumption was 140 units [IQR 84–252]. The median LSM was 5.4 kPa [IQR 4.4 to 7 kPa]. 5 had unreliable TE. Overall, 20% (n = 31) had a LSM of ≥8 kPa (significant fibrosis) and 6% (n = 10) had LSM ≥15 kPa (advanced fibrosis/cirrhosis). In total, 79% of those referred to clinic attended. Of these, 55% reported abstinence from alcohol and a further 27% reduced their intake. Among those with LSM >15 kPa, there was a reduction in alcohol related hospital admissions by 94% in the following 6 months, compared with the 12 months preceding TE.

Conclusion: In a cohort of people with alcohol dependence, half of those offered fibrosis testing attended, identifying clinically significant fibrosis in 20% and cirrhosis in 6%. Most people with cirrhosis were already known to services. Reduction in alcohol consumption was observed in those with advanced fibrosis/cirrhosis identified through this work. Therefore, more proactive fibrosis assessment to identify advanced liver disease may promote behaviour change and reduce alcohol consumption in this high-risk cohort.

SAT-434

Use of FibroScan® to assess hepatic steatosis and fibrosis in community-based settings to promote clinical care linkages along the Southern Arizona United States/Mexico border

David Garcia[1], Adriana Maldonado[1], Edgar Villavicencio[1], Rosi Vogel[1], Caitlin Baird[1], Alejandra Cervantes[1], Ana Gonzalez[1], Estefania Ochoa Mora[2], Naim Alkhouri[3]. *[1]University of Arizona, Mel and Enid Zuckerman College of Public Health, Tucson, United States; [2]University of Arizona, Clinical Translational Sciences, University of Arizona Health Sciences, Tucson, United States; [3]Arizona Liver Health, Chandler, United States*
Email: davidogarcia@arizona.edu

Background and aims: Early detection and screening for metabolic dysfunction-associated steatotic liver disease (MASLD) is needed for at-risk populations. In comparison to other highly prevalent non-communicable chronic conditions (e.g., obesity, type 2 diabetes, and cardiovascular disease), MASLD has received little attention from a public health perspective with global health strategies characterized as inadequate and fragmented. There is a general lack of knowledge around effective screening methods, particularly in community-based settings for high-risk populations. This often leads to a late diagnosis and worse health outcomes for individuals with MASLD. In collaboration with local community partners, we implemented MASLD screenings in community-based settings as part of an ongoing community engaged research study. The purpose of this study is to assess the use of FibroScan® for hepatic steatosis and fibrosis in community-based settings to promote clinical care linkages for liver disease among adults along the Southern Arizona United States/Mexico border.

Method: We used a combination of MASLD screening with FibroScan® and educational and behavioral strategies (e.g., handouts and brief counseling) specific to liver health. Continuous attenuation parameter (CAP) values are measured in decibels per meter (dB/m). MASLD is identified as having a CAP score ≥288 dB/m. Liver stiffness measurements (LSM) in kilopascals (kPa) indicate fibrosis values. Individuals with a ≥280 CAP and ≥6 kPa or ≥8 kPa alone were referred to a clinical care partner (hepatology clinic).

Results: To date, 1, 070 adults (mean age: 52.0 ± 14 years; 37.9% female; 90% Mexican-origin descent) in Southern Arizona have been screened for MASLD. Overall, the prevalence of MASLD is 38%, including 58% men and 42% women ($X^2 = 5.5$, df = 1, p = 0.02). Of the total sample 25% (n = 266) of participants have been referred to hepatology clinic for clinical care follow-up (mean LSM: 10.9 kPa ± 8.6 kPa). Further, in a subsample of participants (n = 623); 79% reporting hearing about fatty liver disease before, primarily from a doctor or media source. Most participants (88%) report that they believe fatty liver disease is preventable; however, 36% are unaware if treatment is available.

Conclusion: MASLD screening with the FibroScan® combined with educational information appears to be a viable strategy to initiate community-based screening efforts as a part of a clinical care pathway model. However, it is necessary to ensure these screening efforts are cost-effective, scalable and a "closed loop" system is developed for the referral process for those seeking clinical care.

SAT-435

Benefits and harms of post-treatment surveillance in patients with early-stage of HCC after curative ablation

Awassada Yangcharoen[1], Supot Nimanong[1], Tawesak Tanwandee[1], Watcharasak Chotiyaputta[1], Phunchai Charatcharoenwitthaya[1], Siwaporn Chainuvati[1]. *[1]Division of Gastroenterology, Department of Medicine Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand*
Email: supotgi@gmail.com

Background and aims: The recurrent rate of HCC after ablation is high. There is no consensus recommendation of post-treatment surveillance. We aimed to investigate benefits and harms of CT/MRI as tools for post-treatment surveillance in patients with early-stage of HCC after curative ablation.

Method: We conducted a retrospective cohort study in HCC BCLC stage 0/A patients, who received curative ablation and underwent CT/MRI over 5-year follow-up. Benefits were rate of recurrent HCC within Milan criteria and received curative treatment. Non-severe harms included number of additional sessions of CT/MRI without recurrent HCC and decline in eGFR while severe harms were contrast injury or invasive procedures.

Results: Among 204 enrolled patients, 88.7% had cirrhosis, 84.3% had single HCC with mean size of 2 cm. The 5-year overall survival rate were 81%. The cumulative 1st-, 2nd-, 5th- year recurrent rate were 25.9%, 41.6% and 55.3% respectively. Rate of recurrent HCC within Milan criteria and received curative treatment were 84% and 73.5%, not significantly different between <120 days and 120–180 days interval groups. Twenty eight percent of patients underwent additional CT/MRI without recurrent HCC, and no severe harms was recorded. Multivariate analysis revealed frequent sessions of CT/MRI (5–8 sessions in 2-years) were predictors of significant decline in eGFR.

Conclusion: CT/MRI are effective tools for post-treatment surveillance in patients with early-stage HCC after curative ablation. However, frequent imaging sessions (<6-months interval in first 2-year) do not increase detection rate of small HCC and are associated with significant decline of eGFR.

SAT-436

Age and sex differences in the incidence of cirrhosis caused by metabolic dysfunction associated steatohepatitis in Manitoba, Canada: a population-based study

Nabiha Faisal[1], Lisa Lix[1], Randy Walld[2], Alexander Singer[2], Harminder Singh[2], Eberhard Renner[2], Alyson Mahar[3]. [1]*University of Manitoba, Winnipeg;* [2]*University of Manitoba, Winnipeg, Canada;* [3]*Queen's University, Kingston, Canada*
Email: nabiha.faisal@umanitoba.ca

Background and aims: Metabolic dysfunction associated steatohepatitis (MASH) has emerged as a predominant cause of cirrhosis, closely linked to the global surge in obesity, diabetes, and metabolic syndrome. The dynamic evolution of cirrhosis risk factors necessitates ongoing efforts in prevention and management. To facilitate the development of these strategies, we aim to investigate the temporal trends in MASH cirrhosis incidence in Manitoba, Canada, and assess changes in cirrhosis rates across age groups and between males and females.
Method: We performed a retrospective population-based cohort study in Manitoba, Canada, using linked administrative healthcare data housed in Manitoba Centre of Health Policy. Patients aged at least 18 years with incident cirrhosis (2010–2020) were identified by use of a validated case finding algorithm (defined as at least one inpatient or outpatient visit with a diagnosis of cirrhosis or related complications), and MASH was defined using a validated hierarchical algorithm (3, 4). Annual cirrhosis incidence rate per 100, 000 person-years was calculated using a generalized linear model and generalized estimating equations with a negative binomial distribution adjusting for age and sex. Linear trends of incidence by calendar year, overall and by age and sex, were tested using linear regression models.
Results: Between 2010 and 2020, 31, 147 individuals with MASH cirrhosis were identified. MASH constituted 69% of all cirrhosis cases in 2020. The incidence of cirrhosis caused by MASH increased approximately by 35% during the study period. The age and sex adjusted incidence of MASH rose from 208/100, 000 (95% CI 192.9–224.7) in 2010 to 281/100, 000 (95% CI 261.4–301.8) in 2020. The mean age at diagnosis was 49.7 years (SD 15.9), with 50.1% being men, 31% having diabetes, and 62% hypertension. Females exhibited a greater increase in incidence compared to males (females: 1.6, 95% CI 1.4–1.8; males: 1.1, 95% CI 0.9–1.3). In terms of age groups, the younger age group (18–44) exhibited a higher increase in incidence compared to those aged 65 and above (18–44: 1.5, 95% CI 1.2–1.8; 65 +: 1.1, 95% CI 0.9–1.4). On average MASH Cirrhosis incidence increased annually by 4%.
Conclusion: The incidence of MASH cirrhosis has increased significantly since 2010, with age, and sex disparity. Public health action is required to implement an effective multi-faceted approach and public awareness efforts to reverse these trends.

SAT-437-YI

MAF-5 improves the detection of advanced and significant fibrosis in FIB-4 underserved individuals in a United States general population

Laurens van Kleef[1], Jesse Pustjens[1], Harry L.A. Janssen[1], Willem Pieter Brouwer[1]. [1]*Erasmus MC, University Medical Center, Rotterdam, Netherlands*
Email: l.vankleef@erasmusmc.nl

Background and aims: The FIB-4 is the cornerstone of referral pathways as proposed by the EASL, AASLD and AGA, despite concerns regarding the diagnostic accuracy in populations aged <35 years or ≥65 years old or individuals with diabetes (DM). Recently three new scores have been developed: steatosis associated fibrosis estimator (SAFE), LiverRisk score (LRS) and metabolic dysfunction associated fibrosis (MAF-5). Whether these scores can benefit these FIB-4 underserved populations remains to be determined.
Method: We used data from the NHANES 2017–2020 cycle, a United States population-based cohort with data on liver stiffness measurements (LSM). We selected patients with metabolic dysfunction according to the guidelines referral pathways with complete data on LSM and the SAFE, LRS and MAF-5. AUC analysis, detection rate, referral rate and NPV were used to assess its diagnostic accuracy regarding LSM ≥8 and ≥12 kPa, which is suggestive of significant or advanced fibrosis. Three FIB-4 underserved populations were analysed: (1) aged <35 years (2) aged ≥65 years and (3) those with DM.
Results: This first cohort comprised 1437 participants aged <35 (age 26 [22–31], 50% male) among which 5.7% and 1.7% had LSM ≥8 and ≥12 kPa. The AUC for detecting LSM ≥8 kPa by the SAFE, LRS and MAF-5 was 0.72, 0.73 and 0.83, all significantly better than the FIB-4 with an AUC of 0.50. Similarly, FIB-4 was outperformed for LSM ≥12 kPa with an AUC of 0.77 (SAFE), 0.67 (LR) and 0.93 (MAF-5) compared to 0.58 (FIB-4). Additionally, we analyzed 1444 participants aged ≥65 (age 72 [68–78], 50% male) among which 13.1% and 4.4% had LSM ≥8 and ≥12 kPa. The AUC for LSM ≥8 kPa of the SAFE, LRS and MAF-5 was 0.69, 0, 68 and 0.75 compared to 0.54 for FIB-4. In this elderly population, results were consistent for LSM ≥12 kPa, with an AUC of 0.76, 0.73 and 0.78 for SAFE, LRS and MAF-5, versus 0.61 for FIB-4. Finally, we focussed on 1191 participants with diabetes (age 61 [43–70], 52% male) among which 22% and 7.3% had LSM ≥8 and ≥12 kPa. Again the AUC for detecting LSM ≥8 kPa was better for SAFE, LRS and MAF-5 with 0.65, 0.61 and 0.77 compared to FIB-4 with 0.55, as well as for LSM ≥12 kPa with 0.74, 0.64 and 0.81 for SAFE, LRS and MAF-5 compared to 0.62 for FIB-4. Implementing these scores in referral strategies to detect LSM ≥8 kPa in these FIB-4 underserved populations combined would result in the detection of 81% of cases with the SAFE score (cut-off 0: referral 55%, NPV 95%), 53% of cases by LRS (cut-off 6: referral 27%, NPV 92%) and 84% with MAF-5 (cut-off 0: referral 46%, NPV 96%), detection rates increased to 86%, 60% and 91% for LSM ≥12 kPa with the SAFE, LRS and MAF-5, respectively.
Conclusion: The FIB-4 was outperformed by the recently developed scores in detecting advanced liver disease in FIB-4 underserved populations. The MAF-5, an age-independent score, had the best performance among the FIB-4 underserved populations and should be considered in referral strategies.

SAT-438

Fatigue is an Important Driver of Work Productivity Loss and Impairment of Patient-Reported Outcomes (PROs) among Patients with Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD)

Email: zobair.younossi@cldq.org

Background and aims: MASLD is associated with fatigue which can have negative impact on clinical outcomes and PROs. We assessed fatigue among MASLD patients seen in real-world practices.
Method: We used data [demographics, medical history, FIB-4 scores, liver stiffness by transient elastography and PRO scores (FACIT-F, CLDQ-NASH, WPAI)] collected by the Global NASH Registry™. Presence of clinically overt fatigue was determined from medical history (MH-based fatigue) or using Fatigue Scale of FACIT-F PRO instrument (FS<30 on a 0–52 scale; PRO-based fatigue).
Results: We included 6783 MASLD patients from 18 countries (Australia, China, Cuba, Egypt, Greece, Hong Kong, India, Italy, Japan, Saudi Arabia, Malaysia, Mexico, Pakistan, Russia, Spain, Taiwan, Turkey, USA): age 51 ± 13 years old, 44% male, 47% employed, 68% obese, 41% type 2 diabetes (T2D), 51% hypertension, 19% with advanced fibrosis (biopsy or transient elastography ≥9.5 kPa or FIB-4 ≥2.67), 24% history of depression, 29% sleep apnea, 20% abdominal pain. Of all patients, 39% had MH-based fatigue and 26% had PRO-based fatigue by FACIT-F. Concordance between the two fatigue definitions was 68%, with 44% of those with MH-based fatigue also having PRO-based fatigue (vs. 9% among those without MH-based fatigue). Regardless of the definition, MASLD patients with fatigue were younger (50 vs. 52 years), more commonly female (67% vs. 49%), obese (75% vs. 64%) with T2D (45% vs. 38%), depression (34% vs. 17%) and abdominal pain (33% vs. 10%) (all $p < 0.05$). Patients with fatigue also reported a substantial impairment in other PRO scores: total CLDQ-NASH score 4.49 (SD 1.08) vs. 5.51 (0.96) in patients with vs. without MH-based fatigue (impairment of −1.02, or −17% of range size), compared to 3.83 (0.91) vs. 5.44 (0.89) in those with vs. without PRO-based fatigue (impairment −1.61, or −27% of range size); similarly total FACIT (4 generic domains of FACIT-F) was −11% by MH-based fatigue and −20% by PRO-based fatigue, and excessive work productivity impairment (WPI) was −13% by the presence of MH-based fatigue and −25% by PRO-based fatigue. After adjustment for clinico-demographic confounders, association of lower PRO scores with fatigue remained significant for all studied PRO scores, with the effect size again being greater for PRO-based fatigue than MH-based fatigue: −20% vs. −10% for total CLDQ-NASH, −16% vs. −6% for FACIT-F, and −21% vs. −7% for WPI (all $p < 0.0001$). Other predictors of lower PRO scores in MASLD included younger age, female sex, advanced fibrosis, non-hepatic comorbidities, and lack of regular exercise ($p < 0.05$).
Conclusion: MASLD patients experience substantial fatigue burden that is partially captured by medical history and more accurately asserted by a fatigue-specific PRO instrument (FACIT-F). Fatigue is associated with a significant impairment of other PROs and work productivity with its negative economic impact.

SAT-439-YI

Socioeconomic deprivation is independently associated with hepatocellular carcinoma mortality in a western european country with single-payer healthcare

Massih Ningarhari[1,2], Alexandre Lacour[3], Simon Dauchy[3], Michael Genin[1], Amelie Bruandet[3], Stéphane Cattan[3], Line Carolle Ntandja Wandji[2,3], Elise Lemaître[3], Valérie Canva[3], Alexandre Louvet[2,4], Philippe Mathurin[2,3], Sébastien Dharancy[3,5], Guillaume Lassailly[2,3]. *[1]CHU Lille, Maladies de l'Appareil Digestif, Lille, France; [2]Université de Lille, INSERM, Infinite, Lille, France; [3]CHU Lille, Lille, France; [4]CHU Lille, Lille; [5]Université de Lille, INSERM, Infinite, Lille*
Email: massih.ningarhari@chu-lille.fr

Background and aims: Socioeconomic deprivation (SED) has been associated with mortality from hepatocellular carcinoma (HCC) in North America. Determinants of this association such as type of health insurance may differ in Europe. Data on the impact of SEP on HCC survival in countries with universal single-payer healthcare system are scarce.
Method: Retrospective study of all consecutive patients discussed for a first diagnosis of HCC in the regional multidisciplinary tumor board (MTB) of a French tertiary center between 01/01/2019 and 31/12/2019. Demographics, distances to the referral center, dates of diagnosis, referral, MTB, and treatment, patient and tumor characteristics, and treatment were collected. SED was inferred for each patient using the FDep score based on residence's postcode. Overall survival (OS) from the date of diagnosis was calculated using the Kaplan-Meier method, and the association between SED and overall survival was analysed using a Cox model.
Results: We included 318 patients: median age 67 years, alcohol-related liver disease 71%, cirrhosis 81%, Child A 65%, HCC diagnosed by screening 47%, maximal tumour size 3 cm (IQR 2–5.5), median AFP 10 ng/ml (IQR 4–100). The median time between first imaging suggestive of HCC and first discussion in MTB was 27 days (14–50). The median distance between patient's residence and the regional referral centre was 28 km (IQR 16–55). Median OS from the date of diagnosis was 20.1 months (95% CI 16.1–25.1). Patients in the fourth quartile (Q4) of the FDep score, the most deprived, had a significantly poorer OS (HR 1.44, CI95% 1.06–1.97, $p = 0.02$) in univariate analysis. Patients in the Q4 lived farther from the referral centre ($p = 0.006$), were more frequently obese ($p = 0.04$), had more frequently history of liver decompensation ($p = 0.004$), ascites ($p = 0.001$) and larger tumour size ($p = 0.02$) at diagnosis. There was no statistically significant association between belonging to Q4 and excessive alcohol consumption ($p = 0.49$), presence of diabetes ($p = 0.58$), cirrhosis ($p = 0.87$), time between diagnosis and treatment ($p = 0.4$). There was a trend towards lower access to curative treatments (29% vs 37%, p = 0, 07). In multivariate analysis, belonging to the Q4 remained significantly associated with increased overall mortality from the date of diagnosis (HR 1.71, CI95% 1.07–2.72, p = 0, 03).
Conclusion: Socioeconomic deprivation was independently associated with poorer overall survival in patients with a diagnosis of HCC, even in a Western European country with single-payer universal healthcare system. Studies are needed to optimize public health strategies targeting patients at risk of HCC.

SAT-440

Risk factors for future development of cirrhosis in UK primary care patients with elevated ALT: a survival analysis of the optimum patient care research database

Kris Bennett[1], Victoria Carter[2], Derek Skinner[2], William Henley[3], David Price[2,4]. [1]*South West Liver Unit, University Hospitals Plymouth NHS Trust, Plymouth, United Kingdom;* [2]*Observational and Pragmatic Research Institute, Midview City, Singapore;* [3]*Department of Health and Community Sciences, University of Exeter Medical School, Exeter, United Kingdom;* [4]*Centre of Academic Primary Care, Division of Applied Health Sciences, University of Aberdeen, Aberdeen, United Kingdom*
Email: kbennett6@nhs.net

Background and aims: Elevated alanine transaminase (ALT) blood tests are common in primary care and may be the first indication of previously unrecognised steatotic liver disease (SLD). Current non-invasive tests primarily focus on detection of advanced fibrosis or cirrhosis. Stratifying risk earlier in the natural history, when preventative strategies are likely to be most effective, remains an important challenge. This study aimed to identify risk factors for earlier development of cirrhosis in patients with elevated ALT in a primary care population.
Method: A historical cohort study of eligible adults with ALT 50–1000 between January 2000 and December 2020 using the Optimum Patient Care Research Database (www.opcrd.co.uk). Index date was the earliest recorded ALT abnormality. Patients were followed up until primary outcome, death or last data extraction. The primary outcome was a diagnosis of cirrhosis or a proxy-condition (e.g. complication of cirrhosis). Patients with pre-existing cirrhosis, baseline bilirubin >50, prior alcohol misuse, malignancy or non-SLD aetiologies were excluded. Data was analysed using Python with multiple imputation of missing lifestyle/biochemical variables. A multivariate, Cox proportional hazards (Cox-PH) model was fit on 80% of the data using comorbidities, lifestyle factors and biochemical results as predictors. Backwards elimination of predictors was performed using the Akaike Information Criterion. 20% of the data was reserved for internal validation.
Results: 1.04 million patients with an ALT of 50–1000 were included, with 11, 478 (1.1%) progressing to cirrhosis. 61% were male, with a median age 49 years and median follow-up 7.1 years. The Cox-PH model identified 13 predictors of cirrhosis, with GLP1-receptor agonist (GLP1-RA) usage (HR = 2.34), smoking (HR = 2.21) and diabetes (HR = 1.68) the strongest predictors. Statin use predicted a lower risk of cirrhosis (HR = 0.73) and this association persisted when controlling for cardiovascular disease, diabetes and smoking. Model performance was good (c-index = 0.7) with similar performance on unseen test data. Inclusion of markers of alcohol misuse after index ALT abnormality improved model performance further (c-index = 0.81).
Conclusion: This study of >1 million primary care patients with abnormal ALT, identifies 13 factors associated with future progression to cirrhosis. GLP1-RA usage is associated with the highest risk which probably serves as a marker of diabetes severity. Statin use is associated with reduced cirrhosis risk. Further observational and randomized studies are warranted to improve prediction of future cirrhosis risk in primary care and identify factors which may slow progression to cirrhosis.

SAT-441-YI

Who doesn't turn up? Exploring patient characteristics associated with non-adherence with regular hepatocellular carcinoma surveillance: a systematic review and meta-analysis

Hannah MacCarthy[1], Ryan M. Buchanan[1,2], Dankmar Böhning[3], Kate Glyn-Owen[1]. [1]*University of Southampton, Southampton, United Kingdom;* [2]*University Hospital Southampton, Southampton, United Kingdom;* [3]*Southampton Statistical Sciences Research Institute, University of Southampton, Southampton, United Kingdom*
Email: hmm1g19@soton.ac.uk

Background and aims: In 2020, hepatocellular carcinoma (HCC) was the sixth most diagnosed cancer and had the third highest mortality globally. Five-year survival is around 18%, stressing the importance of routine six-monthly surveillance, which increases the likelihood of early detection and receipt of curative treatment. Surveillance adherence is around 52%. HCC disproportionately affects socio-economically deprived and under-served groups, and these groups also have low uptake of population screening programmes. We aimed to explore characteristics associated with non-adherence with regular surveillance for HCC.
Method: This study updated a previous systematic review and meta-analysis of HCC patients, to include recent studies and to explore alternative outcomes in relation to attendance at regular surveillance. Ovid and Embase databases were searched from July 2020-November 2023, in addition to the original searches from January 2014. We included cohort studies of patients with diagnosed HCC, which reported data on prior attendance in a surveillance programme. Data were extracted on attendance, sociodemographic characteristics, risk factors for liver disease and underlying aetiology of disease. Data were analysed using STATA, meta-analysis was conducted where appropriate and sensitivity analyses were conducted excluding studies with high risk of bias. Likelihood of surveillance attendance was reported using odds ratios with 95% confidence intervals (CI).
Results: Overall, 36 studies with a total of 1, 398, 994 HCC patients were included in the meta-analysis. Of these, 51.6% attended regular surveillance, and 48.4% did not. Male patients had significantly lower odds of attending surveillance compared to females (OR = 0.73, 95% CI 0.66–0.82). Former and current smokers had significantly lower odds of attending surveillance compared to non-smokers (OR = 0.79, 95% CI 0.68–0.92). Patients with HBV had significantly lower odds of attending regular surveillance compared to patients with HCV (OR = 0.62, 95% CI 0.50–0.77). Patients with HCV also had significantly higher odds of attending regular surveillance when compared against other aetiologies (OR = 2.34, 95% CI 1.84–2.96). Patients with MASLD had significantly lower odds of attending surveillance when compared with other aetiologies (OR = 0.62, 95% CI 0.43–0.91).
Conclusion: Amongst patients with a diagnosis of HCC, the following were less likely to have been attending a regular HCC surveillance programme: Male patients, patients with HBV or MASLD and current/former smokers. This suggests potential targets for interventions aiming to increase surveillance uptake. More research is required to understand why these groups are not attending compared to other groups, such as those with HCV.

SAT-442

Fibro-Predict risk score for liver cirrhosis from nationwide electronic health records

Iris Kalka[1], Rawi Hazzan[2], Nancy-Sarah Yacovzada[1], Saleh Igbaria[2], Eran Segal[1], Ziv Neeman[3], Adina Weinberger[1]. [1]*Weizmann Institute of Science, Rehovot, Israel;* [2]*Emek Medical Center, Afula, Israel;* [3]*Emek Medical Center, Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Afula, Israel*
Email: iris.kalka@weizmann.ac.il

Background and aims: Liver diseases, notably cirrhosis, pose a substantial global health challenge, resulting in millions of annual deaths. Existing diagnostic methods primarily target high-risk groups, leaving a significant portion of patients undiagnosed. This study's objective is to develop an accurate screening approach, utilizing nationwide electronic health records (EHR), to identify individuals at risk of cirrhosis within the general population.
Method: A liver cirrhosis diagnostic framework was constructed by analyzing EHR data from 2, 255, 580 samples. This framework is centered on Fibro-Predict, a machine-learning model capable of predicting five-year disease diagnosis trajectories based on routine blood tests. We conducted a retrospective temporal-validation of the model and an external prospective validation in clinical settings, employing transient elastography.

Results: The temporal-validation of Fibro-Predict demonstrated a promising c-index of 0.80 (95% CI 0.80 ± 6E-5) in the training cohort and 0.79 (95% CI 0.79 ± 9E-5) during validation. In a clinical context, our framework exhibited an impressive True Positive Rate (TPR) of 36.8% (28/76) when comparing predicted risk to observed outcomes, surpassing the gold-standard FIB-4 with a TPR of only 3.7% (1/27).
Conclusion: Fibro-Predict, relying solely on routine blood tests, emerges as a valuable tool for cost-effective patient prioritization in cirrhosis screening within the general population. Leveraging nationwide EHR data, we can efficiently identify individuals in need of clinical follow-ups and expedite cirrhosis diagnosis. This approach holds the potential to significantly improve the early detection of cirrhosis and subsequently reduce its associated morbidity and mortality, particularly within underserved populations.

SAT-443

FIB-4 based referral pathways to identify advanced liver disease have poor clinical utility in a United States general population

Laurens van Kleef[1], Jesse Pustjens[1], Harry L.A. Janssen[1], Willem Pieter Brouwer[1]. [1]*Erasmus MC, University Medical Center, Rotterdam, Netherlands*
Email: l.vankleef@erasmusmc.nl

Background and aims: The fibrosis-4 index (FIB-4) is the cornerstone of the referral pathways provided by the AASLD, EASL and AGA that aim at identifying advanced liver disease among low-prevalence populations. Although the diagnostic accuracy of FIB-4 is acceptable in SLD patients who underwent liver biopsy, its clinical utility in these pathways beyond its intended populations remains to be proven.
Method: We used data from the NHANES 2017–2020 cycle, a United States population-based cohort with data on liver stiffness and FIB-4. Participants at risk for advanced liver disease were selected based on the presence of metabolic dysfunction (a constellation of overweight/obesity, dyslipidaemia and impaired glycaemic control) following the AASLD, EASL and AGA referral pathways. Significant (LSM ≥8 kPa) and advanced fibrosis (LSM ≥12 kPa) prevalence is set out against fibrosis risk estimated with the FIB-4. A general cut-off of 1.3 was used to estimate fibrosis risk. Lastly, the AUROC of the FIB-4 is investigated in the overall population and subgroups.
Results: The cohort comprised 6.191 participants with metabolic dysfunction (aged 52 [36–64] years, 49% male), of them 46% had MASLD, 10.1% significant fibrosis and 3.2% advanced fibrosis. According to the FIB-4-based algorithm, advanced liver disease was ruled out in 72.7% and further work-up was required in 27.3%. However, among those considered to have no advanced liver disease, significant fibrosis was still present in 9.0% and advanced fibrosis in 2.2%. This results in missing out on 59.5% and 48.0% of cases, respectively. When using FIB-4 >2.0 among those aged ≥65 years, even more cases were missed (70.7% of significant fibrosis and 2.4% of advanced fibrosis), but fewer people required further work-up (17.1%). Next, we excluded patients aged <35 years, in which the FIB-4 is known to have poor performance. The proportion that now required further investigation increased to 35.3% and among those considered at low risk of advanced liver disease, still 10.4% had significant and 2.4% advanced fibrosis. The AUROC in the overall population to detect significant fibrosis was 0.61 and for subgroups aged <35, 35–65 and >65 0.50, 0.60 and 0.54 respectively. For advanced fibrosis results were slightly better with an AUROC of 0.67 in the overall population and 0.58, 0.67 and 0.61 in subgroups aged <35, 35–65 and >65 respectively. Diagnostic accuracy did not improve among participants with MASLD.
Conclusion: FIB-4-based referral pathways to identify advanced liver disease among the general population with metabolic dysfunction have poor diagnostic accuracy. Particularly worrisome is the high rate of missing out on significant and advanced fibrosis (up to 70% and 60% respectively). There is an urgent need for a dedicated test that is specifically developed to identify individuals in the general population who may benefit from hepatologist referral.

SAT-444

Large-scale community outreach Fibroscan program to detect advanced fibrosis and cirrhosis for early detection of liver cancer

Basil Ahmad[1], Helen Boothman[2], Michael Tolentino[2], Laura Letham[2], James Attridge-Smith[2], Nina van Zyl[2], Fergus Daly[2], Daniel Forton[1]. [1]*St George's University Hospitals NHS Foundation Trust, London, United Kingdom;* [2]*St George's University Hospitals NHS Foundation Trust, London, United Kingdom*
Email: daniel.forton@nhs.net

Background and aims: Hepatocellular carcinoma (HCC) is mostly diagnosed at a late stage in the UK.
Advanced fibrosis and cirrhosis are the main risk factors, yet profound inequalities in access to healthcare affect many populations at risk. National Health Service England (NHSE) commissioned pilot projects to identify advanced fibrosis and cirrhosis in patients in community settings, using liver stiffness measurements (LSM) from Fibroscan as the primary screening method. We set up an outreach team that delivered services in a mobile clinic van and other remote locations to offer LSM, targeting groups in local drug and alcohol services, community diabetic retinopathy services, hostels, prisons and other community locations in SW London. Our aim was to evaluate the effectiveness of this approach in identifying subjects for ultrasound HCC surveillance.
Method: We extracted data from our program database covering scans from July 2022 to December 2023. We examined LSMs from 2892 persons (1829 Male :1055 Female : 8 transgender), with heavy alcohol consumption in 1735, type II diabetes in 280, previous/current viral hepatitis in 96, known metabolic dysfunction-associated steatotic liver disease (MASLD) in 516 and other indications in 266. LSM ≥11.5 kPa was used as a cut-off for advanced fibrosis. We utilised peer support workers to increase engagement and to accompany patients to subsequent hospital appointments. Food vouchers were used as incentives as necessary.
Results: 209/2892 subjects (7.2%) had LSM ≥11.5 kPa across the overall cohort. The highest prevalence amongst our targeted populations was in current/previous viral hepatitis (10/96; 10.4%), followed by persons with heavy alcohol consumption (161/1735; 9.3%), type II diabetics (15/280; 5.4%), and MASLD (18/516; 3.5%). All patients with LSM ≥11.5 kPa were referred to their local hospital for further hepatology review and investigation, including ultrasound HCC surveillance. In a subgroup analysis of 91 persons referred to onehospital, 65 (71%) have attended their first appointment to date.
Conclusion: Targeted outreach community Fibroscan is successful at detecting advanced fibrosis and cirrhosis (7.2% prevalence of LSM ≥11.5 kPa) in populations that would not otherwise access liver services, but it is a resource-heavy undertaking. The use of dedicated community Fibroscan technicians, a mobile clinic, peer workers and food vouchers facilitated the engagement of persons who do not readily access healthcare. The initial peer-led transition to specialist hospital assessment and ultrasound surveillance appears to be successful but the necessary long-term sustainability of this arrangement is yet to be determined.

SAT-446

Metabolic risk factors and disease risk in patients with metabolic dysfunction-associated steatotic liver disease: findings from an electronic health record biobank

Longgang Zhao[1], Xinyuan Zhang[2], Yun Chen[2], Michelle Lai[3], Xuehong Zhang[2]. [1]*Brigham and Women's Hospital and Harvard Medical School, Boston, United States;* [2]*Brigham and Women's Hospital and Harvard Medical School, Boston, United States;* [3]*Beth Israel Deaconess Medical Center, Boston, United States*
Email: nhlon@channing.harvard.edu.

Background and aims: The long-term prognosis of patients with metabolic dysfunction-associated steatotic liver disease (MASLD) is limited. We aimed to evaluate the difference in baseline characteristics of steatotic liver diseases (SLD) subcategories and further explore the associations between the number of metabolic factors and clinical outcomes.
Method: The Harvard Mass General Brigham Biobank is a health system-based study that incorporates electronic health records and lifestyle data. We included 6, 134 patients diagnosed with SLD via medical records and further grouped them into four subcategories, namely MASLD, MetALD, alcohol-related liver disease (ALD), and cryptogenic SLD. Metabolic factors included obesity, prediabetes or diabetes, hypertension, hyperlipidemia, and low high-density lipoprotein level. Disease outcomes were collected from medical records. We compared the differences in demographics, lifestyles, genetics, clinical biomarkers, and body composition between four SLD subcategories. To assess the associations between numbers of metabolic factors and ~40 types of incident disease outcomes among patients with MASLD, we employed Cox proportional hazard regression models to estimate hazard ratios (HR) and their corresponding 95% confidence intervals (CIs) adjusting for multiple covariates.
Results: Compared with ALD (n = 745), patients with MASLD (n = 4388) were younger, more likely to be female and never smokers. They have higher levels of glucose and HbA1c, but lower levels of cholesterol and low-density lipoprotein. After a median follow-up of ~5 years, the number of metabolic risk factors were associated with higher risk of circulatory disease (HR ≥3 vs 1 factor = 2.37, 95% CI = 1.84–3.06), including atrial fibrillation (HR = 1.76, 95% CI = 1.30–2.39), coronary heart disease (HR = 1.44, 95% CI = 1.20–1.72), ischemic heart diseases (HR = 1.75, 95% CI = 1.39–2.19), heart failure (1.87, 95% CI = 1.40–2.50), ischemic stroke (HR = 1.52, 95% CI = 1.10–2.11), myocardial infarction (1.68, 95% CI = 1.13–2.49), and stroke (HR = 1.51, 95% CI = 1.19–1.93). Metabolic factors were also positively associated with hypertension (HR = 2.38, 95% CI = 1.93–2.93), depression (HR = 1.26, 95% CI = 1.05–1.52) and type 2 diabetes (HR = 2.16, 95% CI = 1.77–2.64). Those associations were robust and stable when we excluded the cases that occurred in the first year of follow-up.
Conclusion: Our results indicate that individuals with MASLD exhibited worse glucose but better lipids profiles when compared to those with ALD. Metabolic factors were positively associated with increased risk of adverse health outcomes, including circulatory diseases, hypertension, depression, and type 2 diabetes. These findings underscore the potential importance of metabolic health in patients with MASLD to enhance overall health.

SAT-447

Community liver health champion support can optimise the engagement of underserved patients with hepatocellular cancer surveillance-results of a 1 year regional pilot

Tanya Walker[1], Kate Glyn-Owen[2], Chris Saison[3], Mhukti Perumal[4], Kelly Gardner[3], Wendy Wilson[3], Heather Parsons[2], Ryan Buchanan[2].
[1]Hepatitis C Trust, London, United Kingdom; [2]University of Southampton, Southampton, United Kingdom; [3]University Hospital Southampton, Southampton, United Kingdom; [4]NHS England, National Cancer Programme, London, United Kingdom
Email: rmb1d14@soton.ac.uk

Background and aims: Hepatocellular carcinoma (HCC) is an important complication of chronic liver disease and HCC is expected to become the 3rd most common cause of cancer death world-wide by 2030. Incident HCC and death from HCC are skewed towards marginalized and socio-economically deprived populations. Engagement with HCC cancer surveillance in these populations is poor.
The aim of the project was to develop and implement a community champions programme to support under-served patients access HCC surveillance.
Method: The programme was funded by NHS England and implemented in 3 acute hospital trusts in Wessex (UK). Each trust appointed an HCC service navigator, and three liver health champions to work across trusts in the community. Champions had a lived experience of marginalisation or working with under-served populations and were tasked with maximising attendance at ultrasound appointments.
Eligible patients were enrolled into the programme if they were 1) known to need HCC surveillance but had not had a scan for >12 months, 2) highlighted at diagnosis by the clinical team as likely to need support to attend or 3) had a recent record of not attending an appointment with the Hepatology service.
Descriptive statistics were calculated using independent samples t-test and chi-squared tests in SPSS for mac version 28.0.1.1.14.
Results: Across two acute trusts, 299 eligible patients were added to the Champions programme in 9 months. Due to data governance and staffing challenges the 3rd hospital did not commence the programme in this time frame. The majority were enrolled due to non-attendance at liver US for >12 months prior (n = 158, 53%). Most patients were male (n = 193, 65%) and the mean age was 56 years (SD 12). The most common underlying aetiology was alcohol (n = 94, 31%).
Navigator contact was made with 189 (63%) patients. 180 (95%) of these patients attended for a scan in a mean follow-up of 4 months. 66 patients were referred for community champion support and 41/180 (23%) only attended with their direct input. The 119/299 patients who did not have a scan were significantly more likely to be from an ethnicity other than white British ($p < 0.01$; 17% vs 11%) but there was no significant difference in index of multiple deprivation, age, sex, or aetiology.
Champions overcame barriers including language, health literacy and homelessness. Their detailed mechanism of effect is subject to an ongoing qualitative study. Referral for champion support was significantly associated with a diagnosis of HCV ($p < 0.01$).
Conclusion: A programme to support underserved patients attend HCC surveillance imaging can be implemented at a regional level and leads to high rates of attendance in patients previously disengaged from care. Further evidence describing the sustainability of benefit and cost-effectiveness is important to support the implementation of a national service.

SAT-448

The prevalence of steatotic liver disease in young adults: applying the new nomenclature to a UK birth cohort

Ann Archer[1,2], Hannah Donnelly[3,4], Jon Heron[3], Fiona Gordon[5], Matthew Hickman[3], Kushala Abeysekera[3,5]. *[1]Population Health Sciences, University of Bristol, Bristol, United Kingdom; [2]University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, United Kingdom; [3]Population Health Sciences, University of Bristol, Bristol, United Kingdom; [4]University Hospital Bristol and Weston NHS Foundation Trust, Bristol, United Kingdom; [5]University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, United Kingdom*
Email: k.abeysekera@bristol.ac.uk

Background and aims: The new steatotic liver disease (SLD) nomenclature provides an overarching term reflecting the overlap between alcohol related liver disease (ALD), metabolic dysfunction associated steatotic liver disease (MASLD), introducing another term-MASLD with greater alcohol consumption (MetALD). In 2019, the Avon Longitudinal Study of Parents and Children (ALSPAC) birth cohort presented the results to EASL of >4000 FibroScan liver stiffness measurements (LSM) on participants (aged 24 years), determining 1 in 5 had steatosis and 1 in 40 had fibrosis. We sought to apply the new nomenclature to our cohort, along with updated thresholds for LSM and controlled attenuation parameter (CAP) to evaluate SLD prevalence in young adults.
Method: 4018 participants had a FibroScan using Echosens 502 Touch. LSMs with an interquartile range/median ratio (IQR/M) >30%

were excluded. Cardiometabolic risk was assessed with waist circumference and body mass index; blood pressure; triglyceride, high density lipoprotein, fasting glucose levels. Cut-offs for cardiometabolic risk were taken from published SLD nomenclature statements. Alcohol consumption was trichotomized into normal/hazardous/harmful based on AUDIT-C questionnaires and alcohol use questionnaires. Hazardous alcohol consumption was an AUDIT-C score >5, with harmful alcohol consumption reflecting DSM-V criteria for alcohol use disorder. Statistical analysis was performed using Stata MP 18.0.

Results: Mean age was 24 years (±0.8). 3765 valid CAP measurements were recorded. Using the EASL CAP cut-off of 275 dB/m, 11.1% of the cohort had steatosis. 3598 valid LSMs were recorded. 89 participants, aged 24 years, had a LSM >/ = 8 kPa (2.4%), of which 8 had LSM >/ = 12 kPa. 13.1% (n = 470/3599) participants met DSM-V criteria for alcohol use disorder. 37.2% (n = 1327/3565) of participants had a BMI >/ = 25 kg/m^2. Applying full SLD nomenclature was possible for 1765 participants with complete data available. 10.5% (n = 186/1765) met criteria for MASLD of which 7 had fibrosis. 7.3% (n = 128/1765) met criteria for MetALD with <5 having fibrosis. 3.4% (n = 60/1751) met criteria for ALD with 30% (n = 18/60) having fibrosis (>8 kPa).

Conclusion: Based on changing CAP and LSM thresholds the proportion of patients with steatosis fell but estimates for fibrosis prevalence were largely unchanged. Amongst those that fulfilled SLD criteria, the commonest cause of fibrosis was ALD. This is in the context that almost 1 in 8 participants met criteria for alcohol use disorder. ALSPAC will repeat a further 4000 fibroscans with our participants now 30 years old to understand the progression of their SLD.

SAT-449

Prevalence of advanced liver fibrosis in the general population of the Paris region according to FIB 4 scores and liver risk score (Cerbafib)

Henri Tran[1], Patrick Ingiliz[1], Vincent Leroy[1], Stefano Caruso[1], Anne Laure Mazialivou1[2], Adrien Ko[2], Odile Rousselet[3], Cecile Fargeat[3]. *[1]CHU Henri Mondor, Créteil, France; [2]Biokortex, Paris, France; [3]Cerba Healthcare, Paris, France*
Email: henri.tran@aphp.fr

Background and aims: Screening for advanced hepatic fibrosis in the general population may help to identify patients at risk for negative hepatic outcome. However, no perfect non-invasive marker exists. Current guidelines (EASL 2021) recommend to use the low rule-out threshold of the FIB-4 score (1.3) as primary screening tool, but low specificity may lead to a large number of potentially false-positives in need for specialists' referral. Recently, the liver risk score (LRS) has been suggested to more accurately identify at-risk patients. The aim of this study was to compare the two markers in a large cohort from the general population.

Method: Cerbafib is a prospective cohort derived from a collaboration with laboratories situated all over the Paris region. The prevalence of advanced liver fibrosis was assessed by applying the non-invasive FIB 4 score (ALT, AST, age, platelets) with a cut-off of 2.67 (rule-in) and 1.3 (rule-out), and the LRS with a cut-off of 6 (low risk), 10 (medium risk) and 15 kPa (high risk). The correlation between the two scores was studied.

Results: Between January and April 2023, 179 865 patients were included into the cohort. The mean age was 52 years, 45% were men. FIB-4 identified 55 376 (31%) individuals in need for specialists' referral (>1.3), and 4 002 patients (2.2%) with suspected advanced fibrosis. LRS identified 38 175 (21%) patients with estimated liver stiffness >6 kPa, 1 933 patients (1%) >10 kPa, and 35 (0.02%) patients >15 kPa. There was a significant while poor correlation between both tests (r = 0.45, p < 0.01). The concordance between the two tests was as follows: No fibrosis with FIB 4 <1.3: 86% have a minimal risk (<6 kPa), 13% low risk (6–10 kPa), 0.6% medium risk (10–15 kPa) and 0.004% high risk (>15 kPa) according to LRS (r = 0.31) Inconclusive result with FIB 4 between 1.3 and 2.67: 64% have a minimal risk, 13% low risk, 1.4% medium risk and 0.02% high risk according to LRS (r = 0.21) Fibrosis with FIB >2.67: 26% have a minimal risk, 64% low risk, 10% medium risk and 0.4% high risk according to LRS (r = 0.35).

Conclusion: The Liver Risk Score identifies a population in need for further hepatological investigation. Its use as a mass screening test in the general population may help to identify more accurately those at-risk for advanced liver disease. The well-established FIB-4 test only partially identifies this subgroup and might generate more false-positive patients and increase the need of confirmatory resources. Indeed, among patients with indication of further investigations according to FIB 4, around 60% are in the minimal risk of fibrosis with the LRS. Further studies with clinical end points are needed to confirm these results.

SAT-450

Exploring racial, ethnic, and demographics representativeness in MASH clinical trials: combined data from multiple therapeutic trials including more than 10, 000 patients

Jörn M. Schattenberg[1], Naim Alkhouri[2], Mazen Noureddin[3], Vlad Ratziu[4], Michael Charlton[5], Julie Dubourg[6], Stephen A. Harrison[7]. *[1]Saarland University Medical Center, Homburg, Germany; [2]Arizona Liver Health, Phoenix, United States; [3]Houston Research Institute, Houston, United States; [4]Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France; [5]University of Chicago, Chicago, United States; [6]Summit Clinical Research, San Antonio, United States; [7]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom*
Email: jdubourg@summitclinicalresearch.com

Background and aims: Racial, ethnic and demographic representativeness in metabolic dysfunction-associated steatohepatitis (MASH) is not well-known. We aimed to investigate potential disparities in trial participation by characterizing participants of MASH clinical trials.

Method: We combined screening data from 10 industry-funded MASH phase 2 trials. The participation-to-prevalence ratio (PPR) was calculated by dividing the percentage of white and racialised participants in each trial by the percentage of white and racialised participants with metabolic dysfunction-associated steatotic liver disease (MASLD), respectively, in the United States. By convention, a PPR of less than 0.8 or greater than 1.2 indicates under-representation or over-representation, respectively. We also calculated the PPR for age groups (20–29, 30–39, 40–49, 50–59, 60–69, 70–79, ≥80 years) and gender.

Results: We identified 10, 528 participants across 10 industry-funded phase 2 MASH trials. The mean age was 54.7 years (SD 11.6). 58% were female, 89% were white and 41% were Hispanics or Latino. Mean BMI, AST, ALT, and HbA1c were 36.4 kg/m^2 (SD 9.0), 36.7 IU/L (26.4), 47.1 IU/L (35.7), and 6.5% (SD 1.4). Men and female were adequately represented with a PPR of 0.92 and 1.07, respectively. Participants aged 40–49 and 50–59 years were over-represented with a PPR of 1.41 and 1.37, respectively, while participants aged from 70–79 and ≥80 years were under-represented with a PPR of 0.41 and 0.02, respectively. Other age-groups were appropriately represented in the 10 included MASH clinical trials. In regard to race and ethnicity, the White and African American population appeared to be adequately represented with a PPR of 1.41 and 1.37, respectively. However, the Hispanic population was over-represented in this group of MASH clinical trials with a PPR of 4.10.

Conclusion: In the setting of industry-funded MASH clinical trials, racialized participants appear to be either adequately or over-represented. The elderly population appears as under-represented as expected from common inclusion/exclusion criteria in clinical trials. Strategies to improve recruitment and enrolment into randomized controlled trial of under-represented population are needed. Further studies are warranted to assess the appropriate

representativeness of the population in MASH clinical trials as a reflect of the disease population.

SAT-451

Characteristics and waitlist outcomes of liver transplant candidates at high risk for food insecurity

Therese Bittermann[1], David Goldberg[2], Elena Byhoff[3]. [1]*University of Pennsylvania Perelman School of Medicine, Penn Transplant Institute, Philadelphia, United States;* [2]*University of Miami Miller School of Medicine, Division of Digestive Health and Liver Diseases, Miami, United States;* [3]*University of Massachussetts Medical School, Department of Medicine, Worcester, United States*
Email: therese.bittermann@pennmedicine.upenn.edu

Background and aims: Studies have shown that neighborhood-level social determinants of health influence pre- and post-transplant outcomes. To date, no studies have evaluated food insecurity (FI) risk in the liver transplant (LT) population. This study evaluates the characteristics and waitlist outcomes of candidates at high risk for FI and compare these to patients at high risk of broad socioeconomic deprivation, as measured by the Social Deprivation Index (SDI).
Method: This was a retrospective cohort study of LT candidates listed between 1/1/2018–12/31/2021 using national registry data from the Organ Procurement and Transplantation Network, linked to county-level FI data and to county-level SDI, a validated composite measure of socioeconomic deprivation. The correlation between county-level percent FI and SDI was assessed. Multivariable logistic regression was used to evaluate patient characteristics associated with home residence in the ≥90th percentile for FI. Covariates were compared to those associated the ≥90th percentile for SDI. Adjusted time-to-event models evaluated the association of county-level FI and SDI with waitlist mortality.
Results: There were 50, 627 LT candidates listed during the study period. The cohort was 62.3% male with median age 58 years (IQR 49–64), and was 69.7% White, 13.4% Hispanic, 7.1% Black, 4.2% Asian. The most common causes of liver disease were: 37.7% alcohol-associated liver disease (ALD), 22.2% metabolic dysfunction-associated steatotic liver disease (MASLD) and 11.2% hepatitis C virus (HCV). The median county-level percent FI for the cohort was 10.9% (IQR 9.0–13.1), while the median SDI score was 49 (IQR: 27–73). There was overall good correlation between county-level percent FI and SDI (Spearman rho 0.682; $p < 0.001$). Race/ethnicity was associated with both high percent FI and high SDI ($p < 0.001$ for both), but the latter relationship was stronger (e.g., aOR 2.98 for Black/SDI and 1.56 for Black/FI). In contrast, liver disease factors were more strongly associated with percent FI than SDI. For example, patients with MASLD were more likely to live in high FI areas (aOR 1.42 versus ALD; $p < 0.001$ overall), while higher albumin was associated with lower odds of being at risk for FI (aOR 0.79; $p < 0.001$). Percent FI was not associated with adjusted waitlist mortality ($p = 0.119$), while SDI had only a modest effect (aHR 1.07; $p = 0.033$).
Conclusion: The link between MASLD and residence in a high percent FI area may be relevant to disease evolution and also to achieving optimal post-LT outcomes, while that between low albumin and county-level FI may lead to added barriers for waitlisted candidates to overcome malnutrition. Neither county-level social determinants of health measure had a substantial impact on waitlist mortality. Further studies are needed to better understand the potential role of FI on outcomes among LT candidates and recipients.

SAT-452

Evolving patterns in the clinical burden of liver cirrhosis: comprehensive analysis from a leading german tertiary center

Julian Pohl[1], Nirbaanjot Walia[1], Matthias Reinhardt[1], Frank Tacke[1], Cornelius Engelmann[1]. [1]*Gastroenterology and Hepatology, Charité-Universitätsmedizin Berlin, Berlin, Germany*
Email: julian.pohl@charite.de

Background and aims: Emerging evidence is highlighting the changes in the burden of cirrhosis. This study aimed to describe the trends in hospitalizations, inpatient mortality and complications of liver cirrhosis in a large tertiary hospital, and comparing this to other major chronic health conditions while taking into account the possible impact of the COVID-19 pandemic. The aim of this study was to derive implications on future patient management in cirrhosis.
Method: The data was acquired retrospectively from the Charité Berlin University hospital's electronic record system from 2011–2022. Included were all patients discharged with an ICD-10 diagnostic code corresponding to cirrhosis (and its complications), and other chronic diseases as control groups (chronic obstructive pulmonary disease, chronic renal failure, ischemic heart disease, chronic heart failure, malignancies, and diabetes). Between 2011–2022 1, 181, 478 (incl. 24, 567 cirrhosis) patient cases were included. To assess the possible impact of the COVID-19 pandemic, mortality trends were compared against the incidence of COVID-related deaths in Germany.
Results: Cirrhosis patients were the youngest of all health conditions assessed, with a median age of 62 (interquartile range 53–70). Since 2017, their total admission numbers decreased, while their in-hospital mortality increased from 6.3 to 8.8%. Ascites and bacterial infections remained the most common acute complications among cirrhosis patients. Proportions of these complications increased during the observational period from 24 to 30% and 23 to 32%. Clear trends in rising mortality of ascites, hepatorenal syndrome and variceal hemorrhage were observed between 2011–2022. Alcohol-related liver disease was the most common etiology of cirrhosis (42%) in each year. Hepatitis C admissions decreased from 14 to 2%, while hepatitis B admissions decreased from 5% (2011) to 1% (2015) and increased from 2016 again to 3%. From 2016, the proportion of admissions for hepatocellular carcinoma increased from 19 to 23% among cirrhosis patients. Compared to other chronic diseases, cirrhosis patients had the second highest likelihood of re-rehospitalization after malignancies. There was a sharp rise in mortality in December 2020 for all chronic health conditions (15.2% for cirrhosis patients, which was the second highest rate). Since then, patients with cirrhosis surpassed heart failure as the disease with the highest in-hospital mortality at the Charité hospital.
Conclusion: Although total cirrhosis-related hospital admissions were falling, a higher proportion of cases experienced complications including in-hospital mortality, more than for any other of chronic health conditions assessed. Trends in mortality further aggravated during the COVID pandemic. These results underscore the need for risk stratification and adapted management strategies in cirrhosis.

SAT-453

Diagnostic accuracy of the LiverRisk score to detect significant and advanced fibrosis among a United States general population and important subgroups

Laurens van Kleef[1], Jesse Pustjens[1], Harry L.A. Janssen[1,2], Willem Pieter Brouwer[1]. [1]*Erasmus MC, University Medical Center, Rotterdam, Netherlands;* [2]*Toronto Center for Liver Disease, University Health Network, Toronto, Canada*
Email: l.vankleef@erasmusmc.nl

Background and aims: The LiverRisk score (LRS) has recently been proposed as a novel score to predict liver fibrosis and the future development of liver-related outcomes in the general population and may be used in referral strategies. Besides simple laboratory parameters, this score includes age, which may hamper its diagnostic accuracy among young and old populations as has been reported for other non-invasive scores that rely on age.
Method: We used data from the NHANES 2017–2020 cycle, a United States population-based cohort with data on liver stiffness and LRS. We assessed the diagnostic accuracy by AUC and detection rates of LSM ≥8 and ≥12 kPa at proposed thresholds of the LRS. Performance was tested both among the entire general population and clinically relevant subgroups. Sensitivity analyses were performed in

participants with metabolic dysfunction (MD), for whom the EASL, AASLD and AGA referral pathways recommend non-invasive testing for the presence of advanced liver disease.
Results: The cohort comprised 7025 participants, aged 49 [33–63] and 49% were male. Among them 9.7% had LSM ≥8 and 3.2% LSM ≥12 kPa. The AUC in the overall population was 0.73 (95%CI 0.71–0.75) and 0.78 (95%CI 0.74–0.81) to detect LSM ≥8 and ≥12 kPa. It significantly outperformed the FIB-4 (AUC 0.62 and AUC 0.68 to detect LSM ≥8 and ≥12 kPa). The LRS however performed differently amongst participants aged 18–40, 40–60 and 60–80: the AUC to detect LSM ≥8 kPa was 0.68, 0.73 and 0.68 and the AUC to detect LSM ≥12 kPa was 0.73, 0.79 and 0.73, respectively. The score had consistent performance among white, Hispanic and Asian participants, however, the AUC was significantly lower among black participants (AUC 0.74 in white vs 0.66 in black for LSM ≥8 kPa). Performance remained comparable across sex or in patients with metabolic dysfunction. Interestingly, the score had excellent predictive value amongst those without MD (thus excluding those with MD), reflected by an AUC of 0.86 and 0.96 in the detection of LSM ≥8 and ≥12 kPa. Despite the adequate performance as reflected in the AUC, its clinical utility at the suggested cut-offs for very low risk (LRS 6) and low risk (LRS 10) is suboptimal. In the overall population (regardless of MD), 53% of participants with an LSM ≥8 kPa had LRS <6 and 91% LRS <10, resulting in a poor sensitivity of 47% and 9%. Detection of LSM ≥12 kPa is slightly better with 60% sensitivity at LRS 6 and 14% sensitivity at LRS 10. Performance differed per subgroup. Particularly worrisome is the low sensitivity among participants aged 18–40, with only 21% for LSM ≥8 kPa and 34% LSM ≥12 kPa at LRS 6.
Conclusion: The LRS score is a promising new tool to predict liver fibrosis, however, its diagnostic accuracy attenuates among patients aged <40 or ≥60 years old, as well as among black individuals. Further studies are required on whether it can be implemented in referral strategies, in which subgroups, and what cut-offs should be utilized.

SAT-454-YI
Non-housing related socioeconomic factors increase risk of liver fibrosis in screening of an urban population with steatotic liver disease

Huw Purssell[1], Stephanie Landi[1,2], Lucy Bennett[3], Oliver Street[1], Jennifer Scott[1], Christopher Mysko[1,2], Neil Guha[4], Karen Piper Hanley[1,5], Neil Hanley[1,6], Varinder Athwal[1,2]. *[1]University of Manchester, Manchester, United Kingdom; [2]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [3]NIHR Nottingham Biomedical Research Centre (BRC), Nottingham University Hospitals NHS Foundation Trust and Nottingham University, Nottingham, United Kingdom; [4]NIHR Nottingham Biomedical Research Centre (BRC), Nottingham University Hospitals NHS Trust and University of Nottingham, Nottingham, United Kingdom; [5]Wellcome Trust Centre for Cell-Matrix Research, The University of Manchester, Manchester, United Kingdom; [6]University of Birmingham, Birmingham, United Kingdom*
Email: Huw.Purssell@doctors.org.uk

Background and aims: Socioeconomic deprivation is associated with increased risk of steatotic liver diseases and increased risk of advanced disease. Socioeconomic deprivation is multi-faceted and it is unclear which specific factors predispose to risk of significant liver disease. Healthcare access is also dependent on deprivation and case finding using clinical risk factors improves identification in asymptomatic populations and reduces disparity. We aimed to assess impact of deprivation and its specific aspects on the detection of liver fibrosis in a population screening study.
Method: Patients were recruited to the ID LIVER project in Manchester, UK. Patients were assessed in Community Liver Assessment clinics with risk factors for liver disease including Type 2 diabetes (T2DM), Body Mass Index >30 kg/m^2, alcohol consumption >280/>400 grams in females/males per week, abnormal ALT or hepatic steatosis. Patients underwent a clinical history, full non-invasive blood based liver aetiological screen and transient elastography (TE). Fibrosis was assessed with FIB-4 score and TE. Fibrosis risk was determined by a liver stiffness measurement (LSM) >8.0 kPa and FIB-4 >1.3. Socio-economic deprivation was assessed by domain and sub-domain of the Index of Multiple Deprivation (IMD) at an individual and ward level.
Results: 1249 patients were recruited to the ID LIVER project. 866 (69.3%) patients were identified as MASLD, 133 (10.9%) MetALD and 162 (13.0%) patients had alcohol related liver disease. 260 (20.8%) patients had a LSM >8.0 kPa. 34 wards across Greater Manchester were assessed and split into quartiles based on the fibrosis incidence. Although there was no correlation at an individual level between IMD score and LSM ($r^2 = 0.01$), wards in the highest quartile for fibrosis detection had a significantly higher IMD score than wards in the lowest quartile (38.01 vs 19.25 ($p = 0.022$, 95% CI 3.10–34.43). Multivariate analysis, adjusted for T2DM, harmful alcohol consumption and obesity, of the subdomains of the IMD score showed that fibrosis detection correlated with income ($r^2 = 0.29$, $p = 0.005$), employment ($r^2 = 0.31$, $p = 0.003$), education and skills ($r^2 = 0.25$, $p = 0.01$), health and disability ($r^2 = 0.28$, $p = 0.006$), crime ($r^2 = 0.33$, $p = 0.002$) and barriers to housing and services subdomains ($r^2 = 0.22$, $p = 0.02$). Although there was no significant correlation with the living environment subdomain ($p = 0.210$), wards in the lowest quartile of fibrosis detection had a significantly better air quality (0.52 vs 0.79 ($p = 0.049$; 95% CI 0.00–0.54)). 3 year mortality was 1.68% (n = 21), of which 15 (71.4%) patients came from areas of high deprivation.
Conclusion: Indoor living environment is the only factor of socioeconomic deprivation not associated with increased risk of liver fibrosis in an urban population with steatotic liver disease.

SAT-455
The rise of metabolic dysfunction-associated steatotic liver disease (MASLD) among adults in Canada between 2012 and 2018

Jessica Burnside[1], Felice Cinque[2], Giada Sebastiani[2], Sahar Saeed[1]. *[1]Queen's University, Kingston, Canada; [2]McGill University Health Centre, Montreal, Canada*
Email: jessica.burnside@queensu.ca

Background and aims: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) is a highly prevalent yet largely underappreciated liver condition, absent from public health agendas. A recent study suggested substantial improvements in epidemiological assessments would be necessary to improve national preparedness. Based on the lack of routine ultrasounds and the paucity of transient elastography across Canada, serum biomarkers are the only option to identify steatosis at a population scale. To address this need for routine surveillance, the NAFLD Ridge Score (NRS) was developed using a machine-learning approach and validated against proton magnetic resonance spectroscopy with a sensitivity of 92% and specificity of 90%. Our purpose is to estimate the prevalence of MASLD using a pan-Canadian cohort between 2012–2018.
Method: We used data from the Canadian Longitudinal Study on Aging (CLSA), which prospectively follows community-dwelling adults (45 to 85 years old) from 11 sites (7 provinces) across Canada. The CLSA collects sociodemographic, lifestyle, and clinical data every three years. We estimated the annual prevalence of MASLD (steatosis + one cardiometabolic risk factor) as well as MetALD (140–350 g alcohol/week (F) and 210–420 g alcohol/week (M)). Steatosis was identified by an NRS >0.44, which utilizes seven components: serum ALT, high-density lipoprotein cholesterol, triglycerides, hemoglobin A1c, leukocyte count, and the presence of hypertension. We compared the prevalence of MASLD using the NRS score to a non-specific measure of liver damage, ALT (>40 U/L).
Results: 30 079 CLSA participants were included in the analysis. At baseline, 51% were female (F), with a median age of 62 years (IQR: 54–71 years), and median ALT was 21 U/L (IQR: 16–27 U/L). 83% met at least one of five MASLD cardiometabolic criteria, the most common being 70% BMI >25 kg/m^2; 41.5% having high triglycerides

≥1.70 mmol/L; 33% HbA1c ≥5.7%; 30% with hypertension; and 25% having high HDL ≤1.0 mmol/L (Males) or ≤1.3 mmol/L (F). There was a significant rise in MASLD prevalence from 32.3% (95%CI 32.2, 32.5%) in 2012 to 39.1% (95%CI: 39.0–39.3%) in 2018. MetALD prevalence varied over time, ranging from 2.2% (95%CI: 2.2–2.2%) in 2016 to 3.5% (95%CI: 3.4–3.5%) in 2012. Males had an average 1.9 times higher prevalence of MASLD and 2.6 times higher prevalence of MetALD compared to females. Only 7.6% (95%CI: 7.5–7.6%) of the cohort had elevated ALT (>40 U/L) and at least one of the cardiometabolic factors.
Conclusion: This is the first Canadian study to estimate MASLD and MetALD prevalence which exceeds previous modelling estimations. Prevalence was consistently significantly greater amongst men. ALT alone vastly underestimated the prevalence of MASLD. Further studies are underway to elicit phenotypes at the greatest risk of MASLD and the bidirectional relationship between liver and metabolic diseases.

SAT-456

A review of lifestyle management guidelines for metabolic dysfunction-associated steatotic liver disease

Dana Ivancovsky Wajcman[1], Christopher Byrne[2], John F. Dillon[2], Paul N. Brennan[2,3], Marcela Villota-Rivas[1], Zobair Younossi[3,4], Alina M. Allen[5], Javier Crespo[6], Lynn H. Gerber[3,4], Jeffrey V. Lazarus[1,3,7]. *[1]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain; [2]Division of Molecular and Clinical Medicine, Ninewells Hospital and Medical School, University of Dundee, Dundee, United Kingdom; [3]The Global NASH Council, Washington DC, United States; [4]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, United States; [5]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States; [6]Valdecilla Research Institute (IDIVAL), Marqués de Valdecilla University Hospital, Santander, Spain; [7]CUNY Graduate School of Public Health and Health Policy (CUNY SPH), New York, United States*
Email: danaivanc@gmail.com

Background and aims: Several clinical management guidelines on metabolic dysfunction-associated steatotic liver disease (MASLD) have been published. We aimed to summarise the lifestyle interventions recommended in these guidelines.
Method: We searched PubMed/MEDLINE, the Cochrane Library, and the Cumulative Index to Nursing and Allied Health Literature (CINAHL) for MASLD clinical management guidelines published from 1 January 2013 to 31 July 2023. Identified documents were thoroughly reviewed for statements regarding weight loss, dietary patterns or habits, dietary supplements, alcohol consumption, physical activity, tobacco smoking, sleeping habits, behaviour change techniques (BCTs), mental health, digital health interventions (DHI), and social, and environmental determinations of health. The authors developed a framework of 8 pre-defined questions that guided the document evaluation, synthesis, and analysis. A statement was considered as a recommendation if: 1) it noted an action would be beneficial and suitable for the patient; and 2) it was repeated in ≥3 guidelines. Recommendations were categorised into six domains: weight reduction, physical activity, diet, dietary supplements, alcohol, and smoking. A recommendation was defined as strong if recommended in a two-thirds majority of the guidelines.
Results: The search identified 33 MASLD management guidelines. 27 recommendations were identified. Six recommendations were considered as strong: increase physical activity (n = 33); achieve a weight reduction of 7–10% to improve steatohepatitis and/or fibrosis (n = 31); consider bariatric surgery for non-cirrhotic patients with obesity (n = 28); achieve a weight reduction of ≥3–5% to reduce liver steatosis (n = 24); exercise 150–300 minutes/week of moderate-intensity or 75–150 minutes/week of vigorous-intensity (n = 24); and decrease consumption of commercially produced fructose (n = 23). In contrast, mental health, psychological or CBT treatment, DHIs or additional BCTs, and social or environmental determinants of health were rarely (in ≤8 guidelines) mentioned in guidelines, and when they were, it was in broad statements lacking specific recommendations.
Conclusion: Most MASLD clinical guidelines include recommendations regarding healthy eating, physical activity, and weight management, as these have proven positive effects on health outcomes when sustained. However, our review reveals substantial gaps concerning statements and recommendations regarding mental health and the social and environmental determinants of MASLD. To improve adherence, we recommend that scientific associations develop comprehensive guidelines encompassing social support, environmental factors, and mental health. Additionally, we propose exploring BCTs and DHIs to optimise behavioural modifications. Further research on recommendation implementation is needed.

SAT-457-YI

A community-based pilot for proactive screening of high-risk groups for chronic liver disease can lead to sustained healthcare engagement of people diagnosed with cirrhosis

Ann Archer[1,2], Sally Tilden[2], Jane Gitahi[2], Grace Cameron[2], Rosemary King'ori[2], Becky Knight[2], James Hawken[2], Fiona Gordon[2], Matthew Hickman[1], Kushala Abeysekera[1,2]. *[1]Population Health Sciences, University of Bristol, Bristol, United Kingdom; [2]University Hospitals Bristol and Weston NHS Trust, Bristol, United Kingdom*
Email: ann.archer@uhbw.nhs.uk

Background and aims: The *Alright My Liver?* service was developed in collaboration with service users to screen for advanced liver fibrosis from alcohol, viral hepatitis and metabolic syndrome in the South West of England. The service aims to reach the most high-risk populations for liver disease and those most likely to experience health inequalities. This study aims to report on markers of engagement for those identified as having cirrhosis by the pilot service.
Method: Liver health screening events were co-located with drug and alcohol services, primary care services in areas with a high index of deprivation, weight loss events and with Caafi Health, an organization providing health outreach to black and ethnic minority communities in the region. Clients identified with advanced fibrosis were booked into hepatology clinic and ultrasound with an offer of funded transport and telephone reminders. Routine data has been analysed here, with index of multiple deprivation calculated based on postcode where recorded, and set to 1 if the patient was living in a prison or hostel.
Results: Of 3191 people screened for liver disease, 228 had liver stiffness measurement (LSM) >11.5 kPa and were referred for further assessment. This cohort was ethnically diverse relative to the local population, 78% white British or other (baseline population 84%). The cohort median index of multiple deprivation (IMD) decile was 3, with 20% reporting experience of homelessness. Attendance at first liver ultrasound was 89% (n = 152/170), rising to 93% (n = 158/170) including those who attended when offered a second attempt. Attendance at 6-month surveillance ultrasound was 76% (n = 41/54), rising to 87% (n = 47/54) including those upon second attempt. For outpatient clinic, 80% (n = 106/132) attended on first opportunity, rising to 84% (n = 111/132) when including those who attended on a second invitation. These compare favourably to baseline attendance of 80% locally for both clinic and ultrasound for hepatology patients. A chi-squared test of independence revealed no association between first clinic attendance and AUDIT-C score ≤4, IMD decile ≤5 or screening setting. All patients diagnosed with active hepatitis C by the pilot service have been commenced on antiviral therapy (n = 6). 4% (n = 10/228) of patients with LSM >11.5 kPa died during the study period. All had suspected ArLD and none had reached their initial appointment date prior to death. Cause of death data was unavailable.
Conclusion: The pilot service is successful in engaging a patient group with their ongoing care despite the presence of potential barriers to attendance including substance dependence, unstable housing and socioeconomic deprivation. The proactive engagement

approach in this pilot could have broader utility in hepatology to support an underserved population and prevent emergency admissions.

SAT-458

Impacts of smoking on alcoholic associated liver disease: a nationwide cohort study

Sang Gyune Kim[1], Jeong-Ju Yoo[1], Jae Young Jang[2], Log Young Kim[3].
[1]Soonchunhyang University Bucheon Hospital, Bucheon, Korea, Rep. of South; [2]Soonchunhyang University Seoul Hospital, Seoul, Korea, Rep. of South; [3]Department of Big Data Strategy, National Health Unsurance Service, Wonju, Korea, Rep. of South
Email: mcnulty@schmc.ac.kr

Background and aims: Smoking is a preventable risk factor for morbidity and mortality in patients with liver disease. This study aims to explore the additional risks of smoking in the development of alcoholic associated liver disease (ALD), cirrhosis, and hepatocellular carcinoma (HCC) in high-risk drinkers.
Method: Data from the National Health Insurance Service, including claims and health check-up information spanning 2011 to 2017, were used. The overall alcohol consumption was calculated, and ALD was defined based on ICD-10 codes. High-risk drinking was defined as 7 or more drinks for men and 5 or more for women, twice weekly.
Results: Half of the high-risk drinkers were smokers, decreasing in men but stable at 20% for women. ALD prevalence was 0.97% in high-risk drinkers and 1.09% in high-risk drinkers who smoked, higher than 0.16% in social drinkers. ALD incidence over 3-years was highest in high-risk drinkers who smoked (2.35%), followed by high-risk drinkers (2.03%) and social drinkers (0.35%). Cirrhosis and HCC followed similar patterns, with prevalence and incidence was highest in drinkers who smoked. 3-year mortality was 0.65% in high-risk drinkers who smoked, compared to 0.50% in high-risk drinkers and 0.24% in social drinkers. Smoking increased the incidence of ALD, cirrhosis, and HCC by 1.30, 1.50, and 1.45 times, respectively.
Conclusion: Women's risk ratio for ALD, cirrhosis, and HCC increased more significantly with smoking compared to men. Smoking significantly raises the risk of ALD, cirrhosis, and HCC in high-risk drinkers, particularly impacting women more than men. Hence, smoking cessation is crucial for female ALD patients.

SAT-459

Assessments of health utilities in patients with metabolic dysfunction-associated steatohepatitis (MASH): cross-walk between CLDQ-NASH, SF-6D, and the EuroQol EQ-5D

Zobair Younossi[1,2], Maria Stepanova[1,2], Jesse Fishman[3], James Dodge[3], Dominic Labriola[3], Rebecca Taub[3], Fatema Nader[1,2,4].
[1]The Global NASH Council, Washington, DC, United States; [2]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, VA, United States; [3]Madrigal Pharmaceuticals, West Conshohocken, PA, United States; [4]Center for Outcomes Research in Liver Disease, Washington, DC, United States
Email: zobair.younossi@cldq.org

Background and aims: Non-alcoholic steatohepatitis (NASH), renamed as MASH, is a progressive liver disease which can negatively impact the health-related quality of life (HRQL) and health utilities (HU). EQ-5D is a commonly used measure of HU to calculate quality-adjusted life years (QALYs). For the clinical trials that use Chronic Liver Disease Questionnaire-NASH (CLDQ-NASH) or Short Form-36 (SF-36), ability to convert the HRQL scores (CLDQ-NASH or SF-36) to EQ-5D scores provides a valuable method to estimate HU. Using baseline HRQL data from MAESTRO-NASH Phase 3 trial, we aimed to estimate EQ-5D scores using 2 methods in patients with NASH and different stages of fibrosis.
Method: Baseline data of non-cirrhotic NASH patients were used in this study. The HRQL was assessed using CLDQ-NASH (36 items in 6 domains) and Short Form-36 (SF-36; 36 items). We used two cross-walk algorithms to estimate EQ-5D scores. The first algorithm used 6 domains of CLDQ-NASH in a fractional logistic model to yield EQ-5D estimates (Fishman 2023). The other algorithm included calculation of SF-6D utility scores from SF-36 items (Kharroubi 2007) which were further fed into a generalized regression model that estimated EQ-5D scores from the SF-6D scores (Younossi 2019). The two EQ-5D estimates were evaluated for correlation with each other and then in pre-defined clinical subgroups.
Results: There were 883 NASH patients with CLDQ-NASH and SF-36 data: 25% aged ≥65 years, 44% male, 80% obese (BMI>30), 67% type diabetes (T2D), 62% F3 fibrosis and 38% F1b or F2 fibrosis. The mean estimated EQ-5D scores in the total sample were 0.851 (SD = 0.146) according to CLDQ-NASH-based algorithm and 0.853 (SD 0.097) according to the SF-36-based algorithm. The correlations between the two estimated EQ-5D scores were +0.704 (Pearson's) and +0.739 (Spearman's). Similar to the total sample, the differences between the mean EQ-5D estimates using either calculation method did not exceed 0.012 in all studied subgroups (by age, sex, obesity, T2D, fibrosis stage). Using the CLDQ-NASH-based algorithm, EQ-5D scores in those subgroups were as follows [mean (SD)]: 0.871 (0.114) in ≥65 years, 0.844 (0.154) in <65 years, 0.884 (0.132) in male, 0.824 (0.151) in female, 0.845 (0.148) in obese, 0.876 (0.136) in non-obese, 0.847 (0.144) in T2D, 0.859 (0.150) in non-T2D, 0.852 (0.138) in F3, and 0.849 (0.158) in F1b or F2. For comparison, the historic EQ-5D estimates for NASH with advanced fibrosis (Younossi 2019) were as follows: 0.835 (0.139) in F3, 0.819 (0.148) in compensated cirrhosis (F4).
Conclusion: Both cross-walk algorithms for calculation of the EQ-5D utility scores in NASH patients were estimable with CLDQ-NASH or SF-36 instruments. A high positive correlation was seen between the total score and subgroup estimates using either method; this improves confidence in their use to calculate quality-adjusted outcomes for cost-effectiveness models.

Email: j.li.1@erasmusmc.nl

Background and aims: Steatotic liver disease (SLD) affects approximately 30% of adults globally, while the prevalence of viral diseases continues to pose a threat to the global population. This study aims to comprehensively investigate the relationship between SLD and major viral diseases.

Method: A systematic search of Medline, Embase, Web of Science and Cochrane Library databases was conducted from inception to July 8, 2022. Cross-sectional and longitudinal observational studies for adults and published in English with full text available were included, if they provided data on the occurrence of SLD events in viral-infected population. Meta-analysis was performed using random-effects (DerSimonian and Laird) models.
Results: The search identified 47, 194 records, and a total of 621 eligible studies involving 390, 728 individuals from 55 countries were included. Among patients with mono-infections, the highest SLD prevalence was observed in those infected with hepatitis C virus (HCV) (49%, 95% confidence interval [CI]: 46%-52%), followed by human immunodeficiency virus (HIV) (40%, 36%–45%), hepatitis B virus (HBV) (38%, 34%-41%) and SARS-CoV-2 (37%, 32%–42%). Coinfection with HCV-HIV (44%, 38%–49%) or HBV-HIV (53%, 38%-68%) was associated with higher prevalence of SLD compared to HIV mono-infection. The prevalence of SLD was 53% (38%–68%) in HCV-HBV co-infected populations. Further analysis showed a positive association between SLD and SARS-CoV-2 infection (odds ratio [OR] 2.13, 95% CI [1.06–4.29]), and a negative association between HBV infection and SLD (OR 0.69, 95% CI [0.58–0.83]). No significant association was found between SLD and HIV or HCV infection. The pooled prevalence of steatohepatitis in all viral-infected populations was 17% (14%–20%), with the highest rate observed in HIV-infected (29%, 20%–37%), followed by HCV-infected (21%, 14%–27%) and HBV-infected (8%, 5%–12%) patients. Hepatic steatosis was significantly associated with an increased risk of developing chronic liver disease and hepatocellular carcinoma in HCV- and/or HIV-infected but not in HBV-infected individuals. Importantly, SLD was identified as a risk factor for severe outcomes in SARS-CoV-2-infected patients and for the diagnosis of AIDS in HIV carriers. In HBV and HCV patients who received antiviral therapy, SLD was significantly associated with lower sustained virologic response.
Conclusion: SLD is highly prevalent in viral-infected populations, and the reciprocal interactions between SLD and viral diseases worsen both conditions, leading to poorer patient outcomes. Therefore, increased awareness and the development of intervention strategies are needed to address the burden of SLD in populations with viral infections.

SAT-463
Association between air pollution and heat stress exposome and liver enzymes in NYC runners
Nicholas DeFelice[1], Aman Patel[1], Anthony Lin[1], Nayab Baloch[1], Andrew Moon[2]. [1]*Icahn School of Medicine at Mount Sinai, New York, United States;* [2]*UNC Gastroenterology and Hepatology, Chapel Hill, United States*
Email: nicholas.defelice@mssm.edu

Background and aims: Chronic and repeated acute heat stress exposures and air pollution can result in damage to the liver, heart, kidney, and muscles. Here, we assessed acute recurrent air pollution and heat stress exposures (internal body temperature, sweat rate, heart rate, etc) in a cohort of long-distance runners to better understand how the natural environment impacts liver function.
Method: During the summer of 2023, 20 athletes provided consent to participate in the study. Subjects were recruited to run 20 km through New York City three times. Prior to the run, participants provided urine and blood, including a comprehensive metabolic panel (CMP), complete blood count (CBC) with differential, and spot creatinine. Approximately a week after the initial blood draw and a week after each run, participants ran 20 km in Manhattan with several environmental sensors to capture individual-level exposures of ambient temperature, humidity, internal core temperature, volume loss, sodium loss, minute ventilation, heart rate variability, and air pollution exposure. After each run, blood and urine samples were collected. We report descriptive data on heat stress and air pollution exposure and subsequent changes to liver enzymes.
Results: Eight men and seven women (of the 20 total enrolled) completed the three 20 km runs in New York City. Environmental exposures while running were highly variable with PM 2.5 air pollution total mass inhaled on a run being 119.0 ug per run (9.8–561.6 ug). Prior to running, all participants' CMP, CBC, and creatinine were within normal ranges. After a 20 km run, one runner had two runs during which AST and ALT increased from a baseline of 19 to 44 and 43 U/L for AST and 24 to 86 and 74 U/L for ALT for runs 1 and 3, respectively. For Run 2, there was no increase in for AST (19 to 20 U/L) or ALT (24 to 24 U/L). For this athlete, we saw no difference in sweat rate or internal body temperature. However, there was a significant difference in PM2.5 air pollution exposure with levels increased above the EPA good air quality for run 1 (217.8 ug) and run 3 (145.2 ug) but normal air pollution levels during run 2 (132.5 ug). Additionally, 3 other runners had an increase in total bilirubin greater than 1.5 times their baseline blood draw and total bilirubin was classified as above normal. Two of the three runs occurred during high air pollution days in which the $PM_{2.5}$ exposure was 3 to 8 times greater than their other run days.
Conclusion: We observed abnormal elevation of ALT, AST, and total bilirubin were more likely to occur in the context of high pollution exposures. It is likely that an increase in AST, ALT, and total bilirubin could reflect muscle breakdown and/or hemolysis. However, this is in line with accumulating literature showing an association between air pollutants exposure and increased liver enzyme levels. These data may be instructive for public health interventions.

SAT-464-YI
Transaminases and older adults: distribution and associations with all-cause mortality
Daniel Clayton-Chubb[1], Ammar Majeed[1], Stuart Roberts[1], Hans Schneider[1], Jessica Fitzpatrick[1], Robyn Woods[2], Monira Hussain[2], Natassia Tan[1], Isabella Commins[3], John Lubel[1], Cammie Tran[2], Alex Hodge[4], John McNeil[2], William Kemp[1]. [1]*Alfred Health, Monash University, Melbourne, Australia;* [2]*Monash University, Melbourne, Australia;* [3]*Alfred Health, Melbourne, Australia;* [4]*Eastern Health, Monash University, Box Hill, Australia*
Email: chubb.daniel@gmail.com

Background and aims: Alanine aminotransferase (ALT) and aspartate aminotransferase (AST) are commonly ordered tests in general medical practice. However, their distribution and significance in older adults is understudied. As such, we aimed to evaluate the gender-stratified distribution of both ALT and AST in older adults, and to assess for any associations of transaminase levels with mortality.
Method: This study is a post-hoc analysis of the Aspirin in Reducing Events in the Elderly (ASPREE) randomised, placebo-controlled trial of daily low-dose aspirin for relatively healthy older persons. Baseline associations were explored with univariate analysis and ordinal logistic regression. Cox regression and restricted cubic splines were used to examine hazard ratios between transaminase levels and mortality.
Results: Of the 11853 participants with both ALT and AST levels recorded, 1054 (8.9%) deaths were recorded over a median of 6.4 (IQR 5.4–7.6) years. All values were above the Australian harmonised reference lower limit of normal. Males and females in the lowest quintile of ALT had an increased hazard of mortality (HR 2.09 [95% CI 1.60–2.74] and HR 1.99 [95% CI 1.49–2.67] respectively). However, for AST, only males in the lowest quintile had an increased hazard of mortality (HR 1.47 [95% CI 1.16–1.87]). These associations remained significant when adjusting for covariates including age, frailty, diabetes, and kidney disease, and when removing outliers.
Conclusion: Low ALT levels independently confer an increased hazard of mortality for older males and females; only low AST impacts older male survival. Further evaluation of mechanism would be worthwhile, and reevaluating the lower limit of normal for ALT in older adults should be considered.

SAT-465

Increasing awareness among primary care physicians about MASLD reduced unnecessary referral rates and an increased cardiovascular evaluation

Eileen Yoon[1], Jihyun An[1], Ha Il Kim[2], Joo Hyun Sohn[2], Bo-Kyeong Kang[3], Eun Chul Jang[4], Huiyul Park[5], Hye-Lin Kim[6], Sang Bong Ahn[7], Joo Hyun Oh[7], Hyunwoo Oh[8], Hyo Young Lee[9], Dae Won Jun[1]. Email: noshin@hanyang.ac.kr

Background and aims: The revised definition of metabolic dysfunction-associated steatotic liver disease (MASLD) is anticipated to enhance awareness among primary care physicians and diminish stigma among patients. This study aimed to assess the impact of an online educational program on MASLD for physicians and its influence on modifying their clinical practice patterns.
Method: A total of 869 physicians [72 physicians at referral centers and 797 primary care physicians (PCPs)], who consented to receive educational materials on MASLD, participated in this study. They completed an initial survey regarding their clinical practices for patients with MASLD, followed by a second online survey eight weeks after receiving a series of seven weekly educational materials on MASLD.
Results: Frequency of utilizing non-invasive tests for liver fibrosis, used as the first tier evaluation in both physicians at referral centers and PCPs, was low at 6.9% and 6.9%, respectively, and there was no difference between the two groups. Regarding barriers to the management of MASLD, specialists in referral centers considered the 'short consultation time' as the primary challenge, while PCPs cited the 'the absence of a fee for this service' as the major barrier. Additionally, the proportion of PCPs considering non-invasive tests testing for patients in the 'at-risk group' increased significantly for those with diabetes (32.6% to 38.5%), cardiovascular disease (9.2% to 16.1%), and ischemic stroke (8.4% to 11.5%). After education, the percentage of PCPs who immediately referred patients to a specialist after a MASLD diagnosis decreased from 15.4% to 12.3% (P value = 0.042).
Conclusion: Increasing awareness among PCPs about MASLD reduced unnecessary referral rates and an increased cardiovascular evaluation.

SAT-466

The association of perceived neighborhood violence and allostatic load with metabolic dysfunction-associated steatotic liver disease in mexican-origin migrant and seasonal farmworkers along the southern Arizona United States/Mexico border

Adriana Maldonado[1], Emma Torres[2], Melissa Flores[3], Edgar Villavicencio[1], Alejandra Hernandez[1], Estefania Ochoa Mora[4], Ana Gonzalez[1], Julio Loya[3], Rogelio Torres[2], Idolina Castro[2], Felicitas Torres[2], Naim Alkhouri[5], David Garcia[1]. [1]*University of Arizona, Mel and Enid Zuckerman College of Public Health, Tucson, Arizona, United States;* [2]*Campesinos sin Fronteras, Somerton, Arizona, United States;* [3]*University of Arizona, Tucson, Arizona, United States;* [4]*University of Arizona, University of Arizona Health Sciences, Tucson, Arizona, United States;* [5]*Arizona Liver Health, Chandler, Arizona, United States*
Email: adrianamaldonado@arizona.edu

Background and aims: In the Southern Arizona United States (U.S.)/Mexico border region, estimates indicate that the overall prevalence of MASLD among Mexican-origin adults is 50%; however, studies exploring MASLD risk among Mexican-origin migrant and seasonal farmworkers (MSFWs) do not exist. This is surprising as MSFWs experience high rates of hypertension, type 2 diabetes, hypercholesterolemia, and obesity. In addition, while it has been found that the social and built environment affect individuals' health outcomes, including allostatic load (AL); to date, the impact of neighborhood context on farmworkers' MASLD risk has not been explored. Using a community-based participatory approach, we aimed to examine the association between perceived neighborhood violence (PNV), AL, and MASLD in a cross-sectional sample of MSFWs. We also examined whether AL was a mediator between perceived violence and MASLD.
Method: Data were collected from a community-based sample of 151 MSFWs (women = 59.6%; men = 40.4%; mean age = 49.7 years ±14.1 years; mean BMI = 31.9, ±6.5) residing in the Southern Arizona U.S./Mexico border region. Self-reported data on PNV was collected. PNV was assessed by summing scores across four, 4-point Likert scale dimensions where respondents indicated prevalence levels from 1 (never) to 4 (often). Allostatic load, calculated as an index of physiologic dysregulation, included systolic and diastolic blood pressure, body mass index (BMI), total cholesterol, HDL cholesterol, total/HDL cholesterol ratio, C-reactive protein, albumin, and creatinine clearance. Hepatic steatosis and fibrosis were assessed by liver stiffness measurements (LSM) and controlled attenuation parameter (CAP) scores via FibroScan®. MASLD was identified as having a CAP score of ≥288 dB/m. Relevant covariates including age, sex, nativity, and acculturative stress were included in all models.
Results: The mean CAP score was, M = 265.81 ± 60.97, ranging from 100.0 to 399.0 with 41.1% of the sample being identified with MASLD. The average PNV was reported as M = 5.42 ± 2.22, ranging from 0 to 13. The mean AL score was M = 4.76 ± 1.33, ranging from 1.5 to 7.5. PNV was not associated with MASLD status, however, contrary to our expectations, was negatively associated with AL, (b = 0.13, SE = 0.05, 95% CI (−0.01, −0.02). AL was positively associated with MASLD status, (OR = 2.22, 95% CI (1.58, 3.12)). Lastly, AL was a negative mediator between PNV and MASLD status (average mediated effect = −0.02, 95% CI (−0.03, −0.01)).
Conclusion: This is one of the first studies to explore PNV and AL in the context of MASLD for MSFWs. While study findings highlight potential areas of focus for MASLD-risk reduction interventions, additional research is needed to fully understand the mechanistic pathways through which AL influences MSFWs' risk for MASLD.

SAT-467

Prioritisation of research to tackle stigma in alcohol-related liver disease: results from the ARMS-Hub partnership

Ashwin Dhanda[1,2], Victoria Allgar[1], Neeraj Bhala[3], Lynne Callaghan[1], Joana Castro[4], Shilpa Chokshi[5], Amanda Clements[4], Ewan H. Forrest[6], Lesley Manning[7], Richard Parker[8], Debbie L. Shawcross[9], Jennifer Towey[10]. Email: ashwin.dhanda@nhs.net

Background and aims: Despite the high disease burden from alcohol-related liver disease (ALD), there is disproportionately low research activity in the field. Reasons for inattention to ALD are multifactorial but certainly include stigma and lack of engagement and inclusion of people with lived experience (PWLE) in developing and participating in research. We developed an ALD multistakeholder hub (ARMS-Hub) of experts and PWLE/carers with an aim to identify the research priorities to tackle stigma and low research and patient engagement in ALD.
Method: Existing clinical and research networks were mapped and stakeholder members identified across disciplines and settings including hepatology, addictions, biomedical science, community services and charities. Patient and public involvement and engagement (PPIE) members were recruited via the British Liver Trust and through charities and support groups. In-person members were recruited through community alcohol services in Plymouth. 5 virtual stakeholder meetings and 3 virtual and 3 in-person PPIE meetings took place between July and December 2023. Discussions focused on stigma, and inclusion and engagement in research. Major themes and sub-themes were identified from written notes and transcripts. Following the discussions, themes were prioritised by ranking at the fifth stakeholder meeting and research questions generated and reviewed by all stakeholders.
Results: The PPIE in-person group consisted of 31 participants (7 female; median age 45–54; 42% living in the most deprived decile), while our virtual PPIE group was composed of 9 participants (3 female; median age 45–54; 11% living in the most deprived decile). 31 experts attended 5 virtual stakeholder meetings (39% senior clinicians 26% senior nurses, 19% allied health professionals, 10% voluntary sector workers and 6% academics). Major themes were identified and ranked by the attendees: 1) education and awareness, 2) accessibility, 3) language and 4) culture. Sub-themes were also discussed and ranked. The following three subthemes were prioritised: 1) the disconnect between liver and mental health services, 2) preconceptions from healthcare professionals and 3) lack of knowledge of alcohol harms. The ARMS-Hub project team generated overarching research questions relating to each prioritised area and obtained consultation from stakeholders and PPIE members. The final 3 research questions are: 1) How can mental health services best be integrated into liver services? 2) Can an educational package be used to reduce stigma in healthcare professionals? 3) Can we design and implement a diverse educational package around the wider harms of alcohol?.
Conclusion: A diverse group of stakeholders, PWLE and carers have prioritised three research areas to tackle stigma and engagement in ALD. Research questions and proposals are being developed to address these crucial issues.

SAT-468

Changing from MAFLD to the new nomenclature: new opportunities to understand the role of alcohol and metabolism to adverse outcomes

Chenlu Yang[1], Shuohua Chen[2], Shouling Wu[2], Li Wang[1]. [1]*Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, Peking Union Medical College, Peking, China;* [2]*Kailuan General Hospital, Tangshan, China*
Email: liwang@ibms.pumc.edu.cn

Background and aims: In June 2023, steatotic liver disease (SLD) was introduced as an overarching term to replay metabolic dysfunction-associated fatty liver disease (MAFLD) to cover the various etiologies of steatosis. This study aims to explore the distinction of long-term outcomes between the subtypes of SLD and MAFLD.
Method: We included 152, 139 adults diagnosed with ultrasonography from the Kailuan Cohort in China between June 2006 and April 2014. The Cox regression or Fine Gray competitive risk models were used to compare the risk of adverse outcomes in the cross-definition grouping of SLD subtypes and MAFLD. Individuals without viral hepatitis and excessive alcohol consumption were included in this analysis. In addition, we compared the risk of adverse outcomes under different alcohol consumption levels based on the definition of SLD.
Results: The prevalence of SLD and MAFLD was 32.1% and 31.3%, respectively. The proportion of MetALD-MAFLD, MetALD-only (lean SLD with moderate alcohol consumption and metabolic abnormalities), MASLD-MAFLD, MASLD-only (lean SLD with light alcohol consumption and metabolic abnormalities), and cryptogenic SLD (lean SLD without metabolic abnormalities) was 7.7%, 0.2%, 89.9%, 1.0%, and 1.2%. Compared to non-SLD individuals, MetALD-only and MASLD-only still had higher risks of mortality (HR $_{\text{MetALD-only}}$=2.14, 95% CI: 1.39, 3.28; HR $_{\text{MASLD-only}}$ = 1.55, 95% CI: 1.21, 1.98) and cancers (HR $_{\text{MetALD-only}}$=2.63, 95% CI: 1.45, 4.79; HR $_{\text{MASLD-only}}$ = 1.55, 95% CI: 1.06, 2.26), but MetALD-MAFLD and MASLD-MAFLD subjects were more prone to CVD (HR $_{\text{MetALD-MAFLD}}$ = 1.31, 95% CI: 1.20, 1.43; HR $_{\text{MASLD-MAFLD}}$ = 1.51, 95% CI: 1.45, 1.56) and CKD (HR $_{\text{MetALD-MAFLD}}$ = 1.48, 95%CI: 1.28, 1.72; HR $_{\text{MASLD-MAFLD}}$ = 1.72, 95% CI: 1.62, 1.82). Cryptogenic SLD did not show an increased risk for adverse outcomes. Based on the classification of alcohol consumption in SLD, ALD has the highest mortality risk (HR $_{\text{ALD vs. MetALD}}$ = 2.19, 95% CI: 1.91, 4.02; HR $_{\text{ALD vs. MASLD}}$ = 2.05, 95% CI: 1.12, 3.75). In comparison to MASLD, the MetALD population has an elevated risk of developing cancers (HR = 1.17, 95% CI: 1.01, 1.35) but a lower risk of CVD (HR = 0.87, 95% CI: 0.80, 0.96) and CKD (HR = 0.86, 95% CI: 0.74, 1.00).
Conclusion: The SLD definition can identify individuals with fatty liver who are lean with metabolic abnormalities and at a higher risk of adverse outcomes, which are overlooked by the MAFLD definition. ALD, MetALD, and MASLD may indicate different outcome risks, and it is recommended to manage them separately.

SAT-471

Relationship between steatotic liver disease, all-cause mortality and cardiovascular related outcomes-20 year follow-up of a longitudinal cohort study

Oyekoya Ayonrinde[1,2,3], Raj Uchila[2], John Olynyk[2,3], Chrianna Bharat[4], Kevin Murray[1]. [1]*The University of Western Australia, Perth, Australia;* [2]*Fiona Stanley Hospital, Murdoch, Australia;* [3]*Curtin University, Bentley, Australia;* [4]*University of New South Wales, Sydney, Australia*
Email: oyekoya.ayonrinde@uwa.edu.au

Background and aims: Steatotic liver disease (SLD) is the most prevalent chronic liver disease globally and has been associated with increased mortality. We examined the longitudinal relationship between the severity of hepatic steatosis, and subsequent mortality and emergence of cardiovascular disease (CVD) in adults participating in the Busselton Health Study, a population-based longitudinal cohort study in Western Australia.
Method: SLD was diagnosed using fatty liver index (FLI), calculated from body mass index, waist circumference, serum triglycerides and gamma glutamyl transferase. Cox proportional hazards models were used to investigate the relationship between FLI and (a) all-cause mortality, (b) CVD mortality, and (c) CVD-related events. Participants were followed for up to 20 years, i.e. from the date of survey (1994/1995) until the date of death or end of follow-up (2014). Restricted cubic splines were used to investigate nonlinear relations between FLI and outcomes of interest, with hazard ratios (HR) and 95% confidence intervals (CI) derived. FLI quintiles were derived and HR estimates reported for the median FLI in each quintile, using the median FLI in quintile 5 as the reference. Models adjusting for age, sex, and history of CVD (model A); age, sex, history of CVD, smoking, diabetes, blood pressure treatment, systolic blood pressure, total cholesterol, and high-density lipoprotein (HDL) cholesterol (model B); and adjusted for all covariates in model B plus alcohol intake (model C) were used in all analyses. Associations were stratified by sex and age <50 vs. 50+ years.
Results: There were 4, 382 participants (56% female) with mean age 51 (SD 17) years recruited in the original cohort. In follow-up there

were 974 (22.2%) deaths, 408 (9.3%) CVD-related deaths, and 1018 (23.2%) CVD events. We found a non-linear association between FLI and all-cause mortality (p <0.01), seen in both sexes. After multivariable adjustment, participants in quintile 1 had a 28% lower risk of all-cause mortality compared with participants in quintile 5 (HR 0.72, 95% CI 0.55-0.94). CVD deaths and events increased with increasing FLI (model A), but this was less apparent after further adjustments (models B and C). There was no association observed between FLI and mortality or CVD outcomes among participants aged <50 years of age. By contrast, in those aged 50+ years there was an increased risk of all-cause mortality in quintile 3 (HR 1.30, 95% CI 1.08-1.563) and in quintile 4 (HR 1.26, 95% CI 1.09-1.458) of FLI, respectively, and HR 1.29, 95% CI 1.11-1.49 for CVD-related events in quintile 3 (p <0.05 for all), compared to quintile 5.
Conclusion: Severity of SLD was associated with all-cause mortality and CVD-related events, particularly in people aged 50+ years. The relationship between SLD and CVD outcomes was attenuated by other CVD risk factors.

Public Health – Viral hepatitis

Progression of hepatitis B virus (HBV)-related liver disease in immune-tolerant, inactive, and grey zone phases: a systematic review and meta-analysis
Zakary Warsop[1,2], Arthur Rakeover[2], Daniela Yucuma[2], Yu Ri Im[2,3], Si Emma Chen[2], Rukmini Jagdish[2,4], Roger Chou[5], Philippa Easterbrook[6], Yusuke Shimakawa[2]. *[1]Imperial College London, London, United Kingdom; [2]Institut Pasteur, Paris, France; [3]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; [4]St George's Hospital, London, United Kingdom; [5]Oregon Health and Science University, Portland, United States; [6]World Health Organisation, Geneva, Switzerland*
Email: zakary.warsop18@imperial.ac.uk

Background and aims: The global burden of chronic hepatitis B virus (HBV) (CHB) infection is a major public health challenge. Antiviral therapy is effective in reducing HBV viral load and the risk of developing cirrhosis and hepatocellular carcinoma (HCC), but not all individuals currently require antiviral therapy as only a subset of untreated patients will develop liver-related complications. To improve our understanding of the natural history of CHB in people not currently indicated for treatment across most professional societies' guidelines, a systematic review and meta-analysis was conducted to assess the risk of liver complications at the inactive carrier, grey zone (GZ) and immune tolerant stages of HBV infection.
Method: We searched PubMed, Embase, Web of Science and the Cochrane Library for cohort studies published up to 6 February 2023. Two reviewers independently reviewed titles, abstracts and extracted data from full-text articles. Outcomes included HCC, cirrhosis, all-cause and liver-related mortality and HBsAg sero-clearance. The incidence rates of each outcome were pooled using a generalized linear mixed model according to the different phases of the natural history. Inactive phase (HBeAg-negative chronic infection) was defined as HBeAg-negative, HBV DNA <2, 000 IU/ml, and ALT <upper limit of normal (ULN). Immunotolerant phase (HBeAg-positive chronic infection) was defined as HBeAg-positive, HBV DNA >20, 000 IU/ml, and ALT <ULN. Patients in the GZ phase were subcategorized into GZ1: HBV DNA <2, 000 IU/ml and ALT 1–2 × ULN, GZ2: HBV DNA 2, 000–20, 000 and ALT <ULN, and GZ3: HBV DNA 2, 000–20, 000 and ALT 1–2 × ULN.
Results: Of 13, 124 studies identified and screened, 36 were included. Two (5.6%) of these were from the African World Health Organisation region. There were 4 studies included in each of the GZ and immune tolerant groups and 15 studies in the inactive carrier group. The pooled incidence rates (per 100 person-years) for developing HCC were: 0.327 (95% CI: 0.258–0.413); 0.390 (0.249–0.611); 0.475 (0.183–1.232) and 0.563 (0.207–1.529) in the GZ1, GZ2, GZ3 and immune tolerant groups respectively. These were significantly higher than in the inactive carrier phase: 0.100 (95% CI 0.064–0.157) (p < 0.01). Similar results were found for other outcomes. Studies with a single assessment of viral load and ALT at baseline appeared to show a higher risk than those with multiple assessments.
Conclusion: Patients in the immune tolerant and grey zone phases have a higher risk of developing HBV-related complications. Further trials are needed to confirm the efficacy of treatment in these populations.

TOP-461-YI
Retreating the off-Nuc clinical relapse with Pegylated interferon much increased HBsAg seroclearance-a propensity score matching study
Yu-Ting Kao[1], Yen-Chun Liu[2], Rong-Nan Chien[2], Rachel Wen-Juei Jeng[2]. *[1]Department of Gastroenterology and Hepatology, Chang Gung Memorial Hospital, Linkou branch, Taoyuan, Taiwan, Taoyuan, Taiwan; [2]Chang Gung Memorial Hospital, Linkou branch, Taiwan, Taoyuan, Taiwan*
Email: rachel.jeng@gmail.com

Background and aims: HBsAg seroclearance is significantly elevated in HBeAg-negative chronic hepatitis B (CHB) patients upon discontinuation of nucleos (t)ide analogue (NUC) therapy comparing to that during long-term viral suppression. The immune response after stopping Nuc may be modulated by the re-appearance of viral antigen which facilitate the HBsAg seroclearance. This study aims to investigate if retreating off-Nuc clinical relapse (CR) patients with pegylated interferon would enhance the likelihood of achieving functional cure.
Method: From the CGMH off-Nuc cohort, 25 HBeAg-negative CHB off-Nuc CR patients retreated with Peg-IFN (Rx-Peg-IFN) and 980 off-Nuc CR patients retreated with Nuc (Rx-Nuc) were enrolled. Propensity score matching (PSM) was employed, adjusting for age, gender, ALT, HBV DNA, and HBsAg levels at retreatment, between off-Nuc CR patients Rx-Peg-IFN and Rx-Nuc at a 1 to 3 ratio. Kaplan-Meier analysis and log-rank tests compared the cumulative HBsAg loss rate among these three groups.
Results: After PSM, there were 25 and 75 patients in Rx-Peg-IFN and Rx-Nuc arms, respectively. The mean age was 50 of all both arms (p = 0.63), 96% (Rx-Peg-IFN) and 86% (Rx-Nuc) were male (p = 0.31). The median ALT level of Rx-Peg-IFN and Rx-NA were 156 and 162U/L (p = 0.29), HBV DNA levels were 5.7 and 6.0 log10IU/ml (p = 0.14), and HBsAg level was 2.8 and 3.3 log10IU/ml (p = 0.62), respectively. The HBsAg reduction during the 1st year of retreatment was −1.14 versus −0.46 log10 IU/ml, respectively, (p = 0.0061). During a median follow-up of 7.1 years (from start of retreatment), 10 and 4 patients lost HBsAg in Rx-Peg-IFN and Rx-Nuc groups, respectively. The cumulative HBsAg seroclearance rates (from start of retreatment) at 1, 2, 5, and 10 years were 12%, 20.2%, 25.5%, and 45.0% in Rex-Peg-IFN arm, versus 0%, 0%, 2.7%, and 4.6% in Rex-Nuc arm, respectively (log rank test, P < 0.0001).
Conclusion: Retreatment with Peg-IFN in HBeAg-negative chronic hepatitis B (CHB) patients experiencing clinical relapse (CR) resulted in a significantly elevated HBsAg loss rate (by end of Rx-Peg-IFN treatment: 12%, 1-year post EOT of Rx-Peg-IFN: 20.2%). This underscores the potential strategy of enhancing functional cure by boosting the off-Nuc immune response.

Screening for viral hepatitis in the emergency department-the methodology to automate a feasible, acceptable and effective solution

Julia Di Girolamo[1,2], David Prince[1,2,3], Basheer Alshiwanna[1,2,3], Robert Porritt[4], David Thomas[4], Shahida Bakridi[4], Hung Tran[4], Sophie Gryllis[4], Maria Tiglao[4], Rebecca Haack[4], Kristian Peralta[4], Melissa Bagatella[1], Irena Petrovski[5], Julie Doan[6], Richard Cracknell[7], Jeremy Lawrence[8], Michael Maley[4], Hong Foo[4], Nathan Jones[9], Gregory Dore[3,10], Miriam Levy[1,2,3]. *[1]Department of Gastroenterology and Liver, Liverpool Hospital, Sydney, Australia; [2]Ingham Institute for Applied Medical Research, Sydney, Australia; [3]The University of New South Wales, Sydney, Australia; [4]NSW Health Pathology, Sydney, Australia; [5]Department of Gastroenterology and Liver, Campbelltown Hospital, Sydney, Australia; [6]Clinical Reporting and Analytics, Liverpool Hospital, Sydney, Australia; [7]Department of Emergency Medicine, Campbelltown Hospital, Sydney, Australia; [8]Department of Emergency Medicine, Fairfield Hospital, Sydney, Australia; [9]Liverpool Hospital, Sydney, Australia; [10]The Kirby Institute, UNSW, Sydney, Australia*
Email: julia.digirolamo@health.nsw.gov.au

Background and aims: Australian guidelines recommend risk factor screening for viral hepatitis in priority populations. Barriers to testing exist in culturally and linguistically diverse (CALD) and Indigenous populations particularly, who may acquire hepatitis via non-injecting use routes. A universal testing strategy may serve hard to reach populations, but implementation remains an issue. We reported Screening of Emergency Admissions at Risk of Chronic Hepatitis (SEARCH) pilot clinical service in Emergency Department (ED) screening of priority populations, efficacy, cost utility, and acceptability. This report describes the methodology required for automation and broad implementation.
Method: A novel pilot clinical service (SEARCH 3X) was developed to automatically test adult ED patient blood specimens for hepatitis B surface antigen (HBsAg) and hepatitis C antibody (HCVAb). A computer algorithm was developed such that at laboratory specimen reception in appropriate specimens, hepatitis serology would be automatically added, directing the specimen through the biochemistry analyser for testing. Positives were confirmed by routine supplementary tests. A re-test order within seven days was automatically denied. The feasibility of reflexive HCV RNA testing on positive HCVAb specimens was examined. Test cancellation mechanism due to patient or clinician request, was developed. Design included the automatic reporting of positive results to the clinical team to precipitate linkage to care. Clinician and patient education resources were developed to promote awareness of viral hepatitis and the testing service, in the form of videos, posters, pamphlets and website including translation into languages for local CALD communities.
Results: Six Australian EDs were identified in metropolitan or rural locations based on feasibility and unmet need. Executive and clinical stakeholders were consulted, and a governing steering committee formed. An initial pilot of 5000 patients per site was set. The automated methodology was successfully implemented in the first two sites with minimal impact on ED services. Ninety-nine percent (n = 10, 204) of eligible patients were successfully tested. The combined HBsAg and HCVAb seroprevalence was 2.5%. Eighty six percent of positive patients were successfully linked to care. No patient or staff complaints were received, nor did any patient decline testing. The proportion of patients tested more than once was 10.5%, of which 80%, were tested twice, 15% tested thrice and remainder 5% tested four to six times.
Conclusion: Automation allows testing of 99% of the target population with no increased work for ED services. The hepatitis seroprevalence justifies the testing and linkage to care is strong. Repeat testing is an issue but may be reduced by optimising the algorithm. Work is underway to test a further 20, 000 patients at 4 other sites during 2024.

WED-423

Estimation of the prevalence of hepatitis delta virus infection in the European Union

Hugh Watson[1,2], Letizia Nidiaci[3], Andrea Nizzardo[3], James Alexander[4]. *[1]Evotec ID, Medical Development and Translational Science, Lyon, France; [2]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [3]Aptuit Srl, Verona, Italy; [4]Alexander Pharma Consulting, Cary, NC, United States*
Email: hugh.watson@evotec.com

Background and aims: Hepatitis delta virus (HDV) prevalence in the general population of the European Union (EU) is unknown. HDV prevalence among HBsAg+ patients referred to hospital hepatology and infectious disease clinics has been described in several EU countries, but there is little information on the prevalence of HDV in the HBsAg+ population not referred to hospital clinics. We aimed to estimate overall prevalence of viraemic HDV in the EU by incorporating data-driven assumptions for the non-referred HBsAg+ population.
Method: Data on HDV prevalence was searched in public databases. Extrapolating from clinic-population estimates of HDV prevalence to estimates of national HDV prevalence required assumptions for (1) the proportion of the HBsAg+ population referred to hospital clinics, and (2) the difference in HDV-RNA prevalence between referred and non-referred patients. The proportion of HBsAg+ patients referred to hospital clinics was derived from literature. As surrogates for non-referred patients, prevalence amongst patients classified as having "inactive disease" and community patients were considered. Corresponding adjustments were made to prevalence estimates derived from hospital clinics. Assumptions were validated by comparison of adjusted estimates from clinic populations with prevalence determined directly in general populations, where available. EU-wide prevalence of HDV was then derived from national HBsAg+ prevalence data using appropriate meta-analytical statistical methods and imputing values for countries lacking data. Sensitivity analyses utilizing alternative assumptions generated a plausible range of prevalence estimates.
Results: 62 estimates of HDV prevalence were identified from 16/27 EU countries. 74% of prevalence estimates were based on hospital clinic HBsAg+ populations. The most likely scenario estimated the proportion of HBsAg+ patients referred to hospitals at 32%, while prevalences of anti-HDV Ab and HDV-RNA in non-referred patients were estimated respectively at 0.28 × and 0.13 × those in referred HBsAg+ patients. Comparison of HDV prevalence derived from clinic and general population samples validated these assumptions. We estimated HDV-RNA prevalence ranging from <1 to 27 in 10, 000 in national populations with an overall figure of 2.9 in 10, 000 (plausible range 2.2 to 4.0) for the EU after imputing values for missing countries.
Conclusion: A general population estimate of HDV-RNA prevalence was obtained for the whole EU with some uncertainty due to the small evidence base for key assumptions.

WED-424

Cost-effectiveness of antiviral therapy in patients with chronic hepatitis B in the high viremic gray zone

Suk-Chan Jang[1], Won-Mook Choi[2], Gi-Ae Kim[3], Hye-Lin Kim[4], Young-Suk Lim[2]. *[1]School of Pharmacy, Sungkyunkwan University, Suwon, Gyeonggi-do, Korea, Rep. of South; [2]Department of Gastroenterology, Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Rep. of South; [3]Department of Internal Medicine, Kyung Hee University School of Medicine, Seoul, Korea, Rep. of South; [4]College of Pharmacy, Sahmyook University, Seoul, Korea, Rep. of South*
Email: limys@amc.seoul.kr

Background and aims: Accumulating evidence indicates that high viremic gray zone patients with low ALT levels have a higher hepatocellular carcinoma (HCC) risk than low viremic individuals with high ALT levels. Recent research shows a not linear but parabolic relationship between HBV DNA levels and HCC risk in gray zone patients. We aimed to assess the cost-effectiveness of initiating antiviral therapy in the gray zone, particularly for patients with HBV DNA levels between 4 and 8 $\log_{10}$ IU/ml associated with a high risk of HCC.
Method: We conducted a cost-utility analysis using a Markov model to compare the expected costs and quality-adjusted life-years (QALYs) of starting antiviral therapy at the gray zone phase (treated gray zone group) compared to delaying treatment until the immune-active phase (untreated gray zone group). The hypothetical cohort of 10, 000 patients with CHB in the gray zone phase (60% male, HBV DNA levels 4–8 $\log_{10}$ IU/ml, ALT levels <40 IU/L, HBeAg-positive 50%) was simulated over a 10-year horizon. Transition probabilities and costs were mainly obtained from a multicentre historical cohort study including adult CHB patients without cirrhosis at five tertiary referral hospitals in South Korea. The incremental cost-effective ratio (ICER) using QALY was calculated between the treated gray zone and the untreated gray zone group from the healthcare system and societal perspective.
Results: In the base-case analysis (serum HBV DNA levels of 4–8 $\log_{10}$ IU/ml and all age groups), the ICER was USD 12, 630/QALY, indicating cost-effectiveness under the willingness-to-pay threshold of USD 25, 000/QALY. Stratified analyses by HBV DNA levels demonstrated the highest cost-effectiveness for levels of 6–7 $\log_{10}$ IU/ml with ICER of USD 2, 418/QALY, followed by 5–6 (USD 7, 726/QALY), 7–8 (USD 20, 390/QALY), and 4–5 (USD 25, 375/QALY) $\log_{10}$ IU/ml, which order was consistent with HCC risk by HBV DNA levels. Age-stratified analyses showed the ICER increased as age decreased; initiating treatment for patients over 40 years old was cost-effective. From a societal perspective considering productivity loss, the treat gray zone strategy was dominant (ICER <0), suggesting that this strategy incurred less cost and had a superior effect.
Conclusion: Initiating antiviral therapy in the high viremic gray zone is cost-effective compared to delaying treatment to the immune-active phase. This study suggests that commencing antiviral therapy in the high viremic gray zone phase should be considered, accounting for both clinical and economic burdens.

WED-425
Effects of direct-acting antivirals on end-stage liver disease and mortality among Florida Medicaid beneficiaries with chronic hepatitis C

Pei-Lin Huang[1], Shao-Hsuan Chang[1], Roniel Cabrera[2], Debbie Wilson[1], Haesuk Park[1]. [1]*University of Florida College of Pharmacy, Gainesville, United States;* [2]*University of Florida College of Medicine, Gainesville, United States*
Email: hpark@cop.ufl.edu

Background and aims: Despite current availability of effective direct-acting antivirals (DAA) therapies, treatment uptake has been suboptimal in the United States (US). Medicaid beneficiaries are known to have the lowest treatment initiation rate due to fewer financial resources and prior authorization policies. We assessed the effects of DAA treatment on the risk end-stage liver disease (i.e., decompensated cirrhosis [DCC], hepatocellular carcinoma [HCC]) and mortality among Medicaid beneficiaries.
Method: We conducted a retrospective cohort study of 2013–2019 Florida Medicaid data of beneficiaries aged 18–64 years with a diagnosis with hepatitis C (HCV). Patients were categorized as those who received DAA therapy and those who did not. The index date was defined as the first DAA initiation date in the DAA group. For each untreated patient, we randomly assigned a hypothetical index date using the distribution of treated patients. The incidence rates of DCC, HCC and all-cause mortality after the index date (i.e., number of events/person-year) were compared between the DAA and untreated groups, stratified by liver severity (with and without cirrhosis). We used inverse probability of treatment weighted multivariable Cox proportional hazards regression modeling to estimate adjusted hazard ratios (aHR) and 95% confidence intervals (CI). We conducted a sensitivity analysis to define outcome events occurring ≥3 months after the index date and a subgroup analysis for patients receiving ≥8 weeks of DAA treatment.
Results: Among 32, 409 Medicaid beneficiaries with HCV (mean age = 45.78, 43% men, 15% Black), 13% received DAAs. Among beneficiaries without cirrhosis DAA treatment was associated with significantly decreased risk of DCC (aHR, 0.46; 95% CI, 0.35–0.60), HCC (aHR, 0.42; 95% 0.22–0.79), and mortality (aHR, 0.16; 95% CI, 0.12–0.21) compared to no treatment. Similarly, among beneficiaries with cirrhosis, DAA treatment was associated with significantly decreased risks of DCC (aHR, 0.33; 95% CI, 0.24–0.45), HCC (aHR, 0.53; 95% 0.32–0.89), and mortality (aHR, 0.17; 95% CI, 0.12–0.25). The findings from sensitivity and subgroup analyses were consistent with the base case analysis.
Conclusion: This cohort study suggests that DAA treatment was associated with decreased risk of DCC, HCC, and mortality among Medicaid beneficiaries with HCV. Despite these promising results, this study demonstrates that only 13% of Florida Medicaid beneficiaries with HCV received DAA treatment. To reach the global health goal of eliminating hepatitis by 2030 in the US, Medicaid programs need to consider offering less-restrictive requirements for HCV treatment and further overcome barriers to the treatment that still exist for vulnerable Medicaid beneficiaries.

WED-426
From kitchen to table: unravelling hepatitis E virus inactivation in pork meat products

Tatjana Locus[1,2,3], Michael Peeters[3], Ellen Lambrecht[1], Steven Van Gucht[3], Thomas Vanwolleghem[2]. [1]*Flanders Research Institute for Agriculture, Fisheries and Food, Melle, Belgium;* [2]*Antwerp University Hospital, Edegem, Belgium;* [3]*Sciensano, Brussels, Belgium*
Email: tatjana.locus@ilvo.vlaanderen.be

Background and aims: Hepatitis E virus (HEV) infection through the consumption of pork and wild boar meat is a significant public health concern, and is recognized as the primary cause of acute viral hepatitis in Europe (ECDC, 2019). Theoretical analyses focusing on HEV contamination and exposure, performed by our research team revealed that ready-to-eat pork products pose the highest risk of HEV contamination (Locus et al., 2023a). However, the impact of diverse meat processing methods on the infectivity of the virus remains poorly understood. Consequently, there is an urgent need to investigate the influence of these methods in relevant matrices. This study aims to elucidate the effects of common meat processing techniques, including heating, drying, and pH reduction, on the inactivation of HEV in pork meat products.
Method: The impact of different core temperatures (68°C, 72°C, 80°C, and 99°C) on the integrity of HEV were assessed by spiking raw liver and pork fat with cell culture produced HEV and preparing pork liver pâtés according to a standard recipe. In a subsequent series of experiments, we prepared both standard and pH-reduced (achieved by adding DL-Lactic acid until pH 4.1) dried pork sausages. These sausages were initially refrigerated for 24 hours and then transferred to a biosafety cabinet for additional drying. At intervals of two, seven, and fourteen days, we assessed the sausages for weight, pH, water activity, and the presence of HEV. Detection of infectious HEV particles was carried out through immunostaining, complemented by in-house proxy methods to evaluate HEV capsid and genome integrity (Locus et al., 2023b) in both sets of experiments.
Results: Significant reductions in HEV particles with intact capsids were observed in pâtés heated to 68°C, 72°C, and 80°C (1.3, 1.3, and 1.5 logs, respectively) compared to unheated controls ($p < 0.001$ ***). No viral RNA was detected at 99°C (more than 3.5 logs reduction, $p <$

0.001 ***). No intact HEV genomes were detected, except in two out of three pâtés heated to 68°C. In standard and pH-reduced dried pork sausages, significant reductions in HEV particles with intact capsids were evident after 14 days (p < 0.001 ***), but complete reduction did not occur (2.2 and 1.2 logs, respectively). After seven days, intact genomes were detected in one and two out of three standard and pH-reduced sausages, respectively. After 14 days, intact genomes were found in one of three pH-reduced sausages.
Conclusion: Our findings suggest that existing meat processing methods may not be entirely effective in disintegrating Hepatitis E virus (HEV) particles in high-risk food products. The experimental framework and assays designed to assess viral capsid and genome integrity provide valuable insights. Further research is warranted to identify and implement optimal meat processing techniques that can significantly reduce the risk of foodborne HEV infections.

WED-427
Progress towards achieving hepatitis C elimination in the country of Georgia, April 2015-November 2023
Tengiz Tsertsvadze[1,2], Akaki Abutidze[1,2], Lali Sharvadze[2,3], Maia Butsashvili[4], Jaba Zarkua[5], Rania Tohme[6], Shaun Shadaker[6], Ekaterine Adamia[7], Tamar Gabunia[7]. *[1]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia; [2]Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia; [3]Hepatology clinic HEPA, Tbilisi, Georgia; [4]Health Research Union, Tbilisi, Georgia; [5]Medical Center Mrcheveli, Tbilisi, Georgia; [6]Division of Viral Hepatitis, Centers for Disease Control and Prevention, Atlanta, United States; [7]Ministry of IDPs from the Occupied Territories, Labour, Health and Social Affairs of Georgia, Tbilisi, Georgia*
Email: tt@aidscenter.ge

Background and aims: The country of Georgia launched the world's first national hepatitis C elimination program in April 2015. Key strategies include nationwide screening, active case finding, linkage to care, decentralized care, and provision of treatment for all persons with hepatitis C virus (HCV) infection, along with effective prevention interventions. The elimination program aims to achieve the following targets by 2025: a) diagnose 90% of HCV-infected persons, b) treat 95% of those diagnosed, and c) cure 95% of those treated (90-95-95 targets). We report progress toward these HCV elimination targets in Georgia.
Method: The estimated number of persons with HCV infection was based on a 2015 population-based national seroprevalence survey, which showed that 5.4% of the general adult population had current HCV infection (approximately 150, 000 persons). We analyzed data in the national HCV screening and treatment databases during April 2015–November 2023.
Results: As of November 30, 2023, 162, 089 adults screened reactive for HCV antibodies. Of those, 135, 547 (83.6%) received HCV RNA or core antigen testing, of whom 105, 328 (77.7%) had current HCV infection, and 84, 928 (80.6%) of them initiated treatment. Of 59, 663 persons who were evaluated for sustained virologic response (SVR) after treatment completion, 59, 055 (99.0%) had no detectable HCV RNA. Based on the 90-95-95 program goals, Georgia has diagnosed 78.0% of the target 135, 000 (90% of the estimated 150, 000 adults with current HCV infection), treated 66.2% of the target 128, 250 (95% of 135, 000), and cured 48.5% of the target 121, 837 (95% of 128, 250). Treatment effectiveness was comparable among persons with advanced fibrosis (elastography score F3-F4 or FIB-4 >3.25) with 98.4% achieving SVR, and among patients with mild or no liver fibrosis (elastography score ≤F2 or FIB-4 <1.25), SVR = 99.2%, p < 0.0001.
Conclusion: Georgia has made substantial progress towards eliminating hepatitis C. More than 70% of persons with current HCV infection have been diagnosed, and most have initiated treatment and experienced high cure rates regardless of fibrosis status. Challenges remain in identifying and linking to care persons with current HCV infection in Georgia. Scaling up the integrated, decentralized model of HCV treatment, which is already implemented in many locations, to cover more sites will be critical to improve linkage to care and close gaps in the HCV cascade of care.

WED-428-YI
Patient, provider, and neighborhood-level factors associated with hepatitis delta testing in an academic health system
Lauren Alpert[1], Anna Mageras[1], Rachel Smith[2], Xiaotao Zhang[1], Tatyana Kushner[1]. *[1]Icahn School of Medicine at Mount Sinai, New York, United States; [2]UPMC Children's Hospital of Pittsburgh, Pittsburgh, United States*
Email: lauren.alpert@icahn.mssm.edu

Background and aims: International guidelines recommend screening all hepatitis B surface antigen (HBsAg) positive patients for hepatitis delta virus (HDV) antibody (Ab) and all HDV Ab positive patients for HDV RNA. However, studies have shown heterogenous HDV testing patterns worldwide. We evaluated the demographic, clinical, and social determinants of HDV testing among HBsAg positive patients in an academic health system.
Method: All patients with a positive HBsAg test between 7/2021 and 7/2023 were identified. Within this cohort, HDV Ab and RNA testing rates were determined. Community deprivation index (CDI), a marker of neighborhood resources based on American Community Survey data, was used to estimate socioeconomic and environmental disparities in the study population. Multivariable logistic regression analysis was performed to determine factors associated with HDV Ab testing.
Results: 2, 495 HBsAg positive patients were identified, among whom 1, 348 (54%) received HDV Ab testing; 44 (3%) were HDV Ab positive. Thirty two (73%) HDV Ab positive patients received HDV RNA testing; 12 (38%) were HDV RNA positive. Those tested for HDV Ab were median age of 50; 60% male, 31% Asian, 25% Black, and 10% Hispanic. Patients with HDV Ab testing were more likely to be younger and Asian, have an active patient portal linked to the electronic health record (EHR), receive their most recent HBsAg test in a liver clinic, have a hepatitis B virus (HBV) diagnosis code in the EHR, receive hepatitis C virus (HCV) Ab or HIV testing, and receive HBV treatment (p < 0.05). The mean CDI for those with HDV Ab testing was higher than for those without, indicating more resource scarcity among tested individuals. On multivariable logistic regression analysis, the following were associated with higher odds of HDV Ab testing: white (OR = 1.39, 95% CI: 1.04, 1.86) and Black (OR = 1.76, 95% CI: 1.37, 2.27) compared to Asian race, HBV diagnosis code in the EHR (OR = 1.39, 95% CI: 1.14, 1.71), HCV Ab (OR = 2.54, 95% CI: 2.01, 3.21) and HIV (OR = 1.31, 95% CI: 1.08, 1.59) testing, HBV treatment (OR = 1.65, 95% CI: 1.36, 2.01), and residence in a high CDI ZIP code (OR = 1.36, 95% CI: 1.13, 1.64). Patients were least likely to receive HDV Ab testing in primary care, inpatient, and emergency room settings; they were most likely to receive testing in liver clinics, followed by gastroenterology, OB/GYN, and infectious disease clinics (p < 0.05).
Conclusion: In an academic health system, only about half of HBsAg positive patients were tested for HDV Ab. Liver specialty care and comprehensive HBV management were associated with higher odds of HDV Ab testing. Resource scarcity did not decrease the likelihood of HDV testing, suggesting that provider factors had more influence on testing rates than social factors. Efforts to test patients less engaged in the health system and provide HDV education to non-liver providers will be critical to improve HDV screening rates.

WED-429
Hepatitis B virus care cascade in Rwanda: a population based-study
Jean Damascene Makuza[1], Dahn Jeong[2], Marie Paul Nisingizwe[3], Phymar Soe[4], Richard Morrow[5], Georgine Cua[5], Héctor Alexander Velásquez García[6], Albert Tuyishime[7], Michael Law[8], Alnoor Ramji[9], Naveed Janjua[10]. *[1]University of British*

Columbia, School of Population and Public Health, Rwanda Biomedical Centre, Kigali, Rwanda, Vancouver, Canada; [2]University of British Columbia, School of Population and Public Health, British Columbia Center for Disease Control, Vancouver, Canada; [3]University of British Columbia, Vancouver, Canada; [4]University of British Columbia, School of Population and Public Health, Vancouver, Canada; [5]University of British Columbia, School of Population and Public Health, British Columbia Centre for Disease Control, Vancouver, Canada; [6]University of British Columbia, School of Population and Public Health, British Columbia Center of Disease Control, Vancouver, Canada; [7]Rwanda Biomedical Center, IHDPC Department, Kigali, Rwanda; [8]University of British Columbia, School of Population and Public Health, Vancouver, Canada; [9]University of British Columbia, Division of Gastroenterology, Vancouver, Canada; [10]British Columbia Center for Disease Control, University of British Columbia, School of Population and Public Health, Vancouver, Canada
Email: makorofr@gmail.com

Background and aims: The global burden of viral hepatitis B (HBV) is substantial, and monitoring progress across the care cascade is essential for effective elimination strategies. In Sub-Saharan Africa, data on the HBV care cascade are limited. We aimed to quantify the HBV care cascade in Rwanda among diagnosed with HBV infection individuals from 2016 to 2023.
Method: In this population-based retrospective cohort study, we used routinely collected data from the District Health Information System 2, which included 4.5 million people screened for HBV from January 2016 to June 2023. During this period, individuals were included if they were >2 years old. The HBV care cascade was analysed across five stages: (1) lifetime prevalence, (2) diagnosis, (3) enrolled in care, (4) treatment initiation, and (5) treatment continuation. Infections were identified by having at least one reactive antigen or nucleic acid test, and lifetime prevalence was estimated as the sum of diagnosed and estimated undiagnosed cases. Multivariable logistic regression was used to identify progression-related factors through the different cascade stages.
Results: Among the 4, 604, 468 persons screened, 55, 820 tested positive for HBsAg (HBV infection diagnosed). Of these individuals, 51, 065 (91.5%) had HBV mono-infection, and 4, 755 (8.5%) had HBV/HIV co-infection. Among all individuals identified with chronic HBV infection, 21, 182 (38.0%) were enrolled in care, 5, 966 (28.2%) were eligible for HBV treatment, 4, 746 (79.6%) initiated treatment, and 4, 621 (97.4%) continued treatment at 1-year post-initiation. Individuals enrolled at district hospitals were more likely to be engaged in care (adjusted odds ratio [aOR], 2.09; 95% CI, 1.93, 2.26), eligible for HBV treatment (aOR: 1.82; 95% CI, 1.61, 2.07), initiate HBV treatment (aOR: 2.41; 95% CI, 1.85, 3.14), and be retained in care (aOR: 5.85; 95% CI, 2.74, 12.49), compared to those followed up at health centers. Compared to those living at ≤30-minute distance, those living at >1 hour to reach a facility were more likely to be engaged with care, eligible for HBV treatment, and initiate treatment, while they were less likely to be retained in care. Individuals living with HIV were more likely to be engaged in care but less likely to initiate HBV treatment.
Conclusion: Overall, engagement with care was low among individuals diagnosed with chronic HBV infection. Individuals followed at district hospitals were more likely to be engaged in care, eligible and initiate the HBV treatment, and retained in care, highlighting the need for strengthening decentralization and integration of HBV services to lower-level health facilities by increasing well-trained healthcare providers, and infrastructure for prevention and treatment of HBV at health centre level.

WED-430

Epidemiological changes and clinical events in the HepCoVe hepatitis C positive cohort. The viral elimination after availability of new antiviral therapies through a 20-year observational study

Luisa Cavalletto[1], Liliana Chemello[2]. *[1]University Hospital, Dept of Medicine DIMED, Padova, Italy; [2]University Hospital, Dept of Medicine DIMED, Padova, Italy*
Email: luisa.cavalletto@unipd.it

Background and aims: Background and aims: Since 2000, the HepCoVe network, by a shared web patient-individual-record among liver units in the Veneto region of Italy, has recruited a cohort of cases with chronic hepatitis C (CHC) and supported the implementation of screening programs and antiviral treatments, with the objectives of: a) comparing the characteristics of the cohort in cases with parenteral risk reported before or after 1995, the date of the mandatory application of anti-HCV testing in Italy, and b) tracking the changes induced by antivirals therapies, by the use previous of interferon (IFN) and then of the direct antiviral therapy (DAA).
Method: A data-set of 3397 cases, with CHC prospectively collected from January 2000 underwent to an accurate report of risk-infection and clinical events, lab and virologic tests, the staging of liver fibrosis with biopsy (Ishak score) or measuring the liver (LS), and the spleen stiffness (SS), to diagnose portal hypertension (PH) by VCTE (Fibroscan®). All cases were genotyped and had a viremia tested by PCR at baseline and at 12-week after therapy to define sustained virologic response (SVR). Mortality and HCC occurrence was analysed by KM curves in cases with and without SVR.
Results: At baseline, the profile of 1949, respect to 978 cases, with parental risk reported before or after 1995, showed higher infection of HCV1b or 2a/c (73.1 vs. 62.8%) and lower HCV1a, 3a and 4c/d (27.2 vs. 37.2%) and higher rate of transfusion (36 vs. 4%). Moreover they were older (56 vs. 53 yrs) and with advanced fibrosis or cirrhosis (24 vs 10%) (all, $p < 0.01$). During a 20.2 ± 5.4 yrs follow-up, we analysed the SVR rate in the IFN-RBV (2000–2014) and in the DAA-era (2015–2023), respectively 60 vs 95% ($p < 0, 01$). In the latter only 24 cases, 83% with advanced fibrosis or cirrhosis, had a relapse viremia, while twenty-nine (6, 1%) cases developed a de novo HCC, 82% within 24-month after stopping DAA therapy. By a multivariate analysis we identified: LS (HR 2.04; CI 1, 8–2.3), virologic relapse (7.71; 2.2–26.8), signs of PH (3.8; 1.5–9.9) and bilirubin levels (1.1; 0.8–1.8) as variables associated to HCC occurrence (all, $p < 0.01$). At 20-year analysis the risk of HCC occurrence in our cohort was of 0.81 and 3.75 per person/yrs in cases with or without SVR ($p < 0.001$).
Conclusion: This 20-year cohort study confirmed the presence of at least 2 epidemiological outbreaks period of HCV exposition in Italy, the first characterized by HCV1b or 2a/c infection, mainly link to transfusions and with a more advanced liver disease, and the second with higher prevalence of genotypes HCV-1a, 3a and 4c/d, related to drug addiction, in younger population. DAA therapy induced pangenotypic HCV eradication, attaining 95% of cases with SVR, however without removing the de-novo HCC risk. Nowadays, the LS and SS measurements remain a pivotal tool for management of cases with advanced liver disease and residual risk of HCC.

WED-431

Testing practice and prevalence of hepatitis delta virus (HDV) among patients with chronic hepatitis B (CHB): a large canadian population-based study

Abdel-Aziz Shaheen[1], Meng Wang[2], Bing Li[2], Carla Coffin[1]. *[1]University of Calgary, Calgary, Canada; [2]Alberta Health Services, Calgary, Canada*
Email: az.shaheen@ucalgary.ca

Background and aims: Patients with chronic hepatitis B (CHB) and hepatitis delta virus (HDV) coinfection have worse clinical outcomes compared to HBV monoinfected individuals. Recent studies estimating the burden of HDV have reported significant heterogeneity of HDV prevalence due to study designs or testing practices. Therefore, we aim to report HDV antibody (anti-HDV) testing, HDV prevalence

rates and identify predictors of testing as well as anti-HDV positivity in a large Canadian population-based study.
Method: We used the Alberta Provincial Laboratory database to identify patients with CHB (≥2 positive HBsAg or HBeAg; or positive testing and negative HBc IgM for ≥6 months) as well as anti-HDV screening and positive result from April 1st, 2012–March 31st, 2022, in Alberta, Canada (population ~4.6 million). We linked HBV monoinfected or HBV/HDV coinfected patients with Alberta ambulatory, inpatient, and pharmacy databases. We compared patient demographics, laboratory, clinical, and HBV therapy in individuals with or without anti-HDV testing and anti-HDV positivity. Adjusted logistic regressions were used to identify predictors of anti-HDV screening and anti-HDV positivity among all CHB patients that were tested.
Results: Over ~10 year period (2012–2022), 11, 000 patients with CHB were identified in Alberta. Anti-HDV testing was reported among 1, 737 patients (15.8%) of which 73 were anti-HDV positive (4.2%). Anti-HDV screening increased between 2012–2020 (11.9%–23.3% with an annual increase of 8.7%, $p < 0.001$), then declined to 16.8% post COVID-19 pandemic. Anti-HDV testing was more common in younger CHB patients (median age 38 vs. 42 years, $p < 0.001$), male sex (63.4% vs. 53.4%, $p < 0.001$), with elevated ALT (58.8% vs. 43.6%, $p < 0.001$), and less likely in anti-HBV treated patients (24.2% vs. 26.6%, $p = 0.037$). In those who were screened, patients with positive anti-HDV had similar age (median: 40 vs. 42 years, $p = 0.148$), male sex (74.7% vs. 64.5%, $p = 0.059$), ALT (68.5% vs. 59.3%, $p = 0.146$), as well as receiving CHB treatment (30.8% vs. 23.7%, $p = 0.156$). The main independent predictors for anti-HDV testing were age (aOR: 0.98: 95%CI: 0.97–0.98), male sex (aOR 1.58: 1.38–1.80), elevated ALT (aOR 1.76: 1.54–1.99), and CHB treatment (aOR 0.56: 0.49–0.65). However, none of the latter predictors were associated with HDV coinfection.
Conclusion: In this large population-based study, HDV testing and positivity rates among patients with CHB are lower than previously reported in Canada. Universal HDV screening along with reflex HDV RNA testing in anti-HDV positive patients, particularly among older and female patients living with CHB are needed to understand the true epidemiology of HBV/HDV coinfection.

WED-432
Systematic review and meta-analysis of barriers and enablers to hepatitis C direct-acting antiviral treatment initiation

Kathleen Bryce[1,2], Fiona Burns[1,2], Colette Smith[2], Alison Rodger[1,2], Douglas Macdonald[1,3]. *[1]Royal Free London NHS Foundation Trust, London, United Kingdom; [2]Institute for Global Health, University College London, London, United Kingdom; [3]Institute of Liver and Digestive Health, University College London, London, United Kingdom*
Email: kathleenbryce@doctors.org.uk

Background and aims: Despite the successes of the direct-acting antiviral (DAA) programme for hepatitis C virus (HCV) infection, many groups still experience challenges to accessing care. We aimed to determine the barriers and enablers associated with hepatitis C DAA initiation and their relative impact.
Method: We performed a systematic review and meta-analysis of the barriers and enablers to HCV treatment initiation in the DAA era in high income settings with free universal healthcare. We searched eight bibliographic databases for studies published between 2014 and May 2022 using pre-defined keywords. We included quantitative studies investigating positive or negative associations with DAA treatment initiation. Data were extracted into a standardised form and a random-effects meta-analysis was conducted to pool the effects of variables on treatment initiation. The I^2 statistic was used to measure heterogeneity across studies.
Results: Of 5198 articles identified, 42 studies conducted in Australia, Canada and Europe were included. Overall quality was 'fair' or 'good' in 37. Significant negative associations with DAA treatment included: unstable housing (14 studies, pooled odds ratio (OR) 0.48, 95% confidence interval (CI) 0.40–0.58, $I^2 = 21.1\%$); active injecting drug use (OR 0.54, CI 0.39–0.74, $I^2 = 97.5\%$); low income or socioeconomic status (seven studies, OR 0.75, CI 0.60–0.94, $I^2 = 73.7\%$) and female gender (26 studies, 0.78, CI 0.69–0.89, $I^2 = 89.9\%$). Positive associations included: increasing age (17 studies, OR 1.76, 95% CI 1.30–2.40, $I^2 = 95.4\%$); previous HCV treatment (nine studies, OR 2.20, CI 1.45–3.34, $I^2 = 85.8\%$); fibrosis stage (13 studies, OR 1.80, CI 1.15–2.79, $I^2 = 95.6\%$) and opioid substitution in people who inject drugs (12 studies, OR 1.54, 95% CI 1.15–2.05, $I^2 = 65.9\%$). There was no overall effect of high-risk alcohol use on treatment initiation when compared with lower (or no) alcohol use (13 studies, OR 0.91, 95% CI 0.64–1.27, $I^2 = 98.3\%$).
Conclusion: The most impactful factors associated with DAA treatment initiation were socioeconomic and fixed demographic or disease characteristics. This should enable pre-emptive identification and intervention in those at risk of disengagement before treatment. Active injecting drug use was the only behavioural characteristic consistently associated with lower treatment initiation but this is significantly mitigated by opiate substitution therapy.

WED-433
Combatting blood-borne viral syndemics with automated electronic based screenings of HBV, HCV, HDV and HIV in a hospital

Su Wang[1,2], Ruth Brogden[1], Jaymie Yango[1], Aryana Velez[1], Nandanie Budhoo[1], Eric Handler[1], Stephen Omahony[3]. *[1]Cooperman Barnabas Medical Center, Livingston NJ, United States; [2]Hepatitis B Foundaiton, Doylestown, United States; [3]RWJBarnabas Health, West Orange, United States*
Email: suwang8@gmail.com

Background and aims: Achieving hepatitis B (HBV) and C (HCV) elimination will require integration into health care systems as part of routine care. A syndemic approach is also important to address other blood-borne viruses (BBV) such as HIV and hepatitis delta (HDV). HDV is believed to be underdiagnosed with an estimated 12 million people with HDV infection. Establishing HBV reflex testing to HDV testing protocols is one way increase testing. In a 597-bed community hospital with an Emergency Department (ED) of 100, 000 yearly visits, an electronic medical record (EMR) based automated screening algorithm was implemented to scale up HCV, HBV, HDV and HIV screening and linkage to care (LTC).
Method: In March 2018, the EMR was modified at Cooperman Barnabas Medical Center (CBMC) in the Emergency Department (ED) and inpatient units to implement automated HCV (HCVAb reflex to HCV RNA) and HBV (HBsAg) screening. In 2020 screening criteria was expanded to follow CDC recommendations for universal HCV screening. To capture the intersection of the opioid epidemic and viral hepatitis, urine/serum toxicology and peer recovery specialist orders also led to automatic hepatitis orders. In 2021, an automated HIV screening was developed for at-risk patients, and in 2022, hepatitis delta (HDVAb) reflex testing from all positive HBsAg tests was implemented. Positive screening tests for all viruses were sent to patient navigator (PN) in real-time who initiated LTC for evaluation and treatment.
Results: Since the beginning of the program, 100, 950 HCV screenings have been conducted with 407 (0.4%) current HCV infection and 343 (84%) LTC. Since 2021, the at-risk HIV screenings totalled 7, 313 with 102 (1.4%) infected and 98 (96%) LTC. Patients screened for HBV totalled 44, 172 with 395 (0.9%) infected and 330 (84%) LTC. Since August 2022, when HDV reflex testing began, 9, 191 HBsAg tests were performed, with 58 HBsAg positive. There were 53 reflex HDV Ab tests performed, with 3 (5.9%) HDV Ab positive. Only one HDV RNA test was successfully performed because the patient who was still hospitalized and was a negative test. The other 2 patients were lost to follow-up and HDV RNA test was not performed.
Conclusion: : Automating EMR based screening for HBV, HCV, HIV and HDV has been a successful approach to integrating and scaling up BBV screening in a community hospital. A pilot reflex HDV testing algorithm was effective for completing HDV Ab tests, but obtaining

manual HDV RNA testing which was not as successful. This emphasizes the need for double reflex HDV testing. Integrating automated EMR testing across blood borne viruses will be critical to reduce liver cancer rates and address public health burden of syndemics.

WED-434

Cost-effectiveness analysis of hepatitis B vaccination policy for newborns in Taiwan

Chia Ling Hsieh[1], Vivian Chia-Rong Hsieh[2], Meng Lun Hsieh[3]. *[1]China Medical University, Taichung City, Taiwan; [2]China Medical University, Taichung, Taiwan; [3]Taichung Veterans General Hospital, Taichung City, Taiwan*
Email: morganpolo@gmail.com

Background and aims: Taiwan was the first in the world to implement universal hepatitis B vaccination for newborns, with proven success in reducing hepatitis B virus (HBV) seroprevalence and childhood hepatocellular carcinoma. However, children born to highly infectious mothers still have a 10% chance of becoming HBV carriers. In 2019, the vaccination policy was revised to administer the first dose of HBV vaccination and hepatitis B immunoglobulin (HBIG) within 24 hours after birth for babies born to hepatitis B surface antigen (HBsAg)-positive mothers. Infants born to HBsAg-negative mothers would still receive the first dose of HBV vaccination. This study seeks to assess the cost-effectiveness of the 2019 HBV vaccination policy (for HBsAg-positive mothers) in comparison to the prior policy, which involved administering HBIG and the first vaccine dose within 24 hours only in HBsAg-positive and hepatitis B e antigen (HBeAg)-positive mothers.
Method: From the payer perspective, a cost-effectiveness model was developed using a decision-tree followed by Markov cohort analysis. The decision-tree captured the different vaccination scenarios based on the infection status (HBeAg and HBsAg) of pregnant mothers and babies under the two vaccination policies. Those that moved through the decision-tree were simulated until 81 years of age with each cycle representing one year. Parameter values were extracted from published literature, including vaccine coverage, effectiveness, and transition probabilities between health states. Our main outcome measures included the incremental cost-effectiveness ratio (ICER) and incremental cost-utility ratio (ICUR), utilizing life-years (LYs) and quality-adjusted life years (QALYs), respectively. Discount rate of 3% was used on both costs and effectiveness measures. One-way and probabilistic sensitivity analyses were performed to test the robustness of model results. TreeAge Pro 2019 version 1.1 (TreeAge Software Inc.) was used to develop the model and simulate the results.
Results: Our findings suggest that compared with the prior policy, the current policy had 248 more susceptible (uninfected) HBV cases, 16 more immune tolerant cases, 3 more cases of inactive carrier, 4 more chronic hepatitis B cases, and 6 more deaths. Baseline ICER value was -USD702.49 per LY gained and baseline ICUR value was -USD1, 393.14 per QALY gained. Sensitivity analysis revealed that results were most sensitive to vaccine effectiveness and coverage in newborns born to HBsAg-positive and HBeAg-negative mothers in the previous policy. Monte Carlo analysis showed that 100% of ICERs fell in the fourth quadrant and below the willingness-to-pay threshold of USD25, 933.59.
Conclusion: The current HBV vaccination policy for newborns may offer better value for money compared to the previous policy with more targeted population.

WED-435

Prevalence of active hepatitis delta infection among new diagnoses of hepatitis B in the Barcelona metropolitan area

Jesús Trejo Zahinos[1], Francisco Rodríguez-Frías[2,3], Marcos Belsol[4], Susana Bernalte[1], Ricard Riel[5], Camila Picchio[6], Maria Francesca Cortese[1,7,8], David Tabernero[1,7,8], Maria Buti[7,8], Ariadna Rando-Segura[1,2,8]. *[1]Department of Microbiology, Vall d'Hebron University Hospital, Barcelona, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain; [3]Liver Unit, Vall d'Hebron University Hospital, Barcelona, Spain; [4]Department of Microbiology, Vall d'Hebron University Hospital, Barcelona, Spain; [5]Primary Care Barcelona, Barcelona, Spain; [6]Barcelona Institute for Global Health (ISGlobal), Clinic Hospital, Barcelona, Spain; [7]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd). Instituto de Salud Carlos III, Madrid, Spain; [8]Liver Unit, Vall d'Hebron University Hospital, Barcelona, Spain*
Email: ariadna.rando@vallhebron.cat

Background and aims: The WHO estimates that hepatitis D virus (HDV) affects approximately 5% of individuals with chronic Hepatitis B virus (HBV) infection worldwide. However, this prevalence may be higher especially in certain geographical areas where the availability of serological tests for the detection of anti-HDV may limited. The aim of this study was to estimate the prevalence of HDV and the proportion of patients with active HDV infection among new HBV diagnoses.
Method: Descriptive study conducted in the clinical laboratories of Vall d'Hebron Hospital (which serves 75% of the Barcelona metropolitan area) between January 2022 and November 2023. Throughout this period, all newly diagnosed HBV cases underwent reflex serological screening for HDV antibodies (LIAISON®XL MUREX Anti-HDV), and if positive, a determination of HDV RNA (in-house PCR, lower limit of quantification 5.75 × 10E2) was performed.
Results: A total of 704 individuals with a newly diagnosed HBV cases were detected (323 cases in primary healthcare, 361 in hospital healthcare and 20 in addiction centers and prisons). Serological screening for HDV was performed in 96.3% (678/704) of them. The overall prevalence of anti-HDV positivity in newly diagnosed HBV cases was 5.3%, and globally 1.6% had an active HDV infection (RNA HDV+, 30.5% if considering the only HDV patients). However, the prevalence was not homogeneous across healthcare levels being higher in addiction centers and prisons (16, 7%, 3/18 anti-HDV tested cases) and hospital healthcare (5.4%, 19/349) than primary healthcare (4.5%, 14/311).
Conclusion: The prevalence of HDV among new diagnoses of HBV in the Barcelona city area was 5.3% (as globally estimated by the WHO), with 30.5% of anti-HDV with active HDV infection (HDV RNA +). However, the prevalence varies depending on the healthcare center considered. More newly diagnosed cases had to be included to confirm the results. Study supported by the Gilead-AEEH Grant for Microelimination Projects in Hepatitis C and Hepatitis D Epidemiology, Code: GLD2023/52.

WED-436

HCV reinfection among people who use drugs (PWUD) treated for HCV infection: a long-term view

Brian Conway[1,2], Rossitta Yung[1], Shawn Sharma[1], Shana Yi[1], Saina Beitari[1]. *[1]Vancouver Infectious Diseases Centre, Vancouver, Canada; [2]Simon Fraser University, Burnaby, Canada*
Email: brian.conway@vidc.ca

Background and aims: Comprehensive programs of care for priority populations such as PWUD are needed to eliminate HCV infection as a public health concern by 2030. A primary challenge associated with such initiatives is the need for effective strategies to mitigate the risk of reinfection. Meta-analyses suggest a reinfection rate of approximately 5 per 100 person-years (py) among key populations. The objective of this analysis is to assess reinfection rates among

populations of PWUD successfully treated for HCV infection and subsequently maintained in long-term follow-up within a multidisciplinary program of care.
Method: In our program, we provide HCV therapy to PWUD within the context of a comprehensive, multidisciplinary program addressing all medical, social, mental health and addiction-related needs with strategies designed to maximize adherence. Once HCV cure has been documented, patients continue to be integrated in care. This includes individualized addiction care, provision of safe supply and education about safer practices to reduce the risk of reinfection. HCV RNA testing is repeated annually, or more frequently if clinically indicated. We conducted an ongoing, prospective evaluation of the last 305 successful courses of HCV therapy administered to PWUD in our center to determine the rate of HCV reinfection and its correlates.
Results: The inception cohort consisted of 291 individuals who were cured of HCV infection between 03/19–10/23. We document median age 47 (22–83) years, 28.2% female, 20.1% identifying as indigenous, 41.2% unstably housed, and 92.2% continuing active drug use (mostly fentanyl). We documented 10 cases of reinfection with a rate of 3.3 cases per 100 person-years. Of these 10 reinfected patients, 2 were female, 2 identified as indigenous, and all were experiencing unstable housing and ongoing drug use.
Conclusion: Even within a very vulnerable group of individuals with a high risk of HCV reinfection, our program with systematic and comprehensive approaches to reduce the risk of reinfection are associated with rates below 5/100 py. As we treat increasing numbers of individuals who are more vulnerable, strategies such as the ones we have implemented will be important in maximizing the benefits of HCV therapy in these priority populations.

WED-437
Viral hepatitis elimination: scale up now to avert the worst yet to come

Devin Razavi-Shearer[1], Ivane Gamkrelidze[1], Kathryn Razavi-Shearer[1], Alexis Voeller[1], Samantha Hall[1], Homie Razavi[1]. [1]*Center for Disease Analysis Foundation, Lafayette, United States*
Email: drazavishearer@cdafound.org

Background and aims: We aim to estimate the impact of all countries meeting the WHO 2030 programmatic targets of 90% diagnosis rate, 80% treated, 90% three-dose coverage, and 90% birth dose coverage on morbidity and mortality due to hepatitis B virus (HBV) and hepatitis C virus (HCV) at the global level through 2050.
Method: The results of a literature review and Delphi process were integrated into country-specific PRoGReSs and Bright Models for the HBV and HCV analyses respectively. These Markov models utilize country specific inputs to estimate the natural history of the disease and future burden. Where prevalence data were unavailable, regional averages were applied to the total population of a country. The elimination scenario was developed for each country, assuming a major scale up in diagnosis, treatment and vaccination would start in 2024.
Results: 170 country level HBV and 117 HCV models were available. In 2015, it was estimated that there were 2.79 million new HBV and HCV chronic infections, with 51% due to HBV; 989, 000 incident cases of hepatocellular carcinoma (HCC), with 81% due to HBV, and 1.27 million deaths due to HBV and HCV, with 80% of them being due to HBV. If current trends in diagnosis and treatment continue, incidence is projected to decrease through 2050, with 2.20 new infections in 2030 and 2.23 million in 2050. The share of incident cases due to HBV is expected to decrease to 19.4% by 2050 as a result of current vaccination programs. Without additional interventions the incident number of cases of HCC are expected to increase through 2050, 1.27 million in 2030 and 1.35 million in 2050. The share of incident HCC due to HBV is expected to increase to 84.6% by 2050. Similarly, deaths will increase to 1.61 million in 2030 and 1.76 million in 2050, with HBV's share increasing to 83.8% in 2050. Deaths due to HBV and HCV are expected to peak at 1.82 million in 2043. If the 2030 programmatic targets are met, we estimate that through 2050 there will be 47.5 million new chronic cases averted, 29.7% due to HBV; 13.2 million incident cases of HCC averted, 69.0% due to HBV; and 20.6 million lives saved, 71.6% due to HBV.
Conclusion: We have a relatively short window, 20 years, to save the greatest number of lives from HBV and HCV. While prevention is an integral part of elimination, most people dying in this timespan were infected decades ago. This study further highlights the immediate need to drastically scale up diagnosis and treatment along with vaccination in areas where it remains suboptimal.

WED-438-YI
Real-world based cost effectiveness analysis of entecavir versus tenofovir on prognosis of hepatitis B virus-related hepatocellular carcinoma after curative hepatectomy

Chun-Ting Ho[1], Chien-Wei Su[2], Elise Chia-Hui Tan[3], Yi-Hsiang Huang[4,5], Ming-Chih Hou[4,6], Jaw-Ching Wu[7]. [1]*Taipei Veterans General Hospital, Taipei, Taiwan;* [2]*Department of General Medicine, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan;* [3]*Department of Health Service Administration, College of Public Health, China Medical University, Taichung, Taiwan;* [4]*Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan;* [5]*School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan;* [6]*School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan;* [7]*Institute of Clinical Medicine, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan*
Email: elisetam.g@gmail.com

Background and aims: For patients with hepatitis B virus (HBV) related hepatocellular carcinoma (HCC), antiviral therapies could reduce the risk of recurrence and improve overall survival (OS) after resection. Entecavir (ETV), tenofovir disoproxil fumarate (TDF), and tenofovir alafenamide (TAF) are currently recommended as first-line antiviral agents in clinical practice guidelines for patients with CHB. However, there is still controversy about whether TAF, TDF and ETV have different effects on clinical outcomes and costs. We aimed to compare the cost and effectiveness among ETV, TDF, and TAF treatment for patients with HBV-related HCC after hepatectomy.
Method: This was a retrospective cohort study compared TAF, TDF and ETV in terms of cost and effectiveness in real-world setting. Patients received either ETV, TDF or TAF at least 28 defined daily dose (DDD) and continued their initial treatment regimen during the study period without change. The liver-related direct medical costs, life-years (LYs), quality-adjusted life-years (QALYs) and Incremental cost-effectiveness ratio (ICER) were estimated. We took the perspective of healthcare payer in Taiwan.
Results: A total of 1, 494 patients were identified during 2010–2020 and the median follow-up was 2.15 years (IQR: 1.39–2.94). After adjusted baseline characteristics, compared to ETV, HCC patients who received TDF (HR: 0.99; 95% CI: 0.72–1.35) or TAF (adj-HR: 0.97; 95% CI: 0.67–1.41) had similar risk of recurrence after hepatectomy. However, compared to ETV, patients who received TAF had a lower risk of all-cause death (adj-HR: 0.50; 95% CI: 0.28–0.80). TAF (US$11, 516 ± 14, 537) had significant lower direct medical cost, compared to ETV (US$12, 882 ± 18, 496) and TDF (US$13, 146 ± 15, 185).
Compared to TAF, patients used ETV and TDF had higher health benefit in terms of LYs and QALY and increased medical cost. The ICER per QALY gained were US$3, 538 for ETV and US$5, 405 for TDF. When using US$9, 000 as the WTP threshold, the probability of ETV and TDF being cost-effectiveness was 100% and 96.1%, respectively. Both ETV, TDF, and TAF showed the similar health benefits in terms of RFS. However, TAF had better OS. The cost-effectiveness analysis found, compared to TAF, ETV and TDF have the ICERs of US$3, 160 and US$5, 405 for the treatment of HCC patient after hepatectomy in Taiwan.
Conclusion: Both ETV and TDF could be considered the cost-effective option, although they had a poorer OS compared to TAF therapy. Compared with previous trial-based CE studies, the results could

reflect the value of antiviral therapy in a real-world setting which can improve the shared decision-making of clinicians and patients.

WED-439

Linkage of anti-HCV reactive persons to HCV care and treatment services in Georgia

Vladimer Getia[1], Rania Tohme[2], Sophia Surguladze[3], Shaun Shadaker[2], Maia Tsereteli[1], Ekaterine Adamia[1], Amiran Gamkrelidze[4], Irina Tskhomelidze[3]. *[1]National Center for Disease Control and Public Health (NCDC), Tbilisi, Georgia; [2]Centers for Disease Control and Prevention, Atlanta, United States; [3]The Task Force for Global Health, Tbilisi, Georgia, Tbilisi, Georgia; [4]University of Georgia, School of Health Sciences, Tbilisi, Georgia*
Email: irinkatskhomelidze@gmail.com

Background and aims: As of October 31, 2023, 78.6% (approximately 2.23 million) of Georgia's adult population has been screened for hepatitis C virus (HCV) infection. However, linkage to care remains a challenge; approximately 13% of individuals who tested reactive for anti-HCV have not undergone viremia testing. Furthermore, 15% of individuals with confirmed current HCV infection have not initiated treatment. In light of this, the National Center for Disease Control implemented a program to promote linkage to care for persons who have been lost to follow-up before receiving viremia testing or HCV treatment. The program aimed to link ≥70% of individuals who tested anti-HCV reactive to viremia testing and ≥50% of those with current infection to treatment.
Method: Key strategies of this initiative included the distribution of reminder text messages, the formation of mobile teams for conducting home-based blood collection, and the provision of lists to healthcare facilities to expedite the treatment process for those who have not yet started. Adults (age ≥18 years) who had not been linked to care more than three months after a reactive antibody or viremia test were contacted by patient navigators via text messaging and phone calls or home visits, guiding them towards HCV viremia testing or treatment. A maximum of two contact attempts were made per person. Navigators received incentives for successfully linking patients to care.
Results: During October 2021–October 2023, a total of 20, 497 adults were identified who had a reactive anti-HCV test but were not linked to viremia testing within 3 months of screening, 18, 063 (88.1%) had valid phone numbers in the HCV screening database, and of those 14, 180 (78.5%) could be reached. The remaining 3, 883 could not be reached, had moved, or emigrated. Of those contacted, 3, 790 (26.7%) presented for viremia testing, including 868 reached by mobile blood collection teams. Overall, 1, 881 (49.6%) of those tested were positive for HCV RNA or core antigen, and 1, 122 (59.6%) of them initiated HCV treatment. From that same period, 14, 397 adults previously diagnosed with current HCV infection were not linked to treatment. Of them, 13, 076 (90.8%), had valid phone numbers, of whom 6, 989 (53.4%) could be reached and 1, 604 (23.0%) initiated treatment. An additional 2, 422 (34.7%) of those reached agreed to be treated but did not enroll in the program.
Conclusion: While the efforts to combat hepatitis C in Georgia have led to significant progress, these results highlight the need for more effective strategies to link diagnosed individuals to care. Developing more engaging patient outreach programs, using novel strategies and clearly communicating the importance of treatment are essential steps towards achieving hepatitis C elimination targets in Georgia.

WED-440

Community-based interventions to increase hepatitis B virus and hepatitic C virus infections screening among at-risk migrant and refugee populations in Italy, Greece, and Spain: 1-year results of the VH-COMSAVAC project

Email: camila.picchio@isglobal.org

Background and aims: Migrants residing in Europe and originating from regions with a mid/high prevalence of hepatitis B (HBV) and hepatitis C (HCV) might be unaware of their status due to the inadequacy of testing and vaccination in their home countries or complicated care pathways in their host countries. Additionally, they can suffer structural and legal barriers to accessing healthcare which leads to an underutilization of services. Viral hepatitis Community Screening, Vaccination, and Care (VH-COMSAVAC) is an ongoing EU co-funded project in Italy, Greece, and Spain which aims to scale-up and implement community-based HBV and HCV testing models of care among migrants and refugees with documented mid/high incidence and prevalence using simplified diagnostic tools and person-centred referral processes.
Method: Between 11/2022–12/2023, viral hepatitis testing was offered to 470 people across four locations (Athens, Barcelona, Madrid, and Milan). Testing in community settings used HBV surface antigen (HBsAg) and anti-HCV rapid lateral flow tests. Each setting structured their care pathways according to operational and legal feasibility. In Barcelona, direct referral for positive cases and whole blood sample collection using a plasma separation cards were provided during community screenings. In Madrid, Milan and Athens, participants were referred for follow-up at collaborating centers to ensure linkage to care, regardless of their status. Community health workers and intercultural mediators supported screening interventions in Spain.
Results: 470 participants were included for analysis, with a median age of 39 years (IQR = 28–49). They were primarily male (71.3%) from Ghana (29.2%), Guinea (8.7%) and Albania (8.3%), and 41.7% arrived to the EU <5 years ago. Most participants had never been tested for HBV nor HCV (58.3%). 8.3% of participants reported being fully vaccinated against HBV. Less than half (43.0%) knew what HBV and/or HCV was. HBsAg+ prevalence was 7.0% (95% CI: 4.7%–9.3%) and anti-HCV+ prevalence was 2.6% (95% CI: 1.3%–4.4%). Migrants residing in Italy showed the highest HBsAg+ prevalence (10.0%), followed by Spain (7.1%), and Greece (6.3%). No anti-HCV+ cases were observed in Italy and three in Spain (1.1%), whereas Greece reported a prevalence of 5.7%. HBsAg+ prevalence was not associated with any risk factor, but anti-HCV+ was associated with multiple sex partners, drug use and unprotected sex ($p < 0.05$).
Conclusion: Community based strategies which are culturally and linguistically appropriate and offer viral hepatitis screening, provide effective models for identifying and providing care to migrant and refugee populations at high risk of HBV and HCV infections who may

otherwise not engage in care, which aligns with the 2030 WHO hepatitis elimination goal.

WED-441-YI

Precise estimation of national HBV prevalence: the importance of double hepatitis B surface antigen and hepatitis B core antibody testing in low endemic countries

Arno Furquim d'Almeida[1], Erwin Ho[1], Christian Schüttler[2], Philippe Beutels[3], Pierre Van Damme[4], Niel Hens[3,5], Heidi Theeten[4], Thomas Vanwolleghem[1,6]. *[1]Viral Hepatitis Research Group, Laboratory of Experimental Medicine and Pediatrics, University of Antwerp, Antwerp, Belgium; [2]Institute of Medical Virology, National Reference Center for Hepatitis B Viruses and Hepatitis D Viruses, Justus Liebig University, Giessen, Germany; [3]Centre for Health Economics Research and Modelling of Infectious Diseases (CHERMID), Vaccine and Infectious Disease Institute (VAXINFECTIO), University of Antwerp, Antwerp, Belgium; [4]Centre for the Evaluation of Vaccination, Vaccine and Infectious Disease Institute (VAXINFECTIO), University of Antwerp, Antwerp, Belgium; [5]Data Science Institute, Interuniversity Institute for Biostatistics and statistical Bioinformatics (I-BioStat), University of Hasselt, Hasselt, Belgium; [6]Department of Gastroenterology and Hepatology, Antwerp University Hospital, Antwerp, Belgium*
Email: arno.furquimdalmeida@uantwerpen.be

Background and aims: In light of the WHO viral hepatitis elimination targets set for 2030, robust and repetitive age-specific HBV prevalence studies are needed. Previous HBV prevalence studies reported a hepatitis B surface antigen (HBsAg) prevalence of 0.7% (1993/1994) and 0.66% (2003) in Belgium. However, automated HBsAg assays are typically designed to be oversensitive and might result in an overestimation of the HBV prevalence. Here, we examine the Belgian HBV seroprevalence in adults and investigate the difference in HBV seroprevalence estimates using either HBsAg positivity alone or hepatitis B core antibodies (anti-HBc) HBsAg double positivity as criterium for HBV infection.

Method: 3840 residual serum samples were collected from adult ambulatory patients in 10 private diagnostic laboratories-geographically representing the whole country-during Q2/Q3 2020 (outside the COVID-19 lockdown). The number of samples in each laboratory was stratified per region, age group (10-year age bands) and sex. HBsAg and anti-HBc were analyzed on automated analyzers (Abbott Alinity I). For HBsAg positive anti-HBc negative samples, anti-HBc confirmatory assays were performed by an independent laboratory. The samples were weighted by comparing the sample and population frequencies by sex, 10-year age band and province.

Results: HBsAg was detected in 27/3840 samples, resulting in a weighted HBsAg seroprevalence of 0.69% (95% CI 0.43%–1.04%). However, 15/27 HBsAg positive samples were anti-HBc negative and thus serodiscordant. Independent hepatitis B core antigen neutralization assays revealed that all 15 serodiscordant samples were truly anti-HBc negative, thereby confirming a significant HBsAg false positivity rate for HBV infections of 55.6%. Therefore, a weighted national HBV seroprevalence, based on HBsAg and anti-HBc double positivity, of 0.27% (95% CI 0.13%–0.49%) was obtained. The weighted age-specific seroprevalence ranged from 0.20% (95% CI 0.01%–0.87%) in the 40–49 age group to 0.91% (95% CI 0.32%–1.97%) in the 60–69 age group. There were no double positive samples in the age groups 20–29, 30–39, 80–89 and >90. Although, 8/12 (66.7%) of the double positive samples originated from males, there was no statistically significant difference between sexes ($p = 0.07$). Since 164/3840 (4.27%) samples were anti-HBc positive, we estimate that 4.37% (95% CI 3.65%–5.18%) of the Belgian population had a past HBV exposure.

Conclusion: This population-based nationwide study estimates a Belgian HBV seroprevalence, based on HBsAg and anti-HBc double positivity, of 0.27% (95% CI 0.13%–0.49%) in 2020. Our results illustrate that HBV prevalence based on HBsAg positivity alone overestimates the number of infections due to a high false positivity of automated HBsAg assays. In low-endemic countries, confirmatory anti-HBc testing is therefore advocated to correctly assess the HBV prevalence.

WED-442

Decreasing trend of hepatitis C in homeless people between 2019–2023: a retrospective study in Madrid, Spain

Daniel Sepúlveda-Crespo[1,2], Pablo Ryan[2,3,4,5], Jorge Valencia[3,6], Rafael Amigot-Sánchez[1], Helena Codina[1], Guillermo Cuevas[3], Jeffrey V Lazarus[7,8], Felipe Pérez-García[2,9,10], Isidoro Martínez[1,2], Salvador Resino Garcia[1,2]. *[1]Unidad de Infección e Viral e Inmunidad, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain; [2]Centro de Investigación Biomédica en Red en Enfermedades Infecciosas (CIBERINFEC), Instituto de Salud Carlos III, Madrid, Spain; [3]Hospital Universitario Infanta Leonor, Madrid, Spain; [4]Universidad Complutense de Madrid (UCM), Madrid, Spain; [5]Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Madrid, Spain; [6]Unidad de Reducción de Daños "SMASD", Madrid, Spain; [7]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, Universidad de Barcelona, Barcelona, Spain; [8]CUNY Graduate School of Public Health and Health Policy (CUNY SPH), New York, United States; [9]Hospital Universitario Príncipe de Asturias, Asturias, Spain; [10]Universidad de Alcalá, Madrid, Spain*
Email: danisecre@hotmail.com

Background and aims: Micro-elimination strategies for hepatitis C, targeting high-risk populations such as people who are homeless, aim to efficiently prevent and treat the disease, contributing to national elimination goals by addressing specific risk factors and barriers to medical care. Implementation of point-of-care HCV RNA testing is key to testing and treatment programs, evaluating cures, and monitoring hepatitis C reinfection. The objective of this study was to estimate the prevalence, associated risk factors, and temporal trend of HCV active infection among the homeless population in Madrid, Spain.

Method: A retrospective study was conducted in Madrid, Spain, spanning from 2019 to 2023 and involving 2, 709 homeless individuals. Participants were recruited through a mobile screening unit with consecutive enrollment based on the order of appearance. The inclusion of homeless people was carried out on the street or in homeless shelters. Screening involved a rapid HCV antibody test followed by HCV RNA testing using Xpert HCV VL Fingerstick. Data were analyzed using logistic regression, and p values were adjusted for multiple testing using the false discovery rate (q-values).

Results: The prevalence of HCV active infection during the study period was 6.3% (from 7.2% in 2019 to 3.4% in 2023; p value = 0.039). The main risk factors for active HCV infection included being an injecting drug user (IDU), encompassing both non-active IDU (adjusted odds ratio (aOR) = 13.1; q-value<0.001) and active IDU in the last year (aOR = 31; q-value<0.001), having no economic income (aOR = 1.8; q-value = 0.015), and alcohol consumption (aOR = 1.8; q-value = 0.004). From 2019 to 2023, there was a significant decrease in the prevalence of HCV active infection across the entire population (from 7.2% to 3.4%, p value = 0.039), among IDU (from 25.3% to 9.4%, p value = 0.040), alcohol consumers (from 12.2% to 6.4%, p value<0.001), and those with no economic income (from 7.0% to 4.4%, p value = 0.033).

Conclusion: Among homeless individuals, IDU was highlighted as the primary risk factor for active HCV infection, followed by other significant factors such as lack of economic income and alcohol consumption. The significant decline in HCV infection rates across the entire population and among major risk groups during the study period suggests the effectiveness of preventive policies in reducing the prevalence of HCV among the homeless population.

WED-443-YI

Usability and acceptability of blood-based hepatitis C virus self-testing (HCVST) among the urban slum population in northern India

Ajeet Bhadoria[1], Kathirvel Selv[2], Rajesh Somvanshi[3], Amrita Mehndiratta[4]. [1]*All India Institute of Medical Sciences Rishikesh, Near Barrage, RISHIKESH, India;* [2]*PGI Chandigarh, Chandigarh, India;* [3]*District Viral Hepatitis Management Unit, Haridwar, India;* [4]*All India Institute of Medical Sciences Rishikesh, Rishikesh, India*
Email: ajeetsinghbhadoria@gmail.com

Background and aims: People living in urban slums are disproportionally affected by hepatitis C virus (HCV) infection and many remain undiagnosed. World Health Organization (WHO) has recommended Hepatitis C virus self-testing (HCVST) as an additional testing strategy that could help to expand access to HCV testing. We conducted a study to document the usability and acceptability of blood-based HCVST among the general population residing in urban slums in Northern India.
Method: We conducted a cross-sectional study nested within a Cluster Randomized Control Trial (CTRI/2023/07/054590) between July–Dec 2023 at urban slums of Haridwar district in Northern India. As a secondary objective we evaluated the feasibility of blood-based HCV self-testing among lay users in two urban primary health centers (UPHCs). The study assessed ease of use (usability) by measuring error rates, user-reported difficulties, and agreement between self-interpretations and interpretations by trained personnel (inter-reader concordance) and between self-tests and tests performed by trained personnel (inter-operator concordance). Acceptability was assessed through a semi-structured interview examining participants' responses to contrived test results ("positive", "negative", and "invalid").
Results: Among 392 participants with mean age 39.7 ± 15.9 years, 56% were females, 23% had education up to primary school or lower and 70% were married. Blood-based HCVST proved highly acceptable among people living in urban slums. While some timekeeping and reading mistakes within the allotted time occurred, most participants successfully performed the tests. There was a strong association between lower education level and observed errors (95% vs 72%; $p < 0.001$). The vast majority, however, expressed high acceptability: 98.3% said they'd use HCV self-testing again, and 97.9% would recommend it to others. Inter-reader and inter-operator concordance were 96.9% (kappa: 0.91) and 98.7% (kappa: 0.94), respectively.
Conclusion: Our study demonstrates that blood-based HCVST are highly acceptable among the general population living in urban slums with satisfactory ability to conduct the tests and interpret the results and TRcould be a very useful additional testing strategy with current testing options. However, more research is needed to determine the most effective way to integrate it with existing facility-based testing to improve access to HCV diagnosis across the country.

WED-444

The burden of chronic hepatitis delta in Italy: potential impacts and effects of bulevirtide through cost of illness and cost consequence analysis

Background and aims: Chronic hepatitis delta virus (HDV) causes the most severe form of viral hepatitis in humans. The purpose of the study was to determine the costs incurred by the National Health Service (NHS) and society due to HDV in Italy, as well as to understand the costs and effects of the introduction of bulevirtide for the treatment of Chronic Hepatitis Delta.
Method: The economic impact of HDV infection was estimated through a cost of illness analysis (COI), while the costs and effects of the introduction of bulevirtide for the treatment of chronic HDV were estimated via a cost-consequence analysis (CCA). The analyses were carried out on a hypothetical cohort of 1000 adult patients with compensated liver disease and a mean age of 45 years over a 10 year time horizon. For the cost consequence analysis, bulevirtide vs no bulevirtide scenarios were compared; pegylated interferon-alpha and best supportive care (BSC) were included in the treatment mix. The analyses were conducted from the NHS perspective and societal perspective. Both direct and indirect costs were included in the model: direct costs considered were healthcare resource utilization costs, monitoring costs and adverse events costs, while indirect costs included total loss of productivity caused by HDV infection. Health outcomes included life years (LYs), quality-adjusted life years (QALYs) and deaths avoided. A discount rate of 3 percent was applied for both costs and health outcomes.
Results: The COI estimated a 10 year economic burden of 27, 455, 757 euros for the management of patients with HDV in Italy. The estimated cost saving of introducing bulevirtide was 1, 557, 994 euros, for a total expenditure of 25, 897, 763 euros. In terms of changes in health outcomes over the 10 years, LYs gained increased by 6.6 percent, QALYs gained increased by 8.7 percent, and the number of deaths were reduced by 12 percent.
Conclusion: Over 10 years, the estimated economic burden of HDV infection for 1000 adult patients was approximately 27 million euros. However, the introduction of bulevirtide resulted in a cost reduction, associated with an increase in LYs and QALYs and a significant decrease in death rate. This study's assessment of burden incurred by the NHS and society in managing HDV infection in Italy indicates that investing in bulevirtide appears to significantly alleviate the clinical and economic burden associated with HDV infection, while increasing morbidity and mortality.

Email: valeriorosato@gmail.com

Background and aims: Direct oral anticoagulants (DOACs) are generally recommended for the management of thrombosis and atrial fibrillation. As substrates of cytochrome P450 (CYP) 3A4 and/or P-glycoprotein, they are implicated in potential co-medicaction drug-drug interactions. NS5A/NS5B inhibitors are hepatitis C direct-acting agents (DAAs) that exert a mild inhibition of p-glycoprotein without effects on CYP3A4, but, theoretically, may lead to an increased risk of bleeding. On this purpose, we retrospectively evaluated the risk of vascular adverse events (bleeding and thrombosis) among HCV patients under DOACs/DAAs therapy.
Method: Patients receiving sofosbuvir-based HCV regimens and DOAC between may 2017 and April 2023 in 12 Italian medical centers were consecutively enrolled. Baseline characteristics, especially on bleeding risk and liver function, were collected. Primary end point of the study was the occurrence of bleeding events, classified as major and minor, thromboembolic events and DAAs viral outcomes. Finally, the DOAC/DAA group was compared with a cohort of patients, matched by demographic characteristics (age and sex), that switched to warfarin during antiviral treatment.
Results: Of 104 total patients, 38 (36, 5%) were cirrhotic, diagnosed by liver stiffness or, when not possible, by clinical characteristics. Sofosbuvir/velpatasvir (78, 8%) was the most commonly prescribed DAA and rivaroxaban (35, 6%) most frequent DOAC, followed by apixaban (26, 9%), dabigatran (19, 2%) and edoxaban (18, 3%). The main indication for anticoagulant therapy was atrial fibrillation (76%). All patients were already receiving DOACs before the start of DAAs. No major bleeding events were recorded. On the contrary, four minor bleeding events occurred during concomitant DOAC/DAA treatment, but none caused DAA or DOAC discontinuation. In order to evaluate the risk factors associated to bleeding events an univariate analysis was performed. The antiplatelet therapy was the only additional risk factors statistically related to bleeding events with a hazard ratio (HR) of 13-fold higher. Moreover, the antiplatelet therapy, evaluated by LOGIT binomial analysis with demographic characteristics, remained statistically associated to bleeding events, leading to a HR of 20-fold higher.
By comparing the main population with the warfarin switched matched cohort, composed by 104 patients matched for demographic charateristics, no significant differences were found in the rate of clinical relevant bleeding. A single major bleeding-event leading to anticoagulation and DAAs discontinuation was reported.
Conclusion: In our study, the concomitant use of NS5A/NS5B inhibitors with DOAC showed a good safety, highlighting the concomitant antiplatelet therapy as the only risk factor associated to bleeding events. These findings support the use of DOAC during sofosbuvir-based HCV treatment.

WED-447

Age at incident cirrhosis among individuals with hepatitis C virus infection: a United States administrative claims analysis

Laura Telep[1], Catherine Frenette[1], Amanda Singer[1], Sundaresan Murugesan[1], Anand Chokkalingam[1], Bruce Kreter[1], Steven Flamm[2]. [1]*Gilead Sciences, Foster City, United States;* [2]*Rush University Medical Center, Chicago, United States*
Email: laura.telep@gilead.com

Background and aims: The United States (US) Centers for Disease Control and Prevention (CDC) reports that the incidence of hepatitis C virus (HCV) infection has increased substantially since 2013, due largely to injection drug use. Given that the development of cirrhosis is associated with cumulative exposure to HCV infection, it may be less likely to occur in younger individuals with HCV. Pre-treatment requirements of cirrhosis assessment in this population may serve as a barrier to treatment initiation. The goal of this study is to examine the incidence and age distribution of cirrhosis in a large US administrative claims dataset among in people with HCV to support the simplification of pre-treatment requirements for those in younger age groups.
Method: A retrospective observational cohort study was conducted with the IQVIA PharMetrics Plus™ database which contains adjudicated medical and pharmacy claims for commercially insured individuals in the US. Index date, the first inpatient or first of two outpatient claims for HCV at least 30 days apart, occurred between 2016 and 2022. Included individuals were adults (18+ years) with continuous enrollment for 365 days prior and at least 1 day of follow-up after the index date, and no evidence of cirrhosis, liver decompensation, or direct-acting antiviral (DAA) treatment at baseline. The incidence rate (IR) of cirrhosis with 95% confidence intervals (CI) was calculated for individuals stratified by index date age group (in 5-year strata). In addition, the age distribution at time of incident cirrhosis was examined by study year, and over the whole study period. Important sub-populations including people who inject drugs (PWID), have evidence of alcohol abuse, or are coinfected with HBV or HIV were also examined.
Results: Among 68, 744 individuals with HCV who met all inclusion/exclusion criteria, 10, 678 (15.5%) were under 35 years. Over the entire study period, 9, 471 claims for incident cirrhosis were recorded. The IR in all age group strata <35 years ranged from 0.8–1.5 per 100 person years (PY), compared to 2.4–10.6 per 100 PY in strata ≥35 years. Each year from 2017 to 2022, the proportion of individuals <35 years with incident cirrhosis was ≤3.5% (range 1.9–3.5%). Over the entire study period, 2.4% of incident claims occurred in this group. The proportion of patients <35 years with cirrhosis claims was similarly low in subgroups of patients with alcohol abuse (4.6%), HBV coinfection (3.0%), and HIV coinfection (0%) in 2017–2019, with similar proportions during the pandemic 2020–2022. The proportion of PWID <35 years with cirrhosis claims was slightly higher at 9.9% in 2017–2019 and 5.5% in 2020–2022.
Conclusion: Cirrhosis in individuals <35 years was uncommon and occurred most frequently in PWID. Due to the benefits of DAA regimens, treatment of younger individuals should be considered without evaluation of cirrhosis status to increase treatment uptake.

WED-448

Peak mortality is on the horizon: will we flatten the curve?

Devin Razavi-Shearer[1], Ivane Gamkrelidze[1], Kathryn Razavi-Shearer[1], Alexis Voeller[1], Samantha Hall[1], Homie Razavi[1]. [1]*Center for Disease Analysis Foundation, Lafayette, United States*
Email: drazavishearer@cdafound.org

Background and aims: This study aims to estimate liver related deaths due to hepatitis B virus (HBV) and hepatitis C virus (HCV) at the global level through 2050 if current trends in diagnosis and treatment continues. Secondarily, a scenario was developed to examine the impact of all countries meeting the 2030 targets of 90% diagnosis rate and 80% of those diagnosed being on treatment.
Method: Historical number of HCC and cirrhosis cases attributed to HBV and HCV were collected when available. In the remaining countries PRoGReSs and Bright Markov models were used to estimate historical viral hepatitis morbidity and associated mortality. The models utilized country specific inputs to estimate the natural history of the disease and future burden (2022–2050). The results were reviewed with national experts to check the absolute number forecasts and trends. Where HCV and HBV prevalence data were unavailable, regional averages were applied to the total population of the country. The elimination scenario was developed for each country, assuming a major scale up in diagnosis and treatment starting in 2024 to meet the WHO 2030 elimination targets.
Results: 170 country level HBV and 117 HCV models were available. In 2015, it was estimated that there were 1.27 million deaths due to HBV and HCV, with 79.5% of them being due to HBV. Total deaths are expected to increase until 2043 when deaths will peak at 1.82 million with 84.4% due to HBV. After this point, deaths attributed to HBV begin to decline as a result of global vaccination programs and all-cause mortality. Deaths due to HCV declined from 2015 to 2020, but this was largely driven by the Egyptian elimination program. Without

additional intervention HCV deaths are expected to increase through 2050. If the programmatic targets are met by 2030, we estimate that there will be 5.8 million lives saved among people living with HCV, and 14.7 million lives saved among people living with HBV.
Conclusion: We have a relatively short window, 20 years, to save the greatest number of lives from HBV and HCV. While prevention is an integral part of elimination, the majority of people dying in this timespan were infected decades ago. This study further highlights the immediate need to drastically scale up diagnosis and treatment.

WED-449
Advancing HCV elimination: emergency department screening beyond risk factors
Anny Camelo Castillo[1], Teresa Maria Jordan Madrid[1], Antonio Duarte Carazo[1], Manuel Rodriguez Maresca[1], Teresa Cabezas Fernandez[1], Alba Carrodeguas[2], José Luis Vega Sáenz[1], Marta Casado-Martin[1]. *[1]Torrecárdenas University Hospital, Almería, Spain; [2]Gilead Sciences, Madrid, Spain*
Email: anjo134@gmail.com

Background and aims: Spain may be one of the first countries to achieve the World Health Organization's goal of eliminating viral hepatitis C by 2030. A serosurvey by the Spanish Ministry of Health 2017–2018 estimated a 0.22% hepatitis C virus (HCV) active infection prevalence among the general population and the guideline recommends hepatitis C screening only in people with exposures or risk situations for Hepatitis C Virus (HCV) infection. However, we know that many of the people who were infected years ago do not meet the screening criteria, so following these guidelines recommendations, many patients with HCV infection would remain undiagnosed. We aimed evaluate HCV screening efficacy in the Emergency Department (ED) of Torrecárdenas University Hospital (Almería, Spain) and identify the prevalence of exposures and risk situations for HCV infection in patients with active HCV infection.
Method: We implemented opportunistic HCV screening in the ED (FOCUS Program), using existing infrastructure and staff since August 2021. With the "one-step strategy", HCV antibodies were detected in adults (between 18 and 69 years old) who needed blood-work for any reason, and then viral RNA was quantified in positive anti-HCV patients. We contacted positive patients to ensure linkage to care, recording any previous history of exposures or situations of risk of HCV infection.
Results: We screened 19110 patients from August 2021 to December 2023, finding 310 anti-HCV positive patients (average age 56 ± 8 y.o, 75% male) and 69 HCV RNA positive patients (83% males).
With these data, the seroprevalence rate in the population attending our hospital's emergency department is 1.62%, and the active infection rate is 0.36%. Of the total number of patients with active infection, 56 (81%) were linked to care and 36 (52%) of these started antiviral treatment. A large percentage of viremic patients had stage F3-F4 liver cirrhosis, indicating a late diagnosis in the course of their HCV infection. We identified exposures or risk situations in 50% of the medical records of viremic patients. The most common were injecting or inhaling drug use (44%), immigrant status (9%), a history of incarceration (8%), and HIV/HBV co-infection (2%) were the main ones. 78% of patients with active HCV infection had a previous visit to the ED and 89% had a previous visit to primary care.
Conclusion: Undocumented HCV infection among our population is higher that estimated in the Spanish population. Half of the patients diagnosed in our ED do not report exposures or risk situations for HCV infection, so following the recommendations of the current screening guideline they would never have been diagnosed. Therefore, Hepatitis C screening in EDs beyond the criteria set out in the screening guideline should be reconsidered as an effective strategy to increase the rate of diagnosis for the elimination of Hepatitis C.

WED-450
Long term outcome among HCV-infected people who use drugs (PWUD) successfully treated for HCV infection with Glecaprevir/Pibrentasvir (G/P)
Brian Conway[1,2], Rossitta Yung[1], Shawn Sharma[3], Shana Yi[4], Saina Beitari[4]. *[1]Vancouver Infectious Diseases Centre, Vancouver, Canada; [2]Simon Fraser University, Burnaby, Canada; [3]Vancouver Infectious Diseases Centre, Vancouver, Canada; [4]Vancouver Infectious Diseases Centre, Vancouver, Canada*
Email: brian.conway@vidc.ca

Background and aims: An increasing number of studies have demonstrated the efficacy of HCV therapy in all priority populations, including active PWUD. Within our GRAND PLAN study, we documented a cure rate of 97.3% (108/111 participants) among a population of active PWUD consisting largely of fentanyl users with unstable housing. There is an interest in determining if the benefit of therapy is preserved over time in this population of vulnerable individuals at high risk of adverse outcomes, including reinfection and death, the latter in the context of an opioid crisis with 6–7 deaths/day in the most affected population in our community.
Method: The inception cohort consisted of 108 individuals cured within the GRAND PLAN study. After HCV cure was achieved participants were maintained in follow-up within a multidisciplinary program of care, to attend to medical, social, mental health and addiction-related needs. This includes systematic monitoring for reinfection, provision of opiate agonist therapy and safe supply and education about safer drug use practices. The outcome of this analysis was survival and rate of reinfection.
Results: Among 108 subjects, we note: median age 47 (22–75) years, 27.8% female, 21.3% Indigenous, 97.2% active drug use, 46.7% with unstable housing. Over a follow-up of 30 (12–60) months, 104 (96.3%) remained alive, and 4 individuals died of an opioid overdose (rate 1.7/100 py). Of the 104 remaining participants, 6 (5.8%) were re-infected (rate 1.8/100 py). All 6 have recently initiated therapy and outcomes of repeat therapy are pending.
Conclusion: Beyond our ability to successfully treat HCV infection in vulnerable inner-city populations, there is a need to maximize the benefit of therapy after a cure has been achieved, especially in the setting of the opioid crisis. Our data suggests that by maintaining these individuals in care post-SVR, our program leads to a reduction in overdose deaths, a systematic detection of reinfection events and prompt re-initiation of HCV therapy when it is required.

WED-451-YI
Characterizing hepatitis B virus infection in children and household contacts in the Democratic Republic of Congo to inform elimination efforts in a resource-limited setting
Camille Morgan[1], Kimberly Powers[1], Jessie Edwards[1], Marcel Yotebieng[2], Michael Emch[1], Stane Biju[1], Upasana Devkota[1], Gavin Cloherty[3], Feng-Chang Lin[1], Jérémie Muwonga[4], Melchior Kashamuka[5], Antoinette Tshefu[5], Sylvia Becker-Drepps[1], Jonathan B. Parr[1], Peyton Thompson[1]. *[1]University of North Carolina at Chapel Hill, Chapel Hill, United States; [2]Albert Einstein College of Medicine, Bronx, United States; [3]Abbott Diagnostics, Abbott Park, United States; [4]Programme National de Lutte Contre le SIDA, Kinshasa, Congo, Dem. Republic of (formally known as Zaire); [5]École de Santé Publique, Université de Kinshasa, Kinshasa, Congo, Dem. Republic of (formally known as Zaire)*
Email: camille_morgan@med.unc.edu

Background and aims: Despite global reductions in hepatitis B virus (HBV) prevalence, an estimated 6.3 million children are infected globally, two-thirds of whom live in Africa. In the Democratic Republic of Congo (DRC), HBV prevalence of all ages is 3 to 5%, implying an estimated 3–5 million chronic infections where hepatology care is virtually inaccessible. The three-dose infant HBV vaccine was first introduced in DRC in 2007 (now within the pentavalent vaccine) and remains one of the only nationally

programmed HBV prevention measures. To inform elimination efforts in resource-constrained settings like the DRC, an improved understanding of HBV epidemiology, particularly among children, is needed.
Method: Using the most recent (2013–14) nationally representative Demographic and Health Survey in DRC, we analysed >8, 000 biospecimens and associated survey data to characterize HBV surface antigen (HBsAg) prevalence and associated factors among children 0–5 years old. HBsAg testing using dried blood spots (DBS) was performed on the Abbott ARCHITECT platform. We also performed HBsAg testing on all adult samples from all households of HBsAg-positive children and on adults in a random 3:1 selection of households without HBsAg-positive children.
Results: We analysed DBS and survey data from 7, 036 children and 1, 091 household members. Among children 0–5 years, weighted HBsAg prevalence was 1.3% (95% CI: 1.0%, 1.6%), with substantial regional variation of 0% to 6% across 26 provinces. HBsAg prevalence among boys (1.8%; 95% CI: 1.2%, 2.6%) was double that of girls (0.8%, 95% CI: 0.5%, 1.4%). HBsAg prevalence did not decrease with decreasing age, counter to what might be expected with improved vaccine roll-out. HBV prevalence was higher among children with *Plasmodium falciparum* malaria compared with children without (1.7% vs 1.1%). Negative tetanus antibodies (proxy for pentavalent vaccination), male sex, rural locale, lower household wealth, and living in nearly all regions outside the capital city's province, Kinshasa, were statistically significantly associated with higher HBsAg prevalence among children. Adults living with HBsAg-positive children had 14.7 (95% CI: 3.5, 25.8) more HBsAg cases per 100 persons compared with those not living with HBsAg-positive children.
Conclusion: DRC remains far from HBV elimination goals of 0.1% prevalence among children, with no evidence of decreasing HBsAg prevalence with declining age, and prevalence above 6% in large rural regions of DRC. Higher prevalence in rural areas and remote provinces could suggest challenges with widespread vaccine implementation. Higher prevalence in boys indicates biological or social factors (e.g. circumcision) for follow-up investigation. This study highlights specific groups and areas for targeted HBV prevention efforts in DRC.

WED-452
Implementing a hepatitis C virus patient search identification tool in primary care settings

Amber Copeland[1], Sarah Montague[1], Stephen D Ryder[1]. [1]*Nottingham University Hospitals NHS Trust, Queen's Medical Centre, Nottingham, United Kingdom*
Email: amber.copeland@nuh.nhs.uk

Background and aims: For England to declare hepatitis C (HCV) elimination by 2025, prevalence in Primary Care must be established. A Patient Search Identification (PSI) tool organised and funded by Merck, Sharp and Dohme (UK) (MSD), to support NHS England's (NHSE) HCV Elimination Strategy, uses a pre-installed search tool on general practice (GP) systems to identify patients coded as positive or at risk for HCV. This enables Operational Delivery Networks (ODNs) to find the estimated 81, 000 missing patients.
Method: Management of this project required one full time post who worked with MSD and a Primary Care Network (PCN) to demonstrate the tool, arrange Data Sharing Agreements, search lists and run testing. The ODN compared PCN HCV positive lists (PL) to hospital records and the national HCV treatment registry to confirm previous treatment, clearance and who needed confirmatory testing. 105 patients from the PL (36.21%) did not need a test. Due to large volumes of patients on the at-risk list (ARL), risks identifying patients as less likely to have ever had a test were prioritised into 'phase 1'. Patients needing a test in the PL and those in 'phase 1' were offered testing, via letter, at their GP and directed to the NHSE/PreventX online testing portal for home-test. Online survey feedback was requested from staff and patients.
Results: In a PCN population (7 GPs) of 65, 807, 290 patients were recorded as HCV positive and 11, 205 at risk. To date 2 of 7 GP's hosted 2 testing events each. 41 patients from HCV PL and 670 from the ARL were invited. Of 711 invited, 68 (9.5%) received a Blood Borne Virus (BBV) screen, 2 of which unsuccessfully tried using a home-test. Results showed; 1 HCV RNA Positive (Lost to Care) (LTC), 1 HIV Ab Positive, 4 HBsAg Positive (1 LTC, 1 false positive). Uptake of GP testing was largest in the ethnicity risk group (83.8%). 643 (90.5%) patients did not attend their GP for a test. It is unknown how many used the home-test. Feedback suggests patients ($N = 25$) were unsure why they had been offered a test. They were hesitant to take a home test, but were satisfied with testing at the GP. Staff ($N = 1$) reported high levels of satisfaction. These actions resulted: 99 patient records required updating due to improper coding and two system search errors were fixed by the MSD team. Concerns around information sharing had prevented other PCN's running the tool. An information governance document to allay concerns was created by NHSE/ODN detailing direct care.
Conclusion: The PSI tool was deployed in a PCN of 7 GP's. The tool is implementable at scale and has an important potential yield as we aim for elimination by enabling the ODN to engage a new group of patients and find those previously LTC. Though quick to run, analysis and recall of patients is time consuming but led to innovative use of technology to save time and increase reach, e.g. text invites. Phase 2 of inviting ARL patients and testing in the remaining GPs will be implemented.

WED-453
Reasons patients with hepatitis B and C declined linkage to care and strategies for re-engaging this reachable cohort

Jihae Jeon[1], Francina Collado[1], Anna Mageras[2], Aura Blanco[1], Tasnim Bhuiyan[1], Lidia Funes[1], Daryin Hummel[1], Daemena Leocadio[1], De Shaunda Page-Cook[1], Lismeiry Paulino[1], Douglas T Dieterich[1]. [1]*Icahn School of Medicine at Mount Sinai, New York, United States;* [2]*Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, New York, United States*
Email: jihae.jeon@mssm.edu

Background and aims: In our large, urban hospital system, we identified patients who declined linkage to viral hepatitis care. Few studies have examined pre-appointment declines in detail, especially drawing on direct conversations. We aimed to describe reasons for and analyze factors associated with declining linkage to care in our system.
Method: From 1/2019 to 12/2023, our patient navigators received lists of patients who engaged with our health system the week prior and whose most recent HCV RNA result was positive. From 9/2022 to 12/2023, they also reached out to patients who were HBsAg-positive. Navigators contacted patients by phone and patient portal to offer liver appointments and documented their encounters and outcomes in REDCap. We summarized this data and, using multivariable logistic regression, assessed factors (age, sex, race, ethnicity, active patient portal, and Medicaid insurance) for possible association with declined care.
Results: Among 186 HBsAg+ patients contacted, 142 (76%) were linked, 28 (15%) lost to follow-up, and 16 (9%) declined, reasons being: upset about outreach (6), unknown (4), not a priority (3), deferring care (1), negative interaction with health system (1). Patient navigators reached out to 1, 834 patients with an HCV RNA+ result. Of these, 430 (24%) were linked to a first liver visit, 542 (30%) had no/incorrect contact information, 538 (29%) did not respond, 130 (7%) stopped responding after initial contact, and 194 (11%) declined linkage. Reasons for declining were: deferring care (48), not a priority (35), old/too ill from other conditions (30), upset over outreach (29), unknown (24), finances (11), did not recall screening visit (6), transportation (5), negative interaction with health system (5), bad experience with interferon (1). Persons who declined HCV linkage had higher odds than those who accepted care of being female (OR =

1.70, 95% CI: 1.16, 2.51), being commercially insured (OR = 2.34; 95% CI: 1.58, 3.48), and having no patient portal (OR = 2.28; 95% CI: 1.49, 3.49). Black patients had almost half the odds of whites of declining care (OR = 0.53; 95% CI: 0.32, 0.87).
Conclusion: Potential explanations for regression results include women prioritizing caretaker responsibilities and commercially insured patients' concerns about copays. For patients with long-past diagnoses, navigator scripts should explain delayed follow-up and include details of the screening visit to reduce patient anger. We plan to follow-up with patients who were upset about phone outreach via letter/patient portal, in case they are more receptive to these media, and include information about financial assistance and new drugs. Mental health support for navigators can reduce burnout from fraught conversations. We also plan to deploy novel education approaches, including videos in multiple languages. We re-open cases after 6 months in case patient priorities have shifted.

WED-454-YI
Accessing healthcare: perspectives of people who use drugs
Zoi Papalamprakopoulou[1,2], Elisavet Ntagianta[3], Vasiliki Triantafyllou[3], George Kalamitsis[3], Arpan Dharia[1], Suzanne Dickerson[4], Angelos Hatzakis[2,5], Andrew Talal[1]. *[1]Division of Gastroenterology, Hepatology, and Nutrition, Jacobs School of Medicine and Biomedical Sciences, University at Buffalo, Buffalo, NY, United States; [2]Hellenic Scientific Society for the Study of AIDS, Sexually Transmitted and Emerging Diseases, Athens, Greece; [3]Hellenic Liver Patient Association "Prometheus", Athens, Greece; [4]Division of Biobehavioral Health and Clinical Science, School of Nursing, University at Buffalo, Buffalo, NY, United States; [5]Department of Hygiene, Epidemiology and Medical Statistics, National and Kapodistrian University of Athens, Athens, Greece*
Email: zoipapal@buffalo.edu

Background and aims: People who use drugs (PWUD) have the highest hepatitis C virus (HCV) incidence and prevalence. This population should be prioritized in HCV elimination programs. PWUD typically avoid conventional healthcare settings due to stigma and shunning. We aimed to comprehend how PWUD in Athens, Greece access healthcare by exploring their experiences, attitudes, and beliefs related to their interactions with the healthcare system. We also sought to identify barriers and facilitators in the process of accessing and navigating conventional healthcare settings.
Method: Between May and September 2023, we conducted nine focus group discussions (FGDs) in Athens, Greece each comprised of 4 to 9 participants (N = 57) recruited through purposive sampling. Inclusion criteria required age at least 18 years, a history of injection drug use, internet access, Greek verbal fluency, and the ability to provide informed consent. The FGDs were conducted using a semi-structured interview guide, audio-recorded, transcribed, translated into English, and de-identified. We analyzed FGD transcripts using grounded theory.
Results: Participants' mean (SD) age was 47.9 (8.9) years, 89.5% (51/57) were male, 91.2% (52/57) were of Greek origin, and 61.4% (35/57) had attended at least 10 years of school. Three main themes emerged from the FGDs: (1) seeking care after an individuals' rapid health decline, (2) encountering barriers when seeking healthcare, and (3) recommending processes to build trust in healthcare providers and institutions. Participants shared personal experiences of rapid deterioration in their health and disclosed a variety of approaches used to access healthcare. Encountering barriers when seeking medical care included delayed access to healthcare, facing stigma in healthcare settings, mistrusting the healthcare system, and addressing competing priorities, such as homelessness, poor mental health, and substance use withdrawal. Building trust in healthcare was facilitated by stigma minimization, empathy encountered in the patient-provider relationship, and engagement of community organizations.
Conclusion: PWUD in Athens, Greece, described healthcare access challenges due to stigma, mistrust of the healthcare system, and competing priorities. Important considerations for building trust in healthcare settings are the curtailment of stigma, an empathetic medical approach, and the engagement of community organizations in healthcare delivery. Addressing these issues is critical to increase healthcare access among PWUD to ultimately enhance HCV elimination efforts.

WED-455
Sex disparities in initiation of direct-acting antivirals for hepatitis C treatment: data from the French national healthcare database (2014–2022, ANRS FANTASIO 2 study)
Clémence Ramier[1], Cécile Brouard[2], Vincent Di Beo[1], Yoann Allier[3], Abbas Mourad[1], Morgane Bureau[1], Philippe Sogni[4,5,6], Sylvie Deuffic-Burban[7], Marc Bourliere[1,8], Patrizia Carrieri[1], Camelia Protopopescu[1], Benjamin Rolland[9,10,11,12], Fabienne Marcellin[1]. *[1]Aix Marseille Univ, Inserm, IRD, SESSTIM, Sciences Economiques and Sociales de la Santé and Traitement de l'Information Médicale, ISSPAM, Marseille, France; [2]Santé publique France, Saint Maurice, France; [3]ANRS | Maladies Infectieuses Emergentes, Paris, France; [4]Université Paris Descartes, Paris, France; [5]INSERM U1223, Institut Pasteur, Paris, France; [6]Service d'Hépatologie, hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Paris, France; [7]Université Paris Cité and Université Sorbonne Paris Nord, Inserm, IAME, Paris, France; [8]Hôpital St Joseph, Service d'Hépato-Gastroentérologie, Marseille, France; [9]PSYR, CNRL, INSERM U1028, CNRS UMR5292, UCBL1, Bron, France; [10]Université Claude Bernard Lyon 1, Lyon, France; [11]Centre Hospitalier Le Vinatier, Bron, France; [12]Service Universitaire d'Addictologie de Lyon (SUAL), HCL, CH Le Vinatier, Lyon, France*
Email: clemence.ramier@inserm.fr

Background and aims: Eradication of hepatitis C by 2025 is a national public health objective in France. To achieve this target, universal access to direct-acting antivirals (DAA) was set up in August 2017 in the country. National surveillance data showed sex disparities in both hepatitis C screening and prevalence, with more women undergoing screening tests and less women diagnosed with chronic hepatitis C. Sex disparities were also found in access to hepatitis C treatment for specific populations, such as people who inject drugs, with less women initiating therapy. Using data from the French national healthcare database (SNDS), we explored potential sex disparities in DAA initiation before and after universal access.
Method: The study population included all adult individuals with chronic hepatitis C residing in metropolitan France between January 2014 (date of DAA arrival) and December 2022 (up-to-date records in the SNDS). Analyses were performed separately on two study periods: before August 2017 (period 1) and after August 2017 (period 2). The study outcome was defined as the time between the baseline of each period and DAA initiation (i.e., first delivery of DAA recorded in the SNDS). Incidence rates of DAA initiation were compared between men and women in the two periods. Cox proportional hazards models were used to test for potential sex disparities in DAA initiation in both periods, after adjustment for age, social vulnerability (benefiting from free complementary health insurance or state medical assistance), as well as disease stage and comorbidities justifying eligibility to DAA treatment before 2017. Comorbidities were identified using standard algorithms developed by the French national health insurance fund (Cnam).
Results: The study population included 152,165 individuals (38.4% of women, 75.7% aged 30 to 64 years) of whom 100,313 initiated DAA treatment between 2014 and 2022 (39.5% of women, 78.4% aged 30 to 64 years). The incidence rate of DAA initiation [95% confidence interval (CI)] was significantly lower in women than in men in period 1 (30.8 [30.4–31.2] vs 33.1 [32.8–33.5] per 100 person-years (PY)) and significantly higher in women than in men in period 2 (22.3 [22.0–22.6] vs 18.6 [18.4–18.8] per 100 PY). Multivariable models showed significant sex disparities in DAA initiation, with adjusted hazard

ratios [95% CI] for women (ref. men) at 0.91 [0.89–0.92] for period 1, and 1.06 [1.04–1.08] for period 2.
Conclusion: DAA initiation was delayed for women before universal access in France, but significantly improved after removal of eligibility criteria for treatment initiation. Differences between men and women in both risk factors of disease progression and use of healthcare services may partially explain these findings. Further research is needed to document potential sex disparities in DAA initiation in specific subpopulations of individuals with chronic hepatitis C.

WED-456
Implementation of an Electronic Medical Record-Based Automatic Alert System for the Care Cascade of Hepatitis-C-Virus Infection in Patients Undergoing Elective Surgery
Jae Seung Lee[1], Ho Soo Chun[2], Hye Won Lee[1], Mi Na Kim[1], Beom Kyung Kim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1], Seung Up Kim[1]. *[1]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Ewha Womans University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: The care cascade for hepatitis C virus (HCV) faces a significant obstacle due to poor awareness, especially in patients undergoing elective surgery. To address this issue, we introduced an electronic medical record (EMR)-based automatic alert system in 2021 to enhance the awareness among surgical healthcare providers regarding HCV screening and referral rates.
Method: Implemented in a tertiary medical center in South Korea, the system alerts surgeons to order preoperative anti-HCV antibody tests, and if needed, consult hepatologists at discharge for patients undergoing elective surgery.
Results: After implementation, the system significantly increased HCV screening rate for 76, 310 patients, compared with 129, 065 patients undergoing surgery between 2016 and 2020 (82·8–96·8%, $P < 0·001$). Out of 73, 834 patients who were tested for anti-HCV antibody, the system alerted 12, 048 (16·3%) patients. However, out of 463 patients who tested positive for anti-HCV antibody after system implementation, only 42 (15·3%) out of 275 (59·4%) who required consultation were referred to hepatologists. Linkage failure was associated with other surgery departments than hepatobiliary and transplant surgery departments (odds ratio [OR] = 5·940, 95% confidence interval [CI], 3·080–12·410, $P < 0·001$) and shorter hospitalization duration (OR = 0·980, 95% CI, 0·950–0·990, $P = 0·012$).
Conclusion: Although EMR-based automatic alert system was effective in increasing HCV screening for patients undergoing elective surgery; however, it could not link them to care cascade in surgery departments. Combining more proactive approaches, such as reflex testing or a call-back strategy, would be beneficial.

WED-457-YI
Eliminating hcv infection from prisons in Sicily: the sintesi project (*)
Lorenza Di Marco[1,2,3], Fabio Cartabellotta[4,5], Fabio Santangelo[3], Fabrizio Scalici[3,6], Rosario Insinna[3,6], Tullio Prestileo[3,7], Maria Giovanna Minissale[3,4], Vincenza Calvaruso[3,8], Antonio Craxi[3], Vito Di Marco[3,8]. *[1]Department of Oncology and Hematology, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy; [2]Clinical and Experimental Medicine PhD Program, University of Modena and Reggio Emilia, Modena, Italy; [3]SIcilian Network for Therapy, Epidemiology and Screening In Hepatology (SINTESI), Palermo, Italy; [4]Department of Medicine Buccheri -La Ferla Hospital, Palermo, Italy; [5]SIcilian Network for Therapy, Epidemiology and Screening In Hepatology (SINTESI), Palermo, Italy; [6]Medical Area of the "Pagliarelli-Lorusso" Prison, Palermo, Italy; [7]UOSD Infectious Pathologies of Vulnerable Populations, ARNAS-Civico Hospital, Palermo, Italy; [8]Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties (PROMISE), University of Palermo, Palermo, Italy*
Email: vito.dimarco@unipa.it

Background and aims: In all countries HCV among prisoners has a higher prevalence than in the general population. Specific models of screening and linkage to care are needed to improve the care cascade.
Method: The SIcilian Network for Therapy, Epidemiology and Screening In Hepatology (SINTESI) run an HCV point-of-care project in all 23 prisons of Sicily. All prisoners received information on HCV screening and the possibility of receiving treatment with Direct Acting Antiviral (DAA) while incarcerated. HCV status was assessed by screening all subjects for anti-HCV by rapid oral test (OraQuick HCV) and immediate reflex testing for HCV-RNA (GeneXpert-HCV Viral Load, Cepheid). HCV RNA positive subjects received DAA therapy within 72 hours of screening. All prisoners signed an informed consent to use personal data. Chi-square test was used to analyze differences between groups.
Results: Among 5, 912 prisoners (98% of entire prison population) informed of the screening project, 4, 911 (83%) accepted to undergo HCV testing. The mean age was 42 years (range 18–86) and 95.8% was males. Non-Italian origin accounted for 12.2% of prisoners (3.7% other EU countries, 7.5% Africa, 0.6% Asia and 0.2% South America). Overall, 245 subjects (5%) testes anti HCV positive, with a prevalence of 4.9% among males and 6.7% among females ($p = 0.25$). We evaluated the risk of drug addiction in subjects with HCV infection in a prison. A prevalence of 25% (25/99) was found among PWUDs on opioid substitution, as compared to 2.9% (30/1, 040) in non-PWUDs ($p < 0.0001$). Among 245 anti HCV positive prisoners, 20 refused to be tested for HCV-RNA, 100 tested negative (80 had a history of viral clearance under previous DAA treatment while 20 did not report previous therapy for HCV) and 125 were HCV-RNA positive. Twelve of the latter refused treatment, while 113 started a cycle of DAAs while incarcerated. Among 56 subjects assessable for SVR, 55 (98%) obtained HCV clearance.
Conclusion: In Sicily, HCV infection is 4 times more common among people in prison than in the general population mostly due to parenteral drug use. Half of the prisoners with a positive screening were unaware of their HCV status and only 32% had received DAAs previously. A one-shot HCV test-and-treat point-of-care approach is highly effective in this setting. (*) The project was approved by the Regional Department of Health and the Regional Department of Prisons and was funded by HCV STAT (Simplification and Test and Treat Strategies toward HCV Elimination) program of Gilead Sciences.

WED-458
Low testing rates but high prevalence of hepatitis delta virus in Saudi Arabia
Faisal M Sanai[1], Khalid A Alswat[2], Mohammed A Babatin[3], Duna Barakeh[4], Majed Almaghrabi[1], Ahmed Saati[1], Adnan Alzanbagi[5], Faisal Abaalkhail[4], Mona H Ismail[6], Hani Tamim[7], Abdullah S Alghamdi[8], Jabir A Alzaidi[3], Asma AlNajjar[4], Abdulaziz Tashkandi[5], Waleed K Al-Hamoudi[4], Norah Jamal Alromaih[6], Habeeb I.A. Razack[2], Saleh A Alqahtani[4]. *[1]King Abdulaziz Medical City, Jeddah, Saudi Arabia; [2]King Saud University, Riyadh, Saudi Arabia; [3]King Fahd General Hospital, Jeddah, Saudi Arabia; [4]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; [5]King Abdullah Medical City, Makkah, Saudi Arabia; [6]King Fahd Hospital of the University, AlKhobar, Saudi Arabia; [7]Alfaisal University, Riyadh, Saudi Arabia; [8]King Fahad General Hospital, Jeddah, Saudi Arabia*
Email: drsaleh.a.alqahtani@gmail.com

Background and aims: Hepatitis delta virus (HDV) significantly impacts public health, often co-infecting with hepatitis B virus (HBV) or superinfecting chronic HBV carriers. Despite its clinical importance, there is a lack of comprehensive data on HDV prevalence, particularly in the Middle East and specifically in Saudi Arabia (SA). This study aimed to fill this gap by investigating the prevalence of

HDV in SA, evaluating HDV testing practices in clinical settings, and exploring the clinicodemographic profile of affected patients.
Method: This retrospective, observational study involved the chart review of consecutive, adult or adolescent (>14 years) patients positive for anti-HBsAg across six medical centers in SA from 2012 to 2022. We assessed anti-HDV seroprevalence in these patients and evaluated various risk factors, comorbidities liver biochemistry (serum biomarkers), and fibrosis stages (by transient elastography).
Results: Among the 2173 HBV-infected patients (mean age 48.3 ± 14.6 years and 60.9% male), 794 (36.5%) patients were tested for anti-HDV. The prevalence of HDV was 8.8% (68 out of 776) among HBsAg-positive patients. Of those who tested positive for anti-HDV, 47.1% (32 out of 68) underwent HDV RNA testing, with 32% (10 out of 32) testing positive. Age, gender, alkaline phosphatase, and albumin level were significantly associated with anti-HDV positivity (all $p < 0.05$). However, no significant correlation was observed with comorbidities like hypertension, diabetes, or dyslipidemia. Notably, HDV co-infected patients exhibited higher rates of advanced fibrosis (stages ≥F3) compared to those with HBV monoinfection (26.9% vs. 15.0%, $p = 0.028$).
Conclusion: The study reveals a relatively high prevalence of anti-HDV among tested patients in SA, with HDV co-infected individuals exhibiting more severe liver disease than those with HBV mono-infection. These findings underscore the need to enhance HDV serological testing, including reflex testing for HDV RNA, across SA to improve the diagnosis and management of this infection.

WED-459-YI
Opt-out hepatitis B testing in urban emergency departments, linkage to healthcare and clinical outcomes

Jonathan Durban[1], Shiny Jaimes[1], Sally Thomas[1], Nina van Zyl[1], Noeleen Bennett[1], Hannah Hesketh[1], Helen Boothman[1], Nick Tatman[1], Markus Gess[2], Sarah Clark[1], Daniel Forton[1]. [1]*St George's University Hospitals NHS Foundation Trust, London, United Kingdom;* [2]*KINGSTON Hospital NHS Foundation Trust, London, United Kingdom*
Email: daniel.forton@nhs.net

Background and aims: Chronic hepatitis B infection (CHB) remains an underdiagnosed condition in the UK. In 2022 the national health service (NHS) in England commissioned opt out emergency department (ED) testing for blood borne viruses (HIV and hepatitis B and C) in regions with a high prevalence of HIV. We report the initial clinical outcomes for hepatitis B (HBV) testing in the 5 EDs in SW London.
Method: All adults undergoing blood tests in EDs had BBV testing, including HBV surface antigen (HBsAg) unless they opted out. Testing information was displayed using widely positioned posters in EDs. The only change to patient flow in the ED was an additional vial of blood taken for BBV testing. All reactive HBsAg results were managed by the SW London Hepatitis Network. We analyzed all data for testing and follow-up between November 2022 and October 2023, as the 5 EDs commenced testing sequentially.
Results: There were 356, 204 adult ED attendances during the testing periods in the 5 EDs. 211, 438 adults had blood tests. 106, 624 adults were tested for HBsAg and 620 had reactive tests giving a CHB prevalence of 0.58% in the tested population. Of these 232 were new diagnoses, 213 were known cases under care, 101 were known but lost to follow-up (LTFU) and 74 remain unknown as contact has not been made. A dedicated team have made successful contact with 540/620 patients (236 at second attempt, 136 at third). 204 of the new diagnoses have now had diagnostic counselling and an assessment by an HBV nurse specialist and 186 (111 M; 75 F) have had medical review. 177/186 (95%) have a country of birth outside of the UK (38% Africa, 18% South Asia, 10% other Asia, 22% South and East Europe, 6% other Europe). The median age was 52 in men, 49 in women, range (19–88) years. 180 patients (97%) were eAg-ve, only 2 patients eAg+ve and 4 were false positives. The median viral load was 611 IU/ml (Q1 25–78, Q2 78–611, Q3 611–370, Q4 370–12×10^6). The median liver stiffness was 5.1kPa (Q1 2.5–4.2, Q2 4.2–5.1, Q3 5.1–6.1, Q4 5.1–20) and CAP was 242 dB/m^2 (Q1 100–212, Q2 212–242, Q3 242–281, Q4 281–392). 30% had a CAP > 275, indicating a high prevalence of concomitant steatosis. 51 patients (27%) were judged to have eAg-ve chronic HBV with a treatment indication and 41 commenced nucleotide therapy. There were no incident cases of hepatocellular carcinoma, 3 patients had positive delta serology. Overall linkage to care for new and LTFU patients was 76%.
Conclusion: In this urban population, at least 37% of detected CHB were new diagnoses in a very mixed ethnic population, with a high proportion having a treatment indication. ED testing is a highly effective method to increase HBV diagnoses and re-engage LTFU patients but requires significant dedicated resource for testing, diagnostic counselling, clinical assessment, and maintenance of engagement. Culturally sensitive, community-based arrangements for ongoing engagement with this cohort will be required.

WED-462
Characteristics of a prospective cohort undergoing assessment for hepatitis C treatment in London and time to treatment initiation

Kathleen Bryce[1,2], Amy Teague[1], Fiona Burns[1,2], Colette Smith[2], Alison Rodger[1,2], Douglas Macdonald[1,3]. [1]*Royal Free London NHS Foundation Trust, London, United Kingdom;* [2]*Institute for Global Health, University College London, London, United Kingdom;* [3]*Institute of Liver and Digestive Health, University College London, London, United Kingdom*
Email: kathleenbryce@doctors.org.uk

Background and aims: The characteristics of individuals living with untreated hepatitis C in the UK have not been well-described and this limits the ability of clinical teams to address barriers to care. We aimed to characterise a cohort of people undergoing assessment for hepatitis C direct-acting antiviral (DAA) treatment and measure time to treatment initiation.
Method: We conducted a prospective cohort study including individuals attending a nurse-led assessment in drug services and hospital clinics in North London between May and December 2022. Baseline questionnaires were self-completed on paper or electronically via a tablet device on the day of assessment and follow-up (by linkage to a clinical patient management system) was for at least three months. Questionnaires collected data on socioeconomic status, drug and alcohol use and mental health, previous experiences of accessing hepatitis C care, beliefs about DAA treatment and experiences of stigma. A descriptive analysis was performed.
Results: Clinic non-attendance was 48% (54/113) but study acceptance was high at 86% (43 of 50 individuals approached to participate). Of the 39 study participants who returned a questionnaire, 67% were male, mean (range) age was 52 (27–86) years, 56% were UK-born, 23% unstably housed, 56% did not always have money for basic needs and 59% of these were severely food insecure (by the Household Food Insecurity Access Scale). Over half (56%) had a mental health diagnosis, 43% had PHQ9 scores consistent with depression and 38% had GAD7 scores in keeping with anxiety. 16% had an AUDIT score suggestive of higher risk drinking. Almost a third (31%) were diagnosed via ED opt-out testing and 21% had previously missed an appointment or declined hepatitis C treatment. 41% reported perceived stigma relating to hepatitis C. Over 90% believed that DAA treatment would be of benefit but 66% thought that it would have side effects and 54% that treatment would require a liver biopsy. The majority (87%) started DAA treatment during follow-up and the median time from assessment to treatment start was 47.5 days (IQR 41, range 13–184). Almost all (97%) of these completed treatment and (of those who had at least three months of follow-up available after completion), 55% (11/20) had a recorded sustained virological response (SVR) check, all with viral cure.
Conclusion: This small cohort demonstrates that factors previously shown to be associated with disengagement from hepatitis C care are highly prevalent in those attending assessment for treatment. Subsequent treatment initiation and completion rates in participants

were high, highlighting the inherent ascertainment bias that complicates prospective studies of patient disengagement. The high non-attendance rate emphasises that greater efforts are needed to enable engagement with care amongst people experiencing barriers to access.

WED-463

Implementation of the educate, test, and treat outreach model in Shabu village, Nigeria: lessons learned

Riham Soliman[1], Ibrahim Alhassan[2], Ruth Bello[3], Akpan Nse[4], Ayman Hassan[5], Ahmed Farahat[6], Ahmed Salem[6], Amr Taha[7], Ramy Sabry[6], Ahmed Geith[6], Ahmed Elshawaf[6], Nabiel Mikhail[8], Gamal Shiha[9]. *[1]Tropical Medicine Dept., Faculty of Medicine, Port Said University, Egyptian Liver Research Institute and Hospital (ELRIAH), Mansoura, Egypt; [2]Department of Public Health, Ministry of Health, Nasrwa, Nigeria; [3]Dalhatu Araf specialist Hospital, Lafia, Nasrwa, Nigeria; [4]Department of Public Health, Ministry of Health, Nasarawa state, Nasarawa, Nigeria; [5]Egyptian Liver Research Institute and Hospital (ELRIAH), Higher Institute of Applied Medical Sciences, Mansoura, Egypt; [6]Egyptian Liver Research Institute and Hospital (ELRIAH), Mansoura, Egypt; [7]Egyptian Liver Research Institute and Hospital (ELRIAH, Mansoura; [8]Egyptian Liver Research Institute and Hospital (ELRIAH), Biostatistics and Cancer Epidemiology Department, South Egypt Cancer Institute, Assuit University, Mansoura, Egypt; [9]Hepatology and Gastroenterology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, Egyptian Liver Research Institute and Hospital (ELRIAH), Mansoura, Egypt*
Email: g_shiha@hotmail.com

Background and aims: More than 90% of people living with hepatitis B and C in Africa lack much needed care with at least 200 000 deaths a year [1] Our aim was to assess the feasibility of application of the "Educate, Test and Treat" outreach model in an African village setting [2].

Method: This work was done from 6th to 17th December 2023 in Shabu Village, Nasarawa State, Nigeria, as a collaborative work between Association of Liver Patients Care (ALPC), African Liver Patients' Association (ALPA), African Scientific, Research and Innovation Council (ASRIC) and Nasarawa State Health Authorities. The village was divided into enumerated segments, assigning each resident a distinct identification number ranging from 1 to 3002. Concurrently, individuals were scheduled for a specific date to undergo Hepatitis screening, This community-based Educate, test-and-treat project consisted of community mobilisation facilitated by a network of village promoters and establishment of partnerships; an educational campaign to raise awareness, comprehensive testing, diagnosis, and treatment. For the educational campaign, we used public awareness events, and promotional materials (e.g., booklets). Risk factors were assessed using a detailed questionnaire covering medical history, household practices, and local cultural procedures potentially contributing to hepatitis transmission. Comprehensive testing, linkage to care, and treatment was offered to all eligible villagers. Testing was done by use of HCV antibody and hepatitis B surface antigen (HBsAg) rapid diagnostic tests, with HCV-RNA PCR confirmation of positive cases, and staging of liver disease by use of transient elastography.

Results: Of 3, 002 eligible individuals, 2532 (84.3%) were screened for HCV antibody and HBsAg by Rapid Diagnostic Test (RDT). 333 (13.1%) were found positive for HCV antibodies and 781 (30.8%) for HBsAg. 96.9% of HCV antibody positive patients were RNA positive and 84.5% of HBsAg positive patients were DNA positive. 12.3% of HCV antibody positive patients and 8.1% of HBsAg positive patients were cirrhotic as indicated by FibroScan. Several practices were identified that may significantly contribute to the risk of Hepatitis transmission, including scarification tattoos utilizing unsterile tools, group male circumcision with non-sterile equipment and unsafe practices by street barbers. HCV-RNA-positive participants were offered a 12-week course of sofosbuvir (400 mg orally, daily) and Daclatsvir (60 mg orally, daily). CHB patients were offered Tenofovir 245 mg mg and 2000 subjects were vaccinated against HBV.

Conclusion: In this work, we demonstrated the feasibility of a community-based "educate, test and treat" program as a model for the elimination of hepatitis infection in rural communities in Africa. This approach could be an important strategy for adoption towards the elimination of hepatitis.

WED-464

Dried blood spot self-collection for hepatitis B, C, and COVID-19 antibodies

Ahreni Saunthar[1], Sarah Sousa Tran[1], Agustina Crespi[1], Aaron Vanderhoff[1], Anne Claude Gingras[2], Karen Colwill[2], Tony Mazzulli[3], Camelia Capraru[1], Mia Biondi[1], Jordan J. Feld[1]. *[1]University Health Network, Toronto, Canada; [2]Mount Sinai Hospital, Toronto, Canada; [3]Mount Sinai Hospital/University Health Network, University of Toronto, Toronto, Canada*
Email: ahreni.saunthar@uhn.ca

Background and aims: Limited access to healthcare providers, particularly in rural/remote areas, hampers diagnosis and serosurveillance of hepatitis C virus (HCV) and hepatitis B virus (HBV). While dried blood spot collection enables testing for multiple infections from a fingerprick, it still requires interaction with the healthcare system. We aimed to evaluate contactless, mail-based self-collection dried blood spot (scDBS) testing, to increase accessibility and flexibility in HCV and HBV testing compared to conventional phlebotomy-based testing.

Method: Participants were recruited from a tertiary care hepatology clinic and a large academic family practice in Toronto, Canada. The study included participants seropositive for HCV, HBV, and COVID-19, and those with unknown serostatus. Interested participants were mailed an scDBS collection kit, with paper instructions, a QR-code to video instructions, a demographic questionnaire, and an acceptability survey. A prepaid return envelope was included to return the DBS card and questionnaire.

Results: Of 390 recruited participants, 39.2% (n = 153) completed the study. Results have been analyzed for a subset of 77 participants (33F, 44M, mean age 54). Of the 77 paired serum and DBS samples, 7 were HCV antibody positive, 16 were HBsAg positive, and 54 had unknown serostatus.

By scDBS, HBsAg detection occurred in all known positive samples (n = 16), with no false positive results (n = 61); and therefore sensitivity was 100% (95% CI 79.4–100.0) and specificity was also 100% (95% CI 94.1–100.0). Of those who tested HCV antibody positive in serum, sensitivity for 7 samples was 85.7% (95% CI 42.1–99.6) with 1 false negative. Not surprisingly, the false negative resulted from a very low signal-to-cut-off ratio (S/CO) observed in serum. The specificity for 70 known negative samples was 97.1% (95% 90.0–99.7) with 2 false positives. There was 100% concordance between serum and scDBS COVID-19 antibody results. Participants highly recommended mail-based testing (n = 72, 96.0%); most rated the process as excellent/good (n = 69, 95.5%); 52.0% (n = 39) reported collection as very easy/easy, and 81.9% (946/1155) of required spots were completed perfectly.

Conclusion: scDBS allowed for collection and testing for HCV, HBV, and COVID-19 exposure without the need for interaction with the healthcare system. High scDBS concordance and simplicity drive scalable disease screening, compensating for the marginal reduction in DBS sensitivity and specificity. Overall, the approach was acceptable to patients and could offer a strategy for reaching groups with structural or geographic barriers to care.

WED-465

Increasing hepatitis C screening rates at a New York City primary care clinic: a continuation

Jake Debroff[1,2], Piya Kositangool[2], Carolina Villarroel[2], Gres Karim[3], Anna Mageras[4], Desiree Chow[2]. [1]*Mount Sinai Beth Israel, New York, United States;* [2]*Mount Sinai Beth Israel, New York, United States;* [3]*New York Presbyterian Brooklyn Methodist Hospital, Brooklyn, United States;* [4]*Icahn School of Medicine at Mount Sinai, Liver Diseases, New York, United States*
Email: jake.debroff@mountsinai.org

Background and aims: According to the Centers for Disease Control (CDC), Hepatitis C virus (HCV) infection has continuously increased in incidence since 2013. The New York City (NYC) Department of Health (DOH) reports that 86, 000 people in NYC are living with chronic HCV. Given the severe complications of chronic HCV infection, including cirrhosis and hepatocellular carcinoma, the DOH is targeting a 50% improvement in HCV screening rates by 2030. Although current screening guidelines recommend a one-time screening test for HCV in all adults aged 18 to 79, the impediment to achieving improved detection rates appears to be rooted in the need for improved provider education. Our quality improvement study aims to increase HCV screening rates by performing stepwise educational interventions at a NYC primary care clinic.
Method: The second iteration of a Plan-Do-Study-Act (PDSA) approach was initiated in August 2023 among a team of internal medicine residents, primary care physicians, and a viral hepatitis program manager. Prior interventions, such as a best practice alert within the electronic medical record (EMR) instituted in 2022, were continued throughout the study period. A cohort of 35 internal medicine residents underwent an educational HCV presentation designed to better their understanding of the current guidelines regarding HCV testing as well as the significance of screening to prevent adverse liver outcomes. This second phase of the intervention emphasized detailed provider education and involved ancillary staff such as nurses and patient care assistants. Following education, all clinic staff were encouraged to place HCV screening orders as appropriate during each patient intake.
Results: Brief surveys to assess provider knowledge were collected before and 4–6 weeks after an educational presentation regarding HCV screening was given to all resident providers. After receiving the educational session, there was a 10% rise in correct responses regarding the population to be screened, with 92.6% of residents answering correctly. An increase of 17.8% was observed for correctly identifying the appropriate screening test. Following the initiation of the comprehensive education program, HCV screening rates were shown to improve steadily over the course of five months to 28 percent. Notably, screening rates were more than double the reported average for primary care clinics throughout the hospital system (28% vs 13%).
Conclusion: The implementation of an educational plan focused on up-to-date screening guidelines and patient awareness was shown to improve screening rates over a 5 month period at a NYC primary care clinic. Furthermore, there was a significant enhancement in the knowledge of internal medicine residents, enabling patient education and ultimately promoting higher compliance with HCV screening to prevent adverse long-term liver outcomes.

WED-466

The cost of HBV and HCV elimination in Ethiopia based on the current disease burden

Alexis Voeller[1], Hailemichael Desalegn[2], Devin Razavi-Shearer[1], Ivane Gamkrelidze[1], Homie Razavi[1]. [1]*Center for Disease Analysis Foundation, Lafayette, United States;* [2]*St. Paul's Hospital Millenium Medical College, Addis Ababa, Ethiopia*
Email: avoeller@cdafound.org

Background and aims: Based on their current trajectory, Ethiopia will not meet the WHO elimination targets for hepatitis B (HBV) or hepatitis C (HCV) without increasing preventative measures. This study aims to evaluate the current and future disease burden for HBV and HCV along with the economic burden to estimate what the necessary steps are to achieve the elimination of viral hepatitis as a public health threat. This will result in the outline of potential paths forward for Ethiopia.
Method: To complete this analysis, we utilized a literature review, conducted a Delphi process with Ethiopian experts and used mathematical modelling to estimate HBV and HCV disease and economic burden within the country. Two modelling scenarios were created for each disease: 2023 Base (reporting the empirical data through 2023); WHO elimination (estimating the number of patients who need to be screened, diagnosed, and treated to reach set targets). For HBV, an additional scenario was created to estimate the prophylaxis coverage needed meet the ≤0.1% prevalence in ≤5-year-olds.
Results: If Ethiopia were to introduce a universal birth dose program in 2024, healthcare providers would be vaccinating 3.9 million infants each year. This intervention alone combined with continued high levels of three dose coverage would meet the WHO prevalence elimination target (≤0.1% in ≤5-year-olds) by 2043 while averting 6, 800–8, 600 new HBV infections per year. To implement this program, Ethiopia would need an annual budget of 39.0 million Birrs. The cost per infection averted could reach up to 8, 630 Birrs if introduced. To achieve HBV elimination, an estimated 892, 000 patients would need to be diagnosed annually along with 821, 400 patients treated. Birth dose vaccination coverage would also need to increase to at least 90% while maintaining a 96% three dose coverage. These number of patients are based on a 2022 estimate of 7.8 million HBV infections with less than 10% of those being diagnosed and less than 1% of the eligible diagnosed population treated. In order to work towards elimination targets for HCV, Ethiopia would need to expand screening and treatment to 74, 000 individuals per year. This is due to the fact that by 2022, there were an estimated 690, 000 viremic HCV infections with less than 6% being diagnosed and less than 1% being treated. To meet the HCV targets Ethiopia will require an annual budget of up to 678 million Birrs until 2032, decreasing to less than 113 million Birrs in 2035 for screening, lab tests and treatment.
Conclusion: If Ethiopia moves forward on the path towards hepatitis elimination, an upfront investment will need to be made to support screening, diagnosis and treatment along with HBV vaccination. By 2035, the HBV interventions will be cost-effective saving 79, 500 lives whereas, by 2036, HCV interventions will be cost saving, sparing 46, 300 lives, and ensuring better health for all Ethiopians.

WED-467-YI

HBV and HCV screening and linkage-to-care in vulnerable people permanently or temporarily living in Tuscany

Monica Monti[1], Teresita Caruso[1,2], Alice Castellaccio[3], Laura Carraresi[4], Renato Brunetti[5], Sara Irene Bonelli[3], Donatella Aquilini[6], Alessandro Nerli[6], Elisabetta Lorefice[7], Pierluigi Blanc[3], Francesco Cipriani[5,8], Anna Linda Zignego[1], Laura Gragnani[2]. [1]*University of Florence, MaSVE Center, Department of Experimental and Clinical Medicine, Florence, Italy;* [2]*University of Pisa, Department of Translational Research and New Technologies in Medicine and Surgery, Pisa, Italy;* [3]*San Jacopo Hospital, Infectious Disease Unit, Pistoia, Italy;* [4]*University of Florence, Department of Neurosciences, Psychology, Drug Research and Child Health, Florence, Italy;* [5]*Epidemiology Unit, Department of Prevention, Central Tuscany Health Authority, Florence, Italy;* [6]*"Santo Stefano" Hospital, Infectious Disease Unit, Prato, Italy;* [7]*"San Giuseppe" Hospital, Gastroenterology Unit, Empoli, Italy;* [8]*Tuscany Regional Centre for Work-Related Injuries and Diseases (CeRIMP), Florence, Italy*
Email: laura.gragnani@unipi.it

Background and aims: The health issue of vulnerable groups is of increasing interest for public health and health inequalities. Accessible healthcare and treatment are essential for improving

living conditions and stopping the spread of infectious diseases. WHO's global hepatitis strategy has the goal to eliminate HBV and HCV infection in the next future. Therefore, we aimed at performing HBV and HCV screenings at different charities supporting migrants and marginal people, to reveal residual and hidden infections and link-to-care positive subjects.

Method: The screenings were conducted with an on-site strategy at meal centers and shelters for migrants. After an explanatory interview and the informed consent procedure, positivity to anti-HCV and HBsAg was tested with rapid finger-prick tests. The positive subjects were immediately referred to the closest outpatient clinic.

Results: From January 2021 to November 2023, 1, 195 subjects were tested, 950 (79%) males (M), mean age: 36 years. 49/1195 (4.1%) subjects were HBsAg+, 42 M (95%), mean age 28 years; 32/1195 (2.7%) were anti-HCV+, 28, 87.5% M, mean age 50 years. While HBsAg positivity was not associated to particular risk factors, anti-HCV positivity was linked to injection drug use (83%) and unprotected sex (50%). On the total 80 positive subjects (one was coinfected), 20 (25%) were lost, 56 (70%, 41 HBsAg+ and 15 anti-HCV+) were linked to care, 4/80 (5%) previously treated subjects refused the appointment. 11/41 (27%) HBsAg+ patients initiated an antiviral treatment while 21/41 (51%) are monitored and 9/41 (22%) have scheduled appointments. Liver evaluation showed an F0-F1 in 88%, F2 in 6% and F3 in 6%. The HBsAg- subjects were referred to the disease control and prevention centers to receive a vaccine. Among the 15 anti-HCV+ linked to care patients, 8/15 (53%) were previously treated SVR patients as confirmed by a negative viremia while all the remaining 7 (100%) were HCV-RNA+ and underwent ATV (4 SVR, 3 still ongoing). Liver evaluation was available for 3 patients (1 F0-F1, 1 F2 and 1 F4).

Conclusion: Compared to the latest national prevalences, our study showed a percentage 5 times higher for HBsAg (4.1% vs 0.8%) and almost 4 times higher for the anti-HCV (2.7% vs 0.74%). Adherence and linkage to care rates are very successful considering the particular setting and the fact that participation did not imply an economic reward. The most alarming data is the young age of HBsAg+ subjects prevalently coming from areas where the vaccination is not universal. Thus, the geographical origin emerged as the main risk factor. Mean age and risk factors for the anti-HCV+ are similar to those described on the general population. The results stress the need to implement the screening of marginal groups to reveal and treat the residual "pockets" of HBV and HCV infection with a benefit for the individual and for the entire community, also limiting disparities in healthcare.

WED-468

Progress in hepatitis C screening as part of the hepatitis C elimination program in Georgia

Maia Tsereteli[1], Vladimer Getia[1], Ekaterine Adamia[1], Irina Tskhomelidze[2], Sophia Surguladze[2], Amiran Gamkrelidze[3], Shaun Shadaker[4], Nancy Glass[4], Rania Tohme[4]. *[1]National Center for Disease Control and Public Health, Tbilisi, Georgia; [2]The Task Force for Global Health, Tbilisi, Georgia; [3]University of Georgia, School of Health Sciences, Tbilisi, Georgia; [4]Centers for Disease Control and Prevention, Atlanta, United States*

Email: mtsereteli2002@yahoo.com

Background and aims: In 2015, Georgia initiated the National Hepatitis C Elimination Program which aimed to reduce the prevalence of chronic hepatitis C virus (HCV) infection among adults by 90% by providing free-of-charge hepatitis C testing and treatment to all citizens. This program was a response to the high burden of chronic HCV infection in Georgia which was estimated to have 150, 000 persons (5.4% prevalence) with HCV infection in 2015 based on a nationally representative serosurvey. Since then, significant progress has been achieved. In 2021, the estimated number of people having HCV infection had dropped to 48, 600 (1.8% prevalence). This study aims to assess HCV antibody (anti-HCV) screening coverage among Georgia's adult population.

Method: We used Georgia's national HCV screening registry data, which collects data from the HCV elimination program utilizing patients' national identification numbers (ID), to determine the number of adults screened for HCV infection during April 28, 2015–November 30, 2023. To calculate the screening coverage in the 2023 adult population, we used the 2023 adult population data from the Georgian National Statistics Office. For the calculation of HCV screening coverage by age and sex, we excluded persons screened anonymously at harm reduction sites (n = 162, 026) to avoid possible duplications and those who had a documented death date in vital statistics as of November 30, 2023.

Results: During April 28, 2015-November 30, 2023, 2, 460, 887 Georgian adults have been screened for anti-HCV (87% of the average annual adult population during those years). After excluding persons who died (n = 231, 756), we estimated that 2, 229, 131 (79%) of the 2.84 million Georgian adult population in 2023 were screened for HCV infection. Screening coverage was 76% for men and 81% for women. Among men, screening rates were above 60% in all age groups; those aged ≥70 years had the highest screening coverage at 87%. The lowest screening coverage in males was 68% among those aged 18–29 years. In the adult female population, screening coverage was above 70% in all age groups ranging from a high of 92% among those aged 30–39 years to a low of 74% among those aged 18–29 years.

Conclusion: Nearly 80% of the 2023 adult population in Georgia has been screened for hepatitis C. However, younger age groups have the lowest screening rates. Innovative approaches to encourage screening in younger age groups such as conducting screening at universities and primary healthcare centers could help identify persons with HCV infection and ultimately achieve HCV elimination goals in Georgia.

WED-469

Investigating household hepatitis B transmission using whole-genome sequencing and serological analysis in Kinshasa Province, Democratic Republic of Congo

Email: camille_morgan@med.unc.edu

Background and aims: The Democratic Republic of Congo (DRC) has a hepatitis B virus (HBV) prevalence of 3–5% but minimal HBV prevention or advanced hepatology care. Limited HBV research in Africa suggests more frequent horizontal transmission than other regions, but regional epidemiology and clinical features remain poorly understood. We sought to characterize HBV transmission within households using whole-genome sequencing (WGS) and serological assays to inform much-needed prevention strategies in DRC.

Method: Building on the largest household study of HBV in DRC, we conducted a sub-study of households with known HBV infections. We performed point-of-care (POC) HBV surface antigen (HBsAg) testing (Abbott DETERMINE II), collected medical histories, and collected venous blood samples for HBV sequencing and serological analyses. Serological analysis was performed using the Abbott ARCHITECT, and included infection markers HBsAg Next (LOD; 0.005 IU/ml) and HBV viral load (VL) with Abbott RealTi*m*e HBV DNA (LLOQ; 20 IU/ml). WGS was performed on an Oxford Nanopore MinION using venous samples and dried blood spots (DBS).
Results: Among 25 households comprising 139 participants (80 female, 59 male) with samples collected in Kinshasa, median age was 15 years (IQR: 7, 29); thirty-five (25%) were born outside Kinshasa Province. Median household size was 6 (IQR: 4, 7). Concordance across HBV infection markers (POC, VL, Next) was limited: 35 (25%) participants were POC-positive, 25 (71%) of whom were Next-positive and 23 (66%) of whom had detectable HBV VL. Five of 104 (4%) POC-negative participants had detectable VL and 10 POC HBsAg-negative (10%) were Next-positive. Eight of 28 viremic participants (29%) had VLs ≥20, 000 IU/ml and eight (29%) were HBeAg-positive, seven of which had both. Five participants reported HIV coinfection and on tenofovir-based therapy, with undetectable HBV DNA. Of 69 children born since the three-dose infant HBV vaccination was introduced in 2007, 30 (43%) had isolated anti-HBs reactivity; eight (12%) were HBV-positive on at least one infection marker and 7 (10%) had detectable anti-HBc. Initial analysis of sequencing data from 33 samples (25 serum; 8 DBS) yielded 25 (76%) full or majority length genomes and confirmed infection by HBV genotypes A, D, and E in this cohort. Within five households with >1 infection fully sequenced, four had highly similar HBV sequences among individuals; however, one household cluster had infections with two distinct genotypes, strongly suggestive of multiple HBV introductions in the household.
Conclusion: Our findings highlight unique HBV transmission and clearance patterns within households in Kinshasa, and provide the first evidence of HBV genotype D circulating in the DRC. These and ongoing analyses will improve our understanding of HBV epidemiology in populations in the WHO Africa region and can be used to inform elimination efforts.

WED-470
Screening emergency admissions at risk of chronic hepatitis 3 extension (SEARCH 3X)-universal is better than risk-based screening for viral hepatitis

Basheer Alshiwanna[1,2,3], Miriam Levy[2,3,4], Julia Di Girolamo[2,3], Melissa Bagatella[1], Irena Petrovski[5], Robert Porritt[1], David Thomas[1], Shahida Bakridi[1], Hung Tran[6], Sophie Gryllis[1], Maria Tiglao[7], Rebecca Haack[5], Kristian Peralta[5], Julie Doan[1], Jeremy Lawrence[8], Richard Cracknell[5], Michael Maley[1], Hong Foo[1], Nathan Jones[5], Gregory Dore[3,9], David Prince[1,3]. *[1]Liverpool Hospital, Sydney, Australia; [2]Ingham Institute for Applied Medical Research, Sydney, Australia; [3]The University of New South Wales, Sydney, Australia; [4]Liverpool Hospital, Liverpool, Sydney, Australia; [5]Campbelltown Hospital, Sydney, Australia; [6]NSW Health Pathology, IT Services, Sydney, Australia; [7]Fairfield Hospital, Sydney, Australia; [8]Fairfield Hospital, Sydney, Australia; [9]The Kirby Institute, Sydney, Australia*
Email: b.shiwanna@gmail.com

Background and aims: Viral hepatitis remains an important public health concern globally. Despite effective therapies for cure of hepatitis C (HCV) and suppression of hepatitis B (HBV), a significant proportion of Australians remain undiagnosed or not linked with care. We evaluate the use of universal, automated hepatitis screening in the emergency department (ED) and assess diagnosis rates and linkage to care (LTC) success.
Method: A novel pilot clinical service utilizing automated universal hepatitis screening in the ED, "SEARCH 3X" (Screening of Emergency Admissions at Risk of Chronic Hepatitis Third Extension) was implemented across two metropolitan hospitals in Sydney, Australia. A computer algorithm solution automatically added Hepatitis B surface antigen (HBsAg) and Hepatitis C antibody (HCV Ab) tests when an adult underwent routine biochemistry testing in ED. Data was collected on patient demographics, overall prevalence of viral hepatitis and effectiveness of LTC (defined as successful contact by the SEARCH team).
Results: 10, 204 unique patients were tested using the SEARCH 3X algorithm. Positive serology for HBsAg and/or HCV Ab was detected in 92 (0.9%) and 170 (1.7%) patients respectively, equating to 259 (2.5%) unique patients overall (3 with HBV-HCV co-infection). The median age of the population tested was 58 years old (IQR 45–66), with a relatively even gender distribution (M:F; 44%:56%). The prevalence of positive HBsAg and/or HCV Ab in Indigenous Australians was 8.0% (3 HBV and 28 HCV from 375 tested), in non-indigenous Australians 1.9% (6 HBV and 79 HCV from 4384 tested), and in Overseas-born (OB) patients 2.7% (83 HBV and 63 HCV from 5445 tested). Of the 259 total positive patients, 251 were eligible for follow-up (too unwell n = 5, deceased n = 3) and 224 (86%) were successfully LTC. HCV diagnosis was new in 16/170 (9%) patients. HCV Ab positive patients were more often male (62% vs 44%; $p < 0.001$) and Indigenous (16.5% vs 3.5%; $p < 0.001$) compared with HCV Ab negative patients. HCV RNA was available in 134/170 HCV patients. RNA test was positive in 16 patients (12%) and negative in 118 (88%). Of RNA negative patients, 77/118 (65%) had previous HCV treatment, 28/118 (24%) had no previous treatment but had a risk factor for blood-borne virus; 13/118 (11%) treatment status and/or risk factor unknown. HBV diagnosis was new in 23/92 (25%) patients. Of those with known diagnosis, only 24/69 (39%) were receiving guideline-based care. HBsAg positive patients were more often OB (90% vs 53%; $p < 0.001$) and non-English speaking (39% vs 15%; $p < 0.001$) compared to HBsAg negative patients.
Conclusion: Opportunistic universal testing in ED represents an effective strategy for identifying cases of viral hepatitis and linking them to care. A substantial proportion of patients with viral hepatitis were previously undiagnosed. To achieve elimination, novel enhanced testing strategies will be required.

WED-471
Retrospective analysis of longitudinal data for UK adults living with chronic HBV: characteristics of the population on dual therapy

Informatics Collaborative, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [13]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; [14]Southampton Emerging Therapies and Technologies Centre, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; [15]NIHR University College London Hospitals Biomedical Research Centre, London, United Kingdom; [16]Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom; [17]Department of Infection, Immunity and Inflammation, UCL Great Ormond Street Institute of Child Health, London, United Kingdom; [18]School of Clinical and Experimental Sciences, Faculty of Medicine, University of Southampton, Southampton, United Kingdom; [19]Cambridge Liver Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [20]The Francis Crick Institute, london, United Kingdom; [21]Division of Infection and Immunity, University College London, London, United Kingdom; [22]Department of Infectious Diseases, University College London Hospital, London, United Kingdom
Email: cedric.tan@crick.ac.uk

Background and aims: The treatment landscape for hepatitis B virus (HBV) is changing as clinical guidelines for use of nucleos/tide analogue (NA) agents move towards simplified assessment and broader treatment eligibility. Dual treatment may be prescribed for people living with HBV who are HIV coinfected, who are accessing Pre-Exposure Prophylaxis (PrEP) to protect against HIV acquisition, and in individuals in whom HBV viraemia is not suppressed on monotherapy. In many global settings, dual therapy is also more widely available and affordable than monotherapy. It is therefore important to explore outcomes of dual therapy, and to consider its impact on outcomes, cost and accessibility.
Method: We analysed routinely-collected longitudinal clinical records from >14000 adults with chronic HBV infection across six secondary care centres in the UK, as part of the National Institute for Health and Care Research (NIHR) Health Informatics Collaborative (HIC) programme to characterise those receiving dual therapy.
Results: In this cohort, 2, 688/14, 587 (18%) individuals had a record of NA treatment, among whom 230/2, 688 (9%) were on dual therapy for at least a year. The most common dual regimens were Entecavir-Tenofovir (93/230) and Lamivudine-Tenofovir (82/230). Males accounted for the majority of individuals on both dual therapy, (158/230, 69%), and monotherapy group (1, 546/2, 458, 63%) ($p = 0.086$). There were no significant differences in median HBV viral load during mono- or dual therapy, after excluding the first six months of therapy ($p = 0.74$). There were also no significant differences between the proportion of patients with abnormal ALT levels (>40 IU/ml), or APRI scores, for patients undergoing mono versus dual therapy both at baseline, and at the last recorded timepoint during therapy (ALT: $p = 1$, $p = 0.65$; APRI: $p = 0.4$, $p = 0.25$). However, patients on dual therapy had significantly higher FIB-4 scores than those on monotherapy, both at baseline ($p = 0.0043$) and at the last timepoint ($p = 0.0082$).
Conclusion: Our finding that 9% of adults receiving HBV therapy in the UK are on dual agents highlights a need for more data collection to characterise this group. In particular, more data are needed to focus on those with HIV coinfection who may be under the care of sexual health services rather than hepatology clinics. Most outcome markers for dual and monotherapy are comparable, however Fib-4 scores may point to a disadvantage in the dual therapy group, with advanced disease potentially being the indication for adding a second agent.

WED-472
Female, mild steatosis, low baseline hepatitis B surface level and over 11.35 months of treatment facilitate clinical cure with interferon therapy in chronic hepatitis B patients

Lili Liu[1], Daqiong Zhou[1], Jiangyu Liu[1], Xinyue Chen[2], Zhenhuan Cao[1]. *[1]The Third Unit, Department of Hepatology, Beijing Youan Hospital, Capital Medical University, Beijing, China, Beijing, China; [2]The First Unit, Department of Hepatology, Beijing Youan Hospital, Capital Medical University, Beijing, China, Beijing, China*
Email: caozhenhuanyu@mail.ccmu.edu.cn

Background and aims: Hepatitis B surface antigen (HBsAg) clearance is a desired functional cure for hepatitis B, which is harder to achieve clinically. Identifying effective predictive markers, especially the impact of hepatic steatosis on achieving a functional cure with interferon therapy, is crucial.
Method: A retrospective cohort from Beijing You'an Hospital spanning 2008–2023, involved chronic hepatitis B (CHB) patients who had received at least 6 months of interferon therapy and underwent Fibroscan examination within one year prior to treatment. Univariate and multivariate logistic regression analysis methods were used to investigate the factors influencing HBsAg clearance.
Results: A total of 1397 CHB patients (median age 36.0 years, 65.4% male) were enrolled and 152 patients (10.88%) achieved HBsAg clearance, with 1-and 2-year cumulative HBsAg clearance rates of 13.36% and 32.34%, respectively. Multivariate logistic regression analysis demonstrated that male (odds ratio [OR] 0.566; 95%CI 0.364–0.880; $p = 0.011$) was adverse to HBsAg clearance. HBsAg<1000 IU/ml (OR 8.731; 95%CI 4.024–18.946; $p < 0.001$), HBsAg<100 IU/ml (OR 43.005; 95%CI 19.295–95.855; $p < 0.001$), mild steatosis (OR 1.830; 95%CI 1.038–3.229; $p = 0.037$) and prolonged interferon therapy (OR 1.147; 95%CI 1.101–1.195; $p < 0.01$) facilitated HBsAg clearance. Cumulative HBsAg clearance was significantly higher in patients with combined mild steatosis than those without combined steatosis ($p = 0.0069$).
Conclusion: Controlled attenuation parameter (CAP) values have a good predictive value in patients on initial interferon therapy and combined mild steatosis facilitates achieving clinical cure. Furthermore female, baseline HBsAg <1000 IU/ml, and longer interferon therapy were strong predictors of HBsAg clearance.

WED-473
Assessing the burden and knowledge, attitudes, and practices of hepatitis B and hepatitis C among dentists in the country of Georgia

Lika Karichashvili[1], Maia Tsereteli[1], Maia Alkhazashvili[1], Nazibrola Chitadze[1], Sophia Surguladze[2], Irina Tskhomelidze[2], Shaun Shadaker[3], Tsira Merabishvili[4], Anna Khoperia[4], Francisco Averhoff[5], Gavin Cloherty[5], Ketevan Gogilashvili[6], Zurab Alkhanishvili[7], Rania Tohme[8]. *[1]National Centre for Disease Control and Public Health, Tbilisi, Georgia, Tbilisi, Georgia; [2]Task Force for Global Health, Tbilisi, Georgia, Tbilisi, Georgia; [3]Division of Viral Hepatitis, Centres for Disease Control and Prevention, Atlanta, USA, Atlanta, United States; [4]National Centre for Disease Control and Public Health, Tbilisi, Georgia, Tbilisi, Georgia; [5]Abbott Diagnostics, Abbott Park, Illinois, USA, Illinois, United States; [6]Tbilisi State Medical University, Tbilisi, Georgia, Tbilisi, Georgia; [7]Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia; [8]Division of Viral Hepatitis, Centres for Disease Control and Prevention, Atlanta, USA, Atlanta, United States*
Email: lika.karichashvili@gmail.com

Background and aims: In 2021, a nationally representative serosurvey revealed a hepatitis C virus (HCV) infection prevalence of 1.8% and a hepatitis B virus (HBV) infection prevalence of 2.7% among adults in Georgia. Healthcare-related HCV and HBV transmission is still a major problem in developing countries, including Georgia. However, limited data are available on the prevalence and awareness of hepatitis B and hepatitis C among dentists and dental health professionals (collectively, dental healthcare workers [DHCW]). We assessed the prevalence, knowledge, attitudes, and practices (KAP) of HBV and HCV infection among DHCWs in Georgia.
Method: We conducted a facility-based survey using a multi-stage cluster design. Using probability-proportional-to-size sampling, we selected 214 dental facilities from the largest cities, Tbilisi, Kutaisi, Batumi, Zugdidi, and Telavi, followed by random selection of

participants in each facility using the Kish Grid. KAP data were obtained through a self-reported questionnaire, and blood samples were collected and tested for HCV antibody (anti-HCV), HCV RNA, Total hepatitis B core antibody (Total anti-HBc), and HBV surface antigen (HBsAg). Analyses were conducted using STATA 17.
Results: Among 519 participants (100% response rate), 81% were in Tbilisi, 76% were dentists, 84% were female, and the median age was 40 years [IQR 33–47 years]. While 44% of DHCW reported a past needlestick injury, only 10% and 8% of participants knew the correct probability of HBV and HCV infection after a single contaminated needlestick, respectively. Most (78%) were aware that hepatitis B is vaccine preventable but 83% thought it is curable. More than half (57%) thought that HCV is vaccine preventable and 80% knew that HCV can be cured. More than 90% believed healthcare workers are at high risk for HBV and HCV exposure. Most (70%) knew the optimal method for pre-sterilizing and aseptically storing instruments. Of 519 participants, 83% and 91% reported previously being screened for HBV and HCV, respectively, and 30% reported being vaccinated against hepatitis B. Among 517 participants who provided blood samples, 12.2% were Total anti-HBc reactive, 0.6% were HBsAg positive, 0.8% were anti-HCV reactive, and none were positive for HCV RNA.
Conclusion: The study revealed limited awareness among DHCWs in Georgia regarding HBV and HCV transmission after a contaminated needlestick injury. Although DHCW demonstrated awareness of hepatitis B vaccination and recognized their occupational risk, less than a third had been vaccinated. However, the prevalence of hepatitis B and hepatitis C was low. Continuous education and training on infection control practices and on viral hepatitis are crucial to enhance DHCW awareness and prevent occupational exposures.

WED-474

Population-based hepatitis C screening in Lithuania: 18-month results of the program and scenarios for achieving WHO elimination targets

Limas Kupcinskas[1], Egle Ciupkeviciene[2], Alexis Voeller[3], Viaceslavas Zaksas[4], Ligita Jancoriene[5], Edita Kazenaite[6], Viktorija Basyte-Basevice[1], Devin Razavi-Shearer[3], John Ward[7], Gediminas Urbonas[8], Janina Petkeviciene[9]. *[1]Department of Gastroenterology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Department of Preventive Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Center for Disease Analysis Foundation, Lafayette, Colorado, United States; [4]National Health Insurance Fund under the Ministry of Health, Vilnius, Lithuania; [5]Clinic of Infectious Diseases and Dermatovenerology, Vilnius University, Kaunas, Lithuania; [6]Clinic of Gastroenterology, Nephrourology and Surgery, Vilnius University, Vilnius, Lithuania; [7]Coalition for Global Hepatitis Elimination, Decatur, United States; [8]Department of Family Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania; [9]Health Research Institute, Lithuanian University of Health Sciences, Kaunas, Lithuania*
Email: l.kupcinskas@gmail.com

Background and aims: Lithuanian HCV screening program started on May, 2022. State health authorities pay general practitioners (GPs) a special promoting fee for performing serological tests for HCV antibodies: 1. For the population born in 1945–1994 (once per life) and 2. For people who inject drugs (PWID) or are HIV-infected (annual HCV testing). Such an initiative is the first in Central and Eastern Europe. This study aimed to evaluate the results of the first 18-month of the program and different scenarios to achieve WHO 2030 targets.
Method: GPs invited people to perform a serum blood test for HCV antibodies. Anti-HCV positive patients were referred to a gastroenterologist or infectologist for HCV RNA testing, and if result was positive, direct-acting antiviral (DAA) therapy was prescribed. Information about patients was obtained from the database of the National Health Insurance Fund. The Markov disease progression model elaborated by the CDA Foundation was used to assess HCV elimination progress. The data from the 2022–2023 screening were used as inputs Three scenarios were developed: the 'Base' scenario-return to pre-screening program level in 2023 and 2 scenarios with different extents of treatment.
Results: At the beginning of 2022, about 1.8 million people born in 1945–1994 lived in Lithuania. Between May 5, 2022 and October 31, 2023 from this population 1026268 people (57, 7%) were tested for HCV antibodies. Positive test results were found in 1.23% of cases. In the risk group, 8751 PWID and HIV+ people were screened, of whom 30, 3% were seropositive. All seropositive patients were referred to specialists. Viremia was detected in 58%. During 18-month period 4068 patients were treated with DAA. Treatment delay for 54% of HCV patients was related to organizational problems (consultation waiting line, some treatment restrictions, delay in drugs supply). Solving organizational challenges, by the end of 2024 we expect to perform HCV antibody testing in 80% of the target population and treatment of 80% of RNA-positive individuals, further aiming to cure all infected patients by 2030. The Markov disease progression model to assess HCV elimination progress showed the following scenarios: Scenario 1: if the same number of patients are treated as before the screening, the WHO targets will not be reached. Scenario 2: treating 70% of infected patients will meet most but not all WHO targets. Scenario 3: by treating all infected patients by 2030, the WHO target will be met by saving 150 lives and preventing 90 new cases of decompensated cirrhosis and 120 cases of hepatocellular carcinoma.
Conclusion: Our data show that in European country with moderate HCV seroprevalence, a population-based screening program can be feasible, screening near 60% (more than 1 million) of the population born between 1945 and 1994 during the first 18 months of the program. We hope that WHO 2030 goals can be achievable in Lithuania.

WED-475

Optimal strategies for eliminating mother-to-child transmission of hepatitis B in Burkina Faso

Andréa Gosset[1], Shevanthi Nayagam[2,3], Sylvie Boyer[1], Alice N. Guingané[4], Nora Schmit[2], Abdoul Salam Eric Tiendrebeogo[5], Dramane Kania[6], Patrizia Carrieri[1], Yusuke Shimakawa[7], Timothy B. Hallett[2]. *[1]Aix Marseille University, INSERM, IRD, SESSTIM, Sciences Economiques and Sociales de la Santé and Traitement de l'Information Médicale, ISSPAM, 13005 Marseille, France, Marseille, France; [2]MRC Centre for Global Infectious Disease Analysis, School of Public Health, Imperial College London, London, United Kingdom, London, United Kingdom; [3]Department of Surgery and Cancer, Imperial College London, London, United Kingdom, London, United Kingdom; [4]Hepatogastroenterology Department, Bogodogo University Hospital Center, Ouagadougou, Burkina Faso, Ouagadougou, Burkina Faso; [5]Laboratoire Mixte International de Vaccinologie (LAMIVAC), Bobo-Dioulasso, Burkina Faso, Bobo-Dioulasso, Burkina Faso; [6]Centre Muraz, Institut national de santé publique, Bobo-Dioulasso, Burkina Faso, Bobo-Dioulasso, Burkina Faso; [7]Unité d'Epidémiologie des Maladies Emergentes, Institut Pasteur, 75015 Paris, France, Paris, France*
Email: andrea.gosset@inserm.fr

Background and aims: High prevalence of hepatitis B (HBV) in West Africa (6%-17%) requires new strategies to prevent mother-to-child transmission (MTCT). Despite current recommendations for tenofovir prophylaxis in pregnant women with HBV DNA ≥200, 000 IU/ml or HBe antigen (HBeAg) positivity, coverage remains low, mainly due to the lack of HBV screening in antenatal care and the high cost of HBV DNA test. We evaluated the impact on the HBV epidemic and MTCT elimination as well as the cost-effectiveness of four alternative strategies to select pregnant women for tenofovir prophylaxis in antenatal care at primary healthcare centres (PHCs) in Burkina Faso: 1) HBV DNA ≥200, 000 IU/ml, 2) HBeAg-positive, 3) HB core antigen (HBcrAg)-positive using rapid diagnostic test, and 4) all HBsAg-positive women (Treat All).

Method: We used a deterministic compartmental dynamic model stratified by age, sex, and transmission mode. We assessed costs from the perspective of the Burkina Faso government health system. We used a micro-costing approach to determine the costs of implementing each strategy during routine antenatal visits at PHCs. We included costs of HBV vaccination (HepB3), birth dose (HepB-BD), and care costs for patients with advanced liver disease. An epidemiological model simulated the strategies from 2024 to 2124, while a cost-effectiveness analysis considered a one-year strategy implementation (in 2024) with a lifetime health and cost impact assessment. The baseline strategy was the current situation in Burkina Faso where HepB-BD is administered alongside HepB3. We assumed 90% HBsAg screening coverage among pregnant women, 90% second test coverage among HBsAg-positive women, and 90% TDF prophylaxis coverage among eligible women. We considered a cost-effectiveness threshold of 0.5 times Burkina Faso's per capita GDP in 2022 (US $416.5). We discounted health outcomes and costs using a 3% discount rate. We conducted deterministic and probabilistic sensitivity analyses.
Results: In the cost-effectiveness model, the Treat All strategy dominated the other strategies and the status quo scenario, with an incremental cost-effectiveness ratio of US$14.1 per DALY averted corresponding to an 81.2% probability of being cost-effective. This finding was most sensitive to transition rates to decompensated cirrhosis and HepB-BD efficacy in mothers with high viral load. Implementing the Treat All strategy from 2024 to 2124 could eliminate HBV MTCT by 2034, and reduce chronic HBV cases, deaths, and DALYs attributable to MTCT by 12.1% [4.9%; 13.9%], 10.0% [4.1%; 13.2%], and 11.4% [5.6%; 16.0%], respectively.
Conclusion: The Treat All strategy emerged as the dominant and cost-effective strategy for implementation in antenatal care, with the potential to eliminate HBV MTCT by 2034. However, further research is needed to assess the acceptability and feasibility of this strategy in real-world settings.

WED-476
Sofosbuvir/Velpatasvir (S/V) for the treatment of HCV infection among vulnerable inner-city residents: extending the results of the SIMPLIFY study

Brian Conway[1,2], Rossitta Yung[1], Shawn Sharma[1], Shana Yi[1], Saina Beitari[1]. [1]*Vancouver Infectious Diseases Centre, Vancouver, Canada;* [2]*Simon Fraser University, Burnaby, Canada*
Email: brian.conway@vidc.ca

Background and aims: The combination of Sofosbuvir/Velpatasvir (S/V) is approved for the treatment of chronic HCV infection. In the SIMPLIFY study of active drug users, 97/103 HCV-infected individuals were cured with a 12-week course of S/V administered as one pill once a day, with no virologic failures. We aimed to extend the results of the SIMPLIFY study, evaluating the safety and efficacy of S/V in a prospective study of HCV-infected inner-city residents enriched for risk behaviors for non-adherence to therapy, including problematic drug use and unstable housing.
Method: Through dedicated outreach events, we identified HCV-infected patients who were not currently engaged in health care and who were eligible to receive government-funded antiviral therapy for HCV infection. We enrolled in a multidisciplinary program of care to address medical, psychological, social, and addiction-related needs, and provided S/V therapy in this context, with enhanced supervision of adherence. The primary end point of this analysis was the achievement of cure, defined as an undetectable HCV RNA 12 or more weeks after the completion of therapy.
Results: In this ongoing study, we have identified 256 eligible subjects, median age 46 (20–81) years, 28.9% female, mostly genotypes 3A/or 1A (46.2%, 43.8%) and 22.7% with advanced fibrosis (F3/F4), 70.3% with unstable housing and 97.6% active drug users, usually fentanyl and/or amphetamines (98%, 74.3%). Of the 256, HCV treatment has been started in 231 cases (within a median 6 weeks of engagement in care), with 22 awaiting treatment and 3 opioid overdose deaths before its initiation. Of 231, 6 discontinued prematurely (all within the first week of treatment), 3 died on treatment (opioid overdoses), 213 have completed treatment and 9 remain on treatment. Of the 213, 24 are in follow-up and await evaluation of outcome, with 184/189 (97.4%) cured with 5 virologic relapses.
Conclusion: Taken together, our data support the efficacy of S/V in populations even more challenging that those enrolled in the SIMPLIFY study with HCV therapy administered within comprehensive multidisciplinary programs such as ours. This information will be essential to the development of strategies to eliminate HCV therapy in all priority populations, including the demographic evaluated in this study.

WED-477-YI
Semi-quantitative interviews with chronic hepatitis B patients to determine their knowledge of hepatitis B, personal experiences and views on decentralisation of care in London, United Kingdom

Alexander Cole[1,2], Thi Thuan Nguyen[3], Yusuke Shimakawa[4], Ameet Dhar[1,2], Belinda Smith[1,2], Shevanthi Nayagam[1], Ashley Brown[1,2], Koen Peteers[3], Maud Lemoine[1,2]. [1]*Imperial College London, London, United Kingdom;* [2]*Imperial College Healthcare NHS Trust, London, United Kingdom;* [3]*University of Antwerp, Antwerp, Belgium;* [4]*Institut Pasteur, Paris, France*
Email: alexander.cole@nhs.net

Background and aims: The World Health Organisation (WHO) hepatitis B elimination plan aims for increased detection and treatment of chronic hepatitis B (CHB) by 2030. Decentralisation of patient care is an important consideration for CHB management. We conducted interviews with CHB patients to determine their knowledge of hepatitis B infection, personal experiences of living with CHB, experiences of consultant-hepatologist led outpatient clinics and potential acceptability of decentralised outpatient care pathways.
Method: Semi-quantitative interviews conducted with 29 CHB patients attending outpatient hepatology clinics between 1st June 2022 and 1st July 2023 at St Mary's Hospital, London. A random sampling method was used to select participants. Individual interviews were conducted face-to-face or via telephone covering the domains of patient knowledge, quality of life (QOL), outpatient clinics at St Mary's Hospital and views of decentralised care pathways.
Results: Patients were able to correctly identify modes of hepatitis B transmission: mother-to-child (79%), sexual intercourse (86%), intravenous drug use (79%), blood transfusions (86%) and tattoos or body piercings (72%). CHB negatively impacted QOL across multiple domains including mental health (62%), employment (41%) and personal relationships (41%). 31% of participants felt stigmatised for having CHB including experiences with friends and employers. At St Mary's Hospital, 93% of participants were satisfied with the level of care provided in outpatient hepatology clinics. For decentralised care, 76% of participants would agree to be seen by a nurse specialist, 69% by a pharmacist and 79% by their local general practitioner (GP) for CHB management. 72% of participants had an overall preference to see a hospital doctor for regular CHB management.
Conclusion: Patients had good knowledge of hepatitis B transmission. CHB negatively impacted patients' QOL across multiple domains and many patients experienced stigma. Patients were satisfied overall with outpatient hepatology clinics at St Mary's Hospital. Most participants would accept clinical reviews by nurse specialists, pharmacists and general practitioners in a decentralised care model. Patients had a preference to receive care from hospital doctors for ongoing CHB management.

WED-478

Telehealth accessibility and acceptability among people who use drugs

Zoi Papalamprakopoulou[1,2], Sotirios Roussos[3], Elisavet Ntagianta[4], Vasiliki Triantafyllou[4], George Kalamitsis[4], Arpan Dharia[1], Vana Sypsa[3], Angelos Hatzakis[2,3], Andrew Talal[1]. *[1]Division of Gastroenterology, Hepatology, and Nutrition, Jacobs School of Medicine and Biomedical Sciences, University at Buffalo, Buffalo, NY, United States; [2]Hellenic Scientific Society for the Study of AIDS, Sexually Transmitted and Emerging Diseases, Athens, Greece; [3]Department of Hygiene, Epidemiology and Medical Statistics, National and Kapodistrian University of Athens, Athens, Greece; [4]Hellenic Liver Patient Association "Prometheus", Athens, Greece*
Email: zoipapal@buffalo.edu

Background and aims: Hepatitis C virus (HCV) elimination programs should prioritize the inclusion of people who use drugs (PWUD), a medically underserved population that often faces stigma and geographical barriers when accessing healthcare. Recent data indicate that telehealth is highly effective in expanding access to HCV care among PWUD. We aimed to investigate telehealth accessibility and acceptability among PWUD in Athens, Greece.
Method: We recruited 162 PWUD through respondent-driven sampling to undergo an interviewer-administered, 109-item, structured questionnaire. Eligibility criteria required age at least 18 years, a history of injection drug use, Greek verbal fluency, and the ability to provide informed consent. Main study outcomes included internet access, computer access, use of social media, and willingness to receive healthcare through telemedicine in an opioid agonist treatment (OAT) program. We employed logistic regression to assess the impact of sociodemographic characteristics and injection drug use (IDU) on these outcomes.
Results: Participants' mean (SD) age was 45.9 (8.8) years, 84.0% (136/162) were male, 90.1% (146/162) were of Greek origin, 77.8% (126/162) reported IDU in the past 12 months, 85.2% (138/162) were not currently linked to an OAT program, and 50.0% (81/162) were experiencing homelessness. Among participants, 66.0% (107/162) and 31.5% (51/162), respectively, reported current internet and computer access. Compared to those with secure housing, participants experiencing homelessness reported decreased internet (50.6% vs 81.5%, $p < 0.001$) and computer access (11.1% vs 51.9%, $p < 0.001$). Multivariable analyses revealed that increasing age (per 1-year increase: odds ratio [OR] = 0.94, 95% confidence interval [CI], [0.89, 0.99], $p = 0.032$), IDU within the past 12 months (0.29 [0.10, 0.88], $p = 0.028$), and homelessness (0.29 [0.13, 0.65], $p = 0.003$) were associated with a lower odds of internet access. Homelessness (0.17 [0.07, 0.41], $p < 0.001$) and unemployment (0.25 [0.07, 0.98], $p = 0.046$) were associated with a lower odds of computer access. Despite limited (1.9%, 3/162) participant experience with telemedicine, 84.0% (136/162) expressed willingness to receive healthcare through telemedicine in an OAT program.
Conclusion: Homelessness is associated with restricted internet and computer access among PWUD in Athens, Greece and poses challenges to expanding healthcare access through telehealth. Among PWUD with secure housing, access to infrastructure is permissive for telehealth interventions. These data should inform telehealth policy and practice for HCV care among PWUD.

WED-479

Improved social outcomes after integrated hepatitis C and opioid use disorder treatment

Andrew Talal[1], Raktim Mukhopadhyay[2], Valentina Veronesi[3], Arpan Dharia[1], Giovanni Saraceno[3], Marianthi Markatou[3]. *[1]University at Buffalo, Jacobs School of Medicine and Biomedical Sciences, Buffalo, United States; [2]University at Buffalo, CDSE, Buffalo, United States; [3]University at Buffalo, Department of Biostatistics, Buffalo, United States*
Email: ahtalal@buffalo.edu

Background and aims: Integrated treatment for hepatitis C virus (HCV) and opioid use disorder (OUD) is widely advocated, although few studies have simultaneously evaluated the outcomes for each entity. Using data obtained from participants in opioid treatment programs (OTPs) that dispense methadone, we explored the associations between OUD and HCV treatment uptake and substance use and social factors.
Method: We utilized administrative data including demographics, social, and substance use factors collected from 522 OTP participants. We evaluated the cumulative percentage change during the initial 5 years after methadone initiation. We subsequently performed factor analysis for mixed-type data, a dimensionality reduction technique used also to investigate the contribution of individual variables. We next used k-means clustering to identify participant subgroups. We used random forests to identify the most important variables that predict HCV treatment initiation.
Results: Data from 522 participants (62.3% male, 46.6% White, 22.8% Black, 30.7% other races, 31.8% Hispanic, median age 49.0 years) revealed cumulative percentage improvements in primary, secondary, and tertiary illicit substance use after 3–4 years on methadone. We also found increased participation in education, employment, and decreases in criminal justice involvement. Through factor analysis, we identified that variables encompassing basic needs (i.e., food, clothing, utilities, healthcare, phone, and childcare) explain 10.4% of the variation. The second most important categorization were variables related to substance use and frequency that explain 8.6% of the variation. Cluster 1 had the greatest improvements in substance use, substance use frequency, residence type, and employment. Demographic characteristics were well balanced over the four subgroups except clusters 2 and 3 that contained a slightly higher proportion of non-Hispanic, White, and unmarried individuals. The random forest application to predict HCV treatment initiation among participants revealed that demographic (e.g., age, sex), treatment group (i.e., facilitated telemedicine, offsite referral), substance use, and social (e.g., housing, marital status) variables had the highest predictive capacity.
Conclusion: We quantified improvements in substance use and social factors after integration of HCV treatment into OTPs through telemedicine. Factor analysis identified social and substance use factors that explain 19.1% of the variation. K-means clustering permitted categorization of individuals on improvements in variables of interest. The random forest approach identifies important demographic, treatment group, substance use, and social variables for predicting HCV treatment initiation. The ability to classify participants could improve patient-centered care delivery for integrating HCV and OUD treatment.

WED-480-YI

Maternal health progression: EMR system's contribution to understanding hepatitis prevalence in Uzbekistan

Samantha Hall[1], Shakhlo Sadirova[2], Erkin Musabaev[3], Homie Razavi[1]. *[1]Center for Disease Analysis, Lafayette, United States; [2]Center for Disease Analysis, Tashkent, Uzbekistan; [3]Research Institute of Virology, Tashkent, Uzbekistan*
Email: shall@cdafound.org

Background and aims: As countries work towards the elimination of mother to child transmission of HIV, syphilis and hepatitis B virus (HBV), it is imperative to assess which strategies can strengthen national programs. In Uzbekistan, there are over 600, 000 births annually, necessitating extensive testing of pregnant women. This study examined the impact of implementing an electronic medical record (EMR) system designed to centralize test results for pregnant women across four regions of Uzbekistan. The primary objective is to demonstrate the utility of this EMR system in efficiently gathering and analyzing data, specifically focusing on estimating the prevalence of infections such as hepatitis B (HBV) and hepatitis C (HCV), by age and region.

Method: Over a 12-month period, 60 trained nurses at 60 maternity hospitals in Tashkent, Samarkand, Surkhandarya, and Syrdarya utilized the Research Electronic Data Capture (REDCap) system to enter test results recorded in patients' medical history files. A total of 81, 017 pregnant women, aged 15–45, were screened for HBsAg and anti-HCV. Manual extraction and entry of test results into REDCap were conducted during patients' visits to maternity hospitals, utilizing a convenient sampling approach. Crude and age-adjusted prevalence were calculated with a 95% confidence interval (CI) for both markers. Associations with HBV and HCV were investigated using Chi-squared analysis and Poisson regression for age group and region.
Results: Among the pregnant women, the overall prevalence of HBsAg stood at 1.36%, with an age-adjusted prevalence of 1.19%. For anti-HCV, the overall prevalence was 0.36%, with an age-adjusted prevalence of 0.33%. The chi-squared analysis revealed a significant association between region and both HBV ($X^2 = 1487$, $p = <0.001$) and HCV ($X^2 = 114$, $p = <0.001$). Similarly, a significant association was found between age group and both HBV ($X^2 = 114$, $p = <0.001$) and HCV ($X^2 = 28$, $p = <0.001$). The highest age-adjusted prevalence was observed among 25- to 29-year-olds for both HBV (1.47%) and HCV (0.39%). Samarkand exhibited the highest prevalence of the sampled regions for both HBV (4.49%) and HCV (0.85%). Regression analyses demonstrated lower rates of both HBV and HCV infection in younger age groups, as compared to 25- to 29-year-olds ($p = <0.01$), and higher rates in residence of Samarkand ($p = <0.001$).
Conclusion: Implementing an EMR system for centralizing test results has proven effective in estimating the prevalence of HBV and HCV infections among pregnant women in Uzbekistan. The findings highlight regional and age-specific variations in infection rates, emphasizing the importance of targeted public health interventions. The study emphasizes the potential of this open access EMR system to streamline data collection, allowing for evidence-based policy decisions and reducing unnecessary testing costs for this vulnerable population.

WED-481
Elimination days-How good clinical practice can contribute to the elimination of hepatitis C

Pedro Lages Martins[1], Mário Jorge Silva[1], João Silva[1], Daniela Rabaça[1], Cláudia Pereira[2], Filipe Mendes[3], Margarida Alves[4], Paulo Caldeira[5], Rita Corte-Real[1], Filipe Calinas[1]. *[1]Unidade Local de Saúde São José, Lisboa, Portugal; [2]Ares do Pinhal-Associação de Recuperação de Toxicodependentes, Lisboa, Portugal; [3]Equipa de Tratamento de Xabregas-Divisão de Intervenção nos Comportamentos Aditivos e nas Dependências, Lisboa, Portugal; [4]IN-Mouraria-Grupo de Ativistas em Tratamentos, Lisboa, Portugal; [5]Ares do Pinhal-Associação de Recuperação de Toxicodependentes, Lisboa, Portugal*
Email: pb.lages.martins@gmail.com

Background and aims: With the ongoing conventional clinical practice, it seems unlikely that the goal of eliminating hepatitis C by 2030 will be achieved in many countries. We presume that there are diagnosed hepatitis C patients who have lost hospital follow-up without receiving treatment. With this initiative, we aim to identify those patients who were once under our care and bring them back into medical care**,** including treatment for HCV infection.
Method: Results of HCV RNA tests requested between 01/2010 and 3/2023 by clinicians from a tertiary hospital service were examined. We identified the patients with detectable HCV viral load in the most recent assessment. Among these, patients currently alive without records of maintained follow-up (at our hospital or other institutions) nor scheduled/initiated treatment at any point were identified. Patients were contacted by mail, phone, and/or email for evaluation in hospital consultations and/or decentralized clinics. Confirmation of active infection was conducted, as well as treatment, and post-treatment follow-up when indicated.
Results: Analyzing the results of 7168 HCV viral loads, 473 patients with detectable HCV RNA in the most recent assessment were identified. Of these, 44 were under specialized care follow-up (37 at our hospital and 7 at other institutions), 147 had initiated treatment (with unknown completion status and/or outcome), and 162 had passed away. We successfully contacted 90 (75%) out of the 120 patients who presumably had never initiated HCV treatment. Sixty-nine percent (62/90) of these patients were reassessed, 55 in hospital consultations and 7 in decentralized clinics. Treatment for hepatitis C was initiated in 56 patients.
Conclusion: This "relink" strategy, which is nothing more than good clinical practice, allows for the recovery of a significant number of previously known hepatitis C patients back into clinical care and their treatment.

WED-482
Local elimination programs leading to global action in HCV (LEGA-C): implementation science studies in Europe aiming to streamline the HCV care pathway

Candido Hernández[1], Julian Elrayes[2], Marinela Mendez[3], Francesca Frigerio[4], Louise Missen[5], Audrey Le Blevec[6], Mehtap Guendogdu[7], Kyung min Kwon[2], Stacey Scherbakovsky[2], Kim Vanstraelen[8], Bruce Kreter[2]. *[1]Gilead Sciences, Madrid; [2]Gilead Sciences, Foster City, United States; [3]Gilead Sciences, Madrid, Spain; [4]Gilead Sciences, Milan, Italy; [5]Gilead Sciences, London, United Kingdom; [6]Gilead Sciences, Paris, France; [7]Gilead Sciences, Munich, Germany; [8]Gilead Sciences, Brussels, Belgium*
Email: candido.hernandez@gilead.com

Background and aims: Since 2016 Gilead Sciences, Inc., has supported over 120 studies in more than 30 countries focused on hepatitis C virus (HCV) elimination under the LEGA-C (Local Elimination programs leading to Global Action in HCV) initiative. In 2020, EASL released the last recommendations on treatment of hepatitis C and identified patients who will benefit from a more streamlined care pathway (e.g., people who inject drugs-PWID, prisoners, homeless individuals, migrants, patients living with mental health or substance use disorders, men who have sex with men, or sex workers). Here we aim to comprehensively describe the studies run under the LEGA-C umbrella in European countries, specifically focusing on populations historically less engaged in healthcare.
Method: We identified the LEGA-C studies performed in European region, and extracted information on the following variables: country, type of population included (as mentioned per EASL 2020 Guidelines), number of patients/individuals reached, use of a simplified care pathway (e.g., simple monitoring, test and treat approach), year of communication/publication, and the impact factor (IF).
Results: 32 (27%) of the studies were conducted in Europe across 12 European countries (Austria, France, Denmark, Georgia, Germany, Greece, Italy, Netherlands, Portugal, Spain, Switzerland, and UK) as of July 2022. In these 32 studies, 25 (73%) focused on special populations with more than 8, 935 individuals reached, including persons who use/inject drugs (n = 13 studies), men who have sex with men (n = 7), prison residents (n = 5), migrants (n = 4), homeless patients (n = 2), psychiatric patients (n = 1), and sex workers (n = 1). At the time of the analysis, 19 out of the 32 studies were presented or published: 6 studies in 2018–19, 2 in 2020, and 11 in 2021–22. During 2021–2022, there was an increase in studies that included patients who were homeless, sex workers, in prison, and PWID. There were 6 studies involving special populations that were cited a total of 48 times with a mean IF of 4.02 (3.00–6.86). Among the 32 studies, the test and treat approach (n = 18) was the most frequent, followed by the screening and monitoring simplification approach (n = 9). Notably, both approaches witnessed an increase in studies during the years 2021 to 2022 compared to 2018 to 2020.

Conclusion: Since 2016, the LEGA-C initiative has supported 32 studies conducted in Europe, with 25 out of the 32 focused on streamlining the care pathway for a variety of populations with HCV infection. The findings highlight the value of multi-stakeholder collaboration reaching nearly 9, 000 individuals who were mostly underserved and difficult to reach. These patients play a crucial role in the goal of achieving the elimination of HCV in Europe.

WED-483
Performance comparison of four hepatitis E antibodies detection methods

Ana Avellon Calvo[1], Milagros Muñoz Chimeno[2], Nazaret Diaz-Sanchez[2], Lucía Morago[2], Alejandra García-Lugo[2], María Isabel Zamora Cintas[3], María Mateo[3], María Simón[3], Monica Sanchez-Martinez[3]. *[1]National Center of Microbiology CIBERESP, Hepatitis Unit, Majadahonda (Madrid), Spain; [2]National Center of Microbiology, Instituto de Salud Carlos III, Majadahonda (Madrid), Spain; [3]Hospital General de la Defensa, Madrid, Spain*
Email: aavellon@isciii.es

Background and aims: Hepatitis E virus antibody detection constitutes the main screening test for Hepatitis E infection. Anti HEV IgM is used as first line detection test for acute infection while anti HEV IgG represents the main tool to assess seroprevalence. Sensitivity and specificity of marketed techniques have been under discussion. The aim of this study is to compare sensitivity and specificity of four of the more widely used techniques in Europe.
Method: Sample panels used for comparison were configured according to immunoblot (Recomline, Mikrogen) (IB) results. They were as follows: Panel I (immediate acute HEV infection) included 21 samples positive to anti-HEV IgM by IB and positive HEV-RNA. Panel II (acute HEV infection in early convalescence phase) included 71 samples positive to anti-HEV IgM by IB and negative for HEV-RNA. Panel III (past HEV infection) included 100 samples positive to anti-HEV IgG. Panel IV (HEV IgM negative) included 101 samples and Panel V (HEV IgG negative) another 100 samples. Compared techniques were: LIAISON® MUREX DiaSorin anti-HEV immunoglobulin (Ig) G and anti-HEV IgM assays (Liaison); Wantai HEV IgM and IgG ELISA (Wantai); VIDAS® BioMérieux anti-HEV IgM and IgG tests (Vidas) and Hepatitis E VIRCLIA® VirCell IgM and IgG monotests (Virclia). Test sensitivity and specificity, Cohen's kappa coefficient (k) for qualitative results and Pearson's correlation coefficient (PS) for concentrations were estimated.
Results: Anti HEV IgM acute phase sensitivity (Panel I) (confident interval (CI) 95%) was 100% for all techniques, while acute and convalescence phase sensitivity (Panel I+II) was 96.74 (93.11–100.37) for Liaison; 82.60 (74.86–90.35) for Wantai; 88.04 (81.41–94.67) for Vidas and 80.90 (72.73–89.07) for Virclia. Anti HEV IgM specificity (Panel IV) was calculated for Liaison and Virclia reaching 100% in both cases. Anti HEV IgM Wantai agreed with Vidas and Virclia with moderate K (0.404 and 0.472). Pearson correlation of quantitative results was higher when comparing anti HEV IgM Liaison-Vidas (0.783) and Wantai-Virclia (0.767) Anti HEV IgG past infection sensitivity (Panel III) (CI 95%) was 100% for Liaison, Vidas and Virclia and 99 (96.07–101.26) for Wantai. Specificity (Panel V) was calculated for Liaison and Virclia reaching 97.17 (94.01–100.33) for Liaison and 90.57 (82.65–94.71) for Virclia.
Conclusion: Anti HEV IgM sensitivity was excellent in acute phase for all techniques, decreasing when including the convalescence phase, as after several days of infection, sensitivity of techniques differs being the highest Liaison (96.74%) and Vidas (88.04%). Anti HEV IgM specificity of Liaison and Virclia was optimal. Anti HEV IgG sensitivity was 100% for Liaison, Vidas and Virclia, being slightly lower for Wantai (99.0%). Anti HEV IgG specificity was higher in Liaison (97.17%) than in Virclia (90.57%).

WED-484
Hepatitis C virus and HIV infection among persons who inject drugs in six sites in Tajikistan, 2022

Aziz Nabidzhonov[1], Rezeda Ashurova[2], Farkhod Saydullaev[3], Patrick Nadol[4], Bolot Kalmyrzaev[5], Hieremila Haile[6], Shaun Shadaker[6], Rania Tohme[6], Safarhon Sattorov[7], Senad Handanagic[6]. *[1]US Centers for Disease Control and Prevention in Tajikistan, Dushanbe, Tajikistan; [2]US Centers for Disease Control and Prevention, Dushanbe, Tajikistan; [3]US Centers for Disease Control and Prevention, Dushanbe, Tajikistan; [4]US Centers for Disease Control and Prevention, Bishkek, Kyrgyz Republic; [5]US Centers for Disease Control and Prevention, Bishkek, Kyrgyzstan; [6]US Centers for Disease Control and Prevention, Atlanta, United States; [7]Tajikistan National AIDS center, Dushanbe, Tajikistan*
Email: wkd9@cdc.gov

Background and aims: Modeling estimates indicate that 3% of people in Tajikistan could be infected with hepatitis C virus (HCV) and 0.2% with HIV. The risk of HCV and HIV infection is higher among persons who inject drugs (PWID). In 2022, the estimated PWID population size in Tajikistan was 18, 000. Persons receiving medication for opioid use disorders receive free testing for anti-HCV, but viremia testing and treatment must be paid out of pocket unless there is support from donor agencies. We estimate the prevalence of exposure and infection and testing history for HCV and HIV among PWID in Tajikistan.
Method: Respondent-driven sampling was used to recruit PWID from six sites in Tajikistan in 2022: Dushanbe, Khujand, Khorog, Kulob, Penjikent and Vahdat. Inclusion criteria included ≥18 years old, self-reported injecting drugs in the past 30 days, and residing in a defined survey area. Participants self-reported demographic and risk behaviors and were offered HIV and HCV rapid testing (RT). Those with reactive HCV RT were tested for viremic infection (HCV RNA). We report unweighted aggregated and city-specific ranges.
Results: We recruited 1, 714 PWID, of whom 95% were >30 years-old (median = 42; Q1–Q3:35–49), 94% were male, 39% were unemployed**,** 41% injected drugs for ≥11 years, 30% reported injecting drugs at least once daily, and 11% reported sharing a needle or syringe in the past 6 months. Heroin was the most frequently injected drug (71%). The aggregated HIV prevalence was 12% (n = 199; range by city 6–21%); anti-HCV prevalence was 28% (n = 472; range 17–43%) and viremic HCV prevalence was 18% (n = 301; range 10–27%). Among 199 PWID with HIV, 72% (n = 143; range 39–90%) were reactive for anti-HCV, and 34% (n = 68; range 17–90%) tested positive for HCV RNA. In total, 53% (n = 869; range 28–85%) of PWID reported ever being tested for HCV, and 87% were ever tested for HIV (n = 1499; range 76–99%). Among PWID who were anti-HCV reactive, 47% (n = 217; range 26–83%) were unaware of their status.
Conclusion: A substantial percentage of PWID were exposed to HCV, almost one in five had viremic HCV infection, and more than one in ten had HIV infection. Only half of PWID reported ever being tested for anti-HCV. Expansion of screening for HCV among PWID is needed. HCV infection was more common among people living with HIV. Integrating prevention, screening and treatment for hepatitis C with harm reduction and HIV services could help reduce the HCV burden among PWID in Tajikistan.

WED-485
Uptake in viral hepatitis screening, vaccination and linkage to care among at-risk migrants in Catalonia, Spain: three years of a community-based intervention

Email: camila.picchio@isglobal.org

Background and aims: Chronic viral hepatitis infections remain a major public health challenge. Migrants from countries with mid/high hepatitis B (HBV) and hepatitis C (HCV) prevalence are disproportionally affected by these infections in Europe. Additionally, they often encounter additional barriers to access and comprehend their host health system, which exacerbate their timely diagnosis. This ongoing study aims to scale-up a community-based model of HBV/HCV screening, HBV vaccination, and linkage to care among migrants born in countries with mid/high HBV/HCV prevalence in Catalonia, Spain.

Method: A total of 48 community-based screening interventions were conducted between 11/2020 and 12/2023 in Catalonia, Spain. Participants were offered HBV and HCV screening through rapid diagnostic tests and simplified blood sample collection using plasma separation cards. Screening for anti-HCV screening was offered from 06/2022. Community health workers were responsible for the recruitment of migrants at risk. All participants were offered linkage to care, including direct referral to a liver specialist for positive cases, the first dose of HBV vaccination administered in the community, or post-test counselling (PTC) to report a past resolved infection. Data were analysed using standard descriptive statistics with Stata v14.0.

Results: 829 and 381 people were tested for HBV and HCV, respectively. Participants were primarily from Ghana (77%) and Senegal (14.2%). Most were men (64.1%) with a mean age of 42 years (SD ± 10.8). Almost half (48.4%) had finished secondary school but had no higher studies and 24.2% were recently arrived migrants (≤5 years). Most reported never having been tested for HBV/HCV before (70.3% and 79.6%, respectively) and 10.2% reported being fully vaccinated against HBV. Prevalence of HBsAg+ was 9.53% (95% IC 7.5–11.5%) and anti-HCV+ was 0.53% (95% IC 0.06–1.89, n = 2) and none had detectable HCV RNA. The prevalence of resolved HBV infection (HBsAg-/anti-HBc+) was 39.5%. The overall linkage to care rate was 59.9%; with 70.9% of those HBsAg+ attending a specialist visit. Among those requiring vaccination/PTC, 58.7% had results communicated, and 76 people (10.4%) are awaiting communication of results due to the second scheduled visit scheduled for a future time. Of those who required vaccination, 60.6% were informed and 82.7% of those offered the first dose of the HBV vaccine in the community received it.

Conclusion: This community-based model of care has proven effective in increasing viral hepatitis screening among migrants in Catalonia by using simplified diagnostic tools and direct referral pathways. Successful linkage to care is expected to increase due to second community visits scheduled in the upcoming months. Community health workers have played a crucial role in minimizing cultural and linguistic barriers often encountered by this at-risk population.

WED-486-YI

Material deprivation is associated with liver stiffness measurement and liver-related events in people with HIV

Felice Cinque[1,2], Clara Long[3], Dana Kablawi[4], Dong Kim[4], Thierry Tadjo[4], Wesal Elgretli[5], Luz Ramos Ballesteros[6], Amanda Lupu[4], Michael Nudo[4], Bertrand Lebouche[7], Nadine Kronfli[7], Joseph Cox[7,8], Cecilia Costiniuk[7], Alexandra De Pokomandy[7], Jean-Pierre Routy[7], Marina B. Klein[7,8], Frederic Lamonde[9], Raman Agnihotram[9], Sahar Saeed[10], Giada Sebastiani[11,12]. *[1]Division of Gastroenterology and Hepatology, McGill University Health Centre, Chronic Viral Illness Service, McGill University Health Centre, Montreal, Canada; [2]SC-Medicina Indirizzo Metabolico, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, Department of Pathophysiology and Transplantation, University of Milan, Italy., Milan, Italy; [3]Division of Gastroenterology and Hepatology, McGill University Health Centre, Chronic Viral Illness Service, Division of Infectious Diseases, Department of Medicine, McGill University Health Centre, MONTREAL, Canada; [4]Division of Gastroenterology and Hepatology, McGill University Health Centre, Chronic Viral Illness Service, Division of Infectious Diseases, Department of Medicine, McGill University Health Centre, Montreal, Canada; [5]Division of Experimental Medicine, McGill University, Montreal, Canada, Montreal, Canada; [6]Division of Gastroenterology and Hepatology, McGill University Health Centre, Montreal, Canada; [7]Chronic Viral Illness Service, Division of Infectious Diseases, Department of Medicine, McGill University Health Centre, Montreal, Canada; [8]Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, Canada; [9]Research Institute, McGill University Health Centre, Montreal, Canada; [10]Department of Public Health Sciences, Queens University, Kingston, Canada; [11]Division of Gastroenterology and Hepatology, McGill University Health Centre, Montreal, Chronic Viral Illness Service, Division of Infectious Diseases, Department of Medicine, McGill University Health Centre, Montreal, Canada; [12]Division of Experimental Medicine, McGill University, Montreal, Canada*
Email: cinque.felice@gmail.com

Background and aims: Socioeconomic status drives health disparities in people with HIV (PWH). The effect of material deprivation on hepatic outcomes in PWH has not been assessed. Aim: to evaluate the association between material deprivation and liver fibrosis, metabolic dysfunction-associated steatotic liver disease (MASLD) and clinical outcomes in PWH.

Method: We included consecutive PWH from the LIVEr disease in HIV (LIVEHIV) cohort with available Fibroscan. MASLD was defined as presence of hepatic steatosis by controlled attenuation parameter (CAP)≥248 dB/m and at least one metabolic abnormality. Significant liver fibrosis was defined as liver stiffness measurement (LSM)≥8. Socioeconomic status was assessed by the Pamplon Material Deprivation Index (MDI). PWH with MDI quintiles 4 and 5 were classified as "deprived" while PWH with MDI quintiles 1 and 2 as "privileged". Multivariable linear regression analysis investigated associations of MDI with LSM and CAP. Incidence of liver outcomes (ascites, variceal bleeding, hepatic encephalopathy, hepatocellular carcinoma, liver transplantation), extrahepatic outcomes (cancer, cardiovascular disease) and overall mortality were evaluated through survival analysis.

Results: Among the 768 PWH included (median age 54 years, 76% male, 25% HBV coinfected, 10% HCV coinfected, 23% with significant liver fibrosis and 33% with MASLD), 40% were materially privileged while 47% were materially deprived. At baseline, materially deprived PWH were more frequently female and of Black ethnicity and had higher prevalence of metabolic comorbidities. After adjustments, material deprivation was associated with increased LSM at baseline (β = 1.858, 95% CI 0.53–3.17; p = 0.006) but not with CAP (β = 6.469, 95% CI −5.55–18.49; p = 0.291). In the survival analysis, during a median follow-up of 3.8 years, the incidence of liver-related events was significantly higher in materially deprived PWH compared to

materially privileged PWH (log rank p = 0.04), while there was no difference in extrahepatic events or all-cause mortality.
Conclusion: Material deprivation, reflecting socioeconomic status, is associated with liver fibrosis and liver-related events in PWH. Future strategies should assess whether improved material security improves liver outcomes.

WED-487
Geographic variability in harm reduction uptake, risk behaviors, and network characteristics among people who inject drugs in Kenya: a key hurdle to hepatitis C elimination
Hannah Manley[1], Lindsey Riback[1], Mercy Nyakowa[2], Chenshu Zhang[3], Rose Wafula[2], Nazila Ganatra[2], Matthew Akiyama[3]. [1]*Albert Einstein College of Medicine, New York, United States;* [2]*Kenya Ministry of Health, Nairobi, Kenya;* [3]*Albert Einstein College of Medicine, New York, United States*
Email: makiyama@montefiore.org

Background and aims: Hepatitis C (HCV) is highly concentrated among people who inject drugs (PWID). In Kenya, there is a strong gradation in HCV prevalence from the Coastal region moving inland. This gradation has been attributed to the introduction of heroin in the Coast in the 1980s; however, regional differences in HCV-related risk behaviors, networks, and harm reduction coverage are not well characterized. We assessed factors associated with HCV among PWID located in the Coastal region and Nairobi.
Method: We are recruiting 3500 PWID from needle and syringe program (NSP) sites in Kenya using respondent driven sampling. Participants complete biobehavioral surveys and receive testing for HCV, hepatitis B (HBV), and HIV. We conducted this analysis using chi-squared tests or t-tests when appropriate.
Results: Thus far, among 2508 participants enrolled in Nairobi (33.0%), Coast (48.8%), and Western (17.7%) region, participants are mainly male (89.9%) and 34.6 years old on average (SD = 8.6). One-fifth (19.8%, N = 496) are HCV antibody positive (HCV+). Regional prevalence is highest in the Coast (25.4%, N = 311/1223), followed by Nairobi (22.1%, N = 183/828), and the Western region (0.5%, N = 2/443). HCV+ participants in Coast were more likely to have injected in the last 30 days than those in Nairobi (96.5% v. 72.1%, p < 0.001) and injected more times on average (86.8 v. 64.3, p < 0.001) in the same timeframe. HCV+ individuals from Coast were more likely to have reused another person's needle (25.1% v. 0%, p < 0.001) or injection equipment (e.g., cookers, cotton, water/solution; 27.3% v. 6.6%, p < 0.001) at last injection when compared to those in Nairobi. Those with HCV in Coast were less likely to have previously accessed HCV testing (64.3% v. 77.6%, p = 0.002), NSP (78.1% v. 98.4%, p < 0.001), and opioid agonist therapy (OAT) (50.8% v. 84.2%, p < 0.001). In looking at social network characteristics, HCV+ participants in Coast knew more PWID (by face or name) in Kenya on average than those in Nairobi (15.6 v. 9.6, p < 0.001) and more individuals who are HCV+ (0.7 v. 0.2, p < 0.001). They also identify a greater proportion of their named network members as injection partners (90.1% v. 5.2% of members seen in last 30 days, p < 0.001), and injected with a greater proportion of their named network members in the same timeframe (90.7% v. 40.5%, p < 0.001). HCV+ participants living in Coast are more likely to report having ever been incarcerated than those in Nairobi (66.9% v. 32.2%, p < 0.001).
Conclusion: While data are preliminary, higher risk behaviors and lower NSP and OST uptake may be drivers of the higher HCV prevalence in Coastal Kenya. Social network characteristics also highlight how injection networks may contribute to higher HCV prevalence in Coastal Kenya as compared to Nairobi. Due to differing risk factors for HCV, once size fits all intervention may not be optimal and targeted, regional approaches may be needed.

WED-490
Optimizing a hepatitis C screening model for general population using easily accessible data
Chi Zhang[1], Yi-Qi Liu[1], Hong Zhao[1], Gui-Qiang Wang[1]. [1]*Peking University First Hospital, Beijing, China*
Email: zhangcdoctor@126.com

Background and aims: Globally, an estimated 58 million chronic hepatitis C virus (HCV) infections. Direct-acting antiviral medicines (DAAs) can cure more than 95% of persons with HCV infection, but access to diagnosis (20%) and treatment (15%) was low. We aimed to develop screening algorithms that accurately identifies HCV infection using easily accessible demographic parameters.
Method: We obtained data from population-based cohorts National Health and Nutrition Examination Survey (NHANES 1990–2020), and divided them into training (6-cycles; n = 46243) and testing (5-cycles; n = 37060) cohort. Then, we applied logistic regression to calculate the odds ratio (OR) of 4 demographic factors (sex, ethnicity, blood transfusion history, birth year) for diagnosing HCV infection. Next, we developed and compared 9 machine learning (ML) algorithms to diagnose HCV infection in training cohort. Finally, we adopted the selected algorithm to establish the diagnostic model and test the performances.
Results: The overall cohort (n = 83303) was 49.0% male; 37.9% White, 23.2% Black, 29.0% Hispanic, and 10.0% other; 8.8% of participates had a history of blood transfusion; with a mean birth year of 1972 ± 23. The positive rates of anti-HCV and HCV RNA among studied population were 1.3% and 0.8% (unweighted). In multivariate analysis, all four parameters were significantly correlated with HCV infection: male sex (OR 2.01; P < 0.001); Black versus White (OR 1.96; P = 0.008); blood transfusion history (OR 2.14; P < 0.001); born 1970 and before (OR 8.98; P < 0.001). Comparing the AUC values of 9 ML algorithms in the training cohort, XGBoost was selected as the best prediction model. The AUC of the XGBoost model for diagnosing HCV infection was 0.891 (95%CI 0.880–0.903) for the training set. In the testing set, the AUC was 0.843 (0.827–0.858), and the sensitivity, specificity, PPV and NPV were 0.78, 0.78, 0.288 and 0.967, respectively.
Conclusion: To predict HCV infection in general population, only 4 easily obtained demographic features are needed using our ML model.

WED-491
Understanding barriers and enablers to hepatitis C treatment initiation: a systematic review of qualitative studies
Kathleen Bryce[1,2], Fiona Burns[1,2], Colette Smith[1], Alison Rodger[1,2], Douglas Macdonald[2,3]. [1]*Institute for Global Health, University College London, London, United Kingdom;* [2]*Royal Free London NHS Foundation Trust, London, United Kingdom;* [3]*Institute of Liver and Digestive Health, University College London, London, United Kingdom*
Email: kathleenbryce@doctors.org.uk

Background and aims: Many factors associated with disengagement from care between hepatitis C diagnosis and treatment initiation have been identified in the direct-acting antiviral (DAA) era. We aimed to better understand and contextualise these factors by undertaking a systematic review of qualitative studies on DAA treatment initiation.
Method: We performed a systematic review of the barriers and enablers to hepatitis C DAA treatment initiation, in high income settings with free publicly-funded universal healthcare provision. We searched eight bibliographic databases for studies published between 2014 and May 2022 using pre-defined keywords. We included provider and patient interview-based qualitative studies investigating positive (enablers) or negative (barriers) associations with DAA treatment initiation. The Capability, Opportunity, Motivation, Behaviour (COM-B) framework was used to synthesise our findings.
Results: Of 5198 articles identified, 21 studies conducted in Australia, Canada and Europe were included. Overall quality was good. Barrier

themes included: lack of knowledge of DAA availability and effectiveness, poor mental and physical health and deferral to stabilise drug use first (Capability); previous negative healthcare experiences including stigma, competing priorities and resource limitations of the patient (such as housing) as well as of the provider and healthcare context (Opportunity); and beliefs about consequences of hepatitis C and of DAA treatment (Motivation). Enabler themes included: peer advocate-led awareness-raising and education (Capability); building trusting patient-provider relationships, simplified integrated/co-located multidisciplinary care services to address multiple needs (Opportunity); and changing beliefs about consequences and individual capabilities (Motivation).
Conclusion: Interview-based studies of barriers and enablers to DAA treatment explain multiple factors associated with lower treatment uptake borne out in quantitative analyses, such as low socioeconomic status, insecure housing, active drug use, disease stage, age and treatment experience. By identifying an individual's Capability, Opportunity and Motivation barriers, pre-emptive supportive interventions can be tailored to efficiently enable engagement with DAA treatment.

WED-492
Evaluation of hepatitis C treatment and care model in primary healthcare centers in the country of Georgia
Akaki Abutidze[1,2], Tengiz Tsertsvadze[1,2], Lali Sharvadze[2,3], Rania Tohme[4], Shaun Shadaker[4], Ekaterine Adamia[5], Tamar Gabunia[5].
[1]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia; [2]Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia; [3]Hepatology clinic HEPA, Tbilisi, Georgia; [4]Division of Viral Hepatitis, Centers for Disease Control and Prevention, Atlanta, United States; [5]Ministry of IDPs from the Occupied Territories, Labour, Health and Social Affairs of Georgia, Tbilisi, Georgia
Email: akakiabutidze@yahoo.com

Background and aims: In April 2015, with a partnership with Gilead Sciences and technical assistance from the US Centers for Disease Control and Prevention, Georgia launched the world's first hepatitis C elimination program. By the end of November 2023, more than 85, 000 patients with current hepatitis C virus (HCV) infection initiated treatment, with 99% cure rates among those tested for sustained virologic response (SVR). Broad access to direct acting antivirals (DAAs) resulted in rapid increase in treatment uptake in 2016, which has since declined due to barriers in diagnosis and linkage to care. To address this issue, Georgia initiated service decentralization in 2018 by integrating HCV screening and treatment in primary healthcare centers (PHCs). We report preliminary results of an integrated model of hepatitis C care in PHCs.
Method: By November 30, 2023, a total of 10 PHCs were providing hepatitis C care services throughout the country. The integrated model was based on "one stop shop" approach, where patients receive all HCV screening, treatment, and care services in selected PHCs. PHCs provided care to HCV treatment-naïve patients with no or mild fibrosis (FIB-4 score<1.45) using simplified diagnostics and a treatment monitoring approach, while persons with advanced liver fibrosis/cirrhosis were referred to specialized clinics. Patients were treated with Sofosbuvir/Ledipasvir and/or Sofosbuvir/Velpatasvir for 12 weeks. SVR was defined as undetectable HCV RNA at 12–24 weeks after end of therapy. The Extension for Community Healthcare Outcomes (ECHO) telemedicine model was used to train and support primary healthcare providers. Regular teleECHO videoconferencing was conducted to provide primary care providers with advice and clinical mentoring.
Results: Overall, 1, 881 persons with current HCV infection were evaluated for FIB-4 score at PHCs as of November 30, 2023. A total of 1, 238 persons initiated treatment, and of them 1, 162 (93.9%) had completed treatment at the time of analysis. Of 1, 134 persons eligible for SVR testing (12–24 weeks post treatment completion), 889 (78.4%) had been tested, and 874 (98.3%) achieved SVR.
Conclusion: Our analysis shows the effectiveness of integrating a simplified HCV diagnosis and treatment model in PHCs. Countrywide expansion of this model is warranted to bridge the gaps in the hepatitis C care continuum and ensure high rates of treatment uptake, enabling Georgia to achieve hepatitis C elimination.

Email: krystyna.dobrowolska98@gmail.com

Background and aims: Eliminating hepatitis C virus (HCV) infection in the population of women of reproductive age is important not only for the health of women themselves, but also for the health of their children. The aim of the analysis is to evaluate the effectiveness of contemporary therapy in a large cohort of women of childbearing age from routine clinical practice and identify the factors reducing therapeutic success in hopes of achieving the goal of complete virus elimination in this group.
Method: The analyzed population consisted of 7, 861 patients with chronic hepatitis C treated with direct-acting antiviral drugs (DAAs) between 2015 and 2022 at 26 hepatology centres, including 3, 388 women aged 15–49 years as defined as reproductive age by the World Health Organization. The comparison group was a population of 4, 473 men of the corresponding age. Data were collected retrospectively using the nationwide EpiTer-2 database.
Results: Females were significantly less often infected with HCV genotype (GT) 3 compared to males (11.2% vs 15.7%, $p < 0.001$). They also had less frequent comorbidities (40.5% vs. 44.2%, $p = 0.001$) and were less likely to use concomitant medications (37.2% vs. 45.2%, $p < 0.001$). Hepatocellular carcinoma and a history of liver transplantation were significantly less frequently documented in women, as were HIV and HBV co-infections. Men were more likely than women to be treatment-experienced (17.4% vs. 13.5%, $p < 0.001$). In both genders, previous antiviral therapy was predominantly IFN-based regimens, significantly more common used in women (94.5% vs. 82.8%, $p < 0.001$). In the current treatment, women were more likely to receive a genotype-specific regimen (55.4%), while there was a slight predominance of pangenotypic options for men (50.5%). The

overall effectiveness in intent-to-treat and per protocol analysis in the female population was 96.3% and 98.8%, respectively, while a 92.9% and 96.8% cure rate was documented in men, p < 0.001. Regardless of the treatment type, GT and the advancement of liver fibrosis, women were significantly more likely to achieve the sustained virologic response as compared to men. GT3 and cirrhosis were independent factors increasing the risk of treatment failure irrespective of gender. Women more frequently reported adverse events as compared to men, with the most common weakness/fatigue (6.9% vs. 5.5%, p = 0.01) and headache (4.4% vs. 2.4%, p < 0.001). Adverse events were mostly mild in nature; deaths occurred in 0.3% of men and 0.1% of women (p = 0.03), and none were considered by the treating physician to be therapy-related.
Conclusion: We have demonstrated an excellent efficacy and safety profile for the treatment of HCV infection in women of reproductive age. This gives hope for the micro-elimination of HCV infections in this population, translating into a reduced risk of severe disease in both women and their children.

WED-494
Local Hepatitis Elimination and Prevention (LHEAP)-Doorstep Model for Elimination of Hepatitis B and Hepatitis C in Rawalpindi, Pakistan
Nida Ali[1], John Ward[2], Ehsan Ghani[3], Qaiser Hussain[4], Muhammad Irfan[4]. *[1]The Task force for Global Health, Coalition for Global Hepatitis Elimination, Decatur, United States; [2]Coalition for Global Hepatitis Elimination, The Task Force for Global Health, Decatur, United States; [3]District Health Authority, Rawalpindi, Pakistan; [4]Local Hepatitis Elimination and Prevention, District Health Authority, Rawalpindi, Pakistan*
Email: nida.ali4883@gmail.com

Background and aims: It is estimated that 5 million people are infected with Hepatitis B Virus (HBV) and 10 million are infected by Hepatitis C Virus (HCV) in Pakistan. This makes Pakistan the highest burden country in terms of HCV cases and 9th highest burden country in terms of HBV cases globally. Thousands of new patients are added every year. The service delivery is centralized with little to no access for marginalized and high-risk communities. Also, the centralized hepatitis care system does not offer the comprehensive services for prevention, testing and treatment.
Ministry of Primary and Secondary Healthcare of Punjab Province, in coordination with the Coalition for Global Hepatitis Elimination USA launched Local Hepatitis Elimination and Prevention (LHEAP) project in June 2023. LHEAP is a 3-year implementation research project providing full menu of essential hepatitis prevention, testing and treatment services at the community doorstep. The overall aim of the project is to generate the evidence for feasibility of HBV and HCV micro-elimination through implementation of decentralized community healthcare model. In the first phase, we intend to test-run the doorstep hepatitis elimination model.
Method: LHEAP is implemented in Rawalpindi district in a population of 100, 000 persons. The trained frontline workers go from door to door to do the following: 1) HBV and HCV Rapid Diagnostic Test (RDT), 2) Reflex testing i.e., on spot blood draw for PCR, 3) Hepatitis B adult vaccination, 4) Treatment for HBV and HCV, 5) Active follow-up to support individuals through the treatment, 6) Referral services for decompensated cases, 7) Follow-up testing for HBV and HCV.
Results: At the end of the first phase of testing, 34445 persons of all age groups were screened in 7 weeks of implementation. Among those 147 (0.43%) were found to be positive for HBsAg. 105 (71.4%) persons received confirmatory viral load testing and 68 (64.8%) tested positive. Treatment with tenofovir was initiated for 7 (10%) patients. Of the 34445, 619 (1.8%) were positive for Anti-HCV. 404 persons received viral load testing and 218 (54%) were found to have active viremia. Of those, treatment was started for 138 (63.3%) patients. Frontline teams vaccinated 14326 adults with the first and then second dose of Hepatitis B vaccine.
Conclusion: The prevalence in the general population of is found to be lower than expected. This may be attributed to the fact that all age groups were included in the sample. Moreover, the population is settled in the urban households with predominant risk of interaction with the healthcare settings and open access to frequent therapeutic injections. Treatment initiation of HBV remain a challenge. Visit to primary care is required after confirmatory testing and the guidelines do not favor inclusive approach.

WED-495
The impact of integration and decentralization of HBV services on enhancing the HBV care continuum: an interrupted time series
Jean Damascene Makuza[1], Dahn Jeong[2], Marie Paul Nisingizwe[2], Phymar Soe[2], Richard Morrow[3], Georgine Cua[3], Héctor Alexander Velásquez García[4], Janvier Serumondo[5], Albert Tuyishime[6], Joseph Puyat[7], Alnoor Ramji[8], Naveed Janjua[4]. *[1]Rwanda Biomedical Center, University of British Columbia, School of Population and Public Health, Vancouver, Canada; [2]University of British Columbia, School of Population and Public Health, Vancouver, Canada; [3]University of British Columbia, School of Population and Public Health, British Columbia Center for Disease Control, Vancouver, Canada; [4]British Columbia Center for Disease Control, University of British Columbia, School of Population and Public Health, Vancouver, Canada; [5]Rwanda Biomedical Center, Kigali, Rwanda; [6]Rwanda Biomedical Centre, Kigali, Rwanda; [7]University of British Columbia, Vancouver, Canada; [8]University of British Columbia, Faculty of Medicine, Division of Gastroenterology, Vancouver, Canada*
Email: makorofr@gmail.com

Background and aims: Rwanda adopted decentralization and integration of hepatitis B virus (HBV) services into existing health services in July 2019. However, the impact of these changes has not been explored. Therefore, we assessed the impact of decentralization and integration of HBV diagnosis, treatment, and follow-up services into existing services on the HBV care cascade in Rwanda, including engagement in care, treatment initiation and continuation.
Method: We used data from the District Health Information System 2 data that included 4.5 million individuals screened for HBV in Rwanda between January 2016 and June 2023. We included individuals aged >2 years and analysed the proportion of individuals enrolled in care among those diagnosed, those who initiated the treatment among those who were eligible for HBV treatment, and those who were retained on treatment. We conducted interrupted time series (ITS) analysis overall and stratified by sex and age categories using a segmented linear regression model to assess the impact of decentralization of HBV services and included first-order autocorrelation terms to control for data correlation.
Results: Among the 4, 604, 468 persons included, 55, 820 (pre-policy: 21, 641 vs. post-policy: 34, 179) were diagnosed with HBV infections. Of those, 21, 182 (37.9%) [pre-policy: 5, 034 (23.3%) vs. post-policy: 16, 148 (47.2%)] were engaged in care, 5, 966 (28.2%) [pre-policy: 2, 435 (48.4%) vs. post-policy: 3, 531 (21.9%)] were eligible for HBV treatment, 4, 746 (79.6%) [pre-policy:1, 950 (80.1%) vs. post-policy: 2, 796 (79.2%)] initiated treatment, and 4, 621 (97.4%) [pre-policy: 1, 942 (99.6%) vs. post-policy: 2, 679 (95.8%)] continued treatment at one-year post-initiation. ITS results showed that the proportion of individuals enrolled in care increased in level by 12.28 [95% confidence interval (CI): 4.46, 33.02] in July 2019 and remained stable since then. The proportion of individuals who retained in care decreased in trend (−2.46, with 95% CI: −3.30, −2.10). In our stratified analyses, we observed these changes in care enrollment in under 55 years old age categories and among males. We found no significant level nor trend change for the proportions of individuals who initiated HBV treatment.
Conclusion: Our findings indicate that decentralization of HBV services had a significant impact on engagement with care but did

not improve treatment initiation. Further investigations and strategic adaptations such as training of more health care providers on HBV management as well as intensive mentorship may be required to optimize the effectiveness of the HBV care continuum post-decentralization.

WED-496

Defining the data requirement to achieve the hepatitis C elimination in the United Kingdom: the Somerset liver improvement project

Emma Saunsbury[1], Almuthana Mohamed[1], Christina Owen[1], Timothy Jobson[1]. [1]*Somerset NHS Foundation Trust, Taunton, United Kingdom*
Email: almuthana700@gmail.com

Background and aims: Despite treatment initiatives to meet the World Health Organisation target of eliminating hepatitis C virus (HCV) by 2030, many patients with HCV in the United Kingdom (UK) are not yet linked to specialist services or treated. Using a novel case finding database in Somerset (609, 474 individuals), we aimed to identify unknown and untreated HCV patients, and determine the impact of deprivation on this patient population by refining the methodology to identify HCV patients for treatment.
Method: The database was configured to identify two groups of patients:-those with persistently abnormal liver function tests (LFTs) and no HCV test; and a second group with positive HCV antibody (Ab) between 2004–2023 (age 18–70). Clinical records and 'high-cost drug' records were reviewed to determine treatment status, spontaneous HCV clearance, and/or sustained virological response (SVR) post-treatment. Postcodes were used to determine patients' Index of Multiple Deprivation (IMD) comparing most deprived deciles (IMD 1–2) with the rest (IMD 3–10) in line with the NHS Core20Plus5 programme. The cohort requiring treatment was queried for overlap with the 'lost positives' (NHS England programme) from 2018.
Results: 14, 525 had persistently abnormal LFTs (ALT>40; 90 days). However, 67% of them had never had HCV Ab tests. 1001 patients were identified with positive HCV Ab (current or prior), significantly weighted towards deprived areas (0.63% in IMD1–2; 0.21% in IMD3–10; $p < 0.0001$). HCV exposure was strongly associated with early mortality. The mortality of HCV Ab positive patients was significantly higher in deprived areas (25.2% in IMD1–2, 18.6% in IMD3–10; $P = 0.045$). Median age at death was 49 years. Overall, 687 alive HCV Ab positive patients were identified. Of them, 442 were either HCV PCR negative or treated. 120 identified as requiring treatment and 132 needed further investigation. Concerningly, 11% (75 patients) had never had HCV PCR test and further 74 had failed to engage with our service (although neither of these groups were associated with IMD). Of the patients requiring treatment now only 13% were also seen in the local 'Lost Positives' cohort identified from the NHS England Programme (2018).
Conclusion: Our data suggests that finding and treating the majority of cases requires a systematic approach to a) ensure all patients with abnormal LFTs have HCV Ab status checked; b) ensuring all HCV Ab positive patients have PCR status checked, and confirmed where negative; c) data across multiple geographies (patients with missing results may have had them elsewhere) and d) regular data refresh and an iterative approach, as while there have been successful prior initiatives, new untreated populations arise. Further work is underway to offer investigation and/or treatment to the relevant patients in Somerset.

WED-497

Presentations of acute hepatitic C in London, focussed in men who have sex with men (MSM)

Maeve Barlow[1], Indrajit Ghosh[1], Angieszka Kemper[1], Philippa C Matthews[1,2], Stuart Flanagan[1]. [1]*Central and North West London NHS Foundation Trust, Mortimer Market Centre, London, United Kingdom;* [2]*The Francis Crick Institute, London, United Kingdom*
Email: maeve.barlow1@nhs.net

Background and aims: WHO Elimination targets for HCV are dependent on early diagnosis and treatment. Since 2020 we have noted an increase in cases of acute HCV infection in North Central London (NCL). We characterised affected individuals to inform future strategies for testing and treating.
Method: We undertook a retrospective clinical audit to identify cases of acute HCV from 1 Jan 2020 to 31 Dec 2023 in individuals aged over 18 years. We identified cases through the NCL Hepatitis database and information was gathered from the Electronic Patient Record. Acute HCV was defined as: a negative HCV antigen result in the 6 months prior to a positive test, a significant risk event had occurred.
We used Stata (v17, StataCorps, Texas, USA) to conduct descriptive and frequency analyses.
Results: 20, 933 HCV antigen tests and 6491 HCV RNA tests were performed in our services during the 4-year period. We identified 35 adults with acute HCV. 5/35 (14.3%) occurred in 2020, 6 (17.1%) in 2021, 10 (28.6%) in 2022 and 14 (40.0%) in 2023. Median age was 37 years (range 22–58), 34/35 (97.1%) identified as male and 15/35 (42.9%) were born in the United Kingdom followed by Brazil (14.3%) and Columbia (8.6%), with 12/35 (34.3%) of cases reporting 12 other countries of birth. Most cases (28/35, 80.0% were detected in the sexual health clinic setting, followed by hospital (8.6%) and primary care (5.7%).33/35 (94.3%) were MSM, and the most identified risk factor for HCV acquisition was unprotected anal intercourse (UAI) in 32/35 (91.4%). Other risk factors included recreational drug use (62.9%), injecting drug use (37.1%) and fisting/sex toy use (14.3%). All individuals had at least one identifiable risk factor, and 22/35 (62.9%) reported multiple risk factors. 21/35 (60%) HCV cases arose in people living with HIV (PLWH), with a median CD4 count of 740 cells/mm^3 (range 340 to 950), all on antiretroviral therapy. Of those eligible, 8/13 (61.5%) were on pre-exposure prophylaxis (PrEP). At HCV diagnosis, of those tested, 16/28 (57.1%) had a concurrent sexually transmitted infection (STI), the most common of which was gonorrhoea (35.7%), then chlamydia (21.4%) and syphilis (21.4%). 3/28 (10.7%) individuals had more than one STI identified. HCV infection was recurrent in 10/35 (28.6%). The most common genotype was 1a (19/35, 54.3%). 34/35 patients were commenced on Direct Acting Antivirals (DAA) and all 34 had completed DAA treatment by 31 Dec 2023, of whom none had detectable HCV RNA at end of treatment. Of those attending for their 12- or 24-week follow-up ($n = 23$), 100% had achieved SVR. Since completing treatment, there have been no known reinfections.
Conclusion: We highlight acute HCV infections in London primarily in MSM living with HIV infection, with UAI the most common risk factor. Targeted testing and intervention is essential to make prompt diagnoses. Ongoing active monitoring will guide screening and prevention interventions.

WED-498

Impact of direct-acting antiviral market access policy barriers and restrictions in patients with hepatitis C virus: A database analysis of US claims from states with and without Medicaid restrictions

Nancy S Reau[1], Krithika Rajagopalan[2], Dilip Makhija[3], Fatema Turkistani[2], Caroline Burk[3], Marvin Rock[3], Michelle Martin[4]. [1]*Rush University, Chicago, United States;* [2]*Anlitiks, Inc., Windermere, United States;* [3]*Gilead Sciences, Inc., Foster City, United States;* [4]*University of Illinois at Chicago, Chicago, United States*
Email: nancy_reau@rush.edu

Background and aims: Market access policy barriers to direct-acting antivirals (DAAs) among patients with hepatitis C virus (HCV)

infection in public health insurance programs (e.g., Medicaid in the US) may result in undesirable outcomes among the vulnerable HCV patient population. While many state Medicaid plans have implemented sobriety restriction policies that require evidence of sobriety before DAAs are prescribed, no studies have examined the real-world consequences of such restrictions. This claims database analysis was conducted to examine the health care resource utilization (e.g., inpatient hospitalizations) impact of sobriety restrictions to DAAs among Medicaid patients with HCV infection in the United States.

Method: Data from the Anlitiks All Payor Claims data, an open-source data representing data from all 50 state Medicaids from January 2020 to June 2022 was used. Patients initiating DAAs (i.e., index date) between January to December 2021 were categorized based on their "state of residence" on index date into States with no sobriety restrictions (S/no-SR) and States with sobriety restrictions (S/SR). All eligible patients had ≥12 months pre-index, ≥6 months of post-index follow-up, and continuous medical enrollment (i.e. ≥1 medical claim during follow-up). Proportion of patients with ≥1 all-cause medical (inpatient, ER, outpatient, office) visits by type for S/no-SR vs S/SR cohort were examined. Cohort differences were analysed using unadjusted and adjusted (i.e., controlling for confounders) logistic regression models and reported as odds ratios (OR) and adjusted odds ratios (AOR) and associated 95% confidence intervals (CI), respectively.

Results: A total of 4, 623 (S/no-SR) and 2, 295 (S/SR) patients were eligible for analysis. The S/no-SR cohort had a mean age of 43.0 (SD = 11.51) years, 58.1% (n = 2, 686) were male, and 59.68% (n = 2, 759) had substance use history. The S/SR cohort had a mean age of 45.0 (SD = 12.02) years, 50.28% (n = 1, 154) were male, and 44.1% (n = 1, 012) had substance use history. All-cause medical visits by type were: 18.14% vs. 22.02% (inpatient), 37.44% vs. 42.34% (ER), 55.39% vs. 62.53% (outpatient), and 69.06% vs.76.43% (office) for S/no-SR vs. S/SR cohorts, respectively. Unadjusted OR showed that all differences were significant and AOR demonstrated significantly ($p < 0.05$) higher odds of inpatient [AOR 2.09 (1.59–2.73] and outpatient visits [AOR 1.52 (1.28–1.82)] for S/SR cohort compared to S/no-SR cohort.

Conclusion: In this analysis, Medicaid patients initiating DAAs in S/SR were 2 times and 1.5 times more likely to have inpatient and outpatient visits, respectively. Findings suggest that restricting DAA access in the vulnerable Medicaid HCV population may be associated with adverse HCRU consequences and potentially impede WHO's 2030 HCV global elimination goals.

WED-499

Predictors of treatment initiation for hepatitis C virus among pregnant and postpartum individuals using health administrative data from Ontario, Canada from 1999 to 2021

Andrew Mendlowitz[1,2,3], Jennifer Flemming[4,5], Tatyana Kushner[6], William WL Wong[2,7,8], Zoe Greenwald[8,9,10], Camelia Capraru[1], Bo Chen[1], Wenbin Li[3], Chelsea Masterman[11], Jordan J. Feld[1], Mia Biondi[1,12]. *[1]Toronto Centre for Liver Disease/Viral Hepatitis Care Network (VIRCAN), University Health Network, Toronto, Canada; [2]Toronto Health Economics and Technology Assessment (THETA) Collaborative, University Health Network, Toronto, Canada; [3]ICES, Queen's University, Kingston, Canada; [4]ICES, Queen's University, Kingston, Canada; [5]Departments of Medicine and Public Health Sciences, Queen's University, Kingston, Canada; [6]Division of Liver Diseases, Icahn School of Medicine at Mount Sinai, New York, United States; [7]School of Pharmacy, University of Waterloo, Waterloo, Canada; [8]ICES, Toronto, Canada; [9]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada; [10]Centre on Drug Policy Evaluation, MAP Centre for Urban Health Solutions, Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, Canada; [11]School of Nursing, University of Western Ontario, London, Canada; [12]School of Nursing, York University, Toronto, Canada*
Email: andrew.mendlowitz@mail.utoronto.ca

Background and aims: With the ongoing overdose epidemic, hepatitis C virus (HCV) prevalence has increased among younger individuals, including women of childbearing potential. Prior work has documented maternal complications and poor post-delivery linkage-to-care among those infected. Understanding factors associated with treatment initiation before, during, and after pregnancy may help develop strategies to enable HCV care for this population.

Method: We performed a population-based retrospective cohort study, linking individuals with pregnancy records (2003 to 2021) and positive HCV RNA test results (1999 to 2021) to provincial health administrative data in Ontario, Canada. Pregnancies were identified as early loss (<20 weeks), induced abortion and live/still births >20 weeks. HCV treatment was identified using outpatient prescription claims or HCV RNA test records. Individuals were followed from first RNA positive, until treatment initiation or censored at earliest date of death, emigration, HCV RNA negative, or end of study. Time-dependent Cox regression was used to evaluate associations between variables and treatment initiation, estimating crude (HR) and adjusted hazard ratios (aHR).

Results: We identified 6, 928 individuals with HCV RNA positive test (s) and ≥1 pregnancy (18, 822 pregnancies in total: 13, 776 (73.0%) prior to first RNA positive, 3, 458 (18.3%) during follow-up, and 1, 628 (8.6%) after treatment initiation). After a median follow-up of 5.93 (95%CI:5.59–6.26) years, 3, 878 people (44.0%) initiated treatment. Median age at RNA positivity was 30 years (IQR:26–36). In crude models, older age (HR 1.02, 95%CI:1.02–1.03), prior pregnancy (HR 1.50, 95%CI:1.39–1.63), substance use (HR 1.21, 95%CI:1.13–1.30), and initiating opioid agonist therapy (OAT) (HR 1.33, 95%CI:1.25–1.42) were associated with increased likelihood of treatment initiation. Number of pregnancies after RNA positive was associated with lower likelihood of treatment initiation (HR 0.90, 95%CI:0.86–0.95). Relative to pre-2012, treatment initiation was more likely among those with their first RNA positive from 2012 to 2017 (HR 2.27, 95%CI: 2.09–2.47) or post-2017 (HR 4.90, 95%CI:4.43–5.43). In a multivariable model stratified by prior pregnancy and era of first RNA positive, treatment initiation was associated with age >30 years at RNA positive, initiating OAT (aHR 1.10, 95%CI:1.01–1.20) and substance use diagnosis (aHR 0.80, 95%CI:0.72–0.88).

Conclusion: Among people who are diagnosed with chronic HCV and experience pregnancy, those of older age at diagnosis were more likely to initiate treatment. In addition, while people with diagnosis of substance use were less likely to initiate treatment, likelihood increased for those engaged in OAT. Additional strategies are needed to improve linkage after diagnosis, but prior to pregnancy; especially if not engaged in drug treatment.

WED-500

Exploring the underlying causes of disengagement from hepatitis C care

Kathleen Bryce[1,2], Fiona Burns[1,3], Colette Smith[4], Alison Rodger[1,3], Douglas Macdonald[1,5]. *[1]Royal Free London NHS Foundation Trust, London, United Kingdom; [2]Institute for Global Health, University College London, London, United Kingdom; [3]Institute for Global Health, University College London, London, United Kingdom; [4]Institute for Global Health University College London, University College London, London, United Kingdom; [5]Institute of Liver and Digestive Health, University College London, London, United Kingdom*
Email: kathleenbryce@doctors.org.uk

Background and aims: Despite established hepatitis C test-to-cure pathways in the community, some people have been unable to engage with treatment. We undertook an interview-based exploration of the barriers and enablers to hepatitis C direct-acting antiviral (DAA) treatment initiation in a key population of people who had delayed treatment.

Method: We conducted semi-structured interviews with individuals who had delayed (for at least six months with one appointment missed) or declined DAA therapy, as well as service providers.

Participants were identified using peer support and outreach networks. The topic guide was informed by a systematic review of barriers and enablers to treatment initiation. Responses were structured within the Capability, Opportunity, Motivation, Behaviour (COM-B) model by reflexive thematic analysis.
Results: Fourteen participants with hepatitis C (two women) were interviewed at drug treatment services, in their place of residence or clinical settings between November 2022 and January 2023. They were aged between 32–66 and diagnosed with hepatitis C between 1–30 (median 7) years ago. Nine participants were of White ethnicity and UK-born, 13 had a mental health diagnosis or concern and 11 had physical comorbidity, five of whom had severely reduced mobility. Six were currently homeless. Ten providers (clinical and allied health professionals, peer advocates and outreach team members) were interviewed in person or online. We identified four themes. "Once bitten, twice shy": negative earlier life experiences and interactions with health and social care were barriers to subsequent engagement with DAA treatment (Opportunity). Previous difficulty navigating the healthcare system and experiencing enacted stigma led to the expectation of poor care again next time, with resultant avoidance. "This is a relief": positive interactions with services, however, had the potential to repair damaged relationships and build trust through addressing the individual's priorities first (Capability, Opportunity). "You can't make plans": lack of service adaptability and patient-provider 'fit' was a barrier to accessing treatment when life circumstances were unpredictable (Capability, Opportunity). "Stepping stones": stability (individually defined) was needed to enable treatment uptake (Capability, Opportunity and Motivation). Most participants wanted treatment but felt a strong aversion to the possibility of 'failing' therapy and so deferred until they felt ready to complete it.
Conclusion: These themes provide a useful starting point and guide for exploring individual beliefs and behaviours surrounding hepatitis C treatment. Understanding the underlying capability, opportunity and motivational causes beneath apparently "chaotic" interactions with care providers might facilitate tailored intervention and support through treatment.

WED-501
"I go as much and to as many doctors I can trust to not be stigmatised": factors in the experience of hepatitis B that affect linkage to care and treatment

Mylisa Vu[1], Sylvester Okeke[2], Robyn Horwitz[2], Elena Cama[2], Loren Brener[2], Thomas Tu[1]. *[1]The Westmead Institute for Medical Research, Sydney, Australia; [2]UNSW, Sydney, Australia*
Email: mylisa.vu@wimr.org.au

Background and aims: The WHO 2030 elimination targets for hepatitis B include reducing new hepatitis infections by 90% and hepatitis B related deaths by 65%. Achieving these targets is impossible without expanding diagnosis, linkage to care, and treatment. Understanding the experiences of those not currently engaged in clinical monitoring and barriers to treatment and care is vital to improving these rates. This study aims to understand the experiences of people living with hepatitis B including barriers to post-diagnosis clinical monitoring and treatment.
Method: An online survey co-designed with members of the affected community was developed to understand engagement in treatment and monitoring among people living with hepatitis B. Participants were recruited from a global online community support group HepBCommunity.org. In contrast to clinically led studies, this approach allowed us to access a population of people who had been diagnosed, but not necessarily linked to care. Survey data included structured and open-ended questions and was collected through Qualtrics. Quality assurance measures were adopted to screen out suspicious responses. Quantitative data were analysed using simple frequency counts while open responses were coded into NVivo and thematically analysed.
Results: A total of 77 responses were received between May and November 2023 with the most responses (34.5%) from people residing in Australia. About a third of participants (33.8%) reported non-regular engagement in care (>1 year interval since last check-up) or had not engaged in care at all. About 50% of the participants disclosed that they have delayed or cancelled monitoring appointments to avoid stigma, with ~3 in 5 participants (57%) reporting having experienced stigma at their health service. Regarding barriers to treatment, two thirds of participants (64%) reported a negative medication experience. For those not taking medication, 50% cited fear of side effects and 33% reported unsatisfactory health provider services as primary reasons. Thematic analysis of responses to open-ended questions found that clinical monitoring and treatment are influenced by access to (i) affordable services; (ii) social networks; (iii) friendly, confidential, and stigma-free services; and (iv) trusted healthcare providers and pharmaceutical companies.
Conclusion: Our study shows that HepBCommuntiy.org can be used to assess the needs and experiences of the affected community who are not linked to care, a key demographic for engagement and elimination efforts. Our interim results highlight the negative effect of stigma in linkage to care and suggest that the fear of adverse experiences with the medication itself or the interactions with the health system act as barriers to treatment. Our work highlights specific areas where public health measures could be most impactful to facilitate global elimination of hepatitis B.

WED-502
Simplified criteria for antiviral initiation in patients with chronic HBV infection: an economic evaluation and budget impact analysis in Thailand

Pisit Tangkijvanich[1], Ratree Sawangjit[2], Maneerat Chayanupatkul[3], Unchalee Permsuwan[4], Piyameth Dilokthornsakul[4]. *[1]Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Department of Clinical Pharmacy, Faculty of Pharmacy, Mahasarakham University, Mahasarakham, Thailand; [3]Department of Physiology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [4]Department of Pharmaceutical Care, Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand*
Email: pisittkvn@yahoo.com

Background and aims: Current criteria for initiating antiviral treatment in patients with chronic hepatitis B virus (HBV) infection are complex and difficult to implement. Simplified criteria could allow general practitioners to start antivirals for eligible patients in the general population to reduce liver-related complications, particularly hepatocellular carcinoma (HCC). However, the expansion of criteria might increase the overall financial burden. Thus, this study aimed to determine the cost-effectiveness of two simplified antiviral treatment initiation criteria among Thai patients with chronic HBV infection, who were naïve to antiviral treatment and aged ≥30 years old.
Method: A hybrid model of the decision tree and Markov model was developed. Two simplified antiviral treatment initiation criteria were (1) the Expanded criteria, defined as treating patients with HBsAg-positive and HBV DNA≥2, 000 IU/ml regardless of alanine transaminase (ALT) level, and patients with cirrhosis by tenofovir alafenamide (TAF) as the first-line drug, and (2) the Test-and-Treat criteria, defined as treating patients with HBsAg-positive and detectable HBV DNA regardless of ALT level, and patients with cirrhosis by TAF. PubMed was searched from its inception to July 2023 to identify input parameters. Best supportive care was chosen for patients who were ineligible for TAF. Incremental cost-effectiveness ratio (ICER) per quality-adjusted life year (QALY) was calculated.
Results: Our data demonstrated that both criteria could improve total patients' life-year and QALY, but they increase total cost. Specifically, the Expanded criteria and Test-and-Treat criteria could improve 0.164 life-years and 0.152 QALYs compared to current practice. Moreover,

both criteria could reduce 4, 846 new cases of HCC per 100, 000 patients. The ICERs for the Expanded criteria and Test-and-Treat criteria were 24, 838 Thai baht (THB) (approximately 711 USD)/QALY and 163, 060 THB (4, 665 USD)/QALY, respectively. Budget impacts of the Expanded criteria and Test-and-Treat criteria for fully implemented after five years were 1, 549 million THB (44 million USD) and 4, 326 million THB (124 million USD), respectively.
Conclusion: At the current willingness-to-pay of 160, 000 THB (4, 578 USD)/QALY, the Expanded criteria were considered a cost-effective strategy. However, the Test-and-Treat criteria might not be cost-effective for initiating antiviral treatment in patients with chronic HBV in Thailand at the current threshold. In this context, health policy decision-makers might consider implementing the simplified criteria based on cost-effectiveness information and budget impacts.

WED-503
Liver stiffness measurement before and after antiviral treatment for hepatitis C: results from an OST-based hepatology service facility
Nikolaos Papadopoulos[1], Ioannis Braimakis[2], Sofia Vasileiadi[3], Eleni-Myrto Trifylli[4], Iosif Galinos[1], Anastasia Drimousi[5], Melanie Deutsch[3]. *[1]2nd Department of Internal Medicine, 401 General Army Hospital of Athens, Athens, Greece; [2]Department of Gastroenterology, 417 Army Share Fund Hospital, Athens, Greece; [3]2nd Department of Internal Medicine, Medical School of National and Kapodistrian University of Athens, Hippokration General Hospital of Athens, Athens, Greece; [4]1st Department of Internal Medicine, 417 Army Share Fund Hospital, Athens, Greece; [5]Emergency Assistance and Support Unit, Organization Against Drugs (OKANA), Athens, Greece*
Email: nipapmed@gmail.com

Background and aims: Direct Acting Antivirals (DAAs) have improved efficacy and tolerability in the treatment of chronic hepatitis C virus (HCV) infection in people who inject drugs (PWIDs). However, data regarding the impact of anti-HCV treatment with DAAs in liver fibrosis is lacking in this group of patients. We determined the stages of liver fibrosis before and after anti-HCV treatment with DAAS in an opiate substitution therapy (OST)-based hepatology service facility in Athens, Greece.
Method: We retrospectively enrolled 122 HCV patients (M/F: 109/13, mean age: 46 ± 8.6) treated for chronic hepatitis C (CHC) with no signs of reinfection. All of them were evaluated with liver stiffness measurement (LSM) before and after complete treatment between September 2018 and December 2023. The following stages of fibrosis were defined: F0–1: <7, F2: 7–8.9, F3: 9–11.9, and F4: ≥12 kPa.
Results: 15/122 (12.5%) were treatment-experienced, 1/122 (0.8%) were HBsAg positive, and 3/122 (2.5%) were HIV positive. Genotype distribution: G1: 18%, G3: 43.4%, G4: 10.7%, HCVRNA positive/no genotype determination: 27.9%. Before treatment, liver fibrosis classification according to LSM was: F0/F1: 20/122 (16.4%), F2: 48/122 (39.3%), F3: 14/122 (11.5%), F4: 40/122 (32.8%), while after treatment was: F0/F1: 60/122 (49.2%), F2: 32/122 (26.2%), F3: 11/122 (9%), F4: 19/122 (15.6%). The mean LSM re-evaluation period was 22.5 ± 10.4 months after the end of the treatment. Two F0/F1 patients (10%) were deteriorated to F2 stage after treatment. One F2 patient (2.1%) deteriorated to the F3 stage after treatment, 13 patients (27.1%) remained in the F2 stage, while 34 patients (70.8%) improved to F0/F1. Two (14.3%) F3 patients were stable after treatment, while 12 (85.7%) were improved. Finally, 19 (47.5) of the F4 patients were stable, while 21 (52.5%) improved. Multivariate analysis demonstrated that the pre-treatment stage of advanced fibrosis/cirrhosis was associated with LSM improvement after treatment (Chi-Square: 48.246, $p < 0.005$).
Conclusion: The liver fibrosis stage, according to LSM, improves significantly after HCV treatment with DAAs in PWIDs, especially in those with advanced fibrosis or cirrhosis before treatment.

WED-513
Automatic opportunistic age screening for hepatitis C virus. A public health strategy in Galicia, Spain. Project 2023
Elena Cruz-Ferro[1], Susana Miras-Carballal[1], Marta Piñeiro-Sotelo[1], Sonia Touceda-Taboada[1], Ignacio Díaz-Vázquez[2], Javier Cereijo-Fernández[3], Juan Turnes Vázquez[4]. *[1]General Directorate of Public Health, santiago, Spain; [2]Preventive medicine service of the University Hospital Complex of A Coruña, A Coruña, Spain; [3]General Directorate of Public Health, santiago, Spain; [4]Pontevedra University Hospital Complex, PONTEVEDRA, Spain*
Email: elena.cruz.ferro@sergas.es

Background and aims: Hepatitis C virus (HCV) is a main cause of liver disease worldwide. All countries, following WHO recommendations, must establish programs to achieve the goal of its elimination as a public health problem by 2030. Galicia is a region with a low prevalence of HCV infection, and it is estimated that 85% of cases are concentrated in the 40–69-year-old cohort, which would mean 3, 864 cases of undiagnosed active infection. For this reason, following the recommendations of the WHO, it has drawn up a strategy to address its elimination. One of its main features is the active recruitment of ≥45% of patients aged 40–69 in three years, since in this group the prevalence of unknown active infection is estimated at 0.33%. The aim of this study is to present the results of the screening and the opportunistic of the cohort of 50–59 years carried out in 2023, the estimated prevalence of active infection is 0.50%.
Method: Descriptive retrospective study Source: Epidemiological Surveillance System (VIXÍA). Scope: Galicia. Period: year 2023. Variables: cohort of 50–59 years, health area (HA), population, start date.
Procedure: automatic request for HCV-RNA analysis to any person in the age group who is requested for an analysis for any reason. Determination of HCV viral load using the sample pooling strategy (pooling of 100 samples).
Results: Opportunistic age screening was progressively implemented throughout Galicia in 2023, reaching 53.26% of the target population. 107, 238 samples were analyzed, with 148 positive results (0.14% active infections). The start date and results are indicated for each HA: - Santiago de Compostela and Barbanza (27/01/2023): 25, 240 samples analyzed (75.66% of the population); 24 positive results; 0.10% active infections. - A Coruña and Cee (20/03/2023): 24, 255 samples analyzed (58.53% of the population); 43 positive results; 0.18% active infections. - Lugo, A Mariña and Monforte de Lemos (12/04/2023): 12, 969 samples analyzed (52.92% of the population); 18 positive results; 0.14% active infections. - Pontevedra and O Salnés (08/05/2023): 14, 689 samples analyzed (63.95% of the population); 20 positive results; 0.14% active infections. - Ferrol (19/06/2023): 5, 298 samples analyzed (37.99% of the population); 5 positive results; 0.09% active infections. - Ourense, Verín and O Barco de Valdeorras (28/06/2023): 8, 400 samples analyzed (37.85% of the population); 12 positive results; 0.14% active infections. - Vigo (05/07/2023): 16, 387 samples analyzed; 26 positive results (38.16% of the population); 0.16% active infections.
Conclusion: The objective of studying 45% of the target population in Galicia and in the HA that started before June was met. A percentage of active infection lower than estimated was observed.

WED-514
High rates of hepatitis C RNA positivity and engagement in care from community pharmacies with a high intensity test and treat (HITT) model
Samuel Uveges[1], Edward Nicholson[2], Clinton Askew[3], Sarah Montague[2], Stephen D Ryder[2]. *[1]Trust Pharmacy, Queen's Medical Centre, Nottingham, United Kingdom; [2]Nottingham University Hospitals NHS Trust, Queen's Medical Centre, Nottingham, United Kingdom; [3]The Hepatitis C Trust, London, United Kingdom*
Email: samuel.uveges2@nuh.nhs.uk

Background and aims: Community pharmacies providing Opioid Substitution Therapy (OST) are a potentially important site for Hepatitis C Virus (HCV) testing and treatment as they interact with patients who may not have undergone testing at, or do not attend, addiction services. We aim to demonstrate the yield of introducing a HITT model in 12 community pharmacies, testing patients on OST prescriptions and not.
Method: Raise awareness of hepatitis C elimination at Local Pharmaceutical Committee and community pharmacy level by providing Continuous Professional Development (CPD) educational sessions to all staff and offering shadowing opportunities with the Operational Delivery Network (ODN) team. An ODN team consisting of Specialist Pharmacy Technician, Viral Hepatitis Clinical Nurse Specialist and Hepatitis C Trust Peer ran the events utilising the pharmacies consultation room to complete the test. The team used dried blood spot tests and provided a £5 incentivisation for patients on OST. Any patient who requested a test was tested regardless of OST status.
Results: Between July 2022 and July 2023, 21 testing events were held at 12 different community pharmacy locations. 252 individuals were tested. 51 were HCV abs positive and 13 were HCV RNA positive. 10 patients have been referred for treatment, 9 have commenced DAA treatment. 4 have achieved SVR12. 1 was HCV RNA negative on retest, 2 have yet to engage in care. 120 patients were in receipt of an OST prescription of which 13 were HCV RNA positive; 10.8% HCV RNA positivity. No HCV RNA positives were found in people not on OST. 36 of 52 HCV Ab positive patients had been treated previously. Of which 8 patients had been lost to follow-up and required an overdue SVR12 blood test. 4 of which were still HCV RNA+.12 education sessions were delivered to between 2 and 10 people per site prior to the testing sessions commencing. Standardised feedback forms were sent to 11 locations and were completed by 8. Feedback suggests this testing model had minimal impact upon the day-to-day running of the pharmacy, all found CPD sessions beneficial and that their knowledge of hepatitis was improved.
Conclusion: The HITT model found patients who were registered with addiction services that had not received BBV testing and/or had not been referred to the ODN for DAA treatment. The data confirms that this group has a high HCV RNA positivity rate in those on OST. Feedback data suggests that this model is acceptable to community pharmacy teams and has helped to foster closer working between the ODN and community pharmacies.

Identifying barriers of hepatitis C linkage to care among beneficiaries of harm reduction centers in Georgia

Maia Butsashvili[1], Lasha Gulbiani[1], George Kamkamidze[1], Ketevan Stvilia[2], Maia Tsereteli[2], Shaun Shadaker[3], Rania Tohme[4].
[1]Health Research Union, Tbilisi, Georgia; [2]National Center for Disease Control and Public Health, Tbilisi, Georgia; [3]Centers for Disease Control and Prevention, Atlanta, United States; [4]US Centers for Disease Control and Prevention, Atlanta, United States
Email: maiabutsashvili@gmail.com

Background and aims: Georgia has one of the highest proportions of people who inject drugs (PWID) representing 2.23% of the adult population, and PWID represent 25% of persons with hepatitis C virus (HCV) infection in Georgia. Despite extensive screening of PWID at harm reduction (HR) centers, a substantial proportion of people with HCV infection are not aware of their status and therefore not linked to care. According to the integrated bio-behavioral survey conducted in 2022 among PWID, 58.1% were HCV antibody reactive and 32.1% had chronic HCV infection. The aim of this study was to identify barriers of HCV linkage to care among HR beneficiaries.
Method: We implemented a cross-sectional study to collect socio-demographic, risk behavior, HCV testing and treatment data among beneficiaries of HR centers in Batumi and Zugdidi cities in Western Georgia. Convenience sampling was used for recruitment. We conducted face-to-face interviews with PWID who had documented detectable HCV virus and assessed their characteristics based on linkage to HCV care. Linked participants were defined as those being enrolled in HCV treatment. Non-linked participants were HCV RNA or HCV core antigen positive individuals without a history of HCV treatment. Bivariate analysis was conducted to elucidate factors associated with linkage to care.
Results: A total of 123 PWID with detectable HCV virus participated in the study, of whom 65.9% (n = 81) were linked and 34.1% (n = 42) were non-linked to HCV care. Age, education level, and employment status were not significantly associated with linkage to HCV care. Linked participants were more likely than non-linked participants to think that HCV treatment is important (97.5% vs. 88.1%, p = 0.04). Non-linked participants were more likely than linked participants to report that they needed more information about hepatitis C (75.0% vs. 53.1%, p = 0.03), and that improving awareness regarding the HCV pre-treatment procedures (e.g. what laboratory tests are needed before treatment, where to receive these services, etc.) was necessary (67.9% vs. 40.5%, p = 0.01), and that receiving more information regarding long-term complications of untreated hepatitis C is important (89.3% vs 64.6%; p = 0.01).
Conclusion: Implementing educational interventions among PWID focusing on the importance of HCV treatment and possible health outcomes of untreated HCV infection are needed to improve linkage to hepatitis C care among beneficiaries of harm reduction centers. Scaling up treatment among PWID is important for the achievement of elimination of hepatitis C in Georgia.

WED-516
Novel approach to re-engage untreated patients with chronic active HCV

Ana Fuentes[1,2,3], Lucía Chaves-Blanco[1], Alberto Vázquez[1], Marta Illescas[1], Lucía Pérez-Rodríguez[1], Fernando García García[1], Federico Garcia Garcia[1,2,4]. *[1]Hospital Universitario Clínico San Cecilio, Granada, Spain; [2]Ibs. Granada, Granada, Spain; [3]CIBERINFEC, Granada, Spain; [4]CIBERINFEC, Madrid, Spain*
Email: anafuenteslop@gmail.com

Background and aims: The World Health Organization (WHO) acknowledges hepatitis C as a significant public health challenge. Identifying and addressing untreated patients with chronic active Hepatitis C Virus (HCV) infection is a critical step towards achieving elimination. Existing strategies have largely been ineffective in reconnecting these patients to care. In this study, we introduce and discuss the outcomes of an "opportunistic" approach for re-engaging chronic active HCV diagnosed patients who have not received treatment.
Method: This prospective study was conducted at the San Cecilio University Clinical Hospital. It involved reviewing laboratory data and medical records of patients with serum or plasma samples submitted for routine analysis. An automated system in the Laboratory Information System (LIS) generated daily reports of patients with prior positive anti-HCV tests. We reviewed LIS data and medical records daily to check for evidence of antiviral treatment, sustained viral response (SVR), or risk-factors for re-infection. If no data was found, we tested samples for HCV-RNA. Positive results were communicated to the referring physician, and the patients were referred to the hepatology unit for treatment evaluation.
Results: The results cover the period from 22 May to 31 December 2023. We identified 1428 HCV-positive patients with available serum samples for unrelated reasons. Upon review, 91% (1296 out of 1428) showed SVR and lacked re-infection risk factors. Among the remaining 132 patients, 42 (2.9% of the total and 32% of those with no previous information) were viremic. Of these, 24 (57%) were engaged in care, 21 (87%) commenced antiviral treatment, 2 declined treatment due to advanced age and comorbidities, 1 were advised to cease alcohol consumption before treatment, and 2 are not attend an appointment.

Conclusion: Our study describes an effective "opportunistic" approach to re-engage untreated patients with chronic active HCV. This strategy leverages the fact that these patients are already in contact with healthcare services, making reintroduction into the hepatitis C care continuum more efficient than other re-engagement strategies. We recommend this approach as a significant advancement towards eliminating hepatitis C.

p.Pro871Arg variant in JAG1 demonstrates a common manifestation of Alagille's syndrome

Preeti Sharma[1], Joanne Mushi[1], Jake Mann[1]. [1]*University of Birmingham, Birmingham, United Kingdom*
Email: jpmann.gsy@gmail.com

Background and aims: Large studies of exome sequencing have demonstrated the existence of common manifestations of severe monogenic disease. These are yet to be described for liver disease. Alagille Syndrome (ALGS), a multisystem monogenic disorder caused by mutations in the JAG1-NOTCH2 pathway. It's hepatic manifestations are characterised by cholestasis, fibrosis, and frequently necessitates transplantation.
Method: Here, we used genome-wide association study summary statistics to identify common variants in JAG1 associated with liver-related traits in otherwise healthy adults. We found genome-wide significant associations ($p < 5 \times 10^{-8}$) between variants (e.g single nucleotide polymorphisms) and liver biochemistry (ALT, bilirubin, GGT, ALP) in n = 1, 654, 950 participants from the Common Metabolic Disease Portal and n = 394, 841 from UK BioBank. Candidate variants were studied using AlphaFold protein modelling and *in silico* saturation mutagenesis of JAG1. Finally, we curated a database of all known human pathogenic JAG1 variants.
Results: We found rs35761929G>C, encoding p.Pro871Arg in JAG1 to be significantly associated with ALT (p = 4.2e-10) and bilirubin (p = 9.7e-10). This is a common variant (effect allele frequency = 0.05) and not reported to be associated with ALGS. It is predicted to affect protein stability however is classified as benign according to AlphaMissense (pathogenicity score = 0.09, where 1 = pathogenic and 0 = benign). p.Pro871Arg variant is found within the cysteine-rich extracellular domain of JAG1. Utilising In-Silico Saturation Mutagenesis, this region was found to be generally tolerant of mutations (median pathogenicity score = 0.24 (IQR 0.12–0.70)), similar to the intracellular domain (median pathogenicity score = 0.25 (IQR 0.14–0.45)), but in contrast to the DSL domain (median pathogenicity score = 0.95 (IQR 0.67–0.99)). This was validated by generating a database of all known JAG1 human variants, through which 671 unique pathogenic variants associated with ALGS were identified. Stop codons at position 871 were linked to ALGS but no other pathogenic missense mutations were found.
Conclusion: These findings underscore the implication of the NOTCH2-JAG1 pathway in common liver diseases such as metabolic dysfunction-associated steatotic liver disease (MASLD) and alcohol-related liver disease (ALD). Deciphering the functional alterations caused by the p.Pro871Arg variant in JAG1 can provide valuable insight for therapeutic interventions, and allow targeting of the NOTCH2-JAG1 pathway.

TOP-146

Activation of the HIF-1alpha pathway in cholangiocytes of patients with biliary atresia and its association with cilia disruption

Patricia Quelhas[1], Rui Oliveira[2], Jorge Luiz dos Santos[1]. [1]*CICS-UBI-Health Sciences Research Centre, University of Beira Interior, Covilhã, Portugal;* [2]*Institute for Clinical and Biomedical Research (iCBR), Serviço de Anatomia Patológica, Centro Hospitalar e Universitário, Universidade de Coimbra (SAP-CHUC), Coimbra, Portugal*
Email: patriciaasquelhas@gmail.com

Background and aims: Biliary atresia (BA) is a progressive hepatic disorder starting in infancy, often leading to liver failure and transplantation. Ischemic cholangiopathy constitutes a biliary disruption resulting from poor arterial blood supply by the peribiliary vascular plexus (PVP). In previous studies, our group demonstrated the presence of an ischemic cholangiopathy in a specific subset of patients with isolated BA, which showed activation of the HIF-1alpha pathway in cholangiocytes. It has been previously demonstrated that ciliopathy occurs in BA, both in syndromic and non-syndromic forms, similar to what happens in polycystic kidney diseases with ductal plate malformation, isolated neonatal cholangitis (DCDC2), and choledochal cyst. Considering that hypoxia can disrupt biliary epithelial cilia thus leading to an ischemic cholangiopathy, we hypothesized that hypoxia may be correlated with absence of cholangiocyte cilia in the subset of BA patients presenting HIF-1alpha pathway activation in the liver. This study aims to unveil whether HIF-1alpha nuclear positivity in cholangiocytes of BA patients correlates with absence of apical cilia and/or alterations in the cellular immunolocalization of Tubulin-4alpha acetylated (TUBA4A).
Method: Using immunofluorescence analysis on liver samples from biliary atresia patients and controls with neonatal cholestasis, this study looked for nuclear HIF-1alpha signals, associated with hypoxia, and TUBA4A signals for cilia analysis in cholangiocytes. Portal spaces, parenchyma, fibrovascular septa and extra-portal ductular reaction were analyzed. At the initial step, cholangiocytes with nuclear HIF1 alpha-positive samples were identified. The presence of cilia in biliary structures was observed through TUBA4A labeling and correlated with the HIF1A positivity status.
Results: A tendency was noted between HIF-positive and HIF-negative samples concerning the number of ducts with cilia, with HIF-positive samples showing a lower number of cilia. It was also observed that when tubulin is expressed in the cytoplasmic form, differences exist between controls and BA in the intensity of tubulin labeling, with higher intensity in BA. Moreover, when comparing BA patients who died within two years post-portoenterostomy with those who did not die or died after the initial two years, those exhibiting weak or moderate cytoplasmic tubulin intensity showed a higher mortality rate during the specified period.
Conclusion: The activation of the HIF1 alpha pathway appears to affect the morphology or presence/absence of cilia in intra- and extra-portal ducts. There also seems to be a difference in the cytoplasmic expression of tubulin in Biliary Atresia, and this alteration seems to worsen the early post-portoenterostomy prognosis, with decreased cytoplasmic tubulin expression being associated with higher early mortality.

Email: pmonian@wavelifesci.com

Background and aims: Alpha-1 antitrypsin (AAT) is an acute-phase protein synthesized by hepatocytes and secreted into circulation, where it protects the lungs from protease-induced damage. A point mutation in the *SERPINA1* gene (Z allele) is the most common cause for AAT deficiency (AATD). The resulting Z-AAT protein misfolds and aggregates in hepatocytes, decreasing functional AAT in circulation. Homozygous ZZ mutation carriers are at risk for severe AATD, which can lead to progressive liver injury and/or chronic obstructive pulmonary disease. Current standard of care addresses only lung disease and aims to restore serum AAT levels to an anticipated therapeutic threshold (≥11 μM) by weekly intravenous AAT from human plasma. Approaches in development address only a subset of patient needs (e.g., silencing approaches to reduce liver aggregates) or do not restore wild-type AAT (e.g., small-molecule approaches). We aim to decrease Z-AAT in liver and restore wild-type AAT in circulation by correcting Z mRNA with AIMers—chemically modified oligonucleotides that direct A-to-I RNA editing by recruiting endogenous ADAR enzymes. To facilitate hepatocyte delivery, AIMers are conjugated to *N*-Acetylgalactosamine (GalNAc-AIMers). This approach is designed to preserve physiological regulation of AAT while protecting the lungs and decreasing Z-AAT aggregation in liver.
Method: NSG-PiZ mice, expressing a human *SERPINA1* Z transgene, were treated with 10 mg/kg GalNAc-AIMer by subcutaneous injection for 13 weeks. Total serum AAT was quantified by ELISA, and the proportion of Z-AAT and M-AAT in serum was measured by mass spectrometry. Human iPSC-derived hepatocytes (ZZ genotype) were treated with GalNAc-AIMer *in vitro*. RNA editing was quantified by Sanger sequencing. The diameter of PAS-D-positive globules in hepatocytes was measured, and lobular inflammation was semi-quantitatively graded. AAT aggregates were quantified *in vitro* using an antibody specific to polymeric AAT.
Results: In NSG-PiZ mice, GalNAc-AIMers direct ~50% editing of the Z mRNA in liver and durably increased serum AAT levels (≥33 mM at 13 weeks). Secreted AAT had the expected wild-type amino acid sequence. Treated mice showed a significant decrease in liver inflammation and hepatocyte turnover, and a reduction in the size of PAS-D-positive globules. GalNAc-AIMers corrected the expression of genes inappropriately upregulated in the NSG-PiZ mouse liver and effectively cleared pre-existing AAT aggregates in human ZZ iPSC-derived hepatocytes *in vitro*.
Conclusion: These findings highlight the potential of GalNAc-AIMers to address both liver and lung manifestations of AATD. Wave Life Sciences is advancing WVE-006, an investigational GalNAc-AIMer, into clinical trials for the treatment of AATD. This clinical program (RestorAATion) is designed to provide proof of concept for the first RNA editing therapy in humans.

FRI-152-YI

Gene editing to treat liver metabolic disorders: harnessing paired Cas9-Nickases for efficient and safe treatment of primary hyperoxaluria type 1

Laura Torella[1], Martin Bilbao-Arribas[2], Julia Klermund[3], Geoffroy Andrieux[4], África Vales Aranguren[2], Cristina Olague Micheltorena[2], Julen Torrens-Baile[2], Eduardo Salido[5], Toni Cathomen[3], Nerea Zabaleta[6], Gloria González-Aseguinolaza[2]. *[1]CIMA University of Navarra, Pamplona, Spain; [2]Center for Applied Medical Research (CIMA), University of Navarra, Pamplona, Spain; [3]Institute for Transfusion Medicine and Gene Therapy, Medical Center-University of Freiburg, Center for Chronic Immunodeficiency (CCI), Medical Center-University of Freiburg, Freiburg, Germany; [4]Institute of Medical Bioinformatics and Systems Medicine, Medical Center-University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany; [5]Hospital Universitario de Canarias, Universidad La Laguna, CIBERER, Tenerife, Spain; [6]Grousbeck Gene Therapy Center, Schepens Eye Research Institute, Mass Eye and Ear, Harvard Medical School, Boston, United States*
Email: ltorella@alumni.unav.es

Background and aims: Primary hyperoxaluria type 1 (PH1) is a rare metabolic disorder with excessive oxalate production in the liver, leading to kidney toxicity. Currently, severe PH1 treatment involves RNA interference to reduce glycolate oxidase (GO) expression, raising concerns about therapy compliance and long-term efficacy. CRISPR-Cas9-mediated gene disruption offers a potential one-time therapeutic strategy. However, nuclease editors pose off-target risks, and adeno-associated vectors (AAV) for CRISPR delivery present challenges due to genome integration into CRISPR-mediated double-strand breaks (DSBs). Investigating paired Cas9 nickases (nCas9) aims to enhance safety by minimizing off-target events and achieving accurate gene disruption.
Method: Comparing paired nCas9, single or paired Cas9 nucleases (wtCas9) with the same guide RNAs (gRNAs), we examined *in vivo* disruption of the *Hao1* gene (GO encoding gene). AAV8 vectors delivered editing tools to PH1 mouse livers, restricting Cas9 expression to hepatocytes using a liver-specific promoter. Molecular and biochemical analyses assessed the efficiency, accuracy, and safety of the editing approaches, along with therapeutic efficacy.
Results: Paired nCas9, delivered via two AAV vectors, were as effective as individual or paired wtCas9 in reducing GO. Single nicks failed to disrupt *Hao1*, while DSBs induced by paired nCas9, likely repaired via the microhomology-mediated end-joining pathway, led to modifications of variable sizes. Single wtCas9-induced DSBs were primarily repaired through the non-homologous end-joining pathway, generating small insertions and deletions, whereas paired wtCas9 consistently resulted in a precise deletion of the sequence between the two cuts in most cases. Investigating AAV integration at the on-target site revealed existing tools consistently underestimated integration frequency. The application of a custom pre-processing pipeline to the analysis showed paired nCas9 significantly reduced AAV integration compared to individual or paired wtCas9. Disparities may be attributed to observed differences in repair mechanisms following nCas9 and wtCas9 editing. An all-in-one AAV vector for nCas9-mediated cleavage maintained editing efficiency with a reduced injected dose, resulting in a significant therapeutic effect while reducing AAV integration dose-dependently. Assessment of gRNA specificity through CIRCLE-seq, CAST-Seq, and long-read nanopore sequencing revealed no off-target activity or chromosomal translocations.
Conclusion: Paired nCas9 demonstrates promise for *in vivo* gene disruption, achieving efficiency comparable to wtCas9. This approach shows therapeutic efficacy, reduces on-target AAV integration frequency, and the risk for off-targets, representing a positive step toward developing a safe and effective long-term treatment for PH1 patients.

FRI-153

High prevalence of steatotic liver disease and systemic inflammation in hereditary fructose intolerance (HFI) patients independent of age, BMI and the presence of metabolic syndrome

Background and aims: Hereditary Fructose Intolerance (HFI) is an autosomal recessive inborn error of metabolism characterized by pathological loss-of-function variants of the aldolase B (*ALDOB*) gene. Although fructose, sucrose and sorbitol (FSS)-restricted diet halts HFI acute life-threatening complications, HFI patients on lifelong FSS-restricted diet are susceptible to a series of metabolic manifestations.
Method: A cohort of HFI patients on long-term FSS-restricted diet (n = 32) was compared to a group of age, gender- and body weight-matched controls (n = 28) in a cross-sectional study. Serum lipidomics profiling by LC/MS was carried out to better understand altered metabolic processes in HFI patients, together with NMR-based serum glycoprotein/lipoprotein analysis, serum amino acids and acylcarnitines profiling and assessment of hepatic steatosis by MRS/MRI. Moreover, silencing of ALDOB and treatment with metformin was evaluated in cultured hepatocytes by measuring lipid content followed by assessment of de novo lipogenesis (DNL) and fatty acid oxidation (FAO).
Results: HFI patients are characterized by a distinct serum lipidomics signature highlighting alterations in inflammation and liver lipid metabolism. Indeed, HFI patients present elevation of serum inflammation markers such as GlycA, early marker of systemic inflammation as well as increased cardiovascular disease (CVD) risk. In agreement, increased serum cholesterol, altered serum lipoprotein profile, mildly increased arterial blood pressure is reported in HFI patients. Also, HFI patients are characterized by marked hepatic steatosis associated with increased DNL index and reduced surrogates of FAO (altered serum b-hydroxybutyrate, plasma acylcarnites and valine amino acid levels). Likewise, silencing of ALDOB in cultured hepatocytes increases lipid cell content by augmenting DNL and diminishing FAO. Liver steatosis in HFI patients is not associated with age, BMI, the amount of ingested fructose and is also unrelated to the presence of metabolic syndrome.
Conclusion: Systemic inflammation and liver steatosis are common chronic complications in long-term FSS-restricted HFI patients independent of classical risk factors for MASLD. HFI patients with higher GlycA, an early marker of systemic inflammation, present a distinct serum lipidomic and lipoprotein profile predicting augmented cardiovascular disease risk. Further studies are necessary to assess the risk of fibrosis progression in HFI patients.

FRI-154

Copper overload promotes steatosis in Wilson disease by inhibiting peroxisome proliferator activated receptor alpha-fatty acid binding protein 1- glutathione peroxidase 4 signaling and inducing ferroptosis

Chen Liang[1], Li Bai[2], Shan Tang[3], Sujun Zheng[4]. *[1]Beijing YouAn Hospital, Capital Medical University, Beijing Key Laboratory of Liver Failure and Artificial Liver Treatment Research, Beijing, China; [2]Beijing YouAn Hospital, Capital Medical University, Beijing Key Laboratory of Liver Failure and Artificial Liver Treatment Research, Beijing, China; [3]Beijing YouAn Hospital, Capital Medical University, Beijing, China; [4]Beijing YouAn Hospital, Capital Medical University, Beijing, China*
Email: zhengsujun@ccmu.edu.dn

Background and aims: ATP7B Arg778Leu is most common mutation in Asian patients with Wilson disease (WD), a disorder of copper excretion. Mild to moderate hepatic steatosis is the most common nonspecific change in WD pathology. Blocking hepatic steatosis early is important for preventing the development of WD and ensuing sequelas. However, the molecular mechanism underlying this phenomenon needs to be elucidated. Herein, we addressed this issue using ATP7B Arg778Leu HepG2 cell model, patient samples and bioinformatics analysis.
Method: The levels of steatosis and ferroptosis were assessed in ATP7B Arg778Leu HepG2 treated with CuSO4 and/or liver tissues from WD patients. The relationship between steatosis and ferroptosis was determined by the administration of ferroptosis inhibitor fer-1. Bioinformatics analysis was performed to screen out hub genes and signaling pathways related to WD steatosis. The regulation among peroxisome proliferator-activated receptor alpha (PPARα), fatty acid binding protein 1 (FABP1), glutathione peroxidase 4 (GPX4) and ferroptosis was analyzed using PPARα inducer fenofibrate (FN) and inhibitor GW6471 (GW) as well as FABP1 recombinant (FABP1rp). The interaction among PPARα, FABP1 and GPX4 was determined using correlation analysis, immunofluorescence staining and CO-IP experiment. Finally, the expression of GPX4, PPARα and FABP1 was detected and compared in the liver tissues from WD patients with or without steatosis and healthy individuals.
Results: The levels of steatosis and ferroptosis indicators were obviously changed in ATP7B Arg778Leu HepG2 treated with CuSO4 and/or liver tissues from WD patients. Inhibiting ferroptosis alleviated steatosis. PPARα and FABP1 were screened out as potential regulators for steatosis according to bioinformatics analysis. The administration of FN led to up-regulated PPARα, FABP1 and GPX4 expression, conversely, GW treatment resulted in down-regulated

expression of these three proteins. In addition, the administration of rFABP1 brought about elevated FABP1 and GPX4, but not PPARα. Moreover, PPARα, FABP1 and GPX4 were co-localization and interacted. The expression of GPX4, PPARα and FABP1 was reduced in liver tissues from WD patients with steatosis compared with that in WD liver tissues without steatosis.
Conclusion: Copper overload promotes ferroptosis and steatosis in WD by down-regulating PPARα-FABP1-GPX4 signaling. Therefore, up-regulating PPARα and FABP1 expression to block ferroptosis is a potential target to prevent steatosis and delaying disease progression in WD patients.

FRI-155
Introduction of class I-III mutations of CFTR in isogenic human iPSCs-derived cholangiocytes and 3D organoids provides pathophysiological information relevant for treatment of cystic fibrosis-related liver disease (CFLD)
Shakila Taleb[1], Saif Zaman[1], Zehra Syeda[1], Mario Strazzabosco[1], Romina Fiorotto[1]. [1]*Yale School of Medicine, New Haven, United States*
Email: romina.fiorotto@yale.edu

Background and aims: Cystic Fibrosis-associated liver disease (CFLD) causes significant morbidity and mortality in patients with CF. Using CF animal models and human induced pluripotent stem cells (iPSC)-derived cholangiocytes bearing the DF508 mutation, we showed that CFTR-defective biliary cells present changes in secretion, cell polarity and innate immune responses. However, the impact of different CFTR mutations on CFLD phenotype and response to therapies remains unclear. In this study, we aimed to generate human cholangiocyte carrying different CFTR mutations using gene editing of iPSC and study the effects of these mutations on biliary cell physiology.
Method: Isogenic iPSC lines bearing the following CFTR mutations W1282X (class I), DF508 (class II) and G551D (class III) were generated using CRISPR/Cas9 gene editing. iPSC lines were differentiated to cholangiocytes and cultured in monolayers or 3D biliary organoids were generated along the differentiation process using Matrigel. Cholangiocyte specification was verified by RT-PCR and IHC. Bulk-RNA-seq was performed in monolayers. Using forskolin-induced swelling (FIS) organoids were tested for differences in CFTR baseline function and response to CFTR modulators.
Results: iPSCs-derived biliary organoids maintained morphological and functional properties of mature biliary epithelium similar to tissue-derived biliary organoids. iPSC-organoids with different CFTR mutations show no or minimal response to FIS (W128<DF508 <G551D). CFTR modulators (ETI) (3 uM) treatment improved FIS in DF508 and G551D but not W1282X organoids. Immunolabeling for β-catenin and ZO-1 showed disarrangement of cellular polarity in all CF organoids. Transcriptome analysis, identified 11 differentially expressed genes (DEGs) in common among all mutations, compared to isogenic controls. Enrichment of DEGs related to cytoskeletal components were present in all CFTR mutated lines compared to the control line. A strongly reduced gene and protein expression of NLRP2, a relatively uncharacterized component of the inflammasome and a negative regulator of TNF-mediated NF-kB signaling, was found in all the CF lines. Decreased expression of NLRP2 in CFTR-mutated cholangiocytes might be mechanistically related to the pro-inflammatory phenotype described in CF cholangiocytes.
Conclusion: Using gene editing of iPSC we have generated human cholangiocytes and organoids carrying mutations that impact CFTR function at different levels. CFTR dysfunction affects the morphology, transcriptome and secretory function of cholangiocytes in a mutation-specific way. Biliary organoids with CFTR mutations with residual protein production respond to CFTR modulators used in the clinic. This iPSC-based platform will be useful to identify new therapeutics.

FRI-158-YI
The cyst microenvironment is spatially patterned to promote polycystic liver disease
Scott Waddell[1], Yuelin Yao[2], Luke Boulter[3]. [1]*MRC Human Genetics Unit, Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom;* [2]*MRC Human Genetics Unit, School of Informatics, University of Edinburgh, Edinburgh, United Kingdom;* [3]*MRC Human Genetics Unit, Institue of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom*
Email: scott.waddell@ed.ac.uk

Background and aims: Polycystic liver diseases (PLDs) are a group of genetically heterogeneous conditions characterised by the presence of multiple fluid-filled cysts within the liver. Cyst growth results in hepatomegaly (liver enlargement), leading to abdominal pain, shortness of breath and malnutrition, and consequently, patients suffer from an extremely poor quality of life. Additionally, cysts are at risk of rupture and infection, which leads to sepsis if left untreated. There are currently no widely approved pharmaceutical treatments for PLD patients and despite several dysregulated molecular targets having been previously identified within cyst cells, none of these have been translated for clinical practice. Cyst epithelial cells are surrounded by a complex cyst microenvironment (CME), which is instructed by the cyst epithelia. Very little work, however, has focused on how non-epithelial cells within the CME contribute to cyst growth within the liver, particularly in human disease, nor whether modulation of the CME represents a therapeutic strategy to target the formation of cysts in patients. In cancer, therapies that target the microenvironment, namely immunotherapy, have revolutionised patient care; *could taking a similar approach and targeting the CME in PLD yield similar clinical successes?* We hypothesise that the formation of a unique CME in PLD offers a number of candidate targets for therapeutic intervention and aim to 1. Spatially map the CME in PLD patients and 2. Identify targetable processes which could reduce cystic growth.
Method: Using patient PLD tissue, we have used GeoMx spatial transcriptomics and Akoya fusion high-plex immunophenotyping to spatially map the formation and composition of the CME in PLD. We have then used a combination of human ductular organoid cultures and mouse models of PLD to identify novel molecular processes that can be pharmacologically manipulated to limit cyst formation.
Results: By combining single cell RNA sequencing from PLD tissue with a forward-phase cytokine arrays from human PLD organoids, we have found that cystic cells significantly increase the expression of a range of cytokines, including *Ccl20*, *Tgfb* and *Tnf*. These data indicate that cystic cells actively recruit an immune infiltrate to cystic lesions thereby promoting cystogenesis. Using spatial mapping technologies enables us to define where within the PLD CME different cells are found and we can show that T cells are the most abundant immune cell type within the cyst microenvironment in human PLD. Furthermore, T cells within the PLD CME express PD-1, suggesting that these T cells are in an exhausted state and susceptible to anti-PD-1 therapeutics.
Conclusion: Cyst cells recruit and pattern immune cells within the CME. These immune cells are largely made up of exhausted, PD-1$^+$ T cells, which represent an immunotherapy candidate for pharmaceutical intervention in human PLD.

FRI-159
The whole genome sequence and transcriptome study on the HCCs derived from patients with Fontan-associated liver disease
Taiji Yamazoe[1], Eiji Kakazu[1], Michitaka Matsuda[1], Taizo Mori[1], Sachiyo Yoshio[1], Tatsuya Kanto[1]. [1]*The Research Center for Hepatitis and Immunology, Ichikawa, Japan*
Email: lb-19yamazoe@hospk.ncgm.go.jp

Background and aims: The Fontan-associated liver disease (FALD) is characterized by a congestive hepatopathy and developed liver cirrhosis and hepatocellular carcinoma (HCC) after 15–20 years

after the Fontan procedure. The prognosis of FALD-HCC patients is significantly worse compared to non-HCC FALD patients, thus indicating the importance of the understanding of genomic and transcriptomic signature of FALD hepatocarcinogenesis. To this end, we performed the analysis of the whole genome sequences (WGS) together with RNA sequences.

Method: We sequenced four paired tumor and nontumor of the surgically resected specimens. The samples were prepared with TruSeq DNA PCR Free kit or NEBNext Poly (A) mRNA Magnetic Isolation/Ultra II Directional RNA Library Prep Kit, and sequenced up to 300G base or 6G base with NovaSeq6000. We used BWA to map to hg38, and executed the pipeline of GATK BaseRecalibrator, Mutect2 and Funcotator. The maf data were analysed by maftools in R software.

Results: The age of patients were 22–43 year old. The tumor subtype of HCC were poor differentiated or mixed hepatocellular cholangiocarcinoma. We identified 3514 nonsynonymous mutations in total. Of them, 2882 (82.0%) were single nucleotide variation, and 315 were indel. The majority of mutations were missense mutations (2804), followed by splice site mutations (377). The variant allele frequency was 0.0926 ± 0.0984 (mean ± SD). The number of mutations were relatively high (878.5 ± 173.0). There was no mutations of TERT promoter, TP53, CTNNB1 or ARID1A, but mutations of PTEN and AXIN1. The affected oncogenic signaling pathways were Hippo, PI3 K, NOTCH, RTK-RAS and WNT pathway. The transversions were significantly higher than the transitions (56.0 ± 0.71 vs 44.0 ± 0.71). The base substitution of C to T was predominant, followed by T to C, C to A, which is similar to other etiological HCC and CCA. The COSMIC signatures were COSMIC 5 and 3 (SBS40, 5, 3). These data indicates that the mutational signatures were different from other etiological HCC but their oncogenic mutations were related on the common tumorigenic pathways. The pathway analysis with the upregulated genes compared to virus-related and non-viral HCC (Riken Japanese HCC database in ICGC) showed the high score in VEGFA-VEGFR2 signaling and G1 to S cell cycle control. These data indicate the rapid tumor growth phenotype of FALD HCC.

Conclusion: We performed WGS and RNAseq of four paired samples derived from HCC patients with FALD. The findings suggested that disease specific phenotype, which is different from the HCC with other etiologies. We are sequencing another four paired samples including one Focal Nodular Hyperplasia to draw the genomic mutation landscape of FALD HCC.

FRI-160-YI
Endoplasmic reticulum stress in biliary atresia: unravelling cholangiocyte dysfunction through organoid-based RNA sequencing

Yara Hamody[1], Adi Har-Zahav[2], Keren Danan[3], Irit Gat-Viks[4], Raanan Shamir[2], Orith Waisbourd-Zinman[2]. *[1]Felsenstein Medical Research Center, Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel, Tel Aviv, Israel; [2]Schneider Children's Medical Center of Israel, Petach Tikva, Israel; [3]Tel Aviv University, Tel Aviv, Israel; [4]Tel Aviv University, Tel Aviv University, Israel*
Email: yarahamody@gmail.com

Background and aims: Biliary atresia (BA) represents a significant form of biliary fibrosis, identified predominantly in neonates under three months, characterized by obstruction of extrahepatic bile ducts and advancing liver fibrosis. The etiology remains elusive. Building on our prior discovery where BA-derived human cholangiocyte organoids (HCOs) exhibited anomalous morphological characteristics compared to controls, we conducted an RNA sequencing analysis. The aim was to delineate the pathways contributing to cholangiocyte injury in BA, with a particular focus on the Endoplasmic Reticulum (ER) stress and the Unfolded Protein Response (UPR) pathways already implicated in various liver disorders.

Method: In this study, we cultivated human cholangiocyte organoids derived from both BA patients and non-BA controls. These organoids underwent comprehensive RNA sequencing to identify key pathways and gene expressions associated with BA. We employed reverse transcription polymerase chain reaction (RT-PCR) to validate the RNA-seq findings and to ensure the functional significance of the identified genes. Subsequent experiments included western blotting and immunofluorescence staining, which were utilized to examine the expression levels of proteins involved in ER stress and to assess the integrity of epithelial cell polarity. Additionally, we investigated the specific involvement of cytochrome P450 enzymes in ER stress within the context of BA, particularly focusing on their role in drug metabolism.

Results: Our RNA sequencing analysis revealed a distinctive expression profile in BA-derived HCOs, implicating numerous biological pathways, prominently ER stress, UPR, and drug metabolism. Key findings include the identification of PERK, an essential UPR regulator, and BiP/GRP78, a heat shock protein, both critical for ER homeostasis, as being markedly upregulated in BA HCOs compared to controls. Immunofluorescent staining confirmed significantly elevated levels of both PERK and BiP/GRP78 in BA samples. Further, our Western blot and RT-PCR analyses corroborated the increased presence of BiP/GRP78 in BA-afflicted organoids. In addition, we examined cytochrome P450 (CYP450) enzymes for their role in ER stress and drug metabolism. Notably, the CYP4A isoforms were found to be overexpressed in BA patients relative to control subjects. The chemical inhibitor HET0016, targeting CYP4A activity, demonstrated a reduction in ER stress markers, with a notable decrease in PERK levels, upon application to BA HCOs, suggesting a possible therapeutic angle through modulation of CYP450 activity.

Conclusion: Our findings suggest that ER stress and the UPR significantly contribute to cholangiocyte damage in BA. These results pave the way for further investigation into targeted therapeutic strategies that may ameliorate ER stress in BA, potentially altering the disease course.

FRI-161
Correlation of non-invasive tests with histological features and intrahepatic Z-alpha-1 antitrypsin burden in patients with alpha-1 antitrypsin deficiency-associated liver disease

Jen-Chieh Chuang, Ruixue Hou[1], Feng Hong[1], Maria D. Paraskevopoulou[1], Jie Cheng[1], Susana Gonzalez[1], Nirav K. Desai, Paresh Thakker[1], Thomas Schluep[2], Javier San Martin[2], Rohit Loomba[3], Pavel Strnad[4]. *[1]Takeda Development Center Americas, Inc., Cambridge, MA, United States; [2]Arrowhead Pharmaceuticals, Inc., Pasadena, CA, United States; [3]University of California San Diego School of Medicine, La Jolla, CA, United States; [4]University Hospital RWTH Aachen, Aachen, Germany*
Email: jen-Chieh.chuang@takeda.com

Background and aims: Alpha-1 antitrypsin deficiency (AATD) is a genetic disease characterized by low levels of serum alpha-1 antitrypsin (AAT), a liver-derived serine protease inhibitor (Pi) that maintains the protease-antiprotease balance in the lungs. The Pi*ZZ genotype produces misfolded AAT (Z-AAT), resulting in hepatic AAT aggregates and reduced antiprotease activity in the lungs. Fibrosis and chronic liver disease (LD) may develop owing to increased cellular stress, apoptosis, inflammation and fibrogenesis. No pharmacological treatments exist and reliable non-invasive tests (NITs) are limited for AATD-associated LD (AATD-LD). We aimed to leverage data from two clinical trials to investigate the correlations of NITs with LD burden in patients (pts) with AATD-LD.

Method: Baseline serum and histology samples from phase 2 AROAAT-2001 (NCT03945292) and AROAAT-2002 (NCT03946449) trials of fazirsiran or placebo in pts with AATD-LD were used. Baseline correlations of NITs (ALT, APRI, AST, FIB-4, LSM via transient elastography, Pro-C3 and serum Z-AAT) and total intrahepatic Z-AAT to histological features (METAVIR fibrosis stage, portal inflammation and PAS-D globule burden) were evaluated by Spearman correlation analysis. Serum and total intrahepatic Z-AAT were

analyzed by LC-MS. Further methodological details are described in Strnad *et al*, *NEJM*, 2022. The performance of individual NITs on the identification of pts with AATD-LD and significant (≥F2) or advanced (≥F3) fibrosis were evaluated by AUROC analysis.
Results: Of 56 pts from the AROAAT-2001 (n = 40) and AROAAT-2002 (n = 16) studies, 40 pts had recorded METAVIR fibrosis stage at baseline: F0, 4 (7%); F1, 11 (20%); F2, 17 (30%); F3, 6 (11%); and F4, 2 (4%). ALT, AST, Pro-C3, LSM, APRI and serum Z-AAT correlated with METAVIR fibrosis stage ($p < 0.05$); AST, Pro-C3, FIB-4 and serum Z-AAT correlated with portal inflammation ($p < 0.05$); and LSM, FIB-4 and serum Z-AAT correlated with PAS-D globule burden ($p < 0.05$). Total intrahepatic Z-AAT correlated with METAVIR fibrosis stage, portal inflammation and PAS-D globule burden ($p < 0.05$). ALT, AST, Pro-C3 and LSM had AUROC scores ≥0.75 for the identification of pts with ≥F2 fibrosis. LSM and serum Z-AAT had AUROC scores ≥0.80 for the identification of pts with ≥F3 fibrosis.
Conclusion: The study identified correlations of NITs (ALT, APRI, AST, FIB-4, LSM, Pro-C3, serum Z-AAT) and total intrahepatic Z-AAT to histological features (METAVIR fibrosis stage, portal inflammation and PAS-D globule burden). ALT, AST, Pro-C3, LSM and serum Z-AAT demonstrated adequate-good discriminatory performance in the identification of pts with ≥F2 and ≥F3 fibrosis. Clinical utilities of these NITs in the identification of pts with AATD-LD and in monitoring treatment responses will require validation in larger studies.

FRI-162
Analysis of cellular crosstalk in fibrocystic liver disease (PKHD1-/- mouse) reveals a central role for cholangiocytes, neutrophils and chronic biliary infection in disease pathogenesis
Zehra Syeda[1], Tory Bauer-Pisani[1], Shakila Taleb[1], Romina Fiorotto[1], Mario Strazzabosco[1]. [1]*Yale School of Medicine, New Haven, United States*
Email: mario.strazzabosco@yale.edu

Background and aims: Caroli disease (CD) and Congenital hepatic fibrosis (CHF) are caused by mutation in Polycystic kidney hepatic disease 1 gene (PKHD1) and lead to biliary malformations, cholangiocyte dysfunction, portal inflammation, portal fibrosis and episodes of cholangitis. PKHD1 encodes for fibrocystin (FPC), a protein expressed in cilia, plasma membrane and centromeres of cholangiocytes. FPC is involved in multiple cellular functions from polarity and cell matrix interactions to differentiation. This study was designed to investigate the relationships among the cell types present in the pericystic infiltrate in Pkhd1-KO mice at single cell level.
Method: We isolated single cells from portal tract of 3 months old Pkhd1-KO and WT mice (n = 2). Single cell transcriptomic profiling of 18, 492 single cells, allowed the identification of the cell types present in the samples. Dataset was analyzed by Seurat and CellChatDB. Cystic area, inflammation, fibrosis was scored histologically (Ck19, CD45 and Sirius red staining), before and after antibiotic treatment. Aerobic and anaerobic microbial cultures and antibiograms were performed.
Results: scRNA-seq analysis revealed 9 distinct cell populations in the portal tract of WT and Pkhd1-KO. Cholangiocytes in Pkhd1-KO have higher expression of the Cxcl1 and Cxcl5 chemokines. Gene ontology analysis of cholangiocytes from Pkhd1-KO showed an enrichment of genes involved in the recruitment of neutrophils and activation of innate immune responses to microbial components. CellChatDB analysis showed a strong connection between Cxcl1/Cxcl5 and the Cxcr2 receptor present in neutrophils, consistent with their recruitment by cholangiocytes. As predicted by transcriptomic analysis, Wright Giemsa staining showed presence of microbial component inside several cysts, identified as *Enterococcus spp*. Treatment of Pkhd1-KO (4 weeks old) for 8 weeks with Sulfamethoxazole/trimethoprim (SMZ/TMP) diet (based on the antibiogram) resulted in the eradication of *Enterococcus*. Immunohistochemistry staining after antibiotics treatment showed statistically significant decrease in inflammation, cystic area and fibrosis in treated Pkhd1-KO mice when compared to untreated Pkhd1-KO mice. scRNA-seq was repeated after antibiotic treatment and confirmed the decrease in inflammatory signaling.
Conclusion: This study shows a complex signaling network originating from cholangiocytes and amplified by the recruited neutrophils. The biliary colonization aligns well with the natural history of disease as patients with fibrocystin deficiency suffer from recurrent cholangitis. Further studies are ongoing to clarify if and how neutrophils interact with cholangiocytes non-destructively and their role in the progression of the disease.

FRI-163-YI
Pronounced vasculature phenotypes in new mouse models with ALGS and BA-associated mutations in Jag1
Anna Maria Frontino[1], Daniel V. Oliveira[1], Eliška Trampotová[1], Mitra Tavakoli[2], Noémi K. M. Van Hul[3], Oren Gozlan[4], Emma Andersson[3], Gabriela Pavlinková[2], David Sprinzak[4], Jan Mašek[1]. [1]*Department of Cell Biology, Faculty of Science, Charles University, Prague, Czech Republic;* [2]*Laboratory of Molecular Pathogenesis, Institute of Biotechnology, CAS, Vestec, Czech Republic;* [3]*Department of Cell and Molecular Biology, Karolinska Institutet, Stockholm, Sweden;* [4]*School of Neurobiology, Biochemistry and Biophysics, George S. Wise Faculty of Life Sciences, Tel Aviv University, Tel Aviv, Israel*
Email: frontina@natur.cuni.cz

Background and aims: Biliary atresia (BA) and Alagille (ALGS) syndrome are the two most common pediatric cholangiopathies typically resulting in liver transplantation. Loss-of-function mutations in the Notch ligand *Jagged1* (*Jag1*) have been associated with ~ 94% of ALGS cases, but intriguingly, other *Jag1* mutations were found in patients with BA. Missense mutations linked to ALGS (R1097W), and BA (R1213Q) target conserved, intracellular regions of Jag1, thus likely pointing at physiologically relevant domains. To test these functions *in vivo*, we recapitulated the missense mutations in C57BL/6 mice.
Results: Using CRISPR/Cas9, we generated two new mouse models with missense mutations in Jag1 intracellular domain ($Jag1^{RW/RW}$ and $Jag1^{RQ/RQ}$). Not triggered by any hepatotoxic insult, $Jag1^{RW/RW}$, and $Jag1^{RQ/RQ}$ mice manifested more significant and contrasting effects on neonatal liver vasculature than biliary morphogenesis. $Jag1^{RW/RW}$ mutants exhibit bile ducts (BDs) with disrupted, yet functional morphology accompanied by 50% ($p < 0.05$) decrease in hepatic artery (HA) quantity. In contrast, $Jag1^{RQ/RQ}$ mutants had hypertrophic and increased HA numbers along highly hypoplastic portal veins, with no impact on BDs at P10 and P30. Furthermore, collagen deposition was significantly higher ($p < 0.05$) in $Jag1^{RQ/RQ}$ animals at P30, suggesting emerging fibrosis, which was not present in $Jag1^{RW/RW}$ and control mice. The progressive liver damage was further illustrated by a ~2-fold increase in blood serum levels of Aspartate Aminotransferase in the $Jag1^{RQ/RQ}$ mutants at P30 stage. Ultrasound analysis revealed portal vein dilation in $Jag1^{RQ/RQ}$ mutants, indicating systemic vascular or blood pressure alterations. Finally, JAG1-NOTCH2 transactivation, monitored via reporter assay, was not altered in cell lines expressing JAG1 RW and JAG1 RQ.
Conclusion: To our knowledge, we have produced the first mouse models recapitulating the exact ALGS and BA mutations found in humans. Our findings from $Jag1^{RQ/RQ}$ mice reveal unaltered biliary morphogenesis accompanied by aberrant HA outgrowth, in contrast to $Jag1^{RW/RW}$ mice, which exhibit disrupted biliary morphogenesis and HA loss. Based on our data, $Jag1^{RW/RW}$ mutants represent a "mild" ALGS model, a condition that can be potentiated with simultaneous deletion of one allele of *Jag1*, while $Jag1^{RQ/RQ}$ mice open possibilities for further investigation, particularly in exploring responses to hepatotoxins like biliatresone. Our data indicate that the vasculature and potentially periportal mesenchyme are more sensitive to Jag1

activity than the BDs; further research is needed to uncover if this is a mouse-specific feature or a shared trait between mice and humans. Our ongoing transcriptomics analysis of the *Jag1*$^{RW/RW}$, and *Jag1*$^{RQ/RQ}$ liver tissue aims to elucidate the different signaling activities originating from the ALGS- and BA-associated mutations.

FRI-164

Proteomic analysis identified fazirsiran treatment-responsive protein biomarkers in patients with alpha-1 antitrypsin deficiency-associated liver disease

Jen-Chieh Chuang, Ruixue Hou[1], Feng Hong[1], Jie Cheng[1], Maria D. Paraskevopoulou[1], Nirav K. Desai, Paresh Thakker[2], Javier San Martin[3], Thomas Schluep[3], Pavel Strnad[4]. *[1]Takeda Development Center Americas, Inc., Cambridge, MA, United States; [2]Takeda Development Center Americas, Inc., Cambridge, United States; [3]Arrowhead Pharmaceuticals, Inc., Pasadena, CA, United States; [4]University Hospital RWTH Aachen, Aachen, Germany*
Email: jen-Chieh.chuang@takeda.com

Background and aims: Alpha-1 antitrypsin deficiency (AATD) is a rare genetic disease characterized by low levels of serum alpha-1 antitrypsin (AAT), primarily affecting the lungs and/or liver. Patients with the protease inhibitor (Pi)*ZZ genotype express misfolded AAT, resulting in hepatic AAT aggregates and reduced antiprotease activity in the lungs. Fibrosis and chronic liver disease may develop owing to cellular stress, inflammation and apoptosis. Currently no pharmacological treatments for AATD-associated liver disease (AATD-LD) exist. Fazirsiran is an investigational N-acetylgalactosamine-conjugated small interfering RNA undergoing phase 3 development in patients with AATD-LD. Proteomics data to identify biomarkers relevant for therapeutic targeting and to elucidate disease pathophysiology are limited. This study aimed to detect treatment-responsive protein biomarkers and cellular pathways by leveraging a novel platform for proteomic discovery from the sera of patients with AATD-LD treated with fazirsiran.
Method: Olink, a dual-antibody-based proteomics platform, was utilized for proteomic discovery. Serum samples were assessed from adults with AATD, a Pi*ZZ genotype, and biopsy-proven liver fibrosis participating in AROAAT-2002 (NCT03946449), a phase 2, open-label trial of fazirsiran (100 or 200 mg) for 24 or 48 weeks. Olink data were integrated with single nucleus RNA-sequencing (Snucseq) data to map expressed proteins to potential source cells in the liver. A mixed effects model was applied to measure biomarker change from baseline over time and false discovery rate-adjusted p value was used to select the top biomarkers. Differentially expressed protein (DEP) and pathway analyses were also conducted.
Results: The concentrations of 3072 proteins were measured in 16 patients with AATD-LD. Fazirsiran treatment resulted in continuous and sustained DEPs in the serum through 48 weeks. DEPs were primarily mapped to hepatocytes, cholangiocytes, immune cells (T cells and macrophages), mesenchymal cells and endothelial cells. Of the liver mesenchymal cell-enriched proteins, many were components of the extracellular matrix associated with hepatic stellate cell activation and liver damage. Pathway analysis showed that fazirsiran-induced proteomic changes were linked to the reduced activity of molecular pathways that promote cellular stress, inflammation, apoptosis and fibrosis.
Conclusion: This study leveraged a novel platform for proteomic discovery in patients with AATD-LD, identified candidate biomarkers reflecting disease severity, and demonstrated potential benefit of fazirsiran treatment in reducing cellular stress, inflammation and damage. Biomarkers identified in these analyses may have clinical utility but require validation in larger studies.

FRI-165

SarsCov2 vaccine does not increase the risk of autoimmune liver disease

Stanislas Pol[1,2], Charlotte Mouliade[1,2], Lucia Parlati[1,2], Samir Bouam[3], Vincent Mallet[1,2]. *[1]AP-HP.Centre Université Paris Centre, Groupe Hospitalier Cochin Port Royal, DMU Cancérologie et spécialités médico-chirurgicales, Service des Maladies du foie, Paris, France; [2]Université Paris Cité, F-75006, Paris, France; [3]AP-HP.Centre Université de Paris, Groupe Hospitalier Cochin Port Royal, DMU PRIM, Service d'Information Médicale, Paris, France*
Email: stanislas.pol@aphp.fr

Background and aims: The European Association for the Study of the Liver (EASL) conference in London, 2021, highlighted a potential link between SarsCov2 vaccines and autoimmune liver diseases, specifically autoimmune hepatitis and primary biliary cholangitis. To explore this further, we conducted a population-level investigation in France. We studied the incidence of autoimmune liver diseases before and after the rollout of SarsCov2 vaccines, which began on December 27, 2020 in France. By October 17, 2021, approximately 75.8% of the French population (50, 889, 053 individuals) had received at least one vaccine dose, and 73.8% (49, 551, 532 people) had completed the initial vaccine series, which typically consisted of two doses.
Method: We selected from the National French Hospital Discharge Database spanning 2013–2022, all adult patients discharged with diagnoses of autoimmune hepatitis (ICD-10: K754) or primary biliary cirrhosis (ICD-10: K743) (N = 10, 869). Severe autoimmune liver disease was defined as hepatic or extrahepatic organ failure within 4 weeks after autoimmune liver disease onset. To examine the incidence of autoimmune liver diseases in relation to the SarsCov2 vaccine rollout, an Interrupted Time Series Analysis (ITSA) was conducted with January 1, 2021 as the reference date, this being the closest date to the vaccine rollout commencement on December 27, 2020. A 3-year washout period (2013–2015) was included to ascertain the measurement of incident cases.
Results: The sample comprised 7, 844 patients with a median age of 58 years (IQR 44–69), of whom 26.6% were male. Approximately 13% progressed to severe autoimmune liver disease and 5.8% either died or underwent liver transplantation, within 12 weeks post-onset. The median (range) incidence of autoimmune liver disease and of severe autoimmune liver disease were 90 (43–125) and 13 (5–21) cases per month, respectively. No statistically significant changes were observed in the incidence of both autoimmune liver disease ($p = 0.83$) and severe autoimmune liver disease ($p = 0.33$) pre- and post-vaccination. Higher age ($p = 0.034$), and significant comorbidities ($p < 0.001$) were more prevalent in patients with autoimmune liver disease onset during the COVID-19 vaccine period. Older age ($p = 0.003$ in multivariate analysis) was the sole risk factor linked to the severity of autoimmune liver disease.
Conclusion: The rollout of SarsCov2 vaccines did not correlate with an increase in the incidence of autoimmune liver disease, including both general cases and those classified as severe, in French hospitals.

FRI-166

Impaired nuclear glycogen metabolism affects liver homeostasis in Argininosuccinic aciduria

Leandro Soria[1], Alfonso D'Alessio[1], Paola Arena[1], Elena Polishchuk[1], Claudia Perna[1], Angela De Angelis[1], Sonam Gurung[2], Dany Perocheau[2], Rossella De Cegli[1], Youngmok Lee[3], Samira Safarikia[4], Marco Spada[4], Carlo Dionisi-Vici[4], Julien Baruteau[2], Nicola Brunetti-Pierri[1]. *[1]Telethon Institute of Genetics and Medicine, Pozzuoli, Italy; [2]UCL Great Ormond Street Institute of Child Health, London, United Kingdom; [3]UCONN Health Center, Farmington, United States; [4]Bambino Gesù Children Hospital, Rome, Italy*
Email: brunetti@tigem.it

Background and aims: Glycogen is synthesized *de novo* in the nucleus, and nuclear glycogenolysis provides a carbon pool for histone acetylation. Abnormal nuclear glycogen catabolism has been

associated with epigenetic changes in gene expression and lung cancer progression. We found abundant hepatic nuclear glycogen storage in $Asl^{Neo/Neo}$ mice, a mouse model of Argininosuccinic Aciduria (ASA), an inherited urea cycle disorder due to argininosuccinate lyase (ASL) deficiency. In $Asl^{Neo/Neo}$ mice we investigated underlying mechanisms of aberrant nuclear glycogen storage and its consequences on liver homeostasis.

Method: Nuclear glycogen storage in hepatocytes was investigated by electron microscopy on liver sections. Enzymes and acetylated histones were determined by Western Blot on nuclear purified fractions. Hepatic gene expression profiling was performed by QuantSeq analysis. Survival of $Asl^{Neo/Neo}$ mice was investigated following intravenous administration of adeno-associated virus vectors encoding the human glycogen phosphorylase (PYGL), the rate-limiting enzyme in glycogenolysis, and after intraperitoneal injections of vorinostat, a pan-Histone Deacetylase (HDAC) inhibitor.

Results: Consistent with $Asl^{Neo/Neo}$ mice, nuclear glycogen storage was observed in a liver specimen of an ASA patient. In the nuclei of $Asl^{Neo/Neo}$ mouse livers, quantification of glycogen metabolizing enzymes suggested increased glycogen synthesis and reduced glycogenolysis. These nuclei also showed reduced acetyl-CoA content, and a marked decrease in lysine acetylation of several histones, especially H3K9. Notably, neither nuclear glycogen accumulation nor reduced histone acetylation were observed in various murine models of defective glycogen metabolism (including PYGL deficiency) or ureagenesis (other urea cycle disorders). Transcriptomic analysis of $Asl^{Neo/Neo}$ mouse livers revealed H3K9-dependent changes. Moreover, increased histone acetylation, by means of hepatocyte-specific PYGL overexpression or HDAC inhibition, improved $Asl^{Neo/Neo}$ mice survival.

Conclusion: Defective hepatic nuclear glycogen mobilization and histone hypoacetylation result in global transcriptomic changes in hepatic gene expression and reduced survival in ASA mice. These findings may have implications for development of improved therapies for liver disease in ASA and potentially, other liver disorders with aberrant nuclear glycogen storage.

FRI-167-YI

Modelling wolman disease using genetically engineered human liver organoids

Davide Selvestrel[1], Beatrice Anfuso[1], Suresh Velnati[2], Luca Fava[3], Giovanni Sorrentino[2,4]. *[1]International Centre for Genetic Engineering and Biotechnology (ICGEB), Equal Contribution, Trieste (TS), Italy; [2]International Centre for Genetic Engineering and Biotechnology (ICGEB), Trieste (TS), Italy; [3]University of Trento, Trento, Italy; [4]University of Trieste-Dipartimento di Scienze Mediche, Chirurgiche e della Salute, Università Degli Studi di Trieste, Triste, Italy*
Email: giovanni.sorrentino@icgeb.org

Background and aims: Wolman disease (WD) is a rare inherited autosomal recessive disease caused by mutations in the lysosomal acid lipase (LAL) gene and characterized by the accumulation of cholesteryl esters and triglycerides in lysosomes, leading to severe liver and visceral dysfunction. There is currently no cure for this devastating disease, and treatments are limited to supportive care. In this project, we aim to develop an in vitro model of WD using liver organoids derived from human induced pluripotent stem cells (iPSCs).

Method: To this aim, we implemented a reproducible method to derive multi-cellular human liver 3D organoids composed of hepatocyte-, stellate-, biliary- and Kupffer-like cells that exhibit gene expression and functions similar to in vivo-derived tissues.

Results: Upon free fatty acid treatment, these organoids recapitulate key features of WD, including steatosis, inflammation, and fibrosis, in a multi-step manner. To design a patient-specific organotypic model of WD, we used CRISPR-Cas9 gene editing to introduce mutations in the LAL gene in iPSCs, and we are currently characterizing the hepatic organoids derived from these cells to assess their capability to model disease-associated phenotypes.

Conclusion: This innovative platform has the potential to recapitulate pathophysiological features of WD, in vitro, including personalized response to therapy, and will offer a new approach for studying the molecular mechanisms underlying development and progression of this disease, thus facilitating the discovery of effective treatments.

FRI-170

Impact of helminth infection on the efficacy of COVID-19 mRNA vaccine in mice

Jinpeng Su[1,2], Youssef Hamway[2,3,4], Julia Schluckebier[3,4], Bo-Hung Liao[1], Zhe Xie[1], Clarissa Prazeres da Costa[2,3,4], Ulrike Protzer[1,2]. *[1]Institute of Virology, Technical University of Munich/Helmholtz Munich, Munich, Germany; [2]German Center for Infection Research (DZIF), Munich partner site, Munich, Germany; [3]Institute for Medical Microbiology, Immunology and Hygiene, Technical University of Munich, Munich, Germany; [4]Center for Global Health, Technical University of Munich, Munich, Germany*
Email: protzer@tum.de

Background and aims: *Schistosoma* are helminth parasites that infect around 250 million humans. The parasite matures in the liver, causes liver damage, and influences host immune responses. The effectiveness of mRNA vaccines, as a newly emerging vaccine type of global importance, in populations with *Schistosoma* infections is uncertain. Here, we aimed to explore how the immunogenicity of the mRNA-based COVID-19 vaccine Comirnaty was influenced by an underlying helminth infection using an experimental *Schistosoma mansoni*-infection model.

Method: Naïve mice and mice chronically infected with *S. mansoni* were vaccinated intramuscularly with 1 µg or 5 µg of Comirnaty and boosted after four weeks. Vaccine-induced humoral and cellular immune responses were evaluated one week after boost immunization by quantifying and subtyping spike-specific IgG responses, assessing SARS-CoV-2 virus-neutralizing activity of sera, and performing intracellular cytokine staining on splenocytes re-stimulated with spike-specific peptide pool.

Results: The titers of spike-specific IgG antibodies were comparable in naïve and helminth-infected mice following low- and high-dose Comirnaty immunization and the sera showed similar SARS-CoV-2 infection-neutralization capacity. Despite this, spike-specific IgG subclasses revealed distinct patterns. Immunization of naïve mice primarily induced the IgG_{2c} subclass associated with a Th1 response, while in helminth-infected mice, a predominance of the IgG_1 subclass was observed, indicative of a Th2-prone response. Comirnaty immunization of helminth-infected mice stimulated strong, dose-dependent spike-specific IFN-gamma+ CD4 T-cell responses comparable to those in the respective naïve mice. By contrast, spike-specific IFN-gamma+ CD8 T-cell responses in helminth-infected mice were significantly lower than those in naïve mice. Moreover, helminth infection remarkably altered the polyfunctionality of vaccine-induced CD8 T cells, as evidenced by a significant decrease in spike-specific IFN-gamma+ TNF-alpha+ IL-2+ CD8 T cells. Of note, the suppression of CD8 T-cell responses caused by helminth infection persisted even if higher vaccine doses were applied.

Conclusion: Chronic infection with a helminth that elicits mainly liver and intestinal inflammation surprisingly altered the characteristics of antibody responses and substantially decreased the magnitude and functionality of CD8 T-cell responses elicited by a COVID-19 mRNA-based vaccine.

FRI-171

Paediatric solid organ transplant recipients (SOTR) demonstrate greater serological response to initial SARS-CoV-2 vaccination than adult SOTR, and comparable rates of antibody degradation

Email: mapibafe@gmail.com

Background and aims: The Covid-19 pandemic has disproportionately affected solid organ transplant recipients (SOTR). Adult patients have decreased responsiveness to SARS-CoV-2 vaccination and higher incidence of infection. The aim of this study was to determine serological response to SARS-CoV-2 vaccination in paediatric liver- and kidney-transplant (LT, KT) recipients, and undertake comparative analyses with adult SOTR patients.

Method: COBALT is a European, prospective, multi-centre, case-control study of SARS-CoV-2 vaccine responses in adult and paediatric patients. For this nested study, samples were taken at 7- and 32-weeks following initial Covid-19 vaccination. Serological end points were measured by ELISA, presented as geometric mean (IU) and 95% CI, and comparative analyses were performed with Mann-Whitney testing.

Results: A total of 42 paediatric SOTR were recruited, from whom serological data were available for 28 participants (9 post-LT and 19 post-KT). Data from 125 adult SOTR were included (all post-LT); these data have been previously published (PMID: 37870985). All paediatric participants received mRNA vaccines and 117 (93.6%) adult participants received mRNA vaccines. Paediatric SOTR patients had significantly higher anti-Spike IgG levels than adult participants at week 7 [121, 130 (57, 584–254, 804) *vs* 9, 676 (6, 330–14, 792) AU/ml, test $p < 0.0001$] and week 32 [76, 947 (13, 586–435, 803) *vs* 7, 917.7 (3, 4890–17, 964) AU/ml, $p = 0.0084$]. No significant difference in week 7 anti-Spike IgG response was found between paediatric LT and KT recipients (126, 459 (34, 292–466, 346) vs 118, 685 (44, 022–319, 984) AU/ml, $p = 0.8838$). No differences were seen between children and adults in the rate of decline of anti-Spike IgG between week 7 and 32 ($p = 0.4928$). No factors were significantly associated with week 7 anti-Spike IgG levels in the paediatric group.

Conclusion: Consistent with data from healthy children, paediatric SOTR demonstrate greater SARS-CoV-2 vaccine responses than comparable adult SOTR patients. These data support efficacy of SARS-CoV-2 vaccination in child SOTR, and may alleviate vaccine hesitancy in this patient group.

FRI-172

Primary adult hepatocytes-derived organoids to characterize intrahepatic cholestasis

Benedetta Blarasin[1,2], Gabriele Codotto[1,3,4], Marco Stebel[2], Claudio Tiribelli[1], Cristina Bellarosa[1]. *[1]Italian Liver Foundation, Liver Brain Unit, Trieste, Italy; [2]University of Trieste, Department of Life Sciences, Trieste, Italy; [3]University of Ferrara, Department of Life Sciences and Biotechnology, Ferrara, Italy; [4]AREA Science Park, Genomics and Epigenomics Platform, Trieste, Italy*
Email: benedetta.blarasin@fegato.it

Background and aims: Intrahepatic cholestasis is an impairment of bile flow involving the bile canaliculi. There are still clinically diagnosed cholestasis that remain without a definition of the molecular mechanisms involved. It is necessary to find an *in vitro* model able to maintain liver cells architecture and polarity and to self-renew. Adult Hepatocytes-derived organoids (Hep-Orgs) model is based on reproducing the environment occurring during liver regeneration upon liver hepatectomy. The main benefits of this model are their long-term culture and the cell maturity. Hepatocytes can be sourced directly from the patient. This study aims to obtain and characterize Hep-Orgs to study the molecular mechanisms involved in intrahepatic cholestasis.
Method: Mouse liver perfusion and digestion were developed to isolate primary adult hepatocytes according to Charni-Natan (DOI: 10.1016/j.xpro.2020.100086). Adult hepatocytes were then plated in Matrigel droplets and cultured according to Peng (DOI: 10.1016/j.cell.2018.11.012). Hep-Orgs growth was followed morphologically. EdU proliferation assay and albumin release by ELISA were performed. To induce intrahepatic cholestasis Hep-Orgs were treated with 10 μM Cyclosporine A (CsA) for 24 hours and with 50 μM CsA for 4 hours. The biliary excretion after treatment with CsA was observed using Dichlorofluorescein (DCF, 0, 5 μM for 2 hours) and DCF clearance was evaluated by Nikon A1 MP microscope. Bile canaliculi deformations were analyzed by rhodamine-phalloidin staining of pericanalicular F-actin and localization of the junctional ZO-1 protein. Immunofluorescence images were captured with Nikon Eclipse Ti-E epifluorescence microscope.
Results: After 10 days organoids showed 100 μm dimensions and, at day 32, they reached 250 μm showing a typical "bunch- of-grape" shape. Organoids were kept in culture for a maximum of 63 days. Hep-Orgs maintained a high proliferation rate at day 34 and albumin release increased over time (days 15, 30, 45, and 55). CsA caused a buildup of cytoplasmic DCF and altered the F-actin cytoskeletal distribution. In untreated Hep-Orgs, a predominant pericanalicular distribution of F-actin around bile canaliculi was observed, while in the CsA-treated a less intense staining was present.
Conclusion: The Hep-Orgs were satisfying in terms of growth and long-term expansion, and maintained the morphological features and a high proliferative potential, with high levels of albumin released in the medium. The treatment with CsA was able to reproduce the cytoskeletal modifications that happen during intrahepatic cholestasis, indicating that this model is suitable for studying the molecular mechanisms involved in intrahepatic cholestasis.

FRI-173

Mutational profile and correlation with Leipzig score in Wilson disease-a comprehensive analysis

Anand Kulkarni[1], V. V. Ravikanth[1], Govardhan Bale[1], Mithun Sharma[1], Sowmya Iyengar[1], Shantan Venishetty[1], Manasa Alla[1], Rajesh Gupta[1], Nagaraja Padaki[1], Nageshwar Reddy[1]. *[1]AIG Hospitals, Hyderabad, India*
Email: anandvk90@gmail.com

Background and aims: The Leipzig score is an excellent tool for diagnosis of Wilson disease (WD). However, mutational analysis is not available widely and most rely on clinical and laboratory diagnosis of WD. We aimed to assess the role of mutational analysis in WD in the Indian population.
Method: Consecutive WD patients being treated with chelation therapy were included. DNA was isolated from 2 ml of whole blood and amplified with primer pools to generate the complete exonic and untranslated regions (UTRs; 3′ and 5′) of *ATP7B* gene (Ion AmpliSeq Designer; Thermo Fisher Scientific). Primary objective was to describe the mutational analysis and then compare the same among probable (Leipzig score 2–3) and high likely WD (Leipzig score >3) assessed through clinical features and lab tests.
Results: A total of 136 patients (median age-19 years; females-35.3%; Leipzig score-4; Nazer score-5 and NWI-5) being treated as WD were included in this analysis. Ninety-two patients underwent genetic analysis. Of them, 56.5% had no pathogenic variants, 21.7% had two pathogenic variants (homozygous-11 and compound heterozygous-9), and 21.7% had one heterozygous pathogenic variant. Of these 20 patients with one pathogenic variant, 13 patients had variants of unknown significance (VUS) and/or other pathogenic conflicting variants and seven had no other variants. Of the 52 patients with no pathogenic variants, 30 had no other variants, while 22 had other VUS/pathogenic conflicting variants. Of these 22 patients, 13 had homozygous or compound heterozygous mutations, while the other nine had only one variant. In total, 50% of patients (46/92) could be genetically labeled as WD, while 16 had one pathogenic variant with no other variants or only one VUS or another pathogenic variant. While 32.6% (n = 30) had no mutations at all. The most common pathogenic variant was p.Gly1061Glu followed by p.Cys271Ter. Of the 59 patients with Leipzig clinical scores 2–3 (probable WD based on clinical and lab parameters), 43 underwent genetic tests, and of the 77 patients with Leipzig clinical scores >3 (high likely WD based on clinical and lab parameters), 49 underwent genetic tests. Of the 43 probable WD, 44.2% (n = 19) had confirmed mutation, while seven had a single variant and 17 had none. Similarly, for patients with high likely WD, 27 (55.1%) had confirmed WD through mutational analysis, nine had one variant, and 13 had none.
Conclusion: Only 50% of patients with proven WD have classical genetic variants of the disease. Expanding the genetic testing to regulatory and other genome regions in the heterozygous carriers and in patients with no variants may uncover newer variants.

FRI-174

Spectrum of UGT1A1 variations in chinese patients with Gilbert's syndrome

Wenting Tan[1], Wenyan Zhang[1], Yan Zhu[1], Yunjie Dan[1], Xiaomei Xiang[2], Xiuhua Wang[2], Yi Zhou[1], Yanzhi Guo[1], Jie Xia[1], Guohong Deng[1]. *[1]Southwest Hospital, Chongqing, China; [2]Southwest Hospital, Chongqing, China*
Email: tan_wenting@126.com

Background and aims: Gilbert syndrome (GS) is an inherited abnormality characterized by moderate unconjugated hyperbilirubinemia without hemolysis. This rare autosomal recessive condition is caused by mutation in *UGT1A1* gene encoding for the UDP-glucuronosyl transferase. The spectrum of *UGT1A1* variations varies markedly between different ethnic populations. In this study, we aimed to investigated genetic causes and related characters for this condition in Chinese population.
Method: Totally, 425 patients with idiopathic jaundice who visited our hospital between Oct 2017 to Nov 2023 were included in this study. All patients were deeply sequenced by targeted next-generation sequencing panel in which 43 disease-causing genes known to be associated with genetic liver disease were involved in, including those resulting in unconjugated (*UGT1A1*) and conjugated hyperbilirubinemia (*ABCC2*, *SLCO1B1* and *SLCO1B3*).
Results: Among the cohort, 213 patients were diagnosed as GS (151 males) with age of 30.9 ± 14.2 years old. Sixteen of them were self-reported with early-onset under 18 years old, 128 of them were adult-onset (median 27.5 yrs, range 18–68 yrs) while 69 of them remains unclear. All of them had unconjugated hyperbilirubinemia with a median IBIL level of 42.1 μmol/L (range 28.5–59.9 μmol/L) and total

bilirubin levels of 54.0 μmol/L (range 38.1–77.4 μmol/L), meanwhile with normal liver enzyme (with average ALT level 24.1 IU/L, range 14.1–43.0 IU/L), kidney and coagulation function. Thirty-three percent of them developed visible yellowish discoloration of the skin and/or mucous membranes. Two hundred and seven patients (97.2%) harbored pathogenic/affected variations on *UGT1A1* gene, top frequent sites are c.-3275T>G and c.-1352A>C (both with MAF 57.9%) located on phenobarbital-responsive enhancer module (PBREM) and distal element respectively, followed by c.221G>A (p.Gly71Arg, MAF 26.7%), c.-54_-53dupAT (24.0%), c.686C>A (p.Pro229Gln, 6.25%), c.1091C>T (p.Pro364Leu, 5.5%) and c.1456T>G (p.Tyr486Asp, 2.4%). Totally, we detected 31 *UGT1A1* allelic variants, 9 of them are novel, including harmful nonsense and frameshift variant which finally resulted in protein translation stop (c.715C>T, p.Gln239*; c.655C>T, p.Gln219*; c.1047delG, p.Ile350fsX). Forty-one patients (19.2%) carried homozygous pathogenic variants and 166 patients (77.9%) showed multiple sites of variants in UGT1A1; however, no significant association have been found between variant (type, number or region) and bilirubin levels ($p > 0.05$).

Conclusion: We described here the spectrum of *UGT1A1* variants and nine novel *UGT1A1* mutations in our DS cohort. Polymorphisms in the enhancer, promoter and coding region of *UGT1A1* were commonly observed in southwestern Chinese GS patients. Our findings expand on the spectrum of *UGT1A1* mutations and provide additional evidence between *UGT1A1* and hyperbilirubinemia.

Rare liver diseases (including paediatric and genetic) – Clinical

Combination of liver steatosis and premenopausal is a risk factor for DILI due to cyclin-dependent kinase 4/6 inhibitors as first-line treatment for metastatic breast cancer

Kreina Sharela Vega-Cano[1], Lourdes Ruiz-Ortega[2], Pau Mascaró Baselga[1], Paula Esteban[2], Oriol Mirallas Viñas[1], Francesca Filippi-Arriaga[3], Laia Joval Ramentol[4], Juan Carlos Ruiz-Cobo[2], Pau Benito Buch[1], Jesus Yaringaño[1], Gaspar Joaquin Molina[1], Diego Gomez Puerto[1], Lucia Sanz Gómez[1], Esther Zamora Adelantado[1], Maria Buti[2,5], Meritxell Bellet Ezquerra[1], Mar Riveiro Barciela[2,5]. *[1]Medical Oncology department, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain, Barcelona, Spain; [2]Liver Unit, Internal Medicine Department, Hospital Universitari Vall d'Hebron, Barcelona, Spain, Barcelona, Spain; [3]Clinical Pharmacology Department, Hospital Universitari Vall d'Hebron, Barcelona, Spain, Barcelona, Spain; [4]Data Science, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain, Barcelona, Spain; [5]CIBERehd, Madrid, Spain*
Email: mar.riveiro@gmail.com

Background and aims: the estimated rate of drug-induced liver injury (DILI) by cyclin-dependent kinase 4/6 inhibitors (CDKi) in clinical trials was 13%, although there are limited data on its characteristics and risk factors in clinical practice. We aimed to assess the incidence, characteristics and risk factors for CDKi-associated DILI.

Method: retrospective study including all patients who received CDKi from 2018 to 2022. Characteristics of DILI ≥grade 2 (CTCAE) were described. A case-control study (1:3) was also performed to investigate associated risk factors.

Results: 472 women were treated with CDKi and 26 (5.5%) developed DILI: 11 (42%) grade-2, 13 (50%) grade-3 and 2 (8%) grade-4, in a median follow-up of 218 days (IQR 37–399). No one developed severe hepatitis. Incidence of DILI related to CDKi: ribociclib 11.6%. abemaciclib 8%, palbociblib 3%, Median age was 61 years and 54% were premenopausal women. 11.5% had risk alcohol intake and 27% metastatic disease. After CKDi discontinuation, DILI was resolved in 88.5% in a median of 44 days (IQR 26–61). CDKi was restarted in 15 (58%) women, 61.5% of whom experienced a recurrence of toxicity. No risk factor was found in the case-control study, although liver steatosis showed a trend to increase DILI rate ($p = 0.08$). The combination of liver steatosis and premenopause (9 patients) was associated with a higher risk of DILI (67% vs. 19%, $p = 0.004$; OR 8.6, 95%CI 2.1–43.6), as was the combination of steatosis and baseline ALT>35 IU/ml (57% vs. 21%, $p = 0.04$; OR 5.15, 95%CI 1.07–27.8). An exploratory analysis showed a lower progression-free survival in the DILI group (22.2 vs 36 months, $p = 0.03$; HR 1.84, 95% CI 1.06–3.22).

Conclusion: 5.5% of patients treated with CDKi experienced DILI, the majority grade-3 and associated with ribociclib therapy. CDKi-DILI was most common among premenopausal women with steatosis and it could be associated with a lower progression-free survival, though these results need to be confirmed prospectively.

Evolution of clinical presentation, treatment and prognosis of patients with alveolar echinococcosis treated at the university hospital Zurich: a 50-year experience

Ansgar Deibel[1], Yannick Kindler[1], Rubens Mita[2], Soleen Ghafoor[3], Cordula Meyer zu Schwabedissen[1], Alexander Schweiger[4], Felix Grimm[5], Michael Reinehr[6], Achim Weber[7], Cäcilia Reiner[3], Andreas E. Email: rudolfansgar.deibel@usz.ch

Background and aims: Alveolar echinococcosis (AE) is an orphan zoonotic liver disease of increasing concern in Europe and other endemic areas across the globe. AE mimics a malignant tumor with infiltrative growth and occasional metastatic spread. Without adequate treatment, the disease has a 90% 10-year-mortality. The mainstay of treatment is surgical resection and medical treatment with benzimidazoles (BMZ). The majority of cases is unresectable due to advanced disease stage at diagnosis. Long-term BMZ therapy is highly effective in stabilizing the disease course for unresectable cases. The study aim was to evaluate the evolution in the presentation, treatment, and prognosis of AE patients over the past 50 years.

Method: Retrospective cohort study of 334 AE patients who were treated at the University Hospital Zurich between 1973–2022. Analysis included patient demographics, symptomatology at diagnosis, AE stage according to PNM classification, treatment strategy (curative or palliative surgical resection; long-term BMZ treatment), treatment outcome, overall survival and causes of death. In order to analyze changes over time, variables were stratified by decade of diagnosis. Overall survival was compared to the general Swiss population through relative survival analysis. Risk of AE-associated death was compared between curatively resected patients and non-

resected participants, propensity-score-matched by PNM-classification.
Results: Over the decades, there was no change in patient demographics. The median age at diagnosis is 58 years with a slight female predominance. Since 2000, a steady increase in new diagnosis of AE was observed, with an increasing proportion attributable to incidental diagnosis. This was accompanied by a stage migration towards earlier AE stages. Nevertheless, fewer patients underwent surgical resection. In total, 126 patients (38%) underwent curative resection, of which 20 patients (16%) suffered disease recurrence. Ninety patients (27%) died but causes of death were predominantly non-AE related. AE-related death occurred after a median of 159 months. Median age at death of any cause was 79 years. The 15-year overall survival was 73% and did not differ by decade of diagnosis or disease stage. Relative survival of AE patients was similar to that of the general Swiss population over the first 13 years after diagnosis. Risk of AE-related death was very low in both resected and matched non-resected cases and similar over 13 years.
Conclusion: Annual AE cases are rising, with considerable changes in clinical presentation, stage of the disease and pursued treatment strategy. Survival is limited primarily by non-AE-related causes of death and similar to the general Swiss population over the first 13 years. Risk of AE-related death was similar over the first 13 years after diagnosis between curatively resected patients and matched non-resected patients.

Email: mfromme@ukaachen.de

Background and aims: Homozygous Pi*Z mutation in *SERPINA1* confers a strong predisposition to lung and liver-related mortality. Current therapeutic approaches address either the pulmonary loss-of-function or the hepatic gain-of-function mechanism. We evaluated the disease course and non-invasive surrogates for the development of hepatic and pulmonary end points in an international, multicenter Pi*ZZ cohort with available longitudinal follow-up.
Method: In cohort 1, 737 Pi*ZZ subjects from 25 centers received a standardized clinical, laboratory, and elastographic assessment. At least six months afterwards, a follow-up interview was performed focusing on liver- and lung related end points. Hepatic end points were defined as first hepatic decompensation/liver transplantation or liver-related death, pulmonary end points comprised (listing for) lung transplantation or lung-related death. Cohort 2 consisted of 135 Pi*ZZ adults without significant liver fibrosis, who received a baseline and follow-up examination at least two years later, both including liver stiffness measurement (LSM).
Results: During 2634 patient-years of follow-up, 39 individuals died, with liver and lung being responsible for 46% and 36% of deaths, respectively (cohort 1). 41 Pi*ZZ subjects that developed a hepatic end point, presented with higher liver fibrosis markers at baseline, i.e., LSM (24 vs. 5 kPa, $p < 0.001$), AST-to-platelet ratio index (APRI, 1.1 vs. 0.3 units, $p < 0.001$) and fibrosis-4 index (FIB-4, 3.8 vs. 1.2, $p < 0.001$). Hepatic end points within five years were most accurately predicted by LSM (AUC 0.95) followed by APRI (0.92) and FIB-4 (0.90). Baseline lung parameters displayed only a moderate predictive utility for lung-related end points (FEV1 AUC 0.76). Notably, out of 540 Pi*ZZ individuals with LSM <7.1 kPa, nobody developed a hepatic end point despite over 1900 follow-up years, while such end points were rare among subjects with APRI <0.5/FIB-4 <1.3 units. An increase in all non-invasive liver fibrosis scores coincided with an increased occurrence of hepatic end points. Similarly, there was an increased incidence of lung end points in subgroups with lower FEV1 values. Interestingly, a Pi*ZZ subject with mild-to moderate pulmonary function impairment/increases in liver stiffness (i.e., FEV1 50–70% vs. LSM 7.1–10 kPa) displayed a three times higher risk of liver- vs. lung-related end points. In cohort 2, 8.9% showed a fibrosis progression based on LSM (</≥7.1 kPa). Progressors displayed higher BMI (27.3 vs. 23.9 kg/m^2, $p = 0.004$), baseline LSM (6.1 vs. 4.6 kPa, $p = 0.002$) and APRI (0.44 vs. 0.28 $p < 0.001$).
Conclusion: Non-invasive surrogates of liver fibrosis were able to stratify hepatic decompensation risk in Pi*ZZ adults. Interestingly, liver risk was higher in those with mild-to moderate increases in liver stiffness, as compared to lung risk in those with mild-moderately impaired pulmonary function.

Safety and efficacy of direct oral anticoagulants in cirrhotic and non-cirrhotic splanchnic vein thrombosis

Lucia Giuli[1], Rosa Talerico[1], Silvia Betti[1], Francesca Bartolomei[1], Elena Rossi[1], Antonio Gasbarrini[1], Maurizio Pompili[2], Valerio De Stefano[1], Roberto Pola[1], Maria Pallozzi[1], Brigida Eleonora Annicchiarico[1], Francesca Romana Ponziani[1], Francesco Santopaolo[1]. *[1]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [2]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy*
Email: lucia.giuli92@gmail.com

Background and aims: Splanchnic vein thrombosis (SVT) is a potentially life-threatening disease that can occur in cirrhotic and non-cirrhotic patients. Anticoagulation with heparins and vitamin K antagonists (VKA) is the mainstay of treatment. Recent studies have suggested that direct oral anticoagulants (DOACs) may offer a viable alternative in these settings. However, data on the safety and efficacy of DOACs are still limited, especially in cirrhotic patients. The aim of our study is to prospectively define the incidence of progression/recurrence of thrombosis and of major bleeding events during therapy with DOACs in patients with SVT.
Method: We conducted a prospective, single-centre, observational study. Consecutive cirrhotic and non-cirrhotic patients with either recent (<6 months) or chronic SVT who started DOACs at therapeutic dose were enrolled between June 2022 and June 2023. At one, three and six months patients were evaluated for clinical manifestation of venous thromboembolism and major bleeding events according to ISTH criteria. At six months a CT scan was performed to assess progression or recurrence of SVT.
Results: Of the 48 patients enrolled (mean age 59, 52% males, 38% cirrhotic), 21 had a recent SVT (43.8%). Of the 27 patients with chronic SVT, 19 (70%) had a cavernous transformation. Of the 18 cirrhotic patients, 83% were Child A and 17% Child B. 24 patients (50%) started rivaroxaban, 22 apixaban (45%) and 2 edoxaban (5%). All patients had received a previous treatment with heparins or VKA. Cirrhotic patients more frequently had varices ($p = 0.002$) and previous episodes of variceal bleeding ($p = 0.002$). Cirrhotic patients were older (67 vs 55, $p = 0.0003$), had lower mean level of platelets (87444 vs 285466, $p = 0.00003$) and higher mean level of bilirubin ($p = 0.01$). At six months follow-up all patients were alive and there were two asymptomatic episodes of recurrence/progression of SVT (4.2%) and one episode of major bleeding (2.1%). No differences in the cumulative incidence of these events were found among cirrhotic and non-cirrhotic patients. Concerning recanalization, 8 patients presented complete recanalization (16.7%), 28 patients presented stability (58.3%) and 10 partial regression of SVT (20.8%). Complete recanalization was significantly more frequent in patients with recent SVT ($p = 0.0009$).
Conclusion: DOACs appear to be a safe and effective alternative for the treatment of SVT in cirrhotic and non-cirrhotic patients.

Email: e_dajti17@hotmail.com

Background and aims: Oxaliplatin has been associated with porto-sinusoidal vascular disease (PSVD), but scarce data is available. We aimed to i) describe PSVD prevalence among patients undergoing resection for liver metastases; ii) assess whether pre-operative liver (LSM) and spleen stiffness measurements (SSM) by transient elastography could diagnose PSVD and predict post-operative complications.
Method: This is a prospective single center study enrolling consecutive patients undergoing hepatic resection for metastases at a tertiary center. For each patient we evaluated previous exposure to chemotherapy, co-morbidities, elastography, type of surgery, histological features at the resection specimen, morbidity (post-hepatectomy liver failure (PHLF), major complications according to Clavien-Dindo), and overall survival.
Results: We included 68 patients in the analysis: 34 (50%) were female, 49 (72%) had a primary colon cancer, and 60 (88%) had undergone previous chemotherapy. At histology, 29 (44%) of the patients had a diagnosis PSVD (of whom 10 with non-specific signs of portal hypertension, PH), and 5 (8%) had steatohepatitis. SSM <21 kPa (NPV 87%) and >40 kPa (PPV 100%) could accurately rule-out and rule-in PSVD; none of the patients with PH signs had SSM <21 kPa. PSVD was associated with a significantly higher need for transfusions (0 vs 14%), incidence of PHLF (22 vs 45%), major complications (11 vs 31%), 90-day mortality (0 vs 14%). Pre-operative LSM was associated with the development of clinically significant PHLF (OR: 1.491, 95%-CI: 1.114–1.996), major complications (OR: 1.346, 95%-CI: 1.063–1.704), and mortality (HR: 1.379, 95%-CI: 1.122–1.696). The cut-offs of <4.5 kPa and >8 kPa were able to stratify for the risk of clinically significant (CS)-PHLF (0%, 11%, and 33% in LSM <4.5 kPa, 4.5–8 kPa, >8 kPa) and major complications (0%, 25%, 44% in LSM <4.5 kPa, 4.5–8 kPa, >8 kPa). The combination of LSM with SSM (LSM <4.5 kPa or LSM 4.5–8 kPa, but SSM <21 kPa) increased the subgroup of patients at low risk of complications (0% CS-PHLF, 3.2% major complications).
Conclusion: PSVD is a very common finding among patients undergoing liver surgery for metastases and it is associated with increased morbidity and mortality. LSM and SSM can correctly identify patients with PSVD and those at risk of clinically relevant post-operative complications. The non-invasive evaluation could improve risk stratification of patients undergoing surgery.

Email: matteo.mureddu@studenti.unimi.it

Background and aims: Apolipoprotein B (ApoB) is fundamental to guarantee stability and secretion of Very Low-Density Lipoprotein (VLDL) from the liver. Loss-of-function mutations of *APOB* gene predispose to Familial Hypobetalipoproteinemia (FHBL) andsteatotic liver disease (SLD). However, whether heterozygosity for rare protein coding *APOB* variants contribute to sporadic cases of severe MASLD with advanced fibrosis and/or hepatocellular carcinoma (HCC) is still disputed.
Aim of this study was to evaluate the prevalence of rare *APOB* mutations in a cohort of patients with advanced metabolic or cryptogenic SLD.
Method: 510 patients with liver disease were examined through Whole Exome Sequencing (WES) or Target Sequencing (TS) and 50 healthy controls.
SLD was defined by the availability of at least one among: 1) Controlled attenuation parameter (CAP) of at least 275 dB/m at Fibroscan; 2) Liver steatosis at ultrasonography, computed tomography or magnetic resonance imaging 3) Histological evidence of liver steatosis.
Rare variants were selected considering a Maximum Allelic Frequency (MAF) of 1%. All stop gained and frameshift mutations were considered in the analysis. Missense mutations were considered only if had CADD_Phred greater than 20. Missense mutations, splicing variants, splicing donor variants, 5′ and 3′ UTR variants, duplications and non_frame deletions were included if located in exons 1–26 or introns 1–25 and predicted by ClinVar and/or Franklin Genox to be pathogenic or likely pathogenic.
Results: Out of 510 subjects, 12 (2%) harbored *APOB* rare variants and 320 (62%) had evidence of steatosis. No mutation respecting selection criteria was found among controls.
The mutated subjects displayed lower LDL-C ($p = 0.009$), suggesting impaired VLDL secretion, ad lower platelets count ($p = 0.01$) and a higher prevalence of FIB-4 >2.67 ($p = 0.03$), irrespective of age and sex, suggesting more severe liver damage.
In the overall cohort, *APOB* variants were not associated with HCC, but after stratification for cirrhosis, HCC was more prevalent in the mutated than non-mutated patients without overt cirrhosis (OR 5.6 for HCC, 95% CI 1.09–8.7; $p = 0.02$ in the mutated versus non mutated patients in the absence of overt cirrhosis).
Conclusion: This study further supports the notion that heterozygous APOB variants predispose to severe SLD and HCC, and the importance of integrating genetic analysis in the management of patients with MASLD and cryptogenic liver disease.

Email: laure_elkrief@yahoo.fr

Background and aims: In patients with noncirrhotic chronic extrahepatic portal vein obstruction (EHPVO), data on morbi-mortality of abdominal surgery unrelated to portal hypertension are scarce.
Method: We retrospectively analyzed the charts of patients with EHPVO undergoing abdominal surgery within the VALDIG and the FILFOIE network. Cox univariate and multivariate regressions analyses were performed to identify factors associated with complications or death. We also compared the cumulative incidence of complications or death after surgery in patients with noncirrhotic EHPVO with matched controls without EHPVO who had similar surgical interventions.
Results: Seventy-six patients with EHPVO (58% male, median age 53 years) were included. Twenty-three (30%) patients had a history of ascites and 34 (45%) a strong risk factor for thrombosis. Seventy-eight interventions were performed, including 14 wall surgeries, 20 cholecystectomies, and 44 other surgeries. Fourteen (14%) had ≥1 major bleeding. Sixteen (21%) patients had ≥1 Dindo-Clavien grade ≥3 postoperative complication within 1 month after surgery. Emergency procedure and surgery other than wall or cholecystectomy were the main factors associated with major bleeding and with Dindo-Clavien grade ≥3 postoperative complications. Twelve (15%) patients had ≥1 portal hypertension related complication within 3 months after surgery, with a favorable outcome under medical therapy in 11/12 patients. Three (4%) patients died within 12 months after surgery. Six-month cumulative risk of death was higher in patients with serum creatinine ≥100 μmol/L at surgery (20%, *vs.* 1%, $p = 0.004$). An unfavorable outcome (*i.e.* either complication or death) occurred in 29 (37%) patients and was associated to the presence of history of ascites and surgery other than wall surgery or cholecystectomy: 17% of the patients with none of these features had an unfavorable outcome, *vs.* 48% and 100% when one or both features were present, respectively. As compared to 126 matched control patients without EHPVO, incidence of both major bleeding ($p < 0.001$) and portal-hypertension related complication ($p < 0.001$) was significantly higher in patients with EHPVO but not that of neither grade ≥3 post-operative complication nor death within 12 months after surgery.
Conclusion: Patients with EHPVO are at high-risk of major bleeding and surgical complications, especially in those with history of ascites and/or undergoing surgery other than wall surgery or cholecystectomy.

WED-130

Prevalence and predictors of porto-sinusoidal vascular disorder in patients with persistent and unexplained gamma-glutamyl transferase elevation: a multicenter study

Email: nicola.pugliese@live.com

Background and aims: Porto-sinusoidal vascular disorder (PSVD) is a group of vascular disorders characterized by lesions involving portal venules and sinusoids, irrespective of the presence of portal hypertension (PH). Liver biopsy (LB) is essential for diagnosis. In a single-center study, we demonstrated high rates of PSVD in patients with persistently elevated gamma-glutamyl transferase (GGT). This multicenter study aims to establish PSVD prevalence in a larger dataset of individuals with persistent and unexplained GGT elevation, and to identify associated risk factors.
Method: The study included all patients who underwent LB for persistent and unexplained GGT elevation in five Italian Hepatology Units between March 2015 and December 2021.
Results: 144 patients met the inclusion criteria. The majority were males (76/144, 52.8%) and mean age was 51.9 years (range 19–74). Twelve (8.3%) had liver stiffness measurements (LSM) >12 kPa, only 7 (4.8%) had ultrasound PH evidence. Histological findings were consistent with PSVD in 96 patients (67%). Alternative diagnoses were metabolic dysfunction-associated steatohepatitis (MASH) in 13 (9%), sarcoidosis in 3 (2%) and congenital hepatic fibrosis in 3 (2%). Histological examination couldn't provide a diagnosis in 29 (20%) patients. Male sex (odds ratio, OR = 2.60, 95% confidence interval, CI: 1.13–5.99), LSM <12 kPa (OR = 11.05, 95% CI: 2.16–56.66) and GGT <200 UI/L (OR = 2.69, 95% CI: 1.22–5.98) were associated with histological findings of PVSD.
Conclusion: PSVD is the main cause of persistent and unexplained elevation of GGT. Male sex, LSM <10 kPa and GGT <200 U/l are associated with PSVD. These findings highlight the role of LB in elucidating the underlying pathology and aiding in the diagnosis of patients with persistent and unexplained GGT elevation.

WED-131-YI
Von Willebrand factor antigen reflects portal hypertension severity in porto-sinusoidal vascular disorder and predicts liver-related outcomes

Lorenz Balcar[1], Georg Semmler[1], Michael Schwarz[1], Emina Halilbasic[1], Albert Friedrich Stättermayer[1], Michael Trauner[1], Mattias Mandorfer[1], Thomas Reiberger[1], Bernhard Scheiner[1].
[1]*Medical University of Vienna, Vienna, Austria*
Email: lorenz.balcar@meduniwien.ac.at

Background and aims: Von Willebrand factor antigen (VWF-Ag) reflects endothelial dysfunction and is a versatile non-invasive marker correlating with portal hypertension severity as well as outcomes in patients with cirrhosis. Patients with porto-sinusoidal vascular disorder (PSVD) are at risk to develop portal hypertension and associated complications, yet no study has so far evaluated the properties of VWF-Ag as a marker for portal hypertension or predictor of complications in PSVD.
Method: Patients with established diagnosis of PSVD at the Medical University of Vienna and available VWF-Ag at the diagnosis of PSVD were retrospectively included. VWF-Ag cut-offs predicting the presence of specific clinical signs of portal hypertension as well as identifying patients at risk for liver-related outcomes (first/further hepatic decompensation + liver-related death) were developed.
Results: One-hundred and eighteen patients were included (mean age 48 ± 16 years; 64% female, 36% male). Forty-seven patients (40%) had a history of decompensation and 22 (19%) a portal vein thrombosis at diagnosis (mean MELD 9 ± 3, mean CTP 6 ± 1 points). Overall, 72% had specific, whereas 88% had unspecific signs of portal hypertension. Mean VWF-Ag was 221 ± 90%, median platelet count (PLT) was 122 (IQR: 71, 192 G/L) and median VITRO score (VWF-Ag/PLT) was 1.6 (IQR: 0.9, 3.1).
VWF-Ag and VITRO score were significantly higher in patients with specific signs of portal hypertension (VWF-Ag: 233 ± 87 vs. 192 ± 94; p = 0.027; VITRO: 2.2 [IQR: 1.1–3.7] vs. 1 [IQR: 0.5–1.9]; p = 0.002), whereas PLT, albumin, Child-Pugh-score or MELD score were not different among both groups. During a median follow-up of 3.8 years, 22 (19%) patients developed one or more liver-related complications. After adjusting for age, MELD, and history of decompensation, VWF-Ag was significantly associated with the outcome of interest (log, per 10; aHR: 2.94 [95%CI: 1.08–8.05]; p = 0.036). A VWF-Ag cut-off at ≥174% identified patients with considerable risk of developing liver-related outcomes during follow-up (at 3 years: 21% vs. 0%). Accordingly, this cut-off also stratified compensated patients at baseline with distinct risk (at 5 years: 17% vs. 0%).
Conclusion: VWF identifies PSVD patients with portal hypertension and associated liver-related outcomes independently of and superior to established prognostic markers.

WED-132
Role of transient elastography in diagnosis and prognosis of Fontan-associated liver disease

Marta Cuadros[1], Marta Abadía[1], Consuelo Froilán[1], Nerea Gonzalo[1], Miriam Romero[1], Araceli García-Sánchez[1], Francisco Javier García-Samaniego[1], Antonio Olveira[1], José Carlos Erdozaín[1], José Ruiz-Cantador[1], Elvira Ana González-García[1], Inés Ponz[1], Pablo Merás[1], Carlos Merino[1], Adriana Rodríguez-Chaverri[1], Enrique Balbacid[1], Maria Dolores Martin-Arranz[1,2,3], Pilar Castillo[1]. [1]*Hospital Universitario La Paz, Madrid, Spain;* [2]*Instituto de Investigación Hospital Universitario La Paz (IdiPAZ), Madrid, Spain;* [3]*Universidad Autónoma de Madrid, Madrid, Spain*
Email: cuadrosmartinez@gmail.com

Background and aims: Fontan-associated liver disease (FALD) is an emerging entity that affects patients with single-ventricle physiology who undergo the Fontan procedure. Recently, a definition of advanced FALD (A-FALD) has been proposed by the European Association for the Study of the Liver (EASL) and the European Reference Network (ERN) on Rare Liver Diseases, based on portal hypertension criteria. In FALD, liver congestion increases liver stiffness. Thus, liver stiffness measurement (LSM) by transient elastography (TE) may have a role in the diagnosis and prognosis of this disease.
Method: Retrospective study in a single-center, Hospital Universitario La Paz (Madrid, Spain). Laboratory data, ultrasound (US) findings (Canon Aplio i800), and LSM by TE (FibroScan ®) were collected. FALD was defined by US criteria (hepatomegaly, liver surface nodularity, parenchymal heterogeneity, hyperechoic lesions, splenomegaly, or collaterals), and A-FALD, based on the EASL-ERN definition (oesophageal varices, portosystemic shunts, ascites, or splenomegaly).
Results: Between January 2017 and November 2023, 91 patients with Fontan surgery were included: mean age 33.3 ± 8.2 years, mean time since Fontan surgery 24.3 ± 7.7 years, 55/91 (60.4%) male. LSM by TE was associated with FALD and A-FALD in univariate and multivariate analysis (p < 0.05). LSM was significantly higher in patients with FALD than those without, median LSM 27.7 kPa (21.9–34.3 kPa) vs 14.6 kPa (11.4–18.5 kPa) (p < 0.001). The area under the receiver

operating characteristic (AUROC) of LSM for FALD was 0.905 (95% CI: 0.814–0.997) (p < 0.001). The optimal cut-off point for FALD was 19 kPa (sensitivity 92.3%, specificity 80.0%). The cut-off point to rule-out FALD was 15 kPa (sensitivity 96.9%). The cut-off point to rule-in FALD was 25 kPa (specificity 100%). Patients with A-FALD had higher LSM compared with those without, median LSM 29.5 kPa (22.4–36.6 kPa) vs 20.2 kPa (14.6–27.7 kPa) (p = 0.001). The AUROC of LSM for A-LSM was 0.764 (95% CI: 0.624–0.905) (p = 0.001). The optimal cut-off point for A-FALD was 25 kPa (sensitivity 69.6%, specificity 68.4%). The cut-off point to rule-out A-FALD was 19 kPa (sensitivity 95.7%). The cut-off point to rule-in A-FALD was 39 kPa (specificity 94.8%). LSM correlated with clinically relevant events (need for heart or heart-liver transplantation, hepatocellular carcinoma and death), with statistically significant differences in multivariate analysis (odds-ratio: 1.07; 95% CI: 1.01–1.13; p = 0.03). Regarding mortality, LSM values were significantly higher in patients who died, median LSM 44.6 kPa (34.6–62.9 kPa) vs 25 kPa (20.2–32.2 kPa) (p = 0.006).
Conclusion: In patients with Fontan surgery, liver stiffness measurement by TE correlates with FALD and clinically relevant events (need for heart or heart-liver transplantation, hepatocellular carcinoma, and death).

WED-133
Quality of life in adults with Wilson disease: a study from the international Wilson disease registry

Claus Niederau[1], Aurélia Poujois[2], George Alex[3], Anil Dhawan[4], Caroline Roatta[5], C. Omar Kamlin[6], Timothy Jenkins[6], Pramod Mistry[7]. *[1]Katholische Kliniken, Oberhausen, Germany; [2]Hôpital Fondation Adolphe de Rothschild, Paris, France; [3]Murdoch Children's Institute, Parkville, Australia; [4]Liver Institute, London, United Kingdom; [5]Bernard Pepin Institute, Service Neurologie Hôpital Lariboisière, Paris, France; [6]Orphalan SA, London, United Kingdom; [7]Yale School of Medicine, New Haven, United States*
Email: pramod.mistry@yale.edu.au

Background and aims: Wilson disease is a prototype inborn error of metabolism that results in a wide spectrum of liver disease and neuropsychiatric symptoms. Multiple therapeutic options are available, however, chronic disease management, may be limited by impaired health related quality of life (HRQoL). Due to extreme heterogeneity of WD, real-world data on HRQoL are needed to harness maximal potential of therapies.
Method: The International Wilson Disease (iWD) registry was established in 2021 (NCT05239858). Patients aged 18 years or greater at first visit, completed a 12-Item Short-Form Health Survey (SF-12), a validated multipurpose indicator of health status. Data were analysed using SPSS v29. Correlations between continuous variables were estimated using Spearman's correlation and between quantitative variables and two or more groups using Mann-Whitney Kruskal-Wallis tests respectively.
Results: Between 29/06/2022 and 30/11/2023, 334 subjects were enrolled, of whom 322 met age eligibility criteria from Germany (76), Belgium (15), Spain (83), Poland (44), UK (47), and France (57). SF-12 was completed by 314/322 (97.5%). Of the 322, 50.6% (163) were female, mean (SD) age of 39.1 (14.6) years. Clinical phenotypes were reported in 298 (hepatic [166], neurologic [72], asymptomatic [48], psychiatric [7], mixed [5] respectively. WD therapy was documented in 318; d-penicillamine (135), zinc salts (79), trientine tetrahydrochloride (52), trientine dihydrochloride (43), chelator plus zinc (9). The majority (222/314; 71%) rated their general health as either good or very good, with only 10/314 (3%) reporting this as poor. The mean (SD) physical health composite summary (PCS) and the mental health composite summary (MCS) for this cohort were 42.8 (4.6) and 45.8 (5.5), respectively. No differences were seen by gender, class of therapy or country. MCS but not PCS was significantly lower with psychiatric phenotype vs other phenotypes.
Conclusion: In a European cross-sectional survey of adults with WD, whilst self-reported general health was rated high in many patients, mean physical and mental health scores were lower than US reference values. These data highlight areas for improvement in HRQoL and underscore the need for research to develop WD specific instruments to address these data gaps *(abstract submitted on behalf of the International Wilson Disease (iWD) Registry Collaborators*).

WED-134
Treatment adherence and associated clinical outcomes for Wilson disease patients: a real-world, retrospective, multinational survey

Niall Hatchell[1], Nathan Ball[1], Kieran Wynne-Cattanach[1], Emily Quinones[1], Jennifer Mellor[1]. *[1]Adelphi Real World, Bollington, United Kingdom*
Email: niall.hatchell@adelphigroup.com

Background and aims: Wilson disease (WD) is a rare, multisystemic disease caused by dysfunctional copper excretion, with hepatic and neuropsychiatric presentation. Prescription of copper-binding medication ensures copper is serum ceruloplasmin-bound and excreted. Complete adherence is key to improving clinical outcomes, however it is unknown to what extent in WD patients. We investigated real-world clinical outcomes for patients with varying adherence to WD treatment, and drivers of adherence.
Method: Data were drawn from the Adelphi Wilson Disease Specific Programme™, a cross-sectional survey of physicians and their consulting patients in Australia, Brazil, Canada, France, Germany, Italy, Spain, and the United Kingdom from June 2022–March 2023. Physicians reported patient demographics, clinical outcomes (including disease presentation via Unified Wilson Disease Rating Scale, UWDRS), treatment, and adherence. Physicians reported patients as "not at all," "a little," "somewhat," "mostly" or "completely" adherent to taking their medication exactly as agreed, and responses were grouped into "patients with complete adherence" (pCA) or "patients with suboptimal adherence" (pSA). Comparisons between groups were made using Fisher's Exact test or t-test. Logistic regression was used to assess the association between outcomes and the likelihood of having "complete adherence." Odds ratios (OR) were calculated.
Results: Data were analysed for 615 WD patients (from 210 WD treating physicians) with known adherence levels, of whom 51% were pCA. Mean (standard deviation; SD) age was 33.4 (14.35) years and 67% were male. Patients' mean (SD) time since diagnosis was 5.9 (6.35) years. D-penicillamine was the most prescribed treatment (68% of patients), and mean (SD) time on any treatment was 4.1 (4.57) years. WD patients experienced a mean (SD) of 8.1 (6.79) symptoms, with pSA experiencing more symptoms, 10.0 (7.28) compared to pCA, (6.4 (5.79) (p < 0.0001). Total mean (SD) UWDRS scores were higher for pSA, 39.8 (43.12) compared to pCA, 20.6 (27.98; p < 0.01). pSA had higher hepatic, psychiatric and neurologic UWDRS domain scores than pCA, 10.4, 13.4 and 25.5, compared to 2.2, 3.9, and 5.1 respectively (all p < 0.01). Side effects of current WD regimen were more common among pSA (19%) than pCA (42%) (p < 0.01). Significant associations were observed between experiencing side effects (OR 0.37; p < 0.01) and total UWDRS score (OR 0.98; p < 0.01) with likelihood of being adherent.
Conclusion: pSA were experiencing more symptoms and greater impairment across all UWDRS domains. Our findings suggest side effects of currently approved WD treatments had an association with suboptimal adherence in these patients. This indicates a need for newer WD treatment options with more manageable side effect profiles to improve adherence and outcomes.

WED-135-YI

Impact of metabolic alterations on liver phenotype of patients with homozygous alpha-1 antitrypsin deficiency (Pi*ZZ)

Christina Schrader[1], Malin Fromme[1], Audrey Payancé[2], Mattias Mandorfer[3], Katrine Thorhauge[4,5], Monica Pons[6,7], Marc Miravitlles[8], Jan Stolk[9], Bart van Hoek[10], Guido Stirnimann[11], Soňa Fraňková[12], Jan Sperl[12], Andreas E. Email: christina.schrader@rwth-aachen.de

Background and aims: Pi*ZZ genotype is responsible for the majority of severe alpha-1 antitrypsin deficiency cases and confers a genetic susceptibility to lung emphysema and liver fibrosis. We analyzed the significance of metabolic factors in the European Pi*ZZ cohort.

Method: A multicenter international cohort consisted of 1160 PiZZ individuals at baseline, 590 of them completed a follow-up assessment at least 6 months later. Inclusion criteria comprised no additional liver comorbidities, an at most moderate alcohol consumption and no liver decompensation prior to baseline. Baseline liver examinations included clinical and laboratory work-up, along with non-invasive liver fibrosis assessment via AST-to-platelet ratio index (APRI). During follow-up interviews, a need for liver transplantation, liver-associated death, the development of decompensated cirrhosis (i.e., ascites, hepatorenal syndrome, or hepatic encephalopathy) were counted as liver end points.

Results: At baseline, 198 participants were obese (BMI ≥30 kg/m^2) and 39 had diabetes. The latter displayed more often than non-diabetic individuals elevated AST and ALT values as well as diminished platelets (OR 2.8–4.2, $p < 0.01$ for all comparisons). APRI suggestive of significant (≥0.5 units) and advanced liver fibrosis (≥1.0 units) was also more common (OR 2.7 and 7.7; $p < 0.01$ for both). Compared to non-obese subjects, obese individuals had more often elevated AST and ALT values and diminished platelets (OR 1.3–2.1, $p < 0.01$ for all comparisons). Over a median follow-up time of 3.54 years, 127 subjects passed away and 41 individuals experienced a hepatic end point. Pi*ZZ individuals with a hepatic end point demonstrated a significantly higher BMI (28.2 vs. 24.8 kg/m^2, $p < 0.001$), were more often male (73.2% vs. 52.3%, $p = 0.01$), and had more frequently diabetes mellitus (15.4% vs. 3.1%, $p < 0.001$). Diabetes (HR 5.1, $p < 0.001$) and obesity (HR 2.7, $p = 0.008$) conferred a higher risk of hepatic end points during follow-up, whereas the impact of male gender was less pronounced (HR 2.2, $p = 0.022$).

Conclusion: In Pi*ZZ subjects, diabetes and obesity are associated with elevated liver injury/fibrosis markers at baseline and an increased risk of hepatic decompensation during follow-up. These factors should be considered in the clinical management of these subjects.

WED-136

Comorbidity burden associated with fatigue or pruritus in patients with primary biliary cholangitis in the United States: a matched case-control study

Nisreen Shamseddine[1], Hongbo Yang[2], Su Zhang[2], Sonal Kumar[3]. *[1]Ipsen Biopharmaceuticals, Inc, Cambridge, United States; [2]Analysis Group, Inc., Boston, United States; [3]Weill Cornell Medical College, New York, United States*
Email: nisreen.shamseddine@ipsen.com

Background and aims: Primary biliary cholangitis (PBC) is a chronic rare cholestatic liver disease with adverse health outcomes including end-stage liver disease. Pruritus and fatigue are common conditions associated with PBC. This study assessed the additional comorbidity burden of PBC-associated pruritus or fatigue in patients living in the United States.

Method: This retrospective study used IQVIA PharMetrics® Plus data (2016–2022). Patients with PBC and pruritus, and those with PBC and fatigue were separately selected as cases. Patients with PBC and neither pruritus nor fatigue were eligible as controls; controls were selected by matching to cases at a 1:1 ratio on the parameters of sex, insurance type, region, PBC duration, and postindex follow-up duration. Index date was defined as a random date for the pruritus/fatigue diagnosis after the initial PBC diagnosis for cases and a random medical visit for controls. The number of comorbidities per patient by 1, 3, and 5 years postindex was compared between cases and matched controls. For each individual comorbidity, the cumulative incidence by 1, 3, and 5 years postindex were compared between cases and matched controls and the hazard ratio of developing the comorbidity in cases vs. controls was estimated.

Results: 760 pruritus cases and matched controls (median follow-up: 23.3 month) and 1839 fatigue cases and matched controls (median follow-up: 21.5 month) were included. At baseline (the 1-year period before index), the mean number of comorbidities per patient was 1.1 for pruritus cases vs 0.5 for controls ($p < 0.001$) and 1.1 for fatigue cases vs 0.5 for controls ($p < 0.001$). The number of comorbidities by 1, 3, and 5 years postindex were significantly higher for cases vs controls: 1.9 vs 0.8, 2.3 vs 1.0, and 2.7 vs 1.0, respectively ($p < 0.001$ for all) for pruritus groups; 1.7 vs 0.7, 2.2 vs 0.9, and 2.5 vs 1.0 ($p < 0.001$ for all) for fatigue groups. The most common comorbidities were fatigue, anxiety, and urinary tract infection (UTI) in patients with pruritus, and anxiety, UTI, and depression in patients with fatigue. The hazard ratio of developing individual comorbidities ranged from 1.5–2.8 for pruritus cases relative to controls ($p < 0.001$ for all), and 1.3–4.0 for fatigue cases relative to controls ($p < 0.01$ for all).

Conclusion: This analysis suggests that patients with PBC with pruritus and fatigue experience a significant comorbidity burden. The findings highlight an unmet need for PBC treatments that reduce the adverse health outcomes associated with PBC.

WED-137-YI

Reviewing the largest experience of liver transplantation for Wilson's disease in the UK: single centre review of patient and graft outcomes and long term survival

James Liu Yin[1], Claire Kelly[1], Adrian Bomford[1], Rosa Miquel[2], Niloufar Safinia[1], Alberto Sanchez-Fueyo[1], Marianne Samyn[3], Deepak Joshi[1], Michael Heneghan[1], Kosh Agarwal[1], Abid Suddle[1], Varuna Aluvihare[1], Krishna Menon[1], Anil Dhawan[4], Nigel Heaton[5], Aftab Ala[1]. Email: aftab.ala1@nhs.net

Background and aims: Wilson's disease (WD) is a genetic metabolic liver condition caused by mutation of the ATP7B transporter leading to accumulation of copper particularly in brain and hepatic tissue resulting in liver failure. Clinically this presents acutely but may be a cause of chronic liver failure. Transplantation is often necessary in those who present with acute liver failure or decompensated chronic liver disease. King's College Hospital, London (KCH) has a large cohort of WD patients. We aim to review the outcomes from liver transplantation performed in our institution.
Method: We reviewed clinical, genetic and biochemical data for all patients transplanted for WD at KCH from 1990 to 2023. Data was collected from current electronic records. Statistical analysis was performed using Microsoft excel and Graphpad Prism.
Results: There were 65 patients transplanted for a clinical diagnosis of WD since 1990 (38F:27M). Age range was from 7 to 56 years (yr) with median age of 20 yr. Listing for transplant was 41 (63%) as super urgent, 16 (25%) as chronic (3 listed as priority) and 12% with unavailable data. 57 transplants were with whole livers, 7 received left lobes and 1 right lobe. There were 61 DBD grafts, 3 DCD (listed for chronic) and 1 living un-related donor. 52% of patients were on single agent immunosuppression, 38% on dual and 10% on three. 5% had graft loss within 90 days and overall 17% required multiple transplants (2Tx: 10 patients, 3Tx:1 patient). Reasons for graft loss were cholangiopathy (2), acute rejection, nodular regenerative hyperplasia, early and late hepatic artery thrombosis, multifactorial graft dysfunction, chronic rejection (3), and de-novo autoimmune hepatitis. Patient survival was 94% at 1 yr, 91% at 5 yr and 91% at 10 yr. Graft survival was 94% at 1 yr, 86% at 5 yr and 82% at 10 yr. For patients listed as super-urgent, survival was 90% at 1 yr and 88% at 5 yr. No statistical significance in graft survival was found between genetic mutations (none/heterozygous/compound/homozygous $p = 0.40$), listing criteria (super urgent/chronic $p = 0.09$) or blood type (A/B/AB/O $p = 0.66$). Using linear regression analysis with length of survival and graft survival as dependent variables comparing age, MELD, UKELD, urinary copper level and tissue copper level, there was no statistically significant result.
Conclusion: This is the largest reported experience of liver transplantation for WD in the UK. Overall survival after transplant for WD was comparable to the national average at 1 yr, but was considerable higher at 5 and 10 yr. Similarly for super-urgent transplants, 1 yr survival was comparable, but at 5 yr was higher. While this may be explained by the younger median age of patients, transplant for WD remains an effective treatment for acute liver failure caused by WD. Further collaborative work at scale is needed to understand outcomes and contributing factors over short and long term periods.

WED-138

Patients with alpha-1-antitrypsin deficiency and the risk of developing liver events: a longitudinal cohort study

Pavel Strnad[1], Tina Landsvig Berentzen[2], Louise Maymann Nitze[2], Klaus Kaae Andersen[2], Michael Soliman[3], Kamal Kant Mangla[2], Mohamed Tawfik[2], Alice Turner[4]. [1]*University Hospital RWTH Aachen, Aachen, Germany;* [2]*Novo Nordisk A/S, Copenhagen, Denmark;* [3]*Novo Nordisk, Boston, United States;* [4]*Institute of Applied Health Research, University of Birmingham, Birmingham, United Kingdom*
Email: pstrnad@ukaachen.de

Background and aims: Alpha-1-antitrypsin (AAT) deficiency (AATD) is a rare genetic disorder that manifests as lung and/or liver disease, but the progression to severe liver disease remains poorly understood. The aim of this study was to characterise a population with AATD at the time of diagnosis and to estimate the subsequent risk of developing severe liver disease.
Method: This longitudinal cohort study included patients with a diagnosis of AATD aged ≥18 years and registered in the Clinical Practice Research Datalink after 1 April 1997, with no alcohol-related disorders, viral, biliary or autoimmune liver diseases or prescriptions of drugs inducing liver disease before or on the date of their AATD diagnosis (index date). Patients were characterised at the index date and followed until time of first severe liver event or 31 March 2021, whichever came first. Events were defined as liver-related hospitalisation or death from hepatocellular carcinoma, liver transplant, chronic liver failure, liver cirrhosis, portal hypertension, or hepatic decompensation recorded in the Hospital Episodes Statistics or Office for National Statistics Death Registration. Aalen-Johansen cumulative incidence functions were estimated and a reference population was matched according to birth year and sex.
Results: In total, 3402 eligible patients had an AATD diagnosis, of whom 74 with a severe liver event before their AATD diagnosis were excluded. In the 3328 patients with no prior liver event, 50.9% were male and median age was 49 years. Few (33%) had serum AAT measured at the index date: median (5%, 95%) 0.80 (0.20, 1.14) g/L. Liver function tests in the AATD vs reference population were: median aspartate aminotransferase (AST) 28 vs 23 u/L, alanine aminotransferase (ALT) 33 vs 22 u/L, gamma-glutamyl transferase (GGT) 53 vs 28 u/L and platelet count 252 vs 251×10^9/L. During a median follow-up of 5.7 years, 122 incident liver events occurred, with cirrhosis (n = 43), hepatic decompensation (n = 37) and portal hypertension (n = 20) being the most common. The cumulative incidence of a liver event at 10 years post-index date was 5.1% and 1.3% in the AATD and reference population ($p < 0.001$), respectively. In patients with AATD with low AAT (<57 mg/dL) or low platelet count (<150, 000), or high levels of AST (>40 U/L), ALT (>40 U/L) or GGT (>30 IU/L) at the index date, the cumulative incidence of a liver event at 10 years was 11%, 45%, 19%, 10% and 9%, respectively.
Conclusion: In this real-world population of patients with AATD registered in general practice, the risk of developing a severe liver event was significantly higher than in the reference population. In patients with AATD with a low level of serum AAT or abnormal liver function tests, the risk of developing severe liver events was even higher. These results highlight a strong unmet medical need for monitoring and treatment of liver-related complications in patients with AATD.

WED-151

Routine cholestasis genetic testing in patients with intrahepatic cholestasis of pregnancy reveals high prevalence of genetic variants of bile acid transport defects

Kelly Dale[1], Anita Kohli[2], Rida Nadeem[1], Naim Alkhouri[2]. [1]*Arizona Liver Health, Phoenix, United States;* [2]*Arizona Liver Health, Phoenix, United States*
Email: kdale@azliver.com

Background and aims: Intrahepatic cholestasis of pregnancy (ICP) is a condition unique to pregnancy causing pruritus, elevated liver

enzymes, and elevated serum bile acids. It has been associated with complications including stillbirth and preterm delivery. Some women continue to experience cholestasis often with pruritus that occurs outside of pregnancy. Genetic predisposition is often implicated in ICP specifically with mutations in the ATP8B1, ABCB11, and ABCB4 genes that are associated with progressive familial intrahepatic cholestasis (PFIC). The aim of this study was to assess the utility of routine cholestasis genetic testing in patients with ICP.

Method: Consecutive patients that presented to a tertiary hepatology clinic for history of cholestasis and ICP were tested prospectively for causes of genetic cholestasis with the cholestasis panel that tests for 77 genes. Routine clinical and laboratory parameters were collected. The severity of liver disease was assessed with vibration controlled transient elastography (VCTE). Descriptive statistics were used to characterize the cohort.

Results: Seven patients with history of ICP were tested. The mean age was 41.3 ± 13.9 years and the mean BMI was 28 ± 3.6 kg/m^2. Laboratory parameters were as follows: ALT 45 ± 20.7 U/L, AST 35 ± 18.5, alkaline phosphatase 120.4 ± 51, GGT 59.4 ± 54, bilirubin 0.44 ± 0.11, and platelet count 326.7 ± 57.4 k/uL. The mean liver stiffness on VCTE was 4.9 ± 1.0 kPa and the mean controlled attenuation parameter was 243.4 ± 62 dB/m indicating no significant liver fibrosis. Genetic testing revealed that 5/7 (71.4%) of patients were heterozygote for a genetic variant in the ABCB4 gene typically associated with PFIC type 3. One patient was heterozygote for a genetic variant of MYO5B associated with PFIC 10. One patient was heterozygote for 3 genetic variants including CC2D2A, NPHP3, and UGT1A1. 6/7 (85.7%) of patients had recurrent episodes of pruritus that continued to occur outside of pregnancy. 4/7 (57.1%) were on ursodeoxycholic acid.

Conclusion: Cholestasis genetic testing in patients presenting to hepatology clinic for history of cholestasis and ICP revealed high prevalence of ABCB4 variants. To our knowledge, the association between MYO5B and ICP is novel. The role of other genetic variants for cholestasis other than PFIC genes needs to be better understood.

WED-152

Design and study population of MITIGATE: the first multinational randomized controlled clinical trial in IgG4 related disease, evaluating the efficacy and safety of the CD19 B cell depleting agent inebilizumab

John Stone[1], Emma Culver[2], Arezou Khosroshahi[3], Wen Zhang[4], Emanuel Della Torre[5], Kazuichi Okazaki[6], Yoshiya Tanaka[7], Matthias Lohr[8], Nicolas Schleinitz[9], Lingli Dong[10], Hisanori Umehara[11], Marco Lanzillotta[5], Zachary Wallace[1], Mikael Ebbo[9], George Webster[12], Yanping Wu[13], Daniel Cimbora[13], Nishi Rampal[13]. *[1]Massachusetts General Hospital, Harvard Medical School, Boston, United States; [2]John Radcliffe Hospital, University of Oxford, Oxford, United Kingdom; [3]Emory University School of Medicine, Atlanta, United States; [4]Peking Union Medical College, Beijing, China; [5]San Raffaele Hospital, Milan, Italy; [6]Kansai Medical University Kori Hospital, Osaka, Japan; [7]University of Occupational and Environmental Health, Kitakyushu, Japan; [8]Karolinska Institutet, Stockholm, Sweden; [9]Hôpital de la Timone, AP-HM, Aix-Marseille Université, Marseille, France; [10]Tongji Medical College, Huazhong University of Science and Technology, Shanghai, China; [11]Nagahama City Hospital, Shiga, Japan; [12]University College Hospital, London, United Kingdom; [13]Amgen, Inc., Thousand Oaks, United States*
Email: jhstone@mgh.harvard.edu

Background and aims: The roles of B cells in the pathophysiology of IgG4 Related Disease (IgG4-RD) and existing clinical experience suggest that B cell depletion may be an effective therapeutic avenue. Inebilizumab is a humanized, glycoengineered CD19 monoclonal antibody that effectively and selectively depletes B cells. The Phase 3 MITIGATE trial (NCT04540497) is a randomized, double-blinded, placebo-controlled trial that aims to demonstrate the efficacy and safety of inebilizumab monotherapy in IgG4-RD.

Method: MITIGATE is being conducted at 80 sites in 22 countries, enrolling IgG4-RD patients who meet the ACR/EULAR Classification Criteria for IgG4-RD with a score of at least 20 as determined by an Eligibility Committee (EC). Eligibility criteria included a history of multiorgan disease and active disease at the time of screening to increase the risk of flares for the primary end point. Subjects were stratified based on newly diagnosed (46%) vs. recurrent (54%) disease to control for differences in flare risk. The primary end point is time to first Adjudication Committee-determined and investigator-treated IgG4-RD flare during the 12-month randomized controlled period. The study is event-driven and is powered on the accrual of 39 disease flares. To permit evaluation of inebilizumab as monotherapy, other immunosuppressive agents are prohibited and glucocorticoids are discontinued at the end of study week 8.

Results: Enrolment completed in April 2023 with 135 subjects enrolled. The mean age was 58.2 years and 65% were male. Time since diagnosis ranged from 0.1 to 20.5 years (median 0.9 years). Baseline ACR/EULAR Classification Criteria scores ranged from 20 to 74. The number of organs affected by IgG4-RD up to the time of enrolment varied from 2 to 13, with 2–3 organs affected in 41% of subjects and ≥6 organs affected in 24% of subjects. The pancreas, bile ducts, and liver were affected in 52%, 31%, and 7% of subjects respectively. Hepatobiliary disease was accompanied by pancreatic involvement in 95% of cases, but only 59% of those with pancreatic involvement also had hepatobiliary disease. The submandibular, lacrimal, and parotid glands, lymph nodes, kidney, sinuses, and lungs were each affected in at least 20% of the study population. These findings suggest that the study population carries substantial hepatobiliary disease burden and is representative of real-world IgG4-RD cohorts.

Conclusion: MITIGATE enrolled a representative IgG4-RD population in terms of both number and distribution of organs affected. More than half of participants had hepato-pancreato-biliary disease, and hepatobiliary disease without pancreatic involvement was rare. Trial results are expected in 2024 and aim to establish the safety and efficacy of CD19-targeted B cell depletion by inebilizumab in IgG4-RD, potentially leading to the first approved treatment for this disease.

Advances in the diagnosis of cholestatic liver diseases with the implementation of exome sequencing

Ignasi Olivas[1,2], Meritxell Jodar[3], Helena Hernández Evole[1,2], Pinelopi Arvaniti[1,2,4], Anna Pocurull[1,2], Zoe Mariño[1,2,5], Celia Badenas[3], María Carlota Londoño[1,2,5], Sergio Rodriguez-Tajes[1,2]. *[1]Liver Unit, Hospital Clínic Barcelona, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), Barcelona, Spain; [3]Biochemistry and Molecular Genetics Department, Hospital Clínic Barcelona, Barcelona, Spain; [4]Department of Medicine and Research Laboratory of Internal Medicine, Expertise Center of Greece in Autoimmune Liver Diseases, ERN RARE-LIVER, University Hospital of Larissa, Larissa, Greece; [5]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain*
Email: ignasiolivasalberch@gmail.com

Background and aims: Clinical practice guidelines recommend performing a genetic testing in patients with chronic idiopathic cholestasis (CIC) after ruling-out common causes of cholestasis. The implementation in clinical practice of techniques of next generation sequencing (NGS) has facilitated the study of genes related to cholestasis. Our aim is to determine the usefulness of genetic study using NGS in the diagnosis of CIC in adults.

Method: Thirty-nine adults with CIC underwent NGS (filtered by a panel of 35 genes associated with cholestasis) in blood samples. Genetic variants were classified according to the American College of

Medical Genetics and Genomics criteria as follows: pathogenic (PV), likely pathogenic (LPV) and variant of uncertain significance (VUS).
Results: Twenty-six patients were women (66%), with a median age of 46 years (IQR 39–53), ALP 1.2 × ULN (IQR 0.8–1.5), GGT 102 U/L (IQR 54–216), bilirubin 0.7 mg/dL (IQR 0.6–1). Twenty-one percent had pruritus, 23% cholestasis of pregnancy, seven (18%) low phospholipid-associated cholelithiasis (LPAC) syndrome and 10% drug-induced liver injury (DILI). Four patients (10%) had a family history of cholestasis and 6 had been previously misdiagnosed. Nineteen (49%) presented a genetic variant in heterozygosis. In 8 patients, we identified a PV or LPV that explained their symptoms: 5 had heterozygous variants in the *ABCB4* gene, 4 of them with LPAC syndrome and one with DILI; one patient had an heterozygous variant in *PRKCSH* gene with a polycystic liver disease, and two patients had a microdeletion of chromosome 17q12 in heterozygosis that contains *HNF1B* gene presenting diabetes mellitus, hypomagnesaemia and alteration of liver enzymes. A VUS was detected in 5 patients, 4 in the *ABCB4* gene and one in *NOTCH2*, which after functional or family segregation studies could be associated with patient symptoms. Finally, six patients had a PV, LPV or VUS in *PKHD1*, *ABCC2*, *HNF1B* and *ATP7B* genes but with unknown correlation to patients' symptoms.
Conclusion: A high percentage of patients with CIC presented variants in genes related to cholestasis, which may explain their symptoms. Given the therapeutic implications for patients and families, patients with CIC should undergo genetic testing to rule-out the presence of genetic cholestasis.

Email: shachiyo2@yahoo.co.jp

Background and aims: A reduction in skeletal muscle mass (sarcopenia) is a known risk factor affecting long-term prognosis and life expectancy of adult cirrhosis cases; however, it has not been previously reported whether sarcopenia is a prognostic factor in patients with Fontan-associated liver disease (FALD). This study aimed to elucidate the relationship between FALD and sarcopenia.
Method: Among 105 post-Fontan procedure cases diagnosed using imaging from January 2012 to December 2022 at our department, 62 cases aged ≥18 years were selected, along with a control group of 50 adults matched for age. Diagnosis of sarcopenia was assessed by measuring skeletal muscle mass using the psoas muscle index at the L3 level.
Results: Among the 62 FALD cases, 38 were diagnosed with sarcopenia. The median skeletal muscle mass was significantly lower in the FALD group compared to that in the control group for both males (7.12 cm^2/m^2 vs. 5.89 cm^2/m^2) and females (5.42 cm^2/m^2 vs. 4.05 cm^2/m^2) ($p < 0.001$). Multivariate Cox hazard analysis was conducted to assess factors related to Fontan circulatory failure and revealed that a New York Heart Association functional classification ≥3, B-type natriuretic peptide levels, and skeletal muscle mass were predictive factors. Furthermore, two cases of heart failure-related deaths were observed among the 62 cases, and both cases matched the diagnosis of sarcopenia. Additionally, liver stiffness values measured using vibration-controlled transient elastography were significantly higher in the sarcopenia group (21.5 kPa) compared to that in the non-sarcopenia group (13.2 kPa) ($p = 0.0014$).
Conclusion: Sarcopenia is considered a predictive factor for Fontan circulatory failure and a risk factor for the progression of liver fibrosis due to FALD. The evaluation of skeletal muscle mass may serve as a comprehensive screening tool for multi-organ failure in cases of Fontan circulation.

WED-155
A ratio of exchangeable copper below 15% accurately excludes Wilson disease and may be useful for the first-line ethiologic work-up within a liver unit
Zoe Mariño[1], Clàudia García-Solà[1], Anna Soria[1], Sabela Lens[1], Adrià Juanola[1], Jordi Gratacós-Ginès[1], Elisa Pose[1], María Carlota Londoño[1], Sergio Rodriguez-Tajes[1], Isabel Graupera[1], Xavier Forns[1], Mercè Torra[2]. *[1]Liver Unit, Hospital Clínic Barcelona, CIBERehd, IDIBAPS, ERN-RARE Liver, Universitat de Barcelona, Barcelona, Spain; [2]Biochemistry and Molecular Genetics Department, Hospital Clínic Barcelona, IDIBAPS, Universitat de Barcelona, Barcelona, Spain*
Email: zmarino@clinic.cat

Background and aims: Diagnosis of Wilson disease (WD) is complex. Exchangeable copper (CuEX) arised some years ago as a biomarker reflecting the free copper systemic pool; its ratio referred to total copper (REC) was shown to be useful for WD diagnosis and has progressively been extended across Europe. REC ≥18% identifies new WD cases (El Balkhi S et al, 2011) whereas WD patients on follow-up usually present REC >15%. Moreover, carriers and healthy individuals present REC <15%. Data on REC values among patients with other liver diseases is scarce. Our aim was to evaluate the usefulness of REC since its availability in our center.
Method: Retrospective unicentric analysis of CuEX/REC indications in clinical practice. CuEX (µg/dL) and REC (%) quantification were performed locally by inductively plasma coupled to mass spectrometry (ICP-MS) since December 2021. In those patients with more than one assessment, only one was considered; among WD patients, one measurement at diagnosis and one in follow-up were retained. Variables were expressed in median (IQR) and statistical analysis was done with SPSS V27.
Results: Up to 341 patients [54% male, median age 47] had a CuEX/REC measurement; most of them were patients followed at the Liver Unit (95.6%). Most cases (275, 80.6%) were classified as non-wilsonian patients, 60 WD cases (17.6%) and 6 carriers of one *ATP7B* mutation (1.8%). Median age at sample extraction was significantly lower among WD patients (38 years) compared to non-WD and carriers [Kruskal-Wallis, $p = 0.003$]. Reasons for REC evaluation were: chronic liver tests and/or imaging abnormalities (54%), WD diagnosis or follow-up (17.3%), acute hepatitis (14.4%), chronic cholestasis (6.2%), high ferritin levels (3.2%), neuro-psychiatric symptoms (2.1%) or copper abnormalities (2.1%). Ceruloplasmin (Cp) levels were significantly lower and urinary copper excretion (UCE) was significantly higher among WD patients compared to non-wilsonian and carrier individuals [Kruskal-Wallis, $p < 0.01$]. However, their negative predictive values (NPV) for excluding WD were suboptimal: 47% for Cp levels <0.2 g/L and 81% for UCE <100 µg/24hs (available in 149). REC was significantly higher among WD patients when compared to carriers and non-wilsonian patients [23.3% (IQR 12.7–39.5%) vs 5% (IQR 4.1–6.4%) vs 4.9% (IQR 3.9–5.9%), Kruskal-Wallis, $p < 0.01$]. REC ≥18% identified 36/60 WD patients (sensibility = 60%) improving to 70% if REC was >15%. The NPV for excluding WD with a REC value below 18% was 90.1% which improved to 93.4% when REC was below 15%. Only one non-wilsonian patient presented REC values above 15%, corresponding to a female patient with an acute autoimmune hepatitis and REC 47%. All carriers showed REC <15%.

Conclusion: REC quantification is an accurate tool for excluding WD at a liver Unit and could be used at the first-line diagnostic biomarker upon validation in larger cohorts.

WED-158-YI

Disease experience and care expectations in european patients with immune-mediated liver disease

Pierre-Antoine Soret[1], Bert Tomsin[2], José A. Willemse[3], Martine Walmsley[4], Victorio Gnutti[5], Wiebke Papenthin[6], Natalie Uhlenbusch[7], Tom J. G. Gevers[8], Nora Cazzagon[9], Christoph Schramm[10], Pierre Corret[11], Sara Lemoinne[1], Angela Leburgue[12]. Email: pierre.soret@aphp.fr

Background and aims: In the context of rare immune-mediated liver diseases, gaps between a physician's perception and patient's experience can mask patients' unmet needs. To identify and reduce those gaps appears crucial to improve patient management, adherence to treatments and quality of life.
Method: We conducted an observational international study based on an online survey, with the participation of Belgian, French, Italian, Dutch, and British patient organisations dealing with immune-mediated liver diseases (on behalf of ERN RARE-LIVER). Patients had to describe their 3 main symptoms and impact of the disease on daily life, provide suggestions to improve their well-being, and rate their overall satisfaction with care, from 0 to 10 (mean ± standard deviation).
Results: 560 patients were included: 256 with primary biliary cholangitis [PBC], 98 with primary sclerosing cholangitis [PSC], 150 with autoimmune hepatitis [AIH] and 56 with overlap AIH-PBC/PSC. The most frequent symptoms declared were fatigue (73%), digestive issues (23%) and itch (19%). 72% of patients reported troubles in daily life mostly due to fatigue (34%), and restrictions in personal (35%) and professional life (19%). 250 patients (44%) declared that they had never asked for or never had satisfactory answers about specific aspects of their disease, in particular regarding the course of the disease (33%), care (29%) and stage of the disease (15%). Out of the 258 patients (46%) who expressed detailed suggestions to improve their well-being, 39% wanted global care (not limited to their liver disease alone but to include comorbidities, symptom management, psychological support), 34% asked for a better dialogue with their doctor and 12% were looking for closer medical follow-up and more empathy. Based on 544 patients, global satisfaction with care was 7.51 (±2.10). No significant difference was observed in answers between PBC, PSC, AIH and overlap patients.
Conclusion: Patients with immune-mediated liver diseases were satisfied overall with their medical care. Nevertheless, improvements in symptom management, better consideration of alterations to quality of life and a more empathic dialogue were identified as needed by patients in order to improve the management of their disease. The burden in the different diseases was equivalent, and underscores a need for a global care approach.

WED-159

Usefulness of serological scores in the diagnosis of Fontan-associated liver disease

Marta Cuadros[1], Marta Abadía[1], Consuelo Froilán[1], Nerea Gonzalo[1], Miriam Romero[1], Araceli García-Sánchez[1], Francisco Javier García-Samaniego[1], Antonio Olveira[1], José Carlos Erdozaín[1], José Ruiz-Cantador[1], Elvira Ana González-García[1], Pablo Merás[1], Carlos Merino[1], Inés Ponz[1], Adriana Rodríguez-Chaverri[1], Enrique Balbacid[1], Maria Dolores Martin-Arranz[1,2,3], Pilar Castillo[1]. [1]*Hospital Universitario La Paz, Madrid, Spain;* [2]*Universidad Autónoma de Madrid, Madrid, Spain;* [3]*Instituto de Investigación Hospital Universitario La Paz (IdiPAZ), Madrid, Spain*
Email: cuadrosmartinez@gmail.com

Background and aims: Fontan-associated liver disease (FALD) is often described in adult patients with Fontan correction of single-ventricle congenital heart disease. The assessment of the severity of FALD through non-invasive methods is challenging and serological scores have not been validated in this setting. We aim to evaluate the role of non-invasive serological scores in the diagnosis of FALD.
Method: Retrospective study in a single-center, Hospital Universitario La Paz (Madrid, Spain). Serological scores of liver fibrosis were evaluated: Forns index, FIB4, and AST-to-platelet ratio index (APRI). FALD was defined by ultrasound (US) criteria (hepatomegaly, liver surface nodularity, parenchymal heterogeneity, hyperechoic lesions, splenomegaly, or collaterals), and A-FALD, based on the EASL-ERN definition (oesophageal varices, portosystemic shunts, ascites, or splenomegaly).
Results: Between January 2017 and November 2023, 91 patients with Fontan surgery were included: mean age 33.3 ± 8.2 years, mean time since Fontan surgery 24.3 ± 7.7 years, 55/91 (60.4%) male. The prevalence of FALD was 81/91 (89.0%). A-FALD was detected in 52/73 (71.2%). Forns index showed statistically significant relationship with FALD and A-FALD in univariate and multivariate analysis. Forns index was significantly higher in patients with FALD, median score 5.8 (interquartile-range 5.0–6.9), compared to patients without FALD, median score 4.5 (interquartile-range 3.5–5.2) ($p = 0.005$). This difference was observed as well in patients with A-FALD, median score 6.3 (interquartile-range 5.4–7.2), compared to patients without A-FALD, median score 5.0 (interquartile-range 4.3–5.6). The area under the receiver operating characteristic (AUROC) of the Forns index score for FALD was 0.772 (95% CI: 0.620–0.924, $p = 0.005$). The cut-off point to rule-out FALD was 4.04 (sensitivity 91.9%). The AUROC of the Forns index score for A-FALD was 0.773 (95% CI: 0.662–0.884, $p < 0.001$). The cut-off point to rule-out A-FALD was 4.00 (sensitivity 96.2%). FIB4 and APRI were associated with FALD and A-FALD in univariant analysis, but not in multivariate analysis.
Conclusion: The relationship between Forns index and FALD in our study suggests that this score may be a useful non-invasive tool in the evaluation of patients with Fontan surgery.

Email: kirchner.theresa@mh-hannover.de

Background and aims: Due to heterogeneous clinical presentation diagnosing pediatric autoimmune hepatitis (pAIH) is challenging. Traditional diagnosis includes immunofluorescence testing (IFT) of antinuclear (ANA) and smooth muscle antibodies (SMA) on rodent tissue sections. Recently polyreactive immunoglobulin G (pIgG) was suggested as a new and more accurate biomarker in adult and pediatric AIH. The aim of this retrospective multicenter study was to assess the diagnostic value of enzyme-linked immunosorbent assay-(ELISA-)based ANA testing in treatment naïve pAIH in comparison with traditional IFT as gold standard according to actual guidelines and scoring systems and the evaluation of diagnostic accuracy for different cut-offs of IFT.
Method: In this multicenter retrospective study three commercial ANA, one anti F-actin ELISA, IFT on rodent tissue sections and HEp-2 cells as well as pIgG measured using a home-made HIP1R/BSA ELISA were performed. Sixty-nine pAIH and 136 non-AIH liver disease patients were included from existing biorepositories. All ELISA and IFT for ANA and SMA were performed centrally in a head-to-head comparison with the performer being blinded to clinical data.
Results: Area under the curve (AUC) to predict pAIH for ANA ELISAs was 0.641 (95% CI 0.558–0.724) to 0.739 (95% CI 0.669–0.810) with higher AUC for ELISA with HEp-2 extracts. AUC for ANA (rodent tissue and HEp2 cells) and SMA in IFT was 0.749 (95% CI 0.676–0.822), 0.757 (95% CI 0.687–0.826) and 0.720 (95% CI 0.637–0.802) respectively. The highest AUCs were achieved by F-actin ELISA (0.831, 95% CI 0.771–0.892) and pIgG (0.846, 95% CI 0.785–0.906). Sensitivities were 24.6 to 62.3% for ANA ELISAs, 89.9% for ANA in IFT on rodent tissue (with recommended cut-off ≥1:20), 95.7% for ANA on HEp2 cells (with recommended cut-off ≥1:20), 61.5% for SMA in IFT (with recommended cut-off ≥1:20), 73.9% for F actin ELISA, and 78.3% for pIgG. Specificities were 66.2 to 90.4% for ANA ELISAs, 26.6% for ANA in IFT on rodent tissue (with recommended cut-off ≥1:20), 18.4% for ANA on HEp2 cells, 39.7% for SMA in IFT, 73.5% for F actin ELISA, and 83.1% for pIgG. Sensitivity in ANA ELISA could be improved by adjusted pediatric cut offs but with no further improvement of overall accuracies (66.8%-69.3%). However, accuracy in IFT could be improved from 47.8 to 73.7% (ANA rodent tissue), from 44.4 to 73.2% (ANA HEp-2) and from 43.7 to 80.3% (SMA) by an adjusted cut off of 1:320. Accuracy of F-actin and pIgG was 81.0% and 80.0% with adjusted pediatric cut-offs.
Conclusion: F-actin and pIgG ELISA exhibited the highest accuracies off all analyzed autoantibodies tests for the prediction of pAIH in pediatric non-viral liver disease. Furthermore, the study suggests an increase of the currently employed diagnostic cut-off values for ANA and SMA in IFT in children for best prediction of pAIH.

WED-161-YI

Liver steatosis and fibrosis in children with diabetes mellitus type 1: single-center analysis including MASLD-associated genetic variants

Jolanta Świderska[1], Wiktor Smyk[2], Sebastian Więckowski[3], Susanne N. Weber[4], Piotr Milkiewicz[5,6], Elżbieta Moszczyńska[1], Piotr Socha[3], Marcin Krawczyk[4,7]. [1]Department of Endocrinology and Diabetology, The Children's Memorial Health Institute, Warsaw, Poland; [2]Department of Gastroenterology and Hepatology, Medical University of Gdansk, Gdańsk, Poland; [3]Department of Gastroenterology, Hepatology and Nutrition Disorders, The Children's Memorial Health Institute, Warsaw, Poland; [4]Department of Medicine II, Saarland University Medical Center, Saarland University, Homburg, Germany; [5]Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland; [6]Translational Medicine Group, Pomeranian Medical University, Szczecin, Poland; [7]Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland
Email: marcin.krawczyk@uks.eu

Background and aims: Diabetes is a recognized metabolic risk factor for excessive hepatic fat accumulation. While the association between type 2 diabetes mellitus (DM2) and metabolic dysfunction-associated steatotic liver disease (MASLD) is well established, data on the incidence of MASLD in the setting of type 1 diabetes mellitus (DM1) is scarce. Here, we investigate an exhaustive cohort of children with DM1 for the presence of fatty liver and liver scarring in conjunction with common genetic polymorphisms associated with MASLD.
Method: Prospectively, we recruited 162 children (71 girls, mean age 14 ± 3 years) with DM1. Liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) were performed to non-invasively evaluate liver fibrosis and steatosis, respectively. Liver function tests, biochemical and metabolic parameters were assessed concurrently with LSM and CAP. Genotyping of the three genetic variants known to influence liver injury (i.e., *PNPLA3* p.I148M, *TM6SF2* p.E167 K, and *MBOAT7* p.G17E) was performed using TaqMan assays with fluorescence detection and compared to the frequencies in Polish adult individuals.
Results: The mean CAP was 208 ± 33 dB/m and values above 249 dB/m, i.e., suggestive of liver steatosis (Ferraioli et al., *BMC Gastroenterol* 2017), were present in 10% of patients. Mean LSM was 4.6 ± 1.1 kPa, and 1% of patients had LSM above 8.6 kPa indicative of advanced fibrosis (Lee et al., *J Pediatr.* 2013). Most of the recruited children with DM1 (91%) exhibited normal AST and ALT activities. The median BMI z-score was 0.18 (range −2.7–2.3). Multivariate linear regression showed that CAP positively correlated with BMI z-score ($\beta = 13.8$, $p < 0.001$) and HbA1c ($\beta = 3.1$, $p = 0.001$), and inversely with age ($\beta = -1.9$, $p = 0.037$). LSM positively correlated with BMI ($\beta = 0.6$, $p = 0.019$). The minor allele frequencies (MAF) for *PNPLA3*, *TM6SF2*, and *MBOAT7* variants were 0.20, 0.10, and 0.47, respectively, aligning with data for the general Polish population (all $p > 0.05$ for genotype distribution comparison). Notably, no significant association was found between the analyzed genetic variants and liver phenotypes in uni- or multivariate models.
Conclusion: Children with DM1 have a low risk of developing significant hepatic steatosis or fibrosis, especially in the absence of metabolic risk factors. These phenotypes do not appear to be significantly influenced by a pro-MASLD genetic predisposition. These findings emphasize the importance of managing metabolic syndrome components in DM1 patients to mitigate the risk of progressive liver injury risks.

WED-162

Performance of transient elastography, Fib4 and APRI in the diagnosis of severe liver fibrosis in patient with HFE hemochromatosis

Lise Trubert[1], Oumnia Masrour[2], Morcet Jeff[2], Laine Fabrice[3], Turlin Bruno[2], Edouard Bardou-Jacquet[2]. [1]*CHU Rennes, Rennes, France;* [2]*CHU Rennes, Rennes, France;* [3]*CHU Rennes, Rennes, France*
Email: edouard.bardou-jacquet@chu-rennes.fr

Background and aims: Liver fibrosis and cirrhosis are the main determinant of death in patients with HFE hemochromatosis (HH). Current EASL guidelines recommend screening for liver fibrosis in all HH patients at the time of diagnosis. While non-invasive tests are preferred, limited evidence exists comparing transient elastography (TE), Fib-4, and APRI to liver biopsy in this context. Our study aimed to evaluate the diagnostic performance of these tests in detecting liver fibrosis in HH patients.
Method: We included HH patients from our database (2005–2023) who underwent both liver biopsy and TE within a year of diagnosis. Patients with TE >7.1 kPa and IQR >0.3 were excluded. Clinical and demographic data were recorded. The diagnostic performance of TE, Fib-4, and APRI was assessed using ROC curves for severe liver fibrosis (Metavir F3F4).
Results: A total of 127 patients (81.9% male, age 49.5 ± 11.3, BMI 25.9 ± 4) were included. Diabetes and excessive alcohol consumption were present in 10.2% and 7.9%, respectively. Ferritin levels were 1508 µg/L ± 1321, and transferrin saturation was 85% ±14.6. Liver iron content (available for 63 patients) had a mean value of 290 µmol/g ± 108 by magnetic resonance imaging. Fibrosis stage prevalence was F0F1 = 48.1%, F2 = 25.2%, F3 = 7.9%, and F4 = 18.9%. Mean TE was 9.8 kPa ± 8.8, Fib-4 was 1.45 ± 0.83, and APRI was 0.69 ± 0.48. AUC for severe fibrosis diagnosis by ferritin, TE, Fib-4, and APRI were 0.92 (0.86–0.96), 0.94 (0.88–0.97), 0.85 (0.77–0.91), and 0.83 (0.75–0.90) respectively.Cutoff value at a fixed sensitivity of 90% were ferritin: 1853 µg/L, TE: 8.6 kPa, Fib-4: 1.18, and APRI: 0.53. Cutoff value at a fixed specificity of 90% were ferritin: 2224 µg/L, TE: 9.9 kPa, Fib-4: 2.04, and APRI: 0.87. Using ferritin cutoffs, 81 (64%) patient were correctly classified and 12 (9.4%) patient would have required liver biopsy. Using TE cutoffs 104 (81%) patients were correctly classified and 10 (7%) would have required a liver biopsy. Combining both criteria resulted in correct classification of 82 (64%) patients, without false negatives/positives. However, 32 (25%) had discrepant results, and 12 (9%) were in the intermediate zone requiring liver biopsy.
Conclusion: Our findings suggest that the ferritin criterion for liver biopsy in HH could be increased to 1800 µg/L while maintaining high sensitivity. APRI and Fib-4 exhibited lower performance compared to ferritin and TE in assessing liver fibrosis in HH patients. We propose TE cutoffs of 8.6 kPa to rule out severe fibrosis and 9.9 kPa to confirm it. Overall, combining non-invasive tests could significantly reduce the need for liver biopsy in HH patients based on previous biopsy criteria while maintaining excellent diagnostic performance.

WED-163

Non-invasive testing reveals fibrosis risk in heterozygous Alpha-1 Antitrypsin deficiency

George Marek[1], Harmeet Malhi[1]. [1]*Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States*
Email: marek.george@mayo.edu

Background and aims: Alpha 1 antitrypsin deficiency (AATD) is caused by proteotoxic alleles of the SERPINA1 gene. The disease is codominant and up to 1:2000 individuals are homozygous (ZZ) and 4% of the population are carriers (MZ). The Z allele is associated with steatotic liver disease in recent GWAS studies. Liver stiffness measurements by transient elastography of UK biobank cohort suggest that there is an increased liver stiffness in MZ. However, the clinical significance of MZ in the outpatient clinical setting is not well understood. In this study, we sought to determine if MZ phenotype is associated with increased fibrosis or steatosis on initial non-invasive testing.
Method: We retrospectively evaluated patients phenotyped for AATD who had transient elastography evaluation of their native liver. Data was collected from separate sites across the Mayo Clinic health system in Minnesota, Wisconsin, Arizona, and Florida. Elastography reports were extracted using Mayo Data Explorer. Statistical comparisons including Shapiro-Wilk testing for normality, Mann-Whitney U testing, and Pearson's Chi-squared testing to compare categorical groups R version 4.3.2. The activities in this study were approved by an institutional review board (IRB) at the Mayo Clinic in Rochester Minnesota.
Results: We abstracted 5461 individual readings from 2259 individuals with a known AAT phenotype. 1858 were MM, 132 were MZ, 6 ZZ, and 81 had rare variants. We compared MM and MZ patients and found the ages at initial elastography were similar 54 (41–64) and 58 (45–64) p = 0.2. The proportion of patients with kpa values >9.5 suggesting advanced fibrosis or cirrhosis was greater in MZ individuals 48 (37%) vs. MM 526 (28%) p = 0.048. Baseline CAP values were 276 (220–329), 269 (229–318) p = 0.3. We compared longitudinal changes for 389 individuals who had at least one year of follow-up. The median (IQR) follow-up was 2.17 (1.41–3.36) years for MM and 1.95 (1.36–3.23) for MZ p = 0.4. The change per year in LSM was −0.15 kPA/yr (−0.95–0.59) for MM and −0.43 (−0.80–1.29) for MZ p = 0.8 likewise, the change in CAP was similar between groups −6 (−21–10) and −1 (−13–14) dB/m/yr p = 0.7.
Conclusion: MM and MZ patients began non-invasive monitoring at similar ages but a higher proportion of MZ individuals had evidence of advanced disease. The prevalence and severity of steatosis was similar amongst MM and MZ individuals. MM and MZ individuals had similar changes in LSM and CAP. This is not a natural history cohort and presumably, after initial evaluation, patients with longitudinal follow-up also had appropriate medical counseling and access to treatment of comorbid conditions. Our data suggest that patients with longitudinal follow-up in both groups showed modest improvements in both steatosis and fibrosis over time. Early identification of liver disease in people with MZ may be useful in preventing advanced disease.

WED-164

Interim safety results of the ongoing international phase I/II GATEWAY gene therapy trial with VTX-801 conducted in adult patients with Wilson disease

Thomas Damgaard Sandahl[1], William M. Lee[2], Aftab Ala[3], Regino P. Gonzalez-Peralta[4], Valentina Medici[5], Fred Askari[6], Sean Rudnick[7], Ulrich Lauer[8], Hartmut Schmidt[9], Sonia Valero[10], Gloria Gonzalez[10], Jean Philippe Combal[10], Lorenzo D'Antiga[11], Bernard Benichou[10], Michael Schilsky[12]. Email: bbenichou@vivet-therapeutics.com

Background and aims: Wilson Disease (WD) is a rare, inherited, debilitating, life-threatening disorder of Cu homeostasis due to pathogenic variants in the ATP7B copper-transporter. Impaired ATP7B function leads to decreased biliary Cu excretion, tissue Cu accumulation, and reduced circulating ceruloplasmin (Cp) levels. Limitations of current management include late diagnosis, constraining life-long treatment with chelators and/or zinc, side effects, and poor adherence affecting long-term outcomes, including survival. VTX-801 is a recombinant adeno-associated viral vector (rAAV) carrying a shortened *ATP7B* gene under the control of a liver-specific promoter. Previous studies with a single VTX-801 injection in 6-week-old WD mice demonstrated the restoration of biliary excretion of iv-injected ^{64}Cu, the restoration of Cu homeostasis and Cp levels the preservation of liver integrity and function, and 100% long-term animal survival.
Method: GATEWAY is an international phase I/II, open-label, 5-year follow-up, single dose-escalation study of VTX-801 in adult patients with WD (NCT04537377). This first-in-human clinical study is assessing the safety, pharmacodynamics and efficacy of VTX-801; standard of care treatment may be withdrawn in VTX-801 responders at 3 months post-infusion based upon ^{64}Cu assessments.
Results: VTX-801 Cohort 1 (low dose) dosing has been completed (N = 2 patients), and no SAE has been reported at time of abstract submission. Both patients experienced mild, transient ALT increase (maximum 95 and 97 IU) following VTX-801 infusion without affecting liver function. One patient experienced a non-serious infusion-associated reaction (chills and fever, rigors, right arm tingling, headache) successfully managed with symptomatic treatment, as well as a self-resolving, transient worsening of low lymphocyte counts; he also experienced a delayed, mild ALT elevation (maximum 104 IU) managed with a course of oral steroid treatment, like what has been reported with other systemic AAV treatments. Collection of pharmacodynamic data is ongoing and will be presented.
Conclusion: Treatment of patients of the GATEWAY Cohort 1 (low dose) has been completed. No serious adverse events have been reported. Follow-up of treated patients and enrolment of Cohort 2 (intermediate dose) are underway. The investigational gene therapy product VTX-801 may provide in the future a valuable alternative to existing treatments by addressing unmet medical needs.

WED-165

Long-term clinical outcomes of patients with acute hepatic porphyria who were not attack-free after 6 months of givosiran treatment in a subgroup analysis of the phase 3 ENVISION study

Paolo Ventura[1], Encarna Guillén-Navarro[2,3], Bruce Wang[4], Weiming Du[5], Ana Camejo[5], Manish Thapar[6]. [1]*Internal Medicine Unit, University of Modena and Reggio Emilia, Modena, Italy;* [2]*Medical Genetics Section, Virgen de la Arrixaca University Hospital, IMIB Pascual Parrilla, University of Murcia (UMU), Murcia, Spain;* [3]*CIBERER-ISCIII, Madrid, Spain;* [4]*UCSF Health, San Francisco, United States;* [5]*Alnylam Pharmaceuticals, Cambridge, United States;* [6]*Thomas Jefferson University, Philadelphia, United States*
Email: paoloven@unimore.it

Background and aims: Acute hepatic porphyria (AHP) is a group of rare, chronic, multisystem disorders characterized by acute attacks, chronic symptoms, progressive elements, and long-term complications requiring proactive management. Givosiran is an RNAi therapeutic approved for AHP treatment. In ENVISION (NCT03338816), givosiran treatment led to sustained reductions in annualized attack rate (AAR). Among patients who completed the study through month (M) 36, 58% were attack-free after their first 6M of givosiran treatment for the duration of the trial. In this analysis, we examined treatment outcomes in patients who were not attack-free after their first 6M of givosiran treatment.
Method: Eligible patients had AHP, were aged ≥12 years, and had experienced ≥2 attacks requiring hospitalization, urgent care, or intravenous (IV) hemin at home within 6 M before study enrollment. A 6M placebo-controlled double-blind (DB) period was followed by a 30 M open-label extension (OLE) period in which all patients received givosiran. This post hoc, descriptive analysis included patients who were randomized in the DB period and completed the OLE period. Subgroups were defined based on patient attack frequency after the first 6 M of givosiran treatment (0 attacks, Group A; ≥1 attack, Group B).
Results: 94 patients were randomized, and 79 completed ENVISION; 46 (58%) and 33 (42%) were in Groups A and B, respectively. In Group B, the mean percentage reduction in composite AAR (attacks requiring hospitalization, urgent care, or IV hemin at home) per 6 M interval were 57% after >6–12 M of givosiran treatment and 85% after >30–36 M, relative to historical composite AAR (mean [SD], 12.8 [9.6]). Quality of life improved in both groups: after 6M and 36M of treatment, mean SF-12 version 2 Physical Component Summary scores increased from baseline by 7.3 and 8.3 points (Group A) and 4.1 and 9.1 (Group B); EQ-VAS scores increased by 6.9 and 19.9 points (Group A) and 2.2 and 17.5 points (Group B). After 6 M and 36 M of givosiran treatment, median percentage reductions from baseline in aminolevulinic acid levels were 88% and 93% (Group A) and 85% and 92% (Group B), and median percentage reductions from baseline in porphobilinogen levels were 88% and 97% (Group A) and 86% and 93% (Group B).
Conclusion: Both patient groups had reduced attacks and other treatment-related improvements within the first 6 M of givosiran treatment. Those who were not attack-free after the first 6 M of treatment experienced further attack reductions and quality of life improvements with longer-term givosiran treatment.

WED-166

Efficacy and safety of odevixibat in a subgroup of adult patients with progressive familial intrahepatic cholestasis in the PEDFIC 2 study

Henkjan J. Verkade[1], Kathleen M. Loomes[2], Janis M. Stoll[3], Tao Gu[4], Anthony Loizides[5], Christof Maucksch[6]. [1]*Pediatric Gastroenterology – Hepatology, University of Groningen, Beatrix Children's Hospital, University Medical Center Groningen, Groningen, Netherlands;* [2]*Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, United States;* [3]*Department of Pediatrics, Washington University School of Medicine, St. Louis, Missouri, United States;* [4]*Albireo Pharma, an Ipsen Company, Cambridge, Massachusetts, United States;* [5]*Albireo Pharma, an Ipsen Company, Cambridge, Massachusetts, United States;* [6]*Ipsen Pharma GmbH, Munich, Germany*
Email: h.j.verkade@umcg.nl

Background and aims: Progressive familial intrahepatic cholestasis (PFIC) is a group of rare genetic liver diseases that present with a range of phenotypes. Although PFIC symptoms typically present in infancy, symptom onset may not occur until adulthood. The safety and efficacy of odevixibat, an ileal bile acid transporter inhibitor, were evaluated in patients with PFIC in the phase 3 PEDFIC 1 and PEDFIC 2 studies (NCT03566238; NCT03659916). To investigate treatment effects of odevixibat in adults with PFIC, we examined its efficacy and safety in an adult subgroup from PEDFIC 2.
Method: PEDFIC 2 is an ongoing, 72-week, open-label extension study evaluating odevixibat 120 μg/kg once daily in patients of any age with any type of PFIC. This analysis spans from patients' first dose of odevixibat to a data cut-off of 31 July 2022. Patient-reported pruritus scores (range, 0–4; higher scores indicate worse symptoms), serum bile acid (sBA) levels, hepatic parameters (total bilirubin and alanine aminotransferase [ALT] levels), and treatment-emergent adverse events (TEAEs) were evaluated.
Results: Overall, 5 adult patients with PFIC (PFIC1, n = 3; PFIC2, n = 2) enrolled in PEDFIC 2 (mean [range] age, 23.3 [19.5–26.0] years; 40% female; mean [range] odevixibat exposure, 56.5 [24.0–90.4] weeks). At baseline, all patients had elevated sBAs and moderate-to-severe pruritus. At the data cut-off, 4 patients were ongoing in the study and

1 patient had discontinued the study due to withdrawal of consent. sBA levels ranged from 213–433 µmol/L at baseline and 11–446 µmol/L at last assessment; 4 of the 5 patients had reductions in sBA levels from baseline. Four patients had reductions in pruritus score from baseline to weeks 21–24; reductions in those 4 patients ranged from 0.2–2.5 points. Four patients who had elevated total bilirubin at baseline (range, 26–1004 µmol/L) experienced reductions by last assessment (range, 14–568 µmol/L). Elevated baseline ALT was observed in 4 patients (range, 64–136 U/L); 3 of these patients experienced reductions by last assessment (range, 51–128 U/L). At least 1 TEAE was reported in 4 of the 5 patients (80%); most were mild to moderate in severity. Two patients experienced serious TEAEs: 1 patient reported streptococcal septic arthritis, and 1 patient with a history of pancreatitis reported acute pancreatitis. None of the TEAEs were considered drug related, and no patient discontinued due to TEAEs.

Conclusion: Most of the adult patients with PFIC enrolled in the ongoing PEDFIC 2 study appeared to experience clinical benefits with odevixibat, including reductions in sBAs, pruritus, and/or improvements in hepatic parameters. Most TEAEs with odevixibat in adults with PFIC were mild or moderate in severity, and none were considered to be drug related. These findings suggest that odevixibat treatment in adult patients with PFIC warrants further clinical investigation.

WED-167

Recanalization for Budd-Chiari syndrome and development of a prognostic score: a multicentre study of 834 cases from China

Qiuhe Wang[1], Bohan Luo[2], Dongdong Xia[3], Chunqing Zhang[4], Ke Xu[5], Kewei Zhang[6], Mingsheng Li[7], Qingrong Fan[8], Wei Bai[2], Guohong Han[2]. *[1]National Clinical Research Centre for Digestive Disease and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Xi'an, China, Xi'an, China; [2]Department of Liver Diseases and Interventional Radiology, Digestive Diseases Hospital, Xi'an International Medical Center Hospital, Northwest University, Xi'an, China, Xi'an, China; [3]National Clinical Research Centre for Digestive Disease and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Xi'an, China, Xi'an, China; [4]Shandong Provincial Hospital affiliated to Shandong University, Jinan, China; [5]Department of Radiology, First Affiliated Hospital of China Medical University, Shenyang 110001, China, Shenyang, China; [6]Henan Provincial People's Hospital, Zhengzhou, China; [7]Department of Vascular Surgery, The First Affiliated Hospital of Zhengzhou University, Zhengzhou 450052, China, Zhengzhou, China; [8]Department of Interventional Radiology, Heze Municipal Hospital, Heze 274000, China, Heze, China*
Email: hangh@fmmu.edu.cn

Background and aims: Large cohort studies on recanalization for Budd-Chiari syndrome (BCS) are lacking. We conducted this multicentre retrospective study to depict characteristics and treatment allocation of Chinese BCS patients; to intensively explore the outcome of recanalization; and to develop a recanalization-specific prognostic score.

Method: A total of 834 BCS patients undergoing recanalization from January 2010 to May 2019 were included from 6 Chinese centres. Cox regression was used to develop the prognostic score.

Results: Recanalization was performed in 83.1% of all screened patients, while inferior vena cava (IVC) obstruction is seen in 87.1% of recanalized patients. Median follow-up was 58.0 (35.2–84.9) months, and 5-year orthotopic liver transplantation (OLT)-free survival was 91.1% (89.0–93.3%). Compared to angioplasty alone, initial stenting significantly reduced 5-year restenosis (11.2% [7.0–15.3%] vs. 24.1% [20.1–27.8%], HR 0.50 [0.34–0.73], log-rank $p < 0.001$) and symptom recurrence (13.7% [9.0–18.2%] vs. 20.5% [16.7–24.1%], HR 0.62 [0.43–0.91], log-rank $p = 0.014$), but did not improve 5-year OLT-free survival (90.2% [86.4–94.1%] vs. 91.6% [89.1–94.3%], HR 1.11 [0.70–1.78], log-rank $p = 0.647$). The results remained consistent after propensity score matching and across subgroups. The BCS-recanalization score for outcome prediction and risk stratification was developed and internally validated, and its performance was superior to existing models.

Conclusion: Being representative of Chinese BCS patients, the current cohort reported the universality of IVC obstruction and the predominance of recanalization. The substantial benefits of stenting are robust. BCS-recanalization score could be used for outcome prediction and risk stratification. Future validations are needed.

WED-170

TRISTAN-Retrospective real world data in management of Wilson disease therapies in Germany

Isabelle Mohr[1], Christian Hartmann[2], Johannes Wiegand[3], Thomas Lang[4], Peter Buggisch[5], Michael Praktiknjo[6], Karl Heinz Weiss[7], Frank Tacke[8], Verena Aliane[9], Annette Athari[9], Carlot Kruse[9]. *[1]Universitätsklinikum Heidelberg, Zentrum für Innere Medizin, Medizinische Klinik IV für Gastroenterologie und Hepatologie, Heidelberg, Germany; [2]Medizinische Fakultät und Universitätsklinikum Düsseldorf, Heinrich-Heine-Universität Düsseldorf, Klinik für Neurologie, Düsseldorf, Germany; [3]Universitätsklinikum Leipzig, Klinik und Poliklinik für Onkologie, Gastroenterologie, Hepatologie und Pneumologie, Leipzig, Germany; [4]Klinikum Starnberg, Klinik für Kinder-, und Jugendmedizin, Starnberg, Germany; [5]MVZ Ifi-Institut Hamburg, Hamburg, Germany, [6]Universitätsklinikum Münster, Medizinische Klinik B (Gastroenterologie, Hepatologie, Endokrinologie, Klinische Infektiologie), Münster, Germany; [7]Krankenhaus Salem, Innere Medizin, Heidelberg, Germany; [8]Charité-Universitätsmedizin Berlin, Department für Hepatologie und Gastroenterologie, Campus Virchow-Klinikum (CVK) und Campus Charité Mitte (CCM), Berlin, Germany; [9]Univar Solutions B.V., Rotterdam, Netherlands*
Email: isabelle.mohr@med.uni-heidelberg.de

Background and aims: Wilson disease (WD) is a rare autosomal recessively inherited disorder of the copper metabolism with pathological copper accumulation mainly in the liver and brain. In Germany D-penicillamine (D-Pen) and zinc salts are approved as first-line treatment. Trientine (Trientine dihydrochloride (TETA-2HCl) and Trientine tetrahydrochloride (TETA-4HCl)) are both available for patients who are intolerant to D-Pen. Data on therapy management of patients, specifically with respect to switch of therapeutic regimen, are sparse. We retrospectively assessed real-world data of patients who were treated with Trientine at least once, regarding the diagnostic and therapeutic management, duration, sequence and dosing of the different therapeutic options in specialized WD centres in Germany.

Method: Anonymized data from WD patients receiving Trientine therapy at least once during their course of treatment was included. Data was collected during 1st of January 2012 and 31st of December 2021 with one or more documented follow-up visits. Data collection included centre structure, WD diagnosis, and therapeutic standards as well as disease and therapy history. This includes all previous and current treatments, switching between therapies, and duration of treatments. Data analysis was exploratorily analyzed (descriptive analysis/graphical display).

Results: In total we included 6 German WD centres and a total of 143 patients (range 5 to 85 years old, 68 males, 75 females), eight of these patients were paediatric (<18 years). The median age at diagnosis was slightly higher for males (18.0 years) compared to females (14.5 years). Most patients showed hepatic symptoms at time of diagnosis ($n = 78$) while neurologic ($n = 39$) and other symptoms ($n = 35$) were less frequent. The neurological patients were diagnosed at a later stage (median 25.0 years) than patients without neurologic symptoms (median 14.5 years). 109 patients revealed with full documentation of therapy switch. From these patients, 50% were switched from D-Pen to Trientine after 7 years of D-Pen therapy with the latest switch observed after 48 years. Dose conversion factors between different chelators or formulations in mg were reported for D-Pen to

TETA-2HCl as 0.75, D-Pen to TETA-4HCl as 0.60, TETA-2HCl to TETA-4HCl as 0.84 and TETA-4HCl to TETA-2HCl as 1.27.
Conclusion: This data helps to understand therapy management of WD patients in German specialized WD centres. Furthermore, this data gives an interesting insight into the real-life dosing of chelators when switching between drugs or formulations and thus might support physicians in future therapy and dosing decisions.

WED-171

Spleen stiffness and VWF-based non-invasive tests reflect severity of prehepatic and presinusoidal portal hypertension

Lorenz Balcar[1], Georg Semmler[1], Michael Schwarz[1], Nina Dominik[1], Benedikt Hofer[1], Katharina Stopfer[1], Anna Schedlbauer[1], Can Hopp[1], David Bauer[1], Lukas Hartl[1], Mathias Jachs[1], Benedikt Simbrunner[1], Albert Friedrich Stättermayer[1], Behrang Mozayani[1], Matthias Pinter[1], Michael Trauner[1], Mattias Mandorfer[1], Thomas Reiberger[1], Bernhard Scheiner[1]. *[1]Medical University of Vienna, Vienna, Austria*
Email: lorenz.balcar@meduniwien.ac.at

Background and aims: Non-cirrhotic portal vein thrombosis (NCPVT) and porto-sinusoidal vascular disorder (PSVD) are frequent causes of prehepatic and/or presinusoidal portal hypertension (PH) in the absence of cirrhosis. However, diagnosis is often delayed as it requires cross-sectional imaging or liver biopsy. Liver stiffness measurement (LSM) is useful to differentiate PSVD from cirrhosis. Spleen stiffness measurement (SSM), von Willebrand factor-antigen (VWF) and its ratio to platelet count (VITRO) may detect prehepatic/presinusoidal PH.
Method: Consecutive patients with established diagnosis of PSVD/NCPVT and controls with compensated cirrhosis with available and valid VCTE-SSM data at the outpatient clinic of the Medical University of Vienna between 08/2022–08/2023 were included. VCTE-LSM, -SSM, PLT, VWF, and VITRO were analysed regarding their potential in differentiating between PSVD, NCPVT, and cirrhosis including subgroups of patients with clinical suspicion of PH.
Results: One-hundred fifty-seven patients were included: 55 with prehepatic/presinusoidal PH (PSVD n = 27, NCPVT n = 25, PSVD+PVT n = 3) and 102 with cirrhosis (mainly alcohol n = 46 and metabolic n = 25 aetiology). Comparing patients with prehepatic/presinusoidal PH vs. cirrhosis, no significant differences regarding Child-Pugh stage (87% vs. 87% stage A), PLT (128 vs. 112 G/L; p = 0.183), or splenomegaly (86% vs. 74%; p = 0.087) were evident. LSM was significantly lower in patients with prehepatic/presinusoidal PH (8.1 vs. 29.7 kPa; p < 0.001); however, SSM was significantly higher (74.3 vs. 50.5 kPa; p < 0.001) leading to an SSM/LSM ratio which differentiated prehepatic/presinusoidal from sinusoidal PH (7.5 vs. 1.63; p < 0.001). VWF (222 ± 74 vs. 260 ± 81; p = 0.005) and VITRO score (1.5 vs. 2.2; p = 0.012) also were lower in prehepatic/presinusoidal PH. Results were similar when only including patients with clinical signs of PH (LSM: 8.3 vs. 30.5 kPa; p < 0.001; SSM: 74.9 vs. 51.3 kPa; p < 0.001; SSM/LSM ratio: 7.56 vs. 1.64; p < 0.001; VWF: 227 ± 73 vs. 259 ± 79%; p = 0.016; VITRO: 1.61 vs. 2.37; p = 0.011). In binomial regression analysis, log-transformed SSM was associated with the presence of specific signs of PH in prehepatic/presinusoidal PH (B: 4.928 ± 2.345; p = 0.036). When sub-stratifying patients with prehepatic/presinusoidal PH, patients with NCPVT had higher SSM (86 vs. 50.2 kPa; p = 0.019) and SSM/LSM ratios (10 vs. 5.14; p = 0.006) compared to PSVD patients. Other NITs were comparable among prehepatic/presinusoidal PH aetiologies.
Conclusion: VCTE-SSM and VWF provide potentially more relevant information on the severity and aetiology of PH (prehepatic/presinusoidal vs. sinusoidal) as compared to LSM and PLT alone, especially when combined with PLT (VITRO) and LSM (LSM/SSM ratio).

WED-172

Transaminase Pattern Over Time Is Not Associated with a More Aggressive Hepatic Evolution: Results from the AEEH Wilson Registry

Marina Berenguer[1], Luis García-Villarreal[2], Antonio Olveira[3], Esther Molina[4], Jose María Moreno Planas[5], Marta Romero-Gutiérrez[6], Jose Pinazo Bandera[7], Helena Masnou[8], Paula Iruzubieta[9], Maria Luisa Gonzalez Dieguez[10], Javier Ampuero[11], José Ramón Fernández[12], Carolina Muñoz Codoceo[13], Ana Arencibia Almeida[14], Sara Lorente[15], Manuel Delgado[16], Diego Burgos Santamaria[17], Víctor Manuel Vargas Blasco[18], Alba Cachero[19], Manuel Hernández Guerra[20], Judith Gómez-Camarero[21], Julia Morillas[22], María Lázaro Ríos[23], Isabel Carmona Soria[24], Gemma Carrión[25], Ariadna Bono[26], Anna Miralpeix[27], Pablo Alonso Castellano[2], Zoe Mariño[27]. *[1]Hospital Universitari i Politècnic La Fe, IISLaFe, Ciberehd, Valencia, Valencia, Spain; [2]Servicio Digestivo, Complejo Hospitalario Universitario Insular Materno Infantil (CHUIMI), Las Palmas de Gran Canaria, Spain; [3]Hospital Universitario La Paz, Madrid, Spain; [4]Hospital Clínico de Santiago, Santiago de Compostela, Spain; [5]Servicio de Aparato Digestivo, Complejo Hospitalario Universitario de Albacete, Facultad de Medicina Universidad de Castilla La Mancha, Albacete, Spain; [6]Hospital Universitario de Toledo, Toledo, Spain; [7]Unidad de Hepatología, Unidad de Gestión Clínica de Aparato Digestivo, Hospital Universitario Virgen de la Victoria, Instituto de Investigación Biomédica de Málaga-Plataforma Bionand, Málaga, Spain; [8]Unitat Hepatologia, Servei Aparell Digestiu, Hospital Universitari Germans Trias i Pujol, Badalona, Spain; [9]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [10]Hospital Universitario Central de Asturias, Oviedo, Spain; [11]Hospital Universitario Virgen del Rocío, Sevilla, Spain; [12]Hospital Universitario de Cruces, Barakaldo, Spain; [13]Hospital Universitario 12 de Octubre, Madrid, Spain; [14]Hospital Universitario Nuestra Señora de La Candelaria, Santa Cruz de Tenerife, Spain; [15]Unidad de Hepatología y Trasplante Hepático, Hospital Clínico Lozano Blesa de Zaragoza, IISS Aragón, Zaragoza, Spain; [16]Hospital Universitario A Coruña, A Coruña, Spain; [17]Hospital Ramón y Cajal, Madrid, Spain; [18]Servicio de Hepatología, Hospital Vall d'Hebron, Universitat Autònoma Barcelona, CIBERehd, Barcelona, Spain; [19]Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Spain; [20]Hospital Universitario de Canarias, Santa Cruz Tenerife, Spain; [21]Hospital Universitario de Burgos, Burgos, Spain; [22]Hospital Universitario Virgen de la Luz, Cuenca, Spain; [23]Hospital Universitario Miguel Servet, Zaragoza, Spain; [24]Hospital Virgen Macarena, Sevilla, Spain; [25]Hospital Universitario Infanta Leonor, Madrid, Spain; [26]Hospital Universitari i Politècnic La Fe, IISLaFe, Ciberehd, Valencia, Spain; [27]Servicio de Hepatología, Hospital Clínic, CIBERehd, IDIBAPS, ERN-RARE Liver, Universitat de Barcelona, Barcelona, Spain*
Email: marina.berenguer@uv.es

Background and aims: The prognosis in Wilson's disease (WD) depends on early diagnosis and adequate compliance with chronic treatment. Copper homeostasis parameters help determine stability in WD, but they do not always correlate with liver enzymes or prognosis. Our aim was to determine the predictive value of transaminases in WD.
Method: Patients with confirmed WD diagnosis (Leipzig Score >3) with hepatic and/or mixed presentation and ≥1 year of follow-up from diagnosis were included in the Registry. Demographic data, phenotype, severity at diagnosis, treatment and compliance, analytical, histological, and elastographic parameters were collected. Patients were stratified by hepatic severity at diagnosis: mild group 1 (without cirrhosis) vs severe group 2. The transaminase pattern during follow-up was analyzed (stable: always normal AST and ALT vs fluctuating: AST and/or ALT >ULN or fluctuating normal/elevated). "Aggressive evolution" was defined as histological or elastographic progression or clinical decompensation, including the need for transplantation or death from liver-related causes.
Results: A total of 228 patients were included (mild group 1, n = 160, 70%; severe group 2, n = 68, 30%). The median follow-up time was 16

years. Group 2 patients were older at diagnosis, had a higher proportion of mixed presentations, a lower proportion of zinc treatment (both at initiation and first year post-treatment), and a lower proportion of patients with elevated ALT at diagnosis ($p < 0.05$). One-third of group 1 patients had an aggressive evolution, mainly due to elastographic worsening, compared to 50% in group 2 ($p = 0.016$), especially due to decompensation and increased hepatic stiffness. A fluctuating or high transaminase pattern was not associated with worse evolution. In group 1, 31% of patients with this pattern progressed compared to 45% of patients with persistently normal transaminases ($p = 0.71$). These percentages were higher in group 2, where 50% of "high/fluctuating transaminases" had a poor prognosis compared to 67% of patients with normal transaminases ($p = 0.47$). Overall, 38% had aggressive progression, which was associated with older age at diagnosis, normal-range transaminases at diagnosis, chelation therapy, and belonging to group 2. A stable transaminase pattern was associated with aggressive progression without reaching statistical significance. Only age at diagnosis remained statistically significant in multivariable analysis.
Conclusion: Aggressive progression in WD patients was not associated with a high/fluctuating transaminase pattern. The type of treatment, its modifications, and adherence may have influenced these results. Early diagnosis, and therefore a high index of suspicion, is essential for a favourable prognosis.

WED-173
Clinical, radiological and demographic characteristics of a female cohort of polycystic liver disease patients from the United Kingdom

Avisnata Das[1], Aleksandra Trojak[1], Benjamin Giles[1], Aqeel Jamil[1], Joanna Dowman[1], Andrew Fowell[1], Richard Aspinall[1]. [1]*Portsmouth Hospitals University NHS Trust, Portsmouth, United Kingdom*
Email: avisnata@gmail.com

Background and aims: Polycystic liver disease (PLD) is a rare genetic disease of the liver that can significantly affect quality of life (QoL) of patients and cause serious complications. PLD-specific questionnaire score (PLD-Q score) (ranging from 0 to 100) can objectively assess severity of PLD-related symptoms. Female sex is known to be a significant factor contributing to severe PLD. We hereby report PLD-related findings in an exclusively female cohort of patients in terms of symptom severity, radiological characteristics, influence of estrogen use and pregnancy, nature of co-morbidities and complications.
Method: We interrogated registry data from a single large secondary care centre regarding 30 women with PLD in terms of PLD-Q scores, age of diagnosis, Qian's grade of liver cysts, presence of dominant cyst (size >8 cm), profile of co-morbidities and complications.
Results: The PLD-Q scores in 30 women ranged from 9 to 83 with a mean of 41.1 and median of 39.5. The age of PLD diagnosis ranged from 14 to 73 years with a mean of 48 years. 4 patients (15%) had Qian's grade 2 disease (11–20 liver cysts), 13 (48%) had Grade 3 liver cysts (>20 cysts), 10 (37%) had Grade 4 liver cysts (>20 cysts with hepatomegaly symptoms). 17 (63%) patients had no dominant cyst while 10 (37%) patients had ≥1 dominant cyst. Out of 20 patients with relevant data, 12 (60%) patients had received estrogen-containing compounds (either as oral contraception or as hormone replacement) for at least a year and this group had a mean PLD-Q score of 41.25 which was higher than the mean PLD-Q score of 36.0 in the group of 8 (40%) patients who had not used estrogen in any form. The difference in mean scores was however not statistically significant. Mean PLD-Q score in the group of 6 patients who had never been pregnant was 38.50 and lower than the mean score (41.77) in the group of 13 patients with one or more pregnancies, though the difference was again not statistically significant. 26 (86.7%) women had at least one co-morbidity while 4 (13.3%) had none. Hypertension (14 patients), Diabetes mellitus (4 patients) and End-stage renal disease (4 patients) were the commonest co-morbidities. 18 women (60%) had at least one PLD-related complication while 12 (40%) had none. Abdominal hernias (7 patients) and cyst infections (3 patients) were the two commonest complications in this cohort. 5 out of the 7 patients needed surgical repair of hernia.
Conclusion: The data demonstrated that the average woman in our cohort was diagnosed with PLD towards end of fifth decade of life and is likely to have more severe symptoms if there is history of estrogen use and previous pregnancy. Hypertension was the commonest co-morbidity and abdominal hernia the commonest complication.

WED-174
Next-generation sequencing for non-cirrhotic portal thrombosis and its impact on portal hypertension

Ilias Kounis[1,2,3,4], Laurence Legros[5], Erica Nicola Lynch[4,6], Clementine Roger[4], Anne Spraul[7], Eleonora De Martin[1,2,3,8], Rodolphe Sobesky[1,2,3,4], Oriana Ciacio[1,2,3,4], Daniel Azoulay[1,2,3,4], Didier Samuel[1,2,3,4], Cyrille Feray[1,2,3,4], Audrey Coilly[1,2,3,4]. Email: ilias.kounis@aphp.fr

Background and aims: Myeloproliferative neoplasms (MPNs) stand out as the leading cause of non-tumoral non-cirrhotic splanchnic vein thrombosis. Next-generation sequencing (NGS) enables the simultaneous assessment of multiple genes implicated in myeloid clonal pathology. This study aims to explore the potential of NGS in elucidating the etiology of portal thrombosis and its role in the development of portal hypertension.
Method: This retrospective monocenter study included all adult patients diagnosed with non-cirrhotic portal thrombosis at our unit from 2020 to 2023. These patients underwent a comprehensive diagnostic evaluation, including NGS, within the hematology department. Diagnosis and follow-up non-cirrhotic portal vein thrombosis adhered to the European Association for the Study of the Liver (EASL) guidelines. Cox regression analysis identified independent risk predictors (HR 95% CI) for the development of portal hypertension.
Results: The study enrolled 46 patients with non-cirrhotic portal thrombosis over a median follow-up period of 3.9 [2.4, 8.7] years. NGS findings were obtained from 36 (78.2%) patients, revealing a total of 19 mutations. Among the cohort, 22 (47.8%) developed portal hypertension. One patient (2.2%) underwent liver transplantation, and four patients (8.7%) underwent mesentericocaval anastomosis. Liver biopsy was performed in 13 (28.3%) patients, with seven meeting the VALDIG criteria for porto-sinusoidal vascular disease. Identified mutations included IDH2, CSF3R, ETV6, JAK2 non V617F, EZH2, TET2, and JAK2 V617F. In the multivariate analysis of portal hypertension development, the combination of JAK2 + non-JAK2 mutation, or the presence of non-JAK mutation showed no statistically significant association with portal hypertension, with hazard ratios of 2.52 (0.99, 6.48) and 1.52 (0.51, 4.52) respectively, and p values of 0.14 and 0.53 respectively.
Conclusion: NGS identified JAK2-exon12 mutations previously undetected by conventional techniques. However, these patients do not seem to have a higher risk of developing portal hypertension.

WED-175

Intrauterine blood transfusion causes dose- and time-dependent signal alterations in the liver and the spleen on fetal magnetic resonance imaging

Michael Schwarz[1], Victor Schmidbauer[2], Nikolaus Nowak[2], Patric Kienast[2], Martin Watzenboeck[2], Marlene Stuempflen[2], Caroline Schwarz[1], Dieter Bettelheim[3], Christina Haberl[3], Julia Binder[3], Herbert Kiss[3], Thomas Reiberger[1], Daniela Prayer[2], Gregor Kasprian[2]. [1]*Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [2]*Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria;* [3]*Department of Obstetrics and Gynecology, Division of Obstetrics and Feto-Maternal Medicine, Medical University of Vienna, Vienna, Austria*
Email: victor.schmidbauer@meduniwien.ac.at

Background and aims: Intrauterine transfusions (IUTs) are life-saving interventions in fetal anemia-a rare but potentially fatal complication in pregnancy. However, with each transfusion iron bypasses iron uptake regulation in the maternal the placenta and accumulates in fetal organs, predominantly in the liver and spleen. Unlike other imaging modalities, magnetic resonance imaging (MRI) is capable of non-invasively assessing fetal liver disease and iron overload. For this study we analyzed the effect of IUTs on prenatal MRI of the fetal liver and spleen.
Method: Eight fetuses who received IUTs and fetal MRI between 2014 and 2023 were retrospectively included in this analysis. Fetuses were gestational age-matched with other fetuses, who also underwent fetal MRI for other indications, but did not receive IUTs. Imaging assessment was performed on T1-/T2-weighted MR data. For all fetuses, volumetry of the liver and spleen as well as signal intensity (SI) measurements in these organs were performed.
Results: Fetuses who received IUTs had significantly larger liver (71.9 vs. 45.1 cm^3 p = 0.003) and spleen (5.5 vs. 2.4 cm^3, p = 0.029) organ volumes compared to age-matched controls. In the IUT cohort, T1-weighted SI for both livers (p = 0.018) and spleens (p = 0.026) was significantly lower. The reduction of T1-weighted SI of the fetal liver showed an inverse correlation with the number of IUTs received (Spearmen's rho = –0.63, p = 0.009). Regarding T2-weighted SI of the liver, we observed a positive correlation with number of days elapsed between transfusion and MRI (rho = 0.86, p = 0.011). Similar, but less pronounced SI changes were found for fetal spleens on both T1- (rho = –0.54, p = 0.029) and T2-weighted (rho 0.57, p = 0.150) imaging.
Conclusion: We observed significant dose-dependent changes in SI of both fetal livers and spleens for T1-weighted imaging that increased with number of transfusions received. For T2-weighted imaging, reduction in hepatic SI following IUT decreased in a time-dependent manner. Furthermore, hepatosplenomegaly was commonly found following IUT. Awareness of these temporary changes following IUTs allows for a better discrimination from other causes of fetal iron overload or splenomegaly with distinct prognosis.

WED-176

Early predictors of successful Kasai portoenterostomy for biliary atresia

Nishant Wadhwa[1], Arjun Maria[2], Sonia Badwal[3], Satish Aggarwal[3], Alpana Prasad[1]. [1]*Sir Ganga Ram Hospital, New Delhi, India;* [2]*Sir Ganga Ram Hospital, Pediatric Surgery, New Delhi, India;* [3]*Sir Ganga Ram Hospital, New Delhi, India*
Email: arjunmaria@hotmail.com

Background and aims: To identify factors associated with successful Kasai Portoenterostomy (KPE).
Method: Retrospective analysis of 49 infants who underwent KPE between January 2018 to October 2023. Successful KPE was defined as total bilirubin <1 mg/dl by 6 months of age. None of the patients received post KPE steroids and none were tested for concomitant CMV.
Results: The median age at KPE was 71 (59–83) days, with 21 (42.9%) less than 65 days. Median follow-up was of 11 (6–36) months with native liver survival in 27 (55.1%).Thirty six (73.5%) were type III biliary atresia and 2 (4%) were associated with other congenital anomalies. Successful KPE was in 22 (44.9%). Age less than 65 days at the time of KPE was significantly associated with successful KPE (42.9% vs 57.1%, OR 5, 95% CI 1.472–16.988, p = 0.009). Weight (p = 0.932), total bilirubin (p = 0.907), direct bilirubin (p = 0.667), AST (p = 0.837), ALT (p = 0.937), Total protein (p = 0.051), albumin (p = 0.201) and INR (p = 0.220) at the time of surgery did not affect outcome. Ishak fibrosis grade (p = 0.267) and inflammation grade (p = 0.743) were not associated with outcome. Post surgery, lower total bilirubin (7.95 mg/dl vs 10.1 mg/dl, MD 0.07 to 4.66, p = 0.043) and direct bilirubin (4.92 mg/dl vs 6.5 mg/dl, MD 0.16 to 3.03, p = 0.03) by post operative day 7 were associated with a successful outcome. Parameters like ascites for more than 7 days (p = 0.071), albumin (p = 0.431), AST (p = 0.091), ALT (p = 0.108) and INR (p = 0.241) at 7 days post KPE did not affect the outcome. Seventeen patients suffered from complications post KPE with sepsis in 17, bowel perforation in 3 and biliary ascites in 2. Presence of complications post KPE did not affect the outcome (p = 0.825). Twenty (40.8%) patients suffered from a median of 1 (1–3) cholangitis episodes. However, cholangitis was not associated with outcome (p = 0.374). On logistic regression analysis age less than 65 days (OR 8.024, 95% CI 1.865 to 34.530, p = 0.005) and lower total bilirubin at day 7 post KPE (OR 0.789, 95% CI 0.642 to 0.970, p = 0.028) were found to be significantly associated with successful KPE increasing the correctness of classification of model from 55.1% to 73.5%.
Conclusion: There is a 8 folds increase in successful outcome if KPE is done at less than 65 days of age. Bilirubin at post operative day 7 is an early predictor of successful KPE.

WED-177

Determination of liver biopsy quality criteria for the diagnosis of porto-sinusoidal vascular disorder (PSVD)

Chloé De Broucker[1,2], Valérie Paradis[2,3], Miguel Albuquerque[2,3], Audrey Payancé[1,2], Aurélie Plessier[1,2], Francois Durand[4], Paul Emile Zafar[2,3], Pierre-Emmanuel Rautou[1,2]. Email: c.debroucker@gmail.com

Background and aims: Baveno VII guidelines defined porto-sinusoidal vascular disorder (PSVD) as clinical or radiological signs of portal hypertension, or histological signs typical for PSVD in the absence of cirrhosis on a liver biopsy. These guidelines arbitrarily defined 20 mm as the minimal size of liver biopsy for the diagnosis of PSVD. This study aimed to establish evidence-based liver biopsy quality criteria to rule out cirrhosis in patients with signs of portal hypertension.
Method: Twenty-four liver explants from patients with cirrhosis or PSVD were selected. Among the twelve patients with cirrhosis, Laennec score was evenly distributed into 4A, 4B and 4C; four patients had hepatocellular carcinoma. Causes of cirrhosis were related to alcohol use disorder (n = 6), metabolic-dysfunction (n = 6), HBV (n = 2) and HCV (n = 2) infections (some had several causes). Among the twelve patients with PSVD, histological lesions included obliterative portal venopathy (n = 11), nodular regenerative hyperplasia (n = 5) and incomplete septal cirrhosis (n = 5) (some had several histological lesions). Slides were stained with picrosirius and Masson's trichrome. 31 200 virtual liver biopsies were generated from these 24 explants, including various lengths (5, 10, 15, 20 and 25 mm) and widths (572 µm corresponding to a transjugular biopsy and 1000 µm corresponding to a percutaneous biopsy). All 31 200

virtual biopsies were classified as "cirrhosis" or "no cirrhosis" by an expert pathologist, who had no information on the clinical data.
Results: Overall sensitivity of percutaneous biopsies for the diagnosis of cirrhosis was 85% (95% confidence interval: 84–85%). Sensitivity was significantly higher with picrosirius [86% (85–87%)] than with Masson's trichrome staining [83% (82–84%)] ($p < 0.001$). Sensitivity increased with the length of percutaneous biopsies, reaching a plateau at 15 mm, at which point sensitivity was 89% (88–91%) for picrosirius and 86% (84–88%) for Masson's trichrome.
When focusing on biopsies longer than 15 mm, sensitivity was significantly higher for percutaneous biopsies [89% (88–90%)] than for transjugular biopsies [84% (84–86%)] ($p < 0.001$). A plateau was also observed from 15 mm for transjugular biopsies.
Specificity, corresponding to the number of correctly diagnosed PSVD, was 89% (88–89%) for percutaneous biopsies, and 87% (86–89%) for transjugular biopsies. Out of the four explants for which specificity was below 90%, irrespective of biopsy size, three had incomplete septal cirrhosis.
Conclusion: For the diagnosis of PSVD, the minimum liver biopsy length to exclude cirrhosis is 15 mm. Picrosirius staining should be preferred. Sensitivity of transjugular is slightly lower than percutaneous, but the transjugular route offers other useful information, including hepatic venous pressure gradient and the presence or not of hepatic vein-to-vein collaterals.

WED-178
Enhanced liver phenotyping in unexplained chronic liver disease: the LIPHE algorithm
Anna Sessa[1,2], Edouard Reizine[2,3], Giuliana Amaddeo[2,4], Mélanie Simoes[5], Jeremy Augustin[5], Stefano Caruso[6], Julien Calderaro[7], Alain Luciani[2,5], Vincent Leroy[2,7]. [1]*Paris Est University UPEC, Henri Mondor Hospital, Créteil, France;* [2]*Inserm U955, Créteil, France;* [3]*Henri Mondor University Hospital, Créteil, France;* [4]*Henri Mondor Universary Hospital, Créteil, France;* [5]*Henri Mondor Hospital, Créteil, France;* [6]*Inserm U 955, UPEC Paris Est University, Créteil, France;* [7]*Henri Mondor Hospital, UPEC Paris Est University, Créteil, France*
Email: asessa1990@gmail.com

Background and aims: Chronic elevation of liver tests is associated with long-term hepatic events and an increased risk of mortality. In nearly 10% of cases, these abnormalities remain unexplained despite a specialized etiological assessment. Our aim was to evaluate the diagnostic performance of dedicated liver phenotyping (LIPHE) using a combination of innovative technics.
Method: This is an ongoing real-life monocentric prospective cohort study. Consecutive patients referred to our centre by gastroenterologists for unexplained chronic elevation of liver tests after a comprehensive work-up including viral serologies, iron and copper evaluation, auto-immunity, ultrasound, CT and/or MRI were included. The LIPHE algorithm consisted of step 1: standardized questionnaire, laboratory tests (auto-antibodies according to reference methods, A1AT, REC, biliary acids, Nt-ProBNP, HOMA) and multi-parametric magnetic resonance imaging (LIPHE-MRI) including fat and iron assessment, T1 dixon, T2 TSE FS, T2 HASTE, diffusion, vMRE, T1 mapping, T1 VIBE with dynamic vascular phases and hepato-biliary phase and 3D cholangio-MRI; step 2: liver biopsy; step 3 genetic or shotgun metagenomic analysis.
Results: The 1-year interim analysis included 72 patients (median age: 53 years, male: 39%). Liver enzymatic profiles were cytolysis in 20 (28%) patients (median ALT: 65 IU/l), cholestasis in 34 patients (median ALP: 162 IU/l), and mixed pattern or others in 18 patients. Cirrhosis was present in 12 patients (17%). Step 1 was performed in all patients, step 2 in 44 and step 3 in 12 patients. Definite diagnosis was made in 52 patients (72%), and probable diagnosis in 13 patients (18%). Definite diagnosis were distributed as follow: MAFLD (n = 5) not fulfilling classical criteria, porto-sinusoidal vascular disease (n = 5), primary biliary cholangitis (n = 5), primary sclerosing cholangitis (n = 5), congestive cardiac liver (n = 4), drug induced liver injury (n = 4), auto-immune hepatitis (n = 4), hyperthyroidism (n = 3), ABCB4 related genetic cholestasis (n = 3), alpha1 antitrypsin deficiency (n = 2), biliary hamartomatosis (n = 2), benign cyst/tumors (n = 2), miscellaneous (n = 8). The main diagnostic contributors were liver biopsy in 23 cases (32%), LIPHE MRI in 21 cases (29%), laboratory tests in 10 cases (14%) and anamnesis in 5 cases (7%). The diagnosis remained not identified in 7 (10%) patients.
Conclusion: The LIPHE algorithm may bring etiologic diagnosis in the majority of patients with non-elucidated liver disease who present with a large spectrum of rare and complex liver diseases. A combination of standardized questionnaire, laboratory tests, and multi-parametric MRI may avoid liver biopsy in 40% of cases and appears to be a promising first-line approach.

WED-179-YI
Liver fibrosis status and circulating polymers in alpha-1 antitrypsin deficiency patients with a Z/rare genotype
Naomi Kappe[1], Jan Stolk[1], Bart van Hoek[1]. [1]*Leiden University Medical Center, Leiden, Netherlands*
Email: b.van_hoek@lumc.nl

Background and aims: Alpha-1 antitrypsin deficiency (AATD) is a hereditary condition caused by mutations in SERPINA1. The Z mutant (Glu342Lys) is a common AATD-deficient allele. Retention of polymerized Z alpha-1 antitrypsin (Z-AAT) in the liver causes hepatocyte damage. Z-AAT polymers in circulation are positively associated with liver injury. Patients with a partial deficiency (MZ genotype, M codes for the wild-type allele) have a small absolute increased risk of developing liver disease compared to healthy controls. It is unknown if patients with a Z allele and a rare deficiency allele (not known to cause AAT polymers) (Z/rare genotype) are at greater risk for the development of liver fibrosis. In this study, we investigated liver fibrosis status and Z-AAT polymer levels in Z/rare individuals. A cohort of MZ individuals, matched according to age and sex, served as the control group.
Method: In this cohort study, clinical data and serum and plasma samples were collected from patients aged ≥18 years with a confirmed Z/rare or MZ AAT genotype who visited the Gastroenterology and Hepatology outpatient clinic at the Leiden University Medical Center (LUMC) in the Netherlands. The samples were retrieved from the LUMC CuraRata Biobank. The groups were matched for age and sex. Liver fibrosis status was assessed by transient elastography, Aspartate aminotransferase to Platelet Ratio Index, fibrosis-4, and the Enhanced Liver Fibrosis test.
Results: 15 individuals with the Z/rare genotype and 15 individuals with a MZ genotype were included. BMI, Diabetes Mellitus type 2, and daily alcohol consumption did not differ between the two groups. Liver fibrosis status did not vary significantly between Z/rare and MZ individuals. All patients had no or very mild fibrosis. The median Z-AAT polymer level in Z/rare individuals was 519.5 µg/ml [432.5–1370.8] compared to 727.7 µg/ml [538.7–1313.8] in MZ individuals ($p = 0.23$).
Conclusion: This study showed no or very mild liver fibrosis in AATD patients with a Z/rare genotype. There was no significant difference between the liver fibrosis status and the presence of Z-AAT polymers between the Z/rare and MZ groups. Although not significantly different, the median polymer level of the MZ cohort was numerically higher than that of the Z/rare cohort, which might suggest an even lower risk of liver disease in Z/rare individuals than in MZ individuals.

WED-180
Clinical profile and outcomes of Wilson's disease in the young and adult population
Anand Kulkarni[1], Mithun Sharma[1], Rajesh Gupta[1], Manasa Alla[1], Sowmya Iyengar[1], Shantan Venishetty[1], Nagaraja Padaki[1], Nageshwar Reddy[1]. [1]*AIG Hospitals, Hyderabad, India*
Email: anandvk90@gmail.com

Background and aims: Wilson's disease (WD) can present with hepatic, neurological, or psychiatric symptoms. There are few studies reporting clinical patterns of WD from Asia; however, none in the recent decade have eluded this aspect in a large cohort of patients, which we aimed to report.
Method: Retrospective data of WD patients from our tertiary care liver hospital from June 2020 to January 2024 were included. The primary objective was to describe the clinical and laboratory characteristics, course, and outcomes of patients with WD and secondary was to compare the same among young (<19 years) and adult (≥19 years) population. Data was analyzed using SPSS ver.29 and most variables are expressed as median (minimum-maximum).
Results: 136 proven WD (females-35.3%) with a median age of 19 years (2–57) with a median Leipzig score of 4; Nazer score and New Wilson Index score of 5 were included. The median ceruloplasmin level, 24-hour urinary copper levels, and liver copper levels (n = 49) were 14.5 (2–39) mg/dl, 135 (13–3467) μg//day, and 98 (55–252) μg/g, respectively. None of the patients had liver copper levels less than 50 μg/g, while only one had liver copper levels>250 μg/g. The most common type of presentation in the cohort was decompensated cirrhosis (25%), followed by acute-on-chronic liver failure (ACLF) in 18.4% and acute liver failure (ALF) in 15.4%. Neurological symptoms (tremors-5; dysarthria-2; ataxia-2; chorea-1; cramps-1 in varying combinations) were present in 6.6% of patients, Kayser-Fleischer (KF) ring in 44.1% of patients, and hemolytic jaundice in 22.8%. After a median duration of 20.5 months follow-up, 108 patients (79.4%) were alive, and 18 (13.2%) had undergone living donor liver transplantation (LDLT). Ten patients (7.4%) had died within 45 days of diagnosis, of which eight were diagnosed with ALF, and two were diagnosed with ACLF. Of the 18 patients (ACLF-10, DCLD-5, ALF-3) who underwent LDLT, two died of sepsis and graft failure, and rest were alive. When we assessed according to age, most patients in younger population presented as ACLF/ALF (48.5%; 32/66), while the most common type of presentation in adults (≥19 years) was decompensated cirrhosis (31.4%, 22/70). Mean ceruloplasmin levels and liver copper levels were similar among the two groups. However, 24 h urine copper levels were higher in the younger population (199.4 [14–3467] mg/d) than the adult population (129 [13–1406] μg//d; P = 0.01). Neurological symptoms were more common in adults (11.4% vs. 1.5%; P = 0.03), while KF ring were more common in young populations (53% vs. 35.7%; P = 0.03). Transplant-free survival was 72.7% in the young population compared to 85.7% in adults (p = 0.06).
Conclusion: WD presents as a severe disease in the younger population, and a trend towards poorer transplant-free survival was noted in the younger population.

WED-181
Use of metallothionein 1 as an ancillary tool for the diagnosis of Wilson disease
Clàudia García-Solà[1], Gabriela Caballero[2], Anna Soria[1], Octavi Bassegoda[1], Anna Pocurull[1], Xavier Forns[1], Isabel Graupera[1], Alba Díaz[2], Zoe Mariño[1]. [1]*Liver Unit, Hospital Clínic of Barcelona, IDIBAPS, CIBERehd, ERN-RARE Liver, Universitat de Barcelona, Barcelona, Spain;* [2]*Pathology Department, Centre de Diagnòstic Biomèdic, Hospital Clínic of Barcelona, IDIBAPS, CIBERehd, Universitat de Barcelona, Barcelona, Spain*
Email: zmarino@clinic.cat

Background and aims: Histological findings of Wilson disease (WD) are nonspecific and can be confused with more prevalent liver diseases, such as metabolic-dysfunction associated steatotic liver disease (MASLD). Classical histochemical stains (orcein, rhodanine) have low sensitivity, whereas intrahepatic copper quantification is only performed with high clinical suspicion, given its low availability and high cost. In 2021, *Rowan DJ et al* suggested the use of a novel immunohistochemical staining for metallothionein-1 (MT-1) (main intrahepatic copper chelator) as a good strategy for differentiating WD from other liver diseases and this was also recently shown by *Wiethoff et al* (2023). Our objective was to evaluate the usefulness of this staining between WD patients and a lean-MASLD group, where differential diagnosis could be more difficult.
Method: Blinded histological evaluation by 2 anatomical pathologists using Ishak/CRN classification of liver biopsies from 20 patients with WD (WD group) and 29 MASLD patients with a BMI <31 kg/m^2 (LEAN group). MT-1 was scored according to *Rowan et al.* Clinical and analytical variables were collected from both groups. Variables were expressed as medians/IQR_{25-75} or percentages. For statistical analysis, Chi^2/U-Mann-Whitney was used, and the kappa index was used for inter-observer agreement.
Results: WD patients were significantly younger than those in the LEAN group (37.5 vs 70 years, p < 0.01) whereas LEAN patients were more frequently diabetic and dyslipemic (p < 0.05). AST and GGT (but not ALT) at the time of liver biopsy were significantly higher in the LEAN group (56 vs 35 IU/L; 104 vs 46 IU/L in WD respectively, p < 0.05). Liver biopsies were mainly performed during follow-up in WD patients (median time after diagnosis: 13 years) due to liver test impairment or suspected comorbidities (50%). Conversely, >70% of liver biopsies in the LEAN group were performed at diagnosis, as part of the etiological study or due to suspected advanced disease. No significant differences were observed in the stage of portal/lobular inflammation, fibrosis, or steatosis (grade, type or distribution) between both groups. In WD biopsies, more glycogenated nuclei were observed (50 vs 20.7%, p = 0.033) whereas steatohepatitis was only seen in LEAN patients (41 vs 0%, p < 0.01). Up to 70% of WD biopsies were positive for MT-1 vs 0% in LEAN biopsies (p < 0.01), with an H score of 205 (IQR_{25-75} 137.5–242.5) vs 0 in LEAN (p < 0.01). Interobserver agreement was excellent (kappa = 0.896). MT-1 scoring was not different among WD patients according to time since diagnosis, treatment received (chelator vs zinc), ceruloplasmin levels or intrahepatic copper (available only in 8).
Conclusion: MT-1 staining could be a good strategy for histological differentiation between WD and MASLD and could be easily incorporated in the diagnostic work-up of patients with liver disease.

WED-182
The enhanced liver fibrosis test in alpha-1 antitrypsin deficiency patients homozygous for the Z-allele
Naomi Kappe[1], Jan Stolk[1], Bart van Hoek[1]. [1]*Leiden University Medical Center, Leiden, Netherlands*
Email: b.van_hoek@lumc.nl

Background and aims: Alpha-1 antitrypsin deficiency (AATD) is a hereditary condition caused by mutations in the SERPINA1 gene. Alpha-1 antitrypsin (AAT) is primarily synthesized in the liver. A common AATD deficiency allele is the Z mutant (Glu342Lys). Homozygous carriage of the Z mutant (ZZ genotype) predisposes to liver fibrosis due to the accumulation of Z-AAT in the liver. Common indirect serum fibrosis markers, such as fibrosis-4 (FIB-4) and aspartate aminotransferase Platelet Ratio Index (APRI), have been analyzed in AATD. The sensitivity and specificity of these markers are too low to be used independently for the assessment of liver fibrosis. The enhanced liver fibrosis test (ELF) is a direct serum biomarker of liver fibrosis with increasing popularity and has not yet been validated in AATD. With transient elastography (TE, FibroScan) we assessed the performance of ELF in the evaluation of fibrosis status in homozygous Z patients. We also assessed APRI and FIB-4 to evaluate whether the ELF test exceeded the performance of these fibrosis serum markers in our cohort.
Method: In this cohort study, clinical data and serum samples were collected from patients with a ZZ genotype who visited the Gastroenterology and Hepatology outpatient clinic at the Leiden University Medical Center (LUMC) in the Netherlands. Samples were retrieved from the LUMC CuraRata biobank. Included patients had a valid TE assessment, and were aged ≥18 years. Patients were excluded if they had any extrahepatic fibrotic disorder or any other liver disease (except for metabolic dysfunction-associated steatotic liver disease)

and if they reported pathological alcohol consumption. The Area under the ROC (AUROC) was calculated to assess the accuracy of the serum fibrosis markers in detecting either significant or advanced fibrosis (≥7.1 kPa and ≥10.0 kPa, respectively as assessed by TE).
Results: 50 patients were included in the study. The cohort was fairly healthy with a mean BMI just above the upper limit of normal, low daily alcohol consumption, and only two patients had diabetes mellitus type 2. APRI had the highest AUROC for the detection of both fibrosis stages, with an AUROC of 0.854 (95% confidence interval (CI) 0.749–0.958) for significant fibrosis and 0.922 (95% CI 0.847–0.998) for advanced fibrosis. For significant fibrosis FIB-4 had the second highest AUROC of 0.790 (95% CI 0.643–0.938), for advanced fibrosis the ELF test had the second highest AUROC of 0.859 (95% CI 0.719–0.998). For significant fibrosis the ELF test had an AUROC of 0.768 (0.629–0.908).
Conclusion: In our cohort, the ELF test did not perform better than the cheaper and more accessible APRI or FIB-4 for the assessment of significant and advanced fibrosis status in homozygous Z AATD patients. Further validation of the ELF test and other fibrosis- and fibrogenesis-markers, preferably with liver biopsy results and longitudinal follow-up, is required.

WED-183-YI
Neurodegeneration in aceruloplasminemia and carriers of heterozygous ceruloplasmin variants: brain atrophy or iron toxicity?

Marlene Panzer[1,2], Christoph Birkl[3,4], Elisabetta Indelicato[5], Bernhard Glodny[4], Benedikt Schaefer[1], Christoph Scherfler[5], Elke Gizewski[3,4], Herbert Tilg[1], Heinz Zoller[1,2]. [1]*Department of Medicine I, Medical University of Innsbruck, Innsbruck, Austria;* [2]*Christian Doppler Laboratory for Iron and Phosphate Biology, Medical University of Innsbruck, Innsbruck, Austria;* [3]*Neuroimaging Research Core Facility, Medical University of Innsbruck, Innsbruck, Austria;* [4]*Department of Neuroradiology, Medical University of Innsbruck, Innsbruck, Austria;* [5]*Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria*
Email: marlene.panzer@i-med.ac.at

Background and aims: The autosomal recessive disease Aceruloplasminemia is caused by mutations in ceruloplasmin and characterized by progressive iron accumulation in the brain, liver and pancreas. Early signs include low ceruloplasmin, hyperferritinemia and low transferrin saturation. First neurological manifestations are typically reported between 40 and 60 years of age. The aim of this study is to describe neurodegeneration in aceruloplasminemia and assess the effect of heterozygous ceruloplasmin variants on brain iron.
Method: Clinical and radiological features of neurodegeneration were assessed in four homozygous or compound heterozygous and three single heterozygous patients. Patient records were reviewed to collect demographic, biochemical and clinical parameters. Neurological impairment was quantified by the Unified Wilson Disease Rating Scale. Magnetic Resonance Imaging (MRI) was performed on a 3 Tesla scanner including R2* relaxometry for iron quantification. R2*-values were analyzed in deep gray matter structures segmented using FSL first. Brain Volumetric measurements were performed using MRI parameters and were compared to sex-and age-matched healthy controls.
Results: Plasma ceruloplasmin concentrations were below the lower limit of normal in all patients included. Three homozygous patients had elevated ferritin and reduced transferrin saturation. Homozygous patients presented with a spectrum of symptoms ranging from mild tremor to severe neurologic impairment. All heterozygous patients were asymptomatic. Significantly increased R2*-values indicating iron overload in thalamus, caudate nuclei and putamen were measured in homozygous patients compared to heterozygous carriers and healthy controls. Increased R2* was also observed in the white matter of homozygous patients. Total intracranial volume differed numerically between homozygous and heterozygous patients and healthy controls.
Conclusion: This study indicates that iron not exclusively accumulates in basal ganglia, dentate nuclei and thalamus as previously described but might also affect white matter. Brain iron accumulation does not prevent automated volume segmentation of subcortical brain regions. Quantitative MRI is feasible in patients with aceruloplasminemia and allows assessment of neurodegeneration.

WED-184
Evaluation of routine outpatient assessment methods for post-Fontan procedure liver complications

Yohei Koizumi[1,2], Hirooka Masashi[1], Yoshiko Nakamura[1], Yano Ryo[1], Makoto Morita[1], Yuki Okazaki[1], Yusuke Imai[1], Takao Watanabe[1], Osamu Yoshida[1], Yoshio Tokumoto[1], Masanori Abe[1], Yoichi Hiasa[3]. [1]*Department of Gastroenterology and Metabology, Ehime University Graduate School of Medicine, Toon City, Japan;* [2]*Saiseikai Matsuyama Hospital, Department of Internal Medicine, Matsuyama, Ehime, Japan;* [3]*Department of Gastroenterology and Metabology, Ehime University Graduate School of Medicine, Toon, Ehime, Japan*
Email: shachiyo2@yahoo.co.jp

Background and aims: Non-invasive ultrasound technique for liver fibrosis and cardiac function assessment in Fontan-associated liver disease (FALD) is needed to evaluate real-time disease progression. However, it is still unclear how to optimally monitor FALD in outpatient settings. We conducted a prospective follow-up study to examine adult cases who underwent the Fontan procedure.
Method: A total of 69 cases out of 105 Fontan postoperative cases who underwent imaging diagnosis at our department from January 2012 to December 2022 were included in this study. Blood test results, liver stiffness measurements, and cardiac ultrasound examinations were performed at the time of follow-up initiation and at one and five years later. Clinical end points (venous aneurysms, hepatocellular carcinoma, Fontan circulatory failure, and death) were set and evaluated.
Results: Among the 69 FALD cases, two cases had hepatocellular carcinoma. There was no significant difference in liver stiffness values at the time of observation initiation and five years later ($p = 0.214$). Univariate analysis revealed that patients with clinical end points were associated with low platelet counts ($p = 0.011$), the presence of liver nodules ($p = 0.052$), ventricular dysfunction ($p = 0.013$), and the number of years after the Fontan procedure. Multivariate analysis showed a correlation between the number of years after the Fontan procedure and liver stiffness values ($p = 0.007$). However, these associations were not significant when adjusted for Fontan type, age at the beginning of observation, cardiac function, and MELD-XI score.
Conclusion: The ideal monitoring approach for patients with FALD remains uncertain. Liver stiffness measurement is a useful non-invasive secondary indicator for cirrhosis, and it may help capture patients who require more frequent continuous monitoring for hepatocellular carcinoma. However, our study did not result in a clear benefit to periodically conducting liver stiffness measurements as there was no significant difference over time in adult cases.

WED-185
Frequency of ATP8B1, ABCB11 and ABCB4 gene mutations in adult patients with idiopathic chronic cholestasis

Paulo Bittencourt[1], Liana Codes[2], Antônio Ricardo Cardia Ferraz de Andrade[3], Raimundo Gama[4], Livia Falcao[4], Raymundo Parana[5], Maria Lucia Ferraz[4], Gilda Porta[6]. D'Or de Pesquisa e Ensino, University Hospital of Salvador, Bahia, Brazil, Salvador, Brazil; [6]Hospital Sirio Libanes, Sao Paulo, Brazil
Email: plbbr@uol.com.br

Background and aims: Several bile transporter gene mutations have been associated with progressive familiar intrahepatic cholestasis (PFIC) types 1 to 6 in children as well as to intrahepatic cholestasis of pregnancy (ICP) and low phospholipid associated cholelithiasis (LPAC) in adults. The purpose of the present study was to assess frequency of those mutations in adults with idiopathic cholestatic chronic liver disease (CLD).
Method: All patients with cholestatic CLD of unknown cause followed in three different reference centers in Brazil were genotyped for ABCB11, ABCB4, ABCC2, ATP8B1, CFTR, JAG1, KIF12, LSR, MYO5B, NR1H4, PPM1F, serpin1, TJP2, USP53, VIPAS39, VPS33B, PEX26 and WDR83OS gene mutations using Illumina NovaSeq 6000 Sequencing. Primary biliary cirrhosis, primary sclerosing cholangitis as well as other causes for cholestatic CLD were excluded in all patients.
Results: 35 patients (69% males, median age at disease onset 28 [14–70] years) were included in the study. Eighteen (51%) had cirrhosis and 7 (20%) had been submitted to liver transplantation. Only one had hepatocellular carcinoma. Twenty-eight (80%) patients were either heterozygous (n = 13), compound heterozygous (n = 11) or homozygous (n = 4) for ABCB4 (n = 24), serpin 1 (n = 3), ABCB11 (n = 1), ABCC2 (n = 1) and PEX26 (n = 1) gene mutations. All but 15 patients exhibited known pathogenic (49%) or likely pathogenic (16%) mutations.
Conclusion: More than half of the Brazilian patients with cholestatic CLD of unknown cause were shown to exhibit pathogenic or likely pathogenic mutations in bile transporter genes, particularly ABCB4. Genotyping may identify most of those subjects as late-onset PFIC III patients.

WED-186

Exchangeable copper quantification fells below normal range in a high proportion of patients with Wilson disease during follow-up

Zoe Mariño[1], Clàudia García-Solà[1], Ariadna Bono[2], Sonia García-García[2], Anna Miralpeix[1], Rocío Andreu[3], Cristina Aguado[3], Xavier Forns[1], Mercè Torra[4], Marina Berenguer[2].
[1]Liver Unit, Hospital Clínic Barcelona, IDIBAPS, CIBERehd, ERN-RARE Liver, Universitat de Barcelona, Barcelona, Spain; [2]La Fe University Hospital, Hepatology and Liver Transplantation Unit, IIS La Fe, Hospital Universitario y Politécnico La Fe, Valencia, Spain; [3]Biochemistry Department La Fe, Hospital UP La Fe, Valencia, Spain; [4]Biochemistry and Molecular Genetics Department, Hospital Clínic Barcelona, IDIBAPS, Universitat de Barcelona, Barcelona, Spain
Email: zmarino@clinic.cat

Background and aims: Defining copper biomarkers for adequate follow-up in Wilson disease (WD) is still a matter for discussion. International recommendations are based on the combination of urinary copper excretion (UCE) and non-specific liver parameters (ALAT) depending on therapy and time from diagnosis. Exchangeable copper (CuEX) arised as a novel biomarker reflecting the free copper pool and was expected to be a good tool assessing copper homeostasis. Although its ratio (REC) was shown to be very useful for diagnosis (when >18%), no recommendation has been published to date for its use during follow-up. Our aim was to define CuEX utility and behavior on clinical follow-up.
Method: Real-life retrospective assessment of serum CuEX quantification performed during a 2-year period among WD patients followed in 2 large tertiary centers in Spain. Patients were considered stable (group 1, G1) if diagnosis had been achieved >1 year before, were compliant to medication and were on stable drug doses; otherwise, they were classified as non-stable and included in group 2 (G2). Serum samples were obtained as required by clinical practice and CuEX/REC were measured by inductively plasma coupled to mass spectrometry (ICP-MS). Reference intervals were set between 4.1–7.1 µg/dL, as published by El Balkhi et al, 2009. UCE was measured by atomic spectroscopy and was considered "adequate" when copper quantification was 200–500 µg/24 h under chelation therapy or <100 µg/24 h when zinc salts were used. Statistical analysis was performed with SPSS-V27.
Results: Ninety-one WD patients were included (median age 38; median years from diagnosis: 19.3): 39 patients (43%) in G1 and 52 (57%) in G2, with no differences in terms of sex, age, therapy or time elapsed from diagnosis. Serum CuEX was quantified in 199 samples (median: 2 times/patient; 35.2% of samples from G1 vs 64.8% in G2). Median CuEX concentrations were not significantly different between G1/G2, with a delta-change <0.5 µg/dL between timepoints. Only 70 (35.2%) samples were within the pre-defined "normal range," with up to 115 (57.8%) being below and 14 (7%) above. Distribution of CuEX was not different between groups, regardless of clinical stability or not, but all samples above 7.1 µg/dL (n = 14, 10.8%) corresponded to patients in G2. No correlation was observed between CuEX and UCE; at baseline only 17 (23%) patients had CuEX and UCE aligned (both being below/within or above their normal ranges). ALAT levels (but not ASAT) were significantly lower among patients with CuEX below normality, when compared to patients with CuEX within or above normality (p = 0.015).
Conclusion: CuEX levels were below normality in more than half of our real-life WD patients and seems an unreliable biomarker for assessing copper homeostasis. It should be used with caution and combined with other parameters. Reference CuEX target ranges should be re-defined for WD patients.

WED-187-YI

Clinical and biochemical characteristics of a Danish and Turkish cohort of incident and prevalent patients with primary biliary cholangitis

Email: hasaneruzun@gmail.com

Background and aims: Primary biliary cholangitis (PBC) is a progressive chronic inflammatory liver disease. Environmental triggers, individual genetic predisposition, and epigenetic factors influence disease development and progression. Although it is observed in all races and regions, the incidence and prevalence show geographical variation. In our study, we compared cohorts of Danish and Turkish PBC patients with different genetic backgrounds.
Method: We compared basic demographic and biochemical data of four cohorts; 1) 155 prevalent Danish patients, 2) 77 incident Danish patients, 3) 103 prevalent Turkish patients, and 4) 101 incident Turkish patients. We evaluated liver disease severity and response

rates to ursodeoxycholic acid (UDCA) treatment in prevalent PBC patients.
Results: More than 90% of the included patients were female, except in the Danish incident cohort with 75% female. Turkish patients had lower median age in the prevalent cohort compared to Danish patients. Median albumin levels were higher in the Turkish cohorts than in the Danish, when comparing incident with incident and prevalent with prevalent, respectively; and more patients were AMA positive in the Turkish cohorts. Other biochemical data were similar between cohorts. Around 15% of the patients in all the cohorts had cirrhosis. More patients in the Turkish prevalent cohort were complete responders to UDCA than in the Danish prevalent cohort.
Conclusion: Turkish and Danish patients have similar age at diagnosis, and the same proportion have cirrhosis, but Turkish patients have higher AMA positivity rates than Danish. More Turkish than Danish patients have a complete response to UDCA treatment.

WED-188
Diagnosis and monitoring pathways using non-invasive tests in patients with alpha-1 antitrypsin deficiency-associated liver disease: results from an expert Delphi panel
Virginia C. Clark[1], Mark A. Price[2], Jon Russo[2], Rohit Loomba[3], Alice Turner[4], Pavel Strnad[5]. *[1]University of Florida, Gainesville, FL, United States; [2]RTI Health Solutions, Research Triangle Park, Durham, NC, United States; [3]University of California San Diego School of Medicine, La Jolla, CA, United States; [4]University of Birmingham, Birmingham, United Kingdom; [5]University Hospital RWTH Aachen, Aachen, United States*
Email: virginia.clark@medicine.ufl.edu

Background and aims: Alpha-1 antitrypsin deficiency (AATD) is a rare genetic condition and the severe protease inhibitor (Pi)*ZZ genotype increases the risk of liver disease (AATD-LD) and/or lung disease. Liver biopsy is the gold standard for assessing AATD-LD, but because of its invasiveness, high cost and sample/reader variability, it is infrequently used in real-world practice. Despite availability of non-invasive tests (NITs), there is a lack of consensus and guidelines for the diagnosis and monitoring of AATD-LD. We conducted a Delphi panel study to address this need.
Method: Healthcare providers with relevant specialties from the USA, Canada, EU and UK who managed at least two patients with AATD-LD in the past two years were recruited for the Delphi panel. Two iterative surveys were developed and administered, with the second survey clarifying the results from the first with an opportunity to provide deeper feedback. Following the surveys, a real-time consensus-building exercise focused on topics lacking consensus from the surveys. Controlled feedback was anonymous, and panellists were able to review individual/aggregated responses and qualify/change their responses.
Results: In total, 20 experts (in hepatology [n = 9], pulmonology [n = 6], transplant hepatology [n = 3], gastroenterology [n = 1] and hepatology and transplant hepatology [n = 1]) completed the study. Consensus was achieved on the topics of usage and evaluation of NITs, risk stratification and monitoring. All panellists agreed that vibration-controlled transient elastography (VCTE) is the preferred NIT for the initial assessment of AATD-LD owing to its accessibility and reliability. Magnetic resonance elastography and enhanced liver fibrosis tests were also considered by all as valuable tools following VCTE. Most (85%) agreed that VCTE <8 kPa could indicate no or mild fibrosis and VCTE ≥8 kPa could indicate clinically significant fibrosis, which may correspond to F2 or higher on the meta-analysis of histological data (METAVIR) scale. Most (85%) agreed that VCTE ≥13 kPa may indicate cirrhosis; however, two panellists suggested different values for this category, and one was unsure. Most (≥85%) also agreed that, to improve disease monitoring, the most important risk stratification for AATD-LD is at the F1 to F2 transition on the METAVIR scale.
Conclusion: Utilizing the Delphi technique, this study identified a clinically applicable framework for diagnosis and monitoring of AATD-LD. A high level of agreement emerged regarding preferred NITs and their usage, risk stratification and monitoring in the context of AATD-LD management. The results provide a foundation for future efforts into NIT validation, further refinement of consensus, and the development of clinical guidelines for AATD-LD.

WED-189
Patient survey of Wilsons disease patients in the United Kingdom
William J. H. Griffiths[1], Nick Probert[2], Catherine Stewart[3], Valerie Wheater[4], Elaine Kamara[5]. *[1]Addenbrooke's Hospital, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [2]Orphalan, London, United Kingdom; [3]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [4]Wilsons Disease Support Group (WDSG), Cambridge, United Kingdom; [5]Orphalan, Medical, London, United Kingdom*
Email: bill.griffiths@nhs.net

Background and aims: Wilson's disease (WD) is a rare disease requiring lifelong therapy. Challenges with long term treatment are well recognised with a risk of increased morbidity, mortality, and liver transplantation in those poorly adherent to therapy. We designed an online survey for WD patients to better understand their needs.
Method: The UK Wilsons Disease Support Group (WDSG) partnered with Orphalan to develop a patient questionnaire hosted on the WDSG website and Facebook page. The domains covered in 35 questions were demographics, presentation, diagnosis, current and past treatments, monitoring, adherence and living with WD. Respondents were given multiple choices to answer or free text as appropriate. Anonymised data were analysed.
Results: Between 1st November 2023 and 11th January 2024, 41 subjects registered and of these 8 were disqualified (parental response [1], not living in UK [3] and less than 50% completed [4]); 33 subject responses were thus analysed. Participants were predominantly female (58%) and white (94%) with 21 (64%) completing all questions. Median (range) age was 43 (14–70) and time since diagnosis was 22 (1–59). Themes from the survey identified a desire for more local laboratory testing, improvement in time to diagnosis and more monitoring of drug tolerability. Data on current and past medication and reasons for changing were provided by 29/33 (88%), of whom 18/29 (62%) were on D-penicillamine (DPA) with majority (75%) continuing since diagnosis and 6 switched (3 intolerant to zinc and 3 declared problems with trientine). 10/29 (34%) of patients were on trientine (6 on branded trientine-2HCl, 3 on trientine-4HCl and 1 generic trientine-2HCl). Only 2 patients were on zinc (1 in combination with trientine-4HCl). Subjects reported experiencing (unspecified) ongoing adverse reactions (9/29; 5 DPA, 2 trientine-4HCl, 1 zinc and 1 trientine-4HCL plus zinc). Inconveniences to therapy were reported by 29/33 and included pill size, taste, losing medication, breaking bottle, remembering and most commonly food restrictions (14/29). Frequency of dosing, timing with food, taste, adverse reactions, and difficulty swallowing medications were recorded as challenges to adherence, with 10% of respondents admitting to missing a dose frequently, defined either as daily or up to 4 times a week.
Conclusion: This is the first online survey of WD patients in the UK which we are aware of. It gives a snapshot of the demographics, challenges, and adherence of UK patients with WD. Unmet needs identified in this survey include patient reported inconveniences to therapy, monitoring and identification of ongoing adverse reactions. All have the potential to impact adherence and further real world data are needed to confirm findings of this survey and to investigate interventions to improve health related quality of life of patients with WD.

WED-190

Elevated hepatic copper content in porto-sinusoidal-vascular disorder: leading down a wrong track

Lorenz Balcar[1], Nina Dominik[1], Behrang Mozayani[1], Georg Semmler[1], Michael Schwarz[1], Emina Halilbasic[1], Michael Trauner[1], Mattias Mandorfer[1], Thomas Reiberger[1], Bernhard Scheiner[1], Albert Friedrich Stättermayer[1]. [1]*Medical University of Vienna, Vienna, Austria*
Email: lorenz.balcar@meduniwien.ac.at

Background and aims: Porto-sinusoidal vascular disorder (PSVD) is a rare vascular liver disorder characterised by clinical evidence of portal hypertension and specific histological findings in the absence of cirrhosis, which is poorly understood in terms of pathophysiology. While elevated hepatic copper content serves as diagnostic hallmark in Wilson disease (WD) and may also be present in cholestasis, there are no data on copper and PSVD so far. Therefore, the objective of this study was to systematically evaluate the prevalence of elevated hepatic copper content and to determine the clinical implications of these pathomechanistic changes in patients with PSVD.
Method: Patients with an established diagnosis of PSVD at the Medical University of Vienna and available hepatic copper content at the time of diagnosis of PSVD were retrospectively included. Elevated hepatic copper content was analysed for liver-related outcomes (first/further hepatic decompensation/liver-related death) in a multistate model.
Results: Overall, 92 patients were included into this study (mean age 49 ± 16; 57% male, 44% female; 40% decompensated; median hepatic copper content 30 [IQR: 18–55] µg/g) of whom 25 (29%) had mildly (≥50 µg/g) and 4 (4%) severely (≥250 µg/g) elevated hepatic copper content. Of the patients with mildly elevated hepatic copper content, 14 (15%) had evidence of cholestasis, but 15 (16%) had not.
Elevated levels of hepatic copper content were associated with younger age in multivariable linear regression analysis. During a median follow-up of 3.6 years, 21 (23%) patients developed one or more liver-related complications. After adjusting for age, Child-Pugh score, and decompensation status, hepatic copper content was significantly associated with the outcome of interest (per 10, log-transformed; aHR: 1.63 [95%CI: 1.19–2.24]; p = 0.002). A cut-off based on maximal rank-tests at ≥90 µg/g identified patients with considerable risk of developing liver-related outcomes during follow-up (at 2 years: 51% vs. 12%; p = 0.007).
Conclusion: Elevated hepatic copper levels may be frequently observed in patients with PSVD in the absence of cholestasis, especially in young patients, which might possibly steer the diagnosis into a wrong direction in sense of WD. Since patients yielding elevated hepatic copper content had higher risks of liver-related complications, the specific pathomechanisms and potential therapeutic consequences remain yet to be explored.

WED-191

The impact on adherence and patient satisfaction following a switch to trientine tetrahydrochloride for the maintenance therapy in Wilson's disease

Massimo Zuin[1], Valentina Medici[2], Nora Cazzagon[3], Alberto Civolani[4], Fabio Tedone[5], Stefania Lopatriello[5], Andrea Crosignani[6], Pier Maria Battezzati[7]. [1]*university of Milan, Milan, Italy;* [2]*University of California Davis, Sacramento, United States;* [3]*University of Padua, Padua, Italy;* [4]*AOU Cagliari, Policlinico di Monserrato, Cagliari, Italy;* [5]*Helaglobe srl, Firenze, Italy;* [6]*Polo universitario San Paolo, Milano, Italy;* [7]*University of Milan, Milano, Italy*
Email: massimo.zuin@gmail.com

Background and aims: Wilson disease (WD), an inherited disorder of copper transport resulting in copper accumulation in the liver and brain. WD can be managed effectively if patients adhere to therapy. All therapies have food restrictions, require multiple daily dosing and side effects are common. We aimed to obtain patient reported data on adherence, satisfaction, and health related quality of life (HQoL) before and after a switch to trientine tetrahydrochloride (TETA4).
Method: An Italian multicenter, retrospective (RP) prospective (P) observational study of WD adults prescribed TETA4 (Orphalan SA, France). Demographic data, 24-hour urinary copper excretion (UCE), posology and pill count at each visit were collected. Patient reported outcomes were obtained from Morisky Medication Adherence Scale (MMAS-4/8), Patient Experiences and Satisfaction with Medication questionnaire (PESaM) and HQoL questionnaire (SF36). Data were collected at two-time points; baseline (T0) and first visit (minimum 3 months) after switching to TETA4 (T1).
Results: Of the 25 patients enrolled, 9 and 16 were in the RP and P cohort respectively and 14 were female. Median (IQR) age and time from diagnosis was 43 (30, 52) and 24 (14, 30) years, respectively. The majority were employed (18/25) and 8/25 had co-morbidities. Pre-switch therapies were zinc (13), penicillamine (6), trientine dihydrochloride (TETA2; 4) and combination TETA2/zinc (2). At both T0 and T1, proportion of UCE outside recommended therapeutic range was unchanged (15; 60%). Mean (range) of pills of TETA4 prescribed was 4 (2–6). Based on returned pills at first follow-up, 16/23 were adherent, 6/23 moderately- and 1/23 non-adherent. In RP cohort, baseline adherence was 33% (MMAS-4) rising to 89% at T1 and in P cohort (MMAS-8), 25% self-reported as very adherent at T0 rising to 50% at T1. Overall patient satisfaction to therapy was high and unchanged. Median scores on 5-point scale in 4/6 domains of perceived effectiveness, satisfaction, impact of adverse events, ease of use and overall satisfaction were 4 at T0 and T1; only change, an increase from 4 to 5 in ease of use. Median (range) scores on a 0–100 scale (SF36) were overall high and unchanged at T0 and T1, with the exception, increasing for general health 56.2 (15–87.5) to 62.5 (6.25–81.3), energy 46.6 (13.3–100) to 60 (20–80) and social function 75 (25–100) to 87.5 (25–100). Statistically significant changes were seen in 2 domains; physical function and role limitations due to emotional state.
Conclusion: Patient reported adherence improved with TETA4 compared with previous therapy. Patient satisfaction and HQoL following switch to TETA4 improved through perceived ease of use (PESaM) and domains of energy, social functioning and general health (SF36) respectively. UCE values are unreliable to assess adherence. Long term data to assess continued adherence and HQoL are needed.

WED-192

Raising awareness of long term chelation therapy challenges in Wilson's disease-Potential implications of monitoring and developing skin and vascular complications

James Liu Yin[1], Jon Salisbury[2], Aftab Ala[1]. [1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom;* [2]*Histopathology, King's College Hospital, London, United Kingdom*
Email: aftab.ala1@nhs.net

Background and aims: Wilson's disease (WD) is a genetic metabolic liver condition that results in excessive copper being retained in the body. Long term penicillamine (DPA), the most commonly used chelator for the treatment of WD, has a recognised association with connective tissue disorders (CTD) such as elastosis perforans serpiginosa and cutis laxa (CL). Crucially, it is not known whether this is directly due to the medication itself, from over treatment leading to copper deficiency or both. There is an additional potential risk of vascular issues due to disruption in the formation of collagen fibres by lysyl oxidase whose action requires copper.The response to treatment and monitoring of WD is assessed with the calculated non-caeruloplasmin bound copper (cNCC) and 24 hr urinary copper excretion (UCE). These inaccurate methods can be hard to clinically interpret and may potentiate over treatment.
Method: We reviewed patients with newly identified skin conditions within our WD cohort at King's College Hospital, London. We used our electronic patient records system including histopathology and

imaging records to review the clinical course of our patients, medication prescribed and biochemical markers.
Results: We identified 4 patients with WD, on long term treatment with chelation therapy and with acquired CL, 1 patient had a biopsy to confirm the diagnosis and the others were made clinically. 2 patients had echocardiograms performed, 1 patient had aortic root dilatation confirmed with a MRI aorta, whilst the other had no abnormalities detected. Patients' ages ranged from 37–57 years (3M: 1F) and years of treatment from 19–45years. Treatment regime was mostly with DPA but 1 patient had only zinc and trientine. On review our patients had results for less than 1 UCE per year and that inter and intra patient results varied greatly (2–46 umol/24 hr). The median value of cNCC for each patient was 0.11, –1.65, 3.95 and 0.5 (normal <1.6 umol/L). Of note, 44% of cNCC values were negative in value and therefore not clinically interpretable (inaccurate due to inherent issues with cNCC formula).
Conclusion: There is a growing cohort of patients who have been exposed to copper chelation for a significant period of time. It is crucial to raise awareness, investigate and understand side effects of medication which may have potential long term serious complications.
Although a small cohort, our data showed wide variations in UCE, regularly un-interpretable cNCC results, skin changes in a patient without DPA use and a significant vascular issue. It highlights the need to develop accurate monitoring of copper to guide medication dosing, understand the mechanism and vascular complications of CTD and to investigate the consequences of over treatment in WD.
International prospective studies are necessary to answer these important questions with further mechanistic studies to understand the underlying pathophysiology.

Viral Hepatitis – Experimental and pathophysiology

TOP-353
An mRNA vaccine exhibits anti-viral activity in mouse model of persistent hepatitis B infection

Aditi Deshpande[1], Aileen Rubio[1], Bharat Dixit[1], Pooja Tiwari[2], Lei Qiugang[3], Sun Ya[3]. [1]*ClearB Therapeutics, Concord, United States;* [2]*Arnav Biotech Corp., Atlanta, United States;* [3]*Wuxi AppTech, Shanghai, China*
Email: adeshpande@clearbtherapeutics.com

Background and aims: We previously reported declines in serum HBsAg levels and concomitant clearance of infected hepatocytes after administration of a therapeutic subunit adjuvanted vaccine, CLB-3000 which consists of two modified HBsAg variants displaying clearance profile (CP) associated loop 1 and 2 epitopes identified from patients who achieve functional cure (EASL 2021 poster 853, AASLD 2021 poster 829). We have developed eight mRNA vaccine candidates with two coding sequences; loop1 (40X) and loop 2 (50X) in combination with different 5′ UTRs (US Patent Application #20190314493; Stadler, C. et al, Nat Med 23, 815–817 (2017); Cao, J., et al, Nat Commun. 12, 4138 (2021)). Two candidates for each coding sequence were selected based on in vitro expression and were formulated into lipid nanoparticles and assessed for anti-viral activity in murine model of persistent Hepatitis B infection.
Method: 8 template DNA sequences were designed for two candidate vaccines, 40X and 50X, using combinations of four 5′ UTRs. The eight mRNA candidates (1-40X, 2-40X, 3-40X, 4-40X, 1-50X, 2-50X, 3-50X, 4-50X) were synthesized by in-vitro transcription using N′-1-methyl pseudouridine. Two 5′ UTRs (1, 3) were prioritized based on protein expression level of candidates 1-40X, 3-40X, 1-50X and 3-50X in A549 and U937 cell lines assessed by western blot. These candidates were formulated in lipid nanoparticles and tested for efficacy in the Hydrodynamic tail vein injection (HDI) model of persistent Hepatitis B infection [Chou H-H et al 2015. PNAS 112 (7) pp2175]. CBA/CaJ mice were given three biweekly intramuscular (IM) injections at a total mRNA dose level of 5 µg and monitored over time for serological markers of HBsAg, HBV DNA and liver HBcAg immunohistochemistry at end of study.
Results: mRNA candidates 1-40X, 3-40X, 1-50X and 3-50X demonstrated robust expression of HBsAg protein of appropriate molecular weight in A549 and U937 cell lines. Treatment of mice in the HDI model with 5 µg total mRNA dose displayed an average reduction of 2.6 log HBsAg from baseline to five weeks post last dose across all treatment groups, with the combination of all four candidates 1-40X +3-40X+1-50X+3-50X displaying the highest reduction of 3 log HBsAg compared to two mRNA candidates 3-40X+1-50X giving a 2.4 log reduction. The HBV DNA had similar trend in reduction as HBsAg in plasma. Liver compartment analysis confirmed clearance of HBcAg positive cells following serum HBsAg clearance. In comparison to mice in the treatment groups, persistent infection was maintained in placebo mice through the study duration.
Conclusion: An mRNA therapeutic vaccine was highly efficacious in a murine model of persistent HBV infection with rapid plasma HBsAg decline and clearance, and clearance of infected hepatocytes. These findings further support the development of an mRNA based therapeutic vaccination approach in chronic hepatitis B patients.

TOP-354
Potent and sustainable HBsAg clearance by a liver-targeting PD-L1 siRNA in mice

Zhiwei Yang[1], Nan Liu[1], Hongli Zhang[1], Ping Chen[1], Hui Chen[1]. [1]*Suzhou Siran Biotechnology Co., Ltd., Suzhou, China*
Email: yangzhiwei@siranbio.com

Background and aims: The efficacy of PD-1/PD-L1 checkpoint antibodies has been proven in chronic hepatic B (CHB) clinical studies. CHB patients with low HBsAg baseline showed HBsAg loss and seroconversion, suggesting that immunomodulatory approach is effective for CHB treatment. However, systemic PD-L1 inhibition may result in intolerable immune response, and its efficacy need to be further improved to increase functional cure ratio. SA012, a N-acetylgalactosamine (GalNAc) conjugated siRNA therapeutic agent, which targets the mRNA of PD-L1 gene, has been developed for the treatment of CHB. Here, we report its pre-clinical data.
Method: hPD-1/PD-L1 AAV-HBV mice have been used in the following studies: 1) SA012 alone was injected subcutaneously at 7.5 mg/kg QW for 8 doses. 2) VIR-2218 (a siRNA targeting HBV-X gene) 1 mg/kg Q4W was injected subcutaneously for 2 doses and SA012 was injected at 7.5 mg/kg QW for 8 doses. Serum HBsAg, HBV DNA and HBsAb were detected at different time points till the end of study at Day 98. Additionally, the safety profile of biochemistry, routine blood test and histopathology were assessed in rat toxicity studies with SA012 100 mg/kg Q2W for 3 doses.
Results: 1) In SA012 monotherapy study, continuous HBsAg reduction was observed. 1/7 mice achieved HBsAg clearance after Day 49, and 4/7 mice achieved HBV DNA detection limit (LLOQ). 5/7 mice achieved HBsAb over 40 mIU/ml. 2) When SA012 was combined with VIR-2218, it showed much faster and higher HBsAg clearance ratio: 4/8 in the combo group compared to 1/7 in SA012 monotherapy group. Meanwhile, no mice showed HBsAg clearance in VIR-2218 monotherapy group. When SA011 (a GalNAc-conjugated siRNA developed by SiranBio, targeting HBV-X gene) was added sequentially to SA012+Vir2218 combo treatments, the highest HBsAg clearance ratio (6/8 mice, 75%) and HBV DNA clearance ratio (8/8 mice, 100%) were achieved. No rebound was observed in HBsAg clearance mice during the entire study. No significant abnormality was observed in rat tox studies.
Conclusion: SA012 has shown potent and sustainable HBsAg and anti-HBV activity in pre-clinical studies when used alone or

combined with VIR-2218/SA011. SA012 monotherapy can elicit prolonged reduction of HBsAg and HBV DNA in mice, and induced high levels of HBsAb. When combined with VIR-2218, faster and higher ratio of HBsAg clearance (50%) was achieved. When SA011 was added to the combo therapy, it showed the highest ratio of HBsAg clearance (75%) and HBV DNA elimination (100%). No viral rebound was observed during our entire studies. These results support further clinical development of SA012. The orthogonal mechanism of SA012 provides many possibilities for combo therapies with other modalities to reach the goal of CHB functional cure.

T cells expressing HBV-specific chimeric antigen receptors harboring a Fab fragment control HBV infection in mice

Zhe Xie[1], Oliver Quitt[2], Anna D. Kosinska[2], Lisa Wolff[2], Elfriede Nößner[2], Ulrike Protzer[2,3]. [1]*Institute of Virology, Technical University of Munich, Munich, Germany;* [2]*Institute of Virology, Technical University of Munich/Helmholtz Munich, Munich, Germany;* [3]*German Center for Infection Research (DZIF), partner site Munich, Munich, Germany*
Email: zhe.xie@tum.de

Background and aims: Chimeric-antigen-receptors (CARs) are synthetic receptors designed to drive antigen-specific activation of T cells upon binding to cognate antigen. CAR-T cells are used in cancer therapy but are also interesting for chronic viral infections. Our study aimed to generate novel CARs that target the hepatitis B virus envelope protein (HBVenv) on the membrane of HBV-infected cells using an antigen binding fragment (Fab) consisting of heavy and light chains instead of a variable single-chain fragment. The aim of this study was to overcome functional alterations of the new format, and to study the antiviral efficacy of FabCAR-engrafted T cells in vitro and in vivo.
Method: We constructed novel CARs containing the Fab fragment of HBVenv-specific monoclonal antibodies as binding domains and CD3 as well as CD28 intracellular signaling domains. We characterized the FabCAR T-cell function by T-cell activation upon HBsAg stimulation and elimination of HBVenv-transgenic hepatoma cells. The antiviral effect was accessed by coculturing FabCAR-T cells with HBV infected HepG2-NTCP cells. To study in vivo efficacy, CD45.1 murine T cells expressing FabCAR were transferred to CD45.2 AAV-HBV infected, HBV-carrier Rag1 knock-out mice.
Results: Multifunctional FabCAR-T cells could be induced via HBsAg stimulation. FabCAR-T cells specifically eliminated HBV envelop protein transgenic cell lines Huh7S and HepG2SML. Elimination of target cells was accompanied by secretion of interferon-gamma, tumor necrosis factor, and granzyme B. FabCAR-T cells showed antiviral activity by significantly decreasing the level of viral antigen, intracellular HBV DNA, and HBV cccDNA in HBV-infected HepG2-NTCP cells. In HBV-carrier mice, after adoptive transfer, FabCAR-T cells proliferated and localized to the liver, resulting in target cell killing indicated by ALT flare and an antiviral effect by HBsAg and HBeAg reduction.
Conclusion: T cells stably transduced with our FabCARs are polyfunctional and could efficiently eliminate HBVenv-positive cells in an antigen-dependent manner in cell culture and in a preclinical animal model. Thus, FabCAR-T cells are promising candidates for treating chronic hepatitis B and HBV-associated hepatocellular carcinoma.

TOP-356

Combination treatment of a TLR7/8 dual agonist with an antisense oligonucleotide bepirovirsen and entecavir leads to additive HBsAg decline in the AAV-HBV mouse model

Ke Qiu[1], Zhiling Deng[1], Taiyu He[1], Zhi-wei Chen[1], Taichang Yuan[2], Guozhi Tang[2], Ming-Li Peng[1], Hong Ren[1]. [1]*Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, the Second Affiliated Hospital of Chongqing Medical University., Chongqing, China;* [2]*Shanghai Visonpharma Co., LTD, Shanghai, China*
Email: renhong0531@vip.sina.com

Background and aims: Achieving high levels of functional cure of chronic hepatitis B (CHB) will likely require a combination regimen that blocks viral replication, reduces antigen load, and activates host immune responses to control residual virus. Bepirovirsen is a promising antisense oligonucleotide (ASO) against HBV which can significantly reduce hepatitis B surface antigen (HBsAg) but the duration is limited.TLR7 and TLR8 agonists induced durable antiviral efficacy in preclinical studies. However, the effect of single-acting TLR agonists in reducing HBsAg in clinical studies is limited. Recently, TLR7/8 dual acting agonists have been reported can induce broad cytokines which may provide novel opportunities towards functional HBV cure. This current work describes the investigation of combinations of a TLR7/8 dual acting agonist (VE03702) with bepirovirsen (ASO) and entecavir (ETV) in a mouse model of HBV infection. Sequential and concomitant treatment of these agents were explored and the results may inform future clinical combination trial design.
Method: C57BL/6 mice infected with rAAV8-1.3HBV were treated ETV and ASO for three weeks then stopped treatment or switched to VE03702 or Peg-IFN treatment for four weeks. ETV was orally administered at 0.1 mg/kg daily, and ASO was dosed at 50 mg/kg, subcutaneously once a week.VE03702 was dosed at 0.05 mg/kg, subcutaneously once a week, and Peg-IFN was dosed at 30 g/kg, subcutaneously twice a week. HBsAg was the key viral end point measured for these studies. Additionally, two potential clinical treatment paradigms were tested where both ASO and Peg-IFN were administered concurrently or ASO preceding treatment with Peg-IFN sequentially.
Results: In the first three weeks, concomitant treatment of ASO and ETV resulted in an up to 1.67 log reduction in HBsAg levels. After stopping treatment of ASO, serum HBsAg rapidly rebounded to pretreatment levels within 4 weeks while HBV DNA was still below the lower detection limit. When switching to VE03702 treatment after stopping ASO administration, additional decreases reaching 4.5 logs in HBsAg were observed. After 4 doses of VE03702, HBsAg loss was observed and anti-HBs antibodies in the serum were detected. For the sequential treatment of ASO followed by Peg-IFN, rapid rebound in HBsAg occurred after discontinuation of ASO resulting in no added benefit in this regimen. There is no significant difference between the sequential and concurrent treatment paradigms of Peg-IFN and ASO.
Conclusion: Combinations of a TLR7/8 dual agonist (VE03702) and bepirovirsen (ASO) and ETV provide additional reduction in HBsAg when dosed sequentially in the AAV-HBV mouse model of HBV. VE03702 showed more effectiveness than Peg-IFN in terms of avoiding HBsAg rebound after ASO discontinuation, suggesting the potential for clinical translation.

Second generation HBV siRNAs with novel chemistries demonstrate improved profiles compared with ALG-125755 and other clinical stage siRNAs

Jin Hong[1], Vivek Rajwanshi[1], Saul Montero[2], Min Luo[1], Kellan Passow[1], Cheng Liu[1], Hyunsoon Kang[1], Jacquelyn Sousa[1], Dana Cho[1], John Cortez[1], Shane Daguison[1], Kusum Gupta[1], Hua Tan[2], Vera Huang[2], Dawei Cai[2], Rostom Ahmed-Belkacem[1], Lawrence Blatt[1], David Smith[1], Leonid Beigelman[2], Julian Symons[1]. [1]*Aligos Therapeutics, Inc., South San Francisco, United States;* [2]*Previous Employee of Aligos Therapeutics, Inc., South San Francisco, United States*
Email: jhong@aligos.com

Background and aims: Hepatitis B virus (HBV) siRNAs have been shown to effectively reduce HBsAg in chronic hepatitis B (CHB) subjects. When combined with interferon or a TLR7 agonist, a significant portion of patients demonstrate HBsAg loss. ALG-125755 is an HBV siRNA currently in Phase I. Single doses have been evaluated

in healthy volunteers and virologically suppressed HBeAg negative CHB subjects. ALG-125755 was well tolerated with a favorable PK profile and viral kinetic data indicated evidence of HBsAg lowering at all dose levels evaluated. In this study, a multi-pronged approach was taken to further improve the potency, stability, hepatocyte-specific delivery and safety of ALG-125755 with the aim of developing a best-in-class HBV siRNA.

Method: In vitro inhibition of HBsAg release by siRNA was performed in the HepG2.2.15 cell line after transfection. Secreted HBsAg was quantified by ELISA. The stability of HBV siRNAs was profiled in mouse liver homogenates. Off target activity was evaluated by RNAseq in HepG2.2.15. The binding of different GalNAc moieties to the asialoglycoprotein receptor (ASGR) was measured in human and mouse liver microsomes. In the AAV-HBV mouse model, HBV siRNAs conjugated with GalNAc were administered subcutaneously (SC) with serial blood collections for HBsAg and ALT assessment.

Results: By applying novel sugar stabilization chemistry at the ALG-125755 antisense strand (AS) 3′ region, 100% of the AS was maintained after 48-hour incubation in mouse liver homogenate, compared with 72% for the parent. Novel acyclic nucleoside chemistry was introduced into the seed region. This improved safety with a total off target reduction of 97% in an RNAseq assay. Surprisingly this also improved efficacy in reducing HBsAg by an additional 1.8 $\log_{10}$ IU/ml compared with parent after a single dose of 5 mg/kg in AAV-HBV mouse model. An optimized GalNAc was assessed for binding to human and mouse ASGRs and exhibited a Kd of 13.6 and 5.9 nM respectively, while parental GalNAc showed a Kd of 97.9 and 15.5 nM respectively. ALG-125839 is a 2nd generation HBV siRNA incorporating some of these novel chemistries. Compared head-to-head with an ALG-125755 analog and another Phase 2 (Ph2) clinical stage HBV siRNA in the AAV-HBV mouse model after 6 repeat doses of 5 mg/kg, every two weeks, ALG-125839 showed an average additional 0.5 $\log_{10}$ IU/ml HBsAg reduction over the ALG-125755 analog across multiple timepoints both during and post treatment. When compared to the Ph2 siRNA, the ALG-125839 HBsAg nadir was 1.5 $\log_{10}$ IU/ml deeper. ALG-125839 was more durable than the Ph2 siRNA with HBsAg nadir maintained for 12 weeks in the follow-up period while HBsAg in Ph2 siRNA group returned to baseline.

Conclusion: ALG-125839 with novel chemistries demonstrated improved activity and potential safety when compared with ALG-125755 and a Ph2 siRNA. Further studies of this novel compound are warranted.

Non-HAP CAM-A ALG-006746 and ALG-006780 induce rapid HBsAg reductions in AAV-HBV mice and have favorable pharmacokinetic profiles

Hannah Vanrusselt[1], Jordi Verheyen[1], Kusum Gupta[2], Lars Degrauwe[1], Cheng Liu[2], Abel Acosta Sanchez[3], Mélanie Bollier[3], Jean-Boris Nshimyumuremyi[3], Benjamin Verburgh[3], Clovis Peter[3], Qingling Zhang[4], Lawrence Blatt[2], Leonid Beigelman[2], Julian Symons[2], Sushmita Chanda[2], David Smith[5], Andreas Jekle[2], Sandrine Vendeville[1], David McGowan[1], Yannick Debing[1]. *[1]Aligos Belgium BV, Leuven, Belgium; [2]Aligos Therapeutics, Inc., South San Francisco, United States; [3]Novalix, Leuven, Belgium; [4]Aligos Therapeutics, Inc, South San Francisco, United States; [5]Aligos Therapeutics, Inc., South San Francisco, Belgium*
Email: hvanrusselt@aligos.com

Background and aims: Hepatitis B virus (HBV) capsid assembly is an attractive target for the treatment of chronic hepatitis B (CHB). Class A capsid assembly modulators (CAM-A) induce HBV core protein (HBc) aggregation and sustained HBsAg reduction in CHB mouse models. We recently presented data on the first non-heteroaryldihydropyrimidine (HAP) CAM-A with sustained in vivo HBsAg declines. Here we present two novel non-HAP CAM-A with rapid HBsAg reductions in AAV-HBV mice and favorable pharmacokinetic (PK) profiles.

Method: HBV DNA antiviral activity was determined in HepG2.117 cells using quantitative PCR, with and without 40% human serum. Effects on cccDNA establishment were assessed in HBV-infected primary human hepatocytes (PHH). Further characterization was performed using electron microscopy visualization and immunofluorescent HBc staining. HBc-dependent CAM-A-induced cell death (CCD) was assessed in HBc-expressing cells. PK properties were evaluated in rat, beagle dog and cynomolgus monkey, whereas in vivo antiviral efficacy was assessed in the adeno-associated virus (AAV)-HBV mouse model.

Results: ALG-006746 and ALG-006780 potently inhibited HBV DNA production in HepG2.117 cells with EC_{50}/EC_{90} values of 10.6/45.0 nM and 7.76/31.6 nM respectively. Inclusion of 40% human serum resulted in modest 2.3- and 1.7-fold shifts in antiviral activity, respectively. Evaluation in PHH demonstrated pronounced inhibition of cccDNA establishment at higher concentrations. Both compounds induced the formation of aberrant viral capsids, as observed by electron microscopy, and small nuclear HBc aggregates, confirming their CAM-A "tiny" (CAM-A_t) subtype. Similar to other CAM-A, ALG-006746 and ALG-006780 induced CCD in HBc-expressing cells upon extended incubation. Both compounds showed low to moderate plasma clearance and moderate volume of distribution in three different species. Following a single oral administration of each compound in rat and dog, good bioavailability (79–91%) was achieved. Both compounds showed the expected immediate declines in HBV DNA in AAV-HBV-transduced mice but also reduced HBsAg with unexpectedly rapid kinetics compared to previously described CAM-A_t molecules. ALG-006746 induced a sharp decline from day 35 on, whereas ALG-006780 reduced HBsAg levels already at day 14, reaching a 1.5 $\log_{10}$ IU/ml reduction by day 35, similar to HAP CAM-A RG7907.

Conclusion: With rapid in vivo HBsAg declines and favorable PK profiles, ALG-006746 and ALG-006780 are promising CAM-A candidates for further development.

Development of a replication-competent Vesicular Stomatitis Virus (VSV) vector for therapeutic hepatitis B vaccination

Jinpeng Su[1,2], Anna D. Kosinska[1,2], Susanne Miko[1], Edanur Ates-Öz[1], Dorothee von Laer[3], Janine Kimpel[3], Ulrike Protzer[1,2]. *[1]Institute of Virology, Technical University of Munich/Helmholtz Munich, Munich, Germany; [2]German Center for Infection Research (DZIF), Munich partner site, Munich, Germany; [3]Institute of Virology, Medical University of Innsbruck, Innsbruck, Austria*
Email: jinpeng.su@tum.de

Background and aims: Eliciting robust immune responses against hepatitis B virus (HBV) through therapeutic vaccination holds significant promise to cure chronic hepatitis B. We have developed a heterologous prime-boost clinical vaccine candidate, *TherVacB*, employing a protein-prime with recombinant HBV surface and core antigens (HBsAg, HBcAg), and a vector-boost with recombinant Modified Vaccinia virus Ankara vector (MVA) expressing HBV antigens. In this study, we aimed to use a replication-competent chimeric Vesicular Stomatitis Virus vector (VSV-GP) known to induce both B- and T-cell responses as an alternative viral vector. We evaluated different regimens incorporating this new vector alongside the original *TherVacB* regimen.

Method: AVSV-GP vector encoding HBsAg and HBcAg (VSV-GP-HBs/c) has been constructed. The new recombinant vector was evaluated for the encoded antigen expression through Western blot and immunofluorescence staining and its immunogenicity and antiviral efficacy were tested in both HBV-naïve and HBV-carrier mice.

Results: *In vitro* analyses demonstrated that the VSV-GP-HBs/c vector was successfully generated, and the encoded antigens were properly expressed. A single immunization with VSV-GP-HBs/c vector could induce HBV-specific immune responses, albeit at a very low level. When the VSV-GP-HBs/c vector was employed to substitute the

protein for prime in *TherVacB* regimen, the resulting immunization induced modest HBV-specific immune responses. It led to minor antiviral effects in HBV-carrier mice. In contrast, utilizing the VSV-GP-HBs/c vector to replace the MVA-HBs/c for boosting in *TherVacB* elicited robust HBV-specific antibody and T-cell responses. Furthermore, the approach resulted in a significant 3-log decrease in serum HBsAg levels, as well as a substantial 60%–70% reduction in the numbers of HBV-positive hepatocytes, intrahepatic HBV-DNA and HBV-RNA in the liver. The efficacy of the heterologous protein-prime/VSV-GP-boost approach was comparable to that of the classical *TherVacB* regimen, highlighting the importance of including protein in the priming phase of therapeutic hepatitis B vaccines. Of note, using a second viral vector, whether homologous or heterologous, after the protein-prime/viral vector-boost regimen did not further enhance vaccine-induced responses.
Conclusion: The protein-prime/vector-boost strategy stands as a promising and optimal therapeutic vaccine approach to cure chronic hepatitis B, in which VSV-GP-HBs/c could efficiently serve as a boost viral vector.

Email: pierre.bablon@inserm.fr

Background and aims: Hepatitis B Virus (HBV) infection leads to one million death per year, almost by cirrhosis and cancer. In contrary, *in vitro* efficient HBV infection remains stealthy. The main role of host immune response in pathogenesis was largely reported but remained unable to cure HBV during decades. Alternative splicing of viral transcripts induces the expression of Hepatitis B Splice-generated Protein (HBSP). On one hand, upregulation of this splicing activity has been reported during liver injury, and on the other hand, HBSP modulates TNF-alpha signaling pathway. Considering that HBSP-transgenic mice were less susceptible to liver inflammation and fibrosis, our study aimed to investigate its contribution when expressed in the context of HBV.
Method: HBSP-invalidated HBV (HBV-HBSPko) or wildtype HBV (HBVwt) viruses and AAV2/8 containing HBV-HBSPko or HBVwt whole genome were used to infect primary human hepatocytes (PHH) cultivated in 2D and 3D models and C57Bl6/J male mice, respectively. Liver cells culture and mouse tissues were analyzed by ELISA, Western Blot, immunofluorescence/immunochemistry, (RT) qPCR, RNAseq, proteomic and FACS.
Results: Transcriptomic analysis of HBVwt-infected PHH in 2D, compared to non-infected (NI), confirmed the stealth effect on infection (only 16/13554 differentially expressed genes (DEGs)). Infection of 3D PHH partially abrogated the stealthy effect of HBVwt (78/13615 DEGs, compared to NI). Surprisingly, infection with HBV-HBSPko increased the number of DEGs (up to 7-fold), in 2D and 3D models). Gene set enrichment of DEGs between HBV-HBSPko and HBVwt infection in 3D PHH showed that they were notably involved in cytokine-receptor interactions ($p = 0.009$) and cytokines signaling pathways ($p = 0.01$). These data led us to study the impact of HBSP invalidation on antiviral activity in AAV-HBV infected mice. Seven weeks post-infection, a striking 12-fold reduction of intra-hepatic HBc positive cells was observed in mice infected with AAV-HBV-HBSPko, compared to AAV-HBVwt (confirmed by WB), with no impact on other viral parameters (HBsAg expression, viral transcription and viral load). Decrease in HBc expression was related to an activation of type I interferon (IFN) in the liver of HBV-HBSPko-infected mice. In contrary, HBVwt infection failed to induce a type I IFN response, strengthening the key role of HBSP in viral immune escape. Intra-hepatic immune cells (flow cytometry) and prime-boost assays are under study in this model.
Conclusion: For the first time, our data demonstrated the major role of HBSP in the stealth effect of viral infection. Targeting the immune escape mechanisms developed by HBV, through HBSP expression, could open new strategies for curing the chronic infection.

Detection of HBV-, HDV- and human mRNAs in archival FFPE tissues by spatial transcriptomics

Sangeetha Mahadevan[1], Ricardo Ramirez[1], Anjali Rao[1], Christina Moon[1], Andrew James[1], Rosanna Win[1], Edith Vaquero[1], Subhra Chaudhuri[1], Kai-Hui Sun[1], Meghan Holdorf[1], Lauri Diehl[1]. [1]*Gilead Sciences, Foster City, United States*
Email: sangeetha.mahadevan1@gilead.com

Background and aims: Chronic infection with both hepatitis delta virus (HDV) and hepatitis B virus (HBV) results in the most severe form of viral hepatitis affecting 12–60 million people worldwide. While spatial transcriptomics (ST) is capable of spatially resolved, genome-wide RNA profiling, querying both viral and human mRNAs on FFPE tissue has not been evaluated to-date. Understanding the consequences of HBV/HDV co-infection on the host and characterizing the regional heterogeneity of each virus could potentially enable development of new therapies. In this study, we designed HBV- and HDV-specific probes to enable human and viral RNA co-detection in liver biopsy samples from a small cohort of HBV mono-infected, and HBV/HDV co-infected patients.
Method: FFPE sections from liver biopsies of 8 individuals (2 Healthy; 5 HBV mono-infected, and 1 HBV/HDV co-infected) were obtained from commercial sources. We designed 17 probes spanning HBV which recognize Surface, X and Core open reading frames (ORF). In addition, we designed probes against the DR1 sequence and anti-sense DNA to decipher between HBV-integration and cccDNA. For HDV, we designed sample specific probes which recognize HDAg ORF (HDAg mRNA, HDV anti-genome), HDV genome, HDV anti-genome from a non-coding region. These probes were spiked into the Human Transcriptome V2 probe set and applied to FFPE sections using the 10X Genomics Visium CytAssist Spatial Gene Expression workflow. A multiplex immunofluorescence (IF) stain detecting Hepatitis B surface antigen (HBsAg), Hepatitis B core antigen (HBcAg) and Hepatitis Delta antigen (HDAg) was performed on a serial section. Chromogenic *In Situ* Hybridization (CISH) from Advanced Cell Diagnostics using custom designed sense- and anti-sense Basescope probes was performed on a serial section to validate the signal from ST.
Results: There was a striking concordance between RNA signal from ST and CISH as well as protein signal from IF, validating the sensitivity and specificity of the ST approach. Areas that were positive for HBsAg and/or HBcAg by IF had a positive signal for their respective ST probes. HBsAg+, HBcAg- areas by IF had positive ST signal from Surface and X-ORFs, but not Core-ORF or DR1 probe, consistent with HBV integration. The HDV co-infected sample lacked both HBcAg (IF and ST) and cccDNA (ST) suggesting all HBsAg+ cells were a result of HBV integration. We identified evidence of cells containing only HDV markers suggestive of HDV-monoinfection, as well as cells containing both markers for HBsAg and HDV suggestive of HDV replication in HBV-integrated cells.
Conclusion: We successfully demonstrated that custom probe spike-ins can enable detection of HBV DNA/RNA, HDV RNA and human

mRNA in archival FFPE tissue. Future efforts will focus on applying this assay to larger sample sets with matched clinically relevant metadata.

Email: andre.goemer@rub.de

Background and aims: Hepatitis E virus (HEV) is a widespread zoonotic virus that can cause acute fulminant as well as chronic hepatitis and has been associated with a range of extrahepatic manifestations. Among these, renal injuries have been reported, including membranoproliferative glomerulonephritis with or without cryoglobulinemia and membranous glomerulonephritis. However, it remains unclear whether a productive infection of kidney related cells causes tissue pathology. We here aim to dissect whether HEV can infect kidney cell in vitro. In addition, we evaluate whether in patients HEV shows mutational signatures that correlate with compartmentalization.
Method: We here use state-of-the-art HEV cell culture models based on HEV-3 Kernow-C1 p6 to study the full replication cycle of HEV in renal cell lines and primary renal cells. In addition, we evaluate the efficacy of commonly used direct acting antivirals. Moreover, we quantify renal biomarkers as proxy for kidney damage in patients with chronic HEV infection (Trial Number NCT03282474). Subsequently, we tested these patients for HEV RNA in urine, stool and blood and analysed sequence composition of viral populations to get insights into intra-host diversity and compartmentalization.
Results: Nine out of nine tested human kidney cell lines allow viral entry, replication and production of infectious progeny particles, indicating that HEV can propagate in kidney-derived cell lines. In addition, more authentic primary kidney cells also support HEV infection. Interestingly, in these cells and cell lines the broad-spectrum antiviral ribavirin was less effective in inhibiting HEV replication. We then identified patients with chronic infection and elevated renal biomarkers who tested positive for HEV RNA in blood, stool, and urine. Followingly, we performed phylogenetic analysis and mutational fingerprinting which showed diversification into sample specimen. In particular, urine-derived virus was divergent from blood- and faecal-derived virus.
Conclusion: In conclusion, renal cells support HEV propagation in vitro with reduced ribavirin sensitivity. In addition, HEV showed compartmentalisation into distinct clusters that correlated with sample type. Taken together, these data suggest extrahepatic replication of HEV, which may clinically serve as a reservoir for patient relapse.

Macrophage-augmented organoids recapitulate the complex pathophysiology of viral diseases affecting the liver and devise advanced treatment strategies

Kuan Liu[1,2], Yining Wang[1], Jiajing Li[1], Jiahua Zhou[1], Ana Maria Gonçalves[3], Zhe Dai[4], Rick Schraauwen[5], Kimberley Ober-Vliegen[2], Martin van Royen[5], Monique M.A. Verstegen[2], Yijin Wang[4], Harry L.A. Janssen[1,6], Maikel P. Peppelenbosch[1], Pengfei Li[1], Amaro Nunes Duarte-Neto[3], Luc van der Laan[2], Qiuwei Pan[1]. *[1]Department of Gastroenterology and Hepatology, Erasmus MC-University Medical Center, Rotterdam, Netherlands; [2]Department of Surgery, Erasmus MC Transplant Institute, University Medical Center, Rotterdam, Netherlands; [3]Departamento de Patologia, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil; [4]School of Medicine, Southern University of Science and Technology, Shenzhen, Guangdong, China; [5]Department of Pathology, Erasmus MC-University Medical Center, Rotterdam, Netherlands; [6]Toronto Center for Liver Disease, Toronto General Hospital, University of Toronto, Toronto, Canada*
Email: k.liu@erasmusmc.nl

Background and aims: The liver is a preferential site for hepatotropic and non-hepatotropic virus invasions. The pathophysiology of viral diseases is complex and often evokes strong inflammatory responses. Currently available in vitro models mainly recapitulate the viral life cycle per se, but fail to model immune cells (such as macrophages) mediated pathogenesis. This study aims to build macrophage-augmented organoids (MaugOs) that simultaneously recapitulate viral infection and the resulting inflammatory response, and to devise advanced treatment strategies.
Method: Human intrahepatic cholangicyte organoids (ICOs) and hepatic macrophages were isolated from healthy donor tissues, and liver donor organ preservation fluid, respectively, Primary macrophages and THP-1 macrophages were derived from peripheral blood mononuclear cells and THP-1 monocyte cells, respectively. Organoids and different types of macrophages were integrated to form MaugOs. Two RNA viruses—hepatitis E virus (HEV) and SARS-CoV-2, and one DNA virus—monkeypox virus (MPXV), either primarily or secondarily affecting the liver, were taken as disease modalities.
Results: Time-lapse confocal showed ICOs and macrophages migrated and integrated into spheroids within 24 hours to form MaugOs. Immunofluorescent staining identified HEV transmission from initially infected ICOs to macrophages. A panel of inflammatory genes were activated in HEV-infected MaugOs. Integration of M1 (versus M0 or M2) polarized macrophages into HEV-infected organoids resulted in the strongest inflammatory response. This led to the effective killing of infected organoids and release of viruses into supernatant. In MaugOs, treatment of human bile inhibited HEV replication through the farnesoid X receptor and reduced inflammatory response partially through Takeda G protein-coupled receptor 5. The combination of NLRP3 inflammasome inhibitor and antiviral compound ribavirin simultaneously inhibited HEV replication and IL-1 beta production in MaugOs. Assessing the liver of a patient died from monkeypox, we observed MPXV infected hepatocytes, cholangiocytes and macrophages, triggering focal hepatitis. Consistently, hepatocyte differentiated and undifferentiated ICOs robustly supported productive infection of MPXV, which spread virus to macrophages and triggered inflammatory responses in MaugOs. Similarly, MaugOs were susceptible to SARS-CoV-2 infection and triggered a moderate inflammatory response.
Conclusion: MaugOs support the productive infections of these three viruses, which in turn triggered inflammatory responses. MaugOs can capture the multi-dimensions of viral pathophysiology, and enable the development of advanced treatment strategies aiming at simultaneously targeting the virus and inflammation.

Background and aims: Chronic viral hepatitis B and C (HBV and HCV) associated hepatocellular carcinoma (HCC) requires early detection for curative treatment. Unfortunately, HCC surveillance with abdominal ultrasound frequently misses early HCC cases. Our goal was to discover biomarkers for determining personalized HCC risk.
Method: Using semi-supervised machine learning, an HCC risk signature was devised from RNA-seq data of liver biopsies from two international nested case-control cohorts of precancerous HBV and HCV patients (training cohort: n = 56, validation cohort n = 51). All patients underwent strict HCC surveillance, with median observation times of 8.5 years (IQR: 5.9–12.2) and 9.5 years (IQR: 6.3–14.6) respectively. An explainable AI-approach leveraged scRNA-seq and RNA-seq deconvolution to elucidate the cellular components defining HCC risk. Immunohistochemistry staining and spatial transcriptomics localized their distribution in the liver. Paired liver transcriptome and clinical data was queried for additional risk factors. A serum protein was measured in a consecutive patient cohort (n = 188, median follow-up 5.9 years, IQR: 3.1–9.3).
Results: In the training cohort, a Cox score capturing HCC risk was calculated for every gene. A leave-one-out-cross-validation retained a 557 gene risk signature. High-risk stratified patients were at higher risk of HCC compared to low-risk patients ($p = 1.82^{*}10^{-9}$, p = 0.017 and p = 0.048 in the respective training cohort, the validation cohort, and an external microarray cohort of HCV patients). HCC patients with a high-risk profile in non-tumoral adjacent tissue in two external cohorts (n = 82 and n = 228) were also more likely to develop HCC recurrence than low-risk patients (p = 0.025 and 0.030). The risk signature reflects the expansion of fibrovascular tissue, a decline in hepatocytes, and higher transcriptional activity of IgA plasma cells localized in the portal areas of the liver.
A paired liver transcriptome and serum IgA analysis showed that serum IgA is a proxy for the liver transcriptome, and a separate cohort (n = 188) demonstrated serum IgA predicts HCC. Patients aged ≥40 with advanced fibrosis and serum IgA ≥400 mg/dL had a risk of 22.5% of HCC within 3 years, ~3-fold higher than patients with serum IgA 150–400 md/dL. Patients with serum IgA<150 mg/dL were free from HCC. Notably, repetitive serum sampling in 62 patients showed serum IgA was stable within these thresholds over a median of 3.7 years (IQR: 1.4–8.0) of follow-up.
Conclusion: In chronic viral hepatitis, intrahepatic IgA plasma cells associate with future HCC development. Serum IgA is a stable, non-invasive HCC risk stratifier that can be integrated into a convenient personalized HCC risk assessment. When coupled to more sensitive imaging techniques, it may improve early detection and patient survival.

SAT-338-YI

Using retrieval augmented generation to increase large language models accuracy: a proof-of-concept pipeline on european hepatitis C virus (HCV) guidelines

Mauro Giuffrè[1], Simone Kresevic[2], Saveria Lory Croce'[3], Dennis Shung[1]. [1]*Department of Internal Medicine (Digestive Diseases), Yale School of Medicine, Connecticut, USA, New Haven, United States;* [2]*Department of Engineering and Architecture, University of Trieste, Italy, Trieste, Italy;* [3]*Department of Medical, Surgical, and Health Sciences, University of Trieste, Italy, Trieste, Italy*
Email: gff.mauro@gmail.com

Background and aims: Large Language Models (LLMs) can potentially improve adherence to evidence-based medicine by providing clinical decision support. However, LLM responses to clinical questions are unstable and inaccurate. We propose a retrieval augmented generation (RAG) and prompt architecture pipeline to provide relevant and accurate responses based on published clinical guidelines regarding managing Hepatitis C Virus (HCV) infection.
Method: We created 15 questions about management recommendations for HCV derived from guideline text and non-text sources (i.e., graphical tables). We present an ablation study to demonstrate the differences in accuracy with each of the design choices in the pipeline and compare them to baseline GPT-4-Turbo using RAG based on the European Association for the Study of the Liver (EASL) guidelines on HCV with a structured format and accompanying custom prompt engineering and conversion of tables to lists. Our primary outcome is accuracy from text and non-text sources (i.e., digital image processing, DIP), with answers being graded as completely accurate vs. inaccurate by two expert hepatologists. The secondary outcome is to assess quantitatively the text similarity between expert-provided answers and LLM-provided answers using the OpenAI Score.
Results: The sole assessment of GPT-4 DIP performances initially resulted in 16% overall accuracy in extracting information from non-text sources. The customized LLM pipeline achieved 98.7% overall accuracy, which was significantly better than the GPT-4-Turbo alone (98.7% vs. 50.7%; P < 0.001). Incorporating in-context guidelines improved accuracy (72% vs. 50.7%; P = 0.02). When the in-context guidelines were cleaned, and tables were converted from images to csv files, accuracy improved to 80% (vs. 50.7%; P < 0.001); after the guidelines were formatted with a consistent structure and tables were re-formatted to lists, accuracy improved further to 92% (vs. 50.7%; P < 0.001). Finally, adding custom prompt engineering led to an improvement in accuracy of 98.7% (vs. 50.7%; P < 0.001), with no further improvement despite few-shot learning with 54 question-answer pairs. We also found systematic statistically significant differences in similarity metrics when the outputs of the in-context experiments were compared to the baseline outputs, as reported in (0.959 vs. 0.0945, P < 0.001). At the same time, we did not find any statistically significant difference when comparing similarity metrics across all the in-context experiments, not reflecting a discrepancy in accuracy when outputs were qualitatively graded by the experts.
Conclusion: Our study demonstrates the potential of LLMs to provide accurate clinical responses based on clinical guidelines. Our pipeline highlights the importance of appropriate guideline formatting for effective LLM integration in future clinical decision support systems.

Sequential administration of siRNA with an mRNA encoding clearance profile associated variants of HBsAg exhibits significant antiviral activity in AAV/HBV mouse model

Aditi Deshpande[1], Bharat Dixit[1], Aileen Rubio[1], Lei Qiugang[2], Sun Ya[3]. [1]*ClearB Therapeutics, Concord, United States;* [2]*Wuxi AppTech, Shanghai, China;* [3]*Wuxi Apptech, Shanghai, China*
Email: adeshpande@clearbtherapeutics.com

Background and aims: We previously reported declines in serum HBsAg levels after administration of an mRNA vaccine comprised of two modified HBsAg sequences encoding functional cure epitopes [EASL 2024 poster #1450] in the Hydrodynamic tail vein injection (HDI) model of persistent Hepatitis B infection. It has been shown in preclinical studies that the effectiveness of therapeutic vaccines can be increased through the knockdown of HBsAg expression via siRNA (Michler, T., et al. 2020. Gastroenterology 158, pp1762–1775). In this study, the bivalent mRNA vaccine in combination with siRNA AD66810 (WO2018/195165; which targets the X gene expression in the HBV genome) was assessed for efficacy in AAV/HBV murine model.
Method: Male C57BL/6 mice were infected with AAV8 virus carrying 1.3 copies of the HBV genome (genotype D, serotype ayw) at 5×10^{10} viral genome equivalents to establish a stable infection of ~4 log IU/ml HBsAg (Yang D, et al 2014 Cell Mol Immunol 11 pp718). A single dose of siRNA AD66810 at 3 mg/Kg was given on day 0, followed by three biweekly intramuscular (IM) injections of mRNA vaccine given on days 14, 28 and 42 at dose levels of 1, 5 and 20 µg. Mice were monitored over time for serological markers of HBsAg, HBV DNA and cellular immune response at end of study.
Results: Mice in the AAV/HBV model treated with siRNA AD66810 at 3 mg/Kg followed by 1, 5 or 20 µg dose levels of mRNA displayed 1.2, 1.6 and 1.2 log IU/ml HBsAg reduction respectively from baseline one-week post-last dose compared to 0.7 log IU/ml HBsAg reduction seen in siRNA monotherapy group. The HBV DNA had similar trend in reduction as HBsAg in plasma. The mice in the placebo group resulted in no significant change in plasma HBsAg and HBV DNA levels over the study duration. The cellular immune response tested by ELISPOT demonstrated significantly higher splenocyte cells expressing IFN-γ compared to the siRNA monotherapy group.
Conclusion: Sequential administration of a single dose of siRNA AD66810 followed by therapeutic vaccination using mRNA encoding two modified HBsAg sequences was highly efficacious in an AAV/HBV murine model compared to siRNA monotherapy. These findings further support the development of combination therapy of anti-viral siRNA and therapeutic mRNA vaccination in Chronic Hepatitis B patients.

SAT-340-YI

Human intestinal enteroids as a new in vitro model to study hepatis E virus

Nanci Santos-Ferreira[1], Xin Zhang[1], Johan Neyts[1], Suzanne J.F. Kaptein[1], Joana Rocha-Pereira[1]. [1]*KU Leuven-Department of Microbiology, Immunology and Transplantation, Rega Institute, Laboratory of Virology and Chemotherapy, Leuven, Belgium*
Email: nanci.ferreira@kuleuven.be

Background and aims: Hepatitis E virus (HEV) is an emerging viral pathogen responsible for acute viral hepatitis globally. No specific vaccines or antivirals against HEV (besides ribavirin) are available to date. This is partly due to fundamental limitations of its *in vitro* cultivation, a shared feature with other hepatotropic and enteric viruses. While HEV is an enteric virus transmitted fecal-orally and shed in high titers in the stool, little attention has been given to the role and contribution of the gut compartment in HEV-induced disease. HEV replication in primary intestinal cells and human liver-derived organoids has been reported (PMID: 31727684; 35044825). Viral dissemination between the gut and liver is poorly understood, and whether the gut functions as an HEV reservoir is unknown. To tackle this and other knowledge gaps in HEV research, we developed an infection model for HEV using Human Intestinal Enteroids (HIEs). HIEs are tissue-derived non-transformed *in vitro* 3D cell cultures arranged in a crypt-villus structure that incorporate the physiological features of the intestinal epithelium, including the presence of different cell populations (enterocytes, goblet cells, enteroendocrine and Paneth cells).
Method: Human fetal ileum 3D-HIEs were used for infection with HEV gt 1 Sar55/S17, HEV gt 3 Kernow-C1 p6 (HEV-p6) strain or p6-G1634R (HEV-p6-R) that contains a fitness-enhancing mutation. HEV infection was performed employing: a) differentiated 3D-HIEs; b) differentiated 2D-HIEs in a transwell system; and c) electroporation of HIEs with full-length HEV capped RNA or HEV-p6-luciferase (luc) subgenomic RNA.
Results: Infection of 3D-HIEs with HEV-p6-R resulted in a ~ 1 $\log_{10}$ increase in HEV RNA up to 7 days post-infection (dpi) in an MOI-dependent manner, with replication peaking at 1 dpi. Infection of HIEs in transwell yielded similar replication levels, with shedding mainly to the apical side of the intestinal epithelial layer. Importantly, electroporation of HIEs with full length genome of HEV-p6 or HEV-p6-R resulted in a sustained increase in viral load over time, reaching 3.1×10^5 and 5.5×10^5 vRNA copies/ml, respectively, at 11 days post electroporation (dpe). Likewise, electroporation of HEV-p6-luc resulted in a 20-fold increase in luciferase signal at 11 dpe; a 5-fold increase was observed upon electroporation of HEV gt1 Sar55/S17-luc. Immunostainings of infected HIEs with a capsid-targeting antibody showed a strong presence of viral antigens.
Conclusion: We here successfully established an HEV cultivation model in HIEs, with electroporation being the most efficient method. We are now determining which specific intestinal cell types are infected. Our next goal is to establish a gut-liver axis model using an organ-on-chip system to gather information on HEV dissemination and host-pathogen interactions, which may advance the discovery of novel HEV therapeutics.

SAT-341

Discovery of a pan-genotypic hepatitis E virus replication inhibitor

Xin Zhang[1], Mara Klöhn[2], Sivi Ouwerkerk-Mahadevan[3], Michelle Jagst[4], Liesbeth Vereyken[3], Peter Verboven[3], Daniel Todt[2], Tim H.M. Jonckers[3], Lotte Coelmont[1], Helen Fletcher[5], Kirandeep Samby[5], Anil Koul[5], Johan Neyts[1], Eike Steinmann[2], Suzanne J.F. Kaptein[1]. [1]*KU Leuven Department of Microbiology, Immunology and Transplantation, Rega Institute for Medical Research, Laboratory of Virology and Chemotherapy, Leuven, Belgium;* [2]*Department of Molecular and Medical Virology, Ruhr University Bochum, Bochum, Germany;* [3]*Janssen Research and Development, Janssen Pharmaceutica N.V., Beerse, Belgium;* [4]*Department of Molecular and Medical Virology, Ruhr University Bochum, Institute of Virology, University of Veterinary Medicine Hannover, Bochum/Hannover, Germany;* [5]*Janssen Global Public Health, Janssen Pharmaceutica, Beerse, Belgium*
Email: xin.zhang@kuleuven.be

Background and aims: Hepatitis E virus (HEV; *Orthohepevirinae* subfamily within the *Hepeviridae* family) constitutes a substantial public health burden with around 20 million human infections annually, including 3.3 million symptomatic cases. Most importantly, appropriate treatment options for HEV-infected pregnant women and immunocompromised patients are lacking, underscoring the pressing requirement for the development of safe and efficacious pan-genotypic therapies to combat HEV.
Method: Different luciferase-based HEV subgenomic replicon systems were used to screen a small library of pre-selected molecules from an antiviral program at Janssen Pharmaceutica. Quantitative assessment of viral RNA replication was achieved by measuring the Gaussia luciferase (GLuc) reporter in cell culture supernatant. The antiviral effect of the selected hit compound on HEV infection was

corroborated by measuring viral antigens and viral RNA. Subsequently, the prophylactic and therapeutic efficacy of the compound was assessed in the athymic nude rat HEV infection model by assessing the viral kinetics in feces and the viral load in different tissues.
Results: We report on the identification of JNJ-64779117 which exerts nanomolar, pan-genotype antiviral activity against HEV in different cell types, including primary human hepatocytes (PHH). JNJ-64779117 is a nucleoside analogue and is assumed to target the viral polymerase as its 5′-triphosphate form. JNJ-64779117 has a promising pharmacokinetic and safety profile in both rats and dogs. In addition, the compound exhibited strong antiviral activity in the nude rat HEV infection model. Remarkably, initiating treatment 5 or 10 days after infection led to a rapid and significant reduction in viral load within 4 days. Moreover, at the highest dose, suppression of viral RNA levels in feces and liver tissue was effectively maintained until the end of the study at day 17 or 22 after treatment discontinuation. An additive effect was observed *in vitro* when combining JNJ-64779117 with ribavirin, a drug that is used off-label for the treatment of HEV infections.
Conclusion: Altogether, these results clearly illustrate the potential of JNJ-64779117 as a potent inhibitor of HEV across genotypes and the *Orthohepevirinae* subfamily. JNJ-64779117 may be an interesting candidate for the treatment of HEV infections.

PegIFNα treatment in NUC-suppressed HBV/HDV-infected mice with high numbers of HDV-monoinfected cells reduces HDV infection below the limit of quantification

Annika Volmari[1,2], Tassilo Volz[1,2], Lena Allweiss[1,2], Marc Luetgehmann[2,3], Simon Fletcher[4], Meghan Holdorf[4], Robert Muench[4], Maura Dandri[1,2]. *[1]University Medical Center Hamburg-Eppendorf, I. Medical Department, Center for Internal Medicine, Hamburg, Germany; [2]German Center for Infection Research (DZIF), Hamburg-Lübeck-Borstel-Riems site, Germany; [3]University Medical Center Hamburg-Eppendorf, Institute of Microbiology, Virology and Hygiene, Hamburg, Germany; [4]Gilead Sciences, Foster City, California, United States*
Email: a.volmari@uke.de

Background and aims: Treatment of patients with chronic hepatitis D (CHD) remains challenging. The relative amounts and intrahepatic distribution of HBV+ and HDV+ cells may vary significantly. To which extent viral distribution is affected by current treatments and whether the intrahepatic virological landscape may also impact drug efficacy remain unclear. Nucleos(t)ide analogs (NUCs) suppress HBV replication and limit intrahepatic spread but do not target HDV, and it remains uncertain whether NUCs also affect HDV spread within the liver. PegIFNα is often used to treat CHD patients, and studies in immunodeficient humanized mice have demonstrated the ability of pegIFNα to suppress patient-derived HDV strains *(Giersch, JHEPRep 2023)*. This study aimed to investigate how treatment with NUCs and pegIFNα impact HDV intrahepatic dissemination, replication activity, and persistence *in vivo* using human liver chimeric mice.
Method: Treatment of humanized mice with the NUC lamivudine (LAM, 0.4 mg/ml in drinking water) was started 3 weeks after HBV/HDV coinfection during the ramp-up phase of viral spreading. After 4 weeks of NUC treatment, one group of mice additionally received pegIFNα (i.p., 25 ng/g body weight) twice a week for 8 weeks, while the control group continued to receive LAM. Virological parameters were analyzed using qPCR and immunofluorescence (IF) staining. Mice stably infected with HBV and superinfected with HDV received 8 weeks pegIFNα for comparison.
Results: LAM treatment initiated during the spreading phase of both viruses reduced HBV DNA in the serum (Δ 1.2 $\log_{10}$ in 4w) and slowed down the intrahepatic spread of HBV but had no effect on the ramp-up phase of HDV viremia (Δ2.9 $\log_{10}$; median HDV RNA 9×10^6 copies/ml). IF imaging showed strong HDV dissemination, resulting in large areas harboring mono-infected HDAg+ cells. ALT levels transiently increased during HDV spread and strongly correlated with HDV RNA in the serum ($r = 0.8047$; $p < 0.0001$). Adding pegIFNα reduced all HDV markers in serum and liver below the LLOQ by 8 weeks of treatment, while levels of intrahepatic HDV RNA did not decrease in animals not receiving pegIFNα (12w LAM). In contrast, 8-week pegIFNα treatment in HDV superinfected mice, where most human hepatocytes are HBV/HDV co-infected, only reduced intrahepatic HDV RNA by 0.5 $\log_{10}$. Expression of human interferon-stimulated genes was enhanced during HDV spread in LAM-suppressed mice (ISG15 1.5 $\log_{10}$) compared to pretreatment and increased further upon treatment with pegIFNα (ISG15 0.7 $\log_{10}$).
Conclusion: NUC treatment in HBV/HDV co-infected mice during the viral ramp-up phase limits HBV intrahepatic spread but does not hinder further HDV dissemination. In a setting where HDV largely persisted in the absence of HBV co-infection, pegIFNα treatment profoundly impacted HDV, nearly clearing HDV infection.

SAT-343

Impact of hepatitis C virus direct acting antivirals on hepatocellular carcinoma evolution

Stanislas Pol[1,2], Laurent Lam[3], Charlotte Mouliade[1,2], Fabrice Carrat[3,4]. *[1]AP-HP.Centre Université Paris Centre, Groupe Hospitalier Cochin Port Royal, DMU Cancérologie et spécialités médico-chirurgicales, Service des Maladies du foie, Paris, France, Paris, France; [2]Université Paris Cité, F-75006, Paris, France; [3]Sorbonne Université, INSERM, Institut Pierre Louis d'Épidémiologie et de Santé Publique, IPLESP, Paris, France; Sorbonne Université, Department of Public Health, Paris, France; [4]Sorbonne Université, Department of Public Health, Assistance Publique-Hôpitaux de Paris, Hôpital Saint-Antoine, Paris, France, Paris, France*
Email: stanislas.pol@aphp.fr

Background and aims: The clinical impact of direct-acting antivirals (DAA) in patients with HCV-related hepatocellular carcinoma (HCC) remains unknown. We aimed to determine the potential benefits of DAA in patients with HCV-related HCC.
Method: We analyzed the French national health insurance system (Système National des Données de Santé-SNDS) which covers more than 99% of the French population. We identified patients with HCV-related HCC between 2013 and December 2021. The impact of DAA exposure after HCC diagnosis on overall mortality, liver transplantation (LT), and HCC recurrence after curative therapy were quantified using marginal structural models and inverse probability of treatment weighting (IPTW) accounting for time dependent exposure and confounders.
Results: Among the 4760 patients with HCV-related HCC, 2585 deaths (54.3%) occurred during the follow-up. The incidence and risk of mortality was reduced after DAA exposure (incidence rate (IR) of 306/1000 person-years (PY) before DAA exposure and 184/1000 PY after DAA exposure, adjusted hazard-ratio (aHR) 0.81; 95% CI 0.74–0.88; $p < 0.001$). A total of 418 LT (8.8%) was performed during the follow-up (IR of 35/1000 PY before DAA exposure and 34/1000 PY after DAA exposure, aHR 0.99; 95% CI 0.78–1.25; $p = 0.93$). DAA exposure was associated with a significant reduction of HCC recurrence in patients undergoing a curative therapy for HCC (aHR 0.53; 95% CI 0.28–0.98; $p = 0.04$). HCC relapse after HCC-related LT occurred in 52 patients out of 225 patients with LT after HCC and naive for HCV treatment. The incidence rates of HCC relapse after LT were 77/1000 PY of DAA exposure and 55/1000 PY of no DAA exposure (aHR 1.30, 95% CI 0.73, 2.33; $p = 0.37$).
Conclusion: After a first diagnosis of HCV-related HCC, DAA treatment, compared to no DAA treatment, was associated with a reduced risk of mortality in patients with HCV-related HCC and a reduced risk HCC recurrence after curative therapy for HCC. DAA exposure did not limit access to transplantation in patients with HCV-related HCC and was not found associated with an increased risk of HCC recurrence after LT. Our findings support the recommendation of DAA therapy in all cases of HCV-related HCC.

SAT-348-YI

Hepatitis B virus-induced collagen VI expression by hepatocytes contributes to liver fibrosis by promoting stellate cell activation

Zakaria Boulahtouf[1], Alessia Virzì[1], Lea Girard[1], Emma Gerges[1], Julien Moehlin[1], Laura Heydmann[1], Sarah Durand[1], Marine Oudot[1], Fabio Giannone[1,2,3], Patrick Pessaux[1,2,3], Eloi Verrier[1], Thomas Baumert[1,2,4], Joachim Lupberger[1]. [1]*Institute for Translational Medicine and Liver Disease (ITM), Inserm U1110, Université de Strasbourg, Strasbourg, France;* [2]*Pôle Hépato-digestif, Strasbourg University Hospitals, Strasbourg, France;* [3]*Institut Hospitalo-Universitaire (IHU), Université de Strasbourg, Strasbourg, France;* [4]*Institut Universitaire de France (IUF), Paris, France*
Email: joachim.lupberger@unistra.fr

Background and aims: Chronic infection with hepatitis B virus (HBV) is a main cause of the progression of chronic liver disease from fibrosis to cirrhosis and cancer. Despite an efficient control of HBV infection by antivirals, liver disease can progress in patients. Whereas the HBV life cycle is well characterized, the understanding of virus-induced fibrosis and HCC is still only partially understood. Stellate cell activation to myofibroblasts differentiation is a hallmark of liver fibrosis characterized by collagen I and IV deposition to the extracellular matrix. Here we aimed to identify the molecular mechanisms of HBV-induced liver fibrosis and to uncover new therapeutic concepts targeting liver disease progression.
Method: Proteomic analyses of HBV-infected HepG2-NTCP cells were performed using liquid chromatography tandem mass spectrometry. Results were validated in primary human hepatocytes and studied mechanistically using cell culture, primary human stellate cells and hepatocytes and liver transcriptomics from HBV patients. The impact of viral proteins on signaling pathways and stellate cell activation were studied using lentiviral expression vectors, FACS and immunoblotting.
Results: Genome-wide proteomic analyses in infected cells revealed a dysregulation of signaling associated with extracellular matrix (ECM) remodeling during HBV infection. Among these we identified collagen VI being upregulated in HBV-infected hepatocytes (HepG2 and primary human hepatocytes) and secreted to the medium. Notably, *COL6A1* silencing attenuated viral transcription, suggesting an immediate pro-viral role for collagen VI. By studying the effect of signaling inducers with link to chronic liver disease we revealed a functional link between Akt/mTOR signaling and collagen VI expression in hepatocytes. Studying the individual viral proteins, we found that predominantly HBs-expressing cells stimulated collagen VI expression. In HBV-infected patients, liver transcriptomic data showed significantly increased collagen VI levels associated with the severity of liver fibrosis. As collagens promote myofibroblast differentiation, we demonstrate that both, recombinant collagen VI and supernatants of hepatocytes overexpressing collagen VI activated patient-derived stellate cell isolates emphasizing the role of collagen VI in promoting hepatic fibrosis.
Conclusion: HBV infection of hepatocytes and HBsAg expression directly triggers Akt signaling and collagen VI secretion that contributes to stellate cell activation in the liver. Our proteomic atlas reveals a previously unrecognized role for collagen VI in HBV pathogenesis and disease biology. The understanding of these mechanisms will contribute to unravel novel therapeutic candidate targets for liver fibrosis and attenuation of cancer risk.

Email: keerthihan.thiyagarajah@pei.de

Background and aims: Hepatitis D virus (HDV), a defective RNA virus with estimated 60 million global infections induces the most severe form of viral hepatitis. To this day, many steps of the HDV life cycle remain enigmatic and diagnostic screenings are suboptimal leading to underestimation. Highly sensitive HDV-specific antibodies are urgently needed for research and diagnosis. Despite the necessity, only limited research is conducted on characterizing HDV specific antibodies. Thus, we first generated highly sensitive HDV-specific polyclonal antibodies and ultimately aimed to characterize the obtained antibodies with respect to the recognized epitopes.
Method: Since HDV only encodes for two protein isoforms termed S- and L-HDAg, which differ by a C-terminal extension in L-HDAg, we immunized two rabbits with purified S-HDAg either in its native or in a denatured form. Epitope mapping of obtained hyperimmune sera was performed using peptide arrays with 15 amino acid long overlapping synthetic peptides covering the full-length S-HDAg protein.
Results: Epitope mapping using the obtained hyperimmune sera revealed several highly reactive B-cell epitopes in S-HDAg. Interestingly, antisera obtained by immunization with denatured S-HDAg were more polyclonal as reflected by more recognized epitopes. For instance, one epitope localized within the oligomerization domain of S-HDAg was exclusively recognized during immunization with the denatured protein. Projection of this epitope into a 3D model of S-HDAg revealed steric shielding of the epitope in the native octameric state of the protein likely preventing recognition of the epitope by B-cells in the native state. In contrast to this, one epitope within the second arginine rich motif was also recognized during immunization with native S-HDAg, likely due to less steric hindrance and higher accessibility in the oligomeric state as reflected by the 3D model.
Conclusion: We identified highly immunogenic S-HDAg epitopes, which are accessible in the native conformation of S-HDAg and therefore are promising target sequences for the generation of highly sensitive HDAg-specific monoclonals useable for diagnosis and research. Synthetic/recombinant variants of these epitope sequences can even be used as potent vaccine candidates. Furthermore, the well characterized sera obtained in this study can be used for CLSM-based analysis of HDV life cycle and for Western blot and ELISA based quantitative analysis of HDAg.

Identification of IGF2BP1 as a novel host factor in regulating HBV RNA stability via N6-methyladenosine modification dependent manner

Deyao Li[1], Jing Ning[2], Xiangmei Chen[3]. [1]*School of Basic Medical Sciences, Peking University Health Science Center, Beijing, China;* [2]*Peking University Third Hospital, Beijing, China;* [3]*School of Basic Medical Sciences, Peking University Health Science Center, Beijing, China*
Email: xm_chen6176@bjmu.edu.cn

Background and aims: Hepatitis B virus (HBV) infection is the primary cause of chronic hepatitis B, cirrhosis, and hepatocellular carcinoma world widely. During HBV replication, HBV RNA undergoes post-transcriptional regulation by host cells which primarily relies on various host RNA binding proteins. However, the detailed mechanisms underlying post-transcriptional regulation of HBV RNA remain unknown. Herein, we investigated the role of RNA binding protein IGF2BP1 in the process of HBV replication.
Method: The host proteins associated with HBV Dane particles was analyzed by mass spectrometry. Gene silencing and ectopic over-expression were used to detect the function of IGF2BP1 in regulating

HBV replication. RNA turnover, RNA pull-down, and RNA immunoprecipitation assays were used to investigate the stability and binding between IGF2BP1 and HBV RNAs.
Results: Our study identified IGF2BP1 as an RNA binding protein that can be encapsulated into HBV Dane particles. According to the HBV replication cell model, the HBV infection cell model, and the HBV replication mouse model, we confirmed that IGF2BP1 promotes HBV replication. To elucidate the underlying mechanism, we found that IGF2BP1 enhanced the stability of all five HBV RNAs through its KH domain. IGF2BP1 recognized and bound to m6A modification sites on HBV RNAs, consequently promoted HBV RNA expression. This increased HBV RNA expression led to elevated protein expression and the formation of rcDNA, ultimately enhancing HBV replication.
Conclusion: Our study demonstrated IGF2BP1 as a critical host factor in enhancing the stability of HBV RNAs and facilitating HBV replication which provided a novel target for the development of anti-HBV drugs.

SAT-363

Hepatocellular carcinoma development post hepatitis C virus cure is associated with distinct changes in the dynamics of the soluble inflammatory milieu

Moana Witte[1,2,3,4], Carlos Oltmanns[1,2,3,4], Jan Tauwaldt[1,2,3,4], Hagen Schmaus[1,2,3,4], Jasmin Mischke[1,2,3,4], Leon Kalix[5,6], Gordon Grabert[5,6], Mara Bretthauer[5,6], Katja Deterding[1], Benjamin Maasoumy[1], Heiner Wedemeyer[1], Tim Kacprowski[5,6], Anke R.M. Kraft[1,2,3,4], Markus Cornberg[1,2,3,4]. *[1]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany; [2]TWINCORE Center of Experimental and Clinical Infection Research, Hannover, Germany; [3]German Center for Infection Research (DZIF), Hannover, Germany; [4]Center for Individualized Infection Medicine (CiiM), Hannover, Germany; [5]Braunschweig Integrated Centre for Systems Biology (BRICS), Technische Universität Braunschweig, Braunschweig, Germany; [6]Division Data Science in Biomedicine, Peter L. Reichertz Institute for Medical Informatics of Technische Universität Braunschweig and Hannover Medical School, Braunschweig, Germany*
Email: witte.moana@mh-hannover.de

Background and aims: Chronic hepatitis C virus (HCV) infection can lead to cirrhosis and an increased risk of developing hepatocellular carcinoma (HCC). Despite successful viral elimination by direct-acting antiviral therapy (DAA), some individuals may still experience sequelae such as HCC. In a previous study, we have demonstrated persistent changes in the inflammatory milieu in chronic HCV patients that are closely related to cirrhosis and the extent of liver damage (EASL 2023). In our current study, we aim to further decipher the role of inflammatory milieu changes and direct interactions in the development of HCC after viral elimination.
Method: The study cohort comprises 92 chronic HCV patients treated with DAA therapy at the Hannover Medical School and studied over several time points. 31 of the 92 patients developed HCC during (n = 3) or after DAA therapy (26/31 male, mean age 59, elastography 24.7 ± 18 kPa) and were compared to 61 propensity score-matched patients who did not develop HCC (52/61 male, mean age 58, mean elastography 33.5 ± 19 kPa). Plasma samples were available at baseline, end of treatment and long-term follow-up (median: 96 weeks), and plasma levels of 92 soluble immune mediators (SIM) were measured by Olink proteomics. 39 inactive HBsAg+ carriers served as controls to validate previous results.
Results: In both cohorts, over 25 SIM remained altered at follow-up compared to HBsAg+ carriers, confirming previous findings. Compared to patients who did not develop HCC, 14 SIM were significantly altered in patients who developed HCC (adjusted p value <0.05). 12 of the 14 SIM were elevated in patients who developed HCC, including hepatocellular growth factor (HGF), the interleukins IL6 and IL8 and the protease uPA, while SCF was decreased. A network analysis demonstrated close interactions between 9 out of the 14 SIM and linked them to pathways in cancer or transcriptional misregulation in cancer (KEGG hsa05202, hsa05200). Patients who developed HCC after viral elimination showed different dynamics for HGF and IL8. Levels remained high during all time points in the HCC group, while patients who did not develop HCC showed a significant decrease over time (adjusted p value <0.05).
Conclusion: Our study validates prior data indicating that individuals with chronic HCV and cirrhosis maintain increased levels of various soluble immune mediators compared to controls. Specifically, the sustained persistence or absence of dynamics in plasma levels of HGF and IL8, recognized for their association with carcinogenesis, in patients developing HCC post HCV cure underscores the potential impact of the soluble inflammatory milieu on HCC risk following viral elimination.

SAT-364

Mathematical modeling of hepatitis B and D viral kinetics during coinfection in humanized mice suggests differences in their infectivity

Ashish Goyal[1], Takuro Uchida[2], Grace N Makokha[3], Hiromi Abe-Chayama[4], Yuji Ishida[5], Chise Tateno[5], Harel Dahari[1], Kazuaki Chayama[3,6]. *[1]The Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, IL, United States; [2]Department of Gastroenterology, Faculty of Medicine, Oita University, Yufu, Japan; [3]Hiroshima Institute of Life Sciences, Hiroshima, Japan; [4]Medical Specialist Graduate Education and Research, Hiroshima University, Hiroshima, Japan; [5]PhoenixBio Co., Ltd., Hiroshima, Japan; [6]RIKEN Center for Integrative Medical Sciences, Yokohama, Japan*
Email: harel.dahari@gmail.com

Background and aims: Understanding of hepatitis D virus (HDV) and hepatitis B virus (HBV) dynamics during acute co-infection in humans is lacking due to the uncertainty of the exact time of infection and sparse kinetic data. We aim to provide insights into HDV/HBV acute co-infection by studying frequently sampled kinetic data in uPA/SCID mice with humanized livers from inoculation to steady state using a mathematical modeling approach.
Method: 4 mice were inoculated with co-infected serum of HDV RNA (6.0 log cp/ml) and HBV DNA (6.0 log cp/ml). HBV DNA and HDV RNA levels were frequently measured from blood samples up to 12 weeks post infection. Using the model selection theory, we identified a mathematical model that best reproduced the observed serum HBV and HDV kinetics. The model incorporated four different states of human hepatocytes (termed cells), (i) uninfected, (ii) HBV mono-infected, (iii) HDV mono-infected, and (iv) HBV/HDV co-infected. Cells were allowed to transition into infectious states by one virus at a time. Furthermore, in HBV and HBV/HDV infected cells, intracellular processes leading to the production of HBV virions was described as in [Hepatology 2023, 78 (Suppl.1): S530–S531]. This intracellular model included saturation in pre-genomic RNA (pgRNA) production from covalently closed circular DNA (cccDNA), and linear production rates of relaxed circular DNA (rcDNA) from pgRNA and rcDNA secretion. In contrast, HDV virions were assumed to be produced by co-infected cells at a constant rate. Several models exploring the impact on intracellular HBV processes by HDV in co-infected cells as well as differences in infectivity for different cell-infection status were tested. We fit the models to the observed serum viral data using a population, nonlinear mixed-effects approach.
Results: The serum kinetics of HBV and HDV in all 4 humanized mice was successfully recapitulated using the best model which assumed different infectivity based on virus and cell type. HDV infectivity of uninfected cells (2×10^{-11} day^{-1}.copies^{-1}) is estimated to be ~40-fold lower compared to HBV infectivity of uninfected cells (8×10^{-10} day^{-1}.copies^{-1}). Moreover, HBV infectivity of HDV mono-infected cells (1.7×10^{-3} day^{-1}.copies^{-1}) is estimated to be many-fold higher compared to HDV infectivity of HBV mono-infected cells (2.6×10^{-9} day^{-1}.copies^{-1}). Analysis also suggests that due to the

presence of HDV, cccDNA per infected cell accumulates to a lower level in co-infected cells (~1.9 copies) compared to HBV mono-infected cells (~5 copies). All parameters were identifiable in the best model.
Conclusion: Modeling suggests that different HBV and HDV infectivity of uninfected and mono-infected cells plays a pivotal role in reproducing the observed viral kinetics from infection to steady state in humanized mice.

SAT-365
Hepatitis B virus mutations associated with hepatocellular carcinomas are regulated by HLA genotype
Aiko Sakai[1], Masaya Sugiyama[1]. [1]*National Center for Global Health and Medicine, Ichikawa, Japan*
Email: msugiyama@hosp.ncgm.go.jp

Background and aims: Several viral mutations have been reported as predictors of the risk of developing hepatocellular carcinoma (HCC) in chronic hepatitis B. In particular, the C1653T and A1762T/G1764A mutations in the core promoter region have been largely reported, but these mutations have sometimes not been reproduced, depending on study reports. The causes of the uncertain reproducibility remain unclear, in part because it is unclear whether it is due to differences in patient populations between studies. On the other hand, in GWAS-based analyses, several groups including ours have reported genetic polymorphisms in the HLA-DPB1 region in patients with HCC development, and the importance of HLA genotypes has attracted attention. In this study, patients were classified according to their HLA-DPB1 genotypes, and the patterns of HBV mutations associated with hepatocarcinogenesis were analysed.
Method: A total of 2996 cases were enrolled in this multicentre study in Japan. These included 408 cases of CHB, 307 cases of HCC and 2281 healthy subjects. In this study, among the HLA-DPB1 genotypes, we focused on HLA-DPB1*05:01 (about 40%) and HLA-DPB1*02:01 (about 20%), which are commonly carried by Japanese, and established four groups of homo- and heterozygotes of each. Within these four groups, HBV sequence comparisons were made between CHB and HCC matched for age, sex and HBV genotype.
Results: In the analysis of the patient carrying HLA-DPB1*05:01 as homozygote, the A1762T/G1764A mutation in the core promoter region was significantly detected in the HCC population compared to the CHB population ($p < 0.001$, OR = 8.8: 95%CI 4.4–17.8). In addition, the C1653T mutation was significantly detected in the HCC population with heterozygous HLA-DPB1*05:01 compared to the CHB population ($p < 0.001$, OR = 4.4: 95%CI 2.0–9.6). In contrast, analysis of the homozygous HLA-DPB1*02:01 population revealed a significant C129 T mutation in the PreS2 region ($p < 0.02$, OR = 23.8: 95%CI 4.5–119.8). Similarly, analysis of the HLA-DPB1*02:01 heterozygote population revealed a significant C129T mutation in the PreS2 region ($p < 0.01$, OR = 33.1: 95%CI 11.3–96.5). The C129T mutation of the HBV genome in the PreS2 region was novel.
Conclusion: The pattern of HBV mutations associated with HCC development varies according to HLA genotype. Stratification using human disease-related genes partly explains why viral mutations differ between individuals. This stratification approach to risk assessment may lead to useful prognostication.

Immune correlates of HDV clearance in chronic HDV infected patients
Arshi Khanam[1], Abutaleb Ameer[2], Alip Ghosh[3], Furkan Kaysin[4], Cihan Yurdaydin[5], Shyamasundaran Kottilil[3]. [1]*Institute of Human Virology University of Maryland School of Medicine, Baltimore, United States;* [2]*GW School of Medicine and Health Sciences, Washington DC, United States;* [3]*Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States;* [4]*Koc University School of Medicine, Intanbul, Turkey;* [5]*Koc University School of Medicine, Istanbul, Turkey*
Email: akhanam@ihv.umaryland.edu

Background and aims: Chronic hepatitis delta (CHD) virus infection causes the most severe form of viral hepatitis due to rapid progression towards end-stage liver disease. In the presence or absence of antivirals, very few patients resolve CHD. An enhanced understanding of what derives the resolution of CHD infection is critical to project future therapeutic strategies. We aimed to investigate hepatitis D virus (HDV)-specific T cell responses to determine the immune correlates of HDV cure.
Method: We examined peripheral blood transcriptomic profiles of patients who are chronically infected with HBV and HDV (CHB/CHD-coinfection, n = 39) and compare them with those who cleared CHD (CHD-resolved, n = 11) and who cleared both CHB and CHD (CHB/CHD-resolved, n = 3) to identify molecular signatures that can predict the correlates of viral clearance and disease severity. Virus-specific (HBV and HDV) functions of peripheral T lymphocytes (CD4 and CD8 T cells) were also tested by flow cytometry.
Results: Transcriptomic profile revealed that MERTK, CDKN1C, RIPK3, and MECOM genes were significantly upregulated in CHB/CHD-coinfection likely contributing to inflammation, fibrosis and tumor development in these patients. While, patients with resolved CHD had upregulated gene expressions of immune recovery such as T cell receptor repertoire, HLA-DRA, CD28, and CD69, implying improved T cell functions associated with HDV clearance. Investigation of virus-specific T cell responses further revealed improved HDV-specific CD4/CD8 T cell functions in terms of IFN-gamma (CD4: $p = 0.001$, CD8: $p = 0.0003$), TNF-alpha (CD4: $p = 0.0001$, CD8: $p = 0.0008$) and IL-21 (CD4: $p = 0.02$, CD8: p = ns) secretion in CHD-resolved patients than CHD-viremic individuals. The functional recovery of virus-specific T cells in CHD-resolved patients was primarily attributed to the presence of higher effectors cells with reduced expression of exhaustion markers PD-1 and TIGIT in CD4/CD8 T cells along with improved T cell proliferation. Patients with resolved CHB/CHD were also enriched in HBs and HDV-specific T cell functions. However, the recovery was lower than HDV-specific responses and seemed inadequate to clear CHB; suggesting robust HDV-specific T cell functions may have secondary response helping in CHB clearance. HDV-specific polyfunctional responses among CD4/CD8 T cells coproducing IFN-gamma, TNF-alpha, IL-2 and IL-21, along with cytotoxic granules perforin and granzymeB were profound in CHB/CHD-resolved patients while a very few with resolved CHD had polyfunctional T cells.
Conclusion: HDV clearance is associated with presence of higher effector T cells producing robust HDV-specific polyfunctional cytokines while reflecting a transcriptional profile implying a broad anti-HDV peripheral immunity. Hence, these results may guide distinct correlates that define HDV functional cure with antiviral therapeutics.

SAT-367
HBV promotes viral replication and autophagic secretion through HBx down-regulation of HDAC6 expression
Lili Wu[1], Huiying Yu[1], Zhiliang Gao[1], Bingliang Lin[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: wulli23@mail.sysu.edu.cn

Background and aims: HDAC6 is an enzyme important for regulating microtubule protein deacetylation and participating in autophagic transport, and its role in HBV replication and autophagic secretion needs to be further elucidated.
Method: Twenty-eight patients with chronic hepatitis B who underwent liver puncture, 12 of them obtained HBsAg <0.05 IU/ml after treatment with pegylated interferon-α (PEG-IFN) combined with nucleotide analogs (NAs), 4 patients had HBsAg levels between 0.05–300 IU/ml after the same regimen, and 14 treatment-naïve

patients had HBsAg levels >300 IU/ml. HepG2, HepG2.2.15 cell line was used for experimental studies.
Results: The level of serum HBsAg was negatively correlated with the expression of HDAC6 in the liver tissue of the patients, in which the higher the level of serum HBsAg, the lower the level of HDAC6 in the liver of patients. HBV could significantly down-regulate HDAC6 expression by up-regulating the methylation level of the HDAC6 promoter region, and the results suggested that it was HBx rather than HBsAg or HBeAg that was involved in the above process. HBV inhibited viral autophagic degradation and promote viral autophagic secretion by up-regulating P62 and Rab11 levels, whereas HDAC6 overexpression was able to reverse the above results. Transcription of virus-associated RNA and replication of HBV DNA were found to be significantly enhanced after the use of HDAC6 selective inhibitor (ACY1215). HDAC6 may be a potential target for HBV antiviral therapy.
Conclusion: HBV promotes viral replication and autophagic secretion through HBx down-regulation of HDAC6 expression.

SAT-370

PRO-C3 determined active fibrogenesis is a predictor of liver-related outcomes in patients with chronic hepatitis C

Emilie Skovgaard[1,2], Thomas Møller[1,3], Morten Karsdal[1], Diana Leeming[4], Keyur Patel[5]. *[1]Nordic Bioscience A/S, Herlev, Denmark; [2]Department of Biomedical Sciences, University of Copenhagen, Denmark, Copenhagen, Denmark; [3]University of Copenhagen, Department of Biomedical Sciences, København N, Denmark; [4]Nordic Bioscience A/S, Herlev; [5]University Health Network, Toronto, Canada*
Email: esk@nordicbio.com

Background and aims: Patients with untreated chronic hepatitis C (CHC) infection are at increased risk of developing a liver related outcome. Despite the availability of simplified direct acting antiviral therapy, the prevalence of CHC remains unchanged in many industrialized countries. Biomarkers that can predict which chronic liver disease patients with inflammatory injury are at greatest risk of developing a clinical outcome are required. In a study population from The Hepatitis C Antiviral Long-Term Treatment Against Cirrhosis Trial (HALT-C) (ClinicalTrials.gov #NCT00006164), we investigated the ability of PRO-C3 as a marker of active fibrogenesis to predict liver-related outcomes compared to METAVIR fibrosis stage on biopsy in patients with hepatitis C virus (HCV) who were non-responders to prior interferon-based standard-of-care.
Method: Serum levels of the fibrogenesis marker, nordicPRO-C3™, was measured in stored serum samples using a competitive ELISA. Fibrosis stage was assessed by liver biopsy at baseline and end-of-study. Cox proportional hazard regression analysis was employed for investigation of the association between baseline PRO-C3 levels or METAVIR stage and risk of clinical outcome. Kaplan-Meier analysis was employed to examine the event-free survival probability when stratifying PRO-C3 into below and above the lower quartile (Q1 = 27.6 ng/ml) and METAVIR stage (F1-F2 vs F3-F4). Data provided by NIDDK CR, a program of the National Institute of Diabetes and Digestive and Kidney Diseases.
Results: This study population included a subgroup of 340 patients from the HALT-C cohort with a median age of 50 years, BMI of 29.4 kg/m^2, and 65% of the patients were male. Sixty-seven patients (20%) had a liver-related outcome over median follow-up 839 days (Q1-Q3: 474–1132). When dividing patients into baseline PRO-C3 above and below the Q1 cut-off, the Hazard Ratio (HR) for having an outcome was 3.71 times higher (95% CI = [1.60–8.57], p < 0.01) in patients with high baseline PRO-C3. For biopsy-determined fibrosis stage, the HR for having an outcome was 3.20 times higher (95% CI = [1.71–5.98], p < 0.001) in patients with F3-F4 compared to F1-F2. For METAVIR stage, F2–4, patients have an estimated HR of appr. 2% per ng/ml change in PRO-C3 for a liver-related outcome. No events occurred in patients with F1 at baseline.
Conclusion: Fibrosis activity, represented by the level of type III collagen formation (PRO-C3), is associated with an increased risk of developing a liver-related outcome in patients with untreated HCV infection. PRO-C3 provided a higher risk predictor for outcomes than advanced fibrosis on biopsy. Pro-fibrogenic markers such as PRO-C3 could provide prognostic utility in other chronic liver disease patients with ongoing inflammatory injury.

Background and aims: Bulevirtide (BLV) is a novel entry inhibitor that binds to the HDV entry receptor, sodium taurocholate cotransporting polypeptide (NTCP), and is approved for the treatment of compensated chronic hepatitis D (CHD) in the EU. Although BLV is a highly potent HDV inhibitor, some patients have suboptimal virologic response likely due to viral and/or host mechanisms. Here, we describe virologic analysis results for participants with suboptimal response to BLV in a recently completed Phase 2b study MYR204 (NCT03852433), which evaluated finite treatment with BLV with or without peginterferon alfa-2a (PegIFN) in patients with CHD.
Method: A total of 174 participants with CHD were randomized (1:2:2:2) to receive (A) PegIFN for 48 weeks (W); (B) BLV 2 mg +PegIFN for 48 W; (C) BLV 10 mg+PegIFN for 48W, then BLV 2 mg (B) or 10 mg (C) monotherapy for 48 W; or (D) BLV 10 mg for 96 W. Participants were followed for 48 W after end of treatment (EOT). Virologic resistance analysis population (RAP) included on-treatment virologic non-responders (NR; HDV RNA decrease <1 log10 IU/ml from baseline [BL] through EOT), participants with virologic breakthrough (VB; a ≥1 log10 increase from nadir for ≥2 consecutive visits through EOT; or ≥2 consecutive HDV RNA ≥LLOQ if previously <LLOQ), participants with unconfirmed VB at EOT (EOT Blip), participants with persistent viremia with HDV RNA >100 IU/ml through EOT (PV), participants with post-treatment viral relapse (undetectable HDV RNA at EOT and detectable HDV RNA at follow-up Week 48 [FU48]) or viral rebound (detectable HDV RNA at EOT and ≥2 log10 IU/ml increase in HDV RNA from EOT). Resistance testing included deep sequencing of HBV PreS1 and HDV hepatitis delta antigen (HDAg) coding regions, phenotypic analysis, and host NTCP polymorphism analysis.
Results: Resistance analysis was performed for 30 participants (NR, n = 1; VB, n = 25; EOT Blip, n = 4; PV, n = 6) through Week 96 (EOT) and 53 participants (relapse, n = 23; rebound, n = 30) at FU48 in Arms B/C/D. No amino acid substitutions at HBV PreS1 BLV region or HDV HDAg associated with reduced susceptibility to BLV were identified from any RAP participants from BL through FU48. The BL amino acid substitutions or emerged substitutions during treatment were also observed in virologic responders (VR; undetectable HDV RNA or a decline in HDV RNA ≥2 log10 IU/ml from BL at EOT) and remained sensitive to BLV in vitro. The BLV EC50 values from n = 124 BL samples in this study were similar across NRs, VBs, EOT Blips, PVs, and VRs. Three NTCP synonymous nucleotide changes were detected in RAP participants but were not associated with treatment outcome.

Conclusion: Suboptimal on-treatment response to BLV in combination with PegIFN as well as post-treatment viral relapse or rebound were not associated to amino acid substitutions in HBV PreS1, HDAg, or NTCP.

Email: wuhm2000@sina.com

Background and aims: Interferon (IFN) plays a dual role of direct antiviral and immune regulation in anti-hepatitis B virus (HBV) therapy. Some patients can obtain early hepatitis B surface antigen (HBsAg) response in the early stage of IFN treatment, but the decline of HBsAg level stagnates in the later stage, and the antiviral effect cannot be continued even if IFN treatment is continued. Currently, how to further explain the cause of this phenomenon from the immunological level is still a problem to be solved. Thus, we aim to investigate changes in phenotype and function of $CD8^+$ T lymphocytes in chronic hepatitis B (CHB) patients undergoing IFN and correlation with clinical response.
Method: CHB patients were divided into three groups according to antiviral treatment. Peg-IFNα was then administered to Naïve group and nucleos (t) ide analogues (NAs)-treated group. For Plateau group, whose HBsAg decline reached a plateau, IFN therapy was stopped and was resumed after an interval. Peripheral blood samples were collected to detect clinical indexs, and T lymphocyte related phenotypes and functions using flow cytometry at corresponding detection points of three groups.
Results: A prospective cohort of 151 CHB patients participated in this study. During IFN treatment, HLA-DR^+CD38^{dim} subset of $CD8^+$ T cells increased and then markedly decreased, while the HLA-DR^+CD38^{hi} subgroup increased significantly in both Naïve and NAs-treated groups (p all <0.0001). For Plateau group, the HLA-$DR^+CD38^{dim}CD8^+$ T cells increased significantly and the HLA-$DR^+CD38^{hi}CD8^+$ T cells greatly decreased after IFN intermittent treatment (p all <0.0001). The changes of HLA-DR^+CD38^{dim} and HLA-DR^+CD38^{hi} subsets during IFN intermittent treatment were strongly positively correlated with the changes of HBsAg during IFN retreatment, respectively (r = 0.4843, p = 0.0066; r = 0.4588, p = 0.0315). Compared with activated HLA-$DR^+CD38^{dim}CD8^+$ T cells, HLA-DR^+CD38^{hi} subgroup expressed lower level of co-stimulatory molecules and killing ability.
Conclusion: IFN treatment made activated HLA-$DR^+CD38^{dim}CD8^+$ T cells gradually differentiated into HLA-DR^+CD38^{hi} subset that indicated impaired killing function. IFN intermittent therapy can reverse this trend and help restore antiviral efficacy of IFN.

SAT-373

Intrahepatic sodium taurocholate co-transporting polypeptide gene transcript and membrane-localized protein expression changes in chronic hepatitis D patients following 48 weeks of treatment with Bulevirtide

Wildaliz Nieves[1], David Pan[1], Abhishek Aggarwal[1], Shiva Zaboli[1], Christina Moon[1], Lauri Diehl[1], Liyun Ni[1], Savrina Manhas[1], Hongmei Mo[1], Lena Allweiss[2], Dmitry Manuilov[1], Grace M. Chee[1], Renee-Claude Mercier[1], Jeffrey Wallin[1], Maura Dandri-Petersen[2]. [1]*Gilead Sciences, Inc., Foster City, United States;* [2]*Department of Internal Medicine, Center for Internal Medicine, University Medical Center Hamburg-Eppendorf, German Center for Infection Research (DZIF), Hamburg, Germany*
Email: wildaliz.nieves@gilead.com

Background and aims: Bulevirtide (BLV), is an N-terminally myristoylated, Hepatitis B virus large envelope protein-derived, synthesized lipopeptide that binds specifically to the sodium taurocholate co-transporting polypeptide (NTCP) and acts as a potent, highly selective entry inhibitor of hepatitis D virus (HDV) into hepatocytes. We investigated whether 48 weeks (W48) of BLV treatment affects NTCP gene and protein expression.
Method: Participants from the ongoing MYR301 Phase 3 study were randomized in a 1:1:1 ratio to receive BLV 2 or 10 mg/day or no treatment (control) for W48. Bile acids (BA), alanine transaminase (ALT), and HDV RNA were assessed at all time points including baseline (BL) and W48. Virologic responders (VR) were defined as those with undetectable HDV RNA (<LLOQ, target not detected) or a decline in HDV RNA from BL of ≥2 $\log_{10}$ IU/ml. A liver biopsy was performed at the screening visit in a subset of patients with a follow-up biopsy at W48. Approximately one-third of the biopsy was immersed in a tissue stabilizer at −20° C until processing for RNAseq (n = 48). The remaining biopsy was formalin-fixed and paraffin embedded following standard procedures for a multiplex immunofluorescence assay including NTCP, sodium-potassium ATPase for cell membrane location and DAPI nuclear stain (n = 162, BL and W48 matched). The image analysis, limited to hepatocytes, measured the median intensity of the NTCP membrane signal.
Results: Transcriptomics did not reveal any differences in NTCP gene expression between treatment arms (p = 0.42) or response groups (p = 0.29) at W48 compared to BL. The NTCP protein expression was similar between arms at W48. However, in participants treated with 2 mg (mean fold-change (FC) = 1.32; p = 0.030) and 10 mg BLV (mean FC = 1.35; p = 0.016), NTCP protein expression was elevated at W48 compared to BL as opposed to the control where no significant change was observed. When assessed by viral response subgroups, change from BL remained significant in the BLV-treated VR group (p = 0.0012, n = 44), but there were too few BLV-treated non-responders (n = 10) to allow for a meaningful comparison. Furthermore, there was no observable difference in the $\log_{10}$ fold-change in median NTCP protein expression for the two categories of ALT normalization at W48: (i) participants with ALT≤ULN and (ii) those that had ALT>ULN. When correlating baseline, W48, and $\log_{10}$ FC of BA levels, HDV RNA levels, and ALT normalization with NTCP protein expression, no significant correlations were observed.
Conclusion: Our results suggest that BLV treatment does not alter NTCP gene expression but may increase NTCP protein levels in the plasma membrane of hepatocytes. BL NTCP and changes in NTCP protein levels do not appear to be a predictor of HDV viral load or BA and ALT changes over W48 of treatment. Further analysis is needed to confirm these findings and determine the potential impact, if any, on clinical outcome.

Email: henarcs@hotmail.com

Background and aims: Restoring the functionality of proliferative progeny (PP) in e-Ag (-) chronic hepatitis B (CHBe (-)) could be achieved by rebalancing energy supply and demand in activated progenitor (AP) HBV-specific CD8 T-cells. IL-15 could readjust cellular metabolism, potentially aiding in achieving a functional cure. The aim of the study was to evaluate the ability of IL-15 combined with anti-PD-L1 to restore the functionality of HBV-specific CD8 T-cell response as a function of the degree of cellular exhaustion estimated by a predictive model using clinical variables (Peña Asensio et al, Aliment Pharmacol 2023).
Method: The predictive model estimated the exhaustion level of HBV-specific CD8 cells in CHBe (-) patients treated with nucleos (t)ide (NUC) analogues. HBV-specific CD8 cells were visualized by pentameric technology. After Ag-specific stimulation, AP and PP were detected by TCF1 staining and forward scatter level. Analysis included the metabolic profile, memory phenotype, and mTORC1 activation in APs. The effector capacities in PP (proliferation, interferon-g, tumour necrosis factor-a and CD107a) were evaluated. The role of IL-15 ± anti-PD-L1 in remodelling the metabolic profile and enhancing effector function was assessed. Analyses were performed by flow cytometry.
Results: The quiescent progenitor (PQ [TCF1+/FSClow]) HBV-specific CD8+ cells showed a memory-like phenotype. After Ag encounter, the generated AP [TCF1+/FSChigh] subset maintained the PD1+/CD127+ phenotype and gave rise to PP ([TCF1-/FSChigh]). In AP cells, IL-15 compared to IL2 decreased the initial mTORC1 boost, but maintained its activation longer, linked to a catabolic profile that correlated with functional improvement of PP. In HCBe (-) cases treated with NUC, the AP subset showed an anabolic phenotype associated with dysfunctional PP. In CHBe (-) cases with low probability of restoration of HBV-specific CD8 cells during NUC treatment, IL-15/anti-PD-L1 treatment restored reactivity of the HBV-core but not HBV-polymerase-specific CD8 T-cell response, whereas cases with high probability of restoration recovered functionality spontaneously during treatment.
Conclusion: In patients with poor prognosis factors for HBV-specific CD8 T-cell response restoration, combined IL-15 and anti-PD-L1 treatment could improve the energy balance of the PA pool, associated with recovery of PP against core but not against polymerase. CHBe (-) patients with favorable prognostic factors for restoration spontaneously recover this effector response during treatment.

SAT-375

Proteomic analysis of plasma exosomes: a novel method to identify potential therapeutic targets for chronic hepatitis B

Meng Zhao[1], Saisai Zhang[1], Danny Ka-Ho Wong[1], Lung-Yi Mak[1,2], Judy Wai-Ping Yam[3], Cherlie Lot-Sum Yeung[3], Rex Wan-Hin Hui[1], Man-Fung Yuen[1,2], Wai-Kay Seto[1,2]. *[1]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China; [2]State Key Laboratory of Liver Research, The University of Hong Kong, Hong Kong, China; [3]Department of Pathology, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China*
Email: mengz014@connect.hku.hk

Background and aims: Chronic hepatitis B (CHB) is characterized by an exhausted immune response against the virus. A possible mechanism is communication between hepatitis B virus (HBV)-infected hepatocytes and the host's immune system via exosomes, contributing to immune-dysregulation in CHB. However, studies of the role of exosomes in CHB are scarce and do not consider the different CHB disease phases. We aimed to investigate the changes in plasma proteome in CHB patients and healthy controls.
Method: We recruited treatment-naïve CHB patients of different disease phases and healthy controls. Exosomes were isolated from plasma using ultracentrifugation method (Optima XL-80 K, Beckman Coulter, United States). Data-independent acquisition (DIA) mass spectrometry was performed to detect the dynamic profiles of exosome proteins. Bioinformatics and annotation analyses of top differentially expressed proteins (DEPs) were performed using Geno ontology (GO) Enrichment Analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) Analysis. The types and proportions of infiltrating immune cells were detected by immune filtration analysis using CIBERSORT.
Results: In this interim analysis involving 10 healthy controls and 30 CHB patients (10 HBeAg-positive, 10 HBeAg-negative, and 10 CHB patients with hepatitis B surface antigen [HBsAg] seroclearance), 2142 exosome proteins were identified, of which 128 proteins were significantly altered in CHB vs. healthy controls (fold change >2 or <0.5, all $p < 0.05$). The most significant DEPs were observed with CIT, KRTDAP, KRT16 and HM13 (fold change = 176.422, 13.774, 0.123 and 0.078 respectively, $p < 0.05$). When comparing HBsAg-positive patients with CHB patients achieving HBsAg seroclearance, 95 significant DEPs (87 downregulated and 8 upregulated proteins) were detected. GO analyses revealed these DEPs to be enriched in multiple immune-related processes; KEGG analyses showed their involvement in the estrogen signaling pathway ($p = 0.002$). When compared to HBsAg-positive patients, CHB patients with HBsAg seroclearance, had a significantly increased fraction of activated dendritic cells (0.006 ± 0.010 vs. 0.028 ± 0.027, $p = 0.026$) and eosinophils (0 vs. 0.002 ± 0.004, $p = 0.047$), while resting dendritic cells were significantly decreased (0.041 ± 0.019 vs. 0.024 ± 0.021, $p = 0.045$). No significant difference was observed between patients with HBsAg seroclearance and healthy controls through immune infiltration.
Conclusion: Plasma exosomes of CHB patients contain proteins associated with host immune response. The estrogen signaling pathway may potentially be associated with HBsAg seroclearance. Annotation of plasma exosomes can potentially identify serum markers in different CHB disease phases and effectors that trigger immunity against HBV. This can be a potential method of identifying novel CHB therapeutic targets.

SAT-376

Hepatitis C virus specific CD8+ T cells of patients with acute and chronic HCV infection display high expression of CD96 and other co-inhibitory molecules

Maximilian Knapp[1], Christin Ackermann[2,3], Leon Cords[1], Tim Westphal[4], Julian Schulze zur Wiesch[5,6]. *[1]University Medical Center Hamburg-Eppendorf, I. Email: knapp_maximilian@t-online.de

Background and aims: The Hepatitis C virus-specific T cell response exhibits significant differences in function and phenotype during acute and chronic as well as in spontaneously resolved, and successfully DAA-treated HCV infection. It was previously described that levels of soluble CD96, a surface protein that was first described as a late activation marker, but also as a marker of leukemic stem cells and a target of oncological antibody therapies, were increased in patients with chronic Hepatitis B and cirrhosis (Gong et al., Clin Exp

Immunol, 2009). Furthermore, CD96 shares CD155 as a ligand with TIGIT, an inhibitory co-receptor also expressed on HCV-specific T cells. The current study aimed to define the characteristics of HCV-specific (HCVs) CD8+ T cells with a focus on the CD96-CD155-TIGIT axis at different stages of infection.
Method: Research was undertaken using class I MHC tetramers on CD8+ T cells specific to HCV in 38 individuals with HLA-A*01:01, *02:01, and *24:02 genotypes. A 21-color flow cytometry panel was used to evaluate the expression patterns of surface proteins CD3, CD4, CD8, CD28, CD38, CD39, CD62L, CD69, CD73, CD96, CD127, TIGIT, PD-1, Slamf6, and transcription factors T-bet, TCF1, NR2F6, TOX and IRF4. Flow cytometry data were analysed using FlowJo10. Data were clustered using UMAP and FlowSOM. GraphPad Prism10 was used for statistical analysis.
Results: Frequencies of HCVs CD8+ T cells expressing PD-1 (mean 27.7% vs. 51.5%, $p < 0.001$) and TIGIT (mean 45.1% vs. 57.1%, $p = 0.0014$) were elevated compared to bulk CD8+ T cells. Moreover, HCV-specific CD8+ T cells also showed significantly higher frequencies of CD96-expressing cells compared to bulk CD8+ T cells (mean 10.8% vs. 41.0%, $p < 0.001$) irrespective of the disease stage. Analysing the frequencies of functional subsets within HCVs CD8+ T cells of CD96+ and CD96- populations revealed significant differences of CD62L- CD127- effector (mean: 26, 5% vs. 29, 7%, p = 0, 0243) and CD62L+ CD127- intermediate (mean: 4, 4% vs.13, 5%, p < 0, 001) subsets. Moreover, CD96+ HCVs CD8+ T cells showed higher frequencies of IRF4+ (mean: 98, 4% vs. 94, 3%, p = 0, 0002), TCF1+ (mean: 29, 7% vs. 20%, p < 0, 0001) and TOX+ (mean: 26, 3% vs. 20, 8%, p = 0, 0001) cells compared to CD96- HCVs CD8+ T cells. Within the HCVs CD8+ T cells, diverse clusters were identified, with CD96 standing out as a distinctly expressed marker of HCV-specific T cells with exhaustive phenotype.
Conclusion: Our study reveals a significant increase of CD96+ HCVs CD8+ T cells with co-expression of known co-inhibitory markers. Furthermore, we measured different frequencies of IRF4+, TCF1+ and TOX+ T cell subsets between CD96+ and CD96- HCVs CD8+ T cells. CD96+ is potentially an additional druggable co-inhibitory checkpoint of exhausted T cells in human viral and oncological diseases with therapeutic potential.

CRISPR-Cas13b-mediated suppression of hepatitis B surface antigen-pre-clinical investigations of a new therapeutic approach

Laura McCoullough[1,2], Mohamed Fareh[3,4], Wenxin Hu[3,4], Vitina Sozzi[1], Christina Makhlouf[1], Yianni Droungas[1,2], Chee Leng Lee[1], Hans Netter[1], Mina Takawy[1,5], Sharon Lewin[5,6,7], Damian Purcell[2], Jacinta Holmes[8], Joseph Trapani[3,4], Margaret Littlejohn[1,5], Peter Revill[1,5]. *[1]Victorian Infectious Diseases Reference Laboratory, Royal Melbourne Hospital, at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia; [2]Department of Microbiology and Immunology, University of Melbourne, at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia; [3]Cancer Immunology Program, Peter MacCallum Cancer Centre, Melbourne, Australia; [4]Sir Peter MacCallum Department of Oncology, The University of Melbourne, Melbourne, Australia; [5]Department of Infectious Diseases, University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia; [6]Victorian Infectious Diseases Service, Royal Melbourne Hospital at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia; [7]Department of Infectious Diseases, Alfred Hospital and Monash University, Melbourne, Australia; [8]Department of Gastroenterology, St. Vincent's Hospital, Melbourne, Australia*
Email: laura.mccoullough@mh.org.au

Background and aims: Low hepatitis B surface antigen (HBsAg) levels are associated with better clinical outcomes, and may be key to achieving a HBV functional cure. The HBV RNAs represent a potential target for new treatments to reduce HBsAg, which has been highlighted by RNA interference and antisense oligonucleotide studies. CRISPR-Cas13b endonuclease, naturally used by bacteria to target and suppress bacteriophage RNAs, has been repurposed to target RNAs in mammalian cells. Cas13b has high specificity due to its 30-nucleotide guide RNA (gRNA) which reduces the possibility of off-target effects. Here, in a world first study, we targeted the HBV RNAs using CRISPR-Cas13b to reduce HBsAg *in vitro* and *in vivo*.
Method: gRNAs were designed to target either the 5′ or 3′ end of the HBV pregenomic RNA (pgRNA). HepG2 cells were transfected with WT HBV clones of multiple genotypes, and plasmids expressing Cas13b-BFP and gRNAs. The replication phenotype of WT HBV was determined five days post-transfection. HepAD38 cells were transfected with Cas13b-BFP and gRNA plasmids and secreted HBeAg and HBsAg was measured. In a pilot experiment, WT HBV, Cas13b and gRNA plasmids were simultaneously hydrodynamically injected into CBA mice and sera HBsAg was measured one week post-HDI.
Results: Cas13b strongly suppressed HBV replication and significantly reduced secreted HBeAg and HBsAg by 95% in HepG2 cells. The effect was pan-genotypic. Despite low transfection efficiency, Cas13b reduced secreted HBsAg in HepAD38 cells. Finally, the *in vivo* pilot experiment showed that sera HBsAg was transiently reduced by ~50% when Cas13b was co-injected with WT HBV.
Conclusion: The HBV RNAs were successfully targeted and degraded using CRISPR-Cas13b to significantly reduce HBsAg in cell culture and *in vivo*, demonstrating its potential as a novel treatment option for chronic HBV infection.

Association between occult hepatitis B virus infection and parenchymal renal cell carcinoma

Daniele Lombardo[1], Marta Rossanese[2], Cristina Musolino[3], Giuseppina Raffa[4], Giuseppe Caminiti[5], Carlo Saitta[6], Giuseppe Mucciardi[2], Michele Chiappetta[6], Maurizio Martini[6], Antonio Ieni[6], Vincenzo Ficarra[1], Giovanni Raimondo[7], Teresa Pollicino[8]. *[1]University Hospital G. Martino Messina, Messina, Italy; [2]University Hospital G. Martino Messina, Messina; [3]University Hospital "G.Martino" Messina, Messina, Italy; [4]University Hospital "G. Martino" of Messina, Messina, Italy; [5]University of Messina, Messina, Italy; [6]University Hospital of Messina, Messina, Italy; [7]Division of Medicine and Hepatology, University Hospital of Messina, Messina, Italy; [8]University Hospital "G Martino" of Messina, Messina, Italy*
Email: tpollicino@unime.it

Background and aims: There is increasing evidence of an association between chronic kidney disease and HBV infection, including cases of occult HBV infection (OBI), which refers to the long-term persistence of HBV genome in individuals who test negative for HBsAg. In addition, an increased incidence of renal cell carcinoma (RCC) has been observed in HBsAg-positive individuals, although data on the prevalence of RCC in OBI individuals remain unexplored. The aims of this study were (1) to determine the prevalence of OBI in patients diagnosed with RCC, and (2) to investigate the molecular characteristics of HBV in both tumour and non-tumour renal tissues.
Method: We conducted a prospective study that included consecutive HBsAg-negative patients who underwent nephrectomy for malignant kidney tumours at the Department of Urology, University Hospital of Messina, from April 2019 to May 2021. For comparison, we included a control group (CG) of patients who underwent nephrectomy for benign kidney tumours. At the end of each surgery, we collected paired samples of tumour and adjacent non-tumour kidney tissue. These samples were then divided; one part was used for histological examination and the other was immediately frozen and stored for molecular analysis. Serum samples were also collected from each patient and stored at –80°C. The study was approved from the local ethics committee. Informed consent was obtained from each participant to the study. To detect and characterise HBV infection in tissue samples, we used highly sensitive PCR approaches to detect total HBV, HBV cccDNA and HBV

RNA. High-throughput hepatitis B virus integration sequencing (HBIS) was also used to investigate HBV DNA integration.
Results: The study recruited 83 HBsAg-negative patients, including 54 with renal cell carcinoma (RCC) and 29 with benign kidney tumours (CG). None of these patients showed clinical, biochemical, or ultrasound signs of liver disease. OBI was found in 19/54 (35.2%) RCC patients and in 1/29 (3.4%) CG patients (p = 0.001). OBI was not detected in any serum samples from either RCC or CG patients. Among the RCC cases, 36/54 had clear cell renal cell carcinoma (ccRCC), and 18/54 had either papillary or chromophobe RCC. OBI occurred in 9/36 (25%) ccRCC cases and in 10/18 (55.5%) non-ccRCC cases (p = 0.03). Further molecular investigations revealed the presence of both the HBV cccDNA and integrated HBV DNA in renal tissues from patients with OBI.
Conclusion: Occult HBV infection (OBI) shows a significant association with renal cell carcinoma (RCC), particularly with non-clear cell RCC (non-ccRCC) histotypes. The identification of replication-competent HBV cccDNA and integrated HBV DNA in both tumour and non-tumour renal tissues suggests the potential for HBV replication within renal cells.

SAT-379

Immune checkpoint proteins are associated with persistently elevated liver stiffness after successful HCV therapy in people with HIV

Rubén Martín-Escolano[1], Ana Virseda-Berdices[1], Juan Berenguer[2], Juan Gonzalez[2], Oscar Brochado-Kith[1], Amanda Fernández Rodríguez[1], Cristina Diez[2], Victor Hontañón[3], Salvador Resino Garcia[1], María Ángeles Jiménez Sousa[1]. *[1]Instituto de Salud Carlos III, Centro Nacional de Microbiologia, Majadahonda, Madrid, Spain; [2]Hospital General Universitario "Gregorio Marañón," Madrid, Spain; [3]Hospital Universitario La Pa, Madrid, Spain*
Email: r.martin@isciii.es

Background and aims: Hepatic cirrhosis remain the main complication of hepatitis C virus (HCV) infection despite the novel direct-acting antiviral (DAA) therapy, being accelerated by the human immunodeficiency virus (HIV). Alternatively, several immune checkpoint proteins are upregulated and correlated with cirrhosis progression. Here, we aimed to evaluate the association of plasma immune checkpoint proteins one year after successful completion of HCV treatment with persistently elevated liver stiffness (liver stiffness measurement (LSM) ≥12.5 kPa) five years after HCV treatment in people with HIV (PWH).
Method: We performed a retrospective study in 39 HIV/HCV-coinfected patients with advanced fibrosis or cirrhosis who achieved sustained virologic response (SVR). Plasma samples were collected one year after treatment, and immune checkpoint proteins and inflammatory biomarkers were analyzed using a Luminex 200TM analyzer. The statistical association analysis used Generalized Linear Models (GLM) with gamma distribution. Correlation between significant immune checkpoint proteins and inflammatory biomarkers was performed using the Spearman correlation test.
Results: There was a downward trend in the value of LSM years after the completion of successful HCV treatment, but it was not significant because there was wide variability among PWH. In this regards, 61.5% of patients showed persistently high liver stiffness five years after HCV treatment. Higher plasma baseline levels of BTLA (aAMR = 1.49; q = 0.022), PD-1 (aAMR = 1.49; q = 0.022), and TIM-3 (aAMR = 1.28; q = 0.039) one year after successful treatment was associated with persistently elevated liver stiffness five years after HCV treatment. These significant immune checkpoints were correlated to inflammatory biomarkers in PWH who had persistently elevated liver stiffness. BTLA and PD-1 correlated negatively with IL-1RA (p = 0.018 and p = 0.049, respectively), PD-1 correlated positively with IP-10 (p = 0.028), and TIM-3 correlated positively with IL-8 (p = 0.018).
Conclusion: Elevated plasma levels of immune checkpoint proteins were associated with persistently elevated liver stiffness five years after HCV eradication, particularly BTLA, PD-1, and TIM-3, suggesting a potential immunopathological role in persistently elevated liver stiffness after HCV eradication in PWH.

Email: charlotte.mouliade@aphp.fr

Background and aims: Data regarding the severity and mortality rate of acute hepatitis A (AHA) in France, especially following the 2017 global AHA outbreak, remain limited. This study aimed to assess the burden of AHA-related hospitalizations from 2013 to 2022 in France and to identify factors contributing to its severity and mortality.
Method: Cases of AHA were identified as primary discharge diagnoses in the French National Uniform Hospital Discharge Data Set from 2013 to 2022 using ICD-10 codes B150 or B159. The study evaluated associations with death/liver transplantation and AHA severity (defined as death/liver transplantation or hepatic/extrahepatic organ failure within 12 weeks post-admission) using adjusted odds ratios (aOR) in both original and propensity-matched samples. AHA cases were categorized as pre- or post-outbreak based on a threshold date of June 15, 2017, the midpoint of 2017.
Results: Among the 6, 734 patients identified (61% male, median age 31.0 years [IQR: 19–49]), 1.6% (n = 108) experienced death or liver transplantation, and 28.7% (n = 1, 931) presented with severe AHA. Independent risk factors for AHA death/liver transplantation included post-outbreak AHA (aOR 1.83, 95% CI: 1.19–2.87, p = 0.007), cirrhosis (aOR 4.75, 95% CI: 2.27–9.78, p < 0.001), and severe comorbidities (aOR 6.31, 95% CI: 3.26–12.5, p < 0.001 for a Charlson comorbidity index ≥3). Factors influencing AHA severity were post-outbreak AHA (aOR 1.19, 95% CI: 1.07–1.33, p = 0.002), older age (aOR 1.19 per decade, 95% CI: 1.14–1.24, p < 0.001), male sex (aOR 1.44, 95% CI: 1.29–1.62, p < 0.001) cirrhosis (aOR 1.54, 95% CI: 1.07 to 2.23, p = 0.021), and HIV infection (aOR 1.34, 95% CI: 1.04–1.72, p = 0.022). Propensity-matched samples showed increased risks of AHA mortality (aOR 1.57, 95% CI: 1.03–2.45, p = 0.043) and severity (aOR 1.18, 95% CI: 1.05–1.32, p = 0.004) post-AHA outbreak.
Conclusion: The severity and mortality of AHA in France have notably increased over the past decade. These findings underscore the importance of promoting hepatitis A virus vaccination, particularly among older and comorbid patients.

Email: mariafcortese@gmail.com

Background and aims: The hepatitis delta virus (HDV) causes a chronic infection and a limited percentage of chronic hepatitis delta patients (CHD, anti-HDV positive) can achieve spontaneous or treatment-related control of HDV replication and/or normalization of ALT levels. The function of T cells is controlled by the activation of the T cell receptor (TCR). Its genetic diversity is essential to recognize the viral antigens and induce the immune response. The interrelation between HDV infection and the TCR repertoire is still unknown. The aim of the present study is to analyze the TCR repertoire diversity in CHD patients versus healthy donors and in relation to the presence of HDV RNA and ALT levels for predicting disease progression.
Method: Peripheral blood mononuclear cells (PBMCs) were obtained from 25 adult patients with CHD (15 with detectable and 10 with undetectable HDV RNA). A group of 27 healthy adult donors was used as control. Biochemistry and virological parameters were collected. T cells (CD3+) were isolated from the PBMC by using an immunomagnetic positive selection commercial kit (Stemcell). T cells' DNA was isolated and the variable (TRBV), diversity (TRBD) and joining (TRBJ) gene rearrangements of the beta chain of the TCR were studied by next-generation sequencing (Miseq, Illumina). The diversity of the TCR repertoire (normalized Shannon Wiener index, SnW, and inverted Simpson index, S) in CHD patients was compared to the healthy group and in the same HDV group considering variables such as HDV RNA detectability or ALT levels (ALT above or below 50 U/L). Moreover, the frequency in using the different TRBV and TRBJ among the HDV patients was also determined.
Results: From the 25 anti-HDV included patients, 16 (64%) presented elevated ALT levels and 8 (32%) had liver cirrhosis. HDV patients presented a lower diversity of the TCR beta repertoire (both SnW and S indices) than healthy donors ($p < 0.05$). No difference in terms of diversity was observed when comparing patients with detectable or undetectable HDV RNA or normal or elevated ALT levels. When we considered the frequency of use of the TCR beta chain gene segments among HDV patients with detectable or undetectable viremia as well as ALT levels, we observed that patients with undetectable HDV RNA or normal ALT presented a higher frequency of use of the TRBV28 segment than patients with detectable HDV RNA or elevated ALT ($p = 0.057$ and 0.031 respectively).
Conclusion: CHD patients presented a lower diversity of the TCR repertoire than healthy donors probably suggesting a kind of enrichment in some clonotypes due to the infection. Patients with undetectable HDV RNA or normal ALT levels presented a high usage of a specific variable genetic segment. These results need to be further evaluated in a larger cohort of patients. Grant PI23/01065, funded by Instituto de Salud Carlos III and co-funded by European Union (ERDF, "A way to make Europe").

SAT-382

Ethanol exposure exacerbates HBV-infection pathogenesis: possible mechanisms and treatment targets

Natalia Osna[1], Murali Ganesan[1], Grace Bybee[1], Ashrafi Sultana[1], Carol Casey[2], Kusum Kharbanda[2], Howard Gendelman[1], Larisa Poluektova[1], Benson Edagwa[1]. *[1]University of Nebraska Medical Center, Omaha, United States; [2]University of Nebraska Medical Center, VA Medical Center, Omaha, United States*
Email: nosna@unmc.edu

Background and aims: About 250 million people suffer from hepatitis B (HBV) infection, with an annual rate of cell death up to 800, 000. The frequency of chronic hepatitis B (CHB) and detrimental outcomes are higher in patients with alcohol use disorders (AUD). However, the mechanisms under these events as well as therapeutic targets are not clear yet and their identification is the main purpose of this study. While HBV replicates only in hepatocytes, the activation of non-permissive macrophages by HBV supports hepatitis persistence. Here, we hypothesized that the protective crosstalk between macrophages and hepatocytes regulates innate immunity in infected hepatocytes and this protection is disrupted by exposure to ethanol.
Method: The study was performed in HBV-expressing hepatocyte-like cells, HepG2.2.15 or HepAD38 and monocyte-derived macrophages (MDMs) exposed or not to acetaldehyde-generating system (AGS) to mimic ethanol metabolism. For in vivo experiments, we used Tg05 HBV-replicating mice.
Results: In in vitro experiments, we found that the expression of HBV DNA, HBV RNA and HBcAg was elevated in AGS-treated hepatocytes due to suppression of Interferon-stimulated genes (ISGs), ISG15, APOBEC 3G and OAS1. HBV-containing supernatants from these cells activated mRNAs of inflammasome receptors, NLRP3 and AIM 2 as well as IL-1b and IL-18 in MDMs and suppressed the induction of ISGs in response to IFN type 1. Extracellular vesicles (EVs) mediated the hepatocyte-MDM crosstalk, which was blocked by the EV inhibitor, GW4869. Supernatants collected from these HBV-activated ethanol-non-exposed MDMs diminished the effects of ethanol on ISGs in hepatocytes and decreased the expression of HBV markers in hepatocytes, which was reversed by MDM exposure to ethanol. The increase in HBV marker expression accompanied by suppression of ISGs and infammasome activation in liver cells were confirmed in vivo on ethanol-fed Tg05 mice. In attempts to reduce an inflammation in the liver, we tested the ability of the immunomodulative drug, tizoxanide (TIZ) to control inflammasome activation in HBV-exposed MDMs. TIZ is an active metabolite of FDA-approved nitazoxanide (NTZ) with low bioavalability that was transformed into hydrophobic lipophilic crystalline prodrug to obtain long-acting properties. We observed that the treatment of activated MDMs with TIZ suppressed AIM2, IL-1b, IL-18 mRNAs and increased IFNa mRNA, indicating that TIZ can downregulate the inflammatory component in HBV-infection.
Conclusion: In conclusion, ethanol suppresses ISG in hepatocytes thereby increasing the expression of HBV. EV-mediated delivery of HBV to macrophages causes activation of inflammasome and hepatitis. This inflammation can be attenuated by the long-acting immunomodulator, TIZ to serve as an additional component of HBV-infection treatment along with the direct anti-viral drugs.

Rapid analysis of HBV-specific T cell secretomes reveals distinct antiviral immune profiles among chronic HBV patients

Nina Le Bert[1], Apostolos Koffas[2], Anthony Tan[1], Rajneesh Kumar[3], Lung-Yi Mak[2], Tizong Miao[2], Yu Lei[2], Smrithi Hariharaputran[1], Shou Kit Hang[1], Yifei Guo[1], Qi Chen[1], Upkar Gill[2], Wan Cheng Chow[3], Antonio Bertoletti[1], Patrick Kennedy[2]. *[1]Programme in Emerging Infectious Diseases, Duke-NUS Medical School, Singapore, Singapore; [2]Barts Liver Center, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom;*

[3]*Gastroenterology and Hepatology, Singapore General Hospital, Singapore, Singapore*
Email: nina@duke-nus.edu.sg

Background and aims: Clinical management of chronic HBV (CHB) patients relies exclusively on assessing virological and biochemical biomarkers despite the importance of HBV-specific T cells in viral control. We developed a robust and rapid whole blood assay (WBA) to measure the functional secretome of HBV-specific T cells. We tested the WBA in a large cohort of CHB patients, across all disease phases, to characterize their T cell immune profile in relation to virological and biochemical parameters.
Method: We sampled a total of 240 CHB patients (20 $HBeAg^+$ infection, 25 $HBeAg^+$ hepatitis, 85 $HBeAg^-$ infection, 10 $HBeAg^-$ hepatitis, 60 $HBeAg^-$ on NUC, 40 $HBsAg^-$) and 30 healthy HepB vaccinees. 20 patients (10 $HBsAg^+$ under NUC, 10 $HBsAg^-$) were tested monthly over 3 time points. A small volume of whole blood (2 ml) was aliquoted and stimulated with 6 customized peptide pools covering all HBV proteins of 4 genotypes (A, B, C, and D). Supernatants were collected at 16hr for cytokine quantification (IFN-gamma, IL-2, granzyme B, TNF-alfa, IL-4) with ELLA. In parallel, PBMCs were isolated from selected patients to perform ex-vivo and in-vitro expansion ELISpot assays. To identify patients with distinct immune profiles, machine learning algorithms such as UMAP were applied for dimensionality reduction, visualization, and clustering of the secretome data from the >1450 whole blood HBV-T cell assays performed.
Results: Secretion of cytokines in response to HBV-peptide pool stimulation was detected in over 90% of all CHB patients. Parallel ex-vivo IFN-gamma ELISpot analysis frequently failed to detect HBV-specific T cell responses, except in those with strong cytokine release in the WBA, suggesting a superior sensitivity. Substantial variability was observed in cytokine quantity (pg/ml), quality (different cytokines), and reactivity towards distinct HBV-proteins (different peptide pools) across all CHB patients, irrespective of their clinical classification. Yet, longitudinal analysis revealed stable profiles within patients. Machine learning algorithms separated CHB patients within similar clinical phases into clusters with distinct HBV-specific immune profiles.
Conclusion: A rapid HBV-specific T cell test, performed in a small volume of blood, can identify CHB patients with distinct immune profiles. The ability to distinguish patients within similar clinical disease phases based on their antiviral T cell function will provide a novel biomarker for interpreting host-viral interactions and can signpost the selection of novel immunotherapies.

Email: mariastellafranze@gmail.com

Background and aims: Chronic hepatitis B virus (HBV) infection is characterized by multiple interplays between virus and host immune response that define distinct clinical phases that were defined arbitrarily. We aimed to characterize the intrahepatic immune microenvironment by evaluating gene expression profiles in a large cohort of untreated HBeAg negative patients to decipher the immune activation profiles according to biochemical, virological and histological characteristics.
Method: Ninety-eight HBsAg positive HBeAg negative patients who underwent liver biopsy at Henri Mondor Hospital between 2005 and 2020 were included. Data were collected for each patient at time of biopsy and during follow-up. According to EASL guidelines, patients were classified as HBeAg negative chronic HBV infection and HBeAg negative chronic hepatitis B (CHB). RNA sequencing was performed for each case.
Results: Seventy-six patients (77.6%) were male, with a median age of 40 (33–52) years. Thirty-seven subjects (38%) had a chronic infection (14 with HBV DNA <2, 000 IU/ml, 23 with >2, 000 IU/ml but <20, 000 IU/ml) and 61 (62%) a CHB. Fibrosis was F0/F1 in 84 patients (85.7%), F2/F3 in 11 (11.2%), F4 in 3 (3.1%). Histological activity was A0/A1 in 75 cases (76.5%) and A2/3 in 23 (23.5%). RNA sequencing analysis by unsupervised hierarchical clustering identified two clusters of patients with differentially expressed genes (DEGs) profiles: 18 cluster 1 (C1) and 80 cluster 2 (C2). C1 was associated to higher age ($p = 0.023$), fibrosis ($p < 0.001$), activity ($p < 0.001$), HBV DNA ($p < 0.001$) and ALT levels ($p < 0.001$) compared to C2. C1 contained only CHB patients ($p = 0.001$). By Microenvironment Cell Populations counter method, we identified an intrahepatic immune infiltrate enriched of fibroblasts, monocytes, cytotoxic lymphocytes, and endothelial, myeloid dendritic, natural killer, B, T, $CD8^+$T cells in C1 vs C2. Supervised analysis for DEGs showed 1265 genes significantly down and 539 up-regulated in C2 vs C1. Gene set enrichment analysis with Molecular Signatures Database performed with a hypergeometric test showed that C1 was associated with gene sets pathways mainly involved in immune response. A sensitivity analysis by unsupervised hierarchical clustering was performed in subgroup of 71 patients that were F0/1-A0/1 and identified again 2 distinct clusters. Immune infiltrate profiles were significantly different for presence of $CD8^+$ T cells and immune pathways activation.
Conclusion: Our analysis of liver immune microenvironment revealed differences in gene profiles of HBeAg negative patients, with immune related pathways in CHB and in a subgroup of HBVs without markers of active infection. These results suggest the need to well characterize HBV patients for identifying those at risk of liver disease progression and requiring early antiviral treatment.

Email: gora.lo@iressef.org

Background and aims: HBV DNA Quantification in whole venous blood or plasma viral load is a key element in the management of chronic hepatitis B, allows a more direct and reliable measurement of viral replication and monitoring of the virological response to therapy. Collecting venous blood for diagnostic purposes, especially in infants and young children, could be challenging in many situations. Alternative solutions using capillary blood (finger stick test) for HBV genome quantification will improve the diagnosis and treatment of HBV, mainly in resource-limited countries, by increasing accessibility to diagnosis and improving disease surveillance. The aim of the current study was to optimize and evaluate the performance of

Xpert® in HBV viral load quantification using capillary blood and plasma.

Method: This is a descriptive cross-sectional study carried out at IRESSEF, Senegal from July to December 2023. Capillary blood and plasma samples were collected from chronic HBV carriers HBV and used for HBV viral load determination with the Xpert® HBV VL test cartridge and Abbott real-time HBV PCR (m2000®) as a gold standard. For capillary blood, sample was diluted 1 in 10 before testing with Xpert® HBV VL assay. Statistical analysis using Meth Val® software focused on determining correlation and concordance.

Results: A total of 95 patients with chronic HBV (37 men and 58 women) were enrolled in the study. The median age was 35 years [20–81]. The mean HBV Xpert® viral load on capillary blood and plasma was 3, 05 and 3, 12 log UI/ml, respectively. Viral load Xpert® measurements between capillary blood and plasma correlated strongly with a correlation coefficient of $r^2 = 0.903$ ($p < 0.001$). Mean (SD) difference of Xpert® viral load values between plasma and capillary blood was –0.236 log UI/ml. There was a high correlation between viral load results in plasma and in Capillary blood/plasma, tested by m2000 and the Xpert® respectively ($r^2 = 0.93$ and 0.88 respectively, $p < 0.001$). Overall, Xpert® viral load values in Capillary blood and plasma tended to be lower than m2000® viral load in plasma with mean (SD) differences of 0.06 log UI/ml for Capillary blood and of 0.29 log UI/ml for plasma. Compared to the plasma tested by Xpert® and m2000, the sensitivity, the specificity were 88, 100% and 83 and 97% respectively.

Conclusion: Capillary blood provided results highly correlated to the plasma values. High detection rate was obtained with Capillary Blood when viral load was >2.0 log UI/ml. Capillary blood collection may provide a reliable method for HBV DNA quantification using Xpert ®HBV VL assay.

SAT-388

Comprehensive analysis of CHB concurrent with NAFLD: a proteomics report based on clinical liver samples

Xin Tong[1], Shengxia Yin[2], Fajuan Rui[3], Chao Wu[4], Jie Li[4]. *[1]Department of infectious diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China; [2]Department of Infectious Diseases, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China; [3]Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, China; [4]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China*
Email: tongxin5694@126.com

Background and aims: In recent years, NAFLD has become more prevalent in patients with chronic hepatitis B as the prevalence of obesity and metabolic syndrome has increased. Both diseases can lead to liver fibrosis and even HCC, but the pathogenesis of each disease and CHB concurrent with NAFLD have not been fully elucidated.

Method: We characterized the protein expression in liver tissues among four groups of people with healthy control (n = 6), CHB (n = 8), NAFLD (n = 7), and CHB concurrent with NAFLD (n = 10) by using proteomic profiling. Based on the obtained DEPs results, further bioinformatics analysis was performed. We also verified the expression of some DEPs in the livers of patients and model mice.

Results: Compared with the CHB group, a total of 109 proteins were differentially expressed in the group of CHB patients combined with NAFLD (73 upregulated and 36 downregulated). Further KEGG analysis showed that the differences in various metabolism-related pathways in the liver of patients with CHB concurrent with fatty liver were more pronounced than in single CHB patients, especially the abnormal activation of cholesterol metabolic pathways, which is consistent with the characteristics of fatty liver disease. In addition, we found that accelerated viral clearance in HBV-infected patients with concurrent fatty liver might be associated with an inflammatory response and activation of a large number of metabolic reactions in the organism. These changes were mainly associated with differential enrichment of proteins such as KRT24, SERPINB3, CDSN, S100A7, SYPL1, AGXT, and PGC1-α. Compared with the NAFLD group, a total of 221 proteins were differentially expressed in the group of CHB patients combined with NAFLD (22 upregulated and 199 downregulated). Including metabolism of xenobiotics by cytochrome P450, IL-17 signaling pathway, retinol metabolism and 36 major down regulated pathways, including Glycolysis/Gluconeogenesis, fatty acid degradation, PPAR signaling pathway, Fat digestion and absorption. This results suggested that metabolic pathways were inhibited when CHB concurrent NAFLD, which provideed a new perspective on the mechanism of interaction between these two diseases.

Conclusion: The prognosis of CHB complicated with NAFLD may not be optimistic compared with that of hepatitis B and NAFLD alone, which is closely related to the differential expression of certain proteins in the liver after the complication of the two diseases. Our study provides new insights into the disease development and clinical mechanisms of CHB and NAFLD.

Email: zuzana.mjilkova@gmail.com

Background and aims: Hepatitis B is a liver infection caused by the Hepatitis B virus (HBV). Infected individuals, who fail to control the viral infection, develop chronic hepatitis B (CHB) and are at risk to develop life-threatening liver diseases, such as cirrhosis or liver cancer. Dendritic cells (DCs) play important roles in the immune response against HBV, but are functionally impaired in CHB patients. The underlying mechanisms involved in HBV-induced DC dysfunctions remain to be elucidated.

Method: We explored DC modulations by HBV and Hepatitis B surface antigen (HBsAg) by exposing blood-derived cDC1s, cDC2s and pDCs from healthy donors to HBV or HBsAg, and stimulating them with TLR-L. Their phenotypic and functional features, as well as their metabolic profile, were analysed through multiparametric flow cytometry and multiplex assays, and further explored on patients' samples.

Results: We found that HBV deeply reshaped DC secretome in response to TLR-L. Strikingly, we observed that HBV-exposed DCs secrete high levels of CX3CL1 (fractalkine), a chemokine responsible for attracting antiviral effectors to the site of infection. HBsAg exposure favored DC activation while drastically altering TRAIL expression in response to TLR-L and increasing the secretion of cytokines/chemokines involved in immune tolerance. HBsAg further dampened the metabolism of DC subsets while driving metabolic switches. Notably, relevance of CX3CL1/CX3CR1 axis, TGF-β and metabolic disturbances was demonstrated within intrahepatic DC subsets in patients according to disease stage.

Conclusion: Our work brings new insights into the immunomodulation induced by HBV on DCs, which contribute to impaired antiviral responses and progression towards chronicity.

Nonclinical phenotypic evaluation of clinically identified baseline and treatment-emergent hepatitis B Virus variants that contain single nucleotide polymorphisms in the bepirovirsen binding site

Alexander Koenig[1], Michael Savarese[1], Elise Turk[1], Chi Lau[1], Nicholas Galwey[2], Jerome Bouquet[1], Robert Elston[2], Dickens Theodore[3], Melanie Paff[1], Shihyun You[1], Christine Livingston[1]. *[1]GSK, Collegeville, United States; [2]GSK, Stevenage, United Kingdom; [3]GSK, Durham, United States*
Email: christine.m.livingston@gsk.com

Background and aims: Bepirovirsen (GSK3228836, BPV) is an antisense oligonucleotide under Phase 3 investigation for treatment of Chronic Hepatitis B. BPV targets a highly conserved 20 nucleotide sequence common among HBV pgRNA and mRNA transcripts, where HBx and HBV pol open reading frames overlap. SNPs in the BPV binding site of HBV genomes from B-Clear Phase 2b (NCT04449029) samples were previously reported among a minority of pre- and post-treatment isolates. Clinically identified baseline (BL) HBV variants were previously evaluated nonclinically for their susceptibility to the GalNAc-conjugated form of BPV, GSK3389404, in primary human hepatocytes (PHH) and to BPV in the case of HBV variant C9A using the RNA Launch model. In this study, we evaluated the susceptibility of BL variants (C9A, T10A, T10G, C20T) and treatment emergent (TE) variants (C9A, G8A, C15T) to BPV in PHH. HBV variant fitness and susceptibility to BPV compared with WT HBV were assessed by the levels of secreted HBsAg and HBeAg.
Method: HBV variant stocks containing clinically identified SNPs in the BPV binding site were generated by transfection of HepG2 cells with 1.3X HBV variant genome plasmids. PHH were infected with WT or HBV variant stocks for 7 days, followed by BPV treatment every 3–4 days totaling 4 sequential doses. After 15 days of BPV treatment, culture supernatant was collected for HBsAg and HBeAg quantification. The susceptibility of HBV variants to BPV compared with WT HBV was determined using dose-response analysis. Mid and high fitness variants were defined as those displaying HBsAg and HBeAg levels of 20–60% or >60% relative to WT HBV, respectively.
Results: HBV variant fitness and susceptibility to BPV were largely consistent between HBsAg and HBeAg readouts. HBV variants exhibited varying levels of fitness, with C9A, T10A, T10G, C20T being high fitness variants, and G8A and C15T being low fitness variants compared with WT HBV. C9A exhibited the lowest susceptibility to BPV compared to WT HBV (about 4.1-fold and 3.6-fold reduction in EC50 as indicated by secreted HBsAg and HBeAg levels, respectively). T10G exhibited approximately 2–3-fold reduction in susceptibility across both readouts. C15T and G8A exhibited approximately 2–3-fold reduction as determined by HBsAg levels and nearly 2-fold reduction as determined by HBeAg levels. T10A and C20T exhibited less than 2-fold reduction across HBsAg and HBeAg readouts.
Conclusion: Using our two-step system of HepG2 and PHH, we evaluated the susceptibility of clinically identified HBV BL and TE variants containing SNPs in the BPV site to BPV. The biological basis for varying levels of fitness of each variant, through potential impact of SNPs on HBx and HBV DNA polymerase function, is under evaluation. While the frequency of these HBV variants is very low, the relevance of the *in vitro* phenotypic data to clinical outcome is subject to further investigation.

SAT-391

Investigation of HBV cccDNA Methylation by Bisulfite sequencing for therapeutic targeting in liver biopsies from hepatitis B patients

Purnima Tyagi[1,1], Akhilesh Saini[1], Jitendra Kumar[1], Shiv Kumar Sarin[1], Vijay Kumar[1]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India*
Email: vijaykumar98@gmail.com

Background and aims: There is a growing need to study novel therapeutics that particularly target cccDNA (covalently closed circular) in hepatitis B virus (HBV), since its eradication may lead to the elimination of chronic hepatitis B (CHB). There is an urgent need to better understand the methylation status of HBV cccDNA throughout the infection, and also the role it plays in viral replication. Thus, identifying novel CpG sites of methylation and demethylation in cccDNA in patients with high and low viral replication may aid in the finding of new targets against cccDNA.
Method: Liver biopsies (n = 20) from CHB patients were collected and were sub-grouped on basis of HBeAg negative (n = 13) and HBeAg positive (n = 7), serum HBsAg positive [$\log_{10}$ IU/ml 3.53 ± 1.04 >6 months], serum HBV DNA [$\log_{10}$ IU/ml 4.3 ± 1.33] and serum HBeAg positive [$\log_{10}$ IU/ml 2.52 ± 0.81]. Isolated cccDNA was treated with Bisulfite treatment and PCR was done of CpG island I, island II, and island III region by using BSP (Bisulfite-specific primers) followed by the sanger sequencing. The HBV DNA level was quantified by qPCR.
Results: The methylation sites in CpG island II, and III were significantly higher in $HBeAg^-$ patients ($p < 0.01$) as compared to $HBeAg^+$ patients. CpG island I (1–236) region cytosines at positions 74, 94, 157, and 161 were found to be in a demethylated state in both patient groups and cytosines at 1201, 1579, 1689, 1698, 1750, and 1774 were frequently methylated in the CpG II island (1126–1804) region in $HBeAg^-$ patients. Furthermore, cytosines at positions 2555, 2597, and 2601 in CpG III island (2497–2642) were found to be in a methylated state in the $HBeAg^-$ group whereas these sites were observed in a demethylated state in the $HBeAg^+$ group. No significant correlation was found between methylation status and HBV DNA levels in the CpG island I ($p > 0.01$). The degree of CpG island II ($p < 0.05$) and CpG island III ($p < 0.01$) methylation was significantly higher in patients with low HBV DNA titer (Log_{10} HBV DNA >4) than that with high HBV DNA titer (Log_{10} HBV DNA <4).
Conclusion: CpG I in the HBV genome was seldom methylated whereas, CpG II and III regions appeared to be the hot spots for methylation in the HBV genome. CpG island III of the HBV cccDNA showed a higher methylation levels in patients associated with lower serum HBV DNA levels indicating that hypermethylation of CpG island II and III contributes to the reduced HBV DNA levels. Thus, our findings suggest cccDNA methylation in CpG island II and III correlates with reduced viral mRNA transcription, which in turn could lower the serum HBV DNA loads. However, there was no significant association was found between CpG islands methylation density and ALT/AST levels. Nevertheless, association between cccDNA methylation and viral replication has provided the basis for developing innovative therapeutic strategies of silencing cccDNA and eventually depleting the cccDNA reservoir.

SAT-392

Perturbed pathways of lipid metabolism in patients with chronic hepatitis B infection after cessation of long term nucleos (t)ide analogue

Fengge Zhu[1], Rex Wan-Hin Hui[1], Liqiong Yang[1], Saisai Zhang[1], Jiaqi Wang[1], Xue Li[1], Tsz Yan Kwok[1], James Fung[1], Wai-Kay Seto[1], Man-Fung Yuen[1], Lung Yi Loey Mak[1]. *[1]The University of Hong Kong, Hong Kong, China*
Email: loeymak@gmail.com

Background and aims: The 'stop-to-cure' approach is a potential strategy to achieve finite duration of nucleoside analogue (NUC) in patients with chronic hepatitis B (CHB) infection. We examined the serial serum metabolomic profiles among flare compared to non-flare CHB patients who had stopped NUCs, followed by *in silico* data mining to identify relevant pathways.
Method: Patients with HBeAg-negative non-cirrhotic CHB on ≥3 years of NUC were recruited. NUCs were stopped and they were prospectively followed up every 6 weeks for virological relapse (VR: serum HBV DNA rise from undetectable to >2000 IU/ml) ± clinical flare (VR plus alanine aminotransferase [ALT] >2 times upper limit of normal), with serial blood sampling for metabolomic profiling at week 0, at NUC resumption (for flare patients, or non-flare patients

with VR or HBeAg sero-reversion), and at ALT normalization following NUC resumption among flare patients. A total of 8 patients (4 flare [among which 2 developed subsequent HBsAg seroclearance, SC], 4 VR or HBeAg sero-reversion) were included in this interim analysis. Serum metabolomics data was acquired with 1D 1H-Nuclear magnetic resonance spectroscopy. Metabolomics data was analysed with MetaboAnalyst 6.0. GEO datasets was analyzed with GEO2R.

Results: Metabolites involved in lipid metabolism (triglyceride and total fatty acid) were significantly downregulated in flare patients compared to non-flare patients at NUC resumption. Among flare patients, succinic acid is significantly downregulated in those who subsequently achieved SC compared to flare-no-SC patients upon ALT normalization. Dimethylsulfone involved in triacylglycerol degradation is upregulated in flare patients with SC, compared to flare-no-SC and non-flare patients, at all timepoints. Compartment specific *in silico* data mining based on GEO DataSets showed genes involved in fatty acid synthesis (FAR1, FASN), fatty acid elongation in mitochondria (NDUFAB1), fatty acid elongation in endoplasmic reticulum (ELOVL1, ELOVL5) were significantly increased in the liver of CHB patients (GSE230397) compared to control, but not in peripheral blood CD8 T cells (GSE217838), indicating a compartment specific imbalance of lipid metabolism. In CHB patients with severe flare, fatty acid beta-oxidation associated genes ACAT1, ACSL1 and ACSL4 were significantly downregulated in the PBMCs of the survival group compared to patients who died (GSE168049).

Conclusion: We demonstrated alterations of lipid metabolism pathways in CHB patients with post-NUC cessation flare that were associated with clinical outcomes. Fatty acid metabolism is perturbed in patients with CHB and is inferred to be associated with survival in those with severe HBV flare based on in silico datasets analysis. Our work reveals an imbalance in lipid metabolism in CHB both in spatial location and molecular signature.

Email: mariafcortese@gmail.com

Background and aims: A limited percentage of chronic hepatitis D (CHD) patients can achieve spontaneous or treatment-related control of hepatitis delta virus (HDV) replication (undetectable HDV RNA), however the mechanism behind this virological control is still unclear. The microRNAs (miRNAs) are small RNAs involved in several biological processes, including the host response to a viral infection. The aim of this study was to analyze the circulating miRNAs profile of CHD patients to identify potential biomarkers that differentiate controllers from non-controllers (HDV patients with respectively undetectable and detectable HDV RNA).

Method: Thirty CHD patients (anti-HDV positive) were included in the study: 15 controllers (with undetectable HDV RNA in at least two consecutive samples) and 15 non-controllers (persistent detectable HDV RNA). Biochemistry values and virological parameters were collected. The small RNAs (including miRNAs, miRNAs precursors and small nucleolar RNA- snoRNA) were isolated from the CHD plasma samples and their profile was analyzed by microarray (Afflimetrix, miRNA array). The differentially expressed miRNAs were identified by adjusting a linear model with empirical Bayes moderation of the variance. The main miRNA targets were catalogued by using different databases (mirecords, mirtarbase, tarbase), and their most represented biological roles were evaluated by enrichment analysis (Gene Ontology-MF and Reactome pathway).

Results: More than 6300 small RNA sequences were included in the differential expression study. Among them, 20 small RNAs were differentially expressed between the two groups (non-adjusted p value <0.05; absolute log2FC >1) mainly targeting genes implicated in DNA transcription and pathways involved in intracellular signaling. When considering an adjusted p value (BH-adjusted $p < 0.25$, absolute log2FC >1 and B-statistic >0 or average expression >1.5), 6 miRNAs were differently expressed between the groups. The HDV controllers (undetectable HDV RNA) showed 5/6 down-regulated (miR-23b-3p, miR-194-5p, miR-122-5p, miR-192-5p and miR-26a-5p with a log2FC of respectively −3.13, −2.62, −4.07, −1.54 and −2.7) and 1/6 (miR-33a-5p; log2FC of 0.29) up-regulated miRNAs in comparison to subjects with detectable HDV RNA.

Conclusion: A different miRNAs profile can be observed in chronic hepatitis D patients that can control the HDV replication or not. The most differentially expressed miRNAs could regulate target genes involved in cellular transcription and intracellular signaling pathway. Further studies are needed to inspect the specific mechanism associated with miRNAs expression, their activity on cellular gene expression and their role in HDV replication. Study supported by the grants PI20/01692 and PI23/01065, funded by Instituto de Salud Carlos III and co-funded by European Union (ERDF, "A way to make Europe").

HBV genotyping: grasping a new window of opportunity?

Marion Delphin[1], Ka Chun Li[2], Elizabeth Waddilove[1], Cedric Tan[1], Jacqueline Martin[3], Catherine De Lara[4], Eleanor Barnes[5], Jose Lourenco[6], Philippa C Matthews[1,7]. *[1]the francis crick institute, london, United Kingdom; [2]university college london, london, United Kingdom; [3]John Radcliffe Hospital, oxford, United Kingdom; [4]Medawar Building for Pathogen Research, University of Oxford, oxford, United Kingdom; [5]Department of Hepatology, John Radcliffe Hospital, oxford, United Kingdom; [6]BioISI (Biosystems and Integrative Sciences Institute), Faculty of Sciences, University of Lisbon, lisbon, Portugal; [7]University college london, london, United Kingdom*
Email: marion.delphin@crick.ac.uk

Background and aims: The Hepatitis B Virus (HBV) accounts for chronic infection in 316 million people worldwide, in spite of a safe and efficient vaccine since the 1990′s. Incomplete immunisation coverage, poor diagnosis and treatment, and high prevalence of infection make HBV a leading contributor to hepatocellular carcinoma and cirrhosis. Ten HBV genotypes have been described (from A to J), defined by >8% divergence in nucleotides. Each has specific geographic distribution, transmission patterns, pathophysiology, treatment outcomes and resistance profiles, however genotyping is still not part of routine testing for people living with HBV (PLWHB). The current gold standard, HBV full genome sequencing and phylogenetic analysis, requires resources, time and expertise, which are not widely accessible in many clinical settings. Other methods have been described, but with varying sensitivity in discriminating between the ten genotypes.

Method: To identify the optimum window for distinguishing between genotypes we used public data from 9, 777 HBV sequences

(representing genotypes A to H; I and J excluded due to recombination). Sequences were aligned, numbered (HBV X02763 reference sequence) and fitted in a Random Forest Algorithm, with a sliding window approach across the viral genome. We identified a window of 450 bp in the HBV polymerase gene (nucleotides 642–1092), which confidently distinguishes between genotypes with the lowest error. We designed PCR primers specific to this window (5′ GGG-TCA-CCA-TAT-TCY-TGG-GAA-CAA-G 3′ and 5′ CTG-TAA-CAC-GAG-AAG-GGG-TCC-TAG 3′) and performed PCR, followed by Sanger sequencing, to two sample sets, (i) A dilution series of plasmids of known sequence/genotypes containing HBV genomes (genotype A, B, C, D, E, F, H, J provided by the Revill lab) or produced using a similar design by GenArt (genotype G and I). (ii) 10 Serum samples obtained from PLWHB (genotype A, B, C, D, E and G), enrolled at Oxford University Hospitals, UK (ethics ref.N17/01/013).

Results: We validated our new PCR primers to amplify the optimum genotyping window, showing that the method works on HBV plasmid genotypes of viral genome equivalent (VGE) down to 10^3/ml. When comparing the known genotype of each plasmid, with the one identified with our method, an accuracy of 100% was observed for all genotypes except HBV-I (identified as HBV-A). Serum samples of PLWHB were then used to further confirm our technique.

Conclusion: We developed an HBV genotyping method capable of distinguishing all major genotypes with a low rate of errors, at high sensitivity (down to 10^3 VGE/ml) using standard techniques that could be deployed in broad settings. This rapid and affordable approach could overcome the existing barriers to implementing HBV genotyping in routine services, contributing to insights into epidemiology, disease outcomes, evaluation of novel therapeutics, and personalised medicine.

ROS-dependent activation of JAK2/STAT3 pathway contributes to HBV-induced liver inflammation

Rui Song[1], Shasha Yu[1], Wenhui Peng[1], Jinglin Tang[2], Min Chen[1].
[1]Department of Infectious Diseases, the Second Affiliated Hospital of Chongqing Medical University, Chongqing, China; [2]Department of Laboratory, the People's Hospital of Chongqing, Chongqing, China
Email: mchen@hospital.cqmu.edu.cn

Background and aims: Recent studies suggested that hepatitis B virus (HBV) might induce mitochondrial dysfunction, resulting in increased reactive oxygen species (ROS) production. However, very little is known about whether ROS is responsible for the occurrence of hepatic inflammation during chronic HBV infection.

Method: An HBV-replicating mouse model was established by performing HBV-expressing plasmids pAAV-HBV1.2 hydrodynamic injection. Levels of intrahepatic ROS, oxidative stress and liver inflammation grade were dynamically evaluated. Meanwhile, inflammation-related cytokines production, immune cell infiltration, and signal pathway activation in liver tissue were examined by RT-PCR, WB, and FACS. Moreover, in vivo antioxidant treatment was applied to explore the potential mechanisms of the occurrence of hepatic inflammation mediated by ROS.

Results: Significantly increased ROS fluorescence intensity and decreased ratio of reduced to oxidized glutathione (GSH/GSSG) were observed in liver tissue from mice at 4 weeks after injection of pAAV-HBV1.2 plasmids. Simultaneously, these mice displayed remarkably higher liver inflammation grade and elevated serum ALT levels with prominent upregulation of inflammatory cytokines production (IL-6 and IL-8) and immune cell infiltration (monocytes). Meanwhile, enhancement of Nrf2 expression and activation of JAK2/STAT3 signaling pathway were found in these mice. Furthermore, ROS scavenging with N-acetylcysteine attenuated activation of JAK2/STAT3 pathway and liver inflammation.

Conclusion: This study revealed that HBV-induced ROS overproduction activates the JAK2/STAT3 pathway and contributes to the liver inflammation. Our findings provide a new look at the key factor to trigger hepatic inflammation during chronic HBV infection.

Differences in the intrahepatic expression of immune checkpoint molecules on T cells and natural killer cells in chronic HBV patients

Lucile Dumolard[1], Marie-Noëlle Hilleret[1], Gerster Théophile[2], Charlotte Costentin[1,2], Thomas Decaens[1,2], Evelyne Jouvin-Marche[1], Patrice N Marche[1], Zuzana Macek Jilkova[1,2]. *[1]Univ. Grenoble Alpes, Inserm U 1209, CNRS UMR 5309, Team Epigenetics, Immunity, Metabolism, Cell Signaling and Cancer, Institute for Advanced Biosciences, Grenoble, France; [2]Service d'hépato-gastroentérologie, Pôle Digidune, CHU Grenoble Alpes, La Tronche, France*
Email: zuzana.mjilkova@gmail.com

Background and aims: Patients with chronic hepatitis B virus (HBV) infection are characterised by impaired immune response that failed to eliminate HBV. Nucleos (t)ide analogs (NUC) are antiviral treatments representing the standard of care, but rarely lead to HBsAg clearance. Future therapies focus on the use of immunotherapies in combination with NUC to remodel the host immune response. Immune checkpoint molecules (ICM) control the amplitude of the activation and function of immune cells, that makes them the key regulators of the immune response.

Method: Here, we performed a multiparametric flow cytometry analysis of ICM and we determined their expression on intrahepatic lymphocyte subsets in untreated and in treated patients with HBV in comparison with non-pathological liver tissue.

Results: Liver of untreated inactive carriers as well as immune active HBV patients exhibited high accumulation of PD-1+CD8+ T cells while the frequencies of TIM-3+CD8+ T cells, 4–1BB+ T cells and 4–1BB+NK cells were highest in immune active phase. Our findings showed that the HBeAg status is linked to a distinct immune phenotype of intrahepatic CD8+ T cells and NK cells characterised by high expression of ICM, particularly 4–1BB. Importantly, antiviral treatment partially restored the normal expression of ICM in the liver compartment in NUC-treated HBV patients. Finally, we described important differences in ICM expression between intrahepatic and circulating NK cells in chronic HBV patients.

Conclusion: Our study shows clear differences in the intrahepatic expression of ICM on NK cells and T cells in chronic HBV patients depending on their clinical stage.

Background and aims: Hepatitis B virus (HBV) infection is a major cause of hepatocellular carcinoma (HCC) development worldwide. One key carcinogenic mechanism of HBV involves the integration of its DNA into the host genome. Recent findings have revealed that mitochondrial DNA (mtDNA) may also be a target for HBV integration. This suggests a novel potential mechanism whereby the integration of HBV into mtDNA could play a role in liver damage and the progression of HCC. The objectives of this study included: (1) Conducting a comprehensive analysis of HBV integration into mtDNA of the HepaD38 cell line, which is derived from HepG2 cells and supports tetracycline (Tet)-off inducible HBV replication; (2)

Assessing the mitochondrial function in HepaD38 cells during HBV replication.
Method: We employed a high-throughput Hepatitis B Virus Integration Sequencing (HBIS) method alongside RNA sequencing (RNASeq) to explore HBV integration within mitochondria isolated from HepaD38 cells, following Tet removal for a period of seven days. Concurrently, at this same time point, we assessed the mitochondrial function of HepG2 and HepaD38 cells using the Seahorse XFp Analyzer.
Results: Seven days post Tet removal, the average quantities of HBV DNA and HBV RNA in HepaD38 cells were $1.1 \times 10^3 \pm 6.0 \times 10^2$ and $1.0 \times 10^1 \pm 5.9 \times 10^{-1}$ copies per cell, respectively. Concurrently, the mean levels of HBV DNA and HBsAg in the cell supernatants were $2 \times 10^6 \pm 2.7 \times 10^4$ copies/ml and $4.1 \times 10^3 \pm 7.2 \times 10^2$ IU/ml, respectively. At the same time point, HBIS revealed an average of 81 ± 11.9 HBV integration sites in the mtDNA of ~ 1.5×10^5 HBV-replicating HepaD38 cells. Notably, these integration sites were predominantly found in the COX1, RNR2, and ND2 mitochondrial genes. Additionally, RNASeq analysis revealed a substantial presence (average ± S.D.: 635 ± 143.7) of HBV-mitochondrial transcript fusions within the same number of HBV-induced HepaD38 cells. We found multiple instances of chimeric transcripts resulting from HBV integration into mtDNA with flanking mitochondrial sequences most frequently corresponding to the COX1, RNR2, ND2, ND4, and ND6 genes. Interrupted HBV open reading frames (ORFs) were common in the surface gene (HBs), X gene (HBx), and between X and core (HBc) regions. Functional analysis of the mitochondria demonstrated that, in comparison to HepaD38 cells without HBV replication and viral integration, those replicating HBV exhibited a two-fold decrease in basal respiration, ATP-linked respiration, and maximal respiration.
Conclusion: The results of this study indicate that: (1) HBV can integrate into the mtDNA of HepaD38 cells during HBV replication; (2) the mtDNA site of HBV insertion may be transcriptionally active; and (3) the replication of HBV and its integration into mtDNA may contribute to mitochondrial dysfunction.

SAT-398
Rapid establishment of enterically-transmitted hepatitis viruses animal model by using lipid nanoparticle-based viral RNA delivery system

Tianxu Liu[1], Lin Wang[2]. [1]*Peking university health science center, Beijing, China;* [2]*School of Basic Medical Sciences, Beijing, China*
Email: lin_wang@pku.edu.cn

Background and aims: HAV and HEV are currently the most common causative agent of acute viral hepatitis in humans. Wild-type HAV and HEV has long been extremely difficult to culture in cells and only limited cell-adapted strains can be used for in vitro culture. The viral stocks used to infect animals are usually prepared directly from feces or liver homogenates collected from infected animals or humans. Using reverse generic system, either after many days or weeks in culture to collect adequate titers of infectious viral stocks or direct injection of in vitro transcribed (IVT) full-length viral genomic RNA (vRNA) into the liver is required to establish animal infection. These procedures are either time-consuming or warrant invasive operation which impede the efficiency, uniformity and quality control of the establishment of a tractable animal model. Therefore, a culture-free, robust and rapid approach for the establishment of in vivo infection is urgently warranted.
Method: By using this innovative LNP-based RNA delivery platform and full-length viral genome RNA (vRNA) system, we successfully encapsulated the full-length viral genome RNAs (vRNAs) of HAV and HEV into LNP, and established the corresponding animal models by intravenous injection of these LNP-vRNA formulations. The effect of the model was evaluated by detecting fecal detoxification, urine antigen, liver tissue HE staining, immunohistochemistry, transcriptome analysis and other experimental methods.
Results: We rationally prepared Lipid nanoparticle (LNP)-encapsulated full-length genomic RNA (vRNA) of HAV and HEV, and establishment of HAV and HEV infection was achieved after intravenous injection in susceptible animals. Upon LNP-vRNA injection, HAV and HEV Infection resulted in rise of viral RNA in feces, liver or bile samples, or viral antigen in urine. 10 μg HEV RNA could induce successful infection in individual rabbit. Liver showed inflammatory infiltration and active transcriptional response against acute HEV infection. The antiviral efficacy of ribavirin and in vivo function of HEV genome mutation and deletion were validated in our model.
Conclusion: By using this innovative LNP-based RNA delivery platform and full-length viral genome RNA (vRNA) system, we successfully encapsulated the full-length viral genome RNAs (vRNAs) of HAV and HEV into LNP, and established the corresponding animal models by intravenous injection of these LNP-vRNA formulations. This novel approach enables rapid and efficient establishment of HAV and HEV in vivo infection in multiple animals, providing a powerful tool to investigate the pathogenesis of these enterically-transmitted hepatitis viruses as well as to evaluate specific countermeasures.

SAT-399
Immune profiling of HBsAg-specific B cells in CHB patients with HBsAg loss

Yifei Guo[1], Yue Guo[1], Yide Kong[1], Haoxiang Zhu[1], Jiming Zhang[1].
[1]*Department of Infectious Diseases, Shanghai Key Laboratory of Infectious Diseases and Biosafety Emergency Response, National Medical Center for Infectious Diseases, Huashan Hospital, Fudan University, Shanghai, China*
Email: yfguo21@m.fudan.edu.cn

Background and aims: HBsAg loss, namely, the functional cure, is the optimal end point of current antiviral therapies. However, little is known about the frequency, phenotype and class-switching of HBsAg-specific B cells in chronic hepatitis B (CHB) patients with HBsAg loss. Here, we compare the HBsAg-specific memory B cells (HBs^+ Bm cells) of CHB patients with and without HBsAg loss, as well as functional cure CHB patients with different anti-HBs levels.
Method: We included 42 treatment-naïve CHB patients without HBsAg loss (chronic HBsAg+), 94 interferon-treated CHB patients with HBsAg loss (chronic HBsAg-), and 20 healthy controls with or without HBsAg-vaccinated. Detailed characterization of memory B cell responses in peripheral blood was determined through high-dimensional flow cytometry. HBs^+ Bm cells were identified and examined using fluorescently labeled HBsAg bait.
Results: No statistically differences in frequency were observed among vaccinated controls (median 0.09%), chronic HBsAg+ (median 0.14%), and chronic HBsAg- (median 0.14%) patients. Similarly, the frequency did not differ significantly across all clinical phases of chronic HBV infection. Of note, we observed that the increased frequency of HBs+ Bm cells was accompanied by concordant elevation of anti-HBs levels, even though there was a trend, not statistical significance, towards elevated frequencies in patients with 10≤anti-HBs <500 IU/L compared with anti-HBs <10 IU/L. A composite sample was generated by merging FCM results of HBs+ Bm cells with non-HBs+ Bm cells from CHB patients. The UMAP showed a clear segregation of HBs+ Bm cells from non-HBs+ Bm cells, indicating the distinct immune profiles of HBs+ Bm cells. Furthermore, compared with global memory B cells, a range of expression of inhibitory markers, including BTLA, CD11c, PD-1, CD22, and FcRL5 were increased, which were consistent with preliminary studies on impaired HBsAg-specific B cell function. When comparing the differences of HBs+ Bm cells in chronic HBsAg+ and chronic HBsAg- patients, there were not significant differences in frequency of resting ($CD21^+CD27^+$), activated ($CD21^-CD27^+$), atypical ($CD21^-CD27^-$), and intermediate ($CD21^+CD27^-$) HBs+ Bm cells. Of note, expressions of T-bet and CXCR5 were decreased in chronic HBsAg- patients. Analysis of class-switching of HBs+ Bm cells detected a trend towards elevated

proportion IgG$^+$ HBs+ Bm cells in chronic HBsAg- compared with chronic HBsAg+ patients. For chronic HBsAg- patients, HBs+ Bm cells in patients with anti-HBs ≥500 IU/L exhibited lower expression of CXCR5 and higher proportion of IgG$^+$ than other two groups (10≤anti-HBs <500 IU/L and anti-HBs <10 IU/L).
Conclusion: HBs$^+$ Bm cells exhibit a distinct immune profile compared to global memory B cells. Low expression of CXCR5 in HBs$^+$ Bm cells might be associated with restored function and a favorable outcome.

SAT-402

Bemnifosbuvir is a potent HCV NS5B inhibitor with a favorable antiviral profile and high resistance barrier

Qi Huang[1], Dawei Cai[1], Steven Good[1], Nancy Agrawal[1], Jean-Pierre Sommadossi[1]. *[1]Atea Pharmaceuticals, Inc., Boston, United States*
Email: huang.qi@ateapharma.com

Background and aims: Bemnifosbuvir (BEM), an oral prodrug of a guanosine nucleotide analog, has demonstrated highly potent, pan-genotypic, best-in-class *in vitro* antiviral activity against all hepatitis C virus (HCV) genotypes (GTs 1–5) tested. Viral resistance has emerged as an important consideration for direct-acting antivirals (DAAs) as it may impact efficacy of HCV infection treatment. The antiviral activity of BEM was profiled against a panel of sofosbuvir (SOF) non-structural protein 5B (NS5B) resistance-associated variants (RAVs) selected *in vitro* or identified in HCV patients. *In vitro* resistance selection was performed using HCV GT-1a and –1b replicon cells to identify NS5B RAVs potentially impacting BEM antiviral activity.
Method: *In vitro* resistance selection was conducted in the presence of G418 and gradually-increasing concentrations of AT-511 (free base of BEM). Cells from each passage were collected for genotypic analysis. Emerging NS5B substitutions (single or linked) were selected for phenotyping in transient replicon assays.
Results: Resistance selection in GT1b replicons identified C223H as the primary substitution that confers resistance to AT-511, which is the same mutant identified in GT-2a (JFH-1) replicons cultured in the presence of PSI-352938 or PSI-353661, two HCV nucleotide analogs that also generate the same active tri-phosphate AT-9010, in previous studies (Lam, JVI, 2011). C223H substitution requires two nucleotide mutations, which confers a higher barrier to resistance. Additional substitutions were identified in GT-1a (C316F, N444D, F574V, I585T) and GT-1b (F54I, N206S, E237G, T344I, Y586C). Phenotypic evaluation of both GT-1a and –1b mutations indicated that single amino acid changes did not significantly reduce AT-511 activity (up to 1.7-fold). However, a combination of amino acid changes in GT-1b (F54I, C223H, E237G, T344I, Y586C) conferred higher levels of resistance (up to 5.9-fold). In addition, SOF did not show cross-resistance to C223H, and only conferred weak resistance to the linked mutants.
Conclusion: BEM is at least 10-fold more potent than SOF across all genotypes tested and is not resistant to SOF RAVs (S282T, L159F/S282T). C223H was found to be the primary BEM RAV in GT-1b and multiple substitutions at other NS5B regions were required to confer meaningful resistance, suggesting a very high barrier to resistance for BEM. BEM is currently being evaluated in combination with ruzasvir (RZR), a highly potent pan-genotypic NS5A inhibitor, in a Phase 2 clinical trial (NCT05904470). Based upon the data demonstrated to date, it is expected that the BEM/RZR combination should have a more compelling antiviral profile against major HCV NS5A RAVs than current standard of care.

SAT-403

Vitamin D supplementation accelerated reduction of HBsAg levels in patients with chronic hepatitis B requiring treatment and in inactive carrier phase

Thitaporn Roongrawee[1], Sirinporn Suksawatamnuay[2], Panarat Thaimai[2], Prooksa Ananchuensook[3], Supachaya Sriphoosanaphan[4], Kessarin Thanapirom[5], Piyawat Komolmit[6]. *[1]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [2]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [3]Chulalongkorn University, Division of Gastroenterology, Department of Medicine, Bangkok, Thailand; [4]Institute for Liver and Digestive Health, University College London, London, United Kingdom; [5]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Bangkok, Thailand; [6]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand*
Email: thitagiftr@gmail.com

Background and aims: Low levels of vitamin D are prevalent among individuals with chronic hepatitis B (CHB) infection. Vitamin D is known to modulate the immune system and potentially influence the immune response to hepatitis B viral replication, as indicated by the quantitative hepatitis B surface antigen (qHBsAg)-a marker of viral replication and predictive indicator for functional cure. Previous studies established a correlation between vitamin D levels and qHBsAg levels. However, the direct impact of vitamin D supplementation on qHBsAg levels remains a subject of ongoing investigation.
Method: Retrospective data from HBV inactive carriers and CHB patients undergoing antiviral treatment with initially low vitamin D levels were analyzed. Quantification of qHBsAg levels before and after vitamin D supplementation over an 18-month period was conducted.
Results: Among 1069 CHB cases follow-up at King Chulalongkorn Memorial Hospital's liver clinic, complete data for qHBsAg and vitamin D levels were available for 203 patients. Of these, 88 were inactive carriers, and 115 were CHB patients. Vitamin D insufficiency (vitamin D levels 20–30 ng/ml) was observed in 77 patients, while 97 patients had vitamin D deficiency (vitamin D levels below 20 ng/ml). Pre-supplementation vitamin D levels averaged 19.5 ± 4.8 ng/ml and significantly increased to 36.69 ± 14.58 ng/ml post-supplementation ($p < 0.01$). Most patients received weekly vitamin D supplements at a dosage of 40, 000 IU/week (N 145; 71.43%), followed by 60, 000 IU/week (N 43; 21.18%) and 20, 000 IU/week (N 15; 7.38%), respectively. The average interval between qHBsAg measurements before starting vitamin D was 10.6 months and the average time after vitamin D initiation was 11.1 months. The level of qHBsAg demonstrated an 11.23% decrease before vitamin D supplementation, significantly reducing further to 18.20% post-supplementation ($p = 0.032$). Subgroup analysis revealed a significant decline of qHBsAg level in 88 inactive carriers (–9.23% vs –19.30%; $p = 0.028$) and in 79 patients with qHBsAg levels more than 1, 000 IU/ml (0.53% vs –14.30%; $p = 0.009$). However, CHB patients on antiviral treatment and patients with qHBsAg levels between 100 and 1, 000 IU/ml showed substantial reduction but lacked statistical significance (-12.77% vs –17.35%; $p = 0.422$, –13.77% vs –18.31%; $p = 0.257$, respectively).
Conclusion: This study demonstrates a significant decrease in qHBsAg levels following vitamin D supplementation, particularly prominent in individuals with high qHBsAg levels exceeding 1, 000 IU/ml and inactive carriers. These findings imply a potential enhancement of qHBsAg decline facilitated by vitamin D. The implications warrant further exploration if vitamin D's role in managing chronic hepatitis B, presenting avenues for future research.

SAT-404

The Lipidome in phenotyping hepatitis B infection ('LiPHe-B'): preliminary results from our pilot study

Marion Delphin[1], Susana Palma-Duran[1,2], Mariana Silva dos Santos[1], Emily Martyn[1], Elizabeth Waddilove[1], Emma Wall[1], Tongai Gibson Maponga[3], Jacqueline Martin[4], Catherine De Lara[5], Paul Klenerman[5], Eleanor Barnes[5], James Macrae[1], Philippa C Matthews[1,6]. Email: marion.delphin@crick.ac.uk

Background and aims: Chronic Hepatitis B infection (CHB) kills 1 million people per year, due to liver fibrosis, cirrhosis, and hepatocellular carcinoma (HCC). Hepatitis B Virus (HBV) has been described as a 'metabolovirus' for its close connection with host metabolism and lipids, but current biomarkers are blunt tools for risk assessment, and guidelines do not account for host and viral genetics, metabolic risk factors, and environmental influences contributing to liver disease. There is a need for improved risk-stratification that accounts for these parameters and can inform patient-stratified approaches. The liver is one of the most important organs in energy metabolism, and the origin of most blood lipids, potentially explaining why host lipid profiles could impact or reflect the antiviral immune response and HCC progression. We set out a pilot study to optimize methods and establish proof-of-principle for this approach in HBV, and to determine whether profiles differed between people living with HBV (PLWHB) vs healthy controls.
Method: Serum samples were obtained from PLWHB, enrolled at Oxford University Hospitals, UK (n = 60) (ethics ref.N17/01/013) and age and sex-matched healthy non-infected adults, from the Legacy Study, London UK (n = 60) (ethics ref.21/YH/0222). Meta-data were recorded at the time of recruitment, supported by Electronic Patient Records where available. Lipids were extracted using a modified Bligh-Dyer extraction method followed by Liquid Chromatography-Mass Spectrometry (LC-MS) analysis for lipidome profile. Data processing and statistical analysis were performed using Xcalibur (Thermo Scientific), MS-DIAL (v 5.1.230517), KniMet pipeline for MS-based and SIMCA 17 (Sartorius, Germany). Principal component analysis (PCA) and orthogonal partial least square-discriminant analysis (OPLS-DA) models were used to explore the differences in the lipidome between CHB and controls.
Results: Comprehensive lipid profiles were obtained for a pilot subset of 40/120 serum samples. Initial multivariate analyses revealed clear differences in the lipidomes of non-infected and infected individuals. Detected features were initially annotated by comparison of molecular and associated fragment ions to compound libraries (both in-house and commercial). Further lipid extraction and identification is currently ongoing, along with additional clustering analysis based on liver disease progression in patients.
Conclusion: Adults living with HBV have a distinct lipidome profile that distinguishes them from matched adult controls. Developing insights into lipid biomarkers may enhance our understanding of the mechanisms that determine infection outcomes and treatment response, support better patient-stratification risk assessment and guide evidence-based interventions.

SAT-405

Differential expression and sequence variants of sodium taurocholate cotransporting polypeptide (NTCP) do not affect HDV inhibition by Bulevirtide (BLV)

Simin Xu[1], Thomas Aeschbacher[1], Savrina Manhas[1], Chunfeng Li[1], Ross Martin[1], Yang Liu[1], Evguenia Maiorova[1], Hongmei Mo[1], Roberto Mateo[1]. [1]*Gilead Sciences Inc, Foster City, United States*
Email: simin.xu@gilead.com

Background and aims: The bile acid transporter sodium taurocholate cotransporting polypeptide (NTCP) is a transmembrane protein expressed on the surface of hepatocytes in the liver. NTCP is also an entry receptor for hepatitis B virus (HBV) and its satellite hepatitis D virus (HDV). The HDV entry inhibitor bulevirtide (BLV) specifically binds NTCP and blocks HDV from entering hepatocytes. The goal of this study was to investigate the role of NTCP expression level and polymorphisms on BLV inhibition of HDV.
Method: Public data were analyzed to identify NTCP single nucleotide polymorphisms (SNPs) with a Minor Allele Frequency (MAF) >1% in United States (US) and global racial groups (White, Black, Asian, Latino). In addition, NTCP whole exon sequencing was performed on primary human hepatocytes (PHHs) from 50 US donors. These were further evaluated for NTCP expression, mRNA levels and HDV sensitivity to BLV in an in vitro phenotyping assay. PHHs from 33 PHH donors carrying identified NTCP SNPs and various expression NTCP levels were evaluated for HDV sensitivity to BLV in an in-vitro phenotyping assay.
Results: Six NTCP SNPs were observed in the public dataset with MAFs >1% in one or more racial group. Of these SNPs, 2 were non-synonymous (C800T, T668C) and 4 were synonymous (G225A, T627C, C960A, C111T). C800T (aaS267F) was found with a MAF of 3.6% in the Asian racial group in the global dataset. T668C (aaI223T) was found in the Black racial group in the US and global datasets with MAFs of 1.6% and 4.1%, respectively. Four NTCP variants were detected in the 50 PHH donors from the US. C800T (aaS267F) and T668C (aaI223T) non-synonymous SNPs were detected in PHHs from an Asian and Black donor, respectively. Synonymous SNPs G225A and T627C were detected in 4 donors (Black, n = 2; Latino, n = 1; White, n = 1) and 2 Black donors, respectively. NTCP surface protein levels varied 5.8-fold and mRNA levels varied 391-fold among the 50 PHH donors. BLV remained active against HDV on PHHs expressing all levels of NTCP and all NTCP SNPs observed in the 50 US donors.
Conclusion: BLV potently inhibits HDV regardless of naturally occurring NTCP sequence variants and differential NTCP expression levels.

HBV dominance is associated with a distinct inflammatory milieu in HBV/HCV coinfection

Carlos Oltmanns[1,2,3], Moana Witte[1,2,3], Anika Wranke[1], Katja Deterding[1], Heiner Wedemeyer[1,4,5], Christine Falk[6], Anke R.M. Kraft[1,2,3,4,5], Steffen Wiegand[7], Markus Cornberg[1,2,3,4,5]. [1]*Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School (MHH), Hannover, Germany;* [2]*Centre for Individualised Infection Medicine (CiiM), a joint venture between the Helmholtz Centre for Infection Research (HZI) and Hannover Medical School (MHH), Hannover, Germany;* [3]*TWINCORE, a joint venture between the Helmholtz-Centre for Infection Research (HZI) and the Hannover Medical School (MHH), Hannover, Germany;* [4]*Cluster of Excellence Resolving Infection Susceptibility (RESIST; EXC 2155), Hannover Medical School, Hannover, Germany;* [5]*German Centre for Infection Research (DZIF), partner site Hannover-Braunschweig, Hannover, Germany;* [6]*Institute of Transplant Immunology, IFB-Tx, Hannover Medical School, Hannover, Germany;* [7]*Department of Anesthesiology and Intensive Care Medicine, Hannover Medical School, Hannover, Germany*
Email: oltmanns.carlos@mh-hannover.de

Background and aims: Hepatitis B (HBV) and C (HCV) virus coinfection is linked to a higher risk of cirrhosis and hepatocellular carcinoma (HCC) compared to monoinfection. Despite this, data is limited, and further investigation is needed to understand the underlying mechanisms. While patients are classified based on dominance patterns, the impact on the immune system remains largely unknown. It is recognized that HBV reactivation may occur following HCV clearance. This study aims to explore the potential immune interactivity between HCV and HBV by analyzing patterns of soluble immune mediators (SIM).
Method: Fifty-nine soluble immune mediators were measured in serum or plasma samples of 49 patients chronically infected with hepatitis B and hepatitis C virus. Patients were classified based on dominance patterns: HBV dominance (n = 8), HCV dominance (n = 22), HBV and HCV codominance (n = 11) and no dominance (n = 8).
Results: SIM expression was distinct based on different dominance patterns. HBV activity induced higher SIM expression and altered the soluble inflammatory milieu (22 SIM altered, $p < 0.05$). Altered pathways included JAK-STAT pathway ($p = 1.36 \times 10^{-20}$), IL-17 signaling ($p = 2.47 \times 10^{-13}$) and Th17 ($p = 1.69 \times 10^{-9}$) cell differentiation. CTACK ($r = -0.69$, $p = 7.02 \times 10^{-6}$) and SDF-1alpha ($r = -0.55$, $p = 0.002$) correlated inversely with HCV-RNA.
Conclusion: Serologically classifying dominance patterns in HBV and HCV coinfection may manifest in a distinct soluble inflammatory milieu. Elevated HBV activity correlates with an increased expression of soluble immune mediators, particularly influencing the alteration of key signaling pathways such as JAK-STAT and the TH17/IL-17 axis. These changes play a crucial role in the development of liver fibrosis.

SAT-407

Long-term sustained decline of anti-HCV neutralizing antibodies in HIV/HCV-coinfected patients after therapy-induced HCV clearance

Daniel Sepúlveda-Crespo[1,2], Camilla Volpi[1,3], Rafael Amigot-Sánchez[1], Marta Quero-Delgado[1], María Yélamos[4], Cristina Diez[2,5,6], Julián Gómez[4], Victor Hontañón[7,8], Juan Berenguer[2,5,6], Juan Gonzalez[2,7,8], Rubén Martín-Escolano[1,2], Salvador Resino Garcia[1,2], Isidoro Martínez[1,2]. *[1]Unidad de Infección Viral e Inmunidad, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain; [2]Centro de Investigación Biomédica en Red en Enfermedades Infecciosas (CIBERINFEC), Instituto de Salud Carlos III, Madrid, Spain; [3]Dipartimento di scienze farmacologiche e biomolecolari, Università degli Studi di Milano, Milan, Italy; [4]Departamento de Bioquímica y Biología Molecular, Facultad de Ciencias Químicas, Universidad Complutense, Madrid, Spain; [5]Unidad de Enfermedades Infecciosas/VIH; Hospital General Universitario Gregorio Marañón, Madrid, Spain; [6]Instituto de Investigación Sanitaria del Gregorio Marañón (IiSGM), Madrid, Spain; [7]Unidad de VIH; Servicio de Medicina Interna, Hospital Universitario La Paz, Madrid, Spain; [8]Instituto de Investigación Hospital Universitario La Paz, (IdIPAZ), Madrid, Spain*
Email: danisecre@hotmail.com

Background and aims: Cross-reactive neutralizing antibodies against hepatitis C virus (HCV), primarily targeting the E2 glycoprotein, play a crucial role in controlling and clearing HCV infection and protecting against HCV reinfection. This study aimed to evaluate the titers and the amplitude of anti-E2 antibodies (anti-E2-Abs) and neutralizing antibodies against HCV (anti-HCV-nAbs) in HIV/HCV-coinfected patients over five years after the sustained viral response (SVR) following IFN-based therapy (PEG-IFNα/RBV or PEG-IFNα/RBV/DAA) or IFN-free DAA therapy.
Method: We followed 76 HIV/HCV-coinfected patients for five years after antiviral therapy-induced SVR. Plasma levels of anti-E2-Abs and anti-HCV-nAbs against five HCV genotypes (Gt1a, Gt1b, Gt2a, Gt3a, and Gt4a) were determined using ELISA and microneutralization assays, respectively. Statistical analyses comparing the three follow-up time points (baseline, one-year, and five-year post-HCV treatment) were performed using Generalized Linear Mixed Models. p values were adjusted using the False Discovery Rate (q-value).
Results: Compared to baseline, plasma anti-E2-Abs titers decreased at one year (1.9 to 2.3-fold, q-value<0.001) and five years (3.4 to 9.1-fold, q-value<0.001) post-HCV treatment. Plasma anti-HCV-nAbs decreased 2.9 to 8.4-fold (q-value <0.002) at one year and 17.8 to 90.4-fold (q-value<0.001) at five years post-HCV treatment. HCV-nAbs titers against Gt3a were consistently the lowest. Low anti-E2-Abs nonresponse rates were observed throughout the follow-up, while anti-HCV-nAbs nonresponse rates increased. At baseline, anti-HCV-nAb were undetected in 4.0–5.3% of patients. At the five-year post-HCV treatment, nonresponse rates increased 1.8 to 13.5-fold (q-value<0.05), with the highest nonresponse rate for Gt3a.
Conclusion: An overall decline in humoral responses against HCV (anti-E2-Abs and anti-HCV-nAbs) among HIV/HCV-coinfected patients at one- and five-years post-HCV treatment was observed, regardless of the analyzed HCV genotype. However, this decline was more pronounced for the anti-HCV-nAbs, particularly in the Gt3.

SAT-408

Molecular and functional analysis of a hepatitis B virus genotype C infection in a vaccinated individual

Maëlenn Delcourt[1], Peter Gowland[2], Christoph Niederhauser[3], Daniel Candotti[1]. *[1]Dept of Virology-Henri Mondor Hospital-Paris-Est University-INSERM U955-IMRB-Team 18, Creteil, France; [2]Interregional Blood Transfusion SRC, Laboratory Diagnostics and RandD Diagnostics, Berne, Switzerland; [3]Interregional Blood Transfusion SRC, Laboratory Diagnostics and RandD Diagnostics, Berne, Switzerland*
Email: daniel.candotti@inserm.fr

Background and aims: Global hepatitis B virus (HBV) vaccination is key to the WHO objective to eradicate hepatitis B by 2030. The present study investigates an acute HBV infection in a regular blood donor from Switzerland with a complete vaccination course (Engerix B; 2001/2002).
Method: HBV infection was monitored by testing for serological markers and HBV DNA in a 6-months follow-up. PreS/S region was sequenced after viral particle concentration. S amino acid substitutions-related phenotype was investigated by site directed mutagenesis and in vitro functional analysis.
Results: At index time, HBV DNA (6 IU/ml) was detected in the presence of anti-HBs (500 mIU/ml) as only serological marker. Anti-HBs level was 14 mIU/ml and all HBV markers were negative in the donation collected six months earlier. HBV subgenotype C1 strain supported recent HBV exposure in Thailand. Follow-up showed transient HBV viraemia, anti-HBs level increase (>1 000 mIU/ml), and no HBsAg and anti-HBc seroconversion. PreS/S amino acid sequence was identical to a consensus sequence from HBV_C-infected Asian donors. The S protein had 19 aa substitutions, including 8 within MHR, compared to a HBV_{A2} consensus sequence. Substitutions S114T, T126I, N131T, and T143S were observed at positions previously associated with immune escape. Quasispecies distribution showed 6 sequences differing by only one aa (W35R, Q51Stop, L89P, I195R, and G202E x2) from the dominant sequence. W35R and I195R were associated with significantly lower HBsAg production and cellular retention. A sW36R substitution resulted in a similar HBsAg production phenotype. The potential function of this conserved WW motif in the S cytosolic domain was investigated further by replacing sW35 with aa carrying positive (H, K, and R) or negative (E) charged lateral, uncharged polar lateral (Q), and hydrophobic side chain (A, M, F, and W). W35K and W35Q lead to intracellular retention of HBsAg. W35K was associated to reduced HBsAg production and W35F substitution leads to no phenotypic change. Results of W35H, E, A, M are pending.
Conclusion: HBV genotype C infection was confirmed in a fully vaccinated individual and was associated with an efficient secondary anti-HBs response leading to transient viraemia without HBsAg and

anti-HBc seroconversion over six months. This supported previous study suggesting that anti-HBs-only occult HBV infection was associated to vaccine escape. Infection may be related to low level of anti-HBs at the time of virus contact and aa variability in S epitopes between HBV_C strain and HBV_{A2}-derived vaccine. In vitro neutralization analysis is ongoing for confirmation. Unusual mutations in S cytosolic domain were associated to HBsAg reduced production and intracellular retention. Further investigations are needed to clarify the potential function of the conserved sW35sW36 motif in HBsAg production and viral replication.

SAT-409

Whole-genome hepatitis B virus sequencing at low viral loads from serum and dried blood spot using a multiplexed tiled amplicon approach

Sheila Lumley[1], Christopher Kent[2], Samuel Wilkinson[2], Camille Morgan[3], Elizabeth Waddilove[4], Marion Delphin[4], George Airey[1], James Campbell[4], Catherine De Lara[1], Jacqueline Martin[5], Patrick Ngimbi[6], Jonathan B. Parr[3], Peyton Thompson[3], Eleanor Barnes[1], Azim Ansari[1], Nick Loman[2], Josh Quick[2], Philippa C Matthews[4]. *[1]University of Oxford, Oxford, United Kingdom; [2]University of Birmingham, Birmingham, United Kingdom; [3]University of North Carolina at Chapel Hill, North Carolina, United States; [4]Francis Crick Institute, London, United Kingdom; [5]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [6]Université Protestante au Congo, Kinshasa, Congo, Dem. Republic of (formally known as Zaire)*
Email: sheila.lumley@trinity.ox.ac.uk

Background and aims: Hepatitis B Virus (HBV) sequencing can be used to investigate viral transmission, evolution and polymorphisms linked to adverse outcomes such as resistance associated mutations (RAMs) and vaccine escape mutations (VEMs). However currently it is not possible to sequence full HBV genomes from approximately half of people with detectable HBV viral loads (VL), due to low median VL v.s. relatively high VLs required for full genome sequencing, high host background, genome structure and viral diversity. For the first time, we utilised an amplicon sequencing approach based on the ARTIC SARS-CoV-2 sequencing protocol for targeted full-genome HBV sequencing. We sequenced eight overlapping 500 bp amplicons to generate high quality consensus genomes from a range of VLs, including low VL samples, which it was previously not possible to sequence.
Method: HBV-specific primers were designed using a developmental version of PrimalScheme3. A multiple sequence alignment was generated from 2001 genomes and from this 94 primers were selected for each amplicon in order to cover the diversity present, resulting in the amplification of 8 amplicons generating a theoretical 100% genome coverage due to the circular genome. Plasma and dried blood spot (DBS) clinical samples with HBV VL 1.5–8.4 log (10) IU/ml from the UK and Democratic Republic of Congo were sequenced. Amplification and library preparation were performed by adapting the nCoV-2019 LoCost v3 sequencing protocol (Quick et al. 2020); 12 UK and 35 DRC samples multiplexed per run. Samples were sequenced on an Oxford Nanopore MinION with flowcell chemistry v10.4.1. Data were basecalled and demultiplexed using guppy (6.5.7). To enable compatibility with artic fieldbioinformatics (1.2.4), which generated the draft consensus genomes, primer.bed files were modified using primalhelper (1.0.0). We calculated genome coverage (at 20x depth) using samtools and bedtools.
Results: 47 clinical samples were sequenced. For samples with VL above 3 log (10) IU/ml, full length HBV genomes were recovered (100% coverage). For samples with VL as low as 1.5 log (10) IU/ml we were still able to achieve 90% genome coverage; the reduction in % coverage was due to lower sequencing depth of one amplicon. Genotypes A-E were identified, and data demonstrated distinct transmission patterns between households. We were able to call polymorphisms at sites of previously reported RAMs and VEMs.
Conclusion: We developed a simple, inexpensive targeted sequencing method to generate full-length HBV genomes at low VLs, which have previously been challenging to sequence. This method is readily deployable in resource-limited settings due to use of the MinION, and can also be easily adapted to other sequencing platforms. This data was used to call genotypes, RAMs, VEMs and perform phylogenetic analysis in previously difficult to sequence samples.

SAT-410

Establishment of a highly effective in vitro model for HBV genotype E infection

Rodrigue Kamga Wouambo[1], Felix Lehmann[2], Maria Pfefferkorn[1], Madlen Matz-Soja[1,3], Thomas Berg[1], Dieter Glebe[4], Florian van Bömmel[1]. *[1]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany; [2]Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Institute of Virology, Berlin, Germany; [3]Rudolf-Schönheimer-Institute for Biochemistry, Leipzig, Germany; [4]Institute for Medical Virology, National Reference Centre for Hepatitis B viruses and Hepatitis D viruses, Justus Liebig University Giessen, Giessen, Germany*
Email: rodrigue.kamgawouamba@medizin.uni-leipzig.de

Background and aims: Hepatitis B virus genotype E (HBV-E) is highly prevalent in Africa and associated with a higher viral replication and higher risk of hepatocellular carcinoma development compared to other HBV genotypes. Although Africa has a disproportionately high burden of hepatitis B, studies concerning this genotype are still under-represented. Our project aims at establishing an effective in vitro model for HBV-E to better understand its biomarker production and pathogenesis.
Method: The 1.1 and 1.5mer overlength HBV DNA constructs were engineered by fast cloning as previously described (Li et al. 2011). In brief, the primers for insert amplification were designed with insert-specific sequences and additional 15–17 bases overlapping with the vector-ends. The 1.5mer was generated from the 1.1mer template and the plasmids were transfected with variable ratios to the transfection reagent (2:1; 3:1; and 4:1) into HepG2-hNTCP cells to produce HBV-E viral particles. Viral particles were concentrated by ultrafiltration using Vivaspin® 20, 300, 000 MWCO PES (Sartorius) and thereafter tested for infectivity in vitro. HBV DNA, HBV RNA, HBeAg and HBsAg composition were quantified from supernatant collected either every 2 or 7 days during transfection or infection experiments.
Results: Transfection of both HBV-E plasmids resulted in successful secretion of HBeAg and HBsAg, with a higher expression from the 1.5mer plasmid. Transfecting 1.5mer at different ratios (2:1; 3:1 and 4:1) revealed similar mean levels of HBV DNA (8.7; 8.19; 8.02 [log10cp/ml]), HBV RNA (5.05; 4.4; 4.8 [log10cp/ml]) and total HBsAg (45.92 ± 7.2; 40.94 ± 3.16; 46.9 ± 4.02 [ng/ml]) at 8 dpi. Interestingly, mean LHBs levels and proportions of secreted HBsAg in supernatant were 3-fold higher using transfection ratio 3:1 (2.7 ng/ml and 6.32%) compared to 2:1 (0.79 ng/ml and 1.68%) and 4:1 (0.72 ng/ml and 1.64%). In vitro infection with the generated HBV-E viruses (Week 5, MOI = 200) lead to de novo infection: HBV DNA and RNA levels decreased from input (7.30 and 4.89 log10cp/ml) to wash-out (3.89 and 0 log10cp/ml) and showed a stable increase to 5.25 and 3.16 log10cp/ml after 10 dpi follow by a sustained expression until 22 dpi.
Conclusion: The newly engineered HBV-E plasmids can be transfected in cell culture and used to generate infectious and replicating HBV-E viruses for in vitro analysis. Our model is ready-for-use in further studies on HBV replication and drug efficacy testing concerning HBV-E.

SAT-411

Absorption, distribution, metabolism, and excretion of [14C]-Bemnifosbuvir in the rats

Alex Vo[1], Steven Good[1], Nancy Agrawal[1], Jean-Pierre Sommadossi[1].
[1]*Atea Pharmaceuticals, Inc., Boston, United States*
Email: vo.alex@ateapharma.com

Background and aims: Bemnifosbuvir (BEM), a phosphoramidate oral prodrug of a unique, 6-modified guanosine nucleotide with potent antiviral activity against the RNA-dependent polymerase (RdRP) of several single stranded RNA viruses, is currently in development for the treatment of COVID-19 and HCV (in combination with the NS5A inhibitor ruzasvir). The mass balance, excretion, and metabolism of [^{14}C]-BEM were characterized in normal and bile-duct cannulated (BDC) rats after a single oral dose.
Method: Male SD and LE rats received a single dose of [^{14}C]-BEM at 60 mg/kg (200 μCi/kg). Urine and feces were collected through 168 h post-dose while plasma was collected for up to 48 h post-dose in normal rats. Urine and feces were collected for up to 96 h post-dose in BDC rats. Radioactivity was quantified by liquid scintillation counting. Tissue distribution was determined by quantitative whole-body autoradiography.
Results: The primary route of elimination of radioactivity was in the urine (50%) and feces (41%) in normal rats, and in the urine (43%), feces (35%), and bile (19%) in BDC rats, with total recovery of radioactivity of 91% in normal rats and 97% in BDC rats. BEM was widely distributed, with quantifiable levels present in many tissues through 24 h. In general, levels in tissues were similar to or lower than those in blood. Relatively high tissue levels were observed in the kidneys, liver, thymus, and small intestine. Low tissue levels were observed in brain, spinal cord, and bone. Concentrations in the eye lens were below the level of quantification. In general, the average elimination half-life for most tissues was <18 hr with no evidence for long-term retention or irreversible binding in skin or eye (uvea). BEM undergoes multistep metabolic activation to its active triphosphate (TP) metabolite AT-9010, which is found intracellularly. The major plasma circulating metabolites were AT-229 and AT-273. In urine, the major components were AT-229, AT-273, and AT-219. In bile, the major metabolite was AT-551. In feces, the major components were AT-229 and AT-273.
Conclusion: Following a single oral dose in rats, BEM has favorable overall ADME properties, including good bioavailability (>60%) and wide distribution to tissues with low penetration into the brain. BEM was highly and rapidly metabolized to the metabolite AT-273, which was a surrogate for the intracellular pharmacologically active TP.

SAT-412

Low risk of drug-drug interactions for Ruzasvir based upon in vitro metabolism and transporter interaction studies

Alex Vo[1], Jocelyn Yabut[2], Michael Hafey[3], Hui Wan[2], Nancy Agrawal[1], Jean-Pierre Sommadossi[1]. *[1]Atea Pharmaceuticals, Inc., Boston, United States; [2]Merck and Co., Inc., West Point, United States; [3]Merck and Co., Inc., Rahway, United States*
Email: vo.alex@ateapharma.com

Background and aims: Ruzasvir (RZR), a potent small molecule inhibitor of hepatitis C nonstructural protein 5A (NS5A), is currently being developed for the treatment of hepatitis C virus (HCV) in combination with bemnifosbuvir, a potent nucleotide prodrug inhibitor of the RNA-dependent RNA polymerase (RdRp) of HCV. The potential of RZR to mediate drug-drug interactions (DDIs) via cytochrome P450 (CYP) metabolizing enzymes and transporters was evaluated *in vitro*.
Method: RZR was incubated *in vitro* with human liver microsomes, hepatocytes, and transporter transfected cells or membrane vesicles to evaluate its interaction with relevant enzymes/transporters.
Results: *In vitro* CYP reaction phenotyping suggested that CYP3A was the primary enzyme involved in the hepatic oxidative metabolism of RZR; however, the extent of CYP-mediated metabolism was observed to be very low *in vivo*. RZR did not exhibit direct nor time-dependent inhibition of any major CYP450 enzymes at concentrations up to 10 μM. In human hepatocytes, RZR did not significantly induce CYP1A2, CYP2B6, or CYP3A4 mRNA. RZR inhibited P-gp-mediated digoxin transport and BCRP-mediated methotrexate uptake with an IC_{50} of 0.049 μM and 0.27 μM, respectively. RZR inhibited uptake of pitavastatin and sulfobromophthalein mediated by OATP1B1 and OATP1B3 with an IC_{50} of 0.092 μM and 0.052 μM, respectively. RZR also inhibited BSEP transporter with IC_{50} of 0.37 μM. RZR did not exhibit any inhibition on OAT1, OAT3, and OCT2 transporters.
Conclusion: Based on *in vitro* data and static DDI risk assessment models, RZR has low potential to be a perpetrator of DDI via inhibition or induction of CYP450. Likewise, it has low potential to inhibit OATP1B1 and OATP1B3. The relevance of BSEP inhibition to DDIs is limited. However, RZR may be a perpetrator of DDI with P-gp and BCRP, which warrants further investigation *in vivo*.

Hepatitis B virus seroepidemiology in the Vukuzazi population programme, KwaZulu Natal, South Africa

Motswedi Anderson[1], Tongai Gibson Maponga[2], Gregory Jording-Jespersen[3], Janine Upton[4], Dickman Gareta[4], Malcolm Ellapen[5], Elizabeth Waddilove[6], Lusanda Mazibuko[4], Stephen Olivier[7], Jacob Busang[8], Gloria Sukali[9], Marion Delphin[6], Resign Gunda[4], Emily Wong[4], Mark Seidner[10], Thandeka Khoza[7], Thumbi Ndungu[7], Kathy Baisley[7], Khanyi Msomi[11], Theresa Smit[7], Collins Iwuji[12], Philippa C Matthews[6]. *[1]Africa Health Research Institute, KwaZulu Natal, South Africa, Durban, South Africa; [2]Tygerberg Hospital and Stellenbosch University, Stellenbosch, South Africa, Stellenbosch, South Africa; [3]Africa Health Institute Partnership (AHRI), Durban, South Africa; [4]Africa Health Research Institute (AHRI), Durban, South Africa; [5]National Health Laboratory Service, Albert Luthuli Hospital, Durban, South Africa; [6]The Francis Crick Institute, London, United Kingdom; [7]Africa Health Research Institute, Durban, South Africa; [8]Africa Health Institute Partnership, Durban, South Africa; [9]Africa Health Research Institute, Durban, South Africa; [10]Africa Health Research Institute, Division of Infectious Diseases, Massachusetts General Hospital, Durban, South Africa; [11]National Health Laboratory Service, Albert Luthuli Hospital, Durban, South Africa; [12]Africa Health Research Institute, Durban, South Africa*
Email: philippa.matthews@crick.ac.uk

Background and aims: There are approximately 80 million people living with chronic Hepatitis B virus (HBV) in the WHO Africa region, but few seroepidemiology data to guide public health and clinical management strategies in African populations, for whom HBV elimination goals are still far from reach. We set out to investigate HBV infection markers in a rural population in South Africa.
Method: The EVOLVE-HBV ('Evaluation of Vukuzazi LiVEr disease') study used stored samples and biometric data collected by the Vukuzazi programme in KwaZulu Natal, South Africa. Vukuzazi enrolled participants who were ≥15 years old between May 2018 and March 2020. We selected 500 participants, stratified by sex, HIV status and age, to include adolescents and younger adults (born after routine HBV vaccine roll out started in South Africa from 1995 onwards). We screened plasma samples (according to availability) for HBV surface antigen (HBsAg), HBV core antibodies (anti-HBc) and HBV surface antibodies (anti-HBs). Two-tail significance tests were run at a 95% confidence interval using ANOVA and T-tests to determine differences in HBV biomarkers by age, sex and HIV status.
Results: Among 500 individuals in this study, 277 (55.4%) were female, 231 (46.2%) were living with HIV infection, and the median age was 31 years (IQR: 25–50). HBV infection (HBsAg) was present in 25/491 (5.1%) samples tested. Of the 25 participants who were HBsAg positive, 15/25 (60%) were male, median age was 46 years (IQR 28–55), 10/25 (40%) were HIV positive, and anti-HBc was present in 17/23 (73.9%). HBsAg was more likely to be positive in older participants ($p = 0.004$).

The overall prevalence of anti-HBc was 155/479 (32.4%), highlighting a high rate of exposure in this population. In this group, 84/155 (54.2%) were female, 75 (48.4%) HIV positive and median age was 50 years (39–61). Anti-HBc was more likely to be positive in older participants ($p < 0.001$).
There were 171/493 (34.7%) participants with anti-HBs titre >10 mIU/ml, of whom 101/171 (59.1%) were female, 86 (50.3%) were HIV positive, and median age was 46 years (IQR 28–57). Vaccine-mediated immunity could be inferred in those with anti-HBs >10 mIU/ml but HBsAg and anti-HBc negative; this serostatus was present in only 44/493 (8.9%) although our cohort was selected to include a cross-section of the population who should have received routine immunisation. Anti-HBs status was more likely to be positive in older participants ($p < 0.001$).
HBsAg, anti-HBc and anti-HBs were not associated with sex or HIV status ($p > 0.05$ for all).
Conclusion: In this population previously neglected by HBV research and clinical services, exposure to HBV is high, but only a minority of participants had evidence of vaccine-mediated immunity. Rapid scale-up of vaccination, diagnosis and treatment of HBV infection will be needed to make progress towards 2030 elimination goals.

SAT-414

Hepatitis B virus particles in serum contain minus strand DNA and degraded pregenomic RNA of variable and inverse lengths

Johan Ringlander[1], Sebastian Malmström[1], Anders Eilard[1], Lucia Gonzales Strömberg[1], Joakim Stenbäck[1], Maria Andersson[1], Simon B. Larsson[1], Michael Kann[1], Staffan Nilsson[1], Kristoffer Hellstrand[1], Gustaf Rydell[1], Magnus Lindh[1]. [1]*Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*
Email: johan.ringlander@gu.se

Background and aims: Quantification of hepatitis B virus (HBV) RNA in serum has emerged as a complementary clinical marker, in particular for the monitoring of the effect of antiviral therapy. However, the nature of RNA particles and their composition of RNA remains incompletely known.
Method: We have used droplet digital PCR (ddPCR) assays that target three gene segments to quantify HBV RNA and HBV DNA in serum samples from 75 patients with chronic HBV infection.
Results: The HBV RNA levels were higher in the core than in the S and X regions (median 7.20 vs. 6.80 and 6.58 log copies/ml; $p < 0.0001$), whereas HBV DNA levels showed an inverse gradient (7.71 vs. 7.73 and 7.77 log copies/ml, $p < 0.001$). By quantification in core on average 80% of the nucleic acid was DNA. The core DNA/RNA ratio was associated with viral load and genotype. In individual patients with paired samples, the relationships between core, S and X RNA levels were stable over time ($n = 29$; $p = 0.006$).
Conclusion: The results suggest that pregenomic RNA is completely reverse transcribed to minus DNA in ≈75% of the virus particles, whereas the remaining 25% contain both RNA and DNA of lengths that reflect variable progression of the polymerase.

SAT-415

Metabolic alteration linked to antiviral treatment response in 3D in-vitro model system of hepatitis B virus infection

Abhishak Gupta[1], Nupur Sharma[2], Sadam H Bhat[1], Jaswinder Maras[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Institute of Liver and Biliary sciences, New Delhi, India*
Email: abhigupta78@gmail.com

Background and aims: Hepatitis B virus (HBV) infection is a global health concern.Metabolic alterations during HBV antiviral reflect the treatment response in liver/hepatocytes remains unclear.Delineation of the metabolic changes in 3D in-vitro model system could help in characterization of cellular metabolic response and clearance of HBV infection. The primary aim was to develop a 3D model system using HepG2.2.15 and metabolic alteration during anti-viral treatment.
Method: 3D in-vitro model was developed for HepG2.2.15 by culturing them for 3days. ETV at a dose of 1and10 micromolars was used for treatment and analyzed post 24, 48or72hrs for the metabolic changes and viral markers. HBsAg, HBeAg and HBV DNA quantification were performed. Secretory metabolites from supernatants were extracted and analyzed using UPLC-HRMS based on comparative metabolomics coupled with pattern recognition methods and network pathway. Significant changes in the secretome were identified using WMCNA and the metabolite module specific to treatment response (temporal) or HBV infection was subjected to pathway analysis and correlation to ETV treatment dynamics.
Results: A 3D in-vitro model system was established with approx 20 K cells/organoids. ETV treatment both at 1 and 10 micromolars significantly lowered antigen secretion, virion production and HBV DNA synthesis without affecting cell viability in HepG2.2.15 organoids. HBsAg, HBeAg, and HBV DNA secretion were decreased temporally from 24 to72 hrs ($p < 0.05$).WMCNA of the secretome led to the identification of 5 metabolite modules. ETV treatment temporally down regulated 83 metabolites linked to inflammatory Tryptophanmetabolism (5-Hydroxy-N-formylkynurenine;Indolepyruvate), Sphingolipid metabolism, Arachidonic acid metabolism, Amino-acid metabolism and Lipid metabolism and others ($FC>1.5$, $FDR<0.01$, $p < 0.05$).Metabolites significantly increased and linked with treatment response were mainly involved in vitamin metabolism (Pantothenate and CoA biosynthesis, riboflavin, ascorbate and others), amino acid metabolism (Arginine, proline, glycine and others), Taurine and hypotaurine metabolism, and energy metabolism (pentose phosphate pathways) and others ($p < 0.05$).Secretome analysis showed that HBV infection induced inflammatory and oxidative metabolic pathways were significantly hampered. Further, increase in energy and amino acid metabolism postETV treatment correlates with the inhibition of HBsAg/HBeAg expression and HBV replication.
Conclusion: 3D in-vitro model reflects changes in the secretory metabotype correlate to anti-viral treatment response and could be used for monitoring HBV replication/infection and development strategies for antiviral.

SAT-418

Prevalence of hepatitis C virus infection in a nursing home: a frequently overlooked submerged population

Paolo Gallo[1], Giulia Di Pasquale[2], Valentina Flagiello[2], Antonio De Vincentis[2], Francesca Terracciani[2], Antonio Picardi[2], Umberto Vespasiani-Gentilucci[2], Raffaele Antonelli Incalzi[2]. [1]*Fondazione policlinico universitario Campus bio-medico, Rome, Italy;* [2]*Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy*
Email: paolo.gallo@policlinicocampus.it

Background and aims: Despite the therapeutic success achieved through direct-acting antiviral agents, a significant number of individuals with undiagnosed hepatitis C virus (HCV) infection, often referred to as the "submerged" population (comprising institutionalized aged subjects living in nursing homes), persists. The objective of this study is to assess the prevalence of HCV antibodies and infection among patients residing in the Italian Hospital Group (IHG) Nursing Home in Guidonia Montecelio, Rome.
Method: The study was conducted across Extensive and Intensive Care Unit, Alzheimer Unit, Geriatric Unit, and Psychiatric Disorders Unit. All participants provided written consent to participate. Collected data encompassed patients' sociodemographic details, blood test results, and risk factors for HCV infection. Anti-HCV testing was done with Advanced Quality Rapid capillary test, followed by confirmation through a serum test. Anti-HCV positive testing has been followed by an HCV-RNA test. Descriptive statistics were employed to present the data, and logistic regressions were applied to assess risk factors for anti-HCV positivity.
Results: 434 patients were included. Both capillary and serum anti-HCV positivity were identified in 13 patients (3%), while the

prevalence of infection was 2.3%. Notably, positive patients exhibited a predominance of males and a younger age compared to their anti-HCV negative counterparts. The Psychiatric unit displayed the highest prevalence, with 46% of the cases (6 out of 13 patients). Logistic regression analysis identified several significant associations with anti-HCV positivity. Age (OR 0.96, 95% CI 0.93–0.99, p = 0.01), sex (OR 0.26, 95% CI 0.06–0.88, p = 0.04), hepatitis B virus (HBV) infection (OR 20.75, 95% CI 3.95–91.7, p < 0.001), dementia (OR 0.14, 95% CI 0.02–0.55, p = 0.01), smoking (OR 6.50, 95% CI 2.09–22.8, p < 0.001), and injection drug use (OR 10.5, 95% CI 1.59–51.09, p = 0.005) were all identified as significantly associated with anti-HCV positivity. Multivariate analysis confirmed only HBV infection (OR 13.7, 95%CI 1.82–94.8, p = 0.008) and smoke (OR 6.23, 95%CI 1.12–40.5, p = 0.04) as independently associated with the positivity.

Conclusion: Our findings reveal a 2.3% prevalence of HCV infection among people living in the Nursing Home; anti-HCV positivity was negatively associated with age and positively associated with dementia. Notably, the highest prevalence was observed in psychiatric patients, who not only exhibited increased susceptibility to HCV infection but were also younger compared to the general Nursing Home population. These preliminary data advocate that institutionalized (particularly psychiatric) patients should be included in HCV infection screening program in the submerged populations.

Transcriptomics reveals the regulation mechanism of the Chinese herbal TiaoGanJianPiJieDu formula on inhibiting hepatitis B virus replication in mice

Ningyi Zhang[1], Xu Cao[1], Hening Chen[1], Jiaxin Zhang[2], Xiaoke Li[2], Xiaobin Zao[3], Yong'an Ye[2]. *[1]Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China; [2]Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing University of Chinese Medicine, Liver Diseases Academy of Traditional Chinese Medicine, Beijing, China; [3]Dongzhimen Hospital, Beijing University of Chinese Medicine, Key Laboratory of Chinese Internal Medicine of Ministry of Education and Beijing, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China*
Email: ningyi0202@163.com

Background and aims: Chronic Hepatitis B (CHB) is a chronic inflammatory liver disease caused by hepatitis B virus (HBV) infection. The Chinese herbal TiaoGanJianPiJieDu formula (TGJP), a representative formula of traditional Chinese medicine (TCM) "immune incubation" therapy, has been widely used in the clinic and proved to be effective in the treatment of CHB. However, the underlying mechanism of TGJP is still unclear and needs to be further explored, which is the purpose of this study.

Method: HBV replicating mice was applied for animal model and treated with intragastric administration of distilled water (1 ml/10 g) or TGJP solution (0.33 g/ml) for 16 weeks. The therapeutic effect of TGJP on CHB was examined by serum HBV biomarker assay, Immunohistochemical (IHC) and qPCR. Hepatic tissue transcriptomic analysis was used to investigate the anti-HBV mechanism of TGJP on CHB. Gene Ontology (GO) and Kyoto Encyclopaedia of Genomes (KEGG) were used for further functional enrichment analysis.

Results: We established a mouse model by hyperbaric hydrodynamic injection (HDI) of 1.2-fold HBV plasmid DNA into the tail vein. Serum HBsAg was measured 48 hours after modelling, and serum HBsAg-positive animals were considered successfully modelling. Compared to the model, the serum HBsAg and HBeAg level were significantly decreased in the TGJP group after 5-week TGJP treatment. Hepatic HBV antigens IHC staining and qPCR showed that TGJP significantly enhanced clearance of hepatic HBsAg and HBcAg deposition and significantly inhibited the relative expression of total HBV DNA and HBV RNA, as compared with the model group. From the second week of TGJP treatment, serum ALT and AST levels in the TGJP group were significantly higher than those in the model group and remained elevated until the fifth week. The decline in serum HBsAg and HBeAg levels followed the elevation of liver transaminases, suggesting finite liver inflammation may promote HBV clearance. Transcriptome analysis showed that there were 275 differentially expressed genes (DEGs) being identified between model group and TGJP group, including 128 up-regulated genes and 296 down-regulated genes. Heatmap suggested that there were significant differences in HBV-replicating mice liver after TGJP treatment compared with the model group. GO enrichment analysis showed that the top 20 enriched functions were mainly related to the activation and migration of immune cells. KEGG enrichment analysis of DEGs showed that the top 3 enriched pathways were mainly involved in the interaction between viral proteins and cytokines and their receptors, cytokine-cytokine receptor interactions, chemokine signalling pathways, which were closely related to the regulation of innate immunity.

Conclusion: Transcriptomics analysis showed that TGJP exerts an inhibition effect on HBV replicating in mice by regulating host immune function, especially innate immune.

SAT-420

The Chinese herbal TiaoGanJianPiJieDu formula exerts an inhibition effect on hepatitis B virus replication by regulating hepatic CCL2-CCR2 signaling pathway and inducing immune-inflammatory response

Ningyi Zhang[1], Hening Chen[1], Xu Cao[1], Xiaobin Zao[2], Yong'an Ye[3]. *[1]Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China; [2]Dongzhimen Hospital, Beijing University of Chinese Medicine, Key Laboratory of Chinese Internal Medicine of Ministry of Education and Beijing, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China; [3]Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing University of Chinese Medicine, Liver Diseases Academy of Traditional Chinese Medicine, Beijing, China*
Email: ningyi0202@163.com

Background and aims: Chronic hepatitis B (CHB) are a chronic inflammatory liver disease with host immune dysfunction caused by hepatitis B virus (HBV) infection. The Chinese herbal TiaoGanJianPiJieDu formula (TGJP) has been widely used in clinical practice and has performed well in the treatment of CHB. However, the underlying mechanism of the TGJP for CHB remains to be studied. In this study, we aimed to explore the mechanism of TGJP in CHB treatment and to explore the targets and pathways of TGJP in modulating immunity.

Method: HBV-replicating mouse was applied as animal model, given TGJP gavage for 16 weeks. Ultra performance liquid chromatography-mass spectrometry/mass spectrometry (UPLC-MS/MS) identified the major components of TGJP. Transcriptomic was used for TGJP mechanism further study. The key pathways and putative targets of TGJP were obtained by network pharmacology analysis and transcriptomic. We validated the putative targets and key pathways of TGJP by immunohistochemistry (IHC), enzyme-linked immunosorbent assay (ELISA) and qPCR.

Results: We identified 174 active components of TGJP by UPLC-MS/MS, then screened 1043 targets of TGJP and 10019 CHB disease targets via public databases. Transcriptomics screened 275 differentially expressed genes in the livers of model and TGJP mice. We intersected above targets and obtained 14 key targets of TGJP in CHB treatment. Based on network pharmacology and transcriptomics analysis, we selected CCL2 as the key gene and CCL2/CCR2 axis as the key pathway for further research. GEO dataset validates the critical role of CCL2 in CHB. Animal experiments confirmed that compared with the model group, the serum and liver CCL2 levels of HBV replicating mice in the TGJP group were significantly higher than those in the model group, and the relative expression of *Ccl2* and *Ccr2* in liver tissues of mice were significantly higher. IHC results showed a significant increase of $CD68^+$ and $CCR2^+$ macrophages count in the liver tissue of the TGJP group compared with the model and control groups. Macrophages performs the role of inducing immune-inflammatory responses and activating adaptive immunity. By gene

set enrichment analysis, we found that TGJP upregulated inflammatory and immune response signalling pathways, which was confirmed by qPCR. Compared with the model group, TGJP up-regulated the expression of inflammatory factors such as *Cxcl10*, *Il33* and *Ifnlr1*, and down-regulated the expression of *Il10*. IHC also showed that $CD8^+$ T cells were significantly increased in the TGJP group compared with the model group and the control group, suggesting that adaptive immunity was activated.
Conclusion: TGJP plays an anti-HBV role by upregulating the intrahepatic CCL2-CCR2 signalling pathway, promoting macrophage chemotaxis to the liver, inducing hepatic immune-inflammatory responses, and activating adaptive immunity.

SAT-421
Hepatitis B core related antigen in South Africa and the United Kingdom-does one size fit all?
Louise Downs[1], Marion Delphin[2], Tingyan Wang[3], Cori Campbell[3], Catherine De Lara[3], Sheila Lumley[4], Sue Wareing[5], Polly Fengou[5], Tongai Gibson Maponga[6], Marije Van Schalkwyk[7], Shiraaz Gabriel[8], Susan Hugo[9], Monique Andersson[10,11], Jacqueline Martin[10], Elizabeth Waddilove[12], Kosh Agarwal[13], Geoffrey Dusheiko[13], Ivana Carey[13], Wolfgang Preiser[14], Eleanor Barnes[15], Gavin Kelly[12], Philippa C Matthews[16]. *[1]Nuffield Department of Medicine, University of Oxford, Department of Infectious Diseases and Microbiology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [2]The Francis Crick Institute, London, United Kingdom; [3]Nuffield Dept of Medicine, University of Oxford, UK, Oxford, United Kingdom; [4]Nuffield Dept of Medicine, University of Oxford, Department of Infectious Diseases and Microbiology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [5]Department of Infectious Diseases and Microbiology, Oxford University Hospitals NHS Foundation Trust, Oxford, UK, Oxford, United Kingdom; [6]Division of Medical Virology, Stellenbosch University, Faculty of Medicine and Health Sciences, Tygerberg, Cape Town, South Africa, Cape Town, South Africa; [7]Division of Infectious Diseases, Department of Medicine, Stellenbosch University/Tygerberg, Cape Town, South Africa; [8]Division of Gastroenterology, Department of Medicine, Stellenbosch University/Tygerberg Academic Hospital, Cape Town, South Africa; [9]Division of Infectious Diseases, Department of Medicine, Stellenbosch University/Tygerberg Academic Hospital, Cape Town, South Africa; [10]Department of Infectious Diseases and Microbiology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [11]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom; [12]The Francis Crick Institute, 1 Midland Road, London, United Kingdom; [13]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [14]Division of Medical Virology, Stellenbosch University, Faculty of Medicine and Health Sciences, Tygerberg, National Health Laboratory Service, Tygerberg Business Unit, Tygerberg, Cape Town, South Africa; [15]Nuffield Dept of Medicine, University of Oxford, Oxford, United Kingdom; [16]The Francis Crick Institute, 1 Midland Road, University College London Hospitals, London, United Kingdom*
Email: louise.downs@exeter.ox.ac.uk

Background and aims: Hepatitis B core related antigen (CrAg) has been associated with disease outcomes in chronic hepatitis B infection (CHB). To date, only the PROLIFICA study (Gambia), has assessed CrAg in Africa and no studies have compared CrAg in different continents. Here we aimed to examine how CrAg varies between cohorts in South Africa (SA) and the United Kingdom (UK) and investigate the association between CrAg and liver outcomes.
Method: Serum samples and clinical metadata were obtained from adults with CHB at Oxford University Hospitals, UK (n = 142), and Tygerberg Hospital in Cape Town, SA (n = 121) (ref. 09/H0604/20 and N17/01/013 respectively). HBV DNA, CrAg, HBsAg, HBeAg and ALT were measured. Liver health was assessed using APRI, Fib-4 and elastography. Associations between liver health and CrAg in the two cohorts were interrogated using complete-case logistic regression with CrAg (linear) and cohort (binary) as covariates against (binary) liver health indicators.
Results: The UK and SA cohorts were of similar age (median 40 and 39 years respectively, $p = 0.2$) and sex (46% and 45% female respectively, $p = 0.8$). Comparing UK and SA cohorts, CrAg levels were lower in the UK (3.4 vs 3.8 $\log_{10}$ IU/ml, $p < 0.002$), fewer people in the UK were HBeAg positive (12% vs 35%, $p < 0.001$) and fewer UK patients were on nucleoside analogue (NA) treatment (31% vs 65%, $p < 0.001$). HBV DNA was overall higher in the UK cohort, but more people in the SA cohort had HBV DNA >200, 000 IU/ml (26% vs 5.6%, $p < 0.001$). By univariate analysis, CrAg was significantly correlated with HBV DNA in both cohorts ($p < 0.0001$) but there was no significant difference in CrAg between those on and off NA therapy in each cohort. We derived heatmaps to explore the extent to which CrAg correlated with markers of liver outcome within each cohort. Within the UK cohort, there was no significant correlation between CrAg and any liver parameter. Within the SA population, there was a significant positive correlation between CrAg and liver inflammation (ALT, $p < 0.05$). The strength of any association of CrAg with liver disease outcome did not significantly vary between cohorts.
Conclusion: Despite similar age and sex structures, HBV characteristics and CrAg distribution significantly differed between cohorts from the UK and SA. We observed no significant correlation between liver fibrosis or cirrhosis and CrAg, although liver inflammation by ALT was positively correlated with CrAg in SA. Associations may be influenced by HIV infection and other genetic, immunological or environmental factors. This novel comparison between geographical settings identifies knowledge gaps in interpretation of CrAg in different population groups.

SAT-422
E-selectin levels in patients with chronic hepatitis C
Petr Husa, Jr [1,2], Svatava Snopkova[1,2], Jiřina Zavřelová[3], Filip Zlámal[4], Radek Svačinka[1,2], David Vydrář[1,2], Petr Husa, Sr [2,5]. *[1]Department of Infectious Diseases, University Hospital Brno, Brno, Czech Republic; [2]Faculty of Medicine, Masaryk University, Brno, Czech Republic; [3]Department of Hematology, University Hospital Brno, Brno, Czech Republic; [4]Research Centre for Toxic Compounds in the Environment, Masaryk University, Brno, Czech Republic; [5]Department of Infectious Diseases, University Hospital Brno, Brno, Czech Republic*
Email: husa.petr2@fnbrno.cz

Background and aims: Selectins (cluster of differentiation, CD62) are a family of transmembrane glycoproteins expressed on the surface of different cells. E-selectin (ES) is primarily present in membranes of endothelial cells. Inflammatory cytokines like tumor necrosis factor alpha or interleukin 1 beta stimulate ES expression. ES bounds with CD15 s on the surface of neutrophils, allowing reversible adhesion of leucocytes and their rolling movement on endothelial cells. By the described mechanism, ES plays a fundamental role at the beginning of the physiological inflammatory response. Elevated ES levels are associated with different diseases like atherosclerosis, rheumatoid arthritis, HIV, or chronic hepatitis C (CHC). Aim of the study was to assess ES concentrations in the group of patients with CHC in comparison with the control group (CG).
Method: A total of 36 patients with CHC treated with direct acting antivirals (DAA) was included in study group (SG). The control group consisted of 40 healthy individuals. ES levels were detected in venous blood using a conventional sandwich ELISA test-Human sE-selectin Platinum ELISA (eBioscience, San Diego, USA). Testing was performed at baseline (BS), at the end of antiviral treatment (ET) and 12 weeks after the last dose of DAA (SVR12). The Mann-Whitney U test was used for comparison of ES levels between two groups.
Results: The median of ES concentration in CG was 6.2 (1.6–13.3) ng/ml, in SG 76.7 (27.8–179.3) ng/ml at BS, 69.9 (21.7–167.4) ng/ml at ET and 57.8 (20.5–120.2) ng/ml at SVR12. The difference between CG and SG at BS, ET, and SVR 12 was statistically significant ($p < 0.001$). All patient with CHC achieved a sustained virological response.

Conclusion: ES concentrations were significantly higher in SG at BS and remained elevated at SVR12 although the decrease during the study was also substantial ($p < 0.001$ between BS and ET as well as between ET and SVR12). The basis of the increased concentration in SG is a systemic inflammatory reaction that persists even after achieving SVR.

SAT-423

Highly expressed CTLA4 on B cells defected BCR signal to inhibit the secretion of anti-HBs in CHB patients

Shengxia Yin[1], Xin Tong[1], Chao Wu[1], Jie Li[1]. [1]*Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China*
Email: att717@163.com

Background and aims: The generation of anti-HBs is lacking in CHB patients. The cause is controversial. B cells activation state has a crucial effect on the secretion level of antibodies. Therefore, B cell status deserves more attention.
Method: Single-Cell RNA-seq analysis was performed in peripheral B cells. Peripheral and liver infiltrated B cells were characterized by flow cytometry. BCR signaling was tested by Ca+ flow and WB assay. Aimed to explore the inhibiting role of CTLA4, we did CTLA4-blocking test in vitro. Further, B6-Ighm-KO mice were injected with HBsAg preimmunized CTLA4-/- B cell after establishing HBV transduction model and HBV serological indicators were detected. CO-IP assay and proteome analysis was made to explore the downstream proteins of CTLA4.
Results: CTLA4 was highly expressed in B cells of CHB patients and more obviously in HBsAg-specific B cells. Moreover, CTAL4 was highly expressed in about 50% of the infiltrating HBsAg-specific B cells. CTLA4+HBsAg+B cells tended to show activated markers. GO analysis, Ca+ flow and WB assay showed that BCR signaling of CTLA4+B cells was defected. Moreover, CTLA4 blocking could partly restore the defection and make B cells secreted more anti-HBs. n mice model, B6-Ighm-KO mice injected with CTLA4-/- B cells showed decreased level of HBV serological indicators. Proteome assay showed SHIP-1 was the down stream of CTLA4.
Conclusion: The circulating and liver infiltrating B cells increased the expression of CTLA4 to defected the BCR signal which might contribute to the deficiency of viral specific humoral response during CHB course.

Evaluation of molnupiravir as an antiviral against hepatitis E virus infection

Siddharth Sridhar[1], Shusheng Wu[1], Jianwen Situ[2], Estie Hon-Kiu Shun[2], Nicholas Foo-Siong Chew[2]. [1]*Department of Microbiology, School of Clinical Medicine, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong;* [2]*Department of Microbiology, School of Clinical Medicine, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong*
Email: sid8998@hku.hk

Background and aims: Hepatitis E virus (HEV) is an important cause of chronic hepatitis in immunocompromised persons. There are few effective treatment options for patients with chronic hepatitis E who are intolerant or unresponsive to ribavirin. Drug repurposing efforts are required to identify new treatment options for this condition. Molnupiravir is a prodrug of a broad-spectrum antiviral nucleoside analogue (N-hydroxycytidine) that induces lethal mutagenesis in viral populations. This drug has recently been licensed globally for treatment of Coronavirus Disease 2019 (COVID-19). This study aimed to evaluate activity of molnupiravir against HEV.
Method: *In vitro* cytotoxicity and antiviral efficacy of varying concentrations of molnupiravir were assessed using infectious cDNA clones (pSK-HEV-2) and patient derived HEV isolates in Huh7 and PLC/PRF/5 cells respectively. Rats were immunosuppressed with a combination of prednisolone, tacrolimus, and mycophenolate mofetil administered by oral gavage. These are commonly used immunosuppressants in organ transplant recipients and are proven to prolong HEV infection in rats (Sridhar S et al, JHEP Reports, 2022). Immunosuppressed rats were infected with HEV for one week and then treated with molnupiravir (dosed at either 250 mg/kg/day or 400 mg/kg/day), ribavirin 50 mg/kg/day, or left untreated. Antiviral effectiveness in clearing HEV in serum, faeces, and liver tissue was compared to control and ribavirin-treated rats over 28 days. Liver histology and immunohistochemistry was assessed.
Results: Molnupiravir demonstrated low cytotoxicity and dose-dependent reduction in supernatant RNA load in both infectious cDNA clone and wildtype HEV cell culture models. In the animal model. untreated animals harbored prolonged HEV infection until end of experiment. The higher dose of molnupiravir (400 mg/kg/day) rapidly reduced viral shedding in serum and stool compared to other treatment groups. A majority of rats treated at the 400 mg/kg/day molnupiravir dose level cleared infection in both compartments by week 4 of treatment. Liver tissue showed improved histology and decreased immunohistochemical staining in the molnupiravir group together with lower viral loads at end of treatment.
Conclusion: Molnupiravir, a licensed antiviral for COVID-19, shows promise against HEV in *in vivo* and *in vitro* models. Further work is required to translate molnupiravir into a clinical solution for ribavirin-refractory chronic hepatitis E.

WED-421

Hepatitis E in Japan: a nationwide survey 2012–2017

Takeshi Matsui[1], Jong-Hon Kang[2], Kazunari Tanaka[2], Hiroaki Okamoto[3]. [1]*Center for Gastroenterology, Teine-Keijinkai Hospital, Sapporo, Japan;* [2]*Center for Gastroenterology, Teine Keijinkai Hospital, Sapporo, Japan;* [3]*Jichi Medical University School of Medicine, Simotsuke, Japan*
Email: mtake0402@gmail.com

Background and aims: In Japan, testing for hepatitis E virus (HEV) has been covered by the medical insurance system since November 2011. Since then, the diagnosis of HEV infection has rapidly expanded in clinical practice throughout the country. These changing circumstances have encouraged us to conduct a nationwide investigation of HEV infection.
Method: To 525 medical facilities, we requested a survey to investigate the medical record for the patients with HEV infection diagnosed from 2012 to 2017. The questionnaire included baseline characteristics, clinical course and virologic aspects of the patients.
Results: A total of 503 cases (407 males, average age of 56.6 years) were registered from 155 medical facilities across Japan. In Eastern Japan, 324 cases were collected from 69 facilities (4.7 cases/facility), and 179 cases were gathered from 86 (2.1 cases/facility) in Western Japan. Among them, 273 patients had habitual alcohol consumption of 30 g/day or more. Pre-existing liver disease was present in 93 patients, hypertension in 84, diabetes mellitus in 82, and dyslipidemia in 93, respectively. The average Body Mass Index (BMI) at onset was 23.9 kg/m^2. Except for four cases, none had traveled to HEV endemic areas. Ninety patients had consumed pork meat within the past two months, 87 had ingested pork offal, 13 had consumed venison, and 18 had eaten wild boar meat. Transfusion transmission of HEV was suspected in 4 patients. For the diagnosis of HEV infection, 468 (98.5%) of 475 patients underwent an anti-HEV IgA test, certified by insurance in Japan, and were positive. HEV RNA was

detected in 222 patients using PCR. Among 178 patients whose HEV genotypes were determined, genotype 3 was identified in 123 patients (69.1%), genotype 4 in 51 (28.7%), and genotype 1 in 4 (2.2%) patients who had traveled to endemic areas. Of the 503 patients, 346 (68.8%) were hospitalized, and 52 (10.3%) developed ALF. Six patients (1.2%) presented with hepatic coma, 2 (0.4%) received liver transplantation, and 4 (0.8%) died. ALF was associated with male gender, alcohol consumption, BMI, genotype 4, and pre-existing liver disease or diabetes. AHE shifted to chronic hepatitis in 6 patients (1.2%). They had undergone organ transplantation or had underlying diseases including hematological disorders, respectively. Extrahepatic manifestations such as neurological disorders including Guillain-Barré syndrome, were observed in six patients.
Conclusion: AHE in Japan was autochthonous with rare exceptions, and genotype 3 of HEV was the dominant strain. A higher incidence in Eastern Japan might be observed compared to the Western area. Whereas AHE was self-limited in almost 90% of patients, ALF developed in 10%, and 1% had a fatal course. This may be the first nationwide study to examine the clinical picture of HEV infection throughout Asian countries including Japan.

Email: ben.da@gilead.com

Background and aims: Hepatitis delta virus (HDV) causes the most severe form of viral hepatitis. While nucleos (t)ide analogues (NAs) are first line treatments for chronic hepatitis B virus (HBV) infection, they have shown no impact on HDV RNA levels in chronic HDV (CHD) patients. Recent HDV guidelines recommend use of NAs in CHD patients with cirrhosis or those without cirrhosis and HBV DNA ≥2000 IU/ml. We evaluated virologic outcomes associated with bulevirtide (BLV) over 48 weeks when given with vs. without concomitant NAs.
Method: Data from 3 studies (MYR203, MYR204, MYR301) were pooled for participants receiving BLV 2 mg/d or 10 mg/d as monotherapy, or no anti-HDV treatment (MYR301 control arm). In MYR204 and MYR301, NA use was allowed based on HBV guidelines. HDV outcomes (virologic response [VR], defined as undetectable HDV RNA or ≥2 $\log_{10}$ IU/ml decrease from baseline [BL], ALT normalization, and combined response [CR], defined as VR and ALT normalization), and HBV outcomes (% with undetectable HBV DNA, defined as <LLOQ [10 IU/ml], target not detected), change from BL in HBV DNA and in HBsAg levels in participants with HBV DNA ≥LLOQ at BL) were assessed over 48 weeks (W) in those receiving vs. not receiving NAs.
Results: 280 participants were included in 4 groups: BLV 2 mg/d (n = 64), BLV 10 mg/d (n = 165), total BLV (n = 229), and no anti-HDV treatment (control; n = 51). Overall, NAs were used concomitantly in 160 participants (57%; group ranges: 48%–63%). BL characteristics were comparable except the proportion with cirrhosis and mean liver stiffness were higher (50% and 14.7 kPa) in those on NAs vs. no NAs (29% and 13.7 kPa). Tenofovir-based therapy was most used (87% [139/160]). For the total BLV group, CR, VR, and ALT normalization with vs. without NAs at W48 were: 45% vs. 47%, 83% vs. 73%, and 50% vs. 58%, respectively; these responses were 3% vs. 0%, 6% vs. 0%, and 9% vs. 16% for controls, respectively. Mean changes from BL in HBV DNA at W48 with and without NAs were −1.37 vs −0.71 $\log_{10}$ IU/ml for the total BLV group, and −0.81 vs −0.15 $\log_{10}$ IU/ml for control. For the total BLV group, 24% (30/126) and 36% (45/124) receiving concomitant NAs had undetectable HBV DNA at BL and W48, respectively, while 13% (13/100) and 21% (20/97) of participants not receiving concomitant NAs had undetectable HBV DNA at these times. For controls, 25% (8/32) and 41% (13/32) on NAs and 21% (4/19) and 11% (2/18) not on NAs had undetectable HBV DNA at BL and W48, respectively. BLV given with or without NAs had no impact on HBsAg levels.
Conclusion: NAs given with BLV for 48 weeks had no impact on HDV responses, while greater reductions in HBV DNA levels were seen when BLV and NAs are combined compared to BLV alone.

Improvement of liver stiffness during nucleo (s)tide analogue treatment in patients with chronic hepatitis B and advanced fibrosis is not associated with a reduction in hepatocellular carcinoma risk

Lesley A. Patmore[1], Yan Liang[2], Mai Kilany[3], Arno Furquim d'Almeida[4], Vincent Wai-Sun Wong[2], Thomas Vanwolleghem[4], Pieter Honkoop[5], Hans Blokzijl[6], Ozgur Koc[7], Harry L.A. Sonneveld[1]. *[1]Erasmus MC, University Medical Center, Rotterdam, Netherlands; [2]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Toronto Centre for Liver Disease, Toronto General Hospital, University of Toronto, Toronto, Canada; [4]Antwerp University Hospital, University of Antwerp, Edegem, Belgium; [5]Albert Schweitzer Hospital, Dordrecht, Netherlands; [6]University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [7]Maastricht University Medical Center, Maastricht, Netherlands; [8]University Medical Center Utrecht, University of Utrecht, Utrecht, Netherlands; [9]Prince of Songkla University, Songkhla, Thailand; [10]Amsterdam University Medical Centers, Amsterdam, Netherlands*
Email: l.patmore@erasmusmc.nl

Background and aims: Chronic hepatitis B (CHB) patients with advanced fibrosis are at high risk for hepatocellular carcinoma (HCC)

and other adverse liver outcomes. Since liver stiffness correlates with severity of fibrosis in untreated patients, an improvement in liver stiffness measurement (LSM) by vibration-controlled transient elastography is used as a surrogate marker for fibrosis regression in patients on antiviral therapy. However, the association between on-treatment LSM with adverse liver-related outcomes is yet unknown.
Method: We conducted an international multicenter retrospective cohort study of mono-infected CHB patients with advanced fibrosis (≥F3 based on liver biopsy or LSM ≥9.0 kPa) and with available on-treatment LSM after at least 3 years of follow-up, at sites in Belgium, Canada, Hong Kong, the Netherlands, and Thailand. On-treatment LSM was categorized into <6 kPa, 6–9 kPa and >9 kPa. We assessed the association between on-treatment LSM with HCC development, as well as liver-related events (first of HCC, liver transplantation and liver-related mortality).
Results: We analyzed 512 patients with a median age at baseline of 50 years, 76% were male. Median baseline HBV DNA was 5.6 log10 IU/ml. At baseline 40.8% had F3 and 59.2% had F4, 71.7% was based on LSM (median 12.7 kPa, IQR 10.5–17.6). All patients initiated antiviral therapy with nucleo(s)tide analogue and 93% had undetectable HBV DNA at on-treatment LSM. The median time between baseline assessment and on-treatment LSM was 4.5 years and median on-treatment LSM was 6.9 kPa (IQR 5.1–10.3). The on-treatment LSM was <6 kPa in 196 (38.3%) patients, 6–9 kPa in 156 (30.5%) patients and >9 kPa in 160 (31.2%) patients. During a median follow-up of 6.8 years after the on-treatment LSM, 53 patients developed HCC. In univariable analysis, on-treatment LSM was not associated with HCC development (hazard ratio [HR] 1.01, p = 0.607). The 5-year cumulative HCC incidence was comparable across on-treatment LSM strata; 4.7% for <6 kPa, 6.2% for 6–9 kPa and 4.3% for >9 kPa (p = 0.454). In multivariable analysis adjusting for age, sex, platelet count, ALT and HBV DNA, only older age (adjusted HR [aHR] 1.056, p < 0.001) and platelet count (aHR 0.992, p = 0.011) were significantly associated with HCC development, whereas on-treatment LSM was not (aHR 1.027, p = 0.833). Findings were consistent for patients with F3 (p = 0.512) or F4 at baseline (p = 0.249). The risk of liver-related events was also comparable across LSM strata (4.7% for <6 kPa, 6.2% for 6–9 kPa and 5.9% for >9 kPa (p = 0.184)).
Conclusion: The majority of CHB patients with advanced fibrosis decreases in LSM during antiviral therapy. Unfortunately, this improvement is not associated with a clinically relevant reduction in the risk of HCC and liver-related events. On-treatment LSM should therefore not be used to guide HCC surveillance strategies, nor as a surrogate end point in clinical trials.

Email: sandmann.lisa@mh-hannover.de

Background and aims: Infection with the hepatitis D virus (HDV) can lead to hepatitis delta, which is associated with a high risk of developing liver-related complications, including hepatic decompensation and hepatocellular carcinoma (HCC). The global epidemiology and disease severity of hepatitis delta is highly heterogeneous and disease presentation has changed over the last decades. There is limited knowledge on disease pathophysiology and host-virus interactions explaining the large inter-individual variability in the course of the disease. We aim to screen a large multicentre cohort of well-defined HDV-infected patients from different European countries to better understand not only the epidemiology but also to identify individual factors that determine the outcome of infection, thus providing the basis for an individualised treatment approach.
Method: We report first findings from an observational, non-interventional, cross-sectional multicentre cohort with the aim of enrolling 1000 European HDV-infected patients from England, France, Italy, Germany, Romania and Sweden. Patients with detectable anti-HDV for at least 6 months can be included. Retrospective data is obtained from databases and patient records for each patient's most recent visit that is eligible for inclusion (index visit). Available biosamples are used for virological and immunological analyses.
Results: To date, 561 patients have been included (England 27%, Italy 9%, Germany 19%, Romania 11%, Sweden 34%). The majority of patients is male (55%) with a mean age of 48 ± 12 years. The top three countries of birth were Romania (17%), Mongolia (15%) and Sierra Leone (8%). Two out of five patients were classified as having cirrhosis at the index visit (39%, 216/560), of whom 14% (29/211) and 31% (65/207) presented with ascites or esophageal varices while only few patients had signs of hepatic encephalopathy (4%, 9/211). A history of previous hepatic decompensation was documented in 11% (57/518) of patients. HCC was reported for only 29 patients (5%) at the index visit. Regarding antiviral treatment, 40% (223/560) of patients had a history of interferon (IFN)-based treatment, while only 3% were receiving IFN-based treatment at the index visit. Nucleos(t)ide analogues were used in 53% of patients and bulevirtide (BLV) in 6% (34/561). The latter is likely to underestimate the number of patients actually treated with BLV, as patients included in other registries and/or clinical trials were excluded. Anti-HCV antibodies were present in 8% of cases, while HCV RNA was not detected in any of the patients. HDV RNA was detected in 47% of patients, respectively.
Conclusion: This study has the potential to elucidate HDV epidemiology, disease burden and cascades of HDV care in a large multicentre cohort. Data collection is still ongoing and the results from the updated dataset will be presented at the conference.

Email: tingyan.wang@ndm.ox.ac.uk

Background and aims: Prediction of hepatitis B surface antigen (HBsAg) seroclearance in individuals with chronic hepatitis B (CHB) is challenging but crucial for understanding outcomes of infection and to support the evaluation of novel therapies aiming at functional cure.
Method: We studied a large ethnically diverse cohort of CHB adults (on or off antiviral treatment) from 7 secondary care centres in England with longitudinal laboratory and clinical monitoring, established by the National Institute for Health and Care Research Health Informatics Collaborative (NIHR HIC) from electronic health records (EHRs), representing data between 1992–2022. HBsAg seroclearance was determined by a negative HBsAg test, confirmed by at least one follow-up negative. Follow-up duration was defined as the interval between the date of CHB diagnosis and the date of HBsAg seroclearance or last HBsAg measurement. We excluded individuals with followed up duration <6 months, or liver transplantation. We conducted univariate analyses to explore the characteristics of individuals with vs without HBsAg seroclearance. Data were randomly split into training and test sets (90% vs 10%). We applied 10 machine learning (ML) models for HBsAg seroclearance prediction based on the most predictive variables selected by univariate analyses. We derived the relative feature importance based on the ML models of best performance, evaluated by area under the receiver operating characteristics curve (AUC).
Results: We included 4, 448 adults who were followed up for 21, 589 person years (median follow-up of 4 years per patient). 55% were male, and the median age was 39 (interquartile range (IQR): 32–49) years, 37% on treatment, comprising 37% Asian, 21% Black, 29% White, and 13% other ethnicities. 304 patients (1.4%) achieved HBsAg seroclearance (226 confirmed with a follow-up result, 1.0%), On univariate analysis, individuals who were older at baseline, male, of White ethnicity, untreated, and had lower baseline HBV viral load (VL) and HBsAg, higher alkaline phosphatase (ALP), lower haemoglobin (Hb), HCV/HBV coinfection, and longer follow-up, were more likely to have HBsAg seroclearance (all $p < 0.05$). The five best predictive ML models (AUC ≥ 0.80) confirmed that baseline age, ethnicity, follow-up duration, baseline HBV VL, ALP, Hb, bilirubin, deprivation score, treatment status, and creatinine, are consistently the top 10 important factors contributing to the prediction performance.
Conclusion: In addition to well-known predictors, we identified ethnicity, deprivation score, and several routine laboratory parameters for HBsAg seroclearance prediction. Big data analytics and ML by utilising large EHRs datasets can be promising to identify individuals with the highest chance of HBsAg loss which is relevant to determining immune-mediated clearance and functional cure using new therapeutic agents.

Burden of liver disease progression in patients with chronic HDV infection: a population-based study for France

Lucia Parlati[1], Charlotte Mouliade[2], Samir Bouam[3], Philippe Sogni[2], Stanislas Pol[2], Vincent Mallet[2]. *[1]AP-HP.Centre Université Paris Centre, Groupe Hospitalier Cochin Port Royal, DMU Cancérologie et spécialités médico-chirurgicales, Service des Maladies du foie, Paris, France, Université Paris Cité, F-75006, Paris, France, Paris, France; [2]AP-HP.Centre Université Paris Centre, Groupe Hospitalier Cochin Port Royal, DMU Cancérologie et spécialités médico-chirurgicales, Service des Maladies du foie, Paris, France, Université Paris Cité, F-75006, Paris, France, Paris, France; [3]AP-HP.Centre Université de Paris, Groupe Hospitalier Cochin Port Royal, DMU PRIM, Service d'Information Médicale, Paris, France, Paris, France*
Email: lucia.parlati85@gmail.com

Background and aims: The burden of liver disease progression to hepatocellular carcinoma or decompensated cirrhosis associated with chronic hepatitis D virus (HDV) infection remains largely unquantified at the population level.
Method: We conducted a retrospective analysis using data from the French National Diagnosis Related Group Database (2014–2023), focusing on cases of chronic HDV infection (ICD-10 code B180) recorded in French hospitals over the past decade. Our objective was to estimate the Population Attributable Fraction (PAF) of alcohol use disorders, non-HDV related chronic liver diseases, type-2 diabetes mellitus, and obesity, in relation to the risk of liver disease progression. We used logistic regression models adjusted for sex, age at censoring, deprivation and major comorbidities, to compute the probability of liver disease progression under both actual conditions and counterfactual scenarios-the latter representing a hypothetical absence of specific risk factors. The PAFs were determined by comparing these probabilities to quantify the contribution of each risk factor to liver disease progression.
Results: Of 5, 954 individuals (median [IQR] age at inception 48 [36–61] years, 54% men), 14% (n = 832) were recorded with liver disease progression (7.2% with hepatocellular carcinoma, 10.5% with decompensated cirrhosis). The median age at the time of liver disease progression was 54 (44–62) years, with an overwhelmingly (76%) male predominance. Among patients with liver disease progression, the prevalence of alcohol use disorders, non-HDV related chronic liver diseases, obesity, and type-2 diabetes mellitus was 41.6%, 28.8%, and 37%, respectively. Key risk factors of liver disease progression ($p < 0.01$) were male sex [aOR 2.2 (95% CI: 1.82 to 2.67)], alcohol use disorders [aOR 4.97 (4.09 to 6.04)], non-HDV related chronic liver diseases [aOR 5.37 (3.73 to 7.70)], type-2 diabetes mellitus [aOR 1.57

(1.23 to 1.99), and obesity [1.47 (1.16 to 1.86)]. Severe comorbidities [aOR 0.42 (0.33 to 0.53)], and deprivation [aOR 0.84 (0.71 to 1.00)] were not association with liver disease progression. The PAF (95% CI) for alcohol use disorders, type-2 diabetes mellitus, non-HDV related chronic liver diseases, and obesity were 28.1% (26.7%–29.4%), 6.4% (6.0%–6.8%), 5.5% (4.6%–6.3%), and 5.4% (5.1%–5.7%), respectively.
Conclusion: Approximately 45% of the liver disease burden linked to chronic HDV infection in France from 2014 to 2023 was found to be attributable to modifiable, non-HDV-related risk factors.

FRI-362-YI

Hepatitis B surface antigen (HBsAg) seroclearance following discontinuation of nucleos (t)ide analogues (NA) treatment has comparable durability to HBsAg seroclearance achieved during NA therapy

Terry Cheuk-Fung Yip[1,2,3], Mandy Sze-Man Lai[1,2], Jimmy Che-To Lai[1,2,3], Yee-Kit Tse[1,2,3], Henry L.Y. Chan[2,4], Vincent Wai-Sun Wong[1,2,3], Grace Lai-Hung Wong[1,2,3]. *[1]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong; [2]Medical Data Analytics Centre (MDAC), The Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Institute of Digestive Disease, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong; [4]Department of Internal Medicine, Union Hospital, Hong Kong, Hong Kong*
Email: tcfyip@cuhk.edu.hk

Background and aims: The durability of hepatitis B surface antigen (HBsAg) seroclearance achieved after nucleos (t)ide analogues (NA) therapy cessation is not well defined. We compared the cumulative rate of HBsAg seroreversion and seroconversion in patients who developed HBsAg loss after stopping NA, during NA therapy, after interferon (IFN) treatment, or spontaneously.
Method: Adult patients with chronic hepatitis B mono-infection who cleared HBsAg from 2000–2022 were identified from a territory-wide database in Hong Kong. Patients with liver transplantation, cancer, or use of immunosuppressants before HBsAg loss were excluded. Time-dependent cause-specific hazard (CSH) models were used to compare different forms of HBsAg loss on the development of HBsAg seroreversion and seroconversion and examine the factors linked to these outcomes.
Results: Of 6, 028 patients with HBsAg loss (mean age 58 ± 13 years; 38.6% female; 3.8% cirrhosis), 259 (4.3%), 865 (14.3%), 100 (1.7%), and 4, 804 (79.7%) lost HBsAg after NA therapy cessation, during NA therapy, after IFN treatment, and spontaneously respectively; their corresponding mean age at HBsAg loss was 54, 56, 50, and 58 years; 30.1%, 28.3%, 23.0%, and 41.3% were female respectively. Most patients had normal liver function at HBsAg loss. In patients who cleared HBsAg after NA therapy cessation, during NA therapy, after IFN treatment, and spontaneously, 9 (3.5%), 51 (5.9%), 4 (4.0%), and 261 (5.4%) developed HBsAg seroreversion at a median (25th–75th percentile) follow-up of 4.9 (2.5–8.3) years. The 10-year overall cumulative risk (95%CI) of HBsAg seroreversion was 9.6% (7.8%–11.6%). Compared to patients with HBsAg loss during NA therapy, those with HBsAg loss after NA therapy cessation (adjusted CSH ratio [aCSHR] [95%CI] 0.58 [0.29–1.19], p = 0.14), after IFN treatment (0.65 [0.23–1.81], p = 0.41), or spontaneously (0.81 [0.59–1.10], p = 0.18) had a comparable rate of HBsAg seroreversion. Male gender (aCSHR [95%CI] 0.76 [0.61–0.95]) and positive anti-HBs (0.44 [0.30–0.64]) were associated with a lower rate of HBsAg seroreversion, while diagnosis of cancer (3.03 [1.89–4.84]) and immunosuppressant use (1.79 [1.17–2.74]) during follow-up were associated with more HBsAg seroreversion. Among 3, 449 patients with antibody to HBsAg (anti-HBs) measurement, the 10-year cumulative incidence (95%CI) of positive anti-HBs was 53.6% (51.7%–55.5%). Patients who achieved HBsAg loss after NA therapy cessation (aCSHR [95%CI] 1.00 [0.77–1.29]), after IFN treatment (1.19 [0.86–1.65]), or spontaneously (0.98 [0.86–1.13]) had a similar rate of developing positive anti-HBs compared to those with HBsAg loss during NA therapy.
Conclusion: HBsAg seroclearance achieved after NA therapy cessation is similarly durable to those achieved during NA therapy, after IFN treatment, and spontaneously, with a comparable chance of HBsAg seroconversion over time.

FRI-363-YI

Association between metabolic dysfunction, severity of liver fibrosis and fibrosis progression in patients with chronic hepatitis B-an individual patient data meta-analysis

Sonneveld[1]. *[1]Erasmus University Medical Center, Rotterdam, Netherlands; [2]Toronto Centre for Liver Disease, University of Toronto, Toronto, Canada; [3]The Chinese University of Hong Kong, Hong Kong, China; [4]Prince of Songkla University, Hat Yai, Thailand; [5]Chang Gung Memorial Hospital, Linkou Branch, Taiwan, College of Medicine, Chang Gung University, Taiwan, Taipei, Taiwan; [6]Roche Products Ltd, Welwyn Garden City, United Kingdom; [7]Gilead Sciences, Foster City, United States; [8]Liver Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [9]CIBER Hepatic and Digestive Diseases (CIBERehd), Instituto Carlos III, Madrid, Spain; [10]Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China*
Email: l.vanvelsen@erasmusmc.nl

Background and aims: Presence of metabolic comorbidities (ie. overweight, diabetes mellitus [DM], hypertension [HT], and dyslipidemia [DL]) has been associated with a higher risk of liver-related outcomes in chronic hepatitis B (CHB) patients. We studied the association between presence of metabolic comorbidities with severity of liver fibrosis before and during antiviral therapy (AVT).
Method: We analyzed data from the SONIC-B database, which comprises data of CHB patients who underwent liver biopsy in two tertiary clinics in the Netherlands and Canada, or as part of 8 global clinical trials. We analyzed the association between the presence of metabolic comorbidities with severity of liver fibrosis in currently untreated patients, and with fibrosis regression (decrease of ≥1 METAVIR class in patients with baseline METAVIR ≥F2) and fibrosis progression (increase from METAVIR F0–2 at baseline to METAVIR F3–4) in biopsies taken at 48–72 weeks after initiation of AVT. Comparisons were performed using the Chi-square test and multivariable logistic regression.
Results: We analysed biopsies from 2821 currently untreated CHB patients. Median age was 37 years, 53% HBeAg positive, with median HBV DNA of 7.17 log IU/ml. Overweight, HT, DM and DL were present in 51%, 6.8%, 4.3% and 3.9% of patients, and 25.4% had advanced fibrosis (METAVIR F3–4). Presence of overweight (30.8 vs 19.8%; $p < 0.001$), HT (39.3 vs 24.4%, $p < 0.001$), DM (42.5 vs 24.7%, $p < 0.001$) and DL (46.8 vs 24.6%, $p < 0.001$) was associated with a higher risk of advanced fibrosis. The highest risk of advanced fibrosis was seen in patients with multiple comorbidities (19.4% if no metabolic comorbidities, 27.9% with 1 comorbidity, 43.6% if ≥2 comorbidities, $p < 0.001$). Findings were consistent in multivariable analysis (adjusted odds ratio [aOR] for 1 comorbidity: 1.135, aOR for ≥2 comorbidities: 1.566, $p = 0.022$). Follow-up biopsy was available for 1307 patients, 757 treated with NUC monotherapy and 550 with PEG-IFN ± NUC. Fibrosis regression was observed in 261 (39.4%) patients, and was more often observed in patients without metabolic comorbidities (49.8%), when compared to patients with 1 (33.9%) or ≥2 metabolic comorbidities (28.0%, $p < 0.001$). Findings were consistent in multivariable analysis (aOR for 1 comorbidity: 0.646, aOR for ≥2 comorbidities: 0.463, $p = 0.020$). Finally, progression to advanced fibrosis during AVT was predominantly seen in patients with metabolic comorbidities: the risk was 4.6% in patients without metabolic comorbidities, compared to 9.8% and 14.3% in patients with 1 or ≥2 metabolic comorbidities ($p = 0.001$).

Conclusion: Presence of metabolic comorbidities in untreated patients with CHB is associated with more severe liver fibrosis. Furthermore, in patients on AVT, presence of metabolic comorbidities is associated with less fibrosis regression, and even a significant risk of fibrosis progression.

FRI-364

Baseline and reduction at 1 year of hepatitis B surface antigen level predicts functional cure and low HBsAg titer: A long-term kinetics of hepatitis B surface antigen

Soon Kyu Lee[1], Jung Hyun Kwon[1], Soon Woo Nam[1]. [1]*Division of Hepatology, Department of Internal Medicine, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Rep. of South*
Email: doctorkwon@catholic.ac.kr

Background and aims: Long-term nucleos (t)ide analogue (NA) therapy is usually mandatory in patients with chronic hepatitis B (CHB) infection. In the stopping rule, a low HBsAg titer (<2 log IU/ml) has been suggested as the cut-off level for stopping NA therapy. However, the long-term kinetics of quantitative HBsAg levels and their predictive role in functional cure or stopping NA strategy remain unclear.
Method: We consecutively enrolled 1661 patients with chronic hepatitis or liver cirrhosis who started NA therapy between 2006 and 2020. Finally, 852 patients (entecavir, n = 287; tenofovir, n = 565), who were serially checked annually for HBsAg levels, were analyzed in our study. Patients were classified into three groups according to the quantitative HBsAg levels: the low HBsAg group (HBsAg <2 log IU/ml), the intermediate HBsAg group (2 log ≤HBsAg<3 log IU/ml), and the high HBsAg group (HBsAg ≥3 log IU/ml). The primary outcome was the identification of the rate and predictive factors of functional cure and achievement of low HBsAg titer during NA treatment. Moreover, we also evaluated the long-term kinetics of HBsAg levels and the development of hepatocellular carcinoma (HCC).
Results: During a mean follow-up of 6.3 ± 3.6 years, the rate of functional cure after NA treatments was 2.28% (n = 19), and 108 patients (12.9%) achieved a low HBsAg group. The rate of the low HBsAg and intermediate group increase from 6.5% and 15.3% at baseline to 7.7% and 17.9% at the first year, and 14.2% and 39.6% at 8 years, respectively. The changes in the mean levels of HBsAg showed a steep reduction in the first year of NA therapy than after the first year in both functional and non-functional cure groups. The HBeAg (+) group demonstrated a higher baseline HBsAg titer and a greater reduction at one year compared to the HBeAg (−) group. Among patients with HBeAg (+), the chronic hepatitis group showed a significant reduction at one year. In multivariate Cox-regression analysis, lower baseline HBsAg titer (<1000 IU/ml), and the presence of reduction in the 1 year of HBsAg titer were both identified as predictive factors for an achievement of functional cure and low HBsAg titer after NA therapy. During follow-up, there was no development of HCC in patients achieving functional cure.
Conclusion: Our study demonstrated the rapid reduction in HBsAg titer in the first year of NA therapy and an increase in low HBsAg group during NA therapy. Moreover, lower baseline HBsAg titer and a decrease in the first year of HBsAg titer may predict functional cure and low HBsAg titer during NA treatments.

FRI-365-YI

Limited use of established risk scores for the prediction of hepatocellular carcinoma in patients with chronic hepatitis D virus infection

Robin Iker[1,2], Anika Wranke[1,2], Hannah Schneider[1], Heiner Wedemeyer[1,2,3,4], Helenie Kefalakes[1,2,3,4], Lisa Sandmann[1,3,4]. [1]*Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany;* [2]*German Center for Infection Research (DZIF), Hannover/Braunschweig, Hannover, Germany;* [3]*D-SOLVE: EU-funded Network on individualized management of hepatitis D, Hannover, Germany;* [4]*Excellence Cluster RESIST, Excellence Initiative Hannover Medical School, Hannover, Germany*
Email: iker.robin@mh-hannover.de

Background and aims: Hepatocellular carcinoma (HCC) is a major health burden and one of the leading causes of cancer-related deaths worldwide. Patients with chronic HDV infection (CHD) are at risk of developing HCC. In chronic HBV or HCV infection, risk scores are commonly used to predict HCC, but none has been validated in CHD. Here, we aim to validate existing HCC risk scores for their predictive potential in patients with CHD.
Method: Data from patients with CHD and a minimum follow-up (FU) of 6 months were retrospectively collected at Hannover Medical School from 1990 to 2023. Patients with HCC development (CHD-HCC) during FU were identified and matched to patients without HCC development (CHD-non-HCC) based on sex, age, INR, and bilirubin in a 1:2 ratio. Time points for data collection were first visit to the clinic (BL), 12 (HCC-12) and 6 months (HCC-6) prior to HCC development, as well as at HCC diagnosis (HCC). Comparable time points were selected for the matched CHD-non-HCC cohort with the last one defined as the last available visit. Validated HCC risk scores were calculated and compared between the cohorts. The following scores were analyzed: PAGE-B (platelets, age, sex), aMAP (age, sex, albumin/bilirubin, platelets), Toronto HCC Risk Index (age, etiology, sex, platelets), REAL-B (age, sex, alcohol, cirrhosis, diabetes, platelets, alpha-fetoprotein (AFP)), CAMD (cirrhosis, age, sex, diabetes), AASL (age, albumin, sex, cirrhosis) and ADRES-HCC (sex, FIB-4 index, AFP).
Results: We retrospectively identified 251 CHD patients of whom 14% (36/251) were diagnosed with HCC during FU. At BL, the majority of CHD-HCC patients were male (75%), cirrhosis was present in 89% of patients and median time to HCC diagnosis was 3.42 years (IQR 1.4–6.96). The prevalence of liver cirrhosis, hepatic comorbidities and prior interferon treatment was similar to the matched 72 CHD-non-HCC patients. When comparing HCC prediction scores between the cohorts, overall test performance was poor. At BL, the REAL-B score reached the highest AUC with 0.655, followed by CAMD (AUC = 0.61) and aMAP (AUC = 0.61). Slightly weaker test performance was detected at HCC-12, with the three best performing tests being REAL-B (0.61), CAMD (AUC = 0.59) and ADRES-HCC (AUC = 0.56). At HCC-6, ADRES-HCC (AUC = 0.69), REAL-B (AUC = 0.66) and aMAP (AUC = 0.62) performed best. At HCC diagnosis, ADRES-HCC (AUC = 0.68) and aMAP (AUC = 0.66) were the two best scores to distinguish between patients with and without HCC. Interestingly, AFP alone outperformed all scores at every time point with an AUC of 0.69, 0.64, 0.75, and 0.78 at BL, HCC-12, HCC-6 and HCC respectively.
Conclusion: In our cohort, none of the analyzed scores predicted HCC development with sufficient accuracy and consistency. However, HCC risk stratification is essential for the management of CHD patients. Thus, the development of a valid HCC risk score should be addressed in future studies.

FRI-366

HBV DNA thresholds and immune tolerance: unveiling new insights from cross-sectional hepatic histology data in hepatitis B

Xiaoke Li[1], Tingyu Zhang[2], Xin Sun[2], Daqiao Zhou[3], Xiaoling Chi[4], Yueqiu Gao[5], Yong-an Ye[1]. [1]*Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China;* [2]*Beijing University of Chinese Medicine, Beijing, China;* [3]*Shenzhen Traditional Chinese Medicine Hospital, Shenzhen, China;* [4]*The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China;* [5]*Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China*
Email: lixiaoke@bucm.edu.cn

Background and aims: Immune tolerance (IT) is pivotal in HBV persistence. Current guidelines, constrained by liver biopsy

limitations, use high HBV viral loads and normal liver enzymes as surrogate IT markers. Yet, defining 'high viral load' lacks uniformity across regional guidelines. Furthermore, the definition of a quasi-immune tolerance phase in HBeAg-negative patients remains a contentious issue. This cross-sectional study in China seeks to clarify the relationship between serum HBV DNA levels and hepatic inflammation grades (from liver biopsy) in untreated chronic hepatitis B patients. It aims to uncover high viral load patterns with concurrent low hepatic inflammation in various infection statuses and to determine a more accurate HBV DNA threshold for IT identification.

Method: Our study encompassed 1, 275 nucleos (t)ide analogue-naive chronic HBV patients from China, including 568 HBeAg-negative and 707 HBeAg-positive subjects. The cohort was stratified based on HBeAg status, following which we delved into the relationship between hepatic inflammation (assessed through biopsy) and serum HBV DNA levels. Spearman's correlation analysis and a stepwise looping algorithm were employed for the precise determination of optimal HBV DNA cut-off values for assessing hepatic inflammation.

Results: The study identified distinct correlations within groups defined by HBV DNA thresholds. In HBeAg-negative patients, a threshold of 6.45 log10 IU/ml was set, showing Spearman correlation coefficients of 0.40 ($p < 0.01$) and −0.32 ($p = 0.036$) below and above this level, respectively. In HBeAg-positive patients, an 8.92 log10 IU/ml threshold resulted in coefficients of −0.10 ($p < 0.01$) and −0.63 ($p < 0.01$). These findings suggest a nuanced, non-linear connection between viral load and liver inflammation in both HBeAg-defined categories, with variable patterns across HBV DNA levels.

Conclusion: This study highlights the diverse relationship between HBV DNA viral load and hepatic inflammation in chronic hepatitis B patients at different DNA levels. Generally, elevated HBV DNA levels correlate with increased liver inflammation, but this trend reverses at higher levels. Interestingly, similar patterns are observed in both HBeAg-positive and -negative groups, albeit with lower HBV DNA thresholds in the latter. These findings challenge the traditional view that immune tolerance is exclusive to HBeAg-positive individuals, introducing the possibility of a quasi-immune tolerance state in HBeAg-negative patients. This revelation suggests a possible shift in our understanding of immune tolerance in chronic hepatitis B and underscores the need for a reevaluation of treatment strategies for these patients, potentially impacting their clinical management.

FRI-367

Prediction of hepatocellular carcinoma risk and liver-related events in chronic hepatitis D, an international retrospective cohort study (RIDE)

Background and aims: Chronic hepatitis D (CHD) is the most severe form of chronic viral hepatitis, with a high risk of developing hepatocellular carcinoma (HCC) and other liver-related events. Risk stratification is urgently needed to guide HCC surveillance strategies and to prioritize treatment with novel antiviral agents.

Method: We conducted a multicenter retrospective cohort of all consecutive anti-HDV positive patients managed at 10 academic and non-academic sites in the Netherlands and the United Kingdom. We excluded patients with current or past hepatitis C or HIV infection. The PAGE-B score was calculated at first visit as previously published based on platelet count, age and sex, and patients were categorized as low (<10), intermediate (10–17) and high risk (>17) for HCC development. We studied the cumulative incidence of HCC and liver-related events, defined as the first of a composite of HCC, liver transplantation and liver-related mortality, in the overall study population, and across PAGE-B risk strata.

Results: We analyzed 269 patients; 58% was male with a median age of 38 years (inter quartile range [IQR] 32–47) at enrolment. At enrolment, 35.5% had cirrhosis and 45% were HDV RNA positive. In 66.5% of patients antiviral therapy was started with either a nucleo(s)tide analogue ($n = 164$) and/or (pegylated) interferon ($n = 41$) during follow-up. During a median follow-up of 4.3 years (IQR 1.5–6.4), a total of 47 first events were recorded (HCC: $n = 13$, liver transplantation: $n = 34$, liver-related death: $n = 13$).The 5-year cumulative incidence of HCC and liver-related events were 3.8% (95% confidence interval [CI] 1.05–6.5), and 15.6% (95% CI 10.5–20.7). The 5-year cumulative incidence of HCC was 0% among patients with a low PAGE-B score ($n = 115$, 44% of cohort), compared to 3.2% in the intermediate risk group ($n = 121$, 46% of cohort) and 25.4% in the high risk group ($n = 26$, 10% of cohort; $p < 0.001$). The 5-year cumulative incidence of liver-related events was 2.1% among patients with a low PAGE-B score, compared to 21.1% in the intermediate risk group and 45.5% in the high risk group ($p < 0.001$). Findings were consistent in patients with cirrhosis at baseline; the 5-year cumulative HCC incidence was 0% in the low PAGE-B group, and 9.1% and 32.4% in the intermediate and high risk groups ($p < 0.001$). Among HDV RNA positive patients, the 5-year cumulative HCC incidence was 0% in the low PAGE-B group compared to 6.8% and 32.5% in the intermediate and high risk groups ($p < 0.001$).

Conclusion: Patients with CHD are at high risk of adverse liver-related outcomes. PAGE-B predicts the risk of HCC development and other liver related events, and can therefore be used to guide HCC surveillance strategies and treatment prioritization.

Email: m-meszaros@chu-montpellier.fr

Background and aims: Bulevirtide (BLV), a breakthrough antiviral inhibiting hepatitis Delta virus (HDV) cell entry, received European Medicine Agency approval in 2020 for HDV chronic infection in compensated liver disease patients. Its use in patients on liver transplant (LT) waiting list (for decompensated liver disease or hepatocarcinoma (HCC) remains underexplored. This study aims to gather real-life data on BLV usage in patients awaiting LT or undergoing LT candidacy evaluation.

Method: Consecutive HDV-infected cirrhotic patients being on liver transplant waiting list or undergoing pretransplant evaluation in whom BLV (2 mg daily) was prescribed were included.
Clinical, biological, and virological characteristics were collected at baseline, week 24 and week 48, and at LT. Liver-related events (HCC, LT) and adverse events were documented. Virological response was defined by HDV RNA undetectable or ≥2-log decline vs. baseline, virologic non-response: HDV-RNA decline <1 log vs baseline and biochemical response: ALT normalization vs baseline.
Results: Fourteen patients from six French LT centers were included. The mean age was 52 ± 9.4 years, 71.4% were men. At BLV initiation 12 patients were Child A (85.8%), 1 (7.1%) Child B and 1 (7.1%) Child C. Four (28.5%) patients received concomitant PEG IFNα 180 μg/week. Mean MELD score was 9.14 ± 2.74. Median platelet count 78 (26–350) ×109/L, liver stiffness measurement (LSM) 17.4 (10–50) kPa, alanine aminotransferase (ALT) 87.5 (32–139) U/L, HBsAg 4402 (315–13899) IU/ml, HDV RNA 6 (2.23–7.4) log IU/ml. Large gastroesophageal varices were present in 9 (64%) patients. Seven (50%) patients had active HCC: 3 (43%) were BCLC-0, 3 (43%) BCLC-B and 1 (14%) BCLC-A. Eleven (78%) patients received 48 weeks (W) of BLV therapy. At W48 HDV RNA declined by a median of 2.56 (IQR 3.02) log IU/ml ($p < 0.001$) vs. baseline, becoming undetectable in 6 (54%) patients. A virological response at W48 was seen in 8 (72.7%) patients and a non-response in 1 (10%) patient. At W48 median ALT decreased to 34 (8–93) U/L ($p < 0.001$ vs baseline). Biochemical response at W48 was 72.8%. Combined response (at W48 was 54, 5%. Median MELD score was unchanged at W48. No significant changes in HBsAg concentrations were observed between W0 vs W24.No symptomatic adverse event was observed. 9 (64%) patients underwent LT after a mean waiting time of 12 (6–20) months. At LT, HDV RNA declined by a median of 1.81 (1.34) log IU/ml ($p < 0.004$) vs. baseline and was undetectable in 4 (44.4%) patients. Two patients died, one from cholangiocarcinoma and another of HCC progression. None of them were attributed to BLV.
Conclusion: BLV demonstrates safety and efficacy in patients on LT waiting list for decompensated liver disease or HCC. A 48-week course of therapy leads to significant virological and biochemical responses, providing valuable insights for the management of chronic hepatitis Delta in the LT setting.

Background and aims: Bulevirtide (BLV) is a first-in-class entry inhibitor approved in the EU for the treatment of chronic hepatitis delta (CHD). In MYR204, a Phase 2b study evaluating finite treatment with BLV with or without pegylated interferon alfa-2a (PegIFN), combination treatment resulted in higher post-treatment virologic response rates compared with either monotherapy regimen. Here we present the predictors of on-treatment and post-treatment responses with combination treatment.
Method: 174 patients with CHD were randomized (1:2:2:2) and stratified based on cirrhosis status to receive (A) PegIFN for 48 weeks (W); or (B) BLV 2 mg + PegIFN, or (C) BLV 10 mg + PegIFN for 48W followed by 48W of monotherapy with BLV 2 mg or 10 mg, respectively; or (D) BLV 10 mg for 96W. All patients were followed up to 48W (FU-48) post-end of treatment (EOT). In this sub-analysis, the univariate logistic regression model was used to examine whether any baseline or on-treatment clinical characteristics predicted responses at EOT and FU-24, and sustained HDV RNA undetectability at FU-48 with combination therapy (arms B and C). The assessed end points included undetectable HDV RNA (target not detected) and composite end point (undetectable HDV RNA and ALT normalization). Predictors with a p value <0.05 was considered significant.
Results: Baseline (BL) characteristics were similar between all arms. BL predictors of undetectable HDV RNA and composite end point at EOT with combination therapy included absence of cirrhosis (odds ratio (OR) 3.6, 4.2; $p \leq 0.006$), HDV RNA<median 5.54 $\log_{10}$ IU/ml (OR 2.6, 2.5; $p = 0.03$), and LS <11.1 kPa (OR 3.8, 6.1; $p \leq 0.003$). The BL predictors of responses at FU-24 included HDV RNA<median (OR 4.5, 4.0; $p \leq 0.002$), no interferon experience (only for undetectable HDV RNA, OR 2.4; $p = 0.04$), LS <11.1 kPa (OR 2.4, 3.2; $p \leq 0.04$) and lower HBsAg (OR 0.4, 0.4; $p \leq 0.02$). In patients who achieved undetectable HDV RNA at EOT ($n = 51$), sustained HDV RNA undetectability at FU-48 was significantly predicted by BL HDV RNA level <median 5.09 $\log_{10}$ IU/ml (OR 4.0; $p = 0.0294$), earlier onset to HDV RNA undetectability ($p = 0.0030$), and longer duration of HDV RNA undetectability ($p = 0.0029$). Importantly, achieving undetectable HDV RNA at W24 after treatment initiation predicted maintained viral suppression at FU-48 (OR 19.1; $p = 0.0005$). In patients who were undetectable at both W24 and EOT, 92% maintained treatment response at FU-48 while only 38% of patients who had positive HDV RNA at W24 and undetectable HDV RNA at EOT maintained the response at FU-48.
Conclusion: In patients with CHD treated with combination therapy with BLV + PegIFN, absence of cirrhosis, lower HDV RNA and liver stiffness at BL were identified as significant predictors of undetectable HDV RNA and composite end point at EOT. Achievement of early undetectable HDV RNA at on-treatment W24 is an important predictor of long term off-treatment viral response.

FRI-372

The effect of age and pregnancy on transition into Immune Active disease in Immune Tolerant patients-a retrospective cohort study of 245 patients

Mai Kilany[1], Edo J. Dongelmans[2], Jordan J. Feld[3], Milan J. Sonneveld[4], Bettina E. Hansen[4], Harry L.A. Janssen[5]. *[1]Toronto Centre for Liver Disease-University of Toronto, Toronto, Canada; [2]Erasmus University Medical Center, Rotterdam, Netherlands; [3]Toronto Center for Liver Disease, Toronto, Canada; [4]Erasmus MC University Medical Center, Rotterdam, Netherlands; [5]Erasmus MC-University Medical Center, Rotterdam, Netherlands*
Email: mai.kilany@uhn.ca

Background and aims: It remains unclear whether starting anti-viral therapy (AVT) in Immune Tolerant (IT) chronic hepatitis B (CHB) patients is beneficial. Patients are likely to transition into Immune Active (IA) disease over time, and is unknown whether AVT could prevent this. We longitudinally followed IT-CHB patients to identify risk factors associated with phase transition to IA and the rates of adverse outcomes (cirrhosis, hepatic decompensation and HCC).
Method: This is a retrospective single center observational study of all IT-CHB patients who were diagnosed between 1990–2020. Strict criteria for IT-disease were used: HBeAg positive, HBV DNA ≥6 log and if ALT ≤40 U/ml. IA disease was defined as ALT ≥80, or >40 for two visits (in the absence of other causes of ALT elevation) or presence of ≥F2 on liver biopsy or non-invasive tests. KM- and Cox-method (including start of AVT as time-dependent covariate) were used for cumulative incidences and identifying predictors, in which first visit with lab was defined as baseline.
Results: In total, 245 patients were included with a median age of 29.6 [24–38] years; 68% were female and 89% were Asian. Median baseline ALT and HBV DNA were 25 [21–32] U/ml and 8.6 [8.2–9.1] log10 U/ml. Those above age 40 at baseline had higher median ALT 31 [24–36] vs. 24 [20–31] U/ml ($p < 0.001$) of those <40, but there were no differences in baseline HBV DNA level (8.7 vs. 8.6 log10 U/ml, $p = 0.49$).
The median follow-up time was 142 [99–181] months. The 5- and 10 year cumulative incidences of IA transition were 38% and 61%, with a median time of 7.0 [3.2–13.8] years. 143 (58%) patients started AVT, of which IA disease was the most common indication (54%). IA transition was more common in patients with increased ALT levels at baseline (aHR 1.08, 95%CI 1.05–1.11, $p < 0.001$) and women who received short-term nucleos (t)ide analogue (NA) therapy during pregnancy (aHR 3.76; 95%CI 0.86–16.35, $p = 0.08$). For the latter group, median time between NA withdrawal and IA transition was 36 [8.2–75.1] months, excluding post-partum flares. Notably, increased age at baseline seemed not associated with a higher risk for phase transition (aHR 1.01; 95%CI 0.99–1.02, $p = 0.89$). Furthermore, changes in ALT- and HBV-DNA levels at 1- and 5-year were equal among different age groups (<25/25–34/35–44/>45 years, all $p > 0.05$). Regarding liver-related adverse events, four patients (1.6%) developed cirrhosis, one patient (0.4%) developed HCC approximately 6 years after transition, two patients (0.8%) achieved HBsAg-loss and no patients decompensated. All events occurred after IA phase transition.
Conclusion: A majority of IT patients transition into IA-disease within 10 years. IA transition rates were higher in patients with increased baseline ALT-levels and after short-term NA therapy during pregnancy. Interestingly, no effect of baseline age was seen.

FRI-373

Impact of pregnancy on global and HBV-specific B-cell immunity

Anna Pocurull[1], Mirea García-López[1], Cristina Collazos[1], Thais Leonel[1], Marta López[2], Simon Fletcher[3], Elena Perpinan[4], Georgios Koutsoudakis[1], Patricia Huelin[5], Carlos Aracil[5], Juan Carlos Hurtado[1], Xavier Forns[1], Mala Maini[6], Sofía Pérez-del-Pulgar[1], Sabela Lens[1]. *[1]Liver Unit, Hospital Clínic Barcelona. University of Barcelona, CIBEREHD, Barcelona, Spain; [2]Gynaecology and Obstetrics, Hospital Clínic Barcelona, IDIBAPS, Barcelona, Spain; [3]Gilead Sciences, Foster City, United States; [4]Institute of Liver Studies, King's College Hospital, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, London, UK, London, United Kingdom; [5]Arnau Vilanova University Hospital, Lleida, Spain; [6]Division of Infection and Immunity, University College of London (UCL), London, United Kingdom*
Email: pocurull@recerca.clinic.cat

Background and aims: Pregnancy represents a particular immunological state induced by the presence of the fetus. However, the role of B-cell immunity, especially regarding virus-specific B cells, has been poorly characterized, and its influence on the virological control of chronic hepatitis B (CHB) during pregnancy remains unclear. We aimed to characterize both the global and specific humoral immunity to Hepatitis B Virus (HBV) during pregnancy and postpartum among patients with CHB. As postpartum ALT flares in HBV suggest alterations of immunity during this transition we aimed to analyze the correlates of B-cell immunity.
Method: We longitudinally collected peripheral blood mononuclear cells (PBMC) from pregnant women diagnosed with CHB (PrandHBV, n = 22) at multiple intervals during pregnancy (2nd and 3rd trimesters) and postpartum (weeks 6, 16, and 48), analyzing them by spectral flow cytometry. Controls included pregnant patients without HBV (Pr, n = 9) and non-pregnant women with CHB (HBV, n = 9). We studied global and memory B cells (MBC) and characterized viral antigen-specific MBC (HBsAg-MBC and HBcAg-MBC) using fluorochrome-labeled baits. Additionally, we examined follicular T cells (Tfh) and regulatory B cells (B regs). ALT flare after delivery was defined by a two-fold increase from the baseline value.
Results: In terms of global B-cell immunity, pregnancy was associated with a reduced frequency of Bregs and Tfh in both groups ($p < 0.05$). However, the percentage of atypical or dysfunctional MBC phenotype (CD21-CD27-) was higher in PrandHBV compared to Pr patients (5% vs. 3%, $p = 0.02$). The frequencies of Tfh and MBC increased after delivery, indicating a potential restoration of T cell-B cell interaction. Regarding virus-specific immunity, the frequency of HBcAg-MBC in PrandHBV patients increased post-delivery (0.4 vs. 0.9%; $p < 0.05$) whereas the frequency of HBsAg-MBC remained stable. Interestingly, PrandHBV patients who developed a postpartum ALT flare (n = 5), had a higher frequency of atypical HBcAg-MBC during pregnancy (5% vs 0%; $p = 0.01$).
Conclusion: While global immunity experiences changes during pregnancy, our study sheds light on the specific B-cell responses directed against HBV. The identification and characterization of virus-specific MBCs, specifically those targeting HBcAg, reveal dynamic changes post-delivery. The increased frequency of HBcAg-MBCs suggests a potential boost in the immune response following childbirth. The changes observed in HBcAg-MBC subpopulations could serve as potential indicators for predicting postpartum ALT flares. However, further studies are essential to comprehensively understand the involvement of these cells in the immunological and virological changes induced by pregnancy.

FRI-374-YI

The UK experience of liver transplantation for HBV: excellent clinical outcomes despite a significant burden of HBV/Delta disease and wide variation in hepatitis B immunoglobulin prophylaxis practices-time for a consistent approach?

Almuthana Mohamed[1], Maria Guerra Veloz[1], Silke François[2], Gemma Botterill[3], Rachel Smith[4], Muhammad Salman[5], Lindsay Greenland[1], Lucy Turner[6], Stuart McPherson[5], Andrew Bathgate[7], Douglas Thorburn[2], William Gelson[4], Mark Aldersley[6], Ahmed M. Elsharkawy[3], Kosh Agarwal[1]. *[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, London, United Kingdom; [3]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [4]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [5]The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle, United Kingdom; [6]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [7]Royal Infirmary of Edinburgh NHS Lothian, Edinburgh, United Kingdom*
Email: almuthana700@gmail.com

Background and aims: Hepatitis B immunoglobulin (HBIG) along with high genetic barrier Nuclos (t)ide analogues (NUCs) are currently the standard care for prophylaxis against Hepatitis B (HBV) recurrence post liver transplantation (LT). Retrospective data from Italy suggests lifelong use of HBIG for high-risk HBV patients post-LT. However, indefinite HBIG therapy remains controversial, with heterogeneity in dosage and duration protocols in LT centres. We

audited the current management of HBV post-LT and outcomes within the UK for the past decade using LT centre's data.
Method: A retrospective, multicentre study was conducted by the British Association for the Study of Liver (BASL), including all patients who had LT for HBV between 2010–2023 in the 7 UK LT centres. Clinical and LT data were collected. HBV recurrence defined by reappearance of HBsAg and/or detectable HBV DNA. Multivariate regression analysis was used to identify predictors of HBV recurrence and survival.
Results: 299 patients were included (78.6% male; median age 52 years). 23.4% had HBV/Hepatitis D (HDV) coinfection. Common indications for HBV LT were decompensated cirrhosis (44.8%) and hepatocellular carcinoma (HCC) (43.5%). At the time of LT, 64.2% had undetectable HBV DNA and 69% with HBV/HDV coinfection had detectable HDV RNA. All patients with available data (96.3%) had NUCs post-LT and 81% received HBIG post-LT regardless of HBV DNA at the time of LT. However, there was heterogeneity in HBIG doses in the first week (range 0 to 10 HBIG doses) and maintenance dosing following LT (51.8% had maintenance HBIG doses, range 1 week to >10 years). During a median follow-up of 5 years, only 15 patients (5%) had HBV recurrence. Of them, 86.7% (n = 13) had high-risk of recurrence pre-LT; 4 had HBV/HDV coinfection, 5 had HCC, and 4 had fulminant HBV. Out of 43 patients (14.4%) who did not receive HBIG post-LT; only 1 patient had HBV recurrence (HBsAg positive at 6 months), and 1 patient died due to non-HBV related graft failure. The median survival post-LT was 54 months (range 0–159 months), and 38 patients died with only 2 deaths related to HBV recurrence. Multivariate regression analysis showed no significant association between number of HBIG doses in the first week post-LT, maintenance HBIG and HBV recurrence (p = 0.192, 0.619 respectively) or mortality (p = 0.301, 0.437 respectively).
Conclusion: UK data confirms that HBV recurrence and survival are not influenced by HBIG use and that survival post-LT, including a significant component of HBV/HDV coinfected patients, is excellent. However, most patients had prolonged maintenance HBIG doses post-LT. Almost all patients who did not receive HBIG post-LT (as per centre protocol) had no recurrence or increase in mortality. Early withdrawal or HBIG- free prophylaxis should be a strategy for most patients in a risk stratified manner, and this should be robustly reflected in clinical practice guidelines.

FRI-375

The coinfection of hepatitis C virus or human immunodeficiency virus in chronic hepatitis B in South Korea: A population-based study using the Korean Health Insurance Review and Assessment Service database

Jae Yoon Jeong[1], Won Sohn[2], Hyunwoo Oh[2,3], Hyo Young Lee[4], Yeonjae Kim[1], Seong Woo Nam[1]. [1]*National Medical Center, Seoul, Korea, Rep. of South;* [2]*Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South;* [3]*Uijeongbu Eulji Medical Center, Uijeongbu, Korea, Rep. of South;* [4]*Inje University Sanggye Paik Hospital, Seoul, Korea, Rep. of South*
Email: jyjeong76@hanmail.net

Background and aims: Concurrent infections such as hepatitis C virus (HCV) and human immunodeficiency virus (HIV) in patients with chronic hepatitis B virus (HBV) infection were associated with the development of liver cirrhosis and hepatocellular carcinoma (HCC). However, there have been few studies for on the prevalence, clinical characteristics, use of antivirals and development of liver related complications such as liver cirrhosis and HCC in HBV/HCV or HBV/HIV coinfection. This study aimed to evaluate the prevalence, comorbidities, treatment patterns and liver related complications of patients with HBV/HCV or HBV/HIV coinfection in South Korea.
Method: A retrospective, cross-sectional study was conducted using the nationwide claims data from the Health Insurance Review and Assessment Service from 2014 to 2021 in South Korea. In this study, the number of chronic hepatitis B (CHB) patients increased annually, starting at 327, 041 individuals (221, 143 men) in 2014 and reaching 473, 811 (269, 981 men) by 2021. These patients were classified into HBV monoinfection, HBV/HCV coinfection, and HBV/HIV coinfection groups, and comparisons were made among these groups annually.
Results: The prevalence of HBV/HCV coinfection among CHB patients between 2014 and 2021 ranged from 0.76% (2, 505/327, 041 in 2014) to 1.00% (4, 053/407, 310 in 2016), while HBV/HIV coinfection prevalence ranged from 0.055% (180/327, 041 in 2014) to 0.067% (308/462, 098 in 2020). The proportion of male gender in HBV monoinfection or HBV/HCV coinfection was approximately 60%, but HBV/HIV coinfection was predominantly observed in males (over 90%). The proportion of patients aged 50 and above among CHB patients consistently increased over time (52.0% in 2014 → 65.6% in 2021), with a higher prevalence observed in the following order: HBV/HCV coinfection (70.1% in 2014 → 81.0% in 2021), HBV monoinfection (51.9% in 2014 → 65.5% in 2021), and HBV/HIV coinfection (39.4% in 2014 → 57.2% in 2021). The presence of liver-related outcomes was higher in HBV/HCV coinfection followed by HBV monoinfection and then HBV/HIV coinfection. The proportion of liver cirrhosis in HBV/HCV coinfection, HBV monoinfection and HBV/HIV coinfection was 7.4%, 5.4%, and 5.1%, respectively (p < 0.001 in 2021). Also, the proportion of HCC in HBV/HCV coinfection, HBV monoinfection and HBV/HIV coinfection was 10.6%, 6.3%, and 5.1%, respectively (p < 0.001 in 2021). Cirrhosis demonstrated a decreasing trend over time (8.5% in 2014 → 5.4% in 2021), while the development of HCC showed no significant changes (6.3% in 2014 → 6.3% in 2021).
Conclusion: Patients with HBV/HCV coinfection are older than HBV monoinfection while those with HBV/HIV coinfection was younger than HBV monoinfection in South Korea. The prevalence of liver related complications among CHB patients was highest in HBV/HCV coinfection, followed by HBV monoinfection, and then HBV/HIV coinfection.

FRI-376

The impact of alanine aminotransferase fluctuation on the hepatocellular carcinoma risk in chronic hepatitis B patients

Youngsu Park[1], Hyunjae Shin[1], Jeong-Hoon Lee[1]. [1]*Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, Korea, Rep. of South*
Email: pindra@empal.com

Background and aims: High alanine aminotransferase (ALT) levels are well-established risk factors for hepatocellular carcinoma (HCC) development in chronic hepatitis B (CHB) patients. However, the impact of ALT fluctuation around normal margin on the development of HCC remains unclear.
Method: Patients with CHB, whose ALT levels were measured at least 4 times for the first two years, were enrolled. Based on the tertiles of coefficient of variation (CV, standard deviation divided by mean) of serial ALT levels, patients were divided into low-, intermediate-, or high-fluctuation groups. The primary outcome was HCC occurrence. Baseline characteristics were balanced using the inverse probability of treatment weighting (IPTW).
Results: Among 4, 413 patients, 76 (1.7%) developed HCC during a median follow-up of 12.6 (interquartile range [IQR] = 6.9–18.7) years. The median CV values of the low-, intermediate-, and high-fluctuation groups were 0.15, 0.30, and 0.71, respectively. Because baseline ALT levels were significantly higher in the high-fluctuation group than the other groups, we focused on the comparison between the low-fluctuation (n = 1, 471) and intermediate-fluctuation groups (n = 1, 471). Before balancing the baseline characteristics, the risk of HCC was significantly higher in the intermediate-fluctuation group compared to the low-fluctuation group (hazard ratio [HR] = 2.15, 95% confidence interval [CI] = 1.18–3.90, P = 0.01). After applying IPTW, the intermediate-fluctuation group maintained a significantly higher risk of HCC than the low-fluctuation group (HR = 1.99, 95% CI = 1.07–3.68, P = 0.03). Sensitivity analyses conducted with various

definitions of ALT fluctuation also reaffirmed the consistent result of the main analysis.
Conclusion: In CHB patients without antiviral treatment, fluctuating ALT, is associated with an increased risk of HCC. Further studies are warranted to evaluate if antiviral treatment for patients with ALT fluctuation could reduce the HCC risk.

FRI-377
Decline of Serum HBV RNA level During the First Week of Nucleos(t)ide Analogues Therapy Is Associated with Liver Injury and More Efficient Clearance of Hepatitis B Virus
Liandong Wu[1], Zhenggang Yang[1], Min Zheng[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China*
Email: minzheng@zju.edu.cn

Background and aims: Chronic hepatitis B (CHB) is a major global health problem. Although nucleos(t)ide analogues (NAs) are effective in controlling hepatitis B virus (HBV) infection, viral eradication remains unattainable due to the persistence of covalently closed circular DNA (cccDNA). Serum HBV RNA is a non-invasive biomarker directly reflecting cccDNA transcriptional activity. It was previously demonstrated that extracellular/serum HBV RNA levels increased after NAs treatment in HBV-producing cell lines and HBV transgenic mice, while serum HBV RNA levels declined under persistent NAs therapy in CHB patients. Early change of serum HBV RNA level after NAs therapy and its influencing factors remain unclear, as well as the clinical significance.
Method: 131 treatment-naïve CHB patients were included in this prospective cohort study with 12-week follow-up. Serum HBV RNA levels at baseline and within the first week of NAs therapy were measured, and patients were divided into three cohorts according to changes in serum HBV RNA levels within the first week of NAs therapy. In cohort A (n = 45), serum HBV RNA levels increased >0.5 $\log_{10}$ copies/ml; in cohort B (n = 41), serum HBV RNA levels changed <0.5 $\log_{10}$ copies/ml; in cohort C (n = 45), serum HBV RNA levels decreased >0.5 $\log_{10}$ copies/ml.
Results: Using ordinal logistic regression, alanine aminotransferase (ALT) was found to be associated with the decreasing trend of serum HBV RNA levels within the first week of NAs therapy (odds ratio = 1.25, P < 0.001). Area under receiver operating characteristic curve (AUC) for ALT to predict patients in cohort A was 0.841 ($p < 0.001$); AUC to predict cohort B was 0.607 ($p = 0.048$); AUC to predict cohort C was 0.902 ($p < 0.001$). ΔHBV RNA was calculated by difference between serum HBV RNA levels from baseline to different time points under NAs therapy (posttreatment level minus baseline level). Median ΔHBV RNA of week 2 among cohorts A, B, and C were 0.55, −0.33, and −1.82 $\log_{10}$ copies/ml, respectively ($p < 0.001$); median ΔHBV RNA of week 4–6 were −0.16, −0.61, and −3.18 $\log_{10}$ copies/ml ($p < 0.001$); median ΔHBV RNA of week 8–12 were −0.73, −1.07, and −4.01 $\log_{10}$ copies/ml ($p < 0.001$). Similarly, median ΔHBV DNA of week 1 were −1.16, −1.65, and −2.17 $\log_{10}$ IU/ml ($p = 0.013$); median ΔHBV DNA of week 2 were −2.21, −2.37, and −3.02 $\log_{10}$ IU/ml ($p = 0.033$); median ΔHBV DNA of week 4–6 were −3.15, −3.17, and −4.15 $\log_{10}$ IU/ml ($p = 0.015$); median ΔHBV DNA of week 8–12 were −3.54, −4.19, and −5.29 $\log_{10}$ IU/ml ($p = 0.073$). Median ΔHBsAg of week 4–6 were 0.02, 0.04, and −0.62 $\log_{10}$ IU/ml ($p = 0.012$); median ΔHBsAg of week 8–12 were −0.03, −0.05, and −0.93 $\log_{10}$ IU/ml ($p = 0.004$).
Conclusion: Serum HBV RNA levels were more likely to decline within the first week of NAs therapy in patients with more severe liver injury. Patients whose serum HBV RNA levels declined significantly within the first week of NAs therapy exhibited higher efficiency of viral clearance.

FRI-378
Effect of diabetes on the risk of fibrosis progression in patients with chronic hepatitis B
Mi Na Kim[1,2], Jae Seung Lee[1,2], Hye Won Lee[1,2], Beom Kyung Kim[1,2], Seung Up Kim[1,2], Jun Yong Park[1,2], Do Young Kim[1,2], Sang Hoon Ahn[1,2]. [1]*Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Yonsei Liver Center, Severance Hospital, Seoul, Korea, Rep. of South*
Email: ahnsh@yuhs.ac

Background and aims: Diabetes is associated with a higher risk of hepatocellular carcinoma in patients with chronic hepatitis B (CHB). However, there are limited data regarding fibrosis progression in CHB patients with diabetes compared with those without diabetes. We investigated the effect of diabetes on the risk of fibrosis progression in patients with CHB.
Method: We recruited 3, 450 patients with CHB who performed transient elastography from 2012 through 2020. The primary cross-sectional outcome was the prevalence of advanced fibrosis. The primary longitudinal outcome was fibrosis progression. Advanced fibrosis was defined, according to guidelines, as a liver stiffness measurement greater than 9.0 kilopascals. Fibrosis progression was defined as incident advanced fibrosis at 3-year of follow-up.
Results: The prevalence of advanced fibrosis in our cohort was 27.4% at baseline. A higher proportion of patients with diabetes had advanced fibrosis than those without diabetes (37.3% vs 24.8%; $p < 0.001$). In multivariate analysis, diabetes was significantly associated with advanced fibrosis (odds ratio [OR], 1.49; 95% confidence interval [CI], 1.24–1.78). The longitudinal analysis was done in 2, 504 patients with fibrosis stage of F0–2 at baseline. Diabetes was significantly associated with a higher risk of fibrosis progression after multivariate-adjustment (OR, 1.98; 95% CI, 1.48–2.65). The independent association of diabetes and the risk of fibrosis progression remained in each cohort of patients without antiviral therapy (OR, 1.83; 95% CI, 1.22–2.75), and those with antiviral therapy (OR, 2.15; 95% CI, 1.42–3.27).
Conclusion: In a large, well-characterized cohort study of patients with CHB, diabetes was associated with advanced fibrosis, and a higher risk for progression to advanced fibrosis.

FRI-379
Feasibility of aMAP combined with liver stiffness assessed using transient elastography for prediction of hepatocellular carcinoma development in patients with chronic hepatitis B
Hye Yeon Chon[1,2], Hyung Joon Yim[3], Su Jong Yu[4], Ja Kyung Kim[1,2], Sang Hoon Ahn[1,5], Sang Gyune Kim[6], Yeon Seok Seo[7], Seung Up Kim[1,5]. [1]*Yonsei University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Yongin Severance Hospital, Yongin, Korea, Rep. of South;* [3]*Korea University Ansan Hospital, Korea University College of Medicine, Ansan, Korea, Rep. of South;* [4]*Seoul National University College of Medicine, Seoul, Korea, Rep. of South;* [5]*Yonsei Liver Center, Severance Hospital, Seoul, Korea, Rep. of South;* [6]*Soonchunhyang University College of Medicine Bucheon Hospital, Bucheon, Korea, Rep. of South;* [7]*Korea University College of Medicine, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: The age-male-albumin-bilirubin-platelet (aMAP) score combined with liver stiffness (LS) assessed using transient elastography was recently suggested to be helpful for estimating fibrotic burden in patients with chronic hepatitis B (CHB). We evaluated the performance of the aMAP score combination with LS for predicting HCC development.
Method: We retrospectively reviewed 944 patients with CHB who initiated antiviral therapy in five tertiary hospitals of Korea between May 2005 and July 2021.
Results: Most patients were male (n = 527, 55.8%), and the median age was 50 years. During the follow-up period (median 47.7 months), 44 patients developed HCC. The aMAP score (66.3 *vs.* 60.1), aMAP-$\text{LSM}_{\text{advanced fibrosis}}$ (aML_{af}; 97.4 *vs.* 72.7), and aMAP-$\text{LSM}_{\text{cirrhosis}}$ (aML_{C};

91.0 *vs*. 55.7) were significantly higher in patients who developed HCC than those who did not (all $P < 0.05$). Similarly, the PAGE-B score (16.0 *vs*. 12.0) and modified PAGE-B (mPAGE-B) score (12.5 *vs*. 10.0) were significantly higher in patients who developed HCC than those who did not (all $P < 0.05$). In multivariate analysis, an increased aMAP (hazard ratio [HR], 1.125; 95% confidence interval [CI], 1.003–1.225), aML_{af} (HR, 1.049; 95% CI, 1.005–1.095), and aML_C (HR, 1.039; 95% CI, 1.008–1.071) were independently associated with the increased risk of HCC development ($p < 0.05$). The PAGE-B score (HR, 1.163; 95% CI, 1.028–1.315) and mPAGE-B score (HR, 1.205; 95% CI, 1.006–1.445) maintained their predictive significance after adjustment ($p < 0.05$). The areas under the curve (AUROCs) at 3 years of antiviral therapy were 0.843 for aML_{af}, 0.839 for aML_C, 0.790 for aMAP, 0.764 for mPAGE-B, and 0.752 for PAGE-B, respectively. The AUROCs at 5 years of antiviral therapy were 0.802 for aML_{af}, 0.799 for aML_C, 0.752 for aMAP, 0.718 for PAGE-B, and 0.716 for mPAGE-B, respectively. The AUROCs of aML_{af} and aML_C at 3 and 5 years of antiviral therapy were significantly higher than those of the PAGE-B and mPAGE-B scores ($p < 0.05$).

Conclusion: The aMAP score combined with LS helped to predict HCC development, and its performance was superior to that of PAGE-B and mPAGE-B.

FRI-380

HBV-specific T cell specificity and functionality can be influenced by stage of chronic HBV disease, antigen levels and age

An De Creus[1], Thierry Verbinnen[1,1], Bart Fevery[1], Simon Verheijden[1], Michael Biermer[1], Sandra De Meyer[1], Oliver Lenz[1]. [1]*Janssen Pharmaceutica NV, Beerse, Belgium*
Email: adecreus@its.jnj.com

Background and aims: To aid the development of immunomodulatory treatments for chronic hepatitis B (CHB) patients, it is essential to better understand HBV-specific T cell immune responses at different stages of CHB infection. Therefore, we investigated breadth and functionality of HBV-specific T cells at different stages of HBV disease.

Method: Peripheral blood mononuclear cells (PBMCs) were isolated from CHB patients: not currently treated (NCT) HBeAg positive (N = 51, of which 21 were immune tolerant (IT)), NCT HBeAg-negative (N = 36), virologically suppressed (VS) HBeAg-postive (N = 25), and VS HBeAg-negative (N = 120). PBMCs were analyzed for T cell responses against peptides covering HBV core, polymerase, and surface antigens using qualified ex vivo overnight IFNγ ELISpot. ELISpot values ≥ positivity threshold (PT) were considered detectable responses, values >3×PT were considered strong responses. Association of T cell responses with viral serum markers and patient characteristics were assessed.

Results: Overall, 148/232 (64%) patients had detectable responses to at least one antigen and 8% had responses to all 3 antigens. The percentage of patients with detectable responses to surface/envelope (15%) was lower compared to core (34%) and polymerase (52%). The percentage of patients with detectable core responses was 0% in IT, low in HBeAg-positive (23% for NCT and 17% for VS) and higher in HBeAg-negative patients (44% for both NCT and VS). Overall, the percentage of patients with detectable core responses was inversely correlated with serum HBcrAg levels (51% vs 9% for <3.0 log U/ml and ≥7.0 log U/ml respectively). For HBeAg-negative patients with HBcrAg levels <4 $\log_{10}$ U/ml, strong core responses were more prevalent (22%) than in HBeAg-negative patients with >4 $\log_{10}$ U/ml (11%). Other factors that influenced frequency of detectable core responses were HBsAg levels (42% vs 22% for ≥10, 000 IU/ml and <10, 000 IU/ml respectively) and age (39% vs 15% for ≥30 years and <30 years respectively).Age impacted percentage of patients with detectable surface responses, with trend in decreasing responses from 20% to 7% as age increased from <30 to ≥60 years, with no apparent impact on percentage of patients with strong surface responses. HBsAg, HBcrAg levels and HBeAg status did not correlate with detectable surface responses. Detectable polymerase responses were not associated with disease stage, viral markers, or age.

Conclusion: This evaluation of breadth and functionality of HBV-specific T-cell responses in 232 CHB patients showed that HBV-specific T cells are detectable ex vivo in most patients across all disease stages, with differences in specificity and strength of the T cell responses by disease state, HBeAg status, HBcrAg and HBsAg levels, and age.

FRI-381

Detection of functional HBV-specific CD8+ response is associated with significant decrease of HBsAg level after treatment withdrawal in eAg (-)chronic hepatitis B

Email: henarcs@hotmail.com

Background and aims: Loss of hepatitis B virus surface antigen (HBsAg) is the goal upon discontinuation of nucleos (t)ide analogues (NUCs) treatment in e-antigen negative (eAg (-)) chronic hepatitis B. However, there are no clear predictive factors defining the population that will experience HBsAg loss after discontinuation of NUCs. The study aim was to evaluate the presence of a decrease in HBsAg level greater than 50% of the baseline level after discontinuation of NUC treatment according to the presence of hepatitis B virus (HBV)-specific CD8+ response against core or polymerase epitopes upon discontinuation of treatment in a 3-year follow-up.

Method: A cohort of 12 patients HLA-A2+ with eAg (-) chronic hepatitis B treated with NUCs for a mean duration of 82 months (95% CI: 64–103), 70% male, with a mean age of 46 years (95%CI 40–53) and with fibrosis <F3 were enrolled. At the time of suspension, the proliferative capacity of CD8+ T cells specific against core18-27 and polymerase455-63 was assessed after 10 days of antigen-specific in-vitro stimulation. HBV-specific CD8+ cells were visualized by flow cytometry after labelling with multimeric complexes and anti-CD3/anti-CD8 antibodies. Interferon-g (IFNg) and tumor necrosis factor-alpha (TNFa) production in culture supernatants were assessed using ELISA. The HBsAg level was quantified at baseline and quarterly after discontinuation of treatment. Patients were followed for 3 years. Kaplan-Meier curves for the presence of a greater than 50% decrease in HBsAg level during follow-up were compared between the cohort with and without functional HBV-specific CD8+ cells. The number of cases that reached functional cure was recorded.

Results: 58% (7/12) of cases had CD8+ T cells specific against core and/or polymerase with proliferative capacity. The supernatants of these cultures showed significantly higher IFNg and TNFa levels than in the non-proliferating cases (Core cultures: IFNg $p < 0.01$; TNFa $p < 0.05$. Polymerase cultures: IFNg $p < 0.01$; TNFa $p < 0.01$). 71% (5/7) of cases with functional HBV-specific CD8+ cells had a greater than 50% decrease in baseline HBsAg level, whereas this occurred in only 20% (1/5) of cases without functional cells, with significantly different Kaplan-Meier survival curves ($p < 0.05$). 42% (3/7) of cases with functional cells achieved functional cure, while no cases in the cohort

without functional HBV-specific CD8+ cells lost HBsAg during follow-up.
Conclusion: The presence of functional HBV-specific CD8+ T cells at the time of NUC discontinuation could select the population of patients with eAg (-) chronic hepatitis B likely to clear HBsAg.

FRI-382
The predictive value of serum HBV RNA level in chronic hepatitis B patients treated with nucleos (t)ide analogues
Yuxuan Song[1], Yandi Xie[2], Xiaojing Zhang[3], Rongkuan Li[4], Sujun Zheng[5], Shuyun Zhang[6], Ping Li[7], Erhei Dai[8], Xuefei Duan[9], Juan Liu[10], Bo Feng[2], Fengmin Lu[11]. *[1]Peking University People's Hospital, Beijing, China; [2]Peking University People's Hospital, Peking University Hepatology Institute, Beijing, China; [3]Hangzhou Xixi Hospital, Hangzhou, China; [4]The Second Affiliated Hospital of Dalian Medical University, Dalian, China; [5]Beijing You'an Hospital, Capital Medical University, Beijing, China; [6]The Second Hospital of Harbin Medical University, Harbin, China; [7]Tianjin Second People's Hospital, Tianjin, China; [8]Shijiazhuang Fifth Hospital, Shijiazhuang, China; [9]Beijing Ditan Hospital, Capital Medical University, Beijing, China; [10]Research Center for Technologies in Nucleic Acid-Based Diagnostics, Hunan, China; [11]Peking University People's Hospital, Peking University Hepatology Institute, School of Basic Medicine, Peking University Health Science Center, Beijing, China*
Email: xieyandee@163.com

Background and aims: Serum hepatitis B virus (HBV) RNA may serve as an important indicator for evaluating the efficacy of antiviral treatment and the activity of HBV in liver tissue. However, further research is needed to ascertain its accuracy and reliability. This study primarily explores the correlation between HBV RNA and other HBV markers, as well as evaluates its predictive ability on virologic response (VR), hepatitis B e antigen (HBeAg) seroconversion and hepatitis B surface antigen (HBsAg) reduction.
Method: A multicenter prospective study was conducted over a 48-week period in HBeAg-positive chronic hepatitis B (CHB) patients who were either undergoing or about to start nucleos (t)ide analog. The correlation between serum HBV RNA and dynamic changes in HBV DNA and HBsAg was described using Spearman correlation analysis. Cox regression analysis was performed to assess the predictive ability of HBV RNA on VR, HBeAg seroconversion and HBsAg reduction.
Results: A total of 427 patients from eight hospitals were enrolled who were divided into the high-viral-load group (n = 214) and the low-viral-load group (n = 213) based on baseline HBV RNA levels. Patients in the low-viral-load group had lower HBV DNA ($p = 0.009$) and HBsAg ($p < 0.001$) levels compared to those in the high-viral-load group. Serum HBV RNA levels were positively correlated with serum HBsAg levels at baseline, 24 weeks, and 48 weeks ($r = 0.193$, $p = 0.008$; $r = 0.336$, $p = 0.004$; $r = 0.480$, $p < 0.001$) and with HBV DNA levels at 12 weeks during follow-up ($r = 0.318$, $p = 0.008$). Stratified analysis revealed that these correlations were more pronounced in the high-viral-load group at baseline. During the follow-up period, 294 patients (68.9%) remained HBV RNA positive after achieving HBV DNA undetectable. A total of 162 patients (38.0%) experienced HBV RNA seroclearance with a median time of 12 weeks. Serum HBV RNA serves as an independent indicator for predicting VR (AUC = 0.852, $p = 0.024$), the seroconversion of HBeAg (AUC = 0.826, $p = 0.003$) and HBsAg reduction (AUC = 0.801, $p = 0.002$). Patients with HBV RNA below 9.12 $\log_{10}$ copies/ml (sensitivity = 0.7, specificity = 0.8) at 12 weeks of treatment were more likely to be VR. Patients with HBV RNA below 4.31 $\log_{10}$ copies/ml (sensitivity = 0.8, specificity = 0.8) prior to treatment were more likely to achieve HBeAg seroconversion.
Conclusion: HBeAg-positive CHB patients with higher initial HBV RNA levels have higher HBV replication capacity compared to those with lower initial HBV RNA levels. Serum HBV RNA can serve as a complementary indicator to HBsAg for better evaluation of whether patients have achieved functional cure. It can also be used as a substitute for HBV DNA in the early stages of treatment to predict VR, particularly in patients with initially high levels of HBV RNA. Pre-treatment HBV RNA levels can predict HBeAg seroconversion during treatment.

FRI-383
Unique characteristics and risk of liver-related events among individuals with hepatitis D virus infection with and without concurrent hepatitis C virus infection: a United States administrative claims analysis
Laura Telep[1], David Wyles[2], Grace M. Chee[1], Anand Chokkalingam[1], Amanda Singer[1], Tatyana Kushner[3]. *[1]Gilead Sciences, Foster City, United States; [2]Denver Health Medical Center, Denver, United States; [3]Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, New York, United States*
Email: laura.telep@gilead.com

Background and aims: Infection with hepatitis delta virus (HDV), an incomplete RNA virus that occurs only in the presence of hepatitis B virus (HBV), is associated with rapid progression to advanced liver disease including compensated and decompensated cirrhosis (CC, DC) and hepatocellular carcinoma (HCC). While some prior United States (US)-based population studies have cited high rates of HCV infection among individuals with HDV, data on the natural history of HDV/HCV infection are limited. This study characterizes the prevalence of HCV infection among individuals with HDV and examines the risk of liver-related events associated with HDV infection with and without HCV.
Method: A retrospective cohort study was conducted using the HealthVerity dataset from 2015 to 2022 that includes medical and pharmacy claims and electronic health records for more than 100 million individuals living in the US. Those included were ≥18 years at cohort entry with one year of prior continuous insurance enrollment and at least one day of available follow-up and one inpatient or two outpatient International Classification of Diseases codes for HDV and HCV. A propensity score (PS) model was constructed using baseline demographics, clinical characteristics, and treatment history, and was used to estimate hazard ratios (HRs) with 95% confidence intervals (CI) comparing risk of advanced liver disease events (CC, DC, HCC, liver transplant [LTx]) among individuals with HDV infection with and without HCV.
Results: From 2015–2022, 9, 632 individuals with HDV infection met inclusion criteria, including continuous enrollment, among which 30% (n = 2, 885) had claims indicating concurrent HCV infection. Those with HCV were older (mean age 54.7 vs 51.5 years), more likely to be male (61.4% vs 44.3%), had more claims for severe liver disease at baseline (CC: 38.5% vs 7.1%; DC: 26.2% vs 5.4%; HCC: 7.7% vs 1.7%; and LTx: 3.7% vs 0.7%) and were more likely to have initiated treatment with hepatitis B nucleos (t)ide analogues (32.7% vs. 19.9%) or interferon (0.6% versus 0%), all with $p < 0.01$. Approximately 25% of individuals with HCV had dispensing claims for direct acting antiviral (DAA) treatment. Baseline evidence of smoking, alcohol and substance abuse, and mental health issues was significantly higher in individuals with vs without HCV ($p < 0.01$). After PS weighting and excluding individuals with evidence of advanced liver disease at baseline, those with HCV had a significant increased risk of developing CC (HR: 4.0, CI: 3.2–5.1). Among those with CC at baseline the risk of developing DC, HCC, or LTx was also increased with concurrent HCV: HR: 2.4, CI: 1.3–4.4.
Conclusion: Among individuals with HDV, concurrent HCV infection was not uncommon (~30%) and was associated with a notably increased risk of developing advanced liver disease. DAA treatment uptake and HDV treatment among HDV/HCV patients is needed to optimize disease outcomes.

FRI-386

Optimizing HDV diagnosis algorithm in Israel: reflex testing, prevalence of HDV seropositive individuals identified in Maccabi HealthCare services and assessment of three commercially available HDV viral load assays

Yael Gozlan[1], Rachel Shirazi[2], Orna Mor[3], Licita Schreiber[4]. [1]*Ministry of Health, Ramat Gan, Israel;* [2]*Ministry of Health, Tel HaShomer, Israel;* [3]*Tel Aviv University, Tel Aviv, Israel;* [4]*Maccabi MEGA lab, Maccabi Healthcare Services, Rehovot, Israel*
Email: yael.gozlan@sheba.health.gov.il

Background and aims: EASL 2023 guidelines call for testing of anti HDV antibodies in all HBsAg positive cases, to identify chronic hepatitis D (HDV). Moreover, quantitation of HDV RNA viral load is highly suggested, but a significant variability between different assays does exist.
We compared the efficiency of anti-HDV reflex testing to previously performed approach in identifying individuals positive for anti HDV antibodies (HDV-Abs), determined the prevalence of HDV-RNA positives in our cohort and evaluated the results of three commercial HDV viral load assays.
Method: We reviewed HDV results in all cases tested for HBsAg in Maccabi virology laboratory since November 2021. HDV viral loads were compared between EuroBioplex, Robogene and Altona RealStar Kits.
Results: Between 1 November 2021 and 31 October 2022, 144, 512 individuals were tested for HBsAg; 1% (1276) were HBsAg positive. Only 28% (356) cases were tested for anti HDV-Abs of which 38 were anti HDV-Abs positive. Between November 2022 and 31 October 2023, after implementation of anti-HDV reflex testing, 151, 594 were tested for HBsAg; 1%, 1428, were HBsAg positive. Anti-HDV reflex testing was performed in all cases (1428, 100%) of which 77 were anti HDV-Abs positive. HDV-RNA was assessed in 97 of all these HDV-Abs positive samples and 61% (59) were found to be HDV-RNA positive. EuroBioplex, Robogene and Altona viral load assays demonstrated consistent inter-assay results, their overall agreement was high, and the average and standard deviation (±) Cq values were comparable (22 ± 7, 23 ± 8 and 24 ± 9, for the three assays, respectively). However, the average and standard deviation of viral loads quantified by each of them were different (7 ± 1.3, 5.4 ± 1.8 and 5.9 ± 1.7, respectively) with EuroBioplex giving the highest IU/ml values.
Conclusion: Anti-HDV reflex testing increased the number of HDV-Abs positive patients by ~ two-fold, and should be implemented in clinical practice. The majority of such patients are HDV-RNA positive presenting with high viral loads. HDV-RNA quantitation should be consistently performed with a single viral load assay, to enable accurate comparison between longitudinal viral load results.

FRI-387

Similarly low risk of hepatocellular carcinoma and cirrhotic complications in patients in the HBeAg-negative indeterminate phase compared with chronic infection

Vicki Wing-Ki Hui[1,2,3], Terry Cheuk-Fung Yip[3,4,5], Yee-Kit Tse[3,4,6], Jimmy Che-To Lai[3,4,6], Henry L.Y. Chan[4,7], Vincent Wai-Sun Wong[3,4,6], Grace Lai-Hung Wong[3,4,6]. [1]*Medical Data Analytics Centre, Hong Kong;* [2]*Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong;* [3]*State Key Laboratory of Digestive Disease, The Chinese University of Hong Kong, Hong Kong;* [4]*Medical Data Analytics Centre, The Chinese University of Hong Kong, Hong Kong;* [5]*Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong;* [6]*Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong;* [7]*Department of Internal Medicine, Union Hospital, Hong Kong*
Email: 1155063467@link.cuhk.edu.hk

Background and aims: Patients with chronic hepatitis B virus (HBV) infection in the indeterminate phase are not covered by the current management guidelines for antiviral treatment. We aimed to evaluate the risk of cirrhotic complications and hepatocellular carcinoma (HCC) in these patients.
Method: All non-cirrhotic patients who were negative for hepatitis B e antigen (HBeAg) at baseline were identified and classified into three HBV phases according to EASL criteria based on their first observed HBV phase: a. immune active phase (alanine aminotransferase [ALT] ≥40 IU/L and HBV DNA ≥2, 000 IU/ml), indeterminate phase (ALT ≥40 IU/L and HBV DNA <2, 000 IU/ml; or ALT<40 IU/L and HBV DNA ≥2, 000 IU/ml), and inactive phase (ALT<40 IU/L and HBV DNA<2, 000 IU/ml). Time-dependent crude incidence rates were used to compare the risk of cirrhotic complications and HCC across different HBV phases.
Results: We identified 55, 012 HBeAg-negative patients (mean age 54 years, 51% male). At study entry, 12, 325 (22.4%), 18, 871 (34.3%), and 23, 816 (43.3%) patients were classified into chronic hepatitis, indeterminate phase, and chronic infection respectively. Baseline HBV DNA, ALT, and FIB-4 in indeterminate group were 3.5 [1.9, 4.3] log10 IU/ml, 35 [24, 58] U/L, and 1.3 [0.8, 2.1], respectively. During a median follow-up of 2.8 [1–6.4] years, there were on average 1.68 phase transitions for each patient, with around 18, 000 patients having transitioned to the indeterminate phase. The time-dependent crude incidence rates of cirrhotic complications and HCC were highest in the chronic hepatitis group (18.9 and 14.0 per 1, 000 person-years, $P < 0.001$ compared with the other two phases), while the rates were not significantly different between patients in the indeterminate and chronic infection phases (cirrhotic complications: 10.3 vs. 10.4, $P = 0.9$; HCC: 4.3 vs. 3.8, $P = 0.6$).
Conclusion: The risks of developing cirrhotic complications and HCC of patients in the indeterminate and inactive phases were similarly low compared to immune active phase.

FRI-388

Clinically significant liver stiffness decrease, as defined by the Baveno VII consensus, is associated with improved long-term prognosis in chronic hepatitis B patients with compensated advanced chronic liver disease

Rex Wan-Hin Hui[1], Lung Yi Loey Mak[1], Trevor Kwan-Hung Wu[1], James Fung[1], Man-Fung Yuen[1], Wai-Kay Seto[1]. [1]*The University of Hong Kong, Hong Kong, Hong Kong*
Email: huirex@connect.hku.hk

Background and aims: The Baveno VII consensus introduced the term "clinically-significant liver stiffness (LS) decrease," yet also highlighted that the criterion required validation. We assessed the long-term implications of clinically-significant LS decrease in chronic hepatitis B (CHB) patients with compensated advanced chronic liver disease (cACLD).
Method: We recruited CHB patients with ACLD (LS ≥10 kPa) and without history of clinical liver decompensation (variceal bleeding, hepatic encephalopathy or ascites) from Queen Mary Hospital, Hong Kong. Vibration controlled transient elastography (VCTE) and comprehensive blood tests were performed at baseline and year 2. Clinically-significant liver stiffness (LS) decrease was defined as LS reduction by ≥20% with LS <20 kPa or any LS decrease to <10 kPa, in accordance with Baveno VII. Patients were monitored for liver-related events (hepatocellular carcinoma [HCC], decompensation, or liver-related mortality).
Results: This analysis included 317 patients (Mean baseline age 60.0 ± 10.4, 65.3% male, 75.7% on nucleos[t]ide analogues [NUCs] at baseline for a median of 53.4 [22.6–87.3] months). The median baseline LS was 13.6 (11.5–18.8) kPa. The baseline Child-Pugh score was 5, 6 and 7 in 298 (94.0%), 16 (5.0%) and 3 (0.9%) patients respectively. In baseline treatment-naïve patients (n = 77), 60 patients (77.9%) were started on NUCs in subsequent follow-up, 12 patients (15.6%) refused NUCs, and 5 patients (6.5%) were not treated due to undetectable HBV DNA. VCTE was performed at an interval of 2.3 (1.9–2.7) years. The median LS at interval VCTE was 11.9 (8.8–16.9) kPa, with 155 patients (48.9%) achieving clinically-significant LS

decrease. NUC initiation in treatment-naïve patients (OR 1.945, 95% CI 1.052–3.594, p = 0.034) and lower baseline LS (OR 0.971, 95% CI 0.944–0.999, p = 0.040) were independent predictors of clinically-significant LS decrease. After median follow-up for 5.9 (3.3–7.8) years, 58 (18.3%) patients developed liver-related events, with 39 (12.3%), 25 (7.9%) and 16 (5.0%) patients developing HCC, decompensation, and liver-related mortality respectively. Clinically-significant LS decrease was an independent protective factor of liver-related events (14 events in patients with LS decrease vs 44 events in patients without; RR 0.201, 95% CI 0.063–0.647, p = 0.007), whereas smoking (RR 4.443, 95% CI 1.299–15.200, p = 0.017) was associated with increased risk. When assessing liver-related events separately, clinically significant LS decrease independently predicted lower HCC risk (RR 0.256, 95% CI 0.066–0.990, p = 0.048), but was not associated with decompensation or liver-related mortality (both p > 0.05).

Conclusion: Clinically-significant LS decrease is achievable in CHB-related cACLD with NUC therapy, and is associated with improved long-term outcomes, primarily through reducing HCC risk.

FRI-389

Hepatitis delta virus infection is associated with significantly greater incidence of cirrhosis and hepatic decompensation in U.S. veterans with chronic hepatitis B

Robert Wong[1], Zeyuan Yang[2], Janice Jou[3], Binu John[4], Joseph K. Lim[5], Ramsey C. Cheung[1]. *[1]Veterans Affairs Palo Alto Health Care System, Stanford University School of Medicine, Palo Alto, United States; [2]Veterans Affairs Palo Alto Health Care System, Palo Alto, United States; [3]Oregon Health and Sciences University, Portland, United States; [4]Miami VA Medical System, University of Miami Miller School of Medicine, Miami, United States; [5]Yale University School of Medicine, New Haven, United States*
Email: rwong123@stanford.edu

Background and aims: Hepatitis delta virus (HDV) infection in patients with chronic hepatitis B (CHB) is associated with significantly greater risks of liver-related morbidity and mortality. However, data on the natural history of HDV are limited, and it remains unclear the magnitude of increased risks of cirrhosis or hepatic decompensation associated with HDV. We aim to evaluate the long-term incidence of cirrhosis or hepatic decompensation among a national cohort of U.S. Veterans with CHB with vs. without concurrent HDV infection.

Method: Using longitudinal data on all U.S. Veterans receiving care within Veteran health systems from 2010 to 2023, we identified patients with CHB with concurrent HDV infection based on laboratory testing (HDV antibody, HDV RNA, HDV antigen). Patients with cirrhosis or hepatocellular carcinoma (HCC) at time of HDV diagnosis or within 6 months were excluded. Patients with HDV were 1:2 propensity score matched to CHB patients without HDV. Incidence (per 100, 000 person-years) of cirrhosis, hepatic decompensation, or HCC (censoring for death) between CHB patients with vs. without HDV were calculated using competing risks Nelson-Aalen methods for estimating cumulative hazards and compared using log-rank testing and the z-statistic as appropriate.

Results: Among 27, 548 CHB patients identified, overall, 16.1% completed HDV testing and 3.25% were positive for HDV. After excluding patients with cirrhosis or HCC at baseline, 71 patients with HDV were included (95.8% male, 47.9% African American, 31.0% non-Hispanic white, 15.5% Asian, mean age 55.4 ± 12.6 years, 16.9% concurrent diabetes, 16.9% reporting high risk alcohol use), who were propensity score matched to 140 CHB patients without HDV. Compared to CHB patients without HDV, those with concurrent HDV had significantly greater incidence of cirrhosis (4.39 vs. 1.30 per 100, 000 person-years, p < 0.01) and hepatic decompensation (2.18 vs. 0.41 per 100, 000 person-years, p = 0.01). The risk of HCC in patients with HDV trended higher compared to CHB patients without HDV, but did not reach statistical significance (1.28 vs. 0.41 per 100, 000 person-years, p = 0.11).

Conclusion: Among a national cohort of Veterans with CHB in the U. S., patients with concurrent HDV infection had more than three times greater risk of cirrhosis and more than five times greater risk of hepatic decompensation compared to CHB patients without HDV. These data highlight the importance of implementing timely and appropriate HDV screening in patients with CHB to ensure early diagnosis and linkage to HDV care and management to reduce long-term risks of liver disease progression and complications.

Email: frida.abramov@gilead.com

Background and aims: Treatment guidelines permit stopping nucleos (t)ide (NA) therapy with appropriate monitoring in patients with undetectable hepatitis B virus (HBV) DNA who are non-cirrhotic and hepatitis B e antigen (HBeAg)-negative, with the aim of potentially achieving functional cure (hepatitis B s antigen [HBsAg] loss) or maintaining virological remission. This analysis characterises outcomes in the subset of patients enrolled in trials of tenofovir alafenamide (TAF) who discontinued NA therapy after up to 8 years of treatment.

Method: Patients with chronic hepatitis B (CHB), enrolled in 2 Phase 3 studies (HBeAg-negative [NCT01940341] and HBeAg-positive [NCT01940471] patients, respectively) of TAF vs tenofovir disoproxil fumarate, who discontinued study treatment for reasons other than HBsAg seroconversion after up to 8 years of treatment, and did not immediately initiate NA therapy, were required to enter a treatment-free follow-up (TFFU) phase for up to 24 weeks. During TFFU, patients were assessed at the end of their treatment (TFFU baseline [BL]) and monitored every 4 weeks for safety, including alanine aminotransferase (ALT) elevation (defined as ALT >2-fold TFFU BL or >10-fold upper limit of normal [ULN; central laboratory cutoff]) or ALT flare (defined as ALT elevation occurring at 2 consecutive visits), and for changes in HBV serology, HBV DNA, and ALT levels.

Results: Of 1298 patients enrolled in the 2 studies, 251 (19%) entered TFFU (96 [38%] were HBeAg-positive and 155 [62%] were HBeAg-negative at TFFU BL); 144 (57%) completed 24 weeks of monitoring (median [quartile (Q)1, Q3] duration, 24.0 [12.3, 24.6] weeks). Of the 107 patients who discontinued from TFFU before 24 weeks, 98 (92%) had resumed NA treatment. By missing-equals-excluded analysis in the subset who completed 24 weeks of TFFU, 31% and 63% had HBV DNA <29 IU/ml and ALT<ULN, respectively, compared with 89% and 82%, respectively, at TFFU BL. Overall, 2 patients had HBsAg loss (1 with anti-HBs seroconversion); both were HBeAg-negative at TFFU baseline. A total of 60/251 (24%) patients experienced a post-

treatment adverse event (AE), of which 6% were Grade ≥3, and 2% were serious AEs (hepatitis exacerbation [n = 5], head injury [n = 1], and plica syndrome [n = 1]). Overall, 31% had a Grade ≥3 laboratory abnormality, the majority being increases in aminotransferases. A total of 35/251 (14%) and 8/251 (3%) experienced ALT elevation or ALT flare, respectively. However, 69% of patients with ALT elevation could not be retested to assess flare due to lack of further follow-up. No deaths or hepatic decompensation events occurred during TFFU.
Conclusion: After up to 24 weeks of stopping NAs, viral and biochemical recurrences were frequent, and few patients achieved HBsAg loss. While severe outcomes were uncommon, close monitoring and timely resumption of NA therapy are both important to avoid adverse outcomes.

FRI-391
Relapse incidence and severe flares in chronic hepatitis B patients with lymphoma post rituximab-based chemotherapy versus HBeAg-negative hepatitis B patients without cancer after nucleos (t)ide analogue cessation
Yen-Chun Liu[1,2], Yu-Jia Shih[2], Rachel Wen-Juei Jeng[1], Chao-Wei Hsu[1,2], Rong-Nan Chien[1,2]. *[1]Chang Gung Memorial Hospital, Linkou branch, Taoyuan, Taiwan; [2]College of Medicine, Chang Gung University, Taoyuan, Taiwan*
Email: rachel.jeng@gmail.com

Background and aims: Rituximab-based chemotherapy (R-CHOP) elevates the risk of reactivation compared to solid tumor regimens, and severe flares may persist post-prophylactic nucleos (t)ide analogue (Nuc) cessation. This study investigates differences in off-Nuc clinical relapse incidence, severity, and HBsAg loss between CHB patients with lymphoma on R-CHOP and HBeAg-negative CHB patients who completed finite Nuc treatment.
Method: Non-cirrhotic HBeAg-negative CHB patients with lymphoma, HBsAg-positive, treated with R-CHOP, ceased prophylactic Nuc after >12-week post-chemotherapy extension, forming the lymphoma-CHB cohort. Their off-therapy clinical relapse, severity, and HBsAg seroclearance rates were compared with HBeAg-negative CHB patients who stopped Nuc per APASL rules (Off-Nuc cohort). Clinical relapse (CR) was defined as HBV DNA ≥2000 IU/ml with ALT >2× ULN. Severe hepatitis criteria included ALT ≥1000 U/L or T.Bil ≥3.5 mg/dL, or flares with hepatic decompensation (HD). HD was defined as T.Bil ≥2 mg/dL and INR ≥1.5, with or without ascites or hepatic encephalopathy. Kaplan-Meier and log-rank tests compared cumulative incidence. 1:1 Propensity Score Matching (PSM) adjusted age, gender, Nuc types, pretherapy HBV DNA, and end-of-treatment HBsAg for sensitivity analysis.
Results: The lymphoma-CHB cohort (117 patients), discontinuing prophylactic Nuc post-R-CHOP, and the off-Nuc cohort (940 patients) treated with finite Nuc therapy were compared. Lymphoma patients, older (57 vs. 52 years, P < 0.001), less male (53% vs. 82%, P < 0.001), with lower HBV DNA (3.2 vs. 6.3 log10IU/ml, P < 0.001), and ALT levels (19 vs. 167 U/L, P < 0.001) at treatment initiation. Off-Nuc CR incidence was comparable at 1-year (33% vs. 37%), but 2-year cumulative incidence was lower in lymphoma (34% vs. 59%, P = 0.001). However, off-Nuc severe flare incidence was significantly higher in lymphoma at both 1- and 2-years (24% and 24% vs. 7% and 11%). The lymphoma arm had much higher annual HBsAg loss incidence than non-cancer off-Nuc patients (4.1% vs. 1.4%, P = 0.011). Cox regression indicated a higher risk for severe flare in lymphoma off-Nuc patients (adjusted hazard ratio: 2.36, P < 0.001). Propensity score-matched cohorts (61 patients each) showed comparable CR at 1- and 2-years (p > 0.5), but relapse severity appeared greater in the lymphoma arm (ALT: 1315 vs. 265 U/L). The 2-year cumulative severe flare incidence remained much higher in the lymphoma group (33% vs. 10%, P = 0.002). Time to relapse timing also appeared shorter in the lymphoma off-Nuc patients (23 vs. 32 weeks, P = 0.019).
Conclusion: HBeAg-negative CHB patients with lymphoma, who stopped Nuc post-R-CHOP, showed earlier CR onset and higher off-Nuc severe flare risk. B cell immunity changes may contribute. Stringent off-therapy monitoring is crucial for CHB patients with Rituximab-based lymphoma regimens.

FRI-392-YI
Chronic HDV coinfection (CHD) is characterized by a more elevated production of Middle and Large HBsAg than HBV monoinfection, that parallels HDV replicative and cytolytic activity

M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, Milan, Italy*
Email: lorenzo.piermatteo@uniroma2.it

Background and aims: HBV surface proteins (HBsAg) enable HBV and HDV entry and morphogenesis. Total HBsAg comprises 3 different forms: Large- (L-HBs), Middle- (M-HBs) and Small-HBs (S-HBs) with L-HBs found in virions and not in subviral particles. Here, we investigate HBs forms levels in the setting of chronic HBV monoinfection (CHB) and HDV coinfection (CHD).
Method: 262 plasma samples from HBeAg-negative patients were included: 143 CHD and 119 CHB. Total HBsAg is measured by COBAS HBsAg II assays (Roche Diagnostics), HBs forms by ad hoc designed ELISAs (Beacle Inc) and HDV RNA by RoboGene HDV RNA Quantification Kit 2.0.
Results: CHD and CHB patients have a comparable age (median [IQR]: 54 [44–60] and 53 [39–64] years; P = 0.8) and rate of NUC treatment (41.2% and 34.5%, P = 0.3). CHD have lower HBV DNA (median [IQR]: 1.3 [0.0–2.3] vs 1.6 [1.2–3.4] logIU/ml, P = 0.002) and higher ALT (median [IQR]: 79 [50–113] vs 36 [22–63] U/L, P < 0.001) and total HBsAg levels (median [IQR]: 5206 [827–8555] vs 1776 [354–6936] IU/ml, P = 0.008). Median (IQR) HDV RNA is 5.2 (3.4–6.0) logIU/ml. Notably, HBs forms composition varies between CHD and CHB with remarkably higher M-HBs and L-HBs in CHD (median [IQR]: 1127 [145–2301] vs 142 [25–707] and 2.0 [0.2–6.3] vs 0.06 [0.2–0.5] ng/ml), P < 0.001) despite similar S-HBs levels in the two groups (median [IQR]: 3221 [587–6497] vs 1039 [239–5438] ng/ml). Multivariable analysis confirms CHD as an independent factor associated with higher levels of M-HBs and L-HBs (OR [95%CI]: 4.7 [1.7–12–4] and 6.2 [2.2–17.9], P < 0.002 for both). Among CHD, the HBs forms positively correlate with HDV RNA levels (Rho = 0.48, 0.49 and 0.43 for S-, M- and L-HBs; P < 0.001 for all) while, in CHB, milder correlation with HBV DNA levels is observed only for L-HBs (Rho = 0.29, 0.02). Furthermore, patients with highly-replicating HDV (HDV RNA >3 log IU/ml) show significantly higher levels of all HBs forms than lowly-replicating HDV (median [IQR] ng/ml: 4431 [1251–6950] vs 274 [25–2640] for S-HBs; 1404 [191–2484] vs 127 [4–1242] for M-HBs; 3.3 [0.2–7.8] vs 0.3 [0.04–1.1] for L-HBs, P < 0.001 for all). Focusing on lowly-replicating HDV patients, 43.5% have altered ALT (median [IQR]: 75 [55–93] U/L). Notably, in this set of patients, M-HBs >200 ng/ml is the best cut-off predicting altered ALT (70% of patients with M-HBs >200 ng/ml vs 30% with M-HBs <200 ng/ml has ALT >40 U/L; PPV = 70%, NPV = 76.9%; P = 0.04), supporting the role of M-

HBs in reflecting cytolytic activity in the setting of low HDV replication.
Conclusion: The composition of HBs forms varies in CHD and CHB patients, with CHD characterized by more elevated M-HBs and L-HBs production paralleling HDV replicative activity. This could reflect a variation in the proportion of circulating viral and subviral particles between CHD and CHB.
Overall, HBs forms can play a role in identifying patients more prone to liver disease progression, in whom treatment could be prioritized.

FRI-393
Healthcare resource utilisation and costs of hepatitis delta virus infection vs hepatitis B virus monoinfection across disease states among hospitalised adults in Italy
Pietro Lampertico[1,2], Valentina Perrone[3], Luca Degli Esposti[3], Melania Leogrande[3], Chong Kim[4], Marvin Rock[4]. *[1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; [2]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; [3]CliCon S.r.l. Società Benefit, Health, Economics and Outcomes Research, Bologna, Italy; [4]HEOR-Global Value and Access, Gilead Sciences, Inc., Foster City, United States*
Email: chong.kim9@gilead.com

Background and aims: Hepatitis delta virus (HDV) infection occurs in individuals with hepatitis B virus (HBV) monoinfection and leads to the most severe form of viral hepatitis. In this retrospective analysis, healthcare resource utilisation (HCRU) and costs were compared between patients with HDV infection vs HBV monoinfection (HBV only) across levels of disease severity among hospitalised adults in Italy.
Method: The administrative databases of local health units in Italy (covering approximately 12 million individuals) were screened for patients aged 18 years or older who had at least 1 HDV or HBV hospitalisation discharge diagnosis (using *International Classification of Diseases, 9th Edition, Clinical Modification* codes) between 1 Jan 2009 and 30 Jun 2022. Included patients had an HDV or HBV-only diagnosis between 1 Jan 2010 and 30 Jun 2022 (identification period), no previous diagnosis, and at least 12 months of continuous enrolment before and after diagnosis. Patients' first diagnosis was used as their index date, and baseline demographics and clinical characteristics were assessed 12 months prior to the index date. Comparisons of mean per patient per year (PPPY) all-cause HCRU and costs between subgroups of liver disease severity were performed using the Mann-Whitney U test, and descriptive statistics were summarised.
Results: Of 15, 628 hospitalised patients, 14, 238 were screened for HDV infection or HBV only, and 9, 945 were included in this analysis (HDV cohort, n = 556; HBV cohort, n = 9, 389). The mean (standard deviation) age (55.8 [15.6] vs 56.8 [16.5] years, p = 0.157) and percentage of patients that were male (66.0% vs 63.6%, p = 0.248) were similar between those with HDV vs HBV only. Compared to patients with HBV only at baseline, a greater proportion of patients with HDV had compensated cirrhosis (CC; 19.6% [HDV] vs 11.5% [HBV], p < 0.001), decompensated cirrhosis (DCC; 10.4% vs 8.0%, p = 0.043), hepatocellular carcinoma (HCC; 7.6% vs 4.0%, p < 0.001), and liver transplantation (LT; 4.9% vs 0.8%, p < 0.001). Patients with HDV spent fewer months in each liver disease state than patients with HBV only. Mean (95% confidence interval) length of hospital stay (days) PPPY was significantly longer for patients with HDV vs HBV only among those with CC (92.7 [48.71–136.67] vs 48.8 [40.37–57.20], p = 0.011) and DCC (113.0 [49.22–176.75] vs 52.2 [44.57–59.77], p = 0.041). Mean total and inpatient costs PPPY were significantly higher for those with HDV vs HBV only who had CC, DCC, HCC, or LT. These costs numerically increased with disease state severity.
Conclusion: In Italy, the mean inpatient length of stay and total healthcare costs were higher for patients with HDV vs HBV only and increased with greater liver disease severity among hospitalised adults. These findings highlight the need for early screening, diagnosis, and treatment of HDV to help reduce the clinical and economic burden of disease.

FRI-394
High burden of cirrhosis and increasing response rates to bulevirtide-based regimens: insights from the austrian prospective hepatitis D registry
Michael Schwarz[1], Caroline Schwarz[1,2], David Bauer[1,2], Marlene Panzer[3], Michael Strasser[4], Silvia Reiter[5], Livia Dorn[6], Andreas Maieron[6], Alexander Moschen[5], Elmar Aigner[4], Michael Trauner[1], Albert Friedrich Stättermayer[1], Mattias Mandorfer[1], Heinz Zoller[3], Michael Gschwantler[2], Thomas Reiberger[1], Mathias Jachs[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Department of Internal Medicine IV, Klinik Ottakring, Vienna, Austria; [3]Department of Internal Medicine I, Medical University of Innsbruck, Innsbruck, Austria; [4]First Department of Medicine, Paracelsus Medical University, Salzburg, Austria; [5]Department of Internal Medicine 2, Johannes Kepler University Linz, Linz, Austria; [6]Department of Internal Medicine 2, Gastroenterology and Hepatology and Rheumatology, Karl Landsteiner University of Health Sciences, University Hospital of St. Pölten, Sankt Pölten, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Chronic hepatitis D (CHD) is the most severe form of viral hepatitis, characterized by a rapid progression towards liver cirrhosis. Bulevirtide (BLV) has been approved for the treatment of CHD patients with compensated liver disease, but real-world data regarding predictors for treatment are limited. This study aimed to comprehensively characterize the Austrian cohort of CHD patients and to analyze their response to BLV treatment.
Method: CHD patients who visited one of the six participating Austrian hospitals from 2020 onwards were prospectively included. Demographic, clinical, laboratory data, liver stiffness measurement (LSM), biomarkers of systemic inflammation and single nuclear polymorphisms (SNPs) in the interleukin 28B (IL28B), Patatin-like phospholipase domain-containing protein 3 (PNPLA3), SERPINA1, and sodium-taurocholate cotransporting polypeptide (NTCP) genes were assessed in a subset of patients. Patients receiving BLV were assessed for the end points "virological response" (VR) defined as HDV-RNA decline of ≥2 log and for "combined response" (CR) defined as VR with ALT normalization at week (W)24, W48, and W96.
Results: We included 84 patients with positive HDV antibodies (median age 46 years [IQR 37–56), 57.1% male) and 59 (70.2%) had detectable HDV-RNA. LSMs available in 67 patients were: F0/1 n = 17 (25.4%), F2 n = 10 (14.9%), F3 n = 9 (13.4%), and F4 n = 31 (46.3%). Nine (10.7%) had already progressed to decompensated cirrhosis. There was no association between PNPLA3 genotype and liver disease severity (G/C or G/G: 14 [58.3%] in cirrhosis vs. 11 [68.8%] without cirrhosis, p = 0.505). BLV treatment was initiated in 50 out of 59 HDV-RNA viremic patients (F3/F4: 70.0%) and median treatment duration was 17 (8–24) months. Pegylated interferon alfa-2a (PEGIFN) was added to BLV treatment in 13 (26%) patients after a median of 10 (7–18) months. VR rates were at W24 63.0% (29/46), W48 68.4% (26/38), and W96 71.2% (16/21). CR was achieved at W24 in 19.6% (9/46), at W48 in 42.1% (16/38), and at W96 in 42.9% (9/21). We found no baseline demographic (age, sex, body mass index) nor laboratory parameters (ALT, CRP, IL-6, HDV RNA, HBV DNA, HBs antigen levels) that were predictive of VR or CR. Polymorphisms in IL28B (distribution among patients with available data: C/C: 16/33, C/T: 16/33, T/T: 1/33) as well as PNPLA3 (C/C: 13/36, C/G: 20/36, G/G: 3/36) were not associated with VR/CR to BLV at W24, W48 nor W96, respectively. No polymorphisms were found for NTCP or SERPINA1.
Conclusion: Within this prospectively characterized cohort of Austrian CHD patients we found >50% with advanced fibrosis and >10% with decompensated cirrhosis. BLV was initiated in 50 patients and increasing VR and CR rates were seen under BLV treatment for up

to two years. PEGIFN was added to BLV in thirteen patients. No laboratory or clinical parameters were found to predict response to BLV treatment.

FRI-395

HDV infection in Israel: epidemiology and co-morbidities

Hisham Sholy[1], Hedy Rennert[2], Eli Zuckerman[1]. [1]*Carmel Medical Center, Haifa, Israel;* [2]*Carmel Medical Center, Haifa*
Email: elizuc56@gmail.com

Background and aims: About 1–5% of people with chronic HBV infection are co-infected with HDV, however global reports from many regions are inaccurate. Epidemiological data of hepatitis D virus infection (HDV) in Israel is limited as large population-based studies have not performed so far. The aim of this study was to collect epidemiological, co-morbidities and natural history data of HDV infection in the largest population-based study performed in Israel.
Method: Data were obtained from the computerized records and database of Clalit Health Services (CHS). The database contains information regarding demographic parameters, laboratory tests and pharmacy records, hospitalization and primary care physician records and death-related data.
Results: Through 1.2002–10.2022, 1, 995, 911 out of 4, 376, 447 (45.6%) CHS ensured individuals were tested for HBsAg. Of 28, 448 positive for HBsAg (1.43%), 10, 667 (37.5%) were tested for HDV-Ab and of them, 728 were tested positive (7.01%). Only 369 HDV-Ab positive individuals were tested for HDV-RNA by PCR (50.6%) and of those, 138 (37%) were HDV-RNA positive (qualitative testing). Of 28, 448 HBsAg+ individuals, 1931 (6.8%) were younger than 20 y/o. Co-infected patients were older than HBV mono-infection (mean age 46.4 ± 14 vs. 42.5 ± 16 y/o, $p < 0.01$). The largest number of HDV-positive patients were born in Russia (28.4%) followed by Israel (23.7%), Ethiopia (19.3%), Uzbekistan (5.3%), and Morocco (4.2%). The prevalence of co-infected patients was higher in Jews compared with Arabs (3.2% vs 1.3%, $p < 0.001$). Alcohol abuse was more prevalent in the co-infection than in the mono-infection group (5.5% vs 2.5%, $p < 0.001$). As expected, the rate of liver transplantation was significantly higher in the co-infected than the mono-infected group: 39/728 (5.4%) vs only 165/27720 (0.6%) ($p < 0.001$, OR 9.4). Those with positive RNA were more likely to undergo liver transplantation than those with negative RNA (10.1% vs 0.4%, OR 25). The prevalence of cirrhosis and HCC were significantly higher among co-infected (24% vs 4.7%, $p < 0.001$, OR 6.5 for cirrhosis, 8.1% vs 1.9%, $p < 0.001$, OR 4.4 for HCC). FIB4 was calculated and reveals more significant liver fibrosis (Fib4>1.45) in the co-infection group (43.3% vs 23.9%). HBV-DNA was undetectable in 23.5% of positive RNA patients compared with 16.1% of RNA negative patients (NS).
Conclusion: This is the largest epidemiological study on HDV infection performed in Israel. The estimated rate of HDV infection among HBsAg-positive individuals is 7.01%. Co-infection is significantly associated with poor prognosis and higher prevalence of cirrhosis, HCC, and liver transplantation. More efforts should be directed to increase diagnosis rate and the number of treated patients.

FRI-396

Risk of hepatocellular carcinoma decreases after antiviral therapy-induced HBsAg seroclearance

Han Ah Lee[1], Hyun Woong Lee[2], Dong Hyun Sinn[3], Sang Hoon Ahn[2], Beom Kyung Kim[2], Seung Up Kim[2]. [1]*Ewha Womans University, Seoul, Korea, Rep. of South;* [2]*Yonsei University College of Medicine, Seoul, Korea, Rep. of South;* [3]*Samsung Medical Center, Seoul, Korea, Rep. of South*
Email: amelia86@naver.com

Background and aims: Antiviral therapy (AVT) reduces the risk of hepatitis B virus-related hepatocellular carcinoma (HCC). The difference in risk of HCC development after hepatitis B surface antigen (HBsAg) seroclearance to the AVT status was explored.
Method: Patients with chronic hepatitis B who achieved HBsAg seroclearance between 2003 and 2022 were retrospectively evaluated. The primary outcome was the development of HCC after HBsAg seroclearance.
Results: Of the study population, 1, 280 (84.2%) and 241 (15.8%) patients achieved HBsAg seroclearance without (spontaneous clearance group) and with AVT (AVT-induced clearance group), respectively. During follow-up (median 4.3 years), 37 (2.4%) patients developed HCC after HBsAg seroclearance. HCC cumulative incidence was comparable between the two groups (hazard ratio [HR] = 0.461; $P = 0.150$; log-rank test, $P = 0.197$), whereas it was significantly lower in the AVT-induced HBsAg clearance group than in the spontaneous HBsAg clearance group in the inverse probability of treatment weighting analysis (HR = 0.442; $P = 0.005$; log-rank test, $P = 0.004$). In multivariate analysis, spontaneous HBsAg clearance, albumin-bilirubin (ALBI) grade ≥2, liver cirrhosis, and platelet count $<50 \times 10^9$/L were independently associated with the increased risk of HCC development. The newly established antiviral therapy, cirrhosis, ALBI, and platelet count (ACAP) scores had a C-index of 0.765, and the time-dependent areas under the curve of HCC prediction at 5 and 8 years were 0774 and 0.823, respectively. The predictive model exhibited good discriminative performance in internal validation and sensitivity analysis.
Conclusion: The risk of HCC differed according to the AVT status after HBsAg seroclearance. The ACAP model may help clinicians implement timely interventions and surveillance strategies.

FRI-397

A machine learning model to predict liver-related outcomes after the functional cure of chronic hepatitis B

Moon Haeng Hur[1], Seung Up Kim[2], Hyun Woong Lee[2], Han Ah Lee[3], Hyung-Chul Lee[1], Sang Hoon Ahn[2], Beom Kyung Kim[2], Hwi Young Kim[3], Yeon Seok Seo[4], Hyunjae Shin[1], Jeayeon Park[1], Yunmi Ko[1], Youngsu Park[1], Yun Bin Lee[1], Su Jong Yu[1], Yoon Jun Kim[1], Jung-Hwan Yoon[1], Jeong-Hoon Lee[1]. [1]*Seoul National University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Yonsei University College of Medicine, Seoul, Korea, Rep. of South;* [3]*Ewha Womans University College of Medicine, Seoul, Korea, Rep. of South;* [4]*Korea University College of Medicine, Seoul, Korea, Rep. of South*
Email: pindra@empal.com

Background and aims: The risk of hepatocellular carcinoma (HCC) and hepatic decompensation persists after hepatitis B surface antigen (HBsAg) seroclearance. This study aimed to develop and validate a machine learning model to predict the risk of liver-related outcomes (LROs) following HBsAg seroclearance.
Method: A total of 2, 046 consecutive patients who achieved HBsAg seroclearance between 2000 and 2022 were enrolled from 6 centers in South Korea: the training and validation cohorts consisted of 944 and 1, 102 patients, respectively. A new model (designated as PLAN-C) was developed using variables based on the results of multivariable Cox analysis and a gradient-boosting machine algorithm. The primary outcome was the development of any LRO, including HCC, cirrhosis-related complications, and liver-related death.
Results: During a median follow-up of 55.2 (interquartile range = 30.1–92.3) months, 123 LROs were confirmed (1.1%/person-year). The PLAN-C was constructed using 6 variables: age, sex, diabetes, alcohol consumption, cirrhosis, and platelet count. Compared to previous HCC prediction models, the PLAN-C showed significantly superior predictive accuracy in both the training (c-index: 0.85 vs. 0.63–0.70, all $P < 0.001$) and the validation (0.84 vs. 0.61–0.81; all $P < 0.05$ except for CU-HCC, $P = 0.09$) cohorts. The calibration plots demonstrated a close correlation between the predicted and observed risks of LRO (Hosmer-Lemeshow test $P > 0.05$ in both cohorts). When entire patients were divided into 3 groups according to the risk predicted by PLAN-C, the low-risk group had a significantly lower 5-year incidence of LRO (0.8%), compared to the intermediate-risk (4.0%) and high-risk (22.8%) groups (both $P < 0.001$).

Conclusion: This novel machine learning model consisting of 6 variables provides reliable risk prediction of LRO after HBsAg seroclearance that can be used for personalized surveillance.

Targeted capture single-cell sequencing provides new insights into persistent hepatitis B virus (HBV) infection

Yanfang Huang[1], Hongyuan Xue[1], Yongping Liu[2], Miaoqu Zhang[1], Qiran Zhang[1], Jinhang He[1], Ning Jiang[3], QuanBao Zhang[1], Zhengxin Wang[1], Chao Qiu[4], Wenhong Zhang[1]. *[1]Huashan Hospital, Fudan University, Shanghai, China; [2]Hangzhou Xixi Hospital, Hangzhou, China; [3]School of Life Sciences, Fudan University, Shanghai, China; [4]Institutes of Biomedical Sciences, Fudan University, Shanghai, China*
Email: zhangwenhong@fudan.edu.cn

Background and aims: At the single-cell level, viral infections show significant heterogeneity. To study these infections, a technique called single-cell transcriptome sequencing which captures polyadenylated transcripts using oligo (dT) is usually used. However, this method is not very effective in capturing viral sequences as the host cellular transcriptome overwhelms, leaving only a small fraction of the viral part. To improve the detection rate of the viral sequence, we have designed five additional HBV-specific probes alongside the oligo (dT) probe to specialize in capturing HBV mRNA or DNA.
Method: Targeted capture single-cell RNA sequencing was utilized to assess the performance of the assay on a mixture of HBV-positive human HepAD38 and HBV-negative mouse 3T3. Fourteen human liver tissues were analyzed, including two healthy donors, four individuals with antivirals-naïve chronic hepatitis B, 2 HBV-associated decompensated cirrhosis, and 6 HBV-associated liver failure. In addition, humanized chimeric URG (Tet-uPA-Rag2 null-γc null) mice (Hu-URG mice) treated with antivirals, including saline solution (used as a control, n = 2), Entecavir (n = 3) and peg-interferon (n = 2), were examined. The hepatocytes were directly observed for HBV replication and transcriptional activity using in situ hybridization.
Results: Hepatocytes that are infected with HBV have high expression of plasma proteins, lipoproteins, and coagulation-related proteins. This suggests that actively synthesizing and metabolizing hepatocytes are more supportive of HBV replication. Multiple splicing factors such as DDX5, DDX17, SRSF2, SRSF5, HNRNPH1, etc. are downregulated in HBV-positive hepatocytes and liver failure and upregulated in Hu-URG mice after anti-viral treatment.
Conclusion: We have developed a specialized method to detect the presence of HBV mRNA or DNA in liver cells at a single-cell resolution.

FRI-399

Hepatitis B core-related antigen is a good predictor for high risk of mother to child transmission in chronic hepatitis B

Ivana Carey[1], Mark Anderson[2], James Lok[1], Zillah Cargill[1], Gavin Cloherty[2], Geoffrey Dusheiko[1], Kosh Agarwal[1]. *[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Department of Infectious Diseases, Abbott Diagnostics, North Chicago, United States*
Email: ivana.kraslova@kcl.ac.uk

Background and aims: HBV mother to child transmission (MTCT) is preventable by HBsAg screening of all pregnant women at 1st trimester, followed by appropriate prophylaxis. WHO guidelines advise treating all HBsAg+ women with HBV DNA >200000 IU/ml from 2nd trimester together with birth dose vaccination and HBIg. While HBV DNA test is available in developed countries, access to molecular testing is sparse in resource-limited countries. Hepatitis B core-related antigen (HBcrAg) is a composite pan-genotypic serological marker, which correlates with HBV DNA levels and could be utilised in resource-limited setting. We aimed to compare HBcrAg plasma levels with other virological (HBV DNA and pre-genomic RNA) and serological markers (HBeAg status and quantitative HBsAg) in a single centre cohort of HBsAg+ pregnant patients tested at the 2nd trimester and evaluate if HBcrAg can assess the risk of HBV MTCT (HBV DNA >200000 IU/ml = high risk).
Method: Plasma samples from the 2nd trimester (median gestation 22 wks) of 1028 HBsAg+ pregnant patients with post-partum follow-up >1 year and information about their infants HBV infection status were collected between 1.1.2012–31.12.2022. We measured levels of HBV DNA by TaqMan PCR [IU/ml], quantitative HBsAg by Abbot Architect® [IU/ml], HBcrAg by CLEIA Fujirebio [$\log_{10}$U/ml] and pgRNA by Abbott Diagnostics dual-target real-time-PCR assay [LLoQ = 0.49 $\log_{10}$U/ml]. The results were compared according to the risk of HBV MTCT stratified by HBV DNA >200000 IU/ml = high risk vs HBV DNA <200000 IU/ml = low risk).
Results: From 1028 enrolled patients (median age 30 yrs): 668 (65%) patients were aware of HBV infection before pregnancy with 165 (16%) already on tenofovir. 144 (14%) patients were HBeAg+ and 175 (17%) had HBV DNA >200000 IU/ml. HBeAg+ patients had predominantly high HBV DNA, but there were 55 (5%) HBeAg-negative patients with HBV DNA >200000 IU/ml. Although HBsAg levels were high (>10000 IU/ml) in 360 (35%) patients, only 102 (10%) patients with high HBsAg had high HBV DNA (>200000 IU/ml). HBcrAg levels were significantly higher in patients with high viral load (7.0 vs. 3.2, $p < 0.05$) irrespective of HBeAg status and all patients with high HBV DNA had HBcrAg levels above 6 $\log_{10}$U/ml. All high viral load patients had high levels of pgRNA >4.5 $\log_{10}$U/ml. There were only 4 patients with low HBV DNA with pgRNA >4.5 $\log_{10}$U/ml. All patients with high HBV DNA started on tenofovir at the 2nd trimester and all had pre-delivery HBV DNA levels <200000 IU/ml. No case of MTCT was reported in our cohort. ROC analysis confirmed that HBcrAg and pgRNA were able to predict more accurately high risk of HBV MTCT than HBsAg (HBcrAg AUROC = 1.0, pgRNA AUROC = 0.98 vs. HBsAg AUROC = 0.68).
Conclusion: Pregnancy plasma HBcrAg levels are more accurate than HBeAg and HBsAg levels to assess HBV MTCT risk. HBcrAg levels >6 $\log_{10}$U/ml predict a high MTCT risk and offers a serological alternative for maternal testing.

FRI-402

The unique role of hepatitis B virus enhancer 1 in unevenly activating preS1 and preS2 promoters of integrated HBV DNA which impacts HBsAg secretion efficiency

Fengmin Lu[1], Zhiqiang Gu[1]. *[1]Department of Microbiology and Infectious Disease Center, School of Basic Medical Sciences, Peking University, Beijing, China, Beijing, China*
Email: lu.fengmin@hsc.pku.edu.cn

Background and aims: The achievement of a "functional cure" for chronic hepatitis B (CHB) remains a formidable challenge. As another source of HBsAg, HBV DNA integration limits the achievement of a functional cure. Thus, uncovering the unique characteristics of HBsAg derived from integrated HBV DNA will shed new light on strategies for achieving a functional cure.
Method: Using clinical cohorts, animal and cell models simulating integrated HBV DNA, we explored the expression and secretion characteristics of HBsAg derived from integrated HBV DNA and the underlying mechanism.
Results: A semi-quantitative analysis of intrahepatic HBsAg protein level in 563 treatment-naïve patients revealed that, in contrast to the significantly lower serum HBsAg levels, no significant decrease of intrahepatic HBsAg protein was observed in the HBeAg-negative patients, as compared to that in HBeAg-positive patients. *In vitro* studies of integrated HBV DNA mimic and long-read RNA sequencing of liver biopsy from patients revealed that, the lower HBsAg secretion efficiency seen in HBeAg-negative patients might be attributed to a relative increased proportion of 2.4 kb HBV RNA derived from integrated HBV DNA than covalently closed circular DNA (cccDNA), which resulted in L-HBsAg over-expression and the subsequent impaired HBsAg secretion. Mechanistically, the change of 2.4 kb HBV

RNA proportion was caused by retargeting and uneven activation on preS1 (SP1) than preS2 (SP2) promoters by HBV enhancer 1 (EnhI) element, largely due to the loss of core promoter (CP) in integrated HBV DNA.
Conclusion: The secretion of HBsAg originated from integrated HBV DNA was impaired. Mechanistically, functional deficiency of CP leads to the promoter (s) retargeting of EnhI and uneven activation of SP1 over SP2, resulting in an increase in proportion of L-HBsAg.

FRI-403
Evaluation of a novel hepatitis B DNA test from fingerstick capillary blood at the point-of-care as a tool to enhance clinical management
Behzad Hajarizadeh[1], Jacob George[2], Miriam Levy[3], Ian Wong[4], Jess Howell[5], Gesalit Cabrera[1], Elise Tu[1], Marianne Martinello[1], Tanya Applegate[1], Gail Matthews[6]. *[1]The Kirby Institute, University of New South Wales (UNSW), Sydney, Australia; [2]Storr Liver Centre, Westmead Hospital, University of Sydney, The Westmead Institute for Medical Research, University of Sydney, Sydney, Australia; [3]Liverpool Hospital, University of New South Wales (UNSW), South Western Clinical School, University of New South Wales (UNSW), Sydney, Australia; [4]Blacktown Hospital, Sydney, Australia; [5]The Burnet Institute, St Vincent's Hospital, Melbourne, Australia; [6]The Kirby Institute, University of New South Wales (UNSW), St Vincent's Hospital, Sydney, Australia*
Email: bhajarizadeh@kirby.unsw.edu.au

Background and aims: HBV DNA tests are essential to guide HBV clinical management, including antiviral treatment eligibility and effectiveness. Standard of care HBV DNA tests are expensive and need central laboratory infrastructure, limiting access while delayed time to result may interrupt continuity of care. This study evaluated the diagnostic performance of the Xpert® HBV Viral Load assay (Cepheid), using fingerstick capillary blood at the point-of-care compared to standard of care HBV DNA testing using venipuncture whole blood.
Method: Participants diagnosed with chronic HBV infection were enrolled from six hospital-based hepatitis clinics in Australia. Participants provided fingerstick capillary blood samples diluted 1 in 10 and tested for quantitative HBV DNA using Xpert® HBV Viral Load assay (adjusted lower limit of quantification: 100 IU/ml). The standard of care assay (gold standard) was Roche COBAS® AmpliPrep/ COBAS® TaqMan® HBV DNA Test, using plasma from venipuncture whole blood samples. Sensitivity and specificity of the Xpert® HBV Viral Load for HBV DNA quantification were compared with the gold standard. A Bland-Altman difference plot was used to assess bias and agreement measurements.
Results: To date, 178 participants have been enrolled (recruitment ongoing, total sample size n = 300). Participants included 46% female, 19% HBeAg positive, 44% on HBV treatment, and 6% with cirrhosis, with a median age of 46 years. As measured by the gold standard test, HBV DNA was undetected in 58 participants (33%), detected <100 IU/ml in 38 (21%), and detected ≥100 IU/ml in 82 (46%; viral load range: 110 to >180 million IU/ml). Sensitivity and specificity of the Xpert® for HBV DNA ≥100 IU/ml (vs. <100 or undetected) was 96.3% (95%CI: 93.6, 99.1) and 89.6% (95%CI: 85.1, 94.1), respectively. Among 13 participants whose HBV viral loads fell in different categories between the Xpert® and gold standard assays, the difference in viral loads detected by two assays ranged from 38 to 388 IU/ml. The Bland-Altman difference plot demonstrated that HBV viral loads detected by the Xpert® were a mean of 0.18 log IU/ml (standard deviation 0.28) higher than those measured by the gold standard. The limits of agreement indicated that 95% of the differences between the two assays were between −0.37 and 0.74 log IU/ml.
Conclusion: This interim analysis showed minimal difference in HBV viral loads detected by the Xpert® compared to the gold standard assay. Among participants with inconsistent HBV viral loads between assays, the difference was not sufficient to impact clinical decision making. If validated, this fingerstick assay has the potential to simplify clinical care for people living with HBV, particularly hard-to-reach population, and those in remote and resource limited settings.

FRI-404
To establish the threshold for transient elastography indicating advanced fibrosis in patients with chronic hepatitis B and hepatic steatosis
Fajuan Rui[1], Yee Hui Yeo[2], Xiaoming Xu[1], Wenjing Ni[1], Liang Xu[3], Jie Li[4]. *[1]Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, China; [2]Cedars-Sinai Medical Center, California, United States; [3]Tianjin Second People's Hospital, Tianjin, China; [4]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China*
Email: lijier@sina.com

Background and aims: Transient elastography (TE) is widely recognized as an effective, non-invasive technique for diagnosing liver fibrosis by assessing liver stiffness. Although specific threshold values have been proposed separately for chronic hepatitis B (CHB) and hepatic steatosis (HS), no such recommendations exist for patients with both CHB and HS. With the rising occurrence of HS in individuals with CHB, it's increasingly important to establish a definitive TE threshold for best clinical outcomes. This study employs a substantial cohort of patients with both CHB and HS, who have undergone liver biopsy and FibroScan, to identify the precise TE threshold for detecting advanced fibrosis.
Method: The study included sequential patients with CHB and HS, who had biopsy data from 2016 to 2021 at Tianjin Second People's Hospital. The Youden index was used to find the ideal TE cutoff for patients with both CHB and HS. We calculated the Area Under the Curve (AUC) for the existing 9.7 kPa TE cutoff for patients with CHB or HS and the new optimal cutoff, comparing them using the DeLong test. Additionally, we compared AUCs for both cutoffs in subgroups with body mass indexes (BMI) below and above 25 kg/m^2.
Results: A total of 613 patients participated in the study, with a median age of 36. Of these, 72% (442) were male, and 12% (74) exhibited advanced fibrosis. The study determined an optimal Transient Elastography (TE) cutoff value at 8.8 kPa, which showed an AUC of 0.733. This was significantly more accurate than the AUC of 0.681 obtained using the recommended TE cutoff of 9.7 kPa ($p = 0.015$). In a subgroup of patients with a BMI<25 kg/m^2, the optimal cutoff yielded an AUC of 0.708, surpassing the AUC of 0.566 for the contemporary cutoff value ($p = 0.003$). The sensitivity (SE) of the optimal cutoff was higher than that of the contemporary cutoff in both the overall cohort and the BMI subgroup analysis (overall cohort: 70.27 vs. 55.41; BMI <25 kg/m^2: 56.00 vs. 24.00; BMI <25 kg/m^2: 77.55 vs. 71.42). However, the specificity (SP) of the optimal cutoff was lower than that of the contemporary cutoff (overall cohort: 76.25 vs. 80.71; BMI <25 kg/m^2: 85.64 vs. 89.23; BMI <25 kg/m^2: 70.93 vs. 75.87).
Conclusion: The optimal TE cutoff for assessing advanced fibrosis in patients with CHB and concurrent HS is 8.8 kPa, lower than the 9.7 kPa for CHB patients without HS. The optimal TE cutoff offers superior SE, making it more effective at ruling in advanced fibrosis. It's more appropriate for screening patients with advanced fibrosis, ensuring they receive the appropriate medical care. For those with both CHB and HS, a stricter (lower) TE value is needed for more accurate assessment, reflecting the unique interaction between CHB and HS and its impact on liver response and fibrosis progression.

Email: rsalpini@yahoo.it

Background and aims: A reliable quantification of serum hepatitis D virus (HDV) RNA is of paramount importance for a proper monitoring of patients under antiviral therapy. This quality control study aimed at comparing the diagnostic performances of different quantitative HDV RNA assays, used in clinical practice.
Method: Two HDV RNA sample panels were quantified at 29 Italian labs by 6 commercial assays defined as #1 (RoboGene 2.0, N = 9 labs), #2 (Eurobio on In/BeGenius ELITech platform, N = 7), #3 (Altona RealStar, N = 5), #4 (Anatolia Bosphore, N = 3), #5 (Dia.Pro.Dia., N = 2), #6 (Nuclear Laser Medicine, N = 1) and 2 in-house assays defined as #7 (N = 2). Panel A comprised 8 serial dilutions of WHO HDV genotype 1 standard from 5 to 0.5 logIU/ml, while Panel B included 20 clinical serum samples with HDV RNA from 6 to 0.5 logIU/ml. Participating labs quantified each dilution of Panel A and B 9 and 5 times, respectively (3 independent runs). Panel A was used to define assay sensitivity by estimating the 95%LOD (limit of detection). Panel B was used to evaluate assay precision by calculating the intra-run and inter-run coefficient of variation (CV). Lastly, the accuracy was assessed by calculating the differences between expected and observed values at each HDV RNA load for both Panels.
Results: By analysing Panel A, 95%LOD varied across the assays highlighting different sensitivities. In particular, #3 had the lowest median 95%LOD (10 [min-max: 3–316] IU/ml), followed by #1 (31 [3–316] IU/ml), #6 (31 IU/ml) and #2 (100 [100–316] IU/ml). The remaining 3 assays had a median 95%LOD ranging from 316 to 1000 IU/ml. Moreover, 5 assays showed a <0.5 logIU/ml difference between expected and observed HDV-RNA values for all dilutions, with #1 showing the best accuracy (Median [IQR]: 0.0 [−0.2–0.0] logIU/ml). Conversely, for #5 and #6 these differences exceeded 0.5 logIU/ml (median [IQR]: −0.7 [−0.7–0.6] and −1.3 [−1.6–1.1] logIU/ml), highlighting substantial HDV RNA underestimation. With Panel B, different reproducibility levels were observed across the assays. Indeed, #2 and #3 had a median intra-run CV <10% (median [IQR]: 8.0% [6.5%–11.2%] and 9.9% [6.8%–12.3%]) while assays #1, #4 and #7 showed a median intra-run CV from 10% to 15% and #5 and #6 of 18.9% and 26.2%. Inter-run CV depicted a similar scenario with the highest reproducibility for #2 and #3. For samples with HDV RNA <5.0 logIU/ml, five assays exhibited a <0.5 logIU/ml difference between expected and observed HDV RNA. Conversely, for HDV RNA >5.0 logIU/ml, an underestimation >1 logIU/ml was observed for most assays (N = 5).
Conclusion: This study underlines different levels of sensitivities, that could hamper the proper quantification of low level HDV RNA. There is a need to improve the accuracy in HDV RNA quantification at high viral load for most assays. These results should be carefully considered for the proper monitoring of virological response to anti-HDV drugs.

Email: joseluis.calleja@uam.es

Background and aims: Hepatitis Delta is considered the most severe form of viral hepatitis. New therapeutic options are now available and, in some countries, therapy prioritization is recommended. We aimed to evaluate the real world outcomes of HDV-infected patients with mild or moderate fibrosis in order to identify risk factors for fibrosis progression.
Method: Multicenter international retrospective study of adult patients with active HDV infection (HDV-RNA+) and absence of advanced fibrosis at diagnosis. Baseline demographical, clinical and virological variables were collected. Cirrhosis development and liver-related events (decompensation, HCC) were recorded. Patients were followed until last follow-up (FU) visit, liver transplantation (LT) or death.
Results: The cohort included 170 adult patients with mild/moderate fibrosis assessed histologically (45%) and/or non-invasively [median (IQR) age at first visit: 37 (31–45) years, males: 53%]. Most patients were Caucasians (55%) or Asians (21%), <5% were coinfected with HIV or HCV and <15% had comorbidities (obesity, diabetes, hypertension). At baseline, only 36% of patients had ALT >2xULN. In 102 cases with LSM within year-1, median (IQR) values were 7.6 (6–9) kPa. During the study period, 33% of patients received Interferon, 36% NA and only 8% bulevirtide therapy. After a median (IQR) follow-up of 62 (21–108) months, 31 (18%) patients developed cirrhosis; of them, 5 developed liver decompensation and 2 HCC. One patient underwent LT and one patient with HCC died. Median LSM (IQR) of patients at cirrhosis diagnosis was 16 (10–17) kPa. By multivariate analysis, higher LSM at baseline (model 1) and albumin and platelet levels (model 2 excluding LSM) were the only independent predictors for cirrhosis development. The best cut-off for LSM value at baseline for cirrhosis development was 7.6 kPa (Se 84%). Neither baseline qHDV-RNA levels nor ALT influenced on cirrhosis development. In addition, 17 (10%) patients achieved HDV-RNA clearance during FU (6 after IFN therapy and 11 spontaneously) with only 1/17 patients developing cirrhosis during FU.
Conclusion: Some patients with active HDV replication and mild-moderate fibrosis may have a benign course, but up to 18% of such patients progress to cirrhosis within 5 years having increased risk for liver-related complications. LSM seems to be a reliable non-invasive predictor, as patients with LSM <7.6 kPa have a low probability of progression to cirrhosis. Dissecting the factors associated with fibrosis progression may be useful to prioritize the need of new antiviral therapies.

Email: varun.saxena@kp.org

Background and aims: Hepatitis delta virus (HDV) among patients with chronic hepatitis B virus (HBV) is the most severe form of viral hepatitis. Despite this, HBV/HDV co-infection prevalence in the United States (US) remains uncertain. In this study, we aim to demonstrate screening rates of HDV, estimates of HBV/HDV prevalence, and natural history data of HBV/HDV vs. HBV alone from a large US integrated healthcare system.
Method: In this retrospective cohort study from Kaiser Permanente Northern California, an integrated healthcare system with over 4.6 million patients, all adult HBV infected patients identified from January 2009 to December 2018 were included. Proportions of anti-HDV testing, positive anti-HDV, HDV RNA testing, and detectable HDV RNA were studied. Three groups were identified: HBV mono-infected (included those without anti-HDV testing), HBV with anti-HDV positive (included those without HDV RNA testing) and HBV/HDV co-infected (those with detectable HDV RNA). Groups were followed until outcome of interest, insurance loss or study termination at end of 2022. Outcomes of interest included fibrosis progression (at least 1 fibrosis stage increase between serial transient elastography measurements), cirrhosis, decompensated cirrhosis, hepatocellular carcinoma (HCC), liver transplantation and all-cause mortality.
Results: We identified 17, 794 HBV infected patients, of which 10, 461 (59%) underwent anti-HDV testing. 83 of 10, 461 patients (0.8%) were anti-HDV positive; 73 of 83 (88%) had HDV RNA tested and 11 of 73 (15%) were HDV RNA detectable. Among the HBV mono-infected (n = 17, 700) vs. HBV with anti-HDV positive (n = 83) vs. HBV/HDV (n = 11) patients, baseline characteristics showed highest proportion of female in HBV mono-infected (47%), median age youngest in HBV/HDV (44 years) and highest BMI in HBV/HDV (27 kg/m^2) (all $p < 0.05$). For comorbidities, diabetes and hypertension were highest in HBV with anti-HDV positive (23% and 13% respectively) with active tobacco users highest in HBV/HDV (10%) (all $p < 0.05$). The HBV/HDV had the highest proportion of patients with baseline cirrhosis at 45% ($p < 0.05$). HBV/HDV (vs. HBV with anti-HDV positive vs. HBV mono-infected) showed the most fibrosis progression (100% vs. 15% vs. 11%), cirrhosis development (75% vs. 18% vs. 7%), decompensation development (30% vs. 7% vs. 0.6%), liver transplantation (18% vs. 6% vs. 0.4%), and mortality (18% vs. 11% vs. 6%) (all $p < 0.05$). HCC development was most common in HBV with anti-HDV positive at 11% vs. 9% in HBV/HDV vs. 2% in HBV mono-infected ($p < 0.01$).
Conclusion: From this large US HBV cohort, HDV screening rate was 59%, revealing<1% anti-HDV positive rate and 0.1% HBV/HDV prevalence. The findings support the aggressive nature of HDV infection and that of HDV exposure as well. Controlled cox-regression analysis will be presented to confirm HDV as the cause for the more severe natural history.

FRI-408

Statins in untreated chronic HBV link with improved survival, liver outcome and inflammation: a large multicenter retrospective real-world cohort study

Mohammed Suki[1], Tamer Safadi[2], Yael Milgrom[1], Mohamad Masarowah[1], Wadiaa Hazo[1], Yariv Tiram[1], Johnny Amer[1], Abed Khakayla[1], Ashraf Imam[1], Esther Forkosh[1], Joseph Sackran[1], Ofer Perzon[1], Ahmad Salhab[1], Sylvia Drazilova[2], Peter Jarčuška[2], Rifaat Safadi[1]. *[1]Liver institute, Hadassah Hebrew University Hospital, Jerusalem, Israel; [2]2nd Department of Internal Medicine, University Hospital and Faculty of Medicine, Pavol Jozef Šafárik University, Košice, Slovakia*

Email: johnnyamer@hotmail.com

Background and aims: Statins link to antiviral and immunomodulatory properties that could benefit chronic hepatitis B virus (HBV) infection. However, clinical data remains restricted to small-scale unmatched trials. This large real-world retrospective cohort study assessed long term outcomes of statins in chronic HBV patients without anti-viral.

Method: TriNetX is a global research platform de-identified database that spanning 135 million patients across 112 healthcare organizations worldwide. We analyzed electronic medical records of 11569 HBV mono-infected adults (18–90 years) during 2003–2023 from the TriNetX network. Patients defined as detectable HBV DNA >10 IU/ml, never treated with HBV anti-viral (at index event and along 15 follow-up years), either started statins only at index event or never treated with statins. Exclusion criteria were ALT and ALP levels >4 UNL, liver transplants, HCC, and past anticoagulation therapy. Outcomes assessed over 1, 5, 10 and 15 years; including mortality and survival, laboratory data (biochemical, hematologic, AFP), manifestations and complications of cirrhosis, viral load trajectories, as well as metabolic and cardiovascular (CV) outcomes. Advanced liver disease and complications of cirrhosis were defined according to ICD9 terms, blood tests (albumin, bilirubin, INR, Platelets) and specific treatments (NSBB, ammonia lowering agents and spironolactone).

Results: Following an extensive matching of 44 clinical and laboratory parameters, propensity score matching created 2 balanced groups for analysis, statin-exposed (n = 935) and unexposed (n = 935). Despite extensive matching, LDL remained significantly higher in the station group, with a non-significant trend of higher TG and HBA1c at baseline. Statin group demonstrated a significant improvement in mortality and survival ($p < 0.005$), as well as manifestations of advanced liver disease ($p < 0.05$), but not HCC and neither liver transplant. Although BMI remained similar in both groups, the statin group exhibited a significant LDL and AST improvements and HBA1c worsening, while CV events equalized. Interestingly, viral load kept similar in both groups in all tested time points.

Conclusion: This long-term real-world study in HBV patients suggests effectiveness of statins on survival and liver outcomes despite the higher metabolic risks at baseline (lipid profile) and along follow-up (HBA1c worsening). Satins improved LDL and equalized CV events despite higher metabolic risks, suggesting survival improvement because of the liver alleviation. Ongoing similar viral load in both groups and AST decline in statin group suggesting an anti-inflammatory mechanism but not a direct viral effect.

Email: anafuenteslop@gmail.com

Background and aims: Hepatitis delta is a significant global health concern, affecting an estimated 15 to 20 million people worldwide. With the recent introduction of Bulevirtide, the first antiviral specifically for hepatitis delta, and forthcoming new antivirals targeting hepatitis B virus, there are now more therapeutic options. These developments could enhance elimination strategies. Our study focuses on assessing the prevalence of undiagnosed hepatitis delta in Southern Spain (Andalusia) and evaluating the feasibility and cost-effectiveness of reflex testing for hepatitis delta.

Method: We conducted an ambispective (both retrospective and prospective) multicentre study across 17 hospitals in Andalusia. During the retrospective phase (January 2018 to June 2022), we analyzed the hepatitis delta diagnostic process, focusing on patients positive for HBsAg. We identified those tested for anti-delta antibodies and those who underwent HDV RNA testing, extracting data from the Laboratory Information Systems (LIS) of participating centers. From October 2022 to March 2023, all centers began the prospective phase, implementing reflex testing for hepatitis delta (testing for anti-HDV in all HBsAg-positive patients who hadn't been previously tested). We evaluated the cost-effectiveness of implementing reflex testing in the prospective phase population versus non-implementation, considering only direct healthcare costs (screening and diagnosis), excluding treatment costs.

Results: In the retrospective phase, we analyzed 18, 583 HBsAg-positive patients. Of these, 3436 (18%) underwent anti-HDV testing, with 205 (6%) testing positive. HDV RNA testing was conducted on 158 patients, identifying 69 (1.9%) as HDV-RNA positive. In the prospective phase, of 3, 370 HBsAg-positive patients, 986 had prior anti-HDV testing. Of the remaining 2, 384, 2, 293 (96%) were tested for anti-HDV, with 109 (4.7%) testing positive. HDV RNA was tested in 97 of these 109 patients (89%), resulting in 30 patients (1.3% of all HBsAg-positive, 31.6% of HDV-RNA tested) being identified as HDV-RNA positive. In the cost-effectiveness analysis, we observed a cost

saving of €132 per HBsAg positive screened of anti-HDV patient and €6, 246 per patient diagnosed with a positive HDV viral load.
Conclusion: Our retrospective analysis reveals an under-diagnosis of HDV in Southern Spain, with only a fifth of HBsAg-positive patients screened for anti-HDV from 2018 to early 2022. Implementing double reflex HDV testing has proven feasible and significantly increases the detection of chronic HDV infection. This approach is crucial in identifying "missing" hepatitis delta patients. Furthermore, our findings suggest that reflex testing for HDV in HBsAg-positive patients is an efficient strategy.

FRI-410
Mitochondrial dysfunction and metabolic plasticity in the hepatitis B virus specific immune response: new insights and implications for hepatitis B virus cure
Saima Ajaz[1], Riham Soliman[1], James Lok[1], Kosh Agarwal[1]. [1]*Institute of liver studies, King's College Hospital NHS Foundation Trust, London, United Kingdom*
Email: saima.ajaz@nhs.net

Background and aims: Hepatitis B virus (HBV) is a leading cause of cirrhosis and hepatocellular carcinoma. Chronic infection is characterized by an exhausted adaptive immune response in which there is reduced proliferative capacity and altered ATP biogenesis. Our aim was to explore the metabolic profile of these immune cells in more detail, including amongst those treated with nucleos(t)ide analogues (NUC).
Method: For this cross-sectional study, adult subjects were divided into three groups: Group 1 (healthy controls, HC, n = 10), Group 2 (chronic HBV infection, NUC suppressed, n = 16) and Group 3 (chronic HBV infection, not currently treated, n = 6). Peripheral blood mononuclear cells were extracted from whole blood using density gradient centrifugation and 300, 000 cells/well were selected for downstream analysis. Oxygen consumption rate (OCR; basal, ATP-linked, and maximal), extracellular acidification rate (ECAR) and reserve capacity were assessed using the Seahorse XFp analyzer (Agilent Technologies). Dependency of mitochondrial respiration for different substrates was explored using the XFp Cell Mito Stress Test Kit, including selective inhibition of glucose, glutamine, and long chain fatty acid pathways.
Results: Subjects were matched for key demographic characteristics, including age (45.5 ± 9.9), sex (male: female ratio of 12:10) and BMI (29 ± 6.5 kg/m^2). HBV-infected individuals demonstrated greater reliance on glucose for ATP generation, irrespective of their treatment status; however, they were significantly less efficient at oxidative phosphorylation when compared to healthy controls (ATP-linked respiration rate 14.6 ± 5.7 vs 87.8 ± 47 pmol/min, p = 0.006). Inhibition of glucose pathway led to an increase in maximal respiration rate amongst HBV patients who were not currently treated (315 pmol/min versus 221 pmol/min); this indicates metabolic flexibility and the potential to activate alternative pathways. Similar compensatory mechanisms were not observed in the NUC-suppressed population, as shown by a reduction in maximal respiration after glucose interference (202 pmol/min versus 312 pmol/min). The same cohort also demonstrated a lower basal respiration rate (93.5 ± 22 pmol/min, p < 0.05), compared with HC (193.5 ± 38 pmol/min) and individuals not on NUCs (192.4 ± 45 pmol/min).
Conclusion: In chronic HBV infection, the adaptive immune response preferentially upregulates glycolysis at the expense of oxidative phosphorylation. This phenomenon, which is reminiscent of the Warburg effect, may contribute to their exhausted phenotype and ultimately HBV persistence. We demonstrate that these immune cells are adaptable and can promote alternative metabolic pathways under the right conditions; manipulation of their metabolic profile, perhaps in combination with checkpoint modulation, represents a viable therapeutic strategy.

Email: doctor_hr@126.com

Background and aims: Definitions of natural phases of chronic hepatitis B virus (HBV) infection vary among international hepatitis B guidelines. A considerable number of patients with chronic HBV infection do not fit into usual phases and were classified into "indeterminate phase." We compared the proportions of indeterminate phase among different international guidelines.
Method: A total of 9, 694 treatment-naïve patients with chronic HBV infection were included from three medical centers. Patients were classified as different natural phases according to guidelines by the 2018 American Association for the Study of Liver Diseases (AASLD), the 2017 European Association for the Study of the Liver (EASL) and the 2015 World Health Organization (WHO). Patients fall outside the defined phases by international guidelines were defined as indeterminate phase. Each natural phase has its corresponding indeterminate phase and thus the indeterminate phase was further divided into four subcategories. Significant liver fibrosis was estimated by non-invasive tests.
Results: The proportion of indeterminate phase of patients with chronic HBV infection was highest according to the definitions by WHO guidelines (36.93%), followed by AASLD guidelines (27.69%) and EASL guidelines (25.96%). The proportion of patients with indeterminate phase increased significantly with age. With regards to different indeterminate phase subtypes, the proportion of indeterminate phase corresponding to HBeAg-negative CHB (HBeAg-negative chronic hepatitis B) was highest according to WHO guidelines (76.54%) followed by EASL (54.43%) and AASLD (38.22%) guidelines (p < 0.001). The proportion of significant liver fibrosis in patients with indeterminate phase were comparable among different international guidelines (EASL: 15.92%; AASLD: 15.21%; WHO: 13.79%, p = 0.117). However, patients with indeterminate phase corresponding to HBeAg-negative CHB had a higher rate of significant fibrosis in EASL guidelines (19.38%) compared to AASLD guidelines (16.91%) and WHO guidelines (14.48%) (p = 0.006).
Conclusion: The proportion of indeterminate phase in chronic HBV-infected patients varied among international hepatitis B guidelines and was lowest according to the definition by EASL guidelines. There is no significant difference in the rates of significant liver fibrosis in patients with indeterminate phase among three guidelines. However, patients in the indeterminate phase corresponding to HBeAg-negative CHB had higher proportion of significant liver fibrosis according to EASL guidelines.

FRI-412

Quantification of plasma hdv rna in untreated and bulevirtide-treated patients with chd: a comparison between robogene 2.0, eurobioplex and altostar

Maria Paola Anolli[1], Sara Uceda Renteria[2], Elisabetta Degasperi[1], Floriana Facchetti[1], Dana Sambarino[1], Marta Borghi[1], Riccardo Perbellini[1], Roberta Soffredini[1], Sara Monico[1], Ferruccio Ceriotti[1], Pietro Lampertico[1,3]. *[1]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Virology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: sara.ucedarenteria@policlinico.mi.it

Background and aims: Accurate HDV-RNA quantification is crucial for diagnosis and management of chronic hepatitis Delta, yet a significant variability between assays do exist. We compared three methods to quantify HDV-RNA levels in untreated and Bulevirtide (BLV)-treated CHD patients.
Method: Frozen plasma from untreated and BLV-treated CHD patients were tested in a single-center retrospective study: Robogene HDV-RNA Quantification Kit 2.0 (Roboscreen GmbH; LOD 6 IU/ml on 7500 Fast Real-Time PCR System [Applied Byosystem]), EurobioPlex HDV PCR quantitative (Eurobio Scientific, LOD 100 IU/m) on CFX96™ real-time PCR detection system [Bio-Rad]) and AltoStar HDV RT-PCR Kit 1.5 (Altona Diagnostics; RUO test, estimated LOD <10 IU/ml).
Results: Overall, 429 plasma samples from 130 CHD (69 untreated and 61 BLV-treated) patients were studied. Median HDV-RNA were higher with Robogene than EurobioPlex [3.78 (0.70–7.99) vs. 4.69 (2.00–8.19) Log IU/ml, $p < 0.0001$]. Compared to Robogene 2.0, EurobioPlex reported similar HDV-RNA (Δ±0.5 Log) in 66 (28%) patients but higher >0.5 Log in 160 (69%). Viremia was lower with Robogene than AltoStar [3.32 (0.70–7.37) vs. 3.91 (0.19–7.54) Log IU/ml, $p < 0.0001$]. AltoStar reported HDV-RNA levels >0.5 Log in 127 (52%). Virological response at week 24 (Robogene vs. Eurobio and AltoStar) and 48 (Robogene vs. AltoStar) did not differ. HDV-RNA undetectability rates at week 24 were 11% vs. 33% with Robogene *vs.* EurobioPlex, and 11% vs. 3% Robogene vs. AltoStar. At week 48, 47 samples collected at on treatment week 48 were analyzed with the three tests: HDV-RNA levels were 3.04 (0.70–6.20) IU m/l vs. 3.62 (2.00–7.12) vs. 3.37 (0.28–6.45) IU/ml with Robogene *vs.* EurobioPlex *vs.* AltoStar, respectively ($p = 0.36$). At week 72 HDV-RNA was undetectable in 42%, 83% and 25% of patients, respectively.
Conclusion: HDV-RNA levels quantified by EurobioPlex and Altostar were 1 and 0.5 logs higher than Robogene 2.0, respectively. HDV-RNA undetectability rates during BLV differed according to the method.

FRI-413

Prevalence, fate and implication of gray zone on the trajectory of hepatitis B surface antigen in treatment-naïve young adults with chronic hepatitis B infection

Lung Yi Loey Mak[1], Apostolos Koffas[2], Grace Dolman[2], Yu Lei[3], Anna Riddell[2], Upkar Gill[2], Patrick Kennedy[2]. *[1]The University of Hong Kong, Queen Mary University of London, Hong Kong, China; [2]Queen Mary University of London, London, United Kingdom; [3]Chongqing Medical University, Queen Mary University of London, London, United Kingdom*
Email: loeymak@gmail.com

Background and aims: Chronic hepatitis B (CHB) patients designated in the grey zone (GZ) are currently excluded from treatment. We aimed to characterize the prevalence of GZ patients and the dynamic profiles of quantitative hepatitis B surface antigen (qHBsAg) in young adults under long-term follow-up.
Method: Treatment-naïve CHB patients aged ≤30 were prospectively recruited with serum qHBsAg (in IU/ml), hepatitis B virus (HBV) DNA (in IU/ml) and alanine aminotransferase (ALT, in U/L) longitudinally monitored. Disease phases were classified according to EASL guidelines, while GZ was defined when the hepatitis B e antigen (HBeAg)-ALT-DNA profile does not fall into any phases, i.e., GZ-A: HBeAg+, ALT ≤40, HBV DNA$<1 \times 10^6$; GZ-B: HBeAg+, ALT >40, HBV DNA$<2 \times 10^4$; GZ-C: HBeAg-, ALT ≤40, HBV DNA >2000; GZ-D: HBeAg-, ALT >40, HBV DNA ≤2000.
Results: A total of 250 patients were recruited (median age 26 years [interquartile range 22–29], 46.4% male, predominant genotype D, 36% White/43.2% Black/17.6% Asian/3.2% unknown). At baseline, 24% were HBeAg-positive, with 28.4% falling into the GZ (A: 2.4%, B: 0.8%, C: 22.8%, D: 2.4%). Over a median follow-up (FU) of 56.5 months, median qHBsAg decreased from 8255 to 7138 ($p < 0.001$). Interestingly, at long-term FU, 29.2% patients experienced an increase in qHBsAg from baseline, more commonly observed in patients with higher qHBsAg levels at 12 months (OR 2.257, 95% CI 1.120–4.500) and patients showing increase in qHBsAg at 12 months compared to baseline (OR 7.556, 95% CI 2.412–23.667). HBsAg seroclearance was observed in 3.8%. After censoring 13 patients started on nucleoside analogues during FU, the proportion of GZ patients reduced to 19.9% (A: 2.2%, B: 0%, C: 12.9%, D: 4.3%). Proportion of patients achieving qHBsAg<100 and qHBsAg<1000 increased from 6.4% to 10.4%, and 15.6% to 21.7%, respectively, at long-term FU. Male gender (OR 2.702, 95% CI 1.031–7.080), baseline qHBsAg (OR 0.015, 95% CI 0.002–0.114), serial change in qHBsAg level (OR 0.036, 95% CI 0.005–0.246) and GZ at 12 months (OR 0.103, 95% CI 0.013–0.833) were associated with achieving qHBsAg<1000 at long-term FU.
Conclusion: More than 25% of young treatment-naïve CHB patients were designated as GZ and the prevalence declined with age, together with a general decline in qHBsAg. A subset of patients demonstrated serial increase in serum qHBsAg levels over long-term FU. GZ and dynamic increase in qHBsAg were associated with higher qHBsAg levels and should be considered for treatment.

FRI-414

Hepatitis B treatment in Africa: experiences from a scale-up program in Ethiopia

Lasse Rossvoll[1], Hailemichael Desalegn[2], Fikadu Girma Gudissa[3], Dawit Birhanu[4], Ahmed Hussen[5], Waqtola Cheneke[6], Asiya Jeylan[3], Esayas Gudina[6], Nega Berhe[7], Asgeir Johannessen[1]. *[1]Vestfold Hospital Trust, Tønsberg, Norway; [2]St.Paul's Hospital Millenium Medical College, Addis Ababa, Ethiopia; [3]Adama Comprehensive Specialized Hospital Medical College, Adama, Ethiopia; [4]Dubti General Hospital, Dubti, Ethiopia; [5]Jigjiga University Sheikh Hassen Yabare Comprehensive Specialized Hospital, Jigjiga, Ethiopia; [6]Jimma University, Jimma, Ethiopia; [7]Addis Ababa University, Addis Ababa, Ethiopia*
Email: lasse.rossvoll@gmail.com

Background and aims: In sub-Saharan Africa treatment for chronic hepatitis B (CHB) is rarely available, and data on the management of CHB from this region is scarce. In 2021/22 we set up a scale-up CHB treatment program at four regional hospitals in Ethiopia. Here we present early experiences from this public-sector scale-up program.
Method: A total of 5, 863 HIV-negative adults with CHB were enrolled between December 2021 and December 2023. The patients were assessed with laboratory tests, including viral markers and liver enzymes. The treatment eligibility criteria were: i) clinically diagnosed cirrhosis, ii) aspartate aminotransferase to platelet ratio index (APRI) ≥0.7, iii) alanine aminotransferase (ALT) >40 U/L and HBV DNA >2, 000 IU/ml, and iv) hepatocellular carcinoma in first-degree relative and HBV DNA >2, 000 IU/ml. Tenofovir disoproxil fumarate was the preferred antiviral drug and was provided free of charge.
Results: The median age was 30 years (interquartile range 25–38) and 2, 861 (48.8%) patients were women. Coinfection with HCV was uncommon (n = 92; 1.6%). Most patients had normal (≤40 U/L) ALT (n = 4, 277; 72.9%) and low (≤0.5) APRI (n = 4, 399; 75.0%). At inclusion, 3, 697 (63, 1%), 986 (16, 8%) and 1, 052 (17, 9%) had HBV DNA<2, 000 IU/ml, 2000–19, 999 IU/ml and ≥20, 000 IU/ml, respectively.

Overall, 2, 954 (50.4%) patients were classified as inactive carriers, defined as HBV DNA<2, 000 IU/ml and ALT ≤40 U/L. 1, 002 (17.1%) patients had APRI ≥0.7, suggestive of cirrhosis. Male sex (adjusted odds ratio (AOR) 3.45; 95% CI 2.93–4.07) and HBV DNA >2, 000 (AOR 3.13; 95% CI 2.70–3.62) were independently associated with cirrhosis. In total, 1, 571 (26.8%) patients were eligible for treatment at baseline evaluation.

Conclusion: Roughly 25% of the patients were eligible for treatment at enrollment, highlighting the importance of improved access to CHB treatment in sub-Saharan Africa. Another 25% were indeterminate and would need longitudinal follow-up to determine treatment eligibility. The remaining 50% were classified as inactive carriers and could probably have less intensive follow-up.

FRI-415

Hepatitis B virus genotype and some baseline characteristics, but not race, affect HBsAg kinetics during nucleos (t)ide analogue therapy

Rachel Wen-Juei Jeng[1,2], Margarita Papatheodoridi[3], Yen-Chun Liu[1,2], Emilia Hadziyannis[4], Spilios Manolakopoulos[4], Rong-Nan Chien[1,2], George Papatheodoridis[3]. *[1]Chang Gung Memorial Hospital, Linkou Medical Center, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan; [2]Chang Gung University, College of Medicine, Taoyuan, Taiwan; [3]National and Kapodistrian University of Athens, General Hospital of Athens "Laiko," Department of Gastroenterology, Athens, Greece; [4]National and Kapodistrian University of Athens, General Hospital of Athens "Hippokratio," 2nd Department of Internal Medicine, Athens, Greece*
Email: gepapath@med.uoa.gr

Background and aims: In a previous multicenter cohort study including chronic hepatitis B (CHB) patients with mixed HBeAg status (89% Asians), there was little impact of ethnicity on HBsAg seroclearance during nucleos (t)ide analogue (NA) therapy (crude hazard ratio: 0.8, Hsu YC et al JID 2021), but the potential impact of ethnicity/race on HBsAg kinetics during NAs remains unclear. We assessed potential differences in HBsAg kinetics between Taiwanese and Greek HBeAg-negative CHB patients.

Method: Non-cirrhotic HBeAg-negative CHB patients (n = 806) from Taiwan (n = 541) and Greece (n = 265) receiving entecavir (ETV) or tenofovir (TDF) were recruited. Baseline host and viral characteristics and NA type were compared between those with and without rapid on-NA HBsAg decline (>0.5 $\log_{10}$ IU/ml/year). Logistic regression identified predictors and a 1:1 propensity score matching for HBV genotypes (GT) B and C/D was performed for sensitivity analysis.

Results: Compared to the Greek, the Taiwanese cohort had greater proportion of males (81% vs. 68%, P < 0.001) and history of past treatment (63% vs. 41%, P < 0.001), increased utilization of ETV (75% vs. 42%, P < 0.001), higher ALT (192 vs. 63 U/L, P < 0.001) and HBV DNA levels (6.5 vs. 5.1 $\log_{10}$ IU/ml, P < 0.001), lower HBsAg levels (3.2 vs. 3.5 log10 IU/ml, P < 0.001) at NA onset, and shorter follow-up (3 vs. 3.9 years, P < 0.001). Multivariate logistic regression identified past treatment history [adjusted Odds Ratio (aOR): 2.03, P = 0.006], ALT>5x ULN (aOR: 2.18, P = 0.003) and higher HBsAg levels at NA onset (aOR: 3.58, P < 0.001) as independent predictors for on-NA rapid HBsAg decline, while ethnicity/race did not reach statistical significance (aOR: 2.1, P = 0.07). Univariate analysis indicated that patients with GT-C (crude OR: 0.47, P = 0.072) or D (crude OR: 0.23, P < 0.001) compared to GT-B were less likely to experience on-NA rapid HBsAg decline. In the PS-matched cohort, adjusting for characteristic differences between GT-B vs. C/D patients, multivariate logistic regression showed that patients with HBV GT-C/D infection were less likely to have rapid on-NA HBsAg decline (aOR: 0.4, P = 0.02). The predominant impact of HBV GT on HBsAg kinetics occurred in the first year of NA therapy (GT-B vs. GT-C/D: HBsAg reduction: −0.35 vs. −0.12 $\log_{10}$ IU/ml/year, P < 0.001), even after adjusting for ALT, HBV DNA, and HBsAg levels at NA onset. The cumulative incidence of on-NA HBsAg loss was comparable between different ethnicity/race (log-rank test, P = 0.4) and HBV GTs (log rank test, P = 0.2).

Conclusion: On-NA HBsAg kinetics are mostly affected by HBV GT and baseline characteristics like high ALT and low HBsAg levels, but not by ethnicity/race. HBV GT influences HBsAg reduction primarily within the first year of NA therapy.

10-year clinical outcomes in chronic hepatitis B patients treated with tenofovir in The Gambia, West Africa

Erwan Vo Quang[1], Gibril Ndow[2], Sulayman Bah[3], Rohey Bangura[3], Lamin Bojang[3], Bakary Dibba[3], Sainabou Drammeh[3], Alhagie Touray[3], Kitabu Jammeh[3], Isabelle Chemin[4], Amie Ceesay[3], Gavin Cloherty[5], Umberto D'Alessandro[3], Mark R. Thursz[3], Yusuke Shimakawa[6], Maud Lemoine[3]. *[1]Medical Research Council Unit, London School of Hygiene and Tropical Medicine, Fajara, Gambia; [2]Medical Research Council Unit The Gambia, London School of Hygiene and Tropical Medicine, Banjul, The Gambia, Fajara, Gambia; [3]Medical Research Council Unit The Gambia, London School of Hygiene and Tropical Medicine, Banjul, The Gambia, Fajara, Gambia; [4]International Agency for Research on Cancer, Lyon, France, Lyon, France; [5]Abbott USA, USA, United States; [6]Institut Pasteur, Paris, France, Paris, France*
Email: erwan.voquang@gmail.com

Background and aims: Effectiveness and safety of long-term tenofovir disoproxil fumarate (TDF) in people with chronic hepatitis B virus infection (CHB) has been inadequately documented in Africa. From the longitudinal PROLIFICA study, we evaluated the long-term clinical outcomes of CHB patients treated with TDF in The Gambia.

Method: In this prospective cohort study, we followed-up participants who were consecutively diagnosed with CHB without HCC between 2012 and 2015 in The Gambia. CHB participants eligible to treatment (EASL guidelines) were initiated on TDF, 300 mg daily. The primary outcome was the overall survival in untreated and treated patients.

Results: From December 2011 to October 2015 1, 117 treatment naïve CHB participants were recruited, including 141/1, 117 (12.6%) initiated on TDF. Treated patients were mainly males (84%) with baseline median age at 35 (IQR: 28–39), median Fibroscan 8.9 (7.0–14.0), including 54/121 (45%) cirrhosis, 3.0% and 7.2% of HCV or HDV coinfections, median HBV DNA 3, 474 (IQR: 142–263, 720) and eAg positive in 37/131 (28%). During a median follow-up of 6.8 (5.6–8.6) years, 62/1117 (4.3%) died of any cause, including 35/141 (24%) on TDF. Deaths were mostly driven by end-stage liver disease (87.5%) followed by HCC (12.5%). The 1-, 6- and 10-year cumulative survival probabilities in treated patients without cirrhosis, with compensated or with decompensated cirrhosis at baseline were 100%, 95% and 92%; 100%, 97% and 96%, 88%, 63% and 57%; respectively (p < 0.01). The mortality rate among non-cirrhotic patients on TDF was similar to that of untreated and ineligible patients (p = 0.28). Cirrhosis (HR: 8.3, 95%CI 1.6–42.7) and ascites (HR 4.7, 1.4–16.0) were independent predictive factors of mortality at baseline among patients on TDF. Proportion of treated patients with undetectable HBV DNA and ALT normalisation were 66% and 45% at year 6, 93% and 88% at year 10. 31/80 (38%) and 11/25 (44%) had significant liver fibrosis regression at year 6 (p < 0.01) and 10 (p = 0.04), including 17/25 (68%) and 5/6 (83%) of cirrhosis regression, respectively. Adherence to TDF was very good in most patients (70% and 87% at year 6 and 10, respectively). Kidney impairment on TDF was observed in only 2/138 (1.4%) patients and was comparable the rate 10 of 503 untreated CHB patients (2.0%) Bone mass analysis in treated and untreated patients is in progress.

Conclusion: In non-cirrhotic patients, TDF is associated with an excellent safety profile and an overall survival at 10 years, comparable to the survival observed in untreated CHB patients who are ineligible for AVT. The suboptimal survival among cirrhotic patients reflects the lack of early diagnosis of cirrhosis in Africa.

FRI-419

Epidemiological characteristics of hepatitis D virus infection in patients with hepatitis B related hepatocellular carcinoma

Tangnuer Talafu[1], Xinting Li[1], Li Yang[1], Rongjiong Zheng[1], Xiaobo Lu[1]. [1]*Xinjiang Clinical Research Center for Infectious Disease (Viral Hepatitis), Center for Infectious Disease and Hepatology of the First Affiliated Hospital of Xinjiang Medical University, Urumqi, China*
Email: xjykdluxiaobo@126.com

Background and aims: The objective of this study was to explore the seroepidemiological features of hepatitis D virus (HDV) infection among individuals diagnosed with HBV-associated primary hepatocellular carcinoma (HCC) at a singular medical center in Xinjiang.
Method: This study emplyed a single-center, cross-sectional analysis, enrolling 180 patients with HBV-associated HCC hospitalized between December 2021 to May 2023 at the Center for Infectious Disease and Hepatology of the First Affiliated Hospital of Xinjiang Medical University. All patients underwent Anti-HDV IgM, anti-HDV IgG and HDV Ag tests to investigate the epidemiological traits of co-infected HDV in HBV-associated HCC patients, as well as the correlation between HDV and HBV virologic and serologic markers.
Results: Out of the 180 patients, with a mean age of 56.67 ± 9.50 years and 156 (86.67%) being male, 23 (12.78%) were HDV seropositive (HDV-IgM and/or HDV-IgG and/or HDV-Ag) individuals. Epidemiological analysis of HDV seropositive patients indicated a mean age of 56.17 ± 12.90 years, with 19 (82.60%) being males, median ALT of 29 U/L and AST of 44.57 U/L. Vertical transmission accounted for 85% of HBV infections, with no history of intravenous drug use. Stratifying by HBV DNA loads revealed HDV seropositivity rates of 15.7%, 10.3% and 5.6% for HBV DNA<20 IU/ml, 20–2000 IU/ml, and>2000 IU/ml, respectively. Correlation analysis suggested an inverse trend between HDV seropositivity and HBV DNA levels ($p > 0.05$), that is the lower the level of HBV DNA, the higher the rate of HDV seropositivity. Grouping by HBsAg levels (HBsAg<0.05 IU/ml, 0.05–250 IU/ml and >250 IU/ml) showed HDV seropositivity rates of 4%, 7.7% and 18.9% respectively, with a significant positive correlation between HDV seropositivity and HBsAg levels ($p < 0.05$), that is the higher the level of HBsAg, the higher the HDV seropositivity rate. Analysis of disease duration, biochemical indices, and coagulation function and other laboratory indicators revealed no statistically significant differences between HDV seropositivity and negative patients ($p > 0.05$).
Conclusion: The seroprevalence of HDV among patients with HBV-associated HCC at a single center in Xinjiang was found to be 12.78%, indicating a notable prevalence. This underscores the importance of emphasizing the role of HDV in the etiology of hepatocellular carcinoma and suggests potential implications for the strategy of hepatocellular carcinoma prevention.

FRI-420

Serum HBsAg rather than HBV DNA reflects liver HBV transcript levels of hepatitis B patients treated by nucleoside analogues

Wenhua Zhang[1], Haitao Tang[1], Qinghua Lu[2], Tingxia Chao[3], Haifang Cao[2], Hongfei Zhang[4], Feng Ren[5]. [1]*Gansu Wuwei Tumour Hospital, Wuwei, China;* [2]*The 4th People's Hospital of Qinghai Province, Xining, China;* [3]*Gansu Wuwei Tumour Hospital, Wuwei, China;* [4]*Jumei Doctor Group Medical (Shenzhen) Co., Ltd, Shenzhen, China;* [5]*Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: 925944468@qq.com

Background and aims: The therapeutic goal of CHB is to achieve a "functional" cure, which is characterized by sustained HBsAg loss and HBV DNA levels below the lower limit of detection. However, it is almost impossible to achieve sustained HBsAg loss with nucleoside analogues (NAs) treatment. It is poor treatment efficacy and low HBsAg conversion rate for antiviral treatment of CHB patients with high HBsAg levels, although serum HBV DNA levels were below the lower limit of detection or undetectable. Here, we evaluated serum HBsAg and serum HBV DNA, which is better for evaluating HBV transcriptional activity in liver tissue of hepatitis B patients treated by NAs.
Method: This study was derived from the "Excellence" project-HBV cohort, which consisted of 20 CHB patients (male/11, female/9) with NAs (ETV/TDF/TAF) treatment for a median interquartile range (IQR) of 36 (4–240) months, whose aged 27–58 years and admitted to the hospital from May 2023 to October 2023. Liver histologic biopsy was performed immediately after admission. Intrahepatic HBV covalent closed loop DNA (cccDNA) was quantified by droplet digital PCR (ddPCR), and intrahepatic HBV DNA was quantified by quantitative real-time PCR (qRT-PCR). Intrahepatic HBV cccDNA and HBV DNA parameters were analyzed in relation to serum HBsAg and HBV DNA levels, respectively.
Results: Serum HBsAg levels of all CHB patients with antiviral treatment were greater than 1500 IU/ml, but serum HBV DNA were already at very low or undetectable levels. Interestingly, for CHB patients with no HBV DNA detection in serum, their liver tissues have high levels of HBV DNA (4.880 ± 0.894, log10 IU/ml) and HBV cccDNA (3.967 ± 0.695, log10 copies/μL) with significantly positively correlation ($r = 0.772$, $P < 0.0001$). Serum HBsAg level was positively correlated with intrahepatic HBV cccDNA level ($r = 0.673$, $P = 0.0011$), and positively correlated with intrahepatic HBV DNA level ($r = 0.728$, $P = 0.0003$). The serum HBsAg and serum HBeAg level had good correlation ($r = 0.618$, $P = 0.0037$), however, serum HBV DNA and serum HBeAg level were no correlated with intrahepatic HBV ccc DNA level and intrahepatic HBV DNA level.
Conclusion: In CHB patients with NAs treatment, serum HBsAg rather than HBV DNA reflects liver HBV transcript levels of hepatitis B patients. It is serum HBsAg level, not HBV DNA level that may comprehensively reflect HBV replication activity and help evaluation of antiviral therapeutic efficacy.

FRI-423

Early treatment of patients with indeterminate HBV viraemia does not improve retention in care and risks overtreating patients who may spontaneously clear HBsAg

Sharon Macleod[1], Fiona Marra[2], Alison Boyle[2], Erica Peters[3], Rachael Swann[3], Ewan H. Forrest[4], Stephen Barclay[4]. [1]*NHS Greater Glasgow and Clyde, Glasgow Royal Infirmary, Pharmacy Department, Glasgow, United Kingdom;* [2]*NHS Greater Glasgow and Clyde, Gartnavel General Hospital, Glasgow, United Kingdom;* [3]*NHS Greater Glasgow and Clyde, Queen Elizabeth Hospital, Glasgow, United Kingdom;* [4]*NHS Greater Glasgow and Clyde, Walton Liver Clinic, Glasgow Royal Infirmary, Glasgow, United Kingdom*
Email: sharon.macleod2@ggc.scot.nhs.uk

Background and aims: Current HBV treatment guidelines include recommendations to observe patients with indeterminant viraemia, and/or ALT elevations to establish their true phase of infection. Recent evidence suggests however that many patients persist in the indeterminant phase of infection, leaving the best course of action unclear. We sought to examine the outcomes of patients with indeterminant viraemia with regards to phase of infection, investigation, and initiation of treatment, along with HBsAg loss.
Method: Samples tested for HBV DNA in our health board with a unique patient identifier between 2009 and 2022 were identified from a virology database, and each individual's first and last HBV DNA identified. Viraemia was classed as indeterminate if between 2, 000 iu/ml and 20, 000 iu/ml and low or high if below or above this range respectively. Adults with indeterminate viraemia, and a minimum of 1 quantifiable viral load at 12 months or later underwent case note interrogation. Data was recorded on demographics, ALT, DNA, liver biopsy, treatment status, HBsAg loss and retention in care. Patients were considered retained in care if they attended their last appointment prior to December 2023, or if relevant discharge, death or transfer out of area. Patients were excluded if case note review demonstrated treatment prior to first recorded DNA.

Results: 26, 522 DNA samples relating to 3, 422 individuals were identified. Of these 1, 1615 had two samples ≥12 m apart (median 59 m, IQR 67), of which 236 (14.6%) were indeterminate (996 (61.7%) low 383 (23.7%) high). 14 indeterminate cases were excluded (13 prior treatment, 1 paediatric). Of the remaining 222, 145 (65.3%) were male, with a median age of 34. 30 (13.5%) also had indeterminate (1–2 × ULN) ALT and 10 (4.5%) high ALT. 11 were born in the UK, with Asia (89) and Africa (67) the most common regions of origin. At 12 months low/indeterminate/high viral loads were seen in 96 (43.2%), 84 (37.8%) and 18 (9.9%) respectively, whilst 22 (9.9%) had commenced treatment. 24 (10.8%) underwent liver biopsy at some point during assessment, of whom 11 received treatment. At last assessment viral loads were high/indeterminate/low or undetectable in 11 (5) %, 61 (27.6%) and 93 (42.1%), including 15 patients (6.8%) who had HBsAg loss. 56 patients (25.3%) received treatment by end of follow-up, 28 within 18 months and 28 beyond. Retention in care was not influenced by starting treatment by 18 months (71.4% vs 69.6%, p = 0.84).
Conclusion: In this cohort 1:4 individuals with initial indeterminate DNA required treatment per current guidelines. Earlier treatment of those with indeterminate HBV DNA levels will simplify care and may avoid liver biopsy, though the minority underwent this. 42% of patients had low level viraemia at the end of follow-up including 6.8% with HBsAg loss who would be overtreated. Early treatment did not appear to influence retention in care.

FRI-424
Effectiveness of immunoprophylaxis for preterm infants of mothers having chronic hepatitis B virus infection: a retrospective study

Guanlun Zhou[1], Guorong Han[1], Yuhao Ju[1], Yan Chen[1], Chao Chen[1]. [1]*The Second Hospital of Nanjing, Nanjing, China*
Email: gl270408@163.com

Background and aims: The long-term effectiveness of immunoprophylaxis for preterm infants delivered by mothers with hepatitis B virus (HBV) infection remains unclear. This study aimed to investigate the effectiveness and indicators of immunoprophylaxis in preterm infants.
Method: 2238 infants delivered by HBsAg-positive mothers were enrolled, including 175 preterm infants and 2063 full-term infants. Preterm infants were administered 10 μg of hepatitis B vaccine immediately after birth and at one, two and seven months while full-term infants received vaccine immediately after birth and at one and six months. All infants were followed up till 24 months. Effectiveness of immunoprophylaxis in preterm infants was analyzed by comparing the dynamics of HBV mark (HBV-M) and responsible factors were investigated using multivariate regression analysis.
Results: The differences in the HBsAb titers between groups were not statistically significant at 7–12 and 24 months of age (p > 0.05), but the titers in the preterm group were lower relative to the full-term group. There were no significant differences (p > 0.05) between the two groups for medium-to-high responses of HBsAb at 7–12 and 24 months. Multivariate logistic regression analysis showed that Apgar score at one minute (2.687 [1.116, 6.472]) was a predictor of medium-to-high response of HBsAb at 7–12 month.
Conclusion: HBsAb titers in preterm infants delivered by HBV-infected mothers who were vaccinated following the "0–1–2–7" immunoprophylaxis protocol were similar to those in full-term infants, thereby indicating good outcomes. One-minute Apgar score could be used to predict HBsAb levels in preterm infants at 7–12 months of age after completion of the immunoprophylaxis regimen.

FRI-425
Hepatitis B core-related antigen (HBcrAg) in a prospective French hospital database on chronic hepatitis B (HBVbiomark)

Erwan Vo Quang[1], Stéphane Chevaliez[1], Scoazec Giovanna[2], Varaut Anne[2], Giuliana Amaddeo[2], Amal Boukraa[2], Mélanie Simoes[2], Anne Laure Mazialivoua[2], Alexandre Soulier[1], Valérie Ortonne[1], Olivia Garrigou[1], Jean-Michel Pawlotsky[1], Vincent Leroy[2], Patrick Ingiliz[2]. [1]*INSERM U955, Creteil, France;* [2]*Hopital Henri-Mondor, Creteil, France*
Email: patrick.ingiliz@aphp.fr

Background and aims: Hepatitis B core-related antigen (HBcrAg) is a composite marker consisting of HBcAg, HBeA gand p22cr, suggested to be used in clinical practice in order to predict hepatitis B virus (HBV) disease stages or outcomes. HBcrAg is a translational product of viral transcription, and may be used in addition to such as ALAT, viral load, HBeAg or quantitative HBsAg (qHBsAg) to characterize eAg-negative patients. Here, we assessed HBcrAg levels in a French mono-centric eAg-negative HBV database.
Method: HBVbiomark is a prospective cohort of HBV patients followed-up in the outpatient department of the Henri-Mondor Hospital in Créteil, France. After informed consent, patients clinical, virological and treatment data are captured on an annual basis, and blood samples are stored for investigation of novel biomarkers. HBcrAg is measured by chemiluminescence method using the automatic Lumipulse G600 II analyzer (Fujirebio Inc, Japan) according to the manufacturer's intructions. HBsAg-positive/HBeAg-negative subjects were classified according to EASL guidelines as: chronic hepatitis B (CHB), e-negative infection (ENI) and grey zone (GZ, -viral load >2000 IU/ml and normal ALT, or viral load<2000 IU/ml and elevated ALT).
Results: Since May 2023, 348 patients have been included and 233 were eAg negative. The median age is 46 years (IQR: 37–58), and 70% are male. 91% of patients were born outside France, most of which (63%) in sub-Saharan Africa. The median ALT level is 27 U/L, the median liver stiffness value is 5 kPa (IQR 4.3–6.2), the median HBV DNA level is 25 U/L (IQR 10–695 UI/ml), the median HBsAg level is 2746 IU/ml (583–11988 IU/ml) and the median HBcrAg level 2.5 (IQR 2.0–3.3) log U/ml. About half of the patients (44%) were on antiviral treatment. 90/233 (74.6%) were classified as ENI, 104/233 (45%) as CHB, and 39/233 (17%) as GZ. HBcrAg levels were 2.3, 2.75, and 2.6 log IU/ml in ENI, CHB, and GZ respectively (p = 0.08), and treatment duration did not change HBcrAg levels. Proportion of patients with HBcrAG levels above 3 log UI/ml was different across CHB, ENI and GZ, with 44%, 26% and 31%, respectively (p = 0.03). No correlation was found with HBV viral load and quantitative HBsAg levels.
Conclusion: HBcrAg may help to define disease stages more accurately, especially for the so-called grey zone in e-negative patients, and the inactive carrier state in patients from Sub-Saharan Africa. Our cohort will further study the relation of novel biomarkers and disease progression.

FRI-426
Comparing the impact of Interferon-based and direct-acting agents therapies on HBsAg seroclearance rates in patients with hepatitis B and hepatitis co-infection

Cheng Er Hsu[1], Yen-Chun Liu[1], Rachel Wen-Juei Jeng[1], Ya-Ting Cheng[1], Yi-Chung Hsieh[1], Wei Teng[1], Rong-Nan Chien[1], I-Shyan Sheen[1], Chun-yen Lin[1]. [1]*Chang Gung Memorial Hospital, Linkou Branch, Taiwan, Taoyuan, Taiwan*
Email: rachel.jeng@gmail.com

Background and aims: The treatment approach for chronic hepatitis C (CHC) has shifted from interferon-based regimens (IFN) to direct-acting agents (DAAs) due to enhanced tolerance and increased sustained virological response (SVR) rates. While pegylated interferon remains a primary therapy for chronic hepatitis B, it is unclear whether HBsAg seroclearance rates in coinfected HBV/HCV patients in an HBV-endemic country, where most HBV infections are acquired perinatally, are higher with IFN-based regimens compared to DAAs, which specifically target HCV. This study aims to compare HBsAg seroclearance rates in HBV/HCV coinfected patients treated with IFN-based or DAA regimens.

Method: Retrospective analysis was conducted on two cohorts from Chang Gung Memorial Hospital, Linkou branch: the IFN-based CHC cohort (July 2002–January 2017) and the DAA CHC cohort (March 2015–December 2019). The study focused on CHC patients with a pre-therapy HBsAg seropositive status, including those with available follow-up HBsAg serostatus and achieved SVR. Cox regression analysis identified independent factors for HBsAg seroclearance. Propensity score matching (PSM) addressed heterogeneity between the IFN and DAA groups, adjusting for age, gender, ALT levels, and qHBsAg levels at start of anti-HCV treatment. Kaplan-Meier analysis and log-rank tests compared the cumulative HBsAg seroclearance incidence between the two groups.
Results: Among 356 HBV/HCV coinfected patients achieving SVR, 130 received IFN-based treatment, and 226 received DAA treatment. The IFN group was younger age (51.3 vs. 59.9 years, $p < 0.001$), predominantly male (69% vs. 54%, $p = 0.0067$), and higher baseline ALT levels (89.5 vs. 50.0 U/L, $p < 0.001$), and longer follow-up (median: 10.3 vs. 4.3 years, $p < 0.001$), had comparable pretherapy HBsAg levels (185 vs. 103 IU/ml, $p = 0.17$). During follow-up, 57 IFN-based and 27 DAA patients achieved HBsAg loss. The 5-year cumulative HBsAg seroclearance rate was numerically higher in IFN than DAA (19% vs. 12%, $p = 0.194$). Multivariate Cox regression identified pre-therapy qHBsAg <100 IU/ml (aHR: 2.85, $p < 0.001$) and post-therapy qHBsAg <100 IU/ml (aHR: 3.54, $p < 0.001$) as independent factors for HBsAg loss, while IFN treatment did not reach significance (crude HR: 1.12, $p = 0.67$). After PSM (59 patients in each arm), age, male proportion, and pre-therapy HBsAg level were comparable. The 5-year cumulative HBsAg seroclearance was numerically higher in the IFN arm (28% vs. 13%, $P = 0.172$) but did not achieve statistical significance.
Conclusion: In an HBV-endemic country with HBV/HCV coinfection, IFN-based therapy did not significantly increase the HBsAg loss rate compared to the DAA regimen. This could be attributed to the initially low HBsAg levels in these patients. Lower HBsAg levels at the beginning or end of anti-HCV treatment are independent factors for post-anti-HCV treatment HBsAg loss.

FRI-427
Chronic hepatitis delta with normal ALT and hepatitis D viremia: unravelling its natural history
Muge Ozari Gulnar[1], Habiba Kamal[2], Adriana Palom[3], Sena Arici[4], Rafael Esteban[5], Esra Tunç[6], Onur Keskin[7], Ramazan Idilman[4], Maria Buti[8], Soo Aleman[9], Cihan Yurdaydin[10]. *[1]Koc University School of Medicine, Department of Gastroenterology, Istanbul, Turkey; [2]Dept of Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden; [3]Vall D'Hebron University Hospital, Barcelona, Spain; [4]Ankara University School of Medicine, Ankara, Turkey; [5]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [6]Ankara University School of Medicine Department of Gastroenterology, Ankara, Turkey; [7]Hacettepe University School of Medicine, Ankara, Turkey; [8]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [9]Department of Infectious Diseases, Karolinska University Hospital/Karolinska Institutet, Stockhom, Sweden; [10]Koc University School of Medicine, Department of Gastroenterology, Istanbul*
Email: muge.ozari@gmail.com

Background and aims: Chronic hepatitis delta (CHD) represents the most severe form of chronic viral hepatitis and the main cause of liver-related mortality due to suboptimal therapy. However, CHD may run a less severe course than in the past (Rosina et al, Gastro 1999, Kamal et al, Hepatology 2020). We had previously described patients with persistent normal ALT and hepatitis D viremia (PNAV) (Arici et al, EASL 2021). The aim of the current study was to increase the size of this patient population and to unravel the natural history of PNAV.
Method: PNAV were arbitrarily defined as patients with normal ALT and hepatitis D viremia on at least three determinations, 3 to 12 months apart within a duration of 2 years among patients who had never received interferon and/or bulevirtide based treatment for CHD. Such patients have been collected between 2014–2023 from the databases of 2 academic hospitals in Turkey, one in Spain and one in Sweden. A total of 44 PNAV are described. Follow-up was 18 months to 12 years.
Results: The centers in Sweden, Spain and two centers in Turkey contributed a total of 20, 12, 8 and 4 patients from database cohorts of 157, 60, 250 and 50, respectively. Cirrhosis was reported in 12 patients based on imaging studies, and FibroScan or liver biopsy. Endoscopy was performed in 20 patients, small varices were detected in one case only. On long term follow-up two type of patient scenarios evolve: one group of patients continue with normal ALT and viremia, in the other group HDVRNA levels tend to decrease or even became undetectable. The 2 groups did not differ in terms of age, gender, ALT, AST, GGT or platelet count (214 ± 86 [x ± SD] [n = 25] vs. 237 ± 81 [n = 18], $p = 0.372$) but patients displaying low or undetectable HDV RNA levels (<1000 IU/ml) appear to have significantly lower qHBsAg levels (7378 ± 5722 vs. 987 ± 1402, $p = 0.0073$). HDVRNA levels were similar (3.60 + 1.11 vs. 4.23 + 1.43 IU.ml). Liver biopsy was available in 10 patients. Histologic activity index and fibrosis stage were lower in PNAVs vs controls (8 [3–13] vs 10 [8–14] and 2 [0–4] vs 3 [2–6], $p = 0.05$ and $p = 0.014$, respectively). In the PNAV group, 2 patients had fibrosis stage 3 and 4 according to Ishak et al and one patient had cirrhosis on biopsy. Three additional patients had clinical or radiologic evidence of cirrhosis. On long-term follow-up patients normal ALT persisted. HDV RNA became undetectable in one patient.
Conclusion: The study suggests that a subgroup of CHD patients present with normal ALT and hepatitis D viremia. The proportional weight of this subgroup in chronic hepatitis D cohorts needs careful assessment. PNAV do not necessarily imply milder disease and advanced fibrosis/cirrhosis may be observed, though clinically significant portal hypertension appears to be rare. Further, 18 (40%) patients developed low levels of viremia and even cleared HDV. The role of qHBsAg levels to predict this latter group needs serious consideration.

FRI-428
Evaluating the effectiveness and safety of tenofovir alafenamide fumarate for preventing mother-to-child transmission of hepatitis B virus
Malipati Aierkenjiang[1], Li Yang[2], Xiaofeng Sun[3], Xiaobo Lu[4].
[1]Infectious Disease and Hepatology No.1 Deaprtment, The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China; [2]Infectious Disease and Hepatology Department, The First Affiliated Hospital of Xinjiang Medical Universtiy, Urumqi, China; [3]Infectious Disease and Hepatolgy No.1 Department, The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China; [4]Infectious Disease and Hepatology Department, The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China
Email: 387663581@qq.com

Background and aims: This investigation addressed the paucity of data on tenofovir allafenamide fumarate's (TAF) utility in preventing mother-to-child transmission (MTCT) of hepatitis B virus (HBV) among infected pregnant women.The study's purpose was to assess the effectiveness and safety of both TAF and tenofovir disoproxil fumarate (TDF) in preventing HBV MTCT.
Method: This single-center retrospective study totally enrolled 97 HBV-infected pregnant women with HBsAg-positive, HBeAg-positive and HBV DNA levels exceeding 200, 000 IU/ml.Participants received treatment with either TAF or TDF at 18–24 weeks of gestation at the Center for Infectious Diseases and Hepatology Department of the First Affiliated Hospital of Xinjiang Medical University from September 2018 to September 2021, Follow-up extended to 7 months postpartum. Standardized immunoprophylaxis was administered to infants within 12 hours of birth and at 1 and 6 months of age. The primary end point was the safety of mothers and infants throughout the treatment and follow-up, with secondary end points focusing on the MTCT rate at 7 months postpartum and virologic decline.

Results: TAF was administered to 43 pregnant women, while TDF was given to 54;there were 43 and 54 live-born infants respectively, with all mothers and infants completing the 7-month follow-up.After delivery, 87 subjects continued TAF or TDF treatment, and both groups were well-tolerated, without treatment discontinuation due to adverse events.The primary adverse events were puerperal anemia (23%) in the TAF group and perinatal rupture of membranes (16%) in the TDF group, unrelated to the therapeutic agents. Laboratory tests showed no alanine transaminase (ALT) flares during treatment and follow-up.No congenital malformations or defects were reported in infants at birth, and their growth parameters remained within the normal range at 7 months of age, no statistically significant differences were observed between the TAF and TDF groups (P > 0.05).Maternal HBV DNA levels exhibited a significant reduction from baseline at delivery, decreasing from 6.44 ± 0.88 to 3.33 ± 1.14 IU/ml in the TAF group, and from 6.57 ± 0.76 to 3.77 ± 0.95 IU/ml in the TDF group, with no statistically significant distinction in the magnitude of reduction between the group (P > 0.05).Infants from both groups tested negative for HBsAg, HBeAg, and HBV DNA at 7 months, displaying no statistical variance between the two groups (P > 0.05).
Conclusion: The effectiveness and safety of TAF in preventing mother-to-child transmission among HBV-infected pregnant women was similar to that of TDF. This was accompanied by a favorable safety and tolerability profile, and both groups achieved 0% HBV MTCT rate. These findings propose TAF as a viable option for future use in the prevention of mother-to-child transmission of HBV.

FRI-429

Detectable HDVRNA is associated with worse outcome in patients infected with HBV and HDV: results from a meta-analysis

Jackie Bitton[1], Laura Weichselbaum[2], Christophe Moreno[2], Pierre Deltenre[2,3]. *[1]Clinique Saint-Luc, Bouge, Belgium; [2]CUB Hôpital Erasme, Brussels, Belgium; [3]Clinique St-Luc, Bouge, Belgium*
Email: pierre.deltenre01@gmail.com

Background and aims: Patients with chronic hepatitis B who are co- or super-infected with hepatitis delta virus (HDV) usually have a more aggressive liver disease than mono-infected hepatitis B virus (HBV) patients. However, whether HDV RNA status is associated with increased risk of liver events in patients with both HBV and HDV infection has not been precisely assessed. We aimed to synthesize the available evidence on whether HDV RNA status is associated with an increased risk of liver-related events in patients infected with HBV and HDV.
Method: Meta-analysis of trials evaluating liver-related events in patients with HBV and HDV infection according to the presence or the absence of detectable HDV RNA. Random effects model was used to obtain a summary estimate of primary outcomes among patients who had detectable HDV RNA vs. those who had undetectable HDV RNA. Differences between groups were expressed as odds ratios (ORs) with 95% CIs. Primary end points were the development of cirrhosis, hepatic decompensation, hepatocellular carcinoma and death or liver transplantation. Heterogeneity was assessed using Cochran's *Q* test and the I^2 statistic.
Results: Six studies with 1391 HBsAg and HDV antibody positive patients were included. 1089 patients had detectable HDVRNA and 302 had undetectable HDV RNA. Median age ranged between 30 and 49 years and 66% of patients were males. Age and sex ratio did not seem to differ between patients who had detectable HDV RNA and those who had undetectable HDV RNA. The median follow-up ranges between 36 and 233 months. Data on cirrhosis was available for 647 patients, data on decompensation for 702 patients, data on hepatocellular carcinoma for 770 patients and data on death or liver transplantation for 773 patients. Compared to patients with undetectable HDV RNA, patients with detectable HDV RNA had a higher risk of cirrhosis (OR = 4.3, 95% CI = 2.1–8.8, $p < 0.01$) with high heterogeneity between studies ($p = 0.01$, $I^2 = 71\%$), a higher risk of decompensation (OR = 3.2, 95% CI = 1.7–6.1, $p < 0.01$) with moderate heterogeneity between studies ($p = 0.15$, $I^2 = 43\%$), a higher risk of hepatocellular carcinoma (OR = 2.0, 95% CI = 1.2–3.6, $p = 0.01$) with low heterogeneity between studies ($p = 0.2$, $I^2 = 27\%$) and a higher risk of death or liver transplantation (OR = 3.9, 95% CI = 2.7–5.6, $p < 0.01$) with no heterogeneity between studies ($p = 0.6$, $I^2 = 0\%$).
Conclusion: Patients infected with HBV and HDV who have detectable HDV RNA have a higher risk of liver disease progression including death or the need for liver transplantation than patients with undetectable HDV RNA.

FRI-430

Efficacy and safety of Tenofovir Amibufenamide in the treatment of chronic hepatitis B: a real-world multicenter clinical study

Yaping Li[1], Hongmei Zu[2], Yongmei Lin[3], Guoe Gou[1], Xiaohong Gao[4], Guang-Hua Xu[4], Dandan Cui[1], Shuangsuo Dang[1]. *[1]The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]The Fourth People's Hospital of Qinghai Province, Xining, China; [3]Hanzhong 3201 Hospital, Hanzhong, China; [4]Affiliated Hospital of Yan 'an University, Yan'an, China*
Email: dang212@126.com

Background and aims: The clinical profile of Tenofovir Amibufenamide (TMF) in patients with chronic hepatitis B (CHB) requires further clarification. This study evaluates the real-world effectiveness and safety of TMF and compares it to tenofovir disoproxil fumarate (TDF) in a CHB cohort.
Method: In this multicenter, prospective, real-world cohort study, we recruited 183 eligible patients with CHB who attended the outpatient clinic of the Department of Infection of the 4 sites from August 2021 to August 2022. 183 subjects were stratified into TMF (n = 94) and TDF (n = 89) groups, as well as treatment-naïve (TN) and treatment-experienced (TE) subgroups. We monitored virological response (VR, defined as HBV DNA <20 IU/ml), alanine transaminase (ALT) normalization rates, renal function markers, and lipid profiles.
Results: In the TN cohort, virological response (VR) rates at weeks 24 and 48 for the TMF group were 42.86% and 90.48%, respectively, compared to 60.00% and 83.33% for the TDF group. The differences in VR rates between TMF and TDF were not statistically significant (χ^2 = 3.615, p = 0.057; χ^2 = 1.386, p = 0.239). ALT normalization rates for the TMF group were 84.85% and 90.91% according to local laboratory standards, and 56.82% and 70.45% per AASLD 2018 standards. Corresponding rates for the TDF group were 92.59% and 96.30% (local laboratory standards), and 61.90% and 78.57% (AASLD 2018 standards). These differences were also not statistically significant (χ^2 = 0.230, p = 0.631; χ^2 = 0.744, p = 0.388). Among the treatment-experienced (TE) group, VR rates at weeks 24 and 48 were 65.71% and 82.86%, respectively. The ratios of ALT normalization for the TE group based on local laboratory standards were 86.67% and 93.33%, and according to AASLD 2018 standards, they were 66.67% and 76.67%. The TE group showed a statistically significant difference in ALT normalization following AASLD 2018 standards (z = –2.822, p = 0.005). VR rates for high-level viremia were similar between TMF and TDF groups (χ^2 = 1.635, p = 0.201; χ^2 = 0.601, p = 0.438), however, the TMF group showed a more marked reduction in viral load after 24 weeks. Additionally, TMF was associated with improved renal safety over TDF, with no significant difference observed in blood lipid levels between the two treatments.
Conclusion: TMF is comparable to TDF in the efficacy of CHB treatment with no adverse impact on renal function or lipid levels. For TE patients, transitioning to TMF from other antiviral therapies does not compromise antiviral efficacy.

Email: erwan.voquang@gmail.com

Background and aims: Hepatitis Delta virus (HDV) infection and its clinical impact in people living with chronic hepatitis B virus infection (CHB) have not been well documented in Africa. From a large-scale population-based and hospital-based cohort of CHB patients, we assessed the long-term clinical outcomes of CHB patients with positive HDV serology in The Gambia.
Method: We analyzed CHB patients who were prospectively enrolled in the PROLIFICA cohort study in The Gambia following a large-scale community- and blood bank-based screening intervention and new referral of CHB diagnosis to our liver clinic. All participants had a comprehension liver assessment including fasting Fibroscan, HBV DNA measurement (GeneXpert, Cepheid) and HDV serology (Diasorin, Italy). The primary end point was the survival probability, and the secondary end point was the proportion of patients who had liver disease progression (≥1 stage increase by Fibroscan compared to baseline).
Results: From November 2012 to April 2024, 3, 074 CHB participants were recruited and 2, 504 were screened for HDV. At enrolment, median age was 33 (IQR: 32–45) and 68/2, 504 (12.6%) patients were tested positive for HDV. HDV-positive patients were mainly male (72%), baseline median age 38 (IQR: 32–50), median HBV DNA 176 (10–1, 732), median Fibroscan 8 kPa (5–28), including 34/80 (42.5%) and 17/86 (20%) with cirrhosis and HCC at enrolment, respectively; 6.0% and 3.5% were coinfected with HIV and HCV. Completion of HDV analysis and genotyping are in progress. Multivariate analysis identified positive HDV serology, male sex, HBeAg positivity, HBV DNA >2000 UI/ml and APRI >2 as risk factors associated with cirrhosis (odds ratio: 8.2 (95%CI: 4.1–16.1, $p < 0.01$; odds ratio: 2.6 (CI: 1.6–4.2, $p < 0.01$; odds ratio: 2.6 (CI: 1.4–4.5, $p < 0.01$; odds ratio: 2.4 (CI: 1.6–3.6); $p < 0.01$; odds ratio: 39.4 (CI: 23.2–70.0); $p < 0.01$, respectively). Of 2, 504 patients, 1, 466 patients (58.5%) attended at least 2 follow-up visits. During a median follow-up of 6.0 (range: 2.1–7.5) years, 72 (4.9%) of the 1, 466 patients died of any cause. The 1-, 5- and 7-year cumulative survival probabilities were lower in HDV positive patients (92%, 84%, 84%, respectively) compared to HDV-negative participants (99%, 96% and 94%) ($p < 0.01$). In the whole cohort of CHB patients, age >40 years (HR 8.90, 2.67–29.71), positive HDV serology (HR 6.42, 2·16–19.14) and HCC (hazard ratio [HR] 27.07, 95% CI 9.25–79.24), were independent predictive factors of overall mortality. Compared to HDV-negative patients, development of cirrhosis but not liver fibrosis progression was more frequently observed in HDV-positive patients ($p < 0.02$).
Conclusion: Positive-HDV serology is frequently observed in individuals living with CHB in The Gambia and is associated with a poor prognosis, highlighting urgent efforts for screening and care of HDV infection in Africa.

FRI-432

The concentration of HDV-RNA correlates with the probability of developing clinical events in patients with chronic hepatitis D

Adriana Palom[1,2], Sergio Rodriguez-Tajes[2,3], Ariadna Bono[4], Antonio Madejón[5], Ariadna Rando-Segura[6], Sabela Lens[2,3], Marina Berenguer[2,4], Francisco Javier Garcia-Samaniego[5], Juan Carlos Ruiz-Cobo[1], Ângela Carvalho-Gomes[2,4], Elena Vargas-Accarino[7], Mar Riveiro Barciela[1,2], Rafael Esteban[1], Maria Buti[1,2]. *[1]Liver Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2]Centro de Investigación Biomédica en Red en Enfermedades Hepáticas y Digestivas, Madrid, Spain; [3]Liver Unit, Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain; [4]Hepatology and Liver Trasplant Department, Hospital Universitario y Politécnico La Fe, Valencia, Spain; [5]Liver Unit, Hospital Universitario La Paz, IdiPAZ, Madrid, Spain; [6]Microbiology Department, Clinical Analysis Laboratory, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [7]Liver Unir, Hospital Universitari Vall d'Hebron, Barcelona, Spain*
Email: mariabutiferret@gmail.com

Background and aims: In patients with hepatitis D, the presence of HDV-RNA in serum is associated with disease progression and the development of clinical events. However, it has not been established whether serum HDV-RNA concentrations could predict clinical events, as is the case with hepatitis B. Our aim was to evaluate the relationship between HDV-RNA concentrations and the risk of developing liver events.
Method: Multicenter retrospective-prospective study including all adult anti-HDV positive patients followed for more than 1 year. HDV-RNA was quantified in an initial sample using an in-house PCR technique with a lower limit of detection (LLD) of 600 IU/ml in a centralized laboratory. Patients were visited every 6 months as per normal practice, and clinical events (decompensation, hepatocellular carcinoma, liver transplant, or liver-related death) were collected during follow-up.
Results: A total of 151 subjects were included; 60.9% male, median age 44 (IQR 36–52) years, all HDV untreated, HDV-RNA 15, 000 (IQR 0–518, 000) IU/ml, ALT 48 (IQR 29–87) IU/ml, and 32 (21%) with liver cirrhosis at inclusion. During a median follow-up of 5.5 (2.2–7.0) years, 25 patients (16.5%) experienced at least one clinical event. Baseline HDV-RNA levels were stratified based on a 1-log increase from the LLD of 600 IU/ml. The studied groups were:<600 IU/ml, between 600–6, 000, >6, 000–60, 000, >60, 000–600, 000, and >600, 000 IU/ml, and clinical events were observed in 4% (1/51), 12% (3/18), 20% (5/19), 24% (6/34), and 40% (10/29) of the patients, respectively ($p = 0.003$). Therefore, HDV-RNA concentrations were positively correlated to the presence of clinical events ($p < 0.001$). However, the rate of subjects with normal ALT was negatively correlated with the HDV-RNA concentrations ($p < 0.001$): 82.4% (42/51), 47.1% (8/17), 33.3% (6/18), 26.5% (9/34), and 21.4% (6/28).
When clustering groups comparing those with HDV-RNA between 600–600, 000 IU/ml and those with HDV-RNA >600, 000 IU/ml, the first group was less likely to present clinical events than the latter (14/71 vs 10/29) ($p = 0.097$). Among the 69 patients without liver cirrhosis, no differences in clinical events were observed between patients with HDV RNA 600–600, 000 vs >600, 000 (5/50 vs 4/19, $p = 0.203$) or normal ALT vs increased ALT (19/49 vs 5/19, $p = 0.250$).
From the 24 patients with detectable HDV RNA without cirrhosis and normal ALT, those with 600–600, 000 IU/ml presented less clinical outcomes than those with >600, 000 IU/ml (0/19 vs 2/5) ($p = 0.036$).
Conclusion: The initial concentrations of HDV-RNA positively correlate with the development of clinical events, so their quantification would help predict the risk of clinical outcomes during subsequent follow-up. Moreover, in non-cirrhotic patients with normal ALT, those with initial HDV-RNA levels<600, 000 IU/ml are less likely to present clinical events than those with higher viraemias.

FRI-433

Metabolic dysfunction-associated steatotic liver disease is not independently associated with complete response to oral antiviral treatment in chronic hepatitis B

Juseok Lee[1], Byung Seok Kim[1], Changhyeong Lee[1], Jeong Eun Song[1].
[1]*Department of Internal Medicine, Daegu Catholic University School of Medicine, Daegu, Korea, Rep. of South*
Email: ssong3004@naver.com

Background and aims: The impact of dysfunction-associated steatotic liver disease (MASLD) on treatment response following nucleos (t)ide analogue (NA) treatment for chronic hepatitis B (CHB) patients has not been clearly elucidated. The aim of this study is to investigate the impact of MASLD on complete viral response (CVR) and biochemical response in CHB patients who received NA treatment.
Method: We retrospectively recruited CHB patients receiving NA therapy from January 2014 to December 2020. CHB patients with decompensated cirrhosis or hepatocelluar carcinoma were excluded. All patients were divided into CHB group and CHB with MASLD group according to MASLD diagnostic criteria. Therapeutic response related data were recorded and compared at multiple time points. Kaplan-Meier and Cox regression analyses were utilized to estimate the impact of MASLD on complete virological response (CVR).
Results: A total of 460 patients were enrolled (356 CHB without MASLD, 104 CHB with MASLD). The majority of patients were male (55.3%) and HBeAg-positive (55.2%). In comparison to non- MASLD patients, those with MASLD were more likely to be HBeAg-positive (65.4% vs. 52.2%, p = 0.018), have hypercholesterolemia (22.9% vs. 12.5%, p = 0.009), and present with a higher mean HBV DNA titer (6.56 ± 1.45 vs. 6.26 ± 1.47, p = 0.064). They also had a higher mean BMI (25.3 ± 3.4 vs. 22.9 ± 4.5 kg/m^2, p < 0.001) at baseline. Both groups achieved similar rates of ALT normalization (MASLD vs non-MASLD; 100% vs 99.7%, p = 0.588), and HBsAg seroclearacne (2.9% vs 3.7%, p = 0.707) during the follow-up of up to 65 months. However, MASLD group had lower cumulative rates of CVR at week 96, compared with non- MASLD patients (81.1% vs 91.3%, p = 0.001). In multivariate analyses, MASLD was not independently associated with CVR outcomes, but higher baseline HBV DNA and HBeAg positivity at baseline was negatively associated with achieving CVR.
Conclusion: The presence of MASLD did not negatively affect CHB treatment outcomes of complete virologic response or biochemical response.

FRI-434

High levels of anti-HBc are associated with higher rates of immune control after 48 weeks of treatment with PegIFN alfa-2a in patients with HBeAg-positive chronic hepatitis B

Maria Pfefferkorn[1], Simon Handrick[1], Melanie Maier[2], Cynthia Wat[3], Thomas Berg[1], Florian van Bömmel[1]. [1]*Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany;* [2]*Institute of Medical Microbiology and Virology, Leipzig University Medical Center, Leipzig, Germany;* [3]*Roche Products Ltd, Welwyn, United Kingdom*
Email: Maria.pfefferkorn@medizin.uni-leipzig.de

Background and aims: The clinical relevance of quantitative antibody levels to HBV core antigen (anti-HBc) as a new biomarker for chronic hepatitis B (CHB) was investigated, but observations on the relationship between anti-HBc levels and treatment response were contradictionary. We aimed to investigate the association of anti-HBc levels with other HBV biomarkers and with treatment response to PegIFN alfa-2a.
Method: A total of 132 patients with HBeAg-positive chronic hepatitis B treated with 180 mg/week PegIFN alfa-2a for 48 weeks in three prospective multicenter studies (WV16240, WV16241 and WV19432; Hoffmann-La Roche) were retrospectively analyzed. Patients were analyzed according to week 72 treatment response in three different subgroups: I) patients with (n = 63) or without (n = 69) serological response (SR; defined by HBeAg SC), II) patients with (n = 69) or without (n = 69) virological response (VR; HBV DNA levels <2000 IU/ml) and III) patients with (n = 50) or without (n = 82) combined response (HBeAg SC and HBV DNA levels <2000 IU/ml. Levels of anti-HBc were measured in samples collected at BL, week 12, 24, 48, and 72 using the anti-HBc II Abbott Architect system and the WHO anti-HBc standard.
Results: Patients with anti-HBc titers >4.0 log IU/ml at baseline had in comparison to patients with anti-HBc titers <4.0 log IU/ml a higher chance of achieving SR (59.1% vs. 43%) VR (72.7% vs. 38.2%) and CR (54.5% vs. 28.0%) while significantly lower probabilities (0% for SR, 28.6% for VR and 0% for CR) were demonstrated for low anti-HBc titers at BL (<2.0 log IU/ml). Interestingly, considering the threshold of 2.5 log IU/ml anti-HBc at BL, in patients with higher anti-HBc (>2.5 log IU/ml at BL) HBV RNA levels were significantly lower at week 48 and 72 (5.4 vs. 7.3 logcp/ml at week 72; p < 0.001), respectively.
Conclusion: In line with previous studies, HBeAg-positive patients benefit from higher anti-HBc levels at the beginning of PegIFN alfa-2a therapy and low levels (<2.0 log U/ml) of anti-HBc might be a marker for a low immune response. The association of anti-HBc levels and response to treatment needs to be investigated for other treatments for chronic hepatitis B.

FRI-435

Serological and nucleic acid testing laboratory screening rates for hepatitis delta virus among adult patients in the United States

Robert Wong[1,2], Robert G. Gish[3], Chong Kim[4], Gary Leung[5], Ira Jacobson[6], Joseph K. Lim[7], Marvin Rock[4]. [1]*Stanford University School of Medicine, Stanford, United States;* [2]*VA Palo Alto Healthcare System, Palo Alto, United States;* [3]*Hepatitis B Foundation, Doylestown, United States;* [4]*HEOR-Global Value and Access, Gilead Sciences, Inc., Foster City, United States;* [5]*RWE-Epidemiology, Gilead Sciences, Inc., Foster City, United States;* [6]*NYU Grossman School of Medicine, New York, United States;* [7]*Yale University School of Medicine, New Haven, United States*
Email: chong.kim9@gilead.com

Background and aims: Limited data exist regarding hepatitis delta virus (HDV) testing patterns. This study investigated real-world HDV laboratory screening and follow-up nucleic acid testing (NAT) rates among adult patients in the United States (US).
Method: Quest Diagnostics national laboratory data were used to identify US adults who completed at least one anti-HDV test without prior HDV RNA (RNA) testing from 1/1/2015 to 31/12/2022, in order to describe patterns of follow-up RNA testing and repeat anti-HDV testing. More specifically, among patients who tested positive for anti-HDV (anti-HDV-pos), we: a) identified the proportion of patients who completed follow-up RNA testing; b) examined results of RNA testing from patients who completed two rounds of follow-up RNA testing; and c) identified the proportion of patients who completed follow-up anti-HDV testing and had anti-HDV pos or anti-HDV negative (anti-HDV-neg) results.
Results: A total of 49, 272 patients completed anti-HDV testing without prior RNA testing, among whom 917 (1.9%) then completed an RNA test. Among 908 anti-HDV-pos patients, 268 (29.5%) completed follow-up RNA testing, of whom 95 (35.4%) had detectable RNA. Among the anti-HDV-pos patients with detectable RNA, a subsequent 51 (53.7%) patients had at least one additional RNA test, of whom 47 (92.2%) had detectable RNA and 4 (7.8%) had undetectable RNA. Among the 173 anti-HDV-pos patients with undetectable RNA, a subsequent 41 (23.7%) patients had at least one additional RNA test. Among 48, 364 patients who first tested negative for anti-HDV, 649 patients completed follow-up RNA testing, of whom 5 (0.8%) had detectable RNA. Moreover, of the 908 patients who were anti-HDV-pos on their initial anti-HDV test, 227 (25%) completed a second anti-HDV test of whom 127 (55.9%) tested positive and 100 (44.1%) tested

negative. All 4, 134 anti-HDV-neg patients who completed a second anti-HDV test remained negative.
Conclusion: Analyses of laboratory data from 2015 to 2022 showed that among anti-HDV-pos patients, follow-up HDV RNA testing rates are suboptimal. These data emphasise the utility and importance of NAT testing following anti-HDV results.

FRI-436
Are healthcare professionals appropriately screening for hepatitis delta virus in patients with chronic hepatitis B? Results from an interactive decision support app
Sarah Anderson[1], Jacqueline Meredith[1], Zachary Schwartz[1], Maria Buti[2]. [1]*Clinical Care Options, Reston, United States;* [2]*Hospital Universitario Vall d'Hebron, CIBEREHD del Instituto Carlos III, Madrid, Spain, Barcelona, Spain*
Email: sanderson@clinicaloptions.com

Background and aims: Patient variables that inform hepatitis B virus (HBV) and hepatitis delta virus (HDV) treatment candidacy and selection are complex and interconnected. In deciding whether and how to treat or monitor HBV, healthcare professionals (HCPs) must consider variables including HBeAg, HBV DNA, ALT, fibrosis, bone and renal alterations. In addition, EASL guidelines recommend that *all* people with HBV should be screened for HDV. To aid HCPs in aligning their management decisions with practice guidance, we developed an interactive decision support tool: an app called *Hep B Consult*. In this analysis, we used app results to examine whether HCPs who wanted to follow the EASL guidelines were appropriately working up patients for HBV and HDV.
Methods: In March 2023, Clinical Care Options (CCO) released the *Hep B Consult* app, available as a mobile app and on our website platform. The app enables HCPs to enter patient variables—if known—related to HBV and HDV infection. After the HCP specifies their intended approach, the app presents management recommendations specific to that patient case based on HCP-selected AASLD, APASL, or EASL practice guidance. To determine whether HCPs looking for EASL guidance were properly working up patients with HBV infection and screening for HDV according to EASL guidelines, we examined cases entered between March 3, 2023, and December 8, 2023. In cases where these HCPs marked any patient variables as "unknown" (HBeAg, HBV DNA, ALT, fibrosis, bone and renal alterations, HDV antibodies, HDV RNA), we considered the HCP's workup incomplete. We measured how often HCPs had an incomplete workup and which variables HCPs failed to include.
Results: During the study period, 206 HCPs entered 419 cases after choosing EASL as their preferred HBV guidance. Of the cases entered by HCPs, most were entered by physicians (72.3%), followed by advanced practice nurses (2.4%), and pharmacists (1.2%). Of these cases entered by HCPs who identified their country (n = 212), 61.3% (n = 130) were entered by HCPs from Europe. The highest proportion of cases were entered by HCPs from the United Kingdom (20.8%), followed by Italy (8.0%) and Portugal (6.1%). None of the 419 cases entered was missing HBeAg, HBV DNA, ALT, fibrosis assessment, or bone or renal data. However, *HDV antibodies* were not screened in 25.2% (106/419) of cases. Of the cases entered by HCPs from European countries, HDV antibodies were not screened in 14.6% (19/130). Of the 78 cases where the patient was HDV antibody positive, 8.9% did not have follow-up screening for *HDV RNA*.
Conclusion: HCPs who used the *Hep B Consult* app to enter a patient case demonstrated a comprehensive patient workup *with the exception of HDV status*. This behavior is not aligned with the EASL HDV guidelines, which recommend screening all people who are HBsAg positive for HDV at least once. HCPs need education on the importance of screening all people with HBV for HDV.

FRI-437
Poor Performance of FIB-4 in Fibrosis Prediction for Chronic Hepatitis B Patients with Metabolic Dysfunction-Associated Liver Disease in Daily Clinical Practice
Fadi Abu Baker[1], Saif Abu Mouch[1], Dorin Nicola[1], Randa Taher[1]. [1]*Technion Faculty of Medicine, Haifa, Israel*
Email: Fa_fd@hotmail.com

Background and aims: The coexistence of chronic hepatitis B (CHB) and metabolic dysfunction-associated liver disease (MASLD) has gained recognition, but the diagnostic accuracy of non-invasive markers in this context remains underexplored. This study aimed to evaluate the utility of the FIB-4 index for fibrosis prediction in CHB patients and investigate its performance in the distinct subgroup of CHB-MASLD.
Method: A prospective study from 2021 to 2022 included 109 CHB and 64 CHB-MASLD patients. All underwent liver stiffness measurement via ShearWave Elastography (SWE) and FIB-4 calculation. MASLD criteria were defined, creating CHB-alone and CHB-MASLD groups. Statistical analyses included t-tests, ROC curves, and correlation assessments.
Results: No significant age, gender, or ethnicity differences were observed between CHB and CHB-MASLD groups. CHB-MASLD patients exhibited higher BMI, increased prevalence of obesity, dysglycemia, and dyslipidemia. HBeAg negativity and nucleoside/tide treatment rates were comparable. FIB-4 and APRI scores were elevated in CHB-MASLD. ROC analysis revealed an AUC of 0.86 for FIB-4 in CHB, with an optimal cutoff of 1.95. Subgroup analysis by BMI showed consistent FIB-4 performance. In CHB-MASLD, the ROC curve showed an AUC of 0.61 (p = 0.12) indicating non-significance.
Conclusion: Our study affirms FIB-4's robust performance in predicting fibrosis for CHB patients across varied BMI profiles. Yet, challenges surface when applying FIB-4 to those with concurrent CHB and MASLD. These limitations stress the urgency for refined fibrosis prediction tools, essential for navigating the complex interplay of viral and metabolic factors in the CHB-MASLD population.

FRI-438
Real-world clinical data-driven modelling on the initiation time of peripartum antiviral prophylaxis among pregnant women with chronic hepatitis B virus infection
Naijuan Yao[1], Shihao He[2], Jing Wang[1], Wenting Zhong[1], Mingwang Shen[2], Tianyan Chen[1]. [1]*Department of Infectious Disease, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, Shaanxi, China;* [2]*China-Australia Joint Research Center for Infectious Diseases, School of Public Health, Xi'an Jiaotong University Health Science Center, Xi'an, Shaanxi, China*
Email: chentianyan@xjtufh.edu.cn

Background and aims: Recommendations for when to initiate antiviral prophylaxis for pregnant women with chronic hepatitis B virus (HBV) infection vary in the guidelines. We aim to explore the timing of antiviral prophylaxis for interrupting mother-to-child transmission (MTCT) of HBV in pregnant women with high viral loads using a mathematical model.
Method: We collected the real-world clinical data of 328 treated pregnant women with chronic HBV infection from July 2010 to December 2020 in the First Affiliated Hospital of Xi'an Jiaotong University. We developed a mathematical model to describe the viral kinetics of how HBV DNA levels decrease after antiviral prophylaxis. We calculated how long it would take exactly to decrease maternal viral load below a threshold of 5.3 $\log_{10}$ IU/ml, at which the MTCT risk was negligible (0.04%), to avoid the usually overestimated time needed due to less frequent DNA testing. We derived the prophylaxis initiation time by using the childbirth gestational week of each woman to subtract the above time needed to reach the threshold value. We performed a sensitivity analysis to explore how a lower threshold of 4.0 $\log_{10}$ IU/ml (corresponding to a 0.0% risk of MTCT) would affect the results.

Results: The median time for all 328 pregnant women with chronic HBV infection to reduce HBV DNA levels below the threshold of 5.3 $\log_{10}$ IU/ml was 4.16 (range: 0.18–12.81) weeks, and it should be initiated to prophylaxis no later than 35.14 (range: 25.19–41.42) weeks. Particularly, prophylaxis initiation time should be no later than 33.93 (range: 25.19–39.45), 35.51 (range: 28.59–39.80), and 36.16 (range: 28.25–41.42) weeks for those women with viral loads >8.0 $\log_{10}$ IU/ml, >7.0 to ≤8.0 $\log_{10}$ IU/ml, and >5.3 to ≤7.0 $\log_{10}$ IU/ml, respectively. If the threshold value decreased to 4.0 $\log_{10}$ IU/ml, the prophylaxis initiation time should be no later than 33.16 (range: 21.69–39.25) gestational weeks.
Conclusion: It is recommended that pregnant women with high HBV DNA level >8.0 $\log_{10}$ IU/ml should initiate antiviral prophylaxis no later than 25.19 gestational weeks to ensure enough safety. To further prevent MTCT of HBV infection and avoid immunoprophylaxis failures for these women, antiviral prophylaxis should be initiated no later than 21.69 gestational weeks.

FRI-439
An online web-based calculator accurately diagnoses immune tolerant phase in chronic HBV-infected patients
Chi Zhang[1], Yi-Qi Liu[1], Hong Zhao[1], Gui-Qiang Wang[1]. [1]*Peking University First Hospital, Beijing, China*
Email: zhangcdoctor@126.com

Background and aims: There were different antiviral treatment strategies and prognoses between immune tolerant (IT) and non-IT in chronic hepatitis B (CHB) patients. However, existing non-invasive diagnostics were not precision. We aimed to explore new non-invasive models for diagnosing IT and assessed the risk of hepatocellular carcinoma (HCC) in IT patients.
Method: We included treatment-naive CHB patients with liver biopsy who serological met the diagnostic criteria of IT (HBeAg-positive, HBV DNA >5 lgIU/ml, normal ALT). This study included four parts: in step 1, we described the clinical characteristics of IT patients. In step 2, we evaluated the value of non-invasive markers recommended by the guidelines for the diagnosis of IT. In step 3, a new model for the diagnosis of IT with non-invasive markers were developed and validated. In step 4, to assess the risk of developing HCC using 15 HCC prediction models for IT and non-IT.
Results: According to the criteria for the diagnosis of IT by WHO 2015 guidelines, 196 patients were finally included in this study, of which 83 were liver biopsy-proven IT. In the IT group age, qAnti-HBc, ALT, AST and LSM were lower. While, HBV DNA and HBsAg were higher. The risk of non-IT increased 1.2-fold and 3.92-fold in patients aged 30–40 (95%CI 1.00–4.81, P = 0.049) and >40 years (95%CI 2.28–10.60, P < 0.001), respectively, compared to those aged <30 years. Compared to HBV DNA >8 lg IU/ml, the risk of non-IT was increased 4.33-fold and 9.96-fold in patients 7–8 lg IU/ml (p = 0.001) and<8 lg IU/ml (p < 0.001), respectively. The accuracy of non-invasive marker combinations for the diagnosis of IT did not exceed 0.800, whether in accordance with EASL2017/APASL2015, AASLD2018 or CHINA2019 criteria (0.709, 0.658 and 0.765, respectively). Using univariate analysis, LASSO regression and multivariate analysis, we created a CALA model (qAnti-HBc, LSM, AST, ALP) to diagnosing IT. The AUROC of CALA model reached 0.890 and 0.892 in training and validation sets, respectively, which were significantly higher than APRI, FIB-4 and LSM. For clinical convenience, we have made CALA model in an online web-based calculator and QR code.We included 15 hepatitis B related HCC prediction models (REACH-B, mREACH-BI, mREACH-BII, GAG-HCC, CU-HCC, LSM-HCC, PAGE-B, mPAGE-B, NGM1-HCC, NGM2-HCC, CAMD, RWS-HCC, AASL-HCC, REAL-B, aMAP) by searching the PubMed database. The risk of HCC was significantly lower in biopsy-proven IT than in biopsy-proven non-IT population (all P < 0.01). Subsequently, the CALA model was used to differentiate IT and the same results were obtained as those confirmed by liver biopsy (all P < 0.01, except CU-HCC model P = 0.066).
Conclusion: Online web-based calculator of CALA model can accurately and conveniently diagnose IT. Patients with liver biopsy or CALA model-proven IT were at a lower risk of developing HCC.

FRI-440
HBV precore and basal core promoter mutations exert direct cytopathic effect in humanized mice
Fengmin Lu[1], Guixin Li[2], Danli Yang[1], Hongsong Chen[2]. [1]*Department of Microbiology and Infectious Disease Center, School of Basic Medical Sciences, Peking University, Beijing, China, Beijing, China;* [2]*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Disease, Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis, Beijing, China, Beijing, China*
Email: lu.fengmin@hsc.pku.edu.cn

Background and aims: Basal core promoter (BCP, A1762T/G1764A) and precore (PC, G1896A) combined mutations occur increasingly with age in chronic HBV-infected patients. The association of the combined mutations and disease progression remains ambiguous. This study aimed to explore the effects of BCP+PC combined mutations on pathogenicity.
Method: Human hepatocyte chimeric mice were infected HBV by tail-vein injection with wild-type or BCP + PC mutant viral suspension. Liver samples of mice were collected at pre-designed point. Paraffin liver sections were used either for Hematoxylin and eosin (HandE) or immunohistochemistry (IHC) staining techniques. Total RNA of the liver tissues was extracted and RNA sequencing or RT-qPCR was conducted.
Results: HandE staining revealed that infection with HBV harboring BCP + PC mutations induced more extensive and severe degeneration of hepatocytes, as well as cytoplasmic vacuolation, paralleled with enhanced accumulation of core proteins. However, no significant change of intrahepatic HBsAg was observed in BCP + PC group. Next, transcriptomic analysis was carried out using RNA-Seq to differentiate the molecular characteristics in livers infected with WT and BCP + PC mutant strains. Gene set enrichment analyses implied that BCP + PC mutants might exacerbate hepatocyte injury by inducing endoplasmic reticulum (ER) stress, unfolded protein response, and activating tumor necrosis factor pathway. We also found that the intrahepatic mRNA level of glucose-regulated protein 78, XBP1, activating transcription factor 4, C/EBP-homologous protein, growth arrest and DNA damage 34, ER sulfhydryl oxidase 1 were potently increased in chimeric mice infected with BCP + PC mutants, suggesting the enhanced ER stress and reactive oxygen species production. Moreover, IHC staining of 8-hydroxyguanine (8-OHdG), a marker of oxidative DNA damage, demonstrated the presence of 8-OHdG-positive cells in BCP + PC groups, whereas few were detected in the WT group.
Conclusion: BCP and PC combined mutations might induce severe hepatocyte damage via aberrant core protein expression in human hepatocyte chimeric mice.

Email: aldo.marrone@unicampania.it

Background and aims: Concomitant occurrence of HBV infection and metabolic dysfunction-associated steatotic liver disease (MASLD) has increased worldwide. Patients with chronic hepatitis B (CHB) and MASLD potentially have different pathophysiological conditions than those with MASLD alone. Experimental data suggest that MASLD may inhibit viral replication; conversely, the virus may exert effects on glycid and lipid metabolism. We aimed to evaluate the prevalence of MASLD in patients with CHB and analyze the associated factors.
Method: We conducted a cross-sectional observational study on HBeAg negative CHB Italian patients, enrolled in 2021–2023. The exclusion criteria were HCV and HDV coinfections, significant alcohol consumption, history or active hepatocellular carcinoma, decompensated cirrhosis, contraindications to transient elastography. Demographic, anthropometric, metabolic, laboratory and virological parameters were evaluated in the population. Liver fibrosis was evaluated non-invasively by FibroScan® and Fibrosis-4 Index, while SLD was assessed by ultrasonography and controlled attenuation parameter (CAP). Population was divided into two groups setting a threshold at CAP ≥248 dB/m to define hepatic steatosis. Logistic regression model was used to identify determinants associated with MASLD. Regression analysis of steatosis based on CAP score and quantitative HBV DNA was performed in HBeAg negative chronic infection subgroup, using Pearson's method.
Results: Study included 149 patients: 58.4% males, with an average age of 57.5 ± 12.3 years; 102/149 (68%) receiving antiviral therapy, among these 48% entecavir and 52% tenofovir. MASLD was observed in 48.3%; impaired fasting blood glucose or diabetes were present in 38.9%. Univariable analysis demonstrated a positive association of several metabolic parameters with MASLD (triglycerides, metabolic syndrome, fasting blood glucose, diabetes, obesity, body mass index-BMI), while inverse relationship between female sex, cirrhosis, HBeAg negative chronic infection and MASLD was revealed. At multivariable logistic regression analysis female gender was linked to a diminished likelihood of MASLD (OR: 0.14; 95% CI: 0.05–0.40; p = 0.0003), while both higher BMI (OR 1.41; 95% CI: 1.21–1.65; p < 0.0001) and diabetes (OR 6.81, 95% CI: 1.28–36.1, p = 0.024) was correlated with an elevated likelihood of MASLD. Regression analysis didn't show a statistically significant correlation between CAP score and HBV-DNA in HBeAg negative chronic infection subgroup (r = −0.23; p = 0.13).
Conclusion: The prevalence of MASLD by CAP evaluation in patients with CHB observed in our study was similar to that reported by previous studies. Diabetes and BMI represent the only metabolic factors associated with MASLD. MASLD in CHB patients is influenced more by obesity, insulin resistance and female sex hormones than by viral features.

FRI-442

Disease progression and persistent alanine aminotransferase elevation in HCV/HIV persons after DAA-related eradication: role of HBV and HDV co-infections

Roberto Rossotti[1], Alessandro Tavelli[2], Vincenzo Malagnino[3], Valentina Svicher[4], Eugenia Quiros-Roldan[5], Alessandra Bandera[6], Francesco Maria Fusco[7], Marco Rivano Capparuccia[8], Giovanni Battista Gaeta[9], Valentina Mazzotta[10], Massimo Puoti[11,12], Antonella D'Arminio Monforte[2]. *[1]ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; [2]ICONA Foundation, Milan, Italy; [3]Department of Medicine of Systems, University of Rome Tor Vergata, Rome, Italy; [4]Department of Experimental Medicine, University of Rome Tor Vergata, Rome, Italy; [5]University of Brescia and ASST Spedali Civili of Brescia, Department of Infectious and Tropical Diseases, Brescia, Italy; [6]Infectious Disease Unit, Department of Internal Medicine, Fondazione IRCCS Ca, Granda, Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milano, Milan, Italy; [7]UOC Infezioni Sistemiche e dell'Immunodepresso, AORN Ospedali dei Colli, P.O. Email: roberto.rossotti@ospedaleniguarda.it

Background and aims: Direct-acting antivirals (DAA) allow to achieve sustained virological response (SVR) also in HIV and especially HBV co-infection, whose replication is generally suppressed by HCV with consequent risks of HBV reactivation after eradication. Few data are available about triple/quadruple HIV/HCV/HBV ± HDV co-infected individuals (3/4CoInf-i) with SVR. Aim of this study is to compare ALT normalization and severe liver-related events in HIV/HCV co-infected vs. HIV/HCV with occult B infection (OBI) vs. 3/4CoInf-i after HCV eradication.
Method: Study population: all HIV/HCV co-infected individuals with available HBV serology enrolled in ICONA/HepaICONA cohorts who achieved SVR after DAAs. Standard survival analysis was used to estimate ALT normalization (i.e., two consecutive values below 42 for men and 30 UI/L for females) and two composite clinical outcomes: the first included liver-related events (hepatocellular carcinoma, hepatic decompensation, transplantation, death) in individuals with and without cirrhosis (CO1); the second evaluated only non-cirrhotics who developed a FIB4 increase >3.25 in addition to CO1 (CO2). Univariate/multivariable Cox regression analyses were performed to assess variables associated to these outcomes.
Results: The analysis included 1, 182 individuals: 476 HIV/HCV, 650 HIV/HCV + OBI, 56 3/4CoInf-i (HDV serology was available for 33 subjects with 15 positivity). The 3/4CoInf-i had significantly higher proportion of cirrhotics (38.3%) and lower CD4 count (589 cell/mmc, IQR 409–867) and all received ART regimens with anti-HBV activity. This group was associated with lower likelihood to normalize ALT (aHR 0.67, 95%CI 0.47–0.97, p = 0.035) but, when HDV co-infection was included in the model, only the quadruple infection retained significance (aHR 0.20, 95%CI 0.05–0.82, p = 0.025).
We observed 54 events for CO1 and 104 for CO2. The adjusted models found that age and male sex were positively associated to both CO1 and CO2, while CD4 count was protective for the two outcomes. The 3/4CoInf-i group was not associated with CO1 or CO2.
Conclusion: Age, male sex and CD4 have an impact on disease progression greater than the presence of triple or quadruple infection under active anti-HBV regimens. The 3/4CoInf-i group achieves normal ALT values less commonly after SVR, but this outcome is mediated by HDV. A wide antiviral combination is essential to maintain liver function.

FRI-443

Compassionate use of REP 2165-Mg in chronic HBV/HDV patients with progressive liver disease and failure to previous pegIFN therapy

Gheorghe Placinta[1], Victor Pantea[1], Lilia Cojuhari[1], Valentin Cebotarescu[1], Michel Bazinet[2], Andrew Vaillant[2]. *[1]Nicolae Testemițanu State University of Medicine and Pharmacy, Chișinău, Moldova; [2]Replicor Inc., Montreal, Canada*
Email: availlant@replicor.com

Background and aims: REP 2165 is an analog of REP 2139 no longer in development with identical activity to REP 2139 in HBV and HDV in clinical studies (achieving HBV functional cure and HDV cure) but with weaker liver accumulation. REP 2165-Mg drug product from the REP 401 study is being deployed to meet international demand for compassionate access to NAP therapy.

Method: Prior to REP 2165-Mg treatment, two chronic HBV/HDV Caucasian patients (1: female 46 y.o. and 2: male 51 y.o.) with rapid progression of liver disease (F3 fibrosis) received therapy with TDF + pegIFN. Patient 1 completed 48 weeks of pegIFN with HDV RNA TND (no HBsAg response) with HDV rebound after removal of pegIFN. After 50 weeks of pegIFN, patient 2 had only achieved a 1 log decline in HDV RNA (no HBsAg response). Existing TDF therapy in both patients was supplemented with weekly IV infusion of 500 mg REP 2165-Mg and 180 µg of pegIFN (pegIFN was uninterrupted in patient 2) scheduled for 48 weeks. Safety and biochemical response were monitored weekly and virologic response every 4 weeks using standard assays for quantitative HBsAg (LLOQ 0.05 IU/ml) and anti-HBs (cutoff for seroconversion 10 mIU/ml), HBV DNA (LLOQ 10 IU/ml) and HDV RNA (LLOQ 10 IU/ml).
Results: Patients 1 and 2 have completed 28 and 30 weeks of combination therapy. IV infusion of REP 2165-Mg in both patients was accompanied by fever and chills requiring supportive therapy for the first 4 weeks. REP 2165-Mg dosing was reduced to 250 mg QW after week 12 due to rapid elimination of HDV RNA. Administration since week 4 was asymptomatic with no supportive therapy and no other AEs have been observed. Patient 1 has experienced three discrete ALT flares during therapy (3× baseline) and patient 2 experienced ALT elevation starting at week persisting at 3× baseline from week 12 onward. ALT flares were otherwise asymptomatic with no changes in liver synthetic function. Patient 1 achieved HDV RNA loss persistent since week 12. HBsAg has declined 1.79 log from baseline (currently 136 IU/ml). Anti-HBs seroconversion has persisted since week 16 (currently 130 mIU/ml). Patient 2 achieved HDV RNA loss persistent since week 8. HBsAg has declined 4.5 log from baseline (currently 0.14 IU/ml). Anti-HBs seroconversion has persisted prior to week 12 (currently 130 mIU/ml).
Conclusion: Although REP 2165-Mg is no longer in clinical development, it demonstrates excellent safety and efficacy against HBV and HDV infection in patients with advanced liver disease with prior pegIFN failure. These results confirm previous clinical data, expand the database of NAP compassionate use and inform on the design of upcoming phase IIA studies.

An initial study of geospatial approach for molecular epidemiology of hepatitis B virus in Indonesia: tale from two regions

Sri Jayanti[1], Turyadi Turyadi[1], Nu'man AS Daud[2,3], AM Luthfi Parewangi[2,3], Rini Rachmawarni Bachtiar[2,3], Irda Handayani[4], Rina Masadah[5], Agustiningsih Agustiningsih[1], Korri Elvanita El Khobar[1], Muhammad Nasrum Massi[6], David Handojo Muljono[3,7], Caecilia Sukowati[1,8]. *[1]Eijkman Research Centre for Molecular Biology, National Research and Innovation Agency of Indonesia, Jakarta, Indonesia; [2]Department of Internal Medicine, Dr. Wahidin Sudirohusodo Hospital, Makassar, Indonesia; [3]Department of Internal Medicine, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia; [4]Department of Clinical Pathology, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia; [5]Department of Pathology Anatomy, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia; [6]Department of Microbiology, Faculty of Medicine, Universitas Hasanuddin, Makassar, Indonesia; [7]Faculty of Medicine and Health, University of Sydney, New South Wales, Australia; [8]Hepatocellular Carcinoma Unit, Italian Liver Foundation ONLUS, Trieste, Italy*
Email: srijayanti.arsan@gmail.com

Background and aims: The complexity of the Hepatitis B Virus (HBV) genetic makeup shows variations across different geographical regions, and specific HBV genotypes are associated with distinct clinical implications and treatment responses. While previous studies have identified predominant genotypes, there is a notable lack of a comprehensive geospatial evaluation of hepatitis B genotypes in Indonesia. This emphasizes the need for thorough investigations into the prevalence of hepatitis B categorized by genotype in different regions.
Method: In our study, we utilized a geospatial approach to analyze the regional molecular epidemiology of HBV genotypes in addition to the determination of HBV subtypes and phylogenetic analysis of genotypes. Two hundred and seventy-eight HBV isolates and their clinical data were obtained from chronic hepatitis B patients located in two distant regions, DKI Jakarta and South Sulawesi, representing western and eastern parts of Indonesia, respectively. HBV surface antigen subtypes (*adw, adr, ayw*, or *ayr*) were determined using deduced amino acid sequences 122 and 160 in the 'a' determinant region. HBV genotype was determined from DNA sequences of the S gene of HBV DNA subjected to phylogenetic analysis using standard reference sequences. Patients' data were characterized according to demographics, genotype likelihood phylogeny, and geospatial hotspot analysis using Getis-Ord Gi* statistics.
Results: Demographic data showed in Jakarta, the predominant HBV subtypes were 73.7% *adw*, 24.2% *adr*, and 2.1% *ayw*, with no detection of *ayr*. In South Sulawesi, the subtype distribution is more balanced, with 42.9% *adr*, 32.1% *adw*, 21.4% *ayw*, and a minor presence of 3.6% *ayr*. HBV isolates from DKI Jakarta were dominated by genotype B while South Sulawesi was genotype C ($p < 0.0001$). Geospatial analysis uncovered a higher prevalence of genotype C in the northern area of DKI Jakarta, contrasting with a more evenly spread occurrence of genotype B. Meanwhile, the distribution of HBV genotypes B and C in South Sulawesi was largely distributed across the region. Among these two regions, North Jakarta and Makassar appeared as significant hotspot cities for both genotype B and genotype C.
Conclusion: This early study indicates the distinct pattern in hepatitis B molecular epidemiology, emphasizing the necessity for a thorough study of the geospatial distribution of HBV genotypes in Indonesia.

Efficacy and safety of tenofovir alafenamide fumarate in preventing HBV vertical transmission in high maternal viral load: a multi-centre, prospective cohort study

Xingfei Pan[1], Fang He[2], Xujing Liang[3], Jiangxia Qin[4], Yanqiu Li[5], Xueting Ou[1], Zicong Liang[1], Panpan Zhai[1], Liyang Zhou[1], Xiaoping Tang[6]. *[1]The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [2]The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [3]The First Affiliated Hospital of Jinan University, Guangzhou, China; [4]Huadu Maternal and Child Health Hospital of Guangzhou, Guangzhou, China; [5]Panyu Maternal and Child Care Service Centre of Guangzhou, Guangzhou, China; [6]Guangzhou Eighth People's Hospital, Guangzhou Medical University, Guangzhou, China*
Email: panxf0125@163.com

Background and aims: Prevention of mother-to-child transmission (MTCT) is a key intervention to reduce the prevalence and burden of HBV. Few efficacy and safety data are published regarding tenofovir alafenamide fumarate (TAF) administered during pregnancy. We designed a multi-centre, prospective cohort study to evaluate efficacy and safety of TAF in pregnant women with chronic HBV infection during mid to late pregnancy.
Method: We enrolled pregnant women with HBV DNA levels >200 000 IU/ml. They were randomized to receive TAF or tenofovir disoproxil fumarate (TDF) from 24–35 weeks of gestation until

delivery. All infants received HBV immune prophylaxis as planned. Primary end points were maternal HBV DNA reduction at delivery and infant's hepatitis B surface antigen (HBsAg) positivity at 7 months. Secondary end points were rates of adverse events and defects in infants.

Results: From 1 June 2021 to 31 January 2023, 168 mothers were enrolled from the Third Affiliated Hospital of Guangzhou Medical University, the First Affiliated Hospital of Jinan University, Huadu Maternal and Child Health Hospital of Guangzhou, and Panyu Maternal and Child Care Service Centre of Guangzhou. Baseline characteristics were comparable between 2 groups. In TAF group, 88 mothers were enrolled and 94 infants were born (six pairs of twins). Mean maternal age, gestational age, alanine aminotransferase (ALT) level and HBV DNA load at baseline were 30.2 ± 4.3 years, 28.6 ± 2.4 weeks, 22.4 ± 15.6 U/L and 7.0 ± 1.1 log10 IU/ml, respectively. Twenty (22.7%) cases were of in vitro fertilization, 20 (22.7%) cases had anemia, and 5 cases (5.7%) had gestational diabetes. In TDF group, 80 mothers were enrolled and 83 infants were born (one set of triplets and one pair of twins). Mean maternal age, gestational age, ALT level and HBV DNA load were 30.5 ± 4.4 years, 28.3 ± 2.3 weeks, 31.3 ± 47.6 U/L and 7.1 ± 1.0 log10 IU/ml, respectively. Eleven (13.8%) cases were of in vitro fertilization, 18 (22.5%) cases had anemia, and 4 (5%) cases had gestational diabetes. The median duration of treatment was 10 (1–16) and 11 (3–15) weeks in TAF and TDF groups, respectively. The serum HBV DNA load was reduced by 3.5 ± 1.1 and 3.6 ± 1.2 log10 IU/ml at delivery in TAF and TDF groups with no statistical difference between groups (p = 0.644). None of infants were HBsAg positive at 7 months of age. Neither mothers nor infants experienced any serious adverse events during following-up. Seventeen (19.3%) maternal complications (mainly preterm labor and premature rupture of membranes) in TAF group and 12 (15%) in TDF's (p = 0.460). Five (5.3%) TAF and 5 (6.0%) TDF cases had fetal intrauterine distress (p = 0.839). None of the babies had any congenital defects. There was 1 case of delayed fetal growth and development in both groups and 1 case of slow fetal growth in TDF group during the follow-up.

Conclusion: TAF is as effective and safe as TDF in interrupting MTCT in both mothers and infants.

WED-391

Long-term virological and clinical outcomes of patients with HDV-related compensated cirrhosis treated with bulevirtide monotherapy for up to 120 weeks: a retrospective multicenter european study (save-d)

Background and aims: Bulevirtide (BLV) has been approved for treatment of chronic hepatitis D virus (HDV) infection in Europe in 2020, however, long-term real-life effectiveness and safety data in large cohorts of HDV patients with cirrhosis treated beyond week 48 are lacking.
Method: Consecutive HDV patients with compensated cirrhosis starting BLV 2 mg/day sc since September 2019 were included in a retrospective multicenter real-life European study (SAVE-D). Clinical, biochemical, virological features and liver-related events were collected. Virological (HDV-RNA undetectable or ≥2-log decline *vs.* baseline), biochemical (ALT <40 U/L), combined response (biochemical + virological) and adverse events were assessed. HDV-RNA was quantified locally.
Results: 243 patients receiving BLV monotherapy up to 120 weeks [median follow-up: 72 (range 24–120) weeks] were included: age 49 (IQR 39–58) years, 60% men, ALT 80 (55–130) U/L, liver stiffness measurement (LSM) 18.2 (13.0–26.2) kPa, platelets 94 (68–146) G/L, 100% CPT score A, 52% with varices, 10% HIV-positive, 11% with a history of ascites, 6% with active HCC, 92% on NUC. Baseline HDV-RNA and HBsAg levels were 5.3 (3.4–4.1) log IU/ml and 3.8 (4.1–6.5) log IU/ml, respectively. Virological responses at W24, W48, W72, W96, W120 were 52%, 66% 70%, 77% and 90%, respectively, while HDV RNA undetectability was achieved by 18%, 31%, 42%, 47%, and 52% of patients. Biochemical and combined responses were 53%, 62%, 63%, 65%, 71%, and 33%, 45%, 50%, 51% and 67%, respectively. Patients with <1 log HDV-RNA decline vs. baseline declined from 23% at W24 to 7% at W96. Responses were similar in HIV positive and negative patients. AST, GGT, albumin, IgG and LSM values significantly improved throughout treatment (LSM baseline 18.2 kPa ⋄ 10.0 kPa W120). Lower baseline HDV-RNA was the only predictor of HDV-RNA undetectability at week 48 (HR 0.75; 95% CI 0.60–0.94, p = 0.01). Bile acids significantly increased, 8% patients reported mild and transient pruritus, 3% injection site reactions. Overall, 19 (8%) patients discontinued treatment for the following reasons: grade 3 maculopapular rash (n = 1), non-compliance (n = 1), long-term HDV-RNA undetectability (n = 2), virological non-response (n = 3), lost to follow-up (n = 7); in additional 5 patients, add-on PegIFN to BLV monotherapy was performed. The W120 cumulative incidence of de-novo HCC and decompensation was 4.2% (95% CI 2–7%) and 3.4% (95% CI 1–6%), respectively. 11 patients underwent liver transplantation (HCC n = 9; decompensation n = 2) and 4 died of BLV-unrelated causes (sepsis, pneumonia, HCC, intestinal infarction).
Conclusion: BLV 2 mg/day monotherapy up to 120 weeks was safe and effective in patients with HDV-related compensated cirrhosis. Virological and clinical responses continued to increase during long-term BLV therapy. Liver-related complications were rare.

Email: ben.da@gilead.com

Background and aims: Patients with chronic HDV (CHD) treated with bulevirtide (BLV) in the Phase 3 study MYR301 showed superior responses at week (W) 48 vs controls based on the combined response end point of virologic response (VR; ≥2 $\log_{10}$ IU/ml decline from baseline [BL] or undetectable HDV RNA) and ALT normalization. Recent sub analyses has shown that ALT improvement often occurs discordant of VR with BLV. We now explore the relationship between virologic, biochemical, and histologic change through 48W in MYR301.
Method: In MYR301, patients were randomized 1:1:1 to 144W of BLV 2 mg or 10 mg or control (48W no BLV followed by 96W of BLV 10 mg), with an additional 96W of follow-up after the end of treatment. Liver biopsy was performed per study protocol at BL and W48 in the absence of contraindications. This analysis focused on the patients with paired biopsies. Viral response categories at W48 included VR, partial response (PR; ≥1 but <2 $\log_{10}$ IU/ml) or non-response (NR; <1$\log_{10}$ IU/ml). Histologic parameters included histologic activity index (HAI; 0–18), HAI category (0–4), and Ishak fibrosis score (0–6). Improvement in HAI or fibrosis was defined as ≥1 point. Histological improvement was defined as ≥2 point improvement in HAI with no worsening of fibrosis. The evolution and correlation of laboratory, virologic, and histologic parameters across groups was examined.
Results: Of the 150 randomized patients, 83 (55%) had paired biopsy data: 25-BLV 2 mg, 31-BLV 10 mg, and 27-control. At BL (n = 83), mean age 42 years, 52% males, 84% White, 33% with compensated cirrhosis and 61% were on concomitant nucleos (t)ide analogue therapy. Mean HDV RNA and median ALT, HAI, and Ishak fibrosis score was 5.1 $\log_{10}$ IU/ml, 92 U/L, 9, and 2. At W48, 80% (45/56), 11% (6/56), and 9% (5/56) of patients treated with BLV achieved VR, PR, and NR while no control achieved VR. Similar median change in ALT U/L was observed across viral response groups: VR, −51; PR, −56; NR, −64; which was superior compared to control, −11. ALT normalization occurred in most with VR (69%, 31/45) and PR (67%, 4/6) but also occurred in 1 with NR (20%, 1/5) and 2 control (7%, 2/27). Decrease in ALT was observed in 89% (50/56) of BLV treated patients (including all patients with PR (n = 6) and NR (n = 5)); of those with ALT decrease, 80% (40/50) also had HAI improvement. A higher likelihood of improvement in HAI category and a greater decrease in median HAI from BL was observed with VR: 69% (31/45), – 4 and PR: 83% (5/6), – 3 compared to NR: 20% (1/5), 0 and control: 30% (8/27), – 1. ALT normalization did not have a clear correlation with the degree of HAI improvement. Improvement in fibrosis occurred in VR: 58% (26/45), PR: 33% (2/6), NR: 25% (1/4), and control: 30% (8/27). Histological improvement occurred in VR: 69% (31/45), PR: 83% (5/6); NR: 25% (1/4); and control: 33% (9/27).
Conclusion: Improvement in liver histology is observed in most patients with CHD after 48 weeks of BLV monotherapy.

WED-393

Association between post-treatment ALT elevation and subsequent hepatitis B surface antigen seroclearance in chronic hepatitis B patients stopping nucleos (t)ide analogue therapy

Yao-Chun (Holden) Hsu[1], Ying-Nan Tsai[2], Jia-Ling Wu[3], Cheng-Hao Tseng[4], Yi-Ling Wu[2], Shang-Chen Tseng[2], Chih-Lung Hung[2], Jaw-Town Lin[2]. *[1]E-Da Hospital, Kaohsiung; [2]E-Da Hospital, Kaohsiung, Taiwan; [3]National Cheng Kung University, Tainan, Taiwan; [4]E-Da Cancer Hospital, Kaohsiung*
Email: holdenhsu@gmail.com

Background and aims: Serum alanine aminotransferase (ALT) frequently rises after chronic hepatitis B (CHB) patients discontinue nucleos (t)ide analogue (NA). ALT elevation was presumed to be conducive of hepatitis B surface antigen (HBsAg) seroclearance but supporting or refuting evidence was lacking. We aimed to clarify the association between ALT elevation and HBsAg seroclearance following NA cessation.
Method: This is a retrospective, multi-center cohort study based on reviewing all CHB patients who had discontinued NA after being treated for one year or longer between April 01, 2004 and May 24, 2022. Patients with malignancy, hepatic insufficiency, viral coinfections, or organ transplantation were excluded. The primary outcome was the association between ALT flares, defined as ALT >5 times the upper limit of normal (ULN) and HBsAg seroclearance after NA cessation. The incidence of HBsAg seroclearance was estimated using the competing risk analysis to account for informative censoring by retreatment. Time-dependent sub-distribution hazard models were developed to clarify the association of ALT elevation with subsequent HBsAg seroclearance.
Results: A total of 850 patients were eligible (74.5% male, with a median age of 53.2 years). During a median post-treatment follow-up of 3.7 years (IQR, 1.4–6.3), HBsAg seroclearance occurred in 47 patients, at an average annual rate of 1.37% (95% confidence interval [CI], 1.01–1.83%) and a cumulative incidence of 13.2% (95% CI, 9.59–17.39%) at 10 years. Peak serum ALT level post-NA cessation was significantly lower in patients achieving HBsAg seroclearance (median, 77 U/L; IQR, 42–136) compared to those who did not achieve HBsAg seroclearance (median, 127 U/L; IQR, 47–341; $p < 0.0001$). Post-treatment ALT flare was associated with a lower incidence of HBsAg seroclearance (sub-distribution hazard ratio, 0.27; 95% CI, 0.12–0.63). The inverse association between ALT elevation and HBsAg seroclearance was consistently observed in the sensitivity tests with ALT threshold set at 2 × ULN or 1 × ULN. Among the subset of 399 patients with quantitative HBsAg data available at end of treatment (EOT), the association between elevated ALT and HBsAg seroclearance was no longer significant after adjusting for EOT HBsAg levels. In this subgroup analysis, a lower EOT HBsAg level was associated with a higher incidence of HBsAg seroclearance regardless of ALT elevation during the follow-up.
Conclusion: Following NA cessation, patients who experienced ALT elevation, whether the threshold was set at 5-, 2-, or 1-fold ULN, had a significantly lower incidence of subsequent HBsAg loss. No independent association between ALT elevation and HBsAg clearance was noted in the subgroup analyses adjusted for EOT qHBsAg. Our data refutes post-treatment ALT elevation may aid in clearing HBsAg and suggest NA cessation be avoided in patients at risk of ALT flares.

WED-394

Hepatic flares after nucleos (t)ide analogue cessation in HBeAg-negative hepatitis B: results from the Nuc-Stop study

Marte Holmberg[1,2], Olav Dalgard[2,3], Soo Aleman[4], Nega Berhe[1,5,6], Hailemichael Dessalegn[5,7], Nina Weis[8,9], Lars Heggelund[10,11], Lars Normann Karlsen[12], Pascal Brugger-Synnes[13], Hans Erling Simonsen[14], Dag Henrik Reikvam[2,6], Asgeir Johannessen[1,2,6]. *[1]Vestfold Hospital Trust, Department of Infectious Diseases, Tønsberg, Norway; [2]University of Oslo, Faculty of Medicine, Institute of Clinical Medicine, Oslo, Norway; [3]Akershus University Hospital, Department of Infectious Diseases, Lørenskog, Norway; [4]Karolinska University Hospital, Department of Infectious Diseases, Stockholm, Sweden; [5]Addis Ababa University, Aklilu Lemma Institute of Pathobiology, Addis Ababa, Ethiopia; [6]Oslo University Hospital, Department of Infectious Diseases, Oslo, Norway; [7]St. Paul's hospital Millennium Medical College, Addis Ababa, Ethiopia; [8]Copenhagen University Hospital, Hvidovre, Department of Infectious Diseases, Hvidovre, Denmark; [9]University of Copenhagen, Faculty of Health and Medical Sciences, Department of Clinical Medicine, Copenhagen, Denmark; [10]Vestre Viken Hospital Trust, Drammen Hospital, Drammen, Norway; [11]University of Bergen, Faculty of Medicine, Department of Clinical Sciences, Bergen, Norway; [12]Stavanger University Hospital, Department of Gastroenterology, Stavanger, Norway; [13]Ålesund Hospital, Department of Medicine, Ålesund, Norway; [14]Bodø Hospital, Department of Medicine, Bodø, Norway*
Email: marte.holmberg@online.no

Background and aims: Hepatic flares are frequently reported after nucleos (t)ide analogue (NA) cessation and can be detrimental leading to liver injury, hepatic decompensation or even death. We aimed to describe flares and predictive factors for flares after NA cessation in a prospective trial.
Method: This was a sub-analysis of the Nuc-Stop Study, a prospective, randomized, multicenter trial where 127 HBeAg-negative patients, virally suppressed for at least 24 months, stopped NA treatment and were followed up for 36 months. Flares were defined as ALT increase above 2 × upper limit of normal (ULN) and divided into three groups: mild (ALT 2–5 × ULN), moderate (ALT 5–20 × ULN), and severe (ALT >20 × ULN). The timing and severity of flares were described. Kruskal Wallis tests were used to compare groups. Logistic regression was used to identify predictors of flares.
Results: A flare was observed in 60 (47.2%) patients. The flare was mild in 28 (22.1%), moderate in 22 (17.3%), and severe in 10 (7.9%) patients. Of these, early flares within 3 months after NA cessation, were observed in 33 (55.0%) patients, whereas 8 (13.3%) had a flare between 3 and 6 months, 5 (8.3%) between 6 and 12 months, and 14 (23.3%) after 12 months. Most of the patients had been treated with tenofovir (97, 76.4%), the remaining with entecavir. The median time from treatment stop to first flare was significantly shorter for patients who stopped tenofovir (2.1 months, IQR 1.9–8.4) than for those who stopped entecavir (5.8, IQR 5.1–12.2) ($p = 0.01$). Genotype was known in 115 (90.6%) patients, 35 (27.6%) had genotype B or C and 80 (63.0%) had other genotypes (A, D, E). Median time in months from treatment stop to flare was 5.7 (IQR 2.0–12.2) for patients with genotype B or C and 2.8 (IQR 1.9–6.5) for patients with other genotypes. Median time to severe flares was 2.1 (IQR 1.8–3.0) months; all except one were observed within 6 months after NA cessation. All 10 patients with severe flares had been treated with tenofovir, the median peak ALT was 1403 (range 874–2600) U/L. Median peak HBV DNA was 20 300 000 (IQR 2 300 000–260 000 000) IU/ml, and most commonly occurred on the last visit before peak ALT. ALT declined to normal levels and HBV DNA was fully suppressed after restart of NA therapy. No patients developed decompensated liver disease. Age (per 1-year increment; adjusted odds ratio 1.07; 95% CI 1.02–1.12) and qHBsAg at the time of NA cessation (per 1 log10 IU/ml increment; adjusted odds ratio 1.96; 95% CI 1.12–3.43) were independent predictors of flares.
Conclusion: Flares occurred in half of the patients after NA cessation and were associated with age and qHBsAg level. Severe flares were uncommon, primarily occurred within 6 months, and normalized quickly after restart of NA therapy.

WED-395

Undetectable hepatitis delta virus RNA at the end of treatment with bulevirtide and pegylated interferon alpha-2a is an important predictor of 48 weeks sustained virologic response in chronic hepatitis delta

Email: renee-claude.mercier@gilead.com

Background and aims: Chronic hepatitis delta (CHD) infection is the most severe form of viral hepatitis. Bulevirtide (BLV), 2 mg, is approved for the treatment of compensated CHD in the European Union. Currently, the clinical relevance of target not detected (TND) versus below the lower limit of quantification (<LLOQ) for HDV RNA levels is unknown. The Phase 2b study MYR204 (NCT03852433) evaluated finite treatment with BLV with or without pegylated interferon alfa-2a (PegIFN) in patients with CHD. Here we compared the ability to maintain the post-treatment virologic response based on achieving undetectable (<LLOQ with TND) HDV RNA or <LLOQ with target detected (<LLOQ, TD) at end of treatment (EOT).
Method: Patients were randomised (N = 174; 1:2:2:2) and stratified based on the absence or presence of compensated cirrhosis to receive (A) PegIFN for 48 weeks (W), (B) BLV 2 mg + PegIFN, (C) BLV 10 mg + PegIFN for 48W followed by 48W of monotherapy with BLV 2 mg or 10 mg, respectively; or (D) BLV 10 mg for 96W. All patients were followed for up to 48W after EOT (FU-48). The primary end point was the proportion of patients who achieved undetectable HDV RNA at 24W post-EOT. HDV RNA levels were determined by RT-qPCR using RoboGene 2.0 (LLOQ 50 IU/ml, limit of detection 6 IU/ml). Virologic response rates at FU-48 were compared between patients with undetectable HDV RNA and those with HDV RNA <LLOQ, TD at EOT.
Results: Demographics and baseline characteristics were similar across groups: male (71%), White (87%), and mean (SD) age 41 (8.7) yrs. Overall, 34% had compensated cirrhosis, 48% received concomitant nucleos (t)ide analogue therapy, and 48% had prior interferon experience. Mean (SD) HDV RNA, alanine aminotransferase, and liver stiffness were 5.3 (1.2) $\log_{10}$ IU/ml, 114 (95) U/L, and 13.1 (7.7) kPa, respectively. At EOT, 42% (73/174) achieved undetectable HDV RNA: A: 21% (5/24), B: 44% (22/50), C: 70% (35/50), and D: 22% (11/50). Additionally, 19% (33/174) were <LLOQ, TD: A: 4% (1/24), B: 18% (9/50), C: 16% (8/50), and D: 30% (15/50). Of the patients with undetectable HDV RNA at EOT, 60% (44/73) maintained undetectable HDV RNA at FU-48: A: 100% (5/5), B: 55% (12/22), C: 60% (21/35), and D: 55% (6/11). Moreover, 29% (21/73) had HDV RNA >LLOQ: B: 27% (6/22), C: 31% (11/35), and D: 36% (4/11). Four patients (5%; 4/73) became <LLOQ, TD, and 5% (4/73) discontinued early by FU-48. Of those who were <LLOQ, TD at EOT, only 6% (2/33) had undetectable HDV RNA (1 each in groups B and C) and 9% (3/33) remained <LLOQ, TD at FU-48, while 73% (24/33) had HDV RNA >LLOQ; A: 100% (1/1), B: 56% (5/9), C: 63% (5/8), and D: 87% (13/15); 4 discontinued early.
Conclusion: In patients with compensated CHD, achieving on-treatment undetectable HDV RNA with TND is a predictor of undetectable HDV RNA in the post-treatment period. The majority of patients with HDV RNA <LLOQ, TD at EOT had virologic rebound at FU-48.

WED-396

Changes in metabolic parameters after switching from tenofovir disoproxil fumarate to tenofovir alafenamide among chronic hepatitis B patients: a randomized, open-label controlled trial

Titinan Veerachit-O-larn[1,2], Thanapat Atthakitmongkol[3], Wanwarang Teerasamit[4], Supot Nimanong[3], Siwaporn Chainuvati[3], Phunchai Charatcharoenwitthaya[3], Tawesak Tanwandee[3], Watcharasak Chotiyaputta[3]. *[1]Division of Gastroenterology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [2]Division of Gastroenterology, Department of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand; [3]Division of Gastroenterology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [4]Division of Diagnostic Radiology, Department of Radiology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand*
Email: watcharagi@gmail.com

Background and aims: Tenofovir alafenamide (TAF) is increasingly preferred over Tenofovir disoproxil fumarate (TDF) due to its lower nephrotoxicity and bone loss. However, the current data have shown controversy regarding metabolic outcomes among patients treated with TAF compared to those treated with TDF. The aim of this study is to evaluate the effect of TAF and TDF on metabolic parameters in chronic hepatitis B (CHB) patients.
Method: A total of ninety CHB patients treated with TDF were enrolled and randomly assigned to either switch to TAF (TAF group, n = 46) or continue TDF (TDF group, n = 44). Metabolic profiles were assessed at baseline, 24-week, and 48-week intervals through biochemical laboratory tests. Carotid Doppler Ultrasonography was conducted by a single radiologist who was blinded to the study group, evaluating carotid intima-media thickness (CIMT) at baseline and at the end of the study. All patients received advice from the dietician nurse and underwent continuous diet monitoring for one year in order to avoid high lipid and high hyperglycemic diets. The primary outcome was the change in lipid profile from baseline.
Results: The mean age of the patients was 59.4 ± 8.2 years, with a male predominance of 63.0%, and the mean body mass index (BMI) was 23.5 ± 4.1 kg/m^2. The baseline characteristics including BMI, fasting blood sugar (FBS), glycated hemoglobin (HbA1c), total cholesterol (TC), triglyceride (TG), high-density lipoprotein (HDL), low-density lipoprotein (LDL), CIMT, and co-morbidities were similar between both groups. At the end of the study, there were significant changes between the TDF and TAF groups in TC (173.6 ± 34.9 and 196.9 ± 37.4 mg/dL, respectively, p = 0.003) and TG (83.2 ± 38.5 and 118.8 ± 78.3 mg/dL, respectively p = 0.007). Significant increases in TC and TG levels were observed in the TAF group compared to the TDF group after 48 weeks of follow-up (p = 0.024 and p = 0.033, respectively). After 48-week, the percentage changes in FBS and HbA1c were significantly greater in the TAF group [FBS; TAF 6.4 ± 10.5% vs TDF 0.6 ± 12.2% (p = 0.017) and HbA1c; TAF 2.1 ± 4.5% vs TDF – 0.03 ± 3.7% (p = 0.015)]. However, no significant differences in HDL and LDL were observed between the groups over 48 weeks. Regarding CIMT, both groups had a slight decrease in mean common carotid artery (CCA) thickness and maximum internal carotid artery (ICA) thickness from baseline [CCA thickness; TAF – 5.6 ± 7.3% vs TDF – 2.5 ± 25.1% (p = 0.416) and maximum ICA thickness; TAF – 7.1 ± 18.3% vs TDF – 9.6 ± 18.5% (p = 0.517)]; however, the differences between the two groups were not statistically significant.

Conclusion: Patients with CHB treated with TAF demonstrated a significant increase in metabolic parameters, including TC, TG, FBS, and HbA1c compared to those treated with TDF. However, no differences were observed in HDL, LDL, and CIMT over the 48 weeks of follow-up. (Trial registration number: TCTR20220209003).

Yee[9], Hongyuan Wang[9], Catherine Frenette[9,10], John F. Flaherty[9], Scott K. Fung[11], Patrick Marcellin[12], Wai-Kay Seto[13], Kosh Agarwal[14], Jinlin Hou[15], Seng Gee Lim[16], Jia-Horng Kao[17], Maria Buti[18]. *[1]Mayo Clinic College of Medicine, Rochester, United States; [2]Asan Medical Center, Seoul, Korea, Rep. of South; [3]Erasmus MC University Hospital, Rotterdam, Netherlands; [4]Toronto Centre for Liver Disease, Toronto, Canada; [5]Yonsei University College of Medicine, Seoul, Korea, Rep. of South; [6]NYU Langone Health, New York, United States; [7]National Center for Global Health and Medicine, Ichikawa, Japan; [8]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [9]Gilead Sciences, Foster City, United States; [10]Scripps Clinic, La Jolla, United States; [11]University of Toronto, Toronto, Canada; [12]Hôpital Beaujon, Clichy, France; [13]The University of Hong Kong, Hong Kong, Hong Kong; [14]Kings College Hospital, London, United Kingdom; [15]Nanfang Hospital of Southern Medical University, Guangzhou, China; [16]National University Hospital, Singapore, Singapore; [17]National Taiwan University Hospital, Taipei, Taiwan; [18]Hospital General Universitari Vall d'Hebron, Ciberehd del Instituto Carlos III, Barcelona, Spain*
Email: wrkim@stanford.edu

Background and aims: Chronic hepatitis B (CHB) is a leading cause of hepatocellular carcinoma (HCC). Antiviral therapy with nucleot (s)ide analogues (NAs) has been shown to reduce HCC risk. This pooled analysis of four phase 3 studies (GS-US-174-0102 [Study 102], GS-US-174-0103 [Study 103], GS-US-320-0108 [Study 108], and GS-US-320-0110 [Study 110]) aimed to assess impact of tenofovir (TFV)-based NAs on long term HCC risk in CHB patients, utilizing three validated risk prediction algorithms.

Method: Studies 102 and 103 randomized patients 2:1 to double-blind (DB) treatment with tenofovir disoproxil fumarate (TDF) or adefovir dipivoxil (ADV) for 48 weeks, then open-label (OL) TDF, whereas Studies 108 and 110 randomized patients 2:1 to DB treatment with tenofovir alafenamide (TAF) or TDF for up to 144 weeks, then OL TAF. All patients were assessed over 384 weeks (8 years). HCC risk was estimated using the following models: Risk Estimation for HCC in Chronic Hepatitis B (REACH-B); modified Platelet Age Gender-HBV (mPAGE-B); and age-Male-ALBI-Platelets (aMAP). Primary outcomes included: HCC incidence (via standardized incidence ratios [SIRs] of HCC based on ratio of observed vs. model-predicted cases [REACH-B]); and the proportions of patients who shifted from baseline risk categories (aMAP and mPAGE-B).

Results: In total, 1, 939 (n = 641 from 102/103 and n = 1, 298 from 108/110) patients were included in the pooled analysis. By Year 8, 41 (2.1%) patients had developed HCC. By multivariate analysis, older age, male sex, and cirrhosis at baseline were associated with HCC development. By REACH-B, the SIR was 0.39 (95% confidence interval: 0.29, 0.53; $p < 0.0001$), indicating the observed incidence to be 61% lower than the predicted incidence; for patients with cirrhosis, the SIR was 46% lower. By aMAP and mPAGE-B models, most patients were at low- or medium-risk for HCC development at baseline, and either stayed the same or shifted to a lower risk category at Year 8, while most high-risk patients had shifted to at least medium-risk by Year 8.

Conclusion: In this large dataset of prospectively followed CHB patients, HCC risk was significantly impacted with long-term TFV-based treatment in CHB patients with and without cirrhosis.

WED-398

HBsAg loss in inactive chronic hepatitis B carriers is dependent on level of qHBsAg and interferon response: a randomised control trial

Seng Gee Lim[1], Guan Huei Lee[2], Yock Young Dan[3], Yin Mei Lee[4], Htet Htet Toe Wai Khine[5], Yuh Ling Amy Tay[6], Cindy Seah[7], Liang Shen[5], Edwin, Shih-Yen Chan[8], Martin Hibberd[9]. *[1]National University Health System, Yong Loo Lin School of Medicine, Singapore, Singapore; [2]National University Health System, Singapore; [3]National University Health System, Yong Loo Lin School of Medicine, Singapore, Singapore; [4]National University Health System, Singapore, Singapore; [5]Yong Loo Lin School of Medicine, Singapore, Singapore; [6]Yong Loo Lin School of Medicine, Singapore, Singapore; [7]National University Health System, Singapore, Singapore; [8]Singapore Clinical Research Institute, Duke-NUS Medical School, Singapore, Singapore; [9]London School of Hygiene and Tropical Medicine, London, United Kingdom*
Email: mdclimsg@nus.edu.sg

Background and aims: Peginterferon therapy of Chronic Hepatitis B (CHB) carriers how mixed results for HBsAg loss, but its unclear whether low qHBsAg (<1000 IU/ml) or low HBV DNA (<2000 IU/ml) are more important.

Method: This was a 3-arm RCT of peginterferon alpha2a (PEG) (pegasys, Roche) 180mcg weekly randomised 1:1:1 to 24 weeks (PEG24), 48 weeks (PEG48) or no treatment (C) in CHB carriers (clinicaltrials.gov:NCT02992704). Patients were randomly assigned based on: HBsAg (+)>6months, HBeAg (−), normal ALT, HBV DNA $\leq 2 \times 10^4$ IU/ml or qHBsAg≤1000 IU/ml; absence of cirrhosis, treatment naive, absence of HCV/HDV/HIV coinfection. The primary end point was HBsAg loss 24weeks after treatment, and study size of 90 patients had 80% power to detect a 25% difference between any PEG arm and control. Data analysis was performed using SPSSv20 based on ITT analysis. Baseline and on-treatment variables and multivariate analysis were used to predict HBsAg loss at end-of-treatment (EOT) and end of 24weeks followup (FU24). PAXgene transcriptome analysis was performed on relevant patients.

Results: Baseline characteristics were similar between groups. HBsAg loss occurred in a total of 7/30 (23.3%) in PEG48, 9/30 (30%) in PEG24 and 0/30 (0%) in C at the EOT ($p = 0.007$) but 5/30 (16.7%) in PEG48, 5/30 (16.7%) in PEG24 and 1/30 (3.4%) in C at FU24 ($p = 0.093$). Baseline predictors of HBsAg loss at FU24 showed qHBsAg and ALT were significant by logistic regression with backwards model selection ($p = 0.002$, and $p = 0.04$ respectively). ROC curve analysis showed AUROC 0.896 (95% CI 0.806–0.986), with threshold of qHBsAg <76 IU/ml, had 100% sensitivity and 62% specificity for HBsAg loss at FU24. There were three distinct patterns (clusters) of interferon response despite qHBsAg <76 IU/ml, based on their HBsAg reduction at week 12. Cluster 1 had a HBsAg reduction of 2.19logIU/ml, cluster 2 had a mean reduction of 1logIU/ml and cluster 3 had a mean reduction of 0.05logI/ml. Responders (HBsAg loss) occurred in 2/2 in cluster 1, 7/13 in cluster 2 and 5/15 in cluster 3. We examined responders and non-responders using PAXgene transcriptome analysis and found that responders had 55 differentially expressed genes of which 37 were upregulated. The most significantly upregulated was MMP8 and a cluster of 13 genes which were enriched in the neutrophil degranulation pathway ($p = 5.59 \times 10^{-12}$). There were 282 adverse events mostly interferon related (90%). There were 4 Serious Adverse Events but no deaths.

Conclusion: HBsAg loss with PEG in inactive carriers leads to 16.7% HBsAg loss with low baseline qHBsAg and interferon responsiveness driving HBsAg loss but not HBV DNA. A novel neutrophil enriched pathway was found in responders based on transcriptome analysis.

WED-399-YI

The composition of HBsAg along with HDV-RNA predicts virological response in chronic hepatitis delta patients treated with bulevirtide for 48 weeks

Background and aims: HDV exploits HBV surface protein (HBsAg) for releasing of progeny and entry into hepatocytes. HBsAg consists of 3 different forms: Large- (L-HBs), Middle- (M-HBs) and Small-HBsAg (S-HBs). L-HBs is predominantly present in virions and mediates binding to NTCP receptor, while the lack of M-HBs production is known to favour the release of replication-competent virions. Here, we investigate the kinetics of HBs forms under bulevirtide treatment (BLV).
Method: 28 consecutive patients with HDV-related compensated cirrhosis starting BLV 2 mg/day monotherapy were enrolled in this retrospective/longitudinal study, all under effective NUC treatment at entry. L-HBs, M-HBs and S-HBs were quantified by *ad-hoc* ELISAs in baseline and week 48 (W48) samples (Beacle). HDV RNA was quantified by Robogene 2.0. Virological response was defined as HDV RNA undetectable or >2log decline compared to baseline, biochemical response as ALT normalization.
Results: At baseline, median (IQR) age was 53 (40–63) years, liver stiffness 19.4 (15.4–32.9) kPa, ALT 106 (77–147) U/l, serum HDV RNA 5.4 (4.4–6.0) log IU/ml and HBsAg levels 3.7 (3.4–4.9) log IU/ml. Pre-treatment median (IQR) levels of S-HBs, M-HBs and L-HBs were 3999 (1482–7184), 1032 (305–2222) and 6 (2–14) ng/ml, respectively. At W48, serum HDV RNA declined by 3.1 (1.8–3.7) log IU/ml while virological and biochemical responses were observed in 71% and 75% of patients, respectively. A >10% decrease of S-HBs, M-HBs and L-HBs levels was observed in 57%, 54% and 39% of patients with a median (IQR) decline of 1095 (839–2403), 145 (39–350) and 10 (4–15) ng/ml, respectively. Baseline HDV RNA <5 log IU/ml was associated with HDV RNA <100 IU/ml at W48 (75% with vs 25% without, P = 0.02). A similar correlation was observed for baseline L-HBs <9 ng/ml (62.5% with vs 25% without, P = 0.05). The combination of pre-treatment L-HBs <9 ng/ml + HDV RNA <5 log IU/ml was the best predictor for achieving HDV RNA <100 IU/ml (PPV:87.5%, NPV:70%; P = 0.01). This combination showed also the best diagnostic accuracy for predicting HDV RNA <100 IU/ml plus ALT normalization (PPV:75%, NPV:75%; P = 0.03). A different scenario was observed for M-HBs. Patients with baseline M-HBs >500 ng/ml had a significantly greater virological response than those with baseline M-HBs <500 ng/ml (HDV RNA decline of 3.4 [2.5–3.8] vs 1.6 [1.2–3.2] log IU/ml, P = 0.03). Baseline M-HBs >500 ng/ml predicted the achievement of virological response at W48 of BLV (PPV: 88.8%, NPV: 60%; P = 0.01). Superimposable results were observed in a subgroup of 12 patients with serum HDV RNA <5 log IU/ml at baseline (PPV: 100%, NPV: 57%; P = 0.038).
Conclusion: Quantification of L-HBs and M-HBs along with serum HDV RNA may reflect the burden of circulating infectious or replication-competent virions in the setting of HBV/HDV co-infection, possibly providing a new tool to identify patients more likely to respond to BLV monotherapy.

WED-402

Risk of hepatocellular carcinoma after curative treatment when switching from Tenofovir Disoproxil Fumarate or Entecavir to Tenofovir Alafenamide: a real-world multicenter cohort study

Hyunjae Shin[1], Yunmi Ko[1], Youngsu Park[1], Yoon Jun Kim[1]. [1]*Seoul National University Hospital, Seoul, Korea, Rep. of South*
Email: yoonjun@snu.ac.kr

Background and aims: Antiviral treatment reduce the risk of developing hepatocellular carcinoma (HCC) in patients with chronic hepatitis B (CHB). However, there is a lack of high-quality evidence regarding the preventive effects of TAF on HCC. We evaluated the impact of TAF use after curative treatment on HCC recurrence.
Method: Patients who underwent surgery or radiofrequency ablation as a curative treatment for HCC were selected. Those patients who continued antiviral treatment with NAs (entecavir [ETV] or tenofovir disoproxil fumarate [TDF]) or switched to TAF were included. The primary outcome was HCC recurrence, and the time-varying effect of NA use on HCC recurrence was analyzed using various statistical methods.
Results: Among 2, 794 consecutive patients with CHB who received curative treatment for HCC, 199 subsequently switched from ETV or TDF to TAF. After a median of 3.0 years, 1, 303 patients (46.6%) experienced HCC recurrence. After propensity score matching (ratio 1:10), switching to TAF was not associated with an increased HCC recurrence (hazard ratio [HR], 1.00 [95% CI, 0.68–1.47]; $p = 1.00$) by time-varying Cox analysis. Switching to TAF was not associated with HCC recurrence in subgroups of NA (HR, 1.06 [95% CI, 0.67–1.67]; $p = 0.81$ for TDF, and 1.09 [95% CI, 0.51–2.33]; $p = 0.82$ for ETV). Kaplan-Meier analysis showed comparable HCC recurrence-free survival between patients who switched to TAF and those who continued with their NA ($p = 0.08$). Time-varying Cox analyses in various subgroups confirmed the primary findings.
Conclusion: TAF is as effective as TDF and ETV in preventing HCC recurrence after curative treatment.

Email: gepapath@med.uoa.gr

Background and aims: Bulevirtide (BLV) has received conditional approval by the European Medicine Agency for the treatment of compensated chronic hepatitis D (CHD) in 2020 and has started to be used in some European countries including Greece, but there are limited real-life data to date. The aim of this study is to assess the efficacy and safety of BLV in CHD patients treated at Greek liver centers.
Method: All adult (>16 years old) patients with CHD followed at any of the participating centers who started BLV before the approvals (05-11/2023) of the HERACLIS_BLV_D study (NCT05928000) were included. All patients were treated with daily BLV subcutaneous injections of 2 mg, with or without concomitant use of a nucleos (t) ide analogue (NA). Patients' monitoring was based on standard clinical practice according to the current recommendations for treatment of CHD. A predefined case report form was used for data collection. Serum HDV RNA during the study was determined by a polymerase chain reaction assay at a central lab (sensitivity: 100 IU/ml).
Results: In total, 76 patients were included; mean age: 50 ± 12 years, males: 37 (49%), born in Greece: 21 (28%), mean BMI: 25.4 ± 3.9 kg/m^2, mean liver stiffness (LS): 15.9 ± 9.5 kPa, cirrhosis: 45 (59%) (decompensated cirrhosis: 6/45), (peg-)interferon (IFN) in the past: 32 (42%) cases. No patient received combination of BLV with pegIFN; BLV alone was given in 9 (12%) and BLV plus a NA in 67 (88%) patients (ETV: 29, TDF: 35, TAF: 3). At 6 months, virological response (VR: serum HDV RNA undetectable or decline ≥2 $\log_{10}$ IU/ml) was observed in 43 (24+19) (70.5%), biochemical response (BR: ALT≤40 IU/L) in 43 (70.5%) and combined VR+BR in 32 (52.5%) of 61 patients. At 12 months, VR was observed in 40 (31+9) (83%), BR in 35 (73%) and combined VR+BR in 28 (58%) of 48 patients. Of the patients with no or partial VR (serum HDV RNA decline <1 or 1–<2 $\log_{10}$ IU/ml), 11/18 and 7/8 cases achieved BR at 6 and 12 months, respectively; all cases without BR had reduced ALT and/or HDV RNA levels. Response rates did not differ between cirrhotic and non-cirrhotic patients. There was no drug-related serious adverse event and no patient discontinued BLV.
Conclusion: BLV therapy with or without NA is safe and effective in the treatment of CHD in real-life at Greek liver centers offering VR and BR rates even higher than those reported in clinical trials perhaps due to different patient characteristics.

WED-404
Comparable outcomes between Besifovir and other antiviral therapies in hepatocellular carcinoma development among patients with chronic hepatitis B

Jae Seung Lee[1], Sung Won Lee[2], Sang Gyune Kim[3], Yeon Seok Seo[4], Su Jong Yu[5], Hyung Joon Yim[6], Hye Won Lee[1], Mi Na Kim[1], Beom Kyung Kim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1], Seung Up Kim[1]. *[1]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Bucheon St. Mary's Hospital, The Catholic University of Korea School of Medicine, Department of Internal Medicine, Bucheon, Korea, Rep. of South; [3]Soonchunhyang University Bucheon Hospital, Soonchunhyang University College of Medicine, Department of Internal Medicine, Bucheon, Korea, Rep. of South; [4]Korea University Anam Hospital, Korea University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [5]Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South; [6]Korea University Ansan Hospital, Korea University College of Medicine, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Ansan, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: Besifovir dipivoxil maleate (BSV), an acyclic nucleotide phosphonate, has potent antiviral efficacy against chronic hepatitis B (CHB), similar to other antiviral agents, such as entecavir (ETV), tenofovir disoproxil fumarate (TDF), and tenofovir alafenamide (TAF). This study compares outcomes between BSV and the other antiviral agents in hepatocellular carcinoma (HCC) development among patients with CHB.
Method: We conducted a retrospective cohort of 2, 684 treatment-naïve patients with CHB who started their first-line antiviral therapy (AVT) between May 2017 and April 2022 with ETV (n = 840), TAF (n = 706), TDF (n = 666), or BSV (n = 472) at six tertiary medical institutions in South Korea. The incidence and hazard ratio (HR) were calculated using Kaplan-Meier and Cox regression analyses, respectively. Selection bias was minimized using inverse probability of treatment weighting (IPTW) and propensity score matching (PSM).
Results: Compared to the patients with other antiviral agents, BSV users showed a higher proportion of male patients (61.2% vs. 50.1–56.2%), alcohol intake >20 g/day (12.1% vs. 5.5–11.2%), and cirrhosis (37.9% vs. 30.5–34.3%). The incidence of HCC in BSV users (n = 6, 4.4 per 1000 person-years [PYs]) was similar to that in TAF users (8.5 per 1000 PYs, log-rank *P* = 0.111, HR 2.098, 95% confidence interval [CI] 0.827–5.324), however, significantly lower than those in ETV (n = 38, 12.7 per 1000 PYs, log-rank *P* = 0.026, HR 2.603, 95% CI 1.087–6.233) and TDF users (12.7 per 1000PYs, log-rank *P* = 0.035, HR 2.539, 95% CI 1.034–6.234). After applying 1:1:1:1 IPTW, the incidence of HCC in BSV users (n = 7 of 591, 3.8 per 1000 PYs) was similar to that in TAF users (n = 17 of 713, 8.6 per 1000 PYs, adjusted HR [aHR] 2.324, 95% CI 0.894–6.043), however, significantly lower than in ETV (n = 32 of 706, 12.4 per 1000 PYs, aHR 2.795 (95% CI 1.138–6.866, E-value 5.035) and TDF users (n = 34 of 674, 14.6 per 1000 PYs, aHR 3.322 (95% CI 1.334–8.274, E- value 6.099). Following separated 1:1 PSM (all 472 pairs), the incidence of HCC in BSV users (n = 6, 4.4 per 1000 PYs) was similar to that in TAF users (n = 12, 8.6 per 1000 PYs, log-rank *P* = 0.782, aHR 1.167, 95% CI 0.392–3.471), however, significantly lower than in ETV (n = 27, 15.2 per 1000 PYs, log-rank P = 0.025, aHR 2.978, 95% CI 1.024–8.659, E-value 5.404), and TDF users (n = 27, 16.6 per 1000 PYs, log-rank P = 0.025, aHR 3.000, 95% CI 1.090–8.254, E-value 5.449).
Conclusion: BSV showed comparable outcomes in HCC development among patients with CHB compared to TAF, ETV, and TDF. Given the small number of events and the relatively short follow-up duration observed in BSV users, further long-term analysis is warranted.

WED-405
Tenofovir disoproxil fumarate and tenofovir alafenamide interruption in hepatitis B and human immunodeficiency virus co-infected individuals in the United States: monitoring practices and incidence of hepatitis B reactivation or hepatitis flare

Douglas T. Dieterich[1], Laurence Brunet[2], Ricky Hsu[3,4], Karam Mounzer[5], Gerald Pierone[6], Michael Wohlfeiler[7], Jennifer Fusco[2], Megan Dunbar[8], Joshua Gruber[8], Leland J. Yee[8], Catherine Frenette[8], Gregory Fusco[2]. *[1]Icahn School of Medicine at Mount Sinai, New York, United States; [2]Epividian, Raleigh, United States; [3]AIDS Healthcare Foundation, New York, United States; [4]NYU Langone Medical Center, New York, United States; [5]Philadelphia FIGHT, Philadelphia, United States; [6]Whole Family Health Center, Vero Beach, United States; [7]AIDS Healthcare Foundation, Miami, United States; [8]Gilead Sciences, Inc., Foster City, United States*
Email: laurence.brunet@epividian.com

Background and aims: Among HBV core antibody positive (cAb+) people with HIV, suppressive HBV treatment including either tenofovir disoproxil fumarate or tenofovir alafenamide (TDF/TAF) is recommended to prevent HBV reactivation. We describe TDF/TAF interruptions and HBV monitoring practices in the United States as well as assess the incidence of HBV reactivation and hepatitis flares during TDF/TAF interruptions in the OPERA cohort.
Method: All TDF/TAF interruptions among HBV surface antigen positive (sAg+) and/or cAb+ people with HIV were categorized by risk of reactivation (high: sAg+; moderate: sAg-/cAb+/HBV surface antibody negative [sAb-]; low: sAg-/cAb+/sAb+). Presence of HBV DNA, sAg and alanine transaminase (ALT) testing was assessed before (within ≤12 months) and during the interruption. Incidence of HBV reactivation and hepatitis flares (AASLD definitions) was assessed with Poisson regression.
Results: Of 31, 241 HBV/HIV co-infected people, 4, 901 (16%) had ≥1 interruption, for a total of 5, 643 interruptions (11% high, 19% moderate, 69% low risk); median duration: 83 weeks (IQR: 28–202). There were no DNA tests before (high: 55%, moderate: 97%, low: 97%) or during interruptions (high: 49%, moderate: 92%, low: 95%). There was no sAg test in 75% of high, 70% of moderate and 72% of low risk interruptions. HBV reactivation occurred in 103 high risk interruptions (16% overall; 32% of those with DNA tests) for an incidence rate [IR] of 9.59 per 100 person-years (95% CI: 7.91, 11.64). Reactivation occurred in 18 moderate risk interruptions (2% overall; 5% of those with DNA and/or sAg tests); IR: 0.58 (95% CI: 0.36, 0.91). Only 5 low risk interruptions resulted in HBV reactivation (0% overall; 0% of those with DNA and/or sAg tests); IR: 0.04 (95% CI: 0.02, 0.11). ALT tests were available before (high: 90%, moderate: 91%, low: 93%) and during interruptions (high: 98%, moderate: 100%, low: 99%). Hepatitis flares occurred in 60 (9%) high-risk interruptions (IR per 100 person-years: 5.28; 95% CI: 4.10, 6.80), 52 (5%) moderate-risk interruptions (IR: 1.72; 95% CI: 1.31, 2.26), and 132 (3%) low-risk interruptions (IR: 1.22; 95% CI: 1.03, 1.45).
Conclusion: In this large US cohort of sAg+ and/or cAb+ people with HIV receiving care in primary or HIV care clinics, TDF/TAF interruptions were common and lengthy, and HBV lab monitoring was suboptimal, suggesting that primary and HIV care providers tend to be unaware of HBV status or overlook HBV monitoring and management in people with co-infection. While sAg+ individuals had the highest HBV reactivation and hepatitis flare risk, all were at-risk regardless of serology. Given infrequent testing, many reactivations were likely missed. Primary and HIV care providers need to incorporate HBV monitoring in their standard of care and proceed with caution if considering a TDF/TAF interruption for people with HBV/HIV co-infection.

WED-406

DARING-B study: 5-year outcomes after nucleos (t)ide analogue (NA) cessation in Caucasian non-cirrhotic patients with HBeAg-negative chronic hepatitis B (CHBe-)

Margarita Papatheodoridi[1], Eirini Rigopoulou[2], Kalliopi Zachou[2], Emilia Hadziyannis[3], Nikolaos Gatselis[4], Ioannis Vlachogiannakos[5], Spilios Manolakopoulos[3], George Dalekos[2], George Papatheodoridis[4]. *[1]Department of Gastroenterology, Medical School of National and Kapodistrian University of Athens, General Hospital of Athens "Laiko," Athens, Greece; [2]Department of Medicine and Research Laboratory of Internal Medicine, Thessaly University Medical School, Larissa, Greece; [3]2nd Department of Internal Medicine, Medical School of National and Kapodistrian University of Athens, General Hospital of Athens "Hippokratio," Athens, Greece; [4]Department of Gastroenterology, Medical School of National and Kapodistrian University of Athens, General Hospital of Athens "Laiko," Athens, Greece; [5]Medical School of National and Kapodistrian University of Athens, General Hospital of Athens "Laiko," Athens, Greece*
Email: gepapath@med.uoa.gr

Background and aims: Cessation of long-term NA therapy has been regarded lately as a potential strategy that may increase the probability of functional cure, ie. HBsAg loss, in CHBe- patients, who should remain under close monitoring after stopping NA. The outcomes within 1–2 years post-NA have been well studied, but there are few data about longer outcomes. We aimed to assess the 5-year outcomes of our non-cirrhotic CHBe- patients included in the DARING-B study.
Method: DARING-B study prospectively enrolled 57 Caucasian patients (mean age: 58 ± 10 years, males: 37) without cirrhosis before NAs from 2 tertiary liver centers in Greece from 12/2015 to 03/2016. Patients with coinfection, cirrhosis, cancer or liver transplantation were excluded. Patient and treatment characteristics before and at end of NA therapy (EOT) were recorded. After NA cessation, patients were followed monthly for the first 3 months, every 2–3 months until completion of the first year and every 6 months thereafter. Predefined criteria for retreatment were used. Study end points were death or liver transplantation, liver decompensation, hepatocellular carcinoma (HCC), virological relapse (VR: HBV DNA>2000 IU/ml), clinical relapse (CR: HBV DNA >2,000 and ALT >2 × ULN), retreatment and HBsAg loss.
Results: Median follow-up (FUP) was 5 (IQR: 3.6–6.5) years after EOT; only 4 patients were lost to FUP (<24 months). No patient died, required liver transplantation, developed liver decompensation or jaundice. Only one patient developed HCC diagnosed at 11 months (cumulative 1-year and 5-year incidence: 1.8%). At 1, 2, 3, 5 and 6 years post-NA, cumulative rates of VR were 70%, 74%, 75%, 75% and 75%, of CR were 33%, 35%, 39%, 39% and 39% and of retreatment were 26%, 30%, 38%, 45% and 45%, respectively. In total, 17/57 (30%) patients achieved HBsAg loss (2 after retreatment) with 1-, 2-, 3-, 5- and 6-year post-NA cumulative rates of 16%, 20%, 21%, 27% and 37%, respectively. EOT HBsAg≤100 IU/ml was associated with more frequent HBsAg loss (HR:6.7, P < 0.001) and less frequent VR (HR:0.35, P = 0.045), whereas EOT HBsAg≤1000 IU/ml was also associated with more frequent HBsAg loss (HR:16.7, P = 0.007) and less frequent CR (HR:0.44, P = 0.057) and retreatment (HR:0.33, P = 0.009).
Conclusion: Functional cure rates increase over the first 5–6 years after NA cessation in non-cirrhotic Caucasian patients with CHBe-, while risk of CR is mainly observed during the first year substantially decreasing thereafter.

WED-407

Characterization of hepatitis D virus RNA and hepatitis B surface antigen kinetics during pegylated interferon-alpha monotherapy: The D-LIVR study

Leeor Hershkovich[1], Harel Dahari[1], Scott Cotler[1], Ingrid Choong[2], Colin Hislop[2], Theo Heller[3], Christopher Koh[3], Jeffrey Glenn[4], Tarik Asselah[5,6], Saeed Sadiq Hamid[7], Ohad Etzion[8]. *[1]Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, IL, United States; [2]Eiger BioPharmaceuticals, Palo Alto, CA, United States; [3]Liver Disease Branch, NIDDK, NIH, Bethesda, MD, United States; [4]Division of Gastroenterology and Hepatology, Departments of Medicine, Microbiology and Immunology, Stanford School of Medicine, Stanford, CA, United States; [5]Hôpital Beaujon, APHP, Clichy and the University of Paris-Cité, Paris, France; [6]INSERM UMR1149, Paris, France; [7]Aga Khan University, Karachi, Pakistan; [8]Soroka University Medical Center, Beersheva, Israel*
Email: harel.dahari@gmail.com

Background and aims: Current understanding of the kinetic profiles of hepatitis D virus (HDV) and hepatitis B surface antigen (HBsAg) during pegylated-interferon-α-2a (pegIFN) monotherapy is based on a 24-week analysis in 12 treated patients with HDV [Hepatology 2014;60:1902–1910]. We analyzed data from the Phase 3 D-LIVR study to further characterize HDV and HBsAg kinetics in patients treated with pegIFN alone.

Method: 52 participants in the D-LIVR study (NCT03719313) were treated with pegIFN and oral placebo for 48 weeks. HDV RNA was measured by Quest laboratories (lower limit of quantification, LLoQ <40 IU/ml; target not detected, TND <4 IU/ml) and HBsAg by Abbott Diagnostics at baseline, Weeks 1, 2, and 4 of therapy, and then every 4 weeks until end of therapy (EOT) and at 24 weeks of follow-up (EOFU). We defined monophasic (MP) pattern as a single HDV decline, biphasic (BP) pattern as an initial rapid decline followed by a slower decline, and triphasic (TP) pattern as two decline phases separated by an intermediary plateau. MP, BP, or TP patterns that were followed by a plateau (≥LLoQ), termed flat partial response (FPR), biphasic FPR (BFPR), and staircase, respectively. A ≥2-fold change in slope was used to distinguish between decline phases.
Results: 28 patients were excluded from analysis: 11 discontinued therapy, 9 had poor adherence or dose reductions, and 8 were non-responders (<1.6 log decline from baseline). Of the remaining 24 patients, 22 experienced an average delay of 8.0 ± 9.7 days before HDV declined from baseline, while 2 experienced very long delays of 20 and 28 weeks. Thereafter, we identified 6 HDV kinetic patterns: MP (n = 3), BP (n = 2), TP (n = 4) which were associated with reaching TND (n = 7), and those who plateaued above TND: FPR (n = 7), BFPR (n = 4), and staircase (n = 4). 12 (50%) patients had HDV rebound (>1.5 log IU/ml increase from nadir) after MP (n = 2/3), BP (n = 1/2), TP (n = 1/4), FPR (n = 4/7), BFPR (n = 3/4), and staircase (n = 1/4) declines, 23 ± 14 weeks into therapy. HDV rebound was not associated with HDV decline patterns. While HBsAg remained at baseline levels (3.6 ± 0.6 log IU/ml) for most patients (19/24), 5 patients (1MP, 1BP, 2TP, and 1 staircase who had a transient rebound before reaching TND) experienced a >1.5 log decline from baseline, all of whom achieved sustained TND until EOFU. Another patient (FPR) was HDV detectable at EOT but achieved TND at EOFU, while HBsAg remained at baseline level. A decline of >1.5 log in HBsAg from baseline by Week 36 had a 100% positive predictive value and a 95% negative predictive value for reaching HDV TND at EOFU.
Conclusion: Complex HDV decline patterns including triphasic and staircase were observed under pegIFN, that were not previously reported. The longer kinetic analysis (48 vs 24 weeks) identified on treatment HDV rebound in 50% of patients who initially responded to pegIFN. A >1.5 log HBsAg decline from baseline by Week 36 was associated HDV TND at EOFU.

WED-408
Factors influencing HBsAg clearance in children with chronic hepatitis B undergoing antiviral therapy: significance of age at treatment onset and HBeAg titer dynamics

Byung-Ho Choe[1], Sukjin Hong[2]. [1]*Kyungpook National University Children's Hospital, Daegu, Korea, Rep. of South;* [2]*Daegu Catholic University Medical Center, Daegu, Korea, Rep. of South*
Email: bhchoi@knu.ac.kr

Background and aims: This study aims to investigate the characteristics and determinants of HBsAg clearance in paediatric patients with HBeAg-positive chronic hepatitis B undergoing antiviral treatment in Korea, where genotype C is predominant.
Method: We enrolled 145 children diagnosed with chronic hepatitis B for antiviral therapy. Eligible patients had a history of HBsAg positivity for at least six months, elevated ALT levels more than twice the upper normal limit for six months or longer, or confirmation through liver biopsy. Treatment with nucleos (t)ide analogues (NA) was continued beyond complete remission (normalization of ALT levels, undetectable HBV DNA levels, and HBeAg seroconversion), followed by an additional NA consolidation therapy, at least 1 year. The duration of consolidation therapy was extended by the revision of EASL and APASL guideline to over 3 years, which was further extended if HBsAg titer decrease rapidly, in the expectation of achieving functional cure. Exclusion criteria included HBeAg-negative hepatitis B, spontaneous HBeAg seroconversion, or acute exacerbation of chronic hepatitis B from other causes. The study analyzed various factors such as gender, pre-treatment ALT and HBV DNA levels, age at the initiation of treatment, and duration of treatment until complete remission, to identify variables that significantly influence HBsAg clearance. Additionally, we assessed the impact of the decrement velocity of HBeAg titer during NA treatment, categorizing the slope of the titer decrease into tertiles, and employing chi-square and logistic regression for analysis.
Results: In the study group of 145 patients, consisting of 80 males (55.2%) and 65 females (44.8%), with an average age of 8.0 ± 5.3 years (mean ± SD) at the start of treatment, 35 (24%) achieved HBsAg clearance. The average duration from treatment initiation to clearance was 32.2 ± 39.2 months (mean ± SD). Identified factors influencing HBsAg clearance included gender, pretreatment ALT levels, and age at the onset of treatment. Notably, female patients ($p = 0.047$) and those with higher pretreatment ALT levels ($p = 0.046$) showed better outcomes. Children under six years exhibited a significantly higher rate of clearance ($p = 0.011$), with a more rapid decrease in HBeAg titer also being a contributing factor ($p = 0.015$). All patients achieving HBsAg clearance eventually developed anti-HBs. No patient who had achieved functional cure has relapsed after discontinuation of NA.
Conclusion: In the treatment of HBeAg-positive chronic hepatitis B with NA, preschoolers or those demonstrating a rapid decline in HBeAg titer during NA treatment are more likely to achieve HBsAg clearance. For patients with Genotype C, particularly those younger than 6 years, a rapid decline in HBeAg titer may indicate the potential benefit of considering an extension of treatment until HBsAg loss is achieved.

WED-409
Improved HBV-RNA quantification by HBV-RNA reverse transcription droplet digital PCR

Bernhard Kleter[1], Sanne Gils[1], Joël Meyboom[1], Thierry Verbinnen[2], Oliver Lenz[3], Leen-Jan Doorn[1]. [1]*Viroclinics-DDL, Rijswijk, Netherlands;* [2]*Janssen Research and Development, Beerse, Belgium;* [3]*Janssen Pharmaceutica, Beerse, Belgium, Beerse, Belgium*
Email: bernhard.kleter@cerbaresearch.com

Background and aims: HBV-RNA is used as an exploratory biomarker in chronic HBV infection. HBV-RNA can be specifically detected in plasma, often even when HBV DNA is completely suppressed by e.g. nucleos (t)ide analogue treatment. The limit of detection (LOD) of the Viroclinics-DDL in-house fully validated HBV-RNA high sensitivity RT-qPCR assay is 25 copies/ml and a lower limit of quantification (LLOQ) 869 copies/ml (158 copies/qPCR). A HBV-RNA RT droplet digital PCR (ddPCR) assay was developed to improve sensitivity and extend the lower quantifiable range as ddPCR is most effective at low copy numbers of target.
Method: A comparison between our validated HBV-RNA high sensitivity RT-qPCR assay using 500 µL of plasma and the HBV RNA RT-ddPCR test was performed using 133 plasma samples from patients with chronic hepatitis B participating in Janssen clinical trials, JADE (NCT03361956), OCTOPUS (NCT05275023) and PENGUIN (NCT04667104). HBV-RNA RT-ddPCR was performed with a plasma sample volume of 400 µL in 81 samples and the remaining 52 samples were tested with 200 µL due to sample volume shortage. From the OCTOPUS and PENGUIN studies baseline samples from virologically suppressed patients were tested (HBV DNA <20 IU/ml detected or negative). Samples from JADE were used to assess longitudinal HBV-RNA, HBV-DNA, HBsAg and HBcrAg profiles in 13 patients. In the JADE series, 28 samples were virologically suppressed.
Results: Based on HBV *in vitro* transcribed pregenomic RNA testing by RT-ddPCR the limit of blank is 0.73 copies/RT-ddPCR using Armbruster's approach. When testing 400 µL plasma samples the 95% LOD by probit analysis was 2.7 copies/RT-ddPCR, corresponding to 16 copies/ml. The LLOQ was determined according to FDA-guidelines at 23.6 copies/RT-ddPCR, corresponding to 141 copies/

ml. In the panel of 133 samples concordant results by both assays were found in 74 (56%) samples. The qPCR and ddPCR assays scored below LOD in 65 (49%) and 39 (29%) samples, respectively. Four of the 39 samples were between LOD and LLOQ in the qPCR assay. By ddPCR, 49 samples were in the range between LOD and LLOQ. By qPCR, 24 of these 49 cases were also in the range between LOD and LLOQ and the remaining 25 samples were below LOD. In the quantifiable range of both assays, far more samples were found quantifiable by the ddPCR assay than by the qPCR assay, 45 (34%) and 15 (11%) respectively. All 15 qPCR quantifiable samples were also quantifiable by the ddPCR assay. Even 5 of them were quantifiable when testing 200 µL plasma in the ddPCR assay.

Conclusion: Results show a clearly improved sensitivity and quantification of HBV RNA by the HBV-RNA RT-ddPCR assay. Due to the higher sensitivity in quantification of low HBV RNA concentrations, the response to treatment can be assessed for a longer period. This makes the HBV-RNA RT-ddPCR assay highly suitable for monitoring patients during antiviral treatment in clinical trials.

Sustained virological response after treatment with Bulevirtide in HDV patients. Data from the french multicenter real-life cohort

Victor de Lédinghen[1], Karine Lacombe[2], Stanislas Pol[2], Laurent Alric[3], Caroline Lascoux-Combe[2], Dulce Alfaiate[4], Marie-Noëlle Hilleret[5], Nathalie Ganne-Carrié[6], Jérôme Gournay[7], Veronique Loustaud-Ratti[8], Miroslava Subic-Levrero[4], Fatoumata Coulibaly[9], Estelle Le Pabic[10], Christelle Tual[10], Segolene Brichler[6], Fabien Zoulim[4]. *[1]CHU Bordeaux, pessac, France; [2]APHP, Paris, France; [3]CHU Toulouse, Toulouse, France; [4]CHU Lyon, Lyon, France; [5]CHU Grenoble, Grenoble, France; [6]APHP, Bobigny, France; [7]CHU Nantes, Nantes, France; [8]CHU Limoges, Limoges, France; [9]ANRS, Paris, France; [10]CHU Rennes, Rennes, France*
Email: victor.deledinghen@chu-bordeaux.fr

Background and aims: Bulevirtide (BLV) has been approved for the treatment of patients with HDV infection. However, the long-term efficacy is unknown. The aim of this analysis was to evaluate the prevalence and factors associated with sustained virological response (SVR) in patients treated with BLV 2 mg daily with or without PEG-IFNα 2a in the French ANRS Buledelta cohort.

Method: Out of the 271 patients enrolled in the BuleDelta cohort, 30 patients with chronic HDV infection who stopped antiviral therapy were included in this analysis. Their characteristics were as follows: male 53.3%, mean age 45.7 ± 11.5 years, mean liver stiffness measurement 12.2 ± 8.3 kPa, cirrhosis 76.7%, median HDV-RNA 5.88 [Interquartile Range (IQR): 5.07; 6.56] $\log_{10}$ (IU/ml), median qHBsAg 3544 [IQR: 878.8; 9356.0] UI/ml. Patients received 16.8 ± 7.7 months of BLV 2 mg QD SC alone (N = 11) or in combination with PEG-IFNα once weekly (N = 19) according to physician's choice. All patients had undetectable or unquantifiable HDV RNA when stopping treatment. SVR was defined as persistently undetectable or unquantifiable HDV-RNA during their follow-up (FU).

Results: During the first 48 weeks FU, 17 patients (56.7%) experienced a relapse (quantifiable HDV RNA). Relapse was observed in 9/17 patients (52.9%) within the first 12 weeks FU. For the other 8, 5 relapsed at FU24 and 3 at FU36. None of the following factors was associated with SVR: age, gender, BLV duration, pegIFN treatment, cirrhosis, HDV RNA viral load, normal ALT at the end of treatment, time between the first unquantifiable HDV RNA and discontinuation of treatment, time between the start of treatment and the first unquantifiable HDV RNA. Three patients had qHBsAg below 100 IU/ml at the end of treatment (68.5, 66.6, 84.0, respectively). Among them, 2 experienced a relapse.

Conclusion: In patients who stopped treatment with BLV with or without pegIFN, SVR was observed in 43.3%. No factor was identified to be associated with SVR. Relapse was observed in more than 50% of patients during the first 12 weeks FU. Larger studies are needed to identify baseline or on-treatment predictive factors of SVR.

WED-411

The large (LHBs) and middle (MHBs) hepatitis B surface antigen are associated with response to bulevirtide or PEG-IFNa treatment in patients with chronic hepatitis Delta (CHD)

Maria Pfefferkorn[1], Jonathan Seltmann[1], Romy Winkler[1], Rodrigue Kamga Wouambo[2], Sara Sopena Santisteve[3,4], Madlen Matz-Soja[1,5], Maria Buti[3,6,7], Heyne Renate[8], Pietro Lampertico[9,10], Thomas Berg[1], Florian van Bömmel[1]. *[1]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany; [2]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Germany, Germany; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain; [4]Liver Pathology Lab, Biochemistry and Microbiology Departments (Clinical Laboratories), Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain; [5]Rudolf-Schönheimer-Institute for Biochemistry, Leipzig, Germany; [6]Universitat Autònoma de Barcelona (UAB), Department of Medicine, Barcelona, Spain; [7]Liver Unit, Internal Medicine Department, Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain; [8]Liver and Study Center Checkpoint, Berlin, Germany; [9]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [10]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: Maria.pfefferkorn@medizin.uni-leipzig.de

Background and aims: CHD can be treated with the entry inhibitor bulevirtide (BLV) or with the immune modulator PEG-IFNa, but predicting treatment response remains uncertain. The composition of hepatitis B surface antigen (HBsAg), including large (L), middle (M), and small (S) forms, has been associated with HBsAg loss in hepatitis B virus (HBV) mono-infection. This study aimed to evaluate HBsAg composition in the natural course of CHD and its association with treatment response.

Method: 42 CHD patients receiving either 180 mg/week PEG-IFNa (n = 30) or 2 mg/day BLV (+ TDF 245 mg/day; n = 12) from 4 European centers (Leipzig, Berlin, Barcelona and Milan) were observed for a mean duration of 33.4 (12–156) months. Patients were divided according to their treatment response (decreases of HDV RNA or undetectability) after 12 months: I) Nonresponse defined as a <2 log decline in HDV RNA levels (NR; n = 17), II) partial response: a ≥2 log IU/ml decline (n = 4), III) complete response: undetectable HDV RNA levels (n = 13) and VI) functional cure with HBsAg loss (n = 4). Six additional patients who underwent liver transplantation (after a mean time of 60 (2–72) months), with (2 with PEG-IFN and 2 with TDF treatment) or without (n = 1) treatment, were included. HBsAg composition, HDV RNA and HBV DNA were quantified in serum samples at time points BL, 6, 12, 18, and 24 months.

Results: Prior to treatment initiation, all groups showed similar levels of HDV RNA (6.5 logIU/ml), total HBsAg (4.1$\log_{10}$ng/ml), LHBs (2.8$\log_{10}$ng/ml) and MHBs (2.9$\log_{10}$ng/ml). Patients with subsequent transplantation or NR receiving either PEG-IFNa or BLV showed the highest proportions of MHBs (%) and LHBs (%) and showed no changes in either HBsAg levels, MHBs (%) and LHBs (%) during treatment (after 6 to 24 months), respectively. In contrast, patients with complete virologic response exhibited a decrease in MHBs (%) from 10.9 (6.9–26.5)% at BL to 2.1 (0–3.1)% after 12 months with PEG-IFNa (n = 7; p = 0.016) and from 10.5 (3.3–19.4)% at BL to 2.9 (2.3–3.5)% after 12 months with BLV (n = 6). Furthermore, establishing a BL-Cutoff for MHBs % and LHBs % showed that patients with <8% MHBs or <4.8% LHBs at the start of either PEG-IFN or BLV treatment had significantly higher likelihood to achieve a complete virologic response during treatment (60% vs. 14.3%; $p < 0.005$ for MHBs and 83% vs. 16% for LHBs; $p < 0.005$).

Conclusion: MHBs and LHBs may serve as valuable markers for monitoring treatment response to PEG-IFNa and BLV in patients with

CHD. However, these findings require validation in a larger patient cohort.

WED-412

Functional cure and prediction analysis of pegylated interferon alpha-2b in HBeAg negative chronic hepatitis B patients with normal ALT (Ice-breaking Project in China): an interim analysis update

Email: zhangchong_83@163.com

Background and aims: In China, the proportion of Hepatitis B e antigen (HBeAg) negative chronic hepatitis B (CHB) patients is gradually increasing, which is related to the pre-C region mutation of long-term HBV infection. The disease progression of HBeAg negative CHB patients is fast, a large proportion of them have moderate or advanced liver inflammation or fibrosis, even if alanine aminotransferase (ALT) is normal, which requires timely antiviral treatment. The purpose of this study was to analyse the efficacy of pegylated interferon alpha-2b (PegIFNα-2b) in HBeAg negative CHB patients with normal ALT, and to explore the predictive factors of virological and serological responses. Preliminary data was presented at EASL2023 and here we update the latest results of this project.
Method: This is a multi-center, prospective, non-interventive, real-world clinical study conducted in China, involving 20 hospitals in 12 provinces or municipalities, which enrolled CHB patients with age of 18–60 years, Hepatitis B surface antigen (HBsAg) positive for more than 6 months, HBeAg negative, HBV DNA >20 IU/ml and normal ALT, without antivirus treatment history. PegIFN α-2b 180 μg/week was applied on a voluntary basis. Examinations were performed every 12 weeks during treatment to monitor antiviral efficacy and adverse effects. The treatment strategy is adjusted according to the virological and serological response every 24 weeks, the total treatment course is not exceeded 96 weeks.
Results: A total of 249 patients were currently enrolled, and statistical analysis only be performed on 120 patients who completed PegIFNα-2b treatment. 72 (60.0%) were male, with an average age of 39.76 ± 8.28 years (21–60 years). The median baseline HBV DNA and HBsAg were 6.87×10^2 IU/ml ($1.00 \times 10^1 \sim 7.62 \times 10^6$) and 297.91 IU/ml (0.12 ~ 32828.22) respectively. The mean duration of PegIFNα-2b treatment was 12.78 months. 43 patients (35.83%) achieved HBsAg loss, and their baseline HBsAg levels were significantly lower than those who did not achieve HBsAg loss (381.29 ± 827.18 vs. 1872.31 ± 4102.32, p <0.001). 23 patients achieved HBsAg loss after a short course of 6–9 months, with lower baseline HBsAg levels compared to those achieved HBsAg loss after a course of ≥12 months (96.34 ± 141.54 vs. 708.98 ± 1130.47, p < 0.001). Furthermore, HBsAg loss rate increased to 52.38% in patients with baseline HBV DNA <1000 IU/ml and HBsAg <500 IU/ml, and 66.67% in those with baseline HBV DNA <100 IU/ml and HBsAg <100 IU/ml. These patients all experienced functional cure with a short course of PegIFNα-2b treatment.
Conclusion: HBeAg negative CHB patients with normal ALT can achieve a high rate of functional cure by PegIFNα-2b therapy, especially for those with low baseline HBV DNA and HBsAg levels, only a short course of PegIFNα-2b treatment is required.

WED-413

10-year results under tenofovir disoproxil fumarate and entecavir in chronic hepatitis B; HBV clearance rare, disease outcomes good

Zülal İstemihan[1], Gamze Kemeç[2], Timurhan Cebeci[2], Okan Cetin[2], Sezen Genç Uluçeçen[1], Aynure Rüstemzade[1], Kanan Nuriyev[1], Bilger Çavuş[1], Asli Çifcibasi Örmeci[1], Filiz Akyuz[1], Kadir Demir[1], Fatih Beşışık[1], Sabahattin Kaymakoğlu[1]. *[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Gastroenterohepatology, Istanbul, Turkey; [2]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*
Email: kaymakoglus@hotmail.com

Background and aims: This study aims to investigate antiviral effectiveness, side effects, and disease outcomes in patients who have been using oral antivirals for a long-term in chronic hepatitis B (CHB).
Method: Patients with CHB who had been using tenofovir disoproxil fumarate (TDF) or entecavir (ETV) for at least 10 years were included in this retrospective study. Co-infected patients, those receiving immunosuppressive therapy, and transplant patients were excluded.
Results: Of the total 173 patients (baseline mean age 43.44 ± 11.74 years) in the study, 110 (63.6%) were men. 33 (19.1%) patients were cirrhotic, and HBeAg was negative in 131 (75.7%) patients at the beginning of treatment. 94 (54.3%) patients were treatment-naive. 92 (53.2%) patients used TDF and 81 (46.8%) patients used ETV for a mean of 156.76 ± 21.60 (120–204) months. HBV-DNA negativity (<10 IU/ml) was achieved in 100% of those who received ETV and in 95.5% of those who received TDF, and there was no statistical difference between them (p = 0.06). Patients who remained HBV-DNA positive were non-compliant with treatment. HBsAg became negative in only 4 (2.3%) patients, 2 of them developed anti-HBs. In the total group ALT normalization (<42 U/L) was observed in 96.8% of patients with elevated baseline ALT. 13 (39.4%) of 33 patients who were cirrhotic at baseline regressed to the noncirrhotic stage, in this group, platelets were significantly high (>150 10^3/μl) before the treatment (p < 0.05). 8 (5.7%) of 140 noncirrhotic patients at baseline progressed to the cirrhotic stage. 7 (4%) of all patients decompensated. In the total group, FIB-4 and APRI scores decreased significantly under treatment (p = 0.009 and p = 0.000, respectively). Hepatocellular carcinoma (HCC) developed in 9 (5.2%) patients. All HCCs occurred after the 5th year of treatment. PAGE-B score was significantly higher in those who developed HCC (p = 0.009). HCC was significantly more common in treatment-naive patients (p = 0.033). The age at HBV diagnosis was significantly higher in HCC patients (p = 0.023), but the most important risk factor for the development of HCC was cirrhosis at baseline. Cirrhosis increased the risk of HCC by 7.8 times. 8 (4.6%) patients died in the follow-up, and 2 were due to liver disease and the remaining non-liver disease. During follow-up, nephropathy (GFR <60 ml/min) developed in 13 (7.5%) patients, and hypophosphatemia (p <2.5 mg/dL) developed in 19 (11%) patients. The rate of side effects in TDF recipients was significantly higher (p = 0.018).
Conclusion: At the end of 10 years, HBV-DNA negativity was achieved in almost all patients, and HBsAg sero-clearance was rarely achieved. Treatment-related side effects were more common in TDF. Nearly half of cirrhotic patients regressed to the noncirrhotic stage. Very few patients developed HCC and the 10-year mortality rate was similar to the general population.

Email: pietro.lampertico@unimi.it

Background and aims: Bulevirtide (BLV) is the only approved drug for patients with chronic hepatitis delta (CHD). In Italy this drug has been available since 2021, but no studies so far have addressed the demographic, virological and clinical features of patients treated with BLV monotherapy or in combination.

Method: Consecutive HDV patients with chronic hepatitis Delta (CHD) starting BLV 2 mg/day as monotherapy or in combination with pegIFNalpha were included in a multicenter real-life Italian study (D-SHIELD). Patients' characteristics before and during BLV treatment were collected. Virological, biochemical, clinical features were assessed.

Results: 257 patients with CHD from 26 centers were enrolled in this ongoing study. 99% received BLV 2 mg/day monotherapy: median age was 53 (28–81) years, 55% men, 96% of European origin, 83% with cirrhosis, 7% HIV-coinfected. Among patients with cirrhosis, 40% had varices, 10% had a history of HCC (active in 7%), 11% had a history of ascites (5% persistent), 3% with previous varices hemorrhage, 6% had decompensated (CPT-B) cirrhosis. At BLV start, median ALT were 79 (18–1, 074) U/L, liver stiffness measurement (LSM) 14.1 (4.0–68.1) kPa, platelets 112 (14–362) × 10^3/mm^3, 97% patients were on NUC therapy, 89% HBeAg negative. Median HDV RNA was 5.3 (1.5–8.2) log IU/ml and HBsAg 3.7 (0.6–4.7) log IU/ml. Patients with cirrhosis had lower HDV RNA values compared to non-cirrhotic patients (5.21 *vs.* 5.69 Log IU/ml, p = 0.03), while no differences were observed concerning HBsAg (3.69 *vs.* 3.83 Log IU/ml, p = 0.2) and ALT levels (80 U/L *vs.* 75, p = 0.4).

Conclusion: D-SHIELD is the largest single country study on BLV treatment for CHD in Europe Almost all Italian patients starting this new treatment option have been treated with 2 mg/day monotherapy. Most patients were European-born, with advanced liver disease, high viral load and elevated ALT levels.

WED-415

Effectiveness and safety analysis of switching to tenofovir alafenamide after entecavir or tenofovir treatment

Xue Liu[1], Zhihao Zhao[1], Xianggen Kong[2], Shiyu Cui[2], Xuemei Jiang[2]. *[1]Shandong university, Jinan, China; [2]Shandong public health clinical center, Jinan, China*
Email: shdjxm@163.com

Background and aims: To investigate the effectiveness and safety of switching to tenofovir alafenamide (TAF) in patients with chronic viral hepatitis B after taking entecavir (ETV) or tenofovir (TDF) in a real-life setting.

Method: A total of 149 patients with chronic viral hepatitis B who had impaired renal function or were potentially at risk, or chronic viral hepatitis B with low viral load, were enrolled in the study from January 1, 2013 to May 1, 2023 by Shandong Public Health Clinical Center. The patients were divided into G1: ETV-TAF (61 patients) and G2: TDF-TAF (88 patients). All patients were followed up for at least 48 weeks. During the follow-up period, HBV DNA levels, HBsAg quantitative levels, liver function, renal function and blood lipids were collected, analyzed and compared between the two groups.

Results: At baseline, there were no statistical differences between the two groups in the rate of complete virologic response, quantitative HBsAg levels, or ALT levels. At 48 weeks of switching to TAF, both groups had significantly higher rates of complete virological response (G1 : 54.1% vs. 67.2%, χ^2 = 48.865, P = 0.000; G2: 63.6% vs. 77.3%, χ^2 = 3.931, P = 0.047) and significantly lower quantitative HBsAg levels (G1: z = – 4.879, p = 0.000; G2: z = 3.174, p = 0.002) and lower mean ALT values (G1: z = 2.237, p = 0.000; G2: z = – 2.571, p = 0.010) compared to baseline. In the both groups, eGFR levels increased compared with baseline, but there was no statistically difference at weeks 48. At baseline, 16 and 33 patients in the ETV-TAF group and TDF-TAF group, had an eGFR of less than 90 ml/min/1.73 m^2, and after 48 weeks of switching to TAF therapy, 6 patients in each group had an eGFR of greater than 90 ml/min/1.73 m^2. Median urinary beta-2 microglobulin levels improved significantly from baseline in both groups after 48 weeks of switching to TAF (G1: z = –2.785, p = 0.005; G2: z = –4.008, p = 0.000). There were no significant differences in triglyceride, LDL, total cholesterol, and HDL levels compared to

baseline at 24 and 48 weeks after switching in the ETV-TAF group, whereas in the TDF-TAF group at 48 weeks after switching, LDL and total cholesterol levels were higher compared to baseline, but there was no statistically difference in the proportion of patients with dyslipidaemia after 48 weeks of switching to TAF treatment in both the ETV-TAF group and the TDF-TAF group compared to baseline.
Conclusion: In patients with impaired renal function or potentially at risk for chronic hepatitis B, or chronic viral hepatitis B with low viral load, switching from ETV or TDF to TAF resulted in sustained enhancement of virologic response, sustained reduction in surface antigen levels, and improvement in ALT. Notably, patients experienced improvements in glomerular function and tubular markers.

WED-418

A national multicenter study on initial antiviral treatment preferences on chronic hepatitis B: Entecavir versus Tenofovir disoproxil fumarate

Tansu Yamazhan[1], Esra Zerdali[2], Yusuf Onlen[3], Selma Tosun[4], Özgür Günal[5], Ayse Batirel[6], İmran Hasanoğlu[7], Tuba Turunç[8], Umay Balcı[9], Sibel Yildiz Kaya[10], Oğuz Karabay[11], Ilknur Esen Yildiz[12], Lütfiye Nilsun Altunal[13], Deniz Cevahir Ozkaya[14], Selçuk Kaya[15], Ayşe İnci[13], Sevil Alkan[16], Dilek Yildiz[13], Tayibe Bal[17], Esma Aslıhan Aydemir[18], Nurullah Eser[19], Serhat Uysal[20], Fehmi Tabak[10], Rahmet Guner[21]. *[1]Ege University Infecitous Diseases and Clinical Microbiology, izmir, Turkey; [2]Sağlık Bilimleri Uiversity, İstanbul, Turkey; [3]Mustafa Kemal University, Hatay, Turkey; [4]Sağlık Bilimleri University, İzmir, Turkey; [5]Samsun University, Samsun, Turkey; [6]Sağlık Bilimleri University, istanbul, Turkey; [7]Sağlık Bilimleri University, ankara, Turkey; [8]Sağlık Bilimleri University, Adana, Turkey; [9]Sağlık Bilimleri University, Antalya, Turkey; [10]Cerrahpaşa University, istanbul, Turkey; [11]Sakarya University, Sakarya, Turkey; [12]Recep Tayyip Erdoğan University, Rize, Turkey; [13]Sağlık Bilimleri University, istanbul, Turkey; [14]Sağlık Bilimleri University, izmir, Turkey; [15]Onsekiz Mart University, Çanakkale, Turkey; [16]Onsekiz Mart University, Çanakkale, Turkey; [17]Abant İzzet Baysal University, Bolu, Turkey; [18]Samsun University, Samsun, Turkey; [19]Sağlık Bilimleri University, İstanbul, Turkey; [20]Fırat University, Elazığ, Turkey; [21]Sağlık Bilimleri University, Ankara, Turkey*
Email: tansuyamazhan@gmail.com

Background and aims: No current medications for chronic HBV treatment aim at eradicating the virus; therefore, the main goal of successful therapy is achieving functional cure through long-term or lifelong treatments. In selecting the initial antiviral drug, identifying comorbidities and monitoring possible long-term side effects are key considerations outlined in national and international guidelines. This study investigates whether there are statistically significant differences/differences in patient or disease parameters when a physician initiates entecavir (ETV) or tenofovir disoproxil fumarate (TDF) in a chronic HBV patient.
Method: Patient data was recorded by "electronic patient follow-up form. Treatment naïve, >18 years old, diagnosed with chronic HBV for at least 1 year since 2010 and initiated on antiviral therapy were included. Patients' data, including age and gender, age at diagnosis and treatment initiation, body mass index (BMI), the presence of comorbidities, liver disease activity, liver biopsy results, presence of cirrhosis and/or hepatic steatosis, the status of the virus via HBeAg positivity result, HBV-DNA levels; host factors including renal functions, cholesterol, triglyceride levels and basal bone mineral density (BMD), assessed using dual-energy X-ray absorptiometry (DEXA) test.
Results: The study involved 31 centers from Türkiye. Data from a total of 2, 259 (1, 391 were male (61.6%)) patients were analyzed. Among the participants, with 1, 270 patients (56.22%) initially opting for TDF and 989 (43.78%) for ETV. ETV was preferred in males, while TDF was chosen more in females ($p = 0.005$). The mean of ages at diagnosis and treatment initiation for ETV were 40, ± 13, and 44, ± 13 and for TDF they were 36, ± 13, and 40, ± 12 ($p < 0.001$). TDF was more often chosen as the initial treatment in patients with lower BMI (median 25.7 versus 26.2 $p = 0.001$). The median initial creatinine level for TDF and ETV was 0.75 and 0.80 respectively ($p < 0.001$). The situation is similar for eGFR, where the median for the ETV group was 94.37, TDF group was 101.12. In patients with an initial eGFR value <60 (n: 36), upon reevaluation, physicians favored ETV as the initial drug choice ($p < 0.001$). BMD was assessed in 365 (16.3%) patients prior to treatment. DEXA tests were conducted in 116 (11.8%) and 249 (19.8%) patients who were to start ETV and TDF, respectively ($p < 0.001$).
Conclusion: Our study is an important national multicenter study with a broad patient series that clearly outlines the factors considered by infectious disease and hepatology specialists when initiating treatment for chronic HBV. Patient-related parameters; gender, age at diagnosis and treatment initiation of the disease, baseline renal functions, and the status and stage of the virus or liver disease have been found to be more important than the disease itself in drug selection.

WED-419

Comparative efficacy of standard and low-dose peginterferon-alpha2a in chronic delta hepatitis: a retrospective controlled study

Asim Qurbanov[1], Elvan Isik[2], Ilker Turan[2], Galip Ersoz[2], Fulya Günsar[2], Zeki Karasu[2], Ulus Akarca[2]. *[1]Ege University, Faculty of Medicine, Department of Internal Medicine, Izmir, Turkey; [2]Ege University, Faculty of Medicine, Department of Gastroenterology, Izmir, Turkey*
Email: ulusakarca@gmail.com

Background and aims: Chronic delta hepatitis represents the most severe form of viral hepatitis, yet therapeutic options remain limited. While interferon-based therapies have been the cornerstone of treatment, their use is hampered by substantial side effects and marginal efficacy. This study assesses the effectiveness and tolerability of standard-dose versus low-dose peginterferon-alpha2a in patients with compensated chronic delta hepatitis.
Method: We conducted a retrospective analysis of patients treated with peginterferon-alpha2a at our center from 2000 to 2020. Patients receiving low-dose therapy (135 or 90 ug per week) over the past 5 years were compared with those treated with the standard dose (180 ug per week). End points included alanine aminotransferase (ALT) normalization and Delta RNA clearance.
Results: Our cohort comprised 45 patients, predominantly male (73%) with a mean age of 45.2 years. Treatment distribution was 20 patients on standard dose and 25 on low dose. Pretreatment transaminase levels, platelets counts, protrombin time, renal functions, HBV DNA and HDV RNA levels, rates of cirrhosis and prior interferon use were comparable. Cirrhosis was present in 38%, and 36% had prior interferon therapy. Median treatment durations in regular and low dose groups were 13 and 12 months, respectively. The complete response rates at 6, 12, and 18 months for standard and low-dose groups were 35%, 45%, 30% and 20%, 24%, 28%, respectively, with no significant differences. Side effect profiles were similar, though less hematological toxicity was noted in the low-dose group.
Conclusion: Low-dose peginterferon-alpha2a demonstrates comparable efficacy to the standard dose in chronic delta hepatitis, with a trend toward a better side effect profile. This approach may offer a cost-effective alternative in managing this challenging condition.

Dosing with the Capsid Assembly Modulator ALG-000184 in Untreated HBeAg Negative CHB Subjects Results in Potent Antiviral Effects Including Suppression of HBV DNA/RNA and Declines in HBcrAg Levels

Kosh Agarwal[1], Edward J. Gane[2], Man-Fung Yuen[3], Christian Schwabe[4], Alina Jucov[5], Alexei Haceatrean[5], Min Wu[6], Kha Le[6], Maida Maderazo[6], Lawrence Blatt[6], Sushmita Chanda[6], Tse-I Lin[6], Matt McClure[6]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]Faculty of Medicine, University of Auckland, Auckland, New Zealand; [3]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China; [4]New Zealand Clinical Research Limited, Auckland, New Zealand; [5]ARENSIA Exploratory Medicine, Republican Clinical Hospital and Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova; [6]Aligos Therapeutics, Inc., South San Francisco, United States*
Email: kosh.agarwal@kcl.ac.uk

Background and aims: ALG-000184 is a prodrug of ALG-001075, a potent chronic hepatitis B (CHB) capsid assembly modulator-empty (CAM-E) that inhibits viral replication and cccDNA establishment in vitro.

Method: ALG-000184-201 is a multi-part, multi-center, double-blind, randomized, placebo-controlled study (NCT04536337). In Part 4 Cohort B, eligible treatment naïve or currently-not-treated HBeAg+ and HBeAg- CHB subjects are receiving open-label daily doses of 300 mg ALG-000184 alone × ≤96 weeks. Previously, we reported that HBeAg+ subjects treated for ≤48 weeks in this cohort experienced potent antiviral effects as seen by declines in HBV DNA, RNA and multiple antigen levels (Yuen et al., AASLD 2023). Here we report for the first time antiviral and safety data in HBeAg- subjects who received 300 mg ALG-000184 monotherapy × ≤40 weeks.

Results: 11 HBeAg- subjects were enrolled with a mean age of 48 years; they were 55% male, 73% non-Asian and had a mean (SEM) BMI of 26 (1.1) kg/m^2. Subjects were infected with HBV genotype D (n = 7, 64%), B (n = 2, 18%), C (n = 1, 9%) and A (n = 1, 9%). At baseline, mean (SEM) viral marker values were: 4.3 (0.2) $\log_{10}$ IU/ml for DNA, 2.0 (0.3) $\log_{10}$ copies/ml for RNA, 3.5 (0.2) $\log_{10}$ IU/ml for HBsAg and 3.1 (0.3) $\log_{10}$ U/ml for HBcrAg. During 300 mg ALG-000184 monotherapy, all subjects achieved undetectable HBV DNA (<10 IU/ml) within 20 weeks and RNA (<10 copies/ml) levels within 42 days. No viral breakthroughs have occurred. HBcrAg levels (iTACT-HBcrAg assay, LLOQ: <1.8 $\log_{10}$ IU/ml) declined rapidly in the first 28 days of treatment followed by a slower downward trend. The maximum mean (SEM) and individual HBcrAg reductions through Week 40 were 0.5 (0.2) $\log_{10}$ IU/ml and 0.7 $\log_{10}$ IU/ml, respectively. HBcrAg reductions ≥0.5 $\log_{10}$ IU/ml have been observed in 40% of subjects and one additional subject (with a low baseline level) became undetectable at Day 28, which has been maintained throughout treatment. No clinically significant decline was observed in HBsAg. The ALG-000184 safety profile remains favorable with no serious adverse events or discontinuations due to treatment-emergent adverse events (TEAEs) reported. Grade ≥3 TEAEs were reported in 2 subjects: an asymptomatic cholesterol and triglycerides increase (n = 1), which has been improving despite continued dosing, and one asymptomatic liver transaminase elevation (n = 1), which resolved despite continued dosing and was without clinically significant changes of liver synthetic function. This event was assessed as not being related to drug toxicity by an independent safety committee.

Conclusion: Consistent with its in vitro antiviral properties, dosing with ALG-000184 demonstrated dual antiviral effects in untreated HBeAg- CHB subjects: complete suppression of HBV DNA and RNA, suggesting inhibition of HBV replication, as well as reducing HBcrAg levels, indicating inhibition of cccDNA establishment/replenishment.

WED-362

Rapid hepatitis B surface antigen reduction in chronic hepatitis B virus infection: preliminary results from a phase I b study evaluating multiple ascending doses of HT-102, a neutralizing antibodies against hepatitis B surface antigen in chronic hepatitis B patients

Dong Wang[1], Shanzhong Zhang[1], Yanqin Ma[1], Lijuan Ding[1], Zhipeng Zhang[1], Ying Qu[2], Lungen Lu[2]. *[1]Suzhou Hepa Thera Biopharmaceutical Co.Ltd., Shanghai, China; [2]Department of Gastroenterology, Shanghai General Hospital, Shanghai, China*
Email: wangdong@hepathera.com

Background and aims: HT-102 is a human monoclonal antibody targeting the conserved antigenic loop of hepatitis B surface antigen (HBsAg) with the potential to functions as 1) inhibition of hepatitis B virus (HBV) entry into cells, 2) elimination of virons and sub-viral particles for the treatment of chronic HBV infection. Single dose of HT-102 up to 600 mg were well tolerated in healthy subjects. Here, we reported preliminary Phase Ib data in subjects with chronic HBV infection.

Method: This was a randomized, double-blind, placebo-controlled, phase Ib, multiple ascending doses study of HT-102 administered via subcutaneous (SC) injection to subjects with chronic HBV infection. The 1b part enrolled subjects who were on nucleos (t)ide reverse transcriptase inhibitor (NRTI) therapy ≥2 months and had HBsAg >200 IU/ml, <3, 000 IU/ml with hepatitis B e antigen (HBeAg) negative at screening and HBV DNA <2, 000 IU/ml within 3 months before screening. Eligible patients were assigned to 50 mg, 150 mg, or 300 mg group to receive 5 SC HT-102 doses, every week for 4 weeks. Eight subjects per cohort were randomized (6:2) to receive HT-102 or placebo. All patients received NRTI treatment throughout the study. Patients were followed-up to Day 70 after the first HT-102 or placebo dosed. The protocol conformed to the Declaration of Helsinki guidelines and was approved by appropriate institutional review committee (s). Written informed consent was obtained prior to study procedures. Preliminary blinded data for the ongoing cohort evaluating 50 mg and 150 mg were presented.

Results: Sixteen subjects were enrolled in 50 mg, 150 mg of HT-102 or placebo and 12 subjects were randomized to receive 5 SC doses of HT-102, and 4 to receive placebo. Demographic and baseline characteristics were well balanced across cohorts (baseline HBsAg: 2.96 ± 0.35 log10 IU/ml for 50 mg group; 2.82 ± 0.24 log10 IU/ml for 150 mg group). In 50 mg group six subjects rapidly achieved mean 2.1 log10 IU/ml decline in HBsAg from baseline at nadir and in 150 mg group six subjects achieved mean HBsAg decreases 2.4 log10 IU/ml at nadir with sustained HBsAg declines for 4 weeks post last dose (4 subjects without HBsAg reduction were excluded in two cohorts). So far, all patients showed good safety and tolerability. All adverse event (AE)s were grade 1 or 2. No serious AEs or discontinuations due to AEs were reported. No subjects developed clinical or laboratory evidence of immune complex disease. Additional follow-up is ongoing.

Conclusion: Multiple doses of HT-102 50 mg or 150 mg was associated with rapid HBsAg reductions in the majority of subjects and greater HBsAg decline with longer sustained duration was observed in 150 mg group. Preliminary safety data suggested that HT-102 is generally well tolerated in CHB patients with NRTI. These early data support further evaluation of HT-102 as a potential functional cure for patients with chronic HBV infection.

WED-363

Promising preliminary data on preclinical efficacy with an innovative plasmid-launched live attenuated virus vaccine for chronic hepatitis B

Frederik Pauwels[1], Goele Bosmans[1], Sarah Provost[1], Thomas Vercruysse[1], Joeri Auwerx[1], Gregory Fanning[1], Mathieu Peeters[1], Wilfried Dalemans[1], Hanne Callewaert[1]. [1]*AstriVax, Leuven, Belgium*
Email: frederik.pauwels@astrivax.com

Background and aims: AstriVax is developing a vaccine platform technology that is suitable for prophylactic and therapeutic applications and is based on a plasmid-launched live attenuated virus (PLLAV) encompassing flaviviruses, like yellow fever virus (YFV) 17D vaccine strain that can carry foreign antigens. The YFV vaccine is one of the most effective vaccines available, inducing long-lived humoral responses as well as strong cellular immunogenicity. With the therapeutic potential of our platform, we initiated development of a potential best-in-class vaccine for chronic hepatitis B infection, where the induction of effective and long-lasting CD8 T-cell responses is considered key in eliminating infected hepatocytes.
Method: The hepatitis B virus (HBV) core (HBc) was used as a model antigen to insert into the polyprotein encoding YFV 17D. The ability of this recombinant live-attenuated virus (LAV) to induce cellular immune responses against HBc was evaluated preclinically in a mouse model permissive for YFV replication (deficient in interferon (IFN) signaling). Given the complexity of the animal models that can be used with this platform we performed an initial assessment of the effect of the induced HBc-specific T-cells on viral parameters in AAV-HBV transduced C57BL/6 mice by adoptive transfer ± liver microenvironment modulation using a toll-like receptor (TLR) 9 agonist.
Results: Single injection of YFV-HBc PLLAV induced YFV and HBc specific T-cell responses in uninfected permissive mice. Similarly, an immunization with PLLAV-derived YFV-HBc LAV resulted in the detection of comparable numbers of IFN-gamma spot-forming cells upon stimulation with peptides for YFV and HBc antigen. Adjuvanted HBc protein prime followed by YFV-HBc LAV vaccination 15 days later increased the number of IFN-gamma secreting HBc-specific T-cells compared to YFV-HBc LAV only vaccination. Isolated splenocytes were then used for passive immunization of C57BL/6 mice with established AAV-HBV infection and high surface antigen (HBsAg) baseline (>4 log IU/ml), resulting in significant decreases in serum HBsAg, transient transaminase increase and a reduction in transduced hepatocytes positive for HBc when combined with a TLR9 agonist.
Conclusion: We found that a YFV PLLAV carrying an HBc antigen induced robust T-cell responses against HBc in a YFV-permissive mouse model. Furthermore, we were able to show that adoptive transfer of heterologous prime-boost generated T-cells resulted in a sustained decline of HBV persistence, despite high baseline HBsAg levels. These promising early efficacy data demonstrate the potential of YFV-vectored vaccines in inducing strong and effective T-cell responses, and warrant further preclinical characterization of the vaccine platform in direct vaccination settings and evaluation in human studies as part of therapeutic regimen for chronic hepatitis B.

WED-364

High-dimensional analysis of flow cytometry data reveals differences in post-treatment frequencies of naïve B cells, CD56dim natural killer cells, and terminally differentiated effector memory CD8+ T cells in responders versus non-responders to bepirovirsen

Thea Hogan[1], Eduardo Gomez Castaneda[1], Esther Perez Garcia[1], Ruth Barnard[1], Avijit Ray[2], Melanie Paff[2], Dickens Theodore[3], Jennifer M. Singh[2]. [1]*GSK, Stevenage, United Kingdom;* [2]*GSK, Collegeville, PA, United States;* [3]*GSK, Durham, United States*
Email: jennifer.m.singh@gsk.com

Background and aims: Bepirovirsen (BPV) is an unconjugated antisense oligonucleotide in development for the treatment of chronic hepatitis B virus (HBV) infection. In the Phase 2b B-Clear study, 9–10% of participants (pts) with chronic HBV infection who received BPV 300 mg for 24 weeks achieved the primary outcome (hepatitis B surface antigen and HBV DNA loss sustained for 24 weeks off-treatment). This post hoc investigation used high-dimensional analysis of flow cytometry data to understand the immunological landscape in pts who received BPV in B-Clear and determine whether cell frequencies and/or phenotypes differ with treatment time and/or response.
Method: Flow cytometric analysis was performed on 114 peripheral blood mononuclear cell samples from 47 pts using a 30-colour deep immunophenotyping panel. Cells were visualised in a reduced dimensionality space (UMAP) and metaclustered using FlowSOM. Metaclusters showing differential abundance according to the pts off-treatment response (e.g. primary outcome responder, null responder) or change in abundance relative to baseline (ARB) at 3 post-treatment timepoints (off-treatment Day 1, 78 and 162) were further evaluated for phenotypic annotation. Analyses were descriptive. Selection was made based on sample availability.
Results: Baseline demographics and disease characteristics were similar between those who had flow analysis and those that did not. The UMAP space revealed unique cell clusters between primary outcome responders and null responders. FlowSOM analysis identified 17 B cell, 18 natural killer (NK) cell and 14 T cell metaclusters. Two B cell metaclusters showed increased ARB in primary outcome responders versus null responders at all post-treatment timepoints; both metaclusters had a phenotype consistent with naïve B cells. One NK cell metacluster showed increased ARB at later timepoints (off-treatment Day 78 and 162) in primary outcome responders versus null responders, with a phenotype consistent with CD56dim NK cells. One T cell metacluster showed increased ARB at all post-treatment timepoints in primary outcome responders versus null responders, with phenotypes consistent with the terminally differentiated effector memory (TEMRA) CD8+ T cell subset (Granzyme B+ and T cell factor 1+) and T cells expressing Valpha 7.2+ T cell receptor.
Conclusion: This high-dimensional analysis revealed increases in the post-treatment abundance of naïve B cells, $CD56^{dim}$ NK cells and TEMRA CD8+ T cells in responders versus non-responders to BPV in B-Clear. This analysis provides a first glance at the immunological landscape in pts treated with BPV. These data will shape analyses that will be applied to subsequent clinical trials to further elucidate the immune response in BPV-treated pts.
Funding: GSK (study 209668).

Email: jlhousmu@163.com

Background and aims: ALG-000184 is a prodrug of ALG-001075, a potent chronic hepatitis B (CHB) capsid assembly modulator-empty that inhibits viral replication and cccDNA establishment in vitro.
Method: ALG-000184-201 is a multi-part, multi-center, double-blind, randomized, placebo-controlled study (NCT04536337). In Part 4, eligible treatment naïve or currently-not-treated HBeAg+ CHB subjects were either randomly assigned (3:1) to receive oral daily doses of 300 mg ALG-000184 or placebo + entecavir (ETV) × 12 weeks followed by open-label treatment with 300 mg ALG-000184 + ETV × ≤96 weeks (Cohort 2); or receive open-label daily doses of 300 mg ALG-000184 alone × ≤96 weeks. Previously, we reported data of up to 48 weeks of treatment from these 2 cohorts, which showed greater reductions in HBV DNA/RNA and HBV antigens for ALG-000184 ± ETV vs. ETV alone. Here we report data after receiving 300 mg ALG-000184 ± ETV × ≤64 weeks.
Results: 22 HBeAg+/HBeAb- subjects were enrolled and received ≥12 weeks of treatment with ALG-000184 + ETV (n = 12) or ALG-000184 alone (n = 10). Mean (SEM) baseline viral marker values were HBV DNA 8.0 (0.2) $\log_{10}$ IU/ml; HBV RNA 6.0 (0.3) $\log_{10}$ copies/ml; HBsAg 4.3 (0.1) $\log_{10}$ IU/ml; HBeAg 2.4 (0.1) $\log_{10}$ PEI U/ml and HBcrAg 8.3 (0.1) $\log_{10}$ U/ml. After receiving 300 mg ALG-000184 ± ETV × ≤64 weeks, maximum (max) mean (SEM) reductions of HBV DNA and RNA were 7.1 (0.4) $\log_{10}$ IU/ml and 4.7 (0.7) $\log_{10}$ copies/ml. Of these subjects, 55% (n = 12) and 100% (n = 22) achieved <LLOQ for HBV DNA and RNA. No viral breakthrough has been observed in subjects receiving ALG-000184 alone. Mean (SEM) and max reductions in HBsAg, HBeAg, and HBcrAg were: 1.2 (0.4) and 2.1 $\log_{10}$ IU/ml, 1.8 (0.2) and 2.2 $\log_{10}$ PEI U/ml, 2.3 (0.3) and 2.7 $\log_{10}$ IU/ml, respectively. In parallel to HBeAg declines, mean (SEM) cut-off index (COI) of ROCHE Elecsys HBeAb assay (≤1 COI indicates anti-HBe positive) trended favorably, i.e. declining from baseline 5.2 (0.7) to 1.4 (0.1), suggestive of more non-HBeAg bound circulatory HBeAb. Two subjects have achieved HBeAb COI <1 along with substantial qHBeAg declines, which may suggest an ongoing transition to HBeAg seroconversion. Safety data continue to indicate ALG-000184 is well tolerated: no serious adverse events or discontinuations due to treatment-emergent adverse events (TEAEs) have been reported; Grade ≥3 TEAEs were reported in 7 subjects: uric acid increase (n = 1), eGFR decrease (n = 1), neutropenia (n = 1), cholesterol, triglycerides increase (n = 1) and ALT/AST elevations (n = 5). All resolved, improved or stabilized despite continued ALG-000184 dosing and were assessed by an independent safety committee as not being related to drug toxicity.
Conclusion: Treatment of HBeAg+ CHB subjects with ALG-000184 ± ETV continues to be well tolerated and lowers key viral markers over time. In parallel, an immunologic response may be emerging as evidenced by favorable trends for anti-HBeAb levels.

WED-366
Characterization of BJT-778, an anti-HBsAg neutralizing monoclonal antibody for treatment of hepatitis B virus and hepatitis D virus infections

Hilario Ramos[1], Ronald Alcala[2,3,4], Maud Michelet[2,3,4], Emmanuel Combe[2,3,4], Jerome Deval[1], Roy Grecko[1], Kevin Lin[1], Nancy Shulman[1], Fabien Zoulim[2,3,4,5], Keting Chu[1], Barbara Testoni[2,3,4], Hassan Javanbakht[1]. *[1]Bluejay Therapeutics, San Mateo, United States; [2]INSERM U1052, CNRS UMR-5286, Cancer Research Center of Lyon (CRCL), Lyon, France; [3]University of Lyon, Université Claude-Bernard (UCBL), Lyon, France; [4]Hepatology Institute of Lyon, Lyon, France; [5]Department of Hepatology, Croix Rousse Hospital, Hospices Civils de Lyon, Lyon, France*
Email: hramos@bluejaytx.com

Background and aims: Chronic hepatitis B (CHB) is a major health problem around the world, impacting millions of people. Compared to CHB infection alone, co-infection with Hepatitis D Virus (HDV) is associated with more severe liver disease, causing faster progression to cirrhosis, hepatocellular carcinoma, and liver failure. In this context, we have characterized BJT-778, a potent, pan-genotypic, fully human immunoglobulin G1 (IgG1) monoclonal antibody (mAb) with anti-HBsAg neutralizing properties, demonstrating its potential for the treatment of CHB and Chronic Hepatitis D (CHD).
Method: The binding affinity of BJT-778 to HBsAg was assessed using surface plasmon resonance. An enzyme-linked immunosorbent assay (ELISA) was used to assess the BJT-778 binding profile with representative HBsAg isolates from the major genotypes of HBV. The specificity of BJT-778 was evaluated using a Retrogenix human plasma membrane protein binding cell array, which includes 4, 955 overexpressed human membrane proteins. Furthermore, in vitro neutralization was determined against HBV and HDV enveloped with HBsAg representing major HBV genotypes. The in vivo efficacy of BJT-778 was also investigated in a humanized Fah/Rag2/IL-2rγ triple knockout (FRG) mouse model of chronic HBV infection.
Results: BJT-778 is a potent, selective, fully human IgG1-neutralizing mAb that targets the antigenic loop present in all forms of HBsAg proteins. It binds with high affinity to the HBsAg protein, with Kd values ranging from 0.22 to 0.39 nM. BJT-778 demonstrates effective binding to HBsAg proteins across major HBV genotypes, with half-maximal inhibitory concentration (IC_{50}) values ranging from 0.02 to 0.07 nM. It neutralizes both HBV and HDV infections in vitro, exhibiting picomolar half-maximal effective concentration (EC_{50}) values. Furthermore, its neutralization activity is pan-genotypic, as evidenced by tests conducted with HDV enveloped with HBsAg from major genotypes. Additionally, BJT-778 is highly specific for HBsAg and did not show significant binding to any of the 4, 955 tested human membrane proteins at a concentration of 2 μg/ml. In a humanized FRG mouse model, a 20 mg/kg dose of BJT-778 demonstrated rapid depletion of HBsAg from serum, achieving a reduction of 2.88_{10} logs within 30 minutes post-antibody administration. In contrast, the IgG control, a negative control antibody, exhibited minimal activity against HBsAg in this model.
Conclusion: BJT-778 is a potent, selective, fully human IgG1-neutralizing mAb that can neutralize HBV and HDV infections in vitro and clear HBsAg-containing particles from serum in a humanized mouse model. BJT-778 is currently undergoing clinical evaluation in subjects with CHB and CHD infections.

WED-367
Viral sequence analysis of chronic hepatitis B (CHB) patients treated with the silencing RNA (siRNA) JNJ-3989 in the REEF-1 and REEF-2 clinical studies

Thierry Verbinnen[1,1], Erkki Lathouwers[1], John Jerzorwski[2], Michael Biermer[1], Craig Grant[3], Kosh Agarwal[4], Man-Fung Yuen[5], Sandra De Meyer[1], Oliver Lenz[1]. *[1]Janssen Pharmaceutica NV, Beerse, Belgium; [2]Janssen Research and Development, LLC, Titusville, United States; [3]Janssen RandD, High Wycombe, United Kingdom; [4]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [5]Department of Medicine, The University of Hong Kong, Hong Kong, China*
Email: tverbinn@its.jnj.com

Background and aims: JNJ-3989 is an siRNA composed of 2 triggers targeting the HBsAg and HBx protein open reading frame. Baseline (BL) polymorphisms in the target region complementary to positions 2–18 of the S- and X-trigger, considered potentially relevant for binding and activity, were present in 10% and 2.4% of not currently treated (NCT) REEF-1 patients, respectively, with no impact on JNJ-3989 induced HBsAg decline.
Here, viral sequence changes in the S-/X-trigger target regions were evaluated in patients with virologic relapse (VR; at least transient off-treatment increase in HBV DNA to >200 IU/ml from <LLOQ) after discontinuation of all treatment in REEF-1 (NCT03982186) and REEF-2 (NCT0412954).
Method: HBV DNA/RNA was extracted from on- and off-treatment plasma samples with sufficiently high HBV DNA/RNA levels and HBV genome was sequenced using Illumina sequencing. Nucleotide (nt)

variants were defined as changes versus the universal HBV reference sequence (sequence read frequency >15%).
Results: In REEF-1, VR occurred in 30/37 (81%) JNJ-3989 treated virologically suppressed (VS) patients stopping all treatment-in REEF-2, in 54/77 (70%) JNJ-3989 treated and 39/40 (98%) NA-control arm patients, respectively. Across both studies 114/123 (93%) VS patients with VR had off-treatment HBV sequence data available. Variants at X-trigger target region positions of interest (POI) were more frequently observed off-treatment in JNJ-3989 treated VS patients than in NA-control arm VS patients with VR (56% and 5.7%, respectively). Variants at X-trigger target region POI 1794, 1785, and 1784 were observed off-treatment with a prevalence of 43%, 18% and 6.5%, respectively, which is higher than the prevalence of these variants off-treatment in either NA-only treated patients with VR (range: 0%–2.9%) or observed at baseline in REEF-1 NCT patients (range: 0%–1.2%). Variants at S-trigger target region POI were present off-treatment in 33% of JNJ-3989- and 19% of NA-only treated VS patients with VR and majority had variant at S-trigger POI 273, also frequently (10%) observed as at baseline in REEF-1 NCT patients. To assess if these variants observed during off-treatment follow-up were selected on-treatment, EOT samples from 30 NCT JNJ 3989-treated patients were evaluated using HBV RNA based sequencing and no emerging variants at S- or X-trigger target POI were detected.
Off-treatment HBsAg kinetics did not differ between JNJ-3989 treated patients with and without variants in S-/X-trigger target POI observed during VR.
Conclusion: In JNJ-3989-treated patients who discontinued all treatment and experienced VR, variants within the X-trigger target region were frequently observed during VR but were not selected on-treatment, suggesting that these X-trigger variants developed off-treatment in JNJ-3989 treated patients. Presence of these variants did not impact off-treatment HBsAg kinetics.

WED-370

Bepirovirsen immune mechanism of action may potentiate infected hepatocyte killing: indirect evidence from B-together peripheral longitudinal biomarker analysis

Shilpy Joshi[1], Johannes Freudenberg[1], Jennifer M. Singh[1], Leigh Felton[2], Susan Dixon[2], Melanie Paff[1], Dickens Theodore[3], Jill Walker[4]. [1]*GSK, Collegeville, PA, United States;* [2]*GSK, London, United Kingdom;* [3]*GSK, Research Triangle Park, NC, United States;* [4]*GSK, San Francisco, CA, United States*
Email: shilpy.s.joshi@gsk.com

Background and aims: B-Together assessed efficacy and safety of sequential bepirovirsen (BPV), an unconjugated antisense oligonucleotide, followed by pegylated interferon (PegIFN) in participants (pts) with chronic hepatitis B virus (HBV) infection. Previously, we demonstrated that pts treated with BPV may experience transient alanine transaminase (ALT) increases. We investigated the role of BPV's immune mechanism of action (MoA) with respect to virological response (VR) and surrogate markers associated with hepatocyte cell death using peripheral longitudinal biomarker exploratory analysis.
Method: B-Together was a Phase 2b trial in 108 pts on stable nucleos(t)ide analogues. Pts were randomised (1:1) to receive BPV for 12 or 24 weeks followed by up to 24 weeks of PegIFN. The primary end point was the proportion of pts with hepatitis B surface antigen and HBV DNA below the limit of detection for 24 weeks after end of treatment (tx). Here, peripheral blood mononuclear cells, blood, and serum samples were subjected to flow cytometry, whole blood transcriptomics (WBT) and proteomics analyses, respectively. Relative expression was measured at baseline (BL) and post-BL at multiple timepoints during the BPV, PegIFN and off-tx phases. To determine differential expression, multivariate models were fit that included tx arms and VR subgroups.
Results: By Week 3, BPV led to a significant increase from BL in mean expression of serum proteins, including several cytokines, independent of arms or VR subgroups. These proteins showed enrichment in immune effector response and apoptotic pathways. After 4 weeks of BPV, upward trends in proliferating activated CD8+ T-cells and B-cells were observed with a significant increase in mean expression from BL of some genes associated with proliferation in WBT independent of arms or response subgroups. After 7 weeks of BPV tx, a subset of proteins including liver and apoptosis-specific proteins showed increased abundance in serum and were more pronounced in BPV responders. Abundance of these proteins was highly correlated with ALT levels, which in turn was sometimes associated with transient low level HBV DNA elevations in serum; indirectly linking the observation to infected hepatocyte death.
Conclusion: BPV led to activation of the immune response in treated pts, providing support for an immune MoA. Three observations provide indirect evidence of a role for BPV in infected hepatocyte death: 1) presence of proliferating, activated adaptive immune cells in all response subgroups before rise in ALT; 2) increases in several liver and apoptosis-specific proteins in the serum concomitant with ALT elevations; 3) intermittent increase in HBV DNA during ALT elevations occurring more frequently in BPV responders than non-responders. Work is ongoing to further elucidate the multiple MoA of BPV and their roles in HBV functional cure.
Funding: GSK [209348/NCT04676724].

Email: ksims@arbutusbio.com

Background and aims: Functional cure of CHB will require suppression of viral replication, reduction of HBsAg and use of an immunomodulator such as pegylated interferon alfa-2a (IFN) to enhance HBV-specific immunity. Imdusiran (AB-729) is a GalNAc-conjugated single trigger siRNA that targets all HBV RNA transcripts and reduces all viral antigens including HBsAg. AB-729-201 is an ongoing Phase 2a study assessing 24 weeks of imdusiran followed by 12 or 24 weeks of IFN ± additional imdusiran doses in HBeAg-negative CHB subjects virally suppressed on nucleos(t)ide analogue (NA) therapy. Interim data through the end of the IFN treatment period (EOT) is available for all subjects.
Method: Forty-three subjects received imdusiran 60 mg every 8 weeks (wks) for 24 wks (4 doses) during the lead-in phase. After Wk

24, subjects were randomized to 1 of 4 sub-groups: A1 (24 wks IFN + 2 imdusiran doses + NA; N = 12), A2 (24 wks IFN + NA; N = 13), B1 (12 wks IFN + 1 imdusiran dose + NA; N = 8) or B2 (12 wks IFN + NA; N = 10). After completing IFN ± imdusiran treatment, subjects continued NA therapy for 24 wks and stopped NA therapy if ALT <2 × upper limit of normal, HBV DNA undetectable and HBsAg <100 IU/ml. Safety, antiviral and immunologic assessments were obtained. HBsAg was assessed via Roche Cobas Elecsys HBsAg II assay (lower limit of quantitation [LLOQ] = 0.05 IU/ml) and results <LLOQ were analyzed by Abbott HBsAg Next assay (sensitivity cutoff = 0.005 IU/ml).

Results: Baseline characteristics were described previously. All subjects have completed IFN dosing, and 18/43 subjects have been assessed for NA discontinuation (d/c) at Wk 76 or 64. In groups A1/A2, 7/25 (28%) subjects had HBsAg ≤LLOQ at EOT (Wk 52) and 5/7 were confirmed to be non-reactive with the Abbott Next assay. All 7 subjects had concurrent anti-HBs levels >10 IU/L, and 5/7 had levels >100 IU/L. In groups B1/B2, 0/18 subjects had HBsAg ≤LLOQ at EOT (Wk 40), although 2 reached <LLOQ during IFN treatment but subsequently rebounded. Group A1 had more profound HBsAg mean (±SE) $\log_{10}$ change from baseline at EOT than other groups; A1 = −2.85 (0.41) $\log_{10}$, A2 = −1.44 (0.43) $\log_{10}$, B1 = −1.85 (0.38) $\log_{10}$, and B2 = −1.68 (0.17) $\log_{10}$. Imdusiran treatment was well-tolerated with no serious adverse events (AEs) or AEs leading to d/c; IFN-related AEs were like those reported previously. Nine of 18 subjects have stopped NA therapy; 1 subject has HBsAg and HBV DNA <LLOQ after 6 months off NA therapy suggestive of functional cure, and 1 subject restarted therapy after 8 wks due to confirmed HBV DNA >20, 000 IU/ml with normal ALT levels.

Conclusion: HBsAg ≤LLOQ with detectable anti-HBs was observed at EOT in 28% of subjects who received 4 or 6 doses of imdusiran plus 24 weeks of IFN, but in 0 subjects who received 4 or 5 doses of imdusiran plus 12 weeks of IFN. The study remains ongoing and additional EOT data, durability of EOT HBsAg loss, and preliminary immunology data for a subset of study subjects will be presented.

WED-372

Downregulation of soluble FASLG as a potential mechanism of enhanced immune-related clearance of infected hepatocytes induced by JNJ-73763989 in HBeAg-negative virologically suppressed chronic hepatitis B patients

Simon Verheijden[1], Marianne Tuefferd[1], Marjolein Crabbe[1], Ewoud de Troyer[1], Thomas Vanwolleghem[2], Harry Janssen[3], Michael Biermer[4], Oliver Lenz[1]. *[1]Johnson and Johnson Innovative Medicine, Beerse, Belgium; [2]Antwerp University Hospital, Edegem, Belgium; [3]Centre for Liver Disease, Toronto, Canada; [4]Johnson and Johnson Innovative Medicine, Neuss, Germany*
Email: Sverhei1@its.jnj.com

Background and aims: Persistent exposure to hepatitis B surface antigen (HBsAg) in chronically infected hepatitis B patients can interfere with the host immune response to clear infected hepatocytes. JNJ-73763989 (JNJ-3989), a small interfering RNA (siRNA) targeting all HBV ribonucleic acid (RNA) transcripts resulting in profound HBV surface antigen (HBsAg) reductions, is currently under development for treatment of chronic hepatitis B. Here, we evaluated serum proteome changes during JNJ-3989 treatment across two clinical studies, to evaluate the effect of JNJ-3989 on host responses.

Method: Serum was collected from HBeAg-negative, virologically suppressed (VS) patients from two phase 2 studies with 48 weeks of JNJ-3989 based treatment: REEF-1 (n = 44) and REEF-2 (n = 35). Soluble serum proteins were evaluated with Olink Explore®, a high-throughput protein biomarker discovery platform used before in chronic hepatitis B studies. A mixed effects model was applied to assess serum protein changes during JNJ-3989 based treatment. Significantly affected proteins were explored by evaluating overlap between both studies and association with HBsAg levels.

Results: 84/1460 (5.8%) proteins (REEF-1) and 669/2943 (22.7%) proteins (REEF-2) were differentially expressed comparing baseline with on-treatment. 62 proteins were consistently changed under JNJ-3989 based treatment across both studies. Network analysis showed apoptosis (FAS, FASLG, TNFRSF10B, CTSF, CTSL) and glyoxylate/dicarboxylate, sphingolipid and carbohydrate metabolism (AGXT, SHMT1, HAO1, SMPD1, ASAH2, ENPP7) as the main pathways affected during JNJ-3989 treatment. Most of the upregulated proteins (56/62; 90.3%) were liver-enriched cytoplasmic proteins involved in hepatocyte metabolism, suggesting increased hepatocyte death. Soluble Fas Ligand (FASLG), a key protein involved in cell death induced by cytotoxic T/NK cells was downregulated in both studies and at multiple timepoints. Strikingly, we did not observe any association with FASLG levels and HBsAg levels at baseline or on-treatment. Only 1/62 protein (PON2) was associated with HBsAg levels at baseline, whereas 4/62 proteins (AGXT, C19orf12, CTSF, SEZ6L) were negatively associated with HBsAg levels at W48 of treatment, but not at baseline.

Conclusion: Serum proteomic analyses in VS HBeAg negative patients across two clinical studies showed that JNJ-3989 treatment reduces soluble FASLG and increases serum levels of intracellular hepatocyte proteins, suggestive of increased hepatocyte cell death. As soluble FASLG can interfere with the pro-apoptotic action of cytotoxic T/NK cells through steric hinderance of the membrane bound FAS/FASLG interaction, these data suggest JNJ-3989 treatment might improve clearance of infected hepatocytes by cytotoxic immune cells through restoration of FAS/FASLG mediated apoptotic signaling.

WED-373-YI

Epidemiological data and clinical profiles of hepatitis B surface antigen levels in chronic hepatitis B: implications for novel drug development

Rex Wan-Hin Hui[1], Trevor Kwan-Hung Wu[1], Ryan Hin-Man Leung[1], Lung Yi Loey Mak[1], Danny Ka-Ho Wong[1], James Fung[1], Wai-Kay Seto[1], Man-Fung Yuen[1]. *[1]The University of Hong Kong, Hong Kong, Hong Kong*
Email: huirex@connect.hku.hk

Background and aims: Quantitative hepatitis B surface antigen (qHBsAg) is an important biomarker in the management of chronic hepatitis B (CHB). qHBsAg <100 IU/ml is associated with spontaneous HBsAg seroclearance, whereas qHBsAg <1000 IU/ml is associated with improved treatment responses to different novel HBV antivirals. Despite its prognostic role, epidemiological data and clinical profiles of qHBsAg in CHB is not well-defined.

Method: We performed a large cohort study on CHB patients who received qHBsAg testing between 2009 and 2020 in Queen Mary Hospital, Hong Kong. Serum qHBsAg was measured by the Elecsys HBsAg II assay (lower limit of detection: 0.05 IU/ml). Patients with undetectable qHBsAg were excluded from this analysis. Tests for serum HBV DNA, hepatitis B e-antigen (HBeAg) and liver biochemistry were measured on the same samples. We reported proportions of patients with different qHBsAg levels and analysed factors associated with qHBsAg <1000 and <100 IU/ml respectively.

Results: This analysis included 4, 293 patients (62.5% male; mean age 48.0 ± 12.9; 20.4% HBeAg positive; 45.2% on nucleos[t]ide analogue [NUC]). The median qHBsAg level was 627.2 (interquartile range 117.0–1868.0) IU/ml. The proportion of patients in each qHBsAg strata were 8.3% with qHBsAg <10 IU/ml, 15.0% with 10–100 IU/ml, 35.5% with 100–1000 IU/ml, 21.5% with 1000–3000 IU/ml, 5.3% with 3000–5000 IU/ml, and 14.4% with ≥5000 IU/ml. This corresponds to 58.8% and 23.3% of patients with qHBsAg <1000 IU/ml and <100 IU/ml respectively. In treatment-naïve patients (n = 2, 354), 47.1%, 23.0% and 10.1% of patients had qHBsAg <1000 IU/ml, <100 IU/ml and <10 IU/ml respectively. In NUC-treated patients (n = 1, 939, median NUC duration 5.4 [3.6–8.1] years), 73.0%, 23.7% and 6.1% of patients had qHBsAg <1000 IU/ml, <100 IU/ml and 10 IU/ml respectively. Female sex (829.7 vs 518.6 IU/ml in males), treatment-naïve status (1242.0 vs 357.7 IU/ml in NUC-treated patients) and HBeAg-positive status (2398.0 vs 398.2 IU/ml in HBeAg-negative) were associated with higher qHBsAg levels respectively (all $p < 0.001$). Older age correlated with lower qHBsAg ($r = -0.157$, $p < 0.001$). Serum HBV DNA ($r = 0.188$),

alanine aminotransferase (r = 0.130) and bilirubin (r = 0.031) all weakly correlated with qHBsAg (all $p < 0.05$). In both treatment-naïve and NUC-treated groups, age and HBeAg status were independent predictors of qHBsAg <1000 IU/ml and <100 IU/ml respectively (all $p < 0.001$).
Conclusion: Over 40% of CHB patients have qHBsAg >1000 IU/ml. These patients are unlikely to have spontaneous HBsAg seroclearance, and will also have suboptimal responses to novel HBV antivirals, highlighting a potential treatment gap. Demographic, viral and treatment factors were associated with qHBsAg. Targeted strategies using different combination therapies and treatment durations for patients with specific characteristics should be studied in future clinical trials.

WED-374

Safety, tolerability, and pharmacokinetics of BJT-778, a monoclonal antibody for treatment of chronic hepatitis B and chronic hepatitis D, following single ascending doses in healthy volunteers

Edward J. Gane[1], Christian Schwabe[2], Patrick Smith[3], Courtney Moc Willeford[3], Carole Moore[4], Roy Grecko[4], Keting Chu[5], Hassan Javanbakht[4], Nancy Shulman[4,4]. [1]*University of Auckland, New Zealand Clinical Research, Auckland, New Zealand;* [2]*New Zealand Clinical Research, Auckland, New Zealand;* [3]*Certara, Inc., Princeton, NJ, United States;* [4]*Bluejay Therapeutics, Inc., San Mateo, CA, United States;* [5]*Bluejay Therapeutics, Inc., San Mateo, Inc, United States*
Email: edgane@adhb.govt.nz

Background and aims: BJT-778 is a potent, selective, fully human immunoglobulin G1-neutralizing monoclonal antibody that targets the antigenic loop present in all forms of hepatitis B surface antigen proteins, which are the key viral protein responsible for recognition, binding, and entry of hepatitis B virus (HBV) and hepatitis delta virus (HDV) virions to hepatocytes. In addition to preventing hepatocyte infection, BJT-778 should facilitate both clearance of circulating virions and presentation to antigen presenting cells, thereby enhancing HBV-specific T-cell responses. BJT-778-001 is an ongoing 2-part study evaluating the safety, tolerability, pharmacokinetics (PK), and antiviral activity of BJT-778 in healthy volunteers (HVs) and in subjects with chronic HBV (CHB) including those with chronic HDV (CHD) infection.
Method: Part 1 of the study is a Phase 1a/1b double-blind, randomized, placebo-controlled single-ascending-dose in HVs (Cohort A), CHB and CHD subjects (Cohorts B-D). Subjects were randomized 6:2 to receive a single subcutaneous dose of BJT-778 75 mg, 300 mg, or 900 mg, or placebo. Part 2 of the study is a multicenter, open-label Phase 2a multiple dose study in CHB and CHD subjects. Preliminary data from Cohort A of Part 1 are reported here.
Results: Among the 24 HVs in Cohort A, 18 HVs were randomized to receive BJT-778. Maximum plasma concentrations (Cmax) of BJT-778 were achieved at 7 days post-dose with mean elimination half-lives of approximately 27 to 37 days across all dose levels. The Cmax and area under the plasma concentration-time curve from time 0 to infinity (AUCinf) increased proportionally between 75 mg to 900 mg and mean values ranged from 6.74 to 87.1 ug/ml (Cmax) and 333 to 5070 day*ug/ml (AUCinf). In vitro, the half maximal effective concentration (EC50) values for neutralization of HBV and HDV infections were 0.09 and 0.01 nM, respectively, and plasma concentrations consistently exceeded the EC50 for all doses levels over the 84-day sampling period. Preliminary safety data are still under blinded review. Among the 24 HVs who received either BJT-778 or placebo, six adverse events (AEs) in five subjects were considered as potentially related to treatment. These events include injection site bruising (n = 4), injection site swelling (n = 1), and fatigue (n = 1), all Grade 1 (mild). There were no serious AEs, Grade 3/4 AEs, or significant laboratory abnormalities reported.
Conclusion: The PK of BJT-778 administered subcutaneously increased dose-proportionally up to the highest dose, 900 mg. The long half-life and sustained plasma concentration surpassing the EC_{50} support the convenient clinical dosing schedules and suggest that dose levels are within the therapeutic range, respectively. All doses were safe and well tolerated. Following these favorable safety and PK results, the proof-of-concept Phase 1b study has been initiated in patients with CHB and CHD.

WED-375

VTP-300 immunotherapeutic, plus low dose PD-1 inhibitor, nivolumab, continues to show meaningful, sustained reductions in HBsAg levels

Dereck Tait[1], Louise Bussey[1], Radka Kolenovska[1], Matt Downs[1], Katie Anderson[1], Antonella Vardeu[1], Man-Fung Yuen[2], Wan-Long Chuang[3], Chun-Jen Liu[4], Apinya Leerapun[5], Pisit Tangkijvanich[6]. Email: dereck.tait@barinthusbio.com

Background and aims: Functional cure of chronic hepatitis B (CHB) is considered to be achieved when HBsAg and HBV DNA are undetectable in the blood and the immune system maintains this state. VTP-300 is a targeted immunotherapeutic consisting of two viral vectors, ChAdOx1 and MVA, containing consensus HBV genotype C sequences; full length surface, modified polymerase, and core sequences. Study HBV003 is an ongoing open-label, randomised, Phase 2b study to assess the safety, immunogenicity, and efficacy of different regimens of VTP-300 in combination with low dose nivolumab in participants with non-cirrhotic CHB who are on suppressive therapy with nucleos (t)ide analogues (NUC).
Method: Up to 120 participants with HBsAg ≥10 and <4000 IU/ml are being enrolled into three groups in HBV003. The protocol was amended to alter the HBsAg inclusion criteria to ≥10 and <200 IU/ml and to exclude participants considered to be at risk of auto-immune thyroiditis. All three groups received ChAdOx1-HBV on Day 1, which was followed by: MVA-HBV and low dose nivolumab on Day 29 in Group 1; MVA-HBV and low-dose nivolumab on Days 29 and 85 in Group 2; MVA-HBV on Days 29 and 85 with low-dose nivolumab administered on Day 36 in Group 3. NUCs may be discontinued if participants meet certain criteria. Safety data, immunology data, and HBV marker data are collected throughout the study to Day 336.
Results: 76 participants have currently been recruited, of whom 24 (32%) have baseline HBsAg levels ≤200 IU/ml. Day 169 data, 6 months after first dose of study drug, are currently available from 70 participants. In total, HBsAg log reductions at Day 169 of ≥0.5 log and ≥1 log in participants with HBsAg ≤200 IU/ml were observed in 59% and 27% participants, respectively, compared to 13% and 2% in participants with HBsAg levels >200 IU/ml. 18 participants have met the eligibility criteria for NUC discontinuation and four have discontinued NUCs. Three participants (two in Group 2 and one in Group 1) have undetectable HBV DNA and HBsAg at Day 113, Day 169, and 10 weeks post-NUC discontinuation. One unrelated SAE has been reported, and thyroid dysfunction was reported in seven participants. Further accumulating data, including safety, HBV markers, NUC discontinuation, and immunology data will be presented.
Conclusion: Preliminary safety data suggest that VTP-300 in combination with low dose nivolumab has been generally well tolerated and has resulted in meaningful, sustained HBsAg reductions, particularly in participants with baseline HBsAg levels ≤200 IU/ml. We believe that VTP-300 is a promising immunotherapeutic candidate for enhancing CHB functional cure rates. VTP-300 is also being investigated in combination with a siRNA inhibitor, imdusiran.

WED-376

Tobevibart (VIR-3434), a monoclonal antibody, resistance analysis in participants with chronic HBV: Results from a Phase 1 single dose study

Hasan Imam[1], Julia di Iulio[1], Thanh Quach[1], Yi-Pei Chen[1], Sonia Maciejewski[1], Keith Boundy[1], Andre Arizpe[1], Kosh Agarwal[2], Man-Fung Yuen[3], Andrea Cathcart[1], Gregory Camus[1]. *[1]Vir Biotechnology, Inc., San Francisco, United States; [2]King's College Hospital, London, United Kingdom; [3]Queen Mary Hospital, The University of Hong Kong, Hong Kong SAR, Hong Kong*
Email: gcamus@vir.bio

Background and aims: Tobevibart (VIR-3434) is an investigational Fc-engineered human monoclonal antibody targeting the conserved antigenic loop of HBsAg in development for the treatment of chronic hepatitis B (CHB) and chronic hepatitis D. Here, we report hepatitis B virus (HBV) sequencing results in participants with CHB given a single dose of tobevibart, before and after treatment.
Method: VIR-3434-1002 was a randomized, double-blind, placebo-controlled phase 1 single ascending dose study that evaluated the safety, tolerability, and antiviral activity of tobevibart. In Part D, participants with CHB were not on NRTIs, had baseline HBV DNA ≥1000 IU/ml, and received a single dose of 75 or 300 mg of tobevibart subcutaneously. The whole HBV virus genome was sequenced in these viremic participants, both at baseline and following tobevibart treatment. HBV genotypes were determined for each participant based on phylogenetic analysis of the viral sequence data and genotype specific HBV reference sequences. Viral sequences at baseline were aligned to their genotype specific reference sequences to identify substitutions from reference. Viral sequences post-treatment were compared to their corresponding baseline sequences to identify potential emergent substitutions. In vitro phenotypic analysis of substitutions in the tobevibart binding site are underway.
Results: Twelve participants enrolled in Part D received a single dose of either 75 or 300 mg tobevibart, while 4 participants were randomized to the placebo group. HBV sequencing was successful in all 16 participants in the tobevibart treatment or placebo groups at both baseline and postbaseline timepoints. Out of the 16 participants enrolled in Part D, 4, 2, 4, and 6 participants had HBV genotypes A, B, C, and D, respectively. At baseline, 2 participants each in the tobevibart 75 mg, 300 mg, and placebo groups had substitutions in the tobevibart binding site when compared to the relevant genotype reference sequences. No binding site emergent substitutions relative to baseline were identified in any of the 12 participants who received tobevibart. Four of these participants had emergent substitutions in the HBV S gene, outside the tobevibart binding site. All of these emergent substitutions in the S gene were found in only 1 participant each. Phenotypic analysis of the binding site substitutions from reference will be presented.
Conclusion: Viral sequencing analysis of 12 participants who received a single dose of tobevibart showed no treatment-emergent substitutions in the tobevibart binding site, and no emergent substitution in the S gene was found in more than 1 participant at any dose evaluated. These findings suggest no emergence of resistance following a single dose of tobevibart, and support its continued development for functional cure of CHB and treatment of HDV.

WED-377

Preclinical profiling of ABI-6250, a novel orally bioavailable small-molecule therapeutic candidate for the treatment of chronic hepatitis D

Marc P. Windisch[1], Nuruddin Unchwaniwala[1], Jinghu Carl Li[1], Yanhong Zhu[1], Heidi Contreras[1], Dinara Azimova[1], Francielle Tramontini Gomes de Sousa[1], Joseph Tan[1], Kirsten Stray[1], Ariel Tang[1], Peter Haggie[1], Gene Schulze[1], Michael Shen[1], Jiaxin Yu[1], Michel Perron[1], Michael A. Walker[1], William E. Delaney[1], Min Zhong[1]. *[1]Assembly Biosciences, Inc., South San Francisco, United States*
Email: mwindisch@assemblybio.com

Background and aims: Chronic hepatitis D virus infection (cHDV) is the most severe form of viral hepatitis. Bulevirtide (BLV), a peptide preventing the binding of HDV to sodium taurocholate co-transporting polypeptide (NTCP), the viral entry receptor, is approved in Europe for the treatment of cHDV. Clinical trials demonstrated the safety and efficacy of injectable BLV. Here we describe the preclinical profiling of a new therapeutic candidate, ABI-6250, a novel orally bioavailable small-molecule HDV entry inhibitor.
Method: ABI-6250 HDV half-maximal effective concentration (EC_{50}) and protein-adjusted EC_{50} were determined in pretreated HepG2-NTCP cells by measuring intracellular hepatitis D antigen (HDAg) following infection. ABI-6250's competitive inhibition of hepatitis B virus (HBV) preS1 NTCP binding, impact on NTCP-dependent bile acid (BA) uptake, and selectivity against a broad panel of BA transporters were assessed by monitoring fluorescently labeled preS1 binding and BA uptake in human embryonic kidney cells. Metabolic stability was assessed in liver microsomes (LMs) from multiple species. Oral bioavailability was determined in both rodents and non-human primates (NHPs). Dose-escalating pharmacokinetic/pharmacodynamic (PK/PD) and tolerability studies were performed in NHPs and rats, monitoring drug exposure and BA elevations.
Results: ABI-6250 potently inhibits the infection of all tested HDV genotypes (1–3), with HBV genotype B or D envelopes (HDV $EC_{50=}$5–16 nM), and a protein-adjusted EC_{50} increase of approximately 35-fold in HDV genotype 3 enveloped with HBV genotype D. ABI-6250 inhibits preS1 binding (half-maximal inhibitory concentration $[IC_{50}]_{=}$22 nM) and NTCP-dependent BA uptake ($IC_{50=}$11 nM), demonstrating the target is NTCP. Furthermore, ABI-6250 has >10-fold selectivity for NTCP *in vitro* compared to other evaluated BA transporters, including organic anion-transporting protein (OATP) 1B1 and OATP1B3. ABI-6250 has high metabolic stability in human, NHP, and rat LMs (predicted clearance = 1.0–2.5 ml/min/kg) and good oral bioavailability (F = 100% in mice, rats, and NHPs), with a terminal half-life of 4 to 5 hours in rodents and 15 hours in NHPs. PK/PD studies in NHPs show dose-dependent ABI-6250 plasma exposure and increasing BA levels at low therapeutic doses, between 0.3 and 3 mg/kg, without affecting OATP1B1 and OATP1B3 (demonstrated by monitoring coproporphyrin plasma levels), indicating ABI-6250 effectively and selectively inhibits NTCP *in vivo*. ABI-6250 is well tolerated at exposures above the expected efficacious concentration when orally dosed daily for 7 consecutive days in rats and NHPs.
Conclusion: ABI-6250 is a highly potent, orally bioavailable HDV entry inhibitor with a preclinical profile supporting a once-daily oral therapy for cHDV and is expected to enter Phase 1 clinical studies by the end of 2024.

WED-378

Association of baseline characteristics and plasma ALG-001075 to HBsAg responses in HBeAg+ CHB subjects following ALG-000184 ± ETV treatment

Kha Le[1], Man-Fung Yuen[2], Edward J. Gane[3], Kosh Agarwal[4], Jinlin Hou[5], Junqi Niu[6], Yanhua Ding[6], Xieer Liang[5], Alina Jucov[7], Min Wu[1], Maida Maderazo[1], Lawrence Blatt[1], Tse-I Lin[1], Matt McClure[1], Sushmita Chanda[1]. *[1]Aligos Therapeutics, Inc., South San Francisco, United States; [2]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China; [3]Faculty of Medicine, University of Auckland, Auckland, New Zealand; [4]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [5]Nanfang Hospital, Southern Medical University, Guangzhou, China; [6]The First Hospital of Jilin University, Changchun, China; [7]ARENSIA Exploratory Medicine, Republican Clinical Hospital and Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova*
Email: schanda@aligos.com

Background and aims: ALG-000184 is a prodrug of ALG-001075, a potent chronic hepatitis B (CHB) capsid assembly modulator-empty that inhibits viral replication and cccDNA establishment in vitro.
Method: ALG-000184-201 is a multi-part, multi-center, double-blind, randomized, placebo-controlled study (NCT04536337). In Part 4, eligible treatment naïve or currently-not-treated HBeAg+ CHB subjects that enrolled in Cohorts 1 and 2 were randomly assigned (3:1) to receive oral daily doses of 100 and 300 mg ALG-000184, respectively or placebo in combination with entecavir (ETV) × 12 weeks followed by open-label treatment with 100 mg ALG-000184 + ETV × ≤12 weeks and 300 mg ALG-000184 + ETV × ≤96 weeks, respectively. Those enrolled in Cohort B received open-label daily doses of 300 mg ALG-000184 alone × ≤96 weeks. A total of 22 subjects (n = 4, 9, and 9 in Cohorts 1, 2 and B, respectively) with at least 24 weeks of ALG-000184 dosing were included in the analysis. Baseline participant characteristics, including age, sex, ethnicity, HBV genotype, HBsAg, HBeAg, HBcrAg and steady state plasma ALG-001075 exposures, and change from baseline of HBsAg at weeks 24, 36 and 48 were measured. Exploratory linear univariate and multiple regression models were used to determine possible associations between selected baseline variables, plasma ALG-001075 exposures and HBsAg reduction.
Results: Substantial reductions in HBV DNA/RNA and HBV antigens have been noted for ALG-000184 + ETV and ALG-000184 monotherapy. In a multiple regression model, baseline HBsAg (< or ≥4 log10 IU/ml) and steady state plasma ALG-001075 exposure (AUC or Ctrough) statistically significantly predicted change from baseline in HBsAg at week 24 ($p < 0.00018$, $R^2 = 0.65$). Baseline HBsAg of ≥4 log10 IU/ml was a significant predictor of having a HBsAg reduction. Higher plasma ALG-001075 exposures added statistically significantly to the prediction ($p < 0.01$). Baseline HBcrAg (≥4 log10 IU/ml) was a significant predictor of HBsAg reduction based on univariate regression analysis but did not add statistical significance to baseline HBsAg and plasma ALG-001075. Similar results were observed at weeks 36 and 48. There were no statistically significant associations found between age, sex, ethnicity, HBV genotype, baseline HBeAg or ALT and change from baseline in HBsAg. HBeAg+ CHB subjects treated with ALG-000184 had dose related decrease in HBeAg and HBcrAg irrespective of their baseline.
Conclusion: Higher baseline HBsAg (≥4 log10 IU/ml) and plasma ALG-001075 levels appear to be predictors of HBsAg response to ALG-000184 treatment while HBV DNA, RNA, HBeAg and HBcrAg declines are independent of their baseline characteristics.

Email: kthys@its.jnj.com

Background and aims: The evaluation of patients with chronic hepatitis B (CHB) focuses primarily on the peripheral compartment due to difficulties obtaining samples directly from the liver, the site of viral infection. In the INSIGHT study, we analyzed intrahepatic changes in CHB patients under JNJ-3989 treatment.
Method: In INSIGHT, CHB patients who were hepatitis B e-antigen (HBeAg) positive and not currently treated (Group 1) or HBeAg-negative and virologically suppressed by nucleos (t)ide analogs (NA) (Group 2) received 48-weeks of siRNA JNJ-3989 + NA ± CAM-E JNJ-6379. Core liver biopsies (CLB) were collected at baseline and week 40 and assessed using Hyperion imaging mass cytometry. This method assessed non-parenchymal and liver immune cells for 30 proteins, including viral HBsAg, Ki67 as a proliferation marker, and several immune markers. All cells were classified into eight distinct phenotypes of lymphocytes/monocytes, hepatocytes, and structural cells using 11 markers: Collagen type1, Pan-keratin, cytokeratin18, CD45, CD20, CD3, CD4, CD8, CD57, CD68, and CD14. HBsAg was used to distinguish infected from non-infected hepatocytes.
Results: Nineteen baseline- and fifteen week 40 CLB samples were assessed. Differential protein abundance analysis showed higher proportions of immune cell markers in infected than non-infected hepatocytes. NKp46, an activation marker of NK cells, was significantly enriched in infected (5%) vs non-infected hepatocytes (<1%). Also, the proportion of PDL-2-positive cells was significantly higher ($p = 0.003$) among the infected hepatocytes. The proportion of Ki67-positive cells was higher ($p = 0.022$) among the non-infected than the infected hepatocytes. The proportion of HBsAg positive hepatocytes was significantly lower ($p < 0.001$) at week 40 compared to baseline in both cohorts, consistent with the effect of JNJ-3989. The proportion of CD8+ T-cells was significantly lower ($p = 0.002$) at week 40 compared to baseline in Group 1 but not in Group 2. Differential abundance analysis of proteins within the different cell types highlighted Ki67 as significantly reduced ($p < 0.05$) in both infected and non-infected hepatocytes at week 40 compared to baseline in Group 1. In addition, the proportion of PDL-1-positive cells among the infected hepatocytes showed a trend for an increase in both groups during treatment ($p = 0.058$). This effect was absent in the non-infected hepatocytes.
Conclusion: Spatial single-cell profiling of immune and viral markers in the liver from CHB patients demonstrated a decrease in the numbers of infected hepatocytes with a trend towards higher proportions of PDL-1 positive hepatocytes after 40 weeks of treatment with JNJ-3989. Although there was a lower proportion of Ki67-positive cells among the infected hepatocytes, proportions were further reduced in all hepatocytes during treatment, indicating less proliferation.

WED-381

A double-blind, placebo-controlled, single-ascending dose phase I a study to evaluate the safety, tolerability, and pharmacokinetics of HT-102, a neutralizing antibodies against the hepatitis B surface antigen in Chinese healthy volunteers

Mingjian Zhang[1], Dong Wang[2], Shanzhong Zhang[2], Yanqin Ma[2], Lijuan Ding[2], Zhipeng Zhang[2], Lungen Lu[3], Xueying Ding[1]. *[1]Department of Clinical Research Center, Shanghai General Hospital, Shanghai, China; [2]Suzhou Hepa Thera Biopharmaceutical Co.Ltd., Shanghai, China; [3]Department of Gastroenterology, Shanghai General Hospital, Shanghai, China*
Email: wangdong@hepathera.com

Background and aims: HT-102, is an investigational monoclonal antibody, targeting the antigenic loop of hepatitis B surface antigen (HBsAg) with the potential to functions as 1) inhibition of hepatitis B

virus (HBV) entry into cells, 2) elimination of virons and sub-viral particles for the treatment of chronic HBV infection. This first-in-human study investigated the safety, tolerability and single-dose pharmacokinetic (PK) profile of HT-102 in Chinese healthy subjects.
Method: The randomized, double-blind, placebo-controlled, single-ascending dose phase I a study enrolled 32 healthy subjects. 8 healthy subjects per cohort were randomized (6:2 ratio) to receive a single subcutaneous (SC) dose of HT-102 (50, 150, 300, 600 mg) or placebo. Serum PK samples were collected over 24 hours (day 1), and on days 2 to days 56 across pre to post-dose period. Anti-drug antibody (ADA) was assessed on day1 (pre-dose), days 14, days 28 and days 56. Safety assessments included adverse events (AEs), clinical laboratory tests, vital signs, physical examinations and 12-lead electrocardiograms. Injection-site tolerability assessments were performed pre-dose 30 min, post-dose 30 min, 2 h, D2 and D3 for first dose and pre-dose 30 min, post-dose 30 min, 2 h for other dosage period. Safety and tolerability was assessed based on CTCAE v5.0.
Results: The results showed good safety and tolerability of HT-102 in healthy volunteers. All treatment-emergent adverse events (TEAEs) were grade 1 or 2 in HT-102 group. No SAE or TEAEs led to premature study discontinuation or death were reported in HT-102 group. The most common TEAEs (>10% subjects) included blood uric acid increased and blood fibrinogen decreased. HT-102 was absorbed after SC injection with a median T_{max} of 119.9–312.5 h, and median serum half-life ($t_{1/2}$) of 428.0–528.6 h. Following administration of 50~600 mg HT-102, the maximum concentrations (C_{max}) and area under the concentration-time curve to the time of the last quantifiable concentration (AUC_{0-t}) ranges of healthy subjects were 5373.0~64895.4 ng/ml and 3515241.8~49624629.1 h*ng/ml, respectively. HT-102 exposure including C_{max} and AUC_{0-last} increased in a dose-proportional manner and PK parameters C_{max}, AUC_{0-168h}, AUC_{0-t}, $AUC_{0-\infty}$ showed linear kinetic characteristics across single SC dose range of 50~600 mg. All samples for ADA test were negative except one sample on Day 56 from 150 mg cohort tested ADA positive (titer 3.6) with a negative result for further Nab test.
Conclusion: A single SC dose of HT-102 at 50~600 mg was safe and well tolerated with a favorable PK profile in Chinese healthy subjects. These data support further clinical development of HT-102 for HBV infection treatment.

WED-382
Modeling dual antiviral activity of lonafarnib to explain hepatitis D virus RNA negativity 24 weeks after end of therapy despite RNA positivity at end of therapy: The D-LIVR study
Adquate Mhlanga[1], Harel Dahari[1], Leeor Hershkovich[1], Scott Cotler[1], Ingrid Choong[2], Colin Hislop[2], Theo Heller[3], Christopher Koh[3], Jeffrey Glenn[4], Tarik Asselah[5,6], Saeed Sadiq Hamid[7], Ohad Etzion[8].

Email: harel.dahari@gmail.com

Background and aims: Recent in vitro studies indicate a loss of hepatitis D virus (HDV) infectivity upon farnesyl transferase inhibitor treatment. We identified 2 patients in the Phase 3 D-LIVR study who had detectable HDV RNA at the end of therapy (EOT) with lonafarnib (LNF) + ritonavir for 48 weeks and became HDV RNA negative at the end of 24-week follow-up (EOFU). This observation prompted us to develop a new mathematical model for HDV that considers infectious (V_i) and non-infectious (V_{ni}) virus.
Method: 144 patients in the D-LIVR study (NCT03719313) were treated with LNF+ritonavir for 48 weeks. 4 patients had HDV target not detected (TND) at EOFU. Two of the 4 patients had HDV detected at EOT, including one who had large HDV fluctuations during therapy with an ALT flare during EOT and follow-up and one who had a biphasic HDV decline until Week 12 that was followed by a plateau (~3 log below baseline) until EOT with normal ALT levels from Week 8 until EOFU. The mathematical model assumes that in addition to LNF blocking V_i and V_{ni} production, LNF further enhanced the ratio of V_{ni} to V_i, which led to <1 infectious-virus particle in the total extracellular body fluid (~13, 500 ml) prior to EOT. Since HBsAg remained at baseline level during LNF therapy, the number of infected cells were held constant. We assume that at baseline, 99% of total virus ($V_i + V_{ni}$) is infectious and that V_i and V_{ni} have similar clearance rate constant from blood. Key parameters of the model include the production rate constants for V_i and V_{ni}, the efficacy of LNF in blocking both V_i and V_{ni} production, and a parameter that accounts for LNF increasing the efficacy of blocking V_i production, resulting in a gradual increase of V_{ni} which increases the ratio of V_{ni} to V_i during therapy.
Results: The model was able to reproduce the total HDV kinetic pattern, i.e., a biphasic viral decline that lasted ~12 weeks followed by a viral plateau until EOT. The model predicts that while V_i declined in a biphasic manner until reaching <1 infectious-virus particle in the extracellular body fluid prior to EOT, V_{ni} had a transient decline at the beginning of therapy that was followed by a V_{ni} plateau. Modeling suggests that in addition to LNF blocking Vi and Vni production (ε~94.4%), LNF further enhanced the ratio of Vni to Vi, thus increasing the log (V_{ni}/V_i) from –2 to 6 by EOT, which led to <1 infectious-virus particle in the extracellular body fluid prior to EOT.
Conclusion: This new HDV model can explain why patients, despite having detectable HDV RNA by EOT, subsequently achieved negative HDV RNA status during follow-up. Further research is needed to validate the existence of V_i and V_{ni} dynamics in LNF-treated patients to be able to test and refine our theoretical efforts in understanding LNF antiviral mode of action.

WED-383
Antiviral efficacy of REP 2139-Mg and effects on HVPG in HDV/HBV coinfected patients with cirrhosis and portal hypertension non-responding to previous bulevirtide treatment
Mathias Jachs[1,2], Michael Schwarz[1,2], Michel Bazinet[3], Mattias Mandorfer[1,2], Thomas Reiberger[1,2], Andrew Vaillant[3].
[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [3]Replicor Inc., Quebec, Canada
Email: availlant@replicor.com

Background and aims: The nucleic acid polymer (NAP) REP 2139-Mg demonstrated safety and antiviral efficacy in patients with hepatitis B/D virus (HBV/HDV) coinfection. We undertook to measure changes in hepatic venous pressure gradient (HVPG) accompanying antiviral response patients with HBV/HDV cirrhosis.
Method: REP 2139-Mg (250 mg SC qW)-available through a named patient use program (NCT05683548)-was administered for 48 weeks together with pegylated interferon (pegIFN, 90 μg SC qW) and concomitant TAF or TDF therapy in 3 HDV/HBV patients, who failed previous bulevirtide therapy. All patients had cirrhosis and clinically significant portal hypertension (CSPH) and thus, also underwent HVPG measurement at baseline (BL), at week (W)12 and W48 (end of therapy, EOT).
Results: Patient 1 (Caucasian male, 69 y.o., Child-A5, large varices, HVPG 17 mmHg) had BL HDV-RNA of 3.28 log10 copies/ml and quantitative HBs antigen (qHBsAg) 1202 IU/ml. By EOT, no antiviral response nor ALT flare was observed despite switching to weekly i.v. administration of REP 2139-Mg week 20 and dose increase to 500 mg

by week 36, but qHBsAg decreased to 760 IU/ml. HVPG at W12 decreased to 14 mmHg (−18%) returned to BL with 17 mmH (0% from BL) at EOT. Patient 2 (Caucasian female, 51 y.o., Child-A5, large varices, HVPG 14 mmHg) had BL HDV-RNA of 4.97 log10 copies/ml and qHBsAg of 626 IU/ml. The patient developed an ALT flare (max. 683 U/L, max. bilirubin 6.9 mg/dL) at W8, which was also seen with previous pegIFN exposure. After pegIFN discontinuation, ALT and bilirubin steadily declined during continued REP 2139-Mg therapy. HDV-RNA was negative by week 16. The patient was switched to IV administration by week 37. By EOT, HDV-RNA remained negative, qHBsAg was at 0.5 IU/ml, and ALT was normal at 28 U/L. HVPG increased to 17 mmHg (+21%) at week 12 but returned to 14 mmHg (0% from BL) at EOT. Patient 3 (Caucasian male, 38 y.o., Child-A5, large varices, HVPG 22 mmHg) had a BL HDV-RNA of 4.52 log10 copies/ml and a qHBsAg of 922 IU/ml. After an initial ALT flare (max. ALT 659 U/L, bilirubin within normal range) at W7, HDV-RNA was negative by week 27. By EOT, HDV-RNA remained negative, qHBsAg was at 0.18 IU/ml, and ALT 41 U/L. HVPG was 18 mmHg (−18%) at W12 and remained decreased to 19 mmHg (−14%) at EOT. REP 2139-Mg was well tolerated with no severe adverse events. SC injections were accompanied by local and transient grade 1 erythema and itching in patient 2. No adverse events were associated with IV infusion.

Conclusion: Weekly REP 2139-Mg in combination with TDF and low-dose pegIFN appeared safe and effective against HBV/HDV infection in patients with cirrhosis and CSPH. Potential ALT flares should be monitored closely but may reflect an immune response triggering the subsequent decrease/loss of HDV-RNA and of HBsAg-as observed in 2 out of our 3 patients. Portal hypertension may remain controlled despite ALT flares during REP 2139-Mg therapy in patients with CSPH.

WED-386

A double-blind, placebo-controlled, single-ascending dose phase I a study to evaluate the safety, tolerability, and pharmacokinetics of HT-101, an investigational small interfering ribonucleic acid targeting hepatitis B virus in Chinese healthy subjects

Jianxiong Zhang[1], Dong Wang[2], Shanzhong Zhang[2], Yanqin Ma[2], Lijuan Ding[2], Zhipeng Zhang[2], Hong Ma[3], Jidong Jia[3], Ruihua Dong[1]. *[1]Research Ward, Beijing Friendship Hospital, Capital Medical University, Beijing, China; [2]Suzhou Hepa Thera Biopharmaceutical Co. Ltd., Shanghai, China; [3]Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China*
Email: wangdong@hepathera.com

Background and aims: HT-101 is an N-acetylgalactosamine (GalNAc)-conjugated small interfering ribonucleic acid (siRNA) targeting hepatitis B virus. Preclinical studies exhibited a promising potential for the treatment of chronic hepatitis B virus (HBV) infection. This first-in-human study investigated the safety, tolerability and single-dose pharmacokinetic profile of HT-101 in Chinese healthy subjects.

Method: The randomized, double-blind, placebo-controlled, single-ascending dose phase I a study enrolled 50 healthy subjects. Two subjects received a single subcutaneous (SC) dose of HT-101 at 25 mg, and in other six cohorts (n = 8 per cohort), healthy subjects were randomized (6:2) to receive a single SC dose of HT-101 (50~800 mg) or placebo. Blood and urine samples were obtained for pharmacokinetic determination across a 48 h post-dose period. Safety assessments included adverse events (AEs), clinical laboratory tests, vital signs, physical examinations and 12-lead electrocardiograms pre- and post-dosing. Safety and tolerability was assessed based on CTCAE v5.0.

Results: The results showed good safety and tolerability of HT-101 in healthy subjects. No subjects discontinued due to any AE, no serious AE nor death were reported. The most common AEs included increased blood triglycerides, decreased lymphocyte percentage and decreased haemoglobin. HT-101 was rapidly absorbed, with consistent pharmacokinetic parameters observed for both sense strand and antisense strand characterizations. Plasma pharmacokinetics characterized by functional antisense strand revealed a median time to peak plasma concentration (T_{max}) of 2.5~6.0 h and median plasma half-life ($t_{1/2}$) of 2.5~6.1 h. Following 25~800 mg SC dose, the maximum concentrations (C_{max}) and area under the concentration-time curve to the time of the last quantifiable concentration (AUC_{0-t}) were 75.3~5120.0 ng/ml and 553~57100 h*ng/ml, respectively. HT-101 exposure increased in a slightly supra-proportional to dose manner following 25~800 mg SC dose, suggesting that at liver target site there might be a saturation mechanism with the dose increasing. After a single SC dose, the average renal clearance rate (CLR) of HT-101 ranged from 4.6 to 6.7 L/h, with fractional excretion (Fe) at 13.1~41.9% and accumulated excretion (Ae) at 3.6~331.0 mg. In 25~200 mg cohorts, Fe was 13~17%, which increased to 30~40% within 400~800 mg cohorts. This shift also suggested saturation of the liver absorption, leading to enhanced urinary excretion. Notably, no metabolites were detected in plasma or urine, aside from the original drug HT-101. The concentration-QTc analysis indicated that risk of prolonged QTc interval was not observed.

Conclusion: A single SC dose of HT-101 at 25~800 mg was safe and well tolerated in Chinese healthy subjects. These data support further clinical development of HT-101 for HBV infection treatment.

WED-387

Study on the role of dendritic cells in CHB patients treated with intermittent Interferon therapy

Liu Yang[1], Tingting Jiang[2], Shiyu Wang[2], Ziyu Zhang[2], Xinxin Li[2], Yao Xie[3], Minghui Li[4]. *[1]Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Beijng, China; [2]Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Beijing, China; [3]Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Department of Hepatology Division 2, Peking University Ditan Teaching Hospital, Beijing, China; [4]Department of Hepatology Division 2, Peking University Ditan Teaching Hospital, Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Beijing, China*
Email: wuhm2000@sina.com

Background and aims: To investigate the relationship between the frequency of DCs subsets and the expression of surface co-stimulatory molecules and chemokine receptors in patients with CHB and the plateau of slow decline of HBsAg and the clinical efficacy during IFN intermittent therapy.

Method: CHB patients were divided into IFN initial treatment group (patients with natural history of CHB without any antiviral treatment before, and were given IFN antiviral treatment after admission, namely NH group, NAs treated group (NA group) and IFN treated plateau arriving group (P group). After perfecting the baseline related examination, the patients in the NH group were given IFN alone or in combination with NAs antiviral therapy; patients in the P group were retreated with IFN after 12–24 W of IFN intermission. For patients in the NH group, at baseline before IFN treatment, at 4 W and 12–24 W after IFN treatment; patients in NA group at baseline; patients in P group at baseline when IFN was stopped, 12–24 W of IFN intermission and 12–24 W of IFN retreatment, the viral, serological, biochemical and DC related indicators were collected.

Results: 49 patients in NH group, 47 patients in NA group and 47 patients in the P group were included. At baseline, the percentage of CD141 and CD1c double negative myeloid dendritic cells (DN mDC) subset, the percentage of $CD86^+$ cells in DN mDC and the CD86 MFI of $CD86^+$ DN mDC, the percentage of $CX3CR1^+$ cells in DN mDC and the CX3CR1 MFI of $CX3CR1^+$ DN mDC in the P group were significantly lower than those in the NA group and NH group. 35 patients in P group were followed up for 12–24 W of IFN intermission. The percentage of DN mDC increased significantly, and the percentage of $CD86^+$ cells in DN mDC, CD86 MFI of $CD86^+$ DN mDC, $CX3CR1^+$ cells in DN mDC and CX3CR1 MFI of $CX3CR1^+$ DN mDC increased significantly; Twelve patients in the P group were followed up until

12–24 W of IFN retreatment, and the data of three follow-up points were obtained. It was found that the proportion of DN mDC increased significantly, and the percentage of $CD86^+$ cells in DN mDC, CD86 MFI of $CD86^+$ DN mDC, $CX3CR1^+$ cells in DN mDC and CX3CR1 MFI of $CX3CR1^+$ DN mDC all showed a trend of increasing first and then decreasing 11 patients in the NH group were followed up until IFN treatment 12–24 W. It was found that the percentage of DN mDC decreased significantly after 4 W and 12–24 W use of IFN; CD86 MFI of $CD86^+$ DN mDC after 4 W and 12–24 W use of IFN were significantly lower than those in baseline; the percentage of $CX3CR1^+$ cells in DN mDC after 4 W and 12–24 W use of IFN decreased significantly compared with baseline; The CX3CR1 MFI of $CX3CR1^+$ DN mDC after 12–24 W use of IFN was significantly lower than that of baseline.
Conclusion: IFN treatment significantly decreased the percentage of DN mDC subsets, and the percentage of $CD86^+$ and $CX3CR1^+$ cells in DN mDC and their CD86 and CX3CR1 MFI. In the P group the above indexes recovered to some extent after 12–24 W of IFN intermission.

WED-388

Safety, tolerability, and hepatitis B surface antigen reduction of HT-101 in chronic hepatitis B patients: preliminary results from a phase I b study

Dong Wang[1], Shanzhong Zhang[2], Yanqin Ma[2], Lijuan Ding[2], Zhipeng Zhang[2], Hong Ma[3], Jidong Jia[3]. [1]*Suzhou Hepa Thera Biopharmaceutical Co. Ltd., Shanghai, China;* [2]*Suzhou Hepa Thera Biopharmaceutical Co. Ltd., Shanghai, China;* [3]*Liver Research Center, Beijing Friendship Hospital, Beijing, China*
Email: wangdong@hepathera.com

Background and aims: HT-101 is an N-acetylgalactosamine (GalNAc) -conjugated small interfering ribonucleic acid (siRNA) targeting hepatitis B virus. Preclinical studies exhibited a promising potential for the treatment of chronic hepatitis B virus (HBV) infection. Here we reported preliminary data from an ongoing study evaluating the safety, tolerability, and antiviral activity of HT-101 in chronic HBV infection participants with nucleos (t)ide reverse transcriptase inhibitor (NRTI) treatment.
Method: This was a randomized, double-blind, placebo-controlled, phase Ib, multiple ascending doses study of HT-101 administered via subcutaneous (SC) injection to chronic hepatitis B patients who received continuous NRTI therapy for ≥6 months. Participants with non-cirrhosis (<F3) were restricted with HBsAg <5, 000 IU/ml at screening. Participants received two subcutaneous HT-101 injections, 4 weeks apart, of 50, 100, 200 or 400 mg. At each dose level, eight participants were randomly assigned to HT-101 or placebo (6:2 ratio). Follow-up was carried out for 24 weeks post first dose. The protocol conformed to the Declaration of Helsinki guidelines and was approved by appropriate institutional review committee (s). Written informed consent was obtained prior to study procedures.
Results: Thirty-three participants with chronic hepatitis B (including 1 participant prematurely discontinued) were randomly assigned to receive two doses of HT-101 (50, 100, 200 or 400 mg) or placebo, given 4 weeks apart. So far, all patients showed good safety and tolerability. No subjects discontinued due to an adverse event (AE), no serious adverse events (SAE) nor death were reported. The follow-up visit is still ongoing and the data has not been un-blinded. According to preliminary pharmacodynamics data available in 50 mg and 100 mg cohorts: Demographic and baseline characteristics were generally well balanced across treatment groups (baseline HBsAg: 2.85 ± 0.37 log10 IU/ml for 50 mg group; 2.94 ± 0.37 log10 IU/ml for 100 mg group). The mean log reduction in HBsAg level in 50 mg and 100 mg cohort plotted against time was depicted in figure (4 participants without HBsAg reduction exclusive). Higher doses of HT-101 were associated with greater HBsAg reduction. In 100 mg HT-101 group, the mean reduction of HBsAg at Week 12 achieved (2.28 ± 0.64 log10 IU/ml) and in 50 mg group, the mean reduction of HBsAg at Week16 achieved (1.50 ± 0.51 log10 IU/ml).
Conclusion: Two monthly doses of HT-101 administered SC were well safe and tolerated in Chinese patients with chronic HBV infection. Dose-dependent significant reductions from baseline in serum HBsAg levels were achieved through up to 16 weeks post last dose. Higher doses of HT-101 will be evaluated in subsequent cohort. These data support the continued development of HT-101 for treatment of chronic HBV infection.

WED-389

Pharmacokinetics and safety of the monoclonal antibody tobevibart (VIR-3434) administered as monotherapy or in combination with the small interfering RNA elebsiran (VIR-2218) in cirrhotic participants with mild hepatic impairment

Li Wang[1], Sneha Gupta[1], Michael A. Chattergoon[1], Asma El-zailik[1], Cheng Huang[1], George Hristopoulos[1], Maribel Reyes[1]. [1]*Vir Biotechnology, Inc., San Francisco, United States*
Email: liwang@vir.bio

Background and aims: Tobevibart (VIR-3434) is a human immunoglobulin G1 (IgG1) monoclonal antibody (mAb) that binds to the antigenic loop present in all forms of hepatitis B surface antigen (HBsAg). Elebsiran (VIR-2218) is a N-acetylgalactosamine (GalNAc)-conjugated, double-stranded RNA interference (RNAi) therapeutic that targets the X region of the hepatitis B virus (HBV) genome that is common to all HBV viral RNA transcripts. Here, we report the pharmacokinetics (PK) and safety of tobevibart administered as monotherapy or in combination with elebsiran in cirrhotic participants who have mild hepatic impairment with a Child-Pugh-Turcotte Class-A (CPT-A) score, and in matched healthy volunteers (HV).
Method: VIR-2218-V107 (NCT05484206) is a Phase 1, open-label, single-dose parallel-group study. CPT-A and HV participants were demographically matched. Participants received a single subcutaneous (SC) dose of tobevibart 300 mg or tobevibart 300 mg + elebsiran 200 mg. Blood samples were collected up to 18 weeks post-dose to measure the concentrations of tobevibart, elebsiran and its major metabolite. Safety and tolerability were monitored throughout the study.
Results: Eight cirrhotic CPT-A participants and 8 HV participants (matched by demographics) were enrolled in each cohort (tobevibart monotherapy and tobevibart/elebsiran combination therapy). Tobevibart PK exposure was comparable in CPT-A and HV participants. Preliminary geometric mean ratios (GMR) of tobevibart C_{max} and AUC_{inf} in CPT-A to HV participants were 0.96 (90% CI: 0.64–1.42) and 0.94 (90% CI: 0.72–1.23) in tobevibart monotherapy, and 1.06 (90% CI: 0.71–1.59) and 1.01 (90% CI: 0.73–1.40) in tobevibart/elebsiran combination therapy, respectively. Tobevibart PK was similar in mono and combo therapy in both CPT-A and HV participants, indicating no PK drug-drug interaction (DDI) between tobevibart and elebsiran. Exposure of elebsiran was also comparable in CPT-A and HV participants. Preliminary GMR of C_{max} and AUC_{inf} in CPT-A to HV was 0.94 (90% CI: 0.53–1.68) and 1.54 (90% CI: 1.15–2.05), respectively. Tobevibart and elebsiran were generally well tolerated in cirrhotic CPT-A participants. One SAE of asthma exacerbation was reported in a CPT-A participant who received tobevibart 300 mg monotherapy. The participant has a prior history of asthma flares requiring emergency department management and the SAE was considered unrelated to tobevibart.
Conclusion: Tobevibart and elebsiran exposures were comparable in CPT-A and HV participants. A single dose of tobevibart 300 mg mono and tobevibart 300 mg + elebsiran 200 mg combo therapy was well tolerated in CPT-A participants and no drug related SAE was observed. The data supports continued evaluation of the tobevibart 300 mg monotherapy and tobevibart 300 mg + elebsiran 200 mg combination therapy in patients with HBV and HDV infection with CPT-A hepatic impairment.

Viral Hepatitis C – Clinical aspects including follow up after SVR

Email: jcarrion@psmar.cat

Background and aims: More than half of hepatitis C virus (HCV) infected patients with advanced chronic liver disease (ACLD) (transient elastography, TE>10 kPa) treated with direct-acting antivirals (DAAs) had cirrhosis (METAVIR = F4) after 3 years of sustained viral response (SVR) (Broquetas et al. Liver Int. 2021 Nov;41 (11):2733–2746). We aimed to evaluate the fibrosis stage in HCV-infected patients with ACLD after 6 years of SVR and to assess the diagnostic reliability of TE to identify cirrhosis and fibrosis regression.
Method: Prospective and multicentric study in patients with ACLD due to HCV that achieved SVR with DAAs. Fibrosis stage was assessed with liver biopsy after 3 (LB3) and 6 (LB6) years of SVR according to the METAVIR scale. Fibrosis progression was defined as METAVIR increase, regression as METAVIR decrease, and stability as METAVIR without change. The TE's diagnostic reliability (c statistic) was evaluated to identify cirrhosis (F4) and fibrosis regression.
Results: We included 76 patients. We excluded 26 (33%) patients from the analysis for different reasons (death, comorbidities, anticoagulant treatment, etc.). Thus, we analyzed data of 50 (67%) patients with LB6, and 32 (64%) of them had paired biopsies (LB3 and LB6). Among patients with LB6 (N = 50), the median (IQR) age was 54 (49–60) and 72% were men. Before treatment, the median (IQR) of TE was 16.9 (13.1–21.8) kPa. Hence, 29 (57%) patients had TE >15 kPa, and 22 (43%) had TE 10–15 kPa. After 6 years of SVR, the median (IQR) of TE was 9.6 (7.5–13.3) kPa. The LB6 showed fibrosis stage (METAVIR) F2 in 13 (26%), F3 in 21 (43%), and F4 in 15 (31%) patients. Among patients with paired biopsies (LB3 and LB6) (n = 32), fibrosis regression was observed in 6 (19%) patients, progression in 11 (34%), and stability in 15 (47%) patients. Patients with fibrosis progression compared to those with regression or stability of fibrosis had more frequently diabetes (46% vs 29%), obesity (50% vs 29%), hypertension (73% vs 52%), and alcohol consumption of >20–30 g/day (22% vs 5%) without reaching statistical significance (all p = ns). The discrimination capacity (c-statistic) of TE to identify patients with cirrhosis after 6 years of SVR was 0.761 and to identify patients with fibrosis regression was 0.423.
Conclusion: Persistent cirrhosis is frequent, even 6 years after SVR, in patients with advanced chronic liver disease. The diagnostic reliability of transient elastography is not enough to identify patients with persistent cirrhosis after SVR. Fibrosis regression after SVR is slow in patients with advanced chronic liver disease requiring invasive techniques for its recognition.

Background and aims: In cirrhotic patients with HCV infection, the clinical challenge for physicians after achieving sustained virological response (SVR) is to accurately identify the subset of patients at-risk of developing liver-related event (LRE). The aims of our study are to: 1) evaluate incidence of and risk factors for LRE in a cohort of advanced chronic liver disease (ACLD) patients treated with DAA; 2) to evaluate the dynamic changes of liver stiffness in a subgroup of patients with favorable outcomes in 5 years of follow-up.
Method: A prospective multicenter study was conducted in 3 Italian centers. Consecutive patients with HCV-related ACLD starting DAA therapy between September 2014 and June 2018 were enrolled. Patients were followed for a mean period of 4.6 years after achieving SVR12 with regular biannual clinical, laboratoristic and instrumental follow-up. The at-risk period for each subject was defined by the time from the SVR12 until the end of follow-up or the onset of event. Cumulative and separate analysis were made according to the development of LRE.
Results: A total of 575 patients with ACLD achieving SVR12 were followed-up for 5 years. The male/female ratio was 1.1 and the mean age was 64.1 ± 12 years. Nearly all subjects (94.4%) belonged to the Child- Pugh A stage. The mean liver stiffness (LSM) at baseline was 19.2 kPa. Overall, 98 (17%) patients developed any type of events and the mortality rate was of 8.8% (3% for liver-related cause). The HCC was the most frequent LRE (7.1%), followed by ascites (5%). The incidence rate was 1.6 (95%CI 1.2–2.2) per 100 person/year (p/y) for both HCC and liver decompensation. Among pre-treatment variables, LSM≥20 kPa (HR 13.5; 95% CI 5.2–35.3) was the only independent predictor of liver decompensation, while liver stiffness≥20 kPa (HR 9.2; 95% CI 4.0–21.3) and male sex (HR 3.6 95% CI 1.6–8.0) both were independent predictors of HCC development. Overall, 477 subjects did not experience LRE during the follow-up and, among these, paired LSM were available for 341 (71.5%) subjects. In this subgroup, the mean LSM, at SVR12, was 16.9 ± 4.2 kPa and decreased to 13.0 ± 4.0 kPa at the end of follow-up (T60). Overall, any LSM reduction was observed in 314 (92.1%) subjects with a mean reduction of 4.4 kPa. Among these 314 subjects, half of them showed a decrease of LSM ≥20%.
Conclusion: This study shows the relevance of baseline LSM as a tool to stratify patients at risk of developing LRE. The dynamic changes over time of LSM require a continuous long term monitoring of this parameter to update changes in fibrosis degree of subjects after SVR.

THU-379

Artificial intelligence model for predicting liver-related events in non-cirrhotic patients after successful treatment by direct-acting antivirals for chronic hepatitis C

Huapeng Lin[1,2], Jimmy Che-To Lai[2], Hye Won Lee[3], Terry Cheuk-Fung Yip[2], Sang Hoon Ahn[3], Grace Lai-Hung Wong[2], Xiangjun Meng[1], Vincent Wai-Sun Wong[2], Victor de Lédinghen[4], Seung Up Kim[3]. *[1]Shanghai Jiao Tong University, Shanghai, China; [2]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Yonsei University, Seoul, Korea, Rep. of South; [4]Bordeaux University, Bordeaux, France*
Email: linhuapeng5@163.com

Background and aims: Current guidelines recommend ultrasound screening every 6 months after sustained virologic response (SVR) in patients with chronic hepatitis C (HCV)-related cirrhosis. Identifying non-cirrhotic patients at higher risk of developing liver-related events (LREs) who could benefit from surveillance programs following HCV eradication are rarely explored. We aimed to develop and validate a machine learning-based model for LREs prediction and risk stratification in non-cirrhotic HCV patients after SVR.
Method: Random Survival Forest model was trained for prediction of LREs in 913 non-cirrhotic HCV patients after SVR in Korea and further tested in a combined cohort from Hong Kong and France (N = 1264, liver stiffness measurement [LSM] <15 kPa and no biopsy diagnosed cirrhosis). Model performance was assessed according to Harrell's C-index and time-dependent receiver operating characteristic (ROC) curve.
Results: We developed the AI-Safe score with LSM, age, sex and other six biochemistry tests. The incidence of LREs and hepatocellular carcinoma (HCC) in the validation cohort were 4.6 and 3.1 per 1000 patient-years, respectively. The C-index of the AI-Safe score in validation cohort was 0.86 (95% confidence interval [CI], 0.82–0.90). The area under ROC curves of the AI-Safe score for LREs in 3 and 5 years were 0.88 (95%CI 0.84–0.92) and 0.79 (95%CI 0.71–0.87) respectively. The C-index of the AI-Safe score for HCC in the validation cohort was 0.87 (95%CI 0.81–0.92). The AUROCs for 3-year and 5-year HCC in the validation cohort were 0.88 (95%CI 0.84–0.93) and 0.82 (95%CI 0.75–0.90). The AI-Safe score had a consistently good performance in patients with LSM <10 or 8 kPa for the predictions of LREs and also HCC. The performance of the AI-Safe score was significantly better than FIB-4, APRI and a Cox regression-based model for the prediction of LREs. Compared with existing HCC risk scores for HCV SVR patients, we could still observe a significantly better performance for AI-Safe score in the predicting of HCC. Using the cutoff of 0.08, the 5-year LREs reached 6.2% in the high-risk group but only 0.6% in the low-risk group. The 5-year HCC rate was 3.5% in the high-risk group, and 0.2% in the low-risk group.
Conclusion: The AI-Safe score is a useful machine learning-based tool to identify non-cirrhotic patients at higher risk of developing LREs.

THU-380-YI

Individualized intervals for streamlined directly observed therapy in PWIDs-a unique approach to continue HCV microelimination throughout the COVID19 pandemic

Caroline Schwarz[1,2], Angelika Schütz[3], David Bauer[1,2], Enisa Gutic[2], Thomas Reiberger[1], Hans Haltmayer[3], Michael Gschwantler[2,4]. *[1]Medical University of Vienna, Vienna, Austria; [2]Klinik Ottakring, Vienna, Austria; [3]Suchthilfe Wien gGmbH, Vienna, Austria; [4]Sigmund Freud University, Vienna, Austria*
Email: michael.gschwantler@gesundheitsverbund.at

Background and aims: Direct-acting antivirals (DAA) administered via directly observed therapy (DOT) are highly effective for treating HCV in people who inject drugs (PWIDs) on opioid agonist therapy (OAT). Our traditional concept of DOT relied on DAA prescription via a low-threshold facility (LTF) and supervised administration alongside OAT at a pharmacy or LTF. In PWIDs with good adherence, intervals of DOT distribution may be extended from daily to once weekly, however, the impact of these adjustments on sustained virologic response (SVR) rates remains unknown. While most HCV elimination efforts were interrupted through the COVID19 pandemic, we present an individualized approach for DOT HCV DAA treatment in PWIDs which was successfully maintained throughout the pandemic.
Method: This study compared DOT distribution intervals, SVR rates, and socioeconomic characteristics between two cohorts of PWIDs on OAT. The first cohort consisted of 239 PWIDs on OAT who initiated DOT with DAA between March 16, 2020, and May 2, 2023, defined as the 'COVID period'. The second cohort included 441 PWIDs starting DOT between September 26, 2014, and March 12, 2020, identified as the 'pre-COVID period'.
Results: Pre-COVID, daily DOT was the most frequent approach used in 348 (78.9%) PWIDs, compared to 19 (4.3%) and 74 (16.8%) PWIDs with 2–3 times/week and once weekly OAT/DAA dispensation, respectively. During COVID daily OAT/DAA schedules were observed in only 75 (31.4%) PWIDs, while 60 (25.1%) and 104 (43.5%) were extended to 2–3 times/week and once weekly intervals, respectively ($p < 0.001$). SVR rates remained high and comparable between groups (167/168 [99.4%] COVID vs. 402/405 [99.3%] pre-COVID according to modified intention-to-treat analysis; $p = 0.849$), with no significant difference in missed visits (59 [0.8%] COVID vs. 84 [0.4%] pre-COVID; $p = 0.239$). However, loss of follow-up post-therapy was more frequent in the COVID period (28.5% vs. 7.5% pre-COVID; $p < 0.001$). Socioeconomic status was equal or even lower during COVID (unemployment: 83.7% vs. 67.3%, $p = 0.967$; homelessness: 38.5% vs. 35.1%, $p = 0.227$; habitual alcohol consumption: 29.3% vs. 10.7%, $p < 0.001$; ongoing intravenous drug use: 64.0% vs. 57.8%, $p = 0.616$). Importantly, no treatment interruptions or COVID19-related deaths were observed.
Conclusion: The traditional "daily" DOT concept targeted adherence issues in PWIDs related to ongoing substance use, psychiatric comorbidities, and low socioeconomic status. Importantly, our novel "relaxed interval" DOT concept, with individualized, extended OAT/DAA schedules, yielded similar SVR rates. Hence, the effectiveness of DOT hinges on more streamlined linkage to HCV care and simplified DAA access through a single visit at an LTF rather than strict daily surveillance.

THU-381

Prognostic implications of liver stiffness impairment after HCV cure in cACLD patients

Background and aims: In patients with hepatitis C (HCV) compensated advanced chronic liver disease (cACLD) cured with oral antivirals, follow-up (FU) liver stiffness measurement (LSM) performed after end of treatment (EOT) helps to stratify the risk of decompensation. However, information regarding prognostic performance of repeated LSM after EOT is still lacking. We aimed to evaluate the risk of liver related events (LRE) using repeated LSM after EOT and explore factors associated with LSM impairment.
Method: We retrospectively analyzed a multicentric European cohort including HCV-cACLD patients cured with oral antivirals with repeated LSM after EOT. We used 3 time-point LSM: after EOT (B-LSM), between 12 months to 36 months after EOT (LSM1) and after 54 months (LSM2). LSM impairment was defined as ≥20% increase with respect to B-LSM with a final LSM ≥10 kPa. The cumulative incidence of LRE was compared between groups. LRE included decompensation events and hepatocellular carcinoma.
Results: 1052 patients with B-LSM were included. In 815 patients LSM1 was performed and in 646 LSM2 was available (in 466 all three LSM were available). During a median follow-up of 6.3 years, 80 patients developed LRE. 68 LRE occurred after LSM1 (with 23 of LRE occurring after LSM2). In 63 patients (7.7%), LSM1 worsened (increase ≥20% with LSM1≥10 kPa) during FU vs 752 patients. Patients with LSM1 impairment had lower baseline mean platelet count (140×10^9/L vs 166×10^9/L, $p < 0.001$), higher bilirubin levels (0.8 mg/dL vs 0.7 mg/dL, $p = 0.016$) and higher GGT levels (45 IU/L vs 36 IU/L, $p = 0.056$) compared to patients without LSM1 impairment. No significant difference was found in metabolic risk factors neither in alcohol consumption between both groups. The incidence rate of LRE in patients with LSM1 impairment was 3.9/1000 patient-years compared to 1.9/1000 patient-years ($p = 0.024$). The risk of LRE at 5-year-FU was 20% in the LSM1 impairment group vs 11.6% in the other group ($p = 0.079$). Due to short FU after LSM2 (median 14 months), incidence of LRE related to LSM impairment was not explored.
Conclusion: In HCV-cACLD patients cured with oral antivirals, impairment in LSM during FU is not frequent but associated with a double risk of presenting LRE. Those patients in whom LSM worsens during FU have a more advanced liver disease. In this cohort, metabolic risk factors did not associate with LSM impairment.

THU-382

Lead-in cohort results from a phase 2 study of a novel 8-week combination regimen of Bemnifosbuvir and Ruzasvir in patients with chronic hepatitis C virus infection

Alina Jucov[1], Brian Conway[2], Laura Iliescu[3], Paul Mitrut[4], Simin Florescu[5], Roxana Cernat[6], Elena Ermacicova[7], Shannan Lynch[8], Marina Majarian[8], Sergey Izmailyan[8], Xiao-Jian Zhou[8], Keith Pietropaolo[8], Bruce Belanger[8], Arantxa Horga[8], Janet Hammond[8]. *[1]Arensia Exploratory Medicine GmbH, Chisinau, Moldova, and Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova; [2]Vancouver Infectious Diseases Centre, Vancouver, Canada; [3]Institutul Clinic Fundeni, Bucharest, Romania; [4]University of Medicine and Pharmacy, Craiova, Romania; [5]5Spitalul Clinic de Boli Infectioase si Tropicale Dr. Victor Babes, Bucharest, Romania; [6]Clinical Hospital for Infectious Diseases, "Ovidius" University Constanta, Constanta, Romania; [7]Arensia Exploratory Medicine GmbH, Chisinau; [8]Atea Pharmaceuticals, Inc., Boston, United States*
Email: alina.jucov@arensia-em.com

Background and aims: Bemnifosbuvir (BEM) and ruzasvir (RZR) are potent, pan-genotypic inhibitors of the HCV NS5B polymerase and the NS5A protein, respectively. In previous studies, the combination of BEM and daclatasvir (n = 10), and uprifosbuvir and RZR (n > 400), were safe, well-tolerated, and each combination achieved high sustained virologic response (SVR) rates in HCV-infected patients. BEM+RZR exhibited synergistic anti-HCV activity *in vitro* with no pharmacokinetic (PK) drug-drug interaction in healthy subjects, prompting evaluation of this novel combination in a phase 2 open-label study assessing efficacy and safety of BEM+RZR administered for 8 weeks in 280 HCV-infected patients (NCT05904470).
Method: In this single arm study, a lead-in cohort (n = 60) of treatment-naïve, non-cirrhotic patients with chronic HCV (any genotype) received 550 mg BEM once daily (QD) + 180 mg RZR QD for 8 weeks. Objectives of this preliminary analysis included assessment of safety (reported adverse events [AEs], laboratory abnormalities, serial electrocardiograms [ECGs]) and efficacy (achievement of SVR4). An SVR4 rate of ≥90% in the lead-in cohort was needed to proceed with further enrollment. Plasma HCV RNA was evaluated using the Roche cobas® HCV quantitative nucleic acid test for use on the cobas® 6800/8800 systems, with a lower limit of quantitation (LLOQ) of 15 IU/ml.
Results: The 60 lead-in patients were infected with GT1 (n = 45), GT2 (n = 2) and GT3 (n = 13), and 17% had F3 fibrosis. 57% were male, 95% were Caucasian, with a median age of 47 (range 25–79) years. All patients completed the 8-week treatment period with no premature treatment discontinuations or drug-related serious AEs. AEs were mostly mild; no clinically significant laboratory or ECG abnormalities were observed. Viral load decreased rapidly after treatment initiation, with 90% of patients achieving below LLOQ by week 4 (residual viral loads of the remaining patients were near LLOQ ranging from 16 to 31 IU/ml) and 100% achieving below LLOQ by end of treatment. At the time of this analysis, 58 subjects reached the SVR4 timepoint. Of these, 57 subjects (98%) achieved SVR4.
Conclusion: BEM+RZR for 8 weeks was well tolerated in HCV-infected patients. A high rate of SVR4 (98%) was documented in this preliminary analysis. All patients will continue to be followed to SVR12. Based on these results, the study will continue to enroll an additional 220 patients, including those with compensated cirrhosis.

THU-383

Predictive performance of HCC risk scores in chronic hepatitis C patients with advanced fibrosis after achieving SVR: real-world experience from a tertiary UK centre

Riham Soliman[1], Saima Ajaz[1], James Lok[1], Mercy Karoney[1], Evangelos Chalatsis[1], Ivana Carey[1], Mary D Cannon[1], Kathryn Oakes[2], Teresa Bowyer[1], Kosh Agarwal[1], Maria Guerra Veloz[1]. [1]*Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom;* [2]*Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom*
Email: riham.soliman@nhs.net

Background and aims: Current guidelines recommend biannual hepatocellular carcinoma (HCC) surveillance in patients with chronic hepatitis C (CHC) infection and advanced liver fibrosis. However, this 'one-size-fits-all' strategy places a huge burden on healthcare systems and regression of fibrosis may occur with disease-modifying treatments. Our aim is to compare the discriminative ability of risk prediction scores for HCC development in patients with CHC who have achieved sustained virological response (SVR).
Method: In this retrospective single centre study we compared the predictive performance of the aMAP, THRI and GES scores in a cohort of patients with treated HCV infection (F3–F4) and achieved SVR with direct acting antivirals (DAAs) between 2014 and 2020. Data was collected until HCC occurrence, death or last follow-up visit. Cumulative incidences were calculated using the Kaplan-Meier method and compared using the log-rank test. The performance of each model was assessed further using Harrell's c statistics.
Results: 508 patients were included in the analysis, 70% males with a median age of 58.0 years. The majority (61.4%) were cirrhotic. By applying the GES score, 264 (52.0%), 174 (36.4%), and 70 (13.8%) of the patients were considered at low, intermediate, and high risk for HCC. Cumulative HCC incidence in the three categories were as follows: low-risk cohort (defined as GES score ≤6, cumulative incidence 1.20%, 95% CI 0.65–2.04), intermediate-risk cohort (defined as score >6 and ≤7.5, incidence 2.26% CI 1.34–3.59), and high-risk cohort (scores >7.5, incidence 5.86%, 95% CI 3.47–9.31). For the aMAP score, 41 (8.1%), 204 (40.2%), and 263 (51.8%) of the studied patients were at low, intermediate, and high risk for HCC. Cumulative HCC incidence was 0.73% (95% CI 0.04–3.60) in their low-risk group, 0.65% (95% CI 0.24–1.43) in their intermediate-risk group, and 3.56% (95% CI 2.56–4.84) in their high-risk group. For the THRI score, 105 (20.7%), 352 (69.3%), and 15 (10.0%) of the studied patients were at low, intermediate, and high risk for HCC; cumulative incidences were 0.79% (95% CI 0.20–2.16), 2.05% (95% CI 1.40–2.91) and 6.31% (95% CI 3.42–10.73), respectively. The Harrell's c-statistic for the three scores were 0.646 (GES), 0.6723 (aMAP) and 0.6314 (THRI).
Conclusion: All three scores effectively stratified our patient cohort into low, intermediate, and high-risk groups. Screening can be safely avoided in low risk, potentially improving the cost-effectiveness of our HCC surveillance programmes.

THU-386-YI

Renin-angiotensin inhibitor intake is associated with improved survival in patients with chronic hepatitis C viral infection following SVR-data from the german hepatitis C-registry (DHC-R)

Tammo Lambert Tergast[1], Marie Griemsmann[1], Leyla Valiyeva[1], Peter Buggisch[2], Stefan Mauss[3], Hartwig Klinker[4], Klaus H.W. Boeker[5], Christine John[6], Ralf Link[7], Stefan Zeuzem[8], Thomas Berg[9], Heiner Wedemeyer[1,10]. Email: tergast.tammo@mh-hannover.de

Background and aims: The role of renin-angiotensin inhibitors (RAS-Inhibitors) on the clinical course of patients with chronic liver disease remains unclear. Antifibrotic effects have been described in animal models and it has been hypothesized that RAS-Inhibitor intake could exert positive effects on the natural history of liver disease, potentially leading to lower rates of hepatocellular carcinoma (HCC), hepatic decompensation (HD) and improved survival. However, clinical data to support this are lacking. This study investigated the impact of RAS-Inhibitor intake on the clinical course of patients with chronic hepatitis C (HCV) in the well-established German Hepatitis C-Registry (DHC-R).
Method: Overall, 10703 patients were included in this study. Patients with malignancies, without sustained virological response (SVR), HIV or history of organ transplantation were excluded. Study end points were mortality, incidence of hepatic decompensation and incidence of HCC, respectively. Survival analysis was conducted via multivariable Cox-regression, adjusting for important confounding factors such as presence of arterial hypertension, type 2 diabetes mellitus, chronic kidney disease, sex or age.
Results: RAS-Inhibitor intake was present in 2207 (21%) patients. In total, 128 events of hepatic decompensation, 130 deaths and 82 HCCs were documented during follow-up of 18783 patient years. Presence of type 2 diabetes mellitus, presence of dyslipidemia, arterial hypertension, chronic kidney disease or coronary artery disease was significantly more frequent in patients with RAS-Inhibitor intake (18% vs. 5%, $P < 0.001$, 6% vs. 1%, $P < 0.001$, 76% vs. 9%, $P < 0.001$, 6% vs. 1%, $P < 0.001$ and 9% vs. 1%, $P < 0.001$, respectively). Intake of RAS-Inhibitors was not associated with a lower incidence of hepatic decompensation (HR: 0.99, 95%CI: 0.65–1.53, $P = 0.99$) or hepatocellular carcinoma (HR: 0.77, 95%CI: 0.46–1.32, $P = 0.34$). However and importantly, RAS-inhibitor intake was independently associated with improved survival (HR: 0.54, 95%CI 0.33–0.87, $P = 0.01$) irrespective of the higher frequency of metabolic comorbidities.
Conclusion: Although the incidences of HCC or hepatic decompensation is unaffected, the intake of RAS inhibitors was associated with a reduced mortality in patients with HCV following SVR.

THU-387

Safety and efficacy of two pangenotypic direct acting antivirals (sofosbuvir/velpatasvir and glecaprevir/pibrentasvir) for the treatment of hepatitis C in children

Maria Pokorska-Śpiewak[1], Ewa Talarek[2], Anna Dobrzeniecka[3], Małgorzata Aniszewska[2], Magdalena Pluta[2], Magdalena Marczyńska[2]. [1]*Medical University of Warsaw, Regional Hospital of Infectious Diseases, Warsaw, Poland;* [2]*Medical University of Warsaw, Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland;* [3]*Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland*
Email: maria.pokorska-spiewak@wum.edu.pl

Background and aims: The aim of this study was to analyze and compare safety and efficacy of two pangenotypic regimens (sofosbuvir/velpatasvir, SOF/VEL and glecaprevir/pibrentasvir, GLE/PIB) used for treatment of chronic hepatitis C (CHC) in children.
Method: In this single-center study we compared outcomes of CHC treatment in two groups of children: 50 participants aged 6–18 years treated with SOF/VEL in PANDAA-PED Project, and 41 patients aged 5 to 18 years treated with GLE/PIB in POLAC Project. We included all children who had been treated since January 2022, whose evaluation of sustained viral response at 12-week posttreatment (SVR12) was performed until December 31, 2023. In all cases, fixed drug doses adjusted to the patients' weight were used.

Results: Both studied groups (SOF/VEL vs. GLE/PIB) did not differ with respect to sex (46% males in SOF/VEL group, and 51% in GLE/PIB group, p = 0.62) and age (10.0 ± 2.5 vs. 9.3 ± 3.2 years, p = 0.18). Most children were infected vertically (94% and 93%, p = 0.8), mainly with genotype 1 HCV (74% and 61%, p = 0.31) followed by genotype 3 and 4. Most children were treatment-naïve (94% vs. 98%, p = 0.41). At baseline, median alanine aminotransferase (ALT) levels did not differ: 48 IU/L (IQR 34–65) vs. 47 IU/L (35–68), p = 0.84, similarly to the HCV viral load (mean $\log_{10}$ 5.8 ± 0.79 IU/ml vs. 5.9 ± 0.97 IU/ml, p = 0.36). One child in SOF/VEL group and 2 in GLE/PIB group presented with significant fibrosis (F2–3 in METAVIR scale). SVR12 was 100% in both groups. At 4-week of treatment, 2/50 (4%) patients in SOF/VEL group and 7/41 (17%) in GLE/PIB group presented with detectable HCV RNA (p = 0.03), but all were negative at the end of treatment. The most intense decrease in ALT level occurred during the first 4 weeks of treatment and it was similar in both groups [29 IU/L (14–43) vs. 28 (14–43) IU/L, p = 0.94]. Adverse events (AEs) were reported in 40% of patients in SOF/VEL group compared to 41.5% in GLE/PIB group (p = 0.96). The most common AEs included headache, abdominal pain, fatigue, asthenia, and somnolence. Asthenia occurred only in the SOF/VEL group (12%, p = 0.02), whereas skin itching only in GLE/PIB group (7%, p = 0.05).
Conclusion: Both pangenotypic regimens were 100% effective. The prevalence of AEs was similar in both groups. Thus, no superiority of any of the studied regimens for treatment of CHC in children was revealed.

THU-389
Sustained virological response after early discontinuation of HCV treatment

Robert Flisiak[1], Dorota Zarębska-Michaluk[2], Ewa Janczewska[3], Anna Parfieniuk-Kowerda[1], Włodzimierz Mazur[4], Marek Sitko[5], Justyna Janocha-Litwin[6], Rafal Krygier[7], Beata Lorenc[8], Anna Piekarska[9], Barbara Sobala-Szczygieł[10], Krystyna Dobrowolska[2], Łukasz Socha[11], Jerzy Jaroszewicz[10]. *[1]Medical University of Białystok, Białystok, Poland; [2]Jan Kochanowski University, Kielce, Poland; [3]ID Clinic, Mysłowice, Poland; [4]Medical University of Silesia, Chorzów, Poland; [5]Jagiellonian University, Kraków, Poland; [6]Wrocław Medical University, Wrocław, Poland; [7]NZOZ Gemini, Żychlin, Poland; [8]Medical University of Gdańsk, Gdańsk, Poland; [9]Medical University of Łódź, Łódź, Poland; [10]Medical University of Silesia, Bytom, Poland; [11]Pomeranian Medical University, Szczecin, Poland*
Email: robert.flisiak1@gmail.com

Background and aims: So far, the effectiveness of therapy with direct-acting antivirals (DAA) discontinued before 4 weeks has not been analyzed in clinical practice. The aim of this study is to determine to what extent such a short therapy will enable achieving a sustained virological response (SVR) under real-world experience.
Method: Of the 16, 815 patients registered in the EpiTer-2 national database, 195 patients (1.2%) discontinued therapy, of which 97 had both the assessment of SVR and the time of discontinuation of therapy available.
Results: The majority (63.9%) patients discontinued treatment after 4 weeks, but 37 discontinued before the end of 4th week, including 12 within 2 weeks. The most common reason for therapy discontinuation was hepatic decompensation (20.6%) or the patient's personal decision (18.6%), and less frequently increased transaminase activity, cardiovascular or gastrointestinal symptoms, and anemia. Patients who discontinued therapy compared to those who completed treatment as planned were significantly older, more likely to have experienced prior therapy failure, more frequently have cirrhosis, a history of decompensation, and a Child-Pugh classification of B or C. SVR was achieved by 93.5% of patients who discontinued treatment after 4 weeks, 60.9% if discontinued at week 3 or 4 and 33.3% at week 1 or 2. The SVR rate after pangenotypic treatment in patients who discontinued after week 4 (100%) did not differ significantly from that observed in patients who completed the therapy planned (97.4%). However, SVR after discontinuation before week 4 compared to discontinuation after that time was significantly lower in both pangenotypic (42.9% vs 100%) and genotype-specific (57.1% vs 92.5%) treated patients. The characteristics of four patients who responded to treatment lasting no longer than 2 weeks suggested that the main positive prognostic factor was a low baseline viral load (<400, 000 IU/ml).
Conclusion: Despite discontinuation of therapy after the 4th week of treatment, the chances of achieving SVR are high and even very early discontinuation of therapy does not exclude therapeutic success, especially in patients with low baseline viral load.

THU-390
Achieving HCV elimination in underserved populations-an austrian initiative for HCV care for homeless people without medical insurance

Caroline Schwarz[1,2], Bernadette Becsi[3], Stephan Leick[3], Stephan Gremmel[3], Lena Wien[4], Enisa Gutic[1], Thomas Reiberger[2], Hans Haltmayer[5], Michael Gschwantler[1,4]. *[1]Klinik Ottakring, Vienna, Austria; [2]Medical University of Vienna, Vienna, Austria; [3]neunerhaus Gesundheitszentrum, Vienna, Austria; [4]Sigmund Freud University, Vienna, Austria; [5]Suchthilfe Wien gGmbH, Vienna, Austria*
Email: schwarz.caroline1990@gmail.com

Background and aims: Direct-acting antiviral agents (DAA) facilitate excellent sustained virologic response (SVR) rates, yet reaching HCV elimination in Austria remains challenging. People experiencing homelessness (PEH) and/or lack of medical insurance (PELI) are at risk for HCV infection, however, specific elimination projects have not been designed for this population. We present the first Austrian HCV elimination project for PEH and PELI.
Method: The project was based at a low-threshold institution (LTI) providing medical care, social support, and housing for >5.000 PEH and PELI in Vienna per year. AntiHCV screening was offered at the LTI or one of its associated 27 housing institutions since 03/2020. AntiHCV (+) blood samples were further tested for HCV-RNA by PCR ("reflex testing"). HCV-viremic persons received DAA via a hepatitis outpatient clinic integrated in the LTI. PEH were provided with housing via the LTI for the duration of therapy, and in PELI treatment was kindly provided by Abbvie® or Gilead®. Adherence to DAA therapy, was supported by social workers of the LTI and in the respective housing facilities.
Results: Between 03/2020 and 07/2023, 601 individuals underwent serologic testing for HCV, and 116 (19.3%) showed antiHCV (+). While in 24/116 (20.7%) persons HCV-RNA PCR remained negative indicating resolved HCV infection, 92 (79.3%) were HCV-viremic. Among these, DAA therapy was initiated in 36/92 (39.1%) so far. At database closure (07/2023), 21/36 (58.3%) persons had completed DAA treatment and SVR was documented in 17 (81.0%), while 4 (19.0%) individuals remained on post-treatment follow-up. No DAA treatment interruptions were observed.
Conclusion: While the COVID19 pandemic limited the number of PEH and PELI reached by our screening effort, a substantial proportion of this underserved population underwent HCV testing through this project. HCV seroprevalence was 19.3%, HCV viremia exceeded expectations with 79.3% (tested) and 15.3% (overall)-underlining the relevance of targeted HCV care for PEH and PELI. Our data show that streamlined treatment with DAA is highly effective in the population of PEH and PELI, however, given that additional supporting measures are taken including social worker assistance and provision of safe housing for the duration of therapy. Future HCV elimination efforts should include the underserved population of PEH and PELI in whom HCV prevalence seems alarmingly high despite the availability of DAA. This study was supported by Abbvie® and Gilead®.

THU-391-YI

Impact of hepatitis C cure on outcomes for patients undergoing curative therapy for hepatocellular carcinoma

Alex Wynne[1], Edward J. Gane[2], Akhilesh Swaminathan[3]. [1]*Auckland City Hospital, Auckland, New Zealand;* [2]*Faculty of Medicine, University of Auckland, Auckland, New Zealand;* [3]*Auckland City Hospital, Liver Unit, Auckland, New Zealand*
Email: alexwynne25@gmail.com

Background and aims: Direct-acting antivirals (DAA) with high cure rates have had a dramatic impact on hepatitis C virus (HCV) and its complications, including reduction in incidence of index hepatocellular carcinoma (HCC). However, the impact on outcomes of hepatitis C cure for patients receiving curative intent treatment for their initial HCC is currently not known. Our aim is to assess the impact of hepatitis C cure on incidence of further (recurrent or metachronous) HCC, and on survival, in individuals who have undergone curative intent treatments.
Method: We conducted retrospective analysis of all patients that have received curative intent treatment (surgical resection or ablation) for HCC secondary to HCV in New Zealand between 2003 and 2023. We compared outcomes of those who achieved sustained viral response (SVR) prior to HCC treatment with those who had not achieved SVR prior. We used Kaplan Meier comparison of recurrence free survival and overall survival using Log-Rank and univariable and multivariable analysis using Cox Regression.
Results: Of the 203 patients included in the analysis, 56% had achieved SVR prior to or at the time of their HCC diagnosis. Our analysis showed that achieving SVR prior to initial HCC therapy reduces risk of HCC recurrence compared to never achieving SVR (Hazard Ratio (HR) = 0.44, 95% Confidence Interval (CI) 0.26–0.64). Our analysis also showed that patients achieving SVR prior to the initial HCC therapy reduces the risk of death compared to those not having achieved SVR (HR = 0.36, 95% CI 0.21–0.64).
Conclusion: These results demonstrate that eradication of HCV infection in patients who present with their index HCC reduces the risk of recurrent HCC following resection or ablation by almost 60%. In the era of highly effective DAA therapy and limited supply of deceased donors, patients with HCV infection who have been diagnosed with their index HCC should be treated with DAAs and offered resection or ablation rather than transplantation.

THU-394

Improvement of hepatitis C virus care cascade by In-hospital Reflex tEsting ALarm-C (REAL-C) model

Jonggi Choi[1], Kanghee Park[1], Jina Park[1], Ji won Yang[1], Hyeyeon Hong[1], Sung Won Chung[1]. [1]*Asan Medical Center, Seoul, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and aims: World Health Organization (WHO) has set targets to eliminate viral hepatitis, including hepatitis C virus (HCV) infection, by 2030. Achieving these goals necessitates improved rates of diagnosis and treatment. We present the results of the in-hospital Reflex tEsting ALarm-C (REAL-C) model, which incorporates reflex HCV RNA testing and sending alarming messages for physicians.
Method: We conducted a retrospective study at Asan Medical Center in Seoul, Republic of Korea, focusing on 1, 730 patients newly testing positive for anti-HCV between March 2020 and June 2023. Three distinct periods were defined: pre-REAL-C (n = 696), incomplete REAL-C (n = 515), and complete REAL-C model periods (n = 519). The primary outcome measured was the rate of HCV RNA testing throughout the study period. Additionally, the referral rate to gastrointestinal (GI) department, linkage time for diagnosis and treatment, and the treatment uptake rate.
Results: The rate of HCV RNA testing increased significantly from 51.0% (pre-REAL-C) to 95.6% (complete REAL-C). This improvement was consistent across clinical departments, regardless of patients' comorbidities. Among patients confirmed with HCV infection, the GI referral rate increased from 57.1% to 81.1% after the implementation of the REAL-C model. Treatment uptake rates among treatment-eligible patients was 92.4% during the study period. The mean days from anti-HCV positivity to HCV RNA testing decreased from 45.1 to 1.9. The mean days from the anti-HCV positivity to direct-acting antiviral treatment also decreased from 89.5 to 49.5 with the REAL-C model.
Conclusion: The REAL-C model, featuring reflex testing and alarming messages, effectively increased HCV RNA testing rates and streamlined care cascades. Our model facilitated progress toward achieving the WHO's elimination goals for HCV infection.

THU-395

Is hepatitis C screening based on risk factors enough in primary care setting?

Elena Vargas-Accarino[1], Ariadna Rando-Segura[2], Ingrid Arcusa[3], Eva de Diego[4], Núria García[5], Elena Monserrat[6], Marta Selvi[7], Maria Asuncion Ubeda Pastor[4], Imma Valls[8], Carla Ventosa[9], Adriana Palom[1], Judit Romero-Vico[1], Juan Carlos Ruiz-Cobo[1,10,11], Mar Riveiro Barciela[1,10,11,12], Rafael Esteban[1,10,11,12], Maria Buti[1,10,11,12]. Email: mariabutiferret@gmail.com

Background and aims: Most international guidelines recommend HCV screening only for individuals with risk factors or elevated ALT. These recommendations are based on descriptive studies in which it was identified that more than 80% of patients with positive anti-HCV had risk factors. However, screening strategies based on risk factors may be insufficient for eradicating the infection in high-income countries, since the undiagnosed population remains stable. The objective of our study was to evaluate the application of hepatitis C screening guidelines in primary care centers (PCC) in Spain.
Method: Retrospective search in the microbiology database of the anti-HCV+ and HCV-RNA+ patients from 7 primary care centers. Medical records of those patients were reviewed to assess the screening recommendation application and treatment indication.
Results: Of a total of 90, 170 different individuals who attended these 7 primary care centers, 9, 052 (10%) were screened for hepatitis C between January 2021 and March 2023. Anti-HCV antibodies were detected in 277 (3%) individuals and 48 (7%) were HCV-RNA+, accounting for 0.5% of the screened patients. Medical records of those 277 anti-HCV+ patients were reviewed to analyze their screening criteria. We found that only 38% of anti-HCV+ patients reported risk factors. Of them, 19% were people who inject drugs, 9% had a previous blood transfusion, 4% had tattoos, 4% had sexual risk behavior and 2% were infected by vertical transmission. Analyzed by transaminases levels, 76% had normal transaminases and 24% presented elevated AST or ALT. When analyzed together, we found that 150 (54%) anti-HCV+ patients neither reported risk factor nor presented elevated transaminases. From the 48 HCV-RNA+ patients, only 42% reported risk factors and 31% elevated transaminases; while analyzing it together we found that 22 (46%) of them neither reported risk factors nor elevated transaminases. Anti-HCV+ participants were 55% male, median age 59 years and 70% were born in Spain. Basal median AST and ALT were 29 and 35 IU/L respectively and had FIB-4 and APRI of 2.2 and 0.4 respectively. However, HCV-RNA+ cases were mainly male (60%), older (median age of 69 years) and had higher AST and ALT levels (41 and 47 IU/L respectively) and FIB-4 and APRI of 0.85 and 0.45, respectively. Age and transaminases were significantly higher in individuals with HCV-RNA ($p < 0.05$).

Conclusion: Only 10% of patients attending primary care centers are screened for hepatitis C, with 0.5% of these patients being viremic. More than a half of anti-HCV+ patients neither reported risk factors nor had elevated transaminases and they would not have been screened for hepatitis C if following current guidelines. Moreover, almost a half of HCV-RNA+ patients would not have been treated. HCV universal screening in PCC could be a good strategy to eliminate hepatitis C.

THU-396

HCV patients achieving sustained virologic response after direct-acting antiviral therapy may still face adverse clinical outcomes: analysis of gene enrichment, marker expression, and clinical outcomes

Daniel Millian[1], Omar Saldarriaga[2], Esteban Arroyave[2], Heather Stevenson[3], Arvind Rao[4], Santhoshi Krishnan[4]. *[1]University of Texas Medical Branch, Galveston, Texas, United States; [2]University of Texas Medical Branch, Galveston, Texas, United States; [3]University of Texas Medical Branch, Galveston, Tx, United States; [4]University of Michigan, Michigan, United States*
Email: damillia@utmb.edu

Background and aim: The incidence of HCV in the United States is on the rise, driven by the opioid epidemic, and even though over 95% of HCV patients respond positively to direct-acting antiviral (DAA) therapy they continue to be at risk of re-infection, and chronic liver disease. In this study, we explore the complex aftermath of DAA treatment for Hepatitis C, focusing on the observation where patients achieving sustained virologic response (SVR) may still face adverse clinical outcomes, including portal hypertension and hepatocellular carcinoma. We aim to determine the gene and protein expression of the hepatic microenvironment before and after DAA treatment to identify key biological markers associated with poor outcomes.
Method: Utilizing cutting-edge multispectral imaging, we scrutinize the nuances of intrahepatic macrophage (CD68, CD14, CD16, MAC387, and CD163) and T cells (CD3, CD4, CD8, CD45, and FoxP3) phenotypes. This involves the comparison of liver biopsies collected before (n = 10) and after (n = 10) SVR attainment (5 were paired biopsies from the same patients; total of 15 patients). Employing advanced imaging analysis and machine learning algorithms, we decoded the changes in these pivotal immune cells. Furthermore, our exploration extends to over 700 genes through RNA isolated from liver biopsies using NanoString nCounter and RNA sequencing (SMART-seq). Both platforms were correlated with clinical outcomes.
Results: The pre and post-treatment (Pre-Tx, Post-Tx) fresh liver tissue data from 15 patients were analyzed and correlated with clinical outcomes. We observed that in the post-Tx liver biopsies of patients without inflammation, the liver enzymes aspartate aminotransferase (AST) (Pre-Tx 122 U/L, SD ± 105 and post-Tx 29 U/L, SD ± 10.3, respectively), and alanine aminotransferase (ALT) (Pre-Tx 96 U/L, SD ± 104 and Post-Tx 20 U/L, SD ± 27) returned to baseline compared to Pre-Tx values. This coincides with the multispectral imaging showing a switch from proinflammatory/M1-like to anti-inflammatory/M2-like macrophage phenotypes pre- and post-treatment, respectively. Nanostring gene expression analysis showed an enrichment of inflammatory and interferon-induced antiviral genes in the pre-treatment group when compared to the Post-Tx. However, after treatment, the fibrosis stage of 5 out of 15 patients did not improve or regress to baseline, and 2 out of these 5 patients died from decompensated cirrhosis and one succumbed to cholangiocarcinoma. These results were subsequently confirmed using RNA sequencing.
Conclusion: In summary, this work reveals distinctive gene and marker expression profiles before the administration of DAAs, which undergo notable changes post-treatment. However, patients with advanced fibrosis or with cirrhosis at the initiation of the antiviral therapy may develop poor clinical outcomes even after achieving sustained virologic response.

THU-397-YI

Long-term histological fibrosis evolution following sustained virological response after hepatitis C-recurrence in liver-transplanted patients

Tibo Lemmens[1], Cindy Serdjebi[2], Guillaume Henin[1], Selda Aydin[1], Pamela Baldin[1], Florine Chandes[2], Géraldine Dahlqvist[1]. *[1]Cliniques universitaires Saint Luc, Brussels, Belgium; [2]Biocellvia, Marseille, France*
Email: tibolemmens123@gmail.com

Background and aims: Hepatitis C (HCV) recurrence after liver transplantation (LT) is universal if HCV-RNA persists at time of LT and progression to fibrosis can occur rapidly. Nowadays, sustained virological response (SVR) is obtained in 97% of HCV-infected patients treated with direct acting antivirals (DAA) after LT. Fibrosis diminishes in HCV patients after SVR but there is paucity of data on fibrosis regression occurring after SVR following LT. In addition, most studies evaluate fibrosis with non-invasive techniques while these are not validated after LT because of LT-specific complications. There are no data evaluating long-term evolution of fibrosis after SVR since the introduction of DAA treatments (>5–10 years). The aim of this study is to histologically evaluate liver fibrosis evolution in short and long term follow-up biopsies after HCV-elimination in LT-patients.
Method: In this retrospective monocentric cohort study, we evaluated 32 patients with SVR after recurrent HCV following LT and treated with IFN (n = 4) or DAA (n = 28). Protocolar liver biopsies were collected between 2011 and 2020. We compared liver biopsies before HCV treatment, with those taken during short-term follow-up (<2 years) and long-term follow-up (≥3 years). Massons' trichrome (MTC) slides were used for METAVIR- and LAF scoring. Picro-Sirius-red (PSR) slides were used for both a semi-quantitative assessment of fibrosis expressed as total fibrosis area (%) and an automated morphometric assessment of fibrosis with artificial intelligence (AI) based technology MorphoQuant.
Results: All 32 patients reached SVR after LT, including 24 with follow-up biopsies. Scoring and AI-based analyses were performed on 19 and 24 patients, respectively. PSR analysis showed a significant reduction in total fibrosis area on the short-term biopsies (−4.9%, $p < 0.002$) in 73% of patients, which remained stable even after long-term assessment (−4.9%, $p < 0.001$). MTC based scoring confirmed fibrosis regression in the long-term biopsies, according to either METAVIR (−0.8, $p < 0.01$) or LAF-Score (−1.5, $p < 0.02$) but not in the short-term biopsies. AI-based analysis showed a significant reduction of collagen proportionate area in the short-term biopsies after HCV treatment, and a stabilization over time (−3.2%, $p < 0.001$). This reduction was notably significant in the perivascular area (−2.5%, $p < 0.002$), but not in the peri-sinusoidal or septal area. Finally, collagen fibres were smaller after short-term evaluation (−0.18%, $p < 0.02$), which was confirmed in long-term follow-up biopsies.
Conclusion: Achieving SVR after post-LT HCV-recurrence results in swift reduction of fibrosis with stabilization on the long term. AI-based analyses show earlier changes than the classical histological scoring systems.

THU-398

Metabolic factors predict significant liver fibrosis in people who use drugs (PWUD) and general population with HCV infection. Time to re-consider the follow-up strategy in chronic hepatitis C patients

Hariklia Kranidioti[1], Olga Anagnostou[2], Georgios Kontos[1], Sofia Vasileiadi[1], Anestis Goulas[1], Nikolaos Papadopoulos[3,4], Melanie Deutsch[1], Spilios Manolakopoulos[1]. *[1]2nd Department of Internal Medicine, National and Kapodistrian University of Athens, General Hospital of Athens Hippocratio, Athens, Greece; [2]Greek Organization against of Drugs (OKANA), Athens, Greece; [3]401 General Army Hospital of Athens, Athens, Greece; [4]401 General Army Hospital of Athens, 2nd Department of Internal Medicine, Athens, Greece*
Email: harakranidioti@yahoo.gr

Background and aims: Comorbidities related to metabolic syndrome are associated with liver fibrosis and affect the management and surveillance of patients with HCV infection. The aim of the study was to address the prevalence of metabolic risk factors in HCV patients and their impact on liver stiffness according to the source of infection.
Method: We included patients with detectable HCV RNA who received treatment with DAAs in our outpatient liver clinic from June 2014 to July 2021. Metabolic profile was based on BMI measurement, medical records and prescribed medication for diabetes mellitus (DM), arterial hypertension (AH) and dyslipidemia (DLD) on baseline evaluation. Liver stiffness was evaluated with transient elastography (TE).
Results: 680 patients were analyzed (71% males, 51 ± 12 years old, 57% >50 years old). 422 (62%) patients reported previous history of drug use (PWUD) and 71% was under substitution with buprenorphine or methadone. Regarding metabolic risk factors, 41 (6%) patients presented DM, 215 (32%) AH, 80 (12%) DLD and 275 (40%) had BMI >25 (mean BMI 24.9 kg/m^2). Compared with PWUD, patients who had HCV infection from other sources (general population) were older (56 vs 47 years, $p < 10^{-3}$), had higher BMI (26 vs 24 kg/m^2, $p < 10^{-3}$), and presented more frequently DM (12.7% vs 1.7%, $p < 10^{-3}$), AH (24% vs 12%, $p < 10^{-3}$) and DLD (12.7% vs 1.9%, $p < 10^{-3}$). In total, 327 (51%) patients (43% PWUD vs 61% general population, $p < 10^{-3}$) had significant fibrosis or cirrhosis (liver stiffness >9 kPa). Logistic regression analysis revealed that predictive factors for significant fibrosis were source of infection (general population) ($p < 10^{-3}$), older age ($p < 10^{-3}$), BMI ($p < 10^{-3}$), BMI>25 kg/m^2 ($p < 10^{-3}$), AH ($p = 0.01$), and the presence of DM ($p < 10^{-3}$). In multivariate analysis, age and BMI were the only independent predictive factors. Sub-cohort analysis for PWUD and general population separately for individuals >or <50 years old, showed that BMI was the only independent predictive factor for significant fibrosis ($p < 10^{-3}$). Liver stiffness addressed an independent positive predictive value ($p = 0.04$) for poor outcome (liver related death or hepatocellular carcinoma).
Conclusion: Our data postulated that metabolic factors could predict significant fibrosis in patients with HCV infection. BMI represents an independent risk factor for significant fibrosis regardless the source of infection and the older age. The presence of metabolic factors should be taken under consideration for the management and follow-up of the chronic HCV patients.

THU-399-YI
Burden of extrahepatic manifestations after HCV cure: assessing the effect of IFN versus DAA-induced SVR in a large population-based cohort in British Columbia, Canada

Dahn Jeong[1], Stanley Wong[2], Jean Damascene Makuza[1], Héctor Alexander Velásquez García[1,2], Mel Krajden[3], Richard Morrow[1], Prince Adu[2], Sofia Bartlett[1,2], Georgine Cua[4], Amanda Yu[2], Maria Alvarez[2], Naveed Janjua[1,2]. [1]*School of Population and Public Health, University of British Columbia, Vancouver, Canada;* [2]*BC Centre for Disease Control, Vancouver, Canada;* [3]*Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, Canada;* [4]*Faculty of Medicine, University of British Columbia, Vancouver, Canada*
Email: dahn.jeong@bccdc.ca

Background and aims: Prior research indicates that hepatic and extrahepatic damage from chronic HCV infection may persist post-virologic cure. While evidence supports HCV treatment benefits in reducing the risk of extrahepatic manifestations (EHMs) among individuals achieving sustained virologic response (SVR) compared to those living with untreated HCV, the burden of EHM after SVR remains unclear. Moreover, differences in health outcomes after interferon (IFN) vs direct-acting antiviral (DAA)-based SVR have been suggested. This analysis assessed the EHM burden among individuals achieving SVR through IFN or DAA treatment in a large, population-based cohort.
Method: We used the British Columbia Hepatitis Testers Cohort (BC-HTC), which includes all individuals diagnosed with HCV from 1990 to 2015, linked with administrative health datasets. Our study sample included individuals receiving IFN or DAA treatment with confirmed SVR. EHM diagnoses were obtained through ICD-9/10 diagnostic and procedure codes in hospitalization and physician billing data, including chronic kidney disease (CKD), type 2 diabetes (DM), major adverse cardiac events (MACE), neurocognitive disorders (NCD) and mood and anxiety disorders (MAAD). We computed incidence rates (IR) of EHMs by treatment type from the date of SVR assessment. To address the differences in baseline sociodemographic and clinical characteristics between people treated with IFN or DAA, we adopted inverse probability of treatment weighting (IPTW) to induce balance across characteristics. Multivariable subdistribution hazard models, weighted with IPTW and accounting for competing mortality risks, were used to estimate risk of incident EHMs.
Results: Study sample included 4, 551 persons treated with IFN and 10, 819 persons treated with DAA, with confirmed SVR. Those treated with DAA were younger, more likely to have a history of drug and alcohol use disorder, with a greater prevalence of EHMs prior to SVR compared to individuals treated with IFN. Persons treated with DAA had a higher IR of CKD, MACE and NCD compared to those treated with IFN. The IR of DM and MAAD didn't differ between people treated with IFN or DAA. When adjusting for differences in baseline characteristics with IPTW and competing mortality risks, people treated with IFN had reduced risks of CKD, MACE and NCD, but higher risk of DM and MAAD compared to those treated with DAA; adjusted subdistribution hazard ratios: CKD 0.68 (95% CI 0.57–0.80), DM 1.37 (95% CI 1.10–1.69), MACE 0.60 (95% CI 0.53–0.69), NCD 0.56 (95% CI 0.47–0.68) and MAAD 1.49 (95% CI 1.24–1.79).
Conclusion: Individuals who were treated with DAA had higher EHM burden before and after virologic cure compared to those treated with IFN. Given the shift to DAA treatments, further research is needed to understand pre-therapeutic EHM risk factors and the impact of curative therapy on EHMs and overall long-term health outcomes.

THU-402
Higher cardiovascular burden in people living with HIV (PLWH) with metabolic syndrome and history of HCV infection

Alessia Siribelli[1], Michele Bellomo[2], Camilla Muccini[2], Riccardo Lolatto[2], Giulia Morsica[2], Sara Diotallevi[2], Nicola Gianotti[2], Simona Bossolasco[1], Costanza Bertoni[1], Vincenzo Spagnuolo[1], Antonella Castagna[3], Hamid Hasson[1]. [1]*San Raffaele Scientific Institute, Milan, Italy;* [2]*San Raffaele Scientific Institute, Milan, Italy;* [3]*Vita-Salute San Raffaele University, San Raffaele Scientific Institute, Milan, Italy*
Email: siribelli.alessia@hsr.it

Background and aims: People living with HIV (PLWH) have higher occurrence of major adverse cardiovascular events (MACE). This study aimed to identify factors associated with MACE in PLWH during a 10-years (yrs) follow-up (FU).
Method: Retrospective study including PLWH followed at San Raffaele Scientific Institute, Italy, between January 2013–December 2023, with at least 3 observations for laboratory data. Metabolic syndrome (MetS) defined according to ATP3 criteria (NCEP). MACE considered were myocardial infarction, unstable angina, stroke, transient ischemic attack, peripheral arterial ischemia, revascularization. Trained binary classification algorithm (simple logistic regression), calculating at each examination the probability of developing at least one MACE within the following year was used. To adjust for residual variability of developing MACE, generalized additive mixed model (GAMM), with random intercept and non-parametric model of variables was used. Continuous variables as age, yrs of MetS, Log HIV viremia and CD4 were modelled with smooth effects, the remaining with standard regression coefficients.
Results: Overall, 5416 PLWH were included: 4363 (81%) were males, 3088 (58%) smokers or ex, 2437 (45%) had MetS, HBV and HCV

coinfection were diagnosed in 377 (7%, of which 1.9% not virologically suppressed) and 1076 (20% of which 1.8% untreated), respectively. During a median FU of 9.7 yrs, 216 (4%) developed at least one MACE. In simple logistic regression, higher occurrence of MACE was significantly associated with age (OR = 1.06;95%CI = 1.04, 1.07;p < 0.0001), male sex (OR = 2.29;95%CI = 1.64, 3.28;p < 0.0001), presence of MetS (OR = 1.72;95%CI = 1.27, 2.29;p < 0.0003), smoking (OR = 2.01;95%CI = 1.58, 2.56;p < 0.0001), co-presence of HCV with MetS (OR = 1.72;95%CI = 1.09, 2.72;p = 0.021), use of protease inhibitors (PI) (OR = 2.1;95%CI = 1.45, 3.03;p < 0.0001) and integrase inhibitors (INSTI) (OR = 1.34;95%CI = 1.03, 1.73;p = 0.0274). In GAMM, age (p = 0.0001), male sex (OR = 2.23;95%CI = 1.46, 3.41;p = 0.0002), smoking (OR = 1.91;95%CI = 1.39, 2.62;p < 0.0001), use of PI (OR = 1.65;95%CI = 1.06, 2.58;p = 0.0278) confirmed to increase occurrence of MACE.
Conclusion: In a large cohort of PLWH, during 10-yrs of FU, MACE are more likely to occur in people with MetS and history of HCV infection, additionally to traditional factors and specific HIV therapy. Surveillance and appropriate management of MetS, particularly in people coinfected with HCV-HIV, could help reduce cardiovascular burden.

THU-403
Liver fibrosis and steatosis in children after effective treatment of chronic hepatitis C using direct acting antivirals
Maria Pokorska-Śpiewak[1], Ewa Talarek[2], Anna Dobrzeniecka[3], Małgorzata Aniszewska[4], Magdalena Pluta[1], Magdalena Marczyńska[1]. *[1]Medical University of Warsaw, Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland; [2]Medical University of Warsaw, Warsaw, Poland; [3]Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland; [4]Medical Univeristy of Warsaw, Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland*
Email: maria.pokorska-spiewak@wum.edu.pl

Background and aims: In this study we aimed to examine the long-term influence of successful treatment with direct acting antivirals (DAAs) on liver fibrosis and steatosis in children with chronic hepatitis C (CHC).
Method: Of 135 children aged 5 to 18 years who had been treated with DAAs due to CHC in our Department between July 2019 and December 2023 as a part of two projects: PANDAA-PED (12-week treatment with sofosbuvir/velpatasvir, SOF/VEL) and POLAC Project (12/24-week treatment with sofosbuvir/ledipasvir, SOF/LDV, and 8-week with glecaprevir/pibrentasvir, GLE/PIB), we selected successfully treated participants, who completed control evaluation at one-year posttreatment. Liver fibrosis and steatosis were assessed using transient elastography at baseline, 12-week posttreatment, and one-year posttreatment. Significant fibrosis was diagnosed when liver stiffness measurement (LSM) was >7 kPa, cirrhosis when LSM was ≥12.5 kPa, and steatosis when controlled attenuation parameter (CAP) was >238 dB/m.
Results: We identified 67 patients (32 boys, 48%) eligible for the study: 49 after SOF/VEL treatment, 9 after GLE/PIB, and 9 after SOF/LDV. At baseline, the mean age was 10.4 ± 2.9 years. There were 62 (93%) patients infected vertically, 58 (87%) were treatment-naïve, 41 (61%) were infected with genotype 1. All children had undetectable HCV RNA at one-year posttreatment. At baseline, 5/67 (7%) participants presented with significant fibrosis, including 2 with cirrhosis. At 12-week posttreatment, only 2 of these patients had LSM >7 kPa, and one-year posttreatement only one cirrhotic patient had abnormal LSM. Mean values of LSM for the study group were 4.9 kPa (95%CI 4.4–5.4) at baseline, 4.8 kPa (3.9–5.8) at 12-week posttreatment, and 4.5 kPa (3.8–5.3) at one-year posttreatment (all p > 0.05), whereas corresponding CAP values were 180 dB/m (170–191), 195 dB/m (185–206), and 191 dB/m (180–201), respectively (for the first two values p = 0.009). Number of patients with steatosis increased from 4 (6%) at baseline to 7 (10%) at 12-week posttreatment, and to 8 (12%) at one-year posttreatment.
Conclusion: Successful treatment with DAAs leads to regression of significant liver fibrosis in most cases. Increased CAP values after therapy require further analysis on larger groups of patients.

THU-404
Impact of hepatitis C treatment on mortality among liver cancer patients in Georgia-2015–2022
Anna Khoperia[1], Maia Butsashvili[2], Shaun Shadaker[3], Susan Gawel[4], Sophia Surguladze[5], Nazibrola Chitadze[1], Konstantine Kazanjan[1], Vladimer Getia[1], Lasha Gulbiani[2], Geoff Beckett[6], Alan Landay[7], Maia Tsereteli[1], Maia Alkhazashvili[1], Amiran Gamkrelidze[8], Francisco Averhoff[4]. *[1]National Center for Disease Control and Public Health, Tbilisi, Georgia; [2]Health Research Union, Tbilisi, Georgia; [3]Centers for Disease Control and Prevention, Atlanta, United States; [4]Abbott Diagnostics, Illinois, United States; [5]The Task Force for Global Health, Tbilisi, Georgia; [6]Centers for Disease Control and Prevention, Retired, Atlanta, United States; [7]Rush University, Chicago, United States; [8]University of Georgia, School of Health Sciences, Tbilisi, Georgia*
Email: annakhoperia@gmail.com

Background and aims: Chronic hepatitis C virus (HCV) infection can result in hepatocellular carcinoma (HCC), the most common form of primary liver cancer (PLC). The country of Georgia has an HCV elimination program providing testing and treatment since 2015. This study uses data from national registries to assess the association of HCV infection and treatment with mortality in individuals with documented history of liver cancer in Georgia.
Method: We conducted a retrospective registry-based cross-sectional study of adult (≥18 years) liver cancer cases in the Georgian Cancer Registry (GCR) during January 2015–December 2022 linked to HCV screening and treatment data using unique national IDs. HCC, defined as ICD-10 of C22.0, was compared to other PLC cases (ICD-10 C22.1–C22.9). Mortality was defined as a recorded death date at the time of analysis. We conducted bivariable and multivariable analyses to compare mortality proportion between the HCC subtype versus other liver cancer subtypes, explore differences in mortality of cases with and without HCV history, and the correlation between HCV treatment and mortality in the HCV-infected subgroup. Logistic regression modeling assessed factors associated with mortality: age, sex (female vs. male), achievement of sustained viral response (SVR) after treatment (yes vs. no), and GCR-assigned liver cancer ICD-10 code (HCC vs. other types of liver cancer). Odds ratios (OR) and 95% confidence intervals (CI) were calculated. Cases with missing vital status were excluded.
Results: Of 1736 adults with PLC, 1388 (79.9%) were deceased at the time of analysis. Although age was associated with increased mortality (OR = 0.7, 95% CI [0.6–0.8]), a statistically significant association was not found between sexes. HCC was reported among 419 (24.1%) PLC cases. Compared to HCC cases, other combined subcategories of liver cancer (OR = 2.1, 95% CI [1.6–2.8]) were associated with increased mortality. Overall, 1393 (80.2%) PLC cases were screened for anti-HCV, and out of 717 (51.5%) tested for viremia, 655 (91.4%) were HCV RNA positive; of those, 495 (75.6%) initiated HCV treatment and 445 (89.9%) completed. No statistically significant differences were observed in mortality between anti-HCV reactive and non-reactive groups with documented PLC. Logistic regression analyses controlling for sex among PLC patients with viremic HCV infection, achievement of SVR (adjusted OR [aOR] = 2.04, 95% CI [1.04–4.17], p = 0.049) and having HCC compared to other liver cancers (aOR = 2.59, 95% CI [1.51–4.45], p < 0.001) were associated with reduced mortality.
Conclusion: While no statistically significant mortality associations were found between anti-HCV reactive and non-reactive cases with documented PLC, achieving sustained virologic response (SVR) is a potential factor associated with reduced mortality among liver cancer patients with a history of HCV infection.

THU-405

Analysis of a decentralized model interdisciplinary for the elimination of HCV in vulnerable population in the province of Huelva (Spain). To continue advancing in the elimination of hepatitis C, it is necessary to establish a clearly defined integrated care plan

Gema Romero[1], Ana Bejarano[1], Francisco Franco[1], Pilar Del Pino[1], Maria Dolores Santos[1]. [1]*Hospital Universitario Juan Ramón Jiménez, Huelva, Spain*
Email: gemarherrera@hotmail.com

Background and aims: the objective of this study is to evaluate the implementation of a comprehensive strategy of microelimination based on the decentralization of the diagnosis and treatment.
Method: prospective observational study in which screening of the HCV infection through rapid serological tests (saliva or whole blood samples), in settlements of immigrant workers in the agricultural campaign in the province of Huelva andpeople who go to centers that serve the vulnerable population in Huelva capital (Cáritas, center Red Cross of Torrejón meeting and reception and Virgen de la Cinta social lunchroom). In the detected positive, an "in situ" viremia study was performed (GeneXpert®). In patients viraemic, a comprehensive out-of-hospital assessment was carried out at the same time by the hepatologist with Fibroscan® and abdominal ultrasound with portable devices and dispensing of the antiviral treatment.
Results: 322 people were screened with close to 100% success in participating in each working day. The majority nationalities of the settlement population were Ghanaian (85), Morocco (70) and Romania (56). In the social centers the majority were Spanish population (64). 5 viremic patients were detected (prevalence of 1.5%), 4 being treated, not leading to treatment was carried out on one of the patients because a lesion was detected in the abdominal ultrasound suggestive of hepatocellular carcinoma. Among the viremic patients, the two detected in settlements were of Romanian origin, with an incidence of 3.5% in said population.
Conclusion: decentralization in virological diagnosis, medical care by experts in HCV and the provision of treatment is feasible and eliminates known barriers. It is necessary for them proactive multidisciplinary teams.

Knowledge, perceptions and barriers to the diagnosis and treatment of hepatitis C among persons who inject drugs: findings from the Educate-Test-Treat (ETT) programme in Singapore

Alyssa Sim[1], Shann Long[1], Sanchalika Acharyya[2], Gerard Wong[3], Ryan Jia Jie Liew[1,4], Kuo Chao Yew[1]. [1]*Department of Gastroenterology and Hepatology, Tan Tock Seng Hospital, Singapore, Singapore;* [2]*Clinical Research and Innovation Office (CRIO), Tan Tock Seng Hospital, Singapore, Singapore;* [3]*HCSA Highpoint Halfway House, HCSA Community Services, Singapore, Singapore;* [4]*Anglo Chinese School (Independent), Singapore, Singapore*
Email: alyssasim@gmail.com

Background and aims: The World Health Organization (WHO) has implemented a global elimination strategy, setting a rate of ≥90% of chronic hepatitis C (HCV) being diagnosed to achieve eradication target goals by 2030. Its prevalence is high among people who inject drugs (PWID). Despite effective, simple oral Direct-Acting Antivirals (DAA), the uptake of diagnosis and treatment for HCV among PWID has been consistently low. We aimed to identify gaps in knowledge and attitudes in our local cohort and uncover local barriers towards achieving elimination of HCV.
Method: PWID from 4 halfway houses in Singapore were recruited from March 2022–April 2023. Using a structured questionnaire, information was gathered on baseline demographics and socio-economic status. We also assessed HCV awareness, knowledge, attitudes and perceptions regarding pursuit of treatment. Seven items were extracted from the questionnaire which pertained to 'knowledge' and 'attitude', each with a total score of 7 and classified into 'poor' (0–2), 'average' (3–5), or 'good' (6–7) for both domains. Statistical analysis was conducted on SPSS version 27 and statistical significance set at $p = 0.05$.
Results: Out of 198 participants, mean age was 54.0 years and 99% were male. Less than 20% of the participants had completed tertiary education. Participants with lower education levels were at greater risk of HCV infection, and although had poorer knowledge, demonstrated better attitude. 45.9% demonstrated average understanding of HCV. 35.9% were found to have poor understanding. The majority displayed good attitude (79.8%) and average attitude (20.2%). Notably, none displayed poor attitude. From univariate analysis, looking at knowledge and awareness of HCV, poor knowledge was associated with increasing age ($p = 0.018$) and lower education levels ($p = 0.034$). There were no significant differences in terms of these patient factors with regards to attitude. However, on multivariate analysis, increasing age (OR1.05, CI 1.01–1.09) $p = 0.02$ and increased knowledge scores (OR1.21, CI 0.98–1.49) $p = 0.073$ were associated with better attitude. When looking at potential barriers to the diagnosis and treatment of HCV, cost was the most important factor (56.6%), followed by side effects (39.5%) and perceived stigma (4.1%). We also identified venepuncture and saliva to be the preferred testing methods for HCV.
Conclusion: In conclusion, there are evident gaps in knowledge of HCV among PWID. It is essential to develop targeted education strategies in addressing misconceptions about HCV. Efforts to improve linkage to care should address barriers at different levels, and system-level changes are important. Targeting this may help us effectively achieve the HCV elimination goals in Singapore.

THU-407

A new pattern for hepatitis C management in hospital: establishment and effectiveness verification

Dong Yan[1], Siheng Zhu[1], Xiaoting Ye[2], Heqing Huang[3]. [1]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China;* [2]*Ruian people's Hospital, Ruian, China;* [3]*Zhuji people's Hospital of Zhejiang Province, Zhuji, China*
Email: yandonh@zju.edu.cn

Background and aims: Viral hepatitis C is a kind of infectious disease caused by hepatitis C virus (HCV) infection. Statistics have shown that the rates of diagnosis and treatment coverage were not high. This study aims to establish a new management pattern of hepatitis C in hospital and verify whether it can improve the rates of diagnosis and treatment.
Method: A new management pattern of hepatitis C in hospital was established and promoted: First, newly-found HCV antibody positive patients were collected through our infection monitoring system every two weeks and followed regularly, then sorting out and analyzing the data; Second, real-time reminders were set up in the electronic case record system and on the results sheets, urging for specialized diagnosis and treatment; Third, all medical stuff needed to receive training to improve their understanding of hepatitis C infection; Fourth, infectious disease report card of hepatitis C was specially added. The RNA testing rates and the treatment rates of hepatitis C in different periods were then compared.
Results: Before the new pattern, the total HCV-RNA testing rate was 68.79% (3002/4364), with the RNA positive rate of 51.53% (1547/3002), and the treatment rate was 32.35% (764/2362). The RNA testing rate of non-infectious disease departments was 52.89% (1363/2577). Among males, 1715/2441 (70.26%) tested RNA, while among females the rate was 1287/1923 (66.93%). The RNA testing rates in different age groups were as follows: aged 0 to 29–76.40% (437/572), aged 30 to 59–70.97% (1907/2687), aged 60 to 89–59.84% (657/1098), and aged 90 and above-14.29% (1/7). Under the new pattern, the total RNA testing rate increased to 86.84% (409/471), with the RNA positive rate of 78.48% (321/409), and the treatment rate achieved 65.00% (195/300). The RNA testing rate in non-infectious disease

departments reached 201/253 (79.45%). The RNA testing rates for males and females increased to 84.47% (261/309) and 91.36% (148/162) respectively. In the first three age groups, the RNA testing rates all increased, specifically: aged 0 to 29–92.11% (35/38), aged 30 to 59–85.02% (278/327), and aged 60 to 89–91.43% (96/105). Comparing the RNA testing rates and treatment rates before and after the new pattern, there were statistical differences ($p < 0.05$). Cases aged 90 and above had the RNA testing rate of 0. After the new pattern, the lost-to-follow-up cases still accounted for 18.67%, which may be one of the reasons affecting the treatment rate. After being followed up, a total of 302 HCV antibody positive cases agreed to get re-examined, of which 35 cases were RNA positive and 33 received treated. After complete treatments and re-examinations, the complete virological response rate was 100%.
Conclusion: The new management pattern of hepatitis C in hospital effectively reduced the missed diagnosis of hepatitis C and increased the treatment rate, which is worth popularizing.

THU-408
The prognostic influence of toll-like receptor 4 +3725G/C gene polymorphism on biochemical profile among chronic HCV hepatitis patients
Tetiana Bevz[1], Iryna Bondaruk[1], Kiarina Myroniuk-Konstantynovych[1], Larysa Moroz[1], Galyna Martyniuk[2], Yaroslav Demchyshyn[1]. *[1]National Pirogov Memorial Medical University, Vinnytsia, Ukraine; [2]Central city hospital, Rivne, Ukraine*
Email: tasya241@gmail.com

Background and aims: The progression of chronic hepatitis C (CHC) and the development of liver fibrosis appear due to the multifaceted morphological response of the liver to hepatocyte damage. Therefore, the main task during choosing of management approaches of patients with CHC is to assess the degree of necro-inflammatory changes and the stage of liver fibrosis.
Method: We examined 131 patients with CHC (diagnosis confirmation by qualitative and quantitative HCV-RNA determination, HCV-genotyping), age 26–72 yrs (average age 43.8 ± 0.84 yrs). Among examined patients there were 59 females and 72 males.
Results: The ALT level of 116.72 ± 9.31 IU/l was determined in the carriers of the GC genotype, which was 1.79 fold higher ($p < 0.001$) than in the carriers of the GG genotype, and in monozygotic carriers of the C allele (CC-genotype) it was 2.57 fold higher ($p < 0.001$). The level of AST in serum of carriers of genotypes GC/CC was 77.09 ± 7.01 IU/l/100.46 ± 11.79 IU/l, vs. among GG genotype carriers-44.39 ± 2.49 IU/l ($p < 0.001$). LDH level was also significantly higher in patients with the C allele of the TLR4 gene ($p < 0.05$). The level of total bilirubin in carriers of the GC and CC genotypes were 1.55 and 1.68 fold higher ($p < 0.001$), accordingly, than among individuals with the GG genotype. The level of GGT in the CC genotype patients was higher ($p < 0.001$) than in individuals with the GG genotype: 155.53 ± 18.38 IU/l vs. 57.56 ± 3.67 IU/l. The presence of the C allele reliably affected the reduction of total protein and albumin levels. Cholesterol level in patients with genotypes GC and CC was higher in 1.22 fold ($p < 0.001$) than in patients with genotype GG. The assessment of the direction, strength and reliability of correlation relations between CC/GC genotypes of the TLR4 gene and indexes of the functional condition of the liver in patients with CHC had shown a direct correlation of significant strength in the presence of the C allele with the level of ALT ($r = 0.52$; $p < 0.05$) and the level of total bilirubin ($r = 0.56$; $p < 0.05$), a direct correlation of moderate strength with the level of AST ($r = 0.44$; $p < 0.05$), GGT ($r = 0.48$; $p < 0.05$) and cholesterol ($r = 0.44$; $p < 0.05$), moderate strength inverse correlation with the level of total protein ($r = –0.34$; $p < 0.05$) and albumin level ($r = –0.51$; $p < 0.05$). ALT (beta = 0.38; $p = 0.004$), albumin level (beta = –0.2; $p = 0.009$) and total bilirubin (beta = 0.32; p = 00001) as independent clinical predictors by means of multivariate analysis and a logistic regression model. The factor logistic model was reliable with the coefficient of determination of 52%.
Conclusion: Carriers with CC and GC genotypes of the TLR4 gene rs11536889 +3725G/C have a significantly more severe course of CHC than GG genotype carriers that is showed by the main cytolytic, cholestatic and hepatocellular insufficiency syndromes indexes.

THU-410
Clinical interventions and use of resources for the management of adverse effects associated with multiple drug interactions in the hepatitis C population
Juan Turnes[1], Antonio Garcia Herola[2], Ramón Morillo Verdugo[3], Marinela Mendez[4], Candido Hernández[5], Antoni Sicras Mainar[6]. *[1]Servicio de Gastroenterología y Hepatología, CHU, Pontevedra, Spain; [2]Sección de Medicina Digestiva. Hospital Marina Baixa de Villajoyosa, Alicante, Spain; [3]Farmacia Hospitalaria, Hospital de Valme, AGS Sur de Sevilla, Sevilla, Spain; [4]Medical Affairs, Gilead Sciences S.L., Madrid, Spain, Madrid, Spain; [5]Medical Affairs, Gilead Sciences S.L., Madrid, Spain; [6]Health Economics and Outcomes Research, Atrys Health, Barcelona, Spain*
Email: jturnesv@gmail.com

Background and aims: Direct-acting antivirals (DAAs) share pharmacokinetic pathways with many comedications commonly administered to patients living with chronic hepatitis C virus (HCV) infection (PLWHCV). Previous studies have analyzed prevalence of potential drug-drug interactions (DDIs) between comedication taken by PLWHC and DAAs, including single and multiple-DDIs (≥2 drug-drug interactions with DAAs) and reported adverse effects (AEs) associated to DDIs. This study aims to evaluate the clinical interventions and resources utilization to manage AEs in patients with multiple-DDIs and the medical specialties that reported AEs.
Method: retrospective observational study, obtained from the BIG-PAC database (Atrys Health), in HCV patients (2017–2020). Potential DDIs treated with DAAs (Sofosbuvir/Velpatasvir [SOF/VEL] and Glecaprevir/Pibrentasvir [GLE/PIB]) were evaluated using the University of Liverpool DDIs database. The AEs, clinical interventions, use of resources for the management of AEs and the specialty that reported AEs were analyzed.
Results: 1620 patients were included (730 treated with SOF/VEL and 890 with GLE/PIB). 27.4% (444/1620) of the total patients who received comedications showed at least ≥1 Potential DDI. About 10% (123/1256) of patients receiving ≥2 comedications had potential multiple-DDIs (52 with SOF/VEL and 71 with GLE/PIB). 18 AEs were reported, of which 16 occurred in patients with potential multiple-DDIs. Therefore, 13% (16/123) of patients with potential multiple-DDIs presented AEs. All AEs required clinical interventions or use of resources for their management. The most frequent interventions were discontinuations (of comedication or DAAs) and reduction of comedication dose, being more frequent in the group treated with GLE/PIB, since this group presented approximately three times more AEs than the group treated with SOF/VEL (18.3% GLE/PIB [13/71]) vs 5.8% SOF/VEL [3/52]; $p < 0.05$). There were three DAAs discontinuations in patients treated with GLE/PIB (two associated with atorvastatin and one with quetiapine) and one in the group treated with SOF/VEL (associated with carvedilol). All dose reductions were reported in the group treated with GLE/PIB (associated with paliperidone, enalapril and simvastatin). AEs were reported mostly by primary care physicians (62.5%).
Conclusion: There is an elevated risk of AEs in hepatitis C patients with potential multiple-DDIs treated with DAAs, particularly with cardiovascular and nervous system comedication, especially with DAAs containing protease inhibitor. These AEs may require clinical interventions and the use of resources for their clinical management. This circumstance is especially relevant in the context of treatment simplification, where HCV specialists usually see the patients only at treatment initiation.

Long term liver-related events in patients with HCV-related liver disease and advanced fibrosis after sustained virological response with direct-acting antivirals

Jorge Barajas[1], Tomás Artaza[1], JuanJosé Sánchez-Ruano[1], Marta Romero-Gutiérrez[1], Carolina Delgado[1], Gema De la Cruz[1], Concepción Gonzalez[1], Raquel Lomas[1], Rafael Gómez Rodríguez[1].
[1]*Complejo Hospitalario Universitario de Toledo, Toledo, Spain*
Email: jorgebarper@gmail.com

Background and aims: Direct-acting antivirals (DAAs) achieve a high rate of sustained virological response (SVR) in patients with hepatitis C virus (HCV) infection. It is not clearly defined whether this SVR is associated with a reduction in liver-related events. We aim to analyze the development of complications related to portal hypertension (PH) as well as de novo hepatocellular carcinoma (HCC) in patients with SVR after DAAs treatment.
Method: An ambispective single-center study included 295 patients with SVR. Patients with HCV-related liver disease and advanced fibrosis treated with DAAs were included. Patients with transient elastography (TE) between 9.5 and 12.5 kPa were classified as F3, while those with TE >12.5 kPa or clinical, analytical, and ultrasound data compatible with cirrhosis were classified as F4. All patients achieved SVR, and consecutive sampling was performed from July 2014 to March 2022. Follow-up was censored at 5 years.
Results: The median age was 60 years and 185 (62.71%) were male. Two hundred thirty-two (78.64%) had cirrhosis. The mean follow-up was 47 months. Thirty-six (12, 2%) had a liver-related event. Complications related to PH were experienced by 20 (6.78%) patients during the first 5 years, all of them F4. Of the 20 patients with PH related complications, 17 (85%) had ascitic decompensation, 4 (20%) had gastrointestinal bleeding and 11 (55%) had hepatic encephalopathy. In our series, de novo HCC was developed by 22 (7.46%) patients. In 21 cases, HCC occurred in patients with F4. The median time to HCC diagnosis was 18 months (95% CI, 0.76–35.23). One patient treated with DAAs had a previous history of HCC and it did not recur. Thirty-four (11.52%) patients died at 5-years, with 12 (35.29%) dying from liver-related events. Among those deceased from liver-related events, 6 died from PH complications, 5 from HCC, and 1 patient died from cholangiocarcinoma. Four (1.36%) patients underwent liver transplantation, 2 for HCC and 2 for decompensated cirrhosis.
Conclusion: The risk of developing liver-related events in patients with advanced fibrosis due to HCV after SVR after DAAs treatment for the first 5 years was significant. In our series, 12.2% had a liver-related event. The most frequent events were the development of HCC (7.46%) and decompensation of liver disease (6.78%). Adequate follow-up in these patients appears crucial to achieve early management of these complications.

THU-412

Hepatitis C lost to follow-up rates in primary care practices in Belgium

Marie Coessens[1,2], Jeoffrey Schouten[1], Wim Verlinden[1,2]. [1]*Department of gastroenterology and hepatology, Vitaz, Sint-Niklaas, Belgium;* [2]*Laboratory of Experimental Medicine and Pediatrics (LEMP), University of Antwerp, Wilrijk, Belgium*
Email: wim.verlinden@vitaz.be

Background and aims: If we aim to eliminate hepatitis C (HCV) by 2030, resources need to be allocated efficiently. Belgian hospital-based lost to follow-up (LTFU) projects have shown that up to 19% of patients drop out of HCV care, with up to half of them being successfully re-admitted. This is the first project to assess LTFU rates in primary care, while promoting patient re-engagement in HCV care and the prevention of LTFU.
Method: A list was compiled by a non-hospital-based clinical laboratory, containing all positive HCV serology results requested between 2010 and 2023 by a general practitioner (GP) based in Antwerp. A member of the study team went through the patient list together with the participating GPs, assessing patient status in the HCV care continuum [(a) negative HCV antibody confirmation test, (b) negative HCV antibody confirmation test and HCV RNA negative, (c) positive HCV serology and HCV RNA negative, (d) positive HCV serology without HCV RNA result available, (e) last available HCV RNA positive, (f) negative HCV RNA <12 weeks after end of treatment (EOT), (g) negative HCV RNA ≥ 12 weeks after end of treatment or sustained virological response (SVR), (h) deceased]. The patient was considered LTFU if no action was taken in case of status d, e, or f. GPs were encouraged to re-engage these patients in HCV care and LTFU rates were re-assessed after one year. A risk profile (age, gender, HCV genotype, presence of cirrhosis, HIV status, lifetime drug use, being born abroad) of patients with status e, f or g was developed to identify patients at risk of LTFU who need additional GP counselling for their referral to the hepatologist.
Results: In total, 167 out of 275 (60, 73%) GPs agreed to participate and 363 primary care patients were analysed for their status in the HCV care continuum [(a) 30/363 (8.26%); (b) 63/363 (17.36%); (c) 82/363 (22.59%); (d) 18/363 (4.96%); (e) 32/363 (8.82%); (f) 5/363 (1.38%); (g) 117/366 (32.23%); (h) 16/363 (4.41%)]. The rate of LTFU was 15.51% (55 out of 363). In addition, a liver-related cause of death was documented in 25% of deceased patients. For 9 patients that were initially considered LTFU [(d) 1/9; (e) 5/9; (f) 3/9], status in the HCV care continuum was already re-assessed one year after the project was launched [(e) 3/9; (f) 4/9; (g) 2/9]. Thanks to our intervention, DAA therapy was initiated in 3 out of 5 patients with an untreated chronic HCV infection and an SVR12 was already documented in 2 out of 9 patients. None of the risk factors for LTFU could be retained.
Conclusion: Hepatitis C LTFU rates in primary care are significant and up to half of patients can be successfully re-admitted to care. Given that the LTFU strategy comes without screening costs, this is a feasible and highly cost-effective strategy on the road towards HCV elimination.

THU-413

Baseline gamma-glutamyl transpeptidase levels are associated with aggravation of esophagogastric varix after direct-acting antiviral therapy in cirrhotic patients with hepatitis C virus

Background and aims: Direct-acting antiviral (DAA) therapy has enabled viral elimination in almost all cirrhotic patients with hepatitis C virus (HCV). Although some cirrhotic patients undergo aggravation of esophagogastric varix after DAA therapy, the factors associated with aggravation of esophagogastric varix in cirrhotic patients, including decompensated cirrhosis, are unclear.
Method: A total of 478 patients with HCV-related compensated or decompensated cirrhosis were treated with DAA between February 2019 and December 2021 at 31 Japanese hospitals. Among them, 207 patients who could evaluate esophagogastric varix before and after DAA therapy were enrolled in this study. Decompensated cirrhosis was defined as baseline Child-Pugh class B (CP-B) or C, or CP-A with decompensating events before DAA therapy. Sustained virologic response (SVR) was defined as serum HCV-RNA undetectable at 12 or 24 weeks after the end of treatment. The form of esophagogastric varix was evaluated according to Japanese general rules: F1 was straight, small-caliber one; F2 was moderately enlarged, beady one; and F3 was markedly enlarged, nodular or tumor-shaped one (Dig Endosc 2010;22:1–9). Patients without esophagogastric varix or those with F1 were defined as low-risk varix, and patients with F2 or more or with a history of varix rupture were defined as high-risk varix. Aggravation of esophagogastric varix was defined as varix rupture or treatment for varix. We examined the cumulative incidence rate and the factors associated with aggravation of esophagogastric varix after DAA therapy.
Results: The median age was 69 years old, 55% of patients were male, 60% were decompensated cirrhosis, and 28% had high-risk varix at baseline. SVR rates of patients with compensated and decompensated cirrhosis were 98.8% and 96.0%, respectively ($p = 0.228$). During the median observation period of 39.2 months from starting DAA therapy, 22 patients underwent treatment for varix, and three experienced varix rupture. The 3-year rate of aggravation of esophagogastric varix was 11.5%. In multivariate Cox proportional hazard analyses, high-risk varix at baseline ($p < 0.001$), baseline higher gamma-glutamyl transpeptidase (GGT) levels ($p = 0.003$), and virologic response ($p = 0.045$) were significantly associated with aggravation of esophagogastric varix, while alcohol consumption was not. The 3-year rates of aggravation of esophagogastric varix were 27.5% in patients with high-risk varix, 5.9% in those with low-risk varix, and 23.8% in patients with GGT of 75U/l or more and 8.2% in those with GGT less than 75U/l, respectively.
Conclusion: In cirrhotic patients with HCV treated with DAA, baseline status of esophagogastric varix, baseline GGT levels, and virologic response to DAA were significantly associated with the aggravation of esophagogastric varix.

Incidence of hepatocellular carcinoma in patients with hepatitis C treated with direct-acting antivirals agents: results of a long-term prospective study period

Emanuela De Santis[1], Alessandro Caioli[1], Fernando De Angelis[1], Adriano De Santis[1]. [1]*Sapienza, University of Rome, Rome, Italy*
Email: emanuela.desantis@uniroma1.it

Background and aims: Hepatocellular carcinoma (HCC) is the most common primary liver tumor. Liver cirrhosis, whose one of the main etiological agents is hepatitis C virus (HCV) infection, represents the most frequent risk factor. Direct-acting antivirals (DAAs) are associated with a sustained virological response (SVR) rate of more than 95%. Despite viral eradication, however, a residual risk of HCC persists in patients with significant fibrosis, especially in cases with concomitant liver-related comorbidities. Several works in the literature have investigated the incidence of HCC after SVR from DAAs. However, in published cases the follow-up is limited to 3 years. This work aims to evaluate the incidence of HCC in patients with hepatitis C who have achieved SVR after being treated with DAAs considering a follow-up time beyond the three years considered in the literature, and to identify predictive factors for development of hepatocellular carcinoma.
Method: We have examined 452 patients suffering from HCV-related chronic hepatitis and undergoing treatment with DAAs. Anthropometric, anamnestic, laboratory, ultrasound and elastography data have been collected for each patient at three times:. T0 (before starting antiviral therapy), T1 (6 months after the end of treatment), T2 (last clinical data relating to the last follow-up visit/date of HCC diagnosis). The total duration of the follow-up has been calculated in all patients.
Results: In our sample, 18 patients (4%) developed hepatocellular carcinoma: 11 (61.1%) had a diagnosis of liver cirrhosis confirmed using elastography and biochemical data, while for the remaining 7 (38.9%), the fibrosis was classified as absent or minimal. A Cox regression model was used to identify predictive factors for the onset of HCC. Variables that were found to be significantly positively associated with the onset of HCC in simple and multiple regression were: AFP levels at T0, APRI levels at T0 and male sex. For the 7 patients in which significant fibrosis had been excluded, histological examination of liver tissue resulted in a diagnosis of liver cirrhosis. In 4 of these individuals, the identification of hepatocarcinoma occurred 5 years after the start of antiviral therapy and in 1 subject more than 7 years later.
Conclusion: In conclusion, in our sample, for 38.8% of the HCC cases the fibrosis stage was underestimated, resulting in the exclusion of these patients from follow-up. Our study demonstrates that AFP and APRI levels at baseline could be useful for selecting patients for whom it is appropriate to continue follow-up despite the absence of significant fibrosis.

THU-418

Screening for chronic hepatitis C in pre-surgical patients

Background and aims: Since the introduction of direct-acting antivirals for the treatment of chronic hepatitis C, the majority of patients have been treated and cured of the infection. However, the remain undetected patients are crucial to be promptly treated to achieve virtual elimination of the virus by 2030. In Spain, screening is not universal and depends on clinical suspicion based on clinical history. Recent published results on emergency screening near our area reflected bimodal distribution of RNA-VHC in our population: men between 50–60 years old and women under 90. We performed automated screening for hepatitis C antibodies (HCV-Ab) in patients over 50 who were undergoing preoperative analysis for elective surgery, both outpatient and inpatient.
Method: All patients over fifty years' old who underwent preoperative analysis were studied with a HCV-Ab detection in the same blood sample as required by the anaesthetists before surgery. Those who were positive, HCV-RNA was determined with the same sample. If a positive value was confirmed, they were referred to the Hepatology Unit for evaluation and treatment through an alert issued from the laboratory directly to the Unit.
Results: Preliminary results obtained from September 1 to December 31, 2023, a total of 2, 121 patients were evaluated. Forty-five (2.1%) were positive for HCV-Ab, of which 4 (0.18%) were positive for HCV-RNA. Two of them were men aged 54 and 55, one of them with cirrhosis criteria by transitional elastography (17.4 Kpa (IQR med 8%). The patients were not previous aware of de HCV infection. Both patients were treated with direct antiviral agents achieving a sustained virological response without any side effects. The other two were 83 and 89 old women respectively without any signs of significant fibrosis neither analytical, echography or elastography criteria (6, 6 and 7.1 KPa respectively), that denied treatment.
Conclusion: Automated preoperative screening in patients over 50 years old makes it possible to detect patients with HCV-RNA not aware of the infection helping to eradicate the virus. Cost effectiveness study of this strategy is pending but the low cost of VHC-Ab and the QALY gained make its effectiveness highly probable.

THU-419

Regression of hepatic fibrosis in patients with chronic hepatitis C treated with direct-acting antivirals (DAAs). A long-term, prospective, observational study

Evdoxia Avramopoulou[1], Efthymios Tsounis[1], Stavros Kanaloupitis[1], Konstanitnos Zisimopoulos[1], Maria Kalafateli[2,3], Ioanna Aggeletopoulou[1], Christos Sotiropoulos[4], Theodora Kafentzi[4], Georgios Geramoutsos[1], Odysseas Ampazis[1], Georgia Diamantopoulou[1], Angeliki Tsintoni[5], Konstantinos Thomopoulos[1], Christos Triantos[1]. *[1]Division of Gastroenterology, Department of Internal Medicine, University Hospital of Patras, Patras, Greece; [2]Department of Gastroenterology, General Hospital of Patras, Patras, Greece; [3]Patras General Hospital "Agios Andreas", Gastroenterology, Patra, Greece; [4]Division of Gastroenterology, Department of Internal Medicine, University Hospital of Patras, Patras, Greece; [5]Department of Internal Medicine, University Hospital of Patras, Patras, Greece*
Email: chtriantos@hotmail.com

Background and aims: Successful hepatitis C virus (HCV) treatment with direct-acting antivirals (DAAs) is associated with an improvement in liver fibrosis post-treatment. This study aims to assess the long-term impact of DAA-based therapy on hepatic fibrosis through extended follow-up (FUP).
Method: Successful HCV treatment with DAAs is associated with an improvement in liver fibrosis post-treatment. This study aims to assess the long-term impact of DAA-based therapy on hepatic fibrosis through extended FUP.
Results: The overall sustained virologic response rate for this cohort was 98.8% (166/168). The median liver stiffness before treatment was 9.9 kPa (IQR: 7.5–18.8) compared to 7.2 kPa (IQR: 5.1–11.6) following DAA-based therapy ($p < 0.001$). In non-cirrhotic patients, the median transient elastography measurements were significantly reduced ($p < 0.001$) from 7.6 kPa (IQR: 6.5–9.2) to 5.8 kPa (IQR: 4.5–7.3). In patients with cirrhosis, the median liver stiffness plummeted from 18.6 kPa (IQR: 12.4–23.7) to 11.6 kPa (IQR: 7.3–17.2) after a FUP period of 31 months (IQR: 12–63.5) ($p < 0.001$). Regression of significant fibrosis (F4 stage) was observed in 18/36 patients (50%) using a cut-off value of 12 kPa. Moreover, the median Child-Pugh (CP) score was decreased from 7 (IQR: 5–7) to 5 (IQR: 5–7) post-treatment ($p = 0.002$). Nine out of 21 (42.9%) patients with baseline Child Pugh (CP) stage B regressed to CP stage A. Regression of liver fibrosis was also evident in various sub-group analyses, including patients with diabetes mellitus [baseline 15.5 kPa (IQR: 10.3–19.1) vs FUP 8.1 kPa (IQR: 5.7–9.9); $p = 0.12$], current intravenous drug user (baseline 9.7 kPa (IQR: 6.2–13.2) vs FUP 6.7 kPa (IQR: 5.2–9.2); $p = 0.049$], and alcohol-abuse [baseline 12 kPa (IQR: 7.7–20.4) vs FUP 7.7 kPa (IQR: 5.4–12); $p < 0.001$].
Conclusion: The current analysis supports a substantial improvement in hepatic fibrosis in HCV across diverse subgroups of HCV patients who received DAA-based treatment during long-term FUP. In cirrhotic patients, treatment with DAAs could lead to cirrhosis regression.

THU-420

Evaluation of LiverRisk score as predictor of liver fibrosis and mortality in patients with HCV-related hepatitis treated with direct acting antivirals

Antonietta Romano[1], Amalia Rita Caspanello[1,2], Salvatore Piano[1], Marta Tonon[1], Carmine Gambino[1], Valeria Calvino[1], Anna Barone[1], Nicola Zeni[1], Simone Incicco[3], Roberta Gagliardi[1], Paolo Angeli[1]. *[1]Unit of Internal Medicine and Hepatology, Department of Medicine, University of Padova, Italy, Padova, Italy; [2]Department of Clinical and Experimental Medicine, Unit of Medicine and Hepatology, University of Messina., Messina, Italy; [3]Unit of Internal Medicine and Hepatology, Department of Medicine, University of Padova, Italy, Padova*
Email: antonietta.romano@aopd.veneto.it

Background and aims: The LiverRisk score has been recently developed and validated as a predictor of liver fibrosis and liver-related outcomes in the general population. This score has never been evaluated as predictor of liver fibrosis and outcomes in secondary care, such as in patients with chronic liver diseases. The aim of this study was to evaluate the role of the LiverRisk score as a predictor of liver fibrosis and mortality in patients with HCV-related hepatitis treated with direct acting antivirals (DAA).
Method: patients were enrolled retrospectively, outpatients with chronic hepatitis C treated with DAA between 2015 and 2017 were included consecutively. Patients were followed-up until September 2023. The exclusion criteria were: liver transplantation before DAAs and presence of HCC. Patient characteristics and LiverRisk score were collected before starting the DAA. The data for the calculation of LiverRisk score were collected the same day the fibroscan was performed. The primary end point was a liver stiffness ≥10 kPa. Area under the receiver operating characteristic (AUROC) curve was evaluated for assessing the discrimination ability of Liver Risk score. Overall mortality was assessed at the end of follow-up.
Results: in this ongoing study, 136 patients of our center with chronic hepatitis C treated with DAA were enrolled. In this population, 51% were men, the mean age was 65.3 ± 12.2 years, 65.4% were genotype

1, 59.6% had liver cirrhosis, the mean liver stiffness measurement was 15.9 KPa (3.5–48.8), sustained virological response (SVR) was 95.5% and the mean follow-up was of 59 months. Coinfection with hepatitis B virus (HBV) was present in 8.8%. Discrimination ability of the LiverRisk score in the prediction of liver stiffness ≥10 KPa was very good as shown by an AUROC of 0.848 (95% confidence interval [CI] = 0.767–0.930; p = 0.000). During follow-up 21 patients (15.4%) died. LiverRisk score was associated with the risk of all cause of mortality (Hazard Ratio = 1.154; 95% CI = 1.01–1.318; p = 0.035).
Conclusion: the liver risk score is a good predictor of fibrosis and mortality in HCV patients treated with DAA.

Viral hepatitis C – Therapy and resistance

THU-362
Ravidasvir in combination with sofosbuvir for 12 or 24 weeks achieved high sustained virological response rates in genotype 3 chronic hepatitis C without or with compensated liver cirrhosis

Soek Siam Tan[1], Caroline Menétrey[2], Isabela Ribeiro[2], Nicolas Salvadori[3], Sabine Yerly[4], Nicole Ngo-Giang-Huong[5], Graciela Diap[2]. *[1]Hospital Selayang, Dept of Hepatology, Batu Caves, Malaysia; [2]DNDi, Geneva, Switzerland; [3]AMS-PHPT Research Platform, Muang, Chiang Mai, Thailand; [4]Hopitaux Universitaires de Genève, Genève, Switzerland; [5]AMS-BAT Laboratory, Muang, Chiang Mai, Thailand*
Email: tanss@selayanghospital.gov.my

Background and aims: Hepatitis C virus (HCV) genotype (GT) 3 is the second most common GT and accounts for approximately 14–17 million of the estimated 58 million HCV cases globally. GT3 is associated with injecting drug use (IDU), the primary mode of HCV transmission, with more severe liver disease and a lower sustained virological response (SVR), especially in patients with cirrhosis, even in the era of direct-acting antiviral therapies. Ravidasvir, a potent NS5A inhibitor with no clinically significant interaction with cytochrome P450 enzymes, was recently added to the WHO Model Lists of Essential Medicines for the treatment of HCV in combination with sofosbuvir, based on the results of the phase 2/3 STORM-C-1 trial. We analysed the GT3 cohort of this trial to report on efficacy in this subpopulation.
Method: An open-label, single-arm phase 2/3 study in people with chronic HCV ± HIV infections of all GT was conducted in Malaysia and Thailand. Ravidasvir (200 mg) and sofosbuvir (400 mg) were administered once-daily for 12 weeks to patients without cirrhosis and for 24 weeks to those with compensated cirrhosis (CC). The primary efficacy end point was SVR at 12 weeks post-treatment. Patients underwent clinical and laboratory assessments at weeks 1 and 4 and then every 4 weeks during treatment and at 4, 12 and 24 weeks post-treatment.
Results: Of the 603 patients enrolled, 296 (49%) had HCV GT3; of these, 258 (87%) had subtype 3a, 34 (11%) had subtype 3b, and 4 (1%) could not be subtyped. The median age was 48 years (IQR 41–56), 77% were male, 53% had cirrhosis, 23% were interferon ± ribavirin treatment-experienced, and 49% reported a history of IDU. SVR at 12 and 24 weeks post-treatment (SVR12/24) was 97.6% (289/296), with similar rates between those without cirrhosis, 97.8% (136/139) and those with CC, 97.5% (153/157). The SVR 12/24 for GT3a was 98.1% (253/258) and for GT3b was 97.1% (33/34). In patients with any baseline resistance-associated substitution (RAS), the SVR12/24 was 96.7% (59/61) in GT3a and 97.1% (33/34) in GT3b. Of the 41 patients with GT3a and baseline Y93H RAS, 39 (95.1%) achieved SVR12/24, including all 9 patients with both S62L and Y93H RAS. Three patients who did not achieve SVR12/SVR24 discontinued treatment early after 2, 3 and 9 doses of study drugs. Virological failure was observed in four of 296 (1.4%) patients. Three had baseline RAS, 93H (n = 2) and 30 K + 31 M (n = 1), but none had treatment-emergent RAS in NS5A or NS5B. One patient had no baseline RAS results as amplification was not possible.
Conclusion: In chronic GT3 hepatitis C, the combination of ravidasvir and sofosbuvir for 12 weeks in patients without cirrhosis and 24 weeks in patients with CC achieved high SVR12/24 of 97.8% and 97.5%, respectively. There was a minimal impact of the presence of Y93H RAS at baseline on response rates and no evidence of treatment-emergent virologic resistance.

THU-363
Validation of a modified pediatric formulation of Sofosbuvir and Daclatasvir in genotype-4 HCV-infected children weighing 17–35 Kg

Ahmed Farrag[1], Maggie Abbassi[1], Fatma Ebeid[2], Tim Cressey[3], Philippa Easterbrook[4], Nirmeen Sabry[5], Manal El-Sayed[6]. *[1]Clinical Pharmacy Department, Faculty of Pharmacy, Cairo University, Cairo, Egypt; [2]Pediatric Department, Faculty of Medicine, Ain Shams University, Clinical Research Center, Faculty of Medicine Ain Shams University Reserach Institute (MASRI-CRC), Cairo, Egypt; [3]AMS-PHPT Research Collaboration, Faculty of Associated Medical Sciences, Chiang Mai University, Chiang Mai, Thailand; [4]World Health Organisation HQ, Geneva, Switzerland; [5]Clinical Pharmacy Department, Faculty of Pharmacy, Cairo University, Cairo, Egypt; [6]Pediatric Department, Faculty of Medicine, Ain-Shams University, Clinical Research Center, Faculty of Medicine Ain Shams University Reserach Institute (MASRI-CRC), Cairo, Egypt*
Email: manalhelsayed@yahoo.co.uk

Background and aims: Sofosbuvir (SOF) plus Daclatasvir (DCV) is the regimen of choice in low and middle-income countries (LMICs) for treatment of chronic hepatitis C virus (HCV) infection in adults and adolescents. Based on extrapolation of efficacy, safety and PK data from studies in adults, adolescents or older children and PK simulation studies, in 2022 the World Health Organization (WHO) recommended this regimen to older children (6–11 years and weighing >26 kg) at adult dose (400/60 mg) and in younger children 3–5 years or weighing 14–25 kg at half the adult dose (ie 200/30 mg). However, clinical data on this dose in younger children is still lacking. We conducted a clinical pharmacokinetic study to assess the pharmacokinetics, safety, efficacy, and acceptability of once daily 30 mg DCV plus 200 mg SOF for 12 weeks in treatment-naïve children weighing 17 to ≤35 kg with chronic HCV infection.
Method: This study is an interventional, single centre, single arm, open label clinical trial that included treatment-naïve children with chronic HCV infection of median age 7 years (range 5–13 years) and weight 17 to ≤35 kg. Children who weighed 17 to ≤35 kg received once daily oral DCV 30 mg in combination with 200 mg SOF (two small 100 mg tablets new formulation) for 12 weeks. A swallowability test was performed before inclusion in the trial. Steady state plasma concentrations were determined. Non-compartmental PK analysis was performed using Pkanalix 2023. Efficacy was assessed using quantitative HCV-PCR at the end of treatment (EOT) and 12 weeks after finishing treatment (SVR12). Patients were followed up for any adverse events. Palatability of the tablets was recorded at each study visit. The study is registered at ClinicalTrials.gov under NCT05854511.
Results: Twelve patients weighing 17 ≤35 kg were included. All patients (12/12) completed the 12 weeks course of SOF + DCV. Mean ± standard deviation for the area under the curve $(AUC)_{24}$, maximum plasma concentration at steady-state (C_{ssmax}), and minimum plasma concentration at steady-state (Cssmin) were: 11, 082 ± 5, 168 h·ng·ml^{-1}, 1, 062 ± 342 ng·ml^{-1} and 198 ± 156 ng·ml^{-1}, respectively for DCV; 2, 127 ± 1, 866 h·ng·ml^{-1}, 952 ± 579 ng·ml^{-1} and 18 ± 21 ng·ml^{-1}, respectively for SOF; 15, 256 ± 4, 113 h·ng·ml^{-1}, 1605 ±

743 ng·ml^{-1} and 312 ± 112 ng·ml^{-1}, respectively for its major metabolite GS331007. Results for DCV values are comparable to those achieved by adults. All patients (12/12) achieved SVR12. No serious adverse events were reported. All patients (12/12) could swallow the medication with no difficulty.
Conclusion: A combination of half of the available adult SOF/DAC dose, 30 mg DCV and 200 mg SOF, provides safe and effective drug exposure, and is well-tolerated orally in children weighing 17–35 Kg. This preparation can provide an affordable formulation for treatment of chronic hepatitis C infection in young children to scale up elimination in this special population.

THU-364

Modeling suggests that undetectable HCV at week 2 of DAA therapy could identify patients for shorter treatment duration

Ashish Goyal[1], Ohad Etzion[2], Kimberly Page[3], Tatyana Kushner[4], Yedidya Saiman[5], Scott Cotler[1], Harel Dahari[1]. *[1]Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, IL, United States; [2]Soroka University Medical Center, Beersheva, Israel; [3]Division of Epidemiology, Biostatistics and Preventive Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States; [4]Division of Liver Diseases, Icahn School of Medicine at Mount Sinai, New York, NY, United States; [5]Department of Medicine, Section of Hepatology, Lewis Katz School of Medicine at Temple University, Temple University Hospital, Philadelphia, PA, United States*
Email: harel.dahari@gmail.com

Background and aims: The World Health Organization (WHO) calls for identifying predictors of successful treatment with reduced duration of DAA therapy. This objective is particularly important in people who inject drugs (PWID), in whom shorter treatment could improve adherence, decrease loss to follow-up, and reduce cost. In addition, there is a need to minimize DAA duration to reduce DAA exposure and increase acceptance in pregnant women. Here we investigate the feasibility of response-guided therapy (RGT) to reduce length of treatment using a computational modeling approach.
Method: Previous modeling efforts based on ~300 patients receiving DAA (such as sofosbuvir + velpatasvir, elbasvir + grazoprevir, sofosbuvir + ledipasvir, or pibrentasvir + glecaprevir) allowed us to characterize viral-host parameters, DAA efficacy in blocking HCV production, and treatment outcomes [Math Biosci. 2022 Jan:343:108756]. Based on this real-life patient data, parameter distributions were identified and then 20, 000 parameter combinations of viral-host and treatment parameters were generated, each representing an in silico patient. Next, viral kinetic profile under DAA treatment for each patient was simulated using a multiscale model [Proc Natl Acad Sci U S A. 2013 Mar 5;110 (10):3991–6]. The time to cure (TTC) for each in silico patient, defined as the time to reach less than one HCV viral copy in the 15L of extracellular body fluid, i.e. V = 7×10^{-5} IU/ml [Sci Rep. 2020 Oct 20;10 (1):17820], was then estimated using mathematical modeling simulations.
Results: Out of 20, 000 *in silico* patients, about 10, 000 (~50%) achieved undetectable HCV (<1 IU/ml) by day 14 after initiation of treatment. Modeling suggests that if HCV is undetectable on or before day 14 of DAA therapy, 90% and 98% of HCV-infected individuals can be cured within 4 and 5 weeks of DAA treatment, respectively. The median predicted TTC was ~22 days with ~0.6% reaching TTC as early as 2 weeks. Approximately 8% of these cases also had undetectable viral load at day 7, predicting that 90% and 98% cure rates could be achieved with 3 and 4 weeks of DAA treatment, respectively.
Conclusion: Mathematical modeling of *in silico* patients that reach undetectable HCV by day 14 predicted that >90% cure rates could be achieved with 4–5 weeks of DAA therapy. This RGT could improve treatment access, facilitate HCV elimination, and reduce cost, particularly in patient groups most affected by HCV such as PWID.

THU-365

Real-world effectiveness and safety of 8-week glecaprevir/pibrentasvir for treatment-naïve patients from Taiwan nationwide HCV registry

Email: fish6069@gmail.com

Background and aims: The once-daily, oral, fixed-dose, direct-acting antiviral combination of glecaprevir/pibrentasvir (G/P) is indicated for chronic hepatitis C (CHC) infection with HCV genotypes 1–6 in patients with or without compensated cirrhosis (CC). Treatment duration of 8 weeks is recommended in all treatment-naïve (TN) patients. As Taiwan government is committed to eliminating HCV by 2025, this study aimed to measure the real-world evidence for TN patients using 8-week G/P in Taiwan HCV Registry (TACR).
Method: The TACR is an ongoing nationwide registry program organized and supervised by Taiwan Association for the Study of the Liver (TASL), which aims to setup a database and biobank of patients with CHC in Taiwan. Data was analyzed as of 31 May 2023 for CHC patients treated with G/P. Effectiveness reported as sustained virologic response at post-treatment week 12 (SVR12) was assessed by modified intent-to-treat (mITT) populations that excluded patients who lost to follow-up or without SVR12 data. Safety profile was assessed in the ITT population.
Results: Of 8, 041 TN patients treated with G/P, 7, 246 patients received 8-week regimen (ITT) and 7, 204 of which had SVR12 data available (mITT). The overall SVR12 rate was 98.9% (7, 122/7, 204) in the mITT population. For selected subgroups including patients with compensated cirrhosis, GT3, diabetes, chronic kidney disease, person who inject drugs, and HIV, the SVR12 rate was 98.3% (342/348), 95.1% (272/286), 98.9% (1, 084/1, 096), 99.0% (1, 171/1, 183), 97.4% (566/581), and 96.1% (248/258), respectively. Overall, 14.1% (1, 021/7, 246) of the patients experienced adverse events (AEs) in the ITT population. Twenty-two patients (0.3%) experienced serious adverse events and fifteen (0.2%) resulted in permanent drug discontinuation. None of them were considered as treatment drug related. The most frequent AEs (>5%) were fatigue (5.6%) and pruritus (5.4%). Laboratory abnormalities of Grade 3 and 4 for bilirubin, AST, and ALT were all 0.2%, respectively.
Conclusion: In this real-world Taiwanese cohort, 8-week G/P therapy was effective and well-tolerated in all TN patients, including general and special populations.

THU-366

Use of proton pump inhibitors among German Hepatitis C patients treated with sofosbuvir/velpatasvir: Data from the German Hepatitis C-Registry (2016–2022)

Markus Cornberg[1], Gerlinde Teuber[2], Ralf Link[3], Uwe Naumann[4], Hartwig Klinker[5], Christine John[6], Candido Hernández[7,8], Marianna Schwenken[9], Christoph Sarrazin[10]. *[1]Hannover Medical School, Hannover, Germany; [2]Private Practice, Frankfurt/Main, Frankfurt am Main, Germany; [3]MVZ-Offenburg GmbH, Offenburg, Germany; [4]UBN/Praxis, Berlin, Germany; [5]University of Würzburg Medical Center, Würzburg, Germany; [6]Private Practice of Internal Medicine, Center of Gastroenterology, Berlin, Germany; [7]Gilead Sciences Europe Ltd, Uxbridge, United Kingdom; [8]Gilead Sciences, S.L, Madrid, Spain; [9]Gilead Sciences GmbH, Munich, Germany; [10]Department of Internal Medicine and Liver Center, Wiesbaden, Germany*
Email: cornberg.markus@mh-hannover.de

Background and aims: Literature and product labels suggest velpatasvir bioavailability may be reduced when administered concomitantly with a proton pump inhibitor (PPI), based on pharmacokinetic studies. We aimed to determine the clinical relationship between PPI use and sustained virologic response rates (SVR) in patients treated with sofosbuvir/velpatasvir (SOF/VEL) ± ribavirin (RBV) in a real-world, ongoing, noninterventional, multicenter, prospective, observational German Hepatitis C-Registry (DHC-R). The DHC-R is a national multicenter real-world registry including about 18, 900 patients.
Method: The present analysis is based on 1, 154 patients enrolled between 2016 and 2022 in the DHC-R, as treated with SOF/VEL, split between those receiving and not receiving PPI drugs as comedication. Baseline characteristics (demographics, viral infection, liver status, number and type of PPI drugs) and SVR (patients with SVR available: based on modified intention to treat (mITT), including patients with ITT SVR and ITT relapses) were analyzed. Also, co-use of metamizole was collected, as this comedication shows the same drug-drug interaction (DDI) profile as PPIs (risk of direct acting antiviral (DAA) exposure), thus checking a multi-drug-drug interaction (DDI) scenario.
Results: Patients receiving PPI represented 8.5% (98/1, 154) of the total SOF/VEL cohort. Pantoprazole was the most common PPI co-used (78/98 patients; dose per day: 20 mg: 28/78, 40 mg: 29/78, 80 mg: 2/78, unspecified: 19/78 patients), followed by omeprazole (19/98 patients; dose per day: 20 mg: 14/19, 40 mg: 2/19, unspecified: 3/19 patients) and esomeprazole (1/98 patients; dose per day: 80 mg: 1/1), with 9.2% of the SOF/VEL+ PPI group also receiving metamizole. Those patients receiving PPI vs. non-PPI seemed older (≥50 years old (yo): 59% and 37%, respectively), with more females (38% and 27%), less genotype 3 (GT3) (47% and 62%), but with a higher proportion of cirrhosis (compensated cirrhosis (CC): 50% and 32%; decompensated cirrhosis (DC): 17% and 4%). In terms of effectiveness, SVR was similar in both groups, also in cirrhosis (≈98%) for all genotypes, and even in the presence of GT3 + CC (both ≥96%). Co-use of metamizole had no impact on SVR (=100%). Besides, no negative PPI dose-dependent SVR trend was noticed with the PPI dose given (20 mg: = 96–100%, 40 mg: = 91–100%, 80 mg: = 100%, unspecified dose: = 100%).
Conclusion: PPI co-use in patients under SOF/VEL therapy included in DHC-R did not impact the SVR. Those results were also not impacted by the cirrhotic status, PPI dose or the presence of a multi-DDI scenario.

THU-367-YI

Effectiveness and safety of direct-acting antivirals in the treatment of elderly people infected with HCV

Email: michal.brzdek@gmail.com

Background and aims: In the interferon (IFN) era, therapeutic options and their efficacy in treating chronic hepatitis C virus (HCV) infection in elderly patients were severely limited. The introduction of direct-acting antivirals (DAAs) with their effectiveness and safety has revolutionized the approach to treating this population. Nevertheless, elderly patients have often been excluded from participation in clinical trials of DAA drugs, so the results of real-world studies are particularly important in the context of the geriatric population. The current study was conducted among patients over the age of 65, with notable inclusion of those over the age of 85. The study aims to analyze the effectiveness and safety of antiviral DAA treatment in an elderly HCV-infected population.
Method: All consecutive patients aged 65 and above selected from 16, 828 individuals with chronic HCV infection from the EpiTer-2 multicenter database were included in the study. The analyzed patients were divided by age into three groups: Group A (65–74 years), Group B (75–84 years) and Group C (85 years or older). Patients started IFN- free therapy at 22 Polish hepatology centers between July 2015 and December 2022. Treatment effectiveness was assessed by sustained virologic response (SVR). Safety data were collected during therapy and at 12-week follow-up.
Results: A total of 3, 505 elderly patients were included in the analysis, and they were divided into three groups: 2, 501 patients in Group A, 893 in Group B, and 111 in Group C. The studied population, regardless of age group, was predominantly female. Patients had a high prevalence of comorbidities (84.9%, 92.2%, and 93.7%, respectively) as well as a high rate of using concomitant medications. In the per-protocol (PP) analysis, both Groups A and B achieved a similarly high SVR rate of up to 97.9%, and in all patients aged 85 and older SVR was documented. Similarly, high SVR rates exceeding 94% were documented in subgroups based on gender, fibrosis severity, HCV genotype, and prior treatment history.
Conclusion: IFN-free therapies are highly effective and well tolerated by the elderly, including those over 85 years. Age should not be a barrier to treatment, but careful management is necessary.

THU-370

Hepatocellular carcinoma may be a viral reservoir during treatment of hepatitis C with direct-acting antivirals

Mário Jorge Silva[1,2,3], Ana Patricia Negrinho[2], Fatima Oliveira Martins[2], Antonio Figueiredo[1,3], Helena Gloria[1,3], Carina Santos[1,3], Pedro Lages Martins[1,2,3], Vasco Ribeiro[1,2,3], Mario Oliveira[1,3], Hugo Pinto Marques[1,2,3], Silvia Vilares Conde[2], Filipe Calinas[1,3]. *[1]Centro Clínico Académico de Lisboa, Lisbon, Portugal; [2]NOVA Medical School, Lisbon, Portugal; [3]Centro Hospitalar Universitário de Lisboa Central/Unidade Local de Saúde São José, Lisbon, Portugal*
Email: mariojorgesilva01@gmail.com

Background and aims: Direct-acting antivirals (DAAs) revolutionized the treatment of chronic hepatitis C virus (HCV) infection. Viable hepatocellular carcinoma (HCC) has been identified as one of the few predictors of non-response to hepatitis C treatment with DAAs. However, it is still unclear why patients with HCC have a lower response to DAAs. Several hypotheses have been raised, including the possible role of HCC as a viral reservoir during antiviral treatment. We aim to assess if HCC acts as a viral reservoir for HCV during treatment of hepatitis C with DAAs.
Method: We characterized quantitatively the presence of HCV in liver explant tissue (obtained during transplant surgery) from a cirrhotic patient with viable HCC. The patient was chronically infected with HCV genotype 3 and at the time of surgery was completing his first month of treatment with sofosbuvir/daclatasvir. HCV quantification was performed with immunofluorescence targeting non-structural protein 3 (NS3). Tissue samples were evaluated through widefield microscopy with Zeiss (R) Observer. Intensity of fluorescence was quantified in Fiji (R) program and compared between HCC and non-tumoral liver tissue regions. Statistical analyses were performed using GraphPad (R), and One-way ANOVA between all groups was calculated. Differences were considered statistically significant when $p < 0.05$ (two-sided). This project is approved by the institutional Ethics Committee.
Results: In this patient undergoing treatment with sofosbuvir + daclatasvir for one month, we found significantly higher levels of immunofluorescence for HCV in the viable HCC tissue than in the non-tumoral liver cirrhosis tissue: fluorescence intensity/area was 55.8 ± 31.5 in tumoral tissue *vs* 0.6 ± 0.3 in non-tumoral tissue ($p < 0.05$)-representing higher density of HCV in HCC tissue than in the remainder cirrhosis non-tumoral tissue.
Conclusion: The present results suggest that HCV clearance is delayed in HCC tissue, compared to non-tumoral cirrhosis liver tissue. HCC may, then, act as viral reservoir for HCV during treatment with DAAs. Further studies are needed to confirm this hypothesis.

THU-371

Impact of a simplified diagnosis-monitoring strategy on Glecaprevir/Pibrentasvir (G/P) treatment initiation and response in patients with chronic hepatitis C virus (HCV) infection receiving opioid substitute therapy in Israel-a real world evidence

Eli Zuckerman[1], Orly Azulay[2]. *[1]Liver Unit, Carmel Medical Center, Technion Faculty of Medicine, Haifa; [2]Liver Unit, Carmel Medical Center, Haifa, Israel*
Email: elizuc56@gmail.com

Background and aims: Although HCV treatment for patients who using drugs (PWIDs) has shown good outcome and is recommended by international guidelines, treatment uptake has remained low. The primary objective was to assess the impact of active intervention model ("simplified") versus conventional approach on treatment initiation and response in patients with chronic HCV infection receiving Opioid-Substitute Therapy (OST) in methadone Clinics in Israel.
Method: The data was collected from one Drug Maintenance Treatment Center (DMTC) in Haifa, containing 324 HCV-Ab-positive patients out of approximately 500 PWIDs treated with OST. Group A

("simplified" approach) included 81 patients tested and prescribed with G/P at the DMTC during 2020–2023. The nurse reviewed the patients' charts, withdrew blood sample included HCV RNA, blood count and chemistry and than performed fibroscan as needed while treatment (G/P) was prescribed by the hepatologist. Follow-up was performed by the Liver Unit staff. Group B- included 50 patients complete all required pre-treatment testing at the community clinics and were referred to to the Liver Unit at Carmel Medical Center (up to December 31, 2019).
Results: Mean age was similar in both groups (49.2 and 50.8 years, respectively). Fibrosis assessment either by fibroscan or fib4 score was available in all patients from group A and in 32/50 in group B. The proportion of patients with advanced disease (F3–4) was significantly higher in group A (28% vs 15%, $p < 0.05$). The mean time elapsed from diagnosis of HCV infection to treatment initiation was significantly shorter in Group B (48 vs 126 months, respectively, $p < 0.0001$) and the same applies to the time from diagnosis to the first HCV PCR-negative test (94 vs 136 months, $p < 0.0001$). In Group A, the mean time elapsed from the time of intervention to treatment initiation was 9.25 months (range 0–33 months). In 74 of 81 of Group A (91%) and in 36 of 50 (72%) of group B, PCR results to determine SVR were available. SVR was achieved in 72 patients of group A (97%) and in 32 patients in group B (88%). Seven patients lost to follow-up in group A and fourteen in group B. In intention-to-treat analysis the SVR rate was significantly higher in group A ($p < 0.05$).
Conclusion: "Simplified" model applied in very difficult-to treat OST patients is effective in reducing time of linkage-to-care and of treatment initiation and increasing the rate of SVR. However, even in this model in "real world" setting, we have faced barriers to better management of these patients.

THU-372-YI
Point of care hepatitis C screening and treatment among people who use drugs in new york city addiction centers: barriers and opportunities
Jessica Siguencia[1], Jhané Phanor[1], Anthony Choi[1], Robert S. Brown, Jr[1], Laura Maroldo[2]. [1]*Weill Cornell Medicine, New York, United States;* [2]*West Midtown Medical Group, New York, United States*
Email: jms4007@med.cornell.edu

Background and aims: Among people who use drugs (PWUDs) in the US, Hepatitis C Virus (HCV) is prevalent in 70% and is often untreated due to limited access to testing and care. The addiction care setting provides a unique opportunity to bridge this accessibility gap by including point-of-care (POC) HCV testing among services used by PWUDs. The AbbVie B20 Study is a randomized study of test, educate, and treat in two drug addiction centers in New York City. Our preliminary results provide lessons on the significant challenges facing HCV screening and treatment in addiction centers.
Method: Patients in addiction care settings were recruited and screened for HCV infection, using HCV antibody with reflex RNA test, and a POC Cepheid HCV Viremia (RNA) test. The ongoing trial randomizes all eligible patients to a video-based patient education and treatment at the drug treatment program versus a standard of care (SOC) referral for Hospital clinic-based HCV therapy.
Results: Out of 12 addiction care locations in New York City contacted, only 2 locations participated, and 21 patients have been screened so far. At site 1, a residential drug and alcohol rehabilitation center, 9 of 148 residents consented. These 9 patients' HCV results came back negative. The most common barriers to participation included unwillingness to interact with a medical team, aversion to undergo phlebotomy, prior negative HCV status, and competing priorities in the rehabilitation center. At site 2, a walk-in addiction treatment center, 11 of 15 patients were screened, seven participants were identified as HCV positive. Three of the seven were randomized to SOC and none came to our clinic. After missing SOC appointments, two of the three SOC patients began medication at the addiction center and have SVR pending. The last SOC patient never began medication due to competing health priorities, which resulted in an emergency room admission. The remaining four participants were randomized to the test-and-treat arm and could start treatment at the site after completing video-based education. Two out of the four struggled with returning to the site for medication initiation and they have yet to reconnect with the facility. Out of the remaining two test-and-treat participants, one lost and stopped taking medication but returned 4 months later to restart medication. The last participant completed medication and had a confirmed sustained virologic response (SVR).
Conclusion: Substantial barriers exist at the individual patient level to HCV treatment, even when a medical provider provides POC testing and therapy. POC testing, ideally without phlebotomy, and treatment is essential for HCV eradication. Strategies to implement mental health services along with a test-and-treat strategy may allow us to overcome the identified barriers to initiating and completing HCV treatment in this vulnerable population.

THU-373-YI
Quality of etiotropic therapy efficasy of chronic hepatitis C patients in accordance of toll-like rececеptor 4 +3725G/C gene polymorfisms variety
Tetiana Bevz[1], Larysa Moroz[1], Kiarina Myroniuk-Konstantynovych[1], Iryna Bondaruk[1], Galyna Martyniuk[2], Yaroslav Demchyshyn[1].
[1]*National Pirogov Memorial Medical University, Vinnytsia, Ukraine;*
[2]*Central City Hospital, Rivne, Ukraine*
Email: tasya241@gmail.com

Background and aims: Antiviral therapy is considered to be the only method that can stop the progression HCV infection, the development of hepatocellular carcinoma and death. The end point of antiviral therapy is the achievement of a sustained virologic response (SVR), which in 99% of cases is associated with the possibility of complete elimination of the virus. The aim of our study was to assess the dependence of the frequency of obtaining a SVR to antiviral therapy on the +3725G/C polymorphism of the toll-like receptor 4 (TLR4) gene.
Method: 111 chronic hepatitis C (1b genotype), patients (78 males, 33 females) were observed. All participants received antiviral treatment with Sofosbuvir/Ledipasvir. The duration of antiviral therapy was 12 weeks in patients without cirrhosis and 24 weeks in patients with liver cirrhosis.
Results: The vast majority of treated patients archieved a SVR (91.89%), the antiviral therapy was ineffective for 9 patients (8.11%). The number of non-RSVs was significantly ($p < 0.05$) higher among patients with the +3725C allele of the TLR4 gene (GC and CC genotypes)-77.8% of all those who did not respond to treatment were carriers of this allele. It was established that among patients with the GG genotype, only 2.41% of patients with chronic hepatitis C did not have a SVR. According to the results of the genotypes distribution comparison according to variants of the TLR4 gene +3725G/C allelic polymorphism by the exact two-tailed Fisher test among patients with chronic hepatitis C who had received antiviral therapy, the significantly higher frequency of carriers of the +3725G allele (genotypes GG and GC) was detected ($p < 0.001$) in the group of patients with RSV vs. the group of patients who did not receive a SVR. According to the odds ratio calculations, it was established that individuals carrying the +3725G allele of the TLR4 gene have a 13 fold higher chance of obtaining a SVR during antiviral therapy use (OR = 13.5; CI 2.61, 69.81). It was established that in the vast majority of patients (68.63% [n = 70]) with chronic hepatitis C, whom a SVR was obtained in, absent liver fibrotic changes (F0) or initial stages of liver fibrosis were observed in 2.26 fold higher number of patients vs. ones with liver fibrosis/cirrhosis (F3-F4). Among non-RSV patients, the degree of liver fibrosis F0–F2 were not detected.
Conclusion: Among patients with chronic hepatitis C who did not have a SVR to administered antiviral therapy, there were 3.2 fold higher number of patients with severe liver fibrosis/cirrhosis (F3–F4).

Most of the patients (77.8%) who did not achieve a SVR were carriers of the +3725C allele of the TLR4 gene ($p < 0.05$). The odds ratios of achieving a SVR in patients with chronic hepatitis C with the 1b genotype were 13 fold higher among carriers of the +3725G allele of the TLR4 gene than among carriers of the +3725C allele.

THU-374

Description of age, sex, and characteristics of hepatitis C patients in the SVR10 K study: a real-world SOF/VEL analysis performed across five global regions

Soo Aleman[1], Fatima Higuera-de-la-Tijera[2], Francisco Javier Garcia-Samaniego[3], Marta Casado-Martin[4], Grace Lai-Hung Wong[5], Mohammed Alzaabi[6], Habiba Kamal[1], Karin Lindahl[1], Aastha Chandak[7], Marta Martinez[8], Artak Khachatryan[7], Linda Chen[9], Candido Hernández[10], Kim Vanstraelen[11], Ming-Lung Yu[12]. *[1]Karolinska University Hospital, Stockholm, Sweden; [2]Hospital General de México "Dr. Eduardo Liceaga," Mexico DF, Mexico; [3]Hospital Universitario La Paz, Madrid, Spain; [4]Hospital de Torrecárdenas, Almeria, Spain; [5]Prince of Wales Hospital, Hong Kong, Hong Kong; [6]Zayed Military Hospital, Abu Dhabi, United Arab Emirates; [7]Certara Inc, Princeton, United States; [8]Certara Inc, Madrid, Spain; [9]Gilead Sciences, Foster City, United States; [10]Gilead Sciences, Madrid, Spain; [11]Gilead Sciences, Brussels, Belgium; [12]National Sun Yat-sen University, Kaohsiung, Taiwan*
Email: soo.aleman@regionstockholm.se

Background and aims: A previously published real-world data analysis demonstrated high effectiveness of sofosbuvir/velpatasvir (SOF/VEL) in >6, 000 HCV patients from 12 clinical cohorts across Australia, Canada, Europe and USA. Irrespective of age, male patients were more likely to have advanced fibrosis and infection with HCV GT 3, and median time to treatment initiation was numerically shorter in male patients across the age spectrum. The aim of this large real-world analysis was to evaluate characteristics of an expanded pool of HCV patients treated with SOF/VEL across regions globally.
Method: This analysis included patients ≥18 years treated with SOF/VEL without ribavirin (RBV) for 12 weeks from 7 sites across Hong Kong, Mexico, Sweden, Spain, Taiwan, and the United Arab Emirates. Baseline characteristics, such as age (in categories</≥50 yo), sex, being treatment experienced (TE), cirrhosis presence (F4, no decompensated), genotype, coinfections (HBV, HDV, HIV), time to treatment initiation (TTI) from HCV diagnosis were described, along with sustained virology response rates (SVR) (4/12/24).
Results: Among 4, 679 patients, 59% (2, 760) were males and 41% (1, 919) were females, with 73% females vs 64% males being ≥50 yo ($p < 0.001$). Coinfections were more prevalent in males (HIV 6.9% vs 1.6% $p < 0.001$; HBV 4.9% vs 3.4%, $p = 0.005$; HDV 0.2% vs 0.1%, $p < 0.001$), they were more often TE (5.9% vs 3.9%, $p = 0.001$) and more often had GT3 (24.2% vs 17.6%, $p < 0.001$); these differences were seen mostly in males ≥50 yo. No differences by sex was observed for patients with compensated cirrhosis (19.9% male vs 21.7% female, $p = 0.34$). Time to treatment initiation with the HCV therapy was shorter in females aged ≥50 yo, with 23% treated in the first month, as compared to 16% of males above 50 yo ($p < 0.001$). In 4, 195 patients with SVR outcomes (effectiveness population), both sex and age groups had SVR greater than 97%, showing a statistically significant difference between female and male patients aged ≥50 yo (99.4% vs 98.5%; $p = 0.0266$).
Conclusion: This new analysis confirms the high effectiveness of using SOF/VEL in diverse populations globally, with real-world SVR higher than 97% across diverse age, sex and geographic groups.

THU-375

When glecaprevir/pibrentasvir ultra-short therapy is enough to eradicate HCV infection

Alberto Grassi[1], Natascia Celli[2], Silvana Maccariello[2], Gabriele Donati[3], Angela Fabbri[2], Giorgio Ballardini[2]. *[1]Ospedale Cervesi, Cattolica (RN), AUSL della Romagna, Cattolica (RN), Italy; [2]Internal Medicine Unit, Infermi Hospital, Rimini, Italy; [3]Internal Medicine Unit, State Hospital of San Marino, Borgo Maggiore, San Marino*
Email: albgrassi@yahoo.com

Background and aims: There is general agreement about the fact that at least 8 weeks of therapy with direct antiviral agents (DAAs) are necessary to achieve definitive hepatitis C virus (HCV) eradication but, probably, the real impact of DAAs in HCV replication is not yet completely known.
Method: From 2018 to 2023, 302 HCV-RNA+ patients received antiviral treatment with glecaprevir/pibrentasvir (G/P) and completed 12 weeks post-treatment follow-up.
Results: Sustained virological response (SVR) was globally obtained in 297 patients (98.3%). Ten patients prematurely suspended treatment, mainly for light side effects (itching, headache weakness).The main characteristics of patients are the following: median age (years): 63 (40–83); male/female: 7/3; liver fibrosis score (metavir): 3 F 1, 3 F 2, 2 F 3, 2 F 4; genotype (G): 3 G 1, 3 G 2, 3 G 3, 1 G 4; median pre-treatment HCV RNA (log IU): 5 (4–7); median pre-treatment alanine transaminase (ALT) (IU): 54 (6–248); median duration of treatment (days): 7 (4–28). Nine of them (90%) were HCV RNA negative at the end of treatment and six of them (60%) resulted SVR; three (30%) relapsed 12 weeks post the end of treatment and only one (10%) resulted non-responder. SVR patients showed pre-treatment ALT level lower than non SVR patients (IU median values: 39 vs 131, $p = 0.017$). Age, gender, liver fibrosis score, genotype, pre-treatment HCV RNA and duration of therapy where not significantly different in the two groups.
Conclusion: In this tiny series of patients, HCV eradication was obtained in 60% of cases with (even extremely) reduced duration of treatment with G/P. Apparently SVR resulted more probable when pre-treatment degree of HCV related hepatic cytonecrosis was low. More studies about this topic would be important to eventually permit ultra-short scheduled of treatment to eradicate HCV infection. This should strengthen the case for offering treatment with DAAs to all HCV + people, even to subjects with presumed reduced compliance with therapy (prisoners, drug addicts, etc) in accordance with the World Health Organisation (WHO) program to eliminate HCV infection within 2030.
